Satisfactory joints are more difficult to make with aluminum than with copper, and special care must be taken when making connections between aluminum and copper. The smaller sizes of steel reinforced aluminum can be held by a clamp gripping the aluminum strands tightly, but with larger sizes at dead ends, it is necessary to grip the steel core directly and the aluminum strands must be held separately.

Eighty per cent or more of the conductor material used in the construction of transmission lines in Canada is either pure aluminum or steel reinforced aluminum. The steel reinforced aluminum conductors are used in sizes from No. 2 to 605,000 circular mils.

Insulators

Two widely different types of insulators are in common use, viz: the pin type, used for voltages up to 66,000 volts or in special cases up to 110,000 volts, and the suspension type, for voltages from 66,000 to 220,000 volts.

The early forms of pin type insulators were not designed with sufficient knowledge of the factors involved and the porcelain body was not homogeneous, often it was porous. The shapes were such that excessive dielectric stresses were set up at certain points, besides which mechanical stresses were present in the insulator body which were exaggerated by extreme temperature changes, and the insulators frequently failed in service due to cracking or puncture. The shells were made of thin and brittle material, and when a power arc passed over the insulator following a lightning flashover, the skirts were often broken off and much of the insulating value destroyed. The modern pin type insulator has, however, been very much improved. The material now is homogeneous and non-porous, the parts are so shaped that the dielectric stresses are reduced to a minimum and the initial mechanical stresses are small. The cement binder between shells has been improved so that expansion stresses are reduced, and the various parts of the insulator are of substantial design, and better able to stand a power arc for the short time required by the switches to clear the line. Besides this horns to keep the arc away from the insulator surface are used in many cases and are of advantage. Modern pin type insulators are giving good service on lines up to 66,000 volts and can be used in certain cases for 88,000 to 110,000 volts.

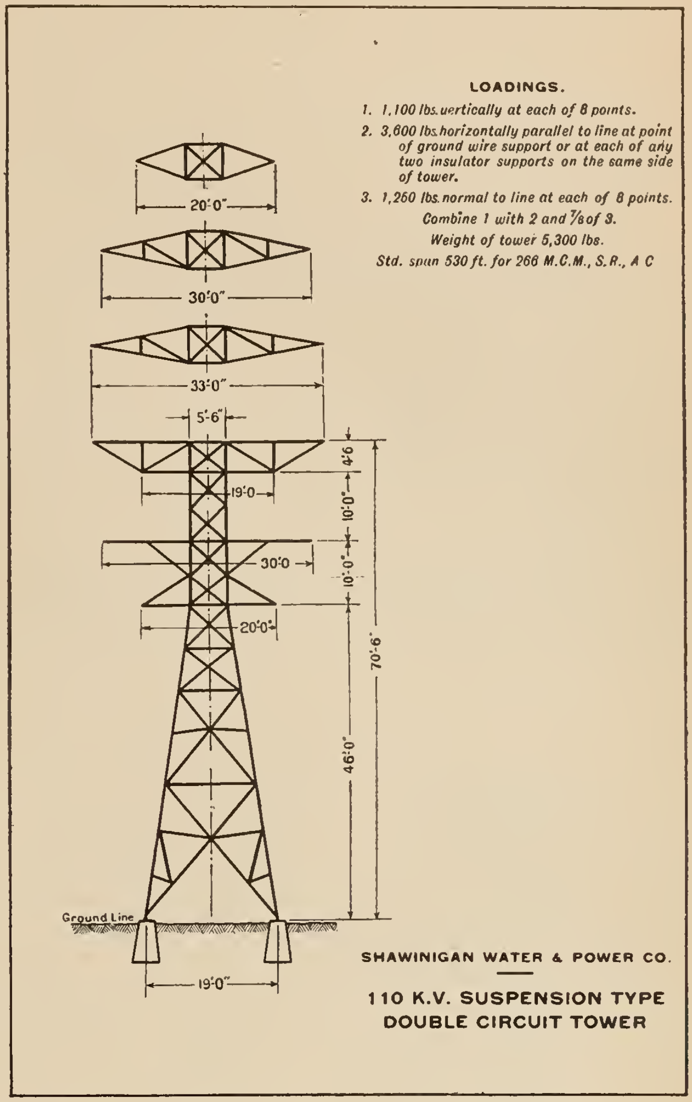

Plate No. D-1, — 110 k.v. Suspension Type Double Circuit Tower.

For higher voltage lines strings of suspension type units are used, one unit for each 10,000 to 12,000 volts to ground. On a 110,000 volt line with 63,500 volts between lines and ground the usual number of units is six or seven. For line voltages of 220,000 volts twelve to fifteen units should be used.

The cemented cap and pin type of suspension unit is the one most commonly used in this country. The link type has not found favour on account of its low ratio between flashover and puncture, and the insulator with the thick porcelain body has not come into general use because of its great weight and the difficulty of connecting and disconnecting the units in the string.

The ordinary 10-inch disc insulator can be constructed for a breaking load of 9,000 or 10,000 pounds, which is quite sufficient for ordinary lines. Where extremely heavy conductors are to be supported the manufacturers can supply heavier discs with a breaking load of 18,000 to 20,000 pounds.

Each suspension unit has a length of about five inches and a string of six units, which will be about 2.5 feet long exclusive of the clamp and the connection to the tower, is suitable for a line voltage of 90,000 to 100,000 volts.

A limitation in the use of long strings of disc insulators has arisen due to the fact that the voltage does not distribute evenly over the various insulators. For instance on strings of five or more units the insulator next to the line takes about 30 per cent of the total voltage. This uneven distribution of voltage is not serious for lines up to 110,000 volts because the factor of safety for dry flashover is still high even on the lowest insulator and in wet weather the voltage distribution over the string becomes more uniform due to water dripping over the discs.

For very long strings of ten or more discs, it is worth while to reduce the voltage across the lowest insulator by means of a shielding ring which ring performs the double function of creating a comparatively uniform voltage distribution over the string and of, at the same time, acting as an arcing ring and thus tending to prevent the destruction of the string by the power arc following a flashover. The shielding ring tends to introduce a complication in tower design as it may seriously reduce the clearance between conductor and tower, when the insulator string swings from the vertical position under excessive wind stresses.

The early types of suspension units failed after a few years of service due to defects both of design and manufacture, and it seemed for a time that the insulator was destined to be a serious limitation in the development of

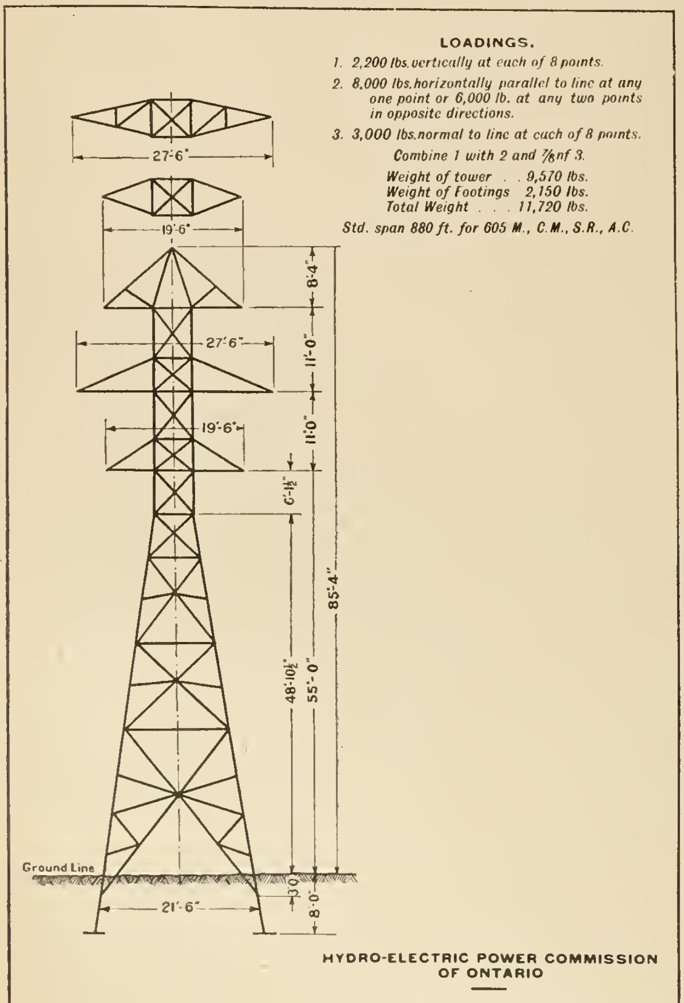

Plate No. D-2, — 110 k.v. 1920 Type Suspension Double Circuit Tower.

high voltage transmission system. Later insulators, however, have given splendid service and with careful inspection of the units before shipment, combined with periodic tests after installation, the danger of interruption of service due to faulty line insulators is very much reduced.

The prevailing practice in trunk line transmission is to provide electrical insulation of the highest possible safety factor against flashover, in an endeavour to eliminate short-circuits caused by lightning. The 90,000-volt pin type trunk line from Niagara Falls to Toronto, which has a very low safety factor against flashover, is in direct contrast to this general practice. This transmission system consists of a double circuit steel tower line of 190,000 circ. mils copper cable with mixed spans of 400 and 600 feet and triangular spacings of 6 feet and 8 feet respectively. The pin type insulators, mounted on steel pins, have a dry flashover of 190,000 volts and a wet flashover of 150,000 volts. The operating voltage at the generating bus varies between 90,000 and 95,000 volts. These lines have been operated successfully at 90,000 volts since October 1918, and the operating results show no indication of any weakness which can be attributed to the low insulation safety factor.

Special Insulation for Dust Areas

In certain parts of the country where there are long dry periods a thick coating of dust collects on insulators. This does not impair the insulation while the dust is dry, but when it becomes damp with dew or fog, the coating becomes conducting and the insulator is liable to flash over with only normal voltage on the line. But as a rule the rain soon washes the dust off and the insulators recover their normal characteristics.

Smoke and the fumes from electro-chemical plants present a more serious problem as they often form a deposit which does not wash off easily with rain and seems at times to be burned into the glaze by the action of the incipient arcs which form, particularly near the conductor. All such deposits tend to collect more particularly in any pockets where the dielectric stress is very high, and so find lodgement beneath the skirts of pin type insulators as well as on top. There does not seem to be any simple solution of this problem except to increase as far as possible the factor of safety of the insulation.

Throughout a part of the asbestos region of Quebec, two 60,000-volt pin type insulators were mounted one on top of the other to insulate a 50,000-volt line, with good results. In another case a 30,000-volt line supplying power to a plant manufacturing calcium carbide was insulated with the same number of suspension units normally used on 100,000 volt lines.

Testing of Insulators after Installation

The improvement in the quality of both suspension and pin type insulators has reduced very largely the interruptions to service due to insulator failures, but it is still necessary to test the insulators on the towers every year or at least every two years to take out those which have become defective and so to reduce the danger of flashover or puncture of the string.

The high range megger has been used very extensively for this inspection but has the disadvantage that at least the section of the line under test must be taken out of service. The method is very slow and even with experienced men many good units are taken off the line and a number of the defective units left.

The "buzz-stick" can be used to test the insulators in a string without taking the line out of service. It takes much less time than the megger test and gives considerably better results. The "buzz-stick" is made up of an insulating rod of dry wood about ten feet long with a U-shaped wire at one end. The prongs of the wire are used to short-circuit successively the insulators of a string. If one prong is held against the line conductor and the second prong is brought into contact with the cap of the lowest insulator and then removed, an arc will be drawn if the unit is good and no arc if it is defective. The remaining units are then tested in the same way.

As a general rule the lowest insulator unit has about 30 per cent of the voltage to ground between its cap and pin and the spark on opening the short-circuit will be long. The lower voltages across the other units are sufficient to draw arcs from one-half to one inch in length if the units are sound and in this way a very large percentage of the defective units can be picked out. These defective units can then be marked in some simple way and removed at any time when the line can be taken out of service conveniently.

The buzz-stick can also be used for testing pin type insulators but the danger of short-circuiting the only good skirt of the insulator and so grounding the line is very much greater than with a string of suspension units. In the majority of cases the head of the pin type insulator fails first and it is a very simple matter to discover the defective heads by short-circuiting the head with a buzz-stick making contact between the conductor and the cement below the head and then removing one point to draw the arc.

Other devices for testing insulators while the line is still in service have been developed during the last few years but as a rule they are more complicated than the buzz-stick and require more expert operators but for testing pin type insulators a testing device which does not short-circuit a part of the insulator is to be preferred to the buzz-stick.

Considerable progress has been made in live line maintenance during the last few years. Apparatus has been developed which makes it possible to change a pin type insulator or a string of suspension insulators or to carry out other operations without taking the line out of service. Such operations, when carried out by skilled crews, are attended by very little risk and while used on only a few Canadian systems will no doubt be employed more extensively when further experience has proved their economy and safety. In the United States live line maintenance is done by contract for a number of companies.

Supporting Structures

The two main types of structures for supporting transmission line conductors are steel towers and wood poles. There are also some lines supported on wood towers and a few on steel poles and concrete poles.

The main trunk lines of the larger power companies are supported on steel towers, either single circuit or two circuit. Most of the lower voltage lines using pin type construction are carried on wood poles but a few are on steel towers. On account of the difficulty of obtaining first class wood poles some companies are making experiments with reinforced concrete poles and they promise to give satisfaction. The first cost and the weight are higher than for wood poles but the life will be very much longer.

Steel Towers

Owing to the great weight and cost of steel towers, the design of these structures has of necessity been carried to a point of high efficiency and the designing engineers make their calculations so that every member of the tower performs its proper functions and the whole tower carries the load for which it was designed without any waste material.

The main factors which must be considered in designing the towers for a transmission line are the following:—

1. Number of circuits to be carried on the tower.
2. Arrangement and spacing of conductors.
3. Length of insulator string.
4. Minimum clearance between conductor and tower members.
5. Minimum clearance from ground.
6. Length of normal span.
7. Size of conductor and maximum tension in conductor.
8. Number and size of ground wires.
9. Assumed ice and wind loads and range of temperature.
10. Dead-ends and transpositions and special crossings and long spans.

Single circuit tower lines are advisable where only two circuits are used to supply an important load, and they should preferably be constructed on separate rights-of-way. When two circuits are carried on one tower occasional interruptions of both circuits are liable to result from direct strokes of lightning or from an arc blowing from one line over to the other or due to a conductor on one circuit breaking and falling across the other circuit. Where four or more circuits are required the double circuit tower line is well justified, especially where the right-of-way is expensive. Plates Nos. D-1 to D-3 show some standard tower constructions.

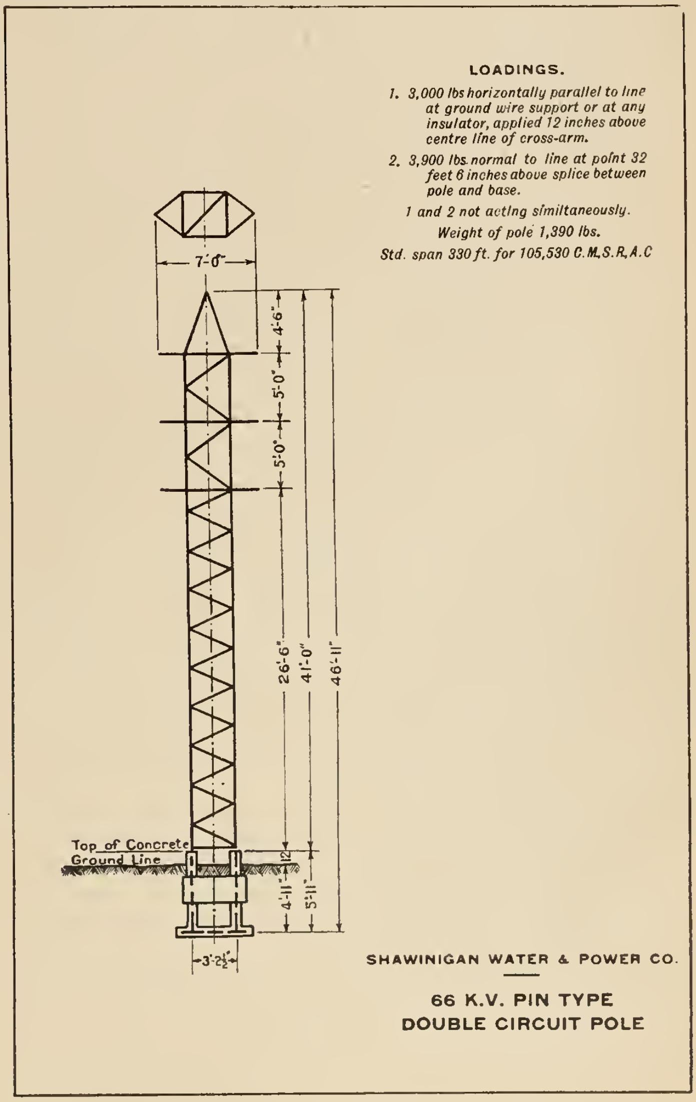

Plate No. D-3, — 66 k.v. Pin Type Double Circuit Pole.

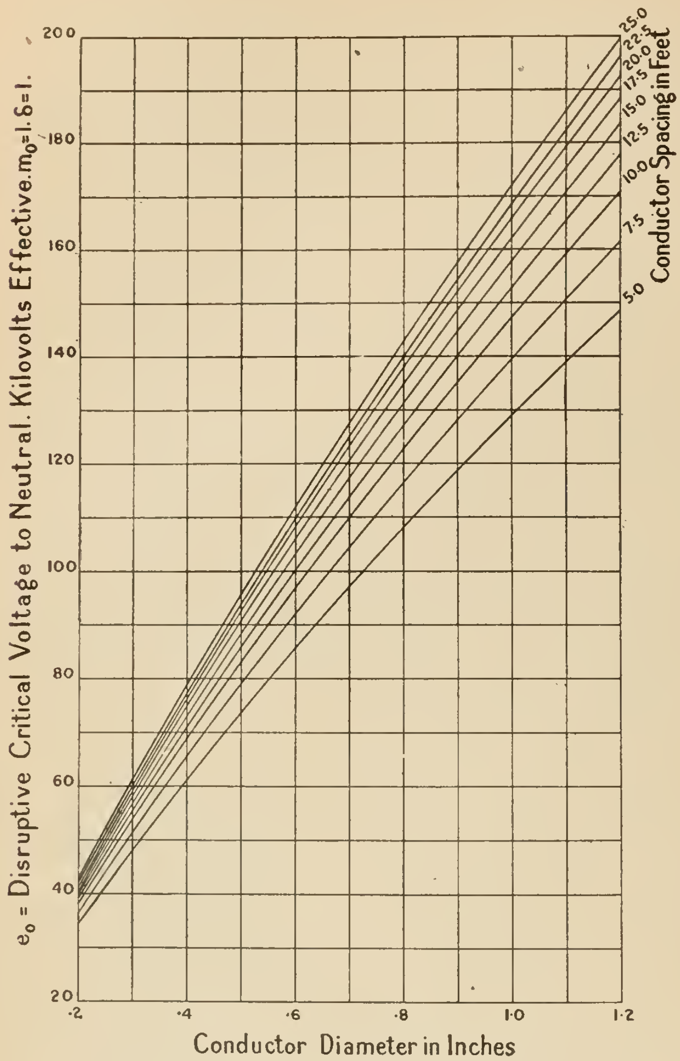

Plate No. D-4, — Disruptive Critical Voltage to Neutral for Various Conductor Spacings.

With single circuit lines the conductors may be arranged in an equilateral triangle or they may be placed in a horizontal plane. With double circuit towers the triangular spacing may be used or a vertical arrangement of the conductors of each circuit. In the latter case it is advisable to set the centre conductor out a short distance as shown in plate No. D-2. This is to prevent the wires coming in contact during sleet storms. If the ice coating should fall from one of the two lower wires in the vertical arrangement before it has fallen from the wire immediately above it, the two wires are liable to swing so close together that an arc will pass between them and interrupt the service. A similar condition may result if the ice load on one of the upper conductors falls off all but one span, since the decreased tensions in the two adjacent spans will allow the loaded span to increase its sag and approach the conductor below it unless it is offset sufficiently.

With two circuits on one tower it is advisable to have the phases symmetrically placed, the two top wires being of one phase, the two middle wires, the second phase and the two bottom wires the third phase, and to maintain this relationship when the lines are transposed. Men working on the lines are less liable to make mistakes if this is done.

Two circuits on a single tower may have five to ten per cent more reactance than if they are carried on separate towers, and this should be taken into consideration in calculating the electrical characteristics of the lines.

Spacing of Conductors

The distance between the centres of conductors should be such that under the worst conditions the voltage required to cause an arc to strike across to an adjacent conductor will be at least twice the normal operating voltage between lines. The usual spacings range from 10 inches to one foot for each 10 kilovolts between lines, with a minimum spacing of about 20 inches. For very long spans greater clearances may be required especially where pure aluminum conductors are used, as these have an excessive sag. For 110,000 volt lines a spacing of 8 feet may be used with a span length of 250 feet, but this should be increased to 10 or 12 feet when the span length is 800 to 1,000 feet.

Extra conductor spacing is not so necessary with steel reinforced aluminum and with copper conductors as with pure aluminum. Smaller spacings may be used with the horizontal arrangements of conductors than with the vertical or triangular arrangement, as the danger of swinging together is less.

In determining the inductive reactance and the capacity reactance of transmission lines, the effective spacing or the equivalent uniform spacing should be used, which is given by the formula:

$$s = \sqrt[3]{s_1 \times s_2 \times s_3}$$

where s is the effective spacing, and s_1, s_2 and s_3 are the actual spacings between pairs of adjacent conductors. When other circuits are located on the same towers accurate determination of the constants of the line requires that the effects of the neighbouring circuits be calculated.

Length of String of Insulators

The length of the insulator string in feet is about 0.4 times the number of units, since each unit of the ordinary cap and pin type occupies a space of about 5 inches, but to this must be added the length of the tower and line fastenings. If the length of the string is so short that it allows the conductor to swing too close to the upper cross-arm under excessive wind stresses, it can be lengthened by making the connection to the cross-arm longer.

The actual arcing distance over the string is usually considerably less than the length of the string when arcing horns are provided to keep the arc away from the insulators when flashover occurs.

Other types of insulators may differ in length from the value given above but the difference will not be very great.

Clearance between Conductor and Tower Members.

The minimum clearance between the conductor and the tower members should be such that an arc will not strike to the tower at a voltage lower than that required to arc over the string of insulators. To meet this condition the minimum clearance should be equal to or greater than the length of the string. In determining the minimum clearance, allowance must be made for the change of the position of the conductor due to wind stresses. With copper or steel reinforced aluminum conductors the insulator string will not usually swing more than 45 degrees from the vertical but with pure aluminum conductors it may swing up 55 or even 60 degrees. The angle of swing from the vertical should be determined for each case based on the assumed ice and wind loadings.

A number of 110,000-volt lines are in operation with a minimum clearance slightly less than the length of the string of insulation, which is normally about 3 feet, and no bad results have been noted, but the added tower expense required to maintain this clearance is not great and would seem to be worth while in the majority of cases.

Minimum Clearance from Ground

The allowable minimum clearance from ground varies in different parts of the country from 22 to 24 feet. This normal distance should not be reduced in agricultural districts but somewhat smaller values may be maintained in uncultivated sections of the country. At special crossings and in the streets of towns and villages the minimum ground clearance of the span may be 30 feet or more and special towers will be required for such locations.

Length of the Normal Span

The length of the normal span for transmission lines varies with the type of supporting structure, and spans up to 880 feet are used with heavy steel towers such as that illustrated in plate No. D-2. There is often a considerable range of span lengths which brings the total cost of the line near to the minimum value, but engineers have hesitated to increase the spans to the maximum to make a small problematical saving fearing the risk of greater operating and maintenance troubles with the extreme span lengths. For 220,000-volt lines it is probable that the most suitable span will be from 800 to 1,000 feet.

Many wood pole lines and some steel tower lines have been designed with too short a span, resulting in a high first cost and excessive maintenance costs. When the time comes to make extensive repairs on such lines it may be good policy to increase the span and in some cases it may pay to replace the wood poles by reinforced concrete poles.

Size of Conductor and the Maximum Tension in the Conductor

The size of the conductor is usually determined to meet the required electrical characteristics of the transmission line. Only where the current to be carried is extremely small will the minimum allowable section of the conductor be fixed by its mechanical strength. For the majority of lines the section is determined from the conductance required to keep the losses below a certain value and Kelvin's law is applied to determine that conductor size which will reduce to a minimum the sum of the interest on the investment in the conductor and the cost of the lost energy.

For very high voltage lines the danger of excessive corona losses on the line in stormy weather may make it advisable to increase the size of the conductor beyond that required by other considerations.

The maximum permissable tension in the conductor depends directly on its section and on the material of which it is made. Conductors should be strung so that under the worst conditions the stress in the conductor will not be greater than 80 per cent of the elastic limit, and since the weight and cost of the towers is directly dependent on the maximum stress in the conductors, it is often found that when the line as a whole is designed for a minimum cost the maximum stress must be kept considerably below 80 per cent of the elastic limit.

Number and Size of Ground Wires

When flexible towers are used, ground wires are necessary as a support for the line and must be designed with sufficient strength for this purpose, but with rigid towers they are of much less value from this point of view. To provide a definite ground for relay protection one ground wire is sufficient but as a protection against lightning two or more wires are more valuable. Many engineers are not convinced that overhead ground wires have any very great value as a protection against lightning and a considerable number of systems are being operated without them. The double circuit tower shown in plate No. D-1 is not equipped with ground wires althouhg the supports are provided. This line parallels an older line on the same right-of-way which is equipped with two ground wires, and it is hoped that a study of the operation of these two lines will add something to the knowledge concerning the adequacy of the protection obtained from overhead ground wires.

Assumed Ice and Wind Loads and Range of Temperature

There is considerable difference of opinion as to what should be taken as the maximum loading in designing a transmission line, but for the majority of lines constructed in Canada the assumption has been made that the ice coating will form uniformly one-half inch thick and that the wind pressure will be eight pounds per square foot of projected area. For some important trunk lines a greater factor of safety has been obtained by considering an ice coating of three-quarters of an inch with a wind pressure of eleven pounds per square foot.

The temperature range varies with the location of the line but it is customary to assume minus 40 degrees fahr. as a minimum and plus 120 degrees as a maximum.

Foundations

There are two main types of foundations for steel towers, structural steel and concrete. The structural steel foundation consists of an angle bolted to each corner of the tower and extending about 6 feet into the ground. To the bottom of these angles is connected a grill of bars or angles and earth is filled in over the grill. This type

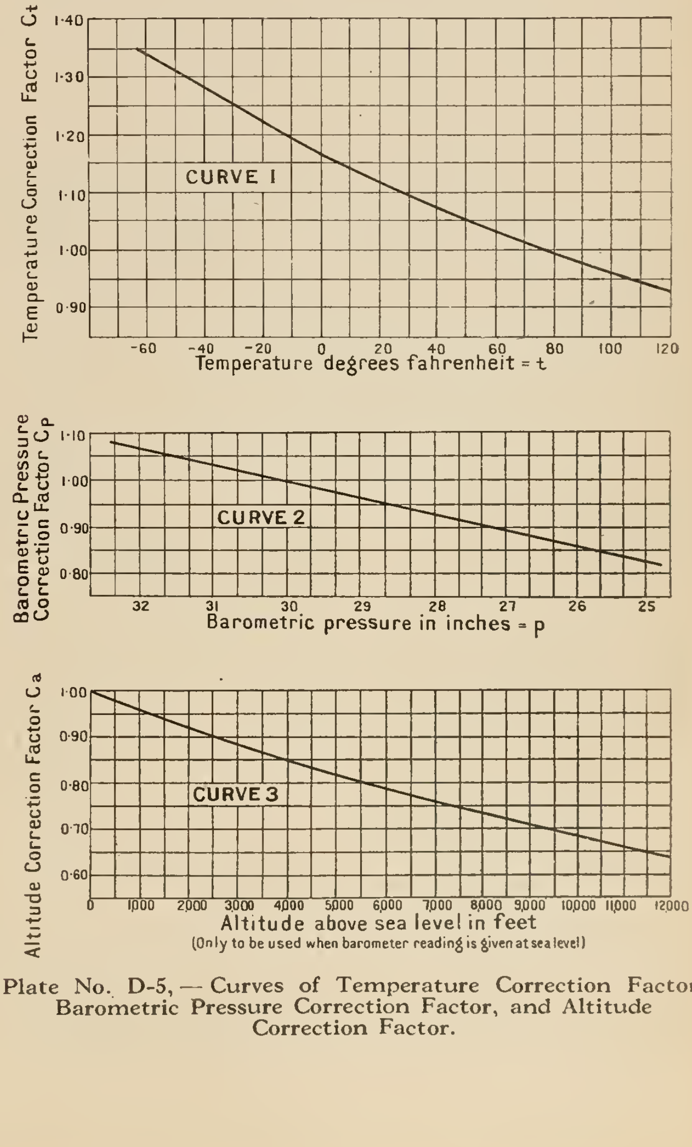

Plate No. D-5, — Curves of Temperature Correction Factor, Barometric Pressure Correction Factor, and Altitude Correction Factor.

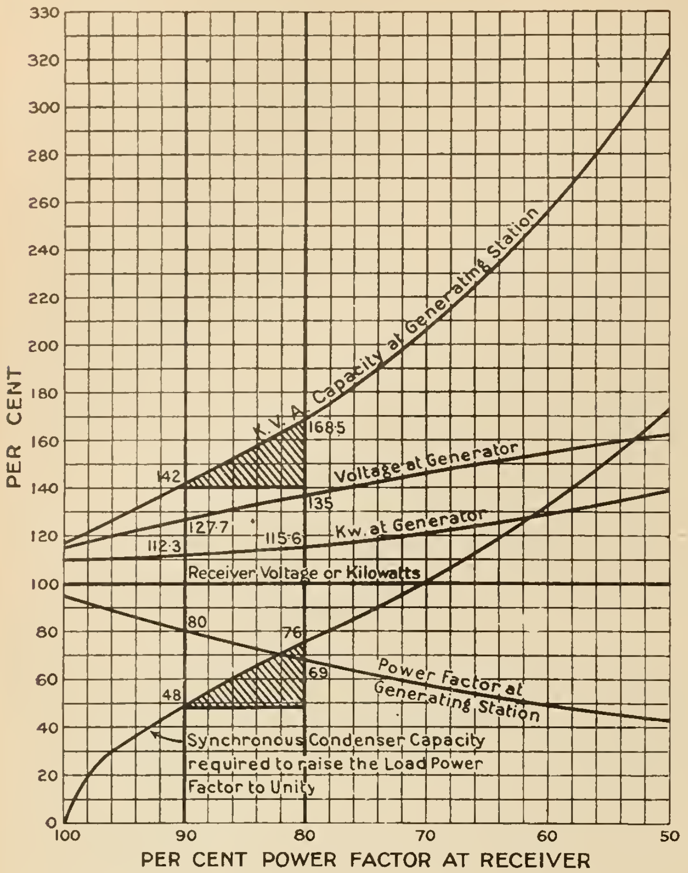

Plate No. D-6, — Effect of Receiver Power Factor.

of foundation is cheap and has been widely used. In good ground no difficulty is experienced with the steel footing but in bad ground the earth is liable to soften and the tower will then pull out of line or tilt over. If the steel which is placed underground is carefully coated with a suitable paint the life of the foundation should be satisfactory.

The second type of foundation consists of a concrete pier either plain or reinforced, containing a heavy foundation bolt to which the corners of the tower are attached. These concrete blocks are built in place by excavating the earth 6 feet below the natural surface and bringing the top of the piers to the proper grade. The concrete foundation has a considerable advantage over the steel footing during erection as it is much easier to line up properly.

Special Towers

On every transmission line a considerable number of special towers are required, anchor towers, angle towers and transposition towers and towers for special spans and crossings. All of these structures are much heavier than the ordinary suspension towers and for economy their number should be kept as low as possible. Some type of tower using insulators in the strain position should be introduced at all points where the angle of the line is in excess of 2 to 5 degrees, and some type of anchor or semi-anchor tower is generally used at least every mile to stiffen the line and to assist in construction.

Single Span Crossing over the St. Lawrence River

The St. Lawrence river, while it provides the main artery for water borne traffic for Montreal and the Great Lakes, is a serious obstacle to the transmission of electric power from the great power developments north of the river to the extensive industrial centres to the south. Above Montreal the river is narrow and there no difficulty was experienced in constructing an overhead crossing, but at Three Rivers and at Quebec the distance was considered too great for a single span and the river was too deep to secure a footing for a tower at the centre. Submarine cables were therefore used at these two points but a great deal of trouble was experienced due to tides and ice injuring the cables.

In 1917 when a larger amount of power was required on the south shore at Victoriaville, it was decided to construct an overhead crossing. The crossing as completed consists of a central span 4,801 feet long and two anchor spans, the north shore span being 571 feet and the south shore span 951 feet long.

There are two towers 350 feet high and 60 feet square at the base, the upstream and downstream faces tapering to a width of 14 feet at the top. A cross arm at the top, 14 feet wide and 100 feet long, carries three double-groove sheaves 50 feet apart over which the anchor cables pass. The tower foundation is made up of four circular reinforced concrete piers, 11 feet in diameter placed at the corners of a 60-foot square. These piers are connected by heavily reinforced concrete beams 4 feet wide by 8 feet deep.

Three steel cables, 50 feet apart, span the river between the two towers. To each end of each centre span cable are yoked two anchor span cables. These are carried over the towers on the main sheaves and then down to a point within 20 feet of the anchors.

It was originally intended to use the main cables as conductors and to insulate them from the towers by means of specially designed insulators but the insulators were not ready at the time of erection and the steel cables have been used as messenger cables only. At first a single No. 0 stranded copper conductor was suspended from each messenger cable, being supported at 250-foot intervals by strings of 8 suspension insulators. Later these copper cables were replaced by two 188,000 circ. mil. steel reinforced aluminum cables suspended from each of the messenger cables but insulated from one another.

The towers were designed for the following loads:—
A vertical load of 530,000 lbs., made up of 350,000 lbs. due to the weight of the tower itself and 180,000 lbs. due to the vertical component of the tension in the cables.
A horizontal load of 26,000 lbs. at the top of the tower normal to the line, due to the wind load on the line.
A wind load on the tower of 400 lbs. per foot of height, or 140,000 lbs. total. The maximum compression on each of the front legs was estimated to be 575,000 lbs. and the maximum uplift on the rear legs was estimated to be 233,000 lbs. per leg.

The cables are 1.375 inches in diameter, of galvanized plough steel, made up of six strands of 19 wires each and a stranded steel core of 30 wires with a small hemp centre. Tests showed the average yield point of the individual wires to be 221,000 lbs. per square inch and the average breaking strength to be 258,000 lbs. per square inch. The yield point of the completed cable was found to be 158,500 lbs., and the ultimate strength 186,400 lbs., which correspond to 193,000 lbs. per square inch and 227,000 lbs. per square inch respectively.

The cables as originally strung allowed the following clearances between the conductor and the average water level during the season of navigation; downstream 172.5 feet, centre 178.8 feet and upstream 180.6 feet. This crossing has given satisfactory service for more than six years and so far has not developed any weaknesses.

General Design

In laying out a new transmission line it is necessary to give careful attention to various features which decide the route, such as the accessibility of the line from existing railroads and highways, the physical characteristics of the country and the cost of right-of-way. It is very desirable that the line should follow existing railroads as this reduces the cost of transporting materials and is of very great advantage in patrolling the lines and making repairs. There is, however, a disadvantage in that telegraph and telephone lines on the railroad right-of-way are susceptible to interference from the power circuit and the transmission line must be constructed so as to cause as little interference as possible. More transpositions of the power wires will be required than when the line is remote from the railroad. Lower voltage lines, up to 50,000 volts, may be carried on the railroad right-of-way on the side remote from the signal wires, if the two circuits are properly co-ordinated, without causing serious interference, but higher voltage lines should be constructed at least 150 to 250 feet from signal circuits.

It is very undesirable for a line to be carried over the crests of hills, on account of the increased liability of trouble from lightning in such localities. A line should not be built across swampy ground as it may be almost impossible to inspect it and make necessary repairs, and any interruptions will therefore be of greater duration and maintenance costs will be higher.

Forests affect the cost of transmission lines very seriously. It is desirable to cut through a forest an opening from 300 to 600 feet wide to make room for two tower lines. In high winds there is a large amount of flying material in the air and small branches of trees are apt to be blown against the wires. There is also the more serious danger of forest fires which would destroy the line completely. The cost of clearing a right-of-way through a heavily wooded country is very great and may reach a figure of $100.00 per acre or even more.

In laying out a new line it is important that accurate information and maps be obtained showing the exact profiles of the proposed route, and giving sufficient information so that the location of every tower can be predetermined and profiles drawn up to show the position of the conductors, both at minimum and maximum sags, for every span throughout the line.

The right-of-way where purchased outright varies in cost from $25.00 per acre for barren lands to $250.00 per acre for well cultivated farm lands, and to $2,000.00 or $3,000.00 per acre for lands near a large city. When pole sites or tower sites are leased for a term of years, instead of being purchased outright, careful consideration must be given to the probable future of the district or at the end of the term the line may have to be abandoned because the value of the land has increased to such an extent that the cost of renewing the lease is too great. If two separate rights-of-way can be purchased instead of a single right-of-way for two tower lines at only a slight additional cost, the increased cost will usually be warranted in view of the increased security from total interruptions of service due to severe lightning storms or wind storms.

Electrical Characteristics of Transmission Lines

Frequency

Two frequencies are standard in Canada, 25 cycles, including the frequency of 31.25 cycles used on part of

Plate No. D-7. — General Map of Location of Generating Stations, Transformer Stations and Transmission Lines, of the Hydro-Electric Power Commission of Ontario.

the system of The Shawinigan Water and Power Company, and 60 cycles, including the frequency of 62.5 cycles used in the Montreal district. The original developments at Niagara Falls were made with a frequency of 25 cycles and this frequency was so firmly intrenched in the Niagara district that the Hydro-Electric Power Commission of Ontario carried out the development of Queenston at the same frequency. A considerable amount of 60-cycle power is developed and consumed in Ontario, and where necessary interconnection is made between the two systems by means of frequency converters.

Practically all other developments in Canada are producing 60-cycle power. The original development at Shawinigan Falls was made at 30 cycles but no additional power will be developed at this frequency and as conditions warrant this frequency will gradually be eliminated from the province of Quebec.

There is little doubt that in the light of present knowledge the frequency of 60 cycles is considered more suitable than the lower frequency of 25 cycles, but the investment in 25-cycle apparatus throughout the province of Ontario is too great to be interfered with. It seems very desirable that future developments in Ontario outside the Niagara district be made at 60 cycles as a uniform frequency throughout Canada will in the future greatly assist the interchange of power between systems.

Voltage

No serious attempt has been made to standardize transmission voltage in Canada as there is no standard of allowable line regulation and the voltages at the two ends of a transmission line may differ by as much as twenty-five or thirty per cent. This is very largely due to the fact that the load power factors are of the order of 80 per cent to 85 per cent or even lower, resulting in a very large line drop. This condition is being very greatly improved by the installation of synchronous motor drives in large industrial establishments and in many cases by the addition of synchronous condensers to the other voltage regulating equipment in the receiving station. This makes it possible to operate lines at more nearly their theoretical maximum capacity and at the same time improve the voltage regulation.

The majority of the transmission systems of Canada fall under the voltage classes of:—

22,000 volts (20,000 to 25,000 volts)
44,000 volts (40,000 to 50,000 volts)
66,000 volts (60,000 to 70,000 volts)
110,000 volts (100,000 to 120,000 volts)

The 110,000 volt range is the highest voltage at present used in Canada but it is probable that the near future will see 165,000 volt and 220,000 volt systems in operation.

The change from 66,000 volts to 110,000 volts is coincident with the change from pin type insulators to suspension insulators, although as already stated there are a few cases of successful operation of pin type lines at 90,000 volts and 110,000 volts.

Losses and Efficiency

Kelvin's law can be applied to determine the most economical size of conductor to be used in a particular case, as when a known load at a definite voltage and power factor is to be delivered over a radial line from a generating station of known capacity. But all of the above conditions are not generally known at the time of construction of the line, and even if they are known conditions will probably change in the future and make the exact calculation of less value. For instance the voltage may be raised: the regulation may be improved by the installation of synchronous condensers, resulting in an increase in the capacity of the line; loads may be taken from the line at some intermediate point or the line may be connected in as part of a network; and further it is difficult to attach a definite value to the losses, since the power lost has a value varying between the power cost at the generating station and that at the terminals of the line. In the average case probably an efficiency at full load of about 90 per cent should be aimed at with a difference in voltage between the two ends of the line of from 10 to 20 per cent. To meet these conditions the full load power factor should not be allowed to fall below 90 per cent. In the case of extra high voltage lines, conditions will probably be much more definitely known and the line voltage at the generating station may be fixed as well as that at the receiving station and the two may not be allowed to differ by more than 5 to 10 per cent. This can only be accomplished by the use of large synchronous condensers, and the power losses in this controlling apparatus must be added to the line losses.

On many lines supplying power at low load factor and on which the peaks are of short duration, the all-day efficiency is of as much importance as the efficiency at maximum load, and it may be advisable to accept a larger power loss at the peak and save the extra investment in the conductor, since the average efficiency will still be high.

When a line serves as a tie line between two generating stations and may be called upon to carry power in either direction, depending on the division of the load, it may not be necessary to provide a conductor with more capacity than that required to carry the transfer current, and the losses may be unimportant. The safe current carrying capacity may then determine the size of the conductor.

Corona Loss on Transmission Lines

In the design of high voltage lines, it is of great importance to know the factors affecting the formation of corona and to be able to estimate with reasonable accuracy the critical voltage at which the corona loss begins and the resulting power loss, on various types of conductors and under different conditions of temperature, pressure and altitude, and in both fair weather and stormy weather.

The critical voltage and the loss of power may be calculated from the following formulae, if the regularity factor of the conductor be known and the state of the weather.

Let — e = effective value of kilovolts to neutral.
t = temperature in deg. fahr.
p = barometric pressure in inches.
δ = specific gravity of air.
$g_o = 53.6$ = disruptive critical gradient for air, in kilovolts per inch, effective value, at a temperature of 77 deg. fahr. and at a barometric pressure of 29.9 inches.
r = radius of conductor in inches.
s = distance between conductor centres in inches.
f = frequency in cycles per second.

Then the disruptive critical voltage or the effective value of voltage to neutral at which corona loss begins is,—

$$e_c = 2.302\ m_o\ g_o\ \delta\ r \log_{10}\frac{s}{r} = m_o\ \delta\ e_o$$

where m_o is the regularity factor for conductors and has approximately the following values:—

m_o = 1 for polished wires.
= 0.98 to 0.93 for roughened or weathered wires.
= 0.87 to 0.83 for seven strand cables.
= 0.90, approximately, for large cables with more than 7 strands.

The usual tables of disruptive critical voltages are not easy to apply and the curves plate No. D-4 have been plotted with critical voltage to neutral in kilovolts e_o on a base of conductor diameter in inches for various conductor spacings for the condition represented by $m_o = 1$ and $\delta = 1$ and the equation of these curves is:—

$$e_o = 123.5\ r \log_{10}\frac{s}{r}$$

The values of e_o obtained from these curves should be multiplied by the proper value of δ as corrected for a change of temperature or barometric pressure or altitude and by the value of m_o representing the condition of the conductor surface, before being substituted in the equation to determine the losses.

The air density $= \delta = \frac{17.9\ p}{459 + t}$ = specific gravity of air referred to air at 77 deg. fahr. and 29.9 inches barometric pressure when it has the value 1.00.

C_t the correction factor to be applied to δ for temperature changes is plotted in curve 1, plate No. D-5.

The equation of this curve is $C_t = \frac{17.9 \times 29.9}{459 + t} = \frac{536}{459 + t}$

C_p the correction factor to be applied to δ for changes of barometric pressure is plotted in curve 2, plate No. D-5.

The equation of this curve is $C_{p_a} = \frac{17.9\ p}{459 + 77} = \frac{17.9\ p}{536}$

C_a the altitude correction factor, curve 3, plate No. D-5, is the ratio of the barometric pressure at the given altitude to the barometric pressure at sea level. It should be applied to δ only if the barometer reading is taken at sea level and the line operated at some other level.

The value of δ to be used in the corona voltage and corona loss equations is $= C_t \times C_p \times C_a \times 1.00$; t being the temperature along the line, p the barometric pressure at sea level, and a being the altitude above sea level.

If the pressure reading is taken at the level of the line the factor C_a is omitted.

The power loss in fair weather, in kilowatts per mile of single conductor is,—

$$P_f = \frac{390}{\delta}(f + 25)\sqrt{\frac{r}{s}}(e - e_c)^2\ 10^{-5}$$

In stormy weather the critical voltage is lowered about 20 per cent, and the power loss in stormy weather in kilowatts per mile of single conductor, may be taken as

$$P_s = \frac{390}{\delta}(f + 25)\sqrt{\frac{r}{s}}(e - 0.8\ e_c)^2\ 10^{-5}$$

In calculating the corona loss it must be remembered that the line is not all at the same voltage since there is usually a drop of 5 or 10 per cent at least between the generating station and the receiving station. The above formulae are based on the assumption that the conductors are uniformly spaced in an equilateral triangle. If the vertical or horizontal arrangement is used corona forms on the middle wire before it forms on the two outer wires. The equivalent uniform spacing may be used without serious error. It is,—

$$s = \sqrt[3]{s_1 \times s_2 \times s_3}$$

where s_1, s_2 and s_3 are the actual distances between the various pairs of conductors.

It is not advisable to operate a line above the critical voltage in fair weather or the loss in stormy weather may be excessive. It is very unlikely, however, that a storm will extend over the whole line at one time. The corona loss on a transmission line will vary from day to day due to differences in temperature and weather conditions, it has a tendency to be lower in winter due to the low temperature. If a line is operated near the disruptive critical voltage any surge appearing as a high voltage on the line will tend to dissipate part of its energy in corona loss, and to this extent the corona will serve as a protection to the terminal apparatus.

The formation of corona changes the apparent capacity of the transmission line and the charging current and introduces a power component of current to supply the loss. It has been shown that a third harmonic of considerable magnitude flows when corona forms and this may interfere with the operation of signal systems.

As an example, determine the corona loss in both fair and stormy weather at a temperature of 32 deg. Fahr.

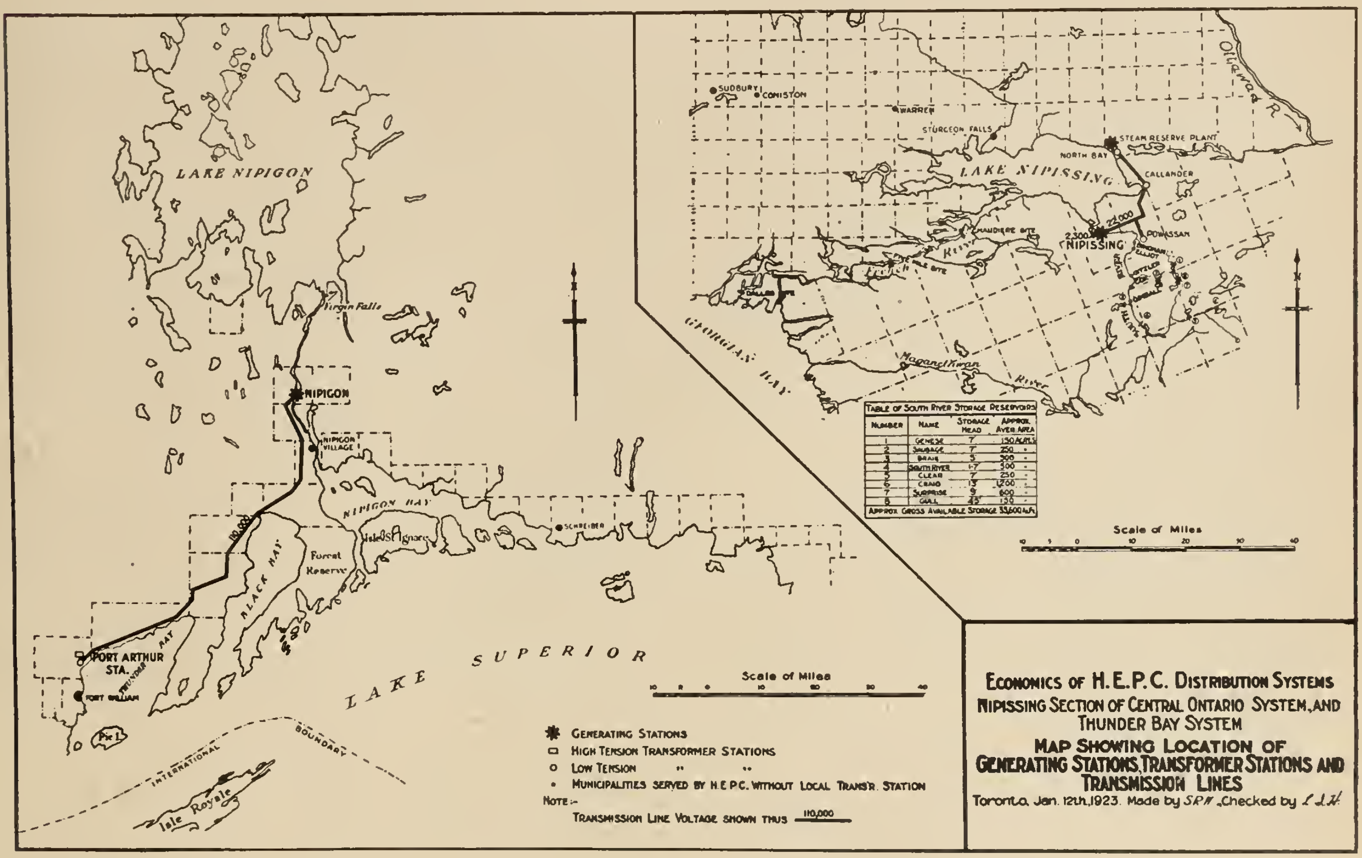

Plate No. D-8, — Location of Generating Stations, Transformer Stations and Transmission Lines, Nipissing Section of Central Ontario System, and Thunder Bay System.

and at an altitude of 500 feet above sea level on a line consisting of three conductors of 500,000 circular mils steel reinforced aluminum, uniformly spaced 15 feet apart and operating at 200,000 volts between lines and at a frequency of 60 cycles per second. This conductor is made up of 30 strands of aluminum over 19 strands of steel and has a diameter of 0.904 inch and may be considered as having a regularity factor of $m_0 = 0.9$.

The temperature correction factor for δ is 0.96 and the altitude correction factor for δ is 1.09.

Assuming normal barometric pressure at sea level the value of δ is $1.00 \times 0.96 \times 1.09 = 1.05$

The disruptive critical voltage obtained from the curve for this spacing is 145 kilovolts and applying the factors above, the disruptive critical voltage under the assumed conditions is,—

$e_c = 1.05 \times 0.9 \times 145 = 137$ kilovolts to neutral.

The operating voltage between conductors and neutral is,—

$$e = \frac{200}{\sqrt{3}} = 115.5 \text{ kilovolts,}$$

and there would therefore be no corona loss in fair weather.

In stormy weather the loss would be,—

$$3P_s = 3 \times \frac{390}{1.05} (60 + 25) \sqrt{\frac{0.452}{15 \times 12}} (115.5 - 0.8 \times 137)^2 \times 10^{-5}$$
$$= 1.65 \text{ kilowatts per mile of line.}$$

This is a negligible loss and even at 220,000 volts the loss would only be 14.25 kilowatts per mile in stormy weather.

Voltage Regulation

The various methods of computing the regulation of transmission lines will not be treated here in detail. For lines up to 50,000 volts the effect of the line capacity may be neglected in the majority of cases, as the line charging current is largely offset by the magnetizing current required for the transformers. The resistance and reactance of the step-up and step-down transformers should always be added to the line resistance and reactance, since in the case of many short lines the impedance voltage drop in the transformers is of the same order as that in the line.

For higher voltage lines up to 100,000 volts, and up to about 100 miles in length, the line capacity may be considered as concentrated at the centre of the line. In the case of still higher voltage and longer lines, calculations involving the use of hyperbolic functions should be employed. They give the exact results with very little more work than the simplified methods.

The drop of voltage in the line and transformer impedance depends to a very great extent on the power factor of the load. A short transmission line may deliver power at 80 per cent power factor without an excessive line drop but when power is delivered at the end of a long line it should be delivered only at power factors of 90 per cent and over.

The diagram, plate No. D-6, illustrates the effect of low load power factor in increasing the voltage regulation of transmission lines of moderate length, and in increasing the required kv.a., capacity of the generators and transformers in the power station. The line in question was assumed to have a 10 per cent resistance drop and a 30 per cent reactance drop, and the effects of the line capacity and the magnetizing current of the sub-station transformers were neglected as they tend to neutralize one another.

With a load of 100 per cent delivered at a voltage of 100 per cent and at a power factor of 90 per cent the line loss is 12.3 per cent, the voltage at the generator is 127.7 per cent of the receiver voltage, the kv.a., at the generating station is 142 per cent of the kilowatts delivered and the generator power factor is 80 per cent.

With the load power factor reduced to 80 per cent and the same load in kilowatts delivered at the same voltage, the line loss is 15.6 per cent, the voltage at the generating station is 135 per cent, the kv.a. capacity required in the generating station is 168.5 per cent and the generator power factor is 69 per cent.

Conditions may be improved by installing synchronous condensers at the substation end of the line to produce at least a part of the lagging current required for the load at this point instead of transmitting all of it through the reactance of the transmission lines.

The load power factor can be increased from 80 to 90 per cent by installing synchronous condensers in the substation of a capacity of 27 per cent of the kilowatts delivered. This reduces the kv.a. capacity required in the generating station by approximately an equal amount and at the same time improves the efficiency of the transmission, as indicated above. A loss of 3 to 4 per cent of the capacity of the synchronous condensers must be added to the line losses.

When considering the transmission of very large amounts of power at voltages of 165,000 volts or 220,000 volts, line drops of 20 to 25 per cent cannot usually be considered, as the line must be constructed and insulated for the highest voltage at any point on it, and the regulation should normally be limited to from 5 to 10 per cent. This may require the installation of synchronous condensers with a rating of 60 to 70 per cent of the kilowatts delivered at full load.

If sufficient synchronous capacity is installed the line can be operated at constant voltage at both the generator and the receiver ends or in the extreme case with the same voltage at the two ends. If it is desired to operate a line 300 or 400 miles in length at the maximum capacity, it may be necessary to place part of the synchronous capacity at the centre of the line to prevent a decrease of the voltage there.

Synchronous Condensers

The term "synchronous condenser" is applied to synchronous motors when they are used primarily for power factor correction or voltage regulation. Such machines are essential on large power systems for the regulation of voltage at the receiving station. At times of heavy load the condensers are over-excited and they can then be considered as drawing leading current over the lines, thus holding up the receiver voltage, or as supplying part or all of the lagging current required for the load. At times of light load they are under excited and draw a lagging current from the lines, which combines with the lagging current required by the reduced load and holds down the receiver voltage to its normal value. It is not practicable to design a synchronous condenser to operate at full capacity lagging, but 60 to 75 per cent capacity lagging can be obtained.

If both the generator voltage and the receiver voltage are to be held constant under all load conditions and are not to differ by more than five or ten per cent the synchronous condenser capacity in kv.a. must be of the order of 60 to 70 per cent of the load kilowatts, or approximately the amount required to raise the load power factor to unity. The generator voltage is held constant by means of automatic voltage regulators and the condensers with automatic voltage regulators operating on their exciters hold the receiver voltage constant at a somewhat lower value.

On the majority of systems at present in operation in Canada, synchronous condensers are being used to only a limited extent to improve the load power factor and to control the receiver voltage, the generator voltage being varied to suit the load conditions. On one system in Manitoba synchronous condensers have been in operation for about ten years and the results have been very satisfactory. A number of synchronous condensers have been installed at various points on the transmission network of the Hydro-Electric Power Commission of Ontario to reduce the amount of lagging current transmitted over the lines to the main centres. Some other large systems have hesitated to connect synchronous condensers of large capacity to their systems fearing that the increase in current fed to short circuits would tax the present circuit breaker equipment beyond its safe capacity.

In the early stages of operation of a transmission system the use of synchronous capacity is not often warranted but when the load increases to the point where new lines are necessary, the installation of condensers should be carefully considered. If the extra lines are required as insurance against interruptions of service as well as to improve the efficiency and regulation, the installation of condensers may not be justified. If, however, it is only a question of increasing the capacity of existing circuits the synchronous condensers will enable this to be done with the minimum of expense. To increase the capacity to the same extent by raising the voltage of the lines would probably cost more, and the improvement in regulation would not be so great.

There is no doubt that the near future will see a great increase in the use of such machines, but it is much better practice for a large distributing system to place synchronous condensers at various points throughout its network, where they will relieve the underground cables of large components of lagging current and so increase the capacity of the system and will at the same time raise the power factor of the load supplied over the main transmission lines. The synchronous condensers installed in the receiving station will then be of much smaller capacity and the danger of excessive short circuit currents will be decreased.

The losses in modern synchronous condensers are very low and vary from about 4 per cent in condensers of 5,000 kv.a. capacity to 2 per cent in those of 30,000 kv.a. capacity. Since they can be constructed as high speed machines the cost is very reasonable and their electrical characteristics are good.

For some years it has been evident to the transmission companies that the power factors of many of the large industrial loads were lower than necessary and they have been insisting on the installation of synchronous motors for driving at least a considerable portion of the machines, with sufficient exciter capacity so that the total load power factor can be kept at 90 per cent or above. It seems reasonable that the transmission companies should not sell power in large blocks below 90 or 95 per cent power factor and that a great portion of the synchronous capacity should be placed on the distributing systems or in the customers premises.

Power Factor Correction on Distributing Systems

Practically all large distribution systems, as well as the transmission systems supplying them, are suffering from troubles due to low power factor or due to the large components of reactive lagging current flowing in their circuits.

These lagging currents are required as magnetizing currents for transformers and induction motors and to produce the magnetic fields surrounding all the circuits, but in the majority of systems they may be considerably reduced by improvement in the connected apparatus and by the application of proper motor types and sizes to the various loads. The two most serious effects of the lagging currents are the impairment of the voltage regulation and the increase of the line losses, both result in

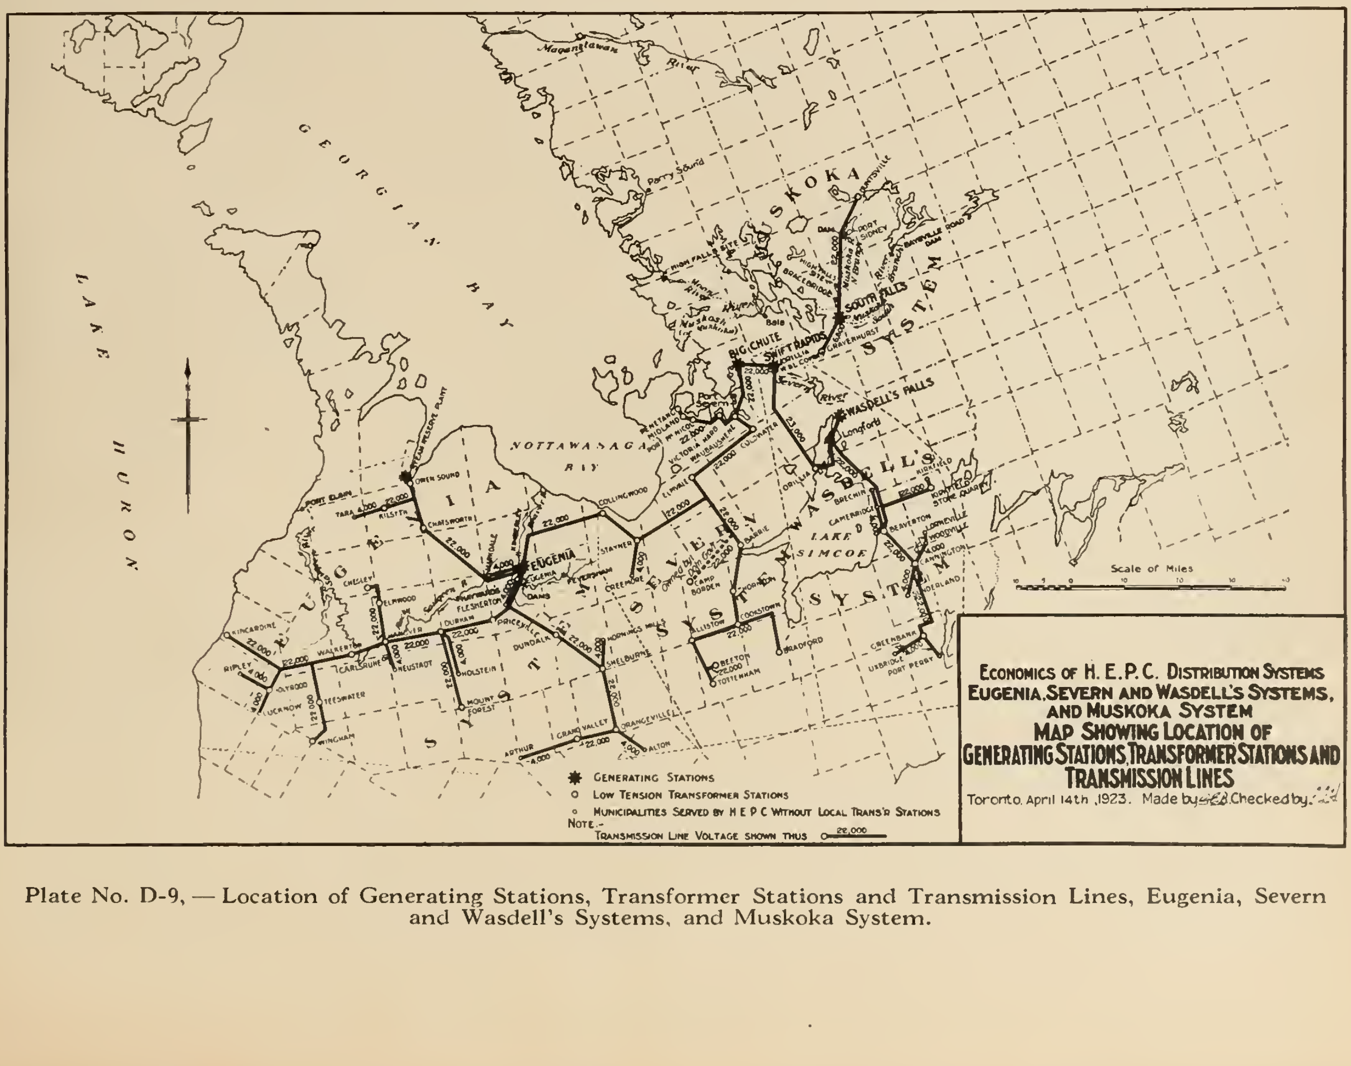

Plate No. D-9, — Location of Generating Stations, Transformer Stations and Transmission Lines, Eugenia, Severn and Wasdell's Systems, and Muskoka System.

reducing the power capacity of the various transformers and circuits.

It is possible to relieve, to a large extent at least, the transformers and the lines of these objectionable lagging currents if the magnetizing current is produced near the point where it is required. Over-excited synchronous motors or static condensers can be used to supply magnetizing current to induction motors on the same circuits and so relieve the supply line. In the substation synchronous condensers or static condensers may be installed to act as generators of lagging current and they will then relieve the cables feeding the substations and will increase their capacity.

The advantages to be gained from the installation of static condensers to reduce the lagging current flowing in the lower voltage circuits are becoming more apparent as the economy of distribution is studied and up to the present time over 8,000 kv.a. of static condensers have been installed on the various distribution systems throughout Canada. For large capacities and for use on the high voltage circuits, the synchronous condenser is more suitable as it can be operated lagging as well as leading to improve voltage regulat'on, while the static condenser can only draw leading current to improve the power factor. When the voltage of the system decreases the synchronous condenser draws an increased leading current and so tends to limit the voltage drop while the corrective effect of the static condenser decreases with the decrease of voltage.

The static condenser has very low losses, these being less than one-half of one per cent. Its operating and maintenance costs are small and it does not add to the short circuit currents on the system. Its first cost is a little greater than the synchronous condenser, except in the very small sizes, and it requires more floor space, but it has the great advantage that it can be subdivided into its individual units and placed at the points on the system where it will show the greatest economy. The condensers for power circuits are made in units for 600-volt service but these can be connected in series for operation on circuits up to 3,000 volts and, when the demand arises, they can be supplied for 6,600-volt circuits.

Any synchronous capacity or electrostatic capacity added to the distributing system not only relieves the distribution circuits of the excess lagging currents but also relieves the transmission lines at the same time and reduces the amount of synchronous capacity required in the terminal station to maintain satisfactory voltage regulation.

Alternating Current Generators and Transformers

Alternating Current Generators

Alternating current generators are in operation in Canada in sizes up to 55,000 kv.a., 25 cycles, 12,000 volts on the system of the Hydro-Electric Power Commission of Ontario and up to 40,000 kv.a., 60 cycles, 11,000 volts at Shawinigan Falls, Que. These machines are all three-phase, star connected machines.

The majority of the smaller generators are rated at 6,600 volts. For capacities below 10,000 to 15,000 kv.a. the armature currents are not excessive and the lower voltage is more economical, but machines of very large capacity will require a number of armature circuits in multiple and the terminals and cables will be very heavy and when the capacity is over 25,000 kv.a. the higher voltage will be warranted in the majority of cases. The increase of voltage limits the mechanical stresses on bus bars and this may be of considerable importance in stations of large capacity.

The short-circuit currents from generators of the later designs are proportionally much smaller than those from machines built eight or ten years ago. The increase in the allowable operating temperatures has resulted in an increase in the permissible rating of a given machine and this has been accompanied by an almost equal increase in the per cent reactance drop and a corresponding reduction in both the instantaneous and the sustained short-circuit currents.

The 40,000 kv.a., 60-cycle, 11,000-volt generator mentioned above has a sustained short-circuit current with normal excitation of about 2.5 times full load current and an instantaneous short-circuit current of less than 3.3 times full load current. Such large internal reactances increase the per cent regulation and extend the range required in automatic voltage regulators but do not seem to present any operating difficulties. This particular machine when short circuited under light load conditions, when the excitation is low, delivers less than full load current to a short-circuit and this has made necessary some changes in the ordinary relay protection.

Step-up transformer banks are being operated as part of the generators in an increasing number of stations and the generators are not paralleled on the low voltage side. The generator bus bars and circuit breakers may then be omitted and the station layout very much simplified.

Transformers

The design of alternating current transformers has more than kept pace with the increase of transmission voltage and it is evident that transformer voltages can be increased to values as high as will be required for economical transmission.

Transformers of both the core and shell types have been built for 220,000-volt service and are now in operation in the United States. The core type seems theoretically to have certain advantages under short-circuit stresses on account of the shape of the coils and for the very high voltages since it is easier to provide the requisite insulation between the high voltage and low voltage windings. For the lower voltages the operating records of both types when built by reliable manufacturers are so good that a choice between the two types is largely a matter of individual preference.

One change in design which has been introduced with the 220,000-volt transformer and which may be copied on some lower voltage designs in the future is the use of only one high voltage bushing, the other end of the high voltage winding being grounded to the core and tank. This arrangement allows the designer to grade the insulation of the high voltage winding from a maximum at the line end to a minimum at the neutral point and so saves a considerable expenditure without reducing the factor of safety.

The later power transformers are being designed with a much larger per cent reactance drop than was the case a few years ago and from 8 to 10 per cent reactance drop on new 60-cycle transformers is common. This large reactance reduces the destructive effects of short circuits. The largest 25-cycle transformers so far built are the new 18,330-kv.a., single-phase units for the Queenston plant in Ontario. They are of the shell type and three of these connected delta-star are used to step up the generator voltage from 12,000 to 110,000 volts, which will later be increased to 132,000 volts.

The largest 60-cycle transformers in operation in Canada are at Shawinigan Falls and are rated at 15,000 kv.a., they also are of the shell type and are connected delta-star for operation at 115,000 volts but they are designed so that when the full high voltage winding is used the line voltage can be raised to 155,000 volts. The fact that both of these transformer banks are constructed to operate later at an increased voltage, illustrates one of the difficulties of transmission line design where load conditions change with great rapidity. Provision must be made in many cases to increase the capacity of lines by an increase of voltage. In some cases this is accomplished by operating transformers delta-delta in the earlier stages, and later changing over to delta-star. On 110,000-volt lines this gives too great an increase of voltage to be taken care of without reconstruction of the line

Three-phase transformers are used in sizes up to 14,000 kv.a., but in the majority of installations of large capacity three single phase units are preferred. In the smaller sizes they are used to a very considerable extent particularly in outdoor pole type transformer stations.

Oil conservator tanks have been installed with a great many of the later power transformers and they are of value in reducing the deterioration of the oil, but many engineers fear that serious damage may result from arcs causing explosions in tanks which have no air to act as a cushion. An attempt has been made to overcome this objection, and at the same time to prevent sludging of the oil, by the development of a breather which will extract all the moisture and oxygen from the air and allow only nitrogen to pass into the transformer tank. The inert gas acts as a cushion to relieve stresses set up by arcs n the oil, and a further safeguard is provided by attaching the manhole cover by springs and placing below it an air-tight diaphram which will rupture under excessive stresses. This new equipment has been provided with the large 25-cycle transformers for the Queenston plant but some years of operating experience will be required to determine its merits.

Three types of bushing are in common use for transformers and oil circuit breakers, the compound filled type, the condenser type and the oil filled type. The compound filled bushing and the condenser bushing have both given very satisfactory service on apparatus up to 110,000 volts but for higher voltages the condenser type and the oil filled type are more suitable. For indoor service the condenser bushing has a smaller diameter than the other bushing which makes it more suitable for use with bushing type current transformers. In outdoor service some troubles have been experienced due to the breakdown of the compound filling the space between the bushing proper and the porcelain sleeve. The oil filled bushing has been used to only a very limited extent in Canada. It has the disadvantage of requiring occasional inspection to test the oil and to replace any which has leaked out.

Since bushings for the higher voltages are so expensive it is of advantage to have them designed to be interchangeable between transformers and circuit breakers to reduce the number of spare bushings carried in stock.

Transformer Connections

The large generators used in modern hydro-electric developments may be either star or delta connected but the majority are star-connected and the neutral is either solidly grounded or grounded through a resistance suited to the requirements of the protective apparatus.

The step-up transformers are more and more being considered as a part of the generator. The standard connection of the transformer banks at the generating station is delta-star and the star neutral is usually solidly grounded. The delta connection is required to give a path for the third harmonic magnetizing current as otherwise the secondary voltage wave will be distorted.

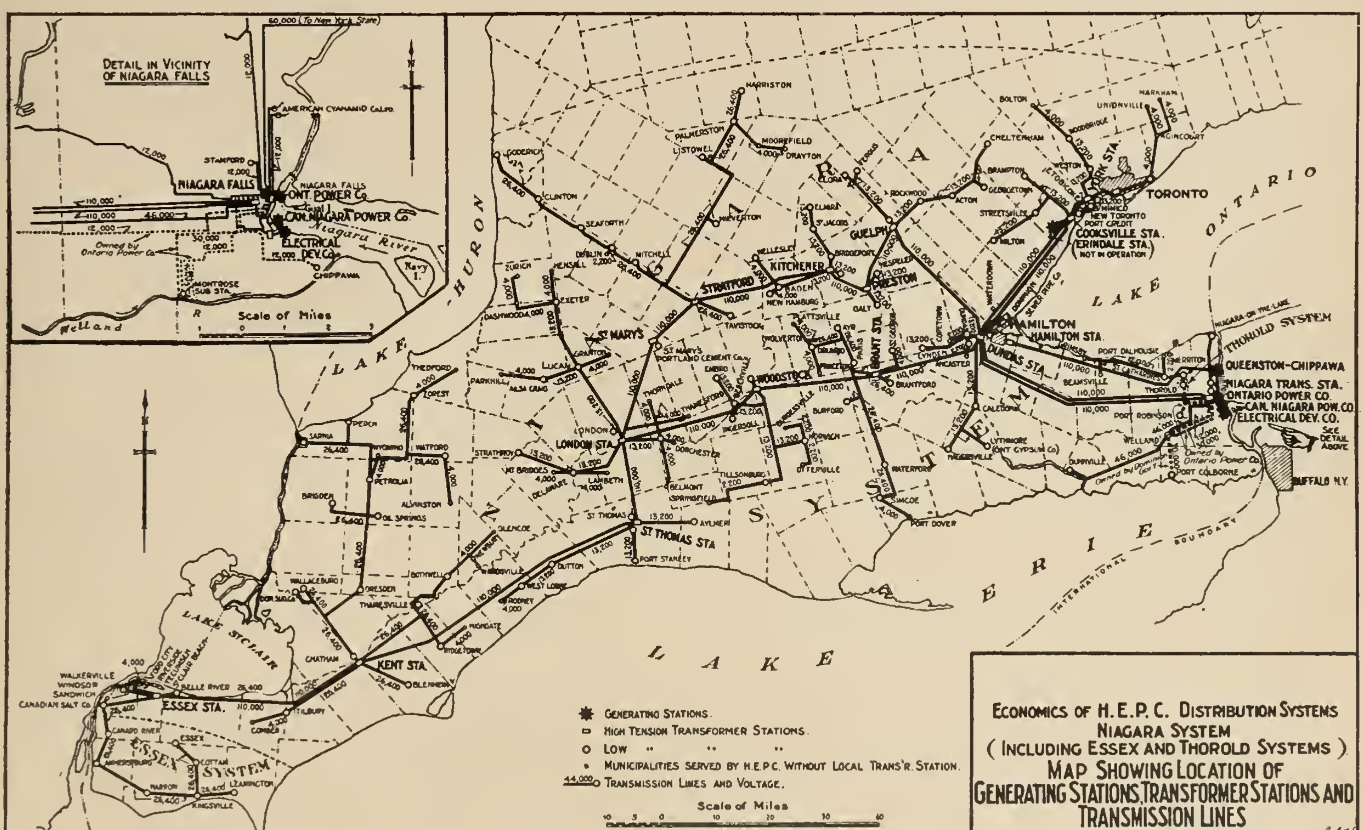

Plate No. D-10, — Location of Generating Stations, Transformer Stations and Transmission Lines, Including Essex and Thorold Systems

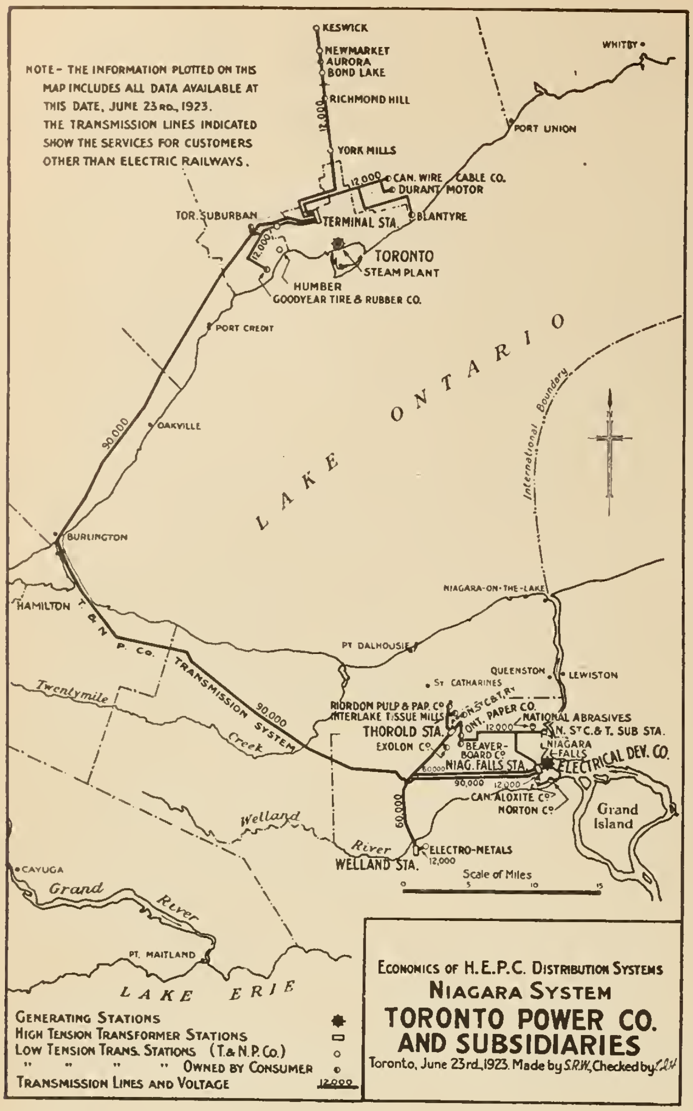

Plate No. D-11, — Location of Generating Station, Transformer Stations, and Transmission Lines, Toronto Power Company and Subsidiaries, Niagara System.

A star-star connection can be used if both the generator and transformer neutrals are solidly grounded but such a connection is not advisable since the third harmonic magnetizing current for the step-up transformers circulates through the generator and transformer neutrals and there is a triple frequency pulsation of the generator leads to ground. The delta-delta connection can also be used if it is not necessary to ground the neutral on the high voltage side.

Passing to the substation end of the line the transformers may be connected star-delta and the high voltage neutral either grounded or isolated. If it is grounded, a part of the third harmonic magnetizing current for the step-down transformers passes over the three line conductors in multiple and returns through the neutrals. This tends to cause a triple frequency induction in neighbouring signal circuits but the closed delta on the secondary side presents an alternative path for this current and interference is not usually serious. If the neutral is not grounded the third harmonic current does not pass over the lines but is confined to the delta. The star-star connection is not advisable as there is no path except the line for the third harmonic current and interference with signal circuits would be serious. This can be partially eliminated by placing a tertiary winding on the transformers to provide the required path for the magnetizing current. Tertiary windings add considerably to the cost of transformers and have not been used in Canada up to the present. Where the tertiary winding can at the same time fulfil some other function such as providing a circuit from which to operate synchronous condensers for voltage control of transmission lines it may become more popular. It will then be quite possible to use the star-star connection of transformers at the substation end of transmission lines.

Where it is not considered necessary to ground the neutral on the line side at the substation the delta-star connection may be used, which has the advantage of providing a neutral on the low voltage distributing system which may be grounded. This of course requires that the transformers should be designed for the full line voltage which makes them considerably more expensive than the corresponding star-delta connected transformers. For 165,000- and 220,000-volt lines the neutrals at both ends of the high voltage lines will be solidly grounded to reduce insulation stresses, and also to permit the use of a single high voltage bushing. In such a case the secondary might well be a star connected 12,000-volt circuit with grounded neutral for secondary distribution and a tertiary winding would be added both to provide a path for the magnetizing current and to supply the proper voltage for operation of the synchronous condensers.

Relay Protection

Since the function of an electric power company is to make electric power available for its customers at all times, and since any even momentary interruption of the service may result in serious loss to the customers, the designing engineer must give the most careful consideration to all means available as insurance against interruption of the power supply. The necessary spare equipment and duplicate lines must be provided and an adequate system of relay protection must be installed.

Relays cannot give perfect protection from interruptions of service but the various types developed and improved during the last ten years give the engineer an opportunity to reduce the number of interruptions due to defective circuits.

It is not possible here to enter into a technical discussion of the problems of relay protection but only to point out the benefits obtained by those companies which have had the faith to spend time and money in developing protective systems to reduce the interruptions to service due to insulation failures or other abnormal operating conditions.

For small systems, with only single lines, overload relays must disconnect the faulty line at the power station before serious permanent damage results and the customer must wait for repairs to be made to the line before his service is resumed.

When duplicate lines are provided and a ground or short circuit occurs on one of them, the protective relays must disconnect the faulty line at both ends with the least disturbance to the other line or lines and without causing any interruption of the service. Such a protective system developed for some of the largest systems in Canada and giving most satisfactory results is briefly described in the following pages.

Differential Current Scheme for the Protection of Two Parallel Lines

With generators at both ends of a double circuit line, such as a double circuit tie line between two power houses, or with generators at one end and synchronous condensers or synchronous motors at the other, a very rapid clearing of a faulty line is required to keep the synchronous machines from falling out of step and to prevent serious power arc destruction of insulators.

On such a system, discriminating protection, requiring only current elements was applied based on the fact that when a ground or short-circuit occurs on one line it will manifest itself by drawing more current than the good line. This will hold true for a short circuit at any point between stations, and a relay, actuated by the excess current, to trip the faulty line and to simultaneously prevent the sound line from tripping, can select and clear the faulty line without affecting the service over the other line. It is essential that the trip circuit of the sound line be blocked before the faulty line is cleared. A protective scheme based on this principle has been in successful operation for the last six years.

Differential Current System for the Protection of Three or More Parallel Lines

For the protection of a system of three or more parallel lines, discriminating action can be obtained by the use of relays energized from current transformers alone. The successful functioning of such a system of protection is based on the fact that the current of a line becomes unbalanced relative to the same phases of other parallel lines when a fault occurs on it, whereas the current in the other parallel lines will remain balanced with respect to each other. This will hold true for a short circuit at any point on a system of three or more parallel lines provided their characteristics are similar.

An arrangement of differential relays coupling one feeder with the other parallel feeders, and having the trip circuits of these relays interconnected in such a way that their joint action will trip the circuit breaker in the unbalanced feeder, will be able to select and clear such a faulty feeder without disturbing the remainder of the system. The faulty feeder will either be disconnected at the two ends simultaneously or in succession depending on the location of the fault.

For the protection of three parallel lines only three differential relays are required, each relay having two independent trip contacts, each contact being inserted in one of the trip circuits of the two lines from which the relay is energized. Only one current transformer is required for each line.

The same principle can also be applied for any system of more than three parallel lines. Each feeder may then be coupled up with two other feeders only or it may be coupled up with all the parallel feeders. The latter arrangement will require more relays but has the advantage in operation that it permits any line to be disconnected without disturbing the effectiveness of the protection so long as three lines remain in service. When two lines only are left in service, the protection will open both lines without discrimination when a fault occurs on one of them.

This differential current system has been in use for a number of years on two of the largest transmission systems in the country and has given very satisfactory results.

Relay Protection for Radial Transmission and Distribution Systems

The ordinary method of protecting a radial distributing system is to provide excess current relays with selective time adjustments. It is based on the assumption that under any short-circuit condition the current in the faulty line will exceed full load current, and this excess current is used to actuate a current relay, which in turn

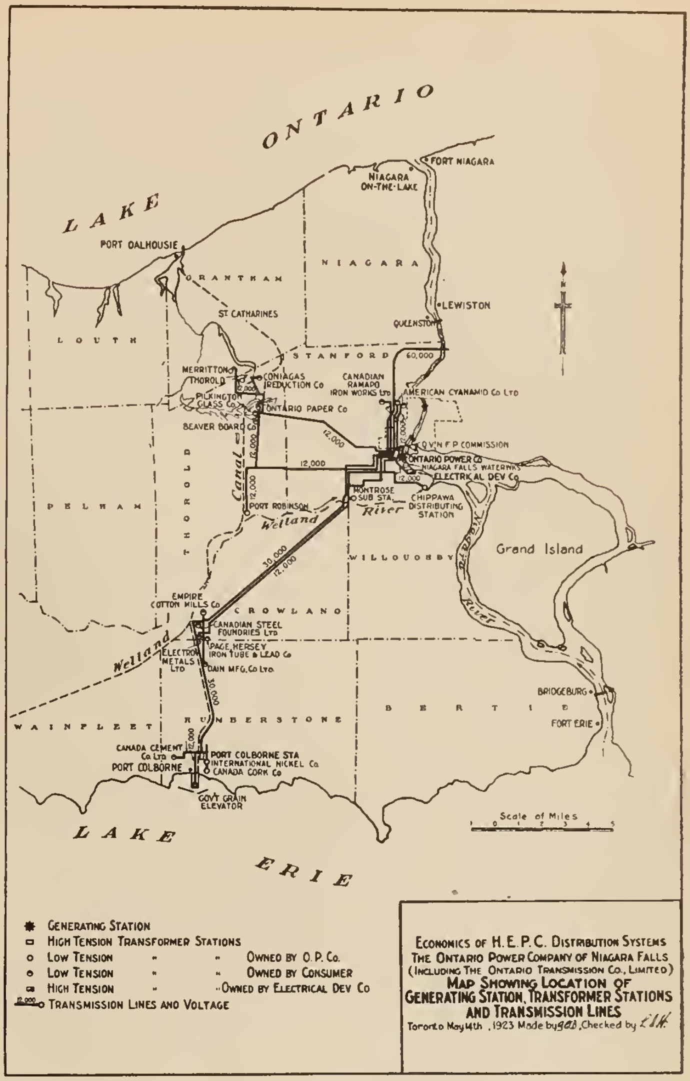

Plate No. D-12, — Location of Generating Station, Transformer Stations, and Transmission Lines, of the Ontario Power Company, Including the Ontario Transmission Company, Limited.

trips the line circuit breaker, thus disconnecting the faulty line. Systems with several substations in series have a time delay feature on the current relays of the various stations. This time delay is made shortest on the distant feeders and is gradually increased towards the generating station and reaches the highest time setting at the generating station. Such a system of time settings will give distant feeders a chance to clear, when in trouble, ahead of main feeders closer to the generating station, even if the short circuit current should be sufficient to start to actuate the excess current relays of the main feeders.

The excess current is used to indicate the abnormal condition of the line due to short circuit, while selectiveness of tripping is obtained by time delay differences on the relays of switches located in series to each other between the point of fault and the generating station. This principle of protection while satisfactory on some systems is found to be inadequate for transmission systems where the whole output of the generators is fed out over a few long lines, since, due to the large reactances in the lines, transformers and generators, the short circuit current after the first instant may fall below normal full load current and the excess current principle therefore fails in this case. However, by making use of the fact that a short circuit manifests itself not only by excess current but also by low voltage a different system of relay protection has been developed for such systems and has had some years of successful operation on one of the largest systems in the Province of Quebec.

In the new system selectiveness of switches placed in series to one another is obtained not only by a time selective setting but by the use of a relay which will respond only if it is close enough to the short circuit to be affected also by the resultant voltage drop.

A differential relay is used, having a beam actuated at one end by a current coil fed from the line and at the other by a voltage coil fed from the station busbars. The operation of the relay depends on the relation between current and voltage regardless of their actual magnitudes and is therefore equally effective at all loads and with all values of generator capacity.

Ground Selector

When a system is operated with the neutral grounded, a ground occurring on any conductor develops immediately into a short circuit of that phase and overload relays will at once disconnect the defective line. Since on circuits over 60,000 volts and also on many of lower voltage, grounding the neutral is the usual practice, grounds developing on such circuits can be very easily cleared and the operation of the rest of the system continued.

A ground, occurring on a non-grounded transmission or distribution system will be felt over the whole system. There is normally no means available of locating the faulty line except by successively disconnecting individual sections of the system until the grounded section is found. Such a method is slow and always necessitates the momentary interruption of a larger part of the system than necessary, since many sound feeders may be disconnected before the faulty feeder is finally located. The ground will cause a 73 per cent increase of voltage on the two sound phases to ground and if left on for any length of time may cause the breakdown of another weak spot at an entirely different part of the system.

To reduce to a minimum the disturbing effect of a ground, it is essential to provide means to disconnect the grounded section within the shortest possible time. This is the function of the ground selector. The fundamental idea of the ground selector is to produce a short circuit immediately after a ground appears on the system. This is accomplished by automatically grounding one of the sound phases at the main station bus by closing an oil switch to ground immediately after the ground appears. Thus a complete phase-to-phase short circuit is produced and as a result overload current will flow into the faulty line and the ordinary overload protection will act and disconnect it. As soon as the line is cleared the ground switch will open automatically and restore the remainder of the system to normal.

Grounding the Neutral of Power Transmission Systems

In the early days of power transmission there was little operating experience available to demonstrate the advantages and disadvantages of operating systems with grounded or with isolated neutrals.

At the present time transmission voltages have increased far beyond those used in the earlier systems and the necessity of grounding the neutral of such systems to avoid excessive insulation strains and in order to provide a more definite method of clearing lines in trouble has been demonstrated. It is now standard practice to ground the neutrals of lines operating at 66,000 volts or higher, although there are still some exceptions due to special circumstances. In the case of overhead systems of 13,200 to 66,000 volts the objections to the isolated neutral are not so great and many of the lower voltage systems are operated in this way.

It is further necessary to consider the character of the ground to be placed on the system, whether the neutral is to be solidly grounded or is to be grounded through a resistance, whether the neutrals of all generators or transformer banks are to be grounded, or only some or even only one of them. A ground through a resistance on each bank of transformers may be more effective or may offer a lower total impedance to the flow of ground current than a solid ground on only one transformer bank.

Sufficient operating experience has now been collected and published to enable engineers on new installations to give a reasoned judgment on the question of grounding and unless some special circumstances are to be considered, the best practice is to ground the neutral of transmission lines solidly at the generating station using delta-star connected transformers.

There is still a difference of opinion as to whether transmission lines should have their neutrals grounded at the substation as well as at the generating station. Part at least of the third harmonic magnetizing current for the substation transformers will flow out along the three line conductors in multiple, and back through the neutral connections. This may affect nearby signal circuits, but the induced voltages do not appear to be serious. If it is not considered necessary to ground the neutral on the high voltage side at the substation, the delta-star connection of step-down transformers may be used, and it establishes a neutral point at the source of power for the secondary network.

The main arguments in favour of the isolated neutral system especially with delta-delta connection of transformers, are discussed below:—

(1) A single broken insulator causing a ground would not result in a short circuit, and consequent interruption of service, but service could be maintained until it was convenient to disconnect and repair the faulty line. To continue operation under such circumstances cannot be considered good engineering practice, as the whole system is endangered. Insulation breakdowns may occur at widely scattered points on the system. If the ground originally formed is an arcing ground, very dangerous high frequency surges will be produced in the circuits which are very destructive. Both of these conditions will cause severe induced voltages to appear in neighbouring signal circuits, and for this reason, if for no other, such operating conditions cannot be tolerated.

(2) With transformers connected delta-delta it is possible to continue operation at reduced capacity when one transformer is damaged and out of service. Such open delta operation of transformers offers some economies in the early stages of a small transmission scheme, but results in a slight voltage unbalance which is objectionable. When a system is operated delta-delta in the early stages, when the load is comparatively light, with the intention of later increasing the line voltage by changing to the delta-star connection, the original operation with isolated neutral may be justified.

When a ground appears on an isolated neutral system there is normally no means available to locate the faulty line except by disconnecting successively individual sections of the system, and observing when the ground disappears. Such a cut-and-try method is very slow and causes momentary interruption of a larger part of the system than necessary. To reduce to a minimum the damaging effect of a ground it is essential to provide means to select and cut out the grounded section within the least possible time.

Systems designed with isolated neutrals may be changed to grounded neutral systems by the use of grounding transformers, but to obtain the equivalent of a solid ground the grounding transformer must have a large capacity and will be expensive. Ground resistances for high voltage systems must likewise be designed with large current capacity and must be thoroughly insulated. They are usually expensive and take up a large amount of space. At a number of points on the system of the Hydro-Electric Power Commission of Ontario, grounding resistances consisting of a number of barrels of water, mounted on insulators and connected in series, are used and they function satisfactorily.

Grounding of Cable Systems

The practice followed in grounding underground cable systems is somewhat different from that employed on overhead lines. The majority of such systems are operated with the neutral grounded, but very few are solidly grounded. One of the main reasons is that the reactance in such systems tending to limit the flow of current to a fault, is much less proportionally than in the case of overhead lines, since the extent of the systems is so much smaller, and at the same time the concentration of power in the underground network is of the same order as that in the transmission system. The safest practice is to operate with a resistance in the ground connection and only reduce or remove it when operation of the system has clearly demonstrated that such a procedure is warranted. If sufficient current limiting reactances are placed in the feeder circuits the ground resistance may not be required.

Lightning Arresters

The primary object of a transmission company is to sell and deliver power and the interruptions of the supply must be brought as close to the irreducible minimum as is possible by economical design and by the installation of the proper protective apparatus.

Lightning arresters are designed to protect the insulation of apparatus and particularly end coil insulation from puncture at or very close to the points where the arresters are installed. If they, at the same time, protect the service it is only a consequence of the protection afforded to the insulation.

On wood pole lines the most prolific cause of interruptions to service is arc-over of insulators due to lightning at points distant from the arresters, and the lightning arrester has no power to prevent such an occurrence. The ground wire however tends to reduce the number and severity of such arc-overs and also reduces the duty of the lightning arrester in relieving such disturbances when they occur near the station.

Lightning arresters may be dispensed with if there are no lightning storms and no severe surges on the lines, if the insulation of the power transforming apparatus has a higher factor of safety than the line insulation, or if the protected apparatus is of such small kilowatt capacity that the relatively high cost of the arrester cannot be justified economically.

There are very few systems which are free from lightning disturbances and surges. Some originally well designed lines have weak line insulation due to the fact that the line operating voltage has been raised above that originally contemplated without a corresponding change in insulation. Such a condition, while not

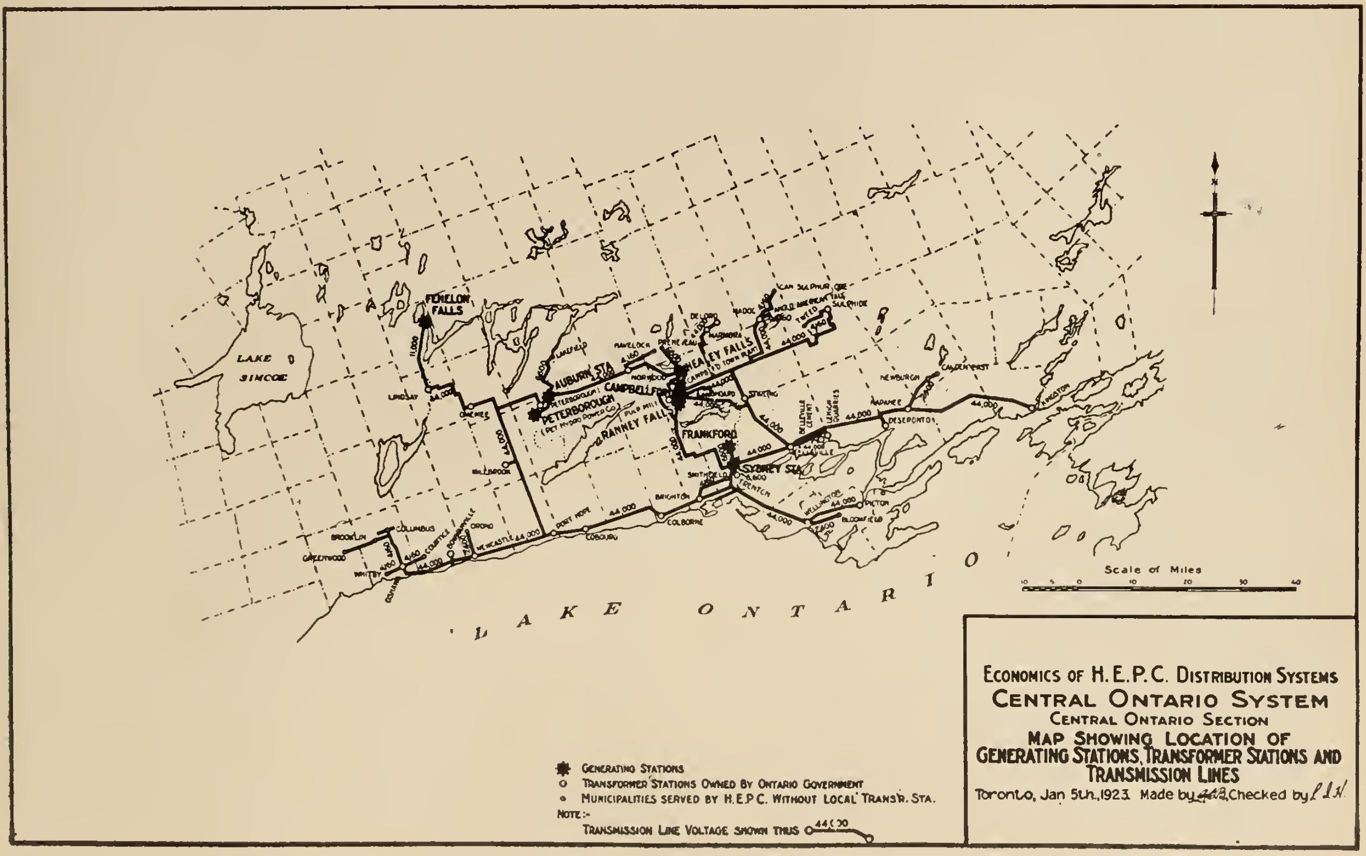

Plate No. D-13, — Location of Generating Stations, Transformer Stations and Transmission Lines, Central Ontario System.

representative of good practice may be of rather frequent occurrence in the development stages of large high voltage systems and networks, and the elimination of lightning arresters in these cases is only a temporary measure of economy. Properly designed relay protection of such lines can reduce to a minimum the time of interruption of service but the insulators on the lines must be provided with some sort of arcing horn so that the power arc following the lightning arc-over will not destroy the insulator and cause a prolonged shut-down. The supply of small amounts of power from transmission lines, particularly in rural districts, has been very much handicapped by the lack of a suitable cheap lightning arrester to protect the customers apparatus. It seems likely that some form of oxide film arrester or similar device will soon relieve this condition.

Types of Arresters in Service on Transmission Lines

Horn gap arresters, with high series resistance with discharge rates of only a few amperes, are still in service on many systems but they have practically no protective value. If the series resistance is reduced and the discharge rate thereby increased, the amount of protection is increased but the cost of the series resistance becomes high. With no series resistance the large arcs formed may be blown against other circuits and extend the damage, and the service is inevitably interrupted. Where efficient relay protection is provided and the momentary disconnecting of a circuit is not serious, the horn gap with low series resistance or without any series resistance may be used, but its protective value is small. Heavy discharges are liable to destroy the ground connection and very careful inspection is necessary to prevent danger to operators.

The development of the electrolytic or aluminum cell lightning arrester making use of the electric valve action overcame many of the objections to the horn gap arrester. When provided with a series gap, there is no discharge at normal line voltage, but at abnormal voltages the discharge current rises to several hundred amperes and relieves the system of the abnormal condition. As the current wave passes through zero the arc is extinguished and the normal line insulation is restored and prevents the power current from following the ground. Unless the disturbance is extremely severe, there is no interruption to service.

Until two or three years ago the installation of aluminum cell arresters was standard practice on all transmission circuits where the cost of their installation was relatively not too great, but experience has shown that they have certain objections; the presence of oil causes a certain fire hazard; they require expert maintenance as daily charging is necessary and careful inspection of the stacks is required to determine their condition, and furthermore the surge set up in the lines when charging the arresters causes considerable annoyance to the operators on neighbouring telephone lines.

The oxide film arrester is rapidly taking the place of the aluminum cell arrester on new installations especially for lines of 60,000 volts and under. It gets rid of the oil and electrolyte and avoids the necessity of daily charging while fundamentally it has characteristics similar to those of the aluminum cell arrester. It depends for its operation on the electric valve action and has but a few milliamperes of discharge current at normal line voltage but at abnormal voltages has the same discharge rate as the aluminum cell. It has the same capacity as the aluminum cell arrester to take care of arcing grounds and, on account of the absence of electrolyte, it can be placed out of doors in the coldest climates.

For low voltage primary distribution circuits such as 2,300 to 13,200 volts and more particularly for the protection of smaller apparatus such as lighting transformers, the standard forms of aluminum cell and oxide film arresters are not economical in view of the relatively low cost of the apparatus requiring protection. This difficulty has been solved by the development of the pellet type of oxide film arrester which brings good protection to the lower voltage circuits at a reasonable cost.

Multigap arresters of the graded resistance type are still used quite extensively on circuits under 11,000 volts.

The autovalve type and the water column surge arrester are new developments, but have not yet had a sufficient length of service to make possible definite conclusions with regard to their efficiency.

Since it seems to be impossible economically to provide sufficient insulation on circuits of 110,000 volts and lower to prevent all lightning trouble, it has become standard practice to use a reasonable amount of insulation and to employ lightning arresters on such circuits. For the higher voltages of 165,000 volts and 220,000 volts, some engineers are inclined to the belief that the insulation of the connected apparatus should be designed with a sufficient factor of safety to take care of any excess voltages. Years of operating experience with the higher voltage systems will be required before any definite conclusions can be drawn with regard to this matter, but if the lightning arresters are omitted, two or more overhead grounded wires should be installed to reduce the danger of disturbances originating at some distance from the stations being carried into the terminal apparatus.

When lines are normally operated near the disruptive critical voltage any surge producing a high voltage on the line will tend to cause corona to form about the conductors and the energy in the disturbance will be to some extent dissipated in this way.

Surge Protection on a Distribution System

The distribution system of the Montreal Light, Heat and Power Company, in Montreal, Que., is supplied from five hydro-electric plants. It consists of a network of approximately eighty miles of 12,000-volt underground cable and seventy-six miles of 12,000-volt overhead tie and distribution lines. The neutral of the system is isolated.

To protect the cables from high frequency surges due to lightning, switching, charging aluminum arresters and other causes, a surge absorber, consisting of a condenser in series with a resistance, is connected to ground on each phase. The condensers have a capacity of 0.007 microfarads and the series resistances are 600 ohms each.

This surge absorber acts as a valve allowing only high frequency currents to pass, and to make it effective for low frequency disturbances, the condenser is shunted by a horn gap. When the frequency of the disturbance is low the voltage across the condenser is sufficiently high to cause the gap to discharge and the discharge current passes to ground through the resistance. The gap setting used corresponds to 15,000 volts. Since the installation of the surge absorbers the number of failures on the 12,000-volt system has decreased materially.

Overhead Grounded Wires

The protective value of overhead grounded wires is difficult to determine quantitatively, but there is little doubt that when properly installed, they are a most effective and most valuable protective device. They tend to keep high voltage disturbances out of the system and by their action as a short circuited secondary they greatly increase the energy dissipation of a travelling

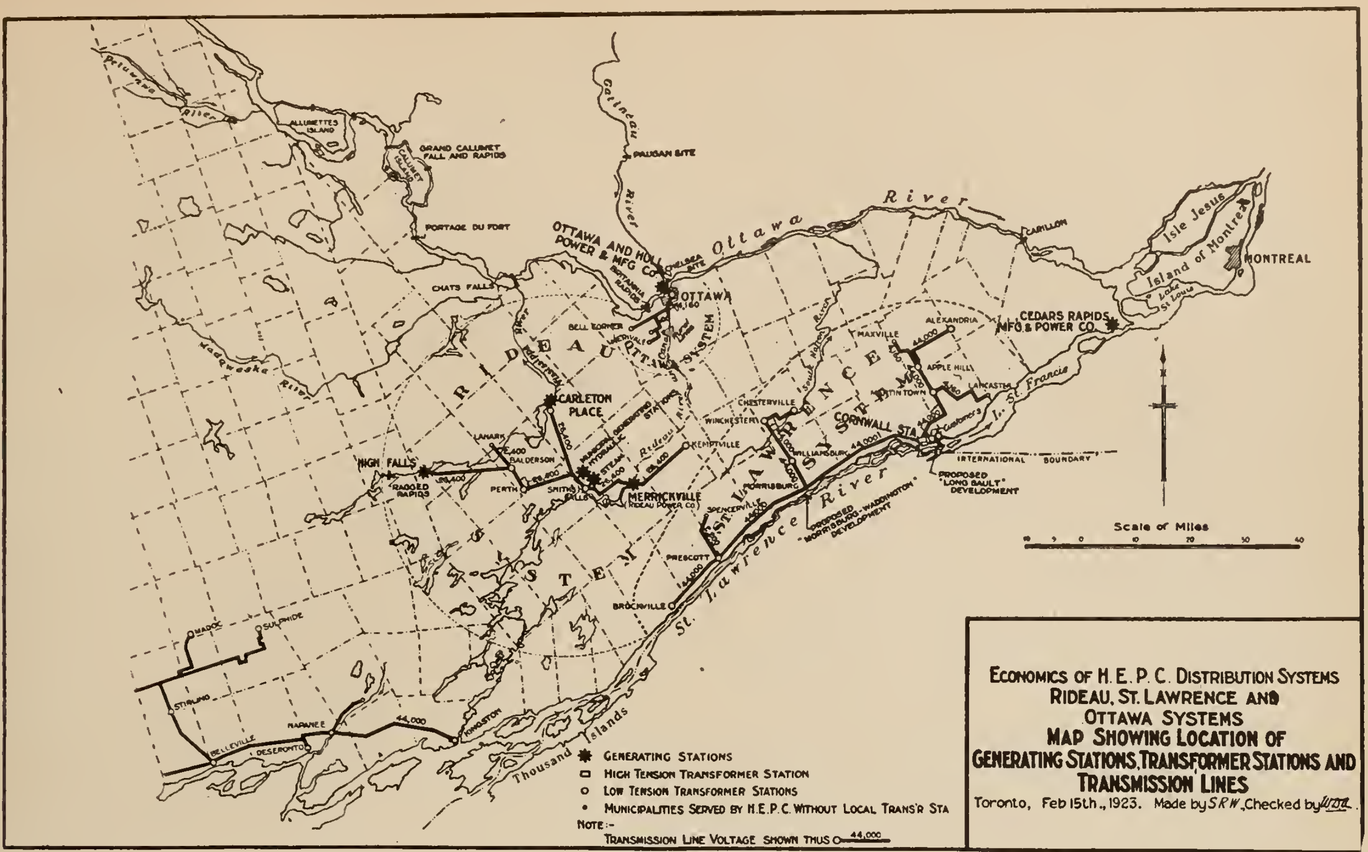

Plate No. D-14, — Location of Generating Stations, Transformer Stations and Transmission Lines, Rideau, St. Lawrence and Ottawa Systems.

wave and are therefore very effective in reducing disturbances originating at a considerable distance from the station. They are also of great value in providing a definite ground for relay protection of the lines and in the case of the grounded neutral systems the ground wires should be connected to the station neutral.

The overhead ground wires tend to lessen the stray electric field which extends out from the power lines to neighbouring communication circuits and therefore tend to reduce the voltages induced in these circuits and the consequent interference with their normal functioning. The overhead grounded wire on wooden pole lines can probably not be justified economically unless it is grounded at every pole and it may even be a detriment unless the pins and crossarms are also grounded.

When the overhead ground wire is not used, the vertical ground wire on each pole is still advisable to prevent burning or shattering of the poles when arc-over occurs. Grounded metal pins are to be recommended for systems above 30,000 volts rather than wooden pins which are liable to be eaten away by the silent discharge, especially at the higher operating voltages.

In the case of extra high voltage lines where the safety factor for flashover of the insulator string is very high and where, therefore, the induced lightning voltage assumes relatively less dangerous proportions and where for economical reasons the line is operated near the critical voltage of corona formation, the protective functions of the grounded wire are not so important as the energy of the travelling wave will be dissipated by the corona loss.

The valuable functions discussed above would appear to justify a properly installed overhead ground wire on the majority of long distance transmission circuits, if not on all of them. However, this is one of the questions which can be settled only by careful study of operating records. Parallel circuits are being operated, only one of which is equipped with overhead ground wires and it is hoped that the comparative records of these lines after a few years of operation will help to a definite solution of the question.

Inductive Co-ordination between Power and Signal Circuits

Where it is necessary to construct power and signal circuits near to one another, both systems must be designed so that the transfer of energy from one to the other will be as small as possible. This will result in a minimum interference with the operation of the signal circuit.

Inductive interference may be defined as the impairment of the serviceability of communication circuits resulting from the transference of energy into them from nearby power circuits or resulting from their absorption of energy from the electric field of the neighbouring power circuits. To reduce interference the power circuit must be designed so that its influence on the signal circuit will be small and the signal circuit must be designed so that it will not be unduly sensitive to the influence of the power circuit.

The normal power circuit frequencies of 25 cycles and 60 cycles cause interference with telegraph circuits, while the higher harmonics of the power circuits are responsible for the greater part of the interference with telephone circuits. Under abnormal conditions of operation the inductive disturbances may be very greatly increased and momentary impulses may be sufficient to cause a physical hazard, to operate protective devices or to cause severe acoustic shocks to the signal circuit operators. Such conditions occur when energizing or de-energizing lines, opening short circuits, charging electrolytic lightning arresters, or when arcing grounds are formed.

It is necessary to distinguish between the voltage induced in the signal circuit by the electrostatic field, which is proportional to the voltage of the power circuit, and the voltage produced by the magnetic field, which is proportional to the current in the power circuit. The one is called electrostatic induction and the other magnetic induction. Induction, whether electrostatic or magnetic, is classified as transverse or longitudinal, depending on whether it tends to produce a current flowing from one signal wire to the other, or to produce currents along the two signal wires in multiple to ground.

In analyzing inductive affects it is necessary to divide the power circuit voltages and currents into two general classes, balanced and residual. Balanced current components in the several conductors of a power circuit are such that their algebraic sum at any instant is zero. The algebraic sum of all currents in the conductors of the power circuit is the residual current. Similarly, the balanced voltages of the several conductors, (balanced with respect to the earth as neutral conductor or point of reference) are such that their algebraic sum at any instant is zero, while the algebraic sum of the several voltages to ground is the residual voltage.

The remedies for induction from balanced and residual voltages and currents are often fundamentally different. Transposition of the power circuit reduces induction from balanced currents but scarcely affects induction from residual currents, while transposition of the telephone circuit will reduce induction from both the balanced and residual components.

Causes of Residuals

Inequality between the capacities to ground of the several conductors of a power circuit causes residuals of the frequencies present in the voltage between conductors.

Unbalanced capacities are caused by differences in the distances of the conductors above ground and from other conductors or ground wires. Transposing the conductors of the power circuit tends to equalize both their capacities and also their inductive reactances. Of common configurations, the equilateral triangle is the most nearly balanced, the unsymmetrical horizontal arrangement is the worst.

If one conductor of a three-phase line, without grounded neutral, becomes grounded, a residual voltage of three times normal voltage appears and a large residual charging current flows.

Defective line insulation will cause leakage currents to flow which are residual currents.

In a delta-star, star-delta connected transmission line with neutrals grounded at both ends, parts of the third harmonic magnetizing currents for the receiver transformers are in phase in the three lines and return through ground. The remainder of the third harmonic current flows in the closed receiver delta.

When transformers are connected star-star at both ends, the residual currents are much greater and this connection should not be used on account of its bad effect on signal circuits unless a low impedance tertiary winding is provided to carry the third harmonic magnetizing current.

Very high voltage transmission lines on which corona forms will carry third harmonic corona forming currents which will be in phase in the three conductors and will be residual currents.

Unbalanced loads will cause residual currents and voltages in the supply lines.

All abnormal operating conditions which set up transient currents and voltages produce very large residual effects.

Causes of Harmonics

The detrimental effect in a telephone receiver varies almost directly as the induced current and it increases roughly as the square of the frequency up to about 1,000 cycles per second. To reduce induction it is necessary to eliminate as far as possible all harmonics from the power circuit. These higher harmonics which appear as irregularities in the voltage and current waves may result from a number of causes:—

(1) The shape of the pole face may result in the introduction of third and fifth harmonics in the voltage wave.

(2) Open slots on the armature cause high frequency ripples on the generated voltage wave which are called tooth harmonics. A long air gap and proper design of the pole face will reduce these tooth harmonics to very small values but more complete elimination may be obtained by skewing the armature slots or by distributing the armature winding in a fractional number of slots per phase per pole.

(3) The operation of transformers at very high densities causes distortion of the current and voltage waves. If the impressed voltage is a sine wave the flux must be a sine wave, but due to magnetic saturation the exciting current cannot be a sine wave but contains prominent third, fifth and higher harmonics.

(4) The presence of an arcing ground or an arc due to a loose switch contact may cause very serious high frequency induction.

Transpositions

One of the most valuable methods of reducing inductive interference under normal operating conditions is to transpose the conductors of each circuit so as to equalize their relations to all other circuits and to earth.

Transpositions of a power circuit tend to equalize the capacitances of its conductors to ground, thereby removing a source of residuals, and to cause the inductive effects from the balanced currents and voltages to neutralize one another in successive lengths of the parallel telephone line. Transposition of a power circuit does not reduce induction from residuals except insofar as it reduces the residuals themselves.

Transpositions of a telephone circuit tend to equalize the capacitance of its conductors to ground, to equalize the inductive effects on the two sides of the circuits due to nearby power circuits and to lessen the induction among the several telephone circuits in the group, but they do not affect the voltages induced between the circuit as a whole and ground, called the longitudinal induction. To be of any value transpositions of the telephone circuit must be very carefully located so that the induction in adjacent sections will be the same and the transpositions in the two classes of circuits must be co-ordinated.

Electric waves take a finite (though very short) time to travel along conductors and the electrical conditions at a given instant will be different at different points along the lines. They will be practically opposite at points one half wave length apart. The length of a barrel or complete transposition of a power circuit should be short compared to the wave lengths for the frequencies under consideration.

Principles to be Applied to Prevent Serious Interference Between Power and Signal Circuits

(1) Avoidance of close proximity to a circuit of the other class. This is the only way to completely prevent interference but can only be applied in isolated cases. It is not a final solution. When the two types of circuits are located on the same highway or railroad right-of-way, they should be placed on opposite sides of it. When the power circuit is on a separate right-of-way it should be kept at least 150 to 250 feet from the signal circuit whenever this is possible.

(2) Co-ordination of the transposition schemes of the two circuits. This is a very effective method of reducing interference.

On the part of the power company

(3) Elimination or suppression of harmonics by proper design and methods of operation of the power apparatus.

(4) Limitation of residuals by proper balance of circuits and loads.

(5) Proper arrangement of conductors of the transmission lines.

(6) Limitation of abnormal conditions by high grade construction and care in maintenance and operation.

On the part of the signal company.

(7) Careful balance of the circuits by high grade construction and maintenance.

(8) Limitation of susceptibility of systems.

A carelessly designed and maintained power system may be a menace to nearby signal circuits, but on the other hand, a highly susceptible signal system or one which is not properly maintained may be a nuisance to a power circuit which is blamed for unwarranted interference.

The signal companies have developed a very ingenious meter, called the "telephone interference factor meter", which indicates the amount of interference which any power circuit will cause to a neighbouring signal circuit. A study of the remedial measures required to reduce the interference to a reasonable amount can then be made.

This meter can be used in testing a generator and will give a direct indication of the amount of interference to be expected due to harmonics in the generator voltage wave. This is one of the standard tests to be applied to new installations.

In Canada the very closest co-operation has existed between the power companies and the signal companies for some years past and all possible precautions have been taken to prevent interference, and it is well understood that inductive co-ordination is purely a technical problem only to be satisfactorily solved by sympathetic co-operation between the engineers of the power and signal companies both before and after new developments and extensions are carried out. It is entirely a question of compromise and should at all cost be kept out of the courts of law.

Both services must be made available conveniently and economically. The highways, in many cases, are the natural location of both services but they must only be used by circuits which are neither too influential nor too susceptible to prevent other circuits being placed on the same highway.

Interconnection of Transmission Lines

The economic value of interconnecting power generating systems is sometimes very great on account of the difference in the characteristics of the rivers on which the developments are located and of the loads supplied from them. Great economies may likewise often be made by interconnecting steam and hydro-electric generating stations.

Developments located near to each other on the same river should, for the best results, not only be interconnected electrically but should be operated under one control so that the water can be used to the best advantage in the combined plants.

When two generating stations are located on different rivers, one of which has a low head, large volume of water and very little storage capacity, while the second has a high head, smaller volume of water and a comparatively large storage capacity, the advantage of interconnection is obvious. By pooling the power of the two systems the low head plant with its continuous flow can be operated continuously at its maximum capacity while the water in the high head plant is stored up to be used to carry the peak load. The interconnection will be of special value at times of low water.

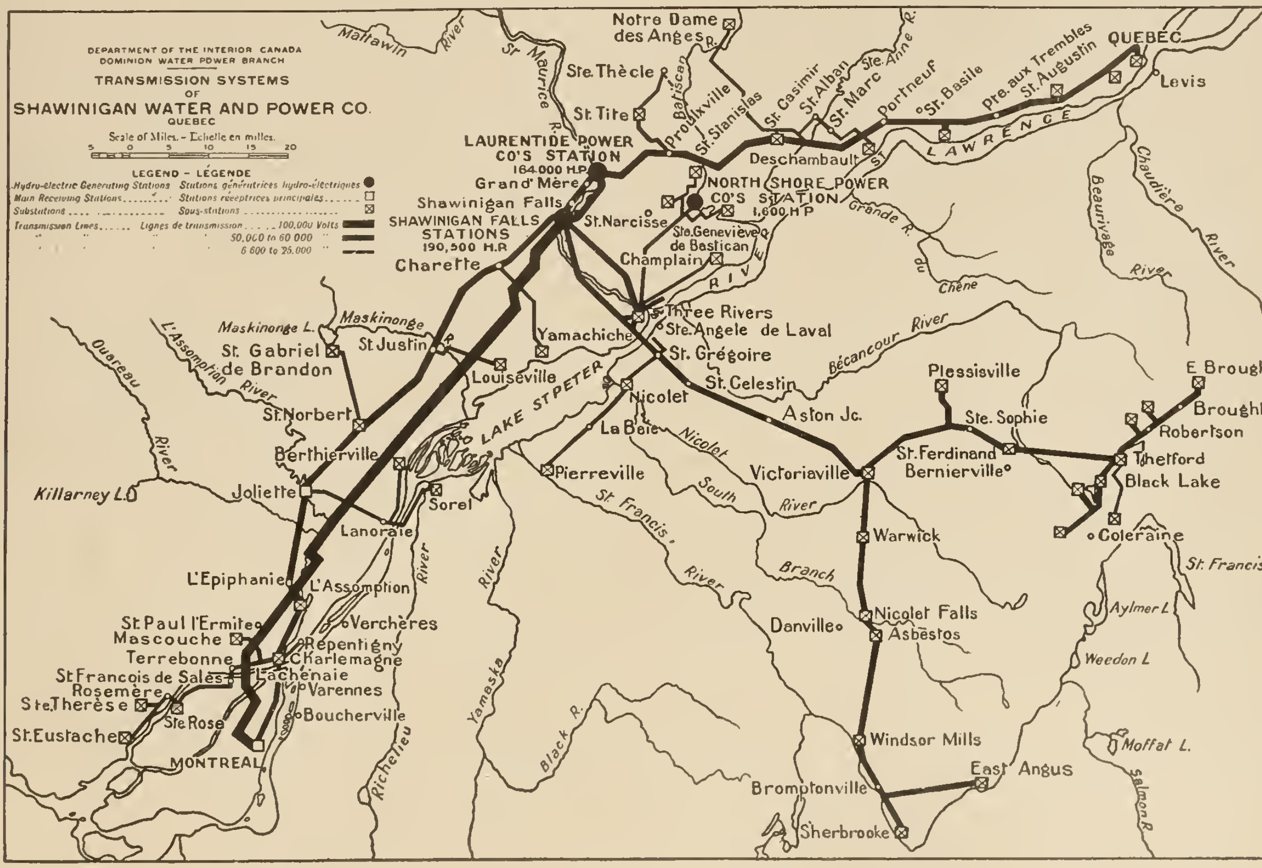

Plate No. D-15, — Shawinigan Water and Power Company,—Transmission Systems.

Interconnection between plants on different water-sheds often enables a development with large natural or artificial storage to help other plants over their low water periods. To get the best results in many cases steam reserve plants should be provided to take care of the peaks and to help out at periods of low water and in emergencies.

The advantages of interconnection have been realized in many of the Canadian systems. The Niagara System of the Hydro-Electric Power Commission of Ontario has a network of 110,000-volt lines and 12,000-volt circuits which are normally fed from generating stations aggregating over 600,000 horse power. These are the Queenston station, the Ontario Power Company and the Electrical Development Company, and when required power can also be supplied to this system from the Canadian Niagara Power Company, and the Niagara Falls Power Company on the American side of the river.

In the province of Quebec, the Cedars Rapids development supplies power to Massena in the United States and to the St. Lawrence System of the Hydro-Electric Power Commission of Ontario in the eastern part of Ontario. It also delivers power to Montreal, and through the 12,000-volt distribution system of Montreal is connected to the lines of the Shawinigan Water and Power Company which extend to the east nearly 200 miles to Quebec where they link up with the system of the Quebec Power Company, which, in turn is connected to the lines of the Laurentian Power Company. The Shawinigan 30-cycle system on the south side of the St. Lawrence river is connected through frequency changers to the system of the Southern Canada Power Company. More than fifteen power developments, some of them more than 200 miles apart, are connected into this Quebec system and the total present capacity is about 600,000 horse power, which will be increased when the new development of the St. Maurice Power Company is put into operation during the present year.

Up to the present time very little steam power has been developed in Canada as a standby for the hydro-electric stations but plans are being made in Ontario to supplement the output of the hydro-electric plants by the construction of one or two large steam plants, and there is no doubt that in the near future additional steam generating stations will be required in some of the largest industrial centres in the province of Quebec. When the load factor of an important load centre is below 60 to 70 per cent the installation of steam stations to take care of peak loads will usually be found to be economical.

Short Circuit Currents

As the concentration of power in a network of lines is increased short circuits become more and more destructive in their effects.

In many cases a small system has operated satisfactorily so long as it was isolated from other systems; the short circuit currents flowing to fau ts were not excessive and the switches were able to handle them without difficulty. The stresses on low voltage busbars were small and no special precautions were required to prevent mechanical damage to the structures. The addition to such a system of more generating capacity or of synchronous condenser capacity or synchronous motors at the receiving end of the line or even the addition of extra transmission lines may reduce the impedance in the path of currents flowing to a short circuit to such an extent that the switches will be stressed beyond their capacity and be destroyed. Or a short circuit on the low voltage bus may result in such a large current flow that the bus structure will be destroyed.

If all the generators in a power station are paralleled on the low voltage bus the greatest concentration of energy will occur when a short circuit occurs on this bus. Switches which were adequate to handle the short circuit currents when only three or four generators were installed are entirely inadequate when the number has been increased to ten or twelve. The severity of a short circuit on the low voltage bus can be reduced by sectionalizing the bus and either operating the sections entirely separate or connected only through bus bar reactances. A greater reduction can be obtained by eliminating the low voltage bus altogether and paralleling only on the high voltage bus. In this case the step-up transformer bank is operated as part of the generator and the two can be designed with the most suitable combined impedance.

The modern generators and transformers are designed with much larger reactances than those of a few years ago and this has largely reduced the amount of current they can feed into a short circuit. When studying the operation of oil switches in clearing short circuits the sustained value of the generator short circuit current is the one to be considered as the current will have fallen to this value before the switch opens the circuit, but to determine the maximum stresses on bus bars or on parts of switches, the instantaneous current must be used and the worst condition assumed which is when the short circuit occurs at the zero point of the generated voltage wave.

At the receiver end of the line, the short circuit currents are usually much smaller than at the generator end as they are limited by the line impedance. If, however, large synchronous condensers or synchronous motors are operated on the low voltage bus they will feed current into the short circuit.

When a number of systems are interconnected they all feed current to any short circuit on the network and the smaller capacity switches on the low powered systems are liable to be destroyed unless care is taken to so arrange the circuits that sufficient impedance either of lines or transformers is in the path of any short circuit.

A few years ago on one of the largest Canadian networks of lines, supplying a load of approximately 300,000 kilowatts, the maximum estimated short circuit kv.a. was 2,000,000, but by re-arrangement of the generators and lines and the insertion of reactances in the low voltage busbars, the estimated short circuit kv.a. has been reduced to 650,000, notwithstanding that in the meantime the load on the system has increased to about 500,000 kilowatts.

Extra High Voltage Lines

Provision has been made in the design of a number of systems in Canada for future operation at voltages up to 150,000 volts, but at the present time no lines are actually in operation above 125,000 volts. Some new developments which are now in the first stages of construction or are projected for the near future will require the use of voltage much higher than those at present in use in order to transmit the large amounts of power, which will be developed, to the distant markets.

It appears probable that transmission at 220,000 volts will only differ in degree from transmission at lower voltages as no new or startling effects are to be expected. The economical amount of power to be carried per circuit will probably be of the order of 75,000 to 100,000 kilowatts and the generator capacity required to charge the lines will be very great. The duty of circuit breakers will be somewhat heavier but this may be kept down by proper arrangements of circuits, and probably switching will be much less frequent.

Conductors of large diameter must be used with very wide spacing, to reduce the corona loss under storm conditions. Conductors of about one inch diameter spaced from 15 to 18 feet apart will probably give satisfactory results. Steel reinforced aluminum will give the required diameter at a lower cost than copper and will have sufficient conductance unless considerably more than 100,000 kilowatts is to be carried per circuit or the line is of extreme length.

It must be remembered in constructing extra high voltage lines, that the maximum voltage at any point on the line is the one that must be considered. A line delivering power to a receiving station at 200,000 volts but having a rise of 25 per cent in voltage at the generating station, is not a 200,000-volt line but is a 250,000-volt line. Since apparatus and insulation costs increase rapidly with increase of voltage it is apparent that the large voltage drops commonly allowed on some of the lower voltage systems will not in general be economical on the 220,000-volt lines, and probably the regulation should be limited to 5 to 10 per cent, except in special cases. If the normal load power factor is not above 85 per cent the synchronous capacity required for such close regulation will be of the order of 50 to 60 per cent of the load kilowatts. When the load reaches very high values such as 150,000 to 200,000 kilowatts per circuit it may be found economical to install more synchronous capacity and to operate at approximately the same fixed voltage at both ends. This would be a very extreme case and if the line were over 200 to 250 miles in length there would probably be a considerable voltage drop at the centre which should be corrected by placing part of the synchronous capacity there. Copper conductors may be used on circuits designed to be operated at such extreme loads, to reduce the line losses.

It is necessary to distinguish between systems supplying large blocks of power to terminal stations at a great distance from the generating stations without any intermediate taps, and the system acting as a main trunk line crossing a network of existing lines and connected into it at a number of points.

The first type of system would suit conditions in the province of Quebec, where the main industrial centres lie along the river St. Lawrence or south of this river, while the principal water power sites, except the group on the St. Lawrence, lie two or three hundred miles north of the river, estimating distance as the probable transmission distance to the markets, the country between being relatively undeveloped industrially. The main transmission lines will be operated at 200,000 to 250,000 volts without taps and a drop of voltage of 15 to 20 per cent may be allowed in the lines, the generator voltage being changed through perhaps a 10 per cent range to suit load conditions. Power should be sold to the main distributing companies at 90 to 95 per cent power factor and only enough synchronous capacity installed in the terminal stations to regulate the voltage and to limit the line drop to the value assumed. Synchronous capacity of 25 to 30 per cent of the load kilowatts should meet these conditions.

The second type of system will probably be more suitable for the province of Ontario. The proposed power

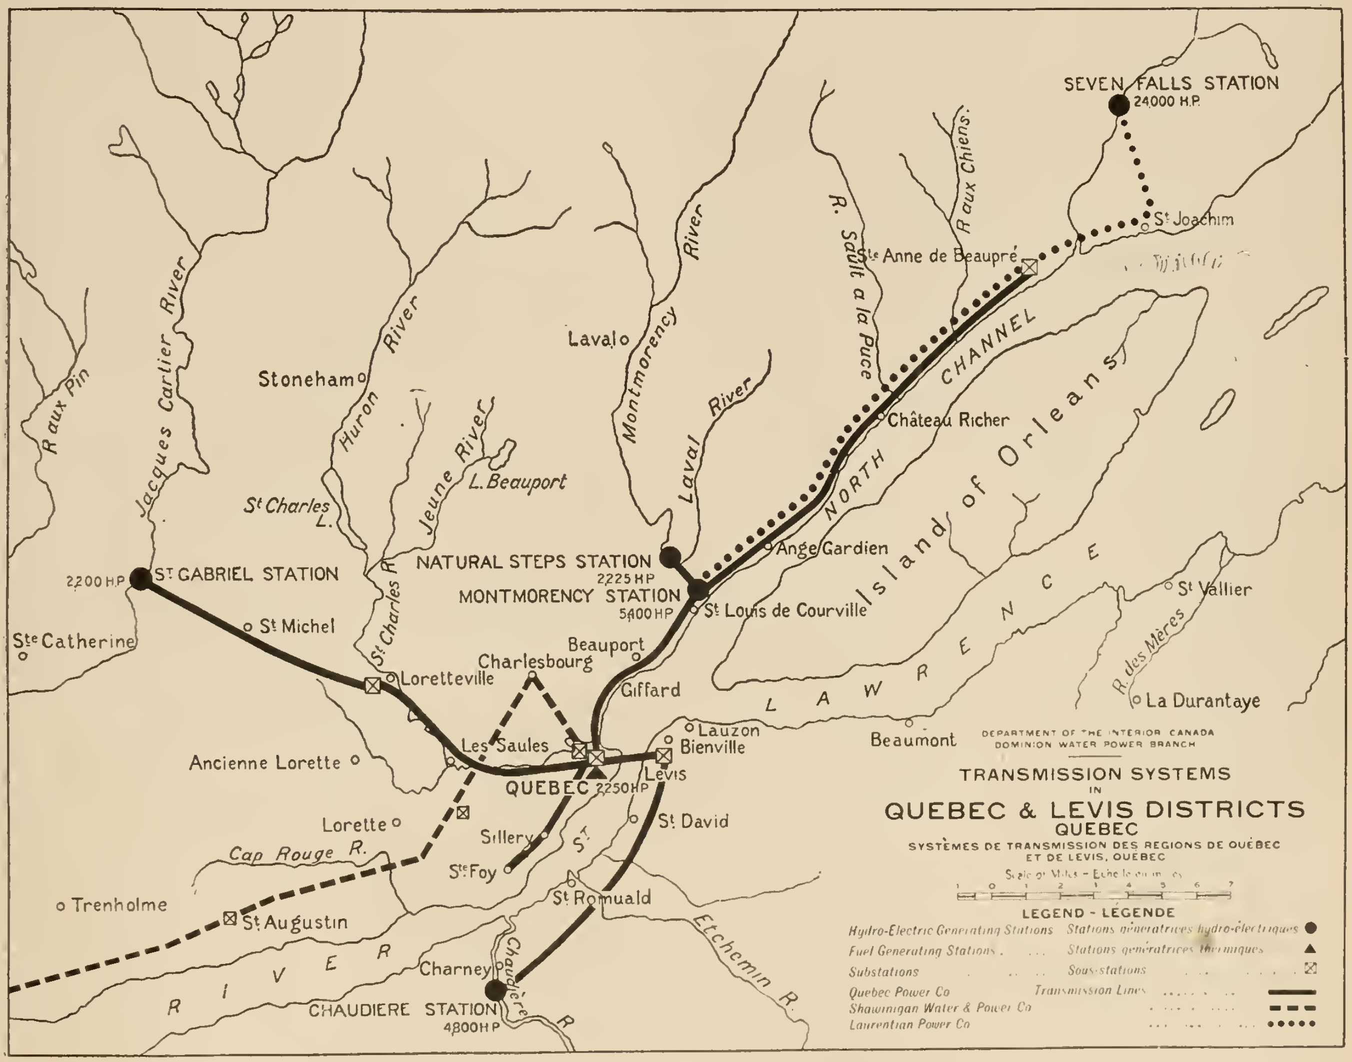

Plate No. D-16, — Quebec and Levis Districts Transmission Systems.

developments on the St. Lawrence river will be linked up with the various developments at Niagara Falls and with any large steam stations located at strategic points through the system of the Hydro-Electric Power Commission of Ontario. Probably 220,000-volt trunk lines will be constructed crossing Ontario from the north-east to the south-west, tapped at the main load centres and linking up all the main sources of power so that the greatest economy may be obtained for the complete system. These lines will be operated of necessity at a fixed voltage throughout and large amounts of synchronous capacity will be required at the load centres to hold the voltage constant.

The objection to the first type of system with its comparatively large voltage drop is that at the generator end the transformers and lines must be constructed for 240,000 to 250,000 volts while the receiver voltage is only 200,000 volts. There will however be no difficulty in obtaining transformers for 250,000-volt operation and if necessary spacings up to 25 feet can be used without any great increase in tower costs. The system will not then differ except in size from the transmission systems of to-day.

The extremely large synchronous condenser capacity required for the second type of system will probably increase the operating difficulties more than the small increase in the voltage at the generating station assumed in the first case. The short circuit currents will be increased and there is danger that the synchronous machines will fall out of step, when serious disturbances occur.

The present is a time of great activity in the field of water power development as the rehabilitation and growth of the industries of the country is in very large measure dependent on an increasing supply of dependable and cheap power. Many available power sites, of a capacity of 50,000 to 100,000 horse power, near the industrial centres are still undeveloped but attention has been turned to some of the larger developments, among which may be noted the Queenston plant of the Hydro-Electric Power Commission of Ontario, which has already a capacity of 350,000 horse power which will probably be increased to 500,000 or 600,000 horse power; the large development on the Saguenay river where nearly 1,000,000 horse power will ultimately be available, and the international developments on the St. Lawrence river.

To market the power from the Saguenay development and from the St. Lawrence stations, higher voltages will be required than those at present in use and this will be accompanied by an extension of the present networks of lines and probably by an interconnection of the systems of Ontario and Quebec.

Utilization of Power

Introductory Statement to Symposium Collated by

P. T. Davies, A.M.I.E.E.

President, Canadian Electrical Association

The term "Utilization of Power", as here used, is the official title of a group of papers on various aspects of power utilization and the purpose of the present remarks is to introduce the twelve Canadian papers on this subject and to briefly summarize the total use of power for all purposes in Canada.

Elsewhere in Canada's contribution to papers for the World Power Conference, her great resources of both water and fuel power have been set forth in detail. Briefly stated, the, at present, recorded water power resources are for maximum commercial development, over 32,000,000 h.p., and the amount now developed is nearly 3,250,000 h.p., a figure which shows Canada to have the second largest utilization of water power of any country in the world, the first being the United States, which however has much less developed water power per capita than Canada. In coal, Canada possesses over 15 per cent of the world's known coal reserve and there are large producing fields of natural gas.

No section of the Dominion is without ample power resources and no section has failed to utilize them. Manufacturing and mining industries are distributed practically throughout the Dominion. Ontario and Quebec are the main centres of manufacturing industry, but the fourth manufacturing city, Winnipeg, is in the centre of the Dominion, and the fifth, Vancouver, is on the Pacific coast.

In Canada the water power is distributed so that it is available at, or near, all centres of population from coast to coast, with the exception of comparatively small areas in the south of Alberta and Saskatchewan, where, however, there are enormous resources of coal. Throughout the Dominion fuel power has now been largely replaced by water power, the present division of power for all purposes except steam railroads, being 70 per cent water power, 30 per cent fuel power.

In Canada the growth of the central station industry has been a marked factor in the power situation, over 70 per cent of all developed water power being in central stations and 98 per cent of the output of central stations being from water power.

The use of power in industry is therefore mainly represented by the growth of water power development and a general view may be obtained from the following table:—

Growth of Manufactures and Power

	Population		Capital Invested in Manufactures		Developed Water Power	
	Total	Increase per cent	Total	Increase per cent	Turbine h.p.	Increase per cent
1900	5,322,000		$ 446,900,000		157,200	
1910	6,917,000	48.7	1,247,600,000	197	965,000	514
1920	8,631,000	24.8	3,443,300,000	176	2,482,000	157
1900 to 1920		57		670		1480

The above table does not include mining and the treatment of ores, and the apparent excess of water power developed is due to its use in this, in the supplanting of fuel power and in a general extension of domestic and other uses. So great however has been the growth of manufactures that the value of product thereof now exceeds that of agriculture and live stock.

Ontario and Quebec, which contain over 60 per cent of the total population and nearly 80 per cent of the total manufacturing development, possess no native coal, and it is clear that the great manufacturing development could not have taken place without the aid of water power.

Reducing the above table to a per capita basis gives the following:—

Capital and Power per 1,000 of Population

	Capital Invested in Manufactures	Water Power Developed h.p.
1900	$ 84	29
1910	180	139
1920	387	288
1924	—	353

Diversified Use in Industries

The widely diversified use of electric energy in industries is well exemplified by the inventories of power users in appendices I, II and III. The first two cover the two largest cities, Montreal and Toronto. The figures for Toronto are based upon the actual tested load being paid for by the customer. For Montreal they are based upon the connected load and a study of several thousand tests has shown that the average load is 65 to 70 per cent of the connected load. Montreal figures include street railway load, and Toronto figures do not.

The third covers a rural territory in the province of Quebec, some 10,000 square miles in area and containing a population of some 69,000, and is of special interest as illustrating the distribution of electric energy over a wide area including a number of towns and villages.

Uses of Central Station Power

In 1922 the uses of central electric station power for the whole of Canada were approximately as follows:—

Lighting and small motors	30.0	per cent
Electric railways	8.0	"
Mining and treatment of ores	10.0	"
Pulp and paper	13.0	"
Electro-chemical and metallurgical	5.0	"
Other manufactures and power	25.0	"
Electric energy exported	9.0	"
	100.0	per cent

The total power in use for all purposes as at January 1st, 1923, was estimated by the Dominion Water Power Branch as follows:—

Water power		2,673,000	45 per cent
Fuel power, Industrial	1,142,000		
Steam railroads	2,130,000		
		3,272,000	55 per cent
		5,945,000	100 per cent

Excluding railroads, the proportion, as before stated, was water power 70 per cent, fuel power 30 per cent. The largest use of power in any single industry in Canada is that in pulp and paper manufacture, over 725,000 h.p.

General Use of Electric Energy

It has been shown that Canada has the largest actual amount of water power developed of any country in the world except the United States. In actual utilization of electric energy Canada exceeds any other country without exception. The following figures are from a table of the "Consumption of Electrical Energy by the Various Nations of the World" published by the *Electrical World*, January 6th, 1923, except those for Canada which are actual census results:—

Kilowatt Hours per Capita 1920

Canada	729
Switzerland	700
Norway	493
United States	472
Sweden	364
France	147
Germany	141

The official figures for Canada in 1922 show that this had then increased to 820 k.w.hrs. per capita.

Dwellers in Electrically Lighted Abodes

The following are also taken from the same source quoted above, the figures being in percentage of the total population:—

Canada	38.3
United States	36.8
New Zealand	30.8
Japan	29.9
Denmark and Iceland	29.8
Switzerland	25.9
Norway	21.3
Sweden	17.0

Size of Distribution Systems

The energy and enterprise that have been shown in the generation and distribution of power in Canada are strikingly illustrated by a United States compilation* of 110 of the largest power generating systems in North America. In annual output the system of the Hydro-Electric Power Commission of Ontario heads the list, and in order of magnitude Canadian systems stand thus:—

1. Hydro-Electric Power Commission of Ontario, (as in 1922).
6. Shawinigan Water and Power Company, (as in 1922).
11. Montreal Light Heat and Power Consolidated, (as in 1923).
15. Ontario Power Company, (as in 1923).

This is the more striking when it is remembered that the population of the United States is about twelve times as large as that of Canada.

Conditions of Distribution

All organizations supplying electric energy throughout the Dominion are alive to the necessity of giving adequate service to all users; this service originally included the free renewal of their lamps but this practice is now being discontinued. The service to-day however does cover the free attention of trouble-men for the purpose of replacing fuses and making minor repairs in the home, the carrying on of electric stores where almost every electrical appliance is obtainable on long term payments, the carrying of a wiring staff, and finally, for industries, free engineering service upon all subjects dealing with the supply given, and continuous advice on the possibilities of its increased use.

*Electrical World, April 12, 1924.

Distribution Voltage

The general distribution voltage from sub-stations is 2,200 volts, with some at 4,000 volts, 3-phase, 4-wire, grounded neutral installations. The secondary service from local transformers is at 110/115 volts, single-phase, for lighting ordinary residences, for larger customers, for lighting and cooking and for multiple street lighting it is usually 110/220 volts, 3-wire. Power is usually supplied at 550 volts, 3-phase, with larger units at 2,200 volts, and units of 3 h.p., or under at 110 volts, single-phase.

There is a little direct current generated for limited distribution, more particularly for passenger elevators in the large cities of Montreal, Toronto and Winnipeg; such service is also available for lighting in some cases in Toronto and Winnipeg.

Frequencies

The principal frequencies of alternating current in use are 25 cycles on the Niagara system of the Hydro-Electric Power Commission of Ontario, 30 cycles in the territory south of the St. Lawrence between Sorel and Levis, and 60 cycles in practically all other parts of Canada.

Construction

In the past most of the construction of distribution systems has been carried on wooden poles and cross arms, the necessary transformers also being hung on the poles where required; some of this construction, especially at corners, was not as trim as it might have been and more modern construction now does away with crossarms, iron brackets and hooks supporting insulators close to the poles with vertical instead of horizontal spacing between the wires becoming more general. The use of concrete poles has also been tried and a considerable installation of these made in Toronto. In the centres of large communities all services are almost invariably underground; duct systems being used with transformer manholes and distribution ducts, usually under the side-walk. No particular difficulties have been found in operating these underground systems even in places where a very heavy snow fall is encountered.

Wiring and Fittings

All wiring and fittings must be approved before electric service can be obtained. In Ontario the approval of the Hydro-Electric Power Commission's laboratories on wiring, fittings and appliances, must be obtained before any material can be placed in service. In the balance of Canada the rules of the Canadian Board of Fire Underwriters, which approximate to the National Electric Code of the U.S.A., must be followed, and all wiring fittings and fixtures approved before their use is permitted. Many disappointments have been caused British and other manufacturers, it not being known that such certificates and approval are required for all material for use in customers' premises in Canada.

Rates

Rates in Canada vary according to the density of population, and in some cases the distance from the power source. Where hydro-electric power is available the rates are usually considerably lower than would be possible through steam generation, especially where an industry has a high load factor.

Contracts

Contracts with customers are generally made on a one-year basis for domestic business, and for some longer period, generally five years, for power service. Customers are required to finance some part of the cost of any necessary extension when business is temporary or the return on the investment necessary too low to permit a profit. Meter rent is not charged, although all meters have to be sealed by the government once every six years, at a cost of 60 cents per seal.

Canada is singularly fortunate in the amount and well distributed availability of its power resources. In spite of the extensive development that has already been made it is estimated that only about eight per cent of its readily available water power has been utilized to date. It stands ready, therefore, to provide for the industrial and domestic needs of a population many times the size of its present one.

The resources of power are ample and development is capable of immediate expansion as required; the whole of the materials needed for such development are produced within its borders, its water powers are being freely developed under favourable laws securing stability of investment, and, as has been shown in the foregoing remarks, Canada stands in the very forefront in the science and practice of power utilization.

Appendix I

Classification of Power Users in Montreal

Kind of Business	Number	Connected load in h.p.	K.w.hrs. per annum
Asylums and institutions	10	978.5	670,738
Air compressors	100	3,550.0	3,120,000
Artificial stone manufacturer	1	422.5	356,640
Automatic typewriter	1	.58	980
Auto accessories dealer	11	63	62,000
Artificial limbs dealer	1	3	551
Asbestos works	2	337	260,000
Automobile manufacturing	1	209	79,500
Aerated water manufacturing	7	181	155,022
Battery chargers	55	950	1,060,000
Broom manufacturing	2	5	1,728
Biscuit manufacturing	8	165	91,254
Bag manufacturing (jute)	2	241.5	146,849
Blue printing machine	4	190	506,000
Bottling machine	22	134	216,500
Barrel manufacturing	4	40	52,000
Bread manufacturing	19	634	421,000
Boiler works	3	28	13,339
Buffers	6	14	1,106
Belt manufacturing	2	27.5	6,706
Bed and mattress making	5	94	141,500
Bed manufacturing	2	992.5	800,268
Bone cutter	2	2	66
Brush manufacturing	5	18.5	32,000
Button making	5	19	25,900
Braiding machine	3	29	39,000
Brass finishing machine	8	69	67,600
Bell ringers	8	38	1,925
Brewery machinery	4	1,446	2,945,187
Brick manufacturing	2	3,835	5,760,960
Butcher machinery	4	9	6,963
Cotton goods manufacturing	3	225	138,000
Cake mixer	8	14	2,500
Confectionery machinery	27	943.75	1,390,767
Cigar manufacturing	6	174	46,000
Caramel making (coloring)	1	16	10,458
Chemical works	51	1,040	364,200
Cleaning and dyeing	27	212	122,200
Chocolate manufacturing	4	1,101	911,724
Cocoanut machine	1	4	1,310
Cash carriers	14	22	440
Coppersmiths	2	2	1,962
Canning machines	2	20	3,179
Can manufacturing	2	412.5	321,993
Cloth cutter	4	8	5,200
Cranes (travelling)	3	165	5,360
Carriage making	20	148	26,400
Coffee grinders	6	5	2,000
Coffee grinder (large mill)	1	80	40,000
Cement mixer	8	58	62,600
Cigar box manufacturing	2	70.75	91,000
Cigarette manufacturing	2	45.5	5,358
Creamery machinery	2	23	4,702
Cement works	1	11,290	54,329,903
Cork cutter	2	5	472
Conveyor (letter)	1	5	3,590
Cheese manufacturing	1	85	55,899
Candy making	3	9.5	2,423
Coal handling machinery	25	697	875,000
Canal gates	1	240	14,400
Cordage manufacturing	1	528.5	743,143
Car puller	1	12	6,530
Celluloid manufacturing	1	81	132,600
Drug supplies	1	12	11,772
Dye making	2	18	11,700
Dough mixer	66	379	52,800
Dairy machinery	19	372	216,000
Drop hammer	1	2	159
Dental machinery	5	12	3,780
Electric distribution systems	4	7,407	5,470,000
Electric heating	9	8,048	3,647,224
Elevators (passenger)	278	10,421.5	19,950,000
Elevators (freight)	740	5,065	935,000
Electric railway systems	2	35,030.6	30,600,000
Embroidery machine	5	21.25	27,816
Engraving machine	5	70.3	6,885
Envelope manufacturing	3	8	13,000
Electrical repair shop	2	11	480
Electric appliances manufacturing	2	260	430,000
Electric testing	11	460	9,912

Electricity in the Canadian Home

F. A. Gaby, D.Sc., B.A.Sc., M.E., M.E.I.C., M.Am.Soc.C.E., F.A.I.E.E.
Chief Engineer, The Hydro-Electric Power Commission of Ontario.

"Do It Electrically," "The Electric Home," and "Electrify Your Home", have become very common phrases in comparatively recent years. In some parts of Canada especially, they are perhaps of greater significance than anywhere else.

The extent and methods of utilization of electricity in the homes of any country are, of course, partially dependent on the local conditions prevailing in that country. A brief outline of conditions in Canada as they effect this question of electricity in the home is necessary if this discussion is to be of value in enabling delegates to decide to what extent the results achieved in Canada are possible of attainment in other countries.

In general, the Canadian climate is moderately hot in summer and decidedly cold in winter. The houses are almost invariably heated by means of a central heating furnace located in the basement, and electricity in some cases is used for heat only as an auxiliary. Apart from other considerations, the severity of the winters precludes the possibility of using electricity for heating, exclusively, at reasonable cost.

Canada is fortunate in having very large resources of water power in proportion to her population, and these have been developed to a remarkable degree. To such an extent is this true in most parts of the country that over 90 per cent of the central-station power in Canada is derived from hydro-electric sources. It is believed that the per capita development of hydro-electric power is greater in Canada than in any other country of the world. The development of power on

Plate No. 1,—Two Storey Residence Electrically Lighted and equipped for Electric Service.

this large scale has resulted in an unusually low unit cost of producing and distributing electrical energy.

The expansion of the household use of electricity has been encouraged, in general, by the electric supply authorities, through the adoption of rate schedules with low secondary or follow-up rates. For instance, in Ontario alone there are over 300 municipalities where the follow-up rate for domestic service is 1.8 cent or less per kilowatt-hour. In many of the larger towns and cities of Ontario the follow-up rate is 0.9 cent net per kilowatt-hour.

Domestic help in many parts of Canada is relatively scarce and expensive. Wherever possible the Canadian housewife, with the help of electrical appliances, does her own work, unassisted by servants. In households whose means permit the employment of servants, the use of electrical appliances is also found to be of great benefit, as the electrically equipped home attracts servants of a better class and enables fewer servants to perform the duties required.

These factors have reacted upon each other, low rates encouraging the use of electricity, and extended use making possible still lower rates. In most municipalities throughout Canada the average family may take advantage of the cleanliness, convenience and safety of electric lighting at a cost of about one dollar per month or less, while for a small additional charge, electric irons, toasters, vacuum cleaners, washing machines, fans and certain classes of light cooking appliances may be utilized. Cooking by electricity is rapidly becoming popular. At the present time it is not unusual, in some parts of Canada, to find electric bills for residential service showing a consumption of from 200 to 1,000 kilowatt-hours per month. The following table is presented with the object of indicating the great amount of electrical service which can be obtained for a relatively small cost at the low rates for electrical energy which now prevail in large sections of Canada.

With reference to the above table it is of interest to note that in all applications of electricity to domestic appliances driven by electric motors, even those of larger size such as washing machines, the current consumption per month is relatively so small that their use would be justified and economical even in communities where much higher rates are charged for current. On the other hand electric cooking and auxiliary heating can only economically be employed where the rates for current are relatively low.

Extent of Use of Electrical Energy for Household Purposes

The great expansion of the use of electrical energy for residential purposes is of comparatively recent date.

Table No. 1, — Number of Hours Electrical Appliances may be Operated for an Energy Cost of Ten Cents in the Majority of Canadian Municipalities*

Appliance	Capacity	Hours of operation for 10 cents
Curling iron	20 watts	555 to 278
Warming pad	40 "	278 " 139
Sewing machine	60 "	185 " 92
Vibrator	60 "	185 " 92
Vacuum cleaner	100 "	111 " 55
Washing machine	200 "	55 " 28
Ten 40-watt lamps	400 "	28 " 14
Percolator	400 "	28 " 14
Hair dryer	440 "	24 " 12
Toaster	550 "	20 " 10
Iron	660 "	17 " 8
Air heater	660 "	17 " 8
Grill	660 "	17 " 8
Water heater	1,000 "	11 " 6
Grate	2,000 "	6 " 3
Range	3,000 "	3⅓ " 2
Ironing machine	3,000 "	3⅓ " 2

*These figures are based on the secondary or follow-up rate, it being assumed that the consumer uses, in addition to the requirements of these appliances, 30 to 90 kilowatt-hours per month for lighting and other primary purposes, depending on the size of the residence.

It is within the memory of the present generation when the first carbon-filament lamps began to replace the kerosene lamps and gas light formerly in use. With the introduction of the more efficient tungsten and gas-filled lamps and the growing realization on the part of the public of the economies and comforts to be derived from the use of electrical appliances, the last decade has seen tremendous strides in the domestic, as well as in the industrial, applications of electric power in Canada.

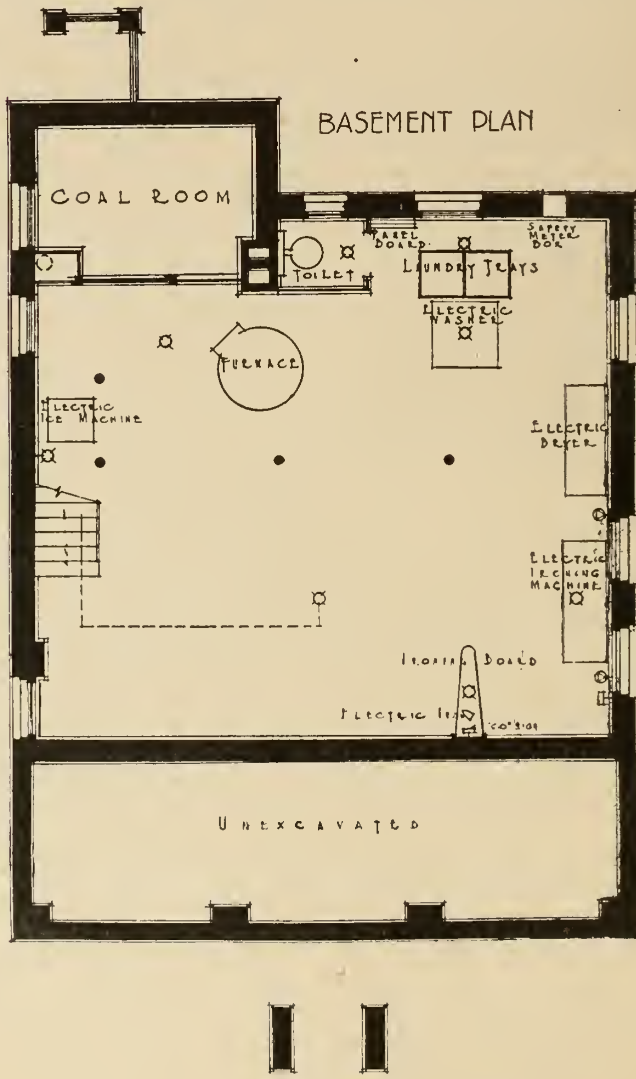

Plate No. 2,—Wiring Diagram for Basement.

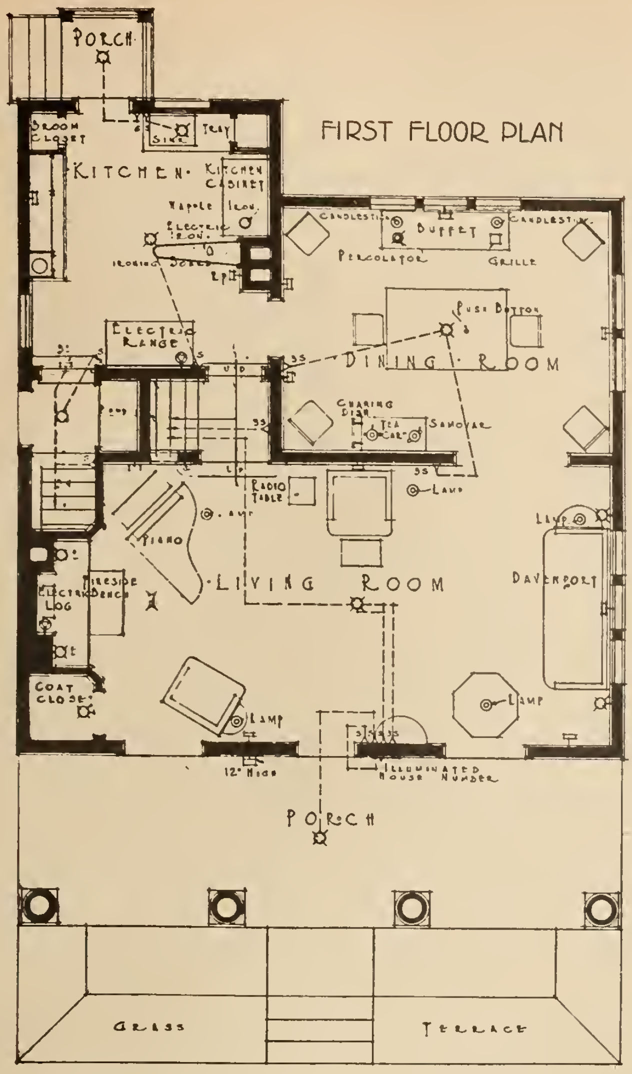

Plate No. 3,—Wiring Diagram of First Floor.

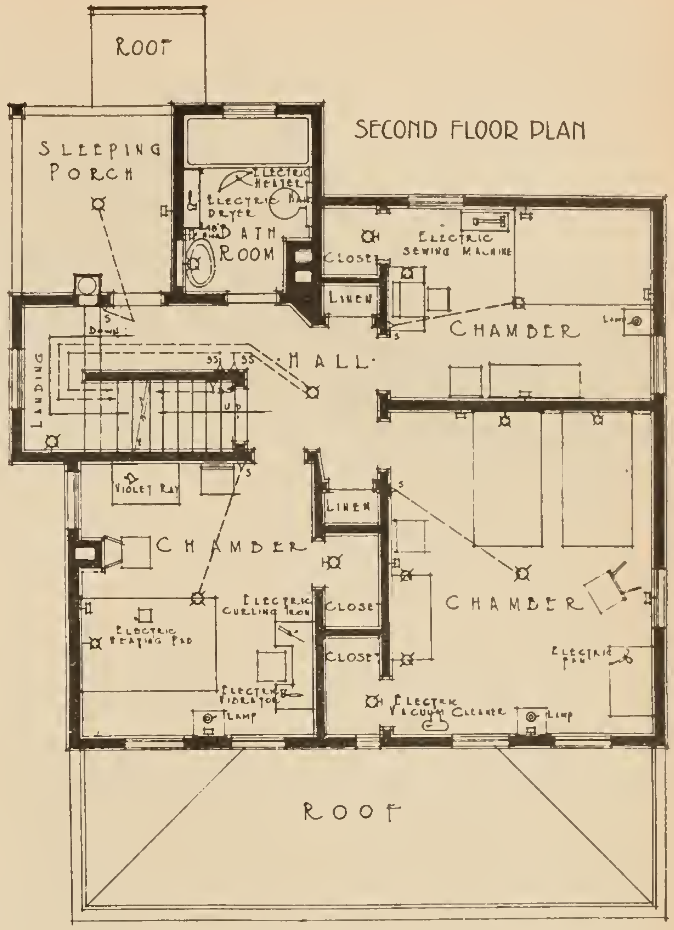

Plate No. 4,—Wiring Diagram of Second Floor.

This can, perhaps, be most clearly illustrated by extracts from the records of the supply authorities in a

Table No. 2, — Electrical Supply Statistics of some Representative Canadian Municipalities.

Municipality	Population	Years	Domestic consumption k.w. hr.	Domestic revenue	Domestic consumers	Average monthly k.w. hr.	Average monthly bill	Net cost per k.w. hr.
							$ c.	c.
Toronto	530,000	1913*	4,220,000	$ 190,370	16,500	25	1.25	4.4

		1923	53,400	1,370	89	51	1.30	2.6

*Statistics for these years, except populations, refer to one supply authority only and not the whole city.

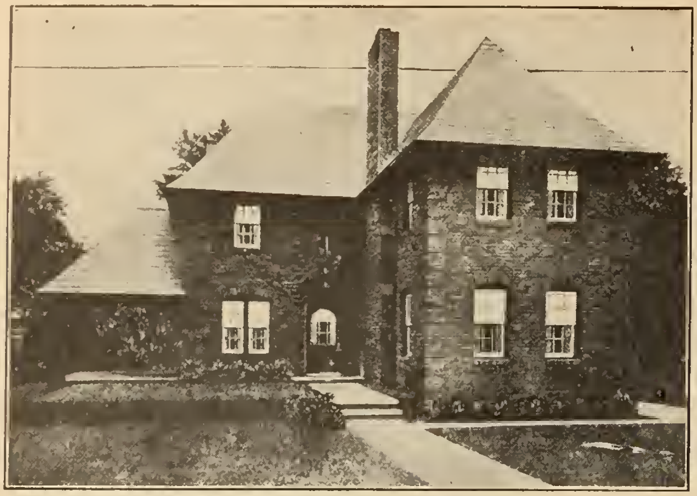

Plate No. 5, — Two Storey Residence Electrically Lighted and Equipped for Electric Service.

few representative municipalities, which are given in table No. 2.

It will be noted that in these municipalities the number of residential services now averages about one to every five inhabitants, — in other words, practically every home is served; in nine years the energy consumption per consumer has increased by from 200 to 600 per cent, and the net average cost per kilowatt-hour has decreased by from 50 to 75 per cent, in spite of the effect of the War in raising prices of practically all other commodities.

Popularity of Electrical Appliances

In the larger proportion of the cities and towns of Canada, the energy used by appliances in the average home now greatly exceeds that used for lighting.

While no survey has ever been made of the number of appliances in use in any or all communities, it is safe to assume that with a great many appliances at least, the point of saturation is being approached very rapidly. A survey recently made of the number of electric ranges in use in some of the larger communities in Ontario show the following results:—

City	Population	Wired homes	Number of ranges	Percentage saturation
Barrie	7,000	1,700	170	10%
Brantford	32,000	5,000	1,400	28%
Chatham	16,000	3,600	660	18%
Galt	14,000	3,200	1,100	34%
Kitchener	22,000	4,400	660	15%
London	61,000	14,000	4,000	29%
Ottawa	113,000	25,000	3,700	15%
Niagara Falls	16,000	3,200	900	28%
Stratford	18,000	3,600	1,500	41%
St. Catharines	20,000	4,500	900	20%
Windsor	43,000	11,000	4,000	36%
Winnipeg	200,000	33,882*	6,621	20%

*Municipal plant only.

It is safe to say that the more popular appliances, such as the iron, toaster, grill, vacuum cleaner, washing machine, and the electric fan, will show much higher percentages than do the ranges in all of these communities, were the figures available for the purpose.

The Canadian home is well equipped electrically. In the 1,000,000 wired homes there are in use over 500,000 irons and toasters; over 100,000 electric ranges, and, in addition thereto, a large number of other appliances, such as are mentioned in this article.

Modes of Utilization of Electricity in the Home

In describing the manner in which electricity is used in the Canadian home, attention will be directed to the principles now being applied in the more modern residences. The equipment and its arrangement in the house will first be dealt with, then the wiring by means of which energy is supplied from the public mains to the individual current-consuming devices, and finally the means adopted to render both the equipment and the wiring free from personal and fire hazards.

As regards the current-consuming equipment, methods of electric lighting will first be considered, after which labour-saving appliances will be briefly discussed.

Lighting the Home

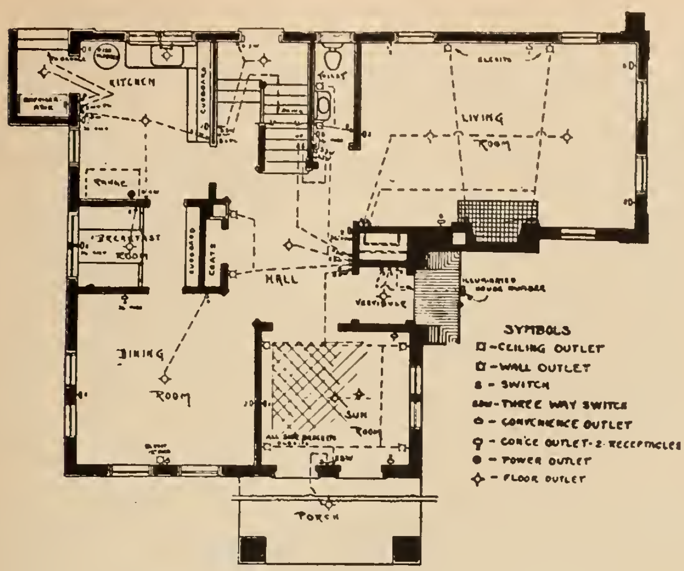
The possibilities of adding to the attractiveness of a home by means of suitable electric lighting are even yet not fully realized by the public. It is upon the guidance of those who manufacture, sell and install outlets and fixtures, who, in turn, are influenced by the advice of experts in illumination, that householders must rely more fully if the greatest benefit is to be secured from the resources at hand.

Without entering too fully into the scientific aspects of illumination, it may be said that there are important hygienic advantages associated with the use of electricity for lighting the home, but its greater service is rendered through making the home cheerful and attractive. In planning the lighting of a home there are certain fundamental principles which should be followed. For exampie, the filaments of incandescent lamps should never be vlsible when the lamps are in the normal direction of vision; such a condition is harmful to the eyes, and detracts greatly from the beauty and comfort of the home.

That light is useful light which falls upon the objects to be seen; bright light, shining in the eye, is not useful light. The layman often confuses glare with overlight. Investigation of places which are said to be overlighted has frequently shown that they are greatly underlighted. As an indication of the greatly varying degrees of light intensity to which the eye can adapt itself it may be stated that upon test, sunlight in an open field measures about 8,000 foot-candles; in a street between buildings,

BASEMENT PLAN

Plate No. 6, — Wiring Diagram for Basement



FIRST FLOOR PLAN

Plate No. 7, — Wiring Diagram for First Floor

3,000 foot-candles; shade in a street between buildings measures 300 foot-candles; under a tree in the open, 500 foot-candles. Light on a table close to a south window has an intensity of 110 foot-candles; on a table 10 feet from a window, 70 foot-candles; and on one 18 feet from a window 50 foot-candles. It is interesting to note that the artificial illumination for homes, as generally recommended, seldom exceeds 10 foot-candles. It is a mistake to have an inadequate number of electric luminaires* and lamps in any room of the home, or to use unshaded glare-creating lamps. Where lamps can be only partly shaded from view, they should have diffusing bulbs, and large lamps with very bright filaments can be used to best advantage in fixtures which shade them completely, diffusing the light, among which may be mentioned the semi-direct fixtures and semi-direct luminaires provided with decorative shades.

The modern smaller Canadian home usually contains an entrance hall, a living-room, a dining-room and a kitchen on the ground floor, and three or four bedrooms and a bathroom on the floor above. To accommodate the central heating plant a basement is provided and this usually extends under the whole of the ground floor. The height of the basement from the concrete floor to the under side of the ground-floor beams is usually from six feet six inches to seven feet six inches. This basement is often divided to provide a separate room for the laundry and frequently a portion is partitioned off to form a storage room for food supplies. Most houses are provided with a verandah or porch at the front. A sun-room is frequently added to many houses. Inasmuch as the various rooms in a house present different lighting problems, they will be dealt with separately.

Lighting the Living-Room

The home is, or should be, the centre of family life. The lighting of the living-room, especially, should be capable of adaptation to the various activities and social affairs which take place in this room. The activities range from those of a quiet, restful nature, such as reading and studying, to those of the joyous occasion, as when Christmas or other festive celebrations are in progress.

*Luminaires — Used here to indicate a light source whether consisting of one lamp or several lamps enclosed in a common shade.

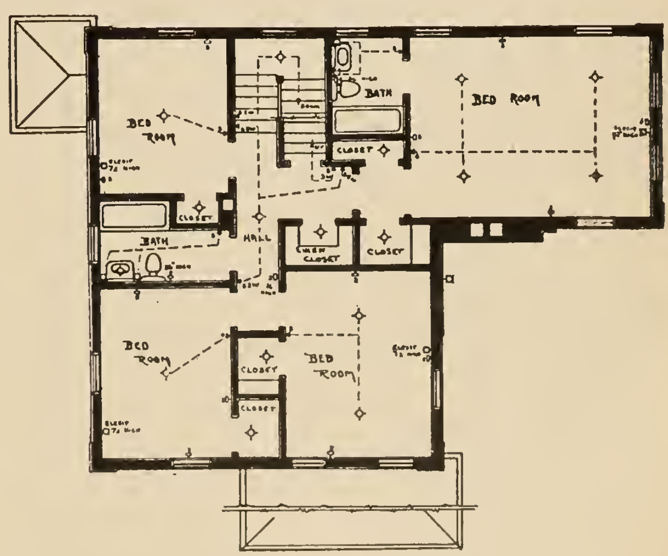
The provision so frequently made for only one central lighting effect, limits the possibilities of illumination and tends towards monotony. At present fixtures and lamps are available in such variety that a number of effects can be obtained without difficulty, if the wiring has been carefully planned. A flood of light is desirable when there is a social occasion, but for quiet evenings, with reading and study, local lighting is best; a table-lamp on the study table, or a floor-lamp beside an easy chair. For reading at a library table, with illumination from a well-designed table-lamp or portable floor-lamp, the visual field surrounding the book may be of medium brightness if desired, but if the remainder of the room is in semi-darkness, the psychological effect is usually conducive to concentrated attention, and the semi-darkness provides a place towards which the eyes may be directed occasionally, for the purpose of resting them.

The living-room, therefore, should, in addition to a powerful source of general illumination, contain floor-lamps and table-lamps. Many pleasing restful and artistic effects are also obtainable by the use of wall brackets, with either tinted or shaded lights.

The Dining-Room

The problem of lighting the dining-room is more definite than that of the living-room. The table is usually confined to a fixed position, and as it may be considered the most important object in the room, it should also be the most intensely illuminated object. Certainly there is a cheerfulness about a well-illuminated table, hemmed in by a semi-darkness.

If in lighting the dining-room, the so-called semi-indirect unit is used, it ordinarily floods the entire room with light, and the table is not always the most highly illuminated spot in the room. Semi-indirect lighting is often unable to fill the requirements for best lighting in the dining-room, and while, to some extent, it is a matter of taste, in modern practice it is usually replaced by a unit which directs dominant light to the table area. This modern unit may be a shower luminaire, with a number of lamps hanging downward, shaded with long dense glass shades, or a large dome suspended from above the table, low enough to shield the eyes from the lamps themselves, yet sufficiently high to permit an unobstructed view across the table.



SECOND FLOOR PLAN

Plate No. 8, — Wiring Diagram for Second Floor

In large dining-rooms, the semi-darkness around the walls is often softly illuminated by the use of shaded and decorative wall-bracket lights, with very pleasing effect.

The Bedrooms

The chief function of light in the bedroom is to facilitate making the toilet; two wall-brackets, one on each side of the dresser or dressing-table, provide the best solution of this problem. Light from a central fixture does not fill the requirements, because the light should fall upon the front of the person facing the mirror, and therefore the light should be on the wall. A light source consisting of one or several small luminaires, each hidden in a dense inverted bowl, provides a useful and pleasing general illumination. In addition, portable decorative and reading lamps may be provided for the bedside table and other situations, or for attaching to the bed itself.

Halls, Closets and Porches

The diversity of the layout of halls and closets makes it difficult to generalize with respect to the best methods of lighting, but the following suggestions may be helpful.

While it is not essential to have very high illumination in the hall, its appearance can be greatly improved by installing an attractive ceiling luminaire, supplemented by well-designed wall brackets.

A light within a clothes closet, arranged to be switched on automatically when the door is opened, or controlled by a pull-chain switch, with a radium-bead attachment, is a convenience which greatly facilitates selection of garments.

The sun-room should be equipped with decorative ceiling lamps, and portable lamps. The modern closed-in sun-room is finished much like an interior room, and, with suitable lighting, forms one of the most delightful parts of the modern residence; the lighting arrangements in the modern sun-room should be similar to those of the modern living-room, because it is virtually a summer living-room.

Bathroom

A satisfactory solution of the lighting problem in the bathroom is to provide a wall-bracket on each side of the mirror controlled by a switch at the door. The man who shaves himself will appreciate this arrangement, and there are many other reasons for such a method of lighting. In large bathrooms, the addition of a single overhead unit may be necessary, and it often adds to the general appearance of the room. This unit should be enclosed in an opalescent globe, and it should be of attractive design, in keeping with the other fixtures installed.

Kitchen

As the average housewife spends a great deal of her time in the kitchen, it is essential and very desirable that the kitchen be particularly well-lighted. A well-chosen location and design for a dwelling provides for proper natural illumination of the kitchen during the daylight hours, but it is too often found that this very important requirement has been sacrificed to other considerations of less value and a great many kitchens must depend for adequate illumination, even in the day-time, upon artificial sources. The efficient kitchen, therefore, must be flooded with light, and, in addition, lights over the kitchen table, and over the sink, so shaded as to prevent glare, are often desirable. A central lighting unit of ample size placed close to the ceiling, and enclosed in a diffusing globe to prevent the casting of sharply-defined shadows will provide a satisfactory general illumination.

Laundry

The basement, where the laundry of the Canadian home is usually located, is frequently one of the neglected parts of the house so far as lighting is concerned, and many essential requirements are often overlooked. The laundry should be provided with sufficient light to illuminate the sections in which the chief operations are carried on. Owing to the relatively small headroom available, it is frequently impossible to install a central lighting unit that will satisfactorily light the tubs, the washing machine, and the ironing machine, and therefore, individual lights placed over these various appliances are often more satisfactory. The proper illumination of the laundry is of direct benefit, not only because of the greater ease in performing many laundry duties, but also in the better results obtained.

Colour Lighting

The effective use of colour in decorative and lighting schemes is a most important consideration in a modern home. Recently the use of coloured lights has been developed as an aid to produce certain effects. They should, however, be used sparingly and with discretion.

References in ancient myths and in early history reveal the fact that mankind has always been sensitive to colour impressions. Colour is a medium by means of which pleasant sensations may be created, and this fact should stimulate the lighting specialist to utilize its power in the home. To those who realize the fact that in many ways lighting should be considered more from a psychological, than from a mechanical standpoint, no plea for utilizing colour effects in residential lighting is necessary.

There are certain fundamental reactions of various colours upon the human organism, common to nearly all individuals, and a knowledge of these may be used by lighting specialists to secure decorative and artistic effects.

Equipping the Home with Labour-Saving Devices

In the foregoing paragraphs an endeavour has been made to outline briefly the lighting equipment suitable for an average modern Canadian home. Even more, however, might be written respecting the equipment of the Canadian home with electric appliances. Before the introduction of modern labour-saving appliances into the home, the housewife's work was much more laborious than at present.

In Canada, electrical appliances are freely used in the home to perform a multiplicity of tasks formerly done in more laborious ways. Certain appliances, such as the *electric flat iron*, are found in almost every home where electrical service is available. Other appliances are introduced from time to time as means permit. A brief reference will be made to the more important electrical appliances which are utilized in a fully-equipped "electric home".

The electric vacuum cleaner is too well known to require description. It can be used in almost every room of the house to remove loose dirt from floors and rugs.

Electric floor-polisher: Many modern Canadian homes have waxed and polished hardwood floors throughout. Where large areas have to be polished regularly the electric floor-polisher is of great assistance.

The electric fan, whose main function in summer is to provide cool comfort, has a number of other uses. It can, for example, be used for drying clothes indoors, drawing cool air into the bedroom, exhausting the cooking odors from the kitchen, drying fruit and vegetables, improving the operation of the central heating system by increasing the heat radiation of a radiator or by improving the circulation of air in a room.

The electric range or cooking-stove has, in the past few years, become exceedingly popular in Canada. This is an appliance that can only economically be used where the rates for current are moderate. Briefly summarized, the advantages of the electric range are better cooking results, a cooler kitchen, an even, controlled heat which eliminates guess-work and supplies in its place an accuracy not hitherto possible with fuel ranges. The electric oven, free from gases that contaminate the food and carry off fine flavours, produces better results; meats are juicier and richer, with less loss of weight in cooking. bread is moister and stays fresh longer, cakes are more delightful in flavour, and biscuits are beautifully brown. Moreover, the same temperature conditions that are found to produce good results at one time can be duplicated on subsequent occasions.

The electric dish-washer is not yet in very general use. In large families where there are a great number of dishes to be washed, it will probably become more popular as it becomes better known.

The electric hand-iron, probably the most universally used of all electric appliances, needs no description.

Other devices frequently found in the modern kitchen include *electric refrigerators, electric fans* to exhaust cooking odors and *electric utility motors* for polishing silverware, grinding cutlery, etc.

The electric washing-machine is, perhaps, the most useful of the larger devices found in the modern home. It saves more labour than any other device.

The electric ironing-machine together with the washing-machine in many cases enables the housewife to dispense with the services of a laundress. Modern ironing-machines can handle over 90 per cent of the laundry of the average home.

The electric clothes-dryer is of use in city dwellings where backyard space is limited and unfit for drying clothes.

Supplementing the electric range is the *electric water-heater.* In some sections of Canada, the use of electric water-heaters has been made economical by the introduction of flat rates, which encourage the employment of low-capacity immersion heaters, used constantly. With heat-insulated hot-water tanks, the cost of hot water on this system is very moderate, and in many localities electric water-heaters are becoming popular. The comfort of having an abundant supply of hot water for washing, shaving, bathing, dishwashing and laundry purposes constantly available in winter and summer is greatly appreciated.

Electric heaters: The *electric log or fire-place* provides useful auxiliary heat in the living-room. As contrasted with the open fire, it is very cleanly, being sootless and smokeless and free from fumes and fine ash. Where provision for a grate or log does not exist, the *portable electric heater* is found useful and can be carried from room to room as required.

In the dining-room, a number of miscellaneous cooking appliances are frequently employed. The best known of these is the *electric toaster.* Small portable *grills, percolators, waffle-irons, chafing-dishes* and *egg-boilers* are among the other appliances frequently used in the dining-room. Many of these are also useful in preparing light meals such as afternoon tea in the living-room or sun-room.

Electrical appliances for the bedroom and the bathroom include such devices as *curling-irons, violet ray, electric vibrator* and *hair-dryer,* also *immersion heaters* for heating shaving-water or warming the infant's milk. The *electric warming-pad* is another useful article, especially in cases of sickness. It is more satisfactory than the hot-water bottle, because of its even heat and because it can be adjusted to any desired temperature.

One other most useful piece of electrical equipment is the electric *sewing-machine.* Sometimes a small independent "general-utility" motor is used which, when not required for driving the sewing-machine, will operate a small fan, a small emery wheel for sharpening tools, or a cream-whipping apparatus, etc. Motors are sold with attachments for performing these various functions.

Wiring of the Home

The necessity of providing adequate wiring for the home when it is built cannot be too strongly emphasized; obviously, the beautifying and labour-saving possibilities of modern electrical equipment cannot be realized in full measure unless the outlets are conveniently located and in sufficient number, and the wires serving them are of ample current-carrying capacity. In Canada, until recently, there was an unfortunate tendency on the part of designers and builders of homes to neglect wiring requirements, and as a consequence many householders have been put to unnecessary expense in making the required alterations, while others are still prevented from taking full advantage of electrical service.

Popular demand, however, now insists that the electric wiring of homes shall be ample for all present or future requirements, and in modern house construction the electric wiring is much improved. Provision is made in each room for all the fixtures and appliances likely to be used at any time in that room. Most important of all, the service wires entering the house are installed of capacity sufficient to serve the maximum requirements of the house as a whole, considering both initial and probable future needs.

Wired furniture is coming greatly into vogue in modern homes, and many are the provisions made in the manufacture of this furniture for the convenient use of portable domestic electrical equipment. Dining tables, buffets, and tea-wagons in the dining room, dressers, dressing-tables and beds in the bedroom, and tables for use in various parts of the house are among the pieces of furniture provided with wiring and outlets for the portable appliances to be used in conjunction with them.

In installing wiring for lighting throughout the home, control switches at the entrance to all rooms are indispensable, and switches which will control the lights on one floor from another floor are generally installed and found very convenient.

Electrical Inspection

The average householder, unfamiliar with the technical aspects of electricity, is not in a position to judge of the safety and desirability of electrical wiring and appliances, and it is essential in the public interest that some qualified body pass upon electrical equipment before its use is permitted. Without supervision, unscrupulous wiring contractors and appliance manufacturers would take advantage of householders, installing and selling poorly designed wiring and equipment, with consequent inconvenience and not infrequent damage by fire to the householders property and in some cases even loss of life.

In some provinces of Canada the Fire Underwriters' Association appoints a body to supervise electrical work. This body formulates and revises from time to time a code of rules for wiring, and inspects all installations. In Ontario the code of rules is issued by the Hydro-Electric Power Commission on behalf of the government, guided by the advice of a joint committee representing the electrical manufacturers, jobbers, wiring contractors, insurance underwriters, central stations and the provincial fire marshal, and the observance of the rules is enforced by a system of wiring permits and inspection administered by the Hydro-Electric Power Commission of Ontario. No wiring can be done without a permit, and no central station may energize a circuit until it has been inspected and approved, without incurring heavy penalties.

Periodical testing of samples of electrical devices is conducted by the Hydro-Electric Power Commission of Ontario. Each device, if approved, is given an approval number, which is stamped on the article by the manufacturer and only devices so stamped may be used or sold in the province. This system of inspection and test has, it is believed, almost entirely eliminated the fire and personal hazards which would otherwise be quite appreciable in a country like Canada where electricity is used so extensively in the home.

Electrical Service for Rural Districts

As Provided by The Hydro-Electric Power Commission of Ontario.

F. A. Gaby, D.Sc., B.A.Sc., M.E., M.E.I.C., M.Am.Soc.C.E., F.A.I.E.E.
Chief Engineer, The Hydro-Electric Power Commission of Ontario.

In the province of Ontario there has been an extensive application of electrical energy throughout many rural and agricultural districts. In order rightly to appraise the remarkable results which have been achieved in this sphere of activity, it is necessary to recognize the fact that settlement, even in the older portions of the province, is spread over relatively large tracts of land, especially as contrasted with settlement in European countries. This fact is of special significance because it implies longer transmission lines and special and more costly physical equipment to serve agricultural customers in the province of Ontario than would be the case if the farmers were grouped along the main highways and their buildings were closer together than is the case. Notwithstanding such difficulties, the growth in agricultural electrical service in the province has been remarkable, and all indications point to a much greater development.

In presenting a statement of what has been accomplished in connection with the furnishing of electrical service throughout portions of the province of Ontario, it will add to the understanding of the statements made if it is explained that the province of Ontario extends from the Great Lakes northwards to James bay and Hudson bay. Of this vast area of 400,000 square miles, the southerly portion in which most of the population is settled is commonly referred to as "Old Ontario", and the newer northerly portions as "Northern Ontario". "Old Ontario" extends from about the head of lake Huron to the Ottawa river and southwards to lakes Erie and Ontario and the St. Lawrence river. In this territory, there is an assessed area of approximately 40,000 square miles. In "Old Ontario" the assessed area in townships is about 24,000,000 acres, of which about 15,000,000 acres is cleared area. According to the census in 1922 as determined for purposes of assessment the population consists of 1,056,238 rural, 549,915 urban, and 1,186,329 in cities, a total of 2,792,482.

Before entering into a description of the special features of the application of electrical energy to agricultural areas in the province of Ontario, brief mention should be made of the chief agency by which all these activities are devised, constructed and operated.

Early Efforts

About the year 1900 a number of leading Ontario manufacturers gave public expression to their opinion that investigation should be made to determine if hydro-electrical energy at rates cheaper than the cost at which power could be generated locally from coal, gas or oil, could be obtained from the extensive water powers of the Niagara river. It was pointed out that the wholesale distribution of electrical energy throughout the more populous portions of Ontario would substantially reduce the importations of coal which the citizens of this province were compelled to obtain from the Pennsylvania and other coal fields in the United States. Special interest in Ontario's power problem was thus aroused and was further greatly stimulated by means of public meetings and by discussions in the press.

It had further been suggested that it might be possible for municipalities to co-operate to secure low-cost electrical energy and distribute it to the citizens of their municipalities just as readily as it had previously been found possible for individuals or corporations to combine in order to secure by common action a desirable end.

Appeals were made to the provincial government for legislation to enable municipalities to take action and finally as a result of the general movement on behalf of cheaper hydro-electrical energy the government of the province of Ontario, in 1903, provided the means by which a commission could be appointed by interested municipalities to investigate the supply and distribution of hydro-electrical energy. The authority thus granted resulted in the appointment by the municipalities of Toronto, London, Brantford, Stratford, Woodstock, Ingersoll and Guelph of the Ontario Power Commission, which, after a thorough investigation, published in 1906 a comprehensive report. In this report the availability and costs of power from various prime sources were set forth, also data respecting the consumption and estimated future requirements of power in the districts concerned, the cost of the development of electrical energy at Niagara and other relevant matters.

When the results of this investigation became known to those interested, the provincial government in 1906 provided by special Act for the creation of the Hydro-Electric Power Commission of Ontario. This commission was empowered by the legislature of the province to act as trustee and agent for such municipalities in the province as desired to co-operate for the securing of electrical energy. The commission was later empowered to harmonize the various requirements and co-ordinate the municipalities into suitable groups or districts. It has been through the instrumentality of the Hydro-Electric

Plate No. 1,—Power Service to a Farm in Ontario

Three-phase rural power service, showing the distribution lines along the road, the service to the farm and the 110,000-volt line in the background.

Power Commission of Ontario that the application of electricity in the agricultural districts has been initiated and carried forward to its present stage of development.

The commission, acting as trustee and agent for the municipalities, exercises both administrative and constructive functions and has evolved a well defined and working policy for the transmission and the distribution of electrical power under municipal ownership. The fundamental basis of the undertaking is a partnership of municipalities formed to obtain electrical energy for its citizens *at cost*. Cost, so far as "hydro" power is concerned, includes all charges arising from the generation, transmission and delivery of power to the municipalities. These charges include for each municipality its proper share of the interest and sinking fund for the cost of lands, stations and equipment required for supplying the power, as well as a proportionate part of administration, operation, maintenance, taxes, renewal and reserve, and of all other costs entering into the business of supplying electricity.

The first distribution of electrical energy by the commission was in the year 1910, and by the end of 1910 it was supplying power to about ten urban municipalities. The small initial load of less than 1,000 horse power increased until in 1920 it was 356,000 horse power. The commission is now, in 1924, distributing about 750,000 horse power. It has under construction in what is known as the Queenston-Chippawa development on the Niagara river, the largest individual water power plant in the world with an ultimate capacity of about 600,000 horse power. This power, it is expected, will all be in use by 1926.

At the present time, the commission operates electrical power undertakings which, when fully developed, will have a potentiality of over 1,000,000 horse power. At the end of fifteen years of its work, the commission finds itself distributing electrical energy throughout practically all of the more populous portions of the province of Ontario. It has main transmission lines totalling 4,000 miles in length, including about 600 miles of 110,000-volt line. The greatest length of continuous 110,000-volt line, is that between Niagara Falls and Windsor, a distance of approximately 250 miles.

When it is appreciated that the co-operating municipalities of the province of Ontario supply power and light to half the population of the province; supplying over 380 municipalities, including cities, towns, villages, police villages and townships, involving in all an investment in connection with the general transmission and distribution of electrical energy of $250,000,000; a better understanding will be had of the auspices under which electrical service to agricultural and rural communities has been established.

Without this brief description of the work of the co-operating municipalities of Ontario through the instrumentality of their Hydro-Electric Power Commission it would be impossible to understand the special

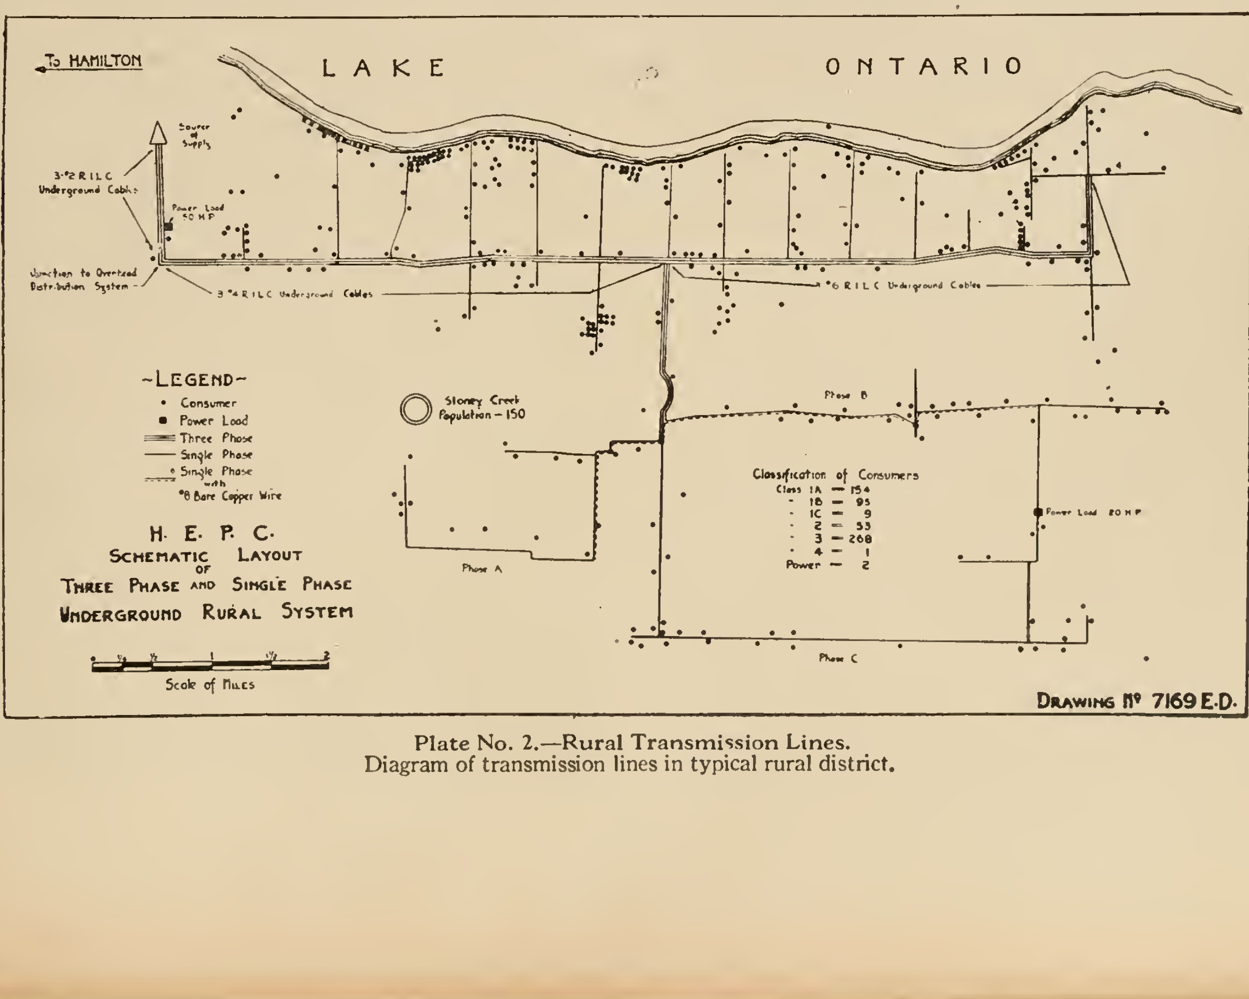


Plate No. 2.—Rural Transmission Lines.
Diagram of transmission lines in typical rural district.

aspects of the problems which the commission's officers have been called upon to solve in their work on behalf of rural communities. It was, in fact, the success of the work of electrical distribution in the cities, towns and other community centres which induced the agriculturists to seek a means of co-ordinating their efforts to the end that they might, in turn, receive like benefits to those which they saw operative in their adjacent municipal centres.

The Hydro-Electric Power Commission has already formed one hundred and seventeen "Rural Power Districts" with definite boundaries, and service has already been given fifty-five of these districts. A typical rural district covers about one hundred square miles. Approximately 55 per cent of the constructional work for these services has been performed within the past two years.

Reaching the Rural Population

The distribution of electrical energy to country districts is a problem which has engaged the earnest attention of the national governments of various countries in Europe and in North America. This attention has been greatly stimulated by the serious shortage of farm labour brought about by the Great War. The governments of France, Denmark and Sweden have assisted rural districts to obtain electrical service either by granting long-term loans to companies composed of farmers or by actually bonusing such companies. In the United States, the Department of Agriculture is at present working in co-operation with a large electrical association with a similar objective.

The number of rural customers using electricity in European countries was greatly increased during the War owing chiefly to the fact that the supply of fuel for internal combustion engines, which were so extensively used, was either radically restricted or entirely cut off. It has been stated that in one of the European countries the number of rural electrical customers increased since the War commenced from 1,200 to 35,000.

It is believed that the Hydro-Electric Power Commission of Ontario is the first organization transmitting and distributing electrical energy in a wholesale way to undertake the delivery of electrical energy direct to the individuals of rural power districts. The method of governmental procedure in other countries, as is also the case in the United States, has been along the line of the delivery of electricity from a general centre *en bloc* to a receiving centre from which the distribution is taken care of by a private organization or distribution company, the personnel of which is made up of consumers.

In the course of the present discussion, it is proposed to outline the problem of electrical rural distribution as it exists in the province of Ontario, the means employed to deal with the problem, the success which has been attained, and the general prospects for the future.

Generally speaking, the difficulties of electrification of country districts appear to be the same, or nearly the same, in all parts of the world. There is, however, one important difference which should be borne in mind, namely, that in many countries of the old world the rural districts have their buildings assembled in a group as in a village, with their small farms around it, while in newer areas, like the province of Ontario, a farm consists of a section of land in one block with the buildings usually situated on a high spot somewhere on the farm, often in the centre, in consequence of which the distance from the set of buildings on one farm to those on the next farm is, on an average, about one-third of a mile. Obviously, with only three possible farm electrical service per mile; as is the average in most Ontario districts, the problem of economical electrical distribution calls for special study, the result of which is not always favourable to proceeding with the work of furnishing the electrical service desired.

Again, Canada, unlike some of the countries of Europe, has available supplies of gasoline and oil at fairly reasonable prices and, therefore, in some sections, electrical power for farm service and other purposes, has a competitor in the internal combustion engine. However, the electrical service from a central station has many points of superiority over an individual lighting plant driven by an internal combustion engine.

Rural settlements spread over extensive areas, as is the case in the province of Ontario, present unusual economic difficulties as a field for the distribution of electrical energy. Except in districts where the requirements for power are considerably larger than the average found in rural districts, or where the service is to areas under intensive cultivation, or to areas adjacent to existing transmission lines, private power companies usually will not extend their lines for rural service. The difficulties of electrification of country districts are universally recognized. Only a small return can be secured from any capital invested; the operating costs, due to the distances to be covered, are excessive; the load per mile of distribution system is small; the load factor is low and the demand irregular, being controlled, in part, by weather conditions which affect most farmers in a given locality in a similar manner.

In spite of the handicaps inherent in rural distribution of electrical energy, the Hydro-Electric Power Commission has, in this department of its activities, made substantial progress and although the aggregate load distributed to the rural dwellers is, and must always be, but a relatively small proportion of the total energy distributed by the commission, its influence upon the economic life of the province of Ontario is already a factor of importance.

Legislation for Rural Service

Having thus noted some of the outstanding general features of electrical rural distribution, it will be interesting to review the legislative enactments which were required in order to initiate and further electrical rural distribution in Ontario.

Farmers in Ontario knew that the high-voltage lines from the generating stations of the Hydro-Electric Power Commission to the high-tension stations and from the latter to the cities, towns and villages of the province were conveying electrical energy which was building up these central communities as well as easing household burdens. It was not long, therefore, before the farmers began to desire for themselves the benefits which they perceived were being enjoyed by their friends in the adjacent cities and towns.

In 1911, — and this was just shortly after the main transmission lines of the commission were made alive, — requests from prospective rural consumers for estimates of cost for electrical service were received by the commission from areas adjacent to the cities and towns served, but as no provision for dealing with such matters had been made in the original Power Commission Act, it became necessary to pass an amendment to the Act providing for the supplying of hydro-electrical service to one or more ratepayers of a township where proper request was made for such service. Under this amendment, the petitioners who wished to obtain a supply of electrical energy might sign a petition to their township

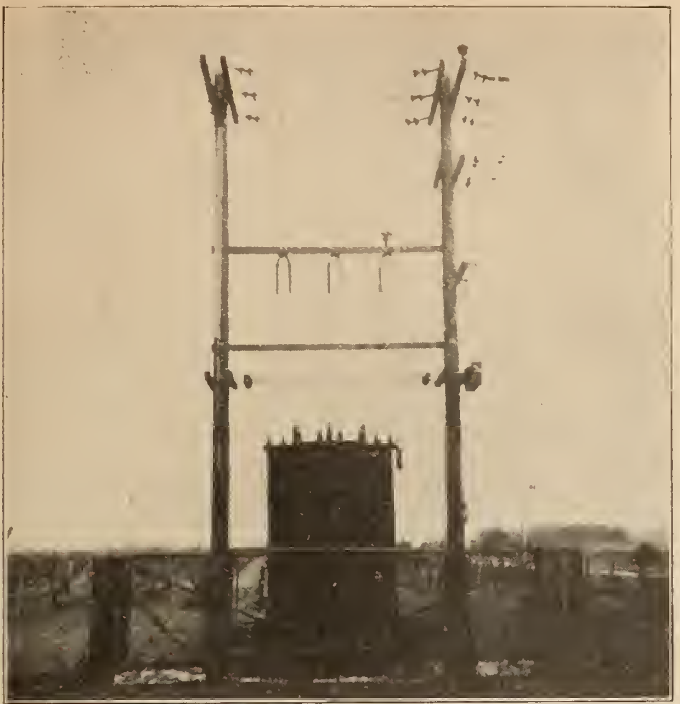

Plate No. 3a,—Rural Transformer Station and overhead Construction.
Outdoor substation serving rural district, primary voltage 12,000, secondary voltage 4,000/2,300.

requesting it to secure from the Hydro-Electric Power Commission an estimate by the commission of the cost of supplying electrical energy for their needs. After such an estimate of the cost and the rates which would apply had been supplied to, and considered by, the petitioners, they could then each enter into a contract with the township for the amount of power individually required. The township would then enter into a contract with the commission for the power necessary to supply the aggregate amount of energy required by the petitioners. This Amending Act also provided for the addition of further power subscribers. The contract would be for the period of the debentures issued for payment of the cost of constructing such lines with their necessary equipment.

About 1920, it was found that the legislation passed in 1911 was resulting in giving service to the more densely populated areas adjacent to towns and cities already receiving service while the rural citizens on the back concession lines were still being more or less excluded from the benefits which it was the desire of the provincial legislature should, so far as possible, flow to all citizens. The legislature, therefore, passed a further amendment providing for the distribution of electrical energy to rural consumers in special districts or zones. The conception underlying this amendment differs from the 1911 arrangement in that the districts supplied are not limited by the geographical boundary lines of the townships, but provision is made for the extension from the distribution centre of a city, town or village receiving electrical energy from the commission or from a centre to be created. Such extension from a distribution centre is limited only by the economic soundness of the extensions. The legislation also provides for the supplying of power for the lighting of streets or roads in townships.

In 1921, another amendment was made to the Power Commission Act whereby primary lines would be bonused by the provincial government up to fifty per cent of their cost. Under this arrangement, transformers and meters are considered as secondary equipment; that is to say, they are excluded from participating in the government bonus.

The Hydro-Electric Power Commission has had requests from many countries for information respecting the legislation under which its rural operations are conducted, and as this is so important a feature of the subject under discussion, an epitome of the commission's legislation as amended and in force at the present time, is, for reference purposes, submitted at the end of this paper.

Initiating the Work

From the standpoint of the Hydro-Electric Power Commission, the supplying of the electrical needs of rural citizens must be initiated and carried forward on a basis that is economically sound. Before authorizing any project, the commission must look well ahead to ensure future, as well as present, requirements of the district under consideration. Any project must absolutely pay its way, including the repayment of all moneys employed for the purchase and installation of the necessary equipment to provide the rural service; the consumers provide their own individual equipment and motors, etc., including the wiring for same. The commission only carries its construction to the entrance to the consumers' premises.

Rural Uses for Power

The conception which many rural residents have of their needs in the way of electrical service is usually confined at first to the providing for lighting requirements, but later it is realized that the greater service is rendered in the form of convenient power, because it is in connection with power service that the farmer effects his chief saving in labour. The experience of the commission enables it to appraise the whole situation so that the selection of equipment, the method of installation and other features, will be such as to ensure the required service at a minimum of cost.

Wherever possible, the load factor of systems is improved by the commission co-operating with manufacturers to secure the development of a better class of farm power-using machinery, with perhaps smaller capacities, thus decreasing the individual demand for power. The effort is made to have smaller motors employed for the driving of such machinery as is required under average present-day farm conditions. As rural distribution of power extends, machinery for power purposes will be employed with increasing regularity. The shortage of farm labour is, to a noticeable extent, being overcome by the employment of mechanical milkers, automatic water systems, and other machinery conveniently arranged to lessen the handling of farm produce. Once power-driven machinery is employed on the farm, its use generally suggests other adaptations. In the sphere of the domestic application of electricity, the cooking range and other appliances found in the homes in urban centres are already being used in farm houses resulting in a great saving of labour and time to the housewife. In numerous cases the farmer employs electrical power for cutting wood for fuel, and in some instances the fuel is sold in the adjacent town and from the money obtained the farmer himself purchases the electrical energy by which his own meals are cooked. These and other uses are shown in the accompanying illustrations.

It is very interesting to observe the rapidity with which industrial uses for electrical energy multiply once an electrical supply is available. In almost every rural power district there are some industries using power such as brickyards, tile yards, cheese and butter factories, gravel plants, stone plants, quarries, chopping mills and flour mills. Such industries thrive and develop under electrical service while such service also attracts new industries. There have been several old-fashioned portable saw mills supplied with electricity, the slabs of wood and sawdust being now sold for other purposes instead of being used, as formerly, for fuel for a steam plant employed to supply the power.

The providing by the commission of the distribution lines and equipment necessary for conveying the electrical energy from the nearest available power centre to the consumers' premises is the chief element of cost determining whether or not rural power service can be furnished on a satisfactory economical basis. Owing, therefore, to the importance of the factor of the distribution system, the commission has bestowed a great deal of effort to determine the best means to employ in order to provide distribution lines and equipment which, from the standpoint of electrical and physical requirements, would be satisfactory and at the same time of a minimum cost. It will be of special interest, therefore, to those considering the problem of electrical rural distribution to have before them a brief review of the features which the commission has employed in the construction of its rural distribution lines.

The Rural Primary Distribution Circuit

The standard circuit for distribution from the substation is 4-wire, 3-phase, 4,000/2,300-volt, star-connected, with the neutral wire grounded; the frequency is 25 or 60 cycles according to that of the generating system. One, or more if required, of these 3-phase circuits, is taken out of the substation and carried into the rural district.

The extent of the 3-phase circuit in any direction is determined by the amount of power to be distributed in that section. It is extended as far as is required to secure the desired voltage regulation, and no further. This limitation of the 3-phase circuit, with resultant economy, is feasible because 3-phase service is not offered to the individual consumer except for exceptionally large loads. In practice, the 3-phase circuit forms approximately one-third of the total length of circuit; located along the main highway it constitutes the backbone of the distribution system and from it, at each intersecting cross-road, are carried single-phase, 2,300-volt branch circuit, connected alternately to the three phases of the main circuit. One conductor of the single-phase circuit is grounded. Connections to the ground are made at the substation and at each service transformer; these being required on the average at about one-quarter of a mile apart.

The Rural Secondary or Service Circuit

Adjacent to or on the property of the consumer, a transformer is installed in order to reduce the voltage from the 2,300-volts of the primary circuit to the 220 or 110 volts for the service circuit. For safety it is found desirable to avoid carrying the 2,300-volt circuit on to the property of the consumer and, therefore, this circuit is confined to the highway unless the consumers' buildings are located at an unusually great distance from the highway.

Single-phase, 110-volt service is supplied for the use of consumers having an average lighting load; 220/110-volt, 3-wire, single-phase service is supplied for consumers with electric cooking ranges or motors of 2, 3 or 5 horse power. Upon the average farm larger demands are uncommon, although occasionally it is found advisable to provide 3-phase, 220-volt service and in exceptional cases, 3-phase, 550-volt service.

Design of Overhead Distribution System

Low First Cost Essential

The distances between consumers along the highway in the country is, of course, much greater than in the cities, and consequently the length and therefore the cost of line per consumer and also the cost of operation and maintenance is likewise greater.

Being familiar with the town service rates, and not always appreciating the extent to which the above-named factors affect the cost of rural power, the rural consumer does not at first take kindly to the necessarily higher rates. It is, therefore, essential to install a type of construction having low capital cost in order to obtain such rates as will be attractive to the farmer. On the other hand, the construction must be mechanically strong for safety in order to avoid interruptions to service and to keep down maintenance costs. The electrical characteristics of the conductors and equipment must be ample because the farmer will not be content with a quality of operating service inferior to that supplied in the towns. All such conditions have been given due consideration in the design and construction of the lines standardized by the Hydro-Electric Power Commission of Ontario. To a

Plate No. 3b,—Rural Transformer Station and Overhead Construction.

Junction between underground cables and overhead constructors; middle cross arm supports fused disconnecting switches, lower cross arm supports cable terminals for two 3-phase underground circuits. Note lightning arresters on top of adjacent pole.

large extent, the commission's experienced construction force is supplemented by local labour, thus reducing the cost of transporting labourers from place to place and the cost of the lost time involved in so doing. The farmers themselves are willing to engage in the work, appreciating the fact that a reduction in the cost will be reflected in the rates, because the power is sold *at cost*. Competitive tenders also are received from contractors and much of the rural work is done on contract basis.

Lines are Built on the Highways

Farm dwellings and barns are usually located reasonably close to the highway and lines on the highway are therefore conveniently situated for the connections to the farm buildings. Trees form perhaps the greatest obstacle to these lines, although telegraph and telephone poles are commonly encountered. The use of the telephone is very general in rural districts in Ontario and telephone lines are frequently found on both sides of the highway. In a few cases arrangements have been made for the joint use of poles for telephone and power wires. Where the poles of a power transmission circuit of higher voltage have already been erected along the highway, such poles are used for the support of the conductors of the rural circuit, thereby avoiding duplication of poles.

Poles, Pole Spacing, Crossarms and Other Pole Fittings

The standard pole used is of eastern Canada cedar and is 30 feet in length, with a diameter at the top of 6 inches. These poles are set 5 feet, 6 inches in the ground on tangents and 6 inches deeper at curves, corners or terminals. Poles of greater height are occasionally required to provide clearance from trees and foreign pole lines. At railway crossings, the poles are required to be of 7-inch diameter at the top and of sufficient height to permit clearance of 30 feet between the rails and the power wires. The maximum spacing between poles is 160 feet, and this spacing is commonly obtained. It is, however, reduced at curves in the road and in spans adjacent to corners, as well as in terminal spans. At consumer's premises, also, poles must be located for convenient connection to the consumer's buildings. For these reasons the average span may be considerably less than 160 feet. Where necessary, guys of stranded galvanized steel are installed. Where the four wires of the 4,000/2,300-volt circuit are to be supported, crossarms are used, the dimensions of which are 3¾ inches by 4¾ inches by 6 feet 4 inches. The material is British Columbia fir. The spacing on the crossarm between the outer and the adjacent conductors is 18 inches with 30 inches between the two conductors adjacent to the pole. The crossarm is secured to the pole by a ⅝-inch machine bolt and by two flat steel braces 30 inches in length. Where only two conductors are required for the 2,300-volt, single-phase circuit, crossarms are not used. The ungrounded conductor is carried on a steel pin projecting above the top of the pole and the grounded conductor on a steel bracket on the side of the pole. Two feet vertical separation is maintained between the two conductors. All hardware used is galvanized. Porcelain insulators are used to insulate the ungrounded conductors and the grounded conductor is supported on glass insulator.

Conductors

For the primary circuit, hard-drawn copper is used, the cross section of which must not be less than No. 6 B. & S. gauge. This minimum is determined for reasons of mechanical strength and not on account of electrical conductivity. Joints in this conductor are made with copper sleeves, twisted. To a small extent, a stranded aluminum conductor with steel core has been used for the primary circuit. Bare wires are the rule for all primary wires in rural districts. Where the primary circuit is 3-phase, the fourth or neutral wire usually consists of ¼-inch steel, stranded and galvanized. In hamlets and occasionally even in the country itself two or more consumers may be found located favourably so that they may be served economically from one transformer. For such cases the 3-wire secondary circuit (220/110 volts) required along the highway is supported in a vertical arrangement on a steel bracket fastened to the side of the pole. The neutral conductor is placed above the others to provide greater safety in the event of a primary wire falling across the secondary circuit. The neutral wire is bare and the other two are provided with a double braid weatherproof covering. The wires of this circuit are, without exception, medium hard-drawn copper and all joints are soldered. No. 6 B. & S. gauge is the minimum size used. For connections from the pole on the highway to the consumer's premises, medium hard-drawn copper conductors are used, all conductors having a double braid weatherproof covering and being not less in cross section than No. 8 B. & S. gauge. All conductors carried over railroads are required to have a strength not less than that of No. 4 B. & S. gauge copper, and to be stranded. This applies to the conductors in the crossing span and the adjacent span on either side of the crossing.

Transformers and Meters

Due to the fact that the average number of consumers per service transformer is small, little advantage is obtained in diversity of the load on the individual transformer. The transformer must be capable of carrying the maximum load which is usually of short duration. On the other hand the number of transformers connected to one feeder is large, due to the relatively small average transformer and also due to the fact that there is a high diversity in the transformer demands on the feeder. At the time of peak load on the rural feeder there is, therefore, a large number of transformers from which the consumers are drawing little or no current, and these lightly loaded transformers result in a low power factor for the load on the feeder, which is of course undesirable. To ameliorate this condition, particular care has been taken in specifying that transformers shall have low exciting current. In other respects, the transformers are similar to those used in urban systems. The rated voltage is 2,200/220-110. The minimum size used is of 2 kv.a. capacity and there is more demand for the 3 kv.a. than for any other size. Each service transformer on the overhead lines is protected by a lightning arrester and fuse cutout. Watthour meters are used for measuring the consumers' power consumption. These are placed inside the consumer's house or barn, or infrequently in a wooden housing on a pole on the consumer's property. The ratings of the meters commonly required are 10-ampere, 2-wire, 110-volt and 15-ampere, 3-wire, 220/110 volts and for either 25 or 60 cycles.

Underground Cable Construction

The increase in cost of labour and material, one of the conditions resulting from the Great War, made itself evident in the building of power lines as in other classes of construction. This led the Commission's engineers to investigate the possibilities of underground construction in rural districts. It is unnecessary to state that the use of cables laid underground is a well-established practice, but it may be of interest to note that their use

Plate No. 4a,—Underground Rural Transmission Lines.
Tractor excavation trench for underground cable.

antedated the use of pole lines. In the year 1843, Morse attempted to lay cables underground for his telegraph system but, due to difficulty in obtaining a proper cable and troubles in connection with his trenching equipment, he abandoned this type of construction and turned to wood poles for the support of his conductors.

The extensive application of underground cables to rural service is however, we believe, quite new, and the methods of installation and the design of material and equipment were given comprehensive study. At the present time the commission has approximately 125 miles of cable installed with 35 miles additional now under construction.

The standard cable is described briefly as follows: Single-conductor, No. 6 B. & S. gauge, 7-strand, tinned copper, insulated with 30 per cent para rubber 3/32 inch in thickness, laid over with a rubber-filled, insulating tape and covered over all with a sheath of pure lead 1/16 inch in thickness. No steel wire or tape or other protective covering is put on the cable. The cable is rated nominally at 2,500 volts and is given a factory test for 7,000 volts for 5 minutes. It is furnished in uniform lengths each of one third of a mile.

In general, the cable is laid close to the fence line and between the fence and the traversed portion of the highway. In some cases, it has been found advisable to lay it immediately inside the fence on private property. A trench is made of from 15 to 18 inches in depth and the cable placed therein without other protection than that afforded by the refilled soil, except at hazardous locations such as road crossings. At such points the trench is made deeper and a creosoted plank is placed above the cable after a few inches of the excavated soil has been replaced.

At advantageous points the location of the buried cable is indicated by a stake of creosoted wood 4 inches by 4 inches by 5 feet long, set 2 feet in the ground. On this stake is placed an embossed aluminum plate with the designation "Hydro Cable" and a space thereon for marking details of location.

Two methods have been employed in making the trench. A plough of exceptional strength, drawn by a gasoline driven caterpillar tractor was originally used and for the greater part of the mileage now installed. The same tractor was used to draw the carriage in which the cable reel is mounted for laying, and the tractor was used also for drawing the backfilling equipment. The method now in use and which is particularly economical where a comparatively short extension is to be made, takes advantage of equipment which is commonly available in rural districts.

The trench is made by alternate trips of a common farm plough to break up the soil and a road scraper by means of which the earth is removed from the trench. The road scraper is a machine made use of generally throughout Ontario in grading the highways. This machine is drawn by horses and the same equipment is used in replacing the earth over the cable. The cable reel carriage is also horse-drawn. Frequently the reel can be carried along close to the trench and the cable laid therein with a minimum amount of handling.

Cable joints are enclosed in lead sleeves, compound filled and sealed with wiped joints to the cable sheath.

At each location where service is required for a consumer a wood pole is erected and the cable carried up the pole, terminating in a pothead with disconnecting apparatus; in order to continue the circuit further along the highway the cable is carried down the pole again from a second pothead. This arrangement eliminates the necessity of a joint at the foot of the pole and the disconnecting potheads form a convenient means of opening the circuit for a test or other purpose. The potheads are installed with wiped joints. The cable on the side of the pole is covered with a protective moulding. On the pole the service transformer is mounted and the secondary circuit is carried overhead to the consumer's premises. An experimental installation is now being made in which the transformer will be placed in a small concrete housing and the secondary wires run underground to the consumer's premises. The concrete housing will be placed on the ground or rather, for stability, with its base slightly below ground level. This departure from the present scheme has some very attractive features and may prove cheaper in cost than the present method.

As between the overhead and underground construction generally, it is not expected that the latter will entirely supplant the former. Local conditions in each

Plate No. 4b,—Underground Rural Transmission Lines.
Trench excavated ready for installation of cable.

Plate No. 4c,—Underground Rural Transmission Lines.
One method of re-filling trench after installing underground cable.

individual district will have a great influence in deciding which type of construction should be installed. Under conditions favourable to the installation of the underground method the capital cost will be less than that of the overhead method. This applies to single-phase circuits only, where the lead sheath is used as the grounded conductor of the circuit, in parallel, of course, with the earth itself. The electrical conductivity of the lead sheath is equal to that of a No. 10 B. & S. gauge copper wire.

Excepting under conditions extremely unfavourable to overhead construction the capital cost of 3 cables laid for a 3-phase circuit will exceed the cost of a similar circuit erected on poles. The cost of maintenance and the rate of depreciation should prove decidedly in favour of the underground system.

In general, the cable now in operation has proved satisfactory. Occasional faults have developed and in nearly every case these are found to be due to lack of care in installation. In fairness to the system, it should be stated that the original work was commenced late in the year and continued in haste under winter conditions. Later installations have been made under more favourable conditions without similar trouble developing. Novel methods have been devised for finding faults in the cable and the location and repair is now accomplished quickly and satisfactorily.

There is considerable popular demand for the underground construction. It is less in evidence than the overhead type and therefore more desirable. It avoids the necessity for cutting shade trees and is immune to sleet storms.

Costs of Rural Distribution Lines

The following table shows the cost of one mile of a typical rural wood-pole line with 3-phase circuit, installed complete, including supervision and overhead charges.

Poles and crossarms	$ 384.77
Hardware and guys	30.55
Conductors and insulators	366.55
Labour and tools	464.21
Engineering	62.30
Total cost per mile	$1,308.38

The following table shows the cost of one mile of a typical rural wood-pole line with single-phase circuit, installed complete, including supervision and overhead charges.

*Poles	$ 318.55
Hardware and guys	58.60
Conductors and insulators	208.41
Labour and tools	426.65
Engineering	50.61
Total cost per mile	$1,062.82

The following table shows the cost of one mile of a typical rural underground cable for single-phase circuit, installed complete, including supervision and overhead charges.

Material	$554.88
Labour and tools	208.38
Engineering	36.00
Total cost per mile	$799.26

NOTE: — At each point where service is required, it is necessary to erect a wood pole on which the cable is terminated. The additional cost at each point of service is $47.21.

Having now reviewed the principal features which characterize the work of the commission in constructing its rural distribution lines, reference will be made to some of the principal uses to which the electrical energy is applied.

*The above cost is for that type of construction known as "pole-top pin construction"; no crossarms are used.

A Basis for Estimating Rates

It was not long before the officers of the Hydro-Electric Power Commission found that the representations made in the petitions from rural residents did not always constitute a safe basis upon which to estimate. It was decided, therefore, to establish a minimum business basis of a minimum connected load per mile upon which to determine the estimated rates to those requesting information upon proposed electrical rural service. The basic cost of the electrical energy is the cost at the distribution centre from which it is proposed to extend the rural line.

In many districts it has been found that the early efforts made by those interested result in the securing of an insufficient number of contracts to meet the assumed basis upon which the rates submitted were made; that is, three farm contracts per mile or the equivalent thereof. In such cases it becomes necessary for a representative of the commission to meet the working rural committees and again deal with the various factors involved, and it usually happens as a result of these further educative efforts and the renewed efforts of those interested, that the necessary amount of business is pledged.

The rates quoted in a rural power district are determined upon the same basis as the commission determines the rates for city or town service; namely, *at cost.* The government bonus for the primary lines is taken into due consideration.

The rates may be said to consist of two parts: First, the service charge, which is designed to cover the annual fixed charges and the operating cost of the distribution system in the district; and second, the power charge which is based on the cost of power at the distribution centre from which the rural lines originate; and is in the form of a charge per kilowatt-hour for the first 14 hours use per month of the consumers' class demand rating, and a follow-up kilowatt-hour charge of two cents, a little over one penny. There is a prompt payment discount of 10 per cent on the total bill.

With respect to the feature of diversity in rural power districts or the resale of power, it may be stated that this diversity varies greatly. It has been found where manufacturing plants are located in rural districts, combining with the general rural load, that, under certain conditions, there is effected a complete resale of the power for at least two purposes, and thus a relatively small amount of power purchased is made to serve a fairly large connected load. This diversity factor varies on the "Hydro" rural systems from 3 to 10.

Rural Electrical Service Classification

In order that the commission would be best able to deal with the various rural situations in a discriminating and fair manner, it became necessary to distinguish between different classes of services. A schedule of classification is furnished to prospective electrical rural users and in contracting with their township they are required to choose, with certain limitations, from the classes enumerated as follows:—

CLASS I : *Hamlet Service* — Includes service in hamlets, where four or more customers are served from one transformer. This class excludes farmers and power users. Service is given under three sub-classes as follows:

I-A : Service to residences where the installation does not exceed six lighting outlets or twelve sockets. Use of appliances over 600 watts is not permitted under this class.

Plate No. 5a,—Rural Distribution of Power.

Cable from underground primary circuit taken up pole to transformer and 220/110 volt service wires carried overhead to consumer's premises.

I-B : Service to residences with more than six lighting outlets or twelve sockets, and stores. Use of appliances over 750 watts permanently installed is not permitted under this class.

I-C: Service to residences with electric range or permanently installed appliances greater than 750 watts. Special or unusual loads will be treated specially.

CLASS VIII : *Syndicates* — Any group of customers with individual contracts in any of the foregoing classes may form a syndicate, provided the summation of their respective class demands will warrant permitting this to be done.

The experiences of the commission in rendering rural electrical service extending over a period of years are embodied in the rates and the classification of services above given, and these have proved satisfactory with respect to all applications for service thus far received.

The following table gives the estimated costs in a rural electrical power district of a 25-cycle system with power at

5 cents per kilowatt-hour for the first 14 hours' use per month of the consumers' class demand rating.

2 cents per kilowatt-hour for all remaining uses. With a prompt payment discount of 10 per cent. (Prompt payment meaning that the consumer must pay his bill within 10 days of the time his account is rendered.)

The Results

An appreciation of the magnitude of the commission's rural electrical undertaking may be gathered from a consideration of what was involved in making surveys requested in the petitions received in the year 1920. In this year, there were 68 petitions from townships covering an aggregate area of 2,895,082 acres. In connection with these petitions, personal visits were made

Table No. 1. — Class demand rating, average monthly kilowatt-hours, estimated consumption charge, estimated service charge and total estimated annual net cost for each class of rural consumer

*Converted at £ = $4.40, being current rate of exchange at date of compilation.

CLASS II.-A : *House Lighting* — Includes such contracts as residences which cannot be grouped as in Class I. This class excludes farmers and power users.

CLASS II-B : *House Lighting* — Includes lighting of buildings and power for miscellaneous small equipment and power for single-phase motor not exceeding 2 horse power or electric range (motor and range not to be used simultaneously) on a small farm of 10 acres or less in fruit growing districts and 50 acres or less in mixed farming or dairy districts.

CLASS III: *Light Farm Service* — Includes lighting of farm buildings, power for miscellaneous small equipment, power for single-phase motors, not to exceed 3-horse power demand, or electric range. Range and motors are not to be used simultaneously.

CLASS IV: *Medium Single-Phase Farm Service* — Includes lighting of farm buildings and power for miscellaneous small equipment, power for single-phase motors, up to 5-horse power demand, or electric range. Range and motor are not to be used simultaneously.

CLASS V : *Medium 3-Phase Farm Service* — Includes lighting of farm buildings and power for miscellaneous small equipment, power for 3-phase motors, up to 5-horse power demand, or electric range. Range and motor are not to be used simultaneously.

CLASS VI : *Heavy Farm Service* — Includes lighting of farm buildings and power for miscellaneous small equipment, power for motors up to 5-horse power demand, and electric range, or 10-horse power demand without electric range.

CLASS VII : *Special Farm Service* — Includes lighting of farm buildings, power for miscellaneous small equipment, power for 3-phase motors from 10 to 20-horse power demand, and electric range.

Plate No. 5b,—Rural Distribution of Power.

Service pole with transformers and 3-phases, 220-volts, service wires to consumer's premises. Note wood housing for meter on pole.

to nearly 22,000 farms and about 1,730 industrial power prospects and it was found that it would be possible instead of serving 68 townships to serve 341 townships in the districts then being served with electrical energy by the commission. These covered an aggregate of about 17,366,000 acres out of a total acreage of approximately 22,600,000 acres in the areas considered.

Customers served from rural power lines would, of course, like to obtain their electrical service at the same rates as their friends 'in town'. Obviously, it is impossible to serve only about three electrical consumers per mile at the same rate at which service could be dispensed to hundreds of consumers per mile. Again, in rural districts there is not the diversity in kinds of loads that is found in urban centres, with the result that rates based on service at cost must carry a service charge much higher than the service charge for an urban municipality. With the introduction of electrical rural service the attention of rural residents has been directed to a broader outlook on the whole problem of electrical distribution and the rural citizens are appreciating more fully the basic conditions which govern in electrical distribution under various circumstances. The net result is that the rural consumers have become contented with the results of electrical service to their districts, preferring to appraise such service on its own basis and in terms of the satisfactory returns which are received for their relatively small yearly expenditure for electricity as compared with the cost of doing similar work by the former methods.

As previously pointed out, there has been a substantial reduction in the cost of service in rural districts where it has been possible to add the power load required for manufacturing industries in the district. Individual electric plants driven by internal combustion engines have, for years, had a place in many rural districts. In such instances, the advantages of electric light to rural residences have served to stimulate the desire for other advantages conferred by a fuller use of electrical energy, and usually when a service is proposed to be installed in a rural district by the Hydro-Electric Power Commission the owners of individual electric plants driven by internal combustion engines are the first to sign the contracts for new service. The commission's field men reporting from rural districts have drawn attention to numerous instances where those contemplating an investment in an individual electric plant are delaying such purchase in the hope that service by the commission may be extended to their township. Viewed, therefore, from certain standpoints, the individual plant, instead of being wholly a competitor, has often proved to be a good forerunner for the introduction of rural electric service by the commission.

The first rural distribution lines were built by the commission in 1912 as rural extensions from towns. The building of such extensions was continued until, in 1917, the cost of material and labour for such work, owing to conditions brought about by the great War became prohibitive and consequently little progress was made between 1917 and the beginning of 1921. During this period, however, the commission conducted operations in 81 townships, primary lines being built to the extent of 305.54 miles to serve 7,117 hamlet and suburban contracts and 1,652 farm contracts, a total of 8,769 contracts.

The amendment to the Power Commission Act providing for the bonusing of rural lines, passed in May, 1921, immediately resulted in a pronounced renewal of electrical activities in rural districts. The following brief summary of work carried out by the commission in rural districts between June 1st, 1921 and October 31st, 1923,— the fiscal year of the commission ends on the 31st of October, — is of interest.

Primary line constructed		753.05 miles
To serve hamlet contracts	3,071 miles	
To serve farm contracts	2,170 miles	
Total		5,241 miles
Total rural contracts to date		$ 14,010
Contracts in hand not yet served		2,098
Capital expended prior to June 1st, 1921		$ 517,911.77
Total expended and approved to October 31st, 1923		$12,125,024.12
Bonuses approved on lines built prior to June 1st, 1921		$ 154,651.90
On lines built between June 1st, 1921 and October 31st 1923		467,612.53
Total		$ 622,264.43

During the fiscal year just closed, the commission built 216.69 miles of overhead, and 21.33 miles of underground extensions to serve 1,484 hamlet users and 745 farms, a total of 2,229 customers.

Power Required for Township Users and Systems

It will be interesting to comment upon the amount of power required by rural districts. The aggregate amount of such power is comparatively small. The commission now supplies a total of 3,500 horse power which serves 14,010 consumers of all classes, including many small hamlet consumers.

The commission, from time to time, has collected and analyzed various information respecting the uses of electricity for different kinds of farm work and it is believed that the following tables Nos. II, III, IV, V, VI and VII convey a fair idea of the requirements of electrical energy for different purposes.

Table No. II shows the amount of electrical energy used for lighting and for appliances. The appliances used on each farm are itemized in table No. V.

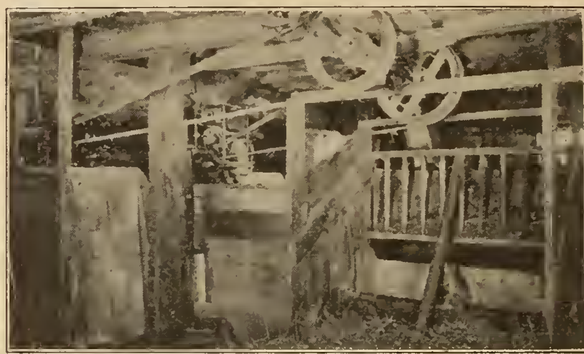
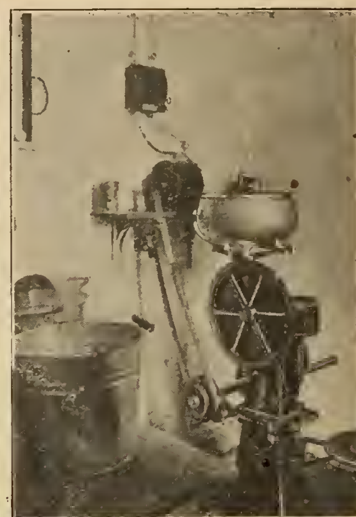
Table No. VII presents the maximum and minimum demands for power for driving the different machines commonly found on Ontario farms. The variation in the amount of power required for electrical appliances is so great that it would take a large amount of space to submit the data in detail. Moreover, such detailed results would not be of special value if for no other reason than that the attention which the average farmer gives his machines is not conducive to obtaining the most efficient results. The commission has devoted considerable attention to the subject of power required for electrical appliances and has used its endeavour to have the various classes of machines as well as the driving equipment reduced to the most efficient types and sizes.





Plates Nos. 6a, 6b, 6c & 6d,—Electrical Power on the Farm

6a,—A 5-horse power motor belted to a line-shaft in the barn. Note starting switch to the left of the motor and chopper in background. The other machinery in this barn is not shown in this picture.

6b,—A one-quarter-horse power motor belted to pump. In the average installation the pump has a capacity of 300 to 500 gallons per hour.

6c,—A one-half-horse power motor driving a cream separator.

6d,—A dairy stable scene showing cows in stations without any divisions and a pressure-vacuum milking machine installation with three units set in place ready for milking.

Toaster..................	....	625
Vacuum cleaner..........	1/8 to 1/4	125
Water pump.............	1/4 to 2	167 to 1,500
Cream separator.........	1/6 to 1/4	167 to 250
Churn — farm size.......	1/8 to 1/2	167 to 375
Milking machine.........	1/4 to 2	188 to 1,500
Ensilage cutting box......	5 to 30	3,750 to 22,000
Thresher................	5 to 20	3,750 to 15,000
Root pulper.............	1 to 3	750 to 2,250
Chopper.................	2 to 20	1,500 to 15,000
Buzz saw................	2 to 10	1,500 to 7,500
Drag saw................	2 to 5	1,500 to 3,750

Power Consumption for Various Operations

Silo-filling..........About ½ ton per kilowatt-hour cut ¾ inch long and elevated 40 feet into silo.
Threshing wheat... 4 bushels per kilowatt-hour.
Threshing oats......6¾ bushels per kilowatt hour.
Chopping grain.....Amount of power taken for this work varies greatly. On farm types of machines it has been found that it takes about 1 kilowatt-hour per 100 pounds.
Rolling oats.........About 1 kilowatt-hour per 100 pounds.
Cutting fodder......2 kilowatt-hours per short ton.

The extensions being made in the main transmission and distribution lines of the municipally-owned hydro-electric undertaking, are constantly opening up new rural territory and present indications are such as to promise for the future an unprecedented extension of rural electrical services. The benefits of such service *at cost* are now being more fully recognized by rural dwellers as a blessing which is revolutionizing domestic and farm labour to an extent never before attained through any other agency. In the broadest sense it is the power of the people being developed by the people for the service of the people.

Appendix

The legislation of the province of Ontario, passed in order to enable the Hydro-Electric Power Commission of Ontario to act in the matter of supplying electrical service to rural consumers, is presented below as an appendix to "Electrical Service for Rural Districts as provided by the Hydro-Electric Power Commission of Ontario".

The sections below quoted are from the legislation appertaining to the work of the Hydro-Electric Power Commission.

The Power Commission Act — Part II

Supply to Individual Users

25. In this Part, *Interpretation.*

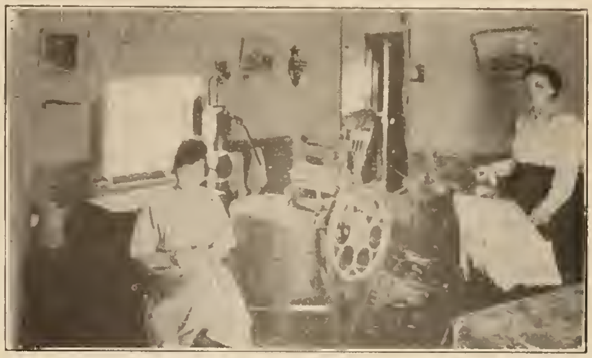
"Corporation" shall mean the corporation of a city, town, township or village municipality. R.S.O. 1914, c. 39, s. 25. *"Corporation."*

26.—(1) Any one or more of the ratepayers in a municipality the corporation of which has not entered into a contract with the Commission under Part I may apply to the corporation requesting it to obtain from the Commission a supply of electrical power or energy for the use of such ratepayer or ratepayers for lighting, heating and power purposes, or for any of such purposes. *Application for supply of power to municipality for use of particular ratepayer.*

(2) The application shall be in writing signed by the applicants and shall state the lots or parts of lots owned or occupied by each of them and the purposes for which the electrical power or energy is required. R.S.O. 1914, c. 39, s. 26. *Form of application*

27.—(1) The Council of the corporation shall thereupon request the Commission to supply the electrical power or energy for the purposes mentioned in the application. *Request for supply.*

(2) Upon such request the Commission shall furnish to the corporation an estimate of the maximum cost per horse-power at which the electrical power or energy will be supplied at the point of development or of its delivery to the Commission, and an estimate of the cost of constructing and providing a transmission line by means of *Estimates, etc., to be furnished by Commission*



Plates Nos. 7a, 7b, 7c & 7d, — Electrical Service in the Farm Home

7a,—Electrical washing machine and iron in the kitchen of an Ontario farm home.

7b,—Kitchen in an Ontario farm house, showing electric stove on which all of the cooking throughout the year is being done. During the past year, hundreds of electric stoves have been installed in Ontario farm homes.

7c,—Kitchen and dining-room in another farm in Ontario, showing washing-machine, electric iron, table grill and electric lighting.

7d,—Kitchen in farm house in Ontario built about 1850 showing on the right, the old fire-place, a part of the original log house.

which the amount of electrical power or energy required is to be supplied and of maintaining the same, and may furnish to the corporation plans and specifications of the work, plant, machinery and appliances necessary for the distribution of such power or energy by the corporation to the applicants, and an estimate of the cost thereof and such other information as the Commission may deem advisable.

By-law authorizing contract with Commission

(3) Within one month after the delivery of the statement and estimates mentioned in the next preceding subsection the council shall, at a special meeting called for that purpose, of which notice shall have been given to each of the applicants, consider the statement and estimates furnished by the Commission, and, with the consent of the applicants or such of them as shall signify their desire to enter into a contract for the supply of electrical power or energy by the Commission, the corporation, without submitting the same to a vote of the electors and without any of the other formalities required in the case of a by-law passed under Part I, may pass a by-law for entering into a contract with the Commission for the supply of the electrical power or energy required by the applicants, and may enter into a contract with the Commission for that purpose.

Debenture issue.

(4) The by-law may provide for the issue of debentures of the corporation, payable within twenty years from the issue thereof, to meet the cost of construction and installation of the works, plant, machinery and appliances necessary for the distribution of the electrical power or energy, and for the levying of a special rate for payment of principal and interest in the manner provided by THE MUNICIPAL ACT. R.S.O. 1914, c. 39, s. 27.

1922, c. 72. Annual payments by corporation

28. All the provisions of Part I, as to the annual payments to be made by corporations which have entered into contracts with the Commission, shall apply to a contract entered into under this Part. R.S.O. 1914, c. 39, s. 28.

Admission of further subscribers

29. The contract may provide for the admission from time to time of further subscribers, or for the making of a contract between the corporation and the Commission under Part I, and the readjustment thereupon of the accounts payable annually to the Commission and of the amounts payable annually by the subscribers in such manner as may be agreed upon or determined by arbitration or otherwise. R.S.O. 1914, c. 39, s. 29.

Amount payable by applicants.

30. The amount payable by the applicants in each year, for the electrical power or energy supplied to them, shall be sufficient to recoup the municipality the amount required to pay the principal and interest of any debentures issued and to meet the annual payments required to be made to the Commission as provided by Part I, and in default of payment any amount due to the corporation under this section may be entered on the collector's roll and collected in the same manner as other taxes. R.S.O. 1914, c. 39, s. 30.

Part II A

Supply of Power for Street Lighting in Townships

Petition of residents in a locality for supply of power for street lighting.

30a.—(1) A majority of the resident freeholders according to the last revised assessment roll, residing within the area described in the petition and situated in the township, may petition the council of the township to take the necessary proceedings to procure from the Commission a supply of electrical power or energy for the purpose of lighting the streets or roads in the locality described in the petition.

Certificate as to sufficiency of signatures.

(2) The petition shall be accompanied by the certificate of the clerk of the township stating that the petition is signed by a majority of the resident freeholders in the locality described in the petition as shown by the last revised assessment roll. 4 Geo. V, c. 16, s. 5, part.

Application by council to the Commission.

30b.—(1) The council of the corporation shall thereupon request the Commission to supply electrical power or energy for the purposes mentioned in the petition.

Estimates etc., of cost to be furnished

(2) Upon such request the Commission shall furnish to the corporation an estimate of the maximum cost per horse power at which the electrical power or energy will be supplied at the point of development or delivery by the Commission, and an estimate of the cost of constructing and providing the transmission lines by means of which the amount of electrical power or energy is to be supplied and of maintaining the same, and may furnish to the corporation plans and specifications of the works, plant, machinery and appliances necessary for the distribution of such power or energy for the purpose of lighting the streets or roads in the locality defined in the petition and an estimate of the cost thereof and such other information as the Commission may deem advisable. 4 Geo. V, c. 16, s. 5, part.

Consideration of the estimates plans, etc., by the council.

30c.—(1) Within one month after the delivery of the statements and estimates mentioned in the next preceding section the council shall at a special meeting called for that purpose, of which notice shall have been given to each of the petitioners, consider the statements and estimates furnished by the Commission.

Withdrawal of petitioners.

(2) If at such meeting the petitioners or any of them desire to withdraw their names from the petition they may do so and should the remaining names be insufficient to constitute a majority of the resident freeholders in the locality described in the petition, no further proceedings shall be taken thereon.

Power of council to pass a by-law authorizing contract.

(3) If at the close of the meeting there are sufficient names remaining of the petitioners to constitute a majority of the resident freeholders in the locality described in the petition, the corporation may, without submitting the same to a vote of the

electors, and without any of the other formalities in the case of a by-law passed under Part I pass a by-law for entering into a contract with the Commission for the supply of electrical power or energy for the purposes required by the petitioners and may enter into a contract with the Commission for that purpose.

Debenture issue. (4) The by-law may provide for the issue of debentures of the corporation payable within twenty years from the issue thereof to meet the cost of construction and installation of the works, plant, machinery and appliances necessary for the distribution of the electrical power or energy, and for the levying of a special rate upon the taxable property within the locality described in the petition for payment of principal and interest in the manner provided by THE MUNICIPAL ACT. *1922, c. 72.*

Special rate of property affected. (5) All moneys required to meet the costs incurred by the corporation under this Part shall be raised, levied and collected by an annual special rate upon the taxable property lying within the locality described in the petition. 4 Geo. V, c. 16, s. 5, part.

Annual payments to the Commission. 30d.—All the provisions of Part I as to the annual payments to be made by corporations which have entered into contracts with the Commission shall apply to the contracts entered into under this Part. 4 Geo. V, c. 16, s. 5, part.

Part II B

Construction and Operation of Distribution Works in Rural Power Districts

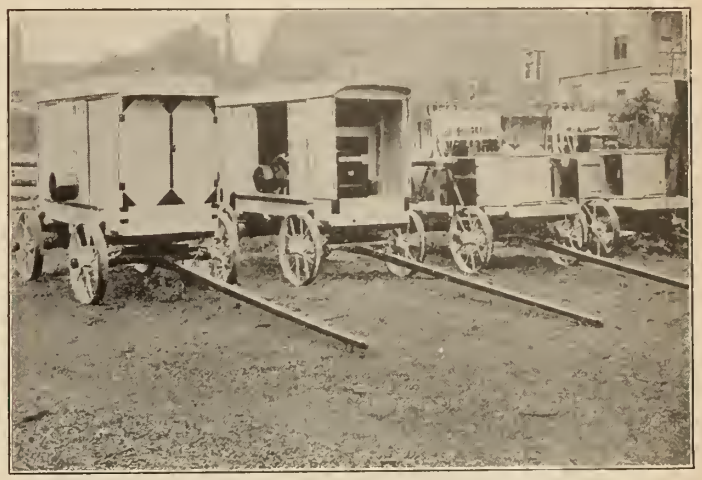
Contracts for construction and operation of distribution works in townships. 30e.—Subject to the approval of the Lieutenant-Governor in Council the Commission may enter into a contract with the municipal corporation of a township, or with the municipal corporations of two or more townships, for the supply or distribution of electrical power or energy in the township or townships, and the Commission may with the approval of the municipal corporation and in pursuance of such contract lay out and define areas hereinafter called "rural power districts" in the township or townships for the distribution of electrical power or energy, and may construct and operate all works necessary for the transmission of electrical power or energy to a rural power district and for the transforming and distributing of such electrical power or energy to the premises of persons within the rural power district, and the Commission may from time to time with the approval of the municipal corporation enlarge, alter or vary the boundaries of any rural power district. 10-11 Geo. V, c. 18, s. 5, part; 12-13 Geo. V, c. 31, s. 4.

By-law. 30f.—The council of the township or the council of each of such townships party to such contract, may pass a by-law for entering into such contract and may execute the same, and it shall not be necessary to submit any such by-law to the vote of the electors or to comply with any of the other forms required in the case of a by-law passed under Part I of this Act. 10-11 Geo. V, c. 18, s. 5, part.

Apportionment of cost on annual adjustment. 30g.—(1) The Commission shall annually fix, adjust and apportion the cost of all the works mentioned in section 30e to be borne by each of the municipal corporations entering into such contract*.

Amount of contributions by townships. (2) The total amount for which each of the corporations shall be liable shall include a sum sufficient to provide annually the corporation's proportionate cost of the capital cost of the work so as to form in thirty years a sinking fund for the payment of the amount expended by the Commission on capital account for the acquisition or construction of the works necessary for transmitting, transforming, distributing and delivering electrical power or energy in a rural power district and a further sum sufficient to pay the Commission interest

NOTE: Section 30e was made retroactive as from the 4th day of June, 1920. 12-13 Geo. V, c. 31, s. 4.



Plates Nos. 8a, and 8b,—Electric Power in Rural Industries

8a,—Two 20-horse power Syndicate Outfits. The motors are mounted in a wagon with the starter. The transformer, secondary cable, primary cable, primary switch and metering equipment are mounted on a second wagon. Syndicates are groups of men who band themselves together for the purpose of owning and operating outfits of this kind for doing the heavier work of threshing and silo-filling. The equipment is moved from farm to farm as required.

8b,—Power plant in a cheese factory. The 7½-horse power steam engine on the left is now superseded by the 5-horse power electric motor on the right.

*See Rural Hydro-Electric Distribution Act.

upon the proportionate part of such expenditure to be borne by the corporation, and a further sum to pay the corporation's proportionate part of the line loss and the costs of operating, maintaining, renewing and insuring of such works and of the other charges set out in section 23. 10-11 Geo. V, c. 18, s. 5, part.

30h. The rates to be charged to customers receiving electrical power or energy from the Commission in a rural power district shall be fixed by the Commission from time to time and shall be sufficient to provide the sum necessary to pay all the charges to be borne by the corporation under section 30g. 10-11 Geo. V, c. 18, s. 5, part. *Rates to be fixed by Commission.*

30i. All the provisions of Part I as to the annual payments to be made by the corporations which have entered into contracts with the Commission shall apply to a contract entered into under this Part. 10-11 Geo. V, c. 18, s. 5, part. *Application of Part I as to annual payments.*

30j. Where any person receiving a supply of electrical power or energy in a rural power district is in default of payment of any account due in respect of such supply, the Commission may notify the corporation of the municipality in which the premises of the person so in default are situate stating the amount due and such amount shall thereupon be entered upon the collectors' roll of the municipality and collected in the same manner as other taxes. 10-11 Geo. V, c. 17, s. 5, part. *Collection of rates in arrears*

The Rural Hydro-Electric Distribution Act, 1921

11 GEORGE V, CHAPTER 21

As amended by 12-13, Geo. V, c. 32

An Act to make more Equal Provision for the Cost of Hydro-Electric Power in Ontario

HIS MAJESTY, by an with the advice and consent of the Legislative Assembly of the Province of Ontario, enacts as follows:—

1. This Act may be cited as THE RURAL HYDRO-ELECTRIC DISTRIBUTION ACT, 1921. 11 Geo. V, c. 21, s. 1. *Short title.*

2. There shall be established a fund to be known as The Hydro-Electric Power Extension Fund, hereinafter called the Fund, and the Treasurer of Ontario shall open in the books of the Province an account to be known as The Hydro-Electric Power Extension Fund Account. 11 Geo. V, c. 21, s. 2. *Fund account.*

3. There shall be placed to the credit of the said fund in such account annually at such time as the Lieutenant-Governor in Council may direct:— *Amounts to be placed annually to credit of fund.*

(a) A sum equivalent to the total amount falling due to the Province from the rentals of water powers since the 1st day of January, 1918, but not including rentals falling due under agreements entered into by the Commissioners of the Queen Victoria Niagara Falls Park for the development of power within the park; *Equivalent of rentals of water powers.*

(b) A sum equivalent to the revenue derived from the rentals payable or collectable under the several agreements between the Commissioners of the Queen Victoria Niagara Falls Park and certain companies developing power in the Queen Victoria Niagara Falls Park after deducting any sums required to meet the charges and payments referred to in sections 21 and 23 of THE QUEEN VICTORIA NIAGARA FALLS PARK ACT; *Equivalent of revenue from rentals re Niagara Falls Park.*

(c) Such additional sums as may from time to time be voted by the Legislature of the Province of Ontario for the purposes hereinafter mentioned. 11 Geo. V, c. 21; s. 3. *Additional sums voted.*

4. Where power is supplied to a rural power district under the provisions of THE POWER COMMISSION ACT and amendments thereto*, there may be paid† to the municipality or commission distributing the power in such rural power district upon the recommendation of The Hydro-Electric Power Commission of Ontario and the order of the Lieutenant-Governor in Council, a sum not exceeding fifty per cent of the capital cost of constructing and erecting in the rural power zone primary transmission lines and cables required for the delivery of power in such rural power district. 11 Geo. V, c. 21, s. 4. *Where power supplied to rural power districts.*

4a. Where the corporation of a town or of an urban municipality supplies or distributes electrical power or energy within any such rural power district there may be paid† to such corporation upon the recommendation of the Hydro-Electric Power Commission of Ontario, and the order of the Lieutenant-Governor in Council a sum not exceeding fifty per cent of the capital cost of constructing and erecting in the rural power district primary transmission lines and cables required for the delivery of power or energy in such rural power district. *Payment of grant where municipality is distributor of power.*

5. The grant made under this Act shall be payable out of the Consolidated Revenue Fund, and the sums required to be credited to the Fund shall be chargeable to the Consolidated Revenue Fund, and every grant of money made under this Act shall be debited to the Fund in the said account and the said account shall be so kept that at all times it shall show the amounts properly credited to the Fund as provided by section 3 and all amounts chargeable thereto. 11 Geo. V, c. 21, s. 5. *Grant, how payable.*

6. The Lieutenant-Governor in Council may make regulations for the better carrying out of the provisions of this Act. 11 Geo. V, c. 21, s. 6. *Regulations.*

7. This Act shall come into force on the 1st day of June, 1921. 11 Geo. V, c. 21, s. 7. *Commencement of Act.*

---

*S. 30 (e).

†Payments and allowances authorized by sections 4 and 4a may be made in respect of works constructed before or since the 1st day of June, 1921. 12-13 Geo. V, c. 32, s. 3.

The Utilization of Power in the Pulp and Paper Industry

R. W. Leeper,
Power Engineer, H. S. Taylor, Consulting Engineer, Montreal, Que.

In the production of pulp and paper an adequate supply of power is almost equal in importance to that of raw materials. The importance of any item entering into a manufacturing or conversion operation can usually be measured by the quantity required per dollar of product. In this respect, the use of power in the paper industry ranks among the highest and is possibly not exceeded in any industry, except those of aluminum or steel.

For brevity, the term "pulp and paper mills" will be used to include pulp mills, pulp and paper mills, and paper or conversion mills.

In Canada, the bulk of the paper produced is newsprint, which consists of approximately 80 per cent mechanical pulp or groundwood, which gives to the sheet its ability to absorb quickly the ink when run through a modern high speed printing press, and 20 per cent chemical or sulphite pulp, which is necessary for the requisite strength. (See plate No. 1.)

Mechanical pulp requires for its production about 75 h.p., per daily ton of 2,000 pounds, chemical pulp about 22 h.p. The actual conversion or paper making process adds from 15 to 25 h.p., so that for a mill for the manufacture of newsprint, complete within itself, from 90 to 100 h.p., per daily ton are average figures for power consumption. (See plate No. 1.)

The cost of power for the pulp and paper industry in Canada varies quite widely according to locality and conditions. A large proportion of the power used is purchased from water power companies, this having the advantage of relieving the manufacturer of large capital expenditure for generating plant, and such purchased power varies under existing contracts from $15. to $25. per horsepower-year. On the other hand, many large manufacturers locate on water power sites and generate their own power and since this eliminates both profit and transmission the cost may be considerably below even $15. In the average 100 ton complete newsprint unit, these power costs of $15. to $25. per horsepower-year represent about $5.00 to $8.35 per ton of product.

Turning to power plants using coal or oil fuel, it has been found by averaging the results secured in several representative plants that the cost per horsepower-year is about $75., the greater cost in comparison with hydro-power being due to fuel and increased labour charges. There are, of course, a few plants using wood refuse under the boilers in which the steam so generated can be used for power purposes. Such mills are, however, limited as to number and capacity.

It is indicated by the foregoing that the relationship of the cost of power to the selling price of paper renders essential an ample supply of cheap power and the industry, therefore, has been in the past, and undoubtedly will be in the future, dependent upon hydraulic energy either directly applied through water wheels to the equipment to be driven or through the medium of electricity.

The Dominion is particularly fortunate in having in close proximity to areas covered with wood suitable for pulp or paper making, large water powers, the greater portion being as yet partially or entirely undeveloped. (See plate No. 2 and plate No. 3.) According to the most reliable estimates available the developed power used in the paper industry is but about 2 per cent of the commercial power remaining to be developed, and in the future this undeveloped power will certainly play a most important part, not only in the development of this essential industry, but of Canada as well. (See table No.1.)

A Large Canadian Pulp and Paper Mill with Hydro-electric Installation.

Table No. 1, — Water Power by Provinces

Province	Available h.p. at ordinary Minimum flow (Estimated)	Used h.p. (By paper mills)
Quebec	6,915,244	368,352
Ontario	4,950,300	271,174
British Columbia	1,931,142	55,140
New Brunswick	50,406	14,378
Nova Scotia	120,751	17,331
Prairie Provinces	4,259,253	....
Totals	18,127,096	726,375

of which the power used is divided as follows:

Hydro-electric purchased	228,755 h.p.
Hydro-electric produced by mill	210,053 "
Direct mechanical drive	287,567 "

The growth of the paper industry in Canada may be considered phenomenal. Since 1908, the first year for which records are available, to and including 1922, the yearly production of pulp, (both groundwood and chemical), has increased approximately six times, to a grand total for 1922 of 2,150,251 short tons. During the same period the groundwood production has increased about 4½ times. The power consumption has of a necessity increased in about the same proportion, which represents an approximate increase of 100 per cent every seven years. (See tables Nos. 2 and 3.)

Kraft	77,292	55,898	81,793	

At present about 40 per cent of the hydraulic energy is supplied through the medium of direct connected water wheels, together with some form of mechanical drive consisting of a system of line shafting, gears and belts. This is not only inefficient but objectionable for various reasons. The mill must be located at the power site even though entirely unsuited from a manufacturing standpoint; the mill buildings must be arranged with reference to power supply; the capacity of the unit is limited to the power available.

As electrical equipment was developed suitable for the service demanded, motors superseded the direct connected water wheel drive in nearly all of the newer developments, until to-day electrical energy, either generated by the mill or purchased, supplies about 60 per cent of the total power consumed. (See table No. 1.)

The advantages of electric drive in a paper mill are many; the mill may be located at the most advantageous point from a manufacturing and shipping standpoint; the equipment is driven at a more uniform speed, which means a better product and increased production; the size of the unit is not limited to the power available from one source. The mill can be designed to comply strictly with manufacturing conditions. To-day electricity possesses so many advantages, that except under the most favourable conditions, it is universally admitted that the power should be developed electrically and applied through the medium of motor drive in the mill.

Electricity in the form of power first became a factor in the pulp and paper industry on this continent about 1900 — and during subsequent years the growth has been remarkable. From the first major installation of less than one thousand kilowatts capacity, the demand of the individual mill has increased until at present there are several installations of approximately ten thousand kilowatts capacity, and a few still larger, the average capacity being far in excess of the first important development. This advancement can be attributed principally to the two following reasons:—

First: Power could be electrically distributed and applied throughout the mill with greatly increased economy over former methods.

Second: The development of electrical equipment suitable for the service.

In the manufacture of pulp and paper as in other commodities, there is an insistent demand for increased production per unit, which has led to three new developments of exceptional interest, that in a very few years have become essential to the industry, and which are large consumers of electricity in the form of power; the magazine pulp grinder, the sectionalized individual paper machine drive, and the electric boiler.

The first wood pulp grinder was patented in 1847, and about 1852 the first practical grinder was built. About 1910 the first magazine grinder was built, and in 1913 it was introduced on this continent. The production of the first grinder was about ½ ton per 24 hours, that of the most modern type of magazine grinder 22 tons, the average production per stone of the hydraulically operated pocket grinder being from 7 to 8 tons. The development of the magazine grinder, therefore, marked a distinct step forward in production. It may be added, however, that the horse power per ton is practically the

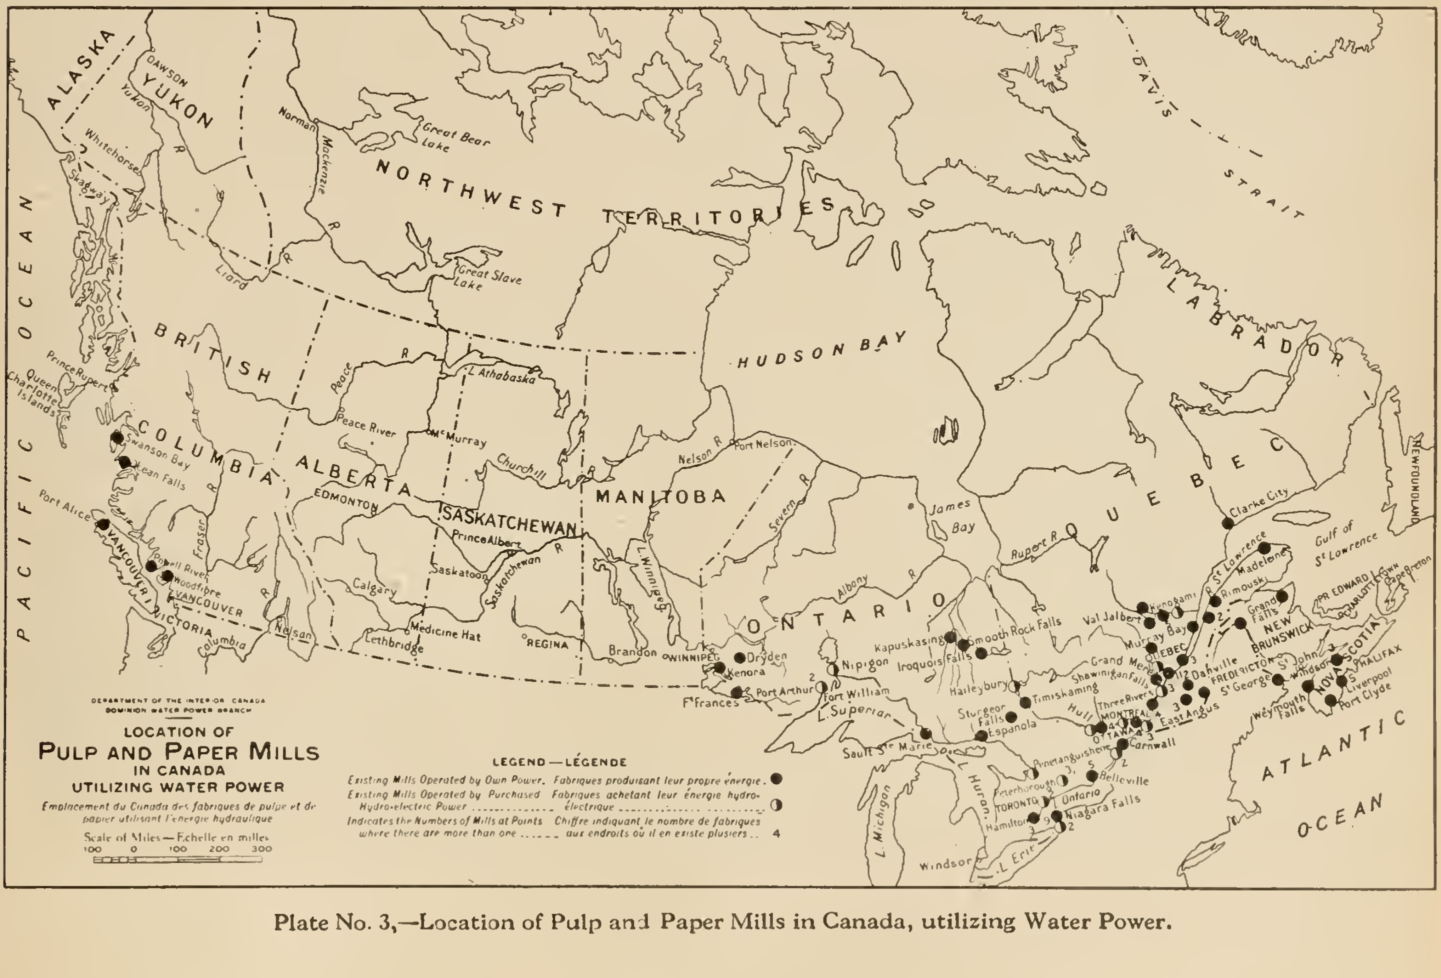

Plate No. 3,—Location of Pulp and Paper Mills in Canada, utilizing Water Power.

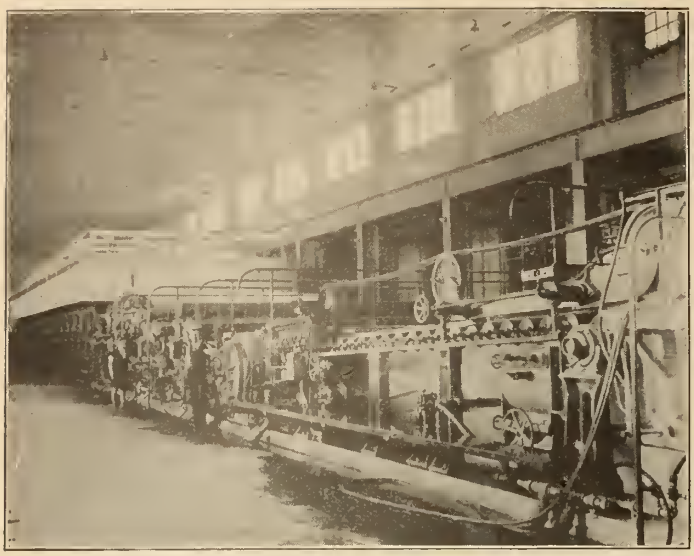

Plate No. 4,—Magazine Grinders

same for either the pocket or magazine type of grinder for the same grade of pulp, the power consumption per stone for the former being about 500 h.p., as compared to 1,400 h.p. for the latter.

In the earlier mills grinders were almost universally driven by direct connection to water wheels, and while this arrangement is unquestionably efficient, its disadvantages more than offset the saving from either an efficiency or initial cost standpoint. In the more modern mills, motors have generally been used, due in so small part to the development of synchronous motors of high rating, suitable for the service to be performed. (Plate No. 4, — Magazine Grinders.)

Before the advent of the sectionalized motor drive for paper machines, the demand was for higher and still higher machine speeds, increased production and lower operating costs. With this demand the problem of maintenance and successful operation of the variable speed drive became more and more serious until the limits of the types in use were reached. For years electrical manufacturers had been experimenting with various schemes by which it was proposed to drive each section of a paper machine with an individual motor. The problem was exceedingly difficult on account of the close regulation required between sections, often over a wide range in speed. It can now be said that the problem is solved as there are to-day in successful operation three different types of sectional individual drives. With this development there is in sight no practical limit to the speed at which a machine can be operated in so far as the drive is concerned. (Plate No. 5, — Sectionalized Individual Paper Machine Drive.)

In the pulp and paper mill steam is required in fairly large quantities, for cooking, drying and heating. The manufacture of chemical pulp requires about 8,000 pounds of steam per ton, the drying process at least 3 pounds per pound of paper produced, heating a varying amount depending upon climatic conditions, but averaging for many mills from one to two pounds per pound of paper made during heating season. A boiler plant is therefore an essential part of each installation. There is generally a certain amount of refuse, possessing a limited heating value, but in addition, to produce the required amount of steam, many tons of coal or barrels of oil must be burned.

To meet this demand for steam, where considerable quantities of surplus and off-peak hydro-electric energy are available, an electric boiler has been developed within the last few years and units totalling over 150,000 h.p., have been placed in operation in Canada, in addition to a considerable number in the United States.

The normal development of hydro-electric plants is such that almost all the total cost of development such as dams, excavations, power house sub-structure, have to be constructed initially, the only varying quantities being the number of wheels and generating units together with their switchboards, etc., which can be installed from time to time as the demand for power warrants their completion.

Where there is a power market such as these steam boilers, which have a low capital cost and can be used together with fuel-fed boilers, it frequently is possible to complete more of the power house than is warranted by existing demand, under an arrangement by which as the industrial power load grows, the power supply to these electric boilers can be reduced. There is again surplus power available on Sundays which can be very readily used on these boilers, and also some seasonal fluctuations in some of the rivers which can be turned into steam.

As one pound of coal is roughly equal to 3 k.w.hrs. from the heating point of view, it is evident that with coal at $10.00 a short ton, electricity must be available at ⅓ of a cent per k.w.hr.

The electrical boiler, however, can be installed at less cost than either an oil or coal fired plant, the attendance and repair items are less, and it can be used where power otherwise wasted is available. With the development of water powers in Canada especially for paper mills, or where it will be mainly used by them, the amount used for steam generation will unquestionably increase. These boilers are described and illustrated in the section of the symposium on utilization of power devoted to electro chemical and metallurgical uses of power.

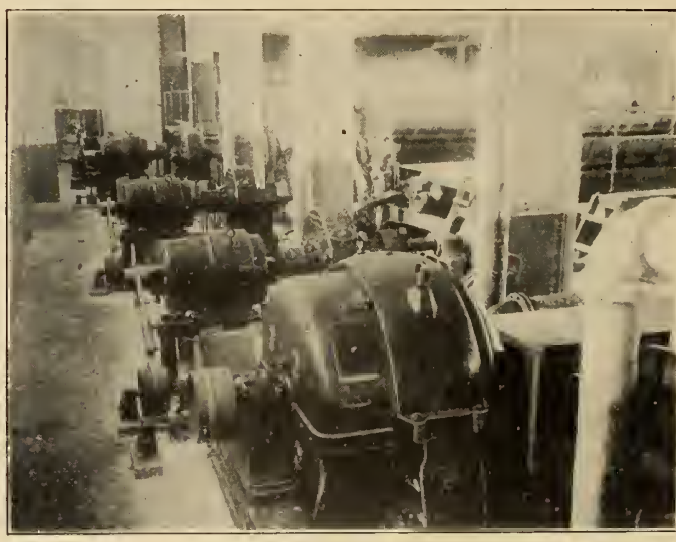

Plate No. 5, — Sectionalized individual Paper Machine Drive.

The Use of Power in the Mineral Industries of Canada

H. E. M. Kensit, M.E.I.C., M.A.I.E.E.
Dominion Water Power Branch, Department of the Interior, Ottawa

Before discussing the use of power in the mineral industries of Canada it is desirable to review briefly the size, nature and distribution of those industries.

The "mineral industries" must be taken to include all branches of mineral production, first because statistics on this subject, while including some processes of a manufacturing nature, are kept separate from those included in the general "Census of Manufactures", and second because it is impossible in many cases to differentiate between "mining" and "metallurgy". For instance, the concentrating, amalgamating and cyaniding of gold ores, the reduction of copper and nickel ores and the amalgamation of placer gold are so intimately connected with the production of the ore in a state for shipment that no distinct division for statistical purposes can be made.

Principal Divisions of the Industry

There are 60 principal items included in the three main divisions of the mineral production of Canada, i.e., metallic 17, non-metallic 27, structural materials and clay products 16. Seventeen of the 60 items had in 1923 a production value of $1,000,000 each or over and these in order of value are:—

1. Coal
2. Gold
3. Nickel
4. Portland cement
5. Copper
6. Silver
7. Clay products
8. Lead
9. Asbestos
10. Natural gas
11. Stone
12. Zinc
13. Lime
14. Cobalt
15. Sand and gravel
16. Gypsum
17. Salt

Size of the Industry

It is not possible to summarize briefly the amount or quantity of output on account of the different measures employed for different products, such as tons, gallons, barrels, bushels, cubic feet, etc. The value of output has been subject to fluctuations due to conditions succeeding the war but may be fairly represented by the average of the 5 years 1919 to 1923. The size of the industry and its distribution by provinces is summarized in the following tables:—

Table No. 1, — Annual Mineral Production of Canada

Year	Value of production	Value per capita
1910	$106,824,000	$14.93
1911	103,221,000	14.32
1912	135,048,000	18.33
1913	145,635,000	19.35
1914	128,863,000	16.75
1915	137,109,000	17.44
1916	177,202,000	22.05
1917	189,647,000	23.18
1918	211,302,000	25.37
1919	176,686,000	20.84
1920	227,860,000	26.40
1921	171,923,000	19.56
1922	184,297,000	20.57
1923	214,020,000	23.40
Increase per cent	100%	57%
Average value for last 5 years	$194,957,000	$22.15

Plate No. 1,—Hydro-Electric Development of Granby Consolidated Mining, Smelting and Power Company at Anyox, British Columbia, 13,400 horse power.

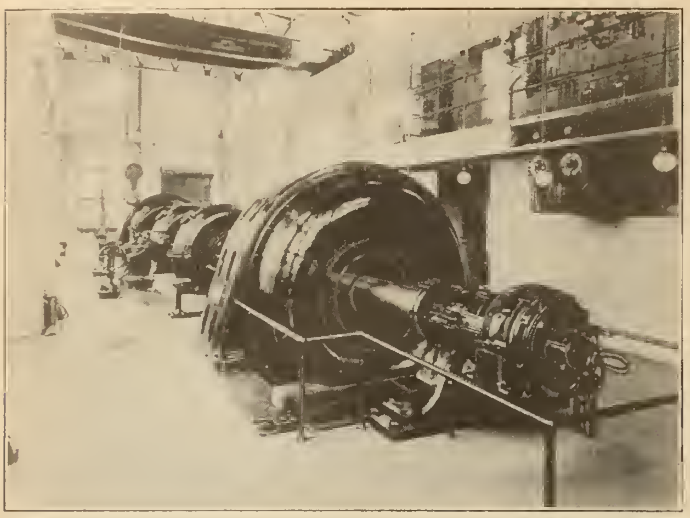

Plate No. 2,—Hydro-Electric Installation of Canadian Collieries (Dunsmuir) Limited on the Puntledge River, British Columbia, 12,000 horse power.

It will be observed that the value of production, since the first reaction in 1921 after the war, has recovered to nearly the peak of the war-period value. Concerning this the Dominion Bureau of Statistics states that:—

"Commodity prices, which reached a peak in 1920, have since receded and this fact must be borne in mind when production is computed in terms of values. A weighted index showing the volume of production would undoubtedly mark 1923 as the banner year in Canada's mineral industry. New output records were established for coal, lead, zinc, asbestos and the value of cobalt."

The value of production by provinces for 1923 stands thus:—

Table No. 2, — Annual Mineral Production by Provinces

Province	Value of production 1923	Per cent of total	Largest items 1921
British Columbia	$ 44,143,000	20.6	Coal, copper, lead.
Yukon	2,642,000	1.2	Gold, silver, lead.
Alberta	31,647,000	14.8	Coal, natural gas, clay products.
Saskatchewan	1,350,000	0.6	Coal, clay products.
Manitoba	1,754,000	0.8	Gypsum, clay products, lime.
Ontario	79,917,000	37.4	Gold, nickel, silver.
Quebec	19,827,000	9.3	Asbestos, cement, clay products.
New Brunswick	2,206,000	1.0	Coal, gypsum, lime.
Nova Scotia	30,534,000	14.3	Coal, gypsum, stone.
	$214,020,000	100.0	

Table No. 3, — Mineral Production by Classes, 1923

Metallic	$ 84,188,000	39.3%
Coal	73,504,000	34.4%
Non-metallic other than coal	19,335,000	9.0%
Structural materials and clay products	36,993,000	17.3%
	$214,020,000	100.0%

Capital Invested

The total capital invested in the mineral industries at the present time is estimated to be not less than $800,000,000, divided as to the source of capital approximately thus:—

		Per cent
Canada	$446,000,000	55.8
United Kingdom	100,000,000	12.5
United States	220,000,000	27.5
Other countries	34,000,000	4.2
	$800,000,000	100.0

Power Used in the Mineral Industry

The following table shows the horse power used in the principal divisions of the industry and the power of each kind in each division, as at January 1st, 1924:—

Table No. 4, — Total Power Used

	Fuel power	Water Power		Total power	Per cent
		Generated	Purchased		
Metallic mining	32,700	26,000	111,700	170,400	33.2
Coal mining	160,900	15,300	15,000	191,200	37.2
Non-metallic	29,500	1,100	62,200	92,800	18.1
Structural materials and clay products	12,800	2,000	44,300	59,100	11.5
Totals	235,900	44,400	233,200	513,500	100.0

The relation of primary power installed at the mines, quarries, etc., and purchased power, may be shown thus:—

Installed Power and Purchased Power

			Per cent
Primary power installed:			
Fuel power	235,900 h.p.		
Water power	44,400 h.p.		
		280,300 h.p.	54.6
Purchased power (all water power)		233,200 h.p.	45.4
		513,500 h.p.	100.0

Proportions of Water and Fuel Power

	H.P.	Per cent
Water power	277,600	54
Fuel power	235,900	46
	513,500	100

Proportion of Fuel Power

	Per cent
Steam	96.3
Gas	2.0
Oil	1.7
	100.0

The total power used in the industry is over 500,000 h.p. and 54 per cent of this is water power.

Examples of Power Supply

Table No. 5 gives examples of power supply to some of the mines requiring over 1,000 h.p. The intention is to illustrate the blocks of power used but the table by no means includes all the companies that could be listed.

The Principal Mineral Industries

Canada contains 16 per cent of the world's known coal reserves, is the third largest gold producer and has the greatest asbestos, nickel and cobalt deposits in the world. All the provinces except Prince Edward Island have large mineral resources and it is an outstanding factor that in all the mineral-bearing areas, except in parts of the coal fields, there is ample water power available for their development.

Below are given brief details of some of the principal mining industries. A tabulation is given in each case from which can be seen the minerals mined in each province and the production. To this has been added particulars of exports and imports to indicate how production compares with home requirements and particulars, where possible, of the capital invested and power used.

Asbestos

The production is entirely in Quebec but during the year a test shipment was made from a newly developed deposit in Deloro township, Ontario. The total produc-

Table No. 5, — Examples of Power Supply to Mines Requiring over 1,000 h.p.

(Those not otherwise specified are water power)

Coal	Nova Scotia Steel & Coal Co., (*steam power*)	Nova Scotia Steel & Coal Co	5,280

tion in 1923 was 233,000 tons, a value of $7,500,000 at the mill. Exports were worth nearly $9,000,000 and imports $700,000.

The asbestos mines occur in the Eastern Townships of Quebec, south of the St. Lawrence and employ approximately 15,000 h.p.

Coal

The production of coal in 1923 was:—

Province	Production		Value
	Quantity—Tons	Per cent	
Alberta	6,848,000	40.4	$28,279,000
Nova Scotia	6,596,000	38.8	29,153,000
British Columbia	2,823,000	16.6	14,088,000
Saskatchewan	440,000	2.6	919,000
New Brunswick	277,000	1.6	1,065,000
	16,984,000	100.0	$73,504,000

The production was slightly in excess of the previous record in 1920. The exports were 1,654,000 tons, — the imports 22,687,000 tons or 57 per cent of the total consumption. Yukon produces a few hundred tons per annum. The capital employed in 1921 was $174,000,000. The power employed in the industry is over 190,000 h.p.

The Use of Water Power for Coal Mining

It would at first sight appear that coal mines are not a very favorable field for the use of water power since they have available for power production the inferior and waste coal that would otherwise go on the dump. The coal required for power may however run to as much as 10 per cent of the total output and the

Plate No. 3,—Hydro-Electric Power Station and Concentrating Mill of Britannia Mining and Smelting Company, Limited, Britannia Beach, British Columbia, 15,000 horse power.

Plate No. 4,—Hydro-Electric Development of International Nickel Company of Canada, Limited, at High Falls on the Spanish River, Ontario, 13,800 horse power.

advantages claimed for purchased power include reduction of fixed charges on the investment; reduction on costs of labour, superintendence, repairs and maintenance; increased flexibility of the energy supply, fixed power costs under long term contracts and additional coal made available for sale.

The following are examples of the application of water power to coal mining in Canada:—

Canadian (Dunsmuir) Limited collieries in Vancouver Island, have been entirely operated by hydro-electric power during the past eight years and no coal is now used except for shunting locomotives. Two 6,000-h.p. water turbines are installed and there are 35 miles of transmission lines to operate the various collieries of the company. The power plant accounts are kept separately and the mines are charged one cent per k.w.hr. Previous to electrification 10 per cent of the output of coal was used to produce power; this portion was valued at $2.00 per ton and required 42 firemen. The cost for coal and labour alone was $10,000. per month, the present cost with water power, including maintenance, is under $2,000. per month.

The East Kootenay Power Company of British Columbia supplies hydro-electric power to all the coal mines operating in its district, the Hillcrest Collieries, the Crow's Nest Pass Coal Company, the International Coal and Coke Company, the Corbin Coal and Coke Company, McGillivray Creek Coal and Coke Company and the Western Canadian Collieries.

Copper

Copper has been produced in Quebec, Ontario, Manitoba, British Columbia and Yukon. Quebec produced 2,692,000 pounds in 1919 but this fell to 352,000 in 1921 and none since; Manitoba produced 3,348,000 pounds in 1919, somewhat less in 1920 and none since; Yukon produced 278,000 pounds in 1920 and none since.

In 1923 the production was:—

	Pounds	Value
British Columbia	56,360,000	$ 8,128,000
Ontario	31,582,000	4,554,000
	87,942,000	$12,682,000

this being about double the total output for Canada for the preceding year.

In addition to Canadian production, over $8,000,000 worth was imported. Recent tariff changes provide for a bounty of 1½ cents per pound on copper bars and rods produced in Canada.

As copper and nickel are in some cases produced from the same ore the industries are intimately interwoven. In 1921, the latest year for which complete statistics are available, the total capital employed was $45,000,000.

Amongst the large power users in British Columbia are the Britannia Mining and Smelting Company, using about 25,000 h.p., the Granby Mining, Smelting and Power Company, 13,000 h.p., and in Ontario the Mond Nickel Company, producing nickel-copper ore, some 10,000 h.p.

Gold

The production of gold in 1923 was:—

Province	Production		Value
	Quantity—Oz.	Per cent	
Ontario	971,340	79.38	$20,079,320
British Columbia	191,180	15.63	3,952,040
Yukon	60,020	4.90	1,240,800
Quebec	630	0.05	13,100
Manitoba	30	0.01	620
Nova Scotia	400	0.03	8,190
	1,223,600	100.0	$25,294,070

The exports were worth nearly $4,000,000 and the imports $47,000. The production was slightly less than in 1922 but this was due to a shortage of power in northern Ontario, now remedied. It is stated that promising discoveries have been made in Quebec adjacent to the gold districts of Ontario and that it is quite probable that Quebec will soon become an important producer.

Some notes on power consumption for gold and silver mining are given under the head of "silver".

Lead

The production in 1923 was:—

Province	Production		Value
	Quantity—Lbs.	Per cent	
Quebec	520,000	0.5	$ 37,000
Ontario	4,559,000	4.1	327,000
British Columbia	99,473,000	89.8	7,141,000
Yukon	6,178,000	5.6	444,000
	110,730,000	100.0	$7,949,000

There were 55,000,000 pounds exported and about 3,500,000 pounds imported. The production was 19 per cent above that of the previous year.

Nickel

The production in 1923 was 62,454,000 pounds valued at $18,322,000, three times as much as in the preceding year. The exports were 51,869,000 pounds valued at $8,726,000; none was imported.

About 85 per cent of the world's nickel supply is mined in the Sudbury district, Ontario, by the following companies:—

The International Nickel Company of Canada Limited. The company has been established twenty years and has two hydro-electric plants totalling 21,300 h.p. to operate its mines and smelter at Copper Cliff, about 27 per cent being used for mining and 63 per cent for smelting. The refinery is at Port Colborne and uses a smelting process requiring about 1,500 h.p., but considerable quantities of matte are exported to Virginia to be made into Monel metal. All the refined nickel produced by this company is now made in Canada, its plant in New Jersey being dismantled.

The Mond Nickel Company, Coniston. Established twenty years. This company controls the Lorne Power Company which has two hydro-electric plants with 9,600 h.p., and supplies the Mond Company with power in bulk for mining and smelting. The company has five mining and reduction plants and the matte is all shipped to Wales.

The British America Nickel Corporation. This company has been established four years and its mines and smelter require 6,000 h.p. The company operates its own steam plant with coal but it expects to replace most, if not all of this, with water power in the near future. The refinery, at Deschênes, Que., is operated by an electrolytic process and power is obtained in bulk from the Ottawa and Hull Power and Manufacturing Company; 7,000 h.p., is contracted for and 5,000 h.p., is being used.

Silver

The production of silver in 1923 was:—

Province	Production		Value
	Quantity—Oz.	Per cent	
Quebec (in ores exported)..	29,563	—	$ 19,178
Ontario..................	10,285,247	58	6,672,348
Manitoba and Nova Scotia.	19	—	12
British Columbia..........	5,964,095	34	3,869,087
Yukon (in placer gold and in ores exported)...........	1,475,782	8	957,383
	17,754,706	100	11,518,008

There were 17,000,000 ounces exported and approximately 1,540 ounces imported. The production was about the same as for the preceding year.

Amongst the large power users for silver and gold mining are the Surf Inlet Power Company, B.C., 1,200 h.p.; the Bradford Mines Limited, N.S., 1,600 h.p.; the Great Northern Power Company, 4,000 h.p.; the Associated Gold Fields Limited, Ont., 2,000 h.p.; the Yukon Gold Company, 3,180 h.p.; the Northern Ontario Light and Power Company supply over 16,000 h.p., to various companies, the Northern Canada Power Company over 19,800 h.p., and the Canadian Klondyke Company nearly 10,000 h.p.

Zinc

The production in 1923 was:—

Province	Production		Value
	Quantity—Lbs.	Per cent	
British Columbia..........	60,050,000	99	$ 3,989,000
Quebec....................	318,000	1	....
	60,368,000	100	$ 3,989,000

There was $2,500,000 worth exported and $500,000 imported. The production exceeded that of the previous year by 7 per cent in quantity and 24 per cent in value. Nearly the whole production was from British Columbia and concerning this the Dominion Bureau of Statistics states that:—

"During the year the new concentrator of the Consolidated Mining and Smelting Company at Kimberley, B.C., was completed and put in operation. The solution of the metallurgical problems involved in the treatment of the complex ores of the Sullivan mine by the staff of this company has been a truly wonderful achievement and it may be said that, due entirely to their efforts, an enormous tonnage of a mineral aggregate with doubtful value has become a great Canadian natural resource."

Plate No. 5,—Hydro-Electric Development of Mond Nickel Company at Nairn Falls on the Spanish River, Ontario, 4,800 horse power.

The Importance of Water Power in the Mining Industry of Canada

Canada may be divided into five main mineral areas, *I* the Maritime Provinces; *II* Quebec; *III* Ontario; *IV* the Prairie Provinces, and *V* British Columbia and the Yukon; and in each of these the influence of the abundant supplies of hydraulic energy advantageously situated, is making itself felt. This is particularly the case in the provinces of Ontario and Quebec, which, being situated in the acute fuel area of Canada, would be almost entirely dependent upon imported coal were it not for hydraulic power. In many cases large-scale operation, which alone marked the difference between profit and loss, would be impossible without the hydraulic energy furnished at relatively low cost to the various mining fields. Many mines on account of their geographical location would find the cost of rail haul on coal or untreated ore prohibitive, but with hydraulic power profitable operation has been possible. Even that phase of super-economy, the generation of electricity from fuel at the pit head, has been abandoned by one coal mining company in favour of hydro-electric energy which has to be transmitted over 20 miles from the generating station; while a considerable number of others have made contracts with central stations for supplies of hydro-electric power.

From estimates made by the Dominion Water Power Branch, Department of the Interior, Ottawa, it is computed that at January 1st, 1924, the hydraulic installation for mining purposes in Canada had reached a total of 277,600 h.p., of which 44,400 h.p. is installed by the mines themselves, and 233,200 h.p. is purchased from central electric stations. A conservative estimate of the capital investment necessary to develop this power is $74,000,000.

Maritime Provinces

Based upon value of product, approximately 90 per cent of the mining carried on in the Maritime Provinces is for the recovery of coal and water power has not yet been utilized for this purpose. In Nova Scotia, however, there are three hydro-electric developments operated by gold mining companies, their installation being 1,600 h.p., 425 h.p. and 30 h.p. respectively.

Quebec

The mineral output of the province of Quebec at the present time is mainly non-metallic, the leading asbestos mines of the world being found in the south-eastern portion of the province. The Shawinigan Water and Power Company supply most of the power used in this field, transmitting it across the St. Lawrence near Three Rivers. Power is also furnished to this field by the St. Francis Water Power Company and the Southern Canada Power Company supply a comparatively small amount of power for copper mining.

Within the last two years prospecting for gold has been actively carried on in Rouyn and adjoining town-ships in Timiskaming county, northwestern Quebec. Important discoveries have been made and large areas staked. Power for the development of this field can be obtained from the numerous rapids and falls of the Quinze and upper Ottawa rivers.

Ontario

Ontario ranks first among the provinces in diversity and value of mineral production and, being situated in the acute fuel area, great advantage to the industry has been derived from the abundant supplies of hydraulic and hydro-electric energy which are available to every field.

The major hydraulic developments for mining are, of course, located in the gold, silver and nickel areas of northern Ontario, where over 107,000 h.p. are installed for this purpose; while several large additional installations are under construction or in contemplation, much of which will be in place by the end of 1924, probably terminating the power shortage which has hampered production in the past. Chief of these new plants will be the 24,000-h.p. station of the Hollinger Consolidated Gold Mines, Ltd., on the Abitibi river, while power will also be available over the recently constructed transmission line of the Northern Canada Power Company from their new 20,000-h.p. station under construction on Quinze river in western Quebec.

Representative companies generating and distributing hydraulic power for mining in northern Ontario are the International Nickel Company with 21,300 h.p. installed in two stations on the Spanish river; the Northern Ontario Light and Power Company with 20,420 h.p. in four hydro-electric stations; and 5,500 h.p. in a hydro-compressed air station in the Cobalt district; the Northern Canada Power Company with two stations totalling 19,800 h.p. near Timmins, while a subsidiary of the latter company has recently installed 4,000 h.p.; the Great Northern Power Company with 4,000 h.p.; the Mond Nickel Company, (Lorne Power Company), with 9,600 h.p. with a prospective addition of 2,750 h.p. in 1924; and the Wanapetei Power Company with 9,900 h.p. There are also a considerable number of smaller organizations distributing power in this area.

In the southern portion of the province mineral production is limited to non-metallics and here the demand for power is met by the extensive transmission systems of the Hydro-Electric Power Commission of Ontario.

The Prairie Provinces

The Prairie Provinces are Manitoba, Saskatchewan and Alberta. Manitoba possesses a comparatively small field of lignite coal. Saskatchewan possesses some 66,000 million tons of lignite and ranks third among the provinces of the Dominion in coal resources; Alberta has anthracite, bituminous and lignite coals, constituting 88 per cent of the total coal resources of the country. No metallic deposits of value had been found in Manitoba and Saskatchewan until comparatively recently when gold was discovered in the northern portions. Even more important than the gold finds have been the copper-zinc sulphide deposits at Flin-Flon and Schist lakes. Hydro-electric power for both these fields may be developed on adjacent power rivers. This area is so far without transportation facilities, and as no local supplies of fuel are found could not be developed profitably without hydraulic energy.

The known coal resources of Alberta are greater than those of any other province and in the past have, as in Nova Scotia, been depended upon to provide power for the industry. Upon the completion of the East Kootenay Power Company's 15,000-h.p. station at Elko, B.C., many of the larger Alberta mines contracted for supplies of hydro-electric power. Among the mines which changed from steam power to hydraulic may be mentioned the West Canadian Collieries at Bellevue and Blairmore; International Coal and Coke Company at Coleman; and Hillcrest Collieries at Hillcrest.

British Columbia and the Yukon

Water power has been extensively developed for mining purposes in both British Columbia and the Yukon Territory, over 81,000 h.p. being installed for that purpose in British Columbia and 13,000 h.p. in the Yukon.

The large-scale operations for the production of zinc-copper and lead carried on in the Kootenay district by the Consolidated Mining and Smelting Company of Canada Ltd., operating such well-known mines as the Centre Star, Le Roi, War Eagle and Josie in West Kootenay, and the Sullivan mines at Kimberley in East Kootenay, are supplied with hydro-electric energy from two plants on the Kootenay river, with a total installation of 38,000 h.p. and one on the Cascade of 3,900 h.p. operated by a subsidiary of the mining company, the West Kootenay Power and Light Company Ltd. Power from these stations is transmitted over 450 miles of line to the various mines and so great is the demand that construction work to provide an additional 30,000 h.p. is at present under way. Power for the Sullivan mines is also being secured from the East Kootenay Power Company.

One of the most important coal mining areas in Canada is that of the Crow's Nest Pass and Elk River district in East Kootenay and here recently completed hydro-electric developments are rapidly replacing coal as a source of power for mining. The East Kootenay Power Company, operating a 7,500-h.p. station on Bull river and a 15,000-h.p. station near Elko, have completed contracts with many of the leading mines of the district, including the Crow's Nest Pass Coal Company, Corbin Coal and Coke Company and the McGillivray Creek Coal and Coke Company. On the Pacific coast the extensive copper and gold areas are supplied with power from a number of important developments. The Britannia Beach Mining and Smelting Company have two developments totalling 19,000 h.p.; the Granby Consolidated Mining Smelting and Power Company, one of 13,200 h.p.; the Hedley Gold Mining Company, one of 1,600 h.p.; the Surf Inlet Company, one of 1,200 h.p.; and there are a large number of smaller installations. Extensive coal mining operations conducted on Vancouver island by the Canadian Collieries Ltd. are supplied with power from a 12,000-h.p. hydro-electric plant operated by the company on Puntledge river.

In the Yukon five water power sites have been developed to supply power for mining, only two of which need be mentioned, viz. that of the New North West Corporation Ltd., with 10,000 h.p. and the Yukon Gold Company with 3,180 h.p.

In conclusion it may be said that there is every indication of the rapidly increasing use of hydraulic power for mining. With the growth of activity which is taking place additional supplies of power must be provided and it is indeed fortunate that latent water power exists in proximity to every mining field with the exception of certain coal-mining areas in the Central Plains.

Summary

A few of the principal facts covered in the preceding pages may be here brought together:

The Value of Production

In 1923 the value of production was $214,000,000 — the average value over the past 5 years $195,000,000. The leading provinces in order of precedence are Ontario, British Columbia, Alberta and Nova Scotia. *(Pages 477 and 478)*.

Progress

The previous record year in value of production was 1920. Prices have fallen since then, but the Bureau of Statistics states that a weighted index probably would show 1923 to be the banner year in value of production, and that new output records were established for coal, lead, zinc and the value of cobalt. (*Page 477*).

Production by Classes

In value of production metallic mining leads, then coal, followed by non-metallic and then structural materials and clay products. (*Page 478*).

Capital Invested

The capital invested now stands at about $800,000,000, of which about 56 per cent is held in Canada, 13 per cent in the United Kingdom, 27 per cent in the United States and 4 per cent in other countries. (*Page 478*).

Power Used

The total horse power used is 514,000 of which 54 per cent is water power and 46 per cent fuel. The proportions of primary power installed and power purchased are about the same. (*Pages 478*).

Principal Mineral Industries

Information showing mineral production by provinces and, as far as possible, the capital invested and power used, is given on *pages 478 to 481*

The Importance of Water Power

In the mineral industry is dealt with on *pages 481 to 483*, which indicate not only that water power replaces fuel wherever it is developed, but also that this low-priced power is essential to the successful exploitation of many of the minerals.

Conclusions

It is claimed that Canada is destined to be the world's greatest mineral producer. The mineral resources already definitely established are so vast that it needs but little investigation to find convincing evidence of this claim. North of the more or less prospected area are still vaster areas which are known to be mineral bearing but which have been prospected but little, and in many cases not at all.

Plate No. 6,—Hydro-Electric Development of the Northern Ontario Light and Power Company, Limited, on the Matabitchouan River, Ontario, supplying power to the Cobalt Silver Mines, 11,000 horse power.

It is of interest to consider why even greater progress has not been made in the past. The mineral wealth of Canada lies mainly in the northern portions of the Dominion, lapping over into the, at present, thinly populated districts and extending far to the north of present settlement. Canada, until recently, was looked upon mainly as an agricultural country; the agricultural land is largely a comparatively narrow strip along the southern border and through this have been built three transcontinental railways, mainly with the object of opening up this agricultural country, but so far but few lines of importance have been built north and south and extended into the mineral fields, those that have been built have brought immediate results in mineral development.

A good example is the Temiskaming and Northern Ontario Railway, running north from North Bay to Cochrane some 250 miles and under process of extension to James bay some 200 miles farther north. This has opened up one of the northern mineral areas and so rapid has been the development that it is now admitted to be one of the richest mineral areas in the world. Other examples are the Algoma Central running north from Sault Ste. Marie and the Hudson Bay Railway through The Pas opening up that and the Flin-Flon districts. It is possible that other lines may be built in the future to the similar areas lying in the north of Quebec, Ontario and the western provinces and that similar results may be expected.

Many of these areas have little or no coal but practically all are known to possess ample and well distributed water powers that will provide in abundance the low-priced power necessary for development of the minerals.

Possessing therefore mineral resources so vast and varied and known water power resources available in practically every area, Canada looks to her mineral development with confidence,

Use of Electric Power in the Cement Industry of Canada

W. G. H. Cam, A.M.E.I.C., A.M.I.E.E.
Electrical Engineer, Canada Cement Company, Limited.

The productive capacity of cement mills in Canada totals about 44,000 barrels or 7,700 tons daily. Hydro-electric power lies behind practically all the cement produced, and it is usual to consider that one horse power per barrel of capacity represents economical usage. Load factors run from 85 to 90 per cent with reasonably good operating.

Kilowatt-hours, per barrel of finished cement, run from 13 to 18 according to the character of the raw materials and the machinery used. The Canadian barrel is 350 pounds, and a mill of 10,000 barrels daily capacity will employ about 300 motors ranging in size from 250 horse power downwards with a total of about 15,000 horse power.

Induction motors are almost exclusively used and squirrel cage rotors up to 175 horse power. A few synchronous motors appear on the list, but they are generally for power-factor corrosion only. Three-phase current at 60 or 25 cycles, and 550 or 440 volts is the form of the distributed supply.

Roughly speaking one-third of the energy used is employed in grinding and pulverizing the raw materials, one-third in grinding clinker and the remainder for various subsidiary purposes. The circle diagram, plate No. 2, shows actual distribution of power consumption in a 3,500-barrel mill.

In the early days of the industry in Canada marl deposits were mainly exploited and a large number of wet process mills were built. At present, however, most of the mills use limestone rock with the addition of the requisite amount of clay or shale to make a true Portland cement mixture, and the dry process of manufacture is almost exclusively used.

Well drills, steam-shovels and electric haulage are typical of the quarry lay-out. Roll, gyratory and jaw crushers and hammer mills do the crushing; ball mills of

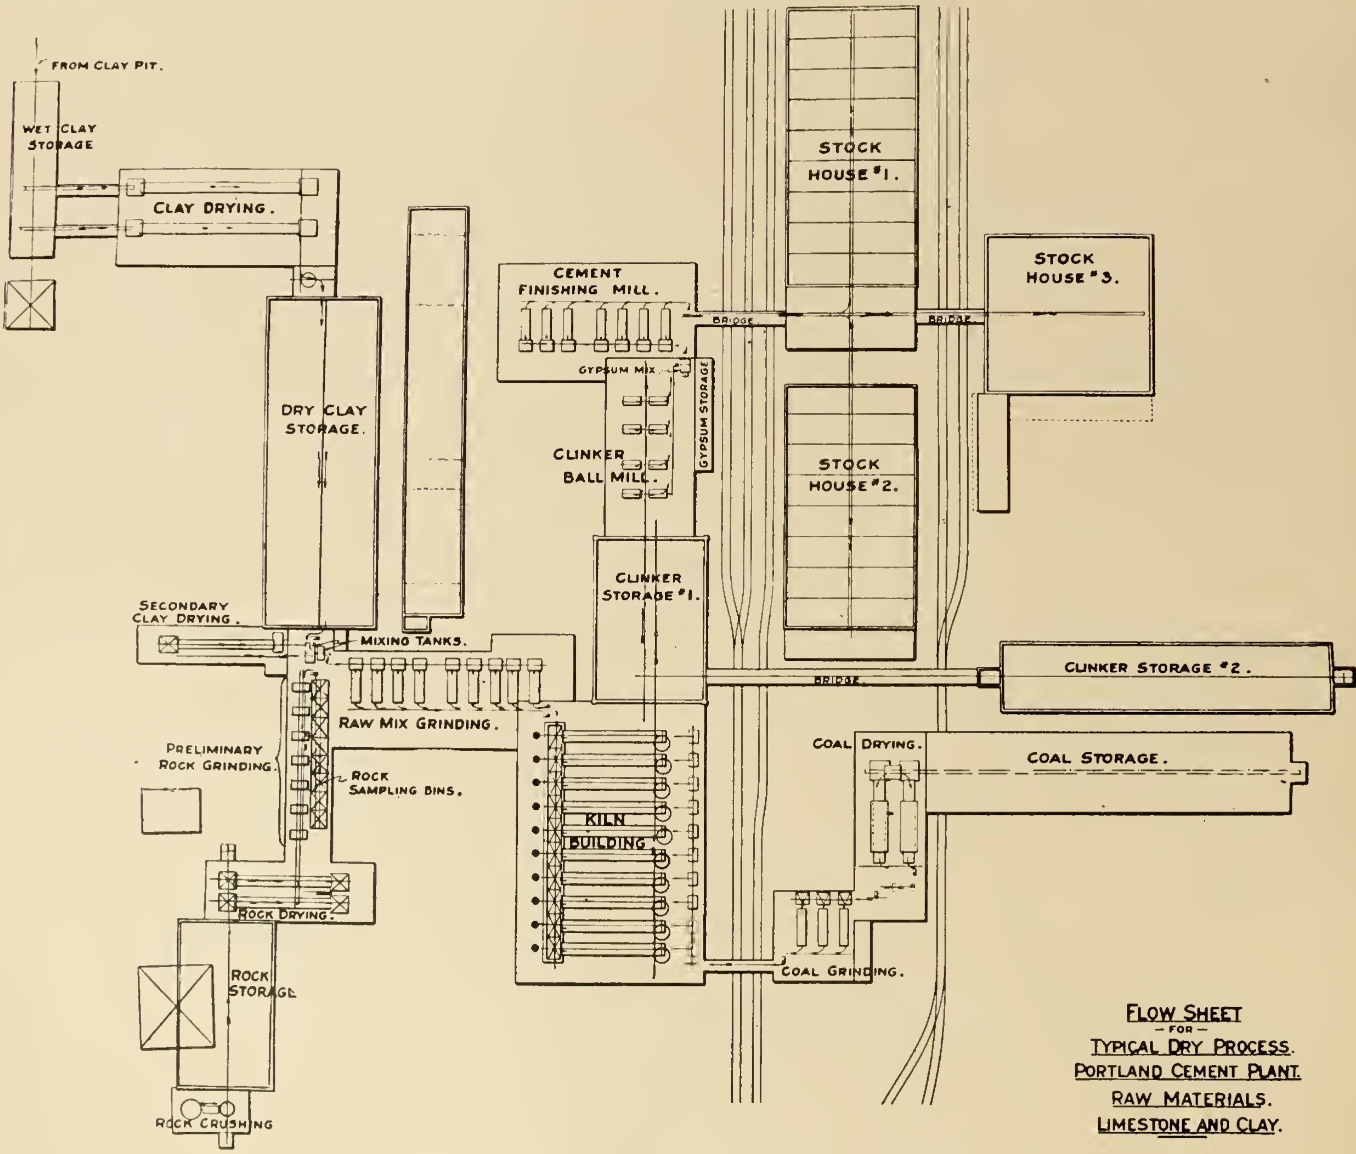

Plate No. 1,—Actual Distribution of Power Consumption in 3,500-barrel Cement Mill.

various kinds and tube mills complete the pulverizing process. Rotary kilns run all lengths from 60 feet to 150 feet, and 8 feet to 10 feet diameter. Conveying is handled by bucket, belt and screw conveyors. Dryers are mainly rotary. Coolers are stationary or rotary. Packing is handled by machine through a valve in the bottom of the sack.

The necessity of keeping up with current repairs, in what is essentially a destructive process, accounts for a considerable proportion of the labour employed, for apart from repairs and machine tending, inanimate power does practically all the hard work.

It should be borne in mind, however, that while an abundance of cheap hydro-electric power cheapens the mechanical process, cement manufacture here as elsewhere is a chemical industry calling for constant technical supervision and continuous sampling, testing and adjustment at every stage of the process, to insure the uniformity and high quality of the product marketed.

The typical flow sheet, plate No. 1, of a 3,000-barrel mill figured, should prove interesting for purpose of comparison with the practice of other countries, while a birds-eye view, plate No. 3, of a 10,000-barrel plant has been included so that those who have not had the opportunity of seeing for themselves may realize the progress that has been made in the last twenty years in what is now one of the basic industries of Canada.

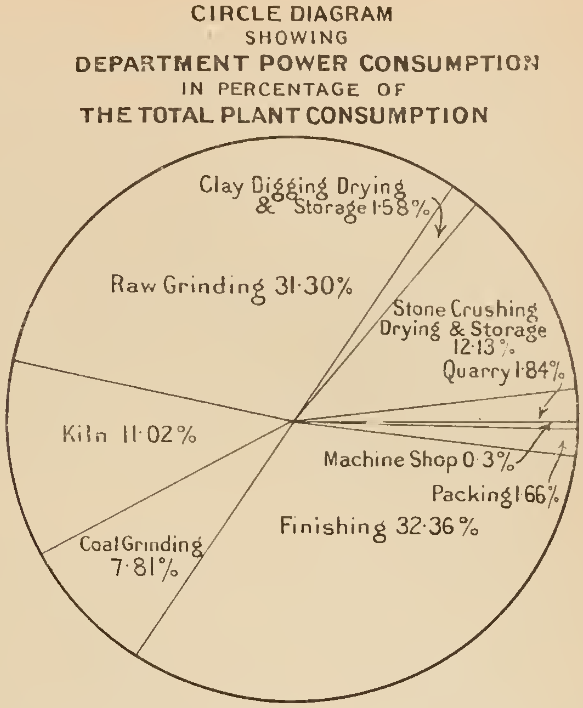

Plate No. 2,—Typical Flow Sheet of a 3,000-barrel Cement Mill.

As compared with the United States the cement market of Canada is seasonal, and this accounts for the large cement storage capacity which is provided in Canadian mills so that operation may be more or less on a twelve-month schedule, although the market may be very dull for the winter months.

Plate No. 3,—Large Canadian Cement Mill, 10,000-barrel Capacity.

The Use of Power for Port Facilities

M. T. S. Casey,
Secretary to the President, Montreal Harbour Commission.

Port facilities in Canada afford a number of very interesting features in connection with the utilization of power, particularly in the matter of the handling of grain, the greatest of Canadian export commodities. Of the numerous ports, both on the seaboard and on the inland waters, the port of Montreal has been selected for the subject matter of this paper, offering as it does an excellent example of the diversified use of power on a large scale for port facilities. This port, situated on the banks of the St. Lawrence river one thousand miles from the ocean, is second in importance of the sea ports of North America and ranks fifth in the harbours of the world.

Growth of Power Requirements

The most important development and growth of the port of Montreal has taken place within the past twenty years. In that period the wharf accommodation for vessels has increased from some 3,000 feet to 8½ miles. In 1904 there was no harbour railway. To-day the system extends the entire length of the port, serving every pier and shipping berth, and every industry adjoining the harbour, and comprising some sixty miles of track. Twenty years ago the grain handling equipment of the port consisted of a few floating grain elevators, with a capacity of 8,000 bushels per hour each. To-day there are four fireproof concrete grain elevators, with a combined storage capacity of 12,150,000 bushels, and with a total handling capacity per day of some 2,000,000 bushels in and the same quantity out to ocean vessels, which means that in all 4,000,000 bushels of grain can, in the course of a day, be handled by the vessel-unloading marine towers, and by the car dumpers, be weighed, conveyed over miles of rubber belting, and delivered to storage bins or drawn from storage and delivered into holds of waiting ocean ships. In 1904, wheat exports through the port of Montreal amounted to 7,425,000 bushels. In 1923 the wheat exports reached the quantity of 89,566,000 bushels, and of all grains a total of 120,107,000 bushels. In the same period the number of ocean vessels trading to the port increased from 796 ships of a net registered tonnage of 1,856,697 tons, to 1,117 vessels of 3,728,740 tons in 1923.

In line with the foregoing has been the increase in the revenue of the port, which in twenty years has grown from $330,659.22 to $3,721,159.99, the latter being the figure for 1923. Naturally, as the facilities and trade of the port have grown, so have the power requirements been extended, and the electrical installation and the organization necessary to take care of these increases have advanced step by step with the other facilities. Thus in 1904 the report of the Harbour Commissioners contained a reference to the electrical requirements, and makes interesting reading now. The only concern of the electrical department at that date was the lighting of the wharves, and the power consumed only amounted to a few thousand horsepower-hours. The cost of this service in that year was $7,135.53. The cost of the electric lighting system in 1923 was $34,604.88, which takes no account of the power used in the grain elevators, for railway operation and at the cold storage warehouse.

The report of the electrical engineer of the port of Montreal for the year 1923 gives the following as the power consumption for the season of navigation:—

Cold storage warehouse	2,966,589	h.p.-hours.
Elevator No. 1	2,463,493	"
Elevator No. 2	2,008,331	"
Railway electrification	1,561,035	"
Elevator "B" and conveyors	1,324,174	"
Grain conveyors at elevators Nos. 1 and 2	1,009,900	"
Harbour lighting	631,821	"
Sheds Nos. 2 to 15	295,059	"
Sawmill on Bickerdike pier	220,216	"
Miscellaneous	136,396	"
Freight hoists	113,637	"
Harbour yard	78,500	"
Sheds Nos. 16 to 19	54,564	"
Engine shops	50,274	"
Elevator No. 3 (construction)	33,718	"
Head office: power and lighting	32,931	"
Sheds Nos. 24 and 25	23,165	"
Elevator "B" extension, construction	13,985	"
Total	13,016,788	h.p.-hours.

As will be seen from the foregoing, the grain elevators and conveyor system, (which is an integral part of the grain handling equipment), consume by far the largest proportion of the power used annually, for this service alone a total of 6,805,898 h.p.-hours having been required during the season of 1923. The cold storage warehouse came next with a consumption of 2,966,589 h.p.-hours, and that portion of the railway system which was operated electrically during 1923 consumed 1,561,035 h.p.-hours. The various other smaller services, including lighting of the wharves, were responsible for the balance.

From this it will be appreciated that the grain elevators, and their auxiliaries such as conveyor galleries, car-dumping machines, etc., are easily the most important branches of the harbour organization from an electrical point of view, and are thus entitled to major consideration in an article such as this one, but the electrical aspect of food preservation, as exemplified in the service at the cold storage warehouse, and the new ground being broken by the electrification of the harbour railway, are well worthy of mention.

For the purposes of distribution, the whole area requiring power has been subdivided into zones or districts, and a substation located in the centre of each, equipped to provide the total requirements of that zone. Because of this arrangement, as the harbour continues almost

Plate No. 1,—Montreal Harbour Electrification, Catenary 2,400-V., D.C.

year by year to expand and increase its area of concentrated activity, so the electrical department is kept busy adding to the capacity of various sub-stations, or providing entirely new and additional sub-stations.

There are at present five sub-stations serving the electrical requirements of the port. The power is purchased by the Harbour Commissioners and is brought in over primary feed lines to the various sub-stations, where it is converted or transformed from 20,000-volt to 550-volt, 3-phase, alternating current for the elevators and cold storage warehouse, etc., and for lighting purposes to 110 volts. These high-tension lines extend from one end of the harbour to the other in duplicate, with additional tie-in lines between sub-stations, to avoid any serious interruptions to the service should a primary connection fail at one or other of the sub-stations. (See plate No. 1.)

Power Requirements of Grain Elevators

The amount of motor power required by one of the grain elevators when in full operation, receiving, weighing, conveying, and delivering grain, is very large indeed. A fully equipped working house requires approximately 1,000 h.p. in motor capacity for every 1,000,000 bushels storage accommodation in the plant. The conveyor galleries, which are the outlets for the grain stored in the plant, and the inter-communicating interior belts connecting the bins with the working house, require approximately 100 h.p. per 1,000 feet of horizontal belting. The following table shows the connected motor load at each of the three elevators at present in service:—

Elevator No. 1 and conveyor galleries	6,000 h.p.
Elevator No. 2 and conveyor galleries	3,500 h.p.
Elevator No. "B" and conveyor galleries	3,500 h.p.

In order to follow intelligently the application of power quantities to the actual working of a grain elevator, it will be necessary to accompany a consignment of grain through the elevator, and note the various phases of the work, and the motor capacity required for the various functions. The grain arrives at the elevator by lake boat, and is taken into the elevator by a marine leg, which delivers it to a lofter leg. The nominal capacity of a marine leg varies from 15,000 to 20,000 bushels "on the dip", or an average capacity of from 9,000 to 10,000 bushels per hour. To operate a marine leg, 100 h.p. is required. The lofter legs elevate the grain to the upper garners, and this in turn requires motor capacity of 100 h.p. The garners deliver to the scales, and the grain is weighed, this function requiring no electrical power, and the scales deposit the grain on belts which carry the grain from the working house to the distributing floor. The capacity of each scale is 60,000 bushels, and this quantity is weighed in approximately four minutes. From the distributing floor the grain is conveyed by belts to any of the storage bins in the house, and for this service the ratio of 100 h.p. per 1,000 feet of belting is maintained.

When the grain is taken out from storage for purposes of delivery to ocean vessels, it is taken from the bottom of the bin to the shipping house, and elevated to the scales by a shipping leg, which has a capacity of approximately 14,000 bushels per hour, and which is operated by a 100-h.p. motor. From here it is delivered to a shipping belt, and taken to the conveyor galleries, from where it is poured down a spout into the holds of waiting ocean vessels. The capacity of the shipping belts is approximately 16,000 bushels per hour, and as already mentioned, 100 h.p. is the approximate capacity required to operate 1,000 feet of belting.

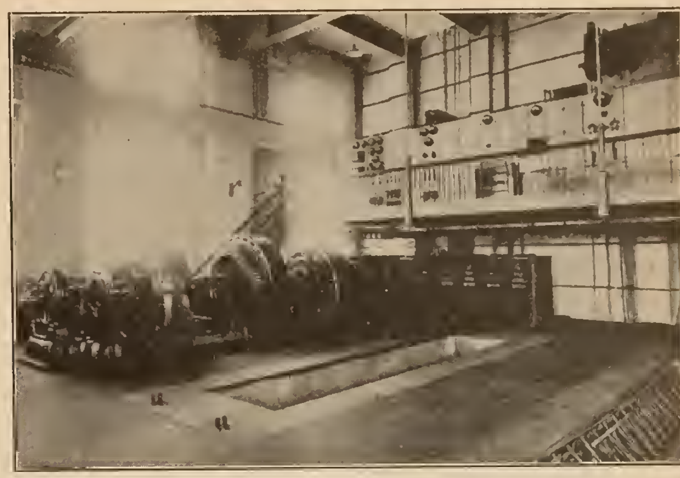

Plate No. 2,—View of Electric Railway Power House taken during installation, showing one Generator Set Mounted—Montreal Harbour.

Electrical Equipment of Cold Storage Warehouse

The cold storage warehouse is a new facility, which was constructed during 1920 and 1921, and was put into operation in the spring of 1922. The enormous demand on its available space which has been a marked feature of the plant since its erection, has demonstrated how valuable a utility it is to the shippers of perishable food stuffs, particularly meats, fish, and dairy products such as cheese, butter and eggs. In addition to a large export business, this plant has been widely availed of by local retailers for the storage of their supplies, and in this way has handled a highly varied list of commodities, ranging from hops, for the use of the manufacturers of ales and beers, to the storage of valuable furs in the hot summer months, and embracing fruits, both fresh and dried, vegetables, liquors, etc.

As in the case of the grain elevators, electrical power is the mainspring of the activities of this plant. The ammonia compressors, of which there are three in the power house adjoining the warehouse itself, send the cooling brine flowing through coils in all the refrigerating rooms, where temperatures of from 15 degrees below zero Fahrenheit to any desired temperature above, may be obtained. These ammonia compressors are driven by electric motors, one of 250 h.p. and the other two of 225 h.p. each. Not so important, perhaps, as these ammonia compressors, but still of great importance for the proper operation of the plant, are various other small facilities, all of which are driven by electric motors, varying from a little 10- or 12-h.p. motor driving an air cooling fan in the conditioning room, to 75-h.p. motors operating the four brine pumps. An air compressor is driven by a 75-h.p. motor, and a water pump by one of 20 h.p. The freight hoists, of which there are four, are each driven by a 25-h.p. motor, and there is a river pump, which is operated by a 40-h.p. motor.

Harbour Railway Electrification

The terminal railroad operated by the Harbour Commissioners of Montreal consists of surface lines situated between Victoria Bridge and the Imperial Oil Wharf, and having various spur tracks and sidings serving every berth and pier in the port, totalling in all some 60 miles of track. In the year 1918, after the Commissioners had visited several important electrified freight terminals, and had closely studied the conditions there, it was decided that since electrification in freight yards and terminals had been found very economical and satisfactory, electric locomotives being considerably more efficient than steam locomotives, particularly during the severe winter climate of Canada; that it would be desirable to have the harbour railway terminals electrified. Accordingly work was begun on this project in 1919, and plans and specifications were prepared calling for tenders for the material, the actual work of erection being undertaken by the electrical department of the commissioners. The work was divided into four main sections as follows:—

1. Power station machinery equipment.
2. Control, protective and signal equipment.
3. Overhead catenary line material.
4. Rail bonding material.

Power Station Apparatus

The station was designed for a capacity of three 1,000-k.w. motor generator sets, the units having a very heavy over-load capacity for a short period to meet railway conditions, and capable of carrying 250 per cent load for five minutes. Each set, (see plate No. 2), consists of a three-piece unit, a 1,500-h.p., 2,300-volt, 3-phase, 60-cycle, 720-r.p.m. synchronous motor directly connected to a 500-k.w., 1,200-volt, 720-r.p.m. compound wound d.c. generator on either end, each generator being permanently connected in series giving 1,000 k.w. at 2,400 volts. Exciters for the synchronous motor and generator fields are mounted on the same bedplate. Each of the motor-generator sets weighs 40 tons, mounted on its frame, and covers a floor-space of 28 feet long by 8 feet wide and approximately 7 feet high. Water-cooled, oil-insulated power transformers of 2,000 kv.a. have been installed, taking the power at the incoming lines at 11,000 volts and stepping it down to 2,300-volts a.c. for the synchronous motors. These transformers weigh approximately 30 tons each.

Control and Protective Apparatus

The switchboards, cell, remote control, oil switches, and protective equipment are mounted on galleries on the second floor and consist of twenty-one marble panels with the necessary meters and indicating mechanism for the complete control of the generator sets, quick acting breakers, storage batteries, power transformers and exciters.

Overhead Catenary Line Apparatus

The overhead line equipment consists of cross span and bracket construction supporting the main messenger which is a 7/16-inch extra galvanized Siemens-Marten steel cable anchored in half-mile sections. The anchor poles are very heavily guyed in all directions. The cross spans are supported by steel poles at spacings of 150 feet on tangent double track, and 120 feet or 105 feet as conditions require on curves or yards. (See plate No. 1.)

Cross-span messengers consist of 5/16-inch high strength galvanized steel cable, the tension on all messengers being maintained at approximately 2,300 pounds. Attached to and supported by the main messenger is the conductor, consisting of 4/0 grooved hard drawn copper, fastened by hangers of various lengths, keeping the trolley at a uniform height of 23 feet above the top of the rail. Steel poles are used, the poles being set in concrete carried well above the ground level.

Rail Bonding

The rail bonding, while not a very noticeable part of the installation is, however, a highly important section of the system. All the return current must get back to the power station by the rails, and close attention must be paid to the method of welding the copper bonds to the rail joints in order to get the best results. The type of bond used is a steel armoured terminal gas-welded copper-stranded bond, capacity 4/0, seven inches long, cold pressed and headed.

By the beginning of 1923, some 40 miles of track had been electrified, and in that season two 85-ton electric locomotives were rented from the Canadian National Railways, and were operated over that part of the system which had been provided with power connections. The service thus obtained, however, was at best only of a partial or temporary nature, as none of the rail connections to piers and sheds had been electrified, but the work of completing the installation was carried on vigourously during 1923 and in the early part of the present year, and it is hoped that by the end of the season of 1924, by which time delivery is expected of four new 100-ton electric freight locomotives, that complete operation of the system by electricity will be possible.

Power Requirements in the Lumbering Industry in British Columbia

A. M. Smith,
Chief Engineer, Vancouver Lumber Company, Vancouver, B.C.

The lumbering industry, especially that carried on on the Pacific coast, requires a large amount of power; in fact a survey of the power requirements in all industries shows that it stands highest on the list. This is partly accounted for by the fact that a large proportion of the raw material is converted into completely finished product before it leaves the sawmill premises, i.e., moulding, flooring, ceiling, etc.

Logging and Sawmill Operations

Before dealing with the power required for the different operations, it may be well to follow the log from the time the 'feller' has whanged his crosscut saw through the tree, delivered his last blow on the head of the wedge and the 150-foot monarch has swished to the ground.

Immediately the tree has been laid low, "Buckers" cut off the branches at the top, and the tree or log is hitched to a steam donkey engine by a heavy cable skidding line, as shown in plate No. 1, and transported to the loading berth. In this case the same engine is used to load the logs on to the cars; drums being provided on the same frame for this purpose.

Plate No. 2 shows the machine used for this purpose. This machine is provided with boilers having up to 1,065 square feet of heating surface and 190 pounds working pressure, twin engine up to 12-inch by 14-inch cylinders capable of developing 500 h.p. for a short period. The drums are made to hold sufficient cable to work over an area with a radius of 2,000 feet.

Plate No. 3 shows the type of machine used for roading, i.e., hauling the logs from the skidder to the railroad or to the water. The boilers and engines are built up to the same size as the skidder but the drums have space for 5,000 to 6,000 feet of 1¼-inch cable. This machine is made necessary where the railroad can not be built up to where the logs are being taken out or where it is less than a mile haul to the water.

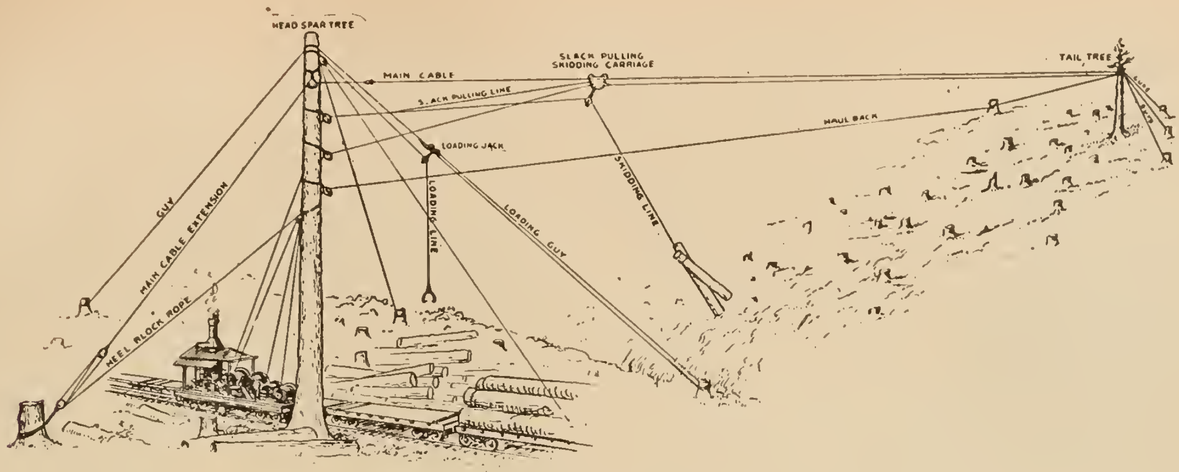

Plate No. 1.—Cable Skidding Line.

On the railroads in use, the tracks are standard and locomotives from 30 to 90 tons are in use, which are usually of the geared type owing to the heavy grades encountered. At present roads 30 miles long are being used to get out logs. The terminus of the railroad is usually a trestle built on piles, out to deep water; one rail being raised to give the cars of logs a tilt or pitch toward one side. When the cars have been run out on this the bunks or chocks are knocked out and the logs allowed to roll into the water. Here they are made up into booms according to grade and specie.

The logs are placed side by side and end to end to the desired width and length. Large holes are bored in the ends of the outside logs, which are picked for the purpose; and heavy chains are passed through from one log to the next, thus forming a barrier around the whole of the logs. Some logs are rolled up on top, crosswise of the logs and chained to the outside logs. This is to prevent logs from leaping over the boom sticks in case of rough weather, while the whole is being towed to the mill, which, in some cases, is 200 to 400 miles away.

When the logs reach the mill-pond, the chains are removed, and each log is guided to the foot of the jack ladder or log haul, (see plate No. 4), up which a massive endless chain is moving and to which are fastened bunks, (large steel castings with teeth or prongs sticking up), and as the end of the log is brought in contact with these bunks, the teeth bite into it and it is pulled up to the log deck. Here it is measured and its contents entered in the log sheet.

Underneath this deck is situated a series of steam cylinders; one of these now comes into operation and "kicks" the log on to an inclined plane, down which it rolls until brought to rest against the stops. These stops, controlled by the sawyer, and actuated by another steam cylinder, are shaped like the rockers of a rocking horse; so that, there being more than one log on the deck, when the stops are moved to allow a log to roll on the loader and thence to the carriage, they prevent the next log from moving until the stops are again returned to the normal position.

The log having rolled on to the loader, another steam cylinder operates a set of pusher arms, by which the sawyer pushes the log hard against the carriage knees and the 'doggers' pull the "dogs teeth" into the log to hold it in position.

The carriage, driven by a twin reversible steam engine, is now run along the track bringing the log in contact with the saw, and a slab is sawn off. The slab falls on to a set of live rolls which carry it along and drop it on a set of chains moving at right angles to the rolls, and which pass beneath the clasher saws, where the slab is cut into four feet lengths. It is then dropped into the main refuse conveyor. This conveyor passes through the lath mill and here the pieces suitable for making lath, broom handles, etc., are picked out and the remainder passes on to the burner or refuse destructor, unless "hog fuel" is required for some purposes; then the slab may be dropped into a hog which cuts it up so that it can be handled by sawdust conveyors and it is fed to the furnaces to produce steam.

Meanwhile the carriage is again run back to the starting point and the log again brought in contact with the saw and a board 1-inch or 2-inches or 3-inches thick is sawn off, drops on the rolls, which this time carry it to a point in front of the edger. Here a steam lift raises another set of chains by which the board is moved to a point directly in front of the edger. Another steam lift raises a live roll and the board is carried on to the edger rolls which feed it through the saws of the edger, taking off the bark at the two edges and sawing the board into the required widths. The board then drops on to the trimmer chains which carry it under a gang of saws set two feet apart. These saws can be raised or lowered at the will of the operator who sits in a cage above the chains where he has a clear view of the lumber passing beneath. In front of this trim-saw man is a set of keys called the

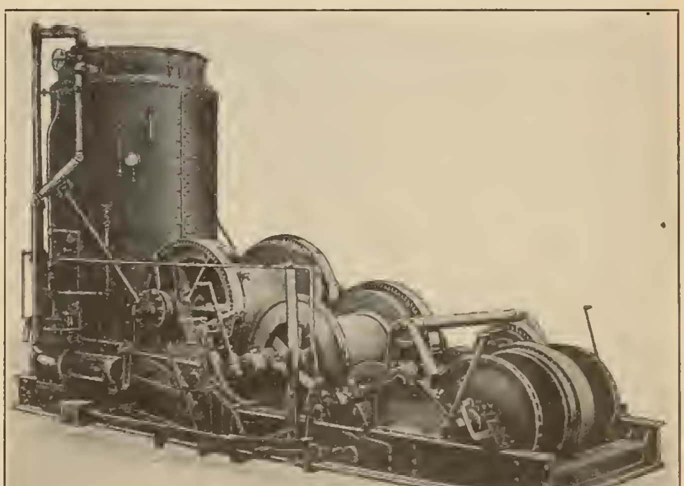

Plate No. 2,—Donkey Engine for Cable Skidding Line.

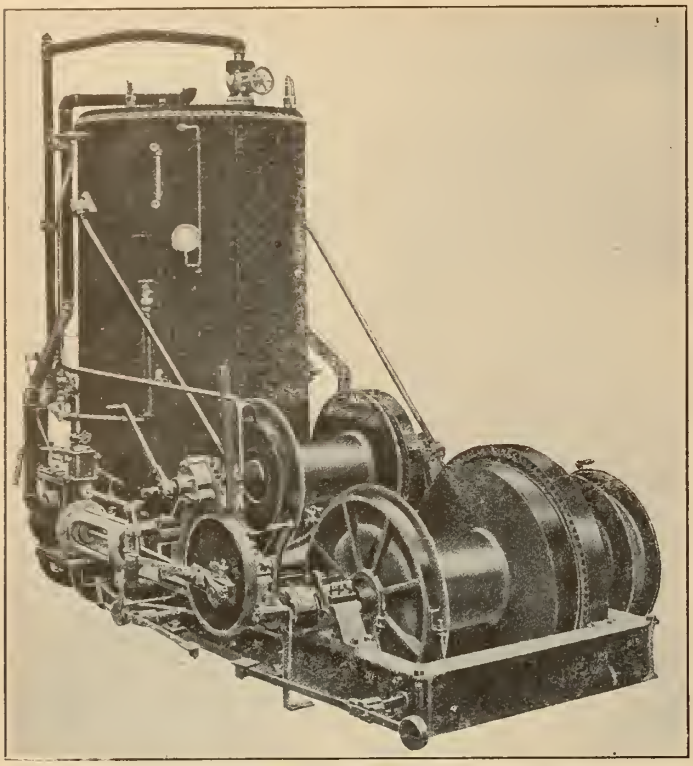

Plate No. 3,—Type of Engine for Roading.

piano. By pressing one or more of these keys compressed air is admitted to the cylinders which control each saw; thus the boards are cut to the length dictated by the quality of the board and the orders called for.

When the boards have passed through the trimmers, they are carried by a series of live rolls and transfer chains to the sorting table where the common is separated from the clear lumber; the clear lumber, i.e. that which has no defects, goes on over chains to the dry kiln stackers, where steel cars are waiting to receive it. On these, 5,000 feet B.M. to 6,000 feet B.M. is mechanically stacked and the cars with their load run into the dry kiln chamber.

After the lumber has been dried to the required moisture content, it is drawn out and unstacked by mechanical means, and conveyor chains again come into action and carry it to the storage sheds. In some cases the unstacker is placed directly behind the planing machine and the boards are unloaded directly on to the feed table.

This table, another automatic contrivance, feeds the lumber, one board at a time, to the machine where it is made into V-jointing, flooring, etc. Coming through the machine it falls on to a series of belt conveyors and transfers by which it is carried to the trim saws where it is cut to exact lengths according to what the board will make. When trimmed, it falls on to another belt conveyor and is carried to the bundlers where it is tied in bundles and is ready to be placed in the railroad car or motor truck, as the case may be. Thus, in an up-to-date mill, a large proportion of the lumber, from the time it is placed on the jack ladder in the shape of a log until it is ready to be shipped, is handled entirely by mechanical means.

Power required for each Operation

The size of logs being manufactured has a large bearing on the question of power required at each machine, but in any case a large surplus has to be provided over the average to take care of a run of extra large logs.

Plate No. 5 shows an extra large log on the jack ladder. This magnificent fir was cut by the Peck Logging Company at Frederick Arm, 125 miles from Vancouver by Union Steamship Company. Here it is shown on the ways at Hastings Mill. Out of this stick were sawed two pieces 54 inches square and 12 feet long. At the Empire Exhibition at London these squares will be exhibited. They will form part of an arch and will support timbers 61 feet long. One of the features of this log is that it is exactly 7 feet at either end. It is the second log of a mammoth tree which contained in all over 30,000 board feet. The average log cut in the mill in the picture will, of course, be considerably smaller than the one depicted, but the machinery must be made to handle just such as these. In cutting the log above, the head saw would probably be taking 400 h.p. although the practice is to allow about 300 h.p. for a band saw mill handling this size of log.

The capacity of a mill is usually stated in thousands of feet, board measure, per 10-hour day, and the power required by coast sawmills is around 6 to 8 h.p. per thousand feet, and for planing mills from 3 to 4 h.p. per thousand. For interior or mountain mills where smaller logs are being cut up, satisfactory operation is carried on with considerably less power than this; some mills using as low as 4 h.p., per thousand for the sawmill and 2 h.p. per thousand for the planing mill.

Size and Type of Motors in General Use in Motor Driven Mills.

	Motor			
	Type*	Size h.p.	r.p.m.	Method of drive

Plate No. 4,—Jack Ladder or Log Haul.

Steam Engine or Motor Drive

The advantage of motor drives for the planing mill and other outside requirements is beyond question; each machine being independent of the other. In the sawmill the advantages of the motor drive is not so obvious for various reasons. Each machine is a link in a complete series and stoppage of a small motor driving the live rolls behind the headsaw or edger or chains to the trimmer, etc., holds up the whole plant.

Owing to the necessity of over motorizing every machine because of the heavy duties infrequently applied the power factor is often so low that in some cases the wattless current is greater than the friction load on a shaft and belt driven mill and it is impossible to find drives where synchronous motors for correction purposes are practicable owing to the fluctuating load. Increase of production has been shown where shaft drive has been changed over to motor drive, but the writer is of opinion that the increase has been due to the provision of greater capacity in the prime mover.

Steam must be supplied to the twin engines or shot gun feed that moves the carriage up and down the track as so far no electric device has been developed that will take their place. Also steam has been found to be the best medium for operating the niggers and turners, loaders, etc. for handling the large logs on the carriage.

Since fuel is not a factor to be considered, first cost and maintenance must be the deciding factor whether the sawmill shall be motor or direct steam engine driven. With regard to breakdowns, any serious ground or short in one of the major motors is invariably a longer repair job than any conceivable break in the shafting or belting. It is obviously out of the question to provide spare motors for each major drive and since the speeds and characteristics of the different motors vary so widely one or two motors will not be sufficient to act as spares in case of breakdown.

If the mill is situated remote from a repair shop and an armature winder not maintained on the pay roll, then the delay due to a motor that must be partly or entirely rewound will be an extended affair depending on how quickly outside help can be secured or how quickly the motor can be sent to a repair shop, or a replacement motor rented. On the other hand there is hardly a break in the shaft and belt transmission that cannot be repaired in a few hours by the mill's own machine shop.

The machines in the sawmill with the exception of the edger, lend themselves to easy shaft and belt transmission so that except for the very largest mills, the engine drive is probably the best and most economical. A combination of sawmill engine drive with exhaust steam or mixed pressure turbine supplying power to the planing mill and other scattered machines has proven successful in many cases.

One horse power for every horse power developed by the main engines and auxiliaries in the mill can be obtained by this means and the efficiency of the combination be as good as a single large turbine; thus the capital charge in the boiler room is about equal and the first cost, at least, up to a mill of 200,000 b.m. per day, will be less.

Source of Power

Until such times as a use can be found for the sawdust, shavings, slabs, and edgings, which make good fuel, the lumberman will find it cheaper to install his own power plant than to buy from an outside source; for even if the outside service is as cheap as he himself can produce it, there is a negative value in this waste material, entailed in the getting rid of it. Those plants now producing their own power and destroying the surplus by burning in a destructor, would have to provide much larger facilities for conveying and burning if they were to discard their own plant and buy power.

From an economic standpoint, it is reprehensible that the waste is as large as it now is. This will be realized when it is known that from 40 per cent to 50 per cent of the solid log is lost in the manufacturing process. There is a loss of 20 per cent in the sawmill in saw-kerf alone, 10 per cent loss in slabs and edgings and 2 per cent in trims, making a total of 32 per cent. Then there is a further loss in the planing mill of over 28 per cent. Of course, it will be understood that only a portion of the total output of the sawmill goes to the planing mill, but at any rate we are safe in saying that 40 per cent of the solid log goes to waste in the sawmill and planing mill.

The heat value of the waste as a fuel runs from 6,000 to 9,800 B.t.u. per pound, when dry, but only that from the planing mill is dry, having passed through the dry

Plate No. 5,—Large Log on Jack Ladder.

kilns; the sawdust and hog fuel containing an average of 35 per cent to 40 per cent moisture.

A test conducted by Professor Killam of the University of British Columbia at the Murphy sawmill, Ladner, B.C. showed an evaporation of 5 pounds of water from and at 212 degrees Fahrenheit per pound of dry fuel, and in a test at the P. Burns and Company's plant at Vancouver, an equivalent evaporation of 2.48 pounds of water from and at per pound of fuel burned. This fuel was from the sawmill only, i.e. sawdust and hog fuel, and was composed of 40 per cent hemlock and the balance spruce and fir. This was fired by hand and difficulty was found in keeping the bars covered. Other tests conducted at the Vancouver Lumber Company's plant have shown an evaporation of 3.9 pounds per pound of fuel fired. In this case dry planing mill shavings formed 25 per cent of the fuel.

Therefore it can safely be assumed that the average evaporation is around 3 pounds of water per pound of fuel as fired. This is close to half the value of the average coals used in this part of the Dominion and some idea of the large economic loss can be had when it is known that the log cut is over 2 billion board feet per annum, and as already stated 40 per cent of this is waste or 800,000,000 feet b.m. The average weight of 1,000 feet b.m. is around 3,900 pounds, making a total waste of 1,560,000 tons, with a heat value equal to 780,000 tons of coal compared with the total coal production of British Columbia for 1923, which was 2,343,675 tons. This 2,000,000,000 board feet per annum, at 10 h.p. per 1,000 feet per day. for sawing and dressing, requires almost 70,000. h.p.

Various authorities estimate that the annual cut can be increased two or three times the present output and still be within the annual increase by new growth, that being estimated at six billion board feet per annum, this, of course, being dependent on how well the forests are protected from fire and other destructive agencies.

The Application of Compressed Air in Industry

Canadian Practice.

F. A. McLean.
Publicity Manager, Canadian Ingersoll-Rand, Company, Ltd.

Compressed air, it has been said, stands second only to electricity in the number and variety of its applications. There are few industries in which this power medium is not now used in some form or other. Mining, contracting and industry in general have developed very rapidly in Canada within the past two or three decades and the use of pneumatic appliances and processes has followed in close step.

Methods of Compressing Air

Compressed air is a power transmitting agency and must, therefore, derive its force from some source of power such as a steam, gas or oil engine, electric motor, water wheel or turbine, or falling water.

Mechanical Methods

With the exception of the last-named, all the above methods require the use of mechanical compressors. Due to the widespread development of hydro-electrical power and its availability throughout Canada, air compressors are driven chiefly by electric motors. Steam-driven units are not as common as in other countries. Oil-engine drive is used for isolated plants and is now receiving considerable attention in the mining field. Gasoline (petrol) engine drive is usually limited to small units such as portable outfits. Direct drive by water-wheels is used to a limited extent. A few rotary or turbo-compressors are still in use for steel plants or smelter service.

Compression by Direct Action of Falling Water

An interesting method of securing compressed air in commercial quantities is by the direct action of falling water. There are, in Canada a number of plants using this method. When air in small bubbles is intimately mixed with water, the water breaks into a foam, through which the bubbles try to rise and escape. But if the mixed air and water be drawn swiftly downward as in a vertical pipe the air is compressed. Then if, after reaching the depth and head of water-column necessary to produce the desired compression, the direction of flow be changed to the horizontal, and the velocity diminished, the bubbles of compressed air will be liberated and may be collected in a suitable chamber. The air pressure in this chamber corresponds to the effective head of water, that is, its depth below the level at the outflow or tailrace. Thus, in this method of compression no pistons, rotors, valves or other moving parts are used.

As the bubbles are small and thoroughly mixed with the water during its descent, the cooling surface is very large and isothermal compression results. The moisture carrying capacity of the air theoretically is, therefore, smaller than if it were compressed adiabatically. During compression the percentage of moisture in each globule of air increases until the point of saturation is reached; on further compression the moisture is deposited, so that when re-expanded the air is relatively dry. This method was first tested on a working scale by I. P. Frizell, of Boston, about 1878.

In 1890 the Taylor Hydraulic Air Compressing Company erected a plant at Magog, Que., for textile mill service. This plant has since been abandoned. In 1895-1898 a plant was installed for the Kootenay Air Supply Co., Ainsworth, B.C. The most important plant of this kind, however, is the Cobalt Power Company's plant installed at Ragged Chutes on the Montreal River in 1909. This plant compresses 40,000 cubic feet of free air per minute corresponding to about 5,500 h.p. The air is carried through nine miles of 20-inch pipe to Cobalt and then distributed to the various mines. The total length of the piping, (20, 5 and 3 inches in diameter), is about twenty-one miles. The total cost exclusive of piping was about $1,000,000. or $185. per horse power. The air is sold by the company at 0.25 cents per 100 cubic feet at 100 pounds gauge.

The cost of operating and maintaining hydraulic compressors is not large, no skilled attendance is required and depreciation is normal. They are generally unsuitable for small plants, however, as the first cost is rather large.

Field of Application of Compressed Air

Compressed air has properties which render it peculiarly suitable in many applications. For driving reciprocating machinery and devices of small capacity, it has all the advantages of steam, with the additional property of permitting the application of the power at

Plate No. 1,—Locomotive and Train of Cars, International Coal and Coke Company, Coleman, Alberta.

considerable distances from the central power source. Unlike electricity or high-pressure steam, it affords a means of storing readily available energy indefinitely at small cost; and unlike gas or oil engines and steam engines with coal-fired boilers, its use does not involve the liberation of noxious gases at or near the point of utilization of the power. It is also peculiarly adapted to the transportation and projection at high velocity of finely divided particles, and even of larger particles as in the case of concrete, to the atomization of liquids, and to the promotion of combustion.

Some of the specific applications in which its properties have proven to be of greatest value in various Canadian industries will be briefly described.

The Application of Compressed Air in Mines and Collieries

Compressed air is used underground for running rock drills and coal cutters; blowing smoke, hoisting, hauling and scraping; operating mucking and loading machines; operating direct-acting air lift or return-air pumps for unwatering, and station or sump pumping. It is also applied to pumping, hoisting and hauling on the surface; operating air brakes and controls on large hoists; unloading cars; opening bin gates and chutes; running drill steel sharpeners, bit punches; blowing smiths' fires and drill steel furnaces; running pneumatic tools and hoists in the repair shop, etc.

Rock Drilling Practice

One of the most important uses for compressed air in mining is for rock drilling. Since the earliest days of power rock drilling there has been no serious rival of the pneumatic drill. Electricity is particularly adapted for producing rotary motion as in the ordinary motor. Compressed air on the other hand is well suited to the operation of reciprocating mechanism as in the pneumatic drill.

Rock drills are of two general classes, the piston and hammer types. The former is the older and the less frequently used at the present time. In this type of drill the steel is rigidly connected to the piston and moves with it. In the hammer drill, invented by Leyner, the piston is free in the cylinder and literally hammers on the steel while the latter is rotated in the hole.

Hammer drills may also be divided into three general types, viz: the "Jackhamer" or self-rotated hand hammer drill, the drifter or mounted hammer drill, and the stoper or air feed hammer drill.

Hand Hammer Drills

Drills of the "Jackhamer" type range in weight from 21 to 75 pounds and are used for shaft sinking and other forms of down hole drilling, trimming, cutting hitches, block holing and many other forms of work. It requires only a few seconds to mount or demount a "Jackhamer", so that it probably represents the nearest approach to a really universal drill so far made.

Drifters or Mounted Drills

Drifters range in size from 130 to 225 pounds or more and are used for drifting, tunnelling, putting in toe holes, drilling deep down holes and to a limited extent for stoping.

Modern drifters will put down holes to a depth of from 10 to 40 feet, depending on the air pressure and the nature of the rock. The lighter drifters are sometimes provided with cross handles to permit their use as hand drills. Heavy drifters have largely superseded piston drills for use on tripods or quarry bars and are sometimes provided with special tower mountings for deep hole work. Mountings of this type are used in one of the large asbestos quarries in the province of Quebec. For underground use drifters are nearly always mounted on columns or shaft bars. Mountings of this class are quickly set up and allow maximum flexibility in the use of the drill.

Methods of Using Rock Drills

All modern hammer drills use hollow steel and employ the Leyner principle for feeding water or a mixture of air and water through the steel to remove the cuttings from the hole. These drills have been highly developed, drilling speeds of 10 to 22 inches a minute in hard rock, (drilling speed depends on nature of rock and the air pressure) now being possible.

In collieries and soft ore mines, small "Jackhamers" with twisted or auger steels have largely replaced the old style hand augers formerly employed.

For open cut mining and quarrying, "Jackhamers" and large tripod mounted hammer drills are generally

Plate No. 2,—Three little Tugger Hoists installed for hauling a 12,000-pound loaded Car of Rock up a Rock Tunnel driven in the Mine of a large Coal Company.

used at the present time. "Jackhamers" are employed for drilling the benches, block holing, etc.

For large operations on which gasoline or electric-drive churn drills were formerly used, the larger types of hammer drills are now extensively employed for tunnelling, putting in snake holes, etc. In some kinds of open cut work, well drills are used to put down deep vertical holes and hammer drills for running snake or toe holes at right angles to these vertical holes, thus permitting very large faces to be blasted out at one time.

For deep hole work, drilling in badly broken ground, etc., the piston drill is still widely used. One large Canadian deep hole piston drill, using hollow steel, will put down holes 60 feet or more in depth.

Coal Cutters

In addition to "Jackhamers" and other types of hammer drills, compressed air coal cutters are employed in Canadian collieries. These are mainly of the puncher and Radialaxe types. The former is the oldest type of power cutter and a big producer, but is generally limited to use in flat seams with a slight angle. It cannot be used with pitching seams.

The Radialaxe coal cutter is of the reciprocating type, mounted on a column with a simple and efficient swinging gear. It can be used in flat or pitching seams and will cut at any height in the seam. It may be operated in long wall, advancing or retreating systems, in advancing and retreating bord and pillar systems, and can be used for cutting out clay bands, and sulphur balls.

The output of these machines varies considerably, depending on local conditions, the existence of sulphur balls, etc. A time study in an eastern colliery showed that 21 minutes were required to make a 6-foot undercut, 12 feet wide. The initial set up required just five minutes.

In addition to the puncher and radial coal cutters previously described, compressed air driven chain, disc or bar machines are sometimes used. This class of equipment, however, is more often electrically driven. Most of these machines are built for a single class of work, so that it is sometimes also necessary to use radial cutters. The radial type comes nearer to being an universal machine than any other type so far developed and also has the advantage of exceptionally low maintenance cost. In one large colliery using over 300 of these machines, which have been in service for six months to three years, the maintenance cost was found to average less than $1.50 per machine per month.

Drill Steel Sharpening

The high drilling speed of the hammer drill demands steels of the highest quality with properly formed shanks and bits. This necessitates the use of air operated drill sharpening machines, which are now standard equipment in practically all mines, collieries or quarries where hammer drills are used. Compressed air is also used to operate shank and bit punches, steel heating and tempering furnaces, grinders and other equipment used in the blacksmith shop.

The problem of maintaining a good supply of sharp steels at hand for each drill becomes increasingly difficult as mine workings become more extensive. Sharpening shops, are, therefore, sometimes established underground, in order to eliminate carrying the steel to and from the surface for redressing. The difference between sharp and dull drill steels is so marked that an almost unbelievable improvement in drilling speed, increased footage per steel and less wear and tear on the drilling machine invariably follows the use of machine made bits.

The output of the modern drill steel sharpener is from 50 to 100 steels per hour. These machines are also used for many other odd forming and forging jobs around a mine such as heading bolts, car draw heads, coal cutter or chamber bits, and sharpening pick axes.

On all modern drilling operations employing hammer drills, hollow drill steel is used. In shanking or forming the bits, the holes have a tendency to close up so that some method of opening them after working is required. This need is met by the air operated shank and bit punch of which there are several sizes and varieties. Some of these can be attached directly to the sharpening machine or mounted on a pedestal as a separate unit.

Repair and Construction Work

Air hoists of both the direct acting and motor types are used in the repair shops of Canadian metal mines, collieries and quarries.

Pneumatic riveting and chipping hammers, drills, reamers, wood borers, grinders, etc., have many applications in mine repair shops. Concrete breakers, clay diggers, drift bolt drivers and other contractors' tools also prove useful for many classes of mine construction and repair work.

Wood borers and drift drivers are particularly useful in the framing of heavy timber structures and cut down the labour required to a large extent. Compressed air jets for cleaning also form a necessary part of mine repair shop equipment.

Pneumatic Hoist Control

Compressed air readily lends itself not only to the operation of mine hoists, but to the control of large electric hoists as well. Two large electric hoists recently built in Canada and installed in northern Ontario are good examples of this practice. In these hoists the following features are operated entirely by compressed air; brakes, friction clutches, liquid rheostat, motor acceleration control, circuit breaker reset, primary reversing oil switches, primary switch interlocks, reverse protection in case of overwind, emergency stop and brake regulators for emergency stop. So completely are these hoists protected that the operator might even fall in a faint when the hoist was running at full speed, and it would be brought to a stop gradually and properly before reaching the end of its travel. On some hoists the brakes alone are controlled by air. The extent to which air is applied for this class of service is determined largely by local conditions and the nature of the equipment used.

Compressed Air Haulage

Compressed air haulage systems have been carried to a high state of development in Canada. In Alberta and British Columbia a number of two-stage locomotive systems are in use, (see plate No. 1), while in other sections stationary reciprocating air haulage engines are used to operate balanced or main and tail rope systems.

In actual practice compressed air locomotives compare favourably with other types in convenience, efficiency and economy. Their outstanding virtue is the entire absence of fire hazard and of danger from electric shock as well as the avoidance of noxious exhaust gases. The air locomotive is self-contained, and after the laying of track there is no supplementary rail bonding to be done; a particular advantage when the trackage is at best only temporarily needed. Modern air locomotives use air expansively in two-stages and the manufacturers state that, except under unusual conditions, the cost of power to operate is no greater than that required for electric types.

In a paper read before the Canadian Mining Institute in 1916, the comparative cost of compressed air and horse haulage in a coal mine was given as follows:—

	Compressed Air	Horses
Labour	$0.046	$0.072
Supplies	0.017	0.022
Depreciation	0.015	0.015
Total cost per ton mile	$0.078	$0.109

These figures apply to a mine working under the following conditions: Seams pitching 25 degrees or more; pit cars containing two to three tons; rails weighing 30 to 40 pounds per yard; grades fluctuating but little from 0.46 to 1.00 per cent in favour of the loads; gangways roomy; tracks fairly well kept; curves few and slight.

The first air-haulage plant in western Canada was installed nineteen years ago at Coleman, Alberta, by the International Coal and Coke Company, Ltd. The compressor has duplex steam cylinders of 16-inch bore and 24-inch stroke and the air is compressed from atmospheric pressure to a final discharge pressure of from 1,000 to 1,200 pounds. The first and the second-stage cylinders are double acting and the third and the fourth stages are single acting. The air line consists of a quantity of extra-heavy piping, tested to a pressure of 1,800 pounds per square inch; and charging stations are placed at the mouth of the mine and at partings. These charging stations are provided with flexible couplings, so that the locomotives can be charged in a fraction of a minute.

It is now nineteen years since this plant was installed and the compressor and two of the three original locomotives are still in continuous service.

Since this original installation further plants have been installed at Bankhead, Lille, Calmene, Jasper Park and Coleman, Alberta, and at Michel, Hosmer and Corbin, B.C., and there are now in all twelve air haulage installations in use.

Air Operated Column Hoists

In the past five years small air-operated column hoists have been evolved and carried to a high state of development. (See plate No. 2.) These hoists are now obtainable in several sizes and types with single or double drums and for wire or manila rope. They range in size from 2½ to 11 h.p. and in rope pull from 1,000 to 2,400 pounds.

These hoists are now widely employed in coal and metal mines for hauling and switching cars; operating drag scrapers, and loaders; hoisting ore, steel, powder or much in winches and prospect shafts; skidding timbers, etc. Due to their small size and light weight they are easily moved about and quickly set up, and may be used where larger hoists or mucking and loading machines could not operate.

Pumping with Compressed Air

Direct Acting Pumps

Compressed air is often employed for mine unwatering and for station or sump pumping. In the open pit excavations of the Thetford-Asbestos District and in many Canadian mines and collieries air-operated simplex direct-acting pumps are used, mainly for the same reasons that causes compressed air to be employed for hoisting. In open pits or in underground workings, steam cannot be employed on account of the condensation losses during the winter season.

Plate No. 3,—Portable Compressor operating Paving Breaker.

The Application of Compressed Air in Construction and Quarrying

The use of compressed air in construction and quarrying operations in Canada has increased very largely in the last few years due to the construction of large hydro-electric power developments, the opening up of the country, the construction of highways and the general industrial expansion.

For example, the recent Chippawa development at Niagara Falls, carried through so successfully by the Hydro-Electric Power Commission of Ontario, used approximately twenty thousand cubic feet of free air per minute, and employed upwards of five thousand men. This project, necessitating the use of hundreds of compressed air driven rock drills, and pneumatic machines, illustrates the transition from a few pneumatically operated machines to present practice.

Compressed Air in Quarrying

Only a few years ago, the average quarry secured ample production by using a few steam operated tripod drills. Holes were drilled on short benches, and block holing was done by sand blasting or mud capping. Large quarries, operating as cited above, in the days of cheap labour and cheap powder, could produce and market their stone at reasonable prices, but with the general advance in the price of labour, and all other commodities, it was necessary to resort to other methods. Working faces were increased and modern compressed air equipment installed. In many quarries where a deep face is now worked, and where electric driven or gasoline driven churn drills, or well drills are employed for the long deep hole drilling, compressed air cuts costs by driving large hammer drills, for drilling toe holes or snake holes. Small self-rotating Jackhamers are used for block holing, etc. Air is also used for running drill sharpening machines, hoists, etc.

In other quarries where short benches of twenty or twenty-five feet are worked, the installation of air compressors, with modern drilling and sharpening equipment, has increased the output as much as 300 per cent.

The quarrying of brick shale has also profited by the use of compressed air, for, the small self-rotated air driven

"Jackhamer", operated by one man, will in one day give as much footage of hole, as was obtained in nearly one week from the old steam operated tripod drill, manned by two men.

The advent of the gasoline or electric driven portable compressor unit. has enabled the small quarry operator to derive all the advantages from the use of compressed air, which formerly was only enjoyed by the owner of a permanent installation. Small isolated quarry operations can now efficiently use compressed air drills, sharpening equipment, etc., with the added advantage of portability.

Compressed Air in Contracting Field

One of the most notable advances in the use of compressed air has been in the contracting field. Only a few years ago in isolated cases a steam driven compressor was employed by some adventurous contractor, whereas to-day practically every town and city has portable compressors in operation on its streets. The field ranges from large hydro-electric developments to small sewer contracts. For instance, on a very large job now being carried out two 2,000 cubic feet direct connected electric driven air compressors, each driven by synchronous motor, furnish air for rock drills, steel sharpening equipment, pumps, pneumatic tools, and other apparatus. It is not so long ago that steam drills, or drills operated by compressed air produced by steam generated by wood fired boilers would have been employed on a contract of this kind. Thus, while compressed air has long been recognized as most valuable on a large construction job, its scope has become so wide that future large construction work will probably necessitate the use of so much compressed air that the contractor will be compelled to demand the utmost efficiency from his air equipment.

Plate No. 4,—Ramming Sand for small Mold with a Bench Type Pneumatic Sand Rammer in a Canadian Foundry.

The portable gasoline driven air compressor unit has made it possible to utilize many labour saving devices, which previously could not be employed on a small contract, owing to the cost of setting up, tearing down, or moving a permanent compressor plant from place to place. At the present time, no matter how isolated the contract, these gasoline driven compressor units permit a supply of compressed air being available at any given point.

One of the most notable examples of the use of compressed air in speeding up work on small contracts is its application to sewer work. Methods of performing this type of work are now being revolutionized by the invention of the pneumatic clay digger. In many cities storm sewers are being constructed by tunnelling through clay underneath the city streets. Recent performances have demonstrated that the pneumatically operated clay diggers have increased production from 90 per cent to 150 per cent per man, over the old fashioned hand pick. The same thing is true of open cut excavations. This tool when fitted with an extension handle in the hands of an experienced operator will loosen enough ground to keep five or six hand shovellers busily engaged. Should hard rock be encountered the contractor has a supply of compressed air at hand to operate the ever-ready Jackhamer drill.

Another labour-saving device whose use has been made possible by the development of the portable compressor is the pneumatic paving breaker, which is proving indispensable to the cities, contractors and public utility corporations. Such work as repairs to concrete or asphalt pavement, manhole excavation, rehabilitation of street railway system, opening up gas services, etc. can be accomplished now-a-days in one half the time formerly taken, due to the application of compressed air. Plate No. 3 illustrates such a portable outfit.

Erection of steel for bridge repairs and the erection and maintenance of steel transmission-line towers come within the scope of the contractor having portable compressed air equipment. The cutting out of old rivets, replacing rivets, cleaning scale, painting or sand-blasting, no longer cause any worry. Compressed air drives riveting hammers, sandblasts, pneumatic wire brushes and paint sprays.

Another important use of compressed air in connection with construction and repair work is for operating cement guns and placing concrete. In using the cement-gun the concrete mixture called "gunite" is applied as a spray. One of the chief applications of the process is in preserving structures such as dams, bridges, buildings, etc. It is also used for lining reservoirs, tunnels and shafts.

In the pneumatic placing of concrete, batches of concrete are blown from a central point through pipes to the forms. Aggregates up to 4 inches in diameter are used. The process is of special value in tunnel work.

Day by day it is possible to see many unique applications of compressed air in contracting work, for instance, operating pneumatic tools under water on harbour improvement work, operating "Jackhamer" drills in the hands of divers, drilling boulders under water for power development, operating dredge gates, etc.

Foundries and Metal-working Plants

An important part of most machine manufacturing plants is the foundry. Compressed air is so valuable in the foundry, and has so many widely varied uses that it would not be very far from the truth to say that compressed air is just as necessary in the modern foundry as sand.

Air hoists have here quite a variety of applications. There are two types of air hoist, each with a definite field of use. The direct-lift hoist consists of cylinder, piston, — to which the hoisting rod is directly attached,—and valve; and is much the simplest and cheapest form of power hoist, both in first cost and operating expense. The motor type of air hoist has a three-cylinder air motor geared to the hoist proper, the motor being of the same type as is used in the pneumatic drill. The motor type of hoist is not limited in lift as the direct lift air hoist is, and does not require so much head-room. Both types find considerable use in foundry work, the direct-lift type for operating core oven doors, etc., the motor type in operating jib cranes, and on runways to handle moulds, etc.

On the foundry moulding floor there are a number of ways in which compressed air is put to work. The core sand is conveniently sifted in an air operated sand riddle; then there is the pneumatic sand-rammer, which is practically the ordinary hand-rammer operated by compressed air, that is to say, the pneumatic sand-rammer accomplishes the work formerly done by the hand-rammer, but very much more quickly and uniformly. Two types of pneumatic rammer are in use, for bench and floor. The pneumatic sand-rammer for foundry work has demonstrated that it is one of the greatest friends and labour savers of the progressive foundryman to-day. Plate No. 4 shows an application of this type.

In the cleaning department of the foundry the sand-blast has proved of great value. Cleaning is performed by a chipping action, and the thousands of sharp particles of clean sand quickly impart the necessary appearance to the product. Handles and levers that have been sand-blasted are much more pleasant to the touch, and the defects in castings or forgings show very plainly after being cleaned in this way.

Three members of the pneumatic tool family are found working in the cleaning department of the foundry: the pneumatic chipper, the grinder and the wire brush. All three of these are in use to remove fins, smooth down corners, and generally improve the appearance of castings. In steel mills pneumatic chippers are also used to chip out seams in order to discover how deep they may be, and determine whether the billet or forging must be scrapped. The pneumatic chipper is an air-operated hammer, in which the piston moves freely in the cylinder and hammers on the chisel head. The number of blows delivered per minute is in the neighbourhood of two thousand. Pneumatic grinders and wire brushes are operated by a three or four cylinder air motor similar to that used in the pneumatic drill.

In the Machine Shop

Pneumatic tools find two main applications in machine-shop practice — in the vise department, and in assembly. All vise work includes a considerable amount of chipping, and this can, as a rule, be done better by the pneumatic chipper than by hand. In the assembly department, particularly where machines are at all bulky, there is work for pneumatic chippers, grinders, wire brushes and drills. The work of the chippers, grinders

Plate No. 5,—Portable Compressor and Jackhammer Drills on Road Construction Work.

and wire brushes is similar to their work in the foundry, removing fins, smoothing down corners, etc. The pneumatic drill is useful because it is portable. The main drilling is done on the ordinary drill-presses, but as a rule there are some holes that can be more conveniently cut with a small portable pneumatic drill.

Air hoists are used in machine-shop work for serving machine-tools. The direct-lift hoist is best adapted for the medium size tools, and the motor type for the heavier boring mills, etc. The air hoist serving the machine-tool saves a great deal of time, and one man can run a machine without having to call on another for help every time he moves a heavy casting.

The war developed the air-operated chuck and mandrel for lathes, which has since proved valuable on many forms of quantity production work.

In one Canadian machine shop the direct-lift air hoist is used in a rather novel way as a "quick-return" on large lathes. It was found that a four-inch hoist placed horizontally at the back of the machine, and yoked to the carriage relieved the operator of a good deal of hard work with a very little expense.

Shipbuilding

The modern shipyard uses compressed air in very large quantities and the speeding up of shipbuilding that took place during the war was due largely to the increased use of compressed air. Many Canadian yards are equipped with the most modern types of pneumatic equipment.

The largest use of compressed air in shipbuilding is for riveting.

Air hoist, wire brushes, sand blasts, paint sprays. deck caulking machines, etc., are also used in the modern shipyard.

Pumping by Compressed Air

Air lift pumping is now widely used in Canada, the system at the well consisting of two pipes, an air pipe and a water pipe with a few fittings. Air is forced to the bottom of a well and mixes with water, forming a foam of bubbles, which is lighter than the water in the surrounding rock and is forced to the surface by the weight of the water surrounding it. To be successful the air must be thoroughly mixed with the water, and all air lift systems have special mixing chambers in which the air is delivered in very small bubbles. An advantage of air lift pumping is that the water is automatically aerated, which improves it considerably for drinking purposes.

Displacement pumping by compressed air is used to a large extent in chemical plants to transfer acids and corrosive liquids; it is also used for moving liquids containing grit or sand, as there are no moving parts to clog. One of the chief advantages of this system of pumping is that in intermittent service a large volume of liquid can be moved very quickly by using the storage capacity of a large air receiver.

An increasingly important application of compressed air is in the use of air jets for different purposes. Oil and powdered coal are becoming more and more important as fuel for steam boilers. These cannot be successfully used without a special form of burner, which blows the oil or coal into the furnace, at the same time thoroughly mixing it with air. A large number of burners have been patented for both types of fuels, all however, include some form of air jet, using either high or low pressure air. The air jet is also very useful in automobile factories for spraying paint and varnish; a number of large plants paint all their motor cars in this way. In smelters, chemical plants, tanneries, ice and refrigeration plants, textile mills, etc., the air jet is widely used for agitating solutions in tanks, cleaning, aerating, etc. For cleaning electric motors, particularly in dusty locations the air jet has no equal.

Railroads

The principal applications of compressed air in railroad work are for operating signal systems, tie-tampers, pneumatic tools in shops and in bridge and building repairs, paint spraying and sand blasting, etc.

Remarkable savings are made by the pneumatic tie-tamper, two men with one of these tools often doing as much as sixteen men working by hand. Two, four, eight and twelve tool gasoline and electric motor driven compressor cars are used to run the tampers. Many railroads also use portable compressors and tools for bridge and building repairs, etc. Pneumatic tools and hoists are very extensively used in railroad shops.

Miscellaneous Applications

Compressed air, in addition to being used for many of the operations previously described, is also used for special purposes in textile mills, grain elevators, flour mills, chemical plants, breweries, public buildings, saw mills, tanneries, oil refineries, and road work (see plate No. 5).

Acknowledgment

The writer especially desires to thank Mr. G. R. Southee of Toronto, Messrs. Robt. Peele, Frank Richards and the Canadian Ingersoll Rand Co., for their kindness in supplying data which has been included in this review.

Electro-Chemical and Electro-Metallurgical uses of Power

L. E. Westman,

General Manager, Canadian Chemistry and Metallurgy.

The use of electric power in chemical and metallurgical operations is one of the outstanding developments of Canadian industry. No other single factor has had so much weight in deciding the location of many large manufacturing plants. In some cases chemical loads have been developed to convert surplus or off-peak hydro-electric energy into marketable products; in other cases the industry has sought the power. The principal plants, which depend wholly upon electric power for the operation of their processes, are located in the vicinity of low-cost hydro-electric developments at Niagara Falls, Ontario; Ottawa, Ontario; Hull, Quebec; and at Shawinigan Falls, Quebec.

The possible applications of electric energy and what has been accomplished in Canada to date are graphically shown in the accompanying chart. (Table No. I.)* Some of the products of these industries are notable for their novelty and for the high grade of the technical skill that developed successful processes on a commercial basis; others are notable chiefly for the capacities of the units and for quantitative production.

Electric energy is used chiefly for the production of heat or to promote chemical actions or reactions. The heat effects may be applied to the fusion of metals or to the fusion of electrolytes; they may also be utilized in a number of industrial operations where temperatures above the normal air temperature are needed. The chemical effects are obtained either in fused electrolytes or by the use of aqueous solutions of salts.

*Prepared for publication in a Report on the Development of Chemical and Metallurgical Industries in Canada, by Alfred W. G. Wilson, Ph.D., M.E.I.C., Mines Branch, Ottawa, (No. 597, 1924).

Metallurgical Products

Fusion Processes

Prior to 1914 electric furnace development in Canada was relatively small; since that date many large furnaces have been put into operation for the melting of non-ferrous metals and alloys such as aluminum, brass, bronze, and Britannia metal. One plant is equipped with large furnaces for the fusion of copper-nickel matte and an induction furnace for melting nickel anodes. Ferro-silicon, steel, certain steel alloys, and grey iron are also made in electric furnaces in Canada.

The furnaces in use are practically all of the 3-phase arc type, operating at 25- or 60-cycles, alternating current, the capacity varying from 50 k.w. in a few small units to 5,500 k.w. in some of the large ferro-alloy furnaces.

There are 36 electric furnaces for steel installed in Canada, having a total rated capacity per heat of 175 tons, and an approximate monthly capacity for producing 20,000 tons of steel. These furnaces range in rated capacity from one ton per heat to seven tons. There are 10 electric furnaces, installed primarily for the production of low phosphorous pig iron. The total rated capacity of these units is 40 tons per heat, and the approximate monthly capacity for production is 3,000 tons. These furnaces range in rated capacity from one-half ton per heat to six tons. There are also nine large furnaces for the production of ferro-silicon with a total capacity of 40,000 k.w., one for ferro-chrome, and a number of small units installed in foundries for the fusion of non-ferrous metals and alloys.

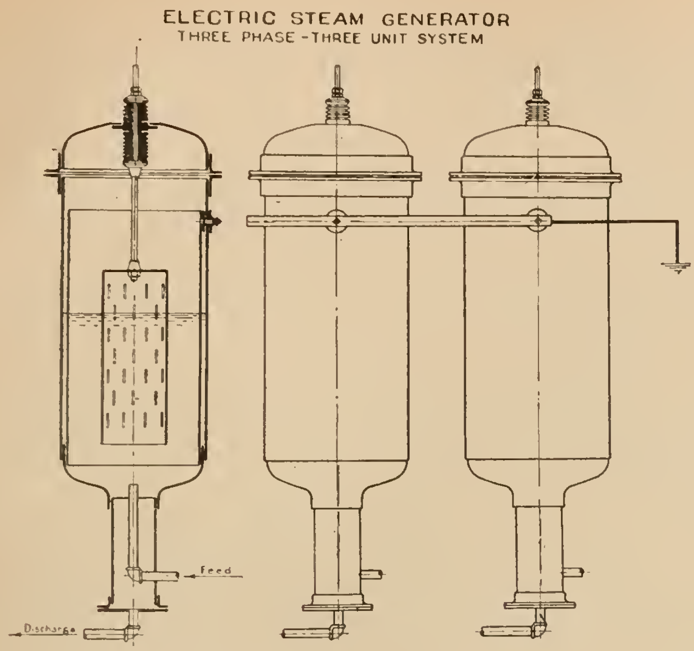

Plate No. 1,—Electric Steam Generator

Electrolytic Process

The following metals are produced by electrolytic processes, the electrolytes being made direct from ores of the metals: — Aluminium, zinc, copper, lead, nickel, magnesium, gold, silver. In addition, the production of electrolytic iron may be foreshadowed when market conditions warrant, because suitable ores are available at sites where the requisite hydro-electric energy is available.

Power Used in Processes

The quantities of power in use in these processes are not definitely known but the following figures are indicative of the extent of its applications in certain plants.

Aluminium

The Northern Aluminum Company at Shawinigan Falls, Que., is using 45,000 horse power for the production of metallic aluminium, the process being the electrolysis of the oxide in a bath of fused cryolite, a sodium aluminium fluoride. The oxide is prepared from the mineral bauxite. In addition, the Cedar Rapids development of the Montreal Light, Heat and Power Company, exports 80,000 horse power to the Aluminum Corporation of America for use at Messina, New York State, U.S.A.

Zinc, Copper and Lead

The following data have been supplied by the Consolidated Smelting and Refining Company, Trail, British Columbia, with respect to the power consumption in their different plants. The power used in the concentrating mill, where ores are prepared for treatment in the electrolytic units, has also been included in the statement.

Zinc Department

Production: 5,535,364 pounds per month.		
Power used for electrolysis 8,056,399 d.c.	= a.c.	9,260,215
Power used for roasters, cottrell, etc.	= a.c.	1,162,607
Zinc plant — Total a.c., k.w.-hours per month		10,422,822

Copper Department

Production: 3,000,000 pounds per month.		
Power used for electrolysis 1,077,000 d.c.	= a.c.	1,230,000
Smelting and converting	= a.c.	700,000
Rod mill	= a.c.	736,000
Total a.c., k.w. hours per month		2,666,000

Lead Department

Production: 7,786,540 pounds per month.		
Power for electrolysis, — k.w. hours per month 650,106 d.c.	= a.c.	747,260
Smelting	= a.c.	1,222,451
Items, transportation, etc	= a.c.	254,293
		2,224,004

Concentrating

1,100 tons per month.		
Power used k.w. hours, a.c. per month	=	667,000
Total power demand in k.w. hours per month, normal operation	=	15,982,000

The British America Nickel Corporation has installed an electrolytic copper refinery at Deschênes, Quebec, which has a rated capacity of about 4,000 tons per annum. A statement as to the power requirements is not available.

Nickel

About 85 per cent of the world's nickel is recovered from copper-nickel ores mines in the Sudbury district, Ontario. Most of the matte to which these ores are reduced is refined by a smelting process due to lack of hydro-electric energy. However, the electrolytic refinery at Deschênes, Quebec, is capable of producing about 7,500 tons of refined nickel annually. The hydro-electric power used in this process is about 6,000 horse power; this will be extended later to 10,000 horse power when additional power now under construction is available. A very considerable quantity of nickel is now exported unrefined in matte; this may later be refined in Canada.

Gold and Silver

Gold is refined electrolytically at the Royal Mint, and at one small private plant. Silver is refined at one private plant.

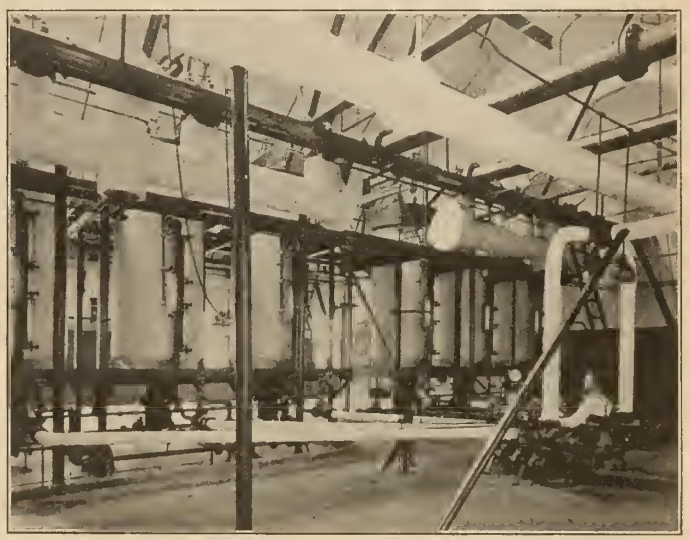

Plate No. 2,—Two Electric Boilers of the Laurentide Company, Grand Mere, Quebec, each 25,000 k.w., 6,600-volt, 3-phase, 60-cycle, 125 pounds steam pressure. Total capacity 150,000 pounds of steam per hour.

Electroplating

Canada is well supplied with gold, silver, copper, nickel, and cobalt, and the electroplating industry is well and widely established, both for custom work and in manufacturing metal appliances.

Chemical Products

Calcium Carbide

This compound is made at four plants. The Canada Carbide Company at Shawinigan Falls uses 30,000 horse power for this purpose; the total power consumption at other points has not been recorded. A considerable portion of the carbide produced at Shawinigan Falls is now converted into acetylene, acetic acid, and acetone through a remarkable series of syntheses. There are also several by-products made at this plant, including acetylene black and a number of organic chemicals. These secondary operations require an additional 14,700 horse power.

Cyanamide

The American Cyanamid Company at Niagara Falls, Ontario, produces and exports very large quantities of calcium cyanamide, all made by direct fixation of nitrogen in suitable electric furnaces. The capacity of the cyanamide works is 60,000 tons per annum. Some sodium cyanamide is also made at this plant. The power consumption in cyanide production is estimated at about 15,000 kilowatt hours per ton of nitrogen fixed. This cyanamide is utilized chiefly in the United States for the production of certain organic chemicals, including urea and concentrated fertilizers.

Phosphorus

Phosphorus is made in Canada at Buckingham, Quebec, chiefly from imported phosphates. The plant is located at this point solely because suitable power is available. The excess power is used for heating purposes.

Abrasives

Carborundum is made at four plants and aluminium oxide abrasives are produced at six plants.

Graphite

Graphite in several forms and graphite electrodes are made in one plant, and anthracite electrodes are produced at four localities.

Nitric Acid

One experimental plant for the production of nitric acid was in operation for a short time in British Columbia. Another plant, to use a new process for the fixation of nitrogen by the use of a rotating arc, is proposed at Merritton, Ontario, in the Niagara district.

Oxygen and Hydrogen

Oxygen and hydrogen are produced by electrolysis of water in Montreal, Toronto, and Winnipeg, about 3,000 horse power being used. Distribution cost is the main factor in regulating the market for these products.

Other Products of Electrolysis

Caustic soda, liquid chlorine, and bleaching powder are produced by Canadian Salt Company at Windsor, Ontario. Hypochlorite bleach is also produced at two wood pulp mills.

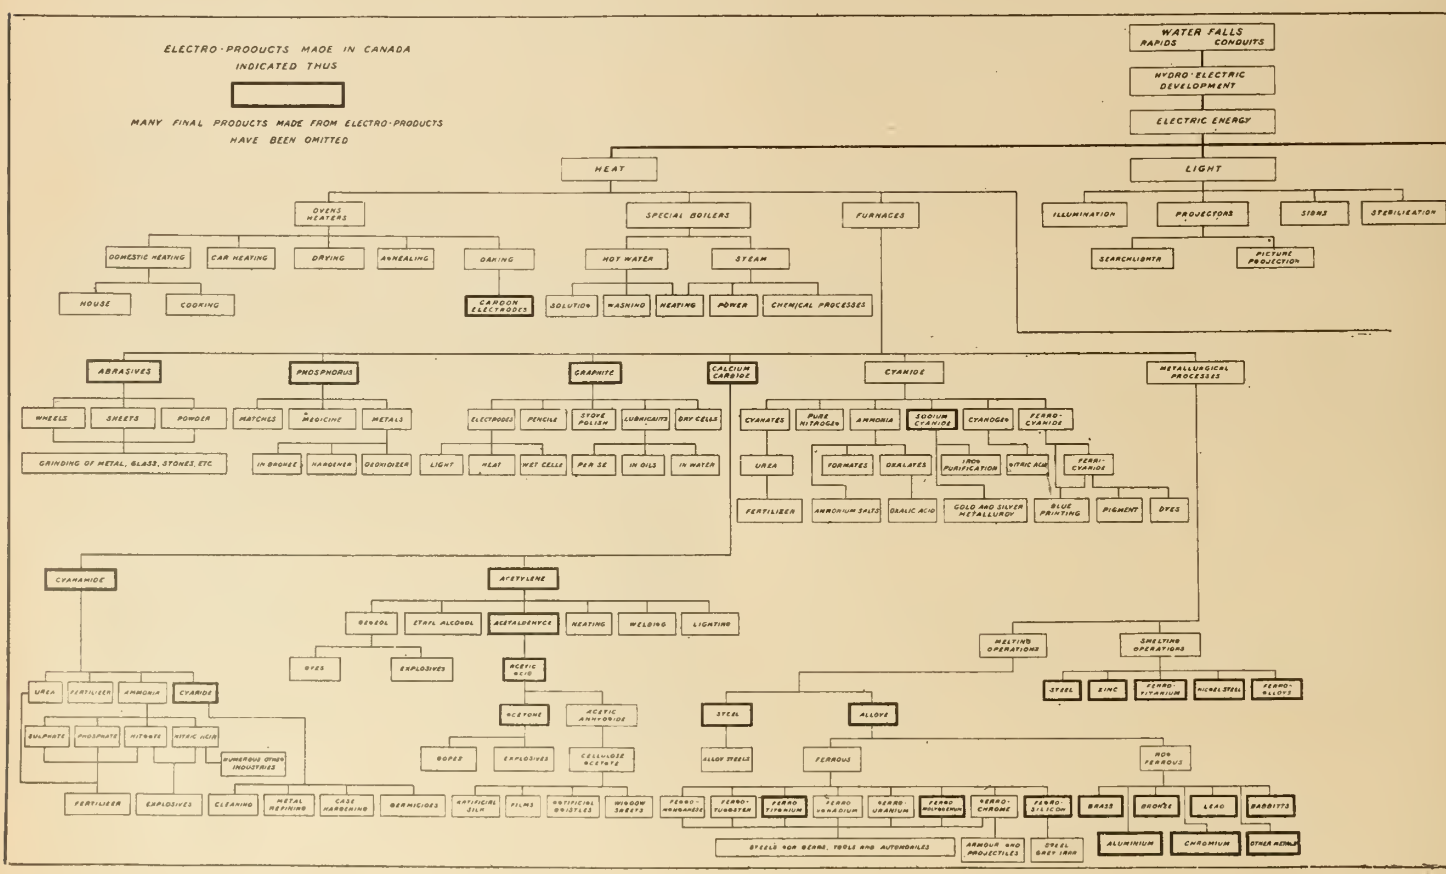

Plate No. 3,—Chart of Electro-Products

Heat Applications

Electric energy is used in a number of industrial processes to develop heat, either in special types of furnaces or for direct local application. A number of plants have installed electric units for core-baking, enameling, and the heat treatment of steels and other alloys. Electric welding appliances, and cutting equipment, are also employed in machine shops where suitable power is available. Surplus power and off-peak power are used for the generation of steam, both for industrial use and for heating at two plants. Heated water has been provided at another plant during the winter months for plant warming.

The most important development in the use of electric power for the production of steam is the installation of the Shawinigan Water and Power Company. The electric boilers used in this installation were designed by F. T. Kaelin, M.E.I.C., chief engineer of the company and the steam is generated for use in pulp and paper mills. There are at present in use 117,000 horse power of these boilers, in units up to 5,000 k.w. each.

These steam generators operate only on surplus power. They are of two types:—(1) Those in which the electric current passes through a combination of metallic resistors and (2) those in which water itself forms the resistance. The metallic type is suitable only for voltages up to 500. The large installations have been of the second type which is in operation on voltages up to 6,600 volts, 3-phase. In this type, the current passes through steam-tight insulating bushings, to a system of stationary electrodes, partly submerged in water.

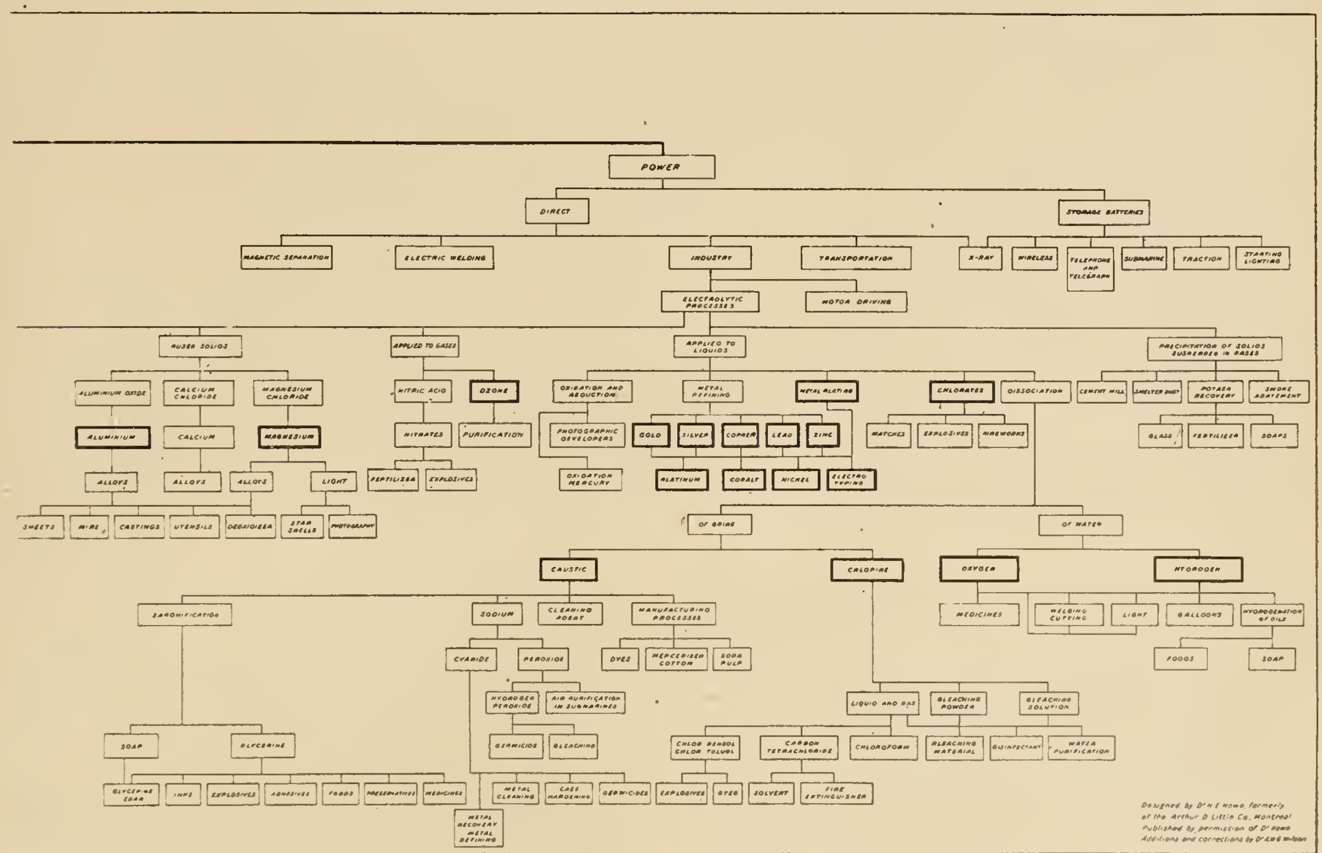
Plates Nos. 1 and 2 show a cross-section through a typical large unit and also a battery of these boilers totalling 50,000 k.w. installed in the Laurentide Company Paper Mill. The voltage in use on the installation noted in plate No. 2 is 6,600 and the installation produces 150,000 pounds of steam per hour.

The introduction of generators of this type in locations where power is available at intervals, and where coal is scarce will form a most economic outlet for large blocks of off-peak power.

Conclusion

It would appear that for the future certain types of chemical industries will find in the use of off-peak power conditions suitable for their development. As equipment for the utilization of peak loads increases, the necessity will increase for the careful development and expansion of industries that will balance in an economic way for the continuous use of all power available. There are also a number of large water powers in Canada, as yet undeveloped, which are located in unsettled districts. In the future these will probably be utilized for the development of chemical industries which require large blocks of continuous power.

Thanks are due officers of the Shawinigan Water and Power Company, Montreal, the Canadian Salt Company, Limited, Windsor, Ontario, and the Consolidated Mining and Smelting Company of Canada, Trail, B.C., for furnishing information concerning the installations of their respective companies. An advance copy of the manuscript of a report on the Development of Chemical and Metallurgical Industries in Canada, by Dr. Alfred W. G. Wilson, M.E.I.C., which will be issued by the Mines Branch, Department of Mines, Ottawa, during the present year, was also made available by the author.



showing those produced in Canada.

Power in Transport

D. E. Blair, B.Sc., A.M.E.I.C.,
Superintendent of Rolling Stock, Montreal Tramways Company.

Section I. Development of Electric Transportation

Early History of Electric Traction in Canada

A study of the history of electric traction will show that Canada was not slow to appreciate the practical possibilities of the early experimental work of European and American engineers before 1880.

It was only about the year of Canadian Confederation, 1867, that it was discovered that an electric generator could drive a similar machine connected to it. Previous experiments were discouraging owing to the expense and limited output of chemical batteries, up to this time, the only means of producing electric current to operate the crude electro-magnetic motors that had been developed.

Although the practicability of electricity as a motive power was demonstrated in Europe by Siemens and Halske in Berlin and Paris in the year 1879 and 1881, it is interesting to note that as early as 1884, a short line was built and operated in Toronto, Canada, as a commercial proposition. This installation ranks as one of the first, if not the first, purely commercial adaptations of the new principle.

In 1886, Van Depoele, the engineer responsible for the Toronto venture, built and operated a line, 1.2 miles long, at Windsor, Ont. The equipment consisted of two cars, each equipped with one 20-h.p. motor. Current was collected, as in Toronto, from an overhead wire with an under-running trolley wheel and return through rails. In 1887, the same engineer built and operated a line seven miles long at St. Catharines, Ont.

In 1891, through the energy and courage of two enterprising pioneers in the electrical field, Messrs. Ahearn and Soper, the Ottawa Electric Railway began operating electric cars on regular schedule in the city of Ottawa. Toronto followed suit in the same year, and the horse-car lines of Montreal were electrified in 1892.

Influences Affecting Development

The severe temperatures and heavy snowfall of the eastern Canadian winter are such that when the operation of street cars was first considered as a commercially sound proposition, very grave doubts were expressed as to the successful operation of vehicles on wheels during the winter months on the streets of Ottawa, Montreal and Quebec. It had been the custom to substitute bob-sleighs or runners under the horse-drawn vehicles in winter.

Very serious trouble was encountered and time schedules were not to be depended upon during the first few winters of electrical operation, but motors and control apparatus rapidly improved and effective means were soon developed to keep the lines clear. It may be stated that, at the present time, none but the heaviest and most protracted storms have any serious effect upon the continuity and quality of the service in the larger eastern cities. Toronto and the western cities have a much lighter snowfall and do not have any serious difficulties in keeping operations normal throughout the winter months.

The general trend of traction development in Canada has followed very closely that of the United States. Being in close contact with this progressive neighbour both geographically and commercially, Canadian operating companies first turned to the American manufacturers for cars and equipment. Satisfactory car bodies could then be built in Canada but features of type and construction were reflected from United States standards. Trucks and motor equipments were at first imported from the same source, but Canadian manufacturers soon showed their ability to supply a satisfactory home-made product. Owing, however, to the close engineering relationship existing between the larger Canadian companies and their United States parent organizations, there has not been any tendency toward a distinctive Canadian type of rolling stock or motor equipment.

Climatic conditions in eastern Canada make it imperative to have every axle motor-driven. For the same reason, there is a tendency toward heavy cars and equipment because of better tractive possibilities on snow-covered rails and a reasonable margin of inherent heat capacity to meet the heavy current demand of operation during bad weather.

Canadian operating men fully appreciate the theoretical advantage of light cars and a high average load factor on small motors, but a survey of all modern cars in Canada will show that other considerations have predominated. It would seem to be a generally accepted principle that continuity of service, freedom from breakdowns and a reasonably long life of equipment windings are more desirable in the end than a possibility of economic savings that seem attractive on paper. Very definite proof of the wisdom of this tendency will be found by comparing the balance sheets of Canadian companies,

Plate No. 1, — Single Truck Closed Car — 1900.

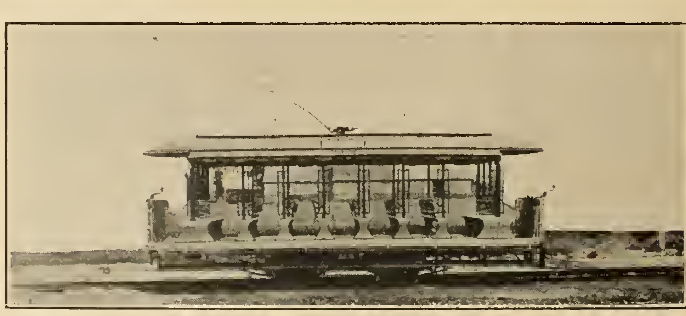


Plate No. 2, — Single Truck Open Car — 1901.

over a period of years, with those of some of the United States properties which have apparently been more progressive and where climatic conditions are much more favourable toward low operating costs.

Urban Tramways

Notes on Development

The population of Canada is at present about 9,100,000. There are seven cities of over 100,000, but outside of these centres, the density of the population is relatively very low as compared with European or eastern United States averages. The opportunities for successful operation of street cars are, therefore, limited.

The larger cities of eastern Canada were quick to take advantage of electric transportation as soon as that method became practicable, about the year 1890. Rapid development of generating machinery and motor equipment followed during the next ten years.

By the year 1900, two types of electric cars had been evolved that were practically the universal standard of American practice. These were the four-wheeled, single truck *closed* car, having longitudinal seats, and the single truck *open* car fitted with wooden slatted cross benches for summer use.

The protection offered by the closed and heated cars was a necessity in winter, but the efficiency and popularity of the open car were so marked that it was the usual practice to have two sets of car bodies for each equipment of trucks and motors. These cars measured about 30 feet overall in length, the closed cars having a seating capacity of about 28 passengers while the open bodies offered from 40 to 45 seats.

The motor equipment usually consisted of two, 25-h.p. series wound motors and the weight varied from 14,000 to 18,000 pounds.

Traffic conditions in the congested parts of the larger cities pointed toward the development of larger cars so as to decrease the number of car units for a given passenger movement. Furthermore, many of the main lines were extended out into more sparsely populated districts. The limited speed of the single truck car did not meet the demands of a satisfactory suburban service. The problem of ever increasing wages improved standards of comfort, safety and reliability; all these considerations had their influence on the development of the double truck car which was in almost universal use by the year 1910.

In the meantime, the use of the highly efficient and economical open car was first discouraged and finally prohibited by various provincial public utility boards. This was principally because of danger to the conductor who had to attend to the collection of fares while standing or moving from seat to seat on an open and unprotected running board along the side of car. The number of accidents resulting from this practice hardly justified the prohibition but the type is now almost obsolete.

The most popular city car in 1910 was known as the double truck, pay-as-you-enter type. The usual dimensions were:

Length overall	42 to 50 feet
Width	8 feet 4 inches to 8 feet 6 inches
Platform length	6 feet to 7 feet 6 inches
Body length	30 feet to 35 feet
Weight	36,000 to 54,000 pounds
Seating capacity	40 to 50 passengers.

This type of car was developed and first used in the city of Montreal in 1904. Its use quickly spread over the whole continent. Its principal feature was that it allowed, without undue delay at loading points, for the collection of fares at the rear end of car. The conductor was then able to supervise the movement of passengers on and off the rear steps and the reduction of accidents was very marked. The movement at front end was under the direct control of the motorman.

Before the year 1910, a very large portion of the street cars in Canada were of wood or wood reinforced with steel plates and angles. Since that time, the tendency has been toward composite bodies having all steel frames and side girders with wood floors, posts and roof, or, in some cases, a car that is practically of all-steel construction with the exception of the floor, headlining and interior finish.

In the larger cities, the large unit is still considered the most desirable type but on the smaller properties, there has been a tendency toward smaller and lighter units preferably designed for one-man operation.

Owing again to climate, it has not been usual to adopt the light standard Birney car so popular in the United States, because of its inability to drive its way through heavy snow. Double floors and heat insulating linings are also considered to be a necessity. The modern Birney car, as used in the United States, weighs from 15,000 to 16,000 pounds and is equipped with two 25-h.p. light weight, ventilated motors. The Canadian equivalent weighs from 16,500 pounds with 25-h.p. motors to 18,000 pounds with 35-h.p. motors.

Trend of Car Design

The controlling factor of modern car design is the saving of time. The constantly increasing volume of automobile traffic in motion and the complementary increase in the number of vehicles "parked" at the curb are making it very difficult to maintain car schedules at satisfactory speeds. Modern life in Canada, as in the United States, demands quick transportation.

The common use of the automobile has changed our ideas of speed. The public demand is for speed of transportation comparable with that of the automobile. The rapid growth of this means of transport is perhaps the greatest hindrance to the free movement of street cars in streets that were once considered broad but are now so obviously narrow.

Plate No. 4, — First Pay-as-you-enter Car, Montreal — 1904.

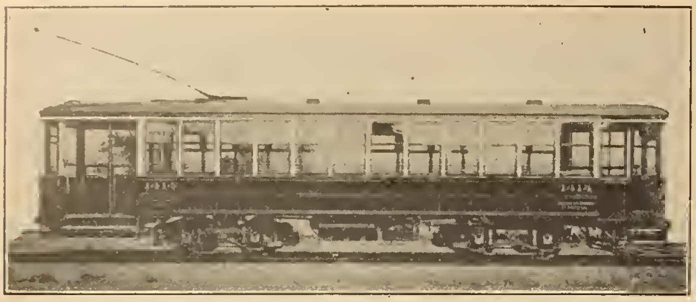

Plate No. 5, — Typical Pay-as-you-enter Car — 1912.

Canadian efforts toward a solution show a strong desire to expedite the loading and unloading of passengers. Maximum practical rates of acceleration and braking, as well as safe maximum speeds, have been reached.

The large rear platform of the pay-as-you-enter car provides sufficient space to accommodate a very large proportion of the groups of boarding passengers that are picked up in a days run. There are, however, congested transfer and initial loading points in every city where certain delays are occasioned by a slowing up of the movement into the car while the conductor is collecting fares, selling tickets, making change and collecting as well as issuing transfers.

The advantage of having the conductor in a fixed position in control of, and in plain view of the doors and steps is so clearly recognized that the next logical step in the evolution of the car is to increase the vestibule space between the street and the fare box.

This feature has been realized in the pay-as-you-pass or "Peter Witt" type of car. This car is usually constructed as a large unit. Its principal feature is that it provides a large space at the front end of car for the accommodation, without delay at fare box, of a rush of boarding passengers at heavy loading points.

Passengers enter a wide door at front end, in a double stream, without interference from descending passengers. The conductor's location is at about the centre of car. In this position he is in plain sight of, and can control the safe operation of doors and steps of the two centre exits while attending to fare collection. While a car is loading at, and after it leaves a crowded corner, the conductor collects fares from and issues transfers to those passengers who wish to enter the rear or "paid" space in the car. These are free to leave car at any time by one of the centre exit doors. Those remaining in the forward area are only required to pay their fare as they pass the conductor, either to reach the "paid" area in rear end of car or to leave directly from a second centre exit door immediately beyond the fare box. Suitable railings are provided to direct all movement in the desired directions.

The car offers great flexibility of operation because in case of a very large crowd entering an empty car at a turning point or at theatres, race tracks, athletic grounds, etc., all doors may be thrown open for entrance and all fares may then be collected as passengers leave the car in small groups.

Certain objections exist, viz.,

First. Opportunity is given for wide abuse of restricted transfer privileges because conductor cannot judge, when collecting a transfer coupon, if passenger was entitled to the use of same at time and place of entry into car.

Second. A part of the advantage gained, at heavy loading points, is offset by the necessary delay in collecting fares at exit, when car stops at heavy transferring points inside the congested area.

Third. What would seem to be an obvious weakness, viz., that passengers without means of paying fare may ride to their destination, has not proved to be a serious factor.

Illustrations of this type of car, as adopted by the new system of the Toronto Transportation Commission, are shown.

A large proportion of the new Toronto motor cars are provided with motor equipment of sufficient capacity to haul fifty-foot trailers during periods of heavy traffic. They may even perform continuous two-car train service on level lines throughout the day. The latest model of trailer has a third centre door. This offers means for loading at the centre as well as at the regular front entrance without interfering with the outward movement of passengers by way of the two regular centre exit doors.

The large number of new cars ordered by the Toronto Transportation Commission are all of the front entrance type. They have, therefore, decided, in order to minimize confusion and delay at loading points, to reconstruct a number of the older pay-as-you-enter cars so that they will also be suitable for front entrance operation.

Multiple Unit Trains in City Service

Experiments with ordinary trailers were made in Montreal in 1913 and 1914. Twenty-five motor cars, weighing 42,000 pounds, and equipped with four 55-h.p. motors, were coupled with twenty-five trailer cars without motors. The trailers weighed 30,000 pounds.

It was found that satisfactory operation, especially during the winter months, was restricted to lines on which the controlling grades were less than six per cent. Since only one of the main routes had grades within these limits and because all detours off this route, in case of blockade, resulted in operation over grades varying from nine per cent to twelve per cent, it was decided to experiment with two-car trains, both cars being equipped with motors and multiple unit control.

The leading car is of the standard pay-as-you-enter type. It is equipped with four 55-h.p. motors, entrance and exit doors at rear and exit door at front. Trailers are equipped with two 55-h.p. motors, with entrance and exit doors at front end only. Both cars are equipped with master controller, main controller, independent systems of air brake with compressor, separate trolley poles and automatic coupling of draw bars and air lines. A semi-automatic electric control cable connection completes the equipment.

Fifty, two-car trains were put into operation in 1917. Their performance has been very satisfactory and twenty-

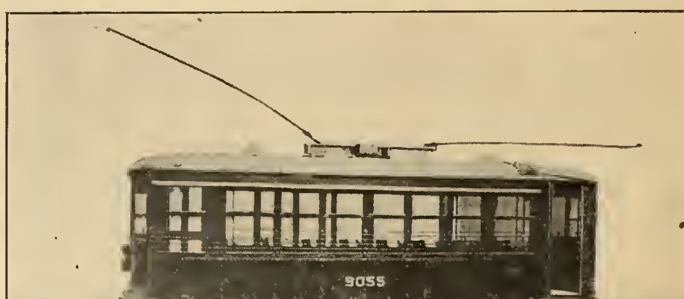

Plate No. 6, — Standard Birney One-man Car.

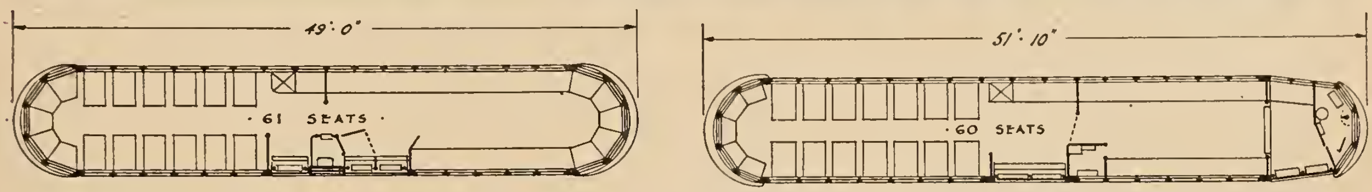

Plate No. 7, — Elevation and Floor Plan of Witt Motor Car with Three-Door Trailer, Toronto — 1922.

five extra trains are now under construction, these to be exact duplicates of the first lot.

The outstanding advantages are:—

First. Reduction in number of separate units on congested tracks.

Second. Reduction in platform operating expense; three men for two cars.

Third. Entrance at rear of motor car in combination with large entrance at front of trailer to provide quick loading facilities at one point thus obviating the confusion and delay that invariably results when entrances of a two-car train are widely separated.

Fourth. Automatic acceleration at a considerably higher rate than practicable with hand control.

Fifth. Flexibility of operation without delay and expense at coupling-up points. Trailer car can be operated to coupling point by conductor of second car and coupled to car ahead within 45 seconds. After performing rush-hour service, trailer can be disconnected at a suitable point without any delay and operated to its berth in car barn by conductor.

Sixth. In case of breakdown of control apparatus on forward car, the train can be operated to nearest car barn from the rear car.

These trains can be stopped and started on grades up to about 12 per cent without difficulty in almost any kind of weather. This is due to the fact that trailer is somewhat lighter than motor car. It has a clean rail for tractive effort and the wheels of the motor-equipped truck carry almost two-thirds of the total weight of trailer.

The maximum power demand of these trains is indicated by the fact that circuit breakers must be set at 480 amps. on the four-motor car and 300 amps. on the two-motor unit, or a total of 780 amps. Normal current during acceleration on level tract at 2 m.p.h.p.sec. is 660 amps. per train with usual full load of one hundred passengers per car or two hundred passengers per train. This is the same current as that required for operating up a 10 per cent grade with motors in parallel.

Power Requirements of Electric Railways in Canada

It has not been found possible to compile complete statistics but the power requirements of the larger cities are shown below for calendar year 1923.

Suburban and Interurban Railways

Opportunities for the rapid development of purely suburban and interurban electric railways in Canada are also limited. The reason is that the more desirable conditions for both agricultural and commercial success are restricted to a relatively narrow belt running east to west and immediately north of the international boundary. As a result of these conditions, the smaller towns have developed along the lines of the three transcontinental steam railways and are, therefore, directly connected with the larger cities and with each other.

Some of the many branch lines of the steam railways have been electrified and present conditions are such that many others can only be operated profitably by the substitution of small units, self propelled by storage battery or oil engines.

Province of Quebec

The electrically operated suburban lines of primary importance are the Montreal and Southern Counties Railway Company and the Montmorency Division of the

	Toronto	Montreal	Winnipeg	Hamilton	Quebec
Car-miles operated	27,250,000	23,261,700	9,574,000	2,963,000	2,424,200
Revenue passengers only	189,143,000	195,707,800	58,253,350	20,963,000	15,721,450
Maximum power demand	31,000 k.w.	40,820 k.w.	12,500 k.w.	2,600 k.w.	3,000 k.w.

Method of car heating	Coal	Electric	Coal	Coal	Electric

NOTES: — (a) Power consumption includes all services such as car heating, lighting, motive power for shops and construction tools and snow equipment in winter.
(b) Maximum demand during winter in Montreal is about 33 per cent higher than in summer.
(c) Average k.w. hrs. per car mile in Montreal during summer — 4.0
Maximum k.w. hrs. per car mile in Montreal during winter — 5.4
Relatively heavy demand due to hilly nature of city, short blocks with excessive number of stops and large proportion of narrow streets where rheostatic losses are abnormal.
(d) All city fares are on a flat rate regardless of distance travelled and number of transfers made to reach destination.

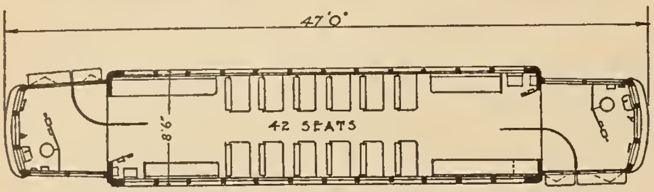

Plate No. 8, — Elevation and Floor Plan of Pay-as-you-enter Car converted to Front Entrance for "One Man" or "Two Man" operation, Toronto.

Quebec Railway and Power Company's system. The former operates about 52 miles of track to various towns between Montreal and the United States border. Twenty-five miles of this total was at one time operated as a steam railway by the Central Vermont Railway Company. There is now a joint steam and electric service over this section. The gross earnings for the year 1922 were $510,662.00. The Montmorency division of the Quebec Railway reports a mileage of 28.60 miles and gross earnings for 1922 of $327,000.00.

Province of Ontario

The principal suburban lines in Ontario are listed below.

Name of Railway	Miles Track	Gross Earnings 1922
Chatham, Wallaceburg and Lake Erie	36.73 d.c. 500 v.	$146,649.00
Grand River	24.36 d.c. 500 v.	377,914.00
Hamilton, Greensby and Beamsville	22.60 d.c. 500 v.	202,371.00
Hamilton Radial	22.86 d.c. 500 v.	188,841.00
Hull Electric Company	16.54 d.c. 500 v.	315,284.00
Lake Erie and Northern	51.00 d.c. 1,500 v.	340,895.00
London and Port Stanley	24.50 d.c. 1,500 v.	564,481.00
Niagara, St. Catharine and Toronto	61.77 d.c. 500 v.	958,089.00
Sandwich, Windsor and Amherstburg	34.75 d.c. 500 v.	574,124.00

Under Construction:—Toronto and Eastern Division C.N.R. 70.0 d.c. 1500 v.

Province of Manitoba

The Winnipeg, Selkirk and Lake Winnipeg Railway has 38.48 miles of track, using d.c. 500-v. power, and had gross earnings in 1922, of $213,741.00.

Province of British Columbia

The British Columbia Electric Railway, besides operating the street railways in Vancouver, New Westminster and Victoria, also operate a very complete and well equipped system of interurban and radial electric lines throughout the Pacific coast area of the province. The line running from New Westminster to Chilliwack, a distance of 64 miles, is the longest electric interurban stretch in Canada. The total interurban mileage is 190 miles, of which 25 miles are on Vancouver Island.

In addition to the carriage of passengers, this company derives a large revenue from the operation of about 425 freight cars and 18 Electric Locomotives.

Province of Nova Scotia

The Cape Breton Electric Company operates 30.59 miles of track in the coal mining and steel manufacturing district of Nova Scotia, and in 1922 had gross earnings of $296,811.00.

High Voltage Traction

A list of the Canadian high voltage systems is given below. These railways do a general passenger and freight business and are operated in much the same manner as the steam trunk lines.

	Lake Erie and Northern	London and Port Stanley	Toronto Suburban Railway	Toronto and Eastern Division C.N.R.	Montrea Tunnel Terminal C.N.R.

Section II. Railroad Electrification in Canada.*

Canada is a country where relatively long distances occur between large centres of population; the cost of electrification therefore between cities is prohibitive at the present time. Schemes have been prepared for the electrification of various sections of the railroads across Canada and there are no physical difficulties to prevent the total electrification.

From a purely operating point of view electrification is very desirable as the power is available and obtainable for practically the whole distance from existing power stations. The bulk of this available power is hydro-electric excepting in the eastern section and the prairie section where ample coal or natural gas exists.

The severity of Canada's winters favours electric operation compared with steam, inasmuch as the capacity of the electrical equipment is increased in cold weather whereas the reverse is the case for steam locomotives.

Outside of suburban electrification referred to elsewhere in this paper, which electrified systems, although built to steam road specifications and carrying on most of the business normally incident to a steam railroad, do not form any part of the main trunk line, there are a few electrifications which have the characteristics of main line railroad operation and operate as part of trunk line systems. These are as follows:—

*Prepared by J. A. Shaw, B.Sc., M.E.I.C., Electrical Engineer, Canadian Pacific Railway, Montreal.

Sarnia Tunnel: This tunnel which extends under the St. Clair river and connects the Canadian National main line tracks in Ontario with those in the state of Michigan on the direct Montreal-Chicago route, was electrified in 1908. The total length of electrification is 10 miles, the system being an overhead trolley, 3,300 volts, single-phase, alternating current. The locomotives are 125 tons, rated at 1,500 h.p. and able to haul 1,000-ton trains up 2 per cent grades at 10 miles per hour.

Montreal Tunnel: The Canadian National Railway operates their system from their Montreal terminal for a distance of some six miles, including the tunnel under Mount Royal, entirely electrically; direct-

Plate No. 11, — Typical Suburban Car — Montreal & Southern Counties Ry.

current, 2,400-volt system is used, 100-ton locomotives taking their service by means of pantagraph collectors from a solid overhead catenary system.

Montreal Harbour: The harbour front, Montreal, has been electrified and 50 miles of track will be put into operation this summer. This electrification will form part of the Canadian National electrification in Montreal and the same 2,400 volt direct system has been installed. Further reference to this electrification will be found in the paper on the "Use of Power for Port Facilities".

As the population of Canada increases and the smaller towns increase, without doubt some main line electrification will take place. Neither Ontario nor Quebec, where the bulk of the railroad mileage exists, has any coal; each of them has very considerable unused reserve in water power. Inevitably, electrification will extend and steam operation diminish.

Section III - Current Practice in use of Electric Power for Tramway Operation

Distribution

Prime Movers

Hydraulic power is the source of nearly all the energy used for traction in Canada. A great proportion of the total is generated by large units at a considerable distance from the 600-volt d.c. substations. General practice as to choice of generator voltage varies widely as elsewhere, a maximum being at about 13,000 volts. In general, the most suitable transmission voltage is much higher than the highest practicable generator voltage and it is therefore common practice to wind generators for 2,300 volts, 25-cycle, 3-phases. This is then stepped up to pressures between 20,000 and 110,000 volts according to distance of transmission.

The Montreal Tramways Company operates a very efficient steam turbine station where power is generated at 13,200 volts in the generator windings. This is tied in with their local distribution trunk lines operated at the same voltage.

Substations

The general practice of electric railways is either to purchase power or to use only a part of the output of a generating station for railway purposes. The only power plants of particular interest in a discussion of transportation are, therefore, the sub-stations where alternating current power is received from one or more sources and there converted to direct current for distribution to the cars.

There can be no fixed rule as to choice of capacity and location of these stations but, since d.c. power at trolley voltages, can only be transmitted economically over a very short distance, it is usual to locate the main distributing point as near the centre of gravity of car movement as is economically possible. More stations are added as necessity or economy requires.

Wide variations will be found in Canada as to type and size of converting units and also as to the means adopted to proportion the load at each station according to its capacity. Rather than attempt to differentiate between the many schemes adopted, it will perhaps be better to give a short description of a typical system of local distribution with which the author is familiar, namely, that of Montreal.

A very complete and interesting description of the development of automatic substations in Canada has been prepared for this report by Mr. F. F. Ambuhl of the Toronto Hydro-Electric System. This will be included in full.

Distribution System - Montreal

Primary alternating current power is purchased under various forms of contract from two power companies who operate six large independent hydro-electric plants. In addition to having these long distance transmission sources of power at their demand, the railway company owns and operates two steam-driven stations. The smaller of these is located at the site of the original steam plant near the centre of the city, which was the only source of supply before hydraulic power was available at a reasonable cost. The present capacity of this station is 3,200 k.w., 600-v., d.c. divided between three small units.

A relatively new steam station has been built at the east end of the city. This consists of:—

Two	1,000 k.w. reciprocating engines,	2,000 k.w.	600 v., d.c.
One	2,000 k.w. " "	2,000 k.w.	600 v., d.c.
Two	12,500 k.w. turbo-generator......	25,000 k.w.	13,200 v., a.c. 3-phase
	Total......................	29,000 k.w.	

The installation of one of the large units is not yet complete.

The steam units up to the present time only produce about 10 per cent of the total kilowatt hours of energy

Plate No. 12, — Modern Substation — Montreal.

Plate No. 13, — Interior View of Modern Substation — Montreal.

consumed, but they serve several very important purposes, as follows:—

First. As a dependable insurance against breakdown or failure of transmission lines.

Second. As a means of maintaining a very high load factor on "horse power per year" and "maximum demand" power contracts. Since the daily "rush-hour" peak load on the tramway system overlaps the commercial load peak, these features are of very great importance. The company is in a position to make favorable 24-hour per day contracts to cover normal demand and can generate a large output to meet peak load demands at a smaller nett cost per kilowatt hour than if it were obliged to contract for an excess of 24-hour power and also pay the usual high penalties for temporary overloads during the maximum demand period.

Third. To meet abnormal demand during snow storms.

The main substation is on Côté street located at almost the exact centre of gravity of load. Outside the central district is a circle of nine substations, each one of which normally supplies the demand of a definite section of the trolley system. All of the stations are ring-connected to the central substation by means of a 13,200-volt, a.c. underground transmission line. A double bus bar system is so arranged at the central distributing station that failure of any of the direct transmission lines, feeding the various substations, can be immediately cor-

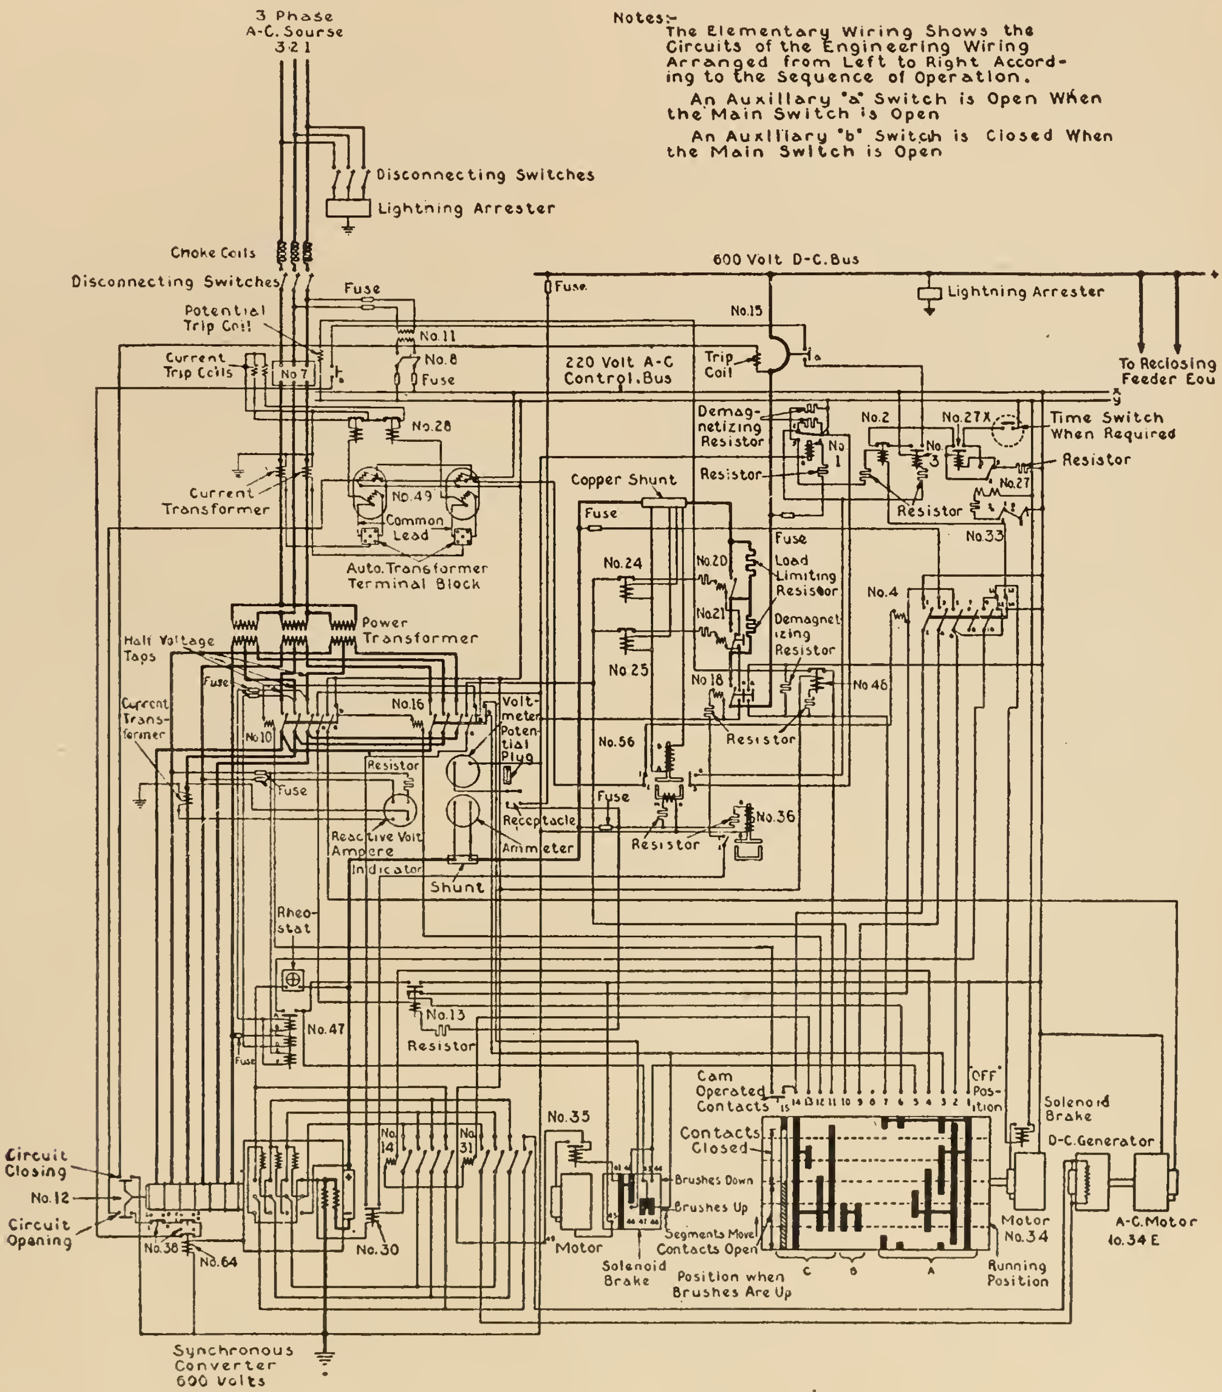

Plate No. 14, — Scheme "A" Wiring Diagram rected. This is done by switching the idle machines on to the intermediate underground feeder system which is energized through the central station from the steam plant. This arrangement also serves to keep the diversity factor of the whole system very near unity because surplus power from any of the substations can, at times, be diverted to an overloaded station.

Purchased power is received under present contracts in various forms, viz.,

600-volt, d.c. (one station only)
2,300-volt, a.c. 2-phase 60-cycle
2,300-volt, a.c. 3-phase 60-cycle
12,500-volt a.c. 3-phase 60-cycle

The a.c. current is converted to d.c. by induction motor-generators, synchronous motor-generators and rotary converters. The synchronous motors serve the useful purpose of regulating the power factor on transmission lines.

Return Circuit

It is customary to take full advantage of rail conductivity and the value of good bonding is fully appreciated. Rail welding is now quite common. Regulations as to definite voltage drop in rails are not so stringent as in Europe but losses are limited as much as is reasonably possible. Through bonding around all intersections is now the regular practice in most cities.

Rail conductivity is supplemented, when advisable, by stranded copper cables bonded to rails at suitable intervals and connected at manholes to underground cables in conduits or to overhead cables carried on the trolley poles at side of street. The track cables are usually laid in wooden box conduits and liberally surrounded with pitch to prevent electrolysis. The practice of running jumper cables to equalize areas of high rail voltage with other areas of low voltage is followed to a limited extent.

Automatic Railway Substations *

The railway converter substation, is an indispensable link in the chain of operations carried on in operating the majority of electric railway systems. This is particularly so where the generating station is too far distant from the load for economic transmission at trolley voltage. Power generation, too, is now carried on by means of much larger units than are suitable for traction work, and the almost universal use of alternating current except for railway, also renders some means of conversion necessary.

An interesting example is the case of Toronto, Ontario, where all of the power used is generated in the hydro-electric plants at Niagara Falls and where the generated voltage of 12,000 is stepped up to 110,000 volts for transmission to Toronto, a distance of approximately 100 miles. In Toronto, this voltage is again stepped down to 13,200 volts for distribution over the city to the different substations. Some of these supply both alternating and direct current power and lighting, whereas others supply direct current to the railway alone.

There are ten substations supplying power to the railway with a total capacity of 31,000 k.w. Of this number, six supply the railway only and two of these are automatic stations. The first of the automatic stations was placed in operation June 20th, 1921, and it is believed to be the first fully automatic station to be operated in Canada. The second was placed in operation December 14th, 1922 and a third automatic station is now under construction and will be placed in operation during the fall of this year. Only synchronous converters are used for railway work, as they are preferable to motor-generator sets for this service, for the reason that the converter has proven its reliability from the operating point of view, while its efficiency including transformers, is from five to eight per cent better than that of a similar motor-generator without transformers. Another feature in favour of the synchronous converter is, when self-started from the alternating current side, it is self-synchronizing, materially reducing the time in restoring service after power failure.

Methods of Control

Three types of control equipment are in use for railway substation work:— (a) Manual control, (b) Remote control, (c) Automatic control.

The three classifications above are given in the order of their development. In the manual controlled station, as the name implies, all switching operations are executed by an attendant. The principal objection to the manually controlled station, is the expense for operating labour, particularly as there is little for the operator to do except start up and shut down.

The high cost of operating the small converter station, led to the development of the remote control station which was introduced about twelve years ago. This type of station was developed out of the manually controlled station and paved the way for the fully automatic station. Along with it, the remote controlled station is showing remarkable progress and is likely to become one of the most popular types.

While it embodies many of the control features now in use in the fully automatic station, starting and stopping together with a number of other operations are performed over control wires by means of control switches in a distant substation.

A number of companies are using this method with certain variations today, and while it is feasible to operate any station by means of control wires for each operation, the manufacturers have developed remote control to a point where any number of switching operations may be performed over comparatively few control wires, usually three, by means of the proper type of supervisory control relays or synchronized switches at sending and receiving points.

The next step was the transformation of the manually controlled to an automatically controlled equipment, and for the same reason as that for the telephone, namely, increasing the efficiency of the station by reducing the operating cost. Just how far-reaching this will be, depends on the saving effected by the installation of this equipment, under different operating conditions. Except for inspection and the usual amount of repairs this type of station requires no manual assistance whatever for its operation.

It is the function of the automatic substation, to perform all the essential duties of the operator which involve starting up the machine at the proper time, connecting it to the line, running under load and shutting down entirely, without manual assistance.

Two general schemes of automatic control are available, one in which a master drum controller initiates the various operations in proper sequence and the other, in which these steps take place through the guidance and control of various relays and interlocks which function according to a predetermined plan, in a step by step fashion, the ultimate results being the same in both cases, namely, that of starting up and shutting down the station

* Prepared by F. F. Ambuhl, Toronto Hydro-Electric System.

as required. These will be referred to as scheme *A* and scheme *B* in this paper.

In both of these schemes it is the general practice to arrange for starting up on load demand which is determined by a suitable contact-making voltmeter and shutting down when the load is reduced to an uneconomical point. In other words, when the trolley voltage is reduced to a minimum amount by the increasing load, a

Panels F and G — D.C. Feeder Panels on which are mounted Automatic Reclosing Circuit Breakers, Time Limit Relays, Reclosing Relays and Time Limit Temperature Relay at bottom of panels.

contact-making voltmeter energizes a relay which starts the sequence of operations for starting up the station.

In place of the circuit breakers opening up and clearing the station, current limiting resistors are inserted between the machine and the machine bus, the amount cut in depending on the severity of the over-load. Should an over-load persist for some time and the resistors tend to over-heat, a thermostat placed in proximity to the resistors operates to shut down the machine. After the resistors have cooled sufficiently, the thermostat circuit is returned to normal and the station will start again on load demand. It was originally the practice to insert resistors in the feeder circuits, as well as in the machine circuits, though many of the later installations use the current limiting resistors only in the machine circuit and short-circuit detector panels for protecting the feeders. Protection is afforded against every possible trouble, electrical or mechanical, thus, the automatic station has a greater amount of assurance against damage from either of these causes, than the manually controlled station.

Automatic stations are arranged for either full automatic operation or for remote controlled starting and stopping. In the latter case, the station can be started up through the use of the oil circuit breaker in the supply station controlling the high tension line or by a pair of telephone wires from any point on the system.

Operation

A brief description of the operating sequence of the two schemes, is outlined as follows: In scheme *A*, a motor operated drum controller is started through the action of a low voltage relay as mentioned above. This causes the high tension breaker to be closed, energizing the transformers and is followed by the closing of the a.c. starting switch, impressing sufficient starting voltage across the rings to bring the machine up to synchronism. When full speed is reached, the converter fields are excited from a small direct current generator, which is driven by the motor on the drum controller. This gives a positive method of obtaining correct polarity. The converter is then connected for self-excitation and the running switch closed, impressing full voltage on the machine and giving normal field excitation. As soon as the machine reaches normal voltage, the direct current line switches are closed, connecting the machine to the line through the current limiting resistors in the machine circuit and if the current taken by the machine is not excessive, the current limiting resistors are immediately cut out. The controller then remains at rest and the converter operates normally on load until the current supplied by the station falls below some predetermined value, when a low current relay operates, starting the controller toward the off position, thus shutting down the station.

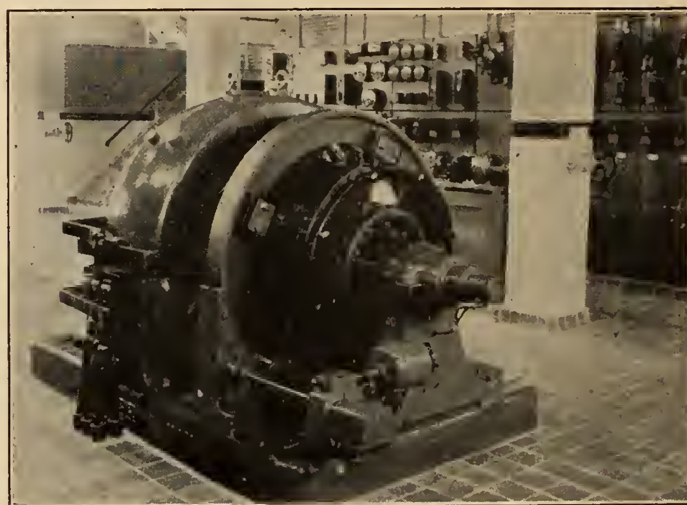

Plate No. 17, — 1,000-k.w. Automatically Controlled Converter and Control Board Described in Scheme "A".

The operation of scheme *B* is briefly described as follows: The rotary transformers are energized through the operation of a low voltage relay and subsequent relays, similarly to the other scheme, after which, the starting contactors are closed and the machine then builds up in speed in the usual manner. During the time interval of starting, the polarity is checked and if found incorrect, is reversed automatically by slipping a pole. This is accomplished by means of a polarized motor relay, driven by a d.c. motor having a permanent magnet field and with the armature connected across the convertor commutator. While the converter is accelerating, the voltage across the commutator is alternating and the relay motor armature merely tends to oscillate. As synchronism is approached, the voltage merges into a direct current potential. The relay armature then revolves in one direction or another, dependent upon the polarity of the machine and turns a drum contactor. If correct polarity is obtained, by the order in which the contacts are closed, the starting contactor drops out, the running contactor is closed and the brushes are lowered. If, on the contrary, the converter builds up with incorrect polarity, the relay armature revolves in the opposite direction and closes a different set of contacts. In this case, the normal field switch is opened and the reverse field switch is closed. As a result, the d.c. voltage dies down and when it reaches zero potential, the reverse field switch is immediately opened and the normal field switch again closed. Polarity usually builds up in the right direction after this operation. But should it fail to do so, the same operation is repeated.

When correct polarity has been obtained, the starting contactor is opened, the running contactor is closed, the brushes are lowered, and the d.c. switches are closed. This connects the machine to the load, through the current limiting resistors which are then shunted out in steps by contactors which close through the functioning of accelerating relays. The machine remains in operation until cut out of service by light load conditions similarly to that of the previously described scheme. The time required for starting, from standstill until the machine is on the line, is from 35 to 60 seconds, depending largely on the acceleration of the armature.

Protective Features

It is most important that provision be made for adequate protection of the apparatus against damage from the numerous causes experienced in operating and especially so in the automatic station. The automatic equipment as supplied affords protection against the following:—

1 Single-phase starting
2 A.C. undervoltage
3 Wrong position of the brushes
4 Incomplete start
5 Under speed
6 Field failure
7 Wrong polarity
8 Reverse power
9 Over heated machine windings
10 Hot bearings
11 D.C. flashover
12 A.C. flashover
13 D.C. overload
14 A.C. overload
15 Overspeed

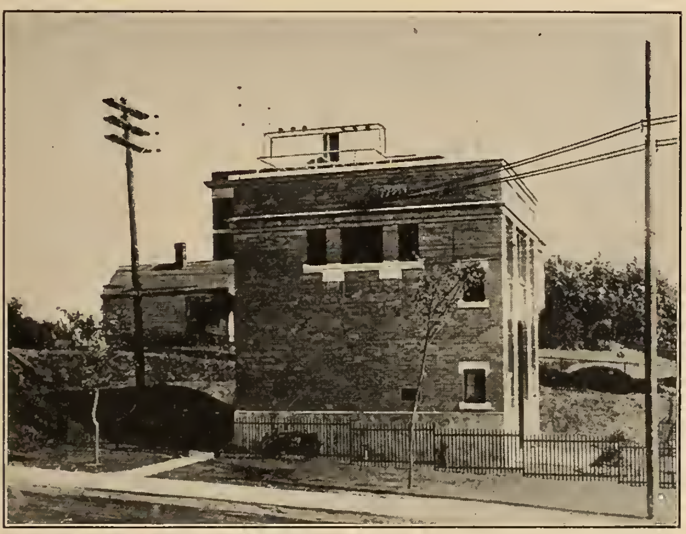

Plate No. 18, — Exterior view of 1,000-k.w. Automatic Converter Substation Toronto — Described in Scheme "B".

The protective features will be discussed in the above order:—

Single-Phase Starting. The possibility of starting the converter on single-phase is protected against by two single-phase relays, the coils of which are connected across the starting taps on the secondary of the power transformer. The contacts of these relays are connected in series with the coil of the starting contactor and in case of a single-phase condition these relays will not close their contacts thereby preventing the starting contactor from closing.

A. C. Undervoltage. The possibility of operating the converter during a period of low a.c. voltage is protected against by an a.c. undervoltage relay. If the voltage is below a predetermined amount, the undervoltage relay prevents the control bus from being made alive, also if low voltage occurs while the machine is operating the converter is caused to shut down.

Wrong Position of Brushes. The proper position of the brushes is assured by the brush operating mechanism. A drum switch attached to this mechanism is electrically interlocked with certain segments on the master drum controller which governs the sequence of switching. If the brushes are not down when the running switch is closed, the drum controller will stop and if after a short period the brushes have not gone down, a relay operates to shut the machine down and wait for an inspector.

Incomplete Start. If the machine starts, but fails to get fully on the line, within a specified time, a time limit relay operates to shut down the machine.

Underspeed. This protection is obtained by a centrifugally operated circuit closing switch, the contacts of which remain open until the converter reaches approximately 95 per cent synchronous speed.

Field Failure. The coil of a relay is connected in series with the shunt field of the converter and its contacts are connected in series with the operating coil of the direct current line contactor. In case of field failure while the machine is operating, the contacts of this relay open, thus opening the coil of the d.c. line contactor. This procedure operates another relay which shuts the machine down to await an inspector.

Wrong Polarity. A d.c. generator, direct connected to the motor used for driving the master drum controller, flashes the field of the machine in order that the converter may come into step with the correct polarity on every start. As an additional precaution, a polarized relay is provided, the coil of which is connected across the positive and negative sides of the machine and must be energized in the proper direction before the d.c. line contactor can close.

Reverse Power. Reverse power protection is obtained in the usual way by a reverse power relay which may be set to operate on a certain predetermined amount of current in the reverse direction.

Overheated Machine Windings. If the machine is running overloaded and the windings become overheated, a circuit opening thermal relay having the same heating characteristics as that of the machine, will open and will

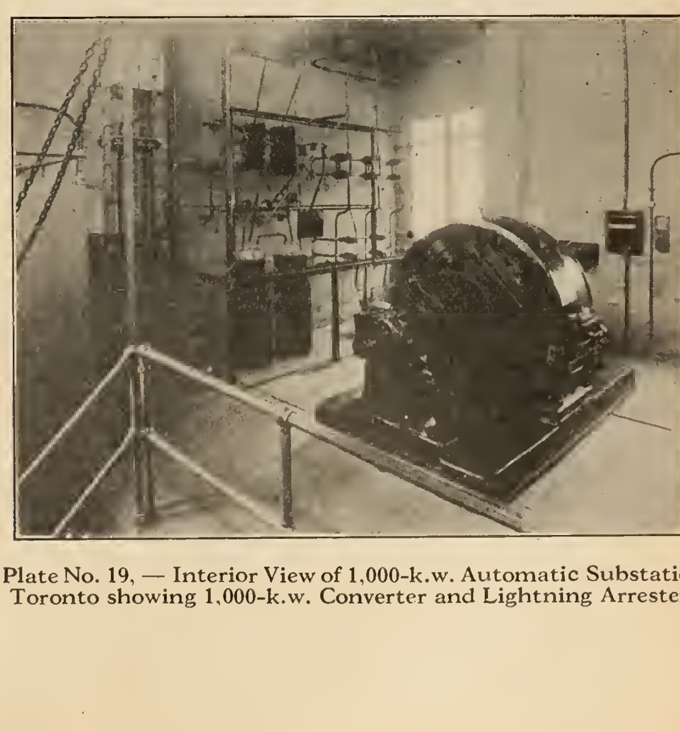

Plate No. 19, — Interior View of 1,000-k.w. Automatic Substation Toronto showing 1,000-k.w. Converter and Lightning Arresters

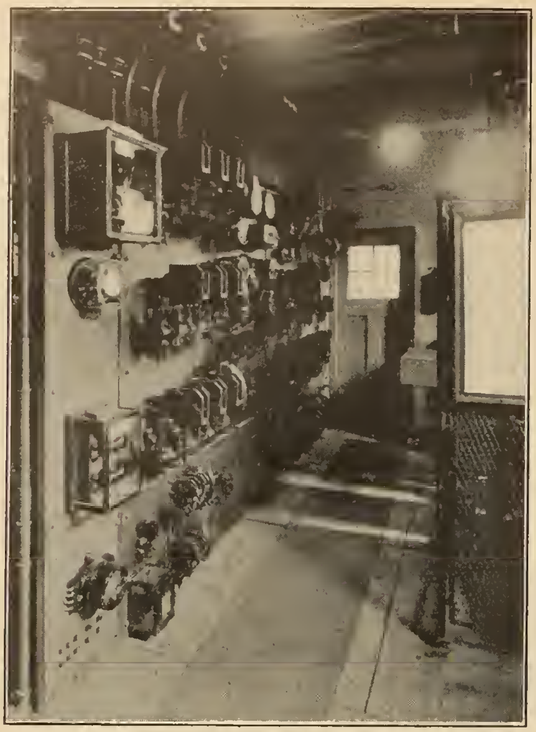

Plate No. 20, — 1,000-k.w. Automatic Control Board in Toronto Described in Scheme "B".

shut the machine down until the machine cools off, after which, it will start up again.

Hot bearings. Protection against hot bearings is obtained by the use of thermal relays consisting of a flexible spun copper bellows connected by a fine copper tube to a metal cylinder. These are inserted in a hole at the bottom of each bearing near the surface of the babbitt where they will be quickly affected by overheating. The bulb and bellows are filled with a non-freezing liquid which has a boiling point of approximately 90° C. In case of hot bearings, the liquid boils and expands the bellows which closes the relay's contacts, tripping the machine out until this relay is again reset by hand.

D. C. Flashover. Repeated d.c. flashover is prevented by a special relay designed for that purpose. It is also a hand reset relay, having a coil of No. 2/0 wire with three-foot leads. It is mounted on the machine frame and connected between the machine frame and ground. When a d.c. flashover occurs, the coil of this relay carries part of the current from the machine frame to ground which causes the relay to operate and shut down the machine.

A.C. Flashing. Flashing protection is obtained by the use of three flashing relays connected to current transformers on the low tension side of the power transformers. The relays are circuit opening and in case of a flashover or short circuit, one of the relays will open its contacts thereby dropping out the control contactor and shutting down the machine.

D.C. Overload. For d.c. overload protection two or more relays are connected by suitable shunts to the d.c. bus and are set to trip in succession as the load increases. When the load on the machine becomes sufficient to trip the first relay it opens a contactor and inserts a section of resistance in the line. If the load increases, another relay will operate to insert another section of resistance in the line. These resistances are designed so that when all are in circuit, the current in the line on short circuit will be limited to a safe value. As the load is removed, the relays cause the resistance to be cut out again in the reverse order and normal conditions of operation are again restored.

The above scheme is intended primarily for heavy overload conditions and a quick acting circuit breaker is used to protect the machine against severe d.c. short circuits that may cause the current to rise to a dangerous value before the resistance described above can be out in. This type of breaker is the fastest device ever developed for opening high capacity d.c. circuits. It starts to reduce the current in .008 of a second and is completely open in .08 of a second. The reduction of current is started in less time than it takes a commutator bar to pass from one brush holder to the other.

The standard breaker takes from .08 to .15 of a second to complete its operation and is too slow to prevent flash-overs.

A.C. Overload. Protection for a.c. overload is affected by the use of two inverse time limit relays connected to current transformers installed on the primary side of the power transformers. When these relays operate, due to overload, the d.c. contactors and high tension switch are opened causing the machine to shut down until started by an inspector.

Overspeed. Protection against overspeed is taken care of by a speed limit device which consists of a centrifugal switch mounted on the end of the converter shaft, similarly to that of the underspeed device mentioned above and trips the d.c. contactor when the speed exceeds 15 per cent of synchronous speed. In this case also it is necessary for the inspector to reset the speed limit device before the machine will start again.

The protective features, outlined above, have reference to the drum type control scheme *A*, though the protective features are similar in both methods of automatic control.

Comparative Cost of Manual and Automatic Stations

From the foregoing, it will be seen that the automatic station requires considerably more apparatus than the manually controlled station. The following shows a comparison between automatic and manually controlled stations without respect to any economies effected in distribution. In other words, these costs are for two stations side by side, one with fully automatic control and the other with manual control.

The data given in these tables is based on prevailing prices in Canada at the time this paper was written. The items making up these tables will be described in the order given.

Buildings. (*Table No. 1, Items 1-A and 1-G.,*) It will be noticed that building costs are only slightly smaller for

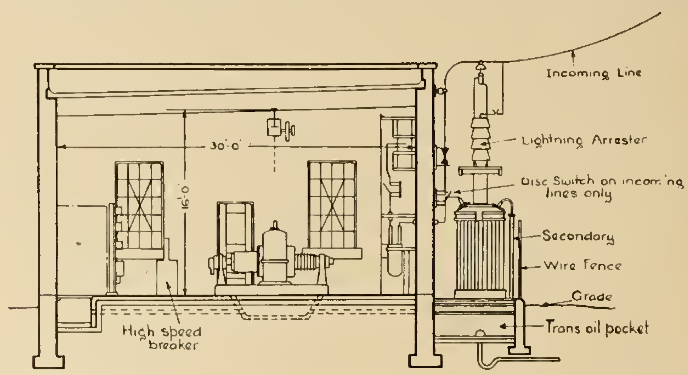

Plate No. 21, — Typical Cross-section of Automatic Station.

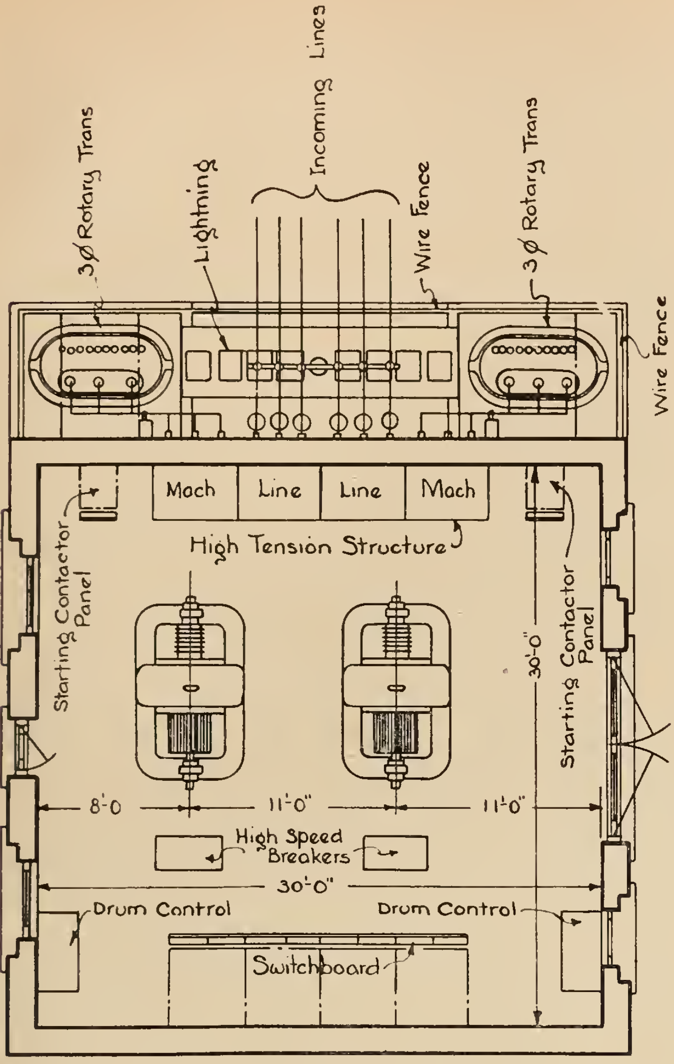

Plate No. 22, — Main Floor Plan of Double Unit Automatically Operated Station.

The type of building considered is one of fireproof construction throughout and of moderate cost, having stock brick walls inside and out, concrete foundations, steel and concrete floors and roof, metal covered doors, steel sash with wire inserted glass and tile coping to walls. Such stonework as is used is confined to door and window trim.

The building on which costs are given under the 1,000-k.w. head is a two unit building and the equipment costs under the same heading are for one machine installed.

Lavatory facilities and service accommodation should be provided in the attended station, while for the automatic type, such facilities are optional. In the smaller sizes, they have been omitted, while in the larger, it is advisable to make some provision in view of the larger amount of construction and maintenance work necessary. It should be emphasized that land costs have not been included.

Lighting and Heating. (*Items 1-B and 1-H, table No. 1.*) These take into account the necessary lighting and heating which is somewhat less in the automatic station than in the manual controlled station.

Switching Equipment. (*Items 1-C and 1-J.*) These items include all switching and connecting material, together with control conduit and wiring. The control conduit and control wiring run into considerably more money for the automatic as against the manually controlled, about six to seven times more, depending on the layout and method of construction used.

Two incoming high tension lines have been considered as forming part of the high tension equipment and their arresters have been assumed as the out-door type, either electrolytic or one of the newer forms of arrester containing no liquid and depending on the breaking down of an oxide film.

The hand operated board, included in the switching costs, has been priced on a basis of one control panel for each feeder, one a.c. panel and one breaker panel for each the automatic as compared to the manually controlled station. Automatic equipment requires the same floor space as does the manual equipment, since while in attended stations more room is required for safety and ease of operation, the accessory equipment such as resistance grids, etc., in the automatic type, counter balance any saving that might otherwise be made. Wherever an automatic station has been crowded into a small area, it will usually be found congested and difficulty will be encountered in the making of repairs and in maintenance. Savings, however, result from less ornamentation and service accommodation.

From the accompanying illustrations, it will be seen that each machine practically takes up the same floor area for the two sizes of stations shown, giving nearly a direct proportion between the capacity of station and its size.

A chain block and trolley have been provided for machinery handling in all stations since this type of equipment results not only in a cheaper building but also in a material saving in cost over that necessitated by a crane of adequate size. The building cost includes the building proper, lavatories in the manual stations, chain block and supporting steel and that portion of the cable pits and ducts usually installed by the contractor, in connection with the concrete work.

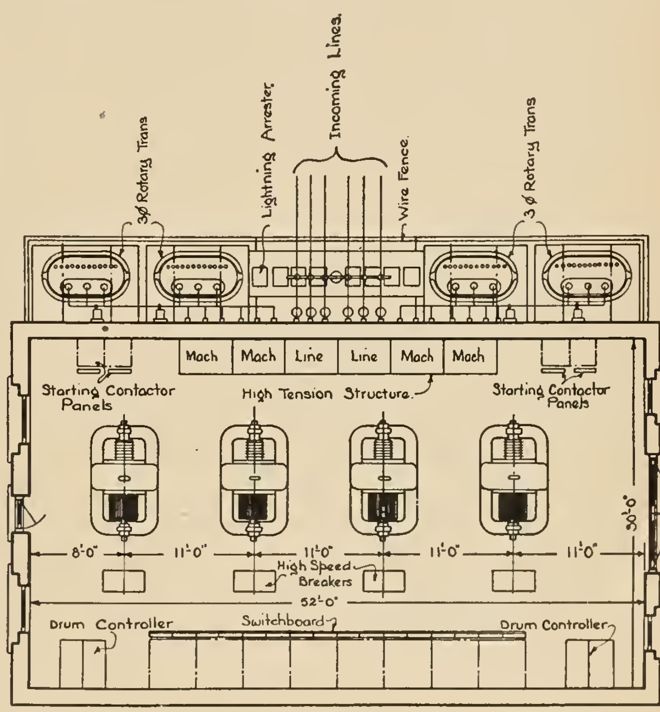

Plate No. 23, — Main Floor plan of 4-unit automatically Operated Station.

Plate No. 24, — Single Truck Snow Sweeper.

machine and three feeder breaker panels for each machine.

The automatic board includes the complete board with relays, starting gear and circuit breakers.

Three feeders per machine, each of 1,250 amperes. capacity have also been assumed.

Transformers. (*Item 1-O and 1-K.*) The transformers have been placed outside, an arrangement originating in the warmer climates and now found quite satisfactory under the more rigorous conditions of the Canadian winter. A catch basin drained to sewer has been provided under each transformer for oil removal in case of fire. The outdoor installation, while resulting in lower building cost also removes a not inconsiderable fire hazard and results usually in decreased insurance rates. The transformers are of the 1,000 kv.a. 3-phase, 13,200-volt primary, 25-cycle, oil-immersed, self-cooled type. They are rated at 150 per cent full load for two hours, following upon a full load run until constant temperature is reached.

Converters. (*Items 1-E and 1-L.*) The converter in all cases has been taken as being one of the standard types of high speed machines, rated at 1,000 k.w. continuous output, 750 r.p.m., 6-phase, diametral, 25-cycle with interpoles and compounding winding. The extra attachments for the automatic converter is included in the cost of switching, item 1-J. Items 1-F and 1-M cover such requirements as painting of apparatus, guards, supplies and equipment not otherwise provided for.

Operating and Maintenance Costs

Table No. 2 covers operating and maintenance costs per kilowatt per year. Operating cost, items 2-A and 2-B, has been based on full time, 24 hours per day, 365 days a year. In the smaller stations, one operator per shift is sufficient but from 3,000-k.w. capacity up, two operators, one first and one second, have been provided.

Inspection and maintenance charges, items 2-C and 2-D, vary with every operating company and with the different types of apparatus used. Those given here are only to be taken as typical of a Canadian city of considerable size. Maintenance material such as brushes, oil, etc., is included.

It will be noticed that this item of inspection and maintenance is considerably higher for the automatic than for the attended station. This has been found to be the case from actual experience.

Comparative Annual Costs

Table No. 3, summarizes in comparative form, the information already given on manual and automatic stations. It will be seen that these costs favour the automatic station throughout, although, for the larger stations, the relative cost of buildings and other factors may throw the balance one way or the other.

The automatic station, in all cases, represents a greater investment and the relative saving will be materially affected by the carrying charges on this investment. A rate of 10 per cent has been taken to cover interest on and repayment of capital charges. Interest is figured at the rate of 5½ per cent and the capital to be wiped out in twenty years. With higher investment charges, the relative annual charges on the automatic station increases.

The most important factor affecting the comparison is that of operator's wages. Referring to table No. 2, it will be noticed that only one operator has been considered for the one and two unit stations, whereas with the three unit or above, two operators have been considered. Where two operators in a one or two-unit station are required by law, or where this is customary, the automatic station will show a still greater saving over the manual controlled station.

From the foregoing, it will be seen that if conditions are such that the building of a substation is warranted, the automatic station especially for the smaller sizes, is more economical than the manually controlled station.

Motor Design and Rating

The design of railway motors in America is fundamentally the same as in European practice. Series wound motors with compensating poles are standard and almost universal practice. Forced ventilation by means of curved vanes integral with the armature end plate is a feature of all motors built for electric traction. Commutators are large and the limits of safe commutation when using a good grade of carbon brush is usually more than 100 per cent greater than the one-hour rating of the motor. Brush holders are rugged and simple and the use of plain clock spring pressure fingers, without pig-tails, is standard practice. Field coils are nearly all ribbon wound and are usually made up in separate layers, graded in size, so as to utilize all available space for windings.

Plate No. 27, — Single Truck Levelling Plow — Montreal.

Special attention is paid to high water, and oil-proofing of insulation on coils because experience has shown that almost any material having high and permanent waterproofing qualities will provide ample dialectric resistance to prevent breakdown under the action of a 600-volt pressure.

The split frame motor has been practically eliminated in favour of the solid frame with end housings. Armature bearings are usually of bronze and are lined with a very thin layer of babbitt metal or "tinning" to provide a soft initial seating for the shaft. Axle bearings are usually of bronze without babbitt lining.

Standard gear practice calls for a very high grade of heat-treated rolled steel of .50 to .60 carbon. Some companies favour a case-hardened gearing for which very long life is claimed but since the life of heat-treated gears, properly lubricated, should be more than fifteen years of continuous service, it is difficult to ascertain the ultimate comparative economy. Both types are highly satisfactory. Helical gearing is also coming into general use, especially on the high speed or light weight type of motor. American practice will likely be standardized on a 7½° angle with a long and short addendum tooth form.

Fears were experienced, at first, that end wear of journal bearings would result from the constant side pressure resulting from the angular meshing of gears. The weight of evidence, so far, would indicate that there is no danger of trouble from this source; also that smoother running and longer life are certain.

Methods of rating motors have changed during the last ten years. It is now the custom to measure the capacity of a motor by its ability to perform continuously under average conditions of service within definite heating limits. Motors are still known commercially by their "One Hour Rating."

It is still necessary to exercise good judgment in making a choice because the inherent heat capacity or ability to stand temporary overloads of the new type of ventilated motor is not as great as in motors of the older type. This feature must be fully considered when equipment may be called upon to haul trailers for a limited period or when overload capacity may be required to meet the operating conditions of heavy winter weather.

Miscellaneous

The usual rates of acceleration as found in actual practice with hand control vary from 1¼ to 2 miles per hour per second. The latter rate requires good judgment on the part of motorman but equipment is usually selected on the higher basis. This rate is equivalent to a tractive effort of 200 pounds per ton under ordinary conditions of city operation. Rate of braking is usually estimated at 2 miles per hour per second on level track.

Owing to the fact that the ultimate capacity for making high schedule speed is usually of paramount importance, there is a strong tendency toward decreasing gear ratios below their most efficient theoretical dimensions. The maximum or free running speeds of cars are therefore considerably higher than is usual in Europe.

When the relatively low cost of power and the higher cost of labour are taken into account, the net result is not as bad as might be expected.

Schedule speeds in city service vary from 8 miles per hour in the congested downtown districts to 13 miles per hour in the more open areas. A usual average for the whole system is about 9 miles per hour.

Section IV. Miscellaneous Use of Power

Compressed Air on Cars

Practically all Canadian street cars are now equipped with air brakes and a large number are fitted with air operated doors and sanding devices. A relatively small number have air operated "line switches" placed underneath the car, the function of which is to open the main motor circuit when power is to be cut off either by means of the controller or upon the operation of safety devices. This feature has the advantage of removing all arcing from the contacts of the controller and overcomes the annoyance to passengers of a circuit breaker operating within the car.

An independent motor-driven air compressor is mounted on each car. The standard unit for city service and for most suburban cars has a capacity of about 15 cubic feet of free air from atmospheric pressure to about 75 pounds per square inch per minute. The motor has a capacity of about 3 h.p. and is series wound for 600 volts. It is started and stopped under load by an automatic pressure governor without rheostatic resistance.

Prevailing practice in regard to maximum brakeshoe pressure varies from 85 per cent to 110 per cent of weight supported by wheel contact when car is empty.

Snow Equipment

The average annual snowfall in the more densely populated parts of Canada varies from about thirty inches in the western and prairie provinces and in southern Ontario to about 140 inches in that part of the province of Quebec in which are situated the cities of Montreal, Three Rivers and Quebec. The task of keeping the tram lines open and in almost normal condition during the winter requires the use of a considerable amount of power for the operation of snow fighting equipment as well as on account of increased rail friction.

The winter conditions west of Ottawa are such that the use of the standard American sweeper is usually sufficient to keep all lines open. Suburban lines in certain districts and on open right-of-way sometimes find it more economical and satisfactory to use nose plows equipped with spreaders in addition to sweepers.

On eastern lines, it has been found advisable to use heavier sweepers with more substantial spreader wings and these units are supplemented with heavy shear plows or levellers having mechanically operated levelling wings from fifteen to eighteen feet long which may be extended outward to a distance of ten to twelve feet from rail.

These wings are usually about thirty inches high and are equipped at their lower edge with removable hardened steel cutting blades. The levellers are both four-wheeled and eight-wheeled types. The former weigh about 30,000 pounds and the latter about 50,000 pounds. Their chief advantage is that they maintain a level hard surface contiguous to the track allowance suitable for vehicular traffic. They prevent the excessive formation of hard packed snow and ice due to the passage of heavy traffic and they push back the ridges or banks of snow that are piled up at a lesser distance from the tracks by the snow sweepers with shorter wings.

The American sweeper is a four-wheeled vehicle consisting of a substantial cab mounted on four cast iron or steel pedestals in which are suitable slides for the spring supported axle boxes. At each end is mounted a rotary broom filled with ¼ inch rattan. These are from five to eight feet long and from thirty-two to thirty-six inches in diameter. They revolve at a speed of from 125 r.p.m. to 400 r.p.m., depending upon the loading of the series wound motor used for driving purposes.

The average sweeper weighs about 24,000 pounds and is equipped with two 50-h.p. motors for propulsion and one 50-h.p. motor for driving the brooms through a chain and sprocket wheel. Some of the later sweepers have been equipped with gear driven brooms. The brooms can be raised and lowered from within the cab and are set at an angle of about 60° to the rails. The four-wheeled sweepers are usually equipped with a short front wing which pulls snow in from the space between trucks and delivers it to the front broom. They also have a short side wing which pushes back accumulations of soft snow to a distance of six or eight feet from rail on the right or curb side of double track.

The more modern sweepers in Ottawa and Montreal are heavy steel structures mounted on double trucks. They are equipped with four 55-h.p. motors for propulsion and two 55-h.p. motors on the brooms. Their weight is about 45,000 pounds and they carry side wings about twelve feet long and thirty inches high. The

Plate No. 28, — Crane Car.

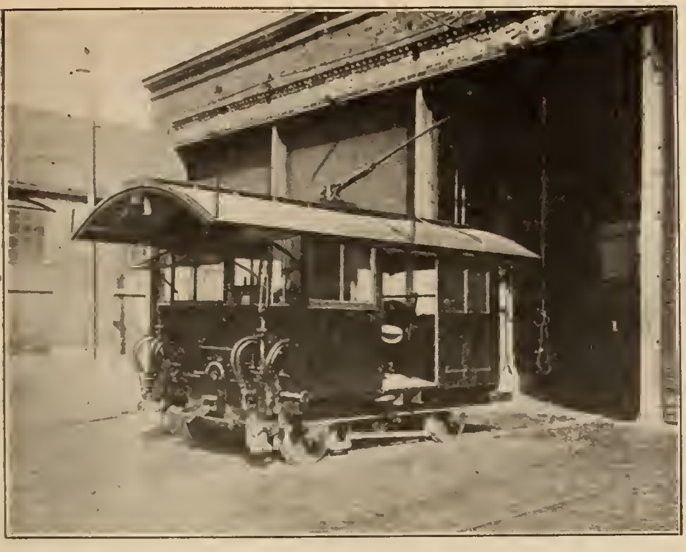

Plate No. 29, — Bond Welding Car.

smaller sweepers operating in fairly heavy snow require a continuous power input of about 125 amperes at 600 volts or 75 k.w. Overloads up to 350 amperes or 210 k.w. are not uncommon. The larger units are often worked up to a maximum load of 700 amperes or 420 k.w. in heavy snow banks and on steep gradients.

All sweepers must be capable of doing effective work at the rate at which normal car traffic moves in city streets, viz., from eight to ten miles per hour.

A small number of rotary plows are in use in eastern Canada. The use of this equipment is only necessary during very heavy and protracted storms or when weather conditions favour continued drifting of snow for some days after a storm. Their use is limited to suburban connections on private right-of-way or along country roads and their most important function is to cut through deep accumulations of snow that would otherwise completely block the traffic. They are usually driven at a slow speed of 6 to 10 miles per hour by four 55-h.p. motors, geared to as low a speed as possible. The rotary knives and ejector blades are about 7 feet in diameter and are driven by two 55-h.p. motors at speeds from about 150 to 200 revolutions per minute. The snow is delivered through a chute at the upper corner of rotor housing with sufficient speed to deposit the snow in powdered form up to a distance of about 40 feet from track.

Shop Machinery and Tools

The usual method of driving shop tools in the smaller shops is by means of a 550-volt, d.c., series wound motor belted to line shafting. In the larger shops, it is usual to adopt a.c., motors with individual machine drive to a large extent although it is common and economical practice to group certain units that are in practically constant operation and to drive these groups by belts connecting to line shafts.

Air Compressors and those machines that are only used intermittently such as wood-working machines, planers, etc., are usually supplied with individual motors. In such shops, the current used is usually 200 or 550, 3-phase, a.c.

Arc Welding is widely used. The a.c. system is very satisfactory for superficial building up operations on armature shafts, axles, etc., but d.c., current is more generally used.

Rivet Heating is very satisfactorily and cheaply done in special machines using a.c., current and suitable transformers.

Baking Ovens for insulating operations are almost always electrically heated.

Electric Soldering Irons and electrically heated retorts for heating of ordinary soldering coppers are in general use.

Portable Tools. Electrically driven drills, reamers, wood-borers and portable grinders are in very common use.

Electric Hoists. Many of the newer car houses and shops are equipped with special car hoists which consist of two parallel I-beams about twenty-five feet long mounted on four substantial screws. Pockets are sometimes provided in floors to house these I-beams when in the "down" position. These I-beams are railed by means of four ball bearing nuts having a worm driven gear at their outer periphery. These are revolved by longitudinal worn shafts driven by a motor and bevel geared cross shaft in pit. They are very highly satisfactory for all car house operations and have practically eliminated the repairing of motors from the uncomfortable and badly lighted pits.

Overhead Cranes. Most shops have adopted the generous use of air hoists on jib cranes but some shops have installed electric hoists on jibs and mono-rails for handling and moving heavy material.

Track Tools

Locomotive Cranes. Modern methods include the use of substantial locomotive cranes for handling special work, braking concrete, loading broken concrete slabs into cars, handling rails in yards, etc. A picture of one of these is shown.

Rail Welding. The usual method adopted by Canadian tramways is to weld special fish plates to head and base of rail, using portable or semi-portable double wound single machines or motor generator sets wound to transform 550-volt, d.c., to about 30-volt, d.c. The machines in general use have a maximum capacity of about 400 amperes, for two welding electrodes. Both the carbon arc and metallic arc are in general use. Carbon welds are made at from 150 to 170 amperes, and metallic welds, at about 200 amperes, using 5/32-inch rods.

Bond Welding. Where bolted fish plates or continuous joints are in use, a very satisfactory machine for obtaining a Thomson weld consists of a small self propelled car on which is mounted a d.c., motor of 30 to 50 h.p. having

Plate No. 30, — Winter conditions on a quiet street — Montreal.

slip rings tapped at back of armature winding for obtaining an a.c., current supply for a step down transformer. The larger machine will weld copper terminals on cables up to 750,000 c.m. This method of bonding is highly efficient and very satisfactory.

Tie Tamping. Compressed air tools are being rapidly introduced for this work. Electric driven air compressors mounted on motor trucks or trailers are used to supply power.

Grinding Rail Joints. It is now general practice to grind off every rail joint, no matter how made, in order that there may be no initial imperfection in the smooth continuity of the rail tread. Electrically driven grinding machines of various designs perform this work cheaply and well. The grinding wheels are given an automatic reciprocating horizontal motion, the vertical adjustments being made by hand.

Section V.—Typical Large Railway Locomotives.

Description of Canadian Pacific Railway Company's Standard Heavy Passenger Locomotive

The passenger trains on the main line of the Canadian Pacific have been handled for the past few years by locomotives of the Pacific type, with driving wheels of 75 inches and 70 inches diameter, to design as illustrated in plate No. 31. This type of locomotive develops a tractive effort of 42,600 pounds, or has capacity to haul the heaviest passenger trains at a maintained speed of sixty miles per hour through the severest winter weather; the average weight of a standard all steel passenger train, consisting of fifteen cars, approximating 800 tons. The main dimensions of the locomotive are given in the accompanying dimension sheet.

Adequate boiler capacity being of prime importance, in order that reserve capacity be always available to permit of successful operation where it is most important that passenger trains be maintained on schedule, and in addition to furnish the heavy demand of steam for heating purposes when the thermometer is below zero and coal frozen and mixed with snow, has led to the boiler, grate area, firebox volume, being made with very ample proportions.

The locomotives are hand fired with fire doors controlled by air operated foot control valves. The locomotive is complete with vestibule type of cab to give locomotive crew the greatest protection through severe weather. The lighting of headlight and cab is carried out by means of a steam turbine driven direct current generator, furnishing power at 34 volts, the headlight projecting a beam of 600,000 candle power. Other specialties include complete superheating equipment, raising steam temperatures 250 degrees over and above normal temperature. The bell is operated by air ringer. Air pump to furnish the heavy demands of compressed air for locomotive and the various auxiliary demands of train apart from the braking, such as for water raising, is furnished by an 8½ inch cross-compound compressor. The reverse gear is of the screw type, permitting of the minimum effort on the part of the enginedriver.

These locomotives are used almost entirely in the hauling of the "Trans Canada", the train operating from Montreal to Vancouver, a distance of 2,900 miles in 92 hours, i.e., the longest and quickest continuous run of any train in the world. Owing to the careful attention given in the design to the proportions and appearance of this locomotive, its power is not as apparent as would be the case where this effect was not achieved.

The following technical description will be of interest.

Table of Dimensions, Weights and Proportions

Railroad	Canadian Pacific
Builder	Montreal Locomotive Works
Type of locomotive	4-6-2
Service	Passenger.
Cylinder, diameter and stroke	25 in. by 30 in.
Valve gear, type	Walschaert.
Valves, piston type, size	14 in.
Maximum travel	7 in.
Outside lap	1 ⅛ in.
Exhaust clearance	¼ in.
Lead in full gear	¼ in.
Cut-off in full gear, per cent	85

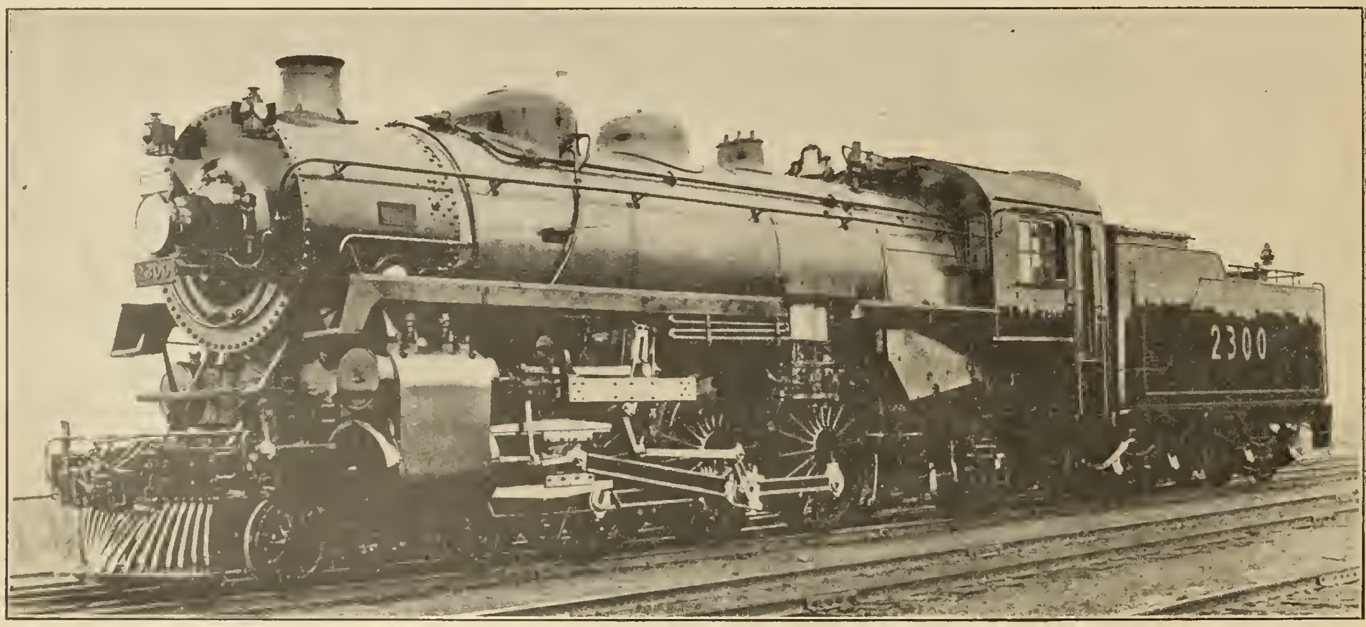

Plate No. 31. — Canadian Pacific Railway Passenger Locomotive.

Plate No. 32, — Largest Locomotive Operating in Canada.

Weights in working order:

On drivers	181,500 lbs.
On front truck	60,000 lbs.
On trailing truck	59,000 lbs.
Total engine	300,500 lbs.
Tender	188,500 lb.

Wheel bases:

Driving	13 ft. 2 in.
Rigid	13 ft. 2 in.
Total engine	34 ft. 9 in.
Total engine and tender	67 ft. 1 in.

Wheels, diameter outside tires:

Driving	75 in.
Front truck	31 in.
Trailing truck	45 in.

Journals, diameter and length:

Driving, main	11½ in. by 21 in.
Driving, others	10½ in. by 14 in.
Front truck	7 in. by 13 in.
Trailing truck	9 in. by 14 in.

Boiler:

Type	St. top-extended wagon bottom
Steam pressure	200 lbs.
Fuel, kind	Bituminous.
Diameter, first ring, inside	78¼ in.
Firebox, length and width	111⅛ in. by 84⅜ in.
Height, mud ring to crown sheet, back	5 ft. 6¼ in.
Height mud ring to crown sheet, front	7 ft. 2½ in.
Arch tubes, number and diameter	5—3 in.
Combustion chamber length	26 in.
Tubes, number and diameter	205—2¼ in.
Flues, number and diameter	38—5½ in.
Length over tube sheets	18 ft. 6 in.
Gas area through tubes	4.6 sq. ft.
Net gas area through flues	3.26 sq. ft.
Total gas area through tubes and flues	7.86 sq. ft.
Air inlet through grates	20.54 sq. ft.
Air inlet to ash pan	9.4 sq. ft.
Grate type	Butt finger, no dump.
Grate area	65 sq. ft.

Heating surfaces:

Firebox and comb. chamber	258 sq. ft.
Arch tubes	40 sq. ft.
Tubes	2,224 sq. ft.
Flues	1,008 sq. ft.
Total evaporative	3,530 sq. ft.
Superheating	830 sq. ft.
Comb. evaporative and superheating	4,360 sq. ft.

Tender:

Style	Rect. water bottom.
Water capacity	8,000 Imp. gal. 9,600 U. S. gal.
Fuel capacity	12 tons.

General data estimated:

Rated tractive force, 85 per cent	42,600 lbs.
Cylinder horse power (Cole)	2,252 h.p.
Boiler horse power (Cole) (est.)	2,293 h.p.
Speed at 1,000 ft. piston speed	44.6 m.p.h.
Steam required per hour	46,840 lbs.
Boiler evaporative capacity, per hour	47,640 lbs.
Coal required per hour, total	7,320 lbs.
Coal rate per sq. ft. grate per hour	112.5 lbs.

Weight proportions:

Weight on drivers divided by total weight engine, per cent	60.5
Weight on drivers divided by tractive force	4.26
Total weight engine divided by cylinder h.p.	133.75
Total weight engine divided by boiler h.p.	131.2
Total weight engine divided by comb. heat. surface	69

Boiler proportions:

Boiler h.p. divided by cylinder h.p. per cent	101.8
Comb. heat. surface divided by cylinder h.p.	1.94
Tractive force divided by comb. heat. surface	9.78
Tractive force × dia. drivers ÷ comb. heat. surface	734
Cylinder h.p. divided by grate area	34.61
Firebox heat. surface divided by grate area	4.58
Cylinder h.p. divided by gas area (tubes and flues)	286
Grate air inlet divided by grate area, per cent	31.6
Ash pan air inlet divided by grate area, per cent	14.45
Firebox heat. surface, per cent of evap. heat, surface	8.4
Superheat surface, per cent of evap. heat. surface	23.5
Tube length divided by inside diameter	110.5

Description of Canadian National Railway Newest Passenger Locomotive

Another notable locomotive is shown in plate No. 32. This is the largest locomotive operating in Canada and it was built at the Canadian Locomotive Company in Kingston, Ontario, and put into service in June 1923 on the Montreal-Toronto run, a distance of 333 miles, which is made without changing the engine. It will pull a passenger train of 15 cars at an average speed of 73 miles per hour.

Among the other leading features of engine No. 6,000, is that it is equipped with everything known to modern railroad practice in regard to safety devices, labour-saving equipment and economy of operation. It has the automatic stoker, which the Canadian National Railways were the first railroad in Canada to adopt, feed water heater, super-heater, power reverse gear and power grate shakers. The fire-box is electrically welded, thereby eliminating riveted seams. The combustion chamber also has the points made by electrical welding. The driving axles and main crank pins are hollow, giving extra strength for the same weight of material:

Apart from its many unique features, engine No. 6,000 will be noted for its new design. The vestibule cab is somewhat shorter than those of other engines, and it has the main steam turrets and connecting pipes located on top of the boiler in front of the cab. There are 16 of these engines now in service and 21 more are on order.

The main technical features are as follows:—

Railroad	Canadian National
Builder	Canadian Locomotive Co.
Type of locomotive	4-8-2.
Class of service	Heavy passenger.
Gauge	4 feet 8½ inches
Cylinder	26 inches x 30 inches
Driving wheels — diameter	73 inches
Boiler — inside diameter — first course	80 ⅞ inches
Boiler — outside " — largest "	90 inches
Working pressure	210 lbs.
Firebox	114 ⅛ inches x 84 ¼ in.
Tubes, No. of 2¼ inches	188
" " 5½ inches	40
Tubes, length	22 feet, 3 inches
Combustion chamber — length	48 inches
Wheel base —driving	19 feet 6 inches
" " — engine	41 feet 9 inches
" " — engine and tender	79 feet 1¾ inches
Weight in working order — engine truck	57,300 lbs.
" " — driving	226,770 lbs.
" " — trailing	54,930 lbs.
" " — tender	239,000 lbs.
" " — total engine and tender	577,000 lbs.
Heating surfaces — tubes and flues	3,731
" " — fireboxes & arch tubes	348
" " — total	4,079
Grate area, sq. ft.	66.7
Maximum tractive power	49,600 lbs.
Factor of adhesion	4.5
Capacity of tender — water	10,000 Imp. gals.
Capacity of tender — coal	17 tons.
Limiting height	15 feet 3 inches
" width	10 feet 8¾ inches
Fuel	Bituminous coal.

Illumination

W. H. Woods,
Chairman, Toronto Chapter, Illuminating Engineering Society.

Illumination in Canada is very largely effected by electricity which is available to about 50 per cent of the population. In districts where electric energy is not available the illuminant is almost always petroleum, an imported product or natural gas which exists in several areas notably at Medicine Hat.

Acetylene derived from calcium carbide manufactured by electric power, is used in a few individual plants and also in river buoys and highway danger signals. (See plates Nos. 1 and 2.) Pintsch gas, a gas derived from oil, is also used to a limited degree for illuminating some of the older railroad cars. Electricity, where available, is installed in over 80 per cent of the homes in Canada, the total number of wired houses being over 1,000,000.

Cost of Lighting to the Consumer

The cost to the consumer for electric light has been consistently reduced as is shown in plate No. 3, based on data compiled by the Department of Labour at Ottawa. It is estimated that the number of kilowatt hours per annum used for the average residence consumer is from 200 to 250. The average cost to the consumer varies with the density of population and the investment necessary to provide the consumer with service, but a fair round figure would be from $10.00 to $15.00 per annum in large cities and from $15.00 to $25.00 per annum in small communities. This amount includes the use of small appliances, irons, toasters, etc., but not cooking or water heating.

Illuminating may be divided under six principal headings:

1. Residences
2. Schools and public buildings
3. Factories
4. Stores
5. Signs
6. Streets.

Residence Lighting

The tendency is always a higher intensity of house lighting and to make more harmonious colour and shade effects. Owing to the intrinsic brilliancy of the nitrogen filled lamps such lamps must always be shaded to prevent direct rays striking the eye.

The lighting of a modern house is well shown in the paper entitled "Domestic Use"; various intensities are in use, from the kitchen which will include a daylight unit of 100 to 150 watts, to the bedroom which will include lights at each side of the mirror, a ceiling fixture, a bedside lamp and other portable lamps as required.

Lighting in Schools and Public Buildings

The standard of illumination is improving all the time, the tendency being to increase the general lighting and do away with individual lamps for specific purposes. From 6- to 8-foot candles at the useful plane is considered a reasonable intensity; it is obtained in various ways, namely, by direct totally enclosed units, semi-indirect, indirect and concealed units. Larger and larger units are required, 300 watt units being quite extensively used.

Factory Lighting

Manufacturers have learned that a high intensity of lighting prevents accidents and permits daylight production to be maintained. Although there is no factory law requiring a minimum standard of lighting such as exists in several states in the United States, it will only be a matter of time until such legislation is enacted in Canada.

Lighting schemes vary with requirements but general lighting has supplanted individual lighting to a great degree and intensities as high as 8-foot candles are used on operations needing close watching. An average condition is represented by 100-watt lamps, suitably reflected, spaced on 10- to 12-foot centres. Blue glass lamps are in general use for colour matching in many textile industries as also in the tobacco industry.

Store Illumination

The merchant, whether he keeps a corner grocery store in a rural town or is proprietor of a mammoth departmental store in a metropolitan city, now knows that light is his best form of advertisement. It enables him to display his goods to the best advantage; it attracts passers-by to look; and everyone who stops to look at a window display or an interior is a prospective customer. The merchants have increased the illumination of their stores from one-half or one foot candle to ten and fifteen foot candles; a fair average being about six foot candles in metropolitan centres where competition is keen, as the customer nowadays does not wish to shop in a dingy, badly lighted store.

Store window lighting has been remarkably improved in the last five years. No longer can the merchant afford to continue low illumination in the store window. The average intensity has increased from ten to fifty and one hundred foot candles in all cases the use of diffusing mediums are recognized. Where high intensities are desired the standard practice is to install the lighting units in suitable reflectors behind a Valency or transparency. Special installations using an intensity of two thousand foot candles exist for the purpose of counteracting mirage on the show window during the daylight. This has become a permanent installation in the large mercantile show windows for emergency use. Stores use general lighting, direct, semi-indirect and total indirect, the average being 100-watt, 200-watt and 300-watt concentrated filament lamps, auxiliary lighting being in the nature of show case lighting where miniature reflectors are in use with 15-watt lamps.

Sign Lighting

During the past few years the electric sign has expanded and every community has one or more signs. In the larger towns and cities the electric sign is very prominent. The growing interest of these signs is evidenced by the building architect including the design of the sign in the building plan in an effort to improve the daytime appearance of the sign. These signs are made up in a large number of styles using 10- to 100-watt lamps. There are almost as many flashing or flickering or running borders and flashing signs as there are still ones. The sign which flashes two or more messages is very popular; signs which obtain curious effects by flashing different colours are quite common; and very effective signs in which the wording drifts by over a bank of lamps are numerous. Building outline lighting has become practically obsolete in this country and there is a tendency of new and beautiful colour effects rather than in greater brilliancy of the light sources in signs. Electric signs will become more extensively used as they become more artistically and architecturally fitting; at present the majority of large signs in daytime are ugly and too frequently offensive to the eye.

Plate No. 1, — St. Lawrence River Buoy.

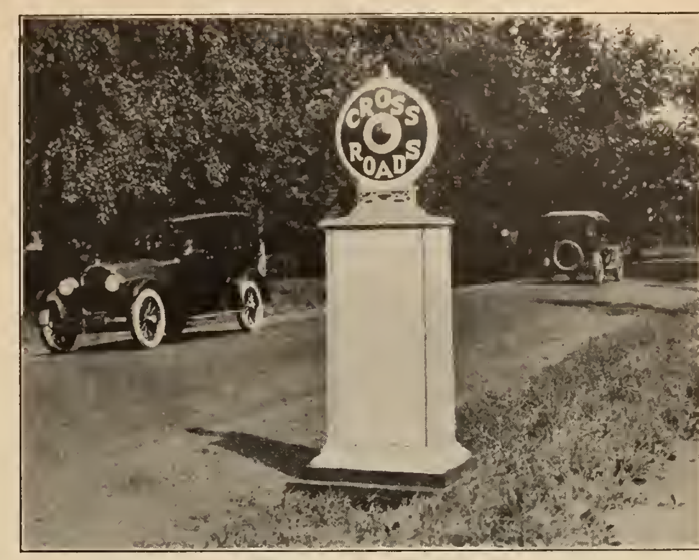

Plate No. 2, — Highway Lighthouse.

Street, Highway, and Canal Lighting

The increased size of incandescent lamps available for street lighting has hastened the retirement of the gas and arc lamps from the streets of the communities. The cluster standard is fast being retired in favour of a single light unit for the latter is a much more attractive architectural design of post, and largely used for "main street" lighting. A distinct change is also noticeable in the character of the glassware, which has expanded from a globular form to the urn-shape, while the tops are covered either with reflector canopies or the glass is so designed as to re-direct light thrown upwards and formerly wasted. Series street lighting circuits predominate; a few com-

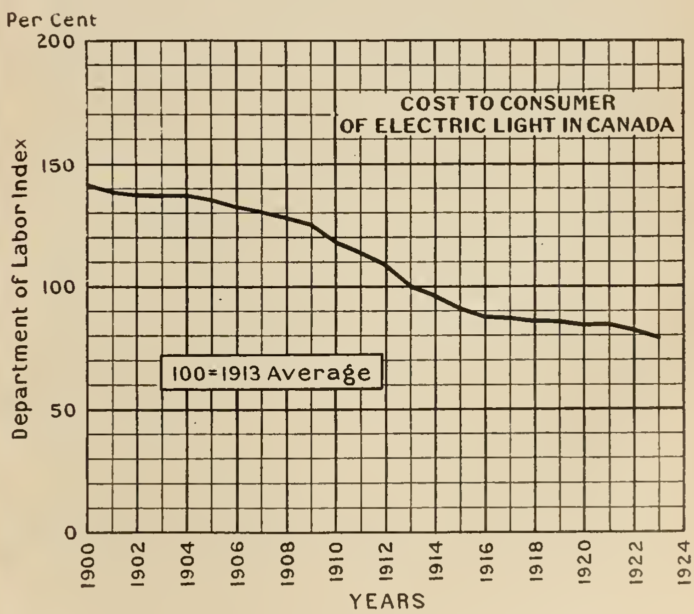

Plate No. 3, — Cost to Consumer of Electric Light in Canada.

munities use the parallel distribution of current. Main streets have an average intensity of one-half foot candles while side streets in best lighting communities have an average of one-tenth foot candles and less. In the metropolitan centres 600-c.p. 20-ampere series units, or

Table No. 1, — Street Lighting Practice in Canada

Town	Type of Unit: Plate No.	Type of Unit: Business Section	Residential Section	Size of Units	No. of Units
Vancouver		5 light units	incandescent	400 & 600 c.p.	. .
New Westminster		5 light units	incandescent	600 c.p.	. .

St. John, N.B.	9	incandescent	incandescent	1,000 c.p. & 100 c.p.	. .

Plate No. 4, — Winnipeg, Manitoba — day view.

Plate No. 5, — Winnipeg, Manitoba, — night view.

500-watt "type C" lamps, spaced 100 feet on each side of the street parallel or staggered, is now common, while for side streets 100-c.p. series or multiple incandescent lamps spaced 100 to 300 feet is the practice. Approximately 95 per cent of the total mileage of the streets of the communities is illuminated.

Table No. 1 shows in some detail the types of lighting in use in the larger cities of Canada.

Arc lighting is gradually being superseded by large nitrogen filled units which are now procurable in 1,000-c.p. sizes; these lamps are operated at 20 amperes from series circuits frequently by means of current transformers stopping up the line current from 6.6 amperes to 20 amperes.

Typical Example of Street Lighting

A typical example of street lighting can be gathered from the following description of the system in Winnipeg:

The city of Winnipeg is perhaps one of the best lighted cities in Canada as far as street lighting is concerned. On the main streets in the downtown section, which are exceptionally wide from building front to

Plate No. 6, — Toronto, Ontario, Sunnyside Boulevard — night view.

Plate No. 7, — Toronto, Ontario, Sunnyside Boulevard — day view.

Plate No. 9, — St. John, N.B. — night view.

building front, there are installed on each trolley pole two 6.6-ampere d.c. luminous arc lamps. On the main thoroughfares through portion of the residential districts the magnetic arc lamp is also used; there being in all 17,000 of these units. In addition there are 1,300 20-ampere 1,000-c.p. series incandescent units, and in the outlying districts 100- and 250-c.p. incandescent lamps are used.

The city of Winnipeg is gradually improving the efficiency of the system by utilizing improved type electrodes for the arc lamps and more efficient glassware. On the incandescent units they are embodying the dome refractor and the outer rippled globe. This brings the incandescent lamp nearer to the standard of the illumination of the luminous arc lamp taking the dead appearance from the lamps by the ripples in the globe, which adds a sparkle to the unit at night and in addition gives the incandescent lamp a whiter appearance which is necessary when used in the vicinity of the arc lamp, which is a very white lamp as compared with the incandescent lamp. In addition to this, with the use of the dome refractor they obtain maximum illumination at about 10 degrees below the horizontal, increasing the intensity on the road surface about 40 to 50 per cent. On all the incandescent units used in Winnipeg they embody the auto transformer enabling the use of the 20-ampere lamp.

General Tendency in Street Lighting

The general tendency in Canada is to increase the intensity, and at the same time install lighting units that will not detract from the general appearance of the street in daytime, but rather improve the appearance of the street in the daytime as well as at night. The tendency is to obtain units which are efficient and which give the maximum illumination for the wattage consumed and not to forget the æsthetic values. Also to obtain the maximum illumination on the road surface, and at the same time to allow a sufficient percentage of light in the upward plane, thus beautifying the general appearance of the street at night. (See plate No. 10.)

Plate No. 8, — Westmount, Quebec — day view.

Plate No. 10, — Peterborough, Ontario — night view.

Plate No. 11, — Calgary, Alberta — night view.

The enormous increase in fast moving vehicle traffic, is making high intensity of street lighting an absolute necessity from the point of view of safety.

A lighting installation in Walkerville which has just been completed is of particular interest. On one of the main highways leading into the city, 75 single highway lighting units, which comprise a nest of reflectors, have been installed. These units are mounted 30 feet high, with a spacing of 325 feet apart, and give even illumination along the highway, making a confined ribbon of light along the highway.

In each unit is utilized a 250-c.p., 6.6-ampere series lamp consuming about 155 watts. The system is fed from pole type constant current transformers, which are automatic and controlled by a season-changing time switch which is electrically wound and which has adjustments on it to open and close the switch at dusk and dawn. This installation marks a new era for highway lighting in Canada and has proven a great success.

Included in this article are to be found the following views:—

Winnipeg, day and night...........	Plates Nos. 4 and 5.
Sunnyside Boulevard, Toronto, day and night.....................	Plates Nos. 6 and 7.
Westmount, day and night.........	Plate No. 8.
St. John, New Brunswick, night.....	Plate No. 9.
Peterborough, night................	Plate No. 10.
Calgary..........................	Plate No. 11.

which show both the type of fixture in use and the appearance of well lighted streets at night.

Recent Developments in Electric Lamps

J. T. Scott,
Sunbeam Lamp Works, Canadian General Electric Company.

The incandescent lamp has kept step with progress in the growth of the electrical industry of Canada. It has been fairly estimated that the present consumption of large lamps for general lighting purposes is about 1.8 per capita. Therefore the demand for incandescent lamps may be placed at about fifteen millions per annum.

There are in Canada approximately one million domestic lighting customers. These customers will average ten lamp sockets per house, with lamps rating at about 50 watts each. The connected load for domestic lighting purposes may be taken at 500,000 k.w.

The million lighting customers represent over four millions of Canada's inhabitants, so we have nearly fifty per cent of the entire population as dwellers in electrically lighted abodes.

Analysis of Demand

The annual demand for incandescent lamps may be divided roughly between the vacuum and the gas-filled types, disregarding the now very small demand for carbon lamps. The consumption of vacuum lamps represents 73 per cent of the demand, and the gas-filled 27 per cent.

There is a very steady trend towards increased demand for the gas-filled lamps as against the vacuum type on account of the higher values in illumination being used both for domestic and industrial lighting. In practically all places where the application of light is carefully studied there is a demand for illumination of higher intensity.

The 25-, 40-, 50- and 60-watt vacuum lamps amount to seventy per cent of the total vacuum lamp demand. The 40-watt size being the most popular, with the 60-watt following closely. In gas-filled types, the 75-, 100- and 200-watt sizes amount to fifty per cent of the total gas-filled demand.

Standard Voltages

Considerable progress has been made in the standardization of voltages. Seventy-five per cent of the lamps used fall within a voltage range of 110 to 120; 115 volts predominating. The remaining twenty-five per cent of the demand is for odd voltages in special areas, private plants, etc.

The advantage of three standard voltages not only enables the dealer to carry a smaller stock and to give prompt service, but allows manufacturing to be standardized for output, higher efficiency, and lower costs. The investment and overhead costs for stock are lower and future improvements are more readily effective and reach the public much sooner than would be the case if many odd voltages had to be carried in stock.

Lamp Rating

The ratings of lamps are now expressed in terms of "lumens per watt", thus permitting any increase in lamp efficiency to be shown by an increase in the number of lumens per watt. A purchaser of lamps is therefore able to easily recognize by the higher figures the lamp having the greatest light output for an equal wattage. The rating of lamps in candle-power without reference to the watts consumed, or the rating in watts without reference to the light output, is not a method which enables the average consumer to purchase the most efficient lamp. Rating in "lumens per watt" is therefore becoming better understood as an indication of lamp value with respect to light output.

Standard Lamp Specifications

The Canadian Engineering Standards Association formed a sub-committee in 1919 to consider a set of specifications for incandescent lamps. The committee included representatives of the various manufacturers interested as well as a number of large purchasers.

The standards were published in October 1923, and as showing the scope of the work we might quote from the preface:

> "The following specification is designed to: (a) Detail the standards and definitions pertaining to tungsten incandescent lamps, the physical and electrical characteristics that constitute good lamps, and the tolerances permissible in their inspection and testing; (b) Provide a scientific and authorative method of determining tungsten lamp quality with respect to mechanical characteristics, lumen maintenance, and life performance; (c) Provide tables of the dimensions and electrical characteristics of the regular classes of tungsten lamps; (d) And thus to afford a technical basis for contracts governing the sale and purchase of tungsten incandescent lamps that will adequately protect both the purchaser and the manufacturer."

The use of these specifications by lamp manufacturers, and their acceptance by the buying public, has done much to eliminate some of the unsatisfactory products made to no standard at all by foreign lamp makers.

This matter of lamps made to a standard specification also has a bearing upon the use of lamps in reflectors of standardized manufacture; the light-center of lamps made in the Dominion being uniform with the correct position in standard reflectors. The lamp makers and reflector manufacturers here working together for uniformity of production and progress by providing lamp and reflector which shall give the maximum value in lighting for industrial purposes.

Lamp Developments

Tipless Lamps

The most important advance in recent lamp development has undoubtedly been the production of the tipless lamp. This is now the standard of manufacture, and lamps of all types for all services are tipless; thus the old style of tipped lamp is entirely superseded. This change necessitated considerable capital outlay to provide for the extensive alterations required in machinery and for new apparatus. The achievement has provided a lamp that is improved in appearance, more rugged in use, and a safer product in transit.

Spray Colour

A colouring material has been produced by the lamp manufacturers which is practically permanent under all conditions. The material is easily applied by a spray process to the lamp bulbs, giving a fine even colouring. The colour will not chip, flake or wash off, and it is unaffected by heat. These features make it possible to provide various colour schemes for indoor or outdoor service by the use of coloured lamps which will retain their initial clearness and beauty of effect. This is an important feature in modern illumination, not only for outside decorative work but in show windows, theatre interiors and stage lighting. In domestic use also, instead of the entire supply of light proceeding from one central fixture or lamp, some coloured lamps individually placed in appropriate fixtures lend charm to the modern living room.

Bowl-enamelling and frosting is also accomplished by means of the spray process. Since the greater use of the gas-filled lamp involves the use of a filament many times more brilliant than that in the older vacuum lamp, a more diffusing finish is necessary in order to cut down the ill effects of glare. By the white spray-coating, the glare is thus modified without any appreciable reduction of transmitted light.

Sign Lamps

Lamps for sign lighting purposes are now made with the coiled, or concentrated, filament, in ring form which ensures greater mechanical strength and increases the end-on, or tip candle-power. This improvement applies to all the sign lamps. It provides a more continuous line of light as reflected by the letter troughs than was secured by the earlier types of lamp.

Street Series Lamps

Owing to the improvement in reflector equipment for street lighting units, higher candlepower lamps have been developed and these are now available for use on 20-ampere constant-current circuits in sizes of 1,000, 1,500 and 2,000 candle power. Prevention of accidents and safe travel on thoroughfares is of such importance that the further advance in the use of these modern units is assured.

Research

Minor developments and improvement of methods are constantly taking place in lamp manufacturing, and while some may seem rather intangible, yet in the aggregate over a period of years they amount to considerable steps in the progress of lamp engineering.

Various Services

Tungsten filament lamps, vacuum and gas-filled, are now specially manufactured for many forms of service, and the Canadian lamp maker is always ready to meet any new demand. Among the wide-spread range of special lamps for particular conditions may be mentioned a few: The railroad signal lamps, operated through track circuit relays from small transformers for semaphore and block signal work; lamps specially developed for light-house service, having a filament which provides correct lighting for the form of lens used; motion picture lamps of all types, from the 30-ampere lamp with heat-resisting glass bulb for regular picture-house work, to the small fourteen volt lamp operated through a transformer for use with the miniature movie picture outfit in the home; and decorative lamps for fancy purposes, including Christmas-tree lamps, spray-coloured and wired eight in series, for use on the house voltage.

Only a very slight indication has been given of the wide demand for lamps for all purposes which go to make up the connected lighting load.

The noticeable increase in the aggregate wattage and lumens serves to show the trend to higher values in general illumination. Increase in efficiency and lamp improvement have played their part in this, besides having had at the same time considerable influence in reducing the cost per unit of light. The reduced cost per unit is a factor in increasing the amount of light used. The increase of light is a stimulant of business in general, it aids the speeding-up of industrial processes, and is a considerable feature in welfare and safety. We have come a long way in half a century, and there is no better measure of civilized progress than the state of development of artificial light and lighting.

The International Joint Commission and the International Water Powers of Canada

The Scope of the Commission's Activities, Its Powers, and Investigations Already Undertaken.

Lawrence J. Burpee, F.R.S.C.,
Secretary for Canada of the International Joint Commission.

Of all the natural resources, remarkable as much for their variety as their extent, with which nature has endowed the Dominion of Canada, none is of more permanent value than its water powers. Coal beds however vast must some day become exhausted. So must oil wells and iron and other mineral deposits. Forests are gradually cut down, and even the products of the soil diminish with its fertility. Water power alone is inexhaustible. As long as rivers run it will remain possible to harness them and use them for the benefit of mankind.

Water Powers along the International Boundary

The water powers of Canada form one of its greatest assets, and not the least important are those that lie along the international boundary, within economic reach of nearly all the principal centres of population of the country. These international water powers, owned jointly by Canada and the United States, represent approximately 8,000,000 horse power, more than the total water power of any country in Europe.

To appreciate the extent of territory served by these international water powers, it must be remembered that eighteen hundred miles of the boundary between Canada and the United States run through waterways. The boundary starts in Passamaquoddy bay, on the Bay of Fundy, and runs up the St. Croix river to its upper waters. Then it strikes overland until it reaches the St. John river near Grand Falls. It then follows the St. John and the St. Francis rivers to a small body of water known as Boundary lake. From there it again runs overland to the upper St. Lawrence, at the head of lake St. Francis, about sixty miles above Montreal. From this point the boundary follows that extraordinary system of waterways known as the Great Lakes, up the St. Lawrence to lake Ontario, from that lake up the Niagara to lake Erie, then up the Detroit river, lake St. Clair and the St. Clair river to lake Huron, from lake Huron up the St. Marys river to lake Superior, and from the latter lake up Pigeon river to the height of land and through an intricate series of small lakes and streams to Rainy lake, Rainy river and the Lake of the Woods. The water boundary ends in what is known as the North West Angle of the Lake of the Woods. From these it goes due south until it reaches the 49th parallel, and follows that line west to the Pacific.

Waterfalls are found on all these rivers, but the largest and most valuable, from the point of view of power, are those on the St. Marys river at the outlet of lake Superior, on the Niagara river, and on the upper St. Lawrence. The total drop from lake Superior to the sea is something over 600 feet, of which 20 feet are at the outlet of lake Superior, 325 feet on the Niagara, and 220 feet between lake Ontario and Montreal. The real value of these international water powers must be measured, as has already been suggested, not so much by their actual extent as by their nearness to large and rapidly-increasing centres of population and industrial development on both sides of the boundary. The proximity of basic raw materials and unrivalled transportation facilities both by land and water has already transformed the Great Lakes region into one of the most important industrial areas of North America, and it is inevitable that when all the available water powers have been brought into service it will become one of the greatest industrial regions of the world. From that point of view the value of these international water powers is almost incalculable.

Creation of the International Joint Commission

Recognizing their present and prospective value, and the importance of conserving them for the benefit of the people of both countries, Canada and the United States entered into a treaty with this as one of its principal objects. This treaty, signed at Washington in 1909, was designed to "prevent disputes regarding the use of boundary waters and to settle all questions which are now pending between the United States and the Dominion of Canada involving the rights, obligations, or interests of either in relation to the other or to the inhabitants of the other, along their common frontier, and to make provision for the adjustment and settlement of all such questions as may hereafter arise".

This treaty created what is known as the International Joint Commission, a body consisting of three members appointed by His Majesty the King, on the recommendation of the Canadian Government, and three appointed by the President of the United States, and endowed it with extraordinarily wide powers.

The mere fact that the commission consists of an equal number of Canadians and Americans, without an umpire or any provision for a casting vote, is significant of the spirit in which the treaty was conceived and the commission created. That spirit has indeed been the keynote of the commission's activities since its establishment, its members endeavouring to approach the varied and important questions brought before them, not as two more or less antagonistic groups jockeying for advantages, but on the contrary as a judicial tribunal pledged to give its best possible judgment, with the utmost impartiality, to the settlement of problems that arise sometimes on one side of the boundary and sometimes on the other.

The commission has now been functioning for over thirteen years, and in that time it has dealt among other things with a number of questions involving the development of water powers on international streams.

The St. Marys River Case

One of the most important of these was the St. Marys River case, which involved the complete control of the outflow of lake Superior, that immense inland sea that ranks among the natural wonders of North America, and which in a comparatively short period of years has been transformed from a waste of waters bearing nothing more than an occasional birchbark canoe paddled by Indians or fur-traders, and surrounded by an almost uninhabited wilderness, into one of the world's great thoroughfares of commerce, up and down which gigantic steamers carry hundreds of millions of tons of freight, and upon whose shores have sprung up populous and enterprising communities and immense industries.

The St. Marys River case came before the commission under the terms of article III of the Treaty of 1909, which vests in the commission the authority to finally determine any question involving the use or obstruction or diversion of boundary waters on either side of the line, affecting the natural level or flow of boundary waters on the other side of the line. In reality there were two applications before the commission, one from the Michigan Northern Power Company, on the United States side, and the other from the Algoma Steel Corporation, a Canadian company.

Each of the companies mentioned applied for authority to build works from its own side to the international boundary, the combined works making one structure across the river. At the hearings, legal and engineering representatives of various municipalities on both sides of lake Superior, and of railway and other corporations, expressed anxiety lest the proposed works should have the effect of raising the level of lake Superior and causing serious damage to wharves, buildings and sewage systems in Duluth, Fort William, and other towns around the lake. After hearing the testimony of a number of expert engineers, including representatives of the United States and Canadian governments, the commission approved of the proposed works upon certain conditions as to construction and operation, which, instead of being detrimental to the interests of navigation and of the several communities around lake Superior, would, by maintaining the level of the lake between certain points, be very much to the public advantage. It must be emphasized that only through such an international organization can the full commercial value of these water powers be obtained.

As part of their Order of Approval, the commission made it a condition that the works, both during construction and thereafter, were to be under the direct control of an international board of engineers, one member of which was to be appointed by the Canadian and the other by the United States government. In case of disagreement the board was to refer the question to the commission for decision.

In this way it was found possible to settle, in a very short time, and to the satisfaction of all the very important interests concerned, American and Canadian, public, navigation, and power, a question which might have dragged along for years under the old diplomatic procedure and been the cause of international irritation and material loss on both sides of the boundary.

It may be noted that the representatives of the various towns on lake Superior, American and Canadian, had been concerned over the possible effect of the proposed works at the outlet of the lake, if they were put under private control, but expressed complete satisfaction with the international control provided for in the commission's orders.

Special Provision for Niagara River

Special provision is made in the treaty for the water power situation on the Niagara river, the terms of article V being as follows:—

> The High Contracting Parties agree that it is expedient to limit the diversion of waters from the Niagara river so that the level of lake Erie and the flow of the stream shall not be appreciably affected. It is the desire of both Parties to accomplish this object with the least possible injury to investments which have already been made in the construction of power plants on the United States side of the river under grants of authority from the state of New York, and on the Canadian side of the river under licenses authorized by the Dominion of Canada and the province of Ontario.
>
> So long as this treaty shall remain in force, no diversion of the waters of the Niagara river above the falls from the natural course and stream thereof shall be permitted except for the purposes and to the extent hereinafter provided.
>
> The United States may authorize and permit the diversion within the state of New York of the waters of said river above the falls of Niagara, for power purposes, not exceeding in the aggregate a daily diversion at the rate of twenty thousand cubic feet of water per second.
>
> The United Kingdom, by the Dominion of Canada, or the province of Ontario, may authorize and permit the diversion within the province of Ontario of the water of said river above the falls of Niagara, for power purposes, not exceeding in the aggregate a daily diversion at the rate of thirty-six thousand cubic feet of water."

Since the date of the treaty momentous changes have taken place in the situation at Niagara Falls. At the present time practically the whole amount of water authorized by the treaty is in use, and by means of new processes of water power development, an enormously greater efficiency is obtained from the quantity of water diverted than was the case ten years ago. The Hydro-Electric Power Commission of Ontario has completed its great Chippewa-Queenston diversion, by means of which practically double the head is obtained which can be secured at the falls, and ultimately all the existing plants on the Canadian side at the falls will probably be scrapped, and Canada's share of the water developed entirely at Queenston.

On the American side of the river, partly because of different physical conditions, another programme is being worked out. There the various plants at the falls are being merged into one great development at the same place, and the drop in the river between the falls and the Whirlpool will probably be utilized by cutting a tunnel through the rock and carrying the water down to a power house below the Whirlpool. Some engineers are now of the opinion that a considerably larger amount than that fixed by the treaty may be diverted from the falls without seriously impairing their scenic beauty; in fact it is said that by means of a submerged weir above the point of the Horseshoe, which is rapidly being transformed into a Hairpin, the erosion will be checked, the appearance of the falls greatly improved, and at the same time a considerably larger amount made available for power development.

Investigations under Article IX of the Treaty

The power situation on the upper St. Lawrence and in connection with the Lake of the Woods, has been dealt with by the Commission under the terms of another article of the treaty, article IX, which reads as follows:—

> "The High Contracting Parties further agree that any other questions or matters of difference arising between them involving the rights, obligations, or interests of either in relation to the other or to the inhabitants of the other, along the common frontier between the United States and the Dominion of Canada, shall be referred from time to time to the International Joint Commission for examination and report, whenever either the Government of the United States or the Government of the Dominion of Canada shall request that such questions or matters of difference be so referred.
>
> The International Joint Commission is authorized in each case so referred to examine into and report upon the facts and circumstances of the particular questions and matters referred, together with such conclusions and recommendation as may be appropriate subject, however, to any restrictions or exceptions which may be imposed with respect thereto by the terms of the reference.
>
> Such reports of the commission shall not be regarded as decisions of the questions or matter so submitted either on the facts or the law, and shall in no way have the character of an arbitral award.
>
> The Commission shall make a joint report to both governments in all cases in which all or a majority of the commissioners agree, and in case of disagreement the minority may make a joint report

to both governments, or separate reports to their respective governments.

In case the commission is evenly divided upon any question or matter referred to it for report, separate reports shall be made by the commissioners on each side to their own government."

Under this article of the treaty the commission becomes an investigating body. It will be seen that an investigation under article IX may be requested by either government; that an obligation to make such a request is involved in the language of the article, the word "shall" being construed as mandatory; and that in making such an investigation the findings of the commission are not binding on the two countries, either as a decision or an arbitral award.

"It would," in the language of an editorial in the *American Journal of International Law,* "be difficult to overestimate the advantage and convenience to both countries of having a permanent body, organized as this is with both countries equally represented, upon which either may call for a thorough investigation of any questions of difference involving the interests of their citizens or subjects along the thousands of miles of their common frontier."

It may be noted here that in actual practice all questions so far referred to the commission for investigation under article IX have been referred jointly by the two governments, although it is obvious from the language of the article that either government could act independently if it saw fit to do so. It is also worth noting that, in the investigations so far reported on, the six commissioners have been in every case in substantial accord in their conclusions and recommendations. Their recommendations under article IX, like their decisions under article III, have been unanimous.

Of the four questions so far referred to the commission under the terms of article IX, the first related to the construction of a dyke in the Detroit river for the benefit of navigation; the second to the fixing of levels in the Lake of the Woods which would be best suited to the requirements of the various interests on both sides of the boundary; the third had to do with the pollution of boundary waters and appropriate remedies therefor; and the last requested recommendations as to the most practicable means of improving the St. Lawrence river between lake Ontario and Montreal for navigation and water power.

St. Lawrence River Navigation and Power Investigation

In the St. Lawrence investigation, the commission was requested to examine into and report upon the most practicable and efficient means of securing the maximum development from the upper St. Lawrence in terms of navigation and water power. This investigation involved many economic and engineering questions of unusual magnitude. In connection with the economic problem the commission held public hearings in a great many Canadian and American centres, from New York, Boston and Montreal in the east, to Calgary, Helena and Boise in the west. The engineering side of the question was dealt with by a board of engineers drawn from the technical staffs of both countries. The commission's final report, dealing exhaustively with every phase of this very big problem, filled about a dozen volumes. Only the main report and the report of the engineering board have so far been printed.

Briefly stated, the recommendations of the commission provide for a waterway from lake Ontario to Montreal with a minimum depth of 25 feet, which at some future time might be extended to 30 feet. In addition to deepening the river channel at certain places, canals and locks are provided for at Cornwall to surmount the Long Sault rapids, between lake St. Francis and lake St. Louis to surmount the Coteau, Cedars and Cascades rapids, and at Montreal to surmount the Lachine rapids. A lock is also provided farther up-stream at Ogden island. Each of the seven locks is to be 860 feet long and 80 feet wide.

For the development of water power, and also as part of the navigation scheme, the commission recommended the construction of two dams across the St. Lawrence, one at Ogden island and the other at the Long Sault rapids. These two dams would make possible a development of power estimated at about 1,500,000, one-half of which would be available for use in Canada and the other half in the United States. Both dams would be in the international section of the river. The commission did not recommend for the present the development of water power in the purely Canadian section of the St. Lawrence, below St. Regis.

The cost of the proposed works for navigation and power in the international section of the river was estimated at $159,000,000 and of the navigation works in the Canadian section of the river at $93,000,000. or a total of $252,000,000. The engineering board estimated that if at some future time it should be thought desirable to develop power in the national section of the river, about 2,260,000 horse power would be available at a cost of about $220,000,000.

Investigation of Levels in the Lake of the Woods

The other investigation involving water power interests related to the fixing of levels in the Lake of the Woods which would be best suited to the requirements of all the various interests on both sides of the boundary. It may not be generally known that the watershed of the Lake of the Woods exceeds twenty-six thousands square miles, equal to the combined areas of the states of Massachusetts, New Hampshire, Rhode Island, Connecticut and Delaware, or some five thousand square miles greater than the area of the province of Nova Scotia. The capital invested in the various industries in this region is considerably over $100,000,000; the resources are enormous, of great variety, and only beginning to be developed; and communities as far apart as Duluth and Winnipeg were more or less directly interested in the fixing of a level on the Lake of the Woods and its tributaries, which would give the maximum benefit to the people on both sides of the boundary.

The extensive field work involved in the investigation was under the direction of two consulting engineers, one an American, and the other a Canadian. After several years' careful work, in which they were of course constantly in touch with the commission and acted under its direction, they submitted their report to the commission in 1916. The commission's final report to the two governments was submitted in 1917. In this report the commission recommended that it be authorized to exercise supervision and control over the operation of all dams and regulating works in these waters extending across the international boundary, as well as the dams and regulating works at Kettle falls and at the outlets of the Lake of the Woods, which are in Canadian territory; and that it be empowered to appoint two engineers, one from each country to act as its representatives under such rules and regulations as it might prescribe. The documents in the Lake of the Woods investigation, which include several volumes of hearings and arguments, the results of the engineers' surveys and other data, and the commission's final report, have all been printed.

The commission's recommendations were designed to secure a level in the Lake of the Woods that would be of most service to the interests of navigation and also to those of water power, the latter being of paramount importance at the present time. In addition to the existing developments at the outlets of the Lake of the Woods, and at the outlet of Rainy lake, there are nine distinct power sites on the Winnipeg river, which discharges the water of the Lake of the Woods into lake Winnipeg. By means of suitable storage, it is possible and economically feasible to develop over 420,000 horse power at these sites. Several of them have already been developed, and the power is being utilized for industrial and other purposes in the city of Winnipeg and the surrounding district. As the level best adapted to water power would result in flooding certain agricultural lands on the shores of the Lake of the Woods, the commission recommended that provision should be made for compensating the owners of these lands.

Applications for Power Developments on Upper St. Lawrence

Under the authority vested in it by the terms of article III of the treaty, the commission has also settled several other cases involving important water power interests along the international frontier between Canada and the United States.

One of these was an application by an American corporation, the St. Lawrence River Power Company, one of the subsidiaries of the Aluminum Company of America, for permission to put a submerged dam in one of the channels of the St. Lawrence, on the American side of the river, at the Long Sault rapids. The application came before the commission in July, 1918, at a time when the issue of the European war was still wrapped in uncertainty. It was urgently represented to the commission, not only by the applicant company but also by the United States War Industries Board, the Bureau of Aircraft Production, and the United States Secretary of War, that the proposed dam was urgently needed to increase the available power at the company's works at Massena, and thereby insure an adequate supply of aluminum for war purposes from the company's plant.

In view of these representations, the commission issued an order permitting the company to build the dam and maintain it for a period of five years, or until the termination of the war if it should extend beyond that period.

Another application involving the development of water power on the upper St. Lawrence was that of the New York and Ontario Power Company, whose proposed works were at Waddington, N.Y. This case came before the commission in 1918, and as before it came up for hearing the commission had been advised of the St. Lawrence investigation, involving a complete scheme of water power development for the international portion of the river, it was not thought advisable to authorize the contemplated works at Waddington until it was known whether or not these would interfere with the larger scheme.

These are the more important water power cases which have come before the commission, either for investigation or final settlement. But power problems represent but one of several classes of questions that, under the terms of the Treaty of 1909, may be brought before the commission. It has already disposed of a very difficult and delicate case involving irrigation interests in Alberta and Montana; it made provision for a water supply for the city of Winnipeg from Shoal lake, which is connected with the Lake of the Woods; and, among other problems, it has approved of certain works for the improvements of navigation in the Detroit and St. Clair rivers. These last are of unusual importance, as they are necessary to the safety and convenience of the enormous and ever-growing commerce of the Great Lakes. It appears from official reports that about 70,000,000 tons of freight, of a total value of about $1,000,000,000 are carried annually during the season of navigation up and down the Detroit and St. Clair rivers and the Great Lakes of which they are the connecting links.

The Pollution of the Great Lakes and other Boundary Waters

A third question which was referred to the commission by the governments of Canada and the United States for investigation and report, was that of the pollution of the Great Lakes and other boundary waters. The investigation, which involved an examination of the waters of the Great Lakes and their connecting rivers, Rainy lake, Rainy river, the Lake of the Woods, and the boundary portion of the St. John river in the east, wherever pollution might extend from one side to the other, disclosed the gratifying fact that the great bulk of the Great Lakes water remains in its pristine purity, in spite of the fact that some seven million people had contracted the very bad habit of dumping all their sewage into these waters, and that the entire shipping of the Great Lakes, carrying in one season not less than 15,000,000 passengers, had followed the same evil practice. Serious pollution was found at many points along boundary waters, and particularly in the Detroit and Niagara rivers, where the cities of Detroit and Buffalo, with a number of smaller communities on both sides of the boundary, had been doing their best to make the waters of these rivers unfit for human consumption.

Severe epidemics of typhoid fever in the lake cities had for years past warned these communities that, while they were spending hundreds of millions on their streets and buildings, and in other ways adding to the comfort and convenience of their inhabitants, the most vital consideration of all, that of public health, was being grossly neglected. If the commission should achieve nothing more than to awaken the cities of the Great Lakes to the vital importance of protecting their water supplies, it would have more than justified its existence.

The commission in its report made certain recommendations designed to remedy the existing situation, and laid down in particular the principle that "effective sanitary administration requires the adoption of the general policy that no untreated sewage from cities or towns shall be discharged into boundary waters".

Questions involving Rights, Obligations or Interests of Either Country

In addition to its jurisdiction as a judicial, or quasi-judicial, body under articles III and IV, and as an investigatory body under article IX, of the Treaty of 1909, the commission is also vested with other and still more significant powers. Under article X it is constituted a tribunal for the final settlement of any question involving the rights, obligations or interests of either country in relation to the other. The importance of this provision of the treaty can hardly be exaggerated. The obligation on the part of the governments to refer questions to the commission under article X is, it is true, moral rather than legal. Article IX reads "shall be referred", while article X reads "may be referred". Nevertheless it will be noted that while under article IX questions are referred to the commission only "for examination and report", under article X they are referred "for decision". The commission therefore becomes under article X in a very real sense a court of final jurisdiction for the two countries.

Another interesting point is that the article contains no limitation as to the character of the questions that may be brought before the commission for adjudication, other than that they must involve "the rights, obligations, or interests of the United States or the Dominion of Canada, either in relation to each other or to their respective inhabitants". That obviously is a very flexible limitation, and embraces a tremendously large field within which article X may be applied. It puts into operation throughout this immensely greater region, and under more promising conditions, much the same principles embodied in the convention creating the Central American Court of Justice in 1908, by which Costa Rica, Guatemala, Honduras, Nicaragua and San Salvador bound themselves to submit to the court all controversies of whatever origin.

It is true that up to the present time no question or matter of difference has been referred under article X to the commission, but that need not be interpreted as a disinclination on the part of either government to entrust such questions to the commission for final settlement. Rather it means that the relations of these two countries have been so cordial, have been, one may say, so extraordinarily fortunate, that since the treaty was signed no occasion has arisen to take advantage of the terms of article X.

The Commission, a Successful Agency for Peaceful Settlement of International Disputes

Those who negotiated the Treaty of 1909 deliberately, and as the result of long and careful consideration, built a covenant designed to bind together these two nations of the New World more closely than any two countries that were not politically one. Someone has said that they builded better than they knew. One is inclined to dispute that statement. This treaty is the fruit of wise and constructive and far-seeing statesmanship. If James Bryce and Elihu Root, who negotiated the Treaty of 1909, had never achieved anything more than that, they would have earned the gratitude of the English-speaking world. And it must not be forgotten that both the creation of the treaty and the settlement of its broad terms owed much to the vision of that great Canadian statesman, the late Sir Wilfrid Laurier. The treaty put into tangible and practicable shape the aspirations of Canadians and Americans for the closest possible union consistent with political independence. Canada's relations to the great republic are to-day only slightly less intimate than her relations to the other members of the British Commonwealth.

In a letter to Sir Wilfrid Laurier, Sir George Gibbons, who had assisted in drafting the treaty, said: "Mr. Root's desire was to dispense with the Hague Tribunal so far as concerns matters between the United States and Canada, and set an example to the world by the creation of a judicial board as distinguished from a diplomatic and partizan agency". So far as Lord Bryce was concerned, up to the time of his death he took the keenest possible interest in the commission, and had complete faith in its possibilities of usefulness to Canada and the United States.

Chief Justice Taft and the late Mr. Roosevelt, among others on the United States side of the line, and the Duke of Connaught, the Duke of Devonshire, the late Earl Grey and the late Sir Wilfrid Laurier on the Canadian side, have on various occasions drawn attention to the importance and significance of the Treaty of 1909 and of the work entrusted to the International Joint Commission. Sir Robert Borden has on more than one occasion used the commission as a conspicuously successful type of agencies for the peaceful settlement of international disputes.

It is sometimes objected that the commission is less effective than it might be, because it has not been clothed with police powers, has no means of enforcing its own decisions. That is surely a mistaken criticism. Oppenheim, speaking of international courts, says, "We have neither desire nor need to equip these courts with executive power", and if that could be said of international courts in general, it is doubly true of this particular court, representing as it does the interests of two neighbouring democracies, bound together by so many ties of sympathy and understanding. The enforcing of the decisions of the commission rests with the governments of these two countries, and they can hardly be conceived as refusing to uphold the decisions of a tribunal they themselves have created.

But it is unquestionably true that the permanent success of the commission as a means of settling disputes and also of preventing them; and perhaps the latter is the more important service; must depend to a very large extent upon public understanding and support in the two countries. The people of the United States and Canada could not be expected to give their wholehearted support to such a radical departure, unless they thoroughly understood why the commission was created and how it has carried on its very important work. Intelligent publicity is as important in this case as in any other undertaking for the public good. While the commission cannot advertise its own activities, it welcomes every effort designed to put the facts before the people, and its consistent policy from the beginning has been to act not behind closed doors but in the open, to avoid everything suggestive of secret diplomacy, to make its procedure as simple and democratic as possible, and to invite to its hearings every man who has anything worth while to say on the question under consideration.

The relations between Canada and the United States are much closer, much more intimate, than between any two countries in Europe. They have to a very large extent the same political and social ideals, the same intellectual point of view, the same manners and customs, even the same prejudices. They have been good friends and neighbours for many generations, and it is to be hoped will remain good friends and neighbours forever. But even the best of friends and neighbours are liable to have their moments of misunderstanding, and if these are not to develop into something more serious, it is important that nothing should stand in the way of their coming together and making up their differences. If that is important in the case of individuals, it is infinitely more important in the case of nations. If the individuals were compelled to resort to some extremely roundabout means of effecting a reconciliation, it is possible that the slight misunderstanding might grow into a formidable grievance before it could be adjusted. And yet this is exactly the strain that for many generations the people of these two countries permitted to be put upon their good nature, on both sides of the boundary.

We have to thank the Treaty of 1909 for cutting the cords of the old bondage, and offering instead a means of getting together and adjusting differences with the minimum of friction and red tape. It does seem that the true measure of the commission's usefulness to the people of the United States and Canada lies not so much in its positive as in its negative qualities, not so much in the cases it has actually settled as in the much larger number of cases that never come before it for consideration, simply because the commission is there, as a sort of international safety-valve.

Lord Curzon at Lausanne referred to the commission as a significant illustration of what might be accomplished in connection with the Dardanelles, and during one of the discussions at the Peace Congress in Paris, Sir Robert Borden made particular reference to its jurisdiction as an illustration of what might be accomplished in connection with such European rivers of an international character as the Rhine and the Danube. One is tempted to speculate what the effect might have been in Europe if in 1914 Austria and Serbia had had a tribunal vested with such wide powers as those possessed by the commission, with jurisdiction centered in the Danube instead of the St. Lawrence. Austrian or Hungarian and Serb, instead of watching each other suspiciously from frontier fortresses, and attempting or pretending to compose their differences along the boundary by means of the cumbersome and roundabout and dangerously slow methods of diplomacy, might have met on common ground before a court in which both countries were equally represented. Old grievances, national sores, instead of being allowed to fester, could have been quickly and impartially examined and a remedy perhaps found for them. Questions bearing within them the seeds of war might have been left to the decision of a commission pledged to find a peaceful remedy.

Had Austria and Serbia possessed such a tribunal, we might have escaped the World War. But one must put a good deal of emphasis on the *might*, because after all, while international commissions endowed with wide powers are very effective weapons of peace, they are only weapons. In peace as in war, it is not the gun but the man behind the gun, that counts. Well-considered treaties are a tremendous asset to the nations concerned, if the people of these nations are determined to back them up.

Such a treaty and such a commission as this would have saved millions of lives and incalculable loss and suffering, if the European nations had been prepared to stand resolutely behind them, but not otherwise.

Canada and the United States possess, what perhaps no two nations have possessed before, an entirely practicable and flexible means of solving their differences that leaves, or should leave, no loophole for a resort to the arbitrament of war. It has functioned quietly and unostentatiously, and its success has measured up to the most sanguine expectations of those who created it. From the point of view of world conditions, it is a useful and suggestive example of what two or more nations may accomplish if they are really anxious to avoid dangerous misunderstandings, and are willing to adopt to that end a simple but very effective procedure.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOL. VII July 1924 No. 7

The July Journal

Since the major portion of Canada's presentation at the World Power Conference is being made by engineers who are national authorities on the various subjects and who are well known members of *The Institute*, it is fitting that *The Engineering Institute of Canada* should make it possible for its members and thousands of others interested in power development to read and possess printed copies of the very excellent and highly creditable papers which form Canada's contribution to this important gathering. This issue, which has a circulation of eleven thousand, contains a wealth of valuable data and information, rendering it desirable as a permanent record, and as such it will serve for a considerable time to the many who require to be informed on the power situation.

In complimenting the authors on the very excellent papers, advantage is taken of the opportunity to acknowledge with sincere thanks their courtesy in assisting editorially with this publication and for their valuable co-operation towards making it a success.

While the editorial pages convey the story of Canada's progress in power development, the advertising pages likewise have an interesting and effective story to tell, as the firms and organizations whose apparatus and equipment are advertised played no small part in bringing Canada to the forefront as a power producing nation, and their announcements provide interesting reading as well as valuable reference.

Canada at the Power Conference

Engineers from thirty-one nations will meet in London from June thirtieth to July twelfth for the World Power Conference, being the first time in history that engineers from different countries have assembled to discuss a subject of common interest. Twenty-four nations have signified their intention of actively participating in the presentation of papers. About thirty Canadian engineers will be in attendance. That the representatives of Canada, who will present papers and take part in the discussions, will acquit themselves creditably is a foregone conclusion. A glance through the papers published in this issue, which comprise the entire subject matter of the Canadian papers, provides sufficient evidence of the high standard of excellence of the contribution being made by the Dominion on this historic occasion.

Although engineering is truly international, this is the first time that any such great gathering of experts and authorities has been organized to discuss an engineering subject, consequently it is believed that this unique event will have outstanding results in bringing engineers of the various nations in closer contact, establishing mutual goodwill and esteem, and possibly leading to the organization of an international group of engineers which will have a powerful influence in promoting arts of peace and in wielding a mighty influence against wars and national illwill. That the World Power Conference is being held at the British Empire Exhibition at Wembley will enable the engineers of other nations to better appreciate the engineering development of the British Empire and particularly the United Kingdom. Engineering works and equipment are being particularly featured and possibly one of the great results of the Exhibition will be a greater appreciation of the important place the engineer holds in the economic life of the civilized nations.

In his foreword, introducing Canada's part in the Conference and preliminary to the papers published in this issue on the Power Resources, Their Development and Utilization in Canada, Doctor Charles Camsell, M.E.I.C., chairman of the Canadian Management Committee, points out that the World Power Conference, initiated by the British Electrical and Allied Manufacturers' Association, and organized by a committee comprising the various technical and scientific institutions and industrial organizations in the British Isles, affords the Dominion of Canada a unique opportunity to present before the world her magnificent power resources, both water and fuel, and the efficient and economic manner in which they have so far been utilized. He mentions that Canada's participation is represented by five papers by recognized experts in the principal technical aspects of power production and use. These, although each is self contained, have been co-ordinated, forming a precise yet comprehensive and analytical summary of the power resources and their utilization. He expresses the opinion of the Canadian Committee in that while conferences of this character cannot, from their very nature, be frequently held, an international discussion of power production problems, say every three or five years, would, by promoting the arts of peace and industry, prove a prime factor for better international understandings. He suggests that the Canadian delegation, on the proper occasion, should suggest a second conference to be held within the sound of the mighty Niagara.

Each of the five papers presented by Canada is introduced by a summary of the paper, in this issue. The first of these, The Water Powers of Canada; Their Nature, Extent and Administration, by J. B. Challies, C.E., M.E.I.C., director and chief engineer, Dominion Water and Reclamation Service, Department of the Interior, Ottawa, is remarkable for the thoroughness with which the subject has been covered by the author, and for the fund of information it contains on this subject. This paper constitutes Part A of the series and is accompanied by a copy of the latest map illustrating the location and extent of the water powers of Canada. Part B is covered by B. F. Haanel, B.Sc., M.E.I.C., chief engineer, Division of Fuel and Fuel Testing, Department of Mines, Ottawa, in his paper, The Fuel Resources of Canada and Their Utilization for the Production of Power and other Purposes. In this paper he points out the problems arising from the use of fuels in Canada owing to their absence in the more populous and industrialized portions of the Dominion. He makes suggestions for overcoming the difficulties, points out present practice, and by the additional means of charts, tables, diagrams and figures, gives a comprehensive analysis of the fuel situation in the Dominion. The Generation of Hydro-Electric Power in Canada forms Part C of the series, being a remarkably clear and complete survey of Canadian hydro-electric practice since 1905, by H. G. Acres, D.Sc., M.E., M.E.I.C., until recently chief hydraulic engineer, Hydro-Electric Power Commission of Ontario. He refers to the individuality of Canadian practice through the study of ice problems, and indicates the trend of future hydro-electric development in the Dominion. Part D, The Transmission and Distribution of Electric Power in Canada, is presented under the joint authorship of Julian C. Smith, E.E., LL.D., M.E.I.C., vice-president, The Shawinigan Water and Power Company, and C. V. Christie, M.A., B.Sc., A.M.E.I.C., consulting engineer and associate professor of electrical engineering, McGill University. This paper details current practice in the design and operation of electrical transmission and distribution systems in Canada, points out that the distribution of water powers in the Dominion is so widespread that exceptionally long transmission lines have not so far been required, and that 110,000 volts is the highest line voltage at present in use, although this may possibly be increased to double that voltage in the near future. It mentions that practically every large industrial centre in Canada is now equipped with electric power. In addition to dealing with current practice, the authors of this paper are in an authoritative position to make suggestions embodying improvements in certain directions. The fifth section of this series, Part E, embodies a symposium on The Utilization of Power in Canada, prepared under the direction of P. T. Davies, president of the Canadian Electrical Association and includes: Electricity in the Canadian Home, by F. A. Gaby, D.Sc., M.E.I.C.; Electrical Service for Rural Districts, by F. A. Gaby, D.Sc., M.E.I.C.; The Utilization of Power in the Pulp and Paper Industry, by R. W. Leeper; The Use of Power in the Mineral Industries of Canada, by H. E. M. Kensit, M.E.I.C.; The Use of Electric Power in the Cement Industry of Canada, by W. G. H. Cam, A.M.E.I.C.; The Use of Power for Port Facilities, by M. T. Sheehy-Casey; Recent Developments in Electric Lamps, by J. T. Scott; The Application of Compressed Air in Industry, by F. A. McLean; Electro-Chemical and Electro-Metallurgical Uses of Power, by L. E. Westman; Power in Transport, by D. E. Blair, A.M.E.I.C.; Illumination, by W. H. Woods; and Power Requirements in the Lumbering Industry in British Columbia, by A. M. Smith.

In view of the unique means of adjusting international waterway questions between Canada and the United States through the agency of the International Joint Commission, it was decided that a paper on the question would be of interest to other countries participating in the World Power Conference, and accordingly The International Joint Commission and the International Water Powers of Canada, by L. J. Burpee, F.R.S.C., secretary of the Canadian Section, International Joint Commission, appears as Part F of the Canadian presentation, the whole series being creditable alike to the authors and the Dominion.

Hon. Charles Stewart, Minister of the Interior, Honorary Chairman, Canadian Management Committee, whose influence and faith in Canada's position have made possible Canadian participation at the Power Conference.

The entire transactions of the Conference will be published by the British Committee, an announcement concerning which will be found in the advertising pages.

The general secretary of the Canadian Management Committee, Mr. J. B. Challies, M.E.I.C., went to London early in June to complete arrangements for the Conference. Headquarters for the Canadian Committee were secured at the Imperial Hotel, Russell Square, where the majority of the Canadian delegates secured accommodation.

While the Conference is primarily technical, British hospitality is abundantly manifest in the arrangements made for the entertainment of visiting delegates. A cordial invitation has been extended to various receptions, luncheons, and banquets by the Institution of Civil Engineers, the Institution of Electrical Engineers and the Institution of Mechanical Engineers, which include as well trips to Cambridge and Birmingham, and the functions connected with the celebration of the Centenary of Lord Kelvin, the presentation of the Kelvin Medal, and special services in Westminster Abbey. The High Commissioner for Canada will entertain the delegates at a Canadian luncheon on Friday, July fourth, at which the Honourable Mr. Larkin will preside, and at the conclusion of the luncheon the Honorary Chairman of the Canadian Committee, the Hon. Charles Stewart, Minister of the Interior, or in his absence, Doctor Camsell, will speak briefly, to be followed by a short address for the occasion by Mr. A. Monro Grier, K.C. Mr. Arthur Surveyer, president of *The Institute*, will also speak briefly in French. In the evening of July third, the American Committee will give a dinner at the Hotel Cecil.

Officers of The Canadian Management Committee

Hon. E. H. Armstrong, Premier of the Province of Nova Scotia, Honorary Vice-Chairman, Canadian Management Committee, Chairman of the Nova Scotia Power Commission, intimately associated with power development in Nova Scotia.

Hon. Sir Adam Beck, LL.D., Chairman of the Hydro-Electric Power Commission of Ontario, Honorary Vice-Chairman, Canadian Management Committee, an outstanding figure in the hydro-electric power development in Ontario.

Canadians have been honoured in invitations to preside at two of the sessions of the Conference. On Thursday, July third, from 3.30 p.m., to 5.00 p.m., Mr. Arthur Surveyer, M.E.I.C., and Dr. F. A. Gaby, M.E.I.C., are named as joint chairmen of the meeting at which the question of Water Power Production is being considered. On Wednesday, July ninth, from 2.30 p.m., to 5.00 p.m., Mr. John Murphy, M.E.I.C., and Mr. O. O. Lefebvre, M.E.I.C., are joint chairmen at the session when the question of Power in Electro-Chemistry and Electro-Metallurgy is being considered.

Members of the Canadian Management Committee who definitely signified their intention of attending the Conference are: Hon. Charles Stewart, Minister of the

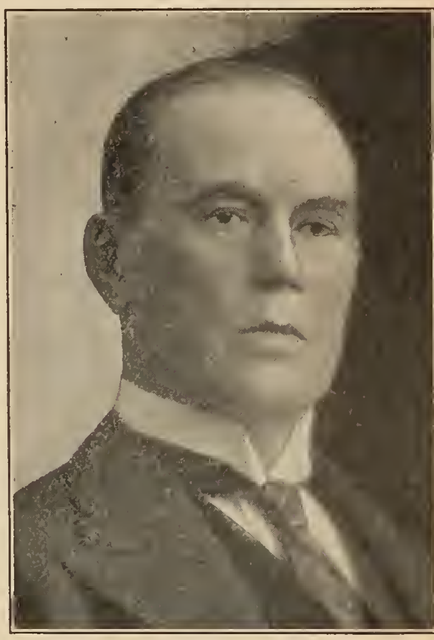
E. W. Beatty, K.C., President of the Canadian Pacific Railway, Honorary Vice-Chairman, Canadian Management Committee, who takes a deep interest in the question of development of Canada's natural resources.

W. W. Cory, C.M.G., Deputy Minister, Department of the Interior, Honorary Vice-Chairman, Canadian Management Committee, under whose department, through the Dominion Water Power Branch, the investigation of Canada's water power resources is carried on.

Officers of The Canadian Management Committee

A. Monro Grier, K.C., President of the Canadian Niagara Power Company, Honorary Vice-Chairman, Canadian Management Committee, Past-President, Canadian Electrical Association, a pioneer in Niagara power development.

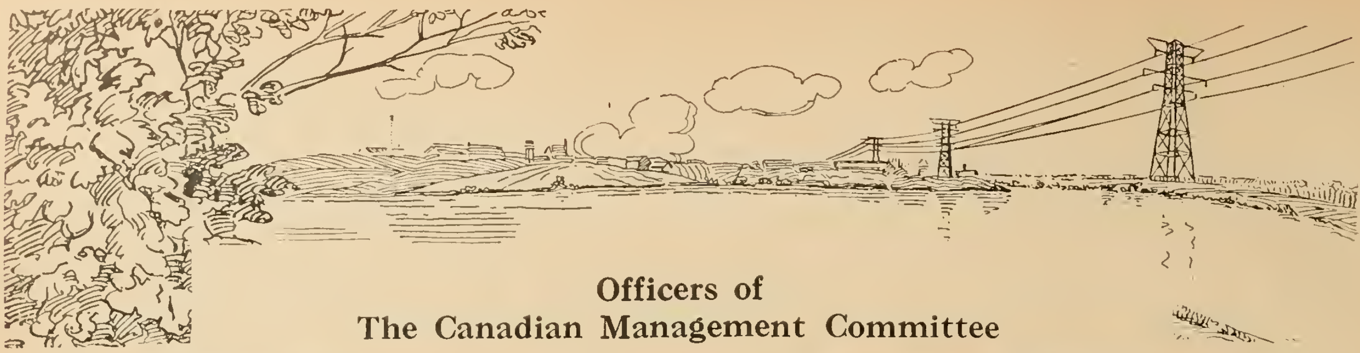
Sir Herbert Holt, M.E.I.C., President of the Montreal Light, Heat and Power Consolidated, Honorary Vice-Chairman, Canadian Management Committee, who has played an important part in building up by private enterprise an enormous power development in the province of Quebec.



Interior; Hon. Sir Adam Beck, Chairman, Ontario Hydro-Electric Power Commission; A. Monro Grier, K.C.; Hon. E. H. Armstrong; Arthur Surveyer, President of *The Institute;* H. G. Acres; Frederick B. Brown; Doctor Charles Camsell; J. B. Challies; E. A. Cleveland; F. A. Gaby; G. Gordon Gale; B. F. Haanel; Fraser S. Keith; O. O. Lefebvre; Brig.-Gen. C. H. Mitchell; W. H. Munro; John Murphy and K. H. Smith. Other members of *The Institute* who will be in attendance are H. S. Van Scoyoc; E. P. Fetherstonhaugh; D. M. Fraser; F. M. Dawson; H. C. Lott; K. R. MacKinnon; A. R. Greig; G. G. Ommanney; Doctor A. W. G. Wilson, S. Svenningson, A. D. Swan and Bernard H. Hughes in addition to members now in England or resident in the British Isles.

C. A. Magrath, M.E.I.C., Chairman, Canadian Section, International Joint Commission, Honorary Vice-Chairman, Canadian Management Committee, whose diplomacy has been an influential factor in adjusting international waterway problems.

Hon. H. Mercier, K.C., Minister of Lands and Forests—Quebec, Honorary Vice-Chairman, Canadian Management Committee. As chairman of the Quebec Streams Commission, Mr. Mercier administers the regulations relating to water powers.



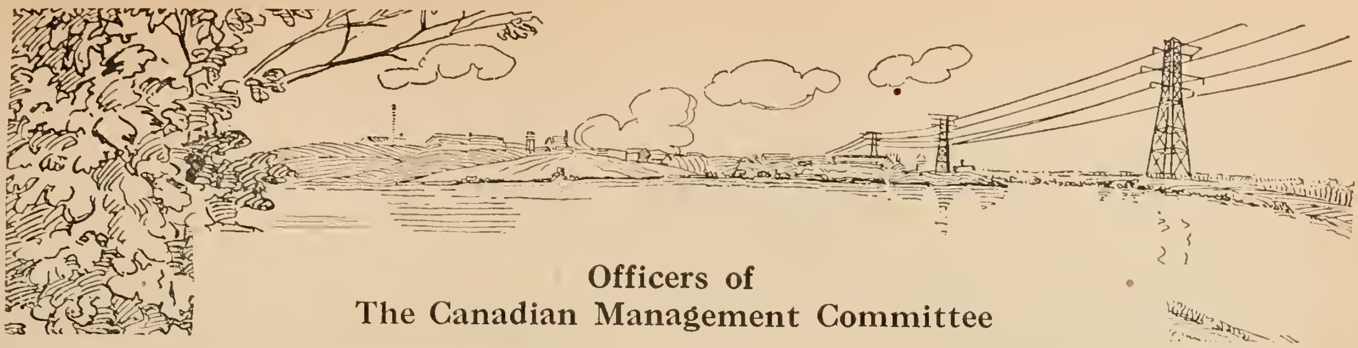
Officers of The Canadian Management Committee

Sir Henry Thornton, K.B.E., B.Sc., M. Inst.C.E., President, Canadian National Railways. Honorary Vice-Chairman, Canadian Management Committee.

H. M. Tory, M.A., D.Sc., F.R.S.C., LL.D., F.R.H.S., Chairman of the Research Council of Canada, Honorary Vice-Chairman, Canadian Management Committee.

Charles Camsell, B.A., LL.D., F.R.S.C., M.E.I.C., Deputy Minister, Department of Mines, Ottawa, Chairman, Dominion Fuel Board, Chairman, Canadian Management Committee.

J. B. Challies, C.E., M.E.I.C., Director, Dominion Water Power Branch and Dominion Reclamation Service, Department of the Interior, Ottawa. General Secretary, Canadian Management Committee.



Officers of
The Canadian Management Committee

H. G. Acres, D.Sc., M.E., M.E.I.C., M. Inst. C.E., M. Am. Soc. C.E., M. Am. Inst. E.E., Chief Hydraulic Engineer, Hydro-Electric Power Commission of Ontario. Vice-Chairman, Canadian Management Committee.

Arthur Amos, B.A.Sc., C.E., A.M.E.I.C., Director of the Hydraulic Service, the Quebec Streams Commission. Vice-Chairman, Canadian Management Committee.

John Murphy, M.E.I.C., F.A.I.E.E., Consulting Electrical Engineer, Department of Railways and Canals, and Dominion Railway Commission, Ottawa. Ont. Vice-Chairman, Canadian Management Committee.

Arthur Surveyer, B.A., B.A.Sc., C.E., M.E.I.C., Consulting Engineer, Montreal. President, The Engineering Institute of Canada. Member, Research Council of Canada. Vice-Chairman, Canadian Management Committee.

The Authors

Water Powers of Canada, their Nature, Extent and Utilization

For fifteen years J. B. Challies, C.E., M.E.I.C., whose paper on the nature, extent, and utilization of the water powers of Canada, constitutes part A of Canada's contribution to the World Power Conference, has been prominently and continuously connected with governmental activities in the investigation and the administration of Canadian water powers. As director and chief engineer of the Dominion Water Power Branch of the Federal Department of the Interior he has had occasion to organize and supervise basic water resource surveys and general power studies covering the principal rivers of the Dominion. In some cases, as for instance, on the Winnipeg river in the province of Manitoba, and on the Bow river in the province of Alberta, the reports of such investigations have not only assisted in a notable way the practical conservation and use of water power resources, but have proven unique contributions to the engineering literature of the Dominion.

Mr. Challies has organized and is now directing the Dominion Hydrometric Survey of Canada which comprehends the collection, the study and dissemination of surface run-off records for practically all important streams throughout the Dominion also the study of such records in relation to the power and other problems of these streams. He has filled important positions of a consulting capacity to the government of Canada in connection with international waterway problems. He is a member of the Dominion Power Board, the Dominion Fuel Board, and various other governmental organizations concerned with special phases of water power problems.

Mr. Challies holds the post-graduate degree of Civil Engineer from the University of Toronto; is a Member and vice-president of *The Engineering Institute of Canada;* a Member of the American Society of Civil Engineers; an Associate of the American Institute of Electrical Engineers; and a Charter Member of the Association of Professional Engineers of the Province of Ontario.

Fuel Resources of Canada, their Utilization for the Production of Power and other Purposes

The second part of the series of papers presented at the First World Power Conference is devoted to a review of the extent and utilization of the fuel resources of Canada. The author, B. F. Haanel, B.Sc., M.E.I.C., has devoted practically his whole life working on various fuel problems, chiefly those of Canada. He is chief engineer, Division of Fuels and Fuel Testing, Mines Branch, Department of Mines, and as such has been in contact and closely associated with the development of Canada's fuel resources. All research and development work conducted by the Mines Branch, including the testing of coal and peat on commercial and technical scales has been directly under his supervision. His book on the utilization of coal, peat and lignite for the production of power and industrial gas in by-product recovery and non-recovery type of producers, is recognized among the standard works on this subject. A paper, "The Fuels of Canada" presented by Mr. Haanel before *The Engineering Institute of Canada* in 1918 resulted in award of the Gzowski Medal the premier award of *The Institute.* During the past few years, when Canada's fuel problem became so acute, he has written many papers, addressed many societies and meetings, and his presentations have created wide interest throughout the Dominion.

Recently, Mr. Haanel has been intimately associated with the many investigations of both technical and commercial nature, conducted by the various boards and agencies of the government, such as the processing of various fuels with the object of conservation in mind, especially high and low temperature carbonization, gasification and many other similar investigations. Probably no one man in Canada is better qualified to explain the status of "Carbo" power development in Canada, as his ability to combine technical and practical knowledge is well known and his contributions towards the solution of Canada's fuel problems universally recognized.

B. F. HAANEL, B.Sc., M.E.I.C.

Mr. Haanel graduated from the Syracuse University in 1899. He is a member of Dominion Fuel Board; secretary and member of Joint Peat Committee (Federal Government and Province of Ontario); Member of the following societies — *The Engineering Institute of Canada,* American Institute of Chemical Engineers, American Institute of Mining and Metallurgy, Canadian Institute of Mining and Metallurgy, American Peat Society.

Transmission and Distribution of Electric Power in Canada

Julian C. Smith, E.E., LL.D., M.E.I.C., has been identified with the development and transmission of hydro-electric power throughout Canada and particularly in the province of Quebec for over twenty years, notably, as hydraulic engineer in charge of the development at Cedar Rapids, Quebec, as supervising engineer on the development of the Manitoba Power Company at Winnipeg, Manitoba, as well as chief engineer in the developments of the Shawinigan Water and Power Company and allied companies.

He is now vice-president and general manager of the Shawinigan Water and Power Company, president of the Quebec Power Company, president of the St. Maurice Power Company and is on the Board of Directors of many of the other power companies in the province of Quebec.

Mr. Smith was granted the degree LL.D. by Queen's University, Kingston, in 1922, in recognition of his great services to Canada in the practice of his profession of hydraulic and electrical engineering.

JULIAN C. SMITH, E.E., LL.D., M.E.I.C.

He is a member of the following engineering societies: *The Engineering Institute of Canada*, Institution of Electrical Engineers, American Institute of Electrical Engineers, American Institute of Civil Engineers, Canadian Electrical Association, National Electric Light Association.

* * *

Clarence V. Christie, M.A., B.Sc., A.M.E.I.C., consulting engineer, associate professor of electrical engineering at McGill University, has been attached to the staff of McGill University for seventeen years. His book "Electrical Engineering" has been widely used as a text book for electrical engineering students, both in the universities of Canada and the United States and he is now engaged in the preparation of a second book dealing with the problems of the transmission and distribution of electric power.

For several years he has been connected in consulting engineering work during the course of which he has had occasion to study some of the large transmission systems of Canada in detail, so that his knowledge of the subject of electric transmission is an intimate one.

He takes an active interest in the work of *The Engineering Institute of Canada* and is serving on the executive of the Montreal Branch. He is a member of one of the main committees of the Canadian Electrical Association and of one of the sub-committees of the Canadian Electrical Standards Association, and of the following societies: *The Engineering Institute of Canada*, American Institute of Electrical Engineers, Canadian Electrical Association, National Electric Light Association, Sigma XI.

CLARENCE V. CHRISTIE, M.A., B.Sc., A.M.E.I.C.

Generation of Hydro-Electric Power in Canada

The author of this paper, H. G. Acres, D.Sc., M.E., E.E., M.E.I.C., has spent practically the whole of his professional life in the various branches of hydraulic engineering, including surveys, design, construction and operation. As chief hydraulic engineer of the Hydro-Electric Power Commission of Ontario, he has under his engineering supervision twenty-five operating hydro-electric installations aggregating 1,020,000 e.h.p., of capacity in operation or under installation. Of this total he has directed the design and construction of eighteen plants, having a total installed capacity of 725,000 e.h.p.

Dr. Acres graduated from the University of Toronto in 1903, and had conferred upon him the degree of Doctor of Science at the convocation of the same university, on May 30th, 1924. He is a Member, and past vice-president, of *The Engineering Institute of Canada*, Member of the Institution of Civil Engineers of Great Britain, of the American Society of Civil Engineers, of the American Institute of Electrical Engineers, and of the Association of Professional Engineers of the Province of Ontario.

Dr. Acres has also acted as the Technical Associate of Counsel in connection with several matters of contention between Canada and the United States, as related to boundary waters.

Utilization of Power

The symposium on the Utilization of Power, being presented at the World Power Conference, has been prepared by a number of authors under the direction of P. T. Davies, A.M.I.E.E.

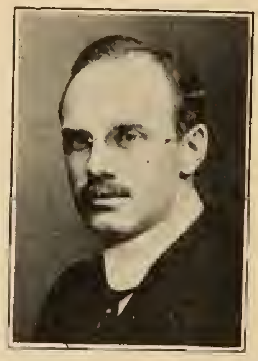
After a period of some seven years on engineering works in the Old Country, Mr. Davies came to Canada in 1907 and entered the services of the Montreal Light, Heat and Power Company, in the motor testing and meter departments. His promotion to assistant operating superintendent and later to operating superintendent of the Company, followed within two years. In 1912 he was appointed assistant to the general superintendent and chief engineer, and was placed in charge of the power sales department, and three years later when the

P. T. DAVIES

activities of the sales department were suspended, due to war activities, he was made manager. In 1917 the opportunity to again associate himself with a growing company led to an appointment as commercial manager with the Southern Canada Power Company, which position he still occupies.

Mr. Davies has always taken an active part in association work and was president of the Montreal Electrical Association in 1912. In the Canadian Electrical Association he was elected third vice-president in 1918, and president for two years 1922 and 1923. He is also a member of the National Electric Light Association, and an associate member of the Institution of Electrical Engineers.

Electric Service in Rural Districts and Electricity in the Canadian Home



F. A. Gaby
.Sc., M.E.I.C.

F. A. Gaby, D.Sc., M.E.I.C., the author of the two papers, Electric Service in Rural Districts and Electricity in the Canadian Home, does not require an introduction to the members of the engineering profession. As chief engineer of the Hydro-Electric Power Commission of Ontario since 1912, he has been constantly in touch with the problems presented through the service of electricity for domestic purposes and for use in rural districts. Mr. Gaby is an honour graduate of the University of Toronto receiving his degree of B.A.Sc., in 1903 and the degrees of M.E. and E.E. in 1904. His first work was with the Canadian General Electric Company as erecting engineer. He was later appointed chief assistant electrical engineer at the Point du Bois power plant on the Winnipeg River. From 1907 until his appointment as chief engineer Mr. Gaby was assistant chief engineer of the Hydro-Electric Power Commission.

The Utilization of Power in the Pulp and Paper Industry

R. W. Leeper

The first paper of the symposium on the utilization of power in Canada, deals with the pulp and paper industry and is by R. W. Leeper, power engineer with H. S. Taylor, consulting engineer of Montreal, Quebec. Mr. Leeper is a graduate in mechanical engineering from the Ohio State University and since graduating in 1907 has devoted his entire time to work in connection with pulp and paper mills. For twelve years after graduating he was with the General Electric Company on testing, construction, turbine engineering, and as paper mill specialist, and in 1919 was appointed to his present position.

The Use of Power in the Mineral Industries of Canada

H. E. M. Kensit,
M.E.I.C.

The extensive use of power in the mineral industries of Canada is described by H. E. M. Kensit, M.E.I.C., who is an honour graduate of the Electrical Standardizing and Training Institute, London. Mr. Kensit's early work was in the Old Country with the Westinghouse Company. After coming to Canada in 1908, he was engaged in the design and installation of the steam power station at Lethbridge, Alta., the construction of the electrical equipment of the Calgary Power Company's hydro-electric plant, and the investigation of existing and proposed power undertakings in Canada and the United States. Since 1912 he has been with the Dominion Water Power Branch, Department of the Interior, on the analysis of the financial and engineering aspects of power undertakings and the study of power markets in various localities. Mr. Kensit has made a continuous study of the water and fuel power resources of all parts of the Dominion and of the past and future demand for power and has furnished reviews of the relationship of water power and coal to the House of Commons and Senate Committees on Fuel Supply and to the Dominion Fuel Board. In 1918-19 he represented the department on the Government Water Power Committee in England and on the water power committee of the Conjoint Board of Scientific Societies.

The Use of Power for Port Facilities

M. T. Sheehy-Casey

The paper entitled, The Use of Power for Port Facilities, which forms part of the symposium on the utilization of power, deals with a particularly interesting feature of recent development in the utilization of electric power. This paper is by M. T. Sheehy-Casey, secretary to the president of the Harbour Commission of Montreal.

Use of Electric Power in the Cement Industry of Canada

William G. H. Cam, A.M.E.I.C.

William G. H. Cam, A.M.E.I.C., is power and safety engineer of the Canada Cement Company, Limited, having been with this company since 1919. Mr. Cam graduated in 1903 in electrical engineering at the City and Guilds of London Central Technical College. His first work was with the British Continental Electric Company, San Remo, Italy, as resident engineer. He came to Canada in 1909 joining the staff of the Montreal, Light, Heat and Power Company, and two years later entered private practice as electrical contractor. He was later with the Shawinigan Water and Power Company and the Southern Canada Power Company, leaving the latter to take over the duties of electrical engineer of the Canada Cement Company in 1919.

The Application of Compressed Air in Industry

Francis Allan McLean

Francis Allan McLean, author of the paper entitled The Application of Compressed Air in Industry, Canadian Practice, has made a special study of this subject for the past nine years. His specialized work in pneumatic machinery commenced in 1915 when he entered the employ of the McKiernan-Kerry Drill Company. Leaving the McKiernan-Kerry Drill Company, in the spring of 1917, he returned to Canada, and entered the employ of the Canadian Ingersoll-Rand Company, but left a few months later to join the Royal Flying Corps. At the close of the war he returned to the Canadian Ingersoll-Rand Company, and was appointed publicity manager the latter part of 1920. Mr. McLean has written many articles on such kindred subjects as construction work, mining, quarrying, oil engines, and the application of compressed air in various industries.

Power Requirements in the Lumbering Industry in British Columbia

A. M. Smith

The description of lumbering in British Columbia with particular reference to the power requirements of that industry as outlined in the paper by A. M. Smith, chief engineer Vancouver Lumber Company, Limited. Mr. Smith's early engineering experience was gained in the Old Country and in Belgium. He came to Canada in 1907 and was (to use his own expression) adopted by the Pulp and Lumbering Industry and has followed this work ever since. In setting forth the power requirements of the lumbering industry, Mr. Smith has outlined the operations required to produce the finished product from the time the tree is felled in the forest.

Electro-Chemical and Electro-Metallurgical Uses of Power

L. E. Westman

The review of the use of power in the electro-chemical and electro-metallurgical industries in Canada, has for its author, L. E. Westman, general manager of Canadian Chemistry and Metallurgy. Mr. Westman is a graduate of the University of Toronto, where he specialized in chemistry and metallurgy. He later entered the editorial field as editor of Canadian Chemistry and Metallurgy, later becoming publisher and business manager. He was chairman of the Toronto Branch of the Society of Chemical Industry in 1922, and is now general secretary of the Canadian Institute of Chemistry.

Power in Transport

D. E. Blair, A.M.E.I.C.

The use of power for transportation purposes is comprehensively treated by D. E. Blair, A.M.E.I.C., superintendent of rolling stock, Montreal Tramways Company. Mr. Blair graduated from McGill University in electrical engineering in 1897 and entered the Quebec District Railway's service the same year, as assistant chief electrician, and mechanical superintendent, remaining with that company and its successor, Quebec Railway, Light, Heat and Power Company until March 1903, when he was appointed assistant general superintendent, Montreal Street Railway, and afterwards superintendent of rolling stock, which position he has remained in since, with that company, and its successor, Montreal Tramways Company.

Recent Developments in Electric Lamps

J. T. Scott

J. T. Scott is a graduate in electrical engineering, of London University, from which he received the degree of B.Sc., in 1907. For twelve years he was engaged in construction and commercial engineering work for several corporations in England, Scandinavia and France, and for the past four years he has held the position of works engineer of the Edison Lamp Works Division of the Canadian General Electric Company, Toronto. Mr. Scott is secretary-treasurer of the Toronto Chapter of the Illuminating Engineering Society and chairman of the Lamp Committee of the Canadian Electrical Association, Montreal.

The International Joint Commission and the International Water Powers of Canada

The last of the series of papers, part F, is devoted to an outline of the activities and powers of the International Joint Commission, of which the author Lawrence J. Burpee, F.R.S.C., is secretary of the Canadian Section.

Mr. Burpee entered the services of the Canadian Government in 1890. He was private secretary to the late Hon. Arthur Dickey, during the Bowell-Tupper administration, and private secretary to Sir Oliver Mowat and the Hon. B. Mills, during the Laurier administration. For seven years from 1905 he devoted his time to library work, as librarian of the Carnegie Public library, Ottawa. In 1912 he was appointed to his present position on the International Joint Commission.

Mr. Burpee has made many contributions to Canadian literature, among which are: Canadian Life in Town and Country (joint author with Dr. H. J. Morgan); Charles Heavysege; A Bibliography of Canadian Fiction; Search for the Western Sea; Flowers from a Canadian Garden; Fragments from Sam Slick; By Canadian Streams; A Little Book of Canadian Essays; Songs of French Canada; A Century of Canadian Sonnets; Canadian Eloquence; An Index and Dictionary of Canadian History; Scouts of Empire; Canadian Humour; Pathfinders of the Great Plains; Among the Canadian Alps; Soldier's Dictionary; Sanford Fleming, Empire Builder. In addition he has contributed a large number of papers and articles, chiefly on Canadian subjects.

Mr. Burpee is a Fellow of the Royal Geographical Society; Fellow and Councillor of the Royal Society of Canada, and also a member of a number of historical societies, and president of the Canadian Authors Association.

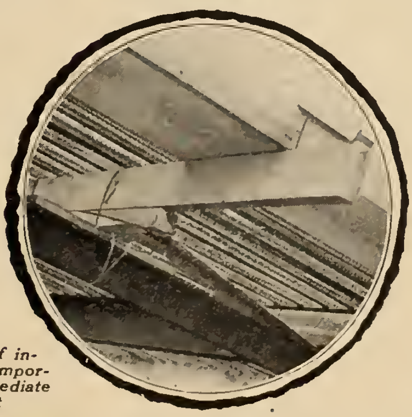
Method of attaching Hy-Rib to structural steel by means of Truscon Plate Clip.

Fastening Hy-Rib to Plate Clip.

Method of installing temporary intermediate supports.



Method of installing temporary intermediate support at gable end.

Office in Federal Building, Toronto, showing Dominion Battleship Linoleum floor.

The Modern Business Floor

Dominion Battleship Linoleum has been chosen as the flooring of many of Canada's largest banks, offices, departmental stores, schools, hospitals and public buildings because its durability, comfort and economy keep pace with the demands of modern progress. It affords a cushion-like treading surface, soft and springy, yet firm and smooth, that relieves foot-fag, subdues distracting noises and therefore promotes efficiency.

DOMINION
Battleship Linoleum

is sanitary and germicidal to a marked degree and is the easiest of all floors to clean and keep clean. This means a distinct saving in janitor costs while the only upkeep needed is the occasional use of a reliable floor wax. Properly applied with waterproof cement, Dominion Battleship, gives years of satisfactory, money-saving service.

Made in four standard shades—brown, green, terra cotta and grey. Special colors for large contracts. Send for free folder and samples.

IRVING
PATENTED

THE FIREPROOF OPEN STEEL FLOORING

You can "fit" a floor of **Irving Subway** into a given space, with as little trouble and usually with less expense, than with any other flooring material. And when you've done so, you've got something—a floor that will last as long as your building, with no upkeep—a floor your men will like, because it's smooth and comfortable—a floor that assures you underfoot safety, because it is absolutely and permanently non-slipping. Write us for Catalog 4A5-60.

McCracken Concrete Sewer Pipe being laid in London, Ontario, for sanitary sewers.

McCracken Concrete Sewer Pipe

is approved by London, Ontario

THE men who know by experience and experiment the necessary qualities of a thoroughly dependable Sewer Pipe are the men who most strongly recommend McCracken Concrete Sewer Pipe.

City engineers in Walkerville, Hamilton, Ottawa, St. Lambert, P.Q., Renfrew, London and more than twenty-five other towns and cities in Ontario, have gone on record as approving the use of this pipe.

McCracken Concrete Sewer Pipe is manufactured in accordance with standard specifications issued by the American Society for Testing Materials, and inspected by the Canadian Inspection and Testing Company, Limited. And because of its absolutely uniform high quality every pipe measures up to the same high standard.

JENKINS MADE-IN-CANADA VALVES

Men who make their purchases from the standpoint of quality, durability and dependability, specify Genuine Jenkins valves because they have no equal.

Jenkins valves are made in a variety of types for different services — water, steam, gas, air, etc. and range in size from 1/8″ to 24″.

Write for a copy of Catalogue No. 9 which gives full details.

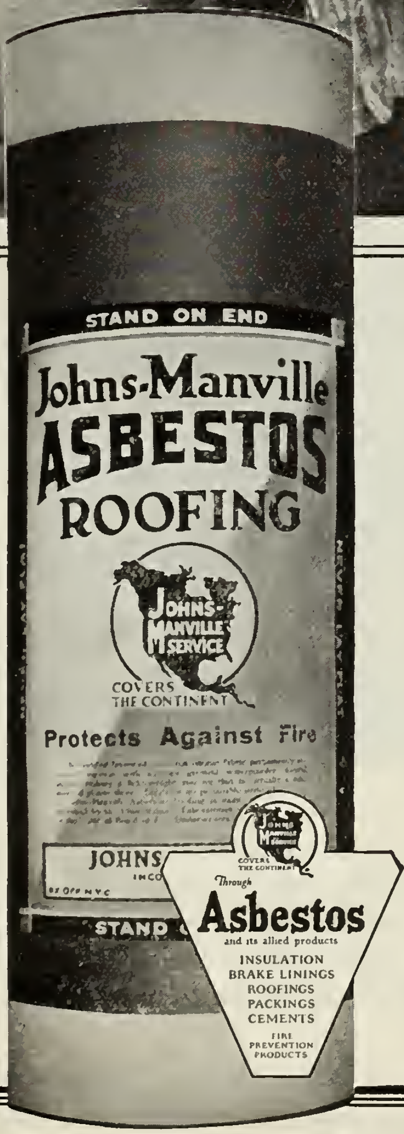
Asbestos Rock Showing Fibres



When you choose a roofing —remember this

Asbestos is the only mineral fibre used in roofing manufacture. It possesses decided advantages over animal or vegetable fibres because it will not burn, rot, or deteriorate in any way.

Asbestos from the Johns-Manville Mines in Quebec is manufactured into many types of roofing in the new Johns-Manville Canadian Factory. These roofings never need paint, give longest and most satisfactory service at least cost, and reduce your fire-risk.

JOHNS-MANVILLE
Asbestos Roofings

This Equipment Meets Emergencies

THE money-saving welding out-fit that eliminates the scrap pile and turns waste into profits. In every industry where machines are used there is a constant loss through worn and broken parts. To carry a reserve stock of spare parts involves a heavy investment, and interest charges. The modern method is to rebuild worn and damaged machine parts by welding.

A cylinder of Dominion Oxygen and a cylinder of Prest-O-Lite Dissolved Acetylene with an oxy-acetylene torch, will repair chipped cog wheels, cracked frames, and boiler tubes, to mention only a few of the applications of the oxy-acetylene process in reclaiming metal parts that would otherwise be "scrapped".

Our Welding Engineers will co-operate with your Factory Executives in applying the oxy-acetylene process in your plant and tell you about our chain of plants and warehouses where large supplies of Dominion Oxygen and Prest-O-Lite Dissolved Acetylene are always available for immediate shipment.

"Cast Iron Welding by the Oxy-Acetylene Process"

A comprehensive and authoritative treatise on what are usually considered difficult problems in the welding of cast iron, will be supplied without charge to the first 200 customers (executive or welding foreman) who request it on their business letterhead.

Why Use a Gang of Men?

WHY not replace that gang of men (and that's a great big pay roll nowadays) with a Link-Belt gasoline operated Crawler Crane, with an operator and perhaps an occasional helper. It is much cheaper, and you have speed when you want it, as it can do the work of 40 men.

Just think, you don't have to worry about keeping a large gang of men working, demurrage on cars, or filling your orders promptly.

It is gasoline operated, and needs no fireman or night watchman.

And then, don't forget how much better you can use your storage space, by more rapid handling, and piling the material higher.

In yards where it used to cost as much as 40c to 50c per cubic yard to handle material, they are now doing it for 5c to 10c with a Link-Belt Crawler Crane. And, besides, they have doubled their business because they are now able to take good care of their customers at all times.

Remember, the Link-Belt Crawler Crane will go any place where there is ground to travel upon—needs no tracks—climbs hills as steep as 25%—and is built to handle a very complete line of labor-saving attachments, such as grab bucket, dragline bucket, dipper shovel, trench shovel, skimmer bucket, pile driver, hookblock, and scrap and pig iron handling electric lifting magnet.

Let us get together. We have some very interesting handling costs, from successful growing concerns, where Link-Belt Crawler Cranes have not only paid for themselves in a very short time, but are earning many thousands of dollars every season.

Book No. 695 tells the story in photographs of actual installations. A copy is waiting for you at our nearest office. Send for it today.

A 50-man-power masterpiece

THIS LATEST INDUSTRIAL crawling tractor locomotive crane is producing 50-man-power results in handling the heavy loads of industry. It is cutting deep into the high costs of manual material-handling and recovering a buried treasure of non-productive dollars.

The new type D is a masterpiece of design and construction. Its outstanding superiority is guaranteed by America's pioneer crane builders. Over fifty years of untarnished business integrity and highly specialized skill and experience form its background.

This newest INDUSTRIAL has a greater field of usefulness in industry than any other material-handling equipment on the market today. As a crawling tractor it goes everywhere. With its accessories, including clamshell bucket, electro-magnet, hook and block, shovel dipper arm, dragline bucket, wood grapple and pile driving loaders, it will conquer any material-handling problem at a tremendous saving in time and labor.

This latest INDUSTRIAL is fully illustrated and described in a 16-page bulletin just off the press. Ask for Book No. E-120 and it will be sent to you promptly.

Metallurgical Re-Heating Furnaces for Blooms, Billets and Slabs

A. P. Theuerkauf, M.E.I.C.

Assistant Chief Engineer, Dominion Iron and Steel Company, Limited

Paper read before the Cape Breton Branch, The Engineering Institute of Canada, October 16th, 1923.

A history of the development of modern re-heating furnaces would be very interesting indeed, but would require more time to prepare than the writer has found available. It is, therefore, necessary to deal with the subject matter as briefly as possible and for this reason it is proposed to treat it in the following order:

(1) A brief history in connection with the original bloom re-heating furnace installed in the Dominion Iron and Steel Company's rail mill in the year 1905.

(2) A discussion of modern types of metallurgical re-heating furnaces for blooms, billets and slabs.

(3) A description of the modern re-heating furnace for rail blooms installed in the Dominion Iron and Steel Company's rail mill in the year 1921.

Before proceeding perhaps it should be state that some familiarity with rolling mill work, is taken for granted.

Original Bloom Re-Heating Furnace installed in 1905

The mill proper consists of 3 stands of rolls arranged abreast, viz: 3-high roughing, 3-high intermediate and 2-high finishing. All rolls are 28 inches pitch diameter nominally, and there are 6 passes in the roughing, 4 in the intermediate and one in the finishing, or 11 passes in all to roll a finished rail from a bloom. The mill operates at 80 r.p.m., and was originally driven by a 54″ x 66″ Porter-Allen steam engine, which was replaced in 1920 by a 3,000-h.p., electric motor. Rails weighing from 60 to 100 pounds per yard can be rolled on this mill at an average production of 750 gross tons per 24 hours, although the mill has rolled repeatedly at a rate of double this tonnage. The size of the blooms used varies from 7¼ inches to 8 5/8 inches square, depending on the size of rail rolled, and while the old furnace was limited to a bloom length of 14 feet, the new furnace can take blooms up to 9 inches square and 17 feet in length.

It was the intention originally to roll the blooms, as they arrived from the blooming mill, direct into rails without re-heating. A furnace was installed, however, intended chiefly for re-heating such cold blooms as might accumulate from time to time owing to delays and breakdowns in the rail mill. In actual practice, however, practically all of the blooms were given a "wash-heat"; at least this was so during the first few years the mill operated.

The old furnace was of the continuous type, coal-fired by hand and of very poor design and construction, as we know it to-day. The method of handling the blooms to and from the furnace caused frequent delays in the mill, because the incoming material to the furnace interfered to a certain extent with the outgoing material to the mill.

Figure No. 1. shows a general arrangement of the old furnace, which was 15 feet wide inside by approximately 46 feet long overall. As stated before, it was coal-fired by hand, the grate being operated on the gas producer principle, primary air for combustion entering underneath the grate by natural draft, and secondary air being forced in, by a motor driven blower, underneath the hearth, thence along through cast iron piping into the admission box on the level with the bridge wall, all as shown on the drawing. Thus only the secondary air received a slight pre-heating.

The blooms to be reheated were pushed into the furnace at the low end and up the sloping furnace bed, by means of a hydraulic cylinder. Arriving at the crest of the gradient it was necessary to crow-bar the blooms, one at a time, down the hearth slope and after lying there for a short time for the purpose of removing the black spots on the bottom, caused by riding on the water-cooled skid pipes, an electrically operated ram bar pushed them out of the furnace on to a roller table, where an electric overhead crane picked them up and transported them to the rail mill approach table.

The products of combustion travelled over the blooms and down through the vertical flues at the charging end of the furnace, finally reaching the stack through a series of parallel, horizontal, flues underneath the furnace bed. A very small portion of the gas also found its way underneath the blooms, joining the bulk of the outgoing gases, on their way to the stack, in the vertical flues at the end of the furnace. The designer of the furnace intended, of course, that a fair percentage of the gases should travel under the blooms in order to give a certain amount of heating from the bottom, as well as from the top. Gases, however, have a tendency to hug the roof in a furnace and the percentage that can be induced to travel under the blooms is disappointingly small and cannot be controlled effectively.

It is an axiom in rolling mill practice that good rolling depends on, and is impossible without good heating. Wash-heating rail blooms is an absolute necessity in our case and has proved of great advantage. Without a furnace; i. e. without re-heating; the finishing temperature of the rails is so low that the cold rolling effect injures the structure of the steel in the rail, resulting in a high percentage of rejected rails. With well re-heated blooms this is obviated to a large extent and also cold blooms can be re-heated and rolled into rails, instead of being melted over again at the open hearth plant.

The old furnace, however, fell far short of the requirements of a good re-heating furnace, for reasons mentioned before and for numerous other reasons, and its use was abandoned in 1914, when the war came along and the mill rolled chiefly shell stock, which did not require to be re-heated. At the conclusion of the war, the furnace had been idle for over four years, and structurally it had suffered greatly during its period of idleness and was practically in a state of collapse by the end of 1918.

No further rail business developed until August 1921, but in the fall of 1920 it was decided to proceed immediately with the design and construction of a new re-heating furnace of the most modern type, in anticipation of such rail business as was to come in the future. Prior to arriving at this decision, we had an opportunity to cast about and thoroughly review the types of furnaces in use.

Modern types of Metallurgical Re-Heating Furnaces for Blooms, Billets and Slabs

While the new furnace to be installed in the "Disco" rail mill was intended chiefly for re-heating rail blooms, we had in mind that it should also be designed to re-heat billets, (small blooms), and slabs to a limited extent, should the occasion ever arise. Hence, we branch out here and embrace the principal features of re-heating furnaces for blooms, billets and slabs.

There are two main types of furnaces in use for this class of work:—(a) The continuous furnace; and (b) The non-continuous, or "batch" type.

Generally speaking, both types are now fired with either coke oven or producer gas. Furnaces with a hand coal-fired grate, operated by natural draft, are not built any more in modern steel plants because of their many deficiencies, such as, inability to regulate the flame, wholesale air leakage into the furnace on account of pressure inside being slightly below atmospheric, small production capacity, large scale loss and high coal consumption.

Stoker fired furnaces with forced draft are somewhat better in these respects and have the additional advantage, over gas fired furnaces, of comparatively lower first cost and smaller space occupied. However, they also have their objections and are built only where coal is relatively cheap and first cost of installation is a serious consideration.

Furnaces have also been installed which are fired with natural gas, some with oil and others with powdered coal, but these are in the minority and will not be dealt with here.

Blast furnace gas is also used for firing re-heating furnaces, but examples of this kind are chiefly confined to European installations, where the problem of conveying this gas through long pipe lines, without incurring explosion risks, seems to have been solved successfully.

Advantages of Gas Firing

There are several reasons why gas firing is superior to the direct firing of coal in furnace operations.

(I) *The attainment of practically perfect combustion and high heats.* Fuel in the gaseous form burns quickly and perfectly, carries no ashes into the furnace and permits any desired temperature to be reached and maintained.

(II) *Economy of fuel.* Gas firing permits the use of regenerators, or recuperators, for restoring a large part of the waste heat to the air before it enters the furnace and this fact, taken together with the perfect combustion secured, results in large fuel economy.

(III) *Easy regulation of the flame, uniformity and no delays.* When coal is fired direct in a furnace, (excepting stoker fired furnaces), there can be no steady maintenance of heat; it fluctuates continually, as the fires burn up or are freshly charged. This has a deteriorating effect on the furnace and diminishes output. Then there are always unavoidable delays in cleaning the fires, during which the furnace cools and the output is stopped.

Both of these drawbacks are avoided by gas firing, the conditions are always uniform, at their highest efficiency, and there are no delays in the regular operation.

(IV) *Less oxidation loss.* A substantial saving is effected in scale loss because with gas firing there need be little, if any, excess air and such little excess as must be present is kept where it can do the least harm, namely nearest the roof of the furnace.

(V) *Saving in labour.* This is obvious in the case of coke oven gas, because no firemen or coal and ash wheelers are required.

(VI) *Saving of by-products.* The by-products, in the case of coke oven gas, have been extracted from the coal during the coking process at the coke ovens, whereas with coal fired furnaces they are lost. Producer gas has the same objection in this respect as direct coal firing.

The sum of these advantages makes a grand total which is usually sufficient to entirely pay for a first class gas fired furnace installation in a comparatively short time.

Recuperators or Regenerators for Pre-Heating Gas and Air

The continuous furnace is generally provided with either recuperators, or regenerators, for pre-heating the combustion air only, whereas the batch furnace is always arranged with regenerators for pre-heating both gas and air, when producer gas is used, and air only when coke oven gas is the fuel. In the continuous furnace the flame travel is always in the same direction through the furnace, while in the batch furnace it is reversed from one end to the other every half hour, or more frequently when necessary.

When coke oven gas is used as fuel it is never pre-heated before entering the furnace, irrespective of whether the continuous or batch type is used, past experience

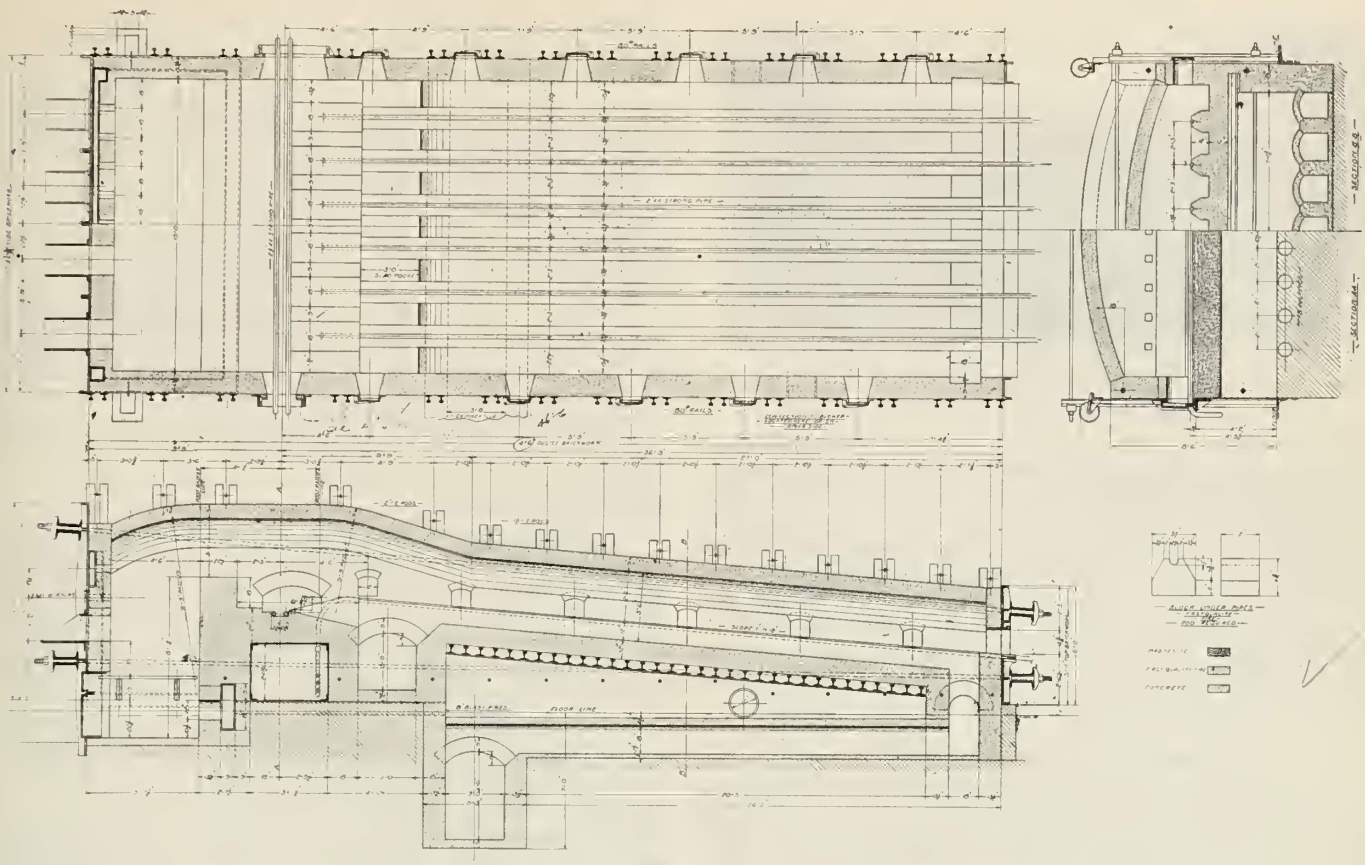

Figure No. 1,—General Arrangement of old Continuous Rail Bloom Heating Furnace.

having shown where pre-heating was attempted that a certain explosive risk is involved in view of the richness of this gas and also there has been trouble with the regenerators sooting up rather quickly; moreover, the saving which results from a preliminary heating of this gas is of little consequence. Besides this, even if, theoretically speaking, it were possible for the gas to traverse chambers heated to high temperatures without dissociation of the hydro-carbons, it would appear impossible to effect this in practice, and the increased sensible heat would be more than balanced by the loss in latent heat resulting from the dissociation. As a matter of fact, the simplification, both in the construction of the furnace and in its maintenance, as well as in its behavior during operation, is sufficient reason to lead coke oven gas into the furnace cold, which gas gives, in any case, a fully sufficient temperature of combustion.

Producer gas when used in continuous furnaces is never pre-heated, because it would be next to impossible to construct a reversing valve capable of resisting the ensuing high temperatures, nor could the resulting complication in construction and operation be justified. In batch furnaces it is, however, quite standard practice to pre-heat both gas and air, when using producer gas as fuel, and in consequence the heat radiation losses which are larger with this type of furnace than with the continuous type, are somewhat made up for. Pre-heating of producer gas can here be indulged in without detriment, because the inherent principle involved in the construction and operation of the batch furnace, (being reversing), is such that no extra complications are required, nor is it necessary for the pre-heated gas to travel through a reversing valve.

Typical Re-Heating Furnaces

Figure No. 2 shows a Morgan continuous suspension-roof furnace and continuous gas producer, for heating billets 1¾ inch to 2½ inches square by 30 feet long. Its bed usually measures 32 feet wide inside by 20 feet long. It slopes towards the hot, or discharging end, at a pitch of 2 inches to the foot. The upper part of the furnace bed consists of watercooled pipes or "skids" on which the billets rest. The central part of the furnace bed is formed with fire-brick; the lower, the hottest, part is paved with magnesite brick. The roof is turned in three arches, each having about 7 feet span. The hanging skew-backs for these arches are supported by 2-inch double extra heavy pipes, through which water is flowing These pipes are suspended from steel girders resting on the furnace walls. Special skew-back bricks, with semi-circular recesses, are placed over the pipe, and against the sloping faces of these bricks the roof arches rest. This construction has been in use since 1896, has proved very durable and satisfactory, and has a great advantage where used over a large, wide bed, *as it makes it possible for the roof to be brought as closely as desired to the bed, thus securing uniform heating of the 30 foot long billets.* Uniform heating is absolutely essential when heating small billets 30 feet long for continuous mill work, where the billet passes through fourteen stands of rolls at the same time, at an ever increasing speed. Above the arched and refractory roof, a hollow space is formed by a second roof of corrugated iron, covered with sand. At the lower end of the furnace air is admitted into this space, whence it is drawn by an exhaust fan. After passing through this fan, the air is returned to the space under the bed of the furnace. Here it passes around a recuperator, or stove,

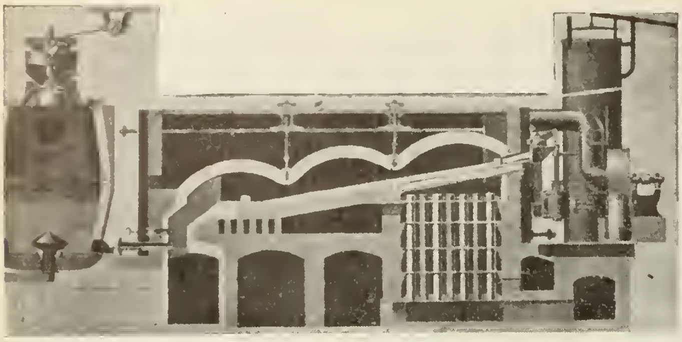

Figure No. 2,—Morgan Continuous Suspension Roof Furnace and Continuous Gas Producer.

built of iron pipes, through which the products of combustion from the furnace pass on their way to the smoke stack. The air is finally led under the bottom of the furnace hearth into the fourteen air ports; each port being about 4½ inches square, and controlled by its own valve. The producer gas enters through fourteen gas ports, 9 inches by 13½ inches in size, each controlled by its independent, water-cooled slide valve. The gas is delivered into these ports through short flues directly from the adjacent gas producers.

Methods of Charging the Furnaces

The draught is entirely regulated by the exhaust fan. The smoke stack is simply a flue for conveying the products of combustion out of the building. The billets are delivered at the upper corner of the furnace on rollers. At this point it is gripped between two pinching feed rollers, which are placed flush with the inside of the furnace wall. These are usually belt driven. When the billet has been carried through these rollers, it is fairly within the furnace. A steam cylinder fastened to the furnace binding on the upper, cold side of the furnace, turns a longitudinal shaft which is armed with five levers working push bars which enter into the interior of the furnace. By lowering the piston of this steam cylinder, the push bars are made to advance, pushing the billets forward. In this manner the furnace hearth is gradually covered by one continuous layer of billets.

In most other types of continuous furnaces the stock is charged into the furnace through the end, the opening and closing of the charging door being in some cases accomplished automatically by the charging pusher. While the door is opened, cold air enters into the gas off-takes to the smoke stack, influencing the draft, or when the pressure in the furnace is above atmospheric, combustion gases leak out into the building and hamper operation. Because of these objections it is the practice in some plants, more particularly where smaller stock is to be reheated, to charge the furnace in batches, thus dispensing with the frequent opening of the charging door. This practice is objectionable, however, because it requires a long stroke pusher if the gas off-takes are to be kept open, and where the billets are withdrawn from the furnace regularly they are not all equally well heated, a matter of considerable importance in the production of wire rods and strip material.

In the Morgan furnace these objectionable features are avoided by charging the billets into the furnace as described above. Thus, the charging opening is not much larger than the cross-section of the billet, therefore very small, and the same is true of the openings for push bars, which are kept reasonably closed by the push bars themselves. Interference with the furnace draft is, therefore, unknown and gas does not leak out at the charging end.

As the billets advance, they come into zones of higher temperature and are gradually and uniformly heated until they arrive at the bottom, or hot end of the furnace, thoroughly soaked and ready for rolling. This furnace contains about one hundred and twenty, 1¾-inch billets, and can, without forcing, deliver one hundred heated billets per hour; the billets always enter the furnace cold. This is roughly equal to 15 tons per hour. As long as the billets arrive at the mill fairly straight, the heating process is nearly automatic, one man feeding the furnace, another discharging the billets into the mill. The heater controls both furnace and gas producers. The working of the latter is indicated by gauges fastened to the furnace binding, close to the gas and air valves. Close to these gauges are valves for regulating the steam pressure used on the producers.

The delivery of the billet from the furnace into the mill is effected by a second pair of driven pinch rollers. Between these is entered a push bar, the forward end of which is placed against the rear end of the billet. By pressing the pinch rollers together against the push bar, the discharger forces the hot billet forward through a small door directly into the first pass of the mill.

It is desirable that the gas should enter the furnace as hot as possible and therefore the producers are placed as closely as practicable to the furnace.

As a definite record of the performance of the combined Morgan producer and furnace, it may be stated that the average quantity of coal used for heating one ton of cold 1¾ inch billets is in the vicinity of 150 pounds.

This furnace has been described rather fully because it is the best of its kind in the market. The Dominion Iron and Steel Company has two of these furnaces, one installed in 1904 and the other in 1913, and they have never given any trouble worth mentioning and are very economical and efficient in operation.

Figure No. 3 illustrates the so-called "Chantraine" patent continuous re-heating furnace for blooms, billets and slabs. This type of furnace has found great favour in England, France and Germany during recent years and is claimed to have a lower coal consumption than any other type.

As the illustration shows, it is provided with a multi-flame arch built over the final heating hearth. It is designed for an output of 6 tons per hour on medium size billets. The stock is pushed in at the front end and right through the furnace, riding on watercooled skid pipes to the crest of the hill from whence it falls down the inclined hearth. As the stock travels through the furnace it gradually increases in heat and reaches rolling temperature under the multi-flame arch. This furnace is designed with shallow recuperators underneath the hearth, attractive where foundation or drainage difficulties are encountered. Producer gas is the fuel used. The hot air from the recuperators is collected and taken to the air reservoir by a fire-brick lined steel pipe as shown. The producer gas comes in at the end forming a blanket through which the jets of air penetrate and form impinging flames, which cover the whole surface of the hearth and speedily and evenly heat the material with a minimum of oxidation. Forty per cent of the products of combustion after leaving the hearth goes to the recuperator. The remaining 60 per cent travels along the downward sloping hearth to the smoke stack. Dampers are provided in each case for simple regulation purposes.

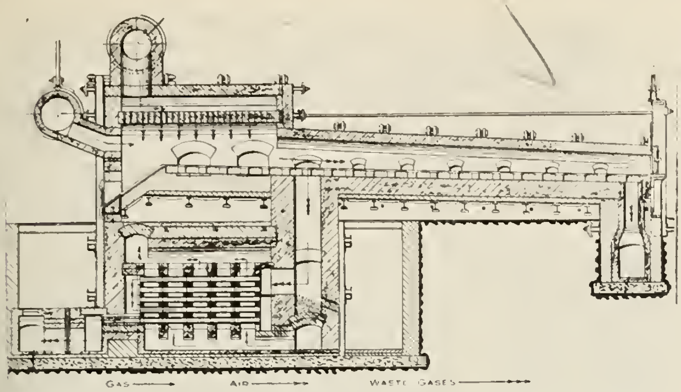

Figure No. 3,—Longitudinal Section of a Chantraine Patent Continuous Re-heating Furnace.

A picture of the recuperators is shown in figure No. 4, in perspective. It clearly indicates the method of building up the special tubular ducts of refractory material which are designed to heat the air to within 300°C., (572°F.), of the waste gas temperature. The solid base and side wall are shown, and a good idea is given of the strength and solidity of the construction. The end to end joints of each recuperator tube are shown staggered, the idea being to prevent leakage as far as possible.

Two Chapman-Stein continuous re-heating furnace for billets and slabs, are installed at the plant of the Youngstown Sheet and Tube Company; these are of the gravity discharge, recuperative type and are designed to use either producer or coke oven gas. Last year the writer saw these furnaces in operation and while they made a good impression, generally speaking, there were some points that would stand improving. A longitudinal cross-section through such a furnace is reproduced in figure No. 5, indicating also the recuperator arrangement for pre-heating the combustion air. The travel of the waste gases and air are shown by the arrows.

The Chapman-Stein Furnace Company claim that a good recuperative furnace will pre-heat the air required for combustion to a temperature about 250° to 350° F., less than the temperature of the spent furnace gases entering the recuperator. This usually means a saving of around 30 per cent of the fuel required as compared with no pre-heating of the air. This economy is brought about not only because of the heat units transferred from the spent gases to the incoming air, but because of the fact that the excess air which is always required for complete combustion is greatly reduced when the air is pre-heated, and thus oxidation losses are also decreased.

There is no question but that if a recuperative furnace could be designed for forced draft operation, with the recuperators remaining tight and free from leaks, it would be an ideal furnace. It would transform the so-called continuous air regenerative furnace into a real continuous type; reversing valves with their flues would fall away and a more uniform heat could be maintained throughout the furnace. This is due to the fact that immediately on reversing, the pre-heated air is at its highest temperature, which drops steadily as the stored heat is abstracted from the air checker chamber.

The recuperative furnace costs less to install and perhaps less to operate; it takes up less space, requires less skillful handling and much less attention, but Professor Trinks, an eminent authority on metallurgical re-heating furnaces, states in one of his articles on the subject of recuperative furnaces, as follows:—

"In practically all of the continuous slab and billet furnaces which I have inspected, the brick recuperators were either abandoned or were about to be abandoned.

"Leakage there is, and the amount is by no means negligible. From a test made some years ago the writer computed that 30 per cent of the air entering the recuperator leaked out before it reached the burners; and in another furnace in the Pittsburgh district, which was equipped with a tile recuperator, 65 per cent of the air leaked out.

"For variable rates of heating a tile recuperator is exposed to the danger of cracking."

Making due allowance for exaggeration and also keeping in mind that Professor Trinks' statements are probably based on "old-style" recuperators, it would appear difficult, in the long run, to keep even the tile recuperators of the Chapman-Stein furnace free from cracks and leaks, particularly as there are a good many joints involved and the wall thickness of the tile brick must be relatively thin in order to get good heat transfer.

Moreover, the recuperative furnace is not suited to conditions which demand a large overload capacity, on account of the absence of forced draft and because the brick volume in the recuperators is not sufficient for storing the necessary heat. Under such conditions the regenerative furnace with its great quantity of checker brick and forced draft is advisable. The recuperative furnace has, however, a very large number of applications, recent advices from the Chapman-Stein Furnace Company. (Mt. Vernon, Ohio) indicating that they have on order eight re-heating furnaces for ingots, blooms and slabs.

The features claimed for the Chapman-Stein recuperator are stated in their catalogue as follows:—

"The distinctive feature of the Stein recuperative furnace is that the recuperator air ducts are vertical and have no turns or off-sets. Sufficient natural draft is thus procured through the recuperator to give a slight pressure in the furnace without requiring a blower for the air. By eliminating a fan we avoid any excessive pressure in the air ducts of the recuperator. In fact the air ducts at the bottom are under a slight suction (about 1/10 inch). This practically balances the suction in the spent gas passages which is about 1/8 inch. There is thus practically no occasion for the air in the air passages to leak through into the spent gas passages. This, in the

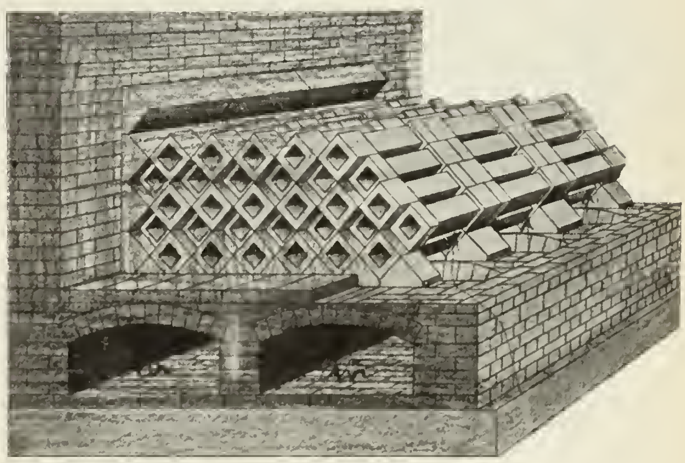

Figure No. 4,—Recuperators, showing the Method of Building up the Special Tubular Ducts of Refractory Material.

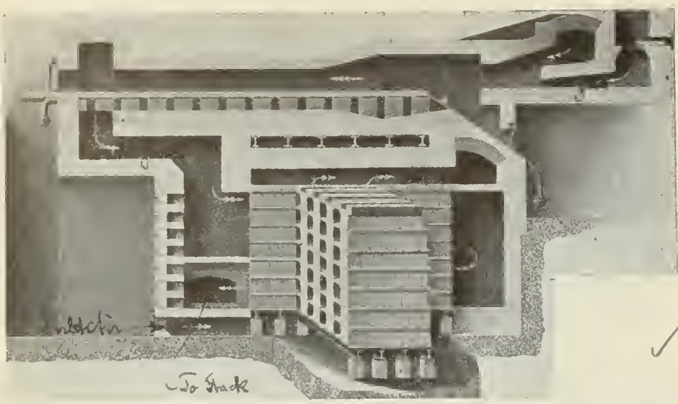

Figure No. 5,—Longitudinal Cross-section through a Chapman-Stein Continuous Re-heating Furnace.

past, has been the chief cause for failure in the recuperative furnace, for no tile joints could be made tight enough to withstand a positive air pressure from a fan on one side of the tile and the minus pressure of the spent gases on the other.

The Stein recuperator in addition to eliminating the air pressure in the tile reduces the stack draft around the tile by making fewer turns and larger passageways for the spent gases. In this way we obtain an approximately balanced draft on each side of the tile. Moreover the entire recuperator is made with overlapping joints doubly closed so as to permit expansion and contraction without leakage. It is thus made practically leakproof.

The special recuperator tile are held in place laterally by slabs that direct the flow of the spent gases and also serve to close the joints between the tile. These slabs in turn are held in place by lugs on the recuperator tile, another patented feature.

Each special recuperator tile is reinforced by two vertical partitions which permit the tile walls to be made only ¾ inch thick, thus making possible a very rapid heat transference. By making the vertical air passages very small we are able to heat the air much hotter as there is no room left in the center of the passage for a core of colder, slower moving air, as has been the case heretofore.

The tile are also made so as to break joints in every direction. In setting these tile, no attempt is made to produce a solid mass by using cement, so as to prevent leakage. The large amount of lap of the doubly closed joints, together with the fact that there is practically no difference in the air and waste gas pressures on either side of the tile, is adequate insurance against leakage. In many cases these recuperators have had to withstand for years the jar from heavy trip hammers located nearby and no harm has resulted."

"Two laws are vital in designing an efficient recuperator:

1. The air and spent gases must flow in opposite directions. This is the only way to bring the hottest air in contact with the hottest tile, thus raising the temperature of the air to the highest point.
2. The air to be heated must flow upward and the spent gases to be cooled must flow downward. This is absolutely necessary in order to keep the air in the recuperator until it is properly heated and to keep the spent gases in the recuperator until they have given up their heat. Otherwise some of the air would escape before it was properly heated and a portion of the spent gases would escape before they were cooled.

Only by scrupulously observing these two laws can correct circulation and good efficiency be obtained."

Another popular type of continuous furnace used in the United States for re-heating blooms, billets and slabs is the so-called Alex. Laughlin furnace, installed in a large number of rolling mills; similarly to the last two furnaces described, it is of the recuperative, gravity-discharge type and either coke oven or producer gas can be used as fuel. This furnace is installed at the 28-inch merchant mill of the Bethlehem Steel Company, at Sparrows Point. It is of the gravity-discharge type and fired with powdered coal, which enters the discharge end of the furnace through overhead pipes and burners, being conveyed through the pipes from the powdered coal preparation plant by means of the air required for combustion.

The batch furnace is similar in construction to a stationery open-hearth furnace, the direction of the flame travel across the hearth being periodically reversed and the furnace is generally always equipped with regenerative checker chambers for pre-heating the air used for combustion. When producer gas is used this is also pre-heated in the same manner as the air.

The blooms or slabs which this type of furnace usually heats are charged on the hearth of the furnace and remain in the one place until hot enough to roll. There is an open space between the stock to be heated, so that three sides are available for directly absorbing the heat from the products of combustion, or roof, while the fourth side is resting on the heated hearth of the furnace and absorbs from it a large amount of heat.

The Dominion Iron and Steel Company installed six batch type re-heating furnaces in connection with its 110 inches plate mill, in the year 1919. These have a hearth 9 feet wide inside by 34 feet long and are designed for heating with coke oven gas, the necessary combustion air being pre-heated in regenerative checker chambers.

Usually this type of furnace has a silica bottom, made by fusing sand in thin layers until the proper thickness is reached. Occasionally sintered magnesite is used instead, which is, perhaps, better but also more expensive. A slight slope toward the rear and center of the furnace permits of periodically drawing-off the slag, which forms, through spouts into slag buggies. The material to be heated is charged and withdrawn through large doors in the front wall of the furnace, in the manner described and illustrated above. Ports are provided at each end of the furnace, through which the gas and air are alternately admitted and withdrawn. Two regenerative checker chambers are located at each end of the furnace for pre-heating either the air, or air and gas, which ever the case might be. The checker chambers are connected to the smoke stack by underground flues containing valves and dampers, so arranged, that the direction of the flow of the hot gases across the hearth may be periodically reversed. In this manner the gas is first burned through one end of the furnace, while the waste gases leave at the opposite end, heating the checkers in their passage to the stack. The flow is reversed in 20 to 30 minutes, the gas is burned through the other end and the air for combustion is pre-heated in the checker chambers which have just received their heat from the waste gases.

Two or more of these furnaces are usually required for a rolling mill, depending on the production required. With one furnace containing heated steel and ready to roll, the first door is opened and the part of the hearth served by this door cleared of steel. Then the second door is started in the same manner, and while drawing the second door, the first is recharged. This is continued until all the hot steel has been drawn and the furnace refilled with cold blooms. The charging crane then moves to the second furnace and repeats the operation. By alternating the furnaces, little time is lost in waiting for hot steel.

Before concluding this part of the programme it should be stated that both, batch and continuous furnaces, can heat either blooms, billets or slabs, within certain limitations. The batch furnace can heat various sizes and shapes at the same time, but is not very economical, nor has it sufficient capacity on small stock. The continuous furnace has a much larger capacity as a rule, but is limited to even size blooms, billets or slabs; it cannot accommodate a mixture of different size stock because doubling up would surely occur in the furnace and make a mess of things.

Modern Re-Heating Furnace installed in 1921

Starting with the inception of the idea that a new modern furnace was required, we corresponded all over the country first to see what the other fellow had accomplished; ascertained his mistakes and shortcomings; listened to good advice; used common sense; spent a month in studying our own peculiar conditions and then went ahead with the design of the new furnace.

The new re-heating furnace referred is of the continuous gravity-discharge type, heated with coke oven gas and equipped with regenerative checker chambers for pre-heating the combustion air. The reasons for its selection, in preference to several furnaces of the batch type, might be listed as follows:—

(1) A capacity of 1,500 tons per 24 hour day was specified on wash heats, and 600 tons per 24 hour day on cold blooms. This would have required at least four furnaces of the batch type, demanding a space 180 feet wide by 160 feet long. It was impossible to find room in the vicinity of the rail. mill for this. Although the new rail mill furnace has practically a capacity equal to the six plate mill furnaces, (which are of the batch type), it requires only about one-third of the ground space of the latter.

Figure No. 6,—Discharging end of Bloom Re-heating Furnace for Rail Mill.

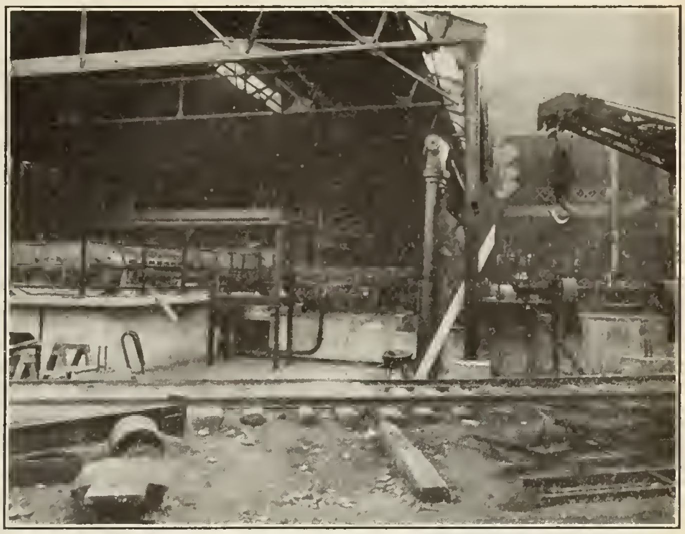

Figure No. 7,—Charging end of Bloom Re-heating Furnace for Rail Mill.

(2) The cost of four-batch type furnaces, complete with all accessories and ready for operation, would have been at least three times that of the continuous furnace actually built.

(3) Batch furnaces with 18 feet wide hearth inside, (the width of furnace required in our case), would involve structural and operating difficulties, because of roof span, heat intensity, and large door openings required on one side of furnace, weakening the roof structure. True, the Morgan type of water-cooled suspension roof might be used, but again we have extra complications.

(4) Overhead and operating charges on four batch furnaces would be considerably in excess of those for a continuous furnace.

(5) Fuel gas consumption of the batch furnaces, not counting standby losses, would easily be double that for a continuous furnace.

(6) Whenever rail mill is operated single shift, the standby losses of the batch furnaces would be far greater.

(7) Maintenance charges on such large batch furnaces, (with 18-feet roof span), particularly when subjected to alternate heating and cooling from day to night shift, and over Sundays, would naturally be more consequential.

(8) For re-heating dead-cold steel the batch furnace is absolutely wrong, because charging cold blooms into a reversing furnace, which is at a high even temperature all over, tends both to kill the flame and chill adjacent material probably just ready to draw. The continuous furnace is the only one to use in this case. Dead-cold steel needs a gradually growing heat, such as it gets in a continuous furnace.

The only advantages of batch furnaces are those of more flexibility and more uniform heating, i. e. they can more readily absorb the usual fluctuations resulting in the supply and demand of ingots and blooms between the open hearth, blooming and rail mills. They can also heat material of mixed sizes and shapes and there is no trouble in keeping the hearth in good condition and in running-off the slag in a molten state.

The continuous furnace gives a certain amount of trouble with accumulation of scale and cinder building up the hearth bottom, involving heavy labor at week-ends chipping it down with hammer and bar. The furnace temperature is not quite hot enough to melt the scale and draw it off in liquid form; if it were it would be too hot for the blooms and they would weld together, as they closely adjoin one another. With the continuous furnace, therefore, some expense will be incurred in cutting down the hearth bottom at week-ends, but we have now several continuous furnaces and never had any serious difficulty in keeping the hearths in shape, nor is there anybody with experience with both types of furnaces who would decide against the continuous furnace for this reason.

The few advantages cited above for the batch furnace are very important, but the price is high for them when continuous furnaces can be and are being successfully operated for reheating rail blooms, at several large steel plants.

Work on Design and Construction of New Furnace

The reasons for selecting the continuous type furnace having been stated, it might now be of interest to briefly review the items of work involved in the design and construction of the new furnace, with its accessories. Arranged in somewhat tabular form, they are:—

Clearing the old site, removing the abandoned furnace with stack, etc.

Preparation of approximately 184 full size drawings, 19 of which were studies.

Excavating 3,300 cubic yards of earthwork and old concrete.
Placing 1,500 cubic yards of new reinforced concrete.
Fabrication and erection of 200 tons of iron castings and Machinery.
Fabrication and erection of 80 tons of structural steel
" " " " 40 " " plates
" " " " 25 " " rails
Total....................345 tons

Laying 390 M fire brick (for furnaces, flues, valves and stack, etc.)

Laying 25 M silica brick (for furnace roof) since changed to clay brick.

Laying 20 M red brick (for filling).

Total 435 M brick (9-inch equivalent).

Laying 46 tons of gas and water piping.

Installation of and wiring for 12 electric motors and control equipment, totaling about 370 h.p.

Installation of a blower, sump pump, the special "Isley" reversing valve, etc.

It required approximately six months to prepare the 184 drawings referred to above and while material was ordered on shops for fabrication as fast as the drawings were completed, actual construction in the field was not started until June 1st, 1921 on account of bad weather conditions and other pressing work. However, the furnace began operating on the August 25th, 1921, or less than three months after commencing field construction. The speed of preparation of the drawings, as well as the time required for the fabrication and construction of the

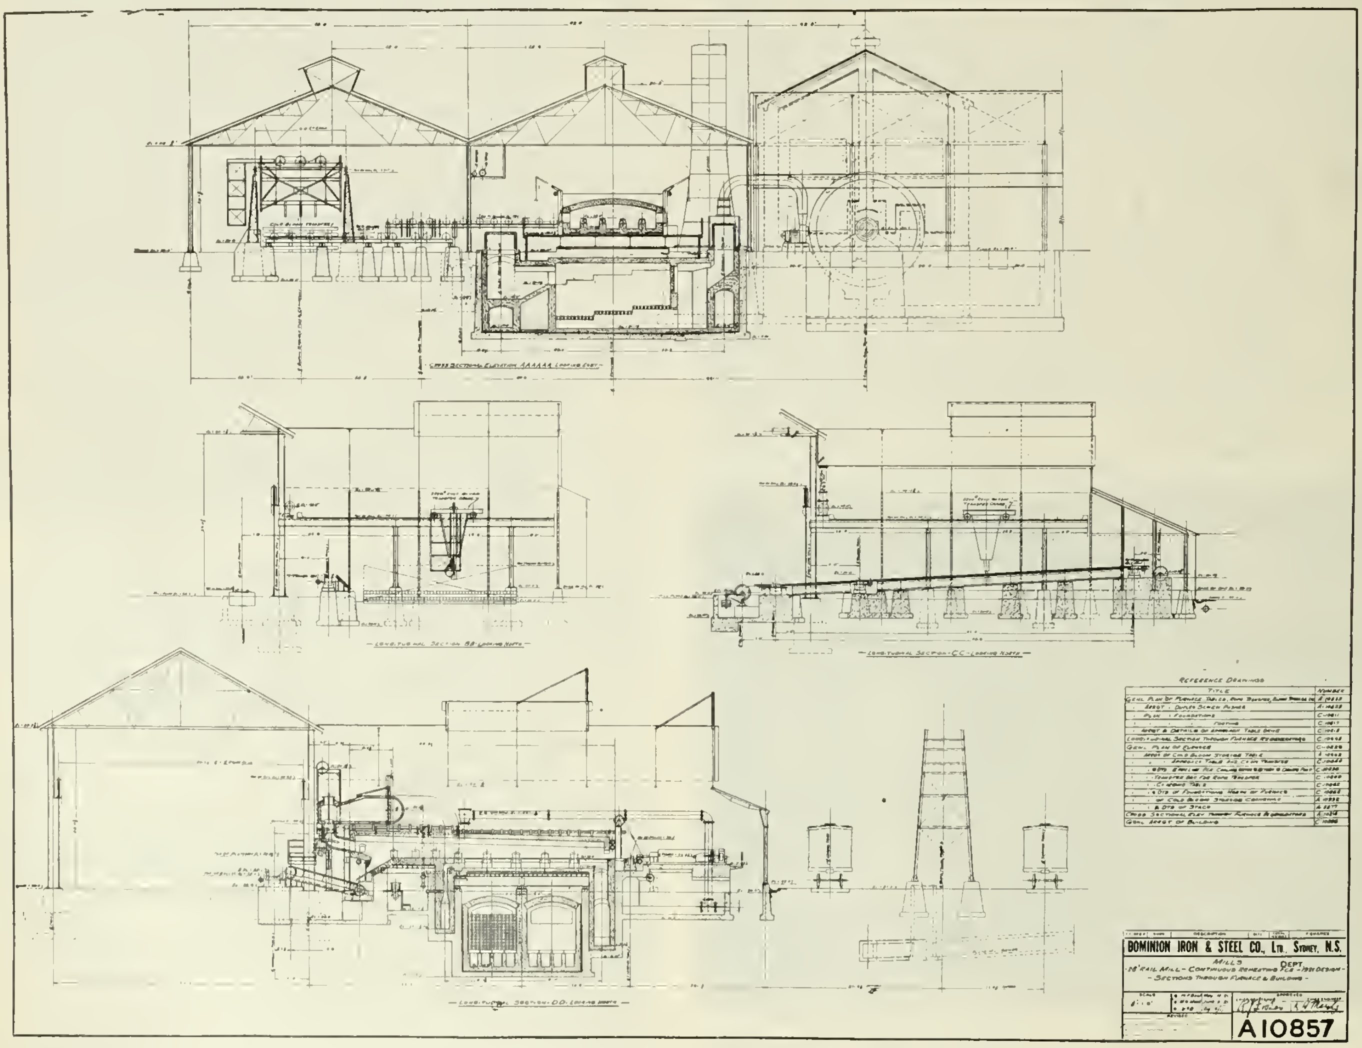

Figure No. 8,—Sections through Furnace and Building of 28-inch Rail Mill—Continuous Re-heating Furnace—1921 Design.

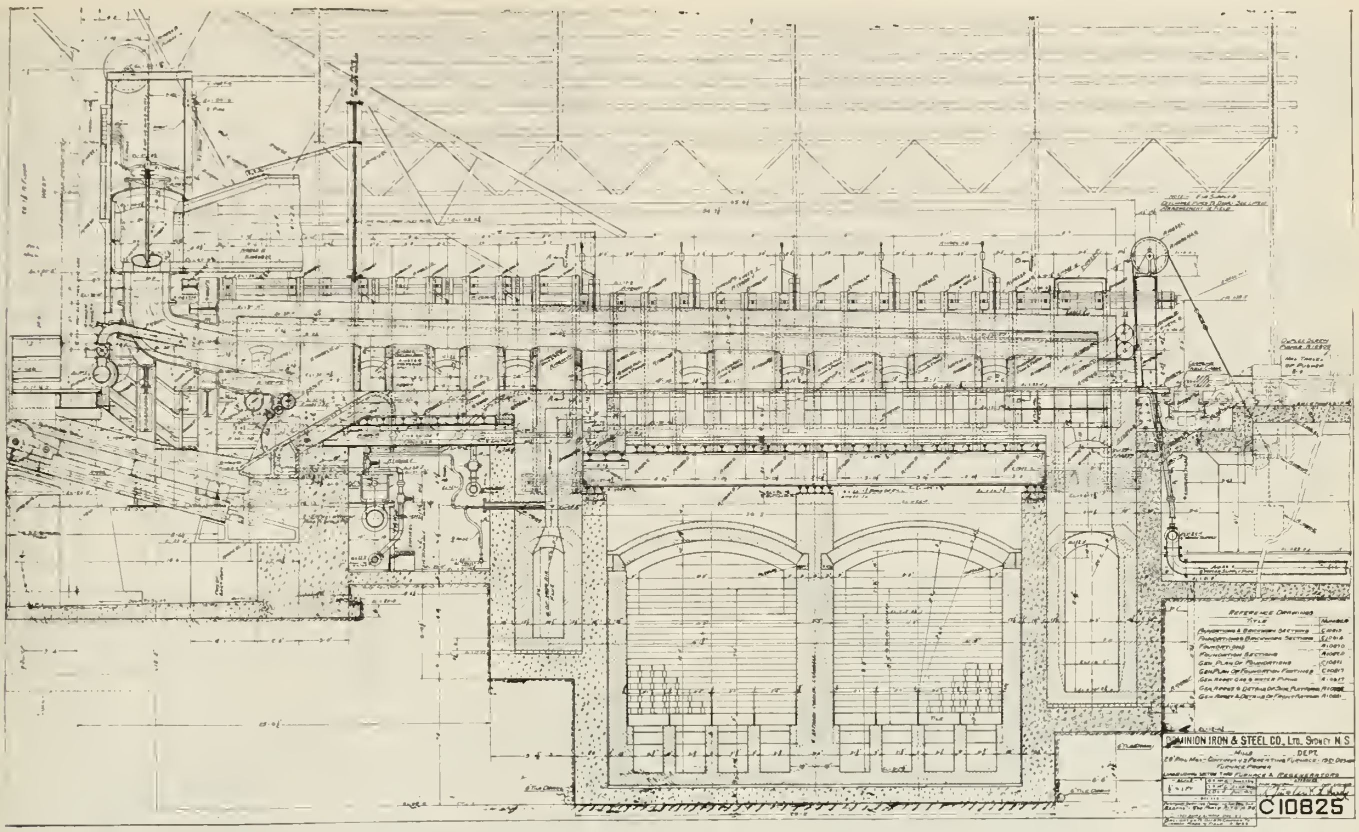

Figure No. 9,—Longitudinal Section through Furnace and Regenerators 28-inch Rail Mill—Continuous Re-heating Furnace—1921 Design.

furnace and its accessories constitute a record of which the personnel involved might well be proud. The actual total cost of the furnace with all accessories was approximately $250,000.

The furnace is heated with by-product coke oven gas having an approximate heat value of 585 B.t.u., per cubic foot. If an adequate supply of coke oven gas is available a furnace of this kind should always be heated with that gas in preference to producer gas, because:—

(1) It eliminates a great part of the first cost; such items as gas producers, with their large piping, coaling platform, etc., fall away entirely.

(2) The labour of operating the producers and for coal and ash handling is dispensed with, hence lower heating cost.

(3) Coke oven gas is a better fuel for such a furnace than producer gas, because it is more uniform in composition and heating value, and because of its cleanliness does not clog the checkerwork in the regenerators nearly so quickly.

(4) With coke oven gas the by-products have been extracted out of the coal, whereas with producer gas they are lost.

Of course, when coke oven gas is used the advisability of feeding it to the furnace at a uniform pressure is apparent and can readily be accomplished by installing a pressure regulator.

Figure No. 9 is a typical longitudinal cross-section through the furnace proper, which it will be noted is of the horizontal continuous gravity-discharge type, the blooms arriving on the furnace charging table, one at a time, from whence an electric pusher pushes them clear across the waste gas flue ports into the furnace, thus moving the entire furnace contents one bloom at a time with the result that at the furnace discharging end a bloom goes over the crest of the hill, thoroughly re-heated, and drops by gravity on to a short chain conveyor which conveys the bloom to the mill approach table. The furnace can re-heat either hot or cold blooms; for obvious reasons they should not be mixed but rather processed separately. Generally the blooms arrive at the furnace hot, direct from the blooming mill, at a temperature of from 1,500° to 1,800°F. They leave the furnace at rolling temperature probably about 2,100°F.

This furnace employs the regenerative principle for pre-heating the air, the coke oven gas being introduced into the furnace cold without pre-heating, for reasons mentioned before. The regenerative checkers were provided not so much for economy but to give maximum tonnage output, more particularly when re-heating cold blooms.

The furnace has a capacity of 1,500 tons on wash heats per 24 hours, or 62½ tons per hour; it could heat 600 tons of cold blooms per 24 hours, or 25 tons per hour. The largest size bloom it will take is 9 inches by 9 inches by 17 feet and the minimum length that can be handled is about 8 feet. The inside width of the furnace is 18 feet and its hearth length 42 feet, which when fully charged holds fifty-six 9-inch square blooms and these, when 17 feet long, would amount to 120 tons of material. At an output of 1,500 tons per 24 hours, (wash heats), the duration of the blooms in the furnace would be approximately 2 hours. On cold blooms this period would be increased to about 5 hours. In regard to the furnace hearth length it might be stated that 30 feet is generally considered sufficient for "wash heats", but for cold blooms a longer hearth, up to 45 feet is desirable. With a longer hearth better results are obtained, because it allows the heat to penetrate and soak into the steel, instead of being mere surface heat. On the other hand someone said jokingly that in a continuous furnace the difficulties increase with the cube of the length.

Professor Trinks states:—

"In designing continuous furnaces the greatest gain in efficiency is not made by lengthening the furnace so as to make the cool end cooler but by pre-heating the air so as to make the hot end hotter. The proper place to utilize heat is at the hot end, not the cold. This is due to the fact that furnaces are slow and the radiation losses correspondingly large if the flame temperature is not considerably in excess of the temperature required in the steel. For example, if the steel had to be heated to 2,200°F., in a furnace having a flame temperature of but 2,400°F., the furnace would be slow and inefficient, while if the air could be pre-heated so that a flame temperature of 2,800°F., could be obtained the furnace would be nearly three times as fast and much more efficient."

Explaining further the design, construction and operation of the furnace, it might be stated that primary combustion is arranged for at the discharging end, the coke oven gas entering through five 6-inch diameter burners at an average pressure of approximately 15 inches of water, mixing with the pre-heated air which has an average temperature of 800°F., and is admitted through five 20-inch diameter watercooled mushroom-type air valves. The products of the primary combustion then travel over the blooms the full length of the furnace to the charging end, where vertical down flues are provided for leading the waste gases to the "Isley" reversing valve, from thence through the checker chamber into the stack reversing valve and finally through the stack flue into the stack.

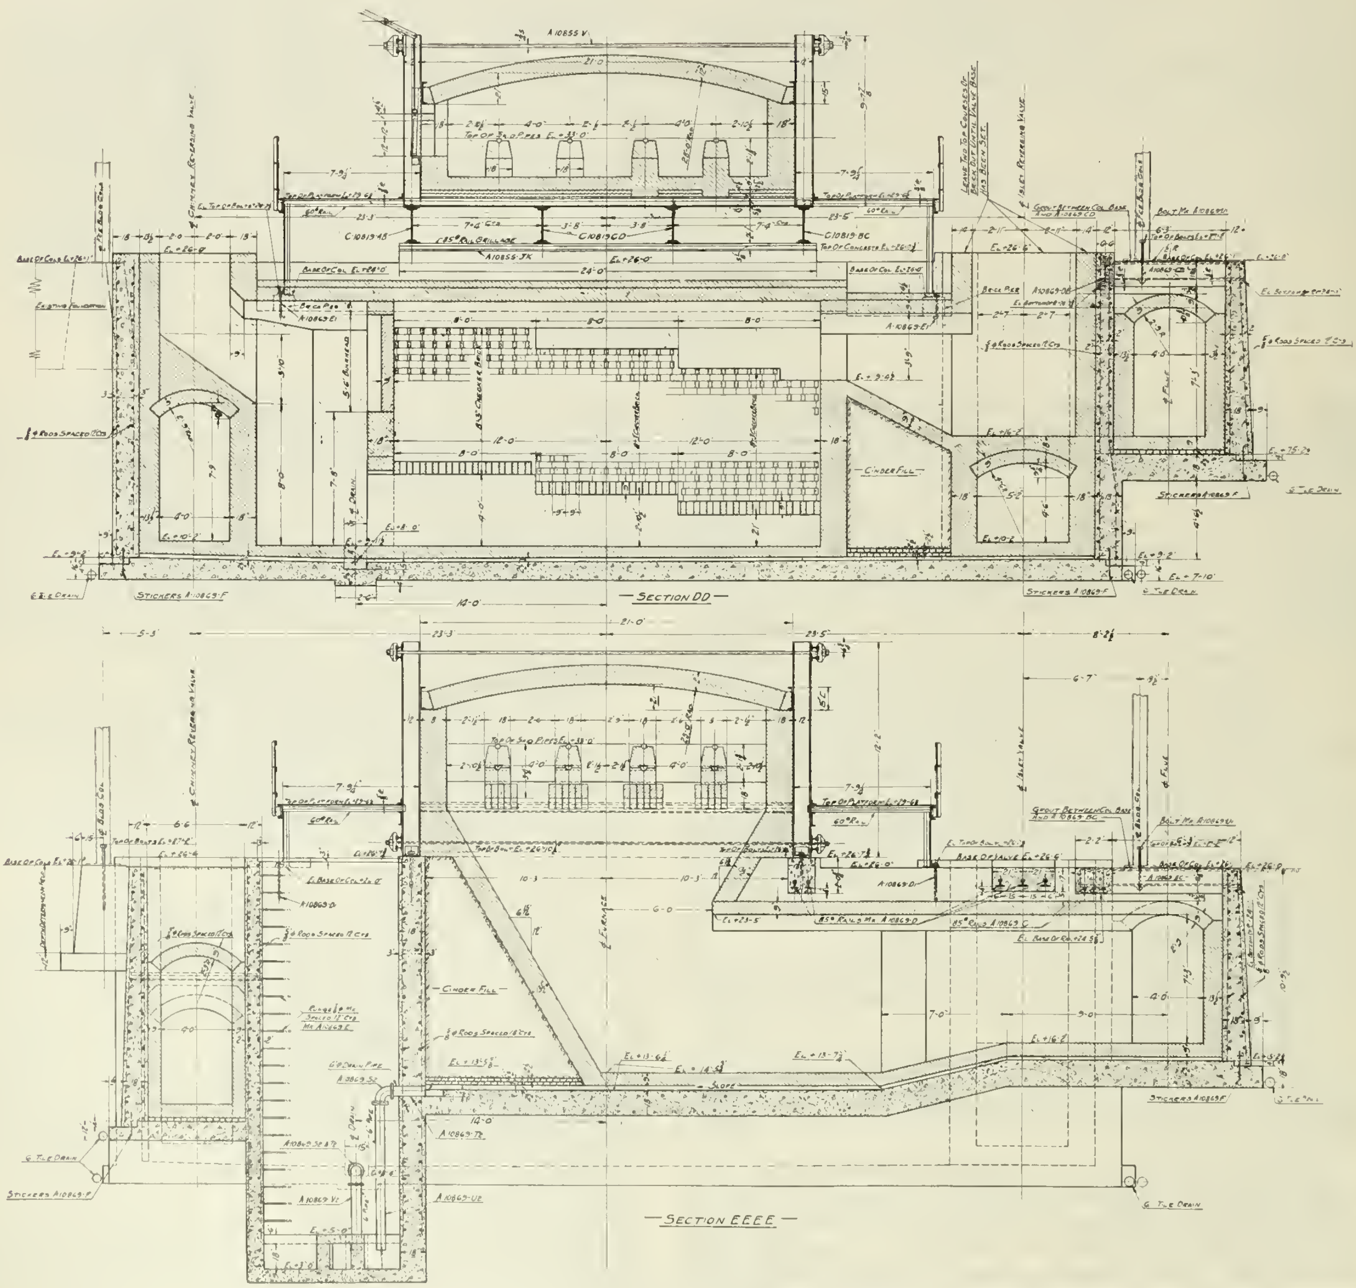

Figure No. 10,—Foundations and Brickwork of 28-inch Rail Mill—Continuous Re-heating Furnace—1921 Design.

Secondary combustion is arranged for underneath the blooms, the coke oven gas entering through four 3 inch diameter burners, the pre-heated combustion air being controlled by five watercooled slide valves, three of which measure 9″ by 2′-4½″ and the other two 9″ x 2′-0¼″. The products of the secondary combustion travel underneath the blooms and meet the products of the primary combustion in the vertical down flues at the charging end of the furnace.

The blooms ride through the furnace on four strands of 2½-inch double extra heavy skid pipes which are watercooled. There is, however, a break in these skid pipes for a distance of about 8 feet just before the blooms go over the top. This section is called the soaking hearth and its purpose is to remove the black spots from the underside of the blooms, caused by riding on the watercooled pipes. Considerable ingenuity has been exercised by others in designing and rolling special sections for watercooled skids for the blooms to ride on, but so far the 2½-inch double extra heavy pipe has survived. Suffice it to say that watercooled skids are a necessary evil.

Details of the Furnace and its Accessories

Other interesting facts in connection with the furnace and its accessories are as follows:—

Furnace dimensions, outside brickwork — 21′-0″ wide x 55′-9½″ long.

Mean height from skid pipes to spring of furnace roof arch — 2′-3″, to which add spring of arch = 21″.

Minimum free area in furnace for flow of gases — 45 sq. ft.

Size of coke oven gas main — 16″ dia.

Combustion air is supplied by motor driven fan capacity 12,000 cu. ft. per min. at 4 oz. (7″ water) pressure per sq. inch, requiring 35 h. p. motor to drive fan.

There are two regenerators (for pre-heating air only), the size of each checker chamber being 10′-3″ wide x 24′-0″ long x 13′-11″ high (all inside dimensions). The volume occupied by checker bricks is 2,030 cu. ft. per chamber. Depth of checker brick filling 8′-3″. Heating surface developed 7,320 sq. ft. per chamber. The quantity of checker brick works out to 4¾ bricks per cu. ft. of checker volume.

The stack is of steel plate construction, self-supporting, 5′-6″ dia. inside of brick lining and 150 ft. high above foundations. It might be said here that a good many furnaces suffer from a too small stack. The stack should be large enough to keep the gases within the furnace at the charging door end, otherwise the smoke and flame leak-out and burn up the castings and binding at this end of the furnace, or hamper the operation otherwise.

Coke oven gas required per ton of steel heated on "wash heats", approximately 1,666 cu. ft. (equivalent to 100 lbs. of coal).

Gas consumption on cold stock would be approximately 4,165 cu. ft. per ton of steel heated (equivalent to 250 lbs. of coal).

Thus the gas consumption per hr. would be 104,125 cu. ft. for either 1,500 tons production on "wash heats", or for 600 tons production on cold stock per 24 hrs. These fuel consumption figures are based on gas of 585 B. t.u., per cu. ft. and furnace working full capacity.

The amount of cooling water required by the Furnace for doors and skid pipes, etc. is 40,000 Imperial gallons per hr.

The inside lining of the furnace is built of "Woodland" clay brick and the roof of silica brick. (Since changed to silica brick).

As special features of the furnace might be listed the following:

(1) Coke oven gas fired with primary combustion over blooms and secondary combustion under blooms.

(2) Regenerative principle of pre-heating combustion air, thus making low fuel consumption and large output possible.

(3) A soaking hearth for elimination of black spots from blooms.

(4) Straight push-through, gravity discharge type, thus handling blooms with a minimum amount of labour and equipment.

(5) Electric double screw pusher for charging blooms into furnace with two motors having special control, working in series on forward stroke thus giving a maximum of power, and working in parallel on return stroke in order to get a quick return. Also the automatic door lifting device in connection with this pusher.

(6) The watercooled charging and discharging doors, as also the watercooled pipe buckstays at front and rear of furnace, and finally the watercooled side doors and door frames.

(7) The large operating platforms on both sides of the furnace.

(8) The facilities provided for the easy control of all necessary operations.

(9) The "Isley" and stack reversing valve design.

(10) The splendid manner in which the furnace is buckstayed and bound.

(11) The large, interlocked, refractory skid pipe supports.

Comparatively speaking, from the start the furnace and its accessories were remarkably free from the usual dose of infantile diseases generally accompanying a new venture of this kind. There have been some minor troubles to be sure, but we have received nothing but praise for the furnace and are proud of the fact.

Since the furnace commenced to operate in August 1921, and up to the present, it has heated about 140,000 tons, (gross), of assorted blooms for 60 lbs., 85 lbs., and 100 lbs., rails and for billets, practically all of which were delivered to the furnace hot from the blooming mill.

In regard to the best tonnage obtained, my information is that we have pushed 60 blooms, weighing about 1½ tons each, inside of one hour, say at the rate of 90 tons per hour of 8¼-inch square blooms on wash heats. When charging cold steel we have pushed thirty 8 ¼-inch square blooms per hour. The best daily tonnage we have obtained is 950 tons of blooms per 24 hours on "wash heats". Of course, in this case the furnace was not the limiting feature, the delays being due to shortage of steel and mill troubles. With everything going well the furnace should be able to easily handle 1,500 tons per 24 hours, which is all the present rail mill can handle.

The fuel consumption has been satisfactory, although it would have been better had the furnace been working up to capacity. The best run we obtained gave 1,950 cubic feet of coke oven gas per ton of blooms. This covered a period of 6 weeks and included all stoppages. The B.t.u., value of the gas averaged 585 cubic feet. We estimate that, with furnace handling 1,500 tons per 24 hours, the fuel consumption would be 1,400 cubic feet per ton of blooms, (wash heats).

While this furnace is not essentially a heat-treating furnace, and was not built with a view of changing the structure of the steel, via heat treatment, it nevertheless is instrumental in improving the finished product for the following reasons.

Before the furnace was installed the rails were rolled direct in one heat from ingot to finished rail. Now the steel is heated twice and therefore there should be less excuse for overheating or burning of the ingots in the pit furnaces, consequently the rail mill gets better blooms. Secondly, the blooms are heated uniformly and at about the same temperature. Previously, the corners and surface of the blooms became chilled before entering the rail mill. This prevented an even flow of metal in the roll passes, causing cracks and other defects in the finished rails. Thirdly, the heating of the blooms tends to relieve internal strains caused by heavy rolling in the blooming mill, giving a tougher rail.

The actual results obtained are that rails are singularly free from surface defects, (flaws, seamy heads and spongy flanges). Rejections due to these defects, since the furnace was installed, have been materially reduced to about as low as one-half of one per cent. As could be expected the grain structure of the rail remains about the same as before and the tensile strength of the finished steel is also very little different.

With the furnace the average production per hour in the rail mill has been materially increased and there should be less wear on the rolls; consequently the tonnage on rolls should be greater than before.

In view of irregularities in the delivery of heats from the open hearth department and interruptions due to breakdowns and delays at the blooming and rail mills, a considerable tonnage of cold blooms accumulated before the advent of the furnace, which blooms had to be cut-up and returned to the steel department for remelting. This represented an appreciable monetary loss which has been entirely overcome with the new furnace.

Last, but not least, the superior results accomplished in the rail mill, partly due to the new furnace, and partly due to the efforts of the present mill organization, have given us a better name with the railroads and the inspection bureaus than we ever had before, and this should be worth something.

The Deterioration and Preservative Treatment of Timber

The Preservation of Timber by Treatment viewed from an Economic Standpoint.

A. S. Dawson, M.E.I.C.,
Chief Engineer, Department of Natural Resources, Canadian Pacific Railway Company.

Abstract of paper read before the Calgary and Lethbridge Branches, of The Engineering Institute of Canada, February 18th, 1924, and February 23rd, 1924, respectively.

Few economic problems of national importance are so vital to the industrial and agricultural welfare of the country as a constant supply of timber at a reasonable cost. Decay is a forest enemy ranking side-by-side with fire, though less spectacular; and it is just as important to arrest the ravages of wood decaying fungi as it is to prevent the forest fire. Each foot of timber saved by longer service means a lesser drain on the forest. Notwithstanding popular conception to the contrary, we are becoming each year more dependent on wood products, instead of less so. The introduction of substitutes does not keep pace with the new and extended uses of wood; the world's needs for forest products are greater than ever before, and they play a more and more important part in the every-day life of man.

Although many of us may seldom buy so much as a single piece of lumber, every individual in the country uses wood every day of their lives. Forest products are consumed in obtaining nearly every raw material; and in mostly every process of manufacture, movement of commerce, and activity of trade. Every ton of steel requires the consumption of wood in mining the ore and the coal used to make the steel. To manufacture cement, coal is used; and therefore wood. Copper and such materials cannot be made without consuming wood. Practically all food is produced with the aid of wood in some form; and much of it is shipped in containers made of wood. About 90 per cent of the paper used is made from wood; and the advance in price of pulp wood has helped to increase the cost of paper, books, periodicals, newspapers, and even advertising. Over 90 per cent of our rural dwellings and from 60 per cent to 90 per cent of our urban dwellings are of wood. The general public, therefore, pays a large portion of its bill for wood in the disguised form of the cost of food, clothing, and other articles that contain no wood at all; and our standards of living are essentially tied-in with adequate wood supplies.

Timber Requirements Increasing

The tendency of requirements for timber to increase is world-wide, in spite of the greater use of substitutes for wood. In the processes of displacing wood from its former use for construction purposes, the substitutes have involved new or enlarged uses of wood incidental to their employment, and chemical research is revealing new uses for wood that were not dreamed of a few years ago. Wood requirements normally increase with industrial progress and growth of population, and such must be met or largely offset by (1) silviculture, (2) a gradual substitution of other materials, (3) better utilization, (4) the saving of waste all the way from the forests to the consumer, (5) the reduction in losses through fire, insects, and disease, (6) the prevention of decay.

In the case of the United States, the present annual drain on their forests is estimated at 25 billion cubic feet, and the present annual growth is only 6¼ billion. The depletion of their supplies and the reduction of their forest area is indeed one of their National problems, and Canada, if not already, will soon be in the same position. An adequate supply of timber is essential to present day civilization. Fire protection, reforestration, scientific lumbering, and elimination of waste, are all necessary for the conservation of this great natural resource, but the waste through decay is equally important and can only be offset by some form of preservative treatment. The latter bears a close relationship to timber conservation and reforestration, since proper preservative treatment converts fast growing, non-durable species into superior durable timbers suitable for structural purposes, and makes possible the use of timber otherwise regarded as little more than worthless. It enables trees removed in thinning the forest to be put to a higher use than for fuel, and also admits of the top and inferior logs being used to better advantage than if left to rot or be sawn into inferior grades. It accelerates the removal of fire-killed and dead timber which is a prey to fire, and enables areas so denuded to be more rapidly re-forested and placed on a profitable basis. It has been truly stated that to a large extent our forests have been mined instead of cropped. They are not inexhaustible, and are being rapidly depleted by increased demands for domestic and foreign consumption.

Estimate of Canada's Timber Resources

The remaining timber supplies of Canada have recently been estimated as: 810,000 million feet b.m., soft wood, and 176,800 million feet b.m., hardwood, including all classes of timber, of which 560,000 million feet b.m., are of saw-timber size. In Canada there are approximately 150 different species and varieties of plants reaching tree size. Only 31 of these are coniferous, but these form 95 per cent of the forest products. The value of the products of the forests of Canada for 1922 were estimated at 550 millions, and this may be considered the second largest industry of the country, with an invested capital of over 231 millions. During the year 1920, the cut for lumber, lath, and shingles, was about 8 billion board feet, valued at 188 million dollars. For the fiscal year ending March 1921, the exports of wood, pulp, and paper, totalled $283,620,000, and were next in value to the exports of agricultural products. During 1922 the total cut for Canadian pulp and paper mills was nearly 4 million cords, and during the same year over one million were exported. Canada's total annual cut, is now estimated at 11 billion board feet, and actually exceeds the annual growth.

The United States uses more wood than any other country in the world, and about two-fifths of the total world consumption. Its per capita consumption is about 212 cubic feet. Their exports and imports about balance; but in addition to their annual cut there are the great losses from fire, wind-falls, disease, insects, and decay, as well as the losses from careless and uneconomical lumbering operations. The per capita annual consumption of timber in the United States steadily increased from 1840 to 1907, since when it has gradually declined on account of shortages and costs. All commodity costs taken at 100 in 1840 had increased to over 200 in 1920, and to 143 in 1921, but it would have required $510 in 1921 to buy the same quantity of a poorer grade of lumber than $100 would have bought in 1840.

Requirements of Railroad Companies

The wood requirements of the railroad companies are enormous for ties, buildings, structures, cars, boats, piles, poles, fences, etc., and are about one-quarter of all the timber cut. The ties in service on Canadian railways probably number 120,000,000. The annual replacements, without consider ng those used for extensions, probably average at least 12,000,000. Preservative treatment has been developed to a degree of effectiveness in various countries which makes it possible to double and even treble the life of many species of wood commonly used for ties, and it is apparent that if even the ties used for replacements were given one of the many well-established processes of preservative treatment, the saving on the annual cut of our forests would be very large, and the same remarks apply with greater force to the still larger quantities of construction timber annually used.

Prolonging the life of wood and increasing its utility through preservative treatment is a large factor in maintaining the net economic service now rendered, by the forests. The National timber supply situation is steadily creating greater interest in wood preservation; and the rising cost of high grade timber tends to decrease the proportionate cost of treatment in the final investment in the treated material. The greater the cost of untreated material, the more important it is to prolong the period of service. Forest conservation implies not only an adequate supply of timber for all requirements, but making timber of its greatest utility, and on both accounts wood preservation is an essential and integral part of conservation. Preservative treatment in making one stick serve where two sticks would otherwise be required, not only helps conserve the forests, but makes available local supplies of wood which are unsuitable for use without treatment.

The Growth, Usable Life and Durability of Timber

There have been erroneous ideas that the forests reproduce, themselves perennially, and that a new cut could be made every ten or twenty years, but as a matter of fact it takes from 60 to 100 years to produce a crop of good merchantable timber.

The usable life and durability of timber varies with its species, its age, the climatic conditions and altitude under which it is produced, the rate at which it has developed previous to being cut, the season at which cut, and in fact from the particular part of the tree from which the stick may have come. Subsequent to cutting, the life will also depend on several factors, such as seasoning, storing, and the handling which it is given during and after construction. The timber supplies of the world have been recklessly exploited, and the conservation and afforestration of these great resources is one of the most important matters with which present-day governments have to deal. The utility and value of timber being so greatly affected by its liability to destruction and decay, it is necessary to consider the sources of deterioration, and the possible avoidance or cures. Timber in service is subject to deterioration from many causes including decay, mechanical abrasion, fire, insects, and marine borers. Any timber placed in contact with the ground will decay at different rates, depending on the species of the wood, the character of the soil, and the climatic conditions of the district in which it is used. It is estimated that the damage to timber through insect attack in the United States alone, amounts to something over 130 million dollars per annum. Fire losses in the United States alone have exceeded 200 million dollars per year, and it is an established fact that in Canada ten trees are lost by fire each year for each one cut by the lumberman's axe.

Primary Causes of Decay in Timber

The primary causes of decay in timber are the presence of sap; exposure to conditions alternately wet and dry; and want of efficient ventilation, especially if accompanied by a warm and moist atmosphere. Some varieties last for an indefinite period when kept continuously under water, and for quite long periods if kept thoroughly dry and well ventilated.

Research has shown that the decay of timber is due to the functions of low forms of plant life termed "fungi". In order to live and develop, wood-destroying fungi require a temperature favourable for growth, and certain amounts of air, moisture, and food. If any of these are absent, the fungus growth is stopped or greatly retarded. Wood which is kept below the surface of water does not decay for lack of air. The interior finish and furniture of a house do not decay, for lack of moisture. Dry-rot and wet-rot are both the result of the decomposition of timber caused by decay; but the former is that chiefly met in practice.

The basic problem in wood preservation is, therefore, to eliminate one of the four essentials necessary to the growth of fungi; and the only one that can generally be eliminated is moisture. The other possibility is to poison the food-supply of the fungus with some toxic or poisonous substance which will readily penetrate it, and that will not readily volatilize or leach out. Fungus growth is started by the spores or reproductive bodies in the fungi, which correspond to the seeds in the higher order of plants, which are blown about by the wind, and find lodgment on the surface and in the cracks of the timber. By some chemical process the wood fibre is dissolved and serves as food for the fungus, thus causing decay; and different forms of fungi differ widely in their methods of attack.

Methods of Seasoning

In general, as soon as timber is cut it begins to lose the water it contains, and this is the first step of the "seasoning" process. Seasoning helps; (1) to prevent injury by insects and decay before service, (2) to increase its durability in service, (3) to prevent shrinking, checking, and warping, (4) to increase its strength, (5) to decrease its handling and shipping weight, (6) to make it more adaptable to injection with preservatives, and for other industrial purposes as well.

Five methods of seasoning or removing the natural moisture present in timber when cut are generally practised; (1) natural or open air, (2) seasoning by saturated steam and vacuum, (3) hot air, or kiln drying, (4) seasoning in superheated steam, (5) seasoning in hot oil. The first two of these are the most commonly practised, where the injection of a preservative is to follow. For the best results in treatment, the timber should first be thoroughly seasoned by some process, and special care should be exercised to see that decay has not already started. Subsequent seasoning is also desirable before the lumber is placed in service. The seasoning has an important effect on the amount of preservative absorbed during treatment, and also by diffusion or capilary action after treatment.

Development of Wood Preservation Industry

No method is known whereby all kinds of wood can be satisfactorily treated, but it is fortunate that the species best adapted to treatment are the most abundant, and possess certain properties both sylvical and commercial, which give them a decided advantage over others. The artificial preservation of wood has been practised from the earliest times. The wooden treasures buried in the tightly sealed tombs of the Egyptian patriarchs, and recently recovered in a perfect state of preservation from King Tutankhamen's resting place after three thousand years, indicate clearly that the ancients were skilled in the art of wood preservation. It was not, however, until the early part of the 19th century that the preservation of wood by the injection of chemicals became scientific in principle, and rapidly developed. The growth of wood preservation in the United States from 1838, when the first chestnut cross-ties were treated has been extraordinary. The greatest modern impulse to the wood preserving industry has been the steady advance in the cost of lumber, and the heavy cost of replacements in certain types of structures.

The growth of this industry in the United States will be apparent from the following figures: for the year 1922, with 128 plants operating, railway ties treated were 41,316,47. The piling treated was 11,085,000 lineal feet; the number of poles treated was 966,400; the wood-blocks treated included 503,880 square yards; the cross-arms treated were 604,758; the construction timber treated was 152,557,000 f.b.m.; and miscellaneous lumber treated was 13,560,430 f.b.m. This represented a consumption of preservative as follows: creosote 86,321,390 gallons, paving oil 1,414,682 gallons, zinc chloride 29,868,640 pounds. Other preservatives 2,176,840 gallons. Creosoting reached a maximum consumption of over 108 million gallons in 1913, and zinc chloride a maximum of over 51 million pounds in 1921, due to a shortage of creosote.

The most extensive use of preservatives has been in connection with construction timber, railway cross-ties, piles, telegraph and telephone poles and cross-arms, car lumber, mine timber, paving blocks, wood stave and wire wound conduits, under-ground conduits, silos, and shingles. There have been issued over 400 patents covering various processes incidental to the preservative treatment of structural timber in the United States alone. Scores of chemicals and compounds have been advocated and tested to preserve wood from decay, but only a comparative few of these possess sufficient merit to justify their use for such. The only successful preservatives are those which either keep the wood comparatively dry, or else impregnate the pores of the wood with a toxic antiseptic, so that the organisms attacking it are killed, or in other words the fungi or bacteria will be unable to develop, and the wood will remain sound. To be an efficient preservative, it must have at least two properties. It must be toxic, that is able to destroy or to inhibit the growth of the organisms that cause the destruction of timber; and it must be as nearly permanent as possible. Experience shows conclusively that coal-tar creosote possesses these properties to a marked degree.

Wood Preservatives Now in Use

Wood preservatives now in use are of two distinct types; (1) inorganic salts which are very soluble in water, such as zinc chloride, sodium fluoride, copper sulphate, and mercuric chloride, and (2) oils such as the creosotes, certain constituents of which are sufficiently soluble to make them poisonous to wood-destroyers.

The use of *zinc chloride* was greatly extended during the war owing to the difficulties in obtaining creosote-oils from England and Germany, and in 1921 amounted to over 51 million pounds in the United States alone. The process was patented in England in 1838, and its use is generally known as Burnettizing. Quite elaborate tests would indicate that as a preservative it will at least double the life of certain kinds of woods for use as railway ties.

Sodium fluoride is even more toxic than zinc chloride or creosote-oil, and is not so readily leached from wood.

It is generally conceded that it has great possibilities as an economical and satisfactory wood preservative.

The creosote oils are the most important wood preservatives now known, and are probably the best, as they are not affected by moisture or temperature, and have a certain lubricating effect on the wood which tends to prevent injury from mechanical wear. The coal tars are products obtained from bituminous or semi-bituminous coal in the process of the manufacture of coal gas, and of coke-oven tar by the by-product process. Dead oil of coal tar, or creosote oil as it is now generally known, is obtained by the distillation of coal tar.

Processes of Treatment

Although a great many processes have been, and are practised in protecting timber from decay, they may logically be divided into two rather distinct groups based on the character of the protection given, viz; superficial processes and impregnation processes, and there is a great diversity of opinion regarding these, both from the standpoint of first cost, and results obtained.

Superficial processes are those which aim to protect the wood by simply giving it a surface protection. This process, however, has much merit where comparatively small quantities of materials are to be treated; as it is cheaper, easily conducted, and under certain conditions efficient. Brush or spray treatments are more extensively practised than any other of the superficial processes. Where facilities are not available for the open-tank or dipping treatment, the results from the brush or spray methods are generally justified. The dipping treatment is acknowledged to give better results, as it permits of the preservative getting into the checks and cracks. A still more effective open-tank treatment consists in a prolonged bath in hot preservative, followed by a bath in cold preservative. Where the expense of some form of pressure treatment is not warranted, the open-tank treatment, using either hot bath only, or hot and cold baths, probably offers the next best method of securing maximum penetration and impregnation.

All *impregnation* processes aim, not only to protect the surface of the wood, but also to force the preservative deeply into it. The depth to which this penetration can be effected, depends on many factors, including the kind and condition of the wood, the character of the treatment, and the kind of preservative used. These processes require quite an elaborate equipment, and therefore cost more, but are generally acknowledged to be the most satisfactory in the end. The impregnation processes may be divided into two classes; non-pressure, or those using no artificial but only atmospheric pressure, and pressure processes using artificial pressure. The first is admirably adapted to the treatment of posts, poles, and mine timbers, where only a portion of the stick is required to be treated. There are about thirty of such plants in operation in the United States, and in many cases good results have been obtained. In general the best results are obtained by means of the pressure processes, which are those generally made use o where large quantities of material and heavy impregnations are involved. There are about two hundred and fifty such plants in operation in the United States to-day, with cylinders ranging from 72 inches to 132 inches in diameter, and up to 172 feet in length.

In Canada the industry is only in its infancy. The first treated ties were used in 1906, and the first commercial plant was erected in 1910. To-day there are six such plants in operation. Plants are also now being erected at three other points.

The pressure processes may be grouped into two general classes:—

(a) *Full-cell* processes, in which the intercellular spaces of the wood are filled as completely as practicable with the preservative.

(b) *Empty-cell* processes, in which a portion of the preservative is withdrawn after it has been forced into the wood as deeply and thoroughly as practicable.

The Economic Value of Preservative Treatment

Up to the present, wood for all purposes in this country has been so plentiful and procurable at such prices, that little thought has been given or steps taken to extend its life or conserve its use. The preservative treatment of timber, however, is not only a requisite to the proper utilization of the available supply of structural wood, but is a real financial economy. Many reckless expenditures have been made, however, because of an improper use of the word "permanence"; and a more correct term to have used and have worked under would have been "reasonable" or "economic" permanence. In any decision as to type of construction, the following features should receive consideration: (1) initial cost, (2) probable life, (3) maintenance expenses, (4) ease of erection, (5) availability of materials, (6) appearance (7) obsoleteness.

Although more lumber is used on farms than in any other one industry and although preventable decay is its greatest destroyer, it is, nevertheless true that farmers use proportionately a less amount of treated lumber than any other class of consumers.

The advantages to the railway companies would be both direct and indirect. The direct results would be reduction in annual cost of maintenance, improved conditions of track due to less frequency in disturbance of the ties, and better track resulting from the use of hardwoods which are well suited for treatment, thus releasing an equivalent quantity of valuable softwoods for other uses. The indirect results are the reduction of ties required by probably 50 per cent, or approximately 12 million ties per annum in Canada, and over 80 million in the United States. It is apparent however that the railway companies should interest themselves not only in the available supplies of ties, but in conserving those they use. Any use made of treated hardwood ties would result in utilizing what is now either used for fuel or left standing as a prey to forest fires, and at the same time admit of an equal quantity of the more valuable softwoods being made available for other purposes. During 1922 the railroads in the United States used about 85 per cent of the total output of the timber treating plants, and operated 22 per cent of them. Tie expenditures are generally considered the second largest material account of most railroads. In 1921 over 100 million ties were used, of which about 75 per cent were treated, and during many years this number reached 125 millions. During 1922, over one-half the ties placed in track by "class 1" railways in the United States were treated. With some companies who have not yet adopted treatment, it is probably a question of finance, or the adherence to an indefinite policy of low first cost, rather than a higher first cost with a lower average over a number of years.

In addition to the railroads many other large users of timber are alive to the economic and other advantages of treated lumber. Granting that any timber can be made more resistant to decay by preservative treatment, such treatment may not be economical, even though the

timber is to be exposed to the most severe fungus attack, and is only to be in service a short time. If, however, the wood is naturally of low durability, and is to be used in a permanent location, preservative treatment will show marked savings.

Records of Results from Treatment of Timber

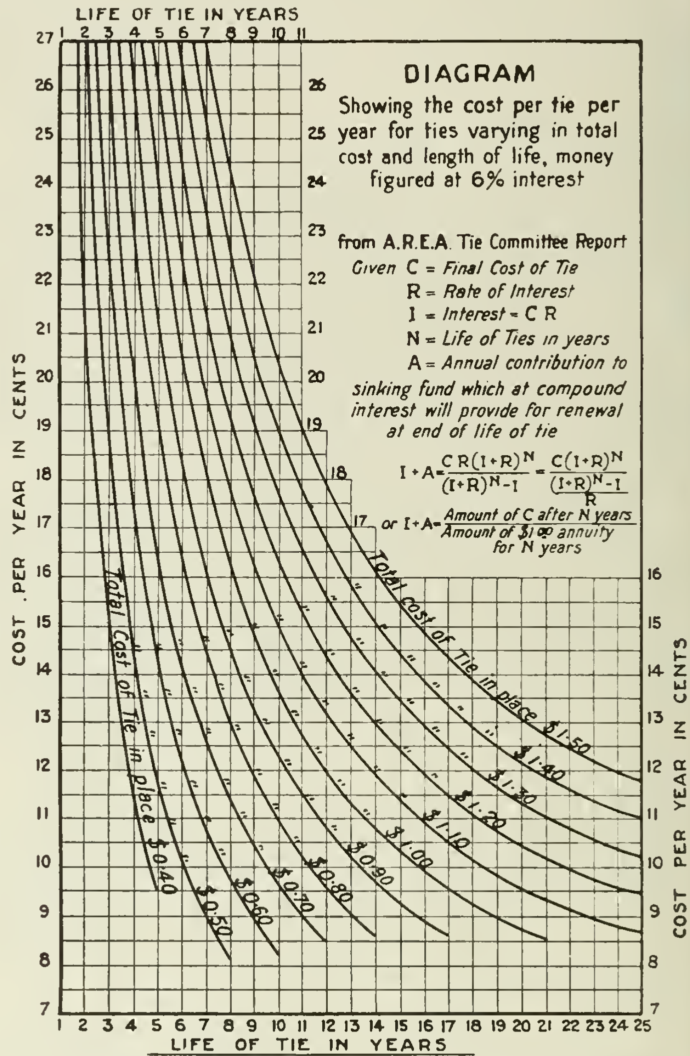
Ties treated by certain processes have now been in use on various railways in the United States for over forty years, and by various creosoting processes for over twenty years. Unfortunately the service records of such have not been as complete as was warranted, as quite a number of the companies discontinued their tests and records after having been convinced of the economic values of treatment. The results of track tests to date indicate however that the best treatments are probably zinc chloride, (Burnettizing); zinc chloride and creosote, (Card Process); and straight creosote.

If the mechanical life of a tie is likely to be shorter than the life to be expected from a full-cell creosote treatment, the cost of the latter may not at the present time be warranted. A decision on the proper treatment to be used must however be regarded largely as an investment problem, and should in the first analysis consist in comparing the life being obtained from untreated ties, with an analysis of the probable fixed annual charges, as against treated ties with a life which has been shown to be a minimum from authentic data available. It is now generally admitted that the use of treated ties of one kind or another for permanent track construction has not only become an economic necessity but an economic duty, except possibly where quantities of naturally long-lived woods are still readily available.

Cost of Treatment compared with Increased Life

If we assume that the cost of creosoting a tie is about equal to its initial cost untreated, and that such treatment would increase its service life from 8 to 25 years, the reduction in annual charges on a 6 per cent basis on the replacements of half the ties in use on Canadian main line railways would represent over 2 million dollars, or 6 per cent interest charges on nearly 40 millions. Or if we assume that the cost of treating such ties by a zinc chloride process were about half the cost of a creosote treatment, and by such treatment the life were extended from 8 to 20 years, the reduction in annual charges above referred to, would be about 3½ million dollars, or the annual interest charges on over 60 millions. Ideal treatment would be one in which the ties failed from decay and wear at the same time.

If the wood is refractory and difficult to treat, heavy treatment of straight creosote is probably best. If, however, the wood is porous and easily treated, some cheaper



EXAMPLE:— C = $1·40 .... N = 20 Years ... R = 6%

From Tables $(1+R)^N$ = 3·20714 .... Log = 0·5061180

" " $\frac{(1+R)^N - 1}{R}$ = 36·7857 .... Log = 1·5656786

$\bar{2}$·9404394

C = $ 1·40 .... Log = 0·1461280

A + I = 0·12234 .... Log = $\bar{1}$·0865674

Figure No. 1,—Cost per Tie per year for Ties varying in Total Cost and Length of Life.

honorary degree of Master of Arts bestowed on him recently at the twenty-fifth anniversary of the founding of Sacred Heart College, Bathurst, N.B. Mr. Thériault was the first graduate to receive the degree of B.A. from this institution.

W. H. Breithaupt, M.E.I.C., of Kitchener, Ont., was elected president of the Ontario Historical Society at their annual meeting in Kitchener recently. In volume XXI of the society's "Papers and Records" is a contribution by Mr. Breithaupt entitled "Dundas Street and Other Early Upper Canada Roads". Mr. Breithaupt is also president of the Waterloo County Society.

Horace L. Seymour, M.E.I.C., town planning engineer of Toronto, has entered into a contract with the council of the township of Waterloo for the planning of the township, which comprises some 120 square miles. The work will include proposals for the improvement of the highway and road system, suggestions for park and parkway development, and the location of public buildings together with zoning and building by-laws.

R. P. Donkin, A.M.E.I.C., assistant professor of mechanical engineering at Nova Scotia Technical College, Halifax, N.S., has resumed his work as consulting mechanical engineer for the Parsons Ocean Power Company, Limited, and is at present engaged in designing and fabricating their large scale experimental plant which is to be installed at Herring Cove, Halifax County, this summer.

John G. Hall, S.E.I.C., who has been assistant superintendent of the Back River Paper Company, Montreal, for the past three years, has been appointed manager of the Winnipeg office of the Combustion Engineering Corporation, Limited. Another recent appointment with this company is that of H. J. McCreery, formerly manager of the Toronto office of the Canadian Sirocco Company, Limited, who becomes manager of the Vancouver office.

E. A. Markham, A.M.E.I.C., has moved to Vancouver where he is managing director of the Vancouver branch of the Poole Construction Company. Mr. Markham is at present engaged for his company on the new Bank of Montreal Building costing $400,000. Mr. Markham was formerly superintendent of construction for the company in Regina and was engaged in recent years on the Weyburn Mental Hospital costing $2,500,000 and the Saskatchewan Co-operative Creameries building.

E. M. Archibald, A.M.E.I.C, has resigned his position with the Provincial Highways Board of Nova Scotia, and entered into partnership with E. F. Powers of St. John to form the firm of E. F. Powers Construction Company, Limited. This firm has recently started work on their contract to dig the canal for the Rugh Falls Development of the Sheet Harbor system of the Nova Scotia Power Commission. The value of the contract is about $200,000.

D. Walter Munn, A.M.E.I.C., professor of mechanical engineering at Nova Scotia Technical College, and consulting mechanical engineer, is superintending the modernizing of the cold storage and fish freezing plant of the North Atlantic Fisheries, Limited, at Halifax, Nova Scotia. The old steam driven equipment is being discarded to a large extent because of its age and lack of capacity for handling the business offering. The new equipment includes two new refrigerating machines, new direct expansion piping in main freezer, new centrifugal circulating and brine pumps, and complete electrical drive for all machinery. Steam driving equipment is being retained as reserve and stand-by. Total cost including minor changes to buildings and wharves will exceed $25,000. Contracts call for the completion of work by 21st of August. With these changes the North Atlantic Fisheries, Limited, will have the most up-to-date and largest general cold storage and fish freezing plant in the city.

Acting City Engineer and Manager, Outremont

Emile Lacroix, A.M.E.I.C., of Outremont, assistant city engineer, was appointed acting city engineer and manager of the city of Outremont, to fill the vacancy occurring through the resignation of Major J. A. Duchastel de Montrouge, who recently accepted the position of general manager of the Quebec Forest Industries Association, Limited. Although a number of applications for the vacancy had been received, the city council was unanimously in favour of Mr. Lacroix's promotion. Mr. Lacroix was born in Montreal in 1885, and following his graduation from Mount St. Louis Institute in commercial and scientific courses, in 1906, he entered Ecole Polytechnique, from which he graduated in 1910. The same year he was appointed assistant city engineer of Outremont, from which position he has just been promoted.

H. M. Scott, M.E.I.C., enters Contracting Field

H. M. Scott, M.E.I.C., has opened an office at 1108 Federal Building, Toronto, under the name of H. M. Scott and Company, general contractors; Mr. Scott has had extensive experience in construction work, having been connected with the P. Lyall and Sons Construction Company, Limited, since 1909. From 1909 to 1911 he was assistant superintendent on various contracts. He was then appointed superintendent in charge of the construction of the Transportation building in Montreal. During 1912 and 1913 he was Toronto manager, and the following year he was appointed western manager for the company. In 1915 he was placed in charge of the company's munitions department, and at the close of the war was made manager of the mechanical department. His most recent work has been on the construction of the Welland Ship Canal.

H. B. Muckleston, M.E.I.C., affiliated with Dr. J. A. L. Waddell, M.E.I.C.

H. B. Muckleston, M.E.I.C., consulting engineer of Vancouver, B.C., announces his affiliation with Dr. J.A.L. Waddell, M.E.I.C., consulting engineer of New York City, for the design and supervision of construction of bridges in Alberta and British Columbia.

Dr. Waddell enjoys an international reputation as an expert in bridge design and economics, having to his credit in Canada and the United States hundreds of bridges of all kinds. He has also designed and constructed many important and difficult bridge structures in Mexico, Japan, New Zealand, Russia, and Cuba.

While Mr. Muckleston has not hitherto specialized in bridge work, he has had a large and varied experience in important and difficult construction, involving complex problems in design and execution, and under the arrangement, Dr. Waddell will make the economic studies, estimates and layout, and will prepare the complete drawings and specifications for such bridge work as is undertaken, and Mr. Muckleston will inspect and supervise construction for the client.

Awarded First Strathcona Memorial Fellowship

Victor Topping, C.E., A.M.E.I.C., of Toronto, has been awarded the first Strathcona Memorial Fellowship, created under the will of the Late Lord Strathcona, for research work, in transportation at Yale University. Mr. Topping is a graduate of the University of Toronto, and has the degrees of M.A., B.A.Sc., and C.E., the latter having been conferred upon him this year. He was born in England and came to this country with his parents in 1912 when he was sixteen years of age. From early in 1912 until December 1913, he was with the Canadian Pacific Railway, and from 1914 to 1917 he was resident engineer on the western sections of the Toronto harbour improvements, during which time he pursued his studies, taking a four years' course in three years. In 1917 he went overseas with the Royal Flying Corps, and while there was badly burned in a flying accident in 1918, when his machine took fire and came crashing to the ground. For the next four years he was in hospital, and since his return in 1922 he has been connected with the Toronto Transportation Commission, with which he holds the position of engineer of traffic analysis. The honour which Mr. Topping has recently received is the result of various studies which he has made in transportation problems.

MAJOR J. A. DUCHASTEL De MONTROUGE, M.E.I.C.

Major J. A. Duchastel de Montrouge resigns as General Manager of Outremont

Major J. A. Duchastel de Montrouge, M.E.I.C., general manager and city engineer of Outremont, Que., has resigned to accept the position of general manager of the Quebec Forest Industries Association. Major Duchastel has been in the services of the city of Outremont for some eighteen years, first as town engineer and latterly in the combined posts of general manager and city engineer, an amendment to the city charter having been made five or six years ago to permit his appointment to the managership. Under his care the city has made immense strides in the efficiency of its public services.

Major Duchastel is a graduate of Ecole Polytechnique, Montreal and Laval University. His early work prior to entering the services of the city of Outremont, was with the Canadian Pacific Railway, and as assistant engineer with H. E. Vautelet, M.E.I.C., on bridge and steel construction.

Major Duchastel has held many public offices. He is a past-president of the Royal Automobile Club of Canada; past-president of Canadian Good Roads Association, and a past district-vice-president of the American Road Builders' Association of New York. In *The Institute* he has been councillor for the past three years.

Canadian Delegate to International Conference on Geodesy and Geophysics

Noel J. Ogilvie, M.E.I.C., director of the Geodetic Survey of Canada, Department of the Interior, has been elected delegate by the National Committee of Canada on Geodesy and Geophysics to attend the Second General Conference of the International Union of Geodesy and Geophysics to be held at Madrid, Spain, from September 24th, to October 10th, 1924.

The National Committee of Canada was formed by the Honorary Advisory Council for Scientific and Industrial Research in 1920, for the promotion and co-ordination in Canada of the study of the various branches of geodesy and geophysics, more especially in relation to their international requirements. The committee has as its aims and organization first, to co-operate with other

NOEL OGILVIE, M.E.I.C.

investigators in the British Empire; to unify and co-ordinate all results with those of the United States and Mexico, so as to build up one complete whole over North America, and secondly, to co-operate as much as possible with all other countries in the obtaining of uniform results and methods which can be used for scientific purposes.

Association of Professional Engineers of Nova Scotia

The Association of Professional Engineers of the province of Nova Scotia will hold a summer meeting at the Norfolk Hotel in New Glasgow on the first Thursday in September. In the morning there will be a business session. In the afternoon there will be an outing arranged by the members of the association residing in New Glasgow and vicinity.

Trade Publication

The Canadian Ingersoll-Rand Company, Limited, 260 St. James St., Montreal, announce the publication of bulletins K-317, Ingersoll-Rand Class "PRE" Duplex Direct Connected Synchronous Motor Driven Air or Gas Compressors and K-318, Ingersoll-Rand Class "ER" and "FR" Belt and Steam Driven Straight Line Air or Gas Compressors. Each of these new forms contains 32 pages and is of standard letter head size. They are profusely illustrated with views of complete machines, parts, cross sections and typical installations in various parts of the Dominion.

full-cell process, or even some empty-cell process might be preferable. It is, however, now generally conceded that any preservative process which will double the natural life of the tie at a total cost for the handling and treatment not exceeding the cost of an untreated tie, is a paying proposition for any railway company. Extensive tests also indicate that the item of cost is of equal importance to that of increased life; that ties treated by inferior processes or preservatives may be less economical than hardy untreated ties, and that ties from less durable woods treated with a mixture of creosote oil with other less expensive toxic agents may be more economical than those treated with straight creosote, notwithstanding the longer life of the latter.

The actual problem involved is one of economics. What is wanted is a reduced cost per year per tie; and the question is how much more life the treated tie will have over the untreated one, and how this extra life will compare with the cost of treatment. One of the principal items influencing the comparative economy of ties is that of making the length of the physical and mechanical life the same. In regard to tie material in Canada, tamarac and oak are rapidly becoming extinct, and future requirements will have to be largely filled by spruce, jackpine, birch, beech, hemlock, fir and maple. Some species of the cotton woods and the poplars treated with straight creosote have been proven to make first-class ties, with a very long life, and will no doubt be used in large quantities.

There are probably 6½ million cubic feet of timber used per annum in connection with mining operations in Canada. In Europe, treated timber has been extensively used in mining for many years; and the reason for apparent lack of interest in timber preservation by the mine operators is that mining timber in most localities has been plentiful and comparatively cheap, and the timber situation not sufficiently acute to cause the mine operators to seriously consider the benefits to be derived from its adoption.

With regard to telegraph, telephone and electrica service poles, the portion of the pole that needs protection from fungi is the section immediately above and below the ground line, i.e., where the air, moisture, heat, food and other conditions for decay are at an optimum. Of the three million poles annually used in the United States over 66 per cent are cedar, and 14 per cent chestnut, or 80 per cent from two kinds of wood. With treatment, however, there is no reason why the pines, spruces, and firs could not be drawn on to a large extent. There are considerably over one-half million poles on telegraph, telephone, and electrical service lines in Alberta alone, and if we assume that even one-tenth of these are annually replaced, the possibility for large savings through doubling their service life cannot but be apparent.

On the basis of 6 per cent interest, an expenditure of $7.36 would require an annual payment or charge of $1.00, if the life of a timber were 10 years, while if the life were increased to 25 years the expenditure could be $12.77 and the annual charge would still remain the same. In regard to the general run of construction timber, it is probable that the annual charges on such could be reduced from $2.00 to $2.50 per m.f.b.m., as a result of a creosote treatment properly selected to meet the particular conditions of service to which the material was to be subjected.

It is probable that in the near future one will be able to procure treated, framed, and dimensioned material, i.e., fabricated creosoted lumber, just as readily as fabricated steel. Structures built of such should give efficient service, and would possess a factor of flexibility which admits of revision, necessary through changed conditions of service, as so often occur in connection with piers, docks, wharves, etc., where not only new types of ships and cargoes have to be taken care of, but new mechanical handling-systems as well.

The subject as a whole is one of National economics, and is vital to the social, industrial, and agricultural welfare of Canada, which since the commencement of the world war has been looked upon as the largest and most important source of coniferous timber within the Empire; and the preservative treatment of wood, exposed to decay and attack of insects or marine borers is becoming an economic necessity.

The writer believes that the day is not far distant when several large treating plants will be established in western Canada; that it will be common practice to treat most of the timber used; and that this will result in large quantities of the timber of northern Alberta, Saskatchewan, and Manitoba, including the poplars and cottonwoods, being used for purposes it is not now considered suitable for; or in more general terms, the preservative treatment of timber, by lengthening its life and by permitting the use of other species of lumber, not only helps conserve a timber-users resources, but the Nation's timber supply as well.

First World Power Conference

Held at Palace of Industry, Wembley Exhibition Grounds. Gathering a Notable Success. Delegates welcomed by H.R.H. Prince of Wales, Hon.M.E.I.C. Canadians take Prominent Part.

Whatever may be the outcome of the World Power Conference, it is quite evident that not only the leading men in the engineering and industrial field in Great Britain but those occupying high place in the political and financial life of the nation consider that the Conference has been an epochal event in the history of nations. On account of the splendid story which Canada had to tell, and due to the able manner in which it was presented by members of the Canadian Delegation, a most favourable impression was created toward Canada which amply justifies any effort necessary in preparing and presenting the various Canadian papers and in the sending of the delegation from the Dominion.

According to those responsible for organizing the Conference, it was a serious effort to obtain international co-operation, not only in experience but also in practical knowledge so that a practical basis might be established for the great events of the future. In a brochure devoted to the Conference they state that it has become more and more evident that the economic prosperity depends on the closer co-operation of engineers, scientists and economists, since the productive value of any theory or any principle depends on its translation into a scheme of development which can be immediately used either to improve the industrial equipment of any country or to make a more scientific use of the natural resources at its disposal and also that it is quite useless to base any scheme of radical improvement solely on the advice of politicians, social theorists or even financiers since under present conditions there is no lack of capital for financing plans provided they have been elaborated in every detail and found to have a direct productive value. Continuing, the booklet states:—

"The real wealth of any country lies in the capacity of the resources at its disposal to make every sphere of activity economically justifiable, the experiences of the last five years have proved that potential or actual industrial equipment is of infinitely greater value than an immense accumulation of capital which is not being used. The kilowatt-hour may be a more reliable symbol of value than any monetary unit, since the latter represents a potential and the former a real value. International co-operation would prepared the way for a closer connection between finance and natural resources, translate one into terms of the other, and ensure a levelling up of all means of production under modern conditions.

A further aspect of the question of natural power resources lies in the realization in a different sphere of the ideal of imperial unity advocated at the Imperial Economic Conference. In the event of international action being impossible, Britain could show, through a closer financial understanding with the Dominions, based on legislation similar to the Trade Facilities Act, that the development of natural power resources may be carried out according to a definite policy for a 'bloc' of countries, in much the same way as international development should take place. This aspect of the problem has been examined by Sir Ernest Harvey, R. P. Wilson, Sir Philip Greame, and certain broad conclusions have been drawn which may be usefully applied. Before any imperial development scheme can be adopted, however, there is necessity for legislation with a broader financial basis than anything hitherto evolved.

The purpose of the World Power Conference was to consider how the industrial and scientific sources of power may be adjusted nationally and internationally:—

By considering the potential resources of each country in hydro-electric power, oil and minerals.

By comparing experiences in the development of scientific agriculture, irrigation, and transportation by land, air and water.

By conferences of civil, electrical, mechanical, marine and mining engineers, technical experts, and authorities on scientific and industrial research.

By consultations of the consumers of power and the manufacturers of the instruments of production.

By conferences on technical education to review the educational methods in different countries, and to consider means by which existing facilities may be improved.

By discussions on the financial and economic aspects of industry, nationally and internationally.

By conferences on the possibility of establishing a permanent world bureau for the collection of data, the preparation of inventories of the world's resources, and the exchange of industrial and scientific information through appointed representatives in the various countries.

Prince of Wales welcomes Delegation

The Conference was inaugurated by an afternoon session at the Palace of Industry, Wembly, and a banquet at Queens Hall in the evening of June 30th, both of which were presided over by Lord Derby, Chairman of the British National Committee. At the former the Prince of Wales, as President of the Exhibition, extended a welcome. His address and those by notable Britishers in the evening revealed to the visitors that England was taking the Conference seriously, believing that in it lay great possibilities for the future economic development of the world.

In his address the Prince said:—

"It is with great pleasure that, as President of the British Empire Exhibition, I now welcome the delegates who are assembled in session to discuss the many vital problems connected with the first World Power Conference. I feel this to be an occasion of great importance, for it may prove the beginning of a series of conferences whereby the combined knowledge and judgment of the world may be devoted to the solution of the many difficulties confronting, not only science and research, but also economic progress throughout the world. We have become accustomed to the idea of an international clearing-house for many things, and in the League of Nations, with its Labour Office and International Court of Justice, have seen international co-operation at work in political and labour questions, and in law; but the deeper questions connected with industrial progress and equipment, with natural resources, with the conservation of energy and of fuel, and with standardization in design and manufacture, have hitherto, I believe, been examined by each country in isolation, with results that are apparent to everyone. In the effort to create for industry, and especially power, what the League of Nations intends for politics, lies, I think, the true significance of the World Power Conference, and in the belief that something more fundamental than merely technical discussions will result, I extend a cordial welcome to the distinguished representatives here to-day. (*cheers.*)

"The study of power, even if we consider the technical aspect, is still in a comparatively elementary stage, and no effort has hitherto been made to find out on what foundations our present industrial structure is built and what part power plays in this structure. It is difficult to conceive any modern industry where power in some shape or form does not play a part — steam, gas, oil, or electricity, it forms the one great instrument in the possession of man by which he is capable of extracting from Nature everything of value that Nature can offer, and of converting this material wealth into something of immediate use. As one expert says:—'The social structure itself is, in a sense, bound up with the effective use of power for industrial purposes, and there are many reasons to support the view that the weakness of the social structure in an industrial state is due to inefficient or inadequate utilization of power. You are all familiar with the main objects of the World Power Conference, and have each, in your own degree, contributed to our knowledge of certain aspects, so that it is unnecessary for me to discuss the matter in detail, but there is one consideration which has specially appealed to me. You each represent the views of the main countries of the world on certain questions attached to power, and though your individual views may not necessarily coincide, the mere fact of discussion in an atmosphere of cordial appreciation must do much to tighten those personal contacts which form the inspiring motive of progress in every great activity connected with the modern industrial state, in finance as well as in science, and in research. (*Cheers.*) All three, finance, science, and research, are universal, but the utilization of the results derived from those three activities is not universal, and in this disparity lies one of the greatest obstacles to progress.

"We should find inspiration in the vision of over 30 countries here contributing, each in its highest capacity, to the discussion of one subject of more than merely temporary importance. You are at grips with fundamentals, and from your deliberations will result the first enunciation of a policy applied internationally which may contribute very largely to the harmony and economic progress of the world. You have before you, in the reports submitted to the World Power Conference, the raw material for a survey of the power resources of the world; you can now explore many countries which have hitherto been veiled in mystery, and assess at their true value the possibilities of an immense industrial development in many of them; you may, from this material, erect the structure which will go beyond the confines of one country, or group of countries, and include all those parts of the world where man can hope to prosper. International co-operation may emerge from the realm of the ideal into the realm of practical utilization as the result of your deliberations, and I sincerely trust that full success will attend them." (*Renewed cheers.*)

Sir Joseph Cook, acknowledging on behalf of the Dominions the Prince's welcome, said that the Dominions represented the greatest untapped reservoirs of power and resources generally in the world. The Dominions aimed at producing something more than the raw materials of Empire, and to confine oneself to that side only was equivalent to a bird trying to fly on one wing. They had in the Dominions everything which ministered to the wants of man, and therefore were proud to take their place in this conference on the development of the resources of power in general. Europe was still sick and in trouble, and what was wanted to-day was a balance of accounts more than one of power. That would never be obtained by going back to pre-war standards, but by seeking and developing new sources of power, as at present the actual development of power was not sufficient either for the needs of the individual or the State. The secrets of nature were age old, but she would surrender them if they knocked at the door long enough. They were grateful to the Prince of Wales for that able speech, and they were under a permanent obligation to him for the interest he gave the great matters of Imperial concern. (*Cheers.*) Sir Guido Semenza, president of the Italian Committee acknowledged the Prince's welcome on behalf of the European nations. He hoped the spirit of co-operation would be reinforced as the Conference continued. He stressed the influence of power in the development of civilization pointing out that ancient civilizations failed to progress because they failed to discover new sources of power. Dr. Kamo, speaking for Japan, said they were at the Conference rather to listen than contribute information. O. C. Merrill, chairman of the American Delegation spoke on behalf of the United States and of South America. He said that electrical energy was the greatest power ever placed in the hands of man. Ancient civilizations were serfdom and slavedom while modern civilization was a progressive liberation of mankind by the utilization of the resources of nature. The Conference, by bringing peoples of different nations into contact, would bring about a mutual understanding which was what the world needed most to-day, for contact between people such as those represented at the Conference rather than between governments counted most heavily in the scale. M. Guillaume, Director of Mines, France, speaking on behalf of his country, expressed the pleasure they felt at the presence of the Prince of Wales. He believed the Conference would be a great benefit in contributing to solve the world problem of power utilization.

The Queens Hall Banquet

At this function many of the visitors who were in England for the first time had their first introduction to British entertainment and hospitality, which throughout the Conference was generous in the extreme. Since the British have been engaged in entertaining for centuries and from generation to generation in their homeland they have developed a true instinct which makes them past masters of the art. This was apparent at the first banquet and was more and more evident as the convention proceded. There were over 600 present: The banquet was given by the Grand Council of the British Committee to all the visitors. In proposing the toast of the First World Power Conference, The Right Hon. Earl Derby, K.G., sounded a buoyant keynote of great expectations for the Conference. He prophesized that from the present Conference would come a fund of knowledge which would advance science to a large extent. The Conference was bringing to a common fund the intelligence and scientific knowledge of the electrical world from all parts of the globe and was bringing with it a desire to contribute something for the common good. Out of it must come something of value to all the countries of the world. Responses were made by M. Arbelot, vice-president of the National Committee, France, and by M. F. V. Hansen, chairman of the National Committee, Sweden, who said that in their earliest geography lessons they learned that Great Britain and her Dominions were a world power. Nevertheless their visit to the Great Exhibition had overwhelmed them. Dr. S. Z. de Ferranti proposed the toast to our guests. He stated that one of the things which would be remarked on in the future would be how very little electricity had been made use of at the present time. Mr. Frank Hodges, M.P., Civil Lord of the Admiralty, in replying, said that those assembled were framing more or less the future of the world. He had always felt that the scientific mind was the dynamic mind of the world and the political mind ought always to be subservient to it. He believed that the Conference would be written down as the starting point in the sharing out of the world's knowledge, not so much for any particular nation's advantage as for the service of mankind. The same sentiment was expressed by M. J. G. Dellaar Spruijt, vice-president of the National Committee of the Netherlands and by Col. The Hon. Sir James Allen, chairman of National Committee, New Zealand. Mr. A. Munro Grier, K.C., Hon. vice-chairman of the National Committee, Canada, proposed in eloquent terms the toast to the chairman, to which Lord Derby replied in humourous vein.

The Technical Sessions

Participation of Canadian Delegates in Conference Sessions

Under the chairmanship of Sir John Snell, the first technical session, on Tuesday morning, July 1st, was devoted to the "Resources of the British Empire and the United States". At this session twenty papers were presented, the first dealing with the "Power Resources of Australia", in which it was pointed out that ample natural resources were available for the production of the necessary energy for the development of the pastoral and mineral industries, and there were abundant supplies not only of black coal, but of brown coal, and of water power up to 10,000,000 h. p.

The paper on "The Coal Resources of the World", by Sir Richard Redmayne, discussed primarily the eventual exhaustion of this source of power, next proceeding to a study of the means whereby the utilization of this power could be more economically effected, and the means necessary for preventing its waste.

In a paper on "The Physical and Chemical Survey of the National Coal Resources of Great Britain", Dr. C. H. Lander examined in a general way the possibility of heavy oil being utilized as a source of power. The United States was mentioned as being the world centre for the production, consumption and exploitation of petrol, between 70 and 80 per cent of the world's production of this material being controlled by that country.

Professor A. H. Gibson, in a paper on "A Review of the Water Power Problem in Great Britain and Ireland", gave an account of the work of the Water Power Resources Committees, and remarked that in Great Britain and Ireland the State did not exercise any proprietary rights of the water power, and that all development that had taken place had been by private enterprise. An examination showed that in Great Britain there remained 210,000 k.w., and in Ireland 280,000 k.w., of water power still undeveloped. Of the water power utilized, 74 per cent was employed for general industrial purposes, 14 per cent in the electro-chemical industry, while 9 per cent was used for public supply, and 3 per cent in agriculture.

In a paper on "National Review of the Water Power Resources of the Indian Empire", Mr. J. W. Meares pointed out that in a tropical and semi-tropical country such as India, the development of water power depended essentially on the storage facilities. The total power now utilized was about 147,000 k.w. Construction was being undertaken to utilize a further 109,500 k.w., and projects with possibilities amounting to not less than 1,158,000 k.w. were under examination.

"The Water Power Resources in New Zealand" were discussed by Mr. Lawrence Birks. Water powers were available in falls from 1,000 h.p. and upwards, rising to 770,000 h.p. in the North Island, and as much as 4,100,000 h.p. in the South Island. Its development of water power had been largely a matter of private enterprise, though in 1903 legislation reserved to the Crown the sole right of developing any new source of power. After a careful study of the whole situation, it was decided in 1918 to adopt as a basis of power requirements 1/5 h.p. per inhabitant, and on this basis, allowing for losses, the total power necessary had been estimated as 160,000 h.p. in the North Island, and 110,000 h.p. in the South Island. In the North Island this power was being developed in three stations which would eventually be inter-connected by a complete system of transmission lines working at 110,000 volts, with a total length of 1,112 miles. There would also be secondary transmission lines operating at lower voltage, with a total length of 309 miles. This programme would be completed within ten years at a cost which would allow power to be produced at £6 per h.p. year, and would lead to an economy of 1,000,000 tons of coal per annum. In the South Island the system of development had not yet been finally determined, but at present 77,000 h.p. were under survey or in course of development.

The entire second day's sessions of the conference were devoted to the Economic Aspect of Power Resources, — Economical and Financial, under the chairmanship of the Right Hon. Sir Robert Horne, G.B.E. He professed to believe the practical point of view the most important aspect of a great subject. The world could only be saved from its present chaotic condition, he stated, by increasing the wealth of the world and by enormously adding to its production.

Major General Sir Philip M. Nash, in presenting a paper on the "Economic and Financial Problems of World Power", made the prophecy that as engineers and industrialists we were only now at the beginning of great developments which might in time change the whole economic aspect of the world. He said the value of an international power policy was evident and that the British Empire constituted the most valuable field in the world, but that, so far as the development of its protentialities had been left to the enterprise of the Dominions themselves. He believed it was time that this vast economic unit should be administered or rather developed by a system of cordial co-operation between the governments concerned, financial and technical.

The Canadians selected to speak at these sessions were Frederick B. Brown and G. Gordon Gale.

Sir Ernest Harvey, director of the British Columbia Electric Company, discussed the subject and suggested that currency depreciation and international financial conditions had had a most adverse effect on the capacity of London to help the development of Empire power and the aid of London was essential if reasonable terms were to be obtained.

The Economic Aspect of Power Resources

Owing to the fact that sixty papers were presented at the conference on Thursday, July 3rd, the conference was divided into three sections with meetings in Halls 1, 2, and 3, the sessions being devoted to Economic Aspect of Power Resources — Legal and Government Policy; Steam Generation — Utilization of Fuels; and Preparation of Fuels — Fuels Generally and Coal.

The subject in Hall 1, for both morning and afternoon session, was "Water Power Production — Economic and Legal". In the morning session Messrs E. A. Cleveland, K. H. Smith and John Murphy took part in the discussion.

Sir Philip Lloyd Greame, M.P., dealing with the functions which belong to the State, said that the central government of a country would best secure rapid and efficient development of power undertakings, not by itself creating and operating projects of this character, but by encouraging and assisting the enterprise of others.

The government departments concerned should create and maintain conditions in which power undertakings could operate to the best advantage. It should be the object of the government to assist companies to raise capital, on the ground that the undertaking which had the financial capacity and the sense of security to enable and justify it in constantly spending money on renewals and replacement and on fresh developments, was the undertaking which would be able to produce and sell power at the lowest rate. In normal times the functions of governments might be limited to the extent indicated, but to-day something more was required, and governments should be ready to use their credit, and, where necessary, even to make direct financial contributions, to secure the development of power projects. By a decision reached at the Economic Conference, either Dominion governments or local authorities or companies within the Empire could now obtain financial aid.

Herbert Hoover, secretary of commerce, United States, presented a contribution, which stated that the work of the centralization of power development and distribution, through the medium of great power systems, would make possible the decentralization of industry, and eliminate the crowded urban conditions and congested terminals which had been brought into existence by the use of direct steam power in factories and workshops. The function of government was to provide an open road for the exercise of individual initiative, to regulate and control, but not to manage or operate.

In discussing the "Economic Aspect of Power Resources", K. H. Smith, M.E.I.C., outlined briefly the situation of the Dominion of Canada, pointing out that the situation is somewhat complicated by the fact that the Dominion of Canada is a federal of nine sovereign provinces and that the federal government has a proprietory interest in the resources of only three provinces organized since confederation and an unorganized territory. The Dominion has a regulatory interest in matters affecting navigation and on international streams. Referring to a previous speaker, in which he strenuously upheld the principle of private against public ownership, Mr. Smith held that as engineers we should make results subservient to principles. He observed that different circumstances required different treatment and pointed out the benefit public ownership had been to the province of Nova Scotia. Mr. Smith's remarks appear in full in another section of issue.

E. A. Cleveland, M.E.I.C., also contributed some pertinent remarks on the subject which are given in full under the heading of discussion.

Canada's International Waterways' Commission

When the chairman opened the meeting on Thursday morning, he announced as the first paper "Canada's International Waterways' Commission", written by the secretary of the commission, Mr. Burpee, but the latter not being in London, the paper was about to be taken as read, when John Murphy, M.E.I.C., stepped into the breach, stating although he had not seen the paper in question he desired to impress upon the representatives of all countries the advisability of reading it carefully because Canada's International Joint Commission was one of the greatest means of promoting and maintaining close, friendly and satisfactory relations between the United States and Canada. While primarily a waterways' commission, almost any question might be submitted to it for investigation and report. Three Americans and three Canadians make up the commission, a citizen of the country where each meeting is held being the chairman. There is never an unbalanced representation because each country has always three votes. Their conclusions and recommendations are usually unanimous because they hold sittings wherever facts or evidence bearing upon their problems may be secured. It is only after thoroughly canvassing the whole problem that they then commence to prepare their conclusions and recommendations to their respective governments. Getting so close, as they thus do, to the intimate details affecting the matters submitted to them, they are in an excellent position to report on the facts, and the thoroughness of their work prevents the possibility of misunderstandings between the peoples concerned.

Preparation of Fuels

"Preparation of Fuels" was discussed on the presentation of the following papers on the morning and afternoon of Thursday July 3rd and on Friday morning July 4th.

Dr. D. S. Jacobus, of New Jersey, U.S.A., was chairman of the morning session; B. F. Haanel (Canada) of the afternoon session and Oscar Taussig of Austria, chairman on the morning of July 4th. At the morning sessions devoted to the preparation of fuels, on July 3rd and 4th, Mr. Haanel represented the Canadian delegation. He opened the discussion on the "Utilization of Powdered Coal for the Generation of Steam", and the discussion continued for some time and was continued on the morning of July 4th. Much favourable information was elicited concerning the value of burning fuel in the powdered form, not only for the generation of power in stationary plants but in locomotives. It was stated that locomotives burning fuel in a powdered form were operated in Chili, Brazil, Japan, and Australia, and that there was a likelihood that the application of powdered fuel for railway purposes will be adopted in other countries at an early date. Lignite in a powdered form can be successfully burned with a moisture up to 23 per cent. This is unusual and indicates a wide field for the utilization of Canadian lignites for railway and other purposes.

In the discussion which followed the presentation of Dr. Franz Fischer's paper on the conversion of coals into oils, Dr. Fischer stated it is his opinion that processes which have so far been developed tried out on a technical and commercial scale were not as yet a commercial success. The opinion of other speakers conversant in this was that any chance of success for the commercial application of these processes was very remote. This was one of the subjects on which Mr. Haanel was especially desirous to have a discussion, since great hopes have been entertained by many that this might be a solution of the liquid fuel problem which will shortly become very grave.

The carbonization of lignite coals and other fuels was discussed at considerable length. Mr. Haanel described the work which had been conducted in Canada concerning the low temperature carbonization and briquetting of Canadian lignites and pointed out Canadian lignites were in no sense similar in chemical and physical properties to those of the European countries and that processes which were capable of successfully treating European lignites could not be employed for treating Canadian lignites. Mr. Haanel brought to the attention of the delegates present at this session that Canada was far advanced in the character and quality of research work which has been conducted by the Fuel Testing

Division of the Federal Department of Mines, and laid great stress on the valuable work being performed by the Dominion Fuel Board and by the Canadian Peat Commission.

The concensus of opinion was that the days for the utilization of raw coal were numbered; that all countries would have to utilize some process which would first extract the valuable by-products such as oils, etc., leaving a practically carbon residue which would be suitable for domestic and other purposes.

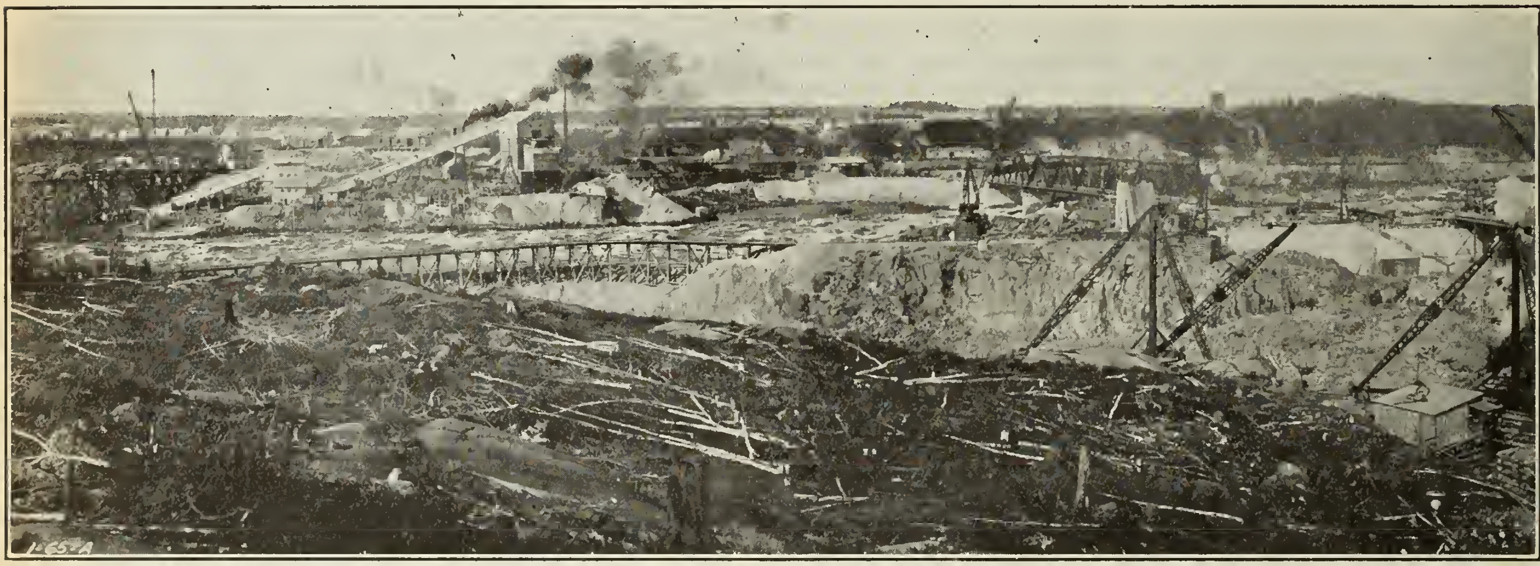
In this connection Mr. Haanel pointed out that Canada was fully alive to this phase of the utilization of coals which despite the enormous fuel resources lying within the boundaries of Canada was of the utmost importance. He described the work which the Dominion Fuel Board is performing in its endeavour to obtain a substitute fuel for the anthracite now used almost entirely for domestic purposes. He stated that findings showed that by the establishment of large by-products recovery coke-oven plants at strategic points, not only would it be economically possible to manufacture an entirely successful domestic fuel from Nova Scotia coals, but a gas which could be used with entire satisfaction for domestic purposes to replace that which is now manufactured in gas retorts.

A paper presented by Prof. Pierce F. Purcell on the "Winning and Utilization of Peat" provoked considerable discussion. Mr. Purcell stated that in his opinion the only process which had ever been devised for manufacturing peat fuel that could be considered economic was the Air-Dried-Machine-Peat process and he stated further as his opinion that he did not believe any processes depending upon mechanical pressing and artificial drying and briquetting would ever be economic, at least not for many generations. Mr. Haanel stated that he was in entire agreement with this opinion and drew the attention of those present to the necessity of having a conference of engineers conducting investigations entirely in this line of endeavour to get together and carefully consider all the processes which have been devised from time to time for manufacturing peat fuel with a view to forming an opinion which should be broadcasted regarding the legitimate lines of investigation which should be followed and those which should be discouraged.

The Generation of Hydro-Electric Power

Dr. F. A. Gaby, M.E.I.C., presided over the afternoon session and the paper of Dr. H. G. Acres, M.E.I.C., on the "Generation of Hydro-Electric Power in Canada" was presented. In presenting this paper Dr. Acres made a short statement with regard to the basis upon which it was conceived and drew particular attention to the fact that the inaugural gathering of the World Power Conference could not be regarded as a fitting occasion upon which to go into minute academic detail on such a broad subject as generation of hydro-electric power and that consequently his paper had been framed with the idea of viewing the situation in general prospective with the inclusion that only so much detail and descriptive theory as might be necessary to elucidate the reasons for various important events in the progress of the hydraulic art in Canada during the last twenty years.

There was no discussion on this paper but at the conclusion of the session the chairman, Dr. Gaby gave a general resume of the water power situation in Canada which was listened to with great interest and was very well received.



Panoramic View of Grand Discharge Power Development, at

The sessions on Friday, July 4th, were a continuation of the subjects under discussion on the previous day. The Canadian speakers were Dr. F. A. Gaby, Dr. H. G. Acres, B. F. Hannel, Prof. Greig and K. H. Smith. In the afternoon session "Water Power Production" was discussed as well as "Illumination" and "Power from Other Sources", under the chairmanship of Dr. A. Russell, president of the Institute of Electrical Engineers. A paper on "Alcohol as a Source of Power", presented by Sir Charles Bedford, attracted considerable attention. He said that alcohol is the hope of the future when the problem of supplies of fuels from internal combustion engines becomes acute. Sir Charles Parsons, pioneer of the modern turbines entertained at the dissertation on that important agent of power. It is estimated that the output of steam turbines, both land and marine, now reached the great total of over 120,000,000 h.p.

Sub-committee on Hydraulic Standards

On Friday, July 4th, K. H. Smith, M.E.I.C., was the Canadian representative at a sub-committee of the World Power Conference to consider hydraulic standards. The meeting was called under the chairmanship of Col. Norrie. Dr. Guido Semenza of Italy was made the chairman of the meeting. He was present for the particular purpose of outlining the work done on hydraulic standards by the International Electrical Technical Commission. In his capacity as president of the commission, he offered the facilities of the commission in co-operation of hydraulic experts of all countries interested for a further consideration of this matters.

Transmission of Power

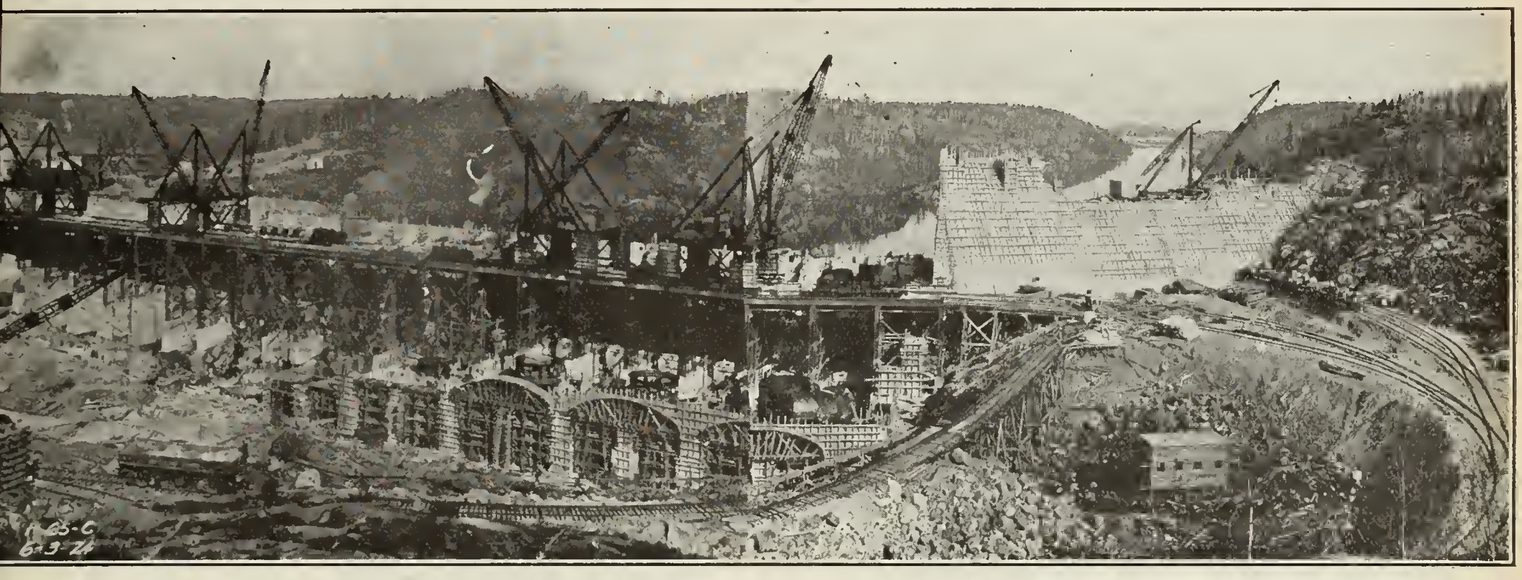
At the session on the "Transmission of Power" on Monday, July 7th, John Murphy, M.E.I.C., described how Canada's Railway Commission looked after the safety features of high tension and other wires when they came near or across railways, telephone or telegraph wires and all other kinds of wires.

The Railway Commission's powers are very broad and no wire can even be brought near federally incorporated railways without its consent. The commission insists on providing extra factors of safety both electrical and mechanical, in all power lines at points where they cross over other lines or wires. Without boasting, Mr. Murphy pointed to the notable fact that no wire crossing which was erected and maintained in accordance with the Railway Commission's regulations had ever failed and those regulations have been in force eighteen years.

John R. Freeman, who presided at this session, announced that a special exhibition of Mr. John Murphy's frazil and anchor ice pictures would be arranged for in the Cinema Theatre of the Engineering Building at Wembley during the week. He told the members that frazil caused much trouble at hydraulic plants in cold climates and those unique moving pictures showed how the ice was formed and how it could be overcomed.

Manufacture of Gas

The fuel session, in the morning and afternoon of Monday, July 7th, was devoted to the discussion of the manufacture of gas by low and high temperature carbonization processes; its utilization for industrial and domestic purposes and the necessity for treating coals in this manner in order to increase the efficiency of the use of fuels for both power and heating purposes. The papers read in the discussion which followed, indicated that the personal element was foremost and that the problem was not being attacked from an impartial point of view, that is, with a view to serving the interests of the countries at large to the best advantage. After much discussion concerning the relative merits of this method for gasifying coal, it was pointed out by a representative of the British Fuel Research Board and Dr. Lessing, (an eminent fuel chemist), that before attempting to weigh the relative economies to be derived from any method of carbonization employing low temperature especially, it would be well to thoroughly investigate ways and means for purifying coal, that is, reducing to the greatest possible extent its ash content. This, it was pointed out, is of the utmost importance in connection with research work and development work in connection with the carbonization of coals in-as-much as the presence of mineral ash has a serious effect, or at least an important one, on the results obtained when coal is submitted to a low or a high temperature carbonization and that the real effect of low or high temperature carbonization can not be determined when ash to a large amount is present. Again, it was pointed out that the necessity for removing the ash from the coal before using it for any purpose was very urgent in view of the congested state of the railways and the labour and expense of removing the ash from power plants after the coal had been burned. The purification of a coal high in ash appears to be especially necessary when the coal is burned in the pulverized state under a boiler for the generation of steam, since when coal is burned in this manner the larger portion of the ash contents of the coal passes out through the chimney. The efficient use of the fuel, however, no matter for what purpose it is used, will be greatly enhanced if the fuel is first purified. This appeared to be the most valuable contribution to the discussion which took place at this session.



St. Joseph d'Alma, Saguenay River, showing progress of work.

On Tuesday July 8th, the morning session on "Internal Combustion Engines" was presided over by Frederick B. Brown, M.E.I.C.

The chairman opened the meeting by a reference to the conditions in Canada outlining the field of application for internal combustion engines, as compared with the possibility of hydro-electric and other power sources. There were discussions from nine different countries by twenty-three representatives, reviewing the present practice of internal combustion engine development.

Prof. Greig, M.E.I.C., Saskatchewan, gave a most interesting contribution showing the best application of internal combustion engines to the conditions as found in the prairie provinces and elaborated on the desirablity of having available tractors and passenger automobiles for the use of the farming community which is so widely scattered that, without these means of transport and cultivation, social intercommunication would be practically prohibited and farming on a large scale impossible.

The chairman emphazied the importance of getting better acquainted with the delegates from other countries and pointed out the value of the personal contact as one of the best results to be looked for from the conference. This was greeted with applause and resulted in considerable fraternization, amongst the delegates present, following the meeting.

John Murphy, M.E.I.C., was the chairman of the meeting on Wednesday July 9th, when "Power in Electro-Metallurgy" was the topic. Papers relating to that subject were presented by delegates from the United States, England, France and Germany. The chairman gave a short review of Canadian enterprises. During the war they were of great magnitude and importance and Canada's water powers and electrical distribution systems played an important part in this work. At present zinc areas are reduced electrolytically in British Columbia and Quebec. The Niagara Peninsula and the Shawinigan district are the chief centres for the electrical manufacture of carbide, cyanamid, aluminum, acetic acid, carborundum as well as other electro-chemical products—many of which, on a smaller scale, are also made in Montreal and Toronto.

There are about 5,000 men employed in those industries; the capital invested in them is about $33,000,000. and the gross revenue from that investment amounts to $27,000,000. With large water power developments approaching the construction stage, Canada's future is very bright in the field of electro-metallurgy.

Exhibition of Ice Pictures

After the regular sessions of the conference were completed on July 9th, the delegates gathered at the Cinema theatre in the Palace of Engineering where John Murphy, M.E.I.C., exhibited his ice pictures and gave a short address explaining how easy it is to prevent frazil, or anchor ice, as it is popularly called, from stopping waterwheels or any other hydraulic works when advantage is taken of the results of experience and scientific research. Canada leads the world in its solutions of ice problems.

Memorandum and Resolutions

At the last meeting of the Conference, the following memorandum and resolutions were presented and passed, having been previously approved by the International Executive Committee.

Actuated by a common desire for the conservation and development of power resources throughout the world, the study of power problems, and generally for the carrying on of the work begun at the First World Power Conference, London, 1924, the foregoing* have, for themselves and the respective national committees in the various countries signed their names hereto.

*Representatives of the various countries, forming the International Executive Committee.

1. It is desirable that the work of the First World Power Conference shall be continued and that consideration shall be given to the advisability of forming a permanent Institution at a later stage under such title as may be found best to fit its activities: and to that end—
2. Each country participating in the First World Power Conference is invited to create and or maintain a permanent National Committee, as far as possible representative of its interests in all aspects of power.
3. The existing representatives of the International Executive Committee of the First World Power Conference shall continue for the time being to carry out the necessary work arising out of the conference as set forth in this memorandum.
4. Each National Committee shall be entitled to appoint one delegate to represent it on the International Committee and such appointments shall be made within six months from the date of this memorandum.
5. In countries where it is not immediately convenient to appoint National Committees a correspondent may be appointed to keep in touch with the International Committee until such time as a National Committee can be appointed.
6. A meeting of the International Committee shall be convened within a reasonable time to decide upon the line on which it would seem advisable to them (after conferring with their National Committees) to further the objects of the First World Power Conference, and in considering their scheme to arrange that there be no interference or overlapping with the functions of any existing International Organization.
7. The present organizing director and his staff shall, for the time being, be the medium of communication between the countries represented on the International Committee of the World Power Conference for all purposes of the conference.
8. The next meeting of the World Power Conference shall be held at a time and place to be determined by the International Committee, subject to the approval of the respective National Committees. So far as practicable future conferences should be held in different countries.

RESOLVED :

(1) That this conference is of the opinion that the world's most crying need to-day is greater production and manufacturing activity among its peoples under conditions which will promote individual prosperity and happiness, and that this can be largely achieved by the fuller development of national power resources and by the establishment of the most economical means for the general distribution and utilization of energy.

(2) The International Executive Committee of the First World Power Conference desires to place on record its thanks to authors of all countries who contributed papers to the conference.

(3) The International Executive Committee of the First World Power Conference desires to express its thanks to the chairmen who presided at the various sessions of the conference.

(4) That the visiting delegates to the First World Power Conference express their deep appreciation of the efficient manner in which the conference has been organized and conducted by Mr. D. N. Dunlop and his associates, and their further appreciation of the gracious courtesies and generous hospitality so abundantly extended to them by their British associates.

(5) The British Executive Committee desires to tender its sincere thanks to the officials and secretaries of the National Committees and to representatives of all countries participating in the First World Power Conference whose effective co-operation contributed so greatly to its ultimate success.

Standard Test Code for Hydraulic Power Plants

At a meeting of the Institution of Mechanical Engineers on Saturday morning July 5th, to consider a draft standard test code for hydraulic power plants drawn up by a Joint Committee of the Institutions of Civil and Mechanical Engineers, there were representatives from the various national delegations to the First World Power Conference.

J. B. Challies, M.E.I.C., as vice-president of *The Engineering Institute of Canada*, was called upon for an opinion. He said that the matter of a standard test code for hydraulic power plants was of great importance to engineering practice in Canada because there were at the present time over three and a quarter million hydraulic horse power installations in use which was being increased annually by over one-quarter million.

Canadian engineers had found the standard test code evolved by the American engineers of great value. It had, however, to be adapted to meet local conditions. Canadian engineers practice had already evolved a technique in connection with hydraulic tests which should be permitted to articulate before a firm decision is taken in connection with standard test code that was intended to be of universal use. Mr. Challies suggested that the best way of securing a considered opinion from Canadian engineers in this important matter would be by appropriate request for advice and assistance from *The Engineering Institute of Canada.*

Dominion Day Dinner

Every member of the Canadian Delegation was present at the Dominion Day Dinner held on July 1st, at the Hotel Cecil with the Hon. P. C. Larkin, High Commissioner for Canada in the chair. The Prince of Wales was the principal guest. In his reply to the toast to the King, the Queen, Queen Alexandra and the other members of the Royal Family, the Prince said he was grateful to be present at the Dominion Day banquet as it gave him an opportunity of meeting, so many representative Canadians who were in London. He expressed his love for Canada and announced that he hoped to visit his ranch again during the coming fall.

The toast to the Dominion of Canada was proposed by the Hon. Newton W. Rowell, K. C., and responded to by the Right Hon. J. H. Thomas, M.P., Secretary of State for the Colonies. He said he was proud of the Empire and was trying to understand and realize all it meant. The remarkable position held by the British Empire to-day was illustrated by a recent speech delivered in the Canadian Parliament, which showed that we are not only a free people but that our strength rested on the fact that we could talk plainly to each other. The Empire was greater than party and the great empire problems should be discussed free from party prejudice. He made the important announcement that the government was taking the necessary steps to get all the Dominions around the table to discuss their problems not from a party point of view and not in the interests of any particular class but to consider them in the interests of the Empire as a whole. Our Guests was proposed by the Hon. Charles Dunning, Premier of Saskatchewan, which was responded to by the Right Hon. Winston Churchill who said the Tories nearly lost the Empire in trying to keep it and the Liberals kept it in trying to throw it away. He did not think there was sufficient material to enable him to describe the Labour Party. So far as the Labour Party was concerned, so long as they endeavoured to keep together the great mass interests of the Empire and safeguard its lasting value they would deserve the respect of all His Majesty' subjects. The Hon. E. H. Armstrong, Premier of Nova Scotia, in proposing the toast of the chairman, speaking of the Homeland, said her troubles seemed to have left her great, and referred to the closeness of the tie of sympathy between here and Canada. The High Commissioner responded briefly.

The American Dinner

The American Committee were the hosts at a splendid dinner given at the Hotel Cecil on the evening of Thursday July 3rd, to which they invited all the World Power Delegates and at which were present about 600 men and women. O. C. Merrill, general chairman of the Committee presided and expressed on behalf of the American Delegation their appreciation of the courtesy extended to the delegation by the people of Great Britain. The Conference, he said, was dealing with the problem which was vital to civilization and it was the result of the vision of one man, Mr. D. N. Dunlop of London, England.

Dr. Arthur T. Hadley, a former president of Yale, gave an address of welcome to the guests. Replying for Great Britain, P. J. Pybus spoke of the credit due Mr. Dunlop the organizer of the Conference for the spirit of idealism which enabled him to conceive this great international gathering of engineers. If there was in the whole range of politics, arts and science any subject which was in essence truly international, it was the conservation of the power resources of the world as a whole. Dr. M. Kamo of Japan and E. Uytborck of Belgium and John Murphy of Canada also spoke. Mr. Murphy was selected by the delegates from Canada and the other British Dominions as their spokesman. He pointed out that there is only an imaginary line running across the continent separating Canada from the United States, without any weapon of an offensive or defensive character upon it. The continuous crossing of that line by the peoples of the two countries in friendly intercourse and in the exchange of engineering as well as other ideas and experiences all tended to make for peace and goodwill between them.

Canadian Delegation Luncheon

As a diversion from their deliberations on technical matters the delegates to the World Power Conference at Wembley, on July 4th, attended a luncheon arranged in their honour by the Canadian Committee at the Hotel Victoria, Northumberland Avenue, at which the Hon. Peter C. Larkin, High Commissioner for Canada, presided over a company of nearly 300. As the delegates have come from all over the world the toast to "The King" was followed by that of "The Sovereigns of the Kingdoms and the Presidents of the Republics represented here to-day."

The chairman, in welcoming the visitors on behalf of the Canadian Committee, observed that it had been well said that the man who could make two blades of grass grow where one had grown before was a great public benefactor; in the same way, those who had drawn electrical power from the waters which had run waste for countless centuries had increased the production of the world and placed the necessities of life before vast numbers of people. This work had been beneficial not only from the economic point of view but also from that of bringing the nations together. No doubt questions would arise when a stretch of water ran through two countries and was capable of being harnessed for power, but he was sure from their experiences in Canada with their neighbours of the south that, as in the case of North America, these problems could be solved in a friendly way by the nations of Europe.

Mr. A. Monro Grier, K.C., vice-chairman of the committee, in submitting the toast of the Grand Council of the conference and the delegates, referred to the fact that they were meeting on Independence Day. England and America had a particular bond in the Fourth of July and he would say to all their foreign visitors that not only was the union of these two countries eminently desirable, but the closer attachment of other nations to one another would be an equally happy thing to bring about.

Mr. D. N. Dunlop, the organizing director of the conference, returned thanks on behalf of the guests, and announced that he had just welcomed the Russian delegates, who had made a late arrival by aeroplane.

They had been considering, he continued, how they might capture the forces of Nature for the service of humanity, and as a practical idealist he believed that these forces would be liberated only when man no longer wanted to use them for the destruction of peace.

The chairman's health was drunk at the call of Signor Guido Semenza of Italy, who declared that his countrymen admired Canada, not only because of her immense resources and possibilities, but also because of her wonderful loyalty to her great mother, Great Britain.

Amongst those present were: Lord Ashfield, Baron E. Quillaume, Sir James Allen, Sir John A. F. Aspinall, Sir Adam Beck, Sir Joseph Cook, Sir James Devonshire, Sir John Dewrance, Sir Philip Dawson, Sir T. O. Callender, Sir Dugald Clerk, Sir Robert Hadfield, Sir James Kempal, Sir Philip Lloyd Greams, Sir Charles Morgan, Major Gen. Sir Philip Nash, Sir Charles Parsons, Sir Richard Tremayne, Sir John Snell, Sir Edgar Walton, The Right Hon. T. P. O'Connor, M. P., The Hon. E. H. Armstrong, The Hon. R.B. Bennett, Mr. J. B. Challies, Mr. John R. Freeman, Mr. B. Longbottom, Mr. O. C. Merrill, Mr. John Murphy, Mr. W. H. Patchell, Mr. Calvert Townley, Mr. Douglas Vicker, Dr. George Otis Smith and Dr. Don Louis Cuervo Marquez.

Their Majesty's Afternoon Party

Through the courtesy of the Canadian High Commissioner and the British Grand Council co-operated by the Engineering Institutions, the entire Canadian Delegation was invited to the King's Garden Party at Buckingham Palace on the afternoon of Saturday July 5th. This party was notable in that from the Canadian viewpoint it was attended by the greatest number of Dominion visitors that were present on any previous similar occasion. On this occasion Mr. and Mrs. J. B. Challies and Dr. and Mrs. Gaby were presented to their Majesties.

Discussion at World Power Conference

Water Power Production.—Civil and Mechanical Engineering

Major W. Hamilton Munro, M.E.I.C., of the Canadian Delegation, in opening the discussion of papers read on Friday morning, July 5th, before the Water Power section of the World Power Conference, said,—

The introduction of some friendly controversy to these discussions may have a tonic effect, for example, — The subject of this morning's meeting is given in the agenda as, "Water Power Production, — *Civil* and *Mechanical* Engineering".

The relative costs of the civil engineering construction work, and the mechanical equipment of an hydraulic power plant were roughly seven to one, and yet, with the exception of the excellent papers dealing exclusively with dams, which had been presented this morning, there were none which aimed particularly at the reduction in cost of the civil engineering work. The papers were almost exclusively mechanical.

Had not the mechanical engineer outdistanced the civil engineer in the common duty of reducing the cost and improving the quality of their respective parts in making cheap power available? Had not the mechanical engineer spent his money on testing laboratories, his time and thought in calculations and inventions, and tests on his turbines and their accessories? Had he not greatly increased the specific speed and was continuing to do so? Was not the speed regulation vastly better than it had been? Had he not improved design and construction until in reliability of operation the turbines were probably the most dependable items in the whole range of apparatus involved? Had he not increased turbine efficiencies to a point where small possible margin for further improvement remained? Did not the mechanical engineer take less profit for the manufacture of his equipment than any other contributor to the construction of an hydro-electric power plant?

And yet the mechanical equipment with its accessories cost only about 6 per cent of the whole, and the civil work anything from 40 per cent to 60 per cent of the whole. The cost of the civil engineering in hydro-electric installations was, owing to circumstances, less subject to competition than the mechanical, and less open to criticism, its sheltered position had had a bad effect upon it.

Is not a stronger effort in that large field of possible cost reduction a reasonable demand; undoubtedly so, especially when one thinks of those cases where the question of whether a steam, oil or gas plant is to be installed on the one hand, or a possible water power site made use of on the other. If the cost of the hydraulic power alternative is brought in as evidence to barely turn the scale against it, a natural resource is thereby lost to the community for many years, because in small and medium sized systems once a steam or oil station is embarked upon it is a great temptation to meet increments of load by the small first cost of an additional boiler or engine rather than to turn again to the hydraulic power site. Such economic losses might be prevented by the possible reduction in cost on the civil engineering side.

Major Munro hoped the civil engineers would argue the case.

Power in Electro-Chemistry

On Wednesday morning, July 9th, Sven Svenningson, M.E.I.C., took part in the discussion on "Power in Electro-Chemistry" as follows:

It is not my intention here to-day to attempt to add anything to the technical discussion regarding the application of power in the electro-chemical industries, but mainly in a sketchy way to give you a picture of how the development of water power and the development of electro-chemical industries have progressed in that part of the province of Quebec generally known as the St. Maurice valley and mainly at Shawinigan Falls.

The St. Maurice river is one of the largest rivers in Canada, with a drainage area at Shawinigan Falls of approximately 18,000 square miles. The total drop of this river over a distance of 250 miles is about 1,250 feet, of which approximately 300 feet takes place within 20 miles of its outlet.

Up to the latter part of the nineties practically no industrial development had taken place along this river with the exception of a few scattered saw mills. Around the year 1900, the first power plant was built at Shawinigan Falls. This plant had to start with only one unit of approximately 5,000 h.p. capacity, which in those days was considered a fairly large unit. By the end of year 1910, the capacity of the original plant had grown to approximately 60,000 h.p. Two other plants, with a total capacity of 30,000 h.p. had been built. These latter plants were both equipped with d.c. generators and were delivering power to the Northern Aluminium Company only. During this period, between the years 1900 and 1910, a calcium carbide plant was erected by interests not directly connected with the power company. This plant, which to start with was not particularly successful, was finally taken over by the power interests and operated by them. Between 1910 and 1914, the power company had erected a second power plant of 100,000 h.p., capacity but the electro-chemical load had not increased to any extent.

At the outbreak of the world war, however, the demand for power for furnace work became very pressing, and fortunately the power companies in the province of Quebec were able to meet the demand, due to the fact that the two large hydro-electric plants at Cedars rapids on the St. Lawrence river and Grand Mere on the St. Maurice river were put into service with a combined capacity of 220,000 h.p. This added power to the Quebec systems allowed the Shawinigan Water and Power Company to greatly increase the capacity of the carbide plant as well as to sell an additional 10,000 k.w., to the Northern Aluminium Company. To the carbide plant, which at that time had five furnaces with a total capacity of approximately 30,000 h.p., was added two 7,500-k.w. units.

At the same time the Shawinigan Water and Power Company, under the name of the Canadian Electric Products Company, erected a chemical plant producing acetic acid. This latter plant was doubled in capacity during 1918. Besides the above mentioned plants other electro-chemical industries producing carborundum, alexite, furco, silicien, magnesium and steel, were erected at Shawinigan Falls, so by the end of the year 1918 the total load and the Shawinigan system for electro-chemical purposes had reached in round figures 105,000 h.p.

During the termination of hostilities this load was considerably reduced due to the fact that some of the industries were running at reduced capacity and others entirely shut down. During the last two years the conditions have greatly improved and the prospect for the future seems fairly good.

In this conclusion it may be of interest to some of the gentlemen present to know that during the period of industrial depression, that not only the entire capacity of generating plants were utilized to the good advantage, but that new equipment was added to all the plants and new generating stations were built. This was done by the installation of large electric-steam boilers in some of the local paper mills. Several of these steam units have a capacity of 25,000 k.w., and the total approximate electric steam load on the Shawinigan system alone runs at times as high as 100,000 to 120,000 k.w.

It is needless to say that loads of this kind greatly help to improve the load factor.

Water Power Resources

Discussion by K. H. Smith, M.E.I.C., and E. A. Cleveland, M.E.I.C.

I desire to outline briefly, in the limited time at my disposal, the situation in the Dominion of Canada as regards the subject under discussion. While as already stated at this conference, Canada has vast fuel power resources, I will limit my contribution to a discussion of water power resources as is appropriate since by far the greater part of central station development in Canada to-day is water power. Complete details of this subject so far as Canada is concerned may be found in section III of paper No. 8, Water Powers of Canada, their nature, extent and administration, which I commend to your careful attention.

The situation is somewhat complicated by the fact that the Dominion of Canada is a federation of nine sovereign provinces. The Federal government has a' proprietory interest only in those three provinces organized since the original confederation and in unorganized territory. It has a regulatory interest throughout the whole Dominion in matters affecting navigation and on International streams, the latter forming a most important factor in the Dominion power resources.

Unrestricted development of power resources in Canada, except in a very minor way, is unknown. There is first of all corporate organization, except in the rare instances of development by single individuals, either by special charter or act of the provincial legislation concerned or under the existing general company laws. In the second place, a license covering the specific site which it is proposed to develop must be obtained from the proper administrative authorities. These licenses while varying in detail all rest on the same fundamental principle of public control and recapture. They involve limited tenure, cancellation and for the most part nominal rentals. Lastly, in the cases of development for public utility purposes, financial arrangements and power rates are subject to control and regulation by public bodies of one kind or another in the various provinces.

Speaking of government policy in general, it is obvious that no question arises as to actual development by the federal government. Its aim is to furnish comprehensive and dependable information as a basis for economically sound and adequate power development schemes and to stimulate development in so far as its own jurisdiction is concerned by reasonable regulations tending to protect both the investor and the public. In this respect it is succeeding to a remarkable degree.

The provincial governments are in a position to actually carry out power development or to render direct assistance and there is a wide divergence of policy among them in that respect.

The government of the province of British Columbia takes no active part whatever in actual power development. The same is true in Alberta and Saskatchewan. In Manitoba, the provincial government has recently instituted a system of power transmission.

In Ontario, we have the enormous generating and transmission system of the Hydro-Electric Power Commission of that province, involving the largest generating station in the world. This is a purely public enterprise, based on the co-operation of the vast number of municipalities involved, with the liabilities underwritten by the provincial government and in a large measure financed by the government directly.

In Quebec, development is wholly by private enterprise. In recent years, however, the provincial government has built and operates enormous storage reservoirs for the benefit of private developments, from which adequate rentals are collected.

In New Brunswick and Nova Scotia, development during recent years is for the most part carried on by public commissions under government auspices. However, in Nova Scotia particularly, development by private enterprise is encouraged. The Nova Scotia Power Commission generates and transmits energy in bulk to public or private corporations for general distribution or immediate use as the case may be.

It is of interest to note that throughout the whole Dominion, the results obtained as to availability and cost under similar conditions are much the same notwithstanding the divergence in policy. It would seem that in each case that policy has been adopted which best meets the conditions obtaining.

Mr. chairman, this is all I had intended to say, but with your kind permission, I would like to make an observation with reference to the remarks of a previous speaker, in which he strenuously upheld the principle of private versus public ownership.

It seems to me, that as engineers, we should make results subservient to principles, and from the results obtained in Canada under widely divergent policy as I have indicated, it may well be that different circumstances require different treatment.

I may illustrate from the province of Nova Scotia where I am particularly engaged at the present time. A careful study of the situation in this old province some time ago led to the opinion that some direct governmental action was necessary if the province was to benefit by the considerable water power resources revealed. Developments involved extensive diversions, long conduits and generally very extensive interference with large numbers of riparian owners in this province of long established and relatively small land holdings. The difficulties involved seemed almost insuperable to other than public agencies. In corroboration of this opinion, it was observed that in the face of ample physical possibilities no considerable development had taken place.

Accordingly a commission was organized as contrasted with a government department and has made very considerable progress in the generation and transmission of hydro-electric energy. It does not seek to supplant existing private public utility corporations, but rather to supplement and co-operate with them. In the case of the city of Halifax, the capital city of the province, for example, the Nova Scotia Power Commission furnishes energy in bulk to the private company which has long been the sole operator of electricity, tramway and gas facilities throughout the city. This company previous to the advent of hydro-electric energy operated a steam station which is still maintained for stand-by and auxiliary purposes.

VOL. VII August 1924 No. 8

The First World Power Conference

At the moment of writing this, the World Power Conference has not completed its sessions nor have the final conclusions of the Conference itself been reduced to a definite commitment as to either a programme for the future or an analysis of the benefit the Conference has been and will be to the world as a whole. Sufficient let it be for the present that the conference, ideal in its conception and vast in the breadth of its programme, has been an unqualified success. Canadian engineers will learn with no small pride that at the gathering of experts on power in its many phases, the Canadian participants made a marked impression and played a proud part in the entire gathering, the result of which cannot be otherwise than of lasting benefit to the Dominion of Canada.

At nearly every session Canada took part and added a quota to the general fund of information. Those participating at the conference were impressed by the fact that Canada is a great power producing country and that Canadian Engineers had been pioneers on long distance and high tension distribution in the use of large units both hydraulic and electric, and that in the latter Canadian practice had reached a stage surpassed by no other nation.

At a technical conference lasting for ten days both morning and afternoon sessions, and for the most part meetings being held in three different halls, it is impossible for anyone to attempt to fully state what took place. The broader aspects of the conference, however, may well be summarized in the statement made in relation thereto by outstanding men:—

"In the effort to create for industry, and especially for power what the League of Nations intends for politics, lies the true significance of the World Power Conference."....*The Prince of Wales.*

"The study of power is still in a comparatively elementary stage, and no effort has been made to find out on what foundations our present industrial structure is built and what part power plays in this structure.".... *The Prince of Wales.*

"From the present conference will come a fund of knowledge which will advance science to a large extent. We are bringing to a common fund the intelligence and scientific knowledge of the electrical world from all parts of the globe and we are bringing it with a desire to contribute something for the common good. Out of it must come something of value to all the countries of the world.".... *The Earl of Derby, President of the Conference.*

"The scientific mind is the dynamic mind in the world and the political mind ought always to be subservient to it." *Mr. Frank Hodges, First Lord of the Admiralty.*

"Electrical energy is the greatest power ever placed in the hands of man. Modern civilization is one progressive liberation of mankind by the utilization of the sources of nature through the medium of machinery so that we may reduce human labour, increase its productivity and add to the amount and lessen the cost of material things and, at the same time, provide the people with leisure by which alone the intellectual capacity can be developed." *Mr. O. C. Merrill, Chairman of the American Delegation.*

"Modern sources of power are engaged in a struggle with matter and in that battle matter is gradually being overcome." *M. Guillaume, Director of Mines, France.*

"I cannot forget that it was an Englishman who, thirty-five years ago, taught us that the proper place for central station was not the place of consumption but the place where there was ample water supply and the facilities for transportation were good, for those things were essential to low cost. It was from him also we learned that it is a necessity to have the energy conveyed at high voltage to the place of consumption." *Mr. Samuel Insull.*

"It is a great inspiration to those whose history spans three short half centuries to come to the Homeland whence springs our language and laws and our engineering." *Mr. F. R. Low, President, American Society of Mechanical Engineers.*

"The forces which are working to make civilization great and which are doing the most to advance civilization are those developed to the production and distribution of power." *Mr. John R. Freeman.*

Speaking of the urge to bring about an international engineering organization and referring to the fact that there were so many engineering societies of the different countries, Mr. W. H. Patchell, president of the Institution of Mechanical Engineers, said: "In Canada, thank God, they were all under one roof".

Those Canadian engineers who are in London for the first time have enjoyed a marvellous experience. It is not often that one finds the people of London eulogizing their city but the following sentiment was expressed in a paragraph which appeared in the *Daily Mail* on Friday July 4th: — "Never before has London seemed more full of interest and delight than in this summer of the great Empire Exhibition at Wembley. To the Londoner, accustomed to take the city and her marvels for granted, the exhibition stands out, but to the visitor from the country or from over-seas the exhibition is but one of the innumerable unique attractions.

"For there are no cities in the world that can really hold a candle to London or give to their visitors such varied wealth of entertainment. Comparing London with all other cities, she is far above and beyond them in offering almost every conceivable kind of amusement and diversion.

"Where else, indeed, could one find within easy reach such brilliant scenes of sport as Wimbledon, Henley, and Lords can show, and where are such new attractions offered every week throughout the season, leading up in regular procession to the glories of Goodwood and Cowes?

"The pageant of London in summer — her crowds thronging the streets or taking the air in the parks, her historic buildings, her famous river — make a sight bewildering in its rich variety and worthy of the greatest city on earth.

"Altogether, England may well be proud of her capital. London is the magnet which draws all travellers and her fame grows mightier every year."

London, England, July 8th, 1924.

Canadian Engineers in London

In order to complete final arrangements for Canadian participation in the Conference, J. B. Challies, vice-president of *The Institute* left Quebec on May 30th, to proceed to London.

The party of Canadian delegates which sailed from Quebec on the Empress of France, on June 18th, reached London on June 25th, and consisted of the following:— The Hon. E. H. Armstrong, Frederick B. Brown, M.E.I.C., G. Gordon Gale, M.E.I.C., F. A. Gaby, M.E.I.C., H. G. Acres, M.E.I.C., K. H. Smith, M.E.I.C., Frank Sawford, E. A. Cleveland, M.E.I.C., and the secretary, Fraser S. Keith, M.E.I.C.

On their arrival they found every detail completed for the conference, and an array of social functions arranged extending over two weeks, including the events associated with the Kelvin Centennial.

On June 26th Mr. Challies called a meeting which took the form of a luncheon in the Oak Room of the Victoria Hotel over which he presided. There were present John Murphy, M.E.I.C., E. A. Cleveland, M.E.I.C., G. Gordon Gale, M.E.I.C., H. G. Acres, M.E.I.C., W. H. Munro, M.E.I.C., F. A. Gaby, M.E.I.C., Frederick B. Brown, Brown, M.E.I.C., B. F. Haanel, M.E.I.C., K. H. Smith, M.E.I.C., and Fraser S. Keith, M.E.I.C. At this meeting a working committee of the Canadian delegation of the World Power Conference was constituted under the chairmanship of the Hon. P. C. Larkin, High Commissioner for Canada, with Mr. Challies as vice-chairman.

Detailed information was given by Mr. Challies of the arrangements made for the Canadian luncheon to be held at the Victoria Hotel on Friday July 4th, at which the Canadian Government would act as host to the visitors. Information was also given by Mr. Challies concerning the arrangements made for the luncheon to be held in Paris on July 17th, under the chairmanship of M. Honoré Roy, the Canadian Commissioner in Paris.

The committee approved of a suggestion from Dr. Camsell that a booklet on Canada be available at the luncheon for those who desired a copy.

Owing to the splendid co-operation of Mr. Dunlop, the organizing director of the conference, it was resolved that the committee present him with a leatherbound copy of the Coat of Arms of the Provinces of Canada, suitably engrossed.

It was the unanimous opinion of those present that the Canadian delegation should favour London as the headquarters for a Secretariat on World Power Affairs, and that the Canadians should use their influence towards that end, insisting on an equal vote with the other nations when it came to a decision on the matter.

It was unanimously resolved that J. B. Challies, secretary of the Canadian Management Committee, be the official Canadian representative on the international committee and that he represent the Canadian delegation at the opening ceremonies, Monday, June 30th.

The second meeting of the committee was held at Kinniard House, office of the Canadian High Commissioner, at which were present J. B. Challies, in the chair, Frederick B. Brown, F. A. Gaby, G. Gordon Gale, John Murphy, K. H. Smith, Prof. Greig, E. A. Cleveland, B. F. Haanel and Fraser S. Keith. It was unanimously resolved that Messrs. B. F. Haanel and F. A. Gaby be nominated as the official speakers at the first session of the conference on Tuesday July 1st, with Messrs. John Murphy and Frederick B. Brown as additional speakers if the opportunity presented itself.

At the meeting there was considerable enthusiasm regarding the part that Canada was to take in the Conference, arising out of the discussion on which it was resolved to present the following programme to the International Committee as the Canadian participation at the various sessions.

Wednesday, July 2nd. Morning

Hall 1. Economic Aspect of Power Resources.
Frederick B. Brown, — *reserve speaker.*

Afternoon

Hall 2. Economic Aspect of Power Resources.
G. Gordon Gale, — *opening speaker.*

Thursday, July 3rd. Morning

Hall 1. Economic Aspect of Power Resources.
E. A. Cleveland and K. H. Smith, — *reserve speakers.*

Hall 2. Steam Generation.
Prof. A. R. Greig.

Hall 3. Preparation of Fuels
B. F. Haanel.

Afternoon

Hall 1. Water Power Production
F. A. Gaby,
H. G. Acres, — *opening speaker.*
K. H. Smith, — *reserve speaker.*

Hall 3. Preparation of Fuels
B. F. Haanel, — *chairman.*

Friday, July 4th. Morning

Hall 1. Water Power Production
W. H. Munro, — *opening speaker.*
F. A. Gaby, H. G. Acres and K. H. Smith,— *reserve speakers.*

Hall 2. Steam Utilization
Prof. A. R. Greig.

Hall 3. Preparation of Fuels
B. F. Haanel.

Afternoon

Hall 1. Water Power Production
John Murphy.

Saturday, July 5th. Morning

Monday, July 7th. Morning

Hall 1. Power Transmission and Distribution
Sven Svenningson.

Hall 2. Gas and Fuel Section
B. F. Haanel.

Afternoon

Hall 1. Power Transmission and Distribution
F. A. Gaby, — *reserve speaker.*

Hall 3. Research

Wednesday, July 9th. Morning

Hall 1. Power in Domestic Use and in Agriculture
F. A. Gaby, — *reserve speaker.*

Hall 2. Power in Electro-Chemistry
Sven Svenningson.

Afternoon

Hall 1. Power for Rail Transport
F. A. Gaby.

Hall 2. Power in Electro-Metallurgy
John Murphy, — *chairman.*

Hall 3. Publicity. Fraser S. Keith.

Thursday, July 10th. Morning

Hall 1. Power for Rail Transport
G. Gordon Gale and John Murphy.

Hall 2. Power for Water Transport
F. A. Gaby.

Hall 3. Education, Technical and Commercial
Prof. A. R. Greig and Fraser S. Keith, — *reserve speakers.*

Afternoon

Hall 1. Standardization
John Murphy, — *opening speaker.*
Frederick B. Brown, — *reserve speaker.*

Hall 3. Education, Technical and Commercial
Prof. A. R. Greig and Fraser S. Keith, — *reserve speakers.*

Standard Tests Code for Hydraulic Power Plants

Mr. Challies read a letter from the Institution of Mechanical Engineers extending an invitation to a discussion on the proposed Standard Test Code for Hydraulic Power Plants. It was considered advisable that Canada be well represented and F. A. Gaby, H. G. Acres and Frederick B. Brown were appointed.

The Centenary of Lord Kelvin

The members of *The Engineering Institute of Canada* are honoured in the opportunity which has been offered to them, of paying a public homage to the memory of Lord Kelvin.

The study of Lord Kelvin's life, and more particularly of his achievements, leaves one in admiration at the comprehensiveness of his genius and at the untiringness of his energy. It would require a mind almost as well developed as that of Lord Kelvin himself to appraise at their true value his discoveries and his inventions.

It is a matter of pride to us as Canadians in our loyalty to the British Empire to feel that as we have derived our language, our literature and our traditions from the Mother country, so do we owe also to the great men of science in Great Britain the broad foundation upon which our engineering knowledge rests. We realize fully that to the conception of the master minds of this country which made possible the great development of our modern civilization and particularly to that supreme genius whose memory at this time we so greatly cherish, the world owes a great debt of gratitude. We cannot forget that it was Lord Kelvin's research work on the application of electricity to submarine telegraphy which made possible the laying of the transatlantic cable. Thus it was he who enabled us to establish rapid communication with the Motherland, drawing us closer together in the bonds of empire union.

As Canadians also, we like to remember that Sir William Thomson was a member of the International Niagara Falls Commission, established in London in 1890 for the purpose of studying the methods in use in the old world for the production and for the transmission of electricity. In this as in every problem he approached, he left the lasting mark of the master mind and again it can be truly said that we owe to him a heritage which has made possible the great power development which we in Canada to-day enjoy.

Presented by Mr. J. B. Challies, C.E., M.E.I.C.,
Vice-president of The Engineering Institute of Canada.

OBITUARY

Charles M. Odell, M.E.I.C.

On Tuesday, June 24, 1924, Charles Monserratt Odell, M.E.I.C., died at his residence in Sydney, Nova Scotia. He had been in ill-health for the past two years, but, except for periods when under the immediate care of his physician, he attended his office until within a few weeks previous to his death.

Mr. Odell was sixty-three years of age, having been born in 1861 at Sarnia, Ontario, the son of James Odell of Fredericton, N.B., and Sarah Monserratt Odell, of Ireland.

At the early age of eighteen he entered the civil engineering profession, when, in 1879, he went to Winnipeg to engage in railway construction work. His work in this connection for the next few years carried him all through the western provinces. In 1886 he came to Cape Breton, still on railway work, and in 1893 he entered the employ of the Dominion Coal Company with supervision over their Sydney and Louisburg Railway. Four years later he was appointed resident engineer of that company, a position he held at the time of his death.

CHARLES M. ODELL, M.E.I.C.

He was not a charter member of the Canadian Society of Civil Engineers, but he joined that Society during the year it was founded. On the formation of the Cape Breton Branch of *The Engineering Institute of Canada*, in 1921, he was elected first chairman and re-elected to that office in 1922. Throughout this life-long membership, his really active interest was of no little benefit to *The Institute* at large and the Cape Breton Branch in particular. Mr. Odell was also an active member of the Mining Society of Nova Scotia, of which he was president for the year 1923. He was re-elected to this office just a few hours before his death.

Throughout the province, and indeed throughout the country, Mr. Odell was known and esteemed. His was a remarkable character. His excellent memory, great sense of humour and never-failing wit, coupled with his ability as raconteur made him popular at gatherings of all kinds.

He is survived by his wife, formerly Miss Emma Vooght, daughter of the late John Vooght of North Sydney, and by one son and two daughters.

The large number of floral tributes, and of friends who attended his funeral testified to the great esteem in which he was held. The Cape Breton Branch attended as a unit, walking in front of the hearse.

Presentations to the Library

Presented by W. Bell Dawson, M.E.I.C.

Instructions to Engineers, by Sir Sandford Fleming, dated 1875.

Presented by L. H. Cole, M.E.I.C.

Mineral Resources of the United States, 1909, Part 2, Nonmetals; 1911, Parts 1 and 2, Metals and Nonmetals; 1912, Parts 1 and 2, Metals and Nonmetals; 1914, Part 1, Metals; 1915, Parts 1 and 2, Metals and Nonmetals.

Presented by A. G. Jeffreys, A.M.E.I.C.

Dictionary of Applied Physics, by Sir Richard Glazebrook; Volume 1, Mechanics Engineering Heat; Volume 2, Electricity; Volume 3, Meteorology, Metrology and Measuring Apparatus; Volume 4, Light Sound Radiology; Volume 5, Aeronautics, Metallurgy, General Index.

PERSONALS

J. D. Murray, S.E.I.C., has joined the staff of the Bell Telephone Company of Canada, at Ottawa.

W. P. Copp, A.M.E.I.C., professor of engineering at Dalhousie University is on bridge inspection during the summer for the province of Nova Scotia.

Lieut. Col. A. C. Garner, M.E.I.C., and J. N. DeStein, M.E.I.C., have been appointed members of the Regina Town Planning Board.

Walter K. Scott, A.M.E.I.C., has accepted a position in the structural department of Canadian Vickers, Limited, and is located at Maisonneuve, Que.

C. O. Whitman, A.M.E.I.C., has been appointed principal of the Thetford Mines Academy, Thetford Mines, Que., and will take up his new duties in the fall.

Col. J. Houliston, A.M.E.I.C., for several years past Officer Commanding Military District No. 7, New Brunswick, has recently been retired and is residing at Ottawa.

F. S. Kuhns, A.M.E.I.C., who was sales manager for the Bishopric Manufacturing Company, of Ottawa, is now in Florida representing the company.

E. J. Peal, S.E.I.C., who graduated this year from Queen's University, is now located in Cleveland, Ohio, with the Bailey Meter Company.

J. R. Freeman, M.E.I.C., has lately removed from Halifax, N.S., to St. John, N.B., on his promotion to senior assistant engineer with Public Works, Canada.

J. W. Wyse, S.E.I.C., who graduated from McGill University this spring, in civil engineering, is at present in Detroit, Michigan, with a construction contractor.

W. L. Reford Stewart, S.E.I.C., is located with the Newton-Dakin Construction Company, Limited, at St. Angele, Que. Mr. Stewart is a graduate of the Royal Military College of Kingston, Ont.

O. R. Harvey, Jr.E.I.C., formerly wire and cable sales engineer with the Northern Electric Company, Limited, at Winnipeg, Man., has joined the company's staff at their Montreal office.

Roy C. Leslie, S.E.I.C., has accepted the position of structural draughtsman with the Dominion Bridge Company, Limited, Lachine, Que. Mr. Leslie received the degree of B.A.Sc. from the University of Toronto in 1923.

J. B. Pringle, S.E.I.C., is with the production department of the Northern Electric Company, Limited, Montreal. Mr. Pringle received his B.Sc. degree this spring from McGill University.

R. McD. Richardson, S.E.I.C., of the class of '24, McGill University, is employed in the plant department of the Bell Telephone Company of Canada in Montreal. Mr. Richardson is a graduate in electrical engineering.

Robert Wood, S.E.I.C., is on transmission work at Victoriaville, Que., for the Shawinigan Water and Power Company. Mr. Wood is an electrical graduate of this year from McGill University.

D. L. Stewart, S.E.I.C., who graduated in mechanical engineering this spring from McGill University, is with the engineering department of the Bell Telephone Company of Canada.

L. S. Cossitt, S.E.I.C., who graduated in mechanical engineering from McGill University this spring, is with the Northern Electric Company, Limited, Montreal, in the planning department.

V. J. Dick, Jr.E.I.C., has been transferred from the Calgary office of the Canadian Westinghouse Company, Limited, and is now in charge of the company's Edmonton office.

J. M. Anderson, A.M.E.I.C., has been appointed resident engineer with the Department of Highways, Edmonton, Alberta. Mr. Anderson was previously with the Edmonton, Dunvegan, and British Columbia Railway.

W. B. Pennock, Jr.E.I.C., has severed his connection with the Canadian Fairbanks-Morse Company, Limited, to enter private practice in Windsor, Ont. Mr. Pennock received his B.Sc. degree in 1915 from McGill University.

M. L. Thompson, S.E.I.C., in now with the installation department of the Northern Electric Company, Limited, being located at Toronto, Ont. Mr. Thompson is a graduate of this year from Queen's University.

F. W. Elliott, S.E.I.C., who until recently was with the Canadian Westinghouse Company, Limited, at Hamilton, Ont., has accepted a position with the Bell Telephone Company of Canada, in Montreal.

W. H. G. Flay, A.M.E.I.C., has resigned from the staff of the Ottawa Public School Board to accept a position on the engineering staff of the Dominion Reinforcing Company of Ottawa and Montreal.

George M. Dick, S.E.I.C., who recently graduated in mechanical engineering from McGill University, has been appointed to the engineering staff of Babcock-Wilcox and Goldie-McCulloch, Limited, of Galt, Ont.

C. J. Yorath, A.M.E.I.C., formerly city commissioner for Edmonton, Alta., has resigned to become president and general manager of the Northwestern Utilities Limited, Edmonton. This company operates the natural gas franchise of that city.

James F. Pedder, S.E.I.C., is at present taking the graduate course of the Westinghouse Electric and Manufacturing Company of East Pittsburgh. Mr. Pedder received his B.A.Sc., degree with honours from the University of Toronto, this spring.

F. Jno. Bell, M.E.I.C., of Toronto, widely known in the Electrical Industry throughout Canada, has been appointed Canadian representative for C. A. Parsons and Company, builders of steam turbines and heavy electrical apparatus, with works at Newcastle-on-Tyne, England.

H. Edwards, M.E.I.C., has recently been appointed to the staff of the construction and engineering division of Stone and Webster, Incorporated, at Boston, Mass. Mr. Edwards was formerly with the New England Telephone and Telegraph Company, Lawrence, Mass.

J. B. Nelson, A.M.E.I.C., is representing the sales and service departments of the A. B. Ormsby Company, Limited, of Toronto, in the Toronto and Hamilton districts. Mr. Nelson was for a time with the Standard Steel Construction Company, Limited, of Welland, Ont.

L. S. Dixon, M.E.I.C., previously manager of engineering with the Eddy Paper Corporation of Three Rivers and White Pigeon, Michigan, is at present with the Riordon Pulp Corporation, Limited, at Temiskaming, Que., as consulting engineer.

W. C. McLaren, A.M.E.I.C., formerly with the construction department of the Canadian National Railways, with offices at Winnipeg, Man., has resigned to accept the position of estimating engineer with the Southern Pacific Lines, Kirkford, Oregon.

Allan T. Bone, A.M.E.I.C., has rejoined the George A. Fuller Company, Limited, Montreal, as estimating engineer. Mr. Bone has recently been with the Shawinigan Engineering Company on design of equipment and plant layout on the new development at La Gabelle.

J. O. McNally, S.E.I.C., of Fredericton, N.B., is at present with the Western Electric Company of New York City in the research laboratories. Mr. McNally graduated from the University of New Brunswick with the class of 1924.

Henri Gauthier, A.M.E.I.C., has resigned from the position of road materials engineer with the Mines Branch, Ottawa, to accept the position of inspector and technologist in the Mines Branch of the Department of Colonization, Mines and Fisheries of the province of Quebec.

J. O'Halloran, Jr.E.I.C., has been appointed to the staff of Price Brothers and Company, Limited, at Kenogami, Que., and will enter upon his new duties early during the present month. Mr. O'Halloran is a graduate of McGill University with the class of '21.

A. L. Mieville, A.M.E.I.C., who has been associated with the firm of Robert Morris and Company, of Farnworth, England, has been appointed general manager for the Howden-Ljungstrom Preheaters (Land) Limited. Govan, Glasgow.

W. F. McKnight, A.M.E.I.C., professor of electrical engineering at Nova Scotia Technical College, Halifax, N.S., and vice-chairman of the Halifax Branch. has gone to Toronto for the summer and is working on the revision of the Canadian Electrical code.

F. R. Faulkner, M.E.I.C., immediate past-chairman of the Halifax Branch, and professor of civil engineering at Nova Scotia Technical College, Halifax, N.S., has entered the engineering department of Stone and Webster, Incorporated, Boston, Mass., for the summer months as designing structural engineer.

W. G. Hardy, A M.E.I.C., assistant professor of civil engineering, Nova Scotia Technical College, Halifax, N.S., left Halifax May 15th for New York to take a boat trip through the Panama canal to California in search of health. He has not yet recovered his strength after his siege of rheumatic fever in the summer of 1923.

R. W. McCullough, A.M.E.I.C., has been promoted to the position of chief engineer of the Provincial Highways Board of the province of Nova Scotia left vacant since the death of the late W. A. Hendry, M.E.I.C. At present he is combining the duties of chief engineer with those of his former position of chief inspecting engineer.

A. A. Paoli, A.M.E.I.C., is at present with the Canadian Ingersoll-Rand Company, Limited, in Sydney, N.S., as sales engineer for Nova Scotia, Prince Edward Island and Newfoundland. Mr. Paoli received his B.A. degree from Queen's University in 1915, and his B.Sc. from the same university, in 1922.

F. W. W. Doane, M.E.I.C., former city engineer of Halifax, N.S., who is now in private practice, has in preparation a plan of the town of Pictou, N.S., where he has recently made a survey, and is to make a report of the municipal lighting system of the town of Antigonish, N.S.

R. M. Robertson, Jr.E.I.C., until recently with the bridge department of the Canadian Pacific Railway, has accepted a position in the designing department of the Dominion Bridge Company, Limited. Mr. Robertson is a graduate from McGill University with the class of 1920.

L. L. Thériault, M.E.I.C., district highway engineer, Public Works Department, New Brunswick, had the

ELECTIONS AND TRANSFERS

On June 7th, 1924, a ballot was canvassed and the following elections and transfers were effected:—

Members

BARNES, Howard Turner, B.A.Sc., M.A.Sc., D.Sc. (McGill Univ.), F.R.S., of Montreal, Que.

BROCK, Reginald Walter, M.A., LL.D. (Queen's Univ.), dean of the faculty of applied science, University of British Columbia, Vancouver, B.C.

HYNDMAN, Walter Eardley, district engr., Dept. Public Works, Canada, Charlottetown, P.E.I.

ROBINSON, Arthur Herbert Ashburner, B.A.Sc. (Univ. of Tor.), mineral technologist, Dept. of Mines, Ottawa, Ont.

Associate Members

BARRY, William Henry, private practice, architect and constructional engr., Peterborough, Ont.

BREEN, Joseph Melville, B.A.Sc. (Univ. of Tor.), roadways engr. for Ontario for Canada Cement Company, Toronto, Ont.

CARMICHAEL, Frederick Norman Dubourdien, B.A.Sc. (Univ. of Tor.), engr., plan examination branch, city arch'ts. dept., City Hall, Toronto. Ont.

COOPER, Herbert Johnstone, Bach. Engrg. (Thomason Civil Engrg. College, India), asst. hydraulic engr. in charge of surveys for the Reclamation Service, Dept. of the Interior, Calgary, Alta.

CUNNINGHAM, William John, supt. power and pumping plants, City of Edmonton, Alta.

KELLY, Edward Arthur, of Lethbridge, Alta., asst. engr. on constrn., C.P.R., Kipp, Alta. to Little Bow River.

KEWIN, George Edwin, B.A.Sc. (Univ. of Tor.), res. elect'l. engr., Queenston-Chippawa Development, H.E.P.C. of Ontario, Niagara Falls South. Ont.

LEGER, Oswald Ernest, sales engr., Canadian Vickers, Limited, Montreal, Que.

LOGAN, Robert Archibald, manager, mapping division, Fairchild Aerial Camera Corporation, New York City.

STEEL, William Arthur, B.A.Sc. (Univ. of Tor.), tech. officer for the Royal Canadian Corps of Signals, Ottawa, Ont.

TAYLOR, Gilbert Ferguson, struct'l. engr. in charge of design and supervision of bridges, works dept., City Hall, Ottawa, Ont.

Juniors

TAKER, Frank Oliver, surveyor on engrg. staff, Hollinger Consolidated Gold Mines, Ltd., Timmins, Ont.

TRUEMAN, James Cobden, B.Sc. (Univ. of Man.), 721 Shuter Street, Montreal, Que.

WILSON, James Moir, B.Sc. (McGill Univ.), of Lachine, Que.

Affiliates

LOCKWOOD, Walter Holmes, dfting., designing and estimating, Waterman Waterbury Mfg. Co. Ltd., Regina, Sask.

McLACHLIN, Dan. manager of an extensive lumber plant at Arnprior, Ont.

Transferred from the class of Associate Member to that of Member

GRAY, Francis William, asst. to the president, British Empire Steel Corporation, Sydney, N.S.

PICKARD, Kenneth Stockton, B.Sc. (McGill Univ.), private practice, Sackville, N.B.

SHANLY, Coote Nisbitt, in charge of special investigations of hydraulic works, Price Bros. & Co. Ltd., Kenogami, Que.

Transferred from the class of Junior to that of Associate Member

BISHOP, Arthur Leonard, (Grad. R.M.C.), 50 Ontario Street, St. Catharines, Ont.

CALKINS, Harold A., B.Sc. (McGill Univ.), of Montreal, Que.

CREIGHTON, Charles Sydney, B.Sc. (N.S. Tech. Coll.), mgr., Creighton Woodworking Co., Woodside, Dartmouth, N.S.

CROSSING, William Berkley, transitman on location, C.P.R., Winnipeg, Man.

GRAY, Earl Alexander, engr. in charge design and special constrn. dept., Public Utilities Commission, London, Ont.

MORRISEY, Thomas Sydney, (Grad. R.M.C.), of 85 Church Hill, Westmount, Que.

NASH, Abram Leland Stanley, B.A.Sc. (Univ. of Tor.), partner, Messrs. Lee and Nash, Brantford, Ont.

REID, John Herbert, B.Sc. (McGill Univ.), asst. professor of elec. engrg., N.S. Tech. Coll., Halifax, N.S.

VANCE, James Alfred, general contractor, Woodstock, Ont.

Transferred from the class of Student to that of Junior

FRY, John Dawson, B.Sc. (McGill Univ.), asst. engr., McDougall, Pease and Friedman, Consulting Engineers, Montreal, Que.

GILBERT, Edgar Valentine, B.Sc. (McGill Univ.), dftsman. at Hemmings' Falls, for Southern Canada Power Company, Montreal, Que.

IRVIN, Wilfrid F., B.A.Sc. (Univ. of Tor.), asst. engr. on traffic study, Toronto Transportation Commission, Toronto, Ont.

PERRITON, Douglas E., B.Sc. (McGill Univ.), checker, Dominion Bridge Company, Lachine, Que.

PREVOST, Edouard, B.S. (Univ. of Montreal), field engr. for the Atlas Construction Co., and dftsman., Messrs. Beaubien, Busfield & Co., Montreal, Que.

ROSE, Hugh Grant, B.A.Sc. (Univ. of Tor.), Geodetic Survey of Canada, Ottawa, Ont.

WHITFORD, Joseph Arthur Hugh, dftsman. on bldg. design, chief engr's. office, C.N.R., Moncton, N.B.

WILLIAMS, Stephen, B.A.Sc. (Univ. of Tor.), Grad. R.M.C., dftsman., Imperial Oil Refineries, Limited, Sarnia, Ont.

WINTER, Thomas Hinton, B.Sc. (N.S. Tech. Coll.), chief asst. to engr. in charge pipe line and forebay constrn., Sir W. G. Armstrong Whitworth & Co. Ltd., Deer Lake, Nfld.

ZEALAND, Edward Lamport, B.A.Sc. (Univ. of Tor.), junior engr., Quebec Development Co. Ltd., St. Joseph d'Alma, Que.

On June 24th, 1924, a ballot was canvassed and the following elections and transfers were effected:—

Members

CALDWELL, Alexander Clyde, (Grad. R.M.C.), Director, Engineer Services, Department National Defence, Ottawa, Ont.

ROY, Georges, B.Sc. (Laval Univ.), officer administering the Royal Canadian Artillery and staff officer for artillery. Chairman, Standing Arms Committee, Ottawa, Ont.

Associate Members

BABBITT, Archie Randolph, B.Sc. (Univ. of N.B.), Provincial Highways Board, Halifax, N.S.

CHAMBERS, Edward Coulthurst Gibbons, captain and adjutant, Royal Canadian Engineers, Ottawa, Ont.

CHETWYND, George Rowland, District Engineer Officer, M.D. No. 12, Regina, Sask.

COOK, William Henry, chief dftsman., mech. bldg. and mtce., Canadian Consolidated Rubber Co., Ltd., Montreal, Que.

CUNNINGHAM, Roy Herbert, B.A.Sc. (Univ. of Tor.), R. H. Cunningham & Company, Industrial Engineers, London, Ont.

Affiliate

DAW, Joseph, engr., Brown Corporation, Quebec, Que.

Transferred from the class of Junior to that of Associate Member

MacNEIL, Hector, res. engr., constrn., C.N.R., Longlac, Ont.

McLEAN, Howard Joseph, field and office engr., Dominion Water Power Branch, Calgary, Alta.

Transferred from the class of Student to that of Junior

BENNETT, Willard Erlandson, B.A.Sc. (Univ. of Tor.), res. engr., Swastika-Wendigo Lake Branch, Nipissing Central Railway, Larder Lake, Ont.

KIRKPATRICK, Harold Thompson, B.Sc. (McGill Univ.), dftsman., Dominion Tar & Chemical Co., Montreal, Que.

OLIVER, Cuthbert Jack, B.Sc. (McGill Univ.), power house layout and design work, Messrs. Kerry & Chace, Ltd., Toronto, Ont.

At the meeting of Council held on May 27th, 1924, the following students were admitted:—

McCAW, John Blaiklock, Staff House, Kenogami, Que.

PHIPPS, Charles Ferdinand, Cascade Inn, Shawinigan Falls, Que.

REID, Kenneth, 348 Sherbrooke Street West, Montreal, Que.

British Columbia's Lumber Exhibit at Wembley

Loren L. Brown, A.M.E.I.C., British Columbia Timber Commissioner

Three thousand people per hour pouring through the British Columbia bungalow illustrates the love of every human being for a *Home* and proves the wisdom of exhibiting our woods in the form of the finished product. Exterior woodwork, shingle siding and roofing, flooring, wall and ceiling panelling, sash and doors incorporated into a home receive infinitely more attention than when shown by themselves in a miscellaneous museum-like collection of exhibits.

One of the main objects of the British Columbia exhibit is to increase the United Kingdom market for our clear grades of fir, hemlock, cedar and spruce and that it will do so is certain if the interest in the exhibit is an indication.

The bungalow consists of two rooms only, a living room and dining room and is in a very prominent position inside of the Canadian building. Both rooms are floored with edge-grained Douglas fir. The living room walls are panelled with Douglas fir. The panels themselves being 3-ply veneer and the stiles and rails being edge-grained strips. The ceiling which is greatly admired, is of Douglas fir with cottonwood panels. This room has a built-in ingle-nook with a fireplace.

The dining room walls are panelled in British Columbia hemlock in the solid. The ceiling is beamed with solid red cedar beams having cottonwood panels between. This room also contains a fireplace which has built-in china cabinets with leaded glass doors on either side of it. The two doorways have been very artistically treated the overhang in each case being carried on carved cedar brackets.

In the chimney stack has been inset a plaster cast of the British Columbia coat-of-arms with the words British Columbia. As this is directly in the centre of the main aisle, no one who visits the Canadian building can fail to realize that British Columbia is very much on the map.

On an adjoining space is shown a miscellaneous exhibit of British Columbia forest products comprising, sash and doors, cedar and cottonwood panelling and sample mouldings and boards.

The Dominion Government exhibit which comprises woods from all the provinces affords generous space to those from British Columbia.

In addition there are a number of exhibits by commercial firms featuring British Columbia woods.

Beside all this an automatic cinema with a daylight screen tells the story of the British Columbia lumber industry and of the province generally twelve hours per day. British Columbia in general and the lumber industry in particular are well represented at Wembley.

In view of the tremendous housing programme which is now well under way the exhibit is very timely and affords the best possible means of showing the many varied and valuable uses of British Columbia timbers to the British timber-merchant, architect and builder and to the ultimate consumer.

British Columbia Lumber Exhibit at Wembly, Exterior and Interior View of Bungalow.

BRANCH NEWS

St. John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer

On the evening of May 30th, the members of the St. John Branch, tendered a farewell banquet at the Dunlop Hotel, to E. G. Cameron, A.M.E.I.C.

C. C. Kirby, M.E.I.C. in proposing the toast to the guest of the evening expressed the regret of the members of the St. John Branch at losing Mr. Cameron, but wished him the best of success in his new position as assistant to the chief engineer on Welland Ship Canal.

In reply Mr. Cameron thanked his friends for their expressions of good wishes and briefly reviewed his six years' stay in St. John. He modestly disclaimed undue credit for the St. John drydock now completed (and built largely under his supervision as chief engineer) but generously gave the credit to his predecessors and assistants. Unfortunately Mr. Cameron left himself open to future trouble when in an unguarded moment he issued an invitation to the members of the St. John Branch to visit him at St. Catharines, Ont.

The toast to *The Institute* was moved by F. P. Vaughan, M.E.I.C. The growth of *The Institute* in recent years and particularly in the past year was mentioned by the speaker. Reference was made to several members who had left the branch territory recently, including V. S. Chesnut, A.M.E.I.C. and other members of the St. John drydock staff, H. F. Bennett, A.M.E.I.C. to Halifax, N. F. Nutter, A.M.E.I.C. to Truro, F. G. Goodspeed, M.E.I.C. to Winnipeg. C. L. Roach, S.E.I.C., a member of *The Institute* for three weeks, replied to this toast.

F. M. Ross, Affiliate of St. John Branch, general manager St. John Drydock and Shipbuilding Company, spoke of his associations with Mr. Cameron and of his regret at losing him, and including in this all the men on the job.

J. L. Rannie, M.E.I.C., chairman Ottawa Branch, tendered the good wishes of the Ottawa Branch to the St. John Branch. Those present gained a clearer idea of the work *The Institute* is doing in making engineers better acquainted throughout Canada, and of more that could be done in this respect from Mr. Rannie's remarks. Forty-one members were present and singing by entertainers and the whole crowd, and recitations were other features of the evening. "Good-Bye, Good-Luck to You !" those present read on their menu cards and repeated this sentiment when later they separately bade farewell to Mr. Cameron.

Moncton Branch

M. J. Murphy, A.M.E.I.C., Secretary-Treasurer

The annual meeting of Moncton Branch was held on Thursday evening, May 15th 1924, with F. O. Condon, M.E.I.C., vice-chairman, presiding

Annual Report of the Executive Committee

The third annual meeting of Moncton Branch was held on June 1st, 1923.

The attendance at our meetings during the past year has been very good considering that we have lost several of our most active members who were transferred to Montreal or other cities at the time of the re-organization of the Canadian National Railways.

During the year there were seven meetings of the branch. The executive committee held five meetings during the branch year and considerable business was transacted.

Papers were read, addresses given and important business transacted as follows:—

1923

Dec. 18—W. R. Pearce, M.E.I.C., chief engineer of the New Brunswick Telephone Co., St. John, read a paper on "*The Telephone*".

1924

Jan. 24—Mr. Hutchinson of the Meteorological Observatory, St. John delivered an address on "*The Winds and Weather*".

Feb. 4—Dr. Howard T. Barnes, of McGill University, Montreal, addressed the members on "*Ice Formation and Prevention*".

Feb. 26—A meeting was held at Mount Allison University, Sackville, N.B., at which A. E. Oulton, A.M.E.I.C., of the Bridge Dep't. Canadian National Railways, Moncton, delivered an address on "*An Outline of Bridge Design*".

Mar. 7—Nominations of officers for the year 1924-25 were held.

Mar. 18—Doctor Bigelow of Mount Allison University addressed the members on "*The Natural Resources of the Province of New Brunswick*".

Apr. 25—Vice-president F. A. Bowman, M.E.I.C., of Halifax, gave a short address of interest to the members of the maritime provinces, and Professor H. W. McKiel, M.E.I.C., addressed the members on "*Canada's Mineral Resources*".

During the past year our membership has decreased owing, as mentioned before, to the transfer of several of our most active members. In May, 1923, we had 86, we have now 79, which number includes the non-resident members. The membership is as follows:—

Resident—............	Members	10	
	Associate Members	26	
	Juniors	5	
	Students	20	
	Affiliate	1	62
Non-resident—.........	Members	1	
	Associate Members	10	
	Juniors	4	
	Students	2	17
	Total..............		79

The sincere thanks of the members of Moncton Branch are due to Major McKie and the ladies and gentlemen who so kindly provided entertainment at our supper-meetings.

The financial statement will show a surplus of $87.66, which amount includes balance in bank after all outstanding bills are paid and rebates for January, February and March due from headquarters.

The thanks of the executive are due G. C. Torrens, A.M.E.I.C., chairman of the Papers Committee; G. E. Smith, A.M.E.I.C., and J. R. Freeman, M.E.I.C., of the Entertainment Committee; M. A. McCabe, Jr.E.I.C., associate editor of the Journal and L. T. Tingley, official stenographer, who have all worked faithfully towards the general welfare of the branch during the past year.

(Signed) M. J. Murphy, A.M.E.I.C., *Secretary-Treasury.*
Fred. Condon, M.E.I.C., *Vice-chairman.*

Election of Officers

The following officers were elected for the ensuing year:

F. O. Condon, M.E.I.C., Engineer, Maintenance of Way, C.N.R., Chairman.

C. S. G. Rogers, A.M.E.I.C., Bridge Engineer, C.N.R., Vice Chairman

M. J. Murphy, A.M.E.I.C., Assistant Engineer, C.N.R., Secretary-Treasurer.

Executive Committee:—
F. B. Fripp, A.M.E.I.C., Harbour Engineer, C.N.R.
G. C. Torrens, A.M.E.I.C., Division Engineer, C.N.R.
G. E. Smith, A.M.E.I.C., Draughtsman, C.N.R.

The following members of the Executive Committee hold office for another year.
H. J. Crudge, A.M.E.I.C., Building-Engineer, C.N.R.
E. G. Evans, M.E.I.C., District Engineer, C.N.R.
J. D. McBeath, M.E.I.C., City Engineer.
A. F. Stewart, M.E.I.C., Chief Engineer, C.N.R., Ex-officio.
W. B. MacKenzie, M.E.I.C., Consulting Engineer, Ex-officio.

Committee Appointments

At a meeting of the Executive Committee held June 12th, the following Committees were appointed for the year 1924-25.

Entertainment Committee:—G. E. Smith, A.M.E.I.C.
J. R. Freeman, M.E.I.C.
Papers Committee:—Prof. H. W. McKiel, M.E.I.C., chairman.
A. C. Selig, M.E.I.C.
A. E. Oulton, A.M.E.I.C.
R. H. Emmerson, A.M.E.I.C.
Auditors:—H. J. Crudge, A.M.E.I.C.
C. S. Rogers, A.M.E.I.C.

M. J. Murphy, A.M.E.I.C.
Moncton, N.B., June 11, 1924. *Secretary-Treasurer.*

Saskatchewan Branch

J. W. D. Farrell, A.M.E.I.C., Secretary-Treasurer

Congratulations are in order to Professor C. J. Mackenzie, M.E.I.C., dean of the faculty of engineering, University of Saskatchewan, on his recent marriage. The wedding took place in Holy Trinity Church, Edmonton, June 11th, when Geraldine Gallon, daughter of Mr. and Mrs. W. J. Gallon, became the bride of Professor Mackenzie.

Professor Mackenzie is chairman of the Saskatchewan Branch, and the members join in extending to him their best wishes at this time.

Special Meeting

A special meeting of the branch was held April 24th, at the Parliament Buildings' dining room, Lieut. Col. Garner, M.E.I.C., past chairman, presiding in the absence of Mr. Blackburn. The meeting commenced with a dinner, at which approximately twenty members were present, several other members coming in later. Following the dinner a communication was read from Mr. E. W. Francis, Jr.E.I.C., a son of the late Walter J. Francis, President of *The Institute,* thanking the branch for its message of sympathy and for the floral tribute. P. C. Perry, A.M.E.I.C., who was to have given a paper on "Development of New Methods and Appliances in Railway Maintenance" was unavoidably detained and could not give his paper.

The Panama Canal

The Chairman then called on Mr. Patton for his paper on the Panama Canal. Mr. Patton gave a very interesting talk on the canal, giving an outline of the history of the canal, a brief account of construction data and difficulties, present day maintenance and operating practices. By means of a map and figures Mr. Patton showed how the canal route was related to the world's traffic routes and within what limits it was economical to pay canal tolls. Mr. Patton also showed a profile of the canal, a relief map of the Zone and an excellent collection of slides made from photos taken during his trip last winter. In closing Mr. Patton suggested that the construction and operation of the Panama canal should, in his opinion, indicate that the successful operation of the Hudson Bay route was quite attainable. In the discussion which followed Mr. Patton answered the questions of members and brought out some interesting points.

Problems of Telephone Maintenance

T. Leach, of the department of telephones, then gave an interesting talk on the problems of telephone maintenance engineering. Mr. Leach outlined the routine work in connection with giving continuous service to the subscribers of the system, touching on methods of repair and the use of instruments in locating line trouble. Mr. Leach also touched on the economics of distributing from a central exchange as compared with several branch exchanges. A general discussion took place which at one time threatened to break out into the electrolysis controversy between Messrs. McGuinness and Parker.

Health Engineering

R. H. Murray, A.M.E.I.C., then gave a talk on health engineering. Mr. Murray, using data referring to our own province, said that within the whole province there were some thirty-six municipalities with a total population of 100,000 with municipal water supplies; also that there were some eighteen municipalities with sewage disposal systems. From these facts it was pointed out that the provincial department of public health was chiefly concerned in assisting small communities and farmers in obtaining safe water supplies and making a sanitary disposal of waste matter. Mr. Murray also touched on milk supplies and bovine tuberculosis. It was shown that the province had a problem of very serious dimensions in this matter and that a wide range of action on the part of the health of animals branch of the Dominion government was urgently needed. The cities of the province are receiving good protection in this matter but this protection needed to be extended throughout the province. The paper was discussed generally, several members giving anecdotes relating to the subject.

Victoria Branch

E. P. Girdwood, M.E.I.C., Secretary-Treasurer

The members of the Victoria Branch were the guests of the officers of H.M.S. Hood on board the battleship while at Victoria, on June 21st. Accompanied by their wives and a number of friends, the members were afforded an opportunity of making a tour of inspection of the Hood. The party which consisted of one hundred and seventy-five and included practically all the prominent engineers of Victoria, had a most interesting and enjoyable time.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

R. Hogg, Jr. E.I.C., Branch News Editor.

Speaking before the annual meeting of the branch, Russell Yuill, A.M.E.I.C., of the St. Lawrence Ship Canal staff, gave a description of the St. Lawrence river together with detailed results of investigations of the ice conditions in the river.

Mr. Yuill has done considerable work on this latter problem during the past winter, and his figures and facts were "straight from the barbed wire" so to speak.

Mr. Yuill's address, and the large assortment of slides with which it was illustrated, were much appreciated by the members present, who, whether of the Department of Railways and Canals, or under the banner of the Hydro Commission, are all equally interested in this projected development.

A feature which added much to the enjoyment of the evening was the rendering of selections of classical music by the Welland Ship Canal Instrumental Trio.

The Branch News Editor was the happy recipient of a handsome pipe "*a real Dunhill,*" presented to him by F. W. Clark, A.M.E.I.C., on behalf of the branch. He appreciates very much the gift itself and the kind thought which prompted it.

Annual Picnic

About seventy members, their wives and guests, attended the annual picnic of the branch, held on July 16th, at the Queens Royal Hotel, Niagara-on-the-Lake.

A tennis tournament, golf and bathing occupied the afternoon. Then came dinner, a pleasant and satisfying affair, followed by the presentation of prizes to the winners of the tennis tournament. First prizes were carried off by J. R. Bond, A.M.E.I.C., and G. Kewin, A.M.E.I.C. while the runners-up were C. H. Mathewson, A.M.E.I.C., and O. B. Bourne, A.M.E.I.C.

S. R. Frost, A.M.E.I.C., past chairman, expressed keen regret at the loss to the branch of A. C. D. Blanchard, M.E.I.C., who leaves this district on August 1st to take a position as chief hydraulic engineer with the New Brunswick Power Commission. Mr. Blanchard has worked energetically for the good of the branch ever since its inception, and has earned the name given him by Mr. Frost, of "Father of the Branch". F. S. Lazier, M.E.I.C., in a few remarks endorsed the sentiments expressed by the former speaker. R. W. Downie, A.M.E.I.C., secretary-treasurer, asked for and received authority from the branch to show some mark of appreciation of the efforts of F.W. Clark, A.M.E.I.C. towards furthering its interests. Mr. Clark has always been a hard worker, both in the council and the executive. He was transferred recently from the Chippawa canal to Shaws falls on the Ottawa, where a preliminary survey for hydro development is being made.

A thunder storm which started during dinner caused the indefinite postponement of a soft ball game which was scheduled to be played between the St. Catharines members and those from the Falls.

The rain that came to the rescue of the Niagara Falls team, and at the same time robbed the St. Kitts team of a victory, did not, however, interfere with a very enjoyable dance in the Hotel pavilion, where the majority of the guests remained till near midnight, when they found their several ways homeward through a heavy downpour, damp in the flesh, but undamped in the spirit.

OTHER SOCIETIES NEWS

Meeting of The British Association for the Advancement of Science

The British Association for the advancement of science will hold its 92nd annual meeting in Toronto, Canada, from the 6th to the 13th of August.

A cordial invitation is extended to all who are interested in science to become members for this meeting. No technical qualifications are required for membership.

The Association, which was founded in 1831, meets annually for one week or longer at important centres, other than London, in England, and it occasionally meets in other parts of the British Empire. The Association has met in Canada on three previous occasions, viz. in 1884, 1897 and 1909. Other overseas meetings have been held once each in South Africa 1905 and Australia 1914.

Scientific Meetings

The inaugural general meeting will be held on Wednesday, August 6th, when Major-General Sir David Bruce, K.C.B., F.R.S., will assume the presidency of the association in succession to Professor Sir Ernest Rutherford, F.R.S., and will deliver the presidential address.

The association is organized in thirteen sections designated as follows:—

	President for 1924.
A. Mathematical and Physical Science,	Sir Wm. Bragg, K.B.E., F.R.S.
B. Chemistry,	Sir Robert Robertson, K.B.E.
C. Geology,	Prof. W. W. Watts, F.R.S.
D. Zoology,	Prof. G. Elliot Smith, F.R.S.
E. Geography,	Prof. J. W. Gregory, F.R.S.
F. Economic Science and Statistics,	Sir William Ashley.
G. Engineering,	Prof. G. W. O. Howe.
H. Anthropology,	Dr. F. C. S. Shrubsall.
I. Physiology,	Dr. H. H. Dale, C.B.E., F.R.S.
J. Psychology,	Prof. W. McDougall, F.R.S.
K. Botany,	Prof. V. H. Blackman, F.R.S.
L. Educational Science,	Principal Ernest Barker.
M. Agriculture,	Sir John Russell, F.R.S.

Addresses will be delivered by the sectional presidents of the respective sections and papers will be read on and after Thursday, August 7th, until the conclusion of the meeting.

Joint meetings of various sections will be held also at which the following are among the subjects to be discussed.

Section.	*Subject.*
A and B	Crystal Structure and Colloid Solutions.
A and G	Optical Study of Elasticity.
B and I	Vitamines and the relation of light to their action.
B and G	Liquid and powdered Fuels.
C and E	Changes of Sea-level in relation to Gravitation, Continental Shelves and Coral Islands.
I and J	Physiological and Psychological Factors of Muscular Efficiency in Industry.
D and K	Species Concept.
D and M	Soil Population.
J and L	Tests for Scholarship and Promotion.
F and M	Diminishing Returns in Agriculture.
H and J	Racial Mental Differences.

During the week of the meetings a number of popular lectures will be delivered by prominent visitors.

Nova Scotia Mining Society Annual Meeting

The thirty-second annual meeting of the Nova Scotia Mining Society was held in New Glasgow, N.S., commencing June 23rd, and proved to be one of the most successful in the long history of the organization. Members of the Society from all sections of Nova Scotia were present, and a series of very interesting papers on mining and geological subjects were presented.

The news of the death of C. M. Odell, president of the Society, on June 24th, the day following his re-election to that high office, came as a great shock to the members. The late Mr. Odell has for years been most energetic in the interests of the Nova Scotia Mining Society.

The officers elected for the ensuing year are: — First vice-president, Alex. S. MacNeil, general colliery superintendent, British Empire Steel Corporation, Glace Bay; second vice-president, F. W. Gray, A.M.E.I.C., assistant to the president of the British Empire Steel Corporation; and E. C. H. Hanrahan, secretary-treasurer.

The executive council of the Society for the present year includes the following members of *The Engineering Institute of Canada:* T. J. Brown, M.E.I.C., J. S. Whyte, M.E.I.C., H. B. Gillis, M.E.I.C., Walter Herd, M.E.I.C., D. H. McDougall, M.E.I.C., and J. J. McDougall, A.M.E.I.C.

EMPLOYMENT BUREAU

Situations Wanted

Technical Assistant

Graduate applied chemistry. Five years experience coke oven works, thoroughly familiar with operation and scientific control, desires change with prospects in similar work or allied industries. Apply box No. 148-W.

Civil Engineer

University graduate, A.M.E.I.C., nine years experience in highway and building construction, wants position with a firm of contractors or manufacturers. Apply box No. 149-W.

Electrical Engineer

Graduate electrical engineer with nineteen years experience, including six years as chief engineer of large power organization in Canada, wishes to secure position as executive or on construction work, either electrical or mechanical. Location immaterial. Knowledge of French, Italian, German and Spanish. Apply box No. 150-W.

Situations Vacant

Senior Electrical Engineer

Senior electrical engineer for temporary employment for the St. Lawrence Canal Enlargement Branch, Department of Railways and Canals. Salary $4,200. per annum. Qualifications: graduation with high standing in electrical engineering from a recognized university, or its equivalent; extensive and recent experience in designing power plants of large size with special reference to electrical and mechanical equipment; extensive experience in the shops and testing laboratories and designing offices of companies who build generators, transformers, and switching apparatus. Candidates must be British subjects with at least three years' residence in Canada. Apply to the Civil Service Commission, Ottawa, not later than August 7th.

Draughtsmen

A paper company in Quebec requires the services of two experienced draughtsmen, preferably men who have worked in paper mills. Salary between $175 and $200. Apply box No. 114-W.

Industrial Engineer

Public utility company in Montreal has an opening for a qualified engineer who has had experience in building and plant maintenance, with a thorough grounding in mechanical engineering, and a general knowledge of construction and architectural work preferred although not essential. Work will entail the general management of a number of buildings of the company. Apply box No. 117-V.

Mechanical Engineer

There is an opening for a mechanical engineer with four or five years experience in engineering practice, who is well up in theory, for the position of assistant to the chief engineer of a pulp and paper company in Ontario. Salary between $300 and $350 per month. Apply box No. 118-V.

Architectural Draughtsmen

One or two architectural draughtsmen with four or five years experience in the design of large buildings. Reply giving full statement of experience and qualifications. Apply box No. 119-V.

Representative

Société Nouvelle des Établissements; Decauville Aîné of Paris (France) manufacturer of permanent and portable railway material would like to secure as representative for Canada reliable firm well established, having store and yard at Montreal.

Write giving particulars and references to:

DECAUVILLE Aîné, 66, Chaussée d'Antin, PARIS.

Recent Additions to the Library

Transactions, Proceedings, etc.

Presented by the Societies.

Transactions of The Institution of Engineers, Australia, Volume 2, 1921.
Year Book of The American Society of Civil Engineers, March 1924.
Transactions and Year Book of The University of Toronto Engineering Society, April 1924.
Transactions of The Society of Naval Architects and Marine Engineers, 1923. Volume XXXI.
Directory of The American Institute of Mining and Metallurgical Engineers, Incorporated, corrected to April 7th, 1924.
Transactions of the Institution of Water Engineers, Volume XXVIII. 1923.

Reports, etc.

Presented by United States Department of Commerce.

Recommended Minimum Requirements for Plumbing in Dwellings and similar buildings, final report of sub-committee on plumbing of the Building Code Committee.
Elimination of Waste, Simplified Practice, Hollow Building Tile.

Presented by The Rockefeller Foundation.

A Review for 1923, by George E. Vincent, President of the Foundation.

Presented by The American Society of Mechanical Engineers.

The Engineering Index, 1923.

Presented by The Dominion Bureau of Statistics, Canada.

Census of Industry, 1922, Central Electric Stations in Canada.

Presented by Corps of Engineers, United States Army.

Statistical Report of Lake Commerce passing through Canals at Sault Ste. Marie, Michigan and Ontario, during the season of 1923.

Presented by the Keeper of Public Records, Dominion of Canada.

Report of the Public Archives for the Year 1923.

Presented by the Technical Association of the Pulp and Paper Industry.

Decayed Wood for Pulp — at a Profit, by John D. Rue.

Presented by Mines Branch, Dept. of the Interior, Ottawa.

The Mineral Industries of Canada, British Empire Exhibition Edition, 1924.

Presented by the Commissioner of Public Works, Boston, U.S.A.

Annual Report of the Public Works Department, City of Boston, 1922.

Presented by the Dominion Bureau of Statistics.

The Canada Year Book, 1922-1923.

Presented by Department of Trade & Commerce, Dominion of Canada.

Annual Report of the Trade of Canada, fiscal year ending March 31st, 1923.

Technical Books.

Presented by Chapman and Hall, Limited, London, England.

Coal and Oil Fired Boilers, by Engineer-Commander, F. J. Drover, R.N.
Constructional Steelwork, by Harry Atkin.

Presented by Williams and Wilkins Company, Baltimore, Md.

Popular Research Narratives, tales of Discovery, Invention and Research.

Presented by Industrial and Educational Publishing Company.

A Handbook of Prospecting, by W. L. Goodwin, D.Sc., LL.D. First Edition.

Preliminary Notice

of Applications for Admission and for Transfer

July 4th, 1924.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in August, 1924.

FRASER S. KEITH, Secretary.

*The professional requirements are as follows:—

Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of n chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as references does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANDERSON—NORMAN RUSSELL, of Camp Borden, Ont. Born at Walkerton, Ont., April 29th, 1893; Educ., High School; Oct. 1916, joined R.F.C.; Dec. 1917 to Aug. 1918, employed as instructor of special flying; July 1920, promoted Flight-Lieut., C.A.F.; Sept. 1921, promoted Squadron Leader, C.A F., and employed as certificate examiner under Air Board; April 1923, appointed Second in Command, Royal Canadian Air Force Station, Camp Borden, and O. i/c Training.

CUFFE—ALBERT LAWSON, of High River, Alta. Born at Mayo, Ireland, May 2nd, 1895; Educ., Sligo Grammar School and Civil Service College, Dublin; May 1917, joined Royal Flying Corps; April 1918, promoted Captain; Aug. 1918 to June 1919, employed as instructor of special flying; Aug. 1920, appointed Flight-Lieut., C.A.F.; Feb. 1922, promoted Squadron Leader; Nov. 1923, appointed to command Royal Canadian Air Force Station, High River, Alta.

References: A. G. L. McNaughton, D. R. Cameron, E. W. Stedman, H. F. J. Lambart, A. Ferrier.

DELISLE—JOSEPH LORENZO, of Chicoutimi, Que. Born at Chicoutimi, Jan. 21st, 1888; Educ., B.A.Sc., Univ. of Toronto, 1916; surveying and machine shop practice during summer vacations; 1916-17, design — constrn. — erection of steel penstock, two turbines and installation of two generators at Ha Ha Bay. Erection of two turbines and ten grinders and other machinery at Val Jalbert; 1917-19, complete design and constrn. of mill No. 4, Chicoutimi Pulp Co. Also installation of all machinery in above mill. Also reconstrn. of Pont Arnault power house; 1919-22, design and constrn. of machine shop and foundry, Chicoutimi Pulp Co.; 1922 to date, in charge of electrical and mechanical dept., Chicoutimi Pulp Co.

HOBBS—BASIL DEACON, of Winnipeg, Man. Born at Arlington, Berkshire, England Dec. 20th, 1895; Educ., Prep. School, Business Course; Dec. 1915, Royal Naval Air Service; June 1917, promoted Flight-Lieut.; Jan. 1918, promoted Flight-Commander; April 1918, Captain, R.A.F.; May 1918, promoted Major, and appointed to British Aviation Mission, U.S.A.; Feb. 1919, appointed to Command No. 213 Squadron, R.A.F.; April 1920, appointed cert. examiner under Air Board; April 1921, appointed supt., Victoria Beach Air Station; May 1922, appointed Squadron Leader, Commanding R.C.A.F. Units, Manitoba.

References: A. G. L. McNaughton, D. R. Cameron, H. F. J. Lambart, A. Ferrier, R. B. McKay.

JOHNSON—GEORGE OWEN, of Ottawa, Ont. Born at Woodstock, Ont., Jan. 24th, 1896; Educ., Honour Matric., Ontario, and 1st Class professional teacher, Alberta; April 1917, joined R.F.C.; April 1918, promoted Captain, R.A.F.; July 1919 to Jan. 1920, O. i/c Canadian Air Force Detachment in Canada; Jan. 1920, appointed supt., Camp Borden Air Station; Oct. 1920, appointed to staff, Air Board, Ottawa; Sept. 1921, promoted Squadron Leader,R.C.A.F.; May 1922,appointed Acting Assistant Director, R.C.A.F., and at present Squadron Leader engaged in co-operative work with engineers of the Dept. of the Interior.

References: R. B. McKay, A. G. L. McNaughton, E. W. Stedman, A. Ferrier, D. R. Cameron.

JOHNSON—LANCELOT LLEWELLYN, of Calgary, Alta. Born at Cwmbran, Monmouthshire, England, Nov. 17th, 1883; Educ., Civil Engr., Renss. Polytech. Inst., Troy, N.Y., 1907; 1900-01, engrg. work, ap'tice mechanic, General Electric Co., Schenectady, N.Y.; 1902-03, mechanic, Westinghouse Electric Co., East Pittsburgh, Pa.; 1904 (summer), bridge foreman, rebuilding bridges over Hudson, Poughkeepsie, N.Y.; 1905 (summer), mechanic, Westinghouse Electric Co., East Pittsburgh;

1907-08, mech. engr., Cohoes Rolling Mills Co., Cohoes, N.Y.; 1909, chief dftsman., Carpenter's Steel Co., Reading, Pa.; 1911, Heddon Constrn. Co., Denver Post Office Bldg., Denver, Col.; 1910, highway and bridge work, State of New Jersey & Penn.; 1912-1913, engr., Wardell & Harrington, Kansas City, on C.N.R. railroad bridges over Thompson's River at Wallachine, B.C.; 1913-14, partner, J. L. Lacompte, Lake Wood, New Jersey, builder of state highways and bridges, N.J. and Pa.; 1915-17, Lieut., Can. Engrs.; 1918, A/District Vocational Officer, Prov. of B.C., D.S.C.R.; 1918-20, Vocational Officer, Prov. of Alta., D.S.C.R.; 1921 to date, Unit Director of Administration for Prov. of Alberta, D.S.C.R.

MARCH—JOSEPH WADE, of Bridgewater, N.S. Born at Bridgewater, N.S., March 28th, 1896; Educ., B.Sc. in C.E., N.S. Tech. Coll. 1923; Summer work: 1912-13, chaining and rodding for Highways Board; 1914, chaining and rodding for land surveying and town work, and inspecting installation of culverts for S. E. March of Highways Commission; 1919, inspecting constrn. of 1¼ miles of tar bound macadam road at Bridgewater and inspecting constrn. of concrete roads and side walks in Lunenburg under S. E. March; 1921, inspecting installation of wood stove pipe water supply main at Bridgewater; 1922, land surveying and town engrg. work; May 1923 to date, transmission line work under R. P. Freeman, for Nova Scotia Power Commission.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of engineering profession.

(For July)

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director

Engineering Societies Library,

29 West Thirty-ninth Street. New York, N.Y.

A

AIR

Dustiness Measurement. The Production and Measurement of Air Dustiness, M. Ingels. Am. Soc. Heat & Vent. Engrs.—Jl., vol. 30, no. 2, Feb. 1924, pp. 133-152. 15 figs. Describes dust liberator, an apparatus developed for adding dust to room air, for testing purposes; tests Anderson and Armspach Dust Determinator for measuring efficiency of air cleaning equipment; gives dust chart and explains its use; sampling moving air.

AIR COMPRESSORS

Cylinder Lubrication. Air Compressor Cylinder Lubrication. Lubrication, vol. 10, no. 3, Mar. 1924, pp. 25-36, 14 figs. Temperatures involved; basic construction features of several types of air compressors; compressor-oil requirements; methods of air-cylinder lubrication, air-compressor explosions.

Portable Sets. Portable Air Compressor Sets. Engineering, vol. 117, no. 3039, Mar. 28, 1924, pp. 398-400, 8 figs. Modifications introduced by Globe Pneumatic Eng. Co., Lond., including new type of light-weight set on much improved frame and carriage, specially designed to conform to regulations regarding trailer vehicles.

AIR CONDITIONING

Air Cleaners. Determining the Efficiency of Air Cleaners, A. M. Goodloe. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 2, Feb. 1924, pp. 115-119, 5 figs. Describes apparatus and method for determining by weight efficiency of average commercial cleaner, devised primarily for purpose of making a forced efficiency test of air cleaners in a laboratory or shop.

AIRCRAFT CONSTRUCTION MATERIALS

Metallic. Some Materials in Aircraft Construction. Roy. Aeronautical Soc.—Jl., vol. 28, no. 160, Apr. 1924, pp. 226-248 and (discussion) 248-259, 6 figs. First article, by J. D. North, discusses materials which should be used to give lightest structure. Second article, by L. Aitchison, deals with properties of metallic aircraft materials.

Steel and Duralumin Tubing. Torsional Strength of Nickel Steel and Duralumin Tubing as Affected by the Ratio of Diameter to Gage Thickness, N. S. Otey. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 189, Apr. 1924, 8 pp., 15 figs. on supp. plates. Tests to determine extent of variations of torsional modulus of rupture with ratio of diameter to gage thickness.

AIRPLANE ENGINES

Evolution. The Evolution of Aircraft Engines (L'évolution des moteurs d'aviation), Martinot-Lagarde. Technique Moderne, vol. 16, no. 7, Apr. 1, 1924, pp. 195-207, 19 figs. General characteristics; principal types—water-cooled and air-cooled engines; rôle of light metals; factors influencing efficiency of engines; compression; engines for high altitudes and high speeds; means of reducing power loss with altitude; setting and installation of engines; technical details of cylinder construction; new cycles for automobiles and aviation.

French Developments. The Great Efforts of French Industry towards Development of New Engines (Le grand effort de l'industrie française vers les moteurs nouveaux). Aérophile, vol. 32, nos. 3-4 and 5-6, Feb. 1-15 and Mar. 1-15, 1924, pp. 61-64 and 102-105, 10 figs. Review of progress made in design of airplane engines and examination of different types, including nearly all of well-known French makes.

AIRPLANE PROPELLERS

Design and Tests. The Analysis of Free Flight Propeller Tests and Its Application to Design, M. M. Munk. Nat. Advisory Committee for Aeronautics—Report, no. 183, 1924, 12 pp., 20 figs. New and useful method suitable for design of propellers and for interpretation of tests with propellers.

AIRPLANES

Beams, Deflection of. Deflection of Beams with Special Reference to Shear Deformations, J. A. Newlin and G. W. Trayer. Nat. Advisory Committee for Aeronautics—Report, no. 180, 1924, 19 pp. 8 figs. Influence of form of wooden beam on its stiffness and strength.

Metal. Metal Airplane Construction (Ueber Metallflugzeugbau). Motorwagen, vol. 27, no. 11, Apr. 20, 1924, pp. 190-194. Comparisons between metal and wooden airplanes, showing advantages of former; properties of metals employed; heat treatment for annealing and for refining. Abstracted and translated into German from Russian journal, Westnik Wosduschnogo Flota.

Performance. Comparing the Performance of Geometrically Similar Airplanes, M. M. Munk. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 190, Apr. 1924, 27 pp. Deals with model rules relating to aeronautical problems, and shows how characteristics of one airplane can be determined from those of another of different weight or size, and of similar type.

Stability. Utilization of Laboratory Charts for Study of the Stability and Centering of Airplanes (L'Utilisation des Courbes de Laboratoire pour l'étude de la stabilité et du centrage des avions), J. Kernéis. Aérophile, vol. 32, nos. 3-4 and 5-6, Feb. 1-15 and Mar. 1-15, 1924, pp. 54-57 and 89-93, 12 figs. It is shown that with regard to stability, laboratory curves lead in very simple manner to desired result; it is essential, before using them, to change them with regard to center of gravity, which can be accomplished by aid of simple graphic method.

Wings. Further Notes on the Design of Wing Spar Sections, E. P. Warner. Aviation, vol. 16, no. 14, Apr. 7, 1924, pp. 358-360, 2 figs. Supplementary to article by author in same journal, May, 29, 1922, and to critical remarks by A. J. Sutton Pippard, July 17, 1922.

AIRSHIPS

Aerodynamic Forces on Hulls. The Aerodynamic Forces on Airship Hulls, M. M. Munk. Nat. Advisory Committee for Aeronautics—Report, no. 184, 1924, 20 pp., 4 figs. New method for making computations in connection with study of rigid airships, used in investigation of Navy's ZR-1; attempt is made to develop results from very fundamental of mechanics, without reference to some of modern highly developed conceptions.

ALLOYS

Aluminum. *See Aluminum Alloys.*

Bearing Metals. *See Bearing Metals.*

Brass. *See Brass.*

Light. Light Alloys for Pistons and Connecting-Rods, L. Aitchison. Automobile Engr., vol. 14, no. 189, May 1924, pp. 148-155, 5 figs. Discusses advantages and disadvantages of light alloys for automobile-engine pistons and connecting rods.

Recent Progress in Light Alloys (Les alliages légers, leurs récents progrès), L. Guillet. Revue Universelle des Mines, vol. 67, no. 1, Apr. 1, 1924, pp. 7-36, 14 figs. Examination of alloys of aluminum and magnesium, their properties, influence of impurities, etc.

ALUMINUM ALLOYS

Aluminum-Copper. Heat Treatment of Aluminum-Copper Alloys, A. Portevin and F. Le Chatelier. Am. Soc. Steel Treating—Trans., vol. 5, no. 5, May 1924, pp. 457-478, 14 figs. Study of properties of light aluminum alloys containing varying proportions of copper, manganese and magnesium; discusses characteristics of alloys containing copper, with and without magnesium; heat treatment and aging, and their effect upon physical properties; hypotheses explaining constitution of aluminum-copper-manganese-magnesium alloys.

Aluminum-Silicon. Aluminum-Silicon Alloys, J. B. Swan. Automobile Engr., vol. 14, no. 188, Apr. 1924, pp. 102-105, 10 figs. Their properties and limitations; aluminum-silicon binary system; making up and casting alloy; reversion; aluminum-silicon as forging and cold-worked metal; effects of heat treatment.

Castings, Hard Spots in. Study Aluminum Hard Spots. A. J. Lyon. Foundry, vol. 52, no. 10, May 15, 1924, pp. 396-397. Methods employed to identify inclusions, and determine effect on mechanical properties, and metallographic structure of oxidizing aluminum cast alloys during melting.

AMMONIA

Anhydrous. Is Anhydrous Ammonia Combustible?, W. F. Schaphorst. Nat. Engr., vol. 28, no. 5, May 1924, pp. 220-221. Opinions of authorities and experts, from which it appears that it is feebly combustible under certain conditions but normally incombustible and actually a retardent of combustion in many cases.

AMMONIA COMPRESSORS

Compound Compression. Effect of Compound Compression of Ammonia, J. E. Starr. Power Plant Eng., vol. 28, No. 8, Apr., 15, 1924, pp. 445-446, 1 fig. Cost of extra equipment, it is claimed, will in most cases offset thermodynamic gains which would result from compound compression.

ASH HANDLING

Power Plants. The Disposal of Ashes in Power Plants, E. K. Scott. Power Engr., vol. 19, nos. 215, 216 and 217, Feb., Mar. and Apr., 1924, pp. 55-56, 90-92 and 145-147, 16 figs. Survey of present practice. Feb.: Trucks and skips; bucket and tray conveyors; scraper and belt conveyor. Mar.: Sluicing ash conveyor.

ATOMS

Theories and Experiments. Outline of the Investigations of the Atom During the Last Decade (Grundragen av det senaste artiondets atomforskning), A. Westgren. Teknisk Tidskrift, vol. 54, no. 13, Mar. 29, 1924, pp. 104-108, (Allmanna Avdelningen), 5 figs. Reports theories and experiments, particularly those of Ernest Rutherford in Cambridge, Eng.

AUTOMOBILE ENGINES

CORROSION. Undue Wear of Engine Parts is Caused by Rust. Automotive Industries, vol. 50, no. 18, May 1, 1924, pp. 956-958, 2 figs. Three hypotheses analyzed in research work conducted in Gen. Motors Corp., namely, acid, oxide and electrolytic theory, all of which agree that presence of moisture is necessary.

OIL RECTIFIERS. Rickenbacker Incorporates Skinner Rectifier in All New Models. Automotive Industries, vol. 50, no. 20, May 15, 1924, pp. 1086-1087, 2 figs. Oil drawn from around piston by inlet suction is subject to distillation process by hot exhaust gases, fuel driven off being returned to intake manifold.

AUTOMOBILE FUELS

LIGNITE AS SOURCE OF. Lignites and the Manufacture of Automobile Fuel (Les lignites et la fabrication des carburants), E. Marcotte. Revue Industrielle, vol. 54, no. 2178, May 1924, pp. 85-94, 5 figs. Notes on extraction of light products; classification of possible treatments; recovery of benzol; objections against distillation of lignite; hydrogenation; Bergius process and its industrial application; liquefaction direct from coal; Mélamid process; Fischer and Schrader processes.

AUTOMOBILES

BODIES, FINISHING. High Brake Pre-Enameled Panels Used in Body Construction. Automotive Mfr., vol. 66, no. 1, Apr. 1924, pp. 9-11, 4 figs. Details of new type of construction which permits easy application of hard permanent finish to metals panels applied over conventional wood frame.

Ultra-Violet Rays Used to Test Body Fabrics and Finishes, W. L. Carver. Automotive Industries, vol. 50, no. 19, May 8, 1924, pp. 1011-1014, 5 figs. Few hours of exposure under suitable conditions may be equal to many months of natural weathering; utilization of quartz-tube mercury-vapor damp which emits ultra-violet rays, which may also be employed to dry varnish.

BRAKES. Study of Gripper Brakes for Automobiles and Lifting Devices (L'étude des freins à machoires pour automobiles et appareils de levage). Génie Civil, vol. 84, no. 19, May 10, 1924, pp. 452-454, 4 figs. General considerations on functioning of brakes; elementary calculation; distribution of pressure; determination of bending.

BRAKES, FOUR-WHEEL. Four-Wheel Braking Systems, F. A. Stepney Acres. Automobile Engr., vol. 14, no. 188, Apr. 1924, pp. 115-118, 4 figs. Arrangement of brakes; brake-power ration; mechanical difficulties; pedal leverage; central steering; compensation; mechanical difficulties; front springs; brake-rod layout.

CHASSIS LUBRICATION. Chassis Lubrication Is Simplified by Bowen System. Automotive Industries, vol. 50, no. 16, Apr. 17, 1924, pp. 876-878, 9 figs. Designed to deliver accurately measured quantities of oil to each bearing slowly for several hours after pump plunger is depressed; air domes over each header valve serve important purpose in metering and controlling flow; special tubing used.

GEAR BOXES. New Morris Production Methods. Machy. (Lond.), vol. 24, no. 602, Apr. 10, 1924, pp. 33-38, 11 figs. Machines and methods used by Morris Engines, Ltd., Coventry, in grinding spline shafts and gears for automobile gear boxes.

AVIATION

NIGHT-FLYING EQUIPMENT. Night-Flying Equipment and Operation, H. R. Harris and D. L. Bruner. Mech. Eng., vol. 46, no. 5, May 1924, pp. 274-278, 9 figs. Non-mathematical discussion of portion work carried on by Engineering Division of Air Service; much of equipment developed has been adapted by Air Mail Service. (Abridged.)

TERMINALS. The Future of the Air Terminal, D. Huntington. Aviation, vol. 16, no. 16, Apr. 21, 1924, pp. 423-425, 3 figs. Importance of air terminals; influence of carriers on terminal design; evolution of field-type terminal; location with respect to community; ideal location of airport; municipal-termina lidea; detail problems.

B

BEARING METALS

BABBITTING BRASSES. Babbitting Brasses for Subway Trains, F. H. Colvin. Am. Mach., vol. 60, no. 17, Apr. 24, 1924, pp. 629-630, 4 figs. Methods and equipment in babbitting room of New York 148th St. shop; simple mandrels used for holding brasses in position for babbitting; two men handle four tons of babbitt per month.

DUREX. Durex, a Bearing Material Which Holds Oil Like a Sponge. Automotive Industries, vol. 50, no. 20, May 15, 1924, pp. 1072-1074, 14 figs. Copper-tin-graphite bronze which absorbs up to one-fourth its own volume by capillarity through myriads of tiny, evenly distributed pores, and maintains oily bushing surface; offers insurance against shortage or stoppage of lubrication.

BEARINGS

ANTI-FRICTION. Anti-Friction Bearings Lower Transportation Costs from Face to Railroad Car, F. H. Kneeland. Coal Age, vol. 25, no. 17, Apr. 24, 1924, pp. 603-606, 5 figs. Need only one-fourth as many applications of lubricant as plain bearings and have nearly twice as long life; lubrication cost reduced by two-thirds; save power and equipment.

CYLINDRICAL. The Design and Performance of Complete Cylindrical Bearings from Mathematical Theory of Lubrication, G. B. Upton. Sibley Jl. of Eng., vol. 38, nos. 3 and 4, Mar. and Apr. 1924, pp. 56-60 and 76, and 97-100, 6 figs. Presentation and discussion of Harrison's equations; and modifications brought about by finite length and its consequences in end leakage of lubricant and lengthwise variation of pressure in lubricating film.

EXPERIMENTS. Some Bearing Investigations, E. G. Gilson. Gen. Elec Rev., vol. 27, no. 5, May 1924, pp. 318-327, 20 figs. Results of investigation made by Research Laboratory of Gen. Elec. Co. into phenomena of bearings.

BEARINGS, BALL

LIFE. The Life of Ball Bearings (Die Lebensdauer von Kugellagern), A. Palmgren. Zeit. des Vereines deutscher Ingenieure, vol. 68, no. 14, Apr. 5, 1924, pp. 339-341. Shows that life of ball bearings subjected to axial or combined stresses depends partly on maximum developed ball pressure and partly on fatigue phenomena which have changed in comparison to conditions with purely radial load.

BEARINGS, ROLLER

BRIDGE. Repairing a Skewed and Displaced Bridge Roller Bearing, Chas. F. Draper. Eng. News-Rec., vol. 92, no. 19, May 8, 1924, p. 810, 2 figs. New rollers placed in bearing of 250-ft. span with cam teeth engaging shoe plates to maintain alignment.

BITUMINOUS SAND

ALBERTA, CANADA. Bituminous Sands of Northern Alberta, S. C. Ells. Can. Min. Jl., vol. 45, nos. 13 and 17, Mar. 28 and Apr. 25, 1924, pp. 298-304 and 400-403, 5 figs. General description of area underlaid by bituminous sand; general description of deposits; prospecting; sampling and laboratory determination; characteristics of sand; use of bituminous materials for pavement construction; recovery of hydrocarbons and bitumen; production of petroleum. Pub. with permission Ottawa, Can., Dept. Mines. See also Petroleum Wld., vol. 21, no. 283, Apr. 1924, p. 152.

BLAST FURNACES

CHARGE, BEHAVIOR OF. The Behavior of the Charge in Blast Furnaces (Ueber das Verhalten der Beschickung im Hochofen), E. Diepschlag. Stahl u. Eisen, vol. 44, no. 16, Apr. 17, 1924, pp. 430-432. Heating and reactions; lowering and suspension of charges; wastes.

REGENERATORS, REVERSING. Theoretical Considerations Respecting Certain Features in the Working and Efficiency of Reversing Regenerators, J. Seigle. Iron & Steel Inst.—advance paper, no. 14, for mtg. May 1924, 47 pp., 28 figs. Author seeks to show that certain relations which have been accepted in metallurgical investigations on influence of mass of refractory bricks of checkerwork, and on amount of calories which are exchanged per sq. m. of heated surface, have been somewhat too roughly approximate.

BLOWERS

REGULATIONS. Report of Committee on Blower Systems. Nat. Fire Protection Assn., Advance Publication, 1924, 13 pp., 6 figs. Regulations for installation of blower and exhaust systems for heating and ventilating systems, systems for removal of flammable vapors, and stock and refuse conveying systems, presented for final adoption.

BOILER FIRING

GAS. Gas Firing—Flame Control, A. C. Ionides, Jr. Gas Jl., vol. 166, no. 3179, Apr. 16, 1924, pp. 176-178 and (discussion) 178-179, 2 figs. Author claims that principles of gas firing mostly employed hitherto are fundamentally wrong; discloses grounds for such a conclusion and establishes an alternative method. See also Gas Wld., vol. 80, no. 2073, Apr. 12, 1924, pp. 334-336 and (discussion) 336-337, 1 fig.

BOILER FURNACES

DESIGN. Problems in Boiler Furnace Design, E. B. Ricketts. Power Plant Eng., vol. 28, no. 9, May 1, 1924, pp. 473-476, 5 figs. Changes in stoker design, high ratings, high capacities, etc.; value of air heaters; materials for furnace-wall construction; effect of high combustion efficiency on superheat; mixing of boiler-furnace gases. Paper presented before Metropolitan Section of A.S.M.E.

INDUCED-DRAFT INSTALLATIONS. Calculation of Induced-Draft Installations (Berechnung einer Saugzug-Anlage), H. R. Karg. Fördertechnik u. Frachtverkehr, vol. 17, no. 6, Mar. 20, 1924, pp. 76-79. Calculation of induced-draft plant and auxiliary exhaustor; determination of excess air.

BOILER PLANTS

FLUE-DUST CONVEYORS. Pneumatic Flue Dust Conveyors, K. Wagner. Eng. Progress, vol. 5, no. 4, Apr. 1924, pp. 61-64, 7 figs. Suction plant designed by Seck Bros., Dresden, erected in boiler room; experienced gained in service.

BOILER PLATES

STRENGTH OF. The Distribution of Strength Properties in a Sheet-Iron Plate (Die Verteilung der Festigkeitseigenschaften innerhalb einer Blechtafel), E. Koch. Zeit. des Bayerischen Revisions-Vereins. vol. 28, nos. 3-4, 5 and 6, Feb. 29, Mar. 15 and 31, 1924, pp. 13-19, 33-38, and 44-47, 17 figs. Results of experimental investigation begun two years ago and still in progress; account of tests carried out in ammonia works of Dr. Wyszomirsky in Merseburg. Contains appendix, giving supplementary test regulations for boiler plate.

TESTING. The Testing of Boiler Plates, Chas. L. Huston. Power, vol. 59, no. 21, May 20, 1924, pp. 820-822, 3 figs. Proposed revival of Tetmayer formula for using unit stresses instead of factor of safety in determining allowable stresses on steel boiler plate in construction of steam boilers and other pressure vessels.

BOILER ROOMS

OPERATION. Boiler-Room Practice, J. Bruce. Elec. Rev., vol. 94, nos. 2414 and 2415, Feb. 29 and Mar. 7, 1924, pp. 324-325 and 365-367, 3 figs. Use of boiler-room instruments for efficient operation.

BOILERMAKING

BABCOCK & WILCOX PLANT, FRANCE. The French Babcock and Wilcox Boiler Works, G. L. Carden. Boiler Maker, vol. 24, no. 4, Apr. 1924, pp. 95-98, 4 figs. Description of plant located at La Courneuve on northern outskirts of Paris.

STANDARDS. Standards Adopted by the American Boiler Manufacturers' Association. Boiler Maker, vol. 24, no. 4, Apr. 1924, pp. 107-109 and 123-124. Report presented at meeting of Am. Boiler Mfrs.' Assn.

BOILERS

DEVELOPMENT. An Outline of Boiler Development, H. Webster. Refrig. Eng., vol. 10, no. 10, Apr. 1924, pp. 367-369. Considers briefly multiplicity of fuels available for steam generation, great number of methods of burning such fuels which have been developed, and the various feedwater conditions that have been encountered, and outline of development of boiler.

FEEDING ARRANGEMENTS. Important Factors in Boiler Feeding, Chas. F. Wade. Power Engr., vol. 19, no. 217, Apr. 1924, pp. 136-137, 1 fig. Aspects of boiler-feeding arrangements which are often overlooked.

LOCOMOTIVE. *See Locomotive Boilers.*

MERCURY. *See Mercury-Vapor Process.*

SETTINGS. Construction of Boiler Settings in Devon Station (Conn.). Power, vol. 59, no. 20, May 13, 1924, pp. 763-765, 6 figs. Furnace walls for 16,800-sq. ft. boilers constructed entirely of firebrick; arches built in walls to relieve loading on brick; expansion joints filled with asbestos fiber divide walls into vertical sections and allow for horizontal expansion; no heat-insulating bricks are used below lower tube line.

3,060 HP. Boilers at Cleveland Rate 3,060 hp. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 517-524, 8 figs. New boilers in Cleveland Elec. Illuminating Co. plant have 30,592-sq. ft. heating surface requiring 8 mi. of tubes; fired by pulverized coal; automatic-combustion control by steam pressure and flow-meters.

BORING MACHINES

LARGE ELECTRICAL MACHINERY. Giant Boring Mill Built in Canada. Iron Age, vol. 113, no. 21, May 22, 1924, pp. 1508-1510, 7 figs. Machine of unusual size for use in manufacture of electrical generating equipment; massive design and convenient control.

BRASS

LEAD AND TIN, INFLUENCE OF. Lead and Tin in Brass (Blei und Zinn im Messing Ms 60), K. Hanser. Zeit. für Metallkunde, vol. 16, no. 3, Mar. 1924, pp. 91-95, 7 figs. Based on existing investigations and author's own tests, influence of lead and tin on strength, elongation, shrinkage, hardness, and hot and cold working of 60/40 brass is shown.

BRIDGES, HIGHWAY

DESIGN. Outstanding Problems in Highway Bridge Design, E. F. Kelley. Good Roads, vol. 66, no. 4, Apr. 1924, pp. 106-108. Deals with live load specifications, future requirements, width of roadway, bridge approaches, bridge floors, wearing surfaces, junction of bridge with highway, and protection of structures and traffic. Paper read before Am. Road Bldr.'s Assn. convention.

BUILDING CONSTRUCTION

Reinforced-Concrete. A Note on Concrete Buildings, M. Ayrton. Roy. Inst. Brit. Architects—Jl., vol. 31, no. 10, Mar. 22, 1924, pp. 298-302, 6 figs. Discusses problems of reinforced-concrete building construction.

C

CABLEWAYS

Types. Cableways (Drahtseilbahnen), Fr. Wernekke. Praktische Maschinen-Konstrukteur, vol. 57, no. 8, Mar. 1, 1924, pp. 79-81, 4 figs. Development of transportation on wire rope is discussed and a few successful installations described, both for passenger and material haulage.

CALORIMETERS

Measuring. Small Heat Intensities Measurement of Small Heat Intensities: Use of Compensating Microcalorimeter (Mesure des intensités des petites sources de chaleur: emploi d'un microcalorimètre à compensation), A. Tian. Académie des Sciences). Comptes Rendus, vol. 178, no. 8, Feb. 18, 1924, pp. 705-707. Thermally insulated vessel immersed in bath at constant temperature serves as calorimeter; temperature differences between bath and vessel are measured using thermopile and galvanometer.

CALORIMETRY

Saturated Fluids. Calorimetry of Saturated Fluids, N. S. Osborne. Optical Soc. Am.—Jl., vol. 8, no. 4, Apr. 1924, pp. 519-540. Deals with theory of certain calorimetric processes for determination of important thermal properties of saturated fluids, and with interpretation of theory as bearing upon its experimental application.

CARS

Cast-Steel Castings, Reclamation by Arc Welding. Reclamation of Cast-Steel Car Castings by Arc Welding, H. R. Pennington. Am. Welding Soc.—Jl., vol. 3, no. 4, Apr. 1924, pp. 28-35, 6 figs. Examples of potential savings in reclamation of such parts as coupler bodies, knuckles, truck sides and bolsters for railways, and practice for reclamation of such parts.

Construction Methods. Railway Carriage and Wagon Building. Machy. (Lond.), vol. 24, no. 601, Apr., 3, 1924, pp. 1-4, 5 figs. Practice of Cammell Laird & Co.; making buffer forgings—upsetting forging machines; buffer forging operations.

CARS, FREIGHT

Box. Single Sheathed Box Cars for the D. T. & I. Ry. Mech. Engr., vol. 98, no. 5, May 1924, pp. 279-281, 4 figs. U. S. Railroad Administration design modified to provide 1 ft. added height and 1 ft. wider door opening.

CARS, REFRIGERATOR

Improved Design. New Refrigerator Cars for the Rock Island. Ry. Mech. Engr., vol. 98, no. 5, May 1924, pp. 286-289, 7 figs. Improved side construction has reduced maintenance costs and improved refrigerating efficiency; new method of insulation; Acme ventilation system used.

Insulation. Economical Thickness of Insulation in Refrigerator Cars, A. J. Wood and P. X. Rice. Refrig. Eng., vol. 10, no. 10, Apr. 1924, pp. 357-362 and (discussion) 362-366, 10 figs. Explains a reasonably simple method for determining quickly and accurately most economical thickness of insulation, and discusses factors which enter into economical design of insulated walls.

CAST IRON

Graphitization. Notes Properties of Cast Iron, E. Touceda. Foundry, vol. 52, no. 9, May 1, 1924, pp. 345-347, 1 fig. Manner and conditions under which graphitization takes place in cast iron has profound influence upon chemical and physical properties of metal; describes special metal made by Ross-Meehan Foundries, Chattanooga, Tenn., called mechanite metal. See also Iron Trade Rev., vol. 74, no. 19, May 8, 1924, pp. 1244-1246, 1 fig.

High-Temperature Growth. High-Temperature Growth of Special Cast Irons, J. H. Andrew and H. Hyman. Iron & Steel Inst.—advance paper, no. 2, for mtg. May 1924, 10 pp., 11 figs. Investigation to ascertain whether presence of silicon is necessary factor for growth; what exactly happens to graphite at end of 50 heats; and whether growth can be mitigated or retarded by presence of certain special elements, especially carbide-forming elements, such as chromium and vanadium in small quantities.

Manufacture. The Influence of Composition and Rate of Cooling upon the Microstructure and Physical Properties of Cast Iron. H. H. Beeny. Foundry Trade Jl., vol. 29, nos. 401 and 402, Apr. 24 and May 1, 1924, pp. 333-340 and (discussion) 365-366, 24 figs. Deals with constitution and physical properties of iron-carbon alloys as a whole, commencing with pure iron, passing through steels, and ending finally with white cast iron; microstructure of each broad type illustrated. Iron-carbide system, and influence of silicon and other elements, and rates of cooling upon this system.

Physical Changes. Physical Changes in Cast Iron due to (i) American Practice; (ii) Secondary Temperatures. Metal Industry (Lond.), vol. 24, no. 10, Mar. 7, 1924, pp. 227-228, 5 figs. Discusses influence of casting into chill pig molds and water spraying, as in American blast-furnace practice, and influence of secondary or foundry temperatures, that is, remelting iron and subsequent casting.

Test Bars, Transverse. Transverse Test-Bars and Engineering Formulae, G. S. Bell and C. H. Adamson. Iron & Steel Inst.—advance paper, no. 4, for mtg. May 1924, 15 pp., 11 figs. Test results show that generally accepted engineering formulas for conversion of transverse test on one sized bar to that on another sized bar do not hold when applied to cast-iron test bars of different sizes; results of tensile and hardness tests.

CEMENT

Alumina. The Action of Frost on Ciment Fondu. Engineering, vol. 117, no. 3039, Mar. 28, 1924, p. 393. Results of tests show that elevation of temperature from normal, which is taken as 64 up to 86 deg. fahr., tends to retard actual setting time of ciment fondu.

CENTRAL-STATIONS

Boiler-Feedwater Circuits. Boiler Feed-Water Circuits in Power Stations, J. G. Weir. Ingenieur, vol. 39, no. 18, May 3, 1924, pp. 332-338 and (discussion) 338-339, 18 figs. Importance of use of regenerative principles is emphasized and a number of possible circuits are described, illustrated and analyzed. (In English.)

Brooklyn Edison, Hudson Ave. Hudson Avenue Station. Elec. World, vol. 83, no. 18, May 3, 1924, pp. 867-876, 13 figs. Unusual features incorporated in design of new 400,000-kw. power house of Brooklyn Edison Co.; vertical-phase isolation used; details of coal-handling facilities, heat-balance arrangements, boilers and stokers, fans and feed pumps, turbines (which are largest in world), signaling system, etc.

Hudson Ave. Plant in Operation. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 549-553, 12 figs. Superpower station embodies refinement in heat balance, electric equipment and mechanical control; first section comprises two 50,000-kw. turbines and 8 boilers each with 19,650 sq. ft. heating surface; condensers with 70,000 sq. ft. cooling surface. See also description in Power, vol. 59, no. 20, May 13, 1924, pp. 750-758, 14 figs.

Combustion Control, Centralized. Centralized Combustion Control in Lowellville, Jos. F. Shadgen. Power, vol. 59, no. 18, Apr. 29, 1924, pp. 676-679, 2 figs. One of first complete remote-machine-regulated combustion systems in large power plants; fuel efficiency main object; pneumatic dispatch system of master controller and individual regulators; novel central-control house with unique instrument board.

Construction Metods. Construction Procedure for a Steam Power Station. Eng. News-Rec., vol. 92, no. 18, May 1, 1924, pp. 754-757, 7 figs. Connecticut Light & Power completes 75,000-kva. unit at Devon; concreting continued through winter; many parts fabricated in field shops.

Diesel-Enginen. Converting a Loser into Profit-Making Plant. Power, vol. 59, no. 20, May 13, 1924, pp. 772-775, 6 figs. Central station at Caruthersville, Mo., supplying both electricity and ice, cut its generating cost from over 6 to less than 1 per cent per kw-hr. by replacing an obsolete steam plant with Diesel engines; waste-heat recovery is employed in nearby house-heating service.

Paper Mills, Kalamazoo. New Power Plant of the Bryant Paper Co. Power, vol. 59, no. 19, May 6, 1924, pp. 710-715, 6 figs. Central plant of 8,000-kw. ultimate capacity, designed to supply power, steam and hot water to four divisions of large paper mill in Kalamazoo, Mich., replaces combination of individual boiler plants and scattered engine units; special features are balancing of power and heating steam, special coal and ash handling, automatic control and complete metering facilities.

Reheating in. Reheating in Central Stations, W. J. Wohlenberg. Mech. Eng., vol. 46, no. 5, May 1924, pp. 259-262, 11 figs. Influence of amounts of energy added in reheating, number of reheating stages, and points in expansion at which reheating should begin; comparison of reheating, regenerative, and combination cycles combining both reheating and bleeding stages; shows that, because of influence on internal machine efficiency thereby, reheating properly applied may lead to higher efficiencies than bleeding; also that combination cycles give promise of realization in practice of appreciably higher efficiencies than would be case for other cycles investigated. Abridged.

Units in Parallel, Efficiency of. Maximum Operating Efficiency of Power Units in Parallel, A. P. Strom. Nat. Engr., vol. 28, no. 5, May 1924, pp. 210-212, 2 figs. Water rates of individual units plotted on a combined chart showing total water rate for any combination of units for various loads; most efficient combination of units can at once be determined by reference to chart. Serves equally well for distribution of load in hydro-electric plants.

CHAIN DRIVE

Efficiency. The Efficiency of Chains as a Power Transmitting Agent, H. Seymour. Elec. Rev., vol. 94, no. 2418, Mar. 28, 1924, pp. 484-486, 5 figs. Advantages of chain drive; suggestions for efficiency operation.

CHAINS

Malleable-Iron. Malleable Iron Chain, J. W. Gardom. Foundry Trade Jl., vol. 29, no. 398, Apr. 3, 1924, pp. 269-272, 8 figs. Description of manufacturing methods, including molding and annealing, and metallurgical considerations. See also discussion in no. 399, Apr. 3, 1924, pp. 301-304.

CIRCUIT BREAKERS

Oil Type. High-Voltage Oil Circuit Breaker Tests, Alabama Power Company. System J. B. MacNeill. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, May 1924, pp. 436-441, 16 figs. Series of 50 high-voltage oil-circuit-breaker tests made during May and June of 1922.

Tests. Circuit Breaker Tests at Bessemer, Ala., J. D. Hilliard. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, May 1924, pp. 430-435, 13 figs. Tests on 300-ampere, 110,000-volt breakers, and on plain break and explosion-chamber 44,-000-volt breakers.

CITY PLANNING

Street Capacity, Increasing. Increasing the Capacity of Existing Streets, A. S. Tuttle. Am. Soc. Civ. Engrs.—Proc., vol. 50, no. 5, May 1924, pp. 593-605, 5 figs. Consideration of following expedients for City of New York: Requiring new buildings to be set back to lines proposed as ultimate limits of widened streets; widening of roadways; more drastic traffic regulations; removal of roadway encroachments; by-passing of traffic; introduction of arcades.

CLUTCHES

Electrically Operated. Electrically-Operated Clutches, M. H. Sabine. Machy. (Lond.), vol. 24, no. 602, Apr. 10, 1924, pp. 44-45, 7 figs. Improved design of solenoid clutch for use where control of power unit from distant position is required.

Friction. Considerations in Friction Clutch Design, A. Clegg. Machy. (N. Y.), vol. 30, no. 9, May 1924, p. 669-670. Factors involved in design; allowable bearing pressures; calculating horse power; types of friction clutches; single-plate, coil, and double-plate clutches.

COAL

Anthracite, Ash Content of. Ash in Anthracite, O. P. Hood. U. S. Bur. Mines, Reports of Investigations, No. 2571, Feb. 1924, 2 pp. Results of tests made by Bur. of Mines on 127 samples of 1,000 lb. each, representing nearly 30,000 tons of anthracite in dealers' yards in 17 cities in State of Massachusetts.

Pulverized. *See Pulverized Coal.*

Testing. A Float-and-Sink Method for Testing Coarse Size Coal, E. R. McMillan and B. M. Bird. Coal Industry, vol. 7, no. 4, Apr. 1924, pp. 164-169, 2 figs. Methods and apparatus used in testing coals; developed at Northwest experiment station of Bur. of Mines in co-operative research work with Univ. of Washington.

Volatile Matter and Ash Content. The Volatile Matter and Ash Contents of Samples of Coal from the Same Seam, T. J. Drakeley and J. R. I. Hepburn. Chem. & Industry, vol. 43, no. 18, May 2, 1924, pp. 134T-137T. Gives equation for calculating, on average samples of dry coal containing no iron pyrites, volatile-matter content of coal on ash-free basis; percentage of volatile-matter yielded by dry shale appears to vary considerably; variations may be due to different methods employed in initial drying of shale; modified equations for calculating volatile-matter content of coal on ash-free bases, for crude-coal samples containing iron pyrites, etc.

COAL HANDLING

Boiler Plants. Coal Handling in Small Boiler Plants. Power Engr., vol. 19, no. 218, May 1924, pp. 171-172, 4 figs. Notes concerning plant with but one or two boilers.

Lowering Down Hillsides. Lowering Coal Down Hillsides with Minimum Breakage, M. L. O'Neale. Coal Age, vol. 25, no. 20, May 15, 1924, pp. 715-721, 12 figs. Points out that type of conveyor to be chosen depends chiefly on such factors as length and inclination of hillside.

COAL MINES

Tunneling. Tunnel Problems Simplified. Sci. & Art of Min., vol. 34, no. 19, Mar 29, 1924, pp. 274-275, 2 figs. Examples illustrating application of simplest or ideas to solution of such problems as arise in connection with practice of tunneling in coal mines and showing that application of principles rather than an attempt to use formulas is essential to correct solution of such problems.

COAL MINING

CUTTING BY MACHINERY. Coal Stripper Uses Ice Harvesters' Method, D. M. Sutor. Coal Age, vol. 25, no. 12, Mar. 20, 1924, pp. 415-417, 4 figs. Turns longwall cutting machine on edge, "sawing" 28-in. seam into panels 12 ft. wide so that pop shots make less screenings; scheme reduces over-all cost of coal.

LONGWALL SYSTEM. Undersea Longwall Mining, J. Moffat. Coal Industry, vol. 7, no. 4, Apr. 1924, pp. 140-142, 1 fig. At distance of 2½ mi. undersea and with cover of 1,350 ft., Nova Scotia mine has changed from room and pillar to longwall with great success.

COAL STORAGE

ECONOMY. Economic Phases of Coal Storage, F. G. Tryon and W. F. McKenney. Universal Engr., vol. 39, no. 4, Apr. 1924, pp. 19-25, 2 figs. Extent to which practice of storage has already been adopted; inducements to store offered by periodic fluctuations in price and supply of coal.

COKE HANDLING

HOISTS FOR. Automatic Coke Hoist, D. Cleave Cross. Gas Wld., vol. 80, no. 2071, Mar. 29, 1924, pp. 292-293, 2 figs. Describes a somewhat novel coke hoist erected at Lea Bridge gas works for use with water-gas plant. Paper read before Lond. & Southern District Jr. Gas Assn.

COMPRESSED AIR

MEASUREMENT. A New Compressed-Air Measuring Method (Ein neues Druckluft-Messverfahren), E. Stach. Glückauf, vol. 60, no. 14, Apr. 5, 1924, pp. 260-262, 3 figs. New method for and equipment determining compressed-air consumption in relation to suction volume in a pipe line or a machine; pressure fluctuations are without influence on measurement results.

CONDENSERS, STEAM

AIR COOLING, EFFECT ON. How External Air Cooling Increases the Effectiveness of Condenser-Tube Surface, P. Bancel. Power, vol. 59, no. 20, May 13, 1924, pp. 769-771, 4 figs. Points out that two distinct processes ordinarily occur inside of surface condensers, namely, steam condensing, which goes on at high rate of heat transfer, and devaporizing air-steam mixture, which is carried out at very low rate of heat transfer; when air coolers are provided outside of condenser to handle latter process, condenser tubes may operate at much higher efficiency.

BAROMETRIC, VACUUM-PUMP CAPACITY. Calculating the Amount of Air Liberated in Barometric Condensers, C. M. Reed. Power, vol. 59, no. 10, Mar. 4, 1924, pp. 370-372, 4 figs. Air enters with cooling water, steam and by leakage, which may be easily calculated from charts.

EJECTOR-AIR. Ejector-Air Condenser (L'Ejecteau-Air Condenseur). Génie Civil, vol. 84, no. 10, Mar. 8, 1924, pp. 234-235, 6 figs. Describes apparatus and principle upon which it is based; output depends solely upon speed of steam transmission in apparatus, and is expressed in function of ratio of weight of steam to cross-section of ejector inlet.

SURFACE. Tendencies in Surface Condenser Practice. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 530-533, 4 figs. Points out that elimination of dead tube space, multiple air-suction openings and variable water supply are important factors in condenser design and application.

CONDENSERS, ELECTRIC

OSCILLATIONS, OVERDAMPED. Overdamped Condenser Oscillations, Chas. P. Steinmetz. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, May 1924, pp. 424-428, 9 figs. Shows effect of condenser leakage on discharge wave.

POWER LOSS, WITH LIQUID DIELECTRICS. The Power Loss in Condensers with Liquid Dielectrics, L. S. McDowell. Physical Rev., vol. 23, no. 4, Apr. 1924, pp. 507-517, 5 figs. Power loss in condensers with liquid dielectrics; variation of equivalent series resistance and capacity with frequency, 600 to 3,500 cycles.

CONDUITS

BACKWATER AND DROP-DOWN CURVES. New Method of Computing Backwater and Drop-Down Curves, A. G. Husted. Eng. News-Rec., vol. 92, no. 17, Apr. 24, 1924, pp. 719-722, 4 figs. Modification of channel subdivision method with elimination of trial calculations; applicable to canals, sewers, etc., under uniform hydraulic conditions.

CONSTRUCTION WORK

HYDRAULIC CARTRIDGE. Hydraulic Cartridge Does Away with Explosives in Construction Operations. Contract Rec. & Eng. Rev., vol. 38, no. 17, Apr. 23, 1924, pp. 396-397, 1 fig. Details of new British machine, known as "hydraulic mining cartridge", especially applicable to removal of heavy concrete where effect of explosives cannot be accurately controlled. Wide range of usefulness.

CONVEYORS

MEDIUM-SIZED SHOPS. Increasing Production by Power Conveyors, Chas. O. Herb. Machy. (N. Y.), vol. 30, no. 9, May 1924, pp. 706-709, 5 figs. Conveyor installations that have proved their economy in plant manufacturing small parts; japanning conveyors; conveyors for cleaning work before nickel-plating, and rinsing and drying afterward; assembly conveyors.

[*See also Ash Handling.*]

COST ACCOUNTING

CAPITAL CONTROL. Capital Requirements and Control, J. H. Bliss. Mgt. & Administration, vol. 7, no. 5, May 1924, pp. 529-532. Surplus and its constructive application.

POINT METHOD. Getting at Costs by the "Point Method," R. E. Roesler. Factory, vol. 32, no. 5, May 1924, pp. 662-663, 2 figs. Describes point cost method and its applications.

CRANES

ELECTRIC CURRENT FOR, CHOICE OF. Choice of Current for Hoists with Special Regard to Harbor Cranes (Wahl der Stromart für Hebezeuge unter besonderer Berücksichtigung der Hafenkrane), H. Gettert. Elektrotechnische Zeit., vol. 45, no. 16, Apr. 17, 1924, pp. 353-359, 17 figs. Author seeks to ascertain which kind of current is most economical with regard to energy consumption.

ELECTRIC EQUIPMENT. Modern Single-Phase Crane Equipment of Brown, Boveri & Cie (Moderne Einphasen-Kran-Ausrüstungen der Brown, Boveri & Cie., A.-G.), H. Gettert. Fördertechnik u. Frachtverkehr, vol. 17, no. 5, Mar. 3, 1924, pp. 59-65, 28 figs. Advantages of Deri motors for drive of hoists; design and operation of motors; selection of control apparatus and arrangement of control for different types of cranes; control of Deri motors with controller and resistance.

CUPOLAS

TILTING DEVICE. Tilting Device Has Advantages on Small Cupola. Can. Foundryman, vol. 15, no. 3, Mar. 1924, p. 16, 1 fig. Shell hung on trunions for convenience in preparing instead of workman getting inside.

D

DAMS

FRENCH REGULATIONS. New French Instructions for the Building of High Dams as Gravity Dams (Neue französksche Instruktion zum Bay hoher Talsperren als Gewichtsmauern), A. Zeerleder. Schweizerische Bauzeitung, vol. 83, no. 16, Apr. 19, 1924, pp. 181-183. Rules and regulations issued by French Minister of Buildings in 1923.

MULTIPLE-ARCH. Reinforced Multi-Arch Dam Design Adopted by Swedish Engineers, Johnstone-Taylor. Concrete, vol. 24, no. 4, Apr. 1924, pp. 152-153, 6 figs. In connection with damming of Great Lule river in Lapland for water power purposes, multiple-arch design constructed of reinforced concrete was decided upon as most economical. Particulars of structures, of which they are two, one having 23 arches and one 15 arches.

DIES

DRAWING, DESIGN OF. Designing Drawing Dies, F. Heller. Machy. (N. Y.), vol. 30, no. 9, May 1924, pp. 687-691, 7 figs. Problems encountered in determining size of blank necessary to produce shell of given dimensions and number of drawing operations required to complete work.

DIESEL ENGINES

BEARDMORE-TOSI, MACHINING. Building Marine Diesel Engines. Machy. (Lond.), vols. 23 and 24, nos. 600 and 601, Mar. 27 and Apr. 3, 1924, pp. 825-828 and 17-21, 25 figs. Machining operations on Beardmore-Tosi Engine.

BETHLEHEM. Types of Modern Power-Plant Oil Engines. Oil Engine Power, vol. 2, no. 3, Mar. 1924, pp. 152-156 and 161, 8 figs. Critique of design features of Bethlehem 2,900-b.hp. 2-cycle unit, and complete details relating to design and method of operation of its axial scavenging valve.

LUBRICATION. Lubricating Diesel Engines and Auxiliary Machinery. Mar. Eng., vol. 29, no. 5, May 1924, pp. 298-300. General rules for selecting lubricants and methods of applying them to promote economy.

The Lubrication of Diesel Engines (Ueber Dieselmaschinen-Schmierfragen), W. Ernst. Zeit. des Vereines deutscher Ingenieure, vol. 68, no. 18, May 3, 1924, pp. 451-454, 14 figs. Points out that in view of the different parts to be lubricated, use of different oils for various applications is desirable, but it is sometimes necessary to use a unit lubricating oil which has to be adapted to the various applications including that of cooling pistons; gives examples of difficulties encountered in lubrication of Diesel engines with a unit oil.

MARINE. Latest Developments in Diesel-Engine Ship Propulsion (Neueste Bestrebungen beim Schiffsantrieb durch Dieselmotoren), E. Goos. Zeit. des Vereines deutscher Ingenieure, vol. 68, no. 18, May 3, 1924, pp. 435-441, 18 figs. Discusses present tendencies in development of marine Diesel engines; examples and practical results; measures for increasing efficiency and improving operating safety and economy; drive of auxiliary machinery; heating and motor oils.

DYNAMOMETERS

BELT. Some Power Studies Through Use of the Ohio Recording Belt Dynamometer, G. W. McCuen. Agricultural Eng., vol. 5, no. 3, Mar. 1924, pp. 51-55, 13 figs. Describes dynamometer that will record power requirements and performance of belt-driven machines; prime mover, in a cradle, swings to make possible recording of a torque due to resistance in a belt. Studies in threshing and baling straw. Tests on effect of sharpness of knives.

E

ELECTRIC ARC

HIGH-INTENSITY. Studies in the Projection of Light. The High-Intensity Arc and the Parabolic Mirror, F. Benford. Gen. Elec. Rev., vol. 27, nos. 3 and 4, Mar. and Apr., 1924, pp. 199-207 and 252-260, 34 figs. Describes 150-amp. arc; its essential feature is a deep and well formed crater that is constantly filled with a highly luminous gas whose temperature is about 5,500 deg. A. Computations and curves on high-intensity arc, in which specific case of a 60-in. high-intensity searchlight is largely used.

ELECTRIC CIRCUITS

GRAPHICAL TREATMENT. The Graphical Treatment of Circuits Containing Iron Core Reactances and Capacity, L. Fleischmann. Gen. Elec. Rev., vol. 27, no. 4, Apr. 1924, pp. 260-262, 11 figs. Graphic method for analytic treatment of circuits possessing variable self induction and capacity.

ELECTRIC DISTRIBUTION SYSTEMS

LOAD DISPATCHING, CENTRALIZED. Load Dispatching System of P. G. & L. Co., C. W. Geiger. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 543-545, 3 figs. Control is centralized in one office; carrier-current system in continuous use.

NETWORKS, ANALYTICAL SOLUTION OF. Analytical Solution of Networks, R. D. Evans. Elec. Jl., vol. 21, nos. 4 and 5, Apr. and May 1924, pp. 149-154 and 207-213, 23 figs. Explanation of how calculations may be made of short-circuit currents for different locations on power system, for proper application of circuit breakers and to secure best operation of relay systems.

SHORT-CIRCUITS, EFFECT AND PREVENTION. Effect and Prevention of Short Circuits, B. G. Jamieson. Elec. World, vol. 83, no. 17, Apr. 26, 1924, pp. 815-817, 3 figs. By extending isolation of phases beyond generating stations to primary distribution points saving of investment and greater reliability will be gained even on small interconnected systems.

ELECTRIC FURNACES

ACID. The Manufacture of Acid Electric Steel for Commercial Castings, L. J. Barton. Am. Soc. Steel Treating—Trans., vol. 5, no. 4, Apr. 1924, pp. 379-398, 8 figs. Discusses manufacture of acid as made in electric furnace, for use in production of commercial castings; selection, segregation and use of scrap metal; details of charging melting furnace; melting-down conditions involved, and various types of slags obtained in both good and bad practices; production of special steels and various alloy steels.

CONTROL GEAR. An Electric Furnace Regulating Gear, H. J. Seymour. Power Engr., vol. 19, no. 218, May 1924, pp. 174-175, 2 figs. Describes one type of automatic apparatus for regulation of 2-phase electric furnaces.

DEVELOPMENTS. Electric Furnace Developments, F. Hodson. Foundry Trade Jl., vol. 29, no. 398, Apr. 3, 1924, pp. 273-274. Growth of electric melting furnace industry. Soderberg electrode. See also Iron & Coal Trades Rev., vol. 108, no. 2928, Apr. 11, 1924, p. 596.

INCREASING CAPACITY FOR LARGE CASTING. Nine Tons in a 3-Ton Furnace, L. J. Barton. Foundry, vol. 52, no. 10, May 15, 1924, pp. 401-403, 9 figs. Capacity of electric furnace increased to melt sufficient iron to pour large gear wheel; operating door banked up about 10 in. with cement made of white sand and sodium silicate; operation at plant of Dibert, Bancroft & Ross Co., New Orleans.

ELECTRIC LAMPS, INCANDESCENT

NEON. The Application of the Neon Lamp to the Comparison of Capacities and High Resistances, J. Taylor and W. Clarkson. Jl. Sci. Instruments, vol. 1, no. 6, May 1924, pp. 173-182, 9 figs. Deals with application of "flashing" of neon discharge tube to measurement of capacities and high resistances; extension of method utilizes beats between two neon lamp circuits "flashing" at high frequencies, for measurement of small capacities.

ELECTRIC LOCOMOTIVES

0-4-4-0 TYPE. Electric Goods Locomotive, Victorian Government Railways. Ry. Gaz., vol. 40, no. 17, Apr. 25, 1924, pp. 596-597. 3 figs. Particulars of two locomotives to be used for service in Melbourne metropolitan railway yards and for hauling goods trains within Melbourne suburban electrified railway area; wheel arrangement 0-4-4-0; voltage and system 1,500 d.c., individual single-geared drive, maximum tractive effort 26,000 lb.

OIL-ENGINE-DRIVEN. New Type Electric Locomotive. Aera, vol. 12, no. 10, May 1924, pp. 1729-1732, 4 figs. Describes locomotive using oil for its fuel, built jointly by Gen. Elec. Co. and Ingersoll-Rand Co., and especially designed for switching service; fuel-oil engine operates d. c. generator supplying current to motors without intervening accelerating resistance; fuel cost exceedingly low, and new engine is smokeless.

Oil-Electric Locomotive with Injection Type Engine. Ry. Age, vol. 76, no. 23, May 10, 1924, p. 1159, 2 figs. Electric locomotive driven by fuel-oil engine built jointly by Gen. Elec. Co. and Ingersoll-Rand Co. See also Ry. Rev., vol. 74, no. 19, May 10, 1924, pp. 846-847, 3 figs.

PARALLEL-CRANK DRIVE. Vibrations of Electric Locomotive with Crank Drive (Die Schüttelschwingungen elektrischer Lokomotiven mit Stangenantrieb), A. Winkler. Elektrotechnik u. Maschinenbau, vol. 42, nos. 16 and 17, Apr. 20 and 27, 1924, pp. 241-248 and 261-265, 7 figs. Problem of parallel-crank drive and its history; ideal parallel-crank drive; forced oscillations of practical parallel-crank drive; elasticity of shafts; play of bearings; quasi- and pseudo-harmonic oscillations; gear springs; damping of systems with rigid speed characteristics; subsequent calculation of actual locomotives with special consideration of gear springs and damping.

PIT AND QUARRY HAULAGE. Locomotives for Haulage at Pits and Quarries, H. H. Johnston. Pit and Quarry, vol. 8, no. 7, Apr. 1924, pp. 97-100, 4 figs. Notes on different types of electric locomotives, and electric equipment for haulage systems.

TURBO-ELECTRIC. *See Locomotives, Turbo-Electric.*

ELECTRIC METERS

KVA.-DEMAND. A New Electricity Meter. Engineer, vol. 137, no. 3567, May 9, 1924, pp. 519-520, 7 figs. A.c. meter which gives direct reading of power factor, total kilowatt-hours, kilovolt-ampere hours, and kilowatt and kilovolt-ampere demand for any predetermined period, and also power factor for over any period; introduced by Am. Westinghouse & Mfg. Co.

ELECTRIC MOTORS, A.C.

CRAWLING. Crawling of Three-Phase Squirrel-Cage Induction Motors, T. F. Wall. World Power, vol. 1, no. 4, Apr. 1924, pp. 224-233, 7 figs. Discusses phenomenon of crawling, i.e., running up of motor to some speed which is only fraction of normal synchronous speed and remaining running at that low speed; cause and remedies.

ELECTRIC TRANSMISSION LINES

CONSTRUCTION. Report of A.R.E.A. Committee on Electricity. Ry. Elec. Engr., vol. 15, no. 4, Apr. 1924, pp. 123-125. Report presented at 25th annual convention giving specifications for electric power transmission and distribution pole lines.

DESIGN AND CONSTRUCTION. Electric Pole Lines. Power Engr., vol. 19, no. 217, Apr. 1924, pp. 131-135, 10 figs. Design and construction of overhead transmission lines, with special reference to smaller industrial lines.

High-TENSION. High-tension Transmission Lines, E. V. Pannell. Engineer, vol. 137, nos. 3559, 3560, 3561, 3562, 3563 and 3564, Mar. 14, 21, 28, Apr. 4, 11 and 18, 1924, pp. 272-273, 300-302, 328-331, 352-354, 378-379 and 418-419, 26 figs. Study of engineering elements of modern transmission lines, grouped under following heads: conductors, insulators, supports; study of general subject of mechanical design; survey of construction economy.

STRINGING CONDUCTORS. Stringing Transmission Cable, O. Davidson. Elec. World, vol. 83, no. 17, Apr. 26, 1924, pp. 819-821, 7 figs. Nature of preliminary study, special equipment and methods employed on Indiana Elec. Corp.'s 74-mi., 132-kv. line between Terre Haute and Indianapolis.

SURVEYS AND FIELD ENGINEERING. Transmission Line Surveys and Field Engineering, O. Davidson. Eng. News-Rec., vol. 92, no. 19, May 8, 1924, pp. 808-809. Preliminary paper location; instrument surveys, records and mapping; two parallel profiles; office and field location of towers; Work of engineers on construction of new 75-mi. high-tension transmission line from Terre Haute to Indianapolis.

VOLTAGE DROP. The Voltage Drop in a Three-Phase Transmission Line with Unsymmetrically Arranged Conductors, H. Cotton. World Power, vol. 1, no. 4, Apr. 1924, pp. 211-215, 5 figs. Calculation of drop due to resistance and inductance.

ELECTRIC WELDING

MACHINES AND PROCESSES. Recent Developments of Electric Welding Machines (Die neuere Entwicklung der elektrischen Schweissmaschinen), A. Neuburger. Elektrotechnik u. Maschinenbau, vol. 42, nos. 14 and 15, Apr. 6 and 13, 1924, pp. 214-219 and 230-235, 20 figs. Description of modern processes and machines, with special reference to resistance welding.

ELECTRIC WELDING, ARC

CAST IRON. Arc Welding Cast Iron. Welding Engr., vol. 9, no. 4, Apr. 1924, pp. 22-23, 3 figs. How to use monel-metal electrode.

COPPER. Summary of Information on Arc Welding of Copper, Brass and Bronze in the Literature Up to March 1923. Am. Welding Soc.—Jl., vol. 3, no. 3, Mar. 1924, pp. 9-15. Digest of literature made by sub-committee of Electric Arc Welding Committee of Am. Bur. Welding.

MANGANESE STEEL. Correct Welding Procedure Retains Qualities of Manganese Steel, H. H. George. Elec. Ry. Jl., vol. 63, no. 16, Apr. 19, 1924, pp. 611-613. By use of arc welding in the field, life of manganese steel special work can be increased one to five years. Type of welding rod, technique employed and speed of cooling affect physical characteristics of welded material.

F

FACTORIES

INSPECTION. Some Problems of Factory Inspection. Int. Labour Rev., vol. 9, no. 3, Mar. 1924, pp. 372-386. Brief account of main lines of development of factory inspection, both in theory and practice, taking as basis reports prepared by Int. Labor Office.

FANS

EXHAUST. Things to Know About Fan Application, H. W. Pfeer. Sheet Metal Worker, vol. 15, no. 8, May 9, 1924, pp. 283-285 and 309, 3 figs. Important truths essential to a complete understanding of how to lay out a successful exhaust system; capacities to figure on; air velocities needed; pipe sizes; general suggestions.

MINE. The Change of Air Supply in Mine Fans, A. Latsinsky. Russian Min. Jl., vol. 100, no. 1, Jan. 1924, pp. 31-34. (In Russian.)

FLIGHT

ELEMENTS OF, CALCULATION. General Method and Chart for Calculating Elements of Airplane Flight (Méthode générale et abaque pour calculer les éléments du vol d'un avion), G. Delanghe. Génie Civil, vol. 84, no. 2169, Mar. 8, 1924, pp. 222-226, 8 figs. Describes new method developed by author.

FLOTATION

ORE. Selective Flotation, C. S. Parsons. Can. Min. Jl., vol. 45, no. 17, Apr. 25, 1924, pp. 404-407. Separation by flotation of one mineral from another, where two or more flotative minerals are present in an ore. Reviews in general way results of investigations conducted in Ore Dressing and Metallurgical Laboratories of Dept. Mines at Ottawa, that have reference to selective flotation as applied to Canadian ores.

FLOW IN PIPES

WATER AND AIR SIMULTANEOUSLY. Simultaneous Flow of Water and Air in Pipes, L. S. O'Bannon. Am. Soc. Heat & Vent. Engrs.—Jl., vol. 30, no. 3, Mar. 1924, pp. 225-234, 14 figs. Describes experiments made to find capacity of pipes for carrying water and air simultaneously, within conditions of steady flow; results and methods of running experiments described under four following heads: Flow of water, flow of air, parallel flow of water and air, and counter flow of water and air.

FLOW OF FLUIDS

DYNAMIC SIMILARITY, PRINCIPLE OF. The Principle of Dynamical Similarity, with Special Reference to Model Experiments, A. H. Gibson. Engineering, vol. 117, nos. 3037, 3038, 3039 and 3040, Mar. 14, 21, 28 and Apr. 4, 1924, pp. 325-327, 357-359, 391-393 and 422-423, 6 figs. Discusses application of principles to flow of fluid through pipes, resistance of wholly submerged and partially submerged bodies; model experiments on resistance of ships; resistance of smooth wires and cylinders; estuary model experiments; surge tanks; sea-going qualities of vessels in rough sea; suction of interaction between passing vessels; critical speed and torsional vibration of shafts.

FLOW OF GASES

MEASUREMENT. Measuring Flow of Gases, Chas. P. Turner and B. W. Winship. Chem. & Met. Eng., vol. 30, no. 16, Apr. 21, 1924, pp. 633-635, 4 figs. Results of application of mixture method, suggested by salt-solution method for measuring flow of water, show that it is of value in related problems of fluid flow.

FLOW OF STEAM

PIPES. Critical Velocity of Steam and Condensate Mixtures in Horizontal, Vertical, and Inclined Pipes, F. C. Houghton and R. L. Lincoln. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 2, Feb. 1924, pp. 153-168, 19 figs. Details of experiments made to obtain a thorough understanding and complete knowledge of factors entering into, and effects taking place when steam is sent through a pipe in which there is a counterflow of condensate. Effect of length and size of pipe and type of entrance, upon critical velocity.

FLOW OF WATER

DISCHARGE MEASUREMENTS. Discharge Measurements for the Control Section Weir, J. L. Savage. Eng. News-Rec., vol. 92, no. 20, May 15, 1924, p. 842, 3 figs. Observations check closely theoretical rating curve; results of set of experiments made by Bur. Reclamation upon new type of measuring structure for which name control section weir has been proposed.

GROUNDWATER, MOVEMENT OF. Geometrical Investigation of the Theory of Movement of Groundwater in Rubble and Water Filtration Through Sand (Geometrische Untersuchung der Theorie der Bewegung des Grundwassers im Gerölle und der Wasserfilterung durch Sand), L. Burmester. Zeit. für angewandte Mathematik u. Mechanik, vol. 4, no. 1, Feb. 1924, pp. 33-52, 28 figs. on supp. plate. Investigation of theory and its practical application.

STREAMS, ICE-COVERED. Effect of Ice on Flow of Mississippi River at Keokuk, Iowa, A. Davis. Stone & Webster Jl., vol. 34, no. 4, Apr. 1924, pp. 475-480, 1 fig. Describes ice effect at Keokuk with idea that it may throw light on general problem of flow under ice cover in other locations.

TURBULENT AND NON-TURBULENT. The Laws of Industrial Hydraulics (Sur les régimes hydrauliques industriels), C. Camichel and M. Ricaud. Technique Moderne, vol. 16, no. 5, Mar. 1, 1924, pp. 129-137, 30 figs. Author seeks to explain certain characteristics of hydraulic flow, showing existence of turbulent flow independent of form of obstacles; transition from one flow to another has its origin frequently in formation of surfaces of discontinuity; study of surfaces of discontinuity.

FLYWHEELS

MANUFACTURE. Maxwell Methods in Flywheel Work, F. H. Colvin. Am. Mach., vol. 60, no. 20, May 15, 1924, pp. 729-730, 5 figs. Machine equipment, together with some of tooling fixtures and handling devices; drilling and tapping in multi-spindle machines; balancing machine.

FORGING

STEAM VS. AIR HAMMERS. Steam vs. Air in Forging-Hammer Practice (Dampf oder Luft für den Hammerbetrieb), F. Beleke. Maschinenbau, vol. 3, no. 12, Mar. 27, 1924, pp. 389-394, 18 figs. Comparison of economy of steam, pneumatic and air hammers; points out applications for which each type is most adaptable.

FORGINGS

HEAVY. The Production of Heavy Forgings. Mech. Eng., vol. 46, no. 5, May 1924, pp. 241-247 and 307, 15 figs. Survey of status of industry in America at present time, together with data helpful to engineer ordering forgings.

FOUNDRIES

BRASS. The Operation of a Brass Foundry under Scientific Control, F. W. Rowe. Foundry Trade Jl., vol. 29, no. 399, Apr. 10, 1924, pp. 291-294 and (discussion) 294-296, 5 figs. Layout of brass foundries, provision of suitable stores, recording stocks, charge sheets, inspection of castings of new design, melting and casting procedure, casting temperature, etc.

COSTS. Why Foundry Costs Vary on Rough Castings, A. Lueuberg. Can. Foundryman, vol. 15, no. 3, Mar. 1924, pp. 14-15, 3 figs. Uniform cost-finding method for foundries; individual cost of castings based on actual time prevents confusion in locating leaks.

Modern Practice. Recent Evolution in Foundry Practice (Evolution récente de la fonderie), E. Ronceray. Revue de Métallurgie, vol. 21, nos. 1, 2 and 3, Jan., Feb. and Mar., 1924, pp. 4-11, 112-120 and 183-194, 16 figs. Jan.: General progress; semi-steel; fuels; American malleable; light metals; melting apparatus; heating furnaces. Feb.: Molding and casting; dry-sand and chill casting; molding machines. Mar.: Core and patternmaking; general layout of foundries.

FUELS

Colloidal. Experimental Preparation of Colloidal Fuel, A. V. Sapoznikow and M. N. Kalinin. Petroleum & Oil-Shale Industry, vol. 5, no. 11-12, Nov.-Dec. 1923, pp. 652-654. (In Russian.)

Combustion, Maximum Temperatures and Pressures in. An Investigation of the Maximum Temperatures and Pressures Attainable in the Combustion of Gaseous and Liquid Fuels, G. A. Goodenough and G. T. Felbeck. Univ. of Ill. Bul., no. 139, Mar. 1924, 158 pp., 27 figs. Résumé of important laws of gas mixtures; general theory of chemical equilibrium, and derivation of equilibrium equations for various reactions; develops energy equation, and shows method of solving system of equations for maximum temperature; comparisons and applications of theory.

Lignite and Bituminous Mixtures. Burning Mixtures of Lignite and Bituminous, A. Canfield. Power Plant Eng., vol. 28, no. 9, May 1, 1924, pp. 476-477, 4 figs. Experiments carried out at power plant of State Mill & Elevator, Grand Forks, N. Dak., during past six months to determine most economical ratio of lignite to be burned with Eastern bituminous.

Lignite Char. Tests of Lignite Char as Reduction Fuel in the Smelting of Zinc Ores, B. M. O'Harra. U. S. Bur. Mines, Reports of Investigations, No. 2575, Feb. 1924, 7 pp. Analysis and characteristics of and experiments made with "char", the fuel produced by a simple carbonizing oven devised by Bur. of Mines which is essentially a vertical shaft with means for supplying raw lignite at top and discharging carbonized lignite at lower end. From Zinc Inst. Bul., Jan. 1924.

Pulpwood Bark. Utilization of Pulpwood Bark for Fuel, J. D. Rue and E. P. Gleason. Paper Trade Jl., vol. 78, no. 16, Apr. 17, 1924, pp. 40-50, 10 figs. Final report of Sub-Committee on Utilization of Bark, Committee on Waste of Technical Assn. Pulp & Paper Industry, dealing with possible methods of utilization, present practice in barking, bark presses, and furnaces for burning bark.

Solid, Cemical Constitution. Modern Theories on the Chemical Constitution of Solid Fuels (Les théories modernes sur la constitution chimique des combustibles solides), E. Audibert and A. Raineau. Chimie & Industrie, vol. 11, nos. 2 and 3, Feb. and Mar. 1924, pp. 229-247 and 434-448, 1 fig. Review of works on this subject during recent years: Constituents of higher plants: carbon hydrates; natural state, properties and constitution of lignines; humic acids; conversion from plant to humic acid and from humic acid to humic substances; investigations tends to confirm existing lack of knowledge on subject of chemical constitution of solid fuels. See also Revue de l'industrie Minérale, no. 78, Mar. 15, 1924, pp. 127-171, 1 fig.

See also Coal; Lignite; Oil Fuel; Pulverized Coal.

FURNACES, INDUSTRIAL

Electricity, Use of. Furnaces and Heat Sources, E. F. Collins. Fuels & Furnaces, vol. 2, no. 5, May 1924, pp. 479-483. Reasons for wider and more general adoption of electric heat in past few years. Some fundamental considerations which determine when electric heat should be used.

Recuperation, Advantages of. Recuperation—Its Advantages, E. R. Posnack. Combustion, vol. 10, no. 5, May 1924, pp. 362-363. Advantages of recuperation in industrial furnaces.

G

GAGES

Hydrostatic. How to Compensate for Temperature Effects on Hydrostatic Gages, J. P. Nikonow. Automotive Industries, vol. 50, no. 18, May 1, 1924, pp. 964-966, 3 figs. Fluctuations in atmospheric temperature change volume of entrapped air and thus vary readings; practical method of balancing this factor is worked out.

GARBAGE DISPOSAL

New Process. New Process of Garbage Disposal at Lebanon, Pa., C. R. Fox and Wm. S. Davis. Eng. News-Rec., vol. 92, no. 20, May 15, 1924, pp. 857. After being ground in bone mill, material will be sent two miles through sewer to Imhoff tanks.

GAS ENGINES

Foundations. Foundations for Gas Engines. Power Engr., vol. 19, no. 217, Apr. 1924, pp. 125-127, 8 figs. Design and construction of foundations suitable for internal-combustion engines, and particularly gas plants.

Ignition Equipment. Ignition Equipment for a 7,500-Hp. Gas Engine. Engineering, vol. 117, no. 3039, Mar. 28, 1924, pp. 394-395, 4 figs. Set of equipment supplied by Lodge Bros. & Co. for gas engine; details of contact maker, igniter, timing unit and sparking plug.

GAS PRODUCERS

Bituminous Coal as Fuel. Central District Bituminous Coals as Water-Gas Generator Fuel, W. E. Odell and W. A. Dunkley. U. S. Bur. Mines, Bul. 203, 1924, 92 pp., 11 figs. Results of investigation made which consists of study of practice already developed and difficulties encountered, development of operating methods that would obviate these difficulties, testing various coals of Central District to determine which might be considered for this purpose, and study of technical conditions involved in manufacture of water gas from bituminous coals.

Regulation. Test on Regulation of Gas Producers and Open-Hearth Furnaces (Versuche zur Einregelung von Gaserzeuger und Siemens-Martin-Ofen), Geo. Bulle. Stahl u. Eisen, vol. 44, no. 15, Apr. 10, 1924, pp. 397-403, 6 figs. Summary of measurements carried out on 7 producer plants and 3 open-hearth works; determination of influence of varying steam consumption, load and treatment on producers; tests on open-hearth furnaces to ascertain correct quantity of air and best mixing conditions of coke-oven and producer gas; description of necessary measuring equipment.

GAS TURBINES

Developments. The Gas Turbine, F. Dollin. Instn. Mech. Engrs.—Proc., vol. 2, no. 6, 1923, pp. 1121-1135, 2 figs. Account of most noteworthy attempts to produce efficient and reliable gas turbine; summary of results obtained and indication of possible future developments. (Abridged.)

GASES

Combustion at High Pressure. Gaseous Combustion at High Pressures, Wm. A. Bone, D. M. Newitt and D. T. A. Townend. Roy. Soc.—Proc., vol. 105, no. A732, Apr. 1, 1924, pp. 406-433, 6 figs. Influence of varying initial pressures upon rate of pressure development and activation of nitrogen in carbon monoxide-air explosions.

GEAR CUTTING

Hobbing Machines. Gould & Eberhardt No. 72-H Automatic Gear Hobbing Machine. Am. Mach., vol. 60, May 1, 1924, pp. 669-670, 2 figs. Adapted for cutting of gears up to 27 in. in diam.

GEARS

Bevel. Spiral Bevel Gears. Machy. (Lond.), vol. 24, no. 605, May 1, 1924, pp. 138-141, 6 figs. Deals with type produced on Gleason principle in which, owing to spiral effect tooth thickness cannot be measured on outer circumference as can be done in case of straight-tooth bevel gears, but should be measured across normal section of tooth.

Differential. Methods of Machine Tool Design, A. L. De Leeuw. Am. Mach., vol. 60, no. 17, Apr. 24, 1924, pp. 621-624, 5 figs. Differential gearing finds its principal machine-tool application in feed mechanism; differential indexing mechanisms.

GRINDING MACHINES

Disk. The Use of Fixtures in Disk-Grinding, H. Campbell. Am. Mach., vol. 60, no. 21, May 22, 1924, pp. 759-761, 9 figs. Grinding production determined largely by types of fixture used; recently developed work holders; grinding piston rings automatically; better work and higher production which less labour.

High-Traverse. New Landis Grinder Has Stationary Head. Automotive Industries, vol. 50, no. 19, May 8, 1924, p. 1017, 2 figs. Designed to meet demand for oversize precision grinding with long-lived speed production; number of pieces ground per dressing of wheel said to offset higher initial cost.

Internal. Productive Internal Grinding. Brit. Machine Tool Eng., vol. 3, no. 26, Mar.-Apr. 1924, pp. 30-32, 5 figs. Describes internal-grinding machine made by Churchill Machine Tool Co., adapted to suit special piece of work; main features and operation.

H

HARDNESS

Ball Hardness Testing. The Accurate Determination of the Hardness of Metals. Engineering, vol. 117, no. 3043, Apr. 25, 1924, pp. 518-519, 5 figs. Investigation of Brinell test with object in view of designing method of testing which yields Brinell hardness numerals of thoroughly reliable order, free from irregularities to which Brinell test is exposed when carried out in ordinary way.

Indentation. In the Indentation Hardness of Metals, K. Honda and K. Takahasi. Iron & Steel Inst.—advance paper, no. 10, for mtg. May 1924, 11 pp., 6 figs. Points out that Brinell hardness, when impression is measured during application of load, is quite correct, and much less than that by usual method of measurement; new definition of hardness is given.

Magnetic Tests. A Correlation between the Mechanical Hardness and the Magneto-restrictive Effects of Ferromagnetic Substances, S. R. Williams. Am. Soc. Steel Treating—Trans., vol. 5, no. 4, Apr. 1924, pp. 362-368, 3 figs. Method of determining physical properties of metals through magnetic means; relative merits of X-ray and magnetic means of determining flaws in metals; Joule effect; discusses experiments wherein endeavour was made to relate magnetostriction and hardness of ferro-magnetic substances.

Steel Balls, Magnetic Test. Hardness of Steel Balls by Magnetic Tests, S. R. Williams. Am. Soc. Steel Treating—Trans., vol. 5, no. 5, May 1924, pp. 479-484, 4 figs. Rapid method of determining magnetically hardness of steel balls; with this method it is possible to conduct 100-per cent inspection on balls for hardness, with considerable rapidity; illustrations showing schematic arrangement of author's apparatus, and set-up and graphs of certain tests made upon balls having different degrees of hardness.

HEAT TRANSMISSION

Boilers. The Transmission of Heat in Boilers, W. N. Booth. Gas Wld., vol. 80, no. 2071, Mar. 29, 1924, pp. 288-290, 6 figs. Conditions which affect flow of gas adjacent to a solid surface; conduction and convection; transmission of heat through boiler plates. Paper read before Lond. & Southern District Jr. Gas Assn. See also Gas Jl., vol. 166, no. 3177, Apr. 2, 1924, pp. 36-38, 6 figs.

Buildings. An Improved Method of Determining the Heat Transfer Through Wall, Floor, and Roof Sections, R. F. Norris, H. H. Germond and C. M. Tuttle. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 2, Feb. 1924, pp. 109-114, 1 fig. Describes method developed in Burgess laboratories and apparatus used.

Problems. Heat Transfer Symposium. Indust. Eng. Chem., vol. 16, no. 5, May 1924. Contains following articles: Heat Transmission from Bare and Insulated Pipes, R. H. Heilman, pp. 451-458, 10 figs.; Heat Transmission in an Inclined Rapid Circulation Type Vacuum Evaporator, D. J. Van Marie, pp. 458-459, 2 figs.; Forced Convention of Heat in Gases and Liquids, Chester W. Rice, pp. 460-467, 4 figs.; Optimum Operating Conditions for Pipe Heating and Cooling Equipment, W. K. Lewis, J. T. Ward and E. Voss, pp. 467-468; Heat Transfer in Enamel-Lined Apparatus, E. P. Poste, pp. 469-470; Characteristics of Air-Blast Heaters, F. R. Ellis and J. D. White, pp. 471-473, 8 figs.; Studies in Evaporator Design—Effect of Surface Conditions, L. A. Pridgeon and W. L. Badger, pp. 474-478, 3 figs.; Evaporator Scale Formation, W. L. McCabe and C. S. Robinson, pp. 478-479, 3 figs.; The Film Concept of Heat Transmission Applied to a Commercial Water Heater, D. K. Dean, pp. 479-483, 3 figs.; Loss of Heat from Furnace Walls, Robt. Calvert and L. Caldwell, pp. 483-490, 11 figs.; A Heat Transmission Meter, P. Nicholls, pp. 490-493, 3 figs.

HEATING AND VENTILATING

Air Leakage in Buildings. Air Leakage Through the Openings in Buildings, F. C. Houghten. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 2, Feb. 1924, pp. 121-134, 11 figs. Method employed in investigation of double hung windows, 2 ft. 8 in. by 5 ft. 2 in. by 1— in., in a 13-in. brick wall, plastered on inside with cement plaster; results are given for leakage, through such a window without weatherstripping and with two types of weather stripping, around frame, and through brick wall itself.

HEATING, HOUSE

Oil-Fired-Boiler Efficiency. Efficiency of the House-Heating Oil-Fired Boiler, J. L. Breese, Jr. Heat. & Vent. Mag., vol. 21, no. 5, May 1924, pp. 51-54. Difficulties which have to be met and overcome in this new field, based upon experiences of an oil-burning boiler manufacturer. From paper read before Am. Assn. Oil Burner Mfrs.

HELIUM

Electrical Properties. Electrical Properties of Helium, J. S. Townsend and S. P. McCallum. Lond., Edinburgh, & Dublin Philosophical Mag. & Jl. Sci., vol. 47, no. 279, May 1924, pp. 577-583, 6 figs. Investigation of conductivity of gases, in order to decide by direct experiment whether there are any additional electrons set free from negative electrode by radiation from molecules of gas, using potentials and gas pressures as in parallel plate experiments where current increases with distances between plates in accordance with given formula.

HIGHWAYS

Cost Keeping. Cost Keeping on County Highway Work, A. K. Hay. Eng. & Contracting (Roads & Streets), vol. 61, no. 4, Apr. 2, 1924, pp. 741-745, 9 figs. System used by Ottawa Suburban Roads Commission, Ottawa, Ont.. Paper read at Annual Conference on Road Construction at Toronto, Ont.

HOTELS

Design. Architect and Engineer Unite in Design of Hotel, G. H. Lippert. Eng. News-Rec., vol. 92, no. 19, May 8, 1924, p. 813. New Belmont hotel at Madison, Wis., has concrete frame, cantilever footings and irregular column spacing; heavy loads of material piled on floors.

HOUSES

Concrete-Brick. Temperature and Moisture Observations on a Concrete Hollow-Brick House (Temperatur- und Feuchtigkeitsbeobachtungen an einem Bau aus Betonhohlsteinen), A. Hummel. Beton u. Eisen, vol. 23, no. 4, Feb. 20, 1924, pp. 43-46, 6 figs. Results of observations carried out for duration of a year show that use of described concrete hollow-brick construction for dwelling houses meets atmospheric requirements of masonry structures with entire satisfaction.

HYDRAULIC MACHINERY

Glycerine, Use in. Study on the Use of Glycerine in Hydraulic Machinery (Etude sur l'emploi de la glycérine dans les appareils hydrauliques), F. Mercier. Revue Industrielle, vol. 54, no. 2177, Apr. 1924, pp. 52-57, 4 figs. Study of properties of glycerine and its action on metals, based on experience of 30 years extending over more than 1,200 apparatus; author concludes that hydraulic or hydropneumatic apparatus of any kind, making use of glycerine, should be constructed so that in no case glycerine can come in contact with surfaces of different metallic nature.

HYDRAULIC TURBINES

Bearings and Vibration Conditions. Experience with Bearings and Vibration Conditions of Large Hydro-electric Units, J. Harisberger. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, May 1924, pp. 428-429, 1 fig. Troubles experienced with hydraulic turbines installed at Snoqualmie Falls and White River power stations, and remedies applied.

Efficiency Tests. Hydraulic Turbine Efficiency, F. Johnstone-Taylor. Power Plant Eng., vol. 28, no. 8, Apr. 15, 1924, pp. 436-437, 3 figs. Describes methods of conducting efficiency tests and gives test results.

Large Installations. Two Modern Turbine Installations (Zwei moderne Turbinenanlagen), R. Hofmann. Zeit. des Vereines deutscher Ingenieure, vol. 68, no. 16, Apr. 19, 1924, pp. 397-400, 12 figs. 14,300-h.p Pelton turbines of the Amsteg hydro-electric plant of the Swiss Federal Ry., and large Francis high-speed turbines of Mauzac hydro-electric plant, France; details of governors, safety arrangements, etc.

Machining Cast-Steel Casings. Machining Massive Parts of the World's Largest Prime Movers, E. J. Armstrong. Mech. Eng., vol. 46, no. 5, May 1924, pp. 263-267, 9 figs. Methods used for machining large cast-steel casings for 70,000-hp. hydraulic turbines installed at Niagara Falls.

Spiral. Large Spiral Turbines for Omine Hydro-electric Plant in Japan (Gross Spiralturbinen für das Kraftwerk Omine in Japan), V. Troeltsch. Zeit. des Vereines deutscher Ingenieure, vol. 68, no. 15, Apr. 12, 1924, pp. 377-378, 3 figs. Describes spiral turbines with vertical shaft built by J. M. Voith, Heidenheim, Germany.

HYDRO-ELECTRIC DEVELOPMENTS

Centralization of. The Tendency Toward Centralization of Power Development, W. L Abbott. Mun. & County Eng., vol. 66, no. 4, Apr. 1924, pp. 165-171, 2 figs. What various states are doing; consolidation of stations; rail transmission of power cheaper than wire transmission; how railway coal freight schedules are made up; etc. Paper read at annual mtg. of Ill. Soc. Engrs.

Davis Bridge Project. Davis Bridge Development of the New England Power Company. Power, vol. 59, no. 20, May 13, 1924, pp. 776-779, 8 figs. Project on Deerfield River involves earth dam 200 ft. high, storage reservoir of 50-000,000,000 cu. ft. capacity, 13,000-ft. tunnel and three 20,000-hp. units for head varying from 300 to 390 ft.

Isle Maligne, Canada. Isle Maligne Hydro-Electric Development, J. P. Chapleau. Can. Engr., vol. 46, no. 19, May 6, 1924, pp. 487-489, 5 figs. Large power development being undertaken by Quebec Development Co., on Saguenay River at Isle Maligne station; 12 turbine units will be installed having a total capacity of 540,000 hp.; details of turbine construction.

Newfoundland. Newfoundland Water Power. Times Trade & Eng. Supp., vol. 14, no. 303, Apr. 26, 1924, p. 167, 3 figs. Progress being made in large scheme for production of hydro-electric power and manufacture of paper, known as Humberarm proposition, in west of Newfoundland; details of dam, pipe line and power house, and paper mill.

HYDRO-ELECTRIC PLANTS

Load Control. Load Control in Automatic Hydro-Electric Generating Stations, R. C. Denny. Power, vol. 59, no. 19, May 6, 1924, pp. 716-717, 3 figs. Float-control method of making load changes; load control where water storage is available.

I

ICE MANUFACTURE

Cracked and Checked Ice Problems. Solving "Cracked and Checked" Ice Problems, E. Ormsby. Power House, vol. 17, no. 7, Apr. 5, 1924, pp. 28-29 and 41, 3 figs. Outline of some remedies for difficulties confronting power plant engineers as a result of strains produced in freezing. Paper read before Nat. Assn. Practical Refrig. Engrs. annual convention. See also Southern Engr., vol. 41, no. 2, Apr. 1924, pp. 50-52.

ICE PLANTS

Huntingdon, Pa. Modern Ice Making and Icing Station at Huntingdon, Pa. Ice & Refrigeration, vol. 66, no. 4, Apr. 1924, pp. 283-290, 15 figs. Describes ice-making plant and car-icing station of Bolye Ice Co. recently completed; built for supplying ice for Fruit Growers' Express and Pennsylvania R. R. Co.

Oil-Engine-Driven. Ice Plants and the Question of Oil Engine Power, C. T. Baker. Oil Engine Power, vol. 11, no. 4, Apr. 1924, pp. 212 and 217-219, 2 figs. Deals with subject of oil-engine drive for ice plants, discussing cost of installation, maintenance and repair costs, fuel and lubricating costs, method of drive, etc. Extracts from paper read before Ga. Ice Assn.

INDUSTRIAL MANAGEMENT

Average Costs, Fallacy of. A Fallacy of Management—That Average Costs Are of Any Value, B. M. Maynard and J. Heywood. Factory, vol. 32, no. 3, Mar. 1924, pp. 330-331 and 366, 1 fig. Discussion based on varied experience with industrial engineering in many plants.

Development. A Decade's Development in Management, H. P. Kendall. Taylor Soc.—Bul., vol. 9, no. 2, Apr. 1924, pp. 55-56. Trends and results of scientific management; developments in manufacturing problems; industrial relations; scientific management and selling.

Executive Function. Management as an Executive Function, J. H. Williams. Taylor Soc.—Bul., vol. 9, no. 2, Apr. 1924, pp. 66-71. Emphasizes modern biology and psychology as essential to development of science of management.

Expense Control. A Method of Expense Control That Paid, M. R. Lott. Indus. Mgt. (N. Y.), vol. 67, no. 5, May 1924, pp. 284-286, 2 figs. Keeping down cost of improvements; describes method which has proved of great benefit in controlling cost of work of expense nature, where large sums are involved.

Machine-Building Industries. Management Problems in Machine Building Industries, E. F. Du Brul. Am. Mach., vol. 60, no. 20, May 15, 1924, pp. 717-721, 2 figs. Effect of business cycle on management policies; handicaps under which builder of production equipment must work; profits of fat years must cover losses suffered in lean ones.

Principles. The Principles Underlying Good Management, H. Diemer. Indus. Mgt. (N. Y.), vol. 67, no. 5, May 1924, pp. 280-283. Investigation and standardization; comprehensive planning; preparation; inspection and records; wage incentives; control; mutual confidence and co-operation.

Production Control. A Workable Production Control Plan for the Small Plant, A. A. Dobson. Factory, vol. 32, no. 5, May 1924, pp. 652-654, 5 figs. Stock file of tickets are printed in addressing machine using metal plates; tickets required in system are stores issue, time ticket, job ticket, move ticket, and work tag.

Tool-Division System. Tool Division Organization and Management, E. C. Cooley. Machy. (N. Y.), vol. 30, no. 9, May 1924, p. 700. Deals with essential points to be considered in developing tool-division system; system successfully employed in number of shops engaged in interchangeable manufacture; making and upkeep of tools; controlling head.

INDUSTRIAL ORGANIZATION

Employers' Associations. Some Tendencies of Employers' Organizations in 1923. Int. Labour Rev., vol. 9, no. 2, Feb. 1924, pp. 208-226. Outstanding tendencies of employers' associations during 12-month period ending in autumn of 1923.

Vertical Trusts. The Vertical Trust, D. T. Farnham. Indus. Mgt. (N. Y.), vol. 67, no. 5, May 1924, pp. 257-263, 4 figs. Newer form of industrial combination and what it portends; its advantages and limitations and place in present industrial order.

INTERCHANGEABLE MANUFACTURE

Munitions. Interchangeable Manufacture and Munitions, E. Buckingham. Army Ordnance, vol. 4, no. 24, May-June, 1924, pp. 361-366, 1 fig. Traces briefly progress of a commodity through all stages of its manufacture, from its inception as a mechanical project to final testing that determines its successful completion.

INTERNAL-COMBUSTION ENGINES

Air Consumption and Power. Air Consumption and Power of Petrol Engines, H. Moss. Engineering, vol. 117, no. 3042, Apr. 18, 1924, pp. 507-509, 5 figs. Relationship of air consumption of brake horse power in internal-combustion engines; road and flight tests. (Abstract.) Paper read before Instn. Mech. Engrs.

Efficiency Standards. Efficiency Standards for Internal Combustion Engines. Engineer, vol. 137, no. 3563, Apr. 11, 1924, p. 394. Discussion by Committee on Tabulating Results of Heat Engine and Boiler Trials on standards of comparison for thermal efficiency of internal-combustion engines. See also Shipbldg. & Shipg. Rec., vol. 23, no. 15, Apr. 10, 1924, pp. 426-427.

Exhaust-Valve Temperatures. Exhaust-Valve and Cylinder-Head Temperatures in High-Speed Petrol Engines, A. H. Gibson and H. W. Baker. Instn. Mech. Engrs.—Proc., vol. 2, no. 6, 1923, pp. 1045-1092 and (discussion) 1093-1119, 31 figs. Investigation shows that, in well-designed overhead-valve engine, either of air- or water-cooled type, under normal conditions of operation, temperature of exhaust valve may be between 600 and 750 deg. cent.; best shape of valve head appears to be one having flat bottom and tulip-shaped top, but as this is impracticable owing to weight, next best is one having tulip-shaped head common in airplane-engine practice; conditions tending to give hot valve also tend to give hot cylinder head.

Flywheel Design, Chart for. Finding the Flywheel Weight Required by an Internal-Combustion Engine, P. H. Schweitzer. Power, vol. 59, no. 18, Apr. 29, 1924, p. 673, 1 fig. Presents chart for flywheel design including full instructions as to steps to be followed when using chart.

Thermal Efficiency of. Standards of Comparison in Connection with the Thermal Efficiency of Internal Combustion Engines, G. J. Wells. Gas Jl., vol. 166, no. 3179, Apr. 16, 1924, pp. 172-175, 4 figs. Traces investigation of subject from commencement of work of original committee appointed by Instn. Civil Engrs. in 1903, to which reference is made to compute ideal efficiency. Standard recommended involves use of air as ideal fluid, together with hypothesis that its specific heat was constant over range of pressures and temperatures involved. See also Gas Wld., vol. 80, no. 2073, Apr. 12, 1924, pp. 338-339.

See also Airplane Engines; Automobile Engines; Diesel Engines; Gas Engines; Motor Buses; Oil Engines.

IRON

Cold Work, Effect of. The Effect of Cold-Work upon the Density of Crystals of α-Iron, H. O'Neill. Iron & Steel Inst.—advance paper, no. 13, for mtg. May 1924, 12 pp., 4 figs. Tests on Armco iron and on single crystal; results.

Deterioration from Rolling Friction. Testing the Deterioration of Iron and Steel from Rolling Friction without Application of Lubricants (Ueber die Prüfung der Abnutzung von Eisen und Stahl bei rollender Reibung ohne Schmiermittel), H. Meyer and F. Nehl. Stahl u. Eisen, vol. 44, no. 17, Apr. 24, 1924, pp. 457-464, 25 figs. Different kinds of deterioration and their testing; wear through rolling friction and its practical importance; method of testing; process of deterioration; testing deterioration of different kinds of hard iron; change in structure through process of deterioration; influence of increased pressure and structure-changing heat treatment; zone of segregation and direction of grain.

Electrolytic. Progress in Electrolytic Iron, D. Belcher. Am. Electrochem. Soc.—advance paper, no. 10, for meeting, Apr. 24-26, 1924, pp. 157-172, 1 fig. Summary of progress made in electro-deposition of iron in last 75 years; describes two plants in commercial operation, and gives account of development work on Milford process for hydro-metallurgy of iron ores.

Wrought, Nick-Bend Test for. The Nick-Bend Test for Wrought Iron, H. S. Rawdon and S. Epstein. U S. Bur. Standards, Technologic Papers, No. 252, Feb. 29, 1924, pp. 115-155, 23 figs. Details of and results obtained from investigation which consisted of fracturing, under different conditions, of nickel bars of a number of grades of wrought iron, and study of character of fracture.

IRON ALLOYS

Preparation and Properties. Preparation and Properties of Pure Iron Alloys, J. F. T. Berliner. U. S. Bur. Standards, Scientific Papers, No. 484, Mar. 5, 1924, pp. 347-356, 4 figs. Determination of critical ranges of pure iron-carbon alloys by thermoelectric method.

IRON ORE

Minnesota. Minnesota and Ontario, C. P. McCormack. Iron & Steel of Canada, vol. 7, no. 4, Apr. 1924, pp. 66-67 and 77-78, 1 fig. Particulars of attempt being made to beneficiate low-grade magnetite of Babbitt, Minn., giving details of ore occurrences, conditions and description of plant, and application to Ontario ores where problem is similar.

IRON METALLURGY

REDUCTION FROM ORE AT LOW TEMPERATURES. The Reduction of Iron from its Ores at Low Temperatures, J. K. Smith. Foundry Trade Jl., vol. 29, no. 398, Apr. 3, 1924, pp. 280-282. Product of blast furnace, energy distribution, functioning of furnace, heat balance considerations, absence of nitrogenization, etc. See also Iron & Coal Trades Rev., vol. 108, no. 2928, Apr. 11, 1924, p. 590.

IRON, PIG

CHARACTERISTICS AND USES. Pig-Iron: Its Characteristics and Uses, H. Field. Foundry Trade Jl., vol. 29, no. 402, May 1, 1924, pp. 353-358, 1 fig. Elementary paper having the object to help foundry worker understand why they are "brands" of iron, why one brand is preferred to another, why pig-iron should be carried the length and breadth of the country, and why various castings in foundry are cast from different mixtures.

OXYGEN IN. Oxygen in Pig Iron (Nagra tankar om syre i tackjärn), J. A. Leffler. Jernkontorets Annaler, vol. 108, no. 3, 1924, pp. 149-177, 4 figs. Superiority of charcoal as a deoxidizer is claimed to be one of the main reasons for superiority of charcoal iron over coke iron. Analyses of Swedish charcoal iron as comgred to German and English coke iron show also the very low contents of sulphur and phosphor of charcoal iron as compared to the much higher contents of these elements in coke iron.

K

KILNS

DRAFTS. The Significance of Drafts in Down-Draft Coal-Fired Kilns, R. A. Sherman, R. F. Lunger and W. E. Rice. Am. Ceramic Soc.—Jl., vol. 7, no. 4, Apr. 1924, pp. 255-270, 12 figs. Applies fundamental laws of gas flow to movement of gases through down-draft kilns; data on pressure conditions in four kilns presented graphically; cause of draft, superiority of down-draft over up-draft kiln, significance of stack draft, relation of draft and excess air, features of kiln design, and comparative merits of forced, induced and natural draft. (Pub. by permission U. S. Bur. Mines.)

L

LABOUR

HOURS OF WORK. Legal Restrictions on Hours of Work in the United States. Nat. Indus. Conference Board, Research Report No. 68, 1924, 125 pp. Systematic analysis of existing legislation restricting hours of work in United States.

LATHES

ELLIPTIC-TURNING ATTACHMENT. Lathe Attachment for Elliptic Turning, I. F. Yeoman. Machy. (N. Y.), vol. 30, no. 9, May 1924, pp. 677-678, 5 figs. Describes attachment primarily employed for elliptical-turning operations on punches and dies used in making oval or elliptical frames for retaining glass windows in automobile tops.

LEAD METALLURGY

SMELTING. Lead Smelter Snapshots, E. H. Robie. Eng. & Min. Jl.—Press, vol. 117, no. 18, May 3, 1924, pp. 716-721, 20 figs. Notes on practice at plants of St. Joseph Lead Co., Herculaneum, Mo.; Federal Lead Co., Federal, near East Alton, Ill.; and St. Louis Smelting & Refining Wks., Collinsville, Ill.; in which three plants all of the Missouri concentrates, are treated.

LIGHTING

SCIENTIFIC, APPLICATION IN PRACTICE. The Application of Scientific Illumination in Practice, G. Herbert and R. A. Ives. Illuminating Engr., vol. 16, no. 10-12, Oct.-Dec. 1923, pp. 233-238 and (discussion) 238-242. Discusses importance of data, fundamentals of good lighting, relation between accidents and inadequate lighting, and shows how good illumination contributed to productive efficiency.

STREET. A Symmetric Illumination Distribution for Ornamental Street Lighting, L. A. S. Wood. Elec. World, vol. 83, no. 20, May 17, 1924, pp. 999-1003, 8 figs. Sheridan Road installation in Chicago meets high-intensity lighting requirements economically and esthetically by directing greatest density at angle of 22½ deg. from curb line.

LIGNITE

CARBONIZATION. Lignite Carbonization, W. W. Odell. U. S. Bur. Mines, Reports of Investigations, No. 2569, Feb. 1924, 6 pp. Figures showing what proportion of fuel requirements of Northwest is industrial or domestic fuel, and what proportion of lignite consumed is used for domestic purposes; notes on carbonization products; briquetting raw lignite.

Low-Temperature Carbonization, Particularly of Lignites (La carbonisation à basse température, en particulier celle des lignites), C. Berthelot. Société d'Encouragement pour l'Industrie Nationale—Bul., vol. 123, no. 1, Jan. 1924, pp. 44-66, 9 figs. Definition and realization of low-temperature carbonization, and its practical importance in metallurgical-coke industry; low-temperature carbonization of lignite.

DISTILLATION, FURNACES FOR. Historical Development of the Rolle Furnace Up to the Present Time (Die geschichltiche Entwicklung des Rolle-Ofens bis zur Neuzeit), A. Thau. Braunkohle, vol. 23, no. 2, Apr. 12, 1924, pp. 17-32, 30 figs. on supp. plates. Development of these furnaces, which serve the purpose of distilling lignite, extends over three-quarters of a century. Rolle's designs, of which a large number are illustrated and described, have not been materially improved upon by later designers.

LIQUIDS

VISCOSITIES. Viscosities of Liquids Experimentally Correlated to Pendulum Dampings, E. H. Barton and H. M. Browning. Lond., Edinburgh, & Dublin Philosophical Mag. & Jl. Sci., vol. 47, no. 279, Mar. 1924, pp. 495-500, 2 figs. Results of experiments showing relations holding between viscosity and damping.

LOCOMOTIVE BOILERS

MANUFACTURE. Building Locomotive Boilers. Eng. Production, vol. 7, no. 139, Apr. 1924, pp. 105-110, 16 figs. Procedure at works of Great Western Ry. Co. at Swindon, Eng.

PAYING WEIGHT. The Paying Weight in Locomotive Boilers, C. A. Seley. Ry. Age, vol. 76, no. 24, May 17, 1924, pp. 1216-1218, 1 fig. Firebox heating surface about twice as effective as tubes and flues per lb. of material.

LOCOMOTIVES

AXLE-REPAIR MACHINES. Machines for Repairing Journals, Cranks and Fly Cranks of Locomotive Axles (Appareils pour rectifier les fusées, tourillons et contre-manivelles des essieux de locomotives), M. Montillier. Génie Civil, vol. 84, No. 12, Mar. 12, 1924, pp. 279-280, 5 figs. Describes portable lathe for repairing axle cranks and journals which can be placed directly under axle, and machine for repairing fly cranks.

DIMENSIONS COMPARISON. The Comparison of Locomotive Dimensions, E. C. Poultney. Ry. Engr., vol. 45, no. 528, Jan. 1924, pp. 19-21 and 35. Discusses factors which it is necessary to consider when a general opinion is to be formed as to comparative capacity of any given locomotive. Locomotive power definitions.

ELECTRIC. *See Electric Locomotives.*

GARRATT ARTICULATED. Garratt Articulated Locomotives. Times Trade & Eng. Supp., vol. 14, no. 304, May 3, 1924, p. 191, 1 fig. Fundamental principle governing design is provision of engine combining great flexibility with comparatively high power, and affording possibility of large boiler dimensions; first of its kind to be used in England, recently delivered by Beyer, Peacock & Co.

INTERNAL-COMBUSTION. Mountain Trains with Internal-Combustion Locomotives (Bergbahnen mit Motorbetrieb), W. Müller. Motorwagen, vol. 27, no. 11, Apr. 20, 1924, pp. 186-190, 6 figs. Describes system recommended by author for rack railway in the Bavarian Alps, consisting of trains with internal-combustion locomotives in place of steam or electric locomotives.

LONG RUNS. Long Locomotive Runs, F. E. Russell. Pacific Ry. Club—Proc., vol. 7, no. 12, Mar. 1924, pp. 9, 11, 13, 15 and 17-27, and (discussion) 27-39. Traces briefly development of steam locomotive in past 100 years. Shows that there is ample opportunity for improvement by obtaining greater mileage out of locomotives by increasing length of locomotive runs; gives list of 34 railways that have increased locomotive runs. Modern appliances and improvements in design and material that contribute to making long locomotive runs economical.

LUBRICATION. Locomotive Valve and Cylinder Lubrication, W. J. Schlacks. Ry. & Locomotive Eng., vol. 37, no. 5, May 1924, pp. 148-150, 1 fig. Schlacks force-feed lubricator; valve and cylinder lubrication of superheater locomotives.

0-8-0 HEAVY SWITCH. New 0-8-0 Heavy Switch Engines for Wabash Ry. Ry. Rev., vol. 74, no. 19, May 10, 1924, pp. 833-838, 8 figs. Modern switch engines for use in yard and transfer service at large terminals.

REPAIRING. A Record in Completing Class III Repairs. Ry. Rev., vol. 74, no. 16, Apr. 19, 1924, pp. 713-715, 12 figs. Time record for making class III locomotive repairs was established on Kansas City Southern Ry., Mar. 17, 1924, when locomotive No. 556 was put through shops at Pittsburg, Kan., in 7 hr. and 55 min. Describes manner in which work was planned, preparations made beforehand, and schedule on which it was executed.

SWITCHING. A New Internal-Combustion Shunting Locomotive. Ry. Gaz., vol. 40, no. 16, Apr. 18, 1924, pp. 572-574, 6 figs. Particulars of the Vermont, gasoline-driven locomotive or tractor, designed to meet requirements of railway companies and industrial concerns; design based on simplicity of detail and economical operation.

TIRE PRACTICE. Locomotive Tire Practice on the Santa Fé, F. H. Colvin. Am. Mach., vol. 60, no. 19, May 8, 1924, pp. 697-698, 6 figs. Wheel gages and calipers, and how they are used; making of tires by carbon content as well as size; standard shims; shrinkage allowance.

TURBO-ELECTRIC. The Ramsay Turbo-Electric Condensing Locomotive. Ry. Engr., vol. 45, no. 528, Jan. 1924, pp. 5-10 and 24, 11 figs. partly on supp. plates. Discusses developing and transmitting power, design of condenser, driving motors, speed regulation, and gives results of tests made on Lond. Midland & Scottish Ry. subsequent to modification of certain details, showing possibilities of this class of locomotive for working main-line passenger traffic.

2-8-2 TYPE. 4-Cylinder 2-8-2 Express Locomotive. Italian State Railways. Ry. Gaz., vol. 40, no. 17, Apr. 25, 1924, pp. 606-607, 2 figs. Particulars of locomotives with large diameter coupled wheels introduced for working heavy passenger trains on heavily graded sections of Rome-Naples and Rome-Florence lines; boiler pressure 200 lb. per sq. in.; tractive effort 8,820 lb.

VALVE GEARS. The Walschaert Locomotive Valve-Gear, R. C. Bond. Instn. Mech. Engrs.—Proc., vol. 2, no. 6, 1923, pp. 1137-1141, 2 figs. Detailed consideration of Walschaert valve gear. (Abridged.)

LUBRICANTS

SPECIFICATIONS AND TESTING METHODS. United States Government Specification for Lubricants and Liquid Fuels and Methods for Testing. U. S. Bur. Mines, Technical Paper 323A, 1924, 89 pp., 21 figs. Specification officially adopted by Federal Specifications Board Feb. 3, 1922, for use of departments and independent establishments of government in purchase of materials covered by it.

ROLLING STOCK. Lubricating Materials Used by the Russian Railroads, A. V. Sapoznikow. Petroleum & Oil-Shale Industry, vol. 5, nos. 7-8, July-Aug. 1923, pp. 75-80. (In Russian.) See also article by A. K. Saytzeff, entitled Railway Car Oils and Lubricating Mixtures, Their Properties, Mechanical Tests, Valuation and Selection, pp. 81-92, 4 figs., with abstract in English, pp. 92-94.

LUBRICATION

METHODS. Methods for Applying Lubricants. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 560-562, 8 figs. Drop-feed method of lubrication; gravity circulation of oil; methods of purifying oil; methods of using purifiers.

M

MACHINE SHOPS

DRAFTING-ROOM MANAGEMENT. A Practical Drafting-room System, I. B. Black. Machy. (N. Y.), vol. 30, nos. 8 and 9, Apr. and May 1924, pp. 605-607 and 671-673, 9 figs. Description of methods successfully applied in management of a drafting room.

MACHINE TOOLS

ATTACHMENTS FOR. Attachments for Standard Machines, A. A. Dowd. Machy. (N. Y.), vol. 30, no. 9, May 1924, pp. 711-712, 4 figs. Important points in design; types of flexible designs.

EARLY FORMS AND PROGRESS. The Master Tools of Industry, D. S. Kimball. Am. Mach., vol. 60, nos. 19 and 20, May 1 and 15, 1924, pp. 679-683 and 723-727, 27 figs. Early attempt of man to supplement his bodily efforts; principle of transfer of skill; modern machines and transfer of thought. Henry Maudsley and his enduring contribution to lathe design; beginnings of interchangeable manufacture; semi-automatic machine; Spencer and full automatic machine.

TABLES. Work-holding Surfaces of Machine Tools. Machy. (Lond.), vol. 24, no. 605, May 1, 1924, pp. 132-137, 20 figs. Table design for different types of machines.

MACHINERY

MANUFACTURE, SIZE CONTROL IN. Workmanship—The New Direct System of Size Control, P. J. Darlington. Sibley Jl. of Eng., vol. 38, no. 4, Apr. 1924, pp. 92-96. Describes new microgage system of production measurement, or size control, in which precision made available by Bur. Standards, and represented in cylindrical standard, is directly transferred to part being produced by means of a new automatic measuring comparator called microgage.

MANGANESE STEEL

SILICO. The Hardening of Silico-Manganese Steel, E. W. Colbeck and D. Hanson. Iron & Steel Inst.—advance paper, no. 5, for mtg. May 1924, 18 pp., 26 figs. Experiments show that temperatures required for complete hardening of steels used are very much higher than corresponding hardening temperatures for straight carbon steels having same carbon content.

MARINE STEAM TURBINES

AUXILIARY MACHINERY FOR. The Application of the Steam Turbine for Auxiliary Machinery, R. W. Allen. Engineering, vol. 117, no. 3041, Apr. 11, 1924, pp. 477-479, 7 figs. Points out advantages of turbine driving for auxiliaries on ships. (Abstract.) Paper read before Instn. Nav. Architects.

HIGH PRESSURE AND SUPERHEATING. Modern Tendencies in Steam Turbine Power Plants, E. Berg. Mar. Eng., vol. 29, no. 5, May 1924, pp. 305-309, 10 figs. Advantages obtained in adoption for marine propulsion of high steam pressure, bigh superheat, steam extraction for heating feedwater and reheating. Abstract of paper read before metropolitan section of A.S.M.E.

MATERIALS HANDLING

COST-SAVING METHODS. Materials Handling Methods That Have Added to Industrial Profits, Geo. E. Hagemann. Mgt. & Administration, vol. 7, no. 5, May 1924, pp. 557-562, 1 fig. Experience data from 55 plants using larger equipment.

EQUIPMENT. Measuring the Savings of Mechanical Handling, W. T. Spivey. Mgt. & Administration, vol. 7, no. 5, May 1924, pp. 551-556, 8 figs. Factors in selection of equipment for an installation.

LABOUR-SAVING EQUIPMET. Quality Production from the Application of Automatic Handling Equipment, C. J. Alfred. Mgt. & Administration, vol. 7, no. 5, May 1924, pp. 563-566, 7 figs. Labour-saving methods of Am. Sugar Refining Co.

PLANT PAINTING DEPARTMENT. Handling Material in Painting Department, E. T. Bennington. Iron Age, vol. 113, no. 20, May 15, 1924, pp. 1413-1416, 6 figs. Overhead tramways witb special carriers take filing cabinets tbrough three dips, a drip and drying oven; automatic equipment featured.

ROUTING. Controlling the Flow of Package Products by Materials Handling Equipment, J. Mendleson. Mgt. & Administration, vol. 7, no. 5, May 1924, pp. 545-550, 8 figs. Labour-saving devices and routing methods employed by B. T. Babbitt Co. in manufacture of chlorinated lime, caustic soda, lye, etc.

MEASURING INSTRUMENTS

PRECISION. Modern Precision Measuring Instruments, W. L. Whitmarsh. Army Ordnance, vol. 4, no. 24, May-June 1924, pp. 381-384 and 400, 8 figs. Describes standard types, including micrometer caliper, vernier tools, vernier bevel protractor, fluid gage, limit gages, etc., and their functioning and use.

Precision Measuring Instruments Used in Gage Inspection, G. K. Burgess. Army Ordnance, vol. 4, no. 24, May-June 1924, pp. 375-380, 8 figs. Deals witb sucb apparatus as is applied in measurement of dimensions of gages and tools used in manufacture of macbine parts, artillery ammunition, etc.

MERCURY-VAPOUR PROCESS

EMMET. The Emmet Mercury-Vapour Process, W. L. R. Emmet. Mech. Eng., vol. 46, no. 5, May 1924, pp. 235-240 and 305, 13 figs. Early experiments; thermodynamic possibilities of process; Hartford installation; boiler problems; mercury turbines; packings and leakage; economies attainable; mercury supply.

METAL CUTTING

HYDROGEN-GAS. Cutting Metal with Hydrogen Gas, W. H. L. Portb. Am. Welding Soc.—Jl., vol. 3, no. 3, Mar. 1924, pp. 15-18. Conditions important in connection with determining use of a fuel gas for cutting of metals. Equipment used for cutting witb hydrogen as fuel gas, and details of operation.

METALS

BRINELL-TENSILE RELATIONSHIP. Experiments on the Brinell-Tensile Relationsbip, A. L. Norbury and T. Samuel. Iron & Steel Inst.—advance paper, no. 12, for mtg. May 1924, 11 pp., 4 figs. Tensile, Brinell, and scleroscope tests on materials used; plotting of results according to Meyer's formula; comparison of Brinell and tensile results.

CLEANING. Metal Cleansing with Alkaline Cleaning Solutions, E. M. Baker and R. Scbneidewind. Am. Electrochem. Soc.—advance paper, no. 15, for meeting Apr. 24-26, 1924, pp. 203-229, 11 figs. Typical analyses of cleaners used for various purposes, and factors entering into mixing of cleaners.

MELTING, FLUXES AND SLAGS IN. Fluxes and Slags in Metal Melting and Working. Foundry Trade Jl., vol. 29, nos. 402 and 403, May 1 and 8, 1924, pp. 359-363 and 388-390. Abstracts of papers read at a general discussion on tbis subject which was held Apr. 28, 1924, at Inst. Mech. Engrs., under joint auspices of Faraday Soc., Instn. Metals, Inst. British Foundrymen, and Britisb Non-Ferrous Researcb Assn., viz.; Oxidizing Fluxes in Melting of Non-Ferrous Metals, A. Portevin; Use of Fluxes in Brass Melting, R. Genders and M. A. Haughton; Note on Slags from Lead, Copper, and Otber Blast Furnaces, G. Rigg; Slags Produced in Melting Silver Alloys, J. Phelps; Sulppurizing and Desulpburizing of Metals by Basic Slags and Fluxes, B. Bogitch; Slag Inclusions in Relation to Fatigue, B. P. Haigh; Fluxing Problems in Welding Mild Steel witb Metallic Arc, H. Ogden; Physical Cbemistry of Slags and Fluxes in Non-Ferrous Metal Industries, C. H. Descb; Fluxes and Slags in Oxy-Acetylene Welding, C. C. Smith.

STRAIN DETECTION. Tbe Detection of Strain in Metals, J. D. Jevons. Metal Industry (Lond.), vol. 24, no. 10, Mar. 7, 1924, p. 225. Survey of work done by various investigators on this subject, together with comments on practical utility of the different methods suggested.

MICA

INSULATION. Mica and Micanite Insulation, A. A. C. Dickson. Elec. Rev., vol. 94, nos. 2416 and 2417, Mar. 14 and 21, 1924, pp. 408-409 and 469-470. Varieties, properties, practical tests and choice of mica, and manufacture and test of commutator micanite.

MINING

MICROSCOPIC INVESTIGATION, APPLICATION OF. Mineralography as an Aid to Mining, E. Tbomson. Can. Inst. Min. & Met.—Bul., no. 144, Apr. 1924, pp. 231-237, 12 figs. Determination of opaque mincrals by microscopic investigation; practical directions in wbich this method may be applied.

MOTOR BUSES

ENGINES. Continental Announces Special Engine for Express Bus Service. Automotive Industries, vol. 50, no. 20, May 15, 1924, pp. 1075-1076, 2 figs. 6-cylinder engine bas piston displacement of 331 cu. in. and develops maximum of over 70 hp. at 2,300 r p.m.; built for rapid, inter-city passenger work with long, non-stop runs.

MOULDING METHODS

GREEN-SAND, MOULDING. Hints on Green-Sand Moulding, C. H. Brown. Foundry Trade Jl., vol. 20, no. 399, Apr. 10, 1924, pp. 297-298 (includes discussion). Ramming of mould, venting of moulds, effects of bad gating, burning on castings, etc.

PIPE, SPECIAL SHAPES. Moulding Special Pipe Shapes, P. Dwyer. Foundry, vol. 52, no. 10, May 15, 1924, pp. 373-378, 10 figs. Equipment developed for production of large valves and special shapes which usually are ordered in single units or in limited numbers; practice of Pittsburgh Valve, Foundry & Constr. Co.

SPIRAL DRUMS. Moulding Spiral Drum From Pattern Swept in Loam, J. Taylor. Can. Foundryman, vol. 25, no. 4, Apr. 1924, pp. 12-14, 7 figs. Pattern swept on arbor in similar manner to sweeping cam core; moulded same as wooden pattern; core also swept in.

N

NAILS

MANUFACTURE. Manufacturing Nails by Automatic Machinery, H. P. Armson. Can. Machy., vol. 31, no. 17, Apr. 24, 1924, pp. 19-21, 3 figs. Practice at Graham Nail Works, Toronto, Can. Raw material first "pickled" to remove scale, then coated with lime to assist lubrication and reduce wear on dies in drawing operation.

NICKEL

ELECTROLYTIC. Mechanically Perfect Eleotrolytic Nickel, Chas. P. Madsen. Am. Electrochem. Soc.—advance paper, no. 28, for meeting, Apr. 24-26, 1924, pp. 371-378 Means are described for producing electro-nickel almost equal to pure gold in ductility; use of bydrogen peroxide in bath is claimed to be absolute cure for pits, and exerts other beneficial effects; anode is described whicb gives consistently good results in above-mentioned bath.

NICKEL ALLOYS

PERMALLOY. Permalloy, A New Magnetic Material of Very High Permeability, H. D. Arnold and G. W. Elmen. Elec. Communication, vol. 2, no. 4, Apr. 1924, pp. 226-231, 7 figs. Describes a magnetic alloy which is a composition of about 78.5 per cent nickel and 21.5 per cent iron and at magnetizing fields in neighbourhood of .04 gauss and with proper treatment has a permeability running as higb as 90,000.

O

OIL ENGINES

DOUBLE-ACTING. A Sliding Cylinder Two-cycle Double-acting Marine Oil Engine. Engineer, vol. 137, nos. 3565 and 3566, Apr. 25 and May 2, 1924, pp. 451-452, 4 figs. and 483-485, 6 figs. Design and performance of 2,000-b.hp. engine built at Nortb Brit. Diesel Engine Works, Glasgow.

HEAVY-OIL, LUBRICATION OF. The Lubrication of Heavy-Oil Engines, C. S. Darling. Mech. Wld., vol. 75, no. 1944, Apr. 4, 1924, pp. 209-210. Deals witb lubrication of pistons, cylinders, air compressors, etc., including discussion on oils.

NICKEL APPLIED TO PARTS. Nickel and Its Alloys Applied to Oil Engine Parts. Motorship, vol. 9, no. 5, May 1924, pp. 361-363, 8 figs. Cast iron is improved by addition of from 3 to 5 per cent of nickel and monel metal reduces maintenance on valves.

SOLID-INJECTION. The Solid-Injection Oil Engine, H. F. Shepherd. Mech. Eng., vol. 46, no. 5, May 1924, pp. 251-257 and (discussion) 257-258 and 278, 30 figs. Presents most pertinent facts on development of engine from former hot-surface unit and points out influence of combustion-cbamber design, spray angle and velocity, atomization, detonation, and otber problems confronting oil-engine designer.

OIL FUEL

BURNERS. Combustion Devices for Liquid Fuel, W. Trinks. Fuels & Furnaces, vol. 2, nos. 1, 2, 3 and 4, Jan., Feb., Mar. and Apr. 1924, pp. 21-24, 135-138, 255-258 and 349-352, 22 figs. Jan.: Burners of vaporization and atomization type or combination of botb. Feb.: How atomization is accomplished. Mar.: High furnace atomization; low-pressure atomization. Apr.: Means for proper mixing of atomized liquid fuel and air.

PROPERTIES. Heating and Motor Oils (Zur Kenntnis der Heiz- und Treiböle), A. Aufhäuser. Zeit. des Vereines deutscber Ingenieure, vol. 68, no. 17, Apr. 26, 1924, pp. 419-422, 1 fig. Points out that properties of oils are functions of degree of distillation, and combustion itself is also a fractionated process; method in use for determination of flasb point is of no value for Diesel-engine practice.

TRANSFORMATION FROM SOLID FUEL. Transformation of Solid into Liquid Fuel, G. L. Stadnikov. Petroleum & Oil-Shale Industry, vol. 5, nos. 11-12, Nov.-Dec. 1923, pp. 655-660. (In Russian.)

OIL PUMPS

SCREW. The Screw Oil Pump, R. H. Pearsall. Automobile Engr., vol. 14, no. 189, May 1924, pp. 145-147, 10 figs. General principle and analysis of pump action; experiments which corroborate analytical results.

OIL SHALES

HEAT TREATMENT. Heat Treatment of Oil Shale, V. Z. Caracristi. Combustion, vol. 10, no. 5, May 1924, pp. 336-340, 7 figs. Position of oil shale in relation to growing consumption of gasoline, and description of apparatus for treating oil shale.

OPEN-HEARTH FURNACES

MOLL END. New Open-Hearth Furnace End, H. Moll. Iron Age, vol. 113, no. 19, May 1, 1924, pp. 1277-1278, 1 fig. Practical results from use of new design by author in Germany; advantages of a mixing flue for gases. Translated from Stahl u. Eisen.

WASTE-HEAT RECOVERY. Recovery of Waste Heat in Open-Hearth Practice, W. Dyrssen. Iron & Steel Inst.—Advance paper, no. 6, for mtg. May 1924, 48 pp., 16 figs. Complete detailed heat balance of fuel for modern American 80-ton producer-gas open-hearth furnace; results of study of beat balance; beat balance for coke-oven gas-fired open-bearth furnace is given for comparison witb producer gas as fuel; steam output for various charges; comparison between blast-furnace and open-hearth practice; economic value of recovery of waste heat in steam in steam in open-hearth practice.

ORDNANCE

PRODUCTION PROBLEMS, U. S. WAR DEPT. Some Production Problems in the War Department's Preparedness Program, H. W. Cburcbill. Mecb. Eng., vol. 46, no. 5, May 1924, pp. 268-270 and (discussion) 270-271. Co-operation of engineering, industrial and commercial bodies with War Department; reserve-officer personnel problem; problem of securing facilities for manufacturing war material; problems typical of those confronting plant production engineers; features of type of contract now being developed; raw materials, gages, machine tools. (Abridged.)

OXY-ACETYLENE CUTTING

ADVANTAGES AND APPLICATIONS. Oxy-Acetylene Process of Cutting Metals. Macby. (Lond.), vol. 24, no. 604, Apr. 24, 1924, pp. 123-125, 3 figs. Advantages of method and modern applications.

OXY-ACETYLENE WELDING

ALUMINUM. Gas Welding Aluminum, S. W. Miller. Am. Welding Soc.—Jl., vol. 3, no. 3, Mar. 1924, pp. 44-50, 2 figs. Flux used, welding without flux, procedure in welding, character of flame, preheating, manipulation of welding rod and torch, etc.

Locomotive Fireboxes. Welding on Copper Fireboxes of Locomotives, J. F. Springer. Ry. Mech. Engr., vol. 98, no. 5, May 1924, pp. 293-294. Successful results obtained in Europe with oxy-acetylene torch and special filler rods.

Oil and Gas Industry. Theory and Practice in Use of Oxygen, L. Balliet. Oil & Gas Jl., vol. 23, no. 22, May 1, 1924, pp. 34 and 106. Results of extensive research in use of oxygen blowpipe, or acetylene torch, in oil and gas industry. Used for cutting slotted screens, welding pipe line, welding broken parts of machinery, filling in broken gear teeth, cutting off bolt heads, pipe and metal bending, etc.

P

PAINTS

Metal-Protective. Paints for Metals, H. A. Gardner. Paint Mfrs.' Assn. of U.S. Nat. Varnish Mfrs' Assn.—Circular, no. 202, Apr. 1924, pp. 302-327, 10 figs. Review of tests with suggestions regarding design and use of metal protectives.

White Lead. Manufacture of White Lead (Fabrication de la Céruse), N. Chercheffsky. Chimie & Industrie, vol. 11, no. 1, Jan. 1924, pp. 45-48. Observations on the Dutch process; average yield of white lead is about 50 per cent of gross weight of lead taken under abnormal conditions it may be as low as 27 to 28 per cent, but under favourable conditions it may attain 67 to 68 per cent.

PATTERNS

Metal Gear. Metal Gear Patterns, J. F. Hines. Machy. (N. Y.), vol. 30, no. 9, May 1924, pp. 692-693, 4 figs. Metal patterns of type shown are especially satisfactory for casting spur and bevel gears; details of construction; making patterns.

PAPER

Analysis. Rapid Analysis of Paper. Paper, vol. 33, no. 25, Apr. 10, 1924, pp. 11-12. Factors that influence character of paper in beating process; determination of degree of sizing in paper; tests for rosin in paper fibers. Translated from Moniteur de la Papeterie Française.

PAPER MANUFACTURE

Decayed Wood Utilization. The Utilization of Decayed Wood in the Chemical Processes, J. D. Rue, R. N. Miller and C. J. Humphrey. Paper Trade Jl., vol. 78, no. 20, May 15, 1924, pp. 44-48, 4 figs. Discussion of use of decayed wood in sulphite and soda processes, chiefly in former.

Names and Terms. Dictionary of Papermaking Terms. Paper, vol. 33, no. 26, Apr. 17, 1924, pp. 66-100 (18 pp.). Names and terms used in paper industry; titles and definitions of sizes and finishes of paper and paper products. Prepared by subcommittee of Committee on Simplifications of Paper Sizes appointed by Bur. Standards, in collaboration with F. A. Curtis.

PHOTOMETERS

Flicker. A New Flicker Photometer for Heterochromatic Photometry, J. Guild. Jl. Sci. Instruments, vol. 1, no. 6, May 1924, pp. 182-189, 3 figs. Specially designed to fulfill conditions requisite to accuracy and precision in use of such instruments.

PILES

Sheet, Precast. Concrete Piles Resist Action of Sea Water for Five Years, Chas. M. Spofford. Eng. News-Rec., vol. 92, no. 18, May 1, 1924, p. 765. Precast sheet piling apparently in good condition in bulkheads at Boston Army Supply Based; special care used to obtain dense concrete.

PLANERS

Equipment for. Tooling Reciprocating Machine Tools. Eng. Production, vol. 7, no. 139, Apr. 1924, pp. 94-97, 10 figs. Tools and special equipment for planers.

PLATES

Flattening Machine. Hydraulic Plate Flattening Machine. Machy. (Lond.), vol. 23, no. 600, Mar. 27, 1924, pp. 838-839, 4 figs. Type which operates on principle of gripping plate at each end and pulling it taut until irregularities and buckles disappear.

PNEUMATIC TOOLS

Waste Elimination. Cutting Out Waste in the Factory Air System, F. Johnston-Taylor. Indus. Mgt. (Lond.), vol. 11, no. 9, May 1, 1924, pp. 239-240 and 242, 4 figs. Explains how wastage and leakage may be detected in connection with pneumatic installations in factory, and how by use of compressed-air meter, economics may be effected.

POWER FACTOR

Reactive Component Measurement. Measuring the Reactive Component, J. Auchincloss. Gen. Elec. Rev., vol. 27, no. 4, Apr. 1924, pp. 263-272, 17 figs. Theory of operation of reactive volt-ampere measuring devices.

PRECIPITATION

Cottrell Process. Cottrell Electrical Precipitation Process, A. Stansfield. Fuels & Furnaces, vol. 2, nos. 3 and 4, Mar. and Apr. 1924, pp. 269-271 and 361-364, 2 figs. Review of various methods of cleaning gases with detailed account of application of Cottrell precipitator to blast-furnace gases; approximate cost and savings possible.

PULVERIZED COAL

Boiler and Metallurgical Furnaces. Powdered Coal Firing for Water-Tube Boilers and Metallurgical Furnaces, H. W. Hollands. Instn. Mech. Engrs.—Proc., vol. 2, no. 6, 1923, pp. 143-151, 6 figs. Describes unit system, which consists of one pulverizer per boiler or furnace, and points out its advantages; coal dryings; savings in use of pulverized coal. (Abridged.)

Calculations. Calculations Respecting Pulverized Fuel, E. Kilburn Scott. Power Engr., vol. 19, no. 217, Apr. 1924, pp. 148 and 157. Also Combustion, vol. 10, no. 5, May 1924, pp. 360-361. Elementary considerations regarding use of pulverized fuel, arranged as calculations.

Preparation and Utilization. Powdered Coal: Its Preparation and Utilization, R. Jackson. Engineering, vol. 117, nos. 3038 and 3039, Mar. 21 and 28, 1924, pp. 381-383 and 415-418, 22 figs. (Abstract.) Paper read before Instn. Mech. Engrs.

Tests. Experiences with Coal Dust and Combustion of Pulverized Coal (Les expériences sur les poussières de houille et la combustion du charbon pulvérisé), J. Arnoul de Grey. Chaleur & Industrie, vol. 5, no. 45, Jan. 1924, pp. 23-26, 2 figs. Calls attention to some of more important results obtained by Taffanel and Audibert from tests carried out at Liévin and Montlucon, and discusses their application to different problems of combustion of pulverized coal, dealing with problem of burners, combustion chambers, and possibility of utilizing certain combustibles in pulverized state.

Unit System. Unit System for Pulverized Coal, S. C. Martin. Power Plant Eng., vol. 28, no. 9, May 1, 1924, pp. 471-172, 1 fig. Advantages of unit system in remodeled plants; results of tests.

PUMPS, CENTRIFUGAL

Characteristic Curves. Use of Centrifugal Pump Curves. Power Plant Eng., vol. 28, no. 9, May 1, 1924, pp. 497-499, 2 figs. Usual forms of characteristic curves for centrifugal pumps based on constant speed.

Specifications. Notes on Centrifugal Pump Specifications, J. D. Morgan. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 555-559, 7 figs. Service requirements are principal data needed by designer; service records show dependability of centrifugal pumps.

PUNCHING MACHINES

Patents. Punching and Perforating Machines and Hand Tools for Cutting, Punching, Perforating, and Tearing Paper, Leather, Fabrics, and the Like. Abridgments of Specification, Period 1916-20, Class 31 (ii), 1924, 29 pp. (illustrated). Patents for inventions.

PYROMETERS

Disappearing-Filament. A Direct-Reading Pyrometer of the Disappearing-Filament Type, F. H. Schofield and D. C. Gall. Jl. Sci. Instruments, vol. 1, no. 7, Apr. 1924, pp. 193-198, 5 figs. Modified form of disappearing-filament pyrometer in which pyrometer lamp forms one arm of a Wheatstone bridge.

Radiation. The "Pyro" Radiation Pyrometer. Engineering, vol. 117, no. 3042, Apr. 18, 1924, pp. 493-494, 6 figs. It is easily portable, weighing only 25 oz., and is completely self-contained, requiring no batteries or other accessory apparatus.

R

RADIOTELEGRAPHY

Receivers. Atmospherics and Their Effect on Wireless Receivers, E. B. Moullin Instn. Elec. Engrs.—Jl., vol. 62, no. 328, Apr. 1924, pp. 353-366 and (discussion) 366-372, 11 figs. Mathematical analysis of effect of atmospheric upon wireless receiver; calculation of effect of each of several wave forms and comparison of results; consideration of possible advantage from use of aperiodic antenna or of slightly distuned periodic circuit; comparison of rectified current produced by atmospheric with that produced by signal.

RADIOTELEPHONY

Railway Trains. Radio Telephony on Railway Trains, E. J. Collier. Elec. Rev., vol. 94, no. 2421, Apr. 18, 1924, pp. 612-613. Experiments made by Great West. Ry. Co. on trains running between Paddington and Birmingham.

Receivers. Self Contained Three-Valve Receiver, W. F. Gildersleve. Wireless Wld., vol. 14, no. 1, Apr. 2, 1924, pp. 14-20, 10 figs. Consists of one stage of H.F. amplification, detector and one note magnifier; easy to construct and makes use of a minimum number of component instruments; easy manipulation.

Short-Period Variations in Reception. Short Period Variations in Radio Reception, G. W. Pickard. Inst. Radio Engrs.—Proc., vol. 12, no. 2, Apr. 1924, pp. 119-158, 39 figs. Continuous records of electric-field intensity at distance of from 11 to 2,600 km. from various broadcasting stations are made by amplifying and rectifying received current from open antenna, and recording galvanometer deflections produced by this current; these records show complex curve containing periodicities ranging from seconds to tens of minutes; transition from day to night conditions is shown; simultaneous records at separated receiving points are found to be dissimilar, and records of different distant stations taken at same receiving point are shown to be unlike; hypothesis for these fluctuations is advanced.

RAILLESS TRACTION

Advantages. The Case for Railless Traction. Tramway & Ry. Wld., vol. 55, no. 14, Mar. 20, 1924, pp. 132-134. Shows by means of actual and hypothetical figures, that for practically the whole field of municipal transport railless electric traction cannot only satisfy all traffic requirements, but can effect considerable saving in capital expenditure and operating costs.

RAILS

Fracture. Broken Rails. Ry. & Locomotive Eng., vol. 37, no. 5, May 1924, pp. 150-152, 4 figs. Extracts from reports on broken rails that caused derailments and loss of life, published by Bur. Safety.

RAILWAY ELECTRIFICATION

Developments. Railway Electrification in Foreign Countries, Stanley P. Smith. Instn. Elec. Engrs.—Jl., vol. 62, no. 328, Apr. 1924, pp. 317-322 and (discussion) 322-324. Deals with various countries, not including Great Britain.

RAILWAY MANAGEMENT

Material Investment. The Railways' Material Investment, L. C. Thomson. Can. Ry. Club, vol. 23, no. 3, Mar. 1924, pp. 20-29 and (discussion) 29-38. Deals with organization, facilities, inspection, distribution, rail, and reclamation.

Tonnage Volume, Forecasting. Railroad Traffic and the Business Cycle, H. B. Vanderblue. Ry. Age, vol. 76, no. 20, Apr. 19, 1924, pp. 987-990, 7 figs. Shows how individual carrier is assisted in forecasting tonnage volume; traffic of Southern Ry.

RAILWAY MOTOR CARS

Electro-mechanically vs. Mechanically Operated. Experimental Operation of Rail Cars Driven by Internal-Combustion Engines by Means of Purely Mechanical Transmission (Het proefbedrijf metb enzine-Maaetschappij), H. J. P. Brunner. Ingenieur, vol. 39, no. 17, Apr. 26, 1924, pp. 312-317, 4 figs. Comparative tests made by Limburg Railway Co. between electro-mechanically and purely mechanically operated rail cars indicate superiority of electro-mechanical system.

RAILWAY OPERATION

Stopping and Starting Trains. Estimated Cost of Stopping and Starting Trains, O. O. Carr. Ry. Rev., vol. 74, no. 18, May 3, 1924, pp. 807-808. Tables giving estimated additional cost to stop and start trains.

Train Control. An Unusual Idea in Automatic Train Control. Ry. Rev., vol. 74, no. 16, Apr. 19, 1924, pp. 723-731, 14 figs. Describes train-control system of Indiana Equipment Corp., designed and developed by C. F. Shadle, which is of the ramp of direct-contact type. Essential parts of device consist of a wayside ramp, a contact shoe having a roller contact, a neutral control relay, an electropneumatic valve, automatic air-brake valve, and a speed controller.

Automatic Cut-Off Control Tested in Service. Ry. Age, vol. 76, no. 21, Apr. 26, 1924, pp. 1033-1037, 9 figs. Describes control device and tells what its performance on two railroads has demonstrated.

Hearing on Automatic Train Control Order. Ry. Age, vol. 76, no. 23, May 10, 1924, pp. 1145-1148. Statement by W. J. Harahan outlining position of railroads and proposing three regional tests on 100 mi. of line in each region; testimony of W. S. Stone that engineers are strongly opposed to automatic control.

RAILWAY REPAIR SHOPS

Denver & Rio Grande Western. Denver & Rio Grande Western Rebuilds Shops. Ry. Age, vol. 76, no. 24, May 17, 1924, pp. 1193-1200, 11 figs. Completes extensive programme of modernization of facilities for repair of cars and locomotives; details of new facilities at Denver, Colo., and at Salt Lake City.

ORGANIZATION. B. R. & P. Has Well Organized Production Shop, (Du Bois, Pa.) Ry. Mech. Engr. vol. 98, no. 5, May 1924, pp. 295-299, 6 figs. Limited programme of repairs facilitates efficient operations; routing of locomotives and parts; department organization and machine-tool operation; shop organization.

STEEL CARS. Pennsylvania Builds Modern Steel Car Shops. Ry. Age, vol. 76, no. 22, May 3, 1924, pp. 1085-1088, 9 figs. Duplicate designs erected at Pitcairn and Enola to handle heavy repairs on Eastern and Central regions; capacity of each shop is 33 cars a day; each car-repair unit consists of rivet-cutting shed housing 8 cars at a time, repair shop with 36 tear-down and 18 set-up positions, combined storeroom, office and welfare building.

RAILWAY SHOPS

GRINDING MACHINES FOR. Machine Tools for Railway Workshops. Ry. Gaz., vol. 40, no. 15, Apr. 11, 1924, pp. 544-546, 6 figs. Describes some electrically-driven grinding machines.

RAILWAY SIGNALING

A. C. SUPPLY WITH BATTERY RESERVE. The Application of Alternating Current Supply with Battery Reserve to Signal Systems, H. G. Morgan. Am. Ry. Assn., Signal Section Proc., Mar. 1924, pp. 698-705. Results obtained with various applications.

BENEFITS OF. How Signaling Has Helped Several Roads. Ry. Age, vol. 76, no. 20, Apr. 19, 1924, pp. 971-974. Prize papers received in contest arranged by Railway Age and Railway Signaling, as follows: Congestion Relieved by Signaling on the B. & M., J. D. Bourne; Increasing Track Capacity by Signaling, Gel. S. Pflasterer; Cost Saving Accomplished by Signals on the B. & O., J. C. Hoffman.

RAILWAY TIES

CONCRETE. Concrete Ties for Light-Traffic Track in France, Adam. Eng. News-Rec., vol. 92, no. 18, May 1, 1924, p. 761, 1 fig. Reduction of maintenance forces and cost follows replacement of wood ties by concrete ties and pairs of blocks.

RAILWAY TRACK

CONCRETE ROADBED. Trials of Concrete Roadbed on Northern Pacific Ry. Eng. News-Rec., vol. 92, no. 20, May 15, 1924, p. 858. Three types of concrete slab base indicate higher maintenance cost than that for ordinary ballasted track construction.

RAIL FIXING. The "V" System of Rail Fixing. Ry. Engr., vol. 45, no. 528, Jan. 1924, pp. 11-12, 7 figs. Description of system for rail attachment in track laying which combines merits of chair and Vignoles systems without disadvantages of either.

RAILWAY YARDS

ELECTRIC POWER SIGNALING. All-Electric Power Signaling Installation and Electric Apparatus, Feltham Yard, Southern Railway, W. J. Thorrowgood. Ry. Engr., vol. 45, nos. 531 and 532, Apr. and May 1924, pp. 126-132 and 140, and 157-163, 19 figs. Speedy operation of points and automatic track-circuit protection are features of shunting yard; track-circuit tests; electrical point detection; push-button signal frames; electric clocks; telephone communication.

REFRACTORIES

ELECTRIC-BRASS-FURNACE. The Electric Brass Furnace Refractory Situation, H. W. Gillett and E. L. Mack. Am. Ceramic Soc.—Jl., vol. 7, no. 4, Apr. 1924, pp. 288-299, 5 figs. Describes the three prominent types of electric brass furnaces, and outlines conditions which they impose on refractories. Limitations which properties of refractories place on applicability of the various furnaces, and lines along which development and improvement are most likely to take place. (Pub. by permission U. S. Bur. Mines.)

REFRIGERANTS

ETHYL CHLORIDE. Thermal Properties of Ethyl Chloride. Ice & Refrigeration, vol. 66, no. 4, Apr. 1924, pp. 347-348. Summary of report of results obtained by C. F. Jenkin and D. N. Shorthose of Univ. of Oxford, Eng. General physical and chemical properties; tables of saturated and superheated vapour.

REFRIGERATION

BRINE HOLD-OVER TANKS, HEAT TRANSFER IN. Heat Transfer in Brine Hold-Over Tanks, C. H. Herter. Refrig. Eng., vol. 10, no. 10, Apr. 1924, pp. 370-371 and 375. Describes three types of hold-over tanks; makes heat-transfer calculations.

NON-CONDENSABLE GASES. Non-Condensable Gases, B. E. Hill. Refrig. Eng., vol. 10, no. 10, Apr. 1924, pp. 372-375, 1 fig. Their causes and effects upon economical and efficient operation of an ice-making or refrigerating system.

ROADS, BITUMINOUS

MAINTENANCE. Methods of Maintaining Bituminous Roads, E. A. James. Eng. & Contracting (Roads & Streets), vol. 61, no. 4, Apr. 2, 1924, pp. 751-755, 2 figs. Experiences of Toronto and York Counties, Ontario, Roads Commission. Paper read at Ontario Road Supts. annual mtg., Feb. 25, 1924.

ROADS, CONCRETE

AGGREGATES, WEIGHING OF. Weighing Aggregates for Concrete Highway Pavement, R. W. Crum. Eng. & Contracting (Roads & Streets), vol. 61, no. 4, Apr. 2, 1924, pp. 730-735, 6 figs. Experiences of Iowa Highway Commission. Paper read at Am. Concrete Inst. Convention, Feb. 26, 1924.

CURING. The Curing Period for Concrete Roads, H. F. Clemmer. Can. Engr., vol. 46, no. 17, Apr. 22, 1924, pp. 455-457, 3 figs. Possibility of cutting down curing period; use of calcium chloride. Experiments conducted by Ill. Dept. Highways. Paper read at Am. Road Bldrs. Assn. convention.

SINGLE-TRACK. Single Track Concrete Highways, A. M. Jackson. Eng. & Contracting (Roads & Streets), vol. 61, no. 4, Apr. 2, 1924, pp. 718-721. Methods of construction and experiences in Brant County, Ontario. Paper presented at Conference on Road Construction, Toronto.

ROLLING MILLS

CONTINUOUS. Continuous Rolling-Mills: Their Growth and Development, Jos. P. Bedson. Iron & Steel Inst.—advance paper, no. 3, for mtg. May 1924, 18 pp., 6 figs. partly on supp. plates. Art as it was practiced 140 years ago; history of development; modern examples of continuous system. See (abstract) in Engineering, vol. 117, no. 3045, May 9, 1924, pp. 620-622, 7 figs.; also Iron Age, vol. 113, no. 21, May 22, 1924, pp. 1493-1495.

DEFECTIVE MATERIAL, DETECTION OF. Statistical Basis for Industrial Control, K. Daeves. Iron Age, vol. 113, no. 20, May 15, 1924, pp. 1441-1443, 3 figs. A "large numbers" method applied in Germany to metallurgy of iron; theory of collective subjects in relation to control of production; detection and control of defective material in rolling mill is claimed possible if certain statistical formulas or data are made use of. Translated from Stahl u. Eisen.

SHEET MILLS. Build Sheet Mill at Golden Gate. Iron Trade Rev., vol. 74, no. 21, May 22, 1924, pp. 1373-1375, 5 figs. Subsidiary of Metal & Thermit Corp. completes new six-mill sheet plant at South San Francisco; oil fuel used in furnaces.

Sheet Mill Represents Latest Practice, E. H. Werner. Forging—Stamping—Heat Treating, vol. 10, no. 4, Apr. 1924, pp. 153-158, 10 figs. New mill of Nat. Enameling & Stamping Co. at Granite City, Ill.; mill equipment and furnaces.

S

SCREW THREADS

COMPARATORS. The Wilson Projection Comparator for Screw Threads. Engineering, vol. 117, no. 3045, May 9, 1924, pp. 606-608, 6 figs. Devised for gaging screw threads and other similar solids of revolution.

CUTTING TOOLS. Position of Thread-cutting Tool and its Effect on Thread Form. Machy. (Lond.), vol. 24, no. 602, Apr. 10, 1924, pp. 54-55, 2 figs. Position of tool for external thread cutting; distortion produced in cutting internal threads; distortion of thread grooves having angular sides.

MEASUREMENT. Measuring Threads Accurately with Micrometers. Can. Machy., vol. 31, no. 18, May 1, 1924, pp. 31-32 and 51, 6 figs. Hints on accurate use of micrometers.

SEWAGE DISPOSAL

IMHOFF TANKS. Imhoff Tanks—Reasons for Differences in Behvaior, H. P. Eddy. Am. Soc. Civ. Engrs.—Proc., vol. 50, no. 5, May 1924, pp. 616-645, and (discussion) 706-723, 14 figs. Investigation to ascertain reasons for differences in operating results obtained from Imhoff tanks, in order that requirements for satisfactory results might be better understood.

SLUDGE. Developments in Sludge Disposal, J. Haworth. Can. Engr., vol. 46, no. 18, Apr. 29, 1924, pp. 481-482. Difficulties of problem are nearer an economical solution; drying sludge on ash beds, gauze bands and with centrifuges. Paper read before Assn. Mgrs. of Sewage Disposal Wks.

SEWERS

HAMILTON, CANADA. Homeside District Sewers, Hamilton, Ont., H. S. Philips and W. M. Johnston. Can. Engr., vol. 46, no. 18, Apr. 29, 1924, pp. 468-472, 14 figs. Description of sewerage system just completed and construction methods employed; storm water run-off coefficient studies; trunk system of sewers comprises five sections; reinforced-concrete and vitrified pipe employed; details of costs for different types of construction.

SHAFTS

WHIRLING. Internal Friction Theory of Shaft Whirling, A. L. Kimball, Jr. Gen. Elec. Rev., vol. 27, no. 4, Apr. 1924, pp. 244-251, 11 figs. Shows Kimball's theory of internal friction in shafts as cause of whirling; shows that internal friction due to bending may cause a shaft to whirl when rotating at any speed about first critical speed.

SHAFT SINKING

SOFT RUNNING GROUND, THROUGH. Shaft Sinking Through Soft Running Ground by Aid of the Francois Cementation Process, G. A. Voskule. Chem., Met., & Min. Soc. of S. Africa—Jl., vol. 24, no. 8, Feb. 1924, pp. 186-189, 1 fig. How problems in course of shaft sinking on Luipaardsvlei No. 10, on far Western Rand, by Coronation Syndicate, Ltd., were met.

SPRINGS

LEAF. Suspension. Automobile Engr., vol. 44, no. 189, May 1924, pp. 135-140, 30 figs. Recent improvements in laminated springs.

STEAM ENGINES

UNIFLOW. The Uniflow or Central Exhaust Engine, E. Dickinson. Inst. Mar. Engrs.—Trans., Mar. 1924, pp. 627-642, 11 figs. Principle and important features of engine; consideration of parts.

STEAM PIPES

HIGH-PRESSURE. Piping for High Pressure and Temperature, R. A. Fiske. Power Plant Eng., vol. 28, no. 8, Apr. 15, 1924, pp. 424-427, 5 figs. Shows effect of temperature upon tensile strength of 15 to 36-point carbon steel and on wrought-iron pipe; friction losses in superheated lines; pressure drop in fittings; heat transmission through pipe walls; joints for high-pressure steam lines.

STEAM POWER PLANTS

INDUSTRIAL PLANTS. Prime Movers for Industrial Plants, J. F. Ferguson. Power, vol. 59, no. 20, May 13, 1924, pp. 766-768, 1 fig. Comparison of various types of engines and turbines for use in industrial plants, with summary on economies and relative advantages.

PHYSICAL LAWS, PRACTICAL BEARING OF. The Bases of Efficiency in Power Production, G. F. Dewynter. Power Engr., vol. 19, no. 218, May 1924, pp. 166-168. Shows practical bearing of physical laws, especially in regard to steam power.

STEAM TURBINES

CHECKING CONDITION. Maintaining Impulse-Turbine Efficiency by Checking the Condition Curve, Rob. R. Walden. Power, vol. 59, no. 21, May 20, 1924, pp. 823-825, 2 figs. Various stage pressures at normal load indicate if turbine is in efficient state of internal damage or undue wear will alter these from normal.

EXHAUST AND LIVE STEAM, COST OF. Finding the Cost of Exhaust as Compared to Live Steam, C. E. Colburn. Power, vol. 59, no. 20, May 13, 1924, pp. 759-760, 1 fig. Why exhaust steam should be cheaper than live steam; typical examples.

HIGH-PRESSURE. High-Pressure Turbines. Engineer, vol. 137, no. 3566, May 2, 1924, pp. 489-490, 5 figs. Special turbines developed by Brown, Boveri & Co.

HIGH PRESSURE, SUPERHEAT, AND VACUUM. The Effect of High Pressure, Superheat and Vacuum on the Efficiency of Large Turbines, C. Sylvester. Elec. Times, vol. 65, no. 1692, Mar. 20, 1924, pp. 327-328, 3 figs. Effects above-mentioned are illustrated by diagrams.

IMPROVEMETS. Improvements in Steam-Turbine Construction (Neuerungen im Dampfturbinenbau), R. Palm. Glückauf, vol. 60, no. 9, Mar. 1, 1924, pp. 152-156, 3 figs. Comparison of different turbine types and discussion of new possible applications; details of recent improvements in turbine and auxiliary machines, and most important improvements in condenser plants.

METROPOLITAN-VICKERS. Recent Developments in Large Turbine Practice. World Power, vol. 1, no. 4, Apr. 1924, pp. 243-248, 6 figs. Improvements in design and construction introduced by Metropolitan-Vickers Elec. Co., tending to reduce steam consumption to minimum.

WHEELS, BUCKET WEAR IN. Bucket Wear in Modern Steam Turbine Wheels, R. M. Norstrom. Nat. Engrs., vol. 28, no. 5, May 1924, pp. 214-215, 6 figs. Factors in design and construction of modern steam turbines affecting wear and efficiency of buckets. Relative advantages of pressure-stage versus velocity-stage turbines in this respect.

STEEL

ELASTIC LIMIT. High Elastic Limit of Mild Steel and Its General Applications, G. W. Barr, F. G. Martin and A. T. Wall. Engineering, vol. 117, no. 3042, Apr. 18, 1924, pp. 510-511, 4 figs. Describes new mild steel which possess very high elastic limit, and discusses some of its possibilities. Paper read before Instn. Nav. Architects. See also Engineer, vol. 137, no. 3565, Apr. 25, 1924, pp. 443-444, 4 figs.

Forging Temperature. On the Forging Temperature of Steels, Kôtarô Honda. Iron & Steel Inst.—advance paper, no. 9, for mtg. May 1924, 5 pp., 4 figs. Investigation shows that in case of carbon steels, elongation-temperature curve has generally maxima and minima, and hence in process of forging low-carbon steels it is better to take every precaution against fall of temperature to 900 deg., where elongation is at minimum; in case of carbon steels, as elongation at ordinary temperature is greater than that at 200 to 300 deg. process of slowly stretching or bending a sample at room temperature rather than at 200 to 300 deg. is safeguard against fracturing.

Grain Growth. An Occurrence of Grain Growth in Steel, A. A. Blue. Iron Age, vol. 113, no. 18, May 1, 1924, pp. 1271-1273, 8 figs. Further results of carbonizing, hardening and drawing back; comparison with double quenching and drawing; band formations.

Hardened, Fundamental Defects. Some Fundamental Defects of Hardened Steels, L. Aitchison. Am. Soc. Steel Treating—Trans., vol. 5, no. 5, May 1924, pp. 491-503, 3 figs. Deals with certain properties of fully hardened steels that can only be regarded as being of nature of defects; discusses two such defects, namely, abnormally low value of limit of proportionality (elastic limit), and instability of volume which characterizes hardened steels; gives values of limit of proportionality in different hardened steels, and shows that there is very large difference between actual stress which produces some perpanent deformation in steel, and stress which is generally called yield point.

Inter-crystalline Fracture. Inter-crystalline Fracture in Steel, R. S. Williams and V. O. Homerberg. Am. Soc. Steel Treating—Trans., vol. 5, no. 4, Apr. 1924, pp. 399-412, 30 figs. Discusses abnormal type of failure in mild steel characterized by inter-crystalline cracking and produced by action of cathodic hydrogen or caustic soda solutions; effect of hydrogen on steel under tension and action of alkaline solutions on inclusions of known chemical composition artificially introduced.

Manganese Steel. *See Manganese Steel.*

Magnetic Analysis. Exploring Within the Steel, A. G. Ingalls. Sci. Am., vol. 130, no. 5, May 1924, pp. 316-317 and 366-367, 6 figs. How magnetic analysis indicates presence of flaws in rails and beams and hoisting cables.

Metallurgical Defects, Detection of. Detecting Metallurgical Defects in Steel, F. C. Thompson. Metal Industry (Lond.), vol. 24, nos. 10 and 11, Mar. 7 and 14, 1924, pp. 229-230 and 261-262, 4 figs. Methods of examination, and causes of troubles occurring.

Perforation, Effect of. Influence of the Method of punching Holes in Steel Bars (Note sur l'influence du mode de perçage des trous dans les barres en acier), A. de Marneffe. Revue Universelle des Mines, vol. 67, no. 1, Apr. 1, 1924, pp. 42-48, 7 figs. Results of tests carried out by author on samples with holes punched according to different methods, to determine effect of perforation on resistance of metal.

Stainless. Ferrous Alloys Resistant to Corrosion, B. D. Saklatwalla. Iron Age, vol. 113, no. 17, Apr. 24, 1924, pp. 1209-1213, 6 figs. Stainless iron for engineering uses; effect of adding other metals, particularly copper; direct process; future of stainless metallurgy. Paper read before Am. section of Soc. Chem. Industry.

STEEL CASTINGS

Cleaning-Cost Records. Keeps Record of Cleaning Costs, B. K. Price. Iron Trade Rev., vol. 74, no. 18, May 1, 1924, pp. 1165-1166 and 1169, 4 figs. Steel foundry pays grinder hands according to amount of metal removed; castings weighed before being delivered to grinder and again after being ground; production and wages stimulated.

Manufacture. Liquid Steel for Light Castings, J. A. Holden. Foundry Trade Jl., vol. 29, no. 402, May 1, 1924, pp. 367-368. Shows that "Stock" plant, in addition to turning out mild steel of good quality, can be adapted for making many types of special steels. Probable cause of porosity in electric process of manufacture.

STEEL, HEAT TREATMENT OF

Problems. Heat-treatment of Steel with Special Reference to Production, J. W. Urquhart. Machy. (Lond.), vol. 23, no. 600, Mar. 27, 1924, pp. 832-835, 6 figs. Machining difficulties with mild steels; difficulties resulting from high and deep carbon casings; typical case in carburizing steels; when double quench is necessary; micrographs; French and American high-temperature initial quenching; distinction between second quenching and hardening; destructive effect of excessive temperature; structure of carbon steel gears.

STEEL WORKS

Power Organization. Power Organization in the Steel Industry, B. Bannister and F. M. van Deventer. Mech. Eng., vol. 46, no. 5, May 1924, pp. 248-250. Authors show by comparison that value of fuels used and complexity of problems incident to operation of power system of representative steel works are of greater magnitude than for representative central station; these facts warrant existence of highly qualified organization for steel company in nature of power department; description of such organization and enumeration of benefits which should result.

STOKERS

Efficiency, Computation of. Computing Guaranteed Stoker Efficiency, H. F. Gauss. Power, vol. 59, no. 21, May 20, 1924, pp. 813-815, 1 fig. Computing stoker efficiency for given fuel, with discussion of various factors entering into problem; typical examples and convenient charts to facilitate work.

Types. Stokers an Essential of Power Plant Economy. Power House, vol. 17, no. 8, Apr. 20, 1924, pp. 24-31, 8 figs. Reasons, from manufacturers of principal types in use in Canada, for reduction in fuel costs and increase in efficiency of "mechanical firemen" effect.

STREAM POLLUTION

Control. Progress Report on Agencies for the Control of Pollution by Industrial Wastes. Am. Water Wks. Assn.—Jl., vol. 11, no. 3, May 1924, pp. 628-648. State and federal authorities on stream pollution control; joint undertakings along sanitary lines, within separate states; European boards for control of stream pollution; international aspects of problem of pollution of waters; conferences on industrial wastes pollution; legislation.

STREET RAILWAYS

Cars. Rear Exit Expedites Passenger Movement. Elec. Ry. Jl., vol. 63, no. 18, May 3, 1924, pp. 693-695, 5 figs. Describes one-man double-truck lightweight cars recently placed in service in Fort Wayne by Indiana Service Corp.; rear exit and inclosed steps.

STRESSES

Internal. Internal Stresses Rendered Visible (Les tensions intérieures rendues visibles), A. Mesnager. Technique Moderne, vol. 16, no. 6, Mar. 15, 1924, pp. 161-171, 52 figs. Discusses method based on theory of polarization which permits accurate measurements of internal stresses of a solid; applications of method.

SUBSTATIONS

Automatic. Automatic Substations for Industrial Plants, C. Lichtenberg. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, pp. 411-415, 7 figs. Principal types of electric-power transforming equipment to which automatic switching has been applied; automatic control of synchronous condensers, motor generators, converters, hydro-electric generators and feeders is treated in such manner as to furnish industrial engineers with data upon which to base designs of automatic stations for factories, mills, mines, shops and other kinds of industrial power supply.

SUPERHEATERS

Radiant-Heat. Operation of Radiant Heat Superheaters. Power Plant Eng., vol. 28, no. 10, May 15, 1924, pp. 528-529, 1 fig. Steam temperature varies slightly with percentage of CO_2; advantages of two-stage superheating.

SURVEYING

Land. Curve Problem Met in Land Surveying, J. T. Ransom. Can. Engr., vol. 46, no. 16, Apr. 15, 1924, pp. 430-431, 2 figs. New ready simple method for computing curved or chord frontages for a lot or series of lots of equal or varying widths with parallel sides on new subdivision surveys.

Hydrographic, Sounding Tube for. New Sounding Tube Devised for Hydrographic Surveying, G. T. Rude. Eng. News-Rec., vol. 92, no. 19, May 8, 1924, pp. 806-807, 1 fig. Capillary block is added feature which gives device developed by U. S. Coast & Geodetic Survey accuracy in measuring water depth.

T

TELEPHONY

Automatic. Some Notes on the Use of the Probability Theory to Determine the Number of Switches in an Automatic Telephone Exchange, M. Merker. Post Office Elec. Engrs.' Jl., vol. 16, Pt. 4, and vol. 17, Pt. 1, Jan. and Apr. 1924, pp. 347-362 and 27-50, 4 figs. Calculations.

TESTING MACHINES

Metal Strip. Notes on the Testing of Metal Strip, L. Aitchison and L. W. Johnson. Iron & Steel Inst.—advance paper, no. 1, for mtg. May 1924, 15 pp., 13 figs. Bend-testing machine; proof stress testing; simple proof stress extensometer. See (abstract) in Iron Trade Rev., vol. 74, no. 21, May 22, 1924, pp. 1361-1364, 5 figs.

TEXTILE MACHINERY

Looms. Textile Machinery. Engineering, vol. 117, no. 3043, Apr. 24, 1924, pp. 549-550, 4 figs. Describes exhibits of Rob. Hall & Sons at Brit. Empire Exhibition, including automatic loom, belt loom for production of cotton, camel hair or hemp driving belts, loom for making horse-hair cloth, and cloth-folding and measuring machine.

TINNING

Thickening of Hot Molten Tin. Origin and Prevention of the Formation of Undesirable Thickening of Hot Molten Tin (Ensttehung und Verhütung schädlicher Verdickungen bezw. Legierungen feuerflüssiger Zinnbäder), B. Haas. Zeit. für die Gesamte Giessereipraxis, vol. 45, no. 15, Apr. 12, 1924, pp. 33-34. Molten tin combines with iron, forming an alloy that thickens tin bath, impairs process of tinning, and wastes metal. It is recommended to tin vessels containing tin bath and to pickle and preheat articles to be tinned.

TRANSFORMERS

Current, Testing of. Ratio and Phase Error Tests on Current Transformer, G. W. Stubbings. Elec. Rev., vol. 94, no. 2421, Apr. 18, 1924, pp. 604-606, 9 figs. Detailed directions for carrying out tests for errors of current transformers by a method which is suited to resources of test rooms attached to ordinary a.c. supply undertakings, consisting in direct measurement of difference between ratio and phase errors of transformer under test and those of a standard transformer of same nominal ratio.

Oils. Dehydration and Testing Transformer Oils and Transformer, W. R. Bowker. Southern Engr., vol. 41, no. 2, Apr. 1924, pp. 54-56, 4 figs. Method for treatment of oils to eliminate moisture; identification of oils; insulation resistance test for transformers.

Transverter. The Transverter. Engineering, vol. 117, no. 3044, May 2, 1924, pp. 563-566, 17 figs. partly on supp. plate. Primary function of apparatus is to convert ordinary alternating into direct current at exceedingly high voltage for purposes of transmission, and to reproduce alternating current by converse operation at point where power is to be distributed or used; name is combination of words transformer and rotary converter; principle upon which design is based and its useful field.

TRANSPORTATION

Factory. Shop Transportation Economics, S. M. Lowry. Mgt. & Administration, vol. 7, no. 5, May 1924, pp. 533-538, 6 figs. Westinghouse Elec. & Mfg. Co.'s methods and results.

Great Lakes System. The Transportation System of The Great Lakes, Geo. A. Marr. Mich. Technic, vol. 37, no. 3, Mar. 1924, pp. 5-9, 22 and 32, 5 figs. Type of vessel employed; loading and unloading facilities; freight and passenger traffic.

Railway. The Place of Railway Transportation in the American Industrial Structure. Inst. Transport—Jl., vol. 5, no. 5, Mar. 1924, pp. 230-237. Report of Research Council of Nat. Transportation Inst. setting forth place of railway transportation in economic structure of America.

TUBES

Solid-Wall, Manufacture of. Making Solid Wall Tubes of Strip Steel. Iron Age, vol. 113, no. 19, May 1, 1924, pp. 1293-1294, 2 figs. New methods of manufacturing brass, copper and steel tubing by continuous process developed by Bundy Tubing Co., Detroit; material wide enough to give double thickness of wall; tinned before rolling; walls soldered together by heat.

TURBO-ALTERNATORS

Ventilation. An Experimental Study of Ventilation of Turbo Alternators, C. J Fechheimer. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, May 1924, pp. 416-423, 11 figs. End bell and pressure measurements; diverging intake to end bells; volume measurement and distribution; systems of ventilation; construction of turbo models; test results.

U

UNEMPLOYMENT

Seasonal. The Problem of Seasonal Unemployment in the Building Industry, Wm. S. Parker. Int. Labour Rev., vol. 9, no. 3, Mar. 1924, pp. 361-371. Indicates economic and civic waste involved in leaving building labour idle for several months in year and considers chief causes of seasonal unemployment.

V

VARNISHES

INSULATING. Varnishes in the Electrical Industry, R. T. Fleming and A. F. Steel. Wld. Power, vol. 1, nos. 3 and 4, Mar. and Apr. 1924, pp. 149-157 and 234-240, 6 figs. Mar.: Classification of varnishes; raw materials employed in manufacture of insulating varnishes; manufacture of varnishes; processes. Apr.: Finishing and bonding varnishes; tests on insulating varnishes.

VISCOSIMETERS

MERCURIAL. A Mercurial Viscosimeter Compensated for Density, F. M. Lidstone. Chem. & Industry, vol. 43, no. 14, Apr. 4, 1924, pp. 87T-88T, 1 fig. Describes apparatus which is modified form of viscosimeter described in previous issues of same journal.

VOLTMETERS

ALTERNATING-CURRENT. A Novel Alternating-Current Voltmeter, L. T. Wilson. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 5, May 1924, pp. 446-448, 5 figs. Improved thermo-volt meter, which may be used at all frequencies up to and including 1,000,000 cycles; retains usual high sensitivity of thermo-volt-meters so that it requires very small current—for full-scale deflection about 2 milliampers.

W

WATER FILTRATION

FLOCCULATION. Study of Flocculation Phenomenon with Microscope, H. R. Baylis. Eng. News-Rec., vol. 92, no. 18, May 1, 1924, pp. 768-769, 4 figs. Excess coagulation, toughness of floc and results of rapid mixing explained largely on physical basis.

WATER HAMMER

MODERATING EFFECTS OF. Water Hammer (Il colpo d'ariete), G. B. Ugolini. Annali dei Lavori Pubblici, vol. 62, nos. 1 and 2, Jan. and Feb. 1924, pp. 7-57 and 101-130, 51 figs. partly on supp. plates. Extended study descriving methods for lessening its harmful effects in pipe lines and means for utilizing it in form of sonic waves for power transmission.

WATER POWER

STEAM AND, RELATIVE COSTS OF. Relative Cost of Water and Steam Power. Power, vol. 59, no. 21, May 20, 1924, pp. 827-828. Construction costs and fixed charges for water plant are as rule twice as great as for steam plant and overbalance smaller operating expense; steam plant has greater reserve capacity and is in position to render better and safer service.

WATER SUPPLY

DISTRIBUTION SYSTEMS. Design and Maintenance of Distribution Systems, W. E. MacDonald. Fire & Water Eng., vol. 75, no. 11, Mar. 12, 1924, pp. 491-492, 514 and 516-517, 1 fig. Fire protection must be considered in planning system; location of gate valves and fire hydrants; detection of water waste. Excerpts from paper read before Can. Soc. Am. Water Wks. Assn. See also Contract Rec. & Eng. Rev., vol. 38, nos. 14 and 15, Apr. 2 and 9, 1924, pp. 329-331 and 360-362, 1 fig.

WATER TREATMENT

VENTURI SPEED CONTROLLER. Venturi Speed Controller for Dry Chemical Feed Devices, E. S. Smith, Jr. and C. G. Richardson. Eng. News-Rec., vol. 92, no. 20, May 15, 1924, pp. 844-845, 2 figs. Installation at mechanical filter plant, Parsons, Kan., varies chemical does according to rate of flow of raw water.

WATER WORKS

QUEBEC, CAN. New Water Works System, Batiscan, Que., R. Morrissette. Can. Engr., vol. 46, no. 16, Apr. 15, 1924, pp. 425-427, 3 figs. Notes on original woodpipe line; difficulties in financing new plant; wells sunk, pumps installed and concrete reservoir constructed.

WEIRS

MOVABLE. The Development of Movable Weirs (Die Entwicklung der beweglichen Wehre), Mangold. Bautechnik, vol. 2, nos. 7, 9 and 16, Feb. 8, 29 and Apr. 11, 1924, pp. 49-51, 68-72 and 164-167, 30 figs. Deals with different types of movable weirs, namely, sluice, pin, roller, drum, and segmental weirs.

WELDING

CHEMICAL ASPECTS. Some Chemical Aspects of Welding, J. R. Booer. Inst. Mar. Engrs.—Trans., Mar. 1924, pp. 642-659, 2 figs. It is shown that crux of chemical aspect is removal and prevention of foreign inclusions in welds, which are chief cause of failures.

ELECTRIC. *See Electric Welding; Electric Welding, Arc.*

FLUXES AND SLAGS IN. Fluxes and Slags in Welding, W. Sraragen. Am. Welding Soc.—Jl., vol. 3, no. 4, Apr. 1924, pp. 36-47. Digest of opinions of experts in America on action of these fluxes in electric arc, gas and resistance welding. Paper to be presented before joint session of Faraday Soc. and Inst. Metals.

OXY-ACETYLENE. *See Oxy-Acetylene Welding.*

WELDING METAL, HIGH-CARBON. High Carbon Welding Metal, C. A. McCune. Am. Welding Soc.—Jl., vol. 3, no. 3, Mar. 1924, pp. 22-33, 16 figs. Results of experiments made in connection with high-carbon welding materials.

WELDS

FLEXIBILITY VS. RIGIDITY. Design of Welds—Flexibility Versus Rigidity. Am. Welding Soc.—Jl., vol. 3, no. 4, Apr. 1924, pp. 15-27, 3 figs. Contains five short papers giving views of experts in each of the welding fields as to whether a weld in a structure should be designed more rigid or flexible than parts which it joins: Carbon Arc Welding, J. C. Lincoln; Gas Welding, S. W. Miller; Metal Arc Welding, C. J. Holslag; Resistance Welding, H. A. Woofter; and Thermit Welding, J. H. Deppeler.

WOOD

SOFT, MICROSCOPIC STRUCTURE. Microscopic Structure of Softwood. Eng. News-Rec., vol. 92, no. 20, May 15, 1924, p. 861, 1 fig. Presents drawing of cel structure of minute block of softwood.

WOOD PRESERVATION

PAINT AS PRESERVATIVE. Does Paint Preserve Wood? H. D. Tiemann. Sci. Am., vol. 130, no. 5, May 1924, pp. 314-315, 6 figs. Points out that paint is not proof against gradual absorption of moisture and will not prevent swelling or shrinkage, but it retards rate of absorption or loss of moisture through surface, thus giving time for partial equalization of moisture and reduetion of moisture gradient within piece.

WOOD-WORKING PLANTS

LUMBER CONSERVATION. Ford Upsets Precedents in Interest of Lumber Conservation. Automotive Industries, vol. 50, no. 16, Apr. 17, 1924, pp. 866-867, 4 figs. System employed at saw mills and woodworking plants of Ford Motor Co.; body parts are cut from unedged green slabs and are kiln-dried afterward; crooked logs, swell at butt and even branches 4 in. or more in diam., formerly discarded, are now utilized effectively.

WORKMEN'S COMPENSATION

LENGTH OF SERVICE. Compensating Employees for Length of Service. Soc. Indus. Engrs.—Bul., vol. 6, no. 3, Mar. 1924, pp. 6-8. Experience of a number of firms in dealing with the question of what is best method of compensating employees for length of service, especially when they are on piece rates and are engaged in work at which their speed and consequent earning power decreases with age.

SOCIAL INSURANCE AND. Workmen's Compensation and Social Insurance. Monthly Labor Rev., vol. 18, no. 4, Apr. 1924, pp. 152-184. Steadying worker's income—establishing unemployment insurance plans; recent workmen's compensation reports; old-age and invalidity pensions of French miners; English unemployment insurance and profit-sharing plan; recommendations of Brit. Imperial Economic Conference respecting workmen's compensation.

(*For August*)

A

ABUTMENTS

MOVEMENTS, ELASTICITY. The Movements of Abutments in Statically Indeterminate Supporting Structures (Widerlagerbewegungen bei statisch unbestimmten Tragwerken), A. Troche. Beton u. Eisen, vol. 23, no. 8, Apr. 20, 1924, pp. 97-99, 5 figs. Describes simple and readily comprehended formulation of equations of elasticity in abutment movements.

AIR COMPRESSORS

PORTABLE. Portable Compressors, F. A. McLean. Can. Min. Jl., vol. 45, no. 21, May 23, 1924, pp. 503-506, 5 figs. Notes on their use in mining and contracting.

AIRCRAFT

ACCESSORIES. British Aeronautical Accessories. Flight, vol. 16, no. 22, May 29, 1924, pp. 340-346, 20 figs. Brief descriptions of accessories put out by the various firms.

BRITISH INDUSTRY. The British Aircraft Industry. Flight, vol. 16, no. 22, May 29, 1924, pp. 302-304. Brief outline of past history and present activities of the various British aviation firms and aero engine firms, with a short reference to personalities responsible for conduct of firms.

AIRCRAFT CONSTRUCTION MATERIALS

DOPES AND FABRIC. Dopes and Fabric, J. E. Ramsbottom. Roy. Aeronautical Soc.—Jl., vol. 28, no. 161, May 1924, pp. 273-305 and (discussion) 305-314, 16 figs. Deals with dopes and fabric as far as they relate to problem of production of structural covering for aircraft which will maintain its tautness under varying conditions of humidity and also retain its strength after prolonged weathering.

AIRPLANE ENGINES

BRITISH TYPES. British Aero Engines. Flight, vol. 16, no. 22, May 29, 1924, pp. 331-339, 24 figs. Gives particulars such as power, weight, consumption, etc., of all modern British aero engines. Brief particulars of two small engines which have been proved suitable for light airplanes, and of one engine which is as yet experimental.

FUEL PUMP. The Bellows (Sylphon) Fuel Pump for Liberty, "12" and Wright "H" Engines, H. C. Osborne. Air Service Information Circular, vol. 5, no. 458, Mar. 15, 1924, 6 pp., 6 figs. Description of pump; overhaul; installation; precautions.

AIRPLANES

AILERON DISPLACEMENT, EFFECT OF. On the Distribution of Lift Along the Span of an Airfoil with Displaced Ailerons, M. M. Munk. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 195, June 1924, 8 pp., 4 figs. Effect of aileron displacement on distribution of lift along span is computed for elliptic wing of aspect ratio 6 for three conditions.

AILERON EFFICIENCY. Aileron Effectiveness, A. L. Morse. Air Service Information Circular, vol. 5, no. 454, Mar. 15, 1924, 8 pp., 19 figs. Wind-tunnel tests of U. S. A.-35 (half-span) airfoil to determine aerodynamic efficiency of ailerons, hinge lines of which were skewed at various angles with transverse or y-axis.

BEAMS, FORM FACTORS. Form Factors of Beams Subjected to Transverse Loading Only, J. A. Newlin and G. W. Trayer. Nat. Advisory Committee for Aeronautics—Report, no. 181, 1924, 19 pp., 8 figs. Tests to determine factors to apply to usual beam formula in order that properties of wood based on tests of rectangular sections might be used as basis of design for beams of any section, and to develop formulas for determining such factors.

CIVIL. British Civil Aircraft. Flight, vol. 16, no. 22, May 29, 1924, pp. 327-331, 3 figs. partly on pp. 324-325. Illustrates and describes commercial, racing, and school machines.

CORPS OBSERVATION. Notes on the Design of a Corps Observation Plane, H. F. Marshall. Aviation, vol. 16, no. 21, May 26, 1924, pp. 561-563, 2 figs. Exhaust silences is said to be desirable; cockpit arrangement; provision for overload; cruising range; landing speed; reporting on observation.

ECONOMY TESTS. Economy Test of the DH-4, W. F. Gerhardt and Rob. Anderson. Air Service Information Circular, vol. 5, no. 461, Apr. 1, 1924, 4 pp., 3 figs. Following development of satisfactory flowmeter installation for airplanes, application was made to determine economical operating conditions of DH-4; attempt to check results of previous economy tests, to ascertain effect of altitude adjustment, and to confirm theory of economical operation previously developed.

GLIDERS. Gliders: Their History and Uses, W. H. Sayers. Roy. Aeronautical Soc.—Jl., vol. 28, no. 161, May 1924, pp. 315-322. Review of development and discussion of possibilities.

WIND-TUNNEL TESTS. Wind Tunnel Test of the Original TA-4 with the Following Airfoils: USA-27C Large, USA-27C Small, Gottingen 387 and Gottingen 255, A. L. Morse. Air Service Information Circular, vol. 5, no. 455, Mar. 15, 1924, 27 pp., 31 figs. Test to determine aerodynamic characteristics.
Wind Tunnel Test of CO-2A Model Airplane, C. E. Archer. Air Service Information Circular, vol. 5, no. 453, Mar. 15, 1924, 17 pp., 12 figs. Results of test to obtain full data on lift, drag, *L/D*, and moment curve about center of gravity for angles from below zero lift to above maximum lift (with and without tail plane and with and without elevator).

ALLOY STEELS

DEVELOPMENT. Alloy Steel Development Rapid, Rob. Hadfield. Iron Trade Rev., vol. 74, no. 25, June 19, 1924, pp. 1627-1628, 1 fig. Traces steps in progress in making of alloy steels; advance from 1882 to present time hastened by increase in volume of research work. (Abstract.) Paper read before Brit. Empire Min. & Met. Congress.

ALLOYS

ALUMINUM. *See Aluminum Alloys;*
NICKEL. *See Nickel Alloys.*

ALUMINUM

CASTINGS. The Production of Aluminum Castings (Die Herstellung von Aluminiumguss), von Zeerleder. Metall u. Erz., vol. 21, no. 5, 1st Mar. issue, 1924, pp. 99-101. Describes recommendable working methods in aluminum foundries; melting arrangements; treatment of metal and production of molds.
MELTING, USE OF FLUXES IN. The Use of Fluxes in the Melting of Aluminium and its Alloys, W. Rosenhain and S. L. Archbutt. Foundry Trade Jl., vol. 29, no. 405, May 22, 1924, pp. 427-428. Paper read at symposium arranged by Faraday Soc., Inst. Metals, Inst. British Foundrymen and Non-Ferrous Research Assn.
PROPERTIES. Investigations of the Properties of Aluminum (Recherches faites au Laboratoire central d'Electricité sur les propriétés de l'aluminium), M Jouaust. Société Française des Electriciens—Bul., vol. 3, no. 30, Dec. 1923, pp. 663-669. Results of investigations carried out at Central Laboratory of Electricity on samples of French, American and English aluminum.

ALUMINUM ALLOYS

ALUMINUM-COPPER. The Heat Treatment of Light Alloys of Aluminum with Copper Base (Le traitement thermique des alliages légers d'aluminium à base de cuivre), A. Portevin and F. Le Chatelier. Revue de Métallurgie, vol. 21, no. 4, Apr. 1924, pp. 233-246, 14 figs. Gives characteristics of alloys containing magnesium and those containing no magnesium, and describes new process of heat-treating alloys without magnesium; influence of hardening temperature; mechanical properties of alloys, etc.; summary of advantages of alloy without magnesium. Bibliography.
METALLOGRAPHY. Metallography of Sand Cast Aluminum Alloys, A. J. Lyon and S. Daniels. Air Service Information Circular, vol. 5, no. 449, Mar. 1, 1924, 19 pp., 54 figs. Defines technique employed in metallography of aluminum and its alloys by Material Section, Engng. Div., Air Service; illustrates and describes common constituents and characteristic micro-structure of cast-aluminum alloys used by Air Service.
PRODUCTION. History of Light Aluminum Alloys and Actual Status of Their Production (Historique des alliages légers d'aluminium et état actuel de leur fabrication), L. Guillet. Génie Civil, vol. 84, nos. 13, 14 and 15, Mar. 29, Apr. 5 and 12, 1924, pp. 298-303, 319-321 and 356-359, 9 figs. Traces history of development and describes latest improvements.

AMMONIA

BY-PRODUCT. By-Product and Synthetic Ammonia, Gas Engr., vol. 40, nos. 574 and 575, Feb. and Mar. 1924, pp. 24-25 and 48- 9. Account and criticism of modern methods of by-product ammonia production. Discusses potential ammonia in coal, ammonia per ton carbonized, excessive addition of lime, heat-interchange devices, and ammonium bicarbonate and chloride and their possibilities as commercial fertilizers.
SYNTHETIC. Catalyst Bombs for Synthetic Ammonia Production, E. K. Scott. Chem Age (Lond.), vol. 10, no. 256, May 10, 1924, pp. 482-483, 3 figs. Describes Haber-Bosch, Claude, and Casale catalyst bombs; catalyst material.

AMMONIA CONDESNERS

SUPERHEAT. Superheat at the Condenser, J. E. Starr. Ice and Refrigeration, vol. 66, no. 5, May 1924, pp. 461-462. Discussion of determination of amount of superheat in ammonia at condenser; effect of power requirements; a possible way of utilizing superheat by absorption system; means of reducing superheat.

APPRENTICES, TRAINING OF

CO-OPERATIVE PLAN. Making the Skilled Mechanic of Tomorrow, F. A. Pope. Indus. Mgt. (N. Y.), vol. 67, no. 6, June 1924, pp. 363-367, 5 figs. Co-operative plan for apprentice training in metal trades, developed by Nat. Metal Trades Assn.
FRANCE. The Training of Apprentices (L'Apprentissage). Société des Ingénieurs Civils—Mémoires et Compte Rendu des Travaux, vol. 76, nos. 10-12, Oct.-Dec. 1923, pp. 1172-1281. Account of what has been accomplished in 13th Ward of Paris, by Ch. Quillard; laws and organization of Syndicate of Mechanics, Boiler Makers and Foundrymen with regard to training of apprentices and vocational instruction, J. Quantin; training of apprentices from pedagogical viewpoint, M. Loffet; training of shop apprentices in its relation to rational organization of work, J. Androuin; rapid development of apprenticeship, M. Lacoin; the crisis in apprenticeship and its remedy, and technical instruction, J. Hiernaux; training of apprentices at steel works of Schneider, Jaquet & Cie, Strasbourg, and Cockerill Works, Belgium, E. Kern; theoretical vocational training and education during period of apprenticeship, M. Bostsarron; apprenticeship in the electrotechnical industry, Geo. Westercamp; school for training of apprentices at works of Dion-Bouton, M. Winder.
RAILWAYS. Training Apprentices, H. L. Shipman. Car Foremen's Assn.—Proc., vol. 18, no. 7, Apr. 1924, 15 pp. between pp. 12 and 52 (including discussion). Basic elements that must be given consideration before an apprenticeship system is undertaken by a railroad. Suggestions regarding establishment of system and training of apprentices.

ARMATURES

RECONNECTING D. C. Reconnecting Direct-Current Armature—Fractional-Pitch Windings, A. C. Roe. Power, vol. 59, no. 25, June 17, 1924, pp. 983-984, 6 figs. Effects of reducing pitch of armature coils and how chording coils may make it possible to use coils that have been made too short for full pitch.

AUTOMOBILE ENGINES

CONSTANT-COMPRESSION. Economy of Fuel Attained by Means of Constant Compression Engine. Automotive Industries, vol. 50, no. 24, June 12, 1924, p. 1278, 1 fig. Gas mixture and air are drawn in successively so that they will remain on different levels of combustion chamber, and so that stratification replaces turbulence of charge in Burtnett 4-cycle engine.

EIGHT-IN-LINE. Falls Eight-in-Line Has Crank-case and Cylinders Cast Integral. Automotive Industries, vol. 50, no. 22, May 29, 1924, pp. 1182-1183, 2 figs. Valve in head-type engine has five-bearing crankshaft lubricated by pressure, integral inlet manifold, and two additional cylinders have same bore and stroke as six of same make.

AUTOMOBILE INDUSTRY

S. A. E. STANDARDS REPORT. Standards Committee Division Reports. Soc. Automotive Engrs.—Jl., vol. 14, no. 6, June 1924, pp. 625-640, 15 figs. Gives following Division Reports: Parts and fittings; agricultural power equipment; ball and roller bearings; lighting; non-ferrous metals; screw threads; springs.

AUTOMOBILE MANUFACTURING PLANTS

MACHINE TOOLS FOR. Large Fixtures and Tools for Building Twin City Tractors, H. Campbell. Am. Mach., vol. 60, no. 25, June 19, 1924, pp. 907-910, 13 figs. Details of operations on large automotive units at plant of Minneapolis Steel & Machy. Co., Minneapolis.

AUTOMOBILES

BRITISH EMPIRE EXHIBITION. Cars at the British Empire Exhibition. Autocar, vol. 52, no. 1489, May 2, 1924, pp. 785-792, 46 figs. Summarized specifications of models on view; 80 cars, ranging from 749-cc. to 7413-cc. cylinder capacity, represent 47 different manufacturers.
CHASSIS LUBRICATION. Chassis Lubrication. Soc. Automotive Engrs.—Jl., vol. 14, no. 6, June 1924, Contains following papers; Notes on Chassis Lubrication and Maintenance, A. F. Masury, pp. 641-646, 14 figs.; Magazine Oiling System of Chassis Lubrication, C. T. Myers, pp. 646-648, 5 figs.
CONSTRUCTION, CAST IRON IN. Cast-Iron in Motor Car Construction, F. H. Hurren. Foundry Trade Jl., vol. 29, no. 405, May 22, 1924, pp. 423-426. Considers technical and metallurgical aspects of production of automobile parts, and extent to which science can assist.
STEERING-GEAR ANALYSIS. Steering-Gear Analyses, F. F. Chandler. Soc. Automotive Engrs.—Jl., vol. 14, no. 6 June 1924 pp. 585-590 and 648, 8 figs. Describes set of automatic recording instruments being developed by author assisted by H. A. Huebotter, that will record not only physical effort needed to steer automobile, but simultaneously, forces and shocks imposed upon entire steering system, so that such records will constitute basis for steering-system design; study of helix characteristics; possibilities of producing variable-ratio helix that gives great mechanical advantage in extreme positions.
TWO-WHEELED. A Revolutionary Proposal, P. Schilovsky. Autocar, vol. 5 , no. 1490, May 9, 1924, pp. 833-835, 3 figs. Advantages and possibilities of gyroscopic two-wheeled car, and its main principles of design and operation. Details of an experimental model.

AVIATION

AERIAL TRANSPORTATION. Air Transport and Its Uses, G. H. Thomas. Inst. Transport—Jl., vol. 5, no. 5, Apr. 1924, pp 245-256 and (discussion) 256-261, 3 figs. Shows that this form of transport is of vital interest to British trade and commerce.

B

BATTERIES

PRIMARY. An Efficient Primary Cell. Engineer, vol. 137, no. 3,571, June 6, 1924, pp. 636-637, 6 figs. New cell, which is invention of Belgian engineer, L. Darimont, is of two-fluid type.

BEARINGS

LUBRICATION. Some Types and Applications of Babbitt, Ball and Roller Hanger Bearings, F. E. Gooding. Indus. Engr., vol. 82, no. 5, May 1924, pp. 229-231 and 257, 9 figs. Methods of lubricating bearing surfaces and reducing friction losses.
OIL ENGINES. White Metal Bearings for Oil Engines, F. J. Taylor. Gas and Oil Power, vol. 19, no. 225, June 5, 1924, pp. 155-156, 2 figs. Causes and prevention of engine-shaft failure.
USE AND MAINTENANCE. Possible Improvements in Bearing Service, G. A. Van Brunt. Indus. Engr., vol. 82, no. 6, June 1924, pp. 264-270 and 304, 11 figs. Manufacturers of sleeve, ball and roller bearings give their viewpoint on things to be considered in connection with use and maintenance of bearings.

BEARINGS, BALL

MACHINE TOOLS, APPLICATION TO. Application of Ball Bearings to Machine Tools. Machy. (N. Y.), vol. 30, no. 10, June 1924, pp. 776-781, 9 figs.; also Machy. (Lond.), vol. 24, no. 609, May 29, 1924, pp. 257-262, 9 figs. Method of applying ball bearings to lathes, grinding machines, drilling-machine spindles, and transmission shafts.

BEARINGS, ROLLER

TAPERED. Production and Application of Tapered Roller Bearings. Machy. (Lond.), vol. 24, nos. 604, 605 and 606, Apr. 24, May 1 and 8, 1924, pp. 108-111, 129-131 and 161-165, 21 figs. Timken bearing and its production by Brit. Timken Ltd., Birmingham, Eng.

BELTING

INSTALLATION AND CARE. Installation and Care of Belting, C. O. Streeter. Paper, vol. 34, no. 3, May 8, 1924, pp. 90-91, 11 figs. Points in the purchasing of leather belting; approved types of belt drives; aligning and care of belts to avoid injury.

BLAST-FURNACE GAS

CLEANING. The Cleaning of Blast Furnace Gas. G. M. Hohl. Iron Age, vol. 113, no. 22, May 29, 1924, pp. 1563-1564. Savings from clean gas; preliminary cleaning; heat saved by dry cleaned gas; flue dust as washer sludge. (Abstract.) Paper read before Am. Iron and Steel Inst.
COMPOSITION. Composition of Blast-Furnace Gas (Sur la composition des gaz de hauts-fourneaux), J. Seigle. Académie des Sciences—Comptes Rendus, vol. 178, no. 17, Apr. 22, 1924, pp. 1426-1429, 2 figs. With aid of graphic presentation author discusses possible proportions of carbon dioxide and monoxide in gas at mouth of blast furnace, Gruner's ideal point, extreme values of volume of oxygen reduced per kg. of carbon, possible compositions of gas produced when dry air containing 20 per cent of oxygen, or air enriched in oxygen, or pure oxygen is used for blast, etc.

BLAST FURNACES

DESIGN, PROGRESS IN. Progress in Blast Furnaces (Considérations sur les progrès réalisés dans les hauts-fourneaux), R. Jordan. Revue de Métallurgie, vol. 21, nos. 3 and 4, Mar. and Apr. 1924, pp. 127-142 and 223-232, 20 figs. Critical examination of problems and solutions relating to progress in blast-furnace design during last 20 years. Mar.; Charging apparatus. Apr.: Determination of cross section; details of construction.
FUEL REGULATION. Uniform Coking Coal is Needed, W. Mathesius. Iron Trade Rev., vol. 74, no. 22, May 29, 1924, pp. 1422-1424, 3 figs. Regulation of blast-furnace fuel in accordance with principles of iron-ore trade; author urges analysis as basis of accounting for furnace fuel. (Abstract.) Paper presented before Am. Iron and Steel Inst.

BOILER EXPLOSIONS

LOCOMOTIVE BOILERS. Low Water Causes Fatal Crown Sheet Explosion. Boiler Maker, vol. 24, no. 5, May 1924, pp. 136-138, 3 figs. Report of Bur. of Locomotive Inspection investigation of A. T. & S. F. Locomotive 1455 disaster which occurred on Feb. 13, 1924.

BOILER FURNACES

AIR PREHEATERS. The Preheating of Combustion Air (Le préchauffage de l'air de la combustion), Roszak. Société des Ingénieurs Civils—Mémoires et Compte Rendu des Travaux, vol. 76, nos. 10-12, Oct.-Dec. 1923, pp. 1145-1170, 8 figs. Study of question as to whether preheating of air of combustion offers same advantage when applied to evaporators as to metallurgical furnaces; derivation of calorific equation and analytical relation between preheating of air and increase of combustion temperature; advantages and disadvantages of process.

GROUND FIREBRICK FOR REPAIR. Ground Firebrick for Furnace Repair, Jos. Harrington. Power, vol. 59, no. 25, June 17, 1924, pp. 976-978, 10 figs. Results from experience with special bond made principally from old firebrick for laying up new walls and of mortar for facing or patching; thick joints of this bond show saving of 35 per cent over thin cement joint construction.

OIL-FIRED. Efficiency in Oil Burning Installations, F. A. Rothwell. Power Plant Eng., vol. 28, nos. 10 and 12, May 15 and June 15, 1924, pp. 526-528 and 639-641, 3 figs. May 15: Furnace design and location of burners. June 15: Selection of burners; method of supplying fuel to burners; necessary auxiliary equipment; operation of fuel-oil-burning furnace.

OPERATION. The Economical Operation of Boiler Furnaces, R. June. Power House, vol. 17, no. 9, May 5, 1924, pp. 21-22, 5 figs. Stresses fact that development of flat suspended arch has been an important factor in reducing maintenance costs.

BOILER PLANTS

IRON AND STEEL INDUSTRY. The Generation and Utilization of Steam in the Iron and Steel Industry, J. A. Hunter. Mech. Eng., vol. 46, no. 6, June 1924, pp. 325-328 and 342, 3 figs. Equipment employed in iron and steel industry for generating and using steam; quantities and cost of fuel, and cost of converting heat in fuel to steam; present-day tendencies toward design and size of equipment, and refinements in control; describes two of latest installations; probable savings which could be made if all of steam required in industry were made and consumed in most efficient apparatus now in use.

BOILER ROOMS

EFFICIENCY IN. Boiler-Room Practice, J. Bruce, Elec. Rev., vol. 94, nos. 2424 and 2425, May 9 and 16, 1924, pp. 736-738 and 809-811, 3 figs. Furnace efficiency, excess air, and critical point of combustion.

BOILERMAKING

LOCOMOTIVE. Building the Longest Locomotive Boilers in the World. Boiler Maker, vol. 24, no. 5, May 1924, pp. 127-133, 13 figs. Details of construction of boilers recently built by Am. Locomotive Co. for an order of 25 simple 2-8-8-2 Mallet locomotives for Chesapeake & Ohio R. R.; overall length of boiler 56 ft. 11 1-8 in.; 205 lb. steam pressure.

BOILERS

BENSON HIGH-PRESSURE. *See Steam Generators, Benson High-Pressure.*

COMBUSTION CONTROL. Combustion Control for Boilers, R. J. S. Piggott. Combustion, vol. 10, no. 6, June 1924, pp. 432-436. General discussion of subject; what combustion control should do, what it usually does, what it can do. Paper read before A.S.M.E.

COMBUSTION PROBLEMS CALCULATION. The Relation of Ash Pit Loss to Flue Gas Analysis, R. Brown. Combustion, vol. 10, no. 6, June 1924, pp. 436-438, 2 figs. Two charts which furnish short-cuts in boiler calculations.

LOCOMOTIVE. *See Locomotive Boilers.*

PRIMING OF. Priming of Boilers, A. A. Pollitt-Gas Engr., vol. 40, no. 576, Apr. 1924, pp. 74-76, 1 fig. Discusses problem of priming and necessity for maintaining low concentrations in feedwater.

SCALE REMOVAL. Boiler Tubes and Boiler Scale. Eng. and Boiler House Rev., vol. 37, no. 10, May 1924, pp. 370 and 372-373, 3 figs. Some of the most modern methods of scale removal.

BOMBING

AERIAL. Aerial Bombing, A. H. Hobley and H. B. Inglis. Mech. Eng., vol. 46, no. 6, June 1924, pp. 309-316, 8 figs. Early practice and conditions; bombing moving targets; theory of bomb trajectory; principles of various sights; ground-speed determination; sources of error and methods of overcoming them.

BREATHING APPARATUS

SELF-RESCUER. The Carbon Monoxide Self-Rescuer, A. C. Fieldner, S. H. Katz and D. A. Reynolds. U. S. Bur. Mines, Reports of Investigations, No. 2591, Apr. 1924, 10 pp., 5 figs. on supp. plates. Describes construction and details of M.S.A. self-rescuer, a pocket-size respirator which protects wearer from air contaminated with poisonous carbon monoxide gas, and discusses its performance under test conditions.

BRIDGES, CONCRETE

ARCH. Reinforced Concrete Bridge of 432 Ft. Span. P. Calfas. Concrete and Constructional Eng., vol. 19, no. 5, May 1924, pp. 281-288, 5 figs. Describes new bridge which replaces old road bridge connecting St. Pierre-du-Vauvray with Andé across Seine, consisting of two arches imbedded in abutments and having a clear span of 432 ft. 6 in.; rise above level of spandrel is 82 ft.

Six-Span Concrete Arch Highway Bridge at Danville, H. H. Edwards. Eng. News-Rec , vol. 92, no. 21, May 22, 1924, pp. 896-898, 5 figs. Bridge is 1037-ft. reinforced-concrete structure, consisting of 6 arches and 7 short approach spans; details of foundation and arch centering.

BRIDGES, HIGHWAY

TORONTO, CAN. Construction of Gerrard Street Bridge, J. S. Burgoyne and G. Alison. Can. Engr., vol. 46, no. 23, June 3, 1924, pp. 573-575, 6 figs. Further details describing construction of new highway bridge over River Don at Toronto; erection of steel grillages for steel spans; falsework for arches; laying concrete deck and sidewalk slabs.

BUSES

TROLLEY. The Trolley-Bus Line between Modane and Lanslebourg (France) (La ligne d'electrobus de Modane à Lanslebourg), A. Chardin. Industrie des Tramways, vol. 18, no. 206, Feb. 1924, pp. 41-46, 4 figs. Brief description of installations, including two substations, trolley lines, passenger buses and trucks; results of tests and economic advantages of system.

BUSHINGS

CAST-IRON. Close Work on a Cast Iron Bushing, D. T. Hamilton. Am. Mach., vol. 60, no. 25, June 19, 1924, pp. 915-917, 5 figs. Accurate guide bushing for gear-shaper spindle; tolerance of 0.0002 in. in bore; insuccessful methods; grinding operations.

C

CABLES, ELECTRIC

CHARGE AND DISCHARGE. Cable Charge and Discharge, Chas. P. Steinmetz. Am. Inst. Elec. Engrs.—Jl , vol. 43, no. 6, June 1924, pp. 525-530. It is shown that phenomenon of "soaking in of charges" or "electrification of cable" is true electric-circuit transient, has nothing to do with hysteresis effects, but is result of inductance and capacity, that is, is in no essential different from usual rapid starting or stopping transient of ordinary circuit, except that it is many thousands of times slower; conclusions are derived, some of which may be pertinent with regard to mechanism of breakdown of insulation.

HIGH-TENSION. High-Voltage Cables. Elec. World, vol. 83, no. 21, May 24, 1924, pp. 1087-1091, 2 figs. Paper-cable insulation, cable splices and splicing methods and cable operation. Report presented before Nat. Elec. Light Assn.

CAISSONS

SINKING. Slim Pneumatic Caissons Penetrate Stone-Filled Crib, C .S. Rindsfoos. Eng. News-Rec., vol. 92, no. 22, May 29, 1924, p. 936, 1 fig. In building foundations for new grain elevator for state of New York, 57 caissons were sunk 45 ft. through riprap, in 70 days, some as close together as 12 in.

CALCULATING MACHINES

COST ACCOUNTING. The Mechanical Compilation of Costs. Eng. Production, vol. 7, no. 140, May 1924, pp. 139-141, 5 figs. Describes machines in connection with Powers system, and their performance; system where one clerical entry is required to produce a master from which all subsequent work may be done by mechanical means.

CANALS

PANAMA. Salt Water Climbs the Locks of the Panama Canal, R. Z. Kirkpatrick. Eng. News-Rec., vol. 92, no. 22, May 29, 1924, pp. 935-936, 1 fig. Up-lockage brings seawater into Miraflores Lake; tests of salinity; conditions controlling increase.

CARBON MONOXIDE

POISONING. Tests of a Commercial Solution Used to Reduce the Hazard of Co Poisoning in Garages. A. C. Fieldner and W. P. Yant. U. S. Bur. Mines, Reports of Investigations, No. 2594, Apr. 1924, 4 pp. Results of analysis made of a compound sold under a trade name for which claims are reported to have been made regarding its efficacy in reducing CO poisoning in automobile garages, to determine its power to absorb, oxidize, or destroy CO10, 810 8.

CAR WHEELS

MANUFACTURE. The Manufacture of Railway Tires. Engineer, vol. 137, no. 3570, May 30, 1924, pp. 602-603. Account of work done in Sheffield, England, 50 years ago.

CARS, FREIGHT

FOUNDATION BRAKE GEAR. Freight Car Foundation Brake Design, W. G. Stenason. Ry. Rev., vol. 74, no. 21, May 24, 1924, pp. 923-924, 5 figs. Describes form of foundation brake gear, with slack compensating attachment, that has given very satisfactory service. (Abstract.) Paper presented before Air Brake Assn.

REBUILDING CONTEST. Box Cars Rebuilt in Record Time, D. & H. Co. Ry. Rev., vol. 74, no. 21, May 24, 1924, pp. 913-921, 12 figs. At freight-car rebuilding contest conducted at Oneonta. N. Y., entire superstructure of 60,000-lb. capacity, steel underframe, double-sheathed box car was rebuilt in record time of 52 man-hours.

CARS, PASSENGER

ORIENTAL LIMITED. New Equipment for Oriental Limited Trains. Ry. Age, vol. 76, no. 26, May 31, 1924, pp. 1303-1305, 8 figs. Great Northern cars of improved design to be placed in service between Chicago, Seattle and Portland; equipment of each train will consist of dynamo baggage car, smoking car, first-class Pullman tourist car, dining car, pullman sleepers and observation car.

STEEL. The Passenger Car Up-to-Date, C. E. Barba. New Eng. Railroad Club, Apr. 8, 1924, pp. 70-81 and (discussion) 81-103. Discussion of construction of steel passenger cars. Ideals to be considered in up-to-date equipment. Tentative specification for painting.

CASE-HARDENING

PREVENTION BY COPPER PLATING. Prevention of Case-Hardening by Copper Plating, J. C. McCullough and O M. Reiff. Indus. and Eng. Chem., vol. 16, no. 6, June 1924, pp. 611-613, 4 figs. Selective case-hardening by carbon-pack method may be secured by protecting desired parts with copper plating; method can always be relied upon when copper plating is perfect.

CAST IRON

CHEMICAL COMPOSITION, INFLUENCE OF. Influence of Chemical Composition on Cast Iron. Metal Industry (Lond.), vol. 24, nos. 14, 15, 16, 17, 18 and 19, Apr. 4, 11, 18, 25, May 2 and 9, 1924, pp. 331-333, 355-356, 379-380, 403-405, 431-432 and 455-457, 3 figs. Influence of silicon, sulphur, phosphorus, and manganese; carbon forms and changes under the various conditions of chemical composition and temperature influences.

COOLING EFFECTS IN. Some Cooling Effects in Cast Iron and Their Correction, R. T. Rolfe. Metal Industry (Lond.), vol. 24, nos. 21, 22 and 23, May 23, 30 and June 6, 1924, pp. 501-502, 525-526 and 551-552, 2 figs. General causes giving rise to internal stresses in castings and methods of relieving them. Particulars of a series of tests carried out into annealing temperatures. Typical cases in which annealing is resorted to.

GRAPHITIC SOFTENING. The Graphitic Softening of Cast Iron, J. W. Shipley and I. R. McHaffie. Indus. and Eng. Chem., vol. 16, no. 6, June 1924, pp. 573-575, 6 figs. Graphitic softening is produced by retention within residual structure of cementite-phosphide cutectic and graphite of some of products of corrosion; wrought iron, steel, and some cast irons corrode out of face and hole, owing to absence of supporting non-corrodible framework.

PEARLITIC. Pearlitic Cast Iron, K. Emmel. Mech. Eng., vol. 46, no. 6, June 1924, pp. 352-353. Methods of production; photomicrographs and structure of piston rings cast in pearlitic metal. Translated and abstracted from Stahl u. Eisen, vol. 44, no. 13, Mar. 27, 1924.

Pearlitic Cast Iron. Metal Industry (Lond.), vol. 24, no. 20, May 16, 1924, pp. 477-478. Comments on recent work, including process of Diefenthaler and Sipp, iron-carbon conditions, mechanism of change on slow-cooling, etc.

CEMENT

ALUMINA. Aluminous Cement in Practice, T. J. Gueritte. Surveyor & Mun. & County Engr., vol. 65, no. 1685, May 2, 1924, pp. 425-426. Deals with practical applications, including practical precautions, effect of temperature, shrinkage, and action of chemicals.

RAPID-HARDENING SLAG. A New Cement (Un nouveau ciment). Revue des Matériaux de Construction et de Travaux Publics, no. 172, Jan. 1924, pp. 1-4 3 figs. Describes new rapid-hardening slag cement and compares its resistance with that of other slag cements commonly employed, showing economy of former.

STORAGE, EFFECT OF. Effect of Storage of Cement Up to Five Years. Eng. News-Rec., vol. 92, no. 22, May 29, 1924, pp. 931. Results of tests of storage in large and small lots, for different times and varying conditions of protection. (Abstract.) Revised Bulletin no. 6, issued by Structural Matls. Research Laboratory.

CEMENT MILLS

PULVERIZED COAL, USE OF. Use of Pulverized Fuel in the Cement Industry, L. N. Duryea. Nat. Engr., vol. 28, no. 6, June 1924, pp. 277-279, 5 figs. Experiences in Portland cement industry point to new economies in boiler house management. Pumping coal through pipes; accident precautions necessary in plants operated with powdered fuel; power requirements in cement industry and latest methods in utilizing waste heat.

CENTRAL STATIONS

ABANDONED, IDLE-EQUIPMENT UTILIZATION. Utilization of Abandoned Steam Power Plants, H. A. Woodworth. Nat. Engr., vol. 28, no. 6, June 1924, pp. 262-264, 3 figs. Constructive suggestion for making use of idle equipment at present located in the many abandoned power plants throughout the country.

PRIVATE PLANT, VS. Central-Station Power Versus the Private Plant, H. C. Thuerk. Elec. World, vol. 83, no. 22, May 31, 1924, pp. 1140-1141. Disadvantages of isolated plant which are sometimes overlooked in comparing relative merits of two sources of power.

SERVICE IMPROVEMENT. Improving Central Station Service by the Application of Current-limiting Reactors to Distribution Feeders, D. K. Blake. Gen. Elec. Rev., vol. 27, no. 6, June 1924, pp. 361-368, 17 figs. Decided advantages that are obtainable by installation of current-limiting reactors in distribution feeders.

UNIT COSTS. Power Plant Unit Costs and Their Engineering Significance, L. Helander. Elec. Jl., vol. 21, no. 6, June 1924, pp. 285-290, 4 figs. Presents unit costs intended to be a guide to engineer undertaking a preliminary survey of desirability of expanding capacity of an existing power station, of building a new station, or of entering into an agreement with an existing power plant for purchase of power, and particularly to assist engineers who are not continuously engaged in power-plant erection but find it, necessary to make occasional surveys of power-generating costs.

CHARTS

PRODUCTION REPORTS. Charts for Report Purposes, H. N. Stronck. Mgt. and Administration, vol. 7, no. 6, June 1924, pp. 705-709, 6 figs. Treatment of large production charts; reproductions of charts; photostat reproduction of special material; lettering of charts; chart showing percentage fluctuations; arrangement of charts in report.

CITY PLANNING

HIGHWAYS AND TRAFFIC. Highways and Traffic, F. S. Besson. Soc. Automotive Engrs.—Jl., vol. 14, no. 6, June 1924 ,pp. 594-601, 18 figs. Dividing streets into three classes, rapid transit and local streets and traffic highways, author defines these terms and, using original plan of City of Washington and present street conditions there as basis of illustration, comments thereon and shows how important adequate city planning is in its bearing on traffic problem and what great foresight it requires.

STREET PLANNING. Street Planning for Relief of Congestion at Bridges, Chas. W. Leavitt. Eng. News-Rec., vol. 92, no. 23, June 5, 1924, pp. 974-975. Widening of approaches; variable-speed traffic zones; separation of rapid-transit lines recommended. (Abstract). Paper read before Nat. Conference on City Planning.

CLUTCHES

RING. Expanding and Contracting Ring Clutches, A. Clegg. Machy. (N. Y.), vol. 30, no. 10, June 1924, pp. 793-796, 6 figs. Expanding ring clutch with unusual adjustment; design operated by toggle levers; Johnson expanding ring clutch; contracting ring clutch.

COAL

CARBONIZATION. Practical Coal Carbonization, F. W. Sperr, Jr. Mech. Eng., vol. 46, no. 6, June 1924, pp. 329-333, 4 figs. Discusses high-temperature and low-temperature carbonization with special reference to American conditions.

Thermal Reactions of Coal During Carbonization, J. D. Davis and P. B. Place. Indus. & Eng. Chem., vol. 16, no. 6, June 1924, pp. 589-592, 4 figs. Discusses thermal behavior of coals during carbonization and compares methods applicable to determination of reaction heats; heat-rate method originally used by Hollings and Cobb for investigating reaction heats of English coals has been applied with slight modification to seven typical American coals and sample of pine sawdust, and attempt made to compare results with those found by direct determination in constant-volume calorimeter; results indicate that for high temperatures prevailing in coke-oven operations reaction heats are endothermic.

LOW-GRADE AND WASTE. The Utilization of Low-Grade and Waste Coals in Power Production, W. S. Coates. Chem. & Industry, vol. 43, no. 21, May 23, 1924, pp. 157T-163T, 5 figs. Notes on furnace design; combustion of carbon in coke; boiler; pulverized fuel.

COAL GAS

CORROSION DUE TO. The Corrosion Caused by Products of Combustion of Coal Gas, U. R. Evans. Chem. & Industry, vol. 43, no. 20, May 16, 1924, pp. 506-507. Investigations as to whether practice of employing coal gas in place of direct combustion of solid fuel tends to increase or reduce damage, with special reference to indoor corrosion.

COAL HANDLING

CONVEYORS AND HAULING ARRANGEMENTS. Modern Developments in Coal Conveyors and Haulage Arrangements for Dealing With the Coal From the Working Face to the Pit Bottom, G. L. Leston. S. Wales Inst. Engrs.—Proc., vol. 40, no. 2, May 8, 1924, pp. 175-205, 10 figs.

PIERS. Modern Practice of Handling Coal in Bulk at Coal Piers, J. W. Speer. Elec. Jl., vol. 21, no. 6, June 1924, pp. 260-265, 11 figs. Turning-type dumper installation, direct-loading stationary lifting-type dumper, direct-loading stationary revolving-type dumper, mechanical coal trimmers, etc.

COAL MINES

SPONTANEOUS COMBUSTION IN. Spontaneous Combustion in Coal Mines, J. I. Graham. Colliery Engr., vol. 1, no. 1, Mar. 1924, pp. 27-31, 3 figs. Survey of underlying causes of this trouble, with indications of practical preventative methods.

VENTILATING DOORS, LEAKAGE OF. Tests on the Leakage of Mine Ventilating Doors, J. W. Paul, G. E. McElroy and H. P. Greenwald. U. S. Bur. Mines, No. 2602, May 1924, 3 pp. Particulars of tests made to determine leakage of two air locks which had been placed in experimental mine as part of equipment for tests on friction factors.

COAL STORAGE

PRECAUTIONARY MEASURES. What to Avoid When Storing Soft Coal, A. J. Hoskin. Coal Age, vol. 25, no. 23, June 5, 1924, pp. 840-842, 2 figs. Conclusions from results of investigation carried out at University of Illinois.

COAL WASHING

SAND FLOTATION. Application of Sand-flotation Process to the Preparation of Bituminous Coal, T. M. Chance. Am. Inst. Min. & Met. Engrs.—Trans., no. 1352-C, June 1924, 10 pp., 4 figs. Types of plant installed; operating results; maintenance; bituminous coal washing; bituminous washery estimates.

COKE

BLAST-FURNACE. Production of High-grade Blast-furnace Coke, H. M. Chance. Am. Inst. Min. & Met. Engrs.—Trans., no. 1351-C, June 1924, 8 pp., 2 figs. Outline of differential separation which makes available vast stores of low-ash coal locked up in coal beds from which it has been impossible to ship anything better than fair grades of steam coal; can be made by any liquid or solution having specific gravity greater than that of coal which is to be floated and less than that of coal that is to be separated by sinking in liquid.

COKE MANUFACTURE

BY-PRODUCT. Making Coke to Combat Canada's Fuel Problem, H. P. Armson. Can. Machy., vol. 31, no. 23, June 5, 1924, pp. 27-30, and 47-48, 4 figs. Description of processes by which Hamilton By-Products Coke Ovens Co. produce foundry and domestic coke, tar, ammonium sulphate, city gas, blue water gas and naphthalene.

CONCRETE

CEMENT CONTENT. Determining the Cement Content of Concrete, H. F. Kriege. Eng. News-Rec., vol. 92, no. 21, May 22, 1924, pp. 892-893. Chemical method of analyzing concrete based on silica content; check results given.

SEA-WATER ACTION. The Action of Sea Water on Concrete. Concrete & Constructional Eng., vol. 19, no. 4, Apr. 1924, pp. 249-256. Discusses the subject under following headings: Impermeability and density; proportioning and mix; quantity of water; forms, spading and temping; curing; proper location and percentage of steel; avoidance of seepage or drainage action; effect of alternate action of air and water during setting; exterior protection of concrete; cement.

CONCRETE CONSTRUCTION, REINFORCED

DIMENSIONING OF CROSS SECTIONS. The Dimensioning of Reinforced-Concrete Cross Section (Beitrag zur Bemssung von Eisenbetonquerschnitten), R. Saliger. Basichgenibau, vol. 5, no. 7, Apr. 15, 1924, pp. 162-166, 2 figs. Method of calculation and its advantages.

CONDENSERS, STEAM

BAROMETRIC, TESTING. Testing Steam Turbine and Barometric Condenser, F. S. Youtsey. Power, vol. 59, no. 25, June 17, 1924, pp. 979-980, 2 figs. Method employed in testing condenser serving mixed-pressure steam turbo-generator.

PUMPS, COOLING-WATER. Economical Operation of Condenser Pumps, Chas. E. Colborn. Power Plant Eng., vol. 28, no. 12, June 15, 1924, pp. 643-645, 4 figs. Study of conditions governing use of one or two circulating pumps with changes in cooling-water temperatures.

CONDUITS

PENSTOCK MANIFOLDS. Penstock Manifolds Designed to Simplify Stresses, H. L. Doolittle and C. W. Larner. Eng. News-Rec., vol. 92, no. 24, June 12, 1924, pp. 1006-1008, 7 figs. Describes unusual penstock manifolds of radically different types installed at two of new power plants, one at Big Creek, no. 3 plant of S. Cal. Edison Co., and other in Vermont at Davis Bridge plant of N. E. Power Co.; both designed to eliminate as many indeterminate stresses as possible.

CONVEYORS

FORGINGS AND SCRAP HANDLING. Conveyors to Handle Forgings and Scrap. Iron Age, vol. 113, no. 24, June 12, 1924, pp. 1711-1712, 3 figs. Application of conveyor equipment for handling flashings and small automobile forgings from cold trimming presses at forge plant of Chevrolet Motor Co., Detroit.

COPPER METALLURGY

ORE TREATMENT. The New Copper Queen Concentrator, E. Wittenau. Eng. & Min. Jl.—Press, vol. 117, no. 21, May 24, 1924, pp. 836-841, 10 figs. Results obtained during first year in treatment of a low-grade sulphide ore in Copper Queen concentrator of Phelps Dodge Corp. at Warren, Ariz., and description of equipment. Three units doing work originally planned for four, making 92 per cent recovery on 2 per cent ore; no ball mills used.

CORROSION

ELECTROLYTIC. Electrolytic Corrosion in a Water-Gas Holder, F. H. Rhodes and E. B. Johnson. Indus. & Eng. Chem., vol. 16, no. 6, June 1924, p. 575. Describes special case of electrolytic corrosion and gives results of investigation.

STUDY OF. A Paradox in Corrosion, U. R. Evans. Chem. & Met. Eng., vol. 30, no. 24, June 16, 1924, pp. 949-953, 3 figs. Mechanism by which currents are produced explains why corrosion depending on oxygen is sometimes greatest where oxygen is excluded.

COST ACCOUNTING

CAPITAL CONTROL. Capital Requirements and Control, J. H. Bliss. Mgt. & Administration, vol. 7, no. 6, June 1924, pp. 653-658. Protection of working capital.

DEPRECIATION SCHEDULES. New Forms of Depreciation Schedules, G. W. Greenwood. Mgt. & Administration, vol. 7, no. 6, June 1924, pp. 689-692, 3 figs. Outlines method called sinking-fund method, which is believed to be new and to have advantages in many cases; comparison with straight-line method.

COTTON MILLS

MECHANICAL ENGINEERING AND MANAGEMENT. The Relation of Mechanical Engineering to Management in the Textile Industry, E. H. McKitterick. Mech. Eng., vol. 46, no. 6, June 1924, pp. 343-344 and 359. Reduction of cost of manufacture by means of improvements in power, lighting, and heating systems, and in handling of goods between processes.

CRANES

QUAY. The Design of Quay Cranes, F. M. Du Plat Taylor. Engineer, vol. 137, no. 3570, May 30, 1924, p. 598, 2 figs. Suggests arrangement and design of cranes to meet requirements of modern large sea-going vessels.

SELF-PROPELLING. A French Automobile Crane. Engineer, vol. 137, no. 3570, May 30, 1924, pp. 604-605, 2 figs. Type of self-propelled crane extensively used in France for railway siding and port work, as well as for town and city transport and cleaning services.

CULVERTS

CORRUGATED. Roads Use Corrugated Culverts Under Fills. Ry. Age, vol. 76, no. 27, June 7, 1924, pp. 1359-1363, 5 figs. Study of many installations in service up to 16 years indicates satisfactory service.

CORRUGATED IRON. Is the Corrugated Iron Culvert Adapted to Railroad Use? W. S. Lacher. Ry. Eng. & Maintenance, vol. 20, no. 6, June 1924, pp. 224-230, 12 figs. Study of problem based on behavior of 10,000 installations in service up to 16 years.

D

DAMS

FAILURES. Experts Charge Gleno Dam Failure to Masonry Base. Eng. News-Rec., vol. 92, no. 24, June 12, 1924, p. 1018. Advance abstract of official report on cause of disaster; base defective in both design and construction.

GRAVITY. Arching Not Effective in Slightly Arched Gravity Dams, B. F. Jakobsen. Eng. News-Rec., vol. 92, no. 24, June 12, 1924, pp. 1020-1022, 2 figs. Relatively small curvature may be harmfull because of reduced stability; arch action cannot be counted on under such conditions; construction costs increased by arching.

DIES

FORGING. Taking the Guesswork Out of Dies, C. C. Rhead. Forging—Stamping—Heat Treating, vol. 10, no. 3, May 1924, pp. 188-193, 3 figs. Records covering die performance essential to efficient production; discusses system for recording performance of dies used in production of pressed-metal parts.

PROGRESSIVE. Progressive Dies for Piercing, Bending, and Blanking, W. Richards. Machy. (Lond.), vol. 24, no. 606, May 8, 1924, pp. 174-175, 5 figs. Comments on progressive die for production of bracket, described in same journal (vol. 23, p. 543), and shows that simpler tool and simpler method of producing piece, in one operation, are both available.

DIESEL ENGINES

DOUBLE-ACTING. Double-Acting Marine Diesel Engines. Engineering, vol. 117, no. 3048, May 30, 1924, pp. 707-708, 7 figs. on supp. plates. Details of 1000-i.hp. experimental 4-cycle North-Eastern-Werkspoor engine. See also Engineer, vol. 137, nos. 3570 and 3571, May 30 and June 6, 1924, pp. 604 and 626-627, 5 figs. partly on p. 630.

MANUFACTURE. One of America's Prominent Diesel Plants. Motorship, vol. 9, no. 6, June 1924, pp. 434-436 and 441, 6 figs. Describes Cleveland, Ohio, plant of Winton Engine Works. Quantity production, handling and routing highly developed.

DREDGES

HYDRAULIC. High-Lift Hydraulic Dredge Has Toothed Cutter Head, V. J. Milkowski. Eng. News-Rec., vol. 92, no. 24, June 12, 1924, pp. 1016-1017, 4 figs. Designed for deep digging and long discharge in Welland River canalization of Chippawa power canal.

DRILLING MACHINES

ANGULAR SETTINGS FOR. Angular Settings for Drilling and Boring. Mech. Wld., vol. 75, nos. 1943, 1945 and 1948, Mar. 28, Apr. 11 and May 2, 1924, pp. 190-192, 222 and 270-271, 16 figs. Describes various methods of angular setting.

RADIAL. A New Portable Universal Radial Drilling Machine. Eng. Production, vol. 7, no. 140, May 1924, pp. 144-145, 4 figs. Describes drilling and tapping machine of Wm. Asquith, Ltd., Halifax.

DYNAMOMETERS

DIRECT-READING POWER INDICATOR. A Direct-Reading Power Indicator (Indicateur de puissance à lecture directe), H. Guillou. Société d'Encouragement pour l'Industrie Nationale—Bul., vol. 135, no. 10, Dec. 1923, pp. 1163-1170, 7 figs. Apparatus developed by author which, in contrast to simple dynamometer, registers actual power transmission at any moment; can be applied in all cases where power is transmitted by means of rotating shaft.

E

EARTHQUAKES

CAUSES. Inside the Earth, and Out, Oliver Lodge. Sci. Am., vol. 130, no. 6, June 1924, pp. 374-375, 3 figs. Conditions in rock crust that lead to earthquakes.

ECONOMIZERS

OPERATION. The Efficient Operation of the Economizer. Eng. & Boiler House Rev., vol. 37, no. 11, June 1924, pp. 425-427, 3 figs. Discusses methods whereby maximum efficiency may be obtained, both as regards reduction in coal bill and satisfactory operation of installation, especially from point of view of length of service.

EDUCATION, ENGINEERING

CALCULUS, VALUE OF. Value of Calculus to the Engineer, R. Fleming. Can. Engr., vol. 46, no. 23, June 3, 1924, pp. 587-588. Divergent views as to value of calculus. Personality of instructor of more importance than text book; better to learn calculus at college than after.

ELECTRICAL EQUIPMENT

ZINC PLANT. Electric Equipment, Consolidated Mining and Smelting Company's Zinc Plant, Trail, B.C., Canada, R. N. Lockyer. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 531-544, 25 figs. Power supply; electrical equipment in distributing station; generator rooms; motor-generator sets; ventilation; switchboards; load characteristics; air compressors; industrial motors; water supply.

ELECTRICAL MACHINERY

SPEED DETERMINATION. Photographic Method of Determining Machine Speeds, R. F. Mundorff. Machy. (N. Y.), vol. 30, no. 10, June 1924, p. 782, 1 fig. Method of determining retardation of machine speeds which eliminates personal equation and possibility of error that exists when successive speed readings are taken in usual way. See also Machy. (Lond.), vol. 24, no. 609, May 29, 1924, p. 271, 1 fig.

ELECTRIC DISTRIBUTION

VOLTAGE INCREASE. Increases in Distribution Voltage, H. P. Seelve. Elec. Light & Power, vol. 2, no. 5, May 1924, pp. 131-133, 5 figs. Discusses some of the factors which bear upon problem of, what adoption of a higher distribution voltage, what that voltage shall be.

ELECTRIC DISTRIBUTION SYSTEMS

UNDERGROUND A. C. NETWORK. Underground Alternating-Current Network Distribution for Central Station Systems, A. H. Kehoe. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 545-554, 27 figs. Experimental arrangements for underground a.c. system; experience with combined light and power network on one set of mains; effect of voltage variation on incandescent-lamp illumination; tests on cables which indicate that for underground distribution conditions, low-voltage cables will eliminate arcing faults which high-voltage cable will not do; description of experimental system.

ELECTRIC DRIVE

SHIPYARDS. Electrical Power Transmission for Shipyards, T. Schwarz. Eng. Progress, vol. 5, no. 5, May 1924, pp. 85-88, 7 figs. Show how all kinds of power transmission, especially hydraulic transmission, have been substituted by electrical drives, which has recently even mastered largest machines for handling plates.

ELECTRIC FURNACES

BRASS. Present Tendencies in Electric Brass-Furnace Practice, H. W. Gillett and E. L. Mack. U. S. Bur. Mines, Reports of Investigations, No. 2597, Apr. 1924, 10 pp. Also Brass Wld., vol. 20, no. 5, May 1924, pp. 163-166. Trend of developments in practice in last two years. Bibliography.

HEATING IN VACUUM. Apparatus for Heating Electrically in a Vacuum to a High Temperature (Sur un dispositif permettant de chauffer électriquement dans le vide à haute température), P. Lebeau and M. Picon. Académie des Sciences —Comptes Rendus, vol. 178, no. 14, Mar. 31, 1924, pp. 1151-1153. Apparatus consists essentially of tube of carbon, molybdenum, or tungsten, which forms resistance and which is placed in flask of Pyrex glass or quartz; authors describe use and calibration of optical pyrometer of double-scale, disappearing-filament type which was used in connection with apparatus.

PIG-IRON. New Norwegian Electric Pig Iron Furnace, F. Hodson and M. Sem. Iron Age, vol. 113, no. 22, May 29, 1924, p. 1585, 1 fig. Open-top furnace successfully operating with charcoal or coke; new ore-reduction process.

PRINCIPLES AND DESIGN. Electric Furnaces (Les Fours électriques). Electricien, vol. 55, nos. 1347 and 1348, May 1 and 15, 1924, pp. 193-197 and 221-225, 15 figs. General considerations; electro-thermal problem; resistance furnaces; arc and induction furnaces.

ELECTRICITY SUPPLY

INTERCONNECTION AND FARM SERVICE. Interconnection and Service to the Farm, Gifford Pinchot. Elec. World, vol. 83, no. 21, May 24, 1924, pp. 1095-1096. Points out that hope of rural electric service lies in regulated private industry with pooling of power for large-area use; state lines should interpose no obstacle to extension of interconnection for good of all. Address before Nat. Elec. Light Assn.

ELECTRIC LOCOMOTIVES

NORFOLK & WEST. RY. New Electric Locomotives of the N. & W. Ry., T. C. Wurts. Ry. Rev., vol. 74, no. 23, June 7, 1924, pp. 1018-1022, 9 figs. Equipment just put in service illustrates advances of 30 years' experience in electric motive power.

SWITCHING. Electric Switchers for Paulista Railway, W. D. Bearce. Elec. Traction, vol. 20, no. 5, May 1924, pp. 214-215, 2 figs. Steeple cab-type electric switching locomotives used on railway in Brazil; running gear consists of two swivel trucks each equipped with two GE-255—1500/3000 volt motors.

2-8-2. The Pennsylvania 2-8-2 Type Electric Locomotive, W. H. Eunson. Ry. & Locomotive Eng., vol. 37, no. 6, June 1924, pp. 173-175, 3 figs. Details of L-5 locomotives for passenger and freight service.

ELECTRIC METERS

KV.A. METERS. A Universal Meter for Electric Power, B. H. Smith. Sibley Jl. of Eng., vol. 38, no. 5, May 1924, pp. 120-123, 14 figs. Describes new kv.a. meter especially well adapted for billing data on large power circuits. Gives direct reading of indicated power factor, total kw. hours, total kv.a. hours, and kw. and kv.a. demand for any pre-determined time interval, also power factor for any time interval, particularly at time of maximum demand, can be readily obtained.

SERVICE FUSES VS. CIRCUIT BREAKERS. Service Fuses Versus Circuit Breakers, G. E. Palmer. Elec. World, vol. 83, no. 24, June 14, 1924, pp. 1225-1227, 3 figs. Universal service entrance and meter requirements met by properly designed combination fuse and switch boxes; disadvantage of circuit breakers.

ELECTRIC MOTORS

AMPERE-TURNS FOR SATURATED TEETH. Ampere-Turns for Saturated Teeth, V. Karapetoff. Elec. World, vol. 83, no. 24, June 14, 1924, p. 1231, 1 fig. Approximate method of computation which will be found sufficiently accurate for purposes of design.

GROUNDS, LOCATING. Locating Grounds on Motor Circuits, A. Haist. Power Plant Eng., vol. 28, no. 12, June 15, 1924, pp. 655-656, 1 fig. In writer's experience one of best methods for locating grounds on any of various motors on 3-phase system is by means of radial switch having contact point for each phase and voltmeter.

ELECTRIC MOTORS, A.C.

OPERATION AND MAINTENANCE. Alternating-Current Motors, Operation and Maintenance. South. Engr., vol. 41, no. 4, June 1924, pp. 42-49, 15 figs. Application of various types of a.c. motors and some of their characteristics.

ELECTRIC RAILWAYS

TRACTION EXHIBIT, ERIE, PA. Electric Traction Exhibit Held at Erie, Pa. Ry. Age, vol. 67, no. 25, May 24, 1924, pp. 1267-1269, 5 figs. Demonstration includes 3000-volt d.c. multiple-unit train for suburban service; current-collection tests; otheograph for recording action on rails of each separate wheel of locomotive or motor car; locomotive tests.

ELECTRIC TRANSMISSION LINES

CALCULATION. A Vector Treatment of Long Transmission Lines, S. Holmes. Instn. Elec. Engrs.—Jl., vol. 62, no. 329, May 1924, pp. 471-476, 2 figs. Equations of transmission line; calculation for 250-mi., 110,000-volt transmission line; calculation for constant-voltage transmission, and of circle diagram. Bibliography.

DESIGN AND ECONOMICS. Overhead Electric Power Transmission, W. T. Taylor. Elec. Rev., vol. 94, nos. 2422 and 2423, Apr. 25 and May 2, 1924, pp. 646, 647 and 721-722. Elements of design and economics.

MAXIMUM OUTPUT, DETERMINATION. Maximum Output of Transmission Systems, R. D. Evans and R. C. Bergvall. Elec. World, vol. 83, no. 23, June 7, 1924, pp. 1171-1173, 5 figs. Simple graphical method for determining maximum output of any given system; determination of maximum permissible load is difficult problem, but estimates may be made.

ELECTRIC WELDING

OIL TANKS. Electric Welding of Large Storage Tanks, H. C. Price. Am. Inst. Min. & Met. Engrs.—Trans., no. 1345-P, June 1924, 11 pp., 12 figs. Describes construction of welded roofs and bottoms and gives their advantages over riveted construction; data and conclusions obtained from observations made during welding of tanks by Welding Eng. Co., Texas City, Tex., and Tonkawa and Burbank, Okla.

ELECTRIC WELDING, ARC

RAIL JOINTS. Improvements in Arc-Welded Rail Joints, R. B. Fehr. Elec. Ry. Jl., vol. 63, no. 20, May 17, 1924, pp. 783-785. Recent developments in method of welding joint plates by means of carbon arc process, and tests on several types of joints.

ELEVATORS

GEARLESS TRACTION MOTOR AND BRAKE. Mechanical Features of the Gearless Traction Elevator Motor and Brake, J. J. Matson. Gen. Elec. Rev., vol. 27, no. 6, June 1924, pp. 390-394, 7 figs. Shows how manufacturer's engineers have made a thorough study of each part and have developed a most capable elevator hoist.

ENGINEERING

MECHANICAL, IN MILITARY SERVICE. The Progress of Mechanical Engineering in the Military Service, G. LeQ. Martel. Instn. Mech. Engrs.—Proc., no. 2, Jan. 1924, pp. 101-138, 9 figs. Brief historical survey of work of mechanical engineer in army up to outbreak of Great War; how work of mechanical engineer was organized and carried out during war and progress made since war; account of work in connection with repair of munitions of war of every kind in field.

EXCAVATORS

DRAGLINE. An Economic Study of Dragline Excavator Operation, C. W. Ullom. Eng. News-Rec., vol. 92, nos. 22 and 23, May 29 and June 5, 1924, pp. 932-934 and 976-979. Performance, operating practices, and costs determined by 13 million yards of excavation for Miami Valley flood-protection works. May 29: Output and cost records. June 5: Operating methods and costs.

F

FIRE EXTINGUISHERS

FOAM. Testing of Foam for Use on Fires, C. K. Swift. Indus. & Eng. Chem., vol. 16, no. 6, June 1924, pp. 580-582, 1 fig. Describes desirable characteristics of foams and foam solutions; analytical methods applicable to solutions, and methods for comparing fire resistance and other physical characteristics of foams.

FLOORS

FLAT-SLAB. Modern Examples of Girderless Flat-Slab Floors (Neuere Ausführungen trägerloser Pilzdecken), H. Marcus. Bauingenieur, vol. 5, no. 7, Apr. 15, 1924, pp. 171-177, 15 figs. Report on progress made in application and design of such floors.

FLOTATION

SELECTIVE. Selective Flotation as Applied to Canadian Ores, C. S. Parsons. Min. Jl., vol. 145, nos. 4628 and 4629, May 3 and 10, 1924, pp. 355-356 and 380-381. Reviews in a general way results of investigations conducted in Ore Dressing & Metallurgical Laboratories of Dept. Mines at Ottawa that have particular reference to selective flotation as applied to Canadian ores; oils used, addition reagents, control of flotation pulp, examples of problems; examples of selective flotation.

FLUE-GAS ANALYSIS

CO_2 METERS. Electrical Carbonic Oxide and Hydrogen Meters, E. Zopf. Eng. Progress, vol. 5, no. 5, May 1924, pp. 91-92, 6 figs. Electric apparatus for testing flue gases for their content of combustible components (especially carbonic oxide and hydrogen).

CO_2 RECORDERS. The "Positif" CO_2 Recorder (Analyseur de CO_2 "positif".) Chaleur & Industrie, vol. 5, no. 48, Apr. 1924, pp. 195-197, 5 figs. Describes new and simple apparatus manufactured by Société Anynome des Appareils de Manutention & Fours Stein, Paris.

FORESTRY

FIRE-STATISTICS COLLECTION. Some Suggestions for Proposed Changes in the Methods of Collecting Forest Fire Statistics, P. W. Stickel. Jl. of Forestry, vol. 22, no. 3, Mar. 1924, pp. 266-274. Discusses importance of forest-fire statistics in relation to question of forest-fire insurance, and suggests some changes in method of collecting such statistics. Bibliography.

FOREST COLONIZATION. Forest Colonization in Sweden, I. H. Baldwin. Jl. of Forestry, vol. 22, no. 3, Mar. 1924, pp. 241-257. Character of forest; climate. Primary object of colonization has been development of a settled population of forest workers. Relation between population and intensity of forestry; previous efforts at colonization in state forests; present grants for colonization; general extent and results of colonization. References.

RESEARCH Use of Statistical Methods in Forest Research, J. Kittredge, Jr. Jl. of Forestry, vol. 22, no. 3, Mar. 1924, pp. 306-314. Author outlines what seems to him to be most promising statistical methods for use in forest research and gives examples of kinds of problems in which their application might prove useful. References.

FORGING

SAFETY CODE FOR. Safety Code for Forging. Nat. Safety News, vol. 9, no. 6, June 1924, pp. 55-61, 23 figs. Tentative draft formulated under general auspices of Am. Eng. Standards Committee, to provide reasonable safety for life, limb and health. Applies to all power forging hammers and incidental operations in connection therewith, including hot saws.

FORGINGS

TESTING LARGE. How English Test Big Forgings. Iron Trade Rev., vol. 74, no. 24, June 12, 1924, pp. 1557-1558, 4 figs. Stresses encountered by turbine rotors and other large forgings have led British steel-makers to examine core by means of special optical instrument; defects usually develop along axis.

FUELS

SLUDGE. Sewage Sludge as a Source of Heat. Contract Rec. & Eng. Rev., vol. 38, no. 20, May 14, 1924, pp. 478-479. Experiments carried out in England by burning sludge direct in a furnace and by utilizing gas made by carbonizing it; special furnace is solution.

See also Coal; Coke; Lignite; Pulverized Coal.

FURNACES, INDUSTRIAL

GAS-FIRED. Gas-Furnace Installations, Hems. Gas Jl., vol. 166, no. 3182, May 7, 1924, pp. 400-403, 1 fig. Describes some of the different types of furnaces and industrial apparatus which manufactures of a city demand, including oven and muffle furnaces, furnaces for melting, tube manufacture, sugar boiling, cyanide hardening, etc. Paper read before Midland Jr. Gas Assn.

RECUPERATORS FOR. Recuperation—Design Requirements, E. R. Posnack. Combustion, vol. 10, no. 6, June 1924, pp. 439-440. Features of design which should be incorporated to eliminate objections usually raised to use of recuperators.

G

GAGES

ORDNANCE-DEPT. PROBLEMS. Gage Problems of the Ordnance Department, C. C. Williams. Am. Mach., vol. 60, no. 22, May 29, 1924, pp. 791-793, 1 fig. Safeguarding gages on hand; studying allowances and tolerances; multiplicity of gages needed.

SINE BAR FOR PLANER WORK. The Sine Bar as a Universal Planning Gage, R. H. Rausch. Mech. Eng., vol. 46, no. 6, June 1924, pp. 345-348, 15 figs. Details of accurate system of gaging for use where large pieces are machined at comparatively long intervals; use of sine bar as templet for setting planer head and toils; formulas.

GALVANIZING

FLUXING. A Study of Fluxing in Galvanizing, H. Bablik. Metal Industry (Lond.), vol. 24, no. 23, June 6, 1924, pp. 541-543. Author describes tests carried out to determine mechanism of sal-ammoniac as a fluxing agent, from which he draws conclusions to guide in efficient control of a galvanizing bath.

GAS ENGINES

STARTING AND STARTERS. Gas Engine Starting and Starters, E. Pagett. Southern Engr., vol. 41, no. 3, May 1924, pp. 58-60, 7 figs. Explanation of various kinds of gas-engine starters and some of the difficulties, encountered in starting an engine.

GAS MANUFACTURE

RETORTS. Refractory Materials and the Design of Retort Settings, V. E. Harston. Gas Wld., vol. 80, no. 2078, May 17, 1924, pp. 444-449 (includes discussion), 1 fig. Behavior of different clays, requirements of a retort setting, design of settings, section of retort, constructional details of a retort bench, producers and generators, segmented retorts, etc. Paper read before East Counties Gas Mgrs.' Assn. See also Gas Jl., vol. 166, no. 3184, May 21, 1924, pp. 530-535, 5 figs.

GAS PRODUCERS

PORTABLE. A Portable Power Generator Using Gas Made From Local Fuel, S. D. Ware. Min. Mag., vol. 30, no. 5, May 1924, pp. 275-277, 3 figs. Describes new type of power generator specially useful in mining and transport abroad, having three features, viz., portability, low fuel costs, and low capital cost.

PRACTICE. Gas Producer Practice, W. Dyrrsen. Blast Furnace & Steel Plant, vol. 12, no. 6, June 1924, pp. 271-273. Savings possible by use of waste gases in place of steam for cooling fire zone; modern types of gas producers. (Abstract.) Paper presented before Am. Iron & Steel Inst.

Notes on Gas-Producer Practice, J. D. Troup. Iron & Coal Trades Rev., vol. 108, nos. 2929 and 2930, Apr. 18 and 25, 1924, pp. 631-632 and 678-679, 4 figs. British and American practice.

GAS TURBINES

PROBLEMS OF. The Gas Turbine, H. Campbell. Inst. Mar. Engrs.—Trans., vol. 35, Apr. 1924, pp. 681-694 and (discussion) 694-701, 5 figs. Review of what is known about gas turbines up to date. Difficulties which have been experienced in dealing with gas turbines both theoretically and practically. Points out that a new material has to be found to stand high temperatures.

WASTE-HEAT RECOVERY. Gas Turbines for Waste Heat-Recovery. Colliery Engr., vol. 1, no. 2, Apr. 1924, pp. 96-98, 4 figs. Notes on German developments with their possible applications to conditions in Great Britain.

GEAR CUTTING

INSTRUMENT. Cutting Instrument Gears. Machy. (Lond.), vol. 24, nos. 604 and 609, Apr. 24 and May 29, 1924, pp. 103-107 and 273-274, 17 figs. Apr. 24: Production of small gears by means of hand-operated and automatic machines of formed-cutter and hobbing types. May 29: Application of hobbing process and production of small pinions in rod form.

RACKS. Rack Cutting. Machy. (Lond.), vol. 24, no. 608, May 22, 1924, pp. 235-237, 5 figs. General practice in cutting racks on machines designed for this work.

GRADING

AGGREGATES. Grading Aggregates by Fineness Modulus Method, C. D. Willett. Eng. News-Rec., vol. 92, no. 24, June 12, 1924, pp. 1010-1011, 3 figs. Abrams theory supplemented by charts for three sizes of aggregates; scientific method of proportioning made easy.

GRINDING

METHODS. Grinding Shop Practice Described, F. B. Jacobs. Abrasive Industry, vol. 5, no. 5, May 1924, pp. 111-115, 11 figs. Methods followed at shops of L. Lawrence Co., Detroit, Mich. Worn cylinders reground and new pistons fitted; large crankshafts refinished by regrinding; broken units welded.

H

HARDNESS

TESTING. The Hardness of Metals and Hardness Testing. Mech. Eng., vol. 46, no. 6, June 1924, pp. 360-362. Observations on nature of hardness, together with descriptions of various methods used in testing. Report prepared at request of Special Research Committee on Cutting and Forming of Metals.

Work-Hardening of Various Metals, E. G. Herbert. Iron Age, vol. 113, no. 25, June 19, 1924, pp. 1792-1793, 3 figs. Measuring extent of progressive change with Herbert pendulum hardness tester.

HEALTH

PHYSIOLOGICAL REACTIONS TO AIR COOLING. Cooling Effect on Human Beings Produced by Various Air Velocities, F. C. Houghten and C. P. Yagloglou. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 2, Feb. 1924, pp. 169-184, 13 figs. Study of relation of temperature, humidity and air motion to human comfort, giving details of tests and results obtained.

PHYSIOLOGICAL REACTIONS TO HIGH TEMPERATURES. Air Motion—High Temperatures and Various Humidities—Reactions on Human Beings, W. J. McConnell and C. P. Yagloglou. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 3, Mar. 1924, pp. 199-224, 19 figs. Results of experiments on physiological reactions to high temperatures and humidities, presented with the view of illustrating influence moving air exerts over still air.

HEAT TRANSMISSION

BUILDINGS. Measuring Heat Transmission in Building Structures and a Heat Transmission Meter, P. Nicholls. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 1, Jan. 1924, pp. 35-70, 30 figs. Deals with measurement of heat flow through walls, more particularly of existing structures. Outlines principles employed and describes in detail work done at A. S. H. V. E. research laboratory in an attempt to develop a heat transmission meter which will indicate instantaneous flows. Difficulties involved in such measurements and variable factors in building materials that will influence heat-transmission constants. Short review of present state of knowledge, future requirements, and indications of probable trend of investigational work.

THERMAL-CONDUCTIVITY VALUES. New Tests on the Thermal Conductivity of Liquids, Insulating Materials and Metals (Nouveaux essais sur la conductibilité calorifique des liquides, matières isolantes et métaux), M. Jakob. Chaleur & Industrie, vol. 5, no. 46, Feb. 1924, pp. 62-65, 3 figs. Shows how to utilize to advantage relations between thermal properties of bodies and their employment in industry.

HEAT TREATMENT

ELECTRICAL PROCESS. Annealing, Hardening, and Tempering by the Electrical Process. Machy. (Lond.), vol. 24, no. 609, May 29, 1924, pp. 263-265, 5 figs. Heat treatment of ferrous and non-ferrous wire and strip.

606

HEATING, ELECTRIC

Advantages and Uses. The Place of Electricity in the General Heating Field, L. P. Hynes. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 1, Jan. 1924, pp. 17-24, 1 fig. Peculiar advantages of electric heat, and practical data for readily determining when and how to use it in solving some of the especially perplexing problems which confront heating engineer.

HEATING, HOT-AIR

Pipe Sizes. Principles of Design in Furnace Heating. Sheet Metal Worker, vol. 15, no. 10, June 6, 1924, pp. 373-376 and 404. Simplified method of determining leader sizes based on standard code for regulating installation of warm-air furnaces in residences.

HEATING, STEAM

Central. Central Station Heating Requirements, H. A. Woodworth. Power Plant Eng., vol. 28, no. 12, June 15, 1924, pp. 658-662, 7 figs. Conservation of fuel due to double use of steam, that is, for electric generation and commercial heating purposes; modern heating system at Grand Rapids, Mich.; modern underground construction.

The Economical Utilization of Heat from Central Station Plants, N. W. Calvert and J. E. Seiter. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 30, no. 1, Jan. 1924, pp. 1-16, 15 figs. Shutting off of steam at night and during day; thermostatic control; vacuum systems; building details for efficient heating; data on heat consumption; etc.

HOISTS

Mine. Novel Features of Electric Mine Hoists Recently Installed in Northern Ontario, H. V. Haight. Elec. News, vol. 33, no. 9, May 1, 1924, pp. 52-55, 5 figs. Details of two hoists recently built for use in Porcupine mining districts double-drum type; controlled by compressed air; 250-hp. motor used in each case; liquid rheostat found most suitable.

HYDRAULIC MACHINERY

Glycerine, Use in. The Use of Glycerine in Hydraulic Machinery, F. Mercier. Mech. Eng., vol. 46, no. 6, June 1924, p. 353. Results of investigation. (Abstract.) Translated from Revue Industrielle, vol. 54, no. 29, Apr. 1924.

HYDRAULIC TURBINES

Characteristic Curves. The Characteristic Equations of Reaction and Impulse Water Turbines, H. W. Coultes. World Power, vol. 1, no. 5, May 1924, pp. 292-296, 5 figs. Shows how quantities are related and how equations can be obtained for characteristic curves of turbines.

Draft Tubes for. Draft Tubes for Hydraulic Turbines, J. M. Dymond. Univ. of Toronto Eng. Soc.—Trans. & Year Book, Apr. 1924, pp. 63-81, 10 figs. Functions of draft tubes; past types of draft tubes, and present outstanding types; present-day tendencies; special devices. List of references.

Factory. The Control of Power Production, Chas. L. Hubbard. Factory, vol. 32, no. 6, June 1924, pp. 822-825 and 908, 20 figs. Hydraulic turbines as factory power source.

Governors. Study of Speed Regulators of Hydraulic Turbines with Regard to Their Influence on Efficiency of Installations, (Etude des régulateurs de vitesse des turbines hydrauliques au point de vue de leur influence sur le rendement global des installations), Cayère. Houille Blanche, vol. 23, no. 85-86, Jan.-Feb. 1924, pp. 10-18, 21 figs. Examination of three distinct elements of problem: Role of governors in maximum distribution of load among the different stations; in maximum utilization of hydraulic energy in plants having no reserve; and in maximum utilization of energy of plants having hydraulic reserve supply.

Hydro-electric Equipment. Recent Developments in Hydro-electric Equipment, Wm. M. White. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 519-524, 10 figs. Facts relating to recent developments in hydro-electric machinery, such as that installed at power house at Mitchell Dam, Alabama.

HYDRO ELECTRIC DEVELOPMENTS

Carolinas. The Catawba River Development. Elec. World, vol. 83, no. 24, June 14, 1924, pp. 1234-1236, 1 fig. How hydro-electric power is utilized in Carolina to supply large group of textile industries; operating conditions.

Interdependence of Irrigation and. The Interdependence of Irrigation and Hydro-electric Power, J. D. Galloway. Jl. of Elec., vol. 52, no. 10, May 15, 1924, pp. 351-354, 2 figs. Exposition of relation of these two factors in Western development and of use of water for both purposes.

LaGabelle, Can. Power Developments on St. Maurice River, L. H. Burpee. Can. Engr., vol. 46, no. 22, May 27, 1924, pp. 553-556 and 570, 6 figs. Existing hydro-electric plants on St. Maurice river produce 450,000 hp.; new development at LaGabelle will increase this by 150,000 hp. Some power house construction details. Paper read at Toronto branch, Eng. Inst. Canada.

HYDRO-ELECTRIC PLANTS

Automatic Operation. Present Practice in the Automatic Operation of Hydro-electric Generating Stations, R. J. Wensley. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 508-513, 3 figs. Various methods of starting and controlling together with their limitations; sequence of operations in modern automatic switching equipment.

Scheme of Arrangement. The Arrangement of Hydro-electric Plant sof High and Medium Head (Quelques notes sur l'organisation des hautes et moyennes chutes d'eau), E. Maurein. Arts & Métiers, vol. 77, no. 43, Apr. 1924, pp. 126-135, 20 figs. Study of scheme of arrangement whereby weir pond is eliminated and head race is replaced by supply tunnel driven in mountain.

I

ICE PLANTS

Distilled-Water. Ice Plant Installs Uniflow Engines. Power, vol. 59, no. 25, June 17, 1924, pp. 981-982, 4 figs. Plant at Memphis, Tenn., economizer by purchasing governmental excess machinery; how water is treated; ice-storage facilities.

Oil Engines in. Oil Engines as a Prime Mover in the Ice Plant, C. T. Baker. Ice & Refrigeration, vol. 66, no. 5, May 1924, pp. 467-469. Discusses various features of primary interest to business man, including dependability, maintenance costs, different methods of drive, kind of fuel, etc. See also Refrig. Wld., vol. 59, no. 5, Apr. 1924, pp. 13-15.

IGNITION

Automobile Engines. Vacuum Tubes Applied to Engine Ignition. Automotive Industries, vol. 50, no. 24, June 12, 1924, pp. 1287-1289, 4 figs. Automotive application of thermionic valve, patented by Robert Bosch, makes it possible to place ignition system anywhere on car and eliminate mechanical interrupter.

INDUSTRIAL MANAGEMENT

Production Control. Results of Scientific Management from the Viewpoint of Corporate Control, M. M. Baker. Mgt. & Administration, vol. 7, no. 6, June 1924, pp. 645-646. Discusses general effect of scientific management upon entire organization of manufacturing institution.

Records. The Works Records Department, W. J. Hiscox. Indus. Management (Lond.), vol. 11, nos. 1, 3, 6 and 10, Jan. 10, Feb. 7, Mar. 20 and May 15, 1924, pp. 6-7, 67-69, 151-152 and 265-266, 9 figs. Describes its function, dealing with delays, what records should show, stock records and costing, and employment records.

Suggestion System. A Suggestion System That Works, K. H. Condit. Am. Mach., vol. 60, no. 25, June 19, 1924, pp. 923-925, 4 figs. Description of system used by the Gilbreths; purpose is to secure from men on job suggestions for improvement in manufacturing methods; useful by-products of system.

INDUSTRIAL ORGANIZATION

Basic Principles. The Basic Principles of Organization, T. H. Jackson. Military Engr., vol. 16, no. 86, Mar.-Apr. 1924, pp. 95-99. Discusses decentralization, selection of group leaders, policy of command, creation of new groups, appointment of group leaders, specialist command, organizing around leaders, support of group leaders, and excessive overhead.

INSULATING MATERIALS, ELECTRIC

Electrical Machinery, for. Insulation of Electrical Apparatus, A. P. M. Fleming. Electrician, vol. 92, no. 2402, May 30, 1924, pp. 656-657, 1 fig. Trend of its development; some striking changes; influence of ventilation.

INSULATORS

Suspension. A New 110,000-Volt Suspension Insulator. Elec. World, vol. 83, no. 24, June 14, 1924, pp. 1229-1230, 3 figs. Single-unit suspension insulator of radical design proposed for high-tension service; details of development and of unit and comments of engineers at A.I.E.E. meeting.

INSULATORS, ELECTRIC

1,000,000-Volt Testing Rooms for. The First European Testing Room for Alternating Current of 1 Million Volts Pressure. Eng. Progress, vol. 5, no. 5, May 1924, pp. 93-95, 8 figs. Reasons for building testing room, which is intended to ascertain quality of suspension, pin-type and leading-in insulators, etc.; building and mechanical equipment; transformer plant; erected at porcelain works in Freiberg (Saxony) of Hermsdorf-Schomburg Insulator Co.

INTERNAL-COMBUSTION ENGINES

Naphthalene. Naphthalene Engines (Les moteurs à naphtaline), C. Anguenot. Société Industrielle de Mulhouse—Bul., vol. 90, no. 1, Jan. 1924, pp. 57-71, 6 figs. Describes types of engine for burning naphthalene, constructed by Société anonyme des moteurs économiques à naphthaline (A. A. M. E. N.), which are said to be particularly well adapted to light industry and farming.

Two-Cycle Double-Acting. A New Two-Cycle Double-Acting Engine (Un nouveau moteur à deux temps et à double effet), R. Mathieu. Outillage, vol. 344, no. 3, Mar. 1924, pp. 17-18, 2 figs. Details of Leroy light explosion-type engine.

See also Automobile Engines; Diesel Engines; Gas Engines; Oil Engines.

IRON

Corrosion. The Relation of Hydrogen Ion Concentration to the Corrosion of Iron, J. W. Shipley and I. R. McHaffie. Can. Chem. & Metallurgy, vol. 8, no. 5, May 1924, pp. 121-124, 6 figs. Corrosion of iron in contact with graphite; corrosion of iron in absence of oxygen; corrosion of gray cast iron in soil water of pH 7 4 and saturated with oxygen; hydrogen-ion concentration obtained when iron is in contact with water; rate of corrosion of iron in absence of oxygen in solutions of various hydrogen-ion concentrations.

Direct Production from Ore. The Direct Production of Iron, E. Fornander. Chem. & Met. Eng., vol. 30, nos. 22 and 23, June 2 and 9, 1924, pp. 864-868 and 907-910, 10 figs. Critical review of more important methods used to produce wrought iron from ore.

IRON MINING

Methods. Straight Line Production, F. J. Crolius. Blast Furnace & Steel Plant, vol. 12, nos. 5 and 6, May and June 1924, pp. 226-232 and 264-267 and 305, 11 figs. Practice at Woodward Iron in Birmingham, Ala., district; chemical composition of ores; mining system; production and consumption of iron ore; typical installations; Crockard furnace top; pig bed machines.

IRON ORE

Canadian, Beneficiation Tests. Beneficiation Tests, W. B. Timm. Can. Min. Jl., vol. 45, no. 20, May 16, 1924, pp. 481-483. Results of experimentsl tests on beneficiation of Canadian iron ores.

IRON CASTINGS

Cupola Mixtures for. Simplifying Cupola Mixtures, Geo. A. Drysdale. Foundry, vol. 52, no. 11, June 1, 1924, pp. 433-434. Claims that chemical composition of pig irons used should closely parallel that for castings required; uniform amounts used in cupola mixture produce more even product.

Monobloc Cylinder. Making a Monobloc Cylinder Casting. Eng. Production, vol. 7, no. 141, June 1924, pp. 176-180, 25 figs. Describes equipment designed for intensive manufacture of small monobloc cylinder castings of 63-mm. bore by 69-mm. stroke. Methods adopted to secure quality in quantity production.

IRRIGATION

Canals. Construction of Concrete Lined Irrigation Canals, W. E. Code. Eng. & Contracting (Water Works), vol. 61, no. 6, June 11, 1924, pp. 1314-1316, 1 fig. Methods and costs on two jobs in Arizona. From recent bulletin of Agricultural Experiment Station of Univ. of Ariz.

L

LATHES

High-Speed. Modern High-Speed Lathes. Eng. Progress, vol. 5, no. 5, May 1924, pp. 81-84, 9 figs. Design of headstock, feed gear, etc. of high-speed lathe manufactured by Heidenreich & Harbeck, Hamburg; comparison of economy with ordinary lathes.

Interchangeable Construction. Building Lathes Interchangeably, Chas. O. Herb. Machy. (N. Y.), vol. 30, no. 10, June 1924, pp. 758-761, 8 figs. Manufacturing methods used by Chard Lathe Co., New Castle, Ind., to facilitate assembly of machines and supply of replacement parts.

LIGHTING

Automobile Factory. The White Motor Company Improves Illumination, H. Hylkema and H. T. Spaulding. Elec. World, vol. 83, no. 23, June 7, 1924, pp. 1177-1181, 6 figs. How engineering investigation recommended 4957 outlets, raising average intensity to 12 foot-candles; new type of reflector partly lights ceiling; more than 1800 units installed.

Factories. The Relation of Illumination to Production, W. E. Bush. Eng. Production, vol. 7, no. 140, May 1924, pp. 124-129 (includes discussion), 14 figs. Foot-candle meter; shadows; illumination and vision; effect of light on output.

INDUSTRIAL, UNIT COSTS OF. Unit Costs of Industrial Lighting, D. H. Tuck. Illuminating Eng. Soc.—Trans., vol. 19, no. 5, May 1924, pp. 411-419 and (discussion) 419-423, 1 fig. Unit costs of installation and operation of various actual systems of lighting in industrial plants. Value of unit costs is in comparing economy of installation and operating costs of various types of lighting and in arriving at a quick estimate of cost of any industrial lighting installation when area to be illuminated, foot-candle intensity to be obtained and type of equipment to be used are known.

RAILWAY YARDS. Railroad Yard Lighting, W. C. Gilman. Ry. Elec. Engr., vol. 15, no. 6, June 1924, pp. 185-189, 6 figs. Discusses various methods of using floodlighting projectors, with advantages of each.

SCHOOL BUILDINGS. Code of Lighting School Buildings. Illuminating Eng. Soc.—Trans., vol. 19, no. 5, May 1924, pp. 375-410, 21 figs. partly on supp. plates. Revision of Illuminating Eng. Soc.'s code issued in 1918.

STREET. Some Notes on Street Lighting, P. S. Millar. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 495-503, 9 figs. Test data upon certain sizes and types of incandescent lamps for street lighting; present status of street lighting; presentation of selected list of modern lamp posts and lighting equipments; data to show character of installations recommended by experts for lighting of various classes of streets.

LIGNITE

SOURCE OF HEAT. Lignite Fuel Source of Heat for Industries, W. Roth. Gas Age-Rec., vol. 53, no. 22, May 31, 1924, pp. 763-764. Recent development, in Germany, described by editor of Chemiker Zeitung, including gas from liguite, by-products from lignite, and lignite for central stations.

LIMESTONE

LIME PRODUCTION FROM SMALL STONE. The Production of Lime From Small Stone, W. M. Myers. U. S. Bur. Mines, Reports of Investigations, No. 2596, Apr. 1924, 9 pp. Conversion of small stone into lime is most desirable means of disposal. Difficulty of burning lime in shaft kiln; calcination of small stone impeded by CO gas; possible alterations in shaft kiln construction; use of rotary kiln, its advantages and disadvantages.

LIQUIDS

HEAT TRANSFER. Heat Transfer vs. Agitation, D. E. Pierce and P. B. Terry. Chem. & Met. Eng., vol. 30, no. 22, June 2, 1924, pp. 872-873, 3 figs. Discusses use of agitation as means of increase of heating or cooling in places where it is difficult to provide more transfer surface.

LOCOMOTIVE BOILERS

FLUE HOLES AND PATCHES. Flue Holes and Patches, T. P. Tulin. Boiler Maker, vol. 24, no. 5, May 1924, pp. 134-135, 6 figs. Methods of installing flue "blinders" with welding process and flue-sheet patches.

LOCOMOTIVES

BRITISH EMPIRE EXHIBITION. Locomotive Development, J. H. Brittain. Engineer, vol. 137, no. 3568, May 16, 1924, 528-531, 9 figs. partly on supp. plate. Description and comparison of Lond. & North-Eastern Ry. (Great Northern) 3-cylinder locomotive, Flying Scotsman, Great Western 4-cylinder locomotive, Caerphilly Castle, both of which are exhibited at Brit. Empire Exhibition, and Vincent Raven's 3-cylinder Pacific, which is not exhibited.

DAILY PROGRAM AND PERFORMANCE. Daily Program and Performance of a Locomotive, R. S. Parsons. Ry. Rev., vol. 74, no. 20, May 17, 1924, pp. 884-886. Discussion from transportation viewpoint of locomotive performance in fast freight, slow freight and switching service. (Abstract.) Paper read before central Ry. Club.

DRAFTING CONDITIONS, CONTROL OF. Exhaust Nozzle and Front End Adjustment, D. L. Derrom. Ry. Mech. Engr., vol. 98, no. 6, June 1924, pp. 362-365, 2 figs. Outlines effective means of controlling changes in drafting conditions.

MECHANICAL DRAFT. Report on Front-Ends, Grates and Ashpans, E. C. Schmidt. Ry. Rev., vol. 74, no. 23, June 7, 1924, pp. 999-1004, 6 figs. Devices for creating mechanical draft in locomotives and description of draft arrangements of oil-burning locomotive. (Abstract.) Report of committee to Int. Ry. Fuel Assn.

LUBRICATING OILS

SPECIFIC HEATS. Specific Heats of Lubricating Oils, E. H. Leslie and J. C. Geniesse. Indus. & Eng. Chem., vol. 16, no. 6, June 1924, pp. 582-583, 1 fig. Measurement of specific heats of six typical lubricating oils over range of temperature from 37.78 to 143.33 deg. cent.

LUBRICATION

ECONOMICS. Economics of Lubrication—Suggestions for a Research Program, W. F. Parish. Nat. Petroleum News, vol. 16, no. 19, May 7, 1924, pp. 59-60 and 63. Deals with lubrication of steam railroads, electric roads, and farming, marine, automotive and industrial machinery.

M

MACHINE SHOPS

ECONOMICAL MACHINING METHODS. Analysis of a Machine-Shop Problem on a Quantity and Final-Economy Basis, A. L. De Leeuw. Mech. Eng., vol. 46, no. 6, June 1924, pp. 335-338 and 362, 1 fig. Discusses nature of analysis which should be followed in determining most economical method of machining work, either in large or small quantities; deals only with items relating to actual machining processes; particular attention is called to difference between saving of labour cost and ultimate economy; as example some of operations on automobile connecting rod are taken. (Abridged.)

SINGLE PIECES, MACHINING OF. Economical Machining of Single Pieces, A. A. Dowd. Iron Age, vol. 113, no. 14, Apr. 3, 1924, pp. 989-991, 4 figs. Cause of loss in setting up machine tools for repair or replacement jobs: handling of work by planning department advantageous.

MACHINE TOOLS

BRITISH EMPIRE EXHIBITION. The British Empire Exhibition. Machy. (Lond.), vol. 24, no. 608, May 22, 1924, pp. 241-250, 17 figs. Machine tools and mechanical equipment.

MAGNETIC CONTROL. Electric Drive and Magnetic Control for Machine Tools, A. L. Harvey. Elec. Jl., vol. 21, no. 6, June 1924, pp. 265-269, 9 figs. Advantages of use of electric drive with magnetic control; reversing drive; suggestions in connection with operation.

SLOTTING MACHINES. Tooling Reciprocating Machine Tools. Eng. Production, vol. 7, no. 141, June 1924, pp. 166-169, 6 figs. Various methods of extending utility and scope of slotting machines.

MAPPING

TOPOGRAPHIC. A Review of Topographic Mapping, G. S. Smith. Military Engr., vol. 16, no. 86, Mar.-Apr. 1924, pp. 108-115, 7 figs. partly on supp. plate. Review of development of topographic mapping, and experience of government organizations.

MATERIALS

CARE AND CONTROL. The Care and Control of Raw Materials. Factory, vol. 32, no. 6, June 1924, pp. 831-834, 872, 874 and 876, 4 figs. Plan adopted by Bausch & Lomb Optical Co. involves use of one central store and branch or divisional stores.

MATERIALS HANDLING

MECHANICAL EQUIPMENT. Speeding Industrial Progress, M. W. Potts. Indus. Mgt. (N. Y.), vol. 67, no. 6, June 1924, pp. 348-355, 12 figs. How mechanical handling is revolutionizing all industry.

METALLURGICAL WORKS, RUHR. Materials Handling in the Metallurgical Industry of the Ruhr (Les engins de manutention dans l'industrie de la Ruhr), R. de Boysson. Vie Technique & Industrielle, vol. 5, no. 54, Mar. 1924, pp. 365-371, 12 figs. Describes gantries and cranes employed in storage houses and yards, blast-furnace, rolling-mill equipment, and foundry equipment, inter-plant transportation, and private railways connecting mines and plants.

MEASUREMENTS

SHOP. Shop Measurements, E. Buckingham. Univ. of Toronto Eng. Soc.—Trans. & Year Book, Apr. 1924, pp. 26-34. English standards of length; metric standards of length; purposes of shop measurement.

METALLURGICAL WORKS

LABOR-SAVING EQUIPMENT. Labor Saving Machinery Adopted, G. H. Charls. Iron Trade Rev., vol. 74, no. 24, June 12, 1924, pp. 1563-1564. Devices used in various departments of coke plants, blast furnaces, steel works and rolling-mills to augment production and reduce costs.

METALS

MOLTEN, TEMPERATURE DETERMINATION OF. The Temperature Determination of Molten Metals, R. L. Binney and N. I. Terbille. Metal Industry (N. Y.), vol. 22, no. 5, May 1924, pp. 189-190. A combination of base metal and rare metal couples which proved trustworthy in brass foundry.

SULPHURIZING AND DESULPHURIZING OF. Sulphurizing and Desulphurizing of Metals by Basic Slags and Fluxes, B. Bogitch. Metal Industry (Lond.), vol. 24, no. 21, May 23, 1924, pp. 498-499. Describes methods and results of experiments. Translated from French, and contributed at symposium arranged by Faraday Soc., Inst. Metals, Inst. British Foundrymen, and Non-Ferrous Research Assn.

THERMAL EMISSIVE POWER. The Relation Between the Total Thermal Emissive Power of a Metal and Its Electrical Resistivity, C. Davisson and J. R. Weeks, Jr. Optical Soc. of Am.—Jl., vol. 8, no. 5, May 1924, pp. 581-605, 6 figs. Theoretical considerations. Details of experiments, and results obtained. Bibliography.

MINES

COMMUNICATION IN. Radio as a Method for Underground Communication in Mines, J. J. Jakosky. U. S. Bur. Mines, Reports of Investigations, No. 2599, Apr. 1924, 4 pp. Discussion of some of the factors involved in applying radio in mines.

EQUIPMENT, MAINTENANCE OF. How to Keep Mining Equipment in Satisfactory Operating Condition at All Times, J. F. MacWilliams. Coal Age, vol. 25, no. 23, June 5, 1924, pp. 843-844, 1 fig. Electrical apparatus should be supplied with rated voltage; repair of worn parts by welding and machining; pumps and fans must not be required to deliver more than their normal capacity. Paper delivered before Min. Inst.

MECHANICAL LOADING. Mechanical Loading—Advantages and Disadvantages. Min. Congress Jl., vol. 10, no. 6, June 1924, pp. 267-271, 3 figs. Rapid development of machine loading; application of various types of loaders; room and pillar mining; mine cars; conveyor haulage; combined cutting and loading machines; etc. Discussion at Am. Min. Congress mtg.

MOLDING METHODS

PROPELLER IN LOAM. Molding a Propeller in Loam, L. V. Johnston. Foundry, vol. 52, no. 11, June 1, 1924, pp. 446-448, 1 fig. Methods and rigging employed for purpose; necessity for skill and observance of care and accuracy.

MOLDING MACHINES

SQUEEZER. The Squeezer Molding Machine, R. E. Search. Metal Industry (N. Y.), vol. 22, no. 5, May 1924, pp. 191-194, 7 figs. Principles of this type of machine. Various makes and their applications.

MORTARS

ALKALI, EFFECT OF. Effect of Alkali on Strength of Mortar, Chas. E. Proudley. Pub. Roads, vol. 5, no. 3, May 1924, pp. 25-26, 2 figs. Tests of mortar briquets made in laboratory of U. S. Bur. of Pub. Roads to determine to what extent presence of alkali in mixing water is harmful.

MOTOR BUSES

TRANSPORTATION WITH. Motorbus Transportation, A. E. Hutt. Soc. Automotive Engrs.—Jl., vol. 14, no. 6, June 1924, pp. 591-593. Outlines underlying principles of motor-bus transportation and makes suggestions concerning certain features conducive to successful operation.

MOTOR-GENERATORS

ARC-WELDING. The Selection of a Single-Operator Arc-Welding Motor-Generator Set, M. S. Hancock. Elec. Jl., vol. 21, no. 6, June 1924, pp. 269-272, 2 figs. Points that should be considered by purchaser in selection.

MOTOR-TRUCK TRANSPORTATION

COST CALCULATION. Cost of Motor-Truck Transportation in Public Works (Coût des transports par camions automobiles dans les travaux publics), A. Mettler. Société des Ingénieurs civils—Mémoires et Compte Rendu des Travaux, vol. 76, nos. 10-12, Oct.-Dec. 1923, pp. 1138-1144, 2 figs. Develops formula and chart for calculating cost of transportation of cubic meter of material for a given distance.

MOTOR TRUCKS

ELECTRIC. Why American Railway Express Uses 1,800 Electric Trucks, Rob. E. M. Cowie. Elec. World, vol. 83, no. 21, May 24, 1924, pp. 1084-1085. Definite reasons for adoption of electric transportation; fifteen specific advantages of electric truck as compared with gasoline and other types of vehicles are enumerated. (Abstract.) Address delivered before Nat. Elec. Light Assn.

LOADING AND UNLOADING. Loading and Unloading Bulk Materials to and from Motor Vehicles. Indus. Mgt. (Lond.), vol. 11, nos. 8, 9 and 10, Apr. 17, May 1 and 15, 1924, pp. 215-217, 246-249 and 277-279, 12 figs. Described different methods.

SPECIFICATIONS. Gas Truck and Tractor Specifications. Power Wagon, vol. 32, no. 234, May 1924, pp. 40-47. Table giving specifications for different makes.

N

NICKEL ALLOYS

Permalloy. The Reluctivity of the Recently Discovered Magnetic Metal Permalloy, A. E. Kennelly. Franklin Inst.—Jl., vol. 197, no. 5, May 1924, pp. 623-627, 2 figs. Gives data on observations of permalloy.

O

OFFICE MANAGEMENT

Standard Paper Forms. Standard Forms for Office and Shop Use. Mgt. & Administration, vol. 7, no. 6, June 1924, pp. 695-698, 1 fig. Notes on selection of paper and sizes of forms.

OIL ENGINES

Production Methods. Production Methods on Large Oil Engines, L. S. Love. Iorn Age, vol. 113, no. 25, June 19, 1924, pp. 1777-1782, 14 figs. Savings effected in use of some special machines; ingenious fixtures on standard machines help to reduce costs.

OIL WELLS

Drilling. The Critical Line of Drilling in Oil-field Development, S. H. Breckunier. Eng. & Min. Jl.—Press, vol. 117, no. 21, May 24, 1924, pp. 850-851, 2 figs. Discussion of evil of overdrilling, with reference to Petrolia-Oil Springs district in Ontario.

OPEN-HEARTH FURNACES

Extensions, Inland Steel Co. Increases Steel-making Capacity, E. C. Boehringer. Iron Trade Rev., vol. 74, no. 24, June 12, 1924, pp. 1566-1567, 3 figs. Extension at open-hearth department of Inland Steel Co. plant at Indiana Harbor, Ind.; augments output 18 per cent; charging doors and reversing valves electrically operated; describes new units.

Heat Losses in. Heat Losses in Open Hearth Furnaces, W. Dyrssen. Fuels & Furnaces, vol. 2, no. 6, June 1924, pp. 565-569, 3 figs. Heat balance showing how 40 per cent of heat in fuel may be obtained in total steam in a furnace without gas checkers passing part of waste gases from melting chamber direct to boiler.

ORE TREATMENT

Chloride Blast Roasting and Leaching. Laboratory Tests for Chloride Blast Roasting and Leaching, T. P. Holt. Eng. & Min. Jl.—Press, vol. 117, no. 23, June 7, 1924, pp. 922-925, 5 figs. Describes practice as how followed, method of analysis used, and gives metallurgical notes bearing on adaptability of ores in general to this treatment.

OXY-ACETYLENE WELDING

Cast Iron, Bronze Welding of. A New Field for the Oxy-Acetylene Process. Acetylene Jl., vol. 25, no. 11, May 1924, pp. 533-536, 9 figs. Bronze welding of cast iron pipe. Bronze welding overcomes practically all of the difficulties of preheating in the field and enables construction of cast-iron lines upon an economic basis.

OXYGEN

Electrolytic Generation. Catalytic Electrolytic Generation of Oxygen, C. G. Fink. Indus. & Eng. Chem., vol. 16, no. 6, June 1924, pp. 566-567. Deals primarily with anodes that form protective film electrolytically.

P

PAPER

Analysis. Rapid Analysis of Paper, J. Crolard. Paper, vol. 34, no. 3, May 8, 1924, pp. 87-89. Necessary conditions in analysis of sizing substances and description of methods employed. From Moniteur de la Papeterie Française.

Coated, Analysis of. Analysis of Coated Papers. Paper, vol. 34, no. 2, May 1, 1924, pp. 48-51. Methods available to paper chemists for ready determination and estimation of binding materials and surface coatings used in manufacture of coated paper.

PAPER MACHINERY

Newsprint Machines. Anti-Friction Bearings on High-Speed Newsprint Machines, G. H. Spencer. Paper Trade Jl., vol. 78, no. 22, May 29, 1924, pp. 46-49, 11 figs. Fundamentals of plain and of anti-friction bearings, and advantages of anti-friction bearings. Paper read at Am. Pulp & Paper Mill Supts.' Assn. convention. See also Wood Pulp News, vol. 48, no. 23, June 7, 1924, pp. 16, 18 and 38, 8 figs.

Suction Rolls on News Machines, W. H. Theroux. Paper Mill, vol. 48, no. 21, May 24, 1924, pp. 44, 46 and 48. Treatment of subject from paper-maker's standpoint.

The Modern News Print Machine, A. N. Russell. Paper Mill, vol. 48, no. 22, May 31, 1924, pp. 26, 28 and 30. Discusses recent improvements, including Fourdriniers, improvements in press sections and in dryer section, etc.; advantages to be derived from driving paper machines by sectional electric drive.

PAPER MANUFACTURE

Beaters. Shartle Continuous Beater. Paper, vol. 34, no. 2, May 1, 1924, pp. 38-39, 8 figs. Describes new invention providing a battery of beaters for continuous operation in combination with raw stock breaker for manufacture of paperboard.

Drying. Drying Paper, F. C. Stamm and E. P. Gleason. Paper Trade Jl., vol. 78, no. 21, May 22, 1924, pp. 54-56, 5 figs. Discusses briefly drying methods in use to-day and brings out factors affecting drying. Outlines simple method of detecting some of the faults most commonly found. Paper read at Am. Pulp & Paper Mills Supts.' Assn. annual convention.

Pulp, Decay of. Decay of Wood and Groundwood Pulp, M. W. Bray. Paper Trade Jl., vol. 78, no. 23, June 5, 1924, pp. 58-60, 3 figs. Relation of loss in weight to chemical properties.

Pulp Manufacture. Soda Pulp Production, H. J. Payne. Chem. & Met. Eng., vol. 30, no. 21, May 26, 1924, pp. 817-822, 11 figs. Survey of methods and equipment, with emphasis on recent developments.

Pulp Sources. Sources of Pulp in North America, G. J. Druckerman. Paper Trade Jl., vol. 78, nos. 23 and 24, June 5 and 12, 1924, pp. 44, 46, 48, 50 and 82; and 36, 38 and 64, 2 figs. Compilation of statistics relating to North American resources in wood and woody substitutes for manufacture of paper.

PAPER MILLS

Electric Drive. Application of Electric Drive to Finishing Room Machinery, O. C. Cordes and W. W. Spratt. Paper Mill, vol. 48, no. 21, May 24, 1924, pp. 50 and 52. Covers, in a general way, machinery used in finishing room, touching on the various methods of electric drive and discussing their relative merits.

Rubber Bearings, Application of. The Adaption of "Cutless" Rubber Bearings to Pulp and Paper Mill Use, C. F. Sherwood. Paper Mill, vol. 48, no. 21, May 24, 1924, pp. 34, 36 and 48. It is impossible to imbed sand or grit in smooth resilient surface of live Olivete rubber, which is used in making rubber Construction of "cutless" rubber bearings, and its use in pulp and paper mills.

Sulphite Mills, Steam Economy in. Heat Problems in a Sulphite Mill, A. H. Lundberg. Paper Trade Jl., vol. 78, no. 22, May 29, 1924, pp. 41-45. Actual steam consumption for cooking, bleaching and drying of sulphite pulp and possibilities of savings. Paper read at Am. Pulp & Paper Mill Supts.' Assn. convention. See also Paper Mill, vol. 48, no. 21, May 24, 1924, pp. 14-16, 62 and 64.

PATENTS

Applications. The Preparation and Prosecution of Patent Applications, J. R. Langley. Elec. Jl., vol. 21, no. 6, June 1924, pp. 290-295.

PIPE, CONCRETE

Manufacture. The Manufacture of Pipe for Spavinaw Water Project. Eng. News-Rec., vol. 92, no. 21, May 22, 1924, pp. 899-902, 8 figs. 53 mi. of reinforced-concrete pipe made in field factory in 13½ months; operation rate at 97-per cent capacity was 1.3 mi. per week.

PISTONS

Accurate, Securing. Maxwell Method of Securing Accurate Pistons, F. H. Colvin. Am. Mach., vol. 60, no. 24, June 12, 1924, pp. 873-874, 4 figs. Novel chuck by which piston is squared with piston-pin hole before final turning; gages used in measuring checking and grading.

PLATES

Steel. The Calculation of the Weight of Steel Plates, E. V. Telfer. Shipbldg. & Shipg. Rec., vol. 23, no. 20, May 15, 1924, pp. 573-574, 1 fig. Considers the various steps entering into calculation of weight of steel plates, and simplification adopted by use of progressively improved methods. Gives nomogram.

PNEUMATIC TOOLS

Repair and Upkeep. Repair and Upkeep of Pneumatic Tools, R. W. Wilson. Instn. Mech. Engrs.—Proc., no. 2, Jan. 1924, pp. 151-163 and (discussion) 163-207, 19 figs. Consideration of what is necessary to maintain in efficient operation and in economical service pneumatic tools commonly used in engineering workshops and shipbuilding yards; these are roughly classified as reciprocating tools or pneumatic hammers, and rotating tools or pneumatic drills.

POLES

Sizes, Determination of. Determination of Pole Sizes, J. H. Mathews. Elec. World, vol. 83, no. 23, June 7, 1924, pp. 1173-1176, 1 fig. Table permitting quick calculating of pole size for almost any type of line and facilitating calculation of type of line that can be carried on selected poles; based on Nat. Elec. Safety Code.

POLES, WOODEN

Calculation. Calculation of Wooden Poles from Mechanical Viewpoint (Calcul des poteaux en bois au point de vue mécanique), P. Burdin. Revue Générale de l'Electricité, vol. 15, no. 18, May 3, 1924, pp. 799-805. Results of calculation, made with aid of logarithmic tables, are given in tabular form and relate to poles of from 9 to 20 m. in height and from 20 to 35 cm. in diam.

POLES, STEEL

Erection. 228 Transmission Towers Built and Erected in 75 Working Days, H. A. Scribner. Elec. News, vol. 33, no. 11, June 1, 1924, pp. 61-62, 4 figs. Methods employed in erection of towers for 132,000-volt double circuit 27-mile tower line erected by Pub. Service Co. of Northern Illinois.

POWER GENERATION

Steam. Modern Steam Power Generation, R. W. Angus. Univ. of Toronto Eng. Soc.—Trans. & Year Book, Apr. 1924, pp. 35-41, 3 figs. Brief discussion of some of the developments in economical generation of power by steam made during past 10 years, including bleeding of steam from turbines, mercury turbines, etc.

PULVERIZED COAL

Combustion. The Combustion of Pulverized Coal, E. Audibert. Colliery Guardian, vol. 127, no. 3306, May 9, 1924, pp. 1188-1189, 3 figs. Results obtained up to the present in a study, made by Comité Central des Houillères de France, of combustion of pulverized ocal, with object of ascertaining precautions to be observed in its application to boiler firing. Primary object of experiments were measurement of duration of combustion, and determination of essential conditions for use of a given coal in form of powder. From Revue de l'Industrie Minérale.

Developments and Advantages. Pulverized Fuel and Efficient Steam Generation, D. Brownlie. Instn. Elec. Engrs.—Jl., vol. 62, no. 329, May 1924 pp. 385-418 and (discussion) 418-469 1 fig. Detailed consideration of latest developments in use of pulverized coal for steam generation, and comparison of its advantages and disadvantages as compared with mechanical stoking under most modern conditions; full account of Lakeside station at Milwaukee with exact working costs, and description of River Rouge plant at Dearborn, Detroit, as representatives of modern pulverized-fuel practice; comparison with Dalmarnock power station, Glasgow, characteristic of best British mechanical-stoker practice; in author's opinion advantages of pulverized fuel are so great that they constitute almost revolution in boiler practice.

Physical Properties. A Study of the Physical Properties of Powdered Coal of Varying Degrees of Fineness; and of the Distribution of Ash and Volatile Matter among the Fractions of Different Size, Chas. Roszak. Fuel, vol. 3, no. 5, May 1924, pp. 161-165, 7 figs. Paper read at Congrès de Chauffage Industriel in Paris, 1923. See reference to original article in Eng. Index 1923, p. 526.

Use, Development in. Development in Use of Pulverized Coal, C. F. Herington. Elec. Light & Power, vol. 2, no. 5, May 1924, pp. 121-125 and 166, 6 figs. Review of development of its use in industrial furnaces, boilers, locomotives, etc.; comparison between pulverized coal and other fuels; future possibilities.

PUMPING STATIONS

Diesel-Engine Operation. Operating Experiences of a Diesel Engine Pumping Station, W. De Witt Vosbury. Fire & Water Eng., vol. 75, no. 23, June 4, 1924, pp. 1215, 1219 and 1224, 4 figs. Statistics showing experiments in use of Diesel engine in Gloucester, N. J., station, a typical small water-works pumping station.

Irrigation. An Electrically Operated Irrigation Plant, C. W. Geiger. Nat. Engr., vol. 28, no. 6, June 1924, pp. 259-261, 3 figs. Description of irrigation pumping plant of River Farms company in California; capacity 504,000,000 gal. per day; screw pumps designed to operate very efficiently at low heads and driven by synchronous motors constitute present equipment.

Irrigation Pumping Machinery (Gezira Scheme), Sudan, R. W. Allen. Engineering, vol. 117, nos. 3046 and 3047, May 16 and 23, 1924, pp. 654-656 and 685-687, 11 figs. Object of scheme is to provide, for purpose of growing cotton, irrigation of northern portion of Gezira plain; construction details of Wad-el-Nau pumping station; drainage arrangements; suction wells ann pipes; discharge pipes; labour employed on erection; trials of machinery. See also Engineer, vol. 137, no. 3568, May 16, 1924, pp. 549-550, 5 figs.

ROAD CONSTRUCTION

Cost Estimating. Notes on Estimating in Road Construction Work. Surveyor & Mun. & County Engr., vol. 65, no. 1687, May 16, 1924, pp. 465-467. Outlines a few examples illustrating how estimating prices are ascertained and numerous items which have to be considered in deducing such prices.

ROADS, BITUMINOUS

Tar-Macadam Plant. Tar Macadam Plant with Scroll Drier and Cube Mixer. Engineering, vol. 117, no. 3048, May 30, 1924, pp. 700-702, 12 figs. Details of plant installed at Port Clarence Works of Wake & Co., where is work is being carried out on large slag heap from which their aggregate is procured.

ROADS, CONCRETE

Impact Tests. Impact Tests on Concrete Pavement Slabs, L. W. Teller. Pub. Roads, vol. 5, no. 2, Apr. 1924, pp. 1-14, 22 figs. Details of tests made by U. S. Bur. Pub. Roads to determine resistance of various designs to impact of motor vehicles, and results obtained.

Tests. Wear of Concrete Pavements Tested, F. H. Jackson. Pub. Roads, vol. 5, no. 3, May 1924, pp. 1-19, 14 figs. Report of accelerated tests by U. S. Bur. of Pub. Roads show (1) no wear from rubber-tired wheels; (2) no strength-wear relation. (See also (abstract.) in Eng. News-Rec., vol. 92, no. 23, June 5, 1924, pp. 984-985, 1 fig.

White Joint Filler. White Joint Filler for Concrete Roads, L. G. Carmick. Pub. Roads, vol. 5, no. 3, May 1924, pp. 21-22, 4 figs. Two-years' trial shows value of new material.

ROADS, EARTH

Oiling of. Oil Test Roads Furnish Valuable Information in Illinois, H. F. Clemmer and F. L. Sperry. Highway Engr. & Contractor, vol. 10, no. 5, May 1924, pp. 37-40, 6 figs. Details regarding tests made by Illinois State Division of Highways in spring of 1923 on Cambridge test road, 3 miles in length and divided into 15 separate sections, and on Rosemond road, divided into 16 sections. Physical and chemical characteristics of oils used on experimental roads; results with oil applied in varying quantities and number of treatments; preparation and shaping of road for oiling; drainage; application of oil; etc.

ROLLING MILLS

Atlantic Steel Co., Atlanta, Ga. A Southern Rolling Mill, M. P. Lawton. Blast Furnace and Steel Plant, vol. 12, no. 6, June 1924, pp. 291-294 and 305 9 figs. Equipment and methods of Atlantic Steel Co.'s plant, Atlanta, for manufacture of hoop and cotton ties.

Sheet Mills. Sheet Steel Plant on Pacific Coast. Iron Age, vol. 113, no. 23, June 5, 1924, pp. 1650-1652, 5 figs. Six-mill installation put in operation by Pac. Sheet Corp. at South San Francisco, Cal.; blue annealed, black and galvanized sheets to suit local market.

ROLLS

Grinding. How Chilled Iron Rolls are Ground. Abrasive Industry, vol. 5, no. 5, May 1924, pp. 119-122, 5 figs. Special machines are provided for finishing steel-mill rolls. Value of grinding over turning.

S

SCREW MACHINES

Magazine Attachments. Design of Magazine Attachments, A. A. Dowd. Machy. (N.Y.), vol. 30, no. 10, June 1924, pp. 771-773, 4 figs. Problems of design; details of bar-stock magazine.

SEPARATION

Ash and Fuel. Recovering Unburned Fuel and Other Matter from Ash, C. H. S. Tupholme. Gas Age-Rec., vol. 53, no. 20, May 17, 1924. pp. 679-682, 7 figs. Description of British apparatus employed for this purpose with results of operation; a type of washer, known as the Columbus, which is actuated by difference in specific gravity between coke and clinker.

SEWAGE DISPOSAL

Activated Sludge. Four Activated-Sludge Plants in California, C. E. Grunsky, Jr. Eng. News-Rec., vol. 92, no. 22, May 29, 1924, pp. 937-939, 1 fig. Various systems of air distribution used include perforated pipes and Trent aerator on Barker-mill principle.

SHAFT SINKING

Freezing Process. Freezing Process Enables Lessees to Sink Shafts in Deep Marsh Land of North Belgium, M. Biquet. Coal Age, vol. 25, no. 23, June 5, 1924, pp. 831-834, 3 figs. Describes sinking of two shafts by refrigeration nearly a mile deep; 46 beds aggregating over 100 ft. of coal made almost unapprochable by hogs thousands of feed deep; shafts sunk with protecting ice wall.

SHEET METAL

Standardization. Standardization of Sheet Metal L. D. Mercer. Sheet Metal Worker, vol. 15, no. 9, May 23, 1924, pp. 327-328 and 350. Facts about waste in this industry, with recommendations on its elimination and on expansion of business.

SOLIDS

Density, Determination of. The Density of Liquid and Solid Substances (Sur la densité des corps liquides et solides), A. Damiens. Société Chimique de France—Bul., vol. 35-36, no. 4, Apr. 1924, pp. 455-463, 5 figs. Describes simple and accurate method of determination developed by author; apparatus employed.

SOUND

Quantitative Testing. The Quantitative Testing of Sound, C. E. Noel-Storr. Testing, vol. 1, no. 3, Mar. 1924, pp. 227-246, 9 figs. Reviews gradual development of sound testing instruments as applied to engineering. Some of the methods which have been devised and which have proven efficient in practical use.

STEAM ENGINES

Admission and Exhaust in. The Zeuner Valve Diagram, H. Smith. Pacific Mar. Rev., vol. 21, no. 5, May 1924, pp. 269-270, 1 fig. Practical use and solution of Zeuner diagram, a method by which a study of the various conditions governing admission and exhaust of steam can be made, in order to obtain a more thorough knowledge of events which take place inside cylinder. Relation to valve positions and indicator diagram.

Rolling Mills. British Rolling Mill Engine Design, Johnstone-Taylor. Iron Age, vol. 113, no. 24, June 12, 1924, pp. 1717-1719, 5 figs. Large and massive engines of marine type with special features; both horizontal and vertical 3-cylinder designs.

STEAM GENERATORS

Benson High-Pressure. The Scientific Principles of the Benson High Pressure Steam Generator, D. Brownlie. Eng. and Boiler House Rev., vol. 37, no. 10, May 1924, pp. 358-360, 2 figs.

STEAM PIPES

High-Pressure. Progress in High Pressure Piping Details. Power Plant Eng., vol. 28, no. 12, June 15, 1924, pp. 656-657. Recent tests show effects of expansion stresses in pipe; progress being made in flangebolt materials and design. (Abstract.) Report of Prime Movers Committee of N.E.L.A.

STEAM POWER

Economy. The Steady Progress in Steam Power Economy, Jas. T. Beard, 2nd. Indus. Mgt. (N. Y.), vol. 67, no. 6, June 1924, pp. 329-335, 8 figs. Review of progress from Newcomen engine to mercury boiler.

STEAM POWER PLANTS

Bonus Systems for. Practical Bonus Systems for Power Plants, G. Burgess. Nat. Engr., vol. 28, no. 6, June, 1924, pp. 255-258, 4 figs. Outline of bonus system methods for average power plant. Value of a bonus system in increasing interest of operators and efficiency of plant.

British and American Practice. Power Station Practice and Progress, W. H. Patchell. Power Plant Eng., vol. 28, no. 11, June 1, 1924, pp. 611-612. Comparison of British and American practice. (Abstract.) Address before (Brit.) Inst. Mech. Engrs.

Oil Refinery. Vacuum Oil Co. Plant at Paulsboro, N. J. Power Plant Eng., vol. 28, no. 12, June 15, 1924, pp. 31-636, 9 figs. All electric power used in refining processes is generated at plant by turbo-generators at potential of 2,300 volts; all turbines operate non-condensing against back pressure of about 20 lb.; details of boiler room and furnace design.

Wood-Refuse Burning. New Plant of American Seating Co. Burns Wood Refuse. Power, vol. 59, no. 23, June 3, 1924, pp. 892-897, 8 figs. Model 1,500-kw. industrial plant employing condensing turbo-generators with bleeder connections to balance exhaust-steam demands; high-pressure steam supplied to manufacturing departments.

STEAM TURBINES

Assembling Runners. Assembling 15,000-Horse-power. Impulse-Turbine Runners, Ralph Brown, Power, vol. 59, no. 22, May 27, 1924, pp. 867-868, 3 figs. Methods employed in assembling rotor spiders for 22,222-kva. generator.

Developments. Developments in Steam-Turbine Field, E. H. Brown. Power, vol. 59, no. 25, June 17, 1924, pp. 989-992, 2 figs. Steam turbine from its inception in 1884, with particular reference to recent developments in American and European practice, such as general application of stage heating, use of high pressures with resuperheating, and improvements designed to give high efficiency at moderate peripheral velocities for rotating parts. Paper presented at Wis. Utilities Assn.

Mixed-Pressure. Mixed-Pressure Turbine versus a New Steam Plant, F. S. Yontsey. Power, vol. 59, no. 24, June 10, 1924, pp. 934-936, 3 figs. To supply power to new mine 4½ mi. distance, mixed-pressure turbine in home plant was selected over steam plant at new mine or additional high-pressure capacity in original plant; salient features are condenser and cooling-water installations.

STEEL

Alloy. *See Alloy Steels.*

Identification by Grindstone Sparks. Differentiation of Steels by Examination of the Grindstone Sparks in Air and in Oxygen (Différenciation des aciers par l'examen des étincelles de meulage dans l'air et dans l'oxygène), E. Pitois. Académie des Sciences—Comptes Rendus, vol. 178, no. 11, Mar. 10, 1924, pp. 942-944. By placing sheet of glass in path of sparks and examining incrustations so obtained, it is found that, in air, most of particles obtained by grinding from ordinary steels undergo fusion; these incrustations are not wholly pearlitic, but exhibit wide regions of ferrite resulting from decarburization, latter becoming complete in atmosphere of oxygen; photographic representations of sparks were obtained; this method of examination is of special value for valve steels.

Magnetic. A study of the Old and the New Magnet Steels, E. Gumlich. Testing, vol. 1, no. 3, Mar. 1924, pp. 194-222, 10 figs. Deductions, based mostly on investigations undertaken in Magnetic Laboratory of Physico-Technical Govt. Inst. (Phys. Techn. Reichsanstalt) at Charlottenburg, reviewing what a permanent magnet is able and is required to accomplish, and which of the older and newer kinds of steel are meeting the respective requirements.

STEEL CASTINGS

Design. Designing Steel Castings, E. R. Young. Machy. (N. Y.), vol. 30, nos. 9 and 10, May and June 1924, pp. 701-703 and 790-792, 8 figs. Problems encountered in production. May: Pattern design; effect of dry sand and green sand molds on shrinkage; cores; rip design; size and shape of castings; chemical composition; finish allowances. June: Engineering or structural design; castings of intricate design; fatigue strength of castings.

Manufacture. The Manufacture of American Steel Castings, W. H. Woodhall. Foundry Trade Jl. vol. 29, no. 404, pp. 399-401. Molding methods, acid or basic melting, physical properties and tests, dirty versus clean steel, sampling, cleaning and inspection, annealing furnaces, annealing period, etc.

STEEL, HEAT TREATMENT OF

Carburizing. Practical Views on Carburizing, J. Sorenson. Fuels and Furnaces, vol. 2, no. 6, June 1924, pp. 583-584 and 587-588, 2 figs. Outlines the various thermal treatments in carburizing and results to be secured with each.

Production Methods. Heat-treatment of Steel with Special Reference to Production, J. W. Urquhart, Machy. (Lond.), vol. 24, no. 608, May 22, 1924, pp. 230-233. Locomotive and car-axle treatments; mild treatment; production of unequal stresses; importance of reduction forging and steel selection for this work; quenching media; dynamic endurance and tensile strength; quenching of coreless pieces.

STEEL MANUFACTURE

Ordnance Steel. Making Steel for Ordnance Use, J. B. Rhodes. Iron Trade Rev., vol. 74, no. 22, May 29, 1924, pp. 1429-1430 and 1433. Points out that reduction of iron oxide to minimum is essential; sulphur and phosphorus should be eliminated; steel quality affected by slag; shop-practice instructions are suggested. (Abstract.) Paper presented before Am. Iron and Steel Inst.

Processes. The Manufacture of Iron and Steel and Tubular Products, R. J. Kaylor. St. Louis Ry. Club—Proc., vol. 28, no. 12, Apr. 11, 1924, pp. 258-273. Describes some of the major processes connected with manufacture of steel of various kinds.

STEEL WORKS

Developments. A Gigantic Automaton, A. R. R. Jones. Iron & Steel of Canada, vol. 7, nos. 4 and 6, Apr. and June 1924, pp. 61-65 and 99-103, 12 figs. Part that mechanism is playing in steel industry, and amelioration that has taken place in working conditions.

STOKERS

Efficiency, Calculation of. Computing Guaranteed Stoker Efficiency, H. F. Gauss. Power, vol. 59, no. 22, May 27, 1924, pp. 858-860, 3 figs. Deals with unaccountable losses, moisture in coal, available hydrogen content and combustible matter in ash.

Water-Tube and Cylindrical Boilers. Mechanical Stokers and Boiler Furnaces. Eng. and Boiler House Rev., vol. 37, no. 11, June 1924, 18 pp. between pp. 397-422, 19 figs. Notes on present-day practice describing some leading types in use for water-tube and cylindrical boilers.

STREET RAILWAYS

Car Lubrication. Lubricating Practice for Electric Cars. Elec. Ry. Jl., vol. 63, no. 20, May 17 1924, pp. 763-766, 4 figs. Analysis of quantity of lubricant used, period of oiling, and methods of applying lubricants as found from a study covering 57 electric railway properties.

Track Structure. Observations on the Track Structure, H. P. Hevenor. Elec. Ry. Jl., vol. 63, no. 19, May 10, 1924, pp. 737-740, 6 figs. Relative advantages of various types of flexible and rigid construction; opinion expressed as to type to be built to meet various conditions; causes of disintegration and beneficial possibilities of standardization.

Trolley Wires, Steel. Overcoming Current-Collection Troubles on Steel Wire, H. M. Robinson. Elec. Ry. Jl., vol. 63, no. 20, May 17, 1924, pp. 767-769, 3 figs. Investigations made at Forth Worth, Tex., where much of the overhead construction is of this material, demonstrated superiority of trolley shoes under those conditions. Describes methods of lubricating trolley wire.

STRESSES

Shearing, on Flat Elastic Strips. On the Stability under Shearing Forces of a Flat Elastic Strip, R. V. Southwell and S. W. Skan. Royal Soc.—Proc. vol. 105, no. A 733, May 1, 1924, pp. 582-607, 6 figs. Investigation relating to a flat elastic strip, of uniform breadth, thickness and material, upon which a uniform shear is imposed by tangential applied at its edges and in its plane.

SUBSTATIONS

Alternating-Current. The Cleveland Heights Substation of the Cleveland Electric Illuminating Company, H. L. Wallau. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 555-556, 6 figs. A.c. station having ultimate capacity of 12,000 kw.

Combined Railway and Power. Railway and Power Substations Combined for Economical Operation. Elec. Ry. Jl., vol. 63, no. 19, May 10, 1924, pp. 729-731, 4 figs. Cicero (Ill.) substation of Chicago Rapid Transit Co. and Pub. Service Co. of Northern Illinois presents example of coordinated efforts to reduce maintenance and operating costs. Details of installations.

SUPERPOWER

Interconnection and. Superpower and Inter-connection, Herbert Hoover. Elec. World, vol. 83, no. 21, May 24, 1924, pp. 1078-1080. Points out that economical expansion is possible in these twin developments and shows necessity of keeping initiative free from deadening influence both of bureaucracy and of socialistic experiment. (Abstract.) Address before Nat. Elec. Light Assn.

SURVEYING

Geodetic. A Simple Form for the Azimuth Equation, L. B. Stewart. Can. Engr., vol. 46, no. 18, Apr. 29, 1924, pp. 475-477, 1 fig. By "azimuth equation" is meant equation used in reducing an observation of Polaris to determine azimuth of a direction, observation being taken at any time. Operation of finding pole star in daylight; taking observation; formulas for reducing, suitable for most precise geodetic observations, or those taken with engineer's transit.

Instruments for. New Instruments and Apparatus for Surveys. Eng. and Contracting (Water Works), vol. 61, no. 5, May 14, 1924, pp. 1085-1089, 6 figs. Recent developments of U. S. Coast and Geodetic Survey.

Stereotopography. Stereotopography and Its Recent Progress. (La stéréotopographie et ses récents progrès), J. Boyer. Nature (Paris), no. 2614, May 10, 1924, pp. 299-304, 7 figs. Discusses development of stereophotogrammetry by Pulfrich, stereocomparator and Orel stereoautograph; advantages of stereoautogrammetry.

T

TELEPHONY

Long-Distance. Long-Distance Transmission, K. W. Wagner and J. F. Dommerque. Telephone Engr., vol. 28, nos. 5 and 6, May and June 1924, pp. 26-28 and 21-23, 7 figs. Discussion of transmission-theory and practice as applied in modern long distance telephone plant. Some technical and economic features of application of repeaters to long distance lines. Cross-talk and balancing of cable pairs.

Transmission-Efficiency Unit. The Transmission Unit and Telephone Transmission Reference Systems, W. H. Martin. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 504-507, 1 fig. Considers method of determining and expressing transmission efficiencies of telephone circuits and apparatus, and of desirable qualifications for unit in which to express these efficiencies; "transmission unit" described has been selected as being much more suitable for this purpose under present conditions than "mile of standard cable" which has been generally used in past.

Trunking. Improved Manual Trunking, J. P. Boylan. Telephone Engr., vol. 28, no. 6, June 1924, pp. 17-20. Development of straightforward trunking methods and equipm ent; elimination of call wire and addition of other features make faster and more accurate service possible.

TERMINALS, LOCOMOTIVE

Turntables. Types of Turntable Developed for Heavier Locomotives. Eng. News-Rec., vol. 92, no. 23, June 5, 1924, pp. 964-967, 6 figs. Continuous and 2-span tables replace cantilever type; larger and heavier locomotives introduce problems not present with light power; lower maintenance cost and quicker operation.

TERMINALS, RAILWAY

Ferry Terminal. New Ferry Terminal Includes Advanced Designs, F. Jasperson. Ry. Age, vol. 76, no. 25, May 24, 1924, pp. 1249-1252, 8 figs. Reading Co. completes installation at Camden, N. J., to handle heavy seashore traffic. See also Ry. Rev., vol. 74, no. 20, May 17, 1924, pp. 871-876, 11 figs.

Smoke-Removal System. Fans to Avoid Smoke Nuisance in Chicago Union Station. Eng. News-Rec.; vol. 92, no. 22, May 29, 1924, pp. 929-931, 3 figs, Low-level viaducts crossing trainshed have smoke chambers in floor with exhaust fans discharging into open air.

TIMBER

Softwood, United States. Our Softwood Timber, W. B. Greeley. Military Engr., vol. 16, no. 86, Mar.-Apr. 1924, pp. 89-94, 9 figs. Extent of softwood forests in the United States; consumption of softwood timber; paper-making woods; exports and imports of softwoods.

TOOLS

Cutting Trials. Tool-Steel and Cutting Trials. D. Smith and I. Hey. Mech. Wld., vol. 75, nos. 1947 and 1948, Apr. 25 and May 2, 1924, pp. 255-258 and 272-274, 9 figs. Investigation of behavior of tools when taking extremely find cuts over a wide range of speeds and quality and treatment of tool steel most suitable for use under such conditions. Report of Lathe Tool Research Committee.

TRAFFIC

Control. Traffic Control by Wireless, R. Twelvetrees. Motor Transport (Lond.), vol. 38, no. 1006, June 9, 1924, pp. 714-716, 6 figs. How London Metropolitan Police Force engineers controlled flow of vehicles to and from Epsom on Derby Day. Explains general scheme and gives details of vehicles used as wireless tenders.

TRANSFORMERS

22,000-Kva. 22,000-kva. Transformers for Niagara Falls Development, F. F. Brand. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 6, June 1924, pp. 514-518, 4 figs. Spacing arrangements; insulation; cooling arrangements.

TRANSPORTATION

St. Lawrence and Hudson Bay Projects. The St. Lawrence River and Hudson Bay Projects. Eng. Jl., vol. 7, no. 6, June 1924. Discussion on Canada's water-transportation problems, including following contributions: Economic Examination of the Hudson Bay Projects, W. Nelson Smith, pp. 269-278. 1 fig.; The Hudson Bay Railway and Port Nelson, L. C. Nesham, pp. 278-282; The Hudson Bay Railway, J. L. Busfield, pp. 282-289, 4 figs.; The St. Lawrence River Waterway—Discussion, pp. 289-290.

TURBO-GENERATORS

12,000-Kw. 12,000-Kw. Steam Turbo-Generator at the British Empire Exhibition. Engineering, vol. 117, no. 3049, June 6, 1924, pp. 721-723, 22 figs. partly on supp. plate. Type of machine built for Colenso power station of African Railways and Harbors Administration, by C. A. Parsons & Co., Newcastle.

V

VAPORS

Pressures. Graphical Vapor Pressure and Specific Gravity Tables, H. G. Deming. Indus. and Eng. Chem., vol. 16, no. 6, June 1924, pp. 614-615, 3 figs. Tables present information commonly given in 40 or 50 pages of print in very much condensed form, and offer advantage of instant visual interpolation between values given in ordinary tables.

VENTILATION

Air-Duct Calculations. Cold Air Ventilating Ducts, H. J. Macintire. Southern Engr., vol. 41, no. 3, May 1924, pp. 47-49, 3 figs. Determining friction heat due to flow of air in ducts, and methods of designing air-duct systems.

W

WASTE HEAT

Utilization. The Utilization of Exhaust Steam (A propos de l'utilisation de la vapeur d'échappement), F. D'Espine. Chaleur et Industrie, vol. 5, no. 46, Feb. 1924, pp. 53-61, 8 figs. Calls attention to fuel economy which can be effected by rational utilization of waste heat, and gives numerical values showing profits which can be realized by installations for this purpose; examples of waste-heat installations.

WATER

Viscosity in Passage through Sand. Tests on the Viscosity of Water in Very Narrow Passage Sections (Versuche über die Viskosität des Wassers in sehr engen Durchgangsquer-schnitten), K. v. Terzaghi. Zeit. für angewandte Mathematik u. Mechanik, vol. 4, no. 2, Apr. 1924, pp. 107-113, 2 figs. Equations are given for expressing relation between pore volume and coefficient of permeability of granular materials for sand, equation agrees well with observed results, whereas with clays, differences are evident, which leads to conclusions on increase of viscosity of water in very narrow capillary tubes.

WATER METERS

Attachment for Fixed Liquid Quantities. Meter Attachment for Delivering Fixed Quantities of Liquids. Engineering, vol. 117, no. 3049, June 6, 1924, p. 749, 2 figs. Fitting exhibited at British Empire Exhibition enables water meter automatically to supply given quantity of liquid and then to cut off flow.

WATER SUPPLY

Waste Detection. Underground Water Waste Detection in New York City, F. B. Nelson. Eng. and Contracting (Water Works), vol. 61, no. 6, June 11, 1924, pp. 1289-1296. Organization, equipment, methods and results obtained. Paper presented before Mun. Engrs. of City of N. Y.

WATER WORKS

Statistics. Water Works Statistics. Pub. Wks., vol. 55, no. 5, May 1924, pp. 161-174. Tabulated from questionnaires filled out by nearly 700 water works officials. Mains laid in 1923; pressures in mains, both regular and for fire service; and pumping plants, with recent changes made in type of plant.

WELDING

Chemical Aspects. Some Chemical Aspects of Welding, J. R. Booer. Welding Engr., vol. 9, nos. 4 and 5, Apr. and May 1924, pp. 29, 44 and 46; and 29 and 32-33. Notes on physical phenomena; principles of oxidation and reduction. Paper read before Instn. Welding Engrs. See also Acetylene Jl., vol. 25. nos. 10 and 11, Apr. and May 1924, pp. 487-488 and 492-494, and 537-539.

Electric. *See Electric Welding; Electric Welding, Arc.*

Oxy-Acetylene. *See Oxy-Acetylene Welding.*

WIND TUNNELS

Resistance of Spheres. The Resistance of Spheres in Wind Tunnels and in Air, D. L. Bacon and E. G. Reid. Nat. Advisory Committee for Aeronautics—Report, no. 185, 1924, 21 pp., 18 figs. Satisfactory confirmation of Reynolds law has been accomplished, effect of means of support determined, range of experiment greatly extended by work in new variable-density tunnel, and effects of turbulence investigated by work in tunnels and by towing and dropping tests in free air.

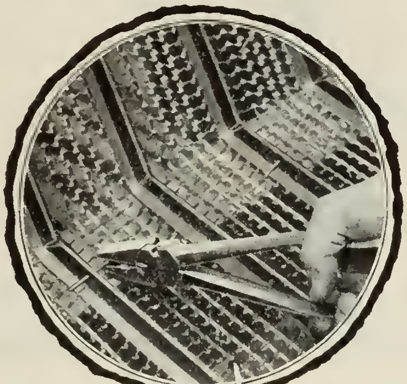
X

X-RAYS

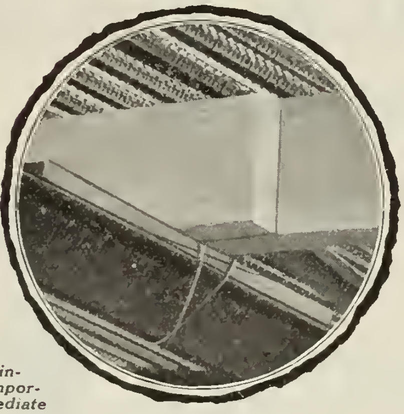
Precision Research Apparatus. An Improved Apparatus for Precision Researches with X-Rays, S. K. Allison and C. L. Clark. Optical Soc. of Am.—Jl., vol. 8, no. 5, May 1924, pp. 681-691, 3 figs. X-ray apparatus which has been in use in laboratory of Wm. Duane at Jefferson Physical Laboratory of Harvard Univ. has been improved so that results may be obtained more accurately and rapidly than before. Describes improved apparatus and mentions some of the technical difficulties which have arisen and been solved, in hope that other workers in the field of x-rays may be benefited.

Hy-Rib Concrete Roof under construction.

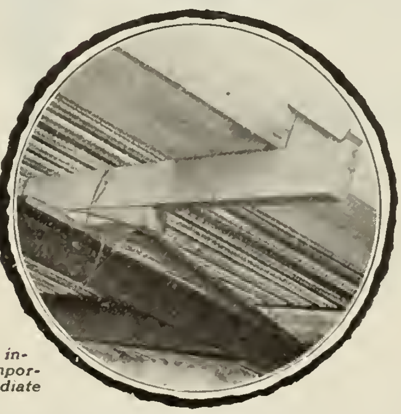
Method of attaching Hy-Rib to structural steel by means of Truscon Plate Clip.



Fastening Hy-Rib to Plate Clip.



Method of installing temporary intermediate supports.



Method of installing temporary intermediate support at gable end.

Fireproof Roofs at Less Cost

Two of the biggest factors in building, speed in construction and safety from fire, are secured through the use of Truscon Hy-Rib for roofs and floors. Building costs are cut because Hy-Rib is easily handled and quickly placed. It is a permanent, fireproof construction, universally adaptable for practically any type of flat slab or arched floor construction.

Truscon ¾-inch Hy-Rib is more than a metal lath. It is a concrete reinforcement for floors, roofs, tanks and arches that saves forms. The heavy reinforcing ribs spaced 4-inches apart, make it possible to have supports as much as 8-feet apart for solid walls 2½-inches thick. For arched floors, balconies and other construction, where elaborate and expensive wood forms are usually required, ¾-inch Hy-Rib can be substituted with a big saving in material and labor.

In building because Hy-Rib acts as a reinforcement to the concrete and because of its extreme rigidity and reinforcing properties, the varieties of its uses with concrete are unlimited.

The character of the uses of Hy-Rib varies with each job. Let the Truscon Engineers co-operate with you in designing your next building. No obligation on your part.

Write us regarding any special building jobs you may have.

TRUSSED CONCRETE STEEL COMPANY
OF CANADA, LTD. - WALKERVILLE, ONT.

Branch Offices in MONTREAL, TORONTO, WINNIPEG, CALGARY, VANCOUVER.

Illustrating ease with which Bates Bars Ties are applied

Sectional View showing Reinforced Bars held in place by Bates Wire Ties.

Firms advertising in The Journal are considered as absolutely reputable.

Boiler room of the Municipal Plant at Bay City, Michigan, where 100 deg. F. of superheat are carried in the three 275 H.P. Connelly Boilers.

More Efficient Water Works Operation with Superheated Steam

Superheated steam reduces cylinder condensation in reciprocating pumping engines and insures a higher duty. More water can be pumped for every dollar spent for operation.

To further increase these savings, the required superheat of 100 deg. F. at the new municipal water works plant at Bay City, Mich., is obtained by the Elesco Superheaters for Bay City, Michigan, which are installed in the three 275 H.P. Connelly Boilers.

Better heat transmission is secured by the ELESCO design because both the interior and exterior heating surfaces stay cleaner in service—first because the steam velocities are higher and second because there is less chance for soot to deposit on the smooth outer walls of the small diameter tubes.

Other advantages are greater safety and more accessible for installation.

THE FIREPROOF OPEN STEEL FLOORING

Foot comfort is a mighty big thing with the man who spends his days on his feet—standing or walking or working or wheeling a load. Give him a floor of **Irving Subway** and you've given him foot comfort—because the **Subway** surface is smooth but non-slipping, always. And if he works in hot, close quarters, he'll welcome the cooling, invigorating ventilation afforded by that 80% open floor space. These things react on your people — in more work and better work from each man. Have you read Catalog 4A25 ?

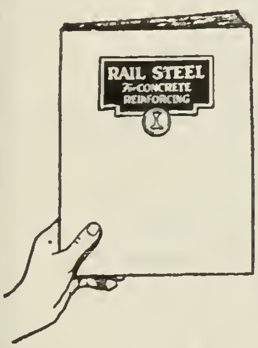
Specifications

A steel specification is a document for guidance to the manufacturer in producing an article, and a protection to the purchaser in accepting it. A specification should be written only after careful study of the production of the article, and an equally careful study of the use to which it is to be put.

Specification A-16-14, covering Rail Steel Bars, was issued by the American Society for Testing Materials only after the most careful investigation that has ever been made of any reinforcing material. In 1913, Professor W. K. Hatt, then of Purdue University (now on Mr. Hoover's staff) made over 3,000 tests on as many samples obtained under normal working conditions from four separate mills. Professor Hatt found that Rail Steel Bars had unusual strength, and furthermore, "excess ductility for its strength above usual grades of steel."

Specification A-16-14 is, therefore, everything that a specification should be. It is a protection to the purchaser. It assures him of getting Rail Steel Bars, proven by over 3,000 tests to have a quality factor (strength and ductility) in excess of usual grades of steel. This specification at the same time prevents any substitution of undesirable rerolled material.

Specify your reinforcing steel to meet A.S.T.M. specifications A-16-14, or Canadian Engineering Standards Association A-9-1923-B.



You will be interested in the facts contained in this valuable book. A copy is yours for the asking.

TENDERS

DEPARTMENT OF ROADS

Tenders

BEAUHARNOIS—SAINT-JEAN

Highways

Tenders made on forms supplied by the Department of Roads and placed under envelopes bearing the word: "Tender" shall be received at the office of the Minister of Roads, in the city of Quebec, Government Building, until one o'clock in the afternoon (daylight saving time), on Friday the twenty-second (22nd) of August, 1924, for the gravelling of Beauharnois—St-Jean highway in the municipalities of parishes of St. Jean, length 10,882 feet; Ste. Marguerite of Blairfindie, length 30,102 feet and of St. Cyprien of Napierville, length 10,835 feet.

The Government of the Province of Quebec does not bind itself to accept any of the tenders.

J. L. BOULANGER,
Quebec, July 31st, 1924. *Deputy Minister.*

CONCRETE HIGHWAYS
Earn More Than They Cost

Money used for Concrete Highways is not spent — it is invested — invested in an enterprise that pays handsome returns.

The big dividends a community receives from its concrete roads, are made possible by concrete's remarkable quality of permanence.

It's the little they cost to maintain that makes Concrete Pavements Economical

With concrete as the road material, a highway does not have to be paid for over and over again in maintenance — its first cost is practically its final cost — and thus it has a chance to pay its builders clear profits in reduced haulage cost, increased tourist trade and the better transportation facilities that go so far toward making life comfortable for both city and rural communities. A concrete road, because of its economy, safety and convenience — because it saves time, saves fuel, and saves wear and tear of vehicles — earns more than it costs. It pays for itself within a short time of its completion. It is truly an investment.

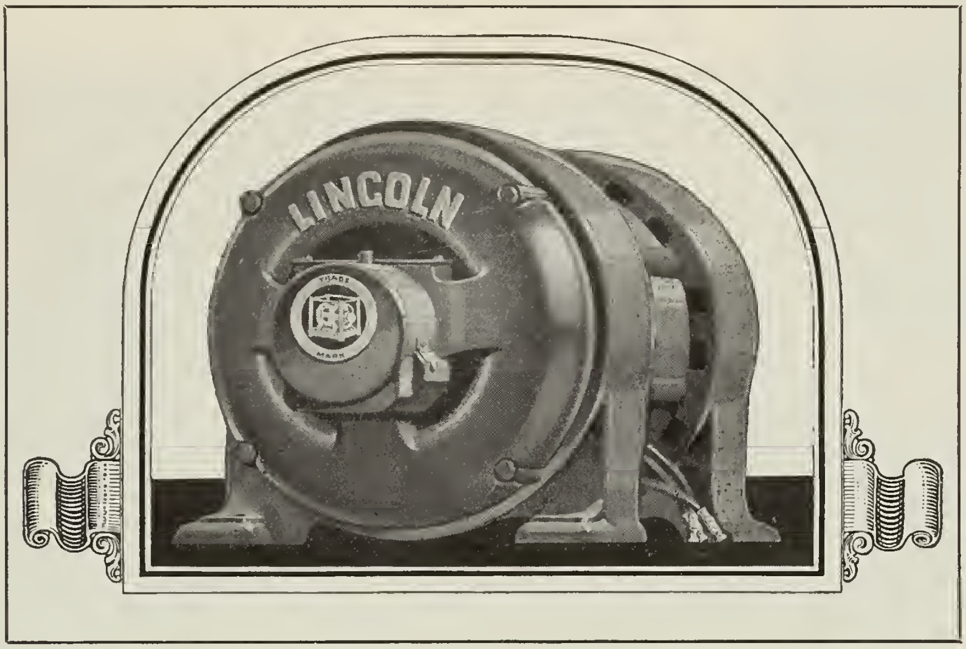
LINCOLN MOTORS

SIMPLICITY HONESTY

NEW TYPE "D" INDUCTION MOTOR

Extra Large Shafts and Bearings

Semi-enclosed, ventilated, all-steel frame.



Rotor Bars Arc-Welded to Rings

Protected Windings

Dust Proof Bearings

The idea of eliminating excessive weight is growing popular. The substitution of steel for cast iron in our motor frames makes Lincoln Motors **stronger** and **lighter** than any motor made of cast iron. It also allows room inside the frame for better arrangement of the coils and better ventilation.

We Know the *Knack* in Welding Cast Iron. Do You?

A BELIEF exists that cast iron cannot be successfully or profitably welded. This belief has led to a great waste of castings which could easily have been reclaimed.

This field of welding is so important that considerable time and energy has been given to the study of the causes of failure in welds made in gray iron castings and in devising methods to overcome these failures.

The problem of welding gray iron castings has been entirely overcome by the oxy-acetylene process, and welds are being produced that meet every demand placed on the parent metal.

Our Service Department will gladly demonstrate to our customers how welds in gray iron will reclaim castings that are now being discarded. The cost of operating oxy-acetylene welding apparatus is but a fraction of the saving that you can effect by reclaiming expensive castings. Your request for full information will receive prompt attention.

A copy of "Cast Iron Welding by the Oxy-Acetylene Process," a comprehensive treatise on this subject, will be mailed without charge to our customers (Executives or Welding Foremen) who request it on their business letterhead.

Housline as it is applied between the walls of the house lasts indefinitely and will not rot, pack, or carry flame. It comes in rolls and is easily and quickly applied.

Warmth, comfort, quiet
for every type of building

HOUSLINE, the high efficiency building insulation, makes houses warmer in Winter, cooler in Summer and quieter all the year 'round.

It keeps the heat in the house in Winter, paying for itself with the fuel it saves in a few heating seasons.

It keeps the heat out in Summer making the house more comfortable. In partitions and floors it deadens sound—which makes it extremely desirable for apartment houses, hospitals, etc.

Housline is the highest efficiency insulation of its kind—it is sanitary and permanent.

INDUSTRIALS at MUSCLE SHOALS
INDUSTRIAL LOCOMOTIVE CRANES have solved the tremendous material-handling problems of practically all of the world's big engineering projects. They placed most of the permanent structure of the Panama Canal, the Halifax terminal, the Welland Canal and the Delaware River Bridge. They are shown here in operation on Uncle Sam's $50,000,000 power project, the Wilson Dam, at Muscle Shoals. This is one of the world's largest masonry jobs. The selection of INDUSTRIALS for these huge engineering undertakings testifies to their superiority.
All types of INDUSTRIAL locomotive cranes, capacities 5 to 200 tons, are fully illustrated and described in our Golden Anniversary Catalog. A copy will be forwarded to you promptly upon request.

Inductive Co-ordination as a Practical Problem

A Review of the Subject of Inductive Interference.

J. L. Clarke, A.M.E.I.C.,

Electrical Engineer, The Bell Telephone Company of Canada.

Paper read before the Montreal Branch, The Engineering Institute of Canada, November 15th, 1923.

As the subject of inductive interference involves a number of considerations which are more or less interrelated, and in order to avoid unnecessary repetitions, it was thought desirable to divide this paper into several parts: Part I, general considerations. Part II, co-ordinated transposition schemes. Part III, elimination of harmonics. Part IV, residual voltage. Part V, abnormal conditions. Part VI, effects produced by extraneous currents.

Part 1.—General Considerations

The commencement of the present century coincided with the inception of a period of great expansion in the production of electrical energy from water power. This development was nowhere more notable than in the Dominion of Canada, being particularly marked in the provinces of Ontario and Quebec.

The facility with which power in the electrical form may be transported to considerable distances from its source, and the comparatively high cost of power produced by the combustion of fuel in localities more or less distant from the source of coal supply, constituted a powerful incentive to the construction of transmission lines whereby electrical energy produced at points where hydro-electric generation of power was relatively cheap could be transported to other points where the cost of producing power by other means was more expensive. With the multiplication of these power transmission lines it was inevitable that a number of these organizations engaged in the distribution of electric power should begin to make use of the public highways.

It soon became apparent that the telephone and telegraph circuits occupying the same highways were being affected detrimentally by the transfer of energy from the power circuits, and that the continual extension of these power lines was creating a serious problem for the communication companies.

Early Investigation of Problem of Inductive Interference

In other parts of the world similar conditions were arising, and in 1915 conditions had become so acute in California that it lead to the appointment of a committee on inductive interference by the California Railroad Board. This committee made an extensive investigation of the whole question and the report made by the committee to the California Railroad Commission forms the most important contribution to the bibliography on inductive interference.

The initiative in investigating these matters was necessarily taken by the communication companies, since the telephone and telegraph circuits do not interfere with the operation of power circuits occupying parallel locations, although the power circuits affect the operation of the communication circuits. This state of affairs has engendered certain difficulties in dealing with the entire problem and the matter was further complicated by the fact that the phenomena of inductive interference involve electro-physical relations which are in general quite dissimilar to those obtaining in the ordinary course of electric power engineering.

Investigation of the subject soon showed that a solution of the problem could not be obtained without the active co-operation of the power supply organizations, and furthermore that conditions existing in both the communication and power supply systems not only within the section in which the two systems were in proximity but also at points remote from the parallel, had very appreciable effect on the magnitude of the interference produced in the communication circuits, and in some cases these latter constituted the dominating factor.

Interference in a telephone circuit arises from the presence of harmonics or high frequency ripples on the voltage and current waves in the power circuit. These high frequency components of voltage and current acting through the mutual impedance between the power circuit and the telephone circuits, generate extraneous currents in the telephone circuits which manifest themselves in the form of noise in the terminating set on the telephone lines. This mutual impedance becomes of appreciable magnitude when the communication and power circuits occupy approximately parallel locations for more than a short distance.

Interference in telegraph circuits is due to the fundamental voltages and currents in the power circuits.

Equations Describing these Phenomena

The general equations mathematically describing these phenomena are similar in form to those involved in the case of a transformer having a plurality of windings; they consist of a series of homogeneous linear differential equations of the following form:

$$\left.\begin{aligned} V_1 &= A_{11}X_1 + A_{12}X_2 + A_{13}X_3 + \ldots\ldots A_{1n}X_n \\ V_2 &= A_{12}X_1 + A_{22}X_2 + A_{23}X_3 + \ldots\ldots A_{2n}X_n \\ V_3 &= A_{13}X_1 + A_{23}X_2 + A_{33}X_3 + \ldots\ldots A_{3n}X_n \\ V_n &= A_{1n}X_1 + A_{2n}X_2 + A_{3n}X_3 + \ldots\ldots A_{nn}X_n \end{aligned}\right\} \ldots\ldots (1)$$

Where V_1, V_2, V_3 ..... V_n are the impressed potentials and X_1, X_2, X_3 ..... X_n are the displacements from equilibrium in the co-ordinates 1, 2, 3 .... n, and A_{11}, A_{12}, A_{13} .... A_{nn} are the coefficients describing the constants of the network.

The general coefficient A_{mn} is defined by the following equation:

$$A_{mn} = L_{mn}\frac{d^2}{dt^2} + R_{mn}\frac{d}{dt} + \frac{1}{C_{mn}} \ldots\ldots\ldots\ldots (2)$$

The displacements X_1, X_2, X_3 ..... X_n are the instantaneous charges existing in the co-ordinates 1, 2, 3 .... n.

These equations describe both the forced and free oscillations of the system.

Where the forced oscillations only are to be considered and the impressed potentials can be expressed in the form of a Fourier series we can replace the differential operator d/dt by jw, and the equations may be solved independently for each component of the Fourier series.

This permits a simplified form of equation (1):

$$\left.\begin{aligned} V_1 &= I_1Z_{11} + I_2Z_{12} + I_3Z_{13} + \ldots\ldots\ldots I_nZ_{1n} \\ V_2 &= I_1Z_{12} + I_2Z_{22} + I_3Z_{23} + \ldots\ldots\ldots I_nZ_{2n} \\ V_3 &= I_1Z_{13} + I_2Z_{23} + I_3Z_{33} + \ldots\ldots\ldots I_nZ_{3n} \\ V_n &= I_1Z_{1n} + I_2Z_{2n} + I_3Z_{3n} + \ldots\ldots\ldots I_nZ_{nn} \end{aligned}\right\} \ldots\ldots (3)$$

Where I_1, I_2, I_3 .... I_n are the currents in the co-ordinates 1, 2, 3 .... n and the general coefficient Z_{mn} is given by the equation:

$$Z_{mn} = jw\,L_{mn} + R_{mn} + \frac{1}{jw\,C_{mn}} \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

The magnitude of these coefficients vary with the frequency of the impressed voltage and with the different conditions of terminating impedances; it is necessary to use superscripts to designate the different values of the coefficients for each condition. For instance $(Z_{11})^a_n$ would be the impedance of co-ordinate (1) under conditions designated by the letter "a" at the frequency "n" when co-ordinates (2), (3) etc., are all open at the sending end, $(Z_{12})^a_n$ would be the negative vector ratio of the open circuit voltage at the sending end of co-ordinate (2) to the input current at the sending end of co-ordinate (1) under the conditions described by the superscripts "a", "n", and when co-ordinates (3), (4) etc., are open at the sending end.

For substituting in equation (3) the impedance coefficients must all be of the same designation and frequency. The solution of these equations gives the relations between the currents and applied potentials for the specific conditions for which the coefficients were obtained.

If the power circuit is a three-phase line, then V_1, V_2 and V_3 are the absolute potentials of the three conductors, and V_4, V_5, V_6 .... V_n are all zero.

Furthermore the induced currents in the communication circuits are so small that they do not react appreciably in the power line, hence we can make the coefficients of all the terms in the first three rows, except those in the first three columns equal to zero.

Now the quantities Z_{45}, Z_{46}, etc., represent the mutual impedance coefficients between the several communication conductors, and in the case in which the parallels between the power and communication circuits is short compared with the total length of the communication circuits, the effects of these mutual impedances can be neglected, hence we can make Z_{45}, Z_{46} etc., equal to zero.

Equation (3) now becomes:—

$$\left.\begin{aligned} V_1 &= I_1Z_{11} + I_2Z_{12} + I_3Z_{13} \\ V_2 &= I_1Z_{12} + I_2Z_{22} + I_3Z_{23} \\ V_3 &= I_1Z_{13} + I_2Z_{23} + I_3Z_{33} \\ O &= I_1Z_{14} + I_2Z_{24} + I_3Z_{34} + I_4Z_{44} \\ O &= I_1Z_{15} + I_2Z_{25} + I_3Z_{35} \ldots + I_5Z_{55} \\ O &= I_1Z_{1n} + I_2Z_{2n} + I_3Z_{3n} \ldots + I_nZ_{nn} \end{aligned}\right\} \ldots\ldots\ldots (5)$$

Hence we can solve for I_1, I_2, I_3 independently and substitute in each succeeding equation and obtain I_4, I_5 etc. since:—

$$I_4 = \frac{I_1Z_{14} + I_2Z_{24} + I_3Z_{34}}{Z_{44}} \ldots\ldots\ldots\ldots\ldots\ldots (6)$$

In this equation the numerator on the right hand side represents the induced potential in co-ordinate (4) which in this case becomes the circuit formed by one of the communication conductors and the ground. The potential absorbed in co-ordinate (4) will be equal to I_4Z_{44}.

We may designate this quantity as (V_4), using the bracket to indicate that relative to the entire system comprising the power and communication conductors, it is not an impressed potential, but relative to the communication conductors considered as a system by itself, we may consider it as an impressed potential.

In the case of a ground return circuit such as a telegraph circuit, this voltage represents the quantity that we wish to discover, but in this case of the telephone circuit the ground is not used as a return conductor and we require to know the difference between the potentials induced in the two conductors forming the telephone circuit. This is obviously $(V_4) - (V_5)$, or if a curve is plotted showing the variation in magnitude and phase of (V_x) with respect to the distance x from the power circuits, then (V_4), (V_5), (V_6) become space functions and $(V_4) - (V_5)$ may be expressed as follows:

$$(V_4) - (V_5) = \frac{dV}{dx}\triangle x \ldots\ldots\ldots\ldots\ldots\ldots (7)$$

where $\frac{dV}{dx}$ represents the rate of change of (V) with respect to x and $\triangle x$ is the distance between the conductors 4 and 5.

In order to reduce the magnitude of this quantity, the relative positions of conductors 4 and 5 may be interchanged for certain distances, and this has the effect of equalizing the absolute potentials of conductors 4 and 5. It does not, however, reduce the mean potential to ground of the conductors and the existance of this potential to ground causes a current to flow through the admittance of each conductor to ground, and if these admittances are not equal the currents will not be equal and this will cause differences of potential between conductors 4 and 5 which cause currents to flow in the terminating apparatus of the telephone circuit.

Similar effects are produced by differences in the series impedances of each conductor. In practice it is not found possible to obtain circuits perfectly balanced to ground.

The degree of balance attainable depends on the type and constitution of the circuit; a circuit composed of aerial wire conductors, and terminated directly by telephone subsets, may be maintained at a very high degree of balance, but where the circuit passes through cables and intermediate exchanges containing much associated apparatus, it is not practicable to obtain a very high degree of balance to ground. Thus, in order to reduce the inductive effects in the latter type of circuit, it becomes necessary to adopt some means of reducing the mean induced potential to ground in the telephone conductors. This of course holds for a telegraph circuit since there is no practicable method of transposing a grounded return circuit.

A method of effecting a reduction in these induced potentials consists in interchanging the relative locations of the power line conductors. This is equivalent to associating each line current with a different impedance coefficient for each particular arrangement of conductors.

Now in order to show the effect of this operation by means of an equation which is not too complicated, two assumptions can be made. First, that the currents I_1, I_2 and I_3 each remain the same in magnitude and phase throughout the portion of the exposure considered; second, the coefficients Z_{11}, Z_{12}, etc., remain constant throughout this section and that implies uniformity of separation between the power and communication lines and equality of length of each of the three sections into which we have divided the part of the parallel considered.

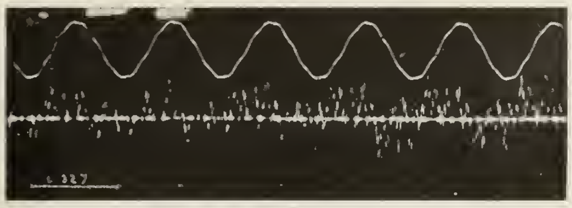

Figure No. 1.—R.M.S. voltage of induced potencial (lower curve) 2.6 volts.

These assumptions are justified if the portion of the power line considered is short compared with the total length of the power line and also short compared with the wave length at the frequency considered, and that physical conditions of the parallel are such that the second assumption can be made. Where no limitations are imposed, the general expressions describing the electrical conditions in parallel, in which there are transpositions in the power line, are very complicated.

In equation (6) we can write $(V_4)_1$, $(V_4)_2$, $(V_4)_3$ for the potentials induced in the communication circuit by the sections of the power line having the conductors arranged in the three configurations obtained by a partial rotation of pin positions.

$$(V_4)_1 = I_1Z_{14} + I_2Z_{24} + I_3Z_{34}$$
$$(V_4)_2 = I_2Z_{14} + I_3Z_{24} + I_1Z_{34} \quad \ldots\ldots (8)$$
$$(V_4)_3 = I_3Z_{14} + I_1Z_{24} + I_2Z_{34}$$

Hence $(V_4)_1 + (V_4)_2 + (V_4)_3 = (I_1 + I_2 + I_3)\ (Z_{14} + Z_{24} + Z_{34}) \ldots\ldots (9)$

Now if $I_1 + I_2 + I_3 = 0$, then the sum of the induced potentials will be equal to zero.*

If $(I_1 + I_2 + I_3) \neq 0$ but equals a quantity I_R then there will be voltage induced given by:

$$V_R = I_R \quad (Z_{14} + Z_{24} + Z_{34}) \ldots\ldots (10)$$

This is known as induction from residual components. Hence we see that induction from residual components cannot be mitigated by transpositions in the power line.*

In order to reduce the effects of residual components it is necessary to investigate the particular conditions in the power system which give rise to these effects with a view to discovering some feasible means of reducing the magnitude of these components. The means for effecting these results will be discussed in Part IV.

In making calculations of inductive effects, it is often found to be convenient to consider the induced voltages to be separated into two components:—First the induced voltage due to the electrostatic fields produced by the power circuit; second, the induced voltage due to the electromagnetic fields produced by the power circuits. If the potential of the ground is assumed to be zero, then the electrostatic component will appear as a potential between the affected conductor and the ground and the electromagnetic component will appear as a potential generated in the conductor and tending to produce a current longitudinally in the conductor. It should be kept in view however that these two effects are merely two manifestations of the same phenomenon.

It may be of interest to note that the coupling between the power circuit and communication circuit increases rapidly with increasing frequency in the fields produced by the power circuit, hence the wave shape

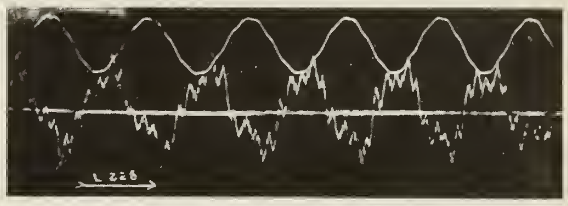

Figure No. 2.—R.M.S. voltage of induced potential (lower curve) 16.6 volts.

of the induced potential in a communication circuit indicates a very marked accentuation of the higher harmonics as compared with the relative magnitudes existing in the power circuit. An example of this is shown in figure No. 1, which shows an oscillogram of an induced voltage in a telephone circuit and also the wave shape of the voltage in the power circuit, which was causing the disturbance. Figure No. 2 shows an oscillogram of the induced voltage in a long circuit due to the cumulative effect of several parallels.

Part II.—Co-ordinated Transposition Schemes

It has been found that the placing of certain transpositions in the power and telephone circuits constitutes the most generally useful method of overcoming inductive effects in the communication circuits.

A co-ordinated transposition scheme may be defined as, a specification covering location of transpositions in the power and telephone circuits so designed that the sum of the induced potentials in any one of telephone conductors is equal to zero and that the difference of potential between any two or more telephone conductors forming a telephone circuit is equal to zero. This desired condition can only be approximately attained by means of a co-ordinated transposition scheme. In the practical case such a scheme consists of a layout of transpositions designed for the power circuit and another designed for the communica-

---

* It might be noted that equations (1) and (3) will be rigidly accurate in all cases, equations (5) and (6) will only be exact in the case of one disturbed conductor at a distance from the disturbing conductors which is large compared with the spacing between the disturbing conductors, and equations (8) and (9) only hold good when all the foregoing assumptions are justified.

* This refers to transpositions within the parallel.

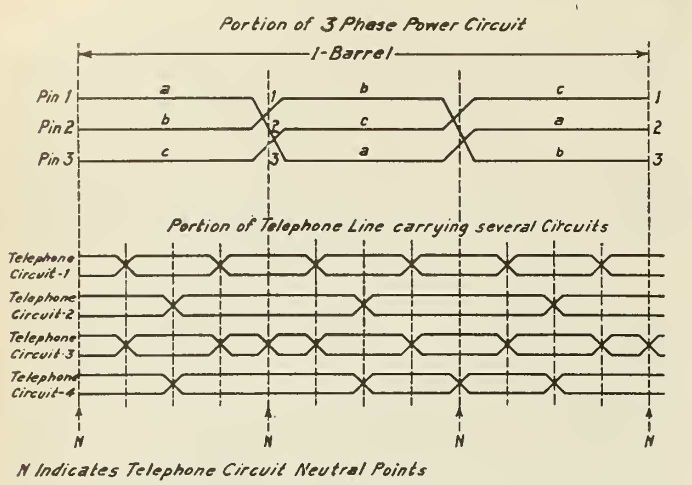

Figure No. 3.—Section of a co-ordinated transposition scheme.

tion system; these two layouts being related to each other by the coincidence of certain definite points in each scheme. These points are known as neutral points.

It was shown in Part I that by changing the relative locations of the power conductors for certain distances, it was possible to cause the induced potentials in the adjacent conductors to be much reduced in magnitude. In a three-phase line there are six possible arrangements of the three conductors, calling the conductors *a*, *b*, *c* and the pin positions 1, 2, 3, the six arrangements can be listed as follows:—

a b c 1 2 3	*b c a* 1 2 3	*c a b* 1 2 3
c b a 1 2 3	*b a c* 1 2 3	*a c b* 1 2 3

It will be seen from this schedule that the arrangements in the first row may be gotten from the one on the left by successively advancing the positions of the conductors *a*, *b*, *c*, at each change between specific arrangements, a third change would bring the conductors back to their original positions. The same condition of affairs holds for the second row. The change of conductor locations occurring between specific arrangements corresponds to a transposition and a combination of three arrangements, such as is shown either in the first or in the second row, is known as a "barrel". If the absolute values of the voltages impressed on each phase were equal and they differed in phase by 120° from one another, then the electrostatic fields (at a given distance from the power circuit), produced by each part of the barrel would be equal in magnitude and differ in phase by 120°. Except in the case of symmetrical configuration power circuits, no simple relation exists between the magnitudes and phase angles of the fields produced by the arrangements in the first and second rows, hence a combination of these two series of arrangements in one transposition scheme is seldom used unless required by some special circumstances. If a transposition, which has the effect of changing conductors *b*, *c*, *a* to the arrangement *c*, *a*, *b* and continuing in the same rotation would change *c*, *a*, *b* to *a*, *b*, *c*, be denoted by the letter *X*; then a series of barrels in the power circuit could be shown as:—

| — *X* — *X* — *X* | — *X* — *X* — *X* | — *X* —
| 1 barrel | 1 barrel |

where the dashes represent nominal thirds of barrels.

This method of transposing is known as continuous barrelling and while it is very effective in balancing out the induced voltages of fundamental frequency, it is not as effective for the higher harmonic components which are the source of the interference in a telephone circuit. This is because the electromagnetic disturbance in the power line is not propagated with infinite velocity, but travels approximately at the speed of light, thus causing a difference in phase between two points in the power line considered at any instant of time; this difference in phase is insignificant at the fundamental frequency but at higher frequencies it has the effect of causing the three induced vector potentials in the telephone circuit to be: (approximately)

$$V,\ V\ \underline{/120^\circ + \theta}\ ,\ V\ \underline{/240^\circ + 2\theta}$$

instead of:

$$V,\ V\ \underline{/120^\circ}\ ,\ V\ \underline{/240^\circ}$$

so that the sum of these potentials is no longer zero.

A considerable improvement in the degree of balance obtained for the higher frequency components may be obtained by omitting the transpositions at the points between successive barrels, this series of barrels could be shown as,

| — *X* — *X* — | — *X* — *X* — | — *X* — *X* — | —
| 1 barrel | 1 barrel | 1 barrel |

This is known as halting barrelling.

In some cases a further improvement may be made by reversing the direction of rotation of alternate pairs of transpositions, this gives a series of barrels which could be shown as,

| — *X* — *X* — | — *Y* — *Y* — | — *X* — *X* — | — *Y* — *Y* — | —
| 1 barrel | 1 barrel | 1 barrel | 1 barrel |

Where *Y* represents a transposition in which the conductors are rotated in the direction opposite to that occurring in a transposition designated "*X*". This is known as halting-reverse barrelling. It should be noted that in the actual case, it is necessary to take into account not only phase charges in the power line but also in the communication circuit; since the induced disturbances are propagated along the communication circuit with a velocity determined by the electrical characteristics of the circuit. These effects may cause the neutralization of induced effects to be much more complete at one end of the communication circuit than at the other end.

In the case of a parallel between a power circuit and a telephone circuit in which transpositions are to be placed in both circuits, it can be shown that the minimum voltage between the two sides of the telephone circuit is obtained when the telephone circuit neutral points coincide with the transposition points and inter-barrel points in the power circuit. That is the telephone circuit is divided into short sections terminated by the neutral points and each short section is so transposed as to balance up as far as possible the effects produced in each conductor. . Now this balance in each section is obtained by approximately equalizing the induced voltages in each section, both conductors in the transposed section are still energized by comparatively large voltages, but the approximately equalized voltages in the adjacent sections in which the induced voltages are successively displaced by 120°, will operate to neutralize these voltages in each other. A section of a co-ordinated transposition scheme is shown in figure No. 3.

This method is in general quite effective in reducing the inductive effect in the paralleled circuits, arising from balanced components of current and voltage in the power circuit, but it is also necessary to arrange the transpositions in the telephone circuits on the affected pole line in such a manner that the inductive effects occurring between every possible combination of telephone circuits, of which there may be as many as 60 (including phantoms) on the pole line, may be maintained at a very small amount. This transfer of energy from one telephone circuit to another is known as crosstalk and it has been found that if the power transferred to any circuit from another telephone circuit exceeds one millionth of the power flowing in the disturbing circuit, the crosstalk becomes appreciable. The necessity of maintaining a very high degree of balance between the various telephone circuits on the communication pole line imposes severe limitations on the methods available for co-ordinating the telephone and power circuit transposition schemes.

The reasons which prevent the obtaining of perfect results, by this method, may be summarized as follows:

First, — The possibility of the existence of residual components of voltage and current in the power circuit.

Second, — The departure from ideal conditions in the actual parallel, such as non-uniform separation between the power and telephone pole lines, non-uniform height of conductors above the ground, branching circuits, and loads, changes of configuration in the portion of the power line included within the exposure. In this connection reference may be again made to the equations given in Part I; in these formulæ the coefficients are functions of the length of the exposure as well as separation and frequency, consequently in exposures of non-uniform separation the equations become much more complicated and although positions for power transpositions may be determined such that the total induced voltage is a minimum it is quite possible that this minimum may be an appreciable fraction of the voltage induced under similar conditions without any transpositions in the power circuit. One reason for this condition is that the space potential at points adjacent to a three-phase power circuit varies not only in magnitude, but also in phase with changes in distance from the power circuit. Figure No. 4 shows graphically the conditions existing in the vicinity of a three-phase triangular configuration circuit. This applies to the effects of balanced components of voltage and current, the fields produced by residual components do not vary in phase with change of location relative to the power circuit. These phase change effects are particularly marked in the case of power circuits whose configuration is vertical or approximately vertical, hence it is particularly desirable in this case to endeavour to maintain separations as uniform as practicable.

Third, — The equations given in Part I describe the conditions occurring at a specific point in the parallel, at any other point a similar set of equations will hold and in order to obtain the total inductive effect in the communication circuits, it is necessary to integrate these incremental quantities over the entire length of the parallel. This procedure is not required in the case of short parallels, but in the case of long parallels it is necessary to take into account the fact that the impressed potentials change in phase with distance along the line. In the case of the fundamental frequency this phase change is quite small, but in the case of the higher harmonics which are the cause of the disturbances in the telephone circuits this phase change with distance becomes quite appreciable. This is the reason why transpositions in the power circuit if placed too far apart become ineffective in reducing the magnitudes of the higher harmonic components of the induced potentials. It should be further noted that this neutralization of induced potentials actually occurs in the communication circuit consequently it is necessary to take into account, not only the phase change effects in the power circuit, but also those occurring in the communication circuits. In addition to this, there is appreciable attenuation of the induced disturbance as it passes along the conductors of the communication circuit and this also operates in such a manner as to reduce the degree of neutralization of induced effects in the affected circuits.

Fourth, — In the case of a pole line carrying a number of telephone circuits, which is exposed to induction from a power circuit, the scheme of telephone circuit transpositions must be designed to serve two purposes, first to prevent crosstalk between any two circuits on the pole line and second to maintain a balanced condition to effects of external fields. It is sometimes difficult to design a system of transpositions which will fulfill both functions with the degree of perfection desired.

Fifth, — In computing coefficients of capacity it is not possible to take into account the effects of trees, buildings and irregularities in the surface of the ground, which all affect the electrostatic fields produced and hence the precision of balance obtainable by means of co-ordinated transposition schemes is limited by the accuracy of the fundamental data available.

In spite of all these limitations the co-ordinated transposition scheme constitutes the most generally useful means of mitigating the effects of interference in signal circuits which are exposed to induction from power circuits.

Part III.—Elimination of Harmonics

The problem of preventing interference in telephone circuits could be attacked from a different angle altogether. The design of a co-ordinated transposition scheme may be likened to the operation of balancing a Wheatstone bridge, or more generally it is similar to making modifications in

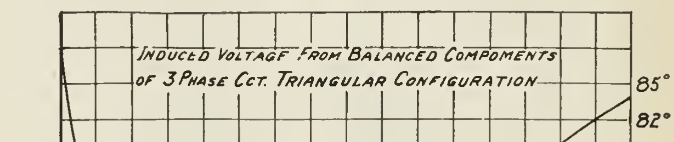

Figure No. 4.—Graphical representation of conditions in vicinity of three-phase triangular configuration circuit.

an electrical network with a view to causing the transfer admittance between certain pairs of meshes equal to zero, that is equivalent to stating that if A_{xy} is the transfer admittance between meshes x and y, then if $A_{xy} = 0$, a source of electromotive force may be inserted in mesh x, without causing any change in the current in mesh y. Now the interference in a telephone circuit is due entirely to currents whose frequency is much higher than the frequencies used in transmitting power and if these higher harmonic components could be prevented from going out in the power transmission line, the problem would be satisfactorily solved. The comparative interfering effect of unit voltage in the power circuit at different frequencies is shown in figure No. 5. Inspection of this graph shows why the telephone engineer is in this case not interested in the magnitude of voltage and current of fundamental frequency, but wants to know what is the voltage and current at various higher frequencies; in general this information is not available and for this reason the American Telephone and Telegraph Company has developed an instrument that measures the relative interfering effect of a certain wave form, it measures the amplitude in each frequency and weights each component according to its relative interfering effect and automatically integrates the whole effect, giving what is known as a telephone interference factor.* This factor is of considerable value in computing inductive effects. For instance, if a power circuit which parallels a telephone circuit is fed from source A, whose potential has a telephone interference

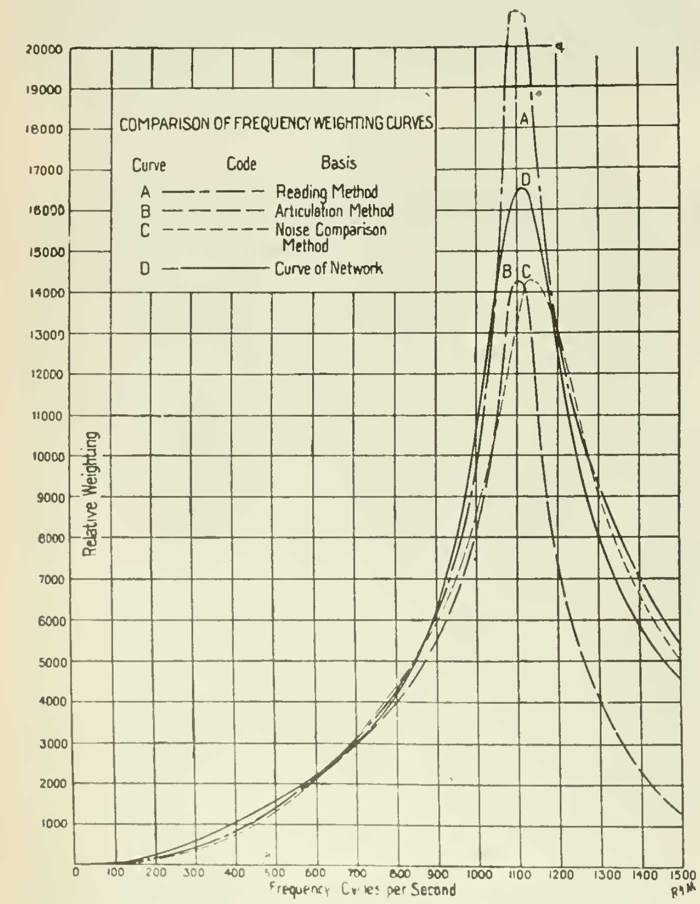

Figure No. 5.—Comperative interfering effect of unit voltage in power circuit at different frequencies.

* A.I.E.E. Trans. 1919 Vol. XXXVIII, article entitled "Review of Work of Sub-Committee on Wave Shape Standard of the Standards Committee".

factor a then if the same power circuit is fed from another source B having a telephone interference factor b the amount of interference in the second case will be equal to b/a times the amount of interference experienced in the first case.*

Higher harmonic voltages are produced by generators which might be expected from consideration of the mechanical structure of such a machine. The potential generated consists of a sum of a number of small potentials produced by a finite number of separate components.** If, however, each one of these components is itself a sine wave of fundamental frequency, their sum will be a sine wave of fundamental frequency. In the case of salient pole machines, these components are in general far from being sine waves of fundamental frequency. In order to attain this condition, it would be necessary to design the generator field in such a manner that the variation in the field flux relative to the circumferential distance of the pole pitch is sinusoidal, that is the double pole pitch is considered to be equivalent to 2π radians and the points corresponding to $\pi/2$ and $3\pi/2$ radians come at the centres of the poles. This condition is difficult to obtain with salient pole machines, but in the case of the slot-wound field it is not difficult to obtain. This type of harmonic is known as a pole harmonic. Stator windings are generally not uniformly distributed on the surface of a core of magnetic material, but are located in slots, these slots disturb the uniformity of the field flux and produce harmonics in the generated voltage. These slot harmonics will appear in pairs and the frequencies will be:

$$f_1 = f_0\,(2n + 1) \quad \ldots\ldots (11)$$
$$f_2 = f_0\,(2n - 1)$$

where f_0 is the fundamental frequency and n is the number of slots per pole. Since the slot harmonic voltage is not itself a pure sine wave, there will also be present superharmonics which will appear as pairs of harmonics differing in frequency by twice the fundamental frequency. There are several methods of substantially preventing the generation of slot harmonics; by making the number of slots per pole fractional, by using tunnel or nearly closed slots, by making the field slots slightly out of parallel with the axis of the machine, (in this case the angle of divergence would be such that $\tan.^{-1}(\phi) = P/W$, where P is the slot pitch and W is the pole width), by dividing the stator longitudinally into two or more sections and staggering the slots in each section, this last method has been used with very satisfactory results by one of the larger manufacturing companies. Slot harmonics are in general much more pronounced than pole harmonics. The relative interfering effects of the voltage wave forms produced by generators measured by the telephone interference factor meter vary widely; modern large machines will usually have a factor between 10 and 30, in some cases this factor is much larger and factors as high as 600 have been noted. The large generator at the Queenston plant of the Hydro-Electric Power Commission of Ontario produces a very good wave shape, the measured telephone interference factors ranging from 3.8 to 4.4. Higher harmonic components are created in transformers and this action is due to the non-linear relation between the flux and the magnetizing force producing it. Since the induced potential in a transformer winding is proportional to the rate of change of the flux,

* This is not strictly true in all cases, since there may be apparatus in the system whose impedance characteristics are non-linear, such as motors whose back E. M. F. contains higher harmonic components and transformers which take from the line a current whose wave shape is badly distorted.

** This excludes the case of the unipolar generator.

every harmonic component existing in the flux must also appear in the windings interlinking this flux; and therefore to obtain a pure sine wave of generated potential in the secondary winding, the flux must be a pure sine function of the time. To obtain this condition there are two requirements, first the impressed potential must be sinusoidal and second the transformer connections must be such as to allow all the components of the magnetizing current to flow freely. In a star-star connected bank of three-phase transformers the third harmonic and its superharmonics in the magnetizing current have no path in which to flow and consequently, the generated voltage wave-form is badly distorted. Various means have been devised to find a path for these components, such as providing the transformers with a tertiary delta winding, using an auxiliary bank of transformers having a secondary winding delta connected, and making the connections as shown in figure No. 6. If the generator is close to the transformers and is star-wound a connection may be made between the generator neutral and the transformer neutral; either of these methods will allow the necessary components of the magnetizing current to flow, but the results are not as satisfactory as those obtained by the use of the star-delta or delta-star connected transformers.

The degree of saturation of the cores has a marked bearing on the magnitude of the harmonics produced, in some cases, the magnitudes of certain harmonic components have been shown to increase as the fifth power of the flux density, when operating considerably above the "knee" of the B-H curve.

Part IV.—Residual Voltages

When a bank of transformers is connected in star on the line side and the neutral is grounded, the third harmonic component of the generated voltage in each phase is producing a potential between the ground and the other end of the transformer winding connected to the line conductor. Now the third harmonic components on each phase are 120° apart and this corresponds to 360° for the third harmonic, hence all these third harmonic components are in phase and this causes the voltages of all three line conductors to oscillate as a unit with respect to the ground at triple frequency.

This voltage is known as a residual voltage. The fields produced by a residual voltage in the power circuit often produce very severe interference in parallel telephone circuits, this is because the charges in and hence the fields produced by each conductor are in phase and add up arithmetically, whereas the charges produced by the normal or so-called balanced voltages are approximately 120° out of phase with each other and hence the field produced at some point external to the power circuit is the vector sum of three separate components which are roughly 120° out of phase with one another. A similar consideration applies in the case of induction from residual currents. In a transformer bank, star-connected on the

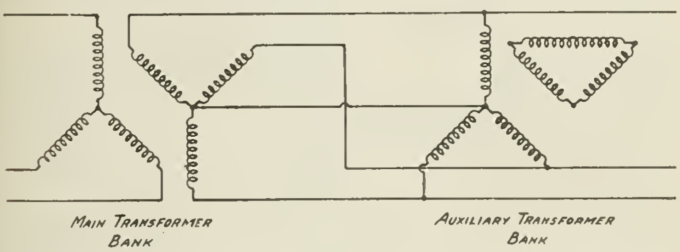

Figure No. 6.—Tertiary delta winding for transformers with auxiliary bank of transformers having secondary winding delta connected.

Oscillogram taken by Hydro-Electric Power Commission of Ontario. Reproduced by permission.

line side, with the neutral grounded, the third harmonic component of the star voltage will cause a charging current to flow between the three line wires and the ground. Figure No. 7 shows an oscillogram of the residual charging current of a three-phase circuit operating with a grounded neutral.

In this connection it may be observed that the e.m.f. produced in the secondary winding of a transformer is proportional to the rate of change of the flux, thus if there were in the flux R per cent of a higher harmonic of n times the fundamental frequency, the percentage of nth harmonic voltage produced in the secondary would be Rn. Now the charging current of the line is proportional to the rate of change of the impressed voltage, hence the percentage of the nth harmonic in the charging current will be Rn^2, similarly the induced voltage in a parallel communication circuit will be proportional to the rate of charge of the charging current in the power line (considering this effect independently) and hence the percentage of the nth harmonic voltage in the communication circuit will be Rn^3. Further, experiment has shown that the interfering effect of unit current in a telephone circuit is approximately proportional to the square of the frequency, hence the comparative interfering effects in the telephone line vary as the fifth power of the frequency of harmonics in the flux, when the interference is due to charging currents. If these currents are residual, i.e., returning through the ground their inductive effects in neighbouring conductors may be ten or twenty times as great as the effects of similar currents which are confined to the conductors. The reason for this effect has been explained above.

These remarks will serve to show that when a power system whose transmission lines parallel telephone circuits is to be operated with a grounded neutral it is desirable to give careful consideration to the wave form of the star voltage which will be applied to the power circuits. Where the generating system is connected star-delta-star the delta connection provides a closed path for the circulation of the third harmonic current and its superharmonics, and this greatly improves the wave form of the star voltage. On lower voltage systems, the generator is often directly connected to the line and may be star-wound with the generator neutral grounded; in this case there is nothing to modify the star-voltage wave form applied to the line and in some cases very severe interference has been experienced in telephone circuits exposed to portions of power systems of this type. At the present time the manufacturers of electrical machinery can produce generators suitable for this kind of service having a very good star voltage wave shape.

Residual voltages in a three-phase power line may be produced by single-phase taps, the magnitude of the residual voltage being dependent on the length of the tap or more precisely on the ratio of the length of the tap to the length of the three-phase line, this residual voltage will appear both in the three-phase line and in the single-phase tap, but if the tap is short compared with the main line, this voltage will not appear in the main line, but it always appears in a single-phase tap however short; this, of course, refers to conductive connection, if the single-phase load is taken off through a transformer, no residual voltage will be produced in either circuit.

Abnormal Conditions

When any sudden change in circuit or load conditions occurs in a power system, it is always productive of a disturbance in the electrical and magnetic fields surrounding the transmission line conductors. These sudden changes may be due to the variety of causes, the operation of overload cut-outs, the use of separate single pole switches for disconnecting three-phase lines, the occurrence of various troubles such as breaks, shorts and grounds, some of these causes produce a transient which dies away in a very short period of time and others produce an abnormal circuit condition which may persist for some time. An arcing ground due to a defective insulator may cause a sustained high frequency oscillation in the power system which has often produced very serious disturbances in parallel telephone circuits in some cases fires have been started in a telephone exchange, due to this cause. The charging of electrolytic arresters through horn gaps gives rise to similar disturbances and in cases in which a power line parallels a telephone circuit, it is desirable that these arresters be charged through resistances and not through horn gaps, and if possible, at times when the telephone circuits are not likely to be in use, for instance between 2 a.m. and 4 a.m.

The operation of circuit breakers and other switching devices on three-phase circuits may give rise to severe disturbances, if conditions are such as to permit prolonged arcing at the contacts, particularly if there is some dissimilarity between the apparatus associated with each of the phases which causes one of the arcs to extinguish before the other two.

There is no general method of solution for cases of interference from transient disturbances, each case must be made the subject of a special study. Where the disturbance is due to one particular type of transient, some specific remedy may be indicated, for instance in the case of interference arising from arcing grounds on a three-phase system having a grounded neutral, the magnitude of the effects produced may be reduced by placing a resistance between the neutral and the ground, thus limiting the maximum current to ground in the periods during which abnormal conditions exist. The extent to which this current may be limited depends on the sensitivity of the relays which are to be operated by this abnormal current in the ground connection to the neutral.

Part VI.—Effects Produced by Extraneous Currents in Communication Circuits

The principal effect of extraneous currents in a telephone circuit is the production of noise in the receiver. Small amounts of noise are productive of a certain amount of annoyance to the persons using the telephone circuit; larger amounts of noise impair the intelligibility of the conversation and if very much noise is present conversation becomes impossible. The amount of extraneous current which produces a certain deterioration in intelligibility depends on the frequency of the disturbing current. It has been found by experiment that the following magnitudes of foreign current in a 70-ohm receiver have about the same effect in impairing the intelligibility of conversations:

Frequency	*Current in microamperes*
100	200
200	110
500	32
1,000	10
1,100	8
1,400	55

These amounts of foreign current are sufficient to cause very appreciable annoyance to the telephone user and also a certain deterioration in the intelligibility of the conversation. Five times this amount of foreign current renders conversation very difficult. Where extraneous currents of several frequencies are present simultaneously the total impairing effect on the intelligibility is approximately proportional to the square root of the sum of the squares of the several components, each component of current being weighted according to its comparative effect on intelligibility.

It has been remarked that the human apparatus of audition and the telephone receiver acting in conjunction with one another make a wonderfully sensitive detector of small alternating currents; a current of 0.02 microamperes at 800 cycles in an efficient 70-ohm receiver is audible. It may be interesting to note that the excursion of the diaphragm is then about 10^{-8} c.m. or about the same order of magnitude as the diameter of an atom.

It is largely owing to the remarkable sensitivity of this combination, the telephone receiver and the ear, that it has been possible to provide telephone service at a cost so low as to be available to everyone. With this great advantage comes the minor disadvantage that it makes the telephone circuit very susceptible to extremely small amounts of energy derived from extraneous sources. Putting this into figures, it will be noted that 10^{-7} watts of foreign power absorbed in the receiver will cause an appreciable impairment in its efficiency as a translator of intelligence.

Now a power transmission line may be delivering 10^6 or even 10^8 watts, so that if $1/10^{15}$ of this power is transferred to a telephone circuit, its effect is quite appreciable. In the case of telegraph circuits the lower frequencies only have any appreciable disturbing effect. A single line Morse circuit will be rendered very difficult to operate by 15-20 milliamperes of 60 cycle foreign current, and 5-10 milliamperes of 25 cycle foreign current will have a similar effect. Printer telegraph systems are much more sensitive and 2 or 3 milliamperes of foreign current flowing in the circuit will cause the reception and printing of incorrect letters or symbols.

Aeroplane Surveying

Progress in the Preparation of Contoured Maps from Air Photographs

Professor H. L. Cooke, M.A.,
Professor of Physics, Princeton University, Princeton, N.J.

Paper read before the Ottawa Branch, The Engineering Institute of Canada, March 24th, 1924.

Although the problem of preparing maps from photographs taken from the air has been the subject of investigation for over fifty years, the present wide-spread interest in this subject only began to be evident after the beginning of the recent war. The extraordinary development in aeroplane design and the technique of air photography which was accomplished very early in the war resulted in the production of air photographs of very high technical perfection. A very cursory examination of these photographs reveals the vast amount of detailed information which can be obtained by means of them and as the photographs appear to have the same general characteristics as drawn maps and in many cases where very close approximations to maps, the conclusion was jumped at that the preparation of accurate maps from these photographs was a simple matter. But a detailed examination of the nature of the problem of preparing contoured maps by means of these photographs reveals at once the extreme complexity of the matter.

Two Classes of Photographs

Photographs taken from the air may be broadly classed in two groups: vertical and oblique views. A vertical photograph has the advantage of being an approximation to a map without contours. The relative positions of all objects shown in the same photograph are approximately true and approximately to scale. But as soon as one attempts to make accurate measurements on such a photograph the errors in scale and exact position become apparent and it is seen that although the photograph is approximately a plan of the country, it lacks precision. The approximate accuracy of these vertical views is utilized in so-called mosaics, in which vertical views covering an area are fitted together and form a reasonably good plan of the country covered. These mosaics show an extraordinary wealth of detail but their inaccuracies are always present to an appreciable degree. Tracings made from these mosaics cannot be regarded as maps in the scientific sense of the word.

The other class of aeroplane photographs, the oblique views, give one a much more realistic impression of the country and indicate in a more or less satisfactory way the nature of the undulations of the ground, but due to the variations in scale in the foreground and distance they are almost useless for an accurate estimation of relative distance and directions. It is the so-called distortion, due to the tilt of the camera, which is evidenced in the form of varying scale.

Types of Distortion

This brings us to a much discussed feature of our problem: that of distortion. The different types of distortion encountered in aeroplane photographs may be classed under several headings: First, there is the lens distortion, due to the fact that no lenses are perfect, and in general this distortion takes such a form that a perfect square when photographed will appear to have either convex or concave sides; these two effects being known respectively as barrel and cushion distortion. In a high grade lens this effect is small and will not be discussed in detail in this paper. Other distortions of negligible magnitude are those due to refraction of the atmosphere and curvature of the earth. But when these effects are disregarded, we are left with two types of distortion of considerable magnitude which are of prime importance in the problem of aeroplane mapping.

The first of these is the distortion which is the characteristic feature of the oblique photograph. This distortion would appear by taking an oblique photograph of a rectangular grid on the ground, in which case the photograph of the grid would in general show two perspective vanishing points. This type of distortion will be referred to as the distortion of perspective and it has to be eliminated in some way before the photographs can be employed directly for mapping. The photograph must be put through a process of horizontalizing or rectifying by means of which it is changed into the photograph which would have been taken if the axis of the camera had been exactly vertical and the plate exactly horizontal at the instant of exposure. A photograph taken under these conditions or rectified so as to conform to them is entirely free from the distortion of perspective.

The last type of distortion to be discussed constitutes the most important and useful feature of photographs from the air. This distortion will be referred to as the radial distortion. The nature of this effect may be understood if one imagines a photograph of a high tower taken from the air in an oblique manner. The top of the tower will occupy the same position on the photograph as an object on the ground lying beyond the tower in a direction radial from the plumb line through the camera position. This effect will at once be seen to depend, amongst other things, on the height of the tower, and it is, in fact, the means of determining heights and contours by means of aeroplane surveying.

This effect is present to a very slight degree in vertical small angle photographs, which are therefore not of great value for accurate contour surveying. On the other hand, radial distortion is present in pronounced form in oblique photographs. But the difficulty in horizontalizing oblique views is much greater than in the case of nearly vertical views. Vertical wide angle photographs combine advantages of both types and for this reason I have devoted a great deal of time to the production of a camera adapted to secure vertical views of this kind, and at the present time I think I am justified in saying that the main difficulties of this problem have been solved.

A detailed examination of the difficulties encountered in the mapping problem will show that they are nearly all either eliminated or simplified by the use of this type of photograph, which appears to be quite free from any characteristic disadvantages. For instance, it may be shown that if a given areas, say ten square miles, is to be covered by a single photograph, the most advantageous position for the camera is over the center of the ground photographed with the camera axis vertical, and from as low a height as will just prevent the serious obstruction of the view of distant objects by higher objects lying nearer to the camera position.

Production of Contoured Maps

We now come to a consideration of the main problem, which is the production of the contoured map from the photographs. To understand this problem we will have to realize at the outset that the geometrical principles on which any scientific method is to be based are in essence identical with those of the method of topographical surveying from the ground; methods which have been understood for thousands of years.

In work from the ground it is necessary for the observer in the field to locate his position by direct or indirect reference to known control points whose positions have been determined. To locate objects in the field the surveyor must determine the bearing or direction of the object as viewed from two located points. The intersection of these bearings determines the position of the object and angles of elevation or depression determine the heights. The fundamental problem of the field surveyor is the determination of the position from which his angles are read. Similarly, the determination of the aeroplane position is the fundamental problem of the aeroplane surveyor.

Although the problems confronting the two types of surveyor are the same as regards their general object, the solution of this resection problem as it is called, is child's play for the ground surveyor as compared with the difficulty which confronts the aeroplane surveyor. The reason for this is that the ground surveyor has a fixed platform to work from and his instruments are fitted with levels which enable all his angles to be read under ideally simple conditions as regards subsequent reduction by the computer. Once the instruments are levelled it makes very slight difference whether the observations are taken photographically or by sighting in a telescope. In the aeroplane, however, the conditions are entirely different.

Attempts have been made to devise instruments which will indicate a true vertical when used on aircraft in flight, and for the purpose of preparing mosaics, instruments of this type have already been produced which are reasonably satisfactory in their performance. But for the purpose of contour surveying, the determination of the vertical must be effected with scientific precision if the contours of the map are to be exact.

The requirements for the determination of the height of the aeroplane also calls for a precision considerably in excess of anything so far attained by the use of altimeters. It appears, therefore, that at the present time it will not be possible to determine the aeroplane position corresponding to a photograph directly by means of instruments carried in the machine. We are in effect thrown back on the same geometrical principles for our position determination as those employed by the ground surveyor. The resection problem on the ground, in two dimensions, becomes in effect the resection problem in space, and its difficulties are multiplied enormously when it becomes a three dimensional problem.

The Problem of Determining Position

Let us now consider the problem in detail. Just as the ground surveyor requires observation on three control points to determine his position, so the aeroplane surveyor requires that three known objects shall appear on each photograph. The angular separation of three control points as viewed from the aeroplane enables the position of the point of sight to be determined, but not without ambiguity. Time prevents a detailed discussion of this ambiguity, but it may be stated that if certain simple precautions are observed this ambiguity disappears and the position is definitely determined by means of the angular separations of the three points photographed on the plate. These angular separations are determined by means of the photograph if the relative position of the lens and plate is known, so that without further discussion we may say that by direct or indirect methods these angles are known from an examination of the plate.

Let us, then, imagine that the plate, after development, is set up in the same relation to the lens and that the images of the three control points are projected as rays passing out from the lens into space and forming the edges of a tetrahedron or pyramid. If, now, we imagine that we are able to construct out of, say a piece of cardboard, a triangle corresponding exactly to the triangle formed in nature by the three control points appearing on the photograph taken in their own plane, (which is not necessarily horizontal, same height), we can imagine that we are able to move this cardboard triangle around in the path of the three rays until we find a position in which the rays exactly coincide with the corresponding corners of the triangle. If this operation is carried out we have reconstructed the geometry of the aeroplane position and the three control points in nature, and the subsequent calculation of the aeroplane position based on this reconstruction of the pyramid is a perfectly straightforward problem of computation or mechanical solution and the horizontalization of the photograph is a simple matter.

But the solution of the pyramid reconstruction is beset with difficulties on every hand. The problem has been solved by direct mathematical methods but the labour involved is enormous and on this account it does not appear at present that this is the practical solution of which we are in search. An idea of the complexity of direct mathematical methods may be gathered from the fact that if simultaneous equations for the aeroplane position are set up, based on the angular separations of the control points, these equations have sixty-four roots, one of which is the position of which we are in search. This direct mathematical method is the work of two German scientists, Hugershoff and Cranz.

There is a second method also due to a German, which consists in a mechanical reconstruction of the pyramid. In this method an adjustable metal tripod is used which is fitted with telescopic legs and angular adjustments and scales at the apex. These angles are adjusted to correspond with the angular separations of the control points as determined by means of the photographs, and a three dimensional reproduction of the three control points is set up by means of adjustable pillars resting on a horizontal surface. The tripod is then moved around until its three feet simultaneously rest on the corresponding three points of the reconstructed triangle, the telescopic legs enabling this adjustment to be carried out without alteration of the apex angles of the tripod. When this adjustment has been effected, a plumb line suspended from the tripod apex indicates the projection of the aeroplane position on the horizontal surface and the height of the apex above this surface corresponds with the height of the aeroplane. This method, due to Dr. Max Gasser, is much more rapid than the method of Hugershoff and Cranz, but it appears to be open to the serious objection that the tripod cannot be constructed of sufficient rigidity and accuracy to compete in its performance with the accuracy of the field theodolite or the mathematical accuracy of the Hugershoff and Cranz method.

The third and last method which I shall describe, is one on which I have been working for a number of years. It consists in essence of mounting the developed photographic plate and projection lens in a camera so that the relation between the plate and lens is similar to that which existed at the time the photograph was exposed and projecting the images of the control points so as to secure coincidence with three points plotted on a screen so as to correspond to scale with the control triangle in nature considered in its own plane. When this adjustment is effected the relative position of projection lens and the three points on the screen corresponds with the pyramid in nature resting on the three control positions with the aeroplane position as apex. This seems at first the obvious and straightforward method of solution, but in practice it is beset with many serious difficulties.

If vertical views of the ordinary sort are employed it is found that the fixing of the aeroplane position cannot be attained with the required accuracy as considerable changes in adjustment do not appreciably affect the coincidence of projective images and plotted points. If oblique views are employed it is necessary, in order to secure sharp focus in the plane of the screen, to decenter the projection lens by swinging it on its center. This introduces errors and mechanical difficulties of a serious nature which very much reduce the accuracy and usefulness of the method.

It thus appears that if this projection method is to be employed, the aeroplane surveyor is on the horns of a dilemma, since the vertical and oblique views each have characteristic disadvantages. The employment of wide angle approximately vertical views eliminates these disadvantages and enables the aeroplane position to be determined with a very high degree of accuracy

The projection apparatus, is based on certain geometrical principles which enables the coincidence of the projected triangle to be effected with great speed and accuracy and the three scales incorporated in the instrument enable the polar co-ordinates of the aeroplane position to be read off directly with the precision of a theodolite. The arrangement of the instrument is also such that a single angular adjustment made after the above coincidence has been effected enables the operator to secure an accurately horizontalized projection of the photograph of which all the constants are determined by scale readings of the apparatus. It appears that this method represents the shortest means to obtain the horizontalized positive to be used for the mapping itself.

In both the other methods referred to, the production of the rectified positive after the aeroplane position has been determined is a much longer and more tedious matter. However, this step in the different processes will not be gone into in detail and we will assume at once that we may obtain these rectified projections by any of the three methods described and go on to a consideration of the method of employing these rectified projections in the production of contoured maps.

Preparing Contoured Maps from Rectified Projections

In order to secure contoured maps from the rectified projections it is necessary to employ these projections in pairs and by a method corresponding to the method of cross bearings and elevations employed in ground surveying to determine the position and height of unknown objects. This involves projecting the horizontalized views on the mapping surface in a certain definite relation to each other corresponding to the relative positions of the projections on a horizontal plane in nature of the objects as viewed from the two aeroplane positions.

When this relative position of the projections has been secured the position and height of unknown objects may be determined by means of the method of cross bearings and radial displacements of the images. Although this method may be employed directly it is an enormous advantage to arrange the projections so that they may be viewed by a direct stereoscopic method or an anaglyphic method, (two color stereoscopic method), or an equivalent of one of these methods.

By a process of this type the draftsman may be made to see the terrain standing out in bold relief and to draw contour lines directly by running his pen through all objects which appear to be in the same plane as the mapping surface. Different contours may be drawn by shifting the mapping surface backwards and forwards from the lenses which are projecting the images on the mapping surface, these lenses being placed to correspond with the aeroplane positions of the two photographs. These stereoscopic methods are capable of a great variety of modifications.

Types of Cameras

A word may now be said about the cameras with which I have been experimenting. In order to secure a satisfactorily exposed wide angle view, it is necessary to employ a slow lens and a much longer duration of exposure than with the fast lenses heretofore used in aeroplane photography in which the exposures are usually about 1/200 of a second. If a wide angle lens is to be employed it is practically necessary to take a time exposure from the moving aircraft. The point of sight of the exposure is changing during the exposure, as evidenced by a drift of the photographic image across the plate, and the camera, with the ordinary type of mounting, is vibrating to such an extent that a time exposure is out of the question.

Two types of camera have been experimented with in which the vibration is eliminated by a suitable stabilizing device in which the drift of the photographic image across the plate is compensated for by an adjustable slow motion. With the first type of camera an exposure of one-third second was employed with resulting good definition over an area of about seven and half square miles in vertical photograph, taken from a height of ten thousand feet. In the second type of camera, which is still being experimented with, an exposure of one second was employed. This camera is designed to take in a very much wider angle of view than the first type. The photographs taken with the first type of camera are being employed for the production of a contoured map of an area of about twelve square miles lying about ten miles to the northwest of Ottawa, Ontario, this area being selected as exhibiting unusual difficulties from the point of view of aeroplane survey, a large part of the ground being extremely hilly and covered with uniform woods. The flying and field work was done with the very kind co-operation of the Canadian Air Board and Survey Department. The constructional and mapping work are being done at the Palmer Physical Laboratory of Princeton University.

Limitations of Aeroplane Surveying

With regard to the ultimate limitations of aeroplane surveying it may safely be said that the time will never come in which all the work will be done from the air. The three methods of aeroplane surveying which have been outlined each look forward to the possibility of enabling aerial traverses to be run between control points many miles apart, so that ultimately we may hope that the necessary ground control will be reduced to geodetic points twenty or thirty miles apart, fixed with the highest accuracy.

The precision of these aerial traverses will depend very largely on the number of over-lapping photographs required to bridge the gap between adjacent geodetic controls. If vertical views of extreme wide angle can be obtained, this problem of working directly on the geodetic control will have been practically solved. It is very largely on this account that I attach so much importance to the wide angle vertical view. But even supposing that these extreme angle photographs are obtainable, we are still left with much work to do on the ground. Names of rivers, towns, etc.; conditions of roads, courses of roads covered by overhanging forests; nature of important land marks and structures, will all have to be ascertained by direct examination on the ground.

The method will probably be for trained men to travel around in small cars with enlarged photographs of aeroplane views covering the terrain on which they are working. Details and information about the terrain will be sketched in and noted on these enlarged photographs to be forwarded to the drafting room where the maps are being drawn. But the work of field surveying as we now understand it with the plane-table and small theodolite, will be practically eliminated for the purposes of mapping. The field surveyor will be employed more and more in the accurate surveying of properties. On the other hand, I can see the work of establishing geodetic controls for the aeroplane surveying being pushed to the limit in the way of speed in order to keep up with the speed of the pursuing aeroplane.

Before closing this paper something may be said about the general situation with regard to aeroplane surveying. A rapid and accurate method of producing contoured maps from aeroplane photographs is urgently required in practically all the civilized countries of the world. In the United States, for instance, there are still about two million square miles which have not been covered by contour maps. At the present rate of progress it will require more than forty years to complete this work. Demands are received in Washington almost every day for maps of almost any kind, of regions in which industrial development is proceeding rapidly. The situation in other countries is very similar. It is this situation which makes all those conversant with the facts so interested in this problem, which is one of utmost importance to the progress of rapidly developing countries.

I have tried in this paper to give you some idea of the problem from a scientific viewpoint and have tried to treat it in as broad a way as possible. We may say that the problem of aeroplane surveying has been solved. The development of methods to a state of very high efficiency may be looked forward to with absolute certainty and in view of the vast interests involved it will undoubtedly be carried out with great rapidity and energy. It is certain that within a quarter of a century this country will be completely mapped and that the contouring of these maps will be far more accurate and reliable than that produced by present means, since stereoscopic methods enable direct observation to be made on each point of a contour line and not merely at considerable intervals, as is done by present methods.

Consideration in the Design and Construction of Highways

Relation of the Design of Highways and Limitations Imposed on Motors Using Them

P. Philip, M.E.I.C.
Chief Engineer, Department of Public Works, Victoria, B.C.

Paper read before the Victoria Branch, The Engineering Institute of Canada, May 28th, 1924.

From the time of building the Great Appian Way, (300 B.C.), to the present date, highway construction has undergone many changes. Appius Claudius decreed that the Via Appia should be built in accordance with the best engineering practice then prevailing, and, as a result, the Appian Way to-day is a credit to the old Roman road builders. For 65 miles this road runs in a straight line to the town of Terracina. At this point it passes under the cliff of Monte Sant Angelo. The Romans had to make a side cut at this point by chiselling the face of the cliff. The outstanding features of this highway are the alignment, the excellent workmanship shown in the cut, the curvature around the cliff, the "easy" grades, the wide road bed, the neatly trimmed shoulders, the retaining walls, and, most important, the foundation, which has carried all manner of traffic. To-day we can learn much from these early Romans.

Subsequent to the construction of the Appian Way, there was a period in the history of road construction which might well be called the "Dark Ages of Road Building", but to-day we are enjoying a period of highway renaissance.

The problem, briefly, as far as the subject of this paper is concerned, has two phases, — *engineering* and *financial.* In this address I will not go into wearying detail. The ensuing discussion, I hope, will bring up further points.

Engineering and Financial Considerations

As to the engineering phase, briefly, the first principle involved is to design and build the road to carry the greatest loads to which it may be subjected, having regard to future traffic development and climatic conditions.

As to the financial phase, the load must be limited to conform to the design of road which can be built in accordance with the funds available. Public bodies always demand the greatest mileage of improved roads at a minimum of cost. This is the "parting of the ways" where engineers must choose a course of either pleasing a fickle public by sacrificing quality for quantity or run the risk of public censure by adhering strictly to good engineering practice at a consequent greater cost. Limitation of loading has its "limit" and the needs of growing industries must not be crippled by too stringent regulations.

Limiting Loads on Highways

In considering the question of limiting loads, we must be governed by the fact that many of our improved road surfaces built, say, ten years ago, were not designed to carry the loads to which they are now daily subjected. For instance, what will be the financial condition of a municipality which builds a first class road surface of say, concrete 8 inches thick or 2-inch asphaltic concrete on a 6-inch concrete base, and permits *unrestricted loads* to be carried over this surface, knowing that these loads must traverse another section of roadway built by the same municipality ten years previous having, say, a 4- or 5-inch concrete base with 1½-inch asphaltic concrete top; the latter financed on the assumption of a pavement having a life of twenty years, bonds having been floated for this purpose? Unless a limit of load and speed is enforced, the latter road surface will be totally destroyed long before the bonds mature; or, if traffic is limited, full use of the more expensive pavement will not be secured.

There is no "ideal" pavement section, in my opinion. Such "ideal" sections have been built, at great cost, and have failed. It is universally conceded that limitation of loads and speeds must be enforced, and this in relation to the locality and the period of the year. Therefore, the "ideal" pavement section may carry the load during a period from April to September but fail when the frost is coming out of the ground.

Automotive engineers argue that permanent highways must be built in order to suit the latest truck design. Arguments are used to show that railroads have undertaken reconstruction of their roadbeds on a large scale, placed heavier steel, built bridges to carry heavier loads, etc. The comparison is hardly fair in that the majority of railroads are financed by private companies, pay dividends, — or attempt to do so, — whereas our highways are financed by the public, are, in a sense, non-revenue producing in that the revenue cannot be shown.

Trunk Roads parallel Railways in British Columbia

If you will examine the map of British Columbia you will note that practically all of our trunk roads, projected and built, are parallel to railways: The Island highway, on Vancouver Island, the Dewdney trunk road, Vancouver to Agassiz, the Provincial highway, Vancouver to Hope and Lytton, Spences Bridge to Kamloops, Kamloops to the north and practically all trunk roads radiating from Kamloops, Ashcroft to Prince George, and Prince George to Hazelton and Prince Rupert. All these main trunk highways are so placed that the finances of the railroads will be seriously affected by competition of transporting companies using the highways built by public funds. These highways cannot be classed as "feeders" to the railways and in this province there are very few roads that might be called "feeders". Is the public then to be regarded as a competitor of railways?

By the above you are not to infer that limitations should be placed on trucks to eliminate competition with railways. Limitations must be placed not only to prevent our road surfaces from being entirely destroyed, but in order that they may be preserved for the use of the greatest number. It is then a question of finance as to what are the loads for which the roads will be designed and built. Is it possible to reasonably foresee what the traffic will be five or ten years hence?

Referring to the load limitations on highways, a large owner of trucks testified at a conference that "the public will have to pay for 1½ ton that is not hauled if this limitation is enforced". On the other hand, the public would require to pay a higher price if the roadbed is destroyed by excessive loads.

Importance of Foundations

As we are in the transient stage in the history of motor traffic on highways, it is my opinion that we should direct our engineering knowledge and skill to the preparation of the sub-foundation. You all know how the Romans built strong foundations, with extra heavy stone slabs laid in mortar. Those foundations are to be seen to-day intact. We are inclined to pay too much attention to the wearing surface, which, after all, has very little to do with the strength of the road. So that in considering the economics of design of surfaces for motor traffic, you must primarily consider the foundation.

Engineers are often faced with the problem as to what thickness of surface should be used when preparing plans for reconstruction of highways. Bituminous "carpet surfaces" cannot and should not be used where the foundation is not uniformly stable. Portland cement concrete attempts to take the middle course to distribute the load and bridge the weak spots in the sub-foundation, this being used as an argument in favour of this type of pavement over all other types.

It is undisputed that the *foundation* carries the load and the condition of the latter solely determines what type of surface should be used, having regard, of course, to loads, grades, etc. And in referring to foundations it must always be understood that drainage is of primary importance. The character of the foundation will solve the above problem. I do not intend to go into the merits of the various types of road surfaces at the present time. This is a subject too controversial and is not altogether essential in this paper. Job said, "Oh, that mine adversary had written a book". The inference is obvious.

In the design of highways, with regard to motor traffic limitations, as stated above, weight of load carried is important. Equally so are width and length of loads, speed, type and *condition* of tires.

What width road surface should be designed and built? Referring to paved roads, it is interesting to note the development from widths of 14 feet to 16 feet, and increasing to 20 feet. The widths of lanes of traffic vary: 8 feet is not "comfortable"; 9 feet is a fair average; if funds permit, 10 feet is most desirable. Two lanes of traffic should be provided for. Even as an expedient single track highways are not desirable. In British Columbia, legislation provides for the regulation of extraordinary traffic. The Lieutenant-Governor-in-Council may specify the gross load which may be hauled over any highway.

Appended hereto is a table showing the number of motor trucks registered in the province of B.C. covering the periods 1922 and 1923. It is interesting to note the decrease in the number of large units.

Statistics of Registration of Motor Trucks for years 1922 and 1923, for the Province of British Columbia

Capacity tons	No. of trucks 1922.		No. of trucks 1923.		Percentage Increases and Decreases.
½	1,808		2,316		
1	2,582	4,710	2,796	5,518	17.2 increase

Grand River Conservation and Power Development

The possibility of Power Development and its Beneficial Effect in preventing Destructive Floods

W. H. Breithaup, M.E.I.C.

Paper read before the Hamilton Branch, The Engineering Institute of Canada, May 15th, 1924.

In what may best be called its physical geography, the peninsula of southwestern Ontario is unique. The surrounding great lakes, the greatest continuous bodies of fresh water in the world, constitute the main feature of this distinction. The land area is in shape a rounded irregular cone, with flattened apex near its northern extremity, Georgian bay. Across the peninsula, from the Niagara river to the Bruce peninsula between Georgian bay and lake Huron, extends the Niagara escarpment, an abrupt break in the surface of the ground with a rise of 300 to 400 feet from below to above. The rim of water is almost level, the drop from lake Huron to lake Erie being only 9 feet, from Georgian bay to the outlet of lake Erie, from where there is fall, over the escarpment, to the level of lake Ontario.

The contour map, figure No. 1, showing also the Grand River drainage basin, is constructed on the well known White's Dictionary of Altitudes, compiled from railway elevations throughout Canada. This map gives an accurate general idea of the topography of the peninsula. The area within the 1,400-foot contour constitutes a tableland, the headwater area, comprising about 1,100 square miles, the greater part of which was originally swamp. On or near this plateau rise all the comparatively larger rivers of the peninsula: the Nottawasanga, Beaver, Sydenham, Maitland, Thames (north branch), and Grand rivers. Below the 1,400-foot contour the surface falls away sharply toward the north, less so toward the west and more gradually toward the southwest and south, the fall in every direction being at first steep and further on less so, becoming flat toward the rim, where smaller streams flow directly to the lake. Toward the north the fall from the highest contour, 1,700-foot, is over 1,100 feet in less than 23 miles.

The original surface condition, up to 100 years and less ago, was in greater part one of dense forestation. Especially in the central part there was one of the finest forests in North America; magnificent pine, 150 to 200 feet in height and 4 to 5 feet and over in diameter, and under them hardwoods, mostly maple and beech. On the headwater area there was much swamp, 700 square miles or more. A policy of intelligent government conservation fifty years ago would have retained all of these swamps as public domain; a continuing supply of cedar, tamarack and other poles and timber, a bird and game sanctuary and a perennial source of stream flow benefitting the entire peninsula. Instead of that, drainage was aided by government funds. The territory is now a flat plain largely of grazing lands with few if any farms of much value and this great natural resource is destroyed.

Grand River Drainage Basin

The Grand River drainage basin occupies the central part of the peninsula, lies on the higher ground directly within the upper edge of the escarpment, is approximately 2,600 square miles in area and comprises practically the whole of the counties of Waterloo, Wellington and Brant and parts of Grey, Dufferin, Perth, Halton, Oxford, Wentworth, Norfolk and Haldimand. The river rises about twenty-three miles from Georgian bay and has a length along its windings of over one hundred and sixty miles. The drainage basin is wide at the source and for some distance down, becoming narrower south of Waterloo county and quite narrow approaching the lake. It may be divided into two parts, the Upper river, extending to the outlet of the Conestoga tributary, and the Lower river from there on. The main tributaries in their order from the source are the Conestoga river from the west, rising on the headwater plateau, the Speed from the east and the Nith from the west. On the headwater plateau, mainly in the townships of East and West Luther, about 400 square miles of the Grand River drainage basin was swamp. This has since 1870, and largely between 1875 and 1895, practically all been drained.

Precipitation

Precipitation data for the immediate Grand River basin are scant. There exist however fairly good records for southwestern Ontario, and extending back for a considerable period. The Canadian Meteorological Service was organized in 1870, but there was observation to a considerable extent for some time before; in Toronto from 1840. Snowfall on the headwater plateau is heavy, ordinarily from 120 to 130 inches. One record 1879, is 153.8 inches. The average annual precipitation has varied from about 30 to over 40 inches of water. There is no evidence that with deforestation in the peninsula, precipitation has decreased. It has varied in cycles, but the general average of rainfall and snowfall remains about the same as at the beginning of observation. Runoff has however greatly changed with deforestation. Where the forest cover prevented quick passage of rainfall to the streams, retarded snow melting and facilitated accumulation of ground water, and the great swamps served as natural storage basins, the bare, compact surface now quickly delivers the water to the streams.

The gulf of Mexico is the great midcontinent source of rainfall and this influence extends to southwestern Ontario. How the large body of water intervening serves as a barrier against extreme precipitation is well shown in the records of March 1913, when occurred the disastrous floods along the Miami river and its tributaries in Ohio.

Precipitations from beginning of the storm to the dates given, were, at various points of observation in Ohio, as follows:—

Wooster	March	26th	9 in.
Upper Sandusky	"	26th	8.44 in.
Bangerville	"	27th	9.5 in.
Bellefontaine	"	27th	11.16 in.
Marion	"	27th	10.6 in.

North of lake Erie daily records are not available. The month's records are:—

	Location	*Rain*	*Snow*	*Total for month*	*Maximum 24 hrs.*
Port Stanley	Lake Erie	4.77	12.1	6.	1.77
Port Burwell	"	3.23	14.5	4.68	—
Port Dover	"	4.59	17.8	6.57	—
London	22 miles inland	2.83	23.5	5.18	1.34
Woodstock	30 "	2.99	10.8	4.07	0.42
Brantford	25 "	3.09	10.8	4.17	—
Guelph	52 "	0.65	11.	1.75	—

For the Grand River basin an average of 35 inches of water may be assumed as the annual precipitation; a little more in the upper river part, due to the large snowfall, and a little less in the lower. This compares with the precipitation in the total drainage area of lakes Erie and Ontario which has been taken at 34 inches.

Flood Records

The greatest floods in the year are invariably in the spring, when the snow melts, and invariably originate on the Upper river. However, heavy snow accumulations do not always cause extreme floods. Groundwater may be low, from lack of fall rains, and a good deal of snow-melting may be absorbed in the ground. Or the snow may pass very gradually, as in 1924. Minor floods occur any time during the summer after continued heavy rains, when the river may rise 6 feet in as many hours. Extreme high water never continues more than three or four hours, and generally less; and flood condition not longer than for a few days. The maximum flood in the history of the river, as far as I have been able to ascertain, was on April 7th, and 8th, 1912. In 1913 there was again an extreme flood, only slightly under that of 1912; but for the past eleven years including this year there has been no spring rise of more than moderate height; an unusually long period of exemption from destructive high water as the history of the river goes.

Discharges at various points on the river, during the 1912 flood, were approximately as follows:—

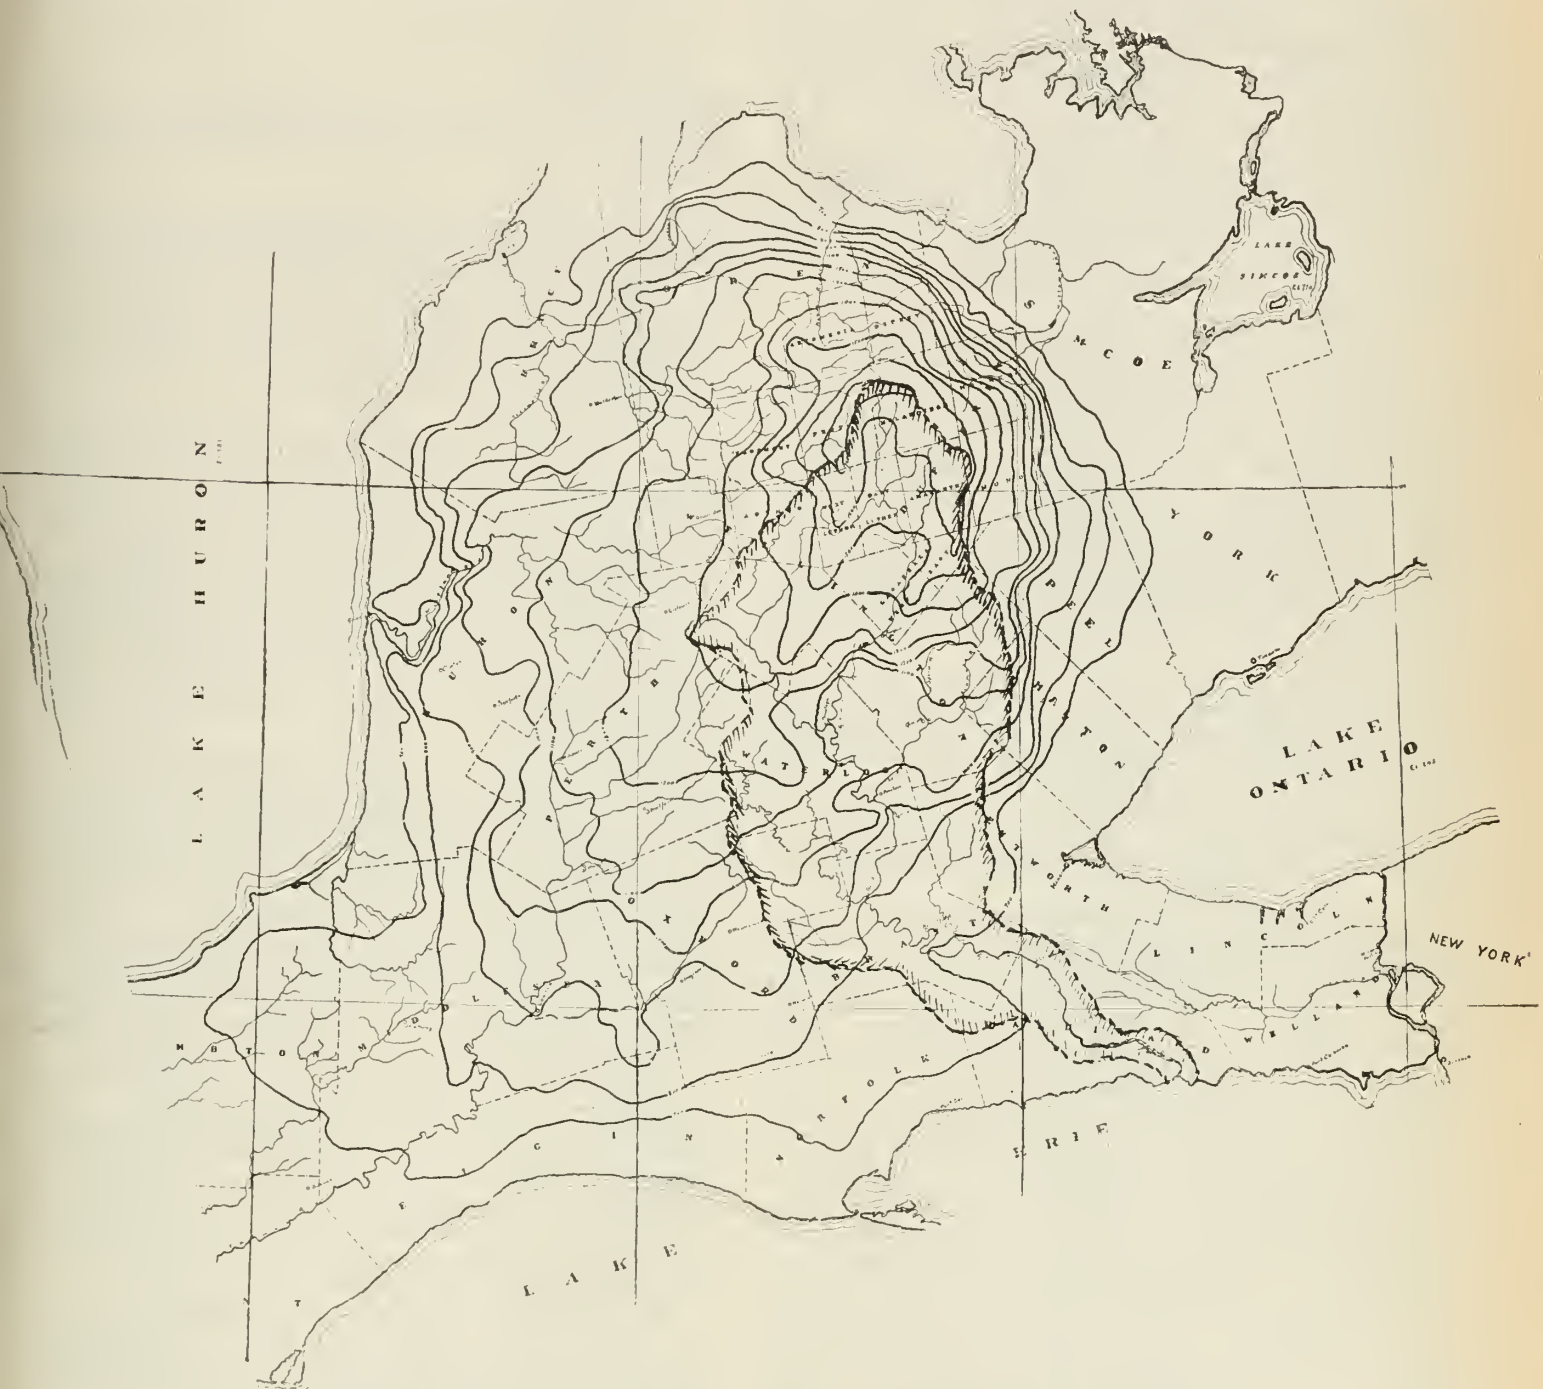

Figure No. 1.—Map showing sources of rivers in Ontario peninsula, with approximate 100-foot contours.

Elora	11 a.m.	Apr. 7	13,000 c.f.s.	
St. Jacobs (On Conestoga tributary)			12,300	"
Bridgeport	3 p.m.	Apr. 7	24,000	"
Galt	9 p.m.	" 7	31,000	"
Brantford	2 a.m.	" 8	51,000	"

Bridgeport shows the combined flow of Elora and St. Jacobs. Above Galt there is the Speed river outlet and above Brantford, at Paris, that of the Nith. A reduction of say 12,000 c.f.s., for a few hours only would have eliminated the destructive crest of the flood; a basin large enough to hold such discharge would therefore be effective in protection against extreme floods.

Storage Possibilities on Grand River

Let us look into the possibilities of storage on the Grand river. The Hydro-Electric Power Commission of Ontario, mainly in 1912 and 1913, made a topographical survey extending up the main river to beyond Elora and to some extent up its tributaries. In the township of Pilkington, just below Elora, the contours show a basin (previously known and called attention to), of about 5 square miles in area, and of capacity of two and three-quarter to three billion cubic feet depending on the dam at its outlet, the possibilities of which have not yet been at fully established. This dam will have a crest length of about 2,400 feet and a height above the river bed of from 60 to 70 feet.

This basin is by far the largest on the river, and in itself determines the economic practicability of conservation, giving not only ample capacity for flood control, but, above that, for very considerable sustained flow throughout the year in addition. Further storage is however available, and very desirable, and that on the Conestoga tributary. By its means a discharge at times approaching that of the main upper river, (compare St. Jacobs and Elora in the 1912 flood), can to a large extent be saved from waste. The practicable Conestoga storage will be only about one-half that of the Pilkington basin. It would bring the total to four and one-half billion cubic feet or over.

A flow of 15,000 c.f.s., for 24 hours would give 1,296,000,000 cubic feet, less than half the capacity of the Pilkington basin alone. Flood control would therefore be readily practicable. Sustained flow is however a very valuable consideration. A total of four billion cubic feet would supply a flow of 500 c.f.s., for 92½ days which is considerably longer than any period of drouth in the basin and there would therefore be replenishment from time to time.

The drainage area above the Pilkington basin would be approximately 440 square miles, and that above the Conestoga basin 180 square miles. There are no direct data on runoff, the proportion of precipitation delivered to the streams, in the Grand River drainage basin. Runoff depends on permeability and declivity of the drainage area. Evaporation, plant growth and ground water take up a large part of precipitation, although ground water will reappear in stream flow further down the valley. In general in the drainage area of the Great Lakes, including their surfaces which form a considerable part, runoff appears fairly established to be somewhat less than one-half of the precipitation. It appears reasonable to assume for the upper river parts of the Grand River drainage area, a runoff of twelve inches, about one-third of the precipitation. This would give for the Pilkington storage a total of over twelve and one-quarter billion cubic feet, and on the Conestoga a little over five billion; together over 17 billion, more than required for a flow of 500 c.f.s., throughout the year.

Above Bridgeport, about midway in Waterloo county, the summer low water flow is 40 c.f.s., while ordinary spring flood flow is 16,000 to 18,000 c.f.s., and has been as high as 24,000 c.f.s., as noted in the 1912 flood; i.e. low water is one-quarter of one per cent, or less, of ordinary spring floods, and one-sixth of one per cent of extreme floods, a condition approaching that of arid countries.

Power Possibilities with Storage Development

We come now to the consideration of power development by reason of conservation of flow. Below the proposed storage there are six power developments on the Grand river, utilizing heads as follows:—

Galt	8½	feet.
Paris	14	"
Brantford, upper dam	16	"
lower dam	33	"
Caledonia	7	"
Dunnville	6½	"

With sustained flow of 400 c.f.s., or more, other developments on the river would become practicable as there are good falls at a number of places, notably one just above Kitchener.

A much greater possibility of power development is by diverting the flow directly to the lake Ontario level. While the drainage area all along lies fairly closely within the edge of the high ground above the escarpment, the river channel does not come near this edge until three miles below Galt, where there is a lateral opening eastward with not more than about 40 feet of rise to the summit of the watershed between the river and lake Ontario.

By means of a dam, water can be taken from the river at this point at elevation 855 feet above sea level. This would give practically 600 feet of fall to the level of lake Ontario. There is no detail survey of the country between the proposed diversion point and Dundas, but the topographical map of the Department of Militia and Defence, with contour intervals of 25 feet, demonstrates the practicability of the project. The first two miles after leaving the river would be the most difficult and might have to be partly in tunnel. Such tunnel would be of about 12-foot bore, and not an undertaking presenting much difficulty.

A flow of 450 c.f.s., would give approximately 26,000 horse power. Development could well be in stages at various points with a first drop of 55 feet to the 800-foot contour, which could be followed, mostly by surface canal and partly by a flume resting on supports, across the provincial highway to the head of Spencer creek, from where on there would be no great difficulty. This route appears more easily practicable than one leading further south to the top of the escarpment nearer Hamilton. A moderate dam further down on Spencer creek could give a good regulating basin. The final drop would be from a forebay and could probably be 300 feet or more.

A diversion of water from the river at Galt may be disputed by municipalities further down stream. As to this there is to be said that if the diversion is no more than of the surplus water, now destructively wasted, to be gained by storage, and the present low water flow is maintained, or even somewhat increased, there can be no just complaint. On the contrary all municipalities will greatly gain by prevention of destructive floods, and must reasonably contribute to the cost of conservation.

The summer flow at Galt, augmented by the Speed river, which has a comparatively better minimum flow than the main river, and other smaller streams below the proposed storage, is approximately 150 c.f.s. An increase of 500 c.f.s. would proportionately benefit the developed water power in Galt.

VOL. VII September 1924 No. 9

Annual Meeting Montreal

The combined annual general meeting and annual professional meeting of *The Institute* will be held in Montreal, commencing Tuesday, January twenty-seventh, nineteen twenty-five.

A committee of the Council is co-operating with the Montreal Branch in arranging definite plans for the professional meeting, it being anticipated that the coming annual meeting will be of particular interest to the engineering profession in the Dominion.

British Association for the Advancement of Science

What is considered the most successful meeting of the British Association yet held was convened in Toronto on August sixth, and concluded on August thirteenth. The sections, to which a large number of valuable papers were presented, included mathematics and physics, chemistry, geology, zoology, geography, economic science and statistics, engineering, anthropology, physiology, psychology, botany, educational science and agriculture. The sessions were held in the various halls of the University of Toronto. In the engineering section a number of papers were presented by members of *The Institute*, all of which were well received.

A Hundred Years of Electrical Engineering

A Hundred Years of Electrical Engineering was the subject of a paper presented by Professor G. W. O. Howe, D.Sc., in which Professor Howe reviewed the entire range of electrical science since its inception. A remarkable prediction made in this paper was that long distance transmission of electrical power may yet take place by direct current of high voltage instead of by alternating current.

Lord Kelvin, said Prof. Howe, who championed the uni-directional system as opposed to the alternating current method, notwithstanding the successful operation of the early alternating installations at Niagara Falls and elsewhere, was the original sponsor of this idea. The constant current principle has again been brought to the fore by the demonstration of a commercial scale at the British Empire Exhibition, of machinery for efficiently producing direct currents of sufficiently high voltage to permit their application to long land lines without undue waste, Dr. Howe reported.

Formerly the only practical means of producing high pressure direct current was by linking in series a large number of dynamos. This required very careful insulation. The new device, known as a transverter, which has been developed during the last three years, obviates this difficulty, but it works on a different principle. The high voltage is secured by the use of step-up transformers as usual, and the ebb-and-flow current from these is converted into a steady supply by the use of a rotating commutator, which switches over the reverse half of the current of each pulsation.

"The machines convert a 3-phase alternating current supply into an almost steady current", Prof. Howe said. The Wembley plant turns out direct current of 100,000 volts, which is about the limit at present in use in transmission lines. The transverter has the double advantage of being reversible in operation, and thus the high voltage direct current can be changed back to alternating at the receiving end for the purpose of putting it through transformers and reducing it to a safe working pressure.

The re-introduction of the older principle on lines already in operation would require little alteration, it is pointed out, as three-phase generating stations and three-phase distributing depots would function as usual but would be connected by direct current lines. The three-phase current, which the transverters require, is used on practically all large installations, owing to its simplification of the electric motor problem, and the fact that lighter transmission lines are possible.

The advantages in favor of the continuous current lines are the facility with which generators can be thrown in or taken out, and the elimination of capacity and inductance effects in the circuits. The fact that the alternating wires must be insulated for a voltage 1.4 times as great as the effective voltage, is a further point in favor of the new proposal, as the "d. c." lines never carry more than the effective voltage. This aspect of the situation was one which appealed strongly to Lord Kelvin during his long but losing fight for the direct currents.

During the course of his address, Prof. Howe traced the development of modern electrical machinery from the time of the discovery of the principle of the electromotor by Faraday in 1821, regarded as the birth of electrical engineering, down to the present day. Showing how the efficiency of the machines for converting mechanical power into electrical energy, and vice versa, has been gradually raised, he pointed out that with the perfection of materials and the increased demand for electricity for all purposes during the last few years, the individual units employed at the generating stations have increased enormously in size. "In 1913, the largest high speed steam turbine alternators had an output of 7,500 kilowatts", he said. "Single generators of this type of 30,000 kilowatt capacity are now in use. Slower speed machines of 60,000 kilowatt capacity have appeared in the past ten years, also". Among the improvements in engineering practice which have contributed to this sudden expansion are the provision of better cooling arrangements for the big coils, and in conjunction with this, changes in their construction so that higher saturation with magnetic waves is possible and heavier electric currents can be carried by the conducting wires for the same waste of energy.

Pointing out that while the first hydraulic turbine dynamos installed at Niagara Falls were rated at only 5,000 horse-power, in comparison with the 70,000 horse-power alternators recently put in operation, Dr. Howe warned against a tendency to the construction of units on too large a scale, suggesting that a limit may have been reached to the size which it is feasible to construct and operate.

"The difference in efficiency between a 10,000 kilowatt and a 60,000 kilowatt alternator is of no practical importance", he declared.

"It is not sufficient to counterbalance the decreased factor of safety due to concentrating the whole power supply in several units, instead of distributing it between a dozen or more generators." While recognizing that the building of mammoth dynamos reduces the capital cost per horsepower, the engineer said: "There are many cases in which too much consideration has been given to this factor, and too little to the importance of a guaranteed continuity of supply."

Successful electric heaters for intermittent use was the possibility entertained by the scientist in his appraisal of the merits of electric heat. Citing the relative cost, convenience and efficiency of coal and electric heating in Glasgow, where anthracite coal costs $22 a ton and electricity is sold for cooking and heating at 2 cents per kilowatt hour, the speaker showed that some radical improvement must be made before current can be used economically as the standard means of heating. The amounts of heat available from the expenditure of a similar amount of money on coal, and on electricity, are in the proportion of 7½ to 1 with the Glasgow prices, which corresponds to the efficiency with which the power station converts the coal into electrical energy. Use of water power instead of coal, at the generating station would not affect the situation, it is pointed out, until there is a big cut in the present cost of water power.

"In view of the high efficiency and convenience of slow combustion stoves, it is evident that electric heating cannot be expected to compete with them for continuous operation", Dr. Howe admitted.

"But for intermittent heating, the comparison is much more favorable to the electric principle", he said, in suggesting that developments may be expected in this field.

That the time is ripe for a continent wide agreement for the purpose of standardizing the equipment of electrified railroads, is borne out by Prof. Howe's reference to the debate among electrical engineers as to the best method of distributing power to electric locomotives. "Five hundred volt direct current supply has been standardized for street tramways", he said. But the relative merit of direct and alternating currents for electric railways has been a burning topic for over twenty years.

"The question is one of increasing interest to engineers. It is comparable to the dispute over guage widths in the early days of the steam railways, because it involves the problem of through running.

"Through running will be facilitated or handicapped in the future, depending upon whether provision is made for it as railways are eletricfied."

Two systems find general favor, Dr. Howe explained. The exponents of the direct current system would cut down the line loss by stepping up the voltage to 1,500 or 2,000 volts, while the advocates of the alternating current system have perfected their motors so that they compare favorable with those used on direct current, and on their side is the advantage of cheap distribution and transmission. A third principle, found successful in Italy, which has not been widely endorsed, is the use of 3-phase alternating currents. This simplifies the design of the motors, but requires a three wire trolley service.

Experts are divided as to the relative merits of the systems, but the need is for the uniform adoption of either of them, the speaker indicated.

In his review of the development of communication by means of electricity, Prof. Howe showed how progress in radio transmission has had a reflex effect on the wired 'phone'.

The three-electrode vacuum tube, used in all radiotelephony work for both transmission and reception, has been applied to the long distance telephone. The tubes are used as amplifiers and repeaters at various points along the line, with the result that the attenuated currents are strengthened and sent along their journey with a new lease of life. This procedure has facilitated telephone communication between New York and San Francisco, for example, but it has been of even greater service owing to the fact that the use of the amplifiers permits greater losses on the wires with the result that lighter and consequently cheaper lines can be utilized.

Commenting on recent rapid progress in radio transmission, the scientist stated: "The accomplishment of long distance communication bristled with difficulties, largely due to unsuspected atmospheric effects which are still little understood.

"Such progress has been made, however, and is continually being made, that one dare not now adopt an incredulous attitude to the wildest dreams or forecasts of what is to be accomplished by 'wireless'.

"The commonplace facts of to-day would have appeared beyond the bounds of possibility ten or twenty years ago."

In concluding his address, Dr. Howe showed how practically the entire practice of modern electrical engineering, has been developed within a century, and that progress has been proceeding at a rapid rate in the last score or so years.

"In preparing this address, I have been greatly impressed by the enormous advances made, especially during the last thirty or forty years, in the mastery of man over the resources of nature, and in the use of these resources to the amelioration of the conditions of life", he declared.

"In no branch of electrical engineering is there any suggestion of having reached finality. On the contrary, rapid development is taking place in every direction, and we can look forward with confidence to an ever-increasing application of electricity to the utilization and distribution of the natural sources of energy for the benefit of mankina."

Five Million Horse Power Available

R. S. Lea, M.E.I.C., consulting engineer of Montreal, stated in an address before the Association on August eighth, on the Deep Waterway from the Great Lakes to the sea, that four-fifths of the potential power resources of the St. Lawrence were within Canada, within transmission distance of its largest industrial centres, mining areas, and its two largest cities, forming one of the country's most valuable assets.

Schemes for the development of this power, with or without added provision for water transportation, must take into account characteristic of the river as regards the volume and variation of flow under summer and winter conditions, and the action of ice in different forms, Mr. Lea pointed out. "Ice is generally the governing factor in determining the best method of developing power in the different reaches of the river", he said.

Describing present conditions along the St. Lawrence: "From the lake Ontario level at Prescott to the ocean port of Montreal, a distance of 120 miles, the St. Lawrence river descends in a series of rapids alternating with navigable reaches, through a total height of 225 feet.

"In the upper half of the stretch, which forms the boundary between Canada and the United States, two-fifths of this fall occurs, and along it each country has equal rights in the use of the water. Below this, the river is wholly within Canadian territory.

"Fourteen-foot navigation by means of a system of canals and locks around the rapids has been available for many years. Power has also been developed to the extent of 350,000 horse power, partly in connection with the canals, but mainly in a few plants, two of large size and recent installation, deriving their power by diverting for themselves a portion of the flow of the river."

Projects for the development of the waterway must choose between the primary purpose of power development on a scale necessitating the utilization of the whole flow of the river, with provision for present and future navigation requirements, and the object of securing deep-draft navigation sufficient for ocean-going vessels, with the incidental creation of opportunities for power development.

The second scheme is part of a more extensive undertaking, to enable ocean shipping to reach the head of the Great Lakes system", said Mr. Lea. "From either point of view, the projects are of exceptional magnitude and importance, the minimum ultimate depth proposed for the locks and navigation channels being 30 feet, and the total power when fully developed amounts to from 4 to 5 million horse power, with individual plants having capacities of from 600,000 to 1,500,000 horse power."

Water Power Development in Canada

The Water Power Development in Canada was the subject of a paper by J. B. Challies, M.E.I.C., before the Conference on August eighth, in which he stated the modern water power industry began in 1895 and has shown a steady and remarkable growth.

Which promises to be even more rapid in the future than in the past. During the last ten years", "while the population increased twenty-two per cent, the developed water increased nearly one hundred per cent and its use in industry two hundred and forty-five per cent. The total water power throughout the Dominion is estimated at over eighteen million horse power, of which about three and a quarter million is now developed and three-quarter million is under construction.

The capital invested in water power development, transmission and distribution has grown from one hundred and twenty-one million dollars in 1910 to six hundred and eighty-eight million in 1923, and the opportunities for further investment in such enterprises are numerous and attractive. Natural resources are abundant, labor conditions are stable, agriculture and manufactures are increasing their yield, and new markets are being developed". The pulp and paper, mining and other industries of the Central Provinces, Mr. Challies pointed out, are dependent on water power development. He also assured the meeting that the conditions under which the Canadian Government permitted the development of its water power resources afforded reasonable protection to capital, combined with such extent of control as was considered necessary in the public interest.

Public Health as an Engineering Science

On August thirteenth, F. A. Dallyn, M.E.I.C., presented a paper on Public Health as an Engineering Science.

In his paper Mr. Dallyn, pointed out that in such branches as sanitation, the supervision of public water supplies, milk supplies, sewerage and sewage disposal, stream protection, garbage collection and disposal, and municipal sanitation generally, including such projects as fly and mosquito control, rodent extermination, etc., the engineering element is very great. The work in those branches could with advantage be left to the direction of engineers and biologists, releasing the medical personnel for their distinctive field-hygiene and nutrition.

Transportation in Canada

A paper by Sir Henry Thornton, president of the Canadian National Railways, was presented, in which he gave a complete sketch of the Development of Railway Transportation in Canada.

Sir Henry Thornton first dealt with the part which railway transportation plays in modern social and economic life. The great difficulties in communication between different parts of the country before railways were built, contrasted with the conveniences of to-day.

The history of Canadian Railway Development was then dealt with in detail. Sir Henry divided this history into four main chronological periods, — prior to Confederation, the Confederation period, the balance of the nineteenth century, and finally, the 20th century. The fact that great obstacles had to be overcome, said Sir Henry, in the laying of trans-Canada railways is a credit to Canada when we consider that there was a relatively small population to carry the burden of expense. The laying of railways was, however, the foundation of national industry, and there is no doubt that railway development would lead to great and greater prosperity, he said. Slides were shown, comparing the Canadian transportation system with that of Great Britain. The lumber industry, the pulp and paper industry, the handling of grain, and other interests were also illustrated on the screen.

OBITUARIES

Death of Am. Soc. C. E. Secretary

The sympathy of the members of *The Institute* goes out at this time to their fellow members of the American Society of Civil Engineers in the loss they have sustained in the tragic death of John H. Dunlap, their secretary. Mr. Dunlap was seriously injured in a train wreck near Buda, Ill., on June 30th, and died at the Presbyterian Hospital, Chicago, on July 29th. The body was accompanied by Charles F. Loweth, past president of the Society, to Franklin, Vt., where the funeral was held.

Taking advantage of the fact that transfer was made at Montreal, the President and members of the Council of *The Institute* were present at Windsor Station to pay their respects, a floral wreath being sent in the name of the President and Council of *The Institute.*

Mr. Dunlap accepted the secretaryship of the American Society of Civil Engineers only two years ago, succeeding Doctor Charles Warren Hunt as permanent secretary of the Society. Previous to this position he was professor of hydraulics and sanitary engineering at the State University of Iowa, Iowa City. The late Mr. Dunlap was a capable executive and his genial disposition has made him many friends in the profession, who regret the untimely ending to so promising a career.

John Alfred Symes, A.M.E.I.C.

Following an illness of some months, John Alfred Symes, A.M.E.I.C., died at his late residence, in Ottawa, on June 4th, 1924. Since returning from overseas in 1919 where he served with the Allied Armies from the time of his enlistment in 1915 until invalided to England in August 1918, he had not regained his health, and while able to attend his work in the Department of the Interior at Ottawa until a few months prior to his death, he never recovered from the effects of his war disability, which ultimately resulted in his death.

The late Mr. Symes was born and educated in Ottawa and, after matriculating from Ashbury College, spent one year at Queen's University. In 1904 he was with the Canadian Pacific Railway Company on survey work near Winnipeg and the following year was attached to the field staff on the company's irrigation work at Calgary. He was later assistant engineer for the company in charge of preliminary location and construction parties on the irrigation work and from 1910 to 1915 was office engineer, first at Brooks, Alta., and later at Calgary, Alta., until he enlisted for overseas service. He was elected an Associate Member of *The Engineering Institute of Canada* on April 9th, 1910.

Thomas Thomson Dunlop, A.M.E.I.C.

News of the untimely death of Thomas Thomson Dunlop, A.M.E.I.C., has been received with sincere regret by his many friends both in the profession and in private life. The late Mr. Dunlop, who for the last seven years has been on the engineering staff of the Public Works Department of the government of British Columbia, was drowned on May 15th, 1924, while inspecting the piers on the highway bridge over the Bukley river near Smithers, B.C.

Mr. Dunlop was an Associate Member of *The Engineering Institute of Canada*, having been admitted to the Canadian Society of Civil Engineers, as such, on December 12th, 1907. He was born at Glasgow, Scotland, on August 28th, 1877, and was educated at Royston Grammar School, Royston, England. His first work in this country in 1900, was on surveys for the Canadian Pacific Railway Company, and in his subsequent railway work, which extended over a number of years, he was continuously with the C.P.R., with the exception of one year with the Chicago and Northwestern Railway.

John St. Vincent Caddy, M.E.I.C.

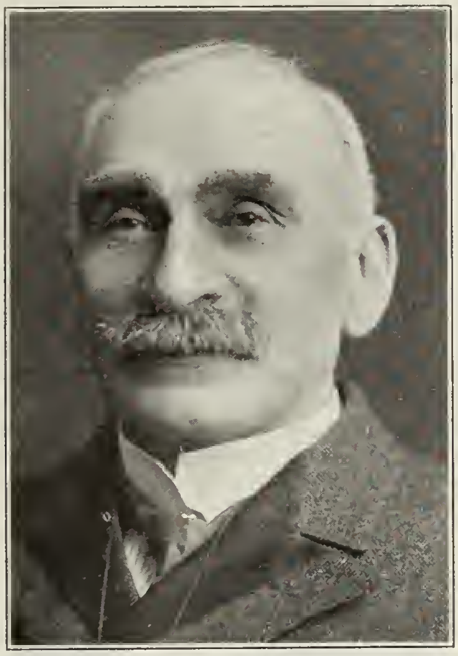
Regret is expressed at the death of John St. Vincent Caddy, M.E.I.C., of Ottawa, which occurred at his late residence 327 Laurier Avenue, East, on May 30th, 1924. The late Mr. Caddy was in his eighty-eighth year at the time of his death and had been a member of *The Institute* for thirty-five years, having been elected a Member of the Canadian Society of Civil Engineers on January 3rd, 1889.

Born at Fort Charlotte, St. Vincent W.I.Is., Mr. Caddy commenced his engineering work with a construction party on the Great Western Railway in 1851, later being appointed assistant draughtsman and then second assistant engineer with the company. In 1858 he was second assistant engineer on the St. Mary's and Sarnia extension of the Grand Trunk Railway, and from 1860 to 1863 he served his apprenticeship with a land surveyor, receiving his certificate as a Dominion and Ontario Land Surveyor in 1866. During the year 1864 he was with the Detroit and Milwaukee Railway as assistant engineer and draughtsman on maintenance work. He was later located at Windsor and Detroit on maintenance and construction of docks and landing aprons, having sole charge of this work in 1868. In 1870 he was resident engineer and the following year, division engineer on the Air Line of the Great Western Railway. For the next four years he was engaged in surveying and locating several short lines in Canada and the State of Ohio. For seven years from 1879 he was with the Canadian Pacific Railway, first as district engineer on construction, then as inspecting engineer and later as resident engineer on construction.

From 1889 to 1892, the late Mr. Caddy was engineer in charge for the Department of Railways and Canals, on the location and construction of the Annapolis and Digby Railway in Nova Scotia. Subsequently, in 1908 he was appointed assistant engineer of the Rideau Canal Branch of that department of the federal government.

Nathan Hanson Greene, A.M.E.I.C.

In the death of Nathan Hanson Greene, A.M.E.I.C., at his home in Montreal on March 24th, 1924, *The Institute* has lost one of its early members and one who for fifty years has been actively identified with the practice of land surveying in the province of Quebec. The late Mr. Greene was born on December 22nd, 1847, in the township of Bolton, in the county of Brome. He studied at St. Francis College, Richmond, Que., and in 1869 he undertook his first work as assistant engineer with the South Eastern Missisquoi and Clyde Rivers and Canada Central Railway. For twelve months prior to the fall of 1872 he was resident engineer in charge of construction work.



NATHAN HANSON GREENE, A.M.E.I.C.

On April 14th, 1873, he was admitted to practise land surveying in the province of Quebec and for eleven years he was chiefly engaged in railway work, being at different periods with the Quebec, Ottawa and Occidental, the Intercolonial, and the Laurentian railways.

In 1882-1883 he was engaged in the preparation of special railway reports for the government, on arbitration work, and on exploration and location work for the department of railways of the Federal government in connection with the Intercolonial Railway.

In later years Mr. Greene has been in private practice giving special attention to municipal water systems as consulting engineer, in the Eastern Townships and elsewhere.

On December 9th, 1897, he was admitted to *The Institute*, (then the Canadian Society of Civil Engineers) as an Associate Member.

PERSONALS

A. L. Farnsworth, S.E.I.C., is at present with Messrs. Price Brothers and Company, Limited, at Kenogami, Que.

G. A. McClintock, S.E.I.C., is located at present at Thetford Mines, Quebec, with the Bell Asbestos Mines.

W. B. Hutcheson, A.M.E.I.C., of the Water Power and Reclamation Branch, Dept. of Interior, Calgary, has been transferred to the same department at Ottawa.

C. F. Draper, M.E.I.C., of the engineering staff of the Canadian Pacific Railway at Montreal has been placed in charge of grade separation work in Toronto, Ont.

N. W. Wade, Jr.E.I.C., formerly with the Department of Telephones, Regina, is at present with Siemens Brothers, London, Eng.

E. K. Macnutt, S.E.I.C., who graduated in civil engineering this year from McGill University has accepted a position with the E. B. Eddy Company at Hull, Que.

Kenneth M. Ramsey, S.E.I.C., who has for two years been construction superintendent of the Citadel Brick Company, Limited, of Quebec, has been made assistant manager of the organization.

H. W. Mahon, A.M.E.I.C., has resigned his position as assistant engineer, Dominion Water Power Branch, Halifax, N.S., and joined the staff of the Nova Scotia Power Commission, Halifax, N.S., as assistant engineer.

E. D. MacDonald, S.E.I.C., is at present employed in the draughting room of the B. F. Sturtevant Company, Hyde Park, Boston, U.S.A. His address is 39 Davison St., Hyde Park., Boston.

J. D. Chisholm, S.E.I.C., who graduated from McGill University in electrical engineering in 1923,is now electrical engineer with the Newfoundland Power and Paper Company, Limited, Cornerbrook, Newfoundland.

Donald G. Robertson, S.E.I.C., is located at Hemming's Falls, Drummondville, Que., with the Southern Canada Power Company. Mr. Robertson is a graduate of this year from Queen's University.

C. H. Frid, S.E.I.C., until recently with the Truscon Steel Company, Youngstown, N.Y., as concrete designer, has resigned to accept a position as engineer for the Frid Construction Company, Incorporated, of Buffalo, N.Y.

Hugh A. McKay, S.E.I.C., of Toronto, Ontario, is at the present time located in New Liskeard, Ont., with the Sutcliffe Company, Limited, as assistant engineer. Mr. McKay received his B.A.Sc., degree from the University of Toronto in 1923.

William F. Stewart, S.E.I.C., of Montreal, Que., is with the Canadian Westinghouse Company, Limited, and is at present located at La Gabelle, Que., at the site of the new hydro-electric power development of the St. Maurice Power Company.

William Watson, S.E.I.C., of Montreal, Que., has been appointed to the staff of the Sir W. G. Armstrong, Whitworth and Company, Limited, being located at Deer Lake, Newfoundland. Mr. Watson received his B.Sc. degree in electrical engineering this Spring from McGill University.

Peter Emslie, A.M.E.I.C., formerly with J. M. Robertson, M.E.I.C., Montreal, and later with A. F. Byers and Company, Limited, has been in Scotland since November 1922. He was recently appointed manager for the Dundee branch of Currie and Company, Limited, large dealers in building supplies.

F. W. Clark, A.M.E.I.C., has been placed in charge of power surveys on the Ottawa river for the Hydro-Electric Power Commission of Ontario. Mr. Clark has been on the engineering staff of the commission for the past thirteen years and was for sometime assistant chief field engineer on the Queenston-Chippawa development.

Noel M. Barclay, A.M.E.I.C., has been appointed assistant engineer with the Technical Service Department of the city of Montreal. Until recently Mr. Barclay has been on the draughting staff of the Bureau of Economics of the Canadian National Railway, prior to which he was on the Arbitration staff and later on the Valuation staff of the Valuation Department of the Grand Trunk Railway.

J. H. Forbes, A.M.E.I.C., formerly division engineer at Smith's Falls, Ont., for the Canadian Pacific Railway, has been transferred to Montreal, Que. Mr. Forbes received his B.Sc. degree from McGill University in 1908 and with the exception of the period of his war services he has been associated with the Canadian Pacific Railway in various capacities ever since.

T. C. Thompson, Jr.E.I.C., has resigned his position as assistant mechanical engineer of the Crosby Steam Gauge and Valve Company of Boston, Mass., to join the staff of the transmission engineering department of the Bell Telephone Company of Canada in Montreal. Mr. Thompson graduated from McGill University with the class of '20 and was for a time demonstrator at McGill.

U. R. Moore, A.M.E.I.C., who until recently has been connected with the engineering department of the Hydro-Electric Power Commission of Ontario at Niagara Falls, Ont., has joined the staff of the Pennsylvania Water and Power Company at Holtwood, Penna., as assistant superintendent in charge of field engineering on the construction of a large steam power plant. The initial development will consist of two 10,000-k.w. units, and will cost approximately $3,000,000., and the ultimate development will contain two, 20,000-k.w., and two, 30,000-k.w., units in addition to the two units at present being installed.

A. C. D. Blanchard, M.E.I.C., who for the past seven years has been connected with the Hydro-Electric Power Commission of Ontario as chief field engineer in charge of surveys, field engineering and inspection on the Queenston-Chippawa power development has resigned to accept an appointment with the New Brunswick Power Commission as hydraulic engineer. Since 1911 when he resigned from the position of assistant engineer with the city of Toronto, Mr. Blanchard was for two years city engineer for the city of Lethbridge, Alta., and for the next four years he was connected with the Greater Winnipeg Water District as locating engineer, assistant chief engineer and division engineer in charge of thirteen miles of the heaviest section of the aqueduct construction and the diversion works at the intake, from which position he resigned to accept his appointment with the Hydro-Electric Power Commission of Ontario.

Rex P. Johnson, A.M.E.I.C., has recently joined the staff of the Pure Gold Manufacturing Company, Limited, and Todhunter, Mitchell and Company, Toronto, as production manager in charge of production costs and factory management, and will be assistant to the general manager. Mr. Johnson graduated in civil engineering from the University of Toronto with the class of '14, and was employed for the next two and a half years as designing draughtsman on the Welland Ship Canal at St. Catharines, Ont. In 1916 he joined the staff of the Hydro-Electric Power Commission of Ontario on the Queenston-Chippawa development. During the last three years that he was with the commission he held the position of office engineer in charge of plant layout, design of temporary structures, construction schedules, etc. After resigning from the commission Mr. Johnson joined the staff of the Forest Products Engineering Company of Chicago and for the next two years he was engaged on factory production, cost finding and business research. While with the Hydro-Electric Power Commission, Mr. Johnson was secretary-treasurer of the Niagara Peninsula Branch of *The Institute* for over two years just prior to his leaving the commission.

Major H. W. L. Doane, M.E.I.C., has been appointed assistant city engineer of Halifax, Nova Scotia, to fill the vacancy left when H. W. Johnstone was elevated to the position of city engineer after the resignation of Colonel F. W. W. Doane, M.E.I.C. Major Doane graduated from Nova Scotia Technical College with the degree of Bachelor of Science in civil engineering in 1913. From 1912 to 1915 he was engaged in sewer design and construction at Springhill, N.S., Chester, N.S., Halifax, N.S., Lunenburg, N.S., and Hazel Hill, N.S.; in water works design and construction at Kentville, N.S., Hazel Hill, N. S., and Trenton, N.S., including the construction of a 1,000,000 gallon reservoir and attendant pipe lines. He assisted in the making of survey and the preparation of plans for and the engineering construction of the electric light system Truro, N.S., and investigated and reported on a proposed hydro-electric development for Parrsboro, N.S. From 1915 to 1919 he was on active service overseas in Palestine and France during which he rose from Lieutenant to Major. After his return to Halifax in 1919 he joined the city engineer's staff. Since then his work has been highly successful. Acting under the direction of Mr. Johnstone he reorganized the waterworks department and of late has had charge of both the waterworks and street and sidewalk departments, including the city's paving plant. Major Doane is one of the most widely known and most active engineers connected with the Halifax Branch of *The Institute* where he has been a member of the executive for several years.

EMILE LACROIX, A.M.E.I.C.
Recently appointed Acting City Engineer and Manager of Outremont, Que.

Outremont's Former General Manager Honoured

Major J. A. Duchastel de Montrouge, M.E.I.C., whose recent appointment as general manager of the Quebec Forest Industries Association was announced in the August issue of *The Journal*, was presented with a "grand-father's" clock by the citizens of Outremont on August eighth, on the occasion of his retirement as general manager and engineer of that city. The presentation was made by Ex-Mayor Alfred Joyce and Mayor Joseph Beaubien of Outremont and took place in the city hall in the presence of a large gathering of representative citizens, the aldermen of Outremont and the mayors and other representatives of adjacent municipalities. Tributes to Major Duchastel's untiring devotion to duty during his eighteen years of service to Outremont, and to his ability as an administrator were the theme of the presentation speeches.

In the evening, Major Duchastel was tendered a banquet by the citizens of Outremont, at Laval-sur-le-lac, at which there were also representatives of the neighbouring cities. At the banquet many tributes were paid to Major Duchastel, not only as an official who has accomplished much within the strict realm of civic endeavour, but also as one who has done much for the general welfare and advancement of the province, and consequently of Canada, and in this connection his work for better roads, and for the automobile traffic generally was referred to. In paying honour to the guest of the evening, Mayor P. W. McLagan, of Westmount, said: "I know of no man who has been a public servant who deserves more of honour which can be given him by his fellow citizens than does Mr. Duchastel".

In its editorial column of August 2nd, *The Gazette* of Montreal makes the following reference to Major Duchastel's appointment, "The Quebec Forest Industries Association, Limited, has made no mistake in its selection of Major J. A. Duchastel de Montrouge for the important and difficult duties connected with its general managership, for as an official of the city of Outremont and a citizen of Greater Montreal, Major Duchastel has amply proven his qualifications for the larger fields of usefulness to which he has gone. His administration of the two civic departments under his charge, his professional equipment, his wide experience of men and affairs, and his faculty of grasping the essentials of technical subjects and of keeping abreast of scientific advancement as it affects practical matters, all combine to mark him as eminently fitted to initiate and carry on the important new activities now being entrusted to his keeping."

Members are earnestly requested to make special note of the dates of the Annual General and General Professional Meeting, January 27th, 28th, and 29th, at Montreal, and to plan to be present as the meeting will be interesting and entertaining.

Brantford Holds Interesting Celebration

On Monday, August 11th, the city of Brantford, Ont., gave itself over to a day of festivity, commencing with the commemoration of the fiftieth anniversary of the invention of the telephone by the late Alexander Graham Bell, which was followed by the celebration of the opening of the New Lorne bridge. The date fixed for the celebration was the nearest anniversary date that could be selected to that time when, in 1874, the human voice in articulate conversation was first transmitted through space by telephonic mechanism at the Bell Homestead in Brantford.

The following record of dates supplied by the inventor of the telephone and recently published by the Brantford Expositor are of interest as substantiating Brantford's claim of the title of "The Telephone City":—

The Invention of the telephone at Tutela Heights	Brantford	1874	Summer
First telephone constructed and speech sounds heard	Boston	1875	June
First draft of the telephone patent specification prepared	Brantford	1875	Sept.
Complete sentences first clearly understood by telephone	Boston	1876	Mar. 10th
The telephone exhibition at the Centennial exhibition	Philadelphia	1876	June 25th
First attempts to transmit speech over telegraph lines	Boston	1876	July 7th, 9th and 12th
First successful attempt to transmit speech over a telegraph line	Brantford	1876	Aug. 10th
First public demonstration of ability to speak over a telegraph line	Brantford	1876	Aug.
First transmission of a number of voices simultaneously over a telegraph line	Brantford	1876	Aug.
First conversation by telephone over a telegraph line (reciprocal communication)	Boston	1876	Oct. 9th
First long-distance conversation over a telegraph line (143 miles)	Boston	1876	Dec. 3rd
First newspaper dispatch sent by telephone	Salem	1877	Feb. 12th
First telephone line opened	Boston	1877	April 4th

The new Lorne Bridge, Brantford, Ont.

The second part of the celebration centred around the official opening of the New Lorne bridge. This bridge, which was officially opened by the Lieutenant-Governor of Ontario, replaces the old steel structure forming the only crossing over the Grand river connecting the rapidly growing western district of the city. The former bridge was opened on September 16th, 1879, on which occasion the city was honoured with a visit from the Marquis of Lorne and H. R. H. The Princess Louise but for some years has rapidly approached a condition unsafe for the heavy present day traffic necessitating the building of the new structure. The design and plans for the present bridge were prepared by city engineer, Major Frank P. Adams, A.M.E.I.C., under whose direction the structure was built by the Port Arthur Construction Company and in the work of the supervision of construction Major Adams was assisted by Edward T. McLaren, assistant city engineer, and C. Ralph Hagey, as resident engineer.

The new bridge has an over all length of 424 feet, the three spans totalling 400 feet, the centre span 140 feet and the side spans 130 feet each. The over all width is 64 feet providing a roadway width of 40 feet and the rise of the centre arch is 19 feet, while that of the side arches is 17.4 feet. Other interesting data regarding the bridge is as follows:—Width of arches 58 feet; thickness of arches at crown 34 inches; thickness of arches at haunches 51 inches; thickness of floor slab 10 inches; thickness of spandrel walls 14 inches; cement used 16,500 barrels; concrete poured 12,811 cubic yards; contract let March 24th, 1923; last cement poured December 24th, 1923; officially opened August 11th, 1924; cost $335,000.

The First World Power Conference

Session on Economic Aspect of Power Resources—Legal and Government Policy

Discussion by E. A. Cleveland, M.E.I.C.

In speaking on the legal and government policy aspects of power development, Mr. Cleveland said that he was not able to agree fully with the policies suggested in the paper of Professor Vanderleys, but he felt that all could subscribe to the general doctrine outlined in the opening paragraphs of the paper by the Rt. Hon. Sir Philip Lloyd-Graenel that governments should encourage and foster the development of power: that encouragement might of course take any suitable form in the wide range from moral support to that of the loan of government credit or the outright ownership and operation of power producing plants.

There were many factors in the practice of construction, equipment and operation that might be standardized, some of which he instanced, but it was hardly to be expected that the contentious subject of state versus private ownership and operation should by discussion be brought much nearer to a deadlevel of uniformity. The subject was a local one, for each state, province or federal authority having complete jurisdiction to deal with.

In respect to hydro-electric power production, he briefly reviewed the situation in each of the provinces of Canada, showing how different the policies of the several governments were in the matter.

He was of opinion that the great contribution to be made by the World Power Conference toward a consideration of this aspect of the problem was in the collection of the views expressed in the several papers and in the discussion and the statements as to the position already taken by the countries or their autonomous subdivisions, so that when published they would form an epitome of present experience and views available to those whose duties might require of them advice or assistance in the framing of government policies in such matters.

He was impressed by such clear statements of a country's laws and regulations respecting water power as that contained in Mr. Larrsen's paper in respect of Norway and by such illuminating discussion on the subject of ownership and operation as that by Dr. Hadley.

The Conference had at least brought together much informative data on the subject even though it could not formulate government policy.

Notes on the World Power Conference and Subsequent visit to Norway and Sweden

G. Gordon Gale, M.E.I.C.

The World Power Conference was inaugurated at the Palace of Industry, Wembly, on Monday the 29th of June, with an address of welcome by H.R.H. the Prince of Wales.

Morning and afternoon sessions followed every day, and several evening meetings were arranged during the two weeks ending on the 11th of July. The meetings were attended by from three to four hundred representatives from forty-one countries.

Four hundred and fifteen papers were presented, giving a complete review of the power resources, their development, and utilization in the different countries. During the time available, it was impossible to do more than summarize the more important features of the different subjects. Some interesting discussions took place, but as most of the papers were not received until after the conference opened, the speakers usually limited their remarks to brief outlines of the contents of their own papers.

The purpose of the first World Power Conference was to consider how the industrial and scientific sources of power may be adjusted nationally and internationally. The frank manner in which the different problems were presented, the complete exchange of thought and information, and the many acquaintenceships which were formed, have, I believe, gone a long way towards the accomplishment of this desirable object.

Favourable comment was made upon the contribution offered by the Canadian delegates, and it is quite evident that this country has secured a place in the foremost rank of hydro-electric developments.

In many countries, the natural resources, and industrial demands have combined to form problems which are widely different.

Great Britain and France contemplate the consolidation of existing steam plants, the development of available water powers, and the construction of supersteam power stations.

Norway and Sweden with a quantity of surplus power, developed, and undeveloped, are negotiating with adjoining countries to provide a market for their surplus electric energy.

Italy, Denmark and Holland are anxious to import electrical power, to provide for their industrial and domestic demands in excess of their own power supply.

Spain, with water powers and minerals, needs financial assistance to aid in the development of its natural resources.

In the United States hydro-electric development has progressed rapidly, particularly in California, while the north eastern section, New England, is looking to Canada to supply the ever increasing demand for hydro-electric power.

In Canada the demand for electric power has been increasing steadily, and hydro-electric developments are under construction from coast to coast.

A number of the papers were not of special personal interest, and it was possible to make use of these intervals to visit the following plants in different sections of England.

Stonebridge, — Steam station, 20,000 h.p. Overhead and terminal electrification, car sheds, and electrical repair shops of the London Midland and Scotish Railway.

Vickers, — Manufacturing plant at Barrow-in-Furness. Inspection of large water wheel under construction for the Ottawa River Power Company's plant at Bryson, and deisel oil engines for marine service.

Cambridge University, — Demonstration of experiments with radio-active elements, the liberation of electrons, etc., under the direction of Sir Ernest Rutherford.

The English Electric Company, — Inspection of electrical equipment, and rotary convertors for railway service.

Armstrong—Whitworth Company, Elswick, Newcastle,—Inspection of deisel oil engines and water wheels for the Humberarm Newfoundland hydro-electric development.

C. A. Parsons & Company, Beaton, Newcastle, — Inspection of large steam turbines under construction for Chicago Edison Company.

Wembley, — Inspection of many extensive exhibits of oil, steam and equipment in the Palace of Engineering.

Immediately following the World Power Conference, a party of thirty-two engineers, representing eleven countries, joined the Scandinavian tour, and the following itinerary was carried out with much enthusiasm, and without any mishap.

Thursday, July 17th.

Excursion on Florien Railway. Left Bergen 4.00 p.m. by rail. Arrived Frengereid 5.36 p.m. and proceeded to Tysse by motor cars. Visited Samnanger 23,000 h.p. hydro-electric plant. Proceeded by motor car to Norheimsund. Arrived 11.30 p.m.

Friday, July 18th.

Left Norheimsund 8.00 a.m. by steamer, called at Aalvick, visited Bjolvo power station, 36,000 h.p. 850 meters head. Left Aalvick and visited Valurfoosen on the Veig river. Possible capacity 175,000 e.h.p. Inspected power station at Tyssedal. 140,000 h.p. development. Arrived Odda midnight.

Saturday, July 19th.

Left Odda by motor and passed over mountains, snow, etc., to Haukelii for lunch, and continued to Dalen.

Members of Canadian Delegation to World Power Conference on Scandinavian tour.

Left to right; E. A. Cleveland, M.E.I.C.; G. Gordon Gale, M.E.I.C.; K. H. Smith, M.E.I.C. and Eugene Vinet, A.M.E.I.C.

Sunday, July 20th.
Left Dalen by steamer to Kvileseid, (Apalsta) proceeded by motor to Notodden. Inspected the Tinfess power plants, six in number of various capacities, heads and designs. By rail to Tinnoset and lake steamer to Mael, rail to Rjukan. Inspected Rjukan No. 2 power plant 190,000 h.p. supplying power to electrio-chemical plant.

Monday, July 21st.
Inspected Rjukan falls and plant No. 1, 180,000 h.p. capacity, supplying power to electric furnaces. Rail to Hael, steamer to Tinnoset. Rail to Notodden and thence to Christiania.

Tuesday, July 22nd.
Visited two substations in Christiania. Inspected patent low capacity electric cooking stove. Inspected trolley system. Wages of employees about 1½ kroner (23 cents) per hour for an 8-hour day and 48-hour week.

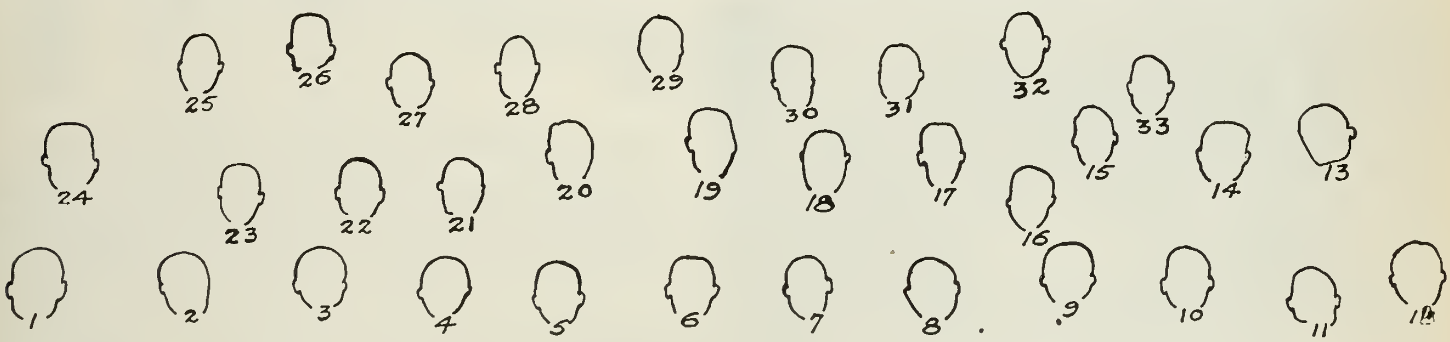
Wednesday, July 23rd.
Proceeded to Askim by motor. Visited plants at Vamma 75,000 h.p. and Mokfos-Solbergfos 150,000 h.p. under construction. Motored to Mysen. Presented cup to Secretary Sandberg, of the Norwegian National Committee. Proceeded by rail to Kornsjo on the frontier.

Thursday, July 24th.
By rail to Lilla Edet. Inspection of 35,000 h.p. hydro-electric plant under construction, 18-foot head. Largest water wheels in the world. Boat up Dal river. Inspection of Trollhattan locks. Visit to Nydgvist and Holm's locomotive and turbine works. Exciter water wheels, also 500 steam locomotives under construction for Russia. Inspected Trollhatian canal, power station 164,000 h.p., and transformer station. Sleepers to Ludvika.

Friday, July 25th.
Visited Swedish General Electric transformer works at Ludvika.

Personnel of the International Executive Committee, World Power Conference—taken at London, August 1924.

This committee was continued, to meet within a year, at the call of the organizing director, to consider ways and means of continuing the World Power Conference and arrange for a conference during the year of 1927.



1. Russell Sinclair (Australia)
2. D. Pedro M. Gonzalez Quijano (Spain)
3. Calvert Townley (U.S.A.)
4. Prof. C. Matschoss (Germany)
5. Dr. H. J. van der Bijl (Union of South Africa)
6. D. N. Dunlop (Organizing Director)
7. B. Longbottom (Great Britain)
8. H. J. Pierce (U.S.A.)
9. M. Genissieu (France)
10. J. B. Challies (Canada)
11. Ing. Barbagellata (Italy)
12. Ing. Luigi Emanueli (Italy)
13. W. Elsdon-Dew (Union of South Africa)
14. F. Zur Nedden (Germany)
15. J. Wolf (Czechoslovakia)
16. D. A. de Artigas (Spain)
17. J. W. Meares (India)
18. Prof. Gorew (Russia)
19. Prof. Glouchkoff (Russia)
20. M. H. F. Zangger (Switzerland)
21. Prof. T. Yamamoto (Japan)
22. M. le Baron Guillaume (Belgium)
23. M. Alexandre Simonis (Belgium)
24. W. van Dalsen (Union of South Africa)
25. M. W. Burt (Secretary to the Organizing Director)
26. E. Velander (Sweden)
27. C. A. Weekes (Great Britain)
28. Mr. Borreson (Denmark)
29. J. G. Bellaar-Spruijt (Holland)
30. Dr. F. Kneidl (Czechoslovakia)
31. F. H. Krebs (Denmark)
32. J. Emjellem (Norway)
33. K. Inouye (Japan)

By Deisel electric engine, 250 h.p. to Vasteras. Two standard sleeping cars and baggage cars, speed 35 m.p.h. Visited Swedish General Electric Company's main works. Generators for Lilla Edet plant under construction. Visited state steam station. Steam turbine generating set running as synchronous condenser. Boiler plant closed down. Generating steam by electricity.

Saturday, July 26th.
Rail to Uppsala. Inspected city buildings, viking mounds, transformer station, farming, plowing, etc., by electricity, tertiary sub-stations and portable motor sub-stations. Rail to Orrskog. Storage battery car 250 amp. 250 volts, to Untra. Inspected city of Stockholm hydro-power station 40,000 kv.a. at Untra. Motored to Alvkarleo.

Sunday, July 27th.
Inspection of 70,000 kv.a. power station at Alvkarleby. Rail to Stockholm. 1,800 h.p. steam turbine locomotive. Presentation to E. Verlander, secretary of the Swedish National Committee.

Monday, July 28th.
Rail to Kristinoheim. Inspection of wheels for Lilla Edet plant and Russian hydro-electric development, also visted laboratory and demonstration tests on water wheels. Motor to Cerlebo.

Tuesday, July 29th.
Rail to Hamburg.

Wednesday, July 30th.
Rail to Paris.

Thursday and Friday, July 31st, Aug. 1st.
Paris.

Saturday, Aug. 2nd.
Rail to Cherbourg.

EMPLOYMENT BUREAU

Situations Wanted

Civil Engineer

University graduate, A.M.E.I.C., nine years experience in highway and building construction, wants position with a firm of contractors or manufacturers. Apply box No. 149-W.

Civil Engineer

B.A.Sc., M.E.I.C., D.L.S., B.C.L.S. Experience covers several years railway exploratory, preliminary and location surveys in Canada, United States and Mexico. Railway construction, hydro power development, investigations ana surveys. Topographical, sub-division surveys and plans, town planning, etc. Mining surveys and exploration. Several years private practice in British Columbia. Capable of handling men successfully under frontier conditions. Best of references. Will go anywhere, and expect to be paid according to results. Apply box No. 151-W.

Situation Vacant

Junior Topographical Engineer

A Junior Topographical Engineer for the Topographical Survey Division, Department of National Defence, Ottawa, at an initial salary of $1,680 per annum, which will be increased upon recommendation for efficient service at the rate of $120 per annum until a maximum of $2,160 is reached. This salary will be supplemented by whatever bonus is provided by law.

Application forms properly filled in must be filed in the office of the Civil Service Commission *not later than September 18, 1924.*

Trade Publication

A publication, which merits special mention and which is more in the nature of a text book than a trade publication, has been issued by The Kidwell Boiler Company and is being distributed by The Combustion Engineering Corporation, Limited, of Toronto. The book is entitled "Kidwell" and while dealing principally with the Kidwell two-flow ring-circuit water tube boiler yet it contains a vast amount of very valuable and interesting information explanatory of the principles of boiler design and operation. The book is cloth bound and its 268 pages are profusely illustrated with diagrams, photographs and coloured plates. This volume should prove of great interest to all those in any way connected with combustion engineering.

Exchange Privileges for Transactions

As a number of enquiries have recently been received regarding privileges extended to members of *The Engineering Institute of Canada* whereby publications of other engineering societies may be secured, the attention of the membership is directed to the arrangements which have been made with the American Institute of Electrical Engineers, American Institute of Mining and Metallurgy, American Society of Civil Engineers, and The American Society of Mechanical Engineers, whereby *our members may receive the transactions of these societies at the same price as that paid by their own members.* The following table can be used as a reference of the various prices, *the first column indicating the amount paid by the members of* The Engineering Institute *for the various publications.*

Victoria and Halifax Branches visit H.M.S. Hood

The Victoria and Halifax branches of *The Institute* have been afforded, during the past few weeks, an opportunity to visit and inspect the world's mightiest battleship, H.M.S. Hood, which is one of the ships comprising the Special Service Squadron of the Royal Navy, now on a cruise around the world. The members of these branches (Victoria on June 21st, and Halifax on August 13th) were the guests of the officers of the Hood, and cannot speak too highly of the courtesies extended to them on the occasions of their visits. The tour of inspection was arranged so that small groups of the guests were conducted around the warship.

H.M.S. Hood has many remarkable features among which is her great speed of and her fuel capacity (oil only is used) which, with her turbine main engines of 140,000 h.p., capacity, enables her to travel for great distances. Other outstanding features are the huge areas covered by heavy armour, strong framing and compact engines and boilers. The cost of the Hood is reported at about £6,025,000 or £145 per ton. The complement of the Hood numbers 1,500, of which about 100 are officers. All trades that are required for a small town are represented on the battle cruiser. The conning tower is an enormous structure consisting of two shells the outer being 12 inches thick and the inner 9 inches thick with air space between.

Saguenay Branch

Burroughs Pelletier, A.M.E.I.C., Secretary-Treasurer

On Saturday August 9th, the Saguenay Branch held the second of its summer outings of the season. The outing consisted in a visit to Lake Kenogami reservoir as developed by the Quebec Streams Commission.

After assembling at Jonquière station as a starting point, the members proceeded by automobiles to a point at the village of St. Cyriac. Members were able to see that even this summer part of the village is inundated by the partial raising of the level of the lake. Next summer when the lake is raised to its highest level the village will entirely disappear.

Then by courtesy of Price Brothers and Company, the members embarked on one of the company's raft-towing boats, (technically called an "Alligator") and the trip was made by water to Portage des Roches, the largest of the dams built in connection with the reservoir. Here the dam was inspected and much admired. The members were entertained at luncheon by courtesy of the Quebec Streams' Commission and also of Mr. Cozzolino of the Nova Scotia Construction Company, the contractor.

During the lunch, O. O. Lefebvre, M.E.I.C., chief engineer of the commission, explained the nature and utility of the undertaking, the various types of dams at the various sites, and he also explained how various difficulties both forseen and unforseen had been or were to be overcome.

As time was pressing, Mr. Rutherford, one of the commissioners, briefly addressed the members and extended to them the thorough welcome of the Quebec Streams' Commission and of the Hon. Mr. Tessier who was enable to be present.

The party then re-embarked on the "Alligator" and the trip back on lake Kenogami was even more enjoyable than the coming as the morning clouds had entirely disappeared and the day had settled out fine. The party then proceeded by automobile to Pibrac, where again the members viewed the dams both finished and under construction at that site.

After viewing the Pibrac dams the outing terminated and all the members of the Saguenay Branch returned with the full conviction of having viewed a very remarkable undertaking, and also of having had a most enjoyable day.

Election of Officers

The general elections of the branch resulted in the following forming the personnel of the branch executive for the coming year.

Chairman.......... W. G. Mitchell, M.E.I.C.
Vice-Chairman..... H. G. Cochrane, A.M.E.I.Ç.
Secretary-Treasurer Burroughs Pelletier, A.M.E.I.C.
Executive.......... H. V. Bignell, A.M.E.I.C. (*one year*).
G. LaMothe, A.M.E.I.C. (*one year*).
C. N. Shanly, M.E.I.C. (*ex officio*).
Edouard Lavoie, M.E.I.C. (*two years*).
J. E. A. McConville, A.M.E.I.C. (*two years*).

Saskatchewan Branch

J. W. D. Farrell, A.M.E.I.C., Secretary-Treasurer.

Picnic at B-Say-Tah

Mr. and Mrs. M. B. Weekes invited the members of the Saskatchewan Branch and their wives to a picnic to be held at their summer cottage at B-Say-Tah Point, Qu'Appelle lakes. The party motored out from Regina on July 12th, and a very enjoyable day is reported by those who were present.

Summer Meeting at Saskatoon

At a regular meeting in April, the branch decided to follow the practice of former years and hold a summer meeting. This meeting was to be held at Saskatoon, and if possible, at the same date as the visit of the British Scientists.

Through the efforts of Prof. C. J. Mackenzie, M.E.I.C., and Prof. A. R. Greig, M.E.I.C., working with the Papers and Library Committee, speakers have been obtained and the following programme arranged:

Date, — Friday, August 22nd.
10 a.m., — Business Meeting, Saskatchewan University.
Afternoon and Evening, — Professional meetings to be addressed by Dr. Howe, professor of electrical engineering, University of Glasgow, and by Sir Charles Parsons, the inventor of the steam turbine. Members will also have opportunities to meet personally other prominent engineers with the British Scientists.

Calgary Branch

G. P. F. Boese, A.M.E.I.C., Secretary-Treasurer.
W. St.J. Miller, A.M.E.I.C., Branch Editor.

On July 19th a number of members set out on a tour of inspection of the power plants of the Calgary Power Company at Kananaskis on the Bow river, some 52 miles west of Calgary. This trip was undertaken in response to the kind invitation of F. J. Robertson and staff of the power company, who certainly went out of their way to entertain the visitors to their fullest ability. Cars were provided by branch members and some forty members took this opportunity of spending a most interesting and instructive time.

New Power Line to Calgary

On the way out it was interesting to note the work on the new power line actually progressing. This is being constructed in more substantial manner than the two existing lines into Calgary, the poles being in duplicate throughout with elaborately stayed poles at every mile of the route. It is anticipated that the line will be completed in ample time this year to assist at peak load periods or as an auxiliary supply as requirements demand. The three overhead cables are of stranded copper wire with a capacity for 125,000 volts.

On arrival at the lower Horseshoe Falls station, we were faced with a sumptuous repast in the community hall on the property, where we did full justice to the call of the inner man. Superintendent Robertson, A.M.E.I.C., P. Turner Bone, M.E.I.C., and others, made some fitting remarks at the conclusion of the luncheon, as did also P. J. Jennings, M.E.I.C., who acted as chairman in the unavoidable absence of R. S. Trowsdale, A.M.E.I.C., branch chairman.

Inspection of Plant

Following lunch parties were formed to fulfil the chief object of the visit, namely, the plant inspection. To many this was a first visit, and it was indeed a pleasant surprise to realize that we have two such up-to-date and efficient plants of this kind in the west. On entering the Horseshoe plant one looks down from a substantial gallery on to two 6,000-h.p., and two 4,000-h.p. turbines, direct connected to generators. Space will not admit of a detailed description of such things as turbines, generators, exciters, valve control apparatus, penstocks, motor-generators, etc., suffice it to mention that at both the upper and lower plants an advanced efficiency was most apparent. At the lower and original plant the horizontal type turbines are employed under a seventy foot (average) head and at the upper plant at Kananaskis, or Seebe, two of the more modern vertically mounted type of turbines and generators are installed, together with one smaller 200-h.p., turbo-generator, all working under an average head of 70 feet. Although full use is made of the head available at these sites the amount of water flowing over the weir at this season would indicate a greater horse power being available still for use. Of course winter conditions determine the actual amount available when maximum power is most needed.

All those who availed themselves of this opportunity to see these power plants are indeed grateful to Mr. Robertson, and his staff, for the cordial consideration extended and the manner in which they so willingly explained the various points of interest.

Members of Calgary Branch on visit to Power Plants of Calgary Power Company at Kananaskis on Bow River.

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

On Wednesday, August 13, 1924, at 10 a.m., about forty of the members of the Halifax Branch left the dock at H.M. Dockyard for a visit to the H.M.S. "Hood" the flagship of the special service squadron which has been carrying the Union Jack to the ports of the world. On board we were the guests of the engineering staff of the ship. The party was split into groups of five each of which was provided with a petty officer as guide. The tour of the ship which followed was replete with acts of courtesy extended to us by officers and men and provided many lessons in the science of being economical of space. After spending two and one-half hours seeing as much as possible we felt we had only touched the high spots. At twelve o'clock the engineering officers of the ship entertained the members of the executive of the Halifax Branch in the Wardroom. Before leaving, F. A. Bowman, M.E.I.C., vice-president of *The Institute* for the maritime provinces extended to Engineer-Captain Goodwin and his staff the cordial thanks of the Halifax Branch for the opportunity of seeing the inside of the greatest battleship in the British Navy and for the many courtesies which had been extended. He also welcomed them to the maritime provinces on behalf of the members of *The Institute* living in them. For arranging the details of the visit and providing the launch to take us to the "Hood" which was anchored in the stream we are greatly indebted to Commander Wood, M.E.I.C., manager of H.M. Dockyard.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

British Scientists visit Ottawa

The occasion of the visit of the British Association for the Advancement of Science to Ottawa on August 5th was of much interest to local members of *The Institute* who went to considerable trouble in assisting the entertainment plans of the local Reception Committee.

Charles Camsell, M.E.I.C., deputy minister of the mines department acted as chairman of the committee in the absence of Dr. Collins through illness. He also presided at the luncheon given to the British Association in the Chateau Laurier at which the Prime Minister gave the address of welcome. F. C. C. Lynch, A.M.E.I.C., and L. L. Bolton acted as joint secretaries and C. P. Edwards, A.M.E.I.C., as chairman of the Entertainment Committee. A drive to various points of interest in the city was arranged for the visitors and many members of *The Institute* loaned their cars or acted as guides in this connection. The British scientists were especially interested in the papermills and the industrial section surrounding Chaudiere falls.

Papers Presented by local Institute Members

A number of local members of *The Institute* prepared papers for presentation at the sessions of the British Association for the Advancement of Science in Toronto, including:

E. H. Finlayson, A.M.E.I.C., on Silviculture practices in Canada,
D. Roy Cameron, A.M.E.I.C., on fire protection methods in Canadian forests,
E. M. Dennis, A.M.E.I.C., on the work of the Topographical Surveys Branch,
W. H. Boyd, M.E.I.C., on the work of the Geological Survey,
Noel Ogilvie, M.E.I.C., on the work of the Geodetic Survey,
Dr. W. Bell Dawson, M.E.I.C., on the work of the Tidal and Current Survey,
A. M. Narraway, M.E.I.C., on magnetic surveys as practised by the Canadian Topographical Surveys,
J. B. Challies, M.E.I.C., on extent and administration of Canadian water powers,
D. W. McLachlan, M.E.I.C., on the St. Lawrence Power and Navigation question,
J. P. Henderson, A.M.E.I.C., on wireless time signals as employed by the Dominion Observatory.

Trade Publications

The Taylor Stoker Company have recently issued a very attractively prepared catalogue of fifty-four pages containing diagrams, illustrations and descriptive matter featuring the new Taylor Stoker. This catalogue will be supplied to members of *The Institute* upon request to Taylor Stoker Company, Limited, Toronto, Ont., or Montreal, Que.

Midwest (Canada) Limited, through their principals, Midwest Air Filters, Incorporated, have issued a new data book on air filters for compressors and internal combustion engines. This book contains twenty-four pages of illustrated matter, describing the principal features of these filters. Copies of the same may be obtained from Midwest (Canada) Limited, 83 Craig Street, West, Montreal.

Recent Additions to the Library

Transactions, Proceedings, Etc.

Presented by the Societies:—

Year Book of The Association of Professional Engineers of the Province of British Columbia, April 1924.
Proceedings of The American Concrete Institute, Twentieth Annual Convention, 1924, Volume XX.

Reports, Etc.

Presented by The Harbour Commissioners of Montreal.
The Harbour of Montreal, Annual Report, 1923.

Presented by R. Dawson Harling, of Canadian Office.
Manchester, Its Ports and Industries.

Presented by The Department of Labour of Canada.
Third Report on Organization in Industry, Commerce and the Professions in Canada (1924).

Presented by The Hydro-Electric Power Commission of Ontario.
Sixteenth Annual Report of the Hydro-Electric Power Commission of the Province of Ontario, for the year ended October 31st, 1923.

Presented by The Institution of Electrical Engineers, London, England.
Lord Kelvin, His Life and Work.

Presented by Librarian of McGill-University.
A Catalogue of Scientific Periodicals in Canadian Libraries.

Presented by The Canadian Engineer, Toronto, Ontario.
Bound volume of "The Canadian Engineer", January 1st, to June 30th, 1924.

Special Institute Meeting

On Thursday, September 25th, 1924, there will be a special meeting of The Institute in the form of a luncheon gathering, at one o'clock, at the Windsor Hotel, Montreal. Sir Ernest Rutherford will be the speaker of the day. The Council of The Institute felt that in securing Sir Ernest's consent to address a meeting, the occasion was of sufficient importance to warrant a general meeting.

Members residing outside of Montreal are requested to advise the Secretary if they intend to be present.

An Exhibit at Wembley

At the British Empire Exhibition, the C. A. Parsons and Co., who have recently appointed F. Jno. Bell, M.E.I.C., of Toronto as Canadian representative, have a number of interesting exhibits.

The principal exhibit is a 12,000 k. w., 3,000 r.p.m. tandem turbo-alternator and exciter, designed for railway traction. The plant is one of five sets with surface condensers constructed during 1923-24 for the Union of South Africa Electricity Supply Commission. These sets will be erected in the new power station at Colenso, Natal, for the electrification of the railway between Glencoe and Pietermaritsburg.

Another exhibit of special interest is a 1/12 scale model of a 50,000 k. w. turbo-alternator and condensing plant which is now nearing completion at Heaton Works, and will be erected in the new 500,000 k. w. station at Crawford Avenue, Chicago, U.S.A.

In order to show the layout of the plant in relation to the engine room, the model includes basement, walls, roof and crane. Some idea of the immensity of the station will be gained from the fact that the crane-rail span is 122 feet, and the height from basement to the apex of the roof is 113 feet.

This plant is the second set exported by the Parsons Company to Chicago, a 25,000 k. w. tandem turbo-alternator having been erected in the "Fisk Street Station" in 1913.

Of considerable historical interest is another exhibit, which is a small ½ kilowatt 2/3 horse power direct-coupled turbo-dynamo, running under steam at about 9,000 r.p.m. It was built some thirty years ago, and is of similar type to the first Parsons machine of 1884 which now rests in the Museum of Science and Technology at South Kensington.

Another interesting exhibit is a patented reflector, by means of which it is possible to vary the shape of the beam produced, from a parallel beam to a spreading beam whose dimensions at a range of one mile are 1,000 feet wide by 200 feet high, with proportional area at other ranges.

Western Canada Irrigation Association Convention

The Eighteenth annual convention of the Western Canada Irrigation Association was held in Calgary on July 29th, 30th, and 31st, and proved to be an entirely successful event.

On the first day A. S. Dawson, M.E.I.C., took the chair in the absence of Hon. Geo. Hoadley. Lieut.-Gov. Brett and Mr. Hoadley were however present on the other days of the convention. Mr. Dawson announced the fact that Calgary was the birthplace of the Association, which was formed here in July 1907. Members of *The Institute* who presented papers were R. S. Stockton, M.E.I.C., on "Profitable farming and the future development of the community", and W. H. Snelson, A.M.E.I.C., on "Irrigation investigations as an aid in the development of the community".

These subjects were as broad as the length of their titles might suggest, and proved amongst the most interesting of the sessions. Other excellent papers and addresses were presented by many from outside points.

At the conclusion of the session the delegates and friends enjoyed an automobile trip to the C.P.R. experimental farm at Strathmore, where an excellent luncheon was served and a very interesting tour of inspection made of the gardens, stock pens, and farm plots. It was on the homeward run that a persistent downpour of rain played havoc with the mental attitude of the irrigationists towards their favourite topic, and while many were caught unprepared, this however did not dampen their ardour concerning the vital necessity of irrigation in this province. Thus terminated, (at midnight for some!), a successful convention of "wets", not however, those who would irrigate the inner man, but rather those who are out:—

"To promote and diffuse knowledge concerning irrigation and other uses of water throughout western Canada.

To facilitate conference and deliberation among the people of the country concerning irrigation and related interests; and

To provide means of bringing the needs of the people as regards irrigation before the Dominion and Provincial governments."

(Extracts from the creed of the Western Canada Irrigation Association.)

University of Michigan Fellowship in Highway Engineering and Highway Transport

The Board of Regents of the University of Michigan will award the following Fellowships not later than November 1st, 1924. Two Fellowships may be awarded about September 10th to men who intend to be in residence during the first semester.

The Roy D. Chapin Fellowship in Highway Transport, which is offered to provide for the investigation of an approved subject relative to Highway Transport.

The Roy D. Chapin Fellowship in Highway Engineering, which is offered to provide for the investigation of an approved subject relative to hard surfaced roads and pavements.

Two Detroit Edison Fellowships in Highway Engineering, which are offered to provide for the investigation of approved subjects relative to moderate cost country roads.

The General Conditions are as follows: Each Fellowship pays the sum of $250 with an allowance of $50 for expenses. Fellows do not have to pay tuition fees. A Fellow must hold a Bachelor's Degree from a college of recognized standing. He must enroll as a graduate student in highway engineering or highway transport and as a candidate for the degree of Master of Science or Master of Science in Engineering. He must be in residence for one of the following periods: First Semester (October to February); Winter Period (December to March); Second Semester (February to June). An application for a Fellowship must include a concise statement of the candidate's educational training and engineering experience, and three references. Applications for Fellowships and requests for information pertaining to the twenty-five advanced courses in Highway Engineering and Highway Transport offered by the Graduate School should be sent to Professor Arthur H. Blanchard, M.E.I.C., 1026 East Engineering Building, University of Michigan, Ann Arbor, Michigan.

New St. Clair Avenue Bridge over Ravine, Toronto, Ont.

View of west Main Pier, showing Concrete Tower, St. Clair Avenue Bridge.

The St. Clair Avenue Bridge, now under construction, will replace the old steel bridge which for many years has occupied the site immediately adjacent, connecting the residential district of Moore Park with Yonge Street at St. Clair avenue. The new bridge will be a combination steel and concrete structure, and will be 508 feet long, with four girder spans and one arch span, its height from bottom of ravine to deck will be about 95 feet, and its width 86 feet. Ground was broken on October 19th, 1923, and first concrete poured on November 28th, 1923.

CORRESPONDENCE

Early Discussion on Railway Construction

St. John, N.B., June 23rd, 1924.

The Editor,
The Engineering Journal;

I attach herewith a copy of an interesting article which I took from an old copy of the *Charlotte Gazette*, printed in St. Andrews in 1847, which I happened to see recently.

As it deals with the proposed construction of one of the earliest railways in Canada, the St. Andrews and Quebec Railway, and gives at some length the views evidently current at that time as to how railways should really be built, (possibly from the Lumbermen's point of view), I thought you might be interested in reproducing it in *The Journal* at some convenient date.

Yours truly,
C. C. Kirby, M.E.I.C.,
District Engineer, Canadian Pacific Railway.

St. Andrews and Quebec Railway

Extract from "Charlotte Gazette", St. Andrews, January 21st, 1847.

D. S. Morrison, Esq., one of the directors of this incorporation, arrived here from St. Andrews on Monday last, and intimated his wish to lecture on the subject of railways. A public meeting was called, to be held the following day at the court house. The meeting was called to order by Charles Perley, Esq., and John Dibblee, Esq., was called to the chair.

Mr. Morrison delivered a most admirable lecture, which was listened to with much attention by a large and respectable audience.

The lecturer, by way of introduction, adverted to the great and wonderful changes which have effected by the invention of the steam engine and its adaptation to the propelling of steam vessels and railway cars. The nature and construction of wood railways was then explained, with the peculiar form and properties of guide wheel carriages, which it is evident answers all purposes, either on an iron or wood railway, much better than the common flange wheel car. On a wood railway the wear occasioned by locomotives and carriages, with guide wheels instead of flanges, is so small as scarcely to be perceptible; and from actual experiment in England, it was shown that a train could pass over a wood rail a number of times, equal to that of twelve trains a day, for seven years, without wearing the saw marks off the rails.

The lecturer next showed that owing to the great friction of iron upon wood, a locomotive could draw double the load, or ascend a plane twice as steep on a wood railway, as was practicable on rails of iron. This necessarily reduces the cost of making a railway to a very great extent, as an iron railroad would require immense excavations, where one of wood might be constructed with slight excavations or none at all. The expense of grading would thus be reduced more than one-half. It was also clearly proved that a curve of much smaller radius could be traversed by a guide wheel carriage on a wood railway, with greater speed and perfect safety, than it was possible to traverse on an iron structure, where flange wheel was employed. The effect of this simply is an uncommon facility in avoiding hills and ravines where great excavations and embankments are unavoidable and consequently great saving in expense in grading.

The next enquiry explained by the lecturer referred to the cost of material. His estimate, of which the particulars were given, made the cost of superstructure for a wood railway amount to £300 per mile while the superstructure for an iron road would cost from £1,580 to £2,000 for the same distance,—showing a decided superiority in favour of wood. The capability of wood to sustain any pressure necessary, and any reasonable wear for a great length of time, was from experiments at Vauxhall and Wimbledon Common, very satisfactorily proved. With a guide wheel carriage, a wood rail will endure the wear of twenty or more trains per day until it decays and rots from exposure to the weather. It was also stated, (a fact which no one can doubt), that wood exposed to the weather will last five years, before it is unfit for use from rot; and if the wood be prepared by a saturation of muriate of zinc, it will last from ten to fifteen years. It was then shown that wood could be relaid every five years, for less than half the interest of the money which an iron railway would cost or every ten years for less than one-fourth the interest; which is an indubitable proof that the inferior durability of wood as compared with iron is far more than compensated by its cheapness.

Tenders called by Department of Public Works

Cross Point, Que. Tenders for extension to wharf at Cross Point, County of Bonaventure, Que., are being received until Sept. 2nd, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, offices of the District Engineers, St. Lawrence Power Building, Rimouski, Que.; Post Office Building, Quebec, Que.; Postal Station "H", Montreal, Que., and Post Office, Cross Point, Que.

Denman Island, B.C. Tenders for wharf repairs at Denman Island, District of Comox-Alberni, B.C., are being received until Sept. 11th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at offices of the District Engineers, Old Post Office Building, Victoria, B.C., and at the Post Offices, Vancouver, and Denman Island, B.C.

Grondines, Que. Tenders for wharf extension at Grondines, County of Portneuf, Que., are being received until Sept. 2nd, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at offices of the District Engineers, Post Office Building, Three Rivers, Que.; Post Office Building, Quebec, Que.; Postal Station "H" Montreal, and Post Office, Grondines, Que.

Lotbinière, Que. Tenders for reconstruction of a portion of wharf at Lotbinière, Lotbinière County, Que., are being received until Sept. 15th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, offices of the District Engineers, Post Office Building, Three Rivers, Que., Post Office Building, Quebec, Que., Postal Station "H" Montreal, Que., and Post Office, Lotbinière, Que.

New Westminster, B.C. Tenders for the Fisheries Patrol Station at New Westminster (Poplar Island) B.C., are being received until Sept. 16th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at offices of the District Engineers, Post Office Building, New Westminster, B.C., Old Post Office Building, Victoria, B.C., and Post Office, Vancouver, B.C.

Port Colborne, Ont. Tenders for repairs to Western Breakwater at Port Colborne, Welland County, Ont., are being received until Sept. 9th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at offices of the District Engineers, Royal Bank Building, London, Ont., 22 Adelaide Street, East, Toronto, Ont., and at Post Office, Port Colborne, Ont.

Port Simpson, B.C. Tenders for wharf repairs at Port Simpson, B.C., are being received until Sept. 4th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at office of the District Engineer, Old Post Office Building, Victoria, B.C., and at the Post offices, Vancouver, B.C.; Prince Rupert, B.C.; Stewart, B.C., and Port Simpson, B.C.

Rimouski, Que. Tenders for reconstruction of breakwater-wharf at Rimouski, Que., are being received until Sept. 15th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa; offices of the District Engineers, St. Lawrence Power Building, Rimouski, Que.; Post Office Building, Quebec, Que., and Postal Station "H", Montreal, Que.

Sayward, B.C. Tenders for replacement of wharf at Sayward, B.C., are being received until Sept. 11th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at office of District Engineer, Old Post Office Building, Victoria, B.C., and at the Post Offices, Vancouver, B.C., and Sayward, B.C.

Ste. Croix, Que. Tenders for wharf repairs at Ste. Croix, County of Lotbinière, Que., are being received until Sept. 15th, 1924, by Public Works Dept. in Ottawa. Plans and specification at Dept. in Ottawa, at offices of the District Engineers, Post Office Building, Three Rivers, Que., Post Office Building, Quebec, Que., Postal Station "H", Montreal, Que., and at the Post Office, Ste. Croix, Que.

Publications

The Ontario Department of Mines, Toronto, have issued for circulation at The British Empire Exhibition 1924 an eighty-seven page guide-book reviewing the mineral resources of the province. While this guide-book contains only a brief general description of the mining industry in the province yet, there is given at the foot of the description of each of the minerals a bibliography of the more detailed reports which may be obtained from the department.

Building and Engineering Catalogue

The 1924 edition of this catalogue has just been issued by Specification Data, Limited, of Toronto, and contains as usual much interesting information regarding building and engineering equipment.

Preliminary Notice

of Applications for Admission and for Transfer

August 19th, 1924.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September, 1924.

FRASER S. KEITH, Secretary.

*The professional requirements are as follows:—

Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, he reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed hy the council. The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain memhers as references does not necessarily mean that their applications are endorsed by such memhers.

FOR ADMISSION

GAREY—JOHN DENNIS, of 401 Douglas Avenue, St. John, N.B. Born at St. John, N.B., Sept. 3rd, 1886; Educ., Amer. Sch. of Corr. private night schools; four years apprenticeship with Phoenix Foundry & Locomotive Works; four mos. as machinist, Dom. Iron & Steel Co., Sydney; two years operating engr., six years mech. supt., Murray & Gregory; ten years as chief engr., St. John Rly. Co. and New Brunswick Power Co.; At present chief engr., New Brunswick Power Company, St. John, N.B.

GODIN—CHARLES, of 1180 St. Denis Street, Montreal, Que. Born at St. Johns, Que. Aug. 19th, 1892; Educ., C.E., Ecole Polytechnique, May 1915; 1916-17, dftsman., L'Air Liquide Society; 1918-19, with Wayagamack Pulp & Paper Co.; with National Shiphldg.and Tidewater Shiphuilders; 1921-22, in charge of constrn. of lime plant for St. Maurice Lime Co., Three Rivers, Que.; 1923-24, asst. engr., Public Works, Canada, Three Rivers, Que.; June 1924 to date, engr. with Trussed Concrete Steel Co., Montreal.

References: B. Grand Mont, P. E. Mercier, A. Frigon, C. L. Arcand.

HASKETT—WESLEY IRWIN, of 197 Belmont Avenue, Ottawa, Ont. Born at Montreal, Que., April 22nd, 1903; Educ., matric., Ottawa Collegiate Institute, 1919. private study; 1920-22, machine design and mech. engrg.; 1920, junior dftsman., 1921 in charge of dfting. room staff of Harold C. Shipman & Co. of Ottawa; 1922, entered into a partnership and has since practised as a patent attorney under the firm name The Ramsay Company. At present vice-president and manager of the company, and a registered attorney-at-patents.

STEPHENS—JOHN, of Fredericton, N.B. Born at Dublin, Ireland, May 19th, 1884; Educ., B.A. 1905, B. Eng., 1906, M. A. 1909, M. Eng. 1911, Dublin Univ.; Member, Inst. C.E. of Ireland, 1912; 1906, machine shop, Panhard & Levasser; London, England; 1908-09 (summers), assisted hy Dr. W. E. Lilly, M.I.M.E., in testing laboratory, Duhlin; 1916-19, overseas, Lieut., 2nd Seige Battery; With the Univ. of New Brunswick as follows: 1907, asst. prof. of engrg., 1908-14, prof. of mech. engrg. and drawing, 1914-16, prof. of mech. engrg., 1919 to date, prof. of mech. engrg., 1921 to date, dean of the faculty of applied science; Summer work included: installation of steam turhine and condensing equipment for Fredericton Gaslight Co. (plans and supervision); reports on power plants and combustion conditions; design of new boiler plant; plans and valuation—Randolph & Baker, Randolph, N. B.; consultation and plans, new geared steam turhine unit, Maritime Electric Co., Fredericton, N. B.; alterations to power plant, Fredericton Puhlic Hospital (design and supervision); tests and reports on engineering materials; Summer 1924, furnace modifications for the use of local fuel, Fredericton Public Hospital. Ventilation, Fredericton Puhlic Hospital. New heating plant, engrg. huilding, Univ. of New Brunswick, Design and supervision.

FOR TRANSFER FROM CLASS OF JUNIOR TO HIGHER GRADE

COSSITT—MURRAY FREDERICK, of Corner Brook, Bay of Islands, Nfld. Born at Sydney, N.S., June 2nd, 1892; Educ., 4 years evening classes in maths., I.C.S.; 1911, rodman, N.S. Mines Dept.; 1914, transitman, on above work; 1915, in charge of survey work etc., for McKenzie, Pickings & McCallum; received P.L.S. cert.; 1918, asst. to chief engr. for Foley Bros. on Halifax Ocean Terminals; 1919, with Pickings & Roland on new layout of devastated area for Halifax Relief Commission; also making assessment survey and plans for city of Halifax; 1920 (Jan.-June), in charge of exams., surveys, etc., Hydro-Electric Development at head of St. Margarets Bay, N.S.; 1920-23, ill-health; 1923 (Jan.-May), private practice, Sydney, N.S.; 1923 (June-July), hydrographic survey, Little Bras d'Or channel, Dom. Public Works; 1923 (Aug.-Sept.), in charge surveys of dam, flowage area, pipe line and sewerage outfall, new town of Corner Brook, Nfld.; Oct. 1923 to date, engr for town constrn. dept. of the Nfld. Power & Paper Co. Ltd., Corner Brook, Nfld.

CRABTREE—HENRY SWIFT, of 41 Standish Avenue, Toronto, Ont. Born, at Halifax, England, March 29th, 1892; Educ., West Vale Mechanics Inst., Halifax, Eng., Toronto Technical School. Articled pupil, Tasker & Crossley, Halifax, Eng., and ap'tice to the Lumby Engineering Works, Greetland, Halifax, Eng.; 1911-13, dftsman., Smith, Kerry & Chace, Toronto; 1913 (Jan.-Feb.), dftsman., W. D. Beath & Sons, Toronto; 1913-17, dftsman., Routly & Summers, Haileybury; 1917-18, dftsman., on reinforced concrete design, Trussed Concrete Steel Co., Walkerville; 1918 (June-Nov.), chief dftsman and designer, Knight Metal Products, Toronto; 1918-21, dftsman., Dept. Public Highways, Ontario; 1921-22, Dominion Machinery Co., Toronto, director, engaged as salesman on machine tools etc.; 1922 (April-Oct.), dftsman., Dept. Public Highways, Ontario; Oct. 1922 to date, engaged on calculations of surveys, compiling geological plans and profiles, etc., Imperial Oil Company, Toronto, Ont.

LIBBY—PHILIP NASON, of 851 University Street, Montreal, Que. Born at Gray, Maine, U.S.A. July 5th, 1896; Educ., B.S., Univ. of Maine, 1917; 1916 (June-Oct.), valuation survey with Bangor Rly. and Elec. Co., Bangor, Me.; 1917 (June-Oct.), forester for Great Northern Paper Co., Bangor, Me.; 1917-19, overseas with U. S. Army; 1919-21, dftsman., with Riordon Co. Ltd., Mattawa, Ont.; 1921 (June-Oct.), topog'l. survey with Donnacona Paper Co., Donnacona, Que.; 1921 (Oct.-Dec.), topog'l. survey with G.R. Heckle, M.E.I.C.; 1921-22, topog'l. survey with Laurentian Power Co., Beaupre, Que., as instr'man., asst. and map maker; 1922 (Apr.-July), in charge of mapping party, Wayagamack Pulp & Paper Co., Three Rivers; 1922-24, with Mead Fibre Co., Kingsport, Tenn., part time as asst. to res. engr. on constrn., later as mill engr. on mtce. and in charge of new constrn. work; June 1924 to date, dftsman. and designer on paper mill constrn., with H. S. Taylor, consltg. engr., Montreal.

References: G. L. Freeman, L. S. Dixon, G. R. Heckle, J. A. Beauchemin, J. R. Montague, James Ruddick.

FOR TRANSFER FROM CLASS OF STUDENT TO HIGHER GRADE

ADLARD—LEONARD STANLEY, of Lahore, Punjab, India. Born at Toronto, Ont., Dec. 3rd., 1893; Educ., B.A.Sc. Univ. of Toronto, 1915; 1912, C.N.R. location surveys; 1913, O. L. Surveys; 1914, Can. Geol. Surveys; 1915-17, sanitary engr., bacteriological and chemical, water supplies and sewage, military laboratories; 1917-18, rly. engr., light logging lines; 1918-19, attached air force (location and drainage of aerodrome sites, constrn. of camps, etc.); Sept. 1919 to date, asst. executive engr., Public Works Dept., Punjab, India, constrn. of roads, bridges, bldgs.

References: A. H. Harkness, C. S. L. Hertzberg, T. R. Loudon, P. Gillespie, J. R. Cockburn.

GREEN—FREDERICK GORDON, of 161 Charlotte Street, St. John, N.B. Born at St. John, N.B., Aug. 15th, 1895; Educ., B.Sc. (Chem. Eng.), McGill Univ. 1921; 1919 (Feb.-July), Royal Technical College, Glasgow; 1912-13, plant dept., Western Union Telegraph Co., St. John; 1914-15, line inspector; 1915-16, instructor in drawing and shop work, Mt. Allison Univ.; 1916-19, overseas; 1920 (summer), asst. chemist, Nashwaak Pulp & Paper Co., St. John, N. B.; 1921 (May-Nov.), chief chemist, D'Arcy Exploration Co., Rosevale, N. B., Wallace Process Oil Shale Plant (Experimental), and from Nov. 1921 to Mar. 1922, plant supt., with entire charge of plant, two engrs. and twenty-six men on staff; 1922-24, supt. N-T-U Co. (Inc. name), Santa Maria, Calif., standardizing operation of twenty ton experimental plant (oil shales), etc.; At present trying to interest local holders of oil shale lands to erect plant to treat Albert, N. B. shales.

References: H. W. McKiel, C. M. McKergow, R. F. Armstrong, G. H. Thurber, N. F. Nutter, R. A. Strong.

MAXWELL—HAROLD JAMES, of 232 Old Orchard Avenue, Montreal, Que., Born at St. John, N.B., July 17th, 1903; Educ., B.Sc. (C. E.), Univ. of N.B., 1923; July 1923 to date, structural detailer, Dom. Bridge Co., Lachine, Que.

References: D. C. Tennant, A. Peden, E. Peden, H. H. Hawkes, F. C. Jewett.

MUIRHEAD—STUART ROBERT, of 2038 Angus Street, Regina, Sask. Born at Chicago, Ill., U.S.A., May 6th, 1899; Educ., B.A.Sc., Univ. of Toronto, 1924; First employed with Sask. Govt. Telephones in 1915—three years experience in central office work, one year as head switchman in an automatic office, and at present, equipment supervisor.

References: W. R. Warren, H. B. Sherman, S. R. Parker, J. D. Peters, R. N Blackburn, R. W. Angus.

ROOT—STEPHEN EASTMAN, of McMasterville, Que. Born at Rochester, N. H., Jan. 3rd, 1898; Educ., McGill Univ. 1922, one year Mass. Inst. Tech.; 1922-23, field engr., St. Lawrence Paper Mills, Ltd.; 1923 (May-Nov.), asst. supt. of constrn., Donnacona Paper Co. Ltd.; 1924 (Jan.-Mar.), engr. for Church Ross Co.; 1924 (Mar.-May), engr. for H. S. Taylor; May 1924, instructor at McGill Survey School; At present, engr. in charge of constrn., Canadian Explosives, Limited.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service wil' be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N Y.

A

ACOUSTICS

Auditoriums. Acoustics in Auditorium Design, P. E. Sabine. Am. Architect, vol. 125, no. 2448, June 18, 1924, pp. 579-586, 7 figs. Study of acoustical difficulties which may be classed under two general heads: those arising from concentration of sound reflected from extended concave surfaces and those arising from excessive reverberation.

AERONAUTICAL INSTRUMENTS

Rate-of-Climb Recorders. Optical Rate-of-Climb Recorders —Their Uses, Theory, and Description, A. H. Mears and D. H. Strothers. Optical Soc. of Am. Jl., vol. 8, no. 6, June 1924, pp. 787-801, 7 figs. Describes instruments developed by staff of Bur. Standards at request and with financial assistance of Air Service, U. S. Army, and Bur. Aeronautics, U. S. Navy.

AIRCRAFT CONSTRUCTION MATERIALS

Three-Ply. Three-Ply and Its Uses in Aircraft Construction, R. N. Liptrot. Instn. Aeronautical Engrs., Min. of Proc. No. 8, 1923, pp. 7-17 and (discussion) 18-22. Discusses physical properties of plywood; shrinkage and prevention of warping; effect of number of piles; figures for use in design; method of manufacture; true monocoque fuselage, semi-monocoque type, and three-ply braced fuselages. Abstract of paper read before Instn. Engrs.' Club.

AIRPLANE PROPELLERS

Design and Performance Calculations. The Application of Propeller Test Data to Design and Performance Calculations, W. S. Diehl. Nat. Advisory Com. for Aeronautics, report no. 186, 1924. Study of test data on family of Durand's propellers (nos. 3, 7, 11, 82, 113, 139).

AIRPLANES

Wings. Calculation of self-contained Wings in Two-and-Three-Ribbed Rigid-Frame Form Zur Berechnung freitragender Flugzeugflügel in zwei- und dreiholmiger Steifrahmenform (Vierendeel-Rostträger)', K. Thalau. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 15, no. 10, May 26, 1924, pp. 103-109, 15 figs. Calculations, for both two-ribbed and three-ribbed wings.

Experimental Results with Slotted Wings (Neuere Versuchsergebuisse mit Spaltflügeln), G. Lachmann. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 15, no. 10, May 26, 1924, pp. 109-116, 20 figs. Influence of arrangement of slots; reduction of profile resistance with normal flight; improvement of steering capacity with lower speeds.

Wood, Use in Construction. Some Recent Developments in the Use of Wood in Airplane Construction, W. M. Moore. Jl. of Forestry, vol. 22, no. 4, Apr. 1924, pp. 353-371. Kinds of wood used, species of wood permitted by Air Service specifications, use of plywood, defects in wood which affect its suitability for airplane manufacture, storage of airplane parts, balloon baskets, and wood versus metal in airplane construction.

ALLOY STEELS

Development. The Development of Alloy Steels, R. Hadfield. Iron and Coal Trades Rev., vol. 108, no. 2939, June 27, 1924, pp. 1120-1122, 1 fig. Gives comprehensive survey, largely historical, of development of alloy steels and important position they have attained in metallurgical and engineering industries. Paper read before Iron and Steel Sec., Empire Min. and Met. Congress.

Locomotives. Alloy Steels versus Carbon Steels for Locomotives. Ry. Engr., vol. 45, no. 533, June 1924, pp. 198-200. Review of subject of alloy steel, advantages of "straight" carbon steels, case-hardening steel, special steels for locomotive work, and alloy steel "defects".

ALLOYS

Copper. *See Copper Alloys.*

Corrosion-Resisting, Properties of. Tabular Presentation of Chemical and Physical Properties of Corrosion-Resisting Alloys. Chem. and Met. Eng., vol. 31, no. 2, July 14, 1924, pp. 79-83. Tables incorporating that part of systemized compilation made by a committee of members of Am. Soc. for Testing Matls. of available data regarding those alloys having iron, nickel or copper as predominating element and offering resistance to various destructive agencies, which is of value to chemical engiueer.

ASPHALT

Sands for, Classifying of. Classifying Asphalt Sands by Graphical Method, W. C. D. Haarman. Eng. News-Rec., vol. 92, no. 26, June 26, 1924, pp. 1090-1091, 2 figs. Triangular diagrams offering simple and rapid means of classifying sands and proportioning sheet asphalt mixture.

AUTOMOBILE ENGINES

Air Cleaners. Testing of Air-Cleaners, A. B. Squyer. Soc. Automotive Engrs.—Jl., vol. 15, no. 1, July 1924, pp. 33-37, 5 figs. Requirements of a good air cleaner are maximum efficiency, minimum of attention from operator and minimum power-loss. Deals with development of laboratory methods to determine relative values of various air cleaners as such, especially first requirement, maximum efficiency.

Crankcase Oil Dilution. A Possible Solution of the Crankcase-Oil Dilution Problem, I. L. Anderson. Soc. Automotive Engrs.—Jl., vol. 15, no. 1, July 1924, pp. 43-46, 6 figs. Describes method which consists of removing gasoline from crankcase by ventilation; apparatus used and results of tests.

Water in Crankcase Oils, A. L. Clayden. Soc. Automotive Engrs.—Jl., vol. 15, no. 1, July 1924, pp. 47-50, 3 figs. Effect of using an emulsifying oil; amounts of water actually deposited because of cylinder-wall condensation; effects on lubrication; determination of water-deposition rate.

Oil Consumption and Dilution. Engine-Oil Consumption and Dilution, N. MacCoull. Soc. Automotive Engrs.—Jl., vol. 15, no. 1, July 1924, pp. 93-100, 15 figs. First results of tests made by Texas Co., New York City, on five 7½-ton trucks during regular course of business deliveries. Curves plotted from data obtained. Details of dynamometer tests. Description of dynamometer apparatus and engine used, and analysis of result of wear of test engine.

AUTOMOBILE MANUFACTURING PLANTS

Ford Motor Company of Canada. Ford's New $10,000,000 Factory at Ford. Can. Mfr., vol. 44, no. 6, June 1924, pp. 11-15, 5 figs. Layout of plant, construction of buildings and description of machine shop.

Parts Handling. Cutting Costs by the Use of Conveyors, F. H. Colvin. Am. Mach., vol. 60, no. 26, June 26, 1924, pp. 969-971, 7 figs. Some of the Maxwell methods of handling chassis and bodies in their various stages, and some time-saving devices employed.

AUTOMOBILES

Bodies, Manufacture of. Manufacturing All Steel Automobile Bodies, J. W. Meadowcroft. Am. Welding Soc.—Jl., vol. 3, no. 5, May 1924, pp. 24-26. Particulars of welding operations.

Brakes, Four-Wheel. Hydraulic Brakes on Test, H. F. Blanchard. Autocar, vol. 52, no. 1495, June 13, 1924, pp. 1070-1072, 5 figs. Further details of Lockheed four-wheel system with data gleaned from actual trials.

Chassis Construction. Lighter Chassis Is Not Likely Until Body Weight Is Decreased, W. L. Carver. Automotive Industries, vol. 51, no. 1, July 3, 1924, pp. 30-33, 4 figs. Advent of leather in place of steel panels among promising possibilities. Balloon tires, smaller wheels and tubular axles help decrease mass of unsprung parts. Present stiff and heavy frames considered necessary to prevent wearing and rattles.

Finishing Materials. What Basic Materials Go Into Automobile Finishes? Automotive Industries, vol. 51, no. 1, July 3, 1924, pp. 34-38. Information regarding nature of materials used in finishing of automobile bodies and chassis.

Headlighting Devices, Laboratory Tests for. Specifications of Laboratory Tests for Approval of Electric Headlighting Devices for Motor Vehicles. U. S. Bur. Labor Statistics—Bul., no. 350, Jan. 1924, 5 pp., 1 fig. Tentative American standard approved Nov. 11, 1922 by Am. Eng. Standards Committee.

B

BAGASSE

Drying with Flue Gases.. Calculation of the Economy of Fuel Realized on Drying Bagasse with Flue Gases, E. Mooyaart. Int. Sugar Jl., vol. 26, no. 305, May 1924, pp. 252-254. According to given calculations, if bagasse having 47 per cent of water be dried by means of flue gases to material having 15 per cent of water, an economy of 15 per cent of fuel can be realized.

BALANCING MACHINES

Dynamic. Balancing of Rotating Masses (Das Auswuchten Umlaufender Massen), M. Krause. Praktische Maschinen-Konstrukteur, vol. 57, no. 17, May 13, 1924, pp. 229-232, 20 figs. Shows that static balancing of machine parts is by no means adequate; describes machine which enables correct dynamic balancing.

BEARINGS, BALL

Function and Mounting of. Ball Bearings: Their Proper Function and Methods of Mounting, F. J. Taylor. Mech. Wld., vol. 75, no. 1953, June 6, 1924, pp. 353-354, 9 figs.

BEARINGS, ROLLER

Design. Roller Bearings Facilitate Speed, D. E. Batesole. Iron Trade Rev., vol. 75, no. 3, July 17, 1924, pp. 164-166, 6 figs. High-precision units of roller type withstand heavy load capacity and resistance to severe shock. Choice of bearing depends upon operating conditions and design. Describes principle of construction.

Mill Motors. Roller Bearing Service In Mill-Type Motors, L. J. Hess. Indus. Engr., vol. 82, no. 4, Apr. 1924, pp. 164-168, 6 figs. Methods of installation and results obtained from use of roller bearings in 300 heavy-duty motors.

BLAST FURNACES

British Practice. Modern British Blast Furnaces, F. Clements. Iron and Coal Trades Rev., vol. 108, nos. 2936 and 2937, June 6 and 13, 1924, pp. 959-965 and (discussion) 1024, 9 figs. Description with statistics of certain blast-furnace plants in England of a more modern type as representing position to which British design and practice has advanced. Paper read at Empire Mining and Metallurgical Congress.

Design. Progress Made in the Production of Pig Iron and the Construction of Blast Furnaces (Progrès réalisés dans la fabrication de la fonte et la construction des hauts fourneaux), J. Estour. Technique Moderne, vol. 16, no. 9, May 1, 1924, pp. 309-319, 13 figs. Notes on constitution of pig iron; manufacture and combustibility of coke; enrichment, briquetting and sintering of ore; cross-section and dimensions of blast furnaces; design; charging apparatus.

Fuel Economy. The Law of Heat Concentration and Fuel Economy in Blast Furnaces (La loi de la compression de la chaleur et l'économie de combustible dans les hauts fourneaux), A. Korevaar. Chimie et Industrie, vol. 11, no. 4, Apr. 1924, pp. 642-650, 2 figs. Deduction of law of heat concentration; variations of factors depending on carbon; problem of combustibility of fuels; factors depending on air and concentration of heat, and on furnace and concentration of heat; influence of conduction; analysis of fuel consumption in blast furnace; influence of inflammability of coke on fuel consumption; influence of preheating of air and of furnace diameter on carbon.

BLASTING

Aluminum Cap. A New Aluminum Blasting Cap, W. H. Pay. Can. Min. Jl., vol. 45, no. 25, June 20, 1924, pp. 604-605, 1 fig. Aluminum detonator is superior to copper detonators. Remarkable features of cap is its moisture-resisting qualities and in point of fact it is practically waterproof.

BOILER FURNACES

Coal vs. Oil Fuel. Fuel Oil or Coal for Steam Generation, F. H. Daniels. Steam Coal Buyer, vol. 1, no. 2, Feb. 1924, pp. 11-15, 8 figs. Shows that fuel oil cannot compete with coal for generation of steam in land plants except for short periods of time.

Firing. Firing a Hand-Fired Down-Draft Furnace, J. F. Barkley. U. S. Bur. Mines, Reports of Investigations, No. 2609, May 1924, 6 pp. Method used and results obtained in testing a hand-fired down-draft furnace at a plant in Wash., D. C. in order to determine method of firing that would give best results with a minimum of smoke.

Lining. Reducing the Cost of Relining Boiler Furnaces. Power, vol. 59, no. 26, June 24, 1924, pp. 1028-1030, 5 figs. Most successful and economical lining material has been found to be combination of crushed used firebrick, fireclay and sodium silicate (water glass) applied by means of air gun in form of spray.

BOILER PLANTS

Flue-Dust Separator. Flue Dust and Forced Draught. Engineer, vol. 137, no. 3,573, June 20, 1924, p. 696, 3 figs. Describes "cindervane" fan for Stepney power house which combines dual functions of dust separator and induced-draft fan.

Instruments. Modern Boiler-room Instruments, J. Wolf. Combustion, vol. 11, no. 1, July 1924, pp. 40-42. Discussion of place held by instruments in modern boiler room and of particular functions and advantages of some of the more important types.

BOILER OPERATION

Efficiency. Operation of Steam Boiler Plants, E. B. Ricketts. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 749-751.Discussion of some of the more important factors which contribute to efficient boiler operation. Emphasizes fact that basis of good boiler operation is a thorough knowledge on part of all men in plant of materials and apparatus with which they must deal and thorough and consistent co-operation of management and men in common aim of stopping all leaks and keeping them stopped. Address before Nat. District Heat Assn.

The Control of Power Production C. L. Hubbard. Factory, vol. 33, no. 1, July 1924, pp. 26-29, 96, 98 and 100, 13 figs. Fundamental functions of a good boiler.

BOILER ROOMS

Electric Drive. Motor Applications in the Boiler Room, H. W. Smith. Power Plant Eng., vol. 28, no. 13, July 1, 1924, pp. 700-703, 6 figs. d. c. motors and control for stoker and clinker grinders; 2 and 4 speed squirrel-cage motors; wound rotor motors; forced- and induced-draft fans; boiler feed pump; coal-handling equipment.

BOILERS

Combustion Control. Combustion Control for Boilers, R. J. S. Pigott. Paper, vol. 34, no. 9, June 19, 1924, pp. 368-371. What automatic regulation of boilers will accomplish in the way of efficiency and control of capacity. Principle of design.

Heat Transmission. Heat Transmission in Boilers, Chas. F. Wade. Power Engr., vol. 19, no. 219, June 1924, pp. 224-226, 4 figs. Discussion of principles and suggestions for improvements; deals with "luminous" flames, conduction, gas films and temperatures.

Heating, Smokeless. Smokeless Heating Boilers, T. N. Thomson. Plumbers Trade Jl., vol. 77, no. 1, July 1, 1924, pp. 26-28 and 29, 3 figs. Development and manufacture of Utica Imperial smokeless boiler.

Marine. *See Marine Boilers.*

BRAKES

Air. The Air Brake Problem. Car Foremen's Assn. of Chicago—Proc., May 1924, pp. 15-35 and (discussion) 35-55. Deals with maintenance discussing fundamentals of air brakes to the end that proper significance be applied to relative parts.

BRAZING

Production. Production Brazing, B. Heyman. Welding Engr., vol. 9, nos. 3, 5 and 6, Mar., May, and June 1924 pp. 19-21, 19-21 and 17-20, 9 figs. Underlying principles. Description of devices and methods employed in carrying through a series of machine-brazing operations on a single product in which numerous difficulties were encountered both from an engineering standpoint in design and also from operating standpoint in shop.

BRIDGES, CONCRETE

Arch. Design of LaBalme Concrete Arch Bridge, J. Polivka. Cornell Cic. Engr., vol. 32, nos. 3, 4, 5 and 6, Nov. and Dec. 1923, and Jan., Feb. and Mar. 1924, pp. 17-19 and VIII, 33-36 and VII, 50-52 and 56, 56-68 and IX, and 82-84, 11 figs. Describes highway bridge which crosses Rhone at Yenne; computation of roadway stresses and stresses in arch rib; results of experiments with glass model.

Reinforced Concrete Bridge with Arches of 590 ft. 6 in. Span, P. Calfas. Concrete and Constructional Eng., vol. 19, no. 6, June 1924, pp. 352-357, 4 figs. Particulars of new bridge to be built across estuary of Elorn between Brest and Daoulas, consisting of 3 huge reinforced-concrete arched bays supported by 2 piers built in stream and 2 abutments on banks. Will have total length of about 2,625 ft.

Arch, Abutment for. Novel Abutment Effects Economy In Concrete Bridge, A. G. Hayden. Eng. News-Rec., vol. 93, no. 1, July 3, 1924, pp. 26-27, 3 figs. Nofel type abutment of Park Avenue bridge over Bronz River Parkway Reservation near Tuckahoe, N. Y. Horizontal thrust taken by wing walls; vertical thrust distributed through abutments acting as vertical beam.

Pouring Method. How to Pour Concrete Bridges with Special Reference to Construction Joints, A. R. Carter. Mun. & County Eng., vol. 46, no. 5, May 1924, pp. 229-231. Relates policy adopted in Winnebago County, Ill., in pouring concrete structures.

BRIDGES, HIGHWAY

Hill-to-Hill. Design and Construction of the Hill-to-Hill Bridge, Bethlehem, Pa., F. W. Skinner. Mun. & County Eng., vol. 66, no. 6, June 1924, pp. 286-292, 7 figs. Bridge, chiefly of concrete-arch construction, serves 70,000 residents of city, crosses Lehigh River, Monocacy Creek, several streets and railway tracks; design; pile foundations; coffer dams; forms and falsework; mixer plants, etc.

BRIDGES, LIFT

Bascule. Completion of Johnson Street Bridge, F. H. Allwood. Can. Engr., vol. 46, no. 26, June 24, 1924, pp. 633-635, 5 figs. Describes construction of bascule bridge connecting Victoria and Esquimalt, B. C. Oxy-acetylene torch employed for demolishing old swing bridge; important features in erection of superstructure of highway and railway sections of bridge.

Vertical. The Vertical Lift Bridge, J. A. L. Waddell. West. Soc. Engrs.—Jl., vol. 29, no. 5, May 1924, pp. 209-216, 7 figs. Describes progress of vertical lift bridge designs with which author has been intimately associated for many years. References are given to other publications in which will be found more detailed information including statistics of bridges erected and detailed analysis of economics of movable spans.

BRIDGES, RAILWAY

Cantilever. Cantilevering a Heavy Bridge Span In Northern Quebec, J. P. Chapleau and C. M. Goodrich. Eng. News-Rec., vol. 93, no. 3, July 17, 1924, pp. 94-95, 2 figs. Special conditions surrounding construction of a railway bridge across Saguenay River led to a remarkable use of cantilever erection method. A 220-ft. double-track span was cantilevered for its full length from a 90-ft. approach span, because of rapid current in river. Construction data.

Plate Girder. The Design of a 50-Ft. Deck Span Plate Girder Railway Bridge, H. F. Cornick. Ry. Engr., vol. 45, nos 533 and 534, June and July 1924, pp. 193-195 and 252-255, 10 figs. Details of design of typical girder bridge, using modern methods of calculation. Summary of tending moments; proportions of main girders; calculation of steer stresses, girder bracing.

BUSES

Operating Results. Bus Operating Results in Providence, R. I. Elec. Ry. Jl., vol. 64, no. 2, July 12, 1924, pp. 43-45, 3 figs. Figures of operating costs and revenue possibilities in various kinds of service on United Elec. Rys. of Providence, R.I., a company which operates buses in coordination with railway service. Only one line of seven made profit although others substituted for rail lines show less than rail operation.

C

CABLES, ELECTRIC

Construction. Report of Sub-Committee on Aerial Cable Construction, T. W. Snell. Jl. of Elec., vol. 52, no. 11, June 1, 1924, pp. 443-445, 3 figs. Relative merits of various types of insulation for overhead conductors, and comparative costs of several types of construction designed to obviate trouble from accidental "grounds" or "shorts" caused by trees in line.

CABLES, HOISTING

Dynamic-Stress Determination. Dynamic Stress of Winding Cables (Die dynamische Beanspruchung der Förderseile), G. Berg. Glückauf, vol. 60, no. 20, May 17, 1924, pp. 400-402, 8 figs. Describes instrument for measuring and recording width between guides, also processes and trials for determining dynamic forces acting on cables.

CABLEWAYS

Aerial. Cableways and Suspended Railways (Schwebende Drahtseilbahnen und Schienenhänge-bahnen), M. Buhle. Bautechnik, vol. 2, no. 26, June 17, 1924, pp. 268-288, 88 figs. Describes and illustrates number of types manufactured by A. Bleichert & Co., Leipzig, for passengers and freight, on land and water, and installed in various parts of world.

Coal-Mine. Aerial Wire Ropeways, J. W. White. Instn. Min. Engrs.—Trans., vol. 67, Pt. 2, May 1924, pp. 114-128, 13 figs. Details of different types designed principally for colliery purposes.

CAMERAS

Photographing Moving Projectiles. A Camera for Studying Projectiles in Flight, H. L. Curtis, W. H. Wadleigh and A. H. Sellman. U. S. Bur. Standards, Technologic Papers, No. 255, Mar. 19, 1924, pp. 189-202, 10 figs. partly on supp. plates. Describes camera which will take pictures of objects moving with high speed, and also measure their velocity. Number of pictures depends on number of lenses, 50 pictures per second per lens being easily obtained.

CAR LIGHTING

Equipment. Report of Committee on Locomotive and Car Lighting, W. E. Dunham. Ry. Age (Daily Edition), vol. 76, no. 32, June 14, 1924, pp. 1558-1560, 3 figs. Discusses design of axle-generator belt drive and photometry of locomotive headlights. Report presented before Am. Ry. Assn.

CAR WHEELS

Chilled-Iron. The Chilled Iron Wheel in Railroad Service, E. Ruker. Assn. Chinese and Am. Engrs.—Jl., vol. 5, no. 3, Mar. 1924, pp. 11-16. Evolution, production, and use of this special kind of wheel and its action in service.

Rolled-Steel. The Manufacture of Solid Rolled Steel Car Wheels, G. A. Richardson. Ry. Club Pittsburgh—Official Proc., vol. 23, no. 5, Mar. 27, 1924, pp. 119-124 and (discussion) 124-126. Factors influencing delivery times and determining extra costs.

Specifications. Report of Committee on Wheels. Ry. Rev., vol. 74, no. 25, June 21, 1924, pp. 1211-1213, 3 figs. Cooling of rolled-steel wheels; specifications for cast-iron and steel wheels; development of cast-iron wheel design; wheel mounting gage; standard steel-wheel gage; tread-worn hollow wheels; grinding of cast-iron wheels. Report presented to Am. Ry. Assn. See also Ry. Age (daily edition), vol. 76, no. 36, June 19, pp. 1730-1735 and (discussion) pp. 1734-1737, 3 figs.

CARS, FREIGHT

DESIGN. Report of the Committee on Car Construction. Ry. Age (Daily Edition), vol. 76, no. 34, June 17, 1924, pp. 1634-1638 (including discussion), 1 fig. Reviews objects of fundamentals of design adopted by Association prior to development of present standard box-car designs; development of theoretical basis of car-framing design. Report presented to Am. Ry. Assn. See also Ry. Rev., vol. 74, no. 25, June 21, 1924, pp. 1186-1189, 1 fig.

SCRAPPING. Scrapping Steel Freight Cars. Welding Engr., vol. 9, no. 6, June 1924, pp. 21-23, 5 figs. Application of electric-arc cutting process to reclaiming and scrapping of rolling stock.

CARS, PASSENGER

HISTORY AND DEVELOPMENT. History and Development of Passenger Car Building, Geo. A. Richardson. Ry. Rev., vol. 74, no. 24, June 14, 1924, pp. 1133-1141, 26 figs. Account of history and present facilities of Bethlehem Shipbldg. Corp., Wilmington, Del., which was pioneer in manufacture of passenger cars.

CARS, TANK

SPECIFICATIONS. Report of Committee on Tank Cars. Ry. Age (Daily Edition), vol. 76, no. 35, June 18, 1924, pp. 1675-1680 and (discussion) 1680-1684, 3 figs. Specifications for Class V and VI tank cars; report on dome covers, bottom-discharge outlets, etc. Report of committee before Am. Ry. Assn. See also Ry. Rev., vol. 74, no. 25, June 21, 1924, pp. 1175-1177, on committee specifications for Class VI tank cars for transportation of helium gas.

CASE-HARDENING

STEEL. The Case-hardening of Steel R. N. Richardson. Eng. Production, vol. 7, no. 142, July 1924, pp. 214-215. Discusses heat treatment of case-hardened steel, methods for preventing carburizing of parts, case-hardening compounds, and causes of failure of case-hardened parts.

CAST IRON

GRAPHITE FORMATION IN. The Formation of Graphite in Cast Iron, L. Northcott. Foundry Trade Jl., vol. 29, nos. 409 and 410, June 19 and 26, 1924, pp. 515-521 and (discussion) 548-550, 37 figs. Describes work undertaken in order to examine process. Effect of annealing white cast iron at different temperatures and under such conditions as to produce temper-carbon or nodular graphite. Observations regarding precipitation of carbon. Experiments on a typical gray cast iron of good quality to determine mechanism of formation of flaky or primary graphite as commonly found in gray irons.

CEMENT

MAGNESIA. Plastic Magnesia Cements, P. Sachs. Asbestos, vol. 5, no. 12, June 1924, pp. 5-12. Describes new cement known as Sorel's oxychloride cement, having very great strength and very high bending power. Chemical nature has not been established with certainty but is believed to be hydrated basic mangesium oxychloride-3 mg 0. mg CI_2 10 H_2 0.

CEMENT, PORTLAND

STUDY OF. Some Requirements in the Study of Portland Cement, T. Merriman. Eng. News-Rec., vol. 93, no. 3, July 17, 1924, pp. 105-106. Outlines fundamental considerations that need to be given extended study in connection with development of tests which will more truly disclose quality of cement than do those now available. Characteristics of "ideal cement".

CENTRAL STATIONS

EUROPE. Central Station Practice in Europe, B. G. Jamieson. West. Soc. Engrs.—Jl., vol. 29, no. 6, June 1924, pp. 247-256, 5 figs. Some noticeable differences in electrical engineering practice including use of mercury-arc rectifiers in place of converters, high-voltage direct current and lack of interconnection of networks, extensive use of underground cable. Attention is given to appearance of central-station buildings and surroundings.

HEAT BALANCE. Heat Balance at Hudson Avenue Station (Brooklyn). Power Plant Eng., vol. 28, no. 13, July 1, 1924, pp. 706-709, 3 figs. Six sources of heat are involved in cycle; control is automatic; vertical isolation of phases is feature of electrical design.

CHAINS

CONNECTING LINKS, PULLING TESTS OF. Results of Pulling Tests of Chain Connecting Links (Mededeeling omtrent de resultaten van trekproeven met sluitings), I. R. Mulder. Ingenieur, vol. 39, no. 20, May 17, 1924, pp. 364-369, 8 figs. Photographs, diagrams and tables of test results for chain connecting links of various sizes. pin diameters varying from ¼ in. to 2 in.

CHIMNEYS

DESIGN. The Design of Chimneys, W. S. Findlay. Power Engr., vol. 19, no. 219, June 1924, pp. 226-228, 5 figs. Factors in design of chimney shafts, with special reference to their stability.

FLUE. Chimneys for Heating Boilers, A. G. King. Domestic Eng. (Chicago), vol. 106, no. 7, Feb. 16, 1924, pp. 20-23, 5 figs. Elements of a chimney flue and its proper position and construction.

CHROMIUM

USES AND ALLOYS. Chromium—Its Uses and Its Alloys, W. M. Mitchell. Forging—Stamping—Heat Treating, vol. 10, nos. 3 and 6, May and June, 1924, pp. 199-202 and 235-238, 7 figs. May: Sources of chromium, chemical properties and technical uses. June: Ferro-chromium; chromium steels.

CITY PLANNING

CANADA. Review of Town Planning in Canada, T. Adams. Can. Engr., vol. 46, no. 26, June 24, 1924, pp. 651-653. Status in Canada before and during War and since that period. Author considers that much progress has been made. Paper presented at Town Planning Inst. Conference.

KITCHENER AND WATERLOO, ONT. Planning of Kitchener and Waterloo, Ont., H. L. Seymour. Can. Engr., vol. 47, no. 2, July 7, 1924, pp. 125-130, 3 figs. Developments leading up to preparation of comprehensive town planning scheme now nearing completion; proposals by experts; summary of conclusions and recommendations submitted by consulting engineers; elimination of level crossings.

TRAFFIC IN RELATION TO. Street Traffic and City Planning. Pub. Works, vol. 55, no. 6, June 1924, pp. 201-206. Extent to which enormous development of city traffic made imperative street widening and other changes in structure and improvements in handling traffic; suggestions made.

CLUTCHES

CONICAL. Conical Clutch Designs, A. Clegg. Machy. (N.Y.), vol. 30, no. 11, July 1924, pp. 867-869, 5 figs. Advantages of conical clutches; construction of conical clutch for radial drilling machine; principles to be followed in design; conical clutch for lathe feed control and applied to planer drive.

COAL

CARBONIZATION. Practical Coal Carbonization, A. R. Powell. Mech. Eng., vol. 46, no. 7, July 1924, pp. 389-394, 6 figs. Enumeration of technical problems of low-temperature carbonization and classification and description of the various processes.

CLEANING. The Improvement of Coal by Mechanical or Thermal Methods of Treatments, J. B. B. Kershaw. Fuel, vol. 3, nos. 5 and 6, May and June 1924, pp. 165-170 and 189-195, 10 figs. Methods of removing impurities from small coal and from all kinds of washery waste and pit refuse, namely (1) hydraulic or wet methods; (2) methods involving use of oil; (3) electrostatic and other dry methods; (4) methods involving use of heat.

COAL BREAKERS

BAKER. Baker—The Latest Glen Alden Breaker. Coal Age, vol. 26, no. 3, July 17, 1924, pp. 76-81, 12 figs. Describes breaker of Glen Alden Coal Co. Reaching breaker from several sources, coal is crushed on ground level and product elevated to top of building; simplicity and neatness foster a good morale.

COAL HANDLING

PLANTS. Coal and Ore Handling Plant at Waalhaven, Rotterdam. Engineer, vol. 137, no. 3574, June 27, 1924, pp. 722-725, 8 figs. Details of installation of Coal Trading Assn. which, when completed, will comprise two quays 350 m. long, with accommodation for ocean-going vessels up to 10 m. draft, and between quays a dock 160 m. long available for river vessels with drafts up to 6 m.; description of transporter bridges, and transformer and load-equalizing station.

COAL MINES

ELECTRICITY, USE OF. Some Researches on the Safe Use of Electricity in Coal Mines, W. M. Thornton. Instn. Elec. Engrs.—Jl., vol. 62, no. 330, June 1924, pp. 481-491 and (discussion) 491-514, 10 figs. Results of investigation; deals with electrical ignition of coal dust alone, coal dust with gas present, of methane and associated gases by disruptive sparks, steady or impulsive, transient arcs, direct or alternating, with varied voltage and frequency, in all percentages of mixture with air; gives examples of application of results to promote safety in mines.

POWER PLANTS. Illinois Mine Generates Own Power Cheaply, A. Allen and H. F. Hebley. Coal Age, vol. 26, no. 1, July 3, 1924, pp. 3-7, 4 figs. Describes power plant of No. 4 mine of Donk Bros. Coal & Coke Co., in Madison County, Ill. All pickings and some slack burned; superheated steam used; exhaust from hoist and auxiliaries utilized in mixed-pressure turbine. Costs reduced to 1.6 cents per kw-hr. with plant at half capacity. Mine has a daily hoisting capacity of 6,000 tons.

ROCK DUSTING. How Old Ben Corporation with Rock Dust Extinguished Seven Mine Explosions, J. E. Jones. Coal Age, vol. 25, no. 25, June 19, 1924, pp. 907-911, 6 figs. Zone system vs. coating system; relative advantages of floor, rib and roof dust; frequencies of application; effectiveness of dust distributed by air current; sampling by vacuum cleaner. See also Coal Industry, vol. 7, No. 6, June 1924, pp. 243-246.

Rock Dusting. Min. Congress Jl., vol. 10, no. 7, July 1924. Contains following papers read at Am. Min. Congress: Actual Experiences with and Tried Methods of Applying Rock Dust, J. E. Jones, pp. 291-293, 1 fig., Occurrence, Characteristics and Behavior of Coal Dust, J. W. Paul, pp. 294 and 302, 1 fig., Investigations Into Rock Dusting for Coal Dust Explosion Prevention, G. S. Rice, pp. 295-296, 1 fig., Rock Dusting of Coal Mines; Efficacy, Methods and Costs, J. T. Ryan, pp. 297 and 302, Rock Dust Versus Water as a Preventive Measure for Mine Explosions, E. Steidle, pp. 298 and 302.

SAFETY METHODS. Mine Safety Methods of the Ford Collieries Company, C. L. Colburn. Nat. Safety News, vol. 10, no. 1, July 1924, pp. 31-33, 4 figs. Company operates 3 mines employing about 1,000 men. Management accomplishes marvelous results by watchword "Safety First".

VENTILATION. The Ventilation of Mines, D. Hay and R. Clive. Iron & Coal Trades Rev., vol. 108, no. 2938, June 20, 1924, pp. 1058-1061, 6 figs. Discusses objects and principles of ventilation, splitting of air, regulation of splits, influence of leakage, size of airway, and natural ventilation effect. From paper read before Min. Soc. Empire Min. & Met. Congress.

COKE MANUFACTURE

BY-PRODUCT. Making Coke to Combat Canada's Fuel Problem, H. P. Armson. Power House, vol. 17, no. 12, June 20, 1924, pp. 23-27, 4 figs. Description of processes by which Hamilton By-Products Coke Ovens Co. produce foundry and domestic coke, tar, ammonium sulphate, city gas, blue water gas and naphthalene.

COKE OVENS

PRACTICE. Comparative Survey of Coke-Oven Practice in Various Countries, G. A. Hebden. Colliery Guardian, vol. 127, no. 3310, June 6, 1924, pp. 1459-1460. Survey of Great Britain, Europe, the Dominions, and America. From paper read before Empire Min. & Metallurgical Congress.

COLUMNS

BUCKLING. Notes on Moments in Pillars Due to Deflection of Beams Monolithic Therewith, O. Faber. Concrete & Constructional Eng., vol. 19, no. 6, June 1924, pp. 342-349, 5 figs. Explains bending of pillars due to deflection of beams monolithic with them.

COMBUSTION

CONTROL. Combustion Control Based on CO_2 in Gas, G. E. Gaster. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 768-769, 2 figs. Variations in CO_2 operate rheostat controlling speed of fan motor.

The Evils of Close Regulation in Automatic Combustion Control, T. A. Peebles. Power, vol. 60, no. 1, July 1, 1924, pp. 13-14. Points out that close regulation is desirable from viewpoint of production or utilization; on other hand, it tends to introduce wear, hunting or surging, and other undesirable conditions; this is particularly true of combustion-control apparatus, as herein described.

COMPRESSED AIR

MACHINERY. Air Machinery, A. Hinz. Mech. Eng., vol. 46, no. 7, July 1924, p. 417. Possibilities of improvements in compressed-air plant operation. Translated and abstracted from Glückauf, nos. 15 and 16, Apr. 12 and 19, 1924.

CONCRETE

ALKALI ACTION. Volume Change a Measure of Alkali Action, D. G. Miller. Pub. Roads, vol. 5, no. 4, June 1924, pp. 12-13 and 17, 3 figs. Effect on concrete measured by changes in length.

CURING. Tests Show How Damp-Sand Curing Improves Quality of Concrete, F. D. Crook and H. Faulkner. Eng. News-Rec., vol. 92, no. 25, June 19, 1924, pp. 1050-1051, 4 figs. Effect of oil on pavements shown by tests on small blocks. Impermeability depends largely on method of curing.

CONCRETE CONSTRUCTION, REINFORCED

REINFORCEMENT EMBEDMENT. Should Reinforcement Embedment Vary with Size of Bar? A. S. Woodle, Jr. Eng. News-Rec., vol. 92, no. 26, June 26, 1924, pp. 1092-1093, 1 fig. Examination into stresses set up by temperature changes in surface areas of reinforced concrete.

CONCRETE MIXERS

STANDARDS. Concrete Mixer Standards Are Revised. Concrete Rec. & Eng. Rev., vol. 38, no. 24, June 11, 1924, pp. 606-608. Regulations adopted at a joint meeting of representatives of concrete mixer manufacturers and Associated General Contractors of America.

CONDENSERS, STEAM

EVAPORATIVE. The Evaporative Condenser, N. E. Webster. Instn., Min. Engrs.—Trans., vol. 67, Pt. 2, May 1924, pp. 192-198, 3 figs. Description of conditions for which this type of condenser seems peculiarly suitable.

CONVEYORS

PNEUMATIC. Experimental Investigation of Pneumatic Conveying Process (Die experimentelle Unter suchung des pneumatischen Fördervorganges), M. Gasterstädt. Zeit. des Vereines Deutscher Ingenieure, vol. 68, no. 24, June 14, 1924, pp. 617-624, 22 figs. Describes experimental plant and measuring arrangements. Effect of quantity conveyed and velocity on pressure drop in conveying system; shows uniform connection between quantity conveyed and drop in pressure, and between velocity of air current and of material.

COPPER ALLOYS

HARDNESS. The Variation in Hardness of Copper Alloys with Temperature (La variation de la dureté des alliages de cuivre avec la température), L. Guillet. Revue de Métallurgie, vol. 21, no. 5, May 1924, pp. 295-302, 7 figs. Results of tests show that variations of hardness with temperature follow laws which vary considerably for alloys of same category; but in same range of thermal diagram, variations follow same laws to great extent; ternary alloys conserve their hardness better than binary alloys.

CORE BOXES

VALVES. Making Globe Valve Corebox, W. C. Ewalt. Foundry, vol. 52, no. 12, June 15, 1924, pp. 483-485, 15 figs. Metal boxes are cast from carefully constructed wood master patterns where foundry output is large; in many cases pattern is built up from number of small segments.

COST ACCOUNTING

WASTAGE IN RELATION TO. The Wastage of Industrial Plant in Relation to Cost Accounting, A. Stewart. World Power, vol. 1, no. 6, June 1924, pp. 318-324, 4 figs. Nature of wastage; methods of measuring depreciation; plant register; cost of additions; repairs and renewals; inclusion of plant register.

CRANES

JIB. "Toplis" Luffing Cranes at Southampton Docks. Engineering, vol. 117, no. 3050, June 13, 1924, pp. 762-763, 4 figs. partly on p. 768. Patent horizontal-luffing type, consisting of travelling truck, in which is mounted a rotating steel lattice structure, forming a mast and carrying jib and combined machinery house and operator's cabin.

CRANKSHAFTS

FAILURES. Stress Distribution in Crankshafts and Its Relation to Crankshaft Failures, D. J. McAdam, Jr. and G. F. Wohlgemuth. Am. Soc. Naval Engrs. Jl., vol. 36, no. 2, May 1924, pp. 244-281, 29 figs. Causes of crankshaft failures; stress distribution in crankshafts as affected by restraint of journals; stress-strain relationship in typical naval crankshafts; measured and calculated angular deflections of Liberty crankshaft; typical crankshaft failures; desirable stress distribution in crankshafts.

CUPOLAS

FUEL ECONOMY. Economical Melting with Cupolas, H. Van Aarst. Foundry Trade Jl., vol. 29, no. 409, June 19, 1924, pp. 522-524, 3 figs. How to be economical with fuel in cupola. Influence of iron on fuel economy, influence of mechanical properties of coke, air supply, and cupola linings. See also Foundry, vol. 52, no. 13, July 1, 1924, pp. 514-515, 3 figs.

CYLINDERS

LOCOMOTIVE, WELDING OF. Locomotive Cylinder Welding, J. S. Heaton. Welding Engr., vol. 9, no. 6, June 1924, pp. 24-25, 10 figs. Firepot made of front end netting greatly reduces cost of preheating cylinders; special preheating torch.

D

DAMS

EARTH. Classification and Definition of Earth Dam Types, J. A. Holmes. Eng. News-Rec., vol. 92, no. 26, June 26, 1924, p. 1102, 7 figs. Descriptions based on methods of construction and materials employed.

FAILURES. The Failure of the Gleno Dam (Italy) (La rupture du barrage du Gleno), J. Boudet. Houille Blanche, vol. 23, no. 187, Mar.-Apr. 1924, pp. 33-47, 14 figs. Descriptive, critical and analytical study.

GRAVITY. Method for the Dimensioning of Gravity Dams (Ueber ein Verfahren Azur Dimensionierung von Gewicht-Staumauern), W. Kienast-Curti. Schweizerische Bauzeitung, vol. 83, no. 20, May 17, 1924, pp. 229-230, 4 figs. Describes methods being applied by Buss Corp. in Basel, Switzerland, according to Gutzwiller cell system, described in previous issue of same journal.

STURGEON FALLS, ONT. Concrete Dam at Sturgeon Falls Built During Temperatures as Low as 50 Below Zero, Geo. H. Kohl. Con. Rec., vol. 38, no. 25, June 18, 1924, pp. 614-617, 5 figs. Interesting construction procedure on dam built by spanish River Pulp & Paper Mills, Ltd. Describes plant and methods and give outline of design.

DIESEL ENGINES

FUEL INJECTION. Investigation of the Fuel-Injection Process in Diesel Engines (Untersuchungen über den Einspritzvorgang bei Dieselmaschinen), W. Riehm. Zeit. des Vereines Deutscher Ingenieure, vol. 68, no. 25, June 21, 1924, pp. 641-645, 10 figs. Discusses fundamentals of injection process; describes experimental plant, tests with water and oil, absorption of heat up to ignition.

LOW-POWERED. Low-Powered Diesel Engines (La question du Diesel de faible puissance), P. Simondet. Arts & Métiers, vol. 77, no. 42, Mar. 1924, pp. 81-105, 22 figs. Deals with technical, financial and manufacturing problems of low-power engines working on Diesel cycle,with special reference to difficulties which may account for comparatively restricted extent to which they have hitherto been employed; among types of engines described are Hindl and Hvid engines.

DREDGES

DIESEL-ELECTRIC. Diesel-Electric Dredge A. Mackenzie Completes Trials. Mar. Eng., vol. 29, no. 7, July 1924, pp. 409-411, 14 figs. Particulars of first of four new diesel-electric sea-going dredges for U. S. army.

OIL TYPE. Design Oil Type Harbor Dredge. Mar. Rev., vol. 54, no. 7, July 1924, pp. 289-292, 12 figs. Particulars of dipper dredge Hell Gate of U. S. Engineer Corps.

DROP FORGING

CRANKSHAFTS. Precautions Needed in Production of Automotive Drop Forgings. Automotive Industries, vol. 50, no. 26, June 26, 1924, pp. 1388-1391, 6 figs. Wyman-Gordon employ special machine to prove running balance of crankshafts and etch section to show direction of flow in finished product, in addition to standard tests.

DRYDOCKS

FLOATING. The Southampton 60,000-Ton Floating Dock. Engineering, vol. 117, no. 3051, June 20, 1924, pp. 789-791, 23 figs. partly on supp. plates. Detailed description of dock provided by Southern Ry. to enable even largest vessels in world, viz., the Majestic and the Leviathan, using port to be repaired and overhauled. Total weight of structure and equipment is 18,800 tons. Dock is of double-sided, self-docking type constructed in seven sections, any one of which can be lifted by others for painting or repairs.

DRYING

METHODS. Drying Methods in Modern Industrial Processes, Chas. L. Hubbard. Nat. Engr., vol. 28, no. 7, July 1924, pp. 309-314, 7 figs. Fundamentals of drying processes and basic factors affecting their operation.

E

EDUCATION, ENGINEERING

COURSES. Engineering Courses for the Functional Rather than the Industrial Divisions of Engineering, E. Bennett. Eng. Education, vol. 14, no. 10, June 1924, pp. 582-599. Functional divisions of engineering are considered to be functional divisions found within any of the large industrial organizations.

LEADERS AND ROUTINE PRACTITIONERS. Educating Leaders and Routine Practitioners, C. C. Williams. Eng. Education, vol. 14, no. 9, May 1924, pp. 528-535. Considers question of whether colleges can effectively train both leaders and routine practitioners simultaneously.

TABULATED RECAPITULATIONS, USE OF. Tabulated Recapitulations as a Means of Education, P. A. Cushman. Eng. Education, vol. 14, no. 8, Apr. 1924, pp. 450-458, 4 figs. Points out in what ways engineering students would gain by use of tabular recapitulations during their study of fundamental courses.

TEACHING, METHODS OF. At What Are We Aiming and With What? F. W. Springer. Eng. Education, vol. 14, no. 10, June 1924, pp. 565-581. Proposes a key or outline of educational theory and makes more apparent desirability and possibility of finding cues for application of theory to engineering education.

ELECTRICAL MACHINERY

ROTATING, TOOTH PULSATION IN. Tooth Pulsation in Rotating Machines, T. Spooner. A.I.E.E.—Jl., vol. 43, no. 7, July 1924, pp. 646-650, 12 figs. Presents experimental method of checking magnitude of flux pulsations in teeth of rotating machines where both members are slotted. Test results compared with pulsation amplitudes as calculated by two methods.

ELECTRIC CONDUCTORS

STEEL-ALUMINUM. Calculation of Steel-Aluminum Conductors (Uber die Berechnung von Stahlaluminiumleitungen), O. Strand. Elektrotechnische Zeit., vol. 45, no. 25, June 19, 1924, pp. 654-657, 6 figs. Develops formulas and diagrams for determining distribution of tension in Fe-Al cables at varying temperatures.

ELECTRIC DISTRIBUTION SYSTEMS

CANADA. Electric Power Transmission and Distribution in Canada, J. C. Smith and C. V. Christie. Eng. Jl., vol. 7, no. 7, July 1924, pp. 421-446, 17 figs. Current practice in design and operation of electrical transmission and distribution systems in Canada. Paper read at World Power Conference.

COST ESTIMATES. Appraisals Based on Number of Meters Connected, R. B. Sleight. Elec. World, vol. 83, no. 26, June 28, 1924, pp. 1322-1323. Analysis of cost estimates on small-town distribution systems; limitations and practical application of method.

NETWORKS, INTERCONNECTING SYSTEM FOR. New Type of High-Tension Network, P. H. Thomas. A.I.E.E.—Jl., vol. 43, no. 7, July 1924, pp. 610-618, 1 fig. Presents a new type of interconnection for high-tension networks for economic supply of electric power over large areas having an already well developed load. Central idea is superposition of a high-tension network of single-circuit lines over whole district for purpose of supplying a medium in which current may flow in any general direction as changing conditions may dictate.

ELECTRIC DRIVE

GROUP AND INDIVIDUAL. When to Use Group and Individual Drives, R. W. Drake. Indus. Engr., vol. 82, nos. 2, 3 and 4, Feb., Mar. and Apr., 1924, pp. 56-60 and 106-107; 118-122; and 174-177, 15 figs. Comparative advantages and disadvantages of group and individual drives in industrial plants; points on layout, installation and operation; fan drives; line-shaft losses.

ELECTRIC FURNACES

DEVELOPMENT. Electric Furnace Development, F. Hodson. Blast Furnace & Steel Plant, vol. 12, no. 7, July 1924, pp. 314-318, 8 figs. Many supposed limitations now being removed suggests unlimited growth.

ELECTRODES. The Use of Söderberg Self-Baking Electrodes in Electric Steel Furnaces (Die Verwendung der Söderbergschen Dauerelektrode an Elektrostahlöfen), W. Eilender and L. Lyche. Berichte der Fachausschüsse des Vereins deutscher Eisenhüttenleute, Stahlwerksausschuss, report no. 78, Jan. 30, 1924, 5 pp. Use of self-baking electrode in 6-ton Héroult furnace; results show decrease in use of electrodes per ton steel; reduction of current consumption per ton steel; reduction in production cost per ton electrodes.

IRON-MELTING. Melts Iron in Twin Furnaces, A. W. Bryant. Foundry, vol. 52, no. 14, July 15, 1924, pp. 556-559, 4 figs. Two electric units mounted on turntable 180 deg. apart and having one set of electrodes, provide small batches of hot iron at short even intervals.

METALLIC-RESISTOR. The Metallic Resistor in Industrial Heating Furnaces, E. F. Collins. Chem. & Met. Eng., vol. 30, nos. 24 and 25, June 16 and 23, 1924, pp. 936-941 and 981-985, 18 figs. Application and design of electrical heating equipment; comparison of types of resistors; advantages of furnace. Chemical physical and economic laws governing use of equipment.

STEEL. Some Applications of Electric Heat to the Reheating of Steel, E. F. Collins. Fuels & Furnaces, vol. 2, nos. 6 and 7, June and July 1924, pp. 575-578 and 655-660, 2 figs. Brief review of past and present day conceptions of heat and laws governing it. Metallic resistors in unmuffled furnaces.

ELECTRIC GENERATORS, A.C.

OPERATION. Operation of A.C. Generating Equipment, V. E. Johnson. Power Plant Eng., vol. 28, nos. 2, 3, 6, 8, 11 and 14, Jan. 15, Feb. 1, Mar. 15, Apr. 15, June 1, and June 15, 1924, pp. 142-144, 183-186, 339-342, 438-440, 600-603, and 758-759, 53 figs. Fundamental considerations which serve as foundation for practical study. Jan. 15: Representing alternating currents by vectors. Feb. 1: Effect of capacity in a.c. circuits; power factor; wattless component. Mar. 15: 3-phase alternator, principles of construction and operation. Apr. 15: Study of characteristics of generators under various conditions. June 1: Conditions necessary for parallel operations, synchronizing, division of load, power-factor correction. July: Summary and principles as applied to generators; hints regarding care of machines.

Power Loads from, Totalizing of. Totalizing Alternating-Current Power Loads, V. H. Todd. Power, vol. 60, no. 2, July 8, 1924, pp. 47-49, 7 figs. Methods that may be used to obtain a combined reading of a number of power loads supplied from a.c. generators.

ELECTRIC LAMPS, INCANDESCENT

Statistics. Statistics on Use of Incandescent Lamps. Elec. News, vol. 33, no. 12, June 15, 1924, pp. 53-54, 2 figs. Gives demand by sizes, lamp-price changes and recent developments.

ELECTRIC LOCOMOTIVES

Current-Generating System. Railway Electrification (Considérations sur l'électrification des chemins de fer), E. Stassano. Génie Civil, vol. 84, no. 20, May 17, 1924, pp. 742-745. Notes on Stassano system of generation of current on locomotive. Supplementary note is appended on observations on Stassano system of traction, setting forth its shortcomings.

Development. Development of the Electric Locomotive, F. H. Shepard. Ry. Age (Daily Edition), vol. 76, no. 32, June 14, 1924, pp. 1568-1579, 17 figs. History of development, with tabulation of practically every electric locomotive in world, built or under construction; showing wheel and cab arrangement of each type in diagram; advantages and disadvantages of each type of drive. Paper presented before Am. Ry. Assn.

ELECTRIC METERS

Transmission of Readings. The Transmission of Meter Readings by the Impulse Method, B. H. Smith. Elec. Jl., vol. 21, no. 5, May 1924, pp. 219-221, 5 figs. System recently developed for making use of d.c. impulses controlled by watthour meter sender and special receiver.

ELECTRIC MOTORS, A.C.

Single-Phase. A New Type of Single-phase Motor, S. R. Bergman. A.I.E.E.—Jl., vol. 43, no. 7, July 1924, pp. 599-603, 11 figs. Development of a constant-speed a.c. motor for application to single-phase current. Describes derivation of this new type of motor from plain repulsion motor. Has characteristics of a shunt motor over running range, and series type characteristics during starting and acceleration. Possesses high power factor.

ELECTRIC POWER

Great Lakes District's Consumption in 1950. Middle West Power in 1950. Elec. Wld., vol. 84, no. 2, July 12, 1924, pp. 64-65, 3 figs. Survey for part of Great Lakes district which has just been completed shows that per capita consumption will amount to 1,760 kw-hr. per annum in 1950. Main reliance will be steam plants connected by transmission systems.

ELECTRIC TRANSMISSION LINES

Long Span. Long Span on Cheat River, C. F. Sheakley. Elec. World, vol. 83, no. 25, June 21, 1924, pp. 1277-1278, 3 figs. West Virginia-Maryland Power Co. has strung at George a 5-conductor span 4,317 ft. long, made with mixed copper and "copper weld" conductors; details of towers and installation.

Protection. Rises in Pressure and Protection of Alternating-Current Circuits, G. W. Partridge. Elec. Rev., vol. 94, no. 2430, June 20, 1924, pp. 992-994, 5 figs. Describes system of actual prevention and protection from rises in pressure installed on an a.c. system after careful observations and experiment over a period of some five years.

Tension Calculation. Computing Tension in Transmission Lines, E. S. Thayer. Elec. Wld., vol. 84, no. 2, July 12, 1924, pp. 72-73, 1 fig. Describes method having correct mathematical and physical basis and giving results that are accurate within 1 per cent.

ELECTRIC WELDING

Boiler Tubes. The Repair of Boiler Tubes by Electric Welding (Réparation des tubes à fumée), Renaud. Revue Générale des Chemins de Fer & des Tramways, vol. 43, no. 5, May 1924, pp. 341-347, 7 figs. Methods and machinery employed at shops of Sotteville-les-Rouen, France.

Spot-Welding Machines. Reflex Action of Material to be Welded on Current and Tension Conditions of a Spot-Welding Machine (Rüchwirkung des Schweissgutes auf die Strom- und Spannungsverhältnisse der Punktschweissmaschine), F. H. Hellmuth. Elektrotechnische Zeit., vol. 45, no. 25, June 19, 1924, pp. 657-658, 3 figs. Tests with 15-kv. spot-welding machine as to effect of large masses of sheet iron, in form of plane or cylinder between electrodes.

ELECTRICITY, APPLICATIONS OF

Canada. Utilization of Power. Eng. Jl., vol. 7, no. 7, July 1924. Group of papers read at World Power Conference. Introductory Statement to Symposium, P. T. Davies, pp. 447-451; Electricity in the Canadian Home, F. A. Gaby, pp. 451-458, 8 figs.; Electrical Service for Rural Districts, F. A. Gaby, pp. 458-472, 19 figs.; Utilization of Power in the Pulp and Paper Industry, R. W. Leeper, pp. 473-476, 6 figs.; Use of Power in the Mineral Industries of Canada, H. E. M. Kensit, pp. 477-483, 6 figs.; Use of Electric Power in the Cement Industry of Canada, W. G. H. Cam, pp. 484-485, 3 figs.; Use of Power for Port Facilities, M. T. S. Casey, pp. 486-488, 2 figs.; Power Requirements in the Lumbering Industry in British Columbia, A. M. Smith, pp. 488-492, 5 figs.; Application of Compressed Air in Industry, F. A. McLean, pp. 492-498, 5 figs.; Electro-Chemical and Electro-Metallurgical Uses of Power, L. E. Westman, pp. 498-501, 3 figs.; Power in Transport, D. E. Blair, pp. 502-505, 32 figs.; Illumination, W. H. Woods, pp. 522-526, 11 figs.; Recent Developments in Electric Lamps, J. T. Scott, pp. 526-527.

ELEMENTS

Non-Metallic. The Non-Metallic Elements. Connections between their Dielectric and other Physical Properties, G. L. Addenbrooke. Lond., Edinburgh, & Dublin Philosophical Mag. & Jl. Sci., vol. 47, no. 281, May 1924, pp. 945-965, 1 fig. Consideration of two actions taking place when dielectric is placed in electric field; relation of attraction to energy reversibly stored; comparison of relative electric values found with relative values of other physical properties; comparison of electric actions with absolute melting points and with absolute boiling points; relation of relative molecular electric actions to heat of vaporization; relations with surface tensions; comparison with capillarity; etc.

EMPLOYMENT MANAGEMENT

Personal-Interview Method. Pitfalls of the Employment Interview, D. A. Laird. Indus. Mgt. (N. Y.), vol. 68, no. 1, July 1924, pp. 58-62, 4 figs. Pitfalls of personal interview employment procedure, and suggestions for eliminating them.

EMPLOYEES, TRAINING OF

Railway, in Air-Brake Equipment. Instructing Railway Employees in Air Brake Equipment, J. P. Stewart. Ry. Rev., vol. 74, no. 24, June 14, 1924, pp. 1131-1132. Methods of interesting and instructing employees in operation and maintenance of air-brake equipment; value of instruction cars and instruction rooms; class instruction preferred. (Abstract.) Paper read before Air Brake Assn.

ENERGY

Transforming and Distributing. The Value of Efficiency in Transforming and Distributing Energy, Chas. E. Lucke. Mech. Eng., vol. 46, nos. 6 and 7, June and July 1924, pp. 317-324 and 380-385, 10 figs. Importance of energy costs; estimates of costs for primary energy and for its power- plant transformation into electrical energy through appropriate steps.

ENGINEERS

Highway, Training of. Technical Training for Highway Engineers, R. DeL. French. Can. Engr., vol. 47, no. 2, July 7, 1924, pp. 141-142. Shows why highway engineer needs thorough and careful training; student natural qualities necessary in three divisions of highway engineering course are technical, finance and economics. Paper read at annual convention of Can. Good Roads Assn.

Responsibility of. The Engineer's Responsibility, M. Knowles. Engrs.' Soc. West. Pa.—Proc., vol. 40, no. 4, May 1924, pp. 143-158 and (discussion) 159-162. Definition of engineer; public influence of engineering work; distribution of responsibility; what engineer can do for himself; directing public opinion; etc.

F

FILTERS

Trickling, Dosing Control of. Butterfly Valve Dosing Control for Trickling Filters, H. R. King. Eng. News-Rec., vol. 92, no. 25, June 19, 1924, pp. 1049-1050, 2 figs. Suggests for trial a method for operating trickling filters so that a good sewage distribution may be maintained, and if possible, filter bed capacities thereby increased. Sliding cam to control valve on outlets to the several filter dosing areas.

FLOW OF GASES

Aeration of Jet of Gas. The Entrainment of Air by alet of Gas issuing from a Small Orifice in a Thin Plate, J. S. G. Thomas. Lond., Edinburgh, & Dublin Philosophical Mag. & Jl. Sci., vol. 47, no. 281, May 1924, pp. 1048-1056, 4 figs. It is shown that constant value of aeration of jet of gas issuing at different pressures from orifice, as referred to in Technologic Paper no. 193 (1921) of Bur. of Standards, characterizes induction-flow system in which induction of air is effected under conditions such that flow of stream of air induced by jet is considerably reduced from its normal value in free air by restricting effective area of induction tube or otherwise.

FLUE-GAS ANALYSIS

CO Indicator. A New Instrument for the Continuous Indication of Carbon Monoxide in Boiler-Flue Gases, W. O. Andrews. S. African Instn. Engrs.—Jl., vol. 22, no. 10, May 1924, pp. 145-152 and (discussion) 152-153, 3 figs. Instrument devised by author as simple and inexpensive means of indicating, by means of color of liquid, presence or absence of small quantities of combustible carbon gases in flue gas.

CO_2 Recorders. Electrically Heated Platinum Tubes Used in CO_2 Recorder. Power Plant Eng., vol. 28, no. 13, July 1, 1924, pp. 729-730, 1 fig. In new recorder made by Uebling Instrument Co., Paterson, N. J., novel scheme is employed to secure motive power for actuating recorder by burning combustible in electrically heated platinum tubes.

FLUMES

V-Section. Irrigation Flume of V-Section Supplies Oregon Project. Eng. News-Rec., vol. 93, no. 1, July 3, 1924, pp. 9-10, 2 figs. Design of 352-ft. V-shaped flume for Silver Lake irrigation district, a recently constructed project in Lake County, Ore. Its advantages. Wedging system makes nails unnecessary to hold plank in place. Only standard sizes of lumber used.

FOUNDRIES

Automobile. Metallurgical Control in Automobile Foundry Practice, A. Harley. Foundry Trade Jl.,vol. 29, nos. 395 and 396, Mar. 13 and 20, 1924, pp. 207-210 and 235-237, 19 figs. Modern conditions and tendencies; organization of labour conditions; discusses cast iron, semi-steel, malleable iron, and cast steel castings; molding sands; non-ferrous metals castings; production of a cast-iron cylinder.

Malleable-Iron. Operates New Malleable Foundry, E. C. Boehringer. Iron Trade Rev., vol. 75, no. 1, July 3, 1924, pp. 29-33, 6 figs. Describes plant, including equipment, and practice of Belle City Malleable Iron Co., Racine, Wis. See also Foundry, vol. 52, no. 13, July 1, 1924, pp. 521-526 and 533, 13 figs.

FUEL ECONOMY

Metallurgical Works. Works Problems and Methods in Fuel Economy, R. Hadfield. Iron & Coal Trades Rev., vol. 108, no. 2938, June 20, 1924, pp. 1066-1067. Certain problems met with in practice and some methods by which they may be attached; general considerations regarding heat balance; furnace efficiency; importance of high-temperature research, use of pyrometers, and temperature colors. Abstract of paper read before Iron & Steel Sec., Empire Min. & Met. Congress.

FUELS

Canadian Resources. Canada's Fuel Problem, C. Camsell. Combustion, vol. 11, no. 1, July 1924, pp. 46-50. Discussion of Canada's fuel resources and fuel requirements and of possibilities for eliminating uncertainties due to importation of fuel.

The Fuel Resources of Canada and Their Utilization for the Production of Power and Other Purposes, B. F. Haanel. Eng. Jl., vol. 7, no. 7, July 1924, pp. 361-382, 15 figs. Fuel resources; production, consumption, imports and exports; preparation of solid fuels for industrial and other uses; value of Canadian solid fuels for steam raising and production of a power and industrial gas; carbonization of peat, oil shales, and lower-grade coals and relation of carbonization of coals to production of power. Paper read at World Power Conference.

Combustion. An Investigation of the Maximum Temperatures and Pressures Attainable in the Combustion of Gaseous and Liquid Fuels, G. A. Goodenough and G. T. Felbeck. Univ. of Ill. Bul., Eng. Experiment Station, No. 139, Mar. 1924, 158 pp., 27 figs. Details of investigation to study conditions of equilibrium and establish necessary equilibrium equations, and to incorporate these equilibrium equations into a formulation by means of which maximum temperature resulting from combustion of a fuel under predetermined conditions may be calculated.

Pulverized Coal. *See Pulverized Coal.*

FURNACES, ENAMELING

Electricity vs. Oil Heating. Electricity Versus Oil for Heating Iron Enameling Furnaces H. A. Mulvancy. Jl. of Elec., vol. 52, no. 12, June 15, 1924, pp. 487-490, 6 figs. Description of application of electricity to manufacturing with resultant improvement in product, reduced spoilage and decreased cost of production.

FURNACES, HEATING

Regenerative, Fuel Oil Atomizing Agents for. Atomizing Agents for Fuel Oil in Regenerative Furnaces, G. H. Heine. Fuels & Furnaces, vol. 2, no. 7, July 1924, pp 650-652, 1 fig. Gives results of series of experiments made to determine proper oil atomizing agent for regenerative re-heating furnaces of Stevens type.

Re-heating. Operation Costs of Re-heating Furnaces Reduced, H. L. Read. Iron Age, vol. 113, no. 26, June 26, 1924, pp. 1864-1865, 2 figs. Installation of burners for coke-oven gas in which air proportion is maintained automatically.

FURNACES, HEAT-TREATING

Continuous, Conveyor-Type. Heat Treating at the Chevrolet Plant. Iron Age, vol. 114, no. 3, July 17, 1924, pp. 129-131, 2 figs. Describes conveyor-type continuous heat-treating furnace of new design recently made in axle and gear plant of Chevrolet Motor Co., Detroit, and its operation. Is a combination continuous hardening and drawing furnace of a double-deck type and a unique feature is that drawing furnace is located above hardening furnace and is fired by waste heat from latter.

FURNACES, METALLURGICAL

Oil-Fired Melting. Use Oil in Malleable Furnace, B. R. Mayne and C. Joseph. Foundry, vol. 52, no. 12, June 15, 1924, pp. 472-475, 5 figs. New method installed when costs become prohibitive; use same construction as was employed in coal-fired furnace; oil consumption considered low.

G

GAGES

Precision Measurement with. Fine Measurement, J. E. Sears. Machy (Lond.), vol. 24, nos. 607, 609 and 610. May 15, 29 and June 5, 1924, pp. 209-212, 266-271 and 299-303, 22 figs. Deals with precision measurement in its relation to mechanical work; methods by which control of standard gages is effected in laboratory; recent developments in methods of precision measurement. Paper read before Instn. Mech. Engrs.

GAS MAINS

Rubber as Jointing Material. Further Experiments and Experiences in Connection with Rubber as a Jointing Material for Gas-Mains, W. Hole. Gas Jl., vol. 166, no. 3189, June 25, 1924, pp. 899-901, 5 figs. Tests carried out to prove that suitably prepared rubber is practically immune from deleterious action by either coal gas or gaseous liquor.

GAS PRODUCERS

Coke. Experiments with Gas Producers (Untersuchungen an Koksgeneratoren), E. Terres and J. Schierenbeck. Gas-und Wasser-fach, vol. 67, nos. 19, 20, 21, 22, and 23, May 10, 17, 24, 31 and June 7, 1924, pp. 257-263, 279-282, 296-299, 311-314 and 325-327, 11 figs. Discusses experiments carried out with gas producers to replace empirical data by exact experimental data and to study effect of constructional changes on processes under consideration. Discusses experimental arrangements, results with flat grates and inclined grates, composition of gas, etc.

GAS TURBINES

Development. History of the Progress of Gas and Oil Turbines (Die Arbeit an der Gas- und Oel-turbine). W. Gentsch. Brennstoff- und Wärmewirtschaft, vol. 6, nos. 2, 3 and 4, Feb., Mar. and Apr. 1924, pp. 28-35, 48—55 and 71—79, 18 figs. Various attempts to solve problem of economical internal-combustion turbine are recorded and described, including Brown, Boveri, Schneider, Westinghouse, Stodola, General Electric, Francke, Rateau, Nash Eng. Co., etc.

GASES

Combustion, Dewpoint Temperature of. The Dewpoint Temperature of Gases from Combustion, J. N. Waite. Elec. Rev., vol. 94, nos. 2429 and 2430, June 13 and 20, 1924, pp. 954-956 and 994-996, 6 figs. Methods of calculating dewpoint temperature for gases resulting for a given fuel taken being a medium grade bituminous coal having a medium hydrogen and moisture content. Effect of change of fuel analysis on dewpoint temperature of resultant gases of combustion. Curves and tables.

Combustion of. The Combustion of Gases [Die Verbrennung von gasförmigen Brennstoffen (Generatorgas)], A. Dosch. Sprechsaal, vol. 57, nos. 14, 15 and 16, Apr. 3, 14 and 17, 1924, pp. 147-149, 157-159 and 171-173, 5 figs. Processes of combustion of various gases analyzed and explained. Quantities of air required for combustion of various gas mixtures computed and illustrated with aid of several examples.

GASOLINE ENGINES

Two-Cycle. Two-Cycle Gasoline Engines (Il motore a benzina a due tempi), Pasquale Borracci. Industria, vol. 38, no. 1, Jan. 15, 1924, pp. 7-11, 4 figs. Discusses their advantages in relation to their possible application in automotive work.

GEARS

Helical. High-Grade Helical Spur Wheel Gears, E. Meyer. Eng. Progress, vol. 5, no. 6, June 1924, pp. 113-117, 7 figs. Cutting teeth; materials; tooth load and velocity; angle of pitch and pitch of teeth; bearings of pinion shaft; toothed wheeled gears for vertical shafts; ratio of gearing and putput; assembly; lubrication; efficiency; silent running; life and use.

Hob Tooth Form. Hob Tooth Form, H. E. Merritt. Machy, (Lond.), vol. 24, no. 613, June 26, 1924, pp. 391-395, 4 figs. Shows that a hob can produce teeth which are mathematically exact involute teeth (neglecting effect of gashes in hob) and examines necessary axial section which hob teeth must have in order to achieve this result.

Lubrication. Gearing and Gear Lubricants, A. F. Brewer. Indus. Mgt. (N. Y.), vol. 68, no. 1, July 1924, pp. 18-24, 10 figs. Specialized needs of various types of modern gears.

H

HARDNESS

Metal-Products Hardness Testing. The Logical Course of Development of Additional Apparatus for Investigating the Hardness of Metal Products in Works' Practice, H. A. Holz. Testing, vol. 1, nos. 3 and 4, Mar. and Apr. 1924, pp. 247-262, and 308-325, 29 figs. States that logical course of development of additional apparatus for investigating hardness of metals and metal products lies entirely in direction of appliances for application of Brinell test to problems for which this method has not been or could not be applied heretofore. Discusses some of the results established by Bur. Standards in its investigation of Brinell Meter, developed by F. H. Schoenfuss.

HEAT TRANSMISSION

Research. Research in Heat Transmission, E. Buckingham. Mech. Eng., vol. 46, no. 7, July 1924, pp. 386-388. Conduction, radiation, and convection; conduct of research in heat transmission; employment of dimensional analysis; variables involved in complete mathematical theory of heat transmission; suggestions in regard to planning of research programs.

HEATING, HOT-AIR

Furnaces and Heating Systems. Investigation of Warm-Air Furnaces and Heating Systems—II, A. C. Willard, A. P. Kratz, V.S. Day. Univ. of Ill. Bul., Eng. Experiment Station, No. 141, May 1924,149 pp.,91 figs. Details of investigation to determine efficiency and capacity of commercial warm-air furnaces; satisfactory and simple methods for rating furnaces; methods of increasing efficiency and capacity of furnace heating equipment; heat losses in furnace heating systems; proper sizes and proportions of leaders, stacks, and registers; etc.

HEATING, STEAM

Central. Low Pressure Steam for District Heating, H. A. Woodworth. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 763-768, 4 figs. Service to customers insures success. Estimating radiation, advantages of district heating, customer's installations, atmospheric steam heating, and operation of a heating system.

HOBBING MACHINES

Spur-Gear. An Interesting Gear Cutting Development. British Machine Tool Eng., vol. 3, no. 27, May-June 1924, pp. 61-62, 1 fig. Describes automatic, spur-gear hobbing machine.

HOUSING

Zoning and. Views on Zoning and Housing. Nat. Mun. Rev., vol. 13, no. 5, May 1924, pp. 274-288. Contains following articles: What the Banker Thinks of Zoning, Geo. S. Edie. What One Realtor Thinks of Zoning, J. W. Cree, Jr., pp. 277-279; Reducing the Cost of Housing by Eliminating Building Law Requirements, I. H. Woolson; Do We Need Rent Control Laws Permanently? Clara S. Taylor.

HYDRAULIC TURBINES

15,000-b. h.p. 15,000 h.p. Water Turbine for the Tata Hydro-Electric Supply Company. English Electric Jl., vol. 2, no. 6, Apr. 1924, pp. 185-293, 8 figs. Description of unit for extension of existing Khopoli Station of Tata Hydro-Electric Supply Co., in India; head 1655 ft., output 15,000 b.h.p., speed 300 r.p.m. Brief reference to geographical situation of Tata power system.

Runner Design. Hydraulic Turbine Progress, F. J. Taylor. Elec. Times, vol. 65, no. 1703, June 5, 1924, pp. 659-661, 6 figs. Trend of runner design. Increased speeds with lighter runners and lower heads.

Storek-Kaplan. Tests on Storek-Kaplan Hydraulic Turbines, H. Mikyska. Mech. Eng., vol. 46, no. 7, July 1924, pp. 420-421, 3 figs. Tests carried out on turbines of various sizes by firm of Ignaz Storek, licensees for Kaplan turbine.

HYDRO-ELECTRIC DEVELOPMENTS

Canada. The Generation of Hydro-Electric Power in Canada, H. G. Acres. Eng. Jl., vol. 7, no. 7, July 1924, pp. 383-420, 65 figs. Progress in Canadian practice in connection with hydraulic power development. Paper read at World Power Conference.

N. E. L. A. Report. Many Developments in Hydro-Electric Field. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 759-763, 6 figs. Report of Hydraulic Power Committee of Nat. Elec. Light Assn., giving features of equipment of new projects and problems of operation.

Pacific Coast, United States. Hydro-Electric Practices and Equipment on the Pacific Coast, S. Barfoed. A. I. E. E.—Jl., vol. 43, no. 7, July 1924, pp. 641-646, 1 fig. Physical features having deciding influence on design and construction of hydro-electric plants.

HYGROMETERS

Types. Humidity and Its Measurement. Sci. and Art of Min., vol. 34, nos. 22 and 23, May 24 and June 7, 1924, pp. 342-343 and 358-359, 2 figs. Deals with chemical and physical hygrometers of different types.

I

ICE PLANTS

New York, N. Y. Mammoth Ice Plant Adopts New Methods, V. H. Vandiver and A. S. Taylor. Compressed, Air Mag., vol. 29, no. 5, May 1924, pp. 851-856, 18 figs. Describes plant and equipment of Artic Hygeia Ice Mfg. Co., New York City; 1,000 tons ice per day capacity; electric drive and raw-water system replace steam drive and distilled-water system.

Raw-Water. Oil Engine-Driven Raw Water Ice Plant at Mattoon, Ill. Ice and Refrigeration, vol. 66, no. 6, June 1924, pp. 513-517, 8 figs. Description of 30-ton plant of Mattoon Crystal Ice Co.; intended primarily for production of ice for refrigerator car service; 50 per cent of production to be used for requirements of local ice trade.

Serv-Ice Co. Builds New Electrically Driven Raw Ice Plant in Columbus, Ind. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 734-738, 5 figs. Describes new 30-ton compression system ice plant built to supply local retail trade. Unusually clear product is obtained by use of lime and soda softening and high-pressure agitation.

INDICATORS

Precision Weak-Spring. A New Precision Type Weak-Spring Indicator, J. Geiger. Oil Engine Power, vol. 2, no. 5, May 1924, pp. 278-279, 9 figs. Advantages of author's new type of engine indicator are illustrated.

INDUSTRIAL MANAGEMENT

Branch Plants, Management of. How We Get Uniform Output from Widely Separated Plants, P. W. Litchfield. Factory, vol. 33, no. 1, July 1924, pp. 23-25, 116, 118 and 120-123, 2 figs. How to manage branch plants so that they function as one; how to do it and get a uniform product; how economies of one plant get themselves adopted in others located at distant points.

Budgeting. Applying the Budget System to Railroads, H. Bruere and A. Lazarus. Indus. Mgt. (N. Y.), vol. 68, no. 1, July 1924, pp. 35-46, 12 figs. Review of present practice and forecast of future possibilities.

Control of Idleness. The Control of Idleness in Industry, W. L. Conrad. Mech. Eng., vol. 46, no. 7, July 1924, pp. 402-404. Points out that one of chief causes of loss in industry is idleness of plant and personnel, due both to lack of orders or to causes within plant itself; accounting system can be made to show not only cost of idleness, but also its causes, and to indicate means of their control.

Definition of. Who Can Hire Management. H. S. Dennson. Taylor Soc.—Bul., vol. 9, no. 3, June 1924, pp. 101-110. Notes on what is "managing", who manages, and who can best choose managers.

Sales Management. An Example of Scientific Marketing Procedure, S. Cowan, Taylor Soc.—Bul., vol. 9, no. 3, June 1924, pp. 143-151, 3 figs. Method of analyzing buying groups and circulation; comparing occupational and income groups; analysis of magazine circulation; circulation by occupational groups. Practical applications.

STORES ACCOUNTING. Balance-of-Stores Accounting System, I. D. Murfield. Elec. Wld., vol. 84, no. 2 July 12, 1924, pp. 66-69, 5 figs. Description of a store accounting system which has resulted in a reduction of amount of money tied up, also a reduction of stock carried. Maximum and minimum stocks to be carried are specified by utility department heads.
STORES MANAGEMENT. The Care and Control of Raw Materials. Factory, vol. 33, no. 1, July 1924, pp. 34-35 and 135-136, 1 fig. Practice at plant of Bausch Lomb Optical Co.
TIME STUDY. *See Time Study.*

INDUSTRIAL PLANTS

RAILWAYS. Industrial Transportation Over Definite Lines of Travel, M. W. Potts. Indus. Mgt. (N. Y.), vol. 68, no. 1, July 1924, pp. 50-57, 10 figs. Summary of advantages and limitations of industrial railway as a means for efficient handling of materials.

INSULATION, HEAT

AIR SPACES. The Heat Insulating Capacity of Air Spaces (Die Isolierfähigkeit von Luftschichten nach, neueren Forschungen), H. Hamester. Wärme- und Kälte Technik, vol. 26, no. 8, Apr. 30, 1924, pp. 64-66. Modern investigations covering conduction connection and radiation of heat through air spaces are reported.

INSULATORS, ELECTRIC

HIGH-TENSION. The Application of High-Tension Insulators, T. B. Fleming. Elec. Jl., vol. 21, no. 5, May 1924, pp. 217-218, 2 figs. It is shown that one-half wet flashover of either suspension string or pin-type insulator can be taken as working voltage under average conditions; locality must be studied and graded in order to determine amount of insulation required either below or above base line of one-half flashover; insulation above actual requirements is good practice.

INTEGRATION

GRAPHIC METHODS. Graphic Integration Methods (Graphische Integrationsmethoden), C. Runge. Zeit. für Technische Physik,vol. 5, no. 5, 1924, pp. 161-165, 6 figs. Discusses linear and quadratic interpolation, calculation of values of whole functions, graphic integration and differential of curves, graphic integration of linear differential equations of first order.

INTERNAL-COMBUSTION ENGINES

CHEMICAL STRUCTURE. Chemical Structure of Motor Engine, E. Sokal. Oil and Gas Jl., vol. 23, no. 5, June 26, 1924, pp. 88, 126-127 and 130-131. Catalytic coating for surface of cylinder head suggested for counter-acting carbon and detonation. Accelerates combustion.
HEAT TRANSMISSION FROM WORKING FLUID. The Rate of Heat Transmission from the Working Fluid in an Internal Combustion Engine, A. H. Gibson. Lond., Edinburgh, & Dublin Philosophical Mag. & Jl., Sci. vol. 47, no. 281, May 1924, pp. 883-895. Results from investigations and conclusions.
[*See also Automobile Engines; Diesel Engines; Gasoline Engines; Oil Engines.*]

IRON AND STEEL

CANADIAN INDUSTRY. The Iron and Steel Industry in Canada, C. S. Cameron. Iron and Coal Trades Rev., vol. 108, no. 2936, June 6, 1924, pp. 971-974. Data regarding different steel works. Confines attention to fundamental processes, smelting of ore and production of primary forms of steel and those made directly from them, such as merchant bars, structural shapes, rails, plates, wire rods, and generally those that are sent from works of origin to others for further fabrication. From paper read at Empire Mining and Metallurgical Congress.
CHEMICAL SPECIFICATIONS. Are Chemical Specifications for Iron and Steel Too Rigid? Iron and Steel Engr., vol. 7, no. 7, July 1924, pp. 130 and 133. Investigation by British Chemical Standards movement. From paper read by C. H. Ridsdale at joint mtg. of Cleveland Instn. Engrs., Soc. Chem. Industry and Inst.

L

LABOR

WAGES AND HOURS. Wages and Hours of Labor in the Automobile Tire Industry, 1923. U. S. Bur. Labor Statistics—Bul., no. 358, Apr. 1924, pp. 1-58. Report shows results of study of wages and hours of labor in automobile tire industry in 1923. Information compiled covers 22,535 male wage earners and 1624 female wage earners working in 49 representative establishments located in Connecticut. Indiana, Massachusetts, Michigan, New Jersey, New York, Ohio, Pennsylvania and Wisconsin. Tables show earning as per hour, full time or curtomary hours per week, hours and days actually worked, and earnings actually received in representative pay period taken.

LATHES

INSPECTION IN BUILDING. The Inspection System in a Lathe Building Plant, H S. Riggs. Machy. (N. Y.), vol. 30, no. 11, July 1924, pp. 835-841, 12 figs. Checking accuracy of lathe parts, assembled units and completed machines.
INTERCHANGEABLE MANUFACTURE. Building Lathes Interchangeably. Machy. (Lond.), vol. 24, no. 613, June 26, 1924, pp. 389-392, 8 figs. Manufacturing methods used to facilitate assembly of machines and supply of replacement parts.
SEMI-AUTOMATIC. Semi-Automatic Lathe of Interesting Design, C. C. Walker. Machy. (N. Y.), vol. 30, no. 11, July 1924, pp. 870-873, 6 figs. Construction of machine; character of work; special form cutter used.

LIGHTING

RESEARCH. Co-ordination of Research in Illuminating Engineering and Some Practical Applications, J. S. Dow. Illuminating Engr.,vol. 17, nos. 1-3, Jan.-Mar. 1924, pp. 6-15 and (discussion) 16-18. Classification of research; research on photometry and standards of light illuminants and lighting appliances; research on glare collection of statistical data on illumination; facilities for research.
HIGHWAYS. Street Lighting in Its Relation to Highway Safety, C. A. B. Halvorson, Jr. and S. C. Rogers. Safety Eng., vol. 283-289, 13 figs. Objects should be seen at night in silhouette rather than by direct light. Glare; cost of lighting; use of signals; etc.
STREET. Some Facts About Street Lighting, G. H. P. Dellman. Jl. of Elec. vol. 52, no. 11, June 1, 1924, pp. 404-408. Review of practice, showing changes which street lighting systems have undergone in past years; modern practices; essential features of proper lighting; methods and financing of lighting; etc.

LIQUIDS

DISTILLING, EVAPORATING AND CONDENSING. Distilling, Concentrating, Evaporating and Condensing Liquids. Abridgments of Specifications, class 32, period 1916-20, 1924, 152 pp. Patents for inventions.
THERMAL CONDUCTIVITY. Convective Cooling in Liquids—Some Thermal Conductivity Data, A. H. Davis. Lond., Edinburgh, and Dublin Philosophical Mag. and Jl. Sci., vol. 47, no. 281, May 1924, pp. 972-975. Direct determinations of thermal conductivity at various temperature, to supplement information previously given.

LOCOMOTIVES

BEHAVIOUR OF WHEELS ON TRACK. Behaviour and Movement of Locomotive Wheels on the Track, J. Buchli. Int. Ry. Congress Assn.—Bul.,vol. 6, no. 6,June 1924, pp. 417-437, 30 figs. Trials carried out on model which reproduced conditions encountered in practice as accurately as possible with object of ascertaining lateral adhesion of wheel on rail under most widely different service conditions. Translated from Schweizerische Bauzeitung.
DIESEL-ELECTRIC. The American Diesel-Electric Locomotive is Here. Oil Engine Power, vol. 2, no. 5, May 1924, pp. 257-259, 5 figs. 300-b. h.p. locomotive constructed by Gen. Elec. and Ingersoll-Rand Companies, with 6-cylinder airless-injection 4-cycle type Ingersoll-Rand oil engine directly connected to 200-kw. Gen. Elec. generator.
ELECTRIC. *See Electric Locomotives.*
ERECTION. An Improved Method of Locomotive Erection by the Use of Erecting Forms, S. R. Limerick. Baldwin Locomotives. vol. 3, no. 1, July 1924, pp. 28-32, 8 figs. Describes mechanical erector, developed by Baldwin Locomotive Wks., a device for absolute control of work of erecting a locomotive, eliminating all possibility of errors in alignment, inequalities of measurement and all variances formerly existent in locomotives incidental to exercise of personal judgment or skill on part of workman. Erection of locomotive by this method.
4-6-0 TYPE. A New Pennsylvania R. R. Locomotive. Ry. Gaz., vol. 40, no. 25, June 20, 1924, pp. 891-892, 2 figs. Particulars of first of a new class of locomotives designed for passenger train service and built at company's shops at Altona, Pa.; 4-6-0 type, with outside cylinders driving middle pair of coupled wheels; steam being distributed to cylinders by piston valves actuated by Walschaerts valve gear; light reciprocating parts; high tractive effort.
RODS, BORING AND TESTING OF. Fixtures for Boring and Testing Locomotive Rods, F. H. Colvin. Am. Mach., vol. 60, no. 26, June 26, 1924, pp. 947-949, 8 figs. Some of the methods and tools used by Lima Locomotive Works in boring and testing side rods of plain and articulated types.
STEAM-TURBINE. A New Geared Turbine Condensing Locomotive. Ry. Engr., vol. 45, no. 533, June 1924, pp. 200-201, 2 figs. Constructed on Reid-Macleod system and patented by North Brit. Locomotive Co.
THERMAL EFFICIENCY. Engineering and Business Considerations of the Steam Locomotive, W. H. Winterrowd. Ry. Age, vol. 76, no. 30, June 13, 1924, pp. 1468-1471 and (discussion) 1471-1473, 3 figs; also Ry. Rev., vol. 74, no. 24, June 14, 1924, pp. 1103-1108, 4 figs. Author disputes impression that steam locomotive is inefficient and losing its vitality; comparison of thermal efficiency curves of locomotive and stationary boiler proves conclusively that locomotive boiler is more efficient generator of steam; and by further development of superheated steam, larger grate area and higher boiler pressure, still greater maximum thermal efficiency can be obtained. Paper read before Am. Ry. Assn.
THREE-CYLINDER. Lehigh Valley Three-Cylinder Locomotive. Ry. Age (Daily Edition), vol. 76, no. 32, June 14, 1924, pp. 1585-1587, 6 figs. Details of 4-8-2 type, weighing 369,000 lb.; boiler is of inverted wagon top type. See also article, entitled, Performance of 3-Cylinder Locomotive No. 5000, in Ry. Rev., vol. 74, no. 24, June 14, 1924, pp. 1079-1093, 13 figs. Gives details of construction and record of results.
The Three-Cylinder Locomotive, J. G. Blunt. Ry. Age, vol. 76, no. 30, June 13, 1924, pp. 1473-1476 and (discussion) 1476-1479, 7 figs. Normal tractive force; economy of 3-cylinder locomotive; crank-axle driving box; middle main rod, valve gear and crosshead.

M

MACHINE SHOPS

EQUIPMENT. American Machinist Shop Equipment Review. Am. Mach., vol. 61, no. 3, July 17, 1924, pp. 89-131, 238 figs. Semi-annual résumé of machines, tools, and accessories described in Shop Equipment News section of Am. Mach. during first six months of 1924.
PROGRESS. Six Months in the Machine Shop Field. Am. Mach., vol. 61, no. 3, July 17, 1924, pp. 81-87. A review, in seven articles, of progress made during first half of 1924 in machinery field, railroad field, automotive industry, electric power and manufacturing industries, distribution of materials and supplies, and in exporting.

MACHINE TOOLS

DEVELOPMENT, NEW ENGLAND. Development of Machine Tools in New England, G. Hubbard. Am. Mach., vol. 60, nos. 4, 5, 6, 7, 8, 12, 17, 24 and 26, Jan. 24, 31, Feb. 7, 14, 21, Mar. 20, Apr. 24, June 12 and 26, 1924, pp. 129-132, 171-173, 205-209, 255-258, 271-274, 437-441, 617-620, 875-878 and 951-954, 70 figs. Jan. 24: American exhibit at Crystal Palace; famous Enfield (England) Armory equipped with machinery and tools from New England; gages sent from England made of wood. Jan. 31: Hartford plant of Robbins & Lawrence turns out world-famous products and finally becomes part of Pratt & Whitney plant. Feb. 7: Windsor machine tools still in use; development of drilling machine, Feb. 14: Examples of early milling machines; first universal milling machine; edging or profiling machine. Feb. 21: Lathes and swiveling headstocks; tailstocks with square spindles; an early bolt-threading machine; evolution of turret lathe. Mar. 20; Officers of Robbins & Lawrence Co.; New England mechanics who have become famous. June 12: Drawings of machine tools in colors; interchangeable work at Harper's Ferry. June 26: Circumstances that led to formation of Jones & Lamson Machine Co.
SPEED CHARTS. Alignment Charts for Speeds (Fluchtlinientafel für Drehzahlen), H. Behr. Werk-staattstechnik, vol. 18, no. 11, June 1, 1924, pp. 294-296, 3 figs. Plotting of alignment chart for determination of geometrically arranged revolution numbers, magnitude of average cutting-speed drop, and of quotients of geometrical series.

MANGANESE STEEL

WELDING OF. Welding of Manganese Steel. Am. Welding Soc.—Jl., vol. 3, no. 5, May 1924, pp. 10-23, 14 figs. Discusses briefly what manganese steel is, its properties, and why it has those properties. Investigations of what happens during welding of manganese steel, how actual operation may be best conducted, and what structural results of welding are in both base metal and weld. Preliminary report of Gas Welding Committee of Am. Bur. Welding.

MAPPING

VARIATIONS IN FIGURE OF EARTH, EFFECT OF. Effect of Variations in the Assumed Figure of the Earth on the Mapping of a Large Area, W. D. Lambert. U. S. Coast & Geodetic Survey, 1924, Serial No. 258, Special Publication No. 100. 35 pp., 11 figs. Various determinations of earth's mean figure, spheroids actually in use for geographic purposes, effect of change in dimensions of spheroid on computation of triangulation, effect of change of spheroid on triangulation covering large area. Gives formulas and makes calculations. Tables.

MARINE BOILERS

TESTS. Tests of Marine Boilers, H. Kreisinger, J. Blizard, A. R. Mumford, B. J. Cross, W. R. Argyle and R. A. Sherman. U. S. Bur. Mines, Bul. 214, 1924, 302 pp. 181 figs. partly on supp. plates. Describes evaporative tests of marine water-tube boilers, and of Scotch marine boiler, including description of method of conducting tests, and of such special studies as were made of: combustion in furnaces; heat absorption by boilers; flow of gases through boilers by means of temperature, pitot-tube, and draft measurements; insulation of furnace walls; circulation of water in boiler; effect on heat transmission of blowing soot off heating surfaces with steam blowers; and use of special equipment to improve combustion or to improve heat absorption.

MATERIALS

RUPTURE. Conditions Causing Rupture of Material (Betingelserna für materialbrott), A. F. Samsioe. Teknisk Tidskrift, vol. 54, no. 24, June 14, 1924, pp. 221-223 (Allmanna Avdelningen), 7 figs. Older theories are recorded. Guest's experiments with tough metals are described. Shearing stress or greatest difference between stresses occurring in different directions are proved to cause ruptures of material. Mohr's theory for brittle materials is explained.

MATERIALS HANDLING

ECONOMIES OF. Fundamental Economies of Materials Handling, M. L. Begeman. Mech. Eng., vol. 46, no. 7, July 1924, pp. 405-409 and (discussion) 410. Discusses advantages of handling materials mechanically without, reference to particular types of equipment; deals with necessity for substitution of mechanical handling of materials for labor and economies to be gained by such substitution; points to be considered in analysis of proposed installation.

MACHINE SHOPS. Train-Despatching in an Automotive-Parts Shop, R. S. Spencer. Am. Mach., vol. 60, no. 26, June 26, 1924, pp. 945-946, 3 figs. How a force of 250 truckers has been reduced to 9 men by application of railroad train-despatching methods to inter-departmental transportation of materials.

MEASURING INSTRUMENTS

THREAD RECORDER. Some Uses of the Thread Recorder in the Measurement of Physical Properties, J. L. Haughton and W. T. Griffiths. Jl. of Sci. Instruments, vol. 1, no. 8, May 1924, pp. 225-233, 9 figs. Methods of employing thread recorder for recording changes of dilation and resistivity of metals and alloys with temperature. Describes also method of combining recorded time-temperature and time-property curves to give a single temperature-property curve.

TORSION METER. The Moulin Torsion Meter. Engineering, vol. 117, no. 3050, June 13, 1924, pp. 764-765, 12 figs. Apparatus for measuring torque in shafts up to in. diam. and transmitting 1500 h.p.

MERCURY-VAPOR PROCESS

PRINCIPLES AND APPLICATIONS. Mercury Vapor as an Industrial Heating Medium, C. Field. Chem. and Met. Eng., vol. 30, no. 25, June 23, 1924, pp. 987-991, 8 figs. Outline of system, with discussion of various other sources of heat at high temperature available for industrial use.

METALS

COLD WORKING. Effect of Severe Cold Working on Scratch and Brinell Hardness, H. S. Rawdon and W. H. Mutchler. Am. Inst. Min. and Met. Engrs.—Trans., No. 1340-N, May 1924, pp. 3-14, 4 figs. Discussion of above paper, presented at New York Mtg., Feb. 1924, and issued as Paper No. 1291-M, with Min. and Metallurgy, Jan. 1924.

Interpretation of Cold Working on the Basis of Electric Measurements (Zur Deutung der Kaltbearbeitung auf Grund elektrischer Messungen), W. Geiss and J. A. M. van Liempt. Zeit. für Anorganische und Allgemeine Chemie, vol. 133, no. 1, Feb. 11, 1924, pp. 107-112. Discusses deformation of metal crystals in cold working and current hypotheses; application of X-ray analysis and its limitations.

CORROSIVE AGENTS, BEHAVIOR UNDER ACTION OF. How Metals Stand Up Against Corrosion. Chem. and Met. Eng., vol. 31, no. 2, July 14, 1924, pp. 70-79. General and specific data from many sources on behavior of iron and steel, copper, aluminum, lead, nickel, tin, and zinc, under action of many destructive agencies encountered in industrial world.

FATIGUE. An Investigation of the Fatigue of Metals, H. F. Moore and T. M. Jasper. University of Ill.—Bul., vol. 21, no. 39, May 26, 1924, 86 pp., 22 figs. Theory of fatigue of metals; evidence of existence of endurance limit for wrought ferrous metals and of improvement in strength of such metals by cycles of reversed stress at or below that limit; resistance to reversed axial stress (tension-compression); miscellaneous tests and results; resistance to repeated stress other than reversed stress. Bibliography.

SURFACES, PROPERTIES OF. The Properties of Metallic Surfaces, J. B. Nevitt. Birmingham Met. Soc.—Jl., vol. 8, no. 10, pp. 425—440 and (discussion) 441-446. Reviews means by which variations in surface conditions may be produced, and outlines effect of these surface conditions upon properties of metal.

MINES

VENTILATION. The Ventilation of Mines, D. Hay and R. Clive. Colliery Guardian, vol. 127, no. 3310, June 6, 1924, pp. 1447-1449, 2 figs. Principles of ventilation. Reviews modern practice and draws attention to recent progress in technique. From paper read before Empire Mining and Metallurgical Congress.

WATER POWER, USE OF. Water Power in the Mining Industry. Can. Min. Jl., vol. 45, no. 27, July 4, 1924, pp. 648-652, 4 figs. General resume of study made by Dominion Water Power Branch, Dept. Interior, of extent to which need of ample supplies of power available at cost that will permit of production and treatment of large quantities of raw materials in districts in which mines occur, has been met by development of Canadian advantageously-located water powers.

MINING

SKIP CHANGING. Homestake Method of Changing Skips, Felix Edgar Wormser. Eng. and Min. Jl.—Press, vol. 117, no. 26, June 28, 1924, pp. 1044-1045, 4 figs. Change is made at bottom of shaft instead of on surface.

MOULDING MACHINES

APPLICATIONS. Molding Machine Practice, R. R. Clarke. Metal Industry (N. Y.), vol. 22, nos. 6 and 7, June and July, 1924, pp. 237-238 and 272-275, 8 figs. Range of application, difficulties, and solution of difficulties. Various methods of pattern mounting.

PERMANENT. Discusses Permanent Molds, R. J. Anderson and M. E. Boyd. Foundry, vol. 52, nos. 12 and 13, June 15 and July 1, 1924, pp. 463-468 and 510-513, 17 figs. Describes five different permanent-mold processes and discusses principles involved; typical molds; materials for molds and cores; mold design; methods of gating; various types of commercial alloys and typical castings. Annual exchange paper of Am. Foundrymen's Assn. presented at Inst. Brit. Foundrymen. See also Foundry Trade Jl., vol. 29, nos. 407 and 408, June 5 and 12, 1924, pp. 464-468 and 477-485, 17 figs. Bibliography.

MOTOR BUSES

SIX-WHEEL. Six-Wheel Bus, Marketed by New Concern, Has Novel Features, H. Chase. Automotive Industries, vol. 51, no. 2, July 10, 1924, pp. 97-100, 9 figs. Particulars of new bus recently announced by a new concern to be known as Six-Wheel Co. of Philadelphia. Easy riding qualities and design which permits all important units to be detached quickly and replaced by spares. Frame of massive and rigid construction. Six-cylinder Continental engine is mounted on rubber blocks.

MOTOR TRUCKS

ELECTRIC. A Front-driven Electric Van, W. F. Bradley. Motor Transport (Lond.), vol. 38, no. 1007. June 16, 1924, pp. 745-746, 3 figs. Details of a battery-driven vehicle which is being used in France for load-up to half a ton; presented by Société d'Applications. Electro-Mécaniques; also steered by its front wheels; compound-wound electric motor of 4 kw. capacity; capable of taking a temporary overload of 300 per cent.

N

NITROGEN

FIXATION. The Air-Nitrogen Processes, J. M. Braham. Commerce Reports-Supp., Trade Information Bul. no. 240, June 16, 1924, pp. 1-41. Describes arc, cyanamide, synthetic ammonia and miscellaneous nitrogen fixing processes; interrelation of nitrogen-fixing processes and products

O

OIL

DEVELOPMENTS IN CANADA. Oil Developments in Canada during 1923, G. S. Hume. Am. Inst. Min. and Met. Engrs.—Trans., no. 1321-P. Feb. 1924, 4 pp.

OIL ENGINES

SURFACE-IGNITION. Types of Modern Power-Plant Oil Engines. Oil Engine Power, vol. 2, no. 5, May 1924, pp. 271-272, 3 figs. New model of Italian surface-ignition engine has crosshead and main oiling system entirely separated from cylinder bore, arrangement whith results in low lubricating-oil consumption; Corliss-type valve controls admission of scavenging air, amount of which is regulated by governor.

OPEN-HEARTH FURNACES

DESIGN AND CALCULATION. Performance and Efficiency as Fundamentals for the Design and Calculation of Open-Hearth Furnaces (Leistung und Wirkungsgrad als Unterlagen für Bau und Berechnung der Siemens-Martin-Oefen), H. Bansen. Berichte der Fachauss-chüsse des Vereins deutscher Eisenhüttenleute, Stahlwerksausschuss, report no. 82, May 10, 1924, 23 pp., 19 figs. Functions of furnace; working conditions for temperature drop; heat circulation; relations of fuel supply and preheating to furnace efficiency and fuel consumption; calculation of heat required and efficiency; special means of influencing temperature drop, combustion, temperature conditions and heat transmission; heat accumulators; waste-heat utilization.

EFFICIENCY. The Efficiency of Open-Hearth Furnaces (Wirkungsgrade im Betriebe des Siemens-Martin-Oefens), G. Bulle. Berichte des Fachausschüsse des Vereins deutscher Eisenhüttenleute, Stahlwekrsausschuss, report no. 80, May 10, 1924, 3 pp. Committee report on metallurgical, furnace and producer performance.

ORE TREATMENT

ELECTROLYTIC REFINING. Improvement in Electrolytic Refining During the Last Decade, S. Skowronski. Am. Electrochem. Soc., paper presented at mtg. Apr. 24-26, 1924, No. 30, pp. 391-402. Deals with refining of a erude metal anode into a refined cathode, which process is strictly "electrolytic refining", and recovery of metals from solutions obtained from ores, coneentrates or metallurgical products, using various solvents.

P

PAINTING

INDUSTRIAL-PLANT PRACTICE. Standardization of Painting Practice, R. C. Sheeler. Indus. Mgt. (N. Y.), vol. 68, no. 1, July 1924, pp. 25-28, 5 figs. Extremes of moisture or steam cause all metal surfaces to rust and corrode with extreme rapidity; other surfaces come in contact with gaseous fumes, weak acid vapors, etc. Much money wasted and much good paint condemned through use of wrong material for protective coat to withstand such contact. Discusses application of standardization to maintenance of plant and equipment through proper use of paint and varnish.

PAPER

AREA AND WEIGHT STANDARDS. Standards for Area, Count and Weight, S. L. Willson. Paper Trade Jl., vol. 79, no. 2, July 10, 1924, pp. 51-51, 58 and 64. Shows that in manufacturing size to-day there is little or no relation to use of papers in this size. Discusses proposed plan of changes and benefits to be drived.

PAPER MACHINERY

BEATERS. Modified Beater for Bamboo. Paper, vol. 24, no. 9, June 19, 1924, pp. 379-380, 1 fig. Describes improved machine pateuted in England by W. A. R. MacRae.

FINISHING-ROOM MACHINERY. Finishing Room Machinery, O. C. Cordes and W. W. Spratt. Paper, vol. 34, no. 10, June 26, 1924, pp. 422-425, 8 figs. Describes and illustrates operation of calender drives, platers and cutters by Westinghouse dual-frequency system.

HIGH-SPEED. High Speed Machine Construction, E. J. Neese. Paper, vol. 34, no. 10, June 26, 1924, pp. 428-431. Increased width and speed of newsprint machines bring many improvements in design and construction.

PAPER MANUFACTURE

BEATING. New Ideas on Beating, J. W. Brassington. Paper, vol. 34, no. 11, July 3, 1924, pp. 461-464 3 figs. More speed and less weight of rolls is suggested in describing new type of beater using centrifugal force.

BIBLIOGRAPHY. Bibliography of Papermaking for 1923, Compiled by C. J. West. Paper Trade Jl., vol. 78, nos. 17, 18, 19, 20, 22, 23, 24 and 25, Apr. 24, May 1, 8, 15, 22, 29, June 5, 12 and 19, 1924, pp. 52-54, 49-54, 53-56, 49-52, 45-47, 51-52, 55-57, 45-46 and 41-43.

BLEACHING BEATERS. Function of the Washing Drum, R. Haas. Paper, vol. 34, no. 11, July 3, 1924, pp. 471-475, 6 figs. Determines consumption of energy and best method of operating washing drum of bleaching beater. Translated from Papierfabrikant.

CENTRIFUGAL FORCE, APPLICATION OF. Flywheel Power or Centrifugal Force, J. W. Brassington, paper, vol. 34, no. 9, June 19, 1924, pp. 365-367, 2 figs. Possibilities of application of centrifugal force to manufacture of pulp and paper. Now used in a limited way.

DRYING. Methods of Drying Paper, T. J. Keenan. Paper, vol. 34, no. 10, June 26, 1924, pp. 427-428. Principles of drying by steam-heated drums and review of recent novelties and difficulties caused by faulty ventilation.

PIERS

CONCRETE, CONSTRUCTION OF. Mobile Tower Chuting Plant Builds Concrete Pier at Havana. Eng. News-Rec., vol. 93, no. 2, July 10, 1924, pp. 52-54, 4 figs. Describes concreting plant and form construction in connection with construction of a massive concrete pier deck and house on concrete piles in deep water in Havana. Stiff-leg tower, having a counterweight chute, travels on apron around pier house. Deck forms suspended from pile tops.

INTERSECTIONS, VOLUMES AND AREAS OF. Formulas for Volumes and Areas of Pipe Intersections, G. Paaswell. Eng. News-Rec., vol. 93, no. 1, July 3, 1924, pp. pp. 28-29, 3 figs. Data covering determination of volumes of cylinder intersections such as those at junction of arches or in special pipe castings.

PIPE, CAST-IRON

WELDING WITH BRONZE. Welding Cast Pipe with Bronze, H. Y. Carson. Iron Trade Rev., vol. 75, no. 2, July 10, 1924, pp. 97-98, 2 figs. In method developed by author for welding cast iron, an ordinary welding rod of tobin bronze is used, joint being pre-heated by playing an oxy-acetylene flame back and forth transversely across joint area; bronze rod is melted and allowed to flow along joint spreading about one inch in width entirely around pipe. Only moderate temperatures required. Abstract of paper read before Nat. Gas Assn. Am. See also Foundry, vol. 52 no. 12, June 15, 1924, pp. 469-470, 2 figs.

PLATES

FLANGING TESTS. Tests on the Flanging of Thin Plates (Essai d'emboutissage sur tôles minces), M. Guillery. Revue de Métallurgie, vol. 21, no. 5, May 1924, pp. 303-311, 17 figs. Describes two machines for testing thin plate, in order to determine their resistance to cold flanging; method of testing, and results of tests.

PRESSES

INCLINABLE. Design of Inclinable Power Presses, P. A. Friedell. Machy. (Lond.), vol. 24, no. 613, June 26, 1924, pp. 409-411, 1 fig. Calculations for designing gearing, driving shaft, back-shaft bearing, flywheel and pulleys.

PRODUCER GAS

COMBUSTION, EXCESS AIR DETERMINATION IN. A Graphical Chart for Determining Excess Air in the Combustion of Producer Gas, G. M. Peltz. Am. Ceramic Soc.—Jl., vol. 7, no. 6, June 1924, pp. 437-441 and (discussion) 441-443, 1 fig. Presents a calculating chart by which it is possible to determine percentage of excess air existing in any producer-gas-fired furnace when analysis of gas and percentage of CO_2 in products of combustion are known.

PROSPECTING

ELECTRICAL. Electrical Prospecting in Canada, S. F. Kelly. Am. Zinc Inst.—Bul., vol. 7, no. 5, May 1924, pp. 21-39, 14 figs. Review of principles and procedure of two methods of Schlumber for electrical prospecting and considers their application to Canadian deposits.

PULLEYS

PRESSED-STEEL BELT. Application of Pressed Metal to Pulleys, S. G. Gaillard, Jr. Forging—Stamping—Heat Treating, vol. 10, no. 6, June 1924, pp. 226-229, 12 figs. Various operations in manufacture of pressed-steel belt pulleys.

PULVERIZED COAL

COMBUSTION OF. The Combustion of Pulverized Coal, E. Audibert. Colliery Guardian, vol. 127, nos. 3306 and 3307, May 9 and 16, 1924, pp. 1188-1189 and 1251-1252, 4 figs. Details of experiments made by Comité Central des Houillères de France, primary object of which is measurement of duration of combustion, and subsidiary object determination of essential conditions for use of a given coal in form of powder. Translated from Revue de l'Industrie Minérale.

SYSTEMS. Pulverized-Fuel Systems, A. L. Cole. Power, vol. 59, nos. 23, 24, 25 and 26, June 3, 10, 17 and 24, 1924, pp. 900-905, 16 figs.; 940-945, 17 figs.; 985-988, 16 figs.; and 1022-1027, 26 figs. Different types of equipment in general use for drying, pulverizing, transporting and burning coal in pulverized form. June 3: Types of dryers. June 10: Types of pulverizers used in unit and multiple systems. June 17: Systems used for conveying coal in pulverized form, construction and operation. Type of feeders and burners used with different systems of firing coal in pulverized form; review of earlier types; typical boiler settings designed in last four years.

PUMPS

AIR-LIFT. Experimental Study of Air Lift Pumps and Application of Results to Design, C. N. Ward and L. H. Kessler. Univ. of Wis.—Bul., Eng. Experiment Station, vol. 9, no. 4, 1924, 166 pp., 60 figs. partly on supp. plates.

VACUUM. An All-metal High-vacuum Pump System, I. Backhurst and G. W. C. Kaye. Lond.,Edinburgh, and Dublin Philosophi cal Mag.and Jl.,Sie.,vol. 47, no. 281, May 1924, pp. 918-929, 3 figs. Describes pump system of two-stage type, constructed wholly of metal and consisting of (1) mercury-vapor jet pump in series with (2) mercury-vapor condensation pump; advantages of system. Bibliography. See also paper by same authors, entitled, A Metal Annular-Jet Vacuum Pump, describing modification of pump described in first paper, pp. 1016-1020, 2 figs.

PUMPS, CENTRIFUGAL

INTERNAL LEAKAGE. Determination of Internal Leakage in Centrifugal Pumps, A. F. Sherzer. Eng. News-Rec., vol. 92, no. 25, June 19, 1924, pp. 1056-1058, 5 figs. Facts regarding coefficient of discharge established by research in hydraulic laboratory of Univ. of Mich.

SUCTION PIPES, EVACUATING. Evacuating the Suction Pipes of Centrifugal Pumps, W. S. Douglas. Power Engr., vol. 19, no. 219, June 1924, pp. 205-207, 4 figs. Study of conditions obtaining during process; develops formulas for predetermination of pump capacities, etc., for given plants.

R

RADIOTELEGRAPHY

MODERN EQUIPMENT. Modern Wireless Equipment. Electrician, vol. 92, nos. 2404 and 2406, June 13 and 27, 1924, pp. 728 and 796-798, 12 figs. Survey of wireless apparatus exhibited at British Empire Exhibition, including, broadcast receiving apparatus, headphones, sectional sets, wireless beam transmitter, receiving valves, molecular vacuum pump, etc.

PROPAGATION PHENOMENA. On Propagation Phenomena and Disturbances of Reception in Radio-Telegraphy, F. Kiebitz. Inst. Radio Engrs.—Proc., vol. 12, no. 3, June 1924, pp. 233-241. Study of propagation of electromagnetic waves over earth's surface, particularly for very long distance transmission, for which it is deduced that short waves are inherently unsuitable; methods of quantitatively determining strength of received signals are shown to be necessary; investigates simultaneous appearance of disturbances of reception at widely separated points and conclusions therefrom.

RAILLESS TRACTION

ROCHESTER, N. Y. Rochester Trackless Trolley Construction. Elec. Ry. Jl., vol. 64, no. 1, July 5, 1924, pp. 11-13, 4 figs. Line is about 3 mi. long and runs through densely populated district; it crosses five electric-car lines and one steam railroad at grade; some of overhead equipment is of special design.

RAILS

FROGS AND CROSSINGS, FINISHING OF. Finishing Steel Track Equipment, F. B. Jacobs. Iron Trade Rev., vol. 74, no. 26, June 25, 1924, pp. 1701-1702, 3 figs. Notes on methods and equipment used at plant of Indianapolis Switch & Frog Co., Springfield, O., in production of solid manganese-steel frogs, switches and crossings.

QUALITY IMPROVEMENT. How the Quality of Rails Can Be Improved, C. W. Gennet, Jr. Ry. Age, vol. 77, no. 2, July 12, 1924, pp. 63-65, 2 figs. Suggestions for changes in specifications to secure a better grade of steel.

RAILWAY ELECTRIFICATION

ILLINOIS CENTRAL. Electrification Progress on the I. C. R. R. Elec. Traction, vol. 20, no. 6, June 1924, pp. 256-257, 4 figs. Work on complete elimination of grade crossings from Chicago to Kankakee are well under way; next cars purchased will be completely equipped for electrical operation.

UNITED STATES. The Electrification of Foreign Railways including Recent Developments and Projects, S. Parker Smith. World Power, vol. 1, no. 6, June 1924, pp. 338-346, 4 figs. United States of America.

RAILWAY MANAGEMENT

PURCHASES AND STORES. Purchases and Stores, Ry. Age (Daily Edition), vol. 76, no. 34, June 17, 1924, pp. 1641-1659, 6 figs. Contains following articles: Purchasing Function of the Government, H. C. Smither; Committee recommendation: Stores Department Book of Rules; Method for Material Procurement, E. J. Remensnyder; Committee report on Material Accounting and Office Appliances; report of Committee on General Accounting; Bonus System for Efficient Stockmen, J. E. Mahaney; Report on Department Buildings and Facilities; Duties of a Travelling Storekeeper,W. Dixon; and other addresses. Papers and reports presented before Am. Ry. Assn. See also Ry. Rev., vol. 74, no. 25, June 21, 1924, pp. 1204-1211.

S. P. Houston Store Has Many Fine Features. Ry. Rev., vol. 74, no. 24, June 14, 1924, pp. 1094-1103, 22 figs. Among practices followed at purchases and stores department of Southern Pac. Co., are unit piling of materials, stores delivery and supply-train operation.

SUPERVISORY FORCES, TRAINING OF. Proper Training of Shop Supervisory Forces, L. W. Baldwin. Ry. Rev., vol. 74, no. 26, June 28, 1924, pp. 1256-1258. Discusses training of supervision and developing of men better fitted for mechanical positions. Systematic record of progressive steps should be kept and stipulated examinations at stated intervals should be given. From paper read before Am. Ry. Assn. annual convention.

RAILWAY MOTOR CARS

HYDRAULIC-DRIVE. Gasoline Passenger Car with Hydraulic Drive. Ry. Age, vol. 76, no. 31, June 14, 1924, pp. 1507-1509, 5 figs. Combination passenger and baggage unit car propelled by 150-h.p. Ricardo engine through transmission consisting of one hydraulic variable-delivery pump and two hydraulic variable-speed motors; in operation on New York, New Haven & Hartford.

RAILWAY OPERATION

CAR SWITCHING. Switching Devices (Hilfsmittelzum Verschieben), Wernekke. Fördertechnik u. Frachtverkehr, vol. 17, no. 8, Apr. 30, 1924, pp. 103-105, 6 figs. Various devices for switching railway cars by means of wire ropes; for use in cases where use of switching locomotives would not be economical. Types of electric motors and controllers for devices.

RAILWAY REPAIR SHOPS

DELIVERY SYSTEM. Transportation of Material in the Roanoke Shops, Jas. M. Thomas. Ry. Rev., vol. 74, no. 24, June 14, 1924, pp. 1126-1130, 9 figs. Describes delivery system of shops of Norfolk & West. Ry.; how materials are delivered to and from shops and yards; organization and system; schedules maintained and equipment used.

DESIGN. Report on Design of Shops and Engine Terminals. Ry. Age, vol. 76, no. 30, June 13, 1924, pp. 1464-1468. Seven specific recommendations for freight-car and repair shops. Am. Ry. Assn. committee report and discussion.

RAILWAY SHOPS

EQUIPMENT STANDARDIZATION. Standardized Shop Work at Topeka, F. H. Colvin. Am. Mach., vol. 61, no. 2, July 10, 1924, pp. 63-64, 1 fig. Outline of how equipment is standardized and manufactured at Topeka shops of Santa Fe, and economies effected by standardization.

MACHINE TOOLS FOR. Machine Tools for Railway Shops, Ry. Engr., vol. 45, nos. 532 and 533, May and June, 1924, pp. 171-173, and 204-206, 8 figs. Boring and turning mills; extra-heavy wheel lathe; cylinder grinding machine; boring rolling-stock wheels; drilling and ovaling rails; boring axle-boxes; new boiler-shop tool; car-wheel-center boring machine.

TRAINING OF FORCES. The Training of Shop Supervisory Forces, L. W. Baldwin. Ry. Age (Daily Edition), vol. 76, no. 34, June 17, 1924, pp. 1627-1630. Selection of apprentices; supervision and encouragement of mechanic; selecting men for promotion; duties of foreman; study of new tools and appliances. Address before Am. Ry. Assn.

RAILWAY SIGNALING

COLORED-LIGHT SIGNALS. Canadian National Color-Light Signals, T. A. Allen. Ry. Signaling, vol. 17, no. 7, July 1924, pp. 268-270, 6 figs. Expanded steel trusses in place of bridges save money; main line switches electrically lighted.

NEON, APPLICATION OF. Neon—A New Gas for Electrical Use, C. S. Treacy. Ry. Signaling, vol. 17, no. 7, July 1924, pp. 279-280, 1 fig. Development of new gas and its application to signal lights and lightning arresters.

RAILWAY TIES

TREATED VS. UNTREATED. Superiority of Treated Ties Proved by a Nine Years' Test on Chicago & North Western Railway. Wood Preserving News, vol. 2, no. 5, May 1924, pp. 72-73. Seven varieties of timber, untreated and treated by three standard processes, installed on eight divisions show great economy of the preservation.

RAILWAY TRACK

CROSSING GATES. Electrically Operated Gates at Mount Pleasant Crossing, Southampton, Southern Railway, W. J. Thorrowgood. Ry. Gaz., vol. 40, no. 25, June 20, 1924, pp. 379-382, 4 figs. Results of power tests of gates; describes operating mechanism; emergency arrangements.

STRESS ON, RELATION TO LOCOMOTIVE DESIGN. Relation of Track Stress to Locomotive Design, C. T. Ripley. Ry. Age (Daily Edition), vol. 76, no. 32, June 14, 1924, pp. 1457-1553 and (discussion) 1553-1558, 10 figs. History of study of track stresses; describes stremmatograph and its use in measuring rail stresses and gives results of number of tests run on A. T. & S. F. Paper read before Am. Ry. Assn.

RAILWAY YARDS

FLOOD LIGHTING. Floodlighting Railroad Yards, E. G. McAllister. Elec. World, vol. 83, no. 26, June 28, 1924, pp. 1329-1332, 6 figs. Adoption of this practice has materially increased operating efficiency and safety on Norfolk & West. R. R.; details of installation; costs and operating results.

RAILWAYS

GOVERNMENT REGULATION. The Development of Railroad Regulation, F. McManamy. Ry. Age (Daily Edition), vol. 76, no. 34, June 17, 1924, pp. 1623-1627. Review of scope and effect of what U. S. Government has done in way of legislation affecting railroads; unification; provisions to stabilize credit. Paper read before Am. Ry. Assn.

MATERIALS SPECIFICATIONS. Report on Specifications and Tests for Materials. Ry. Age (Daily Edition), vol. 76, no. 34, June 17, 1924, pp. 1638-1639, 1 fig. New proposed form for specification of welding wire and rods; specifications for lumber; etc. Report presented to Am. Ry. Assn.

REAMERS

TAPER. Taper Machine Reamers, F. Cooke. Machy. (Lond.), vol. 24, no. 613, June 26, 1924, pp. 385-388, 8 figs. Deals with back piloting roughing reamers and finishing reamers; gives dimensions and formulas.

RECTIFIERS

MERCURY VAPOR. Power Factor of Mercury Vapor Rectifiers (Der Leistungsfaktor der Quecksilberdampf-Gleichrichter), G. W. Müller. Elektrotechnische Zeit., vol. 45, no. 24, June 12, 1924, pp. 624-626, 14 figs. Explains and calculates power factors; gives curves of power factors based on measurements of existing mercury vapour rectifier plants.

REFRIGERATING MACHINES

CO_2 COMPRESSORS. The Carbon Dioxide Compressor, H. J. Macintire. Refrig. Wld., vol. 69, no. 6, June 1924, pp. 16-18, 2 figs. Improvements in recent years have followed along same lines as in ammonia-compressor design.

PRE-COOLING IN. Pre-Cooling by Primary Evaporation and Multiple Effect Compression, as Applied to CO_2 Refrigerating Machines, Henry Brier. Cold Storage, vol. 27, no. 315, June 19, 1924, pp. 246-248, 6 figs. Shows that multiple-effect compression is pre-eminently suited for dealing satisfactorily with two evaporations in closed cycle of CO_2 refrigerating plant arranged for pre-cooling by partial or primary evaporation.

REFRIGERATION

BRINE AND DIRECT-EXPANSION COOLING. Comparison of Direct Expansion and Brine in Applying Refrigeration, H. J. Macintire. Chem. & Met. Eng., vol. 30, no. 26, June 30, 1924, pp. 1027-1029, 4 figs. Conditions governing application of cooling by two methods, with particular emphasis on brine cooling.

REFUSE DISPOSAL

DESTRUCTORS. Refuse Destructor with Unique Features. Contract Rec. & Eng. Rev., vol. 38, no. 26, June 25, 1924, pp. 641-644. Birmingham, England, has installed plant to handle 36,000 tons of refuse per year. Dust conveyed to barges by air pressure; special magnetic separator for cleaning clinker.

RIVETED JOINTS

STRESSES IN. Stresses in the Riveted Joints of Steel Structures (Die Beanspruchung des Nietverbindungen bei Eisenkonstruktionen), Mülleuhoff. Zentralblatt der Bauverwaltung, vol. 43, nos. 101-102, Dec. 19, 1923, pp. 607-611, 13 figs. Theoretical investigations and scientific measurements of stresses occurring. Great influence of quality of workmanship is emphasized.

RIVETING

MACHINES FOR. Giant Portable Compressed Air Riveting Machine, J. C. Hanna. Compressed Air Mag., vol. 29, no. 5, May 1924, pp. 861-863, 4 figs. Description of 150-ton riveter designed and manufactured by Hanna Eng. Wks., Chicago, Ill.; makes use of compressed air in forming rivet heads, and compressed air is also drawn upon in rotating machine as well as in tilting it. Character of work that it performs.

ROADS

BATES EXPERIMENTAL. Results and Application of the Bates Road Tests, Ider. West. Soc. Engrs.—Jl., vol. 29, no. 5, May 1924. Conclusions derived from experiments conducted by State Highway Department at Bates Test Road.

MAINTENANCE COST KEEPING. Establishing a Cost-Keeping System, J. L. Boulanger. Can. Engr., vol. 47, no. 1, July 1, 1924, pp. 113-115. Legislation and organization leading to establishment of accurate system of cost-keeping for road maintenance in Quebec province. Paper read at annual convention of Can. Good Roads Assn.

RESURFACING. Resurfacing and Surfacing Treatments and When They are Justified, Wm. A. VanDuzer. Cornell Civ. Engr., vol. 32, no. 6, Mar. 1924, pp. 78-79 and VI-VIII. Factors in determining resurfacing; preliminary maintenance steps; resurfacing macadam road; application of bituminous material; unbound macadam.

SAND-CLAY AND TOP-SOIL. Sand Clay and Top Soil Roads in Georgia, W. R. Neel. Eng. & Contracting (Roads & Streets), vol. 62, no. 1, July 2, 1924, pp. 16-18. Describes methods of construction and maintenance. From paper read before Am. Soc. Mun. Improvements.

ROADS, ASPHALT

BLACK-BASE-FOUNDATION. "Black Base" Construction in Mercer County, New Jersey, H. F. Harris. Eng. & Contracting (Roads & Streets), vol. 62, no. 1, July 2, 1924, pp. 39-42, 4 figs. Methods and cost of constructing bituminous base for sheet asphalt on heavy traffic highway.

SAND-ASPHALT. Design and Construction of Sand Asphalt Pavements, S. R. Murray. Mun. & County Eng., vol. 66, no. 6, June 1924, pp. 253-256, 9 figs. In author's opinion and based on his experience, this is least expensive type of durable road which can be built in sand community and should give good service for at least 12 to 15 years.

TYPES OF PAVEMENTS. The Design and Construction of Asphalt Pavements, P. Hubbard. Mun. & County Eng., vol. 66, no. 5, May 1924, pp. 221-229. Constituents and types of asphalt pavements; asphalt macadam; asphaltic concrete; sheet asphalt; hot-mix construction; asphalt block; foundations; subgrades; traffic tests on various designs of pavements.

ROADS, BITUMINOUS

SERVICE RENDERED BY. Bituminous Treatment Limitations, I. W. Patterson. Can. Engr., vol. 46, no. 25, June 17, 1924, pp. 621-625, 4 figs. Discussion of service rendered by surface treatments and bituminous macadam pavements under modern traffic; accounting for variable results. Paper read at conference on highway engineering, Univ. of Mich.

ROADS, CONCRETE

CRUSHING AND HEAVING OF BASES. A Study of Crushing and Heaving of Concrete Pavement Bases, R. M. Green. Mun. & County Eng., vol. 66, no. 5, May 1924, pp. 216-219. Change in practice; effect of rise in temperature; effect of change in moisture content; results of tests and conclusions.

DESIGN AND CONSTRUCTION. Developments in the Design and Construction of Concrete Highways, C. R. Ege. Cornell Civ. Engr., vol. 32, no. 9, May 1924, pp. 113-115, IX-X and XII, 4 figs. Independent investigations in various localities, which have made for rapid progress as well as variations in practice.

PONTAM CONSTRUCTION HELLICAL. Pontam Reinforced Concrete Pavements in France. Highway Engr. & Contractor, vol. 2, no. 1, July 1924, pp. 45-46, 2 figs. Pontam is made of reinforced concrete and has been laid chiefly in precast sections heretofore but may also be laid in same manner that other paving is put down, that is by continuous operation not limited to definite dimensions on areas. One of principal advantages of this method lies in fact that coefficient of wear of cast-iron braces is less than that of concrete between braces.

SURFACE FAULTS. Surface Faults in Concrete Roads, J. H. Walker. Surveyor & Mun. & County Engr., vol. 65, no. 1692, June 20, 1924, pp. 569-570, 12 figs. Causes of and remedy for grooving. Surface treatment of concrete.

ROAD CONSTRUCTION

METHODS. Modern Methods of Road Maintenance and Construction, T. Somers. Surveyor & Mun. & County Engr., vol. 65, no. 1691, June 13, 1924, pp. 551-553. Subsoil and surface drainage; foundations; materials; rubber paving; tar and bituminous macadam; asphalt macadam; construction of new roads; etc. Paper read before Instn. Mun. & County Engrs.

ROLLING MILLS

BUTT-WELD. New Butt Weld Mills at Indiana Harbor. Iron Age, vol. 914, no. 1, July 3, 1924, pp. 1-4, 5 figs. Mills, which are part of expansion program of Youngstown Sheet & Tube Co., will roll pipe from ⅛ up to 3 in. and will produce 400 tons daily.

PLATE MILLS. New Three-high Plate Mill at the Clydebridge Works of Messrs. David Colville & Sons, Ltd. English Elec. Jl., vol. 2, no. 6, Apr. 1924, pp. 311-319, 8 figs. Ilgner drive with slow-speed motor direct-coupled to mill and flywheel energy embodied in a separate motor-generator equalizer set. Plant designed to deal with 3,000 tons of plates per week.

S

SAND BLAST

SANDS FOR. Sand Blast Sand, W. M. Weigel. U. S. Bur. Mines, Reports of Investigations, no. 2615, June 1924, 6 pp. Discusses different grades of sand, mining and preparation, and utilization of waste blast sand.

SAND, MOLDING

STEEL CASTINGS. Moulding Sands for Steel Castings, A. Rhydderch. Foundry Trade Jl., vol. 29, nos. 406 and 407, May 29 and June 5, 1924, pp. 445-448 and 460-463, 6 figs. Refractoriness, naturally-bonded sand, examination of clay grades, stripping properties of sands, "compos," mechanical strength and permeability, controlling variables, standardization of testing methods, preparation, strength as affected by milling, drying of sands and compo molds, etc.

TESTING. The Testing of Molding Sands, H. Ries. Sibley Jl., Eng., vol. 38, no. 6, June 1924, pp. 136-138 and 156, 5 figs. Describes three tests thus far adopted, namely permeability, bonding-strength, and fineness test.

SCREWS

LEAD SCREWS, CHASING. Chasing Lead-screws, Chas. O. Herb. Machy. (N. Y.), vol. 30, no. 11, July 1924, pp. 883-884, 2 figs. Practice of Am. Tool Works Co.

SEWAGE DISPOSAL

IMHOFF TANKS. Operation of Imhoff Sewage Tanks, E. L. Waterman. Can. Engr., vol. 46, no. 26, June 24, 1924, pp. 655-657. Discusses essential features of tank; utilization of gas; careful and systematic operation necessary to obtain satisfactory results; schedule of operation generally followed. Paper read at conference on Sewage Treatment at Iowa State College.

SLUDGE DIGESTION. Separate Sludge Digestion, W. DeWitt Vosbury. Pub. Works, vol. 55, no. 6, June 1924, pp. 184-185. Advantages of separation of mechanical sedimentation and biological digestion as compared with combining both processes in septic or two-story tanks. Principles of design.

SEWER CONSTRUCTION

WINNIPEG. Construction of Renfrew Street Sewer, W. Aldridge. Can. Engr., vol. 46, no. 25, June 17, 1924, pp. 626-627, 2 figs. Large main sewer, 72 in. diameter, constructed in Winnipeg to relieve unemployment in winter; construction carried out in zero weather; Ferguson segment vitrified clay block chosen for sewer; is not effected by alkali ground water.

SEWERS

RUN-OFF COEFFICIENT. The Coefficient of Run-Off in Storm Sewer Design, Le Roy K. Sherman. Mun. & County Eng., vol. 66, no. 6, June 1924, pp 297-301, 3 figs. Describes procedure for determining percentage "C" of rainfall run-off for sewered areas by rational method.

SILICON STEEL

ANNEALING, EFFECT OF. Effect of Annealing on the Magnetic Properties of Sheets of Silicon-Steel Employed in Electrical Construction (Influence du recuit sur les propriétés magnétiques des tôles au silicium employées dans la construction électrique), R. Cazaud. Académie des Sciences—Comptes Rendus des Séances, vol. 178, no. 20, May 12, 1924, pp. 1610-1611. Results of a study of effect of varying conditions of annealing of rolled sheets of steel containing various percentages of silicon, on magnetic permeability, hysteresis losses, reluctivity, and Foucault losses.

SMOKE

FILTRATION OF. Electrical Smoke Filtration (Elektrisk gasrening, Cottrell-Möllers metod), Ake Dahlgren. Teknisk Tidskrift, vol. 54, no. 19, May 10, 1924, pp. 34-38 (Kemi), 11 figs. Historical review of development of art of smoke filtration and detailed description of electrical method proposed by Cottrell and a later improved upon by Möller. Number of photographs and figures showing recent installations in Europe.

SOLIDS

INTERNAL PRESSURES OF. The Internal Pressures of Solids, T. W. Richards. Am. Chem. Soc.—Jl., vol. 46, no. 6, June 1924, pp. 1419-1436, 1 fig. Brief analysis of nature of an approximate hyperbolic pressure-volume equation for solids; relation of this hyperbolic equation to an equation of state, in which each of the quantities has definite physical meaning; method which gives a plausible means of calculating internal pressure of isotropic elements from coefficient of expansion by means of a certain equation.

SPRINGS

MANUFACTURE OF. Quality a Vital Factor in Spring Manufacture, H. P. Armson. Can. Machy., vol. 31, no. 25, June 19, 1924, pp. 19-21 and 42, 4 figs. Practice at Hamilton plant of Wallace Barnes Co., work facilitated by equipment of specialized nature; unusual variety of sizes and materials in industry.

632

STEAM

SPECIFIC HEAT. The Specific Heat of Steam, H. L. Callendar. World Power, vol. 1, nos. 5 and 6, May and June 1924, pp. 274-280 and 324-328, 1 fig. May: Explains principles of new methods of research, and illustrates difficulties to be encountered in neighborhood of saturation, which have led to abandonment of many of older methods. June: Rational equation for steam up to its critical point; comparison with experimental results for CO_2

STEAM ACCUMULATORS

TYPES. High-, Medium- and Low-Pressure Accumulators (Der Gefällespeicher für Hoch-, Mittel-, und Niederdruck), C. Hiesselbach. Wärme, vol. 47, no. 17, Apr. 25, 1924, pp. 175-177, 4 figs. Discusses necessary conditions for economic working, describes Ruths and other types, also new type said to fill requirements.

STEAM METERS

TYPES AND CHARACTERISTICS. Meter Types and Their Characteristics, C. D. Zimmerman. Power Plant Eng., vol. 28 no. 13, July 1, 1924, pp. 696-698. Temperature recorders; instruments for boilers in small boiler plants and power plants; economizer instruments, turbine and miscellaneous instruments; improvements.

STEAM PIPES

COVERINGS, HEAT LOSS THROUGH. Heat Loss through Insulating Materials, R. H. Heilman. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 742-745, 1 fig. Method for calculating heat loss through pipe covering used for high steam temperatures. Outlined before A.S.M.E.

STEAM POWER PLANTS

ANTHRACITE-SLUSH-BURNING. Pulverized Anthracite Slush Burned at Lykens (Pa.). Power, vol. 60, no. 1, July 1, 1924, pp. 2-7, 9 figs. One of first power plants to utilize anthracite slush in pulverized form, coal mixed with 75 per cent water pumped 2,500 ft. under 400 ft. head and dewatered at plant; boiler plant contains six 5,000 and six 6,000-sq. ft. water-tube boilers; present generating capacity 6,400 kw.

ISOLATED PLANT VS. CENTRALIZED POWER. Slow-speed Steam Engines for Industrial Purposes, D. S. Capper. World Power, vol. 1, no. 6, June 1924, pp. 353-357, 6 figs. Deals with factors which combine to determine best method of power supply, namely first, cost, working cost, suitability to particular work, liability to stoppage, and insurance risk.

STEAM POWER PLANTS

PINE GROVE, PA. Electrical Features of Pine Grove Station, C. D. Gray and M. M. Samuels. Elec. Wld., vol. 84, no. 2, July 12, 1924, pp. 56-62, 13 figs. How electrical features of a large steam plant, built at mouth of a mine, remote from load center, differ from those of large city plant. Power house of East Penn Elec. Co., on Swatara Creek at Pine Grove, Pa., used to illustrate the various electrical features involved.

RECONSTRUCTION OF. Rebuilding an Old Steam Engine Plant. Power Plant Eng., vol. 28, no. 14, July 15, 1924, pp. 746-748, 7 figs. Description of plant of Stearns Light & Power Co., Ludington, Mich., which is being rebuilt. Owners bought steam under contract, used it to generate electric power and then sold it back to original owners after it had served its purpose.

STEAM TURBINES

CROSS-COMPOUND. The Cross-Compound Turbine Adaptable to a Variety of Conditions, E. H. Thompson. Power, vol. 60, no. 2, July 8, 1924, pp. 50-51, 1 fig. Applications of cross-compound principle indicate a growing appreciation of desirable characteristics of this type. Consideration of such units of to-day brings to light a number of ways in which this construction may be utilized and suggests an increasingly important field in future.

PARSONS LINE. Is the Parsons Line Straight or Curved? C. F. Merriam. Power, vol. 60, no. 1, July 1, 1924, pp. 8-10, 4 figs. Shows fallacy of assuming that Parsons line is necessarily straight.

REACTION. Largest Straight Reaction Turbine—How Internal Conditions Vary with Load, E. H. Thompson. Power, vol. 59, no. 26, June 24, 1924, pp. 1016-1019, 6 figs. Turbine of Brooklyn Edison Co.'s Hudson Ave. station contains no impulse velocity wheel and is entirely a reaction type; it is served by largest surface condenser so far constructed; conical cylinder bores give improved efficiency.

STEEL

ALLOY. *See Alloy Steels.*

BLOWHOLES. An Hypothesis on the Origin of Blowholes in Steel Ingots (Une hypothèse relative à l'origine des ruchages de soufflures dans les lingots d'acier), K.-G. Troubine. Revue de Métallurgie, Jl. 21, no. 5, May 1924, pp. 288-294, 6 figs. Author propounds theory on origin of blowholes. Translated from Russian.

COMBINED IRON AND. Notes on Combined Iron and Steel, H. H. Shephard. Metal Industry (Lond.), vol. 24, no. 24, June 13, 1924, pp. 577-578 and 588, 3 figs. Uses; composition; testing. Author's experience with "combined iron and steel" and "composite steel" is that failures of these materials are due chiefly to faults in manufacture of ingots or billets.

HIGH PRESSURES AND TEMPERATURES. Steel for Higher Pressures and Elevated Temperatures, V. T. Malcolm. Power, vol. 59, no. 26, June 24, 1924, pp. 1020-1021, 3 figs. Physical properties resulting from fine, dense structure.

MANGANESE. *See Manganese Steel.*

SILICON. *See Silicon Steel.*

SPECIAL, DEVELOPMENTS IN METALLURGY OF. Modern Developments in the Metallurgy of Special Steels, W. H. Hatfield. Iron & Coal Trades Rev., vol. 108, no. 2938, June 20, 1924, pp. 1055-1057. Discusses improvement in process of manufacture and manipulation resulting in increased reliability, modified and new compositions resulting in improved or new properties, and more intimate knowledge of properties of steel from designer's viewpoint. From paper read before Iron & Steel Soc., Empire Min. & Met. Congress.

STEEL, HEAT TREATMENT OF

DEFINITIONS. Comparison of Heat-Treatment Definitions. Mech. Eng., vol. 46, no. 7, July 1924, p. 435. Varying v ews held by committees of Am. Soc. Steel Treating, Soc. Automotive Engrs., and Am. Soc. Testing Matls.

HARDENING, CYANIDE PROCESS. Development of a Novel Cyanide Hardening Process, C. Ringstrom. Gas Age-Rec., vol. 53, no. 25, June 21, 1924, pp. 871-873, 3 figs. Describes new and economical process where use of proper fuel has proven necessary for complete success.

TEMPERING, OIL. Modification of Oil Tempering Bath Makes It a Success, E. Ogur. Fuels & Furnaces, vol. 2, no. 7, July 1924, pp. 647-649, 3 figs. Electric heaters at bottom of bath did not heat oil uniformly. Oil is now pumped through cylinder where it is brought to temperature by electrically heated grids.

THEORY AND PRACTICE. The Heat Treatment of Steel. Eng. Production, vol. 7, no. 142, July 1924, pp. 205-207, 5 figs. Discusses thermal critical points of steel, annealing, hardening and tempering, alloy steels, and some practical considerations.

STEEL, HIGH-SPEED

PROPERTIES AND TREATMENT. High Speed Steel, A. R. Page. Birmingham Met. Soc.—Jl., vol. 8, no. 10, pp. 447-463 and (discussion) 463-468, 14 figs. partly on supp. plate. Composition; theory of high-speed steel; microstructure; heat treatment; testing.

STEEL INDUSTRY

SHEET STEEL. Sheet Steel Industry, W. S. Horner. Blast Furnace & Steel Plant, vol. 12, no. 7, July 1924, pp. 319-325. Address of president of Nat. Assn. Sheet and Tin Plate Mfrs. before second annual meeting of sheet steel executives at White Sulphur Springs, W. Va., May 13, 1924.

STEEL WORKS

ELECTRIC POWER STATIONS FOR, AUTOMATIC. Automatic Electric Stations for Steel Mills, C. Lichtenberg. Iron & Steel Engr., vol. 1, no. 5, May 1924, pp. 252-256, 6 figs. Review indicating briefly operation of a typical automatic station and application of some of the equipments. Mentions several unique designs which are especially adapted for steel-mill service.

OPEN-HEARTH, CAR UPKEEP. Reducing Open Hearth Car Upkeep, C. L. Newby. Blast Furnace & Steel Plant, vol. 12, no. 7, July 1924, pp. 331-333, 7 figs. Anti-friction bearings now an important factor in production.

STOKERS

ELECTRIC DRIVE FOR. Motors and Control for Stoker Drive, R. Kelly. Elec. Jl., vol. 21, no. 5, May 1924, pp. 221-224, 7 figs. Discusses factors in selection of motors and control equipment.

UNDERFEED. Solving Clinker Problems with Underfeed Stokers, Jos. G. Worker. Steam Coal Buyer, vol. 1, no. 3, Mar. 1924, pp. 20-26, 4 figs. Shows progress made in securing better combustion and reducing clinkers in burning low-grade high-ash Mid-West coals.

STREET RAILWAYS

CAR MAINTENANCE. 217,728 Car-Miles per Pull-In, Robert M. O'Brien. Elec. Ry. Jl., vol. 63, no. 25, June 21, 1924, pp. 969-971, 5 figs. Well-organized system of inspection and repair has enabled New Orleans Public Service, Inc., in 3½ years to eliminate 95 per cent of pull-ins and cut maintenance costs to half.

SUBSTATIONS

CENTRAL-STATION SERVICE, APPLICATION TO. Application of Automatic Substations to Central Station Service in Metropolitan Districts, C. W. Place. A.I.E.E. Jl., vol. 43, no. 7, July 1924, pp. 634-641, 16 figs. Present trend to interconnection and installation of large-capacity stations, with changing character of city load, make relief of operating crew of a system of greatest importance. This can best be done by use of automatically-controlled substations in the various types of service. Equipment for each class of service is in successful operation showing great dependability and any particular problem of operating companies can be attached, keeping in mind certain fundamentals of design, construction and application.

RAILWAY. Automatic Substations for Supplying 1,500 Volts Direct Current to Suburban Railways, C. A. Butcher. A.I.E.E.—Jl., vol. 43, no. 7, July 1924, pp. 622-626, 3 figs. Important points which should be given careful consideration by those contemplating electrification.

SUPERHEATED STEAM

ADVANTAGES. Convenient Analysis of Modern Plant and Application to Ship Propulsion. Power, vol. 60, no. 1, July 1, 1924, pp. 18-20, 7 figs. Net plant efficiencies with stage bleeding or reheating which may be quickly obtained from simple diagrams with appropriate corrections.

SUPERHEATERS

DETACHABLE-TUBE. A New Detachable Tube Superheater. Engineer, vol. 137, no. 3572, June 13, 1924, pp. 667-668, 4 figs. Improved form evolved by Thos. Sugden.

DEVELOPMENTS. Superheaters and their Latest Developments, B. N. Broido. Combustion, vol. 11, no. 1, July 1924, pp. 42-45, 4 figs. Developments in design of superheaters to meet demands of modern power plants.

T

TAPS

MANUFACTURE. Taps and Tapping, H. Appleyard. Mech. Wld., vol. 75, no. 1954, June 13, 1924, pp. 366-367, 11 figs. Description of how taps are made.

TERMINALS, LOCOMOTIVE

TURNTABLES. A Remarkable Record in a Turntable Renewal. Ry. Age, vol. 76, no. 37, June 21, 1924, pp. 1759-1761, 5 figs. Southern Pacific bridge crews replace 70-ft. structure with 100-ft. in 1 hr. 46 min.

TERMINALS, RAILWAY

EFFICIENCY. Improvement of Efficiency on Terminals, Chas. Burlingame. St. Louis Ry. Club—Proc., vol. 29, no. 2, June 1924, pp. 31-42. Gives general discussion on topic.

TEXTILE MACHINERY

PARTS MANUFACTURE. Making Textile Machine Parts, H. R. Simonds. Foundry, vol. 52, no. 14, July 15, 1924, pp. 537-541, 14 figs. Complicated parts are made of gray-iron and malleable castings and offer interesting problems to foundrymen; find application for roll tamp and special stripping machines.

TIME STUDY

COMPILED FORM OF. Making and Using Time Studies, H. K. Reed. Indus. Mgt. (N.Y.), vol. 68, no. 1, July 1924, pp. 29-34, 5 figs. Deals with compiled form of time study.

TOLERANCES

LIMITS. Requirements of a System of Limits, M. E. Steczynski. Sibley Jl. Eng., vol. 38, no. 6, June 1924, pp. 139-146 and 155-156, 5 figs. Fundamental principles involved in logical development of satisfactory system.

TRACTORS

FARM. The General Purpose Farm Tractor, F. A. Wirt. Agricultural Eng., vol. 5, no. 5, May 1924, pp. 102-104, 1 fig. An efficient source of mechanical power that can be used not only for customary tractor drawbar and belt operations, but also, when properly equipped and adjusted, for efficient cultivating and other light drawbar work now more commonly done with horses. Why next big development in tractor industry is expected to be a general-purpose tractor.

TRAFFIC

CONGESTION RELIEF. Projects for Relief of Traffic Congestion in New York and Its Environs, E. P. Goodrich and H. M. Lewis. Am. City Mag., vol. 31, no. 1, July 1924, pp. 29-31, 2 figs. Summary of causes of congestion and of important specific suggestions for relief.

TRANSFORMERS

Cooling. Transformer Cooling, E. R. Stauffacher. Jl. of Elec., vol. 52, no. 11, June 1, 1924, pp. 451-463, 25 figs. A new development of A.B.O. type transformer; description of some cooling systems; experiments on cooling transformer oil in automobile type radiators; automatic reclosing circuit breaker; status of automatic a.c. substations; relays and relay application; calculating tables for calculating short-circuit currents on system; proposed change in transformer polarity; etc.

Insulation Tests. Insulation Tests of Transformers as Influenced by Time and Frequency, F. J. Vogel. A.I.E.E.—Jl., vol. 43, no. 7, July 1924, pp. 627-633, 26 figs. Types of insulation failure and methods of testing. Application of data to tests on apparatus.

TRANSPORTATION

Metropolitan Planning for Future Requirements. Metropolitan Planning for Future Transportation Requirements, J. R. Bibbins. Engrs. & Eng., vol. 41, no. 5, May 1924, pp. 119-135, 22 figs. General survey of growth, trends and conditions; what some cities have done and have not done; the transportation plan.

Street Railways vs. Trolley- and Motor Buses. Operation of Tramways, Trolley Omnibuses and Motor Omnibuses. Surveyor & Mun. & County Engr., vol. 65, no. 1689, May 30, 1924, pp. 509-510. Advantages and disadvantages of the three systems. Report of Lond. County Council Highways Committee.

TUNNELING

Methods. Advantageous Practices in Tunneling, C. S. Hurter. Du Pont Explosives Service Bul., no. 10, Apr. 1924, 8 pp., 11 figs. Some practical ways of securing greater progress in tunnel operations and lower costs.

V

VALVES

Materials, Tests of. Tests on Valve Materials Made Under Working Conditions. Automotive Industries, vol. 51, no. 2, July 10, 1924, pp. 110-112, 1 fig. Results of tests of poppet-type valves for aircraft engines, made of different materials, described in paper presented to Am. Soc. for Testing Matls. at Atlantic City by J. B. Johnson and S. A. Christianson.

VARNISHES

Photomicroscopic Record of Exposures. Photomicroscopic Records of Varnish Exposures, H. A. Gardner. Paint Mfrs.' Assn. of U. S.—Sci. Section, no. 204, June 1924, 11 pp., 17 figs. Presents photomicrographs that illustrate permanent records made from month to month as deterioration proceeds may be made.

VENTILATION

Air-Duct Calculations. Duct Work in Connection with Ventilation, C. W. Kimball. Architectural Forum, vol. 41, no. 1, July 1924, pp. 33-35. Describes duct system and different materials used.

VIADUCTS

Plate-Girder. Construction Features of the Spring Street Viaduct, Atlanta, J. H. Reed. Contractors' & Engrs.' Monthly, vol. 8, no. 5, May 1924, pp. 47-49, 3 figs. Plate girder structure coated with gunite has eliminated grade crossings and expedited vehicular traffic.

VOLTAGE REGULATION

Regulators. The Application of the Saturated-Core Reactor and Regulator, D. K. Blake. A.I.E.E.—Jl., vol. 43, no. 7, July 1924, pp. 604-607, 4 figs. States briefly use of voltage regulators and reactors in transmission and distribution systems and mentions operating requirements which might be best met by use of saturated-core type regulators or reactors.

W

WAGES

Minimum-Wage Laws. Minimum Wage Legislation in Canada and its Economic Effects, J. W. MacMillan. Int. Labour Rev., vol. 9, no. 4, Apr. 1924, pp. 507-537. Applies almost exclusively to women and girls and is administered by independent boards or commissions; its main effect on wages has been to reduce inequalities previously existing within single industry, while it has not tended to reduce higher wages; it has had marked effect in reducing hours of work and making them more uniform, and no deleterious effect on employment has been noted; relations between employers and workers have been improved.

WATER MAINS

Costs of. Costs of Water Supply Mains of Four Different Materials, D. H. Maury. Eng. News-Rec., vol. 92, no. 25, June 19, 1924, pp. 1052-1054, 1 fig. Estimates for long lines and large sizes of cast-iron, steel, concrete and wood-stave pipe. Abstract of paper and discussion before Am. Water Wks. Assn., May 1924.

WATER POWER

Canada. Utilization of Water Power in Canada. Can. Engr., vol. 46, no. 24, June 10, 1924, pp. 601-604, 1 fig. Review of water-power development in relation to coal production, importation and consumption in Canada. Water-power development has relieved situation, particularly in acute fuel area by saving in coal consumption. See also Eng. Wld., vol. 24, no. 5, May 1924, pp. 287-289.

Water Powers of Canada, J. B. Challies. Eng. Jl., vol. 7, no. 7, July 1924, pp. 323-358, 44 figs. partly on supp. plate. Their nature, extent and administration, a national review. Paper read at World Power Conference.

Flathead River. Power Possibilities of the South Fork, Flathead River, B. E. Jones and E. E. Jones. Eng. News-Rec., vol. 93, no. 3, July 17, 1924, pp. 96-98, 4 figs. Large reservoir site makes economic development of power possible. Increased height of Flathead Lake objectionable.

WATERPROOFING

Asphalt for. United States Government Master Specification for Asphalt for Waterproofing and Dampproofing. U. S. Bur. Standards, Circular No. 160, Master Specification No. 85, Apr. 8, 1924, 9 pp., 3 figs. Specification officially adopted by Federal Specifications Board on Dec. 29, 1923, for use of Departments and Independent Establishments of the Government in purchase of asphalt for waterproofing and dampproofing.

Coal-Tar Pitch for. United States Government Master Specification for Coal-Tar Pitch for Waterproofing and Damp Proofing. U. S. Bur. Standards, Circular No. 155, Master Specification No. 83, Apr. 8, 1924, 11 pp., 3 figs. Specification officially adopted by Federal Specifications Board on Dec. 29, 1923, for use of Departments and Independent Establishments of the Government in purchase of coal-tar pitch for waterproofing and damp proofing.

WATER TREATMENT

Chlorination. Report on Experimental Use of Chlorine Gas in the Chlorination Plant at Köpenick, I. Reichle and M. Weldert. Gesendheits-Ingenieur, vol. 47, no. 24, June 14, 1924, pp. 237-243. Addition of small quantities of chlorine gas has given good results.

WATER WORKS

Planning. Planning Municipal Water Works System. Can. Engr., vol. 46, no. 26, June 24, 1924, pp. 636-638. Points that have to be considered when town contemplates establishing water works system; services of competent engineer must be secured; pumping plant and distributing system must be large enough for increase in population.

WELDING

Aluminum Castings. Hints for Welding an Aluminum Casting, E. E. Thum. Am. Welding Soc.—Jl., vol. 3, no. 5, May 1924, pp. 26-30, 3 figs. Details of actual practice.

Car and Locomotive Parts. Autogenous and Electric Welding. Ry. Age (Daily Edition), vol. 76, no. 36, June 19, 1924, pp. 1718-1723 and (discussion) 1723-1728, 17 figs. Notes on rolled steel wheels; low-carbon-steel; wrought iron; cast iron; torch cutting; recommendations; regulations for welding. Report of committee presented before Am. Ry. Assn.

Electric. *See Electric Welding.*

Manganese Steel. *See Manganese Steel.*

WHARVES

Steel-Pile. Steel Sheetpiling in Salt Water at Havana, Cuba. Eng. News-Rec., vol. 92, no. 26, June 26, 1924, pp. 1086-1088, 4 figs. Particulars of new bulkhead for wharf consisting of steel sheetpiling topped with a concrete wall which extends 2 ft. below water line; steel piling given two coats of red oxide paint; rock is channeled to receive piles. Notes on construction methods and plant.

WINDING ENGINES

Mines. Electric Winding-Engines, D. Weir. Instn. Min. Engrs.—Trans., vol. 67, Pt. 2, May 1924, pp. 129-143 and (discussion) 143-148, 11 figs. Advantages of electric drive for winders; description of different types of winders; controllers; etc. Winding diagrams.

WIRE ROPE

Manufacture. How Wire Rope Is Manufactured and Used and How Its Life May Be Prolonged in Mine Service, L. W. Bevan. Coal Age, vol. 25, no. 24, June 12, 1924, pp. 872-875, 5 figs. Physical and chemical tests constantly check wire-drawing process; saturated core acts as cushion and lubricant; care of ropes and their application to mine-hoist problems.

Z

ZINC

World Conditions. World Zinc Conditions As At 1st May, 1924, A. J. M. Sharpe. Am. Zinc Inst.—Bul., vol. 7, no. 5, May 1924, pp. 14-16. Zinc market in Germany, Poland, Upper Silesia and Great Britain.

Many Water Powers have been cheaply developed by the use of our

WOOD STAVE PIPE

Many are awaiting development.

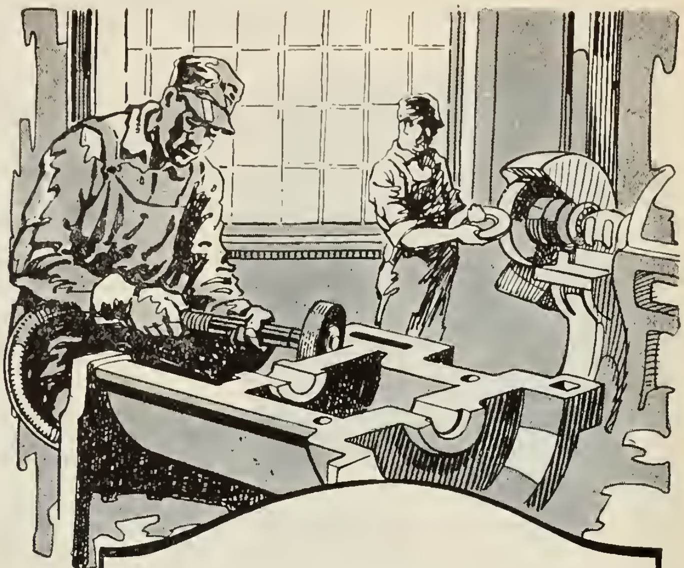
Write us for data on complete installation of our CONTINUOUS WOOD STAVE PIPE made in diameters from 16 inches to 14 ft.

Cheaper than steel pipe. Less friction—Long life. Three distinct advantages—and there are others.

Pacific Coast Pipe Co. Ltd.

1551 Granville St., Vancouver, B.C.

ESTABLISHED 20 YEARS 1904 - 1924



Expert Finishing *on all* Kennedy Castings

EVERY job receives constant inspection during its *progress* through our plants.

The expert finish YOU SEE on Kennedy Castings reflects the perfection of ALL the work put on them.

Send your prints or patterns to Kennedy's when you require sound, clean and accurate castings, no matter for what purpose, or in what size.

Boiler Room of The Bishop Strachan School, Toronto, Ont.

ELESCO Superheaters saved 13 p. c. in Fuel in this small plant.

A little more than three years ago, The Bishop Strachan School of Toronto, Ontario, installed Elesco Superheaters in their two horizontal return tubular boilers. The installation was made without change in any of the existing plant equipment. An immediate improvement in the operation of the turbines followed and no difficulty whatever was experienced in the lubrication of the slide valves of the boiler feed pumps.

The superheaters were designed to deliver 150 degrees superheat at 70 1b. pressure at 100 per cent rating. Since their installation it was found possible to operate the entire plant on only one of the boilers at 50 1b. pressure instead of on both boilers at 70 1b. which previously had been the case. This resulted in an actual average saving of 13 per cent in fuel during the operating months of the year.

And no repairs were necessary after three years of service for eight months in the year. Cleaning and re-rolling tubes is easily accomplished with the Elesco design of superheater.

If your plant is large or small Elesco Superheaters will prove to be a highly paying investment. Our engineers are prepared to tell you why and how.

RELIABLE RADIO BATTERIES

90% OF THOSE WHO TRY THEM---PREFER THEM ALWAYS

The Reliable Radio "A" Battery will surprise you with its long life and low price. Its special hand construction and cloth lining is the secret of its reliable, long-lived energy.

The Reliable "Bluenose" Radio Battery is a less expensive Battery, guaranteed to give equal or better service than Radio "A" Dry Cells of ordinary type.

Reliable Radio Batteries are made in A, B, and C Types and sold by the better class Radio dealers.

For greater economy and satisfaction, specify "Reliable" when buying Radio Batteries.

TENDERS

CITY OF KITCHENER

Sealed tenders plainly marked as to contents, will be received by the undersigned until 5 P. M., Wednesday, September 3rd, 1924, for the supply of material and construction of a reinforced concrete Lock Joint Pipe Sewer 42" and 48" diameter and 4,000 feet long.

Plans and specifications may be seen, and tender forms obtained at the office of the City Engineer.

The City is not bound to accept lowest or any tender.

STANLEY SHUPE, B.A.Sc.,
City Engineer.

DEPARTMENT OF RAILWAYS AND CANALS

WELLAND CANAL

NOTICE TO CONTRACTORS

SEALED TENDERS, addressed to the undersigned and marked "Tender for Repairs to East Pier at Port Maitland" will be received at this office until *12 o'clock noon (standard time), on Wednesday, September 10, 1924.*

Specifications and form of contract to be entered into can be seen on and after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Welland Canal, St. Catharines, Ont.

An accepted bank cheque on a chartered bank of Canada for the sum of $20,000, made payable to the order of the Minister of Railways and Canals, or War Loan Bonds of the Dominion of Canada, to the same amount, or War Loan Bonds and accepted cheques, if required to make up the amount, must accompany each tender which sum will be forfeited if the party tendering declines entering into contract for the work at the rate stated in the offer submitted.

The cheque or bonds thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque or bonds of the successful tenderer will be held as security or part security, for the fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

J. W. PUGSLEY,
Secretary.

Department of Railways and Canals,
Ottawa, August 23, 1924.

Concrete Saves Gasoline

You will find the simple chart, shown above, worth more than a passing glance. It points out a lesson in economy directly connected with every motorist's check book.

The chart shows the average ton-miles per gallon of three types of highway surfaces, as proved by tractive resistance tests conducted by Iowa State University.

Note that a gallon of gasoline carries you more than twice as far on a Concrete Road as on a dirt road and one-third farther than on gravel.

In addition to being skid-proof, rigid and lowest in maintenance cost, Concrete Roads assure a marked saving in gasoline. Their all-around economy goes a long way toward paying for them.

Send for our booklet R-3 which tells many other interesting things about Concrete Roads. Write this office for your copy.

Reads Direct to Ten-thousandths

The Super-Micrometer

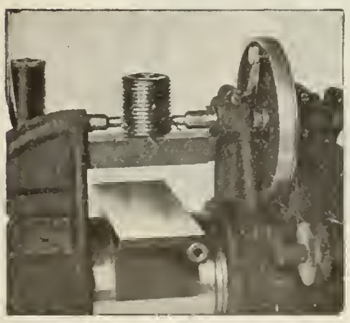
With this new measuring instrument different operators of average skill can make measurements which will agree to the nearest ten-thousandth of an inch.

IN precision manufacturing the ten-thousandth part of an inch is now the accepted unit of linear measurement.

A micrometer in fair condition can be depended upon to measure thousandths, but repeated tests by the most highly skilled toolmakers and inspectors prove that micrometer readings cannot be relied upon to the ten-thousandth.

The P. & W. Standard Measuring Machine is relied upon to sub-divide ten-thousandths but these machines are too fine to place in the shop for general use.

The Super-Micrometer covers the intermediate field because it will duplicate measurements to the nearest ten-thousandth. Simple construction, ruggedness and relatively low price allow its use in the toolroom or workshop where preliminary measurements can be made on work in process, assuring its acceptance by the final inspector.



Measuring a Thread Plug

Accuracy is assured by the use of Standard Inches which are guaranteed permanently accurate to five-millionths of an inch.

The measuring screw is hardened, seasoned, ground and lapped. Our experience in developing the P. & W. Standard Measuring Machines enables us to produce a thread that is accurate under the most rigid and careful methods of inspection.

Whether the work be the making of precision gages or the building of machines to close limits, the Super-micrometer offers a definite help in obtaining the desired accuracy. Measuring Range 0 to 8 inches.

The new Circular No. 291 describes it fully.

Provincial Government Buildings at Edmonton, Alberta

Equipped with genuine Jenkins Valves

No ordinary valves would do for this stately Government Building. Quality was the determining factor so, naturally, the choice was genuine "Jenkins"—the Valves with the quality that is world famous.

High grade materials, coupled with Jenkins design and workmanship make "Diamond" Trade marked Valves the choice where quality is essential.

AN ideal construction for use in large liquid heating applications. Made in three stages of assembly to meet all requirements.

Type "A" is the bare heating element for use where switch box construction is built on the job.

Type "B" is equipped with switch box but no switch, for use on continuous service and to be controlled by service switch.

Type "C" is the complete heater with three heat switch, a popular heater for heating hot water in Apartment blocks and Institutions. It is also used in many forms of Industrial application.

A special 10 Kw. water heater is made for very large installations. Cat. No. W37.

Full particulars will be gladly given on any proposition under consideration.

REQUIRED CAPACITIES FOR VARIOUS TANKS

Diameter of Tank	Length of Tank	Volume Imp. Gals.	Kilowatt Capacity
20″	4′	55.0	3
20″	5′	70.8	3
24″	5′	100.0	5
24″	6′	116.6	5
30″	4′	125.0	5
30″	5′	150.0	7
30″	6′	183.0	8
30″	7′	208.2	10
30″	8′	246.0	10
36″	6′	262.3	10
36″	10′	437.5	20
42″	6′	358.0	15
42″	7′	416.0	20
42″	8′	479.0	20
42″	10′	600.0	25
42″	12′	720.0	30
42″	14′	834.0	35

The above table shows volume in gallons and suitable kilowatt capacities for tanks most commonly used in apartment blocks. To give best satisfaction, tanks should be covered in each case.

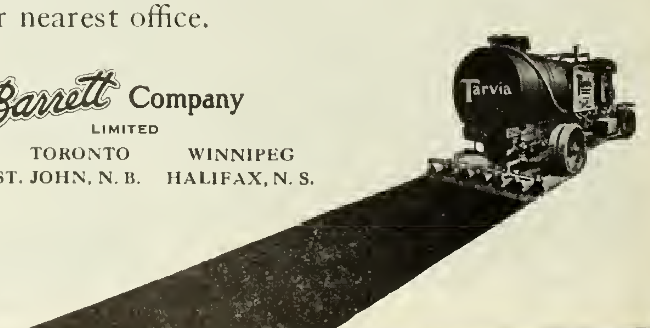
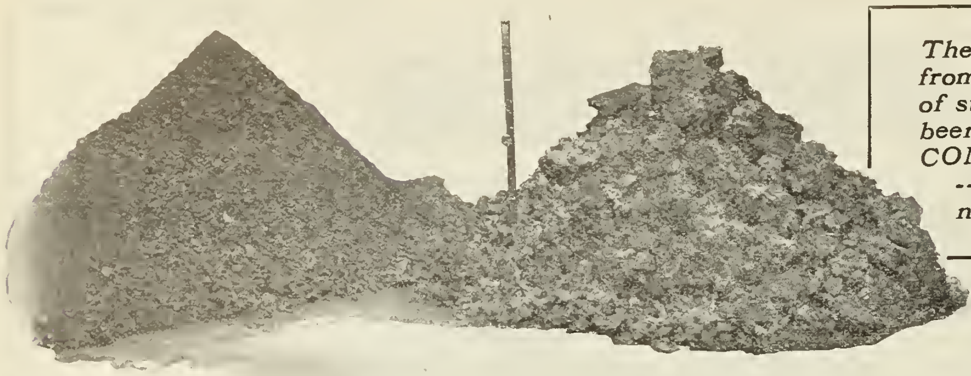
Westinghouse



Tarvia



These two piles of ashes are from the same coal and type of stoker. The left pile has been passed through the COMBUSCO Ash Conveyor ---That on the right has not.

THE COMBUSCO ASH CONVEYOR

THE COMBUSCO ASH CONVEYOR consists of a double chain scraper or drag conveyor moving in a trough containing water, the trough being located under the ash discharge of the stoker. Ashes and clinker fall from the stoker or through the clinker grinder directly into this trough and are quenched and immediately carried along by the conveyor and deposited in a large storage hopper or car.

The Combusco Ash Conveyor, as distinguished from the usual conveyors used for this purpose, operates continuously as opposed to periodic or intermittent operation. It is made in two forms of types—the single and duplex. The conveyor is primarily intended for use with stokers in which the ash is discharged continuously and automatically, such as multiple retort stokers with clinker grinders and travelling or chain grate stokers. It has demonstrated in a practical manner that much of the cost of high basements may be saved—that dust, smoke, hot gas and clouds of steam are unnecessary—that the removal of ashes may be the cleanest job in the plant.

Points Worth Noting

- Dispenses with manual labor.
- Prevents all dust, fumes and heat in the ash tunnel.
- Maintains a perfect air seal in the combustion chamber.
- Improves the efficiency of the boilers by preventing air leakage.
- Operates automatically and continuously.
- Doesn't necessitate that boilers be built above ground, as conveyor can be built in the setting.

Hydraulic Efficiency Tests on 43,000-h.p. Unit by the Gibson Method and the Allen Method

A Description of Tests Carried on Under Operating Conditions.

W. R. Way, B.Sc., Jr.E.I.C.

Chief System Operator, Shawinigan Water and Power Company.

Paper read before the Montreal Branch, The Engineering Institute of Canada, January 17th, 1924.

For economical operation of hydro-electric power stations it is very essential that all the machinery be operated most efficiently at all times. In order to obtain ideal conditions, the percentage of total losses to total output should be kept to a minimum. The losses which occur in hydro-electric power stations may be divided into two classes, namely: — (1) Losses in electrical equipment, such as generators and transformers; (2) losses in the turbine and water passages.

Progress in the art of manufacturing of generators and transformers has advanced to such a stage of development that it is quite common to hear of generators having an efficiency of 97.5 per cent and transformers of 99 per cent efficiency when operated at their rated capacity.

In regard to the hydraulic turbine and water passages such general figures of efficiency cannot be given on account of the fact that so many variables exist. The length and design of the water passages, the available head, the size and type of the turbine and the specific speed of the runner are factors which are generally quite different in various developments. These factors have a direct bearing on the hydraulic efficiency.

Method of Measuring Quantity of Water

The measurement of the efficiency of a turbine may be regarded in the same manner as that of any piece of machinery, namely the measurement of the input and the output. The measurement of the output would suggest using some sort of brake to measure the torque, but on account of the enormous output of present day turbines, it would be practically impossible to provide a brake of sufficient capacity. Furthermore, it is generally impossible to disconnect the generator from the turbine. The output of the turbine, therefore, is usually measured by means of a wattmeter or watthour meter in the generator terminals, a correction being made for the losses caused by the generator.

The input to the turbine necessitates accurate readings of the quantity of water and the head. Many methods are available at the present time for measuring large quantities of water but it will be found on investigation that most of them have such a limited field of application or are so expensive or liable to inaccuracies that their use is prohibitive. Among the numerous methods commonly known may be mentioned the following:—

(1) The weir
(2) Venturi meter
(3) Current meter
(4) Color velocity method
(5) Salt solution, titration or chemical method
(6) Pitot tube
(7) Moving screen

Coincident with the many recent developments in the design and construction of features to improve the efficiency and operation of hydraulic turbines, came the introduction of two vastly improved methods for measuring the large quantities of water required by present day units. These methods are the "Pressure-Time" or Gibson method and the "Salt-Velocity" or Allen method.

Both these methods have been extensively described in the technical press, but in order to appreciate their application in this particular case, it will be necessary to give a general description of the theory of each method and a more detailed description of the application.

Description of Installation Under Test

On October 11th, 1922, the Shawinigan Water and Power Company placed in service, in their No. 2 Power House at Shawinigan Falls, a modern hydro-electric unit of large capacity. The turbine was built by the Dominion Engineering Works at Lachine, Que. The manufacturers' rating of this unit is 41,000 h.p., at 145-foot head at 138.5 r.p.m. It is of the single-runner vertical-shaft type with General Electric thrust bearing. The original Moody draft tube with the short cone is used.

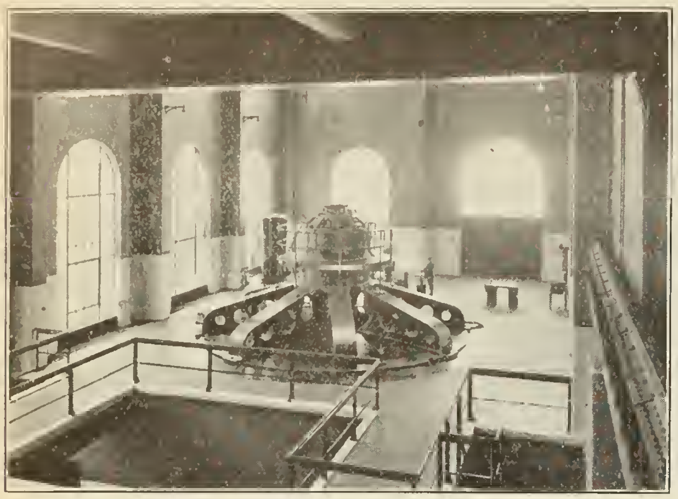

Figure No. 1.—View of 43,000-h.p., Unit Installed at Shawinigan Falls.

The generator was supplied by the General Electric Company of Schenectady, N.Y. The rating of the generator is 40,000 kv.a., at 75 per cent power factor, 11,000 v., 3-phase, 60-cycles. (See figures Nos. 1 and 6).

Tunnel

In order to supply water to this unit, a concrete lined tunnel approximately 500 feet long was constructed. It is of circular cross-section 20 feet in diameter. Approximately 75 feet of the lower portion is lined with steel plate 1⅜ inch thick. At the lower end of the tunnel is a Johnson valve with an inlet of 20 feet in diameter and an outlet of 13 feet in diameter. As the entrance to the spiral casing of the turbine is 14 feet in diameter, a short conical section 25 feet long connects the spiral casing to the Johnson valve.

Inlet

The upper end of the tunnel terminates in a gathering tube which is supplied through five inlets. Four of these inlets are of rectangular cross-section 12 feet wide by 16 feet high, while the fifth inlet is of elliptical section, 11-foot horizontal axis and 16-foot vertical axis. The five inlet tubes vary in length and dimension before joining the gathering tube to the tunnel. The design of the intake was developed by Messrs. R. D. Johnson and P. Wahlman of New York. While the dimensions appear to be very irregular the function of the intake is to cause a uniform flow of water in each of the five inlets, and to accelerate the water gradually from the forebay to the penstock with a minimum of disturbance. This peculiar design of intake presented an unusual case in the application of the Gibson method.

In order to determine whether the unit would meet the guarantee of the manufacturers as regards efficiency, the writer was instructed to conduct efficiency tests on the generator and turbine. The tests on the generator were made jointly by engineers of the General Electric Company and the writer. The deceleration method was used to separate the various losses. Oscillograms were taken to show wave shape and short circuit conditions. It is interesting to note here that the generator showed an efficiency of 97.59 per cent at 35,000 kv.a., 100 per cent power factor, 11,000 v., and at normal speed. However as this paper deals mainly with the hydraulic tests no detailed description of the electrical tests will be given.

The Gibson Method for Measuring the Flow of Water in Closed Conduits

The Gibson method* was developed and perfected by Norman R. Gibson, M.E.I.C. hydraulic engineer of the Niagara Falls Power Company, Niagara Falls, N.Y. The basic principle of this method is found in Newton's Second Law of Motion, which states that "Change of Momentum is proportional to the impressed force and takes place in the direction in which force acts". When expressed in symbols this law becomes:—

$$\text{Force} = \text{Mass} \times \text{acceleration}$$

$$\text{or } F = Ma = \frac{MdV}{dT}$$

where F is the force applied to a body of mass M and $\frac{dV}{dT}$ is the differential coefficient of velocity with respect to time and which is the resulting acceleration or retardation of the moving body due to the action of this force.

A second principle used in this method is the relation between change of pressure and change of velocity of a column of water enclosed in a conduit expressed in terms of the rate at which the change of pressure is transmitted. The transmission of the change of pressure occurs by the propagation of waves and the rate of transmission is the velocity of the pressure waves. (A full description of this principle may be found in Mr. Gibson's paper in the transaction of the American Society of Civil Engineers, page 707, 1920. A more detailed description of the Gibson method was given in New York on December 6th, 1922, by Mr. Gibson before the American Society of Mechanical Engineers.)

In applying these principles practically, consider a typical hydraulic installation consisting of a penstock of length L and mean area A, through which water is passing at a velocity V. The velocity may be kept constant by controlling the turbine gates. Assume the turbine gates are closed gradually in a time T so that the velocity of the water is gradually reduced to zero when the gates are finally closed.

During the closure of the gates, the pressure at a given point rises and after the gates are closed the pressure falls and rises in periodic waves until damped out by friction. This rise of pressure as the gates are being closed is the result of the forces exerted to stop the flow of the mass of water in the pipe. If, therefore, the mass of the water in the pipe is known and the time taken to stop the flow and the average force required in doing so are measured, the original average velocity of the column of water before the closure may be readily determined.

In order to show this in a condensed form, it will be more convenient to resort to symbols.

Let a = Mean area of water passage square feet.
L = Length of pipe in feet.
V = Mean velocity of flow of water in pipe.
T = Time taken to stop flow in seconds.
P = Average pressure in feet of water exerted in stopping the flow in time T.
g = Gravitational constant, — foot-pound units.
w = Weight of cubic foot water.

The mass of water in pipe = length × area × $\frac{w}{g} = \frac{L\,a\,w}{g}$

Average rate of retardation = $\frac{V}{T}$ *f. p. s. s.*

Average force exerted to stop flow = pressure × w × area = $P\,a\,w$

Substituting the original formula of:—

$$F = M\frac{dv}{dt}$$

$$P\,a\,w = \frac{L\,a\,w}{g} \times \frac{V}{T}$$

*Method and Apparatus Pat. Canada 1919-1920, U.S. Oct. 13 and Nov. 22, 1921 Sweden 1923, Norway 1923, other patents applied for in foreign countries.

$$\text{or } V = \frac{P\,g\,T}{L}$$

It is necessary, therefore, in order to find the original velocity to determine $P\,g\,T$ and L. L is the measured length of the pipe, while g is the acceleration due to gravity, which is well known. The quantities P and T are, therefore, the ones required. It is not necessary, however, to determine separately the value of P and T and what is done is to produce a diagram, the net area of which is proportional to the product of P and T.

It will now be in order to describe the apparatus devised by Mr. Gibson which is used to obtain the diagram.

Apparatus

The apparatus consists of U-tube, one end of which is connected to a ¼-inch piezometer plate on the penstock while the other end is open to the atmosphere by means of a ¼-inch riser of uniform bore steel tubing. The length of the steel riser depends, of course, in the difference in elevation of the forebay and of the tap in the penstock. On the lower portion of the other side of the U-tube, a glass tube of uniform bore is placed and held in position by suitable stuffing boxes.

Sufficient mercury is poured into the U-tube so that under running conditions, the pressure in the penstock will maintain the level of the mercury at a point about 3 or 4 inches from the upper end of the glass tube. It is very essential that all air be excluded between the mercury column and the penstock connection. Small valves and blowoff cocks are provided for this purpose.

It may be seen, therefore, that the difference in level of the mercury column is a measure of the pressure existing in the penstock at the point where the tap is made. Changes of pressure in the penstock produce corresponding changes in the level of the mercury column. If the ratio of the areas of the riser and glass tube be known, it follows that records showing changes of level of the top of the mercury in the glass tube will bear a direct relation to corresponding pressure changes in the penstock itself.

In order to record such pressure changes, photographic methods are used. A box is used containing a photographic lens and manually operated shutter, and a pendulum which may be adjusted to beat seconds. One end of this box has a longitudinal slot with a metal shrouding which is clamped to the glass portion of the U-tube. The other end of the box is slotted also and is arranged to receive a revolving drum which may be revolved in a light proof cylinder. On the outside surface of the revolving drum there may be attached, as required, a sensitized photographic film in which the pressure time diagram is to be recorded. Suitable shutters are provided so that transportation of the "loaded" film holders may be made from the dark room to the point where the apparatus is set up.

The drum to which the film is secured may be revolved at a uniform rate by means of a small mechanical motor through suitable pulleys. Constant speed is maintained by means of a governor and flywheel. A mercury vapor lamp is located opposite the glass tube so that light may pass through the water to the film but is stopped by the column of mercury. Therefore, in combination with the revolution of the drum with the film attached and the rise and fall of the mercury column due to changes in pressure in the penstock, an actual photograph is obtained showing the change of pressure conditions, as they actually exist in the penstock.

Calibration

The calibration of the apparatus is performed just before the test with the equipment set up in place. A film is wrapped around one of the drums and the drum placed in the holder and secured in its position on the box. The valve connecting the penstock to the U-tube is closed, an exposure is made on the film and the distance of the top of the mercury from the top of the riser is measured by means of a special micrometer to a 1/1000th of an inch. By means of air pressure the mercury column is depressed slightly and a similar set of measurements taken. This procedure is continued in successive intervals until the working range of the mercury in the glass tube has been covered. The film is then taken out and developed. Now the changes in level of the mercury in the riser tube are divided by changes in level of the mercury in the glass tube as scaled off the film, the quotient being the average value of R or the ratio of the areas of the two tubes. This method of calibration also includes any corrections that might be necessary for parallax or variation in scale.

l = length of diagram in inches.
M = s.p.g. of mercury.
S = value of 1 sec. in inches on diagram.
r = No. of inches on diagram representing 1 foot water $= \frac{1}{12}\left\{M(R+1) - 1\right\}$

$$\text{Now } P = \text{mean rise of pressure} = \frac{\text{area of diagram}}{l \times r}$$

$$T = \frac{\text{length of diagram}}{\text{value of 1 sec. in inches on diagram}} = \frac{l}{S}$$

Substituting these values in the former equation for velocity.

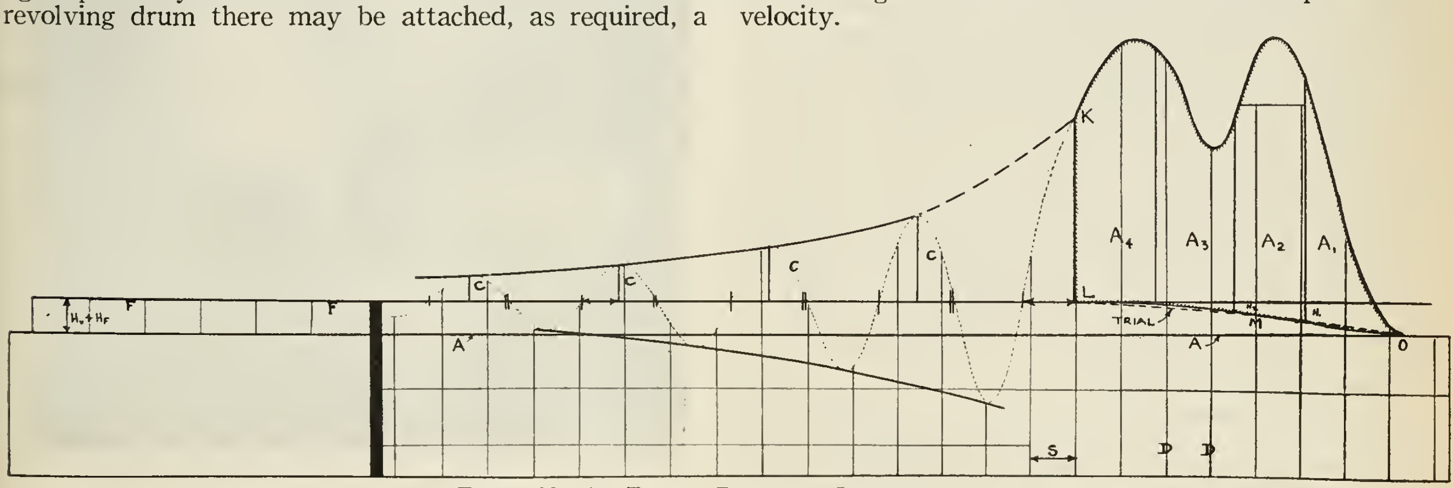

Figure No. 2.—Typical Diagram, Gibson Method.

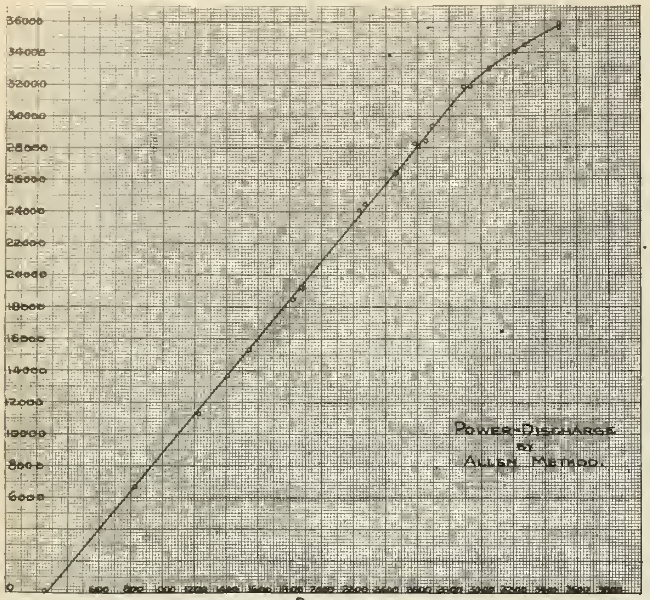

Figure No. 3.—Power Discharge Curve by Gibson Method.

$$V = \frac{P\,g\,T}{L} = \frac{A}{lr} \times \frac{g}{L} \times \frac{l}{S} = \frac{Ag}{r\,s\,L}$$

$\frac{g}{r} = K$ for a given glass tube and riser.

Therefore $V = \frac{K\,A}{S\,L}$

Where A = net area of the diagram in sq. in.
K = a constant.
L = length of penstock along from Gibson tap to point of relief in forebay.
S = value of 1 sec. in inches on diagram.

The quantity = Q = weighted mean area of penstock ×

$$V = a_1\,V = \frac{K\,A\,a_1}{S\,L} = \frac{K\,A}{S \Sigma \frac{Lv}{q}}$$

Where q is an assumed quantity and v the velocity based on the assumed q at the various sections if any in the penstock, weighted in respect to the length of each section.

The actual operation of recording one of these diagrams during a test on an hydro-electric unit is very interesting. Observers are stationed for reading head and tail race, gate opening, power output, etc. A bell signal system, controlled by the operator of the Gibson apparatus, ensures that all readings will be synchronized. The operator of the Gibson apparatus places the loaded film holder in position, the shutter on film holder and lens being closed. The governor is now adjusted so as to keep constant load on the generator. At a given instant, the operator rings two bells and all parties concerned begin to take readings. Approximately two minutes later, conditions still being steady, the operator opens the film holder shutter, starts the motor and pendulum and opens the shutter on the lens. About two seconds later he rings one bell. This is the signal for the switchboard operator to close the turbine gates. These gates are closed in 8 to 20 seconds, depending upon conditions, the load being automatically transferred, the other generators operating in parallel.

During the operation the pendulum keeps swinging to and fro in front of the lens, cutting off of the light each second and causing a break to be recorded on the film at regular intervals. This shows how accurately the time may be obtained as one second may be recorded as one inch or more in length.

After the turbine gates are closed, a break may be observed in the action of the mercury column. Period oscillations then appear and these are recorded for a few seconds. The whole operation lasts about one-half minute. The manually controlled shutter on the lens is then closed. When conditions have become quiet a short exposure is made under the normal static head and two bells are rung to notify the observers to discontinue taking readings and for the switchboard operator to open the gates and take up load again so that the process may be repeated. The shutters are closed and the film taken to the dark room for developing. In a similar manner several diagrams are made for different values of load, gate opening, etc., sufficient points being obtained so that an accurate efficiency curve may be drawn later.

When the films have been developed, blueprints are made from them, leaving a suitable margin on the blueprint so they may be secured to a drawing board. A typical pressure time diagram is shown in figure No. 3. The dark space denotes the mercury in the glass tube. The line of division between the dark and light spaces shows the movement of the mercury column, *A.A.* is the running level. *O* is the beginning of closure and *K L* the end of closure. *C.C.* shows the damped waves which follow the closure. The lines *D.D.* denote the spaces made by the seconds pendulum as it passes in front of the lens. These spaces denote time in seconds. The line *F.F.* is the static line taken a few seconds after the closure when the column of water is at rest. It denotes the final position of the mean line of the damped wave.

Delineation of the Pressure Time Diagram

In order to determine the mean velocity of the water from the pressure time diagram, certain graphical methods must be employed. The running level line *A.A.* and the static line *F.F.* are drawn parallel to the line on the blueprint formed by the cross hairs. The end of the closure is determined from an examination of the damped harmonic pressure waves which follow the closure. The rate of damping may be shown by lines touching the peaks of these after waves. The equation for such a series of curves is $Y = e^{\left(\frac{-r}{K}\right)}$ A curve has been prepared using various values of K. By scaling off the heights of

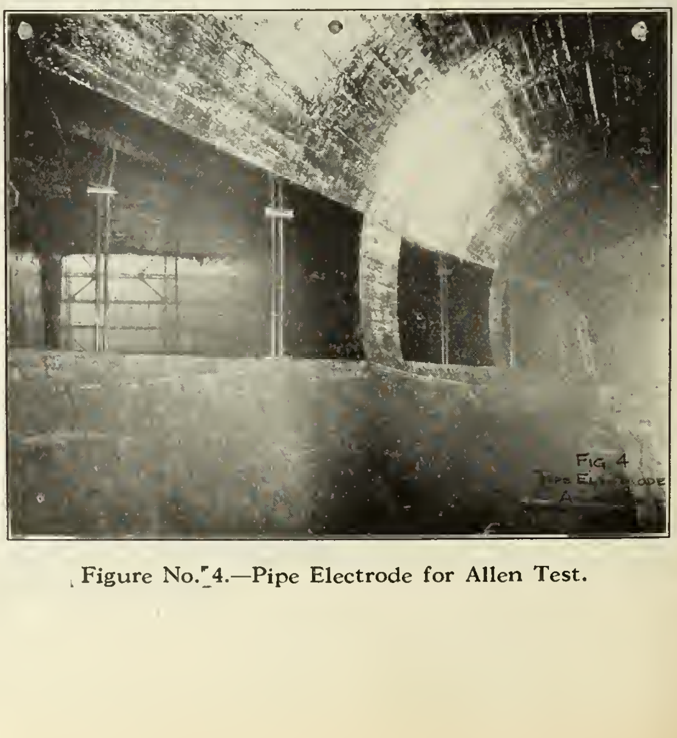

Figure No. 4.—Pipe Electrode for Allen Test.

two or more of the damped waves from the static level line and taking their ratio which shows the rate of damping, the horizontal distance to the ordinate through K may be readily found. This marks what is called the end of the diagram or in other words the beginning of the first damped wave.

Recovery Line

The next problem is to determine the behaviour of the recovery line of friction and velocity heads. A number of vertical lines are drawn dividing the diagram into the areas A_1, A_2, A_3, A_4, etc. A sum of these areas may be called "A". A trial recovery line *O.M.L.* is drawn. It may be shown that when ½ the velocity is destroyed, only ¼ the velocity and friction heads remain. It is simply a matter, therefore, of taking the area in small units and using the above relation to determine lengths h_1, h_2, h_3, etc. After one or two trials the recovery line is readily determined. The sum of the areas a_1, a_2, a_3, a_4 may be obtained by means of a planimeter.

Surges

In certain cases it will be necessary to correct the total area for the effect of surges or disturbances in forebay or surge tanks at the entrance to the conduit. This may be readily done by observing or recording the height or duration of such surges and substracting a corresponding area from the area A. If the surges are very pronounced the conduit may be tapped at two points below the intake or surge tank and a differential diagram obtained. The surges in this case will not have to be taken into account on the diagram. Furthermore, if these two points be located at sections of equal area in the penstock, the velocity head will not appear on the diagram. This is called the differential application of the Gibson method.

Corrections in Area

The gross area of the diagram having been obtained, certain corrections are necessary to find the net area. A correction for the width of slot must be made. This is done by scaling off one side of the diagram the vertical projections of all the upward strokes and multiplying total by 1/32 inch which is the width of slot. This area must be substracted from the gross area.

In regard to the blueprint, stretching or shrinking is bound to occur, and this must be allowed for. The film is taken as correct and in the case of stretching, the gross area after correcting for slot width must be decreased in the proportion of the width of the film to width of blueprint.

Having the net area of the diagram the quantity of water is obtained from the formula given previously.

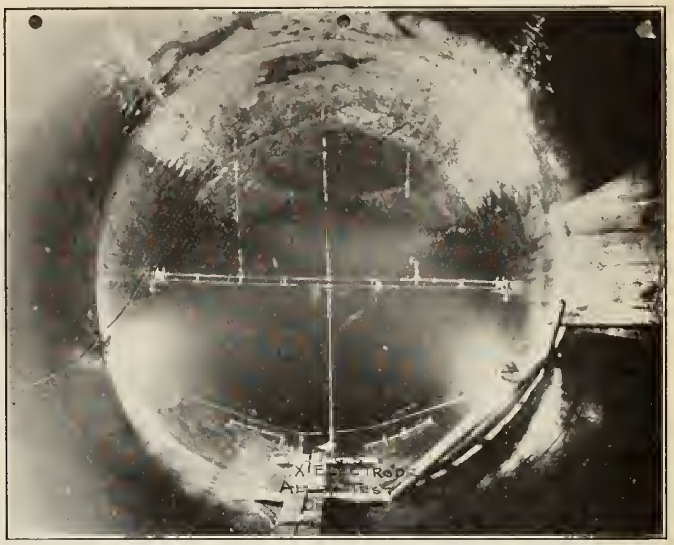

Figure No. 5.—Electrode "X" for Allen Test.

$$Q = \frac{KA}{S \sum \frac{Lv}{q}}$$

Leakage

The amount of leakage through the turbine gates after closure is determined previous to the test by closing the head gates and turbine gates and taking observations of penstock pressure against time. The rates of discharge may be calculated under falling head conditions and the rate of discharge under full head exterpolated.

Where a Johnson valve is available, the valve may be cracked sufficiently to allow the leakage through the turbine gates to take place and at a given instant the valve is closed and a diagram taken on the Gibson apparatus. Since the leakage through the Johnson valve is negligible when closed, the area of the diagram when delineated will represent the leakage under full head.

The leakage should be added to the "quantity" as found by means of the equation in the preceding paragraph.

Loss of Head

The distance ($Hv + Hf$) between the running and static lines when referred to the proper scale, is the sum of the velocity head at the point of tapping and the friction head from the forebay to the tap.

The velocity head may be substracted from the sum since $Hv = \frac{V^2}{2g}$ where V = velocity at the point where

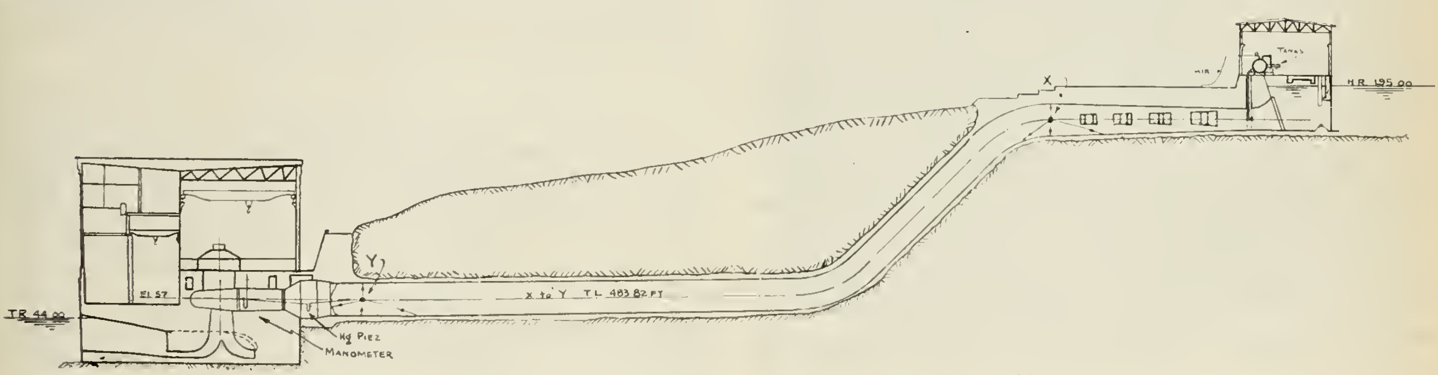

Figure No. 6.—General Arrangement, Salt Velocity Test.

the Gibson tap is placed. The remainder is the loss of head by friction which should be substracted from the gross head to give the net head at the turbine.

The efficiency of the turbine may be, therefore. calculated in the usual manner.

In testing this unit by the Gibson method which was accepted by both parties, the Gibson apparatus was set up in the testing chamber at station 125.50 about 10 feet upstream from the Johnson valve. In the Gatehouse the surge recorder was set up in the middle bay to obtain an average value of the surge so that the diagrams could be corrected.

Physical Dimensions of Conduit

On account of the nature of the water passage, it was found more convenient to determine $\Sigma\frac{LV}{q}$ rather than the average area and length. An arbitrary quantity of 2,700 c.f.s. was chosen and the quantity of water discharged by each inlet was assumed to be equal or 540 c.f.s. $\frac{LV}{q}$ was calculated from the Gibson apparatus to the centre line of the racks for each inlet and the total divided by 5 to obtain the average value. $\Sigma\frac{LV}{q}$ was found under these conditions to be 1.804. It was later found that the flows in the various inlets were unequal to the extent of 5 per cent. On reviewing the calculations $\Sigma\frac{LV}{q}$ was found to be 1.807, a difference of only 1/6 of one per cent showing that unequal flows in the inlet had little effect on the true value.

It was intended to check the above results by the differential application of the Gibson method but due to the cold weather it would not have been practical as a water pipe extending 500 feet on the surface of the ground would have had to be laid and it undoubtedly would have frozen.

Head Readings

Wooden gauges were set up in suitable locations in the head race and tail race to obtain the gross head. The net head was obtained by substracting the loss of head in the penstock and Johnson valve from the gross head. The loss of head in the penstock and intake was obtained from the Gibson diagrams.

The loss of head in the Johnson valve and approach to the spiral casing was measured by means of a mercury piezometer, one end of which was tapped to the U-tube of the Gibson apparatus while the other end was connected up to 4 piezometer plates immediately in front of the spiral casing.

$$H = \text{friction loss feet} = \text{defl. hg. in ft.} \times 12.58 - \frac{Q^2}{2g}\left(\frac{1}{A_1^2} - \frac{1}{A_2^2}\right)$$

Output Readings

Standard indicating and integrating wattmeters were used to obtain the output. The indicating meter was read every 10 seconds while the integrating meter which was a rotating standard was read using a stop watch and snapswitch for 30 seconds to one minute immediately preceding the run. All the meters and metering transformers were calibrated by the meter engineer at the conclusion of the test.

Load Conditions

To minimize the disturbance which would be caused to the large synchronous load and paper mill load connected to the Shawinigan system, when the load on this unit was to be dropped, it was arranged to operate the 43,000-h.p. unit in parallel with two 15,000-k.w. generators on an isolated system. For this purpose use was made of an electric steam generator. On this account the load was limited to 33,000 k.w. which corresponded to 0.73 gate opening.

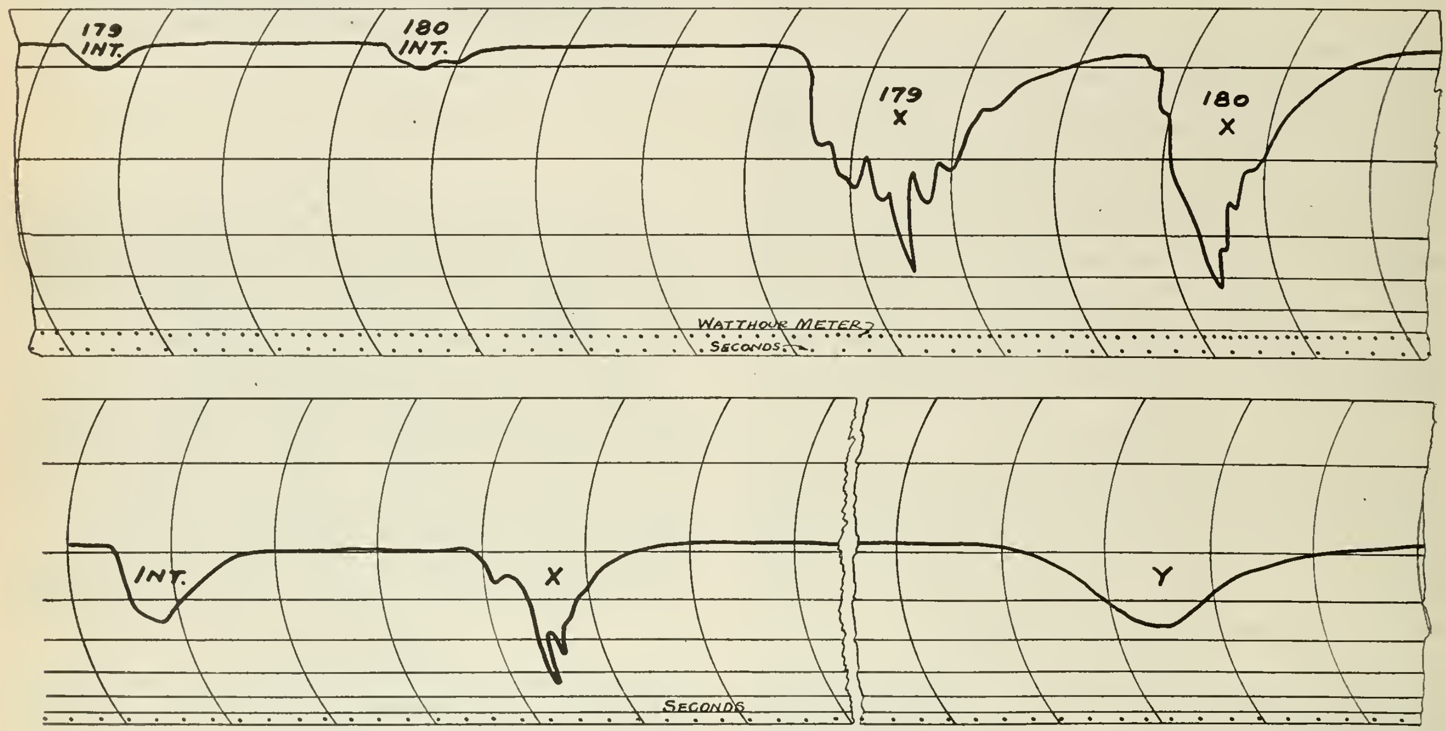

Figure No. 7.—Sample Curves Obtained by Salt Velocity Method.

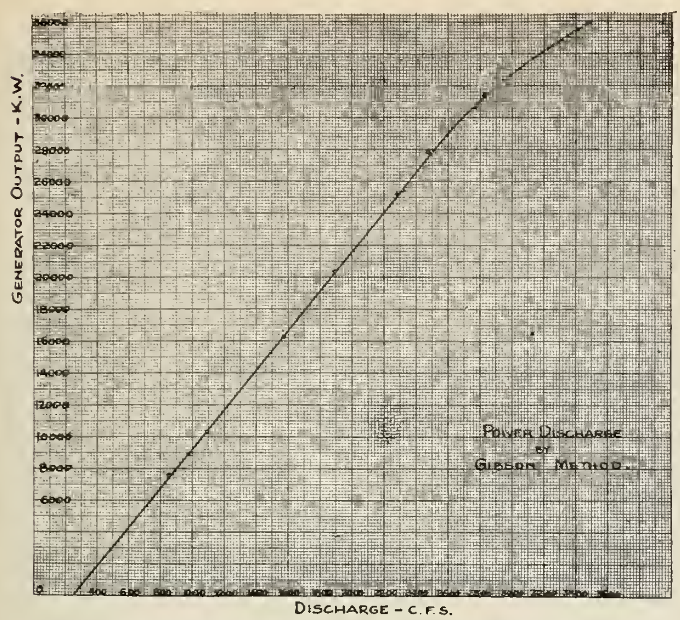

Figure No. 8.—Power Discharge Curve by Salt Velocity Method.

Gate Opening

The gate opening was measured on the operating piston of the governor engine. This had been previously calibrated against calipered readings between the guide vanes so that true gate opening readings could be secured.

Due to the limited time at our disposal only eleven runs could be made. The actual time in making these runs was three hours. The apparatus was set up and the test completed in the field in less than 24 hours.

The essential points brought out by this test were as follows:—

1. The maximum turbine efficiency was found to be 91.0 per cent.
2. The turbine shows very high part gate efficiencies.
3. The maximum overall efficiency was found to be 88 per cent.
4. The total loss of head from turbine to head race at the economical point of operation was measured to be 1.8 foot.

Test by Salt Velocity Method

Since at the time the Gibson test was being made on the 41,000 h.p. unit, we were conducting hydraulic tests on two other plants in the vicinity under the supervision of Prof. Allen, it was considered inadvisable to miss the opportunity of a comparative test. The salt velocity test was conducted, therefore, about eight days later.

General Description

The salt velocity method for the measurement of water in large conduits has been developed during the last four years by Prof. Charles M. Allen, Head of the Hydraulic Dept. of Worcester Polytechnic Institute, Worcester, Mass. After exhaustive experiments in the laboratory and considerable field work, Prof. Allen has brought the method to a state where it may readily be adopted for commercial use.

The principle of this method is that salt in solution will increase the electrical conductivity of water. If a quantity of salt solution can be quickly released at the entrance to a closed conduit, the passage of this solution may be determined by one or more pairs of electrodes inserted in the stream flow further down the conduit. A graphic ammeter may be used for recording the passage of the salt solution.

The passage of the salt solution is accurately timed and knowing the volume of the conduit between the electrodes, the discharge may readily be calculated since volume (cu.ft.) over time (sec.) = cu.ft. per sec. No empirical coefficients or corrections are necessary for accurate results. (A full description of the experimental and field work in connection with this method was presented on December 6th, 1923, before the American Society of Mechanical Engineers at New York by Professor Allen.)

Apparatus

Considering the requirements just given, it was necessary in testing this unit to provide suitable equipment.

Salt Introduction

The apparatus for the salt introduction was installed in the gate house and consisted of a 300-gallon open top mixing tank connected by hose to the gate house water supply and to a 1,200-gallon pressure tank. A 4-inch pipe led from this pressure tank through five 3-inch pipes to ten 2½-inch pipes which terminated at the centre line of the inlet openings in ten 2½-inch pop valves. A 4-inch quick opening valve and five 3-inch valves controlled the distribution of salt solution to the inlet openings. Each of the inlet openings were, therefore, equipped with two pop valves. One pop valve in each bay was equipped with a short electrode in order to denote the instant the charge of brine was introduced into the water. These electrodes were numbered 1, 2, 3, 4 and 5, to correspond to the number of the bay in which it was located.

Pipe Electrodes

At the end of inlet tubes Nos. 2, 3, 4 and 5 two pairs of pipe electrodes were installed. This made eight pairs of vertical electrodes which were designated *A* to *H* inclusive. These electrodes were put in so that the distribution of flow in the complete intake could be determined. The pipe electrodes consisted of extra heavy iron pipes 1½ inch diameter, 1½ apart. The ends of the pipe were fitted into hardwood blocks which had previously been soaked in oil to prevent absorption of salt and surface leakage. The pipes and hard wood blocks were wedged into position.

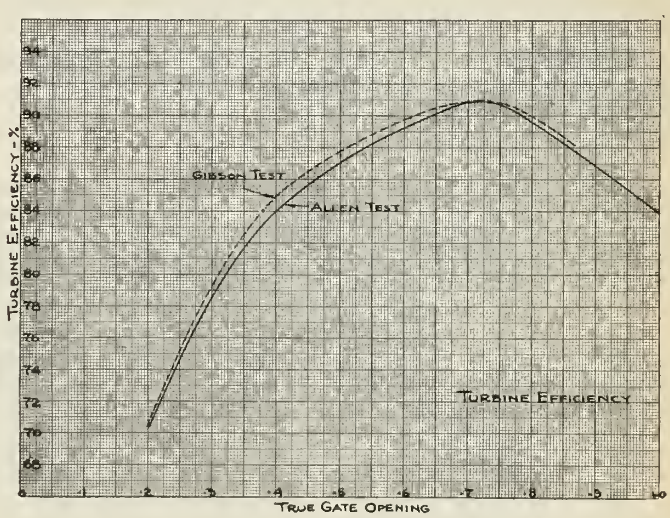

Figure No. 9.—Comparative Efficiency Curves by the Two Methods.

Individual wires were run to each pipe and the completed wiring brought up through conduit to the gatehouse floor. It will be seen that in measuring the flow in each bay salt was introduced into that bay only. As the salt left the pop valve, its passage was recorded on the meter and as it passed the pipe electrodes its passage was again recorded. The time and volume being known the flow in that bay could be readily calculated.

For No. 1 bay, of course, the distance was less than 6 feet, and, therefore, the time was too short to be measured by this method. The flow through this bay was obtained by substracting the sum of the quantities through Nos. 1, 2, 3 and 4 bays from the total discharge, the load being maintained steady.

Main Electrodes

At the junction point of the inlet and the tunnel was located a horizontal electrode *X*. At the lower end of the penstock 483.82 feet below was located a similar electrode *Y*. The general arrangement is shown in figure No. 4. The electrodes were connected in parallel electrically. Each of these electrodes consisted of two steel bars 4 inches by ½ inch, 19.8 feet long, spaced 4 inches apart by porcelain bus bar insulators. Rubber packing was used throughout to prevent chipping of the porcelain when the bolts and turn buckles were tightened. The supports were made of 8-inch by 8-inch by 1-foot angles securely bolted to the inside of the tunnel. Insulated guy wires were extensively used to obtain rigidity and for reasons of safety. The volume of the penstock between *X* and *Y* was calculated to be 152,000 cubic feet.

Electrical Arrangements

All the electrodes were connected in parallel through single pole knife switches to a common bus, one side of which was connected through a Bristol strip chart recording ammeter and a Westinghouse watthour meter. The current used was 110-volt, 60-cycle. The chart on the recording mechanism was arranged to be driven from a variable speed motor so that the most suitable chart speed could be obtained.

Time

The time was recorded on the chart by means of a contact making seconds pendulum and a spark coil. At the lower extremity of the seconds pendulum a pair of permanent magnets were secured which lifted up a small armature at each passage or at intervals of one second. The spark coil, therefore, punctured the chart each second and a suitable graphic record was obtained.

Communication between generator room and gate house was maintained and readings synchronized by connecting up a portable telephone set.

Piezometer across Johnson Valve

A mercury piezometer was connected across the Johnson valve in order to calibrate it for use as a Venturi meter, so that when it is deemed advisable a recording water meter could be installed to obtain a continuous record of the input to the turbine.

Net Head

The net head was measured by means of a mercury manometer located one foot upstream from the entrance to the scroll case. Temporary board gauges were used to obtain head and tail race readings.

Output Readings

The generator output readings were obtained in precisely the same manner as has been already described for the Gibson test.

Nature of Test

Including trial shots, 265 individual tests or charges of salt solution were used and these were grouped into 50 runs of from 1 to 9 shots each. Figure No. 7 shows example of the charts obtained. The time of passage of the salt solution between electrodes was computed by counting the seconds spaces and fractions of seconds between the centres of gravity of the two curves.

In order to determine the centres of gravity quickly and accurately, a watthour meter was inserted in the circuit. On the shaft of this watthour meter there was attached a 24-segment commutator connected to a second spark coil. Normally with a certain *initial* reading the watthour meter disk would rotate at constant speed and a series of holes would be punctured in the paper at regular intervals. If the current through the ammeter tended to increase, the speed of the watthour meter and, therefore, the number of the punctures would increase in direct proportion. Therefore, having the curve practically translated into a straight line, it was an easy matter to determine the centre of gravity quickly and accurately.

Distribution of Flow in Intake

During the test, at three gate openings, 45 per cent, 66 per cent, and 75 per cent, it was possible by holding the loads steady and injecting salt solution in one inlet at a time to obtain the time of passage between the introduction and pipe electrodes and between *X* and *Y*. By this means the percentage of water that each inlet delivered to the main penstock was readily obtained so that the distribution could be calculated. The results show the following distribution of the total:—

Inlet No. 1	—	19.5%
" 2	—	21.5%
" 3	—	22.3%
" 4	—	20.0%
" 5	—	16.7%

The variation in the flow through these inlets may be partially accounted for by the presence of part of an old crib in the forebay which could not be excavated very readily.

For six different runs and five different gate openings simultaneous curves were obtained for the introduction electrodes, *X* and *Y*. The accuracy of the Salt Velocity method was well demonstrated under these conditions as the variation in discharge observed between the introduction electrodes and *X* and between *X* and *Y* was less than one per cent in each case and the average for the six runs checks exactly. The following show the results obtained.

Run No.	Q. Int. to X.	Q. X to Y.	Variation per cent
10	2655	2651	+ 0.2
10A	2618	2604	+ 0.5
11	1884	1891	— 0.4
11A	1874	1891	— 0.3
12A	1595	1584	+ 0.7
16	2904	2924	— 0.7
		Average	0.0

The main points brought out by the Salt Velocity test were:—

1. The maximum overall efficiency is slightly over 87 per cent at 0.72 gate opening.
2. The maximum turbine efficiency is 90.9 per cent at 0.70 gate and 85 per cent full load.
3. The Johnson valve may well be used as a Venturi meter to obtain a continuous record of the flow of water to the unit under steady load.

In reviewing in a general way the tests on this unit, the following points should be noted:—

1. Accuracy. The curves, (see figure No. 9), show the turbine efficiency by both methods. The maximum discrepancy is one per cent but this is confined to only a portion of the curves. The values are practically identical near the point of maximum efficiency.
2. The power discharge curves, (figures Nos. 3 and 8), show how consistently the points form a smooth curve. In the salt velocity test each point represents the average of 1 to 10 values.
3. No serious inconvenience was caused to the load on the system due to these tests.
4. The tests on the intake by the salt velocity method show the remarkable accuracy obtained even with very short and irregular water passages.
5. The choice of either of these methods for measuring the water used by an hydro-electric unit may only be made after a complete study of the local conditions.

Pulverized Fuel for Canadian Locomotives

A review of the Possibilities of Economy in the Use of Fuel for Railway Purposes

A. J. T. Taylor.

President, Combustion Engineering Corporation, Limited, Toronto.

Paper to be presented before the Ottawa Branch, The Engineering Institute of Canada.

Burning coal in a pulverized form has been thoroughly developed and is now widely used for the generation of steam in industrial boiler plants, and in this application has demonstrated its dependability and high efficiency, but in the use of pulverized coal on locomotives, where the possibilities of saving are much greater than in standard power plants, the development has been retarded by a series of circumstances.

During the war when the United States government took over control of the American railroads, five important roads were conducting tests with locomotives which had been equipped to burn pulverized coal, and one of these was making preparation to equip twenty Consolidation locomotives. Government control and war demands made it impracticable to continue this work and it has not since been revived. However, the wide interest in fuel conservation and the great possibility for economy presented by this method of firing would seem to make the time propitious for a resumption of the work.

Fourteen Consolidation locomotives on the Central Railway of Brazil have been equipped to use pulverized coal and have been in operation since 1917. The Imperial Tiawan Railroad in Japan has three so equipped and the Imperial Government Railways have one on order.

Essentials of Pulverized Fuel System

One of the essentials of a pulverized fuel system for locomotives is the coal preparation plants, which should be located at convenient divisional points, and in which the raw coal is pulverized by means of mills, and, in cases where the coal has a high initial moisture content, is first dried before being pulverized. The pulverized coal is then stored in suitable bins where it can be fed by gravity to the locomotive tenders.

The structural changes in apparatus necessary on each locomotive consist essentially of a specially designed closed pulverized coal bin on the locomotive tender, suitable fuel feeding device which is easily driven by a small steam turbine, and a turbine driven air pressure set which conveys the powdered fuel from the bin on the tender to the burner located near the bottom of the fire box. Very few changes are required in the locomotive fire box. The whole layout of a typical Lopulco locomotive system is illustrated by figures Nos. 1 and 2.

It is essential that all the apparatus be rugged and built for continuous service. Altogether its operation is extremely simple, and when a number of engines on a division are equipped it may be expected that no unusual operating difficulties will develop and many of the present inconveniences and abuses will be abolished.

The firing requires no manual effort and is accurately controllable by the fireman from his seat. The team work on the part of the engine driver and fireman permits a locomotive to be put over the division with the minimum possible fuel requirement, as the fireman can in every instance anticipate the action of the engine driver, so that full boiler pressure can be maintained under all conditions and without waste of fuel.

In general, what is desired by the operating department of a railway is motive power in the most flexible form. It is intended, in what follows, to indicate how

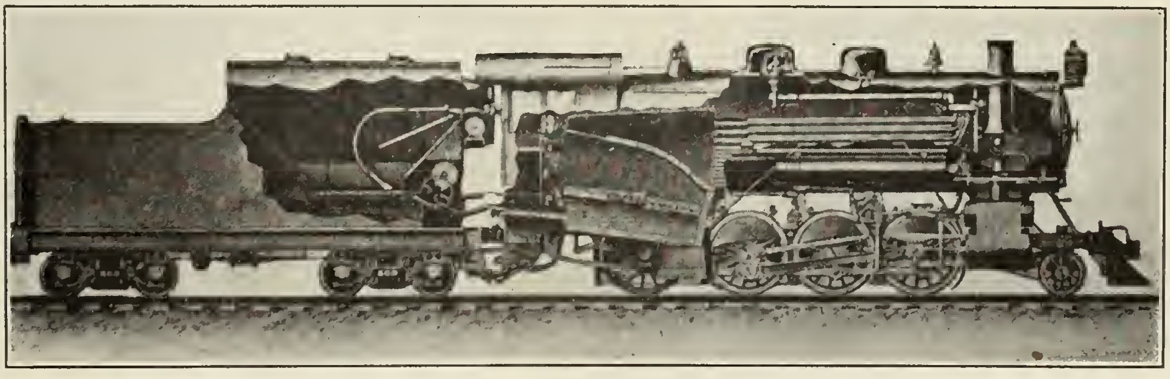

Figure No. 1.—Explanation of Lopulco Pulverized Fuel System for Locomotives.

the use of pulverized fuel, in actual service, would fulfill the above condition.

Regulation of Fuel for Any Service Demand

The amount of fuel fired, per unit of time is under the direct and constant control of the fireman. Each fuel feeder has a capacity range of from 500 to 3,000 or more pounds of fuel per hour, and as from one to five of these feeders may be applied to a locomotive according to its size, and as any number of these feeders may be operated simultaneously, it will be seen that the total amount of fuel required can be regulated to cover any service demands made upon the boiler up to practically the capacity of the injectors. The fuel burns completely immediately as it is introduced into the furnace regardless of the amount fired, provided always that more is not fed than the boiler needs. When the work of the engine eases off the fuel supply can be at once reduced accordingly, and on long drifts or where the train is set off along the road, the supply may be stopped entirely, thus putting out the fire. This flexibility of steam generation has been demonstrated in regular service by the heaviest Consolidation type of locomotive ever built, operating under exceptionally heavy train loads.

Availability for service on call is much enhanced by the use of pulverized fuel. Where engines are required to go out on short notice, the elimination of fire and ash pan cleaning is a great advantage, both in time and labour. A pulverized fuel burning locomotive can be on the train, ready to go, in one hour from the time the fire is started, under ordinary engine-house conditions.

Delays at the fueling plant will not be of moment as fuel is now taken at an average rate of about ten tons in from ten to twelve minutes, and this can be accelerated by enlarging the fueling outlets. It should also be borne in mind that this fuel does not freeze in the bins and make the fueling of engines the very difficult operation which it now often is during the winter months.

Safety in Operation

Safety in train operation is enhanced by the fact that the fireman rides his seat practically over the entire road, and can and should devote a large part of his attention to track and signals. There is little noise from the operation of the apparatus to distract attention of the crew from their other duties, and the glare from the firebox door, especially at night when it sometimes seriously hampers track observations, is eliminated. The fireman's duties, when the train is once on the road, are, in so far as the firing is concerned, of such relatively simple nature that many of them can be performed almost without taking his eyes from the track. After a little practice, work of this kind becomes almost automatic with a man, and the amount of physical and mental labour required is so small that the fireman is able, at all times, to assist the engine driver in whatever way is desirable to enhance the safe and speedy handling of the train. We may go further, however, as regards safety, and say that the use of pulverized fuel will react to give us higher grade engine drivers in the future than we could expect if the laborious hand-firing methods are continued. Detailed explanation of the Lopulco System applied to locomotives.

Figure No. 2.—Section of Engine showing Pulverized Fuel Installation.

modern big locomotive hand-fired is not the most attractive proposition in the world for any young man, and mechanical stokers on locomotives are not in general use.

These notes are not purely theoretical, as there are a sufficient number of engines which have been running for a long enough time, in regular train service, to demonstrate the truth of the theory. It can be definitely stated that the firing of locomotives with pulverized fuel will be a big step forward in the economical operation of railways.

The following are the conclusions as set forth in the report of the Standing Committee on Powdered Fuel before the eighth annual convention of the International Railway Fuel Association at Chicago, May 15th, 1916:

"Summing the results that are being obtained in locomotive service, these may be stated as:—

1. Smokeless, sparkless and cinderless operation.
2. Maintenance of maximum boiler pressure within a uniform average of three pounds without popping.
3. An increase of from 7½ to 15 per cent in boiler efficiency as compared with burning lump coal on grates.
4. Saving of from 15 to 30 per cent in fuel of equivalent heat value fired.
5. Enlarged exhaust nozzle area, resulting in greater drawbar pull and smoother working of locomotive.
6. Elimination of ash-pit delays, facilities, and expense; also reduces time required for firing up.
7. Maintenance of a relatively high degree of superheated steam.
8. No accumulation of cinders, soot or ashes in superheater or boiler flues, smokebox or on superheater elements.
9. No trouble from overheating of firebox, new or old sheets, seams, rivets, patchbolts, stays or flue beads.
10. Elimination of arduous manual labour for building, cleaning and dumping fires and for firing.
11. Eliminates the necessity of front-end and ash-pan inspection and for special fuels, firing tools and appliances for building fires and for stoking and cleaning fires.
12. Equal provision for engine driver and fireman to observe signals and track, thus reducing liability of accident.

"Your committee is of the opinion that the effectiveness and utility of fuel in pulverized form has been demonstrated from the past year's development and that the progress in the use of this method of stoking and burning bituminous and anthracite coals and lignites for generating power, heat and light on railways, will be quite marked from now on.

"The constantly increasing cost of railway fuel at the mine; the scarcity of fuel oil; the domestic and export demand for larger sizes of coal; the prohibitive cost of briquetting the smaller sizes of coal and of lignite for railway use; the payment of labour on the run-of-mine basis for mining bituminous coals; and the necessity for eliminating smoke, sparks and cinders, will all tend towards the inauguration of this practical means and method for increasing the efficiency of steam boiler operation which to-day affords the greatest opportunity for improving locomotive and power plant costs and performance, and for changing public sentiment by smoke abatement."

The burning of anthracite, bituminous or lignite fuels in pulverized form offers opportunity for even greater accomplishment in the steam railway field than has been obtained through its use in industrial furnaces and stationary power plants, where the present annual consumption in the United States of approximately twenty million tons of pulverized bituminous coal has demonstrated the effectiveness and economy of this method of combustion.

Efficiency in Steam Power Plant Operation

The Possibility of Effecting Economy in the Operation of Steam Power Plants

L. M. Arkley, M.E.I.C.

Professor of Mechanical Engineering, Queen's University, Kingston, Ont.

Paper to be read before the Kingston Branch, The Engineering Institute of Canada.

On starting out to save coal in a steam boiler plant, the first thing to do is to find out at what efficiency the plant is operating. This may be done by means of a boiler trial lasting anywhere from ten to twenty-four hours, according to conditions and the particular data required. The method of making these tests may be found in many handbooks and texts, the most authoritative, perhaps being that found in the Power Test Code published by the American Society of Mechanical Engineers.

The efficiency of a boiler is obtained by dividing the heat, (B.t.u.), in the steam obtained from a boiler in a certain time, by the heat contained in the coal burned in the same period of time or if E = efficiency,

$$E = \frac{\text{B.t.u.'s given to steam per 1 pound of combustible}}{\text{B.t.u.'s in 1 pound of combustible}}$$

combustible being defined as coal free from ash and moisture.

The main object in boiler plant operation is to increase this fraction without injuring the boiler or furnace.

Preparations for a Boiler Test

In making a boiler trial the following data should be procured. All water evaporated must be weighed or measured accurately, and all coal fed to the furnace during the trial must be weighed. These are the main items, but other data which should be recorded at half-hour intervals during the test are, steam pressure, draft over the fire, draft in last pass of boiler, (these are measured by means of a water manometer and recorded in inches of water), temperatures of feed water, of the flue gas in breeching near the boiler, and room temperature, dryness of steam, and if it is desired to make out a complete heat balance for the test, analyses of the flue gas should be made at frequent intervals, and an average

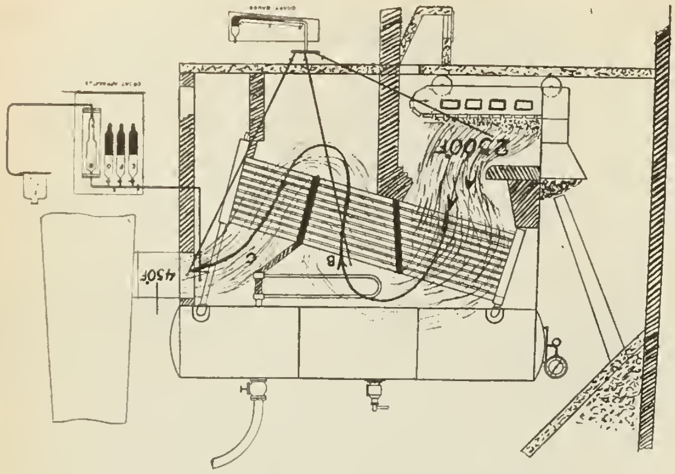

Figure No. 1.—Section through Boiler Plant showing Arrangements made for conducting Test.

sample of the gas should be taken and analyzed after the test.

Before starting the test the height of the water in the gauge glass should be noted and a string tied around the glass to mark the height, the water should be kept as near this point as possible during the test and at its conclusion the water should be at the string. The condition of the fire should be the same at the beginning and the end of the test. From each three or four hundred pounds of coal burned, a ten-pound sample should be taken and kept in a covered box. At the end of the test, an average sample of this coal should be placed in an air tight container, or mason jar, and from this sample the analysis of the coal made, and the B.t.u. content per pound determined. Samples of the ash should be taken as well and a mason jar saved for analyzing, the same as for the coal.

Precautions to be taken before making the test are as follows: —

(a) See that the boiler blow-off cocks are tight and that no water is leaking from the blow-off pipes.

(b) See that there is no possibility of water getting into the boiler except that passing through the meter or weigh tanks.

(c) Have all cracks in the brick setting and openings between the brickwork and metal of the boiler calked with asbestos packing and plastered to prevent air leaks into the boiler.

(d) Take precautions against the boilers blowing off during the test. If this happens, the time the safety valves are open should be taken, so that the proper correction may be made.

From the above data we can find the boiler efficiency as follows: — From the calorimetric test we find the B.t.u.'s in one pound of dry coal, and from the coal analysis we know the percentage of ash. From this we determine the B.t.u.'s per pound of combustible which gives us the denominator of the efficiency fraction. The numerator of the fraction, i.e., the B.t.u.'s given to the steam per pound of combustible, is found by dividing the water evaporated per hour by the combustible burned per hour, which gives the steam produced per pound of combustible. To find the B.t.u.'s in this number of pounds steam, we make use of the steam tables. For example, if the feed water goes to the boiler at an average temperature for test of 190°F. and the average dryness of the steam is 98 per cent = x, then we know from the steam tables that the total heat H in one pound of dry and saturated steam for the absolute boiler pressure is given by the equation $H = xr + q$, where r = the heat of vaporization and q = the heat of the liquid in the steam, but this is above the temperature 32°, therefore for water at 190°F. the total heat $H = xr + q - (190\text{-}32)$, multiply this by the number of pounds of steam evaporated per pound of combustible and we get the numerator of the fraction which gives efficiency.

Heat Losses

As has been said, the whole object in boiler plant operation is to increase the efficiency without injuring the boiler. The best plants operating to-day have reached an efficiency of 90 per cent, but a great many of the smaller plants do not reach an efficiency of 60 per cent and it is in such plants that by properly analyzing results and making changes in equipment and methods of operation that coal may be saved.

This low efficiency is accounted for by heat losses between the point where the coal enters the furnace to be burned and where the hot gases are finally rejected to the chimney.

These main losses of heat are: — (a) Loss due to coal dropping through the grate; (b) loss due to moisture in coal; (c) loss due to incomplete combustion; (d) loss due to heat rejected to the chimney. One of the most important is (d), the heat rejected to the chimney and this is the one that must be watched most carefully.

For example, a heat balance for a boiler based on one pound of combustible might be as follows:—

	B.t.u.	Per cent
B.t.u. per pound of combustible 15,500 by test		
Heat absorbed by the boiler	12,000	77.4
(a) Loss coal through grate	100	0.6
(b) Loss due to moisture	600	3.84
(c) Loss due to incomplete combustion	75	0.48
(d) Loss due to heat rejected to stack	1,600	10.43
(e) Loss due to radiation and unaccounted for	1,125	7.25
		100.00

By separating the losses as above and knowing what percentage should be expected in each case, it is a simple matter to locate the trouble and apply the remedy if a plant is not working efficiently.

Loss (a) is obtained by taking a sample of the ash and testing it in a calorimeter for B.t.u. content in the same way that coal is tested.

Loss (b) is given by the equation,—Heat loss per lb. of combustible = $(9H + W)\{212 - t + 970.4 + .48(T - 212)\}$ where H and W are the percentages of hydrogen and water in one pound of combustible, and t = temperature of air in the boiler-room, and T = the temperature of the flue gases in degrees fahrenheit.

Loss (c) is due to the carbon in the coal burning to carbon monoxide CO, instead of CO_2 and is obtained from the formula:— Heat loss $= 10150 \left\{\frac{CO}{CO + CO_2}\right\} \times C.$

Where C is the percentage of carbon in the combustible and where CO, CO_2 = percentage of carbon monoxide and carbon dioxide respectively in the flue gas. This formula follows from the fact that if carbon burns to CO, there are liberated 4,350 B.t.u., while if it burns completely to CO_2, 14,500 B.t.u. are liberated, the difference represents the loss per pound of carbon due to incomplete combustion.

In order to obtain this loss and loss (d), we must make an analysis of the flue gas by means of the Orsat apparatus as follows,—

For the purpose under consideration, flue gas may be said to contain four constituents, — Carbondioxide, CO_2;

carbon monoxide, CO; oxygen and nitrogen. As air contains 21 per cent by volume of oxygen and 79 per cent of nitrogen, the sum of the free oxygen, CO and CO_2 will never be more than 21 per cent. The Orsat apparatus commonly used for analyzing flue gas, is made as follows, see figure No. 1.

The Orsat Apparatus

G is a glass tube bent in the form of the letter U and half filled with the reagent caustic potash (KOH). *F* and *E* are U-tubes the same as *G*, but contain the reagents pyrogalic acid and cuprous chloride respectively. *H* is a measuring burette graduated in centimeters. *I* is a bottle filled with water and connected to the Orsat by a rubber tube as shown. *K* is a capillary tube connecting reagent tubes with the measuring burette and *J* is a three-way cock, which may be turned so as to connect *K* to the outside air or to the gas supply pipe. To draw in a charge of the gas to be analyzed, cock *J* is opened to the air and the water bottle raised. Water will be forced out at *J*. This is done several times to clear the pipe of air. The cock *J* is now opened to the boiler and the bottle lowered, gas follows the receding water and fills the burette *H*. Cock *J* is now closed and cock *G* opened, the bottle raised and the gas forced over in contact with the reagent, this removes the CO_2. The percentage being read off directly, when the level of the water in the bottle is brought to the same level, as that in the measuring burette *H*. By passing the gas over the reagents in *F* and *E* respectively, the oxygen and carbon monoxide are removed. The operation of the Orsat is a purely mechanical one and a workman of average intelligence can learn it in a short time. To show how a gas analysis as obtained above, may be used to find the heat lost up the chimney, we know that this loss is made up of, the weight of the gas going up the chimney, multiplied by the specific heat of the gas, multiplied by the difference in temperature between the outside air and the flue gas, it may be put in the form of an equation as follows,—

Heat loss per pound of combustible = weight of gas per pound of combustible × rise in temperature × specific heat....................................(1).

The weight of gas passing per pound of combustible = $3.03 \left\{ \frac{N}{CO_2 + CO} \right\} \times C$,..........(2) where N, CO_2 and CO represent the percentages of nitrogen, carbon dioxide, and carbon monoxide in the flue gas and C = the percentage of carbon in the combustible. Now from equation (1), in order to keep the heat loss up the stack low, we must keep the weight of gas passing, as small as possible, and the temperature of the flue gas low. It will be seen from equation (2) that in order to keep the weight of gas small, we must make the denominator of the fraction large and as the percentage of CO_2, is always large compared with the CO, it means that the percentage of CO_2 should be large.

Causes of Low Percentage of CO_2

If the percentage of CO_2 is found to be low, look for the cause, it may be any one of the following.

First, — there may be air leaks in the boiler setting, cracks in the brick work or openings where the brick work has drawn away from the metal of the boiler, these leaks will result in large quantities of oxygen being drawn in with the air, which will not combine with the carbon of the coal, but appear in the analysis as free oxygen, and consequently the percentage of CO_2 will be lowered. The best method of detecting these leaks, is to go over the surface of the boiler setting with a lighted candle, while the boiler is operating, when the flame of the candle will be drawn in wherever there is an opening. When located these openings should be calked with asbestos, rope and then plastered with a substance which will stand considerable expansion and contraction without cracking.

Second, — the fire may be too thin, which allows the air to pass up through the coal bed without combining with the coal.

Third, — there may be holes in the fire which gives the same result as mentioned in item two.

Fourth, — the draft may be too strong for the thickness of the fire and the kinds of coal used.

The methods of correcting troubles 2, 3 and 4 are self evident and a summary of the results to be obtained from a gas analysis is given in figure No. 2.

The loss due to radiation, etc., is obtained by adding the heat absorbed by the boiler to the losses a, b, c, and d, and subtracting this amount from the B.t.u.'s in the original pound of combustible. What has been said in regard to the main loss (d) and the use of the gas analysis, may be summarized as in figure No. 2.

Summary of Procedure to Ascertain Causes of Low Boiler Efficiency

As a general summary of the method of diagnosing the case of a boiler plant which is suspected of using too much coal for the steam furnished, I would suggest that first the temperature of the flue gas be taken, if the plant is operating without an economizer and the temperature is found to be much above 500°F. look for the causes as indicated in figure No. 2, and apply the proper remedy.

Next by the aid of a water manometer as shown in figure No. 1, take the draft at different points in the boiler and furnace, for natural draft conditions and good opera-

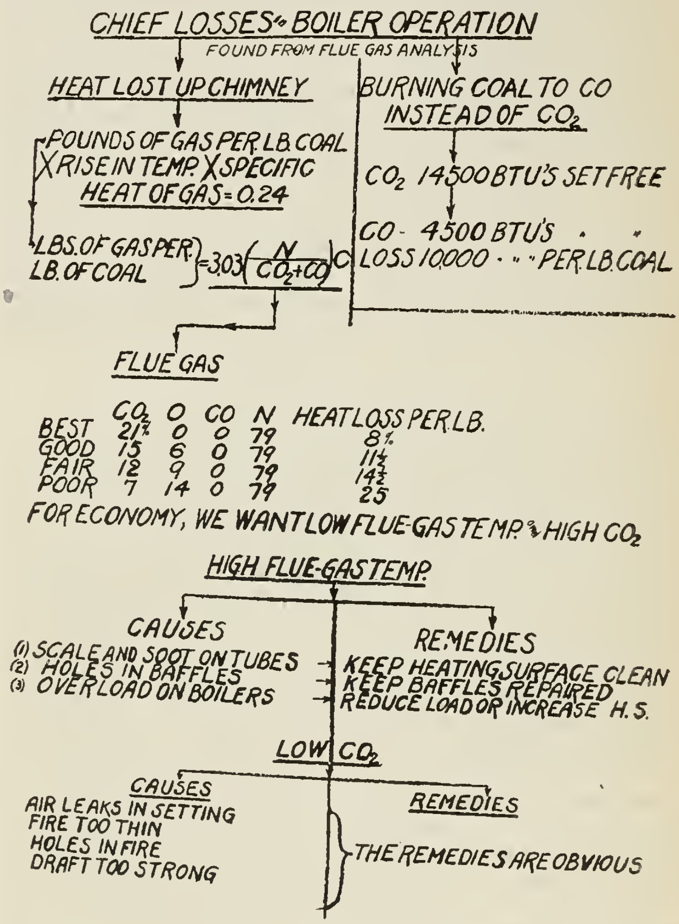

Figure No. 2.—Summary of General Losses in Boiler Operation.

tion, you might expect to get a loss of draft from the furnace to the last pass in the boiler, i.e., in figure No. 1 from the point marked *A* to that marked *C* of about 0.3 inches of water, the loss between the ash pit and the furnace will vary with the kind of coal burned and the type of grate or stoker used and the quantity of coal burned per square foot of grate surface per hour, (see figure No. 1). This may vary from 0.15 inch for run of mine bituminous to 1.0 inch for No. 1 anthracite buck-wheat, when burning the fuel at the rate of 25 pounds per sq. ft. of grate surface per hour. The loss of draft between the boiler and the chimney is usually estimated at 0.1 inch for each 100 feet of steel flue and 0.05 for each right angle bend, and the sum of the above losses should give the draft required at the point where the flue enters the chimney, for example take the case of the No. 1 anthracite assuming 100 feet of flue and two right angle bends, the total draft required would equal,—

From ash pit to furnace.....	=	1.0 inch
From furnace to flue........	=	0.3 "
From flue to chimney.......	=	0.2 "
		1.5 inch of water

To give this draft would require a chimney nearly 250 feet high, and a chimney of this height would be inadequate if we wanted to burn the coal at a higher rate per square foot of grate surface per hour. This indicates the impossibility of burning these finer grades of anthracite without forced draft. It also illustrates how to check up on the draft and the height of chimney required, if the draft is too small a sluggish and smoky fire will result. If the draft is found to be correct, the next thing to do is to analyze the flue gas as indicated above and this will show the excess of free air entering the boiler and whether combustion is complete.

It is clear from what has been said above that there is a certain difference of draft required, between the ash pit and the last pass of the boiler to give best results, now by placing a double draft gauge on the front of the boiler and connecting it to these two points it can be made a real aid to the fireman, by operating the damper to give different draft readings and using the Orsat to analyze the gas at these different damper settings, the proper readings on the draft gauge may be determined to give best results for the given conditions, then by marking these points on the gauge, the fireman can duplicate the best operating conditions by keeping his drafts correct.

CO_2 Recorders

From the Orsat apparatus described above, a gas analysis may be made, giving the percentages of CO_2, O and CO, in the flue gas and while it is advantageous to have all this information, the percentage of CO_2 is the most important. A low percentage of CO_2 is always accompanied by a high percentage of free oxygen and often by an absence of CO, and the reasons that this represents a wasteful condition even with complete combustion as indicated by the absence of CO, is that it means that a large excess of free air is entering the furnace, is being heated from room temperature to that of the flue gas and discharged to the chimney. On the other hand, as the air entering the furnace is cut down, the percentage of CO_2 will increase and if carried too far will result in incomplete combustion and a high percentage of CO. But as a rule, the percentage of CO_2 can be taken as an indication of the condition of combustion in the furnace. For this reason, a number of different makes of CO_2 recorders have been placed on the market. These machines work continuously, automatically draw in a charge of gas, analyze it and record the result on a chart. While there is no doubt that in many cases, these machines are giving satisfaction, the writer knows of many instances, especially in the smaller plants, where they have been tried and have been discarded on account of the time and care required to keep them in operation.

They are a great help when working properly and some large companies have stimulated interest in the proper operation of the boiler plant by offering a bonus to the fireman, based on the average percentage of CO_2 obtained, during a shift, above a minimum limit of, say, 10 per cent.

In addition to periodic boiler tests such as described above, the plant should be equipped with recording instruments by which the evaporation from and at 212°F. per pound of coal, as fired may be found for each day or part of a day. These instruments are, — *First*, some form of water measuring or weighing device, it may be in the form of a venturi meter, an orifice machine,or some form of automatic weigher, in any case there should be an integrating scale giving the total water per hour, and a recording chart from which the variations in the water fed to the boilers may be seen at a glance. On this same chart the temperature of the feed water and the steam pressure may be recorded. *Second*, a coal weigher by which all the coal is weighed before it goes to the furnace. With the information obtained from the above apparatus, the boiler horse power may be obtained and the economical operating rate determined, showing when a second boiler should be put in service.

If the evaporation per pound of coal is less one day than another or during one part of the day, than another, it points the way to finding the trouble and, therefore, improving the efficiency of the boiler operation.

In figure No. 2, the first gas analysis shown is, of course, theoretical, as it is impossible to get, in boiler operation, combustion represented by 21 per cent CO_2, CO = zero and 79 per cent N., but under favourable conditions it should be possible to approximate the condition marked "good" representing a loss per pound of combustible of 11½ per cent, and it should not be at all difficult to attain the condition marked "fair" which shows a loss of 14½ per cent. But the majority of the steam plants in operation in Canada today, especially the smaller ones, are operating according to the condition marked "poor" or worse, with a loss of at least 25 per cent of the heat units of every pound of combustible burned going up the stack.

In 1921 there were burned in Canada for steam making purposes about 25,000,000 tons of soft coal, as a conservative estimate we may say that at least 15,000,000 tons of this was burned under the condition indicated as "poor". If by means of a little more intelligent operation and the use of a little more equipment to help the engineers and firemen, the condition "poor" could be changed to "fair", it would result in a saving of 1,500,000 tons of coal per year which at $6.50 per ton would represent nine and three-quarters million dollars. Or assuming that we had this coal to burn in a fairly efficient plant, we could operate a 150,000 boiler h.p., plant 24 hours per day for one year, and assuming a water rate for direct connected turbines and generators of 10 pounds of steam per kilowatt we could operate a 450,000 k.w., plant with this heat that is wasted up the chimneys.

Here is an economic waste which should be stopped, not only for the benefit of the owners of the plants but for the benefit of the country at large, as the supply of coal for Canada has become a question of national importance.

The author does not claim that there is anything original in the above paper, except perhaps in the method of presenting the well known facts mentioned. The object in writing it is to again remind steam power plant owners and engineers in charge of such plants of the possibilities of savings which may be effected.

Considerations on a Project of Town Planning for the Island of Montreal

An outline of a plan for the establishment of a Town Planning Commission to investigate and report on a project for the Island of Montreal.

S. J. Fortin, M.E.I.C.
Chairman, Technical Commission, City of Montreal, Que.

Paper read before the Montreal Branch, The Engineering Institute of Canada, April 17th, 1924.

Much has been said and written during the last decade regarding town planning. All of us have listened to lectures on this subject, so interesting, yet so little understood. I will not undertake to tell you here what should be done to make Montreal more beautiful, nor will I tell you about new boulevards, widening of streets, opening of new parks and playgrounds or about re-arranging our system railroads. It will be the task of the commission to study out and solve these problems. I will confine myself to a few remarks on the organization, scope and aim of a town planning commission such as I see it; a commission which shall seek the means of gradually and methodically rendering life easier and more cheerful to our urban dwellers. I have the firm conviction that any commission of that nature, starting out without a well-defined programme will fail to produce results, and that any town planning commission for Montreal or for elsewhere which has not the approbation and co-operation of the public and civic authorities will invariably fail.

I will cite one case only, that of Ottawa. Ten or twelve years ago the federal government and the city of Ottawa appointed a commission to prepare a plan of embellishment and development of Ottawa and the surrounding country. The commission worked faithfully and published a lengthy report with maps, etc. The whole was carefully worked out. The report tells about creating a federal district, similar to the District of Columbia at Washington; it tells about a national park extending from Hull to and including the Laurentian hills; it recommends shifting of railroad tracks and many other important improvements. The report failed to receive attention from the public with the result that both the government and the city of Ottawa ignore it completely, with the net result; loss of time and money.

Plan Should Cover Entire Island

The task of a town planning commission is to seek and to formulate "ways and means" to guide the economical and methodical development of a city or district with due regard for public health, comfort and amenity of the population and to its social, commercial and industrial development. The need of such a commission is, to-day, universally recognized. In Europe, this question has been developed a long time ago. In the United States the movement started in Chicago about 1893, (White City of Daniel H. Durnham), and at the present time fifty per cent of all American towns of 100,000 population and over have a town planning commission of one form or another. In France, all communities of 10,000 people and over, must have a town planning organization. In Canada the province of Saskatchewan has taken the lead and in 1917 its legislature passed a law to the effect that all cities and villages must have an organization governing the method of their growth.

Regarding Montreal, a town planning commission should have jurisdiction over the whole of the island of Montreal, because the island forms a natural metropolitan district, and it contains a large proportion of the population of the province of Quebec. The population of the province of Quebec is 2,361,200; the population of the island of Montreal is 1,000,000 (census of 1921). Again, of all the means at the disposal of a town planning commission for the carrying out of its task, the control over the subdivisions of tracts of land, transportation systems and zoning, is, without doubt, the most effective. How can a commission arrive at any satisfactory result if its control does not extend over the whole island?

The Russell Sage Foundation in New York

I have often thought that Montreal occupies, towards Canada, a position similar to that of New York towards the United States. The two cities have the same destiny. What is happening in New York to-day? I met, in Mexico City in 1909, Mr. Nelson P. Lewis, at that time chief engineer of the Board of Estimates and Apportionment of New York and at the present time chief engineer of an organization having for its object the preparation of a regional plan of New York and vicinity. Lately, following letters exchanged, Mr. Lewis sent me a pamphlet entitled, "*Plan of New York and Its Environs*", containing the minutes of a meeting held on May 10th, 1922, which meeting had been called by the trustees of the Russell Sage Foundation. The Russell Sage Foundation, you perhaps know, is an association organized under the terms of Mrs. Russell Sage's will, having in view the improvement of social and living conditions for the benefit of New York and vicinity. The following are a few extracts from the pamphlet which will make known the object of the association and the means taken to arrive at the desired results.

"The problems created by the concentration of the population in and about the city of New York are growing daily in seriousness and are engaging the attention of an increasing number of our citizens. The trustees of the Russell Sage Foundation, organized for the improvement of social and living conditions, have appointed, to consider the subject, a committee consisting of.................

"Substantial progress has already been made in the organization of a series of basic studies looking forward to the formulation and promotion, in co-operation with all concerned, of a regional plan of New York and its environs. It is now desired to hold an informal conference of those who are naturally interested:—the public officials, architects, engineers, artists, city planning experts and other public-spirited men and women who in their own special field and in their own localities are already forcing these problems...

"The first question you may instinctively ask is, —whether it is not a project far beyond the resources of the Foundation. Unquestionably it is, if the Foundation alone is expected to carry this project to fruition. All that the Foundation can wisely do is to outline an initial plan in reliance on the co-operation of others to perfect it and to carry it out.

"Another question which may be properly asked is, whether any such plan can be carried out without the action of public authorities, city and state, and this question may lead to another, as to why some of the public officials of at least the larger cities concerned should not be members of any committee on this subject. Unquestionably no such plan can be carried out except by and through the public authorities, but the Foundation has thought it unfair to these authorities to involve them in a plan at the present time. Ultimately any plan must be presented to these authorities for modification, acceptance or rejection. These authorities to perform their proper functions as representing the people should be left at this initial stage in an absolutely judicial position. They should not now be embarrassed by being asked to take a leading part nor should the Foundation and its advisers be now embarrassed by any personal or political considerations.

"The project of the Foundation while not ignoring congested Manhattan and almost equally congested Brooklyn, involves a regional plan of New York and includes not only Greater New York but its environs. With present methods of transportation the real New York includes every locality within commuting or motor distance and embraces parts of the states of New Jersey and Connecticut. It is perhaps in these environs that city planning has its greatest opportunity."

All of which applies equally to Montreal. Our friends in New York are therefore:—1. Looking ahead and seeking the means of improving the social and living conditions in a large territory around New York. 2. Elaborating a plan of development on a large scale. This is being done by a special organization and not by city employees. 3. Intending to submit the plan, when completed, to the public and to the local authorities.

If adopted in its original form, or modified, the municipalities interested will carry out the recommendations contained in the plan, which will cover, not only the city of New York, but a large territory around New York, because, town planning can accomplish perhaps more in a territory around a city than in the city itself.

Montreal's Favourable Situation

Montreal is the Metropolis of Canada, owing to its geographical location and to other favourable conditions. This however is not a reason why we should not make an effort to help it along. I doubt if there is in Canada and perhaps America, excepting New York, a place where town planning can show better results than around Montreal. We have all the elements needed, and it is up to us to keep and to increase its supremacy over all other Canadian cities. If we wish to grow we must not only keep our population, but we must invite our neighbours to join us, and the best way to arrive at this result, is to make life easier and more agreeable to all classes of the community. This is precisely the aim of a town planning commission.

Regarding the advantageous position of Montreal from a commercial and an industrial point of view, and regarding the beauty of its situation, with a mighty river flowing at its feet and a most beautiful mountain in the centre of the city, much could be said. I will only say that upon my return here, after an extended absence, I found that few of our citizens realize the importance of the city and the part it is called upon to play in our national existence. Many of us still think that we are in a village or a country town. We must give up these ideas and accustom ourselves to think of our city as one of the big cities of the world. Let us have immediately a strong commission which will do effective work. The longer we wait, the more complicated will be the problem. We must not wait until we have reached such intolerable conditions as exist to-day in New York.

In the matter of a town planning commission with jurisdiction over all the island of Montreal, the first action must be taken by the Montreal city council, which should petition the Quebec legislature to create a commission, to define its functions, scope, power and to provide the money. If we assume that such a commission shall have jurisdiction over all the island of Montreal, the legislature must act because the Montreal civic authorities have no power and no control over the other municipalities of the island. Besides, there is the question of funds. It is useless to expect that the various municipalities will furnish the money which the commission will need. Equally useless is it to form a commission if it has no money at its disposal. Therefore, the matter of jurisdiction and money can be arranged only through the legislature.

Obviously, a group of citizens could be brought together in the interest of a plan of improvement, but, without power and money, nothing worth while can be done. In this respect, the conditions in Montreal and in New York are very different. The Russell Sage Foundation has voluntarily undertaken the task of preparing a regional plan of the district surrounding New York but they have the means of doing it. In Montreal we have no such advantages, and the legislature must come to our assistance in the manner suggested below.

As a matter of interest, I may state here that the regional plan of New York covers a territory of 5,500 square miles in which there are 400 different political units, — three states, counties, cities, towns, villages, boroughs, and townships. In that area there is to-day a population of 9,000,000. If the population grows, as it did in the past fifty years, it is expected that the territory will have a population of 20,000,000 in 1960 and 37,000,000 in the year 2000. The New York Census Committee has called attention to the fact that 22.6 per cent of the city's population lives on 1.6 per cent of its area and that 68.8 per cent lives on 10 per cent of its area.

Organization, Staff, Authority

Before speaking of organization, I will read to you what Dr. Robert H. Whitten said in a conference in Detroit in 1915:—

"In American state and city government, almost every expansion of government activity is initiated through the instrumentality of a new commission. There is a fear of entrusting the working out of new functions to existing officials. Existing officials are already loaded with work, and it is thought that they will have neither the time, the inclination nor perhaps the ability to develop the new idea. A new commission composed usually of unpaid members, is used to plan and care for the new undertaking at least during its development period. Often the new function fails to take root as a permanent institution, and the commission dies. If, on the other hand, the new function becomes a recognized governmental function it is sooner or later merged with the governmental organization. The new function is transferred to the proper official or department and the commission disappears. That is inevitable; otherwise, municipal government would soon become an utterly disorganized tangle of boards and commissions.

"The city planning movement will doubtless be no exception to the rule... Doubtless the commission method will be used largely in the earlier stages of the movement but, if the city planning movement endures, it will ultimately be made a part of the general governmental organization. The city plan is so vitally connected with every phase of municipal activity that it must be worked out in as close touch as is possible with the existing administrative and legislative authorities."

This appears to be logical, especially when we deal with town planning, because town planning is a thing not easily defined, — it is hard to say where it begins and where it ends. What is appropriate to one city is not appropriate to another. We must take into consideration the local conditions, even the mentality and temperament of the population. For all these reasons it is better that the researches and studies be entrusted to a special commission.

Then, as I conceive it, the programme should be:— Adoption by the civic authorities of the city of Montreal, of a resolution asking the Quebec legislature to create a town planning commission covering the entire island. The Montreal civic authorities, or, if we prefer it, the legislature, shall define the functions, the scope and the powers of the commission. The legislature shall grant to the commission the necessary powers to raise the money which it will need for the carrying out of its work.

The commission should be composed of from six to ten members, all ratepayers serving without remuneration, all representative men, financially, commercially, and socially. The mayor, the chief executive, and one or two aldermen of the city of Montreal, should be members of the commission. Westmount, Outremont and other municipalities around Montreal should be represented on the commission either singly or in groups. There should be a president, a secretary, (who may or may not devote all his time to the work of the commission), and others. Among the members of the executive body, I would like to see a prominent engineer and a prominent architect. Then, there shall be a paid staff,—first a chief engineer, (a man well up in municipal improvements and familiar with our history, our temperament, aspirations and traditions), and then, engineers, architects, landscape architects, surveyors, draughtsmen, etc., according to the magnitude of the task on hand and to the money at the disposal of the commission. The paid staff shall execute all the work, prepare the plans and maps and write the final report; all in accordance with the instructions received from the executive body of the commission.

The commission itself will not have executive powers, which at all times must remain with the municipalities interested, but it may consult the local authorities and it shall be obligatory upon the municipalities interested, companies, corporations and individuals, to furnish information and documents which may be required or asked for by the commission.

It goes without saying that the suggestions and recommendations of local authorities, city councils or others should receive special attention from the commission. For example, the zoning and restrictions regarding construction should be studied jointly by the commission and the aldermen. Likewise the street traffic problem should be studied out jointly with the tramway commission and the tramways company, and so on.

As soon as the report with plan or plans is completed, it should be submitted to the public and to the municipalities interested, for criticism, modification or approval. The commission should weigh and carefully consider all opinions, suggestions and criticisms, and should make the modifications which it considers judicious. The report and plan should be approved by the Montreal city council, and by the majority of the municipal authorities interested, after which the plan and report should be forwarded to the Quebec legislature for approval and to be transmitted afterwards to the municipalities interested, with instructions to carry out the recommendations and conclusions of the report.

Then, what shall we do with the commission? Simply reduce the staff, but keep the commission alive, for the report will require many modifications and revisions. On this subject Mr. Nelson P. Lewis says, in his book "The Planning of Modern Cities":—

> "The creation of a proper plan will require years of patient work, and the men who do it will be forgotten before it is finally carried out. It is no one-man job and it is never actually finished. However carefully and skillfully the first plan may have been made, unforeseen changes will take place, new methods of transportation will be developed, new inventions will powerfully affect the social life of the community, and the plan, when still susceptible of changes, will be modified to meet these changed conditions."

It is necessary that the commission be kept in existence to interpret its own work, to act as arbitrators in case of dispute, and to make changes in the plan necessitated by changing conditions in the district.

Scope of Work

We must bear in mind from the beginning that the aim of a town planning commission is as much to avoid the repetition of the errors of the past rather as to correct the errors themselves. In reality a commission, even if it had the power to do so, would not recommend, much less order, immediate, radical and costly changes in existing conditions. What has been done is done good or bad. It is very logical that we should seek to correct the errors of the past, but it must be done slowly and gradually, and we must choose the time when the cost will not be excessive. No expropriation or radical changes in the layouts of our city can be made without increasing an already huge debt or increasing the contributions of a taxpayer already heavily burdened. The efforts of a town planning commission should be to prepare for the future, as well as to improve presents conditions. In short, a commission should make certain recommendations only regarding the past and present, excepting however in the case of sanitation, and urgent needs but on the other hand, it must formulate rules and regulations concerning the future. Also, we must bear in mind that results will be slow, and that a town planning commission will labour for our children and grandchildren and not for ourselves.

We must not come to the conclusion, however, that a town planning commission can do nothing to improve the existing conditions within the town itself. On the contrary, it may do much, and that without increasing the debt to any considerable extent. For instance, it may contribute to the beautifying of our parks; it may oppose the erection of ugly signs and posts along our main streets; it may have something to say in regard to building restrictions and should co-operate with the city authorities, the tramways commission and the tramways regarding new car lines and extensions to existing lines.

The first duty of the commission should be the preparation of a general map of the territory under its jurisdiction. This map should be at a scale or scales as required, and should show all the streets, highways, boulevards, parks and parkways, public places, existing subdivisions and an outline of the future subdivisions of tracts of land as laid out by the commission itself, because we must not lose sight of the fact that the "raison d'être" of the commission itself is the control it must exercise over the future subdivisions of land, on the means of transportation and on the zoning of the district, as explained later. Then it will review the laws and by-laws which have contributed to the development of the district or have retarded it.

The question comes up: What will happen, if the commission, in laying out a general plan of development, injuriously affects the interests of a landowner? The law of Saskatchewan, "The Town Planning and Rural Development Act" in this respect says, in section 20, that, when an owner is injuriously affected, the municipality interested shall compensate him for the whole amount of the loss, provided a claim to that effect is filed within a specified time. Section 21 of the same act likewise states that when a property is increased in value by the making of a plan of development, the municipality interested is entitled to one-half of the increased value provided a claim to that effect is filed within a specified time. It is claimed that this arrangement should be satisfactory to all concerned.

It shall be within the power of the commission to:—

1. Gather all information and statistics which it may need, make a brief historical review of each municipality of the island. Prepare a general plan of the island.

2. Divide the territory into four zones, residential, commercial, industrial and indeterminate.

3. Choose the site for new parks, playgrounds and public places. Recommend if needs be enlargement and improvements for existing parks and playgrounds.

4. Choose sites for monuments, historical and otherwise, public and semi-public buildings. Make a preliminary study of location for new bridges between the Island and adjoining municipalities.

5. Study carefully the manner of making all future subdivisions of tracts of land. Determine in a general way the area and form of lots. Determine the grade, width and direction of main highways, width and grade of streets. In short, though leaving freedom of action to proprietors of tracts of land and to real estate agents, the commission or the local authorities shall exercise an effective control on the development of suburbs. No sub-division shall be registered until approved by the commission.

6. Recommend, if needs be, the widening of certain streets and the opening of new thoroughfares in urban districts. This of itself is a large task.

7. Make a thorough investigation of the best means of improving traffic conditions in such congested streets as Sherbrooke, St. Catherine, Notre Dame, St. James, Craig and St. Denis, where circulation is now or soon will have reached the saturation point, especially the tramways service. In reference to the congestion in our main arteries of travel, I will quote here a few figures obtained from Judge J. F. St. Cyr, president of the Montreal Tramways Commission.

"Between five and six o'clock in the afternoon, 302 tramway cars pass the corner of Craig and St. Denis streets; 122 cars pass the east side of Place d'Armes square; 157 pass the west side of the same square; and 420 cars pass the corner of Bleury and Ste. Catherine streets. This is at the rate of one car every 8½ seconds During the same period 366 vehicles pass the same corner of Bleury and Ste. Catherine."*

This will logically lead the commission to study new lines of travel for the tramways and the opportunity of building elevated lines and subways; look into the possibility of establishing new civic centres in the suburbs where the surrounding population will find all its needs in matters of finance, shopping and amusements. The subject of decentralization to-day is the object of a great deal of attention by town planners. It is my belief that the problem of relieving the congestion in our main streets should receive deep and immediate attention if we wish to avoid the intolerable conditions which to-day exist in New York.

8. Control the construction of trunk sewers, water pipes and other public improvements, which sooner or later will serve more than one municipality.

*These figures are as of February 12th this year.

9. Recommend, if advisable, changes ni our system of railroad stations, freight yards and lines of railway, which now prevent or delay the development of certain districts. Control over the location of new stations, freight yards and line of railways.

10. Forbid unhealthy grouping of houses in workmen's districts; establish for each zone the percentage of ground not built upon and number of houses per acre; see that houses receive the maximum amount of air and light; order the removal of slum conditions when health is endangered.

11. Investigate and make recommendations on any other subject coming logically under the jurisdiction of the commission.

Finance

I have already said that we must not depend on our citizens or our municipalities for the necessary funds with which to carry out the work of the commission. On the other hand, such a commission can do nothing without money; that is self-evident. It is impossible to say at present what such a plan would cost, but as a basis for discussion, I estimate that it would cost $200,000.00, and the time required would be three to four years. Please remember that we have no correct plan of the island, all that we have are compilations, more or less correct. A correct topographical map will cost money and will take time to prepare. The legislature must help us to find this sum of $200,000.00. It could be made the object of a special loan, payable in 20 years, principal and interest, by all the municipalities interested, pro rata their population according to official census of 1921.

Summary

First and foremost, we must endeavour to get the public interested; we must explain our project; show the results we are seeking and the means which we wish to employ to solve the problem. Without the approbation and co-operation of the public, nothing can be done.

Once the general public has a clear idea of the utility and scope of the problem, the competent authorities, which are the mouth-pieces of the public, should ask the Quebec legislature to create a town planning commission with jurisdiction over the whole island of Montreal. The powers and scope of the commission should be defined by the legislature or by the petitioners and the legislature should authorize the commission to raise the money which it will require.

There should be an executive body composed of say six to ten persons, all interested in civic matters and representative men of the island in social, commercial and industrial circles. The mayor, the chief executive, and one or two aldermen of Montreal should be members of that body. Then there should be an expert town planner, with engineers, architects, landscape architect, draughtsmen, etc., according to work in hand and money available.

The subjects to be investigated and solved and the various problems which shall have the attention of the commission have been clearly enumerated above.

A report accompanied by plan or plans will be prepared and submitted to the public and municipal authorities for opinions, criticisms or approval. The commission will weigh all opinions and criticisms and will make whatever changes it deems judicious. The report and plan or plans will receive the approval of the Montreal city council and of the majority of the municipalities of the island after which it will be transmitted to the Quebec legislature which shall approve it with or without modifications and will make it obligatory upon the various municipalities of the island to carry out the terms of the report within their respective territory.

There are two reasons why the commission's report should be approved by the legislature. First, the city of Montreal has no authority over the other municipalities of the island, and could not enforce the execution of the terms of the report beyond the limits of the city. Secondly, I believe that a provincial law will have a better chance of being faithfully carried out than a mere by-law. It is so easy and sometimes so tempting to have a municipal by-law amended.

At least the executive body of the commission should be kept alive for the purpose of interpreting its own work, to supervise its application and to make modifications when events and circumstances make it necessary.

Lastly, I believe the task can be accomplished at a cost of approximately $200,000.00, which sum the legislature may authorize the municipalities of the island to borrow, and which may be amortized in 20 years by means of 20 annual payments, each municipality paying its pro rata per capita according to 1921 census.

The creation of a town planning commission for Montreal is an urgent necessity and should not be postponed. It is useless to try to solve the Montreal problems piece-meal by men who can devote only a few leisure hours to them. It has got to be done by men who devote their whole time to them and who will have an opportunity to survey the whole situation as well as to go into the details of each problem.

It has been said that some aldermen fear that a town planning commission will curtail their power and liberty of action. I do not believe that there is any serious ground for that fear. On the contrary, I should think that the aldermen would be glad to be shielded by the law when any unreasonable demands are made upon them by the taxpayers. As to reasonable demands, I am sure the commission will never refuse to grant them. It should not be forgotten that the report of the commission would have to be approved by the Montreal council before it is sent to the legislature.

The whole charter of the city of Montreal, which is a fair-sized book, is a code of restrictions and limitations of power for the executive, the city council and employees. A few more restrictions concerning problems outside the city limits will not curtail the power and usefulness of the city council. Again, a town planning commission, it should be borne in mind, is created for the benefit of the whole community and not to impose needless and harmful restrictions upon its inhabitants.

Evolution of City Planning, Regional Plan

In the early days of city planning in America, the territory covered by the projects were of small extent, for example a scheme of civic centre. Very few, if any, of these projects were ever carried out, simply because the cost was out of proportion to the result obtained. Subsequently it was sought to treat a larger area, such as a residential section, or an industrial centre. Some success was achieved in that direction, but it was soon discovered that the treatment was only local. Later, the idea of town planning was enlarged to embrace a whole city. Efforts were made to remedy the obvious mistakes of the past, due to the haphazard growth of the older built-up portions, and, at the same time, an attempt was made to guide the development of the town along more rational, economical and hygienic lines, where it was yet possible to do so. It was soon recognized that, although in the right direction, the field was yet too limited because immediately beyond the city limits, where the civic authorities had no jurisdiction, the errors of the past could and in fact were repeated, thus nullifying the benefits of the planning within the town itself. In the course of a few years the territory might be annexed, with its ill-advised system of streets and land sub-division. It became evident that any town planning scheme to be effective, must cover not only the town proper but also its environs. Proper legislation to that effect was sought and obtained. Regional planning, so called, thus came into existence and so it came about that, to-day, town planning means a project embracing not only the town proper but a large territory around it. The best example of such a scheme is the one now worked out by the trustees of the Russell Sage Foundation for New York and vicinity. It covers an area of 5,500 square miles, or 30 times the area of the entire island of Montreal.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOL. VII October 1924 No. 10

President Surveyer to be Honoured

The occasion of the centennial celebration of Rensselaer Polytechnic Institute, the oldest college of science and engineering in any English speaking country, at Troy, New York, October 3rd and 4th, 1924, marks an event of historic interest in the engineering world.

It will be memorable from the fact that it will witness the celebration of the hundredth anniversary of Rensselaer Polytechnic Institute, that it will witness the presence of a distinguished gathering, including the presidents of the outstanding engineering societies of the world, as well as the presidents of a number of the leading universities, and also from the fact that President Arthur Surveyer, of *The Engineering Institute of Canada*, will on this occasion number as one of the distinguished guests, and will receive the degree of Doctor of Engineering at a convocation to be held on the morning of October 3rd. In addition to President Surveyer, who will address the convocation, degrees will be conferred upon the Honorable Herbert Hoover, secretary of commerce of the United States, the Honorable Alfred E. Smith, governor of the state of New York, the Honorable Harry E. Clinton, mayor of Troy, President Frank Pierrepont Graves of the University of the State of New York, President Sir Charles Langbridge Morgan, of the Institution of Civil Engineers of Great Britain, President Henri Abraham, of the Society of Electrical Engineers of France, President Luigi Luiggi, of the Society of Civil Engineers of Italy, and Honorary President Roberto Gayol, of the Society of Engineers of Mexico.

There will also be unveiling of tablets in the afternoon, and in the evening a dinner in the State Armory, addressed by President Livingston Farrand, of Cornell University, followed by a pageant on the campus illustrating scenes in the history of science and engineering during the last one hundred years.

On the morning of October 4th, a second convocation will take place at which the following have been selected to receive honorary degrees, and who will address the meeting:—President Angell, of Yale University, President Birge, of the University of Wisconsin, President Stratton, of the Massachusetts Institute of Technology, President Grunsky, of the American Society of Civil Engineers, President Low, of the American Society of Mechanical Engineers, President Kelly, of the American Institute of Mining and Metallurgical Engineers, President Osgood, of the American Institute of Electrical Engineers, and President Michelson, of the National Academy of Sciences.

In the afternoon there will be a reception by President and Mrs. Ricketts of Rensselaer Polytechnic Institute, and in the evening a pageant and Alumni smoker.

Canadian engineers will appreciate the fact that a distinguished Canadian engineer is among the number of notable men to be honoured on this unique occasion.

Concrete Committee makes Progress

A general meeting of *The Institute's* committee on the Deterioration of Concrete in Alkali Soils, was held at the University of Saskatchewan on May 16th and 17th, 1924, at which were present Professor C. J. Mackenzie, chairman; Messrs. A. G. Blaikie, W. P. Brereton, M.E.I.C., J. N. Finlayson, M.E.I.C., J. R. C. Macredie, M.E.I.C., J. W. Shipley, G. M. Williams, A.M.E.I.C., secretary, and Doctor Thorvaldson, in charge of the chemical research.

After discussing the business features of the committee's activities, and additional members, Professor Finlayson, summarizing the field tests in Winnipeg, stated that no data relating to the Deacon blocks were available other than reported last fall after the 1923 inspection of the blocks. Mr. Williams summarized the results of this spring's inspection of the blocks at Cassils, which report had just been received from Mr. Dawson. Owing to high water at Grandora lake no inspection had been made of the Grandora blocks since the fall of 1923. Deterioration seems to be more rapid at Cassils than at the other two sites.

Doctor Thorvaldson outlined briefly the different phases of the chemical work which is being carried on. He was followed by Mr. Larmour, one of his assistants, who has been studying the colloidal changes which take place in mortar bars exposed to alternate wetting and drying. The relative changes in length of bars in distilled water and in different salt solutions were shown by diagrams and lantern slides.

Doctor Shelton, who has been making petrographical studies of the various constituents found in cements, described in detail the preparation of these compounds in the pure state, and outlined the difficulties encountered with the different types of high temperature furnaces. He showed numerous lantern slides to illustrate the different products formed when these pure compounds are hydrated with distilled water and various salt solutions.

On Saturday morning, May 17th, Doctor Thorvaldson continued the discussion of the chemical research, outlining in detail the products formed when tricalcium silicate is hydrated with water and with sulphate solutions. These results show that the presence of sulphate brings about a much more rapid and complete release of the free lime from the silicate compound, and that it is the subsequent combination of the lime with the sulphate which is mainly responsible for disintegration. A possible method for preventing this reaction with the sulphate was outlined.

The afternoon was devoted to a discussion on the chemical data presented and the necessity for getting completed portions of the chemical research on record so that priority and protection may be afforded it.

Although the committee is not in a position to promise a definite solution of the problem, it is certain that splendid progress has been made, the results of which it is anticipated will fully justify all the splendid effort that is being made by the committee.

Fuel Committee's Recommendations

Since its appointment on April 23rd, 1923, the Fuel Committee of *The Institute* has been constantly at work, the members of which, for their untiring efforts in this connection, deserve the thanks of the entire profession.

It was felt at that time, in view of the importance of the fuel problem of Canada, and believing that the profession could do much to add to its solution, that a committee was necessary and one was consequently appointed, the object of the committee being to use the information available on the fuel situation and take advantage of the collective opinions of the various members of the committee.

The Fuel Committee laid down a policy to govern its scope in the early stages of its work that the main Fuel Committee should concern itself solely with the sources, production, transportation and distribution of fuels to the various parts of Canada as a whole. In relation to branch fuel committees, which were also appointed, the committee believed they should confine themselves to the economical utilization of the different fuels available in each locality, and to educational campaigns regarding proper use of heating equipment and domestic fuel, for the benefit of the householder.

The first meeting of the committee was held in Montreal, May 31st, 1923, consisting largely of Montreal members and representatives of the Dominion Fuel Board and the Canadian Institute of Mining and Metallurgy. On June 8th, the E.I.C. Fuel Committee issued its first circular to its members, followed by another on July 25th. These circulars covered:—

(1) Requests for co-ordination of work of the general Fuel Committee with branch fuel committees.

(2) Requests for suggestions and comments.

(3) Requests for views on one or two specific fuel points, and intimation of arrangements for holding meeting of representatives of general E.I.C. Fuel Committee.

Shortly afterwards the committee prepared a special review in draft form of the coal situation in Canada which was first circularized to the Montreal members of the Fuel Committee, followed by a meeting of the local members, the result of which was a circular sent to the general membership of the committee. This circular considered the problem from:—

(1) The Eastern Region of Canada — which apparently is in a position to economically supply from purely Canadian sources all the coal necessary in this region, both for household and power purposes.

(2) The Western Region — where it was considered feasible to supply coal or carbonized lignite briquettes for household purposes from purely Canadian sources, although in some of the larger centres the Alberta coals cannot compete economically with American bituminous coals.

(3) Central or acute fuel area — (a) Ontario and the western portion of Quebec constitute the acute fuel area of Canada, which area imports roughly 13,000,000 tons of bituminous coal per year and 4,500,000 of anthracite. It may also be termed the coal consuming area of Canada. (b) It is non-economic under present conditions to expect coal from any Canadian source to compete in this region either in the householder or power fields with coals coming from the United States. (c) That for household purposes Welsh coal, briquettes of various kinds, and coke, form desirable and apparently economic substitutes for the American anthracite at present consumed.

A copy of the Coal Review, together with a digest of the opinions of the various members was mailed to every member of the Fuel Committee on November 10th, and a letter asking for suggestions on fuel policy and for criticisms on the Coal Review.

A general meeting of the committee was held at headquarters in Montreal, on March 8th, 1924, with fifteen members or representatives present. The discussion at this meeting included:—

(1) Grading and sizing of the coals and regulation of the delivery.

(2) High mining costs in Alberta.

(3) Transportation costs.

(4) The future possibilities of Nova Scotia coals.

(5) General discussion on coke.

Since that time the chairman of the committee, Mr. F. A. Combe, M.E.I.C., and the secretary, Mr. Lesslie R. Thomson, M.E.I.C., have had in hand the preparation of the final report which has now been completed. It includes:—

Section I — Summary of conclusions.

Section II — Introduction. Appointment of committee, terms of reference, personnel and officers.

Section III — Review of preliminary activities. Methods of work, circulars issued, replies received, coal review and criticisms of same, short digest of review.

Section IV — Proceedings of meeting of representatives of whole committee. Five points discussed and opinions expressed.

Section V — Findings and recommendations.

The final conclusions of the committee respecting the fuel problem of Canada are:—

(I) That a solution of the general fuel problem of Canada will only be reached by a very careful study of the different phases of the problem, and the gradual development of a policy. In this connection your committee feels that the work of the Dominion Fuel Board is of very great importance, and wishes to touch upon this matter again under the heading of "Recommendations".

(II) That a solution of the fuel problem in the acute fuel area will be forwarded by a co-ordinated policy of water power and fuel power development. As the use of water power increases coal will be released for heating purposes. In the congested centres also, central heating and steam plants will be conducive to more efficient utilization of coal both for power and heat.

(III) For off-season heating, peat offers a desirable substitute for imported coal, and your committee wishes to record its appreciation of the work accomplished at Alfred by the Peat Committee financed by the Federal and Ontario governments. This is just being put upon a commercial basis.

A number of recommendations are included:—

(1) That the Council of *The Engineering Institute of Canada* memorialize the Federal government to set on foot an inquiry into the actual cost of moving coal in train load lots in order to place this matter beyond the realm of half-informed controversy, and suggests that this duty might be discharged with propriety by the Railway Commission of Canada, but that its findings be not made public without including in the final figure proper allowance for overhead, depreciation and profit. Any other course of action might seriously prejudice the whole question of a long haulage movement of coal.

(2) That Council urge the Federal government to take appropriate action in order that each of the provinces concerned should adopt, after discussion, standards of sizing and grading of coals. Until this is done the public in their purchasing of coal will not be protected in any way.

(3) That the Council place on record with the Federal government its appreciation of the valuable work at present being undertaken by the Dominion Fuel Board, that the government be urged to prosecute this work vigorously, and, further, that any so-called national fuel policy should only be adopted after receiving recommendations and reports by the Dominion Fuel Board.

(4) That Council go on record as opposing any tendency to force the railways to haul commodities at less than cost except in times of national peril; and further, that, if for national reasons, it be desirable to have Ontario become a market for Alberta coals, the Council urge upon the Federal government the wisdom of bringing about a result by subsidies or tariffs, rather than by imposing non-economic operation on the transportation systems.

(5) That Alberta operators be urged to concentrate their efforts on the production of the high grade coals for supply to the western region rather than on the shipment of their low grade coals to Ontario.

(6) That the Canadian Furnace Manufacturers have their attention called in some suitable manner to the desirability of providing furnaces especially designed to burn coke and fuels other than American anthracite.

(7) That the branch fuel committees continue their activities in connection with the solving of local difficulties in regard to fuel; and finally suggests very respectfully that the Council consider the possibility of appointing a standing committee on fuel and fuel policy in order that the professional engineers of this country may be able to express their united views from time to time on a matter that is so vitally important to the national welfare.

OBITUARIES

William Arthur Begg, A.M.E.I.C.

Deep regret is expressed at the death of William Arthur Begg, A.M.E.I.C., of Regina, Saskatchewan, which occurred at his late residence in Regina on August 30th, 1924.

The late Mr. Begg was born in Hamilton, Ontario, in 1882 and he received his early education in the public schools of that city. In 1907 he graduated from the University of Toronto in the Faculty of Applied Science. He spent some years in the mining fields of northern Ontario, later he was engaged in survey work for the Dominion government in Alberta. In 1912 he entered the service of the Saskatchewan government as engineer and surveyor with the Department of Highways. In 1921 he was appointed director of town planning under the Department of Municipal Affairs, which position he held at the time of his death.

The late Mr. Begg took a keen interest in all matters relating to town planning and rural development, being a pioneer in this work in the west where he has done much to improve conditions and to place the subject of town planning before the public in its proper light.

Mr. Begg was a member of the Saskatchewan Land Surveyors' Association, the Dominion Land Surveyors' Association, the Canadian Town Planning Association, and on August 20th, 1917, he was elected an Associate Member of *The Institute.*

In the death of Mr. Begg the engineering profession throughout Canada and more particularly in the west has suffered a distinct loss.

Andrew Johnston Riddell, A.M.E.I.C.

Regret is expressed at the death of Andrew Johnston Riddell, A.M.E.I.C., of Windsor, Ontario, which occurred on April 21st, 1924. Mr. Riddell was born at Rutherglen, Scotland, on August 29th, 1861, and received his education at Glasgow Technical College, Scotland, following which he served his apprenticeship for five years being articled to the late John Douglas of Glasgow, Scotland. Prior to coming to Canada in 1906 he was engaged in Scotland principally on municipal work. His first work in this country was in the capacity of construction engineer on the Walker theatre at Winnipeg, and in 1909 he was engaged in the same capacity with the Canadian Pacific Railway Company on bridge construction over the Old Man river, at Macleod, Alta. Subsequently, in 1909, Mr. Riddell carried on the practice of his profession as an architect in the city of Winnipeg. Later he affiliated with the Trussed Concrete Steel Company of Canada, Limited, and remained with them for a period of upwards of five years, finally going to the town of Walkerville and taking charge of one of the departments of the head office there. He left this company to resume the practice of his profession and affiliated himself with Gilbert Jacques in the city of Windsor, and practised with this party for several years. Later he dissolved this affiliation and commenced practice under his own name, as he had in the city of Winnipeg, and was engaged in his profession at the time of his death. Mr. Riddell was elected an Associate Member of *The Institute* (then the Canadian Society of Civil Engineers), on April 9th, 1910.

Joseph Gosselin, Jr., Affiliate E.I.C.

Joseph Gosselin, Jr., Affiliate E.I.C., died at his home at Levis, Quebec, on July 4th, 1924. The late Mr. Gosselin was vice-president and general manager of Jos. Gosselin, Limited, general contractors, lumber merchants and manufacturers. He was born at St. Nicholas, on November 15th, 1873, and was educated at Levis college. Since completing his schooling he was continuously associated with his father in the contracting and manufacturing business. Mr. Gosselin was a member of the Engineers' Club of Montreal, and the Quebec Automobile Club, and was elected an Affiliate of *The Institute* on September 25th, 1917.

PERSONALS

W. Stanley Vipond, M.E.I.C., has been re-elected president of the Northern Electric Engineering Society, Montreal.

G. B. Elliot, S.E.I.C., of Westmount, Quebec, has been appointed to the sales staff of the A. R. Williams Machinery Company, Montreal. Mr. Elliot is a graduate of McGill University of the class of 1922.

John Buss, S.E.I.C., who has been located with the Bogalusa Paper Company, Inc., Bogalusa, Louisiana, as chief chemist, has returned to Canada and is with the Provincial Paper Mills, Limited, at Thorold, Ontario.

A. E. Eastman, A.M.E.I.C., is with the St. Lawrence Valley Power Company of Potsdam, N.Y., on hydro-electric power plant construction. Mr. Eastman was formerly engaged with Huff Daland and Company, Inc.

H. J. Whiting, Jr.E.I.C., has been appointed to the staff of the Barrett Company, Limited, Montreal. Mr. Whiting was previously with the Newfoundland Power and Paper Company, Montreal.

Lt.-Col. K. M. Perry, D.S.O., A.M.E.I.C., has resigned from the chair of tactics at the Royal Military College, Kingston, Ontario, on appointment to be general staff officer of military district No. 4, Montreal. Lt.-Col. Perry is attached to the Royal Canadian Regiment.

C. R. Davis, S.E.I.C., has been appointed sales engineer with the Canadian International Filter Company, Limited, at Toronto. Mr. Davis graduated from the University of Toronto last spring, and was until recently with the St. Regis Paper Company at Godbout, Que.

Herbert P. Heywood, A.M.E.I.C., who recently joined the staff of the Sterling Appraisal Company, of Toronto and Montreal, is engaged at present in the appraisal of the Western Sanitarium. In his present position Mr. Heywood will devote his time to the appraisal of industrial plants, buildings and institutions.

Frederick E. Bronson, A.M.E.I.C., has been elected vice-president of the Ottawa Light, Heat and Power Company, the holding company and owners of the stock of the Ottawa Electric and Ottawa Gas Companies, of both of which he has also been appointed vice-president, in succession to the late Warren Y. Soper.

C. C. Kirby, M.E.I.C., G. G. Hare, M.E.I.C., and J. N. Flood, A.M.E.I.C., have been appointed a committee to superintend the erection of a war memorial monument to be placed in King square, the principal park of the city of St. John, N.B. The base of the monument will be made of Spoon island, New Brunswick granite.

John Tomkins, S.E.I.C., has been appointed construction engineer for the Temiskaming mill of the Riordon Pulp Corporation, Limited. Following his graduation from Queen's University in 1923, Mr. Tomkins was with the Howard Smith Paper Mills, Limited, at Cornwall, Ontario.

Allan T. Bone, A.M.E.I.C., is with the Geo. A. Fuller Company, Limited, on the construction of the twenty-one storey building in Toronto. Mr. Bone was previously with the Shawinigan Engineering Company Limited at La Gabelle, Quebec, on design and estimating on the new power development of the St. Maurice Power Company, at that site.

Ralph Allingham, A.M.E.I.C., chief engineer for A. W. Menkins, engineers and contractors, on the construction of grain elevators for the government of the Union of South Africa, has returned to Canada. Mr. Allingham has been engaged on this work in South Africa since August 1921 and has returned to this country following the completion of the work.

Garnet Rankin, A.M.E.I.C., of Toronto, sailed for Hong Kong, China, from Vancouver on September 25th to take over his duties as reinforced concrete and structural engineer for the firm of Little, Adams and Wood, lower Albert Road. Mr. Rankin is a graduate of the University of Toronto of the class of 1915, and until recently has been with the city architect's department, of the city of Toronto.

L. S. Dixon, M.E.I.C., consulting engineer with the Riordon Pulp Corporation, Temiskaming, Quebec, is with the Bogalusa Company Inc., Bogalusa, Louisiana. Mr. Dixon was previously assistant engineer with the Riordon Company under G. L. Freeman, M.E.I.C., during the construction of the Kipawa plant, and in 1923 was appointed chief engineer of the Eddy Paper Corporation, Three Rivers, Michigan.

Professor W. G. Hardy, A.M.E.I.C., of the Nova Scotia Technical College, has returned to Halifax after making a holiday trip of eighteen thousand miles, visiting New York, Panama Canal, Los Angeles, Portland, Oregon, Puget Sound, San Francisco, New Orleans and Montreal. While in Los Angeles, Prof. Hardy collaborated in the preparation of a report for the extension of the Los Angeles water supply which is at present serving 1,000,000 people and by 1946 it is estimated will be serving 4,000,000.

Edward Hughes, A.M.E.I.C., has accepted a position with Geo. M. Campbell, railway contractor, at Calumet, Michigan, on the engineering staff of the contracting department. Mr. Hughes was engineer with the Crow's Nest Pass Coal Company, Limited at Fernie, B.C., previous to which he had been engaged on a number of railway construction works in western Canada. He was also assistant on Canadian Geological Survey work for two summers previous to 1919.

Members of *The Institute* who have recently been appointed by the Canadian Ingersoll-Rand Company, Limited to take an eight months course in their works with a view to later appointments to sales and executive positions in the company, are as follows: —Francis G. Ferrabee, S.E.I.C., graduate from McGill university in mechanical engineering last spring; Richard R. Gilbert, S.E.I.C., graduate of 1924 from Nova Scotia Technical College; and Harold J. Maxwell, S.E.I.C., who received his degree from the University of New Brunswick in 1923.

Norman D. Wilson, A.M.E.I.C., of the firm of Wilson and Bunnell, consulting town planning and transportation engineers, has recently left for Mexico city to report on traffic problems there for the Mexico Tramways Company. Mr. Wilson has for the past three years been engineer on traffic study for the Toronto Transportation Commission, assisting in the problems incidental to extensions, re-routing, etc. One of the latest problems handled by Mr. Wilson for the Transportation Commission was a report and recommendation on the transportation requirements of York township, which has since been adopted by the township.

V. R. Davies, A.M.E.I.C., has been appointed acting assistant professor in civil engineering at the University of Saskatchewan, relieving assistant professor R. A. Spencer, A.M.E.I.C., who has been granted leave from the university for one year. Mr. Davies graduated from McGill University in 1920 and received his degrees of B.Sc., and M.Sc., from that university, and M.C.E., from the University of Manitoba in 1923. His post graduate course in McGill University was taken during the season of 1922-1923, when, as demonstrator in the department of geodesy and surveying, he carried on his post graduate work in hydraulics.

A. P. Theuerkauf, M.E.I.C., has been appointed chief engineer of the Dominion Iron and Steel Company and the subsidiary steel plants at New Glasgow and Sydney Mines, succeeding Geo. D. Macdougall, M.E.I.C., who recently resigned from this position. Mr. Theuerkauf joined the Dominion Iron and Steel Company in 1901 as mechanical draughtsman and designer. In 1909 he became designer for the Dominion Coal Company Limited, at Glace Bay and the following year joined the staff of the Canadian Foundry Company, Toronto, in the same capacity. In 1911 he returned to the Dominion Iron and Steel Company as squad leader and was later appointed chief draughtsman and subsequently technical engineer and assistant chief engineer with the company.

Lesslie R. Thomson, M.E.I.C., who for the past six years has been secretary of the Lignite Utilization Board of Montreal, announces that he has opened an office as consulting engineer, specializing in the fields of structural engineering and fuel economy. Mr. Thomson graduated from the University of Toronto in 1905 in mechanical engineering, securing his degree of B.A.Sc. (hydraulics and strength of materials) in 1906, and graduating in civil engineering in 1907. After lecturing in civil engineering in the University of Manitoba for two years, from 1910 to 1912, Mr. Thomson became associated with the Dominion Bridge Company as assistant engineer, in which capacity he remained until 1918. He is at present special lecturer in structural engineering, Department of Architecture, McGill University, Montreal.

H. M. Bigwood, A.M.E.I.C., Receives Promotion

H. M. Bigwood, A.M.E.I.C., chief draughtsman, Public Works Department, Victoria, B.C., has received promotion to assistant district engineer on Vancouver Island, with headquarters at Alberni. On the occasion of his departure, the Victoria Branch tendered Mr. Bigwood a farewell luncheon and presentation, and on motion by G. B. Mitchell, M.E.I.C., seconded by E. P. Girdwood, M.E.I.C., a hearty vote of thanks was extended to him for services as past-chairman and secretary, in making the annual and general meetings outstanding successes.

Mr. Bigwood has made many staunch friends in Victoria and Vancouver, and while they regret his leaving Victoria, good wishes and congratulations accompanied him.

E. T. Spidy, A.M.E.I.C., leaves for New Zealand

E. T. SPIDY, A.M.E.I.C.

E. T. Spidy, A.M.E.I.C., superintendent, Dominion Engineering Works, Montreal, has resigned his position and has left for New Zealand. Mr. Spidy spent the early years of his life in that country, and while his present trip is in the interests of his health, he will in all probability locate there. At the age of twelve Mr. Spidy left New Zealand and returned to Brighton, England, the place of his birth, where he entered the mechanical engineering course at the Brighton Technical College. He has been in Canada for the past fifteen years having joined the staff of the Canadian Pacific Railway Company at the Angus shops in 1909. During the past three and a half years he has been with the Dominion Engineering Works, and in practically all his work in Canada he has specialized on production methods and cost production. One of the specialties which Mr. Spidy has carried out in all his work is the introduction of piece work or premium method of wage payment.

Sir Ernest Rutherford (left) and Sir David Bruce, on the occasion of their visit to Canada to attend the meetings of the British Association for the Advancement of Science. Sir Ernest was the guest of honour at a special luncheon given by the Engineering Institute of Canada at the Windsor hotel, Montreal, on Thursday, September twenty-fifth, when he addressed the members of The Institute on the Advancement of Science.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 23rd, 1924, the following elections and transfers were effected:

Members

CHISHOLM, Donald Cameron, B.A.Sc., (Univ. of Tor.), division engineer, C.P.R., Fort William, Ont.

STEWART, Robert Meldrum, B.A., M.A., (Univ. of Tor.), director, Dominion Observatory, Ottawa, Ont.

THOMAS, George Nevil, (Elec. and Mech. Engrg., Durham Univ.), supt. of constrn. and in charge of constrn. estimating, Canadian General Electric Company, Ltd., Toronto, Ont.

THORNTON, Major-General Sir Henry Worth, K.B.E., B.Sc., D.Sc., M.Inst.C.E.. Order Leopold of Belgium, Comm. Legion of Honour, Am.D.S.M., chairman and president, Canadian National Railways, Montreal, Que.

Associate Members

AGAR, George, (City and Guilds of London), chief mechanical dftsman. and estimator, Canadian Vickers, Limited, Montreal, Que.

CASSELS, Westcote Lewis Lyttleton, B.Sc. (McGill Univ.), partner, Farley & Cassels, and Cassels & McDougall, Ottawa, Ont.

CHINA, Ernest, asst. engr., highways dept., Regina, Sask.

CRAWLEY, Frederick Austin, divn. engr., divn. No. 3, Provincial Highways Board, Halifax, N.S.

DELISLE, Joseph Lorenzo, B.A.Sc. (Univ. of Tor.), in charge of electrical and mechanical department, Chicoutimi Pulp Company, Chicoutimi, Que.

FORTIN, Joachim, B.Sc. (Levis College), supt. for the Nova Scotia Construction Co., at Portage des Roches, Que.

JOHNSON, Lancelot Llewellyn, C.E. (Renss. Poly. Inst.), unit director of administration, for prov. of Alberta, D.S.C.R., Calgary, Alta.

JONES, Morris Herbert, asst. engr., pulp and paper machinery dept., Port Arthur Shipbuilding Co. Ltd., Port Arthur, Ont.

McDONALD, Claude Knox, dftsman., Canadian Line Materials Ltd., Toronto, Ont.

NUTTALL, Albert, (City and Guilds of London), asst. engr., city of St. Lambert, Que.

RAMSAY, Robert, asst. chief engr., Canadian Vickers, Limited, Montreal, Que.

SHECTOR, Sidney Samuel, B.Sc. (Univ. of Wis.), engr. supt. in full charge of constrn. of elevators for John S. Metcalf Co. Ltd., Montreal, Que.

STODART, James, engr., Messrs. Cope & Sons, contractors, Hamilton, Ont.

SWINNERTON, Aylmer Aberffraw, B.A.Sc. (Univ. of Tor.), chemist in charge oil shale investigations, Department of Mines, Ottawa, Ont.

VALIQUETTE, Adrien, C.E., B.Sc.A. (Univ. of Montreal), Quebec Streams Commission, Montreal, Que.

JOHNS, Charles D., estimator, asst. supt., John V. Gray Construction Co., Windsor, Ont.

MARCH, Joseph Wade, B.Sc. (N.S. Tech. Coll.), transmission line work, Nova Scotia Power Commission, Bridgewater, N.S.

ROSS, Donald Grant, B.Sc. (Dalhousie Univ.), engr. in charge of constrn., section 2, transmission line, with Sir W. G. Armstrong Whitworth & Co., Humber development scheme, Newfoundland.

STEEVES, Darrell Darrington, dftsman., John S. Metcalf Co., Ltd., Montreal, Que.

Transferred from the class of Associate Member to that of Member

BARNES, Harry Fairweather, B.Sc. (Univ. of N.B.), municipal engr., British Municipal Council, Tientsin, China.

DeLAPORTE, Antoine Valentine, B.A.Sc. (Univ. of Tor.), special lecturer to the course in municipal engrg., Univ. of Toronto, asst. sanitary engr., and in charge experimental station, Prov. Board of Health of Ontario, Toronto, Ont.

JEFFREYS, Arthur Gerald, The Grove, Lincoln Avenue, Montreal, Que.

MacNAUGHTON, William Gilbert, B.A., B.Sc., (McGill Univ.), secretary, Technical Association of Pulp and Paper Industry, New York, N.Y.

MIEVILLE, Arthur Leonard, general manager, Howden-Ljungstrong Preheaters (Land) Ltd., Govan, Scotland.

RUSSELL, Benjamin, B.Sc. (McGill Univ.), chief field inspr. and hydraulic engr. of irrigation surveys, Water Power and Reclamation Service, Dept. of the Interior, Calgary, Alta.

Transferred from the class of Junior to that of Associate Member

MOORE, Charles Melbourne, B.Sc. (Queen's Univ.), inspecting engr., Reclamation Service, Dominion Government, Calgary, Alta.

Transferred from the class of Student to that of Associate Member

HALL, John G., B.Sc. (McGill Univ.), asst. supt., Back River Power Company, Montreal, Que.

MACDONALD, John Angus, B.Sc. (N.S. Tech. Coll.), junior topog'l. engr., Geol. Survey of Canada, Ottawa, Ont.

MACKENZIE, William Langlands, B.Sc. (McGill Univ.), asst. engr., Welland Ship Canal, St. Catharines, Ont.

Transferred from the class of Student to that of Junior

ABEL, John Stewart, B.Sc. (Univ. of Man.), asst. engr., way and structures, Winnipeg Electric Railway, Winnipeg, Man.

DOIDGE, Henry George, B.Sc. (Univ. of Man.), instructor, science dept., Royal Military College, Kingston, Ont.

SPOTTON, John Greer, B.A.Sc. (Univ. of Tor.), manager, Hepburn & Spotton, Guelph, Ont.

STEWART, Malcolm Davidson, B.A.Sc. (Univ. of Tor.), engrg. dept., Price Bros. & Co. Ltd., Chicoutimi West, Que.

WELDON, Harold Stanley, B.A.Sc. (Univ. of Tor.), district manager Montreal office, Canadian Inspection and Testing Co. Ltd., Toronto.

WHITE, Hazel Marguerite, B.A. (Dalhousie Univ.), asst. plant engr., Dept. of Telephones, Saskatchewan Government, Regina, Sask.

The following Students were admitted:—

ARGUE, Harold Edward, 2111 Osler Street, Regina, Sask.

BALFOUR, Melville W., 931 Seventh Avenue North, Saskatoon, Sask.

GILLETZ, Colly, 2372 Waverly Street, Montreal, Que.

GREENBURG, Harry, 1088 St. Dominique Street, Montreal, Que.

SILLERS, Thomas George Archibald, 411 Third Avenue North, Saskatoon, Sask.

TITUS, Ernest Moulton, 512 Avenue K North, Saskatoon, Sask.

WHITE, Joseph James, 610 Lansdowne Avenue, Saskatoon, Sask.

WILSON, James Harvey, Qu'Appelle, Sask.

The following Students were admitted at the meeting of Council held on August 26th, 1924:—

BUCHANAN, Thomas Gwynne, 1983–57th Avenue West, Vancouver, B.C.

CLUFF, Harold David, Lieut., R.C.C.S., B.Sc. (Univ. of Man.), Camp Borden, Ont.

DIXON, Meredith Fred, 219 Wilson Avenue, Montreal, Que.

FERRABEE, Francis Gilbert, 731 Sherbrooke Street West, Montreal, Que.

FERGUSON, John Clifford, B.Sc. (Queen's Univ.), Queenston, Ont.

McCULLAGH, Karl G., B.Sc. (Univ. of Man.), Camp Borden, Ont.

TAMES, John Alexander, 11247–124th Street, Edmonton, Alta.

WRIGHT, James Frederick Church, 665 Langside Street, Winnipeg, Man.

ANNOUNCEMENT OF MEETINGS

Further information may be secured from the secretaries of the various branches, whose addresses will be found under "Officers of Branches" on page 624 of *The Journal.*

NIAGARA PENINSULA BRANCH:—

Secretary-Treasurer, R. W. Downie, A.M.E.I.C.

Oct.	Trip to inspect the plant of the Horton Steel Works, Bridgeburg.
Nov. 7th.	Dinner meeting at St. Catharines, to commemorate the centenary of the Welland canal. Speaker E. W. Beatty, K.C., president, Canadian Pacific Railway Company. Presentation of branch charter by President Surveyer, M.E.I.C.
Dec. 11th.	Dinner meeting, Niagara Falls. Northern Ontario night. Speaker, The Hon. Chas. McCrea, minister of mines, Ontario.

SASKATCHEWAN BRANCH:—

Secretary-Treasurer, J. W. D. Farrell, A.M.E.I.C.

Oct. 9th.	Address by Colonel Boyden of the Portland Cement Association.
	Meeting at which Major Geo. A. Walkem, M.E.I.C., will present the Branch charter, date to be announced later.

WINNIPEG BRANCH:—

Secretary-Treasurer, P. Burke-Gaffney, A.M.E.I.C.

Oct. 2nd.	Smoking Concert (Jointly with Association of Professional Engineers.) It is expected that the presentation of the branch charter, by Vice-President, Major Geo. A. Walkem, M.E.I.C., will take place at this meeting.
Oct. 16th.	Address on "Design and Operation of Flour Mills", by Theodore Kipp, Jr.E.I.C.
Nov. 6th.	Address on "City Financing", by H. C. Thomson.
Nov. 20th. Dec. 4th.	Prize Papers. Engineering students, University of Manitoba.
Dec. 18th.	Address on "Modern Combustion Engineering", by A. J. T. Taylor.

Memorandum re World Power Conference and Subsequent Visit to France and Switzerland

By Frederick B. Brown, M.E.I.C.

Arrived in London on June 25th, where the following few days were spent in preparation for the World Power Conference which opened at the Palace of Industry, Wembley, on June 29th, where H.R.H. the Prince of Wales made an inaugural address. For the following two weeks, until the 12th of July, morning and afternoon sessions were held at Wembley, some times as many as three meetings proceeding at the same time in different halls. Several hundred representatives from forty-one countries attended the sessions where the keenest interest was displayed in the papers and their discussions. About 425 papers were presented on all phases of power resources, their production, development and utilization in the various countries of the world. The official programme gives the details of the subdivisions, with the authors and the titles of the papers. The papers present a very complete review of the present power situation and will undoubtedly form a most valuable contribution to the literature on the subject. It was impossible to follow all the sessions, but I gave close attention to those subjects of more particular interest to me. The speakers were handicapped in discussing the papers because many of these were not received until after the Conference had begun, and therefore most of the speakers gave brief outlines of the contents of their papers although some very good discussion was developed on several occasions. I took part in the discussion several times, and on one occasion was honoured by being asked to preside over one of the sessions of the Conference. This was on July 9th, when the subject of Internal Combustion Engines was presented in Hall No. 2, at which time there were present between 75 and 100 representatives, and 23 papers were discussed by representatives from 9 different countries. This meeting was typical of the others, and all were very interesting. One of the principal benefits of the Conference was the opportunity of meeting the engineers from the other countries and getting to know them personally, and exchanging views with them and learning something of their problems, and the economic conditions in the various parts of the world. The principal object of the Conference was undoubtedly to bring together the men who are responsible for the development and utilization of power resources and to consider how power matters can be handled scientifically and industrially, taking into consideration international and national limitations, with the ultimate object of providing a central and permanent clearing house of power information. The objects of the Conference I believe were attained, and the importance of the meeting will doubtless be very great.

With regard to the Canadian papers and their presentation, I may safely say that they were second to none, both in subject matter and form. Very high compliments were paid to the Canadian authors, and it was very evident that Canada is looked to as one of the leaders in hydro-electric power development, if not indeed the most advanced of any country.

The problems in the various countries are so widely variant that it is difficult to generalize on the subject, and reference may be had to the papers in detail to appreciate the various points raised. Some countries have few water powers, and others are abundantly endowed therewith. Some countries have very efficient fuel burning plants, and the problems of utilizing and exchanging power were discussed, and brought out the possibilities of future power stations in adjacent countries where the interchange of power and other materials may work for the benefit of both.

During the Power Conference there were certain papers which were not of direct personal interest, and it was possible to arrange for several trips in England to visit power stations and engineering works not on the official programme, as well as to see several points of interest. In this way visits were made to the shops and power plants of the London, Midland and Scottish Railway, including the very efficient steam station at Stonebridge; the Barrow-in-Furness works of Vickers, Limited, where large hydraulic turbines and diesel engines are being manufactured, as well as a great deal of ship-building, gear cutting, and other interesting work is being carried on; some of the works of the English Electric Company, Armstrong-Whitworth, a number of shops in and about London, and particularly the Palace of Engineering at Wembley Exhibition, where a really marvellous collection of exhibits of engineering interest is assembled under one roof, and which would require several volumes to describe.

At the conclusion of the World Power Conference, a party of thirty engineers, representing nine countries, joined the specially conducted tour to France, Switzerland and Italy, where a great many powe plants were inspected and a number of very enjoyable visits were made, and where also we met the leading engineers in various parts of these countries. The following summary of the itinerary give an idea of the ground covered and the plants seen.

Monday, July 14th.

Left London by train for Dover, crossing to Calais, and arrived at Lille in the evening, and inspected local electrical works and distribution system.

Tuesday, July 15th.

Left Lille in early morning and drove to Croix-Wasquehal, and inspected the steam power station there. This plant was designed for 5,000 kilowatts, and has grown to a capacity of 56,000 kilowatts, beyond the efficient capacity of the local water supply for condensing purposes. Interesting powdered coal burning apparatus side by side with chain grate stokers and hand firing, permitting comparison of methods in the same station. Continued by auto car to Roubaix, and from there to Comines, where the new steam power station of 85,000 kilowatts capacity was inspected. This is entirely equipped for burning pulverized fuel and is being extended for a much larger capacity, the ultimate capacity of which may probably be 250,000 or 300,000 kilowatts. The turbine units in this plant are of 25,000 to 30,000 kilowatts capacity each. Returned to Lille at night.

Wednesday, July 16th.

Left Lille by train 7.24, arriving at Aulnoye at 8.54, and from there went to Erquelines in Belgium. After the local system was inspected, which included a very interesting open air substation and transmission lines at 45,000 volts, left for Jeumont in France where the State Installations were inspected, after which took train for Paris, arriving there in the evening. That evening the French Minister of Public Works tendered a banquet to the Canadian Delegation and the visiting engineers at Union Inter-Allied, following which the party left by night train for Lyons, arriving there in time for breakfast.

Thursday, July 17th.

In the morning went to Ivry-Port where the laboratory of Cie Electro-Céramique was inspected and where tests were made at 1,000,000 volts on insulators manufactured by this company. In the afternoon, motor trip to Gennevilliers where the large steam power station, 200,000 kilowatts present capacity, was inspected. These units are 40,000 kilowatts each. Very interesting data obtained from Colonel Mercier, chief engineer, regarding efficiencies and selling methods, load and so forth.

Friday, July 18th.

Left Lyons in early morning and inspected the Thury system of direct current transmission, 100,000 volts at Vaulx-en-Velin. This is 100,000 volts system distributing direct current near Lyons, and fed from a number of hydro-electric power plants in Savoie province at Bellegarde, Chambery and other places. In the afternoon took train from Lyons to Valence, and thence by automobile to Beaumont-Monteux, where the power station on the Lower Isere was inspected. This is a low head plant of 28,000 kilowatts, very similar in general design to the La Gabelle, but on a smaller scale. The system of transmission lines at 120,000 volts, and the outdoor transformer stations were very interesting. Returned to Lyons by automobile at night.

Saturday, July 19th.

Left Lyons at 7 a.m., arriving at Bellegarde near the Swiss border. At Bellegarde we inspected three power plants in the gorge which send their power to Lyons, some of them dating back to the earliest days of power development, but recently re-modelled. Also inspected the site of a very large proposed development at this point where difficult hydraulic conditions have to be met. Thence by auto through a wonderful country in sight of Mont Blanc to Chancy Pougny. This is a hydro-electric station of about 45,000 kilowatts capacity, under a 25-foot head, also very similar in design to La Gabelle. It is an international river between France and Switzerland, one end of the dam being in each country. Some of the hydraulic features at this installation are quite intricate and the workmanship is excellent. After inspecting this plant we drove by auto to Val de Fier where a very neat hydro-electric power plant under 200-foot head is installed. The dam is situated in a narrow rocky gorge, and it was necessary to excavate 130 feet below the bed of the stream to obtain foundations for the dam which has a total height of 250 feet, but is very short. The water is led in a tunnel to a power plant downstream, with the forebay forming the surge tank above the station, which has a capacity of about 15,000 kilowatts. We left Val de Fier in the evening, arriving at Chambery late at night.

Editorial note: — Mr. Frederick B. Brown was asked to give an account of his trip to the World Power Conference, which is published herewith. Mr. Gale's account, which was also sent in by request, covered the trip to Norway and Sweden, while Mr. Brown's touches on the points of interest witnessed by those who took the trip to Switzerland and Italy.

Sunday, July 20th.

Left Chambery 7.10 a.m., and arrived at Bourg St. Maurice on the upper Isere, where there is a high head plant of 25,000 kilowatts, and a transmission system of 120,000 volts at Viclaire. Arrived at Chambery in the late afternoon and inspected the power plant nearby. This is of comparatively small capacity but beautifully designed.

Monday, July 21st.

Further inspection of plants near Chambery, thence to Aix-les-Bains, and after a hot sulphur bath in the famous establishment, left for Culoz and Geneva, arriving at Geneva in the evening.

Tuesday, July 22nd.

Some of the party left Geneva for Chevres, where a 20,000 horse power hydro-electric station constructed 30 years ago is still in efficient service. I went with the other portion of the party to see the arch dam at Broc. This dam is recently completed, forming an artificial lake with three rivers feeding into it. The dam is 150 feet high and about 400 feet long on the crest, and is one of the most interesting pieces of construction in Europe. Full description of the design is contained in the French and Swiss technical press, including two very good papers on temperature measurements and expansion measurements in the dam. It was completed about four years ago, and the plant operates under a head of approximately 100 metres, or 330 feet. It has a capacity of about 20,000 kilowatts fed through two steel penstocks and a long tunnel. After seeing this plant we visited the ancient Chateau of Gruyere, and later in the day the picturesque town of Romont, thence to Berne by train, arriving there in the late evening.

Wednesday, July 23rd.

Left Berne by motor car in the early morning and visited the hydro-electric station at Muhleberg. This plant was completed in 1921-1922, and has a head of 60 feet and a capacity of about 70,000 horse power and utilizes an artificial storage above the dam amounting to about 350,000,000 cubic-metres. The plant is beautifully designed and has a very fine outdoor transformer station. The generation is at 15,000 volts, and there are in the station some large frequency changing sets for railway use.

Other members of the party left Berne for Zurich where the works of Sulzer Brothers at Winterthur, and the works of Brown, Boveri & Company at Baden were inspected, after which the electric station at Olten-Goesgen was inspected. This plant is 59,000 kilowatts and is interesting because it has four different transmission voltages leaving it.

Thursday, July 24th.

Left Berne at eight o'clock in the morning, and arrived at Interlaken, where the Monophase Electric Traction system at 15,000 volts was inspected. We also visited the railroad shops at Spiez, and an interesting power plant nearby under 230 feet head, and having a capacity of 24,000 kilowatts. In this plant a very fine example of the pitting of the turbine runners was seen and four runners of different materials were inspected showing the effects of material on pitting, and also the effect of change in the draft head. This plant also has three different methods of exciting the generators, which is most unusual. Returned to Interlaken late at night.

Friday, July 25th.

Left Interlaken at 8 o'clock in the morning and climbed the Jungfraujoch by rack railway, some grades being as high as 25 per cent, and the tunnel work being extremely interesting. After descending the mountain we inspected the Burglauenen power station built 20 years ago, with a head of 550 feet, and which serves all the electric railroads in the district with a capacity of 5,000 horse-power. We left Lutschental after inspecting the power station, and reached Interlaken in the late evening.

Saturday, July 26th.

Left Interlaken in the early morning, arriving at Lucerne at noon, where the entire Swiss delegation of Power Delegates to London met us, and, with the Minister of Public Works, and the Director of Hydraulic Service, and the leading consulting engineers of Switzerland, tendered us a delightful luncheon at the Schweizerhof hotel overlooking the lake. In the afternoon some of the party took an excursion on the lake, but I, with some others, motored to Zurich, and went through the works of Escher-Wyss Company, arriving back in Lucerne by motor car in time to catch the train.

Sunday, July 27th.

Part of the party left Lucerne in the morning, and visited Amsteg works, Wassen, Goeschenen, Chiasso, and thence into Italy to Milan. The other members of the party visited the very interesting high head plant at Ritom, which takes the waters of Lake Ritom and utilizes them under a head of 828 metres. Some exceptionally interesting tunnel work and pipe line work was observed at Ritom, especially in connection with repairs made to the tunnel after failure of the rock strata. Some of the features of the Pelton wheel installation are very interesting. The four generators have a combined capacity of about 36,000 kilowatts, and are 15,000 volts, single phase, 16-⅔ cycles, 333 r.p.m. The station is designed for two more similar units. A very complete description of the works at Ritom can be found in the Swiss technical press in German.

Monday, July 28th, to Wednesday, July 31st.

Party in Venice sight-seeing and visiting hydro-electric stations at Piave, Santa Croce. The Fadalto station is 88,000 kilowatts, 105 metres head, the Nove station is 55,000 kilowatts, 99 metres head; San Floriano station 4,400 kilowatts, 14 metres head, and at Castelletto 5,200 kilowatts, 62 metres head.

Friday, August 1st, and Saturday, August 2nd.

In Venice and Milan and Stresa, where the works of the Ovesca were inspected, and the hydro-electric stations at Rovesca, 38,000 kilowatts, and at Pallanzeno, 36,000 kilowatts, were inspected.

Sunday, August 3rd.

The party left Stresa for Domodossola, where five high head installations were visited — Goglio 25,000 kilowatts, 525 metres head; Verampio 28,000 kilowatts, 570 metres head; Valdo 30,000 kilowatts, 775 metres; Rivasco 10,000 kilowatts, 346 metres; Crego 21,000 kilowatts, 490 metres. These stations are all of the Imprese Elettriche Conti.

Monday, August 4th.

The party returned to Paris and London.

As my steamer sailed from Cherbourg just before the close of the Tour, I left the party a day or two before the close and returned to Paris and Cherbourg in time to catch the Empress of France for home, spending a pleasant day or two in Paris en route.

Franklin Institute Centenary

On September 17th, 18th and 19th, 1924, the Centenary Celebration of the founding of The Franklin Institute and the inauguration exercises of the Bartol Research Foundation were held in Philadelphia.

Professor Elihu Thomson, Ph.D., Sc.D., was chairman of the Honorary Committee of the Centenary Celebration while the executive committee was presided over by President Wm. C. L. Eglin, Sc.D., of the Franklin Institute.

The morning of Wednesday the seventeenth was given over to addresses of welcome by the Honorable W. Freeland Kendrick, Mayor of Philadelphia, President Wm. C. L. Eglin of the Franklin Institute and Professor Elihu Thomson, the afternoon being devoted to sectional meetings. Addresses were given by distinguished men of science from different parts of the world, a number of whom were British Scientists who had attended the Toronto meeting of the British Association.

The event is unique in the history of scientific organizations in America and attracted considerable attention in the scientific world.

The Institute was represented by Professor W. S. Pardoe, B.A.Sc., C.E., M.E.I.C., of the University of Pennsylvania. The secretary of the Franklin Institute is Doctor R. B. Owens, M.E.I.C.

Prospectors' Map of Northern Manitoba

A map intended for the use of prospectors in the mineral belt north of The Pas, Manitoba, has been prepared by W. T. Thompson, M.E.I.C., and to those interested in this district this map should prove of great assistance.

Trade Publications

The G & W Electric Specialty Company Inc., has issued a pocket size booklet entitled, G & W Potheads Protection for Cable Ends, which is intended for the construction man on installations. This booklet will be sent to readers of *The Journal* upon application to the company.

The Marconi Wireless Telegraph Company, Limited, has issued two interesting booklets; the first entitled "The Marconi Beam System for Long-distance Communications", and the other, a reprint of a paper read before the Royal Society of Arts by Senator Guglielmo Marconi, on the "Results obtained over very Long Distances by Short Wave Directional Wireless Telegraph more generally referred to as the Beam System".

BRANCH NEWS

Victoria Branch

E. P. Girdwood, M.E.I.C., Secretary-Treasurer.

Good progress is being made with the Dominion Drydock, Esquimalt, V.I., and it is planned that the branch will visit the work in the near future.

At the last regular meeting, May 30th, it was requested to have a discussion at our next regular meeting on October 1st, the subject chosen was "British Columbia Dams". E. Davis, M.E.I.C., chief engineer, Water Rights Branch, and E. G. Marriott, A.M.E.I.C., of the Water Rights Branch were chosen as leaders. All members are expected to take part in this discussion.

Word has just come to hand that the branch charter will be presented by Geo. A. Walkem, M.E.I.C., vice-president of zone "A" at an early date.

E. A. Cleveland, M.E.I.C., comptroller of water rights, has consented to address the branch on the World Power Conference, and a discussion will follow.

Farewell Luncheon to H. M. Bigwood, A.M.E.I.C.

There was a good attendance of the Victoria Branch at the farewell luncheon held in honour of H. M. Bigwood, A.M.E.I.C. E. E. Brydone-Jack, M.E.I.C., made the presentation and expressed the regret that Mr. Bigwood was leaving the city. Chief Engineer Patrick Philip, M.E.I.C., also spoke of the great regret of his fellow engineers at Mr. Bigwood's departure.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Luncheon in Honour of Major Stuart McLaren

Declaring that he would attempt a second around-the-world aeroplane trip if only to vindicate the enthusiastic reception he had received from Canadians, Major Stuart McLaren addressed some three hundred local members of *The Institute* and their friends at a special luncheon, given in honour of the British fliers, in the Chateau Laurier, Thursday September 4th.

In the unavoidable absence of Premier Mackenzie King, the Hon. Charles Stewart expressed the Canadian Government's unqualified admiration of the intrepid exploit and sympathy at the hard luck which prevented success.

Major McLaren gave some interesting details of the trip and narrow escapes from death encountered. The nearness to which the party had approached success in their flight was realized when Major McLaren told that had they landed at almost any other point than at the island outside which they met disaster, repairs would have been possible.

Brown Coals and Lignites of British Empire

The Engineering Institute of Canada united with the society of Chemical Industry to hear a splendid address on the brown coals and lignites of the British Empire by Professor William A. Bone, F.R.S., in the Victoria Memorial Museum on Thursday night September 4th. Dr. A. McIntyre, chairman of the Society of Chemical Industry, presided.

Dr. Bone, who is professor of chemical technology in the Imperial College of Science and Technology, London, England, is one of the world's greatest authorities on coals and his remarks with reference to Australian and Canadian lignites were listened to with special eagerness. He is in Canada in connection with the visit of the British Association for the Advancement of Science.

In the course of a very profound address he drew attention to the unusually favourable opportunity for scientific research in coal as presented in the western Canadian coal fields where every grade of coal was represented in order. He was favourable impressed with the advantages of development of power from lignites at the pit mouth, and referred particularly to the work being done along these lines in Australia in the Marwell field in connection with which the speaker had done considerable work. The Australian government was going ahead with power installation in this field where the brown coal could be delivered to the surface at 50 cents per ton and by a specially designed boiler in which the waste gases were used to dry the coal it was anticipated that Australia would shortly have the cheapest commercial power anywhere obtainable. Such power could be economically delivered to Melbourne and other centres.

Professor W. A. Bone has isolated what he thinks is the chemical compound, or family of chemical compounds, which gives to coal its coking properties. By a process of selection and extraction, he has shown that, unless a substance of a certain type is present, the coal will not coke. The material in question appears as a brown powder composed mainly of carbon, when it is in its purest state. Other elements in its constitution are oxygen, hydrogen and nitrogen. It was previously thought that the amount of volatile material held in the coal determined its value for coke-making, but this is incorrect. The practical matter must be present or coking will not take place.

"When the constituent is present in sufficient proportions, the coal melts and intumesces before it decomposes," Professor Bone explained. "This means that it will make satisfactorily coke." The all-important constituent appears in greater proportion as the coal ages. This explains why the mysterious substance is not present in Alberta lignites.

Niagara Peninsula Branch

Peterborough Branch visits Niagara Falls

On August 10th and 11th, about twenty-five members of the Peterborough Branch paid a visit to Niagara Falls. They inspected the plant of The Niagara Falls Power Company, on the American side, on Sunday, and on Monday they viewed the Queenston-Chippawa power development, departing for Peterborough on Monday afternoon.

Visit of London Branch

On August 23rd and 24th, the branch had the pleasure of entertaining twenty-five members of the London Branch, who arrived in St. Catharines by motor at noon on Saturday. After a luncheon in the city, they motored, in company with several local members who acted as guides, to see the new Welland ship canal, which is being rushed to completion as fast as substantial grants of money will permit.

In the evening this branch entertained their guests to dinner on the verandah of the Pavilion, Lakeside Park, Port Dalhousie. The spot was a particularly happy choice. Within a few feet of the tables passed to and fro the grainboats that use the present canal, while into the lake on whose shores the Pavilion is situated, the sun was sinking in a profusion of color, gilding the crest of the Niagara Escarpment which was visible all the way to Hamilton. Our guests remarked on the beauty of the scene. After dinner, E. G. Cameron, A.M.E.I.C., assistant chief engineer of the Welland ship canal, sketched the history of canal building in this district from the turning of the sod for the first Welland canal, in 1824, to the present time.

E. V. Buchanan, M.E.I.C., chairman of the London Branch, expressed thanks for the way in which they were being received. He told how the members of his branch, having decided to do some visiting to other branches, chose the Niagara Peninsula for their first trip because, from write-ups in *The Journal*, and other sources, (We suspect Mr. Near, city engineer for London, was the 'Other Sources' referred to), they felt that the members of this branch spent a lot of time enjoying themselves and entertaining one another. He extended a hearty invitation to his hosts to pay a visit to the London Branch in the near future. London was about eight hundred feet higher above sea level than was St. Catharines. He held out as an inducement the fact that from this superior height a better view of Mars could be obtained by those who wished to give that planet a closer scrutiny.

C. Hellmuth, M.P.P. from Waterloo, was encountered during the afternoon, button-holed and brought to dinner. He spoke, among other things, about the Professional Engineers Act of Ontario. From its introduction, he had supported this act, and fought against its mutilation, feeling that engineers as a body were as much entitled to recognition by parliament as were lawyers or doctors. He advised the society to accept the act in its present form as a beginning, which will lead eventually to fuller recognition.

On Sunday morning the London members were taken charge of by members from Niagara Falls and escorted over the Queenston-Chippawa power development. This branch hopes that, as they climbed the eight hundred feet towards London and Mars on Sunday afternoon, they carried with them pleasant memories, as they did the best wishes of this district.

Members are Guests at Clam-Bake

Another of those delightful functions, which causes the eyes of Londoners and others to turn in envy to the Niagara Peninsula, took place Saturday, September 13th, when David Dick Jr., was host to the membership at a 'clam-bake' given at his summer cottage at Reib's Bay, on the shores of lake Erie. Anyone who has had the supreme pleasure of being a guest of Davy Dick, either at his annual 'St. Andrew's Nicht' or his 'Clam-Bake', will appreciate how hard it would be for the writer to describe this affair in detail. A burlesque soft-ball game was played on the shore, a true description of which would belong rather to the pages of Alice in Wonderland than to those of a staid engineering journal. A brass band supplied music during the afternoon, finally leading the hundred or more guests in Indian fyle along the sands for some distance and then back to the tables which were heaped high with clams and other toothsome viands.

When, at the end of the day, the mover of a vote of thanks to the host, speaking from amongst the debris on a table top, suggested that Davy Dick should be offered to the government to act as entertainer-in-chief to the Prince of Wales, he was cheered to the echo. All insisted, however, that this offer, made for the honour of Canada, should be in the nature of a short term loan. We in this district could not spare Davy for long. An oasis is too valuable these days. Thus did we 'come to the end of a Perfect Day'.

Calgary Branch

G. P. F. Boese, A.M.E.I.C., Secretary-Treasurer.

W. St. J. Miller, A.M.E.I.C., Branch Editor.

Arrangements were carried out under ideal conditions for a visit of the branch by automobile to the experimental farm station of the Canadian Pacific Railway Company (western section), at Strathmore on August 23rd. Great credit is due to Superintendent R. S. Stockton, M.E.I.C., and his staff, together with their ladies, for the splendid entertainment provided for some fifty of our members. After the stock and the station in general were inspected during the afternoon golf and tennis were indulged in. In the evening an excellent display of viands was set before us in the veterans' memorial hall, which was followed by a musical program, G. H. Patrick, A.M.E.I.C., giving some of his best vocal selections. Mrs. Boese's ability as an accompanist was highly commented on by those present. In a short speech Mr. Stockton referred to the advantages of the farm in the midst of such an immense farming community of some 900 settlers on an area of approximately 200,000 acres of irrigable land with 360 miles of canals and some 2,000 miles of distributaries. He stated that the requirements of the farmer were fulfilled by supplying him with an irrigating head of 2 c.f.s., on the basis of irrigating five acres per day to a depth of about nine inches. B. L. Thorne, M.E.I.C., proposed a vote of thanks in suitable terms which was wittily seconded by P. Turner Bone, M.E.I.C. The members returned very favourably impressed with all they saw on the farm and the entertainment extended to them.

During the recent convention of irrigationists in Calgary a very apt remark of Mr. Stockton regarding the proper use of water on the land was, "We must eventually come to support the theory of using the water for maximum returns per acre-foot of water rather than for maximum returns per acre of land irrigated".

British Scientists Welcomed by Branch

Calgary was fortunate in having the opportunity of welcoming the British Scientists on their homeward journey. Although these men paid but a flying visit of only a few hours duration the branch was instrumental in materially assisting in the arrangements for their reception and entertainment. A four-page pamphlet was specially printed for the occasion as a token of welcome for the visiting members from the local branch of the E.I.C. A list of the principal places of engineering interest in the city was given, and summarized paragraphs under the headings of irrigation, current-meter rating station, water powers, coal, and natural gas were included. These were distributed for perusal at Banff and were evidently much appreciated by the members of the association.

Flow of Water on Artificially Constructed Surfaces

On August 28th the branch entertained F. C. Scobie, as guest at a luncheon, when some fifty members were present and A. L. Ford, M.E.I.C., acted as chairman. Following the luncheon at which Mayor Webster, and Commissoner Graves were also present, Mr. Scobie gave a most interesting and instructive discourse on his specialized subject, namely, flow of water on artificially constructed surfaces. He reminded his hearers that the U.S. Reclamation Service was now the U.S. Bureau of Reclamation under the Department of Agriculture, and his particular branch was the Research Bureau.

The speaker described the early works of the Romans when culverts and conduits were constructed of lead and stone and increased volume was attained by increasing the area instead of the grade. Then he jumped a stride to Chezy's well known velocity formula $c\sqrt{rs}$ with c as a non-variable constant at first which was later developed by Kutter and Ganguillet. Kutter's value for the coefficient of roughness "n" was not below 0.014 but after use this figure has invariably proved to be 0.012. For wooden flumes Kutter gave 0.009 under ideal conditions, but the speaker advocated the use of 0.015 to 0.014. Then the efficiency of steel flumes was referred to, and the credit of origination of the flume was given to one Pat McGuiness, a blacksmith. Flumes permitted a velocity of 4 or 5 c.f.s. Wherewith chute flumes permitted a very high velocity, sometimes 28 to even 38 c.f.s. To gauge the velocity at such speeds coloring matter was introduced in the water. He remarked that considerable air was taken down a chute at such high velocities, sometimes as much as 30 per cent air.

Steel pipes were mostly used for power purposes, and he was satisfied that butt joints are less efficient than cylindrical joints, chiefly on account of interference of rivet heads. Anyway he considered that steel was not up to concrete for pipes. Referring to concrete pipes he stated that there were ten to fifteen thousand miles of such pipes in California alone, being used exclusively in the orange groves. He cited the extraordinary area of Los Angeles city, it being some 70,000 acres. This was necessary on account of the peculiar municipal water legislation and the area included much of the orange grove country. Mr. Scobie referred to the possibility of constructing a perfect aqueduct, such as the Victoria aqueduct which was cast in moulds *in situ*. Then he mentioned the bad effect of shoulders at the joints of concrete pipes which in some cases he had found as much as two or three inches high and even five inches in places in the Catskill aqueduct. He laid particular stress on the kind of concrete used, as this was of very great importance. A reasonably strong mix was essential. The use of the cement gun had produced a remarkably firm and dense concrete which would be difficult to improve upon. Density of concrete is important if excessive seepage is to be avoided.

Passing on to wood stave pipes, he said they were first introduced in Denver. In Vermont there were three lines of thirteen feet in diameter. In Montana we will shortly be able to see a fifteen-foot diameter wood-stave pipe. He gave the life of red fir as eighteen to twenty years, and Douglas fir as eight to ten years. He mentioned many rock tunnels built large enough to accommodate the steam shovel in boring. Calculations should be made with the proper desired sections using 0.035 as the value of "n". Excess area due to overbreak can be discounted and will take care of storm or flood conditions.

In announcing the question period Mr. Ford remarked that he understood Mr. Scobie was here to secure first hand information concerning field conditions and was not, on this trip at any rate, so much concerned with laboratory research work. He asked the speaker if he was preparing anything for general publication. Mr. Scobie replied that his investigations would be published in government bulletin form, but he had no intention of introducing, or attempting to introduce any new formulae as he thought there were too many on the market already.

He announced the publication shortly of a U.S. bulletin on steel pipes. He also mentioned that a sand blast on steel pipes had been profitably employed for cleaning them out, also that a coat of two inches of cement had given increased carrying capacity in some cases.

R. S. Stockton, M.E.I.C., proposed a very hearty vote of thanks to the speaker, which was seconded by G. H. Whyte, A.M.E.I.C., while the Mayor stated that if he as a non-technical man had enjoyed the talk so thoroughly, he could only wonder how much the engineers present had enjoyed it also.

Saskatchewan Branch

J. W. D. Farrell, A.M.E.I.C., Secretary-Treasurer.

Summer Meeting and Visit of British Scientists

The annual summer meeting of the branch was held in Saskatoon on the occasion of the visit by the British scientists. The meeting was well attended and the event was made thoroughly enjoyable by the kindness and hospitality of the Saskatoon members. At the opening meeting held at the university at 10.30 a.m., Professor Mackenzie outlined the programme for the day, which of course was closely related to the activities of the visiting British scientists. The chairman briefly described the British Association for the Advancement of Science and said that the party visiting Saskatoon comprised about three hundred and forty of the world's leading scientists. The members of the branch would hear Sir Charles Parsons and Dr. Howe that afternoon and would have opportunities for meeting others of the party during the afternoon and evening. The meeting was then adjourned until 3 p.m., in the afternoon, members being free to follow individual pursuits in the meantime.

At 2.15 p.m. many members of the branch with the newly-arrived Scientists and the assembled towns people witnessed the ceremony of the opening of the new chemistry building at the University. Following this, the building was thrown open for inspection by the public. The completeness of the accommodation and the equipment was the subject of much favourable comment.

At 3 o'clock about forty members of the branch with their friends and members of the British Association assembled in the new chemistry building for the adjourned meeting. Professor Mackenzie in a few introductory remarks welcomed the members of the British Association and thanked Sir Charles Parsons and Dean Howe for coming to address the meeting.

British Association for the Advancement of Science

Dr. Howe being called on first, said the British Association came to Canada to learn as well as to impart knowledge and in engineering had found much to learn. Since landing at Quebec they had seen many triumphs of engineering which were conquering the forces of nature by methods undreamed of years ago. They had seen one of the greatest rivers, the largest grain elevator, the longest bridge, the greatest water fall, the biggest pulp mill, the largest hydro-electric development, the widest streets and the most rapidly developing cities. In short, Canada was a land of superlatives but her claims were justified.

Dr. Howe referred kindly to the hospitality received and said that the meetings of the British Association might be described as being for the "cultivation of intense hospitality". As engineers we take pride in the advance of science and engineering. The development of Canada depended on the advance of engineering.

Dean Howe then spoke on the wide field of the British Association for the Advancement of Science. The association is divided into a number of sections, each dealing with a particular subject such as physics, chemistry, geology, aeronautics, etc. So also the field of engineering had now become very wide. No one man was now known as the Engineer having a knowledge of all branches, the field was too wide. The growth of engineering had given rise to difficulties in connection with engineering courses, difficulties of increasing specialization and increasing syllabuses. Dean Howe thought there was a danger in too early specialization. It is not known what a student will ultimately do, it often happens that the electrical trained man goes to the mechanical field. A graduate's need was for a good thorough grounding, to enable him to tackle any problem; this was more desirable than a highly specialized graduate and especially more desirable in Canada.

The advance of transmission, said Dr. Howe, was one of the greatest advances made, including the transmission of power, of men and materials and of intelligence. Dr. Howe said that he spent much of his spare time on radio, that the development of radio was to him a romance. The inception of radio was due to Professor James Clarke Maxwell and his researches into the nature of wave transmission through the ether and the discovery that light was a form of electro magnetic energy. Maxwell's ideas were realized and further developed by Hertz, a German physicist and finally given practical application by Marconi. Since then progress has been rapid; across Channel transmission was soon followed by transmission across the Athantic. At one time the problem arose as to whether the waves would travel around the curvature of the earth. The mathematicians said no, but Marconi found that they would and did, the waves being reflected from the upper atmosphere. To-day messages are received at the Antipodes. In the earlier work waves of long wave length were employed. Then short waves were used at night and found to travel enormous distances. The use of short waves permitted the practical use of reflectors and directional sending by the proper arrangement of aerials. Dr. Howe suggested the use of a revolving reflector which would always point around the dark portion of the earth.

Address by Sir Charles Parsons

Professor Mackenzie then introduced Sir Charles Parsons, paying tribute to his abilities as an inventor, a scientist and a director of industrial corporations.

Sir Charles said that he had been much impressed by the natural resources and engineering accomplishments mentioned by Dr. Howe. The new chemistry building had greatly impressed him as an indication of our confidence in the future. England, said Sir Charles, was not industrially of much importance until she began to develop her coal resources. Cheap power from coal gave her textile industries their start. The exhibition of 1851 was, in Sir Charles' opinion, a blow to British industry, in that it showed other nations the secret of her progress and prosperity.

He was impressed with the extent of Canadian water power development. From his own investigations Sir Charles had found that it cost approximately double the money to put down mines and develop power from coal that it cost to develop water power. Future movements of population would be influenced by the location of cheap power. Present power developments made living and progress possible here in this country where only a few years ago the only inhabitants were Indians.

Sir Charles then related various steps in the development of the steam turbine. The idea of the water turbine which was supposed to give 80 per cent efficiency was largely followed. By means of diagrams sketched on the black board the speaker showed how the velocity was kept down by staging the pressure drop through short steps. First experiments were encouraging and lead to other developments such as curving the blades and increasing the ratio of expansion by use of partial vacuum. Recent endeavors have been to further increase the ratio of expansion. The turbine has an advantage over the reciprocating engine in being able to expand steam to a lower degree.

The speaker related incidents of the skepticism and distrust connected with the early uses of the steam turbine such as the lighting of the town of Cambridge. Developments in mechanical gearing added to the usefulness of the turbine for such purposes as collieries and slow cargo ships. Using steam at 2,000 pounds pressure and 750° F. superheat a steam turbine will deliver one-third the energy of the coal consumed, which is a better efficiency than that of the best diesel engine. In large installations the turbine has a decided advantage in efficiency over the internal combustion engine.

Sir Charles then spoke briefly of the mercury vapour boiler illustrating his description with diagrams. He did not see much prospect for its general use and pointed out the danger from the very poisonous mercury fumes.

At the conclusion Colonel Garner spoke appreciatively, voicing the gratitude of the branch to the distinguished speakers and complimenting Professor Mackenzie on having arranged so enjoyable and profitable a meeting.

At Professor Mackenzie's request Dean Howe introduced the following members of the British Association who had attended our meeting:

Professor Andrew Robertson of Bristol,
Mr. J. S. Wilson of London,
Mr. Parsons of the Staff of "Engineering", London.

Following the meeting tea was served on Dean Rutherford's lawn, to which the branch members were invited and here had further opportunities to meet members of the British Association.

At 6.30 p.m. the members of the branch were invited to dinner at the King George hotel, given by the city of Saskatoon in honour of the visiting scientists.

In the evening many members attended the open meeting of the British Association when Professor Slossons of Washington gave a very interesting popular lecture on photo chemistry. During the day, through the kindness of Saskatoon members, various points of engineering interest were visited, such as the telephone exchange, the filtration plant and the power house, the visit to the latter being joined by Sir Charles Parsons.

EMPLOYMENT BUREAU

Situations Wanted

A.M.E.I.C., at present employed as sales engineer in connection with metal building products of well known concern, desires change to larger field of responsibility where his varied experience in structural steel and concrete engineering as chief draughtsman, designing engineer, inspector, etc., would be of value. Apply box No. 152-W.

Civil Engineer

Graduate, A.M.E.I.C., desires executive or engineering position. Ten years varied experience, railroad location and construction, highways, municipal engineering, design and construction of hydro-electric plants, and engineer for contractors. Apply box No. 153-W.

Mechanical and Electrical

Graduate Mechanical and Electrical Engineer with 18 years experience including 7 years as Asst. Supt. Punjab Irrigation Constructional Workshops, wants executive position. Location immaterial. Apply box 154-W.

Civil Engineer

Civil engineer, M.E.I.C., twenty-five years experience in railway and harbour construction, and contracting and operating superintendent of department of large industry, wishes engagement in executive capacity. Is good organizer. Apply box No. 155-W.

Situation Vacant

Secretary of the Geological Survey

A Secretary for the Geological Survey (Male), Department of Mines, Ottawa, at an initial salary of $2,220 per annum, which will be increased upon recommendation for efficient service at the rate of $120 per annum until a maximum of $2,700 has been reached.

Duties. — Under direction, to have charge of the Secretary's office of the Geological Survey; to handle all ordinary correspondence of the Geological Survey; to check amounts and requisitions, and to assist in the preparation of estimates and other business statements and reports; to receive and arrange for the examination or treatment of mineral and other specimens; to assist in the selection and appointment of student assistants and other seasonal employees; to receive callers and to conduct interview on behalf of the Director; in the absence of the Director to take charge of the Director's office; and to perform other related work as required.

Qualifications. — Education equivalent to graduation from a University of recognized standing, preferably with specialization in geological science; three years of experience in office work; one year of which preferably shall have been in the Department of Mines, or on work of a similar character; good knowledge of office practice; tact, good judgment and address. While definite age limit has not been fixed, age may be a determining factor in making a selection.

Application forms properly filled in must be filed in the office of the Civil Service Commission, Ottawa, *not later than October 9th, 1924.*

CORRESPONDENCE

Critical Speeds

With Special Reference to Main Shafts of Hydraulic Turbines.

The Editor,
The Engineering Journal,

Lachine, Que.
Sept. 8th, 1924

Dear Sir:—

In the course of my work during the past year or so, I have had to give considerable attention to the study of critical speeds, I decided eventually to try and develop some rapid, as well as fairly accurate, method for their determination and hope that the following analysis, the fruit of my labours, may be of interest to others in the profession.

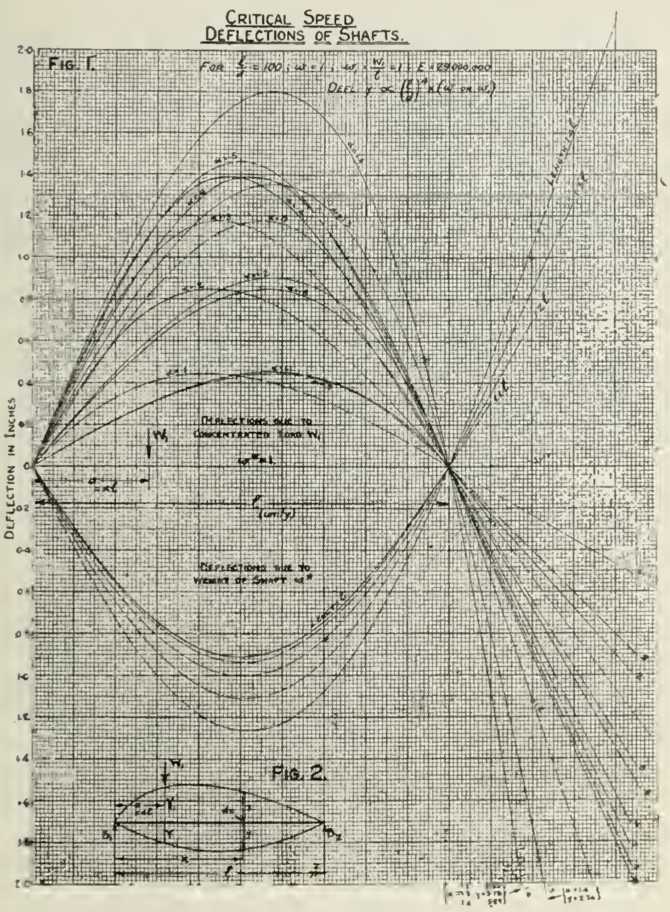
In the design of the main shafts in hydraulic turbine installations, it is frequently necessary to determine the critical speed. In the case of horizontal double-runner units especially, where the distance between bearings is relatively great, the critical speed is sometimes the deciding factor in the design.

The general theory has been investigated quite thoroughly in the past and discussions may be found in all standard text books, but owing to the difficulty in applying the theoretical formulæ to actual cases, various empirical approximations have been developed. The writer has found, in checking several special cases, that the approximations in general use do not always agree closely with the theoretical values obtained by actual integration, the degree of error depending on the nature of the loading. With a view to simplifying the present laborious methods and, at the same time checking up on these empirical formulæ, he has prepared a set of charts for determining the theoretical critical speeds.

A brief explanation of the method of obtaining these charts may be of interest. Taking the general formula for critical speed

$$n^2 = \frac{g}{4\pi^2}\,\frac{\int wydx}{\int wy^2dx}$$

where n = revolutions per second; g = acceleration due to gravity; w = unit loading; y = deflection of shaft at load wdx. We may reduce



Figures Nos. 1 and 2.—Critical Speed—Deflections of Shafts.

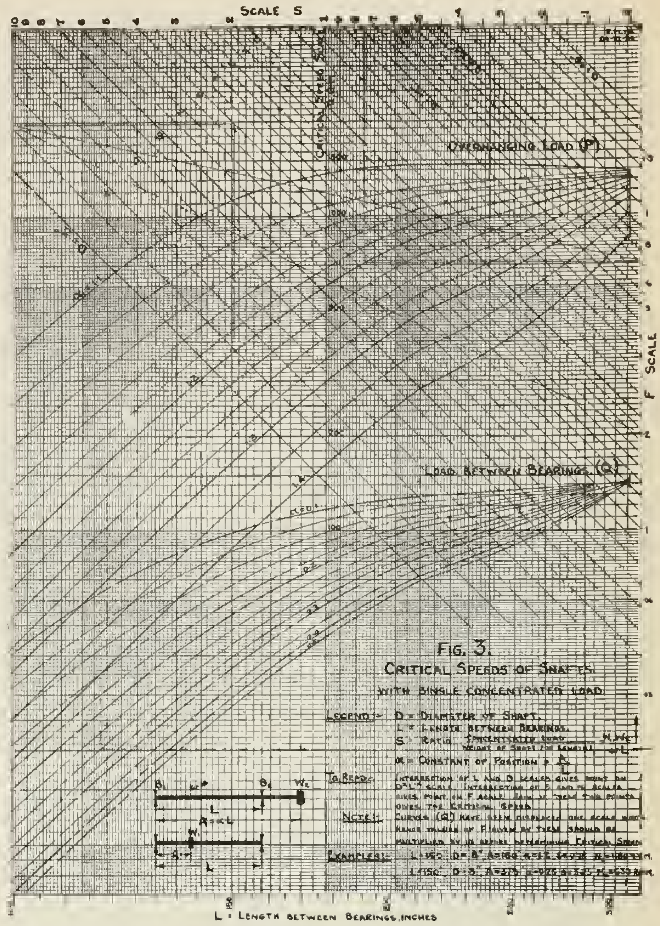


Figure No. 3.—Critical Speeds of Shafts with Single Concentrated Load.

this to the form $N_c = 187.7\sqrt{\frac{\int wydx}{\int wy^2dx}}$ = critical speed in r.p.m.

Here deflections y are in inches. To simplify the work of calculation for deflections, the diagram shown in figure No. 1 was developed which shows the form of the elastic curve for circular shafts. One set of curves gives deflections due to the weight of the shaft only and the other set gives deflections due to the concentrated load only. As will be noted, these deflections are for a unit ratio $\frac{l}{d} = 100$ and for unit weight of shaft $w = 1$ pound per inch length and concentrated load $w_1 = \frac{W_1}{l} = 1$ pound. To reduce deflections for any particular case, the values given here should be varied as $\left(\frac{l}{d}\right)^4 \times \frac{w \text{ or } w_1}{100^4}$

In the case of overhanging loads it is assumed that the overhanging weights act upward. The results given by this assumption will correspond to the condition in which the vibration of the overhanging section of the shaft differs in phase by 180° with that of the main shaft.

It may be mentioned here that some advise the consideration of all overhanging loads as being equivalent to similar loads placed at points on the opposite side of the bearing, but equidistant from it. By comparison of the deflection curves for concentrated loads we see that this is a safe assumption only for cases in which the loads are close to the bearing but as the overhang increases there is a corresponding divergence of the two elastic curves.

Consider the case of a single span with single concentrated load and with no overhang. In figure No. 2 let the curve above the horizontal line denote the elastic curve due to the concentrated load $W_1 = w_1 l$ only, and that below the horizontal line due to the weight of the shaft itself $W = wl$. Let Y_1 and Y denote the deflections at the load W_1 and y_1 and y the deflections at a point distant x from B_1. Then the general formula becomes $N_c = 187.7\sqrt{\frac{\int_0^l w\,(y+y_1)\,dx + W_1\,(Y+Y_1)}{\int_0^l w\,(y+y_1)^2dx + W_1\,(Y+Y_1)^2}}$

Now if we let the ordinates in the deflection chart figure No. 1 be P_1 and P at the concentrated load, and p_1 and p at any point $x = zl$ we have the relations,—

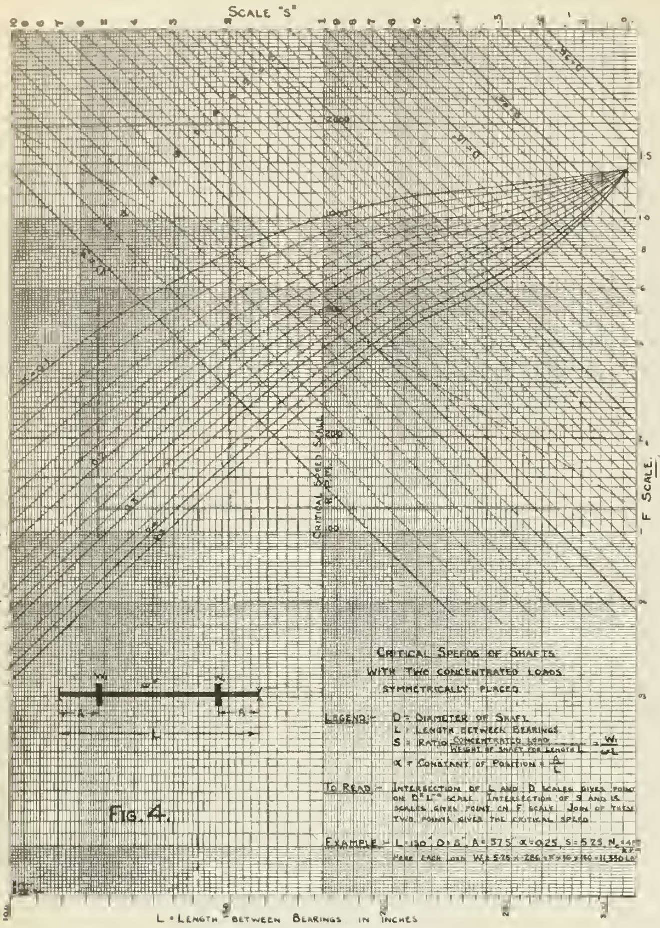

Figure No. 4.—Critical Speeds of Shafts with Two Concentrated Loads Symmetrically Placed.

$$Y = P \times \left\{\frac{l}{100d}\right\}^4 w; \quad Y_1 = P_1 \times \left\{\frac{l}{100d}\right\}^4 w_1.$$

Similarly for y_1 and y, and we get,—

$$N_c = \left[\frac{100d}{l}\right]^2 \times 187.7 \sqrt{\frac{w^2 \int_0^1 p dz + ww_1 \int_0^1 p_1 dz + w_1(wP + w_1P_1)}{w\int_0^1 (wp + w_1p_1)^2 dz + w_1(wP + w_1P_1)^2}}$$

Here we see that $\int_0^1 pdz$ is the area traced out by the ordinate p based on a distance between bearings B_1B_2 = unity. Similarly $\int_0^1 p^2dz$ is half the moment of this area about the horizontal axis. In fact, all the expressions under the radical except w and w_1 are functions of $\propto$ and may be computed and tabulated for different values of $\propto$ from the standard deflection curves in figure No. 1. Let us denote these expressions by the following symbols:—

$\int_0^1 pdz = A$; $\int_0^1 p_1dz = A_1$; $\int_0^1 p^2dz = M$; $\int_0^1 p_1^2dz = M_1$; $\int_0^1 pp_1dz = N$.

We may now simplify our equation to the form,—

$$N_c = \frac{187.7 \times 10^4 d^2}{l^2\sqrt{w}} \sqrt{\frac{A + (A_1 + P)S + P_1S^2}{M + (2N + P^2)S + (M_1 + 2PP_1)S^2 + P_1{}^2S^3}}$$

in which $S = \dfrac{w_1}{w} = \dfrac{\text{concentrated load } W_1}{\text{shaft weight } B_1B_2}$

Here the expression under the radical is seen to be a function of the variables S and $\propto$, and by denoting it by the symbol F and putting $w = .286\,\dfrac{\pi d^2}{4}$ we may reduce to,—

$$N_c^2 = 15.685 \times 10^{12}\frac{d^2}{l^4}F = K\frac{d^2}{l^4}F$$

For the purpose of constructing the diagram (figure No. 3) we may simplify this by taking logs and transforming to the determinant form,—

$$\begin{vmatrix} 2 & \log N_c - 3 & 1 \\ 1 & \log F & 1 \\ 3 & \log\dfrac{kd^2}{l^4 \times 10^6} & 1 \end{vmatrix} = 0$$

which will give us three equidistant parallel logarithmic scales as a basis for our alignment chart; namely, the central scale for N_c, the binary scale F (determined by the intersection of the $\propto$ curves with the scale S) and the binary scale $\dfrac{d^2}{l^4}$

In the case of overhanging beams the development is similar but it should be noted that the areas and moments obtained from figure No. 1 must be treated absolutely and not algebraically in order to conform to the general theory.

Figure No. 4 has been plotted for two equal concentrated loads similarly placed with respect to the bearings. This is found convenient for dealing with double runner hydraulic turbine installations. A few examples are given showing the method of reading the charts.

It will be seen that the effect of end thrust and torque have not been taken into consideration but for practical purposes these are of negligible importance.

Having this convenient weapon with which to attack the theoretical critical speeds it is possible to check up on the different approximate formulæ in general use. The most common one $N_c = 187.7 \div \sqrt{\Sigma y}$; let us call approximation A.

Here Σy = sum of deflections due to the separate loadings considered as ac ing independently. We may express these deflections as follows:—

$$y_e = \frac{5}{384}\frac{wl^4}{EI} = \text{deflection due to shaft weight } B_1B_2$$

$$y_1 = \frac{\propto^2(1-\propto)^2}{3}\frac{w_1l^4}{EI} = \text{deflection due to concentrated load } W_1$$ at its point of application. For overhanging shafts we must replace y_1 by $y_2 = \dfrac{(\propto - 1)^2\propto}{3}\dfrac{w_2l^4}{EI}$ = deflection due to overhanging concentrated load $W_2 = w_2l$, and add the deflection $y_a = \dfrac{(\propto - 1)^3(17\propto + 15)}{384}\dfrac{wl^4}{EI}$ (approx.) = maximum deflection due to overhanging weight of shaft $w(a-l)$.

Another approximation is that developed by Professor Dunkerley which gives $\dfrac{1}{N_c^2} = \dfrac{1}{N_l^2} + \dfrac{1}{N_1^2}$ + etc., where N_c, N_1, etc., are the various critical speeds obtained from the different independent loadings. Let us call this approximation B. By evaluating for $N_c = 187.7\sqrt{\dfrac{\int wydx}{\int wy^2dx}}$ for each of these simple loadings we may obtain the following formulæ, in which the subscripts correspond to those used for approximation A above.

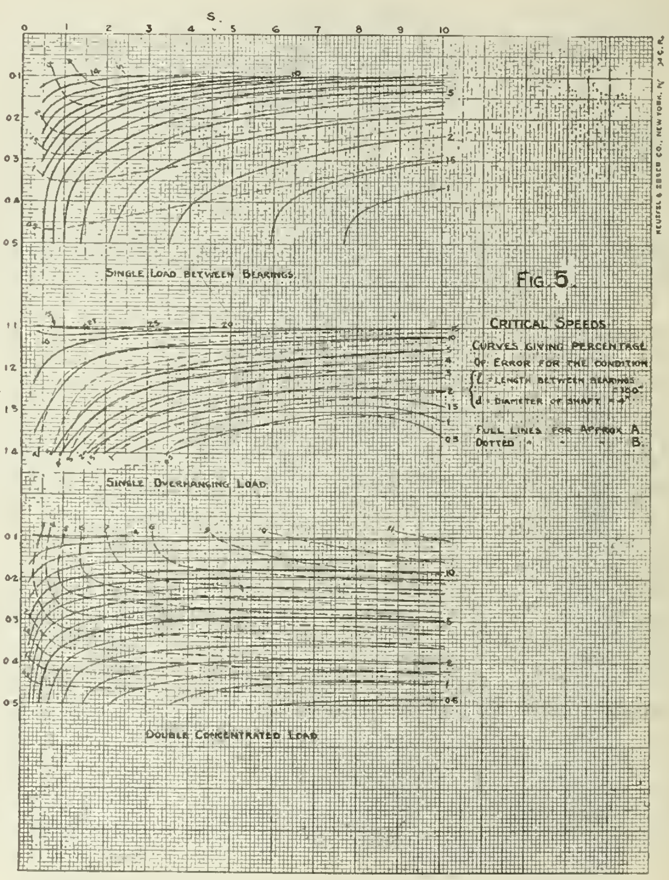

Figure No. 5.—Critical Speeds — Curves giving Percentage of Error.

$$N_l = \frac{4.68 \times 10^6 d}{l^2} \quad N_a = \frac{1.672 \times 10^6 d}{l^2(\propto -1)\sqrt{\propto^2 - 0.63\propto - 0.37}} \text{ (approximately)}$$

$$N_1 = \frac{388{,}000 d^2}{l^2 \propto (1-\propto)\sqrt{w_1}} \quad N_2 = \frac{388{,}000 d^2}{l^2(\propto -1)\sqrt{\propto w_2}}$$

These formulæ are based on $E = 29{,}000{,}000$, weight of metal 0.286 per cubic inch.

By taking particular case $d = 4''$, and $l = 100''$, the critical speeds for the two approximations and also the theoretical speed have been worked out for various values of S and $\propto$. These were compared and the ratios of the theoretical to the approximate speeds are shown in figure No. 5. Curves of percentage of error for each approximation are given.

These charts should not be taken too seriously as they are the combined results of slide rule computations and free interpolation The writer's main reason for plotting them was to obtain some rough idea of the general tendency of error of the two approximations.

In checking over some forty hydraulic turbine installations it has been found that the general run of values of S and $\propto$ are:—

(i) S = 0.3 to 8.8 average 3.13, $\propto$ = 1.1 to 1.5 " 1.33 } for overhanging runners.

(ii) S = about 1, $\propto$ = 0.3 to 0.4 } for single runner between bearings.

(iii) S = 0.2 to 0.5 average 0.36, $\propto$ = 0.15 to 0.4 " 0.23 } for two runners between bearings.

The errors given by the two approximations may be summarized as follows:—

For overhanging runners,—
- maximum errors were 17% for approx. *A*.
- maximum errors were 9% for approx. *B*.
- average errors were 4.3% for approx. *A*.
- average errors were 2.9% for approx. *B*.

For single runner between bearings,—
- average error — approx. "*A*" — 5.5%
- " "*B*" — 1%

For two runners between bearings,—
- average error — approx. "*A*" — 10.7%
- " "*B*" — 2.9%

The length between bearings was taken from centre line to centre line and in cases of proportionally long bearings the eccentricity of the loading "*A*" was obtained by adding one third the bearing length to the free overhang of the concentrated runner load from the edge of the bearing. This seems to be quite conservative.

Of course these ratios will not hold for other values of d and l. They are dependent on the relations existing between the various independent deflections or critical speeds. In general we may say that the ratios will approach unity for cases where one of the independent loads becomes of paramount importance; as for example, for the condition $S = 10$, $\propto = 1.4$, or $S = 0.25$, $\propto = 0.5$. We see that in general approximation B holds closer to the theoretical speed than approximation A. It would appear that the summation of the various maximum deflections irrespective of their relative location is not a very sound procedure and that better results are obtained if the various critical speeds for the several loads are first computed and a final speed arrived at by using some empirical formula incorporating these various speeds, of the type of approximation B.

For cases in which the shaft is of variable diameters some method must be devised of obtaining the equivalent mean diameter. Without the check of experimental data this will involve questionable assumptions, but it is believed that the following empirical method will furnish good results for ordinary cases in practice.

Considering the loadings independently we see that the critical speed for the shaft weight alone varies as the diameter while the speed based on concentrated loads varies as the square of the diameter. For a plain shaft it would therefore seem reasonable to assume that average diameter $d_1 = \Sigma ld \div l;\Sigma$ while considering the concentrated load only, we would have $d_2 = \sqrt{\frac{\Sigma ld^2}{\Sigma l}}$ The correct average under actual load conditions would be intermediate between these two values, being closer to the one or the other according to the relative importance of each loading. There is usually very little difference between these average diameters d_1 and d_2 and probably a simple method of arriving at the required diameter, and one which will be accurate enough for all practical purposes, would be to ascertain the maximum deflections y_1 and y_2 due to the two loadings, (see figure No. 1), and use the empirical formula $D = \frac{y_1 d_1 + y_2 d_2}{y_1 + y_2}$

From experimental data obtained by Dunkerley, Stodola and others, the theoretical values have been checked and agree closely with observed critical speeds for simple cases. Stodola's experiments were made at higher speeds and we may expect them to show the greatest difference. Stodola found that the ratio of theoretical to observed speed varied from 1.06 to 1.16. He found that this ratio was greater for heavier shafts and argued that this was due mostly to light foundations and consequent synthetic vibrations. It would seem advisable to assume a working ratio of say 1.15 per cent for hydraulic turbine shafts, that is to say, shafts should be designed for a critical speed of 15 per cent in excess of the computed runaway speed. This latter speed can in general be arrived at very closely from reliable experimental data on test models and, in some cases, from actual tests on recent installations.

Yours very truly,
F. M. Wood, A.M.E.I.C.,

Repairing Bridge with Electric Arc

The Editor,
The Engineering Journal,
Dear Sir,—

An operation of interest to the engineering profession in general and structural engineers in particular has recently been completed in the reinforcing and building up, of bridge members eaten away by extensive corrosion. The case in point being a bridge in Pittsburgh over the Allegheny river connecting Herrs island with the North Shore, a 240-foot through truss, pin and link span, built about thirty-one years ago. The floor of the bridge was carried on timber stringers supported on cross timbers bolted to the web of floor beams.

While the upper portions of the structure are still in good state of preservation, the parts rendered inaccessible to paint and kept constantly moist by the proximity of the timber were so greatly reduced in section as to be perforated, and in many places almost severed. The webs of the floor beams and bottom of vertical posts suffered particularly, being reduced from 3/8 of an inch to 1/32 of an inch over a large area.

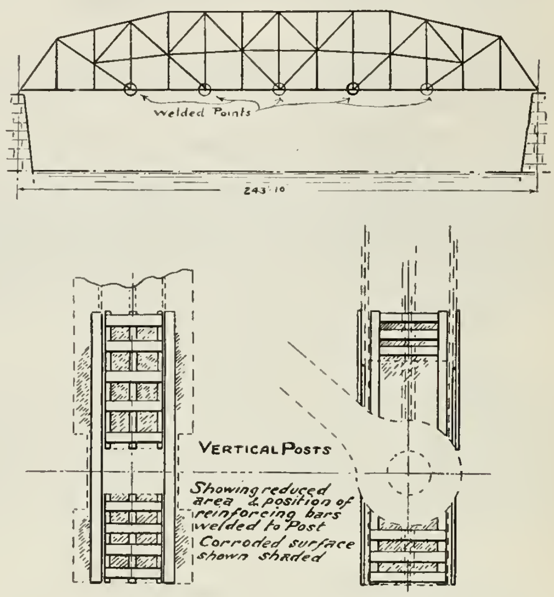

Diagram showing the Points of Welding Operations.

It was decided to renew the entire floor by cutting away the floorbeams and sidewalk brackets from their connection to the vertical posts. This operation presented no very unusual difficulties. The strengthening of columns, however, was a more serious problem. These were compression members built of Z-shaped bars and web plate, and directly above and below the pin bearing plates, were perforated and reduced in section over sixty per cent. There was also tensile stress, below the pin owing to reversal of stress in diagonals of truss.

The difficulty was overcome, both economically and efficiently, by welding, using the electric arc metallic process, and the method adopted by the engineers in charge, was to weld strips of steel, one inch by one-half of an inch extending from the bottom of the column to a point well beyond the corroded portion. After the surface of the original metal had been thoroughly cleaned by use of the acetylene torch, scrapers, and wire brushes, the bars were welded into position vertically, and tied together at close intervals with crossbars of the same section. After each point was completed, the strength of the weld was tested by the bars being subjected to a number of blows with an eight pound maul. Results of physical tests showed practically no deterioration of the original metal when welded by this process.

The reinforcing of the columns was carried out by the Pittsburgh Welding Corporation,* using a General Electric 200-ampere motor generator set, the work being performed under the supervision of the engineering department of the city of Pittsburgh.

It appears to the writer that this method of reinforcing structural members reduced by corrosion at certain points offers great possibilities as an alternative for removing the entire member. A case in point being the bottom of viaduct columns which are particularly susceptible to rust if drainage is neglected. In such cases one operator and a unit generating its own power could perform the work of an erection crew.

To the best of the writer's knowledge this is a new departure in structural engineering and opens up an extensive field.

Yours very truly,

E. H. PACY, A.M.E.I.C.

*Mr. Pacy is President of the Pittsburgh Welding Corporation.

OTHER SOCIETIES NEWS

Toronto Engineering Alumni Re-Union

The Engineering Alumni Association of the University of Toronto will hold its fifth re-union at Toronto on November seventh, eighth and ninth, 1924. The programme as recently announced will be as follows:—

Friday, November seventh,—
- Mid-day — Class Luncheons.
- Afternoon — Meeting old friends and general visiting.
- Evening — Dinner Dance, King Edward Hotel.

Saturday, November eighth,—
- Morning — Business meeting at University.
- Afternoon — Queen's-Varsity Football Match.
- Evening — School Dinner, King Edward Hotel.

Sunday, November ninth,—
- Morning — School Service, Convocation Hall.

More complete information will be made available to graduates in the early part of the present month.

Alberta Professional Engineers' Year Book

The Association of Professional Engineers of Alberta has issued a year book containing the professional engineers' act, the by-laws of the association, and a list of members of the association. The report of the fourth annual general meeting has also been issued which includes an address given on that occasion by E. A. Wheatley, A.M.E.I.C., registrar of the Association of Professional Engineers of British Columbia.

The Technical Association of the Pulp and Paper Industry

The fall meeting of the Technical Association of the Pulp and Paper Industry will be held at the hotel Statler, Buffalo, on October 14th and 15th, 1924. Following the business session the subsequent ones will be devoted to the discussion of such problems as vocational education and training, paper drying operation tests, paper testing and relative humidity conditions, revision of the standard method of testing pulp for strength, prevention of waste in the mill effluent and stream pollution.

Commissioner of the Superior Court

In order to be of greater service to the members, both residing in Montreal, and members who are passing through the city, the secretary of *The Institute* applied for and was granted a commissionership in the Superior Court, authority being granted in a document which reads in part as follows:

> "Know ye, that we, the Honourable Louis Coderre, one of the Justices of His Majesty's Superior Court, for the Province of Quebec, acting in the District of Montreal, by virtue of the powers vested in us by Articles 25 and 26a of the Code of Civil Procedure of the Province of Quebec, confiding in the integrity and ability of you the said Fraser Sanderson Keith, do constitute and appoint you a commissioner under the said law to make and receive in the said District of Montreal, all such Affidavit as any person is willing and desirous to make, in or concerning any cause, matter or thing depending, or to be depending, or in any wise concerning any of the Proceedings to be had in the said Superior Court; and also to receive affidavits to be used in any and every district in the Province of Quebec, in the Court of King's Bench, or in the Superior Court or Circuit Court, or other Court of record."

Members are requested to avail themselves of any advantage this may mean to them.

A Course in Industrial Metallography

Under the auspices of the Dept. of Metallurgy at McGill University an extension course in Metallography will be given as in previous years, by Harold J. Roast, F.C.S., F.C.I.C., and Charles F. Pascoe, F.C.I.C. The course consists of fifteen periods, held on Monday nights at the Chemistry and Mining building, McGill University, commencing on Monday November 3rd, at 8.00 p.m. Application should be made to Dr. Alfred Stansfield, M.E.I.C., Department of Metallurgy, McGill University. The fee for the course is $15.00, payable to the bursar.

In as much as only twelve members can be accommodated at one time students will be enrolled in order of their applications. No previous knowledge is assumed, and the course is essentially practical from first to last. If any students from a previous year desire to continue their work provision will be made for an advanced course if sufficient members are obtained.

Under the auspices of the Department of Metallurgy, McGill University, a new extension course is being given in "Practical Metallurgical Chemical Analysis", by Harold J. Roast.

This course consists of fifteen periods, and will be held on Monday evenings at the Chemistry and Mining building McGill University, from 8.00 p.m. to 10.00 p.m. commencing Monday evening October 6th next. The fees are twenty dollars.

The course covers analysis of brasses, bronzes, white metals, steel and iron, and the ordinary ores and slags in these connections. Only fast and commercially accurate practical methods are taught. Instruction will be given in the installation of a works laboratory, sampling of various works products, and the usual routine of the works chemist.

As the number of students is limited to six, members will be admitted in order of their applications. Anyone desiring to enroll should make application to Dr. Alfred Stansfield, M.E.I.C., Dept. of Metallurgy, McGill University.

The largest construction work in the vicinity of St. John, N.B., at present, is the erection of the new seven storey Admiral Beatty hotel on which the foundation work is now completed and forms in place for the first storey. This hotel when completed will be one of the chain of united hotels. The general contractors for the hotel are E. G. M. Cape and Company, Montreal.

Actual construction on the pump-house at the new government drydock, at Skinners Cove, B.C., will be commenced shortly according to a report of announcement by J. P. Forde, M.E.I.C., district engineer of the Dominion public works department, who has recently made a tour of the western coast with K. M. Cameron, M.E.I.C., chief engineer, Dominion public works, Ottawa, Ontario. It is expected that tenders for the construction of the three drydock gates will be called shortly. All the latest modern equipment will be installed within the four walls of the pump-house and will provide for the pumping of the drydock in four and a half hours. There will be three main pumps with a capacity of 60,000 gallons a minute, while two auxiliary pumps will speed up the work at the rate of 9,000 gallons a minute.

Preliminary Notice

of Applications for Admission and for Transfer

September 19th, 1924.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October, 1924.

FRASER S. KEITH, Secretary.

*The professional requirements are as follows:—

Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council, shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering with special reference to the branch of engineering in which he has been engaged. This examination may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the first year in such a course, shall be required to pass an examination in the following subjects: geography, history (that of Canada in particular), arithmetic, geometry, euclid (books I, IV and VI), trigonometry, algebra up to and including quadratic equations.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed successfully an examination equivalent to the final examination of a high school or the matriculation of an arts or science course. He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination equal to that prescribed for admission to the grade of Junior in the foregoing section and he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as references does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANDERSON—WILLIAM, of Calgary, Alta. Born at Glasgow, Scotland, Jan. 11th, 1889; Educ., 1905-11, evening classes, Glasgow Royal Technical College, and private tuition; 1907-19, with the General Electric Company, England—5 years apprenticeship, and 7½ years in various responsible capacities—in charge of office at Hanover Street, Edinburgh, and then transferred to engrg. dept., Glasgow, as manager and responsible for carrying out contracts with shipbldg. and industrial concerns for G.E.C.; 1919, appointed manager at Glasgow for Wood & Bairns, Limited, electrical engrs.; Oct. 1920, joined the Northern Electric Co. Ltd., at Montreal, as asst. specialist in power apparatus divn., and in 1921 transferred to Calgary as power apparatus specialist. Since Sept. 1921 in charge of power apparatus divn. of the comp ny in Calgary, and responsible for estimating and carrying out all contracts on electric power apparatus.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of engineering profession.

A

AIR COMPRESSORS

LUBRICATION OF. Air Compressor Lubrication. So. Engr., vol. 41, no. 5, July 1924, pp. 44-46, 3 figs. Gives factors of correct lubrication, correct oils for common practice, and methods of application.

AIRPLANES

MONOPLANES. Monoplane Theory, N. K. Bose. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci., vol. 48, no. 283, July 1924, pp. 113-125, 1 fig. Discusses theory of circulation of liquid around airplane equal and opposite to that of vortex formed, and reduces it to mathematical basis.

PRESSURE DISTRIBUTION ON WINGS. Pressure Distribution Over the Wings of an M B-3 Airplane in Flight, F. H. Norton. Nat. Advisory Committee for Aeronautics, report no. 193, 1924, 17 pp., 15 figs. Investigation carried out to determine distribution of load over wings of high-speed airplane under all conditions of flight and pressure distribution, during level flight, over portions of wings in slipstream and, during violent maneuvers, over entire wing surface; results obtained.

SLIPSTRAEM VELOCITY. Investigation of Slipstream Velocity, J. W. Crowley, Jr. Nat. Advisory Committee for Aeronautics, report no. 194, 1924, 7 pp., 9 figs. Results of experiments to investigate velocity of air in slipstream in horizontal and climbing flight to determine form of expression giving slipstream in terms of air speed of airplane.

WINGS. Elements of the Wing Section Theory and of the Wing Theory, M. M. Munk. Nat. Advisory Committee for Aeronautics, report no. 191, 1924, 25 pp., 4 figs. Results of theory of wings and of wing sections which are of immediate practical value; results proven and demonstrated by use of simple conceptions of "kinetic energy" and "momentum."

WOOD MEMBERS, STRESSES IN. Stresses in Wood Members Subjected to Combined Column and Beam Action, J. A. Newlin and G. W. Trayer. Nat. Advisory Committee for Aeronautics, report no. 188, 1924, 13 pp., 9 figs. Results of tests to determine properties of wing beams of standard and proposed sections, conducted by Forest Products Laboratory and financed by Army and Navy.

AIRSHIPS

NAVIGATION. The Airship's Position (Le Point en Aéronef), L. Garin. Arts et Métiers, vol. 77, no. 44, May 1924, pp. 161-170, 5 figs. Discusses navigation charts, gives a number of curves, and develops formulas for determining position.

ALLOYS

ALUMINUM. *See Aluminum Alloys.*

BRASS. *See Brass.*

CORRODED, COATINGS FORMED ON. Coatings Formed on Corroded Metals and Alloys, G. M. Enos and R. J. Anderson. Am. Inst. Min. and Met. Engrs.— Trans., Advance paper No. 1358-N, July 1924, 9 pp., 16 figs. As coating formed affects corrosion rate, duplicate samples of eight non-ferrous alloys were placed in flowing mine water. Alloys tested were as cast or as rolled, and machined or polished. Describes tests and gives corrosion losses and appearance of samples at end of test.

CORROSION-RESISTANT. Corrosion-Resistant Alloys—Past, Present and Future—With Suggestions as to Future Trend, P. A. E. Armstrong. Am. Soc. for Testing Matls., Preprint of paper presented at meeting June 24-27, 1924, No. 19b, 15 pp.

Symposium on Corrosion-Resistant, Heat-Resistant and Electrical-Resistance Alloys. Am. Soc. for Testing Matls., Preprint of paper presented at meeting June 24-27, 1924, No. 19a, 4 pp. Contains tabulation on supplementary pages of manufacturers' data on composition and properties of the alloys.

FUSIBLE. Properties of Fusible Alloys, N. F. Budgen. Chem. & Industry, vol. 43, no. 27, July 4, 1924, pp. 200T-203T, 2 figs. Discusses properties of lead, bismuth, tin, cadmium, and mercury, used for fusible plugs in automatic fire-extinguisher systems, also manufacture of small statuary, etc.

IRON. *See Iron Alloys.*

ALUMINUM

WELDING. Gas Welding of Aluminum, S. W. Miller. Can. Machy., vol. 32, no. 6, Aug. 7, 1924, pp. 33-34 and 50. Discusses porosity in weld, brittle, character of flame, preheating casting, manipulation of welding rod, and welding sheet aluminum. Abstract of paper read before N. Y. sec. Am. Welding Soc.

ALUMINUM ALLOYS

ALUMINUM-COPPER-MAGNESIUM, CASTING AND HEAT TREATMENT. Casting and Heat Treatment of Some Aluminum-Copper-Magnesium Alloys, S. Daniels and J. B. Johnson. Am. Inst. Min. & Met. Engrs.—Trans., Advance paper No. 1350-N, July 1924, 22 pp., 6 figs. Deals with portion of work of Material Section, Engineering Division, Air Service, U. S. A., on casting and extended heat treatment of alloys of duralumin type (copper 2.5-5.0 per cent, magnesium 0.0-1.0 per cent, silicon 0.2-1.0 per cent, iron 0.3-1.5 per cent, manganese 0.0 to 1.0 per cent, chromium, etc.). This range of compositions includes an alloy recently placed on market in cast form and designated as Lynite 195.

PROPERTIES. Light Alloys of Aluminum, W. Rosenhain and S. L. Archbutt. Metal Industry (Lond.), vol. 25, nos. 1 and 2, July 4 and 11, 1924, pp. 3-7, and 27-30 and 44, 14 figs. Specific tenacity; are hardening; casting alloys and wrought alloys in general use; properties of chief alloys; heat treatment; application. Paper read before Empire Min. & Met. Congress.

ARCHES

MULTIPLE. The Design of a Multiple-Arch System and Permissible Simplifications, A. C. Janni. Am. Soc. Civil Engrs. Proc., vol. 50, no. 6, Aug. 1924, pp. 755-794, 21 figs. Discusses permissible simplification or shortening of strictly theoretic method of designing multiple-arch system, arches of which cannot be considered as having fixed ends.

ASPHALT

STATUS OF. The Status of Asphalt. Lubrication, vol. 10, no. 6, June 1924, pp. 61-66. Discusses Economic value, determination of quality, refining and uses of asphalt.

AUTOMOBILE FUELS

CONSUMPTION AND DILUTION. Consumption and Dilution of Automobile Engine Oils. Lubrication, vol. 10, no. 6, June 1924, pp. 66-72, 13 figs. Description of dynamometer apparatus and test routine; discusses dilution, lubricating system, oil viscosity requirements, value of road tests, and oil consumption.

PRODUCER GAS. Producer Gas for Road Transport, Motor Transport (Lond.), vol. 38, no. 1002, May 12, 1924, p. 580, 1 fig. Details of gas-producer plant; question of cost; results of recent French trials with charcoal as fuel.

SHAFTS, STIFFNESS OF. Calculating the Stiffness of Shafts, F. A. W. Livermore. Automobile Engr., vol. 14, no. 191, July 1924, p. 197. Gives simplified formula.

AZIMUTH

DETERMINATION. The Measurement of True Azimuths, E. M. Douglas. Military Engr., vol. 16, no. 87, May-June 1924, pp. 197-199, 3 figs. Discusses variation and uncertainty of compass bearings; advantages of recording true bearings; Polaris and Solar observations for azimuth and instruments used.

B

BAUXITE

OCCURRENCE AND SUPPLY. Occurrence and Supply of Bauxite, E. C. Eckel. Cement, Mill & Quarry, vol. 24, no. 12, June 20, 1924, pp. 23-25. A hydrated oxide of aluminum. Composition and impurities of bauxite; use as a cement material.

BEARINGS, BALL

STAINLESS-STEEL. Carrying Capacity of Ball Bearings Made of Stainless Steel, A. Hultgren. Am. Soc. for Testing Matls., Preprint of paper presented at meeting June 24-27, 1924, No. 19g, 7 pp. Brief summary of series of tests of stainless steel as a ball-bearing material conducted during past six years in Gothenburg Laboratory of Aktiebolaget Svenska Kullagerfabriken; stainless steels from an American, a British and a Swedish source were used.

BEARINGS, ROLLER

TAPER. Taper Roller Bearings. Automobile Engr., vol. 14, no. 191, July 1924, pp. 196-197, 10 figs. New type with rollers guided from race.

BLASTING

LIQUID OXYGEN. Liquid-Oxygen Explosives in Epoch-Making Blast, F. W. O'Neil. Compressed Air Mag., vol. 29, no. 7, July 1924, pp. 913-916, 8 figs. 4,500 tons of rock lifted in Pennsylvania quarry with less than 800 lb. of new explosive.

BOILER FEEDWATER

TREATMENT. Feed Water Treatment. Eng. & Boiler House Rev., vols. 37, and 38, nos. 8, 9 and 1, Mar., Apr. and July 1924, pp. 281-282, 323-324, 5-7, 1 fig. Notes on recent papers read before Instn. Mech. Engrs. Boiler feedwater and scaling; present-day practice with lime-soda process; zeolite process.

The Prevention of Scale Formation by Boiler Water Conditioning, R. E. Hall, C. Fischer and G. W. Smith. Iron and Steel Engr., vol. 1, no. 6, June 1924, pp. 312-327, 18 figs. Discusses conditioning of boiler water based on sulphate concentration and pressure of boiler water, removal of precipitated sludge and suspended insoluble matter, prevention of droplets (moisture) entrained in steam.

BOILER FIRING

PULVERIZED FUEL. Pulverized Fuel for Boilers, W. M. Selvey. Colliery Guardian, vol. 128, no. 3316, July 18, 1924, pp. 157-158. Discusses fuel, preparation, burners, absorption of heat, and application to British conditions. Abstract of paper read before World Power Conference.

BOILER FURNACES

AIR PREHEATERS. Experiments on a Cylindrical Steam Boiler with and without Preheated Air, W. H. Owen. Inst. Mar. Engrs.-Trans., vol. 36, June 1924, pp. 1-37, 12 figs. Discusses preheating air of combustion; describes new form of preheater extracting 65 to 70 per cent of heat in waste gases, and tests made.
The Ljungström Air Preheater, B. G. Brolinson. Iron and Steel Engr., vol. I, no. 6, June 1924, pp. 351-358 and (discussion) 358-360, 22 figs. Discusses application of this preheater based on principle of carrying heat continually in mechanical way from flue gases to incoming air, apparatus being self-contained, compact in design, simple in operation and permiting of ready application. Paper read before Assn. Iron and Steel Elec. Engrs., Fuel Saving Conference.
The Preheating of Combustion Air, J. B. Bullock. So. African Inst. Elec. Engrs.—Trans., vol. 15, part 5, May 1924, pp. 388-396. 4 figs. Describes latest system of recovering and putting to beneficial use maximum amount of heat available in coal as fired to boiler or furnace, and gives some account of results obtainable with system and of their bearing on present boiler practice.

BOILER ROOMS

CONTROL. Measurement of Input and Output in Boiler Rooms, J. M. Spitzglass. Iron and Steel Engr., vol. I, no. 6, June 1924, pp. 299-309 and (discussion) 309-311, 11 figs. Shows how material quantities can be measured accurately and conveniently in steel-plant boiler rooms, including practical application of measuring flow of fluids and of coal; determination of constants.

BOILERS

BAFFLES. Designing Boiler Baffles, A. W. Patterson, Jr. Combustion, vol. 11, no. 2, Aug. 1924, pp. 122-124, 7 figs. Some problems brought about by incorrect baffle design, and methods by which conditions in particular plants were remedied.
CORROSION. Corrosion in Steam Boiler Plant, G. E. Swett. Pac. Mar. Rev., vol. 21, no. 7, July 1924, p. 383, 1 fig. Describes apparatus known as Hickman air separator, an automatic method of eliminating chief cause of depreciation in steam-generating equipment.
ELECTRICALLY HEATED. Electric Boilers (Les chaudières électriques), P. Bergeon. Revue Universelle des Mines, vol. 67, no. 4, Feb. 15, 1924, pp. 241-248. Discusses resistance boilers, induction boilers, and electrode boilers; comparison of cost of steam in electric and other boilers; application of electric boilers.
FIELD, INEFFICIENT HANDLING OF. Inefficient Handling of Field Boilers Source of Waste and Expense, F. G. D. Muller. Nat. Petroleum News, vol. 16, no. 29, July 16, 1924, pp. 77-79, 4 figs. Discusses improving efficiency of boilers, preheating feedwater, driller's ear attuned to exhaust, water filter for field boilers, and uses for old boilers.
LOCOMOTIVES. *See Locomotive Boilers:*
SEAMS, BRITTLENESS AND CRACKS IN. Brittleness and Cracks in Seams of Steam Boilers, H. Kriegsheim. Power Plant Eng., vol. 28, no. 15, Aug. 1, 1924, pp. 792-795, 6 figs. Causes and prevention of so-called caustic embrittlement.
STANDARDIZATION. Sixteen Years of Boiler Standardization, J. A. Stevens. Power, vol. 60, no. 6, Aug. 5, 1924, pp. 217-218. Details of work of Boiler Code Committee.
WASTE-HEAT. Utilizing Waste Heat, K. W. Heinrich. Pac. Mar. Rev., vol. 21, no. 7, July 1924, pp. 376-377, 3 figs. Describes fire-tube steam or hot-water generator especially adapted for reclaiming heat from exhaust gases of Diesel engines, developed by Davis Eng. Corp. Possibilities of application.
Waste-Heat Boilers and Vertical Retort Installations. Gas Jl., vol. 167, no. 3,190, July 2, 1924, pp. 106-122, 20 figs. Twelfth report of Research Sub-Committee of Gas Investigation Committee. Investigation conducted on water-tube waste-heat boilers attached to installations of Woodall-Duckham continuous vertical retorts at Windsor Street works of Birmingham Gas Dept. See also Gas Wld., vol. 80, no. 2,084, June 28, 1924, pp. 633-647, 5 figs.

BONUS SYSTEMS

MAINTENANCE OF. Maintenance of a Standard Time and Bonus System. C. W. Setter. Soc. Indus. Engrs. Bul., vol. 6, nos. 7-8, July-Aug. 1924, pp. 10-14. Details as practised at works of Republic Metalware Co., Buffalo, N. Y.

BRAKES

POWER. The Commission's Report on Power Brakes. Ry. Rev., vol. 75, no. 7, Aug. 16, 1924, pp. 251-257. Mandatory conclusions enunciated by Interstate Commerce Commission as result of its extended investigation of power brakes and appliances.

BRASS

ALPHA-BETA, HEAT TREATMENT OF. Experiments on the Heat Treatment of Alpha-Beta Brass, O. W. Ellis and D. A. Schemnitz. Am. Inst. Min. & Met. Engrs. —Trans., Advance paper No. 1348-N, July 1924, 11 pp., 2 figs. Details of experiments carried out mainly with view of determining whether precipitation of soft particles within a supersaturated solid solution would not enhance its hardness. Effect of reheating quenched alpha-beta brass on its micro structure; results of reheating quenched alpha-beta brass at 100 deg., 200 deg. and 300 deg. cent.; aging at room temperature.
FOUNDRY MIXTURES, NICKEL ADDITIONS TO. The Advantage of Nickel Additions to Brass Foundry Mixtures, W. M. Corse. Metal Industry (Lond.), vol. 25, no. 3, July 18, 1924, pp. 79-80. Discusses advantages of nickel additions and gives typical examples of benefit derived. Lecture before Metropolitan Brass-founders' Assn., New York.

BRIDGES

RAILWAY. Long Girder Spans for Reinforced Concrete Bridge. Ry. Rev., vol. 75, no. 6, Aug. 9, 1924, pp. 202-205, 6 figs. Pennsylvania Ry. uses spans of unusual length for new structures which replaces steel bridge at Becks Run, Pa., Monongahela River.
SYDNEY, AUSTRALIA. The Competitive Designs for the Sydney Harbour Bridge. Engineering, vol. 118, no. 3056, July 25, 1924, pp. 129-132, 18 figs. Discussion of the different designs submitted for construction of Sydney Harbor Bridge. Proposals are of five general types, viz., arch, cantilever-arch, cantilever, suspension and cantilever-suspension.

BRIDGES, CONCRETE

ARCH. Big Four Cutoff Involves Monumental Bridge. Ry. Age, vol. 77. no. 3, July 19, 1924, pp. 99-103, 8 figs. Cleveland, Cincinnati, Chicago and St. Louis constructing 13.7 miles of grade revision and double track work on its Indianapolis-Cleveland line which embraces a seven-mile relocation involving some very heavy and spectacular construction of which most important feature is a reinforced-concrete arch viaduct at Sidney, Ohio. Details of construction of bridge.
Hill to Hill Bridge, Bethlehem, Pa. Ry. Rev., vol. 75, no. 3, July 19, 1924, pp. 77-84, 13 figs. Long viaduct relpaces wooden bridge over Lehigh River and eliminates 8 grade crossings. Bridge is of high level or viaduct type; except for 2 through truss spans and 8 through girder spans, entire structure is of reinforced concrete design.

BRIDGES, LIFT

BASCULE. Bascule Bridge and Viaduct at Coleraine. Ry. Engr., vol. 45, no. 535, Aug. 1924, pp. 265-271, 10 figs. Engineering details and drawings of 11-span viaduct recently completed on L.M. & S.R. (Northern Counties Committee), Ireland. One section of this structure includes first Strauss underhung counterweight Bascule Bridge in British Isles, erected over River Bann to replace old viaduct.

BUILDING CONSTRUCTION

FIREPROOF. Analysis of Cost of Types of Fireproof Construction, A. F. Klein. West. Soc. of Engrs.—Jl., vol. 29, no. 7, July 1924, pp. 290-300, 10 figs. Gives unit costs of different methods of fireproof construction of 3 types of buildings; analyzes 4 types of construction for 16-story hotel, 3 for light manufacturing building, and 3 for heavy warehouse.
Comparison of Types of Fireproof Construction, C. L. Post. West. Soc. of Engrs.—Jl., vol. 29, no. 7, July 1924, pp. 278-289, 11 figs. Compares types of fireproof construction covering foundations, columns and floor construction, hollow clay tile arches, reinforced-concrete joist construction, flat-slab construct on, etc., recognizing fact that no universal rules can be laid down.

BUSES

TROLLEY. The Scope of the Trolley Bus, C. O. Silvers. Motor Transport (Lond.), vol. 39, no. 1010, July 7, 1924, pp. 13-14, 2 figs. Its advantages and disadvantages; traffic and mechanical requirements.
See also Motor Buses.

C

CABLEWAYS

PORTABLE. "Artex" Portable Ropeway. Indus. Mgt. (Lond.), vol. 11 (new series) no. 12, June 1924, pp. 325-326, 2 figs. Discusses Artex system built on mono-cableway system of transportation, including rope coupling by means of which endless-rope track can be shortened or lengthened for altering scope and position of conveyor.

CANALS

HYDRAULIC NOTCH. Calculation of Hydraulic Notch for Channel Control, H. B. Muckleston. Eng. News-Rec., vol. 93, no. 6, Aug. 7, 1924, pp. 232-233. Method employed in designing channel construction to maintain constant energy gradient at change of canal grade.
LOCK GATES. New Type of Canal Lock Gate Developed in Sweden, L. Lawski. Eng. News-Rec., vol. 93, no. 4, July 24, 1924, pp. 135-136, 3 figs. Describes floating sector type canal gate developed to meet peculiar conditions which exist in Sodertalje Canal, at Sodertalje, near Stockholm, a tidal canal where difference in head is small. Filling water admitted around gates.

CAR HOUSES

DESIGN. Fort Wayne Builds Modern Carhouse. Elec. Ry. Jl., vol. 64, no. 6, Aug. 9, 1924, pp. 191-194, 7 figs. Details of design and construction of car house of Indiana Service Corp., giving facilities for inspection repairs and storage.

CAR LIGHTING

MAINTENANCE METHODS. Light, Not Lamps, Determines Economy of Car Lighting, E. E. Dorting. Elec. Ry. Jl., vol. 64, no. 3, July 19, 1924, pp. 80-82, 2 figs. Analysis shows light to be thing purchased in car lighting; old lamps should be discarded; lamps and power for lighting cars cost Interborough Rapid Transit Co. $125,964 per yr.

CARS

AIR-COMPRESSOR. Mobile, Self-Contained Compressor Car for Railroad Service. C. S. Kulp. Compressed Air Mag., vol. 29, no. 8, Aug. 1924, p. 955, 3 figs. Details of compressor car outfit consisting of two type POV-2 compressors directly connected to 50 hp. engine, single-cylinder horizontal type operating on 4-stroke cycle.

CARS, REFRIGERATOR

FRENCH. Refrigerator Cars on the French System (Les wagons frigorifiques), M. A. Sigmann. Revue Générale des Chemins de Fer, vol. 43, no. 6, June 1924, pp. 399-417, 9 figs. Development of refrigerator cars; design and construction of isothermic cars of Orleans Railway; transportation of fruit, meat, milk, etc.

CAST IRON

FORMULAS. Cast Iron Formulae. Metal Industry (Lond.), vol. 25, no. 2, July 11, 1924, pp. 35-37, 3 figs. Use of formulas which purport to give relative proportions of the various constituents, particularly silicon-carbon relations. Criticizes specific formulas which have been proposed. Tenor of author's conclusions seems to be that all such formulas are more dangerous than useful.
POROSITY. Porosity in Cast Iron, A. Marks. Foundry Trade Jl., vol. 30, no. 412, July 10, 1924, pp. 25-27, 8 figs. Also Metal Industry (Lond.), vol. 25, no. 3, July 18, 1924, pp. 61-62. Discusse graphite, shrinkage, gas, and dirt porosity and concludes that there is no single cause or cure of porosity in castings. Each case has to be dealt with on first principles and molding, feeding, chilling and metal all attended to.
SHRINKAGE. Shrinkage. Metal Industry (Lond.), vol. 25, no. 3, July 18, 1924, pp. 83-86, 3 figs. Discusses chief phenomena and causes of shrinkage in cast iron. Deals at some length with classic work of Keep.
The Influence of Various Elements on the Shrinkage of Cast Iron and Steel, I. Jaederstroem. Testing, vol. 1, no. 4, Apr. 1924, pp. 290-307, 16 figs. Shows influence on shrinkage exerted by carbon, silicon, manganese, phosphorus, sulphur, nickel and chromium, determined by varying percentage of one element at a time.
SOLIDIFICATION AND COOLING, CHEMICAL EQUILIBRIA DURING. Chemical Equilibria During Solidification and Cooling of White Cast Iron, H. A. Schwartz and Anna N. Hird. Am. Inst. Min. & Met. Engrs.—Trans., Advance paper No. 1356-S, July 1924, 4 pp. By analyzing cementite separated electrolytically from white cast iron of known composition and history, distribution of silicon between austenite and cementite during and after freezing has been followed. Results constitute a contribution to our knowledge of equilibria in ternary system iron-carbon-silicon. Information also obtained regarding distribution of manganese, silicon, and phosphorus, when only relatively small amounts of each are present.

CASTINGS

STRUCTURE OF. Surface Structure Versus Inner Structure of Metals, V. N. Krivobok and O. E. Romig. Am. Soc. for Steel Treating—Trans., vol. 6, no. 1, July 1924, pp. 66-76, 11 figs. Discusses structures which appear on surface of cast metals and their relation to inner crystalline organization of metal; variety of surface structures and danger of erroneous conclusions based on them solely.

CEMENT

MAGNESIUM OXYCHLORIDE. What is Good Magnesium Oxychloride Cement? H. L. Olin and B. H. Peterson. Chem. and Met. Eng., vol. 31, no. 7, Aug. 18, 1924, pp. 266-267. Effects of adding free lime and calcium carbonate studied and causes of weakening of cement in case of former investigated.

STORAGE. Effect of Storage of Cement, D. A. Abrams. Lewis Inst., Structural Matls. Research Lab.—Bul. no. 6, Apr. 1924, 33 pp. 12 figs. Results of tests with three different lots of portland cement stored up to five years show that increase in strength of concrete in approximately proportional to logarithm of age, also appreciable loss in strength due to storage in small lots. Deterioration is due to absorption of atmospheric moisture which causes partial hydration, etc.

CEMENT, PORTLAND

PUZZOLANA. Effect of Puzzolana on Cements (L'influence des pouzzolanes sur les ciments), O. Raulin. Génie Civil, vol. 85, no. 2, July 12, 1924, pp. 37-39. Discusses special portland cements and their properties; class puzzolana including volcanic slag, trass, blast furnace slag, etc., and their properties.

CENTRAL STATIONS

CHICAGO. ILL. Calumet and Crawford Ave. Stations of the Commonwealth Edison Co., Chicago, Ill., W. F. Sims. Iron & Steel Engr., vol. 1, no. 7, July 1924, pp. 382-386, 5 figs. General layout, coal-handling equipment, boiler plant, feed-water system, switchhouse, connection with other stations.
OPERATING-COSTS ANALYSIS. How to Analyze the Operating Costs in a Municipal System, G. F. Drewry. Elec. News, vol. 33, nos. 13 and 14, July 1 and 15, 1924, pp. 54-55 and 55-56. Advantages of cost analysis; cost of power can be definitely distributed; power factor must be taken into account.
PARSONS LINE. Some Opinions on the "Parsons Line". Power Engr., vol. 19, no. 220, July 1924, pp. 251-253, 4 figs. Number of expressions by station engineers regarding value of this method of checking operating results.
PRACTICE. General Review of Current Practice, P. Junkersfeld and G. A. Orrok. Combustion, vol. 11, no. 2, Aug. 1924, pp. 125-129, 3 figs. Current practice in power-plant field reviewed with particular reference to central stations. Compact chart indicating equipment in 22 of the most modern plants in United States. Paper presented at World Power Conference in London, July 1924.
PULVERIZED-COAL BURNING. Thiers Central Station Fired with Pulverized Coal (Station centrale de Thiers chauffée au charbon pulvérisé), M. L. Champy. Annales des Mines; vol. 5, no. 5, May 1924, pp. 291-317, 3 figs. Storing, drying, and conveying of pulverized coal; combustion chamber, boilers, turbo-alternators, switching facilities and tests made; plant was particularly constructed to use a fuel which was otherwise useless because it was too fine.
REMODELING. Modern Equipment Reduces Cost of Power. Power, vol. 60, no. 6, Aug. 5, 1924, pp. 210-211, 2 figs. Steam equipment of Abbeville, La., municipal light plant replaced by Diesels; cost of generating current reduced; water works served by motor-driven centrifugal pumps and air lift.

CHAINS

SILENT, MANUFACTURE OF. The Story of Morse Chain, C. G. Priebe. Am. Mach., vol. 60, nos. 20, 22, 24 and 26, and vol. 61, nos. 2 and 4, May 15, 29, June 12, 26, July 10 and 24, 1924, pp. 737-740, 811-814, 887-889, 959-962, 69-71 and 145-148, 50 figs. May 15: Development of chain and its manufacture; growth of Morse Chain Co.; layout of units of plant. May 29: How sprocket wheels are made. June 12: Drawing operations; forming pin stock; carbonizing; presswork in pins. June 26: How links are stamped out and hardened. July 10: How chain is assembled, riveted, inspected and packed for shipment. July 24: Typical applications of silent chain for power transmission.

CHIMNEYS

DRAFT CALCULATIONS. Theory of Draft (Théorie du tirage), N. Peters. L'Association des Ingénieurs sortis des Ecoles spéciales de Gand—Annales, vol. 14 (Series 5), 1924, pp. 129-140. Formulas for calculating dimensions of stacks, heat losses, etc.
SIZE DETERMINATION. How to Determine the Proper Size of Chimney, T. S. Clark. Power, vol. 60, no. 5, July 29, 1924, pp. 175-179, 1 fig. Explains in a practical manner necessary elements for determining proper size of chimney for a given installation. Includes typical examples.

CHROME STEEL

PROPERTIES. Chromium—Its Uses and Its Alloys, W. M. Mitchell. Forging—Stamping—Heat Treating, vol. 10, no. 8, Aug. 1924, pp. 303-306, 13 figs. Chromium in steel lessens thermal conductivity; property is of importance when heat treating large forgings.

CHROME-NICKEL STEEL

CARBIDES. The Carbides in Nickel Chromium Steels, J. H. Andrew and H. Hyman. West of Scotland Iron & Steel Inst.—Jl., vol. 31, parts 6 and 7, Mar.-Apr. 1923-1924, pp. 116-123, 10 figs. Discusses analysis of carbides in samples water quenched from 770 deg. Cent., and tempered at 650 deg. Cent. for 3 hr., and water quenched from 1,200 deg. Cent. and tempered at 650 deg. Cent. for 3 hr.
NON-RUSTING. Non-Rusting Chromium-Nickel Steels, B. Strauss. Am. Soc. for Testing Matls., Preprint of paper presented at meeting June 24-27, 1924, No 19e, 10 pp., 5 figs. Valuable properties of chromium as an alloy with iron and steel, and experiments which led to development of two chromium-nickel steels in Physical Research Laboratory of Messrs. Krupp, Germany; results of corrosion tests, physical and metallographic properties, properties under elevated temperatures, and applications of these steels.

CIRCUIT BREAKERS

HIGH-VOLTAGE. High-Voltage Circuit Breakers, J. S. Jenks. Am. Inst. Elec Engrs.—Jl., vol. 43, no. 8, Aug. 1924, pp. 715-718. Discusses question from operators point of view, gives experiences with West Penn system.

CITY PLANNING

SUPER-HIGHWAY PLAN. Greater Detroit's Proposed Super-Highway Plan. Eng. Wld., vol. 25, no. 2, Aug. 1924, pp. 59-61, 1 fig. Discusses congestion problem and more surface lines needed. See also Eng. and Contracting (Roads and Streets), vol. 62, no. 2, Aug. 6, 1924, pp. 283-287, 1 fig.

CLUTCHES

DESIGN. Considerations in Clutch Design, A. Clegg. Machy. (Lond.), vol. 24, no. 614, July 3, 1924, pp. 436-438, 5 figs. Conical clutches.
Plate and Coil Clutches, A. Clegg. Machy. (N. Y.) vol. 30, no. 12, Aug. 1924, pp. 953-955, 6 figs. Notes on design. Describes different types.

COAL

CARBONIZATION. Practical Coal Carbonization, F. W. Sperr, Jr. Universal Engr., vol. 40, no. 2, Aug. 1924, pp. 31-37, 4 figs. Discusses high temperature and low temperature carbonization with special reference to American conditions, yields and values of by-products. Abstract of paper read at meeting of Phila. Local Sec., A. S. M. E.
GASIFICATION. The Regenerative Coal Gasification System at Aylesbury, A. G. Lane. Gas Jl., vol. 167, no. 3190, July 2, 1924, pp. 149-153, 3 figs. Coal is transformed into gas in single operation, leaving only ash liquor and tar as residuals, and renders large proportion of energy of coal available and saleable as town's gas. See also Gas Wld., vol. 80, no. 2084, June 28, 1924, pp. 664-675, 3 figs.

COAL DUST

EXPLOSION PREVENTION. Spreading Stone Dust with Compressed Air to Prevent Coal-Dust Explosions, C. Moran. Compressed Air Mag., vol. 29, no. 7, July 1924, pp. 917-918, 5 figs. Discusses testing of coal dust for explosion properties and application of stone dust distribution and stone dust shelving to prevent or arrest coal dust explosions.

COAL HANDLING

PLANTS. Coal-Handling System, J. A. Beck. Combustion, vol. 11, no. 2, Aug. 1924, pp. 120-121, 3 figs. Description of apparatus installed at plant of Kansas Gas & Elec. Co. at Strauss, Kan., and of method of operation.

COKE

GASIFICATION. The Gasification of Coke in Steam, with Special Reference to Rates of Gasification and the Composition of the Gas, S. Pexton and J. W. Cobb. Gas Jl., vol. 167, no. 3190, July 2, 1924, pp. 161-169, 7 figs. Investigates composition of gas and amount of undecomposed steam as varying with temperature, velocity of gas stream and nature of coke used. See also Gas Wld., vol. 80, no. 2084, June 28, 1924, pp. 675-678.

COMPRESSED AIR

FOUNDRY EQUIPMENT. Pneumatic Apparatus Speed Up Performance in the Foundry, S. G. Roberts. Compressed Air Mag., vol. 29, no. 7, July 1924, pp. 933-936, 13 figs. Discusses pneumatic equipment of Malleable Iron Fittings Co., Branford, Conn., including air operated riddles, knock-out vibrators, jet cleaners and sprayers, etc.

CONCRETE

ADMIXTURES IN. Recommended Admixtures in Concrete, D. A. Abrams. Contract Rec., vol. 38, no. 33, Aug. 13, 1924, pp. 814-815. Results of investigations to determine effects of calcium chloride and other compounds on compressive strength of concrete.
AGGREGATES. Analysis of Grading Curve for Concrete Aggregates, L. I. Hewes. Eng. News-Rec., vol. 93, no. 6, Aug. 7, 1924, pp. 222-226, 2 figs. Mathematical study of size gradation of sand and stone to co-ordinate various measures of grading such as fineness modulus, surface area and density ratio.
FRICTION TESTS. Friction Tests of Concrete on Various Subbases, A. T. Goldbeck. Public Roads, vol. 5, no. 5, July 1924, pp. 19-20 and 23, 1 fig. Discusses determination of frictional resistance a step toward rational design of concrete pavement, description of specimens and method of tests and frictional resistance lowered by wet subbase.
MIXING. Concrete Methods on the C.C.C. and St. L. Ry., J. B. Hunley. Eng. & Contracting (Bldgs.), vol. 61, nos. 3 and 4, Mar. 26 and Apr. 23, 1924, pp. 681-691 and 871-879, 5 figs. Old and new practices, with especial reference to proportioning. Notes on designing concrete mixtures. Paper read at Am. Concrete Inst. convention, Feb. 25-28, 1924.
MOIST SANDS. The Bulking of Moist Sands, A. A. Levison. Public Roads, vol. 5, no. 5, July 1924, pp. 21-23, 5 figs. Effect of phenomenon on strength and yield of concrete.

CONCRETE CONSTRUCTION REINFORCED

BULKHEADS. Reducing the Cost of Concrete Bulkheads, T. Aston. Concrete, vol. 25, no. 1, July 1924, pp. 28-30, 5 figs. Develops hollow stepped-down concrete wall for use as bulkhead for wharves, retaining walls, and the like. Shows step wall system, as applied to dam walls, gives cheaper construction than standard types of dam walls.

CONDENSERS, STEAM

SURFACE. Surface Condensers and Auxiliaries, J. P. Likiak. So. Engr., vol. 41, no. 5, July 1924, pp. 51-55, 11 figs. Size limit, arrangement of passes, method of tube packing and methods of cleaning tubes.

CONDUITS

CONCRETE. Concrete Conduit Gaining Favor. Cement & Eng. News, vol. 36, no. 7, July 1924, pp. 33-34 and 40, 4 figs. Electrical engineers find "stone" product has many advantages over other materials in underground wiring systems.
ELECTRICAL CONCRETE-PIPE. Concrete Pipe Electrical Conduits. Concrete, vol. 25, no. 1, July 1924, pp. 32-34, 4 figs. Gives method of installation, essential qualities of duct material, comparison of various materials, advantages of using concrete conduit and extensive use of concrete conduit.

CONVERTERS

ROTARY. The Generating Effect in Rotary Converters on Short Circuit, F. Hoeberli. Brown Boveri Rev., vol. 11, no. 1, Jan. 1924, pp. 3-12, 12 figs. Details of short circuit test of rotary converters for direct-current traction at 1600 volt, and their favorable behavior.

CONVEYORS

FACTORY. Increasing Production by Power Conveyors. Machy. (Lond.), vol. 24, no. 618, July 31, 1924, pp. 558-561, 5 figs. Conveyor installations that have proved their economy in plant manufacturing small parts.

COPPER DEPOSITS

CANADA. Copper Deposits of Arctic Canada, G. M. Douglas. Eng. & Min. Jl.—Press, vol. 118, no. 3, July 19, 1924, pp. 85-89, 5 figs. Discusses British Government explorations, great extent of mineralized area, copper in three forms, deposits at Bathurst inlet, possibilities of high-grade ore and transportation problem.

CORROSION

ELECTROLYTIC. The Electrolytic Theory of Corrosion, W. D. Bancroft. Physical Chem.—Jl., vol. 28 no. 8, Aug. 1924, pp. 785-871. Reviews electrolytic theory and criticizes some conclusions based on it.

COST ACCOUNTING

FUNCTION OF, MEASURING. Evaluating the Cost Department. Mech. Eng., vol. 46, no. 8, Aug. 1924, pp. 477-479. Varying views of cost accountants, engineers, and others on possibility of measuring cost-accounting function.

COSTS

MACHINE SHOP, ESTIMATING. How to Estimate Machine Shop Costs, A. A. Dowd. Am. Machinist, vol. 61, no. 6, Aug. 7, 1924, pp. 227-230, 3 figs. Estimates of machining time on spline-milling operations; practical examples of keyway and slot cutting; gear milling and hobbing estimates.

COUNTERBORES

MANUFACTURE OF. Manufacturing Interchangeable Counterbores. Machy. (N. Y.), vol. 30, no. 12, Aug. 1924, pp. 943-947, 15 figs. Unusual operations and fixtures employed by Gairing Tool Co., Inc., Detroit, Mich., in making counterbores and holders.

CRANES

CRAWLER. Crawler Crane Built for First Time in Canada, H. P. Armson. Can. Machy., vol. 32, no. 3, July 17, 1924, pp. 19-21 and 42, 3 figs. Designed and built by J. T. Hepburn, Ltd., Toronto, for service in civic yards.

TRAVELING. A Special Running Shed Crane Equipment on the Pennsylvania Railway. Ry. Gaz., vol. 41, no. 2, July 11, 1924, p. 43, 3 figs. Particulars of ten-ton electric overhead traveling crane, operating on circular track and having all wheels of same diameter, at Columbus, O., enginehouse of Penna. Ry.

CRANKSHAFTS

EXPLOSION-ENGINE, RESONANCE OF. Experimental Demonstration and Exact Measurement of Resonance of Crankshafts of Explosion Engines; Rôle of Flywheel; Favorable Effects of Elastic Coupling (Démonstration expérimentale et mesure précise des phénomènes de résonance propre des arbres manivelles des moteurs à explosion; rôle du volant; influence favorable d'un accouplement élastique), A. Blondel and H. Harle. Académie des Sciences—Comptes Rendus des Séances, vol. 178, no. 18, Apr. 28, 1924, pp. 1442-1452, 4 figs. Results of experiments to measure resonance in crankshafts at various speeds and comparison of results with theory.

CURVES

HYPERBOLIC. Plotting Hyperbolic Transformation Curves (Note sur le tracé des courbes hyperboliques de transformation, dans le diagramme). Arts et Métiers, vol. 77, no. 44, May 1924, pp. 170-173, 3 figs. Discusses Brauer's curve showing volume and absolute pressure of gas varying in geometric progression; plotting of hyperbolic curves by means of logarithmic auxiliary curve.

D

DAMS

BARRAGE. Wilson Dam at Muscle Shoals, World's Greatest Hydraulic Development, Development, H. L. Cooper. Universal Engr., vol. 40, no. 2, Aug. 1924, pp. 21-26, 8 figs. At Tennessee River for production of electric power and improvement of navigation; details of power house equipment, 30,000 h.p. turbines, 25,000 kva. generators, 60 cycle, three-phase 12,000 volt 100 r.p.m. etc. See also Nat. Engr. vol. 28, no. 8, Aug. 1924, pp. 388-391, 3 figs.

CONCRETE. Concrete Work at Wilson Dam, Muscle Shoals, R. P. Brown. Eng. and Contracting (Water Works), vol. 62, no. 1, July 9, 1924, pp. 61-66, 6 figs. Construction features of largest concrete project in world. Paper read before Annual Convention of Nat. Lime Assn.

MULTIPLE ARCH. Multiple Arch Barrage Dams and Their Security (Les barrages à voûtes multiples et la sécurité), E. Baticle. Génie Civil, vol. 85, no. 2, July 12, 1924, pp. 36-37. Criticises continued confidence in multiple arch dams after Gleno failure and shows that dams do not give security theoretically that might be expected of them.

DIES

DRAWING. Designing Drawing Dies. Machy, (Lond.), vol. 24, nos. 611 and 614. June 12 and July 3. 1924, pp. 341-344 and 422-426, 14 figs. Radii over which metal can be drawn, type of equipment used, operation of drawing die, design of first-operation die, die for final drawing operation, design of blank holders, computing blank diameter of shells of unusual shapes, determining number of operations required, combination die for blanking and drawing, troubles encountered in drawing light-gage metal, etc.

DIESEL ENGINES

CENTRAL-STATION. Diesel Engines Turn Tables on Central Station. Oil Engine Power, vol. 2, no. 7, July 1924, pp. 366-370, 6 figs. Atlantic Wire Co., Branford, Conn. changed power source from steam plant to Diesel-engine drive; costs chargeable are considerably less per kw-hr. than purchased current cost; two six-cylinder Lombard Diesel engines rated to develop 180 h. h.p. each and direct connected to two Westinghouse 3-phase 200 kva. alternators and 10-kw. direct-connected exciters.

HEAVY-OIL BURNING. Burning Heavy Fuel Oil in Diesel Engines, R. Hildebrand. Power House, vol. 17, no. 14, July 20, 1924, pp. 26 and 39, 1 fig. Satisfactory results were obtained with small three-cylinder, single-acting, four-stroke vertical engine developing 200 h.hp. at 257 r.p.m.

REPLACES WATER POWER. Municipality Replaces Water-Power with Oil Engines. Oil Engine Power, vol. 2, no. 7, July 1924, pp. 379-380 and 385, 3 figs. When city of Marshall, Mich., began to grow so fast that all available water flow was used up in attempt to keep pace with increasing power demands, electric current was purchased outside at moderate rates. Subsequent steep rises in cost of purchased power made city turn to oil-engine power, and Diesels since installed have netted big operating gains.

SCAVENGING BLOWERS FOR. Centrifugal Scavenging Blowers for Two-Cycle Marine Diesel Engines, E. Klingelfuss. Brown Boveri Rev., vol. 11, no. 4, Apr. 1924; pp. 67-80, 28 figs. Details of design and construction of centrifugal scavenging blowers, their advantages, and prime-movers for them; arrangement on board ship; operation in conjunction with Diesel engines.

DIRECTION FINDING

UNILATERAL. A New Unilateral Radiogoniometer (Un nouveau radiogoniomètre avec levée du dute), E. Bellini. L'Onde Electrique, vol. 3, no. 29, May 1924, pp. 233-253, 19 figs. Describes a new device for direction finding.

DOCKS

FLOATING. Reinforced Concrete Dolphins for 60,000-Ton Floating Dock at Southampton. Concrete and Constructional Eng., vol. 19, no. 7, July 1924, pp. 450-454, 1 fig. To provide docking facilities for ships of Majestic type and larger (56,557 tons).

DRAINAGE

DRAINAGE AND RAINFALL, E. V. WILLARD. Nat. Reclamation Mag., vol. 3, no. 2, Feb. 1924, pp. 24-25 and 34-35. Records show that wet cycles alternate with dry cycles and drainage has no effect on rainfall.

DITCHES. Method of Reconstructing Old Open Drainage Ditches, J. L. Parsons. Eng. and Contracting (Water Works), vol. 62, no. 1, July 9, 1924, pp. 77-79, 1 fig. Discusses reconstruction work much of which consists of cleaning out and deepening old ditches.

Open Ditches Replaced by Tile. Nat. Reclamation Mag., vol. 3, no. 3, Mar. 1924, pp. 44-45 and 55, 7 figs. Discussion at Congress in St. Louis shows value of tile replacement for ditches.

SILT DEPOSITS. Handling Silt in Settling Basins, R. M. Towl. Eng. and Contracting (Water Works), vol. 62, no. 2, Aug. 13, 1924, pp. 341-344, 3 figs. Describes how silting problems are being met and results in hall creek settling basin.

DRILLING MACHINES

HEAVY-DUTY, POSSIBILITIES OF. Possibilities of Heavy-duty Drilling, H. L. Tigges. Machy. (N. Y.), vol. 30, no. 12, Aug. 1924, pp. 950-952, 5 figs. Points out possibilities of vertical heavy-duty drilling machine by presenting examples of work done in automobile plants. By term "heavy-duty drilling machine", is meant a machine with a box column.

E

EARTHQUAKES

JAPAN. Six Lessons from the Japan Earthquake, R. F. Moss. Mich. Architect & Engr., vol. 6, no. 2, Feb. 1924, pp. 18-22, 1 fig. Gives six important lessons and recommendations for future construction.

EDUCATION, ENGINEERING

POWER-PLANT ENGINEERING. Training Engineers for Alberta's Power Plants, R. M. Dingwall. Power House, vol. 17, no. 14, July 20, 1924, pp. 19-20 and 40-41, 3 figs. Provincial Inst. of Technology & Art, Calgary, Alberta gives complete course in mechanical engineering consisting of two terms of 8 mos. each; students devote 50 per cent of their time to practical work.

EDUCATION, INDUSTRIAL

CHARACTER AND EXTENT. Education and Training for the Industries. Mech. Eng., vol. 46, no. 8, Aug. 1924, pp. 482-483. Investigation into character and extent of such training. Making industry attractive to high-school and college students. Labor as a means of social salvation.

ELECTRIC CIRCUITS

THEORY. A Generalization of Reciprocal Theorem, J. R. Carson. Bell System Technical Jl., vol. 3, no. 3, July 1924, pp. 393-399. Generalization of Raleigh's theorem as to periodic electromotive force in circuit A giving rise to same current in B as would be excited in A if electro motive force operated in B.

ELECTRIC CONDUCTORS

JOINTS. The Contact Resistance of Large Conductors, A. R. Enger. Elec. Jl., vol. 21, no. 7, July 1924, pp. 316-318, 6 figs. Shows from experiments that voltage across contact will vary inversely with pressure, and that resistance between contacts depends only on total pressure with which they are forced together.

ELECTRIC DISTRIBUTION SYSTEMS

OPERATION. The Continuity and Regularity of Operation of Large Electric Systems, G. Semenza. Engineering, vol. 118, no. 3055, July 18, 1924, p. 112. Shows that improvement of service is an advantage both for consumer and producer, but perhaps more for producer. Causes of bad service.

ELECTRIC FURNACES

INDUCTION. A Six-Ton Induction Furnace Installation, M. Unger. Gen. Elec. Rev., vol. 27, no. 8, Aug. 1924, pp. 498-503, 12 figs. Details of new General Electric Co. three-ton furnace and its auxiliaries, yielding high-grade melt of extreme uniformity.

MELTING WITH. Melts in Twin Electric Furnaces, A. W. Bryant. Iron Trade Rev., vol. 75, no. 4, July 24, 1924, pp. 226-228, 4 figs. At plant of Kelley & Jones Co., Greensburg, Pa., who manufacture a line of plumbing and valve fittings in gray iron, steel and malleable iron, two acid-lined units, 1½ tons capacity each, mounted on turntable 180 deg. apart and having single set of electrodes, provide small batches of hot metal at short-even intervals.

ELECTRIC GENERATORS, A.C.

PARALLEL OPERATION. Parallel Operation of Direct-Connected Auxiliary Generators, H. B. Seeley. Elec. Jl., vol. 21, no. 8, Aug. 1924, pp. 387-390, 6 figs. Discusses operating shaft-driven auxiliary generators in parallel with other sources of auxiliary power, with parallel operation with main bus through transformers, parallel operation with turbine-driven house unit, parallel operation of two-shaft generators.

SHORT CIRCUITS. Short Circuits of Alternating-Current Generators, C. M. Laffoon. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 8, Aug. 1924, pp. 736-743, 17 figs. Presents physical conception and simple non-mathematical analysis of short-circuit phenomena of alternating-current generators. Formulas are developed for maximum instantaneous values of armature and field short-circuit currents delivered by both single and polyphase generators.

ELECTRIC GENERATORS, D.C.

LOW VOLTAGE. Stability of Direct-Current Generators, C. Fynn. Elec. Jl., vol. 21, no. 7, July 1924, pp. 304-308, 6 figs. Discusses d.c. generators separately excited and self-excited gives no-load and full load saturation curves, d.c. generators used as exciters for a.c. generators.

ELECTRIC LOCOMOTIVES

DEVELOPMENT. The Development of the Electric Locomotive, F. H. Shepard. Ry. Elec. Engr., vol. 15, no. 7, July 1924, pp. 225-236, 1 fig. World-wide summary of present-day practice as regards heavy electric traction.

ELECTRIC MACHINERY

IRON LOSSES. Surface Iron Losses with Reference to Laminated Materials, T. Spooner and I. F. Kinnard. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 8, Aug. 1924, pp. 723, 729, 7 figs. Details of tests with experimental salient pole machine and experimental three-phase induction motor, showing that approximately surface losses of air-gap induction, as 1.5 power of tooth frequency, from second to first power of 2 with increase of 2, and as first power of slot pitch.

VIBRATION ABSORBERS. Vibration Absorbers for Large Single-Phase Machines, C. R. Soderberg. Elec. Jl., vol. 21, no. 8, Aug. 1924, pp. 383-387, 8 figs. Discusses elimination of excessive vibrations or of condition of resonance by means of spring-mounted stators, elastic properties of foundations, etc.

ELECTRIC MOTORS

SYNCHRONOUS INDUCTION. The Synchronous Induction Motor, H. Cotton. World Power, vol. 2, nos. 6, and 7, June and July 1924, pp. 329-337 and 45-50, 14 figs. General theory and operation of synchronous induction motors, conditions of slip, equation of slip motion and its solution for special cases.

ELECTRIC MOTORS, A.C.

INDUCTION. Change-Speed Induction Motors, C. W. Kincaid. Elec. Jl., vol. 21, no. 8, Aug. 1924, pp. 357-363, 20 figs. Discusses modifications to obtain speed changes, separate stator windings for each speed desired; three-phase, series-star low speed, parallel-star high speed combinations.

Induction Motors on Unbalanced Circuits, A. M. Dudley. Elec., Jl., vol. 21, no. 7, July 1924, pp. 339-343, 3 figs. Discusses Vector methods of analysis of unsymmetrical systems.

A New Self-Excited Synchronous Induction Motor, V. A. Fynn. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 8, Aug. 1924, pp. 744-748, 7 figs. Comparison of synchronous and asynchronous motors, combination of advantages of both in Danielson synchronous induction motor, self-excited, synchronous induction motor, and gives details of new type of synchronous induction motor giving satisfactory solution of difficulties.

INDUCTION, SPEED REGULATION. The Speed Regulation of Induction Motors by Three-Phase Commutator Motors Connected in Cascade, W. Seiz. Brown Boveri Rev., vol. 11, no. 7, July 1924, pp. 139-142, 3 figs. Details of Brown Boveri-Scherbius and rotating-field cascade systems for speed regulation of induction motors.

SYNCHRONOUS. The Control of Synchronous Motors, H. D. James and J. H. Graybill. Elec. Jl., vol. 21, no. 7, July 1924, pp. 335-339, 4 figs. Discusses field frequency method and time element method of control and both combined.

ELECTRIC MOTORS, D.C.

RECONNECTING. Reconnecting Direct-Current Machines. Change in Speed, A. C. Roe. Power, vol. 60, no. 6, Aug. 5, 1924, pp. 212-215, 5 figs. Three problems worked out showing how to figure winding for change in speed of shunt, compound and series motor.

SPEED REGULATOR. Speed Regulator for Single Motor Drive, J.-H. Ashbaugh. Elec. Jl., vol. 21, no. 8, Aug. 1924, pp. 390-393, 7 figs. Details of speed regulator insuring accuracy and ease of operation which can be used on installations where armature voltage control is impossible and speed regulation must be obtained solely by motor field control.

ELECTRIC TRANSMISSION LINES

CONSTRUCTION IN ROUGH COUNTRY. Line Construction in Rough Country, J. D. Roberts. Elec. Light & Power, vol. 2, no. 7, July 1924, pp. 15-16, 41-45 and 69, 31 figs. Describes type of towers, tower foundations, erection of towers, stringing of conductors and right of way.

DIRECT-CURRENT. High Voltage Electricity Transmission, J. S. and W. E. Highfield. Engineer, vol. 136, no. 3576, July 11, 1924, p. 54, 4 figs. Advqntages of direct-current transmission from point of view of lines and cables. Abstract of paper read at World Power Conference.

LIGHTNING. Lightning and Other Transients on Transmission Lines, F. W. Peek, Jr. Am. Inst. Elec. Engrs.,—Jl., vol. 43, no. 8, Aug. 1924, pp. 697-709, 13 figs. Coordinates researches and observations on lightning with view of determining various types and order of magnitude of predatory voltages to which transmission lines are subject.

OVERHEAD. Comparative Costs of Tower Line, H. S. Brubaker. Elec. Light & Power, vol. 2, no. 8, Aug. 1924, pp. 19-21, 41-46 and 58, 28 figs. Details of construction by three different methods: piece by piece method; towers built prone and later up-end them into place; replacing concrete anchor by grillage type anchor; and their application in construction of Penn Power Co.

WOODEN POLES FOR LONG SPANS. Wooden Pole Towers for Long-Span Construction, K. B. Ayers. Elec. Wld., vol. 83, no. 3, July 19, 1924, pp. 114-115, 3 figs. Details of installation of two spans more than 3,000 ft. long. How installation was made. Steel wires used.

ELECTRIC WELDING, ARC

SAFETY PRECAUTIONS. Using the Arc with Safety, D. H. Devoe. Welding Engr., vol. 9, no. 7, July 1924, pp. 28-29. Methods of protecting eyes and bodies of electric arc welding operators; safeguarding apparatus.

SYSTEMS. Electrical System of Welding, C. N. O. Dutton. So. African Inst. Elec. Engrs.—Trans., vol. 15, part 4, Apr. 1924, pp. 364-374, 18 figs. Gives short description illustrating their advantages for metals to be welded or treated by Bernados system, metallic arc system, spot and butt welding and metallic tipping on depositing by electric arc.

EMPLOYEES, TRAINING OF

FOREMEN. A Successful Experiment in Industrial Education, D. J. Roach. Chem. & Met. Eng., vol. 31, no. 7, Aug. 18, 1924, pp. 272-273. How one large company is training its foremen and operating bosses in economics, mathematics, and technology of its industry.

ENGINEERING

HUMAN FACTOR IN. The Human Factor in Engineering, S. C. Godfrey. Military Engr., vol. 16, no. 87, May-June 1924, pp. 180-183, 1 fig. Discusses "human engineering" or treatment of human tools with as much consideration as materials; including workers' councils, etc.

EVAPORATORS

CHEMICAL PLANTS. Heating an Evaporator with the Exhaust from Condensing Engines, F. H. Nickle. Chem. & Met. Eng., vol. 31, no. 6, Aug. 11, 1924, pp. 226-228, 3 figs. Device designed to act as condenser for multi-expansion engines and evaporator for chemical plant service at same time.

STEAM-JACKETED, HEAT TRANSFER IN. Heat Transfer in Steam-Jacketed Evaporators, H. L. Olin, M. H. Dowell and C. M. Tovnbee. Chem. & Met. Eng., vol. 31, no. 3, July 21, 1924, pp. 116-119, 3 figs. Determining overall transmission and film coefficients as well as operating efficiencies on plant equipment over a wide range of industrial conditions. Paper read before Am. Inst. Chem. Engrs.

EXHAUST STEAM

COST CALCULATION. How Shall We Calculate the Cost of Exhaust Steam? T. Fuwa. Chem. & Met. Eng., vol. 31, no. 4, July 28, 1924, p. 150. Comparison of four possible bases of evaluating exhaust steam and a discussion of advantages of each.

F

FANS

INSTALLATION. Auxiliary Equipment for Blast and Ventilating Fans, D. L. Hubbard. Mech. Wld., vol. 76, no. 1961, Aug. 1, 1924, pp. 70-72, 6 figs. Discusses proper foundations and supports, absorption of vibrations, preferably by means of cork slab; fan and motor noises; fan drives by steam engine and turbine; push-button control.

MINE. Principles of the Design of Mine Fans. Colliery Engr., vol. 1, nos. 4 and 5, June and July 1924, pp. 163-166 and 231-233, 11 figs. Study of fans suited to British colliery conditions. Principal features and functions of exhaustive ventilator, the typical kind of ventilator employed in British mines.

FEEDWATER HEATERS

LOCOMOTIVE. Analysis of Feed Water Heating Devices, E. P. Gangewere. Ry. Mech. Engr., vol. 98, no. 7, July 1924, p. 409. Feedwater heaters with pumps take more heat from exhaust than exhaust-steam injector type.

FIRE PROTECTION

SPRINKLERS. How the Fire Chief Regards Automatic Sprinklers, I. G. Hoagland. Fire & Water Eng., vol. 76, no. 6, Aug. 6, 1924, pp. 253-254 and 278-279. Replies to questionnaire asking for facts as to use chiefs make of this device; opinion as to its usefulness.

FLOORS

LOADS. Strain of Swaying Crowds on Balcony Measured at Iowa. Eng. News-Rec., vol. 93, no. 6, Aug. 7, 1924, p. 231. Stress measurements in floor show effect more than doubled by jumping of excited, cheering students.

FLOW OF STEAM

RESISTANCE OF PIPE BENDS TO. How to Figure the Resistance of Pipe Bends to the Flow of Steam, C. H. Day. Heat & Vent. Mag., vol. 21, no. 7, July 1924, pp. 51-52, 3 figs. Data on four assumed conditions, using standard ells, long-radius ells, minimum radius bends and bends with radius of ten pipe diameters.

FLUE-GAS ANALYSIS

SCIENTIFIC METHODS. Scientific Flue Gas Analysis, D. Brownlie. Eng. & Boiler House Rev., vol. 38, no. 1, July 1924, pp. 3-5, 2 figs. Gives essential facts regarding true scientific methods necessary for flue-gas analysis.

FORGING

SAFETY CODE. Tentative Safety Code of Forging. Forging—Stamping—Heat Treating, vol. 10, no. 8, Aug. 1924, pp. 282-285. Tentative draft formulated under joint sponsorship of Nat. Safety Council and Am. Drop Forging Inst. Reprinted from Nat. Safety News, June 1924.

FOUNDRIES

ECONOMY IN. Economy in Foundry Practice, E. H. Browne. Foundry Trade. Jl., vol. 30, no. 412, July 10, 1924, pp. 38-40. Discusses monotony in foundry practice, case of patternmaker, management, layout of foundry, equipment, care of plant, provision of molding tools, design, patterns, molding and melting.

POWER-GAS CONSUMPTION MEASUREMENT. The Measurement of Power Gas, F. J. Taylor. Foundry Trade Jl., vol. 29, no. 390, Feb. 7, 1924, pp. 105-109, 9 figs. Measurement of amount of gas used for motive power in foundries. Discusses determination of volume passing through gas main by: (1) Estimation in case of engines, (2) pitot tubes, (3) orifices, (4) venturi tubes, and (5) electroflow meter.

FREQUENCY CHANGERS

SET. A 35,000 KW Synchronous Frequency Changer Set, M. W. Smith. Elec. Jl., vol. 21, no. 7, July 1924, pp. 343-346, 4 figs. Describes set of Brooklyn Edison Co. consisting of 35,000 k.w. 11,400 volt, 3-phase, 25-cycle synchronous generator and 47,500 h.p., 3-phase, 60-cycle, 13,800 volt synchronous motor. See Also Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 8, Aug. 1924, p. 709, 1 fig.

FUELS

See Oil Fuel; Peat; Pulverized Coal.

FURNACES

HEAT TRANSFER CAUSED BY RADIATION OF GASES. Heat Transfer in Furnaces as Caused by Radiation of Gases. Fuels & Furnaces, vol. 2, no. 7, July 1924, pp. 675-678, 2 figs. Equations presented which more or less upset modern theory of heat transfer and reestablish truth of older theories.

RECUPERATOR. The Chapman-Stein Recuperator. W. C. Buell, Jr. Iron & Steel Engr., vol. 1, no. 6, June 1924, pp. 327-332 and (discussion) 333-339, 12 figs. Describes number of installations in use of this type, which is said to have best succeeded in eliminating two main troubles, leakage and breakage.

G

GALVANIZING

WIRE. Galvanizing (Étude sur la Galvanisation), A. Knepper. Usine, vol. 33, no. 24, June 14, 1924, pp. 19-23, 2 figs. Discusses thickness of zinc coat for hot galvanizing and exposure to weather; hot galvanizing and interior use; electro lytic galvanizing and exposure to weather; and electrolytic galvanizing for interior use; Develops formulas for calculation.

GAS ENGINES

STEEL WORKS. The Gas Engine in the Steel Industry, A. C. Danks. Mech. Eng., vol. 46, no. 8, Aug. 1924, pp. 450-460 and (discussion) 460-462 and 501, 22 figs. First 4-cycle installation; methods of governing; effect of entering temperatures of gas and air; piston troubles and design; operating costs; engine tests, etc.

GAS

INDUSTRIAL. New Methods of Producing Gas for Industrial Operations, R. Maclaurin. Ceramic Soc.—Trans., vol. 23, part 2, 1923-1924, pp. 121-144, 5 figs. Discusses chemical reactions in making gas; (1) heating bituminous coal to above 400 deg. C. in absence of oxygen; (2) reaction of air with heated carbon, Siemens producer gas; (3) steam contacting with highly heated carbon, water gas reaction, and their combinations.

GAS MANUFACTURE

HORIZONTAL RETORTS. Description of a New Horizontal Setting. Gas Jl., vol. 167, no. 3191, July 9, 1924, pp. 257-258, 1 fig. Describes plant of Robert Dempster & Son, Ltd., Elland, England; features make it unusually flexible and capable of meeting future contingencies in event of more widespread use of smokeless fuel.

GAS PRODUCERS

LARGE-SCALE POWER GENERATION, APPLICATION TO. The Gas Producer as Applied to Large-Scale Power Generation, A. H. Lymn. Iron & Coal Trades Rev., vol. 109, no. 2941, July 11, 1924, pp. 58-59. Describes various methods of applying gas-producer plants to generation of power on large scale and shows economies of different systems as compared with each other and with most modern direct-fired steam practice. Abstract of paper read before World Power Conference.

PRESSURE. Control of Pressure Gas Producers, W. P. Chandler, Jr. Iron & Steel Engr., vol. 1, no. 6, June 1924, pp. 289-293 and (discussion) 293-299, 4 figs. For metallurgical furnaces in steel mills; discusses main factors influencing producer operation and means for obtaining greatest return for given sizes of gas producer and from coal charged.

GEARS

FRICTION. Fieux System of Friction Gearing and Its Application to Railway Motor Cars as Automatic Gearing [Le conjoncteur-disjoncteur à friction (Système Fieux), son application aux véhicules automoteurs comme embrayage automatique], J. Fieux. Société d'Encouragement pour l'Industrie Nationale—Bul., vol. 136, no. 3, Mar. 1924, pp. 279-287, 8 fig. Properties and action of Fieux make-and-break friction gear, and examples of application to railway motor cars.

Transmission by Means of Friction Wheels (Les transmissions par galets de friction). Génie Civil, vol. 84, no. 23, June 7, 1924, pp. 549-551, 6 figs. Use of friction wheels and disks; transmission efficiency; coefficient of friction; etc.

GOLD

PRODUCTION, CANADA. Canada as a Gold Producer, L. D. Huntoon. Min. & Metallurgy, vol. 5, no. 211, July 1924, pp. 315-322, 8 figs. World's gold production. Analysis of Canada's gold production. Railroad building keeping up with prospectors.

GRINDING

MACHINE-TOOL PARTS. Grinding Operations Expedite Manufacture of Machine Tools, W. E. Groene. Abrasive Industry, vol. 5, no. 8, Aug. 1924, pp. 189-192, 6 figs. Describes grinding operations carried on at plant of R. K. LeBlond Machine Tool Co., Cincinnati.

GRINDING MACHINES

INTERNAL AND EXTERNAL. Internal and External Grinding Machines. Machy. (Lond.), vol. 24, no. 617, July 24, 1924, pp. 521-526, 8 figs. Designed by Holroyd & Co., Ltd., Milnrow, for grinding large steel tubes.

GYROSCOPES

THEORY. Some Properties of Spherical Curves, with Applications to the Gyroscope, O. D. Kellogg. Am. Mathematical Soc.—Trans., vol. 25, no. 4, Oct. 1923, pp. 501-524, 2 figs. Discusses certain intrinsic properties of spherical curves and applies results to theory of gyroscope; gives further results and formulas in connection with gyroscope problems.

H

HARDNESS

ALUMINUM BRONZE, HEAT-TREATED. Notes on the Hardness of Heat-Treated Aluminum Bronze, G. F. Comstock. Am. Inst. Min. & Met. Engrs.—Trans., Advance paper No. 1357-N, July 1924, 9 pp., 4 figs. Results of scleroscope and Brinell tests on specimens of cast 10 per cent aluminum bronze, quenched and reheated at various low temperatures.

GRAY IRON, BRINELL TEST. The Value of the Brinell Hardness Test to the Gray-Iron Foundry, I. Jaederstroem. Testing, vol. 1, no. 4, Apr. 1924, pp. 286-289, 2 figs. Results of researches. Main reason for great popularity of Brinell test in investigation of steel is fact that it not only indicates resistance of material to penetration of another, harder body, but that hardness values thus obtained permit also definite conclusions on tensile strength of steel under investigation.

HEATING

BUILDINGS. The Calculation of Thermal Requirements in Buildings by Means of a Graphic Chart, J. N. Victor. Am. Architect, vol. 126, no. 2450, July 16, 1924, pp. 69-71. Chart is adapted to designing of steam, vapor, vacuum and hot-water systems which employ direct, indirect or coil radiation and for all temperature differences.

HIGHWAYS

SPECIFICATIONS. Preparation of Highway Specifications, A. S. Macmillan. Can. Engr., vol. 47, no. 3, July 15, 1924, pp. 152-154. Discusses features from contractors viewpoint contained in paper presented at annual convention of Can. Good Roads Assn.; respecting contractor's interests; position of engineer.

HYDRAULIC PRESSES

RAM SPEED. Ram Speed of Hydraulic Presses, H. S. Cattermole. Mech. Wld., vol. 76, no. 1959, July 18, 1924, p. 37. Discusses required ram speed for given operation, shows relation between press and pump and press and accumulator, and makes calculations.

HYDRAULIC TURBINES

ACCEPTANCE TEST. Proposal for Uniform Rules for Testing Water-Power Plants, G. Sundby. Engineering, vol. 118, no. 3056, July 25, 1924, pp. 145-147. Discusses diversity in specifications and guarantee tests, and various factors to be considered in formulation of standard tests. Abstract of paper read before World Power Conference.

PELTON WHEELS. Pelton Wheels Working at Variable Heads (Au sujet des turbines Pelton travaillant sous une hauteur de chute variable), M. deSparre. Académie des Sciences—Comptes rendus des Séances, vol. 178, no. 24, June 10, 1924, pp. 1942-1948. Mathematical determination of head H_0 serving as basis for calculation, so as to make variation of efficiency minimum when head varies between minimum H_1 and maximum H_2.

REACTION. The Hydraulic Reaction Turbine, H. B. Taylor. Engineering, vol. 118, no. 3054, July 11, 1924, pp. 71-73. Discusses recent improvements including, (1) incorporation of turbine as integral part in power-house construction, (2) division of casing into number of radial sections separated by planes containing turbine axis, (3) adoption of propeller-type turbine of extremely high specific speed, (4) transformation of draft tube, etc. Abstract of paper read before World Power Conference.

HYDRO-ELECTRIC DEVELOPMENTS

FRANCE. Putting Through a Great Hydro-Electric Project in France. Compressed Air Mag., vol. 29, no. 7, July 1924, pp. 919-922, 13 figs. Details of work in Ossau Valley, Pyrenees, for supplying power for electrification of Midi Ry., including reservoir and tunnel work, power-house construction, and equipment.

NEWFOUNDLAND. Hydro-Electric Power Development in Newfoundland. Engineering, vol. 118, no. 3056, July 25, 1924, pp. 125-127, 15 figs. partly on supp. plates. Particulars of hydro-electric scheme being carried out in Humber River district of Newfoundland, where continuous output of 100,000 h.hp. will be utilized in paper mills of Newfoundland Power & Paper Co., Ltd., and for lighting and heating new township of Corner Brook. Work is being carried out by W. G. Armstrong, Whitworth & Co., Ltd., Lond., who are also manufacturing turbines which will be installed at the site.

HYDRO-ELECTRIC PLANTS

ALABAMA. Hydroelectric Practises and Equipment of the South, O. G. Thurlow and J. A. Sirnit. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 8, Aug. 1924, pp. 719-723, 8 figs. Discusses hydraulic power resources of South, design of Alabama Power Co.'s plants, Southern superpower system and advantages of linking up systems.

CANADA. Building Canada's Hydro-Electric Power Units, H. P. Armson. Can. Machy., vol. 32, no. 31, July 31, 1924, pp. 19-22, 5 figs. Outline of water-power development in Dominion, with details of construction features of plant on Isle Maligne and shop methods used in building some units at Canadian Allis-Chalmers Co.'s, Davenport plant in Toronto.

ICE TROUBLES. Ice Troubles in Norwegian Water-Power Plants, A. Ruths. Engineering, vol. 118, no. 3054, July 11, 1924, pp. 73-74. Details of power-house troubles due to frazil ice and drift ice and their elimination. Abstract of paper read before World Power Conference.

I

ICE PLANTS

FREEZING TANKS. Ice Freezing Tank Design, C. Wilkie. Ice & Refrigeration, vol. 67, no. 1, July 1924, pp. 50-55, 13 figs. Points out ways whereby installation of freezing tanks can be safeguarded against errors; influence of harvesting equipment. Paper read before meeting of Chicago subordinate N. A. P. R. E. and Chicago Sec. A. S. R. E.

OIL-ENGINE-DRIVEN. Economy from Oil Engine Power at the Coal Pit's Mouth. Oil Engine Power, vol. 2, no. 7, July 1924, pp. 363-365, 5 figs. Operating at mouth of coal mine and driving Marion County Coal Co.'s, Centralia, Ill., own machinery, three oil engines have been able to produce substantial savings over and above cost of coal-generated power in production of ice and refrigeration

IMPACT TESTING

ROUNDED BARS. Experiments on the Duration of Impacts, Mainly of Bars with Rounded Ends, in Elucidation of the Elastic Theory, J. E. P. Wagstaff. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci., vol. 48, no. 283, July 1924, pp. 147-158, 2 figs. Discusses duration of collision of two perfectly elastic bars and its form of mathematical relation.

INDUSTRIAL MANAGEMENT

BONUS SYSTEMS. *See Bonus Systems.*

BUDGETING. Elements of Budget Control, D. J. Hutchinson. Pit & Quarry, vol. 8, no. 10, July 1924, pp. 75-78. Procedure in establishing budget system.

RATE SETTING. Rate Fixing in Engineering Works. Machy. (Lond.), vol. 24, no. 617, July 24, 1924, pp. 516-518, 2 figs. Payment by results and rate-fixing methods; share of production responsibilities by management and labor.

INDUSTRIAL RELATIONS

LABOUR MANAGEMENT. What We Think of Industrial Democracy After 7 Years, W. P. Hapgood. Factory, vol. 33, no. 2, Aug. 1924, pp. 187-189 and 286-290, 2 figs. Experiences of factory council in working its way up through usual worries about wages and hours of work into constructive effort toward bringing business to higher level of efficiency.

INLAND WATERWAYS

RAILWAYS. Waterway and Railway Equivalents, W. M. Black. Am. Soc. Civil Engrs.—Proc., vol. 50, no. 6, Aug. 1924, pp. 837-851. Discusses considerations that should guide establishment of new waterway lines of transportation, replacing destructive competition by co-operation.

INSULATORS, ELECTRIC

SUSPENSION. The Development of a Suspension-Type Insulator, H. B. Smith. Am. Inst. Elec. Engrs.—Jl., vol. 43, no. 8, Aug. 1924, pp. 689-696, 27 figs. Outlines conditions under which suspension-type insulator has been developed experimentally for long distance transmission conditions of 110,000- and 220,000-volt power lines.

INTERNAL-COMBUSTION ENGINES

AIR SUPPLY. A Note on the Air Supply for Large Motor Ships, P. T. Brown. Inst. Mar. Engrs.—Trans., vol. 36, July 1924, pp. 101-140, 11 figs. Discusses air requirements of Diesel machinery for injecting and pulverizing fuel, and for maneuvring engines and other purposes; Lloyd's rules; air compressors and their size.

IRON ALLOYS

CHROMIUM-IRON. Some Engineering Applications of High-Chromium-Iron Alloys, C. E. MacQuigg. Am. Soc. for Testing Matls., Preprint of paper presented at meeting June 24-27, 1924, No. 19j, 10 pp., 6 figs. Uses and limitations of an alloy with about 25 to 30 per cent of chromium and fractions of one per cent of silicon and manganese, remainder largely iron; carbon varies from about 0.1 to 3 per cent, depending on properties desired.

IRON-CARBON. A Laboratory Method for the Preparation of Small Steel Bars Differing Only in Carbon Content and the Effect of Changes in Carbide Concentration on the Specific Resistance, E. D. Campbell and G. W. Whitney. Am. Soc. for Steel Treating—Trans., vol. 6, no. 1, July 1924, pp. 33-50. Results of laboratory tests by means of which small steel bars varying only in carbon content may be prepared; also specific resistance measurements on these bars when annealed and when hardened by quenching in oil or in water.

IRON CASTINGS

CLEANING. Cleaning Iron Castings Hydraulically. Mech. Wld., vol. 75, no. 1955, June 20, 1924, pp. 389-390. Describes new method of cleaning castings, successfully experimented with at Erie, Pa., foundry of Gen. Elec. Co.; results in considerable saving of labor and time and eliminates dust. Abstract of paper read by C. B. Lockhart before Pittsburgh Foundrymen's Assn.

IRON AND STEEL

CORROSION. The Submerged Corrosion of Iron, W. G. Whitman and R. P. Russell. Chem. & Industry, vol. 43, nos. 26 and 27, June 27, July 4, 1924, pp. 193T-196T and 197T-199T, 4 figs. Discusses corrosion under natural water and solutions of alkali and non-oxidizing acids and its explanation along electro-chemical lines.

EFFECT OF TEMPERATURE ON. Effect of Temperature on Metals. Power Plant Eng., vol. 28, no. 15, Aug. 1, 1924, pp. 801-803, 3 figs. Review of data on irons and steels. Presented before joint meeting of A.S.M.E. end A.S.T.M.

IRRIGATION

U.S.A. The Movement of Water in Irrigated Soils, C. S. Schofield. Agricultural Research—Jl., vol. 27, no. 9, Mar. 1, 1924, pp. 617-696, 16 figs. Discusses certain aspects of alkali problem in relation to irrigation farming which as a whole relates to soluble salts in soil solution.

L

LABOUR

HOURS OF WORK. Effect of Changes in Hours of Work on Output. Monthly Labour Rev., vol. 19, no. 1, July 1924, pp. 120-124. Discusses 8-hr. day entirely from economic standpoint and analyzes existing data on relation between hours of work and production, showing complexity of problem.

LABORATORIES

NATIONAL PHYSICAL LABORATORY, ENGLAND. The National Physical Laboratory. Engineering, vol. 117, no. 3052, and vol. 118, nos. 3053 and 3055, June 27, July 4 and 18, 1924, pp. 823-824, 5-6 and 100-101, 1 fig. Review of work done by the Laboratory during 1923, including work of engineering and aerodynamics departments, work on metallurgy, physics, electrical standards and measurements, wireless, electrotechnics, cables, and photometry.

LATHES

INSPECTION OF PARTS. The Inspection System in a Lathe Building Plant, H. S. Riggs. Machy. (Lond.), vol. 24, no. 616, July 17, 1924, pp. 481-486, 12 figs. Checking accuracy of lathe parts, assembled units and completed machines of Lodge & Shipley Machine Tool Co.

LIGHTING

STREET. Recent Advance in Street Lighting Methods, S. B. Hood. Elec. Light & Power, vol. 2, no. 8, Aug. 1924, pp. 13-15 and 58, 5 figs. Details of application at Minneapolis of low-voltage multiple supply in preference to more commonly used high-voltage series systems.

LIME

HYDRATED. Hydrated Lime in Concrete. Contract Rec. & Eng. Rev., vol. 38, no. 30, July 23, 1924, pp. 743-745, 1 fig. Experimental investigations confirm practical experience that lime in mix facilitates handling and placing of concrete.

LIMESTONE

BUILDING REQUIREMENTS. Building Stone Requirements. Stone, vol. 45, no. 6, June 1924, pp. 349-351, 2 figs. Report of Committee on Building Requirements for Indiana Limestone includes code sections covering all classes of building stone customarily used, thus constituting recommended code of practical value.

LIQUIDS

EVAPORATION. The Rate of Evaporation of Liquids in a Current of Air, T. B. Hine. Physical Rev., vol. 24, no. 1, July 1924, pp. 79-91, 1 fig. Results of experiments show that rate of evaporation is linear function of wind velocity.

HEAT OF EVAPORATION. Apparatus for the Determination of the Heat of Evaporation of Liquids of High Boiling Points, J. H. Awbery and E. Griffiths. Physical Soc. of Lond.—Proc., vol. 36, part 4, June 15, 1924, pp. 303-312, 2 figs. Discusses two new forms of apparatus and their relative merits; tested by determining with them heats of evaporation of alcohol, water, and aniline.

LOCOMOTIVE BOILERS

FIREBOXES. Four-Sheet Fireboxes for Mallet Locomotives. Ry. Rev., vol. 75, no. 5, Aug. 2, 1924, pp. 161-165, 9 figs. Describes firebox construction on Norfolk & Western Ry.; Seven-sheet firebox construction reduced to four by use of unusually large boiler plates.

REPAIRING. Side Lights on Boiler Work at Glenwood Shops. Boiler Maker, vol. 24, no. 7, July 1924, pp. 191-194, 10 figs. Special shop made equipment aids in repairing many different classes of locomotives coming to Glenwood shops, Baltimore & Ohio Ry.

LOCOMOTIVES

DEVELOPMENT. The Steam Locomotive; Engineering and Business Considerations, W. H. Winterrowd. Can. Ry. & Mar. Wld., no. 317, July 1924, pp. 322-325, 3 figs. Discusses development steam locomotive has undergone during past 20 years and lines along which future development may be expected.

ELECTRIC. *See Electric Locomotives.*

LONG RUNS. Extension of Locomotive Runs, F. E. Russel. Ry. Mech. Engr., vol. 98, no. 8, Aug. 1924, pp. 464-467. Discusses advantages of long runs and mechanical difficulties encountered. Abstract of paper read before Pac. Ry. Club.

OIL-ELECTRIC. Oil-Electric Locomotive Comes to New York. Compressed Air Mag., vol. 29, no. 7, July 1924, pp. 923-925, 6 figs. Details of new locomotive with 200-kw. generator directly connected to 300-hp. oil engine for switching service of N. Y. Central; uses low-cost fuel oil.

POWER AND EFFICIENCY IMPROVEMENTS. Power and Efficiency Improvements in Steam Locomotives, G. M. Basford. Engrs. & Eng., vol. 41, nos. 3 and 6, Mar. and June 1924, pp. 61-64 and (discussion) 64-69 and 159-162, 4 figs. Paper read at Conference on Economy in the Use of Fuel, held at Engrs. Club of Phila., Jan. 15, 1924.

STEAM AND ELECTRIC, COMPARISON OF. Steam and Electric Locomotives Compared. Ry. Gaz., vol. 41, no. 3, July 18, 1924, p. 90. Electric-locomotive traction enables large horsepower to be obtained from locomotives of reasonable length and with low axle loads.

TANK Four-Cylinder "Baltic" Tank Engine—London Midland & Scottish Railway. Ry. Gaz., vol. 41, no. 3, July 18, 1924, pp. 82-83, 3 figs. 4-6-4 type four-cylinder tank engine built at Horwich works of London Midland & Scottish Ry. for use in dealing with heavy suburban traffic over severely graded lines, also for hauling express residential trains within radius of about 50 miles.

VALVE GEARS. Development of the Lentz Poppet Valve Gear, A. Niklitchek. Ry. Mech. Engr., vol. 98, no. 7, July 1924, pp. 407-409, 4 figs. Discusses reduction of valve-gear maintenance costs and lubricant and water consumption on Austrian locomotives.

LUBRICATING OILS

CYLINDER. Oils for Valve and Cylinder Lubrication, A. J. Dixon. So. Engr., vol. 41, no. 5, July 1924, pp. 60-61. Why some cylinders take polish and others do not. Selection of cylinder oils.

PURIFICATION. Purification of Marine Turbine and Diesel Engine Lubricating Oils. Am. Mar. Engr., vol. 19, no. 7, July 1924, pp. 11-13, 4 figs. In marine turbines and Diesel engines it is almost universal practice to reuse lubricating oil by means of circulation system; discusses batch and continuous system of purification.

STORAGE AND HANDLING. Oil Storage and Handling Practice. Elec. Ry. Jl., vol. 64, no. 3, July 19, 1924, pp. 77-79, 6 figs. Information obtained from 57 electric railways shows that careful storage of lubricants eliminates waste, prevents contamination, minimizes fire hazard, and facilitates keeping of records; increased use of buses by railways makes necessary storage of gasoline in quantity.

TURBINES. Characteristics of Efficient Turbine Oil, A. F. Brewer. Elec. Light & Power, vol. 2, no. 8, Aug. 1924, pp. 16-18 and 38, 2 figs. Discusses properties of oil, including viscosity, cooling, ability, tendency to evaporate, fluid friction developed, demulsibility, water content, tendency to decompose, foaming and content, carbon content, sulphur and acids.

LUBRICATION

THEORY OF. Some Notes on the Theory of Lubrication with Particular Application to the Michell Thrust and Journal Bearings, J. Ward. Inst. Mar. Engrs.—Trans., vol. 36, July 1924, pp. 141-185, 24 figs. Discusses dry, rolling, greasy and viscous friction; perfect lubrication; Michell viscometer; lubrication of parallel surfaces, inclined surfaces; flow of oil; pressure distribution; bearings, etc.

M

MACHINE SHOPS

FIRE-DEPARTMENT. Efficiency in the Fire Department Machine Shop, J. C. Moran. Fire & Water Eng., vol. 76, no. 3, July 16, 1924, pp. 107-108, 112, 135-136, 7 figs. Methods which make Hartford shop model; personnel and equipment; importance of good location for building. Abstract of paper read before New England Assn. Fire Chiefs.

REPAIRS HANDLING. A Simple and Economical Method of Handling Repairs, F. H. Colvin. Am. Mach., vol. 61, no. 5, July 31, 1924, pp. 189-190, 3 figs. Plan, worked out by Gould & Eberhardt, Newark, N.J., which cuts out much of the paper work and overhead expense in repair work.

MACHINE TOOLS

UNIVERSAL METAL-CUTTING MACHINE. A Combination Type of Metal-Cutting Machine. Machy. (Lond.), vol. 24, no. 617, July 24, 1924, pp. 513-515, 7 figs. Universal machine especially adapted for reproducing various designs from enlarged patterns or drawings, either by punching, profiling, routing, milling or engraving.

MACHINERY

ALTITUDE, INFLUENCE OF. Influence Exerted by Altitude on Apparatus, K. Lubowsky. Elec. Wld., vol. 84, no. 3, July 19, 1924, pp. 109-110. Influence of altitude on calculations connected with all apparatus which generates, distributes or consumes energy. Correction factors for various types of apparatus; influence on heating; outputs and ratings; table for any height.

MACHINING METHODS

ECCENTRICS, TURNING OF. Tools and Fixtures for Turning Eccentrics, F. H. Mayoh. Machy. (N. Y.), vol. 30, no. 12, Aug. 1924, pp. 976-979, 11 figs. Points out methods to be used in machining eccentric parts under different conditions.

MAGNETISM

ANALYSIS. The Elements of Magnetic Analysis, E. H. Crapper. Engineering, vol. 117, nos. 3041, 3045, 3047, 3051 and 3052, Apr. 11, May 9, 23, June 20 27, 1924, pp. 452-454, 601-602, 660-662, 786-788 and 816-817, 21 figs. Points out that no complete system of magnetic analysis has yet been evolved and put into practice; magnetic constants of magnet which require consideration are divided into two groups, according as they refer (1) to nature of material used, and (2) to working qualities or properties of magneto-magents, these constants are obtained directly by experiment, or derived from experimental results obtained.

MATERIALS HANDLING

CONCRETE BUILDING UNITS, MANUFACTURE. Economical Handling of Raw Materials in Building Unit Manufacture. Concrete, vol. 25, no. 1, July 1924, pp. 13-18, 6 figs. Summary of methods in common use in excavating and handling sand and gravel, according to conditions to be met.

MEASUREMENTS

LENGTH. Industrial Length Measurement, Standards of Measurement and Systems of Tolerances (La mesure industrielle des longueurs, Etalons de mesures et systèmes à tolérances), H. Stroh. Génie Civil, vol. 84, nos. 25 and 26, June 21 and 28, 1924, pp. 594-597, 615-617, 12 figs. Discusses length measurement in connection with production of good quantities and of interchangeable parts, establishing standards; mechanical precision and systems of tolerances; discusses symmetrical and asymmetrical tolerances, admissible wear of tolerances; standards for length measurement.

METALLOGRAPHY

LEHIGH UNIVERSITY. Metallography at Lehigh University, H. B. Pulsifer. Forging—Stamping—Heat Treating, vol. 10, no. 7, July 1924, pp. 276-278, 7 figs. Leading engineering colleges are coming to recognize metallography as most important of the aspects commonly assembled under metallurgy.

METALS

DEFORMATION. Torsional Tests of Metals, Elastic and Permanent Deformation (Les essais de torsion des métaux,déformations élastiques et déformations permanentes), J. Seigle and F. Cretin. Génie Civil, vol. 84, nos. 23 and 24, June 7 and 14, 1924, pp. 545-549 and 565-568, 19 figs. Describes apparatus used; studies angles of torsion, torsion curves for elastic and permanent deformation, elastic limit of torsion, etc.

DIFFUSION IN SOLID STATE AND PLASTICITY. The Trend in the Science of Metals, Z. Jeffries. Am. Inst. Min. & Met. Engrs.—Trans., Advance paper No. 1337-N, May 1924, 23 pp., 23 figs. Discusses diffusion in solid state and plasticity of metals.

MACHINING QUALITIES. A Method for Determining the Resistance of Metals to Drilling and Its Application to the Investigation of the Machineability of Metals, A. Kessner. Testing, vol. 1, no. 4, Apr. 1924, pp. 270-285, 11 figs. Describes drilling testing machine; some investigations carried out by means of Kessner machinability testing machine; standard comparison metals for drilling tests.

MELTING. Fluxes and Slags in Metal Melting, Metal Industry (Lond.), vol. 25, no. 5, Aug. 1, 1924, pp. 101-102. Report of chief points in joint discussion of following contributions to recent symposium on slags and fluxes held by Faraday Soc. and Inst. Metals; General Introduction, Oxidizing Fluxes in Milling Non-Ferrous Metals; Slags from Lead, Copper and other Blast Furnaces, Use of Slags in Brass Melting; Slags in Melting Silver Alloys; and Sulphurizing and Desulphurizing by Basic Slags and Fluzes.

NON-METALLIC INCLUSIONS IN. A Note on Non-Metallic Inclusions in Metals, with Special Reference to Aluminium, A. G. Lobley. Foundry Trade Jl., vol. 30, no. 412, July 10, 1924, p. 34. Discusses cryolite present in aluminum, nitrogen, carbon and aluminum; states that electric remelting is not harmful. Abstract of paper read at symposium on Slags and Fluxes, arranged by Faraday Soc., Inst. of Metals, Inst. of British Foundrymen and Non-Ferrous Research Assn.

TESTING. Bending Tests with Rotating Bars (Essais de flexion avec rotation du barreau pour de fortes valeurs de la flèche de flexion), M. Cretin and M. Siegle. Revue de Métallurgie, vol. 21, no. 6, June 1924, pp. 358-367, 24 figs. Discusses principle of fatigue test by rotary bending; bending tests beyond elastic deformation.

The Jannin Method for Testing Metals as to Wear, and Its Application to Testing Antrifriction Metals (Étude de la méthode de M. L. Jannin pour l'essai des métaux à l'usure et de son application à l'essai des métaux antifriction), M. P. Nicolau. Revue de Métallurgie, vol. 21, no. 6, June 1924, pp. 347-355, 1 fig. Shows that by this method resistance to wear of antifriction metals cannot be determined, and that application of this method is limited to rapid determination of friction conditions.

MICROMETERS

CARE OF. Proper Care Essential to Micrometer Accuracy. Can. Machy., vol. 32, no. 4, July 24, 1924, pp. 25-26, 6 figs. Hints on use and care of measuring instruments.

MICROSCOPES

ILLUMINATORS FOR. Vertical Illuminator for Microscopes. Engineering, vol. 118, no. 3053, July 4, 1924, p. 30, 3 figs. Describes vertical illuminator recently introduced by R. & J. Beck, Ltd., London, in which reflector can be moved along two lines at right angles and can also be tilted about both these axes. It is thus possible to adjust position and angle of reflector as required.

METALLURGICAL. The Microscope as an Aid in Metallurgy, F. E. Lee. Can. Inst. Min. & Metallurgy, Bul., no. 147, July 1924, pp. 505-510, 8 figs. Application of microscope in problems arising from various operations of Tadanac Reduction Works.

Ore Problems and the Microscope, W. L. Uglow. Can. Inst. Min. & Metallurgy-Bul., no. 147, July 1924, pp. 495-504. Application of microscope in discovery, development, concentration and reduction of metallic ores; types of microscopes.

MOTOR BUSES

GREAT BRITAIN. Municipal Bus Working in Detail. Motor Transport (Lond.), vol. 39, no. 1012, July 21, 1924, pp. 73-77, 3 figs. How organization and record keeping of Reading omnibuses insure efficiency.

Six-Wheel. Unit Accessibility Features Six-Wheel Bus. Motor Transport (Phila.), vol. 30, no. 8, July 10, 1924, pp. 298-300, 4 figs. Particulars of first motor-bus model of Six-Wheel Co., Phila.; easy riding qualities, durability and easy servicing outstanding features in design; units quickly detached; steel body construction simplifies repair work.

MINES

Development. Reducing the Cost of Prospecting Isolated Mining Properties, F. A. McLean. Can. Inst. Min. & Metallurgy, no. 148, Aug. 1924, pp. 531-538, 2 figs. Discusses development of promising claims, selection of compressed air plant, type of drive, tunneling, drifting, etc.

MOTORS, A.C.

Induction. Winding and Connecting Small Single-Phase Motors, C. A. M. Weber. Elec. Jl., vol. 21, no. 8, Aug. 1924, pp. 377-382, 29 figs. Discusses single-phase a.c. with split phase primaries and squirrel-cage rotors, and with single-phase primaries and wound rotors; methods of winding primaries, slot insulation, etc.

MOTOR-TRUCK TRANSPORTATION

Development. The Position of the Motor Truck in Transportation, T. R. Dahl. Power Wagon, vol. 33, no. 236, July 1924, pp. 15-19, 2 figs. Discusses economics of trucking, savings in marketing, handling local freight, etc. Abstract of paper read before World Motor Transport Congress.

MOTOR TRUCKS

Gas Producers for. Most Recent Application of Transportable Gas Producers (Les dernières applications des gazogènes transportables), C. Mathieu. Industrie des Tramways, Chemins de Fer et Transports Publics Automobiles, vol. 18, no. 210, June 1924, pp. 197-209, 18 figs. Review of latest types of gas producers for traction by road or rail.

Steam. Another Shaft-Driven Steam Waggon. Motor Transport (Lond.), vol. 39, no. 1010, July 7, 1924, pp. 47-49, 6 figs. Details of 6-ton truck combining best features of steam and gasoline practice, made by Mann's Patent Steam Cart and Waggon Co., Ltd.

N

NITROGEN

Fixation. Nitrogen Fixation Processes, L. F. Goodwin. Can. Chem. & Metallurgy, vol. 8, no. 7, July 1924, pp. 158-161. Gives resume of recent progress; discusses synthetic ammonia, Casale and Fauser processes.

O

OIL

Cracking. The Dubbs Process for Cracking Oil. Petroleum Times, vol. 12, no. 287, July 5, 1924, pp. 5-8, 2 figs. Principles of Dubbs process, equipment and operation, commercial results, results with heavy oils and cracking products.

Cut Oil, Electrical Dehydration of. The Electrical Dehydration of Cut Oil, F. D. Mahone. Am. Inst. Min. & Met. Engrs.—Trans., Advance paper No. 1354-P, July 1924, 5 pp. Much crude oil, as produced from well, carried varying amounts of water, which may be present as free water in globules sufficiently large to settle out, in time, if fluid is allowed to stand, or as an emulsion formed by myriads of minute water particles each surrounded and entrapped by a film of oil through which it cannot break under action of gravity alone. Such an emulsified mixture of oil and water is termed "cut oil". Describes apparatus for breaking up emulsion.

Production from Coal. The Director of Fuel Researchon Oil and Coke Production from Coal, C. H. Lander. Gas Wld., vol. 81, no. 2086, July 12, 1924, pp. 8-10 (annual coal supp.). Discusses yield and quality of oil, market for coke, and ammonia yield. Extract of paper read before World Power Conference.

See also Petroleum.

OIL ENGINES

Solid-Injection. Types of Modern Power-Plant Oil Engines. Oil Engine Power, vol. 2, no. 7, July 1924, pp. 386-388, 2 figs. Bessemer Gas Engine Co., Grove City, have joined with Atlas-Imperial Engine Co., Oakland, Cal., in manufacture of airless-injection oil engines by acquiring Eastern manufacturing rights. Gives table showing how oil engine effects savings in comparison with every other type of heat prime mover.

Fuels, Specifications for. Standard Specifications for Oil Engine Fuels. Motorship, vol. 9, no. 7, July 1924, pp. 506-508, 3 figs. Compilation of replies to communication addressed by "Motorship" to representatives of marine and stationary oil-engine industry to users of engines and oil companies on possibility of recommending uniform specifications for oil-engine fuels.

OIL FUEL

Burners. The Fuel Oil Burner from Fire Chief's Standpoint, A. J. Caulfield. Fire & Water Eng., vol. 76, no. 4, July 23, 1924, pp. 157-158 and 180. Discusses hazards of chimney defects; accepted and unaccepted types of burners; some suggestions for better maintenance of burners. Abstract of paper read before New England Assn. Fire Chiefs.

OSCILLOGRAPHS

Cathode-Ray. Wave Form Examination with the Cathode Ray Oscillograph, N. V Kipping. Elec. Communication, vol. 3 no. 1 July 1924, pp. 69-75, 7 figs. Discusses development of Cathode Ray Oscillograph from older vibrating types; production of satisfactory time scale; methods of frequency comparison, etc.

OXY-ACETYLENE WELDING

Manganese Steel. Welding of Manganese Steel, S. W. Miller. Acetylene Jl., vol. 26, no. 2, Aug. 1924, pp. 65-71, 14 figs. Preliminary report of Gas Welding Committee of Am. Bur. Welding. Discusses what happens during welding of manganese steel, how actual operation may be best conducted and what structural results of welding are in both base metal and weld.

Medium High-Carbon Steel. Autogenous Welding. Ry. & Locomotive Eng., vol. 37, no. 7, July 1924, pp. 202-204, 4 figs. Investigation on steel of axles and wheels that fall under classification of medium high-carbon steel; rolled-steel wheels, couplers, low-carbon steel, wrought iron, cast iron, cast-iron wheels non-ferrous metal and torch cutting.

Monel Metal. The Autogenous Welding of Monel Metal by the Oxy-Acetylene Process. Machy. (Lond.), vol. 24, no. 617, July 24, 1924, pp. 528-530, 12 figs. Discusses properties of monel metal, pressure of blow-pipe, oxy-acetylene welding of rods, bars, sheets, plates and castings, and gives examples.

Non-Ferrous Metals. Oxy-acetylene Welding of Non-Ferrous Metals, A. S. Kinsey. Am. Welding Soc.-Jl., vol. 3, no. 6, June 1924, pp. 27-51, 8 figs. Describes oxy-acetylene welding of copper, brass, bronze, aluminum, monel metal, nickel and lead. Bibliography.

Pressure Vessels. An Investigation of Welded Pressure Vessels. Am. Welding Soc., bul. no. 5, June 1924, 152 pp. 120 figs. Report of Pressure Vessel Committee of Am. Bur. of Welding covering recommendations to A.S.M.E. Boiler Code Committee, comments on construction, design, hydrostatic hammer test, welding wire, tests of welded specimens, marking and stamping, etc.

Railway Shops. Report on Autogenous and Electric Welding. Ry. Rev., vol. 75, no. 4, July 26, 1924, pp. 125-133, 23 figs. Gives results of investigations with reference to building up flat spots on steel and steel-tired wheels, building up of worn collars at journal ends of axles, and welding of fractures in couplers; recommendations affecting gas and electric welding limits and regulations of report for 1919. Paper presented before annual convention of Am. Ry. Assn., Div. V. Mechanical.

Torch Uses. Variety of Torch Uses, C. W. Geiger. Welding Engr., vol. 9, no. 7, July 1924, pp. 22-25, 11 figs. Largest industrial firms on Pacific Coast use torch in many different and profitable ways.

OXYGEN

Metallurgical Use. Some Applications of Oxygen to Ferrous Metallurgy, F. W. Davis. Iron & Steel Engr., vol. 1, no. 6, June 1924, pp. 339-346 and (discussion) 346-351, 2 figs. Discusses application of oxygenated air in metallurgic presses, especially iron blast furnaces and ferroalloys, and results to be expected from its use.

P

PAINTS

Red Lead. Some Observations on Red Lead as a Paint Pigment, E. F. Hickson and H. R. Snoke. Paint Manufacturers' Assn. of U. S., Sci. Sec., circular no. 207, July 1924, pp. 47-60, 6 figs. Discusses flow test used in conjunction with brush test for determining painting qualities of red lead. Paper read before Sec. of Paint & Varnish Chemistry at meeting of Am. Chem. Soc.

PAPER INDUSTRY

Water Power. Water Power in Pulp and Paper Industry in Canada. Eng. Wld., vol. 25, no. 2, Aug. 1924, pp. 69-72, 1 fig. Low cost power essential to industry; general conditions in each province; construction activities; future power requirements of industry.

PAPER MANUFACTURE

Liming of Blowpits. What Causes Liming of Blowpits? Paper, vol. 34, no. 14, July 24, 1924, pp. 605-610. Investigation of liming of blowpits in sulphite mills reveals various causes, but cold air is chief factor.

Rag-Cooking Methods. European Rag Cooking Methods, R. Sansone. Paper, vol. 34, no. 13, July 17, 1924, pp. 557-559, 2 figs. Account of various forms and types of boilers used in European paper mills where rags and reeds are cooked for pulp. Translated from Papeterie, pp. 246-253, 1924.

Sizing. Colloid Studies in Rosin, R. Lorenz, Paper Trade Jl., vol. 78, nos. 23, 24, 25 and 26, and vol. 79, no. 1, June 5, 12, 19, 26 and July 3, 1924, pp. 61-66. 47-52, 43-45, 52-54 and 51-55, 13 figs. Colophony and its use; preparation of pure raw material; dispersoid analysis: surface tension and internal friction; chemical equilibrium in sizing beater; flocculation phenomena of rosin sizing; action of aluminum hydrates in sizing and electrostatic sizing theory. Translated from Papier-Fabrikant, 1923.

Vacuum Drying. Drying Paper in a Vacuum, T. J. Keenan. Paper, vol. 34, no. 16, Aug. 7, 1924, pp. 699-701, 2 figs. Describes operation of Minton vacuum paper machine drier at So. Norwalk, Conn. (Norwalk Co.), paper being dried in 28 in. vacuum.

PAPER MILLS

Cutless Bearings for. Cutless Bearings for Paper Mills, C. F. Sherwood. Paper, vol. 34, no. 13, July 17, 1924, pp. 565-567. Application of rubber cutless bearings as substitute for ordinary bearings on wet end of Fourdrinier machine.

Electric Boilers and Digesters. Electric Boilers and Digesters, R. Sansone. Paper, vol. 34, no. 13, July 17, 1924, pp. 561-562, 2 figs. Electrically operated apparatus urged for use in pulp and paper mills for steam generation and direct heating of liquors.

Oil-Fuel Burning. Fuel Oil Burning at Paper Mill, A. Fette. So. Engr., vol. 41, no. 5, July 1924, pp. 35-41, 22 figs. Details of installation of plant of Charles Boldt Paper Mills Co., New Iberia, La., which was designed for burning coal or fuel oil.

PATENTS

Law. Inventors and Patentees, J. R. Langley. Elec. Jl., vol. 21, no. 7, July 1924, pp. 326-330. Discusses U. S. law and patent office practice, covering issue of patents, conception of inventions and reduction to practice, preservation of evidence, interferences, etc.

PATTERNS

Foundry. Rapping and Drawing Patterns, B. Shaw and J. Edgar. Mech. Wld., vol. 76, no. 1960, July 25, 1924, pp. 54-55, 5 figs. Discusses difference for repetition work and for jobbing work, lifting straps and how to fit them.

PAVEMENTS

"Black Base" Construction. "Black Base" Construction in Mercer County, N. J., H. F. Harris. Good Roads, vol. 67, no. 1, July 1924, pp. 12-14, 3 figs. Gives method followed in constructing foundation, and topping "black base" with regular standard sheet asphat pavement 1½ in. thick, Up to present time "black base" work has shown no cracks and is to all intents and purposes in every respect equal to standard practice in constructing sheet asphalt with rigid base.

PAVEMENTS, CONCRETE

Impacts. Impact on Concrete Pavements. Pub. Works, vol. 55, no. 7, July 1924, pp. 221-223, 3 figs. Tests made by Bur. Pub. Roads using specially devised machine, and conclusions drawn from them.

Weighing Aggregates for. Weighing Concrete Aggregates for Highway Pavements, R. W. Crum. Eng. Wld., vol. 25, no. 2, Aug. 1924, pp. 89-91, 6 figs. Iowa Highway Commission has adopted actual weighing of aggregates on road pavement construction; quality in modern highway pavements in highly desirable and any economical method of attaining high degree of quality should be adopted; investment in hard surface pavements should be safeguarded by best methods of construction; materials used should not be abused by careless treatment.

PEAT

Production. The Utilization of Peat for Power Production, G. K. Fletcher. World Power, vol. 2, no. 7, July 1924, pp. 19-22. Discusses difficulties arising from moisture content, cost, and advantages of peat production.

PETROLEUM

Evaporation Loss. Evaporation Loss of Petroleum Theories and Their Application, J. H. Wiggins. Am. Inst. Min. & Met., Engrs.—Trans., Advance paper No. 1353-P. July 1924, 8 pp. Pictures economic phase of evaporation losses and actual evaporative conditions in handling and storing crude and gasoline in United States; discusses some of the theories of physics involved in evaporation loss; and describes application of these theories to handling oil and gas on producing properties.

PHOTOMETERS

MICRO. A Registering Micro-Photometer for Accurate Measurements, M. Siegbahn. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci., vol. 48, no. 283, July 1924, pp. 217-224, 5figs. Describes new registering microphotometer, very convenient in use, enabling measurements of line-distances with precision of 0.002 mm.

PIPE

CEMENT LINING. Prolonging the Life of Pipe by Cement Lining, R. J. Newsom. Fire & Water Eng., vol. 76, no. 6, Aug. 6, 1924, pp. 255-256 and 280-281. How this type of lining lengthens age of pipe and increases delivery of water; fallacy of oversizing; lining of large pipe. Abstract of paper read before Am. Water Works Assn.

CORROSION. Remedies for Subaqueous Corrosion of Pipe, C. W. Foulk. Fire & Water Eng., vol. 76, no. 6, Aug. 6, 1924, pp. 259-260 and 277. Discusses phenomena of corrosion; effect of dissolved oxygen on iron; protective coating deposited by water; formation of acid water. Abstract of paper read before Ohio conference on Water Purification at Columbus, O.

THREADING. Pipe Threading in Oil Field Service, F. D. Bostaph. Oil Trade Jl., vol. 15, no. 7, July 1924, pp. 40-44. Investigation shows that greater percentage of trouble develops when long threaded pieces and couplings are being screwed together in field than when shorter couplings and threads were used. Concludes that threading chasers as in use in all threading machines at present time do not reproduce pitch of their own threads on pipe in all cases.

PIPE, CAST IRON

BRONZE WELDING IN. Bronze Welding Cast Iron Pipe in Chicago. Acetylene Jl., vol. 26, no. 2, Aug. 1924, pp. 78-80, 9 figs. Peoples Gas Light & Coke Co. are laying 6-in cast-iron bronze-welded gas line in Nordica Ave.; welding is accomplished by fusing tobin bronze to cast-iron pipe in band completely around joint.

SPUN. "Spun" Iron Pipes. Roy. Engrs. Jl., vol. 38, no. 2, June 1924, pp. 249-251, 1 fig. Details of preparing chromium-steel mold revolvable at high speed pouring from sector-shape ladle containing exact quantity of metal for one pipe, etc.

PIPE LINES

FRICTION OF. Pipe Friction. Mech. Wld., vol. 76, no. 1958, July 11, 1924, pp. 21-22, 2 figs. Discusses available formulas for calculating frictional resistance in pipe lines for water, applicable mainly to power-plant work.

WELDING. Report on Welding of Pipe, G. O. Carter. Am. Welding Soc.—Jl., vol. 3, no. 7, July 1924, pp. 13-19. Discusses welding applied to very extensive pipe lines, large and small plants and installations, including long oil and gas pipe, etc., organization of welding crews, cost of welding, etc.

PIPE, WOOD-STAVE

CONSTRUCTION. Wood Stave Pipe Lines and Penstocks, J. B. Holdcroft. Can. Engr., vol. 47, no. 3, July 15, 1924, pp. 149-151, 5 figs. Consideration involved in design of wood stave pipe employed for hydraulic power installations; Douglas fir used in manufacture; settling dimensions of staves; design of tongues, bands and cradles.

POLES, CONCRETE

CAST. Making and Erecting Concrete Poles, L. R. Brown. Elec. Ry. Jl., vol. 64, no. 5, Aug. 2, 1924, pp. 159-161, 6 figs. Casting is done in horizontal steel forms with reinforcing rods wired to cast-iron rings and suspended in place; portable derrick is used for erection.

POWER

EARTH'S INTERNAL HEAT, UTILIZATION OF. Power from the Earth's Heat, T. T. Read. Mech. Eng., vol. 46, no. 8, Aug. 1924, pp. 446-449, 8 figs. Discusses increase of earth's temperature toward its center. Gives résumé of published material about actual installations at favorable places on earth's surface, and plans proposed by well-known engineers for further development.

NEW ENGLAND REQUIREMENTS. Power Requirements and Source of Supply of New England, C. T. Main, H. I. Harriman and D. C. Jackson. Boston Soc. Civil Engrs.—Jl., vol. 11, no. 5, May 1924, pp. 193-227. Report of Committee of Associated Industries of Mass., covering kinds and amount of present power, cost, available new sources, probable demand for power from new sources, probable cost of supplying it, coal prices, fuel oil for power, Diesel engine; with summary and general conclusions.

WORLD POWER CONFERENCE. The First World Power Conference. World Power, vol. 2, no. 7, July 1924, pp. 7-18. Detailed program and list of papers, June 30 to July 12, 1924.

The Significance of the First World Power Conference. World Power, vol. 2, no. 7, July 1924, pp. 1-6. Discusses object, focusing information on policy of main countries in development of power resources; evolution of international power policy; natural power resources.

POWER PLANTS

BRITISH EMPIRE EXHIBITION. The First World Power Conference at Wembley. Power House, vol. 17, no. 15, Aug. 5, 1924, pp. 21-33, 3 figs. Complete report of deliberations of engineers from every part of globe at British Empire Exhibition and description of power plant in operation at Wembley.

EQUIPMENT PURCHASING. Purchasing Power Plant Equipment. Power Plant Eng., vol. 28, no. 15, Aug. 1, 1924, pp. 795-796. Specifications must be complete and definite. Bids must be brought to a comparative basis analysis.

POWER TRANSMISSION

ELECTRIC, NORWAY-DENMARK. Transmission of Electric Power From Norway to Denmark, A. R. Angelo. Engineering, vol. 118, no. 3055, July 18, 1924, p. 114. In 1921 three commissions were appointed, one by Danish, one by Norwegian, and one by Swedish State, with object of investigating question of transmission of electric power from Norway to Denmark. Main points of report submitted in 1923 by a Joint Committee elected by these commissions for investigation of technical and financial aspects of the matter. Paper, abridged, contributed to World Power Conference.

WAVE. Wave-Power Transmission, E. A. Barclay-Smith. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci., vol. 48, no. 283, July 1924, pp. 97-109, 9 figs. Discusses phenomena occurring in wave-power transmission through liquids in Constantinesco system.

PROFIT SHARING

FRANCE. Profit-Sharing and Recent French Legislation, P. Pic. Int. Labour Rev., vol. 10, no. 1, July 1924; pp. 1-29. Discusses act passed by French Parliament in 1922 for joint stock companies with profit-sharing schemes, and reluctance in its application.

PUBLIC UTILITIES

CUSTOMERS' SERVICES, INSTALLATION OF. Installating Customers' Services. Elec. Wld., vol. 83, no. 3, July 19, 1924, pp. 1 6-118. Analysis, which refers to methods followed in different parts of United States, indicating tendencies which should be of interest to every electric light and power company throught country.

PULLEYS

CONE. The Calculation of Cone-Pulley Diameters, H. E. Merritt. Mech. Wld., vol. 76, no. 1961, Aug. 1, 1924, pp. 66-67. Details of calculation for crossed belts and its application to open belts by means of correction determined to high degree of accuracy by simple slide-rule calculation.

PULVERIZED COAL

FIRING. Experience with Coal Dust and Combustion of Pulverized Coal (Les expériences sur les poussières de houille et la combustion du charbon pulvérisé), J. A. deGrey. Revue Universelle des Mines, vol. 2 (series 7), no. 5, June 1, 1924, pp. 276-283, 2 figs. Discusses principles of burner construction, combustion chamber, use of low-grade fuels and mixtures.

Pulverized-Coal Firing in a Billet Reheating Furnace, (Le chauffage au charbon pulvérisé d'un four poussant à billettes). Génie Civil, vol. 84, no. 26, June 28, 1924, pp. 621-623, 3 figs. Details of reconstructing furnace for reheating billets before rolling which were formerly fired with half-gas, difficulties met with and advantages of new system.

PLANTS. Self Contained Pulverized Coal Unit, C. H. Tupholme. Power Plant Eng., vol. 28, no. 15, Aug. 1, 1924, pp. 800-801, 2 figs. Describes British development which crushes, separates, dries and delivers pulverized coal to furnace. Requires no auxiliary plant except means for rotating its spindle and provision of a supply of raw coal to hopper; low first cost and compactness; permits low-grade fuels to be burned economically.

PUMPING STATIONS

DIESEL-DRIVEN. Large Paris Pumping Plants are Diesel-Driven. Oil Engine Power, vol. 2, no. 7, July 1924, pp. 388-390, 3 figs. Gives illustrations and account of one of large oil-engined pumping plants of Paris, fitted with two 4-cylinder, 4-cycle engines belt-connected to Rateau double-suction centrifugal pumps.

PUMPS

AIR-LIFT. Experimental Study of Air Lift Pumps and Application of Results to Design, C. N. Ward and L. H. Kessler. Univ. of Wis.—Bul., vol. 9, no. 4, serial no. 1265, 1924, 166 pp. 60 figs. Results of experiments as to footpieces show that conditions of eduction pipe, where energy of air is expended in producing motion of water, are factors determining success or failure.

TESTING. The Comparison of Pump Tests with Special Reference to Low Head Pumps, E. F. Delery. Louisiana Eng. Soc.—Proc., vol. 10, no. 2, Apr. 1924, pp. 98-107. Lays stress on capacity and spouting velocity as related to lift in selecting or designing pumps; gives practical examples of determining efficiency.

VACUUM. Determining the Type of Vacuum Pump for Given Air Removal Conditions, C. M. Reed. Power, vol. 60, no. 2, July 8, 1924, pp. 52-54, 4 figs. Discusses rotative dry-vacuum pump and steam-jet pumps, and gives charts for simplified calculation of relative volumes and weights of dry air in air-steam mixtures.

PUMPS, CENTRIFUGAL

LUBRICATION. Oil System Specially Designed for Municipal Pumping Plant, H. R. Cady. Power, vol. 60, no. 6, Aug. 5, 1924, pp. 203-205, 3 figs. Tells why continuity of service is highly important and how low renewal cost is obtained. Gravity tank provides 15-min. supply without pump, and indicating devices check operation.

PUNCHES

DIES AND, STANDARD SETS. Standard Punch and Die Sets, S. Diamant. Am. Mach., vol. 61, no. 5, July 31, 1924, pp. 199-201, 3 figs. Various types and advantages. Time and original cost saved by standard equipment. Abstract of paper for Metropolitan Sec. A.S.M.E., Apr. 15, 1924.

PYROMETRY
