VOLUME XI | MONTREAL, JANUARY, 1928 | NUMBER 1

The Uniflow Steam Engine

General Notes Including an Historical Reference, Results of Tests, its Application and a Bibliography of the Subject

E. A. Allcut, M.E.I.C.

Associate Professor of Mechanical Engineering, University of Toronto.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 14th to 16th, 1928

In this paper the principal object is to discuss from the thermal standpoint the history and development of the uniflow principle as applied to steam engines. The mechanical details will only be described, therefore, insofar as they influence the heat consumption of the engine for a given amount of work done. It is true that such items as valve gear, governing and cylinder construction are essential to the consideration of the uniflow engine as a power-producing mechanism, but an adequate discussion of all these points would transform the paper into a volume. For this reason, one part of the problem only is covered.

History

The credit for the first application of the uniflow principle to steam engine work is due to Jacob Perkins of London, England, who patented the system in 1827 after two years of working tests.* He also made a compound uniflow engine which was tested in 1828, the next example of this application being the compound uniflow engine exhibited at the Wembley Exhibition in 1924. It is interesting to note that Perkins also anticipated the recent use of high steam pressures by generating his steam at 2,000 lbs. per square inch, and this at a time when the Boulton and Watt engines used steam at pressures of 5 to 10 lbs. per square inch. By these means, Perkins was able to work a pumping engine with a fuel consumption of 1.7 lb. per pump horse power hour. The fuel used was a mixture of coal and coke. These patents, however, were impounded by the creditors of Perkins' partner, and so could not be followed up.

Further experiments along these lines were made by Eaton, (U.S.A.), in 1857, and patent No. 7301 was taken out by Todd, (England), in 1885,* the gradation of temperature from hot inlets to cold outlet and the reduction of condensation being specifically noted.

* Power, March 10th, 1925, and The Power Engineer, August 1925.

In 1849 the South Eastern Railway, (England), had a locomotive running on the uniflow principle which continued in operation for three years, but this was taken off on account of mechanical trouble in 1852.**

A Belgian patent was also taken out by Prof. A. Rateau on May 29th, 1894.*** No great commercial development took place, however, until the matter was taken up by Prof. J. Stumpf of Charlottenburg in 1908, and to him the modern development of the uniflow engine is very largely due. Since that time the application of the uniflow engine has been extending rapidly, and it is now generally recognized as having a definite and important place in the field of power generation.

It seems probable that the revival of the idea in 1885 was partly due to the work done by Sir Dugald Clerk, (1881), and others, on the two-stroke cycle gas engine, and certainly the cylinder design of the two-stroke cycle double-acting Körting gas engine bears a striking similarity to that of the uniflow steam engine.

Cylinder Condensation

One of the principal defects in the ordinary or "counterflow" type of steam engine cylinder results from the interchange of heat between the working fluid and the metallic wall which surrounds it. The Carnot and Rankine

cycles are both based on the assumption that the cylinder walls are non-conducting, but this condition does not, and cannot, obtain in practice, with the result that some loss of heat must necessarily take place. With steam originally superheated, this loss results in lower superheat, or none at all, in the cylinder, and if the steam is initially saturated or wet, considerable condensation takes place during the admission period. The amount of this loss naturally depends upon, (*a*) the ratio of surface to volume in the cylinder during the admission period; (*b*) the facilities for the interchange of heat between the steam and the cylinder walls.

With early cut off, the conditions for heat loss are ideal, as the ratio of surface to volume is large, so that a large ratio of expansion, desirable as it is from a thermal standpoint, may actually be a source of loss.

Apart from this, two factors contribute to a high rate of heat exchange per unit of surface, namely, (1) a large temperature difference between the incoming and exhaust steam; (2) a large percentage of water in the steam itself.

The "counterflow" type of cylinder thus contributes to low thermal efficiency by allowing the cool exhaust steam to pass over the surface of the cylinder during approximately half the cycle. This results in the condensation of 40 to 50 per cent of the incoming steam before the point of cut off, (figure No. 1), and the very fact that this steam is wet causes the heat interchange between steam and cylinder walls to be more rapid by substituting a medium of comparatively high conductivity for the previously dry steam.

The steam turbine does not suffer from this defect, as the live steam enters at one end and the exhaust steam goes out at the other. The uniflow engine is an attempt to reproduce this condition in an engine cylinder, so that the hot steam enters at each end and the cool, wet exhaust steam leaves through ports in the middle of the cylinder. The flow in all cases, therefore, is from the ends to the centre, (figure No. 2), and in place of the temperature fluctuations characteristic of the counterflow type there is a steady fall of temperature from the admission to the exhaust end of the stroke.* The ports in the middle of the cylinder through which the steam is exhausted are 1/10 stroke long, and this means that the subsequent compression must occupy 90 per cent of the return stroke. This is advantageous in keeping the ends of the cylinder hot, but has the disadvantage of reducing the mean effective pressure and of producing a dangerously high compression pressure in non-condensing engines or in cases where the vacuum falls. The uniflow engine is thus essentially a high vacuum engine, but in small installations the attainment of this condition is not always feasible. There are two ways of avoiding the difficulty. One is to provide a large clearance volume, permanently or temporarily, but this is always uneconomical. The other is to delay the start of compression by the use of automatic or mechanically operated auxiliary exhaust valves. This is a departure from the uniflow principle and really makes the engine a counter-uniflow engine, with a consequent loss of economy. The position in which these auxiliary exhaust valves are placed determines the extent to which the hot surfaces are cooled by the passage over them of exhaust steam, and, other things being equal, the further these valves are placed from the end of the cylinder, the better.**

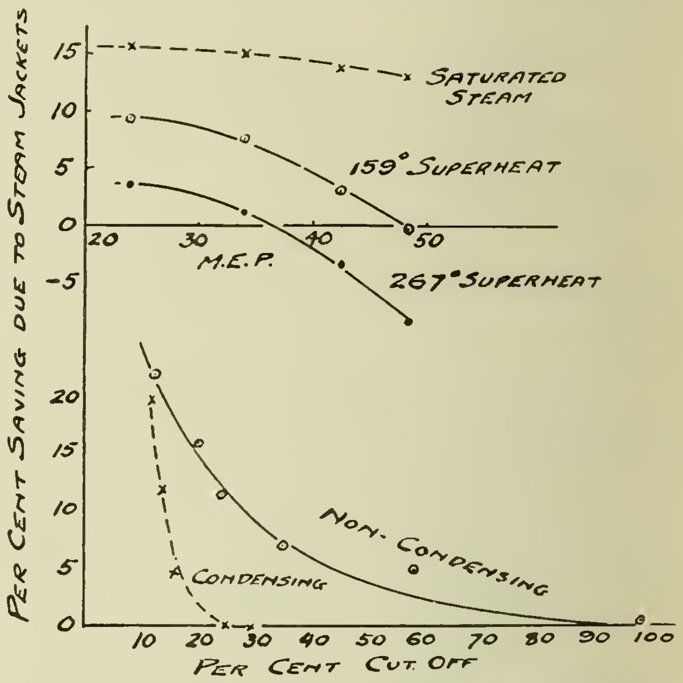

Figure No. 3.—Curves showing Gain Due to Steam Jacketing (Counterflow Engine).

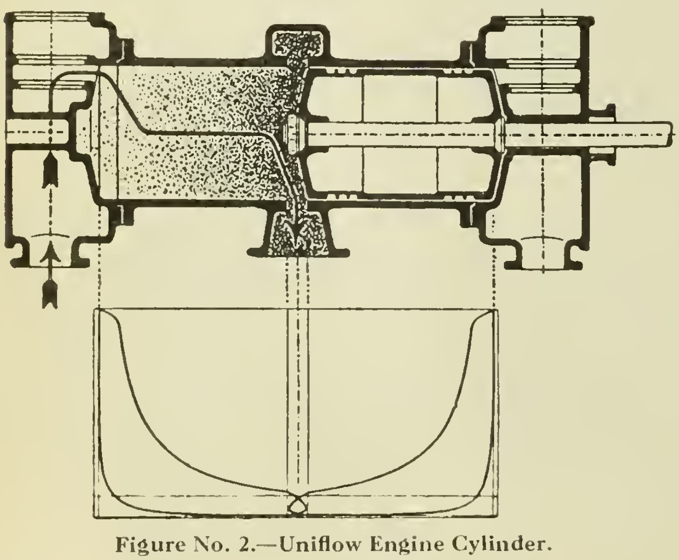

Figure No. 2.—Uniflow Engine Cylinder.

* This was investigated experimentally by Prof. Dr. Nägel, of Dresden, (Z.V.D.I., July 5th, 1913, and the "Una-flow Steam Engine," by J. Stumpf).

** For a full discussion of this factor, see Power, August 29th, 1922.

The influence of wet steam on heat transmission has already been referred to, but another means of reducing the amount of water in the cylinder is to heat it externally by means of a steam jacket. Uniflow engine cylinders are usually steam jacketed, so that in the following pages considerable attention will be given to the action of the jacket.

Factors Influencing Cycle Efficiency

In addition to cylinder condensation there are other factors which need to be balanced up so that losses may be reduced to a minimum. These are steam pressure, back pressure, clearance volume, compression ratio and mean effective pressure. An exhaustive analysis of the interaction of these was made by Professor Stumpf,* and among his conclusions may be noted the following:—

(1) With proper proportioning of the length of compression, the clearance volume must be kept as small as possible.

(2) For given steam pressure, back pressure, m.e.p. and length of compression, the clearance volume must be such that the change of pressure during expansion is equal to the change of pressure during compression.

(3) Change of compression in case of high vacuum has no material effect upon the steam consumption.

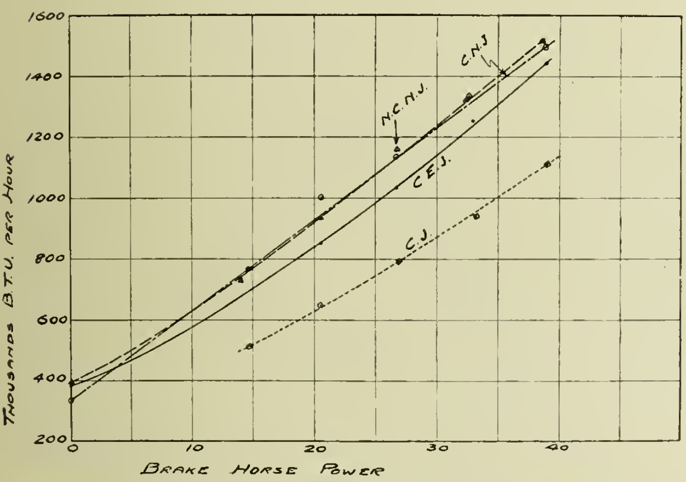

Figure No. 4.—Heat Consumptions of 40 h.p. Uniflow Engine.

It has already been stated, and the statement is susceptible to proof, that large clearance volumes are uneconomical, and the principles enumerated above show that different clearance volumes are required for best economy at different steam pressures, exhaust pressures and expansion ratios. It is evident, therefore, that a compromise must be made in practice whereby the minimum compression volume may be used and the compression ratio either adjusted to suit the conditions of working or chosen to give the best economy at the normal working load. Both systems are used in commercial engines, and both have disadvantages. A further method is that of compressing the steam to a pressure higher than that in the steam chest and delivering the excess through a spring loaded valve back to the steam pipe, but the desirability of generally applying this arrangement is doubtful.** Another engine uses a double compression curve. The compression volume is in two parts, both of which are used during the first part of the stroke. At a predetermined point communication between these is cut off by a valve and compression is completed in the small cylinder clearance. The "spill over" in the auxiliary clearance volume is then allowed to re-expand on the other side of the piston. A special design of uniflow engine has two sets of exhaust ports and a director valve, so that each set may be used alternately to delay the point of compression.* An analysis of twenty of the principal makes of American and European uniflow engines is given in table No. 1.

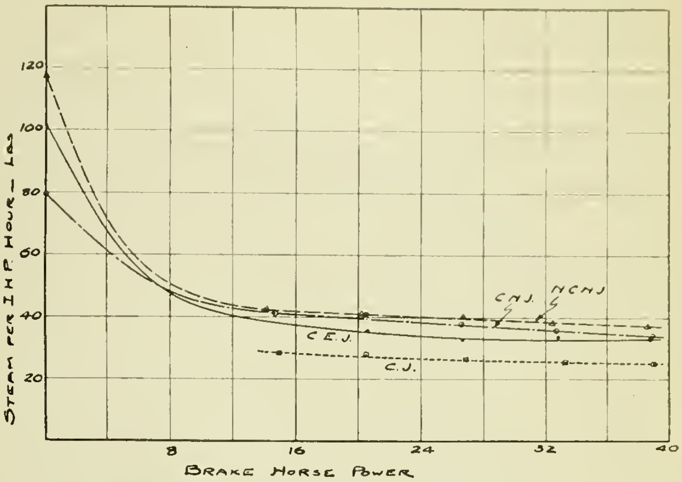

Figure No. 5.—Steam Consumption per I.H.P. Hour of 40-h.p. Uniflow Engine.

Table No. 1—Analysis of Twenty of the Principal Makes of American and European Uniflow Engines.

Steam admission valves	Drop	15
	Piston drop	3
	Piston	3
Jackets	End only	16
	End and body	4

Auxiliary clearance volume with automatic relief valves in most condensing engines. Mechanically operated exhaust valves with most non-condensing engines.

The question of valve leakage is important in all engines, but is particularly so in the uniflow engine, in view of the early cut off and large pressure differences employed.

* For description, see Power Plant Engineering, December 1st, 1922.

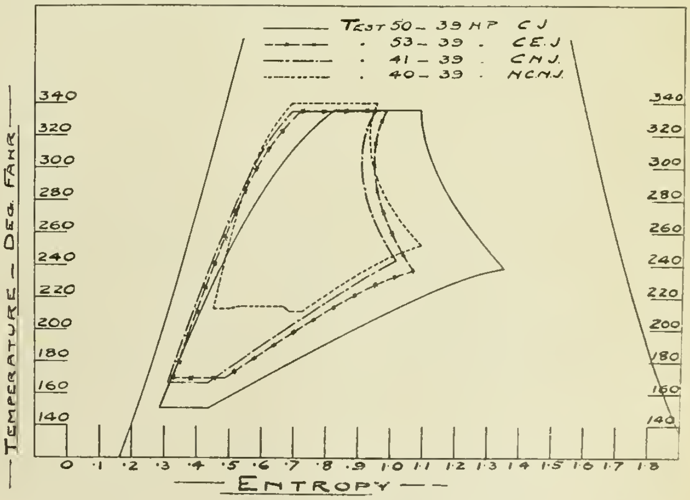

Figure No. 6.—Temperature Entropy Diagrams showing Influence of Steam Jackets.

* "The Una-flow Steam Engine," Second Edition, p. 13-43.

** It has been adopted, however, in a 30- x 60-inch four-cylinder mill engine, but in this case auxiliary exhaust valves are also provided as a safety device. Power, June 22nd, 1926.

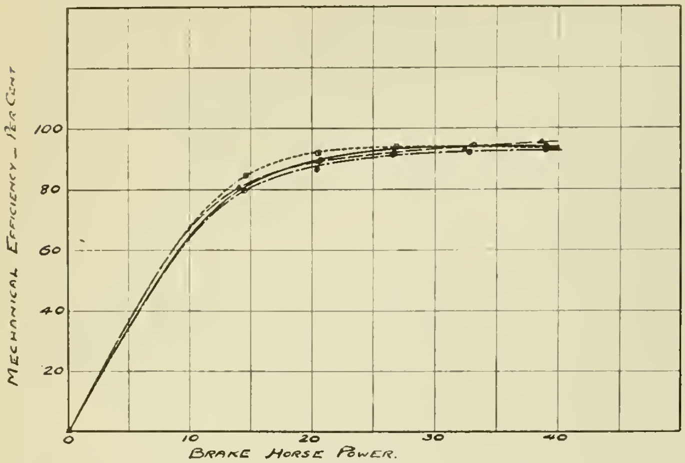

Figure No. 7.—Mechanical Efficiency Curves of 40-h.p. Engine.

This explains the almost universal use of the drop or poppet valve for large engines, the piston valve being only employed in small sizes. The double beat drop valve, however, can only be made tight for one set of pressure and temperature conditions, and therefore some form of automatic adjustment, usually of the spring type, must be provided in the valve or valve seat when high temperatures or pressures are used. Piston and Corliss valves are usually leaky, and their use results in lower thermal efficiencies.

Increased speeds of rotation tend to diminish the amount of surface condensation by reducing the time of the temperature cycle, and therefore the amount of heat passing through the surface. As the uniflow engine uses drop valves, heavy reciprocating parts and high ratios of expansion, it is usually a slow speed engine. Few uniflow engines of large size run at speeds exceeding 200 r.p.m., but some small engines are constructed for speeds up to 400 r.p.m.

Steam Jacketing

Perhaps the most important of James Watt's many contributions to steam engine theory and practice was his statement of the principle that the engine cylinder must at all times be kept as hot as possible, and that cold bodies must be kept away from it. The design of the uniflow cylinder itself may be considered as a natural application of this law, not only because it produces a minimum of temperature fluctuation at each point in the cylinder, but also because it conserves the driest steam for compression. The wettest steam is usually that near the piston, and therefore is the first to be exhausted. As a direct consequence, the heat loss during compression is reduced by the lower heat conductivity of the fluid, and the steam compressed is frequently in the superheated state when the admission point is reached.

Another method of keeping the cylinder hot is to surround it wholly or partly with a steam jacket. Table No. 1 shows that every uniflow engine is supplied with end jackets and that many of them, (chiefly the smaller engines), have also jackets surrounding some part of the cylinder body. The jackets do not usually extend beyond the point of cut off because cylinder condensation is practically complete at that point, and also because a long body jacket entails a constant and considerable heat leakage to the exhaust. The inefficiency of the theoretical steam jacketing cycle is indicated by figure No. 10, where the efficiency of the Rankine cycle is represented by $\frac{ABCD}{ABCEF}$. If it be assumed that the steam jacketing is such as to keep the steam dry during expansion, the extra work done is CDG, but the extra heat loss is $DGHE$, so that the resulting efficiency $\frac{ABCG}{ABCGHF}$ is lower. The work done per pound of steam is increased, but the heat loss is relatively much greater.

In practice, however, the steam jacket is frequently beneficial in transferring condensation from the inside to the outside of the cylinder. The influence of the steam jacket in reducing steam consumption naturally varies with the type of engine and condition of the steam. Tests made by Delafond, (1883),* indicate the saving in the case of low pressure steam in a slow speed horizontal Corliss engine at Creusot. Some of these results are plotted in the form of a curve in figure No. 3. Other tests made on an engine at the Massachusetts Institute of Technology indicate the saving in compound and triple expansion engines.** The experiments of Callendar and Nicolson*** at McGill University also indicate the importance of the piston face in promoting condensation. This is a factor which cannot be controlled by outside jacketing, but an attempt has recently been made in the "Prosser" engine to make the inside of the piston a steam pocket. This is not a uniflow engine, and so will not be described in detail, but is interesting as indicating what results can be obtained with complete steam

jacketing of all surfaces.* Rankine cycle efficiency ratios, (non-condensing), of 82 to 92 per cent are claimed for this engine, and it is stated that tests made in 1916 with and without jackets showed Rankine cycle ratios of 83.7 and 64.7 per cent, respectively, under the same test conditions.

An examination of the various test results obtained under different conditions, and of the opinions of various

designers and makers of uniflow engines, indicates that apart from the fact that all recommend the use of end jackets, (and produce test results to justify this), there are considerable divergencies of opinion on the subject of jacketing. Generally, it is agreed that the gain due to jacketing decreases as the cut off is made later, and that saturated steam shows more gain than superheated steam, (table No. 2).

The latter is to be expected, as the heat conductivity of superheated steam is lower than that of saturated steam. Also, it may be expected that the gain due to jacketing will decrease with increasing cylinder diameter, due to the smaller ratio of surface to volume in large engines. The practically unanimous adoption of the steam chest as an end jacket seems peculiar, in view of the fact that it has generally been held as axiomatic that the steam should not pass through the jacket on its way to the engine, as the beneficial effects of transferring the condensation from the inside to the outside of the cylinder would thereby be lost. It is true that these jackets may be drained to remove the water before the steam enters the cylinder, but it is questionable whether the steam can be completely dried by this means, as it must be in a state of turbulence during the admission period.*

To shed some light on these and other questions, a series of 60 tests was made on the 10- by 15-inch uniflow engine in the mechanical engineering laboratory at the University of Toronto. Different loads and jacket conditions were taken, and the results are summarized in table No. 3 and figures Nos. 4 to 9. The actual figures obtained are of no particular significance, but their relative values indicate a large saving due to the body jackets, and the relative unimportance of the end jackets under these conditions. This is indicated by the curves in figures Nos. 4 and 5, which give the hourly heat consumption and steam used per i.h.p. hour, respectively, at different loads. The saving is shown still more clearly by figure No. 6, which gives the temperature-entropy diagrams under the four conditions with the same load on the engine in each case. Figure No. 7 shows that none of these changes has an appreciable effect on the mechanical efficiency, and figure No. 8 indicates that the use of jackets, when running under condensing conditions, raised the Rankine cycle efficiency ratio to a value approximately to that in non-condensing non-jacketed operation. Figure No. 9 is a temperature entropy diagram showing the effect of jacketing, (condensing operation), when the load was reduced from 39 to 15 b.h.p. The increased amount of re-evaporation due to the heat received from the jackets at light loads is clearly shown, so that the dryness fraction of the steam at the end of expansion varies little at different loads.

* This is confirmed by Barrus, (A.S.M.E. paper no. 1968, May 1925) in tests on a 4-cylinder vertical uniflow engine (para. 3).

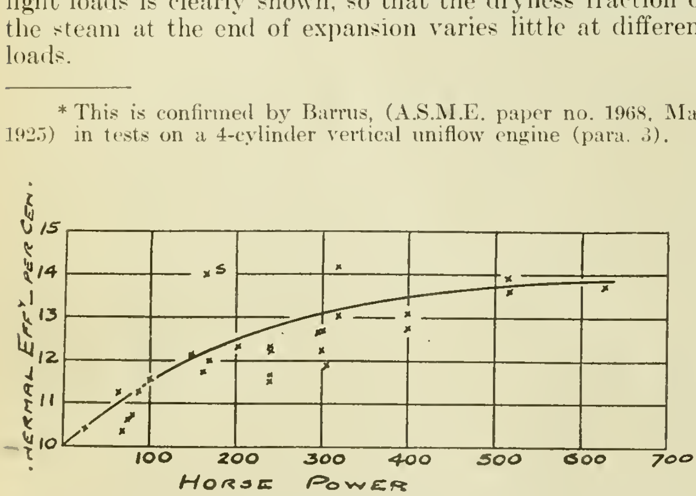

Figure No. 12.—Thermal Efficiencies of Non-condensing Uniflow Engines.

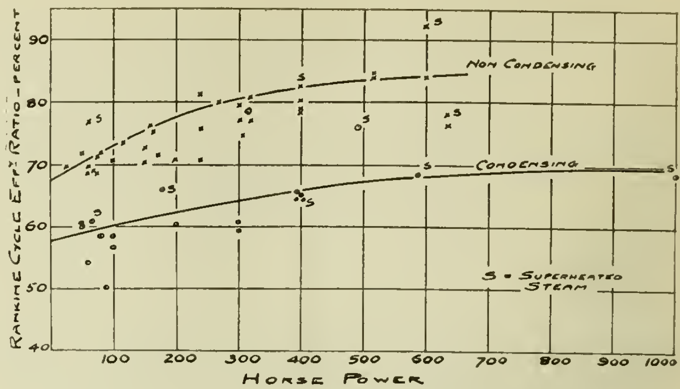

Figure No. 13.—Rankine Cycle Efficiency Ratios of Uniflow Engines.

Test Results and Efficiencies

An analysis of a large number of tests on uniflow engines of different makes and sizes confirms generally the claim that high efficiencies can be obtained, and the steam consumption curves at different loads in most cases are very flat. This clearly indicates the fact that this type of engine is well suited to varying load conditions, as the economy is usually not greatly affected when the engine is run at light loads for comparatively long periods. Practically all the tests referred to were made at steam pressures between 100 and 160 lbs. per square inch gauge, and, in view of the present tendency towards the use of higher pressures, it would be interesting to have some results on the performance of these engines under such conditions. Consumptions as low as 10 lbs. steam per i.h.p. hour with 250° F. superheat and 28 inches vacuum have been obtained on large engines, (500 h.p. and over), but the number of test results available under condensing conditions and their variable natures do not justify any general conclusions on this point beyond the general observation that thermal efficiencies up to 20 per cent have been obtained. (See table No. 4.)

Figure No. 12 shows the thermal efficiencies obtained on a large number of engines using saturated steam and running non-condensing, the limit being about 14 per cent in such cases. Piston speeds range from about 600 feet per minute for cylinders of 15 inches diameter to 800 feet per minute for 43-inch cylinders.

The ratio of the thermal efficiency actually obtained to that of the Rankine cycle under the same conditions, (called the Rankine cycle efficiency ratio), gives a better idea of the relative performance of such engines, particularly as far as their success in reducing cylinder condensation is concerned. The test results for engines of various sizes are plotted in figure No. 13, showing that under non-condensing conditions efficiency ratios of 70 to 85 per cent may be expected and under condensing conditions efficiencies varying from 60 to 70 per cent are usual. In this connection it is interesting to sum up the possibilities of the steam jacketing cycle with different clearance volumes. In figure No. 11 the Rankine cycle $ABCD$ and its efficiency $\frac{ABCD}{ABCEF}$ are again indicated. Assuming that the steam remains dry during expansion, (due to the action of the steam jackets), the expansion line is CG. At G release takes place, followed by the exhaust line GHK. The line KL is taken as roughly parallel with the water line, its position varying with the clearance assumed, so that the work done is $LCGHK$ and the efficiency $\frac{LCGHK}{LCGRNK}$. Plotting these efficiencies on the basis of clearance percentages gives the line marked "actual cycle" in

1109	126	168	590	27	10 4	19 8

figure No. 14.* If it be assumed that compression is adiabatic along ML, the cycle efficiency is increased and follows the line marked "adiabatic cycle" in figure No. 14. These lines indicate the fall of efficiency as the clearance volume increases, and also show the closeness with which the efficiency ratio of the actual uniflow engine approaches that of the ideal cycle.

The influence of superheat in reducing steam consumption and raising thermal efficiencies has already been referred to, and under these conditions the effect of the jacketing is reduced.

Application to Practice

The uniflow engine is generally adopted in cases where moderate amounts of power are required, and the usual limit is about 1,000 to 1,200 h.p., but within recent years large units capable of generating up to 14,000 h.p. have been installed for rolling mill work.** For fluctuating loads of this nature, the flat steam consumption curve of the uniflow engine would seem to be very suitable, particularly as the time of the load cycle is very short, (2 to 3 minutes). It is claimed that the engine will take up to 100 per cent overload, and this flexibility is a decided asset for such work, particularly as a low speed must necessarily be used in any case.

The application of the uniflow engine to locomotive work hardly comes within the scope of this paper, but it is interesting to note that many experiments have been made along these lines by Professor Stumpf and others.*** Tests on the Prussian State Railways showed an economy of 19 per cent over piston valve engines and 28 per cent over Lentz valve locomotives. A steam wagon using a vertical uniflow engine in which the admission valves consist of stainless steel balls is also being made in England. The three cylinders are each 6¾ inches diameter and the stroke is 10 inches. The speed of the engine is 200 r.p.m.*

A single acting vertical engine with two cylinders each 4 inches diameter by 5 inches stroke is made by the Babcock-Wilcox and Goldie-McCulloch Company of Galt, Ont., for driving stokers, blowers, centrifugal pumps, etc., and on account of its simple construction, (32 working parts), is claimed to be very suitable for such purposes where long hours of service and little attention are inevitable. This engine has a plain piston valve, and its maximum rating is 7.8 b.h.p. at 700 r.p.m.

Recently** a 1,500-h.p. three-cylinder marine engine has been put into service on the lake of Geneva. In this engine the mechanical construction of the cylinder is new and the valves are operated by oil pressure.

Multiple cylinder engines of this type have not been adopted to any considerable extent, but they offer the possible advantage of using the exhaust from one cylinder to produce suction in another. It is claimed that as much as 18 inches of vacuum can be produced in this way.

A number of compound uniflow engines have also been made, but in such cases the high pressure cylinder is usually of the counterflow type and the low pressure is uniflow.*** Such engines are usually combined with a heat extraction or bleeding system, and where uniflow engines are used in connection with process work using bled or exhaust steam, remarkably low steam consumptions can be obtained. A new type of compound uniflow engine has recently been developed by Professor Stumpf† for the purpose of avoid-

* The figures for this study were taken from the acceptance tests of a 500-h.p. engine, 140 lbs. steam pressure, atmospheric exhaust, 200 r.p.m.

Figure No. 16.—Compound Marine Engine (Stumpf).

ing the high crank pin pressures obtained with large single cylinder engines. This engine has an uncommon arrangement of crank angles and it is claimed to give a very uniform torque curve and better balancing than is usually obtained in such engines.

The other disadvantages of the uniflow engine are due primarily to the heavy reciprocating parts which introduce large inertia forces and to the long piston, which necessitates a long cylinder or a short stroke, or both. The reduction of mean effective pressure due to the large amount of power used for compression also necessitates the use of larger cylinder diameters than are customary in counterflow engines producing the same powers.

In spite of these disadvantages, however, the reduced fuel consumption of the uniflow engine is so important a factor that this engine is likely to find a considerable market among small power users.

The thanks of the author are due to the authorities of the University of Toronto and to Professor R. W. Angus M.E.I.C., for providing facilities and assistance for the tests made at the University of Toronto. Also to Messrs. G. H. Harlow, S.E.I.C., B.A.Sc., H. E. Saunders, B.A.Sc., and G. L. DeLaplante, B.A.Sc., for their help in carrying out the tests and in making the necessary calculations.

Appendix

The latest type of compound uniflow engine designed by Professor Stumpf for marine work contains several features of interest, so that the following description may be useful. Several three-cylinder uniflow marine engines have been made by Messrs. Burmeister and Wain, and it is claimed that their steam consumption is lower than that of the ordinary triple expansion type. In single-cylinder expansion, however, particularly when the steam pressure is high, the crankpin pressure per cylinder tends to become excessive, and for this reason, and also to avoid heavy losses due to incomplete expansion, the compound system is used in the new engine.* (See figure No. 16.)

The diameters of the high and low pressure cylinders are 16.1 and 35.4 inches respectively and the stroke is 35.4 inches. The high pressure cylinders are made counterflow on account of the higher superheat used and the low pressure cylinders are uniflow. The steam is controlled by a single piston valve between the two cylinders, the Woolf system of compounding being used. It is claimed that the piston valve can be made as tight as the drop valve if properly designed and manufactured, and also has the advantages of simplicity, rapid motion at admission and cut off and less throttling loss.

The valve is perfectly balanced, receives live steam for the high pressure cylinder inside and exhausts to the low pressure cylinder outside the pistons. Four cylinders are used to produce 1,250 h.p., and the arrangement is so compact that the overall length of the cylinders is twelve feet. The high pressure clearance volume is eight per cent and that of the low pressure cylinder six per cent of the stroke volume. Cylinder volume ratios of one to five and one to seven are advised for different exhaust pressures. It is claimed that under these conditions the small pressure drops at the end of expansion in the high pressure and low pressure cylinders, respectively, produce little throttling loss and allow high vacua to be used, so that the steam consumption is expected to be below that of a combined triple expansion engine and exhaust steam turbine.

The arrangement of the cranks is also unusual. The high pressure cranks are spaced 90° apart and the respective low pressure cranks are placed 150° behind them. This arrangement is claimed to give better balancing and a more even crank effort curve than when the cranks are 180° apart. Specimen curves are drawn to substantiate this.

Another smaller engine is also described in which the piston valve is placed before the high pressure cylinder and free exhaust takes place to the low pressure cylinder, the cranks in this case being 120° apart.

The tiials of these engines will be watched with interest, particularly as piston valves have generally been held to be inferior in economy to drop valves.

The Vacuum Paper Machine Dryer

Its Design, Construction and Operation with Special Reference to the Vacuum Dryer Installed at Kenogami, Que.

Ogden Minton, Esq.
Greenwich, Conn., U.S.A.

Paper read before the Montreal Branch of The Engineering Institute of Canada, December 1st, 1927

For the benefit of those unfamiliar with the vacuum dryer, a brief description follows. It comprises a series of standard dryers together with dryer felts, felt carrying rolls, hand and automatic guide rolls for the felt and an automatic stretch roll for the felt, all of which may be made exactly like those used on a standard paper drying unit. The entire drying unit, however, is enclosed in an air-tight box or chamber, usually made of cast iron, suitably ribbed and strengthened to withstand the pressure of the atmosphere. At the front end of this chamber there is a seal which allows the wet paper to enter but does not allow air to enter. Similarly, at the rear or dry end there is another seal which allows the dry paper to pass out of the chamber but also prevents air from entering. Connected to the bottom of the chamber there is a condenser, either of the surface, jet or barometric type, and connected to the condenser is a dry vacuum pump. The operation of this dryer differs from the standard type in that the air is pumped out of the chamber and the paper is dried under a vacuum of approximately 28 inches of mercury.

In December 1926, a vacuum dryer was installed in the paper mill of Price Brothers and Company, Limited, at Kenogami, Que., on their No. 1 machine. This dryer contains twenty dryers, 5 feet in diameter, with a face of 152 inches. It was built at the plant of Charles Walmsley and Company, (Canada), Limited, at Longueuil, Que. To this dryer was attached a suitable condenser, dry vacuum pump, air cooler, etc., a full description of which is given later. This vacuum dryer is now in regular 24-hour production, at a speed of 700 feet per minute, drying standard newsprint paper. This was the first vacuum dryer to be installed drying newsprint and very much the largest ever constructed. Prior to the installation of this vacuum dryer there was little or no data on what might be expected from it, from an operating standpoint. There was a good deal of experimental data available and much also in the form of theoretical considerations. Before this there had not been any vacuum dryer operated at a speed in excess of about 200 feet per minute or any that had taken paper direct from the last wet press of a paper machine and dried it. There was much doubt in the minds of many of the best paper mill engineers as to the results to be obtained, and there was considerable doubt as to the parts of so large a piece of machinery being correctly designed in the first large size machine.

Casing

The casing of the dryer was built up of cast iron plates carefully ribbed for strength. Where these bolt together the surfaces were planed. These surfaces were then covered with a thick mixture of white lead and machine oil and bolted together. This makes an air-tight joint. The castings were made of semi-steel, and care was taken to get this as close grained as possible and free from blow or pin holes. Test bars were frequently taken and tested for strength and texture, with the result that little trouble has been found due to leaks. Holding a vacuum of 28 inches of mercury, however, is no small task and the slightest porosity of the castings will cause serious leaks. After the dryer was assembled it was painted while under a slight vacuum, and the porous spots were thus filled with paint and eliminated. It should be borne in mind here that this vacuum chamber is very much the largest of any type ever constructed, being several times larger than anything heretofore attempted.

In designing the various castings, great care was taken to check each part for strength and deflection and a liberal factor of safety used in every case. While a vacuum of 28 inches only exerts a force of approximately 14 lbs. per square inch, this amounts to about 2,000 lbs. per square foot and on some of the long spans the total pressure runs up into many tons' pressure. Because of certain facts of the design, it was necessary in some cases to limit the deflection of some of these castings to very small amounts, and this called for a great deal of thought, care and ingenuity on the part of the designers in ribbing the castings for stiffness and still not using an excessive amount of cast iron. It is not a simple designing task to take a complicated ribbed cast iron plate subjected to a vacuum load, and often to other loads from adjoining castings, rolls, etc., and calculate its exact deflection. A great deal of satisfaction was felt when the vacuum was first pulled in this dryer and the deflections measured and found to check with the calculations previously made. It was surprising how close they all did check, often within a few thousands of an inch.

All of these castings were doweled together with steel dowel pins as well as bolted, and it is possible to remove any casting and replace it and the steel dowel pins insure it going together again just as it came apart. The entire casing has been made sectional of standardized sections, so that dryers can be added to or taken from it should the need ever come. Special attention was given to the castings where they joined together to insure that the joint would not work and eventually leak. Doors and windows were located where they would be of most use and fitted with special gaskets and in some cases hinged so that they can be quickly opened and closed. Openings were left for the felt carrying rolls so that they may readily be unbolted and pulled out the front of the dryer. The felt carrying rolls were also mounted on roller bearings and the housing for these doweled with special steel dowel pins to the main side castings, insuring that these rolls would be parallel with the dryers and, if removed for any reason, they must of necessity go back in exactly the same location.

The dowel pins locating these rolls were made with a threaded end and a nut so that they may be quickly and easily removed. In fact, this type of dowel pin has been used throughout the whole vacuum dryer. The rear bearings of the felt carrying rolls are held in place by the housing, but the front bearings are left free to slip to take care of contraction and expansion, just as was done in the case of the bearings on the dryer journals. The housings are filled with oil to a predetermined level and will run for a very long time without attention of any kind. Oil grooves have been carefully designed and made a part of the housing to prevent oil running out along the shaft, and thus getting on the felt. The bearings themselves are SKF self-aligning roller bearings, and over-size bearings were used to insure long life and freedom from bearing troubles. After a period of over six months these bearings, like all the rest of the bearings in this dryer, have given no trouble whatever. The housings, however, are so designed and attached to the main casting that, should bearing trouble arise, the bearings can quickly and easily be removed and new bearings substituted. Doors at the dry end of the machine have been conveniently located for putting on dryer felts. Automatic felt stretches of conventional type, hand guide and Moore and White automatic felt guides are used to guide and stretch the dryer felt.

Mechanical Details

It was decided for various reasons to install roller bearings on all the rolls contained in this dryer. Heretofore, engineers have hesitated about installing ball or roller bearings on the dryer journals because of the high temperature of these journals, especially the rear dryer journal, which is hollow and through which the steam is fed into the dryer. Nevertheless, after careful consideration, it was decided to use roller bearings and a bearing was selected with a capacity considerably greater than necessary to carry the load. The size of the journal was, of necessity, large in order to give sufficient area for the steam inlet through the rear journal, and this in reality settled the size of the bearing that would have to be used. For the sake of standardizations, the front dryer bearings were made the same size as the rear bearings. SKF self-aligning roller bearings were selected, and the outer races were slightly freed out to allow for expansion. The bearings were fitted to the shafts on taper sleeve split bushings to insure a good tight fit on the shafts and also to make it easier to take out a bearing if found necessary. The rear bearings were held in the housings to locate the dryer, but the front bearings were left free to slip in the housings to allow for contraction and expansion of the dryer when heating up or cooling off. This construction also definitely locates the rear shafts so that the drive unit is not subject to the contraction and expansion of the dryers.

On the rear bearings an automatic lubricating system was installed to insure a constant supply of lubricant at all times. This system comprises a small pump that pumps the oil to a tank set on top of the dryer, from which tank the oil runs to the stuffing boxes on the rear dryer journals and into a spacer ring set between the packing rings which makes an oil seal for the stuffing box, keeps the packing

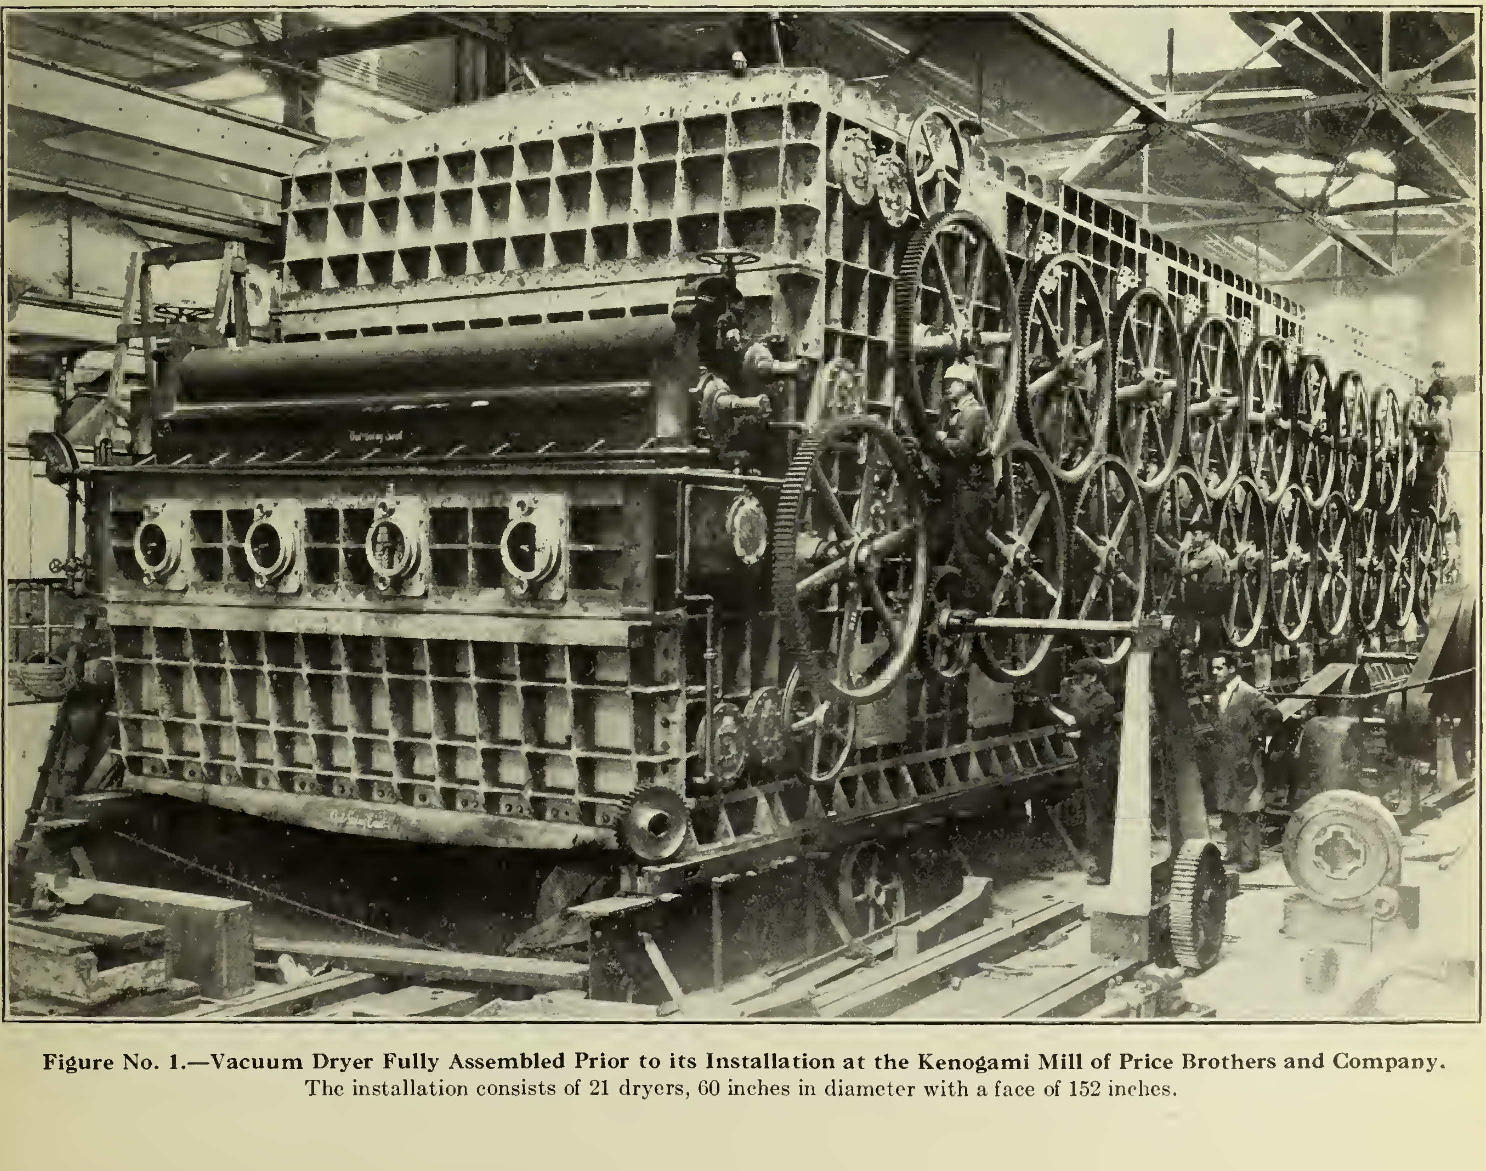

Figure No. 1.—Vacuum Dryer Fully Assembled Prior to its Installation at the Kenogami Mill of Price Brothers and Company.
The installation consists of 21 dryers, 60 inches in diameter with a face of 152 inches.

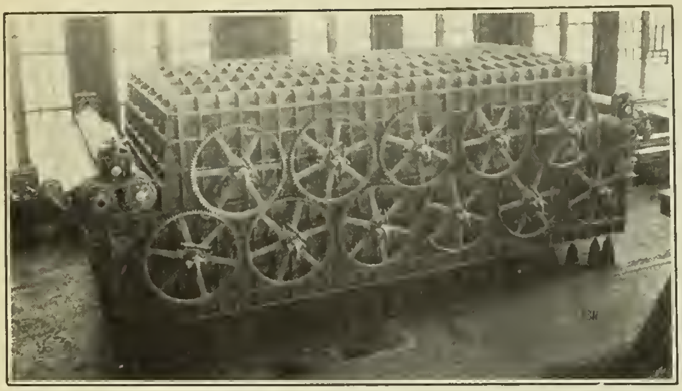

Figure No. 2.—Back View of Vacuum Dryer showing Roof Construction and Gearing.

This dryer was built for Armstrong Cork Company and consists of 11 dryers, 48 inches in diameter with a face of 154 inches.

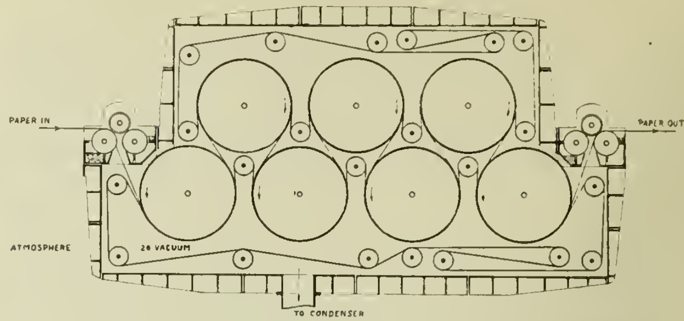

Figure No. 3.—Diagrammatic Cross-section showing a 7-Dryer Vacuum Dryer.

This diagram shows the seals, the course of the paper through the dryer and the dryer felts together with felt carrying rolls, felt take-up rolls and felt guide rolls.

rings always lubricated, and the oil leaking into the vacuum runs directly into the roller bearings. At the correct height there is a small overflow drain in the bearing housing from which the oil runs back to a tank under the dryer and is taken by the pump back to the feeding tank on the top of the dryer. A filter is also included in this oiling system to filter out any impurities or foreign matter from the oil. The front dryer bearings merely have a constant level of oil in which they run and which is so designed that these bearings when filled must always be filled to just the correct height. Suitable oil catching housings are installed and the whole bearing mounted in a substantial and rigid manner.

One of the problems was to determine the correct kind of oil to use. The makers of the bearings specified a long list of things that this oil should not contain as well as a long list of qualities it should have. Added to this was the fact that this oil would be heated up to the temperature of the steam in the rear dryer journal and also would be under a vacuum of 28 inches of mercury. At this temperature and this vacuum, the oil must not vapourize out its lighter components and thereby change its characteristics. Much research was called for, and, after careful considerations of all the requirements, several grades of oil were selected and then tested under the temperature and vacuum conditions, and a suitable oil was found.

The bearings and the oil have now run for a sufficiently long time to vindicate the selection of this type of bearing and oil. There has not been one minute of lost time due to bearings, and the quantity of oil used has been negligible. Actually, these bearings will run for months with one filling of oil and no outside attention.

Paper machine dryer bearings have been noted for giving trouble. It is impossible to make the journals of a dryer turn and stay true. Temperature changes in the dryer and dryer head seem to warp the dryer head just a trifle, and this causes the journal to wobble and has been the cause of no little trouble to paper makers. The self-aligning feature of the roller bearings used have compensated for inaccuracies of the journal movements and eliminating this source of trouble. The cost of this type of bearing is only a little more than a good type of plain bearing. They have a calculated life of twenty years and are easily and quickly replaced when necessary. The wear in this type of bearing is very small and the dryers turn on their correct centres, stay in line and level and run very much easier. Also, the dryer gears run on their true pitch circles, making for smooth running gears with longer life and less noise and vibration. The starting load of dryers mounted on plain bearings has always been large and a serious drawback. When they are stopped, the oil is forced out of the bearings and considerable power is needed to start them, which in turn has called for large and expensive clutches and often causes an overload on the engine or motor in starting.

The Seals

For the sake of those who are not familiar with the operation of the seals, a brief description follows. Reference should here be made to the accompanying illustrations showing the seals. The paper passes into the seal between a rubber covered roll and the lower of two bronze covered rolls. The rubber roll is held tight against the bronze rolls by the pull of the vacuum from within the chamber, or, to speak technically, by the air pressure from outside the chamber, thus forming a rolling seal at this point. The surface of the rubber roll, however, gives enough to allow the paper to pass and yet seal against the air. The ends of all three rolls are fitted with a special form of sealing ring excluding the air at the ends. The bronze covered rolls run on roller bearings and are located in the main seal

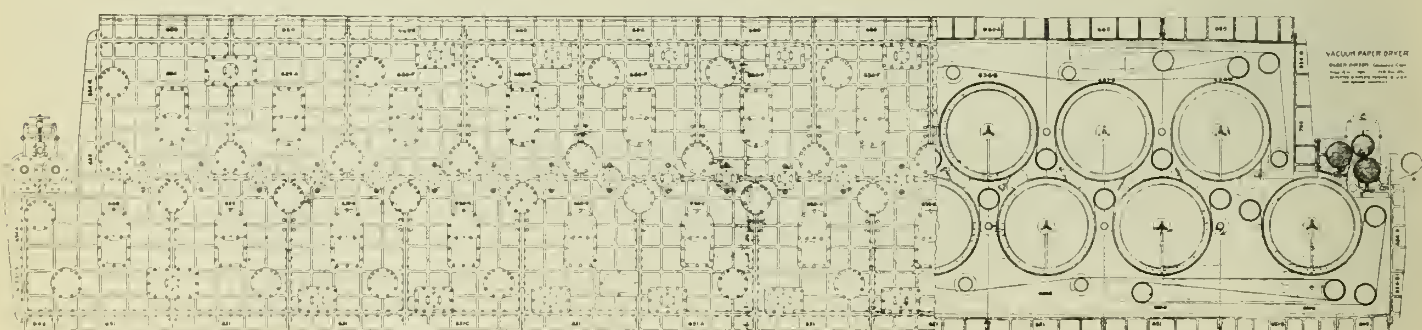

Figure No. 4.—Elevation of Vacuum Dryer Installed in the Kenogami Mill of Price Brothers and Company.

casting, as shown in figure No. 16. In this casting are grooves into which the sealing and wiping rubbers are placed by pulling these rubbers through from the front or back of the dryer. The rubber tube is then drawn through and the ends plugged with special plugs and water is put in the tube to push the sealing and wiping rubbers up against the bronze rolls. A pressure of approximately five pounds per square inch is maintained in these tubes. A small pond of water is supplied, as shown, in front of these rubber strips and some leaks past them into the vacuum, where it is led away to waste or to the condenser. The rubber strips, however, allow only a small amount of this water to leak in. The second rubber in each case acts merely as a wiper to wipe the surface of the bronze covered rolls dry before coming in contact with the paper or the rubber roll, as the case may be. Water makes almost a perfect lubricant for rubber under these conditions, and the resulting friction is very small. Air cannot leak into the vacuum chamber, because it must displace the water ahead of it, which, of course, it cannot do as long as a constant supply of water is kept in the opening and maintained at the same level. This level is maintained by additional water running in slightly faster than needed, the excess flowing to waste or to the condenser over a small weir. The rings on the ends of the rolls are backed up by sponge rubber rings which take care of contraction and expansion of the rolls themselves or the castings in which they are fitted.

The ingoing and outgoing seals on the vacuum dryer at Kenogami are much the same as the earlier type of seals used for this purpose. They comprise two bronze covered rolls 16 inches in diameter and a rubber covered roll 14 inches in diameter. The accompanying illustrations, figures Nos. 11 and 12, show these two seals plainly. Unlike the earlier type of seals, the ingoing seal has the two bronze rolls set at an angle. This was done to allow the paper to draw into the seal better from the third press felt and to lower the paper at this point. The outgoing seal likewise has the two bronze rolls set at an angle and also has the rubber roll underneath, thus making what is termed an inverted seal. This was done to improve the passing of the paper around the 24-inch sweat dryer and up over the 5-foot sweat dryer and into the calendar stack. This arrangement also eliminated the vertical pass from the last dryer up to the nip between the bronze and rubber covered seal rolls, which was necessary with the old type of seal. Now, the paper is doctored off the last top dryer and falls directly down into the nip of the inverted seal, and this pass cannot fail. The sealing rubbers have been made larger than heretofore, being 1¼ inch wide. This makes the rubber tube 1¼ inch in diameter and makes the method of plugging the ends easier, as there is more room available and the parts are not so small and delicate. The accompanying sketch, figure No. 15, shows the form and shape of these rubbers plainly.

A very rare and interesting engineering phenomenon took place recently in connection with these wiping and sealing rubbers. For some reason, these rubbers commenced to fail. They apparently would run hot, partially melt, then seize and be pulled all out of shape. Before the dryer could be stopped, the rubbers would be so mutilated that nothing much could be learned by examining them. A new rubber would be put in, the dryer started up, and there might or might not be any more trouble for a long time. An identical rubber from the same lot would run for weeks and another rubber just exactly like it would run for perhaps only fifteen minutes. No reason could be found for failure of these rubbers. Finally, by stopping the dryer and pulling out the rubbers *before* they failed it was discovered that the rubbers were softening or melting from the underneath side, the side next to the rubber tube and not the side

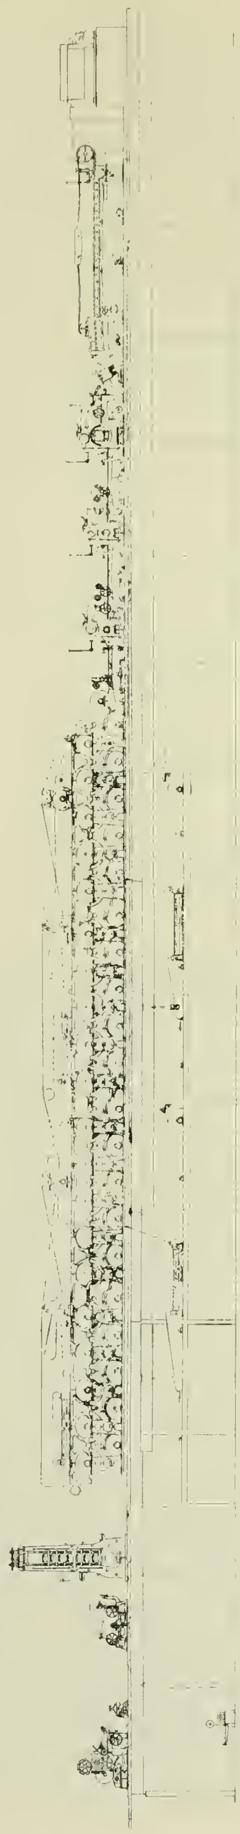

Figure No. 5.—(a) High Speed, 234-inch, News Paper Machine Equipped with Standard Type of Dryers.

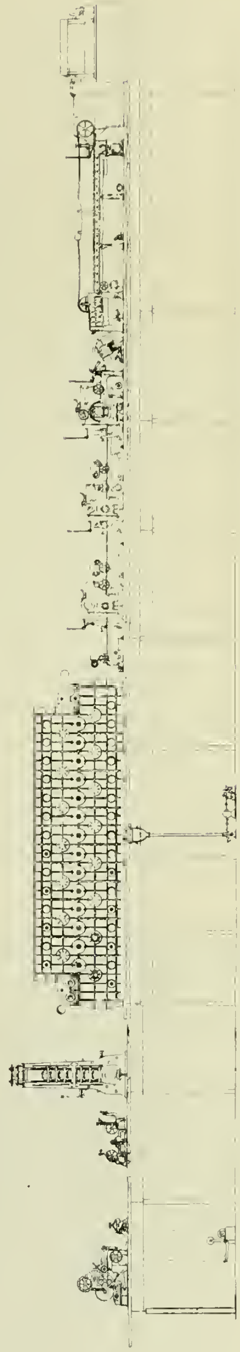

Figure No. 5.—(b) Same Machine as above with Vacuum Dryer Drawn to Same Scale showing the Floor Space Saved by Using Vacuum Dryer.

running in contact with the bronze roll, where friction might have been great and where trouble might be expected.

At about this time it was learned that a certain company had manufactured some special fire hose and that when they were testing this hose, with 150 lbs. of water pressure in it, the hose actually started to melt and smoke with the water flowing inside of it. This was explained as due to the impulses of the fire pump setting up a vibration which caused the rubber and the canvas of the fire hose to rub and enough friction was generated within the wall of the hose to cause it to melt and smoke. With this in mind, a careful analysis of the sealing rubbers showed that the cause of the failure was due to a chattering of the rubber, which set up a vibration, which in turn set up internal friction and generated enough internal heat to destroy the rubber. A rubber was substituted having a different period of vibration, and there was no more trouble from this source. Careful inquiry among the rubber manufacturers has failed to bring to light any other cases of this kind. All of this trouble was traced to one lot of rubbers.

Dryer Felts

The ordinary standard dryer felt is, as a rule, made of cotton duck or canvas. There are many different types, each manufacturer claiming some advantage for his particular variety, either as to weave, texture, flexibility, freedom from wrinkling, small amount of stretch, length of life, etc. Woollen dryer felts are often used in European countries and have many advantages over cotton felts, but are very expensive. They are as a rule put on endless, which on a large dryer section is a long tedious job. However, they run for a long time, often two or three years, and the change does not often have to be made. They have one property that is very superior to the canvas felts, in that they are very porous. In recent years a new type of dryer felt has come on the market known as the asbestos dryer felt. This is a cotton felt with a very open weave on the back and the face is made of asbestos strands woven into the cotton and is finished to give a very smooth surface next to the sheet of paper. This felt is quite porous.

Dryer felts often meet with accidents and are torn, run ashore or wrinkle, after which they must be replaced. Even the cheaper ones are expensive, and the cost of dryer felts per ton of paper is a real item to be considered by the paper maker. Some paper makers prefer to buy cheaper felts, due to the risk involved, in that a very expensive felt may be ruined long before it is worn out. Others buy a more expensive felt with a longer life and then try to protect it against accidents. In the vacuum dryer, tell-tale lights have been installed to warn the paper machine crew if a felt starts to leave the dryers for any reason and is in danger of wrinkling or running ashore.

A thermodynamic consideration of the vapourization of water is necessary to appreciate the task imposed on dryer felts. Lack of appreciation of the above fact was the cause of no little trouble with the vacuum dryer at Kenogami.

In the early types of the vacuum dryer, endless woollen dryer felts were used, principally because high grade bond and ledger paper were being dried and it was desired to keep the surface of such paper very smooth. Later, asbestos felts were substituted. This change was made because the number of dryers was changed and a different felt arrangement made it necessary to get new felts, and it was desired to try this type of felt. Cotton felts were tried for only a very short period of time and practically no experience was had with them. It should be remembered that this early vacuum dryer ran at a very slow speed and was used to dry paper of low moisture content and great strength.

When the vacuum dryer was installed at Kenogami, standard cotton dryer felts were put on and the machine

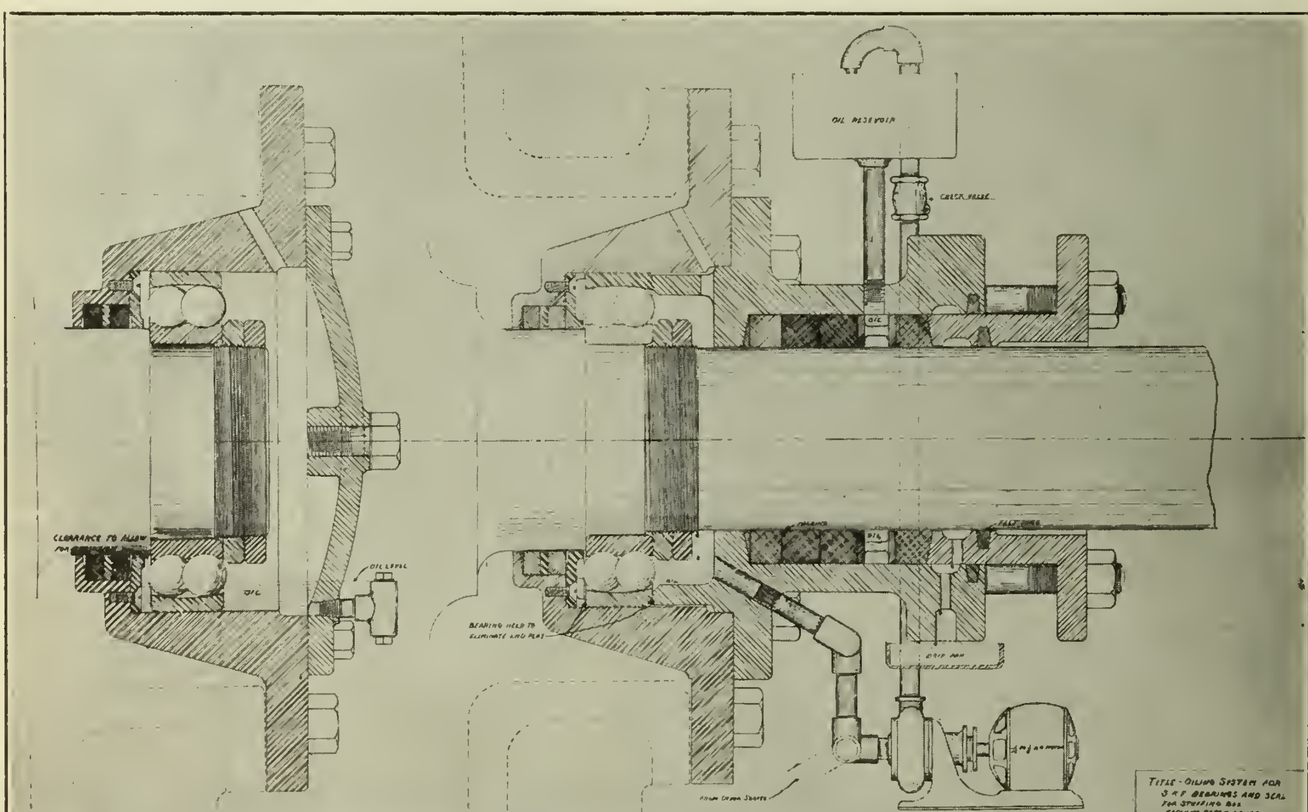

Figure No. 6.—Method Used in Mounting Ball Bearings on Front and Rear Dryers.
The rear dryer bearing is held and the front bearing is allowed to slide to take care of expansion of the dryer when the temperature is raised.

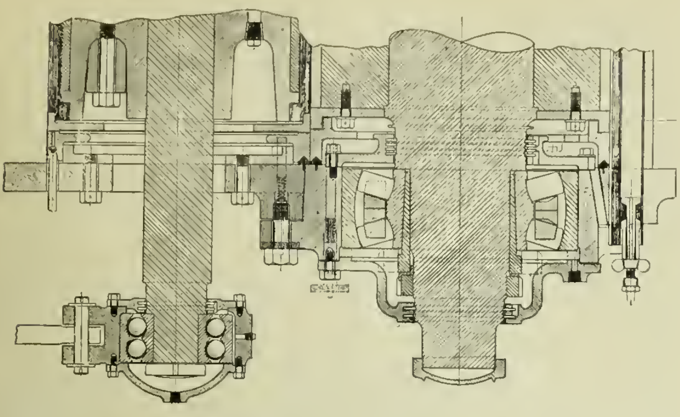

Figure No. 7.—Vacuum Dryer Type 20-60-152, Cross-section of Outgoing Seal Rolls showing End Sealing Rings and Bearings.

started up. This was a news machine running at 700 feet per minute and the paper coming to the dryer at about 72 per cent wet. The wet end of this machine was a standard Fourdrinier with couch roll and three wet presses of standard make. The sheet was 148 inches wide.

There was no difficulty experienced in drying the sheet other than that a serious wet wrinkle appeared about 12 inches in from the front and back edges of the sheet. The sheet was decidedly damper on the front and back edges than it was in the middle. The wet wrinkle was often so bad that it would cut in the calender stack, and at times plugged the stack. Regrinding and recrowning the press rolls to change the moisture content of the incoming sheet of paper did not help matters materially. No reason could be found to cause this condition. Tests of the moisture content of the incoming sheet were taken frequently. Many suggestions were made and were tried out with no results, so far as correcting the wet wrinkle and wet edges. At certain times and under certain conditions the wrinkles would just about disappear of their own accord, only to come back again in a few hours time. Leaky dryer heads were suspected, but were found not to be leaking. Distorted or unevenly woven felts were suspected, but when these same felts were put on one of the standard dryer sections in the same mill they functioned perfectly. Everything anyone could possibly think of was tried to correct the trouble, but without the slightest success. All of the dryers, felt carrying rolls and seal rolls were checked for alignment, and this was found to be perfect. The felts guided perfectly when there was no paper going over the machine, but difficulty was experienced in guiding them when the paper was on the machine. Rubber covered automatic guide rolls corrected this. It finally occurred to someone that the difficulty in guiding the felts was due to the fact that the felts were riding on a film of steam and that this made them hard to guide. If the felts were riding on a film of steam, then the felts were not letting the vapour through and a more porous felt would help.

The early experience with vacuum dryers was called to mind, and asbestos dryer felts substituted for the cotton felt. The felts then guided easily and the wet wrinkles disappeared, and it was then possible to make commercial paper. Carload after carload of this paper has been shipped and there has not been one complaint from the publishers regarding the paper. A careful record was kept of where this paper went, and it was mixed with paper from the other machines in the mill. The publishers were not told how the paper was made or that it was vacuum dried paper.

During test runs when the rate of evaporation was very high there was still a tendency for the edges of the sheet to come slightly wet, and the asbestos felts were suspected of not being porous enough. A very interesting experiment was tried to prove this and other things. This experiment disclosed a remarkable phenomenon. The two top dryer gears were removed. This left the first dryer and the small baby dryer ahead of it geared together and the two top and bottom dryers not connected in any way, other than that the dryer felt was around them and they had to be driven by the dryer felt. As they were mounted on roller bearings and turned very freely, this did not impose any great load on the dryer felt. This change was made over a Sunday. At midnight Sunday the machine was started up and the paper passed through it without difficulty and was put through the calender stack and on the reel. The only difference noted was that the first few draws of the paper from one dryer to the next were more loose. As they had been too tight before, this was considered an improvement. The writer was personally present in the mill. At eight o'clock the next morning the writer returned to the mill, and was told by the machine crew that the paper had broken on the wet end of the machine at about six o'clock, and that they repassed the paper, put it on the reel and no trouble was experienced. About two minutes later one of the machine crew passing the back of the vacuum dryer noticed that No. 1 bottom dryer was not turning, yet the paper was still on the reel and running perfectly. Two of the crew started it turning again and the paper did not break and there was not any sign of trouble from then on. This meant that the paper had been passing over the baby dryer, which was stationary, around the bottom dryer, which was also stationary, yet under the moving felt. How wet paper could do this without breaking was not easily comprehended. At first it was thought that something else must have happened and that the machine crew had reported the circumstances wrongly. However, shortly after nine o'clock the same thing happened again, and this time several engineers were present, and later it happened a third time and was witnessed by the writer. After the phenomenon, a fact was definitely established and it did not take long to analyze the situation.

Table No. 1.—Properties of Saturated Steam.
(From Steam Tables)

Absolute Pres. lbs. per sq. in.	Vacuum in inches of Mercury	Temperature Degrees Fahr.	Volume in cu. ft. for 1 lb. of steam
0.946	28.00	100.	350.8
1.	27.88	101.83	333.0
2.	25.85	126.15	173.5
3.	23.81	141.52	118.5
4.	21.78	153.01	90.5
5.	19.74	162.28	73.33
6.	17.70	170.06	61.89
7.	15.67	176.85	53.56
8.	13.63	182.86	47.27
9.	11.60	188.27	42.36
10.	9.56	193.22	38.38
11.	7.52	197.75	35.10
12.	5.49	201.96	32.36
13.	3.45	205.87	30.03
14.	1.42	209.55	28.02
14.7	0.	212.	26.79

The paper actually was not touching the dryer. It was riding on a film of steam, much the same as water acts when spilled on a very hot stove. Sufficient steam pressure was being developed between the paper and the dryer to force the paper and the dryer felt away from the dryer. It should be noted here that after even a short period without the wet paper on them the dryers heat quite rapidly, and this first dryer had come to a high temperature after the paper broke on the wet press. Because of the method of piping the steam to the various drying cylinders, the temperature of this first dryer comes up to the maximum temperature of any of the dryers soon after the paper is off the machine.

This temperature was sufficient to form the steam film when the paper was repassed after the break had occurred and caused the paper and dryer felt to leave the surface of the first dryer, and, there being nothing to drive it, it stopping turning. Like everything else, when it is understood it is perfectly simple.

A careful investigation was then started on the subject of dryer felts, and the accompanying chart, figure No. 19, of dryer felt tension was worked out. The asbestos felts were operated to best advantage at a felt tension of about 6 lbs. per inch of width, and from the chart where $R = 30$ inches, (the radius of a 5-foot dryer), it is seen that the pressure of the felt against the dryer is only 0.2 lbs. per square inch. In other words, the pressure of the felt against the paper and the dryer under the paper is a very small amount. Steam generated under the felt or paper has to exert only a force of 0.2 lbs. per square inch to lift the paper, or the paper and felt, off the dryer entirely. This is only one-fifth of a pound of steam pressure. The vapour formed from the evaporation of water in the wet sheet of paper must either pass through the felt or else leave the paper while the paper is passing from one dryer to the next. Probably both take place. However, if the felt is not porous enough to allow the vapour to get away steam pressure will be built up and lift the felt away from the dryer, as mentioned above.

Table No. 1, showing some of the properties of saturated steam at pressures less than atmospheric pressure, is shown for reference purposes. The standard paper machine dryer evaporates water at a temperature approximating, say, 170.06° F. From the chart it will be seen that one pound of vapour at this temperature occupies 61.89 cubic feet. In the vacuum dryer, however, with a vacuum of 28 inches of mercury, one pound of vapour occupies 350.8 cubic feet, or a little more than 5½ times as much volume. It should be remembered that in the vacuum dryer the pounds of vapour liberated per square foot of dryer surface are twice the amount they are with a standard paper machine dryer, hence the volume of vapour that actually has to pass through the felt is not 5½ but 11 times as great. This volume of vapour must pass through the felts or else a pressure will be built up under the felts and the felts lifted off the surface of the dryers; hence the need for a very porous felt. This lifting of the felt can be offset to some extent by increasing the tension in the felts, but high tension does not help the length of life of felts and may result in marking the paper. Also, this tension has to be very high to get any real pressure of the felt against the paper, as a study of the chart of dryer felt tension clearly shows. When the paper is wettest the evaporation is greatest. As the sheet

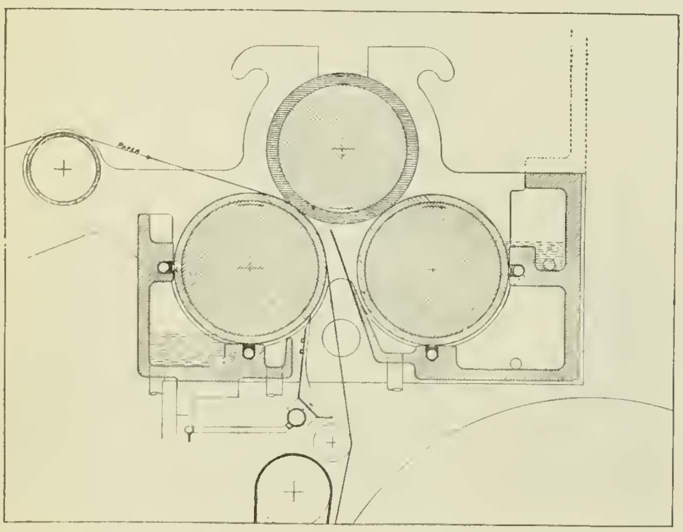

Figure No. 9.—Diagrammatic Drawing of Ingoing Seal for Vacuum Dryer.

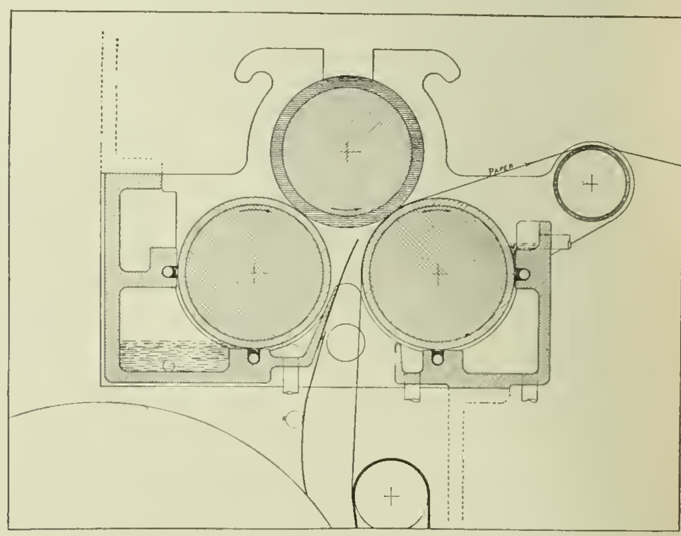

Figure No. 10.—Diagrammatic Drawing of Outgoing Seal for Vacuum Dryer.

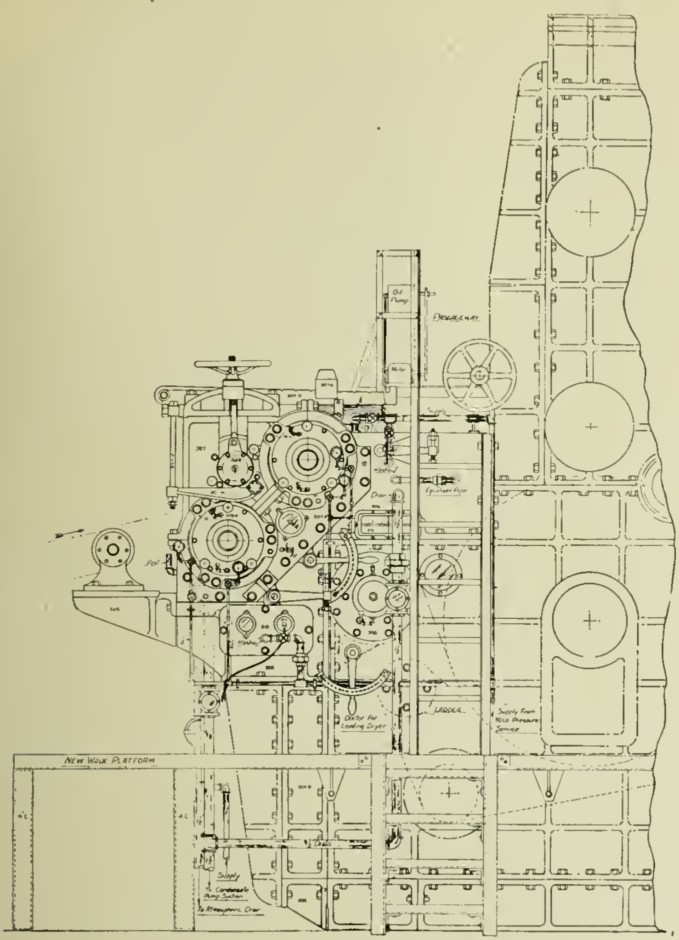


ELEVATION

Figure No. 11.—Vacuum Dryer Type 20-60-152, Elevation of Ingoing Seal.

commences to dry, while passing from dryer to dryer, the rate of evaporation is reduced, and hence the first few dryers of a bank are the worst offenders so far as lifting the paper and felt off the dryers.

While this condition imposes a serious task on the felts in a vacuum dryer, the same thing, to a less extent, takes place in every type of dryer using felts, and in both cases the paper maker should look for a porous felt. It will be found that a very porous felt can be run with very little tension, and where you find it necessary to carry high felt tension you will find a more or less non-porous felt.

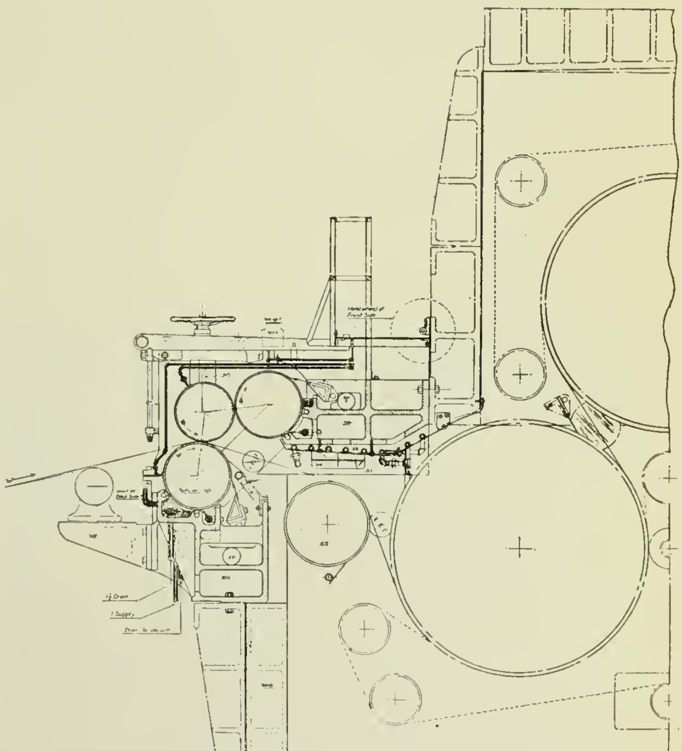
A set of curves showing the properties of saturated steam has been plotted, and is shown in figure No. 20. A study of these curves will show that by lowering the vacuum, even slightly, there is a large drop in the volume of one pound of steam. In fact, if the vacuum were dropped to 17.70 inches of mecury we would have a temperature and volume of one pound of steam just exactly the same as in the case previously cited of the standard paper machine. However, the value of a vacuum dryer lies in carrying high vacuum, which raises the rate of evaporation and shortens the length of the dryer and reduces the evaporating temperature of the water in the paper, all of which work for economy of operation and better and stronger paper.

Before learning that there was pressure being formed under the felt and that the evaporation was taking place at this pressure, and not at the vacuum in the chamber, it had been impossible to account for a few extra degrees of superheat in the vapour going to the condenser. The vapour in the vacuum dryer is slightly heated by the surfaces of the dryer over which there is no paper and also by the ends of the dryers, but this had always been found to be a small amount until the vacuum dryer was installed at Kenogami. The fact that this vapour is formed under a slightly greater pressure than the vacuum properly checked with the superheat, that could not be accounted for otherwise.

Condensing Equipment

The condensing equipment used with the vacuum dryer at Kenogami consists of a surface condenser, an air cooler, two dry vacuum pumps and two condensate pumps. Two pumps of each kind were installed, one of each to be held in reserve as a stand-by in case of accident to the other. The surface condenser at the present time is connected in one of the mill lines and the water simply flows through it just as though it was an elbow in the line. The temperature of the water is raised only about 4° F. under ordinary working conditions. This was installed as a temporary hook-up, but it has worked so satisfactorily that it probably will not be changed. The few degrees change in the water is beneficial to the mill supply line, and the cold water certainly is beneficial to the operation of the condenser. Following is given a full description of this equipment:—

1 Ingersoll-Rand surface condenser No. 11...	
1 Ingersoll-Rand air cooler, size C..........	
Steam capacity, lbs. per hour...............	18,000
Vacuum referred to 30" barometer...........	28 inches
Designed for circulating water at............	70° F.
Gallons per minute, circulating water........	1,500 gals.
Water velocity through tubes...............	7.4 ft. per sec.
Condenser friction in feet of water..........	15 feet
Condenser water temperature discharge (theoretical)	93° F.
Square feet of tube surface..................	1,280 sq. ft.
600 Admiralty metal tubes, 13 ft. long, ⅝-inch O.D. No. 18 B.W.G.	



CROSS SECTION

Figure No. 12.—Vacuum Dryer Type 20-60-152, Cross-section showing General Arrangement of Ingoing Seal.

Two pass construction and maximum pressures on tubes not to exceed 40 lbs. per sq. inch.
Shipping weight, 15,000 lbs.
Two No. XB Ingersoll-Rand dry vacuum pumps.
These are two-cylinder, double acting pumps and are belt driven from a 75-h.p. motor.

Bore	23 inches
Stroke	12 inches
Rated speed	190 r.p.m.
Capacity (piston displacement)	2,188 cu. ft. per minute
B.h.p. at pulley for peak intake load	82 b.h.p.
B.h.p. at pulley for 28-inch vacuum	39 b.h.p.

The condensate pumps are Cameron pumps furnished by Ingersoll-Rand Company.
2 pumps—No. 2 LV centrifugal condensate pumps.

Capacity each	27,000 lbs. per hr.
R.p.m.	1,750
B.h.p.	2.9 each

The dry vacuum pumps have valves so arranged that they can be run at the same time or singly. The same is true of the condensate pumps. Actually, the dry vacuum pumps are operating at a speed of 144 r.p.m., as there was an error made in getting the pulleys for the motors, and these have not been changed, as it was thought best to run these pumps in at this lower speed. Both vacuum pumps are ordinarily operated together. The air cooler was added to this equipment to reduce the temperature of the air going to the dry vacuum pumps, and thus relieve them of some extra work.

When this equipment was selected there was very little data available as to air leaks, and the selection was more or less of a guess. The incoming paper brings in a small amount of entrained air, and the amount of leaks in the casing could, of course, only be estimated very roughly. This guess turned out to be fairly accurate, as operating conditions have shown, and in a new design under the same conditions this same vacuum equipment would again be specified. It should be borne in mind that the type of vacuum equipment depends to a great extent upon conditions at the mill where the equipment is to be used. In some cases, a jet or barometric type of condenser might be preferable. There is a 10-inch piston operated vacuum breaker valve installed in the line running to the vacuum pumps. This can be operated by an air valve in the machine room located in front of the dryer, and it is only a matter of a minute and a half to break the vacuum. Also, switches are located on the front of the dryer to stop the vacuum pump. This vacuum equipment has not given trouble of any kind and has functioned perfectly.

Passing the Paper

It was not anticipated that there would be any difficulty in passing the paper, and it was assumed that the method used on former dryers would apply in this case. This method had been to feed the streamer into the ingoing seal with the end lapped over a piece of cardboard about 10 inches wide and 5 feet long. This would thread its way through the dryer of its own accord, aided only by the doctors on the drying cylinders. When the dryer at Kenogami was started up it was fitted out for this type of feeding. The first time it was turned over it ran at a speed of about 500 feet per minute, and the cardboard streamer, called a *go-devil,* functioned perfectly and no trouble was anticipated. However, the speed of the machine was soon raised to 700 feet per minute and the *go-devil* just would not function. It went everwhere but where it was desired to have it go, and this method of feeding had to be abandoned and a new method devised.

This was accomplished by means of two small air jets

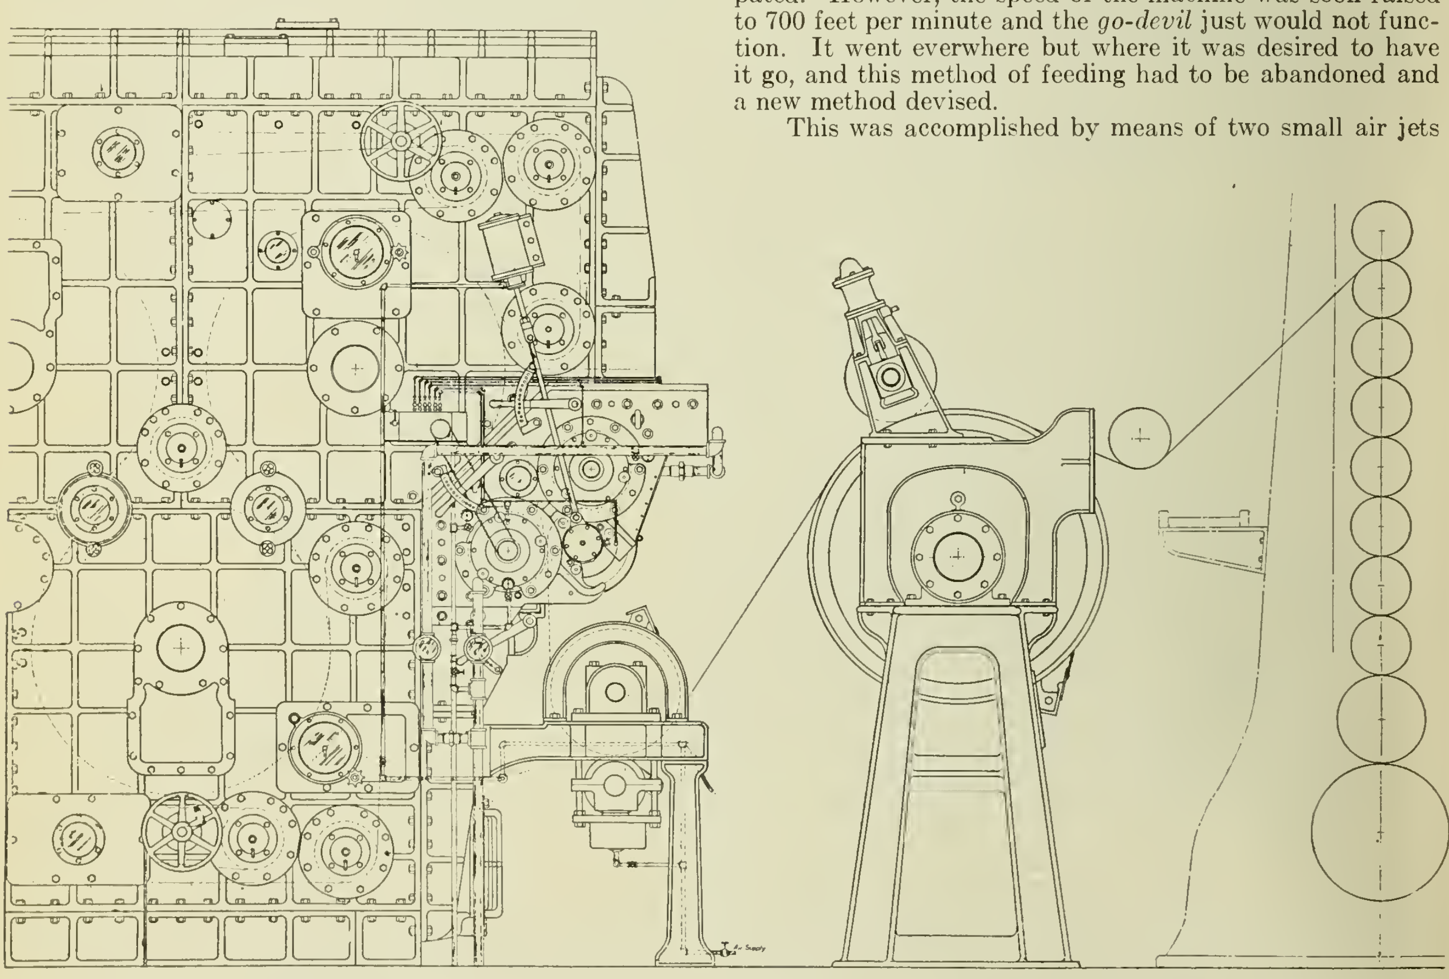


Figure No. 13.—Vacuum Dryer Type 20-60-152, General Arrangement of Outgoing Seal and showing Sweat Dryers.

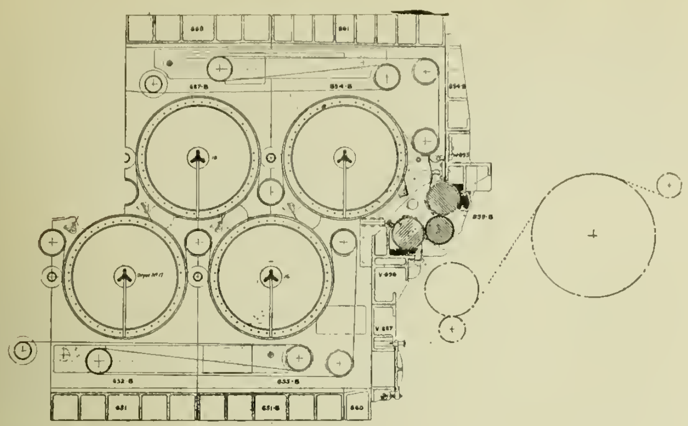

Figure No. 14.—Vacuum Dryer, Type 20-60-152, Cross-section showing General Arrangement of Outgoing Seal.

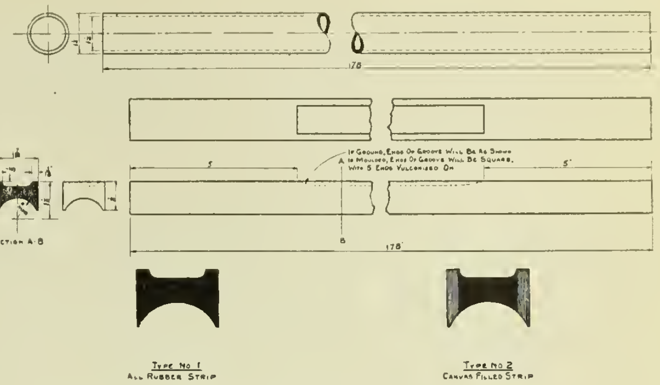

Figure No. 15.—Sealing and Wiping Rubbers.

which were arranged to strike the paper just before it came to the doctor on each bottom dryer. These jets consist of a small pipe with two nozzles. These nozzles were directed to strike the edges of the streamer as the streamer approached the doctor blade on each dryer. The other end of the pipe from these nozzles was brought out through the side of the vacuum dryer and a quick opening valve put on. This in reality was a standard ⅜-inch air or gas cock. When this valve is opened the outside air rushes into the vacuum and the two air jets strike the paper and blow it from the dryer into the nip, (above), between the dryer felt and the next following drying cylinder. A second pipe and valve are placed at each of these upward passes of the paper so that it blows straight across the machine when the valve is opened. The purpose of this is to blow out small pieces of paper that may lodge at this point. These are not often used, but are a great help at times.

The paper is picked up off the third press felt and thrown into the ingoing seal, and the air valves described above are opened. The man passing the paper walks down and closes the valves after the streamer passes each air jet. Paper has repeatedly been put back on the reel within two minutes after a break on the wet end of the machine. This method of passing the paper gives very little trouble. It should be remembered here that passing paper in a vacuum is comparatively simple as there are no air currents to deflect it. The old physics experiment in which the feather and the penny fall at the same speed in a vacuum should be recalled to mind. The paper has sufficient momentum to pass of its own accord, and after passing the first few dryers it actually will do so. Before passing the first few dryers it is so wet and limp that it has to be helped.

It is not at all difficult to fit a Sheehan paper carrier to a vacuum dryer, and this type of carrier would work perfectly. The extra complication of ropes and pulleys, however, is not desirable. At slow speed, the *go-devil* is a perfect method of feeding, while at high speed the air jets accomplish all that is desired.

Breaks

To the best of the writer's knowledge, paper has never broken in a vacuum dryer unless there has been some very good and obvious reason. Paper coming from the third press badly torn on the back edge has at times passed into the dryer and piled up, but as a rule even in this case it will pass on through and out the outgoing seal. Instances of the paper piling up in the dryer have been rare, not over five or six times, including all the experimental period, when many experiments were being tried out. When it does pile up, it is not a serious matter. The vacuum is broken, the doors or windows opened and the paper removed just

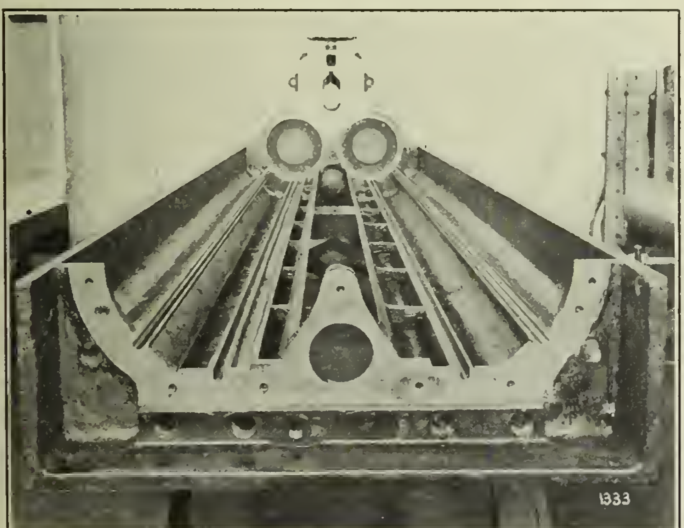

Figure No. 16.—Vacuum Dryer Type 11-48-154, Outgoing Seal Casting—showing Grooves for Rubbers and in the Rear is shown End Frame with Roller Bearings in Place Ready to Receive the Two Bronze Covered Rolls and the Rubber Covered Roll.

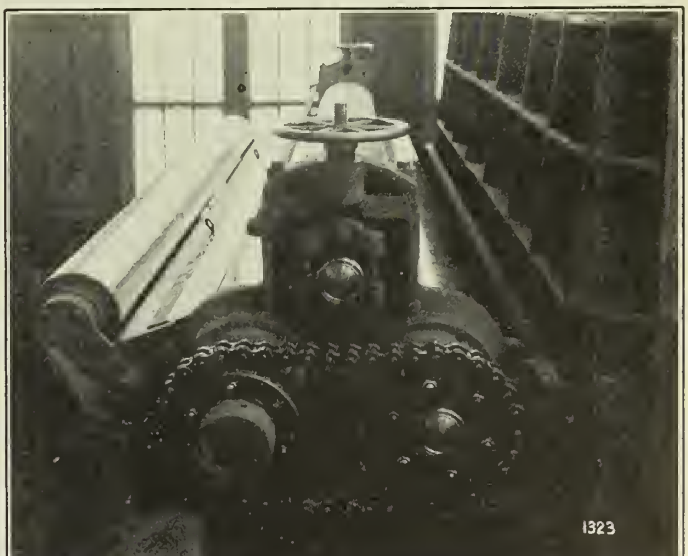

Figure No. 17.—Vacuum Dryer Type 11-48-154, Outgoing Seal Assembled in Place—showing End Frame, Two Bronze Covered Rolls and Rubber Covered Roll with Lifting Device.

as on any other type of dryer. The delay is not long. This vacuum dryer at Kenogami has run for a period of 37 hours without a break of any kind, and whole weeks have been run when there has not been any break or lost time traceable to the dryer. An over-all machine efficiency of 95 per cent was maintained for a full week's run.

Steam Efficiency

A carefully calibrated flow meter has been installed and measures the steam to the vacuum dryer, and test runs showing as high as 97 per cent thermal efficiency have been made. This is calculated from the formula given in the writer's previous paper, "Thermodynamic Comparison of Paper Drying Methods."* This means a higher efficiency than 97 per cent when compared against the standard paper machine dryer. It is regretted that an official steam test cannot be included herewith. It had been planned to run such a test, but paper was needed by the mill and as yet this test has not been made. In making such a test, samples of paper from both the wet and dry end have to be taken, and the paper has to be broken when the wet samples are taken. To get an accurate test, these samples have to be taken frequently, and the production of the machine suffers accordingly.

Just before the vacuum dryer was installed, an official, carefully run, test was made using the original dryer section so that a comparison could be made of the performance of the paper machine before and after the installation of the vacuum dryer. This test was run for a period of two weeks, and the average pounds of steam from and at 212° F. to dry one ton of paper was 9,540. A similar calculation based on readings from the steam flow meter show the vacuum dryer to be using only 5,370 lbs. of steam to do the same work. Or

9,540−5,370=4,170 lbs. of steam saved per ton of paper dried.

4,170÷9,540=43.8 per cent saving in steam.

These figures, as stated above, are only approximate in the case of the vacuum dryer, as no official test has as yet been run and the condensate from the dryers was not weighed. The steam was, however, measured by two steam flow meters in series on the line of steam going to the vacuum dryer and the average readings assumed to be correct. The two readings varied only slightly, and there is every reason to believe that the average of these very nearly represents the actual steam going to the vacuum dryer.

Another indication of the saving of steam is shown by the fact that with the old dryer section all the exhaust steam from the engine, plus 35 per cent of live steam, were used to dry the paper. With the vacuum dryer, all of the exhaust steam could not be used, and some of it is blown to the hot well and no live steam is used. The old dryer section was also supplied with a large quantity of heated air from the machine room, while the vacuum dryer does not use any heated air.

10	0.4166	0.3333	0.2777

The old machine ventilators over the dryer sections have been boarded up and practically no ventilation is used since the installation of the vacuum dryer.

In preparation for an official test of the vacuum dryer, a motor has been installed to run the entire paper machine, and it is proposed to weigh all the condensate and thus get accurate data rather than trust to steam flow meters. With the engine driving the machine the quantity of exhaust blown to the hot well would have to be condensed and weighed, to get accurate results, and this would be difficult to accomplish.

Power

The power required, when all things are taken into consideration, is just about the same as before the installation of the vacuum dryer. The vacuum pumps take about 40 horse power and the condensate pump 2 horse power. To offset this, there was considerable power being used to operate fans to move the air in the ventilating system required when the old bank of dryers were being used. The exact amount of power will be shown as soon as the official test is run.

Space

The old drying section contained thirty-three dryers, each 5 feet in diameter, while the vacuum dryer contains twenty of the same size dryers spaced on slightly closer centres. Also, the original dryer section and the vacuum dryer have a baby dryer and a sweat dryer, in addition to the above. The speed of this particular machine is limited by the wet end to not over 750 feet per minute. The vacuum dryer was designed for and is capable of running at a speed of 1,000 feet per minute. It was made this size so that if at any time later on the wet end was changed the vacuum dryer would be large enough to take care of any additional speed resulting from the change.

Shrinkage of the Paper

Before the installation of the vacuum dryer, the paper shrank just slightly over two inches in width in going from the last press to the calendar stack. Since the installation of the vacuum dyer, this shrinkage is just slightly under one inch, or almost exactly one-half of what it shrank before. This should produce a stronger and better sheet of paper.

In the design of this particular vacuum dryer, only one top and one bottom dryer felt were included. The dryers were all connected together with standard dryer gears and no provision made for any adjustment of the draws of the sheet of paper between dryers. A new type of drive has been since brought out, a good example of which is the drive used on the dryer sections of the Ste. Anne Paper Company, Limited. In their design an individual motor drives only the first two dryers, and the torque supplied to the following dryers can be varied by a rheostat on separate motors that again each drive only the next two following dryers. In another design of the vacuum dryer there will be an individual motor for each dryer. The dryer section will be split into two sections, with two top and two bottom dryer felts and felt dryers put on the first top and first bottom dryer felts. This will allow the paper to pass through the dryer without being drawn so tight between the dryers. These draws can then be adjusted and a much better condition will exist, in that the paper will be stretched less and made still stronger. Where the dryer sections are split, slack can definitely be put into that draw as well as a control of each draw by the rheostats on the individual motors.

The ideal drive would be to have individual felts on each dryer cylinder and an individual drive on each dryer, and then control could absolutely be had of each draw.

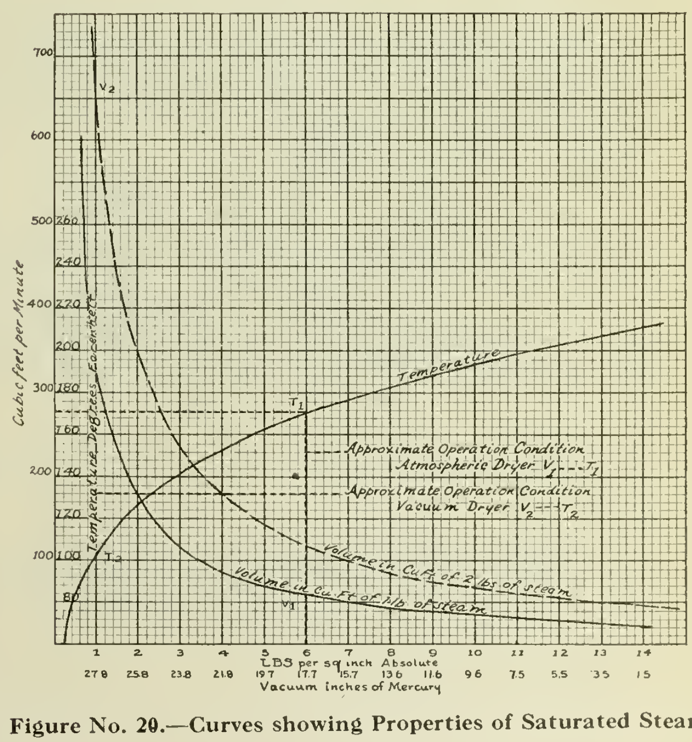

Figure No. 20.—Curves showing Properties of Saturated Steam.

This, however, is much too complicated and out of the question in the case of a modern high speed newspaper machine.

In the vacuum dryer at Kenogami, the draws are tighter than necessary. In the opinion of the writer, this is definitely reducing the strength of the sheet of paper. The paper should test considerably stronger than paper dried in the older dryer sections. At the present time, work is being done on this particular phase of the drying operation. The paper is now testing just about the same as the rest of the paper in the mill, but results so far obtained give good assurance that eventually the vacuum dried paper will be considerably stronger than paper dried in the standard manner.

A very compact worm gear drive has been designed for future installations of vacuum dryers. This comprises a separate motor driving through a worm gear direct to each dryer. The motors are solidly mounted on the back main side frame of the vacuum dryer and the worm drive so located that the back side of the dryer is available for opening windows opposite *all* the draws of the paper from dryer to dryer. This drive does away with the large gears on the present drive which, at the high speeds contemplated in future dryers are not safe due to the peripheral speed of these gears being too high. Also, the new drive is entirely enclosed and it is possible to work around the back side of the dryer without danger. The drive is so designed that the various motors and worm gears can be coupled together in any combination desired. All the bottom gears can be direct connected, or the top gears if so desired, in which case the motors act as boosters for the first motor on the line which is electrically interlocked with the main drive. Some engineers and paper makers will say that this is carrying the flexibility of the drive too far, but the writer is of the opinion that this is not true. Before the advent of high speeds, any drive was good enough, but to-day, when high speed and efficiency are demanded, too much attention cannot be given to matters of this kind. Worms and gears of extreme accuracy must be used, and if these are properly mounted and originally designed for a large overload they will not give any trouble and make the drive as smooth and quiet as possible. A ratio of worm and gear must, of course, be selected that will over-run or coast.

A preliminary drawing of such a drive is shown to more fully explain what is meant. Incidentally, every other motor on either the top or bottom line of the drive may be omitted and a piece of shafting with coupling on each end substituted for the motor if desired.

Results obtained from the dryer drive on the paper machines at the Ste. Anne Pulp and Paper Company, Limited, fully justify a drive such as has been described above. It should be remembered that a vacuum dryer of equivalent capacity to their dryer would only require half as many dryers, and with one motor for each dryer there would only be the same total number of motors that they now use and obtain twice the flexibility.

The writer prefers worm gears rather than small spur gears, not only because of their compactness and silence, but because it is possible to clean up the back of the machine and make it possible for the machine crew to make some use of the back side of the dryer in the ordinary operation; such, for instance, as removing broke.

While refinements, such as this type of drive, the use of modern type of roller bearings, etc., add considerably to the cost of paper machines, they are nevertheless justified by the modern demands made by the paper makers. Paper machines capable of running 1,200 and 1,400 feet per minute are now regularly specified, and if the machinery builder is going to meet this demand he must resort to refinements of this nature. The purchaser must in turn expect to pay the additional cost. Speed has always been an expensive article to purchase, and speed in a paper machine is no exception to this rule.

It is an expensive matter to have to shut down a modern high speed paper machine to make repairs or adjustments. The product, namely, 110 tons of paper at $65 per ton, is worth $7,150 per day, or approximately $298 per hour. Also, a large amount of capital investment and labour charges are continuing at their regular rate and no paper is being produced. With these things in mind, the machine builder is forced to more modern designs, which are more expensive. Still, the paper maker objects to the additional cost of the paper machine, particularly so when business is not good and profits are small. Economies of operation, therefore, become more and more important and the paper maker now, more than ever, is searching for machinery that will make economies possible.

Conclusion

This paper has shown the saving of steam in one particular case brought about by the use of the vacuum dryer. The paper machine at Kenogami was better than the average paper machine before the installation of the vacuum dryer, and still a saving of steam of 43.8 per cent is indicated by the substitution of the vacuum dryer. Savings due to the cost of felts can only be estimated. In a vacuum dryer, the felts are only half as long as on a standard dryer section of the same capacity, and they operate at an average temperature of less than 110° F. against, say, 170° F. on a standard dryer. They run dry, not wet, due to the fact that vapour formed under them is always slightly superheated. It is estimated that dryer felt costs per ton of paper in the case of the vacuum dryer will be one-fourth to one-third of the cost in the case of the standard dryer section. Actual data on this subject will be available only after sufficient time has elapsed to get such data at Kenogami.

Considerably less floor space, hence building cost, is required for a vacuum dryer. The distance from the wet end to the dry end of the paper machine is much less, making the machine easier for the machine crew to operate. The humidity and heat of the machine room is eliminated and working conditions very greatly improved.

Study of the Flow of Gases in Reverberatory Furnaces

With a Short Account of the Chemistry of the Reverberatory Smelting of Copper Concentrates

W. K. Thompson, A.M.E.I.C.
New Brunswick, N.J.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 14th to 16th, 1928

The object of this paper is to present methods of investigation into the manner of working of reverberatory furnaces.

The type of furnace studied is a long furnace, shown in plan and vertical section by figures Nos. 1 and 2. This form of furnace is the standard type used in western American copper smelters. In considering the gaseous atmosphere of a furnace of this type, regard must be taken of the gas evolved from the charge on the hearth. Some who read this may not bear this fact in mind and may be puzzled at the difference in the products of combustion of fuel oil and the exit gases of copper smelting furnaces. Everything set forth below is directly traced back to first principles. Any blind reliance on formula tends to distort the judgment and gives rise to error. A correspondent in one of the recent issues of " Power " cites the case of a consultant who rejected certain gas analyses because their total contents of CO_2, O_2 and CO did not total to 20 per cent. The fuel used happened to be fuel oil and not coal.

As principles are always better understood when referred to concrete examples illustrating their operation, in endeavoring to describe the movement or circulation of gases in a furnace results of actual measurements will be given.

In the design of a furnace of the type shown in figures Nos. 1 and 2, as regards the interior shape, there are two things to consider: (1) a proper size of combustion chamber at one end of the furnace, and (2) the correct ratio of furnace width to depth at the discharge end or waste gas port, that is, the proper height for a given width of furnace, so that a lively flow of gas may take place along the hearth. This will be discussed under the head of " Reverberatory furnaces considered as hydraulic reservoirs " below.

Chemistry of Reverberatory Smelting

For the better understanding of the computations which follow, as well as for its general interest, an explanation of the smelting process itself is given. Coarse ore is suitable for blast furnaces, but fine ores have to be treated in reverberatory furnaces. In the former, fine ores or furnace products have been smelted as briquets or sintered with coarser ore. Generally, fine ores are smelted in reverberatory furnaces. Flotation concentrates previously dried or roasted in Wedge mechanically rabbled furnaces are charged to the reverberatories at a temperature of 450° F. when the material has only been dried, or 850° F. when it has been roasted. The furnaces were not originally intended to serve as roasters, consequently the charge is not

as thoroughly rabbled as is usual in Wedge roasters. The fuel consumption is 3.93 gallons of oil per ton of calcine produced, and when drying only is carried on more fuel is required. As the charge is fine, the sulphur is oxidized at the surface only, hence when the fire is shut off the charge cools rapidly. Electrically driven cars convey the hot concentrate or " calcine " to the furnaces. These cars have a capacity of about 20 tons. The cars dump into hoppers near the bridge wall of the furnace. The material charged into the furnace is dropped through the roof at intervals along the sidewalls. A drag chain operating in a rectangular housing, (see figure No. 3), conveys the " calcine " to the various charge pipes through which it drops. The " calcine " lies in a bank against both sidewalls, and as it smelts

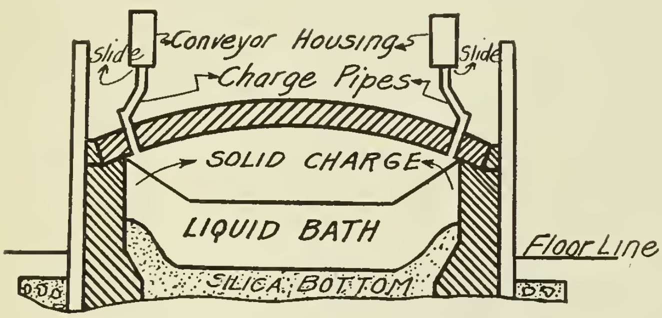

Figure No. 3.—Cross-section near Bridge Wall.

it runs down to the centre of the furnace, forming a liquid bath of two layers. The top layer is the slag and the bottom layer the matte. The chemical composition of a typical " calcine " is, copper 31 per cent, silica 11 per cent, alumina 5 per cent, iron 21 per cent, lime 1.5 per cent and sulphur 23 per cent. The upper layer of the liquid bath, the slag, has the following composition:—copper 0.59 per cent, silica 33.8 per cent, alumina 10.3 per cent, lime 7.4 per cent, sulphur 0.4 per cent, ferrous oxide 43.9 per cent. The matte layer of the bath contains practically all of the copper, its composition being, copper 41 per cent, iron 31 per cent, sulphur 25 per cent. Thus it will be seen that the non-metallic minerals have been formed into a slag carrying with it a certain quantity of iron. A concentration of the copper bearing minerals has taken place by virtue of a partial elimination of sulphur and oxidized iron entering the slag.

The material balance, using monthly figures and reducing them to a daily basis, is given below:—

The above charges and products represent the work of two furnaces.

A typical converter slag has the following composition:—Cu_2S 3.75 per cent,* FeS 2.07 per cent,* FeO 45.00 per cent,* Fe_3O_4 20.7 per cent, AL_2O_3 5.40 per cent, SiO_2 22.40 per cent. The specific gravity of converter slag is 4.24.

* Calculated.

Mattes contain about 7 per cent Fe_3O_4 and furnace slags about 5 per cent. Matte has a specific gravity of 4.92 and furnace slag 3.27. Magnetite† may contribute to the loss of copper in the slag, for it appears to aid in forming a blanket on top of the matte and under the slag, thus preventing the suspended matte particles in the slag from penetrating to the matte bath.

The slag, being a waste product, is skimmed off and conveyed to the dump. The matte is tapped from the furnace into ladles and poured into Bessemer converters. Silica is added for a flux and the charge is blown to an impure bullion known as " blister copper." During the Bessemerizing, iron and silica form a slag. As this slag carried 2 to 3 per cent copper, it is poured in the liquid state into the reverberatory furnaces for settling out the values. This Bessemer slag provides iron for fluxing the siliceous portion of the solid charge in the furnaces.

In the smelting process, 30 per cent of the sulphur in the charge is oxidized or about 138 pounds per ton of " calcine " treated. Most of the sulphur oxidized is first distilled from the charge and then combines with oxygen according to the reaction:—

$$S + O_2 = SO_2 \ (1)$$

After the distillation of the volatile sulphur, we have the following reaction:—

$$14\ FeS + 21\ O_2 = 14\ FeO + 14SO_2 \ (2)$$

The ferrous oxide formed in reaction (2) enters the slag.

Metallurgical calculations indicate that 65 per cent of the sulphur oxidized is accounted for by equation (1) and

† Specimen taken from a furnace bottom contained 8 per cent insoluble matter and had a specific gravity of 4.99.

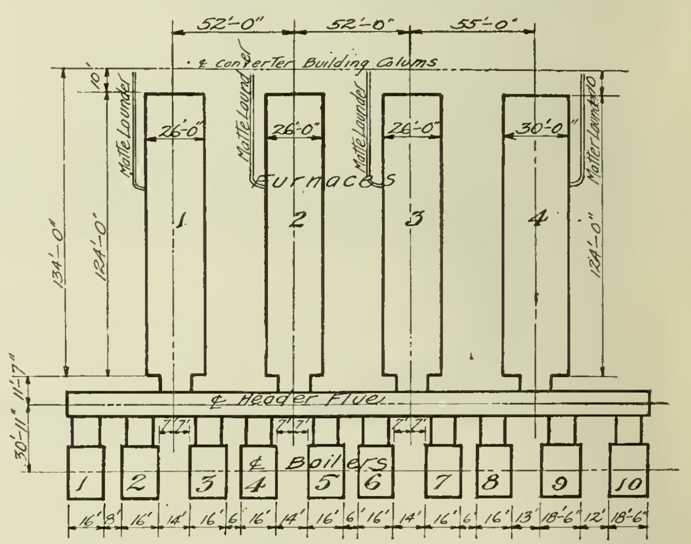

Figure No. 4.—General Plan showing Reverberatory Furnaces and Boilers.

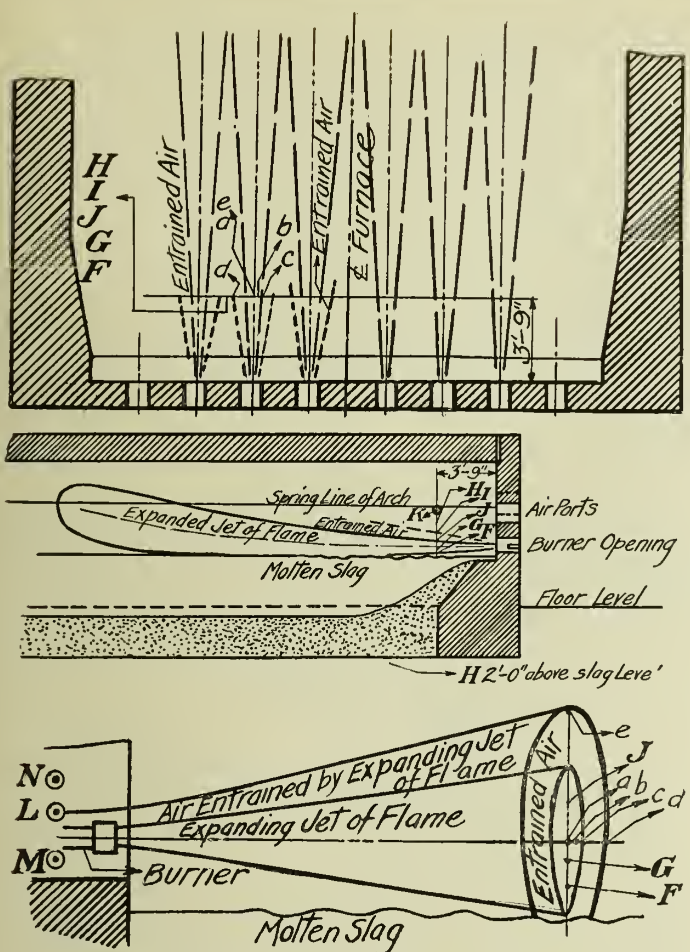

Figures Nos. 5, 6 and 7.—Extended Jets of Flame.

35 per cent by equation (2). The amount of oxygen required is 1.17 pounds per pound of sulphur oxidized. Small amounts of iron are expelled possibly as ferric sulphate and pass off as fume.

When the concentrate is merely dried before smelting, 30 per cent of the sulphur in the charge is oxidized. When the concentrate is partially roasted, less oxidation of sulphur takes place in the reverberatory furnaces.

Combustion of Oil

The furnaces are oil fired. About 35 per cent of the heat value of the oil is recovered as usable steam in waste heat boilers. The oil used has the following composition:—hydrogen 10.2 per cent, carbon 84 per cent, sulphur 3.22 per cent, oxygen 1.29 per cent, nitrogen 0.3 per cent, ash 0.06 per cent, moisture 0.93 per cent. This oil, when burned in the furnace, gives the following products per pound, including the gas evolved from the charge:—

Water vapour	18.3 cu. ft.
Carbon dioxide	25.94 " "
Sulphur dioxide	4.69 " "
Nitrogen	156.29 " "
Total	205.22 cu. ft.

The volumes are given under standard conditions, i.e., 0°C and 760 mm. of mercury pressure.

The figures obtained by an evaporation test are here quoted. They are not typical of present conditions, for the heat recovered as usable steam is slightly over 40 per cent of the heating value of the oil burned in the furnace. The results are for an eight-hour test. The exit gas from the furnace tested* passed into two waste heat boilers.

Comparison of Volume of Air Consumed per Pound of Fuel, and Products of Combustion

If just enough air be used to burn completely one pound of oil of the composition stated above, the gaseous products will occupy a volume which is 9.1 cubic feet in excess of that of the air consumed. Bearing in mind that the oil contains 0.102 pounds of hydrogen, occupying in the gaseous state 18.2 cubic feet, (at 0°C and 760 mm. pressure), we have,—

$$2 \text{ volumes} + 1 \text{ volume} = 2 \text{ volumes}$$
$$2H_2 + O_2 = 2H_2O$$
$$18.2 \text{ cu. ft.} + 9.1 \text{ cu. ft.} = 18.2 \text{ cu. ft.}$$

and the increase in volume as between air and products of combustion is evident.

In making analyses of furnace gases the total percentage of the oxide gases does not come to 20.7. Owing to the presence of hydrogen in fuels, there is an apparent

shrinkage, bringing the total below 20.7 per cent. In figure No. 19 are shown different analyses by the Orsat-Muencke apparatus corresponding to different percentages of excess air. Numerical values in cubic feet per pound of fuel are given in table No. I.

High Pressure Air for Atomizing Oil and Secondary Air for Combustion

For atomizing oil, air at a pressure of 12 pounds per square inch is used. The volume consumed is about 2,000 cubic feet per minute. If 70 pounds of oil be burned per minute, 11,600 cubic feet of secondary air per minute are necessary for combustion. This air is admitted through ports in the bridge wall. The air flow inward through these openings is not primarily a function of the furnace draught, but rather of the displacement. This, of course, does not mean that more air will not enter ports of a given area when the furnace draught is increased, but that the air will enter the ports whether there be a draught in the furnace or a small pressure.

Reverberatory Furnaces Considered as Hydraulic Reservoirs

An entirely new conception of furnaces in general has been stated by Professor Groume-Grjimailo of Petrograd. He considers a furnace as a hydraulic reservoir, the flow of the furnace gases being an inverted stream, bounded on the three sides by the roof and two sidewalls. An illustration of this theory is shown by figure No. 21. A model of a copper reverberatory furnace, made on a scale of 9/16 inch to the foot, having a glass side along a plane through the centre, was placed in a glass tank nearly filled with water. After expelling imprisoned air in the high portion of the model, a stream of kerosene, (coloured red by saturating it with iodine), was injected through three nozzles under a pressure of three inches of mercury. The kerosene displaces the water, flowing through the model and out by virtue of its difference in density as compared to water. The lower surface is free and its position depends on the shape of the furnace and the volume of fluid flowing. The water below the kerosene represents stagnant gas in the furnace. However, it does not of necessity follow that the inert gas has an essentially different chemical composition from the other portions of the furnace atmosphere, but rather that it is cooler. Thus, an up draught furnace is not the most efficient type where circulation of the gases is a matter of first importance, for there is always a tendency for the cooler gases to collect along the hearth. The reverberatory furnace with a drooping arch to some extent overcomes the above defect, for by sufficiently constricting the outlet the gas velocity can be made greater along the hearth. This is shown by figure No. 13.

Flow of Air Through Ports in the Bridge Wall and Its Distribution

The velocity of air flowing through ports and burner openings varies over the cross-section. In a port the velocity is greatest at the centre and smallest just at the wall. In a burner opening, the velocity is greatest just above the

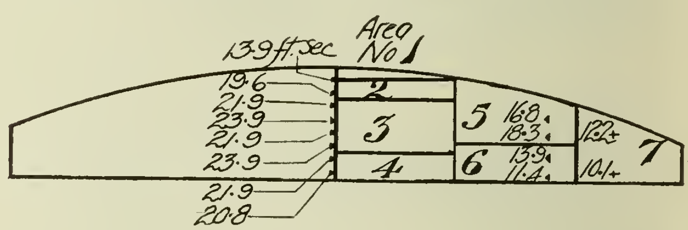

Figure No. 14.

burner. In measuring the velocities in ports and burner openings the central velocity only is read and a coefficient applied to obtain the average velocity. The coefficient of velocity for a burner opening is 0.955 and for the ports and slag openings 0.88.

The velocities of air flowing through different parts of ports and burner openings are shown in figures Nos. 16 and 17 and table No. 2.

Readings were taken inside the furnace with a Pitot tube of the form shown in figure No. 22. A different type of tube was used in the air ports. In taking readings in the furnace, two men work together, one reads the draught gauge and the other handles the tube. The man holding the Pitot tube must wear blue glasses to protect his eyes against the glare. These tubes stand up fairly well; however, they are not held in the furnace long enough to burn up.

The readings were taken in a vertical plane about 3 feet 9 inches inside the furnace from the bridge wall and parallel to it. Unfortunately, temperatures could not be obtained for obvious reasons. The centre of the flame will be cooler than the periphery, as will also be the entrained air. Hence, the velocities cannot be computed, but must be given as inches of water pressure.

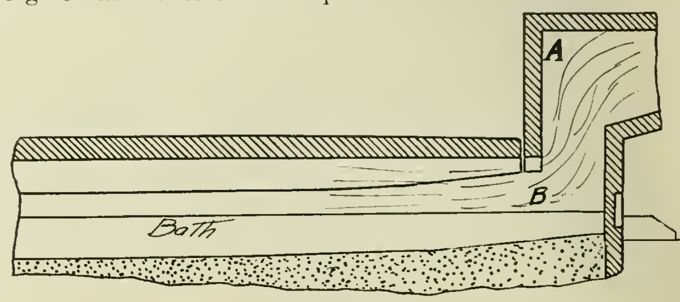

Figure No. 15.

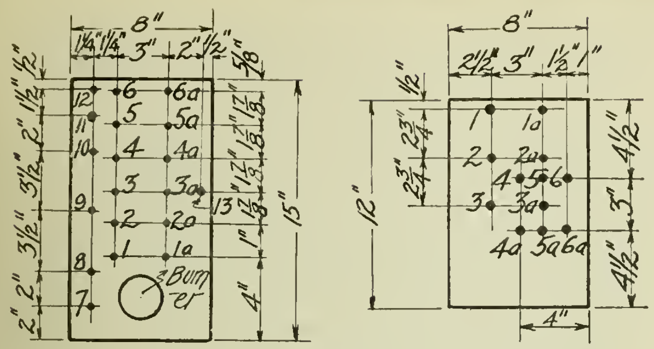

Figures Nos. 16 and 17.—Velocities in Ports and Burner Openings.

After the air enters the furnace the distribution is shown in figures Nos. 5, 6 and 7 and table No. 3. The values shown in columns 2 and 3 of table No. 3 were obtained with Pitot tubes. A study of figures Nos. 5, 6 and 7 and of table No. 3 shows that the air lies as a fluid in a reservoir inside the bridge wall. It moves slowly, wrapping itself around the expanding jet of flame.

At the plane of measurement, (see figure No. 5), the maximum air movement is at the bath or slightly above it. Higher up the movement is somewhat sluggish. The point of lowest pressure in the whole furnace is the centre of the flame.

Measurement of Volume of Gases Flowing Through the Furnace

The discharge of gas at a furnace cross-section is comparable in volume to that of an ordinary river at its flood time. The measurements of velocity can be made with a fair degree of accuracy. This is hot and trying work. Pitot tubes made up of 1/8-inch pipe were used, being inserted in the furnace through openings cut in the arch. These Pitot tubes were compared with a tube obtained from the manufacturers, which was used as a standard. The home made type gave readings corresponding to velocities 1.24 times those obtained by the manufacturer's tube.* The latter was one of the forms that Mr. W. C. Rowse compared with a Thomas electric gas meter.† This particular form gave results 96.8 per cent of the values obtained by the meter.

* Comparison made in cooler gases, with temperatures not greater than 650° F.

† Trans., A.S.M.E., vol. 35, 1913, p. 633.

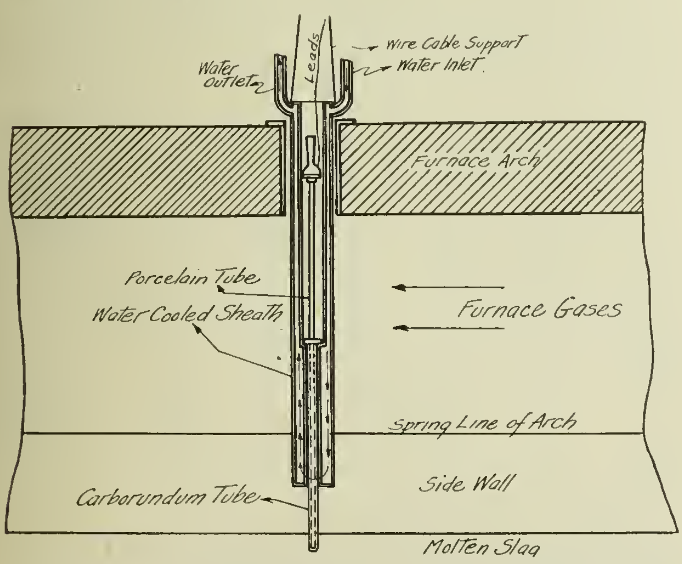

Figure No. 18.—Thermo couple Installation Furnace No. 4.

Now, the rough tube made from 1/8-inch pipe would have a coefficient of $\frac{1}{0.968 \times 1.24} = 0.83$.

The velocities given in figures Nos. 8, 9, 10, 11, 12, 13 and 14 have been corrected by this factor. The form of tube calibrated is shown in figure No. 22. On computing the discharge, (see figure No. 14), the flow is found to be 1,480 cubic feet per second at 670 mm. pressure,‡ and 2,250° F. temperature. Reduced to standard conditions, the discharge is 236 cubic feet per second, (0° C and 760 mm.).

To check this figure, let us calculate the volume of gas flowing from the known rate of fuel consumption. In case the different value here assigned to the volume of the products of combustion of one pound of oil, compared to the value given elsewhere in this article, are confusing, it may be pointed out that the difference consists in the amount of gas evolved from the charge. At the time these velocity measurements were taken the volume of gas produced by burning one pound of oil was 197.73 cubic feet, (0° C and 760 mm.). Of course, a greater volume of gas would exist with the presence of excess air. The fuel consumption was 1.1 lbs. oil per second and the gas contained one per cent of oxygen.* With this amount of free oxygen present there

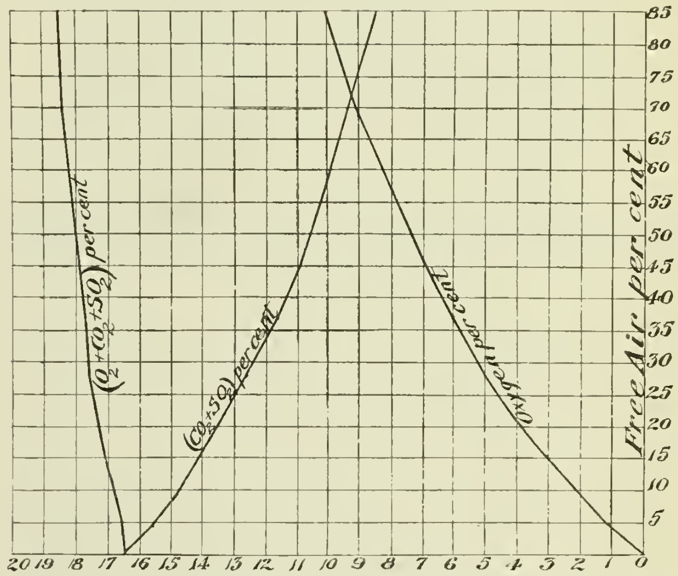

Figure No. 19.—Composition of Furnace Gases with Varying Amounts of Free Air.

Calculated Orsat values based on a fuel ratio of 0.906 barrels oil per ton of solid charge and sulphur oxidation of 30 per cent. These values will vary somewhat with the fuel ratio, lime rock in the charge oxidation of sulphur in the furnace and composition of the fuel oil.

are 197.73 plus 9.05, (excess air), or 206.78 cubic feet of gas produced from burning one pound of oil. Hence 1.1 pound of oil when burned would produce 227.5 cubic feet of gaseous products, which at the furnace temperature and pressure would occupy 1,425 cubic feet.

Flow of Air Into the Furnace

The flow of air into the furnace is confined to the bridge wall. We have not any evidence of air infiltration in the furnace, simultaneous gas analyses in two different locations revealing identical results. This is due to a crust-

‡ At the altitude of the furnaces, atmospheric pressure is 670 mm.

* This figure was obtained by the Orsat-Muencke apparatus. It is higher than the actual value because of the condensation of water vapour in the apparatus.

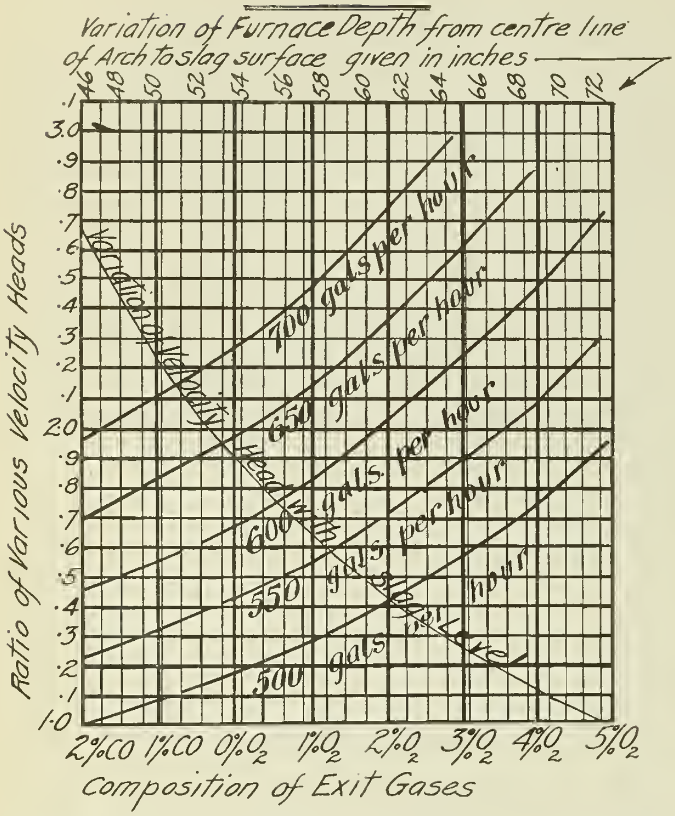

Figure No. 20.—Chart showing Variations of the Force of Velocity Head Required to Remove Furnace Gases Corresponding to Variations in Furnace Depth, Fuel Consumption and Chemical Composition.

ing over of the interior surface of the furnace and the small draught depression within. In general, some leakage at charge pipes in the roof has been found to exist, but it is negligible as to volume. The measurements were taken with a Pitot tube, and the form of tube used was later compared to a standard form and a factor determined, (see figure No. 23). To insure flexibility, a larger number of air ports was provided in the furnace bridge wall than was needed for the existing fuel consumption. The air flow into the furnace is controlled by partially closing up the ports by loose brick or removing them as desired. The opening for the introduction of converter slag has been changed from the furnace roof to the bridge wall.

The volumes given below are computed to standard conditions, viz., 0°C and 760 mm. pressure.

6 burner openings..............	4.85 sq. ft.	103.5 cu. ft. air per sec.
Airports	2.24 " "	34.6 " " " " "
Opening in bridge wall for converter slag launder..........	3.98 " "	54.3 " " " " "
Blast for atomizing the oil....		32.2 " " " " "
Total volume of air entering furnace through the bridge wall		224.6 " " " " "

The measurement of air temperatures in the ports and burner openings presented some difficulty. Approximate data were secured by a base metal thermocouple surrounded by a metal housing covered by asbestos. The air flow into the port was not seriously impeded by the housing, which served to protect the thermo couple from the radiant heat of the flame. The device is shown in figure No. 25. The form of Pitot tube used in the blast pipe is shown in figure No. 24. The tube extends across the whole internal diameter of the pipe. The average velocity pressure over the whole cross-section will be read on the manometer.

Furnace Temperatures

The apparatus used is shown by figure No. 18, and the results are given in table No. 4. The heat transfer at this point is by convection of the hot gases. The difference between the temperature of the slag and the gas stream was 120° F. At this point, a reading with the Fery total radiation pyrometer on the slag, sighting through the roof, was 2,130° F., while the reading with the thermocouple was 2,125° F. Probably heat transfer by radiation takes place from the roof to the slag bath at this point.

Temperatures have been observed with a Fery total radiation pyrometer on the interior walls of the furnace at three different positions.

Sighting through an Opening in the Side Wall		Sighting through an Opening in Uptake Wall	Bath 100 ft. from The Bridge Wall*
37 ft. from Bridge Wall	73 ft. from Bridge Wall		
2480°F	2360°F	2185°F	2210°F

Furnace conditions at the time of making the observations were:—fuel burned, 430 barrels per day, (1 bbl. = 335 lbs.); solid charge smelted, 638 tons; composition of the gas stream, (sample taken 100 feet from the bridge wall), CO_2 and SO_2 16.2 per cent, O_2 0.8 per cent, CO none. The furnace at this time was being forced.

The temperatures taken with the Fery pyrometer are the temperatures of the furnace walls. It is probable that the differences in temperature between the walls and the gas stream at the three positions given above, viz., 37 feet, 73 feet from the bridge wall, and the furnace uptake are 130°F., 115° F. and 75° F. respectively.

Draught Depression Necessary to Remove the Products of Combustion

By reference to figure No. 1, longitudinal section, it will be seen that the gases in leaving the furnaces pass through vertical uptakes. *Here it has been noted by the writer that the velocity head of the flowing gas, (as computed in inches of water pressure), equals about 70 per cent of the draught depression. Within limits, the draught can be adjusted to changed conditions by applying the factors given in figure No. 20.*‡ In applying these ratios, the press-

Observed Data				Computed Data

* Sighted through the furnace roof.

‡ The factors given in figure No. 20 are ratios of velocity heads. Since the draught is 1.43 times the velocity head of the gases, we can use the factors of figure No. 20 as draught ratios also.

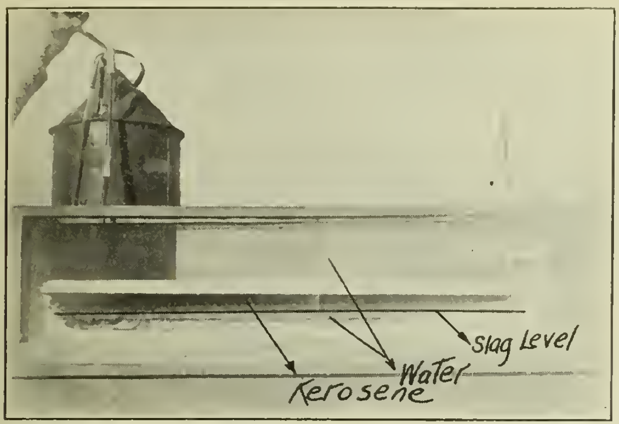

Figure No. 21.

ure of the fuel oil, volume of atomizing air and area of ports in the bridge wall must be kept constant. A few examples are given below from a series of observations extending over thirty days:—

The values listed in column 6 should be constant. For instance, let us take example No. 3 and calculate a draught to give an exit gas containing one per cent oxygen for a fuel consumption of 600 gallons of oil per hour. More gas will be generated, and from figure No. 20 we find that the increase in velocity head will be $\frac{1.77}{2.11}$. If one per cent oxygen be present, as the computation calls for, the velocity head will be less. This decrease is expressed by the ratio $\frac{1.82}{2.11}$. The computation is completed by multiplying the observed draught by the two factors,—

$$0.090 \times \frac{2.11}{1.77} \times \frac{1.82}{2.11} = 0.093$$

The method of computation assumes a constant relationship between draught and velocity head. The assumption is a rough approximation, as will be seen by referring to column 5 of the table above. The relation between draught and velocity head will vary with differences in level of the furnace bath. For a pronounced decrease in the cross-sectional area of the furnace at the verb arch, i.e., just under the uptake, more draught depression will be necessary. If this area be less than the uptake, the flowing gas stream will probably be smaller in cross-section than the uptake shaft. If it were possible to record the difference in draught between points *A* and *B*, figure No. 15, the ratios in figure No. 20 would apply directly. The draught difference between these two points is approximately equal to the velocity head of the flowing gases.*

The author has heard of a case where the throat of the furnace, (opening at entrance to the uptake), was enlarged by radically increasing the depth from arch to the bath. The roof was given an upward slope towards the uptake. The experiment had the disastrous result of freezing the furnace at the end so that slag could not be tapped. This result can be explained as due to stagnant cooled gases collecting at this part of the hearth.

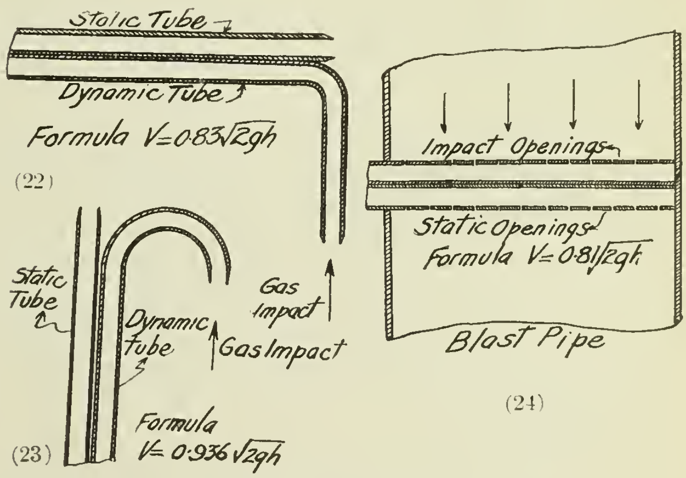
Some metallurgists are of the opinion that a longer flame increases the smelting zone of the furnaces. Generally, however, the practice has been to carry a flame about one-quarter to one-third the length of the furnace. In the case of the longer flame, the temperature of the flame will be lower than that which would be obtained with a shorter flame, i.e., for equal fuel consumption. Some means of determining directly the heat radiated by a flame would be of great benefit in solving such problems.

Figure No. 11 shows the velocities in a furnace operated with a relatively high draught. It will be noticed that the maximum velocity lies well above the slag level. In figure No. 12 the furnace, owing to a shortage of draught, was working under a pressure, and the maximum velocity of the gases lies along the slag. Similarly, in figure No. 13, the maximum velocity lies along the hearth, although the furnace is working under an ample draught. In the case of the furnace shown in figure No. 13 the velocity distribution is due to constriction.

In connection with heat transfer, if we might assume the same temperature difference between roof and slag surface and between slag surface and flowing gases in the case of, say, figures Nos. 11 and 13, the heat transfer will be greater in figure No. 13 than in figure No. 11, the transfers being approximately in the ratio 1.19 to 1 as regards the heat transmissions by convection from the gases to the bath in the two furnaces.

Most of the charge smelted in the furnace is consumed in the first 35 feet of the furnace length. While the matte and slag formed, say, from a pound of charge contain 795 B.t.u., we know from temperature measurements that the heat absorbed from the hot gases in the remaining portion is only 49 B.t.u. per pound of charge smelted. During the process, chemical reactions occur which liberate a large amount of heat. This amounts to 367 B.t.u. per pound of charge, leaving 428 B.t.u. to be supplied by the combustion of fuel. Evidently $\frac{428 - 49}{428} \times 100 = 88$ per cent of the heat is received by the charge in the first 35 feet of furnace

*This is merely another way of saying that the rate of gas flow is proportional to the difference in hydrostatic head between points *A* and *B*.



Figures Nos. 22, 23 and 24.—Measurement of Velocity Pressure.

Velocity pressure is the differential pressure between the static and dynamic tubes of the Pitot tube.
Pitot tubes $V = c\sqrt{gh}$

$h = 5.2\,\frac{p}{w}$ where p = velocity pressure in inches of water.

c = a coefficient, w = weight 1 cubic foot gas. The weight of 144 cubic inches of water is 5.2 pounds.

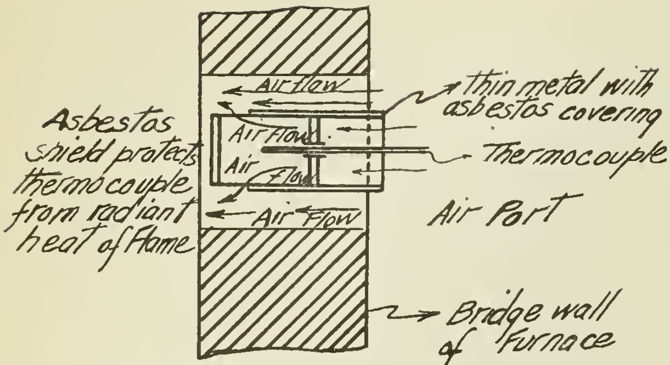


Figure No. 25.—Measurement of Secondary Air Temperature at Bridge Wall.

length. This is the flame swept portion. The approximate overall thermal efficiency of the furnace may be arrived at as follows:—heat value of oil used per pound of charge, 2,360 B.t.u., (0.127 pound of oil at 18,500 B.t.u. per pound); heat received by the charge 428 B.t.u.; hence thermal efficiency is $\frac{428}{2360} \times 100 = 18$ per cent. This comparatively small utilization of heat is due to the high working temperature within the furnace. The temperature difference between the hot gas or flame and the liquid bath is not great, consequently, the gases leave the furnace carrying away practically all the heat generated.

Conclusions

(1) The reverberatory furnace as at present operating consists of two zones: a smelting zone and a settling zone.

(2) No draught depression is necessary in the uptake. The products of combustion will of themselves flow out of the furnace. The author, in operating a small reverberatory furnace which was not connected to a stack, has noticed a perfect evacuation of gas while a pressure existed in the upper portion of the furnace. The plane of atmospheric pressure in this experimental furnace was very close to the hearth.

(3) A high gas velocity along the hearth means a high rate of heat transmission there. An objection to high draught is the fact that the gases flow with greatest rapidity in the centre of the furnace, (see figure No. 11), and the cooler gases move at a lower speed along the hearth.

(4) The increased rate of smelting of hot calcine is not solely due to the difference in heat content of the calcine charged. The hotter charge has a flatter angle of repose, and an effect noticed with hot calcine is that it spreads somewhat towards the centre. This statement does not apply generally, but only with side charging, as illustrated by figure No. 3.

(5) Recent experience in reverberatory smelting seems to indicate that with the burning of larger quantities of oil in unit time the fuel economy is increased. This emphasizes the relation of heat transfer in the two zones of the furnace, as outlined above. Bearing in mind the immense heat transfer taking place by radiation, it would seem advantageous to increase the temperature of the flame to a maximum, and push the charging of the furnace. The extra heat developed in the furnace would not necessarily increase the temperature of the uptake, but would exert itself chiefly in the liquefying of the material charged.

(6) The burners should be placed well above the bath, and pointing down, say 10°, so that the bottom of the flame comes within a foot of the bath. The combustion chamber should be high enough to avoid having the flame lick the roof. Beyond the tip of the flame the roof should be depressed to force the gases down to the bath.

The author is indebted to Mr. H. W. Mossman, an associate, for his kind co-operation and assistance in making observations to obtain certain portions of the numerical data used in this paper.

Draught and Velocity Head and Force and Velocity Head*

The paper is written from the standpoint of hydraulics and hydrostatics.

Coming back to Newton's laws, we see that for a given mass a body is accelerated in direct ratio to the applied force. This holds in both a positive and negative sense. Thus, when a body is brought to rest a retarding force is applied that is proportional to its velocity. When inserting a Pitot tube in a gas stream, we bring a small portion of the gas to rest, i.e., rob it of its speed. The impact is measured by a manometer. The result, when expressed as feet of gas, is called the velocity head, although it is also spoken of as such in inches of water.

The gas has, say, a velocity head of 0.10 inches of water. If the specific weight of the gas be, say, 0.02 pounds per cubic foot, the velocity head of the gas will be $\frac{5.2 \times 0.10}{0.02} = 26$ feet. The velocity will be

$$v = \sqrt{64.32 \times 26} = 41 \text{ feet}$$

per second. A body falling 26 feet attains a velocity of 41 feet per second when acted on by gravity. It possesses a momentum of, say, $0.02 \times 41 = 0.82$ foot-pound-second units, (if we conceive of one cubic foot of gas in a weightless container), falling 26 feet. If the gas flow be stopped, this momentum is brought to zero and by a certain force, hence the force has been originally applied. It is equivalent to the loss in static pressure from position to position in the furnace less the friction. That is why velocity head and force are used synonymously in figure No. 20.

If we notice the draught to be, say, 0.10 inch of water and the velocity head, say, 0.07 inch of water and this relationship exists in a rough way with a fair degree of consistency, there can be no objection to making one the measure of the other. That is the method used in this paper in computing draughts by applying the ratios in figure No. 20.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI JANUARY 1928 No. 1

Ask the Member Who Has Attended

It is not sufficient to-day that a theory is sound,—everything must be put to the test before acceptance. This applies to the new piece of machinery, the new method of construction, and, in fact, to all inventions and discoveries. It also applies to affairs affecting the individual, such as his membership in various organizations and his subsequent interest in their activities.

The test so far as the Annual Meeting of The Institute is concerned has often been made,—in fact, it is made each year,—and to-day these meetings are acknowledged as among the most interesting and valuable to the individual member of any such assemblies held by technical associations.

This is the verdict of those who have attended recent Annual Meetings of The Institute,—ask the member who has attended.

The question of the value of membership in The Engineering Institute of Canada was dealt with in this column in the December issue of the Journal, and the article quite naturally included mention of certain benefits to be derived from attendance at the Annual General Professional and other Professional Meetings, stressing particularly the value of close association with other members of the profession and the resultant bonds of friendship which are established.

This is one valuable feature of our meetings, but, valuable as it is, the holding of a meeting with friendly intercourse as its primary purpose would not completely fulfil the objects of an engineering society. The Annual Professional Meetings of The Institute have as their main purpose the interchange of professional knowledge among the members, and to this end papers on important subjects of current interest, carefully prepared, printed in advance, briefly outlined by the authors at the sessions at which they are presented, and thoroughly discussed, occupy a considerable part of the time of the meeting.

The papers to be presented at the meeting in Montreal in February cover a wide range of subjects of interest to members engaged in nearly every branch of the profession. Two of these papers appear in this issue of the Journal; others will be published in the February number, while the remaining papers will be printed in advance and published in a later issue. In this way all papers to be presented and discussed at the February meeting will be available in advance, so that members will have ample time to prepare their views in the form of oral or written discussions on the various papers.

Discussion of Annual Meeting Papers Invited

The papers on the Uniflow Steam Engine, by A. E. Allcut, M.E.I.C., Associate Professor of Mechanical Engineering, University of Toronto, and the Flow of Gases in Reverberatory Furnaces, by W. K. Thompson, A.M.E.I.C., of New Brunswick, N.J., which appear in this issue of the Journal are to be presented at the Annual General Professional Meeting of The Institute, and are published in advance of the meeting for the purpose of eliciting discussion, either oral or written. Written discussions should be forwarded to the Secretary so soon as possible, so that in the absence of the authors of such discussions, arrangements can be made for their presentation.

Further Proposed Amendments to By-Laws

Certain amendments, proposed by Council and by corporate members, were published for the information of corporate members and in accordance with Sections 75 and 76 of the By-laws, on pages 532-533 of The Engineering Journal for December 1927.

In accordance with the same sections, the following further amendments proposed by Council are now communicated to corporate members, prior to their submission foi discussion at the Annual General Meeting.

Section 52.—Subsection *a* (Management of Branches).

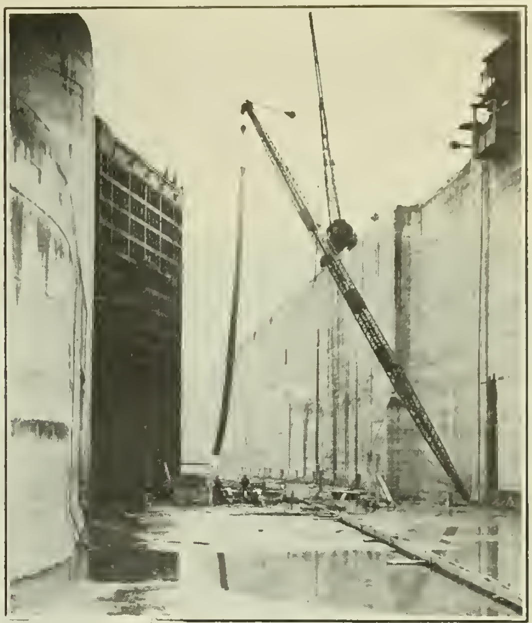
In order to authorize the present practice in a number of branches, it is proposed to add to this subsection the words:—" The Secretary and Treasurer may, as an alternative, be appointed by the Executive Committee, instead of being elected by the members of the branch."

Section 76.—Second paragraph (Amendments to By-laws).

The present wording of this paragraph apparently does not permit any modification of, or alternative to, proposed amendments during their discussion at the Annual General Meeting. Such proposed amendments must now go out to letter ballot exactly as submitted to the Annual Meeting by Council, or as draughted by corporate members.

Council now suggests that in order to permit voting on changes suggested during discussion, the following amendment be made to the second paragraph of Section 76:—

Delete all words in the first sentence after the word " meeting " in the second line and insert a semicolon, then add the words " The members there present may propose modifications or alternatives to any of the proposed amendments, and these modifications or alternatives, as well as the proposals submitted by the Council, shall be printed on a letter ballot to be submitted to the corporate membership of The Institute."



The Annual General *and* General Professional Meeting

of THE INSTITUTE *will be held in* MONTREAL *on*

TUESDAY, WEDNESDAY *and* THURSDAY FEBRUARY 14TH, 15TH *and* 16TH, 1928

With headquarters at THE WINDSOR HOTEL

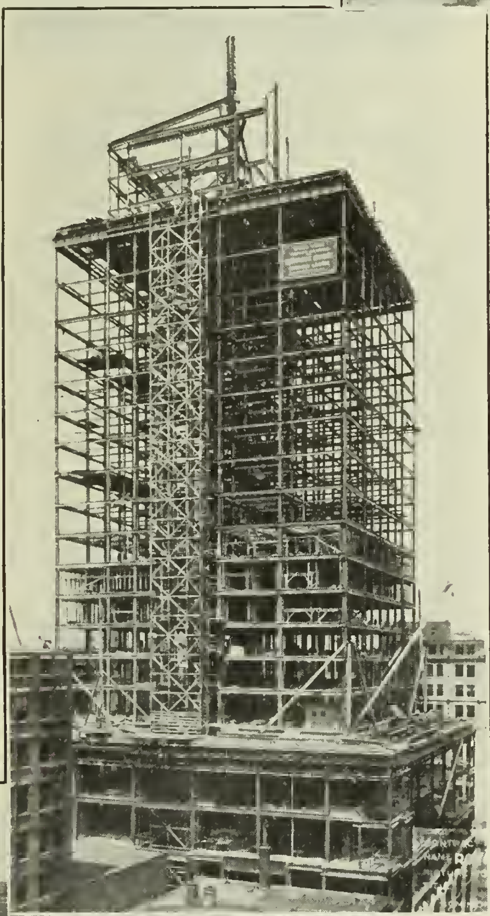
THE accompanying outline of the programme gives an idea of the general features of the meeting and of the work done by the committee of the Montreal Branch in charge of arrangements in providing features of interest to all branches of the profession. As announced in the December issue, His Excellency The Governor-General has graciously consented to attend the Annual Dinner and to address the members on that occasion.

Papers to be Presented and Discussed

"Chippawa Creek Syphon Culvert of the Welland Ship Canal"; "Lock Gates of the Welland Ship Canal"; "Movable Bridges of the Welland Ship Canal"; "Foundations of the Royal Bank Building, Montreal"; "Steelwork for the New Royal Bank Building in Montreal"; "Notes on the Removal of Carbon-Sulphur Compounds from Coal Gas by Oil Washing"; "The Flow of Gases in Reverberatory Furnaces"; "Notes on the Uniflow Steam Engine"; "The Requirements for a Durable Concrete as Observed from Structures in Service"; "The Effect of Steam Treatment of Portland Cement Mortars on their Resistance to Sulphate Action"; "The Electrical Heating of Trash Racks."

Works of Interest to be Visited

Montreal Harbour Bridge; Works of Northern Electric Company; Montreal Terminal Company's Cold Storage Plant; Coking Plant of Montreal Light, Heat and Power, Cons.; New Interceptor Sewers, City of Montreal; Plant of Associated Screen News; Plant of Victor Talking Machine Co. of Canada; New Building of the Royal Bank of Canada; Works of Dominion Engineering Works, Limited.



Outline of Programme

TUESDAY, FEBRUARY 14TH

Morning—
Registration — Annual General Meeting of The Institute, including presentation of reports of Council, Committees and the Branches; Scrutineers' report of the election of officers—Retiring President's address—Induction of newly-elected President.

Noon—Reception and Luncheon.

Afternoon—
Annual General Meeting continued.
Tea for Ladies.

Evening—
Illustrated Address by Dr. L. E. Pariseau.
Smoking Concert.

WEDNESDAY, FEBRUARY 15TH

Morning—Technical Sessions.

Noon—Luncheon.

Afternoon—
Visits to points of interest.

Evening—
Annual Dinner of The Institute.
Dinner for Ladies.

THURSDAY, FEBRUARY 16TH

Morning and Afternoon—
Technical Sessions.

Evening—
Reception and Supper-Dance.

Make a Special Note of the Dates

FEBRUARY 14TH, 15TH AND 16TH, 1928

Professional Meeting

C. K. McLeod, A.M.E.I.C.
Busfield, McLeod Ltd.
Secretary of the Main Committee

E. A. Ryan, M.E.I.C.
Consulting Engineer
Chairman of the Ladies' Committee

W. McG. Gardner, A.M.E.I.C.
Montreal Tramways Company
Chairman of the Committee on Publicity

Geo. R. MacLeod, M.E.I.C.
Engineer-in-Charge
Technical Service, Public Works Dept.
City of Montreal
Chairman of the Committee in Charge of Visits to Works of Interest

J. S. Cameron, A.M.E.I.C.
Assistant General Superintendent
Northern Electric Company, Limited
Chairman of the Sub-committee in Charge of Luncheons

Professor C. M. McKergow, M.E.I.C.
Professor of Mechanical Engineering
McGill University
Chairman of the Sub-committee in Charge of the Smoker

ELECTIONS AND TRANSFERS

At the meeting of Council held on December 28th, 1927, the following elections and transfers were effected:—

Member

DUNN, Charles Putnam, ch. engr., Portland Electric Power Co., Portland, Oregon.

Associate Members

CUMMING, Robert Egerton, engr., design & constrn. rly. trestles, bldgs., wharves, bridges, etc., Brown Corp., Quebec, Que.

DANN, Norman Leslie, acting cable engr., Northern Electric Co., Montreal.

FLEURY, J. Ernest, B.A., C.E., (Ecole Polytechnique), asst. principal at Papermaking School, Three Rivers, Que.

HALE, George Raymond, S.B., M.Sc., (Harvard Univ.), elect'l engr. in operating dept. of Shawinigan Water & Power Co., Montreal, Que.

ROBERTS, James Frank, B.S. in M.E., (Univ. of Wisconsin), hydraulic engr., Power Corp. of Canada, Mount Royal, Que.

WAKEFIELD, William Edward, timber tester to Forest Products Labs. of Canada, Ottawa, Ont.

Juniors

AHARA, Edward Victor, B.A.Sc., (Univ. of Toronto), head of steam accumulator dept., Combustion Engrg. Corp., Montreal, Que.

NAISH, Sidney Gordon, B.Sc., (Durham Univ.), engr., Mtl. div., plant dept., Bell Telephone Co., Montreal, Que.

WINSOR, Roland Blandford Marel, B.Sc., (McGill Univ.), constrn. engr. with W. I. Bishop, Ltd., Quebec, Que.

Affiliate

HERMANN, George Elliott, managing director, Vancouver Creosoting Co., Ltd., N. Vancouver, B.C.

Transferred from the class of Associate Member to that of Member

MUNTZ, Eric Percival, B.A.Sc., (Univ. of Toronto), consulting engr. to Lehigh Valley Coals Sales Co., Hamilton, Ont.

Transferred from the class of Junior to that of Associate Member

DAVIS, Sydney Herbert, B.Sc., (McGill Univ.), asst. res. engr. on constrn. highways and bridges at Chelsea & Paugan Falls with Gatineau Power Co., Ottawa, Ont.

FAHEY, James Vincent, B.Sc., (Queen's Univ.), res. engr., Spanish River Pulp & Paper Mills, Ltd., Sturgeon Falls, Ont.

HAY, Marshall Neil, B.Sc., (Queen's Univ.), asst. supt., Aluminum Co. of Can., Toronto, Ont.

MAXWELL, George Dean, B.A.Sc., (Univ. of Toronto), asst. to supt. of bldgs. & grounds, Univ. of Toronto, Toronto, Ont.

MOODY, Frederick Hayward, B.A.Sc., (Univ. of Toronto), pres. & managing director, F. H. Moody, Limited, Toronto, Ont.

RYAN, Charles Wilbert, B.Sc., (McGill Univ.), gen. supt. of constrn., Industrial Engrg. Co., New York, N.Y.

Transferred from the class of Student to that of Associate Member

BELANGER, Raphael, B.Sc., C.E., (Ecole Polytechnique), city engr., Valleyfield, Que.

HIGGINS, Joseph Alexander, B.Sc., (Queen's Univ.), investigation of pipe line system, Int. Petroleum Co., Negritos, Peru.

SNYDER, Horace H., instrumentman on hydraulic earth fill dam constrn. at Alexander power development with H.E.P.C., Hydro, Ont.

STEWART, Donald Laughlin, B.Sc., (McGill Univ.), with Bell Telephone Co. in outside plant div. of gen. engrg. dept., Montreal, Que.

Transferred from the class of Student to that of Junior

BEAM, Donald Carleton, i/c field party for Shawinigan Engrg. Co. in connection with Seven Falls-Murray Bay transmission line, Quebec-Isle Maligne transmission line and preliminary work for development of the lower Ste. Anne river, Ste. Tite des Caps, Que.

BROWNELL, George Wilson, B.Sc., (N.S. Tech. Coll.), with Electro-Motive Co. of Cleveland, Ohio.

CODE, Melville Clarke, B.Sc., (Univ. of Man.), taking C.G.E. Co.'s students' course, Toronto, Ont.

DION, J. Edgar, B.Sc., (McGill Univ.), Mtl. Engrg. Co., i/c field survey in Bolivia, S.A.

FRANKS, Selwyn Thompson, B.A.Sc., (Univ. of Toronto), research and development work on elect'l power conductors, with Northern Electric Co., Montreal.

HARDY, Albert Edwin, B.A.Sc., (Univ. of Man.), engr., Concrete Steel Co., Akron, Ohio.

MENZIES, John Ross, B.A.Sc., (Univ. of Toronto), instrumentman, with Sutcliffe Co., Ltd., New Liskeard, Ont.

SHIELDS, Stanley, B.A.Sc., (Univ. of Toronto), induction motor engr., C.G.E. Co., Peterborough, Ont.

SMART, George Wallace, B.A.Sc., (Univ. of Toronto), elect'l engrg. research asst., strength lab., Univ. of Toronto, Toronto, Ont.

STEWART, Donald, B.Sc., (McGill Univ.), dial system equipment engr., Montreal div., Bell Telephone Co., Montreal, Que.

WARKENTIN, Cornelius Paul, B.Sc., (Univ. of Man.), dfting and general office work in bridge dept., Good Roads Board, Prov. of Man., Winnipeg, Man.

Meetings of Council

Meeting of November 25th, 1927

A meeting of Council was held at eight o'clock p.m. on Friday, November 25th, 1927; President A. R. Decary in the chair, and ten other members of Council being present.

A letter was submitted from the Niagara Peninsula Branch, embodying a motion passed by that branch and recommending a general increase in the annual fees of all classes of members as being preferable to the increase of the fees of Members only recommended by Council.

It was pointed out that this matter would come up for discussion at the Annual Meeting, when the representatives of all branches would have an opportunity of presenting their points of view.

The Financial Statement to October 31st, 1927, was presented and approved.

Further discussion took place as to the possibility of making the subscription to the Journal optional to Students of The Institute, and after considering the recommendations of the Finance Committee it was felt that the advantages arising from the reduction of all Students' fees from $3.00 to $1.00 would not compensate for the disadvantages of this course.

The recommendations of the Finance Committee with regard to five special cases were approved; two reinstatements were effected, and eight resignations were accepted.

The report of the Board of Examiners on the results of the examinations held on November 1st, 1927, was presented and approved, showing that two candidates out of six had been successful in satisfying the examiners.

Discussion followed on a report from the Board of Examiners regarding the question which has arisen as to whether graduation from the courses in forestry at the four Canadian universities giving such courses can be recognized as graduation from a "school of engineering recognized by the Council." The Board of Examiners was of the opinion that while students in these forestry courses follow more or less completely the regular preliminary engineering curriculum for the first two years, and in the third and fourth years devote from one-third to one-half of the time to engineering subjects, graduation from such courses does not show that the graduate has received a satisfactory engineering training. It is, however, believed that in certain cases such graduates, if they have subsequently been engaged in responsible engineering work and have thereby obtained adequate training in the application of engineering theory, might properly be exempted from The Institute's examinations. This report was approved, and it was pointed out that Council has to deal with each application of this kind individually as regards the candidate's college training and engineering experience. It is accordingly not necessary or advisable to draw up any definite list of approved schools of engineering.

The Secretary submitted a draft of the various amendments to the By-laws which have been recommended by the Legislation and By-laws Committee, and also an amendment to Section 29 of the By-laws proposed by twenty corporate members of the Moncton Branch.

These were considered in detail and were approved in the form appearing on pages 532 and 533 of the December number of the Journal.

With regard to the committee appointed at the Plenary Meeting of Council to study the question of the co-operation of the activities of The Engineering Institute and the various Provincial Associations of Professional Engineers, the Secretary submitted the complete list of its members, as follows:—

Nova Scotia—	Professor F. R. Faulkner, M.E.I.C.
	Major H. W. L. Doane, M.E.I.C.
New Brunswick—	Professor H. W. McKiel, M.E.I.C.
	Alex. Gray, M.E.I.C.
Quebec—	President A. R. Decary, M.E.I.C.
	Geo. R. MacLeod, M.E.I.C.
Ontario—	Lieut.-Col. H. J. Lamb, M.E.I.C.
	Lieut.-Col. A. D. LePan, A.M.E.I.C.
Manitoba—	D. L. McLean, A.M.E.I.C.
	W. M. Scott, M.E.I.C.
Saskatchewan—	L. A. Thornton, M.E.I.C.
	H. R. MacKenzie, A.M.E.I.C.
Alberta—	S. G. Porter, M.E.I.C.
	R. J. Gibb, M.E.I.C.
British Columbia—	Past President Geo. A. Walkem, M.E.I.C.
	Patrick Philip, M.E.I.C.

Geo. R. MacLeod, M.E.I.C., was appointed Chairman.

The Secretary reported that His Excellency the Governor-General has graciously expressed his willingness to attend the Annual Dinner of The Institute on February 15th, 1928, and address the members. The Secretary was directed to communicate to His Excellency Council's gratification at the honour done to The Institute.

A letter was submitted signed by twenty members of the Montreal Branch and presenting the names of two additional nominees for the office of Councillor representing the Montreal Branch district.

The Secretary was directed to add these names to the List of Nominees for Officers to be placed on the ballot in accordance with Section 68 of the By-laws.

The attention of Council was called to an article, which appeared in the October 20th issue of the Engineering News-Record, regarding the recent typhoid epidemic in Montreal, and after discussion a committee was appointed to prepare a letter to be written to the editor of the Engineering News-Record regarding the situation, explaining that an investigation had already taken place, and that the matter had been given immediate attention by the Provincial Board of Health.

A resolution was unanimously passed conveying the sympathy and condolence of Council to the family of the late Mr. W. L. Scott.

The following elections and transfers were effected:—

Elections	
Associate Member	1
Students	27
Transfers	
Junior to Associate Member	4
Student to Associate Member	2
Student to Junior	8

Council rose at 12.15 o'clock a.m. and adjourned to Friday, December 2nd, 1927.

Adjourned Meeting of December 2nd, 1927

An adjourned meeting of Council was held at eight o'clock p.m. on Friday, December 2nd, 1927; President A. R. Decary, M.E.I.C., in the chair, and eleven other members of Council being present.

In accordance with the recommendations of the Legislation and By-laws Committee, the proposed amendments to the Niagara Peninsula Branch By-laws were approved.

The attention of Council was drawn to the fact that as at present worded, Section 76 of The Institute's By-laws does not provide for any modifications, during discussion at the Annual Meeting, of proposals to amend By-laws, which therefore must go out to letter ballot of the corporate members in the precise form in which they are submitted at the Annual General Meeting.

As a result of an active discussion, it was decided to request the Legislation and By-laws Committee to draft a proposal for such a change in Section 76 of the By-laws as will obviate the difficulty complained of, and, while guarding proposed amendments against any change made with little consideration or thought for their relation to other By-laws, will permit the consideration of such modifications as may be suggested at the Annual General Meeting.

A proposal from the Vancouver Branch to hold the forthcoming Western Professional Meeting on June 7th, 8th and 9th, 1928, was approved.

Thirty-three applications for admission and transfer were scrutinized and classified for the ballot returnable December 28th, 1927.

The Council rose at 10.15 o'clock p.m.

Meeting of December 20th, 1927

A meeting of Council was held at eight o'clock p.m. on Tuesday, December 20th, 1927; President A. R. Decary, M.E.I.C., in the chair, and nine other members of Council being present.

A report was submitted from the Legislation and By-laws Committee making recommendations regarding the proposed amendments to Sections 52 and 76 of the By-laws, and after considerable discussion these recommendations were approved, the Secretary being directed to send them out to all corporate members in accordance with the provisions of Section 76 of the By-laws, prior to their discussion at the Annual General Meeting.

The Financial Statement to November 30th, 1927, was submitted and approved.

One reinstatement was approved; nine resignations were accepted and nine special cases dealt with.

The list of officers of the Border Cities Branch of The Institute for the year 1927-28 was submitted and approved.

Twenty applications for admission and transfer were scrutinized and classified for the ballot returnable January 18th, 1928.

At 10.15 o'clock the Council adjourned until 2 o'clock p.m. on Wednesday, the 28th of December, for the purpose of canvassing the ballot returnable on that date.

T. McAvity & Sons, Limited, are issuing books of blue prints showing details of "World" reinforced digester brass valves and fittings for sulphite pulp mills. These blue prints, in addition to giving full details of dimensions, etc., provide an exceedingly novel and useful means for the recording, on the blue print, the service given by the equipment detailed. The McAvity Company also have issued their catalogue A-J covering "Durite" Reinforced Vanstone Joints for steel power pipe installation and of "Durite" copper piping with cupped and flared joints,—instead of threaded joints. This new type of copper water service has recently been installed in the new Pulp and Paper Research Institute at McGill University, Montreal, which is the first installation of its kind on the American continent.

Annual General and General Professional Meeting

The Annual General Meeting will be convened at Headquarters, 2050 Mansfield street, Montreal, on Thursday, January 19th, 1928, at 8.00 p.m. After the reading of the Minutes of the last Annual General Meeting the appointment of Scrutineers to count the Officers' Ballot; and the appointment of Auditors for the ensuing year, the meeting will be adjourned to reconvene at the Windsor Hotel, Montreal, February 14th, 15th and 16th, 1928.

Programme of Meeting at Windsor Hotel, Montreal

(Subject to Revision)

Tuesday, February 14th.

9.00 a.m. Registration at Windsor Hotel.

10.00 a.m. Annual General Meeting in Windsor Hall. Reception and discussion of Reports from Council, Committees and Branches. Discussion of proposed amendments to By-laws.

1.00 p.m. Luncheon in Rose Room. (Complimentary to visiting members and visiting ladies.) Welcome to members by F. C. Laberge, M.E.I.C., Chairman of the Montreal Branch, who will preside. Brief address by the Hon. Mederic Martin, Mayor of Montreal.

2.30 p.m. Continuation of Annual General Meeting. Scrutineers' report and election of officers. Retiring President's address. Induction of new President.

4.30 p.m. Tea for ladies.

8.00 p.m. Illustrated address by Dr. L. E. Pariseau on X-ray Investigations of Egyptian Mummies. Rose Room. (Ladies will be welcome.)

9.30 p.m. Smoking concert and refreshments in Windsor Hall, (complimentary).

Wednesday, February 15th.

9.30 a.m. First Technical Session.

Presentation and discussion of papers.

Windsor Hall—

The Chippawa Creek Syphon Culvert of the Welland Ship Canal—A. J. Grant, M.E.I.C. Construction methods adopted for an important feature of the canal.

Foundations of the Royal Bank Building, Montreal, C. S. Proctor. Foundation design for a twenty-three storey office building.

9.30 a.m. *Prince of Wales Salon.*

Notes on the Uniflow Steam Engine—E. A. Allcut, M.E.I.C. Based on tests made by the Author on the economy and performance of this special type of reciprocating engine.

The Lock Gates of the Welland Ship Canal—Frank E. Sterns, M.E.I.C. Design and erection of lock gates of unusual size and importance.

1.00 p.m. Informal Luncheon.

2.30 p.m. Visits to engineering works.

These have been arranged through the kindness of the organizations named, as follows:—

Montreal Harbour Bridge—Two miles long, with 1,097 feet central span and 162 feet clear headway over navigation channel. Piers are built—steel work is being erected.

Works of Northern Electric Co.—Manufacture of cable, telephone and other electric equipment.

Cold Storage Plant of the Montreal Rail and Water Terminals, Ltd.—Recently constructed modern plant.

Coking Plant of Montreal Light, Heat and Power Cons.—Modern methods of coal carbonization.

New Interceptor Sewers, City of Montreal—Sewer construction on a large scale.

Plant of Associated Screen News—Production of motion picture films.

Plant of Victor Talking Machine Co. of Canada—Production of gramophone records.

New Building of the Royal Bank of Canada—Twenty-three storey office building, almost completed.

Works of Dominion Engineering Works, Ltd.—Construction of a number of large paper machines and hydraulic turbines.

Information regarding transportation will be furnished at the Registration Desk.

7.30 p.m. Annual Dinner of The Institute. The President in the chair. His Excellency the Governor-General has graciously signified his intention of being present.

(Seats and tables can be reserved through the Registration Committee.

7.30 p.m. Dinner for ladies.

Thursday, February 16th.

9.30 a.m. Second Technical Session.

Windsor Hall—

Bridges Over the Welland Ship Canal—M. B. Atkinson, M.E.I.C. Describes a series of movable bridges whose design involves many points of special interest.

Steelwork for the Royal Bank Building in Montreal—R. M. Robertson, A.M.E.I.C. Design and erection methods for a steel structure of considerable importance.

9.30 a.m. *Prince of Wales Salon.*

The Electrical Heating of Trash Racks—C. R. Reid. Methods of dealing with frazil ice in the St. Maurice river.

Notes on Removal of Carbon-Sulphur Compounds from Coal Gas by Oil Washing—K. L. Dawson, A.M.E.I.C. Gives the results of experimental work carried out by the author on a commercial scale.

The Flow of Gases in Reverberatory Furnaces—W. K. Thompson, A.M.E.I.C. An investigation of the conditions and performance of large copper-smelting furnaces.

2.00 p.m. Third Technical Session.

Windsor Hall—

The Requirements for a Durable Concrete as Observed from Structures in Service—R. B. Young, M.E.I.C. A discussion of various instances of deterioration in actual practice.

The Effect of Steam Treatment of Portland Cement Mortars on Their Resistance to Sulphate Action—T. Thorvaldson and V. A. Vigfusson. Deals with the results of experimental study by the expansion method, showing, in certain cases, that a marked increase in durability is produced by steam treatment.

Prince of Wales Salon—

Continuation of discussion on papers already presented, (if desired).

8.45 p.m. Reception and Supper-dance in Windsor Hall.

Reduced Railway Rates for Annual Meeting

In connection with the Annual General Meeting to be held in Montreal on February 14th, 15th and 16th, 1928, arrangements have been made with the Canadian Passenger Association, Eastern Lines, for reduced fares on the certificate plan, applying to points east of Armstrong and Fort William.

According to this arrangement, provided a sufficient attendance is certified at Montreal, members who have purchased an ordinary one-way ticket to Montreal, have obtained a C.P.A. certificate from the ticket agent *at the time of purchase,* and have had this certificate validated *at the meeting,* can purchase a ticket for the return trip at one-half the one-way ordinary first class adult fare, plus twenty-five cents, making the expense for the whole trip one and a half the ordinary fare plus twenty-five cents.

The success of this plan depends entirely on the willingness of our members to take the trouble (a) to obtain a certificate at the time of purchase of the ticket to Montreal and (b) to have this certificate validated by the proper officer at the Annual Meeting.

One hundred and fifty certificates at least must be validated for the arrangement to become effective, otherwise the rate for the return journey is less favourable.

A circular giving full information regarding this plan will be forwarded to all members with the programme for the Annual Meeting, and it is hoped that members will make a special note regarding this matter, since neglect on the part of one or two members to take advantage of it endangers the success of the whole arrangement.

Experience at previous meetings has shown a somewhat surprising difficulty in persuading members to co-operate in this scheme, and we are making a special effort to secure its advantages for members attending the Montreal meeting.

Points to Remember

when planning to attend

The Annual Meeting—

Date—February 14th-16th, 1928.

Place—Montreal, Que.

Headquarters—Windsor Hotel.

Reservations—Make these as early as possible. Cards for this purpose will be mailed to all members the second week in January. By doing this you will greatly assist the Committee in charge of arrangements.

Transportation — Special reduced rates have been arranged. (See announcement on this page.)

Be sure to secure certificate from the ticket agent when you purchase your ticket.

EMPLOYMENT BUREAU

Situation Wanted

Electrical Engineer

Electrical engineer, 27 years of age. University of Toronto graduate, six years diversified experience, two years Westinghouse engineering course, inspection of electrical equipment, industrial construction and maintenance, testing and research; at present employed in United States; wishes to return to Canada. Available on reasonable notice. Apply box No. 231-W, The Engineering Journal.

Situations Vacant

Engineer Wanted as Employment and Personnel Manager for Large Paper Mill

Employment experience not absolutely necessary, but should have had some experience in industry, preferably in Quebec, and ability to get along well with people. Must speak French fluently. Good salary to start and excellent prospects for future. Apply direct to Mr. Thos. A. McDonald, Room 1607, 50 East 42nd street, New York City, or to Employment Bureau, The Engineering Institute of Canada.

Sales Representative

A large bronze foundry in the United States, manufacturing special lines for engineering purposes, wants energetic, technically trained representative now well established in Montreal. Apply box No. 178-V, The Engineering Journal.

Mechanical Draughtsman

Mechanical draughtsman with at least four years experience in newsprint mill work. Good opening for right man in newsprint mill in province of Quebec. Apply, stating salary expected. Apply box No. 179-V, The Engineering Journal.

Designing Engineer

Designing engineer, experienced in pulp and paper machinery design, to take charge of draughting office in large newsprint mill in the province of Quebec. Applicant must be technical graduate. Apply, stating salary expected. Apply box No. 180-V, The Engineering Journal.

Designing Engineers and Draughtsmen

Designing engineers and draughtsmen for a large hydro-electric power development in the province of Quebec. Apply box No. 181, The Engineering Journal.

Sales Engineers

Two engineers required for technical sales work. One for Quebec and one for Ontario. Apply box No. 182-V, The Engineering Journal.

The Forest Service of the United States Department of Agriculture has issued a report containing some interesting information regarding the relation of forests to water supply. The report is entitled "Forests and Water in the Light of Scientific Investigation," and aims to bring together impartially the well-established scientific facts regarding this subject. The closing paragraph of the report contains the following summary of the results of the observations upon which this report is based:—"1. The total discharge of large rivers depends upon climate, precipitation and evaporation. The observed fluctuation in the total amount of water carried by rivers during a long period of years depends upon climatic cycles of wet and dry years. 2. The regularity of flow of rivers and streams throughout the year depends upon the storage capacity of the watershed, which feeds the stored water to the streams during the summer through underground seepage and by springs. In winter the rivers are fed directly by precipitation, which reaches them chiefly as surface run-off. 3. Among the factors, such as climate and character of the soil, which affect the storage capacity of a watershed, and therefore the regularity of stream flow, the forest plays an important part, especially on impermeable soils. The mean low stages as well as the moderately high stages in the rivers depend upon the extent of forest cover on the watersheds. The forest tends to equalize the flow throughout the year by making the low stages higher and the high stages lower. 4. Floods which are produced by exceptional meteorological conditions can not be prevented by forests, but without their mitigating influence the floods are more severe and destructive." The report also contains an extensive bibliography on the subject of the relation of forests to water and climate.

BOOK REVIEWS

Motor Fuels, Their Production and Technology

By Eugene H. Leslie. The Chemical Catalogue Company, New York, 1923. Cloth, 6 x 9 in., 681 pp., figs., diagrams, tables, map, $11.00.

In this book is given a fairly complete outline of the fundamental principles of physics, thermodynamics and chemistry as employed in the operation of petroleum refining for the production of motor fuels. It also contains a review of the various sources of supply of motor fuels with a discussion as to their relative importance.

The chapters on fractional distillation, fluid flow, heat transfer and on cracking are of considerable interest to the refinery engineer and chemist. The volume is well illustrated, contains many references to other authorities on the subject, and with the comparatively large number of tabulations of useful information constitutes a handbook for those occupied in the design and operation of refinery equipment.

The book should be valuable to the student in petroleum technology, who can obtain from same considerable information in regard to the practice followed and apparatus used in the modern refinery. The review of the motor fuel situation will be of interest to the non-technical reader, but as technique and research in petroleum refining have been and are rapidly advancing no technical book on this subject can be completely up to date. The information obtained from this book should be supplemented by that obtained from recent publications which, at present unfortunately, are only fragmentary and appear mostly in technical journals.

Dr. Leslie's book represents a valuable contribution to the literature on petroleum technology.

F. C. Mechin, A.M.E.I.C.
Superintendent, Montreal Refinery, Imperial Oil Refineries, Limited.

Theory of Vibrating Systems and Sound

By Dr. I. B. Crandall, Member of Technical Staff, Bell Telephone Laboratories. D. Van Nostrand Company, New York, 1926. Buckram, 6 x 9 in., 272 pp., figs., tables, $5.00.

The Greek philosopher Heraclitus wrote "Everything flows." To-day we say "Everything waves," and find vibrations from an atom to a cepheid.

Academic subjects which were the delight of a Stokes, a Kelvin, a Rayleigh or a Lamb now find themselves in the front rank of modern engineering,—in the diaphragm of a telephone, the horn of a gramophone or loud speaker, the acoustics of a building, underwater signalling, submarine detection, depth of ocean measurement, airplane detection.

There is a remarkable and close analogy between the transmission of sound and the transmission of electricity, with its accompanying problems of phase difference and attenuation.

Indeed, many engineers approach acoustics from an electric standpoint, whereas the famous Constantinesco, (who timed the Lewis gun bullets through the aeroplane propeller), first mastered acoustics and then found alternating current mere child's play.

Generally speaking, it is easy to write down the differential equations, but it is the devil and all to solve them! So that this book is not easy to read, in some places, except by those trained in Bessel's functions, and in Ber and Bei functions beloved of Kelvin.

Most men have the mathematics they deserve, but few have the mathematics they require. Indeed, the moral of the book is more mathematics, even if the horn of the loud speaker has been evolved by practice rather than theory.

Many engineers have made their pile by grace of God, their mother wit, an engineer's pocket book and a slide rule, so that the young engineer student is apt to hope for the best, rather than to apply himself to the calculus. Perhaps the future may not be as the past, and it has been said that God must despise riches, for he bestows them so often, (not always, please !) on the undeserving.

This, however, is not a book of theology under review, but a useful compendium of those branches of vibrating systems which necessarily impinge on the attention of the Bell Telephone Laboratories.

There are references to useful war work, some of it summarized in Drysdale's "Mechanical Properties of Fluids," (Van Nostrand, 1924), and to two Canadian prophets, of more honour in other countries, Dr. L. V. King, of McGill University, and Dr. R. W. Boyle, M.E.I.C., once of McGill, now a leader at the University of Alberta, who have made notable contributions to acoustics and super-sonics.

The book is clearly written and printed, and Dr. Crandall has done useful work in bringing together and publishing material given in a course at the M.I.T. in 1926, to electrical engineers, students of physics and others who had a background of analytical mechanics, Legrange's equations, elastic deformation and electrical networks. Who runs may read !

Director, Department of Physics, McGill University.

The Metallurgy of Aluminium and Aluminium Alloys

By R. J. Anderson. Henry Carey Baird & Co., Inc., New York, 1925. Cloth, 6 x 9 in., 913 pp., figs, tables, $10.00.

The constantly enlarging demand for aluminium and light alloys in many branches of industry adds greatly to the engineering interest in any book dealing with this metal. It is unfortunate, therefore, that there are so few works of any sort, and still fewer with authoritative and up-to-date information, on aluminium alloys.

This particular volume by R. J. Anderson, published first in 1925, will find wide interest among those who fabricate or use aluminium. It is probably the most complete volume published in America on this subject which undertakes to cover both the production and the properties and uses of aluminium alloys. Unfortunately, because of several factors, among them the rapid change in this industry, the book is already incomplete in many important features. It is notable in its neglect of the fundamental metallurgical studies carried out by some of the most able research men of the Aluminium Company of America, who have published freely in the technical literature during recent years. For example, one fails to find any reference in the author index to the important contributions of Jeffries, Archer, Blough, Frary and several of their associates.

Despite these limitations, some of which are inevitable with the rapidly changing industry, the book is well worth attention and probably the best available for many phases of the aluminium industry. In any event, it will serve the useful purpose of still further stimulating the proper and intelligent use of aluminium and light alloys, which have long been one of the most neglected groups of metals.

R. S. McBride.
Assistant Editor, Chemical and Metallurgical Engineering.

Essentials of Transformer Practice

By Emerson G. Reed. D. Van Nostrand Company, New York, 1927. Cloth, 6 x 9½ in., 401 pp., figs., tables, $5.00.

The second edition of this work is one of the few books published giving complete information on transformers. The first part is well presented and deals with design. The calculations of copper loss and iron loss are clearly treated, as are also the separation of the hysteresis and eddy losses, and the bearing of these losses on such points as the thickness of the laminations and the effect of the form factor of the voltage wave. A further discussion on the relation of iron loss to copper loss is very interesting and includes the consideration of the effect of change of impressed voltage, of frequency and of a number of turns in the winding. These chapters on design are concise, yet complete.

For those interested in the operation and maintenance of transformers, the book contains much useful information. The properties of insulating materials and of oils, the methods of insulation and impregnation of the windings and a general chapter on installation and maintenance are some of the major points presented. The latter half of the volume includes chapters on voltage and current transformers, voltage and phase transformation with single phase and autotransformers, stresses in operation and some data on the economics of the operation of transformers. The chapters on voltage and current transformers are especially well treated, and the discussion on phase transformation with autotransformers is very interesting.

The author has included many points having practical value which are seldom treated in a work of this kind, and the book can be recommended as an excellent reference book for engineers engaged in transformer work, provided their theoretical knowledge is sufficient to enable them to take advantage of its discussions. Notwithstanding its wide scope, the treatment throughout is satisfactory and thorough.

S. A. Craig, Jr.E.I.C.
Demonstrator, Electrical Department, McGill University.

Shale Oil

By Ralph H. McKee, Ph.D., LL.D., and Others. The Chemical Catalogue Company, New York, 1925. Buckram, 6 x 9 in., 326 pp., figs., tables, $6.00.

This volume is one of the monograph series published by the American Chemical Society. The subject matter effectively covers the origin and occurrence of shale oils, the theoretical and practical considerations in their utilization and an interesting review of general economic considerations as applied to the shale oil industry.

Not the least valuable feature of the book is the description of American experimental oil shale distillation plants and the abstracts of shale oil articles.

Anyone having occasion to study or investigate the shale oil industry will find this book valuable. Certain of the economic conclusions based on the study of conditions prior to 1925 illustrate the rapidly changing economic considerations that upset economic theories. At the time this book was published, shale oil deposits seemed to represent the only large reserve supply of fuel for internal combustion engines, and the expected shortage of gasoline about 1927 is particularly stressed. The current over-production in the oil industry has set back the possible development of a shale oil industry indefinitely, and the competition that is arising from the newer coal distillation processes promises to still further put off the day when shale oil deposits will be of great economic value.

J. R. Donald, M.E.I.C.,
Consulting Chemical Engineer, Montreal, Que.

Machine Work

By T. J. Palmateer. Stanford University Press, Cal., 1927. Cloth, 5½ x 8 in., 202 pp., figs., illus., $2.00.

This manual is intended for use in technical schools as a test and reference book to supplement oral instructions.

Part 1 consists essentially of a series of exercises or jobs forming a graded course of instruction in the more fundamental operations performed on the lathe, planer, drill-press, milling and grinding machines. The instructions are detailed and definite and clearly illustrated. Descriptions of machine tools are restricted to those commonly found in school shops.

In Part II, the operations in the manufacture of a hand-power grinder are detailed as an example of quantity production methods on a small scale and of the use of special tools, fixtures and jigs.

The book is well suited for its purpose and should be useful to shop instructors in schools as well as to students.

A. R. Roberts, A.M.E.I.C.
Associate Professor of Mechanical Engineering, McGill University.

Wood Distillation

By L. F. Hawley. Chemical Catalog Company, New York, 1923. Buckram, 6 x 9 in., 141 pp., figs., tables, $4.00.

This book belongs to a series of scientific and technologic monographs which is being edited by the American Chemical Society by arrangement with the Inter-Allied Conference of Pure and Applied Chemistry which met in London and Brussels in July 1919.

The author has divided his subject matter into two parts, first, the distillation of hardwoods, and, second, the distillation of resinous woods. Each part contains chapters on the following commercial processes;—raw materials; the decomposition of wood by heat; the products of wood distillation and their refining. New processes are outlined, together with a brief statement as to the reason for their development.

The chapter on raw material contains an excellent summary of present day knowledge of the chemistry of wood and of its proximate analysis. Numerous tables are given to illustrate the yields obtained from different species where for purposes of comparison a definite set of conditions was used in the distillation.

The effect of the presence of catalysts during the distillation is also discussed, and the monograph is generously supplied with references to the literature of the subject.

E. Parke Cameron, A.M.E.I.C.
Director, Division of Pulp and Paper, Forest Products Laboratories of Canada, Montreal, Que.

BRANCH NEWS

Border Cities Branch

Orville Rolfson, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Border Cities Branch was held in the Prince Edward hotel on Friday evening, December 9th, 1927. After dinner at 6.30 p.m. the following reports of the year were presented:—

Report of Chairman ....L. McGill Allan, A.M.E.I.C.
Report of Secretary-Treasurer ....C. G. R. Armstrong, A.M.E.I.C.
Report of Membership Committee ....A. E. West, A.M.E.I.C.
Report of Entertainment Committee ..R. J. Desmarais, A.M.E.I.C.
Report of Publicity Committee ....J. Clark Keith, A.M.E.I.C.

After the adoption of these reports, the election of officers for the ensuing year was proceeded with, and the following slate was elected:—

Chairman	Harvey Thorne, M.E.I.C.
Vice-Chairman	A. E. West, A.M.E.I.C.
Secretary-Treasurer	Orville Rolfson, A.M.E.I.C.
Executive	R. J. Desmarais, A.M.E.I.C.
	Fred. Stevens, A.M.E.I.C.
	F. H. Kester, M.E.I.C.
Ex-officio	L. McGill Allan, A.M.E.I.C.
	J. Clark Keith, A.M.E.I.C.
	C. G. Russell Armstrong, A.M.E.I.C.

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

The Manufacture of Cement

On November 16th last, W. D. Armstrong, A.M.E.I.C., superintendent of the Canada Cement Company, Limited, at Exshaw, Alberta, delivered a paper to this branch on the manufacture of cement. Mr. Armstrong handled his subject in excellent form and with a clearness and grasp that added much to the pleasure of listening. There was a good attendance and members were shown some interesting reels of cement plant activity at various centres. The trick drawings thrown on the movie screen to show the passage of ore through the mill proved a clever means of illustrating the various processes. A short discussion followed, being led by G. P. F. Boese, A.M.E.I.C., after which Chairman Beach thanked Mr. Armstrong for the excellent paper he had read.

Geology of the Foothills in Relation to Petroleum

On Tuesday night, Dr. John A. Allan, Ph.D., F.R.S.C., R.R.E., professor of geology at the University of Alberta, delivered an address before the members of the branch. The subject of his address was the geology of the foothills in relation to petroleum, which, although necessarily of a highly technical nature, proved both instructional and intensely interesting to his audience, which also included several geologists and oil operators.

Commencing with the history of the Rocky mountains and foothills formation, Dr. Allan pointed out that the former covered an area of some 40,000 square miles in Alberta, or about the size of Nova Scotia, and that the foothills formed a belt some 500 miles from the international boundary to the Peace River valley with an average width of 23 miles and an area of about 11,500 and average elevation of 4,000 feet.

Much of the lecture dealt with complex data and stratigraphy, and it was somewhat disconcerting to theorize that this continent is gradually moving in a westerly direction with a tendency for the west coast to move northward when San Francisco may some day be where Vancouver is to-day. His hearers were, however, assured that they could not expect to live to see the day. He referred to the submergence of the land surface occurring in past ages, forming a sea area extending across Alberta and possibly as far as Manitoba, which at a later period receded towards the east, giving birth to the Rocky mountain uplift.

It was his theory that the old shore line of the sea influenced the quality and strike of the coal beds rather than their varying distance from the mountains. Dr. Allan advocated the fullest co-operation between drill operators and geologists, so that the latter may be able to interpret some of the facts that cannot be observed on the surface.

As far as time went, he mentioned that the Rocky mountains are very young in comparison with the Selkirks, and were almost entirely of sedimentary origin, only two small areas of igneous rock being known. His remarks concerning mountain building were cleverly illustrated with lantern slides, as were also the folding, faulting and overthrust of the formations with a most interesting conclusion that the front range of the Rockies at Kananaskis had been thrust seven miles over the plains, and that the earth's surface had become shortened by some thirty miles in the Rocky mountain system. Dr. Allan stated that the sea floor must have been raised over three miles above its original altitude, naturally a very slow process.

Referring to oil and gas, he said that it is reasonable to believe that under suitable structural conditions production pools may be expected in the Kootenay sandstones, and that the large volumes of gas and naphtha encountered in Turner valley occur in porous dolomite limestones, probably of middle carboniferous age.

It was his contention that the anticlinal fold is only one of several suitable types of structures for the discovery of oil, one other of which was a lens between impervious beds, a very common source of supply and known to occur in Turner valley. He claimed that the largest reservoirs should occur towards the eastern side of the foothills belt and to the northwest.

He was of the opinion, with many other geologists, that the petroleum possibilities in the foothills have not yet been determined, but that there is no cause for discouragement in what the ultimate results will be when the geological conditions are more accurately understood, and that a wide knowledge of the foothills geology is required, also that reading geological books will not interpret the foothill's geology.

Dr. Allan claimed that many mistakes have been made by attempts to extend Turner valley structure almost indefinitely along the strike, which is all wrong in principle and in fact, and that while many structures in the foothills must be unproductive there are many others that may prove productive if tested by drilling.

Recognition of horizons is of the greatest importance in seeking for oil, also three great factors must be considered, mainly, time, qualifications and money.

In conclusion, Dr. Allan said that the working out of the geology of the foothills must not be regarded as a hobbyist's playground, but a real laboratory filled with the most complex problems, and that can only be interpreted and possibly solved by the most highly trained geologists who are willing to spend considerable time in the laboratory of nature.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

Executive Meeting, November 30th

A meeting of the executive of the Hamilton Branch was held in the office of W. L. McFaul, M.E.I.C., city engineer. L. W. Gill, M.E.I.C., chairman of the branch, presided and there were five other members of the executive present. The meeting was mainly devoted to the consideration of applications for admission and transfer and of plans for the remainder of the season.

A communication from the Niagara Peninsula Branch regarding the proposal put forth at the Plenary Meeting of Council to increase the fees of Members $5.00 per annum was considered, and it was decided to bring the communication to the attention of the members of the branch at the next meeting.

Branch Meeting, December 12th

A meeting of the Hamilton Branch was held in the cafeteria of the Hamilton Technical Institute, Monday evening, December 12th. During the temporary absence of L. W. Gill, M.E.I.C., chairman of the branch, W. L. McFaul, M.E.I.C., vice-chairman of the branch, called the meeting to order and routine business was transacted. The communication from the Niagara Peninsula Branch proposing to increase the fees of all members pro rata instead of increasing only the Members fees $5.00 per annum was brought to the attention of the meeting and much discussion ensued. The entrance of the chairman, accompanied by Major-Gen. J. H. MacBrien, C.B., C.M.G., D.S.O., the speaker of the evening, brought the discussion to a close before any decision was reached.

Civil Aviation in Canada

General MacBrien spoke upon the subject of "Civil Aviation in Canada." The talk was illustrated by charts showing the existing airway routes in the continent of Europe and the existing and proposed inter-continental airway routes. A coloured plan of a proposed design for an air port for the city of Hamilton was also shown.

General MacBrien was heartily welcomed by the meeting. Flight, he said in opening, had always been an aspiration of man. Flying had been an attribute of the ancient gods, and until recent times man's attempts to fly have been regarded as sorcery, especially by the Inquisition. It was felt that anyone who attempted to fly must be inspired by the devil.

The old philosophers saw that two things rose through the air, —smoke and birds. These ideas have developed into the lighter-than-air and heavier-than-air craft. These two schools hold distinct and contrasting views.

In 300 B.C., in the Roman forum, a man named Simon raised himself with a sort of balloon and reached so high as to fall back to his death. This is the first recorded instance of successful flight.

The balloon is the forerunner of the dirigible, which was used by the Germans during the Great War. The General gave an interesting description of one he had seen in England, which has accommodation for 100 people, with dining salons, etc., like the modern liner.

Next year, in August, one of these airships will fly to Canada, to the air mast at Montreal. It is believed that a number of these aircraft could be made to pay, charging $500 per passenger per trip. They would fly to Canada in two and a half days, and back, with the wind, in one and a half days. They could fly to Australia in eleven days.

Regarding the heavier-than-air craft, Sir John Carey, an Englishman, laid down the principles which make dynamic flight possible. These principles were used by Langley and the Wright brothers. Twenty-four years ago the first airplane flew for a few seconds. Since then there have been great developments, so that the modern airplane is now a scientific machine. What has been done this year in the heavier-than-air machine is no less than astounding, which is a great tribute to man's ability.

All progressive countries are developing aircraft. There are two reasons, first, commercial, to compete with other countries in trade; and, second, military, as an arm of defence.

To-day flying is safe, provided certain precautions are taken:—

(1) The aeroplane must be of the best type available with multiple engines.
(2) The flying must be over an organized route, that is, with proper airdromes and properly lighted along the route.
(3) There must be an efficient meteorological service and proper wireless communications, so that the plane can be advised of weather conditions at all times, thus enabling the pilot to avoid storms by flying over or around them.
(4) The flying personnel must be highly trained and efficient.

General MacBrien mentioned the "Handley-Page slot" which gives the pilot better control of his machine. When the plane stalls in midair, the Handley-Page slot, which is in the forward edge of the wings, opens and allows the pilot to maintain control and to bring the machine down under control. Previously, when a machine stalled it either went into a side spin or a nose dive, and if there was not sufficient height there would be a bad crash in which the machine would be ruined and the pilot probably killed. With the Handley-Page slot the machine settles down under control with a falling speed of 20 miles per hour. This would probably result in a smashed undercarriage, but it would save the machine and the lives of the passengers. It is reported that the United States has paid $800,000 for the right to use this feature on their military aeroplanes.

In the United States last year planes have flown five million miles over properly organized routes without an accident, but there were hundreds of accidents among aircraft flying over improperly organized routes.

There are 36,000 miles of airways now organized in Europe. People can travel to any part of Europe at slightly more than first-class railway fare and in one-tenth of the time. Germany is the leading country in this development. She could use her civil air force in wartime if necessary. The Germans believe that aviation will help them to recover their lost commercial position. Two German firms are to-day building aircraft for trans-Atlantic flying.

France has made considerable progress in air transportation. They have the finest military air force in the world and have developed scout planes which can manœuvre at a ceiling of 32,000 feet.

In England there are no internal air routes on account of the size of the country, but British planes fly into Europe, and it is proposed for them to fly to Canada and South America. In Australia there are 350,000 miles of airway actually in operation. The government has voted $2,000,000 toward the building of 800,000 miles of additional airways.

In the United States there are twenty-four manufacturing companies operating, several of them making a profit. Sixty-five million people are now served with an air mail in which the planes fly from coast to coast in thirty-six hours. In organizing an airway, the United States federal government lights the routes between cities, but the municipalities themselves establish the air ports. It is expected that this is the policy which will be carried out in Canada.

In Canada there is not a single mile of organized air route. This indicates that we are lagging behind and that those in touch with aviation believe that unless Canada wakes up, other countries, notably the United States, will develop her aviation for her. There are two flying lines in operation in Canada, but not over organized routes, one from the Sioux Lookout to the Red Lake district and the other from Haileybury to the Rouyn district.

With such an enormous hinterland not served by present means of transportation, Canada would benefit materially from proper development of aviation.

Although Canada is behind in the development of commercial aviation, there are two uses of aircraft in which she leads. These are: aerial survey work and forestry protection.

General MacBrien is organizing a Canadian Air League. The objects of this league will be to ensure the development of civil and commercial aviation in Canada, to foster scientific research and education and to secure an adequate military air force. The organization is non-political and will have a headquarters in Ottawa. Each branch must have at least fifty members, and up to the present the organization of branches has been commenced in twenty large cities.

General MacBrien outlined the means whereby the league hopes to fulfil its objects, and mentioned the arrangements which have already been made with the Hamilton Technical Institute and other educational institutions regarding the education of men for the air trades.

After General MacBrien's address, refreshments were served, accompanied by selections rendered by the Technical School orchestra.

After the refreshments there was considerable discussion, and General MacBrien was asked several questions. Mr. McFaul expressed the thanks of the meeting to General MacBrien for his interesting and instructive address.

Kingston Branch

D. G. Geiger, S.E.I.C., Secretary-Treasurer.

The Kingston Branch met in the physics lecture room, Ontario Hall, Queen's University, on December 7th to hear an address by Professor Howard T. Barnes, M.E.I.C., head of the physics department, McGill University, Montreal, on "Ice, Its Formation and Control." Professor L. T. Rutledge, M.E.I.C., chairman of the branch, occupied the chair and fittingly introduced the speaker.

Ice, Its Formation and Control

Professor Howard T. Barnes, M.E.I.C., of McGill University, the internationally recognized authority on ice and ice engineering, made the astounding statement that it will be quite possible within a few years, following the research on which he is now engaged, to keep the St. Lawrence river entirely free of ice during the winter months, thus materially raising the mean temperature in the vast section of Canada through which the river flows and solving some of the problems of engineers whose duty it is to keep power stations and other industries running.

Professor Barnes had for his subject "Ice, Its Formation and Control," and his address, illustrated as it was by lantern slides and moving pictures, proved most interesting and instructive to his large audience.

At the outset of his remarks, Dr. Barnes stated that research had proved that ice was always present in water of whatever temperature and could be frozen at the boiling point if sufficient pressure could be applied. He stressed the facts that ice would not form a solid mass except at a temperature of 32° F. or lower and that the smallest fraction of a degree change in temperature meant the difference between water usually considered free of ice and solid ice.

Concerning the St. Lawrence, Dr. Barnes' theory, summed up in a few words, is that if the waters of the St. Lawrence were all diverted during the winter months, by some mechanical means in the Kingston district, so that they flowed down the south channel the waters would move with greater rapidity, and, being considerably above the freezing temperature, would not tend to form ice until well down the river. In supporting this theory, the speaker drew attention to a curve showing that the St. Lawrence commences to freeze at its mouth. Lake Ontario forms an immense reservoir of warm water feeding the river, and this warm water gives up its heat as it flows down the river.

Dr. Barnes showed some very interesting lantern slides regarding the use of thermit, the new chemical composition containing aluminum and iron oxide which burns at a very high temperature and which he has used in his work of breaking up ice-jams. He also showed slides of his work at the Alleghany gorge and at Belleville, Ontario. At the conclusion of his address, a discussion was led by Dr. L. F. Goodwin, M.E.I.C., after which a vote of thanks was moved by Dr. A. L. Clark, M.E.I.C., and seconded by Professor W. P. Wilgar, M.E.I.C.

Annual Meeting

The annual meeting of the Kingston Branch was held in Carruthers Hall, Queen's University, on December 15th, 1927, with the chairman of the branch, Professor L. T. Rutledge, M.E.I.C., presiding.

The secretary-treasurer presented the annual report of the branch, showing it to be in a sound financial position, and that, although the number of meetings held in the past year had not been large, all had been very well attended. The total membership was shown to be approximately thirty-nine.

The officers for the ensuing year were elected as follows:—

Chairman	Professor D. S. Ellis, A.M.E.I.C.
Vice-Chairman	Professor W. L. Malcolm, M.E.I.C.
Secretary-Treasurer	D. G. Geiger, S.E.I.C.
Executive Committee	Major LeR. F. Grant, M.E.I.C.
	G. MacLachlan, JR.E.I.C.
	Dr. L. F. Goodwin, M.E.I.C.
Ex-officio	Professor L. T. Rutledge, M.E.I.C.
	G. J. Smith, A.M.E.I.C.

Programme Committee

Professor W. L. Malcolm, M.E.I.C.
Professor A. Jackson, A.M.E.I.C.
G. J. Smith, A.M.E.I.C.

After a few remarks by the retiring chairman, L. T. Rutledge, M.E.I.C., in which were expressed his appreciation of the honour of having been chairman of the Kingston Branch, and his thanks to the members of the branch for their assistance and co-operation during his tenure of office, the new officers were installed. In the absence of the newly-elected chairman, the vice-chairman, Professor W. L. Malcolm, M.E.I.C., took the chair.

After the business of the meeting had been finished the members present had the pleasure of hearing an informal address by Dr. L. J. Austin, M.D., on the history of medical science. The lecture proved most interesting and instructive, and at its close the appreciation of the listeners was presented in a vote of thanks moved by Professor W. P. Wilgar, M.E.I.C., and seconded by Professor L. T. Rutledge, M.E.I.C.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

An unusually large attendance of members assembled at a supper-meeting held on November 18th to hear Mr. Dexter P. Cooper describe the gigantic tidal power development at Passamaquoddy bay. Mr. Cooper is the originator of the Passamaquoddy scheme, and has for years been actively engaged in its development. His address was illustrated with maps showing proposed location of dams and gates and charts showing useful head available at all stages of the tidal cycle.

The Passamaquoddy Tidal Development

Passamaquoddy bay is an inlet of the bay of Fundy, situated at the extreme southern portion of New Brunswick, and is crossed by the international boundary separating that province from the state of Maine. Power is to be obtained through the 19-foot variation, at that location, of the bay of Fundy tides. A 17-mile chain of islands forms a great natural barrier between Passamaquoddy bay and the bay of Fundy, and one and a half mile of dam construction is all that is necessary to complete the separation of these waters. Passamaquoddy bay will itself be divided by dams into two parts, an upper or high level basin, supplying power, and a low level or emptying basin. By alternating the opening and closing of gates and connecting one or the other of the basins with the outer bay, a difference in head of between 8 and 9 feet, available for power purposes, will be maintained between these two basins.

The gates will be of the sliding lift type; the gateways being in the form of a half Venturi meter, with the smaller opening on the outside.

The plant is designed to develop 300,000 h.p. Turbines are to be of cast iron, 21 feet in diameter, and will operate at a speed of 50 r.p.m. Variations in power requirements will be taken care of by the installation of a large number of individual units. There will not be any power house. Instead, each unit is to be covered with an enormous steel helmet. A travelling crane will be provided for the purpose of lifting and afterwards replacing these helmets whenever it becomes necessary to repair any of the units.

It was stated that the project will be completed in about four years at a cost of approximately fifty million dollars.

Mr. Cooper's address was followed by a general discussion, after which a hearty vote of thanks, moved by F. O. Condon, M.E.I.C., and seconded by C. S. G. Rogers, A.M.E.I.C., was tendered the speaker by G. C. Torrens, A.M.E.I.C., the presiding chairman.

The Harmony Kings orchestra was in attendance and rendered a number of pleasing selections during the course of the supper.

The Evolution of Industrial Organization

An exceedingly able and scholarly address on the subject "The Evolution of Industrial Organization" was delivered at a supper-meeting of the branch held on December 14th by Norman M. Guy, M.A., professor of commerce and economics, Mount Allison University, Sackville. G. C. Torrens, A.M.E.I.C., chairman of the branch, presided.

The speaker's remarks were confined mainly to the field of production, and in opening he referred to the enlarged field and wider function of the engineer in these modern days. He explained what was meant by the term "industrial organization," pointing out that there had been at least five well defined stages,—"The Direct Appropriation," the "Pastoral," the "Agricultural," the "Handicraft" and the "Industrial." Briefly explaining the fundamental characteristics of each, and reviewing the various inventions that had revolutionized industry in the latter part of the 18th century, the speaker went on to deal with the later patents that were brought out and which have caused the evolution in the industrial life of the world. Modern industrial organization, the speaker said, possesses four outstanding tendencies,—large scale production, specialization, standardization and scientific management.

At the close of his address, Prof. Guy was extended a hearty vote of thanks on the motion of E. G. Evans, M.E.I.C., seconded by G. E. Smith, A.M.E.I.C.

During the evening excellent trombone solos were rendered by Mr. Walter Cosman and several enjoyable vocal selections by Mr. Charles Dodge.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

Target Shooting with the Short Lee Enfield Rifle

A paper indicating keen analysis and considered judgment on the part of the author was presented to the branch on November 17th by J. M. Pope, S.E.I.C., on the subject of "Target Shooting with the Short Lee Enfield Rifle."

The author, in describing the rapid development of the British service small arm since the passing of the old-fashioned flintlock musket in the middle of the last century, declared that the short magazine Lee Enfield is "to-day the most difficult of any military rifle to be put out of action either temporarily or permanently."

This feature of the Lee Enfield results mainly from its dependable bolt action, this being due to the fact that the locking lugs are placed to the rear of the bolt. Though this design unfortunately causes unsymmetrical stresses which produce lateral vibration of the bolt, affecting the accuracy of fire, it has the great merit of avoiding the recess in which the "forelocking" bolt is secured and where dirt may collect to block the bolt action. The principle employed in the Lee Enfield has the added advantage of placing the base of the cartridge right at the breech, where ready access is afforded to remove a jammed case.

After describing the interesting breech mechanism and other mechanical details of this rifle, the speaker referred to its reputed failure to achieve the accurate shooting standards of former and contemporary service arms. This is due principally to the short light barrel which whips or jumps on the discharge of a bullet, causing both vertical and lateral deflection of the muzzle from its original axis. Where this jump is constant, it may be compensated for by varying the height or lateral adjustments of the foresight, but when the whip is unevenly damped by irregular pressure of nose-cap or stock on the barrel, it is necessary to "bed" the rifle by scraping or realigning the stock to fit the barrel.

Afterwards, an interesting discussion on the relative value of open and aperture sights was led by Colonel F. F. Clarke, A.M.E.I.C., chief executive officer of the Ontario Provincial Rifle Association.

A. N. Budden, S.E.I.C., presided over the meeting, and at the conclusion of the paper a vote of thanks was tendered to the author by A. C. Oxley, A.M.E.I.C.

Capacitors

The Montreal Branch was favoured with an interesting description of the elements and uses of "Capacitors" on November 24th in a well illustrated paper by Mr. M. C. Lowe, engineer of the Canadian General Electric Company.

Although employed commercially some thirty years ago, it is but recently that improvements in the manufacture and the increasing demand for high power factor have proved the value of capacitors, or static condensers as they were once called, over other well known electrical apparatus.

The chief difference in the design of capacitors from other electrical appliances is the utilization of a very high voltage gradient in the active dielectric to keep bulk and cost within reasonable limits. As the operating stresses in standard capacitors range from 150 to 300 volts per mill, the highest grade of dielectric material is required, followed by a very careful heat and vacuum process.

The materials used in the construction of the capacitors sections consist of three or more layers of pure linen fibre paper interleaved with aluminum foil, both of approximately one-half mill thickness. The dielectric is first thoroughly dried and evacuated of gas by the application of heat and vacuum for a long period of time before it is thoroughly and slowly impregnated with a high grade treated oil. The units are then thoroughly tested.

Series capacitors secure practically direct current transmission values while retaining all the advantages of alternating current, and may be employed as automatic regulators of transmission voltages for increasing the power limit of long transmission lines or for partially compensating reactance on parallel lines of different characteristics. On the other hand, coupling capacitors, while serving as safe insulating links between carrier current circuits and high voltage transmission lines at ordinary power frequencies, provide a path for the high frequency currents to operate the relays. Capacitors have have also been used as high frequency lightning absorbers and to prevent and diminish contact sparking. Their application to radio equipment is known to all and is a field in itself.

Notwithstanding these uses, it is only in recent years that, from a former position of practically laboratory apparatus, the capacitor has developed to a standard and widely recognized device for correcting power factor on power systems. Since power factors other than unity involve additional investment in generators, transformers, lines and regulating equipment, it is advantageous in a broad sense to employ capacitors wherever it is desirable to improve the power factor.

In the discussion which followed, M. L. de Angelis directed the attention of the meeting to a new type of capacitor called the Silbermann " cable condenser " which has been developed for high voltages and large capacities. The cable condenser consists essentially of a central metal core, a hollow conductor, a metallic envelope and a lead sheet, all separated by insulation.

P. T. Davies, M.E.I.C., while taking part in the discussion, expressed the appreciation of the meeting to the speaker. The meeting was presided over by the branch chairman, Prof. C. V. Christie, M.E.I.C.

Vacuum Process of Paper Manufacturing

The paper submitted to the branch on December 1st by Mr. Ogden Minton on the vacuum process of paper manufacturing, presents an interesting development invented by the author in the art of paper manufacturing. The paper was completely illustrated by lantern slides illustrating the development of the dryer. A special feature of the meeting was the distribution by the author of copies of his paper and illustrations in book form to all those present. The paper is published in full in the current number of the journal.

The interest in the subject was manifested by the number present at the meeting, among whom were many visitors, and considerable discussion followed the presentation of the paper.

The author mentioned that the vacuum dryer is not a completed piece of machinery, but is so far developed that its ultimate success is assured. Its success is due in a great measure to the foresight of Price Bros., who had a trial machine installed at their plant and have carried out a great deal of experimental work with it.

Considerable discussion took place on the subject of dryer felts and their composition, shrinkage, lasting qualities, etc., in which Messrs. G. N. Stevenson, W. G. Mitchell, M.E.I.C., and Van de Carr participated. The latter referred to his experiences with dryer felts on his own dryer machine at the Ste. Anne's mill, where the shortest life was stated to be about 120 days.

The high level of achievement which the inventor had attained in initiating his ingenious improvements in paper manufacturing was remarked on by Julian C. Smith, M.E.I.C., also his efforts to get higher production at cheaper cost. In referring to the possibilities of higher vacuums, which had recently attracted attention when Professor Claude had demonstrated his device for developing power from small temperature variations in sea water, he stated that had the present inventor been able to increase his vacuum slightly he might have dispensed with the use of steam entirely. Not only had the author's efforts benefited the paper industry through the vacuum dryer, but they had also spurred others on to improve the mechanical means for drying paper.

The author stated in his reply that the maximum vacuum he had attained in drying paper was 28.86 inches. He referred to the difficulties in determining the shrinkage of the paper and where this takes place, and also mentioned that 35 to 36 per cent of the moisture can be removed in the pressure process, leaving about 65 per cent to be removed by the dryer.

In reply to a question in regard to steam economy, he stated that in tests made at Price Bros'. mill at Kenogami a saving of steam of 43.8 per cent was shown by the use of the vacuum dryer.

W. G. Mitchell, M.E.I.C., mentioned that there were still opportunities for increased economy in the dryer part of the paper-making equipment, although dryer presses had done a lot in this direction.

It was further stated that in 30 or 40 years no radical changes had been made in paper-making and drying, and that great credit was due to Mr. Minton for his invention.

In reply to remarks by R. A. Ross, D.Sc., M.E.I.C., in which he inquired about the type of pump used for producing the vacuum, Mr. Minton stated that two pumps of 40 h.p. combined were used, manufactured by the Ingersoll-Rand Company, running at 144 r.p.m., which would produce the full vacuum of 28 inches in three minutes.

In expressing the thanks of the meeting, Professor Keay, M.E.I.C., pointed out the great obstacles that arose in the interval between laboratory discovery and field practice, and described the great achievement of the author as a lesson to all in courage and persistence. Mr. G. N. Stevenson added a few remarks in seconding the vote of thanks.

The chairman of the meeting was E. P. Cameron, A.M.E.I.C.

Montreal South Shore Bridge

The following is a synopsis of the address delivered before the Montreal Branch by P. L. Pratley, M.E.I.C., on December 8th, on the progress of this bridge. There was a record attendance at this meeting, which was under the chairmanship of G. H. Duggan, M.E.I.C.

The speaker began by pointing out that he would keep well within the bounds set by the title as printed, and discuss only the actual progress made with the work up to date. In the previous lecture, given in March 1926, the review covered the 1925 season and the commencement of the excavation for pier 25 on the city side of the river, which was started in the winter of 1925-26.

A description of the pneumatic method of sinking caissons as used on this and other piers was entered into and slides were shown of the construction of the caissons used on the bridge. In all, eight pneumatic caissons were employed, two for pier 25 and two for the temporary falsework piers of the Dominion Bridge Company, just north of pier 25, one very large one for the river main pier No. 24 and three others of more moderate dimensions for piers Nos. 13, 14 and 21. These caissons were of different types only as to their upper walls, some being steel throughout, others concrete and others wood. On the south side of St. Helen's island the two built by Messrs. Quinlan, Robertson and Janin were operated by steam, but all the others by electric power. Views were then shown of the large caisson for pier No. 24 being launched at Vickers and being towed up the river to the site. This caisson was a vessel drawing about 12 feet and weighing about 1,030 tons afloat. It was entirely of steel construction and is about the fourth or fifth as to size in the world to date.

The progress of the stone laying and concrete pouring on all the various piers on both contracts and general views showing the gradual completion of the substructure were interspersed with slides of individual piers. Charts indicating the work done during each construction season were presented, and the progress was shown by comparative figures. In 1925, for instance, some 8¼ per cent was done; by the end of 1926 about 68¾ per cent had been completed, and by the close of the 1927 season 95½ per cent. The remainder consists of work in the city on the pedestals and concrete viaduct of the approach, the figures applying to the substructure only.

Allusion was then made to steelwork progress, and a number of views were shown dealing with this interesting feature. It was remarked that, although this to the layman is the real sign of visible progress, to the engineer the completion of the foundations meant a great deal as it is principally in the latter connection that he is dealing with the unknown. Erection of the short spans at the south shore, in September 1926, constituted the first item of the steel placing that means much to the public, but actually anchorage girders had been embedded in the city anchor pier previously. In 1926 the steel was taken out to pier No. 7, and in 1927 it has reached the island and is to be left at pier No. 20 until next season. On the city side, very gratifying progress has been made with the north anchor arm of the main span, and many slides were shown to illustrate the setting of main shoes, falsework bents and trusses, erection travellers, chords, web members and the huge main post sections.

A short study of the economics of the south side steel and masonry layout was given by the lecturer, where the respective costs of substructure and superstructure were compared at various spans.

Mr. Pratley stated that he was not touching on the erection methods and equipment to any greater extent than the presenting of slides, as no doubt the Dominion Bridge Company engineers would be making that the subject of a much more technical paper at a later date. He stated that although there had been delays here and there in certain parts of the work, excellent progress had been achieved on the whole, and nothing had yet occurred to lead the commissioners to fear that the work would not be completed by the date set. The lecture was illustrated by one hundred and twenty lantern slides prepared from progress photographs.

At the close of the address, the chairman proposed a vote of thanks to Mr. Pratley, which was heartily accorded.

Annual Meeting

The annual meeting of the Montreal Branch was held on December 15th, C. V. Christie, M.E.I.C., the chairman of the branch, presiding.

On the motion of H. W. Swabey, M.E.I.C., the minutes of the preceding meeting were taken as read. Thereupon, the chairman presented the annual report of the branch for the year 1927. During the year the executive had held nine meetings, the average attendance being ten. Although the branch membership had shown a slight decrease from 1,023 in 1926 to 1,021 in 1927, this had not been reflected in the financial statement, as the decrease had occurred in the student section, all other sections showing an increase. With regret, the branch reported the loss by death of B. J. Forrest, M.E.I.C., W. L. Scott, M.E.I.C., H. C. Read, A.M.E.I.C., and R. C. Forbes, S.E.I.C. The report described in detail the activities of the branch committees relating to papers, reception, publicity, membership, smoke abatement, annual visit, professional meeting and nominating under the respective chairmanship of A. Duperron, A.M.E.I.C., H. G. Thompson, Jr.E.I.C., H. W. Swabey, M.E.I.C., D. C. Tennant, M.E.I.C., C. M. McKergow, M.E.I.C., J. A. McCrory, M.E.I.C., J. L. Busfield, M.E.I.C., and F. A. Combe, M.E.I.C.

The attendance at the branch meetings during the year proved to be entirely out of keeping with the large resident membership. The average of 98 established in 1926 had fallen to 92 in 1927. It was a cause for regret that in two years 475 members had not attended even one meeting, while 415 others had attended less than six. As a consequence, only 10 per cent of the membership could be considered active.

In presenting the financial statement, the chairman announced that for the first time in the history of the branch it would be possible to hold the professional meeting without calling upon the members for donations. The surplus of 1926 had been increased from $1,533.24 to $2,150.02 at the present time.

On the motions of J. B. Challies, M.E.I.C., and Geo. R. MacLeod, M.E.I.C., respectively, the financial statement and the branch report were adopted unanimously.

On behalf of the scrutineers, F. A. Combe, M.E.I.C., reported the result of the ballot for the election of officers of the branch for the year 1928.

Chairman	F. C. Laberge, M.E.I.C.
Vice-Chairman	J. A. McCrory, M.E.I.C.
Executive Officers	H. Massue, A.M.E.I.C.
	R. DeL. French, M.E.I.C.
	E. A. Ryan, A.M.E.I.C.

On rising to express his personal appreciation, the chairman-elect referred to the honour conferred at the same time upon his French-Canadian confreres. In commenting upon recent engineering developments, Mr. Laberge voiced the opinion that 1928 would prove to be a banner year for the profession in all its branches.

Mr. McCrory, in a few words, expressed his thanks to the members for the honour conferred upon him.

In outlining the progress of the arrangements for the Annual Professional Meeting of The Institute in February, J. L. Busfield, M.E.I.C., chairman of the Annual Meeting Committee of the branch, asked for volunteers to serve on the various committees and announced another interesting paper by Dr. Pariseau, dealing with the Scientific Investigation and History of Egyptian Mummies, to be read at the Annual General Professional Meeting.

Considerable discussion followed, led by Messrs. D. C. Tennant, Geo. R. MacLeod and P. L. Pratley, on the suitability of the grades of membership in The Institute. The secretary, Mr. Durley, reported that Institute committees are working on this subject and announced that His Excellency the Governor-General, Lord Willingdon, had graciously consented to attend and speak at the Annual Dinner.

On a motion of Mr. Tennant, it was resolved that the branch authorize the branch executive to appoint a committee to co-operate with these Institute committees.

O. O. Lefebvre, M.E.I.C., moved a vote of thanks to the outgoing chairman and executive, while Mr. J. A. McCrory expressed the appreciation of the officers to the various branch committees and to the press.

Following an interesting screening of the pictures presenting prominent members of The Institute on the Gatineau trip, obtained through the kindness of the Associated Screen News, the meeting adjourned for refreshment provided by the Reception Committee.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

General F. A. Sutton, M.C., late military adviser to Marshal Chang-Tso-Lin, present head of the Pekin government, was the guest of the Ottawa Branch at a luncheon held in the Chateau Laurier on November 24th. The gathering was so large as to overflow the banquet room. The chairman, Noulan Cauchon, A.M.E.I.C., introduced the noted general, who has had a colourful and varied career in the Argentine, Mexico and Siberia and lost an arm at Gallipoli in the great war. During the past seven years General Sutton has been with Chang-Tso-Lin in China, and, with a large improvised map of the Chinese Republic in the background, the general rose to address the members on his "Experiences as a military adviser to the Chinese government."

General Sutton on China

General Sutton sketched a picture of conditions in China as they are to-day; conditions which he said were not properly presented in the press because the news services come entirely from southern China. Northern China or Manchuria, the general said, is the scene of the most rapid settlement in the world to-day. This he attributed to Chang-Tso-Lin, whose stern measures were responsible for keeping a semblance of law and order in the land, and this in spite of Russian influence. Manchuria, he said, is a wonderful agricultural country and had great possibilities. The Russians, however, are taking a big hand in business in Manchuria and Mongolia, and Russian interests now operate and make a large profit from the Chinese Eastern Railroad.

In southern China, or China proper, beyond the domain of Chang-Tso-Lin, conditions are very much worse. According to General Sutton, nineteen per cent of the people are hopelessly poverty-stricken, or, as he expressed it, "one jump ahead of the wolf." The morning salutation in China was not "How are you ?" but "Have you had any breakfast ?" The Chinese he divided into three classes, the coolie, who lived from hand to mouth and formed the bulk of the population, the Chinese merchants, who formed the backbone of the country, and, thirdly, the three or four million half-baked students. The upper classes treated the lower classes very badly and graft was almost universal and worked as a family system. There were never two parties in China, but always a third and each with his two henchmen and their supporters, so that there were usually eight or nine parties in every contentious issue. In this grouping in threes, when the main contenders got through scrapping there was always someone to jump on the vanquished and finish him up.

In the opinion of General Sutton, the Chinese students, mostly fourteen or fifteen years old, could not have any great influence for the advancement of China; there were more students than jobs, and the youngsters were an easy prey for Russian agitators. Into this maëlstrom, said the general, Russian money to the extent of seventy or eighty millions annually is being poured, and the Bolshevist agitators are under instructions to stop at nothing, even murder, to stir up anti-British hatred. The whole campaign is being directed against the British, and there are, he said, eighteen thousand Soviet propagandists at work seeking to undermine British prestige.

General Sutton thought the principal source of trouble in China as it affected Great Britain was lack of a strong-arm policy. One of the main characteristics of the Chinese was in keeping their face. Once a nation or an individual showed even a suggestion of backing down they lost caste. Britain's policy of conciliation in handing back concessions and rights worth many millions of dollars only resulted in ridicule and contempt. British merchants, he said, should have more backing from the home government. When the concessions were given back, these merchants in many cases were absolutely ruined.

Very interesting was General Sutton's sketch of the meteoric rise of Marshal Chang-Tso-Lin. From being an obscure bandit, he had risen to his present commanding position. "He has real courage," said the general, "and although he received little credit for it, he is the best friend foreign interests have." As for the yellow peril, there need be no fear on that score. No Chinese, he said, could organize an army capable of standing up for ten minutes against that of a foreign power.

A number of prominent military men of Ottawa were among those who were seated at the head table. These included Major-General H. C. Thacker, C.B., Major-General H. H. Panet, C.B., C.M.G., D.S.O., Lt.-Col. Lindsay Gordon and Major T. W. MacDowell, V.C., D.S.O.

National Parks Idealism

At a luncheon at the Chateau Laurier on December 1st, the members of the Ottawa Branch had the pleasure of hearing J. B. Harkin, commissioner of Canadian National Parks, in an inspirational address on Canada's National Parks.

Mr. Harkin chose as the theme of his address "National Parks Idealism," and stressed the necessity for the joys of natural beauty in an age when so many people were huddled into cities and living on their nerves. Concentration of vast population in large cities had not been good for man physically or mentally; now, Mr. Harkin said, mass production had given factory work a character of monotony and drudgery disastrous to the nervous system. In fact, man's whole habits had been changed. Less than a hundred years ago he lived largely on his muscles. Now he lived on his nerves and he had not been doing so long enough to have adapted himself to his new environment. So far man had found no effective antidote for these ills of civilization except beauty and the great out-of-doors.

Forty years ago, said Mr. Harkin, Banff, the first Canadian National Park, was created, in the words of Sir John A. Macdonald, "to recoup the treasury and recuperate the people." In Canada's National Parks to-day are incorporated portions of the Dominion which represent the very soul and spirit of beauty, areas of grandeur and sublimity beyond imagination, which arouse in one feelings of almost religious awe and veneration.

Mr. Harkin briefly touched on the enormous traffic to the National Parks. Last year, he said, they were visited by over 250,000 people and they were bringing millions into the treasury. Monetary considerations, however, Mr. Harkin put second to the great fundamental fact that national parks were intended for the preservation of beauty in its natural state; beauty he looked on not as a national but an international property to be enjoyed by all, and he instanced the art galleries and museums of the world which were open for the enjoyment of people of all nationalities.

Speaking of the engineering staff, Mr. Harkin said that on macadam, gravel and dirt roads the parks engineers produced better roads at less cost than any other engineers in America.

Noulan Cauchon, A.M.E.I.C., chairman of the branch, presided and, in expressing thanks to the speaker, he referred to the hope felt by the majority of the people of Ottawa that the government would acquire as a national park an area of the Gatineau hill country, north of Ottawa.

Pscho-analysis and Mental Health

An unusual pleasure was afforded members of the Ottawa Branch at an evening meeting in the Chateau Laurier on December 8th in listening to an address which might be said to be entirely extraneous to engineering. Professor J. W. Bridges, M.A., Ph.D., associate professor of abnormal psychology at McGill University, came from Montreal especially to address the engineers and their friends on "Psycho-analysis and Mental Health."

Professor Bridges, in introducing his subject, reviewed the original concepts of the personality by James, Hartmann, Freud and Jung. According to James, the average person consisted of several selves, as, for instance, his home self, business self and club self. Freud divided the personality into consciousness, foreconsciousness and unconsciousness. Man's actions were motivated by drives, notably sex instinct, ego instinct or the desire for power or security, while other motivating influences were fear, hunger, pugnacity.

Mental conflict, explained Professor Bridges, arose from the individual not being a perfect unit, and he dealt with the various conflicts which arose in different individuals and their alleviation or cure through an understanding of the principles of psychology. Once understood, man's weaknesses might be resolved by sublimation, and he spoke of the sublimation of various conflicts which really consisted in finding an outlet rather than repressing the tendency. For instance, he said, if a man was of a pugnacious disposition he would find alleviation for this distressful state of mind in taking up boxing or perhaps better still in entering politics, which would furnish the necessary outlet for his combative proclivities through the medium of speech.

"Know yourself, accept yourself and be yourself" were Professor Bridges' fundamental rules for mental health, which afterwards provoked considerable interesting discussion by the audience, particularly as to the possibilities of persons psycho-analyzing themselves to discover their mental conflicts and thus be able to apply the correct antidote or find the outlet. Professor Bridges explained that it is quite possible for a person to make considerable progress in self-analysis by following certain set methods for the application of psycho-analysis to oneself.

The meeting was presided over by Chairman Noulan Cauchon, who thanked Dr. Bridges for his most fascinating outline.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary-Treasurer.

Annual Banquet

Mirth and wisdom were both present at the annual banquet of the Peterborough Branch held November 22nd, 1927, at the Empress hotel. The speeches were short and interspersed with many stories, but in their serious portions conveyed many fine ideas.

A. E. Caddy, M.E.I.C., chairman of the local branch, occupied the chair. Music was provided by "The Musical Engineers," and the dinner served by the Empress staff left nothing to be desired.

Amongst the guests of the branch were His Worship Mayor Holloway, R. J. Durley, M.E.I.C., L. W. Gill, M.E.I.C., of the Hamilton Technical School, C. E. Sisson, chairman of the Toronto Branch, A.I.E.E., D. A. McKenzie, of the Hydro-Electric Power Commission of Ontario, J. Showalter, of the Westinghouse Company, J. A. Johnson, of the English Electric Company, Professor H. E. T. Haultain, M.E.I.C., University of Toronto, and representative of the sister professions.

The chairman proposed the toast to the King, which was duly honoured. He then welcomed all those present from the sister professions and sister associations before calling on His Worship Mayor Holloway to speak.

His Worship referred to the remarks made by the engineers and others at the Great Lakes Harbour Association regarding the work of Canadian engineers, and appreciation of Canada's Welland canal project. In conclusion, the Mayor remarked that the people of Peterborough were proud of the local engineers.

A. L. Killaly, A.M.E.I.C., in proposing the toast to "The Engineering Institute of Canada," referred to the establishment of The Institute as the Canadian Society of Civil Engineers forty years ago and gave a brief history of The Institute up to its present position with twenty-five branches and about five thousand members.

R. J. Durley, M.E.I.C., general secretary of The Institute, expressed pleasure at being present at the annual banquet of the Peterborough Branch. He announced that The Institute had this year for the first time been able to get the members of the Council together for a three-day session of great value. The most important question that came up was, he said, the matter of relations between The Institute and the several associations of professional engineers in Canada. It pleased him to say that steps had been taken toward getting admission into all the associations put on an equal basis.

Other subjects considered by this plenary meeting of Council were, Mr. Durley said, qualifications for admission into the various grades of membership, engineering education, etc.

Mr. Durley announced the next annual general meeting for February 14th, 15th and 16th in Montreal, at which the Governor-General is expected to be present.

L. W. Gill, M.E.I.C., of the Hamilton Technical School, congratulated the Peterborough Branch on the large number present and conveyed the greetings of the Hamilton Branch.

He first touched on the matter of engineering education, which had been discussed at the Council meeting. In fifteen years of teaching he had discovered that the engineer is a pretty hard case to educate, learning only what he thought good for him.

He had been asked to speak on technical education, and hoped he would clear up some of the misconceptions. He declined to be considered an expert, who is a man who knows "more and more about less and less."

Technical education is intended to cover something not included in any other scheme. Before the war, 40 per cent of the children never completed the public school. About 25 per cent entered high school, 10 per cent completed the high school course and 1 per cent entered university. The technical school in Ontario was conceived as an aid to industry. People concerned said that the state was providing training for 30 per cent of the children free, while the others were allowed to go out into the world untrained. To provide free training for every person for four years after leaving public school is the aim of technical education. It gives every boy and girl some opportunity to develop latent talent.

Mr. Gill summarized the work of the technical schools in terms of the qualities required for success, namely, character, judgment, efficiency, executive ability, general knowledge and specialized knowledge or skill.

Tribute to the memory of the late R. B. Rogers, M.E.I.C., who passed away since the last annual banquet, was paid by Mr. Caddy. Forty years ago, said the chairman, Mr. Rogers joined The Institute as one of the first members of the Canadian Society of Civil Engineers and fifty years ago he graduated from McGill. Mr. Caddy announced that the branch had decided to place a memorial on or near the Peterborough lift lock, which was designed by this faithful member of the local branch.

Recollections of the old engineering sextette were sung by a new edition containing only one member of the original six. They responded to an encore with "Engineering All the Time."

The toast to "Sister Associations" was proposed by M. V. Sauer, M.E.I.C., which was honoured by the singing of "For They Are Jolly Good Fellows."

C. E. Sisson, of the Toronto Branch of the American Institute of Electrical Engineers, said that he always felt that he was coming home when he was coming to the annual banquet of the Peterborough Branch. He brought greetings from his branch and extended his best wishes for success of the branch. He had good support, he remarked, having with him D. A. McKenzie of the Hydro; J.

Showalter of the Westinghouse Company; and J. A. Johnson of the English Electric Company. Each of these gentlemen also briefly responded to the toast.

Professor Haultain spoke of the Technical Service Council, recently formed by a committee of men from the Association of Professional Engineers and the Canadian Manufacturers' Association. He gave a list of prominent men who form the advisory board. This council is primarily a selling organization to sell the engineer to the public.

W. E. Ross, A.M.E.I.C., introduced the next item, a moving picture entitled "There's Always Room at the Top," and explained it as a man's dream of success in the engineering profession. This was written by Mr. Ross, photographed by Ross L. Dobbin, M.E.I.C., and the actors were members of the Peterborough Branch, with A. B. Gates, A.M.E.I.C., as the hero and W. M. Cruthers, A.M.E.I.C., as the villain.

E. R. Shirley, M.E.I.C., then proposed the toast to "The Sister Professions," which was responded to by representatives of the Teachers' Association, the Ministerial Association and the Legal Profession.

Mr. F. H. Dobbin was, as usual, one of the speakers, and he suggested that the name of the late Walter J. Francis should also be included in the memorial to the late R. B. Rogers.

The singing of "Auld Lang Syne" brought the banquet to an end.

Regular Meeting

The regular meeting of the Peterborough Branch on December 8th, 1927, was held in conjunction with the Peterborough Radio Club. The branch chairman, A. E. Caddy, M.E.I.C., installed G. H. Burchill, Jr.E.I.C., as chairman for the evening, who introduced the speaker, J. M. Thomson, S.E.I.C., radio engineer of Ferranti Electric, Limited.

Mr. Thomson's subject was "The Modernizing of Old Radio Sets and Correction of Troubles Encountered with B Eliminators." The first part of his address, however, reviewed the changes and advances in the construction of radio receiving sets during the past eighteen months. To meet the demand for simplified control, the use of coupled condensers has been adopted, thus reducing the number of controls to one or two, namely, tuning control and volume control with filament switch. This change has involved several problems which have been solved by the radio engineers.

Other developments have been a.c. batteryless sets, the use of shielding and the increase of the amplification of tubes by reducing plate capacity.

Turning to the subject of troubles in radio sets, the speaker listed a number of these with their remedies. He advised the changing of tubes at the beginning of each season and the frequent checking of the condition of batteries. He pointed out the slight difference in characteristic of tubes of the same type and how this might cause trouble when changing tubes. In connection with lightning arresters, he strongly advised the use of a simple grounding switch. At the conclusion of his address, Mr. Thomson gave an interesting demonstration of a method which has been developed to cure a trouble known as "motor boating." This demonstration showed how by a combination of change in transformer connections and the use of by-pass condensers the "motor boating" could be greatly reduced or entirely eliminated.

At the conclusion of the address, Mr. Thomson answered a number of questions on radio matters.

H. O. Fisk, M.E.I.C., proposed a hearty vote of thanks to the speaker which was endorsed by all those present.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

A meeting of the Saint John Branch was held on December 9th, 1927, with twenty-one persons present. S. R. Weston, M.E.I.C., chairman of the branch, presided.

A resolution of regret was passed at the death, on December 6th, of D. L. Hutchinson, an Affiliate of the Saint John Branch. Mr. Hutchinson had been interested in branch affairs for a number of years as a Branch Affiliate. He had been in the service of the Meteorological Department for forty-one years, and for a number of years had been in charge of this service in the Maritime provinces.

A proposal to increase the fees of members $5.00 per member started a lively discussion. Geoffrey Stead, M.E.I.C., councillor in attendance at Plenary Meeting of Council, explained the necessity for increased revenue. The executive were asked to submit a report at next branch meeting.

Filtration

An address on filtration was given by J. L. Feeney, A.M.E.I.C. The address dealt largely with the principles of rapid sand filtration and was given in general terms for the benefit of a mixed audience of engineers which had not made this subject a specialty.

In order to discuss the various factors entering into the design, a mechanical filtration plant required for a theoretical city with 10,000 assumed population, located on the upper Saint John river in New Brunswick, was described. It was assumed that the city already had a water system installed with mains in good condition and below frost line, and practically all services metered; the problem was only the purification of the water before it entered the mains. The method of determining the capacity of the proposed plant was described, with due allowance for unusual demands such as occur in the case of a conflagration. It was decided to design a plant to be equipped to filter 2,000,000 U.S. gallons, or twice the normal demand, and capable of housing in future sufficient equipment to filter an additional 1,000,000 gallons. To meet abnormal fire demands, the necessary reservoir capacity was to be provided.

The design of various sizes of pipes, pumps, valves, etc., in accordance with hydraulic laws and practical experience was explained in detail. The economy of designing the pumps for present capacity and the mains to provide for future installations was pointed out.

The speaker compared different methods of water purification and referred to various details of the mechanical filtration process.

The address was illustrated by several wall diagrams and was further explained during a discussion after the reading of the paper. A vote of thanks was tendered to Mr. Feeney on motion of H. F. Morrisey, A.M.E.I.C., and E. A. Thomas, A.M.E.I.C.

Demonstration of a Public Address System

A demonstration of a public address system was given by A. A. Turnbull, A.M.E.I.C. The transmitting horn was installed in the room where the meeting was being held and the amplifier on a lower floor. The principles underlying the system were briefly explained and an inspection made of the several pieces of apparatus.

Toronto Branch

W. B. Dunbar, A.M.E.I.C., Secretary-Treasurer.
(Reported by J. W. Falkner, A.M.E.I.C.)

Joint Luncheon Meeting to Professor Peter Gillespie, M.E.I.C.

Following up the generally expressed opinion, and an informal meeting between the chairmen of the various local engineering socities, looking towards all practical measures of co-operation and fraternization, a special committee was appointed during the summer of 1927 from the Toronto Branch, E.I.C., Toronto Section, A.I.E.E., and the Ontario Section, A.S.M.E., to arrange for one joint meeting during the winter season of 1927-28, and this committee decided that a joint luncheon-meeting should be held on December 1st, 1927, at the King Edward hotel, in honour of one who has for many years rendered single-eyed service to the community, and to the engineering profession,—Peter Gillespie, M.E.I.C., professor of civil engineering at the University of Toronto and one of the vice-presidents of The Engineering Institute of Canada.

The luncheon was held on the above date and was exceptionally well attended, over one hundred and fifty engineers sitting down to the luncheon. It was a thoroughly representative gathering from all the numerous Toronto engineering offices and organizations, and the executives of the three engineering societies sponsoring the luncheon were fully represented at the head table.

Professor A. E. Allcut, M.E.I.C., chairman of the Ontario Section, A.S.M.E., acted as chairman, and after referring to the goodly custom in the professions of law and medicine of according recognition to those who had well and truly served their profession and the community, and, after speaking of Professor Gillespie's sterling worth, genial personality and his qualities as a "prophet whom we delight to honour," called upon Professor A. T. De Leury to introduce the guest speaker.

Professor De Leury, in a witty and appreciative speech, then took his hearers back to the years when "Peter" was a raw undergraduate and afterwards a colleague and friend, comparing him with many other famous "Peters" whom he had known, not omitting such notable characters as Peter the Hermit and Saint Peter. The faculty of arts, he said, unlike the school of engineering, played with ideas long before their practical use, solely for their beauty, interest and diversion, and he believed that "Peter" would have been as much at home in "Varsity" as he was at S.P.S., where, like the famous Saint, he had been a contributory "rock" when strong and sure foundations for that institution were being laid.

Professor Gillespie was then called upon to speak, being warmly greeted with vocal honours and the School of Science "yell." After a humorous story and a few opening remarks thanking those present for his reception, Professor Gillespie launched into the subject matter of his speech, which was based on a newly published book he had recently read,—"The Babbit Warren," by C. M. Joad. This book, Professor Gillespie said, had apparently been published in England by an Englishman who had never been in the United States, and, in his opinion, offered a very unflattering view of that country; in fact, he ventured to think it a caricature or burlesque, and evidenced that fact by some dozen or more paragraphs read at random from the book, which were greeted with loud laughter by the meeting.

The favourite United States "indoor pastime" of "twisting the lion's tail," said the speaker, had its counter-part in the British Empire of frequently "plucking feathers from the eagle's tail." Dickens had indulged that propensity eighty years ago, and the book from which he had read extracts was but another example of a very common attitude of mind, but it was an attitude with which he had little sympathy either on this side of the boundary line or the other. Two reasons why he was not in sympathy were, (1) that such an attitude of mind burlesques manners, things and people in the other country which could be found, were we honest, amongst ourselves, and, (2) that the things so burlesqued had in many cases a very worthy foundation. We should remember that the United States was born in a struggle for liberty in which they were supported by the elder Pitt, Chas. James Fox, Burke, and many other such great Englishmen, and that even to-day, after a century of immigration, fifty-five per cent of the United States stock was said to be of British extraction, and two million of that number were said to have been Canadian born.

The Professor then gave the other side of the story to that contained in "The Babbit Warren," showing how in its one hundred and fifty years history that country had given birth to, and was giving birth to, outstanding spiritual, literary and material values that were an asset to the whole world.

Each of these fields were investigated in detail, through the great New England poets and writers; the fearless struggle against slavery, with its modern counterpart promising some solution to the negro problem in the south; the material values given to the world in labour-saving devices, improved building construction methods, and the system of mass production; the Rockefeller, Sage, Carnegie and such like foundations, devoted to the alleviation of suffering, and the investigation of diseases in Korea, China, Japan, Africa, Jugo-Slavia, Netherlands, Great Britain, Canada, and, in fact, all parts of the civilized and uncivilized world, as well as in the United States, evidenced so far as the British Empire is concerned by the munificent foundation and building recently presented to University College Hospital, London, England, filling a sorely felt need at the centre of the Empire, and also by the magnificently equipped and endowed School of Hygiene and Preventive Medicine opened last year at Toronto University. In connection with mass production, the average output of one workman in the United States was said to be thirty times that of one Chinaman and two and one-half times that of one German, and Kettering has said with reference to the automobile industry that the output of one American was ten times that of one European.

In a spirited address, the Professor pleaded for greater appreciation and understanding in the things which we held in common. He felt that engineers on both sides of the line, with their frequent contacts one with another, were in a peculiarly favoured position to exert a most wholesome influence in this matter. He quoted John Bright to show that the influence of each single man was far greater than he realized, with an ever extended radius.

The relations between the United States and the British Empire were never better than they were to-day, as evidenced by the frequent causes for friction during the 19th century, most of them now happily settled, the present good feeling, and the appointment of a Canadian Ambassador at Washington and a United States representative at Ottawa.

In conclusion, the speaker quoted with approbation the United States Secretary of War Davis' words at Washington on November 12th, 1927, in connection with the unveiling of a memorial to those Americans who enlisted in the Canadian forces during the Great War before the United States had joined the Allies:—

> "Canadians and Americans speak the same language, read the same books and think the same thoughts. Jointly, they occupy the largest area of the earth's surface where a single language is spoken. No unfriendly rivalry mars the even tenor of their intercourse. The calamity of one is the calamity of the other and an attack upon one is an attack upon the other. They are jointly engaged in the greatest work of settlement and civilization known to mankind. The young men who crossed the border and enlisted in the Canadian forces are the latest and most precious offering upon the altar of our mutual friendship."

The Grand Falls Power Development

(Reported by H. Neville Mason, A.M.E.I.C.)

A very interesting paper was read before the Toronto Branch at the regular meeting held on Thursday, November 17th, in the Mining building of the University of Toronto. The speaker of the evening was A. C. D. Blanchard, M.E.I.C., resident engineer on the Grand Falls power development in New Brunswick. Mr. Blanchard represents the consulting engineers for the construction of the power plant, Messrs. H. G. Acres and Company, Limited.

The various stages of construction to date were described, and slides shown giving very good illustrations of the various works covered by the address.

One of the most noteworthy achievements lay in the concluding of all the necessary negotiations with the various governments concerned, and the signing of the contract, in a remarkably short space of time after the formation of the Saint John River Power Company of Grand Falls; construction work being started only four months after the company was formed. The work was awarded to the Dominion Construction Company of Toronto, and it is considered to be one of the rare occasions upon which work of such a character has been let on a unit price contract.

The engineers having been so closely associated in the past with the construction of the Queenston-Chippawa power development for the Ontario Hydro-Electric Power Commission, needless to say, brought their vast experience so gained to the advantage of this construction; so that, when completed, it may be said to be the last word in hydro-electric power construction.

The preliminary foundation and sub-aqueous construction had to be arranged to conform to the peculiar behaviour of the Saint John river, having especial regard to the danger of destruction of the coffer dams by the spring freshets, which are very heavy.

The main dam consists of a series of armoured concrete piers and steel screw lift sluice gates extending entirely across the river, by means of which a head-pond is formed, thirty miles in length, impounding over one billion cubic feet of water with the surface at an elevation fifteen feet above ordinary summer water level.

The Johnson-Wahlman intake is located a short distance above the control works. Two gathering tubes of reinforced concrete built in ledge rock converge on a "*Y*" connection to the tunnel. The tunnel is approximately 28 by 28 feet, horseshoe in shape, and was constructed from a heading 9 by 10 feet.

Very great care was taken to ensure that the minimum of rock excavation was done, to the extent that inspectors checked all drillings before blasting, and, the spacing of holes and depths being all predetermined and regularly arranged, the work was carried through very systematically with very little loss of time.

Only two units will be completely installed for the present; provision is being made for two future units in the superstructure and a fifth penstock from the present distributor. There is room for unlimited expansion at the downstream end of the power house.

Work was officially commenced on August 10th, 1926, and the substructure was completed early in the spring of 1927. Drilling of the lower portal of the tunnel was commenced in September 1926, and the heading was completed in March 1927. The lining of the tunnel is scheduled to be completed by November 30th, 1927. The construction force has averaged 350 men, and considerable credit is given to them, as also to the engineering staff, for the very satisfactory progress that has been made.

Many new mechanical features have been introduced by the engineers, tending to greater efficiency of operation.

It is expected that the work will be completed by July 1st, 1928. It is being carried out under the general direction of Mr. A. H. White, M.E.I.C., vice-president and chief engineer of the International Paper Company. The engineering and supervision of the project are in the hands of Messrs. H. G. Acres and Company, Limited, of Niagara Falls, Ontario.

Discussion was entered into and several pertinent questions asked by O. Holden, A.M.E.I.C., P. Gillespie, M.E.I.C., (vote of thanks), A. T. C. McMaster, M.E.I.C., R. O. Wynne-Roberts, M.E.I.C., F. W. Clark, A.M.E.I.C., G. O. Vogan, Jr.E.I.C., J. A. Knight, A.M.E.I.C., J. R. Montague, A.M.E.I.C.

At the conclusion, a vote of thanks was proposed by Professor Peter Gillespie, M.E.I.C., which was unanimously endorsed by those present and presented to Mr. Blanchard by the chairman, R. B. Young, M.E.I.C.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

On Wednesday, November 30th, at the regular meeting of the branch, an excellent paper, illustrated by lantern slides, was given by A. K. Robertson, M.E.I.C., as follows:—

The Reconstruction of Ocean Falls Dam for the Pacific Mills, Ltd., at Ocean Falls, B.C., 1922-1923

The paper-making plant of the Pacific Mills, Ltd., is situated at Ocean Falls, B.C., about 340 miles north of Vancouver, B.C. The first company to operate there was the Ocean Falls Company, Ltd., which built in 1910 a small dam with a spillway at elevation of 225, (datum is 100 at mean tide level), and a small plant, but the company was not successful and the property was taken over by the Crown Williamette Company and the Pacific Mills, Ltd., was formed to operate the plant. In 1915 a gravity section dam with a spillway level of 245 was designed by M. B. C. Condit and built in 1917. Early in 1922 it was decided to add 15 feet to this spillway level. Plans were prepared by Mr. Condit, a contract for the work was let to the writer's firm and work started in July 1922. The raising of the level of the spillway, with consequent alterations in bulkhead sections and necessary increase in thickness, required 17,000 cubic yards of mass concrete 1:3:5 mix, with displacers, and following are the principal figures of the reconstructed dam:—

Type, gravity, mass concrete, 1:3:5 and displacers
Height, (maximum) .... 74.5 feet
Curve, 8 per cent on 716.8-foot radius upstream

Length	691.5 feet on curve
Length of spillway	365 feet
Elevation of spillway	260 feet
Elevation of bulkheads	270 feet
Developed head	171 feet
Average head	140 feet
Storage area, (Link lake)	9 square miles
Length of Link lake	16 miles
Drainage area	140 square miles
Storage	211,000 acre feet at 260-foot elevation

The principal problems in construction arose from climatic conditions, and also from the difficulty in securing a sufficient and satisfactory supply of sand for concrete.

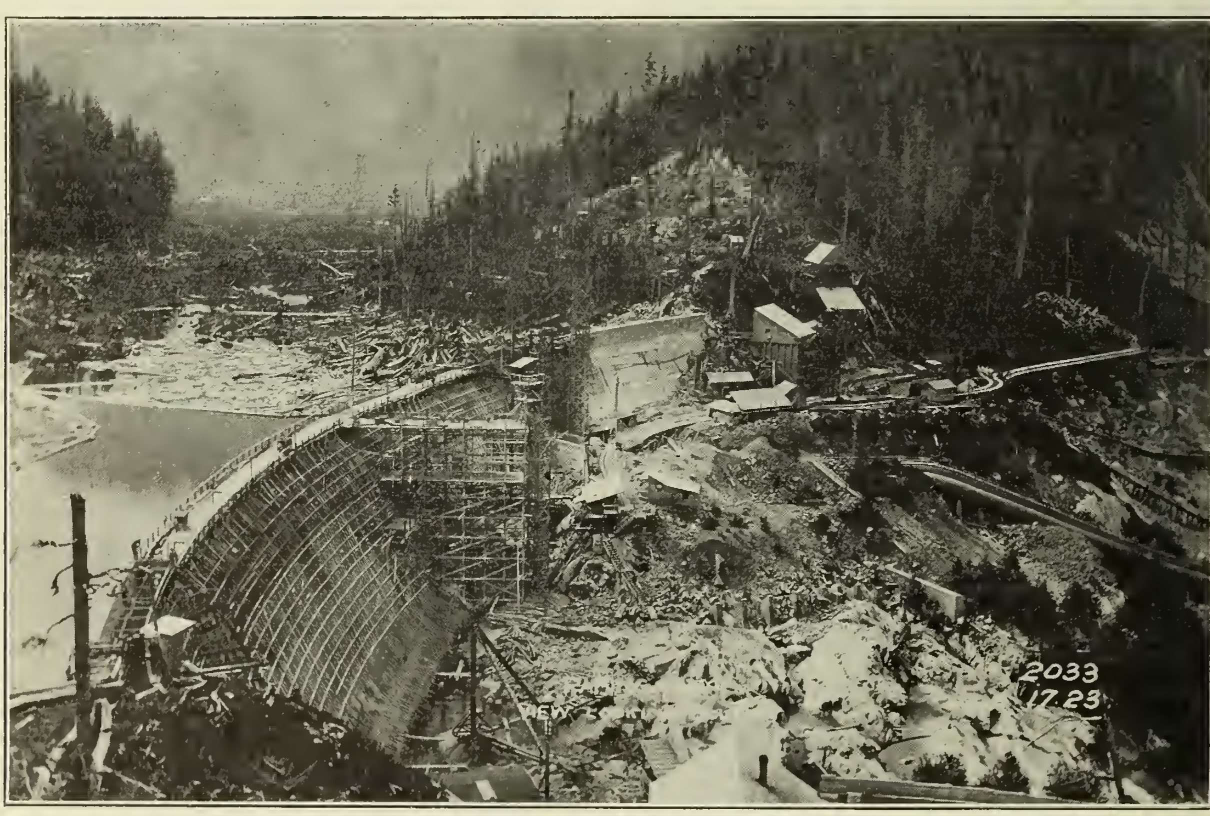
The average annual rainfall at Ocean Falls is about 160 inches and the average snowfall 76 inches, and work is a practical impossibility during the winter months. Construction work could start about March 1st and continue without fear of floods over the spillway until July, when the rise in level of water in Link lake, due to melting snow, reaches its peak. If the water does not go over the spillway then it is a safe assumption that, after July, the water level will fall until the late fall rains bring it up again, usually flowing over the spillway intermittently during the rest of the year. Contractors could therefore count on a safe period from March to July, and if the water did not come over the spillway in July conditions were reasonably safe until about the end of October. This contract was started in July 1922, and during that season all that could be done was the installation of the necessary plant and the building of the south bulkhead. No work was done on the spillway section that season, as with such a late start in the year the risk of doing work on the spillway was too great, and the work was closed down for the season in November. In 1923 work was resumed at the end of February and continued without a stop until completion in August.

Regarding the supply of sand, any of the available sources were very expensive and the contractors decided to supplement the small available supply by using crushing rolls and making sand from the finest product of the rock crushers. In 1922 a set of 24-inch rolls was used, but they were not heavy enough to produce either sufficient or fine enough sand, and in 1923 a set of 36-inch rolls was installed. These were satisfactory, and about 50 per cent of the sand used was provided from the rolls, the balance coming from a local deposit of bank sand. The contractor's view is that, if a project had to depend *entirely* on sand from crushed rock a more elaborate system of rolls would be needed. The rock was granite which shot up well in the quarry and crushed well. The writer has done a considerable amount of concrete work where the supply of sand came altogether from crushed rock.

In addition to the raising of the level of the spillway, the dam was thickened by an average of 10 feet by adding concrete to the downstream face, and great precautions were taken to ensure a good bond and to avoid hydrostatic pressure between the old dam and the new concrete. These precautions were:—a channel about 10 by 10 inches was cut in the old dam along the crest of the spillway. Tile drains were placed in channels cut along the old down stream face and covered with porous concrete to drain any seepage through the old work. The whole of the surface of the old dam on which new concrete was placed was chipped off, (using pneumatic chisels), to a depth of about one inch. Tie rods of twisted steel were set into the old work at intervals of about 4 feet, and these tie rods projected into the new concrete.

The use of displacers was permitted, but except in the south bulkhead where they could be placed without difficulty, their use was discontinued, as the tying wires of the forms and the batter of the form work prevented them being placed easily, and, in addition to that, the organization and plant necessary to move heavy displacers along work in progress interfered very seriously with progress.

In placing concrete it was found that shoots of any length, say, over 30 feet, were not satisfactory as the crushed rock aggregate rolled down the shoots first and the matrix flowed after. Another serious objection was that sometimes a stone would stick in a shoot and, especially at night, this caused serious delay. The system adopted was to have straight short shoots leading from the hoppers at top of towers direct to subsidiary hoppers at different elevations, (which also acted as reservoirs in event of a short delay), and



Reconstruction of Ocean Falls Dam at Ocean Falls, B.C.

take the concrete away from these hoppers in concrete buggies which held about 4 cubic feet. The last lift of 15 feet on the dam was done with small concrete cars which held one batch, (¾ yard), and these fed from hoppers and ran along a steel trestle, 15 feet high, built along the crest of the old dam. This trestle was built of the lightest possible section of steel uprights and braced with lumber. As the concrete rose, the braces were removed and the steel trestle was left embedded in the new work.

The largest month's work was done in June 1923, when 7,000 cubic yards of concrete were placed. At present the daily output of the Ocean Falls plant of the Pacific Mills Limited, is about 270 tons of paper and 20 tons of Kraft pulp.

ANNUAL MEETING

The annual general meeting of the branch was held on Wednesday, December 14th, the ballot for the election of the new officers of the branch for 1928 resulting as follows:—

Chairman	W. Brand Young, A.M.E.I.C.	
Vice-Chairman	W. B. Greig, A.M.E.I.C.	
Secretary-Treasurer	F. P. V. Cowley, A.M.E.I.C.	
Executive Committee	A. S. Wootton, M.E.I.C.	(2 years)
	E. A. Wheatley, A.M.E.I.C.	(2 ")
	H. B. Muckleston, M.E.I.C.	(2 ")
	P. H. Buchan, A.M.E.I.C.	(1 year)
	H. W. Frith, M.E.I.C.	(1 ")
	A. C. R. Yuill, M.E.I.C.	(1 ")
	E. A. Cleveland, M.E.I.C.	(*Ex-officio*)

A full report of the Annual Meeting will appear in a later issue of the Journal.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

TOWN PLANNING

On Wednesday, October 26th, an interesting lecture was given by Mr. J. H. Doughty-Davies, city zoning engineer of Victoria, B.C., on the subject of "Town Planning." Mr. Doughty-Davies said that town planning had been defined by the Town Planning Institute of Canada as the scientific and orderly disposition of land and buildings in use and development with a view to obviating congestion and securing economic and social efficiency, health and well-being in urban and rural communities. He then outlined the five main branches into which town planning is divided, and spoke at length of the situation in Victoria, with particular reference to the district which will be affected by increased port activities in that city.

VISIT TO ROOFING AND PAPER PLANT

On November 11th, on the invitation of Mr. R. Mayhew, manager of the Sidney Roofing and Paper Company, members of the Victoria Branch visited the company's plant and viewed the manufacturing processes used in the production of the company's products.

WATER POWERS OF THE DOMINION

On Wednesday, November 23rd, E. Davis, M.E.I.C., chief engineer of the Water Rights Branch of the British Columbia government, addressed the members of the Victoria Branch on "Water Powers of the Dominion." Mr. Davis' address was illustrated by about fifty lantern slides. He briefly outlined the hydro-electric development which is going on throughout the Dominion. Quoting from a pamphlet recently issued by the federal department of the interior, Mr. Davis gave some outstanding facts of the power situation in this country. One-fifth of the water power utilized in the manufacturing industry is in the manufacture of pulp and paper. His figures also showed that Canada is well ahead of the United States in the use of hydro-electric energy in proportion to the population.

Winnipeg Branch

James Quail, A.M.E.I.C., Secretary-Treasurer.

RESEARCH PROBLEMS IN CANADA

A meeting which aroused considerable interest was held on October 26th, when Theo. Kipp, M.E.I.C., addressed the members on the subject of "Research Problems in Canada." In his opening remarks, Mr. Kipp explained that he had prepared his paper with a view to having it used as a basis for the discussion on research in Canada. He read from journals and newspaper items and editorials to illustrate the interest that has been taken in research and the results which had been obtained, reviewing these results at some length. The speaker then described the various organizations established for the purpose of undertaking research work.

The discussion was opened by Professor J. N. Finlayson, M.E.I.C., who emphasized the importance of the subject and expressed his appreciation of Mr. Kipp's recognition of this. He reviewed the conditions leading to the proposal to establish the National Research Bureau.

It was suggested by Mr. Kipp that the National Research Council might be criticized for not giving sufficient publicity to its activities.

Professor Dorsey drew attention to the fact that the most effective fashion in which impetus was given to research was the demonstration of the money-making aspect of invention. In this connection he defined invention as "The art of the application of scientific principles to practical use." Professor Dorsey supported the idea that effort in research in a country should not be confined to one point or locality, but should be carried on at a number of centres. Conditions peculiar to particular localities and problems of specific interest to them should tend toward the more active and effective research being carried on where the advantage of the conditions utilized and the interest recognized.

E. V. Caton, M.E.I.C., urged that the purely scientific research should be placed well forward in the thought of those formulating a policy toward constructive research; also, that the broader the scope of endeavour, and the wider the field from which is drawn those engaged in research, the more certain is the result.

J. G. Sullivan, M.E.I.C., gave it as his opinion that the more purely scientific research might well be carried on largely at one centre, but that the more practical research could much better be engaged in at a number of centres.

J. W. Sanger, A.M.E.I.C., instanced the difficulty of marketing carbonate of copper produced by the electrolitic process locally as illustrating the necessity of some co-ordinating medium.

G. R. Pratt, A.M.E.I.C., spoke in support of Mr. Sullivan's attitude.

Mr. Kipp suggested that the National Research Council might use The Institute as one of its avenues through which to get publicity. Messrs. Caton and Finlayson spoke with reference to the advantage of publicity.

It was moved by W. P. Brereton, M.E.I.C., seconded by Prof. Dorsey, and carried, that,—The Research Committee of the branch, with power to add to its numbers, approach the University of Manitoba relative to the possibility of co-operating with it in the matter of research; having particularly in mind the activities of the National Research Council or such further activity in research as may or might develop as the result of legislation that may be brought down before the next session of the federal parliament; further, that the Research Committee of the branch report back to the branch at its next regular meeting.

Moved by J. G. Sullivan, M.E.I.C., and seconded by Professor Dorsey, and carried, that the branch address a communication to the governmental authorities advising them that the Winnipeg Branch of The Engineering Institute of Canada was definitely in favour of the enactment of legislation that would stimulate and facilitate research in Canada.

ELECTRIC WIRING REGULATIONS

At the regular meeting of the branch held on November 3rd, Mr. F. A. Cambridge addressed the members on the subject of "Electric Wiring Regulations." He explained the first attempt to formulate rules for governing wiring in 1892, when the New York Board of Fire Underwriters issued rules for safety wiring. In 1897, the first edition of the National Electric Code was issued and adopted by all Fire Insurance Boards.

Following the discussion of the subject of electric wiring of buildings by the Fire, Water and Light Committee of the city of Winnipeg in 1897, a municipal act incorporating the results of the discussion was passed in the following year, 1898. Public feeling on the subject of proper wiring of public buildings was stirred by the Iroquois theatre fire and resulted in the adoption in 1907 of special regulations regarding the wiring of theatres.

In 1913 a by-law was passed calling for metal encased wiring in congested business districts. In 1921 the prohibiting of duplicate services to buildings was covered by a by-law, and the compulsory use of rigid conduit for service wires and grounding, and the use of externally operated service boxes were also covered by the by-law. In 1926 the present by-law was passed which incorporated the 1928 National Electrical Code.

The next portion of the paper dealt with the defects met with as affecting (a) the power company; (b) the safety of the installation; (c) sufficiency of installation; (d) trades other than electrical wiring.

The speaker then mentioned the necessity of revising the electrical codes periodically in order to keep abreast of development, and stated that codes must strike a balance between adequacy and excessive cost. The question of demand factor would need further and careful consideration.

Preliminary Notice

of Applications for Admission and for Transfer

December 16th, 1927.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in January 1928.

R. J. Durley, *Secretary.*

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ALLCHURCH—HARRY, of Lachine, Que., Born at Bradford, Eng., Apr. 17th, 1886; Educ., course in textile mach., Bradford Tech. Coll., 1906-07, course in applied science, Mtl. Tech. School, 1913-14, mathematics, I.C.S.; 1910-11, shop experience, Allis-Chalmers-Bullock; 1911, Can. Crocker Wheeler, St. Catharines, Ont.; 1911-12, Railway Signal Co. of Can.; 1913-14, dfting, Dom. Bridge Co., Lachine; 1919-20, with Dom. Engrg. Works, Lachine, on design for Fourdrinier paper machines, Warren grinders, suction rolls, peels and miscellaneous paper making machinery; 1921-22, with Can. Northwest Steel Co., Vancouver, on design of steel structures for Britannia Mines and Powell River Paper Mills, B.C., highway bridge at Stave Falls, B.C., sluice gates, coal conveyors, etc.; 1922 to date, Dom. Bridge Co., Ltd., Lachine, designing steel coal scows and gate lifting scows, grain car unloaders, electric overhead travelling cranes, and, at present, checking details, Montreal-South Shore bridge.

Chippawa Creek Syphon Culvert of the Welland Ship Canal

Deep Open Pit Excavation in Soft, Water Bearing Material

A. J. Grant, M.E.I.C.

Engineer-in-Charge, Department of Railways and Canals, Welland Ship Canal, St. Catharines, Ont.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 15th, 1928

General Description of Canal

The Welland ship canal, now in course of construction by the Dominion Government across the Niagara peninsula, is one of the most important engineering works in hand at the present time in the British Empire and North America. When completed, about 1930, it will be the fourth canal built by Canada during the past one hundred years across the peninsula for the purpose of connecting lakes Erie and Ontario. The canal will also be the largest link in the projected ship canal project connecting the Great Lakes with the Atlantic ocean via the St. Lawrence river. Its general location and profile are shown in figure No. 1.

The total length of the canal will be 25 miles, and for all practical purposes it will be a straight line throughout; it will be 1¾ miles shorter than the present 14-foot navigation canal, and will have only eight locks in place of twenty-six on the latter. It will be 25 to 27½ feet deep, 200 feet wide on the bottom and 310 feet at the water line. All of its structures will be built for a depth of 30 feet, so that the canal, at some future date, can be enlarged by simply dredging out the canal prism and harbour entrances. There will be twenty-one bridges on the canal; two swing, seven rolling lift and twelve of the vertical lift type.

The fall of 325½ feet between the lakes will be overcome by seven locks of 46½ feet lift each. The direct line of the canal down the face of the escarpment, and the configuration of the plain below it, permitted the adoption of these high lifts, which constitute a peculiar feature in the design of the canal, and have no precedent in actual construction of locks of their size. The usable dimensions of the locks will be 820 feet long, 80 feet wide and 30 feet of water on the sills. The guard lock at Humberstone will have a usable length of 1,355 feet and will have the same width of chamber and depth of water as the other locks of the canal.

These dimensions at once place the present work in the front rank, and, in fact, in some respects it stands absolutely unequalled. The Panama canal, for instance, has a total rise of 85 feet, and the highest lift of any of its locks is 34.29 feet, compared with 46.5 feet by each of the Welland ship canal locks. Furthermore, the Thorold flight of three locks on the Welland ship canal has a rise of practically 140 feet and is comparable in respect to its quantity of mass concrete with the Gatun flight of three locks at Panama.

The summit level of the canal, Thorold to Humberstone, is sixteen miles long and at the city of Welland crosses the Chippawa creek. The present canal is carried over the creek by a cut stone aqueduct which will be dug out as soon as the syphon culvert that is now being built to pass the creek under the ship canal has been completed and placed in commission. As the syphon culvert is one of the important structures of the canal, this paper has been prepared for the express purpose of describing its design and construction.

Chippawa Creek

The Chippawa creek rises in the hills southwest of the city of Hamilton and flows easterly to its confluence with the Niagara river at the village of Chippawa, about 1¾

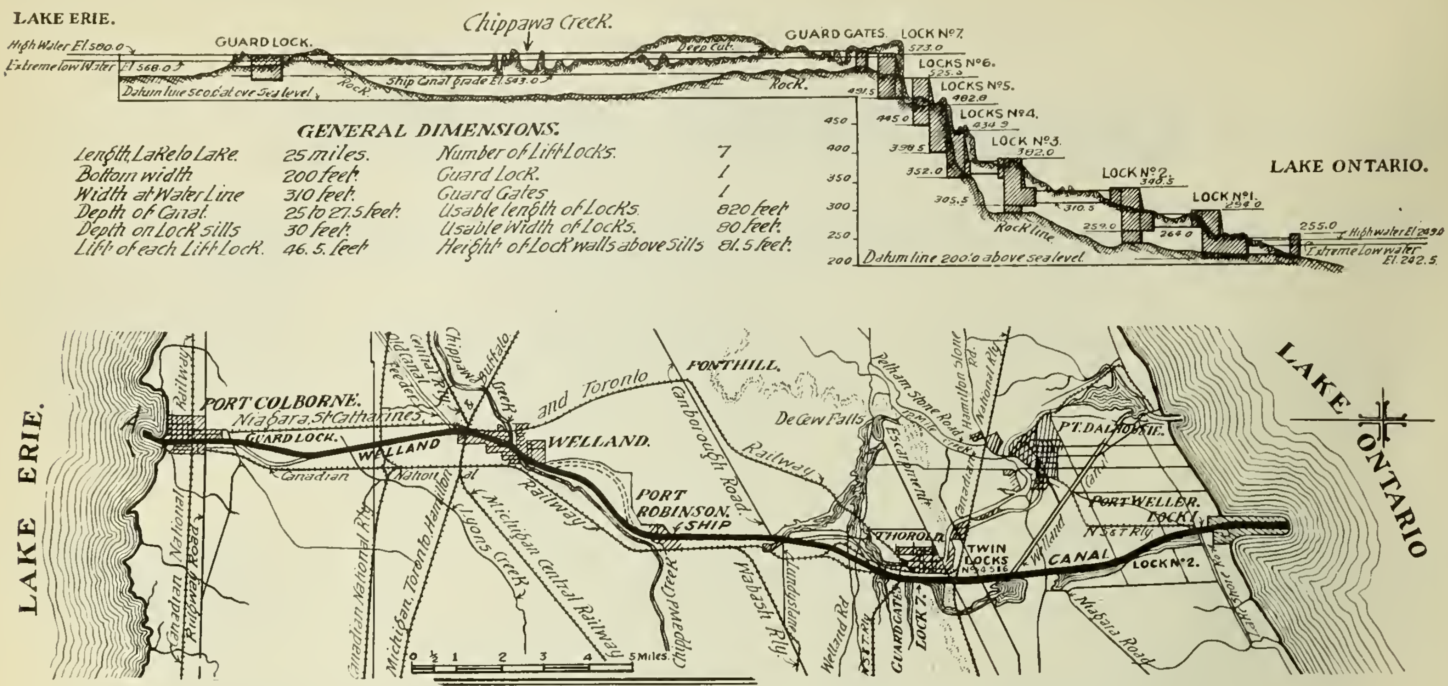

Figure No. 1.—Map showing Location and Profile of Welland Canal.

miles above Niagara Falls. The drainage basin of the creek comprises about 350 square miles and has a summer flow of about 200 c.f.s. The spring freshet flow of the creek varies greatly, as meterings of the stream that have been made by the Welland ship canal office show discharges at Welland varying between 2,600 and 6,400 c.f.s., and from these investigations it has been determined that the March 1908 discharge was probably about 8,700 c.f.s. The conditions that govern extreme flood flow on the creek are maximum winter storage of precipitation due to continued cold weather throughout the season, and heavy rains concurrent with the spring thaw. If these conditions occurred together, an extreme flood flow of 10,000 c.f.s. might be expected.

The water surface of the creek between the Niagara river and Port Davidson, about 27 miles west of Chippawa, is practically level at periods of low flow, and as the heads observed on the canal aqueducts during flood periods of the creek have been less than one foot, a culvert with a large area is essential to pass the extreme flood flow under combined adverse conditions of ice, floating débris, silt, etc., in order to avoid all danger of flooding the city of Welland and the low-lying lands west of the canal. Ordinary summer level of the creek is elevation 562.0 and ordinary flood level west of the canal varies between elevation 567.0 and 569.

Geology

The palæozoic or bed rock formations of the Niagara peninsula pass under the waters of lake Erie with a monoclinal dip of about 30 feet to the mile. As a result of the monoclinal structure of the bed rock formations of the peninsula, successively older beds appear at the surface in following the line of the canal from south to north. Owing to the varying degrees of hardness of the shales and limestones comprising the rock formations, differential erosion has developed, on their surface cropping margins in tertiary times, two north facing scarps trending east and west, each with a lowland plain to the north of it. One of these, the Niagara escarpment, was too prominent a physiographic feature to be buried by the glacial and lake deposits of pleistocene times. The lesser scarp, which has been called the Onondaga escarpment, formed by the Onondaga limestone and Bertie water-lime, is well exposed for a few miles west of Fort Erie, but in the vicinity of the canal zone this north facing scarp has been almost entirely obliterated by the boulder clay of the glacial period and the lake deposits which accumulated in the interval between two advances of the continental ice sheet. The city of Welland lies within the limits of the old Huron plain. This old tertiary lowland was buried in the vicinity of Welland to a depth of 100 feet by the glacial till and associated interglacial lake deposits. The course of the Chippawa creek has its direction determined chiefly by the position of the Onondaga escarpment on the south and the south slope of the Niagara escarpment to the north. The Niagara Falls moraine on the north of the Chippawa creek valley also helps to outline it near the Niagara river. The Welland canal cuts through the latter about a mile north of Port Robinson.

Owing to the southerly dip of the bed rocks in the Niagara peninsula, the water level of lake Erie has no effect on the level to which water may rise at the site of the syphon culvert at Welland from the base of the pleistocene beds or lower. The culvert is located not very far from the junction of the Guelph dolomite and the Camillus shale, (Salina), parting or contact with the overlying pleistocene beds. The level to which water will rise from this source is determined by the highest level attained by water bearing horizons, north, east and west of the culvert. In the case of the Salina-Lockport horizon, this is in the neighbourhood of 600 feet above sea level near Chippawa and Navy island in the Niagara river, northeast of Welland. It might, therefore, be expected that water from the above source would rise to about elevation 600.0 wherever it might be tapped in the Niagara peninsula. The water found in the test borings at the culvert site has risen in pipes to elevation 584.0, and as it is sulphurous it is probably impregnated with hydro-sulphuric acid, (H_2S), formed by the decomposition of pyrites in the saccharoidal more or less porous dolomite, and water impregnated with this gas would be likely to move freely for a considerable distance along the contact of the Guelph dolomite and the overlying Camillus shale, (Salina formation).

Test Borings

For the purpose of determining the class of rock and the material overlying it at the site of the syphon culvert, two holes, one 400 feet left of station 965+70 and one 40 feet right of station 968+00, were put down in 1920. These holes were sunk to rock by a cyclone drill and lined with six-inch pipe. The material was removed by augers from the pipes as they were driven down, and was found to be a soft sticky red clay, containing a few striated stones down to about elevation 490. Between the latter elevation and the surface of the rock the clay was more or less mixed with sand and gravel. The holes also indicated that a thin bed of sand and gravel overlaid the rock found at elevation 489.4 in the hole opposite station 965+70 and at elevation 479.8 in the hole opposite station 968+00. Holes were drilled in the rock in both the holes by a three-inch calyx core drill to elevation 424.0. The cores show the rock to be gypsum, with bands of shaly grey and brown dolomite. Very little water was found in the holes until the rock was uncovered or slightly penetrated, when the water instantly rose in the pipes to elevation 578.0. In the hole at station 968+00 the water rose in the pipe to elevation 584.0 when the bottom of the hole had reached elevation 448.0. The pipe in the hole at station 965+70 has discharged continuously about 15 gallons of sulphurous water per minute since it was put down in 1920.

Previous to the preparation of the plans and specifications for the letting of the contract for section No. 6, two more holes, similar to the above, were drilled in October 1924. One at 353 feet east of station 966+74 and one at 250 feet west of station 969+66. The material found above the rock was the same as in the two previous holes. The rock surface in the first hole is at elevation 484.2, and in the second one at elevation 483.1. The rock was drilled by a diamond drill to elevations 410.1 and 400.6 and was found to be the same as that in the holes drilled in 1920. No water was found in these holes above the rock, but as soon as it was penetrated 18 to 36 inches the water rose in the pipes to elevation 578.0, and rose to elevation 583.0 when the hole

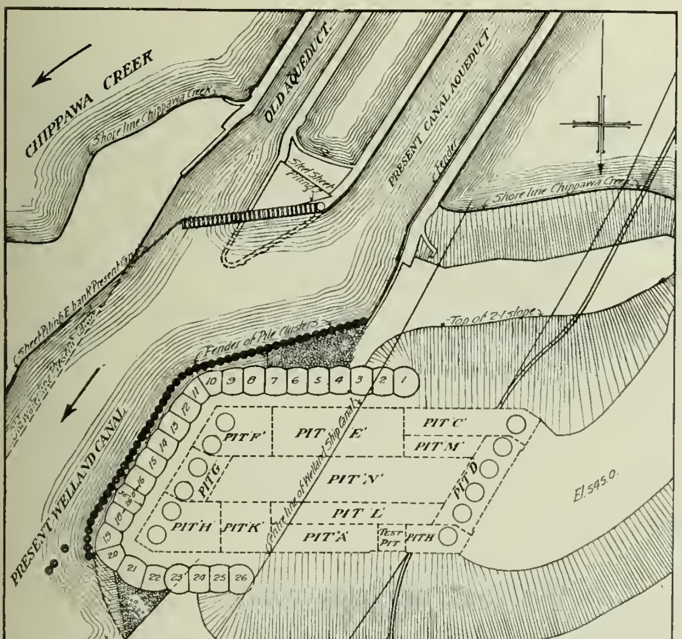

Figure No. 2.—Plan showing Present Canal, Chippawa Creek and Excavation Pits for New Syphon.

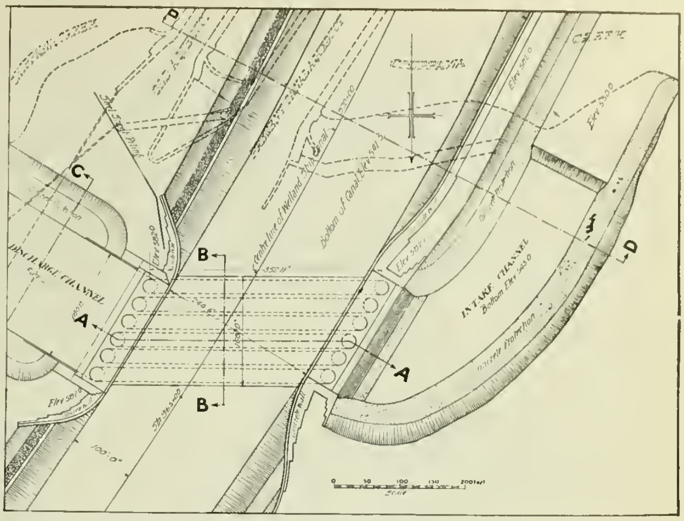

Figure No. 3.—Plan showing Location of Syphon with Relation to New Canal.

250 feet right of station 969+66 had been drilled to elevation 402.0. When the hole 353 feet left of station 966+74 was drilled to elevation 410.1 it produced sulphurous water at the rate of 12 gallons per minute, and stood at elevation 580.3 in the pipe.

After the deflection of the cellular cofferdam in 1926, (described later in this paper), the contractors drove three small test pipes into the material within the culvert area. The results obtained were similar to the above. The material found in the hole driven down in cell No. 14 of the cellular cofferdam showed it to be very soft between elevations 516.0 and 510.0, and when elevation 496.0 was reached wet sand rose in the pipe to elevation 540.0. A few days after the pipe had been driven to refusal water came up in it to elevation 579.4.

The results obtained by the contractors were such that the department deemed it advisable to drive four 10-inch heavy wrought iron pipes to rock, one at each end and side of the culvert site. A derrick was used to handle the pipes and augers and a pile hammer to drive the pipes. The same class of material was found, varying from soft to very soft clay, clay mixed with stones and a mixture of clay, sand and gravel. The clay was generally found to be very soft between elevations 535.0 and 500.0 or lower, and would flow into and rise as much as 10 feet in the pipes. Small striated stones were found in the clay, generally below elevation 535.0, and one of 5 inches in diameter was taken out of one of the pipes. Below elevation 490.0 sand and gravel seams, sometimes mixed with hard clay, were found overlying the rock at elevation 483.0. When the shale rock was penetrated water rose in the pipes to elevation 578.0. Only one large boulder about 4 feet in diameter has been found in the foundation. It was in the "test pit" at elevation 505.0 and was left there.

Aqueduct of Second Canal

The second Welland canal was carried over the Chippawa creek by a cut stone aqueduct whose canal waterway is 44 feet wide at its floor level, elevation 562.5. The creek is passed under the aqueduct by four segmental arch culverts, each 40 feet wide at the springing line of the arches. The floors of these culverts are at elevation 545.0. The height from the floors to the springing lines of the arches is 6 feet and to the soffits of the arches 13 feet. The aggregate area of the culverts for the passage of the creek is 1,699 square feet. The aqueduct is built on a timber pile foundation, was completed in 1846 and is still in existence, but is not now used for the passage of vessels. This aqueduct will be buried by the east embankment of the ship canal.

Aqueduct of the Third or Present Canal

The present canal is carried over the creek by a cut stone aqueduct whose canal waterway is 85 feet wide at its floor level, elevation 555.4. The creek is passed under the aqueduct by means of six segmental arch culverts, each 40 feet wide. The floor of each culvert has an invert of 2 feet. The bottom of the inverts is at elevation 540.7. The height from the bottom of the inverts to the springing lines of the arches is 5 feet and to the soffits of the arches 12 feet. The aggregate area of the arch culverts for the passage of the creek is 2,161 square feet. This aqueduct was completed in 1888 and is situated 82 feet west of the aqueduct of the second canal. The 82 feet space between them is an open pool of the creek. This aqueduct will be dug out when the syphon culvert has been completed and placed in commission. The location of both aqueducts is shown in figures Nos. 2 and 3.

Original Design for Section No. 6

The original design of the ship canal contemplated taking the Chippawa creek into the canal at Welland and discharging its flood waters back into the creek through a weir at Port Robinson. The basic reason for this scheme was the fact that ordinary high water in the Chippawa creek and the lowest stage of lake Erie coincide at elevation 568.0. The design of taking the creek into the canal therefore involved always maintaining the summit level of the ship canal at elevation 568.0. The complications that would have arisen between the department and all parties concerned by the adoption of the scheme, and the large and unknown damages that would have been presented by the municipalities and private parties along the canal and creek as a result of its construction, finally led to its abandonment and to the decision to maintain the " status quo " for the ship canal when preparing the plans and specifications for the letting of section No. 6 on which the syphon culvert is located.

Proposed Syphon in Rock

The first plan prepared for the syphon culvert was one showing two parallel tubes 397 feet long with an aggregate area of 2,400 square feet. The tubes would have been excavated in rock and lined with concrete. The bottom of the tubes were to be at elevation 412.0, or 170 feet below the surface of the ground. Owing to the unknown quantity of water that would have had to be handled at such a depth during the construction of the tubes, and the great depth of the syphon, the design was abandoned in favour of the one now being carried out.

General Description of Syphon Culvert

The syphon culvert now being built to pass the Chippawa creek under the ship canal is shown in plan in figure No. 3 and in section in figures Nos. 5 and 6. It consists of six parallel tubes, each 22 feet in diameter and 353 feet long between centres of the vertical wells at each end of the tubes. The interior bottom of the tubes at the upper end is at elevation 508.0 and the lower end at elevation 507.5. The top of the reinforced concrete block forming the battery of tubes under the canal is at elevation 535.0, or 3 feet lower than the bottom of the canal when ultimately deepened to 30 feet. The aggregate area of the six tubes is 2,281 square feet. This is slightly larger than the aggregate area of the water passages under the aqueduct of the present canal.

The canal prism is formed across the culvert by means of massive walls built across the ends of the tubes. Their adjacent vertical faces are 244.5 feet apart and are parallel to the centre line of the canal. The top of the vertical wells of the tubes is at elevation 550.0. Above this elevation the

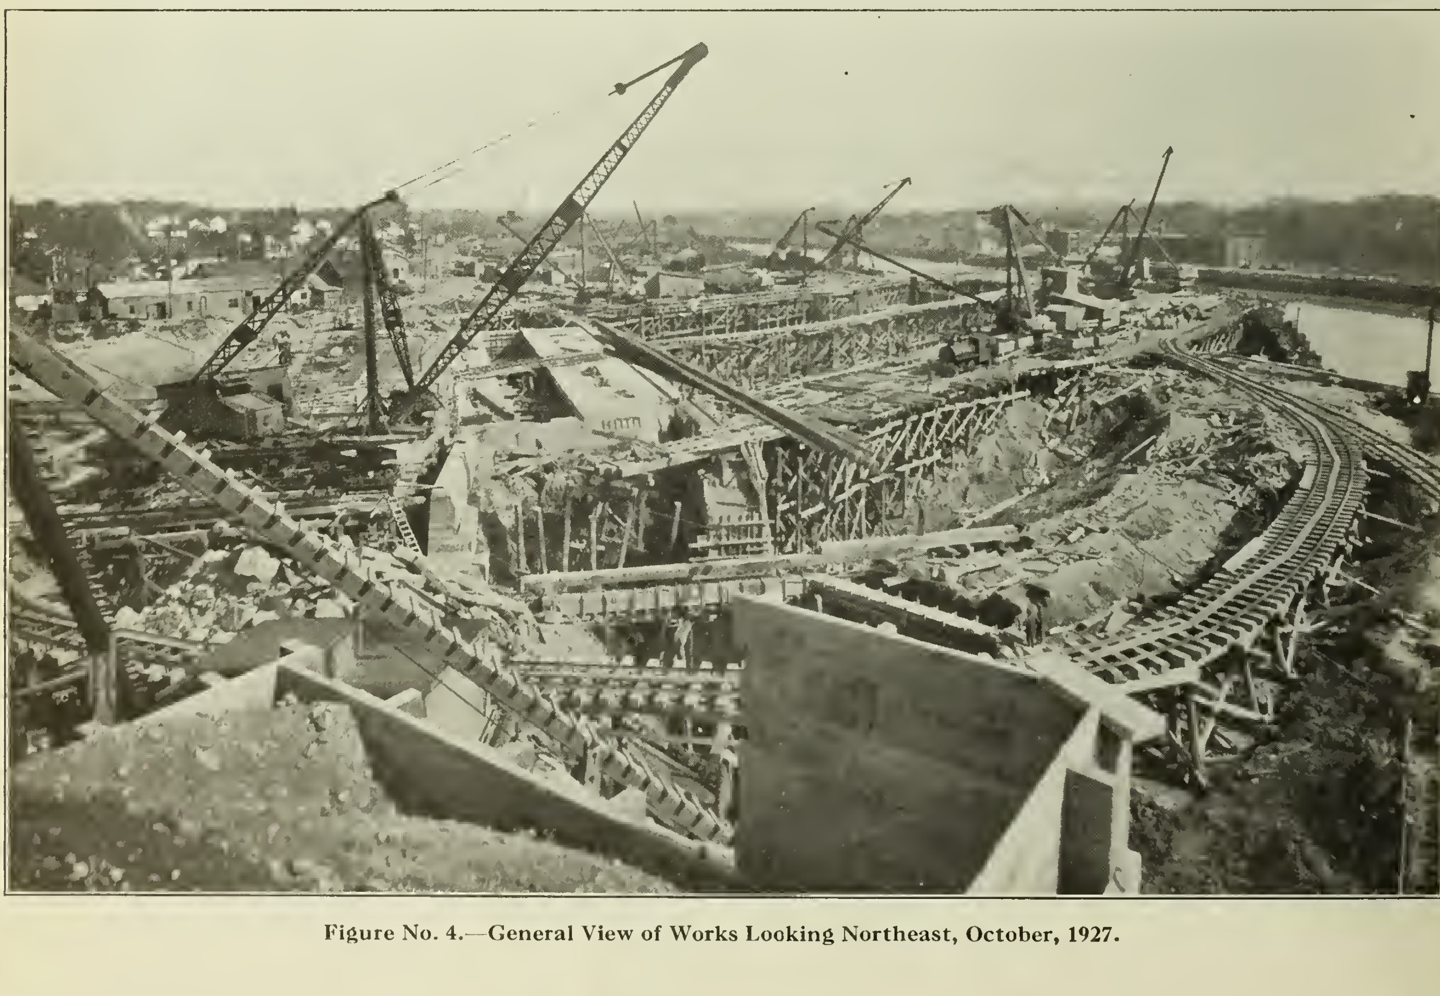

Figure No. 4.—General View of Works Looking Northeast, October, 1927.

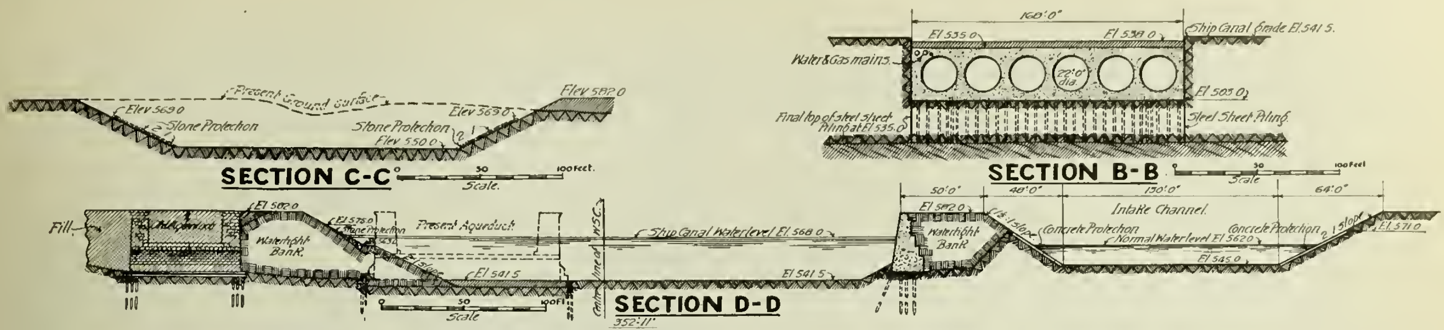

Figure No. 5.—Cross Sections, Showing Syphon, Intake Channel and Canal Prism.

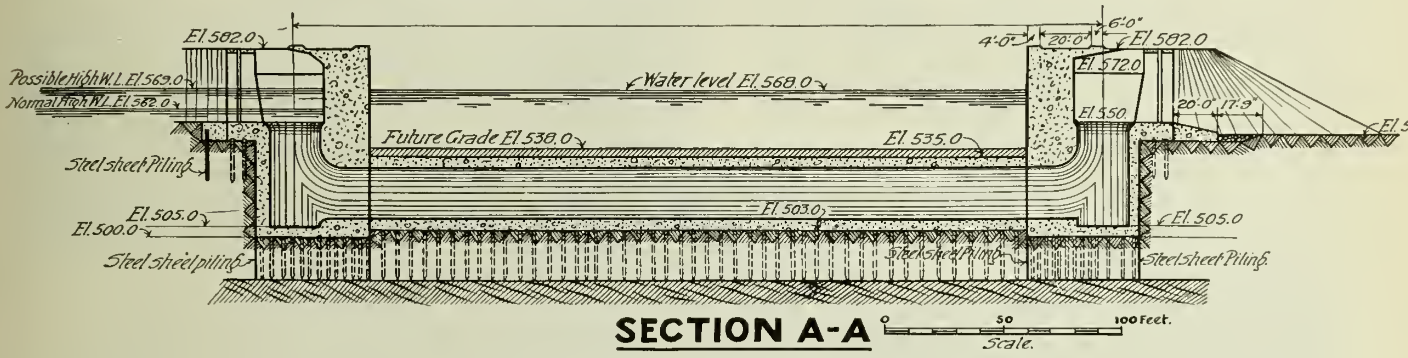

Figure No. 6.—Longitudinal Section of Syphon.

wells are divided into pairs by division walls which also act as buttresses to the canal walls. The forebay in front of each pair of wells is divided into three openings by two small piers. The sides of the piers and division walls are provided with checks for stoplogs for unwatering a pair of tubes at any time for inspection and cleaning purposes. The main walls carry a roadway 20 feet wide and a side walk 5 feet wide across each end of the structure. The outer ends of the division walls and the small piers support a concrete stoplog platform 12 feet wide. The ends of the structure are connected to the embankments forming the canal prism on each side of the culvert by means of long concrete wing walls. The whole of the structure is carried on timber piles driven to rock found at about elevation 483.0.

As the creek passes through the centre of the city of Welland it could not be diverted to a large extent in the vicinity of the canal crossing except at great cost. The culvert was therefore located as close to the north end of the aqueduct of the present canal as navigation and economic construction conditions permitted. The latter necessitated placing the centre line of the culvert at an angle of 59 degrees to the centre line of the canal. The foregoing conditions, together with the necessity of having to maintain uninterrupted traffic in the present canal and the deep foundation in soft material required for the culvert, have made its construction a very interesting problem.

Culvert Pit

The plans for the construction of the culvert, whose eastern end projects about 125 feet into the prism of the Welland canal, indicate that the excavation of the pit, 80 feet deep, was to be taken out in two layers, the upper one in an open cut down to elevation 541.5 and the lower one in steel sheet pile timber braced trenches to elevation 500.0 and 503.0. The extent of the excavation is shown by figures Nos. 2 and 4. The westerly half of the pit is bounded on its southern, western and northern sides by earth slopes, while the easterly half is protected on its three sides by a cellular steel sheet pile cofferdam. Much of the excavation in the upper layer was taken out by dredging while the cellular cofferdam was being built.

Steel Sheet Pile Cellular Cofferdam

The steel sheet pile cellular cofferdam constructed around the eastern end of the pit is about 685 feet long and is built up of twenty-six cells, as shown in figure No. 2. The majority of the cells have parallel partition walls and segmental shaped ends. The major axis of the cells is 36 feet and the minor axis is 26 feet. All the cells are connected together at their corners by *Y* piles fabricated to the required angles. The piling used was Lackawanna 15 by 3/8 inch and 12¾ by 3/8 inch straight web section weighing 42.6 and 37.2 pounds per lineal foot. The piling in the outer walls is 70 feet long and in the inner and partition walls it is 55 feet long. The top of the piles forming the cofferdam were all driven to elevation 580.2, which is one foot higher than the highest water in the canal. The bottoms of the 70-foot piles are therefore at elevation 510.2 and the bottoms of the 55-foot piles at elevation 525.2. Driving the piling was begun about February 1st, 1926, and was completed on July 31st, 1926.

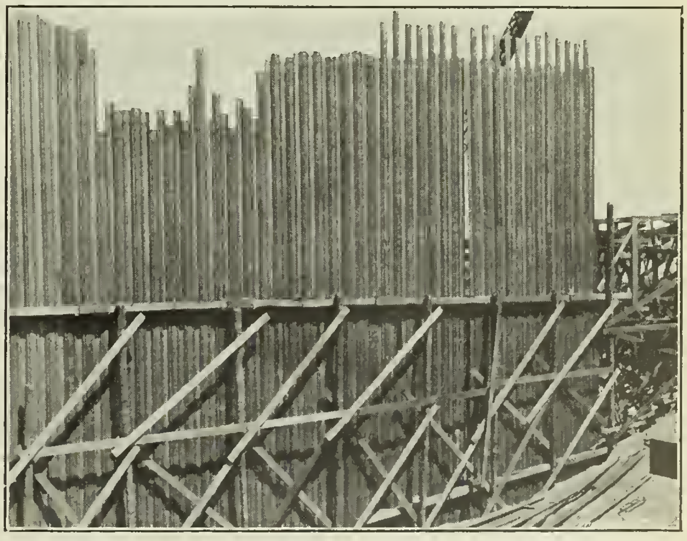

Figure No. 7.—Preassembly of Enclosure Piling.

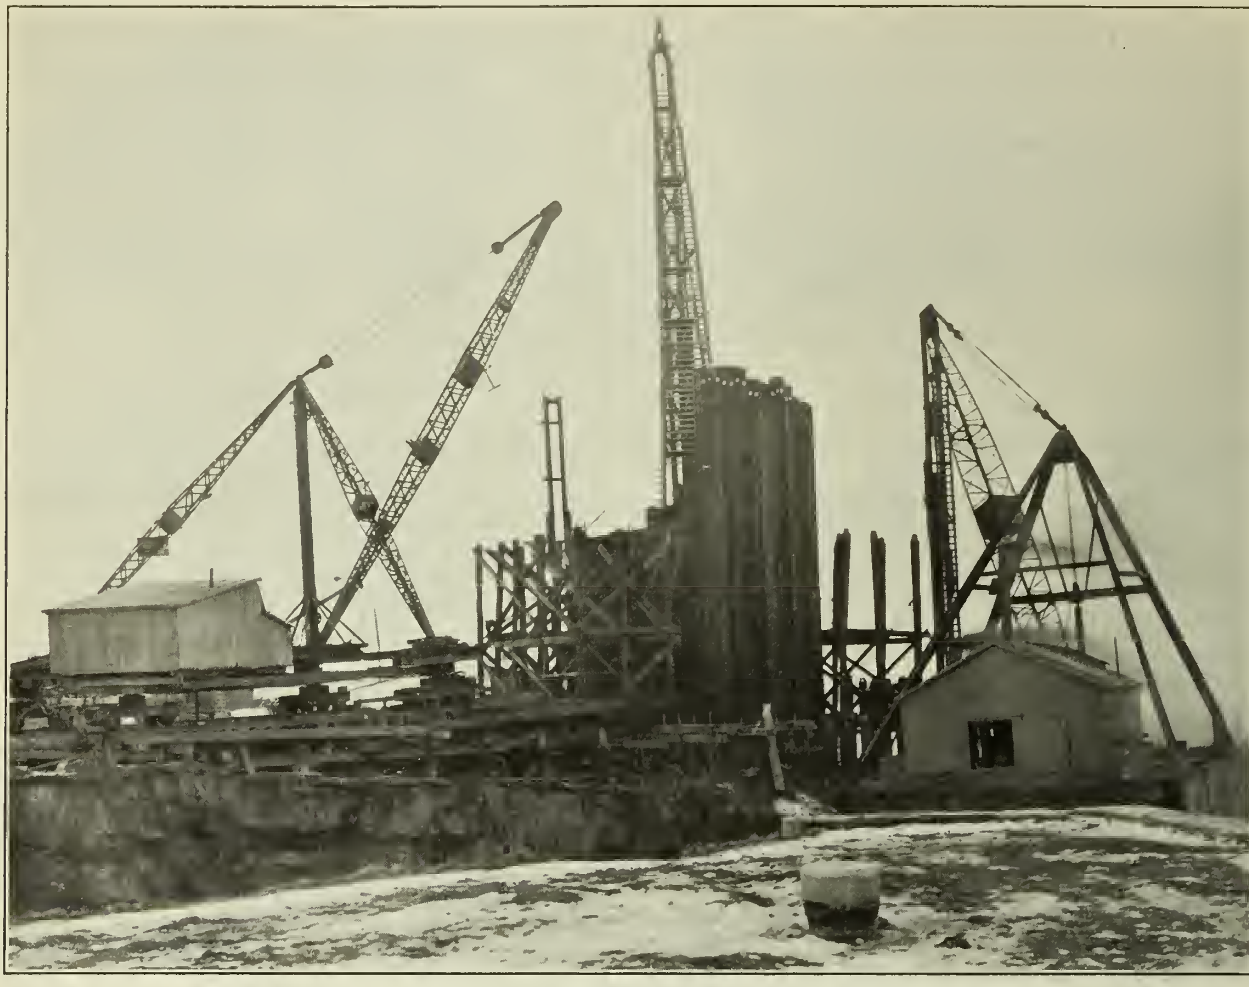

Figure No. 8.—Driving Cell Piling after Preassembly, February, 1926.

The piling of both cells and pits was driven by the preassembly method, (as shown in figure No. 7), which involved first driving, within the area of the sheet pile cell or pit, a timber pile trestle with the timber piles left standing about 30 feet above the ground surface. Around the outside of the timber piles at the ground surface and at their tops were attached square timbers to form templates corresponding to the alignment of the perimeter of the cell or pit to be driven. The steel sheet piling was then assembled around this timber trestle and all the units forming a cell were definitely threaded into each other, including the special *Y* units at the corners of the cells, before very much or any driving was done. When the pile units were assembled and locked together driving was begun. The piles were driven down 10 feet or less at a time all the way around the perimeter of the pit or cell until they were driven to the required elevation. The piles forming the wall of the next cell to be assembled were only driven to the top of the timber preassembly trestle, and were temporarily left at this elevation to act as a starting point for the next cell. The preassembly timber trestle was then removed. The steel piles for the cells of the cofferdam were assembled by a derrick on top of the preassembly trestle and driven by 4,000- and 6,760-pound McKiernan-Terry steam hammers operating in short leads suspended over the piles by a derrick standing on the ground. The cell piling is further shown in figures Nos. 8 and 9.

This type of cofferdam, owing to the friction of the interlock between the piles, can resist considerable lateral pressure without the aid of bracing when its cells are filled with suitable material. It is self-supporting and is watertight, and when in use can be used to support working platforms and superimposed loads, and when it has served its purpose it can readily be removed.

When designing the cellular cofferdam each cell was considered as an independent unit and its weight was assumed as being equal to that of the steel sheet piles and enclosed material. The loading diagram for the exterior cellular cofferdam is shown in figure No. 10. The cofferdam was designed to withstand an unbalanced hydrostatic head of 37.5 feet when the water in the Welland canal was at elevation 579.0 and the excavation and water in the culvert pit at elevation 541.5. Under the above assumptions the resultant pressure falls well within the middle third, and the cells of the cofferdam were therefore considered as being stable. The cells were filld with hard brown clay taken from the excavation of the pit. As the cells were more or less filled with water up to the level of the water in the canal, the clay was in all cases deposited in the water from cars.

On August 7th, 1926, the unwatering of the pit was begun with two 8-inch and one 5-inch centrifugal pumps. The water in the Welland canal was then at elevation 570.1. Pumping was continued day and night until about noon on August 12th, 1926, when two of the piles in the inner wall of cell No. 10 unlocked.

It is pertinent to remark here that the Bethlehem Steel Company recommended a safe working strength of interlock of 3,000 pounds per lineal inch for 15 by ⅜ inch straight web section Lackawanna steel sheet piling. In August, 1926, the Bethlehem Steel Company made for the contractor four breaking load tests of the interlock of 15 by

Figure No. 9.—Cofferdam Under Construction Looking South, June, 1926.

⅜ inch Lackawanna steel sheet piling with the following results:—

Sample	Length of Interlock	Breaking Load in Pounds	Ultimate Interlock Strength per lin. inch. in Pounds
1. A piece of new pile not driven.	1.93	18,000	9,326
2. A piece of driven pile from cell No 7.	2.55	17,400	6,824
3. A piece of driven pile from cell No. 11.	2.82	21,600	7,660
4. A piece of driven pile from cell No. 10.	2.25	19,200	8,533

As the piles of cell No. 10 tore apart, the inner ends of cells Nos. 8 and 9 moved westward and the inner ends of cells Nos. 11, 12 and 13 northward. When the accident happened the water in the pit had been lowered to elevation 549.8. Pumping was immediately stopped and the pit refilled to elevation 570.1. The parted piles in cell No. 10 were then drawn out and examined, when it was found that the interlock of the lower 15 feet of the piles had not given way. They were immediately replaced by driving new ones. A survey of the cofferdam then showed that horizontal and vertical movements had occurred in all the cells, due to the steel piling adjusting itself to the pressure of the clay filling, developing tension in the interlocks, and from the hydrostatic head of 20.3 feet on the cofferdam at the time of its failure. The maximum horizontal deflection was about 4.5 feet at the top of cell No. 13 and the maximum vertical settlement of the inner walls of cells Nos. 13 and 14 was about 2.0 feet. The outer walls of these cells showed no vertical settlement. The cofferdam was then reinforced on the inside by depositing behind it 13,300 cubic yards of gravel. On October 6th pumping out the pit was begun for the second time at the rate of lowering the water 3 feet per twenty-four hours. During the six days that were occupied in pumping out the pit, practically no movement took place in the cofferdam. Since then the cofferdam has shown no further movement except at cells Nos. 1 to 8, at cell No. 6 and at cells Nos. 23 to 26. When pit *C* was being excavated in March and April, 1927, the top of cells Nos. 1 to 8 developed a maximum northward deflection of 2 feet at cell No. 1. A further northward deflection of the top of cells Nos. 1 to 8 has developed since the excavation of pit *E* was begun early in October 1927. When the excavation in pit *F* had reached elevation 516.0 a web plate riveted connection at the centre of the *Y* pile in the southeast corner of cell No. 6 tore apart along the line of rivets with a cannon-like report on August 27th, 1927. The cell was repaired immediately by driving new piles around the outside of the *Y* pile so as to re-establish the connection between the outer walls of cells Nos. 6 and 7. When pit *A* was being excavated in January and March, 1927, the top of cells Nos. 23 to 26 developed a maximum southward deflection of one

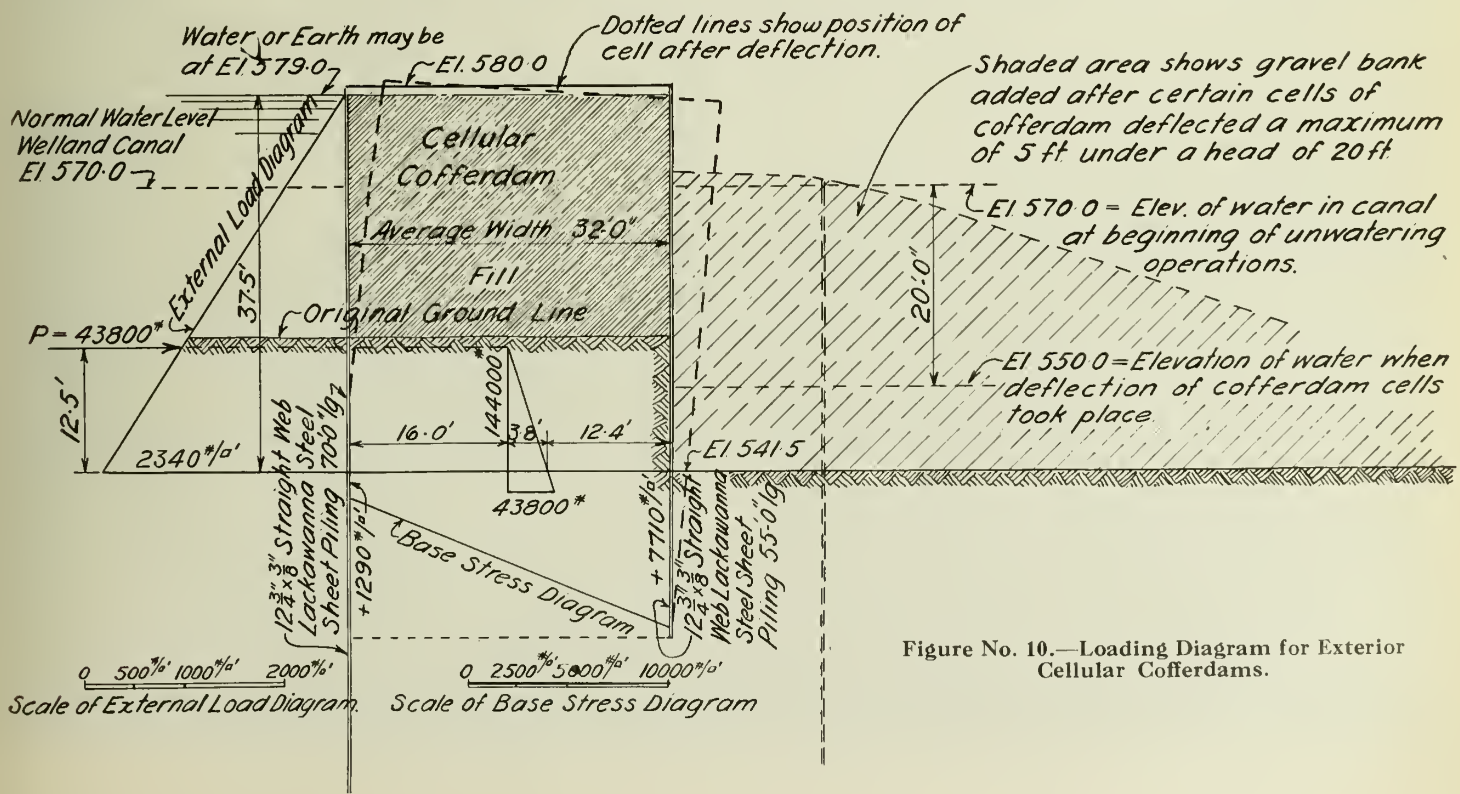

Figure No. 10.—Loading Diagram for Exterior Cellular Cofferdams.

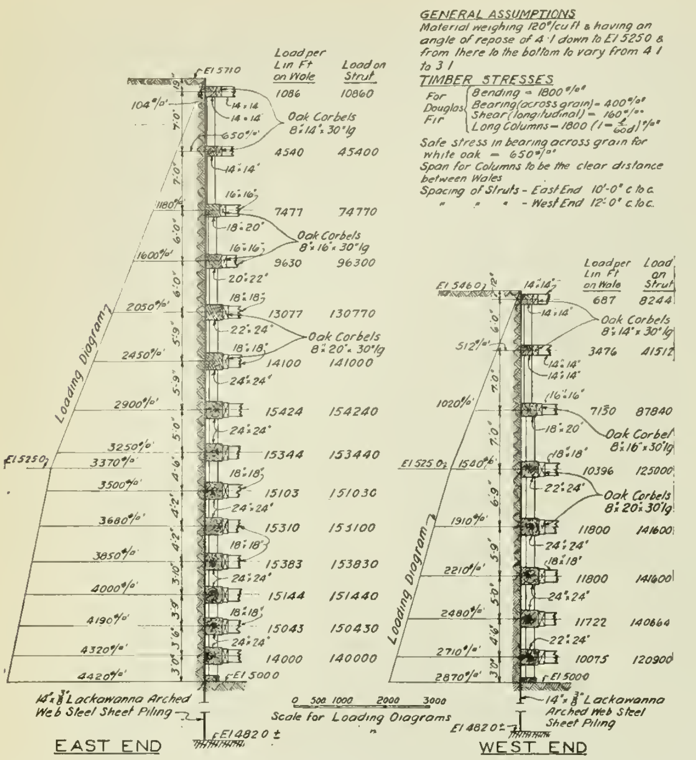

Figure No. 11.—Loading Diagrams and Timber Bracing for Interior Cofferdams.

foot at cell No. 26. The cofferdam has from the date of the first unwatering of the pit been absolutely watertight.

The deflection of the cofferdam was attributed to the piles in the partition and inner walls being too short and to the low shearing value of the clay filling in the cells. Had all the piles been 70 feet long and the cells filled for a height of 30 feet with crushed stone or gravel the cofferdam would in all probability have been stable without any gravel back-filling and could have been made watertight by filling the interlocks of the piles after driving with fine sand or wheat.

The deflection of the cofferdam, and the very soft material in which the pits below elevation 541.5 had to be sunk for the construction of the culvert tubes, made the contractors so dubious as to the possibility of building the culvert according to the contract plans that they would not proceed with the work. The engineer, however, felt that with proper precautions and care the culvert could be built as designed, and ordered the contractors to put down a test pit and to build within it a section of the culvert tube. As this operation was successfully carried out, the balance of the work was at once proceeded with, and the culvert, at the end of October 1927, was about 60 per cent built.

Steel Sheet Pile Braced Pits

The construction of the culvert in the steel sheet-pile timber-braced pits has been of an unusually interesting character, due to the great depth and size of the pits, the very long lengths of steel piling used, and the very large timber bracing required to resist the heavy pressures produced by the very soft plastic clay in which the pits have been sunk. There will be thirteen pits required to build the culvert, as designated by letters on the plan. At the end of October 1927 eight pits, *A, B, C, D, F, H, K* and the test pit, (figure No. 2), had been excavated and sections of the culvert built in them. The work of building this part of the culvert and the troubles that developed in doing so are best told by a brief description of each pit, as follows:—

The contract drawings show the top of the steel sheet pile timber-braced pits for excavating the lower layer of material for the culvert pit at elevation 541.5, and that 14 by 3/8 inch arch web Lackawanna steel sheet piling was to be used in their construction. This piling has great flexural strength. The plans show also that the steel pile wall enclosing the perimeter of the entire structure was to be made with piles 59 feet long, driven to rock, and that all the interior pile walls were to be made with piles 45 to 55 feet long. It was also assumed, when the contract drawings were prepared, that the wells of the tubes could be built in trenches 45 feet wide, and the side tubes of the culvert in trenches 32 feet wide. It was further assumed that when the side tubes and all the wells at each end of the culvert were built, the central portion of the pit thus enclosed could be excavated as an open unbraced pit, except for two zones each 32 feet wide and 60 feet from each end of the pit, which were to be excavated across the pit in trenches, and in which sections of the tubes were to be built to act as buttresses to the completed side tubes before the excavation in the central open portion of the pit was proceeded with.

The above layout of the steel sheet pile timber braced trenches was gradually abandoned as the construction of the culvert progressed, as, owing to the contracted area enclosed by the cellular cofferdam, the gravel bank placed behind the cofferdam over-ran the site of the culvert foundation and necessitated raising the top of the steel sheet pile trenches to elevation 546.0 at the west end, and to elevation 565.0 and 571.0 at the east end, and led to an entirely different layout of the pits.

For the purpose of building the culvert a large and wide heavy timber trestle of round bearing piles and square timber was built around the site of the culvert, (see figure No. 4). The trestle is about 70 feet wide and 35 feet high, with its top at elevation 582.0. The trestle supports the derricks and railway tracks required for the execution of the work. All excavation and concrete trains, etc., are handled over these tracks.

Test Pit

The location chosen for the test pit was near the west end of the north tube, and the size of the pit was limited to 36 feet wide by 43 feet long. The timber work was designed to resist a material weighing 120 pounds per cubic foot and having an angle of repose of 4 to 1. The bracing of the pit resisted external pressures with very few signs of overloading down to elevation 501.0. From the behaviour of the timber bracing in the test pit it was decided to use the following assumptions for designing the bracing of the remaining pits:—120 pounds per cubic foot of material, an angle of repose of 4 to 1 down to elevation 525.0 and from this level to elevation 500.0 an angle of repose of 3 to 1. These assumptions have given good results, although serious difficulties have been encountered in several of the pits due to causes other than the assumed loading. It was also decided to drive all the steel sheet piling to rock. The loading diagrams and timber bracing for the interior cofferdams are shown in figure No. 11.

The preassembly trestle for the test pit was erected between October 4th and 13th, 1926, and the 14 by 3/8 inch arch web Lackawanna steel sheet piling 69 feet long was all assembled and driven to rock by October 24th. Excavation of the pit was begun on October 24th and finished to elevation 501.0 on November 24th, 1926. When the pit had been excavated to elevation 516.0, water came up close to the steel sheet piling on the north side at the rate of about 170 gallons per minute. When elevation 507.6 was reached it was found that two piles had unlocked and it was at this point that the water was entering the pit. The opening between the piles was 1.2 foot wide at elevation 501.0, and at this elevation it was also observed that the width of the pit was reduced from 36 feet to 34 feet 7 inches and that the alignment of the piling was very irregular. The material varied little with the depth and was very difficult to handle owing to its gummy quality. The sizes of the wales were 16 by 16 inches, 18 by 20 inches, 22 by 22 inches and 24 by 24 inches, and the struts were 12 by 12 inches and 14 and 16 inches. Hardwood corbels and steel plates were used between the wales and struts. Many of the one-inch thick steel plates in the lower courses were dished and pressed into the hardwood corbels, which in turn were forced into the Douglas fir wales. Bearing piles 22 feet long spaced 4 feet by 3 feet 7 inches were driven to rock, elevation 481.0. The penetration of these piles was very rapid for the first 10 to 15 feet, after which it decreased slightly until a bed of hardpan was encountered, when the piles reached refusal very quickly. The piles were driven with square ends, consequently they may not have completely penetrated the hardpan to rock. The 756 cubic yards of concrete in the test pit was poured between December 6th, 1926, and January 12th, 1927. The bottom tier of struts was left in place and buried in the concrete when the first course was poured to elevation 507.75. All timber wales and struts above the lowest tier were removed, except some of the wales along the north wall of the steel piling against which the concrete was poured. A lot of time was consumed taking out the wales and struts, setting up concrete forms in such a confined place, waiting for the concrete to harden, and placing struts within the completed portions of the tube before removing more struts above it, etc. A tendency for the whole timber system to sag at the centre was observed and it is believed that the placing of all the wales and struts would have been greatly facilitated had the top course of wales been set level around the four walls of the pit and securely bolted to the top of the piling.

The successful excavation of the test pit and the construction of a section of the culvert tube within it proved beyond all question that the culvert could be built as shown on the contract drawings. A new layout of the steel sheet pile timber braced trenches was then made, the bracing for pits *A*, *B*, *C* and *D* designed, and the contractor ordered to proceed with their construction.

Owing to the tendency shown by the walls of the test pit to squeeze inwards and the impossibility of driving such long steel piles absolutely vertical it was decided to make all the pits for one tube 2 feet wider than the test pit.

Pit A

A view of pit *A* is shown in figure No. 12. This pit was 38 feet wide and 127 feet long, and enclosed a section of the north tube adjacent to and east of the test pit. The assembling and driving of the steel piling was begun on December 23rd and completed an January 6th, 1927. It was all driven to rock, and in order to prevent the piles creeping, wedges were inserted at the bottom of all pile joints as the piles were assembled. Excavation of the pit was begun on January 7th and completed on March 7th. It was found that two piles in the east end wall near the south-east corner had unlocked at elevation 508.0. A similar occurrence at two other points took place in this pit at the same elevation. It was assumed that the unlocking of the piles was due to their hitting boulders in the clay. A small quantity of water entered the pit at one of the open joints in the steel piling. The water entering the pit increased considerably while the bearing piles were being driven. As soon as the piles penetrated the gravel seam overlying the rock, water in some instances forced its way up along the piles. It was estimated that about 70 gallons of water per minute were coming into the pit when the excavation was completed and while the bearing piles were being driven.

The pit was braced longitudinally from end to end by one line of struts. At each intersection of the longitudinal and transverse struts a 12- by 12-inch square timber pile 48 feet long was driven down and the struts bolted to it. These piles prevented the tendency of the bracing to sag at the centre, as observed in the test pit. Owing to there being

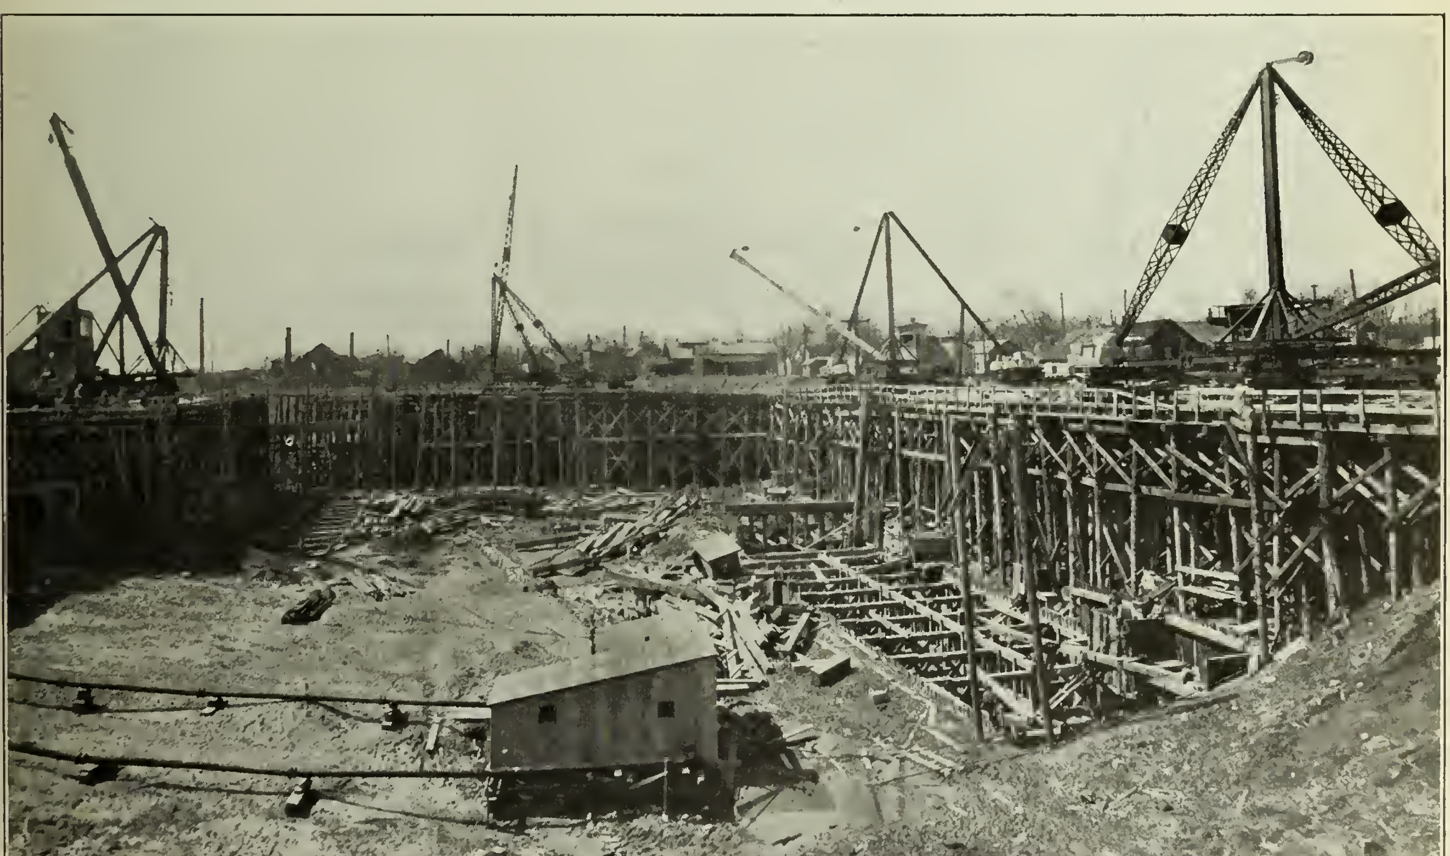

Figure No. 12.—View of Pit A Looking Northwest, April, 1927.

very few boulders in the clay it was possible to drive the 12- by 12-inch square timber piles accurately in a vertical plane. When the excavation had reached elevation 507.0 one of the 12- by 12-inch transverse struts failed in row *D*. This was followed by the failure of two 12- by 14-inch struts in row *E*, and as most of the other struts in *D* and *E* were showing signs of distress additional timbers were placed alongside the struts already in place, which prevented further failures. Before the extra struts were placed one 24- by 24-inch wale in row *E* failed by splitting longitudinally. The pressure had forced many of the steel plates into the hardwood corbels, some of which were badly crushed and split. The movement at the top of the steel piling averaged about 7 inches southward and at wales *D* and *E* the bulging decreased the width of the pit 2 feet. The timber bearing piles were driven between March 8th and 19th, and placing concrete was completed on April 14th, 1927.

PIT B

Pit *B* is adjacent to the west side of the test pit, and in it was built the west end and well of the north tube of the culvert. The pit was 38 feet wide and about 75 feet long. The steel piling was assembled and driven by January 31st. Excavation was begun late in January and completed on March 29th. No water entered the pit until shortly before the excavation was completed, when seven separate streams broke through the floor near the southwest corner of the pit. Water also entered the pit from the test pit. Three small pumps, however, kept the water under control.

The west end of the pit was irregular in shape and detailed timber bracing of special design and the use of long hardwood corbels. From the experience gained in the construction of pit *A* additional 12- by 12-inch struts were placed in rows *C* and *D* of pit *B*. Only one strut failed in this pit, but there was a tendency of the whole pit to move southward. At the top of the pit the greatest movement was 1.8 foot southward. At wale *H* the north wall had a maximum bulge of 2.4 feet, and the south wall was pressed southward one foot.

Driving the bearing piles was done during the last two days of March by a McKiernan-Terry No. 9-B-2 hammer, weighing 6,760 pounds. The weight of the hammer forced the piles down 12 to 14 feet without a blow. Two blows would then drive the piles about 4 feet further, when the piles would begin to drive hard and ultimately bring up on rock. The driving of the bearing piles caused the material to heave up 2 feet all over the bottom. Concreting was commenced on April 1st and completed on the 28th to elevation 535.0.

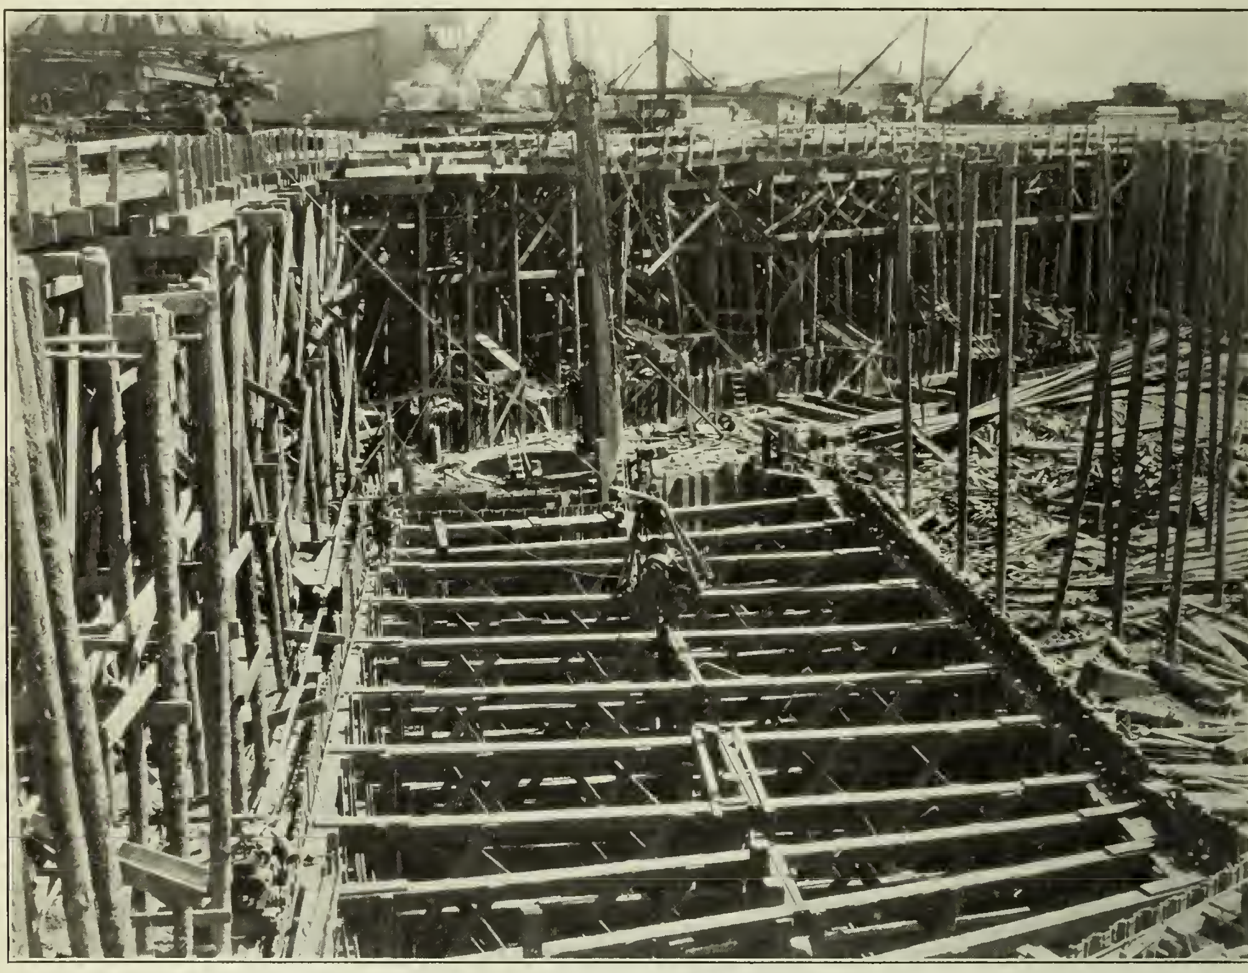

Figure No. 13.—View of Pit D Looking North, June, 1927.

PIT C

Pit *C* enclosed the western half and west end well of the south tube of the culvert. It was 38 feet wide and 170 feet long. On December 30th the work of assembling and driving the steel piling was begun, but was not completed until February 12th, 1927. Excavation was started on January 15th and completed on April 18th. No water other than surface drainage entered the pit until nearly all the bearing piles had been driven, when it started coming up the side of one of the piles.

Like pit *B*, the west end of pit *C* was irregular in shape and entailed timber bracing of special design and the use of long hardwood corbels, and, like pit *A*, it had one line of longitudinal struts from end to end of the pit. Considerable trouble was experienced from the timber bracing in this pit failing. When the excavation was only down to elevation 538.5 a 12- by 12-inch wale failed in the north wall near the east end. When the excavation was down to elevation 523.5 two struts failed in row *C* near the east end. It was then decided that the 12- by 12-inch struts in rows *B* and *C* were too light and all the struts in these rows were doubled. About this time a check survey was made of the cellular cofferdam. It revealed a northward movement of about 2 feet at the top of cell No. 1. The movement extended easterly as far as cell No. 8, being a maximum at cell No. 1 and zero at cell No. 8. The dimensions of all the transverse struts in all the rows below row *C* were then increased to 18- by 18-inch and no further trouble was experienced from breaking struts. When the excavation was down to elevation 512.0, the interlock between the first and second piles at the north-east corner of cell No. 3 of the cellular cofferdam failed, and the wall of the cell was forced out until the opening was about 6 feet wide. This break was repaired by burning off a few of the piles as low down as possible and driving a new wall outside the break. Each end pile of the new wall was driven down on top of a burned-off pile in the old wall and interlocked with the adjoining full length pile of the original wall. Nine new piles, 54 feet long, were required to repair the break. During the excavation of the pit it was observed that the timber construction trestle alongside the pit was gradually settling, and had eventually to be blocked up 3 feet to permit the derricks to travel upon it. It was also observed that the material out in the centre of the culvert site was heaving up opposite the east end of pit *C*. When the excavation was completed a survey of the steel pile walls showed a maximum movement of 4.5 feet northward at the top of the south wall. The top of the north wall moved about one foot in the same direction. This movement extended throughout 100 feet from the east end of the pit. The steel piling was badly bulged in places, but none of its interlocks failed. Driving the bearing piles was begun on the 12th and completed on the 21st of April, with the same characteristics as were experienced in pit *B*. By May 16th, 1927, the tube was completed to elevation 535.0.

Pit D

Pit *D*, (shown in figure No. 13), enclosed the west end of the four central tubes and their vertical wells, and was 54 feet 7 inches wide by 116 feet 6 inches long. The steel piling was assembled and driven between February 15th and 28th. Excavation was begun on April 29th and completed on June 20th. As the end walls of pit *D* did not require to be supported a through longitudinal strut was not required. This was a great advantage in designing the bracing as it enabled the long transverse struts to be placed in position in one length in all the tiers. In this system of bracing the transverse struts were tied together in pairs at the centre with tie rods and short longitudinal struts and supported midway of their length by vertical 12- by 12-inch piles. This left every alternate space between the transverse struts open from side to side. In these spaces the struts were lowered full length and set in place. This system of bracing also had the great advantage of reducing the amount of manual labour required to excavate the pit, and permitted of greater freedom for the operation of the clamshell buckets used for excavating the material. The excavation of the pit was not begun until the concrete in pits *B* and *C* had been built up to about elevation 545.0, since it was deemed advisable to support the concrete tubes in pits *B* and *C* against the side wales of pit *D*, as the tubes were not considered stable against sliding from external pressure. This proved to be the case when the steel piling, separating pit *D* from pits *B* and *C*, was pulled.

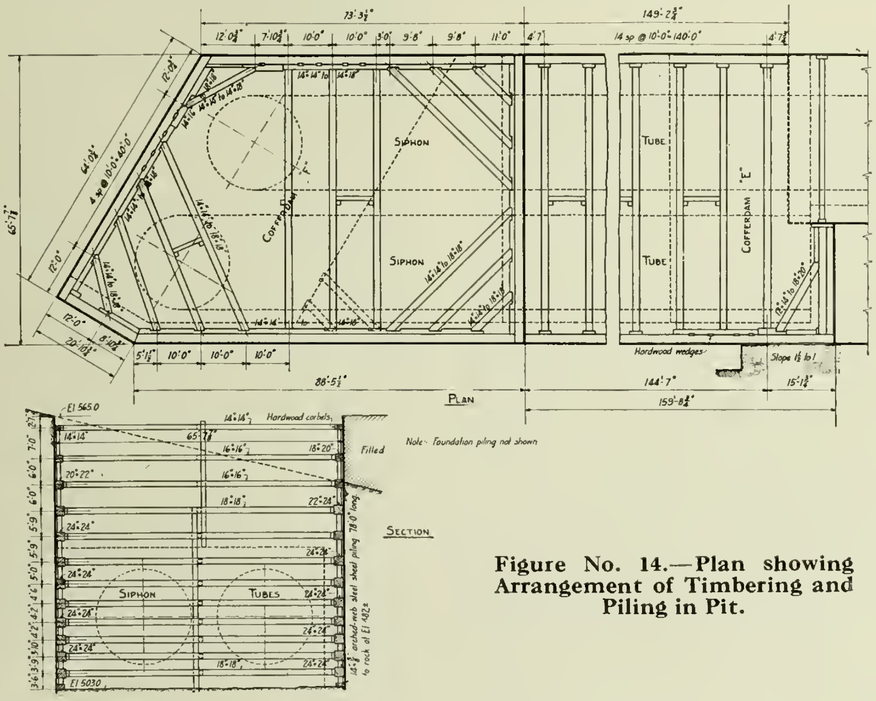

Figure No. 14.—Plan showing Arrangement of Timbering and Piling in Pit.

When the steel piling between pits *B* and *D* was pulled, and the excavation completed to elevation 499.0, a flow of water estimated at 200 gallons per minute, came in from pit *B* and the "test pit." A similar flow occurred at the south end of the pit when the steel piling between pits *C* and *D* was pulled. During this operation the west end of the north tube in pit *B* moved south about 2 inches, opening up slightly the expansion joint between the sections of the north tube in pit *B* and the test pit. This movement was amply taken care of by the metal cut-off in the joint.

Driving the bearing piles was finished on June 23rd.

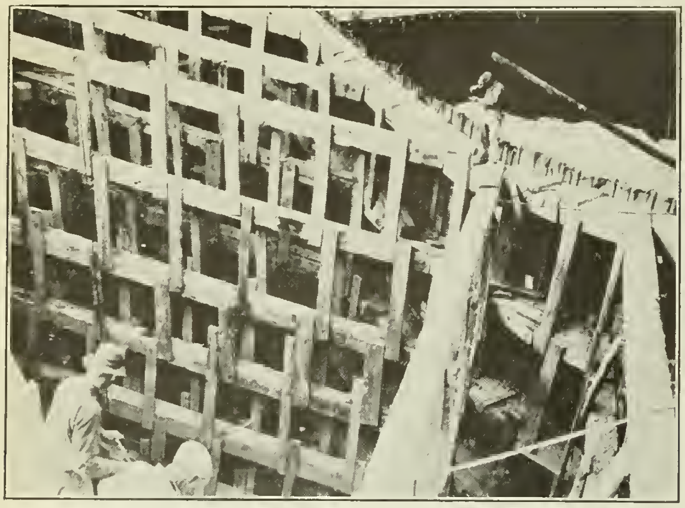

Figure No. 15.—View showing Settlement of Sheet Piling in West Wall of Pit H, August, 1927.

and the placing of concrete was completed up to elevation 546.0 on July 20th, 1927.

As the western end of the culvert was built without any serious troubles developing, it was decided to proceed at once with the construction of the east end of the structure. A study of the conditions surrounding this end of the culvert showed that owing to the gravel bank in rear of the cellular cofferdam the steel sheet pile braced pits would have to be carried up to about elevation 571.0, which meant pits 68 to 71 feet deep, or about 30 feet deeper than originally contemplated, and that, owing to the necessity of having to buttress the cellular cofferdam continually while the culvert pit was unwatered, it would be very difficult and expensive to carry this out if the pits were made only wide enough for one tube, and that if they were made wide enough for two tubes no difficulties would be encountered in continually supporting the cellular cofferdam.

Pits in which two tubes could be built at the same time would have to be 65 feet 8 inches wide. After very serious consideration it was decided to take the risk of using wide pits, and pits *F* and *H* were laid out to enclose respectively the ends of two tubes at the southeast and northeast corners of the culvert.

Pit H

Pit *H* is located at the northeast corner of the culvert area and is similar in shape to pit *C* at the southwest corner, but it is 65 feet 8 inches wide and 111 feet long. The assembling and driving of the steel piling was begun on April 27th and completed on May 31st. The piling was all driven to hardpan or rock, except that for the west wall, which was only driven down to about elevation 488.0, or 15 feet below the bottom of the pit. The piling was unlocked at three places in this pit, and at one place it was pushed so far into the pit that it had to be burned off several times as the excavation proceeded. It was also apparent that the steel piling in the north wall had deflected very badly when it was driven, as it was found to be in particularly bad alignment before the failure of the timber bracing. Along the north wall for a distance of about 30 feet from the west end of the pit the piling was pushed into the pit as much as 9 feet. Along this distance of 30 feet the cross-section of the north tube was flattened in order to obtain sufficient thickness for the north wall, which at this point was reinforced with 40-pound rails.

The excavation was begun on June 4th and was completed on August 3rd. No water entered the pit until the excavation was nearly finished, when water began coming up from the bottom at the rate of about 50 gallons per minute.

The wales were Douglas fir 14 by 14 inches, 18 by 20 inches, 20 by 22 inches, 22 by 24 inches and 24 by 24 inches. Between them and the ends of the struts were placed 8- by 20-inch hardwood corbels. The transverse struts were Douglas fir 14 by 14 inches, 16 by 16 inches and 18 by 18 inches, were all strong enough to act as unsupported columns and were placed in position in full length pieces 60 feet 4 inches to 62 feet long. They were as far as possible tied together in pairs at the centre and supported by 12- by 12-inch piles as in pit *D*. On account of using full length struts there were no through longitudinal struts, consequently the end walls had to be supported by a system of diagonal bracing, which did not prove very satisfactory under heavy loading in the lower tiers.

No trouble developed in excavating the pit until elevation 505.0, (two feet from the bottom of the pit), was reached. On July 28th, when the excavation had been carried down to elevation 505.0, the hardwood corbels in tiers *F* and *K* failed at the centre of the west wall, and the longest diagonal strut across the southwest corner in tier *G* broke. The failure of these timbers was mainly, if not entirely, due to the settling of the steel sheet piling in the west end wall, as shown in figure No. 15. The settlement of this sheet pile wall was evidently due to this piling, in driving, taking an outward slope, so that when the interior of pit *H* was excavated this wall carried the weight of the triangle of material inside the vertical line from the bottom of the piling as driven, and, being unsupported at the bottom, due to the piling not being driven to rock, this added weight forced the piling wall to move vertically, until it came in contact with the hardpan or rock below. This settlement of the piling not only threw the entire west end of the bracing system out of its horizontal plane, but set up destructive torsional stresses in many of the wales of the lower tiers. On July 28th the west end wall of piling settled 4 inches at the centre of the wall, and during that night a further settlement of 8 inches occurred. On the 29th there were a series of failures which made it look as if a complete collapse of the pit were imminent.

Additional 18- by 18-inch struts were placed across the east and west ends in the seven lowest tiers of wales. Three of these extra struts in the east end and four in the west end subsequently failed. At the east end the hardwood corbels, supporting the diagonal struts in tiers *K*, *L* and *M*, failed in a similar manner as they did in tiers *F* and *M* at the west end. In the north wall near the west end wale *M*,

Figure No. 16.—View showing Failure of Timbers in Pit H, August, 1927.

24 by 24 inches, failed and was eventually reduced to a mass of splinters. Another strut in tier *M* failed by crushing. In the north wall the 24- by 24-inch wales in tiers *K*, *L* and *M* rotated about 25 degrees around their longitudinal axis, due to the distortion of the diagonal struts. Many of the diagonal struts across the west end that had not actually failed were showing such signs of distress as to appear to be on the point of collapse. Timber piles were then driven and capped with heavy timbers in an effort to stop the sagging of the wales at the west end. On August 2nd the steel piling of the west wall had settled 4.5 feet at the centre of the wall, but there was no settlement at the two ends of the wall, as the piling at these points in the north and south walls had been driven to hardpan or rock. At this date all the wales on the north side below wale *G* for 50 feet from the northwest corner were broken, the steel sheet piling was wrapped part way around them, and all the diagonal struts in the west end below wale *H* were broken and wale *H* had kicked out. Figures Nos. 16, 17 and 18 show some of the damage to timbers in pit *H*.

Driving the bearing piles was begun on August 2nd and completed on August 4th. The material was so soft that the piles penetrated it 15 feet under the weight of the hammer. It was similar to that found in the preceding pits down to elevation 505.0 and from there to grade elevations 503 and 500 it was very much softer. Borings showed it to be very soft to elevation 485.0.

Every effort was made to get the first layer of concrete, 3 feet deep, laid over the bottom of the pit as soon as possible, and on August 3rd this was begun and completed across the west end of the pit that evening. As soon as this layer of concrete was laid across the west end of the pit for a width of about 20 feet all settlement of the west wall immediately stopped. No attempt was made to remove any part of the bottom tier of timber bracing. It was embedded in the concrete. The concrete was completed to elevation 535.0, (top of tubes), by September 3rd, and to elevation 550.0, (top of wells), by September 20th.

Pit F

Pit *F* is located at the southeast corner of the culvert area and is similar in shape to pit *B* at the northwest corner, but is 65 feet 8 inches wide and 104 feet long. The assembling and driving of the steel sheet piling was begun on June 11th and completed on June 28th. Piling 89 feet long, in two lengths of 50 feet and 39 feet, was used for the east and south walls, 83 feet long for the north wall and 78 feet long for the west wall. In order to prevent settlement of the west wall, such as had occurred when pit *H* was being excavated, every second pair of piles was driven further by adding 6-foot lengths of steel piles and driving them, when possible, until their tops were flush with those not re-driven. The general elevation of the top of the steel piling was elevation 571.0. As the pit was excavated it was noted that the steel piling had deflected badly in driving at several places, and that its alignment was also very irregular in places, there being a deviation of 6 feet in a width of ten piles at one point in the west wall, and in the southeast corner it was found to be very badly deflected; along the east wall it was found bulged as much as 4 feet at elevation 510.0. These irregularities necessitated a great deal of blocking and wedging between the piling and wales. At four points in this pit the steel piling had unlocked at elevations 532.0, 533.0, 536.0 and 539.0.

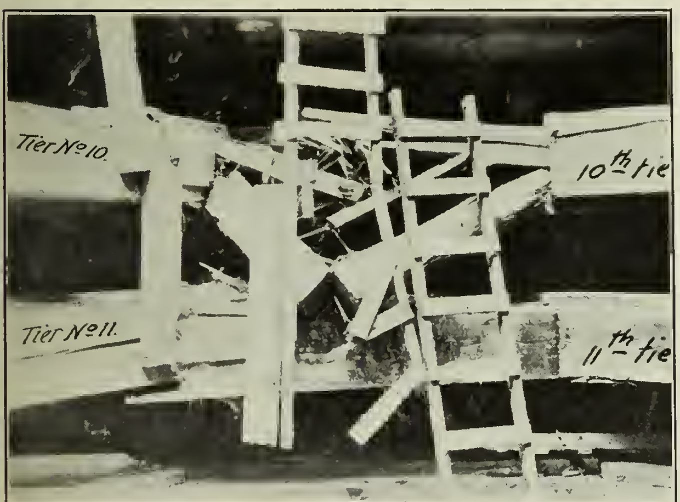

Figure No. 17.—View Showing Failure of Timbers in Pit H, August, 1927.

Figure No. 18.—View showing Failure of Timbers in Pit H, August, 1927.

The excavation was begun on July 4th and completed to elevation 501.5 on September 9th. Due to the deflection of the steel piling and the failure of diagonal struts and corbels in the southeast corner, it was not deemed advisable to carry the excavation down to elevation 500.0 in the east end of the pit. When the excavation had reached elevation 504.0 water began to come in from the bottom. The quantity was small at first, but in less than a week it had increased to about 225 gallons per minute. Pumping this water had the effect of drawing the water away from the pits previously excavated, and these pits have been practically dry ever since, except the test pit, where a small quantity continues to enter the pit.

On August 27th two of the long hardwood corbels in the southeast corner of the pit at tiers *G* and *H* failed, and when the excavation in the east end of the pit had been taken out to elevation 501.5 the wales in tiers *K*, *L* and *M* around this oblique corner also failed badly, due primarily to the failure of the long hardwood corbels supporting the diagonal struts. In order to strengthen the bracing at this point additional 18- by 18-inch struts were placed across the pit at about the centre of the east end pocket in tiers *F*, *G*, *H*, *K* and *L*.

The driving of bearing piles was begun on September 7th and finished on the 9th. They penetrated the soft clay about 15 feet under the weight of the hammer, and after the first few blows the driving was fairly stiff to ultimate refusal. The placing of concrete was begun on September 9th and was completed to elevation 535.0 on October 6th and to elevation 550.0 on October 13th, 1927.

Pit K

Pit *K* formed the connecting link between pits *A* and *H*, and, like the latter, was 65 feet 8 inches wide but only 60 feet long. The assembling and driving of the steel piling was begun on April 27th, but was not completed until September 3rd. The top of the piling was at elevation 565.0 and was 83 feet long in the north wall and 78 feet in the south wall. In the north wall some of the piles either struck boulders or very hard material, as it was found impossible to drive the tops of them lower than elevation 585.0. Excavation was begun on September 9th and completed on October 7th. No trouble was experienced with the timber bracing and no water came into the pit through the floor, but some entered the pit from pit *A* when the steel sheet pile wall between the pits was pulled out. The bearing piles were driven between October 10th and 14th, and the placing of concrete was begun on the 15th and completed on the 31st.

Pit E

Pit *E* forms the connecting link between pits *C* and *F*, and, like the latter, is 65 feet 8 inches wide and is 159 feet long. The assembling and driving of the steel sheet piling was begun on June 29th and completed on September 9th. Before the excavation in the pit was begun there was considerable discussion over the advisability of opening up such a large area at once. At first it was decided to divide it into two sections. This meant that the section which was excavated first would have to be supported at one end by diagonal struts, and as the experience with these struts in pits *H* and *F* had been far from satisfactory, there was, naturally, a desire on the part of all concerned to avoid a repetition of it if at all possible. Excavation was therefore begun throughout the entire length of the pit, with the proviso that if timbering and other conditions developed unfavourably the pit could then be divided and the balance of the excavation completed in two sections. At the end of October the excavation had been taken out to elevation 535.0. After wales in tiers *C* and *D* had been placed, the struts in these tiers began to show signs of severe stress, as their ends were crushing into the hardwood corbels. At this stage a survey of the cellular cofferdam south of pit *E* showed that it was tilting northward, that the top of the north and south walls of pit *E* were also moving northward, and that the material in the culvert pit between pits *E* and *A* was also being pushed northward on to the top of the tube in pit *A*, notwithstanding the bank of gravel 10 feet high that had been placed behind the north wall of pit *E* before excavation of the pit was begun. The material in the foundation of the culvert is very soft at the west end of pit *E*. The northward movement of the pit walls and the weight of the gravel behind the north wall squeezed the soft material up and on to the top of the tube in pit *A*. During October the tops of cells Nos. 3 and 4 of the cellular cofferdam had deflected northward 3.7 feet, and the top of the steel sheet pile walls of pit *E* 4.8 feet. To stop this movement the tops of the cells of the cellular cofferdam were anchored to the masonry of the aqueduct, and the north wall of pit *E* was buttressed by inclined 24- by 24-inch struts supported by the steel sheet piling on the north side of Pit A. These remedial measures stopped further movement of the cellular cofferdam and displacement of the walls of pit *E*. If no further trouble develops it is expected that the excavation in pit *E* will be completed by January 15th.

Date of Completion

The work will be carried on continuously throughout this winter, and it is anticipated that the structure will be completed by midsummer of 1928, provided no unforeseen troubles develop, and that there is sufficient gravel on hand at the close of navigation to meet the requirements of the contractor's concrete operations during the winter.

Excavation

The excavation in the pits has been done as far as possible with 1 and 1½ cubic yard Owens clamshell buckets operated by travelling derricks located on top of the construction trestle surrounding the perimeter of the culvert pit. The thin walls of clay left under the struts, and wales have been undermined by hand and allowed to fall over so that the mass could then be picked up by the clamshell buckets.

The results obtained during the construction of the culvert demonstrate what can be done with arch web steel sheet piling in long units, 83 feet, by carefully preassembling the piling before driving, and by skilful and careful work and close attention in putting simple rigid bracing in place as the excavation proceeds, and that similar work could be carried to a greater depth than obtained in the excavation for the syphon culvert.

Central Concrete Mixing Plant

The concrete is mixed at a central plant of the standard type, consisting of material bins and two one cubic yard Smith mixers. The concrete is transported in cars of 3 cubic yards capacity from the mixers and deposited in place by chutes from the top of the service trestle. The concrete is made from lake gravel and mixed with about 6½ bags of cement to the cubic yard of concrete. The bags contain 87½ pounds of cement each. The gravel is obtained from the bed of lake Erie about 8 miles west of Port Colborne and is delivered on the work by steam hopper barges that pump the gravel into and out of their hoppers.

There will be about 93,000 cubic yards of concrete in the culvert, and at the end of October about 50,000 cubic yards, or 54 per cent, had been built.

Contractors

The building of the syphon culvert is included in the contract of section No. 6 of the Welland ship canal, now being constructed by the Atlas Construction Company and the O. E. Leahey Company, who are jointly the contractors for the execution of all the works embraced in section No. 6. The construction of the culvert is being carried out by the Atlas Construction Company, who have a large plant on the ground consisting of derricks, pile drivers, locomotives, cars, concrete mixers, etc. The four travelling derricks operating on the service trestle surrounding the foundation pit of the culvert have capacities of 15 to 20 tons, and are equipped with 75-h.p. electric motors and 10- to 20-h.p. swinging motors. The contractors' manager on the work, Mr. John Horgan, deserves great praise for the fearless, energetic and efficient manner in which the work has been carried out during the past four months under very trying conditions. Messrs E. P. Johnson, division engineer; D. E. O'Brien, senior assistant engineer, and H. Wellwood, assistant engineer on section No. 6, have all, by their close attention and interest in the work and by their excellent spirit of co-operation, materially assisted in carrying the work through to a successful issue.

The author also desires to express his appreciation of the great interest and close supervision given the work by Mr. E. G. Cameron, principal assistant engineer, and to Mr. E. P. Johnson and Mr. J. B. McAndrew, structural engineer, Welland ship canal, for their assistance in the preparation of this paper.

Bridges Over the Welland Ship Canal

An Outline of Preliminary Investigations, Specifications, and Designs and Construction Features of the Substructures and Superstructures of the Various Bridges—of which there will be Two Swing, Seven Rolling Lift and Twelve Vertical Lift, Bridges

Marshall Brodie Atkinson, M.E.I.C.
Structural Engineer, Welland Ship Canal, St. Catharines, Ont.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

The Welland ship canal, which on completion will supercede the present Welland canal, connects lake Ontario at Port Weller with lake Erie at Port Colborne, the difference in water level being 326.5 feet. It crosses the Niagara peninsula about ten miles west of Niagara falls, is approximately twenty-five miles long, and has seven lift locks between Port Weller and Thorold, each with a lift of 46.5 feet; a guard gate above lock No. 7 and a guard lock No. 8 at Port Colborne. Locks 1, 2, 3, 7 and 8 are single locks, whereas locks 4, 5 and 6 are twin locks in flight. The lock chambers are large enough to accommodate vessels 820 feet long by 80 feet beam with a draft of 30 feet.

The Niagara peninsula is rightly termed the *Garden of Canada*. The district at present is highly developed in agriculture and has many towns and industries, with prospects of still greater increase due to the large amount of electrical power available from Niagara Falls; furthermore, trunk highways and railroads between the United States and Canada are intersected by the canal. All this necessitates providing many movable bridges over the canal which, due to the requirements of navigation and bridge traffic, have to be of a high grade.

Twenty-one bridges will be provided over the ship canal. Bridges Nos. 1, 3, 6, 7, 9 and 19 will be, respectively, over the entrances of locks Nos. 1, 2, 4, 7, the guard gate and lock No. 8. All the other bridges will be over the prism of the various reaches of the canal, with the exception of bridge No. 8, which spans the opening between the flaring upper entrance walls of lock No. 7.

Investigation into the question of the type or types of bridges to be used on the canal had started as early as 1912, and by 1914 a decision had been arrived at between J. L. Weller, M.E.I.C., the then engineer-in-charge of the Welland ship canal, and the late W. A. Bowden, M.E.I.C., chief engineer of the Department of Railways and Canals, that swing spans were undesirable over the locks and that their use on the canal reaches would offer serious obstruction to navigation by reason of the guard piers required; furthermore, the cost of the substructure required either for single or double swing bridges would cause the bascule type of bridge to be more economical. By 1914 it was practically settled that all the bridges, with the exception of bridges Nos. 4, 8 and 15, would be single rolling lifts or heel trunnion bascules, and some substructures were built to accommodate either type. The substructure for bridge No. 4 was built to accommodate a double leaf deck rolling lift or double leaf deck heel trunnion bridge. Bridge No. 8, which was to be located at the then proposed site of the guard gate and would thus have a guard pier, was built as a swing span. The swing span bridge No. 15 had been built in 1910 by the Michigan Central Railroad over that part of the present canal which will form part of the Welland ship canal.

Substructures

The use of the ship canal by vessels of large tonnage requires that all substructures bordering on the channel be of massive character to withstand glancing blows from passing shipping. The substructures for the 80-foot spans form part of the lock walls, but those over the reaches require piers to be built for them, with the exception of bridges Nos. 20 and 21, whose piers form part of the sidewalls to the canal at Port Colborne.

The piers for bridges Nos. 2, 5, 10, 11 and 12 were built with wing walls curving around into the banks; so that these when backfilled form an admirable protection to a bascule or vertical lift bridge and do not require fenders up and down stream. The piers for bridges 2, 5 and 10 were built in the dry, but those for bridges 11 and 12, on account of being on the present canal, had to be built in the wet. Those for bridge No. 11 were founded on rock, but those

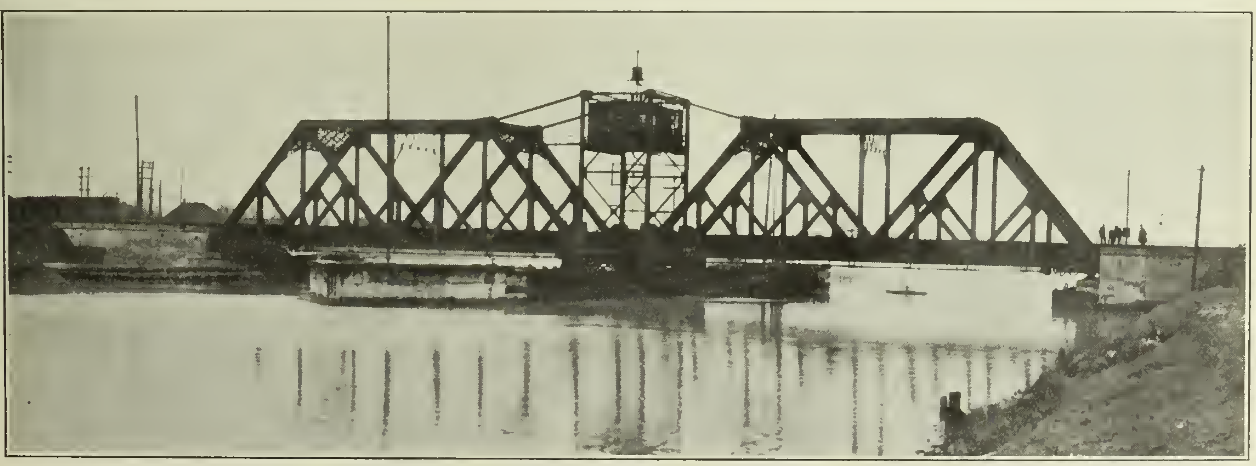

Figure No. 1.—Bridge No. 15.—Side View of Bridge Closed.

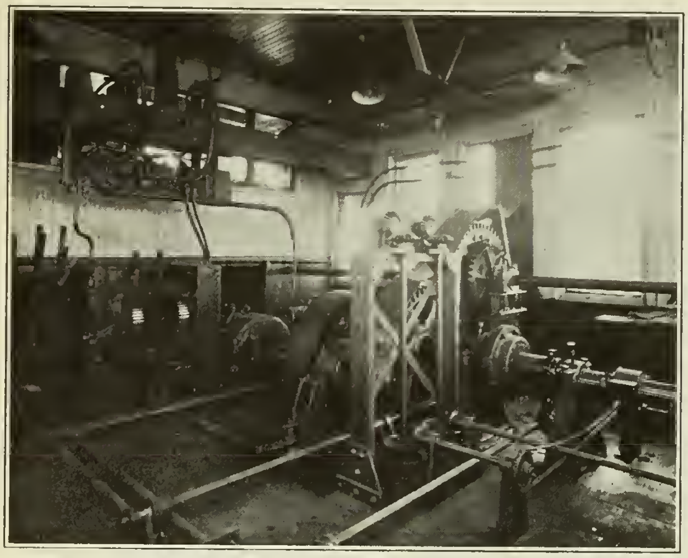

Figure No. 2.—Bridge No. 15.—View Inside of Machinery House.

for bridge No. 12 were on piles, and so much trouble and expense was encountered in building the piers for the latter bridge, due to the long lengths of sheet piling required and the difficulty of keeping the excavation unwatered, that the use of this type of pier was abandoned for bridges Nos. 13, 14, 16, 17 and 18 and oblong channel piers without backfill were substituted.

The new type of piers are built as reinforced concrete caissons with removable watertight timber bottoms. They are built adjacent to the bank of the present canal at an especially prepared construction site. The caisson is built up to a height of 14 feet, supported in what might be called a floating box composed of a shallow pontoon about 10 inches deep as the bottom and four detachable vertical timber walls about 9 feet high as the sides. The area enclosed by the walls corresponds to the size of the flared base of the caisson, and the whole is made watertight and suitably braced against the concrete as it is built up. When the caisson is built up 14 feet it has sufficient buoyancy to float itself, so water is let into the spaces between the floating box and the outside of the caisson. Under this condition the buoyancy of the box, due to weights placed upon the pontoon, is just sufficient to float it. The detachable walls are removed, the pontoon sinks and the caisson is floated down to the bridge site. Here it is built up 23 feet higher and then landed in its permanent position on its piles, which have been previously cut off under water to accurate level elevation. The timber bottoms are removed, the excavated area surrounding the outside of the piles filled up to prism grade with broken stone and the caisson partly filled with concrete poured through a tremie for a height of about 12 feet. The caisson is then unwatered, filled in the dry with concrete and the pier completed to its finished elevation.

Many of the bridge substructures have their footings on rock; others have them on bearing piles driven to refusal. All piles were driven by steam hammer. At certain locations on the canal, the canal banks showed evidence of being unstable, and at the bridge sites in this vicinity the banks were flattened, thus necessitating an increase in the length of the crossing. The practice has been adopted of backfilling abutments and excavation around piers with stone.

Some substructures have caused trouble and anxiety,

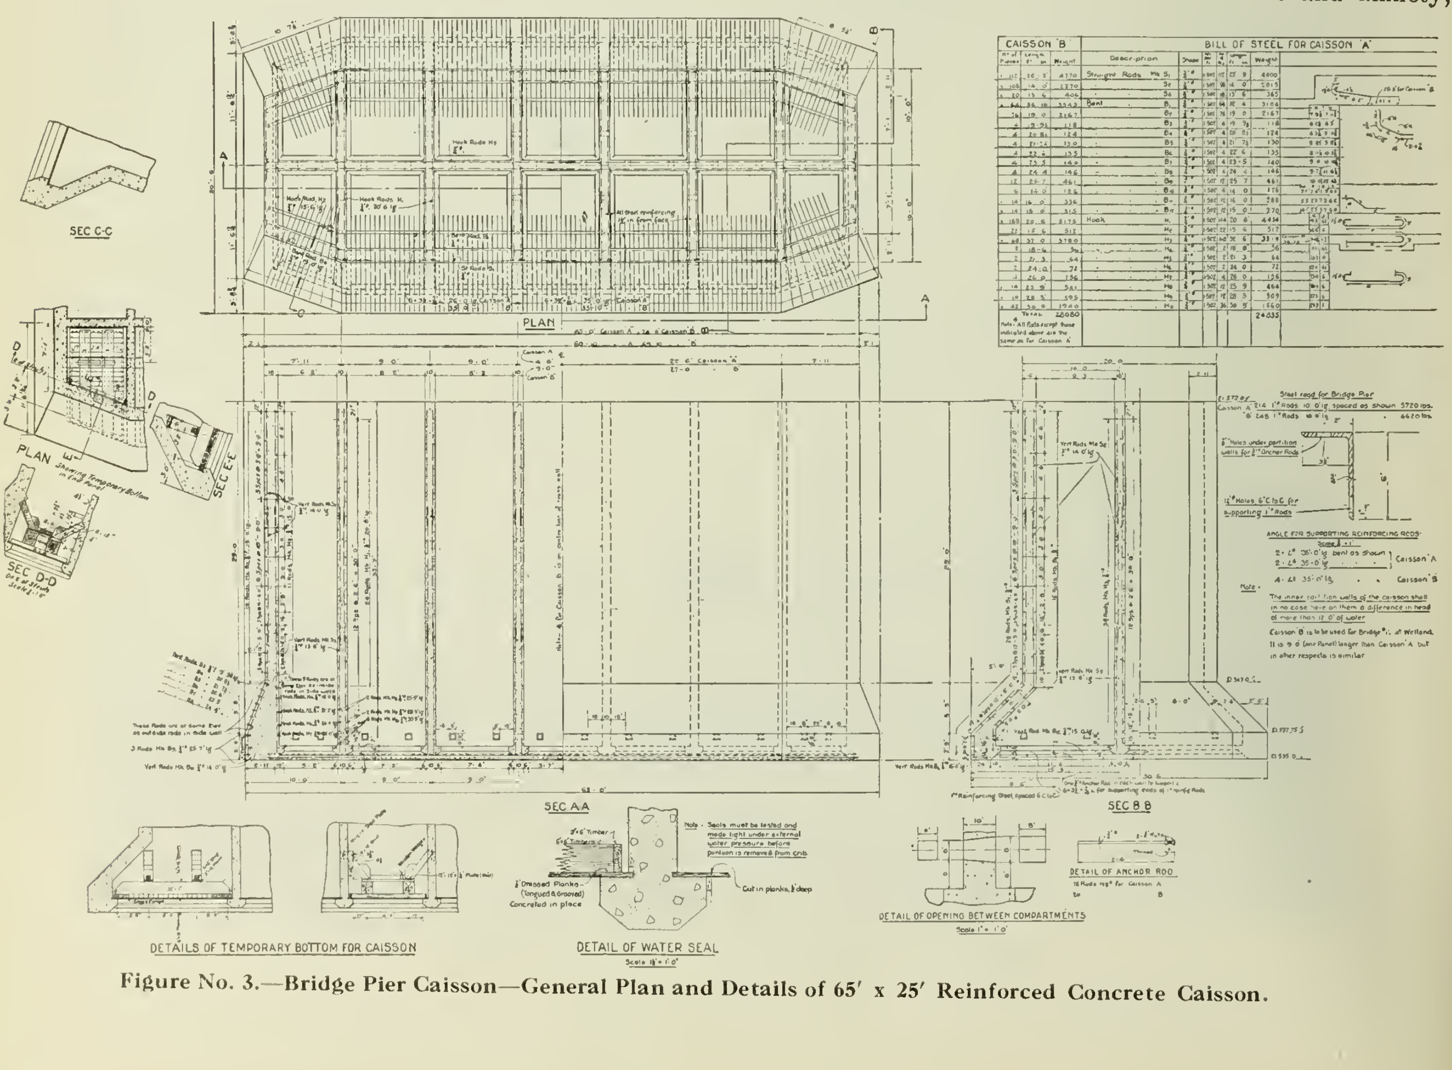

Figure No. 3.—Bridge Pier Caisson—General Plan and Details of 65′ x 25′ Reinforced Concrete Caisson.

and one in particular, bridge No. 4, seemed to have a nemesis. The two old type channel abutments were built at the beginning of the war. Some time later, when the construction of the canal had ceased on account of the Great War, the canal bank on the east side gave way, flowed down and knocked the east channel abutment over. In 1920, after work on the canal had started again, the east bank was flattened out, the old abutment removed and a new pier was put in that required no backfill. Later, in 1926, when driving piles for an extension behind the old west abutment, it was discovered that the monoliths of the abutment were being pushed out. The slopes were flattened out, and three flanking spans will be used at each end of the bridge. The west pier was underpinned and batter piles in the form of cylindrical steel shells were jacked down in front of it with 100-ton jacks and these shells filled with concrete. The piles under the pier were jacked down until they withstood a pressure of 100 tons; and the footing concreted in again and thoroughly grouted. A large trench was dug behind the pier leading out to the canal prism, and this trench was rock-filled so as to provide a drain in case the canal reach is unwatered.

Competitive Designs

After construction of the Welland ship canal had been started again in 1919, Alex. J. Grant, M.E.I.C., who had been appointed engineer-in-charge, kept pressing the Department for a decision on the type of bridges which would be used at the various crossings. Mr. Bowden had in the meantime been giving consideration to bridges of the vertical lift type, and it was finally decided that it would be very desirable to secure, from certain consulting firms, competitive designs for three typical crossings on the canal, for rolling lifts, heel-trunnion bascules and vertical lifts, thoroughly worked up, before actually deciding on the types to be used for the various crossings over the ship canal. On August 31st, 1923, an Order-in-Council was passed authorizing the calling of competitive designs covering rolling lift bascules, heel-trunnion bascules and direct lift spans for the following typical highway bridges:—bridge No. 3, Carleton street, over lock No. 2; bridge No. 4, Queenston road, and bridge No. 12, Port Robinson, and Mr. Bowden, chief engineer of the Department, gave instructions for the preparation of the necessary specifications, plans and data. The bridges on

Figure No. 4.—Bridge No. 8.—Side View of Bridge Closed.

the canal come under the head of fixed and movable bridges for the accommodation of traffic from railroads, electric railways and highways, and, as there seemed no suitable specification available, Mr. Bowden authorized F. E. Sterns, M.E.I.C., and M. B. Atkinson, M.E.I.C., respectively designing engineer and structural engineer of the Welland ship canal, to write a complete bridge specification. At the same time, Mr. Bowden permitted double leaf bascule designs for highway crossings to enter the competition, and he set the vertical overhead clearance for the vertical lift bridges at 120 feet above water.

In writing the specifications, full use was made of, and great help obtained from, the specifications of the Canadian Engineering Standards Association and of the American Railway Engineering Association. Early in December 1923 the specifications were sent to the chief engineer, together with the necessary plans and data, and on December 10th, 1923, Mr. Bowden issued these, with invitations to compete, to the Scherzer Rolling Lift Bridge Company, the Strauss Bascule Bridge Company and the firm of Harrington, Howard and Ash. A time limit for the reception of designs was set at March 31st, 1924, but this was subsequently extended to June 1st, 1924. Mr. Bowden died on February 3rd, 1924, and was succeeded as chief engineer by Colonel A. E. Dubuc, D.S.O., M.E.I.C.

On April 12th, 1924, an Order-in-Council was passed appointing a Board of Engineers to examine and report upon the competitive designs submitted. This Board consisted of Colonel C. N. Monsarrat, M.E.I.C., as chairman, with F. E. Sterns, M.E.I.C., and M. B. Atkinson, M.E.I.C., of the Welland ship canal staff. Designs were received from the three competing firms, as follows:—

Strauss Bascule Bridge Company, bridge No. 3, none; bridge No. 4, none; bridge No. 12, a double leaf through truss heel-trunnion design.

Scherzer Rolling Lift Bridge Company, bridge No. 3, a single leaf through truss rolling lift design; bridge No. 4, a double leaf deck truss rolling lift design; bridge No. 12, none.

Harrington, Howard and Ash, bridge No. 3, a single leaf through girder rolling lift design and a through truss vertical lift design; bridge No. 4, a

Figure No. 5.—Bridge No. 3—(Left) Rear View of Bridge Open. (Centre) Front View of Bridge Closed. (Right) Side View of Bridge Open.

double leaf deck truss simple trunnion design and a through truss vertical lift design; bridge No. 12, a double leaf through truss rolling lift design and a through truss vertical lift design.

The designs submitted included structural stress sheets, calculation sheets and general design plans of the structure in sufficient detail to enable the general and detail design and the operation of the bridge to be thoroughly reviewed and checked over, together with estimates of quantities.

All the designs were investigated, checked and compared. Where they did not fully comply with the department's specifications, suitable corrections in the estimated weights were made in order to bring them to a common basis. The drawings and quantities of material for the various designs were sent to certain bridge companies in Canada, who were asked to furnish the Board with unit prices for each item of material for each design. The Board, in estimating the first cost of the superstructures for the different designs, used for each item a unit price which was an average of the unit prices received for this item from the bridge companies. Reports covering the complete designs for each bridge and recommended amendments to the Department's specifications to be used for contract designs were submitted by the Board to Colonel Dubuc, chief engineer of the Department.

During the competition, W. Chase Thomson, M.E.I.C., submitted to the chief engineer, for consideration, a design of the double swing type for a typical highway crossing similar to bridge No. 12. At the request of Colonel Dubuc, a report covering this type of bridge was submitted to him

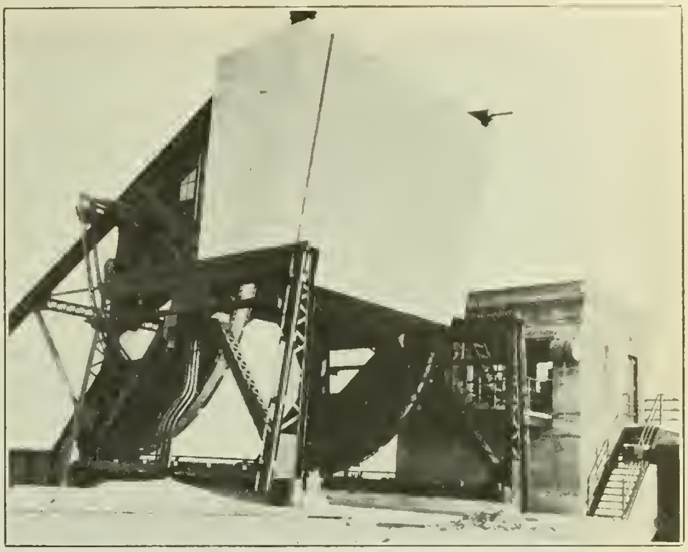

Figure No. 7.—Bridge No. 3—Rear View of Bridge Closed.

from Messrs. Grant, Sterns and Atkinson. Two designs were investigated, as follows:—type *A*, which had the pivot piers placed as close together as the prescribed navigation clearances permitted, on the assumption that fenders composed of pile clusters and floating booms would be considered as giving adequate protection to the bridge and would not necessitate the building of heavy concrete protection;

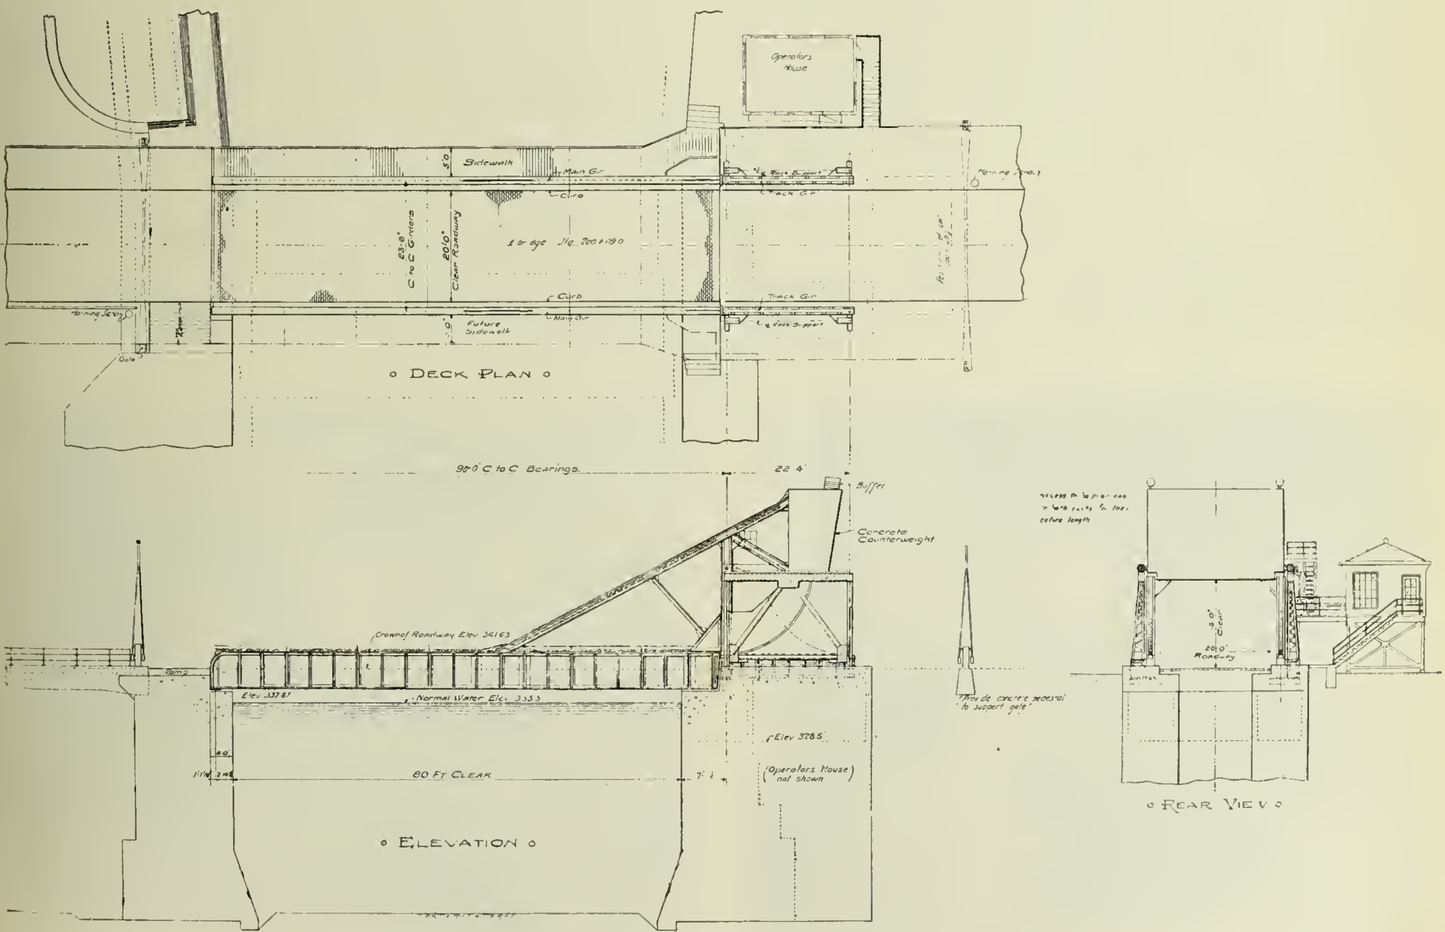

Figure No. 6.—Bridge No. 3—General Plan.

Figure No. 8.—Bridge No. 3—Side View of Bridge Closed.

type *B*, which was designed on the assumption that the piers could be placed far enough up on the slopes of the canal prism as to avoid the need for fenders, (an assumption the acceptance of which was very doubtful). The writer is aware of only two double swing bridges that have been built. one at Teignmouth, England, of about 30 feet clear span, which has been replaced by a single swing, and another at Columbus road, over the Cuyahoga river at Cleveland, Ohio. It is interesting to note that the latter bridge, which is 150 feet centre to centre of pivot piers and has equal arms, was designed by the city engineer's office and built in 1895. Seemingly, this bridge has operated satisfactorily, and yet, so far as the writer is aware, not another bridge of this type has since been built.

Specifications

The specifications were amended and issued for use as "The General Specifications for Steel Bridges Fixed and Movable for Railway or Highway Traffic, 1925, for the Welland Ship Canal, Department of Railways and Canals." The general requirements are in substantial agreement with the findings of recognized technical associations. Below are given some of the general governing features.

The overhead clearance for navigation under vertical lift bridges is 120 feet above water. Overhead clearances for railway and highway traffic are respectively 22 feet 6 inches and 16 feet.

Materials in general have to conform to the American Society for Testing Materials standards. Concrete has to conform to the requirements of the Joint Committee of the American Society of Civil Engineers, American Society for Testing Materials. American Railway Engineering Association, Portland Cement Association and American Concrete Institute, and is to develop a minimum compressive strength of 2,000 pounds per square inch at an age of twenty-eight days. Wire ropes are to have six strands of nineteen wires each and be of the grade known as special plough steel; the wire to have a strength from 225,000 to 270,000 pounds per square inch, and the ropes a strength of $87{,}200D^2 - 6{,}400D^3$ where D is the nominal diameter of the rope in inches.

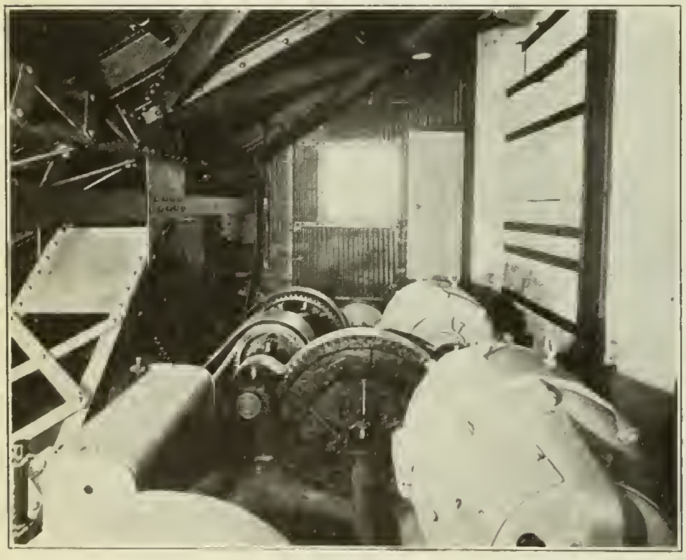

Figure No. 9.—Bridge No. 3—View Inside Machinery Enclosure on Leaf.

Unit Stresses in Pounds per Square Inch for Machinery Parts.

	Axial Tension	Compression	Bending	Shear	Fixed Bearing
Structural steel	12,000	12,000-40 1/r	12,000	8,000	18,000
Rolled or forged steel	12,000	12,000	12,000	10,000	20,000
Steel castings	9,000	11,000	9,000	7,500	20,000
Iron castings	2,000	8,000	2,500	1,500	14,000
Phosphor bronze	6,000	6,000	6,000	4,000	9,000
Brass	......	3,000	2,000	1,500	4,500
Keys	......	......	......	8,000	14,000

For stresses reversing in direction, the above unit stresses are to be multiplied by the factor, $(1 - n \div 30)$, but not less than 0.67, where n equals the number of reversals per minute.

Bearing Pressures at Slow Speed

Swing bridge pivots, hardened tool steel or phosphor bronze	3,000
Bascule trunnion, forged steel on phosphor bronze	1,500
Counterweight sheave journals on phosphor bronze	1,200
Wedges, steel on steel	500
Screws	200
Steel journals on bronze bushings	1,000
Steel journals on babbitt metal	600
Steel journals on cast iron	400

Bearing pressures where speed exceeds 100 feet per minute:—

Journals	$300,000 \div nd$	but not more than 900
Pivots	$100,000 \div nd$	" " " " 600
Collars	$50,000 \div nd$	" " " " 300

Where n = r.p.m. d = diameter of journal, pivot or mean diameter of collar.

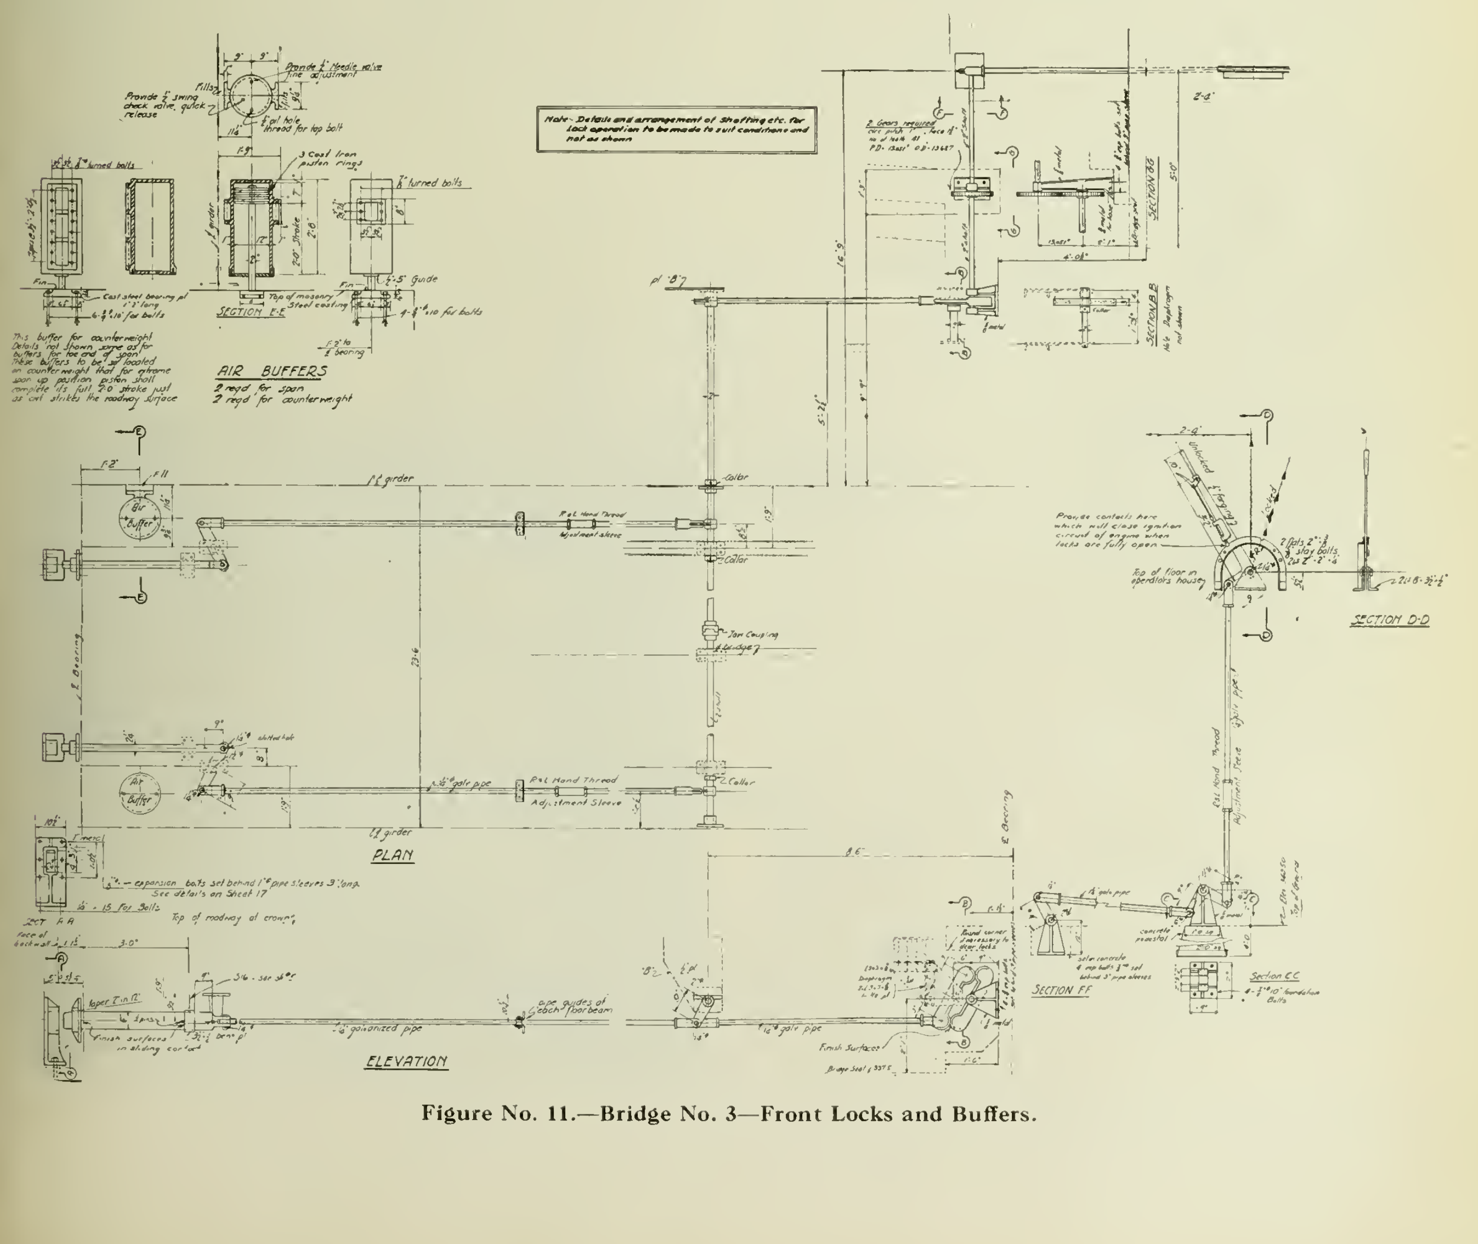

Figure No. 11.—Bridge No. 3—Front Locks and Buffers.

	Forged steel	Cast steel	Bronze
Unit stresses in cut gear teeth reduced by Lewis formula......	20,000	15,000	8,000

Wire Ropes

	Counterweight Ropes	Operating Ropes
Total unit tensile stress...........	43,600-3,200D	72,667-5,333D
Unit stress from direct load	21,800-1,600D	36,333-2,667D
Unit stress from bending $= E \times d \div 2R$		

Where $E = 28{,}500{,}000$ and d = diameter of wire, R = radius of curvature, D = diameter of rope, all in inches.

The ratio of the sheave or drum to the diameter of the rope shall not be less than 75 and 45 respectively for counterweight ropes and operating ropes, the preferable ratios are respectively 90 and 55.

Sockets for counterweight ropes	6,500
Sockets for operating ropes	11,000

Impact

Impact is allowed for in the unit stresses for machinery parts.

Frictional Resistances to be Overcome by Machinery

	For Starting	For Motion
Trunnion friction, one or more revolutions......	0.135	0.09
Trunnion friction, less than one revolution......	0.18	0.12
Centre discs..	0.15	0.10
Segmental girder rolling friction..................	0.009	0.006
Collar friction at ends of conical rollers..........	0.15	0.10
Bending of wire ropes for each sheave in terms of direct tension on the rope; d and D are respectively diameter in inches of rope and sheave	$\frac{d^2}{3D}$	$\frac{d^2}{3D}$

Rolling friction of solid rollers where r = radius of roller in inches.

In contact with one surface only................	$\frac{3}{200r}$	$\frac{3}{200r}$
In contact with two surfaces....................	$\frac{3}{100r}$	$\frac{3}{100r}$
Sliding friction for end and centre wedges		
Top surface..	0.15	0.10
Bottom surface.....................................	0.20	0.15

Friction of Machinery Parts

Efficiency of pairs of gears, including journal friction:—

Spur gears..	0.93
Bevel gears, collar friction included..............	0.85
Friction between worm and wheel....................	0.09
Friction at worm thrust collars....................	0.12
Friction at screw threads	0.15
Friction at screw collars	0.15

Live Loads

The live load for the highway bridges is specified as a uniform load of 100 pounds per square foot on the roadway and sidewalks, to be taken without impact, or a 20-ton auto truck with 30 per cent added for impact, to be taken with no uniform load on the roadway. Electric trolley car loading is specified as 50-ton cars with the percentage added for impact governed by the formula $15{,}000 \div (30{,}000 + L^2)$. Cooper's E.60 engine loading is specified for railroad bridges with the percentage added for impact governed by the A.R.E.A. formula $30{,}000 \div (30{,}000 + L^2)$. The various combinations of co-existing loads are treated in substantial agreement with standard specifications.

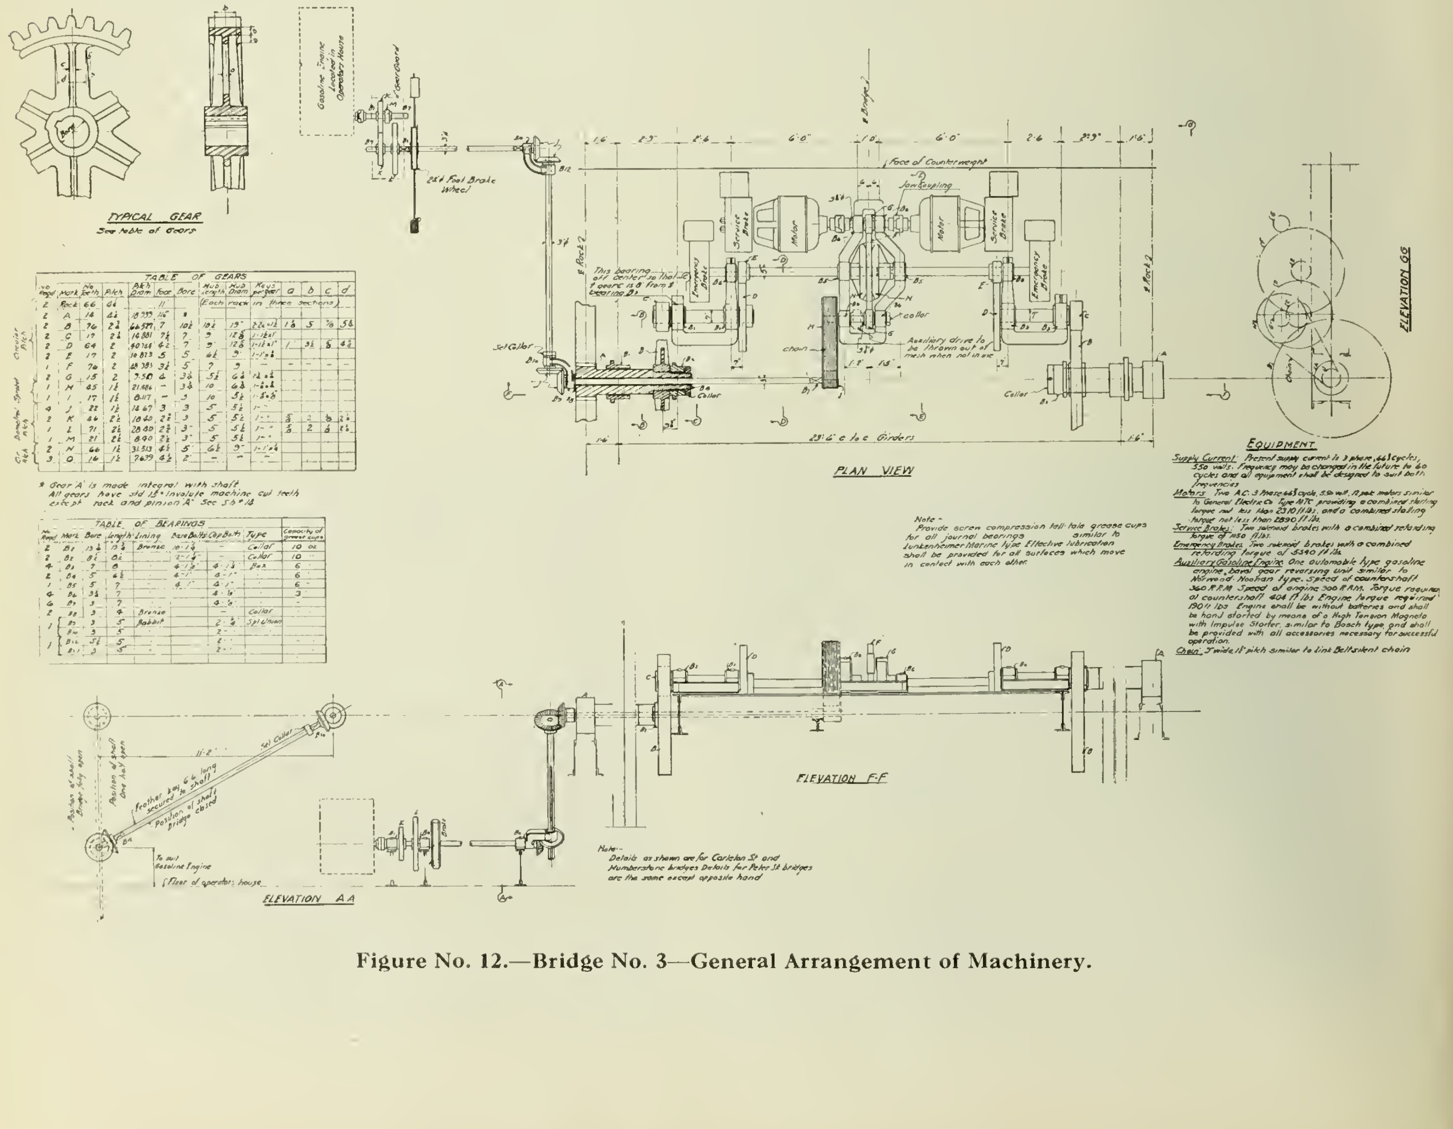

Figure No. 12.—Bridge No. 3—General Arrangement of Machinery.

Combination of Stresses for Bascule Bridges

Case 1. Dead load only, bridge in any position.
Case 2. Dead load only, bridge closed.
Case 3. Wind load only, bridge in any position. The wind being taken at 30 pounds per square foot on the vertical projection of all exposed surfaces of the entire structure, the wind acting in any horizontal direction and at any period during the operation of the bridge.
Case 4. Live load only, bridge closed.

The following combinations are to govern:—

Case 3. Plus 25 per cent for impact, together with increments for reversal, including all effects of stresses from the machinery.
Case 1. With case 3, (structure in any position, but not moving).
Case 2. With case 4, including all increments for impact and reversal due to live load, together with other co-existing loads and forces.

Combination of Stresses for Vertical Lift Bridges

Case 1. Dead load only, span in any position.
Case 2. Wind load only, span in any position. Wind load shall be taken at 30 pounds per square foot on the vertical projections of all exposed surfaces of the entire structure, acting in any horizontal direction and at any period during the operation of the bridge.
Case 3. Live load only, bridge closed.

The following combinations are to govern:—

Case 1. Plus 25 per cent for impact, together with any stresses from the machinery.
Case 1. With case 2, (span in any position but not moving).
Case 1. Bridge closed with case 3, including all increments for impact and reversal due to live load, together with all other co-existing loads and forces.

Bridge Torque Curves

The theoretical power requirements to be used in plotting the bridge torque curves have been taken as sufficient

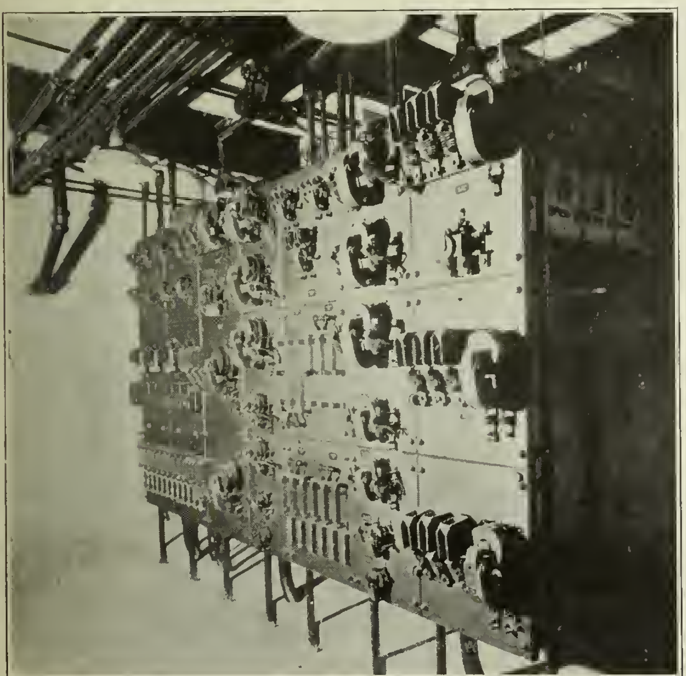

Figure No. 13.—Bridge No. 3—View Inside Lower Storey of Operator's House.

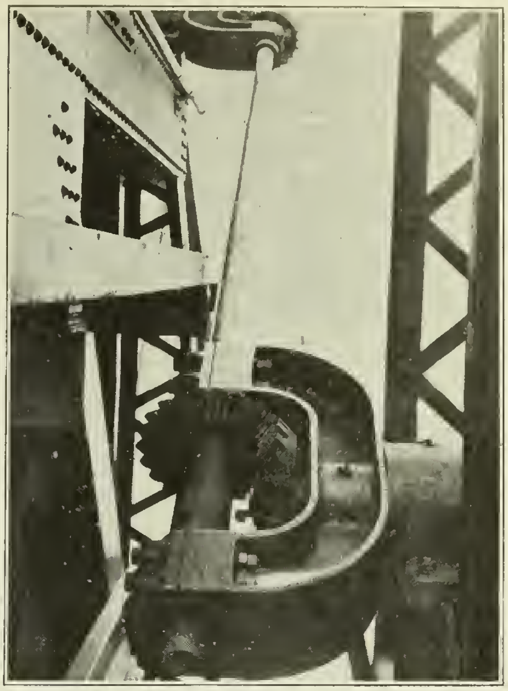

Figure No. 14.—Bridge No. 3—View of Auxiliary Shaft and Yokes.

to move the bridge under the following conditions:—

Case (*a*) In the normal time for opening against frictional resistance, inertia and a wind load of $2\frac{1}{2}$ pounds per square foot on the floor plane area and acting normally to the floor.
Case (*b*) In twice the normal time for opening against the frictional resistance and inertia, together with, in the case of a bascule bridge, a wind load of 10 pounds per square foot on any vertical projection, together with an ice load of $2\frac{1}{2}$ pounds per square foot of floor plane area, and, in the case of a vertical lift span, together with a load of $7\frac{1}{2}$ pounds per square foot of floor plane area.

The prime movers furnished must be capable of delivering the bridge torque curves torques plus 25 per cent, and are to be so governed that they cannot deliver more than the bridge torque curves torques plus 37.5 per cent.

The service brake sets or the emergency brake sets are each to be capable, when aided by 50 per cent of the moving friction and losses in machinery efficiency, of exerting a force on the structure which will overcome the maximum external loads, previously specified, together with the force required to accelerate the span in the normal time for opening. The brakes are to be tested to insure that their coefficient of friction is neither too high nor too low.

The unit stresses given for machinery are used for loads resulting from the bridge torque curves loads. The machinery is also designed to take a load fifty per cent greater at unit stresses twenty-five per cent higher, on the assumption that this results from the maximum torques that the prime movers can possibly deliver to the machinery. The machinery is also designed for the effect of the simultaneous action of the service and emergency brakes helped by one hundred per cent of the moving friction and loss in efficiency with the span travelling at full normal speed, at unit stresses fifty per cent higher than those used for the bridge torque curves loads.

Award of Work

Orders-in-council were passed awarding the work for the preparation and supply of design plans, detail design plans, calculations and data, together with assistance in the supervision of the fabrication and erection of the bridges in accordance with the department's 1925 specifications, as follows:—

October 8th, 1924, to Harrington, Howard and Ash, for four through girder rolling lift bridges,—bridges Nos. 1, 3, 7 and 19 respectively over locks Nos. 1, 2, 7 and 8, and here it should be noted that bridges 3, 7 and 19 are practically duplicates of each other.

April 18th, 1925, to the Scherzer Rolling Lift Bridge Company, for a double leaf deck-truss rolling lift bridge,—bridge No. 4, Queenston road.

September 7th, 1925, to Harrington, Howard and Ash, for two through girder rolling lift bridges,—bridges Nos. 6 and 9, being respectively over locks No. 4 and the guard gate above lock No. 7.

September 7th, 1925, to Harrington, Howard and Ash, for twelve vertical lift bridges,—bridges Nos. 2, 5, 10, 11, 12, 13, 14, 16, 17, 18, 20 and 21.

The bridges included in the foregoing orders-in-council, together with bridges Nos. 8 and 15, which had previously been built, cover all the bridges for the Welland ship canal. The designing firms were furnished by the Welland ship canal office with plans, specifications and data sheets giving all information necessary for the preparation of designs. Below is given a table of bridges showing certain pertinent information for each bridge.

The designing firms prepare for each design, detail design plans, including electrical wiring diagrams, stress sheets, calculation sheets and estimates of quantities and costs. These drawings, calculations, etc., are checked by the canal staff. The tracings when finally completed are signed as approved by Mr. Grant and Colonel Dubuc, after which prints are sent out with tender forms and special specifications to prospective bidders.

Status of the Work

The status of the work on October 31st, 1927, was as follows:—

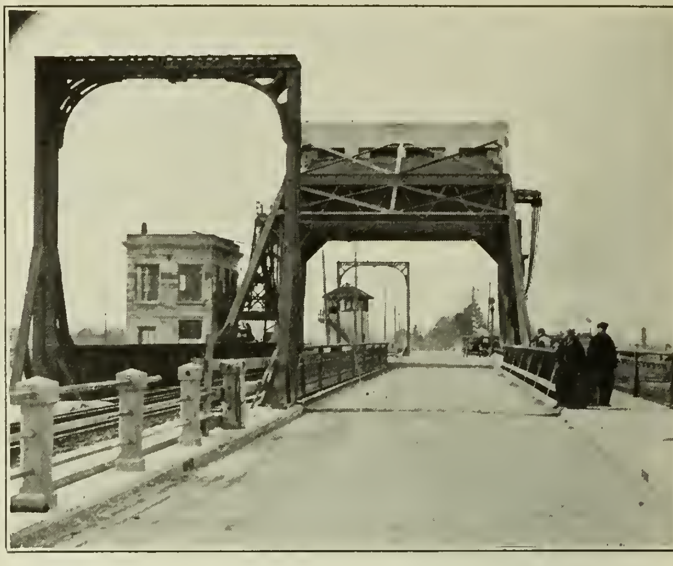

Figure No. 16.—Bridge No. 1—Front View Bridge Closed.

Bridges Nos. 1, 3, 7 and 19 were awarded to the Hamilton Bridge Works on May 18th, 1925,—bridge No. 3 has been operated and the erection of the other three bridges was nearly complete, except for the installation of the electrical equipment.

Bridge No. 17 was awarded to the Canadian Bridge Company on August 25th, 1926, and went into commission on May 23rd, 1927.

Bridge No. 4 was awarded to the Hamilton Bridge Works on December 31st, 1926, and fabrication was about fifty per cent completed, false work was placed and erection would start in November 1927. It is expected to have this bridge completed next spring.

Bridges Nos. 14 and 16, which are duplicates of one another, were awarded to the Canadian Bridge Company on September 12th, 1927, the shop drawings

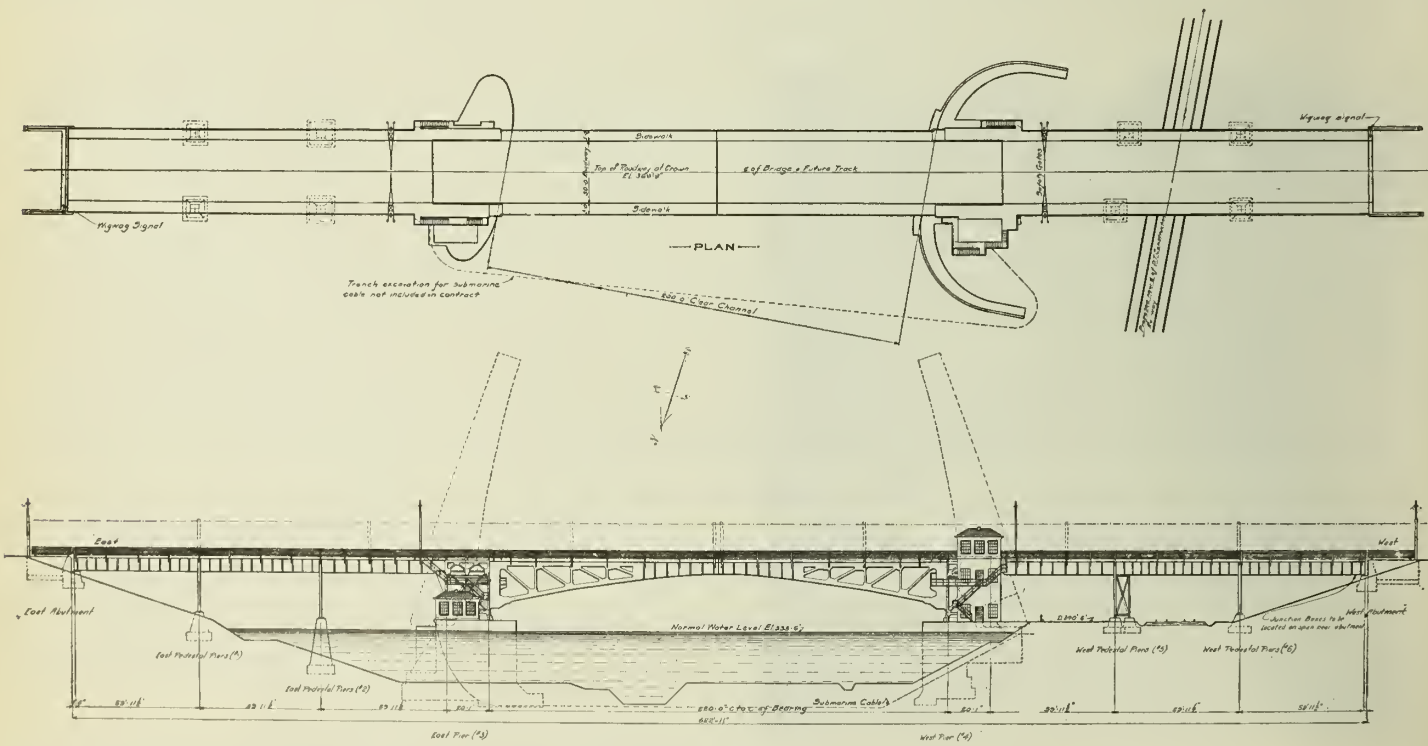

Figure No. 15.—Roller Lift Bridge, Queenston Road—General Plan.

were about ninety per cent approved, fabrication is proceeding and these two bridges will be put into commission about April 15th, 1928.

Bridge No. 20 was awarded to the Hamilton Bridge Works on September 3rd, 1927, but very little progress had been made. The design drawings for bridges Nos. 10 and 21 had been made and were about ready to issue for bids. The design drawings for bridge No. 6 had been made and were being checked in the canal office. The designs for bridges Nos. 5 and 18 were in progress in the office of the designing firm, and that for bridge No. 13 had just been started. The designs for bridges Nos. 2, 9, 11 and 12 had yet to be proceeded with.

General Features for Superstructures

The primary power for operating the bridges will be by means of electric motors of the slip ring induction type; two motors capable together of fulfilling the maximum requirements are provided for each moving leaf or span.

The electric power supply available on the transmission line up and down the canal is three-phase, 22,000-volt at 66 2/3 cycles, which may in the future be changed to 60 cycles. All electrical equipment is designed to work satisfactorily at both frequencies. At the canal locks and at locations suitable to the bridge grouping there will be substations transforming the 22,000-volt current to three-phase, 550-volt current for the electric motors and brakes. At the canal locks, current will also be transformed at the substations to single-phase, 220/110-volt current, the former being used for control and the latter for lights. For the long span bridges the 550-volt current delivered to the bridge will be transformed at the bridge to 220/110-volt for use for control and lighting. The whole electrical equipment of a bridge is so interlocked that it will operate in a pre-determined order for both opening and closing the bridge, and is fully protected against failure of power, overload, under voltage, phase failure, phase reversal and the failure to function of any part of the equipment.

There are about 5,000 through boat passages per annum on the present canal, and it is reasonable to expect a large increase in the future. It is therefore very necessary to provide for operating the movable bridges under mechanical power in the event of failure of the electrical power supply or equipment. This is accomplished by means of an automobile type of gasoline engine which is installed for each movable span or leaf. The use of hand power for auxiliary operation was considered out of the question and is not provided. The times of opening for case (*a*) under electric and gasoline power are respectively one minute and three minutes for the bridges over the locks and 1½ minutes and three minutes for bridges over the canal prism; the times of opening for case (*b*) under electric power is two minutes for bridges over the locks and three minutes for bridges over the prism. The time of opening for case (*b*) under gasoline power will be determined by the torque of the engine and change gear speed.

Racks and gears are of cast steel and pinions of forged steel. All teeth are cut and preferably of the 15-degree involute type. Shafts larger than six-inch diameter have to be forged; below that diameter they may be hot rolled. In order to obtain strength with reasonable size, in some cases, pinions are forged as an integral part of the shaft. In general, the machinery is segregated so that it would be mounted on self-contained cast steel frames to facilitate erection and maintenance of accurate shaft alignment between bearings.

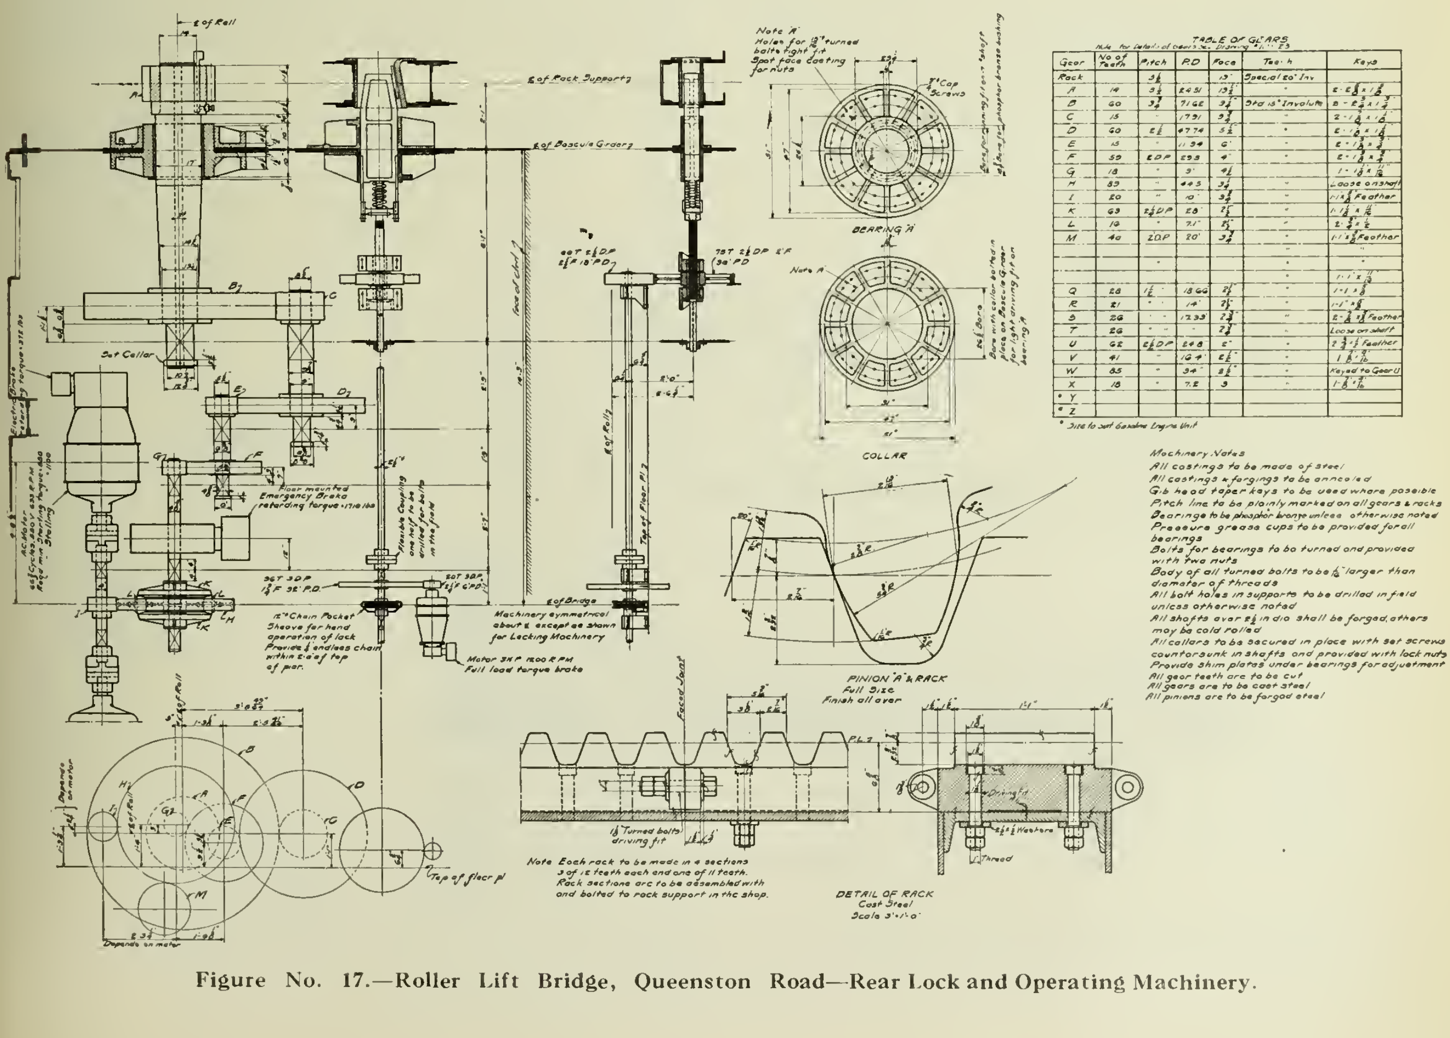

Figure No. 17.—Roller Lift Bridge, Queenston Road—Rear Lock and Operating Machinery.

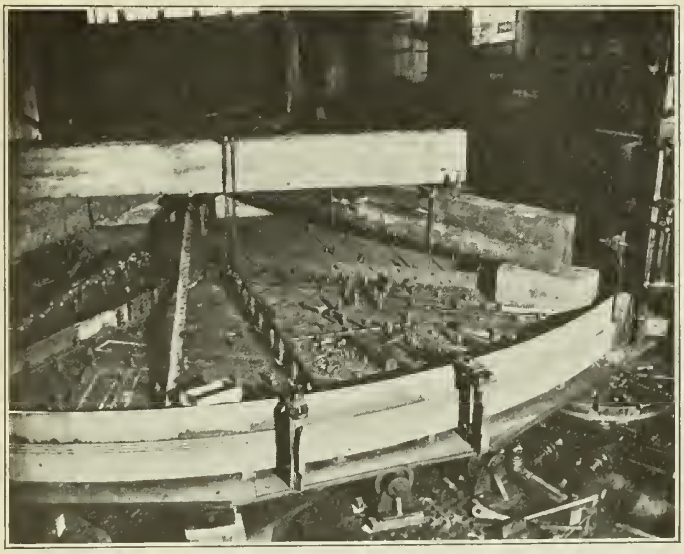

Figure No. 18.—Bridge No. 4—Finishing Segmental Girder.

Lubrication on some of the bridges is performed by the use of screw compression grease cups, but on the remainder of the bridges the Alemite method of lubrication will be used. To secure better maintenance and to reduce noise and vibration to a minimum, the machinery units were shop assembled and put in dynamic balance.

Traffic is warned by sirens. Signal gates and wigwags are provided to warn highway bridge traffic, and railway traffic is warned by the customary railway signals. The gates and signals are interlocked with the bridge locks, the latter being interlocked in turn with the control of the electric motors and the gasoline engine.

Rolling Lift Bridges

The through rolling lift spans over the canal locks have embedded in the concrete substructure two horizontal track girders on which roll two segmental girders forming part of the moving leaf. The forward arm of the leaf consists of a through plate girder span, connected at the heel end to the segmental girders and supported at points towards the centre of the girders by ties sloping back to the top of the trussing built on the segmental girders. The trussing supports an overhead concrete counterweight by means of structural steel framing embedded in the concrete and spanning between the segmental girder trussing. Immediately in front of the counterweight, and above the roadway clearance, there is a machinery house which contains the operating machinery and electric motors. Outside each truss there is a horizontal rack supported by steel framing connected at the bottom to the track girder; these racks are engaged by projecting pinions situated at the centre of roll. The moving leaf must be so balanced that its centre of gravity is on the line passing through the centres of the two pinions; as these pinions are revolved by the operating machinery, they travel horizontally along the racks, causing the leaf to roll back on the track girders. The alignment of the rolling span is maintained by staggered outside slots in the heavy tread plates on the segmental girders, engaging the staggered teeth of the track castings on the track girders.

The two-storey concrete house for the operator is situated outside the track girder towards shipping approaching the canal lock; the operator is placed in the upper storey with the gasoline engine and electrical control; the lower storey is occupied by the electric switch boards. The electric power is delivered to the moving span by means of flexible cables. The power from the gasoline engine is delivered through a gear train to an articulating shaft, hung by a yoke from the near rack pinion shaft through which another

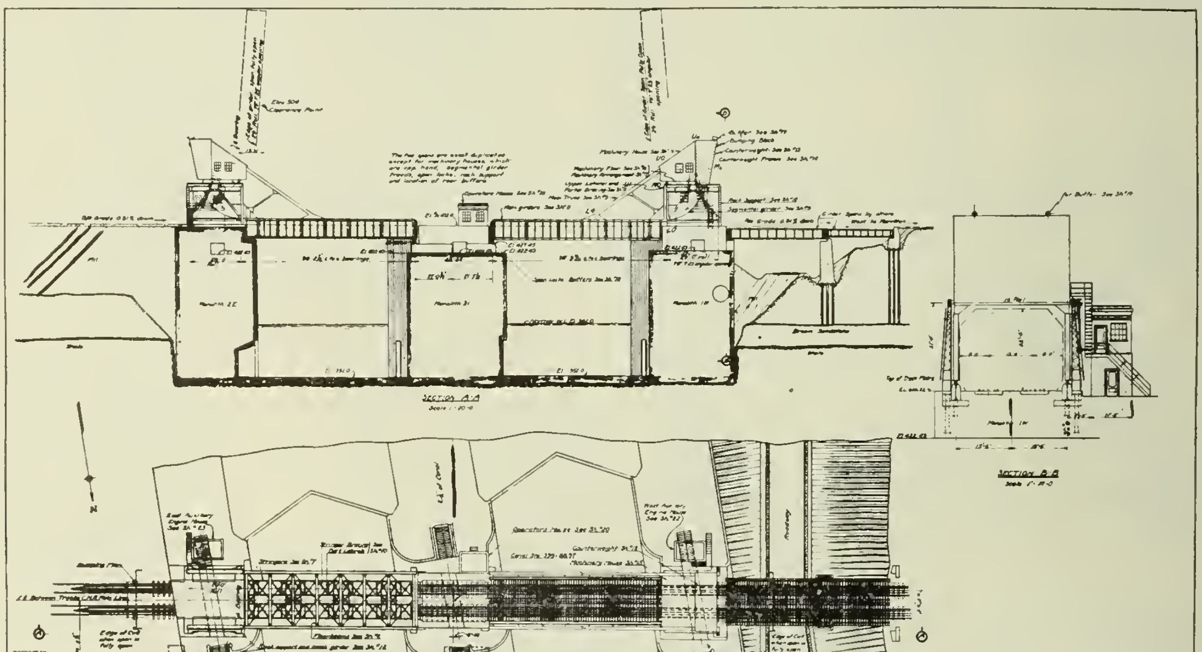

Figure No. 19.—Bridge No. 6—General Plan and Elevation.

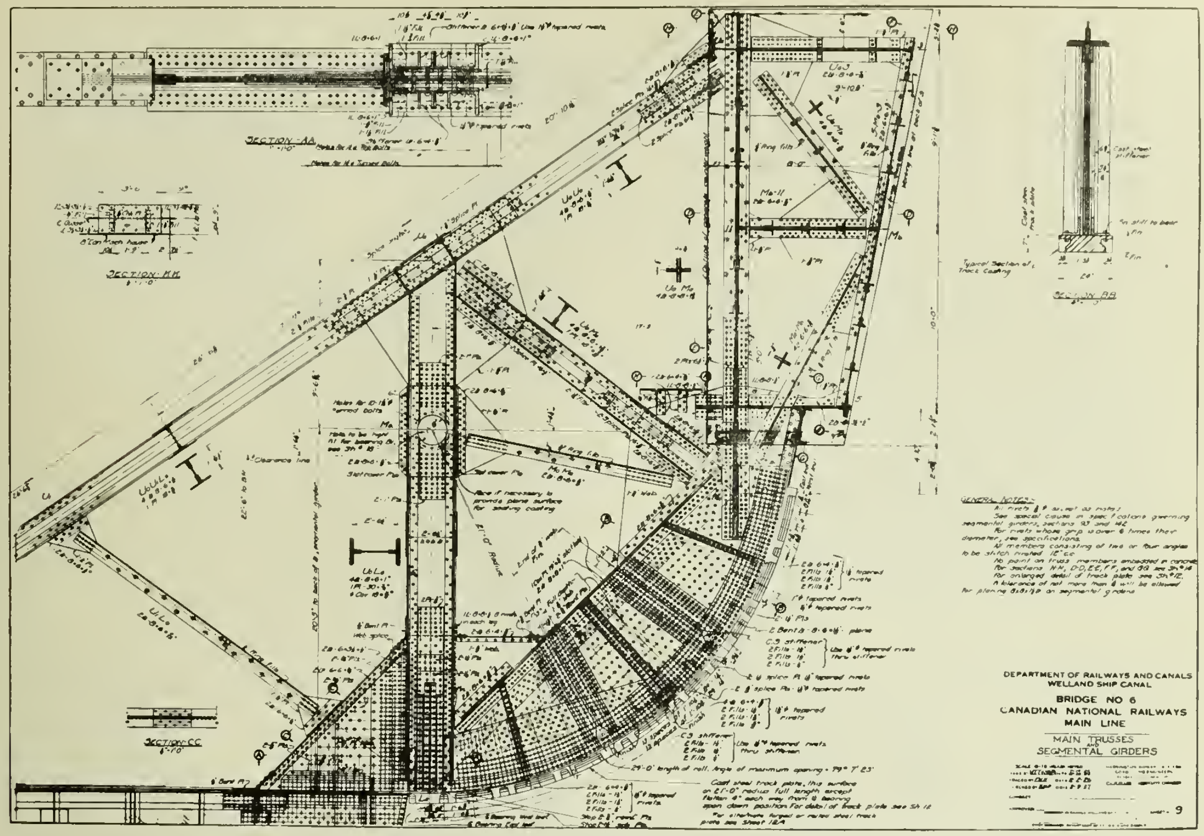

Figure No. 20.—Bridge No. 6—Main Trusses and Segmental Girders.

shaft passes transmitting the auxiliary power to the main machinery by chain drive to a pinion which can be put in or out of mesh. The articulating shaft is carried at each end by yoke castings containing mitre gearing, the shaft sliding on a feather through its lower mitre gear. The lower yoke is so located that the articulating shaft is in a vertical position when the moving leaf is open half way.

The bridges are locked by plunger locks at the toe end, connection being made at the heel end between the mechanism on the span and that on the lock wall by means of a double knuckle bell crank joint which disengages as the span is opened. The bridge is so interlocked electrically with the canal lock gates that the bridge cannot be opened until the lock gates are open, and vice versa. Air buffers are provided under the toe end of the leaf and on top of the counterweight to cushion the moving span when seating or fully opening. The structural steel frames for the concrete counterweight have a sufficient number of angle lugs in two directions to support the counterweight in bearing without depending on any bond between structural members and concrete; reinforcing rods are provided wherever thought advisable. The floor decks are made of creosoted timber, the highways having four-inch blocks on four-inch planking.

The general features of the structural and machinery work for the bridges follow the general lines of good bridge shop practice. There are, however, some special features dealing with the segmental girders which are out of the ordinary. The various designing firms had proposed segmental girders with the bottom flange angles having polygonal peripheries, with steel castings for tread plates having open joints, as this was the practice obtaining in the United States. The Board of Engineers preferred designing the segmental girders with circular peripheries, using rolled steel slabs or forgings for tread plates, with their ends faced to bear against each other; the tread plates were not considered in the design as part of the flange area, but enough bolts were provided to use them as such. Cast steel stiffeners with heavy outstanding legs are provided on both the segmental girder and track girder at the joints in the tread and track plates to distribute the load over and past the joints. The recommendation of the board was carried out, and, although the bridge company at first had considerable trouble in cold bending the curved flange angles and finishing them without planing off more than one-quarter inch of metal, the difficulties met with have been overcome, and the amount taken off runs between ⅛ and 3/16 inch.

A track girder is planed top and bottom with its web and side plates flush with the back of angles before the track castings and the sole plate are riveted on. The sole plate is planed on the surface which is against the girder flange and its two ends are planed on the bottom side where it rests on the planed grillages which are set to accurate position and elevation in the substructure. The rack frames are connected in the field to the track girders and have anchorages into the concrete to take the uplift received from the action of the rack pinion when the combined brakes are applied. There is no bracing between the two track girders, as they are well concreted in place in the slots left for them in the substructure.

The curved flange angles for the segmental girders are bent cold in a bending machine, and, after being carefully checked over to see that they have no warped surfaces and are to proper curvature, are assembled on the girder and rivetted up with the web and side plates projecting. The girder is then set with its side truly horizontal on a carriage which allows it to be rotated horizontally about the centre of roll before a slotting machine, which finishes the outstanding legs of the flange angles with the edges of the side plates and web to accurate radius. The girder is rotated after each cut automatically, and the vertical cutting tool is adjusted by hand.

The rolled slabs used for the tread plates were received bent to approximate radius from the Canadian Steel Foundries and Forgings Company, Limited, set up on an espe-

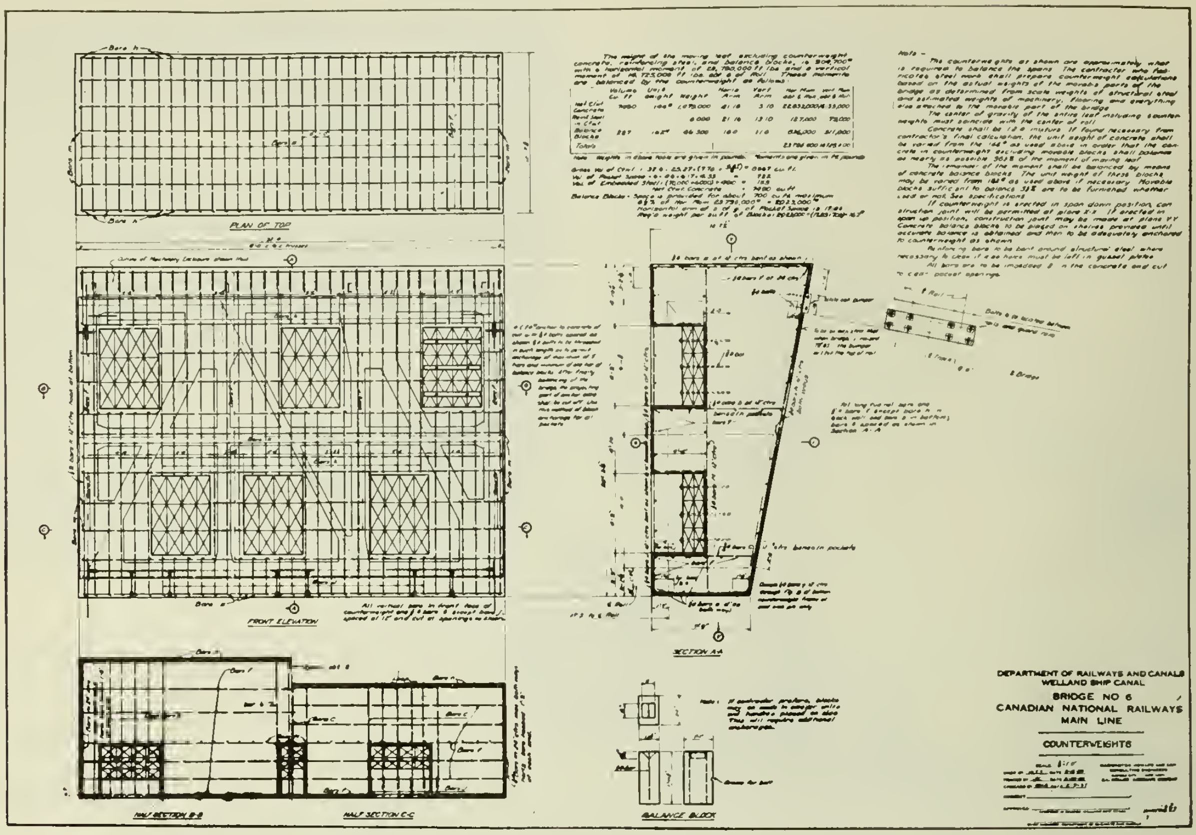

Figure No. 21.—Bridge No. 6—Counterweights.

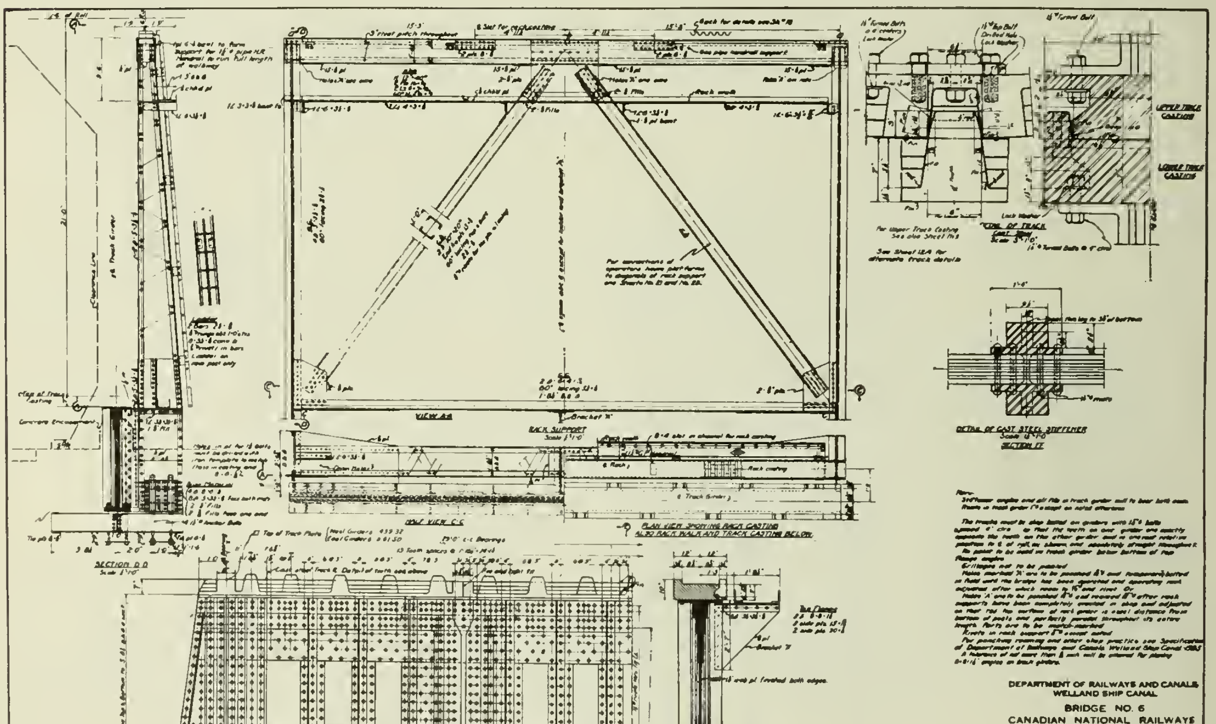

Figure No. 22.—Bridge No. 6—Track Girders, Rack Supports, and Tracks.

cially prepared jig and finished to accurate radius, inside and out, in a manner similar to that used for the segmental girders. A special machine was improvised to cut the slots in the tread plates to fit the teeth of the track castings. They were then accurately mounted on the girder and the holes for the $1\frac{1}{8}$-inch bolts, attaching them to the girder, were drilled from the solid for a driving fit and the plates bolted on.

The track and rack castings had their bottom surfaces planed, after which they were assembled in groups on the bed of the planer, so that their top surfaces and the surfaces of the teeth would be all finished true to shape and plane. The track castings were accurately assembled on the track girder, the holes of the $1\frac{1}{8}$-inch diameter rivets drilled from the solid and the castings riveted on.

Bridge No. 3

Bridge No. 3, which is similar to bridges Nos. 7 and 19, carries the traffic of Carleton street over lock No. 2 on a 20-foot roadway and one 5-foot sidewalk, the eccentric effect of the sidewalk being balanced by cast iron counterweights bolted to the girder on the side away from the sidewalk. The general outline of the structure is shown in the cuts exhibited. It should be noted, however, that the one-storey stucco house on a steel frame has been changed to a two-storey concrete house. The radius of roll is 15 feet 6 inches, and the thickness of the rolled steel tread plates and the cast steel track plates is 6 inches for each and the length of line bearing 11 inches. The bearing thickness of the segmental girder and track girder is $4\frac{3}{8}$ inches, the flange angles for the former are 8 by 8 by $1\frac{1}{8}$ inch and for the latter 8 by 8 by $\frac{7}{8}$ inch. There are two electric motors having a common pinion engaging an equalizing gear which gives flexibility to the gear trains running to each rack. The two electric motors are so controlled as to give combined torques in pounds-feet as follows:—starting, 2,300; running, for case (*a*) at 627 r.p.m., 753; running for case (*b*) at 244 r.p.m., 2,290; the two running torques respectively represent a theoretical output of 90 and 106 horse power, but the Canadian Westinghouse Company rated the two motors provided at 70 horse power each. The gasoline engine is a four-cylinder Sterling engine model FC4; cylinder bore $5\frac{1}{2}$ inches, stroke $6\frac{3}{4}$ inches, governor speed 900 r.p.m. with electric starter, charger and Sterling multiple disc clutch; the maximum torque required of the engine at 900 r.p.m. is 237 pounds-feet, equivalent to 41 horse power. The electrical brakes are of the Cutler Hammer type, each pair of service brakes and each pair of emergency brakes respectively are to furnish combined torques of 1,050 and 5,540 pounds-feet. A hand brake is provided for operation with the gasoline engine.

The bridge was erected in the closed position and presented no difficult features of erection or balancing, and the operation of the bridge shows it to be functioning properly in every particular; of course, it is yet too early to make a proper power analysis, but the power consumed on the trial runs shows very reasonable results. The electrical equipment was furnished and installed by the Canadian Westinghouse Company.

Bridge No. 1

Bridge No. 1, which carries a roadway 17 feet 5 inches wide and a single track of the Niagara, St. Catharines and Toronto Railway, is wider than No. 3 and is designed to carry, over the track, 55-ton coal hopper cars. The electric motors and gas engine used are the same as those for bridges Nos. 3, 7 and 19, the machinery train being so geared that the bridge would be moved at speeds in accordance with the torques furnished. The tread and track plates are each 6 inches thick with a line bearing of 14 inches, the radius of roll being 20 feet; the bearing thickness and flange angles for both upper and lower girders being respectively $6\frac{1}{4}$ inches and 8 by 8 by $1\frac{1}{8}$ inch.

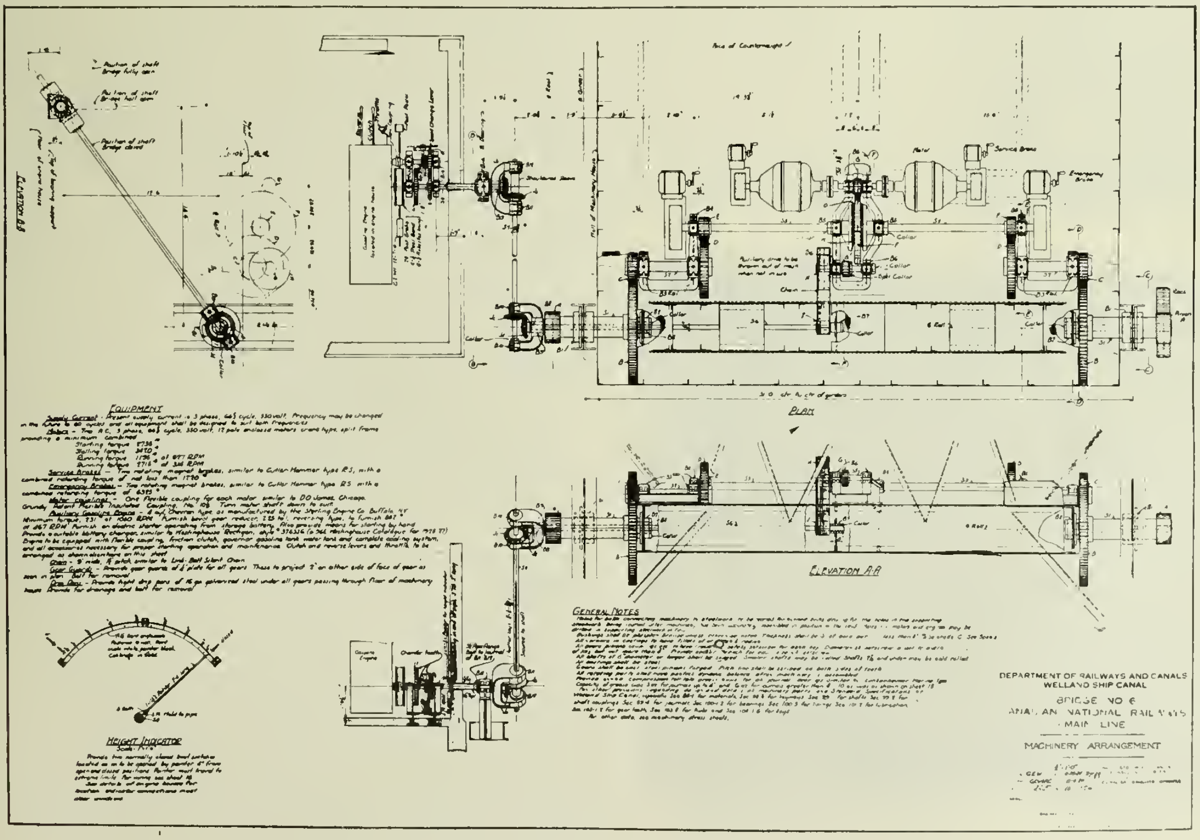

Figure No. 23.—Bridge No. 6—Machinery Arrangement.

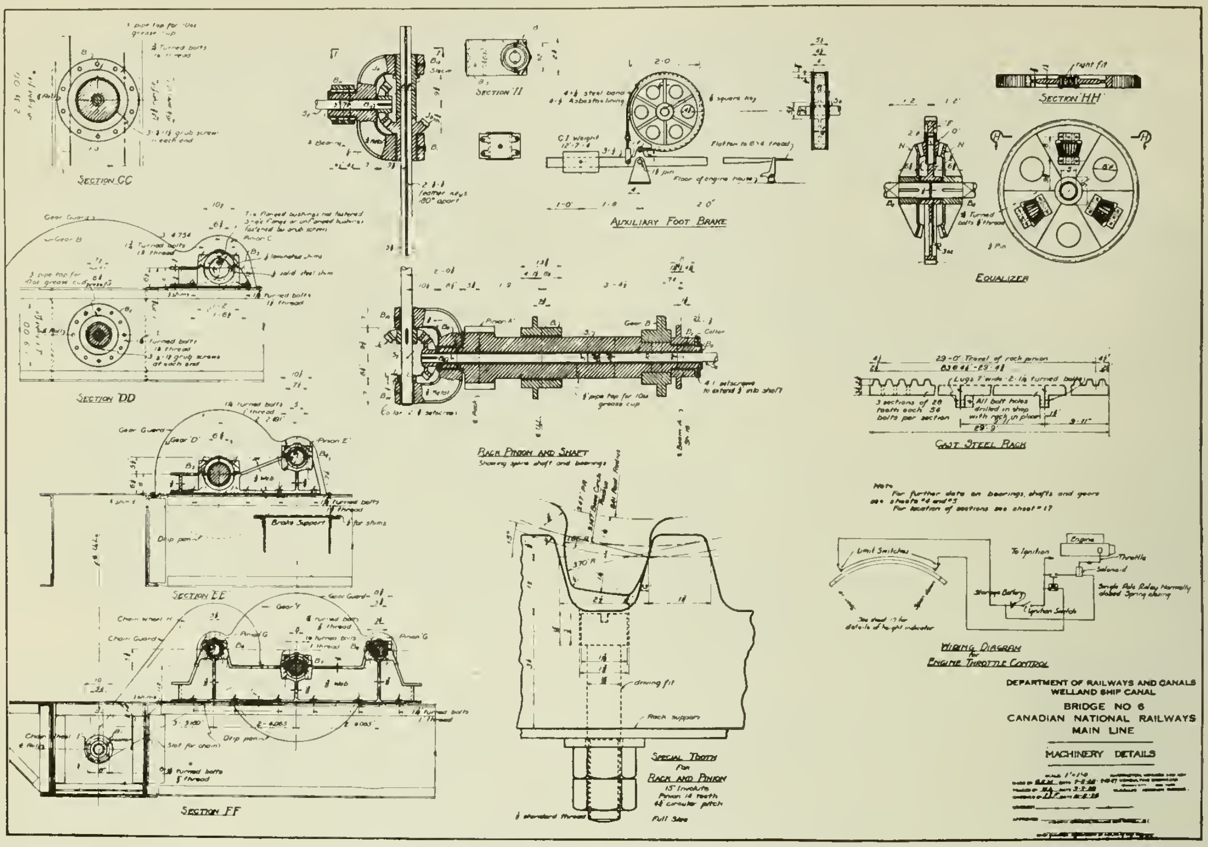

Figure No. 24.—Bridge No. 6—Machinery Details.

Bridge No. 4

Bridge No. 4, which carries the traffic of the Queenston road, is a deck bridge crossing having a 30-foot roadway with a 5-foot sidewalk on each side, and is designed to take a future electric trolley line as well as the regular highway traffic loading. The bridge consists of a 220-foot double leaf rolling lift span with three deck plate girder flanking spans at each end, carried on single bents at the intermediate supports. The bents next to the abutments have pin bearings at the bottom to reduce the bending stress from the accumulated expansion and contraction of the spans, the sliding ends being at the abutments.

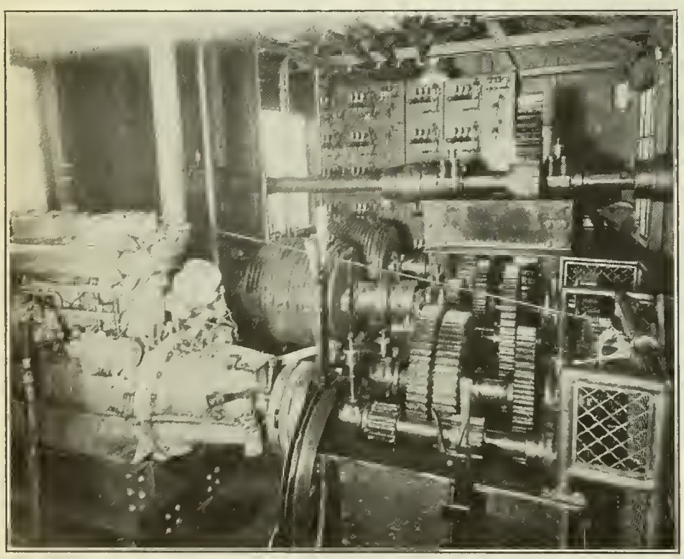

Figure No. 25.—Bridge No. 17—View Inside of Machinery House.

In order to secure direct distribution of load from the counterweight to the trusses and for purposes of maintenance, the trusses of the moving leaves were made single webbed instead of double webbed, that is, they have single gussets at the joints, thus making it necessary for practically all the members to be butt spliced. Out towards the toe ends of the leaves where they become shallow, plate girder construction takes the place of the trussing. The segmental girders are made of solid plate and angle construction from the top chord to the treads, the girder construction being carried out to the rear for the support of the counterweight and its framework. The counterweight is restricted in size in order to keep it out of the water when the bridge is fully open, and this necessitates using a large quantity of punchings to increase the unit weight of concrete in order to balance the forward arm.

The live load on a forward leaf is carried by cantilever action to the front bearing on the track girder, and the moment so generated is resisted by an anchorage girder which projects out laterally from the rear end of the counterweight, bearing against the main girder bottom flanges of the adjacent flanking spans. The girders of the adjacent flanking span connect to columns which extend, for anchorage purposes, deep down into the substructure concrete. Recesses are left in the masonry for the introduction of all substructure metal work belonging to the superstructure, and the metal work will be accurately adjusted in proper position and then concreted in place by the bridge company.

As traffic is carried on the leaf arm back of the centre of roll, it is necessary to provide motor driven tail locks for stability under traffic. The shear lock at the toe ends of the leaves consists of a jaw on one end and a tongue on the other, engaging at the nearly closed position and meshing as the completion of roll moves the two leaves towards each other; this shear lock requires no mechanism, the main

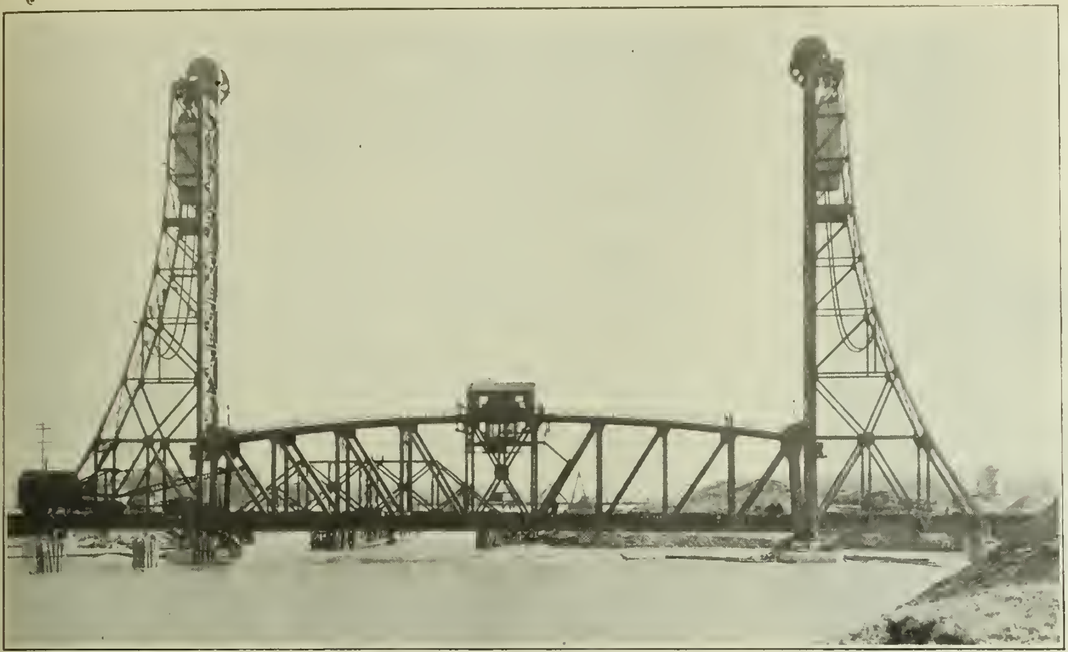

Figure No. 26.—(above) Bridge No. 17—Side View of Bridge Closed.

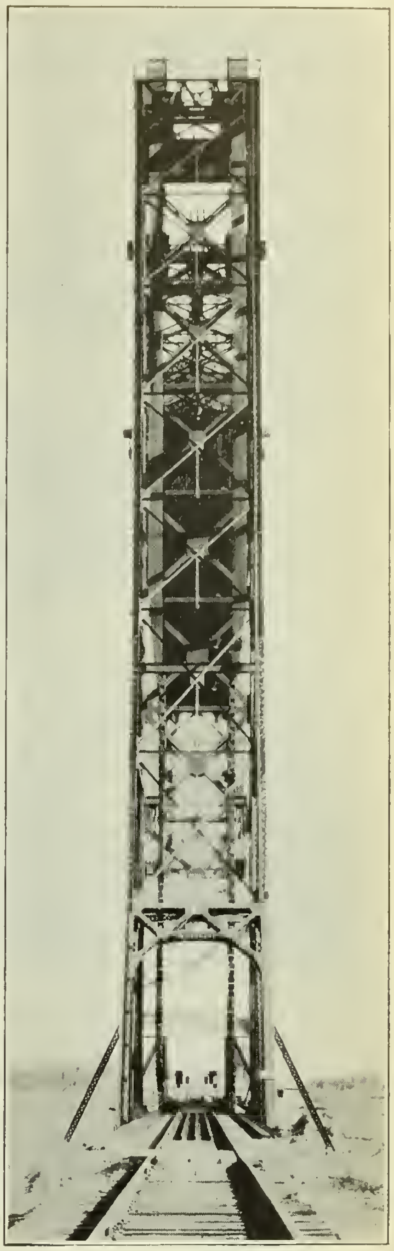

Figure No. 27.—(Right) Bridge No. 17—End View of Bridge Open.

motors being automatically controlled to stop the leaves in the proper position for engaging.

A three-storey reinforced concrete house, on the west channel pier, houses in the top storey the bridge operator and the electrical control for the two leaves, the switchboards in the second storey and the gasoline engine and hand brake for the west leaf and the submarine cable switches in the bottom storey. There is a one-storey concrete house on the east channel pier which houses the gasoline engine and hand brake for the east leaf and the switches for the submarine cable. The general layout of the operating machinery on each leaf is similar to that previously described, and it is housed in an enclosure immediately in front of the counterweight and below the roadway deck. Stairways and platforms are provided for ready access to the houses, machinery and racks, etc. The racks are below the deck and their frames also support the bridge sidewalks from the point where they stop on the moving leaves, at a point about 7 feet in front of the centre of roll in the closed position. The tail end of each leaf, from the point where the sidewalks stop to the rear end, has a width of about 31 feet, and, as the leaf rolls back, the tail moves downward, thus providing a gap in the fixed part of the structure into which the moving leaf can roll.

The tread plates for this bridge are made of forged steel and the methods used for fabricating the various parts of the structure are similar to those used for the other rolling lifts. The radius of roll is 16 feet 4 inches and the thickness of the tread and track plates is 13 inches for each and the length of line bearing 21 inches. The bearing thickness of the segmental girder and track girder is 4¼ inches and flange angles for the segmental girder and track girder are respectively 8 by 8 by 1 inch and 8 by 8 by ⅞ inch. The two electric motors for a leaf will be so controlled as to give combined torques in pounds-feet as follows:—starting, 1,760; running, for case (*a*) at 633 r.p.m., 592; running, for case (*b*) at 274 r.p.m., 1,730; the two running torques respectively represent a theoretical output of 72 and 90 horse power. The gasoline engine for each leaf is the same as provided for bridges Nos. 1, 3, 7 and 19; and the maximum torque required of the engine at 900 r.p.m. is 275 pounds-feet, equivalent to 48 horse power. Electric brakes are of the Cutler Hammer type, each pair of service brakes and each pair of emergency brakes are respectively to fur-

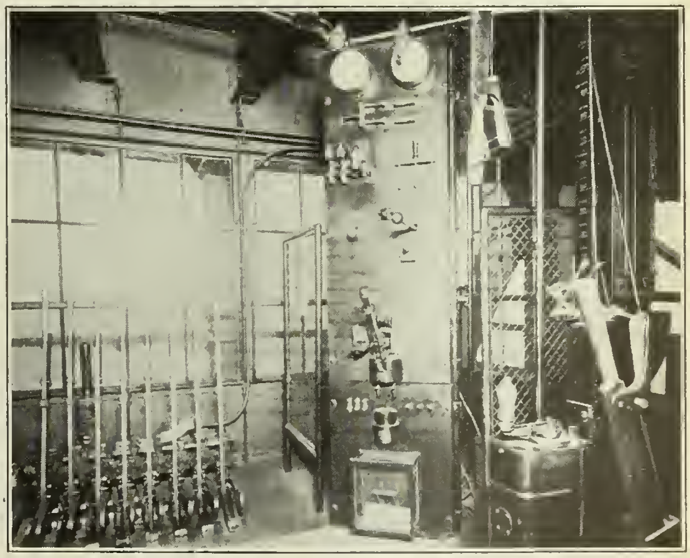

Figure No. 28.—Bridge No. 17—View Inside of Operator's House.

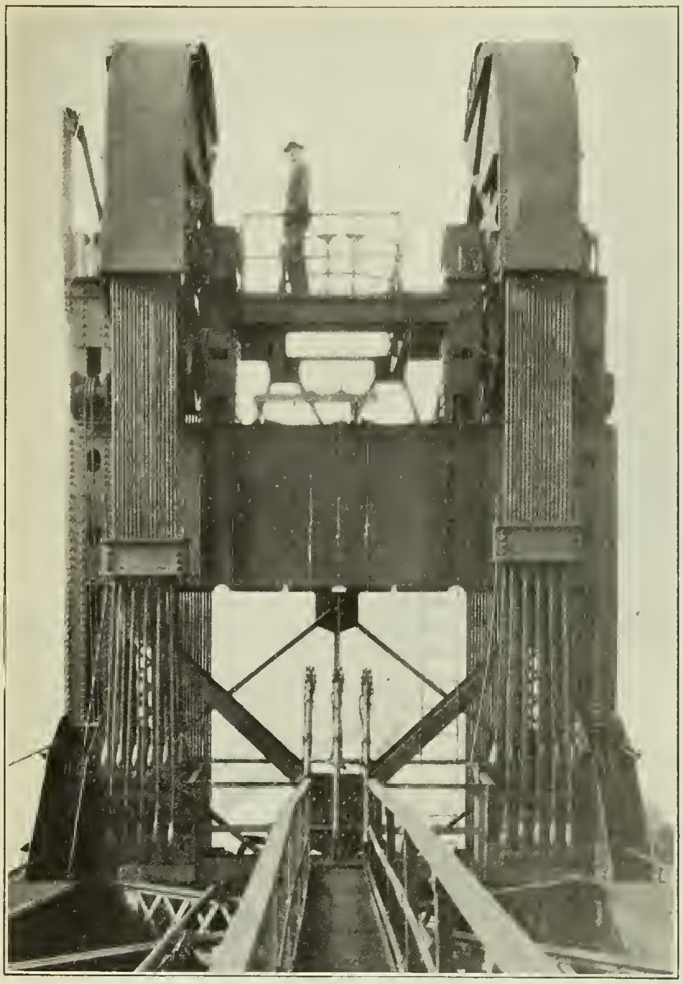

Figure No. 29.—Bridge No. 17—View from Top of Lift Span showing Trolleys, Sheaves, Ropes, etc.

nish combined torques of 744 and 3,430 pounds-feet. A hand brake and mechanical indicator to show the position of the leaf is provided for operation under gasoline power, in which case a bridge operator will be needed for each leaf. Only one operator is needed for electrical operation and the whole equipment for both sides is properly interlocked, with the proper sequence of operation functioning indicated by prismatic bench lights.

Bridge No. 6

Bridge No. 6 consists of two single leaf double track rolling lift through plate-girder spans placed over the entrances to the chambers of lock No. 4. The spans are made duplicates of each other in detail, but the bridge is on a grade of 0.97 per cent, and the track girders will be set horizontal, so that the two spans will differ slightly in the distance centre to centre of end bearings. It is designed to carry Cooper's E 60 loading. The two leaves will be operated electrically by an operator situated in a house on the centre wall, but for operation under auxiliary gasoline power two other operators will be needed, one on each side wall, in the houses containing the gasoline engines. The central operator handles, both under electrical operation and gasoline operation, the mechanical bridge locks and the railroad signals, which will be fed from a storage battery and controlled by an interlocking machine. The electric power used for operating the bridge will be a.c. current, as for the other bridges. The two electric motors for each leaf will be so controlled as to give combined torques in pounds-feet, as follows:—starting, 2,735; running, for case (a) at 627 r.p.m., 1,195; running, for case (b) at 314 r.p.m., 2,715; the two running torques respectively represent a theoretical output of 143 and 162 horse power. The gasoline engine for each leaf will be a four-cylinder Sterling engine type Chevron cylinder bore $5\frac{1}{2}$ inches, stroke $6\frac{3}{4}$ inches, governor speed 1,050 r.p.m. The torque required of the engine is 231 pounds-feet. The combined torques required for the pair of service brakes and for the pair of emergency brakes for each leaf are respectively 1,220 and 6,325 pounds-feet. The

hand brake for auxiliary operation has to deliver a torque of 254 pounds-feet. The radius of roll is 21 feet, the thickness each of tread and track plate 7 inches, length of line bearing 17.5 inches and bearing thickness for the upper and lower girder 7 inches. Mechanically operated rail locks will not be needed, for cast manganese steel rails project out at the toe end of the leaf, and, from the substructure at the heel end, these pieces nest into cast steel chairs on the substructure at the toe end and on the heel end of the span. As the span rolls back the rails are disengaged from their chairs.

Bridge No. 9

Bridge No. 9, which is over the north entrance to the guard gate, will be similar to bridge No. 7, except that its width of roadway will be 24 feet instead of 20 feet.

Vertical Lift Bridges

The vertical lift bridges, which will all be over the canal prism in the reaches, have on each side of the channel a structural steel tower supporting, on a cross girder at the top, the cast steel counterweight sheaves over which pass the special plough steel wire ropes. The ropes are connected

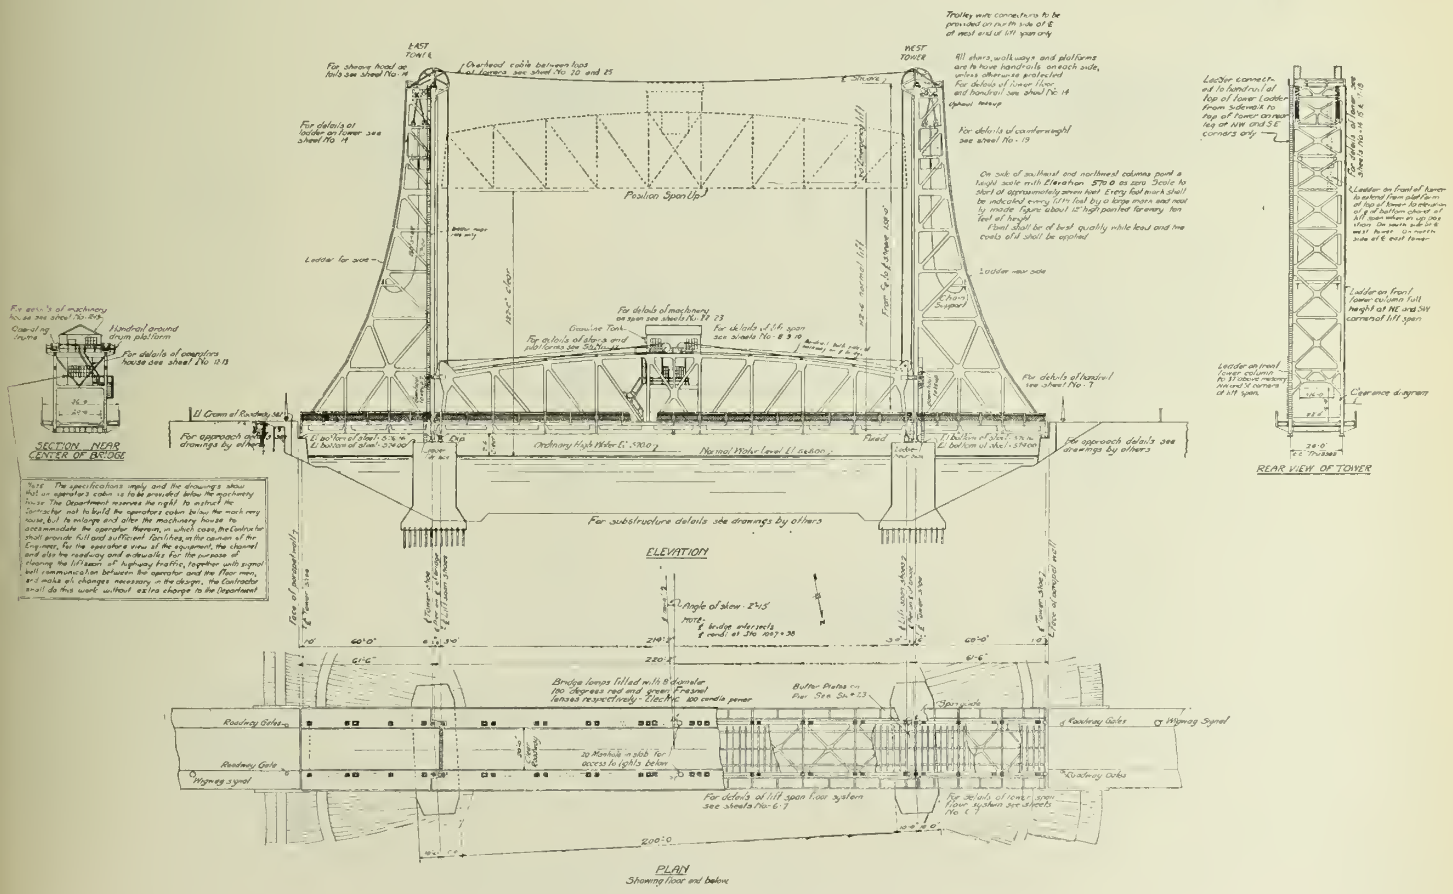

Figure No. 31.—Bridge No. 14—General Plan and Elevation.

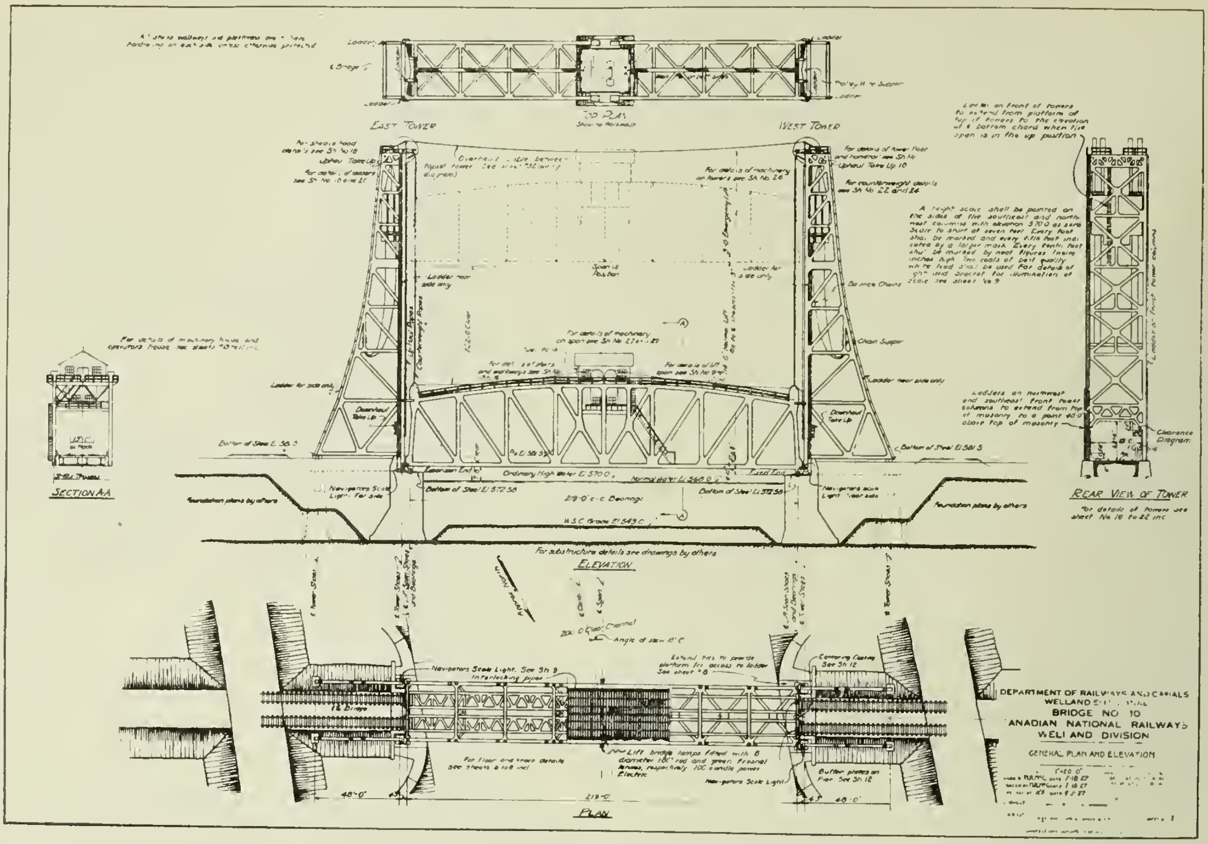

Figure No. 32.—Bridge No. 10—General Plan and Elevation.

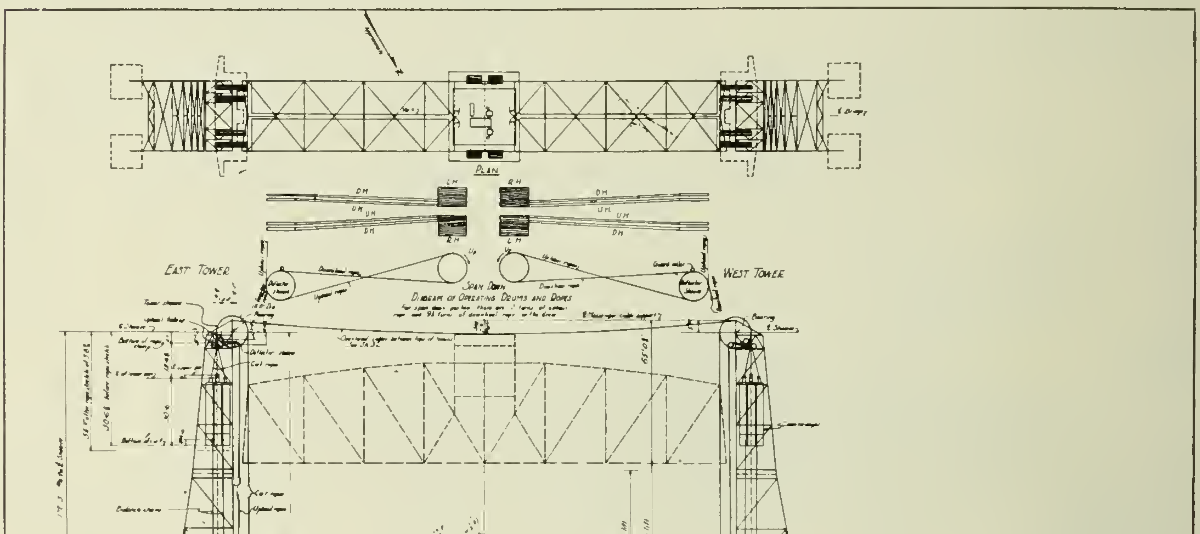

Figure No. 33.—Bridge No. 10—Machinery Layout.

at one end to a cross girder between the two top chord end panel points of a through truss vertical lift span and at the other end to balancing concrete counterweights which move up and down inside the tower. The height of the towers is such as to permit a stretch in the counterweight ropes of 2 per cent of their figured length. The electric motors, main switch boards, gasoline engine and operating machinery are situated in a house on top of and at the centre of the span. The main operating shaft runs across the span near the span centre line. By means of its pinion and an idler pinion, this shaft operates at each end two double threaded grooved drums situated on each top chord, there being four drums in all. Two uphaul and two downhaul operating ropes are fastened to each drum, and, after making a suitable number of turns, lead off one end of the drum, the former off the top and the latter from underneath the drum, from whence they travel along the top chord to two double chord by means of wooden idler rollers mounted in bearings set over the panel joints. After the bridge went into operation it was found that the rollers stuck, wore out rapidly and gave very unsatisfactory service; so they have since been replaced by wooden platforms running along the top chord and composed of longitudinal birch planks fastened to timber cross pieces hook bolted to the chord. Up to date, these platforms have given satisfactory service.

The weight of the lift span is balanced by the counterweights moving vertically inside of the tower in the opposite direction to the movement of the span. In order to provide for balancing the weights of the counterweight ropes, for any position of the span, cast iron counterweight chain loops are attached to the towers and to the bottoms of the concrete counterweights. Vertical guides on the outside and inside of the front tower column retain in proper position respectively the lift span and the counterweights, by en-

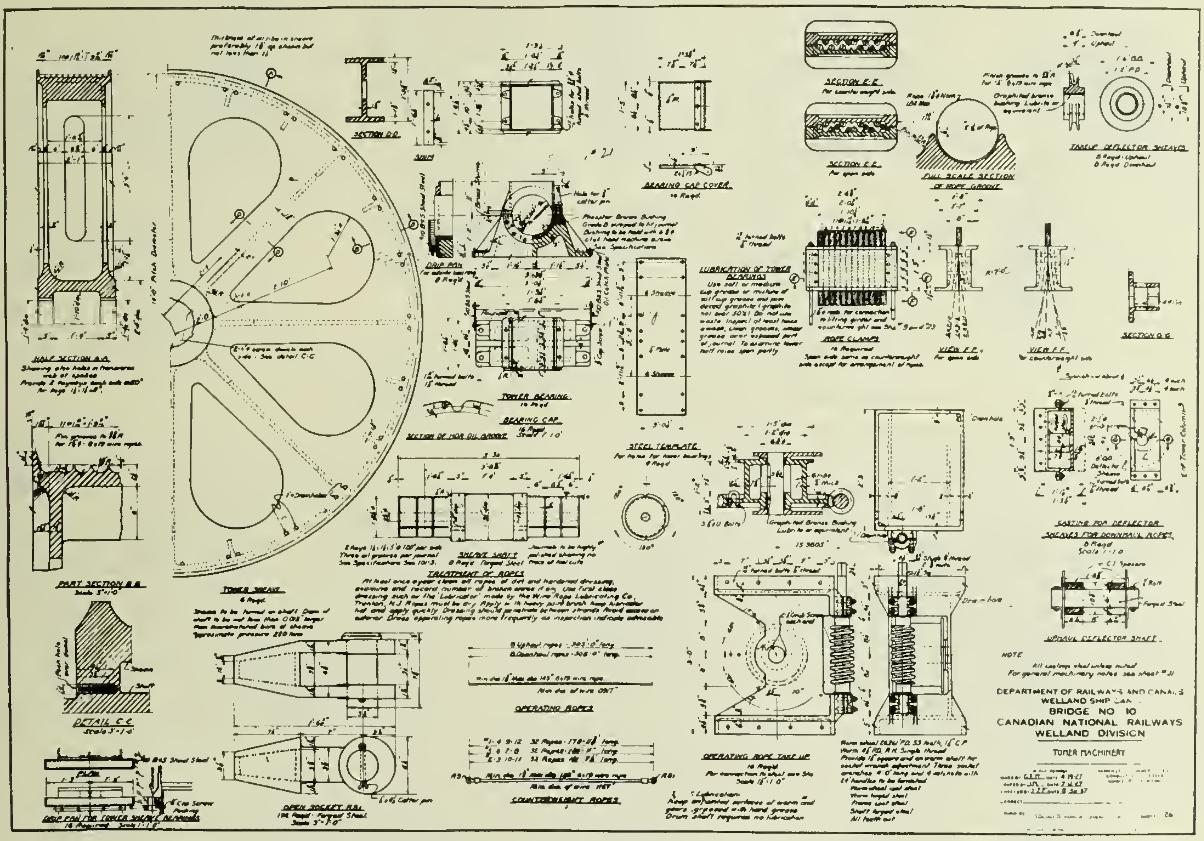

Figure No. 34.—Bridge No. 10—Tower Machinery.

grooved sheaves turning on a common axle mounted between the gusset plates at the end panel top chord joint. The uphaul ropes pass under their sheave and up to the top of the front tower post, while the downhaul ropes pass over their sheave and down to the foot of the tower post. Each rope is fastened to the tower post by means of a take-up arrangement composed of an idler sheave and another sheave geared to a hand operated worm, the rope being fastened to the latter sheave. By means of these take-ups, the ropes can be adjusted to proper tautness. The operation of each pair of drums by the meshing of the main shaft pinion with the one drum gear, and with the idler pinion meshed with the other drum gear, causes all the uphaul ropes to wind on, and all the downhaul ropes to wind off, or vice versa, according to the direction of rotation of the drive shaft, thus raising or lowering the balanced span. The design drawings for bridge No. 17, which is now built, called for the operating ropes to be supported on the top gaging suitable guide castings on the moving parts. The lift span when lifted is held longitudinally at the fixed end only.

The lift span is locked in the down position by plunger locks, at top chord corners of the lift span, engaging with castings on the tower posts. These locks are manually operated through a pipe and bell crank system by the bridge operator, who is situated in a cabin immediately below the machinery house, from where he can operate the bridge under electric or gasoline power. The pier members for the fixed end of the lift span each have a transverse pin, on to which nests the lift span cast steel shoe provided with tapering sides to guide it into its proper longitudinal position as the span is lowered. Pinned to the expansion ends of the lift span trusses are segmental rockers which rest on steel castings and are provided with springs to force the rocker to plumb position when the span is lifted. The span guides on the tower posts taper out laterally towards the bottom while those at the fixed end also taper out longitu-

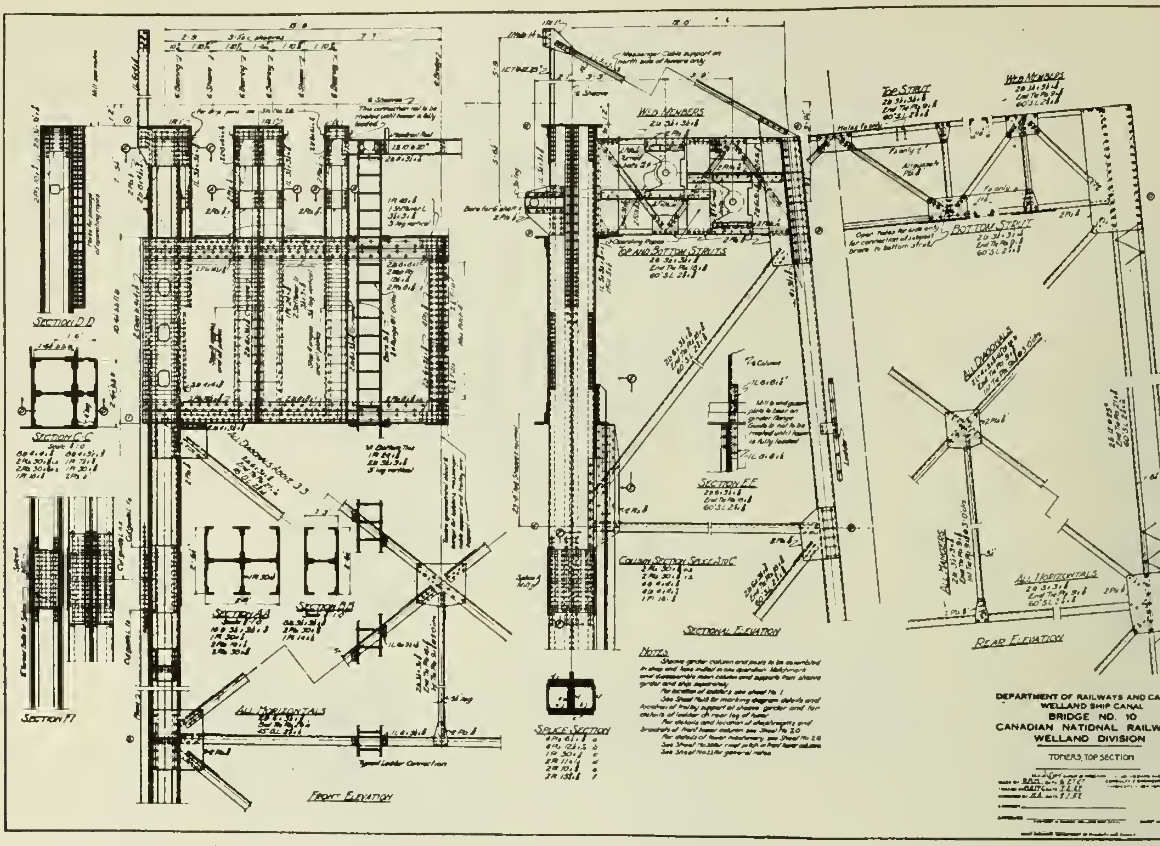

Figure No. 35.—Bridge No. 10—Towers—Top Section.

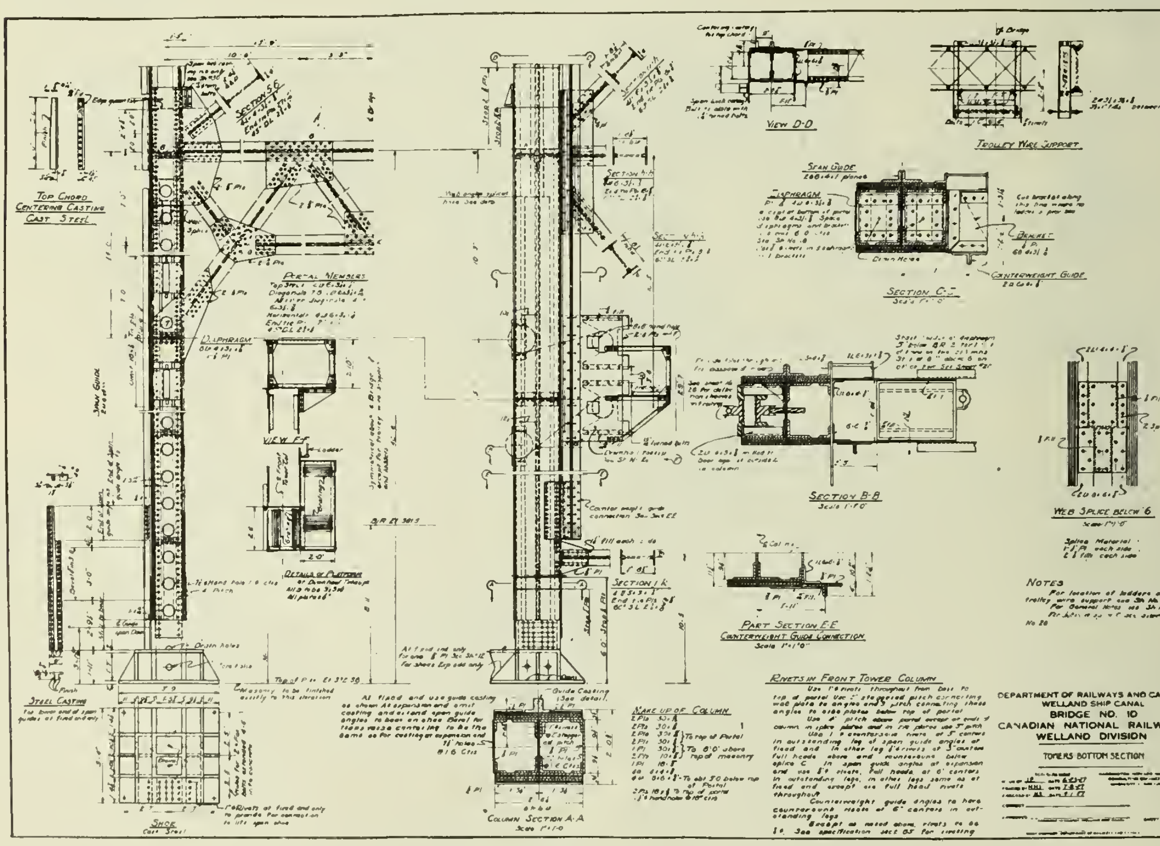

Figure No. 36.—Bridge No. 10—Towers—Bottom Section.

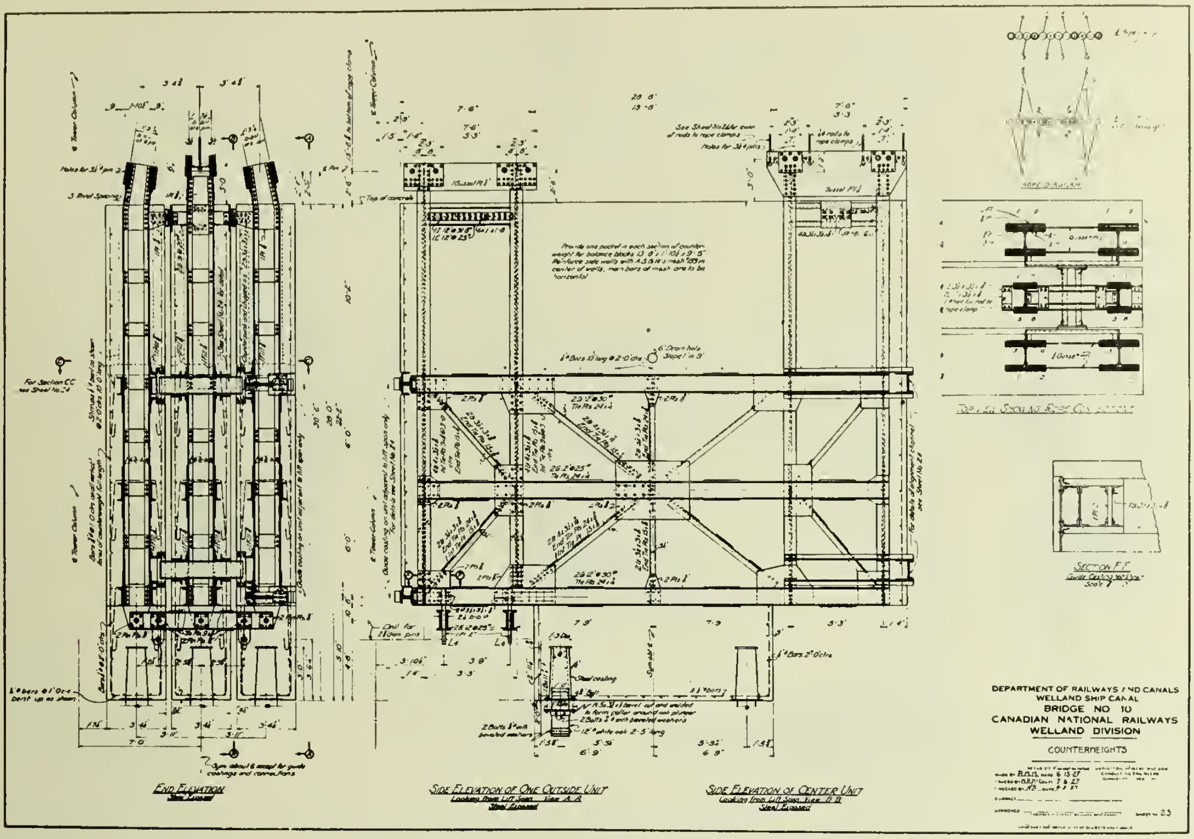

Figure No. 37.—Bridge No. 10—Counterweights.

dinally towards the bottom, all to an amount sufficient to insure accurate seating of the lift span.

The 550-volt current is transferred from the tower to the lift span by a vertical three-wire trolley system. The 110-volt current for the operation and control of bells, signals, gates and wigwags is transferred at each end of the moving span to a tower by means of a flexible cable travelling loop hanging at the side of the tower.

In order to reduce the weight of the floors on the highway vertical lift spans, Haydite concrete is used for the roadway and sidewalk slab, the roadway having a wearing surface of asphaltic concrete one inch thick. The burnt clay aggregate is manufactured by the Haydite Company of Kansas City, who furnish it in sizes to suit requirements; the concrete made from this aggregate, to give 2,000-pound concrete, will weigh only 104 pounds per cubic foot.

Toothed steel castings are used at the break in the floor between the expansion end of the lift span and the tower span, but concrete unfaced with metal is used at the break in the floor for the other end of the lift span.

Bridge No. 17

Bridge No. 17, which carries the single track of the Wabash division of the Canadian National Railways over the canal, has, at each end, a 70-foot deck plate girder span and a 60-foot tower span with a 215-foot lift span over the channel, the whole crossing having a length of 491 feet $\frac{3}{4}$ inch face to face of the abutment parapet walls. This crossing was originally designed without the girder approach spans, but when the design plans were about ready to issue for tenders, slips occurred in the canal embankment in the vicinity of the bridge, so it was considered advisable to flatten the canal banks to a 3 to 1 slope and lengthen out the crossing by adding the girder spans. The heights of the centre line of the counterweight sheaves above base of rail, top of masonry and water level are respectively 161 feet, 169.58 feet and 177 feet. The bottom of the span is 10 feet 5 inches above water level, and the lift to give 120 feet overhead clearance is 109 feet 7 inches.

There are four cast steel counterweight sheaves having a pitch radius of 6 feet 1 inch. Each sheave was grooved to take sixteen $1\frac{1}{2}$-inch diameter wire ropes and was pressed on to its axle with a forced fit of about 200 tons. Two sheaves weighed 22,000 pounds each and the two others 21,000 pounds each. The axles, which weigh 3,130 pounds each, were turned to give an oversize of 0.012 inch over the sheave bore. The journals are $13\frac{1}{2}$ inches in diameter and $18\frac{1}{2}$ inches long and transfer a bearing pressure to the bronze bushings of 1,200 pounds per square inch. Very excellent castings were obtained from the Dominion Steel Foundries, Hamilton, and the machine work, which was done by the John Bertram Company of Canada, was all that could be desired.

The sixty-four counterweight ropes, averaging 164 feet in length, were manufactured by the Dominion Wire Rope Company at Montreal, where the forged steel sockets made by the Canada Steel Foundries and Forgings Company at Welland, Ont., were attached, so that their finished lengths centre to centre of pinholes, while the rope was under a tension of 4,000 pounds, did not vary from the theoretical length required by more than 3/16 inch plus or minus. Before attaching the sockets, the ends of the ropes were broomed out, the wires hooked and cleaned in kerosene, wiped and dried and dipped in muriatic acid, then dried again and dipped in molten tin; after tinning, a socket was put on and adjusted in proper position, after which the basket in the socket was filled with pure molten zinc and allowed to cool slowly. The ropes had to develop an ultimate strength of 174,645 pounds, and specimens about 5 feet centre to centre of socket pinholes were tested to destruction at McGill University. The ropes are pin connected to the structural steel frame work embedded in the concrete counterweights and to the lifting girders on the lift span. The effect of the flare of the ropes necessary for connection

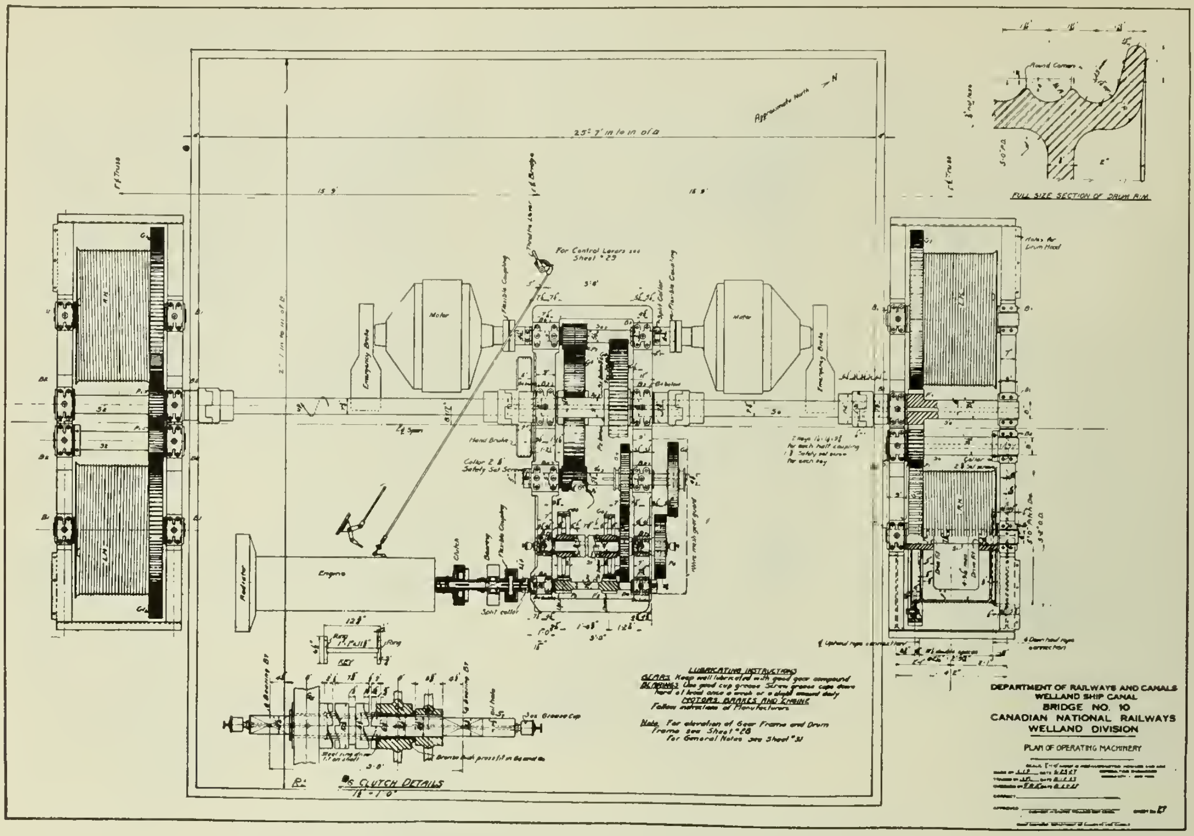

Figure No. 38.—Bridge No. 10—Plan of Operating Machinery.

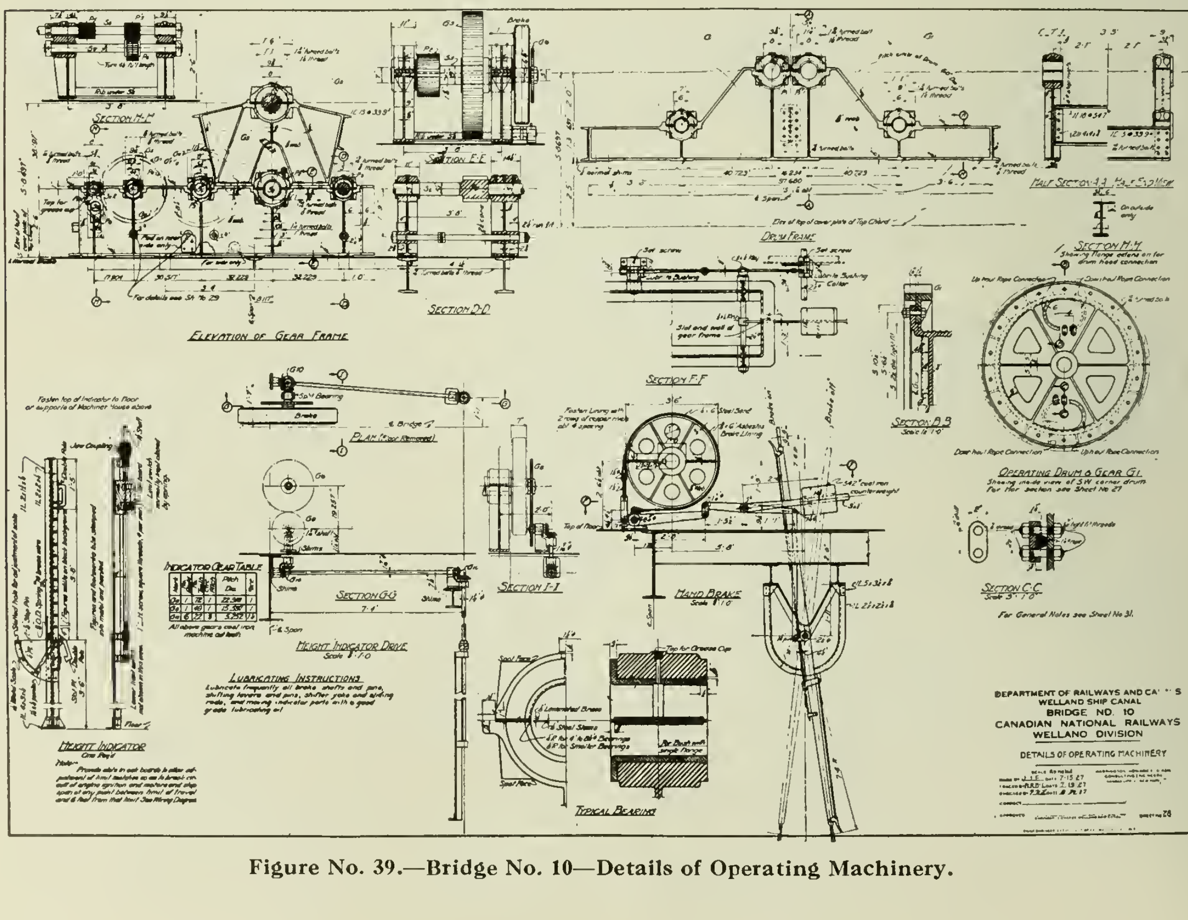

Figure No. 39.—Bridge No. 10—Details of Operating Machinery.

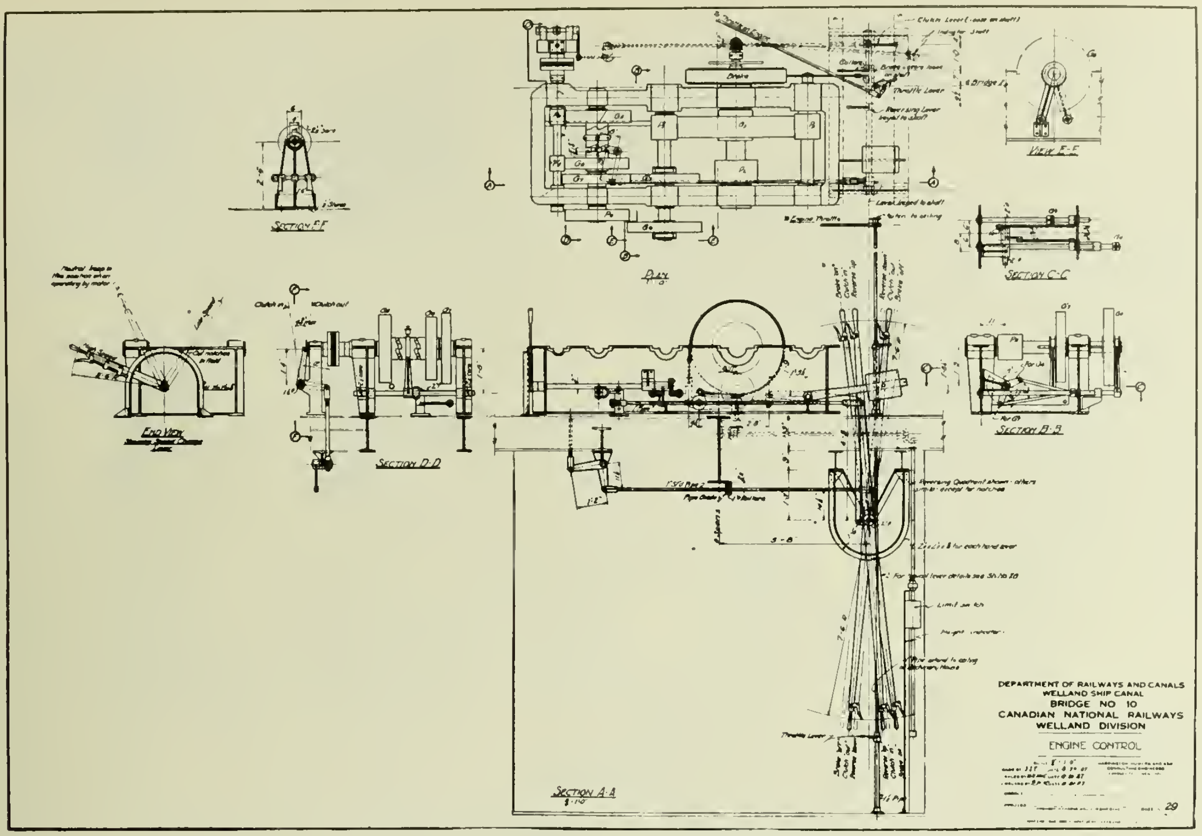

Figure No. 40.—Bridge No. 10—Engine Control.

is taken care of by cast steel flare collars and heavy cast steel rope clamps grooved to fit the ropes and bolted together.

The concrete counterweight consists of twin concrete blocks extending across the inside of the tower. Each concrete block is built around a structural steel frame work suspended from the ropes and the concrete is well reinforced with steel rods. The two blocks are linked together at the top and guide aligned together at the bottom. The block next to the tower front columns has cast steel jaw guides which engage vertical guide angles fastened to the front columns so that the counterweight is kept in proper alignment when moving up or down.

A tower front post is built up of plates and angles to form two channels with their flanges turned in and connected by a central vertical diaphragm, the whole being stayed by horizontal diaphragms spaced at 6-foot intervals. The outer corner of the column has a continuous plate and angle projecting to form a guide for the lift span. This position of the guides allows the use of outside braces from the portal to the masonry, to eliminate the bending in the posts from transverse wind and give a wider base against overturning. On the double track railway bridges and the highway bridges the side braces will not be used, so the span guides are set on the transverse centre line of column and the column below the portal proportioned to take bending from wind.

The bridge was designed to carry Cooper's *E* 60 engine loading. Creosoted Douglas fir ties, 10 by 12 inches, support the 100-pound A.R.A. running rails, with three inner lines of 80-pound steel guard rails and two lines of outside 6- by 8-inch spacer timber; at the ends of the lift span the traffic is carried by manganese steel castings projecting out and nesting into cast steel chairs on the tower span, thus obviating the necessity of having mechanically operated rail locks.

The total load, including counterweights, to be moved by the operating machinery is 1,160 tons. The times for opening under electric and gasoline power are respectively 1½ and 3 minutes for case (*a*) and 3 and 4½ minutes for case (*b*). The uphaul and downhaul pull at each corner of the span is taken by two ⅞-inch diameter wire ropes operated with drums and deflector sheaves 3 feet 6 inches in diameter, the drums having double threaded grooves for a length of 2 feet 6 inches; this, when the span is down, allows two turns of the uphaul ropes and twelve and one-quarter turns of the downhaul ropes, with one-half turns clear between them. There are provided for electrical operation two Canadian General Electric Company motors, capable of giving combined torques in pounds-feet as follows:—starting, 2,930; running at 627 r.p.m., 1,550; and running at 314 r.p.m., 2,550; the two latter torques corresponding to a theoretical horse power output of 186 and 150. The motor brakes, which are of the Cutler Hammer type, furnishing a combined retarding torque of 730 pounds-feet, act as emergency brakes, the service braking being done by means of a positive 4,200 pounds-feet torque mechanical brake whose pressure is released by hand. The gasoline engine is a Sterling four-cylinder, type G.R.C., giving a torque of 542 pounds-feet at 1,200 r.p.m., which corresponds to a theoretical horse power output of about 125. The machinery, which runs very smoothly, is mounted as a unit on a cast steel frame. No equalizing gear is used, but the motors and gasoline engine are connected to the shafting by flexible couplings and the cross drive shaft to the drums has three jaw couplings. The railway signals are operated manually by means of an interlocking machine interlocked with the bridge locks, which in turn are interlocked with the motors and engine. Change over gears are interlocked to prevent simultaneous meshing with the main drive. The machinery house is on top of the span, and the operator is situated in a house immediately below it, where he can view the channel and track and controls the operating equipment.

Owing to the fact that navigation had to be maintained from April 15th to December 15th, the bridge had to be erected during the winter. A derrick car was used to erect the lift span on falsework, placed in the channel after the close of navigation. The derrick car also erected the bottom of the towers up to a height of 65 feet, after which a guyed derrick with a 100-foot mast and a 90-foot boom was used to erect the rest of the tower. No great difficulty was experienced by the contractor, but the method used was slow, due to the long delays caused by the three shifts up of the derrick, and the writer understands that the contractor has devised a much simpler and quicker method for erecting other towers. The counterweights were erected in the up position, supported on blocking on temporary steel transverse beams resting on girders forming part of the lower longitudinal bracing; the span was jacked up in order to connect the counterweight ropes; the bridge swung; the operating ropes adjusted, and the temporary beams removed.

Bridge No. 20

Bridge No. 20, which is now under contract, is also a single track vertical lift bridge similar in construction to that of bridge No. 17, but having no approach or tower spans, the rear part of the towers resting on pedestals carried to rock and buried in the fill. The diameters of the main sheaves, counterweight ropes, operating ropes and drums are respectively 13 feet 3 inches, 1⅝ inch, 1 inch and 4 feet. Some improvements in the layout of the machinery and the control under auxiliary operation were made as a result of the experience obtained with bridge No. 17.

Bridges Nos. 14 and 16

Bridges Nos. 14 and 16, which are duplicates of each other, and also now under contract, are vertical lift highway bridges carrying a 20-foot concrete roadway between the trusses and a 5-foot concrete sidewalk outside each truss. The main dimensions of the structures are as follows:—the length of the crossing is 343 feet 2 inches face to face of parapet walls; the distance centre to centre of trusses, 24 feet; length of towers, 60 feet, centre to centre of end bearings; height of towers, 166 feet from top of masonry to centre line of sheaves; lift span, 214 feet 2 inches, centre to centre of end bearings; heights, centre to centre of chords, 25 feet 6 inches at hip and 35 feet at centre; clearance over roadway, 16 feet; the lift is 112 feet 6 inches. There are four counterweight sheaves, 13 feet 3 inches in diameter, each taking sixteen 1⅝-inch wire ropes which support a total load of 1,270 tons for span, counterweights and ropes. The pair of downhaul and uphaul ropes at each corner are 1⅛ inch diameter, their sheaves and drums have a pitch diameter of 4 feet 6 inches. Two three-phase, 12-pole, 550-volt at 66 2/3 cycles, slip ring induction motors are to be provided, with a combined nominal rating of 300 horse power, or 224 kilowatts; the maximum requirements stipulated are 428 kilovolt amperes and 450 amperes; the theoretical horse power output required for running under cases (*a*) and (*b*) are respectively 208 and 188. The gasoline engine to be furnished will be a six-cylinder Sterling engine of the Dolphin type with minimum torque of 683 pounds-feet at 1,200 r.p.m. The theoretical horse power output required for running the bridge with the engine is 126. Except for providing for the necessities of highway traffic instead of railway traffic, the general features are the same as for bridges Nos. 17 and 20, but, as before mentioned, the outrigger braces at the foot of the columns are omitted, the wind shear being transferred down from the portal by bending in the posts.

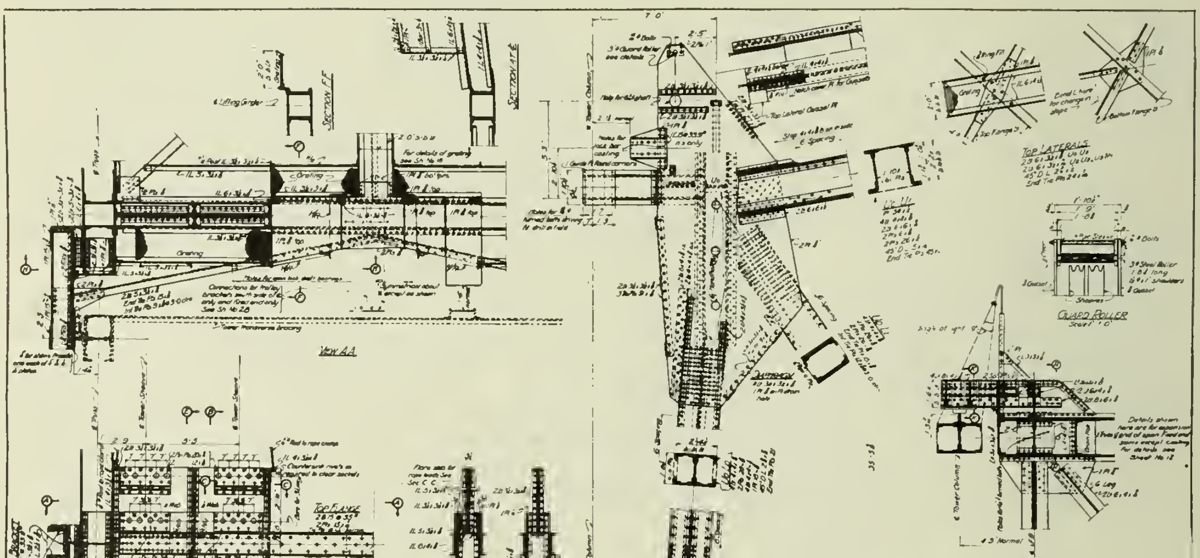

Figure No. 41.—Bridge No. 10—Lift Span, End Section and Lifting Girder.

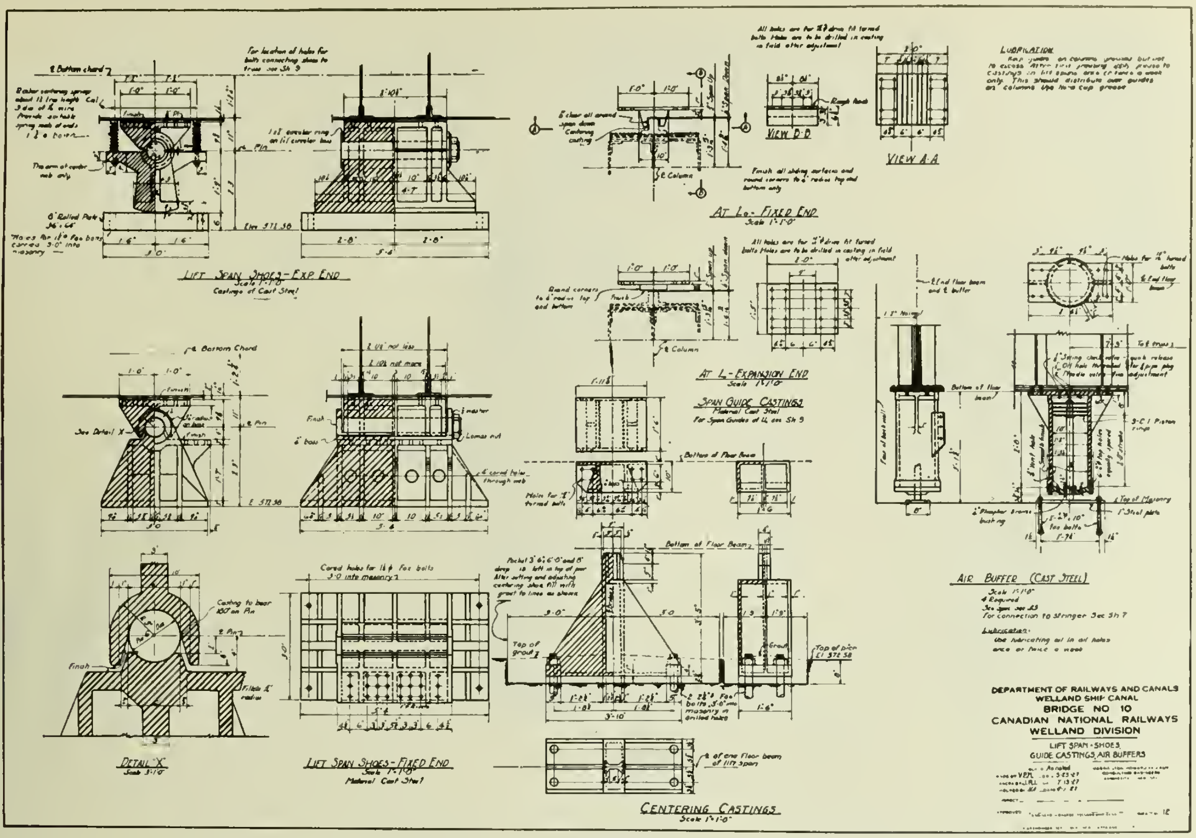

Figure No. 42.—Bridge No. 10—Lift Span, Shoes, Guide Castings, Air Buffers.

Bridges Nos. 10 and 21

Bridges Nos. 10 and 21 will be two of the heaviest vertical lift bridges, the former being for a double-track railway and the latter for a 30-foot highway and two 5-foot sidewalks. The weights of span and counterweights for the two bridges are 2,245 tons for No. 10 and 2,061 tons for No. 21, and it was decided to use the same counterweight sheaves and ropes on both bridges. There will be eight sheaves for each span, two for each corner; each sheave is 14 feet in diameter and carries twelve 1¾-inch diameter ropes; the weight per span of the counterweight sheaves with their axles and bearings will be about 130 tons. The counterweights are built in three sections, each section being supported by sixteen ropes. Although bridge No. 10 will be heavier than bridge No. 21, it will be necessary to provide more power for the latter on account of its having a greater floor area exposed for the unbalanced loads of 2.5 and 7.5 pounds per square foot. The theoretical horse power output required for running under the various conditions for No. 10 and No. 21 respectively are as follows:—case (*a*), 293 and 312; case (*b*), 228 and 276; with gasoline power, 184 and 185. Each span is provided with a 230 horse power

Estimated Costs for Superstructures of Vertical Lift Bridges Nos. 14, 17 and 20 Based on Contract Prices.

Figure No. 43.—Bridge No. 18—General Plan of Bridge.

Sterling eight-cylinder Dolphin type engine, with a minimum torque of 1,005 pounds-feet at 1,200 r.p.m. and the gear train designed accordingly. This will mean that the opening of bridge No. 21 will take slightly more time than that required for bridge No. 10. The electric motors for each bridge will be designed for the requirements of 1.5 minute under case (*a*) and 3 minutes under case (*b*), so that they will be different on the two bridges; the two for No. 10 being rated at 189 horse power each and the two for No. 21 at 220 horse power each.

Bridges Nos. 2, 5, 11, 12, 13 and 18

Bridges Nos. 2, 5, 12 and 18 will have lift spans similar to those of Nos. 14 and 16, except for variations in length to accommodate the angles of skew and the substructures. The traffic for Nos. 2 and 5 will be carried on the back fill behind the channel piers, but floors will be provided in tower spans for Nos. 12 and 18, the tower spans for the latter being made 107 feet 6 inches to accommodate the crossing to flattened slopes without intermediate piers as used for No. 17. Bridges Nos. 11 and 13 will have 30-foot roadways, the latter carrying a single track trolley line on the centre line of roadway. Bridge No. 13 will be the only bridge built with skew ends for the lift and tower spans, and will be a heavier bridge than No. 21.

From the foregoing narrative and descriptions, it can readily be seen that the task of designing and building the bridges for the Welland ship canal has occupied and will occupy the attention of many engineers in all lines of work. It would be impracticable for the writer to give in this paper a list of the personnel concerned, but he does here desire to record his appreciation of the kindly aid extended to the departmental engineers by other engineers situated in various cities of the United States and Canada, through visitations to different structures or information furnished. The various engineers on the staffs of the consulting engineers of the bridge company's different subcontractors have Hamilton Bridge Company, Canadian Westinghouse Company, Canadian General Electric Company and the engineers of the bridge companies' different subcontractors have throughout endeavoured to furnish good design, fabrication and erection of the superstructures, to the satisfaction of the Departmental engineers and the engineers of the Canadian National Railways. The substructures were built by the general contractors for the various sections of the ship canal under the supervision of the Department's division engineers in charge of the sections. The writer would bear witness to the conscientious endeavours of the staff of the Welland ship canal, both in the office and in the field, to secure proper execution of the work in the drawing office, mill, shops and at the site.

The construction of the Welland ship canal is under the jurisdiction of the Department of Railways and Canals, Dominion Government of Canada, of which the Hon. Chas. A. Dunning is minister, Major G. A. Bell, deputy minister, and Colonel A. E. Dubuc, M.E.I.C., chief engineer, and the work is being carried on under the direct control of Alex. J. Grant. M.E.I.C., engineer-in-charge of the Welland ship canal.

The Lock Gates of the Welland Ship Canal

A Description of the Locking Arrangements for the Canal, Types of Gates Chosen, General Features of the Gates, Details of Design, Fabrication, Erection and Cost of the Steel Gates, Operating Machinery, and Details and Fabrication of the Timber Gates

Frank E. Sterns, M.E.I.C.
Designing Engineer, Welland Ship Canal, St. Catharines, Ont.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 15th, 1928

The physical conditions which governed the location and arrangement of the locks of the Welland ship canal may be briefly outlined. The canal is 25 miles long from the shore of lake Ontario to the shore of lake Erie. Figure No. 1 shows the general plan and profile of the site. From Port Weller, on lake Ontario, to the foot of the Niagara escarpment, a distance of 6 miles, the canal traverses ground rising gently to an elevation of about 150 feet above the level of the lake. Within the next mile the ground rises steeply, some 190 feet higher, to the top of the escarpment, which is above the level of lake Erie. For the remaining 18 miles of its length, the canal traverses fairly level country between the towns of Thorold, at the top of the escarpment, and Port Colborne, on the shore of lake Erie. The low water level of lake Erie is 325.5 feet above the low water level of lake Ontario, and the difference between the low and high water levels of lake Erie is 12 feet.

In order to reduce the time spent by a ship in passing through the canal, it is desirable to keep the number of locks through which she must pass as small as possible, by making the lift of each as great as may be found to be practicable and advisable. It is also desirable to have the lift of all the locks the same, in order to use the lockage water efficiently and to have the lock gates interchangeable.

The adopted arrangement of locks provides seven locks of approximately 46.5 feet lift to overcome the total lift of 325.5 feet between the low water levels of the two lakes. These locks are 80 feet wide and have a usable length of 820 feet and a depth of 30 feet of water over the sill platforms. They are all located near the northern end of the canal, between Port Weller and Thorold. In addition to these, a guard lock is provided at Port Colborne. The long summit level between Thorold and Port Colborne will be kept at or near the low water level of lake Erie, and the guard lock will be used to overcome the small variable lift between this level and the actual level of the lake. This lift will usually be around 3 or 4 feet. The guard lock is of the same width and has the same depth of water over the sill platforms as the other locks, but its usable length is 1,355 feet. The increased length of this lock was adopted to expedite traffic by enabling two or more of the smaller ships to be locked through it at the same time.

To suit the profiles of the surfaces of the ground and of the underlying rock, the seven lift locks are located as follows:—Lock No. 1 is ½ mile from the shore of lake Ontario; lock No. 2 is 1¾ mile from lock No. 1, and lock No. 3 is 2¾ miles from lock No. 2. Locks Nos. 4, 5 and 6 are in flight, lock No. 4 being 1¼ mile from lock No. 3. The flight of three locks is ½ mile long, and lock No. 7 is ½ mile above lock No. 6. One mile above lock No. 7 a guard gate is provided to hold back the water in the long summit level in the event of the gates of lock No. 7 being carried

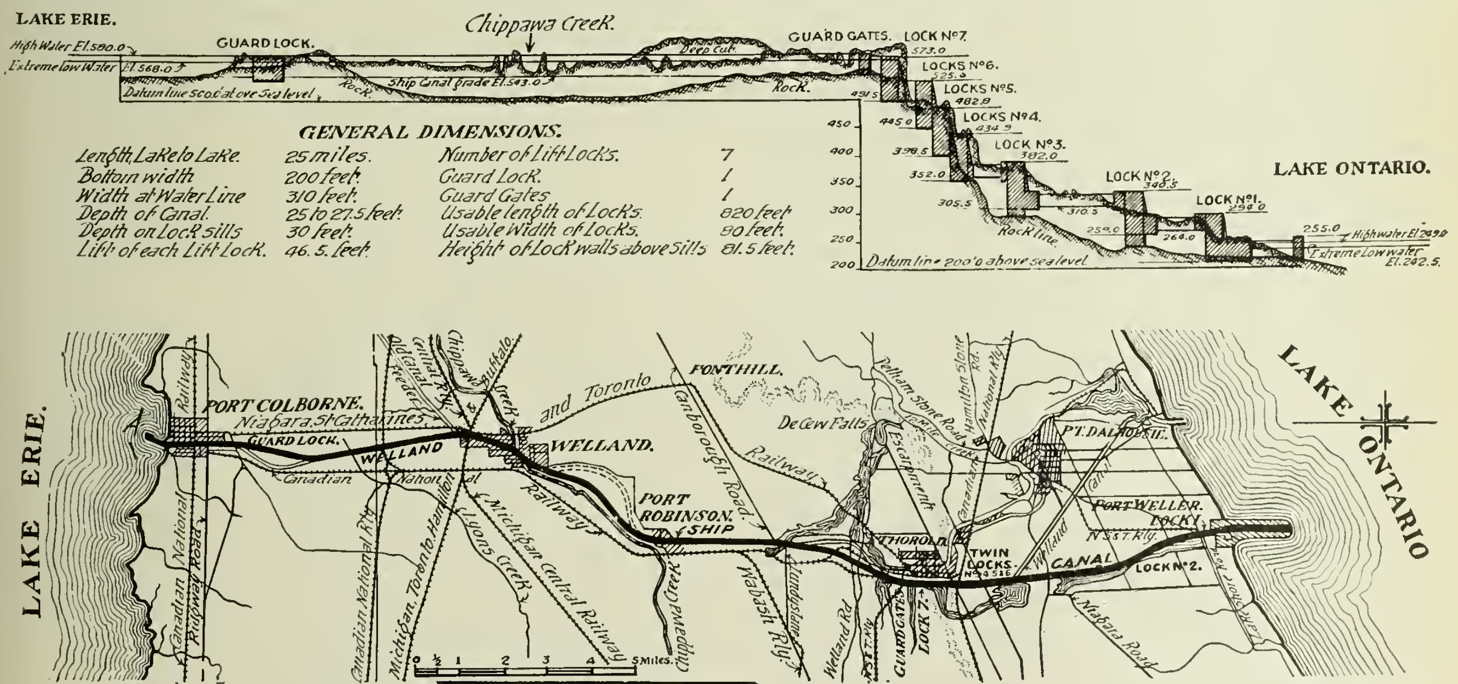

Figure No. 1.—Plan and Profile of Canal.

away. The guard lock No. 8 at Port Colborne is 15½ miles above the guard gate. As the three locks Nos. 4, 5 and 6 in flight could not pass ships in both directions without serious delays to navigation, twin flights side by side are provided so that upbound ships can be passed through one flight and downbound ships through the other.

Should the gates of locks Nos. 6, 7 or 8 be carried away, the canal works, under certain conditions, might be seriously damaged and navigation interrrupted for a period of some months. In these locks, therefore, a guard gate will be provided a short distance upstream from the service gate, both at the head and the foot of the lock, so that in locking at least two gates can always be kept closed, both of which would have to be carried away by a ship before free flow would be established through the lock. The other locks will have only the service gate at each end of the lock.

As a result of the doubling of the gates in lock No. 6, the plan area of its lockage prism is greater than that of either of the two locks in flight below it, by the area of the space between the two gates at its lower end, and, since locks in flight are equalized by emptying one into the next below, the lift of locks Nos. 4 and 5 will be greater, and the lift of lock No. 6 less, than their average lift of 46.5 feet. Locks Nos. 4 and 5 will each have a lift of 47.9 feet and lock No. 6 a lift of 43.7 feet.

The locks must be unwatered from time to time for the purpose of inspecting, painting and repairing the underwater portions of the lock gates, valves, etc. In most cases, this can be done by draining the water from the reaches above and below the locks, but the reaches below lock No. 1 and above lock No. 8 cannot, of course, be drained, as they communicate with lakes Ontario and Erie respectively. Also, the long summit level between lock No. 8 and the guard gate cannot be drained conveniently, on account of the large volume of water it contains, or safely, because its banks in some places are in unstable material. Under these circumstances, to enable locks Nos. 1 and 8 to be unwatered by pumping, an unwatering gate in the reverse position is required at the lower end of each of these locks. An unwatering gate will also be provided above the upper guard gate of lock No. 8, to enable the upstream side of the latter to be unwatered for painting, etc. The unwatering gates will be of timber construction, so that they themselves will not require to have their under water portions painted.

To enable either of the twin locks No. 4 to be unwatered during the navigation season, if desired, without entirely stopping navigation by draining the reach below them, an unwatering gate in the reverse position will be provided at the lower end of each of these locks.

The upstream side of the guard gate can be unwatered by closing the emergency dam above it to hold back the summit level. The downstream side of the guard gate and the upper gates of lock No. 7 can be unwatered by draining the reach between them. There is, however, some dockage on this reach, and it may therefore be inconvenient to drain the reach on some occasions when it may be desired to unwater lock No. 7 or the guard gate. Recesses, sills and supports will therefore be provided below the guard gate in which a spare gate can be temporarily set in the reverse position to enable the guard gate to be unwatered under such conditions. The upper guard gate and upper service gate of lock No. 7 can, if necessary, be used to unwater each other, by transposing them after one of them has been painted, or by dry docking the upper guard gate in the lock chamber.

Table No. 1 gives a list of the different gates which will be provided in accordance with the general scheme outlined above. The height of the gates given in the table is the distance from the top of the sill to the top of the coping of the lock wall, except in the case of the lower unwatering gate of lock No. 8, where the top of the gate is 9.0 feet below the top of the coping. The top of the sill is in all cases set 6 inches below the top of the sill platform, in order to prevent it from being damaged by contact with the keels of vessels.

Table No.1.—List of Gates to be Provided.

Type of Gates

In deciding upon the type of lock gates to be used in a canal of such importance to navigation as the Welland ship canal, the most important features to be considered

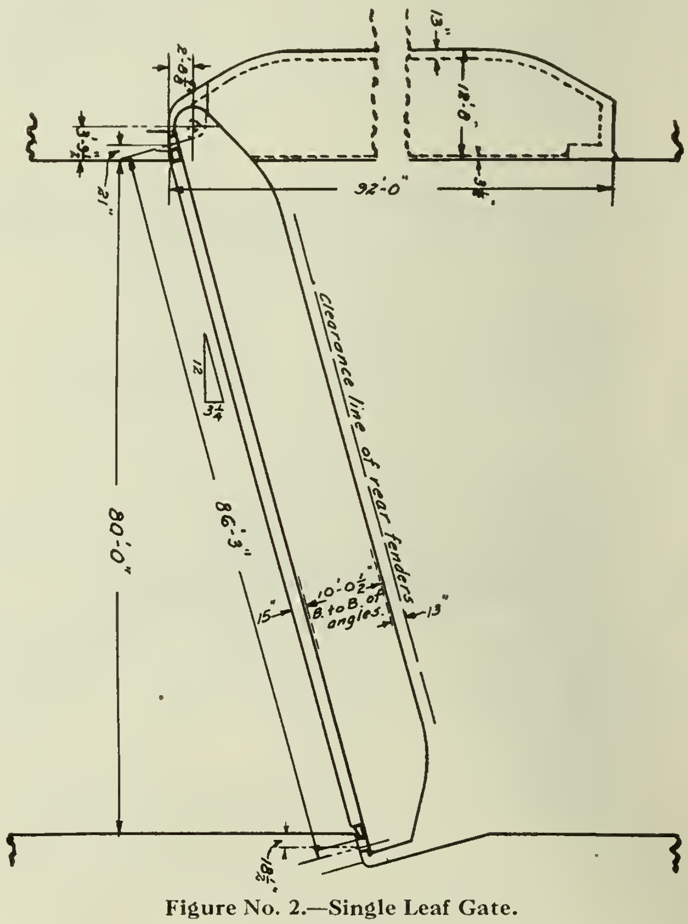

Figure No. 2.—Single Leaf Gate.

are those which affect the safety and speed of navigation, or which tend to prevent or to shorten interruptions of traffic. The difference in first cost of any of the available types of gates is not large, and is therefore of minor importance.

Mitering lock gates have been used more extensively than any other type in locks of all sizes, from the smallest up to the greatest, and have become the standard type. Single leaf gates of various types, distinguished by the manner and direction in which they move in opening are, however, in successful use, and these were also investigated. The form which swings about a vertical axis at one end was found to be the most suitable for use on the Welland ship canal, and was studied most carefully. In order to improve its speed of operation, the toe quoin was placed some 22 feet upstream from the heel quoin, thus making its angle of rotation 15° less than a right angle, at the expense of an increase of only 3½ per cent in the length of the leaf. Figure No. 2 shows the proposed outline of this gate and of its recesses.

Before proceeding with a statement of the relative merits of this type of single leaf gate and the mitering gate, it will be convenient to discuss in more detail the principal objection to mitering gates, viz., that they are easily unmitred under head and carried away as a result of being struck by a ship. Accidents of this sort can be minimized, (1) by measures tending to prevent the gate from being struck, (2) by so constructing the gate as to increase its resistance to being unmitred if it is struck, and (3) by providing two gates, so that if one is struck and unmitred the other will carry the water load and no serious harm will be done.

A very effective means for preventing lock gates from being struck by ships is to provide the lock with long approach walls so that ships can get out their lines at a distance from the gates and enter the lock under full control. Another useful measure is to have the ships equipped with effective modern compressors for snubbing their mooring lines. A very common cause of such accidents, the misunderstanding of engine room signals, can be removed by towing ships through the locks instead of allowing them to proceed under their own power. This, however, is expensive in equipment and labour, and tends to reduce the speed of locking. The danger of the upper gate being struck on its downstream side will be much less if the gate is placed upon the breastwall than if it is placed below the breastwall. Fenders, consisting of heavy chains or plate girders, have been used to prevent ships from coming too close to the gates and have proved useful.

In order to increase the resistance of the gates to being unmitred, safety horns, devised and patented by the late Mr. N. W. Gowan, have been experimented with on the upper gates of some of the locks of the present Welland canal, and have been found to be effective for the purpose. These horns are heavy castings, bolted to the mitre ends of the two leaves and projecting beyond them so as to overlap the mitre end of the mating leaf, so that one leaf must be moved upstream about two feet from the mitred position before it will clear the ends of the horns on the other leaf and leave it unsupported. The patent rights have been acquired by the Department of Railways and Canals.

The effectiveness of such safety measures, and the necessity for them, may be illustrated by considering two typical cases.

On the present Welland canal, accidents in which the mitering gates have been carried away as a result of being struck by vessels have been very frequent. As many as five such accidents have occurred in a single year. The locks were built practically without any of the safety features indicated above, and the only improvement made since their construction has been to install safety horns on the upper gates of 16 of the 26 locks. Only two of the locks have approach walls. The upper gates are below the breast walls. No fenders are provided. There is only one gate at each end of each lock. Furthermore, a large proportion of the vessels which now use the canal have been built of the full size of the locks. Since the safety horns were installed, accidents have been less frequent.

In contrast with the above may be cited another case where mitering gates are used: the locks at Sault Ste. Marie. These locks have carried an extremely heavy traffic for many years. They are provided with three safety features, viz., long approach walls, upper gates placed upon the breastwalls and two service gates at each end of each lock. The Canadian lock and the 3rd and 4th American locks are considerably longer than the longest ship on the lakes, but the value of this as a safety feature is greatly reduced by the practice of locking two or three ships through in one lockage. There has never been an accident of the kind in question at the American locks, and only one at the Canadian lock. This seems to indicate that when proper measures for their protection are taken, mitering lock gates are practically immune from serious accidents caused by ships colliding with them.

The principal advantages of the single leaf gate, shown in figure No. 2, in comparison with the mitering gate, are the following:—

(1) It is less likely to be carried away if struck by a ship. If the mitering gate be equipped with safety horns, the superiority of the single leaf gate in this respect will be reduced, and if reasonable provisions are made to minimize the danger of the gates being struck, the importance of this advantage will be correspondingly decreased.

(2) It cannot be improperly closed, but a mitering gate might be imperfectly mitred so as to carry a small water load, and then give way as the head on it increased. This could be prevented, however, by using safety horns on the mitering gate, as it could not then be improperly mitred.

(3) If it should be caught in a surge, or in a high wind, and get out of control in closing, it cannot fall over the sill as one leaf of a mitering gate could if not supported by the mating leaf.

(4) In the event of the lower gate of a lock being carried away by a ship before the upper gate is fully closed, the closing of the latter, if of the single leaf type, might be successfully completed, whereas a gate of the mitering type would almost certainly be lost. Means for gradually stopping the single leaf gate when it came close to its seat would, of course, be required to prevent its seating with a destructive shock.

The principal advantages of the mitering gate, in comparison with the single leaf gate, are:—

(1) It is more easily and quickly operated than the single leaf gate, on account of the smaller size of the leaves and the smaller angle through which they turn. This reduces the time required for a lockage, and increases the volume of traffic which the canal can handle.

(2) It decreases the total length of the lock chamber required for a given usable length. This decreases the time required to fill and empty the lock, and further increases the capacity of the canal.

(3) It is more easily handled in making replacements of damaged gates, as the floating crane required for the purpose is smaller and more manageable. Furthermore, there might be considerable difficulty and delay in removing a single leaf gate from the lock if the leaf were badly deformed in an accident, whereas with mitering gates the leaves could hardly be so badly deformed as to seriously interfere with their removal.

(4) The gate itself is somewhat less expensive than a single leaf gate, and it decreases the length and cost of the lock walls as well.

In 1913, the late Afred Noble, M.E.I.C., was retained by the Department of Railways and Canals to review and report upon the designs and methods proposed for the construction of the Welland ship canal. In regard to the relative merits of single leaf gates and mitering gates, he concludes as follows:—"After careful consideration of the two types, the relative advantages of either do not appear to me of decisive importance. If I were designing the work, I should adopt the mitering gates as being rather more manageable in ordinary operation, but both forms are in successful use and either will give good service."

However, J. L. Weller, M.E.I.C., who was engineer-in-charge of the Welland ship canal when the work was begun, and had been, for many years previously, superintending engineer of the present Welland canal, was firmly convinced that the greater safety of the single leaf gates outweighed their disadvantages, and they were adopted for use throughout the canal, except for unwatering gates and for the second gate in places where it was considered advisable to use two gates as an additional safety feature. For these gates, which are not so likely to be struck by ships, the cheaper mitering type was adopted.

Work on the construction of the canal was begun in 1913 and was carried on, under the handicap of war conditions, until the spring of 1917, when all work was stopped.

In 1919, work was resumed under the direction of A. J. Grant, M.E.I.C., as engineer-in-charge, who reopened the question as to the type of gates to be used. As no contracts had been let for the lock gates, and as onlv a small portion of the work on the locks had been done, it was still practicable to change the type of gates. Mr. Grant recommended that mitering gates should be used throughout instead of single leaf gates. The pricipal considerations leading to this decision were: the unprecedented size and weight of the single leaf gate required; doubt as to the success of the dash-pot device proposed for bringing the toe of the gate to rest in its quoin without shock; the unwieldy size of the floating crane required for handling single leaf gates in replacements; the great expenditure of money and time that would be required in removing a badly damaged gate from the lock; the greater ease and speed of operation of mitering gates; the probability that if equipped with safety horns their inferiority to single leaf gates as regards safety would be to a large extent eliminated; and the opinion, favourable to the use of mitering gates, expressed by Mr. Noble, as quoted above. Under the original scheme, it was intended to use two gates at the head of each of the twin locks No. 6 and at the head of lock No. 8. With mitering gates, it was decided, as an additional safety feature, to use two gates at the foot of each of the twin locks No. 6, at the head and foot of lock No. 7, and at the foot of lock No. 8 as well. It was also decided to use an unwatering gate at the head of lock No. 8 so as to enable the upper guard gate to be unwatered without moving it to another location, as was intended under the original scheme.

The estimated total cost of making these changes, including the cost of the necessary alterations to existing concrete work and the cost of the additional gates provided, less the saving due to the smaller number of spare gates required and the saving in the cost of the individual gates resulting from the use of the less expensive mitering type, amounted to approximately $600,000. The increase in the usable length of the locks resulting from the change was 20 feet.

The use of mitering lock gates instead of single leaf gates and the provision of additional gates as outlined above were authorized in May 1920 by the late Mr. W. A. Bowden, then chief engineer of the Department of Railways and Canals.

General Features

Steel was adopted as the material of construction for the service gates and timber for the unwatering gates. The water load on the gates, 82 feet high, is so great that their construction in timber is impracticable. For the gates 44 feet 6 inches and 35 feet 6 inches high, timber could be used, but steel was preferred for the service gates for several reasons. Steel is the more reliable material and satisfactory connections are more readily made with it. Timber sticks of the large size required in order to avoid complicated construction are not readily obtainable, and similar sticks for repairs and replacements will be increasingly difficult to find in the future. The service gates can be readily unwatered as often as necessary for inspection and painting. For the unwatering gates, however, timber was preferred, as they cannot be unwatered in place for painting, and, if made of steel, they would, therefore, be expensive to maintain. The timber unwatering gates, on account of their less important functions and the relatively small number used, are of minor interest in comparison with the steel service gates. The remainder of this paper will therefore be devoted principally to a description of the latter, the timber gates being treated separately and briefly afterward.

Shape of Leaf

Mitering lock gates may be of the " arched " type, in which both sides of the leaves are curved in the plan view so as to keep the line of stress at all points near the centre of gravity of the cross-section, or they may be of the " girder " type, in which the downstream side of the leaf, and usually a considerable portion of the upstream side as well, are straight in the plan view.

Gates of the arched type usually weigh less than the corresponding gates of the girder type by from three to eight per cent, but their cost per pound is higher, so that there is little if any saving in total cost to be gained by their use. An important disadvantage of the arched type is the greater depth of the recesses required for them in the face of the lock walls, which is an inconvenience in the operation of the locks and, in the case of twin locks, increases the thickness and cost of the centre wall between the locks. Also, when arched gates are open and the leaves are in their recesses, their concave downstream sides are exposed and ships entering the lock are more likely to strike them heavily than if they were straight. The girder type was adopted for the Welland ship canal.

Five feet was chosen as the thickness of the gate leaves. A smaller dimension would have permitted the use of shallower recesses in the lock walls, but was considered undesirable for gates as high as 82 feet. The gates 44 feet 6 inches and 35 feet 6 inches high could have been made thinner, but were kept of the same thickness as the high gates for the sake of uniformity.

Framing System

The primary framework of a mitering gate may consist either of a series of horizontal girders, or of a heavy horizontal girder at the top of the leaf with vertical girders spanning the space between it and the sill. The former is the less expensive for gates in which the height of the leaf is somewhat greater than its length and the latter for gates which are low in comparison with their length.

For the high gates of the Welland ship canal locks, which are 82 feet high by 48 feet long, the horizontal system of framing was clearly indicated. The cost of the gates 44 feet 6 inches and 35 feet 6 inches high would be practically the same with either system of framing, and therefore in view of the greater rigidity of the horizontal system, and in order to secure uniformity of construction, the horizontal system was adopted for them as well.

Angle of Sill

It was desired to use timber bearings at the quoin and mitre for the gates 35 feet 6 inches and 44 feet 6 inches high on account of the greater ease with which a proper fit can be obtained with them as compared with metallic bearings. These gates are, however, close to the limiting size with which timber bearings are practicable, and it was therefore necessary to avoid unduly high reactions at the quoin and mitre. For the gates 82 feet high the use of timber bearings is out of the question, but here also, on account of the height of the lock walls, it is desirable to avoid unnecessarily high reactions at the quoin, as they will be quite high in any event because of the high head of water these gates will carry, viz., 78 feet at the flight locks. It was therefore desirable to use a fairly large angle for the sills of all of the gates.

Other advantages attending the use of a large angle of sill are a reduction in the pressure that could be transmitted to the lock wall should a closed gate be forced downstream by a ship; and a reduction in the angle through which the gate leaves must turn in opening or closing. This reduction in the angle of operation reduces the energy required to operate the gate in a given time, notwithstanding the contrary effect of the increased length of the gate leaves, up to a sill angle of approximately 42°, beyond which the energy increases again.

Increasing the angle of sill, however, has also some disadvantages which make too large an angle undesirable. It tends to increase the weight and therefore the cost of the gate for sill angles above 22°. It also increases the total length of the lock for a given usable length. This increases both the cost of the lock and the volume of the lockage prism.

The angle whose tangent is 1:2 was adopted.

Sheathing

Mitering lock gates may be built with sheathing plates upon one or both sides. Gates with single sheathing are plated upon the upstream side in order to give lateral support to the compression flanges of the girders of the framework. When a gate plated upon the upstream side only is closed and subjected to a head of water there will be an unbalanced vertical water pressure on the bottom girder, since its lower side is exposed to pressure from the upper pool while its upper side carries only the pressure of the lower pool. This produces an uplift on the gate which, except for low heads, would be greater than its weight if the breadth of the bottom girder were made equal to the full thickness of the gate. For this reason, single sheathed gates usually have to have their sills undercut. As the uplift exists only when the gate is closed, it does not, of course, reduce the load upon the pintles when the gate is being operated, and if an air chamber were used to provide buoyancy for this purpose the sill would have to be under cut still further.

With double sheathing, however, any desired portion of the gate leaf below the level of the lower pool may be used to form an air chamber, the buoyancy of which will balance a portion of the weight of the leaf and reduce the load on the pintle when the gate is being operated. Then, if the interior of the leaf above the air chamber is put into communication with the upper pool through openings in the upstream sheathing, it will fill with water, as the water level above the gate is raised, and increase the weight of the gate leaf as the water uplift on the bottom girder increases.

Another advantage of the use of double sheathing is that it increases the general strength of the gate leaf and its resistance to twisting and buckling. It also takes the place of the diagonal bracing required on the downstream side of a single sheathed gate leaf and serves as a chord to unite the vertical frames into a continuous vertical girder. Its disadvantages are, that it makes the interior of the gate leaf less easily accessible for inspection, painting, etc., and increases the cost of the gate.

As the weight of each leaf of the gates 82 feet high is close to 500 tons, it is important to give them as much buoyancy as possible in order to reduce the operating weight on the pintle. Furthermore, on account of their great height and relatively narrow thickness, great strength to resist buckling and twisting is essential. Double sheathing was therefore adopted for these gates. Buoyancy and strength to resist buckling and twisting are advantageous for the gates 44 feet 6 inches and 35 feet 6 inches high, although not so necessary as in the case of the gates 82 feet high. However, it was considered that these advantages, together with those of uniformity in construction and the avoidance of the undesirable details which accompany the

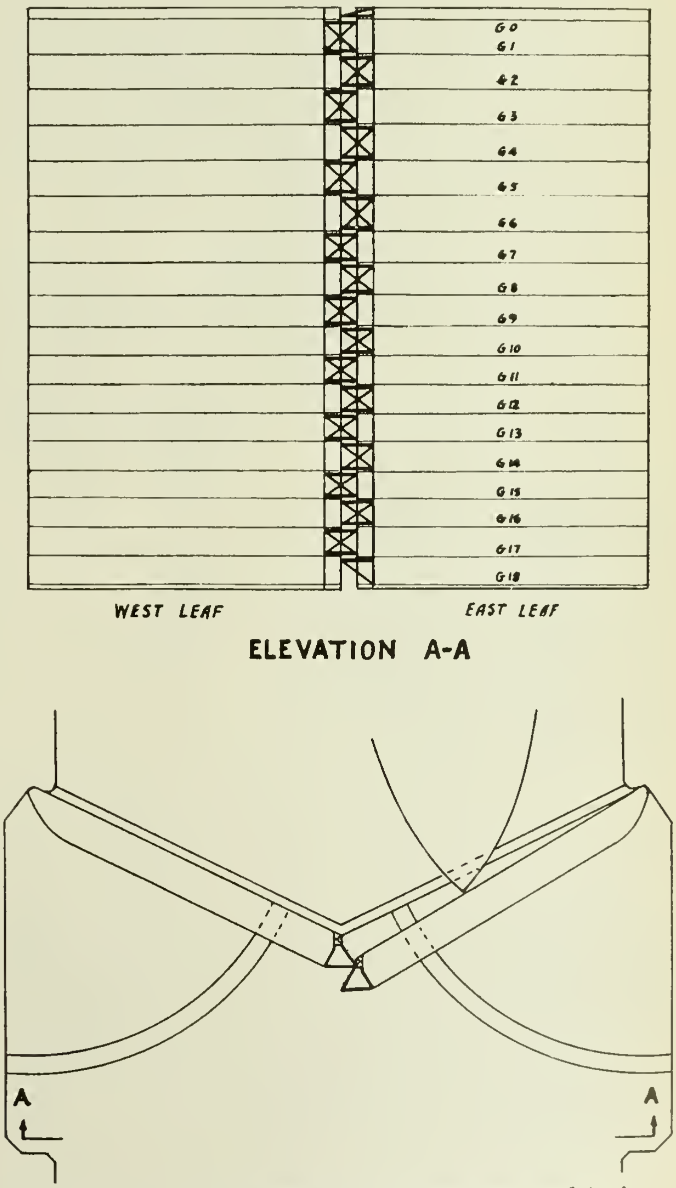

Figure No. 3.—Diagram Showing Arrangement and Action of Safety Horns.

use of an undercut sill, outweighed the disadvantages of increased cost and less easy accessibility and double sheathing was adopted for these gates as well.

Safety Horns

There is nothing new in any of the foregoing features of the lock gates adopted for the Welland ship canal. They involve merely the application of well-known principles to the conditions of the case. In one important feature, however, a radical departure from previous practice has been made. Safety horns have been adopted for all gates except the unwatering gates. So far as the writer knows, this feature has been previously used only on some of the gates of the present Welland canal, as noted above.

Some idea of the value of the horns in preventing accidents may be gained from the history of their use on the present Welland canal. The first set of horns were installed on the upper gates of lock No. 24 in 1911, and the upper gates of seven other locks were equipped with the horns at the beginning of the season of 1914. Safety horns have in no case been used on the lower gate of a lock, as these gates are rarely if ever struck upon their downstream side. Table No. 2 shows the number of ships which passed through the canal in each year from 1914 to 1926 inclusive, the number of locks whose upper gates were equipped with safety horns, and the number of accidents in which lock gates were carried away as a result of being struck by vessels. It will be noted that there has been a marked falling off in the number of accidents since 1922, and, while this is probably due in part to improvement in the equipment of vessels and in the experience of their crews, and possibly to other contributory causes, it is doubtless due in a large measure to the use of the safety horns.

Table No. 2.—Accidents and Traffic on the Present Welland Canal.

Year	Number of Ships passed through the Canal.			Number of Locks with Safety Horns.	Number of Accidents in which Lock Gates were carried away.	
	Up	Down	Total		Total Number	Number in which upper gate was struck by upbound ship.
1914	1734	1779	3513	8	5	4
1915	1394	1388	2782	10	0	0
1916	1249	1360	2609	11	4	3
1917	1352	1529	2881	11	2	2
1918	1335	1579	2914	11	5	5

1924	2397	2364	4761	16	1	1
1925	2560	2548	5108	16	0	0
1926	2381	2343	4724	16	0	0

Figure No. 3 shows the general arrangement of the safety horns as designed for use on the gates of the Welland ship canal, and indicates how they act. The safety horns will permit one leaf of a gate to swing upstream about 4 feet from the mitered position before losing contact with the horns of the other leaf. In the case of the upper gate of a lock carrying an assumed head of 15 feet when struck by a ship, the work done in swinging one leaf against this head, and against the frictional resistance between it and the other leaf, through a distance of 4 feet at the mitre end, would be 1,350 foot tons. This is equivalent to the energy of a ship of 20,000 tons displacement moving at a speed of 2.08 feet per second. To move the lower gate of the lock the same distance, under its full head of 46.5 feet, a 20,000-ton ship would have to have a velocity of 5.6 feet per second. These figures indicate that the safety horns will enable the gates to withstand a blow from a heavy ship moving at considerable speed.

The use of the safety horns increases the cost of the gates by some $360,000 for the entire canal, which is approximately 7.6 per cent of the total cost of the steel gates. The loss resulting from a single accident would probably, however, exceed this figure if we include not only the damage to the canal works but also the damage to the ship and her cargo and demurrage to shipping for the time during which the canal would be closed to traffic.

In addition to their value as a safety measure, the horns also act as an effective mitering device and prevent the leaves from being improperly mitred. The disadvantages attending their use are that they decrease the usable length of the lock chamber by about three feet and slightly increase the resistances to be overcome in operating the gate.

Because of the safety features included in the design of the locks of the Welland ship canal, the danger of the lock gates being struck by ships is comparatively small. The damage that might result from a gate being carried away is, however, so serious that the use of the safety horns was considered advisable.

Toe Wall

Another unusual feature is the curved wall concentric with the pintle centre placed on the bottom of the recess for the gate in the lock floor under each leaf near its mitre end, as shown in figure No. 3. The top of the wall comes about four inches from the bottom of one of the jacking beams of the gate, and is reinforced with a grillage of three curved 12-inch I-beams, so that should the anchorage be broken from any cause, the toe of the leaf will be caught on top of the wall. This will prevent the heel of the leaf from swinging clear of the hollow quoin, except when the leaf is near the open position, and therefore will probably save the leaf from falling to the bottom of the lock. The curved wall also acts as a guide for the wire ropes which are used to operate the gate. By preventing the ropes from leading in straight lines from their anchorages to the gate leaf it rectifies the inequalities of their motion which would otherwise exist. Although this toe wall appears to provide a track for a toe roller which it is common practice in England to use on lock gates, there never was any intention of adopting such a feature, even for the timber gates of the Welland ship canal. Since satisfactory results can be obtained without a toe roller, it is considered to be an unnecessary and objectionable complication.

General Description of Steel Lock Gates

Figure No. 4 shows the general arrangement of one leaf of a gate 82 feet high, and figure No. 5 gives similar information for the gate 35 feet 6 inches high. The gate 44 feet 6 inches high is similar to the gate 35 feet 6 inches high, the increased height being obtained by adding two panels each 4 feet 6 inches high.

Each leaf consists of a series of plate girders placed horizontally one above the other between the vertical quoin and mitre posts of the leaf and connected to each other by vertical diaphragms and frames and the vertical intercostal beams which support the sheathing plates. Each leaf is enclosed on both sides from top to bottom and from end to end with steel sheathing plates riveted to the girders, vertical frames, intercostals and end posts.

In order to reduce the cost of fabrication, special care was taken in working out the design to secure as much duplication as possible both in similar parts of the same leaf and in the corresponding parts of leaves of different heights. Only three different spacings of horizontal girders were used, viz., 5 feet, 4 feet 6 inches and 4 feet, and the 4-foot spacing was used only in the high gates. The use of a closer spacing was avoided in order to keep the interior of the leaf accessible with reasonable ease. Each leaf has five lines of vertical frames spaced at 8 feet 3 inches centre to centre. A large manhole opening is provided through each frame in each panel of the leaf.

The lower part of the interior of each leaf constitutes the air chamber, from which water will at all times be excluded. The upper part, above the air chamber, forms

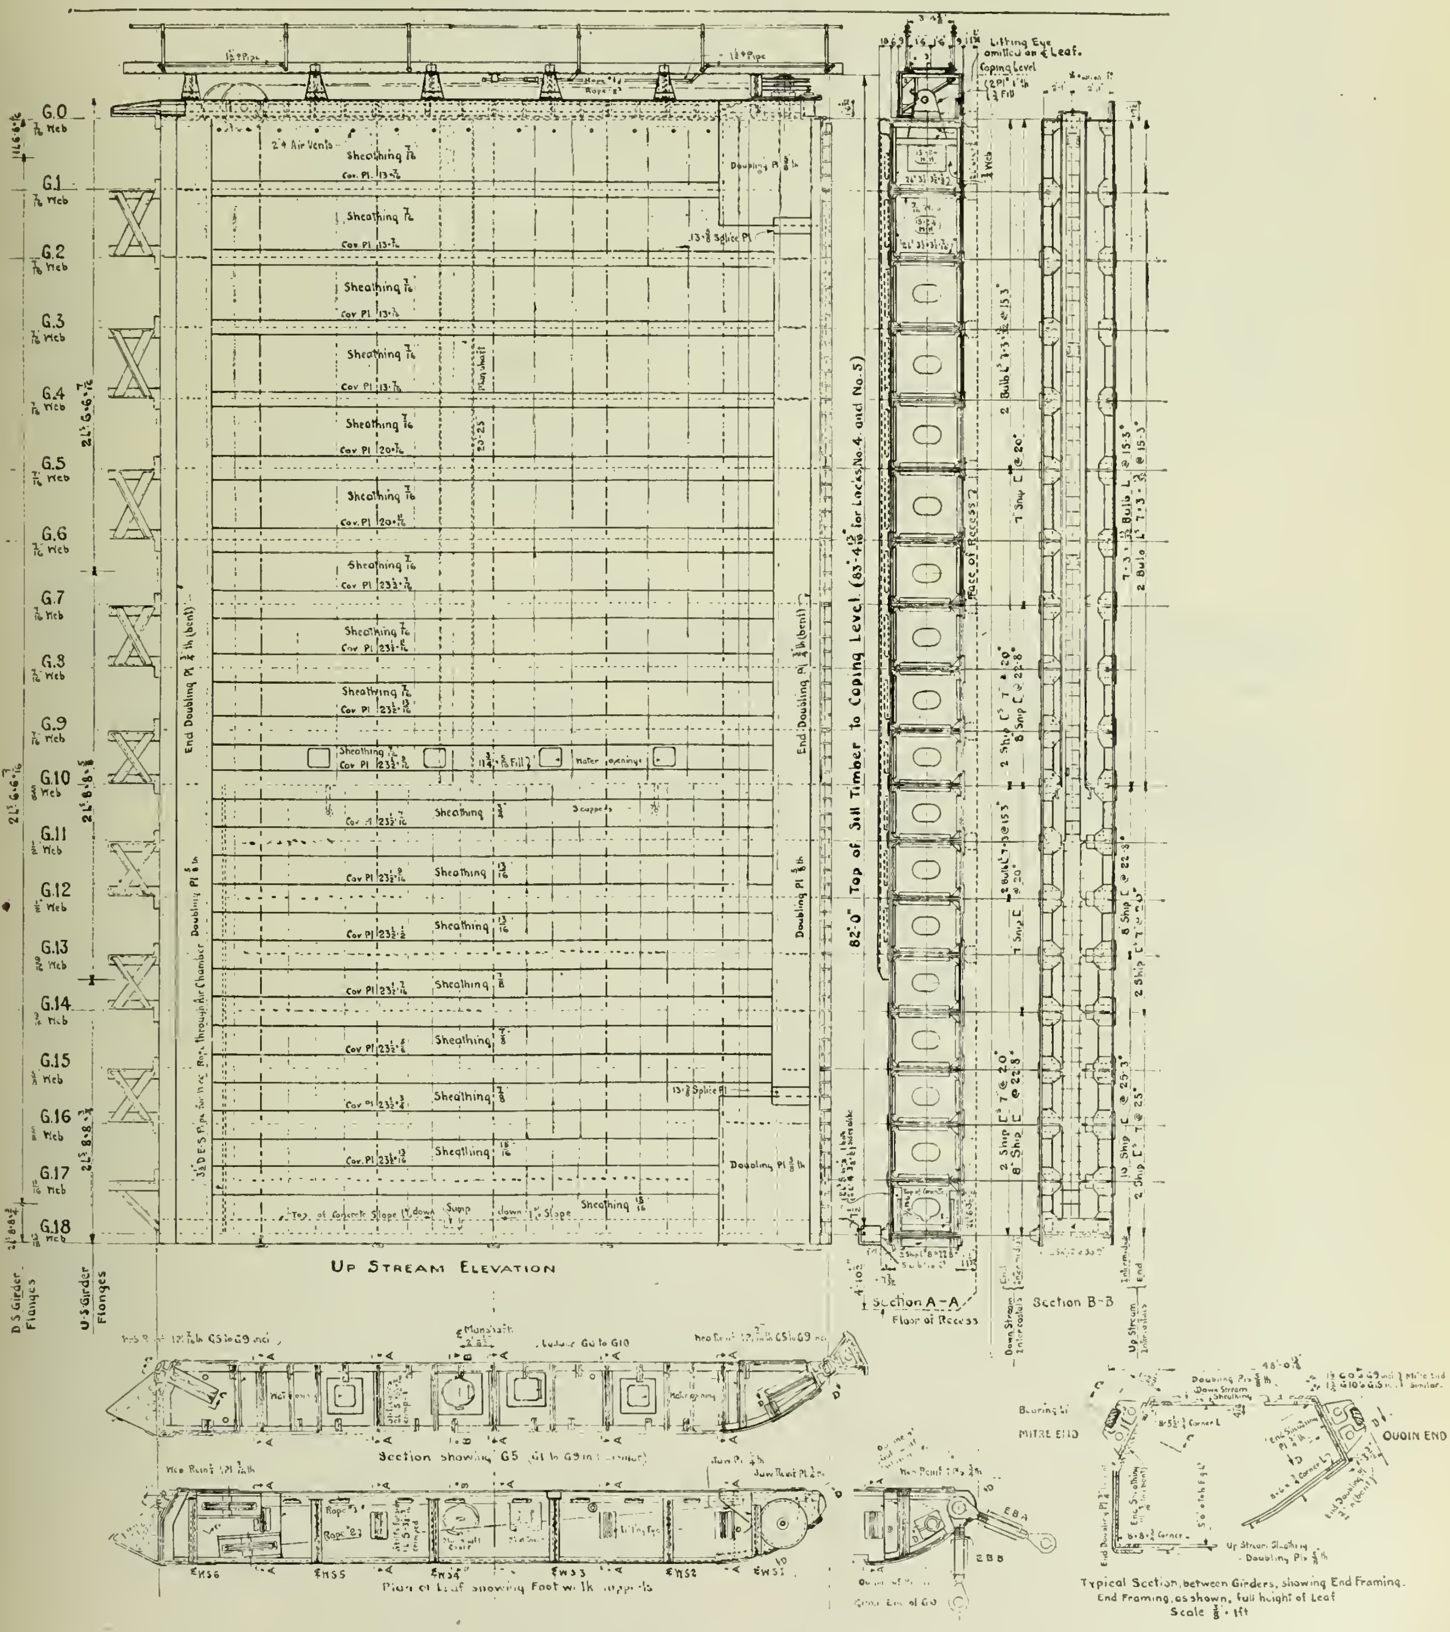

Figure No. 4.—Steel Gate Leaf 82′ High.

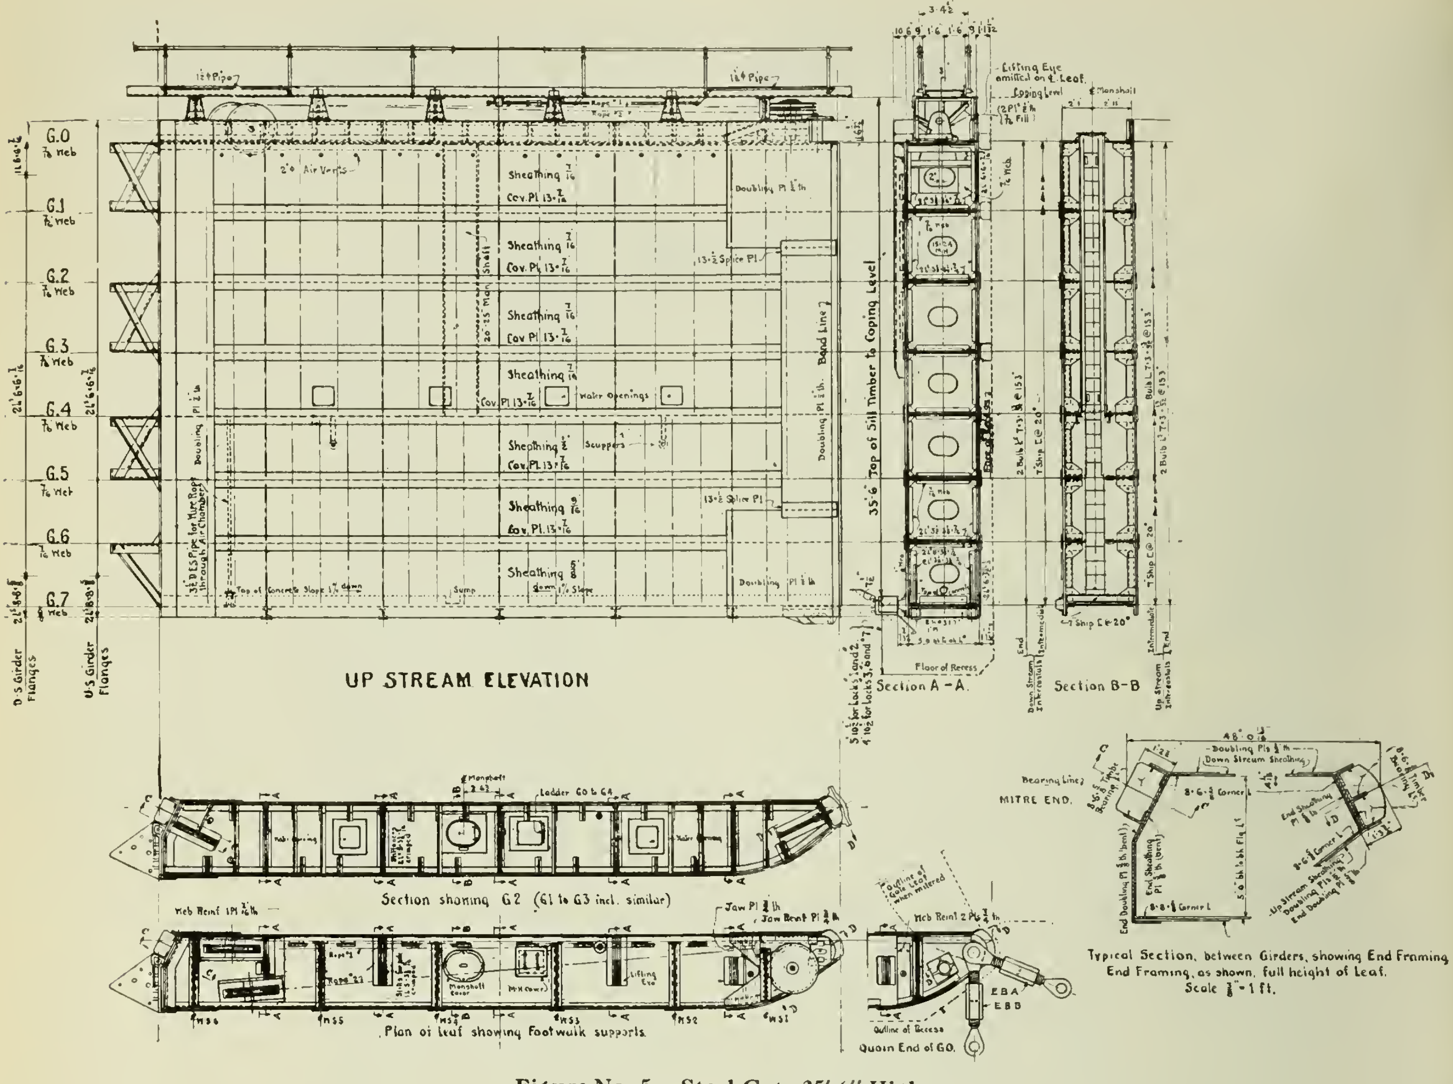

Figure No. 5.—Steel Gate 35′ 6″ High.

the water chamber. Large openings are provided through the upstream sheathing plates, and through the webs of the girders in the water chamber, to permit the free entrance and exit of water so that the water level in this chamber will always be nearly the same as that of the water on the upstream side of the gate. There are vents in the upstream sheathing near the top girder to permit the passage of the displaced air. A manhole is provided in the top girder, in line with one of the water openings in the girders below, and a ladder extends from the top to the bottom of the water chamber at this point to give access to the interior of the chamber for inspection, etc. Access to the air chamber is provided by means of a watertight manshaft extending through the water chamber from the top girder of the leaf to the top of the air chamber. There is a manhole opening in each girder in the air chamber opposite the manshaft, and the ladder in the manshaft is continued down to the bottom of the air chamber. The openings in the top girder for the manhole and manshaft are fitted with watertight covers. To enable the air chamber to be ventilated when the leaf is unwatered for painting, etc., an opening with a removable watertight cover is provided through the downstream sheathing in the bottom panel of the air chamber. The bottom of the air chamber will be covered with a layer of light weight concrete made with burned clay aggregate. The top surface of the concrete will be above the tops of the channel stiffeners of the bottom girder and will be finished to slope from all directions toward a sump formed in the concrete vertically under the manshaft where a small pump can be readily lowered into it for pumping out leakage water.

End Bearings

The end bearings have two functions: (1) to transmit to the lock wall and to the mating leaf the reactions from the water load upon the leaf, and (2) to make a watertight joint at these lines of contact. For the gates 35 feet 6 inches and 44 feet 6 inches high, the end bearings, as shown in figure No. 6, consist of white oak timbers. Each bearing is formed of two timbers, the mitre bearing face being flat and 21½ inches wide. The quoin bearing face is cylindrical of 20½-inch radius and 25¼ inches wide measured on the chord. The hollow quoin bearings consist of iron castings embedded in the concrete of the lock walls and having concave bearing faces smoothly finished to a radius of 20½ inches. For the gates 82 feet high the bearing pressure is so heavy that timber bearings cannot be used. For these gates the bearings, shown in figure No. 7, consist of heavy wrought steel bearing pieces 8 inches wide by 3½ inches thick, supported in recesses in steel castings bolted to the ends of the leaf and bearing, at the quoin end, upon similar steel bearing pieces 12 inches wide by 3¼ inches thick, supported in recesses in the steel quoin castings riveted to the structural steel quoin bearing members, which are embedded in the concrete of the lock wall. The mitre bearing faces are slightly convex of 16 feet radius. The quoin bearing faces on the gate are convex of 18½ inches radius, while on the lock wall they are concave of 20½-inch radius. The bearing faces are accurately finished, and the bearing pieces are adjustable in their recesses in the castings, so that their finished faces can be set to a true straight line from the top to the bottom of the leaf, notwithstanding any slight inaccuracies there may be in the alignment of the castings after erection. . The spaces between the bearing pieces and the castings will be filled with shims planed to the required thickness.

The quoin bearing members, which are embedded in the hollow quoins of the high gates to distribute the gate reactions over the concrete, consist of a pair of structural steel plate girders placed vertically, with their webs, in the plan view, as shown in figure No. 7, lying along the two sides of an isosceles triangle having its apex at the centre of bearing. The forward flanges of the plate girders are close together and are riveted to the vertical line of steel castings which support the bearing pieces. The rear edges of the plate girders are connected by a curved saddle plate which transmits the reaction to the concrete. The object of this design is to distribute the pressure to the concrete as uniformly as possible. The end posts are vertical members composed of plates and angles, extending from top to bottom of the leaf at each end. In order to tie the leaf thoroughly together vertically it was desired to have all parts of the end posts continuous without splices. It was necessary, however, to splice the plates in the end posts of the gates 82 feet high. For these gates, the outer plates of the end posts were designed to be bent to a trough section to enclose the whole end of the leaf, and preliminary inquiries indicated that this would be practicable. The contractor, however, was unable to get these plates bent accurately to the required shapes, and was therefore allowed to fabricate them by electric welding separate flat plates along the bend lines. This procedure was also adopted for the bent plates in the mitre end posts of the gates 35 feet 6 inches and 44 feet 6 inches high.

The end bearing timbers of the low gates, and the steel castings which support the steel bearing pieces of the high gates, are bolted directly to the end posts. The end reactions are transmitted through the end posts to the horizontal girders partly by direct bearing on the finished ends of the

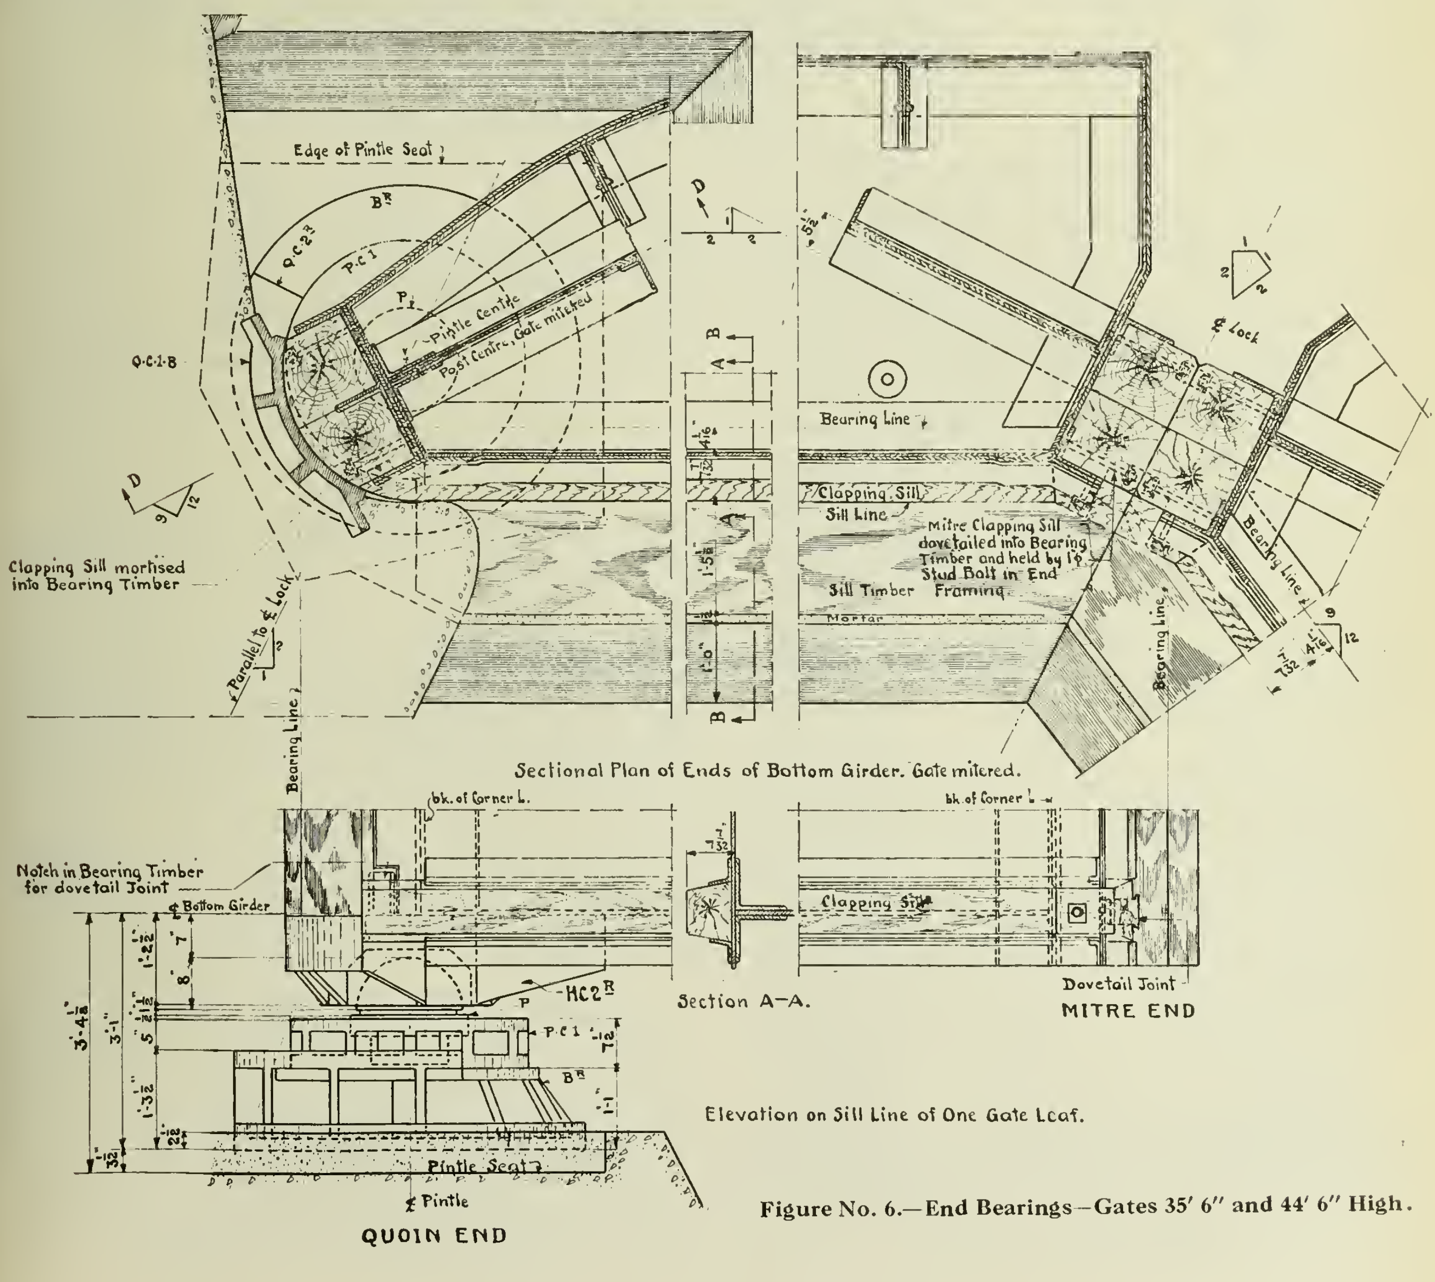

Figure No. 6.—End Bearings—Gates 35′ 6″ and 44′ 6″ High.

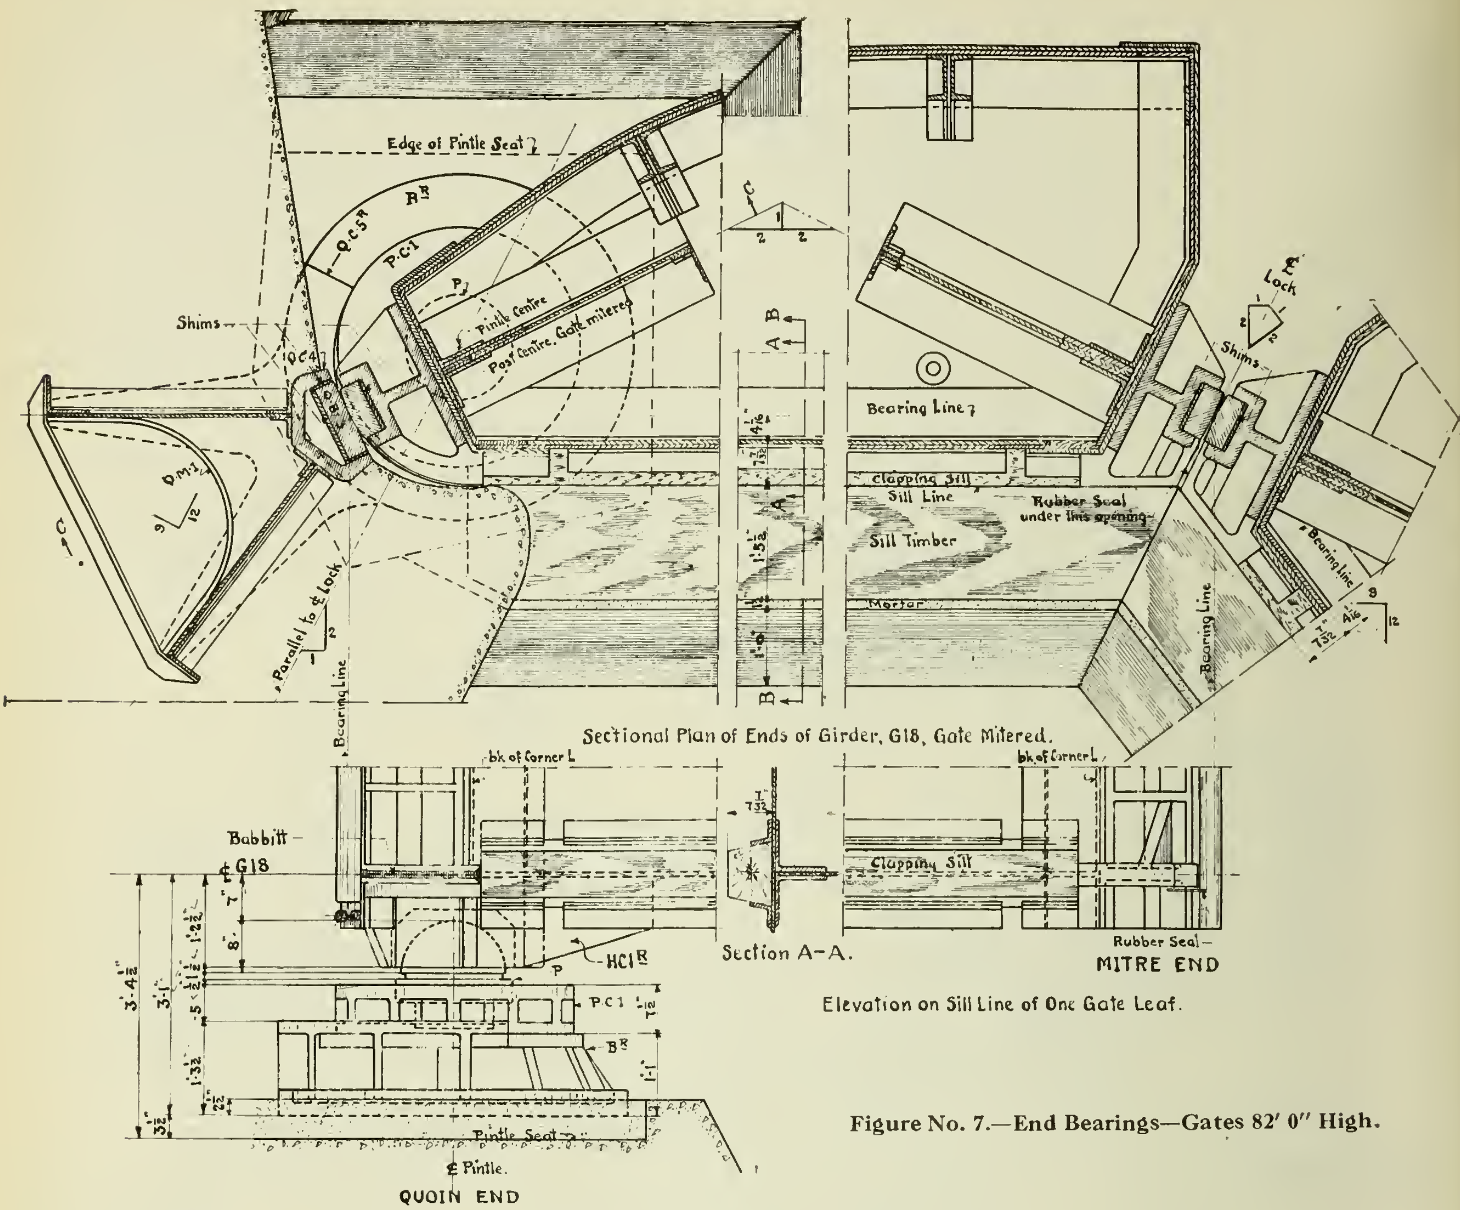

Figure No. 7.—End Bearings—Gates 82′ 0″ High.

girders, partly through the upstream and downstream sheathing, and partly through vertical diaphragms framed between the girders.

Sills

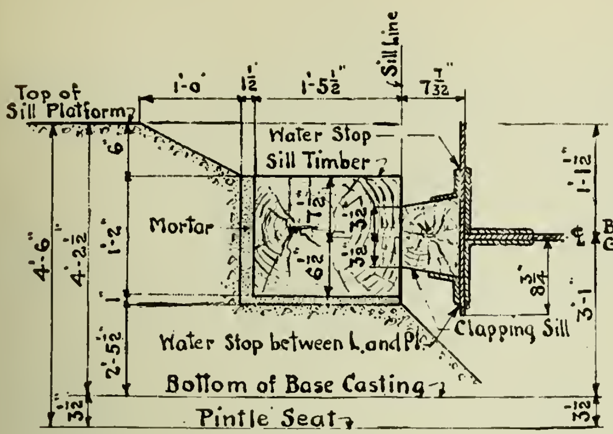
The sills of the gate, like the end bearings, serve to transmit to the lock floor a portion of the water load upon the gate as well as to make a watertight joint along the bottom of the gate. The clapping sills upon the gate leaves, and the fixed sills on the lock floors, are white oak timbers finished to true surfaces along their faces of contact. Figure No. 8 shows the cross-section of the sills. The fixed sill is 14 by 17½ inches and is placed with its short side vertical. The bearing face of the clapping sill is 7 inches wide. The sills for gates of all different heights are the same.

Pintle

A heavy steel heel casting is bolted to the bottom of the leaf at the quoin end. In the bottom of the heel casting, a bronze bushed socket is provided to fit and turn upon the 16-inch diameter hemispherical top of the forged nickel steel pintle mounted in the pintle casting, which is seated upon the base casting embedded in the concrete. Figure No. 9 shows the assembly of the pintle of the gates 82 feet high. The unit bearing pressure on the pintles of these gates is 6,000 pounds per square inch in the dry and 3,000 pounds per square inch under operating conditions in the wet. As the pintles are made the same size for all gates, the bearing pressures in the case of the other gates are less than for the high gates. The pintles are placed 2 inches eccentrically from the centre of the cylindrical bearing faces of the hollow quoins, so that as the gate opens the quoin bearings will swing out of contact, thus reducing the wear upon the bearing surfaces.

Anchorage

The upper hinge pin, 10 inches in diameter, is supported vertically over the pintle in slotted holes in the web of the top girder and in the jaw plate mounted above it. The pin turns in bronze bushings in two anchorage links placed one above the other. The maximum pressure on the bearings will be 4,200 pounds per square inch for the gate 82 feet high in the dry and 2,100 pounds per square inch for this gate under operating conditions in the wet. Figure No. 10 shows the arrangement of the anchorage. The lower anchorage link is at right angles to the centre line of the lock,



Section -B- B.

Figure No. 8.—Cross-Section of Sill.

and the upper one makes an angle of 22° 37′ with the lock centre line. A heavy guide plate is bolted to the top of the pin, and firmly keyed to it by means of a projecting rib formed on the top of the pin which fits a slot cut in the guide plate. The guide plate is free to slide in guides mounted on the top of the jaw plate parallel to the slotted pin hole. This prevents the pin from rotating with reference to the gate, which, experience has shown, there is a strong tendency for it to do when double anchorage links as described above are used, but leaves it free to slide forward when the gate leaf is forced back into the hollow quoin under water load. Each anchorage link has a pin connection to a structural steel anchor embedded in the masonry and the length of each link is made adjustable, by means of a differential turnbuckle, to compensate for any slight errors in the setting of the structural steel anchors. The anchors are generally of the form shown in figure No. 10, but special anchors are required for some special cases.

Fenders

Oak fenders are provided on the downstream side of the leaves to protect them in the open position from contact with ships entering and leaving the locks. When the leaf is in its recess, the surface of the steel work at its downstream side lies approximately 10 inches back from the plane of the face of the lock wall, and the outer surface of the fenders lies about one inch back from the same plane. Each leaf has a horizontal fender 13½ inches wide, placed with its upper edge in line with the web of the top girder and extending over nearly the full length of the leaf. Below the horizontal fender are five lines of vertical fenders 11 inches wide, placed on the lines of the five vertical frames and extending from the horizontal fender to a distance of about 15 feet below the level at which the surface of the water will normally be when the gate is open. At all points where the vertical fenders cross the horizontal girders, they are supported laterally by a tapered oak block at each side, resting against a steel angle bracket riveted to the steelwork of the leaf. To protect the footwalks of the gates 35 feet 6 inches and 44 feet 6 inches high from contact with the overhang of passing ships, these gates are provided with an additional horizontal fender placed above the top girder and supported by structural steel brackets riveted to its web plate. This fender is 13½ inches high by 16 inches wide, and its upper edge is placed 19 inches above the web of the top girder.

When the leaf is in its recess its upstream side is about 12 inches clear of the face of the concrete at the back of the recess, in order to facilitate the entrance of water behind the leaf as it moves out of its recess and reduce the force rquired to operate it. To hold the leaf clear of the concrete

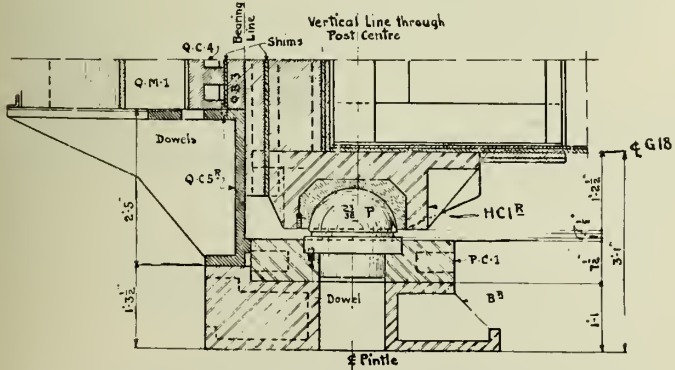


Figure No. 9.—Section Through Pintle.

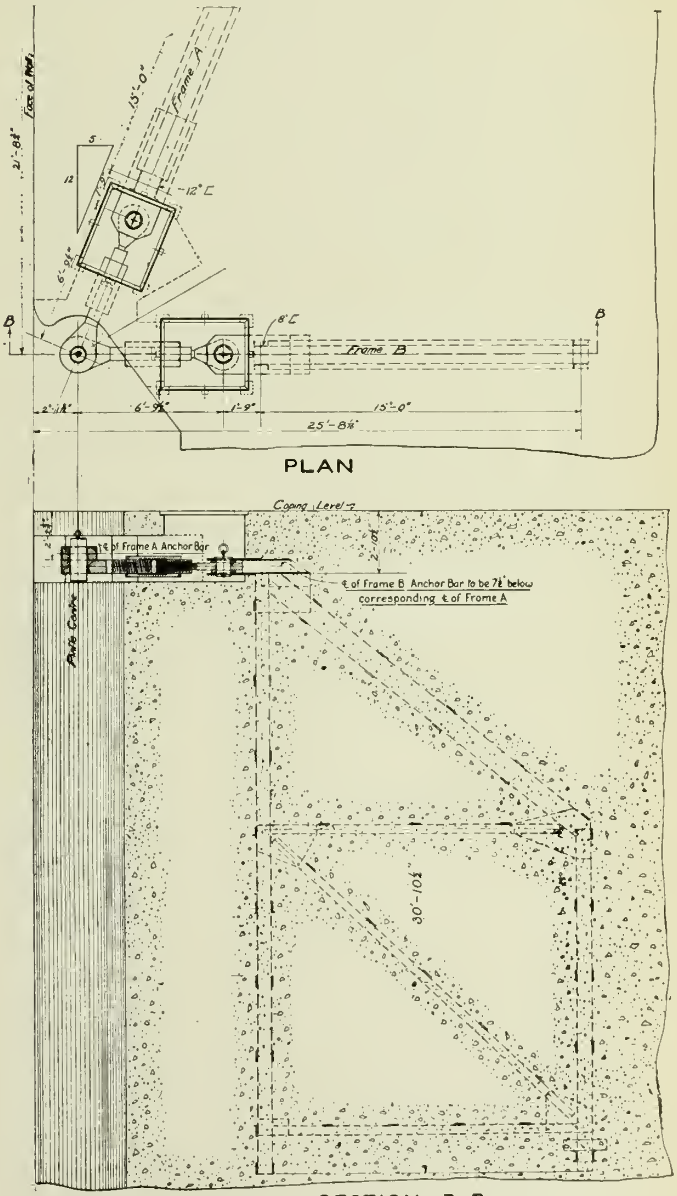

Figure No. 10.—Anchorage.

under pressure from passing ships, horizontal oak timbers 14 inches wide are bolted to the concrete in line with the two upper horizontal girders of the leaf and with the alternate girders below them, down to a level near the lower ends of the vertical fenders on the downstream side of the leaf. The outer faces of these horizontal timbers are finished to fit the surface of the adjacent steelwork of the leaf, the two inner rows of rivets in the girder flanges opposite the timbers being counter-sunk outside, and the corners of the timbers being chamfered to clear the heads of the next two rows of rivets.

Footwalks and Handrailings

The footwalks upon the top of the gates consist of rolled steel checkered plates upon structural steel supports. The walks overlap the coping of the lock walls in order to avoid the necessity of making the quoin end to fit the curved outline of the masonry, as would be required with flush walks. The top of the walk is, however, only 6 inches higher than the top of the lock wall. There is a handrailing at each side of the walk. To prevent the railings from being damaged by contact with the overhang of ships, and to keep them from interfering with the handling of lines along the lock walls, the railings are made collapsible and are designed to fold down automatically to a position below the top of the footwalk stringers whenever the gates are opened. This is done by using a single horizontal handrail and hinging the railing posts to the horizontal handrails at their tops, while at their lower ends they are keyed to tumbler shafts placed transversely under the footwalk, two posts, one at each side of the walk, being keyed to each tumbler shaft. The tumbler shafts are connected to each other by a system of cranks, connecting rods and levers, and this mechanism is connected to one of the anchorage links, so that as the gate is opened the handrailings will be automatically folded down beside the footwalk.

The lower gates of the twin locks Nos. 4 and 5 are 1.4 foot higher than the lower gates of the other locks Nos. 1, 2, 3, 6 and 7, which are all 82 feet high. These gates 83.4 feet high are made the same as the gates 82 feet high in all respects, except that the structural steel supports for the footwalk are 1.4 foot higher, and a vertical shaft in the mechanism connecting the handrailings to the anchorage is 1.4 foot longer. This means that these gates have 1.4 foot less freeboard above normal water level than the other gates. The smaller freeboard is, however, decidedly advantageous for the gates in the lower locks of the flight, which are exposed to the danger of over filling through faulty operation of the valves, as it gives them a greater spilling capacity without flooding the lock coping.

Should a gate be so injured in service as to require it to be sent to the gate yard for repairs, one of the spare gates would be brought from the gate yard and set in the place of the damaged gate in the lock. For this purpose, the department will use a heavy floating crane designed especially for this service, and capable of lifting the heaviest leaf without the aid of the buoyancy of the air chamber. To provide means for attaching the lifting tackle of the crane to the gate leaf, each leaf is furnished with four heavy lifting eyes projecting above the top horizontal girder and placed one at each of the four lines of vertical frames nearest the ends of the leaf. In general, gate leaves will be transported to and from the gate yard floating upon the water. To enable this to be done, removable watertight covers will be provided for all openings into the water chamber. To enable the gate leaf to be jacked up in its recess sufficiently to permit of the inspection of the bearing surface of the pintle, suitable jacking beams are provided upon the bottom of the leaf.

Design

Materials

Mild steel meeting the requirements of the Standard Specifications for Structural Steel for Bridges of the American Society for Testing Materials was adopted for all structural steelwork in the gates.

In order to reduce the number and size of the bolts required for bolting the end bearing castings and safety castings to the leaves, a heat treated alloy steel conforming to the American Society for Testing Materials Standard Specifications for Carbon Steel and Alloy Steel Forgings, class *L*, was specified for these bolts. For the quoin and mitre bearing pieces of the high gates, rolled carbon steel bars conforming to the requirements of class *E* of these specifications were used, but nickel steel forgings, class *H*, were adopted for the pintles and for the pins supporting the sheaves for the operating cables.

Vanadium steel, of 80,000 pounds per square inch ultimate strength, was specified for the heel castings of the gates, but for all other steel castings, including the quoin and mitre bearing castings and the safety castings, medium carbon steel in accordance with the standard specifications of the American Society for Testing Materials was used. Heat treatment of all steel castings was required. Cast iron was used only for a few minor parts.

Phosphor bronze, American Society for Testing Materials, class *A*, was used for the pintle bushings, and class *B* for the upper anchorage pin bushings and for the bushings and journal bearings of the operating rope sheaves.

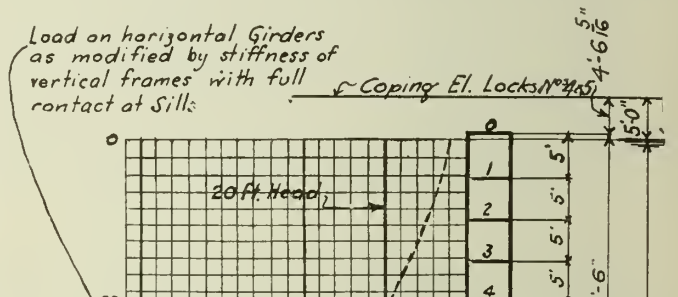

Figure No. 11.—Assumed Load Diagram.

Loads

All gates of the same height are designed to be interchangeable and to be good for the loads which may come upon them in any location in which they could be used.

In order to avoid unduly light construction near the top of the gates, where the theoretical water load decreases toward zero at the assumed level of the upper pool, the water load upon the upper 20 feet of the gate was arbitrarily assumed to be that due to a uniform head of 20 feet. This gives the gates increased strength at the top, where ships are most likely to come into contact with them.

The distribution of the water load to the horizontal girders depends, of course, upon the amount of load transmitted to the sill. As a basis for the design, it was assumed that the extreme conditions in this respect will be (a) no load transmitted to the sill, and (b) full contact at the mitre with no deflection of the bottom girder. Under the latter condition, the vertical stiffness of the leaf will relieve the horizontal girders near the bottom of the leaf of a portion of their load and transmit it, principally to the sill, and partially to other girders higher up the leaf.

In the gates 35 feet 6 inches and 44 feet 6 inches high, the girders whose loads are increased by the vertical stiffness are those near the top of the leaf, and the increase is more than covered by the assumption of a uniform head of 20 feet over the upper part of the leaf. For these gates, therefore, the effect of the vertical stiffness did not govern the design.

In the gates 82 feet high, however, the vertical stiffness, in addition to slightly increasing the loads upon the two upper girders of the leaf where the increase is amply covered by the assumed uniform 20-foot head, also increases the loads upon girders Nos. 7 to 13 inclusive, which are well below the 20-foot zone. For these girders, therefore, the condition of no deflection at the bottom girder governed the design. Figure No. 11 shows the load diagram used for the design of the gates 83.4 feet and 82 feet high.

In order to avoid the lengthy and laborious computations necessary to determine the increase in the girder loads by the elastic theory, the results of the elaborate studies made upon this feature of the design of the gates for the Panama Canal* were used, and applied to the gates of the Welland ship canal by interpolation. As the gates of the two canals are of the same type, have the same angle of sill, and practically the same thickness in proportion to the width of the lock, this procedure was particularly easy of application.

Studies were made of the amount of eccentricity which could be produced in the reactions at the mitre as a result of faulty mitering and deformations of the leaves under load and temperature changes. For the high gates with steel bearings an eccentricity of 3½ inches up or down stream was assumed as a basis for the computation of stresses, and for the gates with timber bearings an eccentricity of 8 inches was taken.

Methods of Design

In the design of the horizontal girders the flange areas were assumed to be concentrated at the backs of the flange angles and to be composed of one-eighth of the web plate, the flange angles, the cover plate and those portions of the sheathing plates which lie between the outside rows of rivets in the cover plate and beyond them to a distance equal to twelve times the thickness of the sheathing plate.

The vertical end bearing diaphragms at the quoin end of the leaf were assumed to carry two-thirds of the total end reaction of the panel in question. But at the mitre end of the leaf, where the upstream sheathing can not receive any load directly from the end bearings, the diaphragms were assumed to carry the total panel reactions.

The intercostals were designed as simple beams to carry their full panel loads without assistance from the sheathing plates. Their end connections, however, were made good for the moments which may come upon them.

For the design of the sheathing plates the Bach formula for flat plates was used in the form:

$$t = 0.402\, b \sqrt{a^2 H \div (a^2+b^2)\, S},$$

in which,

t=required thickness of plate, in inches,
a=effective height of panel, in inches,
b=effective width of panel, in inches,
H=head of water at centre of panel, in feet, and
S=allowable working unit stress, in lbs. per square inch.

No rolled steel plates or shapes of less than 7/16-inch in thickness were used except for fillers.

Working Stresses

For the combined bending and compressive stresses in the horizontal girders and the diaphragms, 14,000 pounds per square inch was used as the allowable working stress. For the bending stresses produced by the unbalanced water pressure on the web plates of the girders at the top and bottom of the air chamber a working stress of 14,000 pounds per square inch was allowed in the web stiffeners, but the working stress in the web plates themselves was restricted to 8,000 pounds per square inch, as these plates when carrying this stress will also be stressed by the loads carried by the girder as a member of the framework of the leaf.

The intercostals at the downstream side of the water chamber and the upstream side of the air chamber, when carrying their maximum bending stress due to water pressure on the sheathing, may also be subjected to stress from the vertical bending of the leaf as a whole, and for them a working stress in bending of 11,000 pounds per square inch was used. For the intercostals at the downstream side of the air chamber a working stress of 16,000 pounds per square inch was allowed, as no stress from the vertical bending of the leaf as a whole can be developed when they are carrying their maximum stress, which occurs when the water level on the downstream side of the leaf is at the level of the upper pool. For the high gates this can of course occur only when they are used as the lower guard gates of locks Nos. 6 and 7. The only water loads which can come upon the intercostals at the upstream side of the water chamber are those due to the small head produced by the lag as the chamber fills and empties, and to the few feet of head to which they will be subjected when the leaf is floating upon the water with the water chamber empty. The smallest sections which it is desirable to use for practical reasons are more than ample for these loads.

The working stresses in the sheathing plates due to bending under water pressure were also modified to provide for stresses from other causes to which the plates may be subjected at the same time. At the downstream side of the water chamber the plates are in tension from the horizontal bending of the leaf as a whole when their local bending is at its maximum, and a working stress of 8,000 pounds per square inch was used. The plates on the downstream side of the air chamber, however, receive their maximum stress in local bending when the gate as a whole carries no load, and for them a working stress of 16,000 pounds per square inch was allowed. The upstream sheathing of the

*"The Distribution of Stresses in Mitering Lock Gates, with Special Reference to the Gates of the Panama Canal," by Henry Goldmark. Transactions, Am. Soc. C.E., Vol. LXXI, p. 1621.

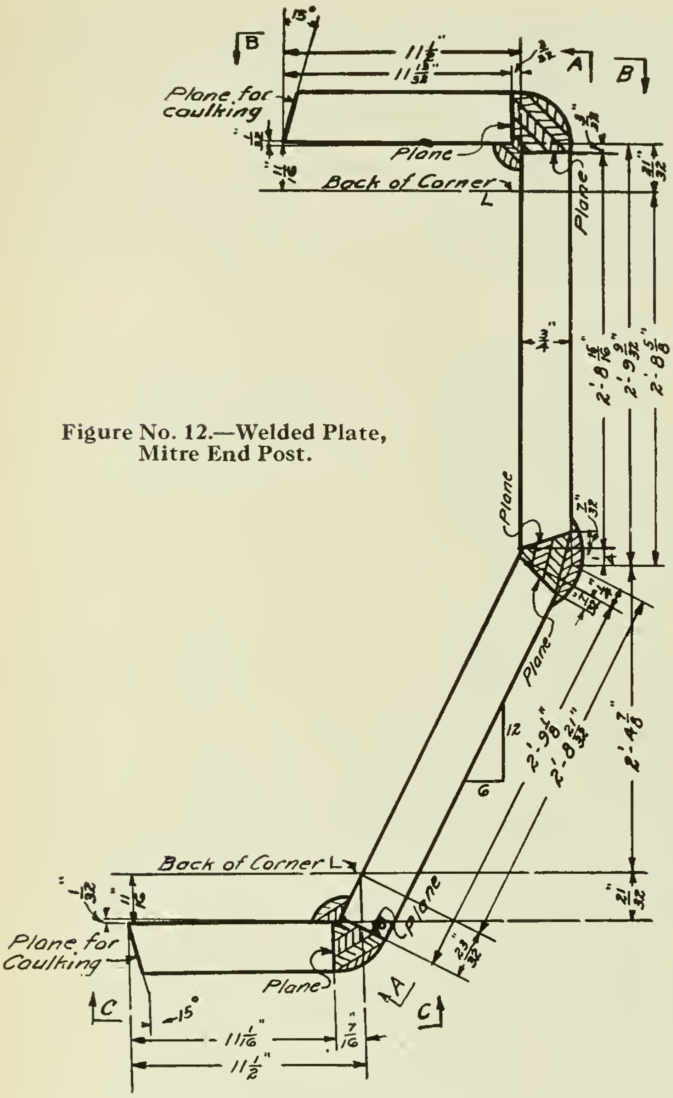

Figure No. 12.—Welded Plate, Mitre End Post.

air chamber will be in compression from the horizontal bending of the leaf as a whole and may also be in compression in the other direction from vertical bending of the leaf, when it carries its maximum stress in local bending. Its working stress was therefore limited to 5,000 pounds per square inch. For the upstream sheathing of the water chamber the adopted minimum thickness of 7/16-inch is ample for any calculable loads.

The allowable working stress in shear on the webs of girders, diaphragms and intercostals was taken as 9,000 pounds per square inch. For shop rivets, working stresses of 11,000 pounds per square inch in shear and 22,000 pounds per square inch in bearing were used, while for field rivets the corresponding stresses were 9,000 and 18,000 pounds per square inch. For rivets in tension a working stress of 8,000 pounds per square inch was allowed. All of the rivets which connect the downstream sheathing of the water chamber to the frame of the gate will be in tension. This is standard practice in double sheathed gates and has been found to be entirely satisfactory.

Fabrication

In general the fabrication of the structural steel work is being done by the methods usually employed in modern shops. Some special features may, however, be noted.

It is, of course, important that all of the horizontal girders of a leaf should be of exactly the same length between the finished surfaces at their ends which bear against the end posts, and that these surfaces should be finished accurately to the proper angle with reference to the centre line of the girder. It is also important that the girders should be of exactly the proper depth back to back of flange angles at their ends which fit between the flanges of the end posts. The girders are therefore assembled with their ends set in cast iron frames or jigs which hold the flange angles to their proper distance apart. Each jig has two reference points 4 feet apart on a line at right angles to the girder centre line. By taking accurate tape measurements from each reference point on one jig to both of the reference points on the other jig they are carefully set in proper position relatively to each other for the assembly of each girder. The jigs when properly set are used as templates, by means of which a group of reference holes are drilled in the outstanding legs of the flange angles at each end of the girder on both the upstream and the downstream side.

The ends of the girders are planed, and the rivet holes for the connection of the end bearing diaphragms are drilled to steel templates having hardened steel nose pieces along the edge to which the ends of the girders are to be planed. These templates are connected by suitable castings to the bottom of a rigid trussed steel frame 48½ feet long, 5 feet wide and 5 feet 4 inches deep, which holds them in the proper relative position. The trussed frame also carries upon its under side castings shaped to fit around the ends of the girder and having holes to match the reference holes drilled in it from the jigs in which it was assembled.

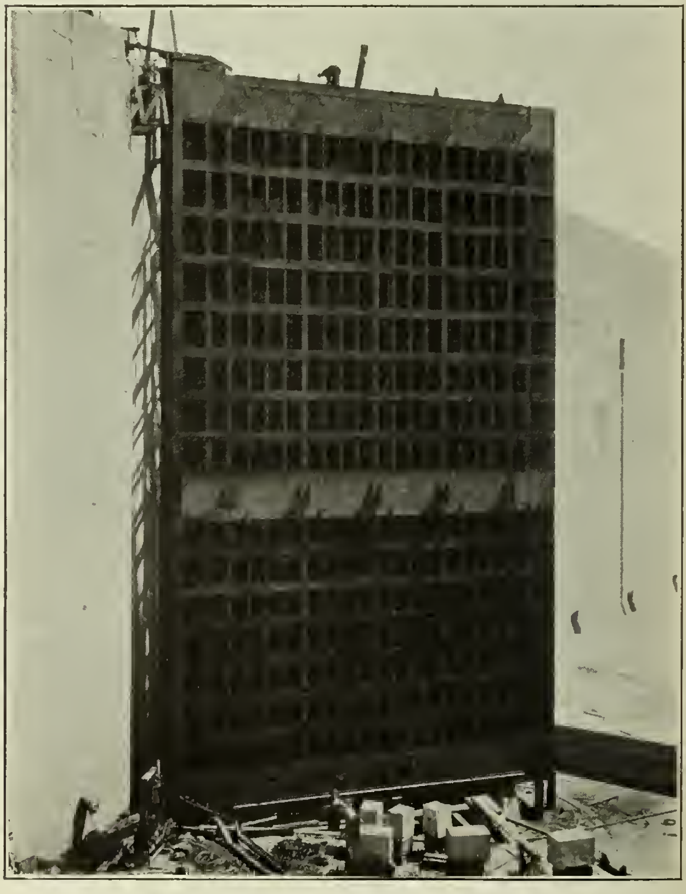

Figure No. 13.—East Leaf, Lower Gate, Lock No. 1.

Therefore when the trussed frame is set upon a girder and adjusted so that the reference holes in its castings match the reference holes in the flanges of the girder, the steel templates must be in proper position with reference to the girder and to each other. The templates are then firmly bolted to the girder for use in planing and drilling the ends after the removal of the carrier frame with its castings.

The most unusual feature of the work in the shop is the fabrication of the bent plates for the end posts by welding separate flat plates together along their edges by means of the electric arc. Figure No. 12 shows typical details of the welded joints in one of the plates for the mitre end post of the gate 82 feet high. The plates are assembled for welding by bolting them to transverse frames of the required outline, spaced about 3 feet centre to centre, and set in accurate alignment with each other upon concrete foundations. Two series of frames are provided, one for the quoin posts and one for the mitre posts. The transverse joints are welded first, and the longitudinal welds are made afterwards, working from one end of the post toward the other. Four courses of welding are used in building up the welds to the required thickness and an additional bead is applied from the inside of the post on some of the joints. The joints are tested by chipping out the weld at two points selected at random. The rivet and bolt holes are drilled after the plates are welded. Owing to the longitudinal contraction due to the welding, the holes required for bolting the plates to the frames do not always remain in their proper location, and some of them have to be welded up and redrilled. The welding of the first end posts progressed slowly, about 270 man-hours being required to weld one quoin post for the 82-foot high gate, and 440 man-hours to weld one mitre post. Considerably better progress is expected in the future.

Some difficulties were found at first in opening out the angles for the end posts. The legs of the angles, instead of remaining flat, tended to curve outward. This was overcome by rounding the outside corner of the angle to a curve concentric with the fillet at the root and by using dies which applied the flaring pressure close to the root of the angle. There was also a tendency for the angle as a whole to curve and twist instead of remaining straight. By going over the angle from end to end several times and opening it out only a small amount each time this tendency was so much diminished that, by carefully straightening the angle whenever a slight twist or curve was produced, satisfactory results were obtained.

Erection

The gates are being erected upright in the locks, each leaf being placed at an angle to the lock wall with the quoin end pointing toward its hollow quoin and at a distance of about 4 feet from it. This is done in order to leave sufficient working space between the steelwork and the lock wall at the upstream side of the leaf and around its quoin end. Figure No. 13 shows the east leaf of the lower gate of lock No. 1 partially erected, and figure No. 14 the west leaf of the lower gate of lock No. 5.

The gate leaves are erected upon temporary concrete pedestals set upon the floor of the lock and so made that they can be removed bodily when the erection of the leaf is completed and used over again for other leaves. The bottom girder is set upon these pedestals and carefully leveled up by wedging so that the accuracy of the erection of the remainder of the leaf can be checked by plumbing. When the erection is completed the leaf will be jacked up and the pedestals removed, their place being taken by roller tracks and treads carrying special screw operated lowering wedges. The leaf will then be set upon the lowering wedges, rolled back into the hollow quoin on the rollers, and lowered on to its pintle by means of the wedges. The upper hinge pin can then be connected to the anchorage, the rollers and wedges removed, and the leaf swung in its final position.

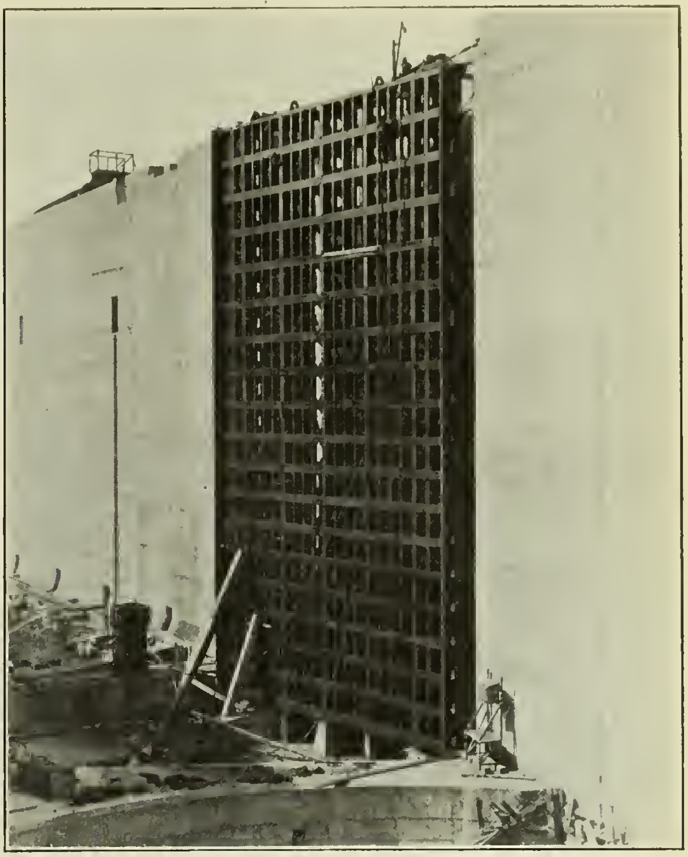

Figure No. 14.—West Leaf, Lower Gate, Lock No. 5.

At most of the locks access by rail can be provided with reasonable ease only to one side of the lock, usually the west side. At these locks, therefore, the east leaf of a gate is being erected before the west leaf, the materials being handled from cars on the west side of the lock into position in the leaf near the east side of the lock chamber by means of a Chicago boom mounted upon the pintle and tied back to the anchorage of the west leaf. When all materials for the east leaf are in place the Chicago boom is taken down and the erection of the west leaf proceeded with, using a locomotive crane operating on the tracks at the west side of the lock for handling the materials. Figure No. 15 shows the Chicago boom in use at lock No. 2.

At the twin locks No. 5, however, rail communication is available to both side walls and to the centre wall as well and the lower gates of these locks are being erected entirely by means of locomotive cranes.

In the erection of the steel bearing plates for the high gates, the alternate plates of a line of bearing plates are first set in place in the recess in the bearing castings and accurately adjusted to their proper positions by means of the bolts and set screws provided for the purpose. The spaces between these bearing plates and the castings are then accurately measured by micrometer calipers at the four corners of each plate. These measurements furnish the information necessary for planing the steel shims, not only for the plates which were set in place but for the intervening plates as well, since all of the plates have been machined accurately to the same thickness. For planing, the shims are bolted to a special adjustable bed plate by means of which they can be finished to any required taper or wind. The alternate bearing plates originally adjusted in place in the bearing castings have, of course, to be removed to enable the line of planed shims to be erected, after which the entire line of bearing plates is finally erected and bolted firmly in place upon the shims.

The biggest single item of the work of erection of the gates is the field riveting. There are over forty thousand field rivets in each leaf 82 feet high, twenty thousand in each leaf 44 feet 6 inches high and sixteen thousand in each leaf 35 feet 6 inches high.

Cost

The cost of one leaf 82 feet high erected in place, including the cost of all materials and labour, but not including the cost of engineering and inspection, or the cost of its operating machinery, is given in table No. 3, the cost of the moving leaf being shown separately from the cost of the pintle, anchorages, reaction bearings and other parts which do not move with the leaf. The cost of one leaf 83.4 feet high is only $69.12 more than the cost of a leaf 82 feet high, the difference being entirely in the cost of the moving leaf.

The cost of the leaves 44 feet 6 inches and 35 feet 6 inches high are given in tables Nos. 4 and 5 respectively in the same manner and covering the same features of the work as given for the leaf 82 feet high in table No. 3.

Figure No. 15.—Chicago Boom Erecting East Leaf, Lower Gate, Lock No. 2.

Lock Gate Operating Machinery

The lock gates will be operated by means of steel wire ropes arranged as shown in figure No. 16. There will be two operating ropes for each lock gate leaf, (one for opening it and one for closing it). The former will be attached to a U-bolt built into the masonry of the lock wall at the back of the lock gate recess, and the latter to a similar U-bolt built into the masonry of the lock gate sill near the centre of the lock, both U-bolts being slightly below the level of the bottom of the gate. From these anchorages the ropes will be led horizontally to a pair of sheaves, (one for each rope), mounted upon the bottom of the lock gate leaf near the mitre end. Between the U-bolt anchorages and the gate leaf the ropes will lie against the face of the curved toe wall, shown in figure No. 16, which is concentric with the pintle centre. The sheaves on the bottom of the leaf are set in planes tangential to the face of the toe wall, so that the ropes will lead truly on to the sheaves from the wall in any position of the leaf. Near either end of the travel of the leaf, however, one of the ropes will lose its contact with the circular wall due to the near approach of its sheave to the U-bolt anchor. This will cause the rope to deviate at a slight angle from the plane of the sheave, but the anchors are so located that this angle will in no case exceed 3°. From the sheaves on the bottom of the leaf the operating ropes will be led vertically up through the leaf to two sheaves mounted upon the top girder at the mitre end and thence horizontally underneath the footwalk to a pair of sheaves at the quoin end of the leaf. From these sheaves the ropes will be led horizontally, through a shallow slot formed in the top of the lock wall, to the drums of the lock gate operating machine.

Action of Operating Ropes

When the opening rope No. 1 is placed under tension by the operating machine, the part of the rope between the machine and the sheave near the quoin, and the part between the sheave at the bottom of the leaf and the U-bolt anchorage, exert external forces on the leaf. The former force acts through or close to the pintle centre and produces no appreciable moment tending to rotate the leaf. The latter, however, acts at a radius of about 41 feet from the pintle centre and produces a large moment tending to rotate the leaf toward its open position. Similarly, tension in the closing rope No. 2 produces a large moment tending to rotate the leaf toward its closed position. One advantage of this arrangement of the operating ropes is, that as the leaf moves, the parts of the ropes between the U-bolt anchorages and the sheaves at the bottom of the leaf do not move toward or from the leaf, but these sheaves simply roll along the ropes. There is therefore no tendency for the ropes to be worn by rubbing on the underwater portions of the lock. Another advantage is that, for each leaf, only two sheaves are placed under water.

A third advantage of having the operating ropes arranged as described above is, that the amount to be hauled in on one rope will be very nearly equal to the amount to be paid out on the other rope during the same interval of time over any portion of the travel of the gate leaf. There will, however, be slight variations in the relative travel of the two ropes in different positions of the leaf, due to the movement of the sheaves at the quoin end of the leaf, and to the loss of contact between a rope and the toe wall under the gate leaf, near either end of the travel of the leaf. The amount of these variations are shown by the curves in figure No. 17. Curve No. 1 shows the effect of the movement, away from the operating machine, of the sheaves at the quoin end of the leaf as the leaf moves from the open to the closed position. This movement tends to increase the total length of the two operating ropes. Curve No. 2 shows the compensating effect of the unwrapping of the operating ropes around these sheaves, which tends to decrease the total length of the two ropes. Curve No. 3 shows the combination of these two effects. Curve No. 4 shows the effect of the loss of contact of one rope with the toe wall near either end of the travel of the leaf. This tends to increase the total length of the two ropes as the leaf leaves its open position, and to decrease it again, but by a smaller amount, as the leaf approaches its closed position. Curve No. 5 is the sum of curves Nos. 3 and 4 and shows the combined effect of all the above mentioned variations. This curve shows that the aggregate length of both ropes between the operating machine and the rope anchorages has a minimum and a maximum value which differ from each other by about 8¾ inches and which occur at 15 per cent and 100 per cent respectively of the travel of the leaf from its open to its closed position. The difference between this aggregate length of the ropes at either end of the travel of the leaf is 8 inches and is compensated for by making the drum upon which the opening rope No. 1 is wound slightly larger in diameter than the drum for the closing rope No. 2. The effect of the difference in the diameter of the drums is shown by curve No. 6. Curve No. 7 shows the remaining uncompensated variation which amounts to 3 inches of slack rope at each end of the travel of the leaf. This small amount of slack is taken up by means of spring connections between the drums of the operating machine and their driving gears.

Operating Machine

The operating machine is simply a large double drum winch driven by an electric motor through a train of spur

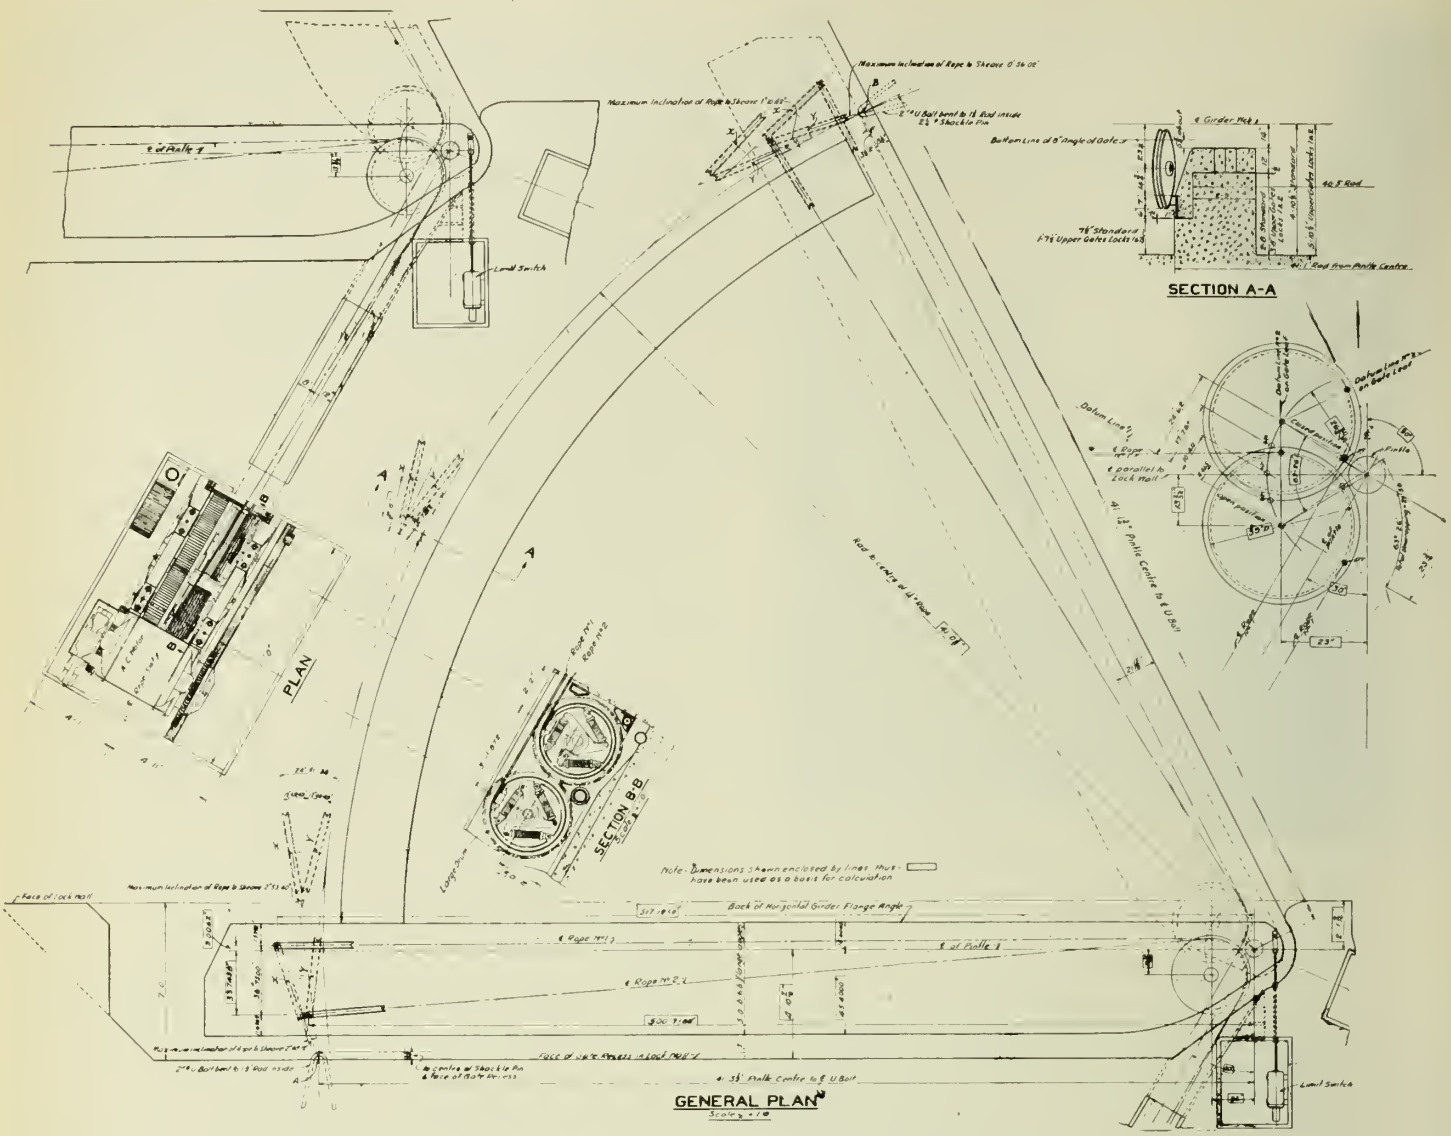

Figure No. 16.—Arrangement of Gate Operating Ropes.

gearing. Figure No. 18 shows the general arrangement of the machine, the motor being omitted in the plan view. A separate drum is used for each of the two operating ropes for the following reasons: (a) to enable provision to be made for the slight variations in the relative travel of the two ropes by making one drum slightly larger than the other, and by permitting slight variations in the relative movements of the drums; (b) to enable both ropes to pay out simultaneously in the event of the gate leaf being carried away by a ship, thus preventing the machine from being subjected to the breaking load of the ropes, and, incidentally (c) to provide a convenient means for taking up slack due to the stretching of the ropes. The two main spur gears which drive the two drums mesh with each other and therefore have a uniform relative motion. The variation in the relative motion of the two drums is provided for by making each drum free to rotate, with reference to its driving gear, under the action of heavy springs acting against the pull of the rope, stops being provided to limit the relative movement of the drum and the gear and to furnish a positive drive for the rope which is operating the gate leaf.

Figure No. 19 shows the drum shaft assembly. There is mounted upon each drum shaft the driving gear, a drive disc, the drum, and a spring spider, arranged in the order named. The drive disc and the spring spider are keyed to the shaft, but the drum and the gear are bronze bushed and made free to rotate upon the shaft. The driving torque is transmitted from the gear to the drum through the drive disc, which is connected to the main gear by means of a single pin in shear passing through holes in the adjacent rims of the two parts. This pin is designed to shear off and release the drum from the gear whenever the tension in the rope exceeds 75,000 pounds. In this way the machine is protected against excessive loads in an accident to the gate. There are six holes for the shear pin in the rim of the gear and 25 in the rim of the drive disc, thus providing for the adjustment of the relative position of the gear and the disc in steps of 0.84 inch at the pitch of the rope. By means of this adjustment any considerable increase in the length of the rope, due to its stretching in service, can readily be taken up. In the rim of the drive disc, on the side adjacent to the drum, a notch is cut, into which projects a heavy steel key dovetailed and bolted into the rim of the drum, the slot being so much larger than the key as to allow the drum to rotate through an angle of 25° be-

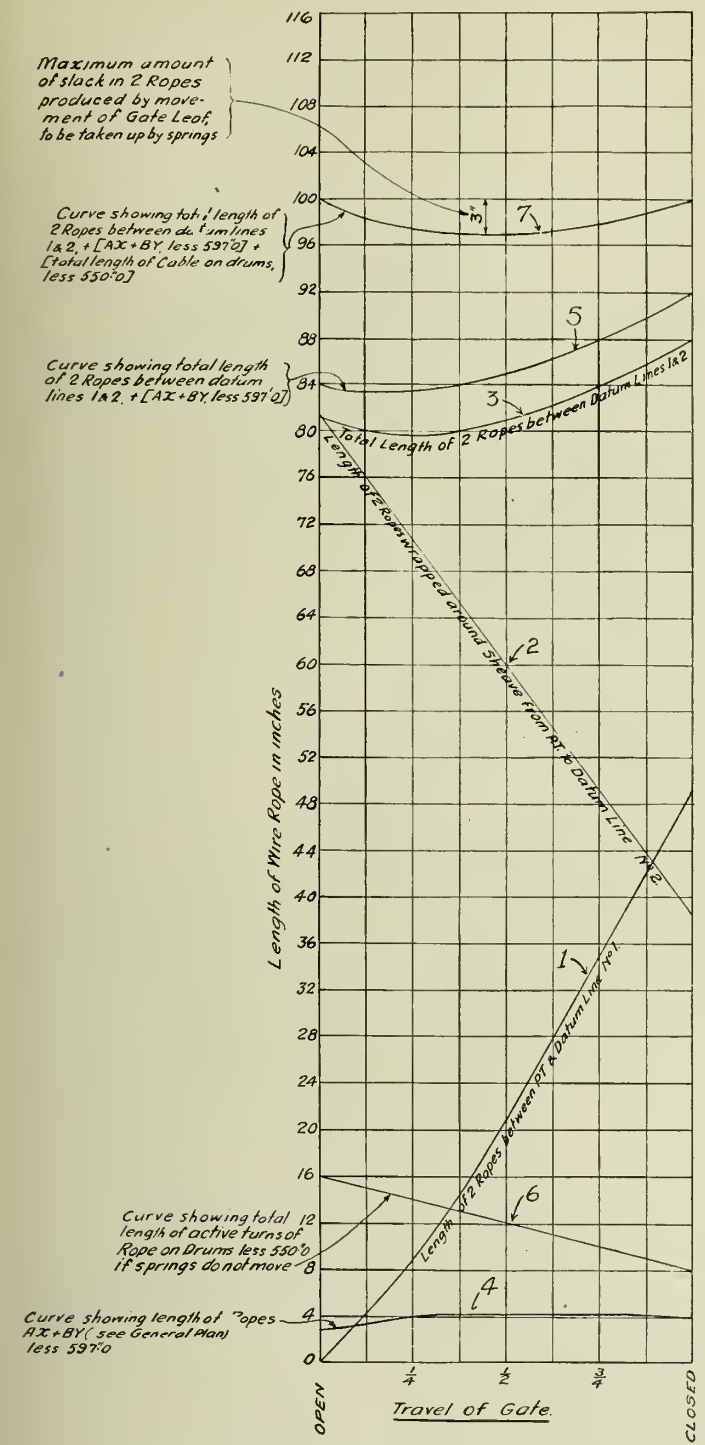

Figure No. 17.—Variations in Rope Travel.

tween the positions of contact of the key with either end of the notch. The other end of the drum overhangs the spring spider and three spiral springs, mounted between the spider and the drum, tend to cause the drum to rotate with reference to the spider in the direction which would wind in the rope. The rope is attached to the drum by means of a clamp bolted to the side of the rim. The clamp anchors the rope securely against a tangential pull, but will allow it to be ripped free from the clamp with comparative ease should the direction of pull have a considerable radial component, as would be the case in the event of all of the rope being unwound as a result of the lock gate being carried away by a ship.

A slip friction is provided in the gear which meshes with the motor pinion. The purpose of this is to prevent any part of the mechanism from being damaged should the gate meet unusually high resistance to its operation due to surges, wave action or the presence of some obstruction in the lock, or should the gate be moved by a head of water, or by contact with a ship when the brake is set.

Under normal conditions the operating machine will open or close the gate in 1½ minute.

The operating ropes are steel armoured wire ropes composed of six strands of nineteen wires each, laid around a hemp centre, each strand being completely covered with an armour of flat steel tape wound around it before being laid up into the rope. The ropes are 1¼ inch in diameter over the armour and have an ultimate strength of 112,000 pounds.

The motor is a 550-volt, three-phase, totally enclosed, wound rotor induction motor with a split frame. Its nominal capacity is 45 h.p. and its synchronous speed, with 60-cycle current, is 600 r.p.m. The motor is equipped with a solenoid brake in order to stop the machine promptly when the gate leaf reaches the end of its travel.

The motor will be operated by remote control from the lock control board, upon which there will be a control handle for each gate leaf. The control handle will have three positions: forward, off and reverse. It will be connected with the motor control panel, located close to the operating machine, by 220-volt control circuits. A control switch is also provided on the control panel to enable the motor to be controlled from that point when desired. The 550-volt power current to the motor will be controlled by magnetic contactors mounted upon the control panel. The motor will be started with resistance in three legs of the secondary circuit, a portion of which will be cut out automatically when the motor has attained the proper speed. The remainder will be left in the circuit to give the motor a slip of about 20 per cent when it is exerting its full load torque. This is done in order to reduce the peak load by causing the gate to move more slowly under heavy load and thus reduce the hydraulic resistances to its motion. The forward and reverse contactors are interlocked so that both cannot be closed at the same time. An inverse time element overload relay and a low voltage protection relay are provided in each of two legs of the circuit which will open all three legs. Upon tripping, either of the relays will reset when the control switch is placed in the off position. The overload relay will be so adjusted that should the gate leaf meet some obstruction in its course which will cause the slip friction to slip, the overload so produced will quickly open the relay and stop the motor.

The motor is automatically stopped and the brake applied, when the gate leaf reaches its open or its closed position, by means of a limit switch operated by direct connection to the heel of the leaf, as indicated in figure No. 16. The limit switch does this by opening the control circuit for the direction in which the gate has been moving, the control circuit for the other direction being opened at the other end of the travel of the leaf.

Timber Gates

The unwatering gates are of solid timber construction, timber being preferred to steel for these gates for the reasons stated previously. The gate at the foot of lock No. 1 is 41 feet high. The three gates at the lower ends of locks Nos. 4 and 8 are 35 feet 6 inches high. The highest timber gate required is that at the head of lock No. 8, which is 44 feet 6 inches high. Figure No. 20 shows the general arrangement of one leaf of the latter gate. The gates 35 feet 6 inches high are of similar construction. The gate 41 feet high for

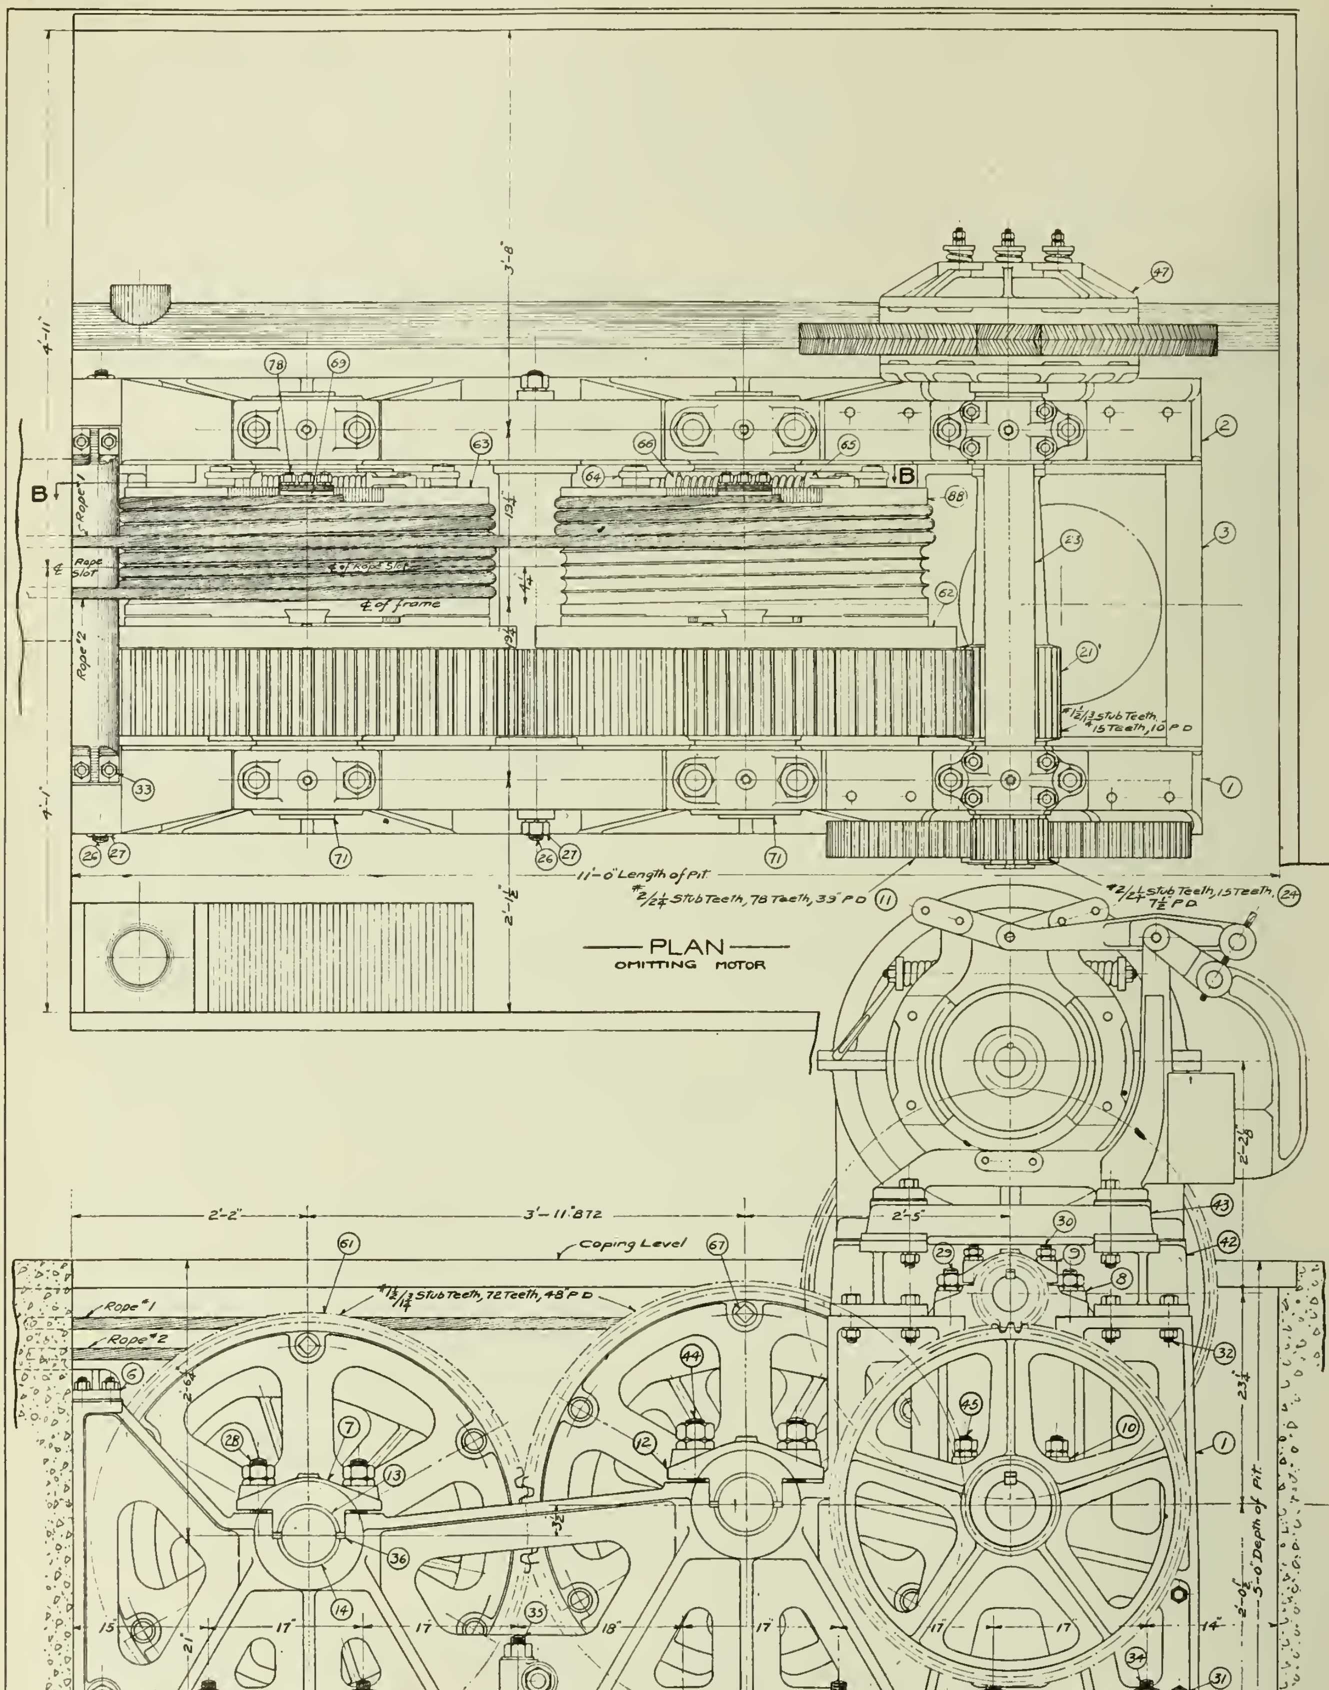

Figure No. 18.—General Arrangement of Gate Operating Machine.

lock No. 1 was built first, and differs from the other gates in a few details which were changed for subsequent gates, as noted hereinafter.

The pintles, anchorages and sills for the timber gates are the same as those for the steel gates. Their bearings in the hollow quoin also are the same as those for the steel gates 35 feet 6 inches and 44 feet 6 inches high, which have timber end bearings. The unwatering gates are not provided with operating machines. They will normally require to be operated only once each year, and this can readily be done by means of lines from the lock capstans. The gates will usually stand open in their recesses, a heavy recess lock being provided near the top of each leaf to anchor it securely to the lock wall and prevent it from being moved by wave action.

Each leaf consists of a series of timber girders of rectangular cross section placed one on top of the other. The downstream sides of all except the bottom girder are in line with each other and form a plane surface. The downstream side of the bottom girder, however, projects 3 inches beyond this surface to meet the fixed sill. The bottom girder of the gate 44 feet 6 inches high is 63 inches deep. The bottom girder of each of the other gates is 60 inches deep. The depth of the top girders of all of the gates is 39 inches. For convenience in construction, the depth of the intermediate girders is not increased uniformly from the top to the bottom of the leaf, but a group of girders all of the same depth is followed by another group of a depth from three to nine inches greater.

Douglas fir was adopted as the material for the girders in order to make it possible to secure sticks of such large dimensions that each girder could be made of one or, at most, two timbers. Girders up to 45 inches in depth are each made from a single stick of timber, but for girders of greater depth two timbers are used. It was somewhat difficult to obtain the considerable number of large timbers required, and some latitude was allowed in the thickness of the timbers furnished, provided that they were of the necessary depth. A few spare sticks were ordered to provide for the possible loss of timbers due to spoiling during fabrication or to the discovery of concealed imperfections. The final detail plans were made after the timbers were received, to suit the thickness of the timbers furnished.

Girders built up of two timbers consist of a large timber running the full length of the girder, reinforced upon its upstream side by a smaller and shorter stick bolted to it to give the required total depth at the centre of the girder, as shown in figure No. 18. The longitudinal shear between the two timbers is carried by steel key castings at the two ends of the shorter timber and by 2½- by 6-inch keys and 4-inch diameter dowels of lignum vitæ. In the gate 41 feet high, these and other keys and dowels are of steel. The quoin ends of the girders are accurately finished to a cylindrical surface of 20½ inches radius to form the quoin bearing of the leaf, and the mitre bearing is formed in a similar manner by finishing the mitre ends of the girders accurately to the required bevel.

The leaf as a whole is firmly bolted together by sixteen long vertical bolts, 2½ inches in diameter, passing through all girders from the top to the bottom of the leaf. There are also four shorter vertical bolts through the upstream timbers of the built-up girders in the lower part of the leaf. The ends of the leaf are stiffened by means of vertical 12-inch steel channel binders placed one at each side of the leaf near each end, and held in place by bolts passing through the leaf. Shear in the horizontal joints between the girders is provided for by means of 4- by 4-inch keys and 4-inch diameter dowels of lignum vitæ. The tendency of the leaf to droop at the toe under its own weight is resisted by two diagonal braces of steel eyebars, one at each side of the leaf, extending from the upper corner at the quoin end to the lower corner at the mitre end. A similar but lighter pair of diagonal eyebar braces is also provided between the upper corner at the mitre end and the lower corner at the quoin end to prevent distortion of the leaf in this direction. The stresses in the eyebars are distributed to the timber at each corner of the leaf by means of a steel cap or shoe, made to fit over the corner, to which the eyebars are connected by means of pins.

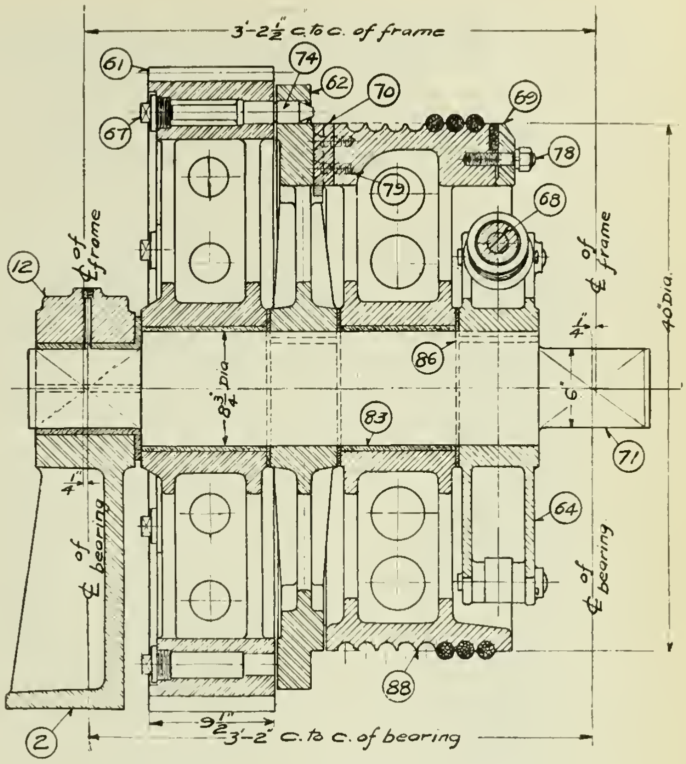

Figure No. 19.--Drum Shaft Assembly.

The shoes at the lower corners of the leaf are of cast steel. The heel casting carries on its under side a bronze lined hemispherical socket to fit the 16-inch diameter pintle. Its rear face is finished to a cylindrical surface of 20½ inches radius to fit the hollow quoin bearing plates. Its downstream surface is flush with the downstream side of the leaf, but has two projecting ribs forming a horizontal dovetail slot into which a short piece of oak clapping sill is fitted. The outer surface of the oak sill is finished flush with the downstream side of the bottom girder and continues the surface of sill contact over that portion of the girder which is cut back to fit inside the heel casting. The sill and mitre bearing surfaces are carried over the mitre shoe casting in a similar manner by means of short pieces of oak fitted into dovetail slots formed on the outside of the mitre shoe castings. The mitre and quoin caps are of riveted structural steel. The mitre bearing, in way of the mitre cap, consists of a strip of oak held in a dovetail slot formed by two vertical angle castings bolted to the cap. In the gate for lock No. 1 the mitre bearing pieces on the mitre shoe and the mitre cap were of cast steel, the bearing faces being finished slightly convex, to a radius of 48 inches. The quoin cap does not cover the quoin bearing surface of the timber girders, but is prevented from sliding forward along the leaf by a heavy rib fitted into a transverse slot cut in the upper surface of the top girder. The quoin cap is provided with heavy horizontal pin plates in which are slotted holes to receive the upper hinge pin of the leaf, which

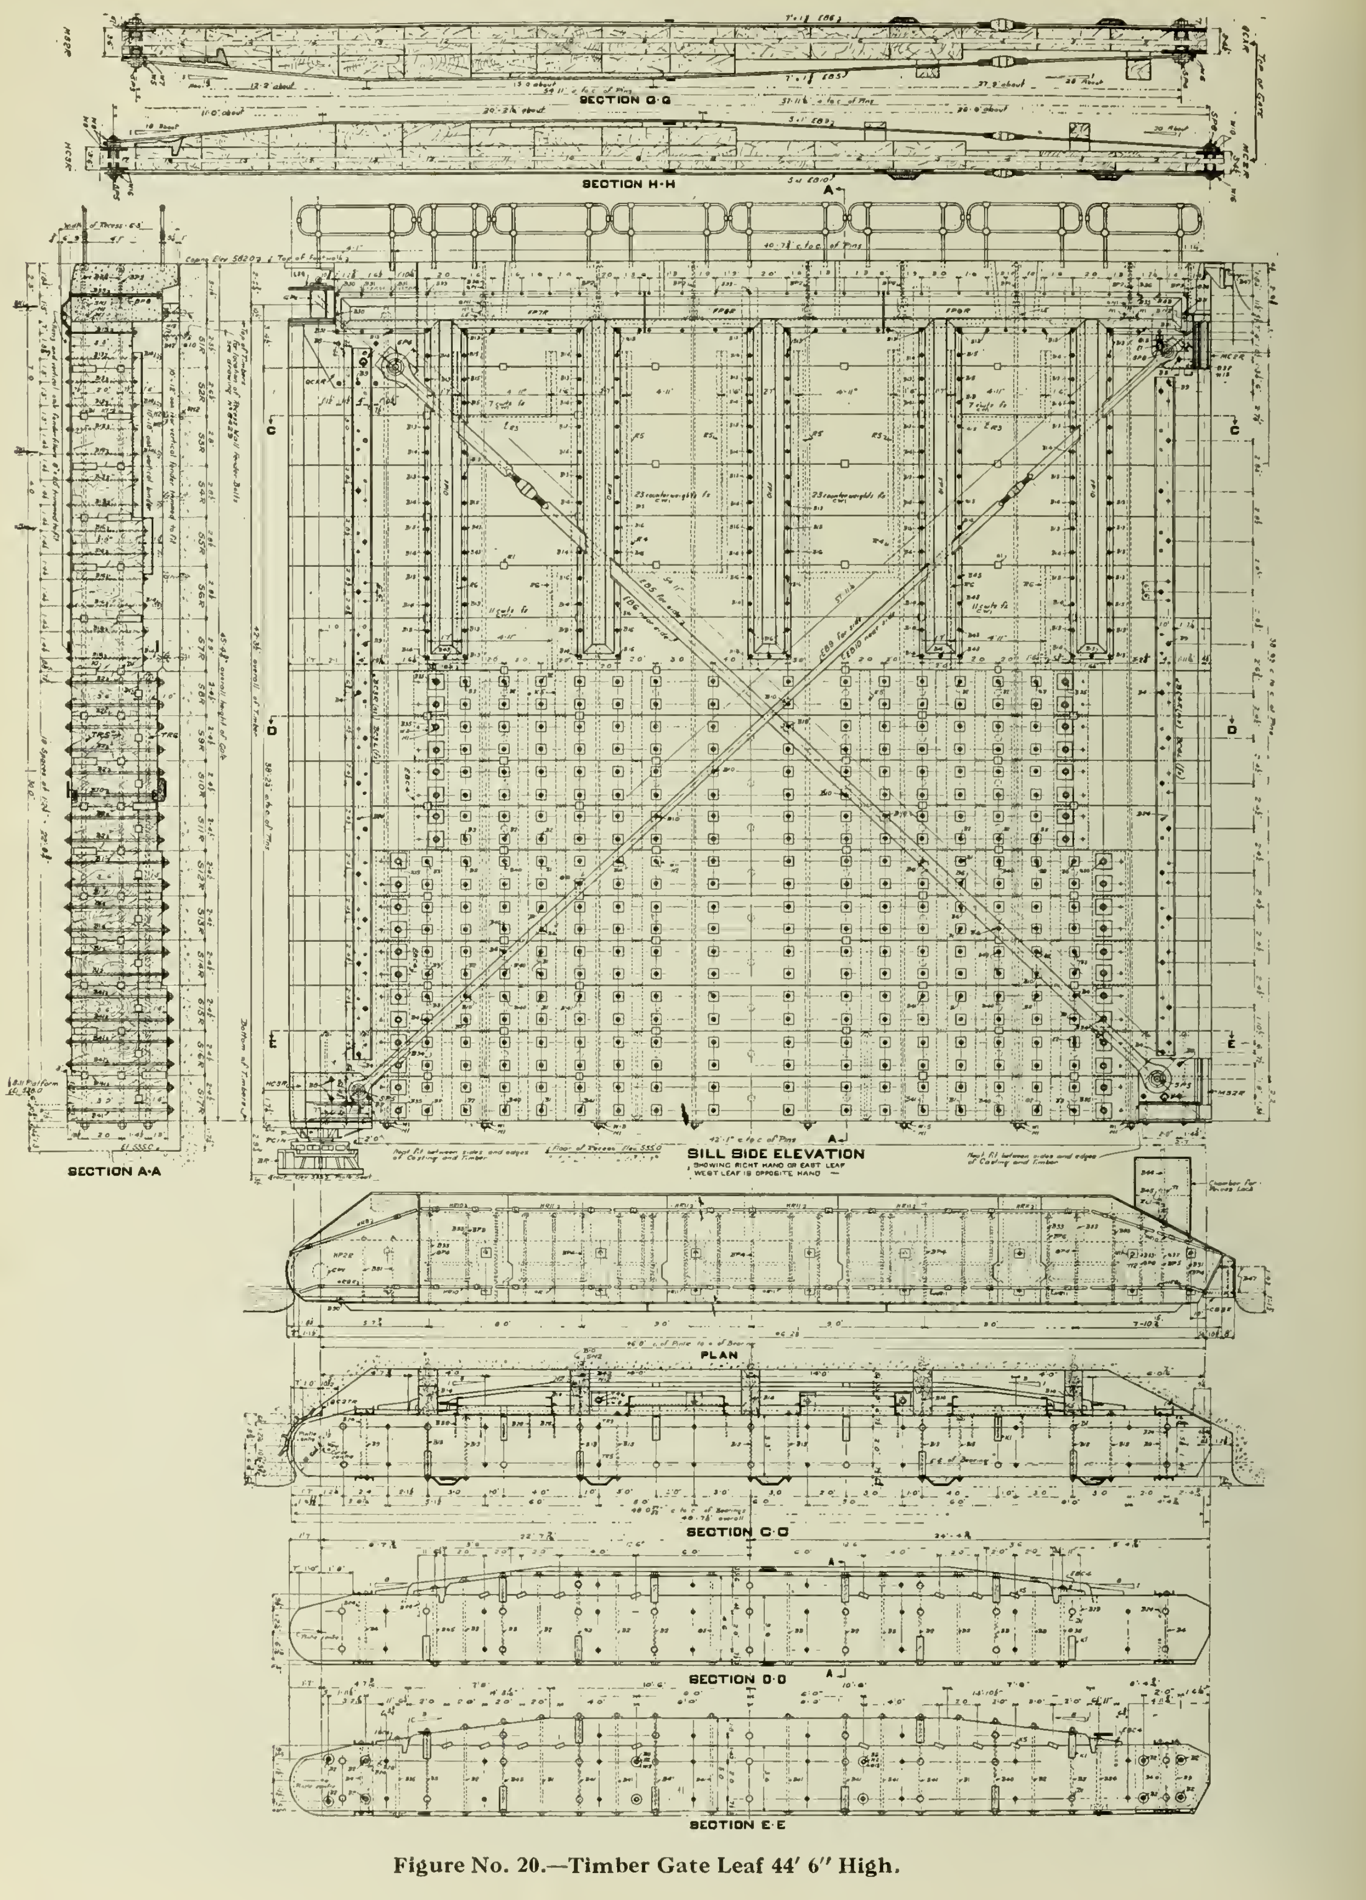

Figure No. 20.—Timber Gate Leaf 44′ 6″ High.

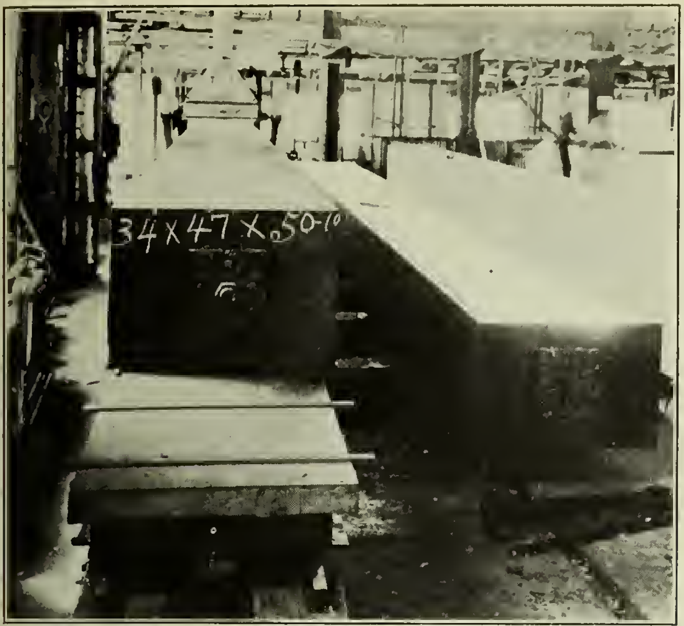

Figure No. 21.—Planning Gate Timbers in Shop.

is of the same diameter as the hinge pins of the steel gates, and is held against rotation but left free to slide in its pin plates in the same manner. The quoin cap extends up to the coping level, where its upper surface consists of a rolled steel checkered plate forming part of the footwalk of the gate. Nickel steel was used for steel parts which will be under water in order to increase their resistance to corrosion.

To prevent the leaf from being lifted off its pintle by the buoyancy of the timber, it is counterweighted with cast iron blocks. The blocks are placed in Z-bar racks bolted to the upstream side of the leaf.

Each leaf of the gate 41 feet high has four horizontal fenders spaced at 4 feet $10\frac{1}{2}$ inches centres on the side of the leaf which is toward the lock when the gate is open. The top and bottom edges of these fenders are beveled at 45° to prevent fenders or other projections on the sides of ships from catching on them and exerting large vertical forces on the leaf. The fenders are covered with $\frac{3}{4}$-inch steel plates bent to the required shape. The other gates are provided with fenders of similar construction, but arranged in a different way. A single horizontal fender near the top of the leaf is used, with five vertical fenders below it, arranged in a manner similar to that described above for the steel gates. Fenders arranged in this way are considered to be less likely to be heavily engaged with projecting fenders on ships. Each timber gate leaf has five vertical oak fenders on its rear face, planed to bear against five corresponding oak timbers bolted to the face of the concrete at the back of the gate recess, so as to transmit pressure from passing ships to the lock walls. The fenders on both sides of the leaves cover roughly the upper half of the leaves only.

As the leaf will usually stand in the open position in

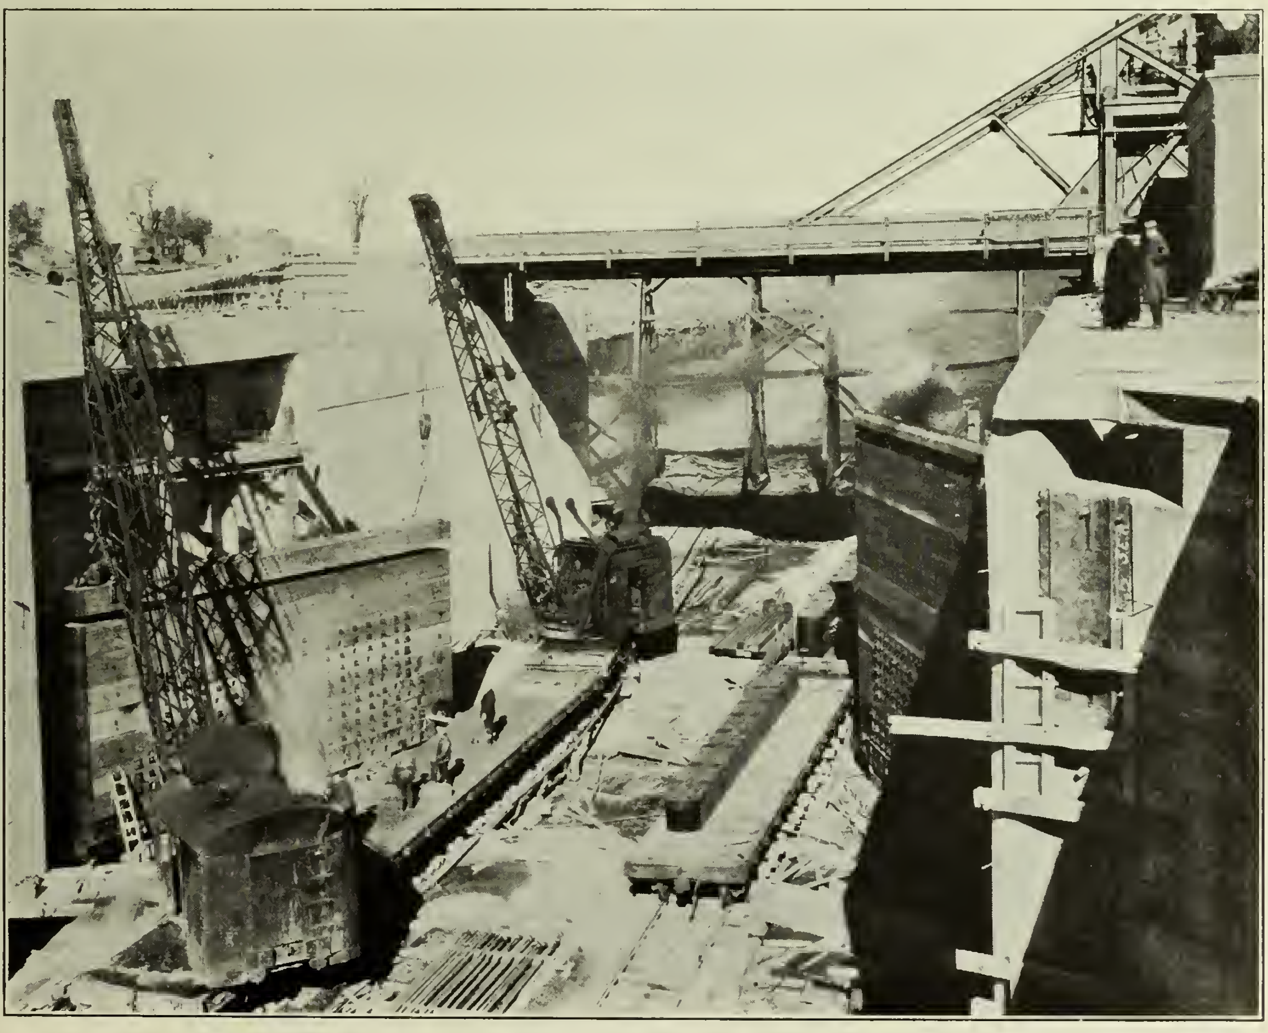

Figure No. 22.—Erecting Lower Unwatering Gate in Lock No. 8.

its recess, the top of the footwalk is made flush with the lock coping and its outline is made to fit the outline of the recess closely, except at the mitre end. Here the footwalk must be kept clear of the mitre bearing face of the leaf and thus leaves a triangular gap between it and the end of the recess. The gap is filled by means of checkered steel plate carried on removable brackets attached to the lock wall. This plate must, of course, be removed before the leaf is moved out of its recess. Removable pipe handrailings, made in short sections for ease of handling, are provided for use at each side of the footwalk when the gate is closed. Sockets are furnished in the top of the footwalk to receive the posts of the handrailings. In order to reduce the total weight of counterweight blocks required, the footwalk is made heavy. In the gate 41 feet high it consists of small reinforced concrete piers standing upon the top of the upper girder of the leaf, which is about 3 feet below the coping level, and carrying reinforced concrete walk slabs. The piers and slabs are made with structural steel connections and frames to provide for bolting the piers to the gate and the slabs to the tops of the piers. In the gates 35 feet 6 inches and 44 feet 6 inches high the footwalks consist of a series of large concrete blocks solidly filling the space between the top girder and the coping level. The footwalks are removable, to give access to the cast steel lifting eyes which are set upon the top girder and connected to the leaf by the long 2½-inch bolts which pass through it from top to bottom.

Fabrication of Timber Gates

A planer of the size required to dress the large timbers of the gate could not be found in stock, and the prices submitted for building one to order seemed prohibitive. The timbers for the first gate were therefore dressed entirely by hand. A planer of the cylinder type and of 24 by 48 inches capacity was afterward secured at second hand and rebuilt to handle timbers 48 by 48 inches and 60 feet long. This planer was used for rough dressing the timbers of the remaining four gates, but hand planing was used for finishing the timbers to their final dimensions. Bolt holes, dowel holes and key seats were accurately laid off by means of templates of the full length of the girders. To facilitate the handling and turning of the large timbers in the shop, a cast steel trunnion was bolted to each end of the timber. When hung on these trunnions from overhead cranes the timber could be easily turned by means of long wrenches fitting the hexagonal ends of the trunnions. Figure No. 21 shows some of the timbers being planed in the shop. The ends of the timbers were finished last, as this entailed the removal of the trunnions. The quoin and mitre bearing faces were finished to within ¼ inch of their final lines in the shop. The final planing of these surfaces was not done until after the leaf was erected.

The leaves were erected in the locks close to their final positions. Each leaf was erected upon a timber skidway upon which, when nearly completed, it was slid back into position over its pintle by means of jacks. It was then jacked up on eight 35-ton jacks, to permit the removal of the skidway, after which the leaf was lowered by the jacks upon its pintle. The concrete footwalk and the counterweight blocks were not placed upon the leaf until after it was set upon its pintle and connected to its anchorage. Figure No. 22 shows one leaf of the lower unwatering gate of lock No. 8 being erected and figure No. 23 shows one leaf of the unwatering gate of lock No. 1 completed with the exception of the footwalk.

The lock gates and their operating machinery were designed by the writer, his principal assistants in the work on the lock gates being M. B. Atkinson, M.E.I.C., and O. W.

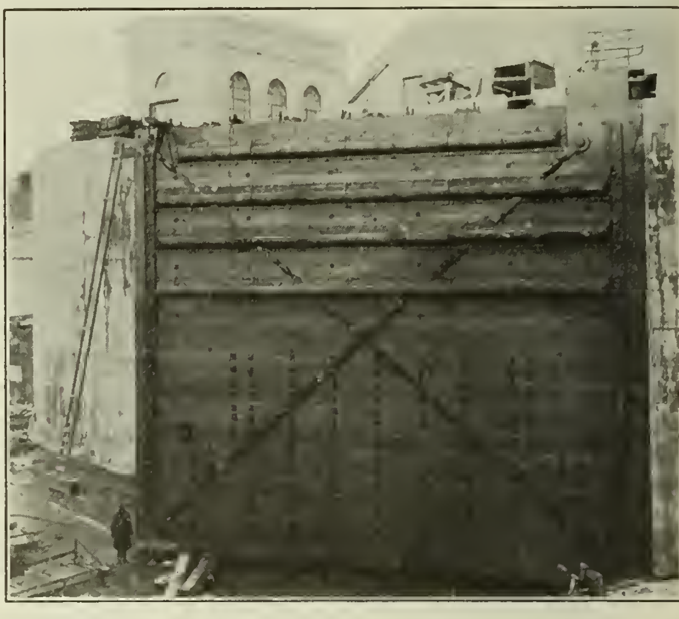

Figure No. 23.—East Leaf, Unwatering Gate Lock No. 1.

Ross, A.M.E.I.C.; on the operating machinery, J. B. McAndrew, A.M.E.I.C., and W. T. Porter, and on the electrical equipment for the operating machinery, L. P. Rundle, to each of whom much credit is due.

Contracts for the lock gate anchorage frames, quoin bearings, base castings and other fixed parts which are built into the masonry of the locks were let from time to time over a period of five years, from 1921 to 1925, to various manufacturing firms as required to suit the progress of the work on the locks.

The contract for the steel gates was let in June 1926 to the Steel Gates Company, Limited, a company formed for the purpose, with E. S. Mattice, M.E.I.C., as manager and chief engineer. Sub-contracts for the shop work were let by the general contractor; to the Hamilton Bridge Works Company, Limited, for the fabrication of nearly all of the structural steelwork; to the Montreal Locomotive Works Company, for the castings and forgings; to McGregor and McIntyre, Toronto, for the footwalks and handrailings, and to the Canadian Power Specialty Company, Limited, St. Catharines, for the manshafts. The gates are being erected by the general contractor, with J. O. Childers as superintendent of erection.

The metalwork for the timber gates and the lignum vitæ dowels and keys were furnished under contract, but the dressing and framing of the timbers in the shop and the erection of all parts of the work were carried out by Welland ship canal forces under the superintendence of Major W. J. Gander.

The contract for the lock gate operating machines for lock No. 1 was let in January 1927 to the Dominion Bridge Company, Limited.

John Rankin, M.E.I.C., was in charge of the inspection for the Welland ship canal of all work in the shop and in the field up to March 1926, when he resigned. He was succeeded by R. R. Stevenson.

Steelwork for the Royal Bank Building in Montreal

Some Features in the Design of the Steelwork for the New Twenty-Three Storey Head Office Building for the Royal Bank of Canada in Montreal

R. M. Robertson, A.M.E.I.C.
Structural Designer, Dominion Bridge Company, Limited.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

The first building of the skyscraper type to be erected in Montreal is the new twenty-three storey head office building for the Royal Bank of Canada, situated in the block bounded by St. James, St. Peter and Notre Dame streets and Dollard lane.

A new by-law affecting the height of buildings within the city limits was passed by the city council on August 18th, 1924. Briefly, the by-law states:—

> "No building more than one ground-floor and eleven storeys in height, from the level of the sidewalk or of the street, or more than one hundred and thirty feet in height, from the level of the sidewalk or of the street to the highest point of the roof, shall be erected within the city limits.
>
> "The provision of this section shall not, however, apply to the erection of buildings, the frontage of which shall not exceed the height therein mentioned, but having central portions exceeding such height, provided that such central portions shall be set back from the frontage at least twenty-three feet, and provided furthermore that the floor area of such buildings, from and including the ground-floor to the roof, shall not exceed the area of a building containing eleven storeys and one ground-floor and erected over the entire lot."

The building occupies a lot of irregular shape, having a frontage on St. James street of 180 feet 8 inches, on St. Peter street of 172 feet 11 inches, on Notre Dame street of 156 feet 11⅝ inches and on Dollard lane of 170 feet 8 inches. Conforming to the by-law, a set-back of approximately 23 feet occurs at the third floor level, 104 feet 7 inches above grade, and a further set-back of fifteen feet takes place at the 19th floor level, 307 feet above grade. The top of the lantern is 393 feet above grade and 415 feet above sub-basement level. Figure No. 1 shows an elevation of the building and indicates the floor levels and set-backs.

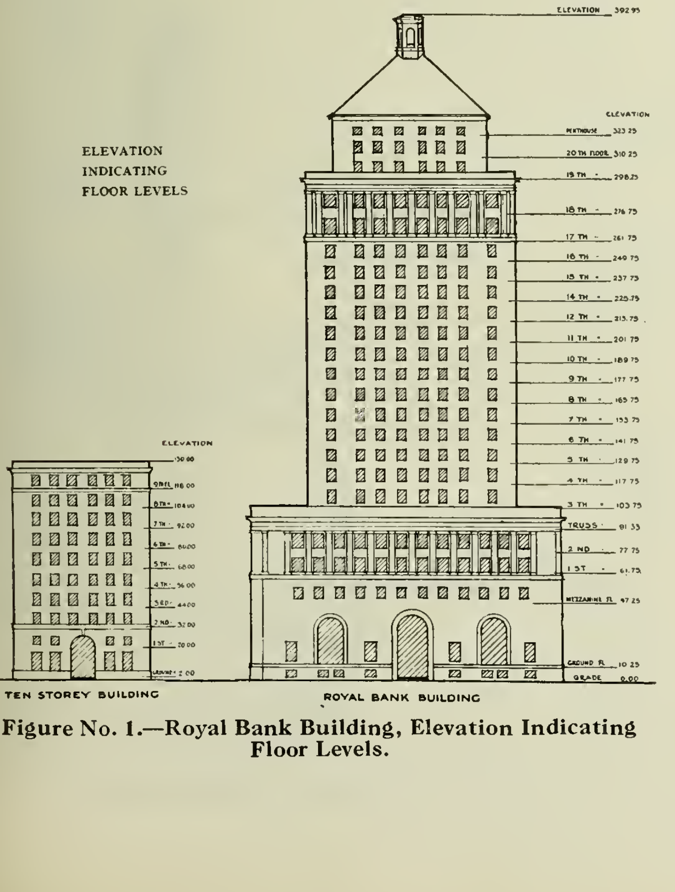

Figure No. 1.—Royal Bank Building, Elevation Indicating Floor Levels.

There are twenty-six floors, including sub-basement, basement and penthouse. Seven floors, the sub-basement, basement, main, mezzanine, first, second and truss are situated in the lower portion of the building. Fifteen typical office floors occupy the portion between the two set-backs, and in the tower above the second set-back there are two office floors in addition to the penthouse.

The lower portion of the building will be occupied exclusively by the bank, and the balance, from the third to the twentieth floor, will be available for rental as general office space.

Safety deposit and security vaults are located on the sub-basement floor in addition to the boilers and other mechanical equipment.

The banking room proper is on the main floor, adjacent to the Notre Dame street side of the building, and occupies an area 49 feet wide, extending from St. Peter street to Dollard lane uninterrupted by any columns. The ceiling over this room is immediately below the first floor and is 46 feet above the main floor level.

A truss floor, introduced between the second and third floors, made it possible to get ample space for trusses, girders and ducts without interfering with architectural requirements. This floor will be used for general storage, also for fans and other ventilating equipment.

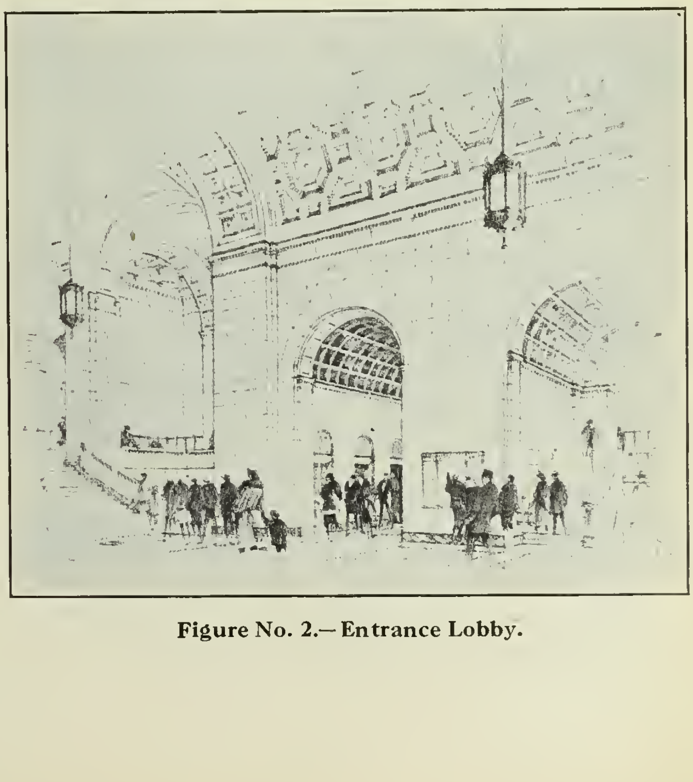

Figure No. 2.—Entrance Lobby.

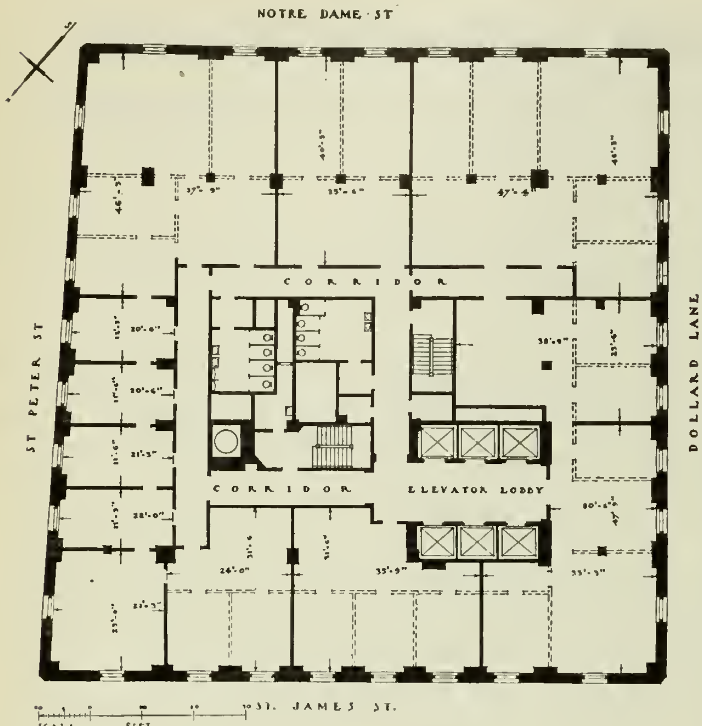

Figure No. 3.—Typical Plan of Floors—Third to Eighteenth.

The main entrance is on the St. James street side of the building and leads to a lobby 20 feet wide, at the end of which is a monumental staircase leading up to the banking room and down on either side to the basement. Elevator halls are located on each side of the entrance lobby, the upper floors being served by six elevators, five passenger and one freight, making their first stop at the fifth floor. The elevator service on the lower floors will be taken care of by two elevators running to the fifth floor and one elevator near the corner of Notre Dame street and Dollard lane running to the second floor. In addition to these, there are two elevators for the use of the bank employees, running to the mezzanine floor, on which is located the cafeteria and employees' rest and locker rooms.

Figure No. 2 shows an architect's picture of the entrance lobby and elevator halls. The main staircase leading to the banking room can be seen at the left, while the stairway shown at the right leads to the general working space on the main floor. This view also shows the general architectural treatment of the main floor, the stone facing on the walls and arches being 80 per cent "Indiana limestone" in varying colours and tones from a warm buff to a cold grey, with 20 per cent "Briarhill sandstone" of warm colour with strong vein markings.

The main structural problem encountered in the design of the steelwork was that of carrying typical floor columns on trusses or girders at the third floor level.

Of the sixty-two columns carried on the foundations, only four, numbers 29, 30, 37 and 38, extend to the roof; six end at the penthouse floor; ten at the nineteenth floor and the remainder at the third floor level. Thirty-one columns are carried on trusses or girders at the third floor level.

Floor Construction

A typical floor plan is shown in figure No. 3. The floor framing, with the exception of girders and trusses at the third floor, consists mainly of I-beams.

Columns are spaced approximately 24 feet centres in each direction on the lower floors and 24 feet by 12 feet in the upper storeys.

A twelve plus two long-span concrete joist construction is used throughout, with the exception of the main and basement floors, on which the floor construction is a four-inch stone concrete slab supported on steel stringers approximately 8 feet centres.

On the typical floors the joists span 24 feet, and are supported on a 10 x 10 H-beam framing to the columns 12 feet apart. Ten-inch I-beams running in the direction parallel to the joist are used as ties between the columns. By the use of these shallow beams it was possible to conceal the steelwork in the floor construction, thus giving large areas of ceiling without any beams projecting below.

The material used for floor fill throughout the building is aerocrete. This substance, which weighs 60 lbs. per cubic foot, is composed of one part cement, four parts very fine sand and seventy-five drams per cubic foot of cement of finely powdered metallic aluminum, the whole when mixed with hot water liberates hydrogen and causes the substance to rise like yeast. It is easily screeded and sets in about the same length of time as ordinary concrete.

"Marble mosaic" will be used as a finish on the main floor, and on all other floors the corridors will be finished with terrazzo and the remaining portions with one inch of cement.

Walls

The walls in the lower portion of the building are eight-inch Queenston limestone backed with eight inches of brick. They are self-supporting up to the first floor, a height of 62 feet above grade. Massive stone pillars, spaced at 12 feet centres, and surmounted by a heavy cornice, form the main architectural treatment between the first and third floor levels.

Above the third floor the walls are four-inch Montreal

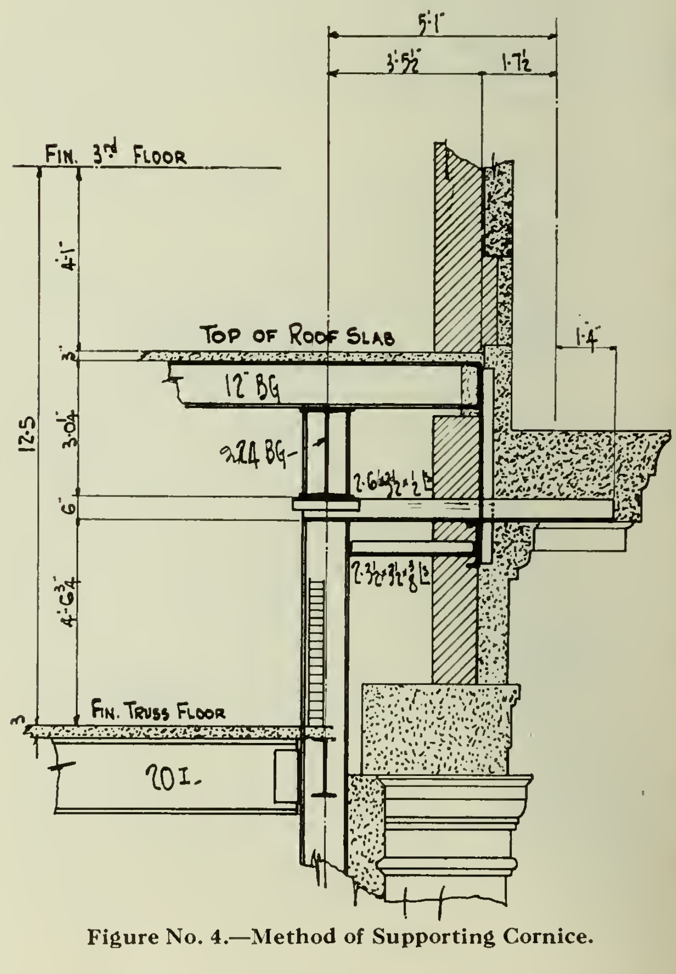

Figure No. 4.—Method of Supporting Cornice.

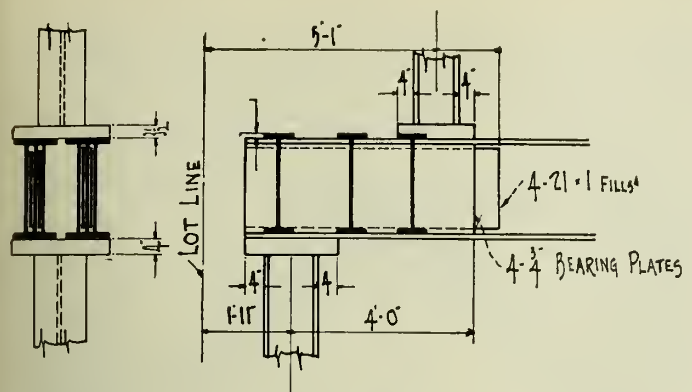

Figure No. 5.—Support for Wall Columns—First Floor.

limestone with eight inches of brick backing, and are supported on spandrel beams at each floor level.

Cornices, similar to the one at the third floor, occur at the nineteenth floor and roof levels. A detail showing the method of supporting the cornice is shown on figure No. 4. Pairs of angles spaced about four feet centres were cantilevered out over the spandrel beams, the angles being arranged so as to come at the stone joints, and in order to provide for adjustment in setting the stone they were fastened to the beams by means of square hook bolts.

The wall columns between the first and third floors had to be set back to clear the stone pillars, these set-back columns being carried on double beams at the first floor level. A detail of the ends of these beams is shown in figure No. 5.

Loading and Unit Stresses

The live loads assumed on the various floors were in accordance with the Montreal Building By-law, as follows:

Basement	100 lbs. per sq. ft.
Main floor	100 " " " "
Mezzanine floor	60 " " " "
First floor	60 " " " "
Second floor	60 " " " "
Truss floor	100 " " " "
Typical office floors	60 " " " "
Roofs	40 " " " "
Elevator and tank supports	Actual loads

In designing the floor beams and girders, partition loads were taken as they actually occurred and not figured as a load per square foot uniformly distributed over the floor area.

The unit stresses used in the design were as follows:

Tension, net section	18,000
Tension on rivets	10,000
Compression, gross section, struts and columns	$\dfrac{18,000}{1+\dfrac{l^2}{18,000r^2}}$
with a maximum of 15,000 lbs., where l is the unsupported length and r the least radius of gyration applicable to this length.	
Bending on extreme fibres,—tension,—net section, if lateral deflection is prevented	18,000
Bending on extreme fibres, compression	$\dfrac{20,000}{1+\dfrac{l^2}{2,000b^2}}$
where l is the unsupported length and b the width of the flange.	
Shear, webs of beams and girders, (gross area), where h, the height between flanges in inches, is not more than 60 times t, the thickness of the web in inches	12,000
Shear on pins and power driven rivets	13,500

	Double Shear	*Single Shear*
Bearing, pins and power driven rivets	30,000	24,000
Bearing, turned bolts in reamed holes	30,000	20,000
Bearing, hand driven rivets and unfinished bolts	20,000	16,000

Main Trusses

Figure No. 6 shows the framing plan at the third floor level. This plan shows the location of the trusses and girders carrying columns over the main banking room, also girders in other portions of this floor carrying upper storey columns.

Five trusses spanning 49 feet, and spaced 23 feet 9 inches apart, were used over the main banking room. Each consisted of two individual trusses with chords and webs of I-section. The two units were designed to be self-supporting under their own portion of the load, but for increased stiffness were connected together by tie plates.

These trusses support three lines of girders 5 feet deep on which the upper storey columns are carried. It was decided to support the girders framing into these trusses by direct bearing in preference to riveted connections, and for this purpose rolled steel slabs were extensively used. The major problem in the design of these trusses was that of eliminating eccentric stresses induced by unequal reactions of the girders framing in on opposite sides of a truss. It will be noted from the plan that the columns carried at this floor are not spaced symmetrically about the trusses, also that the centre line of the girders supporting the outer row of columns is 6 inches off the centre line of the columns below.

The use of slabs materially decreased the number of rivets to be driven in the field, and, furthermore, had the advantage that it was possible by adjusting the centre of bearing of the girders framing in from opposite sides of the truss to locate the centre of gravity of the reactions from these girders directly on the centre line of the truss, thus making each half carry an equal portion of the load.

Figure No. 7 shows a detail of the truss between columns 38 and 50. The stresses and make-up of the members are shown on the diagram and need not be repeated here. This drawing also shows in section the double girder framing in at the centre of the truss and the single girder framing in 6 inches from the right hand end.

A detail of the support on the truss for one of the double girders is shown on figure No. 8. The end reactions from these girders are transferred through bearing stiffeners to a rolled steel slab, which in turn rests on another slab

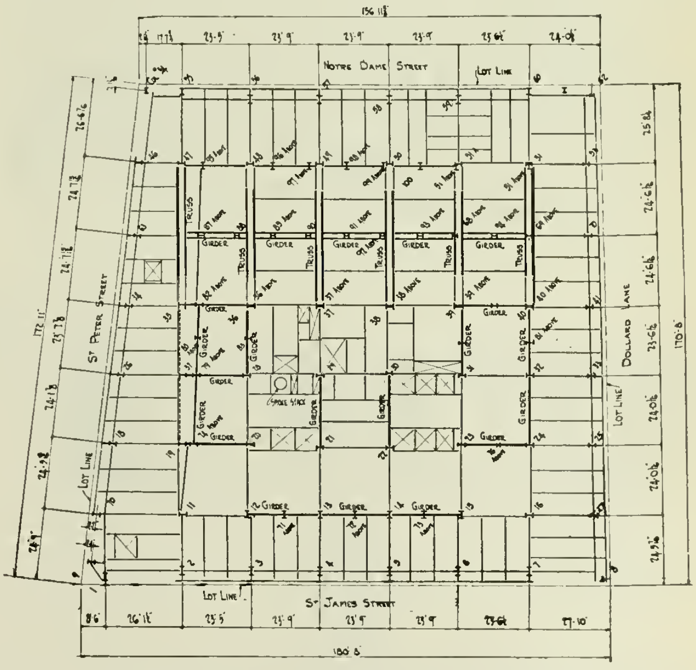

Figure No. 6.—Framing Plan at Third Floor.

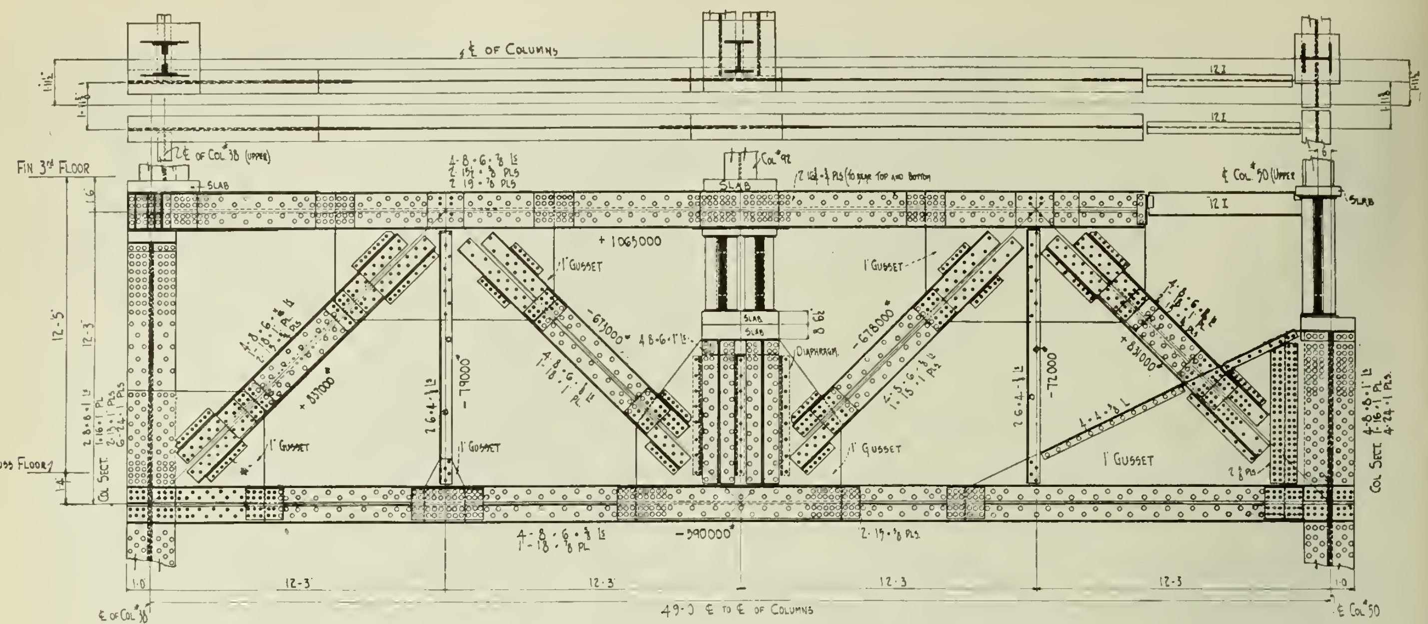

Figure No. 7.—Details of Truss between Columns Thirty-eight and Fifty.
Material and Stresses are for Half of Truss.

supported directly on the gussets of the truss. The bearing area between the two slabs was restricted to a width of 12 inches situated symmetrically about the centre line between the gussets, so as to ensure as far as possible an equal distribution of the load to each half of the truss. It was necessary to cut away the upper portion of the ends of these girders, in order to clear the top chord of the truss; and, to take care of the shear and moment at this point, reinforcing plates and angles were added, as indicated on the sketch.

It will be noted from the detail shown on figure No. 7 that the slab under column 92 rests partly on the girder and partly on the top chord of the truss. This made it necessary to transfer a portion of the load through the chord to the girder below. The web of the chord at this particular point was faced top and bottom, and, in addition, bearing plates riveted to the web were made to bear against the inside of the chord angles, the load then being transferred through a slab to the stiffeners on the lower portion of the girder.

Care had to be taken to ensure an even bearing for the slab under this column, and it was, therefore, necessary to make sure that the depth of the cutaway portion of the girder was exactly equal to the depth of the chord, plus the thickness of the slab underneath it. Actual measurements were taken on the chord and the girder as fabricated before the slab was finally planed.

Another feature in the design of these trusses was the necessity of providing for the eccentric loads from the girders framing in 6 inches from the ends of the truss, as shown in figure No. 7. The eccentricity due to the girder reaction was taken care of by extending the gusset plate to the first panel point and designing the plate to take the bending stress developed, in addition to the stress from the end post and bottom chord. At the other end, where a column rests directly on the truss, the direct load was transferred through bearing plates and the bending stress taken care of by the top chord.

Care had to be taken in fabricating the line of double girders framing between the centre points of the trusses. The load from the columns supported by these girders was transferred to each half by means of a slab, and it was, therefore, necessary to ensure that the tops of these girders were at the same height and perfectly level.

Owing to the build-up of cover plates and also to the fact that flange angles are liable to be slightly off square, it is difficult to obtain a girder exactly square and true. It was, therefore, necessary in this case to plane the portion of the flanges underneath the column slab so as to ensure a perfectly horizontal bearing for the column above.

With the exception of the line of columns described above, all other girders on this floor carrying upper storey columns were of the single web type, generally 60 inches

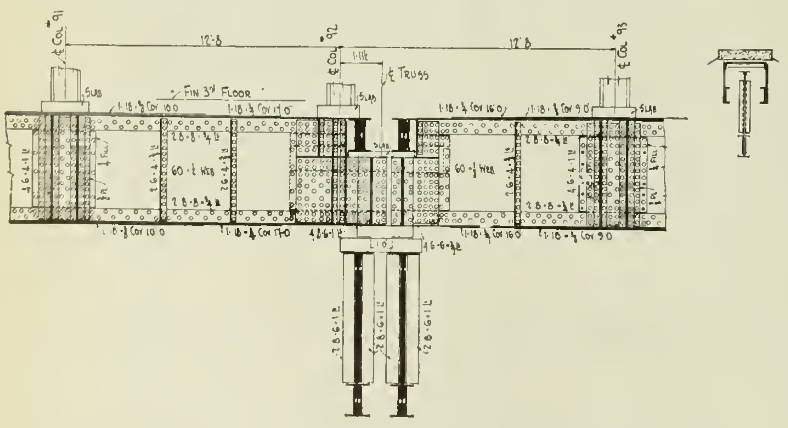

Figure No. 8.—Detail of Support for Girder at Centre of Truss.

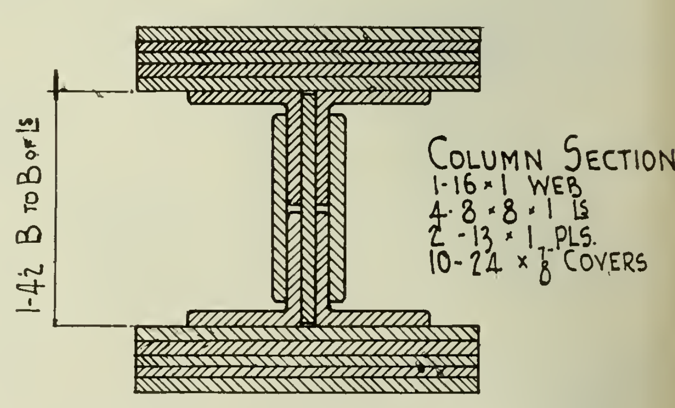

Figure No. 9.—Cross-Section of Heaviest Column.

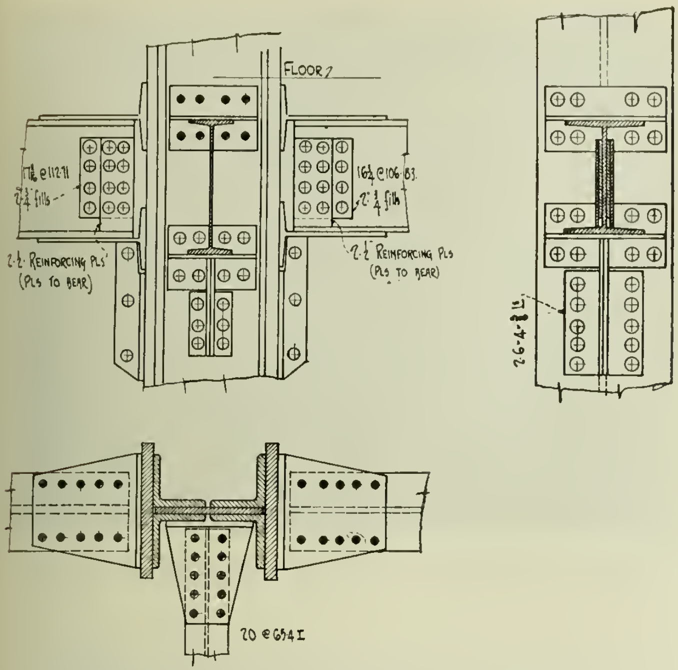

Figure No. 10.—Typical Wind Connection T-type.

deep. The heaviest girder is that between columns 48 and 49, carrying columns 96 and 97. The make-up of this girder was as follows:

One 60" x ⅝" web plate
Four 8" x 8" x 1" angles
One 22" x 1" plate } top
One 18" x 1" " } top
One 18" x ¾" " } top
Two 18" x 1" " } bottom
One 18" x ¾" " } bottom

It was originally intended to hang the portion of the first and second floors over the main banking room from the trusses at the third floor. However, it was found possible to carry this portion of these two floors on a latticed girder placed in the duct space between the first floor and the ceiling over the banking room.

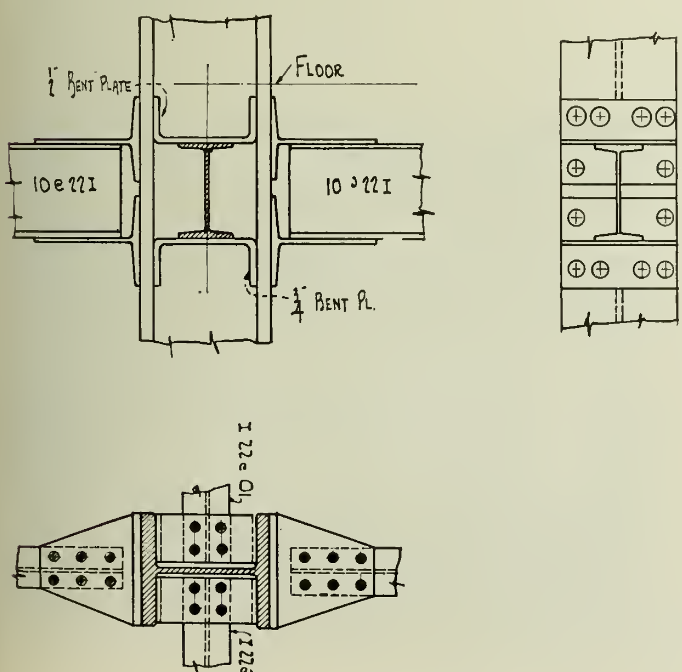

Figure No. 11.—Typical Wind Connection U-type.

The use of this girder greatly facilitated the erection of the main trusses, as it was only necessary to shore the bottom chord of the truss from the second floor instead of assembling each half of the truss on the main floor and hoisting it into place as was originally contemplated.

The large end gusset plates on the truss were shop riveted to the bottom chord, and, instead of being field riveted to the column direct, a field splice was made just clear of the column, in order to reduce the number of long rivets to be driven in the field.

One complete double truss weighed 60 tons, the heaviest piece to be handled being a bottom chord section which weighed 14 tons.

Columns and Slabs

The columns generally in the upper storeys and the wall columns in the lower storeys were rolled Skelton or Bethlehem H-sections. Built-up sections of angles and plates were used for the heavier loads on the lower storeys.

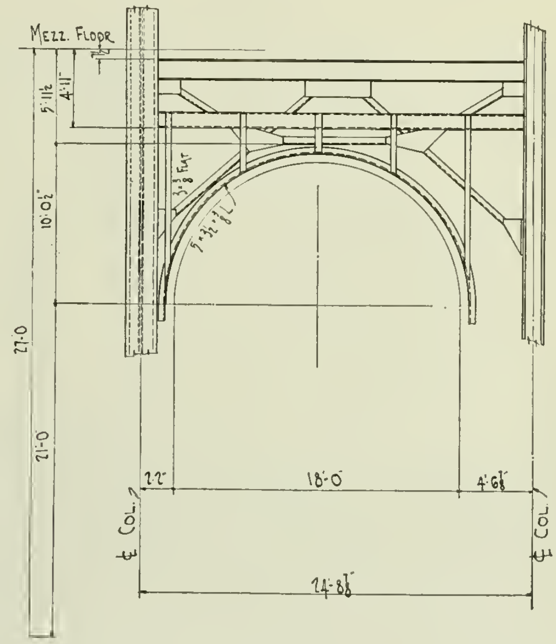

Figure No. 12.—Portal and Support for Interior Stone Arches.

A cross-section of one of the heaviest columns which supported a load of 2,200 tons is shown on figure No. 9. It was made up of:—

Four 8" x 8" x 1" angles
One 16" x 1" web plate
Two 13" x 1" " "
Ten 24" x ⅞" cover plates

Lower storey columns were spliced at the main, mezzanine, second and third floors, the upper storey columns being spliced every third floor.

Rolled steel slabs were used under the columns to distribute the loads to the grillages or footings. The columns were anchored to these slabs by two 1¼-inch diameter studs tapped 2 inches into the slab, the weight of the slab being considered sufficient to hold the column in place during erection.

In certain cases it was impossible to obtain from the mills slabs of sufficient area and thickness to distribute the load over the concrete footings, and in these cases a double layer of slabs was used, the lower slab being split in two, the additional area being obtained by increasing the size of the slab in one direction only.

Wind Stresses

The problem of wind stresses in a building of this type, although not a serious one, had to be given consideration.

The by-law required that the building should be designed to resist a wind pressure equivalent to 30 pounds per square foot on its exposed surface.

It was assumed that the permanent partitions and exterior walls would resist a pressure of 15 pounds per square foot on that portion of the building above the first set-back and 30 pounds per square foot on the portion from the first set-back to grade.

The steelwork was, therefore, designed to resist, in addition to the dead and live loads, a wind pressure of 15 pounds per square foot on the exposed surface of the building from the third floor to the roof.

A fifty per cent increase in the ordinary unit stresses was allowed when considering wind loads combined with dead and live loads. It was thus possible to design the structural frame for dead and live load stresses only and then investigate its capacity for resisting wind loads.

Figure No. 14.—Progress of Steel Erection February 9th, 1927.

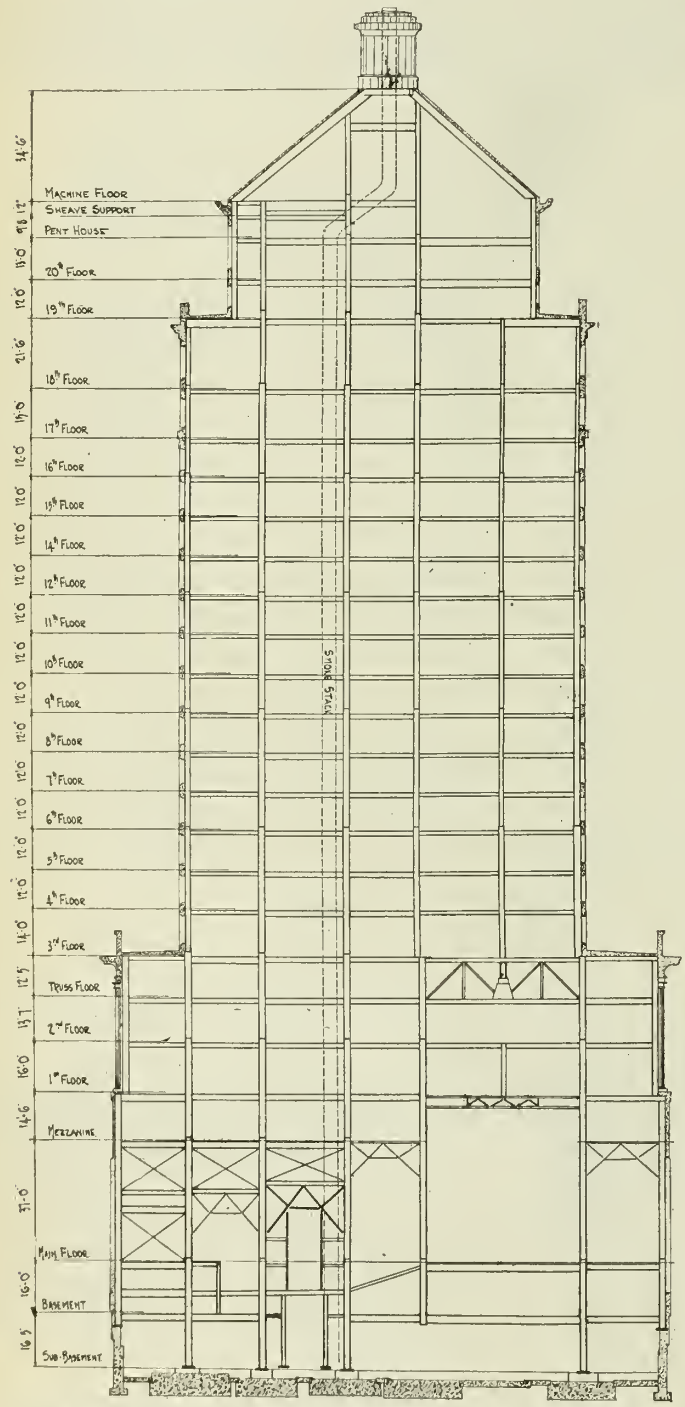

Figure No. 13.—Cross-Section of Completed Building.

Typical wind connections are shown in figures Nos. 10 and 11. The T-type of connection, shown in figure No. 10, was principally used on beams connecting to the flanges of rolled columns, also on beams connecting to both flanges and webs of built-up columns. This type of connection has the advantage of being able to develop a large moment of resistance at the ends of a beam and is easily concealed in the fireproofing of the columns or beams.

For beams framing into the webs of columns with webs up to one inch thick, a T-type of connection would generally overstress the web, therefore, in such cases a U-type of connection, shown on figure No. 11, was used. The advantages of this connection are apparent in that the stress is transferred directly to the flange of the column, thus obviating any necessity for reinforcing the web.

As a general rule, owing to the amount of space occupied by the tees on the flanges, it was impossible to get an adequate web connection capable of resisting the end shear of the beams, and it was, therefore, necessary to place stiffeners under the lower tee in order to transfer the load from the beam to the column. The amount of projection of these stiffeners beyond the flange of the column was limited by architectural requirements, thus confining the actual bearing to a very short distance, so that in certain cases it was necessary to reinforce the web of the beams to take care of excessive web crippling stresses.

The tees used for these connections were cut from 24-inch at 84.5-pound and 18-inch 64.5 pound Bethlehem I's, the U-type connection being made from a ¾-inch plate bent to shape in a die while hot.

As a general rule, the connections were shop riveted to the columns, and, to allow for over-run in the beams, the tees were kept apart ⅜ inch more than the depth of the beam.

A system of portal and X bracing was introduced immediately below the mezzanine floor, the portals being concealed by the stone arches forming the architectural treatment for the ceiling of the main floor. A typical detail of a portal at this point is shown on figure No. 12. This figure also shows the method of supporting the face stones of the arches by means of bent angles suspended from the structural frame above.

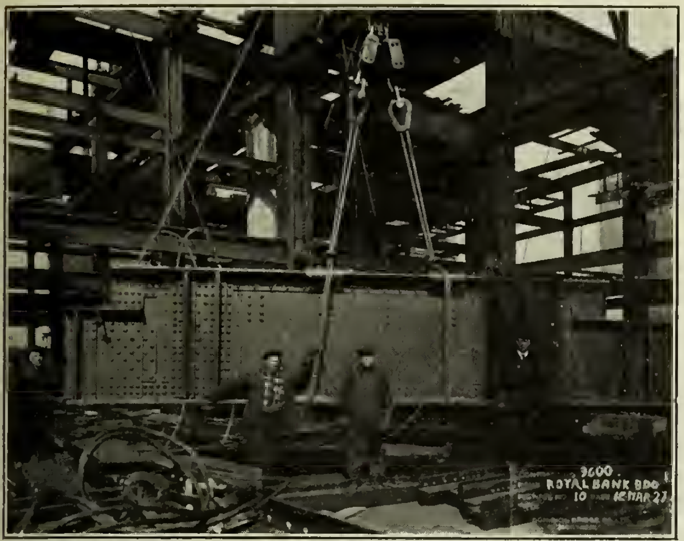

Figure No. 15.—Progress of Steel Erection, March 12th, 1927.

The following assumptions were made for the purpose of investigating wind stresses:—

(1) That the floor slab would distribute the horizontal shear to all the columns passing through that floor.

(2) That the wind shear at any storey would be resisted by all the columns in that particular storey, and that the amount of shear resisted by any one column would be governed by the shear that could be transmitted by either,—

  (a) The column.

  (b) The beams connecting to that column in any one direction.

  (c) The connection of these beams to the column.

(3) Points of contraflexure were assumed at mid-storey heights for columns.

(4) Intersection points of beams and columns were assumed as fixed.

The actual method used in designing wind connections was to apply a certain type of connection to any one floor,

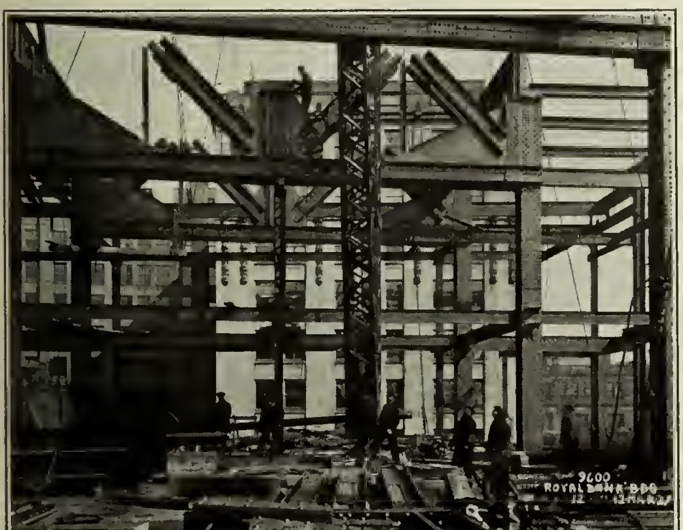

Figure No. 16.—Progress of Steel Erection, March 12th, 1927.

this type being used on all beams, regardless of their size. The use of a minimum number of different types of connections on any one floor greatly facilitated the detailing of beams and columns.

Each column was then investigated in accordance with the foregoing assumptions in order to find how much wind shear it was capable of resisting. The shears thus found were summed up for all the columns at that floor and equated to the actual wind shear required to be resisted.

Fireproofing

Concrete, terra cotta, aerocrete and brick were used as fireproofing for the structural steel. The use of these materials gave a total weight for the building lighter than any other fireproof construction possible.

The floor beams, chords of trusses and top flanges of girders are haunched with 2 inches of concrete, the remainder of the girders and webs of trusses being fireproofed with terra cotta.

Figure No. 17.—Progress of Steel Erection, March 12th, 1927.

For all the exterior wall columns a 4-inch brick covering is used, and for the interior columns the fireproofing is aerocrete and terra cotta.

Tanks, etc.

House tanks of 10,000 gallons and 7,500 gallons capacity are located at the penthouse and eleventh floor respectively. There is also a balance tank of 1,000 gallons capacity on the truss floor and a suction tank of 10,000 gallons capacity in the sub-basement.

It may be mentioned here that the tanks are rectangular in shape and entirely of welded construction, the various pieces being welded together at the site, using the latest type of portable welder.

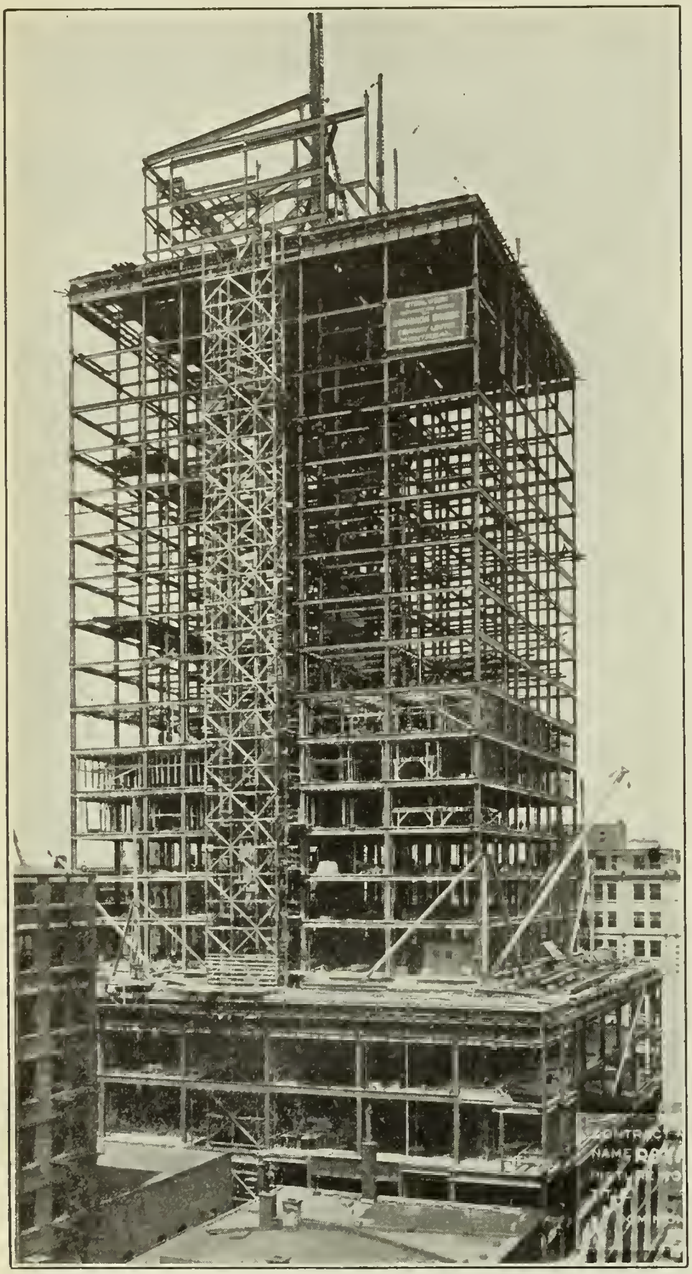

Figure No. 18.—Progress of Steel Erection, May 26th, 1927.

The position of the shaft for the 52-inch diameter smoke stack is indicated on the third floor plan, figure No. 6. This stack continues in this position from the basement to the penthouse floor, at which point it offsets to the centre of the building, as indicated on the section, figure No. 13.

The stack is supported every second floor, ⅜-inch plate being used for the lower portion up to the mezzanine floor, also for the top twenty feet, the remainder of the stack being 5/16 inch thick.

The stack was erected concurrently with the rest of the steelwork and was used by various contractors as an outlet for smoke from their hoisting engines.

A three-ton underhung travelling hand crane is provided in the penthouse for lifting the elevator machines.

Transportation of Materials

All of the steelwork for this building was transported by trucks from the shops of the Dominion Bridge Company at Lachine to the site, a distance of eight miles. Six 5-ton trucks with trailers were used for this purpose, the maximum tonnage transported in one day being 300 tons.

The unloading of the material for this building from two of Montreal's busiest downtown thoroughfares did not in any way interfere with ordinary traffic.

Erection

Two 20-ton guy derricks, each with a 95-foot mast and an 80-foot boom, and two 12-ton derricks, each with a 90-foot mast and an 80-foot boom, were used for the erection of the steelwork up to the first set-back. From this point up to the nineteenth floor the two 12-ton guy derricks were used, while for the portion above the nineteenth floor only one 12-ton derrick was required.

All the material for the portion above the third floor was unloaded and hoisted to that floor by two 12-ton stiff leg derricks, located one on the St. James street side and one on the Notre Dame street side of the building.

The floors immediately above the riveting gangs were completely planked over, and it is a significant fact that the 6,000 tons of steel work in this building were erected without any fatal accident.

Erection of the steelwork was started on January 15th, 1927, and completed by June 13th, 1927. The fact that the building was erected in the winter did not in any way delay the progress of the work.

The progress of the erection is indicated in figures Nos. 14, 15, 16, 17 and 18. Figure No. 14 shows the steelwork immediately above the main floor, with some of the portal and X-bracing in place. Figures Nos. 15, 16 and 17 show some of the trusses and girders in place; the shoring necessary for supporting the bottom chord of the trusses can be seen in the centre of figure No. 16.

Figure No. 18 shows the erection of steelwork nearing completion. On this picture can be seen one of the four main hip rafters supporting the roof. These rafters were 64 feet long and were made of 30-inch 190-pound Bethlehem girder beams with two 12 by ⅜ inch cover plates.

Architects and Engineers

The architects for this building were Messrs. York and Sawyer, of New York, and Mr. S. G. Davenport, of Montreal, consulting architect.

Consulting engineers for the foundations were Messrs. Moran, Maurice and Proctor, of New York. Messrs. Purdy and Henderson, consulting engineers, were responsible for the design of the concrete floors and co-operated with the Dominion Bridge Company, who were responsible for the design of the steelwork.

The thanks of the author are due to the following gentlemen: Mr. J. R. Colean, of Messrs. York and Sawyer; Mr. H. V. Spurr, of Messrs. Purdy and Henderson, and Mr. O. A. Barwick, of the Royal Bank staff, who gave material assistance in supplying data for this paper.

The Foundations for the New Building of the Royal Bank of Canada, Montreal

General Discussion of the Features of Design and the Methods Adopted for the Foundations of this Building

C. S. Proctor,
Consulting Engineer, New York City.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 15th, 1928

The monumental character of the new Royal Bank of Canada Building at Montreal, now rapidly nearing completion, makes it appropriate at this time that it should be a topic of general interest. This building, by its size and importance, is a fitting memorial to the progress and advancement of the banking industry and the architectural profession. The architectural treatment of such a building, including elaborate stone façades and interior ornamentation, must be protected from cracks or settlements which would detract from its beauty. This protection of necessity draws our attention to the material upon which the building is founded.

Early investigations to determine the character of the subsoil were carried on by means of dry sample core borings taken at various points on the lot, and also by a centrally located test pit. The data resulting from these experiments developed the fact that bed rock, located approximately 80 feet below St. James street, is overlaid with alluvial deposits of sand, varying from fine to coarse, together with sand and gravel admixtures including varying proportions of clay and boulders. Ground water was encountered at approximately 25 feet below St. James street in the open test pit, and this level remained practically constant during the period of observation. In order to ascertain the flow of water through the materials of the site, it was decided to install pumps in the test pit and observe the lowering of the water level at this point. The use of 6-inch tandem pulsometers day and night demonstrated that the supply of water to the site was of such quantity that it would be impossible to lower the water sufficiently to reach bed rock in the open.

Choice of Type of Substructure Design

With the wide choice of suitable methods for foundation work, economics played a large part in the final decision as to the best type of substructure design. If only from a standpoint of insurance, a natural first choice for a structure of this character would be a foundation upon rock, provided that it could be obtained at a reasonable cost over other types. To reach bed rock in the open was impossible because of the presence of large quantities of water.

Since any deep excavation could be made only by the use of compressed air, a study which provided for a pneumatic caisson cofferdam around the entire plot with cellars carried to rock level, was made. This design was discarded for economic reasons, since the space thus provided was not commensurate with the cost. The cost of independent pneumatic piers to rock was proportionately high.

The next consideration was a study using simple spread footings, not extending materially below ground water level, and this appeared to provide a very economic and adequate foundation, provided certain weaknesses, which will be discussed later, could be overcome.

The next step in the investigation was a study based upon the use of piles, but the character of the subsoil materials precluded the use of any type of pile except piles driven by the use of a jet. This was highly undesirable, due to probable disturbance of adjacent building foundations as a result of the agitation of sand particles which would permit readjustments of position with a resultant settlement.

The use of bearing piles driven to bed rock could not be considered, owing to the presence of the extensive boulder deposits, clearly indicated by the borings and the test pit, which would have made it impossible to reach bed rock support with any type of bearing pile. It was further developed in the course of studies that any type of friction pile would offer no greater resistance against differential settlement between adjacent columns than would spread footings, and would be considerably more expensive.

The result of these investigations indicated that only two general types of foundations could be properly considered; namely, the pneumatic pier to rock, or the spread foundation; the latter of which was by far the most economical. If a way could be found to insure its stability on all occasions, it was the reasonable choice.

Foundation Materials

For the purpose of arbitrary classification, foundation materials may be divided into two classes: non-yielding materials and yielding materials. In general, the usual characteristic of the non-yielding material is that it has sufficient internal strength so it will not move laterally under a vertical load within the limits of its strength. Generally speaking, the vertical contraction under load, in non-yielding materials, is extremely small. On the other hand, yielding materials do not possess these properties, though most of them possess an internal resistance, against lateral movement, which, however, is small in comparison with that developed in the solid or non-yielding material. Nearly all of our foundation materials lie between the two widely separated extremes of the solid and the fluid.

In granular materials there is necessarily a certain amount of void space between the various particles. The size of the particles, their grading, and their shapes afford a rather crude means of classification of such materials. In nature the larger sizes are represented by boulders or broken stone, depending upon their shape, and as the size becomes smaller we have coarse gravel, coarse sand, fine sand, silt, clay, and other fine materials. These appear either separately or in combination; either dry or water-bearing, and sometimes with varying admixtures of vegetable matter or humus.

From experiments we may draw the following conclusions:—Settlement in granular material is brought about either by lack of lateral support or by consolidation. Also that consolidation may be brought about in a material of high void content by loading, by vibration, and by readjustment of position due to flowing water. Another conclusion which may be drawn is that granular material such as sand and gravel deposited under water usually has a rather low void content as compared with the dry, loose material such as exists in sand dunes and the like. It is well to note that we have been dealing purely with the larger grained material of fairly regular shape and have not touched upon the properties of fine materials of small, irregular shaped particles usually encountered in the clays, since at this particular site such material only existed in very small quantities and its presence could have but small influence on the problem at hand.

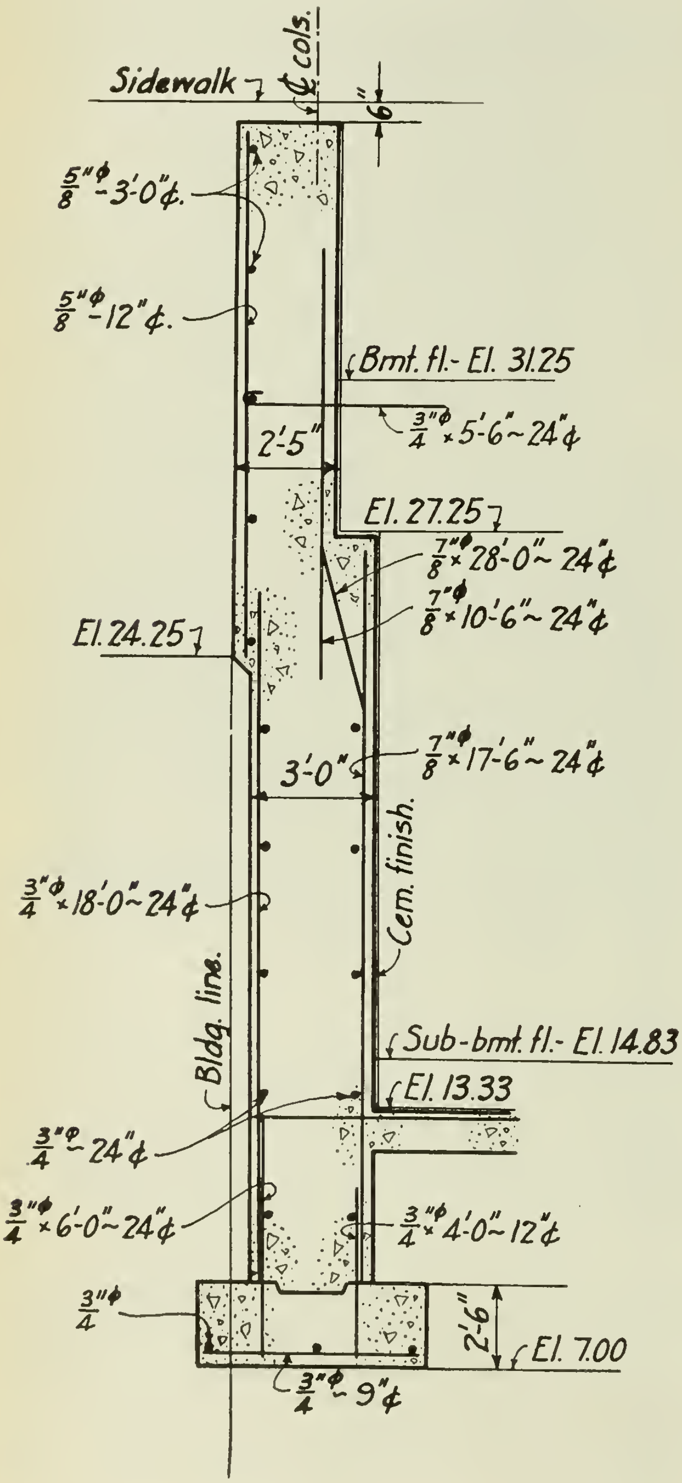

Figure No. 1.—Typical Wall Section in Sub-basement.

TYPES OF FOUNDATION SETTLEMENT IN YIELDING MATERIAL

In the yielding type of foundation material we may divide settlements into three classes, uniform, rotational and local. In order to discuss the various types, let us consider a building foundation in the form of a mat, resting upon what we may term a foundation plane. In the uniform type of settlement the foundation plane is subjected to a uniform subsidence. This type is not harmful to the superstructure, since there is no difference of settlement present, and if the settlement is comparatively small no harm will result to the structure or annoyance to its occupants.

The rotational type of settlement is usually a result of one of three causes. First; If the foundation bed overlying solid material is uniform in thickness but the centre of gravity of the applied loading does not coincide with the centre of gravity of the foundation mat, a high pressure will naturally result upon one side, causing a subsidence in that locality. Second; if the foundation bed lies upon an inclined rock surface it is quite natural that it, at that point where the foundation plane is nearest to the rock, will have the minimum settlement, while at that point where the rock is further removed from the foundation plane the greatest settlement will naturally occur. Third; the same effect is produced if the material under one portion of the foundation has been disturbed by neighbouring deeper excavation or pumping operations, of if the material is of different supporting value under different parts of the foundations.

The third type, local settlement, is perhaps the most disturbing of all forms, and may be due to numerous causes. Local settlements can take place in granular materials even where the foundation bed is of uniform character throughout; that is, the foundation bed may be overloaded, resulting in a consolidation or a lateral movement of the materials. But, unfortunately, we are very ap to encounter so-called spotty conditions, such as small quicksand pockets or pockets of peat, which are purely local and which may have large void contents usually occupied by water, which under compression is rapidly squeezed out, allowing settlement to take place. In the case of isolated spread footings this will cause a difference in settlement between two adjacent footings. Excavation below the level of a spread foundation destroys the lateral support and allows the material to flow into the open excavation. This usually results in a tipping or tilting of the particular footing, which condition is frequently aggravated by water flowing through the subsoil and carrying with it additional material into the open exacavation. It is this local type of settlement, generally speaking, which gives us the greatest difficulty, because of the so-called difference in settlement or variation from the general foundation plane. To eleminate absolutely settlement on a yielding material is practically impossible, so that the best we can hope to do is to minimize and otherwise control the extent and action of such a settlement.

To limit uniform settlement successfully is purely a question of limiting the amount of load which can be placed upon the soil. Numerous tables and building codes indicate certain allowable pressures based upon local experience which show a general agreement for the various classifications, although there are extreme examples as in New Orleans, where the local building code limits the maximum load to 1,400 pounds per square foot. In this case the entire city is located on an alluvial delta formation which consists of a clay with a high water filled void content.

In the case of the rotational type of settlement, the foundation engineer must always know the position of the rock with reference to the horizontal, and must take special precautions where this is inclined, so that settlement of a rotating nature does not occur. If the rock surface, however, is at a considerable depth from the foundation mat, in comparison with the maximum length of the building, the importance of the angle of the rock to the horizontal becomes of lesser magnitude, due to the distribution of the foundation loads through the foundation material as the depth increases; hence the possibility of rotational action taking place grows more remote. On the other hand, if the foundation material has a very high degree of compressibility, the greater becomes the importance of the location of the centre of gravity with reference to the applied load, and it is therefore necessary to co-operate with the architects in securing a building with its centre of gravity located as nearly as possible at the centre of the foundation area.

In order to prevent localized settlement, the first consideration of the engineer is to see that the load on individual footings is such as to produce uniform settlement. It is therefore necessary to proportion the individual footings so that the pressure under individual footings shall be correct under average loading conditions. In so proportioning the area of footings, small differences in settlement actually take place during construction, but the action of the foundation material is subject to the time effect which has the beneficial result of diminishing these, so that when our completed structure is occupied the settlement is virtually uniform throughout the footings. It is quite essential, however, that no footing when subjected to the total of dead and design live load has a pressure in excess of the allowable value for the particular material. Proper proportioning of footings as outlined usually will prevent the tendency to "hogging" or "sagging," the first being the result of heavy exterior wall construction, while the latter is more common in buildings with heavy central towers, such as are commonly seen in the so-called "set-back" type of building. It is to be noted that hogging or sagging are not in themselves very serious defects, since the differences between adjacent columns are usually small, but the undesirable effects are principally experienced in the exterior walls of the buildings, where they show in the form of cracks. In the interior of any building which is of highly ornamental character, partition walls may crack with objectionable results. A purely local settlement is generally the result of the loss of bearing under some portion of an individual footing. To make up for this difference it is frequently desirable to place two columns upon one footing, so that this loss may be equalized, and also to prevent rotation of the individual footing. A further advantage, secured by having a tie between individual footings, is that a loss of material is generally accompanied by a lateral movement, hence by restraining the footing from lateral movement a great deal of the vertical settlement is prevented.

Governing Features of the Design

In the design of the spread type of foundation for the Royal Bank of Canada, in order to control the magnitude of uniform settlement, it was decided that a soil pressure of 4 tons per square foot, exclusive of the footing weight, should be allowed. Footings were then carefully proportioned on the basis of the actual dead load plus a probable actual live load of 20 pounds per square foot of floor area. The question of rotational settlement did not require special treatment, due to the great depth at which rock was encountered and its generally horizontal plane. In order to provide against severe local settlement and tilting action, the footings for the interior columns were designed to support no less than two columns, while in one place six columns rested on the same footing. The exterior columns rested upon a heavy foundation wall designed to distribute the load under either hogging or sagging action, and this wall was placed upon a single continuous footing. The basement floor slab was thickened and strengthened above normal requirements, and designed as a stiffening and tying diaphragm to act with the footings so as to approximate the effect of a continuous mat over the entire area. Each footing and the entire outside wall footing had its steel reinforcement extended out into the basement floor slab, so that additional bearing area might be developed; so that any tendency towards lateral movement in any footing or footings would be restrained; and so as to compensate for any loss of bearing area or local reduction of soil bearing value resulting from soil disturbance caused by pumping operations, either those necessary for the installation of these foundations, or those involved in adjoining future deep cellar excavations.

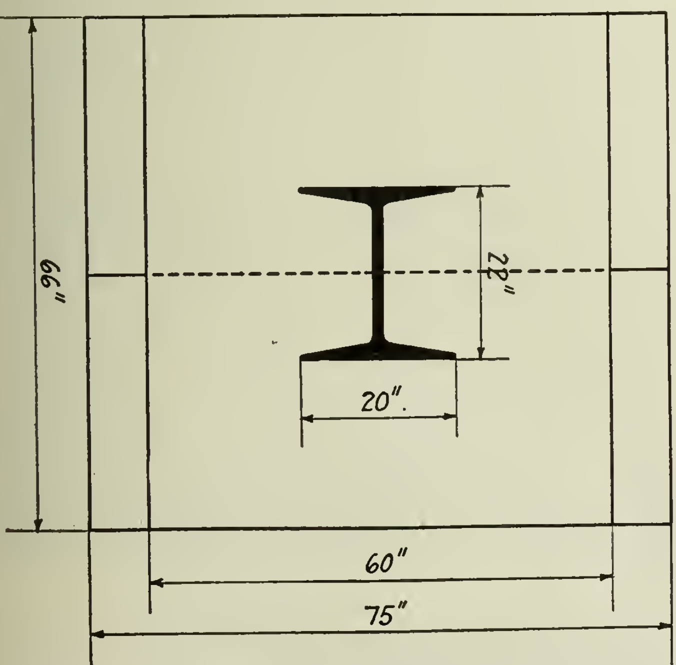

Figure No. 2.—Arrangement of Billet Supports for Column.

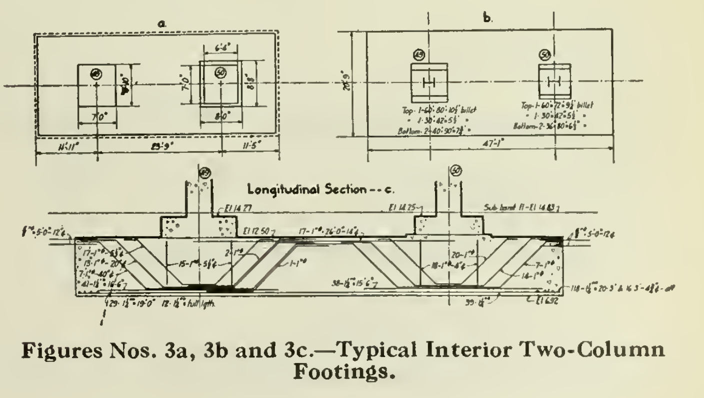
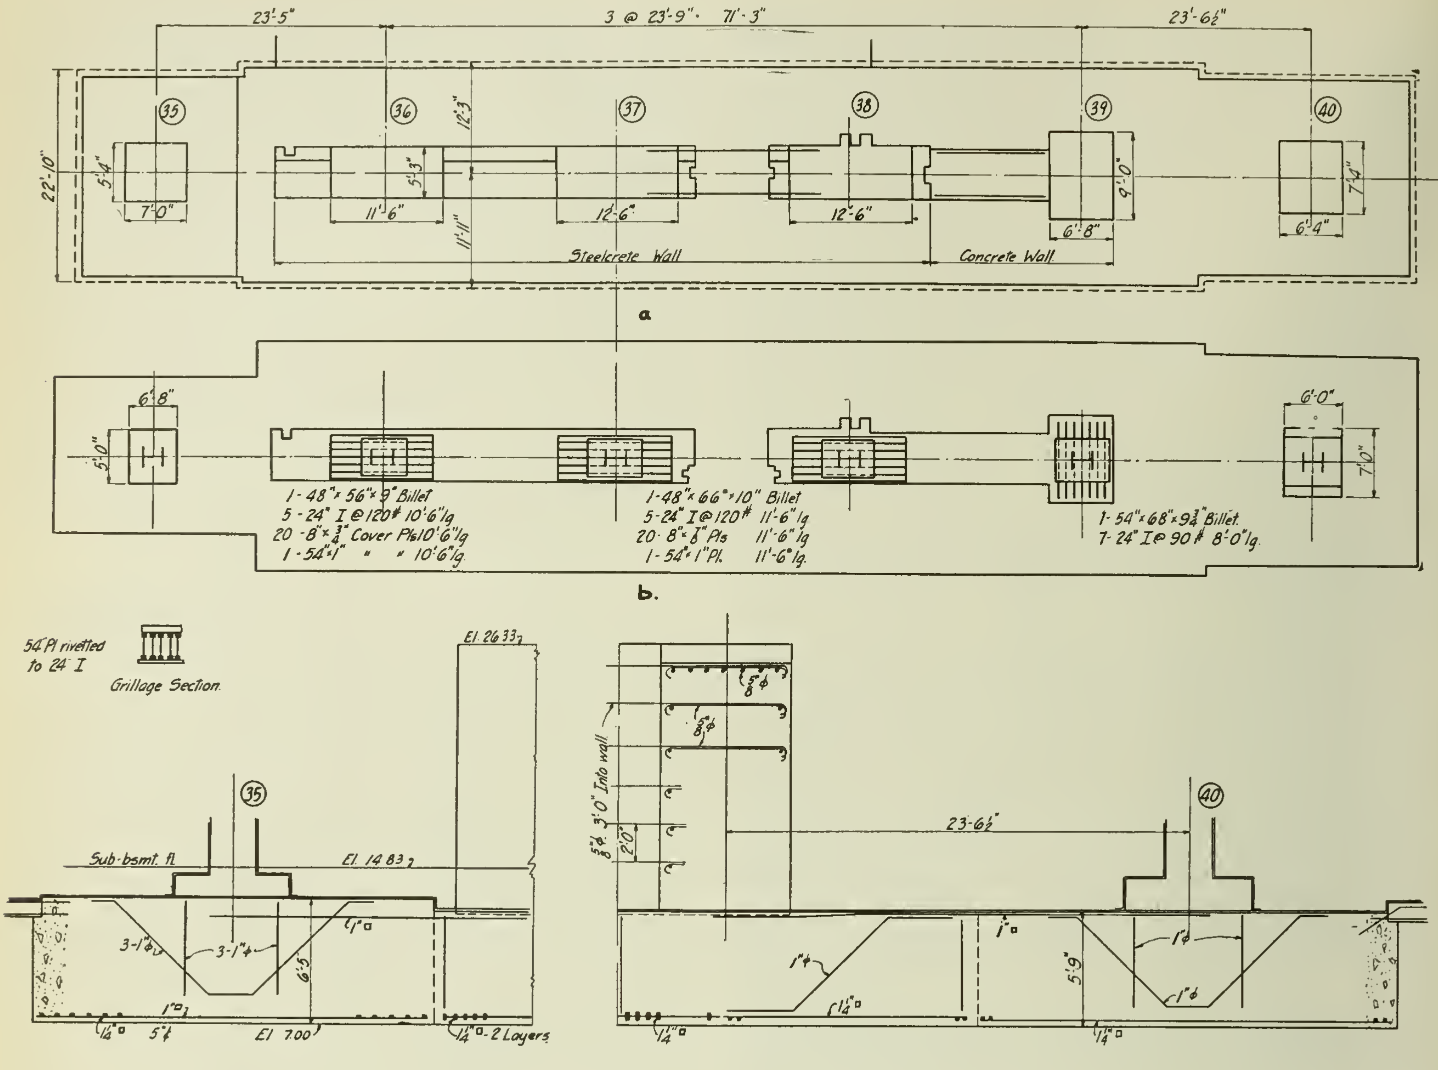
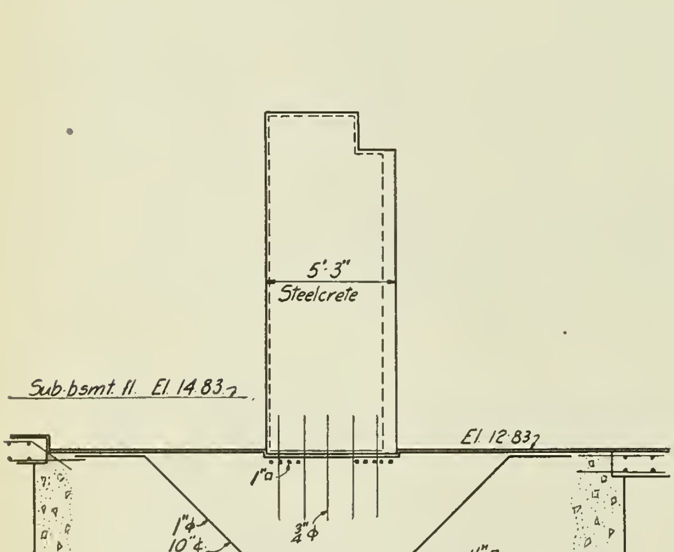


Figures Nos. 3a, 3b and 3c.—Typical Interior Two-Column Footings.





Figures Nos. 4a, 4b, 4c and 4d.—Special Design for Support of Six Columns on One Footing.

Design to Provide Maximum Cellar Space

It was desirable that the foundation design should provide the maximum of cellar space, and at the same time it was essential that the maximum depth of excavation below normal ground water level should be such that the unwatering processes would not cause the disturbance and loosening of soil materials which would result from "boiling" or the upward flow of water. This consideration limited the depth of underside of foundations, so that it was felt that with the use of sump filter beds to prevent the flow of fine materials and by careful pumping operations, the ground water level could be lowered without subsoil disturbance, but the design provided insurance against unavoidable soil disturbances which might develop locally regardless of the care in pumping operations, or from an accident to the pumping equipment. It is therefore believed that this design will insure against local settlement, and if a tendency to local settlement or tilting should occur, the loads will be thoroughly distributed throughout the general foundation system. Any other type of settlement which might develop must be of essentially uniform nature within controllable limits.

The requirement for maximum cellar space, combined with the difficulty of lowering the water level at the site, led to several novel developments. Steel billets or slabs were used to distribute the load of interior columns, but the mills

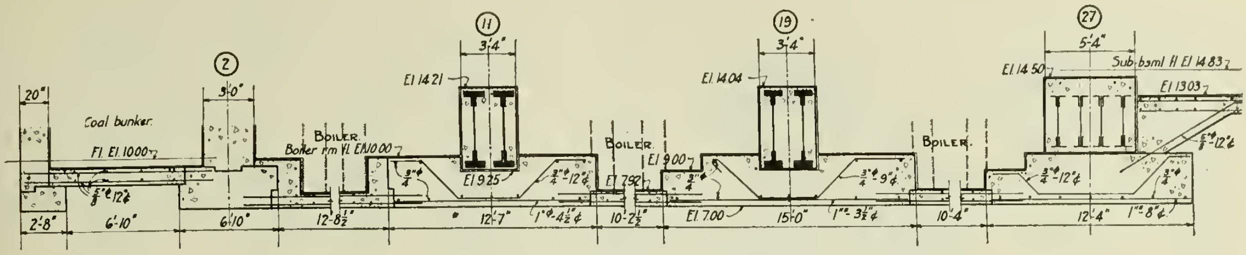


Figure No. 5.—Section showing Foundation in Boiler Room.

supplying these could do so only within certain size limitations. To overcome this handicap, a thick narrow billet was used to distribute the load upon two wider and thinner slabs placed transversely to the first. This solution, while not as economical as the single large slab, proved quite satisfactory. In general, the column footings were entirely of reinforced concrete about 6 feet in thickness, and continuous under two columns. In the boiler room, where headroom and working space were at a premium, since nearly 5 feet of additional space were required, it was found desirable to use steel girders resting on thin concrete cantilever spread footings, and the girders were placed in the division walls where possible. At the boiler pits, in order to secure even greater clearance, the bottoms of the floor slabs for the boiler pits were placed at the same level as the footings, thus providing additional space for insulation and other protection under the ash pits. The steel girders supporting the columns adjacent to the boilers were run parallel to the boiler settings, so as to not interfere with equipment, pipes, and other necessary floor space requirements. At one place the proximity of an elevator to one of the columns caused considerable difficulty, until a design was evolved consisting of two cantilever spread footings placed on either side of the pit and composed of shallow I-beams, which in turn supported deep steel girders carrying the column; thus the necessary pit depth and clearance were maintained without a loss of bearing area or decrease in the pit requirements. At another point a question involving two elevator pits was more easily overcome, since the pits were so located that a combined footing could be placed between them by properly increasing the spread of this footing. The clearances were much larger in this instance, but the pits had a further requirement of greater depth in order to install oil bumpers. It was finally decided that this difficulty could be best overcome by driving short lengths of steel pipe of considerable size to a depth several feet below the plunger pit bottom. These pipes were then cleaned out and concreted to the elevation of the necessary pit bottom and left in readiness to receive the plunger casing. It is interesting to note that all these provisions were made within the narrow confines of approximately 8 feet from the finished basement floor to the underside of the foundation, and are intended to provide fully the inherent stability essential to the structure, and at the same time take the economic advantage of the use of spread footings.

Principal Features of the Design

In order to illustrate the use of principles developed above a description of a few of the most interesting features of the design will be given.

The first problem, namely, that of determining the bearing areas and proportioning them so that the settlement of the structure should be uniform, was solved by means of the Moran method* of load distribution. This method is applied as follows: From the assumed total column loads, (dead plus live and wind), the mean loads, (dead plus 50 per cent of live and wind), are determined. The ratio of the mean load to the assumed total load is computed for each column and the lowest such ratio for any column is adopted as controlling the design. The mean unit load is then determined by multiplying the allowable unit bearing stress, (in this case 8,000 pounds per square foot), by the adopted ratio. The bearing area for each column is then found by

* See Kidder's Architects' and Builders' Handbook, 17th Edition, Page 152.

dividing the mean load by the mean unit load. From an analysis of the tabulation following, it will be found that the bearing stress under the column whose ratio was used as controlling is the allowable unit stress and is higher than for any other column.

The following table gives the above described values for a few columns selected at random:

It is interesting to note the difference in the bearing areas as found by the common method of assumed total load divided by the allowable bearing stress and those found by the Moran method.

The exterior wall, (see figure No. 1), was so designed as to distribute the load to the footings uniformly. In order to accomplish this and also to give the maximum cellar volume, in addition to providing sufficient width so that the billets would not be excessively long and narrow, a 3-foot wall thickness was adopted. For architectural reasons all exterior column flanges were parallel with the walls. Due to the stiffness of the billet under the column section, the billet thickness was computed by the bending moment taken at a point one-quarter of the flange width from the column centre. The billets were placed approximately 4 feet below the basement floor level. The subgrade of the wall was approximately 20 feet below the billet bearing level, so that the wall could be assumed to distribute the column load to the footing uniformly. The footing widths were varied as required by the bearing areas.

After making a preliminary design of the billets for the interior columns, it was found that the steel fabricators could not supply billets of the required size and thickness. Therefore, it was necessary to adopt a double tier billet design; the lower tier of which was to be made up of two billets; the bearing between the two tiers to be milled so as to insure a uniform load distribution.

The billets were designed to have their long axis parallel with the transverse, or short, dimension of the concrete mats. The bearing areas of the billets on the concrete were established by trial.

The size and thickness of the top and bottom billets were determined with a view to using economical dimensions while keeping within such sizes as the steel fabricators could supply. The top billet was then designed for its controlling bending moment, which was taken either at the edge of the column flange or at one quarter of the flange width from the column centre. The long axes of the bottom billets were perpendicular to the long axis of the top billet. In determining the thickness of the bottom billets centre bending moments were used. While the difference in the deflections of the top billet is not to be neglected, the use of centre bending moments may be justified by the fact that the greater stiffness of the billets at the column section will tend to compensate for the section of the billet having a maximum deflection.

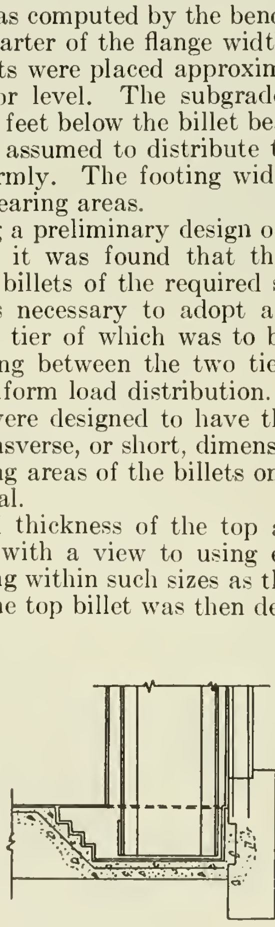

Figure No. 8.—Details of Pockets for Cantilever Girders.

As an example of this design, we will take as typical column No. 29, (see figure No. 2).

Column Load = 3,218,000 lbs.
Bearing area = 3,218,000 ÷ 650 = 4,940 sq. in. or 66 × 75 inches = 4,950 sq. in.

$$\text{Bottom billet:—}t=\sqrt{\frac{3{,}218{,}000\left(\frac{75-60}{4}\right)3}{66\times 18{,}000}} = 5\tfrac{1}{2}\text{ inches.}$$

$$\text{Top billet:—Bearing stress} = \frac{3{,}218{,}000}{60\times 66} = 812\text{ lbs. per sq. in.}$$

$$L = \frac{60-10}{2} = 25\text{ inches.}$$

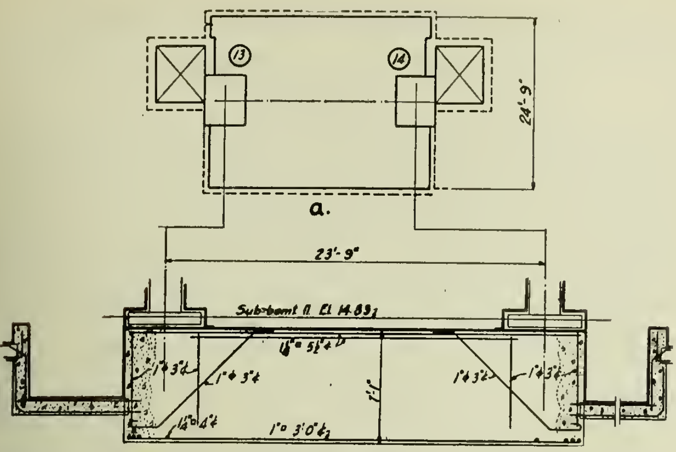
$$t = \sqrt{\frac{812\times 25^2\times 6}{18{,}000\times 2}} = 9\tfrac{1}{4}\text{ inches.}$$

Note:— 60 inches was the greatest width of billet that the fabricator could deliver.

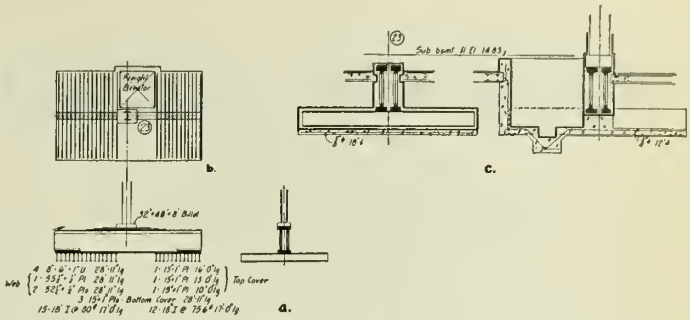
Billets to be used:—Top, one – 60 × 66 × 9¼ inches.
Bottom, two – 33 × 75 × 5½ inches.

The typical interior two-column footings were constructed of double tier billets and a heavy concrete slab, (see figures Nos. 3*a*, 3*b* and 3*c*).

The centre of gravity of the bearing area was made to coincide with the centre of gravity of the loads. In establishing the dimensions of the bearing area, not only had the necessary area, as computed by the Moran method, to be provided, but it was also necessary to consider the limitations of the available space as controlled by adjacent elevator pits, etc. The footing was then designed as a beam on two supports with overhanging ends. The effective width of the beam was assumed as equal to the billet width plus not more than twice the thickness of the footing, and the footing was reinforced longitudinally. In addition to this longitudinal reinforcement, the footing was also reinforced for punching shear, diagonal tension and centre transverse bending moments. As the depth between the sub-basement floor and the established maximum footing subgrade was one of the controlling features of the design, it was found that in many cases the required thickness could not be obtained to satisfy the punching shear requirement. Where this stress exceeded the usual allowable 120 pounds per square inch, as it did in many cases by 40 to 50 pounds per square inch, rods were placed at 45 degrees to the vertical to compensate for the excess punching shear. Diagonal



Figures Nos. 9a and 9b.—Concrete Slab and Billet Foundation at Elevator Pit.



Figures Nos. 10a, 10b and 10c.—Foundation with Elevator Pit showing Divided Bearing Area with Steel Mat Construction.

tension reinforcement was only used when the shear stress exceeded the allowable amount on the footing cross-section taken at the base of a 45 degree slope drawn from the edge of the billet.

In the special case where six columns were supported on one footing, (see figures Nos. 4*a*, 4*b*, 4*c* and 4*d*), the dimensions were established from the required bearing areas and centre of gravity of the loads. The four interior columns have grillages rather than billets and bear on a wall 5 feet 3 inches reinforced with "Steelcrete," so that this wall acts not only as one side of the security vault but also as a girder to distribute the load to the footing. The footing under the wall was designed as a cantilever, and at the doorway through the vault wall it was reinforced so as to act as a beam across this opening. The two columns in this row beyond the wall length were supported directly on the footing, which was designed in the same way as that outlined above for the typical footing, except that a beam was developed spanning from the isolated column to the vault wall.

Owing to the limitations of space in the boiler room, between the boilers and below the finished floor level, the footings there were constructed of concrete mats and steel girders, (see figure No. 5). The mats were designed as cantilevers and reinforced accordingly. In the case of a footing supporting two columns, the steel girders were designed as simply supported with overhanging ends, as was the case for columns Nos. 12, 20, 27 and 28, (see figures Nos. 6*a* and 6*b*). In the case of columns Nos. 11 and 19, between the boilers, the steel girders were designed as cantilevers, (see figures Nos. 5, 7*a* and 7*b*), which were to distribute the column load to the eccentrically placed bearing area. The reaction against uplift from these cantilevers was provided for by the walls and wall columns. Pockets were built in the wall to receive these girders, the upper faces of which consisted of steps having horizontal and vertical planes, (see figure No. 8). The cantilever girders had a bearing plate across the top flanges in order to distribute the load into the wall at the allowable unit bearing stress.

A rather unusual condition had to be provided for in the case of column No. 23, which was immediately adjacent to an elevator pit. It was impossible to combine this column with an adjacent column on one footing as its load was considerably greater than that of its neighbours and as the proximity of the elevator pit did not allow a sufficient area beyond the column centre to develop the economical bearing area. In the case of the footing under columns Nos. 13 and 14, (see figures Nos. 9*a* and 9*b*), the elevator pits were at a sufficient distance from the column centres, and their loads were practically the same, so that the concrete slab and billet type of footing could be adopted.

The finished pit floor level of the elevator next to column No. 23 was 9 inches above the maximum allowable footing subgrade. Obviously, with only 9 inches of depth adjacent to the column, the bearing area had to be developed beyond the pit limits, and this necessitated the division of the bearing area. These areas were proportional to the loads they were to receive. The load was brought on to these bearing areas by two narrow and deep girders, (see figure No. 10*a*), which again were rendered necessary by the clearance requirements of the elevator. The remaining depth from the bottom of the girders to the established subgrade was insufficient to provide for a concrete slab

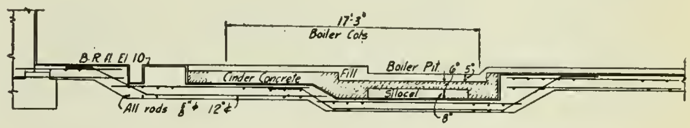


Figure No. 11.—Method of Insulation under Boilers.

capable of transferring the load from the girder to the bearing area. Steel mats of 18-inch I-beams were therefore used, distributing the load to a thin reinforced concrete mat. The construction employed is illustrated in figures Nos. 10*a*, 10*b* and 10*c*.

Figure No. 11 shows the method used to insulate and protect the cement waterproofing and concrete slab against the excessive temperatures under the boilers.

All walls and footings, as will be noted in the various illustrations, irrespective of their types, were tied together with a 12-inch floor slab, which had continuous top and bottom reinforcement between the footings and walls. The purpose of this heavy slab was three-fold, first, to resist the tendency of a possible pull; secondly, to support the floor loads between the footing should the fill tend to settle; and thirdly, to resist the uplift resulting from ground water head.

The foregoing gives a general idea of the basis of the design, and some of the problems which presented themselves in the course of the development of the means required for the safe and economical support of the building.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME XI . FEBRUARY 1928 No. 2

Annual General and General Professional Meeting

WINDSOR HOTEL, MONTREAL, QUE.

February 14th, 15th and 16th, 1928

Details of the programme appeared on page 40 of the January issue of The Journal. Complete programmes, with a return post card to be used in making reservations, and a card explaining the arrangements regarding reduced railway rates, have been mailed to all members of The Institute. Members are urged to make their reservations as early as possible, using the special card for this purpose.

A special Committee under the convenership of Mrs. F. P. Shearwood has made extensive plans for the entertainment of the ladies attending the meeting and visiting ladies are assured of a warm welcome and an enjoyable sojourn in Montreal.

The St. Lawrence Waterway Project*

Notes on the Appendices to the Report of the Joint Board of Engineers

The text of the main report of the Joint Board was made public several months ago, and in The Engineering Journal for March, 1927, there appeared an editorial commenting on the conclusions reached. Since that date engineers have looked forward to the publication of the complete report with the promised appendices containing the technical data on which the main report is based. The completed document was issued recently, and the extent of the investigations of the Board can now be realized even more fully than was possible when the main report was published. The main report covers fifty-five pages, and the seven appendices, bound with it, cover 400 pages, including many plates in explanation of the text. In addition there is a separate folder containing eighty-eight plates referring to the appendices. Obviously such a work cannot be reviewed in a short article, but the following outline of its contents has been prepared so that our members may form some idea of the nature of the information published. It is doubtful whether there has ever been issued in connection with a project of national importance, such an amount of technical data. In its completeness and manner of presentation the report indicates the thoroughness of the inquiry. Members of the engineering profession will find in the report and appendices the detailed history of the St. Lawrence river, a record of work done in the past few years, a complete exposition of the views of the Board as to the power and navigational possibilities of this great waterway, and estimates of the cost of the works contemplated.

In the covering letter issued with the appendices, the Board points out that alternatives are presented to the schemes described in the main report, and invites attention to the Crysler-island two-stage project as presented by the Canadian Section for the International Rapids Section of the river. (Appendix C.)

The following is a brief account of the contents of the various appendices:

APPENDIX A—FIELD INVESTIGATIONS—PP. 57 TO 72

This appendix outlines the work undertaken by the Canadian and United States Sections of the Board, which included (a) boring operations and surveys, (b) preparation of stage relation diagrams for the St. Lawrence, above and below Montreal; study of the effect of outlet changes at critical points in the Great Lakes system; lake regulation, (c) layout of power houses, equipment data, etc., (d) plans and estimates for bridges, (e) methods employed in compilation of data and preparation of designs and estimates.

The personnel of the staff is enumerated. A synopsis of the results of the boring tests made to determine the nature of foundations at the proposed power-house sites forms the greater part of the appendix, and brief reference is made to the surveys, valuations and properties affected, investigation of ice jams and packs, experiments on strength of ice, discharge measurements, etc.—subjects providing material for the various other Appendices.

APPENDIX B—LAKE LEVELS AND OUTFLOWS—PP. 73 TO 238

This appendix presents the data on which are based the conclusions in Part II of the main report, relating to the Great Lakes. It discusses, (a) the extent to which levels of the Great Lakes are affected by diversion of water, (b) feasible measures for raising levels to correct the effects

*By Prof. E. Brown, M.E.I.C.

of authorized diversions, and reduce the cost of improving lake channels, (c) the extent to which the outflows can be improved by manipulation of lake levels, (d) cost of deepening the channels through and between the lakes.

After giving a description of the Great Lakes area, storage capacity, supply, annual fluctuation of levels, extreme ranges of monthly mean lake levels, etc., there follows a discussion of diversions and outlets as affecting levels; improvement of levels and outflows; supplies to the lakes; permissible high levels; programme of regulation to secure maximum benefit to levels; compensating works; effect of control of lake levels on cost of inter-lake channels, and the vitally important question of the regulation of lake Ontario. The general discussion outlined covers forty-nine pages, in which are given the formulae used for outflows, backwaters, etc. About ninety-four pages of tabulated data on supply and regulation, and twenty-two plates giving hydrographic data for the river and lakes, form the balance of the appendix. The effect of the programme of regulation is summarized as follows:—Proper regulation would maintain the flow during the summer and fall months sufficiently to preserve completely the low water levels of Montreal Harbour resulting from the unregulated flow. The regulated flows during the first half of April would not exceed in amount or frequency the unregulated flow. The maximum regulated flow for May would not exceed that which has occurred in nature. The conclusion reached is that " the regulation of lake Ontario in such manner as to injure no interest, and at the same time to effect some improvement of lake levels and outflow, is therefore wholly practicable."

Appendix C—Detailed Plans and Estimates for the Improvement of the St. Lawrence—pp. 239 to 392a

This appendix deals in detail with the various schemes considered by the Board, and defines at the outset a scale of unit costs used for estimating purposes. The general character of the various sections of the river is outlined, along with the standards adopted for navigation channels, bridges and locks. The questions of power house design and of power units, which would be of larger dimensions than have yet been built, involved extended study, and from tentative designs, based on current practice, quantity curves were prepared. Power house equipment estimates were based on direct quotations and actual cost of recent developments. All the above general data with standard designs for dykes are given in plates. The various sections of the river are then considered in detail. Thus in the International Section, mile 67-115, the report covers, (a) description of section, (b) present navigation conditions and power developments, (c) plans for improvement, including,—

(1) Full single-stage schemes with the Long Sault reach at maximum level and a free navigation channel at Galops rapids.

(2) Two-stage schemes with upper dam and powerhouses either at Ogden island or Crysler island, and lower dam and power house at Barnhart island.

(3) Partial single-stage schemes with lock and control dam at Galops rapids, and the Long Sault reach held at nearly maximum level with a long free spillway.

Various methods of dealing with these alternative projects are separately considered and illustrated by river charts and drawings, and navigation improvements are discussed. The necessary works in the Soulanges and lake St. Francis Sections of the river are described, and the Lachine Section is dealt with in the same complete manner as the International Section. Considerable space is devoted to economic considerations, different rates of absorption of power being assumed in estimating the overall costs of the various projects. Approximately one hundred and ten pages are devoted to tabulated estimates of cost of the projects outlined, details quantities and unit prices being given in all cases. Thus for the dam and power house at Barnhart island the cost estimates are under the following general headings, (a) dam, except unwatering, (b) power house substructures, (c) unwatering and power house, (d) abutments to power house, (e) trailrace excavation, (f) rail connections to power house, (g) superstructure and machinery.

As showing the nature of information contained in the plates referring to this appendix, the following may be selected:—

Relation between quantity of concrete in power houses and height from draft tube floor to coping.
Relation between cost of generators, turbines, exciters and governors.
Relation between head and cost of turbines and governors.
Relation between head, cubic feet per second unit, and throat diameter.
Relation between head, speed, and throat diameter.
River charts showing location of proposed works.
Results of backwater calculations.

Each project is similarly dealt with in detail, and the complete cost estimates are worked out in every case.

In the main report the American Section of the Board recommended a single-stage development, while the Canadian Section suggested a two-stage development for the International Rapids Section of the river. In the latter scheme it was proposed to locate the upper dam and power house at Ogden island, above Morrisburg. An alternative proposal, to which the Board now directs attention, is to locate the upper dam at Crysler island, below Morrisburg, where boring operations during recent months have shown satisfactory foundation conditions to exist. It is stated that this project will cost about four million dollars more than the Ogden island scheme, but promises better financial returns. The project is estimated to furnish 300,000 h.p. more than the Ogden island scheme in the initial development. The operating head would be 34 feet until such time as the level in the lower reach is raised by the building of the lower plant at Barnhart island. The normal head would then be 24 feet in summer and 18.5 feet in winter. It is estimated that the Crysler island scheme would produce 10,000 h.p. more than the Ogden island scheme during the winter.

Appendix D—River Levels and Discharges at and Below Montreal—pp. 393-405

This appendix contains the basic data and computations considered by the Board in reaching the conclusions set forth in the main Report and in Appendix B with regard to, (1) the manner in which regulation of outflow from lake Ontario changes water levels in Montreal harbour, (2) the extent to which diversions from the Great Lakes system, and from the St. Lawrence river above Montreal, lower the water levels at and below Montreal. There are eight pages of tabulated records of river flow, and five pages of discussion, in which is included a table showing the effect of a diversion of 8,500 cubic feet per second (Chicago diversion) on the river levels, at and below Montreal. The effect at Montreal is a lowering by 0.37 feet, diminishing to 0.03 feet at Quebec. Other influences affecting levels are discussed, and estimates quoted for the cost of compensating works, including the dredging of the harbour and river channels, and corresponding lowering of the foundations of docks and wharves in the harbour.

Appendix E—Ice Formation on the St. Lawrence and Other Rivers—pp. 406-422.

When the preparation of plans for the improvement of the St. Lawrence was first undertaken, comparatively little was known about the ice conditions of the river. During the past ten years systematic study has been made of ice covers, packs and gorges, and the information obtained is contained in this appendix. The subject is discussed under the following general headings:—(1) ice pressure, (2) ice formation in rapid water, (3) effect on power improvement, (4) factors affecting ice covers, (5) limiting velocities for advance of ice packs, (6) rates of ice production, (7) river slopes through ice covered sections.

Extended observations have been made of the formation of ice covers; movement of ice bridges; velocities at which frazil is carried under ice cover and deposited to form hanging dams, etc. Measurements were made of actual contents of hanging dams in different locations, and these, when related to the water surface exposed, indicate a production of from 8 to 15 cubic feet of ice per square foot of exposure. Variations depend on the location, and degree of coldness of the water. Cross-sections have been measured and metered in winter and summer, and studies made of the minute differences of temperature on which so many phenomena of ice formation depend. Eight pages of tabulated data are given, showing river slopes for open water, under ice cover and through ice packs; average air temperature; amounts of frazil or slush formed, etc. Among other conclusions it is stated that ice pressure against dams may reach twenty-two thousand pounds per linear foot; that smooth ice covers may be expected to form in rivers with velocities up to 1.25 feet per second in zero weather, provided there is no high wind preventing such action, and that ice covers may pack upstream up to a velocity of 2.25 feet per second without danger of ice going under the cover. A formula is also given for the amount of frazil formed from a given water surface exposed to cooling action, and values of the roughness co-efficients which can be used in open channel calculations to determine winter slopes under ice covers are quoted.

Appendix F—Experiments on Strength of Ice—pp. 423 to 453

This appendix contains the results of tests carried out by the Board at the cold storage warehouse of the Harbour Commissioners of Montreal, where rooms at steady temperatures ranging from 0°F. to 32°F. were available. The main purpose of the tests was to determine the behaviour of ice at different temperatures when compressed normally to the crystals, as may occur under natural conditions above dams, power houses, bridges, etc. A supply of river ice from the LaPrairie basin, off Verdun, was cut and stored at the warehouse for use in the tests. The testing machines and necessary equipment were loaned from McGill University. During the preliminary work, which included the devising of the means of using mirror extensometers capable of recording strains of $\frac{1}{200{,}000}$, it was found that the rate of loading was a very important factor, and a scheme of loading was developed in which definite load increments were applied at regular intervals to the test specimens, which were approximately 5-inch cubes. The rates of yielding and general behaviour were noted. The series of tests included: —

(a) Compression tests at about 30°F., 16°F. and 3°F. with load increments of about ten pounds per square inch, applied at regular intervals ranging from five seconds to three hundred and twenty seconds.

(b) Crushing strength of ice at the above temperatures under loads applied gradually and suddenly.

(c) Observations on the continuous yielding of ice in compression at 30°F. under loads as low as twenty pounds per square inch, and the yielding in compression at 14°F. under sustained loads of different intensities from one hundred pounds per square inch to four hundred pounds per square inch.

(d) Bending tests at 30°F. and 14°F. at four different rates of loading.

(e) Miscellaneous tests.

Temperature and rate of loading were found to be the important factors. As an example, the results of crushing tests in which the five-inch cubes were loaded at the rate of one thousand pounds in two seconds, were as follows:—

Temp. Deg. F.	Crushing Strength—lbs. per sq. in
28	300
14	693
3	811

This appendix states that for other loading rates different figures would be obtained, and points out that conclusions based on statements of crushing strength alone, apart from rate of loading, are valueless.

As showing the effect of sustained loads of different intensities the following figures may be quoted for tests at temperatures 14°F. to 16°F. Deformations were measured on a length of two inches. For a sustained load of one hundred and three pounds per square inch the total deformation was 0.0016 inch in three hours and thirty minutes; for a sustained load of 300 pounds per square inch the total deformation was 0.021 inch in about eight minutes.

The ice frequently "flowed" during the tests, the "flow" being dependent on the rate of loading and temperature. Sometimes a block, originally 5 inches by 5 inches, would flow beyond the edges of the loading plate measuring 6 inches by 6 inches, and a block originally 5 inches high was frequently and rapidly reduced to 3½ inches height under sustained high load at the end of a test.

In general the rate of yielding under similar conditions was reduced as the temperature was lowered. The modulus of elasticity decreases as load intensity increases under all conditions, and as the length of the loading time interval increases. The modulus of rupture also increases as the temperature is lowered, and does not vary much with the loading rate.

The appendix includes about ten pages of tabulated records of tests, and eight plates showing the apparatus used and results obtained.

Appendix G—Construction Programme—pp. 454 to 459

This is a brief statement dealing with the work to be done in each of the five sections of the river: Thousand Islands, International Rapids, Lake St. Francis, Soulanges and Lachine. It is pointed out that the nature and magnitude of the work will call for the acquisition of a large amount of new plant, which will have relatively small value after the completion of construction. The value of such plant has, therefore, been absorbed into the cost of the work, and this, with interest accumulations during the construction period, indicates that maximum economy will be secured by planning for a construction period of about seven years for the heaviest work. Three pages of tabulated data show the items of work to be undertaken in each section, and the year in which it is suggested that they be carried out.

The above notes are necessarily inadequate and have been prepared solely with the object of stating broadly the contents of the appendices, so that members may realize what an immense amount of valuable information has now been placed at the disposal of the engineering profession. It is understood that a limited number of copies of the complete report, with appendices and plates, are available for interested persons and can be obtained from the secretary of the National Advisory Committee, St. Lawrence Waterway, Ottawa, for five dollars per copy.

Meeting of Council

Meeting of January 18th, 1928

A meeting of Council was held at Headquarters at eight o'clock p.m. on Wednesday, January 18th, 1928, President A. R. Decary, M.E.I.C., in the chair, and eleven other members of Council being present.

Attention was drawn to a communication from the Moncton Branch regarding the proposed amendments to Section 76 of the By-laws, and after considerable discussion the Secretary was directed to address a communication to the Moncton Branch explaining Council's meaning in connection with the proposed amendment as follows: that the amendment at present proposed is intended to provide that future proposed amendments to the By-laws may be modified during discussion at the Annual Meeting and that both the original amendments and the amendments as modified shall be placed on the letter ballot to be voted upon by the corporate membership at large.

The Financial Statement for the year 1927 was presented and received.

Discussion took place with regard to the method of dealing with members resignations when received at Headquarters, as a result of which the following procedure was prescribed for the Secretary's guidance: upon receipt of the resignation of a member in good standing, the name of the member is to be removed from the mailing list so that he incurs no further financial liability to the Institute, the branch concerned is to be notified immediately, and if no action is taken by that branch within sixty days, at the end of that period the resignation is to be brought to the attention of Council for acceptance.

Various arrangements in connection with the forthcoming Annual Meeting were considered.

A resolution passed by the Winnipeg Branch at its meeting on October 6th, 1927, dealing with the enactment of legislation that would stimulate and facilitate research in Canada was submitted and approved.

A list of reports received from a number of the Institute's Committees was submitted and noted.

The resignation of Professor Peter Gillespie, M.E.I.C., from the Chairmanship of the Committee on Biographies was noted with regret.

Professor C. M. McKergow, M.E.I.C., was unanimously renominated as a representative of the Institute on the Main Committee of the Canadian Engineering Standards Association.

A list of reports received from branches was submitted and noted.

The recommendations of the Finance Committee in connection with seven special cases were approved.

Two reinstatements were effected.

Fourteen resignations were accepted.

The following elections and transfers were effected:

ELECTIONS

Associate Members	7
Affiliates	2
Students	16

TRANSFERS

Associate Member to Member	3
Student to Associate Member	3
Student to Junior	4

Twenty-nine applications for admission and transfer were scrutinized and classified for the ballot returnable February 10th, 1928.

The Council rose at eleven o'clock p.m.

The Canadian Electrical Code

The Canadian Engineering Standards Association is performing a valuable service to industry and to the Canadian public, in preparing and publishing standards for engineering materials and structures. The most recent of these and one of the most important is the Canadian Electrical Code. This publication is a compilation of rules respecting electrical equipment, designed to minimize the fire and life hazards attendant upon the use of electricity. It is expected that it will replace the many diverse rules now in existence throughout Canada.

Evolution of Local Rules

These rules were modelled upon the "National Electrical Code" of the United States, a document sponsored by the Fire Underwriters of that country and dealing originally with fire hazards. Within its limits The National Electrical Code has set the standards for electrical work in the United States for many years, and as electrical practice in Canada has from the beginning followed American practice, it has been used by many inspection departments in this country. In the course of its evolution it has been enlarged in scope to include also the life hazard, but before this was done the demand for rules covering the life hazard had resulted in a "National Electrical Safety Code," published by the Bureau of Standards, which has been largely used by inspection authorities to supplement the National Electrical Code. Since electrical inspection is as a rule in the hands of municipal authorities, it was natural that the ideas of local inspectors should be embodied in rules superimposed upon the codes adopted, and the result of this is the existence of a multiplicity of rules covering the fire and life hazard in varying degrees, and in many cases not consistent one with another.

The Situation in Canada

The situation in Canada at the time the code work was undertaken was roughly as follows:

In British Columbia provincial legislation placed in the hands of the Workmen's Compensation Board the administration of rules which were binding over the whole province. In Ontario, the Hydro-Electric Power Commission, empowered by the provincial government, had prepared and was administering rules which were also binding over the whole province. In Quebec province-wide rules applying to public buildings were administered by the Department of Labour. In the rest of Canada inspection was carried on either by municipal authorities, (where required by local by-law), or by the Fire Underwriters.

These various rules were not in agreement in many important features and it was becoming apparent that the existence of so many different rules was undesirable. The manufacturers found it necessary to carry in stock several types of equipment for the same type of service because of local requirements. This increased the cost of such equipment and was thus not in the public interest. This situation also increased the difficulties of inspection authorities in their contacts with the public and the manufacturers.

There thus arose a demand among inspectors and manufacturers for rules which could be adopted universally throughout the country. The Canadian Engineering Standards Association, after ascertaining that the appearance of rules would be welcomed by the industry at large, undertook the task.

The Preparation of the Code

It was decided to separate the work into three parts, the first to contain rules for electrical installations in, on or over buildings using potentials up to 5,000 volts. The second part was to contain specifications for the construction and test of electrical equipment, and the third, rules for overhead electric lines.

The difficulties in the way were serious. Perhaps the greatest obstacle to overcome was geographical. It was realized that the holding of many meetings, at which all parts of the country could be represented, was impossible, and after considerable thought the work was organized by appointing a Main Code Committee representative of all sections of the country and all interests. It was also decided that an effort should be made to appoint a committee in each province for the purpose of obtaining as complete an expression as possible of local opinion. Committees were appointed in five provinces. The work of preparing the code was entrusted to two engineers who were instructed to submit a complete draft for Part 1 of the Rules, making use of the National Electrical Code, the National Electrical Safety Code, the rules of the Hydro-Electric Power Commission of Ontario and other rules in use in Canada.

The first draft submitted by the compilers was studied and criticized by the provincial committees, and while it was in the main acceptable, opinion was not unanimous. During the discussion which followed an extensive revision of the National Electrical Code was undertaken in the United States and it was considered advisable to prepare a second draft embodying certain features of this revision. At a meeting held in Winnipeg in June 1927, this draft was considered by representatives of seven provinces and, with minor revisions, adopted. It was published in September 1927 as publication C22-1927 of the Canadian Engineering Standards Association.

Adoption by Inspection Authorities

The interest which the appearance of the Code has aroused, and the action of local and provincial authorities in adopting it, is ample justification of the decision of the Canadian Engineering Standards Association to undertake its preparation, and is very gratifying to those who expended so much time and energy in its preparation. Within a short time after its publication it had been officially adopted by the Department of Telephones and the City of Saskatoon in Saskatchewan, and by the Hydro-Electric Power Commission in Ontario. Its adoption by all those represented at the Winnipeg meeting will follow shortly, in accordance with the agreement entered into at that meeting. A further result of the Winnipeg meeting was the appointment of committees in two provinces not previously represented, so that all provinces except New Brunswick and Prince Edward Island are now represented by Code committees. The existence of these committees is very necessary to assist in future revisions of the Code.

Contents of the Code

The main features of the Code are, the attention given to the fire hazard, and the form and arrangement. It is believed that in these respects it is in advance of most existing codes in America at least. A special effort was made to obtain logical arrangement and clarity of expression. All rules dealing with any particular subject are grouped together; this will, it is hoped, assist those using the Code in avoiding error and confusion. It is also believed that the rules are so worded as to minimize the possibility of ambiguity.

The scope of the Code, as mentioned above, includes "all electrical work and equipment operating at potentials up to 5,000 volts, which is installed in, on, or over any building, structure or premise." In this connection it should be mentioned that most of the rules are meant to apply to private residences, public buildings and industrial establishments. They were not primarily intended to apply to power houses, transformer stations, etc., in which the equipment has been designed and installed under engineering supervision and which is under the continuous superintendence of competent operators.

Provision is made for seventy sections, of which twenty-four are used in this draft.

All definitions of terms used in a restricted sense are grouped in one section, and all terms so defined are printed throughout the rules in bold face type.

An important section is that on wiring methods. This recognizes seven methods of wiring, specifying the conditions under which each is acceptable or required.

The section on grounding specifies what shall be grounded and indicates acceptable methods of grounding. Other important sections deal with conductors, protective and control equipment, outlet boxes and cabinets, hazardous locations, garages, motion picture studios, radio installations, signs, theatres, small isolated plants, high potential installations. The concluding section contains recommendations for maintenance and operation.

Approval Testing

An important rule in the Code requires that all equipment, (which by definition includes materials and fittings), shall be aproved, hence the definition of "approved" is of interest:

> "Approved: When used with reference to any particular electrical equipment, means that such equipment has been submitted for examination and test to Underwriters' Laboratories of Chicago, or the Laboratory of the Hydro-Electric Power Commission of Ontario, or a recognized Canadian Government Laboratory, and that a formal written report thereon has been obtained, to the effect that such equipment is suitable for sale and use."

The establishment of an approval laboratory under the National Research Council has been discussed, but pending such action the matter of approval should be adequately taken care of by the requirement just quoted. The Underwriters' Laboratories has been carrying on approval testing in the United States and Canada for many years. The Hydro-Electric Power Commission of Ontario established an approval laboratory about ten years ago and its findings have the force of law in Ontario. They have also been accepted in other provinces of the Dominion. The standards of these two laboratories are in substantial agreement.

Future Work

It is intended to issue a revision of the Code in September 1928, after which periodical revisions will be made as necessity may dictate.

The Main and Provincial Committees will continue to function and to make suggestions for changes, which experience in the use of the Code will no doubt promote.

The preparation of Part II (specifications) and Part III (rules for overhead lines) has not yet been undertaken.

The preparation of the Canadian Electrical Code is probably the most important work which the Canadian Engineering Standards Association has undertaken, because of its immediate consequences and its potential influence upon the future of the industry. The production of a standard which is acceptable to all sections of the country confers all the benefits of standardization which are so well understood by engineers and need not be recapitulated.

The special significance of this particular standard is the fact that it will become legally enforceable wherever it is adopted, and will therefore be of more direct interest to the public at large than most of the standards published by the Association. Its appearance has caused a great increase of interest in electrical inspection, the result of which will no doubt be the enactment of legislation providing for inspection in districts not now served. This will advance the cause of public safety.

The acceptance by inspection authorities of uniform standards for electrical equipment will remove one of the causes of hardship which former conditions imposed upon electrical manufacturers, and should result in lower manufacturing costs. This will benefit the public and encourage the more extensive use of electricity. The demand for approved equipment will stop the dumping of "junk" on the market, much of which is poorly constructed equipment of foreign manufacture, embodying features dangerous to both life and property.

One of the most important features of the Code work is the establishment of contacts between men in different parts of the country having a common interest in a national problem. The Code has served and will continue to act as a bond uniting different sections of the country in the pursuit of a common aim. Its preparation was accomplished by co-operative effort on the part of all participants; desire to understand the other man's point of view marked the discussions; concessions were made by all sections in the interest of the larger good. While it is admittedly imperfect in many respects, it forms a point of departure for further progress in a branch of standardization in which the public has a direct interest.

Important —

Do not forget to secure a certificate from the ticket agent when you purchase your railway ticket to Montreal for the Annual Meeting.

See announcement on page 41 of the January Journal.

OBITUARIES

Granville Carlyle Cunningham, M.E.I.C.

It is with deep regret that we record the death of Granville Carlyle Cunningham, M.E.I.C., which occurred suddenly at Farnham Common, Bucks, England, on December 18th, 1927. A member of The Institute since its inception as the Canadian Society of Civil Engineers, Mr. Cunningham has always taken a keen interest in its affairs, and in fact served for five years on the Council.

The late Mr. Cunningham was born at Edinburgh, Scotland, on April 27th, 1847, and received his education at Edinburgh Academy and University. In 1870 he went to Honduras, Central America, in charge of a railway location survey. Upon coming to Canada in 1871 he was engaged on various railway works in Ontario and the following year was with the Canadian Pacific Railway on exploration and location work. From 1875-79 he was engineer-in-charge of the Prince Edward Island Railway and of harbours on the island, and the following four years he was engaged with the Canada Southern Railway, later becoming chief engineer. In 1884 he was appointed general assistant to manager of construction of the Rocky Mountain division of the Canadian Pacific Railway. He later engaged in railway contracting in Lower Canada and had contract for part of the Temiscouata Railway, Rivière du Loup, Que. From 1889-92 he was assistant city engineer and subsequently city engineer for the city of Toronto, Ont., and during the next five years he was employed with the Montreal Electric Street Railway as general manager and chief engineer. In 1897 on his return to the Old Country, he was appointed managing director of the City of Birmingham Tramways and the next year general manager of the Central London (Tube) Railway.

Mr. Cunningham joined The Institute in the days of The Canadian Society of Civil Engineers, having been elected a Member on February 3rd, 1887. He served on the Council during the years 1889 and from 1893 until 1897 inclusive, and in 1919 was made a Life Member of The Institute.

James Herbert Bartlett, M.E.I.C.

In the death of James Herbert Bartlett, M.E.I.C., which occurred at his home in Anchorage, Ky., on December 17th, 1927, there has passed another of The Institute's first members.

The late Mr. Bartlett was born at Whetstone, near London, England, on January 22nd, 1850, and received his education, first at a private school in Brighton and afterwards at the Clapham Grammar School, Clapham, and at Owens College, Manchester. At the early age of fifteen he entered the works of Messrs. Beyer, Peacock and Company, locomotive and tool makers, of Gorton, and served a pupilage of six years, passing through the various departments, following which he was employed in the locomotive repair shops and on the line and works of the Manchester, Sheffield and Lincolnshire Railway Company.

The late Mr. Bartlett came to Canada in October 1871 as assistant locomotive superintendent of the Northern Railway Company of Canada, but left this company the following spring to enter the office of Messrs. D. C. Ridout and Company, mechanical engineers. Three years later he entered into private practice in Toronto, until 1878, during which time he erected numerous bridges in various parts of the Dominion. In 1878 he organized the Toronto Bridge Company and in the position of general manager of the company he was engaged in the construction and erection of iron and steel railway and highway bridges until 1882, when he resigned. In 1882 he visited England to arrange for the construction of the bridge over the Fraser river, British Columbia, on the line of the Canadian Pacific Railway Company. The following year he entered private practice as a consulting engineer in Montreal, specializing in the manufacture of iron in Canada.

Some time in 1885 he published a work entitled "The Manufacture, Consumption and Production of Iron, Steel and Coal in the Dominion of Canada," which has been acknowledged as the standard authority on this subject.

The late Mr. Bartlett was elected a Member of The Canadian Society of Civil Engineers on February 3rd, 1887, prior to its incorporation as The Engineering Institute of Canada.

James Hutcheon, A.M.E.I.C.

Deep regret is expressed in recording the death of James Hutcheon, A.M.E.I.C., which occurred at Toronto, Ont., on January 18th, 1928.

The late Mr. Hutcheon was born at Nassagaweya, Ont., on September 8th, 1860, and graduated from the School of Practical Science, University of Toronto, in civil engineering in 1890. In July 1890 he was articled with W. R. Burke, Ontario Land Surveyor, of Ingersoll, and served with him on government surveys in Albert, the North-West Territories, and in the Nipissing district in 1890, and again in 1891 and 1892. In November of 1891 he was commissioned as an Ontario Land Surveyor. At intervals during those years he worked under C. H. Keefer, M.E.I.C., consulting engineer, at Toronto, Mr. Alex. Baird, of Leamington, Ont., and Mr. Henry Carre of Belleville, Ont. In April 1893 he was appointed city engineer of Guelph, Ont., which position he held until 1915 when he joined the surveys branch of the province of Ontario, with which he was connected at the time of his death.

The late Mr. Hutcheon joint The Institute as a Student on October 8th, 1891, and was transferred to an Associate Member on October 11th, 1900.

Eugene O'Sullivan, A.M.E.I.C.

Sincere regret is expressed at the news of the death of Eugene O'Sullivan, A.M.E.I.C., which occurred in Montreal, Que., on January 14th, 1928, following a long illness.

The late Mr. O'Sullivan was born at St. Catharines, Ont., on August 14th, 1870, and received his early education at Ottawa University and by private studies abroad. His first engineering work was with the Department of Public Works of Canada as rodman and leveller. From 1891 to 1894 he was engaged with Mr. Henry O'Sullivan on inspection, township and exploratory surveys, and as assistant to Mr. J. H. Sullivan, engineer of the town of Valleyfield, Que., on general municipal work. In 1900 he was appointed assistant engineer to Messrs. Dean and Main, civil engineers, Boston, Mass., in charge of construction of Gault mills at Valleyfield. The next two years he was engaged as engineer for the Montreal Cotton Company on the construction of the company's mills and the development of water power by Messrs. Wighton and Morrison. Later he had charge of the drainage system for the Truro Condensed Milk Company, at Huntingdon, Que., and the next year he had charge of railway location for the Atlantic, Quebec and Western Railway, at Gaspe, and survey and soundings at the upper entrance of the Soulanges canal for the construction of a breakwater. In 1905 he was placed in charge of a survey for the town of Westmount, under the town engineer, for the proposed waterworks system. Subsequently he was appointed assistant engineer with the Montreal Waterworks, under Messrs. Janin and Lesage, and was resident engineer during the construction of the aqueduct.

Mr. O'Sullivan joined The Institute as an Associate Member on May 14th, 1908.

Pierre Danais, A.M.E.I.C.

In the death of Pierre Danais, A.M.E.I.C., which occurred at Quebec on November 27th, 1927, The Institute has lost one of its young and promising members. At the time of his death Mr. Danais was in the employ of the Department of Roads of the province of Quebec, and had been in ill health for months.

He was a native of the province of Quebec, having been born at Baie Saint Paul on April 25th, 1890. His early education was received at the primary school of that village and at the Seminary of Chicoutimi. He continued his studies at Laval University and at Queen's University, from which he received the degree of B.Sc. in 1917. Following graduation he commenced the practice of his profession and was employed as leveller in connection with water power development at Chicoutimi. From 1918 to 1920 he was in private practice on survey work and for part of the time he was engaged with Provincial Land Surveyors. In 1920 he occupied various positions such as draughtsman on preliminary railway surveys, topographer and transitman, and in 1921 he entered the services of the Department of Roads of the province of Quebec, with which he remained until the time of his death. His work with this department included both field and office duties.

The late Mr. Danais had a host of friends and particularly among his fellow engineers. He was devoted to his chosen work so much that on many occasions during his illness he had been known to say that his duty was to complete the work that was given to him and he would take a rest and care for himself afterwards. As an indication of the high esteem in which he was held by those to whom he was responsible there appears in "La Voirie Sportive," the official organ of the Quebec Sportif de la Voirie, an appreciation by Jos. L. Boulanger, Deputy Minister of the Department of Roads.

Mr. Danais joined The Institute as a Junior on April 27th, 1920 and was transferred to an Associate Member on April 29th, 1924.

PERSONALS

Chas. W. Dill, A.M.E.I.C., who for the past three years has been located in Toronto, Ont., has joined the staff of the Carter-Halls-Aldinger Company, Limited, at Vancouver, B.C.

C. L. Dodge, A.M.E.I.C., of Calgary, Alta., has joined the staff of the Canada Land Irrigation Company, Limited, Medicine Hat, Alta. Mr. Dodge graduated from Colorado State College with the degree of B.Sc. in 1911.

John G. Hall, A.M.E.I.C., of the staff of the Combustion Engineering Corporation, Limited, at Winnipeg, Man., has been transferred to the Montreal office of the company. Mr. Hall is a graduate of McGill University of the year 1921.

A. J. Macdonald, A.M.E.I.C., of Black Avon, N.S., has accepted a position on the staff of the Department of Highways, Halifax, N.S. Mr. Macdonald was for a short time with the Aluminum Company of Canada at Jonquiere, Que.

William Anderson, A.M.E.I.C., who has been power apparatus specialist with the Northern Electric Company, Limited, Calgary, Alta., has been appointed to the position of sales engineer with the Canadian Westinghouse Company, Limited, in the same city.

T. A. McElhanney, A.M.E.I.C., acting superintendent, Forest Products Laboratories of Canada, at the University of British Columbia, Vancouver, B.C., has been appointed superintendent, Forest Products Laboratories of Canada, Department of the Interior, Ottawa, Ont.

C. L. Breithaupt, A.M.E.I.C., chemical engineer, Breithaupt Leather Company, Kitchener, Ont., has joined the staff of the acids and heavy chemical division of the E. I. du Pont de Nemours and Company, Philadelphia, Pa. Mr. Breithaupt is a graduate of the University of Toronto of the year 1922.

Major E. L. M. Burns, R.C.E., A.M.E.I.C., has left to attend the staff course at the Staff College, Quetta, India. Major Burns is a graduate of the Royal Military College, Kingston, of the year 1915, and spent three years on active service during the late war. Major Burns expects to be in India for a period of two years.

Ross M. Carmichael, A.M.E.I.C., has resigned his position as designing engineer, Hydro-Electric Power Commission of Ontario, to join the engineering staff of the Aluminum Company of Canada, at Arvida, Que. Mr. Carmichael is a graduate of the University of Toronto of the year 1913.

Chas. B. Rorke, S.E.I.C., has returned to Canada to accept a position with the Canadian and General Finance Company at Toronto, Ont. Following his graduation from McGill University in 1923, Mr. Rorke went to East Pittsburgh, Pa., where he entered the graduate students' course of the Westinghouse Electric and Manufacturing Company.

R. B. Stewart, M.E.I.C., is managing director of I. Matheson and Son, New Glasgow, N.S. Mr. Stewart is a graduate of McGill University of the year 1910. He was for several years with the Dominion Bridge Company, Limited, and later manager and engineer for the Maritime Bridge Company, at New Glasgow, N.S.

G. R. Adams, S.E.I.C., who graduated from Queen's University in 1927, has joined the staff of the Tropical Oil Company, Barranca, Bermeja, Colombia, S.A. In June 1926 Mr. Adams was with Messrs. Fraser, Brace, Limited, at Gatineau, Que., and later joined the staff of Price Brothers and Company, Riverbend, Que.

Major N. C. Sherman, R.C.O.C., M.E.I.C., inspector of ordnance machinery, ordnance office, Esquimalt, B.C., has been moved to Headquarters, Military District No. 3, at Kingston, Ont., and is carrying out the same work as in the west, viz., maintenance and inspection of all artillery and ordnance equipment and the technical stores connected with them.

Douglas Norman, S.E.I.C., has been transferred from the engineering department of the Canadian General Electric Company, Limited, at Peterborough, Ont., to the transformer engineering department of the company at Toronto, Ont. Mr. Norman graduated from the University of Manitoba with the degree of B.Sc. in electrical engineering in 1926.

George H. Burgess, M.E.I.C., who for the past three years has been associated with Coverdale and Colpitts, consulting engineers, 66 Broadway, New York city, has now been appointed a member of this firm. Mr. Burgess was for a number of years with the Delaware and Hudson Company as chairman of valuation committee and real estate agent, having first joined the company as chief engineer in 1908.

Willis Chipman, M.E.I.C., well-known consulting engineer of Toronto, has left for an extended trip to the West Indies. Mr. Chipman is one of the first members of The Institute, having accepted membership on June 13th, 1887. He was a member of Council for the years 1899, 1901 and 1902 and has always taken an active part in the affairs of The Institute. He is the founder of the Ontario Land Surveyors' Association, of which he is a past-president.

Duncan Kennedy, A.M.E.I.C., recently with Messrs. Monsarrat and Pratley on the substructure work of the Montreal South Shore bridge, is now acting as resident engineer for Messrs. Robert White and Partners of Westminster, England, on the construction of wharves and jetties at Bharnagar, Kathiawar, India. Mr. Kennedy's engineering work has taken him into many countries, and on coming to Canada in 1924 he became engaged on the hydro-electric project at Isle Maligne, Que., with the Quebec Development Company.

W. Nelson Smith, M.E.I.C., who about a year ago returned to the United States from Winnipeg, Man., in connection with the valuation of the Philadelphia Electric Company's property at Philadelphia, Pa., is now with the organization of E. L. Phillips and Company, engineers, 50 Church street, New York city. While in Winnipeg, Mr. Smith was consulting electrical engineer of the Winnipeg Electric Company and was engaged on several other matters of valuation for that company. He was also on work in Vancouver for the Sydney E. Junkins Company, Limited.

Geo. O. Vogan, Jr.E.I.C., has resigned his position with the Hydro-Electric Power Commission of Ontario to join the engineering staff of the Aluminum Company of Canada, at Arvida, Que. Mr. Vogan graduated from Queen's University with the degree of B.Sc. in 1917. Following graduation he was appointed field draughtsman for the railway department of the Hydro-Electric Power Commission of Ontario until September of the same year when he was transferred to the hydraulic department, with which he has remained ever since.

W. Hamilton Munro, M.E.I.C., has resigned his position as manager of the Nova Scotia Tramways and Power Company and has joined the staff of the Montreal Engineering Company, Limited. In 1919 he joined the staff of Vickers Limited, London, England, and was engaged in field inspection of water power developments, and was later appointed senior hydraulic engineer, hydro-electric department. In 1925 he returned to Canada to take over the duties of sales manager of the Canadian branch of the firm at Maisonneuve, Montreal. Mr. Munro is a graduate of the University of Toronto, (Science), of the year 1904.

Moses Burpee, M.E.I.C., who since 1891 has been the chief engineer of the Bangor and Aroostook Railroad Company, has retired from that position and has been appointed consulting engineer to the company. Mr. Burpee is a native of Sheffield, N.B., where he was born in 1847. His first work in railway engineering was as rodman on the Fredericton Railway in 1868 and on the European and North American Railway in New Brunswick in 1869. He was for many years engaged as assistant engineer on construction, transitman on surveys, assistant engineer-in-charge of surveys and draughtsman on different railways. In 1890 he was appointed chief engineer of the New Brunswick Railway, which was taken over by the Canadian Pacific Railway in the same year.

J. R. Donald, M.E.I.C., managing-director, J. T. Donald and Company, Limited, is spending six weeks in Europe investigating chemical processes and plants. Mr. Donald graduated from McGill University in 1913, following which he joined the Nichols Chemical Company, Limited, at Sulphide, Ont. The next year he was engaged in general consulting with J. T. Donald and Company, Limited. From 1916-18 he was chief inspector of explosives, chemicals, for Ministry of Munitions, Canada. In 1919 he was appointed chemical engineer and chief chemist of the Canadian Packing Company, Limited, Toronto, and later joined the firm with which he is now connected.

F. H. Hibbard, A.M.E.I.C., engineer, maintenance-of-way, of the Quebec Central Railway Company, has been appointed engineer, taking over the duties of the former chief engineer, who has recently been superannuated. Mr. Hibbard has had extensive and varied experience on railway work, particularly with the construction of the National Transcontinental Railway and the Saint John Valley Railway. In June 1913 he become connected with the Quebec Central Railway Company as engineer-in-charge of construction and three years later was appointed assistant engineer with the company, later being promoted to the position which he occupied until recently.

Robert Morham, A.M.E.I.C., has resigned his position with the hydraulic department of the Hydro-Electric Power Commission of Ontario to join the engineering staff of the Aluminum Company of Canada, at Arvida, Que., and will be engaged on the design of the new power plant at Chute a Caron on the Saguenay river. Prior to coming to Canada in 1912, Mr. Morham had considerable experience on engineering works in the Old Country. His first work in Canada was with the Highway Department of the province of Saskatchewan. He was later engaged with the Steel Company of Canada at Hamilton, Ont., and with the Department of Works for the city of Toronto until being appointed to the engineering staff of the Hydro-Electric Power Commission.

W. G. MacNaughton, M.E.I.C., has resigned his position as secretary of the Technical Association of the Pulp and Paper Industry and has joined the staff of the News Print Service Bureau, New York city. Mr. MacNaughton is a graduate of McGill University of the year 1904 and for three years following graduation he was employed as chemist with the Canadian Consolidated Rubber Company, Montreal, and also had supervision of rubber cement department and crude rubber preparation. In 1908 he became connected with the Nekoosa Edwards Paper Company, Port Edwards, Wis., as chemist, and in 1912 was promoted to the position of plant manager. In April 1917 he was appointed general manager of the Inland Empire Paper Company, at Spokane, Wash.

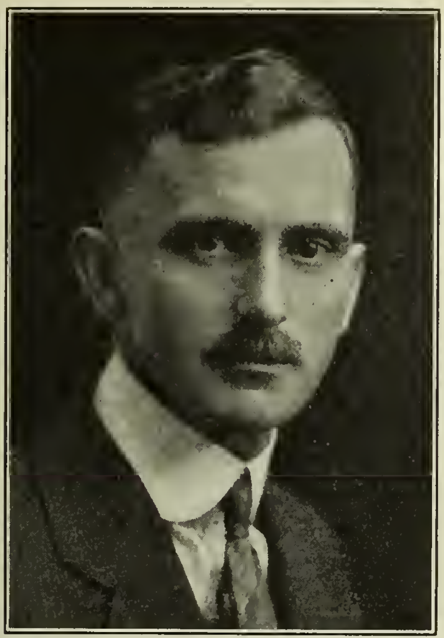
E. A. Cross, A.M.E.I.C., who since 1920 has been engaged as structural engineer with Albert Kahn, architect in Detroit, Mich., on the design of reinforced concrete and steel structures, industrial plants, etc., has joined the staff of Messrs. Chapman and Oxley, Toronto, Ont. Mr. Cross is a native of Petersfield, Hunts, England, and graduated from Birmingham University in 1909. Following graduation he was appointed assistant engineer with Birmingham Canal Navigations, engaged on surveys, designs, estimates and specifications for numerous canal works. In 1920 he came to New York and joined the H. D. Best Company as reinforced concrete designer, following which he was appointed superintendent of construction for W. L. Stoddart, architect, New York city.

A. L. Harkness, A.M.E.I.C., has recently left the staff of the Welland Ship Canal to accept a position with Newton-Dakin Construction Company and will be located in Montreal. Prior to going on the Welland Ship Canal work, Mr. Harkness was chief engineer of the Robert W. Hunt and Company, Limited. He is a graduate in civil engineering of the School of Practical Science of the year 1906 and received the degree of B.A.Sc. from the University of Toronto in 1908. After a number of years engagement in various positions with the Dominion Bridge Company, Montreal, he was transferred, in 1911, to the designing staff of the St. Lawrence Bridge Company in connection with the work on the Quebec bridge and in August 1914 he became assistant engineer, which position he held until the completion of the Quebec bridge contract.

J. A. Knight, A.M.E.I.C., of Toronto, Ont., has been appointed to the engineering staff of the Aluminum Company of Canada, at Arvida, Que., in connection with the design of the proposed power plant at Chute a Caron on the Saguenay river. Mr. Knight is a graduate of the University of Toronto of the year 1914. During the Great War Mr. Knight saw service overseas with the 2nd Canadian Tunnelling Company and with the 11th Battalion Canadian Engineers and was awarded the Military Cross. On his return he joined the staff of the Hydro-Electric Power Commission of Ontario and has been engaged on hydraulic design with the Commission ever since. He has been an active member of the Toronto Branch of The Institute, having been secretary of the branch and on the executive for a number of years and occupying the office of vice-chairman during the present year.

A. Duperron, M.E.I.C., Chief Engineer, Montreal Tramways Commission

A. Duperron, M.E.I.C., engineer of the Quebec Streams Commission, has been appointed chief engineer of the Montreal Tramways Commission. Mr. Duperron is a graduate of Ecole Polytechnique, Montreal, from which he received the degree of B.A.Sc. in 1911. During his college course he was engaged on various survey works and immediately following graduation he was associated with Mr. E. Laignon on hydro-electric and building construction. In September of the same year he was engaged on railway location with the Central Railway of Canada between Hawkesbury and Ottawa. In January of 1912 he accepted a position with W. I. Bishop, M.E.I.C., on hydro-electric surveys on the St. Francis river and on construction work at Drummondville, Que. From September 1912 until May 1913 he was employed in the office of the construction department of the Canadian Pacific Railway at Montreal, subsequently being transferred to the bridge department on the design and



A. DUPERRON, M.E.I.C.

preparation of bridge plans. In August 1915 he joined the staff of the Quebec Streams Commission, first as chief of a survey party in the Lake St. John district and later in charge of construction of the superstructure of a bridge over the Sauvage river in connection with the Lake St. Francis reservoir. Following this he was on the staff of the Commission at Montreal. Mr. Duperron has served on the Executive Committee of the Montreal Branch of The Institute and in connection with the forthcoming Annual Meeting he is chairman of the Papers Committee.

BOOK REVIEWS

The Propagation of Electric Currents in Telephone and Telegraph Conductors

By J. A. Fleming. D. Van Nostrand Company, New York, 1927, Fourth Edition, Buckram, 9 x 6 in., figs., tables, diagrs., $8.00.

This book is primarily intended for engineers and experts in dealing problems of communication, both telephonic and telegraphic, over metallic circuits. However, it contains valuable information for power transmission engineers, such as, harmonic analysis and the solution of transmission problems by hyperbolic trigonometry.

The opening chapter deals briefly with simple periodic functions and their representation by complex notation. This forms a fitting introduction for the work to follow. The balance of the chapter is devoted to an exposition of hyperbolic trigonometry and the development of the various functions. The theory is outlined in a remarkably clear manner and anyone desiring a knowledge of this branch of mathematics would be amply repaid by a careful study of these pages.

In the second chapter a theory for the propagation of electromagnetic waves along wires is developed. The author is successful in explaining this phenomenon by simple illustrations and by the more elaborate method of the calculus.

Equations for the propagation of simple periodic currents in telephone cables are developed in the third chapter. These are identical with equations used in power transmission problems. Practical examples are worked out which are helpful from the mathematical point of view.

The fourth chapter deals with the specific problem of telephony. The analysis of single valued periodic curves into a Fourier's series is explained in detail. The analysis and synthesis of sound and the effect of distortion through different attenuations of the component frequencies serves to emphasize the most important obstacle to be overcome in successful telephone communication. Dr. Pupin's and Campbell's theory of the loaded cable are presented in mathematical detail. It is well known that the invention of the loaded cable made long-distance telephony possible.

Special problems relating to currents in submarine cables are taken up in the fifth chapter. The treatment of this subject is carried out in similar manner to that on telephony in the previous chapter with necessary modifications as the case demands. Following this is a related chapter on the transmission of very high and very low frequency currents.

All classes of cables are nowadays subjected to accurate measurements and tests of their characteristics. The author describes methods for making various tests and in addition detailed descriptions of a number of instruments with diagrams are included. This chapter, number seven, is of special interest to cable manufacturers.

Elaborate theories are valueless unless they can be substantiated by experiment. Chapter eight deals specifically with a comparison of constants as predetermined by calculation and verified by test. Chapter nine is devoted to the practical performance of loaded cables.

Chapter ten is entirely devoted to recent improvements in the field of communication. It treats such subjects as, improvements in construction of loading coils, phantom circuits, characteristics of permalloy and other alloys of high permeability, thermionic repeaters and carrier wave telephony.

Taking the book as a whole it is one which yields its information only through careful and intensive study. It represents a valuable contribution to the art of communication which today is such an essential factor in the business and social world.

W. F. McKnight,, A.M.E.I.C.
Professor of Electrical Engineering,
Nova Scotia Technical College.

Geophysical Methods of Prospecting for Ore, Oil, Etc.

A concise pamphlet on this subject has just been published as technical paper No. 420 of the United States Bureau of Mines, and contains a brief account of the principles involved in these modern methods of prospecting or ore detection.

The authors are two Canadian physicists, Dr. A. S. Eve and Dr. D. A. Keys, who for some time past have been engaged in testing the efficacy of nearly all the known methods of scientific prospecting by geophysical means.

Interest in possible methods of detecting bodies of ore buried beneath the surface is naturally wide-spread, and subject is important on account of the large sums of money and the vast amount of work which can be saved if such methods can be successfully applied.

The authors' investigations lead to the conclusion that the particular geophysical method to be employed must be chosen to suit the particular region and circumstances, each method having its own field of usefulness.

Geophysical prospecting methods may be magnetic, gravitational, electrical or seismic. Those first named depend on the measurements of local variations in the earth's magnetic force by magnetometers or earth inductors, or by means of magnetic variometers. In gravitational methods a sensitive pendulum or a special torsion balance is employed, so as to map out the changes in the earth's gravitational force which are caused by the proximity of masses of material of abnormally high or abnormally low density; electrical methods may depend on the measurements of natural currents existing in the ground, or measurements of the earth's resistance, or on the distribution of an artificially produced electromagnetic field, or on the measurement of equipotential lines due to currents passing between two electrodes placed on the ground.

In nearly all cases the desired result of the observations is a map, on which the hidden mass of material is indicated by irregularities or distortions of the lines or contours of equal potential, equal values of g, or as the case may be.

The pamphlet also describes methods involving the use of so-called seismic methods, in which the time taken for an explosion impulse to pass through the ground is noted and compared with the time taken by the same impulse to pass through another path, usually a quicker one, leading through ore bodies or subterranean masses of low density. These methods are finding application particularly in searching for salt domes in connection with oil explorations.

It will be noted that all the methods in review are based on rational and scientific study; they employ definite physical principles which are generally known. They have nothing in common with the "divining rod" or any other systems whose efficacy, (if any), depends on principles which elude scientific explanation.

The paper will be read with interest by all who are concerned with prospecting or mining developments, and its methods may be found of wide application in connection with other types of engineering work.

EMPLOYMENT BUREAU

Situations Vacant

MECHANICAL DRAUGHTSMAN

Mechanical draughtsman with at least four years experience in newsprint mill work. Good opening for right man in newsprint mill in province of Quebec. Apply, stating salary expected. Apply box No. 179-V, The Engineering Journal.

DESIGNING ENGINEER

Designing engineer, experienced in pulp and paper machinery design, to take charge of draughting office in large newsprint mill in the province of Quebec. Applicant must be technical graduate. Apply, stating salary expected, to box No. 180-V, The Engineering Journal.

DRAUGHTSMAN

Wanted, draughtsman familiar with papermill machinery and experienced in paperboard mill design. Apply box No. 183-V, The Engineering Journal.

DRAUGHTSMAN

Mechanical draughtsman experienced in steam power plant design. Apply box No. 184-V, The Engineering Journal.

MECHANICAL DRAUGHTSMAN

Young mechanical draughtsman with technical training and some practical experience in plant layout and upkeep for large firm in western Canada. Apply Box No. 185-V, The Engineering Journal.

ASSISTANT ENGINEER IN CHARGE OF BUILDING MAINTENANCE

Applications will be received until February 18th for the position of assistant to the engineer in charge of building maintenance with a large financial institution which owns, in addition to a large office building in Montreal, buildings in various centres in Canada. Work to comprise supervision of plant operation and maintenance, purchasing of equipment and supplies, and office equipment. Applicants must be recent graduates in engineering, preferably mechanical or electrical. Apply Box No. 186-V, The Engineering Journal.

MECHANICAL ENGINEER

A well-known company manufacturing equipment for hydraulic plants, pulp and paper mills, and mining, requires the services of a young engineer with shop experience and other relative work, as general assistant in the engineering department. Applicant should have some shop experience and should be a graduate in mechanical engineering. Apply giving full particulars of qualifications, to box No. 187-V, The Engineering Journal.

FOREST PRODUCTS ENGINEER, GRADE 3

A Forest Products Engineer, Grade 3, (Male), Forest Branch, Department of the Interior, Ottawa, at an initial salary of $2,820 per annum, which will be increased upon recommendation for efficient service at the rate of $120 per annum, until a maximum of $3,240 per annum has been reached.

Duties.—To plan, collect and prepare exhibits of forest products; to design and supervise construction of experimental wooden equipment and structures; to prepare exhibits of forest products for educational purposes; to write suitable specifications and descriptions of all wooden materials and structures used in exhibits and in industry; to supervise wood workers; to write special articles regarding wood utilization, and to perform other related work as required.

Qualifications Required.—Education equivalent to graduation in forestry or applied science from a university of recognized standing; at least two years experience with educational, administrative or industrial organizations directly concerned with wood utilization; supervisory ability. Experience in exhibition methods is an important qualification for this position. While no definite age limit has been set for this competition, age may be a determining factor in making a selection.

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, *not later than February 16, 1928.* Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at Prince Rupert, Vancouver, Victoria, Edmonton, Calgary, Regina, Saskatoon, Winnipeg, Quebec, Fredericton, St. John, Charlottetown, and Halifax, or from the Secretary of the Civil Service Commission.

Situations Wanted

DESIGNING ENGINEER

Extensive experience in design, manufacture and sale of all types of cranes, also works and office organization, seeks position as chief engineer. Can undertake complete development of crane production. Apply box No. 232-W, The Engineering Journal.

ELECTRICAL ENGINEER

Electrical engineer, 27 years of age, University of Toronto graduate, six years diversified experience, two years Westinghouse engineering course, inspection of electrical equipment, industrial construction and maintenance, testing and research; at present employed in United States; wishes to return to Canada. Available on reasonable notice. Apply box No. 231-W, The Engineering Journal.

ELECTIONS AND TRANSFERS

At the Meeting of Council held on January 18th, 1928, the following elections and transfers were effected:—

Associate Members

ARCHIBALD, Samuel Wallace, B.A.Sc., (Univ. of Toronto), private practice in engineering and surveying, Seaforth, Ont.

BARRETTE, Adrien, B.Sc., (Ecole Polytechnique), asst. engr., Tech. Service, city of Montreal, Montreal, Que.

BONAVENTURE, Joseph Eugene, B.A.Sc., (Ecole Polytechnique), asst. dist. engr., Dept. of Public Works, Canada, Three Rivers, Que.

BOURBONNAIS, Paul Emile, C.E., B.A.Sc., (Laval Univ.), senior staff engr., Quebec Streams Commission, Montreal, Que.

HUMPHREYS, David, asst. to ch. engr., hydro-electric dept., Sir W. G. Armstrong, Whitworth and Co., i/c field work installing hydro control equipment and auxiliary plant on the Humberarm development, Deer Lake, Nfld.

McCLELLAND, Harold Langdon, B.A.Sc., (Univ. of Toronto), demonstrator and research asst., Dept. of Mining Engrg., Univ. of Toronto, Toronto, Ont.

McPHAIL, Alexander Lyall, B.A.Sc., (Univ. of Toronto), asst. city engr., St. Catharines, Ont.

Affiliates

CUNNINGHAM, John Ferguson, supt. of test labs., Dept. of Civil Engrg., Univ. of Manitoba, Winnipeg, Man.

TOWNSEND, Charles Rowlatt, B.Sc. and M.Sc., (Univ. of N.B.), with logging division of Laurentide Co. i/c field work of various projects, Grand'Mere, Que.

Transferred from the class of Associate Member to that of Member

DUPERRON, Arthur, B.A.Sc., (Ecole Polytechnique), ch. engr., Montreal Tramways Commission, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

KIDD, William Sidney, B.A.Sc., (Univ of Toronto), asst. ch. engr., E. B. Eddy Co., Hull, Que.

MACKENZIE, John Fenwick Fraser, with Dom. Bridge Co. as asst. ch. dftsman, Montreal.

WALKER, George Stuart, B.Sc., (Queen's Univ.), i/c constrn. and mtce. of roads and ry., inc. location, constrn. and operation, with Imp. Oil Co., Negritos, Peru.

Transferred from the class of Student to that of Associate Member

FARMER, Eric Westover, B.Sc., (McGill Univ.), elect'l engr. on short-wave transmitter development with Can. Marconi Co.

GEIGER, Douglas George, B.Sc., (Queen's Univ.), lecturer, elect'l engr., Queen's Univ., Kingston, Ont.

METHE, Philippe, B.A., C.E., (Ecole Polytechnique), principal, Quebec Tech. School, Quebec, Que.

Transferred from the class of Student to that of Junior

CREASE, Charles Edward, B.Sc., (N.S. Tech. Coll.), industrial control engrg., C.G.E. Co., Peterborough, Ont.

HOLMES, Everett Eric, B.Sc., (McGill Univ.), i/c service order section, plant operations, general plant dept., Bell Telephone Co., Montreal, Que.

SHAW, Gerald Edison, B.Sc., (McGill Univ.), designing reinforced concrete and steel structures, bridge dept., C.P.R., Montreal, Que.

TOUPIN, Valerien, B.A., (Laval Univ.), B.A.Sc., (Ecole Polytechnique), with St. George and Gauvreau, Limited, Montreal, Que.

BRANCH NEWS

Border Cities Branch

Orville Rolfson, A.M.E.I.C., Secretary-Treasurer.

The first meeting of the New Year was held by this branch on January 13th, at the Prince Edward hotel, Windsor, and was one of the largest and most successful meetings in recent years.

The speaker of the evening was E. J. Paulus, chief construction engineer for the McClintic-Marshall Company on the Detroit River International bridge. In beginning his address, Mr. Paulus expressed his appreciation of the splendid co-operation which the builders of this bridge are receiving from the Dominion and provincial govemments, the municipal authorities and the public in general on this side of the river. He also paid a glowing tribute to Lt.-Col. C. N. Monsarrat, M.E.I.C., in regard to his work on the bridge project, in reviewing the design and the report submitted by him thereon to the Minister of Railways and Canals.

Proceeding with a description of the bridge, the speaker explained that it is to be of the suspension type, the main river span being 1,850 feet centre to centre of piers, a record span, until recently, when the McClintic-Marshall Company projected a new bridge across the Hudson river, with a span of 3,500 feet. There will be two parallel wire cables, 20 inches in diameter, of 37 strands each, 216 wires per strand, No. 6 gauge galvanized high carbon heat treated steel, passing over flexible steel towers, approximately 380 feet in height, and fastening to anchors consisting of two concrete blocks 22½ by 100 feet on rock, fastened together by a concrete strut and having a balancing superstructure of concrete as a counterweight.

The pull to be resisted by the anchorage is 20,000,000 pounds. Rock is 117 feet below ground level, but in the design no account is taken of the earth resistance. The cables will be connected to the anchorage a short distance below ground,—about twenty feet,—where the overturning moment on the anchor piers is balanced by the counterweight. The portion of the bridge between main span and anchorages is supported independently. The distance, anchor to anchor, is 3,560 feet, and the entire length of the bridge, including approaches, is 9,000 feet. The maximum grade on the approaches is 5 per cent occurring on the American side, where it has been necessary to introduce an *S* curve. Stiffening trusses, hung from the cable between the main towers, will be 22 feet deep, of the pony truss type. The deck type floor system will be used.

Clearance above recorded high water is 152 feet, at the centre of the span, and 135 feet at the piers. This is about 156 feet above the present water level at the centre of span. Street clearances have been fixed at a minimum of 15 feet.

The width of the roadway is 47 feet to accommodate five lines of traffic. This is a new departure, as traffic lines are usually provided in even numbers, but in this case it was felt that traffic would be greater in one direction. An 8-foot sidewalk is provided on one side of the bridge. Owing to the length of the bridge, the grades to be overcome and the rapid abandonment of the walking habit in these times, it is felt that the tolls from pedestrians will hardly justify the expense of its inclusion.

The progress made to date is satisfactory. The main piers each consisting of two concrete caissons 38 feet in diameter, with an 18-foot well in the centre, are being put in by the Foundation Company. One is down to rock on the American side, and work is being carried on under air.

Several members of the branch engaged in the discussion which followed the address. Harvey Thorne, M.E.I.C., the chairman, in voicing our appreciation of Mr. Paulus' interesting talk, expressed the hope that at some future time, when the work has progressed further, we may again hear from Mr. Paulus, on the problems of construction encountered and the methods used to solve them.

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

There was a record attendance at the annual dinner and smoker held on January 6th at the Elizabethan room of the Hudson Bay store. Nearly one hundred members and guests sat down to enjoy the evening's repast and entertainment as F. K. Beach, A.M.E.I.C., took the chair by virtue of his office as chairman of the branch. A specially designed programme was produced containing the menu, toasts, and concert features. The chairman had the honour of introducing several prominent citizens and guests some of whom were scheduled on the toast list for speeches. Their words were listened to with much interest and gratification. Both the Mayor and the Ex-mayor of Calgary spoke eulogistically concerning The Institute, its members, its aims, and the engineering profession in general. Mayor Osborne in his reply to the toast to the guests pointed out how dependent civic governments were on heads of departments which often included technical men, and stated that the city of Calgary in particular was fortunate in the calibre of the engineers residing here. His New Year resolution for Calgary would be—a home city of happy citizens in useful occupations.

Ex-mayor Webster was in a reminiscent mood when referring to his early experiences as an engineer-contractor, reminding his hearers of his nickname of "Classification" Webster when on railroad work. There was a third Mayor present at this function in the person of Mayor Stewart of Yorkton, Saskatchewan, whose spontaneous discourse was one of the humorous features of the evening.

J. H. Ross, A.M.E.I.C., in a forceful speech urged that the engineer should aim to secure and hold fast his rightful place among the professions. Engineering failures, he said, produced only an added stimulus to the profession of engineering, and he stressed the point that the part played in the world to-day by the engineer was a most important one, but sadly left out of the picture of success. The speaker questioned how many knew the maker of the engine which carried Col. Lindbergh to Paris, yet his success was due largely to the designer and maker of the plane and engine. Failure of the mechanism has too often been the cause of unsuccessful attempts of flying, and the world looks to the engineer for the remedy. He pointed out how much a government and city council depended on the engineer, and that if he failed the governing body was likely to lose favour and office.

R. M. Dingwall, A.M.E.I.C., replied to R. A. Brown's proposed toast to the E.I.C. in a humorous vein, amusing those present with his jocular personal reflections.

J. W. Crawford, President of the Bar Association, paid compliments to the profession of engineering, going so far as to acknowledge the possibility that it might take precedence in point of age over that of his own profession in reference to the construction of the crude huts of prehistoric man.

Several amusing caricatures were thrown on the screen, which were interspersed with jokes at the expense of the members present. Vocal selections and community singing brought a successful event in the annals of the branch to a close.

W. B. Trotter, A.M.E.I.C., is now a member of the firm of Trotter and Morton, Limited, in Calgary, having taken over the local firm of the James Ballantyne Company, Limited, by whom he was employed for a considerable number of years. His firm is now in the market as contractors for plumbing, heating and power work, also automatic sprinkler systems.

The annual general meeting of the branch is to be held in Saturday, March 10th, at which the election of officers for the coming year will take place.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

Executive Meeting

A meeting of the executive of the Hamilton Branch was held at 5 o'clock on Friday, January 6th. L. W. Gill, M.E.I.C., the chairman of the branch, presided. Six other members of the executive were present together with some members of past executive committees who were present by invitation.

Two applications for transfer were considered and recommendations made. H. A. Lumsden, M.E.I.C., chairman of the Meetings and Papers Committee, reported that arrangements were practically completed for a meeting to be held on January 31st, the subject being on the St. Lawrence Waterways Development. Other plans for branch activities for the coming year were also discussed.

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.

Visit to Lime Quarries

The regular October meeting of the London Branch was combined with an inspection trip to the Beachville lime quarries and a dinner at Woodstock. The quarries of the Beachville White Lime Company and the operation of their plant proved very interesting.

Members from London, St. Thomas and Woodstock, met at the limestone quarries where officials of the company were present to act as guides. The party was conducted over the quarries and allowed to inspect a charge that had been set ready to "shoot." Drilling operations were also under way for the next "shot." After an inspection of these and the loading and stripping work the quarry was cleared and the shot was fired. Members of the party were interested in the fuse that was used and in the manner in which the stone was completely broken up by the shot. The trip was continued over the crushing and screening plants and to the lime kilns. Many points of interest were found by the members and all questions were ably answered by officials of the company.

Limestone and Its Derivatives

The party motored to Woodstock where dinner was served at the Hotel Oxford, Mayor Parker, of Woodstock, being one of the guests. A paper by Bruce C. Matson, S.E.I.C., on "Limestone and Its Derivatives" was read by W. G. Ure, A.M.E.I.C., in the absence of Mr. Matson. The author of the paper is thoroughly conversant with the limestone industry in Canada, and his paper revealed to the engineers the extent of this industry and the many uses to which limestone and its products are put.

The origin of limestone rocks was briefly described and their classification according to texture and to chemical composition was given in detail. The distribution of limestones in Ontario was quoted from a government report and then the production of limestone products was described with special reference to lime burning and "slaking." The varied uses of limestone products proved to be of the greatest interest to the members present. The paper dealt with the possible discovery of the character of slaked lime and its most common use in mortar. Other uses of lime include its use in aggregates, plasters, Portland cement, and sand lime bricks, paints and varnishes, dyes, paper, textiles, radiators, furnaces, glass goods, leather goods, glues, rubber goods, water purification and softening, ammonia, linoleum, pottery, cosmetics, oils or greases, sugar, etc.

The uses of limestone and its derivatives were divided into three main classes; in agriculture, construction and the chemical industry. The method of using limestone in various ways in these three classes was gone into in some detail. The limestone quarried at Beachville is a high-calcium limestone used entirely for chemical purposes, so the paper included descriptions of many uses under this heading.

Electric Steam Generation

On November 23rd, 1927, a regular monthly meeting was held in the Board Room of the Public Utilities Commission. D. M. Bright, A.M.E.I.C. a member of the London Branch, was the speaker and his subject "Electric Steam Generation."

The method of generation of steam described by Mr. Bright was one not in very common use and therefore was of particular interest to the engineers present.

There are two classes of electric steam generators, (1) metallic resistance type, (2) water resistance type. The latter type was described by Mr. Bright, who pointed out that it can be used only with alternating current. Where there is surplus current and where the demand is intermittent this method is specially adaptable and gives a great saving in labour cost over the coal-fired boiler method.

Cast iron electrodes are immersed in water and current is passed through the water. The resistance of the water raises its temperature to a degree sufficient to generate steam. One advantage of this system is that it lends itself very easily to automatic control, the pressure of the steam generated lowers the level of the water, forcing it back into the storage tank and thus decreasing the area of electrode immersed and reducing the rate of generation of steam until the pressure decreases. At this stage the pressure in the storage tank, controlled by a check valve on the steam line, again raises the water level and increases the rate of steam generation. This simple automatic control is responsible for the great saving in labour cost.

Mr. Bright described, with the aid of drawings and a small working model, the different types used for working pressures up to 250 pounds per square inch. As part of the discussion following the address, E. V. Buchanan, M.E.I.C., spoke on the general aspects and possibilities of electric heating.

W. C. Miller, A.M.E.I.C., our local representative on Council gave a report of the recent Plenary Meeting of Council, explaining in detail some of the more important proceedings.

Executive Meeting

At the executive meeting on December 14th, 1927, the proposed increase in fees was discussed and the situation was explained by Mr. Miller. In view of the points discussed at the Council session the members of this branch executive were of the opinion that the proposal to limit the increase in fees to Members was justified and therefore no action was taken by the London Branch to offer an amendment to the amendment proposed by Council.

Highway and Bridge Construction

The speaker at the December meeting held on December 28th, 1927, was Jas. A Vance, A.M.E.I.C., vice-chairman of the London Branch. Mr. Vance gave an interesting illustrated description of some of the highway and bridge construction jobs with which he has been connected during fourteen years of engineering and contracting.

The illustrations showed the methods of construction and the equipment used in constructing various concrete arch and steel bridges. The speaker also described methods of placing large plate girders and of replacing railroad bridges with a minimum of the interruption of regular traffic. Mr. Vance supplemented the story of his own experiences with illustrations and descriptions of some of the leading Canadian and European bridges of reinforced concrete and steel design.

At the end of the meeting the members and guests spent a social hour together during which time light refreshments were served by the executive.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The regular monthly supper-meeting of the branch was held at the Y.M.C.A. on January 11th. During the evening, members were pleasantly entertained by vocal solos by Mrs. George Ross, and violin selections by Mr. Avard Carter.

Immediately after the supper, the meeting took up the matter of Council's proposed amendment to Section 76 of the By-Laws. The consensus of opinion was that the result of the adoption of this amendment would be that suggestions originating with members from outlying branches might never be allowed to go to ballot. Following a vigorous discussion, a motion condemning the proposed amendment was moved by C. S. G. Rogers, A.M.E.I.C., seconded by A. S. Gunn, A.M.E.I.C., and carried unanimously. The secretary was instructed to advise the various branches and members of Council of the action taken by Moncton Branch. G. C. Torrens, A.M.E.I.C., the presiding chairman, then introduced P. L. Pratley, M.E.I.C., who addressed the branch on the subject of the Montreal South Shore Bridge.

The Montreal South Shore Bridge

For the reason that the single roadway over the Victoria bridge could but inadequately handle the tremendous volume of motor traffic pouring into Montreal from that part of Quebec south of the St. Lawrence river and from the United States the need for additional highway facilities connecting Montreal with the south shore had become imperative. The new structure which will be completed in 1930 will have a total length of two miles and will cost in the vicinity of twelve million dollars. Mr. Pratley discussed at some length the various proposed designs and locations. The progress of the work was described with painstaking attention to detail, and illustrated by slides depicting every phase of construction.

At the conclusion of the address a hearty vote of thanks was accorded the speaker on motion of C. S. G. Rogers, A.M.E.I.C., seconded by J. R. Freeman, A.M.E.I.C.

Niagara Peninsula Branch

Walter Jackson, M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

A number of branch members motored to Niagara Falls, N.Y., on the evening of January 13th to attend a joint dinner meeting with the Niagara Frontier Section of the American Institute of Electrical Engineers and the Electrical Section of the Empire State Gas and Electric Association.

Electrical Transients

The programme consisted of an address by Prof. Vladimir Karapetoff of Cornell University on "Electrical Transients." His subject was divided into two parts, "Transients in Time" and and "Transients in Space," and treated in a very simple manner with frequent reference to analogous hydraulic occurrences.

Transients are most important particularly in the design of electrical apparatus, said Professor Karapetoff; and my mission to-night is not to treat with the technical aspects of the subject but rather to try and interest some of the younger engineers in order that they may be able to carry on the studies which have so far been made. Steimetz, Magneson, Franklin, Russel, Rudenberg and Wagner were some of the authorities mentioned by Professor Karapetoff and the "Transactions" of the American Institute of Electrical Engineers to carry a wealth of informative detail.

The facilities for observing and measuring transients have improved greatly in the last generation. Thirty years ago a 300-cycle oscillograph was the most sensitive instrument, to-day the surge-recorder or clynonigraph and the cathode-ray oscillograph will record about 100 oscillations in one micro-second or a hundred million oscillations a second.

Electrical terminal equipment, as it is to-day, evolved mainly from a process of trial and error, but with the present facilities for observation and study the aim of the scientist should be to predict. "To predict rather than to be sorry."

Many of the large corporations have set aside tremendous sums for research along these lines, but individual effort is not to be ignored; "history has indicated that research solely after truth has given greater and better results than that undertaken for purely practical or utilitarian reasons."

During the short intermission between the two parts of his subject this remarkable man sat at the piano and gave a brilliant interpretation of one of Macdowell's latest suites. Both the lecture and the music—or either—were very high examples of artistic ability. Part of the audience wished that he had played for a longer time, part wished that he had talked more and some were satisfied that they had had a glimpse of that rare combination,—"Genius tempered with Humour."

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

Marking the conclusion of a year of considerable progress, the Ottawa Branch of The Engineering Institute of Canada, at its annual meeting, which took place in the Daffodil tea room January 12th, elected Dr. Charles Camsell, M.E.I.C., deputy minister of the Department of Mines, to the chairmanship for the ensuing year.

The report of F. C. C. Lynch, A.M.E.I.C., who was again elected secretary-treasurer, indicated that finances were satisfactory and that the membership of the branch had been augmented.

F. H. Peters, M.E.I.C., chairman of the Proceedings Committee, in his report, pointed out that the large attendance at the luncheons given by The Institute attested to their popularity. Reference was made by Mr. Peters to the suggestion that evening meetings which would produce discussions amongst the members on technical subjects of general interest be revived.

This aroused considerable discussion and it was felt that in the future civic engineering and planning matters should be given special attention. The McGregor lake scheme was mentioned in this connection, the idea being that both sides of the question at issue should be under debate.

Other reports adopted were: Membership, Col. A. E. Dubuc, M.E.I.C.; Librarian, M. F. Cochrane, M.E.I.C.; Sub-committee on Advertising, Alan K. Hay, A.M.E.I.C.

N. Cauchon, A.M.E.I.C., retiring chairman, gave a brief address wherein he expressed appreciation of the co-operation of the various committees, and Dr. Camsell on assuming the chair expressed appreciation of the honour conferred on him.

In addition to Dr. Camsell and Mr. Lynch, the following comprise the committees for the ensuing year: A. K. Hay, A.M.E.I.C., W. Blue, A.M.E.I.C., F. H. Peters, M.E.I.C., V. M. Meek, M.E.I.C., G. A. Browne, A.M.E.I.C.

Consequent to the election of officers, refreshments were served and a motion picture was screened, furnished through the courtesy of B. E. Norrish, A.M.E.I.C., of Montreal, a former member of the Ottawa Branch of The Institute. Mr. Charles O'Reilly officiated at the piano.

Members of Branch Invited to Other Meetings

A lecture on "Making of Optical Lenses in England during War Time" under the auspices of the Royal Astronomical Society of Canada (Ottawa Branch) was given in the Victoria Memorial Museum on the evening of January 17th by A. J. Ames, AFFILIATE E.I.C., of Instruments Limited. A cordial invitation to attend this lecture was extended to the members of the Ottawa Branch of The Engineering Institute.

Through the courtesy of the Department of Mines the Ottawa Branch of The Engineering Institute of Canada was invited to attend a lecture in the Victoria Memorial Museum on the evening of January 9th by Dr. Etienne S. Bieler, professor in the Department of Physics, McGill University. The lecture, which was on the subject of "Electrical Prospecting," gave a brief review of the various methods of prospecting by electric currents and was illustrated by lantern slides and practical demonstrations.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

A regular meeting of the Peterborough Branch was held on the evening of January 12th, 1928, at which the speaker was Flight Lieutenant A. Ferrier, A.M.E.I.C., of the aeronautical engineering division of the Department of National Defence. Taking as his subject "The Aeroplane as an Engineering Problem," Lieut. Ferrier described in a most interesting and lucid manner the methods by which the aeronautical engineer attacks the problems in the design and production of an aeroplane.

The Aeroplane as an Engineering Problem

Dealing with his subject under several main headings, the speaker stated that the first important step was to make up specifications for the machine to be designed. This led to definitions of some of the terms used, including bare weight, useful load, gross weight, pay load, disposable load, etc. The speaker defined the maximum range as number of hours at full throttle. Performance requirements vary very widely depending on the service for which the plane is required. The speaker mentioned that the gross weight of a plane may vary from as low as three pounds per horse power in a racing machine to twenty-five pounds in commercial transport planes. Landing speed is settled by considerations of safety and is taken as 40 to 50 miles per hour in this country.

Proceeding to the subject of wing or aerofoil design, the speaker mentioned that aerodynamic and structural requirements are in complete discord and that the design is mostly a question of compromise. A clear exposition of the advantages and disadvantages of monoplanes, biplanes, and sesquiplanes was then given.

The speaker next dealt with the design of the body or fuselage and the requirements for longitudinal balance.

The power plant was the next subject to be discussed and it was shown how the development of aeroplane engines had been carried on by the automobile industry. The weight of modern aeroplane engines varies from three pounds per horse power to less than one pound per horse power in racing machines. Among the important points emphasized were reliability and compactness. The reasons governing the choice of the radial air-cooled and the "in line" water-cooled types were given.

The speaker then described the use of super chargers and boosters for working at high altitudes. The materials entering into the construction of planes were briefly discussed. It was mentioned that with the use of wood on the decrease, steel was most commonly used in England and duralumin in Europe, whereas both materials were used on this continent.

There was considerable discussion subsequent to the paper and Lieut. Ferrier answered a large number of questions. Besides the members of the branch, there were present several representatives from the Canadian Air Services Company, including Captain Ayres. A hearty vote of thanks was accorded Lieut. Ferrier for his paper.

Executive Meeting

A pleasant departure in the way of executive meetings took place on January 4th when the executive and past chairmen of the branch were invited by the chairman, A. E. Caddy, M.E.I.C., to meet at his house. After the business had been dealt with, there was a very enjoyable evening's entertainment at bridge and supper. Novel table decorations were a compass with sights over one hundred years old, a theodolite and a transit theodolite.

Mr. Caddy also exhibited an interesting model of the old railway bridge across Rice lake.

Quebec Branch

Philippe Méthé, S.E.I.C., Secretary-Treasurer.

A general meeting of the Quebec Branch of The Institute was held at the Chateau Frontenac, on November 7th, under the chairmanship of A. B. Normandin, A.M.E.I.C., A. R. Decary, D.A.SC., M.E.I.C., president of The Institute, and about seventy members and friends were present.

Col. H. C. Boyden, formerly dean of the College of Engineering, Ohio Northern University, and well known to members through his previous lectures under the auspices of the Portland Cement Association, addressed the members. The subject chosen was, "Workability in Concrete with Particular Reference to the Use of Diatomaceous Silica."

Col. Boyden reviewed the history of cement. Portland Cement is over a century old. Since its discovery, the building of concrete structures has been a rapidly increasing practice, until to-day there is no more universally used building material known to men.

The production of cement in the United States and Canada was 175 million barrels in 1926, against 85 million in 1919. Allowing 1½ barrel of cement, at an average cost of $10.00 per cubic yard of concrete, there were placed last year, 117 million cubic yards, at a cost of $1,170,000,000. The problem of obtaining the greatest value for the money spent is confronting the constructor everywhere.

Expensive and exhaustive investigations have been and are being carried on, and have given much knowledge regarding the factors that control the quality of concrete. Good results, however, can only be obtained from co-operation between the engineer and the man on the job.

The speaker explained that diatomaceous silica composed of the remains of the simplest form of plant life, called "diatoms," added to the mix to the extent of say two to three per cent, greatly increases the workability, and adds to its bulk, so that construction cost is lowered.

A series of lantern slides showed the greater workability resulting in structures of improved beauty and quality.

Numerous examples were shown of structures embellished with artistic designs, absolutely perfect through the use of this product in the concrete, and the speaker stated that no trowel work was required after the forms were removed.

The members were much interested in the subject, and the speaker had to answer a great number of questions.

Luncheon Meeting

At the Chateau Frontenac, on Monday, December 19th, the members of the Quebec Branch were invited to a luncheon. The guest of honour, the Honourable Frank Carrel, member of the Legislative Council, addressed the members and visitors, on "Industrial Evolution."

Hon. Mr. Carrel outlined the history of the growth of industry in the province of Quebec from the individual or family industry of the time of the pioneers, to the huge consolidations of to-day. "To-day," said Mr. Carrel, "if I were asked who has most contributed to the development of our province and of the whole of Canada, I would not hesitate to answer that it is the engineer. Yet, you engineers do not seem to have confidence in publicity to tell the public of your achievements."

"The large industries of the province of Quebec and Canada will be a lasting monument to the science and skill of the engineers. Canada is proud of their works by which our country is known and appreciated and our natural resources developed.

"The engineers are not sufficiently known to the public; their names are omitted when the papers relate the history of large buildings, magnificent plants, splendid monuments which they have built, and which they have conceived.

"Quebec can judge of the value of engineers by the important positions they hold in the administration of large industrial organizations."

The luncheon was presided over by A. B. Normandin, A.M.E.I.C., chairman of the branch, and was attended by about forty members and guests. W. G. Mitchell, M.E.I.C., heartily thanked the Honourable Mr. Frank Carrel on behalf of the members.

Executive Meeting

At a business meeting of the Executive Committee of the Quebec Branch, held on November 22nd, it was unanimously decided to express the sincere gratitude of the branch to Miss Boswell who generously gave all the books from the library of her father, the late Mr. St. George Boswell, for many years a prominent member of the engineering profession in Canada.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting, Association Professional Engineers, N.B.

On the afternoon of January 10th, 1928, the annual meeting of the Association of Professional Engineers of New Brunswick was held at the Admiral Beatty hotel. The meeting was devoted to routine business and the election of officers for the coming year. The election of officers resulted as follows:—

President—S. R. Weston, M.E.I.C., Saint John; Vice-President—Professor H. W. McKiel, M.E.I.C., Sackville; Councillors—Saint John District—J. P. Mooney, A.M.E.I.C., and W. R. Pearce, M.E.I.C.; Moncton District—G. C. Torrens, A.M.E.I.C., F. Williams, A.M.E.I.C.; Fredericton District—Professor J. S. Stephens, M.E.I.C.; Chatham District—J. O. B. Stevens of Campbellton; Auditors—H. F. Morrissey, A.M.E.I.C., and E. J. Owens, A.M.E.I.C.; Secretary—J. A. W. Waring, A.M.E.I.C.

Joint Dinner—Branch Meeting

In the evening a joint dinner was held of the Saint John Branch of The Engineering Institute of Canada and the Association of Professional Engineers of New Brunswick. S. R. Weston, M.E.I.C., chairman of the Saint John Branch of The Institute, presided. A guest at this dinner was P. L. Pratley, M.E.I.C., of Montreal.

A toast list was observed and was introduced by the toast to The King. The toast to The Engineering Institute of Canada was proposed by C. C. Kirby, M.E.I.C., of Saint John, and replied to by G. C. Torrens, A.M.E.I.C., of Moncton. The toast to the Association of Professional Engineers of New Brunswick was proposed by G. G. Murdoch, M.E.I.C., of Saint John, and responded to by Geoffrey Stead, M.E.I.C., of Saint John.

Following the dinner an illustrated address on the Montreal South Shore Bridge was given by P. L. Pratley, M.E.I.C., of the firm of Monsarrat and Pratley, Montreal. This address was illustrated by a large number of slides and enabled the audience to grasp the various construction features and difficulties met with in the construction of this bridge. To the laymen present probably the most interesting part of the address was the history of the earlier bridges built across the St. Lawrence at Montreal, of the various enlargements of existing bridges to meet ever-increasing traffic, of the need of the present bridge now under construction to take care of motor traffic, and of the various studies made of the locality until the final site was decided on. It was a very interesting address throughout. A vote of thanks to Mr. Pratley was moved by J. N. Flood, A.M.E.I.C., of Saint John and W. J. Lawson, A.M.E.I.C., of Fredericton.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

The December meeting of the Saskatchewan Branch was held at the Hotel Saskatchewan, Regina, on December 19th. Guests present included Hon. George Spence, minister of highways for Saskatchewan, Mayor McAra and Alderman N. J. Taylor of the city of Regina.

This meeting was referred to as a "Convention Meeting," the purpose being to have reports on a number of Conventions held during the past season, which have been attended by members of the branch. The programme as arranged provided a fund of material and proved to be of a highly educative value to those in attendance.

The Value of Conventions

H. N. Macpherson, A.M.E.I.C., spoke of the value of conventions where papers are read and discussions follow amongst experts closely in touch with their respective lines of work. The delegates are thrown into intimate contact with other representatives, and frequently acquaintanceships and friendships are formed which prove of lasting value. It enables an organization to advertise its work and activities through its delegates.

Street Railway Convention

T. McGuinness, A.M.E.I.C., in a humorous vein told of the Street Railway Convention held in Winnipeg last summer. The exhibits displayed at this convention are of particular merit and value. The attendance at this convention, which is held at various centres each year, has grown to large proportions.

Canadian Telephone Association Convention

Mr. C. W. Doody, traffic superintendent, Department of Telephones, outlined the activities of the delegates at the convention of the Canadian Telephone Association, held at Minaki, Ont., in August last. He referred to the formation of this association some years ago due to necessity of co-operation in the telephone business, where the constituent organizations are closely related one to the other and through traffic is dependent on efficiency of each particular section.

At these conventions the principle of segregating the delegates into groups for round table conferences has been adopted and found to be much superior to the general open convention. Many of the papers presented are of a highly technical nature. These are usually printed and distributed to members of the profession, who look upon them as text books.

Canadian Good Roads Convention

H. S. Carpenter, M.E.I.C., dealt with some of the papers read before the recent Good Roads Convention held at Niagara Falls, Ont., in September last. His remarks covered, bridges, contractors' problems, sand and clay roads, and winter roads. He referred to the work of the Bridge Department of Saskatchewan in erecting and maintaining over 2200 bridges in this province including 3 highway bridges over the Saskatchewan river, also traffic attachments to several of the railway bridges. The use of a mixture of sand and clay is found to be very satisfactory on earth roads in the Prairie Provinces where the nature of the surface soil is unsuitable as a road surface. Right-angled intersections on provincial highways are being abandoned in favour of curves. The latter are found to be more suitable for present day traffic and the reduction in the length of grade more than compensates for the cost of the extra land required. Present day tendency is to build higher grades, thus overcoming drainage problems and snow in winter. Experiments are being carried out at present on the clearing of certain highways in this province for automobile traffic. The opinion was expressed that the packing method would not be found the most practical owing to the delay and damage which would result to the road bed by the melting of this packed surface in the spring of the year. The most generally accepted practice of making winter roads for autos is to clear the snow from the road grade, by means of snow plows, etc.

D. A. R. McCannel, A.M.E.I.C., dealt with gravel roads and their maintenance. A "spring blade" grader attached to a truck and propelled at the rate of 12 to 15 miles per hour is found to be very suitable for maintenance work. He also referred to the consolidation of these roads by a tamping roller and the reshaping of the road bed by means of the blade grader. The use of calcium chloride has proven very effective as a dust palliative.

Mr. McCannel also dealt with traffic regulation and enforcement, and the need for uniformity in the rules of the road, legal speed and road signs. Accidents can be materially reduced by education of both drivers and pedestrians. Enforcement should be logical and enforceable. He referred to the use of various engineering devices such as lights, breaks,' guard rails, traffic signs and safety zones, all of which were for the purpose of preventing accidents.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The annual meeting was held in the Y.W.C.A. rooms on December 16th, 1927, following a dinner.

Chairman G. H. Kohl, M.E.I.C., called the meeting to order and the various standing committees reported on their activities during the past year. The Papers and Publicity Committee under J. H. Jenkinson, A.M.E.I.C., is to be commended upon the splendid programme of papers and inspection trips arranged for during 1927.

The secretary-treasurer's report showed the branch in good standing and the average attendance at meetings was thirty-five, which was higher than last year.

The Nominating Committee reported the result of the elections for 1928 as follows:

Chairman	W. S. Wilson, A.M.E.I.C.
Vice-Chairman	J. Hayes Jenkinson, A.M.E.I.C.
Secretary-Treasurer	A. H. Russell, A.M.E.I.C.
Executive	A. E. Pickering, M.E.I.C.
	R. A. Campbell, A.M.E.I.C.
	J. V. Fahey, J.E.I.C.
	J. G. Dickenson, M.E.I.C.
Ex-Officio	C. H. E. Rounthwaite, A.M.E.I.C.
	G. H. Kohl, M.E.I.C.

The retiring chairman, Mr. Kohl, gave a short review of the year's activities under his leadership. He expressed his appreciation for the assistance and co-operation of the members and the various committees during the past year and he felt sure that the branch was in safe hands this year after looking over the new executive. He promised to help in any way that he could to make it a more successful year than the past.

The chairman-elect, W. S. Wilson, A.M.E.I.C., thanked the members for the confidence that they had expressed in him by electing him to fill Mr. Kohl's place for 1928. He gave a short talk on branch activities and the importance of Canadian engineers in Canadian development.

The auditors appointed for 1928 were C. H. E. Rounthwaite, A.M.E.I.C., and C. H. Speer, M.E.I.C.

The advisability of buying a lantern and screen by the branch was discussed and the following resolution was passed.

"That the chairman appoint a committee of three with power to select and purchase a suitable lantern, also a screen mounted upon a roller, the whole to be paid out of the funds of the branch and said committee draw up certain rules regulating the handling of the machine." Mr. Wilson appointed the following committee for this purpose: C. H. Speer, M.E.I.C., F. Smallwood, M.E.I.C., G. H. Kohl, M.E.I.C.

Toronto Branch

Recent Developments in Highway Construction in the Province of Ontario

(Meeting reported by F. B. Goedike, A.M.E.I.C.)

The regular meeting of the Toronto Branch was held in the Mining building, Toronto University, Thursday evening, December 15th, 1927, at 8.15 p.m., with the chairman, R. B. Young, M.E.I.C., presiding. After reading the minutes of the last regular meeting, the chairman in a few words introduced the speaker of the evening, Mr. R. M. Smith, deputy minister of highways for the province of Ontario, who gave a very interesting and instructive paper entitled "Recent Developments in Highway Construction in the Province of Ontario."

Mr. Smith showed that, although Ontario in 1920 had only 42 miles of "hard surface" roads, at the end of 1927 it would have 1561 miles made up as follows:—

577.0	miles	concrete
203.4	"	asphaltic concrete
59.6	"	mixed macadam
288.0	"	bituminous penetration
433.0	"	macadam

The total cost, together with 910 miles of gravel, will amount to approximately $66,000,000. The speaker showed that this expenditure was justified alone by the fact that whereas the ordinary motor tire a few years back was only guaranteed for 5,000 miles; its life on hard surface roads has now increased to 20,000 miles. This saving to the motorist on one item alone amounts to ten per cent on the money invested.

Mr. Smith stressed the point that whereas ten years back, concrete pavements, thick at the centre and thinner at the edges, with transverse joints, were the accepted standard, his Department found that for the varying traffic and climatic conditions in the province. it was at a very early date found justifiable to decrease the thickness at the centre and increase the thickness at the edges, and to do away with the transverse joint and in its stead construct a longitudinal metal joint. They had thus been in the forefront in the development of the present type of standard American concrete highway.

With reference to the asphalt used in the construction of asphalt pavements, it was found that the usual 40 penetration asphalt, as used in the United States, was too brittle for the range of winter temperatures in Ontario, and they are now using 58 to 63 penetration which is giving very satisfactory results.

The Department has developed a new type of highway called "asphaltic mixed macadam" which has been found very satisfactory and economical. This pavement is laid hot under traffic conditions without inconvenience, and the thickness depends on the traffic anticipated. The road when finished has a mosaic appearance, is non-skid, with first class riding qualities, and the cheapness of construction, lack of detours, and the safety of surface commend this pavement for extensive use.

Mr. Smith showed some excellent moving picture reels and lantern slides indicative of different types of Ontario pavements at various stages of construction and also discussed the future policies of the Department, and the likely development of highways influenced by the new International bridges at Fort Erie and Windsor.

The paper was well received, and a discussion then followed, among those taking part being: R. B. Young, M.E.I.C., Hydro-Electric Power Commission; H. C. Patten, Toronto Transportation Commission; Geo. McCarthy, M.E.I.C., Sewer Department, City Hall; H. W. Tate, A.M.E.I.C., Toronto Transportation Commission; R. O. Wynne-Roberts, M.E.I.C., consulting engineer.

A hearty vote of thanks was then moved and tendered to the speaker, after which the meeting adjourned.

Farewell Dinner to J. A. Knight, A.M.E.I.C., Vice-Chairman of the Branch

A dinner was tendered by the Toronto Branch Executive on the evening of Thursday, December 29th, 1927, at the Faculty Union, Hart House, to J. A. Knight, A.M.E.I.C., Vice-Chairman of the branch, to bid farewell to him previous to his regretted departure for Arvida, Que., to join the engineering staff of the Aluminum Company of Canada, in connection with proposed hydro-electric developments there.

The chairman of the branch, R. B. Young, M.E.I.C., after referring with sincere appreciation to Mr. Knight's active, continuous, and always willing work during the last five years in the interests of the branch, first as secretary-treasurer, and then as a member of the branch executive, expressed the great regret of all our members that Mr. Knight had been called away at this time from the branch territory. Seeing that other Toronto members were accompanying their vice-chairman, he fully expected, however, (speaking in a humorous vein), that a new branch of The Engineering Institute would be shortly organized at Arvida, and then the Toronto Branch would have to look to its laurels! As a small mark of the executive's appreciation, he then made the presentation of a writing set.

Mr. Knight replied suitably, expressing his regret at leaving and the pleasure that he had always derived from his work and association with the branch, so that any work he had done had not seemed like work, and thanking the members for the very acceptable mark of their appreciation.

The Design and Construction of Viaduct Structure at the New Union Station, Toronto

(Reported by J. W. Falkner, A.M.E.I.C.)

As has been the custom this year when out-of-town speakers have come to Toronto to address the local branch, the regular meeting of the Toronto Branch on Thursday evening, January 5th, 1928, was preceded by a well attended executive committee dinner to welcome the speaker of the evening, A. R. Ketterson, A.M.E.I.C., assistant engineer, Canadian Pacific Railway. The dinner was held at the Faculty Union, Hart House, and its interest was added to by the presence of our General Secretary, R. J. Durley, M.E.I.C., from Montreal, also by distinguished visitors from the engineering staffs of the Canadian Pacific, Canadian National, and Toronto Terminals Railways.

The meeting was afterwards held in the Mining building, one hundred members being present.

After humorously referring to the fact that as a Montreal man they would not expect him to attempt to describe to a Toronto audience the protracted, musty, and arduous negotiations between "'parties" of the "first," "second," "third," "fourth" . . ."*M*th" and "*N*th" parts that had preceded the final viaduct agreement between the city and the railroads, Mr. Ketterson then launched into his subject,—"The Design and Construction of the Viaduct Structure at the New Union Station, Toronto."

Mr. Ketterson's treatment was most clear and explicit, and after a general description of the general design requirements, he specified the reasons that had led to the choice of 'flat slab" construction. The large size of the panels and the very heavy unsymmetrical moving and concentrated loadings were then discussed, and the derivation of the flat slab design formula, and of the equivalent design loadings were given, the Joint Committee formula, primarily based on tall building conditions, not being considered applicable to a one-storey heavy railroad structure. The use of the slope deflection method in checking these design assumptions was set forth in detail, also extensometer tests on the completed structure. Thus, while the stresses in structure were "statically indeterminate," (it being designed as a monolith five bays long by five bays wide), the design formulae and loadings were for all practical purposes considered reasonably economical, and reasonably conservative. A description of the construction methods and the problem of maintenance of traffic at the station was then given, the paper being illustrated throughout by some fifty excellent lantern slides.

The discussion, contributed to by P. B. Motley, M.E.I.C., engineer of bridges, Canadian Pacific Railway; Wm. Gore, M.E.I.C., G. A. Tobias, A.M.E.I.C., J. R. W. Ambrose, M.E.I.C., chief engineer of the Toronto Terminals, and Prof. Peter Gillespie, M.E.I.C., brought out the fact that the panel size was the largest known to those present as having been yet used for such intensive loadings, and that the method of design had had therefore to be largely based on original work The size of the structure was indicated by its equivalence to a double track structure three miles long.

General Secretary R. J. Durley then briefly addressed the members, and the meeting adjourned after the moving and presentation of a very hearty vote of thanks to the speaker.

Victoria Branch

K. M. Chadwick, A.M.E.I.C., Secretary-Treasurer.

At a meeting of the Victoria Branch on December 21st, J. D. Galloway, provincial mineralogist, addressed the members on the mining industry in British Columbia.

In his opening remarks, Mr. Galloway pointed out that there were many openings for young engineers in the mining field in the province. He then reviewed the mining situation in the province. The value of the production in 1927 was about $62,000,000, as compared with some $67,750,000 for 1926.

"The industry, however," said he, "is in a healthy condition, and I look forward to the province reaching a production of $100,-000,000 a year in the near future.

"Mining," said Mr. Galloway, "is the basic industry in material progress. All modern civilization was built up on the use of metals. The stage of civilization and development of the countries were in proportion to the use that was made of these metals. In America and Europe there were vast quantities used. In Asia there was little."

The speaker, in reviewing the outstanding developments in the province at the present time, paid a great compliment to the work done by the Consolidated Mining and Smelting Company, and remarked with satisfaction the interest that the company was manifesting in coast properties. It was therefore with a good deal of hope that the expectation was held out that the company would carry on on the coast something in the treating of ore that was being done with such great success by that organization at Trail.

It was a matter of regret that there was not the prospecting carried on in the province at present that there should be. He, however, was of the opinion that more prospecting would follow with the taking up of more properties that were now held by prospectors for mining companies. There was now a marked increase in the taking up of prospects upon which some work had been done, and the situation, he felt, would soon right itself.

The public did not realize what was done for the industry by the metallurgists. The development of new processes for the treating of ores was working wonders in the world of mining to-day. In this the Consolidated was carrying on a wonderful work. Not only was that company looking after its own ores, but it was giving the small owner the opportunity to have his ores tested out, and the best methods of handling it conveyed to the owners.

At the Consolidated now there were 90 per cent of the ores treated by concentration before they went to the smelter. The same was true to an extent at Anyox. There a few years ago all the ores went direct to the smelter. Now practically all of these were treated by flotation. The result was that lower grade ores than ever before were being handled there and bigger profits were being made from them than from the higher ones when sent direct to the smelter. The speaker then mentioned that a very large part of the money invested in the British Columbia mining industry came from outside of the province and said he would like to see a greater proportion from residents of the province.

In the coal situation, which was one of special interest on Vancouver Island, the situation was not as encouraging as it might be. This was due to the competition of fuel oil from the United States. There had been various processes discussed of late looking to the devising of means for the getting of greater efficiency from the coal.

At the recent meeting of the Mining Institute in Nanaimo the coal mining men had discussed the situation very frankly. They had been united in expressing the opinion that while these processes might be of importance in some parts of the world they were not likely to be applicable here. The opinion was further frankly admitted by them that coal mining had lagged behind in research work, as compared with the metal mining. The modernizing of the business in which they were engaged was urged as the need to meet competition.

Following the address, Mr. Galloway presented a number of views relating to mining in this province, and which served to exemplify some of the facts that he had brought out in his address.

He was introduced by R. F. Davy, A.M.E.I.C., chairman of the Victoria Branch.

Winnipeg Branch

James Quail, A.M.E.I.C., Secretary-Treasurer.

At a meeting of the Winnipeg Branch on November 17th, J. M. Morton, A.M.E.I.C., presented a paper on the work of increasing the pondage at the Point du Bois plant of the City of Winnipeg Hydro-Electric System by the placing of flash-boards on the existing concrete dam.

In 1925 it was realized by the officials of the city hydro-electric system that in periods of low water the forebay was too small if the head of water was on a level with the spillway. The normal discharge over the spillway was usually about 10 cubic feet per second. To assure some control on the head of supply water, I-beams were placed on top of spillway dam and flash-boards dropped between the I-beams. A walk-way was made over the top of the I-beams to allow for handling the flash-boards. Owing to very high levels of water in the spring of 1927 a number of flash-boards and supports were carried away.

To make a rigid superstructure to support the flash-boards, pre-cast concrete piers were fitted over the existing dam surface, iron pipes being cast vertically in the piers to allow of drilling the dam to obtain anchorage. The bottom of the new piers fitted the curved surface of the dam, irregularities being taken care of by means of wood and felt.

To place these piers in position a floating wooden dam and raft were cantilevered across the piers. The force of the water held the raft in position and the wooden dam kept the level of water over the old concrete dam at a level suitable to carry on the work. There was approximately 6 feet of water flowing over dam at time the work was undertaken.

Fifteen hundred feet of spillway was treated in the manner outlined, giving a forebay level regulation of 5 feet.

The paper was illustrated by lantern slides.

C. H. Attwood, A.M.E.I.C., complimented the Hydro on the excellent work performed under very difficult conditions, pointing out that the methods used were unique and very effective.

Professor N. M. Hall, M.E.I.C., enquired as to method used to hold the bottom of the steel form to the surface of the concrete of the spillway dam. Mr. Morton explained that steel forms were in two halves and anchorage of the form was obtained by holding on to the tip of the forms around the I-beam. Irregularities of the dam surface were taken up by means of wood and felt.

J. W. Sanger, A.M.E.I.C., added to Mr. Attwood's remarks in complimenting Mr. Morton on the paper, and pointed out the difficulties under which the work had been performed.

D. L. McLean, A.M.E.I.C., complimented Mr. Morton on the paper, and on the excellency of work performed, and proposed a hearty vote of thanks to the speaker.

Preliminary Notice

of Applications for Admission and for Transfer

January 18th, 1928

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in February 1928.

R. J. Durley, *Secretary.*

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANDERSON—VIGGO, of Montreal, Born at Roskilde, Denmark, Nov. 23, 1898; Educ., B.Sc., Royal Tech. College, Copenhagen, Denmark, 1923; 1923-24, designing of paving and sewers, inspection and surveying, Roskilde; 1924-25, structural dfting, Chicago Rapid Transit Co.; May to Sept. 1925, designing of paving and sewers, inspection and surveying, Ferndale, Mich.; June 1926 to Mch. 1927, designing and calculation of reinforced concrete, steel and wood constrns., Mun. Gas Works, Copenhagen; May 1927 to date, structural dftsman, Dom. Bridge Co., Lachine.

The Requirements for a Durable Concrete as Observed from Structures in Service

An Inquiry into the Question of What Makes Concrete Good or Poor Based on a Consideration of the Conditions Responsible for the Failure of Existing Concrete Works

Roderick B. Young, M.E.I.C.

Testing Engineer, in charge of Engineering Materials Laboratory, Hydro-Electric Power Commission of Ontario.

Paper presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

If properly made and properly used, concrete is an enduring material. Just what its life may be is not yet known, for Portland cement was invented only a little over a hundred years ago, and did not come into common use until the present century. Most of the works made with it are less than fifteen years old, but there are, both here and in Europe, older structures from which may be formed some idea of the probable life of well-made concrete.

A little observation in almost any locality will convince one that, while some concrete is enduring, much of it is not, for in many structures it is already visibly deteriorating although only a few years old. Presumably concrete that deteriorates readily is not good concrete, but granting this, what makes concrete good or poor with respect to its ability to endure in service? It is the author's purpose to inquire into this question by considering the lessons to be learned from concrete that is failing, so that we, as engineers and constructors, may, in future work, avoid similar mistakes and make concrete that is durable and of long life.

How are concretes destroyed in service? They may be attacked chemically by alkali, sea water, dilute acids or even pure water, mechanically by abrasion, frost action or volume changes, or their constituent materials may be faulty and the concretes fail through a breakdown of the cement, or by the disintegration of the aggregate.

These destructive agencies are always present to some degree and the durable concrete is not one that is free from attack but one that has built into it a resistance to attack or is protected externally.

Sea and Alkali Waters

Of the agencies that attack concrete chemically, the best known are sea and alkaline ground waters. Both forms of disintegration are believed to be due principally to the sulphate salts of magnesium, sodium and calcium, reacting with the different ingredients of set cement to form new compounds within the cementing matrix of the concrete. These new compounds occupy greater space than those they replace, and in expanding, shatter the cementing matrix in which they form. In sea water, magnesium sulphate is the principal active salt; in alkaline ground waters they are the sulphates of magnesium and sodium.

More recently, the experiments of Thorvaldson[1] have led him to conclude that the foregoing reactions are supplemented by others more important. He maintains that the sulphate salts interfere with the normal hydration of the cement. At first it assists and speeds the reactions but, in the words of Prof. C. J. Mackenzie, M.E.I.C.[2], "the hydration or hydrolysis does not stop at the point of optimum strength for the cement, as it ordinarily does in pure water, but it is carried on and on until so much of the calcium has been removed by hydrolysis that sufficient strength to withstand the physical action of the crystallation is gone."

Exact knowledge of the mechanism of failure from alkali and sea water is, of course, of first importance to

(1) Dr. T. Thorvaldson, Journal of Industrial and Engineering Chemistry, May 1925.

Figure No. 1.—Disintegration Around the Ends of the Drains in a Wall, Due to Frost Action on Concrete Saturated with Water.
It is significant that the rest of the wall, although presumably made of concrete of equal porosity, is in perfect condition.

engineers, but, for the purpose of this paper, some of the less scientific findings of the investigators of these problems are of more immediate significance. For alkali action the more important of these are:

(1) Portland cement, as now constituted, is inherently subject to attack by sulphate salts and no Portland cement mortar or concrete, however well made, is immune from attack if the sulphate content of the ground water in contact with it is sufficiently great.

(2) Field experience has shown that a concrete, to be resistant to sulphate attack, must be of the highest quality, strong, well made and impermeable.

The same general conclusions apply equally to concrete in sea water, but there is some divergence of thought in other particulars. Wig and Ferguson[3], for instance, lay great stress on the protection to concrete in sea water afforded by the carbonated surface skin formed in casting. They observed, in their extended investigations of sea water structures in the United States and Canada, that chemical disintegration always followed the removal of this outer skin. On the other hand, general experience with concrete exposed to alkali attack has not shown that the carbonated surface is a factor of any importance in the resistance of the concrete to sulphate action in alkali soils.

If, as is probable, alkali and sea water attack concrete in a similar manner, then the greater rapidity with which the alkali waters destroy concrete is due to their higher concentrations of sulphate salts. It is the general conclusion of most investigators of the problem, that concrete can be made, which, for practical purposes, may be classed as permanent in sea water, but that, until a cement is found that is immune from the action of both magnesium and sodium sulphate, concrete cannot be made that will withstand severe alkali exposure.

For service in sea water, concrete should be made of selected materials, properly proportioned, well mixed and placed in a manner to avoid all surface imperfections such as construction joints, honeycomb, etc., particularly above low-water level where practically all the deterioration takes place. Where abrasion or erosion of the surfaces may occur, protection of some sort should be employed, such as wooden sheeting or granite facing.

Concrete liable to alkali attack should be equally well made but there seems no certain method of preserving the concrete from deterioration except by preventing its contact with the offending ground water either by adequate drainage or by encasing it with some protective material immune to alkali attack.

Many nostrums claimed to increase the resistance of concrete to the attack of alkali and sea water have been offered to engineers in the form of integral compounds or inert admixtures to be incorporated in the mix. Theoretically it would seem that any material added to concrete that would fill its pores or coat them with a water-repellent substance should be beneficial but available evidence does not entirely support this view.

Concretes to which such substances have been added have been tested by the Committee on Deterioration of Concrete in Alkali Soils[4]. After two years these concretes were reported disintegrating in each of the three localities in which they had been placed. Wig and Ferguson[5], after inspecting a great many structures in sea water, reported that "waterproofing compounds have no beneficial effect." Somewhat the same conclusion has been arrived by the harbour authorities of Los Angeles in connection with marine piling. They found that "neither the painting, the admixtures used, nor the oil residue that collects on the piling in Los Angeles harbour, served to have any effect in retarding the progress of decomposition. The painted piles as well as the piles containing the admixtures seem to deteriorate as rapidly as the untreated piles."[6]

On the other hand Miller[7], from his drain tile tests in Minnesota has come to the tentative conclusion "that certain admixtures, if properly handled, may have sufficient value in developing resistance to justify their use under special conditions," and Tapley[8], from his tests at Saint John, N.B. concludes that, "There are a number of powdered admixtures which have been tried out and which are undoubtedly beneficial to the concrete and greatly lengthen the period of its permanency, especially when used in sea water."

Somewhat the same uncertainty exists with respect to the addition of trass or pozzuolana to concrete. Consider-

The concrete at the left is similar in all respects except that a different coarse aggregate was used.

able success has been obtained in Europe by its use, yet, there, many structures have been reported where apparently no benefit was obtained. Atwood and Johnson[9] made a very comprehensive study of the technical literature on the use of cement in sea water and found that, " The majority of the authorities agree that this disintegration (sea water) can be prevented by the addition to standard Portland cement of a properly constituted siliceous material, which, by combination with the free lime released in the process of setting, will form a cementing material insoluble in sulphate-bearing waters." The tests of Miller[10] already referred to, indicate that this conclusion may hold for concrete subjected to alkali waters.

This opinion is not shared by Jewett[11]. In a series of tests conducted by the United States Reclamation Service, test blocks were made in which were used " sand cements manufactured by the Service, an " alkali-proof " cement containing blast-furnace slag as the siliceous material as well as various other materials and processes, for which claims of waterproofing properties were made." Quoting Mr. Jewett, who was connected with these tests, " Observations of the action on these specimens showed that a rich mixture of Portland cement concrete was more resistant to the alkali action than any other material used."

The author would venture the opinion that the substances formed when a siliceous material such as trass is added to cement are not insoluble as stated by Atwood and Johnson, but only relatively insoluble, that when they are in contact with sea water they dissolve so slowly that they protect the concrete indefinitely, but when exposed to the more severe conditions of alkali they are dissolved more rapidly and only prevent the destruction of the concrete for a time. It should also be noted that certain siliceous materials combine with lime more readily than others and would therefore give more efficient protection, which might account for the different results obtained by different users.

It seems therefore, in view of the foregoing, that engineers are justified in being somewhat sceptical of the value of any substance, which when added to concrete is claimed to protect it against sulphate-bearing waters. If, however, it is considered desirable to use such a material in concrete, then too great a reliance should not be placed on its protective value, nor should the essential precautions already outlined for the construction of concrete in sea or alkali waters be omitted in any degree.

A slightly different situation exists with surface treatments, for some of these have been used with considerable success in both sea and alkaline waters. Surface treatments depend for their success on preventing the destructive agent from penetrating the concrete. If this is not completely accomplished, and it seldom is, deterioration will take place behind the treated or coated surface of the concrete, in which case the protective treatment may be actually harmful. Surface treatments are likewise to be used with caution and only after satisfactory evidence of the thoroughness of the protection offered by them.

The destruction of concrete by alkali attack is ordinarily believed to be confined to the western portions of the United States and Canada, but such is not the case. Typical examples of sulphate disintegration are occasionally met with in the east, and are probably more common than is generally realized, for eastern engineers are not familiar with this form of deterioration. The author reported a case of this kind two years ago and others have come to his attention[12].

Fresh Waters

Deterioration of concrete may result from the dissolving action of fresh water alone. For instance, Thorvaldson[13] has found that if pure water is allowed to percolate freely through a porous concrete, the cement will eventually become completely disintegrated. The Board of Water Supply, New York City[14], found that the strength of concrete was reduced to a small fraction of its normal strength by allowing water to percolate through it for one year. Lerch and Bogue[15] have also found that all of the six recognized constituent chemical compounds of cement, in their pure form at least, will undergo complete hydrolysis in aqueous solutions, if the solution products are removed as formed.

Carbon dioxide may be an important factor in the corrosion of concrete by natural waters. Newhall[16] states, " When a concrete structure is exposed to moisture and car-

Figure No. 4.—Spalling Caused by the Decay of Unsound Stone. Moisture Reached the Stone Through the Porous Concrete, Causing it to Swell.

bon dioxide, a condition develops whereby normal calcium carbonate is first formed, followed by the change to the bicarbonate of calcium, the latter being relatively very soluble. The solubility of calcium in the form of bicarbonate is generally increased if the water carries dissolved organic matter. All natural ground waters, sewage, and even rainwater are highly charged with carbon dioxide and thus are corrosive to concrete through the bicarbonate reaction."

Similarly the experiments of Baylis[17] show that natural waters will attack the calcium compounds of the hydrated cement, changing some into calcium carbonate and washing some away entirely. He states that if the concrete is porous, this action will proceed until the concrete eventually disintegrates, but with an impermeable concrete the action is confined to the surface and becomes of negligible importance.

Evidence of the truth of these observations is not entirely experimental. Gore[18] reports that in a very porous concrete (cemented gravel) in the floor of a water filter at Toronto, " the cement was being slowly dissolved by the water, so that the bed, although sound, was more open than when placed, six years earlier." Mackenzie[19] reports that two different hydraulic structures of large magnitude of his knowledge, " showed marked signs of water seepage " which he attributes to the same cause. At Vannes, Brittany, a concrete conduit was destroyed in about thirteen years by the corrosive action of the very pure water it carried[20]. The author also knows of structures where the deterioration of the concrete is due to the solution of the cement by the movement of water in its mass.

Another example of this same action is the whitish deposits frequently observed wherever water seeps through concrete. These deposits are usually found to be calcium carbonate and result from the solution of the calcium in the concrete by the passing water. A further instance is the sandy surface of concretes in contact with the soft waters of some of our Canadian rivers. Here the surface is being slowly removed by the waters of these streams which are very corrosive to calcium compounds.

Mechanical Agencies

Mechanical agencies play an important part in the destruction of concrete. Abrasion, as met with in highway slabs; erosion by water, as in hydraulic structures; and volume changes caused either by variations in the temperature of the concrete or its moisture content, are some of these. Others are the action of frost upon moisture held in its pores, and the less common but related phenomenon, the concentration and crystallization of salts in the pores brought about by moisture and evaporation.

In many structures, such as floors, sidewalks and highways, abrasion is a normal condition of service, to be expected, and therefore to be provided for in the design of the concrete. With other types of structures this is likewise true of erosion. Since this paper is intended to deal only with those destructive forces that are natural agencies, and not with those hazards that would ordinarily result from the particular service for which the concrete is intended, neither of these mechanical agencies can properly be considered here. In the majority of cases where concrete is being destroyed unduly by either abrasion or erosion, it will be found to be of an inferior quality, and it is probable that a better concrete would have successfully withstood the same conditions of service.

Volume Changes

Volume changes are caused by differences in temperature, by variations in the moisture content of the concrete, by chemical action and by prolonged stress. Experiments show that the unit changes brought about by temperature are not a constant, for the coefficient of expansion of concrete varies with its temperature, its moisture content and the quantity of cement it contains. Other experiments demonstrate that when concrete dries it shrinks, when wet it expands, and the magnitude of the volume changes resulting are several times as great as those caused by temperature. It has also been found that where concrete dries after having been wet, the volume is not always the same as before. Many investigators have studied these phenomena and in particular instances have reported their action and extent, others have commented upon their possible effect on the integrity of concrete, but our actual knowledge regarding them and how they act to destroy concrete is meagre and the subject but partially understood[21].

A little thought, however, shows some of the possible effects of volume changes. For instance, concrete conducts heat but slowly, and it is possible to have a considerable difference in temperature between the concrete at the surface of a wall and that a fraction of an inch below the surface. If the surface is cooler than the interior, a temperature difference of this kind might easily stress the former so greatly that cracks would develop. The same circumstances would also produce stresses parallel to the surface, which would tend to cause scaling.

Since differences in the richness of concrete cause differences in the coefficient of expansion, variations in the cement content between the surface and interior would cause stresses similar in effect to those brought about by variations in temperature. It is also conceivable that the repeated stressing of the concrete caused by temperature changes might bring about cracking at the surface through fatigue, and cracks thus started would undoubtedly deepen as time goes on.

Volume changes due to moisture cannot occur with the frequency of temperature changes, but because of their greater magnitude will individually have a greater destructive effect. Concrete expands rapidly on wetting, the bulk of the expansion taking place in a few hours, but contracts very slowly on drying, since the drying of the concrete is a slow process, taking days and even weeks to complete. In

experiments by the author, water was found to penetrate dry concrete (mix about 1:6) at the rate of an inch an hour by capillary action alone, and the concrete ultimately absorbed about 12 per cent of its own volume of water. In this process, the surface concrete would expand before that of the interior and, as in the case of temperature differences, stresses would be set up.

Frost Action and Crystallization

Frost alone is not destructive to hardened concrete; moisture must be present in its pores or openings before frost can have any harmful effect. But if moisture is present, frost will cause enormous expansive forces within the concrete, for the water gains some 10 per cent in volume on freezing. If the concrete is strong, and the pores few, it will resist this action, but if sufficient pores full of water exist the concrete will be gradually destroyed, and strength alone will not save it. Freeman[22] reports a concrete that disintegrated by frost action although it tested 2,166 pounds per square inch, and the author has seen similar instances where concrete commenced within a year to fail from the same cause although testing 2,500 pounds per square inch and more.

It would seem, with concrete as porous as it is, that in our northern climate disintegration due to frost action would be more common, but several factors work to protect the concrete. Freezing must occur with the pores full of water and it is seldom that such a condition exists. A concrete surface may be saturated by a prolonged rain, yet before it freezes natural drainage and evaporation will remove sufficient water to protect it and this fact saves much poor concrete from destruction. When freezing occurs with the pores full, as at the water line in dams, harbour walls, etc., only the very best concrete can resist the destructive forces set up.

Bates, Philips and Wig[23] report, as a result of their investigations at the Bureau of Standards, that " Portland cement mortar or concrete, if porous, can be disintegrated by the mechanical forces exerted by the crystallization of almost any salt in its pores, if a sufficient amount of it is permitted to accumulate. . . ." Crystallization is a factor in the disruption of concrete by alkali and sea water, but authorities now generally agree that, excepting the freezing of water, crystallization of substances within the pores of concrete is seldom the direct cause of failure, although frequently it is a contributory factor.

Materials

It is obvious that a concrete to be durable must be made from durable materials. Poor materials are naturally to be avoided, and most engineers, recognizing this, take steps to prevent their being used. With cement and water, prevention usually consists of testing the cement and using only potable water. These precautions seem ample, for few failures due to either of these causes have been recorded.

With aggregates, the situation is more complicated. Aggregates may be unsatisfactory in three ways: they may be poorly graded, dirty, or unsound, and if they are deficient in any one of these respects, they lessen the durability of the concrete in which they are used.

A poorly graded aggregate is objectionable largely because of its effect on porosity, and, as will be shown later, porosity and durability are closely related. A dirty aggregate lowers the resistance of concrete to attack in several ways. Lumps of clay, roots, etc., cause unsightly surface spalling, weaken the concrete in which they occur, and tend to break it up. Excessive silt distributes itself throughout the concrete, increasing porosity, coating the particles of aggregate and destroying the bond between them and the cement. Organic impurities lower the strength of the concrete and there is some evidence to show that they will in time cause serious internal deterioration.

Both poorly graded and dirty material can be prevented by requiring that all aggregates meet the specifications of either the American Society for Testing Materials or the Joint Committee on Concrete and Reinforced Concrete. The

tests for grading and cleanliness given in these specifications are simple, and if regularly applied, amply protect the user against materials faulty in these two respects.

Occasional cases are met with where concrete is failing because the aggregates from which they are made lack durability. These cases have been widely scattered and no one type of rock has been to blame. Although considerable investigation has been made of these unsound aggregates, our knowledge of them is meagre and does not permit us to generalize as to what rocks are safe and what are not.

Shale is generally recognized as an undesirable constituent of concrete aggregates and few engineers will knowingly permit its use. Occasionally its presence has not been recognized and it has caused serious trouble. In a case of this kind examined by the author, a gravel containing shale was used in a very porous concrete, and water, penetrating to the shale particles, caused them to swell and crack the structure badly. This action went on at considerable depths, affected particles being found fifteen inches and more below the surface.

Chert has proved objectionable in several instances. Reagel[24] reports that certain of the cherts of Missouri are unsound in concrete, causing cracks to form and the surface to spall. Similar experience has been recorded in the case of building stone, for Ries and Watson[25] report " cases are known of bridge abutments constructed of cherty limestone, which split so badly that they had to be torn down and replaced." The author has observed in certain limestones, chert inclusions that disintegrated with successive freezings. However, it should not be concluded from this that all cherts are unsuitable in concrete, for this is not necessarily so, and each case must be investigated on its merits.

(Published by permission of the American Concrete Institute)

Several widely scattered failures have been traced to the use of an unsound argillaceous limestone. The defective stone has acted differently in different cases, causing surface spalling in some, in others cracking the concrete to considerable depths. In several of these cases, where a petrographical study was made, the limestone was found to contain the mineral beidellite, which disintegrates on exposure to air.

Pearson and Loughlin [26] cite a series of failures that occurred in 1919 in the vicinity of Los Angeles. In these cases the coarse aggregate proved to be unstable when exposed to the air and the concrete made from it completely disintegrated. The offending rock was an altered soda-lime feldspar of the plagioclase variety known as anorthosite. Anorthosite is not usually a dangerous rock, but was so in this case, because its feldspar had become altered and existed in an unstable form.

Cases have also come to the author's attention where a sandstone has proved unsatisfactory, where the presence of micaceous schist and rotten particles in gravel has resulted in surface imperfections and where serious surface spalling has occurred with blast furnace slag.

Of these aggregates, shale and schist can be identified by visual examination, but it is not possible thus to determine whether an argillaceous limestone, a chert or a sandstone is sound or not. Certain tests are helpful in this respect, such as the sodium sulphate test[27], also absorption and compressive strength tests, but it has not yet been proved that any of these will positively detect unsound materials. However, aggregates that fail to pass the sodium-sulphate test and have a high absorption and a low compressive strength should be avoided, as they are apt to weather badly.

In gravel, the safest way is to determine the quantity and character of the different rock types composing it, by examining and classifying one to two hundred of its particles, and to reject it if found to contain shale, schist or decayed material to more than a few per cent. The percentages that warrant rejection are not as yet agreed upon. Committee E-1 of the American Concrete Institute [28] have limited shale to 1½ per cent and schist and decayed particles to 3 per cent. The state highway departments of Kansas, Iowa and Minnesota limit shale to 0.5 per cent; Kentucky limits shale, slate, etc., to 1 per cent, and Michigan, shale and other non-durable particles to 3 per cent [29]. Reagel[30] recommends that chert be kept below 5 per cent. If more than one type of undesirable material is present the total quantity should not exceed the maximum percentage allowed for any one of them, say from 3 to 5 per cent.

With crushed rock, the surest way by which an engineer, equipped with only the usual knowledge of mineralogy, can protect himself against unsound stone, is by a personal examination of the quarries from which the coarse aggregate is to be obtained, particularly of old ledges of the same rock that have been exposed to the weather for several years. Such an examination will usually reveal the presence of un-

sound material in the quarry, and if such is found, the product of that quarry should not be used.

Reinforcement

Reinforced concrete structures are subject to an additional hazard due to the steel reinforcement. If moisture and air can penetrate to the reinforcing steel, it will cause rusting. Rust requires 2.7 times the space occupied by the original metal, and therefore in forming exerts great pressure on the surrounding concrete. If the reinforcement is not deeply imbedded, these forces spall or crack the concrete, weakening the structure, and in many cases exposing the steel to further attack. This action is particularly common in structures in sea water and along the adjacent coasts where they are reached by air-borne salt spray.

The remedy is to imbed the reinforcement deeply and to surround it with a tight, impermeable concrete. The Joint Committee on Concrete and Reinforced Concrete recommended that "Metal reinforcement in wall footings and column footings shall have a minimum covering of three inches of concrete. At surfaces of concrete exposed to the weather, metal reinforcement shall be protected by not less than two inches of concrete," and for sea water construction they recommend that, "metal reinforcement shall be placed at least three inches from any plane or curved surface, except at corners when it shall be at least four inches from adjacent surfaces."

Porosity

At this point it is interesting to consider the frequency with which porosity and its related properties, permeability and absorption, are cited as factors in the durability of concrete, but first it might be well to digress for a moment and consider what is meant by these three terms.

Figure No. 9.—A Concrete in which Pockets and Seams of Laitance were Allowed to Remain.

These have weathered away for considerable depths. Apparently this concrete was all deposited at one point and allowed to flow into place.

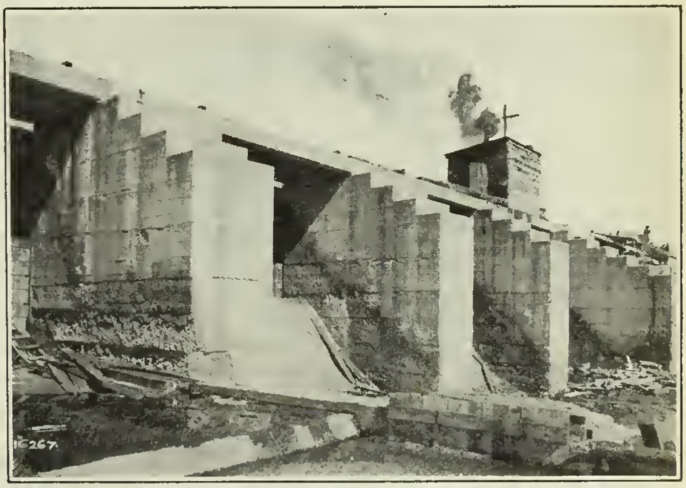

Figure No. 10.—An Example showing that Deterioration Starts First at the Top of the Lift where the Concrete is more Porous because of Accumulation of Water and Laitance and the Settlement of the Coarse Aggregate.

Porosity is a condition of the concrete; permeability and absorption are properties of the concrete dependent upon its porosity. The porosity of a concrete cannot be determined directly, because the total pore space of a concrete cannot be measured, as many of the pores have no access to the surface or are blocked in such a way that they cannot be filled by any measuring medium. Hence porosity must be determined indirectly by measuring the volume of the pores that can be filled, i.e. by determining the absorption. Permeability is usually determined by bringing one surface of a test slab in contact with water under pressure and noting the rate at which water will pass through. Sometimes a hollow block is used instead of the slab. Permeability, therefore, merely indicates a condition of the pores which permits the passage of a fluid through the concrete.

With this explanation, let us return to a consideration of the influence of porosity on the durability of concrete. As has been said, frost cannot harm concrete except its pores contain moisture. The moisture that causes volume changes, that carries the corrosive agents which attack the cement binder and that rusts the embedded reinforcement also enters concrete through its pores. These pores or passages have access to the surface and exist to some extent in all concrete.

The resistance of concrete to the different agencies of attack will depend on the size, character and frequency of its pores. The majority being of capillary size, it is probable that under ordinary exposures they chiefly determine the durability of the concrete. By capillary action such pores will draw water from the surface inward, and once filled, will not be drained by the forces of gravity. Thus if one end comes in contact with a source of moisture, the pore is filled and it does not immediately empty when the source of moisture is removed. This is of importance in frost action, where the pores must be nearly full of water to be dangerous.

Capillary pores will conduct moisture from one point to another. A familiar example of this is the moist band often found above the water level of partially submerged concrete. Here, capillarity lifts the moisture from the water level below to the surface, from which it is removed by evaporation, so that there is a continuous movement of water through the concrete. This movement of water will, in time, dissolve the cement of the concrete through which it passes, and evaporation will cause the dissolved material to be deposited in the pores with disruptive effect. As pointed out by Johnson[31] it is possible that in many cases the deposition of the dissolved salts takes place at some depth and causes a progressive internal disintegration which may lead to ultimate failure. Johnson[32] in his microscopic investigations, found that in crushing a concrete the planes of failure ran from pore to pore and thus the presence of pores in a concrete also deleteriously affects its strength.

In order to separate capillary absorption from absorption as customarily determined, the author has developed an apparatus which he has named a "capillary pore determin-

(31) N. C. Johnson, Mechanical Disintegration of Defective Concretes, Engineering Record, Feb. 6, 1915, p. 160.

(32) N. C. Johnson, Microscope as an Aid in Proportioning Concrete for Strength, Engineering Record, Feb. 13, 1915.

ator." In this apparatus, shown in figure No. 6, the concrete is in contact with water at the lower surface only, and all absorption is capillary. Absorption-time curves of the type shown in figure No. 15 are obtained. As yet, the apparatus has had but a very limited use and it is described here only because some of the results obtained with it will be referred to later in this paper.

The principal causes of excess porosity in a concrete are lack of cement, poorly graded aggregate, the use of excess water in mixing, improper placing and lack of curing. Excepting only concrete exposed to alkali attack, it is probable that 90 per cent of the faulty concrete existing in Canada is defective because of porosity, due to one or more of these five factors, irrespective of whether the immediate cause of its destruction is sea water, corrosion, frost action or volume changes.

Lack of Cement

Cement plays a dual rôle in concrete: it binds the aggregates, and it fills and seals the spaces between them. If the cement content of the concrete is reduced too greatly, its porosity is increased to the danger point. Concretes of low cement content such as those containing one barrel of cement per cubic yard or less are almost certain to disintegrate if the exposure is severe and even concretes containing 1.25 barrel to the cubic yard will fail unless specifically designed to give low porosity.

Instances of disintegrating concretes due to lack of cement are not uncommon. An interesting example was cited in a report of the American Concrete Institute(33). The structure was a breakwater. "That portion which was built of 1:2:4 concrete has stood up remarkably well for twenty years under the extremely severe exposure of a Lake Michigan waterfront, while the portion built two years later with a 1:3:5 concrete has been badly attacked, requiring extensive repairs. Both sections of this wall were carefully placed. . . ." There is another example at an hydro-electric power plant in Ontario. Concrete retaining walls, well made, but containing less than one barrel of cement per cubic yard, were built along a canal. During the early operation of the plant the water level in the canal reached the elevation of these walls and surface disintegration commenced. Similar concrete containing approximately an additional sack of cement per cubic yard has withstood the same exposure for six years without any evidence of distress.

(33) Report of Committee E-6 on Destructive Agents and Protective Treatments, Proc., American Concrete Institute, vol. 21, (1925), p. 266.

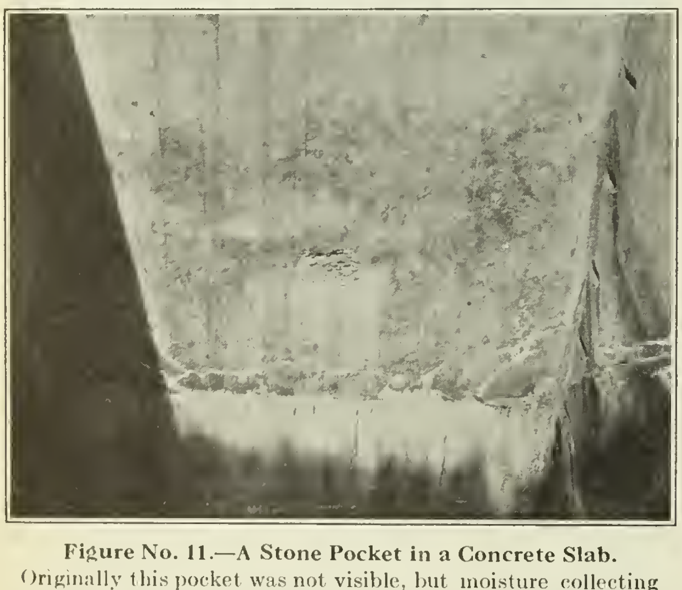

Figure No. 11.—A Stone Pocket in a Concrete Slab.
Originally this pocket was not visible, but moisture collecting and freezing in it has spalled the surface. The concrete immediately surrounding this pocket is more porous than the main body of the slab and it is beginning to deteriorate as evidenced by the darkest areas

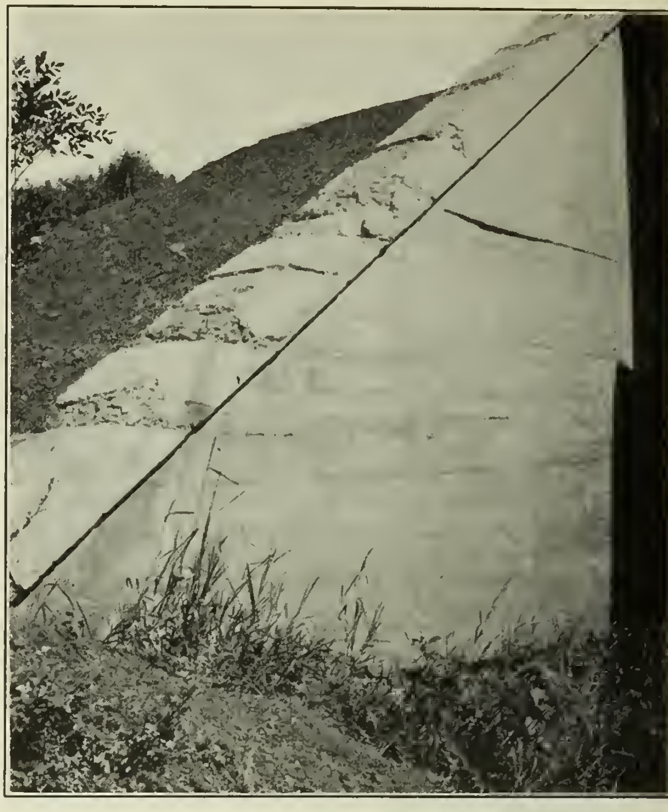

Figure No. 12.—An Example of the Effect of Segregation of Mortar at Corners, along Edges and at the Surface.

The experience of the author has led him to the opinion that any structure in which the concrete is in contact with water, such as dams, power house foundations, etc., should contain not less than 1.25 barrels of cement per cubic yard. For concrete exposed to the weather but not in contact with water, such as bridge piers above high water, retaining walls, etc., the cement content may be reduced safely to 1.10 barrels. For concrete not exposed to weathering, such as the interior columns, beams and walls of buildings, the cement content can be reduced further, but in these cases the amount of cement is usually governed by the strength required and not by the necessity of providing durability.

The foregoing estimates are absolute minima, and are based on a concrete designed for impermeability and manufactured under expert supervision. If the concrete mixtures are not so designed and supervised, these quantities should be increased by at least a bag per cubic yard and in some cases more. For concretes to be deposited under water, for concretes in sea water,—especially reinforced concrete,—and liable to alkali attack, these minimum quantities should also be substantially increased.

Poorly Graded Aggregates

Properly speaking, the grading of the fine and coarse aggregates should be considered together and not separately as is customary. In most cases, however, it is the former that principally determines the character of the porosity and therefore the durability of the concrete; hence it only will be considered here.

Porosity is affected by the relation of the fine and coarse aggregates. There is an optimum ratio at which the porosity is lowest, and if less or more fine aggregate is used, the porosity is increased. From a limited series of tests made with the capillary pore determinator previously described, it appears that the character of the porosity is different in the two cases. Lack of sand tends to cause large pores, there being insufficient mortar to fill the voids in the coarse aggregate, while an excess of sand tends to divide the pore space into smaller units. It is impossible to say positively which of these conditions is the more detrimental, but field experience has demonstrated that both are harmful.

The fine aggregate should not contain too small an amount of the finer particles. Recent specifications of both the American Society for Testing Materials and the Joint Committee on Concrete and Reinforced Concrete place a minimum as well as a maximum requirement on the amount of fine particles passing the No. 50 sieve. The absence of these finer sizes has a tendency to increase the pore space in a concrete and makes placing more difficult. Sands of this character are of common occurrence, and in some localities it is difficult to obtain any other kind. Very coarse sands are almost always of this type, and it is a frequent fault of sands that have been washed and of those obtained by dredging.

Another type of fine aggregate that has proved undesirable is one in which one or two sizes of particles predominate. Very fine and very coarse sands are both of this type, as are sands composed largely of one or two intermediate sizes. Standard specifications ordinarily prohibit the use of very fine and very coarse sands but make no mention of the latter, which are equally objectionable. To provide against such sands the specifications of the Hydro-Electric Power Commission require that " Not more than 75 per cent by weight of the fine aggregate shall lie between the No. 8 and 30 sieves or between the No. 16 and 50 sieves."

Excess Water

Engineers are being told repeatedly that excess water is detrimental to concrete but most writers have emphasized only its ill effect on strength. The harm done, however, is not confined to strength; it increases porosity, causes segregation, washes out the cement and generally makes the concrete more liable to deterioration.

Water is added to concrete partly to hydrate the cement and partly to give it workability. The part that combines with the cement is small,—at most only a few per cent of the total,—leaving the remainder distributed throughout the concrete. Since water is incompressible and therefore will occupy space in proportion to the quantity present, it follows that any water above that required for hydration increases the volume of the concrete by an amount equal to its own volume. The concrete hardens with this water in place, but, as time goes on, the water dries out and leaves pores through which, given proper conditions, water will again enter. The possible effect of excess water is better appreciated if we consider an excess of, say 20 per cent,—a not unusual amount. In a cubic yard of concrete this would add one cubic foot of pore space, which, in a concrete of average density, is an increase of about 25 per cent in the total volume of space present.

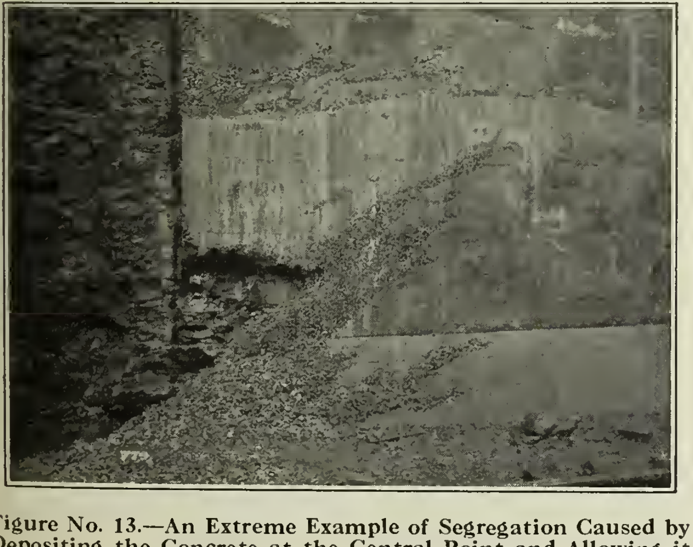

Figure No. 13.—An Extreme Example of Segregation Caused by Depositing the Concrete at the Central Point and Allowing it to Flow into Place.

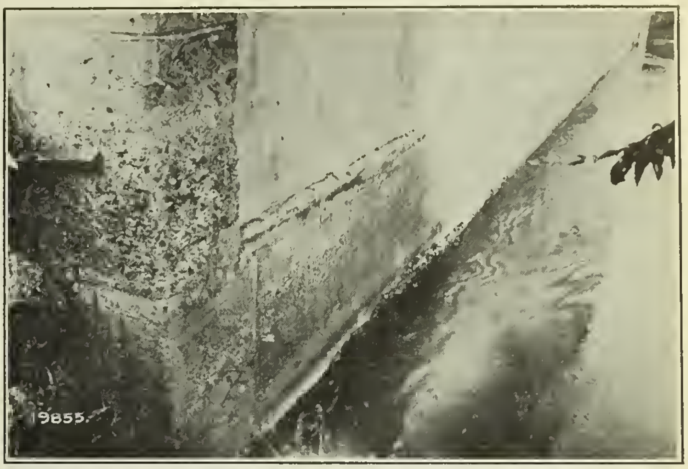

Figure No. 14.—Segregation Caused by the Settlement of the Aggregate through an Over Wet Mix.

Note the coarse aggregate at the bottom, followed by the mortar and topped by a layer of laitance. The concrete is subjected here to a moderate exposure, in fact, the laitance layer is intact, yet the concrete has weathered badly.

Excess water washes the fine particles of the cement and aggregate to the surface as laitance where it collects. Laitance is objectionable, for it not only lacks strength, but is very porous and easily weathered. It also forms planes along which water can readily gain access to and attack the interior of the concrete. Specifications usually require that laitance be removed before concrete is again placed and the necessity for this is generally understood. Unfortunately, all the laitance does not reach the surface but some is trapped, together with water, at varying distances below, forming at the top of each lift, a layer of very porous concrete, which is readily attacked.

Excess water is one of the principal causes of the segregation of concrete mixtures during handling and placing. Concrete must be plastic and workable before it can be placed properly and this requires more water than is needed for the hydration of the cement. The addition of any considerable amount over and above this basic requirement merely thins the mixture to a point where the cement grout cannot float the aggregate. When an attempt is made to handle and place concrete in this condition, segregation is inevitable and trouble results. Segregation is one of the principal causes of lack of durability in concrete and excess water is one of the principal causes of segregation.

Segregation

While segregation is ordinarily due to the use of excess water in the concrete mixtures, yet it may also be caused by improper handling. In fact, almost any concrete mixture will segregate if mishandled, therefore, from the standpoint of quality, the handling and placing of concrete is or is not successful in the degree to which segregation of the ingredients is prevented or overcome.

Segregation influences porosity in various ways. It is obvious that if the coarse aggregate is allowed to collect in pockets, such pockets, containing as they do little or no mortar, will be very porous. If the separation of the mixture is not complete and part of the mortar remains with the coarse aggregate, the porosity is still increased, for then the concrete is in the condition previously referred to, where it lacks the proper complement of fine aggregate. Theo-

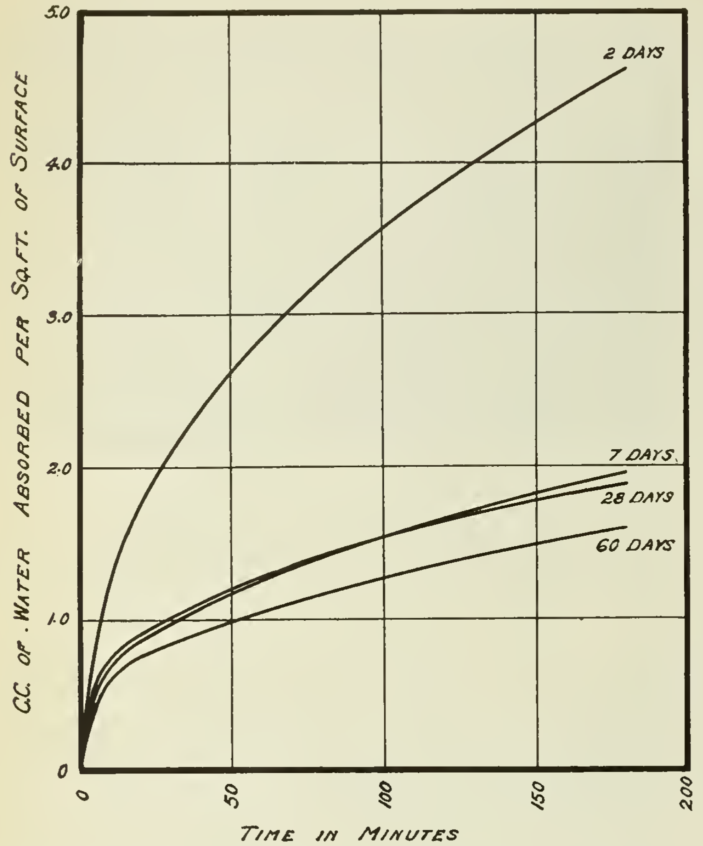

Figure No. 15.—Effect of Curing on the Absorption of Concrete. Absorption Time Curves Obtained with Capillary Pore Determinator.

retically, segregation of the coarse aggregate should not change the porosity of the mortar that separates from it, but practically, where a concrete segregates, the separation of materials usually extends to the mortar,—the fine aggregate also separating from the cement and water. When this occurs the tendency is for such grout to collect in corners, along shoulders, at surfaces and joints, that is, at just those points where experience has shown that concrete structures are particularly liable to deterioration.

Segregation is common to all systems of transporting concrete, whether by chutes, buggies, buckets, belt conveyors, railway or truck, but by proper use, any one of these methods can be made to yield satisfactory results. Even the much maligned chute, if correctly arranged, fed and handled, will transport concrete without segregation, while modern central mixing plants have demonstrated the practicability of long distance transportation of concrete by motor truck,—a method once generally condemned on account of the difficulty of preventing the separation of the aggregates and mortar.

If concrete is dropped from any considerable height, the coarse aggregate will collect in one place and stone pockets result. Dropping concrete through reinforcing steel is also an effective way of separating the stone from the mortar and another is to allow the concrete to strike and bounce off the sides of the forms. A further practice that has proved objectionable, is to dump all concrete at one point in the forms and then to depend upon puddling and shovelling to place it in its final position. In placing concrete the safe rule to follow is to deposit it, with a minimum of interference, as nearly as practicable at its final resting place, puddling and reworking it only sufficiently to consolidate the mass, eliminate entrained air and remove stone pockets.

A little forethought will largely prevent segregation. The first requirement is a properly designed mixture,—one in which the fine and coarse aggregates are correctly balanced. The second is adequate mixing,—not less than a full minute, longer if practicable,—for the cohesiveness of a concrete is increased the longer it is mixed. The third requirement is to use a consistency as dry as circumstances permit, keeping the mixture fully plastic and workable at all times. Most engineers are inclined to use a mixture that is wetter than required. Even in reinforced concrete, it is seldom necessary to use mixtures having a slump greater than three or four inches, and where a mix wetter than this is required, it is usually because the methods of handling and placing are poorly arranged or mismanaged.

Curing

The influence of curing on porosity is more difficult of direct proof than is the lack of cement or the use of excess water. It is usually impossible to ascertain the amount of curing that a given concrete has received, therefore few cases of disintegrating concrete can be definitely attributed to this cause. However, the effect of curing has been investigated experimentally. The author has made tests using four similarly proportioned concretes, cured in water for two, seven, twenty-eight, and sixty days, and when these were tested in the capillary pore determinator previously referred to, absorptions were obtained at the end of a thirty-minute period of 2.1, 1.02, 0.96 and 0.84 cubic centimetres of water per square inch of exposed area respectively, or in the ratio of 1.00, 0.48, 0.46 and 0.40. The results are shown graphically in figure No. 15.

Tests made by other investigators have brought out the same point. Withey[34] has shown that the permeability of concrete decreases very rapidly as the curing period increases. In his tests, concrete cured in water for one day passed five times as much water as that cured similarly for six days, and concrete cured for four days, more than four times as much water as that cured for thirteen days.

Lack of curing has a further detrimental effect on concrete since it reduces its strength and thus its ability to resist attack. Gilkey[35] has shown that concrete cured in water for two days has only 80 per cent of the compressive strength of concrete cured for seven days, and 60 per cent of that cured for a month.

Cold Weather Curing

Lack of curing is one of the dangers of cold weather construction. If concrete is repeatedly frozen before it becomes thoroughly set, its strength is almost totally destroyed and its porosity is greatly increased by the formation of ice in its interior. There is little excuse for allowing concrete to freeze, for freezing can be avoided by simple means, which have been so often described that they should be well-known to all. A number of cases have occurred where complete failure of a structure has resulted from omitting these precautions, but fortunately such failures usually occur before the structure is completed. More frequently, especially in mass work, only the outer surfaces of concrete will be damaged by freezing and the rest will be sound. But whether complete or partial freezing occurs, it may be accepted as a fact that any concrete so damaged will disintegrate, if exposed to the weather or to other destructive agencies.

A less immediate but more subtle effect of lack of curing in cold weather occurs when concrete, although protected

(34) M. O. Withey, Trans. Western Society of Engineers, vol. 19, p. 833.

(35) H. J. Gilkey, The Effect of Varied Curing upon the Compressive Strength of Mortars and Concretes, Proc. American Concrete Institute, vol. 22, (1926), p. 395.

from freezing, is not kept warm while hardening. Standard specifications usually require that concrete be maintained at a temperature of 50° F. or more, for at least seventy-two hours after placing. Concrete so treated, if otherwise sound, will have sufficient resistance to withstand frost action for one season, by which time it will have attained the necessary strength to protect it indefinitely. If less curing has been provided, it is liable to be destroyed while still weak, particularly if it becomes frozen while saturated with moisture. Any structure where the volume of concrete is small or its exposed area is large in relation to its mass is particularly liable to attack of this sort and special care needs to be taken in its curing.

Several cases where trouble has resulted from this cause have come to the author's attention. In one the structure was a thin platform built in the early winter. The aggregates and water were heated, the concrete was protected and steamed, but steaming was discontinued at the end of thirty-six hours. After its initial curing the concrete had no further opportunity to gain strength on account of the continued cold weather. In the spring the melting snow saturated the platform with water and while in this condition it was frozen a number of times by recurring cold nights. The concrete lacked the strength to withstand this treatment and was so badly damaged that it had to be replaced. Seventy-two hours of curing at 50° F. as required by the standard specifications would have saved this structure, for, in tests made by the author in the laboratory of the Hydro-Electric Power Commission of Ontario, similar concrete cured seventy-two hours was undamaged by fifteen alternations of freezing and thawing, but when cured only thirty-six hours it was so badly disintegrated by the same treatment that further tests were impossible.

Figure No. 17.--A Concrete Footing Built in the Late Fall.
It was protected until hardened, but never had a chance to cure properly. In the spring it became saturated with water and was frozen.

Determining Causes

It is seldom that the deterioration of a concrete is caused by a single agency for if it is of such poor quality that it is susceptible to one form of attack it is usually susceptible to others. Thus, one finds a concrete being weathered by frost action in which the cement is also being dissolved by an internal movement of water, or one in which both alkali and frost are acting jointly, or another where frost, sulphate decay and spalling from the rusting of the reinforcement are all taking place simultaneously. Engineers, in such cases, are apt to give as the cause the factor most in evidence or the one with which they are most familiar.

Few engineers go beyond these more or less obvious outward manifestations of deterioration and attempt to differentiate between the agency of attack, the condition of the concrete that permitted the attack and the cause of that condition, and it is necessary to do this if means are to be devised whereby the agencies of destruction are to be circumvented. For example, frost may be the immediate agent of destruction through its action on moisture in the pores of the concrete, but the pores are the means by which it is enabled to destroy the concrete. It is seldom possible to

Figure No. 18.—Concrete Eight Years Old that Was Designed to Have Low Porosity but which Tested only about 1,500 pounds per Square Inch at Twenty-eight days.

Note the absence of disintegration and excellent condition of the concrete.

protect an exposed concrete from freezing temperatures, but it is possible to build one in which the porosity has been reduced to a point where it is no longer damaged by frost action.

Durability and Strength

The probable durability of concrete should not be judged by its strength alone. The fact that a concrete has a high compressive strength is no guarantee that it will be durable. This point has already been referred to in discussing frost action, but it will bear repeating. It is true that usually concrete of high strength is durable, but usually the same concrete is also highly impermeable and of low absorption, and it is these qualities, more than strength, that determine its resistance. Concrete of low strength can be made durable, for the Hydro-Electric Power Commission of Ontario have used large yardages of concrete in such places as canal linings, dams and retaining walls that at twenty-eight days tested from 1,500 to 1,800 pounds per square inch. This concrete was proportioned for impermeability as well as strength, and it is proving very durable in service.

Examples of Durable Concrete

The author has dwelt at some length on the ills to which concrete is subject. He has done so purposely, hoping that if the desire to have a good concrete is not sufficient to cause engineers to insist on the requirements necessary to achieve that end, a fear of the consequences might do so. But he would not leave this subject without offering evidence of the enduring qualities of well-made concrete. There are a great many concrete structures that have given years of satisfactory service without appreciable deterioration, but space will permit the citation of only a limited number of these.

For the earliest examples, one has to go to England, where Portland cement was invented. Portland cement was used in 1862 in the mass foundations of the Crystal Palace, London. It was also used in the same structure where the brickwork was stuccoed or rendered, and here it is reported[36] to be standing today, finely moulded with the mitres perfect. Other examples of about the same age are the Thames Embankment and the Metropolitan Main Drainage both built in the same city between the years 1858 and 1865. They are also reported[36] as being in good condition.

A row of fourteen five storey houses was built at Folkestone, England, in 1870, and is still in use. Concrete was used for the front and back steps of these houses and is reported[37] in the same condition as when built over fifty years ago. A flight of about one hundred and fifty stairs leading up the cliff, built at the same time, have been in constant use since and are still in excellent condition and show no signs of wear.

About 1874, a Mr. A. T. Peterson built, near Southampton, England, a tower of Portland cement concrete, 220 feet high and 22 feet square at the base. Figure No. 19 is a picture of this tower, taken in January 1924 by Mr. H. C. Badder of London, England. Mr. Badder, reporting[38] on the condition of the concrete says, "There the tower stands, practically as perfect as it was fifty years ago. . . . Now that it is protected from lightning there is no visible reason why it should not stand for another fifty or even one hundred years."

The oldest concrete structures on this continent of which the author could find record were a concrete barn and several other buildings built at Croton-on-the-Hudson in 1865. The barn is a building 60 by 75 feet, two storeys in height with walls 18 inches thick. The interior of this barn was completely burned out about thirty years ago and since that time the structure has not been in use. In 1923 the concrete of this barn was reported as "exceptionally good"[39].

Crystal Springs dam, San Mateo, Calif., was built between 1887 and 1890. The concrete was mixed approximately 1:2:6, very dry, being rammed into place by heavy iron tampers. In 1923 this concrete was inspected by engineers of the Portland Cement Association, who reported "the structure in very good condition with no deterioration whatever"[40].

During 1888, a number of concrete structures were built in the harbours of Nova Scotia by government engineers. Some of these are in the Bay of Fundy, where tidal conditions are very severe. Mr. R. J. Wig, who examined them a few years ago, reported[41] that at that time "on some, the form marks are yet visible," and that they "will last many more years."

The oldest concrete pavement is thought to exist at Bellefontain, Ohio. It was built in 1892 in the streets surrounding the courthouse and in the courthouse square of that city. A concrete driveway was also built for a local lumber company at about the same time. Both were still in use in 1924[42].

In 1894 the United States government used Portland cement concrete in the construction of locks at Rock Island, Ill., on the Illinois-Mississippi canal. They were made of 1:2:4½ concrete, placed in layers and rammed. Special provision was made for curing. When these, and two other locks built about the same time, were examined in 1923 they were found to be in excellent shape after being in constant use under severe weather conditions for approximately thirty years[43].

The Stanford University building, Palo Alto, Calif., was built in 1896. This building withstood the San Francisco earthquake of 1906 and is still in use at the present time. There has been no deterioration of the concrete in this structure due to weathering[43].

Another building in the same locality is the Ferry

Building, also at San Francisco. This building was built in 1898 and consists of concrete arches and abutments with a small amount of reinforcement. Part of the work is below and part above sea level. The mixture is not known. When inspected in 1923, no deterioration was noticeable and it was apparently in as good condition as when placed[43].

Between 1900 and 1902, the Illinois Central Railroad built a large number of concrete bridges in southern Illinois. In every case the concrete was of a consistency that would quake slightly after being thoroughly rammed. Abutments and wing walls were mixed 1:2½:6 and arch rings, 1:2:5. Four of these bridges were inspected in 1923, three showed little or no deterioration, while in the fourth there were a few cases of spalling and some disintegration in abutment walls where drainage was improperly taken care of. In all cases the concrete was structurally sound[43].

Figure No. 19.—Peterson's Tower, near Southampton, England, Built of Concrete about 1874, 220 feet High, 22 feet Square at the Base.
(*Published by permission of Concrete*)

In 1901-02 the New York Central Railroad built a reinforced concrete arch bridge made up of ten arches of 60-foot span, over West Canada creek, at Herkimer, N.Y. The concrete was mixed very dry and placed by means of buggies. An inspection of this structure in 1923 showed it to be in very good condition[43].

Life of Concrete

These examples serve to show something of the possible life of well-made concrete. The oldest is over sixty years old: others are from twenty-five to fifty years old and all are in good condition. They represent different types of structures,—buildings, bridges, hydraulic and marine,—and different exposures varying from mild California to the rigorous climate of Nova Scotia. The condition of these old structures does not indicate that the concrete is nearing the end of its useful life. They indicate rather that well-made concrete is an enduring material and one that will give long years of satisfactory service under a variety of conditions.

If well-made concrete has proved durable, and poorly-made concrete has not, the lesson is obvious. As the author has attempted to show, the characteristics of a durable concrete are that it shall have low porosity and be made of sound ingredients. Neither special equipment nor methods are necessary to obtain these. What is required is that the concrete shall be made of selected materials, properly proportioned, handled and placed without separation, and well cured.

All materials have their limitations, concrete is no exception to this, but rightly made and rightly used, few materials will give more satisfactory service. Concrete is probably as permanent as any material made by human hands but it is permanent not by chance but by intention. There is no material that is more truly a monument to its builder. Use good materials and right methods and the monument is enduring, but use poor materials and wrong methods and it is only a few years at best before the most inexperienced layman can read the story of the builder's shame. "By their works shall ye know them" is as true of builders of concrete as of others.

The Effect of Steam Treatment of Portland Cement Mortars on Their Resistance to Sulphate Action*

T. Thorvaldson and *V. A. Vigfusson.*
University of Saskatchewan, Saskatoon, Canada.

Paper presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

In the prairie provinces of Canada and the corresponding states to the south, failures of concrete structures imbedded in the soil are common. It is now generally accepted that the active agent causing the disintegration of these structures is the sulphate which is often present in large quantities in the ground water. Further, that whereas poorly made concrete disintegrates very rapidly, even the very best concrete made according to the usual methods disintegrates in time under the very severe conditions found in some localities.

During the summer of 1925, the authors began a study of the effect of steam treatment on Portland cement mortars as a part of a general investigation on the action of sulphate waters on cements and concrete. The method used for following the progress of the action of the sulphate solutions on the mortar specimens was that described by Thorvaldson, Larmour and Vigfusson.† This depends on the determination of the curve for the expansion of mortar test pieces during the course of the disintegration. Portland cement mortar specimens when undergoing sulphate action expand in a regular manner, and from the expansion at any point it is possible to predict the extent to which the tensile strength of the specimen has decreased through the action of the sulphate.

This method has decided advantages over the method of following the progress of the action by means of the determination of the tensile or compressive strength of mortar or concrete test pieces. When the latter method is used it is very difficult to predict the time intervals at which the tests are necessary, and this is likely to result in wastage of test pieces broken either too soon or too late. When the expansion method is used the same specimens can be used throughout the course of the experiment, irrespective of the time required for disintegration, as the specimens are not destroyed in making the test as in the case of the other method.

Dalton G. Miller‡ has published results of tests on the sulphate resistance of concrete cylinders cured in water vapour. Cylinders cured in water vapour at 212° F. showed, during exposure to the waters of Medicine lake, South Dakota, which, according to analysis submitted, contains 1.7 to 2.9 per cent sulphate, (SO_4), greatly increased resistance as compared with specimens cured in the damp closet or in water. On the other hand, it was found that similar cylinders cured in water vapour at 100° F. and 155° F. showed less resistance than those cured in water at about 70° F.

In experiments carried out at the United States Bureau of Standards* it was found that "steam up to 80 pounds per square inch gauge pressure has an accelerating action on the hardening of Portland cement mortar and concrete," the effect on the compressive strength increasing with the steam pressure used and with the time of exposure to steam. A compressive strength in some cases of over 100 per cent in excess of that obtained normally after ageing for six months was obtained in two days by using steam under pressure.

This suggests that the increase in sulphate resistance observed by Miller may be due to an increase in the strength of the test pieces during the steam treatment. The results of the experiments described in this paper indicate that this does not constitute a complete explanation.

Figure No. 1.

Sulphate Solutions

The solutions of sodium and magnesium sulphate were prepared from recrystallized salts and contained only traces of impurities. The adjustment of the initial concentrations was made by gravimetric sulphate determinations and was accurate to within less than 0.5 per cent of the sulphate content in the solution.

The calcium sulphate was prepared by precipitation from very pure recrystallized calcium nitrate, the precipitate of calcium sulphate being washed thoroughly by decantation.

Preparation of Mortar Specimens

The specimens used for the tensile strength determinations were briquets of the usual form, using cement, standard Ottawa sand and distilled water in the proportions by weight indicated. The mortar bars were made in the same way, using collapsible steel frames to give bars measuring ⅝ by ⅝ by 7½ inches. The bars had a thin layer of neat cement on each end. The ends were thus suitable for making accurate measurements of length, being smooth and free from easily detachable material. They were more resistant to sulphate action than the remainder of the bar so that in general the ends show no appreciable action by the time the bar falls to pieces. The specimens were removed from the moulds as soon as they were strong enough to handle, the time varying from one to eight days according to the richness of the mix, which varied from 1:5 to 1:10. They were stored in a damp closet until treated with steam or placed in the sulphate solutions.

Exposure of the Specimens to Steam and to the Solutions

After the initial period of curing of the bars in the damp chamber their length was determined by means of a micrometer head set in a frame of tool steel. The micrometer was read to one ten-thousandth of an inch. The bars were then exposed to steam either in a vacuum desiccator, over water, placed in an oven regulated to the required temperature, or in a vacuum oven so regulated. The bars cured in water were kept in sealed glass jars filled with water at the required temperature.

After cooling a day in the damp closet the bars were again measured and then exposed to the sulphate solutions in stoppered glass jars. Three bars were placed in one and one-half liters of the solution. Measurements of length were then made as often as necessary for the duration of the experiment and the average percentage increase in length plotted against time of exposure. The curves of figures Nos. 1 and 2 were obtained under the conditions of an ordinary laboratory room where the temperature varied from day to day. As sulphate action is rather sensitive to changes in temperature* this caused certain irregularities in the curves. The curves of figures Nos. 3 to 7 were obtained in a constant temperature room which did not vary more than a few tenths of a degree from the temperature indicated.

Effect of Exposure of 1:5 Mortar Bars to Water Vapour at Different Temperatures

Changes in Length

During the curing of Portland cement mortar bars either in damp air or in water at 21°C. a slight increase in length takes place. The rate of expansion is most rapid at first after removal from the moulds and decreases gradually until the bars attain a constant length. The total expansion during curing is least for lean mixes and increases gradually with the richness of mix.

When Portland cement mortar bars are cured in an atmosphere of steam at the boiling point of water an expansion takes place which varies with the cement used, the richness of mix, the age of the bars and the length of the steam treatment. There is a tendency for well-cured bars to contract during steam curing for short periods, which, however, changes to expansion on longer steam treatment. With 1:5 mortar bars made from cement No. 555, cured five months in the damp closet, the average total linear expansion after three days' steam treatment at 98°C. was 0.04 per cent. There was no further increase in length on five days' treatment. Similar bars treated with water vapour at temperatures below the boiling point of water also showed contraction and subsequent expansion, but at a slower rate. Thus the bars in saturated water vapour at 85°C. showed very slight contraction in five days, which was changed to a slight expansion in ten days. At 75°C. there was contraction in five days, while the bars came back to their original length in ten days, and at 50°C. the bars showed contraction at the end of ten days' treatment.

* The Engineering Journal, vol. 10, p. 199, (1927).

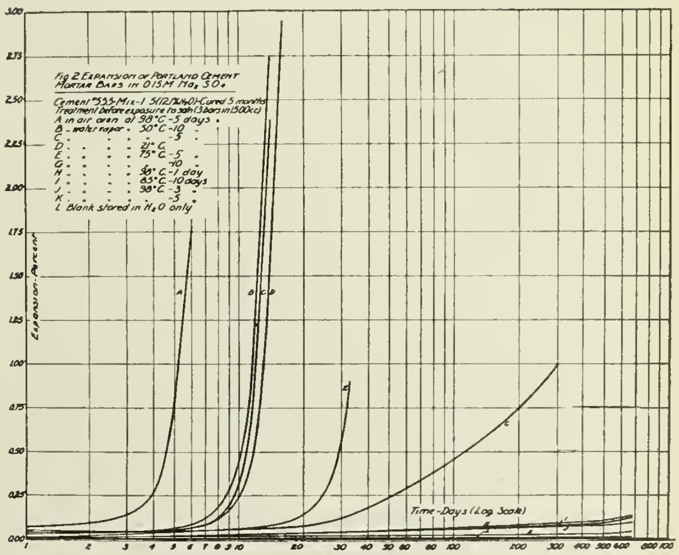

Figure No. 2.

This is rather interesting in view of the differences between the effect of steam treatment at the various temperatures on the sulphate resistance of the mortar. The beneficial effect of steam treatment on the resistance to sulphates seems to be accompanied by an expansion of the mortar.

Changes in Sulphate Resistance

Figure No. 1 indicates the relative rate of expansion of 1:5 mortar bars treated in various ways, in 0.15 molar solutions of magnesium sulphate, (1.8 per cent $MgSO_4$), and Figure No. 2 indicates the relative rate of expansion of similarly treated bars in 0.15 molar solutions of sodium sulphate, (2.1 per cent Na_2SO_4).

In each case the bars after curing for five months in the damp closet were treated with saturated water vapour at 21°, 50°, 75°, 85° and 98°C. respectively, and then cooled in the damp closet before immersion in the sulphate solutions. Comparison of the curves of Figures Nos. 1 and 2 shows that exposure to water vapour at 50°C. for five days, (curve C), causes an increase in the rate of expansion in solutions of magnesium and sodium sulphate as compared with the bars kept at 21°C., (curve D), and that this effect is increased for a treatment of ten days at 50°C., (curve B). On the other hand, exposure to water vapour at 75°, 85° and 98°C., (curves E to K), retards the rate of expansion in both sulphate solutions markedly, the effect increasing with the time of exposure and the temperature, being most marked in steam at 98°C. It is rather striking that heating the bars in dry air at 98°C., (curve A), speeds up the rate of expansion in both sulphate solutions about two and one-half times as compared with the bars cured in moist air at 21°C.

A further comparison of the curves for the bars treated with 0.15 molar magnesium sulphate, (figure No. 1), shows that while a five days' treatment at 98°C., (curve K), retards the expansion enormously, an expansion of 0.33 per cent being attained in seven hundred days as against the same expansion in about ten days for the bars not treated with steam, (curve D), yet this expansion is considerable when compared with the bars stored in pure water, (curve L), which expanded less than 0.02 per cent in seven hundred days. However, the bars treated with steam at 98°C., do not show any visible signs of sulphate action at the end of seven hundred days except that they are coated with a white deposit, while the bars treated ten

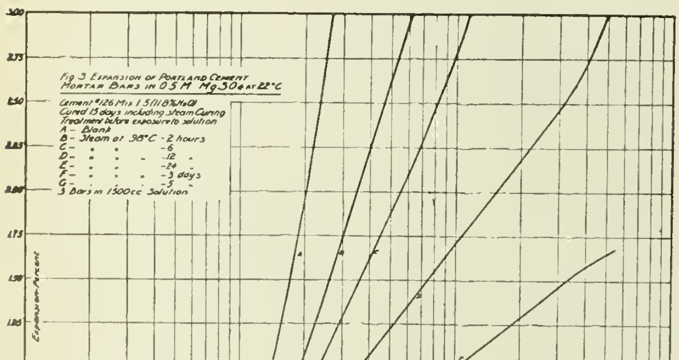

Figure No. 3.

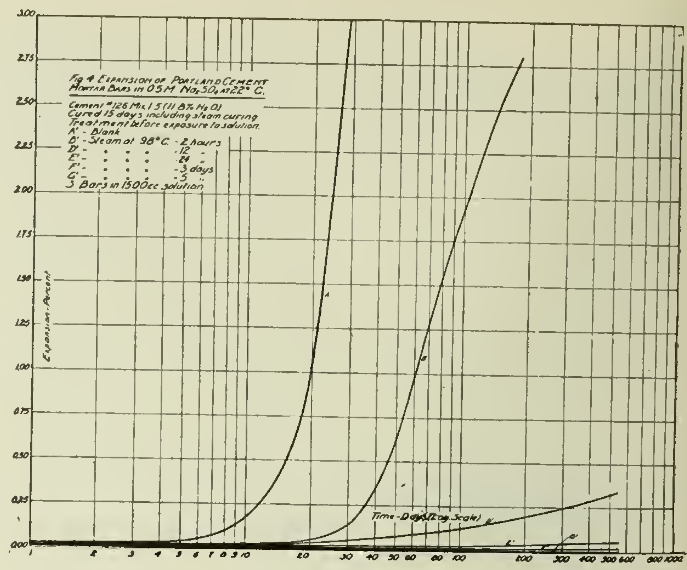

Figure No. 4.

days at 85°C., (curve I), are more heavily coated and are in addition very slightly bent.

On the other hand we see from figure No. 2 that the steam treatment is much more effective in preventing expansion of the mortar bars in 0.15 molar sodium sulphate. Five days' treatment at 75°C., (curve E), more than doubles the time necessary for expansion of 0.75 per cent, and a ten-day treatment at the same temperature, (curve G), increases the time eighteen fold. But these bars, (curves E and G), fall to pieces at an abnormally low expansion of less than one per cent. Treatment at 85°C., for ten days, or at 98°C., for from one to five days almost prevents expansion of the 1:5 mortar bars in 0.15 molar solutions of sodium sulphate. The bars treated at 85°C., show slight signs of attack, while the bars treated with steam at 98°C., all appear in perfect condition at the end of seven hundred days, those treated five days having expanded less than 0.04 per cent as compared with 0.015 per cent for the bars in distilled water.

It may be mentioned here that a comparison* of the expansion of mortar bars and the loss in tensile strength of mortar briquets made from a normal Portland cement and standard Ottawa sand 1:5, cured seven days before exposure to a 0.15 molar solution of sodium sulphate, indicated that a linear expansion of one-half of one per cent corresponds to a loss of approximately sixty per cent of the tensile strength of the specimen.

Figures Nos. 3 and 4 illustrate the effect of steam treatment at 98°C. The bars were of a 1:5 mix. They were cured only fifteen days including the time necessary for the steam curing, before immersion in 0.5 molar solutions of magnesium and sodium sulphate, (5.7 per cent $MgSO_4$ and 6.5 per cent Na_2SO_4). Figure No. 3 shows that the effect of steam on the resistance to the action of magnesium sulphate is evident after a treatment of two hours at 98°C., (curve B), and increases gradually as the time of treatment is lengthened. A five days' treatment with steam at 98°C. increases the time necessary for an expansion of 0.5 per cent thirty fold, (three hundred and sixty days as compared to less than twelve days for the untreated bars). The bars treated in steam three and five days appear in good condition at the end of a five hundred and fifty days' exposure to 0.5 molar magnesium sulphate except that they are covered with a white coating and have expanded

* The Engineering Journal, vol. 10, p. 199, (1927), figure No. 3.

0.95 per cent and 0.60 per cent respectively. There is marked increase in the rate of expansion of the bars in 0.5 molar magnesium sulphate, (figure No. 3), as compared with the 0.15 molar solution, (figure No. 1).

Figure No. 4 again shows the great resistance to the action of sodium sulphate produced by the steam treatment. Two hours' treatment in steam at 98°C., (curve B′), increases the time necessary for an expansion of one per cent more than three-fold, while a twelve-hour treatment, (curve D′), increases the time necessary for an expansion of 0.25 per cent twenty-five fold. Bars treated twenty-four hours and three days respectively show very little expansion in 0.5 molar sodium sulphate, the former expanding as much in one year as the untreated bars in six days, while the latter expanded as much in one year as the untreated bars in two days. The bars treated five days in steam at 98°C. expanded no more during more than five hundred days' exposure to 0.5 molar sodium sulphate than bars stored in distilled water.

Effect of Curing in Hot Water on the Sulphate Resistance of Mortar Bars

Figure No. 5 shows the effect of curing mortar bars in water at 98°C. The mortar bars were of the same batch as those used in obtaining the curves of figures Nos. 3 and 4 and the corresponding curves are therefore directly comparable. A comparison will show that in each case the treatment with water is very slightly less effective than the steam treatment at the same temperature in preventing the expansion of the bars in sulphate solutions, but otherwise the effect is similar. Relatively similar results were obtained from bars cured in steam and water at 85°C., 75°C. and 50°C.

Figure No. 5 gives also a direct comparison of the relative effect of hot water curing on the expansion of 1:5 mortar bars in sodium and magnesium sulphate, curves A, C, E and G and curves A′, C′, E′ and G′ giving corresponding values for expansion in 0.5 molar magnesium sulphate and 0.5 molar sodium sulphate respectively. This shows clearly the much greater increase in the resistance to sodium sulphate produced by the treatment.

Steam Curing of Very Lean Mortars

In order to make certain that the great resistance of steam-treated mortar to sulphate action is due to a change in the cement itself, and not to a physical change in the mortar, such as a decrease in permeability, a series of experiments was started with bars made of one part of cement to ten parts of standard sand. The results so far obtained over a period of nine months show that the 1:10 mortar after steam treatment has as high a resistance to the action of sodium sulphate as 1:5 mortar similarly treated. This fact seems to indicate that steam treatment produces a chemical change in the cement itself which makes it almost immune to the action of the sodium sulphate and which slows up enormously the action of magnesium sulphate.

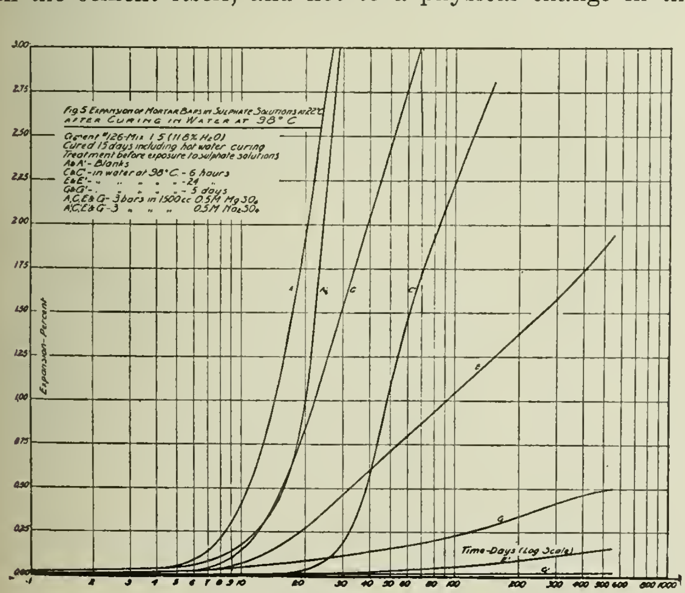

Figure No. 5.

The Action of Sulphates on the Substances Generally Considered to be Present in Portland Cement Clinker

In a paper read before Section III of the Royal Society of Canada, the authors* reported on experiments dealing with the action of solutions of sodium and magnesium sulphate on mortar bars of tricalcium silicate and dicalcium silicate alone and mixed with tricalcium aluminate. According to the researches of Shepherd, Rankin and Wright† these three substances compose over 90 per cent of normal Portland cement clinker, and the action of sulphates on Portland cement should therefore be determined by the action of sulphates on the individual components. It was found that mortar bars prepared from pure tricalcium silicate or from pure dicalcium silicate were not affected when exposed to solutions of sodium sulphate. Mortar bars made from these substances did, however, expand and disintegrate slowly when exposed to solutions of magnesium sulphate. If tricalcium aluminate was present with the silicates in the bars it was found that they expanded and disintegrated rapidly both in solutions of sodium sulphate and magnesium sulphate. Thus, if one accepts the above conclusions of Shepherd, Rankin and Wright, it appears that the disintegration of Portland cement mortars and concrete in solutions of sodium sulphate is due solely to the action of the sulphate on one of the components of the cement, namely, tricalcium aluminate, and that while the rapid deterioration of the same mortar in solutions of magnesium sulphate is due mainly to a reaction with the tricalcium aluminate, the other two components are also vulnerable to the action of solutions of this salt.

Applying these facts to explain the action of steam on Portland cement mortars, it is only necessary to assume that the change produced by steam renders the tricalcium aluminate of the cement resistant to sulphate action. The mortar should then on steam treatment become completely resistant to solutions of sodium sulphate but not immune to the action of magnesium sulphate unless the silicates also were changed so as to become resistant. The action in solutions of magnesium sulphate should be retarded very much, and the expansion of the treated bars in solutions of this salt should be comparable to that of a mortar made of the pure silicates. This is entirely in agreement with the facts as to the effect of steam and hot water treatment of cement mortars, as illustrated in figures Nos. 1 to 5 above.

The Addition of Tricalcium Aluminate to Portland Cement

Further experiments were carried out to determine the effect of adding tricalcium aluminate to Portland cement, and the effect of steam treatment on mortars made from the cement thus modified. In considering the results, it must

* Thorvaldson, Vigfusson and Larmour. Transactions of the Royal Society of Canada. Section III, 1927.

† Jl. Ind. & Eng. Chem. 3, 211, (1911).
Zeitschrift anorg. Chemie 92, 213, (1915).
Jl. Ind. & Eng. Chem. 7, 466, (1915).

be remembered that the cement and the aluminate, after grinding the latter to pass a 200-mesh sieve, were mixed only by mechanical shaking and that we are therefore probably not dealing with such an intimate mixture as in a commercial cement.

It was found that addition of tricalcium aluminate increases the expansion produced during steam treatment of the mortar bars. This expansion rapidly increases with the amount of aluminate, as shown by the following table:—

Cement	Mix of Mortar	Per cent Expansion, 10 days in Steam at 98°C.
No. 326	1:7½	0.028
No. 326 + 5% $3CaO.Al_2O_3$	1:7½	0.036
No. 326 + 15% $3CaO.Al_2O_3$	1:10	0.14
No. 326 + 25% $3CaO.Al_2O_3$	1:7½	0.46

The bars containing 25 per cent added aluminate showed a tendency to warp during the steam treatment.

Figures Nos. 6 and 7 illustrate the effect of the addition of 5 per cent of tricalcium aluminate to Portland cement, on the expansion of cement mortar bars when immersed in sulphate solutions. They also show the effect of steam treatment on the sulphate resistance of mortar bars made from the normal and modified cements. It is evident that addition of tricalcium aluminate increases the rate of expansion in 0.15 and 0.50 molar sodium sulphate, and magnesium sulphate and in saturated calcium sulphate, the increase being greatest for the solutions of highest concentration. There is a rather interesting point brought out by these curves. Mortar bars made from all Portland cements so far examined by the authors expand faster in concentrated than in dilute solutions of magnesium sulphate. But Portland cements fall into two classes with respect to their behaviour with sodium sulphate. Except for the first few days of the expansion curve, where the rate of expansion increases with the concentration, one finds that mortar bars from some cements expand more rapidly in concentrated than in dilute solutions of sodium sulphate while with others the reverse is the case. Cement No. 326 belongs to the latter class, (figure No. 6, curves 1A and 1B). After addition of 5 per cent tricalcium aluminate the modified cement, however, belongs to the first class, expanding more rapidly in the more concentrated solution, (curves 2A and 2B). This suggests that this difference in Portland cements may be determined by the amount of tricalcium aluminate they contain.

A study of the expansion curves of figure No. 6, (A′, B′ and C′), recording the expansion of the bars made from the modified cement, (No. 326+5 per cent tricalcium aluminate), and subsequently treated with steam at 98°C. for ten days, indicates that these bars have become highly resisting to the action of sodium sulphate. The steam treatment, however, has not been quite as effective with the bars from the modified cement as with the bars from the normal cement.

It was found that as the amount of tricalcium aluminate added to cement No. 326 increased, the steam treatment became less and less effective in retarding sulphate action. When 25 per cent of tricalcium aluminate was added to the cement, (the mix being 1 part cement: 0.25 parts 3 $CaO.Al_2O_3$:7½ parts sand), the steam-treated bars expanded in solutions of sodium sulphate at a rate which was approximately one-third of the rate of similar untreated bars made from the normal cement. The bars containing the largest quantity of aluminate expanded so much during the steam treatment that this in itself damaged them.

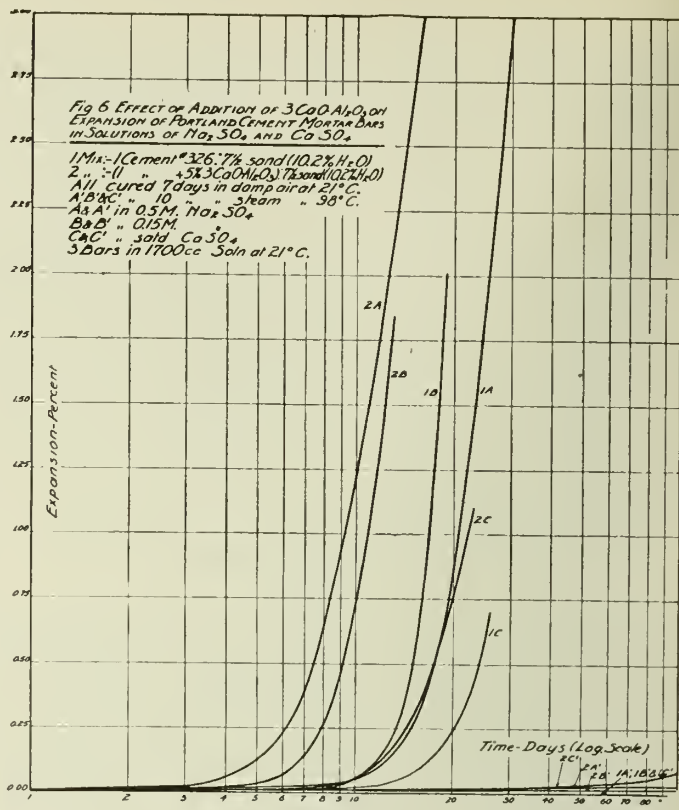

Figure No. 6.

It seems that if the alumina in Portland cement is present in the form of tricalcium aluminate, the failure of the steam treatment in the case of the bars made from the modified cements must be due to some physical factor. It is possible that an intimate mixture of the aluminate and the silicates, such as occurs in a sintered cement clinker, is necessary before the changes produced during steam treatment of a mortar can take place at a reasonable velocity. If this were so then the efficiency of steam treatment would rapidly decrease as the amount of tricalcium aluminate added to a cement is increased. It is also possible that there is a limiting value for the amount of tricalcium aluminate which may be present in a cement if the steam treatment is to be effective and that the aluminate in cement No. 326 was already approaching that value.

Considering the large amount of careful work which has been done on the constitution of Portland cement clinker the alternative explanation of the failure of the steam treatment of mortar bars containing cement and tricalcium aluminate, that the alumina is not present in Portland cement clinker in the form of tricalcium aluminate, seems unlikely.

The Effect of Steam Treatment on the Tensile Strength of Portland Cement Mortars

Figure No. 8 gives the effect of steam treatment on the tensile strength of mortar briquets made from cement No. 126. The first and most pronounced effect of steam is to decrease the tensile strength of the briquets. On continued steam treatment the briquets again gain in strength. As the temperature of the saturated steam increases, the rate at which the briquets lose and gain strength is increased. If one compares the *rate of loss in tensile strength* of the briquets with the *increase in resistance* of similar bars to sulphate action as shown in Figures Nos. 1 and 5, one sees that these are in the same order, the treatment which pro-

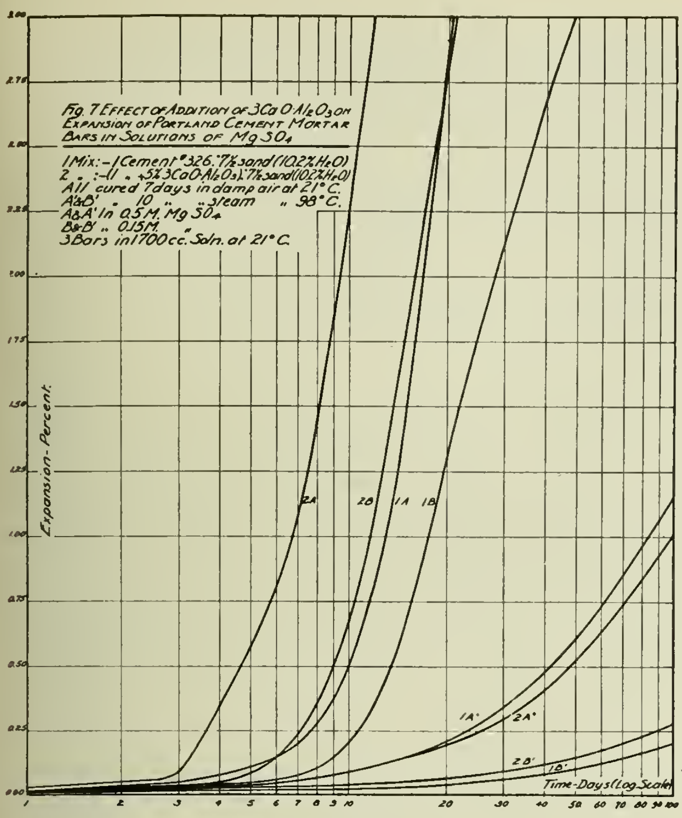

Figure No. 7.

duces the most rapid loss in tensile strength at the beginning of the steam treatment, also producing the greatest increase in the resistance to the action of sulphate solutions. Steam treatment at 50°C. shows no decrease in strength during the first twenty-four hours, and as shown above this treatment lowers sulphate resistance. As the temperature of the saturated steam increases to 75°, 85°, 98° and 150°C., (about 70 pounds per square inch), the rate of the initial loss in strength increases, and the rate of subsequent increase in strength also increases. If one were to reason by analogy one would predict that saturated steam at 70 pounds pressure, (150°C.), would be more effective in increasing sulphate resistance than steam at 98°C. Experiments which are in progress seem to confirm this conclusion.

From consideration of the tensile strength curves, it is evident that two independent changes are taking place during steam treatment, one causing loss in strength, the other an increase in strength of the briquets. Accepting the views of Shepherd, Rankin and Wright as to the constitution of Portland cement clinker, and bearing in mind the studies summarized above on the behaviour of mortars made from tricalcium silicate, dicalcium silicate and tricalcium aluminate in sulphate solutions, and the effect of steam treatment on the sulphate resistance of mortars, as shown in figures Nos. 1 to 5 above, it seems probable that the first action, causing a loss in tensile strength, is due to a change in the tricalcium aluminate of the cement and that this change is the primary cause of the increase in the sulphate resistance of the mortar. The second change, causing an increase in tensile strength, would then probably be due to hydration of the silicates, speeded up by the action of steam or possibly partly due to the formation of stable cementing substances from the aluminate. The change in the shape of the curves as the temperature rises would then be explained on the assumption that the increase in the temperature and pressure of steam speeds up the first action proportionally more than the second action.

Further work, with a view to determining the exact nature of the changes which take place during steam treatment, is now in progress.

Summary

(1) Expansion measurements of Portland cement mortar bars were used to study the effect of steam treatment of mortars on their resistance to the action of the sulphates of magnesium and sodium and calcium.

(2) Treatment of mortars with saturated water vapour at 50°C. reduces their resistance to sulphate action. Saturated water vapour of 75°C. or above 75°C. increases the resistance, the higher the temperature the more effective the treatment is and the shorter the time of treatment required.

(3) Steam treatment of mortars at the boiling point of water makes them practically completely resistant to the action of solutions of sodium sulphate and increases very materially the resistance to the action of solutions of magnesium sulphate.

(4) Immersion of mortars in hot water is nearly as effective in increasing the sulphate resistance as treatment with steam at the same temperature.

(5) Addition of tricalcium aluminate to Portland cement speeds up the rate of expansion of its mortar in solutions of the sulphates of sodium, magnesium and calcium. Steam treatment of these mortars is not as effective in preventing expansion in solutions of sodium and calcium sulphate as steam treatment of mortars from the same cement without the addition of tricalcium aluminate.

(6) The effect of steam treatment on the tensile strength of mortar briquets was determined for temperatures from 50°C. to 150°C.

(7) The theory is suggested that the greatly increased resistance to sulphate action brought about by steam treatment of Portland cement mortars is primarily due to action of the steam on the aluminate in the cement. The speeding up of the hydration of the silicates by the steam treatment, while increasing the strength, is probably of secondary importance in relation to sulphate resistance.

Notes on the Relative Resistance of Various Cements to the Action of Sulphate Waters

Being Appendix A. to the 1927 Report of the Committee on the Deterioration of Concrete in Alkali Soils to the Council of The Engineering Institute of Canada

Dr. T. Thorvaldson.
Professor of Chemistry, University of Saskatchewan, Saskatoon, Sask.

Presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

The resistance of a concrete structure to the action of alkali water is determined by a number of factors, one of which is the natural resistance of the cement itself to the action of sulphates. Other factors influencing the resistance of the concrete produced from the cement may be grouped under two headings; first, those pertaining to the method of manufacture of the concrete, such as richness of mix, proportioning of aggregate, amount of mixing water, uniformity of mixing, etc.; second, the factors influencing the physical and chemical changes which take place during the curing period, such as the temperature during curing, the humidity of the atmosphere during curing and any treatment of the concrete after manufacture.

The present discussion deals almost wholly with the first of these, namely, the natural resistance to sulphate action possessed by the cement when exposed under conditions where the sulphate water has free access to the cementing material. Some data will be introduced incidentally on the effect of richness of mix, but the effect of other conditions pertaining to the manufacture and curing of the test specimens was eliminated as far as possible by the adoption of a standard procedure modelled on that used for the preparation of the mortar test pieces used in testing cement according to standard methods.

The natural resistance of a cement to alkali action may be studied by exposing the finely ground hydrated cement to alkali water and measuring the rate of the chemical reactions which take place. The difficulty met with is in interpreting the results of such a study in terms of the effect on a piece of mortar or concrete or in terms of the life of a concrete structure. A method expressing its results in terms of some fundamental change taking place in a mortar or concrete specimen during the action of alkali would be much better suited to actual conditions met with in practice. Such a method* depending on the determination of the expansion of mortar test pieces during the course of disintegration by alkali waters has been developed. Portland cement mortar specimens when immersed in solutions of alkali salts, (sulphates), expand in a regular manner during the action of the sulphate on the mortar. From the amount of expansion which has taken place one can predict the changes which have taken place in the tensile strength of the specimen. Thus, it has been found that in the case of specimens made from a Portland cement and standard Ottawa sand 1:5 cured seven days before exposure to a 2 per cent solution of sodium sulphate a linear expansion of one-half per cent corresponds to a loss of approximately 60 per cent of the tensile strength.

A study of the natural resistance of a cement to sulphate action can be made effectively by this method, by using test pieces of very lean sand mortar. Such test pieces are very permeable to the salt solutions. The sulphate has then almost as free an access to each particle of cement as if the cement, in finely powdered condition, were shaken with the solution, yet the results of the action may be determined directly in terms of changes in a mortar test piece. In making the comparisons given below, mortar bars, 5/8 by 5/8 by 7½ inches, made of 1 part of cement to 10 parts of standard Ottawa sand, (20-30), were usually used, although for some of the comparisons mortar bars of 1:5 and 1:3 mix were used. These bars, prepared and cured under carefully standardized conditions, were exposed to sulphate solutions and the expansion curve determined until disintegration took place. This method is described in detail in the paper referred to above.

* Thodvaldson, Larmour and Vigfusson, The Engineering Journal, April 1927.

Factors Which Have to be Considered When Comparing the Sulphate Resistance of Cements

When one attempts to make a general statement as to the resistance of a cement to alkali action, or to make a definite statement as to the relative resistance of several cements, difficulties are met which should be discussed briefly. The so-called " alkali " action on cement is caused primarily by sulphates. While a large number of different sulphates studied in this laboratory were all found to cause disintegration of cement mortars, the action is modified very markedly by the nature of the metal combined with the sulphate radical. The action on cement mortars is also modified materially by the presence of other salts, such as chlorides and carbonates. The alkali waters on the Canadian prairies are found to contain mainly the sulphates of sodium, magnesium and calcium, but sometimes contain also large quantities of chlorides and carbonates. In some places sodium sulphate is found to predominate, while in other places magnesium or calcium sulphate may be the predominating salt.

When making a study of the action of the three sulphates which are the most common in natural alkali waters, one finds not only that the resistance of two Portland cements, (both of which have passed the prescribed standard tests equally well), to solutions of sodium sulphate may differ markedly, but also that their relative resistance to solutions of sodium sulphate may differ from their relative resistance to solutions of magnesium sulphate or solutions of calcium sulphate. Thus, cement No. 1 may show greater resistance than cement No. 2 to solutions of sodium sulphate but lower resistance than No. 2 to solutions of magnesium sulphate. It is therefore not possible to make a general statement as to the resistance of a cement to alkali water without reference to the kind of sulphate present. In the comparisons made below the sulphate used is therefore stated in each case.

Another matter which must be considered in making comparisons is the peculiar difference in the case of some Portland cements between the action of dilute and concentrated solutions of sulphates. All the Portland cements studied in this laboratory disintegrate faster in concentrated solutions than in dilute solutions of magnesium sulphate. On the other hand, while one cement may disintegrate faster in concentrated than in dilute solutions of sodium sulphate, a second cement may disintegrate at the same rate in both, and a third cement may disintegrate much more rapidly in the dilute solution. Thus, comparing cements by exposing concrete specimens under natural conditions to alkali water, in the one case to low concentration of alkali and in the second case to high concentration,—usually referred to as "the most severe conditions of alkali,"—might lead to opposite conclusions as to the relative sulphate resistance of the cements. Therefore if one wishes to make a general statement as to the relative resistance of two cements in solutions of a particular sulphate it is necessary to take an average of the results over a wide range of concentrations of the sulphate or else state the concentration at which the comparison was made.

A Comparison of the Resistance of Five Cements to Sulphate Solutions

The comparisons given below are made only for the two sulphates present in high concentration in western alkali waters, namely, sodium sulphate and magnesium sulphate. The curves represent averages for each sulphate, the comparisons being made at two concentrations, namely, 0.15 molar and 0.50 molar solutions of the salts. (2.1 per cent and 6.7 per cent for sodium sulphate; 1.8 per cent and 5.7 per cent for magnesium sulphate.) The bars were prepared from cement and standard Ottawa sand in the proportion of 1:10 by weight. The amount of mixing water was that called for by the standard specifications for making 1:3 standard sand briquets for tension tests. The bars were cured for two weeks before being exposed to the sulphate solutions.

Figure No. 1 gives the average expansion curves in sodium sulphate solutions for the five cements *A*, *B*, *C*, *D* and *E* which were obtained from different sources. The time required for an expansion of one per cent of the total length varies from thirteen days for cement *A* to thirty-four days for cement *E*, indicating a large variation in the sulphate resistance of the cements.

Figure No. 2 gives the average expansion curves for similar mortar bars in solutions of magnesium sulphate. Here the time for attaining an expansion of one per cent varies from eight days for cement *B* to eighteen days for cement *E*. It will also be noticed that the order of expansion of the cements, while in general the same, is not identical in solutions of the two salts, cement *A* being the least resistant in solutions of sodium sulphate, while cement *B* is the least resistant in solutions of magnesium sulphate. Much larger variations of this nature are sometimes found in making comparisons of Portland cements.

The bars immersed in solutions of magnesium sulphate expand much faster than those immersed in solutions of sodium sulphate of equivalent concentrations. It is, however, not safe to assume that this would be the case when richer mixes of mortar are used. During the action of magnesium sulphate on the mortar, insoluble magnesium hydroxide is formed, and this deposits in the pores of the mortar, hindering free access of further quantities of magnesium sulphate and thus slowing up the action. As the mortar becomes richer and less permeable this effect becomes more marked.*

It is of interest to compare these cements as to their tensile and compressive strengths. The tests were made by Professor G. M. Williams, of the College of Engineering, University of Saskatchewan. The values for tension are given in pounds per square inch for 1:3 standard sand briquets, while the values for compression are given in pounds per square inch for 1:3 standard sand cylinders 2 by 4 inches.

* Thorvaldson, Larmour and Vigfusson, The Engineering Journal, April 1927, figure No. 6.

Cement	Tension Tests			Compression Tests	
	3-day	7-day	28-day	7-day	28-day
A	210	235	340	1370	2540
B	320	375	435	3085	3785
C	275	305	415	2740	3185
D		240	340	2170	3290
E		300	415	1980	2810

It is evident that there is no direct relation between the sulphate resistance of a cement as determined above and the strength of the cement as determined by tension and compression tests with 1:3 mortar. Thus, the two cements lowest in resistance to sulphate solutions give the lowest and the highest values respectively for tension and compression.

While the primary factor causing high resistance to sulphate action in a cement does not seem to be necessarily connected with the capacity of developing high strength, it seems that high strength is an important secondary factor contributing to sulphate resistance, especially in richer mixes. Thus, it was found that as the proportion of cement to sand is increased, mortar bars made from cement *C* above increase much more rapidly in sulphate resistance than similar mortar bars made from cement *A*.

Of the above cements, *A*, *C* and *E* are ordinary Portland cements manufactured by the Canada Cement Co., *A* being the Portland cement used in the field tests in 1921. *D* is a super cement supplied by the Super Cement Co., (of Detroit), from one of their mills, and *B* is a special Portland cement recommended for its high strength.

High Alumina Cements

High alumina cements such as "ciment electrique," "ciment fondu" and "lumnite" are so different from Portland cement in their behaviour with sulphate solutions that a comparison can hardly be made by the same methods. An extensive laboratory investigation on these cements has been in progress during the last five years, one of the cements used being the "ciment electrique No. 170" used in the field tests. This cement has been found to have an extremely high resistance to sulphates, especially to solutions of magnesium sulphate. Lean mixes disintegrate slowly in solutions of sodium sulphate, but richer mortars exposed to concentrations up to 5 per cent show no appreciable action in the course of years. This cement disintegrates much more rapidly in solutions of ferrous sulphate than in solutions of the sulphates of sodium and magnesium. It also disintegrates fairly rapidly in solutions of sodium carbonate and in solutions of sodium phosphate. The action of sodium carbonate is rather important in view of the fact that natural carbonate waters are common.

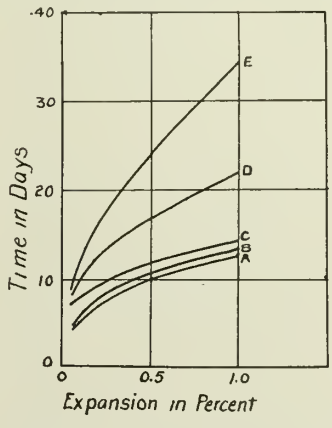

Figure No. 1.—Expansion of 1:10 Cement Mortar Bars in Solutions of Na_2SO_4.

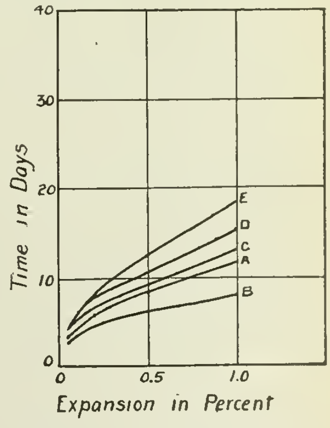

Figure No. 2.—Expansion of 1:10 Cement Mortar Bars in Solutions of $Mg.SO_4$.

Other samples of high alumina cements available on the American market have been found to be low in sulphate resistance when compared with cement No. 170 used in the field tests. These cements do not show the exceptional resistance to magnesium sulphate shown by cement No. 170. The variation in sulphate resistance between different brands of high alumina cement was found to be greater than the variation with different brands of Portland cement. It should, however, be stated that the resistance of all the samples of high alumina cement in *moderately rich mixes* was found to be greater than that of any Portland cement. In very lean mixes the alumina cements of low resistance do not possess materially greater resistance than mortars of corresponding mix made from Portland cements of high resistance.

Slag Cements and Natural Cements

Other cements, such as slag cements and natural cements, have also been compared in the laboratory as to sulphate resistance. The difference between different brands as compared in the laboratory varies from cements of very low natural resistance to some of much higher resistance than that of the best Portland cement. This is especially the case when comparing the resistance to solutions of sodium sulphate, the resistance to solutions of magnesium sulphate being usually much lower.

In connection with the interpretation of these results one very important fact must be mentioned. Test pieces from slag and natural cements as a rule have low strengths when compared with test pieces from normal Portland cements, and the structures made from them are as a rule more permeable to water than those made from good Portland cement concrete. The strain imposed on structures made from these low strength cements when exposed both to sulphate and frost action is therefore much greater in proportion to their strength than is the case with concrete of higher strength. The result is that while these cements may show high resistance in the laboratory, concrete made from them may fail during the first winter of exposure to field conditions. For the same reasons, laboratory experiments with low strength Portland cements must always be discounted heavily if one wishes to predict the resistance of these cements to combined alkali and frost action.

Super Cement

One of the interesting points raised by the field experiments is the comparison between concrete specimens made from Portland cement and Super cement. The writer has been asked to present any evidence he may have obtained in the laboratory tests which could throw light on the question whether the apparent superiority of the Super cement specimens is due to a higher resistance to sulphate action of the clinker from which the Super cement was made, or if the higher resistance observed in the field tests was due to the special treatment used in the manufacture of Super cement.

Unfortunately, the writer did not obtain a sample of the Super cement used in the field experiments, or of the ordinary cement produced at that time by the mill where the particular sample of Super cement was manufactured. No direct comparison can therefore be made with the cement actually used. A number of tests have, however, been made on the sulphate resistance of samples of Super cement, and also an especially careful study of cement *D*, for which curves are given in figures Nos. 1 and 2 above. It will be seen that this cement, supplied directly by the manufacturer to Professor G. M. Williams, has a fairly high resistance to sulphate action, although the ordinary Portland cement *E* has a materially higher resistance.

The manufacturer of Super cement *D* forwarded to Professor Williams at the same time a sample of an ordinary Portland cement *F*, said to be made from the same clinker as Super cement *D*. Careful comparisons of the sulphate resistance of the two cements were made, using mortar bars of the following mixes by weight:—

1 part of cement to 10 parts of standard Ottawa sand.
1 part of cement to 5 parts of standard Ottawa sand.
1 part of cement to 3 parts of standard Ottawa sand.

With the 1:10 bars two series of comparisons were made, i.e., one series with bars cured fourteen days, the second series with bars cured twenty-eight days. With the 1:5 bars three similar series were made with curing of seven, fourteen and twenty-eight days respectively, while with the 1:3 bars two series of comparisons with bars cured seven and twenty-eight days are being made, the results of the first series being given below.

The figures given below represent averages for all the series done with each mix, using 0.15 and 0.50 molar solutions of sodium sulphate and solutions of magnesium sulphate of the same molar concentration.

Table Showing Sulphate Resistance of Cements "*D*" and "*F*."

Mix	Expansion in per cent	Time required for Expansion—in Days			
		In Na_2SO_4 Solution		In $MgSO_4$ Solution	
		Cement "*D*"	Cement "*F*"	Cement "*D*"	Cement "*F*"
1:10	0.05	8	7	4	4
	0.1	10	9	5.5	5
	0.2	13	11	7.5	7.5
	0.5	17	16	10	10
	1.0	22	21	15	14.5
1:5	0.05	7.5	7.5	4.5	4.5
	0.1	9.5	10	6	6.5
	0.2	12	12	8	9
	0.5	17	17	13	14
	1.0	21.5	21.5	19	21
1:3	0.05	10	10.5	4	4
	0.1	17.5	16.5	7.5	7.5
	0.2	26	26	13	14.5
	0.5	35	36	24.5	26.5
Average for all mixes	0.05	8	8	4	4
	0.1	12	12	6	6
	0.2	17	16	9.5	10
	0.5	23	23	16	17

Note;—Cement *D*—Super cement
Cement *F*—Portland cement from same clinker.

The two cements thus behave very similarly when exposed in the form of 1:10, 1:5 or 1:3 mortar bars to sulphate solutions. The values for time corresponding to a certain expansion agree usually within one day, which is all that can be expected for duplicate determinations on the same cement. What slight difference there is is in favour of cement *D* for the 1:10 mix and in favour of cement *F* for the 1:5 and 1:3 mixes. Averaging the results for the three mixes makes the curves for the two cements identical.

It may also be pointed out that as the richness of the mix is increased from 1;10 to 1:3 there is no greater increase in resistance of cement *D* than cement *F* to sulphate action.

In the above discussion, only the expansion of the bars has been considered. Careful observations as to visible signs of action such as bending, softening at the edges and cracking were made from the time the exposure to the sulphate solutions began until the bars had disintegrated. No distinction could be drawn between the behaviour of the test pieces made from the two cements.

From the experiments described above, there is no evidence that the treatment which cement *D* was exposed to in the manufacture of Super cement has increased the resistance of the cement to the action of solutions of either sodium or magnesium sulphate as compared with the Portland cement *F* made from the same clinker.

The Action of Sulphates on Neat Cement

In the spring of 1926, two of the neat cement cylinders, one of batch No. 1, (Portland cement), and one of batch No. 2, (Super cement), exposed to alkali water at Brooks, Alberta, were reported to have cracked into pieces. There was only a slight evidence of sulphate action on the surface of the cylinders while the mass of the material appeared perfectly sound and unaffected except for the peculiar fracture. It seemed, therefore, that the primary cause of these failures might be weathering or frost.

In a series of laboratory experiments begun in 1923 a study was made of the action of solutions of sulphates and other salts on Portland cement mortars varying in richness from 1:7½ to neat cement. The test pieces were bars ⅝ by ⅝ by 7½ inches, these being immersed in the solutions contained in stoppered glass jars. Among the liquids used were (1) distilled water, (2) sodium sulphate 0.4 molar, (5.4 per cent), (3) magnesium sulphate 0.4 molar, (4.6 per cent), and several other salt solutions.

The results of the experiments with the neat cement bars only will be considered here. After immersion for nearly four years the bars in water have expanded about 0.16 per cent of their length. Otherwise there is no evidence of any effect on the bars. The results with the neat bars immersed in solutions not containing sulphate were similar except that the expansion proceeds more slowly than in distilled water.

On the other hand, there was evidence of action on the neat cement bars immersed in solutions of sodium and magnesium sulphate within less than one year, small cracks appearing at the edges and corners. Within less than two years large transverse cracks appeared in some of the specimens and during the third and fourth year a number of the bars cracked into small pieces. There was some considerable decay of cement on the surface of the bars, especially at the corners, but when this was scraped off the remaining pieces of neat cement appeared entirely sound. The expansion of bars at the time of breaking varied, but averaged about one-half of one per cent.

A determination of the sulphate content of the bars, which have been immersed in sodium sulphate, was made. The pieces were first scrubbed to remove all decayed material and the determinations made on the apparently sound core. The loss on ignition was 25 per cent and the sulphate calculated on the basis of the ignited residue was 3.25 per cent sulphur trioxide, (SO_3). The cement used for preparing the neat cement test pieces contained originally 1.77 per cent sulphur trioxide, (SO_3), calculated to the ignited basis, so that the apparently sound core had taken up sulphate from the solution to the extent of 1.5 per cent of its weight as sulphur trioxide (SO_3). Neat cement briquets stored in sulphate solutions in the laboratory have also fractured in a similar manner. Neat cement briquets made from several cements, including the Canada Portland and the Commercial cement used in preparing the original specimens for the field tests, have been in the laboratory, exposed to the laboratory air, for a number of years without showing any similar effects.

Since the neat cement bars immersed in water and in the other salt solutions, not containing sulphates, and the briquets exposed to the laboratory air, show no tendency to fracture in the same way as the bars and briquets stored in sulphate solutions, it would seem that the cracking of the apparently sound core of the bars is connected with the absorption of sulphates. As neat cement bars stored in sulphate solutions expand considerably before they fracture, an explanation of the failure may be proposed on the basis of stresses caused by the progressive action of the sulphate from the surface inwards.

It has been found* that the extent to which a concrete structure has undergone sulphate action may be estimated by determining the sulphate which has been taken up by the concrete, provided that conditions after the action has taken place have not been favourable for leaching out the sulphate from the damaged concrete. This method could be used to obtain evidence as to the extent of the action of the sulphate on different parts of a specimen of neat cement. If the fracture is due to stress caused by a tendency of the specimen to expand unevenly, then taking the apparently undecayed portion of the test piece we should find uneven distribution of sulphate.

Two samples were selected from the broken Portland cement cylinder. Sample 1 was taken from the apparently sound surface layer after all loose or foreign material had been removed, and sample 2 was taken near the centre of the cylinder. The loss on ignition and sulphate were determined with the following results:—

Sample	1 per cent	2 per cent
Loss on Ignition	23.3	23.3
Sulphate (SO_3) calculated for ignited sample	2.30	1.68

This specimen was made in 1921 from a Portland cement which contained, according to analysis made at that time, 1.67 per cent sulphur trioxide, (SO_3). Thus, it appears that while the portion of the cylinder represented by sample 1 has taken up sulphate to the extent of about 0.6 per cent sulphur trioxide, the central portion has not undergone any appreciable sulphate action.

Analyses of corresponding portions of the fractured Super cement cylinder showed that, calculated on the same basis, the surface layer had taken up sulphate to the extent of 0.6 per cent, (SO_3), as compared with the central portion, the sulphate content of which had remained unchanged.

If the fracture of the field specimens is caused by uneven expansion due to the action of the sulphate on the neat cement, then one would expect that the cylinders partly buried in the soil and partly exposed to air would be subjected to the greatest stress near the surface of the soil. This is the point at which fracture usually occurs in the field tests. It is, of course, evident that stresses caused by rapid and extreme changes in temperature may contribute to the final failure in the field. In explaining the cracking of the bars in the laboratory experiments this factor was, however, excluded.

Considering both the laboratory experiments with neat cement bars and the analysis of the fractured cylinder used in the field tests, it appears probable that the results observed at Brooks represent failures of neat cement through sulphate action.

It is a great pleasure to acknowledge the very efficient assistance of Messrs. R. K. Larmour, C. R. Peaker, V. A. Vigfusson and D. Wolochow, who have at various times co-operated in the experiments on which the conclusions arrived at in this paper are based. The further financial aid which has been received from the National Research Council of Canada towards defraying the expenses of the investigation is also recorded with appreciation.

The Condition of Field Specimens of Concrete Exposed to Alkali Soils and Waters Examined in December, 1927

Being Appendix B of the 1927 Report of the Committee on the Deterioration of Concrete in Alkali Soils to the Council of The Engineering Institute of Canada

Presented at the Annual General Professional Meeting of the Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

At the first Committee meeting held in April 1921 it was agreed that no extensive programme of field exposure tests should be undertaken in view of the results of previous field tests and investigations which had been made in Canada and the United States. These previous studies had demonstrated that Portland cement concretes of good quality would be disintegrated when exposed to high concentrations of the so-called "alkali" soils and waters, consisting mainly of sulphates of sodium and magnesium. However, in order that there might be a basis for comparison of the durability of plain Portland cement concretes with concretes treated with the numerous alkali and waterproofing compounds on the market, as well as modified or improved cements which might be developed in the chemical laboratory, a limited programme of exposure tests was authorized.

Programme of Work

As a result of consultations with Committee members a programme was drawn up for the preparation of field test specimens to be exposed in duplicate at each of three sites to be located in the three Prairie provinces.

The bulk of the specimens were to be made with Portland cement and concrete aggregate commonly used in the vicinity of Saskatoon. Similar concretes were to be made with the same lot of cement and aggregates available in Manitoba and Alberta. Two qualities of concrete were to be made, one having a compressive strength of 1,200 to 1,500 pounds per square inch at twenty-eight days and the other 2,500 to 2,800 at the same period, to be moulded in the form of cylinders 7 inches in diameter and 21 inches long. Additional specimens in the form of 6-inch by 12-inch cylinders were prepared for compressive strength tests. In addition to the above, such other cements and special treatments as might be suggested by Committee members were to be included for comparison. The preparation of test pieces, as described later, was carried out substantially as planned, and the bulk of the specimens were prepared in the concrete laboratory at the University of Saskatchewan during the summer of 1921 and later shipped to the sites which had previously been selected by the Committee.

Selection of Exposure Sites

The deciding factor in the selection of exposure sites was the concentration of sulphate salts in soils and ground waters.

In Manitoba the site selected was near mile post 15.2 along the line of the Winnipeg aqueduct, near Deacon. Since the ground water level was about eight feet below the ground surface and it was desired to place the specimens so that the lower ends would be embedded in moist soil a great portion of the time, it was necessary to excavate a pit about eight feet deep and 50 feet square, provided with drainage, so that inspections could readily be made.

In Saskatchewan, high sulphate concentrations were found in Grandora lake, about 14 miles west of Saskatoon, and it was decided to place the specimens in the saturated soil along the water line.

In Alberta, the site selected was located near Cassils syphon on seeped ground below an irrigation canal on the eastern block of the Canadian Pacific Railway irrigation project. The ground water level was near the surface of the ground and the concentration of soluble salts was high, so that the installations, as at Grandora, consisted of digging shallow holes and imbedding the blocks to one-half their length. Later in 1923, due to change in ground water level, which reduced the severity of exposure, the unaffected specimens were moved to a new site near Antelope Creek syphon.

Chemical analyses of waters from the exposure sites are shown in table No. 1.

Materials Employed

The following is a list of materials used in the preparation of test pieces. The date following each material indicates the year it was used:—

Cements.

Canada Portland cement from Winnipeg mill of the Canada Cement Company,—1921.

St. Mary's Super cement furnished by the Super Cement, (America), Ltd.,—1921.

"Commercial" Natural cement supplied by the Commercial Cement Co. Winnipeg,—1921.

"Cement Electrique," a high alumina cement made in France,—1922.

"Watch Tower" cement, made in France,—1924.

Ciment de Laitier, made in France,—1924.

Aggregates.

Warman pit-run aggregate,—a natural bank gravel from Warman, Sask., used for concrete construction in Saskatoon,—1921.

Carseland aggregate—a natural gravel from near Carseland, Alberta,—1921.

Winnipeg aggregate—a natural sand passing a ¼ inch screen and coarse aggregate of crushed limestone passing a 1½ inch screen,—1921.

Integral Compounds.

Sodium silicate,—1921.
Medusa water proofing powder,—1921.
Truscon waterproofing paste,—1921.
Toxement waterproofing powder,—1921.
Waterex, a liquid waterproofing,—1921.
Erdahl's Alkagel,—1921.

Surface Coatings.

Vulcan asphalt,—1921.
Barrett tar,—1921.
Ironite,—1921.
City of Calgary asphalt,—1921.

Sodium silicate,—1921.
Vortex asphalt,—1921.
Hard rubber varnish,—1924.
Paravar rubber varnish,—1924.

Special Treatment.

Impregnation with molten sulphur,—1923.

The materials listed above were used in preparing concretes during the years indicated, most of them having been included during the first year. Chemical analyses of the cements are shown in table No. 2, and the results of routine physical tests are given in table No. 3. Physical characteristics of aggregates are shown in table No. 4.

Following are descriptions of the use of the various integral compounds and surface coatings:—

Sodium Silicate—Integral. The sodium silicate as received was in the form of a 59.4 per cent solution. It was diluted in mixing so as to result in a 5 per cent solution in the mixing water as used.

Medusa Waterproofing Compound.—Two per cent by weight of cement in the batch.

Truscon Paste.—One part paste mixed with 24 parts of water, by weight, and the resultant mixture used.

Toxement Powder.—Two per cent by weight of the cement in the batch.

Waterex.—A liquid used in the proportion of 15 pounds per bag of cement.

Alkagle.—Received in the form of a quaking bluish tinted gel having a strong odor of ammonia. Prepared according to manufacturer's directions.

Vulcan Asphalt.—First application of an asphaltic paint followed by asphalt which was heated and mopped onto the surface of the hardened concrete.

Barret Co. Tar.—Tar was heated and mopped on in two coats.

Ironite.—Surface of block wetted, and one coat Ironite applied with medium stiff brush. The ironite was in the form of a thin paste. After drying twenty-four hours the previous application was repeated, followed by a 1 cement—1 sand mortar of whitewash consistency to which 1 per cent ironite was added.

City of Calgary Asphalt.—Heated and mopped on to the surface of specimen. Two coats.

Sodium Silicate.—Three per cent solution mopped on to surface, allowed to dry one day, followed by 5 per cent solution.

Vortex Asphalt.—First coat mopped on after dilution with naphtha, followed with coat of unthinned asphalt.

Hard Rubber Varnish.—Applied to surface with a brush.

Paravar Rubber Varnish.—Applied to surface with a brush.

Preparation of Concrete

Prior to the preparation of test specimens, preliminary tests were made with the aggregates which had been provided. The Warman aggregate as received contained from 60 to 90 per cent sand with about 90 per cent of the total passing the ¾-inch screen. There appeared to be considerable pulverized clay in the sand which was removed by washing. The preliminary tests indicated a sand-gravel ratio of .45-.55 to furnish concrete of best quality, and this combination of fine and coarse was used throughout the work for Warman material. As noted in table No. 4, the Carseland sand was rather fine and the usual 1-2 sand gravel ratio was found best. The Winnipeg fine aggregate was found to give best concretes when two volumes of sand were combined with three volumes of the Winnipeg limestone coarse aggregate.

The preliminary tests on Warman aggregate indicated that a proportion of 1-5 by volume would furnish the 1,200-1,500-pound concrete and that a 1-3 mix by volume would result in a 2,500-pound strength for the flowabilities employed.

For accuracy in preparing successive batches, all quantities of cement, aggregate and water were weighed, the weights being dependent upon the previously determined unit weights of each. Each batch of concrete prepared was large enough to provide six, (in most cases eight), cylinders 7 by 21 inches, three compression test cylinders 6 by 12 inches, and two permeability slabs 2½ by 12 by 12 inches. All specimens moulded from a single batch were given the same batch number, stamped into brass plates and pressed into the green concrete.

Since a sufficiently large mixer could not be obtained to take the batch which weighed more than 750 pounds dry, the mixtures were prepared by hand on a concrete floor in the following manner:—after the concrete floor was first sprinkled to reduce absorption of mixing water, the proper quantities of coarse aggregate, fine aggregate and cement were spread in consecutive thin layers and the whole mass shoveled through until of uniform colour. The dry mixture was then formed into a crater and the mixing water added as dry material from the outside was thrown in. After adding sufficient mixing water to result in a fairly plastic consistency the mix was shoveled through a minimum of three times with as many additional turnings as was necessary to result in a homogeneous uniform appearance of the desired flowability.

Flowabilities were determined and controlled by means of the flow table. As much mixing water was used as would result in the desired flow. No predetermined quantity of water was employed, but the amount used was noted in every case. It was aimed in all cases to attain a flow of about 180. This is a plastic, mushy consistency well suited to shallow mass work or portions of a structure which can be well tamped, spaded and vibrated, but which does not contain the excess of water which is required when concrete is chuted. The consistency employed is one which should result in low permeability and give a concrete of high strength for the cement content used.

All cylinder test specimens were moulded in tight sheet metal forms with bottoms. Concrete was placed in approximately 6-inch layers and each tamped in succession. The compacting was aided by tapping the sides of the form. The form was heaped full at the last filling and allowed to stand for thirty minutes, after which the excess was cut away with a trowel, the brass identification plate placed in position and the top trowelled smooth. The top was then covered with an oiled metal plate to prevent evaporation. Permeability slabs were cast on edge so that the 12- by 12-inch faces would be free from trowelling. After 24 hours the specimens were removed from the moulds and placed in wet sand in tar paper enclosures where they were sprinkled daily for twenty-seven days. Comparative tests during the period indicated this method of curing to be fully as effective as curing in water.

Test pieces for compression tests were moulded and cured in the same manner.

Such specimens as were to be given the different surface coatings were treated after removal from sand storage and after they had become air dried.

To protect specimens during shipment, each was wrapped in heavy building paper and placed in a separate wooden crate. The shipment to each exposure site included two specimens from each batch of concrete. As indicated in table No. 5, practically all of the specimens were prepared during the summer of 1921 and shipped early in the fall, so that installations could be made before the cold weather. A few additional specimens were prepared in

1922, 1923 and 1924 with cements or special treatments which were not available when the work was started. Most of these later specimens were in the form of 6- by 12-inch cylinders.

A list of all concretes prepared is included in table No. 5.

Inspection of Field Concretes

The plan of making yearly inspections at each site was not fully carried out owing to water and weather conditions in the fall when inspections were usually undertaken. Results of analyses of water samples taken during inspection periods are shown in table No. 1. The chemical analyses of samples from Cassils and Grandora were made by the Chemistry Department of Saskatchewan University under Dr. Thorvaldson's supervision, and those on Deacon samples by the testing laboratory of the city of Winnipeg under the supervision of Mr. Blackie. Inspection generally consisted in the withdrawal or tilting of each specimen so that the condition of the surface embedded might be noted. The first visible signs of disintegration, (in the case of high strength concretes), is the flaking off and pitting of the smooth mortar surface of the specimen. This exposes sand grains still embedded in the unattacked mortar just within, a condition which is easily apparent to the eye and as easily detected to the touch if a metal scraper is rubbed over the injured surface. The contrast between the smooth surface of an apparently undamaged specimen and one in the first stage of disintegration is unmistakable, but it is not so easy to distinguish, in a few words, between different degrees of disintegration, since the rate of roughening and pitting of the surface concrete is very slow in the best quality specimens.

The tables Nos. 6, 7 and 8 show the condition of all specimens after the 1927 inspections. Inspection at Cassils and at the new Antelope Creek syphon site was made in April 1927 by engineers of the Irrigation Branch, Department of Natural Resources, Canadian Pacific Railway. Inspections of specimens at Deacon and at Grandora were made in September 1927 by members of the Committee.

Summary and Conclusions

The results of observations and inspections of the concrete blocks during 1927 are included in tables Nos. 6, 7 and 8. It should be kept in mind in comparing the results of the field tests that the specimens have been exposed to liquids of varying concentrations and of different relative proportions of sulphate and other salts at the three exposure sites as indicated by the water analyses of table No. 1. In order to avoid reaching unwarranted conclusions from observations of the field specimens, all field tests should be considered in the light of the finding of the laboratory research as set down in appendix A of this report.

(1) Severity of Action at the Block Sites.

Basing the severity of alkali action upon the number of blocks found unattacked at each site the rating would be as follows:—

Site	Number of Undamaged Specimens
Grandora, Sask.	5
Cassils and Antelope Creek, Alta	7
Deacon, Man.	20

All specimens reported in "good" or "perfect condition" have been classed as undamaged. Specimens reported as "weathered," "roughened" or having "scaled surface" have been classed as damaged since this condition is usually the first stage of progressive disintegration.

The same tabulation indicates more severe exposure conditions at the Alberta and Saskatchewan sites than at the Manitoba sites.

At Cassils and Antelope Creek syphons in Alberta the ground water level has been high, and constant seepage during the summer months has subjected the blocks to fresh supplies of ground water. At Grandora, Saskatchewan, the blocks have been completely submerged at times with the ground at the surface completely saturated during the intervals between immersions. At Deacon, Manitoba, the soil at the surface level has been saturated for a great portion of the time, but the salts are probably more evenly distributed through the soil than is the case at the other two sites, so that concentrations have probably been lower. A comparison of ground water analyses given in table No. 1 shows that at the Saskatchewan and Alberta sites the predominating sulphate is sodium sulphate, while at the Manitoba site the magnesium sulphate predominates, it also indicates lower concentrations at Manitoba than at the other sites.

The results obtained from these exposure tests when compared with results obtained in previous field investigations of the durability of concrete in alkali soils, would indicate that the exposures were fully as severe as anticipated by the Committee in selecting these particular sites.

(2) Quality of Concretes as Affected by Aggregates.

Aggregates from the three provinces were made up into concretes with approximately equal compressive strengths and exposed at each site. From the results of exposure tests it cannot be said that one aggregate has shown itself to be superior to the others. The types and gradings employed appear to constitute a minor factor in determining resistance of concrete to alkali action.

(3) Integral Compounds.

Results obtained with various so called integral waterproofing and alkali-proofing compounds are consistent with the findings reported by other investigators. No integral compound used appreciably prolonged the life of the concrete beyond that found for untreated concrete of the same mix and in some cases the use of such a compound seemed to accelerate the disintegration.

(4) Surface Coatings.

Surface coatings of the bituminous types tend to retard the disintegration during the early exposure periods but none employed in this work have proven to be permanent. Eventually the surface protection is broken down and disintegration proceeds in the usual manner.

(5) Portland Cement.

Portland cement from one mill only was used in preparing the test blocks. Excluding from the comparison those Portland cement specimens containing integral compounds or treated with surface coatings, it will be found that of a total of fifty-six Portland cement specimens installed four have been found unaffected. These four specimens include two neat, one rich concrete, and one lean concrete, the latter being exposed since 1923 as a part of the sulphur treated group. The lean concretes have in most cases been entirely disintegrated, while with one exception the rich concretes have been seriously affected. The neat cement specimens, excepting those at Deacon, have been shattered and broken up above the ground line. The shattered pieces appear hard and sound, but, as indicated by Dr. Thorvaldson in appendix A under "the action of sulphates on neat cement, the sulphate content has been considerably increased." In a previous investigation* of the durability of Portland cement in sea water it was also found that neat cement specimens were less resistant than mortars for a number of the cements employed. Since this investigation was started it has been proved beyond question (see appendix A under "Comparison of the Resistance of five Cements to Sulphate Solutions"), that different Portland cements, all meeting standard specifications and often with similar chemical analyses, have widely different resistances to the action of sulphate solutions. It is an important fact, as found in the laboratory, that the Portland cement used in these field tests was one with a very low resistance to sulphate solutions as compared with other Portland cements of Canadian manufacture.

(6) Natural Cement.

Natural cement from one mill only was used in the preparation of the field test specimens. Of a total of twelve natural cement specimens none are reported in good condition. At Deacon the tops of the two neat specimens have broken off while the tops of the two rich concrete specimens are reported as chipped. In Saskatchewan and Alberta all specimens have been badly disintegrated above ground but the portions of the neat specimens are apparently undamaged below ground. The combination of salt in the ground water together with frost action results in a short life for natural cement specimens. The field tests furnish no information as to the relative severity of these factors.

(7) High Alumina Cement.

One high alumina cement, "Cement Electrique" of French manufacture was used in the preparation of the field test specimens. Of a total of twelve high alumina cement concrete specimens two are reported in good condition. The unattacked specimens are two of rich concrete exposed at Deacon. All lean concretes have deteriorated. Disintegration has generally been slower than for the Portland cement specimens with most of the apparent action above the ground line. It has been found in the laboratory that this particular cement shows an especially high resistance to magnesium sulphate, which is the predominating salt at Deacon where the rich concretes have apparently not been attacked.

(8) Super Cement.

Super cement (Canadian) from one mill only was employed in preparing the test blocks. Of a total of forty-two Super cement specimens installed, twenty-three have been found unaffected. These twenty-three specimens include three neat, fifteen rich concrete and five lean concrete. Two neat specimens at Grandora, Sask., and one neat specimen at Antelope Creek, Alta., have been cracked and shattered above the ground line in a similar way to the neat Portland specimens referred to.

A comparison of the Super and Portland cement specimens in our field tests show that the former are less affected than the latter, however, as stated before (see Appendix A under "Comparison of the Resistance of five Cements to Sulphate Solutions,") we now know that different Portland cements show equally great variations in their resistances to sulphate action.

* Technologic Paper No. 12, United States Bureau of Standards.

It will be seen from the above information that we did not have in our field tests comparable blocks of Super cement and of a Portland cement made from the same clinker. We have, however, the results of laboratory tests on a Super cement and a Portland cement from the same clinker supplied by the Super Cement Co., and as reported by Dr. Thorvaldson in Appendix A, under "Super cement," it is possible to state that with the cements tested the special treatment given, the Super cement has not increased its resistance to sulphate action in the mixes used in the experiment, i.e., 1-3; 1-5 and 1-10 parts by weight of cement to standard sand.

Summing up all the available evidence, the general conclusions from both field and laboratory experiments are as follows:—

(1) Our field tests indicate that the particular Super cement used is more resistant to alkali action than the particular Portland cement used. It was found, however, in the laboratory that the particular Portland cement used is much less resistant to sulphate action than Portland cements from some other mills.

(2) That as our field investigation did not include tests with Portland cement and Super cement from the same clinker we have no evidence that one is more resistant to alkali action than the other when subjected to the same field conditions.

(9) General.

The results obtained from the field exposure tests are quite in accord with those obtained in other field investigations, as well as with the objects which the Committee had in mind when the field work was planned. That the main effort should be centred upon the research in the chemical laboratory was the original decision of the Committee, and this plan has proven sound. Few new data or ideas have been brought out by the field, but the chemical research has greatly extended our knowledge of the behaviour of cements when exposed to sulphate solutions. Perhaps one point of greatest interest to the cement user is the fact that there are chemical differences in the constitution of the so-called standard Portland cements which greatly shorten or extend the life of these cements when exposed to sulphate soils and waters. It has been known to testing engineers that Portland cements differ considerably in their concrete making properties as measured by compressive strength, but the variation in resistance to alkaline solutions has only been brought out by investigators in the last few years.

The field investigation has indicated that with the cement produced from any given clinker, durability as well as compressive strength increases as permeability decreases, up to some undetermined richness of mix, beyond which point durability in sulphates decreases rapidly. Rich concretes are more resistant than lean concretes but neat cements are less resistant than rich concretes. Impermeability increases and density decreases from lean concretes toward neat cements, but sulphate resistance drops off as neat mixtures are approached. The results of this investigation do not establish this point, but it is believed that the richest concretes generally used in practice are well within such a limit. It should also be emphasized that conclusions drawn from a small group of field exposure tests, such as was included in this work, may be too broad and in some cases contrary to the truth, unless consideration is given to laboratory studies where important variable factors can be more accurately controlled and measured.

Table No. 2—Chemical Analyses of Cements

Cement	*CaO*	SeO_2	Al_2O_3+ Mn_3O_4	Fe_2O_3	*MgO*	SO_3	Ignition Loss	Insol. Residue
"Commercial" Natural	53 22	20.92	10.76	3.74	.86	4.99	1.91	1.78
Canada Portland	61.20	20.38	7.90	2 58	3.56	1.67	2.37	0.37
St. Mary's Super	63 22	21.22	7.23	2.75	3.89	1.62	2.03	0.34
Ciment Electrique (French)*	38.67	7.44	42.38	12.60	2.32	0.19	.....	.....

*The cement gained considerably in weight on ignition. Only a small quantity of the iron present was in the ferric state, the greater proportion being in the form of metallic iron. The cement evolved hydrogen sulphide on treatment with acid, the sulphur (0.58 per cent) being present mainly as sulphide.

Table No. 3— Physical Tests of Cements

Cement	Mixing Water per cent	Fineness through 200 mesh	5-hour Steam test	Time of Setting Gillmore		Tensile strength 1-3 briquettes Pounds	
				Initial	Final	7-day	28-day

*Specimens exceeded capacity of available testing machine.

†Not enough aggregate to permit moulding of strength-test specimens.

Table No. 6—Inspection of Concrete Blocks, Deacon, Manitoba, 1927

Batch No.	Cement and Mixture	Special Treatment	Condition, September 1927
*1-5	Neat Canada		No action. Side chipped with trowel during examination.
1-6	Neat Canada		Perfect condition.
2-5	Neat Super		No action. Side chipped during examination.
2-6	Neat Super		Perfect condition.
3-5	Neat Commercial		‡No alkali action. About 5 inches of top broken off probably due to frost action.
3-6	Neat Commercial		‡No alkali action. Top broken off probably due to frost action.
4-5	Rich Canada		Base very badly affected, quite soft.
4-6	Rich Canada		Alkali action on one corner of base.
5-5	Rich Super		No action.
5-6	Rich Super		Perfect condition.
6-5	Rich Canada		Distinct action all around base. Slight action at ground line.
6-6	Rich Canada		Slight action at one spot at side near large stone in aggregate.
7-5	Rich Super		No action.
7-6	Rich Super		Perfect condition.
20-5	Rich Canada		Slight action on one side of base.
20-6	Rich Canada		Perfect condition.
21-5	Rich Super		No action.
21-6	Rich Super		Perfect condition.
22-5	Rich Commercial		No alkali action. Top chipped.
22-6	Rich Commercial		No alkali action. Top chipped.
23-5	Rich Electrique		Perfect condition.
23-6	Rich Electrique		Perfect condition.
30-3	Rich Canada	Sulphur impregnated	Very badly affected all over surface.
30-4	Rich Canada	“ “	Top and bottom affected. Worse than 30-12.
30-11	Rich Canada	Untreated	Badly affected around base.
30-12	Rich Canada	“	One corner of base affected.
60-5	Lean Canada		Very badly affected.
60-6	Lean Canada		Alkali action all around top. No action on base or sides.
61-5	Lean Super		Perfect condition.
61-6	Lean Super		Perfect condition.
62-5	Lean Canada	Integral sodium silicate	Badly affected on top and base.
62-6	Lean Canada	“ “ “	Badly affected—top broken off.
63-5	Lean Canada	“ Medusa	Badly affected top and bottom—not so bad as 62.
63-6	Lean Canada	“ “	Base badly affected on all sides—no action on sides or top.
64-5	Lean Canada	“ Truscon	Badly affected on bottom and sides—no action on top.
64-6	Lean Canada	“ “	Slightly worse than 63—also affected spot on side.
65-5	Lean Canada	“ Toxement	Badly affected on top bottom and sides. About the same as 63.
65-6	Lean Canada	“ “	About same as 64 but no spot on sides.
66-5	Lean Canada	“ Waterex	Badly affected top and ground line.
66-6	Lean Canada	“ “	About same as 65.
69-5	Lean Canada	“ Alkagel	Almost completely gone.
69-6	Lean Canada	“ “	Almost completely gone—top broken off.
70-5	Rich Canada	“ “	Completely gone.
70-6	Rich Canada	“ “	Completely gone.
72-5	Lean Canada	Vulcan asphalt coating	Not examined.
72-6	Lean Canada	“ “ “	Alkali action on top.
73-5	Lean Canada	Barrett tar coating	Badly affected all around the base.
73-6	Lean Canada	“ “ “	No action.
74-5	Lean Canada	Ironite coating	Badly affected all around base at ground line.
74-6	Lean Canada	“ “	Two affected spots on base line.
76-5	Lean Canada	Calgary asphalt coating	Badly affected on one side of base. Coating perished above ground line.
76-6	Lean Canada	“ “ “	No alkali action. Coating perished.
77-5	Lean Canada	Sodium silicate coating	Base badly affected.
77-6	Lean Canada	“ “ “	Two affected spots on base, no action on sides or top.
78-5	Lean Canada	Vortex asphalt “	Very badly affected all over surface.
78-6	Lean Canada	“ “ “	Two affected spots on base. One side also affected.
80-5	Lean Canada	Integral Alkagel	Completely gone.
80-6	Lean Canada	“ “	Completely gone.
81-5	Lean Canada		Badly affected all over—base affected spots on sides. Scaling on top.
81-6	Lean Canada		Top affected all round. One corner of base affected.
82-5	Lean Super		Distinct action over two-thirds of base. Affected spot on sides, not so bad as 81.
82-6	Lean Super		No action.
83-5	Lean Canada		Badly affected on top base, at ground line and on top.
83-6	Lean Canada		Two spots on base and one spot on side affected.
84-5	Lean Super		No action.
84-6	Lean Super		Perfect condition.
85-5	Lean Electrique		No action.
85-6	Lean Electrique		No action, top weathered.
86-3	Lean Canada	Sulphur impregnated mortar	Slight action on base and top.
86-4	Lean Canada	“ “ “	No alkali action—frost action on top.
86-11	Lean Canada	Untreated	Completely gone.
86-12	Lean Canada	“	Almost completely gone.
87-5	Lean Canada	Hard rubber varnish coating	Top affected. No action on sides and base.
87-6	Lean Canada	“ “ “ “	Two spots on base and half of top affected.
88-5	Lean Canada	Paravar varnish coating	Distinct action on top base and sides.
88-6	Lean Canada	“ “ “	One spot on base and one spot on top affected.
89-5	Lean "Watchtower"		Top and base completely gone.
89-6	Lean "Watchtower"		Top affected on all sides. No action on base.
90-5	"Ciment de laitier"		Very badly affected.
90-6	"Ciment de laitier"		Top affected on all sides—no action on base.

*Numbers in first column are batch numbers which correspond to the numbers in the first column of table No. 5. Second column numbers indicate the block numbers.

‡In the case of Portland and Super cements this cracking has been found to be due to sulphate action.

Table No. 7—Inspection of Concrete Blocks, Grandora, Sask., 1927

Batch No.	Cement and Mixture	Special Treatment	Condition, September 1927
*1-3	Neat Canada		Sound below ground. Top split by sulphate action.
1-3	“		“ “ “ “ “ “ “ “

Report of Council for the Year 1927

During the past year members of The Institute have continued to take a prominent part in the industrial activity of the country, and in the construction of the numerous engineering works which are being carried on or contemplated. When we note such enterprises as the Welland canal, the Montreal South Shore bridge, the Toronto railway terminals and the general activity in construction, power development and the engineering industries, it is evident that the engineer is doing his share in building up the Dominion.

As regards The Institute's affairs, the outstanding feature of the year has been the evidence of a more active interest on the part of our branches in the development and progress of The Institute. This has been indicated by the action taken by a number of the branches in forwarding expressions of opinion regarding such subjects as the proposed amendments to By-laws and the work of various Institute committees, showing that our members regard themselves as belonging to an active organization and are concerned with its growth, development and betterment, a state of things which is most encouraging.

This year, for the first time in the history of the Institute, special arrangements were made for a three-day Plenary Meeting of Council, at which The Institute's affairs were debated with all the advantages arising from personal intercourse and exchange of opinion. The topics discussed included such important questions as the relations of the Institute with the various Provincial Associations of Professional Engineers, the desirability of making changes in the present qualifications for membership, and the vital problem of Engineering Education. Proposals regarding the formation of Students' Sections and the relations between the employer and the young engineer also received attention, and the members of Council present at the meeting were able to take back and communicate to their Branch Executive Committees a comprehensive view of the working of the Institute as a whole which would otherwise not have been possible.

During the past year an unusually large number of amendments to the By-laws have been proposed by Council and by Corporate Members; some of them are of considerable importance as affecting the method of election of members, the annual fees payable, and the way in which proposed amendments are to be discussed and decided upon. These proposals have been duly considered by Council, and will all be submitted to the Annual General Meeting, at which time they will be open to full discussion.

An important series of papers was presented at the Annual General Professional meeting in Quebec, on the success of which the Quebec Branch is to be congratulated. The discussions which form so prominent a part of the work of a professional meeting were unusually active, particularly in regard to the recent hydro-electric developments in Quebec and British Columbia, and lines of work associated with various engineering pulpwood operations and mining.

Council would draw attention, however, to the fact that while the papers presented at our professional meetings have given rise to good discussions, many of those submitted at Branch meetings during the year have merited a more ample discussion than they received. The usefulness of such papers, many of which deal with important engineering works, would be enhanced if more effective measures were taken to ensure an organized discussion. This would require the co-operation of authors, in sending in their papers in time to permit of their circulation before the meeting, and would place an additional tax upon the time of the Branch officers and secretaries, but it is believed that the benefits resulting would be well worth while.

Council recognizes with special appreciation the debt which the Institute owes to the officers of its Branches, for branch activities are one of the means by which the benefits of membership in the Institute are effectively demonstrated.

During the year the relations of the Institute to the Associations of Professional Engineers of the various provinces have been the subject of considerable thought and discussion, and it is satisfactory to record that the first step has been taken towards the very desirable object of greater uniformity in the requirements of admission to these bodies and the Institute itself. The Institute's Board of Examiners and Education, in preparing its revised syllabus for examinations for admission, is in consultation with the Examination Boards of the several Professional Associations with a view of ascertaining what steps can be taken towards uniformity in this matter.

The Committee appointed in 1926 to study the best method of utilizing the funds available for The Institute's prizes has completed its work, and its report, which recommends a number of changes in the present system and proposes a set of rules governing the various awards, will be submitted for the approval of the Annual General Meeting.

Attention should be drawn to the further satisfactory progress of the work of the Committee on the Deterioration of Concrete in Alkali Soils, the latest results of its important investigations being shown by the paper on the subject and the report of the Committee, which are to be presented at the forthcoming General Professional Meeting.

Council records with regret the deaths during the past year of a number of prominent senior members of the Institute, including three Past-Presidents, W. P. Anderson (President 1904), G. A. Mountain (President 1909), and C. H. Rust (President 1911), and four members who joined the Canadian Society of Civil Engineers at its inception, J. H. Kennedy, R. B. Rogers, W. L. Scott and H. K. Wicksteed.

The finances of The Institute as shown on the report of the Finance Committee are in sound condition, the revenue having been spent with due economy, as is evident from the existence of a surplus. It will be noted that neither Transactions nor Year Book have been issued this year; both of these are, however, to be issued during 1928, and it has been possible by the exercise of care to set aside a reserve against the 1927 share of the cost of these publications, and, in addition, to add to the fund set aside to pay off the mortgage on the Headquarters building.

Meetings

Annual General Meeting

The Forty-first Annual General and General Professional Meeting convened at Headquarters on Thursday evening, January 23rd, 1927, Vice-President K. B. Thornton, M.E.I.C., in the chair. After the reading of minutes and appointment of the scrutineers the meeting was adjourned to reconvene on Tuesday, February 15th, at the Chateau Frontenac, Quebec.

At the Quebec sessions, Vice-President K. B. Thornton, M.E.I.C., took the chair on the morning of February 15th, when the report of Council for 1926 was considered and adopted, together with the reports of the various Committees and Branches.

In the unavoidable absence of the retiring president, Major Geo. A. Walkem, M.E.I.C., his valedictory address was read by the secretary and the thanks of the meeting were forwarded to Major Walkem, the message also expressing regret that he was unable to be present.

The afternoon session was devoted to a discussion arising from the report of the Committee on Engineering Education, after which the scrutineers' report was presented, and the newly-elected president, Dr. A. R. Decary, M.E.I.C., took the Chair.

General Professional Meeting

On February 16th and 17th three technical sessions were held, at which thirteen papers were presented, all giving rise to active discussion.

Other functions in connection with the meeting included a luncheon on the first day given by the Quebec Branch, a smoking concert, visits to the Quebec Bridge on the ice-breaker "Mikula," and to the Anglo-Canadian Pulp and Paper Mills; the Annual Dinner of The Institute, at which the principal speaker was Sir Henry Thornton, president of the Canadian National Railways, and a very enjoyable supper-dance held on the last evening.

All present felt that the Quebec meeting was an outstanding success, and that the thanks of The Institute were due to the officers, members and ladies of the Quebec Branch for their untiring efforts and generous hospitality.

Branch Meetings

Particulars of the meetings and financial condition of the various branches will be found in the attached Branch reports, which show that the Branch activities have been well maintained during the year.

Roll of The Institute

During the year nineteen-twenty-seven, one hundred and eighty-eight persons have been elected to various grades of The Institute. These are classified as follows:—thirteen Members, forty-eight Associate Members, sixteen Juniors, one hundred and seven Students, and four Affiliates. The elections during the year nineteen hundred and twenty-six totalled two hundred and twelve.

Transfers from one grade to another were as follows:—Associate Member to Member, twenty-two; Junior to Associate Member, thirty-three; Junior to Affiliate, two; Student to Associate Member, thirty-three; Student to Junior, forty-four; Affiliate to Associate Members, one; a total of one hundred and thirty-five, as compared with one hundred and fifty-seven in 1926.

A summary of these elections is given below. The names of those elected or transferred are published each month in the Journal, immediately following the election, and are added to the membership roll.

Removals from the Roll

There have been removed from the membership roll during the year nineteen hundred and twenty-seven, by resignation and for non-payment of dues, sixteen Members; thirty-seven Associate Members; twenty-seven Juniors; eighty Students; and one Affiliate; a total of one hundred and sixty-one. Twenty-three reinstatements were effected, and two Life Memberships were granted in 1927.

Deceased Members

During the year 1927 the deaths of thirty-three of The Institute's Members have been reported as follows:—

Members

Anderson, Col. W. P., C.M.G.
Boswell, St. George James
Campbell, Archibald William
Donnelly, Col. O'Connor Coslette
Forrest, Benjamin James
Gamble, Francis Clarke
Going, Alvah Seymour
Hamilton, James
Haney, Michael James
James, Edgar Augustus
Kennedy, James Henry
Kircher, Paul
Mountain, William Alphonso
Pilsworth, William Robert
Russell, William Russell
Rust, Charles Henry
Scott, William Lemuel
Shewen, Edward Thornbrough Parker
Wetmore, Andrew Rainsford
Wicksteed, Henry King

Associate Members

Brown, Donald McDonald
Cole, Donald
Dawson, Heber William
d'Orsonnens, Arthur
Gardner, Col. Robert
Hutchinson, Eric Charles
Locke, Robert T.
Read, Guy Carleton
Roe, William Evlyn
Webster, Jas. Clarence
Wilson, Joseph Lovitt
Wrong, Frederick Hay

Students

Forbes, Robert Clarence

Total Membership

The membership of The Institute at present totals four thousand, seven hundred and eighty-one. The corresponding number for 1926 was four thousand seven hundred and thirty-eight.

The total number of corporate members stands at three thousand five hundred and one, as compared with three thousand four hundred and fifty-three on December 31st, 1926.

	Dec. 31st, 1927	Dec. 31st, 1926
Honorary Members	10	9
Members	1,151	1,154
Associate Members	2,349	2,298
Juniors	460	460
Students	758	770
Affiliates	53	47
	4,781	4,738

Respectfully submitted on behalf of the Council.

A. R. Decary, M.E.I.C., *President.*
R. J. Durley, M.E.I.C., *Secretary.*

Finance Committee

The President and Council:

It will be seen from the attached financial statement for the year ending December 31st, 1927, that expenditures have been kept well within the budgeted amount. After reserving amounts to cover the 1927 portion of costs for Year Book and Transactions, the Balance Sheet shows a surplus of receipts over expenditures of $3,458.41.

Your committee wish to point out, however, that the above mentioned reserve and surplus was made possible by the increased advertising earnings of the *Journal*, amounting to $3,172.00, and to collecting of arrears of dues, totalling $3,636.16, also by practising the strictest economy throughout the year in all departments, and by the curtailment of any new activities on the part of The Institute which would entail extra expenditure.

While it is hoped that the earnings of the *Journal* will continue to be as favourable during the coming year as they were in 1927, there is no guarantee that they will be. The amount collected from arrears of dues will be reduced considerably during 1928, as the outstanding amounts are now considerably reduced.

Respectfully submitted,

JAS. H. HUNTER, M.E.I.C., *Chairman.*

Nominating Committee—1928

The following nominations to the Nominating Committee for the year 1928 have been made by the various branches, have been noted by Council, and are herewith presented to be announced at the Annual Meeting in accordance with the By-laws.

Halifax Branch	C. H. Wright, M.E.I.C.
Cape Breton	A. L. Hay, M.E.I.C.
Saint John	J. N. Flood, A.M.E.I.C.
Moncton	L. H. Robinson, M.E.I.C.
Saguenay	C. N. Shanly, M.E.I.C.
Quebec	P. Méthé, A.M.E.I.C.
St. Maurice Valley	H. Dessaulles, A.M.E.I.C.
Montreal	J. G. Caron, A.M.E.I.C.
Ottawa	W. A. Rush, A.M.E.I.C.
Peterborough	A. L. Killaly, A.M.E.I.C.
Kingston	W. P. Wilgar, M.E.I.C.
Toronto	J. J. Traill, M.E.I.C.
Hamilton	J. A. McFarlane, M.E.I.C.
London	Frank C. Ball, A.M.E.I.C.
Niagara Peninsula	C. G. Moon, A.M.E.I.C.
Border Cities	J. E. Porter, A.M.E.I.C.
Sault Ste. Marie	J. W. LeB. Ross, M.E.I.C.
Lakehead	F. C. Graham, A.M.E.I.C.
Winnipeg	J. N. Finlayson, M.E.I.C.
Saskatchewan	M. B. Weekes, M.E.I.C.
Lethbridge	C. Raley, A.M.E.I.C.
Edmonton	R. W. Boyle, M.E.I.C.
Calgary	B. L. Thorne, M.E.I.C.
Vancouver	J. M. Begg, A.M.E.I.C.
Victoria	A. L. Carruthers, M.E.I.C.

Legislation and By-Laws Committee

The President and Council:

The amendments to the By-laws proposed last year were submitted to letter ballot of the membership and duly approved; these, applying to Sections 13 and 38, accordingly become effective in due course.

During the year 1927, amendments have been proposed by Council to the following Sections of the By-laws:—Nos. 9, 10, 18, 24, 52, 53, 68, 69, 70, 74 and 76.

An amendment to Section 29, dealing with the method of election of members by letter ballot of Council, has also been proposed by twenty corporate members of the Moncton Branch.

All these proposals have been circulated to the membership and will come up for discussion at the Annual General Meeting prior to their submission to a letter ballot vote of the members. In the opinion of your Committee, three of these proposals are of special importance; namely that amending Section 29, as mentioned above, that amending Section 35, regarding the amount of the annual fees of Members, and that amending Section 76, involving a change in the procedure to be followed in amending the By-laws.

Your Committee would express the hope that in considering all these proposals, and particularly the three just named, members will realize the complexity of the questions raised, and the unsatisfactory and sometimes unforeseen results which are apt to follow the adoption of suggestions or changes in wording which have not received adequate and reasoned discussion.

The views of your Committee on these matters have already been presented to Council in reports submitted during the year.

Respectfully submitted,

Geo. R. MacLeod, M.E.I.C.,
Chairman.

Papers Committee

The President and Council:

In view of the Papers Committee being spread from coast to coast, it has not been possible to prepare a report of the committee as a whole. As a substitute, this is a report by the chairman of the Committee.

The same policy as last year, of appointing an eastern and western vice-chairman of the Committee was followed out. W. J. Johnston, A.M.E.I.C., of St. John acted for the Maritimes, and E. A. Wheatley, A.M.E.I.C., represented the western Branches.

An attempt was made to carry out the recommendations made at the last Annual Meeting to the effect that each Branch should appoint a special representative to this Committee. This, however, did not work out entirely satisfactorily in practice. The general secretary requested every Branch to appoint a representative to this Committee but only half of the Branches took any action in this regard. It therefore looks as though many Branches feel that they have no use for the Papers Committee of the Institute, and do not desire to co-operate with other Branches in this feature of the activities of the Institute.

Through the activities, however, of the vice-chairman for Maritime provinces, arrangements were made, similar to last year, for one speaker to make a comprehensive tour, visiting all the Branches in the Maritimes.

One cannot write with any degree of enthusiasm of the work of this Committee because of the lack of co-operation. There is a cry from many Branches that they have difficulty in getting speakers, and yet they do not take advantage of the possibility of being assisted through the Papers Committee of Headquarters.

Respectfully submitted,

J. L. Busfield, M.E.I.C., *Chairman.*

Publications Committee

The President and Council:

I have much pleasure in reporting that the Publications Committee has had no business which necessitated its being called together during the year 1927. On one or two occasions its chairman has been consulted by the General Secretary regarding notices in the Journal, with mutually satisfactory results, but not even this would afford justification for describing the duties of the Committee as onerous.

Respectfully submitted,

P. L. Pratley, M.E.I.C., *Chairman.*

Board of Examiners and Education

The President and Council:

During the past year, your Board of Examiners has examined fifteen candidates for admission to The Institute, with results as set forth in the table below:

Subjects	Passed	Failed
Schedule "B"	1	3
Mechanical Engineering	1	0
Railway Engineering	5	1
Structural Engineering	0	4
Totals	7	8

The figures of the above table would suggest that candidates are perhaps disposed to regard the Institute examinations largely as formalities, and this is borne out by the papers submitted. Many of these are so poor as to indicate that the candidate has little knowledge of the subject upon which he is writing. In conducting its examinations, the Board tries to maintain a standard approximately equal to that of the Canadian universities, a fact of which candidates should take due notice.

During the year, the Board has recommended to Council, (1) that the Dominion Land Surveyors' certificate should not be accepted as exempting the holder from examination for admission, and (2) that a degree in forestry, or forestry engineering, should not be considered as equivalent to a degree in those branches of engineering already recognized by the Institute, but that the holder of such a degree might be admitted without examination provided his experience had been of satisfactory engineering character.

The syllabus of examinations is being revised, as there were many features of the old syllabus giving rise to difficulty. The proposed new syllabus will, it is hoped, obviate these troubles.

The consideration of the revised syllabus, and of the Institute's relations to the various provincial examining boards are matters which should receive the early attention of your Board of Examiners to be appointed by the incoming Council.

In closing, the Board would like to express its appreciation of the co-operation received from the Secretary and his staff, without which its efficient functioning would have been difficult, if not impossible.

Respectfully submitted,

R. DeL. French, m.e.i.c., *Chairman.*

Committee on Engineering Education

The President and Council:

The Committee on Engineering Education has been holding itself in readiness to co-operate with the Society for the Promotion of Engineering Education, but no specific problems have been presented to your Committee.

Respectfully submitted,

Frederick B. Brown, m.e.i.c., *Chairman.*

Gzowski Medal and Students' Prizes Committee

The President and Council:

Your Committee has studied carefully the papers presented during the year ending June 1st, 1927. The papers reviewed covered a wide range of topics, including reports of original research, records of natural resources and descriptions of recently completed engineering projects. Some of the papers were the work of two or more authors, and those dealing with original research appeared to be progress reports rather than papers dealing broadly with the subjects under investigation.

There was a marked difference of opinion as to the order of merit of the papers reviewed, but a general agreement that none of them could be ranked as forming a sufficiently valuable contribution to engineering literature and professional knowledge to warrant the award of the Gzowski Medal.

Your Committee, therefore, recommends that no medal be awarded this year.

The Committee recommends that a Student's Prize be awarded in the electrical section, to W. T. Fanjoy, s.e.i.c., for his excellent paper on the "Control of Common Types of A. C. Motors."

Respectfully submitted,

C. V. Christie, m.e.i.c., *Chairman.*

Leonard Medal Committee

The President and Council:

On behalf of the Leonard Medal Committee of The Institute, I beg to report that we have carefully considered the eligible papers and it is our unanimous opinion that in this instance the award be made to Sir Stopford Brunton, a.m.e.i.c., for his paper on "The Gold Deposits of Nova Scotia." We are of the opinion that on the question of originality, and composition combined with appropriateness it fulfils the idea of the founder.

Respectfully submitted,

Geo. D. Macdougall, m.e.i.c., *Chairman.*

Plummer Medal Committee

The President and Council:

Your Committee has carefully examined the various papers which they feel come within the scope of the Plummer Medal.

These papers are as follows:—

"The Characteristics and Utilization of Nova Scotia Coals," by W. S. Wilson, a.m.e.i.c., and M. W. Booth, a.m.e.i.c.

"Alternating Current Electrolysis," by J. W. Shipley and Chas. F. Goodeve.

"The Wood Consuming Industries of Canada," by John Stadler, m.e.i.c.

"The Expansion of Portland Cement Mortar Bars During Disintegration in Sulphate Solutions," by T. Thorvaldson, R. K. Larmour and V. A. Vigfusson.

"Bearing Metal Bronzes," by Harold J. Roast, and Fred Newell, m.e.i.c.

"Oil Paints and Their Application," by A. K. Light.

In judging these papers your Committee felt that originality of work should be one of the primary factors in their decision and should have consideration over mere statements of already known facts or compilations of other authors' works.

Following the consideration of subject matter, consideration was given to English, style and method of handling the subject.

Taking all these points into consideration, it is the majority opinion of your Committee that the paper as presented in the January 1927 number of the Journal entitled "Alternating Current Electrolysis," by J. W. Shipley and Charles F. Goodeve, should receive the Plummer Medal for the period under review.

Respectfully submitted,

J. R. Donald, m.e.i.c., *Chairman.*

Committee on Biographies

The President and Council:

During the year the work of the Committee on Biographies has consisted largely of correspondence conducted with actual and potential authors of memoirs of deceased engineers. Twelve biographies of varying length have already been compiled, six others are in progress, and six additional ones have been assigned to authors.

The work of the Committee is continuing as opportunity offers, but has been somewhat delayed by the illness of the chairman, who desires to express his appreciation of the work of his colleagues on the Committee.

Respectfully submitted,

Peter Gillespie, m.e.i.c., *Chairman.*

Library and House Committee

The President and Council:

The work of recataloguing the library was completed early in the year, with the exception of the files of periodicals, transactions and reports, the work on the latter being at present well advanced. As a result of this work greater facilities are afforded the members of the Institute in the use of the library and there has been an appreciable increase in the number of members who have availed themselves of the library facilities during the past year.

A record of library service for the past eight months shows that 141 books were borrowed of which 28 were loaned to members living outside of Montreal. This figure does not include the large number of books borrowed for reference within the Headquarters building.

Requests are constantly received at Headquarters for information which might be classed under the heading of "library reference service." These requests involved the search for articles on specified subjects in periodicals, transactions, reports, etc.; the listing of text books or articles dealing with a particular subject, and numerous other services. These services are most valuable to members residing in places where they have not access to technical libraries, and it is hoped that as the demand increases greater facilities will be provided to carry on this work.

In connection with this some 525 separate references were requested during the eight months period mentioned above.

While various regulations governing the operation of the library had been formulated and approved from time to time it was deemed advisable that these should be collated and amended so as to establish an authorized set of rules and regulations for the library, and with this in view your Committee submitted the regulations as printed on page 468 of the October issue of the Engineering Journal, which were approved by Council at the meeting held on September 27th, 1927.

During the year some 70 new technical books were added to the library in addition to various technical periodicals, transactions of other societies, and reports of numerous organizations. The majority of the technical books received were presented by the publishers for review in the Engineering Journal. Each month there has appeared in the Journal a list of books, etc., which have been received and added to the library. These lists may be found on pages 58, 236, 325, 440, 471, 506 and 542 of volume X, of the Journal.

Your Committee wishes to acknowledge with thanks the books, reports and other publications which were presented to the library by a number of individuals and organizations, and also to record the appreciation of the Institute of the service rendered by a number of members and others in reviewing books presented by publishers.

During the year there was presented to The Institute, by Mrs. William McNab, a large view of the original Victoria Tubular Bridge over the St. Lawrence River at Montreal, with the construction of which the late Mr. McNab was connected.

The expenditure on the library during the year amounted to one thousand, six hundred and six dollars and fifty-five cents, which includes the cost of the new books, expenses relative to the work of recataloguing, and the salary of the librarian.

At the meeting of Council held on June 21st, 1927, it was proposed that certain repairs should be made to the Headquarters building, and at the request of Council your Committee examined the building and found it badly in need of renovation and approved of the following work, which was subsequently carried out:

Office—Repairing plaster; tinting ceiling; painting walls, woodwork, partitions, etc.; installation of new lighting system to replace old library lights in the general office.

Lecture Hall—Washing and retinting ceiling, repapering walls, and painting woodwork.

Technical Reading Room—Repairing plaster, tinting ceiling, repapering walls and painting woodwork.

Repairs in connection with the Headquarters building entailed the expenditure of six hundred and sixty-four dollars and thirty-five cents, of which five hundred and fifty-one dollars and sixty-eight cents is accounted for by the repairs mentioned above.

Respectfully submitted,

W. C. Adams, M.E.I.C., *Chairman.*

Committee on International Co-operation

The President and Council:

The Institute's Committee on International Co-operation was not called into official action last year.

Italy, however, in 1927, in commemoration of the one hundredth anniversary of the death of Alessandro Volta invited the International Electrotechnical Commission, the World Power Conference, the Illuminating Engineers, the Meteorologists, the Physicists and the Telephonists and Telegraphers of the world to visit the Exhibition at Como (the old city where Volta had worked and died), to hold separate conventions around Lake Como and to join in a grand demonstration in honour of the "father of electricity," from whose name the word "volt" was derived. The writer was fortunate in being able to attend the meetings and functions of the two first mentioned organizations above, as an official delegate from Canada, and with pleasure takes advantage of this opportunity to tell the members of the Institute something about them, because national pride and "international co-operation" were the keynotes of all the proceedings.

Great Britain sent forty delegates to Italy; the United States sent twenty-one, France sent seventeen, and Germany fifteen, delegates to the plenary meetings of the International Electrotechnical Commission. Were it not for the fact that the Board of Railway Commissioners for Canada, (with the concurrence of the officials of the Department of Railways and Canals), took a special interest in the work relating to safety rules and regulations for electric power transmission systems, Canada would not have been represented at all at those great Italian gatherings, and this, in the writer's opinion, would have been most regrettable. Twenty countries were represented; many sent large delegations. Australia and Canada were the only countries represented by a single delegate and even far-off Japan sent two delegates.

Canada, in common with other countries, has National Committees of the International Electrotechnical Commission and of the World Power Conference,—both of which bodies have their head offices in London, England. Those National or home committees continuously carry out such work as is assigned to them at the plenary meetings or conventions of the parent bodies and their reports are considered and amended or approved at plenary meetings like those recently held in Italy. Lists of the subjects handled appear on pages 541 and 542 of the December issue of The Engineering Journal. The Illuminating Engineers handled the following matters:—Automobile lighting, factory lighting, photometric methods, and international definitions, while committees were appointed to deal with diffusing glassware, signal lenses, daylight motion pictures, street lighting, and glare research.

Although greatly handicapped by being alone while three concurrent committee meetings were being held at Bellagio, and, for several days, while another meeting was under way at the same time at Cernobbio, twenty miles away, the writer had abundant evidence to show that the presence of even one Canadian delegate at those International gatherings was greatly appreciated by the Italians and by the representatives of the other countries, who have spent much money and a great amount of time and energy in their efforts to develop international standardization.

The Italian committees had the hearty approval and active support of Premier Mussolini and his whole administration. They know Italy is well worth visiting and they gave us a great welcome. We could not help being much impressed by the abundant evidences of peace and progress on every hand while we were being taken to Milan, Venice, Florence, Rome, Pisa, Genoa and Turin on a special complimentary train and shown the treasures of science, art and history with which every step of the way is filled. In each city the Podesta extended the freedom of his district. At Rome the Governor and Premier Mussolini gave receptions in our honour and most of the delegates had an audience with His Holiness Pope Pius XI.

Visitors to Europe cannot fail to comment on the thousands of miles of main line electrified railways—in operation and in course of reconstruction. France, Switzerland and Italy seem to be vying with each other in their attempts to speedily electrify all their railways. In those three countries the American—and Canadian—contention, that the cost of railway electrification makes it prohibitive, has been side-tracked by the European conclusion that the value of the better electrical service and the comfort of the traveller are of more importance than the first cost of the change.

When invitations to International and other meetings are received, instead of asking ourselves:—"What is there in this for me?" would it not be well for those receiving them to say: "Can we help the other fellows if we attend?" Even though time, energy and money must be spent in connection with such affairs, the net gain to all concerned is, in the writer's opinion, very great. It does every human being a lot of good when he does something for some one else. That is true of family affairs, of Institute affairs and of International affairs.

Respectfully submitted,

John Murphy, M.E.I.C., *Chairman.*

Canadian National Committee of the International Electrotechnical Commission

The President and Council:

The Secretary regrets to report the untimely death on May 1st, 1927, of Mr. James Kynoch, chairman of the Canadian National Committee of the International Electrotechnical Commission, and chief engineer of the Canadian General Electric Company. Mr. Kynoch had been ill for a short time and was resting at his summer home at Lake Simcoe when he unexpectedly expired. He had taken a great interest in the work of the Committee and had planned many schemes for its extension and usefulness. He had taken a special interest in sending a Canadian representative to Italy to take part in the Volta Centennial Celebrations and did much towards making it possible for our representative to attend.

At a meeting of the Committee on July 11th, John Murphy, M.E.I.C., vice-chairman, was elected to succeed Mr. Kynoch as chairman. As our new chairman's attendance at the Italian meeting has, I am informed, been reported under the head of the International Co-operation Committee, there is no necessity to repeat it here.

A subject greatly to the fore at present is the question of co-ordinating the work of the International Electrotechnical Commission and that of the recently formed International Standards Association, and it is sincerely hoped that a universally satisfactory solution may be found as soon as possible.

In the meantime the International Electrotechnical Commission is vigorously carrying on its programme.

Respectfully submitted,

H. A. Dupré, M.E.I.C., *Secretary.*

Honour Roll and War Trophies Committee

The President and Council:

The task of compiling and checking the nominal rolls of members who fell or served in the Great War has occupied a considerable portion of the time of the staff of the Institute during the year 1927.

The list of members who fell has been checked by National Defence Headquarters, but identification is still required for a considerable number of members who either served in the Imperial Forces or in the Allied Armies.

The nominal roll of members who served has now been sent to National Defence Headquarters for confirmation and checking, and your Committee has been informed by the Director of Records that it will not be possible to undertake the work in connection with this roll for some months, owing to the vast number of similar rolls for various institutions throughout Canada and the United States, which have priority over our list, on account of their earlier date of receipt.

The sum necessary for the completion of the Memorial and the Record in Bronze has been collected. When the checking of the nominal rolls has been finally completed the work of erection will be put in hand by your committee.

Respectfully submitted,

Charles J. Armstrong, M.E.I.C., *Chairman.*

Committee on the Deterioration of Concrete in Alkali Soils

The President and Council:

In submitting our annual report this year we wish to set forth in detail the result of six years' exposure of the field specimens, and it is desired to call attention to certain phases of the chemical research which bear on the interpretation of the field tests.

Financial

As shown in detail in another part of this report, we have collected and spent on our investigation to date the sum of $47,821.93, contributed by the parties and in the amounts shown. Our Committee funds became practically exhausted about April of this year, but the chemical research has been continued on other funds in order to conclude certain work which will enable us to make a final report on behalf of our Committee.

Chemical Research

Much important work has been done during the year on the chemical research. One paper entitled, "The Expansion of Portland Cement Mortar Bars During Disintegration in Sulphate Solution," by Thorvaldson, Larmour and Vigfusson was printed in the Engineering Journal, April, 1927. This paper presents the method developed and used to measure quantitatively the progress of disintegration in mortar subjected to sulphate solutions. A paper, "The Effect of Steam Treatment of Portland Cement Mortars on their Resistance to Sulphate Solutions," by Thorvaldson and Vigfusson, is being presented at this annual meeting and is a contribution to engineering. A paper entitled "Action of Sulphates on the Components of Portland Cement" by Thorvaldson, Vigfusson and Larmour was presented to the Royal Society of Canada in May and appears in the 1927 Proceedings of that Society. This paper deals with the action of sulphates on the supposed constituents of Portland cement, and of the action on a synthetic cement made from the pure compounds, and presents some interesting and significant observations. A fourth paper on "The Action of Sulphate Solutions on High Alumina Cements" by Thorvaldson and Wolochow is ready for publication.

Up to the present eleven scientific papers have been prepared on various aspects of the chemical research, besides many reports similar to that now presented, which have been made to the annual meetings of the Institute and Branch meetings. In all we have published through the agency of this Committee some twenty-five papers, reports and articles on both the physical and chemical work since we started this work.

Field Work

When organizing the investigational work to be undertaken by this Committee in 1921, the members agreed that previous investigations, notably those of the Bureau of Standards, Washington, as well as the tests of several of the members of this Committee, had established certain facts regarding the disintegration of concrete by so-called alkali waters as follows:—

(1) That normal Portland cement concrete will be disintegrated if subjected to an "alkali" solution of sufficient concentration.

(2) That the better the concrete (i.e. the richer in cement content, the stronger, the more impermeable) the greater its resistance to alkali action.

(3) That none of the so-called alkali-proofing compounds either of the integral or surface type gave immunity.

(4) That the concentration and composition of ground waters in the field varied widely within a comparatively short radius and over periods of time.

(5) That in the absence of any real understanding of the nature of the reactions and in the light of the above facts *that conclusions based on small differences in rate of decay of field specimens over a limited period of years must be accepted with reservations.*

The Committee then decided that there was nothing to be gained by undertaking extensive field tests at that time, and that it was wise to allocate the major portion of the funds to a fundamental chemical research, in an attempt to ascertain the real reason of the decay and to search for possible methods of preventing such action. It was decided, however, to undertake a limited programme of field tests in order to corroborate previous findings and try out new materials submitted.

Our experience gained during the past six years has only confirmed us in our previous judgment, and we feel that the results obtained from the chemical research have even now justified our programme, as the many valuable findings made by Dr. Thorvaldson and his assistants have given us sound scientific facts to support our original contention that the results of field tests must be interpreted with care to avoid arriving at false conclusions. Besides the contributions made to the general understanding of the chemistry of cements and its decay, all of which will be reported in full at a future date, we desire to mention here a few findings which have a bearing on the interpretation of the field tests.

(1) It was found that contrary to general opinion, the actions of $MgSO_4$ and $NaSO_4$ solutions on cements were fundamentally different, and that certain cements which were highly resistant to one of these solutions decayed rapidly in the other. This has explained many apparently contradictory tests under what were thought to be similar alkali conditions.

(2) It was found that changes in concentration of the sulphate solutions had very different effects on different brands of Portland cement of standard specification.

(3) It was found that the conditions under which the concrete was cured bear on the resistance to sulphate action.

(4) It was found that two cements might have equal resistance to a sulphate solution when exposed in 1-10 mortar bars but very different relative resistances to the same solution when 1-3 mortar bars were used.

(5) It has been found that Portland cements, all of which meet standard specifications, often vary greatly in their "resistance" to sulphate action. Mention should be made in this connection of the corroborative work of Mr. D. G. Miller* of the United States Department of Agriculture, who found with concrete cylinders of high strength (over 4,000 pounds per square inch) but made of different brands of cement, that after exposure for two years in alkali waters some of the cylinders were practically unaffected, while others were completely disintegrated.

(6) A development of an analytical method of distinguishing between "alkali action," "acid action" and "frost action" has made it possible to eliminate considerable uncertainties in field observations.

(7) Data gathered on the high concentrations sometimes obtained by means of capillary action and subsequent evaporation has shown that often an analysis of the water does not give a measure of the real exposure conditions.

(8) It has been found that neat Portland cement blocks fail, in a most extraordinary manner, when subjected to sulphate solutions, and are less resistant than rich concrete blocks.

We feel that if unwarranted and erroneous conclusions from our field tests are to be avoided, they must be properly interpreted.

Two appendices† to this report have therefore been prepared, and are now submitted herewith as separate papers.

In the first, (Appendix A), Dr. Thorvaldson discusses those portions of his chemical findings which bear upon the interpretation of the field tests, and the second, (Appendix B), gives in detail the results of the field tests as observed up to December 1927.

---

*Miller, Journal Am. Soc. Agr. Engrs., Feb. 1927.

†To be presented at the Technical Sessions of the General Professional Meeting.

Financial Statement

The following summary of expenditures and receipts as to December 1st, 1927, is submitted; a detail statement of expenditures from December 1st, 1925 to December 1st, 1926, is being sent to the financial supporters of the research.

It will be noted that our funds became exhausted early in the year.

Expenditures During Year Dec. 1st, 1926—Dec. 1st, 1927

General—Reprints of paper in Journal	$ 60.84	
Chemical—Salaries research assistants	1,182.50	
Research—Materials	1,238.51	
		$ 2,481.85

Total Expenditures to December 1st, 1927

General—Committee meetings, travelling expenses	$1,836.56	
Misc. telegrams, office expenses	414.69	
		$ 2,251.25
Physical Tests—Travelling allowance and expenses	$1,123.66	
Material, labour and equipment	1,745.67	
Freight and cartage	353.09	
		$ 3,222.42
Chemical Research—Travelling Expenses	$ 340.81	
Salaries research assistants	33,842.35	
Materials	8,165.10	
		$42,348.26
Total		$47,821.93

Total Receipts to December 1st, 1927

	1921	1922	1923	1924	1925	1926	1927	Total
Research Council	$5,000	$5,000	$5,000	......	......	$5,000	......	$20,000.00
Can. Cement Co.	3,000	3,000	3,000	......	2,997	......	......	11,997.00
Saskatchewan	3,000	3,000	3,000	......	......	......	......	9,000.00
Alberta	1,000	1,000	......	......	......	......	......	2,000.00
Can. Pac. Ry.	1,000	1,000	1,000	......	......	......	......	3,000.00
Winnipeg	200	200	300	......	......	......	......	700.00
Interest on Bank Account			139.41	422.14	190.65	193.71	179.02	1,124.93
Total receipts								$47,821.93

It will be noted that of the total money spent, over 70 per cent has been paid in salaries to laboratory assistants, which does not include any salary to the Director, who contributed his services, and that less than 5 per cent has been expended in overhead, including Committee meetings, etc., and considering the size of the Committee this seems quite small. We feel, therefore, that it may be justly claimed that the funds contributed have been well and efficiently used.

Respectfully submitted.

C. J. Mackenzie, m.e.i.c., *Chairman.*

Report of the E.I.C. Members of the Main Committee of the Canadian Engineering Standards Association

The President and Council:

The Institute's nominees on the Main Committee of the Canadian Engineering Standards Association are now as follows:—

Prof. C. M. McKergow, m.e.i.c. Retires March, 1928 (Renominated for three years)
Dean C. J. Mackenzie, m.e.i.c. " " 1929
Frederick B. Brown, m.e.i.c. " " 1930

The total number of active working committees and panels now stands at sixty-seven.

The arrangement with the National Research Council has been continued, whereby the Main Committee of the Association operates as an Associate Committee on Engineering Standards of the National Research Council. Under the understanding with the Research Council, a campaign for financial support was inaugurated and the sum of $5,171 was subscribed by various industrial firms who are interested or who have been associated with the work of the Association. This somewhat exceeds the amount set by the Research Council of $5,000.

The year has been marked by a great awakening of interest on the part of industry in the work of standardization and simplification, and technical papers and the press have co-operated in giving much valuable publicity to the work.

The first year-book of the Association was published in February, and has been very useful in promoting knowledge of the Association and its method of work. A quarterly bulletin was also inaugurated, the first issue appearing on March 31st. This serves as the official organ of the Association, and gives detailed information on the progress made by committees, the activities of the secretary, and a report on publicity and contact with industrial associations. It has been found very useful in the work, and many requests have been received for current copies as issued.

Publications Issued During 1927

A5-1927. Standard Specification for Portland Cement

A second edition of this specification was published during the summer, the only revision being an increase in the required minimum tensile strength for mortar briquettes. This has been increased from 200 to 225 pounds per square inch for seven-day tests, and from 300 to 325 for twenty-eight-day tests.

A20-1927. Standard Specification for Movable Bridges

This was published in October, 1927, and is an amplification of the section on movable bridges which appeared in the first specification for Steel Railway Bridges in 1920. It covers requirements for movable bridges of all types, such as special stresses, materials, attachments and operating equipment. It does not contain general specifications for bridges, but references to the Canadian Engineering Standards Association specifications for Steel Railway and Highway bridges are made in proper places.

C21-1927. Standard Specifications for Control Cable for Electrical Power Plant Equipment

This is a brief specification covering construction of control cable, and includes a colour code by means of which fifteen different conductors may be identified by the use of not more than two colours in the braid at any one time, and one standard design for the weave. This project was suggested by practical construction and operating men and the specification has already been used on several cable orders.

C22-1927. Canadian Electrical Code—Part I; Essential Requirements and Minimum Standards for Electrical Installations in, on or over Buildings Using Potentials of from 0-5000 Volts

This has been issued with the object of promoting uniform wiring regulations throughout Canada, as at the present time there is a great confusion between the rules now in operation in the different provinces. The Association has been working on this project since 1920, and the publication of the Code has been an outstanding event in the electrical field in Canada. It is a combined fire and personal safety code, and in this respect is unique; it has been based on the National Electrical Code, the National Electrical Safety Code, the Rules and Regulations of the Hydro-Electric Power Commission of Ontario, and many other provincial or municipal regulations. It has been very favourably received, and prospects for adoption in the different provinces are bright, for it has already been adopted in the province of Ontario and will shortly be adopted in the provinces of British Columbia and Quebec. Committees are now at work to promote the adoption of the Code in the Provinces of Alberta, Saskatchewan and Nova Scotia.

A complete list of the publications issued by the Association to date is as follows:—

A 1—1922	Standard Specifications for Steel Railway Bridges.
A1a—1922	Material Specifications, Steel Railway Bridges (reprint).
C 2—1920	Standard Requirements for Distribution Type Transformers.
C 3—1924	Standard Specification for Galvanized Telegraph and Telephone Wire.
B 4—1921	Standard Specification for Wire Rope for Mining, Dredging and Steam Shovel Purposes.
A 5—1927	Standard Specification for Portland Cement.
A 6—1922	Standard Specification for Steel Highway Bridges.
D 7—1922	Standard Specification for Flexible Steel Wire Rope and Strand for Aircraft Purposes.
G 8—1923	Standard General Specifications for Commercial Bar Steels.
A 9—1923	Standard Specifications for Reinforcing Materials for Concrete.
C10—1923	Standard Specification for Tungsten Incandescent Lamps.
D11—1924	Interim Report on the manufacture, Testing and Use of Gasoline.
B12—1924	Standard General Specification for Galvanized Steel Wire Strand.
E13—1924	Standard Specification for Railway Wire-Fencing and Gates.
C14—1924	Standard Specification for Reinforced Concrete Poles. .
C15—1924	Standard Specification for Eastern Cedar Poles.
A16—1924	Standard Specification for Steel Structures for Buildings.
C17—1925	Standard Requirements for A.C. Watthour Meters.
B18—1925	Standard Specifications for Stove Bolts.
A19—1926	Standard Classification of Items of Highway Expenditure.
A20—1927	Standard Specification for Movable Bridges.
C21—1927	Standard Specification for Control Cable.
C22—1927	Canadian Electrical Code—Part I.

Work in Progress

Civil Engineering and Construction

Concrete and Reinforced Concrete. Reports have been received from all the panels of this committee, and the first draft specification has now been prepared and will be considered by the committee at an early date.

Reinforcing Materials for Concrete. A list of recommended bars has been added to specification No. A9-1923.

Road Materials and Construction. Owing to pressure of other work, there has been no change in the status of the different specifications under this heading during the year, but it is hoped to take them up actively again this year.

Steel Railway Bridges. Final revisions to the specification for Steel Railway Bridges were considered by the committee on December 8th, and have been approved by letter ballot. Approval of the Sectional Committee and the Main Committee will now be obtained and copy for the revised specification is now being prepared. It has been decided to omit the specification for bridge paint until such time as a satisfactory arrangement can be made with the paint manufacturers.

Steel Highway Bridges. Revisions to the specification for Steel Highway Bridges are now being considered, and a new edition will be published during the coming year.

Steel Structures for Buildings. It will be necessary to issue a revised edition of this specification shortly, and the raising of the allowable unit stress from 16,000 to 18,000 pounds per square inch will be one of the features.

Mechanical Engineering

Machine Screws. A committee is now considering data sheets giving a reasonable list of machine screws for all practical purposes. The original list presented by the panel showed forty-three generally used machine screws on the market in Canada, but after discussion by the committee this has been reduced to eighteen, and it is probable that this revised list will be approved by the Committee.

Sheet Metal Gauges. Nothing further has been done on this project, but the Sheet Metal Exchange have sent out a circular to the trade, asking for approval of the adoption of a standard gauge for Canada. Nothing can be done until this approval has been received.

Cast Iron Pipe. The first draft specification was considered by the Committee on May 3rd, 1927, and revisions decided upon have been sent out to the committee again for comment. Arrangements are being made to carry out certain physical tests, from which it is expected to obtain data which can be used in the specification.

Electrical Engineering

Rating and Testing of Electrical Machinery. Reports have now been received from all three panels of this committee, and have been summarized and sent out to the members of the committee for comment. A meeting of the committee will be held to consider these reports on January 18th in Toronto.

Automotive Work

Traffic Signals for Highways. This project has been held up owing to a difference of opinion on colours for signals, and arrangements have been made for co-operation with the Canadian Good Roads Association at a conference in Quebec in January, when it is hoped to come to some satisfactory agreement on this question.

Ferrous Metals

Steel Castings. A report from the panel appointed to prepare a specification was reviewed by the committee at a meeting in Montreal on November 18th, and it has been proposed to follow the latest American Society for Testing Materials specification, but to add a section dealing with castings subject to heavy duty such as rotating parts of machines, housings, etc. A complete draft specification has now been prepared and is before the members of the committee for their comment.

Sampling for Check Analysis. Forging Quality of Bar and Billet Steel. A committee has been working jointly on these two projects, and has held two meetings during the year in Toronto, as a result of which a final draft specification is now before the members of the committee for comment. It is hoped to issue these specifications shortly.

Co-operation

Co-operation with other standardizing bodies has been fairly active, especially with the British Engineering Standards Association and the American Engineering Standards Committee. The support received from industry during the year has been very encouraging, especially in the obtaining of the objective set by the 1927 budget. Many requests have been received for representation on working committees, and enquiries for copies of the Year Book and the Bulletin and orders for publications have been particularly numerous towards the end of the year.

The Association is deeply indebted to those who have voluntarily given their time and experience in the work of the various committees and in the preparation of the specifications published during the year.

Respectfully submitted,

C. M. McKergow, M.E.I.C.
C. J. Mackenzie, M.E.I.C.
Frederick B. Brown, M.E.I.C.

Branch Reports

Border Cities Branch

The President and Council,—

There were seven regular meetings throughout the year, with an average attendance of 20 members, this figure includes members who may not have attended the dinner but who came only to the address. I am sure this attendance record is not a source of pride or gratification, since last year the average attendance was reported as 31, with a total membership of 130, whereas this year our membership totals 135.

The credit balance of the branch has increased from $101.92 on December 16th, 1926, to $201.17 at the present time; representing an increase of $99.25, which includes rebates, branch dues, etc., to the end of the year.

Meetings

Papers and addresses of the year are as follows:—

Jan. 14.—"**Street Car and Bus Transportation,**" by W. R. Robertson, general superintendent of railways, Hydro-Electric Power Commission of Ontario.

Feb. 11.—Charles F. Craig, of the American Brass Co., of Detroit, who presented the Anaconda film "**From Mine to Consumer.**"

Mar. 11.—The U.S. Steel Products Co. presented the film "**The Story of Steel.**"

Apr. 22.—"**The Manufacture of Modern Newsprint,**" by T. L. Crossley, A.M.E.I.C.

May 20.—"**Accident Prevention,**" by W. H. Cox, secretary of Essex and Kent Division of the Accident Prevention Association.

Oct. 14.—Col. H. C. Boyden, of Celite Products of Los Angeles.

Nov. 11.—"**The Evolution of Brickmaking,**" by E. C. Glenn, of Cooksville Brick Co.

Committees

The branch activities for the year were in the hands of the following committees:—

Papers	E. G. Ryley, A.M.E.I.C. (Chairman)
	E. A. Stone, M.E.I.C.
	O. Rolfson, A.M.E.I.C.
Entertainment	R. J. Desmarais, A.M.E.I.C. (Chairman)
	W. B. Pennock, Jr.E.I.C.
	R. C. Leslie, Jr.E.I.C.
	W. A. Messenger, S.E.I.C.
	J. H. Bradley, A.M.E.I.C.
Membership	A. E. West, A.M.E.I.C. (Chairman)
	Fred. Stevens, A.M.E.I.C.
	G. V. Davies, A.M.E.I.C.
	H. J. Coulter, Jr.E.I.C.
By-laws	Harvey Thorne, M.E.I.C.
Publicity	J. Clark Keith, A.M.E.I.C.
Nominating	M. E. Brian, A.M.E.I.C.
Assistant Secretary	A. W. Hammersley, A.M.E.I.C.

The thanks of the secretary are gratefully tendered to the chairmen and all the committees, and especially to Mr. Hammersley, who assisted in the sending out of the cards during the spring term.

Calgary Branch

The President and Council,—

On behalf of the Executive Committee, we beg to submit the following report on the activities of the Calgary Branch for the year ending December 31st, 1927:—

Officers

The slate of officers elected on March 13th, 1926, held office until March 12th, 1927. The following is a list of the officers elected on March 12th, 1927, for the branch year 1927-1928:—

Chairman	F. K. Beach, A.M.E.I.C.
Vice-Chairman	Thos. Lees, A.M.E.I.C.
Secretary-Treasurer	H. R. Carscallen, A.M.E.I.C.
Committee	J. H. Ross, A.M.E.I.C., Past-Chairman
	F. J. Robertson, A.M.E.I.C.
	J. J. Hanna, A.M.E.I.C.
	F. M. Steel, M.E.I.C.
Ex-officio	S. G. Porter, M.E.I.C.
	A. L. Ford, M.E.I.C.
Auditors	O. H. Hoover, A.M.E.I.C.
	J. C. Milligan, A.M.E.I.C.
Branch Editor	W. St. J. Miller, A.M.E.I.C.

Membership

The membership of the branch is as follows:—

	Resident	Non-Resident	Total as at Dec. 31, 1927	Total at end previous year
Members	20	6	26	25
Associate Members	47	23	70	66
Juniors	3	1	4	6
Students	1	1	2	3
Branch Affiliates	14	..	14	16
Totals	85	31	116	116

Meetings

Seven executive meetings were held during the year in taking care of the business of the branch.

General meetings, dinners, inspections, trips, etc., were as follows:—

Jan. 5.—Annual dinner.

Jan. 20.—"**Mining at Kimberly and Smelting Operations at Trail,**" by B. L. Thorne, M.E.I.C., Coal Mines Branch, Canadian Pacific Railways, Department of Natural Resources, Calgary.

Feb. 4.—"**The Coming Biological Age,**" by Dr. R. W. Boyle, F.R.S.C., M.E.I.C., Dean of the Faculty of Applied Science, University of Alberta.

Feb. 17.—"**Forest Conservation and Timber Preservation,**" by A. S. Dawson, M.E.I.C., chief engineer, Canadian Pacific Railway, Department of Natural Resources.

Mar. 3.—"**The Development of the Art of Communication,**" by A. M. Mitchell, auditor, Alberta Government Telephones, Edmonton.

Mar. 12.—Annual meeting.

June 4.—Inspection of the new plant of the Riverside Ironworks, Limited, Calgary.

June 25.—Inspection of local exchanges of the Alberta Government Telephone System.

Aug. 20.—Picnic to Calgary Power Company's plants, Seebe, Alberta.

Sept. 3.—Dinner and special meeting to discuss items on the proposed agenda of the Plenary Meeting of Council in Montreal, October 10, 11 and 12. Representatives from the Edmonton and Lethbridge Branches attended.

Oct. 27.—Dance at the Palliser hotel.

Nov. 16.—"**The Manufacture of Cement,**" by W. D. Armstrong, A.M.E.I.C., superintendent of Canada Cement Company, Exshaw, Alta.

Dec. 8.—"**The Geology of the Foothills in Relation to Petroleum,**" by Dr. John A. Allan, Professor of Geology, University of Alberta.

The average attendance at the above meetings was 52.

Cape Breton Branch

The President and Council,—

The Executive Committee of the Cape Breton Branch submits the following report of the branch activities for the year 1927:—

The annual dinner was held December 6th, 1927, and W. E. Clarke, M.E.I.C., was appointed chairman.

The following compose the Executive Committee:—

Chairman	W. E. Clarke, M.E.I.C.
Vice-Chairman	M. Dwyer, A.M.E.I.C.
Secretary-Treasurer	E. L. Ganter, A.M.E.I.C.
Executive	S. C. Mifflen, A.M.E.I.C.
	W. J. Ripley, M.E.I.C.
Ex-officio	W. S. Wilson, A.M.E.I.C.
	W. C. Risley, M.E.I.C.

The number of resident branch members last year was 36; it is now 37.

The following meetings were held during the year:—

Jan. 31.—"**Welland Ship Canal,**" by Alex. J. Grant, M.E.I.C., Department of Railways and Canals.

Feb. 8.—"**Sidelights of Radio Broadcasting,**" by F. W. Johnson, Northern Electric Company, Halifax.

Mar. 8.—"**Telephone Transmission,**" by W. E. Jefferson, Maritime Telephone and Telegraph Company, Halifax.

May 17.—"**Electric Motors for Various Applications,**" by C. H. Wright, M.E.I.C., Canadian General Electric Company, Halifax.

"**Industrial Motor Control,**" by A. G. Turnbull, Canadian General Electric Company.

Dec. 15.—"**Motion Pictures on Wireless and Transformer Construction.**"

On September 10th the Second Triennial Congress paid a visit to Sydney, and our Institute, combined with the Mining Society of Nova Scotia, conducted the party on an inspection trip of the Dominion Iron and Steel Company's plant and the coal mines of the Dominion Coal Company.

Edmonton Branch

The President and Council,—

The Executive Committee of the Edmonton Branch begs to submit herewith the following report on the activities of the branch during the year 1927.

Officers

The branch officers, elected on April 16th and approved by Council on May 20th, for the branch year 1927-28, were as follows:—

Chairman	A. I. Payne, M.E.I.C.
Vice-Chairman	W. R. Mount, A.M.E.I.C.
Secretary-Treasurer	H. R. Webb, Jr.E.I.C.
Committee	C. A. Robb, M.E.I.C.
	H. P. Keith, A.M.E.I.C.
	R. W. Ross, A.M.E.I.C.
	W. J. Cunningham, A.M.E.I.C.
Ex-officio	T. W. White, A.M.E.I.C.
	R. W. Boyle, M.E.I.C.

Meetings

Four Executive Committee meetings were held during the year. A programme committee consisting of C. A. Robb, M.E.I.C., R. W. Ross, A.M.E.I.C., and H. R. Webb, Jr.E.I.C., was appointed to develop the programme of meetings for the winter season, 1927-28.

Lectures and papers given before the branch were as follows:—

Mar. 14.—"**Forest Conservation and Timber Preservation,**" by A. S. Dawson, M.E.I.C., chief engineer, Department of Natural Resources, Canadian Pacific Railway, Calgary, Alberta. Attendance, 45.

Oct. 17.—"**Timber Conservation,**" by R. W. Ross, A.M.E.I.C., division engineer, Canadian National Railways, Edmonton, Alberta. Attendance, 20.

Nov. 21.—"**The St. Lawrence Waterway,**" by Dr. D. A. MacGibbon, professor of political economy at the University of Alberta, Edmonton. Attendance, 40.

Dec. 19.—"**Fuel vs. Water Power for the Generation of Electrical Power.**" This was the subject of an open discussion. The discussion was led by N. C. Pitcher, professor of mining engineering at the University of Alberta, and W. J. Cunningham, A.M.E.I.C., superintendent of the city power plant and street railway department, Edmonton. It was expected that R. A. Brown and G. H. Thompson, A.M.E.I.C., of Calgary, would help lead the discussion, but they were unable to attend. Attendance, 55.

A special meeting was held on July 18th on the occasion of the visit of R. J. Durley, M.E.I.C., general secretary. Mr. Durley addressed the meeting on the forthcoming Plenary Council Meeting in October, and his remarks were much appreciated by all.

All except the March meeting were preceded by branch dinners.

We would like to mention that special co-operation between the Northern Alberta branch of the Canadian Institute of Mining and Metallurgy and the Edmonton Branch of The Engineering Institute of Canada is bringing good results in stimulating interest and attendance. Meetings of the two branches alternate on the first and third Mondays of each month. A common programme was printed and distributed to members of both bodies and members of both Institutes are invited to all meetings. The December meeting mentioned above was arranged as a joint meeting.

MEMBERSHIP

The branch membership now stands as follows:—

	Resident	Non-resident
Members	16	3
Associate Members	28	6
Juniors	3	2
Students	9	1
Branch Affiliates	2	0
Total	70	

Increased interest in branch activities on the part of engineering students at the University of Alberta has been quite apparent this season.

Halifax Branch

The President and Council,—

During the year 1927 the Halifax Branch held six meetings; five regular monthly meetings and the annual meeting and dinner, as follows:—

Jan. 6.—"**The Life of Sir Sanford Fleming,**" by Capt. The Hon. J. F. Cahan, A.M.E.I.C. Attendance, 46.

Jan. 27.—"**Welland Ship Canal,**" by Alex. J. Grant, M.E.I.C. Attendance, 50.

Mar. 4.—"**Maintenance of Gravel Roads,**" by Lieut.-Col. J. M. Miller; "**Construction of Gravel Roads,**" by A. B. Blanchard, M.E.I.C.; "**Highway Bridges,**" by J. E. Belliveau, A.M.E.I.C.; "**Prevention of Dust,**" by H. F. Laurence, M.E.I.C. Attendance, 35.

Oct. 20.—"**Engineering Education,**" by Prof. F. R. Faulkner, M.E.I.C. Attendance, 38.

Nov. 24.—"**Canadian History,**" by H. F. Munro, Ph.D. Attendance, 27.

Dec. 22.—Annual meeting and dinner. "**Subjects for Engineering Research,**" by Hon. Mr. Justice Mellish. Attendance, 73.

Hamilton Branch

The President and Council,—

The Executive Committee of the Hamilton Branch submit the following report for the year 1927:—

OFFICERS

The branch year dates from June 1st, but this year the same executive exists for each half-year.

Chairman	L. W. Gill, M.E.I.C.	
Vice-Chairman	W. L. McFaul, M.E.I.C.	
Secretary-Treasurer and Councillor	W. F. McLaren, M.E.I.C.	
Members	H. A. Lumsden, M.E.I.C.	(1 yr.)
	G. R. Marston, A.M.E.I.C.	(1 yr.)
	F. P. Adams, A.M.E.I.C.	(2 yrs.)
	A. H. Munson, A.M.E.I.C.	(2 yrs.)
Branch News Editor	J. R. Dunbar, A.M.E.I.C.	
Past Chairman	C. J. Nicholson, A.M.E.I.C.	
Past Secretary-Treasurer	H. B. Stuart, A.M.E.I.C.	

MEETINGS

The following meetings were held:—

Jan. 7.—"**Arc Welding of Structural Steel Buildings,**" by A. M. Candy, of the Westinghouse Company, Pittsburgh, Pa. Attendance, 200.

Jan. 26.—"**Engineering Works and Traffic on the Great Lakes,**" by Lieut.-Col. H. J. Lamb, D.S.O., M.E.I.C. Attendance, 50.

Feb. 16.—"**Electric Control of Bridges,**" by J. P. Fraser; "**Street Illumination,**" by G. F. Mudgett; "**The Manufacture of Pig Iron,**" by H. G. Girvin; "**Traffic Signals,**" by A. R. Hannaford, A.M.E.I.C. Attendance, 45.

Mar. 16.—"**The Determination of the Strength of Concrete,**" by A. M. Jackson, A.M.E.I.C.; "**The Sewage Disposal Plant at Kitchener,**" by Stanley Shupe, M.E.I.C.; "**Caterpillar Tractors,**" by W. H. Mackie. Attendance, 30.

Apr. 22.—"**A Mechanical Analogy of Transmission Line Characteristics,**" by R. C. Bergvall, of the Westinghouse Company, Pittsburgh. This was the annual joint meeting with the Toronto Branch of the A.I.E.E., held in the Westinghouse auditorium. Attendance, 187.

Sept. 19, 21 and 22.—"**The Design and Control of Concrete Mixtures,**" by Rufus S. Phillips, of the Lewis Institute, Chicago. Attendance, 50.

Oct. 28.—Inspection trip to Welland Ship Canal under the auspices of the Niagara Peninsula Branch, followed by dinner at the Welland House, St. Catharines, and a meeting afterwards at the Collegiate Institute, where addresses were given as follows:—
"**The Welland Ship Canal,**" by A. J. Grant, M.E.I.C.
"**Conserving Niagara Falls,**" by F. D. Corey.
"**St. Lawrence Power,**" by H. G. Acres, M.E.I.C.
"**The Peace Bridge,**" by Mr. Lupfer.

Dec. 12.—"**Aviation,**" by Major-Gen. J. H. MacBrien, C.B., C.M.G., D.S.O. Attendance, 50.
About 35 were present from the Hamilton Branch.

Kingston Branch

The President and Council,—

The Executive Committee of the Kingston Branch begs to submit the following report for the year 1927.

During the year five papers were presented to the branch, as follows:—

Feb. 1.—"**Petroleum, With Particular Reference to Western Canada,**" by Dr. Bruce Rose, of the geology department, Queen's University.

Mar. 11.—"**The Lighthouse Service of Canada,**" by J. G. Macphail, M.E.I.C., commissioner of lights in the Department of Marine and Fisheries, Dominion Government, Ottawa.

Mar. 23.—"**Long Span Bridges,**" by Prof. C. R. Young, M.E.I.C., of the department of civil engineering, University of Toronto.

Oct. 18.—"**The Differential Vacuum System of Steam Heating,**" by Mr. M. W. Shears, heating engineer of the C. A. Dunham Company, Limited, Toronto.

Dec. 6.—"**Ice Engineering,**" by Professor Howard T. Barnes, M.E.I.C., of the physics department of McGill University.

Lakehead Branch

The President and Council,—

On behalf of the Executive Committee, I beg to submit the following annual report of the Lakehead Branch of The Engineering Institute of Canada:—

Membership

On January 1st, 1927, there were 36 corporate members and 8 non-corporate members, and on December 31st, 1927, there were 39 corporate members and 13 non-corporate members, showing a gain during the year of 3 corporate and 5 non-corporate members.

Meetings

Two meetings were held during the year, due to the fact that there was a big boom in construction work in the district, which kept our members very busy, and also, the Lakehead Branch, taking in the two cities of Port Arthur and Fort William, each with its separate service clubs and other organizations, is a difficult branch at which to find a night suitable to the members of both cities.

May 18.—A business meeting of the branch was held, after which the members joined the Port Arthur Chamber of Commerce at a luncheon at the Prince Arthur hotel, at which Prof. Wallace, of Manitoba University, gave a most interesting talk on "**Northland Development.**"

July 11.—Our General Secretary, R. J. Durley, M.E.I.C., arrived. Some of our members took him around the harbour in a yacht and later entertained him at luncheon.

Officers

The officers for the past year were as follows:—

Chairman	C. B. Symes, A.M.E.I.C.
Vice-Chairman	D. G. Calvert, A.M.E.I.C.
Secretary-Treasurer	Geo. P. Brophy, A.M.E.I.C.
Executive Committee	D. C. Chisholm, M.E.I.C.
	J. C. Meader, A.M.E.I.C.
	W. H. Souba, M.E.I.C.
	G. R. Duncan, A.M.E.I.C.

Financial Statement

Receipts

Balance in bank, Dec. 31, 1926	$130.96	
Rebates on fees	69.90	
" due and not deposited	8.40	
Interest	3.19	
		$212.45

Expenditures

Telegrams	$ 2.19	
Postage	3.00	
Printing	1.60	
Sundries	30.89	
Balance in bank, Dec. 31, 1927	174.77	
		$212.45

The following members were nominated in connection with the annual elections of The Institute for Councillors to represent the Lakehead Branch on the Council of The Institute:—

R. B. Chandler, M.E.I.C., Port Arthur.
G. R. Duncan, A.M.E.I.C., Fort William.

Respectfully submitted,

Geo. P. Brophy, A.M.E.I.C., *Secretary-Treasurer.*

Lethbridge Branch

The President and Council,—

On behalf of the Executive Committee of the Lethbridge Branch, the following report for the year ending December 31st, 1927, is submitted:—

The annual meeting of the branch was held on March 19th, 1927, at the conclusion of a most interesting and instructive season.

Officers

In the selection of new officers for the year 1927-28, the following gentlemen were elected:—

Chairman	Geo. S. Brown, A.M.E.I.C.
Vice-Chairman	N. Marshall, M.E.I.C.
Secretary-Treasurer	Wm. Meldrum, A.M.E.I.C.
Executive	N. H. Bradley, A.M.E.I.C.
	C. S. Clendening, A.M.E.I.C.
	J. B. deHart, M.E.I.C.
Ex-officio	J. T. Watson, A.M.E.I.C.
	R. Livingstone, M.E.I.C.
Auditors	C. S. Clendening, A.M.E.I.C.
	W. L. McKenzie, A.M.E.I.C.

During the year the branch lost the support of one of our most active members, J. T. Watson, A.M.E.I.C., who was chairman during the previous year, he having accepted the position of superintendent of the steam power plant of the East Kootenay Electric Light and Power Company.

MEETINGS

Five executive meetings were held during the year and ten regular meetings, with an average attendance at the latter of 35.

Jan 8.—"**Field Control of Strength of Concrete by Water Cement Ratio,**" by K. MacKenzie, service engineer, Canada Cement Company, Winnipeg.

Jan. 22.—"**Water Power Development in Canada,**" by A. L. Ford, M.E.I.C., district chief engineer, Water Power Branch, Department of the Interior, Calgary.

Feb. 5.—"**Irrigation Possibilities of Southern Alberta,**" by B. Russell, M.E.I.C., reclamation engineer, Department of the Interior, Calgary.

Feb. 19.—"**Artillery Development in the Late War,**" by Brig.-Gen. J. S. Stewart, D.S.O., Lethbridge.

Mar. 5.—"**Mine Timber Tests,**" by Prof. R. S. L. Wilson, M.E.I.C., University of Alberta, Edmonton.

Mar. 19.—Annual meeting.

Oct. 15.—"**Explosives,**" by C. E. Wood, Canadian Giant, Limited, Calgary.

Oct. 29.—"**Power Plant and Combustion Problems,**" by J. G. Hall, A.M.E.I.C., Combustion Engineering Corporation, Winnipeg.

Nov. 12.—"**Methods of Printing, Past and Present,**" by F. T. Robins, Robins Printing Company, Lethbridge.

Dec. 10.—"**Highway Construction and Maintenance,**" by N. H. Bradley, A.M.E.I.C., district engineer, Department of Public Works, Alberta Government, Lethbridge.

MEMBERSHIP

The membership of the branch is as follows:—

	Residents	Non-residents	Total

WM. MELDRUM, A.M.E.I.C., *Secretary-Treasurer.*

London Branch

The President and Council,—

On behalf of the Executive Committee of the London Branch, we beg to submit the following report for the year ending December 31st, 1927:—

During the year there were eight executive meetings, nine general meetings, a smoker and social, an inspection trip and a course of three lectures on concrete.

The year's activities began with the annual dinner meeting, held at the Blue Dragon Tea Room. Brig.-Gen. C. J. Armstrong, M.E.I.C., was the speaker and his subject was "**Some Military Engineering in the Great War.**" Solos were rendered during the meeting and the members joined in songs from The Institute's Song Sheet.

On February 23rd the members and friends gathered at the Armouries Annex for a smoker and social evening, as the guests of the 7th Field Company, Canadian Engineers. Entertainment and lunch proved an excellent means of promoting comradeship and good feeling among the members and of stimulating interest in the local branch.

A regular meeting was held in the board room of the Public Utilities Commission on March 16th. A very interesting paper on "**Recent Progress in Electric Welding**" was given by R. E. Smythies, M.E.I.C., of the Lincoln Electric Company. The paper was illustrated with lantern slides.

A special meeting was held in the city engineer's office on March 30th, at which Mr. Mackie, of the Best and Holt Caterpillar Tractor Company, showed moving pictures of tractors on various engineering jobs.

The April meeting, held on April 23rd, included an inspection trip to two of London's sewage disposal plants,—the South End plant and the East End plant,—where W. M. Veitch, A.M.E.I.C., engineer of sewage disposal for London, acted as guide. Following the visit to the plants, Mr. Veitch read a paper on "**The Principles of Sewage Disposal.**" At 6.00 o'clock lunch was served at the Armouries Annex.

The regular May meeting, on May 16th, was held in the Board of Education room in the Public Utilities Building. The branch was honoured by the presence of General Secretary R. J. Durley, M.E.I.C., who addressed the members on Headquarters' matters. E. Viens, M.E.I.C., director of testing laboratories, Department of Public Works of Canada, gave a paper on "**The Principles Involved in the Making of Economically Durable Concrete.**" The results of tests under Mr. Viens' direction proved very interesting.

An inspection trip was conducted on May 19th, when members of the branch were allowed to inspect the new Hotel London and the London Life building, both in course of construction. This inspection was made possible through the courtesy of the architects, John M. Moore and Company.

For the annual inspection trip the members of the branch motored to the New Peace bridge and the Horton Steel Works. The trip was arranged for August 6th and 7th to include the official opening of the bridge. The cars left London Saturday morning and returned Sunday evening.

On September 27th, 28th and 29th a course of three lectures on "**The Design and Control of Concrete Mixtures**" was given at the London Technical School. These lectures were given by arrangement with the Portland Cement Association by their lecturer, Mr. R. S. Phillips.

The October meeting was combined with an inspection trip to the quarries of the Beachville White Lime Company on Saturday, October 15th. The party motored to Beachville for the inspection and then to Woodstock, where supper was served at the Hotel Oxford and a paper by Mr. Bruce Matson, of the Beachville White Lime Company, on "**Limestone and Its Derivatives**" was read.

An address by D. M. Bright, A.M.E.I.C., on "**Electric Steam Generation**" was given at the regular meeting on November 23rd. The members were also interested in a full report of the recent Plenary Session of Council, given by W. C. Miller, A.M.E.I.C., the branch representative on Council.

The last meeting of the year was held in the Public Utilities board room on December 28th. Jas A. Vance, A.M.E.I.C., vice-chairman of the branch, gave an interesting talk on highway and bridge contracts with which he had been connected during fifteen years of engineering and contracting. The address was illustrated with photographs showing various phases of the work on these jobs. During a social hour at the end of the meeting, light refreshments were served.

The average attendance at meetings during the year showed an increase of fifteen over the previous year. It has been the policy of the branch to invite to its meetings many contractors, architects and others who might be interested in the subjects to be discussed.

MEMBERSHIP

The membership of the London Branch is as follows:—

	1926	1927
Members	12	13
Associate Members	30	31
Juniors	6	5
Students	10	12
Affiliates	..	1
Total	58	62

FINANCIAL STATEMENT

(For year ending December 31st, 1927)

Receipts

Balance in bank, Jan. 1, 1927	$181.79	
Collections from members at dinners	38.00	
Rebates from Headquarters:		
Dues	91.50

Total expenditures		$338.84

We have examined the above statement prepared by the secretary-treasurer and find the same to be a correct and true account of the financial standing of the London Branch.

W. R. SMITH, A.M.E.I.C. }
R. W. GARRETT, A.M.E.I.C. } Auditors.

Respectfully submitted,

JNO. R. ROSTRON, A.M.E.I.C., *Chairman.*
FRANK C. BALL, A.M.E.I.C., *Secretary-Treasurer.*

Moncton Branch

The President and Council,—

On behalf of the Executive Committee, we beg to submit the eighth annual report of the Moncton Branch.

The Executive Committee held nine meetings during the year. There were ten meetings of the branch held, seven of which were supper-meetings, and one was open to the public. One meeting was held at Sackville for the benefit of the engineering students of Mount Allison University.

Our membership at present consists of 54 members, as follows:—

	Resident	Non-resident
Members	8	2
Associate Members	23	6
Juniors	3	2
Students	6	3
Affiliates	1	..
Totals	41	13

The annual meeting of the branch was held on May 19th, 1927. The following officers were elected for 1927-28:—

Chairman	G. C. Torrens, A.M.E.I.C.
Vice-Chairman	H. J. Crudge, A.M.E.I.C.
Secretary-Treasurer	V. C. Blackett, A.M.E.I.C.
Executive Committee,	E. T. Cain, A.M.E.I.C.
	M. J. Murphy, A.M.E.I.C.
	H. B. Titus, A.M.E.I.C.

The members of the executive committee in addition to the above are as follows:—

Jas. Pullar, A.M.E.I.C.
G. E. Smith, A.M.E.I.C.
F. L. West, M.E.I.C.
A. S. Gunn, A.M.E.I.C. (*Ex-officio*)
H. W. McKiel, M.E.I.C. (*Ex-officio*)

FINANCIAL STATEMENT

The financial statement for the year ending December 31st, 1927, is as follows:—

Revenue

Balance in bank, Jan. 1, 1927	$ 59.38	
Cash on hand	7.33	
Rebates on dues and branch news	110.35	
Tickets sold for supper-meetings	158.00	
Bank interest	2.03	
Rebates due from Headquarters	5.40	
		$342.49

Expenditures

Expenses of meetings	$163.25	
Postage	5.00	
Printing and advertising	31.05	
Telegrams and telephones	3.95	
Express charges	6.72	
Miscellaneous	10.22	
Balance in bank	114.29	
Cash on hand	2.61	
Rebates due from Headquarters	5.40	
		$342.49

Respectfully submitted,

G. C. TORRENS, A.M.E.I.C., *Chairman.*
V. C. BLACKETT, A.M.E.I.C., *Secretary-Treasurer.*

Montreal Branch

The President and Council,—

On behalf of the Executive Committee, we beg to make the following report covering the activities of the Montreal Branch for the year 1927:—

The personnel of the Executive Committe was comprised as follows:—

C. V. Christie, M.E.I.C.	Chairman, 1927.	
F. C. Laberge, M.E.I.C.	Vice-Chairman, 1927.	
A. Duperron, M.E.I.C.	Elected, 1926.	
A. R. Ketterson, A.M.E.I.C.	" "	
J. A. McCrory, M.E.I.C.	" "	
J. G. Caron, A.M.E.I.C.	" 1927.	
D. Hillman, M.E.I.C.	" "	
D. C. Tennant, M.E.I.C.	" "	
C. K. McLeod, A.M.E.I.C.	Secretary-Treasurer.	
J. M. R. Fairbairn, M.E.I.C.	*Ex-officio,* Past President, E.I.C.	
Arthur Surveyer, M.E.I.C.	" " " "	
C. J. Desbaillets, M.E.I.C.	" " Branch Chairman.	
W. C. Adams, M.E.I.C.	" Councillor, E.I.C.	
J. L. Busfield, M.E.I.C.	" " "	
J. T. Farmer, M.E.I.C.	" " "	
J. H. Hunter, M.E.I.C.	" " "	
Geo. R. MacLeod, M.E.I.C.	" " "	
C. M. McKergow, M.E.I.C.	" " "	
P. L. Pratley, M.E.I.C.	" " "	

The Executive Committee met nine times during the year, and the attendance at all meetings was good, the average attendance being 10. R. J. Durley, M.E.I.C., attended several of these meetings throughout the year.

PAPERS AND MEETINGS COMMITTEE

The Papers and Meetings Committee consisted of a chairman, vice-chairman, together with the chairman and vice-chairman of the various sections of the branch. In order to co-relate the activities of the Papers and Meetings Committee with the Executive Committee, the chairman was chosen from the Executive of the branch. The following is the personnel of this Committee:—

Chairman — A. Duperron, M.E.I.C.
Vice-Chairman — G. A. Wallace, A.M.E.I.C.

Civil Section	J. S. Hall, A.M.E.I.C.	Chairman
	H. Massue, A.M.E.I.C.	Vice-Chairman
Electrical Section	L. A. Kenyon, A.M.E.I.C.	Chairman
	N. L. Morgan, A.M.E.I.C.	Vice-Chairman

Mechanical Section	F. S. B. Heward, A.M.E.I.C.	Chairman
	G. H. Dickson, A.M.E.I.C.	Vice-Chairman
Municipal Section	J. F. Brett, A.M.E.I.C.	Chairman
	J. A. Jette, M.E.I.C.	Vice-Chairman
Railway Section	J. A. Ellis, A.M.E.I.C.	Chairman
	J. H. Forbes, A.M.E.I.C.	Vice-Chairman
Students' Section	A. N. Budden, Jr.E.I.C.	Chairman
	Marc Boyer, S.E.I.C.	Vice-Chairman

The meetings for the first half of the year were arranged by the 1926 committee. The meetings from October 1st to April 26th have been arranged by Mr. Duperron's committee.

The complete list of all these meetings with the details of the papers and the names of the authors is appended.

The general attendance at these meetings has not been very large, and it would seem that a concentrated effort should be made by the more active members to arouse the interest of other members, and to encourage attendance.

This matter is given fuller attention in the report of the Reception Committee, an extract of which is as follows:—

"There has been a gradual falling-off in attendance during the past two years, the average total attendance for 1925 being 110, for 1926, 98, and for 1927, 92. This would appear to be entirely out of keeping with the total resident membership of the branch and with the quality of the papers presented.

"Out of a total resident membership numbering approximately 1,000, 475 have not registered attendance at a single meeting in the last two years, and a further 415 have not registered at more than five meetings in the same period. It would therefore appear that only about ten per cent of the membership can be considered as being active."

Membership

The membership of the branch is given in the following table, and shows no appreciable change from last year except a slight increase in the number of resident Associate Members:—

		1924	1925	1926	1927
Honorary Member	Resident	1	1	1	1
Members	Resident	205	212	217	224
	Non-resident	16	15	8	9
Associate Members	Resident	410	406	399	413
	Non-resident	46	48	24	25
Juniors	Resident	70	65	76	79
	Non-resident	13	12	8	8
Students	Resident	285	280	249	212
	Non-resident	30	35	7	11
Affiliates	Institute	10	11	14	17
	Branch	28	20	19	22
	Total	1,114	1,105	1,022	1,021

Membership Committee

A Membership Committee was appointed under the chairmanship of D. C. Tennant, M.E.I.C., and their efforts have met with considerable success. There is an increase of seven in the resident members and of fourteen in the number of resident associate members, the total membership of the branch standing at 1,021, as against 1,023 reported a year ago. Due to the policy of Headquarters of removing from the lists those members who have been constantly in arrears in the payment of dues, there has been a large number of names dropped from the roll. Therefore, the fact that there is no appreciable decrease in the membership shows that the Membership Committee has done good work.

It is with deepest regret that we have to record the loss to the branch, by death, during the past year of the following members:—

B. J. Forrest, M.E.I.C.
W. L. Scott, M.E.I.C.
G. C. Read, A.M.E.I.C.
R. C. Forbes, S.E.I.C.

Reception Committee

The Reception Committee, under the chairmanship of H. G. Thompson, Jr.E.I.C., was composed of the following members:—

A. B. Rogers, A.M.E.I.C.
E. T. Harbert, S.E.I.C.
J. B. O. Saint-Laurent, A.M.E.I.C.
D. K. Addie, Jr.E.I.C.
T. M. Dechene, A.M.E.I.C.
W. V. Cheshire, S.E.I.C.

Members of this committee have been on hand at every meeting of the branch, and have added materially to the sociability of the meetings. It is recommended that members bringing in visitors or other members not acquainted with the membership as a whole should make use of this committee on Thursday evenings.

In addition, this committee has kept a record of the attendance at the meetings, the results of which are remarked upon in more detail above.

Publicity Committee

The Publicity Committee, composed of two members,—H. W. B. Swabey, M.E.I.C., and Wm. McG. Gardner, A.M.E.I.C.,—has devoted its attention mainly to reporting particulars of the meetings for the Journal, including a synopsis of the papers presented. They have also been active in securing the co-operation of the daily papers in giving publicity to the meetings of the branch.

During the year over seven pages of Branch News have been published in the Journal, bringing in a revenue of $79.68 to the branch funds.

The proper functioning of this committee in its publicity work was made much more difficult by the fact that in many cases copies of the papers to be read were not available before the meeting.

Special Committees

Throughout the year, in addition to the Membership Committee other special committees were appointed when required. Amongst those might be specially mentioned:—

(1) A committee to study the best method of co-operating with the Board of Trade in case where such co-operation might seem advisable. In this connection, members of the branch were appointed to confer with a committee of the Board of Trade in a study of the best methods of Smoke Abatement. C. M. McKergow, M.E.I.C., R. DeL. French, M.E.I.C., and F. A. Combe, M.E.I.C., have given a considerable amount of time to this important study.

(2) A committee under the chairmanship of J. A. McCrory, M.E.I.C., was appointed to arrange the details of a trip to inspect the new hydro-electric developments on the Gatineau river, as the guests of the Gatineau Power Company. The great success of this trip was in large measure due to the untiring efforts of the chairman and J. L. Busfield, M.E.I.C., and the secretary.

(3) A committee, under the chairmanship of J. L. Busfield, M.E.I.C., is making all arrangements for the Annual General and Professional Meeting, which is to be held in Montreal on February 14th, 15th and 16th.

Nominating Committee

Following the requirements of the By-laws, a Nominating Committee was appointed to make nominations for the 1928 Executive Committee. Three members, F. A. Combe, M.E.I.C., G. E. Templeman, M.E.I.C., and F. S. B. Heward, A.M.E.I.C., were appointed at the special general meeting of the branch held on November 3rd, while J. G. Caron, A.M.E.I.C., and C. K. McLeod, A.M.E.I.C., were later appointed by the Executive Committee. This committee made the nominations which were placed before the membership for ballot.

This committee, in accordance with By-laws, also acted as scrutineers, and the results of elections for the year 1928 are as follows:—

Chairman	F. C. Laberge, M.E.I.C.
Vice-Chairman	J. A. McCrory, M.E.I.C.
Member of Executive	R. DeL. French, M.E.I.C.
" " "	H. Massue, A.M.E.I.C.
" " "	E. A. Ryan, M.E.I.C.

Meetings Held During 1927

Jan. 6.—"**Recent Development in Boiler Furnaces,**" by B. N. Broido. Attendance, 87.

Jan. 13.—"**Mercury-Arc Rectifiers,**" by Othmar K. Marti. Attendance, 114.

Jan. 20.—"**Power Film.**" Attendance, 143.

Jan. 27.—"**Railway Lands—Titles, Surveys, Leases and Taxes,**" by Frank Taylor, M.E.I.C. Attendance, 57.

Feb. 3.—"**Traffic Regulations by Automatic Signals,**" by K. W. Mackall. Attendance, 73.

Feb. 10.—"**Radium Experiments,**" by J. E. Gendreau, M.D. Attendance, 142.

Feb. 15-17.—Annual General and Professional Meeting at Quebec.

Feb. 24.—"**Aerial Surveying,**" by F. G. Wait. Attendance, 53.

Mar. 3.—"**The Scientific Method in Industry,**" by G. Percy Cole, M.E.I.C.. Attendance, 69.

Mar. 10.—"**The Purification of Water for Boiler Feed Purposes,**" by T. R. Duggan, Ph.D. Attendance, 47.

Mar. 17.—"**Locomotive Feed Water Heating,**" by W. C. Hamm. Attendance, 45.

Mar. 24.—"**General Geological Features of the District of Montreal,**" by A. Mailhot. Attendance, 76.

Apr. 7.—"**The Theory of Telephony Made Visible,**" by L. St. J. Haskill. Attendance, 133.

Apr. 14.—"**Manufacture and Uses of Carbon-Dioxide,**" by J. R. Donald, M.E.I.C. Attendance, 43.

Apr. 21.—"**Vallee Street Substation,**" by H. Milliken, M.E.I.C. Attendance, 82.

Apr. 28.—"**Gatineau Power Development,**" by W. E. Blue, A.M.E.I.C. Attendance, 120.

Oct. 6.—"**The Arc Welding of Structural Steel,**" by A. M. Candy. Attendance, 101.

Oct. 13.—"**Induction Regulators,**" by N. D. Seaton, A.M.E.I.C. Attendance, 64.

Oct. 20.—"**The Substructure of the Buctouche River Bridge,**" by Major C. S. G. Rogers, A.M.E.I.C. Attendance, 78.

Oct. 27.—"**Manufacture of Ball and Roller Bearings,**" by Gordon Janes, M.E.I.C. Attendance, 97.

Nov. 3.—"**Manufacture of High-Pressure Boilers,**" by J. O. Twinberrow, A.M.E.I.C. Attendance, 78.

Nov. 10.—"**Tramways System of Montreal,**" by Judge St. Cyr. Attendance, 142.

Nov. 17.—"**Target Shooting with the Short Lee-Enfield Rifle,**" by J. M. Pope. Attendance, 16.

Nov. 24.—"**Capacitors,**" by M. C. Lowe, S.E.I.C. Attendance, 60.

Dec. 1.—"**Vacuum Process of Paper Manufacturing,**" by Ogden Minton. Attendance, 138.

Dec. 8.—"**Montreal Harbour Bridge,**" by P. L. Pratley, M.E.I.C. Attendance, 240.

Dec. 15.—Annual meeting of the branch.

Financial Statement

The financial statement shows that the branch has been looking forward to the necessity of underwriting a considerable portion of the expenses of the professional meeting to be held in conjunction with the annual meeting next February. The members of the branch will be gratified to learn that for the first time in the history of the branch it will be possible to hold the Professional Meeting without making a special collection from the members for entertainment.

The Executive Committee desires that every member of the branch should realize that it is his duty to promote the welfare of the branch in every way possible. If members will not contribute papers, or take part in the discussions, the least they can do is to attend the meetings and so encourage those who are spending their time and energy in maintaining the prestige of The Institute.

Niagara Peninsula Branch

The President and Council,—

On behalf of the Executive Committee of the Niagara Peninsula Branch, we take pleasure in presenting the annual report of the branch for the calendar year 1927.

As the branch by-laws provide that the term of office of the Executive Committee shall start on June 1st of each year, in the hope that more continuity may exist throughout the winter or programme season, the Executive Committees for the calendar year 1927 were as follows:—

Jan. 1 to May 31, 1927		June 1 to Dec. 31, 1927
A. Milne, A.M.E.I.C.	Chairman	C. H. Scheman, M.E.I.C.
T. S. Scott, M.E.I.C.	Vice-Chair	E. G. Cameron, A.M.E.I.C.
R. W. Downie, A.M.E.I.C.	Sec.-Treas	Walter Jackson, M.E.I.C.
E. G. Cameron, A.M.E.I.C.		R. W. Downie, A.M.E.I.C.
L. L. Gisborne, A.M.E.I.C.		L. L. Gisborne, A.M.E.I.C.
J. C. Street, M.E.I.C.		R. H. Harcourt, A.M.E.I.C.
W. S. Orr, A.M.E.I.C.		C. G. Moon, A.M.E.I.C.
H. L. Bucke, M.E.I.C.	*Ex-officio*	A. Milne, A.M.E.I.C.
		E. P. Johnson, A.M.E.I.C.

Membership

The membership of the branch, except for the class of Student, has been practically constant. Because of the completion of the Queenston-Chippawa hydro-electric development at Niagara Falls and the increased activities on the Welland ship canal there has been a marked removal of members from the territory of the former and an increase in membership in the territory of the latter work. The decrease in Student membership can be accounted for by the "age limit" in existence f[illegible] class and by their advance to higher classes.

Following is a statement [illegible]ection with this subject which will give at a glance our sta[illegible]en compared with the previous report.

	At end of year 1926	At end of year 1927	Loss	Gain
Members	24	23	1	..
Associate Members	78	77	1	..
Juniors	15	16	..	1
Students	30	15	15	..
Affiliate	0	1	..	1
Branch Affiliates	15	14	1	..
Net loss			16	

Meetings

It has been the policy of the Executive Committee to have meetings at least once a month. Generally speaking, these meetings include a trip in the afternoon, a dinner at a convenient point and a programme in the evening. The trip is usually over some part of a construction work in progress or through some plant in the vicinity, and the programme includes a speaker to describe the work just visited.

During the past year this arrangement has worked very well, but perhaps our branch territory is more favourably situated for it.

Following is a table giving details of our meetings:—

Jan. 25.—Dinner and meeting at Hotel Reeta, Welland. "**Dredges and Dredging,**" by W. E. Bonn, A.M.E.I.C. Meeting well attended, but number not recorded.

Feb. 28.—Dinner and meeting at Welland hotel, St. Catharines. "**Recent Progress in Electric Arc Welding,**" by R. E. Smythies, M.E.I.C. Meeting well attended, but number not recorded.

Apr. 27.—Trip, dinner and meeting at Dexter House, Welland. "**Welland Ship Canal,**" by Alex. J. Grant, M.E.I.C. Attendance, 67.

May 18.—Dinner and annual meeting of branch at Welland hotel, St. Catharines. "**Some Observations on Present Day Life in America,**" by Principal Hutton and R. J. Durley, M.E.I.C. Meeting well attended, but number not recorded.

June 16.—Trip, outing and dinner at Erie Downs club, Bridgeburg. No principal speaker, but trips through the Horton Steel Works and New Peace bridge. Attendance, 102.

July 23.—Trip, luncheon and meeting at new filtration plant at St. Catharines. "**Water Filtration,**" by A. Milne, A.M.E.I.C. Attendance practically nil because of weather and road conditions.

Oct. 1.—Trip, dinner and meeting at Port Colborne, Ont. "**Early History and Development of the Nickel Industry,**" by H. W. Walter. Attendance, 75.

Oct. 28.—Trip, dinner and meeting at Welland hotel, St. Catharines. "**Welland Ship Canal,**" by Alex. J. Grant, M.E.I.C. "**More Power from Niagara,**" by F. D. Corey. "**New Peace Bridge,**" by E. P. Lupfer. "**Power from St. Lawrence,**" by H. G. Acres, M.E.I.C. Attendance of 300 at dinner and 700 at meeting.

Nov. 9.—Business meeting at Engineers' club, Thorold. No principal speaker, but business was to consider a revision of by-laws. Attendance, 12.

Nov. 16.—Dinner and meeting at King Edward hotel, Niagara Falls. "**Automatic Traffic Control,**" by R. M. Love. Attendance, 28.

Dec. 8.—Trip to Buffalo, N.Y. Inspection of the plants of the Curtis Aeroplane and Motor Company and Consolidated Aircraft Corporation. Attendance marred by weather.

Expenditures

Telephone, telegraph, exchange, postage, incidentals	$ 17.32

EXECUTIVE COMMITTEE MEETINGS DURING YEAR 1927

Date 1927	*Place*	*Business*	*Attendance*
Feb. 28	Welland Hotel, St. Catharines	General business and planning for future meetings.	6
Apr. 4	Engineers' Club, Thorold	General business and receiving the report of the Nominating Committee	7
May 31	Engineers' Club, Thorold	New Executive—Appointment of Standing Committees	8
Aug. 29	Offices of Ontario Power Company, Niagara Falls	General business and planning for future meetings.	5
Oct. 5	Hotel Reeta, Welland	Receiving of report of the By-laws Committee and review of agenda for plenary Council Meeting of October 10 to 12	9 (100%)
Oct. 21	Refectory at Niagara Falls	Amending draught on revision to the By-laws for presentation to general business meeting	8

[illegible]ERSHIP

Meetings requiring specia[illegible]n were those of June 16th, October 1st and October 28th. [illegible] June 16th was the first under the present Executive Committ[illegible] the outing and dinner consisted of a golf tournament and [illegible]n dinner at the Erie Downs Golf Club, at Fort Erie, through [illegible] courtesy of the Horton Steel Works. The meeting of October 1st was at Port Colborne, and the trip was through the International Nickel Company and over the harbour works. The dinner was provided through the courtesy of the C. S. Boone Dredging Company. The meeting of October 28th consisted of a trip over the Welland ship canal in process of construction, a dinner at St. Catharines, and a joint meeting with the local sections of the American Institute of Electrical Engineers. On this trip, which took all day, and at the dinner at St. Catharines were visting members of The Engineering Institute of Canada from neighbouring branches, who were entertained by this branch to the number of 123. Transportation was mostly by automobile, but a construction train provided by the Welland ship canal authorities was made available for those requiring it, and a tug and scow was fitted up by the C. S. Boone Dredging Company for the trip over the Port Colborne end.

COMMITTEES

The branch's executive committee met at the call of the chairman as occasion required, and the above table gives a detail of the meetings.

By recommendation from the last to the present Executive Committee, the By-laws Committee was particularly active in framing a revision of the by-laws known as the Second Amendment, whereby the members will hereafter vote for members of an Executive Committee, and they will in turn elect from their members the chairman and vice-chairman and appoint from the branch membership the secretary-treasurer. Draught of these revisions has been accepted by the branch members at a general business meeting, approved by Council at Headquarters and letter ballots mailed to each member.

FINANCIAL STATEMENT

Financially, the branch is in fair condition, having on hand a balance which is in excess of last year's balance by over $60.00. This is due to added economies throughout the year. Details of the receipts and disbursements follow:—

(For period of January 1, 1927, to December 31, 1927)

Receipts

Balance brought forward	$203.70	
Proceeds from meetings	351.26	
Rebate on members' fees paid to Headquarters	247.50	
Branch Affiliates' fees	77.20	
Branch news	33.06	
Bank interest	2.16	
		$914.88

The members of our branch, on the occasion of their annual meeting held on May 18, 1927, appreciated a visit to them by the General Secretary and his wife, Mr. and Mrs. R. J. Durley.

Respectfully submitted,

C. H. SCHEMAN, M.E.I.C., *Chairman.*
WALTER JACKSON, M.E.I.C., *Secretary-Treasurer.*

Ottawa Branch

The President and Council,—

On behalf of the Managing Committee of the Ottawa Branch, we beg to submit the following report for the calendar year 1927:—

During the year the Managing Committee held eight meetings. In addition, the branch held eight evening meetings and eight luncheons. In August, the Empire Mining and Metallurgical Congress held a session in Ottawa. The branch co-operated with the Rotary, Kiwanis and Lions clubs and with the Canadian Mining and Metallurgical Institute in providing entertainment for the delegates to the Congress during their stay in the city.

The annual ball was held at the Chateau Laurier, and, as usual, was a great success. Every year this function is becoming more and more of a social event in Ottawa.

The balance sheets show a very successful year financially. Our assets have increased by $158.16, so that our working capital is now $1,862.62.

It is with deep regret that we report the loss through death of five members, namely, W. P. Anderson, M.E.I.C., A. W. Campbell, M.E.I.C., G. A. Mountain, M.E.I.C., A. d'Orsonnens, A.M.E.I.C., and F. H. Wrong, A.M.E.I.C.

MEETINGS

During the year eight luncheons and eight evening meetings were held and a visit was made to the Canadian International Paper Company's plant at Gatineau, Que. The meetings were as follows:—

Jan. 13.—"**Celestial Engineering,**" by R. Meldrum Stewart, M.E.I.C.; luncheon meeting at Chateau Laurier.

Jan. 13.—Annual meeting—Daffodil Tea Rooms.

Feb. 10.—"**Engineering Development in Fighting Ships,**" by Engineer Commander T. C. Phillips, R.C.W., M.E.I.C.; luncheon meeting at Chateau Laurier.

Feb. 17.—"**Surveying in the Mountains,**" by M. P. Bridgland, M.E.I.C.; evening meeting in the Palm Room, Chateau Laurier.

Feb. 25.—"**The Bituminous Sands of Northern Alberta,**" by S. C. Ells, M.E.I.C.; evening meeting in the Palm Room, Chateau Laurier.

Mar. 1.—Joint luncheon meeting with the Canadian Institute of Mining and Metallurgy at the Chateau Laurier; address by Dr. D. A. Lyon, chief metallurgist of the Bureau of Mines, Washington.

Mar. 4.—"**Operation and Construction of Water Tube Boilers,**" by J. O. Twinberrow, A.M.E.I.C.; evening meeting at the Victoria Memorial Museum.

Mar. 24.—"**Sidelights on Northern Canada,**" by G. H. Blanchet, F.R.G.S., A.M.E.I.C., and Major L. T. Burwash, M.E., F.R.G.S., M.E.I.C.; evening meeting in the Palm Room, Chateau Laurier.

Mar. 31.—"**Commercial Aviation in Canada,**" by Ellwood Wilson, M.E.I.C., president of the Fairchild Aerial Surveys Company of Canada; luncheon meeting at the Chateau Laurier.

Apr. 7.—"**Some Practical Notes on Oil Paints and Their Application,**" by A. K. Light, chemist, Department of Public Works; evening meeting in the Palm Room, Chateau Laurier.

Oct. 15.—Visit to Canadian International Paper Company's plant at Gatineau, Que.

Oct. 27.—"**Recent Power Developments in Ottawa Vicinity,**" by W. E. Blue, A.M.E.I.C., of the Gatineau Power Company; luncheon meeting at the Chateau Laurier.

Nov. 8.—"**Workability in Concrete, with Particular Reference to the Use of Diatomaceous Silica,**" by Col. H. C. Boyden; evening meeting at the University Club.

Nov. 17.—"**My Trip to Italy,**" by John Murphy, M.E.I.C.; luncheon meeting at the Chateau Laurier.

Nov. 24.—"**Experiences as a Military Adviser to the Chinese Government,**" by Gen. F. A. Sutton, M.C.; luncheon meeting at the Chateau Laurier.

Dec. 1.—"**National Parks Idealism,**" by J. B. Harkin, Commissioner of Canadian National Parks; luncheon meeting at the Chateau Laurier.

Dec. 8.—"**Psychoanalysis and Mental Health,**" by Professor J. W. Bridges, PH.D.; evening meeting in the Palm Room, Chateau Laurier.

The attendance at the luncheons averaged over 100, the largest attendance being at the luncheon address by Gen. Sutton. While engineering subjects were discussed to some extent, the policy was to have addresses with a popular appeal.

Membership

During the year several members were lost through death, transfers, etc. A number of new members were gained, however, so that the total membership of the branch shows a net increase of five. The membership of the branch from 1909 to date is shown graphically on the accompanying chart.

The following table shows in detail the comparative figures of the branch membership for the years 1925, 1926 and 1927:—

	1925	1926	1927
Honorary Members	1	0	1
Members	113	112	110
Associate Members	244	213	212
Juniors	35	26	28
Students	34	22	22
Affiliates of Institute	8	7	8
Branch Affiliates	37	37	41
Totals	472	417	422

Rooms and Library

The branch library is still situated on the third floor of the Stephen building, where it is open to consultation by members under the same conditions that have previously prevailed.

Finances

The attached statements of assets and liabilities and of receipts and expenditures show the financial position of the branch to be a very satisfactory one. Our bank balance is approximately $160.00 more than last year and our assets have increased approximately the same amount.

The year was closed with a balance of $616.00 in the bank, $5.12 cash on hand and $1,000 in Victory bonds, a total balance of $1,621.22. In addition to this balance the branch has assets of $22.50 in rebates due from Headquarters, $17.90 for advertising in the Journal for the year and $201.00 in furniture, equipment, etc., making a total balance of $1,862.62. The accompanying chart shows the financial standing of the branch from 1910 to date.

The income for the past two years was:—for 1926, $1,043.81, and for 1927, $893.42; the expenditure for 1926, $1,146.41, and for 1927, $734.46. An annual income of $52.50 is derived from Victory bonds.

Officers for 1927

The annual meeting of the branch will be held in Ottawa on January 12th, when the officers and members of the Managing Committee for 1928 will be elected.

Peterborough Branch

The President and Council,—

On behalf of the Executive Committee of the Peterborough Branch, we beg to submit to you the following report to cover the activities of the branch for the calendar year 1927:—

Meetings and Papers

Jan. 13.—"**The Manufacture of Carbon Products,**" by the late J. C. Webster, M.E.I.C., Canadian National Carbon Company, Limited.

Jan. 27.—"**The Hemmings Falls Development,**" by J. S. H. Wurtele, M.E.I.C.

Feb. 10.—*Students' Night.*
"**Full Voltage Starting of Induction Motors,**" by S. O. Shields, S.E.I.C.
"**Control of A.C. Motors,**" by W. T. Fanjoy, S.E.I.C.
"**Some Interesting Facts About Northern Alberta,**" by F. J. Stewart, S.E.I.C.

Feb. 24.—"**With Canadian Engineers in Palestine,**" by Prof. J. Roy Cockburn, M.E.I.C.

Mar. 10.—"**Ancient Engineering,**" by F. H. Dobbin.

Mar. 31.—"**Recent Progress in Electric Welding,**" by R. E. Smythies, M.E.I.C., Lincoln Electric Company, Limited.

Apr. 14.—"**Long Span Bridges,**" by Prof. C. R. Young, M.E.I.C.

Apr. 28.—"**Ice Engineering,**" by Dr. Howard T. Barnes, M.E.I.C.

Oct. 27.—"**Electrical Equipment of International Paper Company's Gatineau Mill,**" joint paper by A. B. Gates, A.M.E.I.C., B. Ottewell, A.M.E.I.C., W. E. Ross, A.M.E.I.C.

Dec. 8.—"**Modernizing of Old Radio Sets and Use of B Eliminators,**" by J. H. Thomson, Ferranti Electric, Limited.

Special Meetings

May 17.—Annual general business meeting and election.

Aug. 30.—Special dinner-meeting and presentation to Paul Manning, A.M.E.I.C.

Nov. 22.—Annual banquet.

The average attendance of the membership at the regular meetings has been very gratifying, and, in addition, these meetings, in accordance with the policy of the branch, have been given notices in the local press inviting the general public.

A general invitation was extended by the committee in charge of arrangements for the celebrations of the Confederation Jubilee in the city of Peterborough to all organizations to assist in the preparations. The Peterborough Branch offered to erect a decorative arch, and in order to carry out this project it was decided to forego the usual summer outing and devote the time to the construction and erection of the arch.

This work was carried out by a party of the members working evenings and Saturday afternoons and resulted in the erection of an arch which took the form of a scale model of the Quebec bridge, which occupied a prominent position on the main thoroughfare of the city during the celebration. The arch was later presented to the Peterborough Exhibition Board, who have had it erected in the exhibition grounds.

Membership

The membership now stands as follows:—

Members	19
Associate Members	37
Juniors	10
Students	18
Affiliates and Branch Affiliates	15
Total	99

During the year the branch suffered the loss of one of its most esteemed and prominent members, the late R. B. Rogers, M.E.I.C., a Life Member of The Institute and past chairman of the Peterborough Branch.

There is a slight loss in the membership due to transfers and one resignation. In the case of Students a loss is shown, but this is due to the fact that the Peterborough Branch is peculiarly situated in this respect, the total in this grade being susceptible to change from month to month due to transfers of student engineers to and from the Canadian General Electric Company's works.

Executive Committee

Ten meetings of the Executive Committee have been held during the year, at which routine and special business has been transacted.

The members of the Executive Committee are:—

Chairman	A. E. Caddy, M.E.I.C.
Secretary	W. E. Ross, A.M.E.I.C.
Treasurer	A. B. Gates, A.M.E.I.C.
	B. L. Barns, A.M.E.I.C.
	G. H. Burchill, JR.E.I.C.
	W. M. Cruthers, A.M.E.I.C.
Councillor	R. L. Dobbin, M.E.I.C.
	R. C. Flitton, A.M.E.I.C.
	J. A. G. Goulet, M.E.I.C.
	B. Ottewell, A.M.E.I.C.

Student Activities

In order to further the interest of the Students in Institute affairs, a Student Section has been formed, which section appoints a chairman, who is invited to attend meetings of the Branch Executive Committee.

The results to date have been gratifying, and it is hoped to develop this section still further in the near future.

Financial Statement

(For the year ending December 31st, 1927)

Receipts

ANNUAL MEETING

The annual meeting of the Quebec Branch was held on May 30th, 1927, under the chairmanship of A. B. Normandin, A.M.E.I.C. The following officers were elected for the year 1927-28:—

Honorary Chairman for Life.........
A. R. Décary, D.A.SC., M.E.I.C., President of The Institute.
Chairman ....A. B. Normandin, A.M.E.I.C.
Vice-Chairman ....S. L. de Carteret, M.E.I.C.
Secretary-Treasurer ....Philippe Méthé, A.M.E.I.C.
Committeemen ....Alex. Larivière, A.M.E.I.C.
L. C. Dupuis, A.M.E.I.C.
Hector Cimon, A.M.E.I.C.
T. J. F. King, A.M.E.I.C.
Ex-officio ....W. G. Mitchell, M.E.I.C.
" ....Louis Beaudry, A.M.E.I.C.

MEETINGS

The executive of the Quebec Branch held its meetings regularly during the year 1927. The two outstanding events of the year were the Annual General and General Professional Meeting of The Institute, held in the old city of Quebec, February 15th to 17th, 1927, and the election to the presidency of The Institute of A. R. Décary, D.A.SC., M.E.I.C., one of the most distinguished members of the engineering profession in Canada and an active member of the Quebec Branch.

During the general meeting, many engineers from all parts of the country, and also prominent men in governmental, industrial, commercial, economical, intellectual and administrative spheres, honoured the Quebec Branch by their presence and took an active part in the discussion of papers presented at the various sessions of the meeting.

Our membership increased from 112 to 125.

All questions submitted by the Council of The Institute have been studied, discussed and transacted.

Our branch has followed with interest the deliberations on The Institute, and has devoted its full energy to all matters aiming to the protection and promotion of the interests of The Institute and its members.

Our special committee has followed closely, studied seriously and made as complete reports as possible on all applications for membership which have been referred to this branch, and the necessary recommendations have been made to the Council of The Institute, who has kindly taken them into consideration.

ADDRESSES

The following addresses were given at our different luncheons and evening meetings:—

"**The Montreal Harbour Bridge,**" by P. L. Pratley, M.E.I.C., consulting engineer, Montreal.

"**Workability in Concrete, with Special Reference to the Use of Diatomaceous Silica,**" by Col. H. C. Boyden.

"**Economical and Industrial Evolution,**" by Hon. Frank Carrel, Member of the Legislative Council of Quebec.

RAPPORT ANNUEL DE LA SECTION DE QUÉBEC POUR L'ANNÉE 1927

Au président et aux membres de l'Institut des Ingénieurs du Canada.

Le conseil de la Section de Québec a l'honneur de vous soumettre son rapport annuel pour l'année 1927, comme suit:—

ROLE DES MEMBRES

	Résidents	Non-résidents	Total
Membres Honoraires	1	..	1
Membres	17	1	18
Membres Associés	66	11	77
Membres Juniors	11	3	14
Membres étudiants	11	3	14
Membres Affiliés	1	..	1

ASSEMBLÉE ANNUELLE

L'assemblée annuelle de la Section de Québec a été tenue le 30 mai 1927, sous la présidence de Monsieur A. B. Normandin, A.M.E.I.C., et les Officiers dont les noms suivent ont été élus pour l'année 1927-28:—

Président Honoraire, à vie ....M. A. R. Décary, D.A.SC., M.E.I.C.
Président ....M. A. B. Normandin, A.M.E.I.C.
Vice-Président ....M. S. L. de Carteret, M.E.I.C.
Secrétaire-Trésorier ....M. Philippe Méthé, A.M.E.I.C.
Conseillers ....M. Alex. Larivière, A.M.E.I.C.
M. L. C. Dupuis, A.M.E.I.C.
M. Hector Cimon, A.M.E.I.C.
M. J. T. F. King, A.M.E.I.C.
Ex-officio ....M. W. G. Mitchell, M.E.I.C.
" ....M. Louis Beaudry, A.M.E.I.C.

ASSEMBLÉES

Le Conseil de la Section de Québec a tenu ses assemblées regulièrement durant l'année 1927.

Deux évènements mémorables ont marqué l'année écoulée: la tenue de l'Assemblée annuelle de l'Institut dans la vieille Cité de Champlain, et le choix de Monsieur A. R. Décary, D.A.SC., l'un des membres les plus distingués de la profession d'ingénieur au Canada, et membre dévoué de la Section de Quebec, comme Président général de l'Institut.

A l'occasion de l'assemblée générale, un grand nombre d'ingénieurs venus de toutes les parties du pays, et des personnages marquants de toutes les sphères, gouvernementale, industrielle, commercialle, économique, intellectuelle et administrative ont bien voulu nous honorer de leur visite, et prendre part aux travaux présentés à l'assemblée.

Le nombre de nos membres s'est accru de 112 à 125.

Toutes les questions soumises par le Conseil général à la Section de Québec ont été étudiées, discutées et expédiées.

Notre Section a suivi avec intérêt, les travaux de l'Institut et a prêté son plein concours à toutes les questions ayant pour but de protéger et promouvoir les intérêts de l'Institut et de ses membres.

Notre comité spécial s'est efforcé, après étude sérieuse, de faire un rapport aussi complet que possible sur toutes les demandes d'admission qui lui ont été référées, et les recommandations nécessaires ont été faites au Conseil général de l'Institut qui a bien voulu en tenir compte.

CAUSERIES

Les causeries suivantes ont été donnés à nos différentes réunions.

"**Le Pont Montréal-Longueuil,**" par P. L. Pratley, M.E.I.C., ingénieur conseil de Montréal.

"**La plasticité du béton et les effets de l'emploi de silice 'diatomacée',**" par Col. H. C. Boyden, B.SC., I.C.

"**L'évolution économique et industrielle,**" L'hon. Frank Carrel, conseiller législatif.

Saguenay Branch

The President and Council,—

On behalf of the Executive Committee, we take pleasure in submitting the following report for the year 1927.

The year 1927 was a very quiet one for our branch. Owing to certain changes in the policy of one of the large paper companies, several of our oldest and most capable members were either removed from our branch by being transferred to Quebec or elsewhere out of our territory or else stationed at various places about lake St. John, thus decentralizing an important group of our members, to the great disadvantage of the branch.

Several attempts at executive and other meetings were made, but owing to the greater difficulty in assembling the scattered members it was almost impossible to reach a quorum, the disadvantage of a scattered membership being thus plainly brought to light.

It has been agreed that the best way to obviate this will be, for any given year, to elect officers from among those living in a certain centre, thus giving a greater chance of successful meetings. The centre would, of course, vary every year, thus allowing everyone an equal opportunity for election. This policy, without being made a definite by-law of the Saguenay Branch, will nevertheless be considered as an accepted custom and will be tried out at the coming spring elections. We hope thereby to get a satisfactory means of holding meetings and reviving the former activities of the branch.

Officers

The officers of the branch are as follows:—

Chairman	Edouard Lavoie, m.e.i.c.
Secretary-Treasurer	Burroughs Pelletier, a.m.e.i.c.
Executive	J. L. Delisle, a.m.e.i.c.
	C. C. Lindsay, a.m.e.i.c.
	G. F. Layne, a.m.e.i.c.

Membership

The membership of the branch is as follows:—

Members	4
Associate Members	25
Juniors	10
Students	11
	50

Financial Statement

(As at January 1st, 1928)

Receipts

Balance on hand from previous report	$ 73.82	
Remittances from headquarters (Jan.)	10.65	
" " " (Aug.)	69.30	
" " " (Oct.)	14.10	
		$167.87

Expenditures

Stationery, postage, incidentals	$ 6.75	
Balance on hand	161.12	
		$167.87

Respectfully submitted,

Edouard Lavoie, m.e.i.c., *Chairman.*
Burroughs Pelletier, a.m.e.i.c., *Secretary-Treasurer.*

Saint John Branch

The President and Council,—

The Saint John Branch of The Engineering Institute of Canada records the end of another calendar year by submitting its tenth annual report.

The executive has transacted business of the branch by meeting nine times during the year. Seven branch meetings were held in Saint John, at which addresses were given, in addition to the joint dinner with the Association of Professional Engineers of the province of New Brunswick in January and the annual meeting and dinner in May. The branch maintained its interest in the engineering college within its branch territory by holding a joint meeting with the Engineering Society of the University of New Brunswick in Fredericton during March; this trip is eagerly looked forward to by our members and proves very enjoyable.

A motor trip was made during Labour Day week-end to Grand Falls, distant about 200 miles from Saint John, to inspect the hydro-electric construction works. This trip gave our branch members, resident and branch district, a chance to become better acquainted. Thanks are due to A. C. D. Blanchard, m.e.i.c., for excellent arrangements provided at Grand Falls, and to the Dominion Construction Company for courtesies extended there.

At branch meetings, various engineering subjects have been discussed. Good interest has been maintained in meetings. Committees continue to give efficient service in several features of branch endeavour.

This branch takes its place in the community by assisting in any worth-while work outside what may be regarded as strictly Institute affairs. It assisted in Fire Prevention Week, drew attention to need of adoption of town planning, worked in close harmony with the Board of Trade. Some branch members have become identified with Board of Trade work and done good service. Branch members have been active in local service clubs. In other words, Saint John Branch members are taking part in various features of civic community life.

Of interest to engineers in various activities within branch territory during the past year may be mentioned hydro-electric and pulp mill construction and some interest in mineral development. The transfer of the harbour of Saint John to the control of a Harbour Commission during the past year is recorded.

This branch was represented at the Plenary Meeting of Council held at Montreal in October.

Membership

The nine western counties of New Brunswick are included in the territory of this branch. Statement of membership on December 31, 1927, is as follows:—

	Residents	Non-residents	Total
Members	14	7	21
Associate Members	28	16	44
Juniors	6	2	8
Students	3	5	8
Affiliates	2	..	2
Total	53	30	83

Total at end of 1926—79; total at end of 1927—83; net gain—4.

Meetings

Jan. 25.—Joint dinner with Association of Professional Engineers of New Brunswick.
"**Welland Ship Canal,**" by Alex. J. Grant, m.e.i.c.

Mch. 4.—Joint meeting with Engineering Society of University of New Brunswick, at Fredericton, N.B.
"**Railway Location,**" by A. S. Gunn, a.m.e.i.c.
"**Electrical Operation,**" by G. A. Vandervoort, a.m.e.i.c.
"**Some Features of the Saint John River Power Company's Developments at Grand Falls, N.B.,**" by A. C. D. Blanchard, m.e.i.c.

Mch. 31.—"**Town Planning for Saint John,**" by W. F. Burditt.

Apr. 7.—"**Maritime Harbours, How Treated and What They Mean to Us,**" by Thos. J. Locke.

Apr. 21.—"**Engineering in Contracting,**" by J. N. Flood, a.m.e.i.c.

May 4.—Annual meeting.

Sept. 3-5.—Summer excursion to Grand Falls, N.B.

Oct. 28.—"**Sanitary Drainage,**" by G. G. Murdoch, m.e.i.c.

Nov. 17.—"**Passamaquoddy Bay Tidal Development,**" by Dexter P. Cooper.

Dec. 9.—"**Filtration,**" by J. L. Feeney, a.m.e.i.c.

Saskatchewan Branch

The President and Council,—

On behalf of the Executive Committee, we beg to submit the following report concerning the activities of the Saskatchewan Branch for the calendar year 1927.

Membership

The membership of the branch has shown a gain of 8 with the usual fluctuations due to transfers, etc.

The present membership of the branch is:—

	Residents	Non-residents	Total
Members	6	13	19
Associate Members	39	30	69
Juniors	3	5	8
Students	3	8	11
Affiliates	1	1	2
Branch Affiliates	5	0	5
Total	57	57	114

Executive Committee

The present executive was elected on March 8th at the branch annual meeting, and with those continuing in office is as follows:—

Chairman ....M. B. Weekes, M.E.I.C., Regina, Sask.
Vice-Chairman ......A. M. Macgillivray, A.M.E.I.C., Saskatoon, Sask.
Secretary-Treasurer ..R. W. E. Loucks, A.M.E.I.C., Regina, Sask.
Executive (2 years)...D. A. R. McCannel, A.M.E.I.C., Regina, Sask.
W. R. Warren, A.M.E.I.C., Regina, Sask.
W. G. Worcester, M.E.I.C., Saskatoon, Sask.
(1 year)...J. W. D. Farrell, A.M.E.I.C., Regina, Sask.
P. C. Perry, A.M.E.I.C., Regina, Sask.
W. H. Greene, M.E.I.C., Moose Jaw, Sask. (past-chairman).
H. R. MacKenzie, A.M.E.I.C., Regina, Sask. (councillor).
Auditors ....D. H. Lunam, BR. AFFIL., Regina, Sask.
G. G. Fitzgerald, A.M.E.I.C., Regina, Sask.

Committees

Chairmen of the standing committees are:—

Papers and Library ....D. A. R. McCannel, A.M.E.I.C.
Legislation ....R. N. Blackburn, M.E.I.C.
Nominating ....J. R. C. Macredie, M.E.I.C.
Attendance ....J. G. Schaeffer, S.E.I.C.
D. C. M. Davies, A.M.E.I.C.
Publicity ....R. W. E. Loucks, A.M.E.I.C.
Meetings ....W. T. E. Smith, Br. Affil.

The Saskatchewan Branch representative on the Nominating Committee of The Institute is M. B. Weekes, M.E.I.C.

Meetings

The executive held six meetings for the transaction of branch affairs. There were five regular meetings of the branch and two special meetings. In January a very pleasant social evening was spent at the home of H. N. Macpherson, A.M.E.I.C., at which the ladies were present, and in August a basket picnic was held at River Park, in the town of Lumsden. R. J. Durley, M.E.I.C., general secretary of The Institute, was scheduled to attend the picnic and to meet the members at an informal dinner on the following day. Owing to sudden news of illness in his family, Mr. Durley was unfortunately unable to be with us on this occasion.

The regular meetings have been well attended and considerable interest and enthusiasm shown by the officers and members. They were in each case preceded by a dinner. At the present time the meetings are being held in the Saskatchewan hotel, Regina.

Meetings

The programme for the year was as follows:—

Jan. 7.—Ladies' night. Social evening at the home of H. N. Macpherson, A.M.E.I.C.

Jan. 27.—"**The Engineer and the Immigration Problem,**" by A. G. Dalzell, M.E.I.C., consulting engineer, Toronto, Ont.

Feb. 18.—"**The Construction of the Canadian Pacific Railway (Saskatchewan) Hotel at Regina,**" by H. S. Bare, A.M.E.I.C., resident engineer, Canadian Pacific Railway.
"**The Management of the Hotel,**" by Mr. T. E. Chester, manager.
"**Mining Claims and Mineral Prospects in the Mineral Belt North of The Pas, Manitoba,**" by Wm. T. Thompson, M.E.I.C.
Personal inspection of the Canadian Pacific Railway hotel during the afternoon by members of the branch, conducted by H. S. Bare, A.M.E.I.C.

Mar. 8.—Tenth annual meeting. Reports of committees, election of officers, banquet, toast list and other entertainment.
Address by Prof. A. R. Greig, M.E.I.C., on his recent tour of Europe, from an engineering standpoint.

Aug. 24.—Basket picnic at River Park, Lumsden; sports, games, refreshments, etc.

Nov. 18.—Addresses on "**Departmental Activities for the Past Season,**" by J. W. D. Farrell, A.M.E.I.C., superintendent, water works, Regina; R. H. Murray, A.M.E.I.C., sanitary engineer, Saskatchewan Department of Public Health, and S. T. Lewis, division engineer, Canadian Pacific Railway.

Dec. 19.—Address on "Conventions" by:—H. N. Macpherson, A.M.E.I.C., "**Benefits to Be Derived from Conventions.**"
T. A. McGuinness, A.M.E.I.C., "**Electrical Railway Convention.**"
C. W. Doody, traffic superintendent, Saskatchewan Department of Telephones, "**Canadian Telephone Association Convention.**"
H. S. Carpenter, M.E.I.C., "**Canadian Good Roads Convention.**"
D. A. R. McCannel, A.M.E.I.C., "**Canadian Good Roads Convention.**"

Scholarship

The annual scholarship of $50.00 offered by the branch to the most deserving student in the graduating class in engineering of the University of Saskatchewan, was awarded to Mr. L. W. Llewellyn.

Financial Statement

M. B. Weekes, M.E.I.C., *Chairman.*
R. W. E. Loucks, A.M.E.I.C., *Secretary-Treasurer.*

Sault Ste. Marie Branch

The President and Council,—

The attendance at the meetings for the year averaged thirty-five, and nearly all the meetings were held at the Y.W.C.A. rooms following a dinner. The attendance this year has been about the same as in 1926, averaging over 50 per cent of our resident members. The number of guests were larger this year, as we held two public meetings, one in St. Luke's hall on April 29th and one in the Y.M.C.A. on October 28th.

The Papers and Publicity Committee and the Entertainment Committee are to be congratulated upon the splendid papers and meetings that they arranged for and carried out. On account of our geographical location the arranging for outside speakers is a problem and requires considerable effort on the part of the Papers Committee to keep up a good programme.

The entertaining of R. J. Durley, M.E.I.C., general secretary of The Institute, on July 8th and the dinner and inspection trip through the Union Carbide plant, Sault Ste. Marie, Michigan, were two very interesting events during the year.

Meetings

The regular meetings were held on the last Friday of each month, except the special meetings held in April and July, and the papers given and the inspection trips made were as follows:—

Jan. 28.—An inspection trip through the local plant of the Spanish River Pulp and Paper Company, under the guidance of company's officials.

Feb. 25.—"**Economy in Steam Generation,**" by E. V. Ahara, JR.E.I.C., of the Combustion Engineering Corporation of Montreal.

Apr. 15.—An inspection trip through the calcining plant of the Union Carbide Company, Sault Ste. Marie, Mich., following a dinner given by the officials of the Carbide Company.

Apr. 29.—"**Radio and the Wizardy of Wireless,**" by Mr. Richardson, of the Canadian General Electric Company, of Toronto.

May 27.—"**The Army Water Supply in France,**" by B. M. Owen, of Babcock-Wilcox and Goldie-McCulloch, Limited, of Galt, Ont.

July 8.—A special dinner meeting was held to welcome R. J. Durley, M.E.I.C., the general secretary of The Institute.

Sept. 30.—Lecture and slides prepared by C. H. Speer, M.E.I.C., on "**The Steel Industry**" for use in the Provincial Schools under the Department of Education supervision.

Oct. 28.—"**The Construction and Operation of Modern High Pressure Boilers,**" by J. O. Twinberrow, A.M.E.I.C., chief engineer of boiler department of Babcock-Wilcox and Goldie-McCulloch, Limited, of Galt, Ont.

Nov. 14.—Special meeting to discuss the engineering features of the proposed hydro-electrical development of the St. Mary's river rapids.

Dec. 16.—Annual meeting. Reports of all committees. Election of officers for 1928. Address by retiring chairman, G. H. Kohl, M.E.I.C.

Membership

	Residents	Non-residents	Total
Members	12	13	25
Associate Members	11	42	53
Juniors	6	7	13
Students	2	12	14
Affiliate	1	..	1
Branch Affiliates	15	..	15
Total			121

This is an increase of four members as shown by the 1926 report. Conditions are somewhat better industrially throughout this district this year. At present we have four or five elections and transfers pending.

Financial Statement

Receipts

Balance from 1926	$ 87.04

St. Maurice Valley Branch

The President and Council,—

We have the honour to submit to you the annual report of the St. Maurice Valley Branch of The Institute for the year 1927:—

The branch was established in 1926, and the first meeting was held on the 27th of November, 1926.

Officers

The first executive was as follows:—

President	Ellwood Wilson, M.E.I.C.
Councillor (one year)	Bruno Grand Mont, A.M.E.I.C.
" (two years)	Henri Dessaulles, A.M.E.I.C.
" (three years)	S. W. Slater, A.M.E.I.C.
Secretary-Treasurer	Romeo Morrissette, A.M.E.I.C.

The same executive was maintained in office for 1927.

Meetings

The by-laws of the branch were adopted, and the meetings of the branch in 1927 were held as follows:—

Jan. 15.—At the Chateau de Blois, in Three Rivers; "**Municipal Finances,**" by Romeo Morrissette, A.M.E.I.C.

Mar. 19.—"**Aerial Surveys,**" by Ellwood Wilson, M.E.I.C.

May 7.—At Grand'Mere; speaker, Mr. E. B. Wardle, of the Laurentide Company, Limited, who gave an address followed by a visit to the mill.

Oct. 22.—At Shawinigan Falls; "**The Role of the Engineer,**" by Julian C. Smith, M.E.I.C.

Nov. 24.—At Three Rivers; general discussion.

Dec. 13.—Annual election of officers, resulting as follows:—Ellwood Wilson, M.E.I.C., was re-elected chairman for 1928. Bruno Grand Mont, A.M.E.I.C., member of Executive Committee, and Romeo Morrissette, A.M.E.I.C., *secretary-treasurer.*

Financial Statement

Receipts for 1927	$169.67
Expenses for 1927	91.51
Balance on hand	$78.16

Respectfully submitted,

ELLWOOD WILSON, M.E.I.C., *Chairman.*
ROMEO MORRISSETTE, A.M.E.I.C., *Secretary-Treasurer.*

Toronto Branch

The President and Council,—

The Executive Committee of the Toronto Branch respectfully submit the following report for the calendar year of 1927:—

The Executive Committee holding office during this period are as follows, the present members being elected at the branch annual meeting on March 24th.

Executive Committee

January to March 1927		March to December 1927
J. G. R. Wainwright, A.M.E.I.C.	Chairman	R. B. Young, M.E.I.C.
R. B. Young, M.E.I.C.	Vice-Chair.	J. A. Knight, A.M.E.I.C.
J. W. Falkner, A.M.E.I.C.	Sec.-Treas.	W. B. Dunbar, A.M.E.I.C.
A. E. K. Bunnell, M.E.I.C.	Executive	C. S. L. Hertzberg, M.E.I.C.

H. W. Tate, A.M.E.I.C.		J. J. Traill, M.E.I.C.
L. W. Wynne-Roberts, A.M.E.I.C.		T. Taylor, M.E.I.C.
A. T. C. McMaster, M.E.I.C.		A. E. K. Bunnell, M.E.I.C.
I. H. Nevitt, M.E.I.C.		H. W. Tate, A.M.E.I.C.
J. A. Knight, A.M.E.I.C.		L. W. Wynne-Roberts, A.M.E.I.C.
T. R. Loudon, M.E.I.C.	*Ex-officio*.	T. R. Loudon, M.E.I.C.
E. G. Hewson, M.E.I.C.	"	J. M. Oxley, M.E.I.C.
J. M. Oxley, M.E.I.C.	"	*H. K. Wicksteed, M.E.I.C.
H. K. Wicksteed, M.E.I.C.	"	J. G. R. Wainwright, A.M.E.I.C.
C. B. Ferris, A.M.E.I.C.	"	J. W. Falkner, A.M.E.I.C.
		P. Gillespie, M.E.I.C.

* *Deceased.*

Standing Committees

The following standing committees with the chairman of each were appointed by the executive:—

January to March		April to December
J. G. R. Wainwright, A.M.E.I.C.	Papers (Programme)	R. B. Young, M.E.I.C.
R. B. Young, M.E.I.C.	Finance	J. A. Knight, A.M.E.I.C.
J. Hyslop, M.E.I.C.	Publicity	J. W. Falkner, A.M.E.I.C.
E. T. J. Brandon, A.M.E.I.C.	Membership	L. W. Wynne-Roberts, A.M.E.I.C.
L. W. Wynne-Roberts, A.M.E.I.C.	Meetings (Attendance)	T. Taylor, M.E.I.C.
A. T. C. McMaster, M.E.I.C.	Library	C. S. L. Hertzberg, M.E.I.C.
W. B. Dunbar, A.M.E.I.C.	Student Relations	W. B. Dunbar, A.M.E.I.C.

The Executive Committee of the branch held fifteen meetings throughout the year for the transaction of branch business and eleven general meetings, of which one was a luncheon meeting.

A feature of the activities of the branch this year has been its co-operation with other engineering bodies. On October 28th there was a trip over the new Welland ship canal. The party was composed of members of the following societies:—The American Institute of Electrical Engineers of Hamilton, Niagara Peninsula and Toronto Branches; The Engineering Institute of Canada of the Niagara Peninsula and Toronto Branches; The Engineering Society of Buffalo, N.Y.

In the evening dinner was served in the Welland Inn, St. Catharines, at which the visiting members of The Engineering Institute of Canada were the guests of the Niagara Peninsula Branch. A joint meeting in the auditorium of the Collegiate Institute at night was addressed by Mr. E. P. Lupfer, chief engineer of the Peace Bridge, A. J. Grant, M.E.I.C., engineer-in-charge of the Welland ship canal, and H. G. Acres, M.E.I.C., consulting engineer, of Niagara Falls, who spoke on the "**St. Lawrence Development.**"

Twenty-seven members of our branch spent a very enjoyable and profitable day.

A luncheon meeting was held on December 1st at the King Edward hotel jointly with the Toronto Sections of the A.I.E.E. and A.S.M.E., to honour Professor Peter Gillespie, M.E.I.C., who, in addition to being a respected member of our branch, is also a vice-president of The Institute. This meeting was attended by 150 members.

The regular evening meetings were arranged to cover as far as possible the various subdivisions of the engineering profession. During the early part of the year the papers were mostly by local men, whereas the latter papers were mostly by out-of-town men.

A policy which has turned out very successful is that of welcoming the out-of-town speakers at an informal dinner attended by members of the executive and those who purpose taking part in the discussion of the paper.

After the meeting on the evening of January 27th the members were the guests of the staff in Applied Mechanics of the Faculty of Applied Science and Engineering, University of Toronto, at the inauguration of their new 200-ton Riehle testing machine. An opportunity was also given those present to investigate the facilities of the laboratory for testing various structural and highway materials. Lunch was served at the close of the demonstration.

The attendance at the meetings has been in general good, with an average of 100. At the meeting addressed by Dr. Howard T. Barnes, M.E.I.C., of Montreal, the room capacity was sorely taxed with an attendance of 325.

The programme for the year was as follows:—

Jan. 13.—"**Recent Progress in Electric Arc Welding,**" by R. E. Smythies, M.E.I.C., vice-president, Lincoln Electric Company.

Jan. 27.—"**Some Dredging Problems,**" by W. E. Bonn, A.M.E.I.C., Toronto Harbour Commission.

Feb. 10.—"**Quality Concrete,**" by R. B. Young, M.E.I.C., laboratory engineer, Hydro-Electric Power Commission of Ontario.

Feb. 24.—"**The Contribution of the Engineer to the Immigration Problem,**" by A. G. Dalzell, M.E.I.C.

Mar. 10.—"**Valuation Work from the Engineer's Standpoint,**" by J. Hole, A.M.E.I.C.

Mar. 24.—Branch annual meeting.

Oct. 20.—"**Ice Engineering,**" by Dr. Howard T. Barnes, M.E.I.C., McGill University.

Nov. 3.—"**Non-bituminous Highway Materials and Their Uses,**" by A. T. Goldbeck, National Crushed Rock Association.

Nov. 17.—"**Grand Falls Power Development,**" by A. C. D. Blanchard, M.E.I.C., resident engineer for H. G. Acres and Company.

Dec. 1.—Luncheon meeting in honour of Prof. P. Gillespie, M.E.I.C., Vice-President of The Institute.

Dec. 15.—"**Recent Developments in Highway Construction,**" by R. M. Smith, A.M.E.I.C., acting deputy minister, Department of Highways, Ontario.

The membership of the branch shows a healthy condition. While subject to the normal fluctuations, the total shows an increase of 38 over the preceding year.

We regret to report the loss by death during the year of three valued members:—H. K. Wicksteed, M.E.I.C., C. H. Rust, M.E.I.C., and E. A. James, M.E.I.C.

Membership

The membership on December 31st, 1927, was as follows:—

	Residents	Non-residents	Total
Members	131	4	135
Associate Members	259	19	278
Juniors	52	5	57
Students	79	6	85
Affiliates	4	..	4
Branch Affiliates	2	..	2
Total	527	34	561
1926 total	496	27	523
Increase over 1926	31	7	38

Vancouver Branch

The President and Council,—

I have the honour to report on the affairs of the Vancouver Branch for the year 1927, as follows:—

In pursuance of the policy adopted during 1926, a programme of weekly meetings was continued during the months of January, February, March and April, 1927. To these meetings the Vancouver Section of the American Institute of Electrical Engineers, and the B.C. Division of the Canadian Institute of Mining and Metallurgy were invited; and throughout the year the closest co-operation has existed between the branch and the Association of Professional Engineers of British Columbia, many of the meetings being held jointly, and personal notices sent to members of both organizations. The Vancouver Branch of the Town Planning Institute of Canada and of the Royal Military College Club were also visitors at meetings which were of special interest to their members. The average attendance at all meetings throughout the year was 56.

Meetings

The following meetings were held by the branch during the year:—

Jan. 5.—"**The Development of an Engineer's Education,**" by E. E. Brydone-Jack, Ph.D., M.E.I.C.
Jan. 12.—"**Mountain Roads,**" by W. G. Swan, M.E.I.C.
Jan. 19.—"**Oscillographs,**" by H. Bickers, Ph.D.
Jan. 26.—"**The Mines of the Province,**" by J. D. Galloway.
Feb. 9.—"**Coast Range of British Columbia,**" by V. Dolmage, Ph.D.
Feb. 16.—"**Recent Developments in Oil Engines,**" by H. F. C. Letson, M.C., Ph.D.
Mar. 9.—"**Recent Advances in Metallurgy,**" by Prof. H. N. Thomson.
Mar. 16.—"**The Reading and Writing of an Engineer,**" by J. Porter.
Mar. 23.—"**The Work of the Vancouver and Districts Joint Sewerage and Drainage Board,**" by J. M. Begg, A.M.E.I.C.
Apr. 6.—"**The Engineering Profession and Its Relation to Engineering Education,**" by E. A. Wheatley, A.M.E.I.C.
Apr. 13.—"**B.C. Silver Mines,**" by C. A. Banks.
Apr. 27.—"**The Need for Wider Streets, as Developed by Investigation in Cities in America and Europe,**" by W. H. Tiedeman.
May 4.—"**Engineering Education,**" by Prof. W. E. Duckering.
May 11.—"**Britannia Mines,**" by C. P. Browning.
Nov. 9.—"**Kenya Colony and the Kenya and Uganda Railway,**" by Brig.-Gen. G. D. Rhodes, C.B.E., D.S.O., M.E.I.C.
Nov. 30.—"**The Reconstruction of the Ocean Falls Dam, 1922-1923,**" by A. K. Robertson, M.E.I.C.
Dec. 14.—Annual meeting.

Executive Committee

The Executive Committee held six regular meetings during 1927, the business of the branch being transacted by it. General meetings were confined strictly to a speaker and his subject, with the exception of the annual meeting. A special meeting of the executive was held on August 8th to meet R. J. Durley, M.E.I.C., general secretary of The Institute, when plans for the Western Professional Meeting to be held in Vancouver in June 1928 were discussed.

General Review of 1927 Business

Branch Elections:—Sixty-nine ballots were returned out of a total of 154 mailed, which is about the average.

Library:—Arrangements are now under way to arrange and index the library, to make it of more value to members.

Walter Moberly Memorial Prize:—The third award of this prize, consisting of eight books from the University Library, was made in May to G. W. Waddington, A.M.E.I.C., for the year 1927.

Royal Engineers Memorial Tablet:—In co-operation with the Association of Professional Engineers, a committee raised the necessary funds by subscriptions from members and erected at Alexandra bridge on the Cariboo road a cairn and bronze Memorial Tablet to the Royal Engineers who first constructed this historic highway. The tablet will be unveiled on July 1st, 1928, the dedication ceremony being conducted by Judge Howay.

Financial Statement

(December 15th, 1926, to December 14th, 1927)

Receipts

Dominion of Canada, " " "	5.00	
Bank interest	1.77	
		$77.15

Disbursements

Prize awarded to G. W. Waddington, A.M.E.I.C., (8 books)	$ 25.00	
Cash on hand, Dec. 14, 1927	52.15	
		$77.15

Bonds held for Trust:—	
City of Vancouver Bond No. 663, 5%, 1964	$500.00
Dominion of Canada, No. T.A. 065189, 5%, 1943	100.00
	$600.00

Audited and found correct,
J. Hardie Young, C.A.

The balance of cash on hand, $170.06, shows a slight improvement over the previous year. This will, however, be offset at the close of the year by an expenditure to be met of a minimum of $25.00 for the arranging and indexing of the library.

One cheque was drawn on the Walter Moberly Memorial Fund for $25.00 to cover the prize to G. W. Waddington, A.M.E.I.C., the balance on hand in this account now being $52.15.

It will be noted that rebates to the branch in 1927 were approximately $80.00 less than in 1926, accounted for almost entirely by the non-payment of fees by members.

In the passing of Messrs. James H. Kennedy, M.E.I.C., and E. Dundas Todd, A.M.E.I.C., the branch has suffered the loss of two of its truest friends.

On August 11th, F. W. Alexander, M.E.I.C., tendered his resignation as chairman of the branch. This was necessitated by his transfer from Vancouver to Winnipeg in the employ of his company. Since then W. Brand Young, A.M.E.I.C., vice-chairman, has guided the affairs of the branch, Mr. Alexander's chairmanship running to the present date.

Respectfully submitted,

W. BRAND YOUNG, A.M.E.I.C., *Chairman.*
F. P. V. COWLEY, A.M.E.I.C., *Secretary-Treasurer.*

Victoria Branch

The President and Council,—

On behalf of the Executive Committee, we beg to submit the following report of the Victoria Branch for the year ending November 30th, 1927:—

Membership

Many changes have appeared in the membership during the year. Three new members have come from other parts of Canada to reside in the district, D. A. Livingstone, A.M.E.I.C., Engr.-Commander A. D. M. Curry, M.E.I.C., and W. A. Richardson, A.M.E.I.C., and have been added to the roll. Eight members have left the district or severed their connection with the branch. The executive particularly regrets the loss of two members by the removal of their names from The Institute roll for non-payment of dues. The executive also regrets to record the death of Lt.-Col. Charles O'C. Donnelly, M.E.I.C., of Nanaimo, B.C., who died on December 20th, 1926.

The numerical standing of the branch is now:—

	Resident	Non-resident
Members	26	2
Associate Members	23	5
Juniors	0	0
Students	3	0
Branch Affiliates	1	0
	53	7

The total membership is 60, as compared with a total of 68 last year.

Officers

The Branch Executive for the year has been:—

Chairman ....E. Davis, M.E.I.C.
Vice-Chairman ....R. F. Davy, A.M.E.I.C.
Secretary-Treasurer ....K. M. Chadwick, M.E.I.C.
Executive ....H. F. Bourne, A.M.E.I.C.
W. S. Drewry, A.M.E.I.C.
E. P. Girdwood, M.E.I.C.
Ex-officio ....J. N. Anderson, A.M.E.I.C.
Councillor and Past-Chairman.

The executive held eight meetings during the year at which branch business was conducted.

Committees

The conveners of committees were as follows:—

Papers ....F. L. Macpherson, M.E.I.C.
Social ....W. M. Everall, A.M.E.I.C.
Library ....F. W. Knewstubb, A.M.E.I.C.
Town Planning ....E. G. Marriott, A.M.E.I.C.
Publicity ....G. B. Mitchell, M.E.I.C.

The whole executive acted as Attendance, Legislative and Credentials Committees.

In connection with the library, F. W. Knewstubb, A.M.E.I.C., reported that there were no changes during the year.

Meetings

The branch was fortunate during the past year in having an excellent series of addresses, luncheons and outings, which were arranged as follows:—

Dec. 1.—Address on "**Some Experience of a Land Surveyor,**" by F. C. Green, M.E.I.C.

Dec. 15.—Address on "**The Manufacture of Sulphite Pulp,**" by W. L. Ketchen, M.E.I.C., manager, British Columbia Pulp and Paper Company, Port Alice, B.C.

Jan. 11.—Members invited to attend meeting of British Columbia Land Surveyors' Association, to hear address by H. L. Seymour, M.E.I.C., on "**Town Planning,**"

Jan. 13.—Luncheon meeting, at which Mayor C. Pendray was the guest of honour and addressed the members on the advantages of the West Coast business to Victoria. Major Geo. A. Walkem, M.E.I.C., president of The Institute, was present at this meeting.

Jan. 26.—Illustrated address on "**Palestine and Syria,**" by F. G. Aldous, A.M.E.I.C., Lieutenant of the Royal Engineers.

Feb. 25.—Address on "**Town Planning,**" by W. Brand Young, A.M.E.I.C.

Mar. 16.—Address on "**Engineering in Warfare,**" by Major N. C. Sherman, M.E.I.C.

Apr. 7.—Address on "**Alouette and Stave Lakes Development,**" by E. E. Carpenter, M.E.I.C., consulting engineer, British Columbia Electric Railway Company, and on the "**Electric Equipment,**" by C. W. Colvin, assistant electrical engineer, of the same company.

Apr. 22.—Visit to the lithographing department of the *Daily Colonist,* followed in the evening by an illustrated address on "**Rainfall and Run-off,**" by E. G. Marriott, A.M.E.I.C.

Apr. 29.—Visit to mill of Canadian Puget Sound Lumber Company.

July 1.—Official opening of Esquimalt drydock, to which members of the branch were invited by the Celebration Committee of the Diamond Jubilee of Confederation.

Aug. 4.—Luncheon meeting in honour of R. J. Durley, M.E.I.C., General Secretary of The Institute, at which Institute affairs were discussed.

Aug. 10.—Visit to Jordon river power plant of the British Columbia Electric Railway Company.

Oct. 26.—Address on "**Town Planning,**" by Mr. Doughty-Davies.

Nov. 11.—Visit to plant of Sidney Roofing and Paper Company, by invitation of Mr. R. Mayhew, manager.

Meetings of Vancouver Island Prospectors' Association, to which members of the branch were invited. At the first meeting moving pictures of China were given by Mr. Hutcheson, member of the Royal College of Mines, London. At the second meeting, on,—

Nov. 15.—Address on "**Finley River District and Its Mining Possibilities,**" by Mr. Victor Dolmage, of the Dominion Geological Survey Department.

Nov. 23.—Address on "**Water Powers of the Dominion,**" by E. Davis, M.E.I.C.

Winnipeg Branch

The President and Council,—

On behalf of the Executive Committee, we beg to submit the following annual report of the Winnipeg Branch:—

The active membership on the books of the branch is 265, being as follows:—

Members	46
Associate Members	140
Juniors	21
Students	45
Local Affiliates	13
Total	265

Thirteen regular meetings were held in 1927 with an average attendance of 42. A special meeting, held jointly with the Association of Professional Engineers of the Province of Manitoba, was held in March. It took the form of a dinner-dance and entertainment in the Royal Alexandra hotel, Winnipeg. Some 250 members and guests attended this function. Another meeting deserving special mention was a complimentary luncheon tendered to the members of the Executive Committee and chairmen of standing and special committees by the chairman of the branch, Theo. Kipp, M.E.I.C. The luncheon was given in the Manitoba Club on March 8th. Its purpose was to provide an opportunity for the organization of the branch's activities for the year.

Following its custom, the branch presented prizes to four students of the University of Manitoba for the four best competitive papers. Two of the prizes went to the civil engineering section and two to the electrical engineering section. The winners in the civil section were: (1st) Harold Payne, S.E.I.C.; (2nd) A. Bain, S.E.I.C. The winners in the electrical section were: (1st) I. C. Ingimundson; (2nd) E. V. Hunt.

An event of the summer was the visit of General Secretary R. J. Durley, M.E.I.C.

The following is the financial report of the branch:—

Financial Statement

Receipts

Bank balance, Feb. 17, 1927	$1,148.08

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI MARCH 1928 No. 3

Report of Committee on Institute's Prizes and Medals

On page 284 of the May 1927 issue of The Engineering Journal there appears, under the column "Correspondence," the interim report of the Committee on The Institute's Prizes and Medals, in which the Committee outlined the situation with regard to the prizes and medals awarded by The Institute, and made certain recommendations with a view to revising the rules governing the award of Students' Prizes and the establishment of additional prizes. In the editorial column on page 278 of the same issue of the Journal there appeared a brief review of the report of this Committee.

Subsequently, at the Annual Meeting which has just taken place in Montreal, on February 14th, 1928, the Committee's final report was presented and adopted, and there are reproduced herewith, for the information of the membership at large, the rules governing the award of prizes to Students and Juniors; the rules governing the award of the Sir John Kennedy Medal and the rules governing the award of the Past-Presidents' Prize.

Rules Governing Award of Prizes to Students and Juniors

(1) Five prizes may be awarded annually for the best papers presented by Students or Juniors of The Institute in the Vice-Presidential zones of The Institute, as follows:—

The H. N. Ruttan Prize,—
in Zone A—The four western provinces.

The John Galbraith Prize,—
in Zone B—The province of Ontario.

The Phelps Johnson Prize,—
for an English Student or Junior in Zone C—The province of Quebec.

The Ernest Marceau Prize,—
for a French Student or Junior in Zone C—The province of Quebec.

The Martin Murphy Prize,—
in Zone D—The Maritime provinces.

(2) Awards shall only be made if, in the opinion of the examiners for a Zone, a paper of sufficient merit has been presented to a branch in that particular Zone.

(3) The winner of a prize shall be required to specify such technical books or instruments as he may desire to the total value of approximately twenty-five dollars when suitably bound and printed or engraved, as the case may be.

(4) The award of prizes shall be for the year ending June thirtieth. On that date, each branch secretary shall forward to the examiners for his particular Zone all papers presented to his branch by Students and Juniors during the prize year, regardless of whether they have been read before the branch or not.

(5) The prizes shall be awarded only to those who are in good standing as Students or Juniors of The Institute on June thirtieth following the presentation of the paper.

(6) The papers must be the bona fide production of those contributing them and must not have been previously made public or contributed to any other society in whole or in part. It is to be understood, however, that a paper which has won or been considered for a branch prize is nevertheless eligible for The Institute Prize. No paper shall be considered for more than one of the five prizes.

(7) The examiners for each Zone shall consist of the Vice-President of that Zone and two Councillors resident in the Zone, appointed by Council. In the case of Zone C, two groups of examiners shall be appointed under the two Vice-Presidents, one for the English award and one for the French award. The awards shall be reported to the Annual Meeting of The Institute next following the prize year, and the prizes presented as soon thereafter as is reasonably possible.

Rules Governing Award of the Sir John Kennedy Medal

A gold medal, to be called the "Sir John Kennedy Medal," may be struck and awarded under the following rules, in commemoration of the great services rendered to the development of Canada, to engineering science and to the profession by the late Sir John Kennedy, Past-President of The Engineering Institute of Canada.

(1) The medal shall be awarded by the Council of The Institute, but only when the occasion warrants, as a recognition of outstanding merit in the profession or of noteworthy contribution to the science of engineering or to the benefit of The Institute.

(2) As a guide in making the award, the Council of The Institute shall take into consideration the life, activities and standing in the community and profession of the late Sir John Kennedy.

(3) Awards shall be limited to corporate members.

(4) At the beginning of each year, every branch of The Institute shall be asked for its recommendation, supported by reasons, for the award of the medal, which must be submitted to Council not later than May 1st. The Council of The Institute shall then give consideration to the recommendations, but will not necessarily adopt any of them. If, in the opinion of the Council, no corporate member of The Institute thus recommended is of sufficient merit or distinction, no award shall be made.

(5) The award shall be decided by letter ballot of the Council in a form to be prescribed by the Council. The ballot shall be mailed to each member of the Council and shall state the date of the Council meeting at which it is proposed to canvass the ballot, which shall not be less than twenty days after the issue of the ballot. At least twenty votes shall be cast to constitute an award. Three or more negative votes shall exclude from an award.

(6) Announcement of an award shall be made in The Engineering Journal and at the Annual Meeting, and, if possible, the presentation shall take place at that meeting.

Rules Governing Award of the Past-Presidents' Prize

In recognition of the fund established in 1923 by the then living past-presidents and contributed to by subsequent past-presidents, a prize, to be called "The Past-Presidents' Prize," may be awarded annually according to the following rules:—

(1) The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July first to June thirtieth.

(2) In deciding on the subject to be specified, the Council shall confer with the branches, and use its discretion, with the object of selecting a subject which may appear desirable in order to facilitate the acquirement and the interchange of professional knowledge among the members of The Institute.

(3) The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

(4) The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved, as the case may be.

(5) All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

(6) All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local branch.

(7) The award shall be announced in The Engineering Journal and at the Annual Meeting, and, if possible, the presentation shall take place at that meeting.

Meetings of Council

Meeting of February 10th, 1928

A meeting of Council was held at 8 o'clock p.m. on Friday, February 10th, 1928, at Headquarters: President A. R. Decary, M.E.I.C., in the chair and eight other members of Council being present.

The secretary presented a report regarding the expense involved in the holding of Plenary Meetings of Council, and the benefits to be derived from such meetings, and was directed to publish this in an early issue of the Journal for the information of members.

The membership of the Nominating Committee for the current year was announced, as contained in the Report of Council for 1927, and D. C. Tennant, M.E.I.C., was appointed Chairman.

The Report of Council and the reports of the various committees of Council were considered, and approved for presentation at the Annual General Meeting.

A letter was submitted from the Calgary Branch containing a resolution passed by that branch favouring the continuation of research work in connection with the deterioration of concrete in alkali soils, and the secretary was directed to communicate with the National Research Council drawing their attention to the desirability of appropriating funds for the continuation of this important work.

An announcement regarding a World Engineering Congress to be held in Tokio in October 1929 was noted, and the secretary was directed to forward information regarding this to all the branches of The Institute.

Five applications for reinstatement were considered and approved.

Six special cases were given consideration.

Ten resignations were accepted.

The following elections and transfers were effected:—

Elections	
Member	1
Associate Members	4
Juniors	4
Students	6
Affiliate	1

Transfers	
Associate Member to Member	1
Junior to Associate Member	4
Student to Associate Member	7
Student to Junior	3
Affiliate to Associate Member	1

The Council rose at 10.30 o'clock p.m.

Meeting of February 13th, 1928

A special meeting of Council was held at Headquarters on Monday, February 13th, 1928, at 8 o'clock p.m.: President A. R. Decary, M.E.I.C., in the chair and eight other members of Council being present.

At this special meeting, Council was occupied with the consideration of the proposals for the amendment of By-laws; particularly with the objection which had been raised by one of the branches to the proposed amendment to Section 76.

An opinion having been obtained from Council's legal adviser as to the legality of making such changes in the wording of this amendment as would meet the objection referred to, it was decided that this should be done before the amendment is presented for discussion at the Annual General Meeting.

Suggestions having been received from the Ottawa and Hamilton Branches regarding the possibility of holding the Annual Meeting for 1929 in those cities, the secretary was directed to place this matter on the agenda for the Annual General Meeting.

The Council rose at 9 o'clock p.m.

Meeting of February 14th, 1928

A meeting of Council was held at 5.20 o'clock p.m. at the Windsor Hotel, Montreal, on Tuesday, February 14th, 1928: President Julian C. Smith, M.E.I.C., in the chair and ten other members of Council being present.

R. J. Durley, M.E.I.C., was unanimously reappointed as Secretary.

F. P. Shearwood, M.E.I.C., was unanimously reappointed as Treasurer.

The chairmen of the standing committees of The Institute were unanimously appointed as follows:—

Finance Committee ....J. H. Hunter, M.E.I.C.
Library and House Committee .....W. C. Adams, M.E.I.C.
Publications Committee ....P. L. Pratley, M.E.I.C.
Legislation and By-laws Committee. O. O. Lefebvre, M.E.I.C.

The attention of Council was drawn to a communication received from Colonel E. G. M. Cape, M.E.I.C., regarding the development of a standard contract form governing engineering construction work. P. L. Pratley, M.E.I.C., was appointed chairman of a committee to discuss this matter with the Canadian Construction Association, the other members of his committee to be appointed at the next meeting of Council.

The Council rose at 6.15 o'clock p.m.

ELECTIONS AND TRANSFERS

At the meeting of Council held on February 10th, 1928, the following elections and transfers were effected:—

Member

ANGELIS, Marius Lewis de, B.Sc. and A.C.G.I., (London City and Guilds Engrg. College), asst. elect'l engr., Mtl. Tramways Co., Montreal, Que.

Associate Members

HEROUX, Joseph Edmond Napoleon, B.A.Sc., (Laval Univ.), asst. engr. with tech. service, city of Montreal, Montreal, Que.

LAURIAULT, Wilfred Eldige, chem. engr., (Univ. of Mtl.), engr., tech. service, city of Montreal, Montreal, Que.

PRUD'HOMME, Michael Alexander, ch. dftsman, design and constrn. of ry. freight cars of spec. constrn. with Hart-Otis Car Co., Montreal, Que.

STE. MARIE, Louis Alexandre, B.A.Sc., (Laval Univ.), asst. engr., tech. service, city of Montreal, Montreal, Que.

Juniors

CHVILIVITZKY, Jakov, 4th year student, dept. of C.E., Univ. of Toronto, Toronto, Ont.

JACKSON, Charles H., B.A.Sc., (Univ. of Toronto), asst. supt., constrn.), paper mill constrn., Price Bros. & Co., Ltd., Riverbend, Que.

MATHIESON, T. Stanley, B.Sc., (Queen's Univ.), dftsman, Can. Int. Paper Co., Temiskaming and Hawkesbury, Ont.

SCHONI, Willy, dipl. elect'l engrg., (Swiss Polytechnique Inst.), asst. engr., switchboard engrg. dept., C.G.E. Co., Peterborough, Ont.

Affiliate

CHAPPELL, Melbourne Russell, general mgr. and vice-president, Chappell Bros. & Co., Ltd., Sydney, N.S.

Transferred from the class of Associate Member to that of Member

McVEAN, Harold Gordon, B.A.Sc., (Univ. of Toronto), consultant re business and personal estate org., estate taxation, life ins., business and personal trusts, etc., Toronto, Ont.

Transferred from the class of Junior to that of Associate Member

LUCAS, Leslie, plant mgr., Northern Canada Power Ltd., Timmins, Ont.

ROSE, Alexander Andrew, B.A.Sc., (Univ. of Toronto), head of tech. dept., Sault Ste. Marie Tech. School, Sault Ste. Marie, Ont.

ROSE, John Thorborn, B.A.Sc., (Univ. of Toronto), asst. engr. on Int. Hydrographic Aerial Survey, Winnipeg, Man.

ZEALAND, Edward L., B.A.Sc., (Univ. of Toronto), constrn. engr. on plant constrn., Aluminum Co. of Canada, Arvida, Que.

Transferred from the class of Student to that of Associate Member

BEECROFT, George William, B.A.Sc,. (Univ. of Toronto), field engr., El Centro Tropical Oil Co., Colombia, S.A.; at present on vacation.

BONNEVILLE, Sydney, B.Sc., (McGill Univ.), protection engr., reporting to transmission engr., Bell Tel. Co., Montreal, Que.

CHALMERS, Andrew Edward, B.Sc., (Queen's Univ.), engr. and road supt., twp. of Bertie in Welland county, Ont.

FLEMING, John Murray, B.A.Sc., (Univ. of Man.), designing engr. with C. D. Howe &. Co., Port Arthur, Ont.

GWYTHER, Valentine Mackenzie William, B.A.Sc., (Univ. of B.C.), ch. of party on land survey work, North Vancouver, B.C.

MESSENGER, William Aubrey, B.Sc., (McGill Univ.), vice-president and engr. with G. H. Emery Constrn. Co., Windsor, Ont.

WHITE, Joseph James, B.E., (Univ. of Sask.), supt. of general constrn. work and design with Miners and Ball, Ltd., Saskatoon, Sask.

Transferred from the class of Student to that of Junior

HARLOW, George Hammond, B.A.Sc., (Univ. of Toronto), instructor in thermodynamics at Univ. of Toronto, Toronto, Ont.

MORGAN, Frederick Stewart, B.A.Sc., (Univ. of B.C.), designer of struct. steel and reinforced concrete in constrn. dept., Knickerbocker Ice Co., New York, N.Y.

WESTREN, J. Harvey, B.A.Sc., (Univ. of Toronto), asst. supt., mech. goods div., Dunlop Tire and Rubber Corp., Toronto, Ont.

Transferred from the class of Affiliate to that of Associate Member

NELSON, Maxwell Stuart, B.Sc., (McGill Univ.), i/c design, detail, manufacture and installation of architectural and bldg. constrn., ironwork and light structural steel, A. Faustin, Ltd., Montreal.

Institute's Prizes Awarded

The reports of the committees on the award of Institute prizes for the past year, as presented at the Annual Meeting in Montreal on February 14th, 1928, are published in this issue of the Journal and show the following awards:—

THE LEONARD MEDAL to Sir Stopford Brunton, A.M.E.I.C., for his paper on "The Gold Deposits of Nova Scotia," which was published in July 1926 issue of the Bulletin of the Canadian Institute of Mining and Metallurgy.

THE PLUMMER MEDAL to Professor J. W. Shipley and Mr. Chas. F. Goodeve for their paper entitled "Alternating Current Electrolysis," which was published in the January 1927 issue of The Engineering Journal.

A STUDENTS' PRIZE to W. T. Fanjoy, S.E.I.C., for his paper on "Control of Common Types of A.C. Motors."

Of interest to the members is the report of a special committee of Council, which, after a careful study of the existing rules and regulations regarding the award of The Institute's Prizes, has recommended a revision of the rules regarding the award of prizes to Students and Juniors, the establishment of a prize in the form of a gold medal to be known as the Sir John Kennedy Medal, and rules regarding the award of this medal, and also rules governing the award of the Past-Presidents' Prize. The report of this committee was presented at the Annual Meeting in Montreal on February 14th, 1928, and was adopted by the meeting, and the rules recommended by the committee are published on another page of this issue for the information of the membership at large.

OBITUARY

Malcolm Hugh MacLeod, M.E.I.C.

In the death of Malcolm Hugh MacLeod, M.E.I.C., which occurred at his home in Toronto, Ont., on February 9th, 1928, The Institute has lost another of its first members, whose election as a Member of The Canadian Society of Civil Engineers took place on June 9th, 1887.

The late Mr. MacLeod was born in Scotland in 1857 and came to America with his parents in 1862, receiving his education in the public and private schools of Franklin, Pa., and New York. His first engineering work was as rodman on the Victoria Railway in 1875, and in 1879 he was appointed assistant on construction of the Credit Valley Railway. The following year he was employed with the Ontario Pacific Junction Railway, first as leveller and later as transitman on location surveys. In 1881 he joined the Ontario and Sault Ste. Marie Railway as transitman, and the next year was appointed resident engineer on construction of the Toronto and Ottawa Railway.

During the next two years Mr. MacLeod was engaged as resident engineer on the construction of the Lake Superior Division of the Canadian Pacific Railway Company, and the following year was in charge of the location survey and construction of the Atlantic and Northwest Railway. Subsequently, he was appointed superintendent of operations for the Crow's Nest Pass Division of the Canadian Pacific Railway Company. In 1900 he left the Canadian Pacific to become chief engineer of the Canadian Northern Railways, and was appointed general manager and chief engineer in 1907. Previous to the amalgamation of the Grand Trunk Pacific and the Canadian Northern Railways in 1923, he was appointed vice-president in charge of construction and after the amalgamation he became advisory engineer to the executive, in which position he remained until the time of his death.

Mr. MacLeod took an active interest in the affairs of The Institute and served on the Council during the years 1906, 1918 and 1919.

PERSONALS

George C. Clarke, A.M.E.I.C., who has been on the staff of the Harbour Drydock Company, Inc., New York City, has accepted a position in Montreal with Fraser-Brace Engineering Company, Limited.

Philip Hughes, S.E.I.C., who graduated from McGill University with the degree of B.Sc. in 1926, has joined the staff of the Bureau of Tests of the International Paper Company at Glen Falls, N.Y.

W. H. Abbott, A.M.E.I.C., has joined the staff of Busfield, McLeod Limited, and is taking charge of their heavy oil engine department. Mr. Abbott is now spending some months in England visiting various plants and studying latest developments in the oil engine field.

F. E. Emery, A.M.E.I.C., formerly employed in the construction department of Swift and Company, Chicago, Ill., has joined the staff of the International Steel and Iron Company at Chicago. Prior to going to Chicago in 1925, Mr. Emery was Alberta representative of The Manitoba Bridge and Iron Works.

A. D. Huether, A.M.E.I.C., has recently joined the organization of Busfield, McLeod Limited, as manager for Ontario, and has taken charge of the Toronto office of this company. Mr. Huether has been for a number of years with the construction department of the Ontario Hydro-Electric Power Commission, and is also well-known in Ontario as a former member of the Argonaut football team.

G. B. Lomer, A.M.E.I.C., who for some time past was designing engineer for the Power Corporation of Canada, is now located in Georgetown, British Guiana, as acting manager of The Demerara Electric Company, Limited. Mr. Lomer is a graduate of McGill University, from which he received the degree of B.Sc. in 1910. Following graduation, he was for a number of years with the following companies: Canadian Pacific Railway Company, Canadian Explosives, Limited, and the Wayagamack Pulp and Paper Company, Limited. From 1919 to 1920 he was with Smitch, Hinchman and Grylls, engineers, Detroit, Mich., as designing engineer. The following two years he spent with the Riordon Pulp and Paper Company as combustion engineer and subsequently with the E. B. Eddy Company in the same capacity.

W. R. Pearce, M.E.I.C., Receives Appointment in South America

W. R. Pearce, M.E.I.C., chief engineer of the New Brunswick Telephone Company, Limited, has severed his connection with that concern to accept the position of general superintendent of plants for the International Telephone and Telegraph Corporation of South America, and will have his headquarters in Montevideo, Uruguay. Mr. Pearce first entered the telephone field in 1905, immediately following graduation from Queen's University, becoming engaged with the Western Electric Company as an electrical student. He was first sent to Chicago, where he remained for four years, then going to Alberta. In 1909 he accepted a position with the Alberta Government Telephones and in 1912 was placed in charge of engineering construction and maintenance of the plant, with headquarters at Edmonton, Alta. Subsequently, in 1914, in addition to the engineering and plant department, he was placed in charge of the entire system. On March 1st, 1921, he accepted the position of chief engineer of the New Brunswick Telephone Company, Limited.

Major Chas. A. Doherty, A.M.E.I.C., now Located in Malta

Major Chas. A. Doherty, A.M.E.I.C., formerly connected with the Air Ministry, England, is now located in Valletta, Malta, where he is engaged upon construction work and the installation of a pumping plant and sewage system.

Major Doherty is a native of Erin, Ont., and entered the Faculty of Applied Science at the University of Toronto in 1913, but on account of the war he did not complete his course. He began his engineering work in 1911 as chainman with the Grand Trunk Pacific Railway, and was later with a firm of building contractors at Toronto and Scarboro, and subsequently with another firm of contractors as assistant to the chief engineer, and later in charge of all excavation and concrete work on No. 2 section of the Welland ship canal.

In 1916, he proceeded overseas with the Canadian Field Artillery and in July 1917 was seconded to the Department of Fortifications and Works War Office on aerodrome construction, subsequently being appointed resident engineer in charge of the construction of the Rockford Aerodrome, Essex. The following year he held the same position in charge of the construction of Norwich Acceptance Park and two training schools. In September 1918 he was transferred to the Air Construction Service, Royal Air Force, and placed in charge of all engineering and works services on aerodromes in Eastern and Midland counties, which territory was afterwards enlarged to include Western and Northern counties. Following the reorganization of this service, he was appointed sub-area officer with the rank of Major in charge of new construction and maintenance of permanent air stations from London and Bristol as far north as Liverpool and Hull.

Julian Cleveland Smith, LL.D., M.E.I.C.

President of The Engineering Institute of Canada

Occupying a prominent position in the engineering, industrial and business life of the Dominion, and with personal characteristics differing greatly from those usually associated with the great captains of industry, the newly-elected President of The Institute, Julian C. Smith, LL.D., M.E.I.C., M.I.E.E., F.AM.I.E.E., brings to the Council of The Institute, as its presiding officer, the experience and understanding of one who has advanced from a very junior position in his chosen profession to the responsible duty of directing one of Canada's greatest engineering industrial organizations.

JULIAN CLEVELAND SMITH, LL.D., M.E.I.C.

Mr. Smith was born on October 7th, 1878, at Elmira, N.Y., receiving his early education at the Central High School, Buffalo, and his engineering training at Cornell University, from which he graduated, with the degree of M.E., in 1900.

He began his business career as a draughtsman with Wallace C. Johnston, at Niagara Falls, N.Y., and in 1902 joined the organization of the Shawinigan Water and Power Company as assistant engineer of the Company's plant at Shawinigan Falls, Que. In 1903, he was appointed superintendent of the plant, and gradually advanced to the position of general superintendent and chief engineer of the Company. The next change was in 1913, when he became vice-president of the Company, and this was followed by his appointment as vice-president and general manager in 1916. The phenomenal development of the Shawinigan Water and Power Company and its subsidiary and associated companies, is in no small measure due to the genius of Mr. Smith, for his has been the dominating personality responsible for the growth which has taken place during the twenty-six years of his association with the Company.

The Company of which he is vice-president and general manager, from a small beginning, has become one of the greatest power companies in the world, controlling extensive resources, and serving a very large part of the inhabited portion of the province of Quebec. Besides the positions which he holds with the Shawinigan Water and Power Company, Mr. Smith presides over the activities of its many subsidiary companies. He is president of the United Securities Limited; the Montreal Tramways Company; the Quebec Power Company; the North Shore Power Company, Limited; the Shawinigan Chemicals, Limited; and the St. Maurice Power Company, Limited, and is vice-president of the Dominion Engineering Works, Limited, and director of a large number of companies, including the Dominion Bridge Company, Limited.

Mr. Smith has been the recipient of many honours, and in 1922 the degree of Doctor of Laws was conferred upon him by Queen's University, in recognition of his high attainments.

In addition to a thorough technical training, enriched by wide experience, Mr. Smith possesses a keen memory and discernment far above the average. He is by nature generous and sympathetic and modest to a degree and enjoys to a remarkable extent the esteem and affection of his associates.

Mr. Smith is a member of various clubs in New York and Montreal, and of the leading technical associations in England and the United States. He joined The Institute before its change of name, being elected a Student on January 14th, 1904. He was transferred in April of the same year to the grade of Associate Member, and was elected a Member on April 8th, 1911.

The Forty-Second Annual General and General Professional Meeting

Convened at Headquarters, Montreal, January 19th, 1928, and Adjourned to the Windsor Hotel, Montreal, February 14th, 1928.

Annual General Meeting at Institute Headquarters

The Forty-Second Annual General Meeting of The Institute was held at Headquarters on Thursday, January nineteenth, nineteen hundred and twenty-eight, at eight o'clock p.m., with President A. R. Decary, M.E.I.C., in the chair.

The secretary having read the notice convening the meeting, the minutes of the Forty-First Annual General Meeting were submitted, and, on the motion of F. S. B. Heward, A.M.E.I.C., seconded by B. Grand Mont, A.M.E.I.C., were taken as read and confirmed.

Appointment of Scrutineers

On the motion of J. L. Busfield, M.E.I.C., seconded by J. G. Caron, A.M.E.I.C., John S. Brisbane, A.M.E.I.C., and A. I. Vallieres, A.M.E.I.C., were appointed scrutineers to report the result of the Officers' Ballot.

Appointment of Auditors

On the motion of Geo. R. MacLeod, M.E.I.C., seconded by J. T. Farmer, M.E.I.C., Messrs. Riddell, Stead, Graham and Hutchison were appointed auditors for the ensuing year.

There being no other formal business, it was resolved, on the motion of K. B. Thornton, M.E.I.C., seconded by C. K. McLeod, A.M.E.I.C., that the meeting do adjourn to reconvene on Tuesday, February fourteenth, nineteen hundred and twenty-eight, at ten o'clock a.m., at the Windsor Hotel, Montreal.

The meeting accordingly adjourned at five minutes past eight o'clock p.m.

Meeting at Windsor Hotel, Montreal

The adjourned meeting was called to order by President A. R. Decary, M.E.I.C., in Windsor Hall, at the Windsor Hotel, at 10 o'clock a.m., on February fourteenth, nineteen hundred and twenty-eight.

The secretary having announced the messages of regret received from members and invited guests, the question of approval of the Prize Fund Regulations was considered. After a short discussion, the regulations, having already been approved by Council, were unanimously approved as governing the award of prizes to Students and Juniors, the award of the Sir John Kennedy Medal and the award of the Past-President's Prize.

As directed by Council, the secretary presented a statement which he had prepared regarding the Plenary Meeting of Council which was held in October last, giving information as to the cost and the benefits to be derived from such meetings. This memorandum was unanimously approved, the sense of the meeting being that the policy of holding Plenary Meetings should certainly be continued, and the hope being expressed that it might even be possible to hold two such meetings each year. This matter, however, was left for the decision of Council.

Reports of Council and Committees

On the motion of Geoffrey Stead, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C., the report of Council for 1927, as published on page 193 of the March issue of the Journal, was taken as read and approved, and consideration of the reports of the various committees followed.

The chairman of the Finance Committee, in presenting its report, drew attention to the satisfactory condition of The Institute's finances, and particularly to the way in which the expenses of publishing the Journal had been met. On the motion of J. H. Hunter, M.E.I.C., seconded by J. L. Rannie, M.E.I.C., the report of the Finance Committee was adopted.

The report of the Nominating Committee for 1928 was presented by the secretary, and, on the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by Geoffrey Stead, M.E.I.C., was unanimously adopted. The chairman stated that the Council had appointed D. C. Tennant, M.E.I.C., as chairman of the Nominating Committee for 1928 and announced its membership as printed on page 197 of the March issue of the Journal.

The report of the Papers Committee, as published on page 197 of the March issue of the Journal, was taken as read and was unanimously adopted, on the motion of J. L. Rannie, M.E.I.C., seconded by F. T. Kaelin, M.E.I.C.

The report of the Publications Committee, as published on page 197 of the March issue of the Journal, was unanimously adopted on the motion of P. L. Pratley, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C.

On the motion of C. K. McLeod, A.M.E.I.C., seconded by F. C. Laberge, M.E.I.C., the reports of the Board of Examiners and Education and of the Committee on Engineering Education, as published on pages 197 and 198 of the March issue of the Journal, were unanimously adopted.

The secretary read the reports of the committees dealing with the award of the Gzowski Medal, Leonard Medal, Plummer Medal and the Students' Prizes, as published on page 198 of the March issue of the Journal, and they were adopted on the motion of A. J. Grant, M.E.I.C., seconded by F. P. Shearwood, M.E.I.C.

The report of the Committee on Biographies, as published on page 198 of the March issue of the Journal, was adopted on the motion of Prof. P. Gillespie, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C.

The report of the Library and House Committee, as published on page 199 of the March issue of the Journal, was adopted on the motion of W. C. Adams, M.E.I.C., seconded by C. K. McLeod, A.M.E.I.C.

The report of the Committee on International Co-operation, as published on page 199 of the March issue of the Journal, was presented by B. S. McKenzie, M.E.I.C., and, on his motion, seconded by J. H. Hunter, M.E.I.C., was adopted.

The report of the Canadian National Committee of the International Electrotechnical Commission, as published on page 200 of the March issue of the Journal, was adopted on the motion of L. W. Gill, M.E.I.C., seconded by F. C. Laberge, M.E.I.C.

The report of the Honour Roll and War Trophies Committee, as published on page 200 of the March issue of the Journal, was adopted on the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C.

In presenting the report of the Committee on the

Deterioration of Concrete in Alkali Soils, as published on pages 200-202 of the March issue of the Journal, the secretary pointed out that this report should be read in connection with its two appendices, A and B, which, on account of the important technical information they contained, were being printed separately and presented at the General Professional Meeting on the 16th instant, these appendices giving respectively the complete history of the Committee's field specimens of concrete and the chemical findings which had been based on these field tests. C. J. Mackenzie, M.E.I.C., as chairman of the Committee, pointed out that the work of the Committee had involved the expenditure of over $40,000, a large proportion of which had been furnished by the National Research Council; that the Committee's funds had now been exhausted, and that it was very desirable to continue the investigations. He hoped that The Institute would approach the National Research Council with the request that they provide funds for the continuation of this work. Dean Mackenzie's views were supported by B. S. McKenzie, M.E.I.C., Brig.-Gen. C. H. Mitchell, M.E.I.C., and by Dean F. D. Adams, HON.M.E.I.C., and, on the motion of Geo. R. MacLeod, M.E.I.C., seconded by W. G. Mitchell, M.E.I.C., the Committee's report was adopted, on the understanding that a resolution would be drawn up and presented at a later period of the meeting, with the view of making representations to the National Research Council regarding the matter.

The report of The Institute's Members of the Main Committee of the Canadian Engineering Standards Association, as published on page 202 of the March issue of the Journal, was taken as read and adopted on the motion of F. P. Shearwood, M.E.I.C., seconded by K. L. Dawson, A.M.E.I.C.

Amendments to By-laws

In presenting for discussion the amendments proposed to the By-laws, the secretary pointed out that these were exceptionally numerous, that they had been published in the Journal for December 1927, page 532, and for January 1928, page 34, and that while the majority had been proposed by Council on the recommendation of the Legislation and By-laws Committee, a very important amendment affecting the method of electing members by letter ballot of the Council had been proposed by twenty corporate members of the Moncton Branch. The president pointed out that some of the proposed amendments involved merely minor changes in wording and could, perhaps, be dealt with first, and, after a brief discussion, on the motion of Geoffrey Stead, M.E.I.C., seconded by K. L. Dawson, A.M.E.I.C., it was resolved that the proposed amendments to Sections 68, 69 and 70 be submitted to the membership by letter ballot. Similar action followed in connection with the proposed amendments to Sections 9, 10, 18 and 24.

With regard to the proposed amendment to Section 35 dealing with the annual fees payable by members, the secretary drew attention to letters received regarding this matter from the Niagara Peninsula Branch, London Branch, Lethbridge Branch, Sault Ste. Marie Branch, Saskatchewan Branch, Peterborough Branch, Calgary Branch and Halifax Branch. Considerable discussion followed, during which W. J. Johnston, A.M.E.I.C., stated the views of the Saint John Branch, and it was pointed out that the proposal, which seeks to increase the fees of Members only, originated with the Plenary Meeting of Council in October last. The treasurer, Mr. Shearwood, drew attention to the difference in the expenditure per member for various purposes in the case of The Engineering Institute and the American Society of Civil Engineers, submitting figures showing that the expenditure on salaries, publications, travelling expenses and meetings is very much less per member in the case of The Engineering Institute, while the expenditure on local branches is much greater. W. G. Mitchell, M.E.I.C., pointed out that the progress and development of The Institute were dependent upon the provision of additional funds, and after prolonged discussion, the sense of the meeting appeared to be that while an increase in members' fees was desirable, the best method of allocating the increase between the various classes of membership was by no means clear. After further discussion, the chairman, in accordance with the provisions of Section 76 of the By-laws, appointed W. G. Mitchell, M.E.I.C., and K. L. Dawson, A.M.E.I.C., to state the reasons to be advanced in favour of the proposal, and O. O. Lefebvre, M.E.I.C., and C. H. Wright, M.E.I.C., to state the reasons for opposing the proposal, these statements to be sent out with the letter ballot.

The meeting adjourned at 12.45 p.m.

On re-assembling at 3 o'clock p.m., discussion was resumed on the report of the Committee on the Deterioration of Concrete in Alkali Soils, and, on the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by Professor C. M. McKergow, M.E.I.C., the following resolution was unanimously adopted.

> "This General Meeting of The Engineering Institute of Canada desires to place on record its great appreciation of the excellent work which has been done by the Committee on the Deterioration of Concrete in Alkali Soils, and realizes the enormous amount of time and attention which the Committee has devoted to the task involved in approaching and securing the funds for furthering its investigations.
>
> "The Meeting desires also to congratulate the Committee on its results.
>
> "This Annual Meeting, while desirous that the Committee be continued, recommend to the incoming Council that representations be made to the Research Council of Canada, which has so generously and sympathetically supported this useful work in the past, and urge that a further investigation into this subject be continued by them, believing that it is one of the most important subjects for research which they can undertake at this time.
>
> "Further, it recommends that if the Committee be continued the Council express to the Research Council that the past and future services of the Committee and the support of The Institute generally be available to the Research Council in this valuable work."

Discussion on the proposed amendments to the By-laws was then resumed, and the amendment proposed by Council to Section 52 was unanimously approved, without discussion, for inclusion in the letter ballot, as follows:—

> "In order to authorize the present practice in a number of branches, it is proposed to add to subsection (a) the words 'the secretary and treasurer may, as an alternative, be appointed by the Executive Committee instead of being elected by the members of the branch.'"

Similar action was taken as regards the proposed amendment to Section 53 which provides that in order to provide for the formation of Students' Sections in connection with branches, it is proposed to add to this Section an additional paragraph reading as follows:—

> "Students' Sections may likewise be established at the request of members of a branch, made in writing to the secretary of the branch, and approved by the Executive Committee. The rules for such Students' Sections shall be submitted to Council for approval."

The proposed amendment to Section 74 was also approved for inclusion in the letter ballot, reading as follows:—

> In order to authorize the present practice of not requiring subscriptions to the Journal from Honorary Members, Life Members and members who have compounded their fees, it is proposed to amend Section 74 as follows:—
>
> *Line 1*—Insert after the word "classes" the words "(except Honorary Members, Life Members and Members who have compounded their fees, who shall receive the Journal gratis)."
>
> *Line 2*—Delete the words "(form E in the appendix)."

Discussion followed on the amendment proposed by Council to Section 76, dealing with the procedure in amending By-laws, and the secretary explained the action which had been taken by Council to which exception had been taken by the Moncton Branch. A communication, comprising a preamble and resolution, forwarded by that branch under date of January 14th, 1928, was read to the meeting, together with subsequent correspondence between the secretary and the secretary-treasurer of the Moncton Branch.

The secretary then stated that subsequent to this correspondence, Council had taken legal advice as to whether, in order to meet the objections of the Moncton Branch, Council could legally change the wording but not the meaning or intent of its proposed amendments before submission to the Annual General Meeting for discussion, and also whether a proposal to amend a By-law could be withdrawn before submission to the Annual General Meeting. Counsel's reply to the first question was in the affirmative, provided that the modification is for clarity only and does not change the intent and purpose, and the reply to the second question was in the affirmative.

Having heard the explanation of Council's action on this matter, it was unanimously resolved, without further discussion, that the proposed amendment should go out to ballot in the revised form submitted by Council, as follows:—

It is proposed to change the second paragraph of Sectoin 76 so as to read:—

> "All proposals shall be submitted for discussion at the Annual Meeting; the members there present may propose an amendment or amendments thereto, and all proposals made with any such amendment or amendments shall be printed on the letter ballot to be submitted to the corporate membership of The Institute."

In presenting the amendment proposed to Section 29, dealing with the method of election of members by letter ballot of the Council, the secretary read the original communication dated January 12th, 1927, signed by twenty corporate members of the Moncton Branch, and explained that this proposal had been considered at the Plenary Meeting of Council, that Council had suggested the advisability of withdrawing it pending further consideration of the question, but that the members signing desired that the proposal should go out to ballot as it stood.

An active discussion followed, from which it appeared to be the sense of the meeting that some modification in the present method of electing members by letter ballot of Council was desirable, but that probably the proposal of the Moncton members, if carried, would not prove altogether satisfactory when put in operation. It was felt that Council should give the matter further study before putting forward a proposal for ballot. At the conclusion of the discussion, the president appointed J. H. Hunter, M.E.I.C., and C. E. Fraser, M.E.I.C., to prepare a statement giving the reasons for the proposed amendment, and O. O. Lefebvre, M.E.I.C., and W. G. Mitchell, M.E.I.C., to prepare a statement of the reasons against, for inclusion in the letter ballot.

With regard to the reports of the several branches, the president suggested that in view of the fact that these were in the members' hands in printed form, they might be dealt with in one resolution, unless discussion was desired on any particular report.

This was agreed to, and, on the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by J. H. Hunter, M.E.I.C., it was unanimously resolved that the branch reports be taken as read and accepted.

Col. E. G. M. Cape, M.E.I.C., drew attention to the development during the past few years of standard contract forms by the Canadian Construction Association, these forms at present three in number, covering respectively the relations between the general contractor and the owner, the general contractor and the sub-contractors, and the nature of contracts to be carried out on a cost-plus basis. The forms had now been tried in practice for some years, and had been extensively modified as the result of experience; the Canadian Construction Association now desired their consideration by The Engineering Institute of Canada. After discussion, on the motion of Col. E. G. M. Cape, M.E.I.C., seconded by J. H. Hunter, M.E.I.C., the following resolution was unanimously adopted:—

> "Resolved, that the Council of The Engineering Institute of Canada be requested to appoint a Committee to consider the standard contract forms adopted by the Canadian Construction Association at its 1928 Convention in Winnipeg, that this Committee be instructed to report to Council concerning these forms and that Council be authorized to act on this report."

Prof. H. E. T. Haultain, M.E.I.C., drew attention to the excellence of the arrangements made by the Montreal Branch in connection with the meeting, and, on his motion, seconded by L. W. Gill, M.E.I.C., it was unanimously resolved that the enthusiastic thanks of this Meeting be accorded to the officers and members of the Montreal Branch for their hospitality and activity in connection with the Annual General Meeting.

Election of Officers

The secretary having read the report of the scrutineers appointed to canvass the officers' ballot for 1928, the following were declared elected:—

President	Julian C. Smith, M.E.I.C.
Vice-Presidents	
Zone B.	A. J. Grant, M.E.I.C.
Zone C.	W. G. Mitchell, M.E.I.C.
Zone D.	F. O. Condon, M.E.I.C.
Councillors	
Victoria Branch	E. Davis, M.E.I.C.
Vancouver Branch	W. H. Powell, M.E.I.C.
Calgary Branch	P. J. Jennings, M.E.I.C.
Edmonton Branch	R. J. Gibb, M.E.I.C.
Lethbridge Branch	R. Livingstone, M.E.I.C.
Saskatchewan Branch	H. R. MacKenzie, A.M.E.I.C.
Winnipeg Branch	H. A. Dixon, A.M.E.I.C.
Sault Ste. Marie Branch	J. M. Silliman, A.M.E.I.C.
Lakehead Branch	R. B. Chandler, M.E.I.C.
Border Cities Branch	A. J. M. Bowman, A.M.E.I.C.
Niagara Peninsula Branch	M. B. Atkinson, M.E.I.C.
London Branch	W. P. Near, M.E.I.C.
Hamilton Branch	W. F. McLaren, M.E.I.C.
Toronto Branch	J. G. R. Wainwright, A.M.E.I.C.
Peterborough Branch	R. L. Dobbin, M.E.I.C.
Kingston Branch	L. T. Rutledge, M.E.I.C.
Ottawa Branch	J. D. Craig, M.E.I.C.

Montreal Branch	Fraser S. Keith, M.E.I.C.
	O. O. Lefebvre, M.E.I.C.
St. Maurice Valley Branch	B. Grand Mont, A.M.E.I.C.
Quebec Branch	A. B. Normandin, A.M.E.I.C.
Saguenay Branch	N. F. McCaghey, A.M.E.I.C.
Moncton Branch	F. L. West, M.E.I.C.
Saint John Branch	J. Stephens, M.E.I.C.
Cape Breton Branch	W. E. Clarke, M.E.I.C.
Halifax Branch	H. W. L. Doane, M.E.I.C.

On the motion of Geoffrey Stead, M.E.I.C., seconded by P. L. Pratley, M.E.I.C., it was unanimously resolved that the report of the scrutineers be accepted, and that the ballot papers be destroyed.

President Decary, before relinquishing the Chair, expressed his thanks for the honour of presiding over the affairs of The Institute for the year 1927, and congratulated The Institute on the benefits which had accrued from the Plenary Meeting of Council held in October 1927. He hoped that this would be only the first of a number of such meetings, and believed that it would be beneficial to have two such meetings each year, if possible. He thanked the members of Council and The Institute's staff for their support and assistance during the year.

On the suggestion of J. L. Rannie, M.E.I.C., the Meeting expressed its appreciation of President Decary's conduct of the business of The Institute by prolonged and enthusiastic applause.

Induction of Newly-Elected President

On relinquishing the Chair, President Decary asked Dr. A. Surveyer, M.E.I.C., past-president, and Brig.-Gen. C. H. Mitchell, M.E.I.C., to escort the president-elect to the Chair, and the gentlemen named complied with his request amidst applause, upon which the retiring president welcomed Julian C. Smith, M.E.I.C., to the Presidential Chair, and bespoke for him the same loyalty and the same measure of co-operation which had been accorded to himself.

In taking the Chair as president, Mr. Smith expressed his appreciation of the honour conferred upon him, which he took as a compliment, not only to himself personally, but also to those men who had been associated with him for many years in engineering work.

The secretary reported the receipt of suggestions from two branches, namely, Hamilton and Ottawa, that the Annual General Meeting for 1929 should be held at one of those cities, and the invitations were confirmed by E. H. Darling, M.E.I.C., and W. L. McFaul, M.E.I.C., on behalf of the Hamilton Branch, and by J. L. Rannie, M.E.I.C., on behalf of the Ottawa Branch.

The president expressed appreciation of these invitations, and pointed out that the locality for the next Annual Meeting is not usually decided at the Annual General Meeting, but is considered by Council. After further discussion, on the motion of L. W. Gill, M.E.I.C., seconded by Prof. C. M. McKergow, M.E.I.C., it was resolved that the question of the locality for the next Annual General Meeting be referred to Council.

There being no further business, the president declared the meeting adjourned.

The Annual General Professional Meeting

Luncheon

At the noon hour between the morning and afternoon sessions of the Annual General Meeting on Tuesday, February 14th, a complimentary luncheon to visiting members and ladies was held in the Rose Room of the Windsor Hotel at which F. C. Laberge, M.E.I.C., chairman of the Montreal Branch, presided and in a short address welcomed the visiting members and ladies. Alderman Mercure, representing His Worship the Mayor of Montreal, welcomed the visitors to the city, following which Mr. George Henderson, president of the Montreal Board of Trade, also addressed the members.

Ladies' Tea

During the afternoon of the same day the ladies were entertained at tea in the Prince of Wales Salon, which was graced by the presence of Lady Willingdon, who had graciously expressed a desire to meet the ladies who were attending the meeting. Mrs. Julian C. Smith thanked Her Excellency for her kindness in honouring the function by her presence, following which a bouquet of orchids and lilies-of-the-valley was presented to Her Excellency.

Popular Lecture

In the evening, Dr. L. E. Pariseau, radiologist at Hôtel Dieu, Montreal, gave a very interesting, instructive and entertaining address and demonstration on "What the Electrical Engineers Have Done for the Physicians of To-day" before a large gathering in the Windsor Hall. Dr. Pariseau had addressed the members of the Montreal Branch on several occasions, but never had he delighted his audience more than on this occasion.

Smoker

After a short intermission following Dr. Pariseau's address, during which tables were set, the members and guests returned to the Windsor Hall, where the remaining hours of the evening were given over to the enjoyment of a smoking concert which, for the quality of the entertainment, deserves special mention. The large hall was filled to capacity, and while refreshments were served the various features of the programme were introduced in rapid succession.

First Technical Session

On Wednesday, February 15th, at 9.30 a.m. the first of the technical sessions was held; two separate meetings being carried on simultaneously, one in Windsor Hall and the other in the Prince of Wales Salon.

The meeting in Windsor Hall was under the chairmanship of F. C. Laberge, M.E.I.C., and the following papers were presented in abstract and discussed:—

"The Chippawa Creek Syphon Culvert of the Welland Ship Canal," by A. J. Grant, M.E.I.C.

"Foundations of the Royal Bank Building, Montreal," by C. S. Proctor.

At the meeting in the Prince of Wales Salon, under the chairmanship of A. A. Bowman, M.E.I.C., the papers presented and discussed were:—

"Notes on the Uniflow Steam Engine," by A. E. Allcut, M.E.I.C.

"The Lock Gates of the Welland Ship Canal," by Frank E. Sterns, M.E.I.C.

Luncheon

At noon an informal luncheon was held in the Rose Room and was attended by a large number of members and ladies.

Visits to Engineering Works

The visits on Wednesday afternoon, February 15th, were deservedly popular, and the arrangements were most favourably commented upon. Through the courtesy of the Montreal Tramways Company, seven busses were provided to transport the visitors to and from the works. As each bus had been supplied with a destination sign, the parties were quickly formed and left the Dorchester street entrance of the hotel sharply at 2.30 p.m.

Montreal South Shore Bridge

The forty or more members of The Institute who visited the site of the Montreal South Shore Bridge left the bus at Delorimier avenue near the end of the city approach, and, under the guidance of P. L. Pratley, M.E.I.C., and engineers of the Dominion Bridge Company, viewed the foundations of the city approach and inspected the north anchor pier. Those who so desired were taken to the deck of the bridge by the contractor's elevator, where they viewed the steelwork of the main span at close range.

Northern Electric Company

A party of fifteen enjoyed a visit to the Northern Electric Company, where they were received by Mr. Campbell. This establishment has about 4,000 employees. The party was conducted through the various departments and had a splendid opportunity to observe the processes by which the different products of the company are manufactured. Of outstanding interest were the large braiders of the cable department.

New Filtration Plant and Water Works

As the result of the mild weather, the new interceptor sewer of the city of Montreal had become filled with mud and water and could not be inspected, so that those who had anticipated taking this visit were, through the courtesy of C. J. Desbaillets, M.E.I.C., shown the new filtration plant and water works of the city of Montreal.

New Cold Storage Plant

The new cold storage plant of the Montreal Rail and Water Terminals, Limited, was visited by a party of members of The Institute. Mr. Curtis, president and general manager, Mr. Webber, assistant general manager, Mr. Carmel, superintendent, and Mr. Patterson, chief engineer, met the party at the plant and made the visit both interesting and instructive.

Associated Screen News

While the party to the plant of the Associated Screen News had been limited to twenty, over forty members of The Institute availed themselves of the opportunity to visit this interesting works. The manager, B. E. Norrish, A.M.E.I.C., welcomed the visitors and conducted them through the plant, where they viewed the various processes of grading, developing, printing, colouring, drying, polishing, waxing, inspecting, producing and reproducing all varieties of art and studio and commercial motion picture films.

Victor Talking Machine Company

A party of forty-eight members and friends visited the Victor Talking Machine Company of Canada, Limited, where they were cordially received by Mr. G. J. White, and were conducted through the plant, visiting all the various departments. Of particular interest was the record department, where records were being made on hydraulic presses at 2,200 pounds pressure.

Royal Bank Building

The new head office building of the Royal Bank of Canada was visited by twenty-seven members and were welcomed by R. M. Robertson, A.M.E.I.C., representing the Dominion Bridge Company, and Mr. H. Ferguson, of the Geo. Fuller Company, and O. A. Barwick, A.M.E.I.C., representing the architectural department of the Royal Bank. The members had an opportunity of inspecting the building from the sub-basement to its uppermost storey.

Dominion Engineering Works

About forty engineers availed themselves of the opportunity to visit the works of the Dominion Engineering Company at Lachine, whither they were conveyed in two busses, under the direction of C. E. Herd, A.M.E.I.C., of the company's staff. They were met on arrival at the plant by G. H. Duggan, M.E.I.C., president of the company, H. G. Welsford, A.M.E.I.C., the general manager, and several other officers of the company, who conducted the party through the works. The main products of this well-equipped plant are paper machines and water turbines, of which a large number were in all stages of manufacture. One of the features of the visit was the pouring of a large head-cover casting in the foundry, weighing about twenty-five tons, to be used in the manufacture of a 28,000-h.p. turbine for the Manitoba Power Company. Great interest was manifested in the large machine and erection shop, which contains some very heavy machinery for turning out the largest paper machines and water wheels.

Ladies Entertained

On Wednesday afternoon, February 15th, by the kindness of Lady Van Horne, the visiting ladies were invited to view the private collection of pictures of the late Sir William Van Horne. Following this the ladies were entertained by Mrs. Geo. H. Duggan at tea at her residence.

Annual Dinner

The Annual Dinner of The Institute, which took place in the Rose Room on the evening of Wednesday, February 15th, was perhaps the outstanding feature of the series of functions of the meeting, each of which in turn was proclaimed a remarkable success. Honoured by the presence of His Excellency Lord Willingdon, HON. M.E.I.C., and presided over by President Julian C. Smith, M.E.I.C., with a distinguished gathering of guests at the head table, the dinner was one of the most successful in the history of The Institute.

After a few introductory remarks by the president, His Excellency addressed the gathering, and in a felicitous speech he dealt with the profound influence exerted by engineers and their work on every phase of present-day life, and described some of his own experiences in Madras, where one of the great modern irrigation schemes was completed and opened during his period of office, bringing under cultivation some 800,000 acres of what was practically desert. This was only one example of the services rendered by engineers in Madras which had done so much to prevent famine and disaster in that great country.

The Hon. Honore Mercier, provincial minister of lands and forests, paid high tribute to the service rendered by engineers to the province, and was followed by Beaudry Leman, A.M.E.I.C., general manager of the Banque Canadienne Nationale, who recalled his early association as an engineer with Mr. Julian Smith, and appealed, on behalf of business, for a larger quota from the ranks of technically-trained university men.

Mr. J. P. Hines, president of the Royal Architectural Institute of Canada, brought the greetings of that association, and an address from Dr. R. A. Ross, M.E.I.C., past-president of The Engineering Institute of Canada, concluded the programme.

Ladies' Dinner

At the same hour as the Annual Dinner, the ladies were entertained at a dinner at the Cercle Universitaire de Montréal, which was presided over by Mrs. F. P. Shearwood. Following the dinner, the ladies were addressed by Mrs. Shearwood, Mrs. B. Grand Mont and Mrs. W. G. Mitchell.

Second Technical Session

The second technical session was held on Thursday morning, February 16th, commencing at 9.30 a.m., when two separate meetings were again held, one in Windsor Hall, under the chairmanship of P. L. Pratley, M.E.I.C., and the other in the Prince of Wales Salon, under the chairmanship of J. A. McCrory, M.E.I.C.

The papers presented and discussed in the Windsor Hall were:—

"Bridges Over the Welland Ship Canal," by M. B. Atkinson, M.E.I.C.

"Steel Work for the Royal Bank Building in Montreal," by R. M. Robertson, A.M.E.I.C.

At the meeting in the Prince of Wales Salon the following papers were presented:—

"The Electrical Heating of Rack Bars in Hydro-Electric Plants," by C. R. Reid.

"Notes on Removal of Carbon-Sulphur Compounds from Coal Gas by Oil Washing," by K. L. Dawson, A.M.E.I.C.

"The Flow of Gases in Reverberatory Furnaces," by W. K. Thompson, A.M.E.I.C.

Third Technical Session

The last of the series of technical sessions was held on the afternoon of Thursday, February 16th, in the Windsor Hall, during which the Chair was occupied by A. Duperron, M.E.I.C., and the following papers were presented and discussed:—

"The Requirements of a Durable Concrete, as Observed from Structures in Service," by R. B. Young, M.E.I.C.

"The Effect of Steam Treatment of Portland Cement Mortars on Their Resistance to Sulphate Action," by T. Thorvaldson and V. A. Vigfusson.

"Appendices A and B to the Report of the Committee on the Deterioration of Concrete in Alkali Soils."

All of the technical sessions were well attended, and in each case the papers gave rise to interesting discussions.

Reception for Ladies

On Thursday afternoon, February 16th, Mrs. W. L. McDougald received the ladies at her residence.

Reception and Supper-Dance

The final function of the meeting was the reception and supper-dance held on the evening of February 16th. Dancing commenced at 9 p.m. in the Windsor Hall, and supper was served about midnight in the Rose Room. The guests on their arrival were received by Mrs. Julian C. Smith, Mrs. J. L. Busfield and Mrs. F. P. Shearwood. This was one of the most delightful functions of the meeting and proved a fitting ending to the three days of business sessions and social functions.

EMPLOYMENT BUREAU

Situation Wanted

Electrical Engineer

McGill graduate, 1926. Experienced in estimating, factory production, mechanical and electrical design, switchboard layouts. Available at short notice. Apply box No. 232-W, The Engineering Journal.

Situations Vacant

Mechanical Draughtsman

Mechanical draughtsman with at least four years experience in newsprint mill work. Good opening for right man in newsprint mill in province of Quebec. Apply, stating salary expected. Apply box No. 179-V, The Engineering Journal.

Designing Engineer

Designing engineer, experienced in pulp and paper machinery design, to take charge of draughting office in large newsprint mill in the province of Quebec. Applicant must be technical graduate. Apply, stating salary expected, to box No. 180-V, The Engineering Journal.

Young engineer with several years experience to spend part time on machine design work and remainder on survey work in connection with large newsprint mill in province of Quebec. Apply, stating salary expected, to box No. 188-V, The Engineering Journal.

BOOK REVIEWS

Introduction to Contemporary Physics

By Karl K. Darrow, New York, D. Van Nostrand Company, 1926. Buckram, 6 x 9½ in., 453 pp., diagrs., tables, $6.00.

Research workers in physics today are confronted with the task of keeping abreast with the progress of investigation, not only in their particular fields, but also in closely connected domains. The output of scientific papers from laboratories the world over has practically doubled in the last decade. Much new information on properties of matter and radiation is added from year to year as the number of investigators in various countries contribute their share. Many of these new discoveries are certain to be of service to many branches of engineering. To enable the research engineers of the Bell Telephone laboratories to keep fully informed of the latest advances in physics, and physics today is largely atomic physics, Dr. Darrow has made it his special task to prepare for his colleagues, and for the scientific world at large, careful digests of contemporary publications. A perusal of his book is evidence of the thoroughness and success with which he has achieved a difficult piece of writing. So intimately are experimental and theoretical physics connected today, that the mathematical language of the latter is largely employed by experimenters in describing their results, so that scientific papers as published need interpretation to others than specialists. Dr. Darrow has essentially the gift of simple exposition. In simple yet accurate language, with a minimum of mathematical exposition, he develops the entrancing history of atomic discoveries, how electrons are selected, counted, weighed and measured with respect to electric charge, and how by analogous means, utilizing a stream of positively charged atoms, the masses of atomic nuclei may be measured to an accuracy of one part in a thousand, this work of Aston's revealing the existence of elements called isotopes chemically indistinguishable. Rutherford's studies of atomic nuclei are dealt with in an interesting chapter, in such a way as to reveal something of their complex structure, high speed electrons and α-particles being used as projectiles to dissociate atoms and to give us some information as to the intense electrical fields in their innermost recesses. A discussion of X-rays and optical spectra, with their interpretation in terms of Bohr's atom model, occupies the final third of the volume. The final word has not been said, however. . . . So rapid is the output of new material that a book is almost out of date when printed, so much so that in point of fact Dr. Darrow publishes serially in the Bell System Technical Journal current chapters on contemporary advances in physics. The scientific public will look forward with great interest to the publication of this collection as a sequel to the volume just reviewed.

Louis V. King,
Professor of Physics,
McGill University.

The Water Supply of Towns

By W. K. Burton and J. E. Dumbleton, 2 vols., 4th Edition. London, Crosby, Lockwood & Son, 1928, Buckram, 7½ x 10 in., 296 pp., diagrs., tables, $6.00.

This is the fourth edition of Mr. Burton's well-known work which originally appeared some twenty years ago, revised and brought up to date by Mr. Dumbleton.

This book is that comparatively rare thing, a well-written general text without a great deal of specific data. Consequently, it may be recommended to those engineers who desire a general knowledge of water supply engineering and can refer to other sources for more detailed information and data. This type of engineering treatise is much more popular across the Atlantic than on this side; perhaps we try to crowd too much information into too little space here.

The authors have succeeded in producing a most readable book. Its literary qualities are much in advance of those with which we are most familiar, as some of our texts, the very best from a technical standpoint, are exceedingly poor when considered as examples of English composition.

Two appendices, one dealing with the effect of earthquakes on water supply structures, by Prof. John Milne, F.R.S., and the other on sand dunes as a source of water supply, by Mr. John de Rijke, add a good deal to our rather limited knowledge of these two particular subjects.

A somewhat exotic flavour is given to this treatise by frequent references to Japanese practice. These are accounted for by the fact that Mr. Burton was for many years professor of sanitary engineering at the Imperial University in Tokio as well as sanitary engineer to the Japanese Home Department.

Burton and Dumbleton can be recommended as a useful work of this type, but should not be purchased by the practising engineer in the expectation that he will find it a compendium of engineering data relating to water supply, as that is most precisely what the book is not.

R. De L. French, M.E.I.C.

Professor of Highway and Municipal Engineering, McGill University.

Faults and Failures in Hot-Water Work

By Frederick W. Dye. E. & F. N. Spon, Ltd., London, 1927. Buckram, 7½ x 5 in., 216 pp., figs., $2.00.

This interesting reference book takes the form of a series of questions and answers regarding practical problems and difficulties which have actually presented themselves. These illustrate a great variety of mistakes that are frequently made, and show how they may be avoided or overcome. The work thus deals entirely with faults and failures in hot-water installations, both central heating and domestic hot-water supply, and is evidently based on long experience.

The general principles and theories involved are outlined to a limited extent, and are analyzed sufficiently for the purpose of the book, which should prove valuable to anyone engaged in the design and installation of such classes of work.

E. A. Ryan, M.E.I.C.

Consulting Engineer, Montreal, Que.

Mining Engineers' Handbook

By Robert Peele, 2nd Edition. John Wiley & Sons, 1927. Leather, 7 x 4 in., 2,523 pp., diagrs., tables, $10.00.

The new edition of "Peele" recognizes the advances which have been made in mining practice since the publication of the first edition in 1918. It remains the handy reference book for tables and data of use in the every-day work of the mining engineer. A corps of assistant editors, each a specialist in his particular field, supply information in concise form on the various phases of the mining industry. It is interesting to note that Canadian mining is regarded as of sufficient importance to include a summary of the mining laws and regulations of the various provinces. Costs at certain Canadian mines have also secured a place.

Special attention is paid to the increasing use of electric power in mine plants, costs have been brought up to date, some sections have been enlarged and several rewritten. More information is available on surveying, particularly aerial, on flotation and ventilation of mines. Ore dressing as the subject of a chapter has been dropped and replaced by notes found on breaking, crushing and sorting of ore. "Peele" will be found a useful necessity to the student as well as to the operating engineer, the latter finding it advisable to replace his volume with one of the new edition.

J. G. Ross.

Consulting Mining Engineer, Milton Hersey Company, Limited.

Diesel Engines

By A. P. Chalkey. D. Van Nostrand Company, New York, 1927, 6th Edition. Buckram, 6 x 9½ in., 320 pp., tables, figs., diagrs., $8.00.

This book, first published in 1912 when the Diesel engine was comparatively young, has now reached its sixth edition, and this is no small testimony to its value.

The rapid development of the Diesel engine and its increasing application to stationary, locomotive and marine engine practice makes it very difficult to write or revise any book dealing with so progressive a subject. It may be premised, therefore, that this edition contains the principal advances made in Diesel engine practice up to the end of 1926.

The various heat cycles for internal combustion engines are first dealt with, the importance of compression and expansion ratios being duly noted. Necessary modifications in the theoretical cycle due to practical considerations and the advantages and limitations of the four- and two-stroke cycles are then discussed. A noteworthy omission from this part of the book is a reference to the effect of variable specific heat of the gases on the practical application of the various cycles. This might well have been briefly summarized for the benefit of the readers.

Reasons for the increase in the power obtainable from engine cylinders and the properties necessary in the fuels employed are then considered in detail. A very large section of the book is occupied by descriptions of the various designs used in practice, and this section is very copiously illustrated. First, low- and medium-speed engines for use on land or as marine auxiliaries are treated. There follows a discussion of two-cycle engines, scavenging, air compressors and supercharging. The rise to importance of airless injection by the use of precombustion and pump injection, and its influence on the design of high-speed engines for locomotive and similar work, is illustrated by a brief description of engines running at 700-1,500 revolutions per minute. In this connection, much recent research work has been done, particularly relating to the shape of combustion chamber, size of fuel drops, atomization and penetration, but no mention of this appears in this work.

Practical points with reference to installation, space, costs and test results are fully described. A minor criticism in connection with the test results on pages 140-1 and 151-2 is that such figures might reasonably be expressed in FPS units, as the average engineer for whom the book was designed cannot visualize the meaning of some of the figures given in the CGS system and will have to convert them and make up new tables for himself before they can be useful to him.

The large and powerful four- and two-stroke engines now used for marine work are fully described and the problem of reversing is adequately handled.

Altogether, the book is a useful addition to the library of any engineer who is principally interested in practical mechanical detail, but gives little information on problems relating to combustion and the advances made in this connection by recent research. As a compendium of present-day practice and a book of reference in this respect it is admirable.

E. A. Allcut, M.E.I.C.

Associate Professor, Mechanical Engineering, University of Toronto.

A Short History of Physics

By H. Buckley. D. Van Nostrand Company, New York, 1927. Buckram, 7 x 5 in., 263 pp., $3.00.

A prominent automobile manufacturer once made the arresting observation that "history is bunk!" Doubtless, the critic hardly intended his stricture to include the history of a science, but rather meant that inconsequential mass of less significant narratives about battles, kings and dynasties, (with copious dates), to which we used to be exposed as the significant history of the race and earth. There is at present a reaction, and the early twentieth century crop of popularized, though more significant, history is blossoming. Vide:—Outlines of History, (Wells), History of Science, (Thompson), Story of Philosophy, (Durant), History of Religion, History of Civilization, and many other histories. We soon shall have as many histories as Francis Bacon asked for. We may be sure that this popularized history will be followed by more erudite examinations of the same great topics.

The present book is history rather than a story of the science of physics. It could not be called "popular," yet is easy reading and is sound. Since the book comprises only 254 pages of clear print, it has to confine itself to successful survivals of the principles of physical science and pays little attention to theories which lacked survival power against the accumulating evidence of practical experiment. It deals, not with histories and developments of physical devices, instruments and machines, but the evolution of foundation principles underlying all these applications is well traced out.

In method, the author compiles no mere chronological record of physical discovery, rather, he treats a great topic, indicated by the headings of his chapters, by weaving its tale through the centuries to the present day, explaining as he goes the meaning of each discovery and correlating it with previous ones.

Since most of engineering is applied physics or chemistry, the engineer will find in this little book the foundation principles of his profession. For, although the title is "History of *Physics*," the contents of the chapters on Conservation of Mass, The Atomic Theory of Matter, The Atomic Theory of Electricity, The Quantam Theory and The Structure of the Atom give a fine understanding of the combined modern chemico-physics, and include the basic history of much of the chemistry which is of interest to the engineer. These chapters, together with those on Planetary Theory and Mechanics, The Corpuscular and Elastic Solid and Electro-magnetic Wave Theories of Light, Magnetism and Electricity, Radiation and Theory of Relativity cover well the current views of physics of the present day.

The reviewer wishes, even though the book would thereby have grown a little larger, that a short chapter or two had been added tracing historically the successful principles of hydro-dynamics and elasticity, and a short chapter to constitute in essence the evolution of mathematical physics. With these the book would have been even more complete and more useful to the engineer.

It is significant that fully one-third of the book is devoted to the physics of the last thirty or forty years, which shows how rapidly the progress,—or should the reviewer rather say the pursuit,—of science is accelerating. And one who reads may learn of the puzzles and incompatibilities between quantam theory and wave theory, of the necessary revisions in our fundamental formulations in mechanics and physics introduced by the theory of relativity, and of the prevailing physical models of the structure of the atom. If the author had included a brief account of the new wave mechanics, with its unaccountable "Ψ-waves" moving inconceivably fast in a medium of we don't know what, his history might have been said to be "up to the very last minute!" But perhaps the author, instead of including these new surmises, decided it was better to wait.

A useful feature of this short history is the list of "general references" mentioned at the end of each chapter. If a reader wished to pursue the study of physics or of its history and acquired all the books here named he would be the owner of a first-rate physics library.

Dean, Faculty of Applied Science, University of Alberta.

Pyroxylin Enamels and Lacquers

By S. P. Wilson. D. Van Nostrand Company, New York, 1927, 2nd Edition. Buckram, 9 x 6 in., 253 pp., figs., $3.50.

The importance of the subject treated lies in the ever-increasing application of such enamels and lacquers to the automotive industry, the manufacture of artificial leather and their use for the finishing of iceless refrigerators, railway equipment and furniture. The raw material is cellulose, and this implies an increasing consumption of Canadian wood pulp for this purpose.

An interesting feature of the industry lies in the development of new solvents for pyroxylin, such as glycol ethers, synthetic amyl alcohol, (from petroleum), and its acetate, and butyl alcohol. All these developments have been accompanied by a decline in price of the raw materials and finished lacquers, thus further stimulating consumption.

Whilst large and comprehensive textbooks on the subject are available for the expert, this handbook seems calculated to fill the need experienced by many engineers and chemists for a source of recent and accurate information for manufacturing purposes. It is that; and is well printed, as well.

The increasing consumption of pyroxylin lacquers and thinners is shown by the following figures: 1921, 1,410,000 gallons; 1925, 7,390,000 gallons; 1926, 12,980,000 gallons.

The scope of the book is as follows: pyroxylin, solvents and non-solvents, plasticisers, gums and resins, pigments and dyes; bronzing liquids, leather dopes, lacquers, enamels and their manufacture, applications and analytical methods.

It is claimed that by the use of lacquers a car can be finished in two days, as against the one to three weeks formerly required, and that it is very easy to train a man in the use of the spray gun employed.

The chapter on solvents is particularly well written, giving as it does not only an account of their properties but also a brief description of the manufacture of synthetic methyl, ethyl and amyl alcohols, (fusel oil). The only serious omission noticed is the failure to mention the manufacture of synthetic acetone from acetylene at Shawinigan Falls. The reviewer is also pleased to note the warning uttered about the toxicity of synthetic methanol when used for spraying lacquers.

BRANCH NEWS

Border Cities Branch

Orville Rolfson, A.M.E.I.C., Secretary-Treasurer.
(Reported by R. C. Leslie, Jr.E.I.C.)

Bridges

Frank Barber, M.E.I.C., consulting engineer, from Toronto, was the speaker at the February meeting of the Border Cities Branch, held, as usual, in the Prince Edward hotel, Windsor. Mr. Barber's topic was "Bridges," and he brings to his subject a background of highly successful endeavour along the line of bridge construction. Among Mr. Barber's outstanding achievements are his bridges at Peterborough and Leaside.

The speaker went back to the early feats of bridge building that are on record. He spoke very highly of the quality of work done by the ancients in their structures, and cited the case of the Porte Rotto, in Rome, which, though built in 178 B.C., was still standing. It was noted that at the present time over 50 per cent of the bridges in Europe are over one hundred years old, which shows that they were designed and constructed with a view to permanence. In contrast to the thoroughness of the ancients, and even the builders of one to two hundred years ago, their modern successors were building less durable structures. In recent years in America some twenty-nine bridges had failed to stand up as much as two years after being built. The cause of this seemed to be, in most cases, the undermining of the bases by spring freshets.

The importance of proper architectural treatment was emphasized. The engineer was in many cases too prone to neglect this feature, and the result was that often bridges do not properly fit in with their surroundings. While the architectural features of bridges are of great importance, the engineer is still the responsible party for the vital members, making sure that the structure is safe and serviceable for the traffic it must carry.

The speaker illustrated his address by pictures on the screen dealing with the various features upon which he touched.

Mr. Barber was followed by several members of the branch who entered into a general discussion of the subject.

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

Practical Results of Recent Research on Decay of Concrete by Sulphate Solutions

The following synopsis of the paper delivered by C. J. Mackenzie, M.E.I.C., dean of engineering, University of Saskatchewan, on January 18th, will give some idea of the importance of the subject dealt with, namely, "Practical Results of Recent Research on Decay of Concrete by Sulphate Solutions." He dealt primarily with the findings of a committee which was created as a result of a resolution passed at the Western Professional Meeting of The Institute in Banff during 1920, which committee was also authorized to solicit funds to defray expenses of such a research. Under the chairmanship of Dean Mackenzie, some $47,000 was raised to carry on a very limited programme of field tests at points in Manitoba, Saskatchewan and Alberta where alkali conditions were severe, but the major portion of the fund was allocated to chemical research, of which Dr. Thorvaldson, professor of chemistry at the University of Saskatchewan, was in charge. He explained that a large number of papers and reports have been issued in which the general nature of the problem had been clearly set down. It was in 1905, he said, that the matter of the action of alkali waters of western Canada and the United States on concrete was brought home to western engineers very forcibly. Prominent engineers and architects had before that time refused to admit that well-made concrete could be so destroyed. By the time of the Banff meeting in 1920 it was generally recognized by engineers of the prairie provinces, largely as the result of field tests by committees of the Calgary, Saskatchewan and Winnipeg Branches of The Institute,—(1) that any Portland cement concrete, no matter how well made, would be affected if exposed to alkali ground waters of sufficient strength; (2) that alkali action on concrete was due chiefly to sodium sulphate and magnesium sulphate; (3) that the richer, stronger and more impermeable the concrete the greater its resistance to alkali action; (4) that the sulphates reacted with the free lime to form calcium sulpho aluminate, causing a shattering of the weakened concrete.

He claimed that chemists were now of the opinion that very little was really known about the setting, hardening and nature of Portland cement, either before or after attack by alkali waters, and that laboratory tests have proven conclusively that any Portland cement concrete will be disintegrated by alkali waters if such waters are of sufficient strength. An important finding resulting from the tests made by competent engineers of recent years is that different standard Portland cements which may have similar strengths are very different in their sulphate resistance, and that such cements made at different mills vary even more widely in their resistance to sulphate waters. He pointed out that any extensive series of field tests should undoubtedly be dictated by laboratory leads, especially when such great differences in Portland cements have to be contended with. Also, it has been found that the relative sulphate resistance of two cements may differ with different mixes. Such work as that carried out by Dr. Thorvaldson and others along these lines makes it possible to analyze a local condition with more discrimination, and by tests select a cement that will serve perhaps two or three times as long as some concretes made in the past.

Professor Mackenzie went on to explain the method adopted by Dr. Thorvaldson in testing the action of sulphate solution on cement when in 1922 he discovered a quantitative method, an account of which appeared in the Journal in April of last year. This method saved endless labour and the testing of some hundred and eighty briquet samples in place of the one bar of cement used by him. In short, he found that a Portland cement mortar bar expands continuously until complete failure occurs, when immersed in sulphate solutions, sometimes as much as 3 per cent in excess of normal, and that this increase in length is related definitely to the loss of strength of the bar for every practical cement and mix. Instead of breaking many thousands of briquets, a few bars can be measured at various intervals of time, and the same information obtained, without destruction of the bars. The bars are exactly ⅝ x ⅝ x 7½ inches and the expansion is measured by micrometer. An expansion of 0.5 per cent on an average corresponds to a loss in strength of 60 per cent and one of 1 per cent to a loss of about 70 per cent in strength, which in practice would probably mean the failure of any structure. Full particulars of this method will be published later, some having already appeared in the April 1927 issue of the Journal.

The speaker discoursed at length on the variation of sulphate resistance of different Portland cements and of the claims of the so-called high alumina cements, referring to some extensive tests in France made on this product. He also touched on the steam treatment for the curing of concrete. He paid a tribute to the generosity of the Canadian Pacific Railway Company, the Prairie provinces, the Canada Cement Company and the National Research Council for the financial support which made the work of these researches possible, citing also the latter's extra contribution, beyond that originally offered, and their moral support, and he appealed to engineers as a whole to support freely the objects of the National Research Council, describing it as the most helpful agency in Canada to-day for the placing of individual and scientific research on an effective basis.

Some excellent resolutions in support of the splendid work that the special committee under Dean Mackenzie is doing were carried, being made by A. S. Dawson, M.E.I.C., and seconded by S. G. Porter, M.E.I.C. An interesting discussion on the subject of the lecture followed, after which the thanks of the meeting were tendered to the speaker by the chairman, F. K. Beach, A.M.E.I.C.

Maintaining Efficiency in Hydro-Electric Plants

On Thursday evening last, H. J. McLean, A.M.E.I.C., presented a paper to the Calgary Branch in the Board of Trade rooms on "Maintaining Efficiency in Hydro-Electric Plants," with especial reference to the plants of the Calgary Power Company, Limited, at Seebe, of which he is resident construction engineer. The speaker covered his subject in a very able manner and with the aid of charts gave a clear insight into the methods adopted to improve the plant efficiency, especially when dealing with expected load demands. He explained that the problem at hand at the upper and lower dams is to ensure a continuous, adequate supply at the power plants where at Kananaskis the stored water is used in driving turbines delivering at 12,000 volts to the Horseshoe falls plant lower down the river. Here it is boosted up by transformers to 55,000 volts for transmission to Cochrane, Calgary and south lines.

Situated some fifty miles west of Calgary, the two plants at Kananaskis and Seebe have a capacity of 13,000 h.p. at 73-foot head and 22,000 h.p. at 72-foot head respectively, the combined installed capacity of the two plants being 35,000 h.p. Water in the forebay at Kananaskis is used at both the upper and lower plants, and it has been ascertained that at least 216 k.w. hrs. may be expected from each second-foot of water passing, while a storage of 873 acre-feet is worth an output of over 95,000 k.w. hrs. Similarly, the pondage at Horseshoe falls plant is worth over 26,000 k.w. hrs. Lake Minnewanka, which is situated some thirty-three miles from the plants, forms an additional reserve storage capacity of 44,000 acre-feet.

In explaining plant efficiency, he pointed out that one problem was to discover the most effective load for each machine to carry, emphasizing how inefficient it was to try and carry a load of say, 1,000 k.w. on a 5,000 k.w. unit. Such proper knowledge, correctly applied, enables the operators to adjust their units to the demand, which under the best conditions can exceed the 80 per cent efficiency value generally accepted as a maximum in modern engineering. He explained the salt-velocity, or Allen, method of determining the amount of water required to generate a given load, when electrodes are placed in the penstock and the saline solution affects the electrical apparatus at each end where ammeter readings indicate the velocity.

Communication is hourly kept up by telephone between the two plants in connection with operator's records to show how well each is operating. The hourly records are checked and plotted to show daily combined plant efficiency, daily gross and net output, and the output in kilowatts per second-foot of water available. The local warm Chinook winds have a very disturbing effect on the running of a plant of this kind. In reference to steam electric plants, he pointed out that the bugbear known as " peak load demands " is a source of considerable annoyance to most of them, but with hydro-electric this particular phase offers no trouble at all, providing the pondage is adequate.

This address was followed by a very interesting discussion in which many members took part and a number of technical questions were ably answered by the speaker. Vice-Chairman Thos. Lees, A.M.E.I.C., took the chair for the evening in the absence of the chairman, F. K. Beach, A.M.E.I.C., and he thanked Mr. McLean for a very well presented and valuable paper.

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

Engineering Education

The Halifax Branch opened its season 1927-28 by a supper-meeting at the " Green Lantern " on Thursday, October 20th, 1927.

Professor F. R. Faulkner, M.E.I.C., addressed the gathering on " Engineering Education." Professor Faulkner dealt with the subject in a skilful manner, showing the faults and merits of college curriculi, and recounted the methods used to analyze the opinions of engineers concerning them and the results of the analyses so obtained. He pointed out that the practising engineer must continue a system of education, particularly in regard to the ethics of his profession and the advances rapidly taking place in structural methods.

Following the address, considerable discussion took place, practically all members present joining in the discussion.

Canadian History

The November meeting of the branch, which was held on November 24th, 1927, was addressed by Dr. H. F. Munro, superintendent of education for the province of Nova Scotia. Dr. Munro's subject was " Canadian History," and in discussing the purpose and scope of history he stated that it is essential that we know whence we and our institutions came and our probable future trend. History was a difficult subject to teach in public schools, because most people have a very vague sense of time and find it very difficult to link the present with the past. The purpose of history is to teach the cause of things and thereby enable individuals to better understand the duties of the present, that is, to become better citizens. The scope of history in the past has been chiefly to chronicle the amours and battles of kings and warriors or other national crises. The true scope of history more suited to modern ideas should include the study of national institutions.

Dr. Munro emphasized the value of local history; national and international events can be vitalized by linking them with local conditions. Even the names of towns, counties, people, etc., are influenced by historical events occurring at some time during the past.

Canada has made a unique and perhaps momentous contribution to history in four outstanding ways:—

(1) Canada has realized responsible government without a revolution and still remains an integral part of the British Commonwealth.

(2) Canada has shown how two peoples, hereditary rivals, can live in harmony together through the will to be one nation.

(3) Canada has developed a government in which are fused the best of the federal and parliamentary systems. It is the federal type of government on a parliamentary basis.

(4) Canada has evolved the Dominion type of government, possessing thereby complete autonomy while remaining part of the British Commonwealth of nations. This type of government is the keystone of the Commonwealth and is now used by all the Dominions.

A hearty vote of thanks was extended to Dr. Munro for his very excellent address.

At the conclusion of the address, two motion pictures showing the manufacture of the electric bulb and the principles of radio transmission and reception were shown through the courtesy of the Canadian General Electric Company, Limited, and C. H. Wright, M.E.I.C., district manager of that company.

Annual Meeting

The ninth annual meeting of the Halifax Branch was held in the St. Julien room of the Halifax hotel on Thursday, December 22nd, 1927. Seventy-two members and guests assembled for dinner. Entertainment was supplied by " The Gas House Quartette," including Paul Mosher, Ken. Dawson, Fred. Faulkner and " Cy " Cox.

Among the guests present were:—

Mr. Justice Mellish, of the Supreme Court of Nova Scotia.
Mr. J. B. Kenny, mayor of Halifax.
Hon. W. L. Hall, attorney-general of Nova Scotia.
Hon. Gordon S. Harrington, minister of mines.
Hon. J. Fred. Fraser, chairman, Nova Scotia Power Commission.
Hon. J. A. Walker, minister of natural resources.
Dr. F. H. Sexton, president, Nova Scotia Technical College.
Lieut.-Col. Bun Russell, O.C., R.C.E.

The address of the evening was given by Mr. Justice Mellish, who spoke in a very humorous way on the elementary engineering implements used by our forefathers. Judge Mellish, in his inimitable way, presented these facts to the great pleasure of his audience.

The following officers were elected for 1928:—

Chairman......J. F. Lumsden, M.E.I.C., general manager of the Nova Scotia Tramways and Power Company, Limited.

W. J. DeWolf, A.M.E.I.C., city engineer's office.

W. B. McKay, A.M.E.I.C., heating engineer, Halifax.

H. W. Mahon, A.M.E.I.C., Nova Scotia Power Commission.

A. R. Chambers, A.M.E.I.C., vice-president, The Malagash Salt Products, Limited.

H. C. Burchell, M.E.I.C., Windsor, N.S.

C. B. McDougall, M.E.I.C.

Montreal South Shore Bridge

The January meeting of the branch was held in the " Green Lantern " on January 12th, 1928. The new chairman, J. F. Lumsden, M.E.I.C., was in the chair, and prior to the address of the evening the matter of increase of fees to members was taken up. Owing to the fact that the meeting was a public meeting at 8.00 o'clock, the question was not finally settled.

P. L. Pratley, M.E.I.C., of Monsarrat and Pratley, consulting engineers, Montreal, then addressed a large gathering on the construction of the Montreal South Shore Bridge. In introducing Mr. Pratley to the meeting, C. E. W. Dodwell, HON.M.E.I.C., spoke reminiscently of his connection with early attempts to build bridges across the St. Lawrence. Mr. Pratley's address was followed very closely, and it was the consensus of opinion that the paper, in its subject matter and presentation, could not have been excelled. A vote of thanks to Mr. Pratley was moved by C. A. Fowler, M.E.I.C., and seconded by R. W. McColough, M.E.I.C.

This address was opportune in the city of Halifax, as it was at the time of the inception of a committee to look into the construction of a bridge connecting Halifax with Dartmouth. In this campaign, the Halifax Branch, through its individual members, is taking a prominent part.

Special Meeting

A special meeting of the Halifax Branch was called on February 2nd, 1928, for the purpose of discussing the matter of closer relationship between The Engineering Institute of Canada in Nova Scotia and the Association of Professional Engineers of Nova Scotia; also the matter of increase in fees to members. The discussion in both matters was very general, and the conclusions reached are summarized in the resolutions which were adopted. H. S. Johnston, M.E.I.C., moved, and W. F. McKnight, A.M.E.I.C., seconded, the following resolution, which was adopted:—

" Whereas, the Association of Professional Engineers of Nova Scotia has authorized its Council to appoint a committee to investigate the possibilities of closer co-operation and even possible affiliation with The Engineering Institute of Canada in Nova Scotia;

"And whereas, the Council of The Engineering Institute of Canada has expressed its opinion that the consideration of the above question is desirable;

"Therefore, be it resolved

"That the Executive Committee of the Halifax Branch appoint a special committee of three to co-operate with the committee appointed by the Council of the Association of Professional Engineers of Nova Scotia for the purpose of investigating and reporting upon the possibilities of closer co-operation and even ultimate affiliation between the said Association and the said Institute in Nova Scotia, and that a copy of this resolution be sent to the Sydney, N.S., Branch of the said Institute seeking its co-operation towards the attainment of this report, and also that a copy of this resolution be sent to the general secretary of the said Institute."

In the matter of the increase in fees, the following committee was appointed to prepare a statement for Council of The Institute, summarizing the opinions of the members of this Branch. This committee consisted of:—

W. A. Winfield, M.E.I.C.
Prof. F. R. Faulkner, M.E.I.C.
W. J. DeWolfe, A.M.E.I.C.
H. F. Bennett, A.M.E.I.C.

This committee forwarded to the Council, prior to the Annual Meeting, a lengthy document in this matter, the gist of which may be summarized as follows:—

"That so long as the standards of Member and Associate Member remain as at present no extra difference in fees should be proposed.

"That the $5.00 increase in fees to Members will force a number of resignations which might be avoided by a small increase to all corporate members and Juniors.

"That the $5.00 increase in fees to Members only will help to restrict that grade to those who can pay rather than to those whose qualifications and responsibilities warrant special recognition.

"That it is most unfortunate that this proposal is made at this time, and we would strongly recommend that the proposed amendment be withdrawn, or defeated in balloting, so that Council can institute a thorough canvass of the membership and have ready for submission at the next Annual Meeting a revision worthy of The Institute as a whole."

A letter was read by the chairman from the Hon. Gordon S. Harrington, minister of mines of the province of Nova Scotia, asking that The Engineering Institute of Canada appoint a member on an Advisory Board to be convened by the Department of Mines of Nova Scotia for the investigation now going on as to the best methods of using Nova Scotian coals. The meeting appreciated the privilege of appointing a member, and recommended to Mr. Harrington the name of K. L. Dawson, A.M.E.I.C., to act for The Engineering Institute of Canada.

The Romance of Railway Location

The regular February meeting of the branch was held on February 16th at the "Green Lantern." The address of the evening was given by A. S. Gunn, A.M.E.I.C., assistant engineer in charge of construction, Canadian National Railways, Moncton, N.B. Mr. Gunn's subject dealt with the "Romance of Railway Location," and his very interesting talk took the members back to the days when large railway undertakings were in progress in this country. That Mr. Gunn's talk was appreciated was shown by the general discussion which followed.

During the meeting, motion pictures showing the "Caterpillar" tractors operating in the removal of snow and on highway construction were shown through the courtesy of R. R. Murray, A.M.E.I.C.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

Branch Meeting, January 31st, 1928

A meeting of the Hamilton Branch was held in the cafeteria of the Technical School on the evening of Tuesday, January 31st, with L. W. Gill, M.E.I.C., in the chair. There was an attendance of well over one hundred, including A. J. Grant, M.E.I.C., chief engineer of the Welland ship canal, and E. G. Cameron, A.M.E.I.C., assistant engineer from St. Catharines, and T. J. Mahoney, M.L.A. On the recommendation of the Executive Committee and on the motion of E. H. Darling, M.E.I.C., seconded by H. A. Lumsden, M.E.I.C., it was unanimously decided to invite the parent society to hold the Annual General and General Professional Meeting for 1929 in Hamilton.

St. Lawrence Waterways Project

Mr. Gill then introduced F. I. Ker, A.M.E.I.C., who spoke on the economic and political features of the St. Lawrence waterways project. Mr. Ker briefly outlined the history of navigation on the Great Lakes and St. Lawrence river, including the canals at Sault Ste. Marie, the channels through the St. Clair and Detroit rivers, the Welland canal and the St. Lawrence canals. He read several interesting extracts from the records of the original undertaking. Up to the present time, including the Welland ship canal, Canada has appropriated $235,000,000 upon improvement of navigation on the St. Lawrence and the Great Lakes, whereas the United States has spent $44,700,000.

At the present time the large freighters on the upper lakes can only proceed as far as the foot of lake Erie. The result of this restriction has been to create transfer elevator centres on the Georgian bay and at Port Colborne and Buffalo. The elevator capacity at Buffalo is 35,000,000 bushels, whereas the total capacity on lake Huron and Georgian bay is 23,000,000 bushels.

Mr. Ker gave figures regarding the cost of movement of Canadian wheat over existing routes and stated that the present movement is approximately 240,000,000 bushels. Proponents of the deep waterway say that the new rate with the deep waterway in operation would mean a saving of five cents a bushel or $12,000,000 on 240,000,000 bushels. It is, however, exceedingly unlikely that more than half this saving would be realized.

An estimated cost of enlarging the St. Lawrence waterways, according to the report of the Joint Board of Engineers, is approximately $180,000,000, of which $142,000,000 would be spent by Canada and $38,000,000 by the United States. It is obvious, therefore, that the saving effected by Canada on the grain movement would not justify the expenditure on the St. Lawrence waterways.

The deep waterways system would, however, result in a much greater saving for the people of the United States. The Hoover Commission estimates that approximately 20,000,000 tons of American shipping would be available for the St. Lawrence route, and it is estimated that there will be a saving of $3.00 a ton or $60,000,000 a year. The people of the United States quite realize the difficulties of the position and are quite willing to negotiate a fair division of the cost.

According to treaties now in existence, the British and American shipping have equal rights on all international rivers including the St. Lawrence, Columbia, Yukon and even the Mississippi. It is, therefore, impossible for Canada to develop the St. Lawrence waterways and charge tolls to American shipping without charging Canadian shipping at the same time. There are proposals regarding the division of cost, either by direct contribution from the United States or by a schedule of tolls collected from the shipping from both countries with the United States Government guarantee of a minimum of 20,000,000 tons. It would seem that this would be the better plan, in that it does not allow the United States to have any equity, actual or moral, in the capital cost of public works carried out in this country.

Power Development

The people of Ontario are primarily interested in the project from the view point of the power to be developed. At present the Niagara system supplies over 86 per cent of the total power distributed by the Hydro-Electric Power Commission of Ontario. In the area supplied by the Niagara system, the per capita consumption last year was 1,534 kilowatt hours. In eastern and central Ontario there is scarcely one-fourth of the power presently available per capita in the southwest of the province and the average rates are much higher. In the area which would be served by the St. Lawrence river power, the average consumption per capita was 378 kilowatt hours. This illustrates that there is the demand for St. Lawrence power in Ontario. To meet current requirements the Hydro-Electric Power Commission of Ontario recently contracted with the Gatineau Power Company for 260,000 horse power for a period of thirty years. This Quebec power is regarded as a stop gap pending the development of Ontario's power on the St. Lawrence.

Mr. Ker then went into the report of the Joint Board of Engineers in a general way and outlined the various alternative schemes which were proposed.

The harmony of our relations with the United States and the joint use of the St. Lawrence river for over a century have been largely a result of British diplomacy. Their recent proposal that we should join with them in carrying out the recommendations of the commissions affords one of the major opportunities that Canadian statesmanship has had of showing that it possesses the breadth of vision and quality of fair dealing so essential to the amicable settlement of international questions.

J. W. Tyrrell, M.E.I.C., in moving a vote of thanks, remarked that the large audience must have been intensely interested in the address they had listened to that evening, and that Mr. Ker must have devoted a great deal of time and study to the subject to present it with such clearness. J. J. MacKay, M.E.I.C., in a short speech, seconded the motion.

Executive Meeting

A meeting of the Executive Committee of the branch was held in the office of W. L. McFaul, M.E.I.C., on February 6th, 1928, with L. W. Gill, M.E.I.C., in the chair, and four other members of the executive present.

L. W. Gill, M.E.I.C., and E. H. Darling, M.E.I.C., were appointed official representatives of the Hamilton Branch at the Annual Meeting in Montreal. They were requested to present the invitation of the branch to hold the next Annual Meeting in Hamilton in accordance with the resolution passed at the branch meeting held on January 31st.

It was decided to ask the co-operation of the Niagara Peninsula Branch in the proposal to hold the next Annual Meeting in Hamilton and to offer the assistance of the Hamilton Branch in their proposed summer meeting.

Since the Hamilton Chamber of Commerce was very desirous of obtaining the Annual Meeting for Hamilton and had offered their support, the secretary was instructed to advise them of the proposal to invite The Institute to hold the 1929 Annual Meeting in Hamilton.

Kingston Branch

D. G. Geiger, A.M.E.I.C., Secretary-Treasurer.

A well attended meeting of the Kingston Branch was held in Carruthers Hall, Queen's University, on February 1st, 1928, Prof. D. S. Ellis, A.M.E.I.C., chairman of the branch, presiding.

The speaker of the evening, P. L. Pratley, M.E.I.C., of the firm of Monsarrat and Pratley, consulting engineers, Montreal, was introduced by Prof. W. P. Wilgar, M.E.I.C., and spoke on the history and construction of the Montreal harbour bridge.

At the close of Mr. Pratley's address a vote of thanks was moved by Prof. A. Macphail, M.E.I.C., and seconded by Prof. W. L. Malcolm, M.E.I.C.

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.

Annual Dinner Meeting

On Wednesday, January 25th, the London Branch held its annual dinner and election of officers. Members and friends enjoyed the accommodation and cuisine of the new Hotel London. This meeting rivalled other meetings of the past year in surpassing the attendance of former meetings.

The business session was preceded by dinner served in the Grill room of the hotel. A report of the past year's activities was read by the secretary and the financial statement was read by one of the auditors, Roy W. Garrett, A.M.E.I.C.

Following the acceptance of these reports the officers for the year 1928 were elected by ballot of those present at the meeting. The election resulted as follows:—

Chairman	Jas. A. Vance, A.M.E.I.C. (acclamation)
Vice-Chairman	G. E. Martin, A.M.E.I.C.
Secretary-Treasurer	Frank C. Ball, A.M.E.I.C.
Executive Committee	J. A. Coombs, A.M.E.I.C.
	R. W. Garrett, A.M.E.I.C.
	W. C. Miller, A.M.E.I.C.
	W. P. Near, M.E.I.C.
	W. M. Veitch, A.M.E.I.C.

Jno. R. Rostron, A.M.E.I.C., the retiring chairman, who becomes an ex-officio member of this year's executive, addressed the meeting and turned the chairmanship over to the chairman-elect. Mr. Vance spoke briefly, and then called on W. P. Near, M.E.I.C., to introduce the speaker of the evening, H. G. Acres, M.E.I.C.

St. Lawrence Deep Waterways Scheme

Mr. Acres read his paper on the "St. Lawrence Deep Waterways Scheme." His hearers were greatly impressed with the magnitude of the project and the difficulties encountered, a great many of which were not of an engineering character. They also recognized the vast amount of study and time that had been given to the question in order to give to the two countries the fullest benefits to be derived from that great river. Those present were grateful to Mr. Acres for bringing to them the findings and opinions of one who has been so closely connected with the project from its earliest days.

A hearty vote of thanks to Mr. Acres was moved by H. B. R. Craig, M.E.I.C., and seconded by J. R. Rostron, A.M.E.I.C. In seconding the vote of thanks, Mr. Rostron expressed his opinion that everything possible should be done to get the project under way, and he pointed out some of the advantages to be derived from the waterway.

During the evening, members and guests were entertained by Mr. E. G. Wood and Mr. E. D. Carpenter, who sang numerous solos. The company joined in songs from The Institute song sheet at intervals through the evening.

The members were pleased to have as their guests His Worship Mayor Wenige and Aldermen Towe, Hayman and Kilbourne. The Mayor addressed the meeting briefly, referring to Mr. Acres' connection with the new Springbank dam to be constructed near London.

A large number of friends of members of the branch were present.

It is the intention of the London Branch to hold a "smoker" and social evening as its February meeting. The success of last year's "smoker" warranted an evening of the same kind this year.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

Montreal Building Code

The Montreal Branch held its first meeting of the year on January 12th, when Paul Baily, A.M.E.I.C., presented the branch with an interesting description of the many considerations that were provided for in the formulation of the "Montreal Building Code."

After a brief historical outline of building by-law legislation in Montreal, the speaker declared that as it was inadmissible that a city of Montreal's importance should be without a modern building code, radical changes had had to be made in the old building by-law No. 260 passed by the city in 1901. While this old by-law had served its day, the many recent developments in the art of reinforced concrete and structural steel construction had rendered it inadequate for present-day requirements.

The Building Department of Montreal thereupon examined the essential features that should be covered in the preparation of a modern building code. These conditions are seven in number and constitute the main object of the present by-laws.

1. To protect the public in prohibiting the construction or erection of dangerous structures.
2. To promote better construction at all times.
3. To establish definite rulings and principles that should be followed by all the engineers, architects and builders of this city.
4. To limitate the stresses and loads that should be used in any design and calculation of structures.
5. To protect the building profession against friction with civic employees.
6. To open the door to any progress and improvement and to eliminate any incompetence in the building trade.
7. To obtain a fair and logical competition among the engineers, architects and builders, and provide fair market conditions.

In elaborating on these requirements, the speaker held that the present by-laws were liberal in their conception, that they afforded an opportunity for experienced engineers to profit by their skill and that, although the author had to be mindful of the possibility of unfavourable working conditions and inferior materials, he was also anxious to avoid waste by unnecessarily stringent demands.

In conclusion, the speaker referred to the need to follow up the by-laws with responsible supervision of the designs and adequate inspection of the work.

Five by-laws have been prepared and may be obtained at the City Hall on request. These are No. 915—Reinforced Concrete; No. 917—Structural Steel; No. 895—Timber Construction; No. 914—Live and Dead Loads; No. 887—Construction Blocks.

The animated discussion which followed, led by Prof. E. Nobbs, favoured the preparation of further by-laws along these lines and their publication each year with added amendments.

J. T. Farmer, M.E.I.C., expressed the appreciation of the meeting to the speaker for his effort to crystallize public opinion on this important endeavour.

The chairman of the branch, F. C. Laberge, M.E.I.C., presided.

The First Commercial 1,200-Pound Steam Plant

A paper of particular interest in that it dealt with the first commercial 1,200-pound steam plant in the world was presented to the branch on January 19th, by I. E. Moultrop, chief engineer for the Edison Electric Illuminating Company of Boston.

In opening his paper, the speaker referred to the New England hydro-electrical development as being probably the greatest in America, and yet amid such surroundings it was economical to obtain power from coal costing $6.00 a ton and possible to produce electricity by that means for less than four mills per kilowatt hour.

While the location of the steam plant at tidewater was essential by reason of the tremendous demand for water to meet condensation requirements, and economical for the delivery of coal by boat, at the same time such a situation required heavy expense for transmission lines when the maximum voltage is limited to 30,000 volts and a two-tower line costs up to $20,000 a mile.

With the materials readily available at present, 750° Fahrenheit is approximately the highest safe temperature for steam. Steam heated above this temperature calls for materials of excessive cost, and is therefore uneconomical.

The great advantage of a high temperature and high pressure installation is the notable increase in efficiency for the same capital cost of plant.

In the plant under consideration the four and one-half inch drum forging, weighing 96,000 pounds and measuring 4 feet in diameter, was tested and analyzed, by means of X-rays, with wonderful result.

An important adjunct to successful operation of these high pressure plants is the purity of the feedwater, for not only must the water be 100 per cent chemically pure, but it must also be entirely free from oxygen, which would at these high temperatures speedily cause rusting in the turbine.

The speaker referred to the utilization of superheaters, reheaters, air heaters, water-cooled furnace walls and steel-supported refractory walls in the intelligent design of this large plant.

Mr. Gates, engineer of The Superheater Company, J. A. Combe, M.E.I.C., and J. T. Farmer, M.E.I.C., took a leading part in an interesting discussion. The former mentioned the untimely and sudden death of his associate, B. N. Broido, following shortly after presenting his paper to the branch in January 1927. Prof. C. M. McKergow, M.E.I.C., in moving the thanks of the meeting, commented on the cordiality and frankness of the speaker and the pleasant means he had chosen to present such an informing and well-illustrated address. K. B. Thornton, M.E.I.C., presiding as the chairman, presented the motion in fitting terms.

Annual Meeting of Institute

Preceding the branch meeting, President A. R. Decary, M.E.I.C., called to order the 42nd Annual Meeting of The Institute for the purpose of appointing scrutineers and auditors and the reading of minutes of the last annual meeting, all of which is reported elsewhere.

Some Special Features in Engine and Car Terminals

An interesting description dealing with the coach and engine house facilities of the extensive and well-nigh ideal rearrangement of the Canadian National Railways' Toronto yards was presented to the branch, presided over by J. E. Armstrong, A.M.E.I.C., on January 26th by S. B. Wass, A.M.E.I.C., in a paper entitled "Some Special Features in Engine and Car Terminals."

The locomotive coaling plant consists of six 100-ton circular reinforced concrete bins capable of supplying coal to engines on four tracks. Engine sand, after being dried in an adjacent building, is hoisted by compressed air and stored in the interstices between the bins, while a continuous chain and bucket conveyor is utilized to elevate the coal.

Another continuous chain conveyor passing under hoppers placed in each of five engine tracks transports the cinders up an incline to be discharged over cars on the cinder track.

Three standpipes serving six engine tracks supply water from the 150,000 gallon storage tank. A locomotive turntable 100 feet long, of the twin span type, has eliminated the necessity of balancing the load on the table and is especially advantageous in handling dead equipment. It is approached by fifty tracks, five of which are running tracks.

The engine house has a capacity of thirty-six stalls and is constructed with wooden frame, brick walls and a mill type roof, the latter as being least likely to cause condensation in cold weather.

Light structural steel frame doors are provided with hinges having adjustable pins. All the service piping inside the engine house has been installed in leadized pipe to assure protection against acid-bearing gases.

Drop wheel pits equipped with electro-pneumatic jacks and Cardwell spring tracks have been provided for changing wheels and springs.

A special exhaust system for locomotives has been provided by which the smoke from the engines is collected and driven up a tall chimney. To accomplish this, a rectangular duct of asbestos board has been constructed around the house above the stacks of the locomotives. The stacks are connected to it by means of aluminum jacks, having both universal and telescopic joints and have spherical bowl ends to provide tight connections with the stacks.

The smoke is exhausted from the duct by a fan and forced up a chimney 7 feet in diameter and 165 feet high. This apparatus provides the draught to fire the engines and obviates the need of a steam blower.

Large machine, wheel and coach shops adjoin the engine house. These are all of reinforced concrete, fireproof construction and equipped in the most up-to-date manner. These shops are heated with featherweight unit heaters which have proved both satisfactory in operation and economical to install. A three-storey stores building serves the shops and a bunk house provides fine accommodation for out-of-town crews.

The coach yard, with concrete platforms and service facilities, adjoins a commissary and car building. A freight car repair yard with attending buildings has also been provided.

The yard is well lighted at all working points by a flood light system which has been installed on five 120-foot steel towers bearing clusters of powerful lamps.

An animated discussion followed, led by E. A. Ryan, A.M.E.I.C., and J. H. Hunter, M.E.I.C., and a hearty vote of thanks was tendered the speaker by W. McG. Gardner, A.M.E.I.C.

Reproduction of Sound

(Reported by A. B. Rogers, A.M.E.I.C.)

On February 2nd an interesting and instructive talk on "Sound Reproduction," accompanied by slides and a demonstration on a special sound reproducer, was given by H. J. Vennes, A.M.E.I.C., transmission engineer of the Northern Electric Company, Limited.

Mr. Vennes began with a brief history of the study of sound analysis. One of the recent authorities, Professor Dayton C. Miller, of Cleveland, constructed a special instrument called a "Phonodyke" for analyzing sound. This study has been carried on by the telephone engineers as a necessary adjunct to the proper design of reproduction equipment.

In principle, each sound is caused by wave disturbances in the atmosphere. The waves corresponding to a particular sound are alike and periodic. They are more or less compounded, and can be resolved into their simple components, consisting of a fundamental and some harmonics. The character of the sound is dependent on the various harmonics and the amplitude thereof.

What is known as a "sound spectrum" is obtained by plotting on a frequency base, vertical lines representing the various components, the amplitude being represented by the length of the line above the base. The sounds of various musical instruments were represented by their spectra thrown on the screen from slides prepared for this purpose.

Slides were also shown showing the range of the auditory sensation areas. These show that at low frequencies more energy is required.

The analyses of the various vowel sounds were indicated by slides showing their spectra.

It was pointed out by Mr. Vennes that unfaithful reproduction of a sound or distortion is due to two main causes, namely:—

1. Eliminating the fundamental or certain harmonics.
2. Introducing additional harmonics.

A third, but lesser important, cause was by changing the phase of the sound. This was done by the character of the reproduction apparatus.

The demonstration of these effects was well shown by means of gramophone records reproduced on the special sound reproducer mentioned above.

The meeting was presided over by G. A. Wallace, A.M.E.I.C., and J. L. Busfield, M.E.I.C., expressed the thanks of the meeting to the speaker for his paper, which was at once very technical and withal very popular.

What Aviation Means to Canada

(Reported by T. C. Thompson, Jr.E.I.C.)

At the regular meeting of the Montreal Branch on February 9th, Wing-Commander E. W. Stedman, O.B.E., M.E.I.C., chief aeronautical engineer, Department of National Defence, gave an address on "What Aviation Means to Canada."

The speaker opened his remarks by explaining that such a subject would compel an original and broad study of the effects of aviation on our Dominion.

Aviation was once a question of transportation and photography, whereas now it materially assists the discovery and exploitation of Canada's natural resources. Whereas, in Europe and the United States rapid mail and express and passenger transportation were the predominating demands encouraging the development of aviation, in Canada the situation is unique. It is Canada's natural resources which afford the predominating demand.

The speaker then dealt briefly with the part played by aviation in agriculture, in patrol work for the Customs Department, in geological surveys, in payment of Indian treaty money, in surveys of water powers, in surveys of transmission line routes, in mapping, in fire detection and prevention, in surveying timber limits, in topographical surveys, in assisting parties travelling by ground routes, in fishery patrol work, in establishing submarine channels and reefs, in mail service to winter-bound places and reporting ice conditions for navigation. Excellent slides were shown illustrating each phase of the work done by aeroplanes.

In agriculture, much loss is encountered yearly through rust spore, and it was found that these spores exist everywhere in the atmosphere, at all heights investigated, like volcanic dust. Combating this condition and others similar, such as the spruce bud-worm, can be done conveniently from aeroplanes by dusting the locality with sulphur or other preventative chemicals. Fertilizers may also be spread by dusting.

The Customs Department has found that narcotics are frequently dropped overboard from inbound vessels near the Canadian shore to be picked up by small boats and smuggled into the country. Aeroplane patrol has prevented, to a marked degree, this practice by watching the actions of any boat intent on retrieving the parcel.

Geological surveys conducted by aero-photography give a more accurate account of the structure of the country, such as rock-outcrop, dykes, etc., and over a range greatly exceeding that possible by ground methods and in much less time. In addition, air photographs afford permanent records which can be referred to perpetually as an answer to a large number of distinct questions relative to the country.

In distributing treaty money to the Indians, the trip, which previously took three months, now requires only a month using aeroplanes.

Power engineers tell, Commander Stedman pointed out, some of the economies effected by employing aeroplanes in securing data by photography for the choice of the location of dams, power house sites, transmission line routes and land contours along these routes.

Mapping outlying country by aerial photography is not only much quicker than by ground methods, but is very much more accurate in the case of rapid surveys. This was strikingly illustrated by a slide showing Island lake mapped by aerial photographs and spattered by islands, whereas the same lake shown as in existing maps obtained by ground methods is apparently practically devoid of islands.

The work of fire prevention and protection by aeroplane was briefly reviewed by the speaker, and in connection with forestry work he showed that the extent and value of timber limits can easily, accurately and quickly be determined by examination of aerial photographs Again the speaker emphasized the value of the permanence of the record and its possible repeated consultation

Its enforcing fishery laws regarding the length of nets, etc., used by the fisherman, the aeroplane is much superior to the older patrol steamer method. The smoke of such an inspecting vessel of maximum speed of about ten knots per hour on the horizon would give ample warning to the fishing craft using illegal methods which could easily be corrected before the advent of the inspector. This, of course, is not the case with the aeroplane.

The Public Works Department can use the aeroplane to great advantage in securing photographic data regarding channels in a river, hidden reefs, etc. These, besides being a great boon to navigation, are very valuable in directing dredging operations.

Aeroplanes afford an additional aid to navigation in reporting ice conditions. This was illustrated by two incidents in the vicinity of Hudson bay.

An example of transportation by aeroplane where other means were quite impossible within the time limit was mentioned. Eight thousand pounds of explosives were required in Churchill. Dogs or horses were quite impossible and the contract for delivery by plane was let out. The quantity was later increased to fifteen thousand pounds and the whole amount delivered very easily in twenty-seven trips.

Advantage is taken of the aeroplane for transportation where rapid delivery is required. Such articles as gold, women's hats and gowns, flowers, financial papers, etc., are often delivered by air in other countries. Insurance rates are lower, since the risk of tampering is reduced and packing expense is reduced to a minimum. Commander Stedman prophesied an air route to New York from Montreal for such purposes in the comparatively near future.

In a short discussion, it was remarked the difficulty of fueling planes in remote territories during trips of say a month's duration. This was answered by the speaker by stating that fuel caches were established at various points taken there by ground methods.

The members of the Montreal Branch were privileged to hear such an entertaining and instructive lecture, and J. A. McCrory, M.E.I.C., expressed the appreciation of the audience. The meeting was presided over by J. S. Hall, A.M.E.I.C. and F. S. B. Heward, A.M.E.I.C.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

During the past month the Ottawa Branch has had two luncheons at the Chateau Laurier, and the Annual Ball was held on February 6th, also at the Chateau. The latter was a brilliant social function held under the distinguished patronage of Their Excellencies the Governor-General and the Viscountess Willingdon. Upwards of 300, including members and friends, were in attendance and were received by Mrs. Chas. Camsell, wife of the newly-elected chairman of the Ottawa Branch, Mrs. F. H. Peters and Mrs. H. A. K. Drury. A feature of this year's ball which added to the enjoyment of the occasion was the excellent supper served at tables in the main dining room.

Professional Engineers and the E.I.C.

Professor H. E. T. Haultain, M.E.I.C., came from Toronto to address the members of the Ottawa Branch at luncheon on January 26th on the subject of "Professional Engineers and the E.I.C." Announced as a talk to the family, Professor Haultain outlined the relations existing between the Association of Professional Engineers of Ontario and The Engineering Institute of Canada, and gave his views on the general policy and future of both organizations. He expressed gratification at the formation of a Technical Service Council, which commenced to function in December last and numbered on its advisory committee such distinguished figures as Dr. H. J. Cody, chairman, Board of Governors, University of Toronto; C. A. Magrath, M.E.I.C., Sir Edward Kemp, Sir John Aird and S. R. Parsons.

The Council, according to the speaker, is co-operating with the Canadian Manufacturers' Association in an effort to stem the exodus of Canadian brains to the United States and to bring back those Canadian engineers who have already gone there. Professor Haultain dwelt on the hopes and aspirations of professional engineers generally and stressed the necessity of co-operation.

Some Phases of Railway Development in Canada

It is not very often that engineers are accorded the privilege of listening to an address from the business viewpoint on an engineering development of such magnitude as the Canadian railway system. Mr. E. P. Flintoft, assistant general solicitor in the law department of the Canadian Pacific Railway Company in Montreal, is especially well posted on the development of Canada's 40,000 miles of railway, and delivered an exceptionally interesting address, choosing as his subject, "Some Phases of Railway Development in Canada." Mr. Flintoft touched briefly, but in a most interesting manner, on the development of Canada's main systems of railway since the first road was constructed, a distance of 16 miles, from La Prairie to St. Johns, Quebec, to the present, when Canada had the greatest per capita mileage in the world.

How little the marvellous developments in railway construction in a few decades were realized only a short time prior to Confederation might be visualized, said Mr. Flintoft, by the statement made in 1863 by Captain Palliser, sent out by the British government to explore the territory west of the Great Lakes. He declared that the location of the international boundary along the 49th parallel forever precluded the possibility of building a railway through Canada to the Pacific coast. Yet others held more optimistic views, and one of the cardinal terms of the treaty of union between British Columbia and the Dominion in 1871 was that such a railway should be built.

Mr. Flintoft traced in turn the early struggles of the Grand Trunk, the Intercolonial, the Canadian Pacific, Canadian Northern and the Grand Trunk Pacific. He referred to the building of 725 miles of railway into Calgary in the early eighties during the course of fifteen months, involving the handling of a million tons of material, as a record in construction then unequalled in the history of railroad construction.

The result of all these efforts was that Canada had to-day over 40,000 miles of railway, the greatest per capita mileage in the world, with a capitalization which exceeded $3,500,000,000. This country's roads, Mr. Flintoft said, were equipped in a manner to compare favourably with those of the United States, and in no other part of the world was a sustained and reliable railway service maintained under such adverse conditions.

Touching on rates, Mr. Flintoft stressed the impossibility of Canada's roads operating with any degree of prosperity on the existing schedules. The rates allowed on the carriage of grain on the United States roads were from 25 to 90 cents higher in the western area than in Canada, and this only permitted them to pay a reasonable dividend to their shareholders. He emphasized the enormously increased competition by water on the Great Lakes and the effect of haulage by motor truck. The great difficulty, he contended, is that railway service in Canada on practically all roads was being provided at less than cost.

Dr. Chas. Camsell, M.E.I.C., the new chairman of the Ottawa Branch, presided at both luncheons, taking the place of Naulon Cauchon, A.M.E.I.C., chairman last year.

Ottawa members have learned with regret of the death at Winnipeg of H. V. Brayley, who was secretary of the Ottawa Branch from 1910 to 1913, succeeding S. J. Chapleau, M.E.I.C., the first secretary. Mr. Brayley when in Ottawa was connected with the engineering department of the Transcontinental Railway and took an active interest in the Ottawa Branch of The Engineering Institute of Canada from its inception in 1909. After leaving Ottawa, he was for some years connected with the firm of Gunn, Richards and Company, industrial engineers, and later conducted industrial investigations for various financial interests. Latterly, he had been occupying the post of income tax inspector of the Department of National Revenue, Montreal, and it was while returning from an investigation he had been conducting for the department at Calgary that he was stricken with acute indigestion and passed away at the Royal Alexander hotel, Winnipeg. Mr. Brayley was in his fifty-first year, and had been in normal health.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

The Welland Ship Canal

A regular meeting of the Peterborough Branch was held on January 26th, 1928, when A. J. Grant, M.E.I.C., engineer-in-charge of the Welland ship canal, gave a most interesting address, being a general description of the work on the new Welland ship canal. As a former resident of Peterborough and engineer-in-charge of construction of the Trent canal, Mr. Grant was especially welcome. As the various phases of the work on the canal are given in several papers presented at the Annual Meeting and published in the February issue of the Journal, details of Mr. Grant's paper are not given here.

After a lengthy and interesting discussion, a cordial vote of thanks was given to Mr. Grant for his address.

Regular Meeting, February 9th, 1928

This meeting was arranged entirely by the Juniors and Students of the branch, the chairman for the evening being S. O. Shields, S.E.I.C. Three papers were presented, as follows:—

1. "Tirrill Voltage Regulators and Their Application," by M. C. Lowe, S.E.I.C.
2. "A Power Site Survey," by O. T. Foulkes, S.E.I.C.
3. "Fisheries of Nova Scotia," by St. C. J. Hayes, S.E.I.C.

A brief summary of each of these papers is given below.

This is the second occasion on which the Students and Juniors of the Peterborough Branch have provided the entire programme for a regular meeting, and mention might be made that all the three speakers are members of the engineering department of the Canadian General Electric Company.

An active discussion followed each paper, and at the close of the programme the three speakers were accorded a very hearty vote of thanks for their papers.

Tirrill Voltage Regulators and Their Application

M. C. Lowe, S.E.I.C., introduced his subject with a brief historical survey of the origin and development of the voltage regulator, as applied first to direct current generators and then to alternating current machines. The benefits due to improved voltage regulation by the use of the Tirrill regulator were mentioned. With the help of a diagram, Mr. Lowe gave a detailed explanation of the construction, methods of connection and operation of this type of regulator.

With the generators in parallel, the exciters may be operated separately or in parallel under control of the regulator. For holding constant voltage at the end of a long line, the line drop compensator is used.

In conclusion, the speaker described the various adjustments necessary for proper operation, and cited an example of a regulator which gave poor results due to several errors in connections and adjustment. When these points were corrected the regulator operated perfectly.

A Power Site Survey

Experiences during the summer of 1925 on survey work in the Saint John river valley, New Brunswick, were described by O. T. Foulkes, S.E.I.C., in this paper.

This work was a preliminary to the development of the Grand Falls power site by the Saint John River Power Company. The flow at this point varied from 100,000 to as low as 800 second-feet, thus making the question of storage of primary importance. Approximately one-half of the available storage lies in Canada and the other in the United States.

The initial development at Grand Falls will be 50,000 h.p. using only Canadian storage. The total possible development is 150,000 h.p.

The author then described three types of survey in which he took part,—storage survey on the St. Francis river, a flowage survey to determine the area of the land to be flooded and a transmission line survey.

Details of the methods used were clearly explained and the address was well illustrated by diagrams and photographs of the country surveyed.

The Fisheries of Nova Scotia

The paper by St. C. J. Hayes, Jr.E.I.C., described briefly the history of the fishing industry on the Atlantic coast. It is known that previous to John Cabot's time the cod-banks of Newfoundland were frequented by the Normans, the Bretons and Basques. One of the oldest place names in America is Cape Breton, which is a memorial of the early French fishermen who frequented that vicinity previous to 1502.

Nova Scotia occupies a remarkable geographical location within easy reach of the most extensive fisheries in the world. The smaller fishing banks, such as Roseway, Lahave, Browns and Sambro, are all within a few hours sail of the fishing ports. The larger banks, viz., Georges, Middle, Banquereau and Sable, are within a radius of 150 miles of the principal fishing ports, and the Grand Banks are only 600 miles from Lunenburg.

The fisheries are of three distinct types so far as the operating methods are concerned. These types are (1) the in-shore, (2) the off-shore, and (3) the deep sea fisheries.

The in-shore fisheries are carried on by fishermen in smaller vessels and motor boats. These boats set out from the villages and ports very early in the morning for the nearby fishing grounds and return to port the same day with their catch.

The off-shore fisheries are essentially an extension of the in-shore fishery. Larger boats are used, accommodating two to six men, and are usually absent from port three to six days during the season.

Lunenburg is the chief centre of the deep sea fishery, but vessels sail from Canso, Yarmouth, Liverpool, Port Hawkesbury and Halifax. The fishermen use vessels for the salt fish trade, while the larger corporations are using steam-trawlers for the fresh fish trade. The vessels are from 60 to 100 tons and are equipped with sail and also with oil engines. Each vessel carries six to ten dories and the average crew numbers twenty men. On arriving at the banks, the men go out two to a dory and use trawl lines which are sometimes a mile long and have baited hooks every four feet. Some twelve vessels use the hand-line method and catch the fish by jigging. This method is more laborious than the trawl line, but has the advantage that no bait is necessary. The vessels make three trips per year.

As the steam trawlers operate primarily for the fresh fish trade, their trips occupy only ten days to two weeks and the average catch is 150,000 pounds. Some eleven ships are now engaged in this industry.

The striking characteristic of the Lunenburg fishery is that the ownership of the vessels and the operation is largely co-operative. The result is that the property is well cared for and the industry intelligently operated.

The fishing industry gives employment to about 20,000 people. The fishermen are daring and resourceful and highly prize the independence which comes from the direct ownership of their means of livelihood.

Following this paper, a motion picture film depicting these Canadian fisheries was shown.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

A meeting of the Saint John Branch was held on the evening of February 3rd, 1928, in the New Brunswick Telephone Company building, at which S. R. Weston, M.E.I.C, presided.

A report from the Executive Committee on the question of proposed increase in fees of $5.00 to members was read. The report was the result of a thorough study of the question carried on at several meetings of the executive. The report favoured an increase of fees of Associate Members $1.00 and of Members $3.00, so as to obtain the same amount of extra revenue required, and also gave a list of several preferred ways in which revenue should be expended. The report was adopted as presented, with instructions to have it sent to Headquarters and all branches of The Institute.

The Functions of the Courts

An address on a legal subject, "The Functions of the Courts," was given by H. O. McInerney, K.C., Judge of Probate. In introducing his subject, the speaker explained the reason for various courts of justice to decide different legal problems of varying degree of importance and of the limits of jurisdiction of judges in the several courts deciding on different questions. It was a clear description of the various courts told in a manner so that anyone not of the legal profession could understand it.

Beginning with the lowest court, presided over by a justice of the peace, the speaker in turn described the police and stipendiary magistrates' courts, county courts and the various divisions of the

Supreme Court of Canada. In detail, the various functions of the Appeal Division, Chancery Division and the King's Bench Division were described. Courts dealing with special classes of cases were mentioned, including bankruptcy, divorce, exchequer, admiralty and probate.

The method of appointment of judges in the different courts by provincial and Dominion authorities was also explained, and also of exceptions in some of the provinces. The Privy Council of England was mentioned as being the final court of appeal and the several methods described in which permission was granted for hearing cases before this court.

A vote of thanks to Judge McInerney was moved by Geoffrey Stead, M.E.I.C., and J. N. Flood, A.M.E.I.C.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting was held on Friday, January 27th, 1928, at 8 p.m., in the Y.W.C.A. rooms. At the dinner held at 6.45 p.m. there were guests from Espanola and Sturgeon falls, besides the speakers for the evening.

W. S. Wilson, A.M.E.I.C., chairman, called the meeting to order and disposed of the regular business. C. H. E. Rounthwaite, A.M.E.I.C., reported for the auditors and the report showed a nice balance to the credit of the branch.

C. H. Speer, M.E.I.C., reported for the special committee on the purchasing of a lantern and screen for the branch. The committee hoped to have the equipment on hand for the February meeting.

Mr. Wilson introduced Mr. C. A. Price, of the Canadian Westinghouse Company of Hamilton, and Mr. J. W. R. Taylor, of the same company of Toronto. Mr. Price gave an excellent talk on " Making a Motor " and Mr. Taylor handled the slides for him.

Making a Motor

Mr. Price, in choosing the subject for his paper, specialized in the design and manufacture of the induction motor. "A motor," he said, " was the agency used to change electrical energy to do mechanical work, and in the design of such a machine there was always something new turning up to meet the requirements of the users." By the use of numerous slides and blackboard diagrams, he showed the graphs used in getting the relationship between the torque, the revolutions per minute and efficiency for the various designs that they were required to put on the market, and more especially those for special purposes. They carry about 115 standard motors listed in stock, but for the special ones the windings are changed to give the required specifications.

The slides showing the construction of a motor, giving the details of all its parts, were very interesting and showed very clearly to what an expense in special machinery such a manufacture had to go to to turn out the finished product.

A general discussion followed, and the electrical men present gave Mr. Price a merry time of it, judging by the numerous questions asked him. In this discussion a better understanding of the motor was arrived at, and all present felt that they owed Mr. Price a hearty vote of thanks for his splendid and instructive address. This vote was given on motion of Messrs. Rounthwaite and Kohl.

Toronto Branch

W. B. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. W. Falkner, A.M.E.I.C., Branch News Editor.

The Photo-Elastic Method of Determining Stress

(Reported by J. R. Montague, A.M.E.I.C.)

On Thursday evening, January 19th, in the Mining building of the University of Toronto, Professor T. R. Loudon, M.E.I.C., assisted by Mr. K. B. Jackson, presented to a well-attended meeting of the Toronto Branch a most interesting paper on the "Photo-Elastic Method of Determining Stress." The meeting was ably presided over by the chairman, R. B. Young, M.E.I.C. The lecture was illustrated in a most interesting way with lantern slides, and with the photo-elastic apparatus used by Professor Loudon in the extensive investigations being carried on by him at the University of Toronto.

Briefly, the method employed consists of the projection of polarized light rays through celluloid models of structural members, or mechanical parts, under stress conditions corresponding to that to be expected under actual working conditions, and observing the distribution, inclination and intensity of the principal stresses, as determined from varying colours and shades on the image projected on the screen.

The polarized light used in these investigations is obtained by passing the rays from an ordinary arc light through two Nicol prisms with axes at right angles to each other. The difference *(P-Q)* between the principal stresses at the different points of the model is brought out on the screen by coloured areas which vary from a pale yellow to green, blue, red, and black, depending on the intensity of the stresses. As additional loads are added to the model, the colour range is repeated until failure occurs.

The models used are made of celluloid, great care being necessary in their preparation to obtain a uniform texture and thickness, and to avoid the setting up of initial stresses. Failure in these respects would tend to confuse the results obtained.

The three principal kinds of stress usually considered by designing engineers are uniform, uniformly varying, and combinations of these two. In many cases the stress distribution resulting from these combinations presents indeterminate solutions. It is with a view to isolating these stresses that polarized light is used, enabling a thorough study of the stress intensities at all points to be made.

While it is generally assumed for designing purposes that stresses are uniform across the section of a member, it has been found that there is often a very appreciable complex variation across the sections, particularly in structural members, in the vicinity of rivet holes. This variation was strikingly illustrated by Professor Loudon through the photo-elastic projections of models.

Some very interesting results have been obtained in the investigation of structural members and machine parts; a striking example given showed the variation of stress in a gusset plate of a roof truss model. In another instance the stress lines in a machine gear, under operating load, as determined by the photo-elastic method, demonstrated that the actual stresses followed closely to the assumptions used in gear design.

While the application of the photo-elastic method is only in its infancy in this country, it has reached an advanced state of application in Europe, particularly in England. Its field of application is by no means confined to determinate stresses, but promises to find a very practical application, as well, in the investigation of indeterminate stresses in structures such as bridge bents, building frames, and rectangular water conduits and other hydraulic structures.

Interesting sidelights were brought out in discussion by William Gore, M.E.I.C., Professor C. R. Young, M.E.I.C., R. B. Young, M.E.I.C., George McCarthy, M.E.I.C., J. G. R. Wainwright, A.M.E.I.C., J. M. Oxley, M.E.I.C., F. M. Byam, M.E.I.C., J. W. Falkner, A.M.E.I.C.

A vote of thanks, proposed by George McCarthy, M.E.I.C., was heartily endorsed by the audience, and proffered to the speaker and his assistant by the chairman.

The Montreal Harbour South Shore Bridge

(Reported by J. W. Falkner, A.M.E.I.C.)

The regular meeting of the Toronto Branch on Thursday evening, February 2nd, was preceded by a well attended dinner at the Faculty Union, Hart House, to welcome the speaker of the evening, P. L. Pratley, M.E.I.C., who had made the journey from Montreal especially for this meeting. The dinner was followed by an opportunity for informal discussion with the speaker before the meeting, which was much appreciated by members of the branch.

Mr. Pratley afterwards presented at the regular meeting of the branch, held in the Mining building, and with R. B. Young, M.E.I.C., chairman of the branch presiding, a most interesting and exceptionally well illustrated paper on the " Montreal South Shore Bridge," dealing in detail with the history, design, economics and construction to date of this most important Canadian bridge-engineering project. Especially interesting was the description of the pneumatic caisson methods used, also the description of the caisson for pier No. 24, probably the fourth or fifth as to size in the world.

At the outset the speaker sketched the historic background of this important project, illustrating by slides the many schemes and ideas which had been put forward between 1876 and 1924, when the present undertaking was authorized and begun. Mention was made of the original site of the Victoria bridge, and the elaborate design for the Royal Albert bridge which was proposed for this same site twenty years later in 1876. Again, after some twenty years, in 1897, the Royal Albert bridge project was revived, a competition arranged after much preliminary data had been collected, many interesting designs being submitted, and a winning plan selected.

As before, however, the plan was doomed to failure through want of authoritative support, financial and political. Further designs following at intervals up to the war period were likewise unfruitful except insofar as they provided food for study when the present engineers took up the problem again after the 1920 fire on the Victoria bridge. Into this history of the various efforts to bridge the St. Lawrence at Montreal, Mr. Pratley wove the theme of the varying needs that from time to time prompted the citizens, engineers or promoters to re-open the question. He also showed how the erection and replacement of other bridges in the neighbourhood had affected the chances of success by supplying the needs of railway transport. The Lachine bridge of the Canadian Pacific Railway, the double-tracking of the Grand Trunk Railway Victoria bridge, the replacing and doubling of the Lachine bridge, served in succession to relieve the railway situation between 1885 and 1912.

The speaker then went on to show that the advent of the motor-car had entirely changed the problem, and that from about 1909 on, highway traffic had begun to show signs of congestion at the entrances to and exits from the large centres of population and industry. The war served to accentuate the importance of automobile transport, and the tremendous growth in the number of motor vehicles simultaneously provided a huge new source of revenue for bridge finances. Thus when the fire absolutely stopped traffic on the Victoria bridge, the citizens of Montreal and district became urgent in their demands for some alternative and more convenient means of crossing to the south shore. While the public were seeking favourable consideration from the Federal Government, the engineers were studying the physical and economic problems and making preparatory designs.

The government were not at first able to see their way to do very much, but finally the chairman of the Harbour Commissioners persuaded them to grant powers to this body to undertake the financing and construction. The enabling legislation passed the house in 1924, the engineers were appointed, designs established and the first contract let in May 1925 for the southern half of the substructure. including twenty piers. Mr. Pratley spoke of the advantages and disadvantages of different sites and pointed out the fact that the one chosen was almost exactly that proposed fifty years ago. Views of alternative types of span were shown and the choice of the *K.* cantilever explained.

The capacity of the new structure was stated to be a clear 37½-foot vehicular roadway, with separated rapid-transit tracks on either side, and footwalks outside these again. The total length of the bridge is just two miles, including the city viaducts and the south shore embankment, the main channel span being 1,097 feet, giving a 1,000-foot channel for vessels and 163 feet vertical clearance. There are in all forty-seven steel spans, besides thirteen towers and six concrete girder spans at the north end. There are twenty-six piers beside the south abutment and the thirty-four pairs of pedestals on the north side. In addition there are the retaining walls and 200 feet of reinforced concrete viaduct at the north end and the abutment and three pairs of pedestals on the island ramp. Well over 100,000 cubic yards of concrete and 30,000 tons of steel are included in the three main contracts, in addition to which are the flooring slabs, asphalt surfacing, macadam bases on fills, fences and handrails, and the island pavilion.

This latter is a concrete and steel building on St. Helen's island, forming part of the bridge-deck and providing recreational facilities, elevators to the island roads and the Swimming Club grounds, and the ramp for motor and vehicular connection to the municipal playground which will be developed in the near future. After touching on the financing and the expectations with regard to revenue the lecturer proceeded to show considerably over a hundred slides illustrating progress with the various parts of the work. Especially interesting were those dealing with the pneumatic caissons which were used for the main river piers. The foundation work was stated to be of extreme importance and to have comprised many types of construction, on land and in water, by open and pneumatic excavation, on piles, on rocks, on hard-pan, and on boulder clay. Headway with the steel work was also indicated, and reference made to the economic choice of spans. The programme for the future was detailed and the approximate date of completion mentioned as the fall of 1930. Satisfaction was expressed at the rate of progress, with the class of workmanship, and with the fact that Canadian engineers and contractors were building in Montreal a truly monumental bridge structure, of outstanding usefulness and impressive magnitude.

The hour being late, and the speaker having to catch the night train to Montreal, many members who wished to ask questions, or to take part in the discussion, were unfortunately unable to do so for lack of time. J. M. Oxley, M.E.I.C., therefore, at the chairman's request, moved the vote of thanks, which was most heartily concurred in by the meeting and suitably presented by the chairman; and the speaker, in his reply, very kindly offered to answer any questions sent to him at Montreal, mentioning that the paper would not be printed, as it had been agreed upon between the consulting engineers and the bridge company not to release any paper or papers for publication until the completion of the project.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

The annual meeting of the Vancouver Branch was held on Wednesday, December 14th, 1927, at 8 o'clock. The notice calling the meeting and the minutes of the previous annual meeting held on December 16th, 1926, were read by the secretary and the chairman then called upon J. R. Grant, M.E.I.C., and T. E. Price, A.M.E.I.C., to act as scrutineers for the counting of the ballots. The secretary then read the annual report of the branch, which, upon the resolution of Major Geo. A. Walkem, M.E.I.C., and W. H. Powell, M.E.I.C., was received and adopted.

W. Brand Young, A.M.E.I.C., then addressed the members, expressing regret that F. W. Alexander, M.E.I.C., the retiring chairman, was not present, and suggested that, if it was the wish of the meeting, a letter be sent Mr. Alexander expressing the regrets of the branch at his absence.

Referring to the meetings of the branch held during the year 1927, special attention was drawn to the high order of the papers given and regret expressed that there had not been a larger turn-out of members to hear them.

The papers which will be given before the branch during the balance of the winter were then briefly sketched, showing that different branches of the profession would be dealt with.

Special reference was made to the excellent work of the Royal Engineers Tablet Committee, and of the committee responsible for the creation of the student section at the University of British Columbia.

The members were urged to support the Western Professional Meeting to be held in Vancouver June 7th to 9th, 1928, and it was pointed out that a successful meeting would do much to help The Institute as a whole and the branch in particular.

Mr. Young concluded by expressing the regrets of the branch at the loss of two of its active members, J. H. Kennedy (life member) and E. Dundas Todd.

Mr. Young's address was received with applause by the members.

At the conclusion of the chairman's address, it was moved by Major Geo. A. Walkem, M.E.I.C., seconded by A. C. R. Yuill, M.E.I.C., and carried unanimously, "that a letter be sent to F. W. Alexander, M.E.I.C., regretting his inability to be present, and wishing him every success in his new position."

Major Geo. A. Walkem, M.E.I.C., then read a paper on "The Inception of the Canadian Society of Civil Engineers, Now the Engineering Institute of Canada," by R. A. Davy, M.E.I.C.

At the conclusion of the reading of the paper it was moved by Major Walkem, M.E.I.C., seconded by W. H. Powell, M.E.I.C., and carried, "that the general secretary of The Institute be asked to write to Mr. Davy notifying him that his paper had been read before the annual meeting of the Vancouver Branch, and thanking him for his valuable record."

E. A. Wheatley, A.M.E.I.C., then reported on behalf of the Royal Engineers' Tablet Committee, and it was moved by Major Geo. A. Walkem, M.E.I.C., seconded by A. S. Wootton, M.E.I.C., and carried, "that a vote of thanks be tendered Messrs. Greig and Wheatley for their efforts in connection with this committee."

The chairman then called upon J. R. Grant, M.E.I.C., to take the chair, and the scrutineers reported the result of the ballot as follows:—W. Brand Young, A.M.E.I.C., chairman; W. B. Greig, A.M.E.I.C., vice-chairman; F. P. V. Cowley, A.M.E.I.C., secretary-treasurer; A. S. Wootton, M.E.I.C., E. A. Wheatley, A.M.E.I.C., and H. B. Muckleston, M.E.I.C.

These, together with those elected in 1926 for the two-year period, namely, P. H. Buchan, A.M.E.I.C., H. W. Frith, M.E.I.C., and A. C. R. Yuill, M.E.I.C., and with the ex-officio member, E. A. Cleveland, M.E.I.C., (councillor), constitute the Executive Committee of the branch for the year 1928.

The report was received with applause by the members.

Mr. Grant then called upon Mr. Young to take the chair, and Mr. Young thanked the members for the honour tendered him and said that the co-operation of the members did much to help him in his duties, and asked for its continuance.

Mr. Greig thanked the members for electing him vice-chairman.

After further business of the annual meeting had been disposed of a general discussion of the forthcoming Western Professional Meeting took place.

The Lethbridge Northern Irrigation District

At the regular meeting of the branch, held on January 12th, the speaker of the evening was H. B. Muckleston, M.E.I.C., who gave a most interesting paper on "The Lethbridge Northern Irrigation District."

Mr. Muckleston was chief engineer of this district and directly in charge of all the construction work, and was thus able to explain lucidly and minutely the many difficulties met with and overcome during the progress of the work. Some fifty lantern slides were shown, illustrating both the work of construction and the country in general, and bringing before his hearers more clearly than words the extreme variations of the precipitation and run-off.

Brief reference was made to the early attempts at irrigation in the district, especially on the part of Mr. Harris as long ago as 1873, the speaker complimenting his work by showing that the general scheme as now in operation follows very closely, although of course on a much larger scale, the original scheme of this pioneer.

The history of the district was then dealt with, reference being made to the Northwest Irrigation Act of 1898, the settlement of the district following 1907, and the work done by the federal government making topographical surveys. The Lethbridge Northern Irrigation District was created in 1919, but it was only in 1921, when the bonds of the district were guaranteed by the government, that the money was raised to actively push on the work.

During the period of construction, 1921-23, the personnel of the irrigation council consisted by C. M. Arnold, H. G. Cochrane, A.M.E.I.C., P. M. Sauder, M.E.I.C., and F. S. Dyke, A.M.E.I.C. The many types of construction work undertaken are well illustrated by the various contracting firms undertaking the work, amongst whom might be mentioned: Grant Smith and Co. and McDonnell, A. G. Creelman and Co., H. G. McDonald, H. H. Boomer, Smith Bros. and Wilson, Dominion Bridge Company, Canadian Wood Pipe Company, Pacific Sheet Metal Works, Manitoba Bridge and Iron Works.

The headworks of the system were located on the Old Man river and the total area brought under irrigation was 105,000 acres.

The Forest Products Laboratory, Vancouver

The second general meeting of the month was held on January 18th and was addressed by J. B. Alexander, supervisor of timber tests of the Forest Products Laboratory, Vancouver, on the work of the laboratory with special reference to the timber mechanics' division. The speaker first reviewed the economic importance of forest products in British Columbia and throughout the Dominion, quoting official statistics issued by the federal and provincial governments. He then gave a short historical sketch of the development of testing of materials for specific information, and continued with a detailed description of the work of the Vancouver laboratory. The work of the laboratory, he explained, is distributed between two technical sections—timber products and timber mechanics—and it was more particularly with the latter section, which has to do with the determination of the strength of woods and manufactured articles, that he confined his remarks.

Student Section of the Vancouver Branch

The Cariboo Highway

The activities of the student section of the branch have been very marked since the students' return after the holidays, well attended meetings having been held on January 18th, January 25th and February 1st, at the University of British Columbia. The meeting of January 18th was an exceptionally good one, and raised the interest in the student section considerably. The support received from those outsiders who are interested in the engineering students and in The Institute will be a factor in making this first year a success.

The speaker of the meeting was P. Philip, M.E.I.C., deputy minister of public works, who presented an excellent address on the "Cariboo Highway."

Mr. Philip preceded his subject with a few remarks on the character of the engineering student. He then gave a brief history of the old Cariboo road and the construction of the present modern highway recently opened to traffic. He added some comparative statistics on British Columbia and also gave an idea of the standards adopted in road construction in this province.

A great many lantern slides were shown, illustrating the scenic wonders of this new highway.

About one hundred and thirty students, members of the faculty and visitors, attended the meeting.

Town Planning

Another splendid meeting was held on January 25th, when "Town Planning" was the subject of the meeting and the address was delivered by H. L. Seymour, M.E.I.C., resident engineer of the Vancouver Town Planning Commission.

Mr. Seymour explained the meaning of town planning, what it involves and what it means to the modern city. He gave examples of what it means to those large cities which are spending huge sums of money to rectify the errors of laying out without due regard for the future. He gave the six chief headings under which town planning is handled, as: (1) major streets, (2) transit or the routing of traffic, (3) transportation, rail and water, (4) public recreation, (5) zoning, (6) civic art.

The speaker then summed up under the short phrase "Community Foresight." The lecture was illustrated by lantern slides. About seventy students were present.

Requirements of a Municipal Engineer

At the meeting of the student section of the Vancouver Branch, held on Wednesday, February 1st, W. B. Young, A.M.E.I.C., assistant city engineer and chairman of the branch, presented an address on the "Requirements of a Municipal Engineer." A new angle from which to consider engineering was introduced by the speaker, since his remarks dealt with the human side of the profession rather than with the technical side.

Although making specific reference to municipal engineering, Mr. Young's address applied equally well to any other engineering activity. He showed that there are many corners in the mind of an engineer which cannot be filled by technical training. While technical education is perhaps the fundamental requirement, there are other things which the engineer must acquire by his own initiative outside the walls of university or office. The engineer who has not the ability to present his problems to the business or non-technical man in lucid form, who cannot convincingly address and correspond with those in other walks of life, who is unsympathetic to the viewpoint which is outside the rut of his profession, or who does not understand the workings of the business and social world, cannot hope to be truly successful. The tendency of the engineer is to choose his circle of friends from among those of his own profession. This, in the mind of the speaker, is unwise, and that the young engineer should include in this circle those of other professions, business men and non-technical men, whenever possible. In closing, the speaker pointed out that in The Engineering Institute of Canada is found the best organized method of broadening the mind of the engineer.

Cuprous-oxide Current Rectifier

An examination of the subject will show that the increasing use of alternating-current distribution must bring in its train a greater demand for devices for generating direct current without the use of revolving machinery. As it is, at the heavy-current end of the scale the mercury rectifier and its modifications are being more and more employed, both for general and traction work, while at the light-current end the requirements of wireless, control and measuring apparatus of various kinds, open up even more important fields of application for such devices. From the commercial point of view, perhaps, the most fertile of these fields is the wireless market, where it is often desirable for even the amateur to be able to obtain direct current from an alternating supply for charging his batteries or even for operating his set directly. The apparatus that can, at present, be used for these purposes may be classed under the headings of valve rectifiers, vibratory rectifiers and chemical rectifiers, respectively. The first of these gives very efficient rectification, but it consumes energy for heating the filament and generally has a fairly high resistance. The vibrating rectifier works well and its efficiency is high, but it requires attention, while in chemical rectifiers, though there is only a small loss of energy and little attention is required, the use of liquids is a disadvantage. It is stated that most of the advantages claimed for the various types of rectifier, without the accompanying disadvantages, are obtainable by using what is known as a metal rectifier, an interesting example of which is being developed in this country by the Westinghouse Brake and Saxby Signal Company, Limited, of King's Cross, London, N.

This rectifier, the discovery of which is due to Mr. L. O. Grondahl, consists essentially of a disc of copper, on one face of which a layer of cuprous oxide has been formed at a high temperature. It has been found that a plate of this kind is an unsymmetrical conductor of electricity; that is, the resistance to the passage of current in the direction from the oxide to the copper to the passage of current in the opposite direction is in ratio of about 1:1,000, or even higher.

It will be obvious from what has been said that if this rectifier is connected in an alternating-current circuit, one-half of the wave will practically be suppressed.—*Engineering.*

Long Distance Flights

It may not be out of place to emphasize that the true purpose of long-distance aeroplane flights is to test the engine and the machine, and not to cover the aviator with glory or oblivion, as the case may be, nor to provide stunts for the newspapers. Some of the flights, which have recently been attempted, have had in them more than a little of the foolhardy, and even when they have proved successful, have not always been so useful from the point of view of design and construction as they would have been had they been less spectacular. A great deal more that is useful can be learnt from a flight which is within the capacity of the engine, the machine and the pilot than from one which only proves, what was pretty evident beforehand, that there are certain tasks that cannot be successfully accomplished at present. At the moment, no less than five long distance flights are in progress. Capt. R. H. McIntosh and Mr. Hinkler are making a journey to India on a Fokker machine, driven by a British Bristol engine, though they were not successful in doing this without a stop. A group of four R.A.F. flying boats, under Group-Capt. A. M. Cave-Browne-Cave, and an Avro, with Captain Lancaster and Mrs. Keith Miller on board, are all bound for Australia. Two R.A.F. Fairey biplanes are on their way from Cairo to Nigeria, and Sir Alan Cobham, accompanied by Capt. H. V. Worrall, has begun his survey tour of 20,000 miles through and round Africa. The first of these, though it has failed to beat Mr. Clarence Chamberlin's long distance record from New York to Eisleben, should help to establish an air route between this country and India. We may be forgiven for holding that the latter is the more important result of the two. Sir Alan Cobham will have ample opportunity of testing the capabilities of his machine, not the less because he will have to take off and alight no less than 43 times. But he will also carry out a most useful survey of what is still a little known country, and perform an Imperial service in trying to secure the support of the administrations in Africa for aviation, and in attempting to convince them that air transport is an important factor in the development of their country. The machine which Sir Alan is flying is a Short-Singapore flying boat, and has been lent by the Air Ministry. It is the first all-metal machine which Great Britain has produced, and has a span of 93 ft. with a length of 63 ft. Its total weight, in flying trim, is 9 tons, of which 3 tons is the disposable load. It is equipped with two 700-h.p. Rolls-Royce Condor, (Series IIIA), engines, and has a speed, in still air, of about 120 m.p.h. Its radius of action, with full load, is 1,000 miles. The present boat will carry a crew of six, but Messrs. Short Brothers have under construction a similar machine which is designed to accommodate 15 passengers.—*Engineering.*

The Deterioration of Steam Turbine Blades

So long as steam speeds remained low there was very little erosion of steam-turbine blading. In fact, speaking at a meeting of the Institute of Metals on September 17, 1915, Admiral Oram stated that blade erosion was unknown in the navy, and in land practice it is certainly true that the blading of old-type reaction turbines showed no material wear even after two or three years' continuous service. Such slight erosion as did occur was evident rather to the sense of touch than to that of sight. If the finger were run along the leading edges of the blades near the tips, a certain roughening could be detected, much as if the object felt had been a very fine saw. Such blades were also apt to be coated with a layer of lime derived from the drops of water entrained in the steam and carried by it into the superheater. The evidence available until comparatively recently was insufficient to show whether the erosion observed was due to this lime or to the water, and, so far as they went, Admiral Oram's observations seemed rather to point to the lime as the agent responsible for the erosion, since in the navy distilled water is used for making up the feed. It was, therefore, not unnatural to connect this absence of erosion with the absence of entrained solids.

The evidence now secured, however, seems to show very definitely that, in general, it is the water suspended in the steam which is the main agent of destruction. The modern power station employs a feed as free from dissolved solids as that used in the navy. Nevertheless, erosion, at times of a very serious character, has been far from uncommon. We have seen blades of 5 per cent nickel steel of which the leading edges in the neighbourhood of the tips were as full of holes as a colander. At times, moreover, this erosion is curiously selective. In a certain impulse turbine where, in the high-pressure section, the steam was expanded down from the stop-valve pressure to atmospheric pressure in seven stages, the fifth-stage blading was cut to pieces in the course of a few weeks and had to be replaced by blades made from more resistant material. The succeeding stages had suffered very little, although traversed by a still larger proportion of water. It has been suggested that this peculiarly limited attack was due to air entrained in the steam, which it was assumed became an active corrosive agent near the saturation line, when the separation out of moisture wetted the blades, and thus provided the catalytic agent without which Professor Armstrong has ever emphatically maintained that chemical reactions are impossible.

The escape of the succeeding stages was attributed to the fact that all the oxygen was used up in oxidizing the blading of the row first attacked. It is, however, very difficult to believe that this could be the case, and it seems much more probable that the selective effect observed was really connected with the phenomenon of supersaturation.—*Engineering.*

Structural Steel and the Safety of Buildings

The basic causes of corrosion have been the subject of many theories from the time of Faraday onwards, none of which have received universal acceptance, though the electro-chemical theory is probably the most popular at the present time, and none of which have provided a complete explanation of the many apparently discordant phenomena which occur.

This being so, Mr. Frank W. Skinner has done a real service to engineering in presenting in a paper on "The Unlimited Potential Durability of Structural Steel," which he read before the Brooklyn Engineers' Club in the early part of the present year, a mass of data, collected from many sources, on the extent to which corrosion occurs on structures of all kinds, and the methods that have been adopted to check its inroads. This important subject is approached from a somewhat unusual angle. Mr. Skinner states that, on account of the widely-spread misleading and disquieting statements regarding the safety, reliability and stability of structural steel, particularly in the frameworks of large buildings, which have been published in New York, he determined to make an elaborate investigation of the subject.

Mr. Skinner's paper indeed amply disproves the possibility of any danger from corrosion in structures which are designed to comply with present standards and are properly protected, inspected and maintained. In those qualifications, of course, lie the gravamen of the charge, which Mr. Skinner has successfully refuted. Failures of steel structures there have been. But those failures can usually be ascribed to faulty design or to overloading; and it is hard to find an instance where the attrition of the material by corrosion has occurred, if care has been taken in the first place to guard against it. To quote Mr. Skinner again:—Though corrosion may possibly occur owing to improper design, construction or unjustifiable conditions, these possibilities can be enumerated and explained and methods for preventing them are known, so that any danger can be easily and permanently eliminated. He goes so far as to add that when structural steel is properly treated by ordinary methods and at reasonable expense all risk of rusting is removed.—*Engineering.*

Preliminary Notice

of Applications for Admission and for Transfer

February 18th, 1928.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in March 1928.

R. J. Durley, *Secretary.*

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

FARQUHARSON—STANLEY, of Arvida, Que., Born at Christchurch, New Zealand, Jan. 25th, 1899; Educ., 5 yrs. civil engrg., Canterbury Univ., 1923; 1919-22, articled cadet, Haumer & Barker, engrs. trigonometrical and plane surveying, laying out streets and sewerage systems; 1922-1923, instrumentman. stadia & plane table trig. surveying, investigation, Warmakariri development for city of Christchurch; 1924-27, instrumentman, dftsman, estimating reinforced concrete detailing and design with B.C. Electric Ry. Co., Vancouver; 1927-28, designer with Power Corp. of Canada, Montreal; at present, on design and construction of development on Saguenay river with Aluminum Co. of Canada, Arvida, Que.

References: E. E. Carpenter, W. H. Powell, P. Buchan, H. G. Cochrane, H. S. Grove, E. A. Wheatley, A. C. Eddy, J. H. Trimingham.

GRIME—LEONARD, of Toledo, Ohio, Born at Stretford, England, May 26th, 1904; Educ., B.A.Sc., Univ. of Toronto, 1926; May to Oct. 1926, concrete detailer with Truscon Steel Co., Detroit; June 9, 1927, to date, structural dftsman with Am. Bridge Co., Toledo, Ohio.

References: P. Gillespie, T. R. Loudon, C. R. Young, J. R. Cockburn, W. J. Smither.

WALTON—CLARKE GIBBS, of Sandwich, Ont., Born at Gananoque, Ont., Mch. 20th, 1892; Educ., B.Sc., Queen's Univ., 1915; 1910-11, Nat. Trans. Ry. as instrumentman; 1915-16, asst. engr., Corbin Coal & Coke Co., Corbin, B.C.; 1917 (3 mos.), mining engr., Algoma Steel Corp.; 1916-19, engr and res. mgr. of Globe Graphite Mining & Refining Co., Port Elmsley, Ont.; 1919-20, mining work for Chas. Spearman, Montreal; 1920, bldg. constrn. in Detroit; 1921, engr. and supt. for Storrington Feldspar Co. at Rock Lake, and also with Chas. Spearman on spec. mining work; 1922 to date, constrn. engr. with Ford Motor Co. of Canada, Ltd., Sandwich, Ont.

FOR TRANSFER FROM ASSOCIATE MEMBER TO A HIGHER GRADE

DAVIS—GEORGE SANFORD, of Montreal, Que., Born at Cincinnati, Ohio, Nov. 28th, 1874; Educ., 1883-91, public school, and 1892-93, private preparatory school. Cincinnati; 1894-95, general repairs with Cincinnati Edison Co.; 1895-96, general repairs and testing, Cincinnati Elec. Light & Gas Co.; 1896-98, contracting and general repairs, built power plant and wired town of Olney, Ill., for street and house lighting; 1898-1900, general foreman, lines and distribution, Niagara Falls Hydro Pr. Co.; 1900-1901, foreman for house wiring for New York and Brooklyn contractors; Jan. to Mch. 1901, general foreman, Niag. Falls Hyd. Pr. Co.; 1901-02, general electrical work, Shawinigan Water & Power Co. for Wallace C. Johnson; Apl. to Dec. 1902, general foreman in experimental dept., Pittsburgh Reduction Co., Niagara Falls, N.Y.; 1902-04, switchboard and wiring cable work, Shaw. Water & Power Co.; 1904-05, supt., constrn. bldg. and remodelling lines, power houses and substations, Albion Power Co., Albion, N.Y.; Mar. to Nov. 1905, general foreman, temporary power & lighting and on final testing when plant put in operation, Ontario Power Co.; 1905-20, erecting engineer with Can. General Electric Co.; 1920 to date, electrical engineer with J. M. Robertson, Montreal.

References: A. C. Tagge, J. M. Robertson, F. Thomson, F. T. Kaelin, R. S. Kelsch, P. T. Davies, W. H. Wardwell, W. A. Bucke.

DINGWALL—ROBERT MACFARLANE, of Calgary, Alta., Born at Glasgow, Scotland, Mch. 16th, 1880; Educ., Assoc. Royal Tech. College, Glasgow, 1914; 1906-11, apptce. as mech. engr.; 1912-14 (summers), marine engr., i/c watch and leading mech.; 1917-19, lieut., R.E., i/c power plants, British Forestry Corps; 1919, master mech., N.A. Collieries, Ltd., Alberta; 1920, master mech., Mountain Park Coal Co., Ltd., Alta.; 1920-26, head of mechanical dept., Pro. Institute of Technology, Calgary; 1926 to date, engr. sales mgr., Riverside Iron Wks., Ltd., Calgary.

References: J. Haddin, C. C. Richards, A. S. Dawson, B. L. Thorne, R. W. Boyle, P. T. Bone.

HOLLOWAY—EDWARD S., of St. Hilaire, Que., Born at Montreal, July 18th, 1885; Educ., B.Sc., McGill Univ., 1908; 1905 (summer), instrumentman, C.P.R.; 1906 (summer), i/c constrn. bridge substructures, C.P.R.; 1907 (summer), instrumentman. Toronto terminals, C.P.R., constrn. of shops, roundhouses, track mtce., etc.; 1908, engr. i/c surveys and location of Canada and Gulf Terminal Ry.; 1910-11, i/c constrn. same road during winters exploration for extension of line to Gaspé; Oct. 1911 to Jan. 1912, locating engr. for Quebec Eastern Ry., Sherbrooke to Levis; Jan. to Oct. 1912, ch. engr., same road, design all structures; 1912-20, ch. engr. with Canada Gulf & Terminal Ry., also doing design and constrn. work, reports on harbour work, Matane and Cap Chat, Que., investigational work in logging pulpwood operations, pulp mills, etc.; 1920-27, i/c Matane operations, designed wharf, loading plant, flumes, piers, booms, etc., and also constructed same with Hammermill Paper Company; summer 1927, reports on harbour improvements, Moisie river, Que.; at present, engaged in reporting on various pulpwood operations, wharves, loading plants, etc., i/c, for Kerry & Chace, of surveys, hydro-power, on Ottawa river.

References: J. G. C. Kerry, J. M. R. Fairbairn, R. de B. Corriveau, K. M. Cameron, H. Cimon, A. B. Normandin.

FOR TRANSFER FROM JUNIOR TO A HIGHER GRADE

LECLAIR—WILLIAM JAMES, of Dalbeattie, Scotland, Born at Ottawa, Ont., Aug. 24th, 1891; Educ., grad. with honours, Ottawa Collegiate Institute, 1909, extra-mural course, Queen's Univ., in higher maths., physics and languages, 1911-12, 3rd year., B.A.Sc. course., Univ. of Toronto, 1915-16; 1909-11, served under and acted as asst. to supt. of constrn. on hydro-electric development works for the Bronson Co., Ottawa Power Co., Ottawa Elec. Ry., etc.; 1911-16, with Dept. of Pub. Works, Canada, preparing plans and specifications. general constrn., surveying and levelling, last 2 yrs. ranked as asst. engr.; 1916-19, tech. officer in Can. Forestry Corps, for 2 yrs. i/c sawmill, camps, railroad and road constrn. and operation of La Freese dist. in France; 1920 to date, ch. engr. and managing partner of Lawson & LeClair, Dalbeattie.

References: C. R. Coutlee, J. Murphy, A. Gray, J. L. Lang, F. E. Bronson, G. F. Dalton.

PERRITON—DOUGLAS ERIC, of Westmount, Que., Born at Montreal, Que., Jan. 16th, 1898; Educ., B.Sc., McGill Univ., 1922; 1919 (summer), mechanical design, P. Lyall & Sons; 1920-21, estimator, Grand Trunk arbitration; 1922 to date, with Dom. Bridge Co., Ltd., as: 1922-24, checking and designing, and May 1924 to date, estimating and contracting, as assistant to contracting engr.

References: D. C. Tennant, F. P. Shearwood, L. R. Wilson, F. Newell, P. L. Pratley, C. M. McKergow.

VOGAN—GEORGE OLIVER, of York Mills, Ont., Born at Riceville, Ont., Dec. 18th, 1892; Educ., B.Sc., Queen's Univ., 1917; asst. designing engr. for the hydraulic dept., H.E.P.C., Toronto, in responsible charge of detailed design of South Falls plant; during 1926-27, i/c detailed design of the Alexander power development for the H.E.P.C. of Ont.; since Jan. 1st, 1928, designing engr. for the Alcoa Power Co., Ltd., Arvida, Que.

References: T. H. Hogg, O. Holden, J. J. Traill, R. L. Hearn, A. E. Nourse, J. A. Knight.

FOR TRANSFER FROM STUDENT TO A HIGHER GRADE

CROSS—GEORGE ESPLIN, of Westmount, Que., Born at Westmount, Mch. 14th, 1899; Educ., B.Sc., McGill Univ., 1923; gold medallist, Mtl. Tech. School, 1919; estimator and dftsman with Geo. W. Reed & Co., Ltd., from May 1923 to Feb. 1926; March 1926 to date, structural dftsman with Dom. Bridge Co., Lachine, Que.

References: A. Peden, A. R. Roberts, C. M. McKergow, J. Weir, E. Brown, D. C. Tennant, N. Cageorge.

JONES—HERBERT CECIL, of Peterborough, Ont., Born Ninga, Man., Feb. 20th, 1900; Educ., B.Sc., Univ. of Man., 1926; May 1926 to date, with Can. General Electric Co., Peterborough, in test. dept., A.C. eng. dept., and, at present, induction regulator and meter eng. dept.

References: N. D. Seaton, B. L. Barns, A. B. Gates, W. M. Cruthers, B. Ottewell, E. P. Fetherstonhaugh.

LEADLEY—FRANCIS ROBERT, of Hamilton, Ont., Born at Hamilton, Mch. 7th, 1898; Educ., B.Sc., Queen's Univ., 1925; 1925-26, course for grad. engrs. in commerce and finance, Queen's Univ.; 1922-23-24 and 25 (summers), engrg. dept., Toronto, Hamilton & Buffalo Ry.; Jan. to Aug. 1927, res. engr. at Port Maitland during constrn. of coal dock and yards for Toronto, Hamilton & Buffalo Ry.; from Aug. 1927, res. engr. during double-track grading, east mountain section, with same company.

The Viaduct Structure at the New Union Station, Toronto

Features of Design and Construction

Major A. R. Ketterson, D.S.O., A.M.E.I.C.
Assistant Engineer, Canadian Pacific Railway Company.

Paper read before the Toronto Branch of The Engineering Institute of Canada, January 5th, 1928

General Description

The scheme of grade separation along the Toronto waterfront involves, generally speaking, the elevation of the tracks from a point near Bathurst street,—the westerly limit,—to a point in the vicinity of Queen street (on the line of the Canadian Pacific Railway) and Logan avenue on the line of the Canadian National Railways)—the easterly limits—making a total length of about 3.6 miles. Between these two limits, *i.e.*, Bathurst street and Logan avenue, the elevated tracks will be carried on an earth embankment, with subways at intervals in order that certain intersecting streets may pass under the tracks and give access to the waterfront area, which lies to the south.

At the new Union station, which is located between the two limits mentioned, this track elevation reaches its peak. Here the top of the rail is 29.5 feet above the zero on the harbour gauge, *i.e.*, about 20 feet higher than the old Union station tracks.

The new Union station building extends throughout the block from Bay street on the east to York street on the west, and will have, when the project is complete, twelve station tracks and ten platforms running alongside its south face.

Immediately south of these station tracks there are the Canadian Pacific Railway coach yard tracks, and adjoining these to the south are the Canadian National Railway

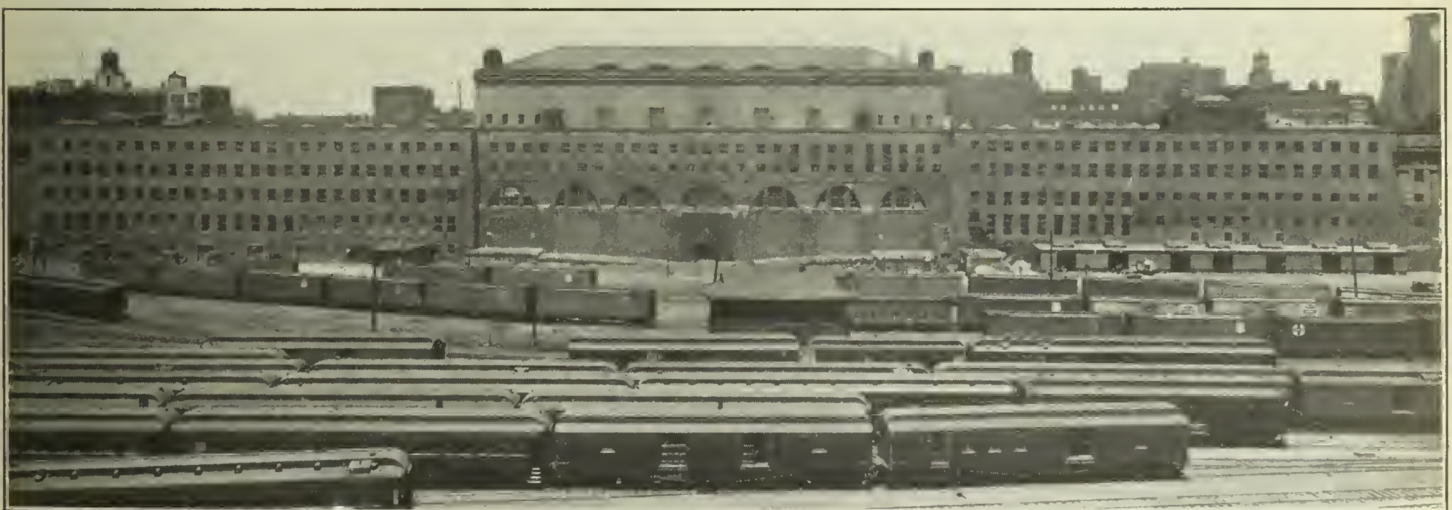

Figure No. 1.—View Looking North showing Rear of Station Building and a Portion of the Site before Construction.
The finished tracks are about the same elevation as the centre of the lower row of windows in the station building, i.e., 20 feet higher than those shown in the foreground.

through freight tracks. All these tracks will be on the high level.

As previously stated, the track elevation is being accomplished by earth fill, but in order to provide ample facilities for baggage, mail, express, waiting room and other services connected with the station, the scheme required that the twelve station tracks and platforms be carried on a structure in order that the area underneath be available for these purposes. The floor of this sub-track area is a continuation of the nearest floor on the adjoining station building, and access to the platforms above is obtained by an elevator on each baggage platform.

In the case of the sub-track waiting room, its floor is connected by a ramp with the main ticket concourse in the station building and access to the tracks is obtained by stairs leading up to each passenger platform. (Figure No. 5.)

The structure, as illustrated in figure No. 2, extends from 90 feet east of Bay street to 90 feet west of York street and embraces a part of Bay and York street subways. The portion carrying the twelve station tracks and platforms will be about 1,180 feet long with a width of approximately 300 feet.

In addition to passing under the station tracks and platforms, the Bay street subway continues under the neck of the Canadian Pacific Railway coach yard and the Canadian National Railway's through freight tracks, making the total length of this subway about 420 feet and its width 80 feet. At York street the coach yard trackage has increased, making the total length of this subway about 826 feet and width 66 feet.

The 90-foot strip, east of Bay street, provides trucking area under the tracks for the Canadian Pacific Express Company. The floor of this trucking area will be on the same elevation as the ground floor of the Canadian Pacific Express building to be erected east of Bay street and north of the tracks, and its north end will connect with the express building. This area has elevator access to each baggage platform above. A similar 90-foot strip, west of York street, provides identical facilities for the Canadian National Express Company building which will be constructed west of York street and north of the tracks.

Between Bay and York streets the structure is, roughly speaking, divided into three parts. The eastern portion, 310 feet long and 300 feet wide, which adjoins the post office wing of the station building, is devoted to mail service. The western portion, also 310 feet long and 300 feet wide, which adjoins the baggage wing of the station building, is devoted to baggage and other services incidental to the operation of the terminal. Both of these areas have direct elevator access to the baggage platforms above and their floor level is practically a continuation of the corresponding floor in the respective wings of the station building. The post office portion has a teamway about 45 feet wide alongside Bay street, while the baggage portion has an identical teamway alongside York street.

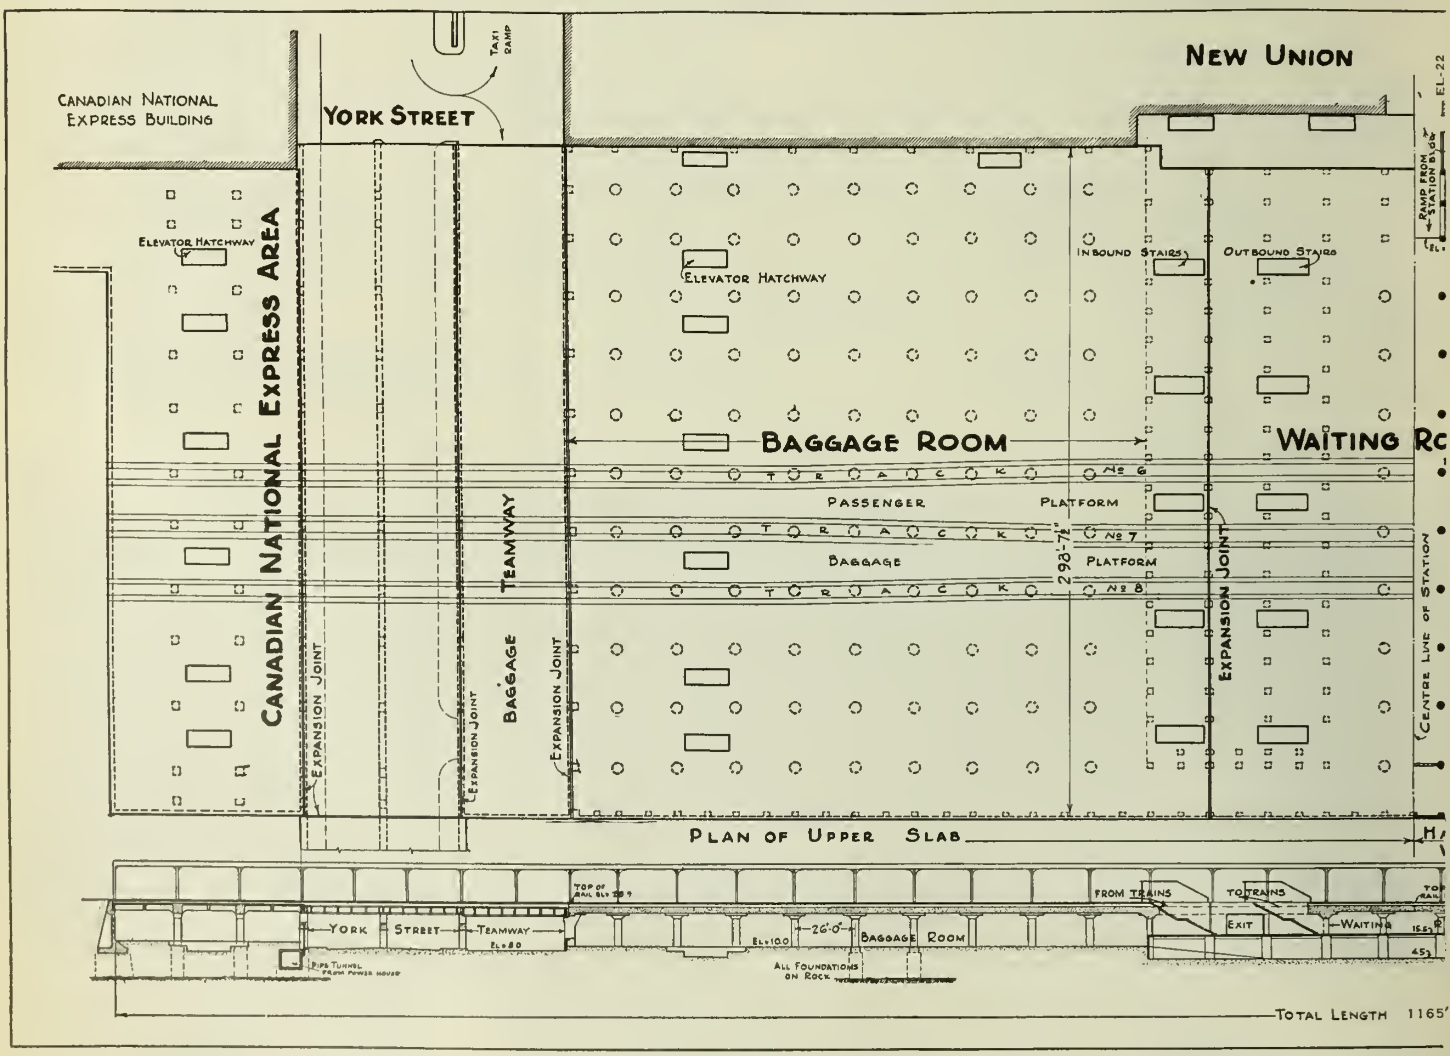

Figure No. 2.—Viaduct Structure, General

The central portion, 236 feet long by 300 feet wide, is constructed with two floors under the tracks. The so-called 15.5 level provides for sub-track waiting room, exit passages, concession spaces and certain offices. This sub-track waiting room, irrespective of concession spaces, etc., is 78 feet wide by 280 feet long, with stairways at intervals along each side leading up to each passenger platform. Underneath this waiting room, a floor at the 4.5 level provides suitable accommodation for various railway services and storage purposes.

Outbound passengers proceed from the ticket concourse in the station, (see figure No. 5), through the ramp passage leading to the sub-track waiting room on the 15.5 level, and thence through one of the train gates which are located at the foot of the stairs leading up to the various passenger platforms, (see figures Nos. 2 and 6b).

Each passenger platform is served by two direct stairways from the sub-track waiting room. One leads up from the east side of the room and the other from a point directly opposite on the west side. Thus when an eastbound and a westbound train occupy the same track, the passengers are directed to the east or west stairway, (as the case may be), and reach track level alongside their respective trains.

The inbound passengers take the nearest stairway leading to one or other of the two exit passages. These passages, each 16 feet wide, which lead to the main exit concourse in the station building, are located symmetrically with respect to the centre of the structure (one on east side of the waiting room and the other on the west side), and

(Taken before diagonal bands were placed.)

each is served by stairways leading from the passenger platforms.

Outgoing or incoming baggage, mail or express reaches or leaves the baggage platform by means of the elevators leading to their respective areas. As each track is provided with a separate passenger and baggage platform all trucking is carried out without inconvenience to passengers.

Design

In deciding on the type of construction to be used, due consideration was given to the respective merits of structural steel and reinforced concrete. Preliminary designs were drawn up covering the typical features of both types, and the estimates indicated a very large saving in favour of reinforced concrete with none of the annoyance to adjacent offices, which would be the case during the erection of structural steel. This is not intended as a general statement applicable to all similar cases, but certainly applied to the greater portion of the viaduct structure. There are certain portions of the work, however, for which steel was naturally more suitable; for instance, the 47-foot spans over the post office and baggage teamways, also those carrying the station tracks and platforms over Bay and York streets.

Various types of reinforced concrete construction were also investigated as to the cost, utility and general appearance. Mr. Ambrose, chief engineer of the Terminal Company, recommended the type commonly known as "flat slab" construction, and visits to similar structures on the East Orange improvement work of the Delaware and Lackawanna Railway impressed one with their " clean cut " and efficient appearance.

Although this type of construction has been employed quite extensively for buildings designed for heavy floor loads, it has not, except in comparatively few cases, been used for the heavy concentrations which exist with railway loading. A few such structures for railway loading have been built in the United States, but in no case, (as far as the writer is aware), do they cover as *large an area* as the one now under construction in Toronto, or do they exceed it in the size of the individual panel, viz., 26 feet by 25 feet $8\frac{3}{4}$ inches, centre to centre of columns.(1)

The practically uniform ceiling surface which this type affords, with no downward projections except the isolated drop panels around the column head, allows the maximum headroom to be obtained throughout the panel and permits the piping, (a very extensive feature in this structure), to be carried close to the ceiling with the minimum intrusion into the clear headroom. This consideration was especially important in the case of the sub-track waiting room. Here, the relationship between the floor level of the main concourse in the station building and the floor of the sub-

(1) The complete viaduct structure at the Union station is confined within a comparatively short length, but it is equivalent to a double track viaduct about three miles long.

track waiting room required that the latter be at elevation 15.5, while the elevation of the underside of the slab carrying the tracks above is 25.75, *i.e.*, a total headroom of 10 feet 3 inches. When it is considered that this waiting room will be 78 feet wide by about 280 feet long, the necessity of maintaining a uniform ceiling surface, without the breaks which would be obtained with a beam and slab design, is apparent.

In the architectural finish of this waiting room, the architects endeavoured to maintain the engineering features of the construction. (See photographs.)

The structure is designed for a track live load based on Cooper's E-60 loading with an impact allowance of $\frac{L^2}{L+D}$. Allowance was also made for platform live load and the concentrations from the train shed columns. The "four way" system of reinforcing was adopted as the most suitable for distributing the heavy irregular loading involved.

The theory of flat slab design being largely empirical, there is some difference of opinion among designing engineers as to the best practical method of calculating the total moment in a panel for railway loading and the distribution of that moment among the various reinforcing bands.

During the last few years considerable research work has been done by various authorities both in the mathematical analysis of the moments and in tests of actual flat slab buildings, and although these investigations have been confined mostly to the specific case where the load is uniformly distributed throughout the panel, the results have been most valuable in clearing up much of the uncertainty hitherto connected with this type of construction.

The Joint Committee,(2) when preparing their latest specification, evidently devoted considerable attention to the question of flat slab design, and recommended the formula $M_0 = 0.09Wl\,(1 - \frac{2}{3}\frac{c}{l})^2$, where M_0 equals the sum of the positive and negative moments in the rectangular direction in which the moments are considered; l equals the length centre to centre of columns in the rectangular direction in which the moments are considered; c equals the diameter of the column capital; W equals the total load uniformly distributed over a single panel area. Of this total moment 62 per cent is assumed to be negative, and 38 per cent positive, this latter being assumed equally divided between the column strip and middle strip, *i.e.*, 19 per cent to each.

The Masonry Committee of the American Railway Engineering Association in last year's report to that organization stated that "the recommendations of the Joint Committee for designing of flat slabs are formulated for structures which carry uniformly distributed loads such as occur in buildings," adding that, while it did not approve these recommendations for railway loading, it was not prepared at that time to offer any definite alternative, and suggested further study by the committee during the succeeding year.

In the computation for this structure, the Joint Committee recommendations were used as the means of arriving at approximate moments, but as these are based on a load uniformly distributed throughout the panel, whereas the actual panel load consists of heavy loaded track strips alternating with relatively light loaded platform strips, the moments thus found were checked by an independent analysis applying the slope-deflection theory.

An equivalent uniformly distributed load was computed by static analysis, (see diagram 4, figure No. 7). This figure was used in the Joint Committee's formula and the total

(2) The Joint Committee on Standard Specifications for Concrete and Reinforced Concrete, which consisted of representatives of the American Society of Civil Engineers, American Society for Testing Materials, American Railway Engineering Association, American Concrete Institute, and Portland Cement Association.

Figure No. 8.—View Looking South from Station Building showing the "Four-way" Reinforcing in Place in the Background and a Portion of the Finished Slab in the Foreground.

Figure No. 9.—Interior View of the Post Office Area showing Construction around Elevator Hatchways.

moment thus found was divided among the various bands as recommended in the Joint Committee's specifications. From these sub-divisions of the total moment and the shears, the thickness of the slab, dimensions of drop panel and reinforcing in the various bands were established. The diameter and reinforcing in the columns were ascertained for concentric and unbalanced loading.

As previously stated, in checking the maximum positive and negative moments used in the foregoing a method of analysis based on the theory of slope-deflections was employed, and in order to simplify the work, certain assumptions were made which were considered justified in view of the very indeterminate nature of the problem, and the fact that the actual stresses in flat slab structures as found by extensometer tests are in almost every instance less than the design stresses. Instead, therefore, of attempting to use a variable moment of inertia for the slab an average moment was assumed constant throughout the span.

A similar assumption was made in the case of the columns which were also taken as rigidly fixed at their base, since at that point they are anchored into large pedestals founded on rock, and are also held laterally by a thick concrete floor where column and pedestal connect. It was, therefore, assumed that the foot of the column has no rotational movement when the structure distorts under load. It was also assumed that the only movement at the top of the column was rotational, or in other words, any translational movement was neglected.

The computations were based on a structure five 26-foot panels long and five 26-foot panels wide. The actual distance between expansion joints is more than this, but for reasons previously stated it was considered an unnecessary refinement to assume more than five panels, as it would have involved needless additional labour with only a slight modification in the result from a practical standpoint.

The panel was divided into the usual strips which have become associated with flat slab design. These were subdivided into the elementary areas *A*, *B*, *C*, *D*, *E* and *F*, shown in diagram 3, figure No. 7, and the moments due to the load on each were considered as resisted in either the longitudinal or transverse direction, depending upon the location of the area in the panel. For instance, the effect of a load distributed over *A* is, (in a square panel), resisted equally in both directions. Moments due to loads on areas *B* and *E* were assumed to be resisted entirely by the transverse bands, and *C* and *F* by the longitudinal bands, while the load on area *D*, which is located on the corner of the cantilever and immediately over both the longitudinal and transverse bands, was assumed divided equally in two directions.

In computing the various moments, only those spans were loaded which would give the maximum in the span considered in the same manner as for any slab continuous over five spans. (Figure No. 7, diagrams 6a to 6d).

Lateral Distribution of Track Live Load

The track live load is directly applied through the ballast on a surface of slab 10 feet in width, (see diagram 5a, figure No. 7), and this 10 feet wide concentration was considered as carried by 26 feet width of slab, the intensity of the distribution throughout this width varying from a maximum under the track to zero along the edges, as indicated by diagram 5c, figure No. 7.

From the published results of tests made on simple slabs, it appears that, when the width of the slab exceeds 1.5 times the span, the stresses due to a concentrated load placed in the centre may be considered as uniformly resisted over a width of slab equal to 72 per cent of the span, which width in this case would be 16 feet.

On this basis, therefore, if the 10 feet wide concentration on the slab surface be divided, say, into ten 1-foot concentrations, each of these could be considered as uniformly distributed over a width of 16 feet, as shown in diagram 5b, figure No. 7, and the summation of these unit distributions would give the intensity diagram indicated by diagram 5c.

As the tests cited are reported to have been made on simple slabs with no transverse reinforcement, the foregoing distribution for a " four way " flat slab would certainly be conservative. For tracks placed on centre line of columns diagram 5c would give a distribution of approximately 70 per cent of the live load to the column strips, and 15 per cent to each of the adjoining middle strips.

After deciding on the distribution of the live load, (platform and track), over reach of the elementary areas *A*, *B*, *C*, *D*, *E* and *F*, (diagram 3, figure No. 7), the maximum negative and positive moments, due to the loads on each area are calculated in either the longitudinal or transverse directions as indicated in diagrams 6a to 6d and allotted to their respective moment sections in the strips.

An equation was written for the resisting moment at the top of each of the six columns and at the ends of each of the five spans. These were in the form of the general slope-deflection equations,[3] omitting the term which would

[3] See Wilson Richart and Weiss,—Analysis of Statically Indeterminate Structures by Slope-Deflection Method. University of Illinois Bulletin No. 108, 1918.

Figure No. 10.—Post Office Teamway before Erection of the Steel Spans which Carry the Overhead Tracks.

represent translational movement of the column capital, (if any), since the only movement there is assumed to be rotational.

For column Bb (diagram 6a, figure No. 7) $M_{Bb} = 4\,EK_1\,\theta_B$

and for span $A\,B$ $\begin{cases} M_{AB} = 2\,EK_2\,(2\theta_A + \theta_B) - C_{AB} \\ M_{BA} = 2\,EK_2\,(2\theta_B + \theta_A) + C_{BA} \end{cases}$

where the letters have their usual significance, viz.:—

M_{Bb} = Resisting moment, (or moment of internal stresses), at top of column Bb.

M_{AB} and M_{BA} = Resisting moment at A end and B end respectively of span AB.

θ_A and θ_B = Change in slope of the tangent to the elastic curve at the A end and B end respectively of the span when the column capital rotates.

K_1 = Ratio of moment of inertia of column to its height.

K_2 = Ratio of moment of inertia of slab, (26 feet wide), to its net span, $(l - \frac{2}{3}c)$.

C_{AB} and C_{BA} = The resisting moment at the A end and B end respectively of an absolutely fixed beam, of the same span and loading as span $A\,B$.

E = Modulus of elasticity.

By writing the corresponding equation to the foregoing for the top of each column and for the end of the span or spans which connect at the column, the following are typical for, say, the joint at top of column $Dd.$, (diagram 6b, figure No. 7).

$M_{Dd} = 4\,EK_1\,\theta_D.$

$M_{DC} = 2\,EK_2\,(2\theta_D + \theta_C) + C_{DC} = 4\,EK_2\,\theta_D + 2\,EK_2\,\theta_C + C_{DC}.$

$M_{DE} = 2\,EK_2\,(2\theta_D + \theta_E) - C_{DE} = 4\,EK_2\,\theta_D + 2EK_2\,\theta_E - C_{DE}.$

As the algebraic sum of the resisting moments at each joint must equal zero.

$M_{Dd} + M_{DC} + M_{DE} =$

$2\,EK_2\,\theta_C + (4\,EK_1 + 8\,EK_2)\,\theta_D + 2\,EK_2\,\theta_E + C_{DC} - C_{DE} = 0.$

Since the numerical value of K_1 and K_2 is known from the preliminary design, also C_{DC} and C_{DE} from the loading, the only unknowns in the equation are the θs, and the equation may therefore be written—

$$P\theta_C + Q\theta_D + P\theta_E + C_{DC} - C_{DE} = 0$$

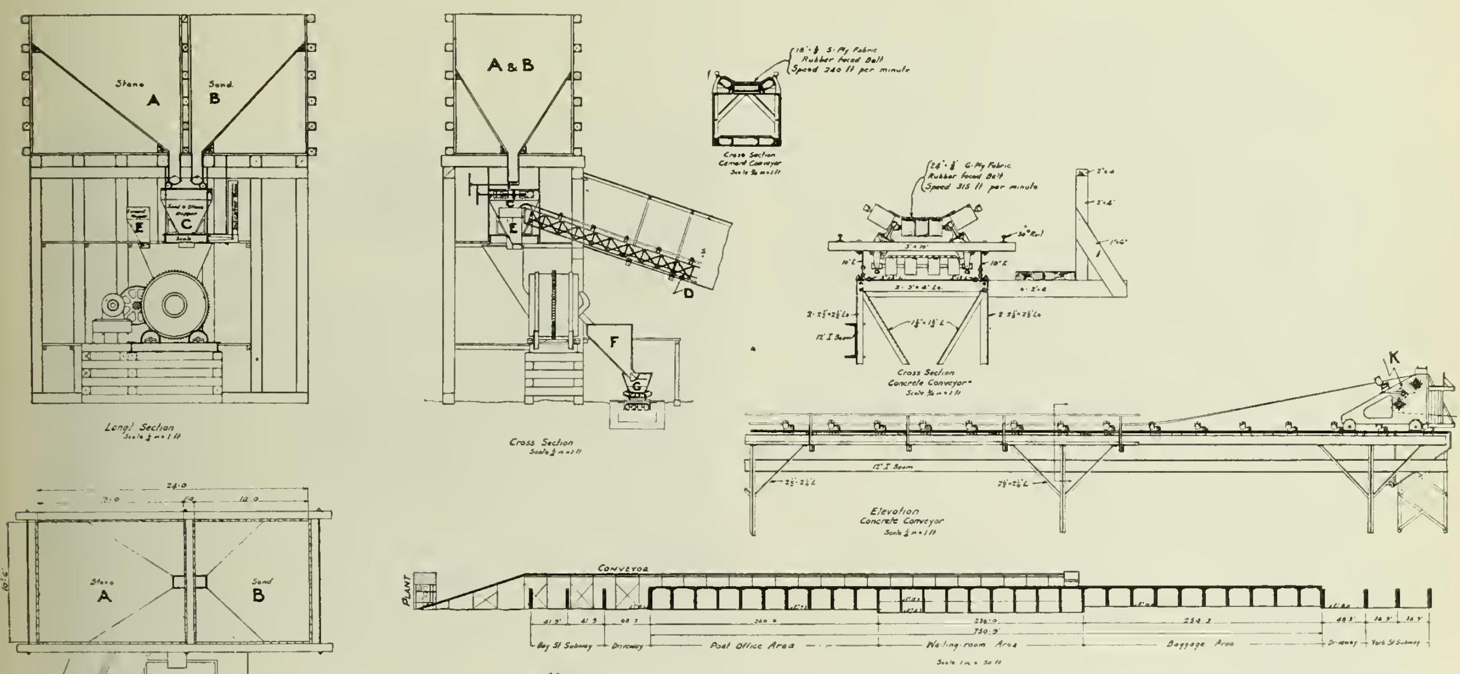
where P, Q, C_{DC} and C_{DE} have a known value.

A similar equation being written for each of the six capitals, six equations are found involving the six unknown θs, and, by solving these as simultaneous, the value of each θ is obtained.

Knowing the value of each θ, the resisting moment at the ends of the various spans is obtained directly from the slope-deflection equations.

If the negative moment at the column head section is required, say, at D for span CD, (diagrams 6b and 6d, figure No. 7), it will be equal, (numerically), to the resisting moment M_{DC}.

If the positive moment in the column strip or middle strip is required, say, for span CD, (diagrams 6a and 6c, figure No. 7), it will be equal to the moment at the centre of a simple supported span of same length and loading minus half the sum of the resisting moments M_{CD} and M_{DC}.[4]



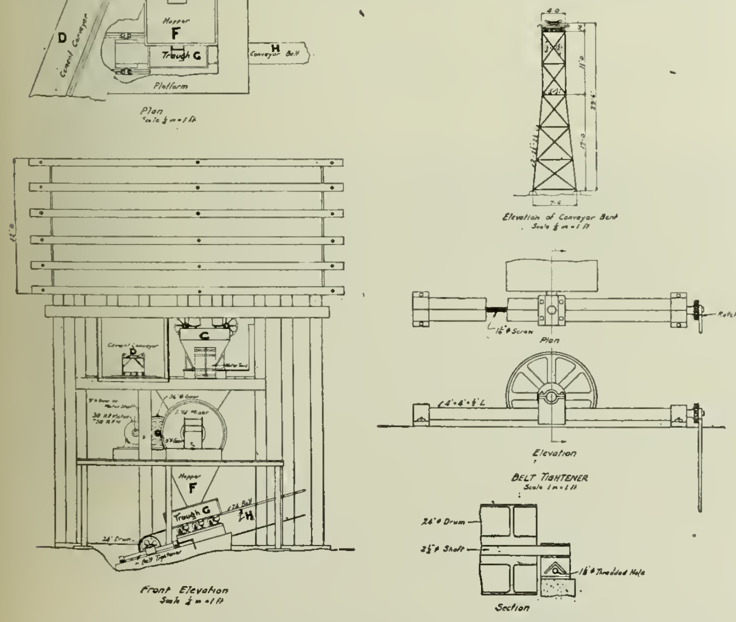


Figure No. 11.—Plan of Contractor's Concrete Mixing Plant.

[4] This is a general statement. In the case of span CD, which is the centre span of a symmetrical structure symmetrically loaded, $M_{CD} = M_{DC}$.

Figure No. 12.—One of the Arch "Bents" on Bay Street Subway which Support the Steel Spans Carrying the Overhead Tracks.

Comparison with Results Based on Joint Committee Formula

Comparing the total moment and its distribution as found by the foregoing analysis, using slope-deflection equations, with the corresponding moments using the Joint Committee's formula and an equivalent load uniformly distributed throughout the panel, it was found that the total moment in the ruling direction agreed to within about 5 per cent for tracks on centre line of column and about 4 per cent for tracks located along centre line of panel. The following table gives the percentage distribution of the moments calculated for panel strips of alternating light and heavy loading by the analysis described, and the distribution recommended by the Joint Committee's specification where uniformly distributed load is assumed. The three cases given represent the comparisons for a square interior panel having columns at 26-foot centres.

Case 1—Tracks on centre line of columns, *i.e.*, at 26-foot centres with platforms intervening.

Case 2—Tracks offset 1 foot 6 inches from centre line of columns in alternate panels, *i.e.*, tracks alternating at 23- and 29-foot centres with platforms intervening.

Case 3—Tracks on centre line of panel, *i.e.*, at 26-foot centres with platforms intervening.

The difference in the percentage of total negative and total positive moment in slope-deflection column for each case, and the corresponding distribution recommended by the Joint Committee for an equivalent uniformly distributed load is, (considering the type of structure), negligible as far as practical design is concerned.

In the calculations, average moments of inertia were assumed for the slab and column, and a comparatively small variation in the $\frac{I}{h}$ of column and $\frac{I}{l}$ of slab, (*i.e.*, the ratio of their respective rigidity), would give a small redistribution of the total moment between the postive and negative.

The table shows, however, a considerable difference in the division of the total positive moment as calculated, and the Joint Committee distribution for uniform load. In the latter, this moment is divided equally between the column strips and middle strip, whereas the calculated moment was much larger for the column strips, which seems more reasonable for the design loading.

While the Joint Committee moment distribution gives results which are conservative for uniformly distributed loads or the ordinary irregular intensities common to buildings, the writer believes that for railway structures of this type, (the columns of which are usually only one storey high), it is advisable to analyze the moment distribution with reference to the relative rigidity of the actual columns and slab, and the irregular loading, by first arriving at a preliminary design based on the Joint Committee's recommendations, using an equivalent uniformly distributed load which would give the same static moment on a span of $\left(l - \frac{2}{3}c\right)$ as the design loading), and then checking the result by some analysis which takes the relative restraint of the component parts of the assumed structure into consideration in the calculations.

Figure No. 13.—View showing Junction of East and West Exit Passages under the Bridge Carrying the Ramped Passage Connecting Ticket Concourse (El.22) with Train Waiting Room (El.15.5).

It is the case that, although the slope-deflection equations are exact in theory, their application to flat slabs with the assumptions herein stated, in order to simplify

	Joint Committee's Distribution for Uniformly Distributed load	Calculated by Slope—Deflections		
		Case I	Case II	Case III
Total Moment *Mo* (in Ruling Direction)		Agreed with Joint Committee within 5 per cent.	Agreed with Joint Committee	Agreed with Joint Committee within 4 per cent.
Total neg. moment (per cent of *Mo*)	62	60.5	60.5	60
Total pos. moment (per cent of *Mo*)	38	39.5	39.5	40

Figure No. 14.—Portion of Train Waiting Room (El.15.5) after Stripping the Forms.

the work, must give results which are more or less approximate, but this statement could apply to any method of analysis except one which would involve so much labour and abstruse mathematics as to make it unsuitable for ordinary use. By using the slope-deflection method with judicious assumptions, the labour involved is not excessive and the results should be sufficiently accurate for practical purposes.

Construction

In order that interference in the operation of the terminal be reduced to a minimum, the structure is being built in two sections. The first section, (now under way), is the northerly strip, extending the full length and wide enough to accommodate six tracks and platforms.

As several of the old station tracks and platforms were on the site of the westerly end of this strip and its approach, it was necessary to re-vamp the station track layout and locate them south of and parallel to this first construction strip. This change was not made until the work had reached the stage when the new station could be put into operation, which was done as soon as the sub-track structure was completed from Bay to York streets. Both outgoing and incoming passengers use the centre portion of the structure as a means of access between the temporary station tracks, which lie to the south of it, and the station building on the north. The east wing is being used for mail purposes as intended, and the Canadian Pacific Express occupy temporarily the greater portion of the west wing.

When the filling, etc., on the east and west end of the whole project has reached the proper stage, all operation will be transferred to the viaduct tracks, after which the second, (or southerly), section of the structure will be built on the site now occupied by station tracks.

Foundations

The character of the ground in the vicinity of the station is such that all track carrying structures are being taken down to rock, the elevation of which has a gradual dip towards the bay. For the northerly pedestals, rock was met about 15 feet below ground line, (elevation —5), increasing to about 19 feet for pedestals along the south side. At the southerly end of York street subway, however, the foundations of the abutments under the through freight tracks are about 25 feet below street level. Steel sheet piling has been used throughout for all pedestal foundations.

Concrete

Three classes of concrete are being used in the construction, viz.:—

1,500-pound concrete for all pedestals from rock up to an elevation about 2½ feet from their top.

2,000-pound concrete for the upper 2½ feet of pedestal and the short stub column for the dowels, also for the beams and floor slab of the sub-track waiting room.

2,500-pound concrete for the columns and the track slab.

Figure No. 15.—Portion of Train Waiting Room after Completion.

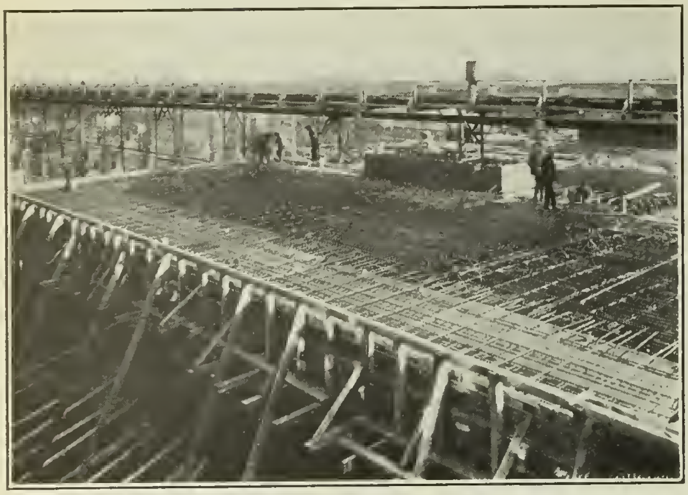

Figure No. 16.—View showing Belt Conveyor and Reinforcing of Double Track (simple) Slab in Place Ready for Concreting.

After deciding on the source from which the aggregates would be supplied, the contractor made extensive tests to ascertain the proportions which would give the strength of concrete specified under varying conditions.

This procedure was advisable, not only in the contractor's interests, but also in the owners', as it established ratios for the particular aggregates before the work began, and thereby assisted in maintaining uniform strength throughout.

This was checked from time to time by tests made by the engineers from samples taken from every pour.

The track slab was poured in strips of such width as would permit concreting to be carried on continuously between expansion joints. For this purpose, longitudinal bulkheads were placed in the forms at the desired construction joints, which are in all cases located under a platform. In addition to the ordinary slab reinforcing, short bent bars projected through the bulkhead at nine-inch centres to reinforce the joint for shear. Before proceeding with the adjoining pour, the surface of the joint was thoroughly cleaned and washed to insure bond.

Where conditions prevented the ground floor slab being poured in advance of the track slab, care was taken to guard against settlement of the posts supporting the heavily loaded forms, since these posts thus lacked the assistance of the ground slab to distribute their load over a soil of low bearing value. To take care of settlement should it occur, wedges were placed between the foot of the posts and the sills and wires were stretched horizontally alongside series of posts across the strip about to be poured, marks being placed in the posts at the elevation of the stretched wire. Constant observation was kept on the relative position of these marks and the horizontal wire during the pour and any settlement immediately corrected by tightening up the wedges.

The forms were set so that the track slab would have a drainage slope of one inch per panel, (26 feet), longitudinally. The peak of the slope is located at the centre of the structure to correspond with the peak of the track grade and the dip is east and west from that point.

Waterproofing

The waterproofing specification for the track slab was substantially in accordance with the recommendations of the American Railway Engineering Association, with slight modifications to suit the particular conditions.

Plant

The only portion of the site which was not occupied by tracks in constant use was the strip located alongside the station building and extending from a point east of Bay street to the east boundary of York street, approximately 1,000 feet long and 180 feet wide.

As practically all of this strip was required for the first section of the structure, probably the most critical problem in the construction was the location of the central mixing plant and its accessories and the method by which the concrete could be efficiently distributed over the large area involved.

The chief engineer of The Terminals Company and the contractor, after a careful study of the application of the more commonly adopted methods to this particular work, recommended that the interests of the contractor and the owners would be best served by locating the plant east of Bay street, (at eastern extremity of the work), and transporting the mixed concrete by an endless belt conveyor carried by a trestle running from the mixer westward about 800 feet, the belt being at an elevation nine feet above the track slab. This plant is shown diagrammatically on figure No. 11. The fine and coarse aggregates are raised from the material dump to the main bins *A* and *B* above the plant by clam shell operated by a derrick. These bins have sufficient capacity to furnish 125 cubic yards of concrete without refilling, which represents a three-hours' continuous pour.

From them the coarse aggregate is fed, as required, into a lower hopper *C* mounted on a scale, and is shut off when the pointer indicates that the required weight of this aggregate is in this hopper. In like manner, the required weight of fine aggregate is dropped into this lower hopper. At the same time, in the adjacent cement house, the necessary quantity of cement is deposited on a covered belt conveyor *D* which carries it to hopper *E* alongside the aggregate hopper above the mixer. On a bell signal, these two hoppers are opened and their contents dropped into the one-yard mixer. The prescribed quantity of water for each batch is furnished from a tank also located above the mixer. The batch is turned for about one minute, and then dumped into hopper *F*, then to regulating trough *G* which feeds it on to the moving belt conveyor *H*, which in turn carries it out to the work, where it is taken from the belt by means of a tripper arrangement *K*, (which can be placed where desired), and dropped into a hopper underneath. From this it is fed into man-handled buggies and wheeled to the place of deposit in the forms.

The length of the conveyor is 800 feet and total length of belt is 1,600 feet. The belt is 24 inches wide and is dished in the centre, which prevents the concrete spilling over the sides. The pulleys on which it travels are so located as to ensure that the dish is maintained. The rate of travel is 315 feet per minute and the average capacity is about 35 cubic yards per hour. The longest continuous pour was 1,400 cubic yards of track slab in forty-one hours.

Personnel

The consulting engineers for all work in connection with the grade separation are J. M. R. Fairbairn, D.Sc., M.E.I.C., chief engineer, Canadian Pacific Railway, and C. B. Brown, M.E.I.C., chief engineer, Canadian National Railways.

J. R. W. Ambrose, M.E.I.C., chief engineer, Toronto Terminals Railway, assisted by Mr. Erskine Duncan, is in direct charge of construction work. The planning and design of the viaduct structure were done by the chief engineer's office, Canadian Pacific Railway, in the department of P. B. Motley, M.E.I.C., engineer of bridges, (assisted by the writer); W. A. Duff, M.E.I.C., engineer of standards of Canadian National Railways, co-operating. The heating and ventilating were planned by Mr. E. B. Plant, of the engineer of buildings department, Canadian Pacific Railway, and electrical installation by J. A. Shaw, M.E.I.C., chief electrical engineer, Canadian Pacific Railway, with Mr. R. Meadows in charge. Mr. Hugh G. Jones and Associates carried out the decorative and architectural features.

Messrs. P. Lyall and Sons are the general contractors for the structure, and are represented on the work by Mr. P. Lyall, Jr., with N. L. Morgan, A.M.E.I.C., as general superintendent.

Electric Heating of Rack-Bars in Hydro-Electric Plants

Method of Application and Results Obtained, with Particular Reference to an Installation at Shawinigan Falls, Que.

C. R. Reid,
Superintendent of Generating Stations, Shawinigan Water and Power Company.

Paper presented at the Annual General Professional Meeting of the Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

Frazil ice is formed in turbulent open water at zero temperature. The turbulency may be caused by conditions of stream flow or it may be due to high wind. When ice begins to form on the water surface it is in the shape of slender needle-like crystals which, if undisturbed, spread over the surface and unite to form a continuous sheet. However, if the water is turbulent, the needles are swept beneath the surface and distributed throughout the body of water to a depth depending on the turbulency. When these needles reach a set of rack-bars at zero temperature they are caught on the bars like so many fibres and a matted layer is soon formed at and near the surface of the water.

This layer is more or less porous and will continue to build up until it is six inches or more in thickness. The needles freeze together and to the rack to form a mass that, while not nearly so strong as solid ice, it is practically impossible to clear off by mechanical means. At first the layer of ice forms on the bars only to the depth to which the needles have been carried by the turbulency of the water, but, as the openings are stopped up near the surface, they are carried downward by the entering water. Thus, the layer is extended downward until the flow is practically cut off. The head is apt to drop on the lower side of the racks due to the water draining away through the turbines, and the resultant unbalanced pressure may be sufficient to crush the rack structure.

Methods of Overcoming Frazil Ice Troubles

The best method of overcoming frazil ice troubles is through proper design of the hydraulic system above the rack-bars. A large body of quiet water will freeze over quickly and an ice covering of sufficient size will intercept the frazil ice. This is due to the ice needles either adhering to the under side of the ice covering or being remelted in the warmer water under the ice. If the velocity of approach is low and the racks are set at a considerable depth, and if, in addition, the bed of the approach channel is smooth and grades down easily to the bottom of the racks or even considerably below that, frazil ice troubles should be entirely eliminated.

The most common method of dealing with frazil is to raise the racks and let it pass through the turbines. Racks are usually made in two or more sections to reach from top to bottom. It is usually sufficient to raise the top section from three to six feet. The upper rack will be covered with frazil, but after that the needles are carried down and pass through the opening, leaving the lower part of the racks free of ice. Except in the case of very low heads the frazil passes through the turbine without giving any trouble. In some low head plants electric heating has been applied to the runner to keep it clear of ice. The worst objection to raising the racks is that it defeats the purpose for which the racks are intended, i.e., to keep trash out of the turbines. Trash entering the turbines blocks the water passages, reducing the output of the unit; causes unbalance of the runner, with consequent vibration; and may do considerable damage to the runner and guide vanes. It is necessary to shut down the turbines frequently for cleaning during the time the racks are raised. As a usual thing, frazil ice trouble lasts for only a week or two while the river is freezing up and occasionally in the spring after the ice has gone out.

Electric Heating of Rack Bars

If it is desired to operate without raising the racks, it is necessary to provide some form of heating for the rack-bars in order to prevent the adherence of the frazil ice. At Shawinigan Falls, electric heating has been successfully applied for this purpose. This paper will describe the method of application and results so far obtained.

In the design of the installation at Shawinigan Falls, use was made of the published data on the rack heating equipment in several Norwegian and Swedish plants. This data was obtained from a paper entitled "Ice Troubles in Norwegian Power Plants," by Mr. Ruth, published in the

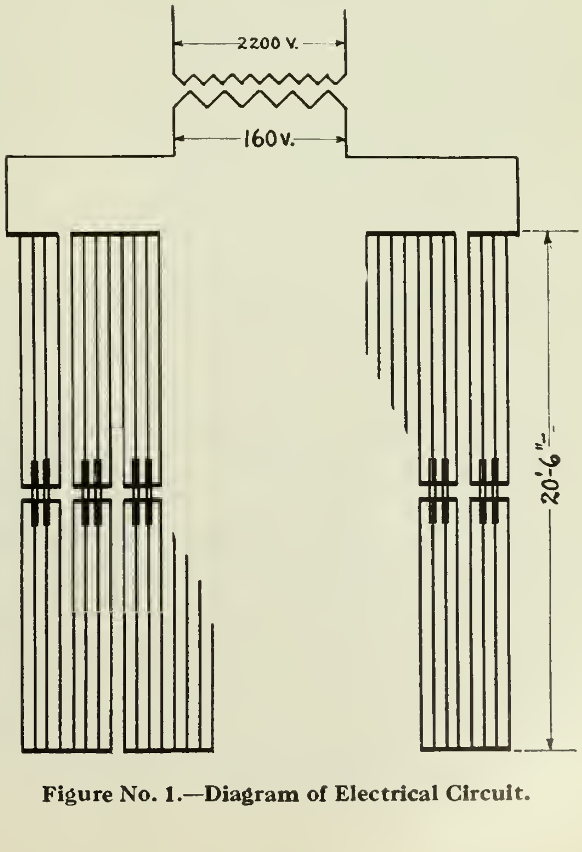

Figure No. 1.—Diagram of Electrical Circuit.

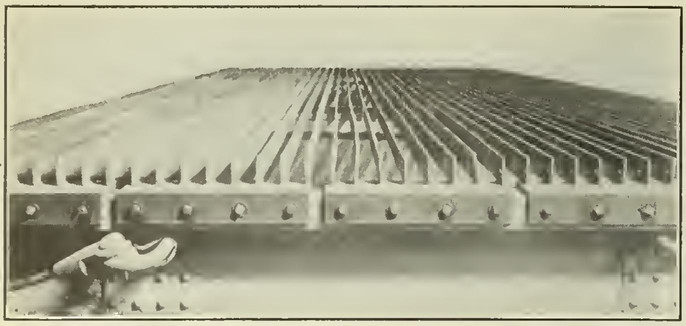

Figure No. 2.—Upper End of Rack showing Arrangement of Bars in Groups.

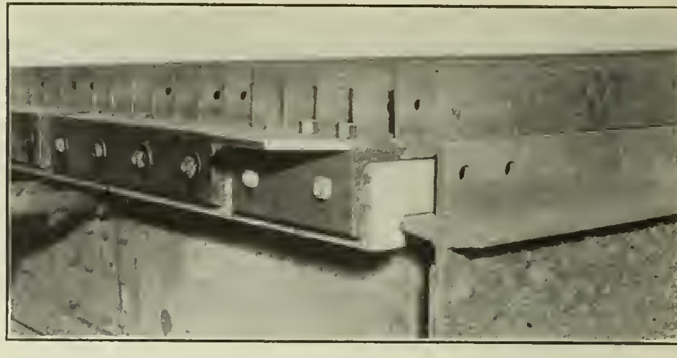

Figure No. 4.—Upper End of Rack showing Insulation of Bars.

Transactions of the World's Power Conference, London, 1924, and from an article in the Swedish "Teknisk Tidskrift Electrotechnic," No. 1, 1917, describing the rack heating equipment at Trollhattan.

It is apparent that it is difficult to determine exactly the amount of energy required to keep the racks free from ice. An installation might work successfully on a number of occasions and then, due perhaps to a combination of severe ice conditions and low voltage on the heating circuit, might prove inadequate. The data available on the Norwegian and Swedish installations show an energy consumption of from 140 to 425 watts per cubic foot of water per second. Further, these installations were reported as working satisfactorily. For the installation at Shawinigan Falls, provision was made to obtain an energy input of 225 watts per cubic foot of water per second with transformer taps provided to allow for a maximum of 425 watts if required.

Electrical Layout

The racks of the 40,000 kv.a. unit are arranged in five bays. Each bay is 12 feet wide and the racks extend to a depth of 25 feet 6 inches, made up of three sections. The top section, 10 feet 6 inches, and the middle section, 10 feet in length, are heated. There are forty-eight bars of 3½ by 5/16 inch section in each bay. These are grouped four in parallel and twelve such groups in series. Connection is made between the bays so that two and a half bays constitute one series circuit with thirty groups of four multiple bars connected in series. This gives a circuit length of 20.5 by 30, or 615 feet exclusive of connections. The two circuits obtained in this way are supplied with two-phase, 30-cycle current from the secondaries of two 750 kv.a. transformers which are connected to a 2,200-volt circuit direct from the power house bus bar.

Structural Details

The rack-bars are supported by being electrically welded to pieces of structural steel angles. At top and bottom these angles are long enough to bridge eight bars, and thus serve to connect electrically one group of four bars to the next. The intermediate angles bridge four bars only. The angles are supported on oak pieces that are attached to the rack frame and serve as insulation. The oak pieces are "L" shaped in order to support the weight of the bars in compression. Connection is made between the bars in the upper section and the middle section by means of fish plates. Connection between the transformers and the racks is made with two 5/16 by 5 inch copper bars in parallel laid in ducts and insulated by hardwood cleats.

Performance

An average set of electrical readings on one transformer secondary and rack circuit is as follows:—

Voltage at transformer terminals	135.5 volts
Voltage at rack terminals	126.5 volts
Current	3680. amps.
Output at transformer terminals	347. kw.
Loss in connections	7. kw.
Input into one rack circuit	340. kw.
Total input into racks	680. kw.
Power factor measured at transformer terminals	69.7%
Power factor measured at rack terminals	73.2%
Power per cubic feet per second	227.0 watts

Sufficient experience has been gained with this installation to demonstrate that just about the right amount of

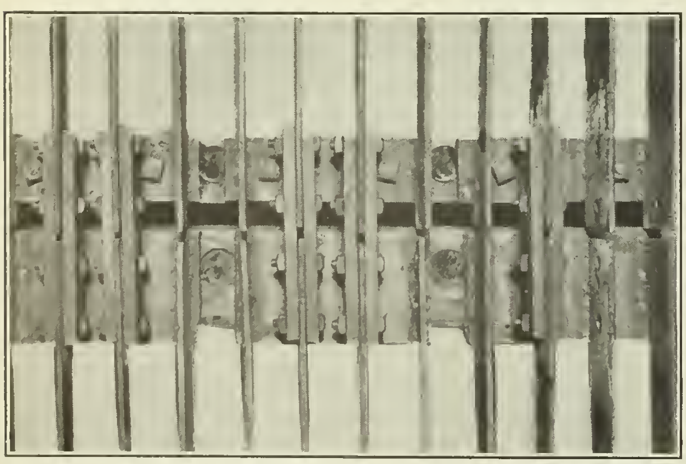

Figure No. 3.—Connection between Upper and Lower Section of Rack.

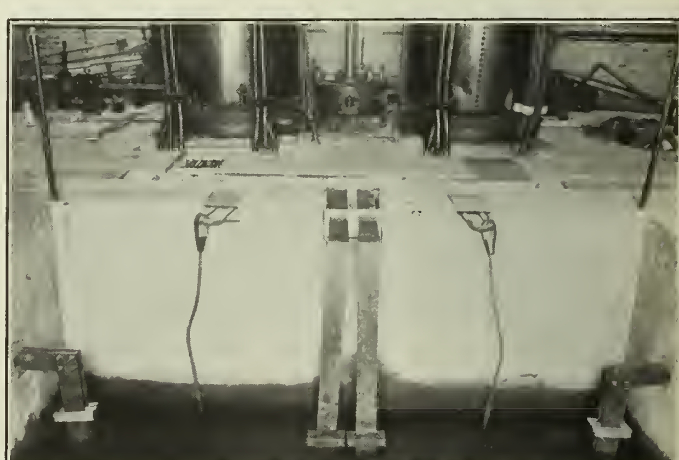

Figure No. 5.—View showing Connection between Bus and Racks and between Bays.

Figure No. 6.—Severe Ice Conditions in Forebay, Shawinigan Falls.

energy input has been provided. Severe frazil ice conditions have been handled with entire success on several occasions. It has been found, however, that broken ice is cleared slowly by melting. If it comes on to the racks in considerable quantities it is necessary to clear it off by hand in order to prevent the drop through the racks becoming excessive.

The power required for given installation may be assumed to be directly proportional to the total length of rack-bar and velocity of the water passing the bars. This relationship may be expressed by the formula,—

(1) $P = K.n.l.V.$

in which P is the power in kilowatts, K a constant to be determined, n the number of bars, l the length of each bar, and V the velocity of the water entering the racks.

Formula (1) may be modified as follows:—

(2) $P = K\frac{N.s.l.V.}{s} = K\frac{AV}{s} = K\frac{Q}{s}$

in which s is the spacing of the bars, A is the area of the racks and Q the quantity of water. It will be convenient to take s in inches and Q in cubic feet per second. A further variable which might enter into the formula is the width of rack-bar. The wider the bar the more subject it will be to the cooling action of the water. However, since rack-bars for modern installations are usually between three and four inches in width, this factor may be neglected, at least for a first approximation.

Substituting in formula (2) the values P, Q and s used in our installation gives K the value 0.7 in round numbers.

The empirical formula:—

(3) $P = 0.7\frac{Q}{s}$

is to be considered as a first approximation in determining the power required. On this basis low head plants are not economically barred from the use of heated racks. If the rack spacing can be increased in proportion to the increase in the quantity of water required per unit of output, the percentage of energy required for heating should remain the same.

In the above calculations it has been assumed that all the water passes through the heated portion of the racks. Since the lower five feet which is unheated is apt to be stopped up at times with logs and trash, this assumption is valid. However, it would be satisfactory to heat the racks only as far down below the surface as the turbulency of the approaching water carries the frazil ice, if such a point could be determined. In such a case the energy requirement could be cut down in proportion. In a more recent installation the upper halves of the racks only have been heated.

Electric heating of racks is of particular value in locations where frazil ice trouble develops quickly and where it is not of long duration. When such trouble is experienced more or less continuously, it would no doubt be more economical to install rack-bars made of tubing welded into headers and to circulate warm water through them.

From an operator's viewpoint, it is very reassuring during ice troubles, to know that the units with heated racks may be relied on to carry their full load.

Notes on Removal of Carbon-Sulphur Compounds from Coal Gas by Oil Washing

K. L. Dawson, A.M.E.I.C.
Superintendent, Gas Department, Nova Scotia Tramways and Power Company, Limited.

Paper presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., February 16th, 1928

At the gas works of the Nova Scotia Tramways and Power Company, Limited, which operates electric light, tramway and gas utilities in Halifax, N.S., partial removal of the carbon-sulphur compounds from coal gas is being accomplished by washing the gas with oil. The process was conceived from the published results of investigations of the change in the quality of gas produced when benzol was removed by scrubbing the gas with oil, which indicated that the same oil, which absorbed benzol, also absorbed CS_2.[(1)] After some months of laboratory and draughting room work carried out at the company's plant at Halifax under the direction of Mr. E. R. Hamilton, the existing scrubbing equipment was designed. The reasons for its subsequent installation are, briefly, low installation cost, low operating cost, the opportunity of utilizing unused apparatus designed for distillation of tar, and the fact that something had to be done at once to reduce the quantity of sulphur in the finished gas which was being made from Nova Scotia coals.[(2)]

After four years of operation the original design remains practically unchanged. A few details have been altered. At present its operation is almost automatic. With proper control of the temperatures of the gas and the oil a reduction of 50 per cent in the carbon-sulphur compounds can be obtained. The fundamental laws of physical chemistry may be employed to predict and explain results, but no tests having sufficient accuracy have been made which might be used to indicate the accuracy with which these laws apply.

Description of Apparatus

The arrangement of apparatus is illustrated by the sketch, figure No. 1. The gas enters No. 1 scrubber at the bottom, is conducted upwards through scrubbers Nos. 1, 2 and 3 in turn and leaves No. 3 scrubber at the top. The renewed oil is taken from its storage tank and forced to circulating tank No. 3 by a gear pump driven by a motor which is controlled by a switch operated by a float in circulating tank No. 3. From circulating tank No. 3 the oil is forced by a second gear pump through the cooling coil to the top of scrubber No. 3. After spreading downwards over the packing in a thin film it collects in the bottom and overflows through a seal into circulating tank No. 2. A third gear pump raises it from tank No. 2 to the top of scrubber No. 2. The oil from scrubber No. 2 runs into tank No. 1, from which it is raised to the top of scrubber No. 1. From scrubber No. 1 it overflows into the storage tank for used oil. The flow of oil through the scrubbers is controlled by a system of valves on the oil circulating lines. The oil in No. 3 circulating tank is replenished at intervals. The surface of the oil in this tank rises and falls through a distance of about a foot. At the same time oil is being removed from it at a practically constant rate and discharged into the top of scrubber No. 3. The rate of removal is controlled by the valves A and B, which are adjusted by hand to keep the oil in the pipes between them under pressure and to permit the desired quantity to enter scrubber No. 3 while the excess is returned to circulating tank No. 3. The flow of oil through scrubber No. 2 is governed in a similar manner except that the opening in the valve through which the excess oil is returned to circulating tank No. 2 is regulated by a lever which has one end fastened to the plug of the valve and the other end attached to a ball floating on the surface of the oil in the circulating tank. The flow of oil through scrubber No. 1 is controlled in the same manner as for scrubber No. 2. The use of the float-controlled valves provides the means of automatically adjusting the rates of flow in scrubbers Nos. 2 and 1 to equal the rate through scrubber No. 3. From the used oil storage tank the oil is pumped to the continuous still, from which it flows through a seal into the hot oil container. A fifth gear pump takes it from the hot oil container and forces it through a cooler into the storage tank for renewed oil.

The vapours which are driven from the oil in the still pass from the top to the water-cooled worm condenser. The condensate flows into the gravity separator, where it is divided into water and benzol.

Each scrubber is a steel shell four feet in diameter by sixteen feet high. Beginning two feet from the bottom and extending to within two feet of the top is the packing which consists of four layers of excelsior of about 21 inches deep separated and supported by wooden grids 12 inches deep. For the details of the grids and packing, see figure No. 2. By actual measurement the packing occupies the entire cross-section of the shell for a height of 12 feet, giving a scrubbing volume of 150.8 cubic feet for each scrubber or 452.4 cubic feet for the three. The oil is admitted to each scrubber through a ¼-inch orifice made by drilling a hole in a ½-inch pipe cap. The jet so formed impinges on a metal disc about ⅝-inch in diameter. After striking the disc the oil spreads out into a thin film about 12 inches across, of which the edges break into drops which fall on the top of the packing in the tower.

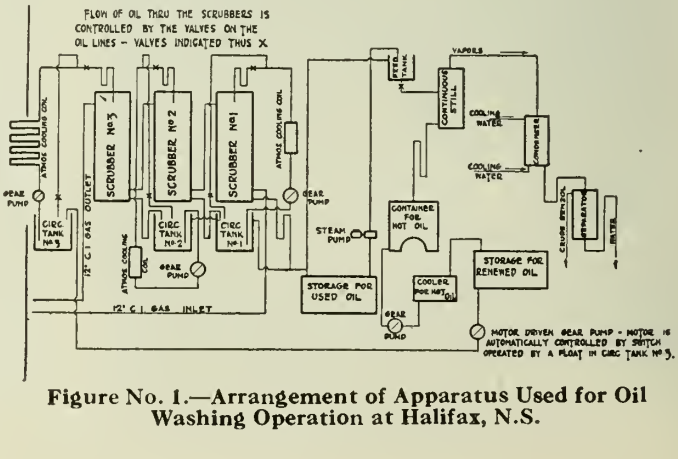

Figure No. 1.—Arrangement of Apparatus Used for Oil Washing Operation at Halifax, N.S.

(1) L. J. Willien, American Gas Institute News, Dec. 1917, mentions a reduction of 50 per cent in the quantity of CS_2.

(2) E. R. Hamilton, Proc., Canadian Gas Association, 1920-21.

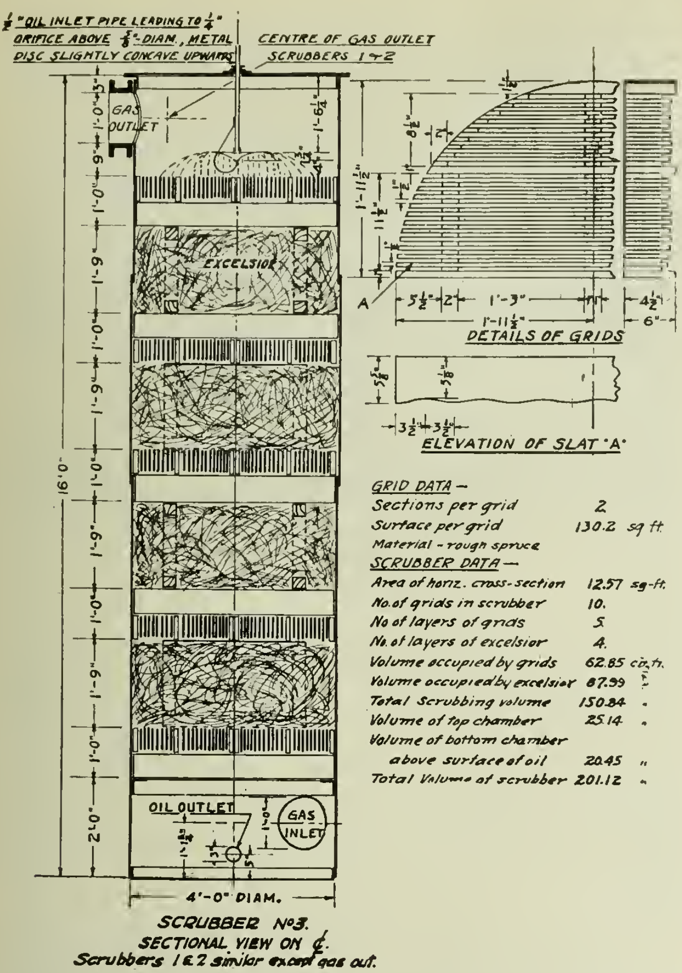

Figure No. 2.—Details of Scrubber Packing for CS_2 Removal.

The equipment for treating the wash oil is shown in figure No. 3. From the feed tank the oil enters the continuous still through an orifice in the oil inlet nozzle under a constant head provided by the feed tank. Passing downward through the column it is heated by the steam coils in sections 3, 2 and 1 in succession. The vapours which are driven from it by the heating pass upwards through sections 3, 4 and 5 to the vapour outlet at the top. A small quantity of steam is admitted near the oil level in section 3 to assist in quickly removing the vapours from contact with the oil, and to control the temperature at the vapour outlet.

Sections 3, 4 and 5 act as a short fractionating column. After passing from the top of the column the vapours go to the worm condenser in which they are liquefied. The condensate flows to a separator which divides it into two parts, water and benzol.

Three hours per day of one man's time are required to check temperatures, etc., and to handle the benzol produced, which, without any rectification, is retailed as a fuel for automobiles and motor boats.

Facts Concerning the Type of Oil Used

Just one type of oil has been investigated. It is a straight distillate from "Pennsylvania Crude" and is known by the trade name of "No. 1 Pale Paraffin." It has the following properties:—Specific gravity, (by Westphal balance), at 60°F. 0.8831, at 66°F. 0.8790, at 72°F. 0.8740; freezing point 25°F., flash point 310°F.; viscosity 60°-70° Saybolt at 100°F.; mean molecular weight, 250; colour, pale yellow with a greenish fluorescence; sulphur content 0.25 per cent.

After passing through the system several times the colour changes to a dirty brown, but the same greenish fluorescence remains. There is no marked change in the specific gravity through use. The molecular weight, however, of conditioned oil after several months in the system increases to 300, and there is a small increase in its content of sulphur.

No investigations have been made at Halifax to determine the reasons for the change in colour, the increase in molecular weight, the difference in the behaviour of the oil towards benzol which is indicated by the change in the slope of the graphs in figure No. 4, or the increase in sulphur nor to determine whether the molecular weight of the conditioned oil varies between heat treatments.

About 800 Imperial gallons of oil are needed for continuous operation. To make up for losses due to leaks and stoppages, with consequent overflows, quantities of about 400 gallons each are put into the storage tank for renewed oil from time to time. During 1924, 2,000 gallons were added in this way. The price of the oil is roughly twenty-two cents per Imperial gallon. After each addition of fresh oil there is an increase in the capacity of the scrubbers to remove benzol from the gas which is readily apparent from the reduction of the luminosity of the flame from an open burner; there is also an increase in the capacity of the scrubbers to remove carbon-sulphur compounds, but there is insufficient evidence to indicate its relationship to the quantity of fresh oil which is added. This increased capacity is only evident during the first trip through the system after the addition.

Carbon-Sulphur Compounds Encountered

Before proceeding further, it may be well to assemble a few facts concerning the carbon-sulphur compounds found in coal gas and their presence in it.

After the removal of sulphuretted hydrogen[3] there remains in coal gas a quantity of sulphur in combination with carbon alone or with carbon and hydrogen. In general, five-sixths[4] of the total exists as carbon bisulphide. Of the rest, 60-70 per cent exists as thiophene, whilst it seems probable that a portion is accounted for by ethyl and methyl sulphides and mercaptans.[5]

The physical and chemical properties of carbon bisulphide can be readily learned from any good book of physical and chemical properties, but data concerning thiophene is not so readily obtainable and is therefore given here in considerable detail.

All benzol[6] (from coal) which has not been purified by freezing and filtering off the crystals with subsequent repeated washing by H_2SO_4 contains an interesting compound, C_4H_4S, named thiophene, which was discovered by V. Meyer. Thiophene resembles benzol very closely in chemical and physical properties, and for this reason cannot be separated from it except by repeated treatment with sulphuric acid which dissolves thiophene more readily than it does the hydro-carbon.

For the following physical constants of thiophene the writer is indebted to Professor H. J. Creighton, D.Sc., of

---

[3] It should be kept in mind that sulphuretted hydrogen is easily removed by passing the gas through iron oxide, (bog iron ore or manufactured equivalent), in suitable containers where the absence of oxygen permits reaction between the iron oxide and the sulphuretted hydrogen, which may be indicated thus,—

$$Fe_2 O_3 (nH_2O) + H_2S \longrightarrow Fe_2S_3 + H_2O$$

also, that the entire removal of all the sulphuretted hydrogen is simply a matter of adequate facilities.

There are two classes of organic compounds derived from hydrogen and sulphide[7], of which

Ethyl hydro-sulphide C_2H_5SH

Ethyl sulphide $(C_2H_5)_2S$

are samples. The organic hydro-sulphides or sulphydrates are usually called mercaptans on account of their property of combining readily with mercuric oxide to form crystalline compounds. No data on the physical properties of these compounds were collected.

For the purpose of this paper all carbon-sulphur compounds other than CS_2 will be considered as C_4H_4S. The error involved in this should be small because the sulphur in the compounds other than the two just mentioned is probably less than 5 per cent of the total and the physical properties of the compounds containing it not excessively different from those of C_4H_4S. Furthermore, the ratio of sulphur as CS_2 to sulphur other than as CS_2 will be assumed at 5 to 1 in conformity with what has been recorded at other places. It would be interesting and perhaps enlightening to know just how closely this generally accepted ratio applies to gas from Cape Breton coals. Because of lack of time and facilities at Halifax no tests were made and no information was available from any other source. Also, as a convenience in writing, and to indicate that it is difficult to remove from a city's gas supply, and to distinguish it from sulphur as H_2S which is easy to remove, the total sulphur as CS_2, C_4H_4S, etc., may be called "fixed sulphur."

Figure No. 3.—Apparatus for Treating Wash Oil.

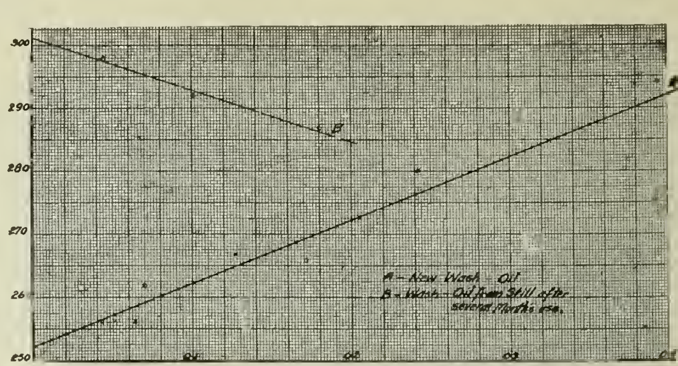

Figure No. 4.

Relation of Sulphur Quantities in Coal and Gas

Sufficient information has been collected for the inclined coal carbonizing retorts at the Halifax gas works to show that *on the average* there is a definite relation between the sulphur in the coal and the fixed sulphur in the gas. This relation is not apparent for individual or spot tests but is apparent where the average of daily tests for fixed sulphur in the gas is available over a period of, say, two weeks during which a coal of a known sulphur content was used. The data compiled in table No. 1 are representative, and plotted on figure No. 4a give points which lie close to a smooth curve.

The direct inference to be drawn from the data and curve is that the mean quantity of fixed sulphur to be found in the effluent gas from a given type of gas making equipment under ordinary operating conditions is a function of the quantity of sulphur present in the original coal rather than of the type of compound in which it exists there.

As a matter of general interest rather than of connection with this paper, the similar data and curves for horizontal retorts and continuous vertical retorts which were compiled for another purpose are given in tables Nos. 2 and 3 and figure No. 4a.

It seems scarcely necessary to point out that where high sulphur coals are to be used inclined slot retorts should not be considered, and that among the three types mentioned continuous vertical retorts are much preferable.

If it is acknowledged that the upper limit of fixed sulphur which can be allowed in the gas supplied by a public utility company or corporation is about 35 grains per hundred cubic feet it can be learned from figure No. 4a and the data in tables Nos. 1, 2 and 3 that the coal from which it is made must not contain more than 2 per cent of sulphur for continuous vertical retorts, 1.2 per cent for horizontal retorts and 1 per cent for inclined slot retorts.

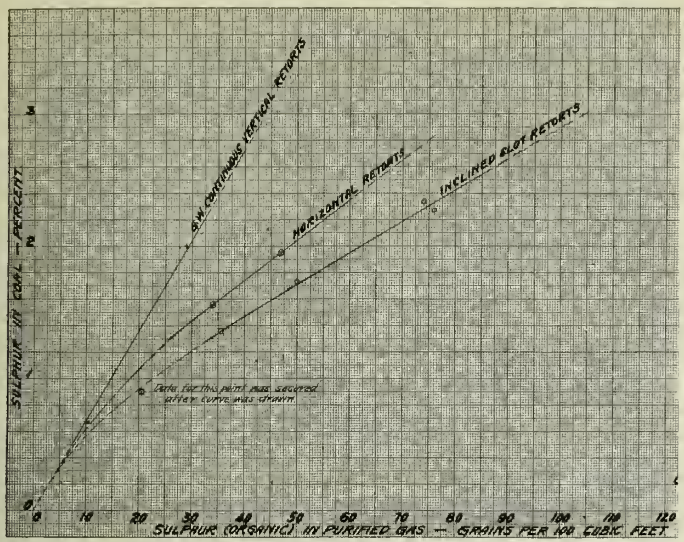

Figure No. 4a.

It may be taken as axiomatic that the ideal gas would contain no sulphur; but, as long as the original coal contains sulphur, there will be some sulphur in the finished gas from all coal gas works unless some means is used to remove it.

The cost of producing an ideal gas must be balanced against the economic good to accrue from it. Wherever coals containing less than 1 per cent of sulphur are available there seems to be little need or desire to attempt it. Wherever coals containing more than 1.8 per cent are the only ones available the production of a suitable gas becomes a problem such as has bothered the gas company at Halifax for years.

Reasons for Removing Some of the Fixed Sulphur

The products of combustion of a gas containing 45 grains of fixed sulphur per 100 cubic feet when burned in an unvented appliance may be objectionable to a sensitive olfactory organ.[8]

Halifax experience indicates that odour complaints traceable to the quality of the gas practically disappear when the sulphur is kept below 35 grains per 100 cubic feet.

Claims have been made at Halifax that the products of combustion of a gas containing 50 grains of fixed sulphur per 100 cubic feet are injurious to plants and stain silverware. These are hard to establish, but are generally believed.

At the instigation of public utility commissions and other regulatory bodies, investigations of the deleterious action of the products of combustion of fixed sulphur have been conducted for the purpose of establishing the maximum permissible quantity.

The Board of Commissioners of Public Utilities of Nova Scotia have placed the limit at 35 grains per 100 cubic feet after examining the available data on the subject and the rulings of other similar bodies. They have prescribed a penalty equivalent to a fine of $600 per month for every month in which 35 grains is exceeded three times or 45 grains is exceeded once.

Solutions of Sulphur in the Oil and the Gas

The solution of sulphur in the oil is very dilute. It will presently be shown that a concentration of 40 grains of sulphur in one molecular form per Imperial gallon of oil is a generous maximum. Expressed by ordinary mathematics, this means less than 40 parts in 60,000 or one part in 1,500. Expressed in the terms of physical chemistry, it means 0.00003 molecular per cent when the sulphur exists as CS_2 and the molecular weight of the oil is taken at 300.

The chief compounds in which the sulphur exists in the gas, CS_2 and C_4H_4S, are not active chemically, as is witnessed by their behaviour towards sulphuric acid. The oil possesses little chemical activity. These facts added to the diluteness of the solution seem to warrant treating the solution as closely approaching the ideal. Support for this is found from the experiments of Wilson, Wylde and Davis[9] on the lowering of the vapour pressure of benzol by an oil solute in which they found a deviation from the laws of the ideal solution of less than 2 per cent for a 10 per cent molecular concentration and infer that the deviation decreases as the solution becomes more dilute.

The concentration of the sulphur in the gas is also very dilute, and it is therefore inferred that the vapours of the carbon-sulphur compounds may be considered as obeying the perfect gas laws.

On the assumption that the perfect gas laws apply to the sulphur vapours in the gas and that the solution formed, when the oil absorbs carbon-sulphur compounds from the gas, is ideal, that is, the carbon-sulphur compounds are absorbed by the oil without any change in volume, temperature or composition of any of the constituents, the process can be examined and explained by the application of three fundamental laws of physical chemistry, Raoult's law of vapour pressure lowering, Dalton's law of partial pressures and the distribution law for dilute solution.

Raoult's law of vapour pressure lowering as it applies to this discussion may be stated thus:—

> "The partial pressure of any molecular species above an ideal solution is equal to its vapour pressure as a pure liquid at the same temperature and pressure multiplied by its molecular fraction in the solution."[10]

Dalton's law of partial pressure stated in words is,—[11]

> "In a mixture of gases, each gas exerts the same pressure as it would exert if it were alone present in the volume occupied by the mixture."

Because equal volumes of all gases at the same temperature and pressure contain the same number of molecules,[12] and the mean kinetic energies of the molecules of all gases are identical at the same temperature,[13] it follows that this law may be stated thus:—

$$p = \frac{PV}{100}$$

in which p is the partial pressure of constituent A in a mixture of gases, P is the total pressure in the container of the mixture and V is the percentage by volume of the constituent A in the mixture.

The distribution law for dilute solutions says,—[14]

> "When any molecular species in dilute solution is in distribution equilibrium between two immiscible solvents the ratio of its mole fractions in the two solvents is always equal to a constant whose value is characteristic of the species in question and of the two thermodynamic environments which respectively exist in the two solvents."

Figure No. 5.

Ratio of the Sulphur in the Gas to the Sulphur in the Oil at Equilibrium

The ratio of sulphur, (one molecular form), in grains per 100 cubic feet of gas, to the sulphur (same molecular form) in grains per Imperial gallon at equilibrium, which will be referred to in the future as R, may be found from the following equation which is developed on the laws of Raoult and Dalton:—

$$R = \frac{0.1808\, Pm_o}{(460 + T)\, D_o} \qquad (1)$$

In it, P = vapour pressure of volatile sulphur compound in question at temperature T.
m_o = mean molecular weight of the oil.
T = temperature in degrees Fahrenheit.
D_o = density of the oil at temperature T.

The specific gravity of the oil varies so slightly between the temperatures of 40° and 80°F. that the value of R will not be affected by more than one one-hundredth of one per cent if D_o is taken as constant at 8.85 pounds per Imperial gallon. Equation (1) then becomes,—

$$R = \frac{0.0204\, Pm_o}{(460 + T)} \qquad (2)$$

By substituting the corresponding values of T and P from the vapour pressure curve for CS_2 in figure No. 6 and giving several values to m_o the curves in figure No. 7 have been plotted to indicate how R for CS_2 varies with the temperature and the molecular weight of the oil, assuming that oils can be obtained of differing molecular weights but of the same density of 8.85 pounds per Imperial gallon.

Similarly, the curves for R referred to C_4H_4S as plotted in figure No. 8 have been developed.

Methods of Expressing the Efficiency of the Scrubbers

There are two methods of expressing the efficiency of the scrubbers; as the ratio of the sulphur transferred to the quantity originally present in the gas, and as the ratio of the sulphur transferred to the maximum quantity transferable under the governing conditions.

For the sake of convenience, the efficiency as determined by the first method may be called the efficiency of reduction, efficiency B or shortly E; and that by the second method as the efficiency of transfer. When the latter is determined by the capacity of the oil for absorbing sulphur from the gas it may be called efficiency A or shortly E_a; when it is determined by the capacity of the gas to give up sulphur to the oil it may be called efficiency C or shortly E_c.

The significance of thus defining the methods for determining the efficiencies of a scrubbing system is apparent from the following examples. When the scrubbing system is removing sulphur from a gas containing 50 grains sulphur per 100 cubic feet using an oil which contains 5 grains of sulphur per Imperial gallon at the rate of one gallon per hundred cubic feet flowing counter-current to the gas, and at equilibrium the sulphur in 100 cubic feet of gas is twice the quantity in one Imperial gallon of oil, the maximum quantity of sulphur which 100 cubic feet of gas can deliver is 50 minus 5 by 2 equals 40 grains; but the maximum quantity of sulphur which one gallon of oil in contact with the inlet can hold is 50 divided by 2 or 25 grains per Imperial gallon and the maximum quantity of sulphur which can be transferred to one gallon of oil is 25 minus 5 equals 20 grains. If this quantity, (20 grains), is transferred by the system the efficiency of transfer E_a is 1.00 or 100 per cent. At the same time the efficiency of reduction, E, will be 20 divided by 50, equals 0.40 or 40 per cent.

On the other hand, should equilibrium be reached when the sulphur in 100 cubic feet of gas is one-half the quantity in one Imperial gallon of oil, the maximum quantity of sulphur which one Imperial gallon of oil can hold in contact and in equilibrium with the inlet gas is 50 by 2 equals 100 grains; but the maximum quantity which the gas can deliver is 50 minus 5 by 0.5 equals 47.5 grains. If this quantity, (47.5 grains), is transferred by the system the efficiency of transfer E_c is 100 per cent, and it follows that the efficiency of reduction E_b is $\frac{47.5}{50}$, which equals 0.95 or 95 per cent.

Reference to the curves for R in figures Nos. 7 and 8 show that the equilibrium ratio of 2 corresponds to R for S as CS_2 when using an oil of molecular weight 250 at 51

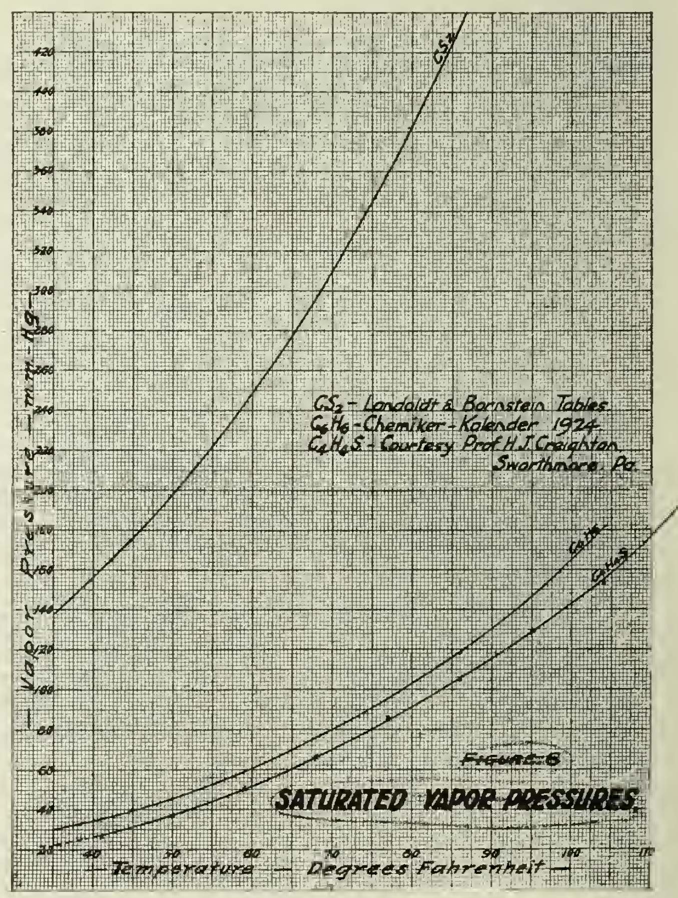

Figure No. 6.

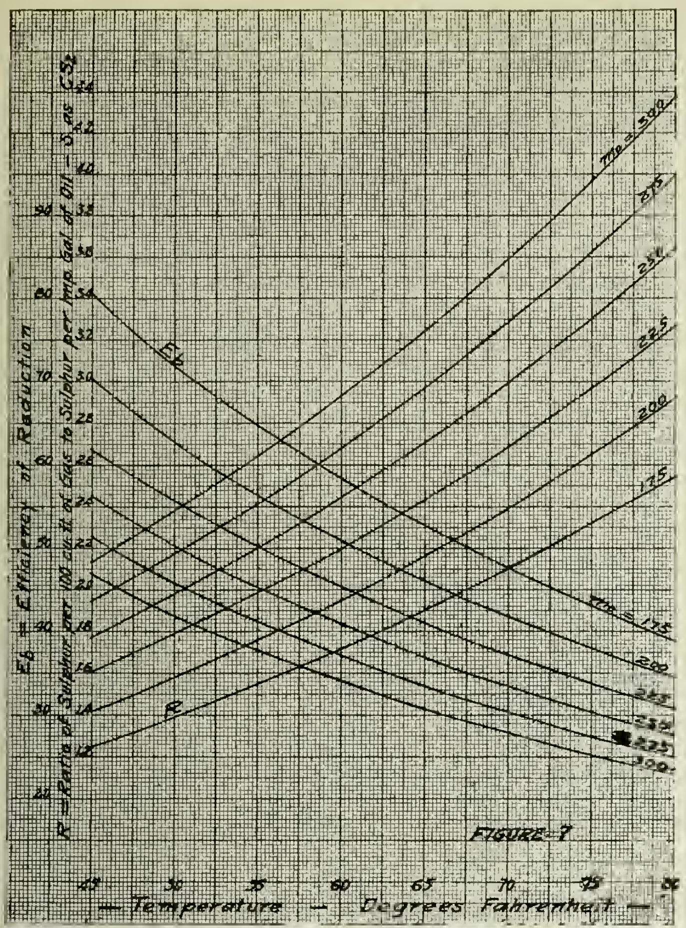

Figure No. 7.

degrees F. and that the ratio of 0.5 corresponds to R for S as C_4H_4S when using an oil of molecular weight 250 at 59½°F.

It follows that the transfer of CS_2 to the oil is limited by the capacity of the oil to accept it and that the transfer of C_4H_4S to the oil is limited by the capacity of the gas to give it up. Therefore, all symbols referring to sulphur and used in conjujnction with E^a will infer that the sulphur exists as CS_2, but used in conjunction with E_c will infer that the sulphur exists as C_4H_4S.

Maximum Efficiencies of Reduction

In figure No. 7 are curves showing how the efficiency of reduction (E_b) for a system, using oil which contains no CS_2 or other volatile sulphur compound at the rate of one Imperial gallon per hundred cubic feet of gas to remove sulphur from a gas which contains CS_2 only, will vary with the same variables that affect R. Points on these curves are found by letting G equal the quantity of sulphur in one hundred cubic feet of the original gas. Then $\frac{G}{R}$ is the maximum quantity of sulphur which can be transferred from one unit of gas to one unit of oil, and

$$E_b = \frac{G}{R} \div G = \frac{1}{R} \text{ or } \frac{100}{R} \text{ per cent} \qquad (3)$$

Similar curves have been prepared for thiophene and are shown in figure No. 8.

Further study of the method of developing the curves in figures Nos. 7 and 8 will show that the numerical value of the ratio R for sulphur as CS_2 is the minimum number of Imperial gallons of oil per 100 cubic feet of gas which is necessary to remove all the sulphur present in the gas at a given temperature; also, that for temperatures below 70°F. and with oils having mean molecular weights of less than 300 one gallon of oil is theoretically capable of dissolving more thiophene than 100 cubic feet of gas can carry; and that, other things being equal, the lower the temperature and the smaller the molecular weight of the oil the greater the quantity of sulphur which will be removed from the gas by a given quantity of oil.

Mathematical Treatment of the Action in the Scrubbers

The action which takes place in the scrubbers may be visualized as a two-film resistance to diffusion through two surface layers of molecular thickness under a driving potential which is caused by a difference in pressures or concentrations. It is analogous to the resistance of a copper wire to the flow of electric current caused by the difference between the electric potentials at two points in a wire.

Suppose that CS_2 vapour, for instance, is diffusing from a concentrated mixture with gas into a dilute solution inside a drop of oil suspended in the gaseous mixture, as in figure No. 5 (after Whitman and Keats).[15] Denoting the pressure of CS_2 in the gas by P and its pressure in the drop by p then the driving pressure of the diffusion is P-p. p is the equilibrium or back pressure of CS_2 above a solution of concentration X, the concentration being determined from the solubility of CS_2 in oil at the temperature of the drop, (i.e., P and p must be measured in the same units and referred to the same phase).

The general equation for absorption will be

$$W = \frac{\triangle p}{R_g + R_o} = k'A\ (P\text{-}p) = k'aV\ (P\text{-}p) = KV\ (P\text{-}p)$$

where W = units of material absorbed per minute.
$\triangle p$ = driving pressure in units of pressure or concentration.
R_g = resistance of gas layer to diffusion.
R_o = resistance of oil layer to diffusion.
k' = overall conductance of oil layer and gas layer per unit area.
a = area of films per unit of volume.

Then, $\frac{1}{R_g + R_o} = k'aV$

and A = total area of films.
P = units of pressure or concentration of CS_2 in gas.
p = units of pressure or concentration of CS_2 in gas which will be in equilibrium with the solution in the oil.
V = volume of apparatus in cubic feet.
K = coefficient of absorption in units of material absorbed per cubic feet per minute per unit difference of pressure or concentration equals $k'a$.

To adapt the general formula to this particular application of it, let
Q = quantity of gas scrubbed per minute in hundreds of cubic feet.
G = quantity of sulphur in inlet gas in grains per hundred cubic feet.
g = quantity of sulphur in outlet gas in grains per hundred cubic feet.

[15] Rates of Absorption and Heat Transfer Between Gases and Liquids, W. G. Whitman and J. L. Keats, Ind. and Eng. Chem., vol. 14, p. 186.

Then the quantity of sulphur transferred per minute will be $Q\ (G-g)$.

In addition, let

G_o = quantity of sulphur in the gas in grains per hundred cubic feet which will be in equilibrium with the sulphur in the inlet oil.

g_o = the same for the outlet oil.

Then $G - g_o$ = force available to drive sulphur from the gas into the oil at the inlet to the scrubbers.

And $g - G_o$ = force available to drive sulphur from the gas into the oil at the outlet of the scrubbers.

Because the driving potential of the interaction is directly determined by the distance from equilibrium and the rate at which energy or matter is transferred from gas to liquid or vice versa in any definite system decreases as equilibrium is approached, the use of the smaller logarithmic mean difference in concentration is advocated by Whitman and Keats when either one of the above terms is less than half of the other. The equation applicable to this case will then be

$$Q\,(G-g) = KV\,\frac{(G-g_o)-(g-G_o)}{\log_e \dfrac{G-g_o}{g-G_o}} \qquad (4)$$

in which K is the number of grains of sulphur transferred from the gas to the oil per minute per cubic foot of scrubbing volume per grain per hundred cubic feet difference between the mean concentration of the sulphur in the gas being scrubbed, and the concentration of the sulphur in a theoretical gas containing that quantity of sulphur which will be in equilibrium with the mean quantity of sulphur in the scrubbing oil.

Whitman and Keats claim that this treatment for liquid-gas reactions as summed up in equation (4) has been checked by experimental data from various types of laboratory and commercial equipment and has been found to apply in all cases studied.

Equation (4) indicates that the quantity of sulphur which will be transferred per minute is directly proportioned to the active scrubbing volume and the mean driving potential. These are functions of the equipment, i.e., are primarily decided by the design of the container in which the reaction takes place and by the selection of the oil.

Some Factors Influencing K

In the case of tower scrubbers the scrubbing volume is a constant quantity, and it is obvious that the coefficient K should be high when the material with which the towers are packed presents a large area of surface per unit of volume. At the time the towers at Halifax were erected the scrubbing volume was packed entirely with the wooden grids. Later some grids were removed and wooden excelsior substituted, (see figure No. 2), but there is nothing among the data collected to show that the effectiveness of the scrubbers was increased. It may be that they had excess capacity at the beginning and that the change in the filling simply served to increase something which was already large enough.

When the scrubbers were erected pale paraffin oil, as previously described, was recommended by the Imperial Oil Company for our purpose. It possessed the desirable factors of availability, comparatively low price, low volatility, fairly low freezing point and low viscosity. Some other oil of lower molecular weight might prove more suitable.

The most important variables of operation of the tower scrubbers are temperature, rate of flow of oil and gas velocity. Of these, temperature is the only one which affects the potential term. Any change in it will change the equilibrium pressure over the oil and therefore the driving potential. This is completely allowed for in the potential term and does not affect K, the specific coefficient per unit of potential.

The effect of temperature on K will be produced chiefly through its effect on the oil, by changing its viscosity and surface tension and thereby the resistance of the oil film to the transfer of the carbon-sulphur compounds. No laboratory tests were made at Halifax to determine how the viscosity varied with the temperature.

No means are available for controlling the temperature of the gas as it enters the scrubbers, but no abrupt changes are encountered. The pipe through which it flows after leaving the purifiers runs underground for over sixty feet and emerges just below the inlet to the oil scrubbers. In general, the temperature varies with the time of year from 40°F. in February to 75°F. in August. By the use of the cooling coils between the scrubbers, (figure No. 1), the average temperature of the oil can be kept within one or two degrees of that of the gas with maximum differences of about plus or minus 6 degrees.

The velocity of the gas past the liquid surface has shown the most marked effect on K in all cases studied by Whitman and Keats. High gas velocity exerts a brushing or tearing action on the surface of the film of oil, reducing its effective thickness and thus decreasing its resistance to diffusion, but the good to be obtained from high velocities must be weighed against the cost of obtaining it. At Halifax, no pressure was available to produce high velocities

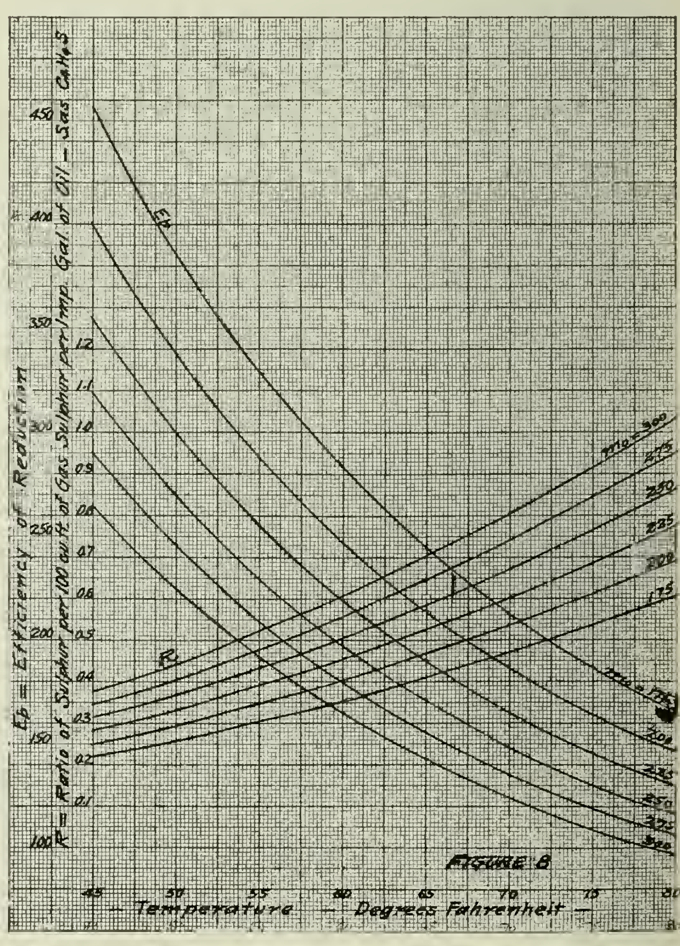

Figure No. 8.

and other considerations demanded that the pressure drop across the scrubbers be kept as near zero as possible. Actually, the velocity of the gas through the scrubbers is continually changing between a minimum of 160 cubic feet per minute or 13 cubic feet per minute per square foot of cross-sectional area, and 220 cubic feet per minute or 17 cubic feet per minute per square foot of cross-sectional area, with an average of about 180 cubic feet per minute or 14 cubic feet per minute per square foot of cross-sectional area.

Increases in the rate of flow of the oil will increase the area of contact of the oil, and therefore K, until the rate is reached which is necessary to keep the entire packing surface wet. Beyond this limit further increases will merely cause a thicker layer with relatively little increase in surface of contact.

After the scrubbers were first installed at Halifax the rate of flow of the oil was varied from 25 to 150 gallons per hour. The data obtained were very indefinite due to the effect on the results of other variables which could not be prevented from changing at the same time. Better results appeared to come when the rate of flow of the oil was 100-120 gallons per hour or about 10 gallons per 1,000 cubic feet of gas. This rate has been maintained since, with the exception of one test when the rate was raised to 150 gallons per hour. Unfortunately, other changes were made at another point in the system at the same time. The results of the increase were disappointing and the previous rate was again adopted. This is mentioned later in connection with the effect of the oil rate in the scrubbers to the efficiency of reduction (E_b).

Further Mathematical Treatment of Scrubbing Action

Pursuing the assumption that the solutions of sulphur in the gas and the oil are ideal, equation (4) may be changed to—

$$Q\,(G-g) = KV\,\frac{E_a\,(R-n)\,(G-Rg_1)}{R\,\log_e \dfrac{R-nE_a}{1-E_a}} \quad \dots\dots\dots (5)$$

or to,—

$$Q\,(G-g) = KV\,\frac{E_c\,(R-n)\,(G-Rg_1)}{n\,\log_e \dfrac{n\,(1-E_c)}{n-RE_c}} \quad \dots\dots\dots (6)$$

by using an elementary procedure, (in which the processes of simple algebra seem somewhat intricate because of the large number of symbols involved), to apply the laws of Raoult and Dalton. In these equations

n = the quantity of oil used in Imperial gallons per 100 cubic feet of gas.

g_1 = the initial quantity of sulphur in the oil in grains per Imperial gallon,

while the other symbols represent the quantities or ratios to which they have been assigned previously.

From the definitions of E_a and E_c and the conclusions drawn from figures Nos. 7 and 8 it is readily apparent that equation (5) applies to the transfer of CS_2 and (6) to the transfer of C_4H_4S.

By further algebraic simplification, the following equations may be evolved

$$Q = KV\,\frac{R-n}{n\,\log_e \dfrac{R-nE_a}{1-E_a}} \quad \dots\dots\dots\dots\dots\dots (7a)$$

$$Q = KV\,\frac{R-n}{n\,\log_e \dfrac{n\,(1-E_c)}{n-RE_c}} \quad \dots\dots\dots\dots\dots\dots (7b)$$

Equations (7a) and (7b) show clearly that K, E_a and E_c are entirely independent, theoretically, of the quantities of sulphur carried by either the gas or the oil; that K is a function of E_a or E_c whenever Q, V, R and n are constant, i.e., the same variables which affect K also affect E_a or E_c, and when E_a or E_c are constant K is a constant.

From the foregoing paragraphs, it seems clear that in a given system when Q, V, the efficiency of transfer, (E_c or E_a), and the temperature are constant, K will be a constant and therefore $G—g$ or the quantity of sulphur transferred from each 100 cubic feet of gas is directly proportional to the potential term. Granting this to be true, then in a system of three units in series through which the flow of oil is counter-current to that of the gas, the quantity of sulphur which is transferred in one unit is proportional to the mean driving potential in that unit and the quantity which is transferred by the system is proportional to the mean driving potential through the system. If the three units are identical in all respects the time of contact of the gas with the oil in all of them will be the same. Thus, when the driving potentials at the inlet to the system and outlet from the system are known it is possible to find the driving potentials at the inlets to the second and third units by using the exponential curve and its equation in figure No. 9. First locate the ordinates to the curve which correspond with the driving potentials at the inlet and outlet of the system. The abscissa between the ordinates of these two points may be considered to represent the time which it takes a unit quantity of gas to pass through the system. A third of it will represent the time for the passage of one unit of gas through each scrubber. The ordinates from the third points will represent the driving potentials at the inlets to scrubbers two and three. Knowing these and ($G—g$) for the system it is an easy matter to find the percentage of ($G—g$) and the percentage of the original sulphur in the gas which is transferred in each scrubber.

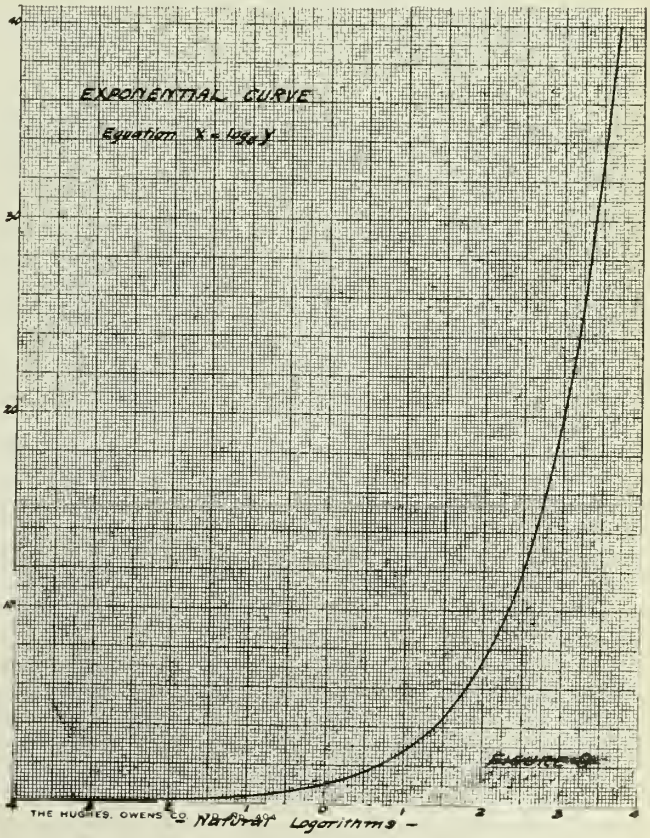

Figure No. 9.

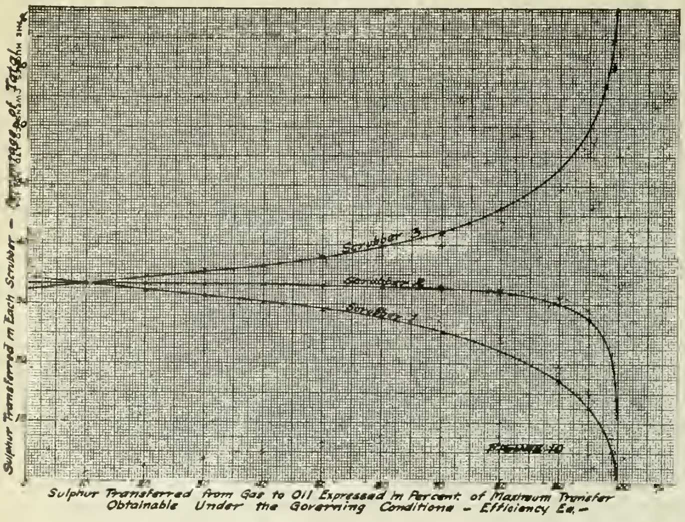

Figure No. 10.

Under the assumptions predicated, it may be shown that for sulphur as CS_2

$$G - g_o = (1 - E_a)\ (G - Rg_1) \quad \ldots\ldots (8)$$

$$g - G_o = (1 - \frac{n\,E_a}{R})\ (G - Rg_1) \quad \ldots\ldots (9)$$

$$G - g = n\,E_a\ (\frac{G}{R} - g_1) \quad \ldots\ldots (10)$$

$$E_b = \frac{n\,E_a\ (G - Rg_1)}{RG} \quad \ldots\ldots (11)$$

also for sulphur as C_4H_4S

$$G - g_o = (1 - \frac{RE_c}{n})\ (G - Rg_1) \quad \ldots\ldots (8a)$$

$$g - G_o = (1 - E_c)\ (G - Rg_1) \quad \ldots\ldots (9a)$$

$$G - g = E_c\ (G - Rg_1) \quad \ldots\ldots (10a)$$

$$E_b = E_c\ (1 - \frac{Rg_1}{G}) \quad \ldots\ldots (11a)$$

From the above equations it is apparent that when G, R, g_1 and n are constant, $G—g$ and E_b for the system and each scrubber will vary with E_a and E_c, as the case may be.

To illustrate, let G equal 50 grains sulphur as CS_2, g_1 equal 5, n equal 1, R equal 2 while E_a is varied from 0 to 99.75. This value of R, referred to figure No. 7, fixes the temperature at 46°F., if the molecular weight of the oil is 300. Using the properties of the exponential curve and the equations given above for sulphur as CS_2, sufficient points may now be calculated for plotting the curves shown in figures Nos. 10 and 11.

From these figures Nos. 10 and 11 it is apparent that, in the case of sulphur as CS_2, equilibrium between the sulphur in the gas and the sulphur in the oil is approached in the first scrubber and the greatest transfer occurs in the third scrubber of a series of three scrubbers, numbered in the direction of flow of the gas. The reason for this is that one gallon of oil per 100 cubic feet of gas is insufficient to absorb all the CS_2 which is present.

If, however, the sulphur occurs as thiophene and the same conditions maintain the value of R will be 0.39, (see figure No. 8), and the equations for sulphur as C_4H_4S should be applied. The calculations and curves derived from their use will show that equilibrium between the sulphur in the gas and the sulphur in the oil is approached in the third scrubber and that the greatest transfer will occur in the first scrubber, occurrences exactly opposite to those found for sulphur as CS_2. The reason for this is that one gallon of oil per 100 cubic feet of gas is more than sufficient to absorb all the C_4H_4S which can be present.

Solvent Effect of Absorbed Benzol

In practice, it is found that a considerable quantity of benzol is removed at the same time as the sulphur. It may amount to 0.02 Imperial gallons per hundred cubic feet of gas. The effect of its presence in the oil may be studied by assuming that it is a second solvent used in conjunction with the oil and that the distribution law for dilute solutions applies to the mixture of the two solvents. There may be some error in this because the benzol is miscible with the oil in all proportions, yet such a study will illuminate one way, perhaps the chief, in which it may affect the transfer.

The oil entering the system after treatment in the heating column, (figure No. 2), may bring with it a small quantity of benzol of which no notice need be taken for its effect is allowed for in the mean molecular weight of the treated oil when the latter is determined by the " freezing point " method. Of the benzol, which is picked up by the oil during its passage through the scrubbers and is removed during its passage through the heating column, none is present at the gas outlet oil inlet end of the scrubbers. At the gas-inlet-oil-outlet of the scrubbers this benzol will be present in the oil to the maximum extent.

As the benzol is removed from the gas and its quantity in the oil grows larger it is always in intimate contact with the oil. It is therefore probable that, assuming the application of the law, at all times the quantity of sulphur carried by the mixture is divided between the oil and the benzol in the proportion demanded by the law. At the same time the law demands that the pressure of the sulphur from each solution be proportional to the quantity of sulphur in the gas above it. The ratio of the sulphur in the gas to the sulphur in the oil at equilibrium is found by equation (1). This is a general equation applying to dilute solutions, therefore the value of R for CS_2 and benzol can be found by letting m equal 78 and D_o equal the density of benzol. The densities of benzol and oil are so nearly equal that R for CS_2 and benzol at a given temperature may be found with sufficient accuracy for this study, by taking R at the given temperature for CS_2 and oil from any curve in figure No. 7, multiplying it by 78 the molecular weight of benzol, and dividing the product by

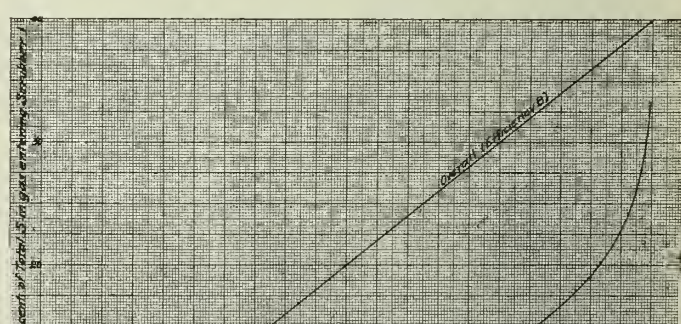

Figure No. 11.

the molecular weight of the oil marked on the curve. Similarly, the value of R at a given temperature for thiophene, (molecular weight 84), and benzol may be found from the curves in figure No. 8.

In the case where the sulphur exists as CS_2 it has been shown that equilibrium between the sulphur in the gas and the sulphur in the oil is approached as the oil reaches the gas inlet oil outlet end of the scrubbers. At this point the benzol is present in its greatest quantity. The sulphur as CS_2 in the mixture will be divided between the oil and the benzol in such a way as to have the back pressure from each proportional to the forward pressure of the sulphur as CS_2 carried by the gas entering the scrubbers. Thus, the capacity of the benzol to absorb sulphur as CS_2 can be added to the capacity of the oil and equation (10) can be used to determine the transfer of sulphur to each solvent by referring n, R and g, first to oil and then to benzol, the actual quantity of sulphur which the scrubbers can be expected to remove being the sum of the two values found for $G—g$.

In the case of the transfer of sulphur as C_4H_4S the effect of the presence of benzol in the oil must be studied in a different manner. It has been mentioned that equilibrium between the sulphur as C_4H_4S in the gas and sulphur as C_4H_4S in the oil is approached as the gas reaches the gas-outlet-oil-inlet of the scrubbers; also, that none of the quantity of benzol of which the effect is being studied is present at this point. In addition, it is readily seen that the gas which is leaving the system cannot have its content of sulphur as C_4H_4S reduced below that quantity which is necessary for equilibrium with the quantity of the same kind of sulphur which is carried by the entering oil. Therefore the quantity of sulphur as C_4H_4S which can be transferred to the oil-benzol mixture is limited. According to this distribution law for dilute solutions this quantity will be divided between the oil and the benzol and its back pressure will be less than that of the same quantity from its solution in oil alone. The mean potential difference through the scrubbers is thereby increased and a higher efficiency of transfer may be expected for sulphur as C_4H_4S than for sulphur as CS_2.

For the purpose of determining the quantity of sulphur as C_4H_4S which is transferred in the scrubbers, equation (10a) may be used

$$G - g = E_c\,(G - Rg_1)$$

When the driving potential at each end of the scrubbers must be known in order to find the quantities of sulphur which each unit may be expected to remove the following procedure may be used.

For sulphur as CS_2 it has been assumed that the oil and benzol may be treated as separate solvents which obey the laws of dilute solutions. The driving potential forcing sulphur from the gas into each of them must be the same at the gas-inlet-oil-outlet and an equation which gives its value for one of them is all that is needed. Equation (8) gives the value of the potential difference $G—g_o$ for oil. At the gas-inlet-oil-outlet the driving potential will be found from the equation

$$g - G_o = g - Rg_1$$

because G_o equals Rg_1. In this equation g must be found by subtracting from G the sum of the quantities of sulphur as CS_2 transferred to the oil and the benzol.

For the sulphur as C_4H_4S the effect of the presence of benzol has been translated into an increase in efficiency. Therefore the potential difference at the gas-outlet-oil-inlet may be found by the equation (9a). The potential difference at the gas-inlet-oil-outlet depends on the application of the distribution law, and may be found from the following equation

$$G - g_o = G - R\left\{\frac{R_1}{Rn_1 + R_1n}\right\}\left\{(n - E_cR)\,g_1 + E_cG)\right\}$$

in which

R = the ratio between the quantity of C_4H_4S per hundred cubic feet of gas and the quantity of C_4H_4S per Imperial gallon of oil at equilibrium.

R_1 = the same ratio for C_4H_4S and benzol.

n = the number of gallons of oil per hundred cubic feet of gas.

n_1 = the number of gallons of benzol per hundred cubic feet of gas.

It may be well to record here under the definitions of the above symbols that the quantity of sulphur as C_4H_4S in one gallon of the oil which opposes 100 cubic feet of gas will in future be termed g_2 and may be found from the equation,—

$$g_2 = \frac{R_1}{Rn_1 + R_1n}\,(ng_1 + G - g)$$

Application of Theory

There are a number of reasons for believing that the average results of the operation of the oil scrubbers will agree more closely with theoretical predictions than will the results of individual tests covering periods of hours.

To begin with, a number of the variables of operation are not under the control of the operator and others are but nominally so. Equations (5), (6), (7a) and (7b) together with equation (1) show that the quantity of sulphur transferred from one hundred cubic feet of gas to the oil in one minute is dependent on eleven different things, Q, K, V, E_a or E_c, P, m_o, T, D_o, n, G and g_1. In addition, the accompanying absorption of benzol adds another variable. At Halifax, Q is under no control; V and D_o may be considered as constants since the selection of the equipment and the oil; K is dependent on E_a or E_c; T controls P and influences K but is very hard to control itself; G is under no control; n cannot be kept constant because of the uncontrollable variations in Q; g_1 is determined by the treatment given to the oil between trips through the scrubbers; and m_o suffers changes the nature and extent of which are not known. Q varies in cycles covering three or four hours, depending upon the rate at which gas is being delivered from retorts, from a maximum just after a series of retorts has been freshly charged to a minimum when the next series is emptied. It also varies with the number of retorts charged per hour, etc. T varies with atmospheric conditions as the scrubbers are out of doors, from a low point in the early morning to a high point in the afternoon, the limiting temperatures depending upon the time of year. n is a composite rate found by dividing N Imperial gallons of oil per minute by Q hundreds of cubic feet of gas per minute. N can be kept constant by the use of the control valves, therefore n must vary inversely as Q. G varies from minute to minute and hour to hour with the conditions in the retorts in much the same way as Q.

Referees' sulphur tests which have been used almost exclusively for determining the concentration in the inlet and outlet gases give results which probably have errors of plus or minus 0.5 grains per hundred cubic feet.

Having in mind the information contained in the last two paragraphs it is suggested that actual average results which differ from the theoretical are to be expected and that differences as high as 15 to 20 per cent will not prove that the theory does not hold or needs a correction factor.

One way in which the application of the theory can be disproved is to show that the sulphur transferred from the gas to the oil does not retain the form it possessed in the gas. This will probably require a method combining physics and chemistry and exceptional accuracy of execution, for the change in the concentration of the sulphur in the oil while it passes through the scrubbers has been shown to be very small. The difficulty of locating less than 30 grains of CS_2 or C_4H_4S in 62,000 is not insurmountable, but it requires most careful work.

The best argument in favour of the theory is the way in which it can be used to interpret the results of operation.

The log sheet[16] for scrubbing units for the month of March 1924 indicates that on the eighth a change was made in the operation of the apparatus for treating the wash-oil between trips through the scrubbers which increased the production of benzol by about 30 gallons per day. From experience, it is known that such a change does not reach its full effect on the quantities of sulphur left in the treated oil until it has been maintained for several days and the oil has passed through the system several times. For this reason the oil which passed through the system on the tenth would be very similar to that which was in use previous to the ninth. Examining now the results of the parallel tests for total sulphur which were run on the gas at the inlets of scrubbers Nos. 1 and 2 it is seen that the first shows that the gas picked up 0.8 grains. The following tests show that as the benzol decreased due to troubles in the oil-heating column the efficiency "B" of number one scrubber decreased. This progression tends to prove that there is a relation between the quantity of benzol produced and the condition of the treated oil and between the benzol produced and the quantity of sulphur transferred from the gas to the oil.

Referring again to the tenth of the month, it is seen that the efficiency "B" of scrubber one is minus 2.5 per cent while the overall efficiency of the three scrubbers is plus 5.0 per cent, and the total fixed sulphur in the entering gas is 32.3 grains per 100 cubic feet. Such results would be expected if E_a equals 0.95, E_c equals 0.998 and an oil of molecular weight 300 containing 7 grains of sulphur in the form of CS_2 and 18 grains in the form of C_4H_4S is being used at the rate of 1.1 Imperial gallons per 100 cubic feet of gas to wash gas in which 5/6 of the surplus occurs as CS_2 and 1/6 as C_4H_4S when the temperature of both gas and oil is 50°F. and benzol is being simultaneously absorbed at the rate of 0.010 Imperial gallons per 100 cubic feet of gas. If the equations given in the theoretical discussion are properly applied to the foregoing data it will be found that for a gas originally containing 30 grains of fixed sulphur the efficiency of reduction for the first scrubber will be minus 2.7 per cent[17] and the overall efficiency 4.7 per cent. Such calculations and in addition those for a 60-grain gas were fully worked out for the original copy of these notes but must be left out here in order to keep this paper within reasonable bounds. Furthermore, sufficient values of E_b were calculated to permit the plotting of the lower curve in figure No. 12. About it are plotted the results, expressed as efficiencies "B," of the tests for total sulphur, made on the gas at the inlet and outlet of the series of scrubbers up to and including the first test on the tenth. It is notable that only one point is much above this line. For this one departure there is a reason, the addition of 400 gallons of new oil with consequent dilution of the volatile sulphur compounds in the wash oil on the same day.

The results of the examination of the empirical data according to theory coupled with the recorded results of operation as discussed in the last paragraph indicate rather definitely that for purposes such as this the sulphur in the gas must be considered to exist in at least two forms. It would be difficult to explain reasonably the negative transfer in scrubber one if the sulphur were considered to exist as CS_2 only.

The efficiencies of the scrubbers after the change in the operation of the heating column on the ninth are in general higher. To indicate, in a comparative manner at least, just how much the change affected the quantity of sulphur in the oil a second curve is shown in figure No. 12, which was located by the same method as the first after changing the quantity of benzol produced to 0.015 Imperial gallons, the quantity of thiophene sulphur in the wash oil to 10 grains and the quantity of carbon bisulphide sulphur to 4 grains. It passes through the points indicating the efficiencies shown by the individual tests made after the tenth. In many cases these efficiencies are not to be considered correct in themselves. They have been found, (or estimated), by using a value for the sulphur in the inlet gas, which was not obtained by test, but was assumed because it appears to fit in with the tests made on the gas at other points in the scrubbers coupled with the results of tests for sulphur made on the gas in the street mains. Where the quantity of sulphur in the inlet gas was falling over a period of days such efficiencies are

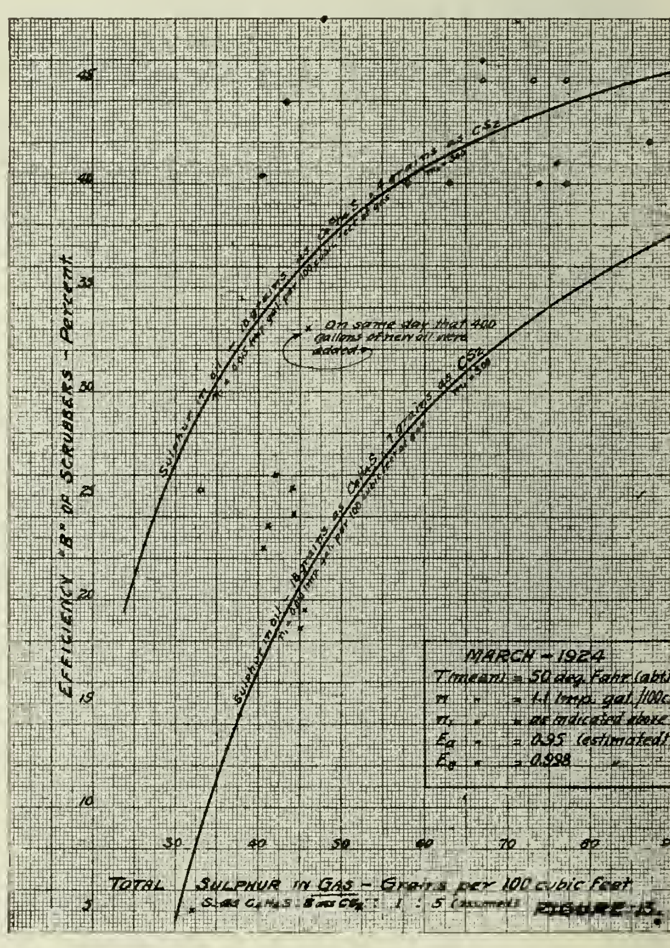

Figure No. 12.

(16) See table No. 4.

(17) In establishing this value it was assumed that E_c equals 0.90 because those factors which act to increase the positive transfer are then in the opposite direction.

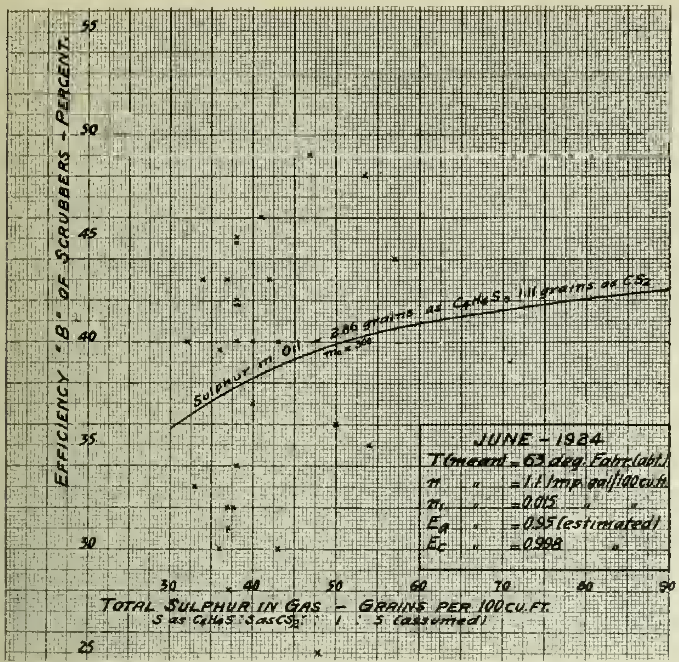

Figure No. 13.

probably low; where the quantity of sulphur in the inlet gas was rising over a period of days they are probably high, other things being equal.

The sulphur data on the curves indicate the extent of the reduction in the sulphur content of the treated oil which was accomplished by the unrecorded change in the operation of the heating column which resulted in the increased production of benzol. A reduction would be expected. The similarity between the properties of benzol and thiophene shows that it is scarcely possible to remove one from the oil without the other, and the comparison of the vapour pressure curves, (figure No. 6), indicates that the benzol will be completely removed before the thiophene, while the CS_2 will precede the benzol.

Considering the manner in which some of the efficiencies "*B*" were found, together with the number and variety of the notations under the heading "Remarks," it was felt that this study of the month's operation did little more than point to the heating column as a place where investigation might bring results.

Following this lead, during the months of April, May and June more attention was given to the treatment of the oil between trips through the scrubbers. The consequence was very pleasing when examined in the light of the previous inference that the mean results of the operation of the scrubbers will approximate more closely those predicted by the projected theory than any particular test. In figure No. 13 the daily values of efficiency "*B*" for the month of June are plotted against the corresponding quantities of sulphur in the inlet gas. The curve, which passes through the points, indicates in a general way average efficiency "*B*" for the month. (It might be argued that the curve could have many directions and still represent the average E_b, but laboratory accuracy was impossible and what has been evolved was considered next best.)

The change in the sulphur content of the oil indicated by the difference between the 18 grains as C_4H_4S and the 7 grains as CS_2 on the lower curve in figure No. 12 and the 2.86 grains as C_4H_4S and the 1.11 grains as CS_2 on the curve in figure No. 13 represents the result of maintaining a fairly close watch on the temperature at the vapour outlet of the heating column and of gradually reducing the rate at which the foul oil was permitted to enter the column.

The study of the relation of the efficiency "*B*" of the scrubbers to the operation of the heating column is summed up in figure No. 14, which shows graphically how the rate of flow of oil through the heating column influences the sulphur content of the oil, the quantity of benzol removed from the gas and the efficiency "*B*" of the scrubbers. It is important to remember the temperatures and rates in the upper part of the figure when studying the curves; also, that only the points where the "E_b" curve and the "benzol produced" curve cross the 175 Imperial gallons per hour ordinate have been fixed by actual mean results of operation. With the exception of these points, all the curves are perhaps more diagrammatic than correct. It was not found possible to keep everything else constant while the rate of flow of oil through the heating column was varied; therefore, the curves are built up from a mixture of data, experience and assumptions based on a theory which has not been proven to apply exactly but which has been very useful in explaining and directing.

In connection with the operation of the heating column there are two things to be considered, the removal of the sulphur from the oil and the production of a benzol product ready for immediate sale. A rate of flow of the oil through the heating column of 175 Imperial gallons per hour or less coupled with a temperature between 202° and 204°F. at the vapour outlet seems to serve both purposes fairly well. The condition of the oil has been described. The resulting benzol product is almost water white and 90 per cent of it will distill over at 212°F. Higher temperatures give the benzol product a yellow tinge and more odour. Lower temperatures, like higher rates, leave more sulphur in the oil and decrease the quantity of benzol made. There are insufficient data, however, for a diagram like figure No. 14 with temperature at the vapour outlet as the base.

From what has been written, it has perhaps become apparent that other things being equal the quantity of benzol produced is a rough indication of the efficiency with which the column removes the sulphur from the oil.

Influence of Oil Rate in Scrubbers on E_b

The logsheet for March shows that the rate of flow was increased from 110 to 115 Imperial gallons per hour to 150 to 160 Imperial gallons per hour on the twenty-eighth of March. At the same time the rate of flow of oil through the heating column was decreased and an increased production of benzol was obtained. Allowing the changes a day to make itself felt. The following data are

	Inlet Sulphur	Outlet Sulphur	E_b Per cent
March 30	40.5	27.9	41.1
" 31	43.4	24.5	43.5
April 1	42.	20.	52.
	46.	22.	52.

worthy of note because they show a decided increase in efficiency "*B*" over what had occurred previously. It is unfortunate that the two changes in the operation of the system were made at the same time, because the one to which the change is due in whole or greater part cannot be distinguished.

As to continue the increased rate would necessitate making some permanent and expensive changes in piping, etc., it was abandoned on April 2nd in favour of the old rate of 110 to 115 Imperial gallons per hour, but the slower rate was maintained through the column. Immediately the efficiency "*B*" became lower. This indicates that decreasing the oil flow through the scrubbers did decrease the efficiency "*B*."

The comparison of the equation for sulphur as CS_2

$$(G - g) = n\, E_a \left(\frac{G}{R} - g_1\right)$$

with the equation for sulphur as C_4H_4S

$$(G - g) = E_c\, (G - R\, g_1)$$

shows that an increase in the quantity of oil can have no effect on the quantity of sulphur as C_4H_4S which is transferred, because *n*, the quantity of oil per 100 cubic feet of gas, does not appear in the second equation at all. Whatever increase in the efficiency "*B*" comes from the increase in oil must be due to the transfer of additional CS_2. Theoretically, when an oil which has a molecular weight of 300 is being used to remove sulphur from a gas containing 50 grains under the conditions described in figure No. 16, (except that *T* equals 53°F.), it is only necessary to increase the rate of flow of oil to about 2 Imperial gallons per 100 cubic feet of gas in order to attain the 75 per cent reduction of the original sulphur in the oil which Mr. E. L. Hall claims is possible.[18] At Halifax, this rate in the scrubbers would mean 210 gallons per hour through the heating column, which is somewhat too large for good operation, (see figure No. 14).

As has been mentioned before, there is no proof that a higher rate of oil will not be advantageous at Halifax from the standpoint of the reduction of the sulphur compounds. On the other hand, the evidence that it will has all been given in the few paragraphs immediately preceding. There is no data for a discussion on its economy.

Influence of Temperature on E_b

When the efficiencies "*B*," as shown by a number of parallel tests made on the inlet and outlet gases at the scrubbers during April 1924, are arranged according to the time of day during which they were made they appear as follows:—

	Day Per Cent	Night Per Cent
	43.7	42.2
	50.2	47.0
	35.7	39.3
	44.4	48.5
	42.5	47.1
	38.5	42.1
Average......	42.5	44.4

These show that the mean efficiency "*B*" at night is about 2 per cent better than the mean efficiency during the day under the conditions maintaining at that time. This is what might be expected. It could be predicted by the projected theory as it is known that the mean temperature in the scrubbers during the night at the time of year is 3° to 4° lower than during the day. According to the theory it should be about 2 per cent, and the mean value as found above is 1.9 per cent.

What Becomes of the CS_2 and C_4H_4S Which Is Driven from the Oil ?

In August 1924, when the gas at the inlet to the scrubbers contained about 25 grains sulphur and the mean reduction accomplished by the scrubbers was about 5 grains, benzol was being made at the rate of about 25 gallons per day. A sample of this benzol was analyzed for sulphur and found to contain 0.98 per cent by weight. Assuming that 280,000 cubic feet of gas were washed and that the benzol weighs 8.8 pounds per gallon the total quantity of sulphur given up to the oil by the gas is 280,000 ÷ 100 × 5 = 14,000 grains, and the quantity of sulphur contained by the benzol is 8.8 × 7,000 × 0.0098 × 25 = 15,000 grains. These figures are sufficiently close to show that the sulphur removed from the gas will be found in the benzol under ordinary conditions.

Effect of the Process on the Heating Value of the Gas

On several days in January 1924, tests were made to determine the effect of the process on the heating value of the gas. As only one calorimeter, (Junkers type, manufactured by the McDonald Meter Company), was available, parallel tests could not be run. Two meters were employed, one connected to the test pipe leading to the gas main at the inlet to the scrubbers and one to the test pipe leading to the gas main at the outlet of the scrubbers. The procedure was to keep a meker burner going full blast at outlet of the free meter while the gas passing through the other was being tested. Tests were run alternately, first on the inlet gas and then on the outlet gas, with the following results:—

Average B.T.U.'s per Cubic Foot.

	Inlet	Outlet	Loss	Number of Tests
January 15	500	462	38	10
" 16	528	492	36	10
" 17	536	506	30	10
" 18	523	492	31	7

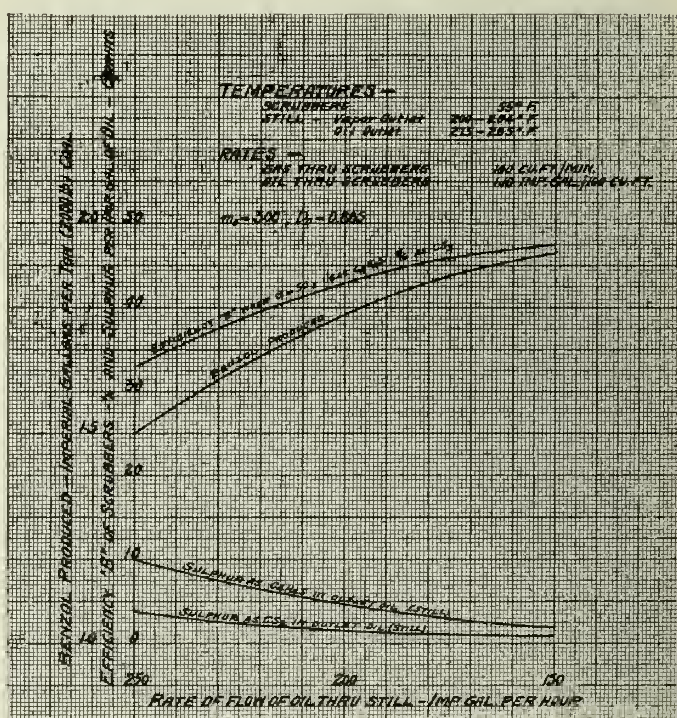

Figure No. 14.

(18) Proc., Amer. Gas Assoc., 1923, p. 1198.

Cost of the Process per Thousand Cubic Feet of Gas Washed

The cost of the operation of this system for a year may be seen from the following figures, which are based on the best average conditions obtained during the experimenting of 1924:—

	Total
Supervision, laboratory, etc.	$ 250.00
Labour, 730 hours at 40 cents	292.00
Steam, 3,504 M. lbs. at 60 cents	2,102.40
Water, 4,015 M. gals. at 12 cents	481.80
Oil, 2,000 gals. at 22 cents	440.00
Electric power, 12,000 kw. hr. at 1.5 cents	180.00
Repairs	50.00
Total operating cost per year	$3,796.20
Benzol credit, 10,950 gals. at 20 cents	2,190.00
Net operating cost	$1,606.20

On the assumption that the whole of the gas made during 1924, 96,000,000 cubic feet was washed, the costs per thousand cubic feet will be:—

Total operating cost	3.95 cents
Net operating cost	1.66 cents

Tests Used

For finding the quantity of sulphur carried by the gas the Referees' apparatus and the gravimetric method described in the Gas Chemists' Handbook of the American Gas Association was used throughout.

For finding the quantity of sulphur carried by the oil various methods were tried, with all of which it was extremely difficult to obtain check analyses on the same sample. Aspirating the products of combustion from a mixture of oil and benzol burned at a miniature burner, which admitted air under a slight pressure to the centre of the flame, through a 10 per cent solution of $NaOH$ with the subsequent gravimetric determination of sulphur as $BaSO_4$ was just as successful as the Parr sulphur bomb method. Neither gave checks which were within the limits of the change in the sulphur content of the oil due to the addition of sulphur from the gas. The oxygen bomb method employing a bomb having a capacity of 300 cubic centimetres and oxygen at 40 atmospheres was not available.

Conclusion

The records of the operation of the oil scrubbing equipment at Halifax show definitely that it removes carbon-sulphur compounds from the gas and that the efficiency of removal (E) fluctuates widely.

The reason for the fluctuating efficiency is obscured in the number of the variables which influence the transfer of sulphur from the gas to the oil, but it is thought that further investigation of the operation of the heating column, with the end in view of obtaining greater uniformity in the rate of flow of the oil through it and more uniform temperature conditions, will bring improvement. This study may indicate that its design should be changed or that it is too small.

The records also show that, for the rates of flow of oil used in scrubbers, the greatest transfer of sulphur always occurs in scrubber No. 3 and the least in scrubber No. 1, and that the gas on leaving scrubber No. 1 may contain more sulphur than when it entered, at times when the temperature conditions through the scrubbers cannot be blamed. The explanation lies in the existence of at least two volatile sulphur compounds in the gas which are soluble in the oil.

In general, the quantity of sulphur in the gas at the outlet of the scrubbers can be kept below the standard of 35 grains per hundred cubic feet, when the quantity of sulphur in the gas making coal is less than 1.5 per cent, if the mean temperature of the gas and the oil in the scrubbers is below 60°F., the mean rate of flow of the oil through the scrubbers is about 1.10 Imperial gallons per hundred cubic feet of gas, the mean temperatures of the heating column are 202°-204°F. at the vapour outlet and 275°-285°F. at the oil outlet, and the mean rate of flow of oil through the heating column is not greater than 175 Imperial gallons per hour.

Because higher gas velocities tend to produce greater efficiencies of transfer, it is probable that the scrubbing units will maintain a high efficiency of transfer on daily outputs up to 400,000 cubic feet per day. On the outputs higher than this their efficiency may be limited by the area of the packing.

The described theory, which has been very useful in predicting and explaining the occurrences in the scrubbing units and thereby of great assistance in the development of the process in use at Halifax, has been built on the mathematical treatment of absorption processes, advocated by Professor W. K. Lewis[19] and Professor W. G. Whitman,[20] in conjunction with the elementary laws of physical chemistry. This theory has not been proven to apply with the accuracy demanded by a chemist, but from the standpoint of the mechanical engineer its application is good. It explains the fluctuation of the efficiency (E_b) of the removal of the sulphur from the gas, the comparatively very large transfer of sulphur which occurs in scrubber No. 3, and the occasional negative transfers occurring in scrubber No. 1.

It has served to establish that in connection with the transfer of sulphur from the gas to the oil the sulphur must be considered as existing in at least two forms which for convenience and with reason have been considered as CS_2 and C_4H_4S; and that the efficiency of transfer, as defined, is the real measure of the efficiency of the scrubbing units; and that the efficiency of transfer is uniformly high, probably well over 90 per cent under ordinary conditions of operation; and that the solutions of the sulphur compounds in both the gas and the oil obey closely, if not exactly, the elementary laws for dilute solutions. By means of it, equations have been derived which can be used to predict what the performance of the process will be under given conditions.

Unless the values of R which have been used for both CS_2 and C_4H_4S are proven to be so much too high that values less than 0.80 can be assumed for the efficiencies of transfer, (E_a and E_c), it is probably apparent that there is nothing to be gained from recirculating the oil in any one or all the scrubbers.

The development of methods for the accurate and rapid determination of the small quantities of sulphur as CS_2 encountered in the gas, and the smaller quantities of sulphur which, as this study seems to prove, are carried by the oil from the heating column, appears to be a necessity before E_a, E_c, R and K can be evaluated, or much further progress can be made in building up a complete set of rules for the operation of the system at Halifax, and in finding the degree of accuracy with which the projected theory applies.

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI APRIL 1928 No. 4

Western General Professional Meeting

Vancouver, B.C., June 7th, 8th, and 9th, 1928.

The Work of the British Aeronautical Research Committee

The rush of modern business does not usually allow an engineer sufficient leisure to enable him to follow the activities in specialized branches of the profession other than his own. For this reason, few engineers, not directly connected with aeronautics, have followed the excellent work being done under the guidance of the Aeronautical Research Committee in England and similarly under the National Advisory Committee for Aeronautics in the United States of America.

In 1909, the British Government appointed an Advisory Committee for Aeronautics " for general advice on the scientific problems . . . in aerial navigation," and organized a branch of the National Physical Laboratory for the purpose of investigating aeronautical problems.

About this time an explanation of the duties of the committee given in the House of Commons stated " it is no part of the duty of the Advisory Committee for Aeronautics either to construct or to invent; its function is not to initiate, but to consider what is initiated elsewhere." The organization of this committee has passed through a number of changes, but its functions to-day under the name of the Aeronautical Research Committee are substantially the same as when it was originally formed.

The main committee deals with such a wide range of highly specialized subjects that it has become necessary to handle the details of the investigations through sub-committees, e.g., Accidents, Aerodynamics, Airships, Elasticity and Fatigue, Engines, Light Alloys, Seaplanes, etc.

These sub-committees in turn divide their work among panels. For instance, the Aerodynamics Sub-committee has panels for design, scale effect, stability and control and vortex investigations.

Funds are provided for the payment of fees and expenses of members of the committees and panels, and members are selected from the eminent men in the various subjects and from representatives of the various government departments concerned.

A great many of the wonderful advances that have been made, during recent years, in aeronautics, have been due to the fact that the government and the industry have had the valuable and considered opinion of a thoroughly reliable consultative body to aid its researches.

The effect of this has not been limited to aeronautics, but has extended into many other branches. For instance, the need for better aviation engines and the large amount of research carried out towards this end has led to great improvements in the general practice of internal combustion engineering, and similarly the need for new and reliable materials for aircraft construction has led to improvements in the metallurgy of light alloys for other purposes.

For these reasons, the annual technical reports of the committee since 1909 contain a wealth of valuable information upon many subjects. The annual report for the year 1925-26 is no exception. It is absolutely indispensable to the aeronautical engineer, and its perusal is recommended to all scientists and to any engineer who seeks up-to-date information.

Leaving aside for the present the subjects which have special application to aerodynamics only, it is interesting to see what items are dealt with in this volume that may be of interest to engineers in other branches. From the heading " Materials," the following items have been selected:—

(a) Report on the use of artificial sources of light as a substitute in the weathering of fabric.
(b) High frequency fatigue tests.
(c) The behaviour of single crystals of aluminum under static and repeated stresses.
(d) Some mechanical tests of cast bars of Alpax, (a commercial silicon-aluminum alloy with valuable properties.)
(e) Second report on study of mechanical properties of silicon-aluminum alloys.

Similarly, under the heading " Engines " we find amongst others:—

(a) Closed vessel explosions of mixtures of air and liquid fuel.
(b) Notes on detonation temperatures in closed vessel explosions.
(c) Reports on dopes and detonation.

An important conclusion has been reached that a sleeve valve engine offers great possibilities for aircraft purposes, due to the fact that the absence of the hot exhaust valves reduces the tendency to detonation and allows the use of a higher compression than a poppet valve engine of the same size.

It will at once be appreciated that these articles are of considerable interest and value to engineers in many other branches.

Research in aeronautics has provided a sound footing upon which the development of new ideas can proceed, and this result has been shown during the year of the report under review in a remarkable degree.

The autogyro, which was invented by a Spaniard, Senor De La Cierva, was the subject of a good deal of research both in the form of models and full scale aircraft. The theory of the autogyro was developed by a member of the staff of the Royal Aircraft Establishment, and, from the information so obtained, improved autogyros have been constructed for test purposes.

A novel experiment carried out under the guidance of the Aeronautical Research Committee was that of the Hill tailless light aeroplane, which was designed by Captain G. T. R. Hill as an independent research worker, aided by grants from the committee. Full scale experiments show that this type of aeroplane possesses several inherent advantages, and that its performance is not inferior to the normal type of aeroplane. The construction of a larger experimental aircraft of this type has been recommended.

Since the beginning of aviation there have been numberless accidents due to the fact that when an aircraft reached a stalled position, due to loss of forward speed, it also became uncontrollable, with the result that if there was insufficient height for the aeroplane to regain flying speed during its uncontrolled dive following the stall, an accident occurred.

The subject of control when the aeroplane is in a stalled position has become one of the utmost importance, and has occupied the attention of the Aeronautical Research Committee during a number of years.

In the report mentioned, a good deal of attention has been given to the use of combined aileron and leading edge slots invented by Mr. Handley Page, the well-known aircraft designer. This device is now being developed under the Aeronautical Research Committee, and it has great possibilities towards overcoming the defects of control under stalled conditions. As a result of these tests, a number of aircraft for general service are now being fitted with controls of this type.

During the past eighteen years a number of aeronautical laboratories have been equipped with wind tunnels, and these have naturally varied considerably in design and method of operation, with the result that it has now become necessary to investigate the standardization of the results obtained from the different wind tunnels. A series of standard models have been constructed and circulated to the different aeronautical laboratories for test, and the results so obtained are all being compared with a view to obtaining a proper basis for comparison between the different laboratories. This work naturally takes a considerable amount of time, and results obtained on the standard models at the National Physical Laboratory and at the Royal Aircraft Establishment in England are given in the report. The variation in the results obtained between these two establishments is itself sufficient to indicate the necessity for these comparisons, and the results obtained by the other laboratories will be awaited with considerable interest.

With the proposed construction of an airship mooring mast in Canada, attention will be directed to the reports upon airship accidents when at the mast, and the investigations upon the wind forces likely to come upon an airship under these conditions.

Close connection with the work of the Aeronautical Research Committee has resulted in a high scientific standard in the aeronautical engineering profession, and it is considered that too much credit cannot be given to the far-sighted governmental policy which provided for the inauguration and continuation of the work of this committee.

Meeting of Council

Meeting of March 13th, 1928

A meeting of Council was held at 8 o'clock p.m. on Tuesday, March 13th, 1928. Vice-President J. H. Hunter, M.E.I.C., in the Chair and nine other members of Council being present.

A resolution passed at the Annual General Meeting requesting further support from the National Research Council in connection with the investigations on the deterioration of concrete in alkali soils was considered, and the Secretary directed to transmit it to the National Research Council with a request for favourable consideration.

The Secretary presented a brief report of his visit to the Maritime provinces, and submitted a number of suggestions made at the branch meetings attended there.

In this connection, it was decided that when members' fees are compounded the branches to which the members concerned are attached should receive a pro rata payment annually from the interest on the money invested, the payments to be transferred should a member move, and to terminate on his death.

In view of the suggestion made by the Halifax Branch that the further publication of Transactions should not be undertaken unless on the general desire of the membership, it was decided to suspend the publication of Transactions until the matter has been fully discussed and considered at the Plenary Meeting of Council to be held this year.

The Budget for 1928 was considered and approved.

An opinion from the Council's legal adviser was presented, advising that in connection with proposals for the amendment, repeal or introduction of By-laws, it is proper for the Council of The Institute, or a body of twenty or more corporate members, to withdraw a proposal after discussion at the Annual Meeting, provided that no amendment thereto has been made by the Annual Meeting.

Having regard to this opinion, and in view of the suggestions at the Annual General Meeting and elsewhere regarding Council's proposal for the amendment of Section 35 of the By-laws referring to the proposed increase in Members' fees, it was unanimously resolved that Council's proposal for the amendment of this Section be withdrawn and not sent out to ballot.

Consideration was given to the operation of the new prize scheme and the financial arrangements necessary to put this into effect.

The chairmen of the following committees were appointed, with a request that they submit suggestions for the membership of their committees as soon as possible:—

Gzowski Medal Committee.
Leonard Medal Committee.
Plummer Medal Committee.
Engineering Education.

The following committees were reappointed with the same membership as last year, except as noted:—

Board of Examiners and Education.

Canadian National Committee of the International Electrotechnical Commission,—The name of B. S. McKenzie, M.E.I.C., was added to this committee and that of H. A. Dupre, M.E.I.C., omitted.

Committee on International Co-operation.

Honour Roll and War Trophies,—The name of Brig.-General G. E. McCuaig, A.M.E.I.C., added.

Committee on the Deterioration of Concrete in Alkali Soils.

Committee on Biographies,—Professor P. Gillespie, M.E.I.C., having resigned from the chairmanship of this Committee, it was decided to request

J. M. R. Fairbairn, M.E.I.C., to accept this office, Professor Gillespie being retained as a member of the Committee.

Two reinstatements were effected and four resignations accepted.

The following elections and transfers were effected:—

Elections.

Associate Members	2
Juniors	5
Students	14
Affiliates	3

Transfers.

Associate Members to Member	1
Junior to Associate Member	1
Student to Associate Member	1
Student to Junior	4

Seventeen applications for admission and transfer were scrutinized and classified for the ballot returnable April 20th, 1928.

The Council rose at 11.45 o'clock p.m.

ELECTIONS AND TRANSFERS

At the Meeting of Council held on March 13th, the following elections and transfers were effected:—

Associate Members

ALLCHURCH, Harry, checking details, Montreal South Shore Bridge, with Dom. Bridge Co., Montreal.

KARN, Herbert Christopher, B.A.Sc., (Univ. of Toronto), elect'l, mech'l and general commercial engrg., engrg. dept., Can. Industries, Ltd., Montreal.

Juniors

ANDERSON, Viggo, B.Sc., (Royal Tech. College, Copenhagen), structural dftsman, Dom. Bridge Co., Montreal.

BECKER, Fred., B.A.Sc., (Univ. of Toronto), sales engr., C.G.E. Co., Winnipeg, Man.

DUBOIS, Marcel, M.Sc., (Mass. Institute of Technology), hydraulic dept., Dom. Engrg. Works, Montreal.

DUNLOP, Ronald William, B.A.Sc., (Univ. of Toronto), dftsman, Imp. Oil Refineries, Ltd., Calgary, Alta.

LAZENBY, Thomas William, ch. dftsman, E. Leonard & Sons, Ltd., London, Ont.

Affiliates

BANKS, Osborne Henry, teacher, London pub. schools, i/c constrn. work of 1st Signal Batt., London, Ont.

HURST, William, pres., Hurst Engrg. & Constrn. Co., Ltd., Winnipeg, Man.

SAUNDERS, Clare Britton, asst. city engr., Sault Ste. Marie, Ont.

Transferred from the class of Associate Member to that of Member

DEY, Victor Albert George, div. engr., C.P.R., Toronto terminals div., Toronto, Ont.

Transferred from the class of Junior to that of Associate Member

HOPPER, Garnet Henry, B.A.Sc., (Univ. of Toronto), heating engr., Taylor Forbes Co., Ltd., Toronto, Ont.

THOMPSON, Howard Grant, B.A.Sc., (Univ. of Toronto), dept. head on design, installation, service and sale of mechanical stokers, etc., with Affiliated Engrg. Co., Montreal.

Transferred from the class of Student to that of Associate Member

MORRISSETTE, Gordon Joseph, B.Sc., (McGill Univ.), mech. supt., Abitibi Power & Paper Co., Iroquois Falls, Ont.

Transferred from the class of Student to that of Junior

HINCHLIFFE, Joseph Edward, B.Sc., (McGill Univ.), dftsman with Can. Bridge Co., Walkerville, Ont.

LLOYD, David Stevenson, B.A.Sc., (Univ. of Toronto), welding engr. in engrg. service dept., Dom. Oxygen Co., Ltd., Toronto, Ont.

RIDDELL, William Forest, B.Sc., (Univ. of Man.), designing and estimating, Dom. Bridge Co., Winnipeg, Man.

ROWAT, G. H., B.A.Sc., (Univ. of Toronto), sales engr., Can. SKF Co., Toronto, Ont.

Recent Additions to the Library

Proceedings, Transactions, etc.

Presented by the Societies:

The American Society of Mechanical Engineers: Membership List, 1928.

Presented by McGraw-Hill Book Company:

Pyrometry, by W. P. Wood and J. M. Cork.

Highway Materials, by E. E. Bauer.

The Western

General Professional Meeting

WILL BE HELD AT

VANCOUVER, B.C.

JUNE 7th, 8th, and 9th, 1928

Address of His Excellency Lord Willingdon

Delivered at the Annual Dinner of The Engineering Institute of Canada, at the Windsor Hotel, Montreal, February 15th, 1928

" Mr. President and Gentlemen:—

" May I thank you, sir, very sincerely for the kind expressions to which you have given voice in introducing my name to this distinguished gathering, a gathering which, I understand from you, represents an Institute of very large membership. I assure you, it was quite unnecessary to tell me that your members had a great feeling of loyalty to His Majesty the King and a great love for the British Empire. I feel, wherever I am in Canada, in whatever public gathering or assembly, that we are all fellow-citizens of the greatest Empire the world has ever known. But, gentlemen, I must admit to-night that I have discovered, during my short experience as Governor General of Canada, that I am often invited to these very pleasant and interesting gatherings of professional men in various parts of this country and that I am always expected to make a speech, and I always have the uncomfortable feeling when I rise to make that speech that my audience knows a great deal more of the subject about which I am supposed to speak than I can possibly know myself. That is my difficulty this evening.

" You gentlemen are all engineering experts. I really think that your profession is very disturbing to the peaceful life of the people of the world, from the fact that you are always introducing new appliances, new schemes and new inventions which are making life more rapid, more active and more hectic than it has ever been before. I look back,—yes, I am old enough to look back,—on those days, years ago, when the only form of conveyance, when you lived in the country, was a horse and carriage, and when anybody who lived more than twenty-five miles away from you could not possibly be called a near neighbour. Now, owing to your engineering science, there is no distance which can possibly prevent these neighbourly attentions; people rush at you in their Rolls Royces and their Ford cars; they descend upon you from the sky; you have but little chance for a peaceful moment in your family life.

" This state of things is very largely due to you and your confreres, but I do not think that I, individually, should put the entire blame upon the engineering profession for the many activities which I have had generally in my public life, during which I have been whirled about doing public service in all parts of the British Empire.

THE RT. HON. VISCOUNT WILLINGDON,
G.B.E., G.C.S.I., G.C.M.G., G.C.I.E., HON.M.E.I.C.,
GOVERNOR GENERAL OF CANADA.

" Gentlemen, may I now come to some slightly more serious matters? It has always seemed to me, in my life, that the engineers stand very much in the same position in relation to their country as a doctor to his patients, because in every country where the engineer's work is carried on you make that country more healthy, more prosperous, more happy and more liveable in every way. Think how water works and drainage systems in your great cities have made life much more healthy for the people who live in those cities. Consider your railways; I think it is perfectly true that if it had not been for these great railways which run from the eastern to the western limits of this great continent, there would have been very little chance of the successful issue of Confederation in this country, because the railways have brought the people of this country together in a way which would otherwise have been quite impossible. Consider your roads; consider those great harbours which have brought such prosperity to this country; consider your forests, for, after all, it is the engineers who have to develop those forests,—and perhaps I might just say here what has come into my mind, that when I was in the Presidency of Madras, India, and we were anxious to develop the great forests in that country, it was to Canada we had to come for a forest engineer and a lumbering engineer, who did great service for us in that far-distant part of the British Empire. Again, consider your mines, which are in only the first stages of development at the present time. It is the mining engineer who has developed the great prosperity of Canada in that particular respect.

" Then let us consider the electrical engineers, who, by their hydro-electric schemes and by their achievements in radio work, have made life for the people far more happy, far more cheery and far better in every way. That, I think, is very largely due to the engineering profession, and upon that I congratulate the engineering profession very warmly indeed.

"May I, for a moment, take you over to a country which I know very well, and one in which I lived for a good many years,—India. There, again,—and I speak rather from a more practical point of view with regard to India, because while I was there I was the executive head of the Public Works Department, and gratefully remember the wonderful services performed by the engineers in that Public Works Department in that particular province of Madras,—there, again, it was exactly the same thing; if you go to India, you will see a similar development of railways, harbours, roads and forests,—all accomplished by the engineering profession. But there is one matter in connection with India for which we all feel particularly grateful to the engineering profession,—and I am sure the Indian people feel this also,—and that is the matter of irrigation.

"You all know, of course, that India is a very dry country, with a very sparse rainfall, and that famine in the olden days took a tremendous toll of the population. I can assure you of this, that in all parts of that country now, through the skill of the engineers, literally millions of acres are now under control, through great irrigation schemes which have largely eliminated all of the troubles we formerly had in bringing down food supplies and resources to an area which was dried up owing to lack of rain.

"I have a very personal recollection with regard to my executive authority as head of the Public Works Department in the Madras Presidency. On more than one occasion when I went down to open a great water scheme, I really wore borrowed feathers, because I was always the fellow who was in the picture and had all the credit for what the engineers had done. I can remember on one particular occasion making a visit to an area at which there was a great irrigation scheme which it had taken five or six years to complete and which was to irrigate eight hundred thousand acres of land in a very dry area. All of the agricultural people in this area came to the particular rendezvous where the works were. They crowded in there by tens of thousands to see the 'Great Man,'—not the engineer,—pull the lever to lift up the shutter to let the stream of water flow down the canal, and when I did the necessary deed and pulled down the lever, the cries of all those tens of thousands of uneducated people went up,—not to Heaven,—but to Lord Willingdon, as being a sort of magician who had produced this amazing result of sending down the water which was to make them happy and safe from famine for all time. And I have a great feeling of gratitude to those engineers in Madras who accepted that situation with a smile, having themselves gone through all the wear and tear, and I can assure you that in that climate building a great irrigation dam is not a very comfortable thing. I hope you will be pleased to hear that we did recognize the excellent services these men had given us and gave them their proper reward.

"Now, gentlemen, I have but one more word to add, and it is this: Since I have lived in this country, I have had very many opportunities of observing and inspecting great engineering works which have been constructed and completed in this country, and I notice that many of them have been financed by, and much of the engineering work has been done by, those who have come from outside countries. This may be unavoidable in a young country such as this, but I sincerely hope that before many years have passed Canada will stand on her own feet, and that all of these vast engineering works, of whatever nature they may be, will be either financed by Canada or within the British Empire, and that the engineering profession of Canada may be given ample opportunity of developing all these great engineering works, in the best interests of their own people and of their own country and their own nation."

OBITUARIES

James White, M.E.I.C.

In the death of James White, M.E.I.C., which occurred at his home, 450 Wilbrod Street, Ottawa, Ont., on February 26th, 1928, Canada has lost a prominent government official and an outstanding public servant, and The Institute one who for many years took an active interest in its affairs. Although enjoying but indifferent health for some years past, he had continued active in his official duties almost to the last, and his death was sudden and unexpected.

The late Mr. White was born at Ingersoll, Ontario, on February 3rd, 1863. He received his early education at Atkin's Private School, Ingersoll, Ingersoll Public School and the Ingersoll Collegiate Institute, afterwards proceeding to the Royal Military College, Kingston, from which he graduated in 1883. In 1884 he joined the Geological Survey of Canada as assistant topographer, and in this capacity carried out surveys in the Rocky mountains and in various

JAMES WHITE, M.E.I.C.

sections of Ontario and Quebec. The ability and energy he displayed in this early work won him well-merited recognition, and in 1894 he was appointed geographer and chief draughtsman of the Geological Survey, a position he resigned in 1899 to become chief geographer of the Department of the Interior. In this capacity, he was actively identified with the work of the Alaskan Boundary Commission, and in 1906 conducted an investigation of rapid trans-Atlantic steamship service, (All-Red Line). In 1909, he was appointed secretary of the Commission of Conservation, of which body he later, in 1913, became assistant to the chairman and deputy head. While occupying this position, he was responsible for the publication, as reports of the Commission, of numerous works dealing with the natural resources of the Dominion. On the abolition of the Commission of Conservation, in 1922, he was appointed technical adviser to the Minister of Justice, a post that he held at the time of his death.

While serving in this capacity, he assisted counsel for the Dominion in the preparation of the British Case, and at the hearing of oral argument in 1925 before the British-American Pecuniary Claims Arbitrar Tribunal at Washington, D.C., in the claim presented by Great Britain on behalf of the Cayuga Nation of Indians against the United States Government. He was also entrusted with the preparation of the map evidence and other duties in connection with the Labrador boundary dispute between Canada and Newfoundland and assisted counsel at the hearing of this case before the Judicial Committee of His Majesty's Privy Council in London in 1926.

In addition to his departmental appointments, he had been since 1898 member of the Geographic Board of Canada and was elected chairman of that body in 1927. He had also served as chairman, since its inception in 1917, of the Advisory Board on Wild Life Protection, (Canada).

Mr. White's contributions to the technical literature of Canadian geography are many and important. He was the editor of the Canadian sections of numerous geographies and geographical works, particularly those published in Great Britain and the United States. He was responsible for the publication of an eight-sheet map of Canada, on a scale of 35 miles to one inch. He was the author of "Altitudes in Canada," (1901); "Dictionary of Altitudes in Canada," (1903); and of the revised editions of both these works, (1915-16); "Place-Names in Quebec," (1910); "Place-Names, Northern Canada," (1910); "Place-Names, Thousand Islands," (1910); "Boundaries and Treaties," (1913). He was also author of "Atlas of Canada," (1906), a work which he regarded as his most important technical contribution. This important work was revised in 1915 by J. E. Chalifour, his successor in the office of chief geographer, and secured jointly for its co-authors the Roquette gold medal of the Geographical Society of France.

A devoted and tireless worker, Mr. White was actively connected with numerous institutions, to the interests of which he devoted a great deal of his time. His first connection with The Institute was in the year 1888, when he was elected an Associate of the Canadian Society of Civil Engineers. The following year he was transferred to the grade of Associate Member, but in January 1891 resigned from the Society and was subsequently re-elected a Member on April 19th, 1906. He was made a Life Member on March 25th, 1925, and served on the Council during the years 1917 to 1919 inclusive. He was a Fellow of the Royal Geographical Society; Fellow of the Royal Society of Canada; and member Champlain Society. He served as vice-president, Sections C and E, of the British Association for the Advancement of Science in 1924, and was president, Section 4, of the Royal Society of Canada, 1924.

He was a member of the Royal Military College Club and of the Authors' Club, (London).

Mr. White's forty-four years of meritorious service with the Canadian government are an unbroken record of valuable and devoted work of a practical and scientific nature. His passing is a national loss.

Francis Ashley Hibbard, M.E.I.C.

The death of Francis Ashley Hibbard, M.E.I.C., which occurred at Sherbrooke, Que., on February 28th, 1928, has removed one whose associations with The Institute dates back to the year of the establishment of the Canadian Society of Civil Engineers.

The late Mr. Hibbard was born at Montreal, Que., on January 23rd, 1853. He commenced work at his chosen profession at an early age, when, in July 1871, he occupied the junior positions of chainman, rodman and draughtsman on the Northern Colonization Railway and later on the Montreal and City of Ottawa Junction Railway. In 1874 he was appointed to the position of assistant engineer on construction, Montreal, Portland and Boston Railway and the following year resident engineer in charge of grading of road from Stanbridge to Frelighsburg. The next year he was engaged as engineer-in-charge and transitman on surveys of the then proposed railway line from St. Jerome to Ste. Agathe, in the province of Quebec, making plans, profiles and estimates on this work. He returned to the Montreal, Portland and Boston Railway in 1877 as resident engineer and superintendent of construction. Upon completion of this work, he was engaged on many important works of railway construction and location, such as the Pontiac Pacific Railway system and the Montreal and Western Railway, now parts of the Canadian Pacific Railway system, also as chief engineer of the Chastiquay and Northern Railway, now part of the Canadian National Railways. In 1885, Mr. Hibbard was appointed locating engineer, and later engineer in charge of construction, of the

FRANCIS ASHLEY HIBBARD, M.E.I.C.

Alexandria bridge over the Ottawa river between Ottawa and Hull. Later he was offered and accepted several responsible positions on location and construction work for several lines in the United States, but returned to Canada to become assistant district engineer for the Northern Transcontinental Railway.

For several years failing health had compelled him to relinquish his active work, and he had resided during his retirement in Sherbrooke, Que.

Mr. Hibbard joined The Institute as a Member on June 13th, 1887, and was made a Life Member on September 27th, 1921.

Arthur Willard Wilbur, A.M.E.I.C.

Arthur Willard Wilbur, A.M.E.I.C., assistant engineer in the Saint John office of the Department of Public Works of Canada, died at the Saint John Infirmary on Thursday, February 23rd, 1928.

The late Mr. Wilbur was born at Dorchester, N.B., on March 5th, 1883, receiving his early education at the high school at Dorchester and in 1901 he entered the University of New Brunswick, graduating with the degree of B.A.I. in 1905. Shortly after graduation he became attached to the staff of the maintenance department of the Intercolonial Railway and in August of the same year he received the appointment of assistant engineer in the Department of Public Works of Canada with offices at Chatham, N.B. In 1921, when the Saint John and Chatham districts of the Public Works Department were combined, Mr. Wilbur was transferred to the headquarters in Saint John. His work with the department took him over the greater part of the province where his kindly and obliging disposition made for him many friends by whom he will be greatly missed.

Mr. Wilbur joined The Institute in 1921 when he was elected an Associate Member on March 22nd of that year. He was also a member of the Association of Professional Engineers of the Province of New Brunswick.

Gordon Wilson Brown, S.E.I.C.

Deep regret is expressed at the untimely death of Gordon Wilson Brown, S.E.I.C., which occurred at Peterborough, Ont., on February 28th, 1928, as a result of an electric shock received while engaged in the test department of the Canadian General Electric Company. At the time of his death he was taking the students' course with the company.

The late Mr. Brown was born at Falmouth, N.S., on November 15th, 1905, and completed his junior matriculation in 1922 and graduated from Nova Scotia Technical College with the degree of B.Sc. in 1927. During the summers of his university course he was engaged on surveying, first with the Highway Department of the province of Nova Scotia and later with the Avon River Power Company. After going to Peterborough he became interested in the activities of The Institute and was admitted as Student on January 20th of this year.

PERSONALS

G. C. Reid, A.M.E.I.C., of Halifax, N.S., is at present at The Pas, Man., in connection with the Flin Flon branch of the Canadian National Railways.

J. S. Bryant, S.E.I.C., is located at Aldermac, Que., with the Towagmac Exploration Company. Mr. Bryant graduated from McGill University with the degree of B.Sc. in 1927.

M. Nathanson, S.E.I.C., has been appointed junior engineer with the Radiore Company of Canada and is located at Rouyn, Que. Mr. Nathanson graduated from McGill University in 1926 with the degree of B.Sc.

Maurice Polet, A.M.E.I.C., has been appointed Consul for Belgium in Edmonton, Alta., with jurisdiction over the province of Alberta. Mr. Polet is a native of Belgium, and received his education at the University of Louvain.

M. J. Spratt, A.M.E.I.C., who until recently has been with the C. D. Howe and Company, Port Arthur, Ont., is now on the staff of the construction department of the Saskatchewan Pool Elevators, Limited, Regina, Sask. Mr. Spratt graduated from McGill University in 1922.

W. J. Bishop, A.M.E.I.C., is located at The Pas, Man., on Residency No. 3 of the Flin Flon branch of the Canadian National Railways. Mr. Bishop was for a number of years with the National Transcontinental Railway and later with the Temiskaming and Northern Ontario Railway.

D. C. Macpherson, S.E.I.C., has been transferred by the Dominion Bridge Company, Limited, from the new construction of the Chateau Laurier Hotel in Ottawa to the field staff of the company engaged on the Royal York Hotel in Toronto. Mr. Macpherson graduated from Queen's University with the degree of B.Sc. in 1924.

D. Newton Culver, S.E.I.C., who graduated from Queen's University last year, is with the Bell Telephone Company of Canada, transmission division of engineering department, at Montreal. Mr. Culver spent one summer of his university course with the Bell Telephone Company and the summers of 1925 and 1926 with the Hydro-Electric Power Commission of Ontario.

Lt.-Col. K. M. Perry, A.M.E.I.C., resigned from the permanent force of the Canadian Militia on January 1st, 1928, and has resumed engineering practice with headquarters in Montreal. Col. Perry is a graduate of McGill University, from which he received the degree of B.A. in 1906 and B.Sc. in electrical engineering in 1908. He was formerly G.S.O.1, Military District No. 4, at Montreal.

J. T. Watson, A.M.E.I.C., formerly chief engineer, light and power department, city of Lethbridge, Alta., is now with the East Kootenay Power Company at Coleman, Alta. Mr. Watson was appointed to the position which he has just left in 1916, prior to which he was for five years superintendent with the Western Electric Company, Red Deer, Alta.

Morley G. Taylor, S.E.I.C., of Parrsboro, N.S., is at present located at Maracaibo, Venezuela, with the Venezuela Power Company, Limited. Mr. Taylor graduated from Nova Scotia Technical College in 1927 with the degree of B.Sc. in electrical engineering. Following graduation, he was for a short time with the Nova Scotia Tramways and Power Company at Halifax, and was subsequently sent to Venezuela by the Montreal Engineering Company.

Ed. Hughes, A.M.E.I.C., has left the Granby Mining, Smelting and Power Company, Limited, and is resident engineer on Residency No. 5 of the Flin Flon branch of the Canadian National Railways, with headquarters at The Pas, Man. Mr. Hughes is a native of North Wales and received his engineering education at the University of Alberta. He has had extensive experience in railway location and construction work and on mine surveying in western Canada.

C. Arthur Scott, A.M.E.I.C., formerly assistant engineer, Department of Works, Toronto, Ont., has accepted an appointment with the special contract department of The Robert Simpson Company, Limited, Toronto. Mr. Scott graduated from the University of Toronto in 1909. During the summers of his university course he was engaged on various works with the roadway department of the city of Toronto, and immediately following graduation he was appointed chief clerk and estimator with the same department. The following year he became assistant engineer in charge of maintenance, surveys, draughting and estimating and, with the exception of the period of his service overseas, has remained with the Department of Works, Toronto, ever since.

K. L. Dawson, A.M.E.I.C., has been appointed sales manager of the Nova Scotia Tramways and Power Company, Limited, Halifax in charge of the sales of the company's several services in addition to his former duties as superintendent of the company's gas department. Mr. Dawson is a native of Nova Scotia and received his degree of B.Sc. in civil engineering from the Nova Scotia Technical College in 1917. He joined the staff of the Nova Scotia Tramways and Power Company in 1917 as assistant superintendent of the gas department and remained in this capacity during the period while Messrs. Stone and Webster were managers of the company. Mr. Dawson has taken an active interest in the affairs of The Institute and has been secretary of the Halifax Branch for a number of years and represented that branch on Council during the year 1927. At the recent Annual Meeting he presented a paper entitled "Notes on Removal of Carbon-Sulphur Compounds from Coal Gas by Oil Washing."

BOOK REVIEWS

Highway Materials

By Edward E. Bauer, B.S., C.E., First Edition, New York, McGraw-Hill Book Company, 1928, 6 x 9 in., 353 pp., tables, figs., $3.50.

This book, more especially written for university students, will also be of great value to practising engineers interested in road work.

It contains up-to-date and complete data relating to the inspection, the various tests and fundamental qualities of highway materials.

The work is divided into four parts. The first one deals with the standard definitions of terms relating to such materials as are used in highway work and then with their production, standard tests and specifications.

In the second part will be found a description of the qualities required of the materials used in each type of pavement, together with typical specifications as generally adopted by practising engineers.

The third part deals with the important question of the sampling of road materials. The careful selection of samples to be used for laboratory tests is of the utmost importance if we want such tests to be of real practical value.

The fourth part is devoted to the description of the most modern methods of testing. The practices followed by the writer are those specified by the American Society for Testing Materials. For those tests not specified by the A.S.T.M., the suggestions of the various bulletins of the United States Department of Agriculture have been adhered to.

Altogether, the book will be found very useful, not only to students in highway engineering, but also to every highway engineer, as it is an excellent compendium of the most recent practice followed in the use, sampling, testing and specifications of road materials.

Alex. Fraser, A.M.E.I.C.,
Chief Engineer, Department of Roads, Quebec, P.Q.

Heating and Ventilation

By C. W. Brabbée, McGraw-Hill Book Co., New York, 1927, First Edition, Buckram, 9 x 6 in., 332 pp., charts, figs., $6.00.

This is a translation of the German work on Heating and Ventilation by Dr. R. Rietschel, which has been revised by C. W. Brabbée for application to American practice and to suit American equipment in general.

It includes the general principles of heating and ventilation, and shows the requirements for such and the methods used in the design. It describes also the different types of heating apparatus and systems. An interesting piece of equipment not used to any extent in this country is a cast iron sectional heater for utilizing the exhaust gases from Diesel engines.

The work contains little original matter, but re-states a number of well-known principles and is partly based on the contents of equipment catalogues. An interesting feature is a collection of charts on hot water heating systems, both gravity and forced circulation and on high, low and vacuum heating systems.

E. A. Ryan, M.E.I.C.
Consulting Engineer, Montreal.

Applied Magnetism

By T. F. Wall, New York, D. Van Nostrand Company, 1927. Buckram, 7½ x 10 in., 262 pp., figs., $6.00.

This book gives, in the first six chapters, a short but very interesting and timely review of the subject of magnetism. Chapter vii outlines the electron theory of magnetism and chapter viii explains the author's method for generating very intense magnetic fields.

The second part of the book treats of magnetic testing and discusses the application of magnetic methods to the testing of steel products in an effort to correlate the magnetic and mechanical properties.

The book as a whole might be considered as an essay on the subject treated. The matter is well presented, and the treatment is stimulating, but the cost of the book is out of all proportion to the amount of material presented.

C. V. Christie, M.E.I.C.,
Professor of Electrical Engineering, McGill University.

Permanent-Way Materials Plate-Laying and Points and Crossings

By W. H. Cole, revised by Col. Sir G. Hearn, London, E. & F. N. Spon, Ltd., Buckram 7½ x 5 in., 245 pp., figs., diagrs., tables, $3.00.

This book deals primarily with British practice in regard to permanent way, but makes numerous references to practice in other countries. The first edition appeared in 1885, and its quality is indicated by the fact that in forty-three years a total of eight editions have been absorbed and a ninth is now in demand.

The gauges of track in various countries are cited. There is a discussion of stresses in track and of the relative merits of bull-head, double-head and flat bottom rails. Spacing of sleepers (ties) and depth of ballast and the reasons therefore are noted together with some remarks on the elements of cost of track.

The design of rail sections, fish plates, chairs and keys is discussed. Fastenings for flat bottom rails, anti-creep appliances and check (guard) rails and their fastenings are noted. Cast iron, steel and concrete ties and some of their users are cited. The conditions which a sleeper (tie) should fulfill are listed.

The manufacture of iron and steel is described and the manufacture and testing of rails, fastenings and steel sleepers (ties) are discussed. The essentials of plate laying (track laying) and the organization, tools and machines necessary or desirable therefore are noted. Train resistance, particularly that due to curvature, and both the theory and practice of super-elevation on curves are cited.

The duties of the Permanent Way Inspector and of his subordinate supervisory forces are noted. Maintenance of way tools and work are discussed and the solution of certain field problems is demonstrated. The organization for and method of renewing track materials is outlined. The practice and theory of point (switch) and crossing (frog) design and installation are dealt with and the layout of turnouts and crossovers under different conditions of alignment are developed.

British practice in regard to signalling and interlocking is recorded and the book closes with eight tables in regard to track materials and track work and a statement of standard and recommended dimensions, and additions to standard dimensions on account of curvature, as applied to Indian Railways.

The book is well condensed and is unquestionably of value to those dealing with British permanent way. Practice on this continent varies so greatly from British practice, however, that the chief value of the book here lies in its presentation of practice relatively little known in this country. As one may best understand his own problems by viewing them in the light of different practices, those who are concerned in the design and use of track materials in this country will find the time spent in reading this book to have been well invested.

J. E. Armstrong, A.M.E.I.C.,
Assistant Engineer, Canadian Pacific Railways, Montreal, Que.

The World of Atoms

By Arthur Haas, D. Van Nostrand Company, New York, 1928. Buckram, 9½ x 6 in., 137 pp., figs., $3.00.

In ancient Greece Democritus taught about a world of atoms, but his teaching found little experimental support until the discovery of radio-activity by Becquerel in 1896, soon followed by the discovery of radium by the Curies and of the disruption of radio-active substances by Rutherford. The disruption or disintegration of radio-active substances gave a key to the riddle of the atom, leading to other discoveries in rapid succession, and giving a great stimulus to scientific research. The result has been that during the last thirty years research in physical laboratories has tended to go more and more into this interesting field, until at the present time scientific journals devoted to physics are filled with researches on atomic physics to the exclusion of almost all other lines of investigation.

This book gives not only a clear and connected account of practically all that has been done and is being done in this field of endeavour, but also covers an elementary account of certain principles in physics and chemistry which are necessary to an understanding of this subject. Thus we have a book which while comprehensive is nevertheless easy to read, at least in the major portion. A minor part of the book, however, especially the last chapter, will require careful study.

A noteworthy point is the concise and clear-cut way in which the author makes all his statements without any needless verbiage. He states, for instance, that atoms disintegrate, forming new elements. He does not allow this, however, to lead to any ambiguity as to the nature of an element, it being plainly stated that an element is a substance which cannot be further decomposed by chemical means. Similarly this changing of one element into another leads to the possibility of changing the baser metals into gold, and the question arises: Can we turn mercury into gold by means of powerful electric discharges, as has been stated to have been done? He answers that it has been proved that the artificially prepared gold is always contained as an impurity in the mercury from the very beginning, and, furthermore, the atomic weight of this so-called artificially prepared gold is the same as that of ordinary gold, which would not be true if the gold were actually prepared artificially. In another place he states that the greatest experimental physicist of the 19th century was Michael Faraday—high praise indeed for an English physicist from an Austrian. Great appreciation is also given to the work of Sir Ernest Rutherford, formerly a Professor at McGill University. In a chronological summary at the end of the book, in which twenty-six important advancements are listed in this field of science, two of the twenty-six are referred to Rutherford and a third to Rutherford and Soddy, who was also a Professor at McGill University.

The book should be very interesting to the general reader who desires an understanding of our present knowledge of the world of atoms. For those who already have a good knowledge of the subject, the book will well repay reading, as it gives a very complete account of what is known of this subject condensed into the space of 133 pages. Much less prominence is given to Bohr's theory of the Atom and of Spectra than is usual in books of this character, but space is found for later theories, such as that of De Broglie on Wave Mechanics and of Schroedinger on the new Atomic Mechanics.

The translation is by Dr. Uhler, an associate Professor at Yale University, himself an active research worker along these lines, and of no mean reputation. That he should have thought well enough of the book to make a translation is of itself a high recommendation.

W. B. Cartmel, M.E.I.C.,
Engineering Department,
Northern Electric Company, Limited.

Properties and Testing of Magnetic Materials

By Thomas Spooner, 1st Edition, New York, McGraw-Hill Book Company, 1927. Buckram, 6 x 9½ in., 385 pp., figs., tables, $5.00

This book is a very valuable addition to the literature dealing with magnetic materials, and is written by one who, as research engineer of the Westinghouse Electric and Manufacturing Company, has had the most direct contact with the varied problems of a magnetic nature, which are met in the design and construction of all types of electrical apparatus.

Little space has been given to the discussion of magnetic theories, but the aim of the author has been to provide, in convenient form, that information on magnetic properties which should be included in the working knowledge of all men who are engaged in the design of electrical machinery or who are attempting to teach this subject in the universities.

Methods of test are described which are suitable for the commercial inspection of magnetic materials and for research investigations, together with a critical examination of their accuracy and limitations.

The various chapters are followed by a comprehensive list of references to the literature dealing with the subject matter of the chapter. This book should be on the desk of every electrical designer and in every technical library. The author and the publishers are to be congratulated on the production of a book containing such a wealth of information in such small compass and written in such an interesting way.

C. V. Christie, M.E.I.C.,
Professor of Electrical Engineering,
McGill University.

Water Channels

By George Higgins, Crosby, Lockwood & Sons, London, 1927. Cloth, 8½ x 11 in., 135 pp., figs., plates.

This treatise deals with problems met with in design of channels, particularly with irrigation channels. Flow in natural channels is entirely outside the scope of the work, and is not considered by the author.

Four formulae for computing flow in channels are considered briefly, viz., those of Bazin, Kutter, Barnes and Manning, the author favouring the use of Bazin's formula, for the solution of which he gives some excellent diagrams. A discussion follows on the most suitable size, shape and slope of a channel for a given service, after which, flow in circular and egg-shaped channels is considered. There is a very full discussion of flumes of lintearia section. An excellent feature is a study of the movement of solids in water following the methods suggested by R. G. Kennedy.

About half the text is taken up with a discussion of off-takes from canals, control works and devices for controlling and measuring the supply drawn from a canal. Brief descriptive notes drawn from many sources are given of control works in operation.

A casual examination leads one to conclude that the text is poorly proportioned as regards the amount of space devoted to the various subjects considered. This would be a correct view if the book was considered as a complete treatise on channel flow. However, it is evident that the author is treating a number of special subjects as he has covered them in practice, and is giving the reader the benefit of his special experience in the design of irrigation channels.

The plates collected at the end of the text comprise a series of diagrams for use in design of channels. They are generally clear and of such a size as to be useful.

J. J. Traill, M.E.I.C.,
Hydraulic Department,
Hydro-Electric Power Commission of Ontario.

EMPLOYMENT BUREAU

Situations Wanted

Electrical Engineer

Electrical engineer, 27 years of age University of Toronto graduate, six years diversified experience, two years Westinghouse engineering course, inspection of electrical equipment, industrial construction and maintenance, testing and research; at present employed in United States; wishes to return to Canada. Available on reasonably notice. Apply box No. 231-W, The Engineering Journal.

Metallurgical Engineer

Graduate in metallurgical engineering desires position. Experience: three years laboratory, one year plant executive. Speaks Spanish. Apply box No. 233-W, The Engineering Journal.

Situations Vacant

Young engineer with several years experience to spend part time on machine design work and remainder on survey work in connection with large newsprint mill in province of Quebec. Apply, stating salary expected, to box No. 188-V, The Engineering Journal.

Chief Draughtsman

Growing Canadian steel fabricating company, one thousand tons per month, permanent position. State age, experience and salary. Apply to box No. 189-V, The Engineering Journal.

Company's Corporate Name Changed

The Dominion Insulator and Manufacturing Company, Limited, announces the change of its corporate name to Canadian Ohio Brass Company, Limited. The change is one of name only as the company will continue without alteration its business of manufacturing O-B products in Canada. Mr. Merrill W. Manz, who has been associated with this company in Canada and with the Ohio Brass Company in the United States, has been appointed manager of the factory and sales with headquarters at Niagara Falls, Ont.

Canadian Trade Index

The fourth annual issue of the Canadian Trade Index, a copy of which has just been placed in the library of The Institute, contains this year the added feature of a special section dealing with exports, which has been supplied by the Department of Trade and Commerce at Ottawa. This volume, which has shown steady growth from year to year, provides as its main feature a dependable list of the articles made in Canada and the names of the manufacturers making them.

A new bulletin has just been issued by the Reliance Electric and Engineering Company of Cleveland, Ohio, which is known as bulletin No. 202, illustrating and describing the new direct current type "T" heavy duty Reliance motor, with ball and roller bearings, and giving full information as to its various applications. A copy can be obtained from any of the branches of the *Northern Electric Company, Limited.*

Modern Building Regulations for Reinforced Concrete

*F. R. McMillan**

Toronto Branch, March 15th, 1928

The purpose of a building code is to prescribe such regulations for the design and construction of buildings as are needed to safeguard the lives of occupants of buildings or of the public at large, and to insure sanitary conditions in buildings open to the public for residence or business purposes.

In theory, the preparation of a code should be simple, requiring only the statement of those general principles which govern safe design and construction, and such rules as are necessary for fire-safety, proper sanitation, etc.

In practice, however, it is not so simple. There are so many different materials of construction requiring special conditions to avoid unfair discriminations; so many matters of design in which the judgment of the engineer must play an important part; and so many minor details, the omission of which would necessitate special rulings or interpretation, that a simple code calling only for the exercise of good engineering, as desirable as such a code would be, is not sufficient.

In the case of reinforced concrete construction, the problem is even more complex than for the older forms of construction. This is due in part to the newness of the art, but principally to two other factors which are not present to any considerable degree in the older forms of construction. These factors are:—The various ways or systems of construction made possible by the adaptability of reinforced concrete and the rapidly accumulating and extensive test data relating to all phases of the art. With these special conditions superimposed on those of the general nature previously mentioned, the preparation of a set of regulations for the use of reinforced concrete becomes a task of some importance.

In presenting on this occasion the proposed Standard Building Regulations for Reinforced Concrete of the American Concrete Institute and the Concrete Reinforcing Steel Institute, it is not done in any sense with the feeling that it is the last word in building code provisions; in fact, those of us who have been closest to its preparation realize more fully than others the full significance of its limitations. It is presented, however, with the feeling that it represents a serious attempt, involving several years of effort on the part of properly qualified bodies, to provide a set of regulations that will be in accord with the advances in the art, and, at the same time, not too difficult to apply or enforce.

A bit of history will not be out of place. These building regulations had their beginning in the work of the Joint Committee on Specifications for Concrete and Reinforced Concrete. This committee, which was organized in 1919, consisted of twenty-five members representing the following organizations:—American Society of Civil Engineers, American Railway Engineering Association, American Society for Testing Materials, American Concrete Institute and Portland Cement Association.

This committee, after a very extended study of the field of concrete and reinforced concrete, issued its first report in 1921. This report, which was modified in the light of the very thorough public discussion, and resubmitted in 1924, marked a distinct advance in the design of reinforced concrete. It was the first authoritative document to attempt to control the quality of the concrete for the purpose of design and to fix the design stresses as a percentage of the ultimate strength. While some controversy was raised by certain of the provisions in the Joint Committee specifications, the report has received a wide recognition and has profoundly affected practice.

Following the appearance of the 1924 Joint Committee report, the Committee on Reinforced Concrete Building Design and Specifications of the American Concrete Institute was commissioned by the Board of Directors of the Institute to prepare a set of building regulations based upon it. Such regulations were submitted in 1925, and, with some modifications, were adopted in 1927 as a Tentative Standard of the Institute.

About the time of the adoption of the 1927 Tentative Standard by the American Concrete Institute, the Concrete Reinforcing Steel Institute adopted a similar set of regulations which were in substantial agreement with those of the American Concrete Institute in most of the essential items, but quite different in form and in many of the lesser items. Both of these documents were being put forth as suitable bases for building codes for cities and towns.

Because of the essential similarity of the two regulations in all major items and because of the desirability of having a single document, to be jointly offered as a basis of a code, the committees of the two organizations arranged a joint meeting to consider the possibility of a single report that would better serve the purpose than either of the two existing reports. Following this first meeting there was a series of meetings, from which developed the joint proposed regulations which is the subject of this discussion. This joint production, in the opinion of both committees, is a distinct improvement over any of the former documents and furnishes a modern set of building regulations for reinforced concrete.

From this brief sketch it will be seen that these regulations are not a mere incident in committee activities, but rather the result of careful study by many individuals, with the definite purpose in view of providing building regulations that would embody the recognized advances in reinforced concrete design and construction.

In spite of the long study leading up to this code and the care taken in its preparation, its limitations and shortcomings are freely admitted. The committees hope to strengthen and improve this report wherever possible, but they entertain no hope that it will be their privilege to write the first perfect building code.

It may well be the purpose for this occasion to point out some of the more important features in which this set of regulations differs from what has generally been the practice. This will be done in order, beginning with the first important difference in chapter 2.

Load Tests (Section 202)

The right to require a load test on the completed floor system in case of doubt concerning any feature of the construction has generally been provided in building regulations. The usual requirement has been a test with a superimposed load of twice the live load plus the dead load, with no stipulation as to the length of the time the test load should remain in place. This code requirement is a superimposed load one and one-half times the live load plus one-half the dead load to be held in place twenty-four hours, with the further provision that within twenty-four hours after the test load is removed the slabs or beams shall show a recovery of at least 75 per cent of the maximum deflection during the twenty-four hours under load.

Inspection (Section 203)

The architect or engineer is responsible for the inspection of the construction under these regulations. Inspection records must be kept showing many details in the placing of concrete and the reinforcement.

Concrete Aggregates (Section 205)

The quality of the aggregates is covered by the usual requirements as to cleanliness and the presence of undesirable characteristics, but a departure has been made from the usual practice in that definite percentage limits are given for the various deleterious materials. Grading of the aggregate is not covered under the quality specification, for under the other provisions of the code this resolves itself into a question of economy and not of quality. This is a basic improvement, for the many attempts to control quality of concrete through careful grading requirements with fixed proportions, while resulting in excellent concrete in individual cases, have in the main added to the cost and delayed the general recognition of the fundamental principles of concrete mixtures.

Quality of Concrete (Section 301)

In respect to the requirements covering the quality of concrete, the advance from the former practice is probably the most pronounced. In this code, full recognition is given to the definite dependence of the concrete strength upon the quantity of mixing water. Two methods of arriving at the quality of concrete are provided:—

(1) On the basis of definite water-cement ratio strength relation in accordance with the established values for average materials.

(2) By specific test to determine a water-cement strength relation for the particular materials to be used.

Under this latter method, with certain follow-up tests which are required, concrete of any desired strength may be used. This feature is of real advantage, as it will extend considerably the usefulness and economy of reinforced concrete construction.

With the water-cement ratio fixed by one of these two methods, the proportions of cement and aggregate and fine to coarse aggregate are fixed by the requirements of consistency and placing; this leaves open other opportunities for economies in the selection of materials and in the plant and methods of handling.

* Director of Research, Portland Cement Association, Chicago, Ill.

Unit Stresses in Concrete (Section 306)

Unit stresses in concrete are in accord with the recommended specifications of the Joint Committee in all respects except one. The exception occurs in the use of shearing stresses in excess of 0.09 of the ultimate strength of the concrete. The use of shearing stress greater than this will require special certification on the part of the designing engineer that he has personally supervised the placing of the reinforcement and the concrete in all members in which these higher stresses are used, and that in all respects the provisions of the code have been fully met.

Unit Stresses in Reinforcement (Section 307)

The unit tensile stress in reinforcement has been raised from the 18,000 lbs. per sq. in. allowed by the Joint Committee to 20,000 lbs. per sq. in. This stress applies alike to intermediate grade of billet steel and to rail steel reinforcing bars. Billet steel bars of structural grade and hard grade, which are not contemplated as standard materials when present stocks have been exhausted, are provided for by a footnote in the code at values of 18,000 lbs. per sq. in. for the former and 20,000 lbs. per sq. in. for the latter.

Slight revision has been made over the Joint Committee requirements in the provisions for stress on structural steel or cast-iron sections in composite columns. These provisions allow a flat unit stress on the steel or cast-iron sections, instead of a unit stress reduced for slenderness, as was the case in the Joint Committee provisions. Slenderness is taken care of under the new provisions by the long column formula applied to the composite column as a whole. This is a much more logical and more easily applied method.

Mixing, Placing and Details of Construction (Chapters 4 and 5)

Provisions in these chapters are substantially in accord with the recommendations of the Joint Committee. Such changes as have been made are in the direction of simplification in the text and greater suitability for building code purposes.

Design Assumptions (601)

Design assumptions with but one change are in accord with the recognized practice as typified by the Joint Committee specifications. This change is in respect to the value of n, the ratio of the modulus of elasticity of steel to that of concrete. This is made a direct function of the strength instead of using a series of step values, such as 15, 12 and 10, each to apply to a certain group of concrete strengths, as has been the custom in the past. In this code

$$n = \frac{30,000}{f^1_c}$$

This is a particularly desirable improvement where advantage is to be taken of the opportunity for using concrete of any desired strength. It also simplifies the preparation of design tables and diagrams for concrete of any strength.

Moment Calculations (Chapter 7)

For the usual cases of equal spans and uniform loads, these are in accordance with the Joint Committee recommendations, except that the negative moment required at the end supports of series of spans only slightly restrained is slightly less than in former provisions.

Sections have been provided for ribbed floor construction and floors reinforced in two directions. Neither of these subjects were covered by the Joint Committee. The committee is not satisfied with the provision in its code covering floors reinforced in two directions. It hopes during the present year to develop a more rational treatment than that contained in the report.

Shear (Chapter 8)

Shearing unit stresses are essentially in accord with the provisions of the Joint Committee, except for the provision covering stresses in excess of 0.09 of the ultimate strength of the concrete, as previously mentioned. The provisions relating to the design of web reinforcement, however, have been materially altered and clarified in the manner of presentation.

Bond and Anchorage (Chapter 9)

This chapter is in general accord with the provisions of the Joint Committee, except that where special anchorage is provided, bond stresses to be used are obtained by doubling the values specified for ordinary anchorage. In the Joint Committee report these values were obtained by a formula that was not simple to apply, but which gave values not greatly different from those obtained under the revised provision.

Flat Slabs (Chapter 10)

As in the case of the shear and bond, these provisions, though of the same material effect as those of the Joint Committee, have been considerably revised in respect to the manner of presentation. There has also been added a set of coefficients directly applicable to the 4-way slab with dropped panels for the special case where the diameter of the column capital is 0.225 times the average span length of the panel. These coefficients are in accord with the general provisions and their addition merely simplifies the solution for this particular type of construction.

Columns and Walls (Chapter 11)

In the matter of columns, change in the provisions covering composite columns has already been referred to. In addition to this some clauses have been added to provide for a positive loading of the metal section in columns of this kind, and to provide better details at the base of the column.

There has also been a slight change in the formula for computing the load on combination columns. These are columns with structural steel sections encased in concrete but without the spiral and longitudinal reinforcing required in the composite columns. The loads allowed are materially less than for the latter.

The provisions for design of spiral columns are the same as in the Joint Committee report. These have evoked much comment. Engineers who have not given special study to the matter have wondered why the permissible unit stress on the concrete is made a function of the amount of longitudinal reinforcement, also why the ratio of spiral reinforcement bears a fixed relation to the ratio of longitudinal reinforcement. These two questions are readily answered by a consideration of the inter-action of the concrete and the embedded steel.

During the period of hardening of the concrete when the column begins to dry out there is a shrinkage of the concrete that is resisted by the longitudinal reinforcement, with the result that the steel is under some compression independent of that due to the load. Combined with this condition, which is not recognized in the older forms of column formulæ, there is a further increase in steel stress due to the fact that under continued load concrete takes on a slight permanent deformation, thus giving a value of n, (the ratio of the Modulus of Elasticity of the Steel to that of the Concrete), somewhat higher than that used in the ordinary computations.

The formula of the Joint Committee was built up to give recognition to these two independent phenomena. While this purpose is not readily apparent from the form in which the formula appears, the formula does indicate the advantage which results from using higher ratios of longitudinal reinforcement. This is in accord with the basic considerations just referred to in which the limiting condition is the stress in longitudinal steel. Both the analysis of the problem and available test data indicate the soundness of this method of treatment. Incidentally, the values obtained by the use of this formula do not greatly differ from those obtained by the formula which has been in effect in a number of cities for many years. It has the advantage, however, of being on a more logical basis and indicates more accurately the direction in which true economy in column design lies.

The requirement that the spiral reinforcement be always 25 per cent of the longitudinal is to insure an increasing amount of lateral reinforcement with increasing loads and unit stresses. The only purpose of the lateral reinforcement is to supply a factor of safety against sudden collapse, as no test data have shown the lateral reinforcement to have any major influence on the column stresses under working loads.

In this chapter on concrete columns and walls, there has been added a section covering the design of monolithic walls. The provisions in this section are based on the provisions in the Seattle code, which are the result of considerable experience in this type of construction.

In conclusion, reference was again made to the vast amount of research and engineering study which has been given to concrete and its combination with steel. No other building material has had the benefit of such intensified study, and yet the practice of the art is far behind present knowledge. Naturally, practice must lag somewhat behind the ever-advancing knowledge, because building regulations are an obvious necessity and they cannot be amended at the conclusion of every new experiment. It is important, however, that from time to time our building codes be revised to bring them in line with the recognized advances. It is believed that the "Proposed Standard Building Regulations for Reinforced Concrete" which we have been discussing will admirably serve this purpose at the present time.

BRANCH NEWS

Border Cities Branch

R. C. Leslie, Jr.E.I.C., Branch News Editor.

The Welland Canal

Alex. J. Grant, M.E.I.C., newly-elected vice-president of The Institute and engineer-in-charge of the Welland canal, was the speaker of the evening at the meeting of the branch on March 9th. The dinner was held in the ballroom of the Prince Edward hotel, and a good crowd attended. Well over a hundred persons were present, including the Mayors of Windsor, Walkerville, Ford City and Ojibway, O. E. Fleming, K.C., of the Deep Waterways Association, visitors from Detroit and members of the Border Cities Branch.

Mr. Grant's lecture was most instructive and interesting. He outlined the history of canals in Canada from the earliest times, tracing the development of the Great Lakes system of navigable waterways up to this latest huge undertaking, the Welland canal. A great difference was noted between the first Welland canal opened in 1816 with forty wooden locks, 110 by 22 by 8 feet, and the new canal begun in 1913 with seven locks, 859 by 80 by 30 feet, having lifts unprecedented in a canal of this size. Three flights of twin locks give a lift of 140 feet, as against a maximum rise of 85 feet in the Panama canal. The guard lock at Port Colborne is 1,300 feet long and will accommodate two large vessels at one time.

Slides were shown illustrating the various features of the project at different periods in its construction. The huge steel gates were of great interest, as were also the wooden ones, whose timbers, of Douglas fir, were brought all the way from the Pacific coast. Nine hundred thousand board feet of this timber have been used, many pieces having a cross-section as large as 50 by 40 inches and a length of 60 feet. The method of placing concrete in the locks and the steel forms for the same were shown and explained. The syphon which is to make the Chippawa creek under the canal consists of six 22-foot diameter barrel tubes with vertical end shafts.

Numerous movable bridges have been and are being built over the canal. The type which is being used most is the vertical lift bridge. There are also some rolling lift bascules, one of which is a double leaf structure. The clearance provided under the vertical lift bridge is 120 feet at high water, which is more than ample to meet the requirements of both lake and ocean navigation companies.

Seven million three hundred thousand tons of shipping had passed through the Welland canal in 1927, and, in answer to queries about the possibilities of trade development which might result from full utilization of the St. Lawrence, Mr. Grand expressed the opinion that a comparatively short length of time should see an annual tonnage of at least twenty-five millions.

After Mr. Grant's address, O. E. Fleming, K.C., spoke briefly from the viewpoint of a Deep Waterways Association official, and expressed the hope that the St. Lawrence canalization would follow soon after the completion of such an important link in the chain of lake to ocean waterways as the Welland canal. Mr. W. Molitor, of Detroit, who has been connected with various canal projects, including the Panama, expressed admiration for the manner in which the Welland work has been handled, and, in closing, called upon the gathering to extend its appreciation to Mr. Grant for his very fine lecture.

Calgary Branch

W. H. Broughton, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

At the meeting of the branch held on February 16th, J. D. Baker, plant superintendent of the Alberta Government Telephones, Edmonton, addressed the members on "Development in Long Distance Telephony."

Development in Long Distance Telephony

The speaker started out with a brief history of telephony, in which he recalled the fact that last year was the fiftieth birthday of the telephone. He stated, however, that the greatest developments had occurred in the last fifteen years and improvements are taking place very fast at the present time. To illustrate this, Mr. Baker stated that when in New York recently he learned that the United States Bell Telephone System found the research work in connection with telephony had become so great that they had deemed it advisable to form a subsidiary company to look after this work. He was privileged to be shown through the laboratory building of this company, in which some 3,200 scientists, experts in various lines, were engaged in experimental work in connection with telephony.

He recalled that twenty years ago there existed in Alberta only one long distance line, namely, between Calgary and Edmonton, and even it was none too satisfactory. Now it is possible to talk to any part of the continent and to Central America. The carrying of photographs by wire is now an everyday affair in the United States and could be made so here at any time if the demand arose. Mr. Baker stated that television also will soon be an established fact.

The speaker showed a number of lantern slides of oscillographs to illustrate voice modulations and frequencies and described how by continuous experimental work the tones of low and high frequencies can now be filtered out of sound waves travelling over a circuit to make conversation clear.

Repeaters are now inserted in the line about every 500 miles to amplify the sound waves by which means it is possible to carry on conversations over very long distances. Mr. Baker stated that in a very short time a Canadian all-red line from the Atlantic coast to the Pacific coast would be an established fact.

At the present time it would be quite feasible to carry on a conversation between Calgary and London, England, but no demand for this service has yet arisen. This would cost about $90 for a three-minute call.*

A short interesting description was given of the organization called into play for transmitting the programme from Ottawa to all parts of Canada on the first of July last. An all-Canadian route was used, although United States companies co-operated by organizing an alternative line in case anything went wrong on the Canadian hook-up. All telephone and telegraph companies in Canada joined together to make this possible, and some 9,000 miles of telephone lines and about 4,000 miles of telegraph lines were used.

The speaker mentioned that there are at present in the province of Alberta some 27,000 miles of pole lines and 170,000 miles of telephone wire. There is now about $25,500,000 invested in the Alberta Government Telephone System, and Mr. Baker gave it as his opinion that it is the most up-to-date of any system serving a similar area. He formed this opinion after having had the privilege of looking over the lines of the greatest corporation of this kind in the world, the American Telephone and Telegraph Company.

The lecturer concluded with a demonstration of the filtering out process of objectionable sound waves by means of specially prepared phonographic records, the phonograph being hooked-up to an amplifier and thence to several types of loud speakers. This practical demonstration caused considerable interest amongst those present, and was cleverly arranged by the speaker.

Mr. Baker handled this highly technical subject in a manner which made it clear to those present, and a very interesting discussion followed.

The Significance of Water in Oil Field Operations

The speaker of the evening at the meeting of the branch held on March 1st was T. G. Madgwick, petroleum engineer of the Department of the Interior. Mr. Madgwick's subject,—"The Significance of Water in Oil Field Operations,"—was well chosen at this time when drilling and prospecting for oil in this province has reached such an important phase in determining the extent and value of our natural resources. The probability of encountering water is always one to be faced in the search for oil, and, although so far our known fields have not suffered to any appreciable extent in this respect, such knowledge as he gave out is valuable should such a contingency ever occur.

He pointed out that one great menace that water invasion of an oil or gas field offers is that of trapping a large part of the oil still underground, and also the resultant effect of driving the oil to neighbouring properties. The occurrence of water means increased cost of pumping when emulsion is formed, followed by the necessity of dehydration. He illustrated and explained what actually constitutes an impervious formation, and showed his audience by means of slides the travel of water through underground strata. He defined an impervious bed as one whose pores are so fine as to present such frictional resistance as will stop anything but infinitesimal movement through them. An anticlinal fold, he explained, was a good trap in the path of subsurface water flow.

The paper was of a highly technical nature, and such sentences as this were not infrequent,—"The conditions of deposition tend to lenticularity parallel to the former shore line which are often parallel to the axis of the geo-syncline,"—which had more or less to be taken for granted by the engineer who was not fortunate enough to be a geologist also.

With further reference to water occurrence, the speaker mentioned that water is the primary factor in the accumulation of oil and gas, especially on the plains of western Canada, where one is liable to find around the margin of the pool being developed a practically inexhaustible body of edge water. He went on to explain that it was the alterations that we introduce into the equilibrium of

* Since this address, a ten-minute experimental conversation has been clearly transmitted.

nature that is the principal cause of the water trouble that affects so many fields. He explained the plugging of wells, showing many methods sometimes thoughtlessly adopted that would prove detrimental to neighbouring drill holes. Sometimes an oil well will become flooded with top water, but this should be more easily remedied. That careful and systematic cementing at the proper level, and in the proper way, would always repay the operators was the theme of a large part of Mr. Madgwick's paper. He also advocated the absolute necessity, and to the advantage of all concerned in drilling for gas or oil, that all waters encountered must be sampled and analyzed. He stressed the importance of this if we are ever going to deal successfully with water problems.

The speaker concluded by mentioning methods of dye and other fluid detectors for passage of water, and stated that a strict adherence to legislation in drilling operations would always pay in the long run. The discussion following Mr. Madgwick's address was interesting, several important points being well explained.

Annual Meeting

The annual meeting of the Calgary Branch was held on Saturday, March 10th, at which there was a good attendance. The secretary-treasurer's report for the year ended showed that a number of very interesting addresses had been given of a high standard, at which the average attendance was good.

Reports of the several conveners of committees were then received, all of which were passed and accepted with satisfaction. A brief ceremony then followed at which the secretary, H. R. Carscallen, A.M.E.I.C., and the branch news editor, W. St. J. Miller, A.M.E.I.C., each received a beautifully engraved silver cigarette container, "in recognition of services rendered." I would like it to go on record that, for my own part at least, I was completely taken by surprise, and, chiefly for the benefit of those members of the branch who were unable to be present, I wish to express my sincere appreciation for both the prompting thought and the valued gift.

Following the report of scrutineers J. J. Hanna, A.M.E.I.C., and M. H. French, A.M.E.I.C., Chairman F. K. Beach, A.M.E.I.C., announced the result of the ballot count:—

Chairman	Thos. Lees, A.M.E.I.C.
Vice-Chairman	F. J. Robertson, A.M.E.I.C.
Secretary-Treasurer	W. H. Broughton, A.M.E.I.C.
Executive Committee	F. M. Steel, M.E.I.C.
	B. Russell, M.E.I.C.
	O. H. Hoover, A.M.E.I.C.
Auditors	J. J. Hanna, A.M.E.I.C.
	F. C. Tempest, A.M.E.I.C.
Ex-officio	S. G. Porter, M.E.I.C.
	P. J. Jennings, M.E.I.C. (councillor)
	F. K. Beach, A.M.E.I.C. (past-chairman)
	H. R. Carscallen, A.M.E.I.C. (past secretary-treasurer)

Past-Chairman F. K. Beach, A.M.E.I.C., gratefully acknowledged the assistance of the executive through the past year, and handed over the duties to the vice-chairman, F. J. Robertson, A.M.E.I.C., in the unavoidable absence of the newly-elected chairman, Thomas Lees, A.M.E.I.C.

A motion of thanks to the retiring chairman, secretary and executive was proposed by S. J. Davies, A.M.E.I.C., and cordially received by all present.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

A meeting of the branch was held at the Hamilton Technical Institute on Friday, February 17th, at which L. W. Gill, M.E.I.C., occupied the chair.

The minutes of the last meeting were read and approved, following which it was moved by J. C. Nash, A.M.E.I.C., seconded by J. E. Grady, A.M.E.I.C., and carried, that last year's Nominating Committee, composed of A. H. Munson, A.M.E.I.C., W. B. Ford, A.M.E.I.C., A. R. Hannaford, A.M.E.I.C., Alex. Love, A.M.E.I.C., and E. H. Darling, M.E.I.C., be re-elected.

Major Hugh Lumsden, M.E.I.C., introduced the speaker, R. M. Smith, A.M.E.I.C., deputy minister of highways of the province of Ontario.

Highways in Ontario

(Reported by the Secretary)

Mr. Smith said that there were four types of highways being built in the province of Ontario, gravel, traffic bound macadam, concrete and asphalt. He reviewed the development of highways, beginning with the concrete highway from Toronto to Hamilton in 1915. This was constructed 18 feet wide and with expansion joints every 35 feet. The mix was 1:1½:3 and the thickness 8 inches in centre and 6 inches at edges. At that time, United States specifications had to be depended upon. Now, however, the department has developed its own specifications. Pavements are standardized at 20 feet in width, concrete being laid thicker at the edges than the centre, viz., 10 and 7 inches, and no expansion joint is required. The pavement, although laid as a 20-foot slab, is divided into two 10-foot strips by metal plate, with the consequence that a crack develops along the centre, no transverse expansion joint being used. The mix, which is 1:1½:3, is richer than generally used in the United States. The department requires that the aggregate remain in the mixer only one minute, however, while the American specifications generally ask for one and a half minutes. It is felt that the richer mix is justified and that in the long run a cheaper job is secured. In any case, it is interesting to note that the cost of concrete pavements to the province of Ontario is approximately $10,000 per mile less than the same class of pavement laid on the other side of the international boundary.

The Ingersoll-Thamesford highway, built in 1924, cost only $20,000 per mile. While screened material was used, no washing was required. The next year washed and screened gravel or crushed stone was used on all work. This, while slightly increasing the cost per mile, made for greater uniformity in construction, with the result that a demand was created for this type of construction. Up to the present time, 577 miles of concrete roads on Ontario Provincial Highways have been completed.

As a comparison between the old type of concrete design and the new, an examination of the Burlington Beach highway, which has been down four years, should be made. This pavement shows practically no cracks. The Toronto-Hamilton highway developed cracks in the second year, which, while partly due to its being paved immediately after grading, was principally due to the fact that design was not correct.

It has been found that concrete tends to creep. For this reason, a 6-inch expansion joint behind the ballast wall is provided in every case where bridges are located on concrete highways.

Penetration macadam is built by placing a 3¾-inch layer of loose 2-inch stone on an old macadam base. This is then slightly rolled and filled with asphalt or tar, after which the road is thoroughly consolidated. Many miles of this type of road have been successfully constructed in the province of Ontario. While it has some advantages in that it requires a minimum supply of equipment and is fairly cheap to construct, it has also some disadvantage in that it requires the road to be closed during construction. The life of the pavement is also open to question.

Having these conditions in mind, the department undertook the construction of what has been classified as asphaltic mixed macadam. The aggregate in this pavement consists of crushed stone, varying in size from 2 inches to dust, mixed with asphalt approximately 4½ per cent by weight and having a penetration of 77 to 83. The surface is applied by the ton and is laid in such depths as may be sufficient to carry the traffic. The surface of the road when completed is slightly rough and has many of the riding qualities of a gravel road.

In connection with the construction of asphaltic roads, it is rather interesting to note the change in specifications since work of this nature was first started on the provincial system in 1919. At that time, Ontario accepted, as with concrete, specifications in use in the United States. It was found, however, that an asphalt penetration of approximately 40, while suitable for their requirements, was much too hard when used in Ontario with the changing climatic conditions. The Hamilton-Galt road is typical of the early construction. This road has many hair cracks which, it is believed, were largely caused by the fact that the asphalt was too brittle. In any case, the construction of asphalt roads during the last few years with the increased penetration seems to provide a much improved surface. Up to the present time, 263 miles of asphaltic pavement have been laid.

The transportation problem of to-day is very greatly changed from the days of macadam. The slow-moving vehicle at that time with the steel tire assisted, if anything, in compacting and preserving the macadam road as then designed. The rubber-tired vehicle of to-day, with its speed, affects the surface in just the opposite way from the steel-tired vehicle of olden times. Consequently, macadam pavement has more or less become obsolete. While it can be used and is used on township and county roads where traffic is slight, it does not recommend itself for provincial highways.

In addition to the various types of pavement mentioned above, the department has been experimenting with what has been classified as "Poor Man's Pavement." This is simply a matter of treating gravel surface with tar or asphalt, with a view to providing a dustless road and at the same time conserving the gravel or stone. The policy of the Department of Highways of Ontario is to construct this type in many sections where pavement of a higher type will eventually be laid.

In the bridge construction being undertaken, the department confines itself to concrete and steel, depending entirely on the type of foundation which can be secured; the concrete arch predominating where first-class shale or rock foundations is obtainable; the steel structure being used where any uncertainty exists. The concrete bridge constructed at Caledonia last season is typical of the type of construction the department recommends. This structure, approximately 700 feet in length, built in nine spans, was started on July 8th and completed November 15th, rather a record, the speaker felt, in construction of this kind. The department has also under construction at this time what is known as the Hog's Hollow bridge at the north entrance to Toronto. This structure is of steel with concrete sub-structure. It is 1,225 feet in length, has a 54-foot floor with two 6-foot sidewalks and is of sufficient weight to carry street railway lines.

Up to the present time nearly $175,000,000 has been spent. A trip through the province of Ontario will indicate that tremendous improvement has been made during the last ten years. The opening of the highway into the north is serving a section where there are 20,000,000 acres of fertile clay belt. A mining area of third importance in the world is being provided with an outlet. This road is serving the tourist traffic which has been demanding a highway to the Ontario mining district for many years.

Aside from the development in Northern Ontario, the changing conditions in Old Ontario are astonishing. There has been a tremendous increase in tourist traffic. During 1926, 1,290,000 vehicles came into Ontario via Ontario ports. During 1927 this was increased by more than 20 per cent.

There has been a great improvement from an industrial point of view, the opening of highways for winter traffic tending to improve conditions materially in this regard.

After a brief discussion, the meeting closed with a vote of thanks moved by E. H. Darling, M.E.I.C., which was carried with applause.

Regular Meeting, March 9th, 1928

(*Reported by H. E. Treble,* S.E.I.C.)

A regular meeting of the Hamilton Branch was held in the auditorium of the Hamilton Technical Institute on Friday evening, March 9th, when the members of the branch were the guests of the Canadian Westinghouse Apprentice Club at their fortnightly meeting, the occasion being a lecture and film presented by the Carborundum Company of Niagara Falls, describing the manufacture of carborundum and aloxite. E. F. Connolly, (B.A.SC., Toronto), president of the Apprentice Club, occupied the chair.

In welcoming the guests, Mr. Connolly referred to the visit of the club to the meeting of The Engineering Institute a short time ago, "When they heard the splendid address given by Mr. F. I. Ker, on the St. Lawrence Deep Waterways. This gathering together of the younger and of the more mature of the engineering profession should be of mutual benefit."

L. W. Gill, M.E.I.C., chairman of the branch, was then invited to say a few words. After thanking the club for its invitation, he went on to explain the organization of The Institute with its branches from the Atlantic to the Pacific. He explained that there are four grades of members, and he urged upon his hearers the value of membership in The Institute, especially to those young men who were heading toward the profession, and recommended that they take an interest in their profession.

Carborundum and Aloxite

F. A. Bowman, advertising manager of the Carborundum Company, was greeted with applause as he rose to address the meeting. Referring to the salesmen and sales engineers of the company present with him, he explained that not being a technical man he had brought his technical advisers with him and any questions asked would be taken care of to the best of their ability.

"I see," he said, "you are a body of serious deep thinking gentlemen, and thus the story of the invention and development of carborundum will be of great interest to you."

It was discovered in 1893 by Edward Goodrich Acheson, who had been associated with Edison in the development of the incandescent lamp filament. Mr. Acheson dreamed he could find an abrasive which would improve upon the natural products of emery and sandstone. He worked in Monongahela, Pa., in a ramshackle shop with the crudest of apparatus, including a small dynamo which supplied his electric power. One day he was experimenting with an electric arc in a small bowl such as plumbers use. In the bowl he had placed some clay and crushed coke and had packed it around a piece of carbon to which was fastened a wire leading from one pole of his dynamo. The heat generated by the electric current fused the two ingredients in the bowl, and when the carbon was withdrawn the trained eye of Mr. Acheson discovered some minute crystals adhering to it. These tiny jewel-like bits were found to be amazingly hard and sharp. It almost induced the hope that here had been found a way to make synthetic diamonds, but a few simple tests soon dispelled this idea. The fact remained that they were second only to the diamond in hardness and that they were destined to revolutionize the grinding world.

The inventor experimented again and managed to collect enough of the material to fill a small vial. This tiny vessel he tucked in his pocket, and, having determined to call the new material carborundum, he journeyed to New York. The possibilities of the new abrasive as a substitute for diamond dust for jewel polishing appealed to him, and accordingly Mr. Acheson interviewed several diamond experts, and after some persuasion they were induced to give the new material a trial. The results were successful, startlingly so, and accordingly Mr. Acheson got his first order for carborundum and the price paid was 40 cents per carat or $880 per pound.

That was the beginning of the commercial career of carborundum, and to-day there are thirty large electric furnaces instead of the one little plumber's bowl and the crude carborundum sells for practically ten to twelve cents per pound.

Carborundum is the trade name given to silicon carbide. This chemical transformation is brought about in the following way:—The element carbon is supplied by crushed coke and the element silicon by sand. These two materials are mixed in certain proportions and loaded into an electric furnace. A little sawdust is added to the mixture to make it porous so that certain gases which form in heating the material can escape, and a little salt is also added to drive out certain impurities.

The electric furnace is rectangular in shape, built of fire brick, about 20 feet long, 7 feet wide and 6 feet high. At each end of the furnace are large carbon rod electrodes to which the electric current is brought through large cables. The furnace bed is filled with the mixture of sand, coke, sawdust and salt, the power is turned on and a heat of approximately 4,060°F. is generated due to the high resistance of the materials between the electrodes. At the end of thirty-six hours the sides of the furnace are taken down, the thick outer crust of slag is removed and the masses of carborundum crystals are revealed.

These crystal masses are taken from the furnace and crushed or broken into individual crystals under iron wheels. The grains or powders thus produced are carefully washed free from all foreign materials and are then dried in immense rotary driers. From the driers the grains are sent to the sifting room, and, much after the manner in which flour is bolted, are sieved through silk screens into grits or sizes corresponding to emery. The graded grains and powders are then mixed with certain bonding materials such as spar, mixtures of clay, rubber and other materials, and are fashioned into the various sharpening stones and grinding wheels, in moulds placed in great hydraulic presses. The moulded shapes are then loaded into fire clay "saggers" or holders and are placed in kilns and for a week are baked at a heat of about 2,500°F. After coming from the kiln the wheels are dressed to the desired sizes, and, after rigid inspection and certified speed tests, are ready to leave the factory.

Carborundum has several predominating characteristics. It is unequalled in its degree of hardness and sharpness. The diamond may be harder, but not sharper. It is also slightly brittle, so that when it comes in contact with the material to be ground it breaks, forming new crystal surfaces and thus new cutting edges. It is also insoluble in any re-agent such as acids or alkalies and is not affected by temperature except at a heat greater than that at which it is formed. Thus, in its various grades and binders, carborundum may be used for cutting, polishing, rubbing or any process in which an abrasive may be used.

For those processes requiring a tougher crystal than that of carborundum there has been developed the abrasive called aloxite. This is made in an electric furnace similar to that used for carborundum from two materials, bauxite clay and coke.

The moving pictures showed the United States and Canadian plants, the process of manufacture and many of the almost innumerable ways in which the abrasive is used in industry. Many questions were asked between the reels and after, by the interested audience, and at the conclusion of the showing a vote of thanks was accorded to Mr. Bowman and his colleagues on the motion of H. E. Treble, S.E.I.C., secretary of the Apprentice Club.

Executive Meeting, March 12th, 1928

A meeting of the Executive Committee of the Hamilton Branch was held on March 12th in the office of W. F. McFaul, M.E.I.C. L. W. Gill, M.E.I.C., chairman of the branch, presided, and there were five other members present.

One application for transfer was considered and recommended.

Plans for a meeting early in April were discussed, also for a dinner-meeting to be held in May.

It was announced that the annual joint meeting with the Toronto Section A.I.E.E. would be held on April 27th in the Westinghouse Auditorium. At this meeting, G. E. Stoltz, of the Westinghouse Electric and Manufacturing Company, will speak on "General Power Application."

Toronto Dinner, March 15th, 1928

The members of the Hamilton Branch were the guests of the Toronto Branch at dinner on March 15th, 1928, and at their meeting afterward at which F. R. McMillan, director of research, Portland Cement Association, was the speaker. The hospitality of the Toronto Branch was much appreciated.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

Manufacture of Coke from Alberta Coals

On January 21st, a well-attended meeting was addressed on a subject of more than special interest to Lethbridge people, that of "The Manufacture of Coke from Alberta Coals."

The speaker, Edgar Stansfield, M.E.I.C., honorary secretary of the Scientific and Industrial Research Council of Alberta, exploded the report,—common in the west,—that Alberta had not any coking coals by illustrating tests he had made of various coals from all parts of the province, also those made from imported coals in Winnipeg and other places, showing that coke produced from some of the Alberta coals was excellent in quality and compared very favourably indeed with that from imported coals.

Quotations from provincial statistics showed that, to date, upwards of a million tons of coke had been manufactured in Alberta from its own coals.

Mr. Stansfield stated that the fuel situation was such an important one that it was one of the foremost problems facing the federal government to-day. The Dominion Fuel Board in 1922 recommended the installation of coking plants throughout the "acute fuel area" with the idea that Canadian coals would be used. Unfortunately for Alberta and Nova Scotia, however, American coal secured the market on account of cheaper transportation.

American interests have for some time been looking over the prairie provinces for plant locations. Gas for cooking and lighting would be manufactured to supply the larger centres and the coke sold in the neighbouring territory. Such companies would naturally select American coal for their enterprises, with the result that a further cut would be made into the Alberta trade.

The speaker dwelt at some length on the federal assistance given to coking plants using up to 70 per cent of Canadian coals.

Referring to the necessity of eliminating the smoke nuisance in the larger cities, Mr. Stansfield mentioned that in London, England, the annual deposit of soot amounted to 55,000 tons, creating a material damage of about £4,000,000. In Pittsburgh, it was estimated that from 600 to 2,000 tons of soot was deposited per square mile. London, however, is improving in this respect and scientists declare that within a few years smoke and soot will practically be evils of the past.

Prior to the lecture, the usual community singing was indulged in and very enjoyable violin and piano selections by Mr. and Mrs. Geo. Brown and vocal solos by Mr. G. Frost were thoroughly appreciated by the members.

The meeting closed with a hearty vote of thanks to Mr. Stansfield and to the Research Council.

The Manufacture of Pottery

At the regular bi-monthly meeting held on February 4th, the speaker of the evening was Mr. Charles Pratt, of the Medalta Potteries, Medicine Hat. Following the dinner and business routine, community singing was enjoyed, as also were vocal solos by Messrs. F. Mills and H. Moore.

In opening his subject on the manufacture of pottery, Mr. Pratt stated that in the region of the Nile, evidences had been found in tombs of the period 5000 to 3000 B.C. of vases of terra cotta; likewise, all over the world explorations showed that the earliest tribes were moulding clay into vessels of many descriptions.

Records of chinaware date back to 2000 B.C., but the finest examples of pottery ever seen were made at the time of the Ming dynasty, which began in 1368.

John Wedgewood of England, probably the most outstanding ceramist of present times, developed the factory system of the division of labour, earlier potters having carried their work out individually. England has been fortunate in the possession of deposits of some of the finest china clay ever discovered. The United States, though not having the same grade of fine clays, has made rapid advancement in the pottery industry, made possible through sufficiently high tariffs to encourage local developments.

In Canada, all whiteware is imported, not a single piece being manufactured in this country, but a considerable quantity of stoneware is being produced which holds its place in competition with imported products.

At the plant in Medicine Hat, natural gas is used as fuel, this giving a very dependable and steady heat. The speaker followed the various processes of the manufacture, showing a thorough mastery of his subject, and at the close was accorded a hearty vote of thanks.

Development of Oil in Alberta

The bi-monthly meeting of the Lethbridge Branch was held on February 18th, in the form of a joint meeting with the Association of Professional Engineers of Alberta. The Professional Engineers held their district annual session during the afternoon of the same day, and combined with the members of the Lethbridge Branch of the Institute for the evening meeting. The meeting was preceded by a dinner at which about seventy-five members and guests were present.

The guest of the evening was Mr. T. J. Madgwick, petroleum engineer, of the Department of the Interior. Mr. Madgwick gave a highly interesting illustrated address on the "Development of Oil in Alberta." Coming from the University of Birmingham, England, Mr. Madgwick has been for the past two years with the Dominion Government, stationed in Calgary, and has given the oil structure in Alberta an extensive study. His remarks were most optimistic as to the future of the oil industry in that province, and in the course of his remarks he stated that it is no exaggeration to say that the province of Alberta contains the greatest undeveloped area underlain by known deposits of oil and gas in the world, and, judging by the results of the prospecting and development to date, certainly the most promising.

The members were entertained during the meeting by a delightful musical programme by Messrs. Lawrence, Teague and Meldrum, supported by the Rainbow orchestra, and to well received humorous monologues by Mr. P. Gaynor.

Paints and Varnishes

Southern Alberta flax produces the highest grade of linseed oil known, said W. A. Church, manager of the Alberta Linseed Oil Company, of Medicine Hat, in the course of his address before the Lethbridge Branch on Saturday, March 3rd. During the discussion which followed, it came out that the flax grown in this region was equal to the best Russian flax and superior to that grown in the Argentine and other warm countries. Mr. Church's address was on "Paints and Varnishes," and revealed the great strides made in the manufacture of these products.

Speaking on varnishes, Mr. Church said they are complex mixtures and combinations of organic matter, consisting chiefly of gums, oils, volatiles and oxidizing agents. The gums supply hardness and gloss; the oils contribute elasticity, flowing qualities, tenacity and weather resistance; the volatile matter acts both as a solvent and also reduces the viscosity of the mixture to a point where it can be conveniently applied with a brush or a spray-gun, and the oxidizing agents promote the oxidization, or, in other words, the drying of the film. Generally speaking, these four groups of materials are admixed, or fused together, under great heat.

The gums, of which there is a considerable variety, are the resins of trees. Kauri gum is the fossilized resin of the kauri tree, found only in New Zealand deep in the earth; it is an extremely hard gum and is used in varnishes of the highest grade; it has a melting point of about 550°F. Then we have the gums from the Congo, East Indies, Straits Settlements and from many other parts of the world, most of which are bush gums, that is to say, they are the exudations from living trees; lastly, there are the humble resins from Georgia, Louisiana and other southern states. The melting points and other characteristics of these different gums vary within a wide range, and in the design of a varnish formula, gums are selected which will furnish the particular characteristics which the varnish is required to possess.

The chief oils are linseed oil and tung oil. Soya bean oil, perilla oil, menhaden fish oil, rape seed oil and many other oils are also used to a lesser extent.

Paints are usually made by grinding a mixture of pigment and oil through millstones to an extremely fine state and until each particle of pigment is "whetted" or covered with oil. The mixture is then known as paste, and, within the memory of many of us, it was customary to sell paint in paste form to be subsequently thinned out by the user by the addition of oil and turpentine. Nowadays paint is largely sold in a ready mixed form, although the sale of white lead in a paste form still continues to the same degree as in the past.

The body and covering power of a paint is dependent upon the amount and nature of the pigment it contains in suspension, and, as a rule, the finer the subdivision of these particles, the greater will be the body and covering power; thus, it is most important that paint should be thoroughly and carefully ground in the manufacturing process.

In addition to the true pigments, which have been briefly referred to in the foregoing, there are the extenders, such as barytes, silica, whiting, etc. These materials when admixed in oil or varnish are not opaque, but faintly translucent, and consequently they do not impart hiding or covering qualities to the film. At one time they were looked upon simply as adulterations, although there is a school of thought at the present time which believes that these materials, provided they are used in limited quantities, do tend to compact the mass and thus prolong the life of the paint.

Paints on exposure over a period of years may chalk, crack, blister or flake off, and the original colour may also change or even completely disappear. A high-class durable paint for outdoor use should wear well over four years, retain its colour and chalk only to a moderate degree so that on washing down a good surface remains for repainting.

A lengthy discussion took place after the paper, and Mr. Church was asked to describe the making of linseed oil, the difference between boiled and raw oil and other intimate matters.

The meeting was well attended by Lethbridge engineers, Affiliates of the branch and visitors, who enjoyed the music of the Rainbow Orchestra during lunch. Following the lunch, community songs, a violin solo and a vocal solo by Messrs. Vallance and King respectively were enjoyed.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The regular monthly supper-meeting was held in the Y.M.C.A. on February 22nd, at which G. C. Torrens, A.M.E.I.C., chairman of the branch, presided.

Immediately following the supper, the members were favoured with several delightful solos by Mrs. Harold N. Price.

A. S. Gunn, A.M.E.I.C., referred to the recent election of F. O. Condon, M.E.I.C., and F. L. West, M.E.I.C., to the respective offices of vice-president of Zone D and councillor for Moncton Branch, and moved that the congratulations of the meeting be tendered these gentlemen This was seconded by J. G. Dryden, A.M.E.I.C., and carried unanimously. Mr. Condon replied briefly, expressing his appreciation.

The chairman then introduced Mr. E. W. Jeffrey, sales engineer, Northern Electric Company, Halifax, N.S., who addressed the branch on the subject of "Illumination."

Illumination

Until quite recent years, very little progress had been made in the science of illumination. The oil-filled stone jar of the ancients, with its wick of dried moss, was practically the same in principle as the modern kerosene lamp. The invention of the Edison incandescent lamp in 1896 marked the beginning of a new era. The carbon lamp was hailed as a wonderful discovery, as indeed it was. At the same time, it was very inefficient. The next forward step was the coming of the tungsten light in 1907. This lamp, although very efficient, was very fragile, and four years of experiment were necessary to overcome this defect.

Mr. Jeffrey described in detail the manufacture of the tiny tungsten filament, which, it is interesting to note, has a strength nine times that of steel. Tungsten possesses the peculiar property of retaining, or returning to, when cold, the shape into which it was moulded when hot. Thus, a length of filament wire may be moulded hot, afterwards cooled, then stretched straight and wound on a spool. Later, when removed from the spool and the tension released, the wire springs back into the shape required of the filament and it is then ready for insertion in the electric light bulb.

Objections have been made to electric lighting on account of the glare. Frosting the outside of the globe has not been found a satisfactory remedy. The amount of light was reduced and the frosting was easily soiled and scratched. Recently the problem has been solved by frosting the inside of the globe. Not only is the amount of light given off practically the same as that of the clear globe, but there is also an actual reduction in cost.

By means of a demonstration set, the effects produced by direct, indirect, coloured and insufficient lighting were graphically shown. In some of the states of the United States, factories are now required by law to conform to a given standard of lighting. In this connection, Mr. Jeffrey humorously remarked that in certain shops where improved lighting had been found necessary, tools were found that had been lost for ten years.

On the conclusion of the address, Mr. Jeffrey was tendered a vote of thanks, on motion of G. E. Smith, A.M.E.I.C., seconded by B. E. Bayne, A.M.E.I.C.

Visit of the General Secretary

A protracted but exceedingly interesting meeting was held on March 6th, at which members of the branch had the pleasure of meeting the general secretary, R. J. Durley, M.E.I.C., and of discussing with him various matters affecting The Institute, more particularly certain proposed amendments to the By-laws.

The general secretary made very flattering reference to the activity of the Moncton Branch, and commended the members on the interest shown in the welfare of The Institute.

In introducing the subject of the proposed amendment to Section 29 of the By-laws, an amendment sponsored by members of Moncton Branch, Mr. Durley agreed that the whole question of qualifications for the various grades of membership needed careful study. He felt that the requirements as outlined in the By-laws were neither clear nor satisfactory, and suggested that the present proposed amendment be withdrawn so that Council could give more time and consideration to the whole problem.

On the other hand, Moncton members pointed out that the present amendment has been before Council since February 1927,—considerably over a year,—and the feeling was expressed that if no constructive suggestions had been made in that time the better plan would be to try out the proposed amendment. If any defects developed in the working of the amendment, no serious harm could result. The amendment was at least superior to the present anomaly, and engineers were not the men who could not make a third attempt at improvement.

Further to the discussion of the amendment to Section 29, the suggestion was made that, in the case of a candidate making application for admission or transfer, all councillors should be furnished with the opinions of his sponsors. At present, this information is only available to councillors actually present at a meeting of Council. Those unable to attend have only the brief synopsis printed in the Journal to guide them in deciding on the qualifications of a candidate, and this, it was felt, was not enough to enable them to come to an intelligent decision.

The suggestion was also made that when action is taken by Council in connection with an application for admission or transfer, the branch concerned should be notified immediately. The executive committee of a branch has an important part to play in these matters, and it is only right that it should be advised as to the outcome of the cases in which the branch has an interest.

During the latter part of the discussions, light refreshments were served, after which the meeting adjourned.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
W. McG. Gardner, A.M.E.I.C., Branch News Editor.

The New By-Product Coke Plant of the Montreal Coke and Manufacturing Company

(Reported by W. McG. Gardner, A.M.E.I.C.)

On February 23rd, the branch was privileged to welcome a friendly discussion on a most timely subject when Mr. D. G. Munroe, managing director of the Montreal Coke and Manufacturing Company, gave an entertaining and instructive description of the new by-product coke plant now under construction by his company in the town of LaSalle.

In referring to the history of the development of the coke industry, the speaker maintained that even as the production of coke by the bee-hive oven had sprung from the soft coal regions of Pennsylvania, so to-day the Carnegie Steel Company still led the industry with a tremendous plant capable of coking over 30,000 tons of coal per day.

Despite the rapid expansion of the bee-hive coke industry, the growth of the by-product coking plants had been even more phenomenal. From their introduction only thirty-five years ago, they have progressed to equal in production the output of the former early in 1919. Even more striking are the figures for 1926, when of the 520 million tons of coal mined in America, more than 63 million tons were converted to coke by the by-product process, while only 11 millions were utilized in the bee-hive ovens. This marked development in favour of the by-product plant may be appreciated when it is realized that, besides conserving a vast quantity of coal, they provided the industry with by-products valued at some $66,000,000.

However, to derive a profitable advantage from the sale of these by-products, consisting mainly of gas, tar, ammonia and the benzols, it was essential to locate the coking industry adjacent to either a large centre of population or to a metallurgical industry where the products of the plant would be readily saleable.

Such an outlet was being sought in Montreal by the new by-product coking plant situated in the town of LaSalle. This plant, built to utilize 400,000 tons of coal a year, besides providing some 300,000 tons of coke, would produce 5 billion cubic feet of gas and

4 million gallons of tar and 9,600,000 pounds of ammonia sulphate annually.

Owing to the strong market already prevailing in this locality for anthracite coal, it was quite evident that not only must a substitute be eminently satisfactory, but it must also offer an attractive price inducement.

With this object in view, the new plant was designed to utilize carefully selected coals that would yield a coke dense enough to obviate frequent firings, tough enough to withstand rough handling and sized to suit any boiler. Besides these primary qualities, the coke produced must not only be low in ash content, but the ash that is present must be free of any tendency toward fusing at low temperatures.

The coal arriving at the new LaSalle plant, on being unloaded from the barges, is stored in a huge pile by two travelling bridges 300 feet wide. From the pile it is carried on belt conveyors to a hammer mill, where it is pulverized, sufficient pulverized fuel being stored in eight hours to serve the plant in a 24-hour run. The pulverized fuel is then delivered to the fifty-nine ovens through their manholes by a travelling larry.

The long, narrow ovens lined with silica blocks bound with steel are provided on the one side by a ram for pushing out the coke and on the other by a movable car to receive the finished product and carry it to the screens.

The gas, passing off to water-cooled condensers, where the tar is extracted, eventually flows through a lead lined sulphuric acid tank, where the ammonia is precipitated out as ammonia sulphate. Two 6-million cubic feet gas holders store the gas.

The very fine slides and moving picture films with which the speaker illustrated his paper were a feature of the meeting.

In the animated discussion which followed, it was explained that with care the silica linings would last fifteen to twenty years and that the coke weighing 30 pounds per cubic foot must be selected to suit the size of the furnace.

The speaker believed that in a short while coke was destined to be the common fuel.

E. J. Turley, A.M.E.I.C., presiding as the chairman, tendered the vote of thanks, ably moved by Dean H. M. MacKay, M.E.I.C., to the speaker.

Study of Transmission Line Power Arcs

(Reported by N. S. Walsh, A.M.E.I.C.)

A most enjoyable and well illustrated paper of high original merit and outstanding interest was presented to the branch on March 1st by P. Ackerman, A.M.E.I.C., on "A Study of Transmission Line Power Arcs."

The tests which formed the basis of the study were performed by the author at the La Gabelle power house of the Shawinigan Water and Power Company, where the most ingenious arrangements were utilized to control and record these ordinarily ungovernable phenomena.

The study was initiated with a view to determining the main characteristics of these power arcs and to establish a theory that would explain adequately their properties and behaviour.

The theory thereupon developed by the speaker was founded upon the general principle of a heat balance between the heat generated in the arc and that dissipated from its surface. Application of this theory to various combinations of current voltage, insulators and conductors permitted an estimate to be deduced in each case of the pressure and strength as well as of the dimensions of the arc which were then checked by actual observations obtained with oscillograph and kinetograph on artificially created arcs.

The simultaneous acquisition of oscillographic and moving picture records permitted the observations to be preserved, analyzed and studied at leisure.

From the data obtained, it was at this stage possible to reach the following conclusions:—

(a) The duration of the arc does more damage than the value of the current. If the arc is cleared within one-tenth of a second, complete immunity could be expected.

(b) With arcs between parallel conductors wind perpendicular to the lines is the most serious and damaging.

(c) Arcs over suspension insulators usually damage the end units. Arc horns and rings help to protect these units.

(d) Pin type insulators are more sensitive to arc damage than the suspension type because the hot gases are caught under the bottom petticoats and break them.

(e) The arc assumes very large dimensions within one-thousandth of a second.

(f) The pressure during the arc formation is very great.

(g) Arcs tend to spread upward due to a natural chimney effect and are very susceptible to air currents spreading in the direction of the prevailing wind.

(h) There is a fixed relationship between arc voltage, arc current and arc length.

The author emphasized the necessity of clearing a power arc quickly, and stated that the arc voltage is practically independent of the current magnitude, but is proportioned to the length of the arc.

One of the most interesting features of the evening was the slow motion picture demonstration whereby half-second, second and one and one-half second power arcs were lengthened to about five times their duration, rendering their form more easily discernible.

In the discussion which followed, Dr. R. A. Ross, M.E.I.C., and H. Milliken, A.M.E.I.C., drew some interesting comparisons, following which, on a motion of W. C. Adams, M.E.I.C., the chairman, A. B. Rogers, A.M.E.I.C., presented the thanks of the meeting.

Diesel Engines

(Reported by W. McG. Gardner, A.M.E.I.C.)

Following a lucid description of the construction and operation of the "Diesel Engine" before the branch on March 8th, Marc Boyer, S.E.I.C., revealed a wide field of adaptability of this engine as a prime mover to modern industry.

In entering upon his subject, the speaker pointed out that the main difference of the Diesel engine from all other engines employing liquid and gaseous fuels was its method of utilizing the fuel by internal combustion, in contrast with other oil and gas engines, which are, so far as fuel is concerned, strictly speaking, internal explosion engines.

In the Diesel cycle, air alone is compressed to upwards of 500 pounds per square inch and until it reaches a temperature approaching 1,000° Fahrenheit. On the conclusion of this stroke, but previous to the attainment of the dead centre, fuel is admitted gradually in a finely atomized condition during about one-tenth of the working stroke. This fuel is ignited by the prevailing high temperature of the compressed air. There then occurs a gradual burning of the charge which further heats and expands driving the piston outwards. This constant pressure cycle permits 35 per cent of the heating value of the fuel to be directly recuperated in brake horse power at the crankshaft.

With the high temperatures and pressures prevailing in the cylinders of this engine, the pistons, cylinders and cylinder covers are subjected to very high stresses requiring careful study from a metallurgical viewpoint, as well as from that respecting the actual design of these parts.

The importance of this fact in the success and failure of the Diesel engine has now been fully recognized by the metallurgist and the founder.

One of the outstanding features of the Diesel engine is the fuel valve. Of the two systems of fuel injection, known as the air-blast injection and the mechanical or solid injection, the latter has proven its superiority in simplified mechanism and higher efficiency. Unfortunately, it cannot yet be applied to the higher powered units, owing to a deficiency in the inlet velocity, necessary to thoroughly mix the fuel and compressed air. However, research is proceeding and there is reason to believe that this system will be extended, in the near future, to embrace more developments of economical operation.

In the wide field of application for which the Diesel motor is so eminently suited, it is owing to its economy of fuel space and attendance, its high efficiency, low cost of maintenance, absence of ashes, smoke and need for large funnels, reliability and cleanliness of operation, ease of manœuvre and its instantaneous availability becoming increasingly popular for marine propulsion, particularly for submarines.

For stationary installations, these advantages are equally apparent. Its cleanliness recommends it to the flour mill, its high efficiency at any load and overload suits it for application to the peak load problem, and, to the cement mill, its economy of operation has favored its adoption as a source of power for transportation units in both the automotive and the locomotive traction fields. These and other illustrations indicate its great flexibility of adoption to any possible industrial and commercial enterprise.

Following an interesting discussion, H. W. Swabey, M.E.I.C., moved the thanks of the meeting, which was presided over by T. J. Durley, S.E.I.C.

Ladies' Tea

The proposed new club composed of the wives of the Montreal members of The Engineering Institute of Canada held their first tea meeting in the Blue Room of the Windsor hotel on Friday afternoon, March 16th.

The seventy ladies present were received by a committee consisting of Mrs. Geo. R. MacLeod, Mrs. J. L. Busfield and Mrs. W.

C. Adams. The remaining member of the committee, Mrs. F. C. Laberge, was absent on account of illness in her family.

Mrs. MacLeod, who presided, described the aims and objects of the proposed club.

For the present, the activities will be purely social. The next meeting will be in April, and, following that, in October there will be a business and organizing meeting.

The tables were artistically decorated with spring flowers provided by branch members.

Niagara Peninsula Branch

Walter Jackson, M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

On February 24th, the Branch had a dinner meeting and evening business session at the Hotel Dexter in Welland city. The local Lions Club also happened to be meeting there at the same time and quite a few of the Lions remained to hear the addresses.

A "roar" was given for the engineers and one of our most prominent members participated. The exact ethics of an Engineering-Lion "roaring" for himself as an engineer is being hotly debated. The question being as to whether he should not also join in the applause for his roar.

After dinner a short business session was held and among other things the scrutineers announced that the recent amendments to the branch by-laws were adopted by a vote of 35 for and 3 against.

Congratulations were extended to A. J. Grant, M.E.I.C., upon his recent election to the vice-chairmanship of the Institute for Ontario and to M. B. Atkinson, M.E.I.C., as councillor representing the branch.

The branch recorded an approval of the action taken by the Toronto Branch in withdrawing from the vice-presidential contest this year with the expressed intention of assisting the membership in electing to this office a nominee from one of the numerically smaller branches.

Grand Falls, Hydro-Electric Development

Gordon Kribbs, M.E.I.C., of H. G. Acres and Company, was the intended speaker on the subject of Grand Falls development, but at the last minute he was unavoidably detained and his place was filled by Messrs. J. C. Krumm, H. E. Barnett, JR.E.I.C., A. W. McQueen, JR.E.I.C., and W. D. MacDonald, S.E.I.C., all of whom belong to the same organization,—filled most successfully, judging from the interest shown and the number of questions that were being asked.

Mr. Krumm began by giving a general description of the plant illustrated by a very fine set of lantern slides. The stream flow at Grand Falls, he said, is very fluctuating with a minimum flow of 800 c.f.s and maximum 133,000 c.f.s, thus requiring considerable storage capacity for the operation of the plant. Storage is now being developed for three units at 20,000 h.p. with two units installed, provision for two similar units in the future and a potential capacity of seven or eight units, when sufficient storage can be made available.

There is a head of 132 feet available at Grand Falls with a tunnel about 2,700 feet in length. The single tunnel already built is of horse-shoe shape with a nominal diameter of 24 feet 6 inches. It will serve the first four units.

The head works include a dam with nine Stoney sluice gates, each 23 feet high and 50 feet wide, as well as two gates 24 feet wide between concrete piers. The wide gates are controlled by a travelling hoist and the two smaller gates each by a stationary hoist, the intake is of the Johnson-Wahlman draught distributor type, consisting of two concrete tubes extending for a distance of 160 feet in opposite directions from the tunnel, carrying the water to the power house. The tubes are throughout their length provided with a slot for admission of water, the width of which gradually decreases from the end of the tube towards the tunnel entrance, thus providing equal draught throughout the length of the tube and also an even distribution through the rack.

At the lower end of the tunnel and immediately behind the power house stands the huge differential surge tank 73 feet in diameter and 37 feet high, with a capacity of approximately 1¼ million gallons. This tank is also one of the notable features of the plant. It is supported on a tower consisting of eighteen columns, 95 feet high, built of H-section, and provided with adjustable bracing to be finally tightened when the tank is filled to normal operating water level.

The external riser connecting the penstock with the bottom of the tank is 21 feet in diameter. Inside the tank and concentric with the external riser is an internal riser of 19 feet in diameter. This extends for a certain distance down into the external riser, leaving an annular opening, through which water can enter or leave the tank. This opening, or port, is so proportioned that under load changes an artificial—differential—head is created to accelerate or decelerate the flow of water in the tunnel within a predetermined limit of head variation.

Extreme precautions were taken to prevent any frost action both at the top of the tank and at the penstock junction. The sides, however, were left more or less unprotected, as experience has proved that a maximum of six inches of ice would form and this would not seriously interfere with the proper performance of the tank.

Mr. McQueen explained the details and operation of this surge tank and also the newest type of water seal, which was used in conjunction with the butterfly regulating valve at the power house.

The valve disc is set about 1/16 inch clear of the housing. In this is a recess which holds the rubber hose ring seal. The hose is prevented from collapsing by means of an internal spiral spring. When the valve is shut, water pressure is let into the hose, thus expanding it and closing the 1/16 inch opening. Tests have shown this type of seal to be highly successful.

Mr. Barnett dealt with both the political and economic phases of water power development in New Brunswick and questions as to the electrical equipment were answered by Mr. MacDonald.

E. C. Cameron, A.M.E.I.C., who was in the chair, thanked the speakers most cordially on behalf of the branch and took occasion to say that the scenery along the St. John valley was particularly fine and worthy of inspection if any member ever happened to be motoring through that part of Canada.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Ottawa Branch activities in the past month included three Thursday luncheons at the Chateau Laurier, at which the speakers were:—Wyatt Malcolm, of the Geological Survey, Department of Mines; Col. David Carnegie, C.B.E., F.R.S., and A. C. Fieldner, Member, American Chem. Soc., chief engineer of the Experiment Stations Division, United States Bureau of Mines.

On February 23rd, Mr. Malcolm, who is chief of the Division of Geological Information in the Geological Survey, described the trip which he made to Newfoundland with the Empire Mining and Metallurgical Congress last summer, and gave the members first-hand information on the mining resources of that country.

Mining Resources of Newfoundland

Newfoundland, Mr. Malcolm said, now has a population of about 263,000, and its largest city, St. John's, has 40,000 inhabitants. Touching on the geological history of the island, he described it as a peneplain with a structural trend to the northeast descending from an altitude of 2,000 feet at the west to 700 feet at the east, with a westerly coast line indented by deep fiords of picturesque beauty and an east coast of numerous peninsulas and long bays.

The Congress party crossed over from Sydney, Nova Scotia, to Port aux Basques and travelled across Newfoundland by railway. They were given excellent opportunities for studying the resources of the island, the extensive stands of timber, the pulp and paper industries at Corner Brook and Grand Falls, the water powers, etc.

The minerals of Newfoundland, Mr. Malcolm said, consist of iron, lead and zinc, copper, pyrites, limestone, gypsum and coal. At Buchan's mine there are extensive deposits of lead and zinc. The American Smelting and Refining Company had entered that field and is carrying on electrical prospecting. Development work to date has indicated 3,000,000 tons of ore, carrying 3 ounces of silver to the ton, 2 per cent copper, 7 per cent lead and 16 per cent zinc. A concentrator is being erected to handle 600 tons per day. Very wonderful developments in zinc, lead and copper might be expected, Mr. Malcolm thought, if an active campaign of prospecting was undertaken similar to that in Ontario and Quebec.

The greatest mineral wealth yet disclosed in Newfoundland was, however, the great Wabana or Bell island iron ore deposits, which had been worked for 30 years and there was still not the slightest indication of any exhaustion. There was no danger, the speaker said, of these deposits being exhausted in the present generation. Sea erosion had stripped all but a remnant of the red hematite iron ore from Bell island, but the strata dip under Conception bay and the iron is recovered in extensive submarine mining operations, which Mr. Malcolm described in considerable detail. The limit of recoverable ore will depend on the distance to which submarine mining can be carried, and the ore had been estimated at 3,500,000,000 tons to a distance of five miles. This year's programme calls for taking out 1,300,000 tons, 800,000 tons of which are for Germany, 400,000 to be shipped to Sydney, Nova Scotia, and 100,000 tons elsewhere. There are three ore beds, in thickness ranging from 5 to 8 feet, 7 to 10 feet and 13 to 24 feet. These beds are separated by sediments 58 feet and 240 feet in thickness. Submarine mining is carried on for 1 to 2½ miles under the sea.

Dr. Chas. Camsell, M.E.I.C., chairman of the Ottawa Branch, presided and extended the thanks of the members to Mr. Malcolm for an interesting and instructive address.

Armaments Problem

On March 1st, Col. David Carnegie was the guest of the Ottawa Branch, and delivered a forcible address on the "Armaments Problem from the National and International Viewpoint." Col. Carnegie is well-known to Ottawa members through his work during the war as technical adviser to the Canadian government in the manufacture of munitions. He was the Canadian member of the Temporary Mixed Commission for the Reduction of Armaments, 1921-24, and has recently been engaged in giving a series of addresses in England for the League of Nations Union.

Introduced by Dr. Chas. Camsell, in the chair, Col. Carnegie declared that there is a very serious danger of a repetition of 1914 unless armaments are reduced. During the war he had been engaged in munitions work, not for war, but to help to put out the conflagration in Europe, and he saw danger of another conflagration for which the faggots were being piled in international competition in armaments. "There is a limit," the speaker said, "beyond which armaments provoke war, and it was the function of the League of Nations to keep within that limit."

Col. Carnegie outlined the efforts of the League to establish a just basis for the reduction of war armaments. A certain amount of armament was necessary for protection of trade routes; the problem was to find an equitable limit for each nation and to get them to agree to it. As it is now, Nation A builds certain armament and Nation B, through fear, immediately embarks on a building programme, not of equal strength, but adding an increment claimed to be necessary for her own safety, and so the process goes on. Human nature, Col. Carnegie contended, had not changed a bit.

The failure of the League to establish a just basis for reduction of armaments was ascribed by the speaker to three underlying causes:—non-ratification of the Treaty of St. Germain; the subsidizing by governments of the public and private manufacture of poison gas, and the freedom of the seas. Referring to the latter, Col. Carnegie contended that Great Britain was no longer able to exercise what she considered her right to search and blockade, owing to the introduction of aerial warfare, and considered that the right of blockade should be relinquished to the League of Nations.

Col. Carnegie made a strong plea for the adoption by Great Britain and Canada of the optional clause, which recognizes the jurisdiction of the Permanent Court of International Justice in any classes of legal disputes, the interpretation of a treaty, any question of international law and the nature or extent of the reparation for the breach of an international obligation.

"The public mind in Great Britain," stated Col. Carnegie, "is not yet adjusted to the acceptance of a third party judgment." The speaker stressed the fact that Canada was devoid of entangling relations with neighbours, and without any armament along her frontier has for years settled all her disputes by arbitration. These were given as reasons why Canada should accept the optional clause. It had been accepted by twenty-eight nations, but there is not one state within the British Empire which has signed it. That is why a campaign is going on all over Britain "to shake from the minds of the people the stubborn idea that they are so superior to justice itself." The acceptance by Canada of the optional clause would, Col. Carnegie thought, have a far-reaching effect on Great Britain.

Experimental Stations, United States Bureau of Mines

On March 15th, A. C. Fieldner, chief engineer of the Experiment Stations Division of the United States Bureau of Mines, was the guest of the Ottawa Branch, and gave the members a comprehensive outline of the research work carried out under his supervision.

The speaker was introduced by Dr. Charles Camsell, M.E.I.C., in the chair, who feelingly alluded to the generous and prompt action of the Pittsburgh Experiment Station in forwarding by special train a car equipped for mine rescue work to Porcupine at the time of the disaster at the Hollinger mine.

Mr. Fieldner traced the history of the formation of the experiment stations, which now number eleven, the Pittsburgh station, the oldest and largest, owing its inception to a realization of the necessity of taking adequate steps to safeguard coal mines. At Pittsburgh, stated Mr. Fieldner, there is a staff of 250 research workers; at Bartlesville, Oklahoma, 60, and at the remaining nine stations an average of 6 each.

The Pittsburgh station is engaged primarily in research problems relating to coal and coke. The field of work covers mining and utilization, and includes safety and efficiency or the reduction of waste so as to conserve coal as a natural resource. The safety work of the experiment station is not entirely confined to mines, and, in fact, Mr. Fieldner said, was much in demand outside. A great many studies centered around carbon monoxide—the dangerous product of incomplete combustion. He said that through the work of the experiment station apparatus had been perfected which would determine the proportion of carbon monoxide in air to 1/1,000 of one per cent. The instruments had been installed in the new vehicular traffic tunnel under the Hudson river at New York, and gave the engineers absolute control of atmospheric conditions at all times. At times, when traffic is light, the volume of air supplied to the tunnel can be curtailed and again increased for rush hour traffic—this control being possible with safety due to the carbon monoxide indicators. The economies effected in power consumption, in the opinion of the engineers, would pay for the installation in the first year. Tetraethyl lead was investigated as to toxicity at the Pittsburgh station, this at the request of General Motors Corporation. Mr. Fieldner said that the station frequently carried out investigations for private interests at the expense of the applicant, but that such research work must be on broad problems of public interest and with the understanding that the researches will be published.

The station at Bartlesville, Oklahoma, in which 60 research workers are engaged, is for petroleum research. The other nine stations are what are termed "Foster Experiment Stations," Mr. Fieldner said, because they were provided for under the Foster Act. They are located in close proximity to the mining fields. They work in co-operation with the state, which supplies part of the appropriation, and they are usually located at the state university, but control rests with the federal Bureau of Mines.

Mr. Fieldner closed his talk with a sketch of the investigations at present being carried on at these Foster Experimental stations, and stated that a great deal of valuable assistance had been given to the mining industries through this decentralized system of handling research in stations close to the industry. The list of stations and their principal work was stated by Mr. Fieldner to be:—Minneapolis, Minn., iron ores, beneficiation, reduction of slag, blast furnace problems; Mosco, Idaho, concentration problems of Coeur d'Alene ores; Seattle, Wash., clays and non-metallic minerals, coal washing; Berkeley, California, physical constants, metal oxides and sulphides, metallurgical processes; Reno, Nevada, rare and uncommon minerals, research on gold, silver, platinum, etc.; Salt Lake, Utah, flotation problems of lead-silver, lead-zinc and copper ores; Tucson, Arizona, low-grade copper ores, leaching, reaction in converters; Rolla, Missouri, ore dressing problems, lead and zinc ores; Tuscaloosa, Alabama, beneficiation of low-grade bauxite, flotation of low-grade phosphate ores, coal washing.

Fuel Station to Operate in Ottawa

Dr. Camsell, in thanking the speaker for his interesting address, stated that the Dominion government had set aside $100,000 for the erection of an experimental fuel research station in Ottawa destined to be the most complete of its kind under one roof in North America. It would be in operation next fall, he said, and its erection had been made possible through the interest manifested by Hon. Chas. Stewart, Minister of Mines.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

The usual fortnightly meeting of the branch was held on Thursday, February 23rd, the speaker being B. E. Norrish, M.E.I.C., managing director of the Associated Screen News, Limited, Montreal. His subject was "The New Era of the Motion Picture." This meeting was somewhat of a departure from the usual engineering subjects, but Mr. Norrish pointed out several instances where the motion picture camera could be utilized by engineers and others in developing particular lines of business.

The New Era of the Motion Picture

Mr. Norrish stated that we are entering a new era of the motion picture in which it is about to be discovered as a new tool of general utility. The time is near at hand when an understanding of the capacities of the camera and the projecting machine is likely to be as fundamentally important to the engineer and the industrialist as the table of logarithms or any of the common instruments of applied science. Fundamentally, the motion picture is but the most recently evolved of a long line of instruments of expression and record, running through history from the stylus, pen, brush and printing press to the evolution of the camera.

The speaker mentioned that until recently there was a continual striving towards more powerful light sources for the taking of motion pictures, but due to the development of illumination we now have all the light necessary for this purpose. Moreover, the film emulsions are now many times more sensitive than those in use years ago. Lenses have been developed to admit eight or more times as much light as formerly.

In the purely mechanical aspects of the camera and the cinema machinery we are already pretty close to perfection. The best of our cameras now work to precision limits well within one ten-thousandth of an inch. Something of their accuracy may be understood from the fact that a single negative can be put through a camera ten times for a series of multiple exposures and yet so perfectly register each of those exposures with reference to the others that the picture is steady within itself as though it had all been exposed at one passage through the mechanism. This accuracy is made necessary because of the tremendous magnifications to which the picture is subjected in screen projection. The tiniest error casts a vast shadow of itself on the screen.

At the close of the lecture, Mr. Norrish showed several short films illustrating very well the points he had brought out in his paper. An interesting discussion concluded the evening, and Mr. Norrish was accorded a hearty vote of thanks.

Presentations to Students

At the regular meeting of the Peterborough Branch held on Thursday, March 8th, 1928, several presentations were first of all made by the chairman, A. E. Caddy, M.E.I.C. Messrs. M. C. Lowe, S. J. Hayes and O. T. Foulkes, Student members of the branch, were presented with Institute badges for having prepared and delivered papers before the branch at a recent meeting. W. T. Fanjoy, S.E.I.C., was then presented with The Institute prize for his paper on "Controls of Common Types of A.C. Motors," which was given last year and entered for the Student prize competition. This presentation was made by B. L. Barns, M.E.I.C., past-chairman, who instituted the Student Section of the Peterborough Branch. Mr. Barns called attention to the honour reflected on Peterborough Branch through the winning of the prize by Mr. Fanjoy. The recipient, in reply, expressed the hope that the prize might come to Peterborough again in the future. He had derived real benefit from the work of preparing the prize-winning paper.

The Lengthening of Niagara Falls

The speaker of the evening was Mr. W. K. Bradbury, of the Public Relations Department of the Niagara Falls Power Company, his subject being "The Lengthening of Niagara Falls" and covering the proposed remedial works for the preservation of the natural beauty of the falls. The speaker used a large number of very fine lantern slides to illustrate his address. He commenced with the progress of the Niagara Falls Power Company from 1906 to the present time, pointing out the various additions to the power plant during that time. A detailed description of the most recent extension, including the three 70,000 h.p. waterwheel units, both during construction and on completion, was given. The illustrations of this plant during construction gave a good idea of the magnitude of the undertaking.

Pictures of other power plants, both on the Canadian and American sides, were in turn explained, and the speaker passed on to discuss the problem of preserving the natural beauty of the American and Canadian falls. By diagrams, pictures and finally by showing a model of the entire district, built to scale, Mr. Bradbury told of steps necessary and feasible whereby the constant wearing away of the Horseshoe falls might be checked, and concluded by answering a number of questions from his auditors, ranging from inquiries for technical details to his opinion of the Chicago water diversion.

A hearty vote of thanks was accorded the speaker at the close of the meeting.

St. Maurice Valley Branch

Romeo Morrissette, A.M.E.I.C., Secretary-Treasurer.

At a meeting of the St. Maurice Valley Branch held at Grand'-Mere on January 21st, 1928, an interesting address was given by Mr. J. S. Riddile.

The speaker dealt with various features of modern water power development and referred to the improvements in the design of hydraulic equipment; the greater control of the run-off of streams; and the proper design of plants to ensure the full use of the maximum power available as items which have greatly increased the efficiency of power developments and thus provided much greater returns to the operating companies. He also discussed briefly the excellent research work which is being carried on through experiments with modern equipment.

A Glimpse of Our Rivers Through the Eyes of the Law

On March 17th, Hector Cimon, A.M.E.I.C., engineer, Price Brothers and Company, Limited, Quebec, presented before the branch a very interesting paper entitled "A Glimpse of Our Rivers Through the Eyes of the Law." After briefly outlining the present stage of development of the water power resources, the speaker gave various extracts from the Statutes in order to explain the principles and laws which govern the administration of the rivers in the province of Quebec. He then explained the present practice of the government in granting power rights.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting was held on Friday, February 24th, in the Y.W.C.A. rooms.

W. S. Wilson, A.M.E.I.C., the chairman, called the meeting to order, and, the regular business being completed, he gave a brief account of his trip to Montreal when he attended the Annual General Meeting held in February, and while there he met several of our old members who are now in and around Montreal.

The Legal Aspect of a Contract from an Engineer's Standpoint

The speaker, Mr. H. S. Hamilton, of the firm of O'Flynn, Hamilton and Carmichael, solicitors, of this city, gave an address on "The Legal Aspect of a Contract from an Engineer's Standpoint." He used as a basis the "Laws of England" by the Earl of Halsbury and followed through a building contract in relation to the engineer and architect. After carefully explaining the preliminary work and specifications which lead up to the letting of a contract, he said that "A tender or bid is an offer from a contractor to owner, and once accepted it becomes a binding and legal contract and must be carried out by all parties concerned; also, that a contract in writing must be varied only by a written agreement by both parties and that municipal corporations are governed by statutory laws in regard to contracts."

A lengthy discussion followed and all the members and guests took an active part in it, many interesting local cases were aired and Mr. Hamilton was kept busy answering and explaining questions. Messrs. Seymour and Ross moved a hearty vote of thanks to Mr. Hamilton for his splendid address.

Toronto Branch

W. B. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. W. Falkner, A.M.E.I.C., Branch News Editor.

The Requirements for a Durable Concrete as Observed from Structures in Service

Owing to the Annual General and Professional Meeting held in Montreal from February 14th to 16th, 1928, the regular meeting of the Toronto Branch was postponed from Thursday, February 16th, to Thursday, February 23rd, when the chairman of the branch, R. B. Young, M.E.I.C., presented, before a good attendance of the branch, the same paper presented by him a week previously before the Annual Meeting at Montreal, the subject being "The Requirements for a Durable Concrete as Observed from Structures in Service."

The speaker dealt with his subject in a most interesting and useful manner, first reviewing our present knowledge regarding the action of the various natural destructive agencies on concrete as revealed by structures in service, and then pointing out the important part that porosity plays in each of these. The conclusion was reached that much of the lack of durability displayed by concrete structures is preventable by the exercise of ordinary care in the selection of the concrete materials, and by the use of right methods of protection. The paper was well illustrated with numerous slides showing structures in excellent condition after 25 to 60 years of service, and also by numerous slides showing different types of concrete deterioration, the reasons for which were explained in detail. No more than a summary of the paper will be here given, as the paper was printed in full in the March issue of the Journal.

The interest taken by the membership in the paper was exemplified by the live discussion and the numerous questions put to the speaker following his paper, after which Geo. A. McCarthy, M.E.I.C., moved a hearty vote of thanks to the chairman for his paper, mention being made that while Mr. Young had not this year given a chairman's address to open the season's work, he had now more than made up for the deficiency by the paper he had given. The motion was enthusiastically carried by the meeting, and at the unanimous request of the members was presented by the chairman, (in his capacity as chairman), to the speaker, (in his capacity as speaker).

Tendencies in Steel Building Design

(*Reported by G. A. Tobias,* A.M.E.I.C.)

The feature of the regular meeting on March 1st, 1928, was the presentation by D. C. Tennant, M.E.I.C., designing engineer of the

Dominion Bridge Company, Montreal, of a highly interesting paper dealing with "Tendencies in Steel Building Design," the meeting being preceded by a well-attended dinner at the Faculty Union, Hart House, to welcome the speaker. A large number of members were present, and L. W. Wynne-Roberts, A.M.E.I.C., was chairman of the meeting, owing to the unavoidable absence of R. B. Young, M.E.I.C.

Mr. Tennant first traced the development of steel as a building material, from the early days, when metal structures were composed almost exclusively of wrought iron, showing that gradually iron was displaced by carbon steel, until at the beginning of the twentieth century the use of iron for this purpose had been almost wholly discontinued. At the present time, alloy steels have made their appearance and have been incorporated to a small extent in structures.

Certain of the structural shapes evolved at the beginning have persisted to the present, whereas many others have become obsolete.

The steady increase in the design stress, as improvements took place in manufacturing and fabricating methods, was clearly shown by reference to various bridge and building specifications which made their appearance as the use of structural steel developed.

The speaker laid emphasis on the great divergence in the building code regulations prepared by various municipal and technical bodies, but while stressing the importance of uniformity, he pointed out the dangers of too much standardization.

Up to this point, Mr. Tennant's paper dealt with structures in general, but, to be more specific, he stated that he wished to confine his further remarks to high buildings in particular.

A comparison of the building codes of twelve large cities would show very little variation in the unit weights specified for dead loads; but a similar comparison, made on the basis of unit live loads, and permissible reductions therein, unit stresses for dead and live loads, wind loads, and allowable stresses for same, indicated a wide discrepancy.

The various points referred to were brought out clearly by slides thrown on the screen.

To illustrate some of the results brought about by applying different theories of wind stresses, Mr. Tennant quoted from the words of a chief engineer of a large fabricating concern, who points out "that, of four large buildings passing through our shops, in one case, where the wind bracing might be called reasonable and sufficient, the provisions for taking care of the wind stresses were about twelve per cent by weight of the connecting beams and girders, whereas in another building, designed for a similar purpose, these extra provisions for taking the wind stress were about five times those carrying the vertical load, and the total beam connections were nearly forty per cent of the weight of connecting beams and girders." A considerable difference, indeed !

Mr. Tennant then spoke of the general problem of ascertaining the amount of horizontal shear, both transversely and longitudinally, transmitted from floor to floor, and the part played by each unit of the structure in transmitting this shear.

The effect of the wall and partition resistance, their bond to the steel work, the assistance given the steel skeleton by the concrete, were matters of uncertainty, and, in the opinion of the speaker, called for further research work to establish the validity of the assumptions upon which our present analytical methods are based.

Each high building brought its own problems, due to different limiting conditions, and it was not to be expected that any one method of solution would find a universal application.

An illuminating example then followed of the wide difference in results to be expected from applying the regulations of three different building codes to the design of a given structure. A hypothetical twenty-one storey office building was chosen, of regular outline and uniform column centering in both directions. All assumptions were simplified in order to carry out the designs, three of which were made, one each in conformity with the codes of Winnipeg, Montreal and Toronto. The columns were designed to Bethlehem sections, and the beams to the new Carnegie sections. The Winnipeg code gave a structure showing the lowest unit weight, or 1.1 pounds per cubic foot. Montreal came next with 1.16 pounds, whereas Toronto code gave 1.38 pounds, or a variation between Toronto and Winnipeg of 25 per cent. These unit weights were comparative only, inasmuch as simply the steel skeleton proper had been considered, whereas the supplementary features of the building, such as stairs, cornices, pilasters, corbels, etc., would add considerably to the weight. These, however, would be common to each design and would not affect the relationship of the unit weights to any extent.

Mr. Tennant had suggested before commencing his paper that it might be better for discussion to take place during the reading of the paper, and in the discussion which ensued at this juncture, attention was drawn to the economic significance of these figures by J. M. Oxley, M.E.I.C. The rigid application of the provisions of a building code of an unduly conservative nature imposed a severe burden on the building industry. Capital seeking investment looks askance at high building costs. Manufacturers in weighing the advantages of this or that city considered the capital outlay required for building, and any city in which too severe regulations prevailed would find itself hampered in attracting new industries.

The speaker then mentioned alloy steels and pointed out the conditions under which their use could be made profitable.

The uses of welding in fabrication were next considered, and results were given of tests made at the Rensselaer Polytechnic Institute and also in the Dominion Bridge shops at Lachine. It was stated that research in welding has not yet progressed to a point where it is possible to safely establish working unit stresses for tension and transverse shear in welded joints, but that the future for this recent development in fabrication seemed very bright, and those engaged in research in this field were doing a work for which all engineers should feel thankful.

An interesting discussion ensued, but the speaker having arranged to catch the night train, it unfortunately became necessary to curtail the discussion, and the presentation of a vote of thanks to the speaker closed a most successful meeting.

Modern Building Regulations for Reinforced Concrete

(Meeting reported by F. N. D. Carmichael, A.M.E.I.C.)

The regular meeting of the Toronto Branch was held on Thursday, March 15th, in the Mining Building, University of Toronto.

Previous to the meeting a dinner was given at Hart House, where a number of members of the branch, as well as several guests from Brantford, Hamilton, St. Catharines, Niagara Falls, etc., and also representative architects, availed themselves of the opportunity to meet the speaker of the evening, F. R. McMillan, director of research, Portland Cement Association, Chicago.

At 8.15 the meeting was opened, with one hundred members present and R. B. Young, M.E.I.C., chairman of the branch, presiding, who introduced Mr. McMillan, and an intensely interesting paper followed, the subject being "Modern Building Regulations for Reinforced Concrete."

Mr. McMillan summarized the steps, covering a number of years and embracing a vast amount of research work, which resulted in previous standard codes and finally in the proposed Standard Building Code for Reinforced Concrete, which was presented in February of 1928 at the Convention of the American Concrete Institute, Philadelphia. This code was prepared jointly by the American Concrete Institute and the Concrete Reinforcing Steel Institute.

The problem of a standard code is extremely complex, more so than for the older forms of construction, due to (1) the comparative newness of this form of construction, (2) the various ways or systems of construction, (3) the rapidly accumulating test data relating to reinforced concrete.

The value of such a code is readily seen, as at present practically every city works on different regulations and a standard code would serve as a basis for the different cities to revise their regulations in keeping with the times, tending to bring more consistency of design in the various parts of the country.

Some outstanding variations from the Joint Committee and other reports were dealt with very capably by Mr. McMillan.

The new regulation for load tests calls for less live and dead load, but requires more rigid attention to the duration of the test, the amount of permanent distortion and the percentage of recovery after the removal of the test load.

The importance of competent inspection by the owner, which would be certified for the benefit of the local building department, is very apparent, as it is impossible for the various building departments to superintend everything.

In respect to the quality of concrete, full recognition is given to the definite dependence of the concrete strength on the water-cement ratio, and with this ratio fixed the proportions of aggregates are fixed by the requirements of consistency and placing.

Unit stresses in concrete are in accord with the Joint Committee, with the exception of a higher shearing stress under certain conditions, the requirements being certified inspection as to placing of reinforcing by the designing engineer.

The unit tensile stress in reinforcement has been raised to 20,000 pounds per square inch for intermediate grade of billet steel and rail steel reinforcing bars.

The design assumptions vary from present methods in regard to the value of "n" and for negative moment in end spans slightly restrained.

Changes have been made in the method of computing the safe load on steel columns encased in concrete, and also in that of spiral columns, where the requirement is that the spiral reinforcement shall always be 25 per cent of the longitudinal to insure an increasing amount of lateral reinforcement with increasing loads and unit stresses.

At the conclusion of the paper the meeting was thrown open to general discussion and some very appropriate points were raised which Mr. McMillan answered to the satisfaction of the large and interested audience. After a hearty vote of thanks to the speaker, the meeting was adjourned.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

A regular meeting of the branch was held at the University Club on February 15th, at which W. L. Ketchen, M.E.I.C., gave a most interesting paper on "The Manufacture of Bleached Sulphite Pulp on the Pacific Coast of British Columbia."

The Manufacture of Bleached Sulphite Pulp on the Pacific Coast of British Columbia

Mr. Ketchen described briefly the preliminary information necessary before a site for a mill can be decided upon, and then went into the different features entering into the choice of equipment and the marketing of the product. He dealt at some length with the pulp wood resources of the province of British Columbia, and explained briefly the process of manufacturing bleached sulphite pulp, describing in turn various types of equipment used in such a mill.

In closing, he emphasized the importance of the research work which is being carried on in order to find new and profitable uses of the by-products and cellulose.

Executive Committee Meeting

During the period from February 8th to March 14th, one meeting of the executive committee of the branch and five regular meetings of the Student Section of the branch were held, the latter being reported elsewhere.

At the executive committee meeting which was held on February 17th, the subject uppermost in the minds of the members was the forthcoming Western Professional Meeting to be held June 7th to 9th, 1928. Great interest is being taken in the meeting, and preliminary organization work is being undertaken.

Student Section of the Vancouver Branch

The Student Section of the Vancouver Branch has held a number of interesting meetings since its formation, some of which were reported in the last issue of the Journal. The officers of this section are:—E. Bebb, president, J. H. Legg, S.E.I.C., vice-president, and A. Peebles, S.E.I.C., secretary-treasurer.

The Major Street Plan for Greater Vancouver

At the Students' Section meeting, held on Wednesday, February 8th, at the University of British Columbia, the speaker was A. E. Foreman, M.E.I.C., chairman of the Major Streets Committee of the Vancouver Town Planning Commission. His subject was "The Major Street Plan for Greater Vancouver." Mr. Foreman gave the audience a clear insight into the future of Vancouver from a population and traffic standpoint and of the future conditions of traffic density in this city. He showed the necessity of meeting these conditions in the present by means of a liberal street development. The cost of such development, while appearing considerable just now, would be negligible compared with the future cost after the streets have been built up. This was illustrated by examples from large cities which are now experiencing this problem. Mr. Foreman illustrated the street planning in Vancouver on the screen.

About 60 students and members of the faculty were present.

Rail and Water Transportation Facilities of Vancouver

At the meeting held on Wednesday, February 15th, at the university, the speaker was H. L. Seymour, M.E.I.C., who gave the scheduled lecture on "Rail and Water Transportation Facilities of Vancouver." This address was to have been delivered by Major W. G. Swan, M.E.I.C., who was unable to be present. The president read a letter from Major Swan expressing regret at his absence and promising to address the club in the near future.

Mr. Seymour undertook to give the address on very short notice, but he gave a clear view of the harbour possibilities of Vancouver, and also of the plans of the Town Planning Commission to regulate this development. The lecture was illustrated by a number of lantern slides.

About 70 students and members of the faculty were present.

Address on Forestry

At the meeting held on Monday, February 21st, at the university, the speaker, Dr. C. A. Schenck, was introduced by Prof. H. R. Christie. Dr. Schenck is a well-known German forestry expert who is at present making a tour of North America. He gave a very interesting address, partly informative, partly philosophical, showing how he combined philosophy with study and teaching. His remarks on forestry were general and designed to reveal it in the light in which it should be regarded. In closing, he warned the people of British Columbia to protect their forests or they will be left with barren wastes, which is all that remains of some of the mediæval European forests.

About 120 students and members of the faculty were present.

Bridges, Ancient and Modern

At the meeting held on Wednesday, February 29th, at the university, the speaker was Mr. Robert Bayliss, civil engineering graduate of the University of British Columbia, who gave a lecture on "Bridges, Ancient and Modern." By means of lantern slides, Mr. Bayliss showed the developments in bridge building from ancient times down to the present. He illustrated the various types of bridges and showed also some of the famous bridges of the world.

About 50 students and members of the faculty were present.

Enlarging the Capacity of City Streets

At the meeting held on Thursday, March 8th, at the university, the speaker, J. C. Oliver, S.E.I.C., civil engineering graduate of the University of British Columbia, gave a very interesting address on "Enlarging the Capacity of City Streets." Mr. Oliver treated this problem from the standpoint of ways and means of relieving existing traffic congestion. He indicated the various methods adopted under various circumstances to meet this situation, and showed cases where such methods are being carried out. The speaker presented some real information, which will be valuable to all those fortunate enough to be present.

The lecture was illustrated by excellent lantern slides. About 75 students, members of the faculty and visitors were present. The chairman announced a trip of inspection for those interested to the Harbour Board grain elevator and Ballantyne pier.

Examination of High-speed Rotor Forgings

Most of the defects and irregularities of forgings are found, in an accentuated degree, in larger forgings, and consequently, attention is directed first to the very large forgings such as are required for the field rotors of turbo-alternators. The quality of a forging is determined very much at its birth, i.e., at the ingot, and in order to appreciate the purpose of some of the tests made at a later stage, it is desirable to notice some of the more common birth-marks. The problem of the heterogeneity of steel ingots is now being investigated by a sub-committee of the Iron and Steel Institute, with the co-operation of the leading steel manufacturers of this country, and a valuable report has already been issued.

Defects most likely to arise are due to segregation cavities and slag inclusions, and methods of test must be employed which will ascertain the degree to which these are present.

No steel-maker can guarantee the axial soundness of a large ingot, and therefore all high-speed rotors should be bored and the bore closely inspected for defects. The usual inspection is made by means of a periscope, of which various forms are available.

This visual inspection, where necessary, is supplemented by sulphur printing, and magnetic testing may, in special cases, be applied with advantage. Further, in all important cases, a core is trepanned from the rotor in the boring process. This core is carefully inspected visually, microscopically and by means of physical tests. Periscopic examination reveals cavities, slag inclusions and other discontinuities in the metal, and sulphur printing shows whether what may appear to be small isolated cavities or irregularities are parts of a large cavity which has been closed up by forging. This examination and the tests upon the core, taken in conjunction, enable the axial soundness of a rotor forging to be judged. The other tests found soundness are made at the outside and ends of the forging, and, apart from physical tests, consist in visual inspection and sulphur printing.—*Engineering.*

Britain and Canadian Commerce

The activity in Canada is astonishing. This autumn she has harvested a wheat crop which, if not a record, is said to have been better than that of any previous year but one. Her output of electrical power is increasing by giant strides. The year 1926 showed an increase in total business of 14.5 per cent over that of 1925, the United States showing only one-third of this rate, though, of course, on a larger total. Sales of stocks and shares in Canada in 1926 increased no less than 56.5 per cent, and of bonds no less than 14 per cent, while in the United States in the same period the former increased by only 4 per cent and the latter actually decreased by 13 per cent. Building contracts showed a growth of 25 per cent, and the production of coal a like increase. How important in the world this scion of our house is becoming is seldom realized. Canada, in the matter of imports, stood seventh among the world's nations in 1926, surpassed only by the United Kingdom, Germany, the United States, France, Japan and Italy. In exports, from tenth on the list in 1913, Canada has moved up to fifth, in total trade occupying the same position, being surpassed only by the United States, the United Kingdom, Germany and France. In total trade per capita the country shows up still better, being second in the world; while to-day with her population of less than ten millions, her exports exceed those of the United States when that country had a population of 75 millions.

At the present time, of the outside capital invested in Canada, some three thousand million dollars represent United States property. Against this, British investments are only responsible for a value about two-thirds of that amount. Moreover, the former figure is advancing very rapidly, while the latter shows almost complete stagnation. The country is full of branch works of United States firms, necessarily carrying with them close touch and constant dealings with the parent bodies across the border. Is it surprising that Canada complains of our lack of interest in the opportunities she has to offer, and of our unwillingness to embark on new ventures, leaving the risks to be gladly taken by the United States, and, of course, by the Canadians themselves, staking their all on their country's future ?

As in capital, so in our trade, our record is an extremely unsatisfactory one. Forty years ago no less than 41 per cent of Canada's import trade was derived from this country, while 47 per cent of her exports were destined to these islands. While the latter have dropped to 36 per cent, the former figure has steadily shrunk till it is now reduced to 16 per cent. In the same period her imports from the United States have increased from 44.6 per cent to 67 per cent. Thus, we have lost a great deal of ground, though the position in 1927 shows some little improvement on that for 1922. Totals, of course, have grown, and the percentages are figured on very much larger amounts, but the position is anything but satisfactory, in spite of a preferential tariff in our favour. That this has had some effect is clear from the fact that from 1886 to 1896 our imports to Canada fell off to the extent of 16 per cent, while after the establishment of the preferential tariff the tide turned, and to 1927 has shown an increase of 400 per cent; but we cannot close our eyes to the fact that in this same period the United States imports have increased, not by 400 per cent, but by 1,200 per cent.—*Engineering.*

A British Locomotive in the U.S.A.

Considerable interest has been aroused, both in this country and in the United States, by the presence at the centenary celebrations of the Baltimore and Ohio Railroad, held at Baltimore from September 24 to October 8 last, of the Great Western Railway locomotives North Star and King George V, the former having been built in 1837, and the latter, of course, being the first of a new class recently designed by C. B. Collett, C.B.E., and built at the Swindon Works.

After the conclusion of the centenary celebrations, the King George V was employed on a run in passenger service on the Baltimore and Ohio Railway, from Baltimore to Washington, thence to Philadelphia and back to Baltimore, the total distance covered in the three sections being 271.8 miles. The report on this run of the Baltimore and Ohio Test Bureau is reprinted in the current issue of the *Great Western Railway Magazine,* from which we gather that the performance of the engine was regarded as particularly creditable by the officials present. The train consisted of three passenger coaches, two Pullman sleepers, an official car and a dynamometer car, the total weight hauled being 543.6 tons, and records were taken of drawbar pull, speed, boiler pressure, throttle opening and reversing-level position throughout the whole of the run; no record of coal or water consumption was kept. The first section, of about 39 miles, from Baltimore to Washington, was completed in 58 minues 45 seconds, actual time in motion, the maximum speed attained being 74 m.p.h. From Washington to Philadelphia, some 135 miles, the running time was 2 hours 56 minutes, and the maximum speed 73 m.p.h., while for the third section, of about 96 miles, from Philadelphia to Baltimore, the time in motion was 2 hours 14 minutes 50 seconds, and the maximum speed 69.3 m.p.h. Throughout the trip, no difficulty was experienced in starting or in hauling the load, although the fuel used, a hard gas coal for which the form of grate was not well suited, gave some trouble from clinkering . When it is remembered that Driver W. Young and Fireman G. Pearce, both of the Great Western Railway, were unfamiliar with the road and with the class of fuel used, it will be evident that some, at least, of the credit for the satisfactory performance of the engine is due to these two men,—a fact which was fully acknowledged by the American officials. The latter commented particularly on the smooth-running qualities of the engine, as well as on its performance, workmanship and appearance. The engine has thus worthily upheld the high traditions of British locomotive engineering, and the reception accorded it by American engineers must be gratifying to the directors of the Great Western Railway Company, as it is also to British engineers in general.—*Engineering.*

Light and Heat in Medicine and Hygiene

An international conference on light and heat in medicine, surgery and hygiene, combined with an exhibition, was opened in the Central Hall, Westminster, on Tuesday afternoon, December 13. The conference will conclude its afternoon and evening sessions to-day. Dr. R. King Brown, chairman of the Committee of Hygiene and editor of the *British Journal of Actinotherapy,* which has organized the exhibition, presided at the inaugural meeting, and Lieut.-Col. F. Fremantle, M.B., M.P., chairman of the Medical Committee of the House of Commons, delivered the opening address in place of Sir Alfred Mond, who was unable to attend. Like Dr. K. Brown, who mentioned that he had introduced sunlight treatment into Bermondsey, Colonel Fremantle dwelt upon the great benefits that light, natural or artificial, could confer upon healthy and enfeebled or diseased organisms, while warning also against the home-use, especially of strong light, without due medical advice. The conference, he said, was the first of its kind, and papers on actinotherapy and on vision would be presented by the leaders of British science in this field, as well as by Drs. Nagelschmidt and Huidschinsky, of Berlin, and Dufestel and Saïdman, of Paris. Light treatment, long since appreciated by botanists, had recently found also industrial application; for instance, in the leather industry. So many of the exhibits, which are arranged in sixty stands, are of cognate nature that we hesitate to mention names of the firms, most of which show appliances due to several experts. We may mention the vita and other glasses which allow part of the ultra-violet rays to pass, shown as windows and roof glazings, the rest-light lamps which absorb the excess of orange red in the spectrum, and the sunlight lamps, much used in the textile industry, to imitate the colour of sunlight. The medical profession makes use of ordinary light, and particularly also of ultra-violet and infra-red radiations. The lamps used are ordinary arcs with electrodes of carbon, of tungsten and of tungsten-cored carbons and further quartz-mercury lamps. In one type of tungsten lamp the tungsten rod is replaced by two tungsten discs, which are fixed to copper rods flanged with large copper radiators. In the vilite lamp two Jablochkoff candles for ultra-violet radiations are combined, (in parallel), with a spiral resistance for infra-red radiations, each of the sources of light having its own movable parabolic mirror; the candle electrodes are said to be made of carbon, tungsten and rare earths. A new pantaphos lamp which eliminates shadows in its strong beam by the aid of parabolic and cylindrical mirrors was also demonstrated.—*Engineering.*

De Laval Steam Turbine Company has just issued a leaflet describing the pumps installed at the new water filtration plant at Wenatchee, Wash., copies of which may be obtained from the Trenton, N.J., office.

The Northern Electric Company, Limited, 121 Shearer Street, Montreal, has published a new bulletin, No. 100-C, on Sangamo meters, which brings all the printed information on the S-2 Sangamo meter up to date and gives a full description of this meter in its various applications, together with useful shipping data, etc.

The Gypsum Industries, 844 Rush Street, Chicago, Ill., has issued a twenty-three page booklet entitled "Gypsum Partition Tile," which is made up of three parts as follows: Part I, Fire Tests; Part II, Specifications for the Erection of Gypsum; Part III, American Society for Testing Materials Standard Specifications for Gypsum Partition Tile or Block.

Preliminary Notice

of Applications for Admission and for Transfer

March 14th, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in April 1928.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ABBEY—CHARLES GARFIELD, of Montreal, Born at London, Eng., Dec. 14th, 1891; Educ., Brighton Tech. College, 1907-10; apprentice, Lancs. Dynamo & Motor Co., Ltd., Manchester, Eng., 1910-13; 1913-16, asst. & outside engr. to Messrs. Kelsall & Parsons, Glasgow, agents in Scotland for L.D. & M. Co.; 1916-18, plant engr. in charge of outside work for L.D. & M. Co., Manchester; 1918-26, return to Kelsall & Parsons, Glasgow, and later made partner with company as Kelsall, Parsons & Co.; 1926 to date, president, Lancs. Dynamo & Motor Co. of Canada, Ltd.

FRY—ALBERT EDWARD, of Montreal, Born at Cornwall, Ont., Dec. 27th, 1885; Educ., public school, 1892-98, machine shop practice and mech'l engrg. courses with I.C.S.; 1902-06, machinist apptce. with J. Smart Mfg. Co., Brockville, Ont., and Miller's Machine Shop and Foundry, Cornwall, Ont.; 1906-09, machinist with Toronto Paper Mills at Cornwall, Ont., and C.P.R. Angus Shops, Montreal; 1909-12, master mechanic, Merchants' Branch, Dom. Textile Co., Montreal; 1912-15, installation of machinery and equipment and then taking mech'l charge of Dom. Mahogany Veneer Co., Montreal West; Mch. to Dec. 1915, designed and built pan conveyors and biscuit icing trolley, Mooney Biscuit Co., Montreal; 1915-18, designed major proportion of tooling for Steel Co. of Canada's 9.2 shell shop, supt. when it went into operation, also worked on design of a central steam power plant; 1918-19, with Dougall Varnish Co., Montreal; 1919-20, with Steel Co. of Canada; 1920 to date, general mechanical engrg. work with Dom. Glass Co., Montreal.

JACKSON—WILLIAM, of Edmonton, Alta, Born at Manchester, Eng., Oct. 16th, 1883; Educ., Allen Glen High School, Glasgow, Glasgow Tech. College; 1900-04, articled to Kyle, Dennison and Laing, Glasgow, general office work, dfting, surveying, constrn. of macadam roads and whin sett streets with concrete base, sewers and sewage disposal plants, etc.; 1904-05, employed by father, A. Jackson, as foreman on constrn. of sewers, macadam roads, etc.; 1905-06, with father, engr. i/c of same class of work as above and experience in preparing tenders; 1907-09, dftsman on preliminary and location with C.P.R., took topography, ran transit and level and projected when required; 1909, C.N.R. Winnipeg office, dfting, checking location plans and profiles, making approval plans, etc.; 1910-11, A. & G.W.R., Edmonton, ch. dftsman, G.T.P.R., Edmonton, dftsman, same experience as with Can. Northern Ry.; 1911-17, E.D. and B.C.R., i/c location, constrn. and mtce., supervised preparation of all standard plans and specifications, prepared general design for steel bridges, checked steel work and prepared substructure plans, etc.; 1917-28, Dept. of Rlys. and Canals at Edmonton, worked on lifting and relaying of 200 miles steel on Can. Northern and G.T.P. Rly. west of Edmonton, on Can. Northern Ry. investigation, investigated dispute between G.T.P. and C.N.R., etc.; 1920-28, inspecting engr., highways branch, Dept. of Rlys. and Canals, for three prairie provinces.

TREASURER
F. P. SHEARWOOD, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, J. F. LUMSDEN
Sec.-Treas., R. R. MURRAY, 4 Carleton Street, Halifax, N.S.
Executive, W. J. DeWOLFE, W. B. MacKAY, H. W. MAHON, A. R. CHAMBERS, H. C. BURCHELL, C. B. McDOUGALD
(Ex-Officio) C. A. D. FOWLER, H. W. L. DOANE

CAPE BRETON
Chairman, W. E. CLARKE
Vice-Chair., M. DWYER
Sec.-Treas., E. L. GANTER, P.O. Box 310, Sydney, N.S.
Executive, S. C. MIFFLEN, W. J. RIPLEY
(Ex-Officio) W. E. CLARKE, W. S. WILSON

SAINT JOHN
Chairman, S. R. WESTON
Vice-Chair., E. A. THOMAS
Sec.-Treas., W. J. JOHNSTON, P.O. Box 1417, St. John, N.B.
Executive, J. D. GAREY, J. R. FREEMAN, J. P. MOONEY
(Ex-Officio) J. STEPHENS, A. R. CROOKSHANK

MONCTON
Chairman, H. J. CRUDGE
Vice-Chair., M. J. MURPHY
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, E. T. CAIN, J. R. FREEMAN, L. H. ROBINSON, G. E. SMITH, H. B. TITUS, F. WILLIAMS
(Ex-Officio) F. O. CONDON, G. C. TORRENS, F. L. WEST

SAGUENAY
Chairman, EDOUARD LAVOIE
Sec.-Treas., B. PELLETIER, City Engr., Chicoutimi, Que.
Executive, J. L. DELISLE, C. C. LINDSAY
(Ex-Officio) N. F. McCAGHEY

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive A. LARIVIERE, L. C. DUPUIS, H. CIMON, J. T. F. KING
(Ex-Officio) W. G. MITCHELL, LOUIS BEAUDRY

ST. MAURICE VALLEY
Chairman, ELLWOOD WILSON
Sec-Treas., R. MORRISSETTE, City Engr., Cap de la Madeleine, Que.
Executive, H. DESSAULLES, B. GRAND MONT, S. W. SLATER

MONTREAL
Chairman, F. C. LABERGE
Vice-Chair., J. A. McCRORY
Sec.-Treas. C. K. McLEOD, 698 St. Catherine St. W., Montreal, Que.
Executive, J. G. CARON, R. deL. FRENCH, D. HILLMAN, H. MASSUE, E. A. RYAN
Ex-Officio, C. V. CHRISTIE, P. L. PRATLEY, C. M. McKERGOW, J. H. HUNTER, W. C. ADAMS, J. L. BUSFIELD, FRASER S. KEITH, O. O. LEFEBVRE, ARTHUR SURVEYER

OTTAWA
Chairman, C. CAMSELL
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Service, Dept. of the Interior, Ottawa, Ont.
Executive, A. K. HAY, W. BLUE, F. H. PETERS, V. M. MEEK, G. A. BROWNE
(Ex-Officio) N. CAUCHON, A. F. MACALLUM, J. D. CRAIG

PETERBOROUGH
Chairman, A. E. CADDY
Secretary, W. E. ROSS, 317 Boswell Ave., Peterborough, Ont.
Treasurer, A. B. GATES
Executive, G. H. BURCHELL, W. M. CRUTHERS, J. A. G. GOULET, P. MANNING, B. OTTEWELL
(Ex-Officio) R. L. DOBBIN, B. L. BARNS

KINGSTON
Chairman, D. S. ELLIS
Vice-Chair., W. L. MALCOLM
Sec.-Treas., D. G. GEIGER, Fleming Hall, Kingston, Ont.
Executive LeR. F. GRANT, A. G. MacLACHLAN, L. F. GOODWIN
Ex-Officio L. T. RUTLEGDE, G. J. SMITH

TORONTO
Chairman, L. W. WYNNE-ROBERTS
Vice-Chair., T. TAYLOR
Sec.-Treas., J. J. SPENCE, Eng. Bldg., Univ. Toronto, Toronto, Ont.
Executive, G. H. DAVIS, A. B. CREALOCK, H. N. MASON, J. W. FALKNER, J. J. TRAILL, C. S. L. HERTZBERG
(Ex-Officio) R. B. YOUNG, W. B. DUNBAR, J. G. R. WAINWRIGHT, T. R. LOUDON, J. M. OXLEY

HAMILTON
Chairman, L. W. GILL
Vice-Chair., W. L. McFAUL
Sec.-Treas., W. F. McLAREN, Can. Westinghouse Co. Ltd., Hamilton, Ont.
Executive, H. A. LUMSDEN, G. R. MARSTON, F. P. ADAMS, ARTHUR MUNSON
(Ex-Officio) C. J. NICHOLSON, H. B. STUART

LONDON
Chairman J. A. VANCE
Vice-Chair., G. E. MARTIN
Sec-Treas., FRANK C. BALL, City Engineer's Dept., London, Ont.
Executive, J. A. COOMBS, R. W. GARRETT, W. C. MILLER, W. P. NEAR, W. M. VEITCH
Ex-Officio, J. R. ROSTRON, W. P. NEAR

SAULT STE. MARIE
Chairman, W. S. WILSON
Vice-Chair., J. H. JENKINSON
Sec.-Treas. A. H. RUSSELL, City Engr., Sault Ste Marie, Ont.
Executive, A. E. PICKERING, R. A. CAMPBELL, J. V. FAHEY, J. G. DICKINSON
(Ex-Officio) J. M. SILLIMAN, G. H. KOHL

LAKEHEAD
Chairman, C. B. SYMES
Vice-Chair., D. G. CALVERT
Sec.-Treas., GEO. P. BROPHY, P.O. Box 86, Port Arthur, Ont.
Executive, D. C. CHISHOLM, J. C. MEADER, W. H. SOUBA, G. R. DUNCAN
(Ex-Officio) H. S. HANCOCK, R. B. CHANDLER

WINNIPEG
Chairman, J. N. FINLAYSON
Sec.-Treas., E. W. M. JAMES, 255 Balfour Ave., Winnipeg, Man.
Executive, W. G. CHACE, A. J. TAUNTON, G. H. HERRIOTT, A. W. FOSNESS, C. T. BARNES, H. M. WHITE
(Ex-Officio) THEO. KIPP, H. A. DIXON, A. McGILLIVRAY

SASKATCHEWAN
Chairman, A. M. MacGILLIVRAY
Vice-Chair., H. R. MacKENZIE
Sec.-Treas., R. W. E. LOUCKS, Surveys Br., Land Titles Office, Regina, Sask.
Executive J. M. CAMPBELL, J. W. D. FARRELL, STEWART YOUNG, D. A. R. McCANNEL, W. R. WARREN, W. G. WORCESTER
(Ex-Officio) M. B. WEEKES

LETHBRIDGE
Chairman, N. H. BRADLEY
Sec.-Treas., WM. MELDRUM, Galt Mines, C.P.R., Lethbridge, Alta.
Executive, J. B. deHART, G. N. HOUSTON, C. S. CLENDENING, C. S. DONALDSON
(Ex-Officio) G. S. BROWN, R. LIVINGSTONE

EDMONTON
Chairman, A. I. PAYNE
Vice-Chair., W. R. MOUNT
Sec.-Treas., H. R. WEBB, University of Alberta, Edmonton, Alta.
Executive, C. A. ROBB, H. P. KEITH, R. W. ROSS, W. J. CUNNINGHAM
(Ex-Officio) T. W. WHITE, R. J. GIBB

CALGARY
Chairman, THOS. LEES
Vice-Chair., F. J. ROBERTSON
Sec.-Treas., W. H. BROUGHTON, Inst. of Technology and Art, Calgary, Alta.
Executive, B. RUSSELL, F. M. STEEL, O. H. HOOVER
(Ex-Officio) S. G. PORTER, P. J. JENNINGS, F. K. BEACH, H. R. CARSCALLEN

VANCOUVER
Chairman, W. BRAND YOUNG
Vice-Chair., W. B. GREIG
Sec.-Treas., F. P. V. COWLEY, 930 Birks Bldg., Vancouver, B.C.
Executive, O. S. WOOTTON, E. A. WHEATLEY, H. B. MUCKLESTON, P. H. BUCHAN, H. W. FRITH, A. C. R. YUILL
(Ex-Officio) W. H. POWELL, GEO. A. WALKEM

VICTORIA
Chairman, R. F. DAVY
Vice-Chair., F. G. ALDOUS
Sec.-Treas., K. M. CHADWICK, 25 Brown Bldg., Victoria, B.C.
Executive, H. F. BOURNE, A. L. CARRUTHERS, W. S. DREWRY, L. W. TOMS
(Ex-Officio) E. DAVIS

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter

Volume XI | Montreal, May, 1928 | Number 5

A Study of Transmission Line Power-Arcs

A Study of Transmission Line Power-Arcs, the Practical Results of a Series of Power-Arc Tests carried out by the Shawinigan Water and Power Company, with the Theoretical Analysis of the Power-Arc

Paul Ackerman, A.M.E.I.C.

Electrical Engineer, The Shawinigan Water and Power Company, Montreal, Que.

Paper read before the Montreal Branch of The Engineering Institute of Canada, March 1st, 1928 and to be presented for discussion at the Western General Professional Meeting in Vancouver, B.C., June 7th to 9th, 1928

In connection with relay protective work, it is essential that the properties and behaviour of the power arc be known.

In order to acquire this knowledge, the Shawinigan Water and Power Company has carried out a series of power arc tests with simultaneous oscillographic and moving picture records. This permitted the synchronizing of electrical and physical conditions of the arc.

This paper is to present the practical results of these tests, along with a theoretical analysis of the power arc. The tests were to supply the knowledge regarding the following points:—

(1) Arc voltage in relation to arc current to determine the sensitiveness of directional relays required.

(2) Power arc damage in relation to current and time, to establish the importance of quick clearance of arcs so as to avoid permanent damage.

(3) Spreading of the arc in relation to time, to show the importance of quick clearance of arcs to avoid spreading of the arc into other phases or adjacent circuits.

In order to cover as much as possible the whole range of practical conditions, it was decided to extend the tests over a current range of approximately 100 to 10,000 amperes and to include arcs over pin insulators of representative voltages from 2,200 to 60,000 volts, suspension insulators for 110 k.v. and arcs across line conductors. It is natural that actual conditions out on the transmission line are so largely different that it is impossible to cover all conditions. It is felt, however, that the series of tests made are giving sufficient data to learn about the main characteristics of the power arc.

The first chapter deals with the general characteristics of the power-arc and the second chapter with the practical conclusions deducted from the power-arc tests. In Appendix I the test arrangement is discussed. Appendix II develops a theory for the power-arc based on the theory of heat balance between ohmic heat generated in the arc and heat radiated from the surface of the arc. Appendix III treats theoretically the condition of the unstable arc under which condition self-extinction of the arc will occur.

Definition and General Characteristics of a Power-Arc

Lightning flashing over an insulator causes a fine filament of air to heat up to arc temperature. The resistance in this air path is thus lowered and thus offers a ready path to the power current of the system itself.

The heat produced in the narrow air or puncture path is enormous, and as a result thereof the hot air will explode to a larger diameter and thus form the large arc known as power-arc.

The same condition will be created where wires are getting within striking distance of one another, the voltage thus puncturing the air and thus creating the low resistance path for the power current.

The power-arc, when expanding, will lower the ohmic resistance of the arc, and in consequence the ohmic heat generated within will drop. On the other hand, the heat radiation from the arc surface will increase because of the increasing arc surface. The arc will therefore expand to such dimensions until the dropping ohmic heat generated in the arc will strike a balance with the increasing heat radiated from the arc surface.

The theory of the power-arc is developed in detail in Appendix II. It is seen from this appendix that the physical dimensions and the voltage of the arc are in direct dependence of the arc current.

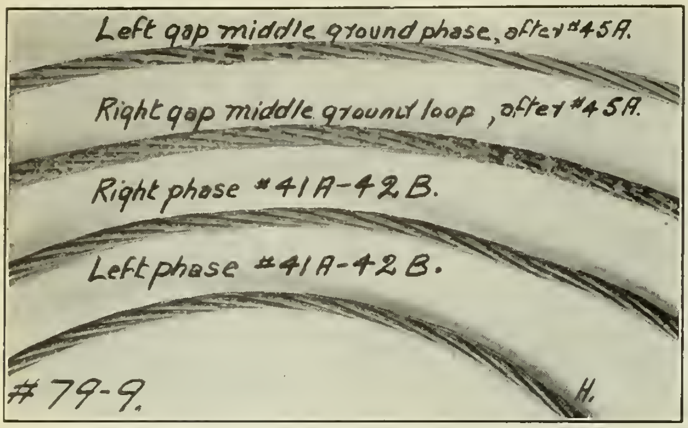

Figure No. 1.—Arc Damage on Conductors.
600-ampere and 1200-ampere arcs of 0.5 second.

The tests have brought out the following chief features of the power-arc:—

(1) *The initial explosive expansion* of the puncture path to the final dimensions of the power-arc takes place within approximately 1/1,000 of a second, (see oscilligram, figure No. 12*a*).

In our tests the puncture path was represented by a No. 34 copper wire which has a diameter of 0.006 inches. The arc diameter was in most cases between 2 and 3 feet. In other words, the arc exploded within 1/1,000 second to a diameter about 5,000 times its original size.

(2) *The specific resistance* of the arc vapour is approximately 14 ohms per cubic inch, compared with 7 x 10^{-7} ohms per cubic inch for copper. This means that the specific resistance of the arc vapour is approximately 20,000,000 times greater than the specific resistance of copper.

(3) *The energy in the power-arc* in its initial stage is ranging anywhere from 50 to 3,600 k.w. for 600- to 1,200-ampere arcs and 3,000 to 15,000 k.w. for 10,000-ampere arcs.

(4) *The radiating constant,* that is, the power radiated from the arc surface, seems to vary largely in different tests. Table No. 2, column 9, shows the results obtained for the various tests. It will be noticed that most of the values for k_1 are ranging from 150 to 350 watts per square inch arc surface for currents below 1,500 amperes, whereas for 10,000-ampere arcs it varies between 2,000 and 4,300 watts per square inch. It is suspected that the large variation for k_1 is largely apparent only, due to the possible unavoidable error in judging and calculating the arc surface because of the inability to judge the depth of the arc. The increased value for k_1 for large currents cannot be fully explained. Partly, it may be due to a change in the heat radiating facility, these tests having been made under different conditions and with certain air currents present. Partly, it may be only apparent because of the inaccuracy and natural error in the arc measurements.

It appears reasonable to consider $k_1 = 300$ watts per square inch as an average value for all practical short circuit currents up to several thousand amperes. How far this value may be increased by prevailing winds is uncertain.

(5) *The arc diameter* of the initial arc increases only slightly with the current.

For the long stretched arc, the relation of arc diameter and arc current is found as, (see formula 5, appendix II),

$$D = m_D \sqrt[3]{I^2}$$

where $m_D = .24$

The results of the actual tests for the long stretched arc, (see table No. 1), are somewhat irregular. This, however, is to be expected because of the possible error in determining the arc dimensions. No formula has been worked out for the diameter of arcs over insulators, as the problem becomes too complex. It is to be expected, however, that the arc diameter would increase in a slower proportion than is expressed in the above formula for the long stretched arc because of the arc forming a hollow conductor with the insulator obstructing the passage of the current within. This seems to check with the results as per table No. 2 for the various items of insulator flashovers.

It is important to note that the power-arcs for 600 to 1,200 amperes are always about 2 to 3 feet in diameter, irrespective of the size or type of insulator. Arcs for 10,000 amperes increase the diameter to 4 to 5 feet.

(a) 600 amperes, 1.5 second. (b) 1200 amperes, 0.5 second.

Top or Ground Units

Figure No. 2.—Ground and Line Units

(6) *The arc voltage* for long stretched arcs is given in appendix II, formula 6.

$$V = m_v \frac{L}{\sqrt[3]{I}}$$

where $m_v = 250$

This formula indicates that the voltage changes very little with a change in current, its tendency being downwards with increasing current. The arc voltage, however, is directly proportional to the arc length, which indicates that the voltage will increase with the spreading of the arc.

No attempt has been made to develop a formula for the flashover voltage for insulators, as this problem becomes too complex. Test results, (see table No. 2), indicate the interesting fact that for a range of current from 70 to 10,000 amperes the voltage for the initial arc is about the same for the same type of insulator or the same length of arc. The average values for the various types of insulators and conductor spacings was found to be approximately the following:—

7 disc suspension insulator	1200 volts
60 kv. pin insulator	900 "
27 kv. " "	500 "
2 2 kv. " "	250 "
Conductors:	
18-inch spacing	600 "
60- " "	1900 "
96- " "	2800 "

The arc voltage is thus chiefly dependent on the arc length. The voltage will therefore change in the course of the development of the arc along the following lines:—

(a) If the power-arc breaks up the insulator, then the arc voltage may drop slightly.

(b) If the arc on an insulator bulges out due to heavy wind, the arc voltage may increase. Such increase will, however, never be very large because of the tendency of the arc vapours to rise and short-circuit the loop, thus not allowing a long stretched arc to form. This is borne out by the tests, where in no case the arc voltage at the end of a one and one-half second arc was more than four to six times its original value.

(c) An arc between widely-spaced conductors may, under certain conditions, develop a very long stretched arc with the result of the arc voltage increasing proportionally. This is chiefly borne out by some of the tests, where, by its natural chimney effect, the arc rose in about three-quarters of a second to a height of 30 feet or more, corresponding to an approximate arc length of 60 feet, the voltage in this case exceeding 20,000 volts.

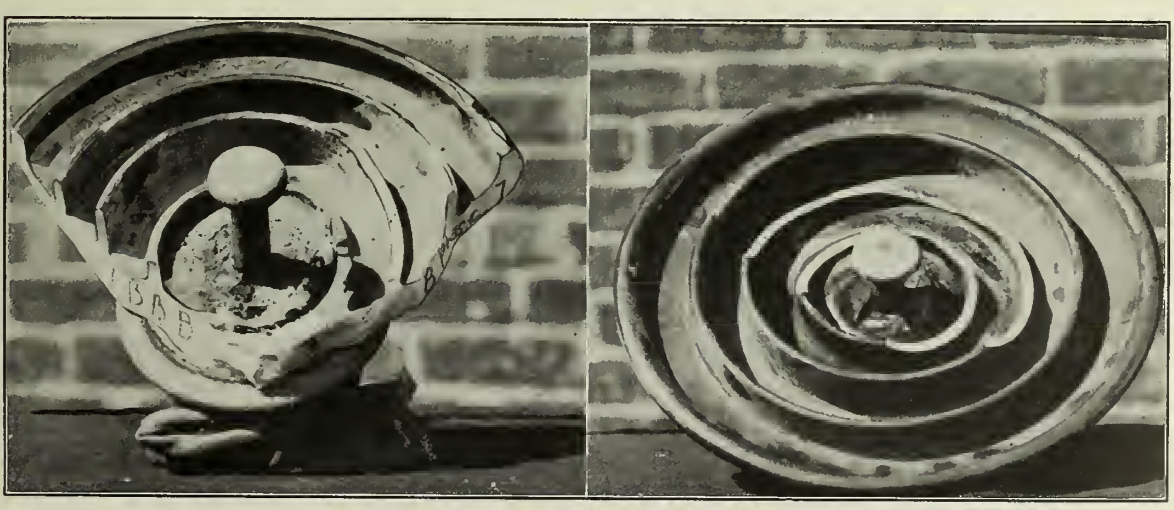
For practical purposes, it may be assumed that the arc voltage will be approximately 400 volts per foot length of arc, irrespective of the short-circuit current.

Practical Conclusions Regarding Tests

Power-Arc Damage

The tests show clearly that the duration of the arc is more serious and more damaging than the current magnitude. The arc has an excessively high temperature, likely in excess of 3,000°C. As a result, wherever the arc clings to the insulating material or the conductor, damage must result if this condition prevails for any length of time, irrespective of the current magnitude. If the arc, on the other hand, is cleared instantaneously, then only the very surface of the insulating material or the conductor is touched and therefore no damage will result if the arc is quenched before the heat had time to penetrate. Complete immunity to damage from power-arc could be expected if the arc was cleared within one-tenth to two-tenths of a second. Under this condition, full control of the situation would be obtained. With present-type oil breakers, such quick clearance cannot be obtained. The quickest arc clearance to be expected with so-called instantaneous protection is approximately one-half second or slightly less. Even with this time delay, the damage is usually found to be comparatively small. With power-arcs in excess of one-half second duration the extent of damage is entirely dependent on circumstances.

In case of arcs between conductors, wind at right angle to the transmission line will be most serious and may result in burning-off of the conductors or seriously damaging same. With the wind in the direction of the line or under a small angle to the line, the arc will travel along the conductors and thus avoid serious damage at any one point, causing simply a pitting of the surface of the conductor. Figure No. 1 indicates how variable the damage may be,



(c) 1200 amperes, 0.5 second. (d) 1200 amperes, 0.5 second.

Bottom or Line Units

of 7-Disc Suspension Insulators.

depending on how stationary the arc is. The damage in test 45*A* is very pronounced. All these tests involved 600- to 1,200-ampere arcs of one-half second duration.

In case of suspension insulators, the power-arc damage is usually confined to the top and bottom units. The discs in between are shielded until the end units are broken up. This takes a fraction of a second. Wind in the direction of the transmission line also tends to immediately carry the arc away from the insulator along the conductor and up into the supporting structure, thus completely protecting the insulator. Wind at right angle to the transmission line may affect the bottom skirts, whereas the top unit again is likely protected by the arc passing off into the structure. Arc horns and arc rings help to deflect the arc, and thus tend to protect the end units.

With quick clearance of arcs, the suspension insulator is quite safe from serious power-arc damage, even without protecting arc horns or rings. This is borne out by practical experience, which indicates that with instantaneous line protection there are hardly ever any insulators found damaged from lightning flashovers, or if such damage occurs it is confined to a slight chipping of the bottom unit without affecting the insulation of the line. In figure No. 2 are shown damages to top and bottom units, tests 1*B*, 1*BB* and 1*BBB* being 1,200-ampere arcs of one-half second and 1*D* a 600-ampere arc of one and one-half second, unit No. 1 being top unit and unit No. 7 the bottom unit.

Pin type insulators are more sensitive to power-arc damage because of the hot gases being caught underneath the bottom skirt, breaking them even with arcs cleared within one-half second. Power-arc damage in case of pin type insulators is particularly serious because of the smaller safety factor existing on the pin type insulator by nature of its construction, consisting as a rule of only two to three skirts. Thus, with two of these skirts broken up, the flashover value of the insulator may be greatly reduced. With pin type insulators, there exists also a great danger of burning off the tie wires, thus leaving a mechanical weakness which may later on result in the cable falling off the insulator. The tests, however, indicate that with instantaneous clearance there is a fair chance also on pin type insulators to get away without permanent damage under most conditions. This is verified by actual experience on transmission lines, where lightning flashovers hardly ever cause a permanently disabled line. Figures Nos. 3, 4 and 5 show the effects of power-arcs of different magnitude on different type insulators. The damaging effects are very irregular, depending chiefly on the speed with which the arc is deflected.

The tests clearly indicate that it cannot be sufficiently emphasized how everything possible is to be done to reduce the duration of a power-arc if full control over power-arc damage is to be obtained. It is not sufficient to provide instantaneous relays, but it is necessary also that the switch manufacturer does everything possible to speed up the total opening time of the oil circuit-breakers.

Spreading of Arc

There are different conditions which may cause the spreading of an arc into adjacent phases or circuits.

Initial Explosive Expansion of the Arc

The tests indicate that the initial explosive expansion of the arc after the air has been punctured assumes within 1/1,000 of a second or less a very large diameter of several feet. This diameter will be 2 to 3 feet for currents of a magnitude of 600 to 1,200 amperes, whereas with 10,000 amperes the diameter may extend to 4 to 5 feet. The com-

parative size of arcs of various current magnitude can be seen in figure No. 6, showing the initial arc formation on 110 k.v. suspension insulators for different currents. Each picture shows the first three exposures of the moving picture film.

It is evident that with a small separation of conductors between phases or circuits, such as is customary on low voltage lines, the arc will have spread into adjacent phases or lines almost instantaneously. Nothing can be done to prevent this, except isolated phase construction, as far as station work is concerned. On transmission lines, separation of phases, to avoid such spreading of the arc into adjacent phases, would have to be made far too great to warrant it for economic reasons. With quick clearance of the arc, no harm, however, should be experienced from such arcs.

In case of higher voltage systems, the currents are usually less than 4,000 amperes, so that the initial arc should not exceed 3 to 4 feet diameter, whereas the separation of phases is usually larger. With quick clearance, there should be no danger, therefore, in this case, of the first initial arc reaching into other phases.

Arcs, discharged in a wooden box, indicate the high pressure forming in the arc before the arc is completely exploded. Figure No. 7 shows the wreckage of two 4-foot long boxes of 9 by 9 inches and 12 by 12 inches cross-section, through which 10,000-ampere arcs were discharged. The boxes exploded completely, blowing the sides as far as 10 to 20 feet away. If it is assumed that the law of gas compression applies to the arc vapours, then the arc pressure within the 9- by 9-inch box before its explosion would have been about twenty-eight times greater than atmospheric pressure, its diameter being only 1/5.2 of the stable arc of 4 feet. This result explains readily the reason of switch cell doors or loose-phase partitions being found blown off after local short-circuits.

Figure No. 7 indicates a blackening of the inside walls of the wooden boxes. This blackening is only on the surface of the wood, there having been no tendency of ignition whatsoever. This indicates how even inflammable material is immune to ignition from power-arcs if the arc is extinguished instantly. This observation is verified by the practical experience of switch bushings, with a compound surface, flashing over and being cleared instantly. The only harm to such bushings was a very slight surface charing which could be easily scraped off.

Chimney Effect of Arc

Hot air has the tendency to rise, so that the arcs will tend to spread upwards. The tests were conducted on windstill days, so that, whatever spreading of the arc has been observed, such spreading was chiefly due to the natural chimney effect of the arc.

Figures Nos. 8, 9 and 10 show the development and spreading of arcs across 110-k.v. suspension, 60-k.v. pin and 2,200-volt pin insulators respectively. The three pictures of each figure represent a series of three successive exposures cut out of the moving picture film at different stages of the arc. The pictures show plainly how the expansion and the spreading of the arc, in case of insulator flashovers, is rather limited and how the arc retains a compact form. The decided reduction in the size of the arc noticed in figure No. 10*c* is caused by the breaking of the insulator.

Figure No. 12*a* represents the oscillogram of a 600-ampere arc over a 110-k.v. suspension insulator. The fluctuation noticed in the arc voltage is to be attributed to a corresponding fluctuation in the length of the arc. Arcs between conductors have a tendency to rise to considerable heights, as can be seen from figure No. 11, showing the development and spreading of an arc between conductors 60 inches apart. The first picture series shows the initial development of the arc, which gives a shape similar to the arc over insulators. The second picture series shows how, after three-quarters of a second, the arc gradually bulges out upwards due to the chimney effect of the arc, rising from then on very rapidly. This rapid rise is seen from the last picture series, showing exposures of the moving picture film after one and one-half seconds.

The tests clearly indicate that only quick acting protection will be able to save spreading of power-arcs into other phases or other wires located above.

It is often customary to string low voltage circuits on the same pole line located above each other. The tests indicate how in such cases it is not impossible for the arc to rise into the upper circuits, with the result that different circuits will be involved simultaneously.

In case of high tension lines, it is very essential that ground faults are cleared as such without developing into phase short-circuits to keep down the disturbing effect on the whole system. It will be essential, therefore, that the arc of lower phases is cleared quickly if it is to be avoided that the arc will rise into upper phases.

In order to avoid arcs blowing into other circuits, the layout of switching stations should be such that the least number of crossings of apparatus leads are provided, and that in those cases where such crossings are unavoidable effective separation is provided, irrespective of the operating voltage, unless instantaneous zone protection is provided. This point should be particularly observed in all those cases where multi-phase short-circuits are disastrous to the synchronous stability of the system.

Wind Effect on the Arc

The arc is very susceptible to air currents. The arc will always spread very readily in the direction of the wind. All tests have been made during comparatively wind-still days, but they all indicate the effect from only very slight wind currents of driving the arc in its direction.

If we consider that a wind at 60 miles an hour corresponds to approximately 100 feet per second, it will be realized that it is comparatively easy for a power-arc to be blown into an adjacent line 20 feet away with a heavy gale blowing at right angle to the line. This indicates that if full control of this condition is to be obtained it will be necessary to extinguish the arc within a small fraction of a second.

It may be stated, therefore, that even with the quickest clearance of arcs it will not be possible to fully prevent arcs from spreading into other phases or other lines, but it will be possible at least to reduce such hazard to an absolute minimum.

Persistency of Power-Arcs

In appendix III, the theory has been developed for the possible self-extinction of power-arcs. From this appendix, it will be noticed that there is a certain fixed inter-relation between arc voltage, arc current and arc length, which, if disturbed, will result in the extinction of the arc. It was further found that for currents between 100 and 10,000 amperes the critical relation of volts and arc length is practically the same. Tests indicate that this critical relation is approximately 400 volts per foot of arc length. In other words, if the voltage is less than 400 volts per one foot of arc length, then an unstable condition is created which will result in the complete extinction of the arc.

(a) 70 amperes. (b) 200 amperes. (c) 10,000 amperes.
Figure No. 6.—Initial Arcs over 110-kv. Suspension Insulators.

This comparatively low voltage required to maintain an arc explains the persistency of a power-arc. It means, for example, that with 60,000 volts across an arc the arc is able to expand to 150 feet without danger of rupture, provided the system is able to supply the current without pulling down the voltage. Table No. 4 of appendix III shows how great the critical arc length may be for different operating voltages and currents. The values in the table may not be exact, but they should show at least the trend.

It will be clearly seen from the table that arcs, even of moderate amperage, are readily able to reach into adjacent circuits on the same tower line or even adjacent tower lines of the same right-of-way, if the arc hangs on long enough to permit such long arc to develop.

The table further indicates and explains the reason why a power-arc is so persistent. There is little prospect of a power-arc being extinguished except under most favourable conditions of very strong wind and ideal condition of a long loop being possible without vapours short-circuiting out the loop. This condition, favourable to arc extinction, seems to be only possible in case of power-arcs between conductors. It appears next to impossible in case of insulator flashovers.

It is interesting to consider a few practical conditions usually handled by air-break switches in the light of the foregoing.

Cutting Out Line Sections Under Voltage

In this case, the capacity current is to be interrupted. At higher voltages and longer sections, this current may readily amount to a few amperes.

With good air-break switches, this method of disconnecting a line section may be satisfactory under good weather conditions where the arc can rise vertically and finally exceed the critical arc length. With wind, such arc may, however, be blown into adjacent phases, developing into grounds or short-circuits. This is liable to happen, even with comparatively great spacing, if the wind is very strong and is blowing directly across the phases. Under all circumstances will the arc take in excess of one second until it has developed to its critical length, where snapping-off occurs.

Rupturing of the Magnetizing Current of a Transformer Bank

On smaller transformer banks and high voltages, this current may readily be less than one ampere, so that the critical arc length may be within the possible scope of an air-break switch. It will be appreciated, however, that as soon as the bank capacity gets larger, with correspondingly higher magnetizing current, such an arc will be more persistent, and, depending on the wind, there will be a limit reached in the safe handling and rupturing of such magnetizing current.

To Break a Parallel with Disconnecting Switches

On longer transmission lines, trouble is often experienced in transferring customers between transmission lines at the instant of separating the two circuits with disconnecting switches or air-break switches. Depending on the operating condition, it is possible sometimes to have to break a considerable load current when separating the two lines with a possible difference of several thousand volts across the arc.

It will be noticed from table No. 4 that, based on the assumption that the table can be considered correct, even with 2,200 volts across the switch and with 100 amperes in the arc the critical arc length would be almost 4 feet before the arc would have a chance to rupture. With special air-break switches of liberal dimensions and favourable weather conditions, no trouble may result. If this break, however, is made with ordinary disconnecting switches a ground or short-circuit may be developed if conditions are unfavourable. It will be well to analyze the possible condition of current and voltage in any such case to fully appreciate how far such operating method is to be permitted.

Under very exceptional conditions, it is also possible sometimes to have an arc cleared on a transmission line by self-extinction after the short-circuit hung on for a few seconds. The writer feels that this condition can only arise in case of an arc existing between or having been blown up into the wires. The condition must be such that either by the natural chimney effect of the arc or by the prevailing wind, an unlimited loop length can be created until the arc reaches the critical length and snaps off. In this connection, it is considered further essential that the generator feeding into the short-circuit has been completely demagnetized by the short-circuit current, thus reducing the voltage across the arc so that a comparatively small critical arc length will cause the snapping off.

The very same condition had been observed in a series of tests with only approximately 6,000 volts across the air gap. In all these cases, it was found that after approximately three-tenths of a second the arc snapped off on its own account, with the current rapidly diminishing within a few cycles to zero. It is contended that in these cases the short-circuit current demagnetized the field of the generator, thus bringing gradually the voltage across the arc down below the critical arc voltage of the corresponding arc distance. Figure No. 12*b* shows the oscillogram for such a test. The gradual dying out of the current can be noticed distinctly.

There is another type of self-extinguishing arc observed on transmission systems. With a short-circuit of a multi-line system occurring close to a power house, it is often observed that the respective line switch at the power house end only opens, causing apparently the power-

Figure No. 8.—Development of 600-ampere Arc over 110-kv. Suspension Insulators.

arc to extinguish before the other end of the transmission line has opened. In this case, the extinction of the arc is to be explained by the fact that the current will be largely changed in magnitude at the instant of the power house oil-switch opening up. It has been found from investigating actual cases of transmission line troubles that self-extinction does only take place if the short-circuit current changes considerably in magnitude after the oil-switch has opened up. The reason of such arc extinction under this condition is apparently due to the fact that the arc volume at the instant of the current change has still the dimensions corresponding to the original arc. For instance, with the current reduced to one-fifth of its original magnitude, the ohmic heat produced in the arc would be reduced to $I^2R = 1/25$. At that instant, however, the radiating surface would be still the same as at the time of the large current, thus the radiating ability of the arc would be twenty-five times greater than the heat produced. This doubtlessly results in a rapid cooling, with consequential snapping off of the arc.

Conclusion

The tests fully confirm the necessity of quick clearance of power-arcs, if arc damage and spreading into other phases or lines is to be avoided.

The tests bring out the interesting fact that the arc voltage is practically independent of the current magnitude. It is proportional, however, to the arc length, that is, approximately 400 volts per foot arc length, which explains the persistency of arcs on high voltage systems.

In closing, appreciation is to be expressed to the operating staff of the Shawinigan Water and Power Company for the efficient and punctual way of carrying out the large number of short-circuits without a single mishap to equipment. Acknowledgment is also made to E. W. Knapp, Jr.E.I.C., for his assistance in collecting and analyzing the various test data.

Appendix I.

Test Arrangement

It was aimed to cover as much as possible the full range of short-circuit currents to be expected on various transmission systems.

The tests cover a range of 70 to 10,000 amperes. The chief concern, when arranging for the tests, was to arrange for a test which would avoid as much as possible stressing or endangering any equipment. In line with this, it was decided to have all tests carried out as 3-phase short-circuits so as to keep down the magnetic stresses on the generators. This was carried out, even in those cases where only two arcs could be arranged, by having the middle phase directly grounded. A power house was chosen with generators of high reactance so as to limit the short-circuit stresses on the generators.

(a) Initial. (b) After 0.75 sec. (c) After 1.5 sec.
Figure No. 11.—Development and Spreading of 600-ampere Arc between Conductors of 60-inch Spacing.

The arrangement for the tests is shown in the various diagrams in figure No. 13. The arrangement as per figure No. 13*a* was used for the currents of 70 to 1,200 amperes. A 60-k.v. transmission line was tapped outside the power house and connected to a special structure with three insulators with grounded pins. The necessary number of 30,000-k.v.a., 6,600-volt generators, and the corresponding 60-k.v. step-up banks were connected in normal fashion through the bus to the respective line. The short-circuit current magnitude was obtained as follows:—

For 600 amperes short-circuit current, one 30,000-k.v.a. unit built up to normal 60 k.v., high-tension, no-load voltage.

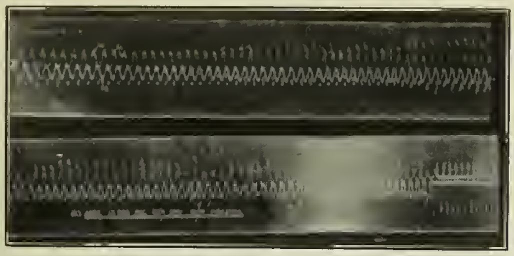

Figure No 12a.—Oscillographic Record of 600 amperes, 1.5 second, Arc over a 110-kv. Suspension Insulator.

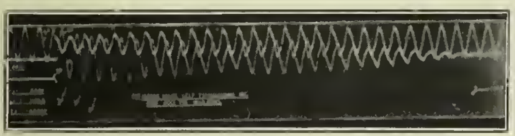

Figure No. 12b.—Oscillographic Record of 10,000 amperes, self-extinguishing Arc over a 60-kv. Pin Insulator.

For 1,200 amperes short-circuit current, two units built up to normal 60 k.v., high-tension voltage.

For 70 to 300 amperes, one generator with the field reduced to give the desired short-circuit current value.

The voltage on the generators was adjusted to the desired point with the line switch open. The three insulators were by-passed with a fine copper wire to start the short-circuit. The 3-phase short-circuit was then established by closing the disconnecting switch, (1) with oil-switch, (2) already being in closed position. Oil-switch (2) then cleared by its normal line protection, the time of clearing being adjusted to suit the specific condition.

For the 10,000-ampere test, it was necessary to resort to 6,600 volts, as it was not possible to obtain as large a current in any other way.

In this case, the whole 120,000-k.v.a. power house was made use of by providing an arrangement as shown in figure No. 13*b;* three generators were stepped-up to the 60-k.v. bus and the transformer of the fourth unit was used to step-down to this point; the corresponding generator was disconnected during this test. The 6,600-volt leads were then connected to a similar structure as used in the previous tests, except that in all these cases only two arcs were established because of lack of space. In this latter case, the short-circuit was closed in by means of the disconnecting switch, (1) of the respective unit with the oil-switch of the bank already in closed position. Switch (2) was then tripped with current protection of the desired time lag.

The various records were obtained by the following means:—

Arc Potential

A 6,600/110-volt potential transformer was located across the respective insulator or air gap. In order to avoid too high voltage and possible breakdown of the potential transformer to the secondary, a safety gap of one-half inch was installed across the potential transformer.

Arc Current

This current was obtained from a special bushing type current transformer placed on the specific phase on the oil-switch. Potential and amperes were recorded on the oscillograph. Generator voltage was also recorded on the oscillograph.

Motion picture and oscillographic records were made for all tests. In order to synchronize the starting of the oscillograph and the motion picture, an arrangement was made whereby with a knife switch the electric controlled disconnecting switch was energized to close, starting at the same time an alarm signal for the camera man, and also a definite time relay which in turn started the motor of the oscillograph just an instant before the disconnecting switch closed and started the arc.

Figure No. 13*c* shows the arrangement for short-circuits between conductors. Semi-circular loops of 150,000 cm. aluminium were provided opposite each other with a certain separation ranging from 18 to 96 inches. All these tests were carried out with two arcs only because of lack of space for the three arcs.

The semi-circular loop was chosen to try to obtain the worst case of arcing across conductors at right angle to the line. It was hoped that whichever way the arc would be blown by the air current, it would instantly assume a position as indicated in sketch by the dotted lines *a, b* or *c*, thus still representing the arc across the conductor.

The arc was started in all cases with No. 34 copper wire for all tests above 600 amperes and No. 42 copper wire for the tests at 300 amperes or less, the copper wire being connected across the insulator or the air gap respectively.

In order to cover approximately the conditions of all commercial voltages, the tests were carried out for the following conditions:—

Current range	70 to 12,000 amperes
Insulators	2.2 kv. pin
	27 kv. pin
	60 kv. pin
	110 kv. suspension (7 discs)
Conductor spacings	18 inches
(150,000 cm. Al.)	30 "
	60 "
	96 "
Arc time	0.5 second
	1.0 "
	1.5 "

Figure No. 14 shows the structure for the insulators. Figure No. 15 shows the structure for the conductor loops. Figure No. 16 shows the picture of the various insulators with approximate over-all dimensions of the insulators and initial arc dimensions. The approximate arc voltage is also recorded for each insulator.

In addition to these arc tests on the insulators and conductors, a few tests were made to study the explosive effect of the arc when enclosed in a wooden box of various cross-sections. In this case, wooden boxes of dif-

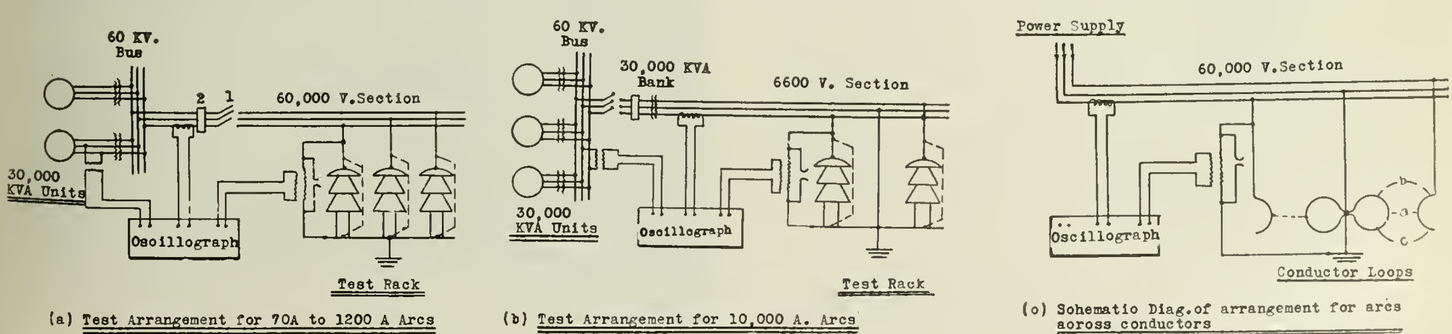

Figure No. 13.—Schematic Diagram of Test Arrangements.

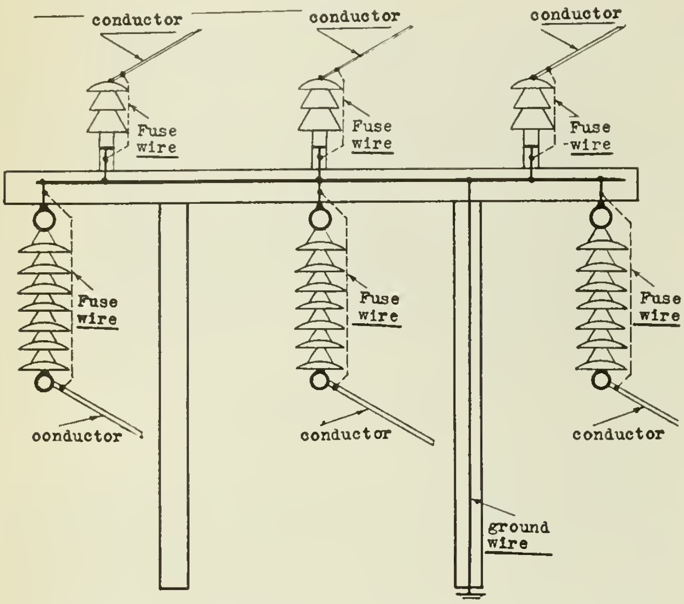

Figure No. 14.—Schematic Sketch of Structure used for Arc Tests of Pin and Suspension Insulators.

ferent sizes were made up to take the place of the insulator. Terminals were provided in top and bottom of the box, with a small fuse wire being placed between the terminals. A first series of tests was made with 4 and 6 feet cubical boxes and thereafter with 9- by 9-inch and 12- by 12-inch cross-section, 48-inch long boxes. The same records and general arrangement was used as in the other tests.

Appendix II.

Theory of the Power-Arc

It is shown hereafter that the inter-relation between arc current, arc dimensions and arc voltage, can be established by applying to the power-arc the same basic law of heat balance as is applied to conductors. In other words, it will be shown that a power-arc assumes such dimensions that the heat generated in the arc will be balanced with the heat radiated from the arc's surface.

Theory of Heat Balance Applied to Air Viewed as a Conductor

A resistance wire, upon application of voltage across its terminals, will heat up due to the ohmic heat generated in the wire from the current passing through same. The temperature of the wire will rise until the temperature drop to the surrounding air has risen sufficiently to increase the heat radiating power of the surface to establish an equilibrium between heat generated in the wire and the heat radiated from the surface of the wire. If the voltage is raised sufficiently, the wire may be heated to the fusion point. On the other hand, if the voltage is kept low, the temperature of the wire may be only slightly above normal. Because of the positive temperature coefficient of the resistance of metallic conductors, such heat balance can be effected at almost any temperature of the wire between normal and melting temperature, depending on the voltage applied. The following general formula controls this problem. The heat generated in the wire may be expressed by,—

$$H_G = I^2R = \frac{V^2}{R}$$

The heat radiated from the surface of the wire may be expressed as,—

$$H_R = k\,(T_1 - T)\,S$$

wherein

H_G = generated heat.
H_R = radiated heat.
V = voltage across the wire.
I = amperage in the wire.
R = resistance of the wire.
k = specific heat radiating power per unit surface and per degree temperature difference.
T_1 = temperature of the wire.
T = temperature of the surrounding wire.
S = surface of the wire.

The equilibrium or heat balance is established with,—

$$H_G = H_R$$

$$\text{or } \frac{V^2}{R} = k\,(T_1 - T)\,S \qquad (1)$$

$$\text{or } I^2R = k\,(T_1 - T)\,S$$

The behaviour of air, whether in its cold state as an insulator or in its hot state in the power-arc, may be looked upon as being governed at all times by the same general laws of heat balance.

Air Used as an Insulator

Cold air looked upon as an insulator may more properly be termed a very bad conductor. In other words, it is assumed that the voltage applied across a given air space will always create a certain current to flow in the air path. Only the current is so small that it is not measurable. The heat generated in the air path under this condition is so small that it is carried off at practically no temperature rise in the air path.

Referring to formula (1). Every voltage within permissible limits of electric stresses creates a new equilibrium by increasing the temperature T_1 accordingly until the heat generated becomes equal to the heat radiated.

This represents the balanced condition of cold air used as so-called insulator within the permissible voltage stresses.

Air Vapour in the Power-Arc

Air, in contrast to metallic conductors, has a negative temperature coefficient of resistance.

If the voltage, therefore, is raised to a point where the temperature of the air is increased so much that the resistance is dropping rapidly, then the current and accordingly the wattage in the air path is more rapidly increased, thus creating an unstable condition. This leads rapidly to the so-called puncture, that is, the heating up of the air path to arc temperature. This in turn causes a violent expansion of the air path, thus leading to the formation of the so-called power-arc. The dimensions of the power-arc are so large that the resistance of the path becomes small, allowing unlimited current to flow, thus creating what is termed a short-circuit. The power-arc, in its final dimensions, may be looked upon as the new state of equilibrium governed again by the same general law of heat balance.

In this case, however, the governing factor of the balance is no more the voltage across the arc, such as was the

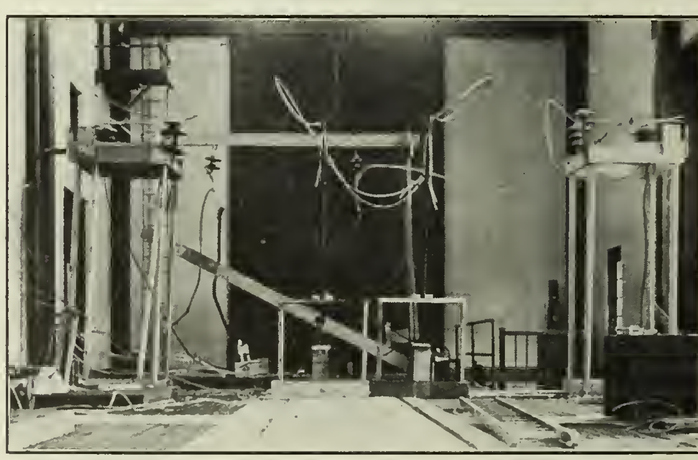

Figure No. 15.—View showing Structure and Loops over which Arcs were Formed.

case with the cold air acting as insulation, but instead it is the short-circuit current which the system is able to discharge through the power-arc.

In this paper, only this last condition, that is, the heat balance of the power-arc, is to be discussed, with the aim of trying to establish the relation of arc amperage, arc voltage and arc dimensions based on the theory of heat balance.

General Formula for Power-Arc

Assume the power-arc to be the stable condition of the heat balance between heat generated in the arc and heat radiated from the arc surface, then,—

$$H_G = I^2R$$
$$H_R = kS\,(T_1 - T)$$

If we assume that the arc temperature is always the same, then we may write,—

$$k_1 = k\,(T_1 - T)$$

In this case, therefore,—

$$H_R = k_1 S$$

wherein

- H_G = heat generated in arc (watts).
- H_R = heat radiated from the arc surface (watts).
- I = current in arc (amperes).
- R = resistance of arc (ohms).
- k = specific heat radiating power per unit arc surface per degree temperature difference (w/sq. ins./1°).
- k_1 = specific heat radiating power per unit arc surface (w/sq. in.). (average value 300 w/sq. in. arc surface.)
- S = arc surface (sq. ins.).

For the heat balance it is found, therefore,—

$$H_G = H_R$$
$$I^2R = k_1 S$$
$$\text{or } \frac{S}{R} = \frac{I^2}{k_1} \qquad (2)$$

Both values S and R are dependent on the physical dimensions of the arc. With increasing dimensions of the arc, S will increase, whereas the resistance R will decrease. This peculiarity permits the ratio S to R to adjust itself to any requirement determined by the ratio I^2/k_1.

Formula for Long Stretched Arcs

In this case the arc may be looked upon as being a circular conductor, see figure No. 17a. Then,—

$$R = r_s \frac{L}{A} = \frac{4\,r_s}{\pi}\frac{L}{D^2}$$
$$S = D\pi L$$

Entered in formula for heat balance,—

$$\frac{S}{R} = \frac{\pi^2 D^3}{4\,r_s} = \frac{I^2}{k_1}$$

From this the diameter of the arc is found as,—

$$D = m_D \sqrt[3]{I^2} \qquad (3)$$

$$\text{where } m_D = \sqrt[3]{\frac{4}{\pi^2}\,\frac{r_s}{k_1}}$$

The voltage across the arc is found from,—

$$V = \frac{k_1 S}{I} = \sqrt[3]{k_1{}^2\,\pi\,4\,r_s}\;\frac{L}{\sqrt[3]{I}} = m_v \frac{L}{\sqrt[3]{I}} \qquad (4)$$

$$\text{where } m_v = \sqrt[3]{k_1{}^2\,\pi\,4 r_s}$$

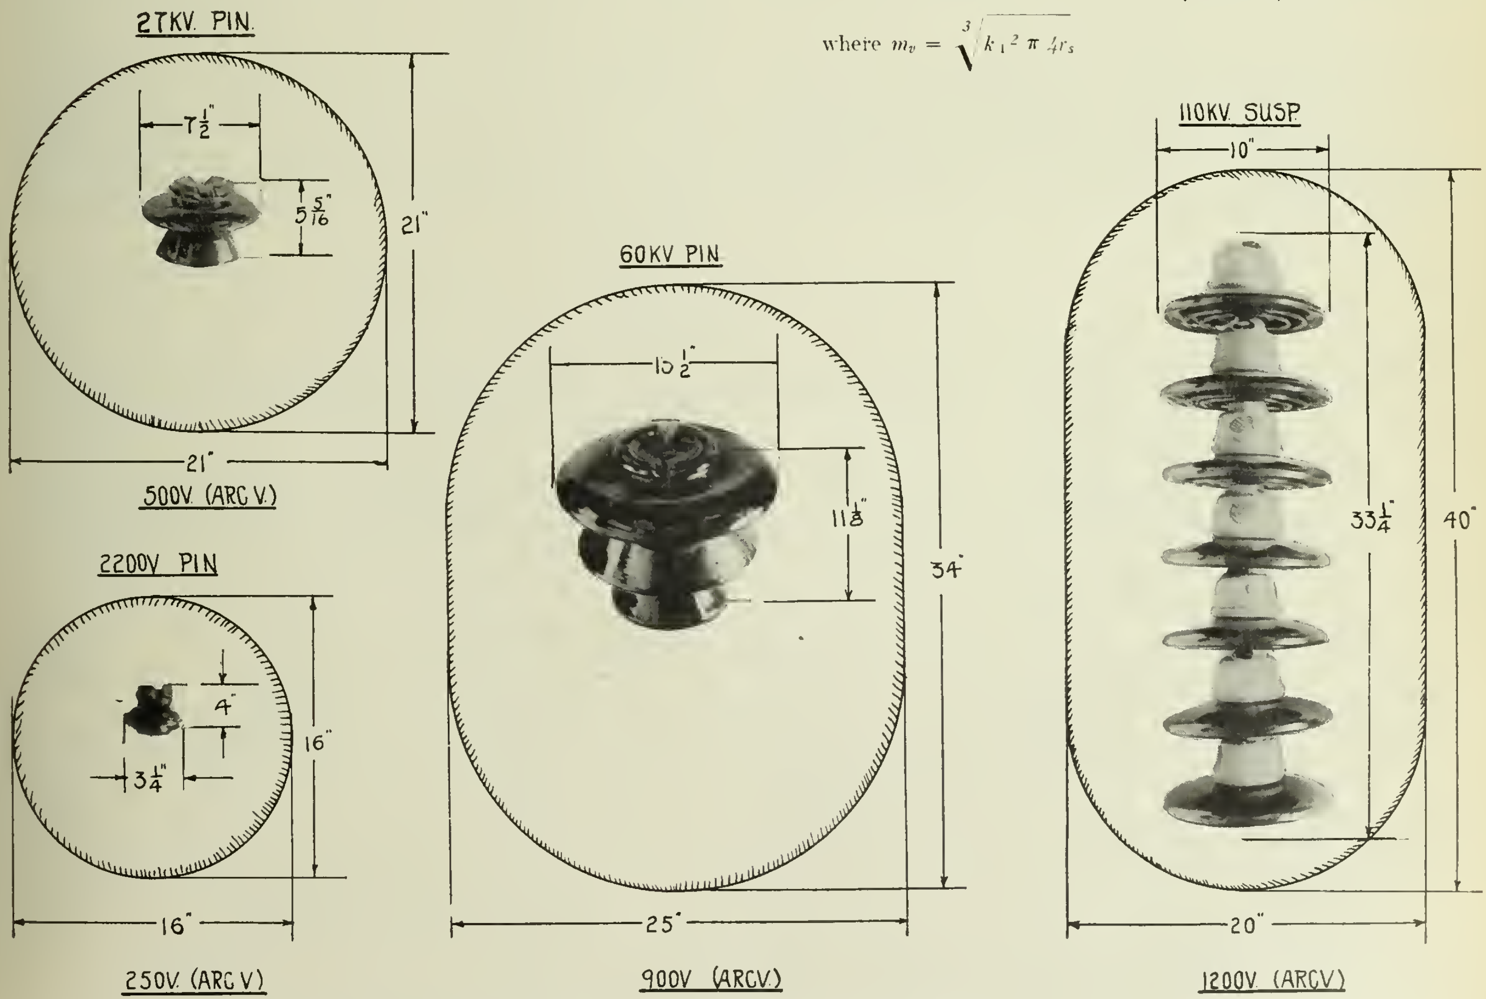

Figure No. 16.—Condensed Summary Results

Showing

Pictures and dimensions of insulators used during tests.
Approximate size and shape of initial arc at 600 amperes before it becomes distorted.
Approximate initial arc volts for currents between 70 and 10,000 amperes.

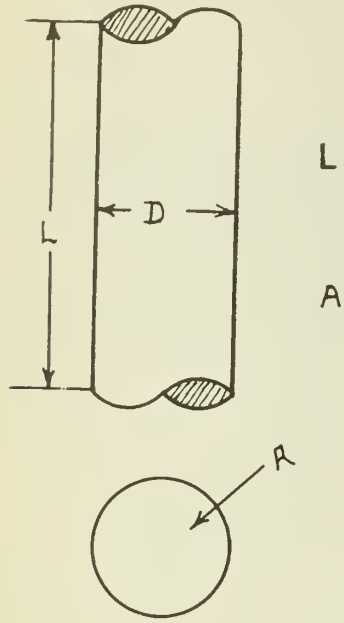

Figure No. 17a.—Assumed Shape of Long Stretched Arc.

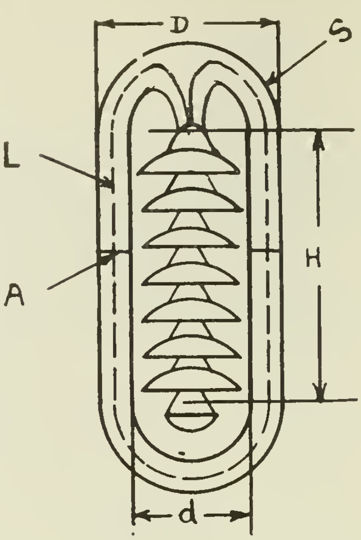

Figure No. 17b.—Shape of Arc Path on Suspension Insulator.

From the tests it is known that the specific resistance (r_s) of the arc vapour is approximately,—

$$r_s = 14 \text{ ohms/cu. inch}$$

and the specific heat radiating constant of the arc surface k_1 = approximately 300 watts per square inch.

Thus, the two practical formulæ for diameter and voltage in relation to the current for the long stretched arc are found as,—

$$D = m_D \sqrt[3]{I^2} \qquad (5)$$

$$V = m_v \frac{L}{\sqrt[3]{I}} \qquad (6)$$

where m_D = 0.26 (based on k_1 = 300 w./sq. inch and r_s = 14 ohms/cu. inch).
m_v = 250.
D = diameter of arc (inches).
L = length of arc (inches).
V = arc voltage (volts).
I = arc current (amperes).
r_s = specific resistance of arc vapour (ohms/cu. inch).

Formula for the Long Suspension Insulator

In this case, the determination of the formula is principally complicated because of the irregularity of the resistance path at the electrode ends which makes it difficult to express the resistance R in a simple formula.

It is beyond the scope of this paper to establish the correct formula for this condition, but it is interesting to bring out this case as an example of a more complex physical shape so as to illustrate the difficulties to obtain a correct formula of the interdependence of diameter, current and voltage of the arc.

In this case, the surface of the arc may be considered as consisting of a cylindrical portion of a height corresponding to the insulator height and two semi-sphere surfaces at the two ends of a diameter corresponding to the arc diameter.

Based on this assumption, the arc surface could be expressed as,—

$$S = D^2 \pi + D \pi H \qquad (7)$$

The resistance of the arc in this case is expressed by,—

$$R = r_s \Sigma \frac{(L)}{A} \qquad (8)$$

From figure No. 17*b*, it can be seen that it is rather difficult to develop the correct formula for the resistance because of the greatly irregular shape of the arc path at the terminal ends. No attempt has been made, for this reason, to solve the mathematical formula for this condition.

Practical Values for the Constants as Deducted from the Various Tests

Specific Resistance of the Arc Vapour

The long stretched arc, as obtained in several of the tests, was considered the ideal test to determine the specific resistance of the arc vapour. In this case of the long stretched arc, the arc shape approaches the simple form of the cylindrical conductor.

No attempt has been made to determine the true wattage in the arc. The oscillographs indicate that there seems to be no shifting between the current and voltage wave, so that it was assumed that the product of volts and amps. would correspond to the true wattage. Also, no attempt was made to determine the true effective voltage from the distorted voltage wave of the arc voltage, but instead the calibration is based on the peak voltage of the distorted wave to correspond to an equivalent sine wave.

All these factors introduce, naturally, a certain error which, from a physicist's viewpoint, would not be acceptable. From a practical viewpoint, however, these assumptions may be considered acceptable, in view of other natural errors of possibly far greater proportions in the determination of the arc dimensions, because of one view of the arc being available, whereas the depth of the arc being not definitely known.

Table No. 1 shows the values obtained from an analysis of the long stretched arc for different stages of the developing arc.

It will be noticed that the results are fairly close, and that, as a result thereof, the specific resistance of the arc vapour may be taken as approximately 14 ohms per cubic inch.

Compared with copper, which is 7 x 10^{-7} ohms per cubic inch, the resistance of the arc vapour is about 20,000,000 times greater than the specific resistance of copper.

It is felt that the specific resistance of the arc vapour should change very little. In other words, it should be a constant value under practically all atmospheric conditions.

Radiating Constant k_1

From the moving pictures, it is possible to determine the approximate arc surface for the various arcs. If we further accept that the wattage of the arc is represented by the product of volts and amperes, it is possible to determine the watts per square inch surface of radiating power of the arc. The long stretched arc used for determining the specific resistance of the arc vapour is found to be satisfactory also for the determination of this constant, giving comparatively close values, as indicated in table No. 1.

In a similar way, as above, (k_1) has been determined for other tests with other shapes of arcs. It is found, however, that these values, in some extreme cases, are rather largely different. This large variation may partly be due to the crude method and uncertainty of measurement of the arc dimensions because of not knowing the actual depth of the arc. Partly, the difference in values may be due to different radiating conditions either influenced by the shape of the arc or by the air conditions. Table No. 2 shows the values obtained for the various tests.

The average value may be taken as $k_1 = 300$ watts per square inch for arcs below 1,500 amperes. Some of the values have been, however, as low as 60 watts and a few values as high as 600 watts per square inch. For 10,000-ampere arcs (k_1) has been found to vary between 2,000 and 4,000 watts per square inch. It is not quite clear whether these high values are to be attributed to the higher

current values combined with the larger wattage creating a greater steering motion in the arc or whether they are due to the greater depth of the arc because of the larger explosive effect of this type of arc along the electrode. Another factor responsible for the higher values may be the altered test condition with somewhat greater air currents prevailing. Beyond doubt, it has to be assumed that this factor (k_1) is not a constant value and is probably largely dependent on wind and the shape of the arc changing the radiating condition.

Appendix III.

Theory of Self-Extinction of a Power-Arc

In appendix II, discussing the theory of the power-arc, it is shown that a power-arc assumes such dimensions until the generated heat within the arc and the radiated heat from the arc surface are striking a balance for a given amperage. The physical dimensions of the arc are therefore entirely controlled by the current in the arc.

For any such given condition, the voltage across the arc will be a certain definite value. Suppose, now, that the system is unable to maintain the voltage across the arc which is required for the respective set of conditions, that is, for the given amperes and the given length of the arc, then an unstable condition would be created which will tend to extinguish the arc rapidly. This can be appreciated from the following:—

Assume that the voltage across the arc is lowered below the critical arc voltage, then with certain given arc dimensions the current will be lowered. This causes the arc diameter to shrink, which in turn increases the resistance of the arc. This in turn again causes a further lowering of the current, which further accentuates the shrinking of the arc, etc. This will continue until the arc is completely ruptured.

The criterion for the critical voltage which is just able to maintain an arc can be deducted from the heat balance theory of the arc.

From the heat theory, it is known that the arc assumes physical proportions until the balance is established between generated heat and radiated heat.

The moment where the generated heat is smaller than the radiated heat, then a rapid cooling of the arc must result.

The generated heat may be expressed as,—

$$H_G = \frac{V^2}{R}$$

and the radiated heat,—

$$H_R = k_1 S$$

A cooling of the arc and consequential self-extinction is to take place, therefore, if,—

$$H_G < H_R$$

$$\frac{V^2}{R} < k_1 S$$

$$V < \sqrt{k_1 S R} \qquad (9)$$

The above is the general formula for the voltage of any kind of an arc.

Self-extinction can be expected only with a long stretched arc, the critical arc length depending on the available voltage. It is possible, therefore, to determine S and R for this particular shape of an arc assuming the shape of the arc path to be cylindrical.

The surface is then expressed by,—

$$S = D \pi L$$

and the resistance of the arc,—

$$R = r_s \frac{L}{\frac{D^2 \pi}{4}}$$

With the above values entered in the general formula, it is found that for self-extinction the voltage must fulfil the following condition,—

$$V < \sqrt[3]{k_1^2 \, r_s \, 4 \, \pi} \; \frac{L}{\sqrt[3]{I}} \qquad (10)$$

From the tests, values have been determined for k_1 and r_s and it is found, therefore, by inserting these values

Table No. 4.—Critical Arc Lengths.

Critical arc length for different operating voltages and arc currents, calculated from $L_c = \frac{V}{M_v} \times \sqrt[3]{I}$

based on assumed values (k_1 - 300 w./sq. in. (r_s - 14 ohms./cu.in. (m_v - 250

Operating voltage	Arc Amp.	Critical Arc length in feet
2200 V.	1A	0.73 ft.
	100	3.42
	1000	7.30
6600 V.	1	2.2
	100	10.2
	1000	22.0
13000 V.	1	4.4
	100	20.2
	1000	44.0
60000 V.	1	20.2
	100	93.0
	1000	194
110000 V.	1	37
	100	171
	1000	370
220000 V.	1	73
	100	342
	1000	730

that for the long stretched arc the critical voltage can be found as being,—

$$V_c < m_v \frac{L}{\sqrt[3]{I}} \qquad (11)$$

where

$m_v = 250$ (*based on $k_1 = 300$ w/sq. inch and $r_s = 14$ ohms/cu. inch*).

The above indicates that for any given amperes and arc length, there is a certain critical voltage necessary to maintain an arc, or that for any given amperes and voltage across an arc, there exists a certain critical arc length which, if extended further, will cause a snapping off of the arc.

A theoretical study of the inter-relation of the three values of voltage, current and arc length will give a clearer conception of certain facts known by experience.

Assume $m_v = 250$, this being the average found from the tests of the long stretched arc, and assume that the factor is unchanged for the most extreme conditions, then it is possible to work up a table showing the inter-relation of critical voltage, arc current and arc length.

Table No. 3 illustrates, for an arc of one-foot length, how the critical arc voltage changes with the current. For any given current, the arc would snap off, if the voltage across the arc would drop, for any reason, below the corresponding critical voltage.

The table indicates clearly how little voltage is required to maintain a power-arc after it has been established. This explains the reason for the tenacity and persistency of a power-arc. Even arcs on isolated neutral systems of only a few amperes capacity current will readily persist, as according to the table a one-ampere arc will only require 2,600 volts across the arc.

It is interesting to note that cold air used as insulating medium and subjected to any voltage below its breakdown voltage, that is, less than 120,000 volts for one-foot gap, must have a leakage current of less than 0.000016 amperes. Otherwise, no stable condition could exist. As soon as the air is subjected to breakdown voltage, then the leakage current increases rapidly and an unstable condition is created which ultimately ends with the formation of the complete power-arc which finds its new state of stability only after the arc has developed to the dimensions corresponding to the short-circuit current, which the power system is capable of discharging through the arc. With 1,000 amperes passing through the arc, the arc voltage, according to the table, would only be 260 volts; that is, only 0.2 per cent of the breakdown voltage of cold air.

The apparent relation of volts and amperes for cold air as insulator and for arc vapour is illustrated arbitrarily by the curve shown in figure No. 18.

Table No. 4 indicates how far an arc would have to be lengthened out for different operating voltages and currents before the arc would tend to snap off.

This table shows further the reasons of the tenacity of the arc hanging on and also how easily it is possible for the arc to reach out into adjacent phases or circuits.

The table shows clearly how little prospect there exists of self-extinction of a power-arc except under most favourable conditions of very strong wind and ideal condition of a long loop being able to form without arc vapours short-circuiting out the loop.

Tendencies in Steel Building Design

A Review of the Development in the use of Structural Steel in Building Construction

D. C. Tennant, M.E.I.C.
Structural Engineer, Dominion Bridge Company, Limited, Montreal.

Paper read before the Toronto Branch of The Engineering Institute of Canada, March 1st, 1928

The development of the use of structural steel in building construction is interesting. In the year 1881 there was published a " Pocket Companion of Useful Information and Tables Appertaining to the Use of Wrought Iron as Manufactured by Carnegie Brothers and Company, Limited, Proprietors, Union Iron Mills, Pittsburgh, Pa." This book was one of the earliest pioneers in the industry and may be considered as a classic. However, it does not make any mention of steel, but deals entirely with wrought iron. It shows beams and channels up to 15 inches deep only, and angles as large as 6 by 4 inches and 6 by 6 inches. It includes also tees and some now obsolete shapes such as half tees, star irons, corrugated columns, octagon columns and patent rivetless columns. The allowable unit stresses used for wrought iron are,—shear, 9,000 pounds; fibre stress in bending either tension or compression, 12,000 pounds per square inch, which is decreased to 10,000 pounds on the gross area of built-up girders in order to compensate for the loss in section due to rivet holes.

In 1887, the Pottsville Iron and Steel Company published a handbook illustrating much the same shapes as those in the 1881 edition of the Carnegie Pocket Companion, but showing strengths for both iron and steel, the allowable unit stresses on extreme fibres in bending being respectively 12,000 and 15,600 pounds per square inch.

In the early eighties, fabricating companies began to assume some importance in Canada, the first being the Toronto Bridge Company, which afterwards became the Dominion Bridge Company, with branches in several cities. The Hamilton Bridge Company came into existence shortly after this. In those days, production was on a very small scale and the fabricating companies, as their names would indicate, were concerned chiefly with bridges. Many of the bridges first built are still doing good service, carrying much greater loads than the designers intended. In fact, bridge work constituted at least seventy-five per cent of the tonnage of the day.

Iron was in general use for all purposes and was only gradually displaced by steel, iron rivets being in use until well on in the nineties. The feeling was that steel might not be thoroughly reliable, and some engineers insisted on built-up members being annealed after fabrication was complete. Sometimes the members emerged from this process badly twisted and sometimes not. By the end of the nineteenth century, steel had entirely replaced iron except for very special purposes, its quality was assured, essentials of good practice in design, fabrication and erection became recognized and bridge specifications were written.

Development of Specifications

Two specifications might be mentioned as helping to crystallize these essentials for bridges, namely, the 1905 Specification of the Department of Railways and Canals in Canada and the 1910 Specification of the American Railway Engineering Association. These required for mild steel an ultimate breaking stress in tension of 55,000 to 65,000 pounds per square inch and an elastic limit of one-half the ultimate strength. The allowable working stress in tension was given as 16,000 pounds per square inch. Due largely to the work of the American Society for Testing Materials, the steel now obtained from the American and Canadian mills is of uniformly high quality, the elastic limit ranging generally from 35,000 to 38,000 pounds per square inch and always rather more than one-half the ultimate strength.

In 1922, the Canadian Engineering Standards Association published two steel specifications, one on railway bridges and one on highway bridges. These have been for some time closely adhered to by all Canadian railroads and by most provincial highway departments. These two Canadian Engineering Standards Association's specifications call for a unit stress in tension of 16,000 pounds per square inch.

It was not until 1924 that the Canadian Engineering Standards Association's specification for Steel Building Construction was issued, being the first effort to standardize throughout Canada rules applicable to structural steel in buildings. The effort was timely. Previously, such regulations had been made in the larger cities by means of building codes, in other cases by the architect or engineer of the structure and sometimes by the steel contractor. Great variety resulted. Importance attaches to the situation owing to the fact that in the past thirty years the amount of building steel fabricated has increased from less than twenty-five to more than seventy-five per cent of the total, and the columns, girders and trusses of some of the larger buildings are among the heaviest and most complex members that occur in steel structures anywhere.

Of course, there is a danger of too much standardization. Some engineers hold that the first clause in all specifications should read, " This specification is not to be followed if good reason can be shown to the contrary." Others go further and remark that "Any organization that gets out a set of standards is bound for the grave." Undoubtedly, the best results are obtained only when those responsible for interpreting a specification have also written it or are capable of doing so.

Comparison of Building Code Requirements in Six Cities

It may be instructive to compare the present requirements regarding structural steel in the building codes of the six largest cities in Canada with those of six cities in the northerly portion of the United States. The six Canadian cities are Ottawa, Hamilton, Vancouver, Winnipeg, Toronto and Montreal. The others are Rochester, Buffalo, Cleveland, Detroit, Chicago and New York. Comparisons can be made regarding assumed live loads, allowable reduction of live loads, allowable unit stresses, specified wind loads and allowable stresses in connection with wind. The American Institute of Steel Construction has succeeded to some extent in standardizing steel requirements in building codes.

Of the cities considered, the Specification of the American Institute of Steel Construction has been adopted in whole or in part by Hamilton, Winnipeg, Montreal, Rochester, Buffalo and Detroit. As regards live loads, good work has been done by the United States Department of Commerce Building Code Committee, which issued in 1925 a

Table No. 1.—Assumed Weights of Various Building Materials.

	Per Cu. Foot

" ceiling on large public rooms, such as dining rooms, ball rooms and lobby, including steel furring	15 "
Roofing, based on 5-ply felt and tar and gravel	8 "

book, "Minimum Live Loads Allowable for Use in Design of Buildings," and it is well to compare live loads as listed in this book with those required by the various cities.

From a structural steel standpoint, the larger buildings, such as churches, schools, hospitals, hotels, office buildings, public buildings, and particularly those over ten storeys high, are of most interest, and high buildings will therefore be the ones specially dealt with here. The dead load is almost always described as including walls, partitions, framing, floors, roofs and all permanent construction. Only a few of the codes actually list the unit weights to be assumed for various building materials. There are a few unimportant discrepancies in these weights as given by different cities. Table No. 1 shows assumed unit weights acceptable to both Toronto and Montreal and probably to most other cities. This table of unit weights was actually used in the design of the steelwork for the Canadian Pacific Railway Royal York hotel, Toronto, on which the erection of steelwork is progressing.

A comparison of the live loads to be provided for in the various cities is shown in table No. 2, and there are also indicated the live loads called for by the Building Code Committee of the Department of Commerce at Washington. The dates shown for the various codes are those on which the latest revisions were made. Cases occur in the codes where more than one interpretation might be made of the live load requirements for a particular room, but it is believed that the table gives a fair comparison.

In the allowable reduction of live loads the codes show quite a variation, and table No. 3 illustrates this. Concentrated loads such as safes, vaults, ovens, pipe organs, elevators, elevator machinery and tanks should be specially provided for.

Again, in specifying unit stresses the different cities are at variance, as shown in table No. 4. It is notable that exactly one-half of the codes considered adopt the increased unit stresses allowed by the American Institute of Steel Construction, and this in spite of the fact that the Institute's specification is only five years old. The increasing use of these higher unit stresses is no doubt due to the feeling that constantly growing knowledge and care in the manufacture of the steel itself and improvements in accurate methods of fabrication and erection justify the change. In fact, a majority in the American Society of Civil Engineers actually favoured an allowable stress in tension of 20,000 instead of 18,000 pounds per square inch. The latter stress was adopted in order to obtain unanimity. Needless to say, however, it would be a mistake in any city to decide on allowable unit stresses without taking into account the likelihood of the assumptions regarding live load, special load or wind being fully realized.

Wind Loads and Allowable Stresses

The cities do not agree any better about wind loads and allowable stresses therefrom than they do about other clauses. This is apparent from table No. 5. Canada is as free from earthquakes and hurricanes as any country in the world, and it would therefore seem reasonable that wind loads should be assumed somewhat less than would be desirable for Florida, San Francisco or Japan. Observations over many years of wind velocities at the top of Mount Royal show a maximum of 72 miles per hour, which occurred during a hurricane. This would correspond to a wind pressure of about 17 pounds per square foot. It will be seen from table No. 5 that most cities call for wind loads in excess of this 17 pounds. It seems unlikely, therefore, that the wind loads specified will ever occur. Moreover, once the building is complete the walls will surely relieve the steel of much of the wind stress.

Prior to the building of the walls there is likely to be very little exposed surface to obstruct the wind. At the same time, it is absolutely necessary, even in calm weather, to provide some considerable stiffness for general stability, especially during the erection of the steelwork, and ordinarily some adequate provision for wind will obviate the possibility of the steelwork shaking and getting out of plumb under the action of the erection derricks before any walls are built. The codes do not direct how the wind pressure is to be carried to the foundations, but it is often assumed to be resisted entirely by the steel, and engineering journals at present are replete with theories on the subject.

The engineer of a prominent fabricating company says:—"There has been so much written about this subject of late that it seems that our structural engineers are wandering far afield trying to follow some of the theories expressed by wind enthusiasts. We have recently gone over the details of four buildings going through one of our shops, where one might expect that the provision for taking care of wind stresses would be somewhat similar, that is, what would be safe for one building should be sufficient for all. In one case, where the wind bracing might be called reasonable, and for all practicable purposes sufficient, the beam and girder connections were about twelve per cent of weight of the beams, while in another the extra provisions made for taking the wind force were about four to five times those for carrying the vertical load, and the total beam connections were between thirty-five and forty per cent of the connecting beams or girders. The amount of wind bracing for the other two buildings was between these two extremes. Theorists start out with the wrong assumptions as to loading, without giving sufficient consideration to the construction of each individual unit, and then making use of one of the numerous methods of computing stresses they try to develop connections that will take care of the lateral forces they have discovered." The general problem resolves itself into finding, from the areas exposed to wind, the horizontal shear to be transmitted from each floor to the floor directly below it and making sure that the walls, partitions, vertical sway bracing and the stiffness of the steel frame exclusive of sway bracing, will give together a resistance sufficient to transmit this shear satisfactorily. This resistance should be considered both transversely and longitudinally. Opinions regarding wind loads differ, as has already been noted. Then the effectiveness of the resistance offered by walls and partitions, and their bond to the steelwork, and the reinforcing supplied to the steels beams and columns by the concrete floor slab, haunch or encasement, are matters of considerable conjecture. So that until our assumed wind loads and resistances are more fully known, it is not only foolish but impossible to expect accurate diagnoses of the results. There seems to be here a field for research.

It is not to be expected that one method of solution for the wind problem will apply to all high buildings. This one, owing to the great area of its base may not need any X bracing or knee braces, while that one, with perhaps lighter live and dead loads and narrower base, will demand it. Among recent buildings by the Dominion Bridge Company may be mentioned the Canadian Pacific Railway hotel at Banff, Alta., with a tower of sixteen storeys and specially strong wind connections on the tower portion only and for just about half the height; the Royal Bank building, Montreal, twenty-three storeys, with wind connections from beams to columns for practically the whole height, also X bracing and portal bracing wherever possible on the long storey height at the main floor level to accommodate the large banking room; the Canadian National Railways extension to Chateau Laurier in Ottawa, a ten-storey building with no special connections for wind and connecting to a portion already built; the Sun Life Assurance building, Montreal, where the new extension is eight storeys above the sidewalk, with provision for ultimately about twenty-four storeys and with no special provision for wind until the fifth floor, where heavy flange connections are used on the beams; the Canadian Pacific Railway Royal York hotel, Toronto, a twenty-six storey building with special wind connections almost to the top but with no X bracing at all; and the Bell Telephone building, Montreal, a twenty-one storey building with provision for wind resistance similar to that in the Royal Bank building.

Figure No. 1 shows a rather peculiar-looking building, the steelwork being designed with no provision for doors or elevators and assuming a uniform load per square foot of floor for partitions. In fact, it is a hypothetical office building with all assumptions simplified to facilitate the steel design. In height, number of floors, spacing of columns, area of base, cubical contents and exposed wind surface, this hypothetical building is about the same as the new Bell Telephone building in Montreal.

Three trial designs have been made, one to conform to the code of each of the three largest cities in Canada,—Winnipeg, Toronto and Montreal. The beams have been designed, as far as possible, to the new Carnegie beam section and the columns to the Bethlehem section, using special Bethlehem 14-inch, 149-pound H's where cover plates are necessary. Heavy slabs are used in all cases at the column footings, assuming an allowable soil pressure of

50,000 pounds per square foot. Actually, it is not supposed that any real building of this size and shape would be built with so little total steel as these designs show, because special cornices, corbels, pilasters, offsets and skews would undoubtedly be introduced for appearance sake, to say nothing of necessary doors, windows, elevators, stairs and other irregularities which would all tend to increase the steel.

The diagram shows the differences in design data and in weight of steel per cubic foot of building. It will be noted that the Winnipeg code results in lighter steelwork than either of the other two. Incidentally, taken as a whole, it is the most recently written of the three, and thus naturally takes the fullest advantage of the trend towards a slight reduction in assumed live loads and a slight increase in allowable unit stresses. It is fair, also, to mention that had the steel beams been designed to standard sections, instead of special shapes, the differences would have partially disappeared, because it so happened that in a large number of them the variation in codes was not sufficient to justify the use of a different standard beam. A careful perusal of the Winnipeg code is well worth while. One is impressed with what it contains and how it is arranged.

To have a good garden, it is most desirable to have good garden tools and to keep them in shape, but a wise gardener with poor tools will often produce better results than a more ignorant one with the best equipment. The application of our building codes is much more important than the codes themselves, the smaller towns and villages near any large city are prone to make use of that city's building code, even when they are not fully conversant with the reasons underlying the code, and for that reason it may be well that the code be conservative. But in these large cities themselves there is always a very efficient architectural and engineering staff engaged by the city to interpret its rules, and such engineers look on the code not as a fetter but as a basis for the exercise of their sound judgment. At least, that is the case in the city of Toronto, and, so far as the writer's experience goes, it is also true of other large cities.

There is no sign that the end of improvements and economies in steel design for buildings is yet in sight. In 1924, under the guidance of Professor P. Gillespie, M.E.I.C., of the University of Toronto, Professor H. M. Mackay, M.E.I.C., of McGill University, and Professor C. C. Leluau, M.E.I.C., of the University of Montreal, tests were conducted on the strength of steel beams embedded in concrete slabs, and a set of tables was published as a result of these tests showing formulæ and increased carrying capacities for beams of various sizes with different concrete slabs. For some reason or other, engineers in general have been cautious in using these tables, even where they might do so without infringing on any regulation. It is not known that anyone seriously doubts the results of the tests, and it would be interesting to hear of any experimental data that would conflict with these results.

Use of Special or Alloy Steels

From time to time suggestions are heard that on the larger loft building columns, and even on other buildings, economic use might be made of special or alloy steels where higher unit stresses might be allowed. Special high carbon steel and silicon steel may be considered and table No. 6 shows some instances where such steels have been used in actual structures,—not all of them buildings.

An interesting example not shown in table No. 6 may be noted. The specifications of the Canadian National Railways in the past have provided for an elastic limit of 27,500 pounds per square inch, with a minimum ultimate tensile strength of 55,000 pounds per square inch. In connection with the Point St. Charles shops now being built, the Canadian National Railways specifications provide for a minimum elastic limit of 35,000 pounds per square inch and a minimum ultimate tensile strength of 60,000 pounds per square inch. With this quality of steel, a design stress of 22,000 pounds per square inch was used. Silicon steel has, to the writer's knowledge, been used for only two important building structures on this continent, and these were by the American Bridge Company. In a power house for the Philadelphia Electric Company, silicon steel was used throughout in the design. This was modified somewhat in order to meet mill conditions by substituting carbon steel for shapes that were little used or that were not rolled at the same mills as the rest of the material. Thus, the rolling of the silicon steel was confined to one mill.

The other use of silicon steel was in the Cleveland terminal work, where, to some advantage, it was substituted for carbon steel in the heaviest columns and some of the large supporting girders. Experience seems to show

Table No. 6—Special Steels and Allowable Unit Stress.

Structure	Steel	Unit Stress pounds per sq. inch
Bear Mountain Bridge	Silicon Special	27,000
Philadelphia-Camden Bridge	Silicon A.S.T.M.	{24,000 in Towers 32,000 in Stiff Tr.

that it is not worth while to attempt the use of silicon steel throughout a structure. It pays only when the tonnage produced by the mill on one order makes it worth while preparing ingots for rolling and where the use of this material in extremely heavy members makes a saving sufficient to warrant its use.

Nickel steel has not been used in buildings to any extent. With gradual increase in the size of building columns, owing to increasing number of storeys, there may emerge more pronounced advantages from the use of special steels.

Welding Structural Steel

Another important development in structural steel for both bridges and buildings is the use of acetylene and electric welding, especially the latter. Many structural concerns are using electric welding to some extent, both in their shop and erection work. With increased skill and knowledge, due to experience, the results are surprisingly reliable. Two of the most spectacular examples of welding in structural steelwork are a complete five-storey building for the Westinghouse Electric and Manufacturing Company at Sharon, Pa., by the American Bridge Company, and a complete one-storey building two acres in extent for the Westinghouse High-Voltage Insulator Company at Derry, Pa., by the Jones and Laughlin Steel Corporation.

As a result of welding developments, there is a demand for reasonable unit stresses usable by designers. A fillet weld may be stressed and fail in three ways,—longitudinal shear, transverse shear or tension. In structural steel work, welds can be and usually are designed for their value in longitudinal shear. Moreover, Mr. Andrew Vogel, of the General Electric Company, has just recently reported on a series of ninety-six tests performed by the Rensselaer Polytechnic Institute showing ultimate strengths in longitudinal shear. He suggests working strengths per lineal inch of 2,600 pounds per ¼-inch weld, 2,900 pounds for 5/16-inch weld and 3,200 pounds for ⅜-inch weld.

Electric welds are considerably affected by the quality of the welding wire used, also by the accessibility of the joint to be welded. Ideal conditions would be with the joint horizontal or on a slight incline and with the weld to be deposited from above; good results can also be obtained on vertical seams; but if horizontal or inclined seams have to be welded with the weld applied from below, it is difficult, if not impossible, to obtain the best results.

Experimental data are not yet sufficient to establish economical working stresses for tension and transverse shear in electric welds. It is hoped that these may come soon, and research along these lines is progressing. Meanwhile, structural welders may look to the future with hope and confidence. The advantages of welding are simplicity of equipment, rigidity of connections, saving in main material and details, watertightness, quietness of the operation. Its disadvantages are possible inexperience or inefficiency of the operator, introduction of heat stresses with crystallization. The research workers in the welding field deserve the thanks of all engineers.

Discussion of Paper on the Electric Heating of Rack Bars in Hydro-Electric Plants by C. R. Reid.[1]

Mr. C. R. Reid.[2]

Mr. Reid, in presenting the paper, desired to bring out a few points which he had omitted.

The possibility of contending with ice troubles by heating rack bars electrically had no doubt occurred to a great many operating engineers. Since preparing this paper he had learned that John Murphy, M.E.I.C., of the Department of Railways and Canals at Ottawa, had read a paper on the subject before the Canadian Electrical Association in 1907, had done some experimental work and had taken out patents which had since expired.

The installation at Shawinigan Falls had given satisfactory results, and the author believed that the features of its design and structural details would be of interest to the members of The Institute.

The cost of insulating the rack bars was approximately $10.00 per kilowatt of input. If racks were insulated when first built the additional cost for insulation should not exceed one-half of the above amount. The leakage current was calculated to be 1.6 per cent, this being based on the experimental determination of the resistance to ground on the racks in one bay. On this basis, a higher voltage might be used without leakage becoming excessive. He might also say that the leakage which passed through the water was not considered to be of any special value; it merely heated the water in general, while the important feature in this method of dealing with the ice was the heating of the rack bar, keeping it a fraction of a degree above the freezing point, so that the ice would not stick to it, and the frazil ice, as it came down, instead of adhering to the rack bar, would slip through.

He would not recommend using a higher voltage than 220, on account of the danger of breaking down the insulation, and more particularly on account of the danger to the employees who might be working on the racks. In this connection, he would point out that while it is possible to rake the racks while the power is on, it is the practice to shut off the power while raking. The circuits throughout the rack were so arranged that an ice rake could bridge over a portion of the circuit, creating a shunt through which the current would flow. Thus, putting a rake down and bridging across from one branch of the circuit to the next might cause rather severe sparking in the water and a slight amount of pitting or burning on the rack. Due to self-induction, the current tended to be crowded into the outer bars of a parallel group.

The ideal arrangement in this respect called for not more than two bars in a parallel. However, with the four-bar parallel used at Shawinigan Falls the distribution of current in the bars was uniform enough for all practical purposes, and, of course, the more bars in parallel the lower would be the cost of insulation. The power factor on a circuit made up of rack bars was quite low, and for this reason it had been found advantageous to use electrical energy of the lowest frequency available. In the case described, 30-cycle current was available and was chosen because it was the most convenient and also because it would give a slightly better power factor.

Mr. J. S. Riddile.[3]

Mr. Riddile believed that engineers and operating companies would welcome this concise and explicit description of a successful installation of electrical rack heating to prevent frazil troubles in power station operation.

He wished to mention another form of specific constant which would be found useful in first approximation to requirements for electrical heating of racks for a given unit or plant and which is mentioned in the literature of the subject. The power required for heating had a fairly definite relation to the rate of water flow through the racks. By computation from some of the author's constants, it appeared that this power is equivalent to that rate of flow taken at about three feet head. In the author's installation, this would amount to about two per cent of the unit rating.

The constant expressed in terms of head made it simple to rough out the heating requirements for any plant, the power equivalent to about 3 to 6 feet head being a good first guess.

In considering the possibilities for ice hazard, due attention should be given to all of the generally accepted conditions conducive to the formation of frazil. Briefly, these conditions consisted of:—

1. High wind or other source of turbulence;
2. Sudden substantial drop in temperature below the freezing point when there is
3. Incomplete or inadequate ice cover on the pond of forebay.

Sometimes a period of years would elapse without these coincident conditions, leading to a false sense of security.

The experience of the Laurentide Power Company was a definite case in point. The pond is large,—some twenty-five miles long. The normal velocity through the pond is low. There is a curtain wall upstream from the racks and extending down some 15 feet below the water surface. The bottom of the intake and racks is 60 feet below the water surface. The rack and head-gate chambers are covered by the gate-house, where the air temperature is always well above the freezing point.

During the first nine years of operation there was no trouble from frazil, and scarcely any indication of its presence. It was surprising, therefore, in the tenth year to have an attack of frazil which required two days' hard work to combat. For part of that time a large percentage interruption could not be avoided with the means at hand. There was no structural damage,—merely a large fractional stoppage of flow through the racks.

To produce this tenth year attack, all of the elements combined. There was early winter high water, producing abnormal forebay velocities; there was mild, cloudy weather and no ice cover. And then a bitter north wind carried the temperature down many degrees below freezing and whipped the surface of the pond.

In the twelfth year like conditions prevailed, with somewhat like results. Experience and better protective measures were of material benefit.

Mr. Riddile felt that he should not refrain from citing these adverse experiences at a development where conditions were all thought so favourable that frazil trouble

might never happen. Nine years of smooth sailing had tended to confirm this earlier opinion.

Even to-day, and in important plants, the basis of the design of the rack structure was sometimes too optimistic. Ordinarily, the structure was planned to withstand nearly the entire head that would be imposed if the racks were completely obstructed,—as they could be by frazil. Experience with frazil-producing streams warranted such full protection.

E. V. Caton, M.E.I.C.[4]

Mr. Caton remarked that the information given in this paper would undoubtedly prove of value to those who are troubled with ice conditions similar to those described. His company had had some trouble at the Pinawa plant with frazil owing to the local conditions, and in general their experience had been exactly along the lines outlined by the author. The type of racks installed at Pinawa would, however, necessitate considerable alterations to be suitable for the electrical method of heating.

He had secured very good results by closing in the rack room and heating this partly by air from the generator room and with supplementary steam radiators for extreme weather. Steam radiators were laid along the top of the racks at floor level above the water, and it was found that the heat conducted down through the rack bars effectually prevented frazil formation.

He believed that in many cases closing in the rack room and relying on the conductivity on the part of the rack structure projecting above water to carry the heat down below would satisfactorily serve the purpose, but in the case he had mentioned the racks were comparatively small and the depth of water was around thirty feet, which was quite different to the size of racks and water conditions existing at Shawinigan. The conditions were, in fact, such that the methods which prove satisfactory in this case might not be satisfactory at other plants.

In Mr. Caton's opinion, the prevention of ice trouble was largely a matter which must be given consideration in each individual case, and such papers as that now presented enabled one to profit by the experiences of other companies when laying out new plants or when endeavouring to prevent trouble on existing plants.

John Murphy, M.E.I.C.[5]

Mr. Murphy pointed out that the author had given definite data which should be useful to operators of hydraulic plants troubled with frazil. He had shown how his own racks were constructed, how much electrical energy was required to heat them and the beneficial results of heating them. If he did not have faith in rack-heating, he would not have made the installation.

Had his paper been published a few years ago, he undoubtedly would have heard from Mr. Murphy's solicitors; but, as the patent rights had expired, he would not hear from them now.

Buried in the 1904 Transactions of the Canadian Society of Civil Engineers,—the predecessor of The Engineering Institute of Canada,—under the title "Loss of Heat in Iron Pipe," by Col. R. W. Leonard, M.E.I.C., would be found an interesting paper and discussion relating to the virtue of passing hot water through hollow rack bars, just as the author had suggested at the end of his paper. All, save one, of those who discussed Col. Leonard's paper in 1904 were so saturated with knowledge concerning the immense quantities of *heat required to melt ice and to heat water* that they lost sight of what he advocated altogether; J. G. G. Kerry, M.E.I.C., said: "He is not trying to heat the water or to melt the ice,—he is *heating the metal* so that the ice will not stick to it." Mr. Murphy's own moving pictures, which were staged and photographed in Ottawa just after his ice-prevention demonstrations at the Chateau Laurier at The Institute's annual meeting in 1919, showed clearly the reasonableness of all the author's contentions.

Mr. C. R. Reid.

The author, in referring to Mr. Riddile's discussion, found it not quite clear with reference to a means of calculating the power required to heat the racks for a given installation. The evident intention is to assume that from three to six feet of the total head available will be used in heating the racks. For a head of 150 feet, this would represent from 2 to 4 per cent of the energy developed by the total head. No doubt this method of treating the question would be useful to the hydraulic engineer.

In the paper, the author had brought out the point that it would be possible to keep the energy requirements more or less a constant percentage of the output of the unit by the use of wider rack spacing for the lower heads. Rack spacing should be proportionate to the openings through the runners, and should be a little less than the opening through the runners, so that anything that would go through the racks would go through the turbine. If the spacing were a little larger the bucket openings would soon be blocked up with pieces of wood, and it would be necessary to shut down and punch them out. For lower heads, assuming the size of the unit to be constant, it was necessary to have larger turbines and larger openings between the buckets, and therefore wider spacing between the rack bars would be permissible. The formula which he had developed showed that the power required is proportional to the quantity of water passed, divided by the spacing between the bars; so that for a given power output, if the head is reduced, the spacing can be increased in proportion; further, the percentage of power required for heating would be constant.

Mr. Riddile, indirectly, had criticized his statement that the best means of combating frazil ice trouble was to provide a proper condition in the design of the forebay and rack structure, so that there would be little or no tendency for the frazil ice to gather on the rack bars; having pointed out that at Grand'Mere he had the ideal conditions which the paper indicates as the best means of preventing ice trouble. The author's idea was that prevention is better than cure, and that it is always better to make a favourable layout of the hydraulic structure, forebay and rack, so as to have as little frazil trouble as possible. In his company's later power houses there had as yet been no frazil trouble, but they had been laid out with this point in view.

Mr. Caton had stated that he had found it quite sufficient to heat the rack bars at the top where they project above the water, and no doubt for short bars that would be a very satisfactory solution. It would also be the cheapest solution, and in engineering practice the cheapest solution is usually the best, but at Shawinigan Falls the rack bars extend under the water some thirty feet. The heat should travel at least half of that distance, and he thought it out of the question to convey or conduct that heat so far down the bars from the surface. The gate-house at Shawinigan is heated; there is an arrangement made for hot air to be blown in on top of the rack bars where they project from the water, and no doubt that gave a certain amount of assistance, but it had not proved sufficient for the need.

Discussion of Paper on the Foundations of the Royal Bank Building by Mr. C. S. Proctor[1]

Mr. C. S. Proctor.[2]

In presenting his paper, the author remarked that in deciding upon the type of foundation to be employed for a building of this magnitude, it was realized that the monumental character of the building and the ornamental interior would have made the settling of the building a very serious matter. In this case, it was essential that the design provide against the possibility of even a slight difference in settlement between adjacent columns which might have caused unsightly cracks in the structure.

Another feature that had to be taken into consideration, because it was felt that the building was to be of long life, was the possibility of a future subway on St. James street and the possibility of deep cellars or foundations at adjoining sites on either side of the building, which might in the future affect or disturb its foundations.

The original data as to the character of the sub-soil were obtained by drill sample core borings, the usual method, and a centrally located test pit, the test pit being placed where it would not interfere with any future column footings and where it could be used for sump purposes during the operations. This indicated bed rock at approximately 80 feet below St. James street, and, above it, alluvial deposits of sand varying from very fine to very coarse, together with sand and gravel, including a varying proportion of clay and boulders. Ground water was found 25 feet below St. James street, and the presence of this ground water in very considerable quantities largely influenced the decision as to the type of design to be used.

The natural desire on the part of everyone at the start was to have a foundation to rock for this type of building, but it was found impossible to lower the water in the test pit beyond a certain point. Further, the boulder deposits made it impossible by any means to reach rock with sheet piling, in fact, the nature of the ground quite precluded the use of piles; so that the problem reduced itself to the consideration of spread foundations. Pneumatic construction was necessarily discarded if there was any way of providing a suitable foundation by other means, because its cost would be so greatly out of proportion with the cost of spread footings. There were, however, two arguments against the use of spread footings; first, that a spread footing could not be placed sufficiently deep to give the amount of cellar space which could have been used; second, the possibility of disturbance of the soil under the spread footings due to pumping operations for the creation of pits and sumps for this building or for subway operations in the future. Therefore it became a question as to how far the water level could safely be lowered, because the nature of the sand at about plus six became quite fine, and it was a type of sand which would have tended to flow with any major pumping operations carried too deep. The test pit operations were therefore continued to see how far the water level could be lowered without encountering any boil in the sand, and the level of plus six for the maximum depth was then decided upon.

In the actual construction, the test pit was used as a sump and the excavation was gradually carried down so that the work was done in the dry at all times.

All of the original building on the sides of the site had heavy masonry walls, and, by leaving these in place and leaving a berm and excavating from that berm at an angle of about forty-five degrees, it was possible to reach subgrade over approximately 80 per cent of the area without the introduction of any timber.

Having made this central excavation within the berm, the second line of footings were then installed by cutting into the berm at alternate footings to act as heels for the spurs to be used. This being done, the intermediate footings were placed prior to any footings on the property line, then in alternate sections the wall was carried down through the berm to the footings already installed, and was then spur-braced directly to those footings; in this way, all cross-bracing as such was done away with.

T. Kennard Thomson, m.e.i.c.[3]

Mr. Thomson observed that in New York the water level had been lowered in many places as much as from ten to thirty feet by subways, tunnels or buildings, but that on Manhattan Island rock could be reached for foundation, except in a very few places.

It seemed a pity that New York did not amend its building laws, so that the owner would be obliged to complete his own building instead of making his neighbour do so.

For instance, if he did not carry his foundations to solid material, and his neighbour wanted to go deeper with his foundations, the neighbour had to underpin the building. In fact, it had been proposed, (and nothing in the building laws would have prevented), to build the Singer building tower, (612 feet above the sidewalk), on a spread footing on New York quicksand.

The only reason this was not done was because the engineer refused to go ahead with the design for the steel work unless they went to rock for the foundation. Needless to say, if the Singer building tower had been founded on quicksand no one could have put in a rock foundation on adjoining property. As a matter of fact, a thirteen-storey structure was built on adjoining property at the same time, the north side of which settled 4 inches more than the south side during construction. He considered it possible that an excavation a block or more away might endanger such a tower.

A six-storey building had been underpinned by driving four 16-inch pipes to refusal and filling them with concrete,—wedges on top of these underpinning cylinders were driven between granite blocks,—until a hair line crack appeared in the brick work above in each individual case, but when pneumatic caissons were sunk alongside, the friction around the piles was loosened and the building settled.

Mr. Thomson had never found concrete all the way to the bottom of such pipes, which meant that all the weight came on the steel cutting edge, which either buckled or cut into the underlying material.

He had been called upon to underpin a three-year-old building in Pennsylvania which had settled from 2 inches in some places to 2 feet in others. The piles had stopped 20 feet from hard material, and in the bottom 4 feet of one which was removed nothing but water was found.

Subway construction in New York had caused a good deal of settlement, and he had seen many buildings thrown 4 or 5 inches out of plumb, and one as much as 18 inches. In that case, the contractor had to remove the floors and terra cotta of the uncompleted fifteen-storey building and jack it back to place.

[2] Consulting Engineer, New York, N.Y.

[3] Consulting Engineer, New York, N.Y.

Mr. C. S. Proctor.

The author remarked that, in the case of the Royal Bank building, the foundations were put at a level which was believed to be safe against disturbances by subway construction; the information available having indicated that no subway would be carried deeper than the level selected for the footings. In addition, the walls had been tied together and acted as girders; they were tied into the basement floor, and tied again at the street floor line, so if there should be a tendency to disturbance there could be no lateral movement.

It was, of course, obviously desirable that a building of this character should, if possible, be on rock, but the cost of that would have been quite prohibitive.

Wm. Kennedy, m.e.i.c.[4]

Mr. Kennedy had been greatly interested in Mr. Thomson's remarks on settlement, having had experience on this grave building question.

The Union Bank building in Winnipeg, a ten-storey building, was founded on caissons on concrete pillars, and everybody thought they were safe, but there was a settlement 7 inches in the centre of the building, and his problem had been to get under these caissons and put them down to rock.

In the Winnipeg district there is about from 50 to 70 feet of clay, with a little hardpan, which is a kind of cemented gravel; they had been handicapped in this instance because there was no indication of how deep they had gone. Some of the oldest inhabitants stated that the caissons were only down about 30 feet, others were sure that some of them were down to rock.

A pit was sunk and a drift started, which fortunately happened to hit the right level and did not get too far below the other foundations. In the case of one caisson, the oldest inhabitant had assured him that he had watched the construction, and there was no need to worry because he knew it was down to rock. On this particular occasion, when the drift came near the foundation, rods were pushed ahead and they were surprised to find no resistance at all, in fact, they drifted right into the caisson, and, to their amazement, found the old lagging there and that the unresisting material was nothing but a belt of clay right through the caisson, with concrete below and concrete above. Investigation showed that when the caisson had been sunk about half-wav something went wrong and the clay had been carried in by water. In Winnipeg clay, the cleavage might be vertical, horizontal or at any angle, while the cleavage surfaces looked like oiled silk; and with any water on it the whole countryside might come in; in fact, this clay was extremely treacherous. His personal view was that in Winnipeg it is necessary to go to rock, because of the condition of the clay and the fluctuating ground water level.

F. T. Gnaedinger, a.m.e.i.c.[5]

Mr. Gnaedinger desired to ask the author what method was used in determining the probable uniform settlement of his building. Were there any available data showing the actual settlement found to take place in buildings in which the bearing surfaces were designed according to the method employed in the Royal Bank building?

After a building had been designed, erected and was occupied and in use—had the author ever taken measurements to see whereabouts in the building the maximum settlement was reached?

Mr. C. S. Proctor.

The author replied that such settlements had been measured accurately on two or three occasions. About ninety per cent of the buildings with which he had been connected had gone to rock,—probably ninety-five or ninety-six per cent at least to hardpan. It was rarely possible to float an important structure. He had not been fortunate enough to be connected with an ordinary commercial structure where settlement need not be taken into account, so that he had not had many opportunities to get information. As Mr. Thomson had pointed out, the sand in New York is so fine and so quick that it is not safe to put any building upon it; it was therefore the practice to go through the sand to hardpan, where the action is quite different and where a treatment can be adopted similar to that needed for rock. In the few cases where it had been possible to take measurements, however, the theory had been proved, as he had already indicated.

Discussion of Paper on Steel Work for the Royal Bank Building of Montreal by R. M. Robertson, A.M.E.I.C.[1]

F. P. Shearwood, m.e.i.c.[2]

Mr. Shearwood remarked that the designing of complicated steel frames for tall buildings was of increasing importance to Canadian engineers, since our larger cities are being forced to adopt the sky-scraper.

It frequently happened that the preliminary architectural plans supplied for the engineer's design of the structural steel frame presented eccentricities of spacing in the columns and beams. These eccentricities could prove very troublesome and often gave rise to unforeseen difficulties, which must, however, be overcome by the ingenuity of the engineer.

The greatest difficulties were met in the detail designing, and required the engineer to be familiar with the most modern methods of fabrication and erection, and to be conversant with the qualities and composition of the other materials which touch upon or connect with the steelwork. He must not only select sections for the steel members which are efficient, but he must choose those which can be economically fabricated and which can be readily assembled and easily riveted both in shop and field.

Throughout the design of the steelwork of the Royal Bank building, great care had been taken to avoid difficult field connections. This had resulted in rapid erection, and there was a minimum of loose or faulty rivets to be removed. It should be borne in mind that first rate workmanship could only be hoped for if the type of the main sections and the details were such that the workmen could easily reach their work and make the most advantageous use of their tools.

The heavy trusses shown on figure No. 7 illustrated some of the difficulties encountered in designing steelwork

(1) This paper was presented at the Annual General Professional Meeting of The Institute, Montreal, February 16th, 1928, and published in The Engineering Journal, February 1928.

Material and Stresses are for Half of Truss.

for buildings which had large clear spans in the lower floors. The large thick gussets at the connections would suggest inquiry as to what sort of stress occurred in the rivets and in the surrounding material, as well as the amount of secondary stress in the members between the plates which are relatively weak and short.

Experience had shown that structural steelwork possessed remarkable elasticity and ductility, and adjusted itself with safety to distortions, to unequal stresses, and even to unexpected settlements. This quality was lacking in some of the materials which are popular in replacing steel, but it was generally recognized as permissible to trust to the slip of the rivets, and the elasticity and the ductility of the steel, to adjust the unknown strains. The incompleteness of the computations in showing the real fibre strain on the metal should be appreciated by the careful designer, who would adapt his methods, and allow for this, by detecting and reinforcing any likely plane of weakness where distortions could concentrate and produce excessive strains.

The calculations for what are regarded as wind stresses were a familiar and favourite point of controversy. Very many methods for calculating these stresses had been advocated, and each one had been claimed to give the most accurate solution, but he desired to point out that these are all based, not on actual happenings, but on assumptions of happenings which do not always materialize, e.g., rigid joints, fixed position of point of contra-flexure, no initial erection strains, no stiffening influence from flooring or walls, etc., etc. It should be acknowledged that an exact solution is practically unattainable, on account of the fact that there are several different paths of resistance which are capable of carrying the forces on their way to their final reaction.

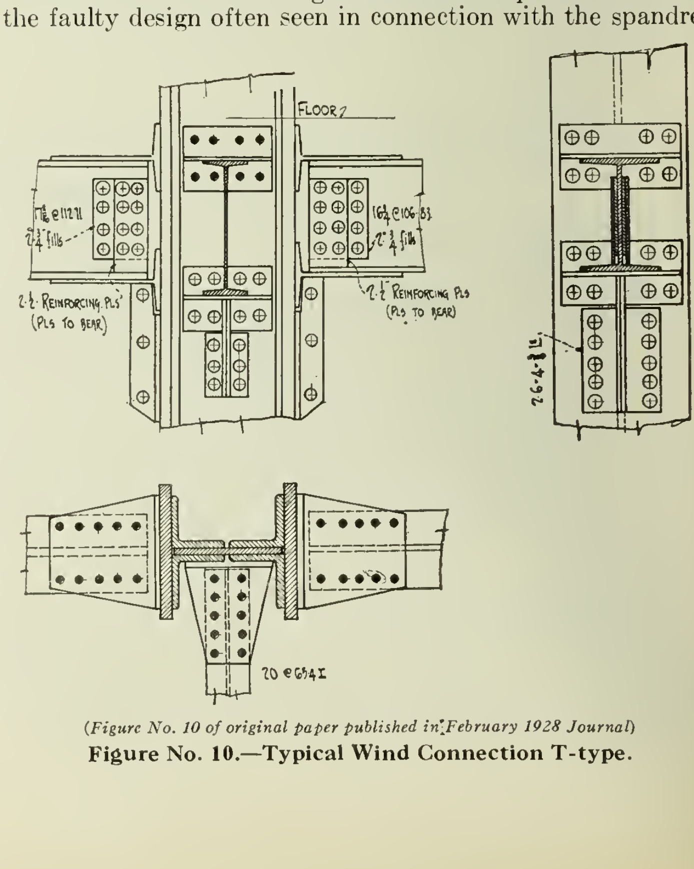
This latter fact, in conjunction with the property of steel to deflect and distort, would enable sufficient resistance from each path to come into play before the most severely strained member became dangerously overstrained, at least in buildings which are of fairly normal type.

While discussing the calculations for the lateral resistance of steel frames, it would be interesting to consider whether the present practice of assuming the steel frame as being independent of the walls and flooring represents the true condition of stress, or if it is an economical and safe assumption.

The steel frame being usually encased in the walls and flooring, these must all act together as a unit until slip takes place between them. If this slip does occur, the steel would then act as an independent frame and its deflection would be greater. The enclosed walls must show a corresponding deflection, but being more rigid than the steel, great strains would be developed in them.

The principles of engineering would seem to indicate that the steel frame should be definitely bonded to the masonry, both acting as a unit, and preventing movement of the masonry on the steel, as well as procuring the maximum resistance and rigidity from the materials in use.

Such efficient bonding would also help to correct for the faulty design often seen in connection with the spandrel



(Figure No. 10 of original paper published in February 1928 Journal)

beams, which are frequently assumed to support the eccentric wall loads independently, whereas, as a matter of fact, they act only as a part of a system composed of walls, floors and beams.

W. B. Dunbar, A.M.E.I.C.[1]

Mr. Dunbar remarked that from the section of the building given in the paper, it would appear that no wind bracing had been provided above the mezzanine floor level. He presumed that the columns of the building above that level were adequate to take any wind stresses that might occur.

[1] Lecturer, University of Toronto, Toronto.

The author in reply said that above the mezzanine floor no cross or portal bracing had been provided. The type of wind bracing used on this floor and also on the main and basement floors was shown in figures Nos. 10 and 11, and it had been found that columns of the size necessary to carry the dead and live loads were adequate to transfer the wind shears, an increase of fifty per cent in the ordinary unit stresses being allowed for a combination of dead, live and wind loads.

P. L. Pratley, M.E.I.C.[2]

Mr. Pratley remarked that in the specifications for bearing there were two sets of figures, one for bearing in double shear and one for single shear. He inquired in what circumstances single shear would occur, and also asked whether consideration had been given to the use of higher strength steel in any of the heavy girders in the building.

The author replied that single shear bearing would occur in the outer plates or angles of any riveted connection. The bearing value of the rivet, however, would only govern when these plates or angles were thin enough to give a bearing value less than the single shear value of the rivet. No consideration had been given to the use of higher strength steels.

D. C. Tennant, M.E.I.C.[3]

Mr. Tennant observed that while the Montreal Building By-laws did not mention higher strength steel, he believed that the Montreal authorities would be willing to consider any intelligent suggestion for bettering their by-laws.

The use of special steel in small quantities in such a building as this would hardly be economical as such steel must be used in large quantities to get economical results. When the mills roll steel of this kind they like to roll it at one mill, at which there would probably not be rolls for all sections required, so that considerable extra expenditure would be involved in trying to get a small amount of special steel of many different sections.

[2] Consulting Engineer, Montreal.
[3] Structural Engineer, Dominion Bridge Co., Montreal.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI MAY 1928 No. 5

Western General Professional Meeting

Vancouver, B.C., June 7th, 8th, and 9th, 1928.

Fondation George Montefiore Prize

In connection with the Institut Electrotechnique Montefiore, Liege, Belgium, there has been founded a prize, known as the "Fondation George Montefiore," awarded every three years, for the most meritorious original work presented on scientific progress, particularly in the technical application of electricity in all spheres of activity. Works which merely popularize knowledge or are mere compilations are excluded from competition for this prize.

The papers, which may be in English or French, should, of course, be printed or typewritten, and are judged by a committee of ten electrical engineers, of whom five are Belgian and five foreigners, one of the Belgian delegates being, ex-officio, the director of the Institut. The prize is only awarded if, in the opinion of the committee, a work of sufficient merit is submitted, although in certain circumstances the prize may be divided.

The competitor must furnish twelve copies of his paper, which are to be delivered post free to the secretary, George Montefiore Fondation, rue Saint Gilles 31, Liege, Belgium.

Papers submitted in competition, which the committee decide to have printed, are published in the Bulletin of the Association.

For the competition of 1929, the value of the prize is 29,000 Belgian francs, and the last date for the reception of papers is April 30th, 1929.

Such papers should be headed, "Travail soumis au concours de la Fondation George Montefiore, session de 1927-1929."

Further information can be obtained from the general secretary, Institut Electrotechnique Montefiore, rue Saint Gilles 31, Liege, Belgium.

Publications of Other Engineering Societies

As previously announced in the Journal, an exchange arrangement exists between The Engineering Institute of Canada and the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Civil Engineers and the American Society of Mechanical Engineers.

Subscriptions may be sent either directly to New York or through Headquarters. The following list of rates gives in the first column the amounts payable by members of The Engineering Institute for the various publications:—

	Rate to Members	Rate to Non-Members
American Institute of Electrical Engineers		
Journal, single copies	$0.50	$ 1.00
" per year	5.50	10.50
Transactions, per year, paper	5.00	10.00
" " " cloth	5.00	10.00
Year Book	1.00	2.00
Pamphlets	.25	.50
American Institute of Mining and Metallurgical Engineers		
Magazine, single copies	0.50	1.00
" per year	5.00	10.00
Transactions, per volume, with pamphlets, paper	2.50	5.00
(Other publications, same rate E.I.C. members as to A.I.M.M.E. members.)		
American Society of Civil Engineers		
Proceedings, single copies	0.50	1.00
" per year	4.00	8.00*
Transactions, " "	6.00	12.00†
Year Book	1.00	2.00
(Other publications 50 per cent reduction on catalogue price to E.I.C. members.)		
American Society of Mechanical Engineers		
Journal, single copies	0.50	0.60
" per year	4.00	5.00
Transactions, per year	6.00	8.00
Year Book	1.00	2.00
(Other publications, same rate to E.I.C. members as to A.S.M.E. members.)		

**If subscription is received before January 1st, otherwise $10.00.*

†If received before February 1st, otherwise price $10.00.

Back Numbers of the Journal

The supply of certain issues of The Engineering Journal is completely exhausted, and as a number of requests have been received at headquarters for copies of these particular issues, principally to complete library sets, it would be greatly appreciated if members who have spare copies would forward them to headquarters.

The issues required are:—

1918:—June, July, August and October.
1919:—March, April and May.
1920:—May, June and July.
1921:—January, March and April.
1922:—September.
1924:—November and December.
1925:—April.

Western General Professional Meeting

Hotel Vancouver—Vancouver, B.C.

June 7th, 8th and 9th, 1928

The Western General Professional Meeting will be held at the Hotel Vancouver, Vancouver, B.C., June 7th, 8th and 9th, 1928. Final details of the programme are being arranged. A number of interesting technical papers will be presented and discussed, and ample provision is being made for the entertainment of visiting members.

The following outline of the programme will give a general idea of the plans for the various functions, details of which will be available to the members at the registration desk:—

Outline of Programme

(Subject to Minor Changes)

Thursday, June 7th.

9.00 a.m. Registration.
10.15 a.m. Address of welcome by His Worship the Mayor of Vancouver.
10.45 a.m. First Technical Session. Presentation and discussion of technical papers.
1.00 p.m. Luncheon (Ladies will be welcome).
2.30 p.m. Cruise around the Harbour and visit to Grain Elevator (by courtesy of the Vancouver Harbour Commissioners).
4.30 p.m. Ladies' tea.
8.00 p.m. Second Technical Session. Discussion of technical papers.
9.30 p.m. Smoking concert.

Friday, June 8th.

10.00 a.m. Third Technical Session. Presentation and discussion of technical papers.
2.30 p.m. Excursion to Lumber Industrial Plant at New Westminster, B.C.
8.00 p.m. Dinner (formal). His Honour the Lieutenant-Governor of British Columbia will be the Guest of Honour.
7.30 p.m. Ladies' dinner and theatre party.

Saturday, June 9th.

10.00 a.m. Fourth Technical Session. Presentation and discussion of technical papers. General résumé of papers and informal discussion on Institute affairs.
1.00 p.m. Luncheon.
2.30 p.m. Motor drive around City and District.
8.00 p.m. Reception and Supper-Dance at Grouse Mountain Chalet (the elevation of the Chalet is 4,000 feet).

Technical Papers

The following technical papers will be presented and discussed at the various sessions:—

"*Forest Conservation in the West*," by Mr. P. Z. Caverhill, Chief Forester, Department of Lands, Forest Branch, Province of British Columbia, Victoria, B.C.

"*The Cariboo Road*," by Patrick Philip, M.E.I.C., Deputy Minister, Department of Public Works, Victoria, B.C.

"*Some Engineering Aspects of the Bridge River Project*," by E. E. Carpenter, M.E.I.C., Consulting Engineer, British Columbia Electric Railway Company, Vancouver, B.C.

"*Irrigation in Mountainous Country*," by F. W. Groves, M.E.I.C., Consulting Engineer, Kelowna, B.C.

"*A Study of Transmission Line Power-Arcs*," by Paul Ackerman, M.E.I.C., Electrical Engineer, The Shawinigan Water and Power Company, Montreal, Que. (To be presented at the meeting by A. C. R. Yuill, M.E.I.C.)

Committees

The committees in charge of the various features of the meeting have their arrangements well in hand and are devoting a great deal of time and energy in their effort to make this Western Professional Meeting even more successful than similar meetings in the past.

The personnel of the main committee and the chairmen of the various sub-committees are as follows:—

Convention and Programme Committee
Chairman—W. Brand Young, A.M.E.I.C.
W. H. Powell, M.E.I.C.
J. Alex. Walker, A.M.E.I.C.
E. A. Cleveland, M.E.I.C.
W. B. Greig, A.M.E.I.C.
Geo. A. Walkem, M.E.I.C.
E. A. Wheatley, A.M.E.I.C.
F. P. V. Cowley, A.M.E.I.C.

Finance
Chairman—A. C. R. Yuill, M.E.I.C.

Registration and Reception
Chairman—E. A. Cleveland, M.E.I.C.

Publicity and Printing
Chairman—E. A. Wheatley, A.M.E.I.C.

Excursions
Chairman—W. H. Powell, M.E.I.C.

Papers and Discussions
Chairman—H. B. Muckleston, M.E.I.C.

Transportation
Chairman—A. E. Foreman, M.E.I.C.

Entertainment
Chairman—A. S. Wootton, M.E.I.C.

Reception and Dance
Chairman—J. Alex. Walker, A.M.E.I.C.

Ladies' Committee
Convener—Mrs. Geo. A. Walkem.

Make a note of the dates—

JUNE 7th, 8th *and* 9th

OBITUARY

Henry Edward Cranmer Carry, M.E.I.C.

It is with regret that we record the death of Henry Edward Cranmer Carry, M.E.I.C., which occurred suddenly in Vancouver on March 16th, 1928.

The late Mr. Carry was born at Leeds, in the province of Quebec, on February 9th, 1854. He served as an articled apprentice with the Northern Railway of Canada during the years 1871 to 1875. His first work after completing his apprenticeship was on the barometrical exploration, north of lake Huron, for the Canadian Pacific Railway in 1876. The following year he was engaged on the trial location surveys for the same company in the French river district. From July 1878 to May 1881 he was with the Canada Central Railway engaged alternatively as topographer on location work, engineer in charge of an exploration party, resident engineer on the construction of two sections, and in the office in the capacity of chief assistant engineer.

In 1881, Mr. Carry returned to the Canadian Pacific Railway and was engineer in charge of exploration, north of lake Superior. During 1884 and 1885 he was engineer in charge of construction of a division in the same district. The following year he was engaged in the location of the section of the Algoma Branch of the Canadian Pacific Railway. In 1887 he undertook the contract of constructing the pile and trestle work between Algoma Mills and Sault Ste. Marie on the Algoma Branch of the Canadian Pacific Railway.

During the year 1888, Mr. Carry spent a few months prospecting for gold in the Sudbury district and in 1889 engaged in private practice. During the next three years he was chief engineer of the Toronto Belt Line Railway, and in this capacity had charge of the preliminary surveys and final construction. His next work was with the Canadian Pacific Railway on preliminary surveys on the Renfrew-Parry Sound Branch, following which in 1894 he became engaged in mining and prospecting in British Columbia. For nine years he continued this work and also private practice in his profession. In 1904 he was again engaged on the Canadian Pacific Railway on reduction of grade location in Ontario, Quebec and New Brunswick, and the location of a section of the Toronto and Sudbury Branch of the same railway. His work with this company continued during the succeeding years and from 1906 to 1909 he was located in British Columbia on preliminary and location surveys of the Cowichan Lake and Merritt-Penticton Branches.

From 1909 to 1912, Mr. Carry was in charge of the development of the residential district of Shaughnessy Heights, Vancouver, B.C., when he once more engaged in private practice, which he continued until 1923, when he retired.

The late Mr. Carry was always an active supporter of The Institute and took a great interest in its affairs and particularly those of the Vancouver Branch. He was elected a Member of The Institute on May 10th, 1888, in the days of the Canadian Society of Civil Engineers, and was made a Life Member by Council in December 1921.

PERSONALS

C. H. F. Donkin, A.M.E.I.C., of Amherst, Nova Scotia, is resident engineer with the Canadian National Railways on the Flin Flon survey at The Pas, Manitoba.

E. R. Millidge, M.E.I.C., has been transferred by the Canadian National Railways from Edson, Alta., to Winnipeg, Man., where he has been appointed division engineer.

Eric C. Molke, Jr.E.I.C., structural engineer with the Trussed Concrete Steel Company, has been transferred by the company from Walkerville, Ont., to Montreal.

J. B. Phillips, Jr.E.I.C., who graduated from McGill University in 1927, has been awarded bursaries by the National Research Council to be held at McGill University in cellulose chemistry.

A. R. Chadwick, S.E.I.C., who until recently has been located at Chicago, Ill., with the Construction Equipment Company, Limited, has been moved by the company to Montreal. Mr. Chadwick is a graduate of the University of Toronto of the year 1924.

Frank Ll. Grindley, S.E.I.C., has accepted the position as resident engineer of the Canadian National Railways on the construction of the Ashmont-Bonnyville line in Alberta. Mr. Grindley graduated from the University of Alberta in civil engineering in 1926.

J. H. Irvine, A.M.E.I.C., has been appointed to represent the Dominion Reinforcing Company, Limited, at Toronto, Ont. He is a graduate of the University of Manitoba in civil engineering of the year 1912 and has had extensive experience in general construction work.

E. L. Johnson, S.E.I.C., has been appointed assistant to the works manager of the Dominion Cartridge Company, Limited, at Brownsburg, Que. Mr. Johnson has until recently been with the American Steel Foundries at Chicago, Ill.

George F. MacRae, S.E.I.C., is located with Johnston and Ward, stock and bond brokers, Montreal. Mr. MacRae graduated in electrical engineering from the University of New Brunswick in 1925, and was for a time engineer in the plant engineer's office of the Bell Telephone Company of Canada, at Montreal.

W. T. Moodie, M.E.I.C., superintendent for the Canadian National Railways at Port Arthur, Ont., has been transferred to North Bay, Ont., where he has been appointed to the position of general superintendent, in accordance with an announcement issued by the company.

Donald A. Killam, S.E.I.C., has accepted a position with the Canada Paper Company, Limited, in Montreal, having resigned his position on the engineering staff of the Abitibi Fibre Company, Limited, at Smooth Rock Falls, Ont. Mr. Killam graduated from McGill University with honours in civil engineering in 1927.

H. H. Snyder, A.M.E.I.C., is located at Kenogami, Que., on the staff of the Alcoa Power Company in connection with the new power development which the company is carrying out on the Saguenay river. Until his recent appointment, Mr. Snyder was with the Hydro-Electric Power Commission of Ontario at Hydro, Ont. He is a graduate of Queen's University of the year 1926.

L. S. Adlard, A.M.E.I.C., who has been located in Punjab, India, for some years as assistant executive engineer of the Public Works Department, is returning to Canada on eight months leave and while here will be located at 60 Howard street, Toronto, Ont. Mr. Adlard is a graduate of the University of Toronto of the class of 1915. His last leave from India was three years ago, at which time he also returned to Canada.

F. H. Kester, M.E.I.C., vice-president of the Canadian Bridge Company, Limited, Walkerville, Ontario, has recently been notified that he has been elected to the New Zealand Society of Civil Engineers. Mr. Kester was elected a director and vice-president of The Canadian Bridge Company, Limited, last year, prior to which he was contracting engineer for the company.

G. Ernest Booker, A.M.E.I.C., has joined the staff of the Metabetchouan Sulphite and Power Company, Limited, at Desbiens, Que. Until recently Mr. Booker was engaged with James Ruddick, M.E.I.C., consulting engineer, Quebec city. He was for a short time in private practice in Halifax and subsequently accepted a position as mechanical engineer with the British-American Nickel Corporation, at Deschenes, Que.

G. W. Volckman, M.E.I.C., has accepted the appointment of chief engineer and representative in India and the Far East of Sir Alexander Gibb and Partners, consulting engineers, of Westminster, England. Mr. Volckman has arrived in Bombay, where he will reside in future. Mr. Volckman resided in Canada for a number of years, having first come to this country from England in 1907. He was for a while engaged on the Georgian Bay Canal investigation as a member of the staff of the Montreal, Ottawa and Georgian Bay Canal Company.

E. L. Zealand, A.M.E.I.C., is located in Hamilton, Ont., where he has accepted a position with the Pigott-Healy Construction Company. Mr. Zealand graduated from the University of Toronto in 1922, and after a short period with the Canadian Pacific Railway, as concrete inspector and instrumentman, he joined the staff of the Quebec Development Company, Limited, at St. Joseph d'Alma, Que., in 1923. Subsequently, in 1926, he was engaged with the Aluminum Company of Canada, Limited, at Arvida, Que., where he remained until the early part of this year.

A. A. Oldfield, A.M.E.I.C., has been appointed director of safety of the Wisconsin Power and Light Company at Madison, Wis., the appointment being a promotion from his former position of engineer of maintenance-of-way for the company. Mr. Oldfield is a native of Leversedge, Yorks, England, and came to Canada in 1906, when he was appointed on the engineering staff of the Electric Railway Company at Winnipeg, Man. He was appointed to the position from which he has just been promoted in 1922, at which time he also held the position of assistant to the manager.

S. H. Frame, A.M.E.I.C., has been appointed field engineer of the Water Rights Branch of the Department of Lands of the Province of British Columbia. He was for a number of years connected with the Department of Natural Resources of the Canadian Pacific Railway Company as assistant engineer on the Eastern Section of the Irrigation Block with headquarters at Brooks, Alta. On his new work Mr. Frame will be in charge, as field engineer, of the investigation of an extensive project of the Chilko river, which now flows eastward into the Fraser river. The scheme is to divert this river through the Coast Range of the Rocky Mountains.

Award of Ramsay Memorial Fellowship

William H. Barnes, S.E.I.C., has again been awarded the Ramsay Memorial Fellowship for research, according to a recent announcement. The award is made by the National Research Council and is the highest award made by the Council. This is the second year in succession that Mr. Barnes has been awarded this fellowship. He is a graduate of McGill University of the year 1927 and is the son of Dr. Howard T. Barnes, M.E.I.C., professor of physics, McGill University. Mr. Barnes will continue the work that he has been carrying on at the Royal Institution of Great Britain in London on the action of X-rays in crystals.

McGill University to Honour President Julian C. Smith, LL.D., M.E.I.C.

At the spring Convocation of McGill University the degree of Doctor of Laws will be conferred upon the President of The Institute, Julian C. Smith, LL.D., M.E.I.C. Mr. Smith, who is vice-president and general manager of the Shawinigan Water and Power Company and director of a large number of utility companies and industrial corporations, will receive this honour in recognition of the high position which he has attained in the public utility and industrial development of this country. Mr. Smith is a graduate of Cornell University of the year 1900 and received the honorary degree of LL.D. from Queen's University in 1923.

Meeting of Council

Meeting of April 20th, 1928

A meeting of Council was held at eight o'clock p.m. on Friday, April 20th, 1928, President Julian C. Smith, M.E.I.C., in the Chair and nine other members of Council being present.

The secretary reported that in accordance with the direction of Council the following examiners had been appointed in connection with the new prize scheme:

Zone A.—	Vice-President S. G. Porter, M.E.I.C.
	Councillor R. J. Gibb, M.E.I.C., Edmonton.
	Councillor W. H. Powell, M.E.I.C., Vancouver.
Zone B.—	Vice-President A. J. Grant, M.E.I.C.
	Councillor R. L. Dobbin, M.E.I.C., Peterborough.
	Councillor T. R. Loudon, M.E.I.C., Toronto.
Zone C.—	Vice-President W. G. Mitchell, M.E.I.C.
(*English*)	Councillor W. C. Adams, M.E.I.C., Montreal.
	Councillor Fraser S. Keith, M.E.I.C., Montreal.
(*French*)	Vice-President J. H. Hunter, M.E.I.C.
	Councillor O. O. Lefebvre, M.E.I.C., Montreal.
	Councillor A. B. Normandin, A.M.E.I.C., Quebec.
Zone D.—	Vice-President F. O. Condon, M.E.I.C.
	Councillor H. W. L. Doane, M.E.I.C., Halifax.
	Councillor J. Stephens, M.E.I.C., Fredericton.

Discussion took place with reference to the place at which the Annual General Meeting for 1929 is to be held, invitations having been received both from Ottawa and Hamilton. After consideration it was unanimously decided that the meeting should be held in Hamilton, the Thursday, Friday and Saturday of the second week in February 1929 being suggested as a suitable date.

Scrutineers were appointed to canvass the ballot for the amendments to By-laws, returnable May 12th, 1928.

On a report from the Board of Examiners and Education, it was decided that in connection with The Institute's examinations it will be desirable to arrange for a proportion of the papers to be set by members conversant with the various subjects and who do not belong to the Board. It was also resolved that the present policy of paying a nominal fee for the setting and reading of papers for The Institute's examinations should no longer be continued. Dr. A. Frigon, A.M.E.I.C., Director of The Ecole Polytechnique, Montreal, was appointed a member of the Board of Examiners in succession to Dr. A. Surveyer, M.E.I.C., who has resigned.

The membership of the following committees was reported and approved:

Engineering Education.
Plummer Medal Committee.
Library and House Committee.

The list of officers of the Calgary Branch for the current year was approved as follows:

Chairman	Thos. Lees, A.M.E.I.C.
Vice-Chairman	F. J. Robertson, A.M.E.I.C.
Sec.-Treas.	W. H. Broughton, A.M.E.I.C.
Executive	B. Russell, M.E.I.C.
	F. M. Steel, M.E.I.C.
	O. H. Hoover, A.M.E.I.C.
(Ex-officio)	S. G. Porter, M.E.I.C.
	P. J. Jennings, M.E.I.C.
	F. K. Beach, A.M.E.I.C.
	H. R. Carscallen, A.M.E.I.C.

Prof. T. R. Loudon, M.E.I.C., reported progress on behalf of the Service Bureau Committee, and stated that that Committee was at present engaged in collecting information on various topics connected with its work.

A resolution was presented, passed by the Executive Committee of the Vancouver Branch, requesting that the subscription to the Journal in the case of Students of The Institute should be made optional, and the secretary was directed to reply that this was a matter which could only be dealt with by an amendment to section 74 of the By-laws.

The secretary reported that communications had been received from a number of councillors indicating that the dates suggested for the forthcoming Plenary Meeting, namely, October 15th, 16th and 17th, 1928, would be suitable.

A representative was appointed to attend the Conference on the Standardization of Fire Hose Connections to be held at Ottawa on May 3rd.

Life membership was granted to J. A. Bell, M.E.I.C., St. Thomas, Ont., as one of the oldest members of The Institute, to which he has belonged since 1887.

The financial statement to March 31st, 1928, was presented and approved.

Four reinstatements were effected; fifteen resignations were accepted, and one removal was effected.

The following elections and transfers were effected:

Elections		Transfers	
Associate Member	1	Junior to Associate Member	2
Juniors	4	Student to Junior	6
Students	15		

Nineteen applications for admission and transfer were scrutinized and classified for the ballot returnable May 18th, 1928.

The Council rose at 11.15 o'clock p.m.

Erratum

In correction of the statement appearing in the report of the Council Meeting of March 13th, on page 283 of the April number of the Journal, it should be noted that H. A. Dupre, M.E.I.C., although resigning the secretaryship of the Canadian National Committee of the International Electrotechnical Commission, retains his membership of that committee.

EMPLOYMENT BUREAU

Situations Vacant

CIVIL ENGINEER

Young civil engineer with some railway experience for general engineering work. Location Montreal. Apply box No. 190-V, The Engineering Journal.

TOWN MANAGER

The position of town manager in a northern Ontario mining town is available to engineers with the required experience. Applicants must speak both English and French fluently. Applications must contain a statement of experience, qualifications, and salary expected. Apply box No. 191-V, The Engineering Journal.

FIELD ENGINEER

Recent graduate with at least two years experience in pulp and paper mill for the position of field engineer. Apply box No. 192-V, The Engineering Journal.

DRAUGHTSMEN

Two draughtsmen for mechanical details, design, and general draughting for a pulp and paper company. Apply box No. 193-V, The Engineering Journal.

MECHANICAL ENGINEER

Recent graduate in mechanical engineering for a pulp and paper company in Northern Ontario. Apply box No. 194-V, The Engineering Journal.

STRUCTURAL STEEL DETAILERS

A company in Ontario has two openings for experienced structural steel detailers. Apply box No. 195-V, The Engineering Journal.

SALES ENGINEER

A manufacturing company requires the services of a graduate engineer with four or five years experience in steam power plant or kindred work, for their sales organization in the province of Quebec. Applicants must speak French fluently. Apply box No. 196-V, The Engineering Journal.

PULP AND PAPER MILL DESIGNER

A pulp and paper company in Northern Quebec has an opening for a competent designer. Preferably one with pulp and paper mill, or at least industrial experience. Preference will be given to an unmarried, university graduate. Apply box No. 197-V, The Engineering Journal.

Situations Wanted

ELECTRICAL ENGINEER

Electrical engineer, 27 years of age, University of Toronto graduate, six years diversified experience, two years Westinghouse engineering course, inspection of electrical equipment, industrial construction and maintenance, testing and research; at present employed in United States; wishes to return to Canada. Available on reasonable notice. Apply box No. 231-W, The Engineering Journal.

MECHANICAL DRAUGHTSMAN

Experienced mechanical draughtsman will be open for a position in the near future, requiring initiative and ingenuity in designing machinery, or layout of steam or hydro-electric power equipment. Present position in Montreal. Accustomed to having charge of design. Apply box No. 234-W, The Engineering Journal.

CIVIL ENGINEER

Twenty years experience in construction, (railway, highway, foundations, etc.), field surveys of all kinds, considerable office experience, general knowledge of accounts and cost accounts. Will go anywhere. Good permanent prospects larger consideration than immediate salary. Apply box No. 235-W, The Engineering Journal.

Specifications for Steel Railway Bridges

The Canadian Engineering Standards Association has issued a third edition of their Standard Specifications for Steel Railway Bridges. The previous editions have for some time been exhausted and the committee, in preparing the revised issue, has taken the opportunity to bring the specification up to date and to make certain desirable improvements.

ELECTIONS AND TRANSFERS

At the meeting of Council held on April 20th, 1928, the following elections and transfers were effected:—

Associate Members

DEWEY, Philip Andrew, B.S.C.E., (Univ. of Vt.), engrg. dept., Can. Ramapo Iron Work, Ltd., Niagara Falls, Ont.

Juniors

BACKMAN, Walter Henry, B.Sc., (N. S. Tech. Coll.), cost engrg., Fraser Brace Engrg. Co., Ltd., Gatineau, Que.

GRIME, Leonard, B.A.Sc., (Univ. of Toronto), structural dftsman. with Am. Bridge Co., Toledo, Ohio.

MIDGLEY, George Henry, B.Sc., (N. S. Tech. Coll.), Dodge Mfg. Co. of Canada, Ltd., Montreal.

Transferred from the class of Associate Member to that of Member

DAVIS, George Sanford, electrical engr., with J. M. Robertson, Montreal.

Transferred from the class of Junior to that of Associate Member

PERRITON, Douglas Eric, B.Sc., (McGill Univ.), estimating and contracting, as asst. to contracting engr., Dom. Bridge Co., Ltd., Montreal.

SHOTWELL, John Stuart Gloshan, B.Sc., (McGill Univ.), chemist, i/c control testing and research chemist, Price Bros. & Co., Ltd., Riverbend, Que.

Transferred from the class of Student to that of Junior

CROSS, George Esplin, B.Sc., (McGill Univ.), structural dftsman., Dom. Bridge Co., Ltd., Montreal.

FLEMING, Canmore Drake, B.Sc., (McGill Univ.), Anglin Norcross, Ltd., Royal York Hotel, Toronto, Ont.

IRWIN, Karl Webster, M.A.Sc., (Univ. of Toronto), transmission dept., plant engr's office, Bell Telephone Co., Toronto, Ont.

JONES, Herbert Cecil, B.Sc., (Univ. of Man.), Can. General Electric Co., Peterborough, Ont.

PLOW, John Foss, asst. engr., mechanical dept., Price Bros. & Co., Ltd., Riverbend, Que.

TRUEMAN, Mark Cecil, B.Sc., (Univ. of Man.), power engr., sales dept., Wpg. Hydro-Electric System, Winnipeg, Man.

Foundry Research at Mellon Institute

Announcement has been made by Dr. Edward R. Weidlein, director, Mellon Institute of Industrial Research, Pittsburgh, Pa., that the Whiting Corporation, Harvey, Ill., has established in the institution an Industrial Fellowship, whose holder, Dr. Edward E. Marbaker, will conduct research on cast iron. The results of these investigations will be published for the general benefit of the foundry industry.

For a number of years the Whiting Corporation has been carrying on a systematic programme of development for the purpose of improving equipment and methods for the production of cast iron. It has recently been determined to expand this work and in consequence the Corporation will sustain research at Mellon Institute. Dr. Marbaker, the Whiting Corporation Fellow, will work in close co-operation with the research committee of the American Foundrymen's Association.

Dr. Marbaker has been a Fellow of Mellon Institute since 1921. Previously he was chief chemist for the Westinghouse Lamp Company and for the Cleveland Wire Division of the National Lamp Works of the General Electric Company. He received his professional training at the University of Pennsylvania (B.S., 1910; Ph.D., 1914).

BOOK REVIEW

Principles of Chemical Engineering

By William H. Walker, Warren K. Lewis and William H. McAdams, McGraw-Hill Book Company, New York, 1927, Second Edition, Buckram, 6 x 9½ in., 770 pp., figs., tables, $5.50.

This volume is one of a series of texts and reference works, (Chemical Texts), published by McGraw-Hill Book Company, Inc.

The writers have selected for treatment basic operations common to all chemical industry rather than details of specific processes. In the first chapter on Stoichiometry emphasis has been put on the utility of the pound mol. as a unit for calculations and the ease with which the units of one system may be transferred into those of another. Problems and their solutions are given showing the advantages derived from this method of calculation and the simplicity thereof.

Chapters on Flow of Fluids and Flow of Heat consider the laws giving these phenomena in detail.

The subject of Fuels with special reference to their economical use in furnaces and kilns is dealt with in a clear and descriptive manner.

Gas producers are treated in a separate chapter, in which certain types are described and the reactions involved discussed at length.

The chapters on "Crushing and Grinding" cover the main principles involved and describe the methods used at some length.

Gas Scrubbing, Filtration, Lixiviation and Filtration are admirably dealt with.

The chapters on Drying and Distillation are complete in theoretical consideration and give excellent examples of the various types of apparatus employed.

The subjects throughout are clearly set forth and easily understandable, the latter through a generous use of problems and their solutions.

The work should form an admirable text book for students of chemical engineering, and an invaluable reference book for the chemical engineer. It should accomplish the wish of the writers that it will "Stimulate engineers to design apparatus adapted for any particular purpose, rather than just to build it and then to rely on large scale experimentation with expensive changes in construction to effect efficient operation."

J. R. Macaulay,
J. T. Donald & Co., Limited.

Foster Wheeler Limited Succeeding Canadian Power Specialty Company, Limited

Announcement is made of a change in name of the Canadian Power Specialty Company, Limited, to that of Foster Wheeler, Limited, which change has been authorized by the Dominion Government. The head offices of the company are in the Canadian Pacific Building, Toronto, and district sales offices are located in the Canada Cement Building, Montreal, and the Board of Trade Building, Vancouver, B.C.

The B. F. Sturtevant Company has issued an attractive book entitled the "Eighth Wonder," which describes the construction of the Holland tunnel which connects Manhattan Island with Jersey City. This book contains sixty-eight pages and is well illustrated and handsomely bound.

The Canadian Ingersoll-Rand Company, Limited, has issued the sixth edition of its book entitled "100 and 1 Ways to Save Money With Portable Compressors." This book, which contains one hundred and forty pages, is well illustrated and embodies comparative cost data on the company's portable air compressors and air-operated tools, the information being compiled in a handy reference, cross-indexed form.

The company has also issued a book of reprint articles entitled "Important Rock Drilling Projects" covering a number of important works carried on during 1927.

Copies of both these booklets may be secured from any of the branches of the Canadian Ingersoll-Rand Company or from the head office, 10 Phillips Square, Montreal, Que.

Combustion Engineering Corporation, Limited, has issued a small pamphlet entitled "The Story of Combustion" which is a reprint from an article appearing in "World's Work." Copies of this booklet may be secured from the company's head office at Montreal.

BRANCH NEWS

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Lethbridge Branch was held on March 24th, when the season's work and the statement of finances were reviewed. The meeting commenced with a dinner at which about thirty members and affiliates were present, and during which the Rainbow Orchestra rendered delightful selections. Vocal solos by Mr. E. Rannard were greatly appreciated and closed the musical part of the programme.

In closing his term of office as chairman, Geo. S. Brown, A.M.E.I.C., thanked all those through whose help a most successful year's work had been accomplished, and expressed his trust that a continuation of the good work would be carried on. The results of elections under the amended branch by-laws for that work, which proved very satisfactory, were as follows:

Chairman	N. H. Bradley, A.M.E.I.C.
Executive	J. B. deHart, M.E.I.C.
	G. N. Houston, M.E.I.C.
	C. S. Clendening, A.M.E.I.C.
	C. S. Donaldson, A.M.E.I.C.
Ex-officio	Geo. S. Brown, A.M.E.I.C.
Member of Council	R. Livingstone, M.E.I.C.

Mr. Bradley, on being congratulated upon his election, thanked the members for the honour conferred on him and expressed his desire that the good relations and responsiveness of the various committees would be continued.

Oxy-Acetylene Welding

The business being completed, the chairman introduced the speaker of the evening, Mr. J. A. Jardine, who addressed the members on the subject "Oxy-Acetylene Welding," showing pronounced familiarity with the work. Contrary to the general public idea that welding is more associated with repairs, the speaker explained to what extent it is entering into construction work and with what tremendous force there is behind the oxy-acetylene torch. The incessant hammering of rivets now gives way to welding in steel constructed buildings, and even under water such work can be successfully carried on. When it is considered that the toughest metal known to man lays at the mercy of the welder's torch, with its flame at a temperature of 6,000°F., some idea of its great importance in the future can be seen.

Mr. Jardine submitted for the members' inspection samples of ornamentation work in brass, copper and iron, which had been welded in the local plant, and which proved most interesting.

A hearty vote of thanks to the speaker and the singing of the National Anthem brought the meeting to a conclusion.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"Coal, Oil and Wood—Something of Their Past Performance and Future Promise" was the subject of an address given before the branch, on March 30th, by H. E. Bigelow, Ph.D., dean of the Science Faculty, Mount Allison University, Sackville, N.B. The meeting was held in the City Hall, and C. S. G. Rogers, A.M.E.I.C., was the presiding chairman.

Coal, Oil and Wood

The subject is one that ever fascinates, for in these substances the chemist finds the great store of those elements, carbon, hydrogen and oxygen, that he touches with his seeming magic wand, and converts into the multitude of necessities used in the manufacturing processes of modern industry.

Coal was originally distilled to obtain illuminating gas, with coke as the next article of value. The ammoniacal liquor obtained in the process of purifying gas was almost a waste,—the coal-tar residue even more so. In the present manufacturing methods the ammoniacal liquor is the source of supply of many ammonium compounds used as fertilizer and of ammonia itself used in many industries, while coal-tar is the raw material which chemistry turns into the brilliant dyes of commerce and various flavouring essences that flowers and fruits once supplied.

All of us remember the waste that occurred when wood was roasted to form charcoal. All the gases, the watery liquid with its valuable contents, such as the ascetic acids, metheyl alcohol, etc., and the wood-tar and its constituents were driven off,—wasted. Now the charcoal is the by-product and the former by-products are the prizes sought.

In all the modern methods of chemistry in the treatment of coal, oil and wood, at the basis of the reasoning that has brought about such marvellous results, has been the recognition of the fact that these three substances contain in available form the great store of the elements oxygen, hydrogen and carbon that are the components of that great family of compounds with which the study of the so-called organic chemistry deals. The problem facing the chemist is to break up this supply and recombine the elements into the specific compound sought in modern industry. Fascinating indeed, in this regard, has been the discovery of certain agents that by their presence only, with seemingly no change in themselves, cause chemical reaction and compel the union of elements and substances that otherwise refuse to unite. These are the catalysts. Nickel acts on one group of substances, and even water is a great catalyst. In the discovery of other catalysts there is a great opening for further development.

So the future has great promise. No one can doubt this in view of the startling developments and discoveries of recent years.

Bakelite, so familiar to radio fans, is a coal derivative. Gas refrigeration is a very recent discovery that threatens in time to entirely supplant electric refrigeration, owing to its cheapness and absence of moving parts. It is said that German scientists are now able to make wood alcohol from water gas, for sixty cents per gallon. This water gas is obtained by the treatment of coal with steam. It is quite probable that these same scientists have already put on their thinking caps and will soon develop a cheap process for the manufacture of alcohol to be used in intoxicating liquors. A substitute for gasoline, made by forcing hydrogen into coal, heated under pressure, has also been discovered, and this substance is largely used in Germany.

Dr. Bigelow referred briefly to the progress made in the distillation of petroleum. The paint business will in all probability be revolutionized by the recent discovery of a solvent for lacquers that is manufactured from petroleum. Synthetic sugar derived from oils is also a recent discovery, and, strange as it may seem, there is every probability that meat and other foods will be obtained from petroleum.

At the conclusion of the address, a hearty vote of thanks, moved by F. O. Condon, M.E.I.C., was tendered Dr. Bigelow by the chairman.

Election of Officers

Officers for 1928-29 were nominated at this meeting, and the following will carry on the work of the branch during the ensuing year:

Chairman	H. J. Crudge, A.M.E.I.C.
Vice-Chairman	M. J. Murphy, A.M.E.I.C.
Secretary-Treasurer	V. C. Blackett, A.M.E.I.C.
Executive Committee	E. T. Cain, A.M.E.I.C.
	J. R. Freeman, A.M.E.I.C.
	L. H. Robinson, M.E.I.C.
	G. E. Smith, A.M.E.I.C.
	H. B. Titus, A.M.E.I.C.
	Frank Williams, A.M.E.I.C.
Ex-officio	F. O. Condon, M.E.I.C.
	G. C. Torrens, A.M.E.I.C.
	F. L. West, M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
W. McG. Gardner, A.M.E.I.C., Branch News Editor.

Harbours of the Great Lakes

(Reported by H. W. B. Swabey, M.E.I.C.)

On March 15th, an interesting paper was read to the branch by Lt.-Col. H. J. Lamb, M.E.I.C., describing the "Harbours of the Great Lakes."

The paper, splendidly illustrated by lantern slides of charts and photographs, opened with a brief description of these great freshwater seas having a combined area of 95,160 square miles and a sailing distance from Kingston to Duluth of 1,160 miles.

The drainage of this system is so well regulated by nature and the supply so balances the discharge that at all seasons a sufficient depth of water is provided over the major portion of the lakes to cover all the requirements of deep water navigation. Further, it has been repeatedly stated that nowhere else on the face of the globe on a comparable scale can such a wonderful combination of freshwater reservoirs be found or can any river comparable in size be found to compare with the St. Lawrence in uniformity of flow.

To utilize these waterways efficiently and in safety, the Dominion government has, since Confederation, expended approximately fifty-two millions of dollars on the construction and maintenance of harbours and other improvements. This work has involved the establishment of a boundary line between Canada and the United States; charting of the whole system and providing aids to navigation; construction of harbours both for traffic and refuge, and of canals and locks to overcome the Niagara and St. Mary's falls. Improvements have also been effected in the connecting channels of the Detroit, St. Clair and St. Mary's rivers and in the channel across lake St. Clair.

On the Canadian shores of the Great Lakes some seventy harbours have been constructed.

The minimum navigable depth of most of the harbours on lake Ontario is 14 feet or the present draft of the St. Lawrence and Welland canals. On the upper portion of the Great Lakes many of the harbours have been dredged to provide for an average navigable draft of 20 feet which obtains throughout the greater portion of the waterway above the foot of lake Erie.

Various types of harbour design have been introduced to the Great Lakes. Sometimes the discharge of rivers has been confined between two parallel piers or between piers diverging from the entrance to provide turning space for vessels. Frequently the piers are of uneven length, the longer pier giving increased protection. Occasionally detached breakwaters are constructed beyond these piers to further reduce wave action in the inner harbour and are sufficiently extensive at times to provide an outside harbour. Many of the harbours are more or less protected by being located in deep bays, or are practically landlocked.

Formerly the general type of harbour structure on the lakes was timber cribwork filled with stone ballast, but for some years the tendency has been to build the superstructure of concrete. In some instances, where the bottom was soft, pile structures, all timber, have been used or pile substructures with concrete superstructures. Reinforced concrete cribs filled with sand, gravel or stone have been successfully utilized in the breakwater and lately the rubble mound has been frequently adopted.

Here the author described in detail the more important Canadian harbours on the lakes from Port Arthur and Fort William down to Kingston, in most instances illustrating his remarks by lantern slides, some of which were taken from aerial photographs. In referring to the harbours at the head of the lakes, aptly termed the Gateways of the Canadian Northwest, in regard to shipping, he mentioned that these two ports combined lead the world in grain capacity, the combined storage capacity of the twenty-six elevators being approximately 72,500,000 bushels. During the past season 280,500,000 bushels of grain left these ports, although this did not approach the 1926 record of 323 million bushels. During the 1927 season 5,756 vessels of a combined registered tonnage of over 16,000,000 tons arrived and departed from these ports. As an instance of the quick dispatch in loading grain for which these ports are noted, 130,000 bushels of grain had been loaded into a steamer in exactly one hour, while on the 28th of November, 1922, twenty-eight vessels loaded nearly 7,000,000 bushels at these twin ports during twenty-four hours.

Sault Ste. Marie, the world renowned gateway of lake Superior, with its five great locks, its unsurpassed volume of traffic and important compensating works for controlling the water level of lake Superior, forms one of the most important links in the chain of navigation on the Great Lakes. Some 85,500,000 tons were carried by vessels through these locks during the season of 1926.

Many other harbours were described by the speaker, among the more important being Port McNichol, Midland and Tiffin, Goderich, Sarnia, Windsor, Port Burwell, Port Colborne, Hamilton, Toronto and Kingston.

That the expenditure on the lakes by the United States and Canadian governments was amply justified was illustrated by the growth of the fleet from 320 steamers and 1,152 sailing vessels of 383,309 gross tons in 1862 to 885 vessels totalling 3,245,000 tons in 1927.

In conclusion, the author expressed, as his considered opinion, that the possibility of future trade and development on the lakes was almost beyond estimation.

After a short discussion, Fraser S. Keith, M.E.I.C., expressed the appreciation of the meeting, over which R. deL. French, M.E.I.C., presided.

Utilization of Metallurgical Gases

(*Reported by W. R. McGlaughrin*)

An original paper of outstanding importance to all interested in the conservation of Canada's natural resources was presented to the branch on March 22nd, by W. H. deBlois, M.E.I.C., who spoke on the "Utilization of Metallurgical Gases."

In introducing his subject the author referred to a specialist as "one knowing more and more about less and less." Then, at the risk of coming within this description, proceeded to limit his subject to the metallurgical gases containing sulphur.

The chief sulphur bearing minerals of economic importance found in Canada are pyrite, pyrohotite, galena, sphalerite, chalcopyrite and such less widely known sulphides as pentlandite, the principal ore of nickel in the Sudbury district.

As the sulphur common to these ores must be largely expelled either before or during smelting, vast quantities of this element in the form of sulphur dioxide gas are discharged into the atmosphere, there to constitute a menace to surrounding vegetation, besides being forever lost to any useful purpose. A conservative estimate of this waste in Canada amounts to 1,500 tons of sulphur daily.

A further incentive to the study of this problem arises from the fact that Canadian pulp mills and users of sulphuric acid are importing close to 500 tons of sulphur per day, representing a trade balance adverse to Canada of some four million dollars per year. There is thus created a problem of major importance.

The Mond Nickel Company at Coniston, Ont., has already proceeded to solve this problem with the only plant in existence using the contact process for manufacturing sulphuric acid from the escaping sulphur dioxide, but the consumption in the form of acid in Canada is so limited that but 75,000 tons per year is marketable, representing only some 70 tons of sulphur per day or less than 5 per cent of the total amount wasted.

The author then proceeded to describe the manufacture of sulphuric acid, which was first produced on a commercial scale in England. The acid was obtained by introducing sulphur dioxide obtained from burning sulphur into a lead chamber, together with steam and oxides of nitrogen. The latter act as promoters for the oxidization of the sulphur dioxide and are recoverable.

The largest plant in the world of this type is situated at Copperhill, Tennessee, operated by the Tennessee Copper Company. It is capable of producing 1,000 tons of sulphuric acid per day.

Originally operated as a copper smelter, this plant installed a chamber process in 1904, following vigorous complaints from surrounding agricultural interests, and the gases are recovered completely for the manufacture of sulphuric acid, copper becoming but a by-product of the operation. This acid is employed in the production of acid phosphate which is sold locally in this cotton district as a fertilizer. Unfortunately, Canada has hardly the beginning of a fertilizer industry and no phosphate deposits of economic importance are within reach.

As a chamber plant is limited to the production of 80 per cent acid, and as several industries have created a demand for oleum and 98 per cent acid, the art of chemical engineering has attained an outstanding achievement by developing the contact or catalytic process for the production of strong acid.

The contact process consists essentially in the combination of SO_2 and O_2 in the presence of a catalyst which, while it does not appear among the products of the change, alters the velocity of the reaction. Platinum in a finely divided form is usually considered to be the most active catalyst and has been almost exclusively employed, though it is very susceptible to the presence of poisons, such as arsenic.

The contact process involves the production of sulphur dioxide gas; its purification from dust and mist with attendant cooling and drying; its subsequent conversion to the trioxide by catalysts and finally its absorption to form 98 per cent sulphuric acid. The reactions may be stated as,

$$2\,Fe\,S_2 + 5\tfrac{1}{2}\,O_2 \rightarrow 4SO_2 + F_2O_3$$

$$SO_2 + \tfrac{1}{2}O_2 \rightarrow SO_3\ (catalytic)$$

$$SO_3 + H_2O \rightarrow H_2\,SO_4$$

The mist is one of the most troublesome factors of the process and must be completely removed, for it is mainly responsible for carrying the poisons to the catalyst. The converting temperature of 750°F. at which the oxidization of the sulphur dioxide is performed is sustained by the heat of the reaction and the trioxide gas formed can be absorbed most efficiently in sulphuric acid, already of 98 per cent strength.

As the market for sulphuric acid is strictly limited, other means have been sought to utilize this daily waste. Several economic means of recovering the elemental sulphur from the gases have been suggested but the difficulties and expense of these solutions have prevented a satisfactory development.

However, one of the most favourable is now in use for refrigerating plants. The sulphur dioxide, on being cleaned, is dissolved in water from which it is expelled by heat as 100 per cent dioxide gas. This gas is compressed to the liquid state for convenience of transporting and storing. Nevertheless it is only economical to employ this process where waste heat is available, such as in those smelters using reverberatory furnaces.

A distinct advantage to the paper mills of such a 100 per cent gas so readily available in place of the 16 per cent usually obtained from burning sulphur is the notable reduction of plant. In conclusion the speaker emphasized the importance of the problem and the need for careful and thorough investigation.

Dr. Alfred Stansfield, M.E.I.C., expressed to the speaker the appreciation of the meeting, which was presided over by J. R. Donald, M.E.I.C.

Papers and Meetings Committee

The personnel of the Papers and Meetings Committee of the Montreal Branch for the year 1928-1929 is as follows:

Chairman ....H. Massue, A.M.E.I.C.
Vice-Chairman ....J. L. T. Martin, A.M.E.I.C.
Civil Section
Chairman ....A. Plamondon, A.M.E.I.C.
Vice-Chairman ....L. L. O'Sullivan, A.M.E.I.C.
Electrical Section
Chairman ....N. L. Morgan, A.M.E.I.C.
Vice-Chairman ....A. S. Runciman, A.M.E.I.C.
Mechanical Section
Chairman ....G. H. Dickson, A.M.E.I.C.
Vice-Chairman ....H. G. Thompson, A.M.E.I.C.
Municipal Section
Chairman ....J. F. Brett, A.M.E.I.C.
Vice-Chairman ....P. E. Jarman, A.M.E.I.C.
Railway Section
Chairman ....F. F. Clarke, A.M.E.I.C.
Vice-Chairman ....H. B. Montizambert, A.M.E.I.C.

The committee was appointed by the executive of the branch to make arrangements for the fall programme. The members of the branch are earnestly requested to suggest subjects of interest. This offers an opportunity for the members who have felt that past programmes have been inadequate to present their ideas. Such suggestions will be greatly appreciated by the committee.

Niagara Peninsula Branch

Walter Jackson, M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The Uses of Structural Steel in Engineering Practice

On March 27th this branch had a very well attended meeting at St. Catharines to hear Mr. Lee H. Miller, chief engineer of the American Institute of Steel Construction, speak on the subject of "The Uses of Structural Steel in Engineering Practice," with special reference to the new Handbook issued by that Institute, and experiments which have been conducted.

Mr. Miller began by emphasizing the part played by steel in our present-day civilization. The exact periods of the stone age, the copper age and the iron age are lost in the mists of antiquity, but the steel age definitely started between the years 1885 and 1890. Since then the progress of civilization has been phenomenal. The world has advanced further and faster in scientific and economic developments than ever before.

The speaker referred to steel as the "perfect metal" about which there is no guesswork. The modulus of elasticity, the elastic limit and the yield point are exactly known quantities and within these limits it's behaviour does not vary. Up to the elastic limit it is absolutely and uniformly elastic and to the yield point it is also elastic but not necessarily uniformly elastic.

The "hot" steel industries such as smelting works, etc., and the "cold" steel industries,—the manufacturers,—are now working together and the old 16,000-pounds working stress will soon be a thing of the past. It was devised in the first place to cover errors due to ignorance of the exact behaviour of the Bessemer product and ignorance of designers.

The A.I.S.C. have now adopted 18,000 pounds per square inch as its basic working stress and the new specifications for railway bridges will allow 20,000 pounds, and in some cases as high as 24,000 pounds, for scientifically designed structures.

Tests have proved that the lines of stress lie always at an angle of 45° with the neutral axis. Consequently stiffeners spaced further apart than the depth between flanges are valueless. On the other hand, by using the proper formula they can now be so spaced as to save as much as 50 per cent in the web thickness without any weakening of the girder as far as buckling is concerned.

Wind loads have never been thoroughly understood and the empirical formulæ used today are good only for high velocities. Mr. Miller doubted very much whether wind loads of 30 pounds or more are ever attained and illustrated his point by remarking that he, himself, presented an area of some six square feet to the wind and theoretically a 10-pound wind would be sufficient to blow him along like a leaf,—but he had never encountered such a wind. The highest recorded pressure was only 16¾ pounds per square foot. Differences in barometric pressures were probably just as important, if not more so, than actual wind pressures. At sea level a change of one-seventh of an inch reading will give a pressure of 10 pounds per square foot, and between the windward side and the leeward side of a tall structure there may easily be that difference. The whole question is now under investigation and one new building has been especially fitted with extensometers for the purpose of observation.

Fire protection and danger temperatures are also being studied with the object of limiting the quantity of combustible material in rooms and offices. With 20 pounds of such material per square foot a temperature of 1,850°F. will be attained in the two hours in which the material will burn. The highest recorded temperature during the San Francisco fire was 2,200°F. after a period of eight hours.

Steel welding is a matter that must have the attention of engineers. It has come to stay and undoubtedly has great usefulness. However, at the present time no fair and proper method of inspection has been devised, and until this is discovered welding will remain in what Mr. Miller described as the "bootleg stage." Costs of completed buildings indicate that the welded structure is no cheaper than the riveted.

In conclusion, Mr. Miller mentioned a revolutionary idea presented recently by an English scientist who suggests that the moment of inertia may be replaced in the investigation and design of structural members. The moment of inertia does not take shear into account and therefore is in error to that extent. By following along this new train of thought it is just possible that the long sought "Coefficient of Elasticity in Shear" may be mathematically determined.

Alex. J. Grant, M.E.I.C., thanked the speaker on behalf of the branch for his excellent address and intimated that many of these investigations would be of great value not only in the design of buildings but also in canal construction.

Chairman Carl Scheman, M.E.I.C., then asked for discussion and mentioned that in steel tank construction with skilled mechanics and careful supervision welding had proved a complete success.

Mr. Miller then replied to various questions as follows:—

To A. T. C. McMaster, M.E.I.C.:—The behaviour of steel beams embedded and haunched in concrete is not yet fully understood. The steel will absolutely recover its original form if the elastic limit has not been passed, whereas the concrete will not. There has not been any conclusive test to show that bond still exists after such a beam has been subjected to repeated loadings which stress the steel near the elastic limit.

To Mr. Krumm:—The question of internal tension stress in rivets is under investigation by Professor C. R. Young, M.E.I.C., of Toronto. Unquestionably rivets that are cold driven fill the hole better and are stronger than rivets driven while hot, but on account of the pressures required the method is impracticable for field work. Heating steel naturally causes internal stresses and at certain temperatures a molecular change occurs in the steel whereby these stresses are relieved. At about 1,250°F. such a change occurs,—steel is nonmagnetic at this temperature. Again at 600°F. there is this molecular transformation,—steel is stronger at 600°F. than when cold. At 800°F. steel has about the same strength as when cold and then the strength falls off rapidly as the temperature rises. It is practically certain that some such molecular change does help to relieve the tension in hot rivets.

To Walter Jackson, M.E.I.C.:—There are many reasons for the high cost of welded structures at the present time. Welding causes the maximum bending moment to lie at the support,—right at the weld,—the beading or welding wire costs seven or eight times as much per pound as rivets, although there is less used,—some one per cent of wire as against three per cent of rivets. It is found that practically nothing can be saved in the draughting room. Just as much detail must be given for the weld as for the riveted joint.

To M. B. Atkinson, M.E.I.C.:—Silicon steel flanges might be used economically with carbon steel webs if some method can be devised to prevent the web being stressed beyond the yield point. Otherwise there is no advantage in this method of construction.

To Walter Jackson, M.E.I.C.:—Gas heated rivets appear to be best if gas can be easily obtained. The rivets can "soak" better and attain a more uniform temperature. Electric heating may cause the core of the rivet to burn if not closely watched and forge heating may cause the skin to burn.

Aircraft

Under the auspices of the Engineering Society of Buffalo, about seventy members of this branch spent the afternoon and evening of April 17th inspecting aeroplane factories and airports in the city of Buffalo. The dinner meeting, however, was held on the Canadian side and the membership met and welcomed R. J. Durley, M.E.I.C., general secretary of The Institute. Mr. Durley was late; entirely due, he explained, to the fact that our vice-chairman insisted on taking him up into the clouds in an airship and getting them both lost in a blizzard. There was but little time before the evening session at the Hotel Statler, but he wished to assure the membership of the branch that The Institute was flourishing. It has prospered during the last year and was in an exceedingly sound state of health, financially, mentally, morally and scientifically.

During the afternoon, visits were made to the factories of the Curtis Aeroplane and Motor Company, the Consolidated Aircraft Corporation and the Municipal Airport. The Curtis plant was assembling an order of some 156 fighting two-seater biplanes, for the

Type of Plane purchased by the Canadian Government for Training Purposes at Camp Borden.

United States government. The planes are all equipped with the most modern safety and offensive devices, machine guns fore and aft and mounted in the wings, bombing and camera attachments. Part of the order is equipped with Liberty motors, water cooled, but the balance has the new Curtis D.12 engine, also water cooled but much lighter in pounds per horse power and occupying less space than the Liberty motor.

At the Consolidated factory an entirely different type of plane was inspected—two-seater instruction biplanes equipped with the "Wright whirlwind" air cooled engine. At this plant, where they are producing about one plane a day, some three hundred and fifty men are employed. The machines are the standard training planes for the United States army and navy services.

Two types are produced, the P.T.3, army type with landing wheels, and the N.Y.2, navy type with pontoons. Both types are dual control, and are built of welded steel tubular fusilages.

Orders have been filled for Cuba, Peru, Brazil and the Canadian governments, and in the last three years more than 8,000,000 flying miles are credited.

At the Airport, members were invited to test the air at a nominal charge. Four-passenger, enclosed biplanes were used and the enthusiasm was such that all reservations were quickly booked. Some seventy-five members experienced a new sensation, including the vice-president and general secretary, as previously noted. Fortunately the branch news editor arrived late at the field and was allowed to depart in peace.

The evening meeting at the Hotel Statler was addressed by Mr. C. R. Keyes, president of the Curtis Company, who reviewed recent progress in aeronautics, and by Mr. H. C. Ritchie, of the General Electric Company, who showed some excellent pictures illustrating the lighting of airports. Of great interest also were some slow motion pictures of air currents taken by a special camera having a speed of some 20,000 pictures a second. One picture, showing the action of bullet piercing an electric light bulb, was truly remarkable.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Palm Room of the Chateau Laurier was filled to overflowing at luncheon on April 12th, when the members of the Ottawa Branch gathered to listen to Mr. Dexter P. Cooper describe his project for the development of power from the tides at Passamaquoddy bay.

The Passamaquoddy Bay Power Development

Mr. Cooper described in a general way the main features of the proposed tidal power development which has for its object the generation of 600,000 to 700,000 horse power of electrical energy. Passamaquoddy bay, where it is proposed to harness the tides of the Bay of Fundy, is situated at the mouth of the St. Croix river, the lower reaches of which form the international boundary between New Brunswick and the state of Maine.

The project has been studied by Mr. Cooper for nine years and during the last two years he has been actively engaged in investigation work, including the working out of the principal features of design of dams, control gates and the power house.

The mammoth development, to cost from $50,000,000 to $60,000,000, which the Dexter P. Cooper Company proposes to carry out, unique as it may seem to develop power from tides, involves nothing radically different from the ordinary hydro-electric enterprise, explained Mr. Cooper, except that it will be a varying low-head development utilizing salt water instead of fresh water. There will be two pools or reservoirs, the upper one to be filled at high-tide and the lower one to be emptied at low-tide. The power house situated between would utilize the head thus created.

With a large wall map, Mr. Cooper pointed out the natural features in the way of islands and headlands which will permit of the development by constructing three main dams and two gate sections. The project extends, from one end to the other, a total distance of 16 miles. The area of the upper basin, which lies almost entirely in New Brunswick, would be 110 square miles, and the lower basin, in Maine, 35 to 40 square miles. While the lower basin has a much smaller area, the deeply indented bays give it a total shore line of 176 miles, compared with 150 miles for the upper basin.

Explaining the operation of the scheme, Mr. Cooper pointed out that the total interval elapsing between low and high tide is six hours. When the water outside the gates rises to the level of the upper pool the gates are opened. A large gate section is required for rapid filling. With gates aggregating 220,000 square feet in cross-section, it is calculated that the upper pool will fill to within 2 or 3 feet of maximum tide. The filling period is about two hours. The gates of the lower pool function similarly in quickly discharging the water at low-tide. At some time within the six-hour period the level of the lower pool may be lowered to within about 6 inches of low-tide.

The scheme, Mr. Cooper said, figures out as potential power of 3,000,000 horse power, or 18,000,000,000 kilowatt hours theoretically available, but not all can be developed as that is on the basis of lowering the upper pool and filling the lower pool until they come to the same level. Practically on the basis of a minimum head of 8 feet, the development is expected to yield between 600,000 and 700,000 horse power continuous throughout the twenty-four hours. It is proposed to install thirty turbines of 25,000 horse power each. These would be of the propeller type with no governors but with the blades of some arranged at a different angle than others to get the greatest efficiency for varying heads. The power house would be about 2,500 feet long and in the interests of economy the design involves no superstructure, the top of the power house being about 8 feet above high-water level.

Forty engineers and field men are at work, Mr. Cooper said, and they have a well equipped laboratory for testing materials and trying out experimental models of gates, etc. He intimated that all the principal problems have been solved. The experimental work has included elaborate tests of the effect of salt water on concrete.

Dealing with the building of the dams, Mr. Cooper said that these would be rock, with clay in the right proportions mixed with it. These materials would be taken from the excavation for the power house and conveyed to the dam sites in bottom-dump barges. The maximum depth to be filled in is at the main channel of the St. Croix, where the water is 185 feet deep but of a narrow V-section. Another dam will have a maximum of 50 feet, and the third principal dam 40 feet. The gate sections which are across separate channels from the dams will have to be built behind coffer dams. So as not to obstruct navigation, locks are necessary at the main St. Croix channel and at the gate section of the upper pool.

Mr. Cooper also gave a short review of the political features in the United States and Canada. In the state of Maine one of the principal obstacles was the legislation on the statutes against the export of power. In 1925 a bill to permit the export of power, (the power house is to be located in Maine), was passed after a referendum to the people. In 1926 a Dominion charter was obtained. A permit had also been obtained at Washington, and just recently the legislature of New Brunswick passed a bill relating to the project.

At the conclusion of his address, Mr. Cooper answered many questions. Replying to one member he said that he was of the opinion that the division of the power as between the province of New Brunswick and the state of Maine was a matter for the International Joint Waterways Commission. He also stated that the project would be financed as a private enterprise.

Several of the members emphasized the importance of the project for the development of industries in New Brunswick, especially pulp and paper.

In the absence of the chairman, Dr. Chas. Camsell, M.E.I.C., K. M. Cameron, M.E.I.C., presided and thanked Mr. Cooper for coming to Ottawa and giving the members of The Engineering Institute first-hand information on such an important project.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Montreal Harbour Bridge

About two years ago, P. L. Pratley, M.E.I.C., of Messrs. Monsarrat and Pratley, consulting engineers, Montreal, addressed the Peterborough Branch on the subject of "The Montreal Harbour Bridge," outlining the general design of the bridge and the work on the substructure up to that time. This proved of such interest that Mr. Pratley was invited to make a second visit to the branch in order to describe the progress of the bridge during the past two years. The meeting was held on March 22nd, 1928, under the chairmanship of A. E. Caddy, M.E.I.C., and was well attended. A large number of fine lantern slides were used to illustrate the address.

The greater part of the address dealt with the piers, eight of which were of the pneumatic type. For pier 25 at the north end of the 1097-foot main span, two steel caissons 29 by 47 feet were used. Each caisson had two material locks and one man lock, and a pressure of 23 to 24 pounds per square inch was used. Twelve "sandjacks" were operated in alternate sets of six to lower the caisson in steps averaging 20 inches.

A chart showed the nature of the material passed through and the regularity of the steps. After the two caissons had reached their final position, an 8-foot thick slab of reinforced concrete was laid across them, upon which the stone work and upper portion of the pier was built. Pier 25 has a total load of 51,000 tons or 11 tons per square foot.

Mention was made of the north anchor pier, built on gravel hard pan, with a permanent load of 3.2 tons per square foot, and the speaker then passed on to pier 24 at the south end of the main span, considered the most important. One of the largest steel caissons ever built, 127 by 50½ by 47 feet, containing 453 tons of steel and constructed by Vickers, Ltd., was shown being towed up-stream to the site by six powerful tugs. After dredging the overburden this caisson was then lowered in the same manner, using twenty-four sandjacks.

Similar descriptions were given of all the other piers from 1 on the south shore to 23. Some of these, for example, 13, 14 and 21, were of the pneumatic type whilst others required only simple cofferdams for their foundations.

The speaker concluded with the work on the steel, showing illustrations of the erection of the main cantilevers by means of falsework truss, traversing derrick and 300-ton traveller. Considerable progress had meanwhile been made with the steel on the southern approach spans. Brief mention was also made of the economics of the structure, illustrated by charts.

An interesting discussion ensued and Mr. Pratley was formally and enthusiastically thanked for his address.

The Toronto Waterworks

The next regular meeting of the branch was held on April 12th, 1928, at which William Gore, M.E.I.C., of Messrs. Gore, Nasmith and Storrie, consulting engineers, Toronto, gave an illustrated address on "The Toronto Waterworks." R. H. Parsons, M.E.I.C., city engineer, Peterborough, acted as chairman.

Mr. Gore commenced with a description of the old pumping plant on Toronto island, with a capacity of 100,000,000 gallons a day and the distribution to the various parts of the city, explaining the necessity for pumping as many as three or four times to serve certain districts at high levels. He then dealt with the new plant, on the lake shore at Victoria Park, east of the city, having a capacity of 200,000,000 gallons per day. The consumption of water in Toronto is very high and the city waterworks supply the largest quantity of any single plant in the British Empire.

The problem of pure water supply for the city is a difficult one owing to the contamination of the lake water by sewage and the fact that this contamination varies from hour to hour due to movement under varying winds. The speaker detailed the various steps taken to ensure a pure supply of water at all times. The intake at the new plant is some 7,500 feet out from shore and in 50 feet of water, the first 3,000 feet being a tunnel cut in the shale and the remainder a pipe laid on the lake bottom. Views of the intake end, the knuckle joints and the laying of the pipe were shown.

Passing to the filtration plants, Mr. Gore showed that there are two radically different types, the slow sand filter and the drifting sand filter. Each installation deals with approximately the same quantity of water, but the difference in the area covered is very marked.

The slow sand filters have 30 inches of fine sand over gravel in which there are perforated underdrains. Illustrations were shown of the scraping of these filters and the special methods of sand washing, this being done every three weeks.

The drifting sand type filters, of which there are ten, each with a normal capacity of 6,000,000 and a maximum of 7,200,000 gallons per day, consist of cylindrical steel tanks, beneath which are thirty automatic ejector type sand washing devices. The sand and water are forced upwards through these and overflow at the tops of thirty vertical pipes. At each of these the sand forms a continually drifting conical filter bed through which the water passes. The sand travels through a complete cycle around the filter in about one day. These filters are normally run for a week but have been run for as long as five weeks in emergency. The sand is cleaned at these intervals by forcing water through perforated pipes in the bottom of the tank, up through the sand to outlet troughs at the top.

An interesting automatic chemical feed device, with electrically operated valves, is used to regulate the addition of alum, which is necessary for proper functioning of this type of sand filter. The benefits of chlorination were mentioned and a diagram showing the great reduction in deaths from typhoid fever since the water was first chlorinated, some thirty years ago, was proof of this.

It is a curious fact that while the normal amount of chlorination gives a somewhat objectionable taste to the water, super-chlorination and the subsequent removal of the excess chlorine overcomes this and produces palatable water. The Toronto plant first chlorinates to ten times the extent necessary, and then removes the excess chlorine by means of sulphurous acid.

Power for the pumping station is normally obtained from the Hydro-Electric Power Commission, but a 1,200-kv.a. steam turbine standby unit is available. The various types of pump drives include slow speed steam engines, geared steam turbines, and electric motors.

After an interesting discussion, a vote of thanks was proposed by R. L. Dobbin, M.E.I.C., and cordially approved by those present.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Meeting at University of New Brunswick

On April 3rd, 1928, a joint meeting of the Saint John Branch of The Engineering Institute of Canada and The Engineering Society of the University of New Brunswick was held at Fredericton, N.B. This is one feature of the yearly programme of the branch which Papers Committee tries to meet and is eagerly looked forward to by our branch members. The trip is taken to keep in touch with the scattered membership of this branch and as part of the policy of The Institute to maintain contact with the engineering students attending the universities.

A party of fourteen left Saint John by train at 4 p.m. for the 65-mile run to Fredericton. Arrangements had previously been made for stopping the train in Fredericton at the University Avenue crossing and the members went directly to University buildings. The Saint John men were guests at supper of the engineering students and later the hydraulic laboratory installed several years ago was visited.

The meeting was opened with G. W. Babbitt, S.E.I.C., president of the Engineering Society of the University of New Brunswick, acting as chairman. In a brief address the members of the Saint John Branch were welcomed and S. R. Weston, M.E.I.C., chairman of the branch, was asked to preside.

The Substructure of the Buctouche River Bridge

An illustrated address on "The Substructure of the Buctouche River Bridge" was given by C. S. G. Rogers, A.M.E.I.C., of the Canadian National Railways, Moncton. This bridge is on the Moncton-Buctouche subdivision of the Canadian National Railways in New Brunswick and its replacement at a reasonable figure called for considerable engineering ingenuity. Situated on a branch line of railway producing a limited revenue it was not desirable to spend a greater amount than absolutely necessary on this bridge. As this bridge site crossed a river entering an inland bay or harbour it was found that in this protected area the teredo was particularly active and wooden piles had been destroyed in a few months. For a pier foundation steel pipes were driven through mud to rock and filled with concrete, while the concrete in the pier began at 2½ feet below low water. To overcome danger of disintegration of the concrete in salt water the piers were sheathed with creosoted hardwood plank.

Public Address Systems

A demonstration of a Public Address System was given by A. A. Turnbull, A.M.E.I.C., on apparatus kindly loaned by the New Brunswick Telephone Company. A short address was first given describing the principles of public broadcasting and amplification of sound. The tuning up of the instrument so that finally the ticking of a watch could be clearly heard throughout the room proved particularly interesting.

Sanitary Drainage

A paper on Sanitary Drainage by G. G. Murdoch, M.E.I.C., gave an outline of the earliest known forms of sewerage systems and in turn traced all improvements down to the present. Speaking of modern practice in this specialty, a number of examples of installations with which the speaker was familiar was referred to.

A vote of thanks on behalf of the Saint John Branch, E.I.C., to the Applied Science Faculty for permission to use the college buildings and invitation to hold the joint meeting and to the Engineering Society of the University of New Brunswick for their hospitality was moved by J. N. Flood, A.M.E.I.C., and Geoffrey Stead, M.E.I.C. The branch meeting was then adjourned.

With the president of the Engineering Society resuming charge of the meeting, a vote of thanks to the three speakers of the evening was moved by M. E. Dines, S.E.I.C., and seconded by C. A. Wakeham, S.E.I.C.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

The Flin Flon Mine Area

W. H. Hastings, A.M.E.I.C., geologist with the Bureau of Labour and Industries, of the Province of Saskatchewan, delivered an address at the January meeting of the Saskatchewan Branch on the "Flin Flon Mine Area of Northern Saskatchewan and Manitoba." His address was illustrated with maps.

"Occasionally," said Mr. Hastings, "we hear the cry that Saskatchewan and Manitoba are making a gift of their resources to the United States. In my opinion this is a rather unreasonable attitude to take. Canadian and English capital have had an opportunity of carrying out this development but have not been willing to accept the risks involved. Without capital, no development could take place, and capital from whatever source is surely entitled to a fair return on investment. That profits will not be out of proportion is evident.

"At the Flin Flon, for instance, the ore is comparatively low grade. Mining costs, milling costs, smelting costs, marketing costs and the cost of financing will make the profit per ton small, and only by large scale operations can over-all profit be made," said Mr. Hastings. "Only the interest on the investment will go to the United States, while the greater percentage of income from the mine will be turned back to the people of Saskatchewan, Manitoba and Canada generally, for wages and supplies. Work will be made available for a large number of our people and a new market for a great variety of products will be created. Our engineering college graduates will find a new field of employment and one that is near home.

"The investors are gambling on the future, on the continued prosperity of Canada, on their ability to overcome obstacles which are sure to arise, for they are dealing with a new combination of minerals and must develop a new process for their treatment. In my opinion the Flin Flon is the greatest prospective mine on the continent and the Flin Flon and adjacent area will in the next fifteen to twenty years constitute Canada's greatest mining camp and will not be excelled by any in British Columbia, northern Ontario or northern Quebec," said Mr. Hastings. "The 16,000,000 tons of Flin Flon ore which average in mineral values $13.00 represent a total of $200,000,000. This is only the ore so far tested by diamond drilling.

"The wages of several thousand workmen will be earned and spent in Canada and large quantities of mine supplies will be bought from Canadian firms. Our railways will benefit directly from increased freight and passenger traffic. Machinery and supplies will be carried into the mining area and mine products will be brought out. New industries must follow the mineral development," declared the speaker, in summing up the advantages which would quite ordinarily follow mining development, even on a small scale. An important link would be formed between the water power of the north and the population area of the south, he believed. "The mines themselves will require large blocks of electrical power and the fur and fishing industries will grow and expand," he said.

"There were wide areas of timber and pulp wood to be also brought within development range," Mr. Hastings observed, "and with the completion of the line to The Pas by Sturgis, Regina would become 130 miles closer to the mines than Winnipeg."

It was not to be expected that the mining industry will surpass the agricultural industry, when Saskatchewan alone produces wheat valued at $37,000,000 more than the value of the total mineral production in Canada last year, but the mines could do much to alleviate the present periodical employment condition of the prairies during the quiet seasons in agriculture.

The Constitution of Matter

R. N. Blackburn, M.E.I.C., in opening his address on "The Constitution of Matter," explained briefly the theories held by the ancients on "Matter." Democritus came to the conclusion that matter was made up of atoms combined in various ways. When Dalton's atomic law became generally accepted efforts were made to determine the size of atoms. Films of oil were experimented with and it was found that films one fifty-millionth of an inch could be produced, hence the conclusion was arrived at that atoms were not more than one hundred-millionth of an inch in diameter.

A cubic centimetre of air contains about twenty-seven million million million atoms. Atoms of all the known elements have now been measured.

An atom of oxygen consists of a nucleus containing sixteen protons, (positive charges of electricity), and eight electrons, (negative charges of electricity). The eight electrons revolve in orbits around the central nucleus. The diameter of an atom of oxygen is about 1.3 Angstrom units. (An Angstrom unit is 1/10,000 millionth part of a meter.) If an atom of oxygen were magnified ten billion times the atom would appear about 60 inches in diameter with a central nucleus about one hundredth of an inch in diameter and eight electrons revolving around the nucleus each about one thousandth of an inch in diameter. The weight of an atom is principally in its protons as the electrons have relatively little weight.

The electrons are separated by relatively immense spaces and are continually in motion. Electrons can in some cases travel at the rate of 150,000 miles per second. Professor Bohr states that the electron of an hydrogen atom travels around its orbit at a velocity of 1,300 miles per second. At this rate it would make about 6,000 billion revolutions per second around the nucleus. The electrons do not move in circles but in ellipses and probably in more than one plane. Under certain circumstances an electron may leap outward into a new orbit about four times its original diameter. When the atom reacts to its original size light rays are propagated.

By passing an electric current through a vacuum tube and causing the current to jump from one electrode to another a luminescence is produced. In this manner it was discovered that there was an emission from the negative electrode,—some energy was passing through the tube which has since been proven to be a discharge of electrons. Prior to this time electric current was considered as passing from the positive pole to the negative pole. This test proved the opposite to be the case. By using a concave electrode, the stream of electrons can be focussed to a point.

Experimenters were able to calculate the mass and velocity of the electrons and later on the charge of an electron was calculated. This test proved the electrons to be travelling at rates of order of 18,000 miles per second. This immense speed causes electrons to fly outward from other atoms.

Some years ago there were supposed to be sixty-four elements. At the present date it has been proven that there are ninety-two elements, five of which are still unknown.

By means of spectroscopic analysis the elements can be separated and classified. The elements bear a distinct ratio one to the other and in this scale there are still five undiscovered elements.

The various elements are classified according to the number of protons and electrons of which each is constituted. The atomic number is the number of electrons in the outer orbits and the atomic weight is the number of protons in the nucleus.

As elements only differ one from another in the number of protons and electrons in each element it has been discovered that one element reduces to another by "knocking off" some of the electrons and protons from the nucleus of an atom. Uranium changes to radium and finally to lead.

In this change of elements rays are given off. Such rays are classified as Alpha, Beta and Gamma rays. The Alpha rays are a stream of helium nuclei. The Beta rays are a stream of electrons. The Gamma rays are electro-magnetic waves of very short wave length, much shorter than the X-ray.

By bombarding atoms with Alpha rays Rutherford has knocked electrons out of various elements. In this manner others have claimed to have knocked helium atoms out of mercury and produced gold.

We do not know what electrons are other than "negative charges of electricity" nor do we know what electricity essentially is. An electric current is a stream of electrons. These pass through an ordinary 50-watt electric bulb at the rate of three millions of millions of millions of electrons per second.

We cannot see "force" nor do we know what "gravity" is, although we can measure force and the co-efficient of gravity. We have not the faintest idea of the real nature of the forces represented in the various kinds of energy, such as heat, electricity, mechanical energy, etc., although they are all essentially the same. We cannot destroy energy nor can we create it.

Due to the great speed at which electrons move, the possibilities of the energy locked up in atoms can be realized. The energy in the atoms of one ton of coal has been calculated to be sufficient to produce enough heat, power and light to supply forty million people for 100 years. The unlocking of this great source of energy is thought by scientists to be within the range of possibility. Sir Oliver Lodge has expressed the hope that this great secret will not be discovered by man until he has attained sufficient mental balance to use this power sanely.

Atoms are not permanent. A number of substances are radioactive and it is possible that many if not all atoms are undergoing a process of degeneration. The heat of the sun is supposed to be maintained in considerable measure by this effect. We appear to be now in a period of the degradation of the atom, the period of *creation* having been passed.

Matter is thus a form of energy and it is this energy which gives rise to the sensations we all experience such as sight, feeling, taste, smell, etc. Matter, as ordinarily thought of, then does not exist.

Probably the whole physical universe can be resolved into force, mind and, (possibly), ether. Scientists are not agreed as to the existence of ether. Light which travels over immense distances at the rate of 186,000 miles per second is usually considered to travel by wave motion and presumably through ether, which is assumed to fill all the spaces of the universe. If we assume the ether to exist, it must have certain physical properties. It must be infinitely rare and frictionless. It must be a solid since light is transmitted by a transverse wave, and transverse waves cannot pass through liquids. It is through this medium that the immense forces of gravity are assumed to act. The pull of the sun on the earth is equal to the tensile strength of one million million columns of steel, each 17 feet in diameter. It is difficult to conceive of such a substance as ether and consequently many scientists are now trying to explain such phenomena as gravity and transmission of light without postulating the existence of the ether.

Social Evening

A very enjoyable social evening was spent at the home of Mr. and Mrs. H. N. Macpherson, on February 14th, when the members of the branch were the guests of the ladies at a Valentine party. The game of "Klondyke Whist" provided much in the way of entertainment and suitable prizes were distributed to those having the highest scores and also to the lowest scores. Other games, together with music, were interspersed during the evening. After refreshments were served those present concluded the evening with dancing. About sixty guests were present and all voted the function a very successful event.

Kinks and Notions in Engineering Office Practice

At the February meeting of the branch the chairman introduced the subject of the evening, "Kinks and Notions in Engineering Office Practice," and called on W. W. Perrie, A.M.E.I.C., of the provincial highways department, to lead the discussion. Mr. Perrie outlined the filing system used for correspondence in the office of the chief field engineer, Department of Highways, showing the convenience and facility of indexing correspondence, plans and field notes according to the locations referred to. The speaker showed how the office could be kept in close touch with the work in all parts of the province by means of progress charts and force reports. He also showed how the use of suitable scales simplified the estimating of quantities. In conclusion, Mr. Perrie illustrated the points dealt with by reference to specific examples.

R. W. Allen, A.M.E.I.C., assistant city engineer, Regina, was then called on to give his paper on the same topic. Mr. Allen outlined the general requisites for efficient office work, laying special stress on the need for co-operation, incentive, consistency and uniformity. Reference was made to a labour saving lettering device and to the handiness of reducing plans to foolscap size by a photographic method. The office work and system of a city engineer department was described and an outline given of the steps connected with a programme of capital expenditure.

Nearly every member present took part in the discussion of the two papers referred to above and much information was exchanged regarding the merits of different filing systems.

Engineering Education and Training

P. C. Perry, A.M.E.I.C., division engineer, Canadian National Railways, Regina Division, being called upon for his paper, explained that with the approval of the Papers and Library Committee he had chosen as his subject,—"Engineering Education and Training." Mr. Perry spoke of the duty incumbent on an engineer to assist in the training of the juniors on his staff both for their benefit and his own. He advocated the placing of responsibility with the younger men and giving them a varied experience. Mr. Perry classified engineering education under the heads of physical, social and cultural, describing what he meant by each. The speaker urged that one's education should continue after graduation, particularly along social lines and in matters of public affairs. He illustrated his remarks by many references to The Engineering Journal and voiced the criticism that The Institute as a whole did not appear to be sufficiently interested in sociological subjects.

Mr. Perry's paper was well discussed and the speaker was complimented on the thought promoting value of its contents.

A vote of thanks to the speakers of the evening was sponsored by R. N. Blackburn, M.E.I.C., and heartily endorsed by the meeting.

The chairman then introduced a visitor, J. T. Farmer, M.E.I.C., of Montreal, Que. Mr. Farmer remarked that it was fifteen years since he had been in Regina and complimented the branch on the evident success of its meetings. Mr. Farmer said he was particularly impressed with the readiness of the discussion given the papers presented. Speaking of Institute matters, Mr. Farmer urged that the best interests of The Institute would be served by allowing the proposed increase in fees to apply to Members only, although appreciating the fairmindedness of those who advocated wider distribution.

Annual Meeting

The eleventh annual meeting of the branch was celebrated by a banquet at the Saskatchewan hotel, Regina, on the evening of March 28th, 1928. M. B. Weeks, M.E.I.C., of Regina, presided over the gathering, which numbered fifty-two. Members of the Saskatchewan Section of The American Institute of Electrical Engineers attended the meeting in considerable number.

The chairman opened the meeting by proposing a toast to "The King," after which the minutes of the last annual and last regular meetings of the branch were read and adopted. P. R. Genders, A.M.E.I.C., and J. G. Schaeffer, A.M.E.I.C., were appointed scrutineers to count the ballots and report the election of officers.

The Rev. M. G. Melvin, pastor of Knox United Church, Regina, delivered an inspiring address on the life and work of Robert Louis Stevenson. The speaker outlined Stevenson's early life and training and mentioned that his parents had planned for him an engineering career which was the profession followed by his ancestors. He referred to the various works produced by Stevenson and indicated wherein these works portrayed the character of the man.

Mr. W. G. Laird delighted the audience with a rousing song, which was followed by an encore.

M. B. Weekes, M.E.I.C., the retiring chairman, made a few brief remarks on "The Conditions of the Engineer To-day and Yesterday."

Visit of Councillor J. L. Busfield, M.E.I.C.

J. L. Busfield, M.E.I.C., of Montreal, member of Council and ex-chairman of the Montreal Branch, spoke first on the affairs of The Institute. He referred to matters dealt with at the recent annual meeting in Montreal. The question of increase in fees of members has been held over for another year for further consideration and modification. Changes have been made in the method of awarding Students' prizes. He referred to the probability of holding the next annual meeting in Winnipeg.

The speaker then introduced his subject, "The Relation of the Engineer to the Community." Most professions are founded on human interests but the engineer deals with physical and material resources. He is not trained to properly sell his services to the community. The engineer is mainly employed by corporations, whereas doctors, lawyers, etc., are serving individuals. Mr. Busfield suggested that the individual engineer himself is largely responsible for the condition of his profession.

Mr. Busfield spoke on the question of an Association of Professional Engineers in Saskatchewan. Several of the other provinces of the Dominion have Acts which are not restrictive or effective. Engineers can in a friendly way often accomplish more than can be effected by legislation.

The speaker asked for a full discussion of Institute matters in order that he might obtain the views of the various branches on matters affecting the welfare of The Institute and the profession in general.

A general discussion on matters of interest to members of The Institute followed and Mr. Busfield suggested that the branch submit its recommendations to the next Plenary meeting, which will probably be held in Montreal during October next.

H. R. MacKenzie, A.M.E.I.C., councillor for this branch, corroborated the remarks of Mr. Busfield relating to the care given to classification of members when considering applicants for admission and transfer. He was of the opinion that the engineer must not consider his profession inferior to any other profession. Engineers in this province are holding as responsible positions and are as highly valued as members of any other profession represented in the province.

A hearty vote of thanks was tendered Rev. Mr. Melvin and Mr. Busfield for the addresses of the evening, on motion of R. N. Blackburn, M.E.I.C., and H. S. Carpenter, M.E.I.C.

Mr. LaPointe performed some clever tricks with cards, etc. He produced some excellent music, using a violin bow on an ordinary hand saw. He also rendered a violin solo.

Election of Officers

The scrutineers presented their report as showing the election of officers to be as follows:—

Chairman:—A. M. Macgillivray, A.M.E.I.C., Saskatoon.
Vice-Chairman:—H. R. MacKenzie, A.M.E.I.C., Regina.
Secretary-Treasurer:—R. W. E. Loucks, A.M.E.I.C., Regina.

Executive Committee (2 years).

J. M. Campbell, A.M.E.I.C., Moose Jaw.
J. W. D. Farrell, A.M.E.I.C., Regina.
Stewart Young, A.M.E.I.C., Regina.

Nominating Committee.

C. J. Mackenzie, M.E.I.C., Saskatoon, (chairman).
R. N. Blackburn, M.E.I.C., Regina.
W. H. Greene, M.E.I.C., Moose Jaw.
D. W. Houston, A.M.E.I.C., Regina.
H. McIvor Weir, M.E.I.C., Saskatoon.

Representative on Senate of the University of Saskatchewan.

H. S. Carpenter, M.E.I.C., Regina.

Auditors.

C. S. Cameron, A.M.E.I.C., Regina.
E. A. Duschak, A.M.E.I.C., Regina.

Mr. Weekes then vacated the chair and called on the newly elected chairman, A. M. Macgillivray, A.M.E.I.C., to preside.

Mr. Macgillivray referred to the place of the engineer in the community and humorously referred to the possibilities in this connection. The development of the natural resources in this province is now opening up great opportunities for the engineer. He thanked the members for the honour conferred upon him in electing him to the chairmanship of the branch and expressed his desire to do all within his power for the success of the branch.

R. N. Blackburn, M.E.I.C., chairman of the Legislation Committee, made a verbal report. The time for legislation in this province is not considered opportune and hence very little has been accomplished during the past year by his committee.

The report of the Executive Committee was presented by R. W. E. Loucks, A.M.E.I.C., secretary-treasurer of the branch, and adopted on motion of Mr. Loucks and D. W. Houston, A.M.E.I.C.

D. A. R. McCannel, A.M.E.I.C., chairman of the Papers and Library Committee, reported on behalf of that committee. This report was adopted on motion of Mr. McCannel and H. N. Macpherson, A.M.E.I.C.

The chairman then called on the Hon. Geo. Spence, Minister of Railways, Industries and Labour in Saskatchewan, for a few remarks. Mr. Spence stated that we have in this province the agricultural engineer. He referred to the progress which has been made in this province in the last decade. He first passed through Regina and Moose Jaw en route to the Klondyke twenty-eight years ago. The gold he had been seeking was passed by on the prairies. Mr. Spence stated that the newly formed department, of which he is head, intends to co-operate with the Dominion government in the investigation and development of northern Saskatchewan. In the last four or five years greater results in prospecting have been made than in the past one hundred years, due principally to the ease of modern transportation. He also referred to the possibilities of using the tar sands of northern Alberta and Saskatchewan for road construction in this province.

Report of Executive Committee

Your Executive Committee respectfully submits the following report covering the conditions of the branch and its operation during the past year:—

The membership is 113 as compared with 107 reported at the last annual meeting, and is made up as follows:—

Honorary Members	1
Members	17
Associate Members	70
Juniors	9
Students	7
Affiliates	2
Branch Affiliates	7
Total	113

The executive held six meetings for the transaction of branch affairs. There were five regular meetings of the branch, one social evening arranged by the ladies and one summer meeting in the nature of a picnic. The picnic was held at River park, in the town of Lumsden, in conjunction with the members of the Saskatchewan Section of The American Institute of Electrical Engineers. The ladies arranged a very successful Valentine party, which was held at the home of Mr. and Mrs. H. N. Macpherson, on February 14th.

Our councillor, H. R. MacKenzie, A.M.E.I.C., attended the Plenary Meeting of Council at Montreal in October last, and gave the branch a full report of matters dealt with at that meeting.

Special matters referred to the executive were dealt with by that committee and in some cases by the branch at the regular meetings. The major items consisted of the proposed changes in the By-laws of The Institute. The executive, as you are aware, passes upon and makes recommendations on all applicants for admission and transfer within Saskatchewan, and a number of these were dealt with. One applicant was given an examination and successfully passed the test, your branch secretary acting as presiding examiner.

Negotiations carried on by your executive have resulted in the Saskatchewan Branch of The Engineering Institute of Canada being allowed representation on the Senate of the University of Saskatchewan. Elections to the Senate take place in May each year, the representative elected holding office for three years.

The average attendance at the branch meetings has been 35. Each meeting has been preceded by a banquet. The programme as arranged by the Papers and Library Committee has resulted in considerable interest on the part of all members in attendance. Your executive is highly satisfied with the activities of the various committees and the general interest displayed in the affairs of the branch.

Attached hereto is the financial statement for the year, showing revenue and expenditure, also assets and liabilities. This statement has been examined by your auditors. Although no branch assessments have been levied since 1925, the assets show a surplus over liabilities of $510.55, being an increase of $91.76 over the surplus shown last year and an increase of $192.94 over the surplus of the previous year. Accounts payable this year are $19.69 as against $48.75 last year and $156.47 the previous year. Branch News produced a revenue of $30.40. The meetings have been practically self-sustaining.

Financial Statement—1927-28.

Revenue

On hand from 1927	$115.54	
Headquarters rebates	208.50	
Branch dues	86.00	
Branch News	30.40	
		$440.44

Expenditure

Office expenses	$ 48.71	
Meeting expenses	62.53	
Honorarium	100.00	
Scholarship	50.00	
Sundries	9.55	
Bank balance	169.65	
		$440.44

Assets

Bank balance	$169.65	
Est'd. Headquarters rebates 1928	226.80	
" " arrears	122.29	
" Branch dues 1928	15.00	
" " " 1927	5.00	
" " assessments—arrears	14.50	
Furniture and library	50.00	
		$603.24

Liabilities

Branch dues paid in advance	$ 23.00	
Scholarship for 1928	50.00	
Accounts payable	19.69	
Surplus	510.55	
		$603.24

This is to certify that we, your Auditors, have examined the books and vouchers of the Saskatchewan Branch, The Engineering Institute of Canada, and believe the above statement represents the correct financial position of the branch.

(Signed) D. W. Houston, A.M.E.I.C., D. H. Lunam, } Auditors.

On behalf of the Executive,

R. W. E. Loucks, A.M.E.I.C.,
Secretary-Treasurer.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held on Friday, March 30th, 1928. C. H. Speer, M.E.I.C., acting chairman, called the meeting to order and the business was disposed of. The secretary was instructed to get in touch with the Carpenter-Hixon Company, of Blind River, to arrange for a trip through their plant in June.

Construction of Transmission Lines

J. L. Lang, M.E.I.C., of the firm of Lang and Ross, contractors and surveyors, of Sault Ste. Marie, Ont., gave a most interesting paper on the "Construction of Transmission Lines." He gave the early history of transmission lines, showing the improvements during the last few years since high voltages have become universal, and also enumerating some of the outstanding lines on the continent.

A transmission line consists essentially of three parts, the conductor, the supporting structure and the insulating material, he said, and then he explained the different types of conductors in use and their special values. Aluminum cable, steel reinforced, is somewhat lighter and stronger than copper of equal conductivity and is, moreover, cheaper by a percentage varying from 8 to 15 per cent.

The material used for the supporting structures are wood, steel and concrete. Temporary lines and those of low voltage are usually supported on wooden poles or on wooden H-frame construction.

On long spans, and where permanency is essential, steel lattice poles and steel towers are used. These are usually built on steel grillages and concrete foundations, he stated, and also that spans in current practice range from 800 to 1,000 feet for rigid tower lines, from 400 to 600 feet for H-frame wood pole lines and from 200 to 300 feet for single pole lines.

The largest span on this continent is one of over 5,000 feet on the line of the Knoville Power Company of Tennessee. Mr. Lang has built one on the Seine river power line crossing Rainy lake, a distance of approximately 2,900 feet. It was supported on steel anchor towers 160 feet high, and he pointed out that the height of the towers depend upon the span, as a minimum distance from the ground must be maintained by law, and that this distance varies depending upon the locality. The insulators carrying the lines are of two classes, the pin type and the suspension type, and he said that the present practice is to use the suspension type for all voltages over 40,000 volts.

Getting down to the details of the actual construction of a transmission line, Mr. Lang said that, as a preliminary, aerial surveys are often desirable if possible and are being increasingly used, especially in the northern parts of the country, or anywhere that is thinly settled. These surveys assist greatly in choosing the location, which is very important, as some of the factors entering into the work are accessibility for delivery of materials for construction, the construction road costs and the ease and cost of maintenance.

The speaker then clearly outlined some of his own experiences in building power lines and described some of the unforeseen difficulties met with by a contractor on such work through a country unsettled and without roads for transporting his material in.

A general discussion followed and Mr. Lang was kept busy explaining and answering questions. A hearty vote of thanks was tendered to Mr. Lang for his most instructive address by A. E. Pickering, M.E.I.C., and Carl Stenbol, M.E.I.C.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
J. W. Falkner, A.M.E.I.C., Branch News Editor.

DINNER TO RETIRING CHAIRMAN, R. B. YOUNG, M.E.I.C.

Preceding the annual meeting of the branch, on March 29th, an informal dinner was arranged for by the branch executive at Hart House in honour of the retiring chairman, R. B. Young, M.E.I.C., some thirty members being present.

Prof. Peter Gillespie, M.E.I.C., vice-president of The Institute, in a happy speech expressed the sentiments of those present, and the appreciation of branch members at the success attending Mr. Young's year of office, and the good work done by him.

Mr. Young suitably replied, thanking the members for the support which they had accorded him, and bespeaking the same support for the chairman-elect, L. W. Wynne-Roberts, A.M.E.I.C. After a few remarks from Mr. Wynne-Roberts the members present then adjourned to the annual meeting.

It was a great pleasure to welcome at this dinner the genial personality of our general secretary, R. J. Durley, M.E.I.C.

ANNUAL MEETING

The annual meeting of the Toronto Branch was held in the Mining building of the University of Toronto on Thursday evening, March 29th. There were about 35 members present.

Following the reading of the notice calling the annual meeting, the secretary read the minutes of the previous annual meeting, which were confirmed.

After a few opening remarks, the chairman, R. B. Young, M.E.I.C., called for the secretary-treasurer's report and the financial statement of the year. The adoption of this report was moved by the secretary, seconded by Prof. T. R. Loudon, M.E.I.C., and carried without further discussion.

It was moved by L. W. Wynne-Roberts, A.M.E.I.C., seconded by J. G. R. Wainwright, A.M.E.I.C., that F. N. D. Carmichael, A.M.E.I.C., and E. C. Higgins, S.E.I.C., act as auditors. Having examined the books and checked the same with vouchers and rebate statements, they reported everything in order and correct with vouchers supplied and Bank Pass Book. It was then moved by R. O. Wynne-Roberts, M.E.I.C., seconded by R. B. Young, M.E.I.C., that the report be adopted.

Prof. T. R. Loudon, M.E.I.C., suggested, in order to have record in the minutes, that the principle of sending the councillors at least once to Montreal, be continued.

Reports were then called for from the chairmen of various committees, as follows:—

Papers Committee.

R. B. Young, M.E.I.C., reviewed the various papers given throughout the year and strongly recommended continuance of the policy of welcoming the out-of-town speakers at dinner the evening of the meeting.

Finance Committee.

L. W. Wynne-Roberts, A.M.E.I.C., brought out the fact that after all outstanding indebtedness against the branch was cleared there remained a small surplus in spite of a somewhat reduced income.

Publicity Committee.

J. W. Falkner, A.M.E.I.C., reviewed reports in the Press, news and papers in The Journal, and publicity matter for monthly programme post card.

Membership Committee.

L. W. Wynne-Roberts, A.M.E.I.C., reported various interviews and correspondence with members who had resigned from The Institute.

Meetings Committee.

T. Taylor, M.E.I.C., reported the work done in securing and organizing discussion for the regular meetings.

Library Committee.

C. S. L. Hertzberg, M.E.I.C., reported the moving of the library to the Electrical building of the University of Toronto, and the arrangements which had been made, and also the list of periodicals added during the year.

Student Relations Committee.

W. B. Dunbar, A.M.E.I.C., reported no further work than keeping The Institute before the student body.

These reports all indicated the good work done and the interest taken in the activities of the branch, and the adoption of each in turn was moved and seconded by members present.

A letter was read from the secretary-treasurer of the Niagara Peninsula Branch expressing appreciation of the branch's attitude by reason of which A. J. Grant, M.E.I.C., was elected vice-president of The Institute.

Members of the Nominating Committee, consisting of G. A. McCarthy, M.E.I.C., chairman; A. E. Nourse, A.M.E.I.C.; F. M. Byam, M.E.I.C.; F. B. Goedike, A.M.E.I.C.; J. C. Higbee, Jr.E.I.C., who had acted as scrutineers of the ballots, reported the results as follows:—

Chairman	L. W. Wynne-Roberts, A.M.E.I.C., (acclamation).
Vice-chairman	T. Taylor, M.E.I.C.
Committee	G. H. Davis, M.E.I.C.
	A. B. Crealock, A.M.E.I.C., (2 years).
	H. N. Mason, A.M.E.I.C.
	J. W. Falkner, A.M.E.I.C., (1 year).

The remaining members of the committee are:—

	J. J. Traill, M.E.I.C.
	C. S. L. Hertzberg, M.E.I.C.
(Ex-officio)	R. B. Young, M.E.I.C.
	W. B. Dunbar, A.M.E.I.C.
	J. G. R. Wainwright, A.M.E.I.C.
	T. R. Loudon, M.E.I.C.
	J. M. Oxley, M.E.I.C.

A vote of thanks moved by Prof. C. R. Young, M.E.I.C., and seconded by G. A. McCarthy, M.E.I.C., was tendered to the old executive for the good work done and the very successful year. This was replied to by R. B. Young, M.E.I.C.

The installation of new officers was then proceeded with. The chairman, L. W. Wynne-Roberts, A.M.E.I.C., thanked the members for the honour and asked the support of the incoming executive. Appropriate speeches were also made by T. Taylor, M.E.I.C., J. J. Spence, A.M.E.I.C., H. N. Mason, A.M.E.I.C., J. W. Falkner, A.M.E.I.C.

A vote of thanks to the nominating committee was then moved by J. W. Falkner, A.M.E.I.C., and seconded by J. J. Traill, M.E.I.C., and was replied to by G. A. McCarthy, M.E.I.C.

A vote of thanks to auditors was moved by R. B. Young, M.E.I.C., seconded by W. B. Dunbar, A.M.E.I.C.

R. J. Durley, M.E.I.C., the general secretary, was then called on. He spoke on The Institute membership and finances. He also suggested that it might be possible to supply missing volumes of periodicals, transactions, etc., to the branch library from duplicate sets at Headquarters.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

At the regular meeting of the branch held at the Board of Trade auditorium on March 15th, Mr. Harland Bartholomew, of Harland Bartholomew and Associates, town planning consultants to the city of Vancouver, gave a most interesting talk on the "Vancouver City Plan."

This meeting was called as an open meeting, the reeves and councils of the adjoining municipalities having been invited, as well as kindred organizations and boards of trade and service clubs. An attendance of 141 testified to the interest taken in the address, and in the subject of town planning for the city.

The outstanding points of the subject were touched on by the speaker, and at the conclusion of his remarks, many excellent slides were shown and explained by H. L. Seymour, M.E.I.C., of the Vancouver Town Planning Commission.

THE VANCOUVER CITY PLAN

Mr. Bartholomew described town planning as engineering plus other necessary considerations such as the aesthetic; not only planning bridges, but planning where they should be placed. Town planning is to do what has to be done to fulfill the requirements of the whole of a growing town; a town being a growing organism, which should be attractive and should provide for the best development of its citizens. The laying out or designing of a city plan is much more than surveying, as it means a study of the purpose to which each section will eventually be put.

The complete planning of a city is composed of five phases. The programme for Vancouver is now two-thirds complete, and the whole will be completed this year. Two phases are now complete, (1) streets, (2) zoning.

The future population of the city must be studied, not only as to the probable numbers, but how they will be distributed; natural, unguided distribution not being satisfactory. Excluding that portion north of Burrard inlet, the estimated population in 1960 is 1,000,000. In studying the distribution of this number, one point to be considered is the slope of the ground. In Vancouver the ground lends itself admirably to a satisfactory distribution, the low land being suitable for industries and the high land for residences.

Where must the business district be, and how large? Study shows that if False creek had been land, that would have been the business centre. As matters are, Hastings and Granville and parallel streets will be the business district, and will be large enough for the estimated population of 1,000,000. The present feeder streets, however, to this district are not sufficient, and more must be developed, such as Burrard, Oak and Kingsway.

Consider the business district as a gridiron with a distribution street around it. Radial streets must enter at different points on the gridiron. The present layout of wider streets for intra district traffic is at present quite good. But a comprehensive plan of street widening is essential, or much money will be wasted in widening indiscriminately.

How is a street widening scheme to be carried out and how is it to be paid for? First, by establishing building lines or "set back" lines. Second, in subdividing new areas allow for expected growth. Third, expropriation to get desired width. Dealing with present conditions there are 335 miles of streets in the city of Vancouver. Of these 9 per cent are to be major streets; 55 miles are at present wide enough; 30 miles need to be widened, but of these many are not built upon.

Dealing with the second phase, "zoning," the following interesting facts were brought out. Of all growth, 75 to 80 per cent places itself in its logical location. It is the remaining 25 per cent which causes all the trouble by locating in the wrong position. Where zoning is in force, 95 per cent of all growth easily and readily adjusts itself to the controlling plan. There are now 4,425 stores in Vancouver. There are 662 apartments housing 13,000 people, and only occupying 90 acres or one per cent of the area of the city. In one extreme case there is only allotted 100 square feet of ground space per family. In the zoning plan there are 140,000 people allowed for in the apartment house area. In preventing crowding and congestion, leading to ill-health, there are three types of regulations in force, (1) allowable uses of property, (2) limitation of heights of buildings, (3) open spaces requirements.

THE MODERN TREND OF ENGINEERING PRACTICE

At a regular meeting of the branch on April 4th, J. L. Busfield, M.E.I.C., of Montreal, addressed the members on "The Modern Trend of Engineering Practice" with specific reference to the personal side of the situation. Mr. Busfield is a member of Council, member of the Finance Committee, and chairman of the Papers Committee of The Institute, and in his remarks dealt almost exclusively with Institute affairs, throwing light on many subjects with which the Vancouver members were not thoroughly familiar.

The need of the proposed $5.00 increase in the fees of Members was explained, but as general opinion seemed to favour an increase also in the fees of Associate Members, the motion was being withdrawn for one year.

Dealing with the activities of the Papers Committee, it was pointed out that its function is now to help branches get speakers, and to arrange for the interchange of speakers. Last year $200 was voted to help defray the expenses of speakers going from branch to branch. P. L. Pratley, M.E.I.C., had visited Halifax, St. John, Fredericton and Moncton, on a lecturing tour. This year a somewhat larger grant is available, and arrangements for a visit from some eminent speaker are being made by some of the branches.

The annual meeting, held in Montreal February 14th to 17th, had been a great success. A record had been established at one meeting when over 400 were present. The possibility of holding the next annual meeting in Winnipeg was mentioned and the speaker suggested that branches might send representatives to the annual meeting and members club together to meet the expense.

Many subjects of great interest to the branch and to The Institute in general were touched on by Mr. Busfield, such as classification, which is being studied by a special committee; the new prize regulations now in effect; modern trend of engineering practice; the difference between the engineering profession dealing with the forces of nature and sister professions dealing with human interest; relationship between The Engineering Institute of Canada and the Professional Engineers' Associations; need for a new policy for The Institute; more encouragement for research work, and the admission of companies to membership in The Institute.

In a general discussion following Mr. Busfield's address it was brought out that the suggestion of the branch "That the subscription to the Journal on the part of Students actually attending a University be made optional," had not been accepted by Council, and grounds for its non-acceptance were made very clear.

The branch regrets to record that on March 15th there suddenly passed away Henry Edward Cranmer Carry, M.E.I.C., in his 75th year. Mr. Carry had, for many years, taken an active interest in the affairs of The Institute in general and of the branch in particular, being a constant attendant at all meetings. He was a Life Member of The Institute and will be sorely missed by the branch.

The efforts of all members of the branch are being directed toward making the Western Professional Meeting, to be held in Vancouver, June 7th to 9th, an unqualified success. The general committee and necessary sub-committees have been appointed, and an outline programme for the three days decided upon. Some excellent papers will be given, and an interesting convention is in prospect.

Student Section of the Vancouver Branch

VISIT TO HARBOUR GRAIN ELEVATOR NO. 2

The Student Section of the branch held a trip on Saturday, March 10th, to the Vancouver Harbour Commissioners' grain elevator No. 2. Eighteen students visited the elevator and were shown through the building and shipping galleries. The details of grain handling methods and equipment were explained by members of the staff.

The party was also conducted through the Ballantyne pier and was shown the grain and freight handling cranes and the equipment of the freight sheds.

TOWN PLANNING

A regular meeting of the Section was held on Wednesday, March 14th, at the University, when an address was given by Mr. Harland Bartholomew, of Bartholomew and Associates of St. Louis, town planning consultants to the city of Vancouver. Mr. Bartholomew gave a general outline of town planning, its objectives, its field, and its causes and effects. He outlined the conditions which govern town planning as a science, forming a background which becomes the objective of the town planner.

About eighty students, members of the faculty, and visitors were present.

THE FIRE UNDERWRITERS' LABORATORIES OF CHICAGO

At a meeting held on Wednesday, March 21st, 1928, at the University, an address was given by Mr. J. L. Noble, British Columbia representative of the National Fire Underwriters' Association, who spoke on the Fire Underwriters' Laboratories of Chicago. Mr. Noble gave an interesting description, together with views on the screen, of the work carried on in the testing laboratories. He showed the elaborate and very severe tests to which products of every description are subjected before being stamped with the approval of the Fire Underwriters' Association. Such products can be relied upon to possess the highest degree of durability even under the extreme conditions of a fire. About sixty students and members of the faculty were present.

THE ENGINEERING INSTITUTE OF CANADA

At the meeting held on Wednesday, March 28th, at the University, a short address was given by W. H. Powell, M.E.I.C., on "The Engineering Institute of Canada." Mr. Powell gave his conception of The Institute and its value to the members, student or otherwise. He also outlined its relations to the various engineering societies in Canada and the United States, with special reference to the provincial licensing bodies.

A vote of thanks was accorded Mr. Powell for the interest which he had shown in the Student Section in its first year.

Following Mr. Powell's address the annual elections were held. The following executive was elected:

Hon. President,	Prof. William E. Dickering, A.B., B.S. in C.E., C.E.
President,	A. Peebles, S.E.I.C., Sc.' 29.
Vice-President,	J. H. Legg, S.E.I.C., Sc.' 29.
Secretary-Treas.,	R. L. Morrison, S.E.I.C., Sc.' 29.
Assistant Secy.,	(to be chosen by the Secretary-Treasurer.)
Ex-officio,	E. Bebb, Sc.' 30, (Past President).

This was the last meeting of the year, and the hope was expressed that proportionate success would attend the efforts of the Students during the next session. During the past session thirteen meetings were held, the average attendance being about 80. The maximum attendance at any meeting was 130. One trip was held at which eighteen members were present.

Winnipeg Branch

James Quail, A.M.E.I.C., Secretary-Treasurer.

ELECTRICAL CHARACTERISTICS OF THE GREAT FALLS-TO-WINNIPEG TRANSMISSION LINE.

At a meeting of the Winnipeg Branch, held on December 15th, 1927, L. M. Hovey, S.E.I.C., of the Winnipeg Electric Company, presented a paper on the "Electrical Characteristics of the Great Falls-to-Winnipeg Transmission Line." This line was built to meet the requirements of the increased power load, and after careful investigations it was decided by the company to purchase an entirely new right-of-way from the Great Falls to the northwest section of Winnipeg and to build a new terminal station. A width of 200 feet is provided throughout the right-of-way except where it passes through the town of Selkirk and the city of Winnipeg, where it is reduced to 150 feet.

The initial installation consists of one steel tower line with two 3-phase circuits and a wood pole telephone line. The towers are of galvanized steel. The conductors, of which there are six carried by each tower, have a vertical spacing of 10 feet with the centre conductor offset 3½ feet horizontally.

The size of the conductors is 266,800 C.M., A.C.S.R., six strands aluminum and seven strands steel, having an overall diameter of 0.633 inches with an ultimate strength of 9,385 pounds and an elastic limit of 6,470 pounds. The safe working tension is 4,100 and the current carrying capacity is 305 amperes with a 40°C. rise in temperature.

The insulators are of the ball socket suspension type; seven units per string for 110-kv., vertical, and five units per string for 60-kv., vertical. On dead ends eight units are used for 110-kv., and six for 60-kv., strings.

Suspension clamps which grip the cable are provided with arcing horns for the protection of the insulators in case of flashover to the tower. The minimum conductor clearance to ground is 4 feet, the dry flashover value for seven units is 340,000 volts, and with heavy rains this is reduced to 280,000 volts. Lightning arresters and choke coils are installed at each end of the lines.

At the power house each 21-000-kv.a., 3-phase generator is connected to three 7,000-kv.a. transformers, then on to the main bus. The resistance and reactance cannot be so lumped in with that of the line in determining the overall performance. All calculations refer to the high tension bus voltage only.

At the receiver end three 10,000-kv.a. transformers will be installed per line; 30,000-kv.a. being the load at 100,000 volts.

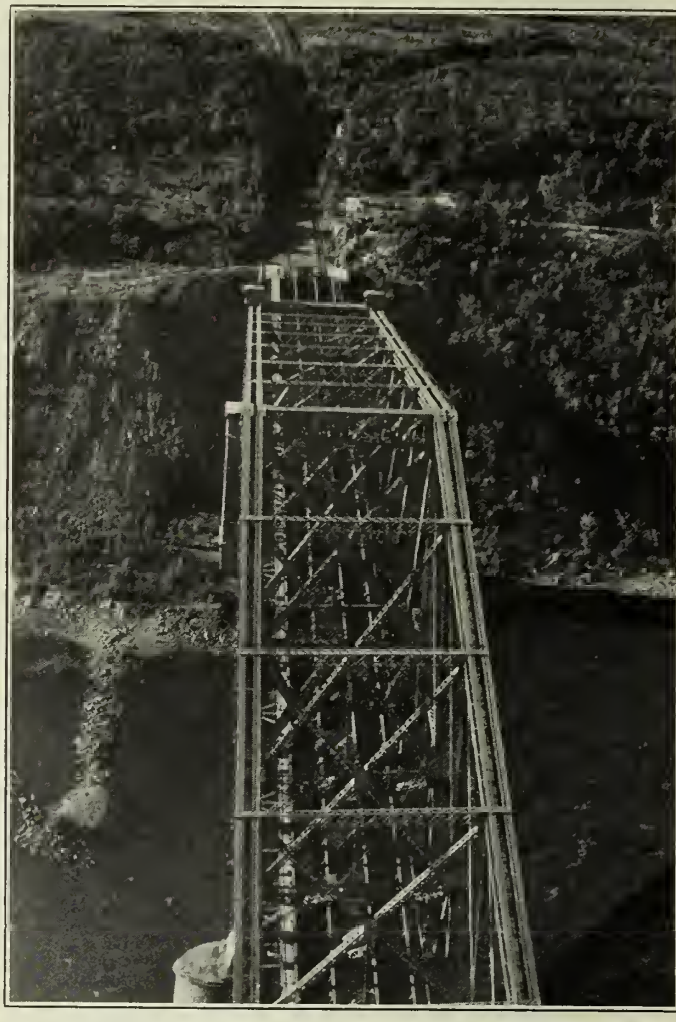
The circle diagram was used for the calculation of efficiency and voltage regulation. Power loss circles, sending end power factor circles, were obtained in a similar manner to those shown in 1926 issue of The American Institute of Electrical Engineers, "Circle Diagram of a Transmission Network," by F. E. Terman.

The ultimate capacity of the lines will call for a 15,000-kv.a. synchronous condenser per circuit, based on a 30,000-kv.a. load at 95 per cent power factor per line; power house voltage 110-kv., and receiver voltage 100 kv. Under emergency conditions the circuit should be capable of carrying 52,000 kv.a. without exceeding the carrying capacity of the conductor.

At the Red River crossing at Selkirk the span is 2,045 feet, copper clad cable, the equivalent of 0000 B. & S. copper was used. The ultimate strength of the cable is 14,000 pounds, the elastic limits is 7,000 pounds, and the maximum allowable working tension under class "B" conditions is 7,000 pounds.

There are nine transposition towers, two sectionalizing towers, and one sectionalizing and tap-off tower for a branch line for each circuit on this line.

A number of very interesting slides were shown of the circle diagram used in the calculations, and various photographs taken on the line.



An Interesting Aerial View of the Quebec Bridge.

Preliminary Notice

of Applications for Admission and for Transfer

April 17th, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in May 1928.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BARNES—FRANK HARVEY, of Sault Ste. Marie, Ont., Born at Port Hope, Ont., Nov. 27th, 1890; Educ., B.Sc., McGill Univ., 1912; 1912-14 and also during college vacations apptce. in C.P.R. shops and roundhouses; 1914-17, shop foreman at Dom. Arsenal, Quebec; 1917-20, mech'l. supt. and production mgr. at Dom. Arsenal; 1920-21, asst. to head of Planning Dept. Laurentide Co.; 1922, shop supt. Can. Brill. Co., Preston; 1923, operating an auto electric service station at Oshawa; 1924, plant mgr. Thomas Watson Ltd., Woodstock; 1924-26, designer on paper machinery for Charles Walmsley & Co. Ltd.; 1926 to date with Northern Foundry & Machine Co. as 1926-27, designing engr. and 1927 to date, designing engr. and asst. manager.
