FOR TRANSFER FROM ASSOCIATE MEMBER TO MEMBER

GAMBLE—CLARKE WILLIAM, of Cairo, Ill., Born at Lachute, Que., Oct. 31st, 1877; Educ., B.Sc., McGill Univ., 1907; 1907-08, asst. to ch. engr., Pro. B.C., reports, surveys for roads, supervising constrn roads, bridges, wharves, etc.; 1908-15, employed by F. Darling & Co., Vancouver, on design and supervising constrn. of grain sacking plant for C.P.R., etc., also, on design and erection of bridges for Govt. of B.C.; 1916-18, serving with Can. Rly. troops and Can. Engrs. overseas, lieut.; 1918-19, head surveyor, Soldiers' Civil Re-establishment Dept., Victoria, B.C.; 1919-24, member, firm Layard Swan & Gamble, Ltd., design and constrn, mostly mech'l and marine, also, surveys, design and installation, farm drainage projects; 1924-26, private practice, mostly surveys and reports; 1926 to date, res. engr. for Waddell & Hardesty, on bridge over Mississippi river at Cairo, also, preliminary work on proposed bridge over Ohio river at Cairo.

References: J. A. L. Waddell, A. B. Ritchie, J. E. Griffith, F. J. O'Reilly, J. C. Kemp

JONES—WILLIAM JONES, of London, Eng., Born at Taffs Well, South Wales, Nov. 7th, 1887; Educ., B.Sc., Univ. of Man., 1914; 1914-19, military training and active service with Can. Engrs. and R.A.F.; 1904-14, ry. engrg. with C.P.R., rodman, inspector, instrumentman, municipal engrg., asst. city engr., Medicine Hat, Alta.; 1919-22, various temporary occupations, manager and superintendent on organization and construction work, including housing, factories, roads, railway structures, also part time demonstrating and lecturing in engrg., Univ. of Man.; 1922, Roxana Petroleum Corp., St. Louis, Mo., as ch. surveyor i/c field work for refinery constrn and as head of the cracking dept.; 1924, supt., London office, M. W. Kellogg Co., refinery contractors, etc., N.Y., i/c engrg. constrn and technical work, European contracts; 1926, sr. asst. engr. i/c development work refineries, Anglo-Persian Oil Co., London office; at present, asst. mgr. i/c production, Medway Oil & Storage Co., Isle of Grain, England.

References: B. Ripley, G. L. Shanks, A. McGillivray, E. P. Fetherstonhaugh, J. R. C. Macredie, E. E. Brydone-Jack, H. Rindal.

LEES—THOMAS, of Calgary, Alta., Born at Girvan, Scotland, Mch. 15th, 1881; Educ., Associate, Royal Tech. College, Glasgow, 1904; 1904-05, asst. engr., North British Railway Co., Glasgow; 1905 to date, with C.P.R., as follows; 1905-12, div. engr. at various places in Western Canada; 1912-14, asst. engr., double tracking B.C. district; 1914-16, asst. dist. engr., Calgary; 1916-18, div. engr., Calgary; 1918-23, engr. of water service, Winnipeg; 1923 to date, dist engr., Calgary.

References: S. G. Porter, F. W. Alexander, F. J. Robertson, A. R. Ketterson, P. B. Motley, W. A. James, J. C. Holden.

PROCTOR—EDWARD MOORE, of Toronto, Ont., Born at Sarnia, Ont., May 11th, 1888; Educ., B.A.Sc., Univ. of Toronto, 1909; field survey work for C.P.R. navig. dept., Nat. Transcontinental, Willis Chipman, structural detailer, Can. Foundry Co.; 4½ yrs. bridge and structural designer, Dept. of Railways and Bridges, Toronto; 1916 to date, member of James Proctor & Redfern, Ltd.; 1918-27, managing director; 1927 to date, president; general consulting work on waterworks, sewerage work, pavements, bridges, bldgs., etc.

References: T. H. Hogg, J. M. R. Fairbairn, F. S. Keith, C. H. Scheman, P. Gillespie, C. H. Mitchell.

FOR TRANSFER FROM JUNIOR TO A HIGHER GRADE

FRASER—ISAAC MATHESON, of Saskatoon, Sask., Born at Pictou, N.S., Nov. 1, 1890; Educ., B.Sc., McGill Univ., 1919, 3 mos. millwright, 1 yr. dftsman, N.S. Steel & Coal Co., Ltd., New Glasgow, N.S.; 3 mos. iron worker, Dom. Iron & Steel Co., Ltd., Sydney; 1 session lecturer and demonstrator, mech'l dept., McGill Univ.; 1 yr., dftsman, Dom. Engrg. Works, Ltd., Montreal; 1921-28, asst. prof., mech'l engrg., Univ. of Saskatchewan, Saskatoon

References: A. R. Roberts, C. M. McKergow, R. B. Stewart, C. J. Mackenzie, A. R. Greig, G. M. Williams.

JOSLIN—JAMES ALEXANDER, of Toronto, Ont., Born at Bexhill-on-Sea, Eng., Oct. 24th, 1893; Educ., 3 yrs., Duncombe High School, Eng., I.C.S. structural engrg.; 1913, shop experience with Dom. Bridge Co., Toronto; 1916, dftsman with R. Simpson Co., Ltd., Toronto; 1917-22 and 1923-25, structural checker, squad leader and i/c contracts of various kinds, both bridges and bldg. works, Dom. Bridge Co., Toronto; 1922-23, with Standard Steel Constrn Co., Welland, Ont., and American Bridge Co.; 1925-27, Can. Bridge Co., Walkerville; 1927, resigned, owing to ill-health; Nov. 1927 to date, with Dom. Bridge Co., Ltd., Toronto; from 1919, has had charge of all kinds of bldg. and bridge work in the preparation of detail drawings and general supervision of the work in the dfting office.

References: G. E. Evans, W. W. Gunn, J. W. Smith, A. Pedan, A. E. West, F. Stevens.

KEITH—WILLIAM HARGREAVE, of Islington, Ont., Born at Newmarket, Ont., March 28th, 1900; Educ., B.A.Sc., Univ. of Toronto, 1924; 1916 and 17 (summers), rodman, chainman, etc., James, Proctor & Redfern, Toronto; 1918, in R.A.F.; 1922, cost accountant, Warren Paving Co.; 1919-20-21-23, res. engr. on various waterworks, sewer, pavement and bridge contracts for James, Proctor & Redfern; 1924-27, asst. engr., twp. of Etobicoke, Ont., i/c waterworks and pavement design and constrn, topographic surveys and concrete designer; May 1927 to date, dist. engr., municipal roads, Dept. of Public Highways, Ont.

References: J. A. Lumsden, J. A. P. Marshall, A. T. Byram, W. B. Redfern, A. L. McPhail, R. J. Griesbach.

FOR TRANSFER FROM STUDENT TO A HIGHER GRADE

GAUVIN—HERVE ALFRED, of Ottawa, Ont., Born at Lewiston, Maine, U.S.A., Nov. 7th, 1900; Educ., B.Sc., Univ. of Sask., 1922, B.Sc. (C.E.) McGill Univ., 1926; summers previous to 1922, utility man, general constrn, Saskatoon, Sask.; 1922 (summer), i/c insulating crew, Capital Contractors, Ottawa; 1922-23, dftsman, Ottawa Car Mfg. Co.; May to Oct. 1924, design and estimates, same company; May to Oct. 1925, design and estimates, Gauvin, Ltd., general contractors, Ottawa; 1926 to date, sec.-treas. and i/c design and estimates, Gauvin, Ltd.

References: N. Cauchon, F. C. C. Lynch, C. J. Mackenzie, H. M. MacKay, E. Brown, R. de L. French.

McBRIDE—ERNEST WILLARD, of Iroquois Falls, Ont., Born at Churchville, Ont., July 24th, 1901; Educ., B.A.Sc., Univ. of Toronto, 1923; 1923 (7 mos.), research at Can. Paper Co., Windsor Mills, Que.; 1924 to date, Abitibi Power & Paper Co.—one yr. efficiency dept.—the department of records, where all mill data is compiled both for mill, operation and accounting purposes; 9 mos. i/c efficiency dept.; 1 yr., 9 mos. asst. to control dept.—this dept. covers stock testing in the sulphite, groundwood and paper mills, waste control, etc.; July 1927 to date, i/c control dept.

References: T. R. Loudon, L. E. Kendall, J. P. Freeman, W. B. Crombie.

MOON—GEORGE DOUGLAS, of Quebec, Que., Born at Port Hoyse, Ont., Nov. 20th, 1900; Educ., B.A.Sc., Univ. of Toronto, 1923; 1923-25, Can. Westinghouse Company's apptce. course in elect'l engrg; 1925-26, demonstrator in elect'l engrg., Univ. of Toronto; May to Oct. 1926, constrn. dept., Bell Telephone Co., Montreal; 1926 to date, asst. field engr., Bell Telephone Co., Quebec, Que.

References: J. A. Loy, A. M. Reid, A. Lariviere, H. W. R. Shepherd, W. F. McLaren, J. R. Dunbar.

SMYE—GORDON RENFREW, of Galt, Ont, Born at Ayr, Ont., Nov. 3rd, 1900; Educ., B.A.Sc., Univ. of Toronto, 1923; 1923-27, analytical chemist, Dom. Tire Factory, Kitchener; at present, asst. to ch. chemist, Firestone Tire & Rubber Co., Hamilton, Ont.

References: L. W. Gill, P. Gillespie, C. R. Young, T. R. Loudon, H. W. Angus, A. M. Reid.

THWAITES—JOSEPH TAYLOR, of Hamilton, Ont., Born at Bolton, Eng., Mch. 2nd, 1901; Educ., B.Sc., Queen's Univ., 1925, post-grad. work term of 1925-26; 1916-21, Can. Westinghouse Company; 1926-27, instructor in physics, Queen's Univ.; 1927-28, sales engr., Smart Turner Machine Co., Hamilton; Feb. 1928 to date, i/c service dept., Wentworth Radio and Auto Supply Co., Hamilton.

References: W. J. McLelland, F. B. Goedike, D. M. Jemmett, A. Jackson, W. P. Wilgar.

VICKERSON—GEORGE LOCKER, of Montreal, Que. Born at Montreal, Sept. 6th, 1904; Educ., B.Sc., McGill Univ., 1925; changes from steam to electric plant of peat bog machinery, Alfred, Ont.; estimator and asst. foreman of the G. R. Locker Co., tile contractors and fireplace bldrs.

TREASURER
F. P. SHEARWOOD, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

ASSISTANT SECRETARY
N. E. D. SHEPPARD, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, J. F. LUMSDEN
Sec.-Treas., R. R. MURRAY, 4 Carleton Street, Halifax, N.S.
Executive, W. J. DeWOLFE, W. B. MacKAY, H. W. MAHON, A. R. CHAMBERS, H. C. BURCHELL, C. B. McDOUGALD
(Ex-Officio) C. A. D. FOWLER, H. W. L. DOANE

CAPE BRETON
Chairman, W. E. CLARKE
Vice-Chair., M. DWYER
Sec.-Treas., E. L. GANTER, P.O. Box 310, Sydney, N.S.
Executive, S. C. MIFFLEN, W. J. RIPLEY
(Ex-Officio) W. E. CLARKE, W. S. WILSON

SAINT JOHN
Chairman, GEOFFREY STEAD
Vice-Chair., W. J. JOHNSTON
Sec.-Treas., E. J. OWENS, P.O. Box 820, St. John, N.B.
Executive, J. R. FREEMAN, J. P. MOONEY, J. N. FLOOD
(Ex-Officio) S. R. WESTON, J. STEPHENS

MONCTON
Chairman, H. J. CRUDGE
Vice-Chair., M. J. MURPHY
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, E. T. CAIN, J. R. FREEMAN, L. H. ROBINSON, G. E. SMITH, H. B. TITUS, F. WILLIAMS
(Ex-Officio) F. O. CONDON, G. C. TORRENS, F. L. WEST

SAGUENAY
Chairman, EDOUARD LAVOIE
Sec.-Treas., B. PELLETIER, City Engr., Chicoutimi, Que.
Executive, J. L. DELISLE, C. C. LINDSAY
(Ex-Officio) N. F. McCAGHEY

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive, A. LARIVIERE, L. C. DUPUIS, H. CIMON, J. T. F. KING
(Ex-Officio) W. G. MITCHELL, LOUIS BEAUDRY

ST. MAURICE VALLEY
Chairman, ELLWOOD WILSON
Sec-Treas., R. MORRISSETTE, City Engr., Cap de la Madeleine, Que.
Executive, H. DESSAULLES, B. GRAND MONT, S. W. SLATER

MONTREAL
Chairman, F. C. LABERGE
Vice-Chair., J. A. McCRORY
Sec.-Treas. C. K. McLEOD, 698 St. Catherine St. W., Montreal, Que.
Executive, J. G. CARON, R. deL. FRENCH, D. HILLMAN, H. MASSUE, E. A. RYAN
Ex-Officio, C. V. CHRISTIE, P. L. PRATLEY, C. M. McKERGOW, J. H. HUNTER, W. C. ADAMS, J. L. BUSFIELD, FRASER S. KEITH, O. O. LEFEBVRE, ARTHUR SURVEYER

OTTAWA
Chairman, C. CAMSELL
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Service, Dept. of the Interior, Ottawa, Ont.
Executive, A. K. HAY, W. BLUE, F. H. PETERS, V. M. MEEK, G. A. BROWNE
(Ex-Officio) N. CAUCHON, A. F. MACALLUM, J. D. CRAIG

PETERBOROUGH
Chairman, A. E. CADDY
Secretary, W. E. ROSS, 317 Boswell Ave., Peterborough, Ont.
Treasurer, A. B. GATES
Executive, G. H. BURCHELL, W. M. CRUTHERS, J. A. G. GOULET, P. MANNING, B. OTTEWELL
(Ex-Officio) R. L. DOBBIN, B. L. BARNS

KINGSTON
Chairman, D. S. ELLIS
Vice-Chair., W. L. MALCOLM
Sec.-Treas., D. G. GEIGER, Fleming Hall, Kingston, Ont.
Executive LeR. F. GRANT, A. G. MacLACHLAN, L. F. GOODWIN
Ex-Officio L. T. RUTLEGDE, G. J. SMITH

TORONTO
Chairman, L. W. WYNNE-ROBERTS
Vice-Chair., T. TAYLOR
Sec.-Treas., J. J. SPENCE, Eng. Bldg., Univ. Toronto, Toronto, Ont.
Executive, G. H. DAVIS, A. B. CREALOCK, H. N. MASON, J. W. FALKNER, J. J. TRAILL, C. S. L. HERTZBERG

SASKATCHEWAN
Chairman, A. M. MacGILLIVRAY
Vice-Chair., H. R. MacKENZIE
Sec.-Treas., R. W. E. LOUCKS, Surveys Br., Land Titles Office, Regina, Sask.
Executive J. M. CAMPBELL, J. W. D. FARRELL, STEWART YOUNG, D. A. R. McCANNEL, W.R.WARREN, W.G.WORCESTER
(Ex-Officio) M. B. WEEKES

LETHBRIDGE
Chairman, N. H. BRADLEY
Sec.-Treas., WM. MELDRUM, Galt Mines, C.P.R., Lethbridge, Alta.
Executive, J. B. deHART, G. N. HOUSTON, C. S. CLENDENING, C. S. DONALDSON
(Ex-Officio) G. S. BROWN, R. LIVINGSTONE

EDMONTON
Chairman, A. I. PAYNE
Vice-Chair., W. R. MOUNT
Sec.-Treas., H. R. WEBB, University of Alberta, Edmonton, Alta.
Executive, C. A. ROBB, H. P. KEITH, R. W. ROSS, W. J. CUNNINGHAM
(Ex-Officio) T. W. WHITE, R. J. GIBB

CALGARY
Chairman, THOS. LEES
Vice-Chair., F. J. ROBERTSON
Sec.-Treas., W. H. BROUGHTON, Inst. of Technology and Art, Calgary, Alta.
Executive, B. RUSSELL, F. M. STEEL, O. H. HOOVER
(Ex-Officio) S. G. PORTER, P. J. JENNINGS, F. K. BEACH, H. R. CARSCALLEN

VANCOUVER
Chairman, W. BRAND YOUNG
Vice-Chair., W. B. GREIG
Sec.-Treas., F. P. V. COWLEY, 930 Birks Bldg., Vancouver, B.C.
Executive, O. S. WOOTTON, E. A. WHEATLEY, H. B. MUCKLESTON, P. H. BUCHAN, H. W. FRITH, A. C. R. YUILL
(Ex-Officio) W. H. POWELL, GEO. A. WALKEM

VICTORIA
Chairman, R. F. DAVY
Vice-Chair., F. G. ALDOUS
Sec.-Treas., K. M. CHADWICK, 25 Brown Bldg., Victoria, B.C.
Executive, H. F. BOURNE, A. L. CARRUTHERS, W. S. DREWRY, L. W. TOMS
(Ex-Officio) E. DAVIS

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume XI | Montreal, June, 1928 | Number 6

The First Commercial 1,200-Pound Steam Plant in the World

Features of the Ultra-High Pressure Steam-Electric Generating Station of The Edison Electric Illuminating Company of Boston, Mass.

Irving E. Moultrop,
Chief Engineer, The Edison Electric Illuminating Company of Boston.

Paper read before the Montreal Branch of The Engineering Institute of Canada, January 19th, 1928

The real reason for building a 1,200-pound steam plant was the belief, backed by conservative estimates of the cost of construction, that enough coal could be saved to pay a handsome profit on the money invested. In other words, we were after dollar efficiency and not thermal efficiency alone.

The territory of The Edison Electric Illuminating Company of Boston is almost a circle with the city of Boston on its eastern periphery. It has an area of approximately 604 square miles.

Before the construction of the new Edgar station at Weymouth the system was served principally by our L street station located in South Boston. Municipal laws require that all transmission in this district must be underground. Cables limit the transmission voltage and underground construction is expensive. This meant that the cost of the transmission lines to the outlying districts was unusually high. To remedy this condition the new station was located on the south shore at Weymouth and the first section of a 110,000-volt overhead transmission line was built. It is expected eventually to extend this line so as to circle our system. This will allow the outlying territory to be served from the Edgar station and leave the L street station to carry the highly concentrated downtown load near which it is located.

Progress in Increasing Thermal Efficiency

The curve on the left of figure No. 1 shows what has been accomplished in the past fifteen years toward increasing the thermal efficiency of steam-electric generating stations. The period since the war has been one of accomplishment of which all should be proud. As may be seen, the B.t.u. required to generate a kilowatt hour has been reduced approximately 30 per cent. In fact, it is believed at this time that the maximum commercial possibilities of the steam cycle is being approached.

Curve No. 5, on the right, shows that the result of the increase in thermal efficiency has been a decrease in the total cost of power generation. Curves Nos. 3 and 4, however, show that this reduction has been due to coal saving alone. Curve No. 4, however, shows that the fixed charge cost of generating has not been reduced along with the coal cost. Attention should be turned from thermal efficiency to dollar efficiency. If attention is focussed on the problem of reducing the cost of construction with the same enthusiasm that has been shown in pursuing the elusive B.t.u. much can be accomplished toward further reducing the cost of generation.

As an average in the United States, for over 70 per cent of the days during the year, the daily system peaks are less than 60 per cent of the annual peak. The cost of the boiler plant of a generating station is approximately 40 per cent of the total cost of the station. This indicates that by building steam generating units capable of operating at very high steaming rates a high annual overall thermal efficiency can still be maintained and also a material reduction in the cost of construction effected.

Steam Pressures and Temperatures Studied

In the design of the new Edgar station an exhaustive study was made of the possibilities of various steam pressures and temperatures.

It was found that it was economical to use steam at as high a temperature as possible irrespective of the pres-

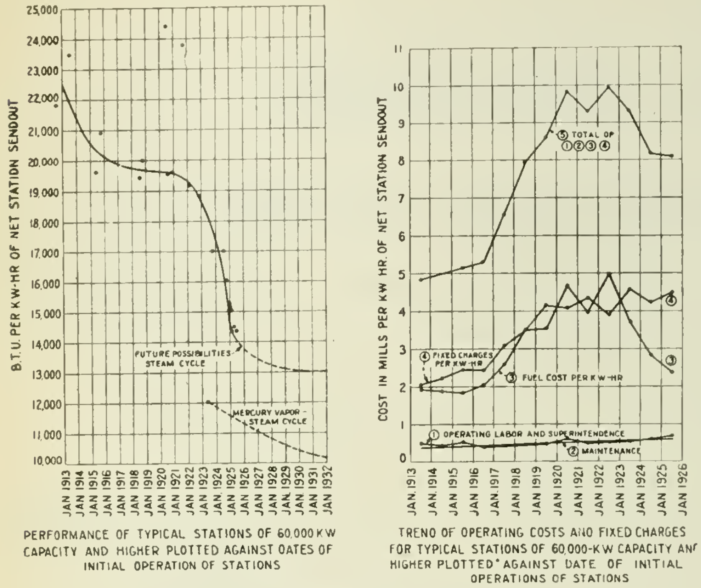

Figure No. 1.

sure. The materials available for construction show a decided falling-off in strength at temperatures above 750°F., and for the sake of safety it was decided to use a steam temperature of about 700°F. for the initial installation. It is expected to go to a higher temperature just as soon as suitable materials were available at reasonable prices.

The question of the proper pressure was next studied, and it was found that for a station employing the regenerative cycle but no reheating there appears to be no economic justification in going to pressure higher than 350 pounds at the turbine throttle. For pressures much higher than this the studies indicated that for our conditions the coal saving would not justify the additional cost of construction.

When the problem was studied from the standpoint of the regenerative reheat cycle, however, it was found that there was a decided advantage in raising the throttle pressure to somewhere between 1,200 and 1,500 pounds. In fact, the studies indicated that a net coal saving of 12 per cent could probably be obtained by raising the throttle pressure from 350 to 1,200 pounds, if the steam was reheated at about 350 pounds.

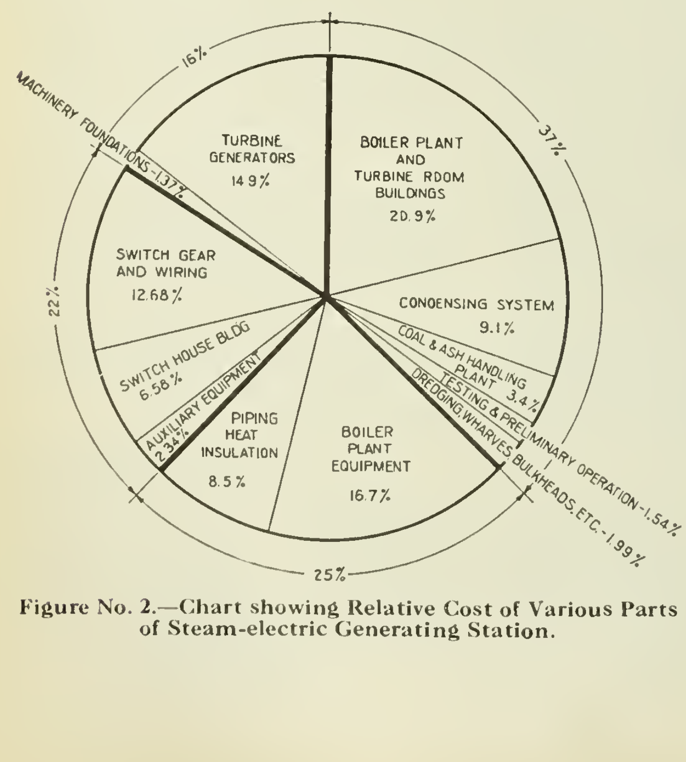

Figure No. 2.—Chart showing Relative Cost of Various Parts of Steam-electric Generating Station.

The more the possibilities of this arrangement were studied the more attractive it looked. It would allow us to build a first-class 350-pound station and confine our experiments in high pressure to a single boiler and a single small size turbine-generator unit. Our estimates indicated that the kilowatts generated by the high-pressure turbine would justify the additional cost of the high-pressure boiler and turbine. It was possible, furthermore, to operate the high-pressure installation at full load whenever it was available for service. In this way we were reasonably sure that we could experiment without losing money and the chances were good that the high-pressure equipment could be made to pay a handsome dividend on the money invested.

Figure No. 2 shows the B.t.u. per kilowatt-hour possibilities in the turbine room for several pressures and temperatures. On the left is shown the comparison for stations that do not extract steam from the main turbines for heating the feed water, and on the right the comparison on the basis of extracting steam to heat the feed water to a temperature of 340°F.

As can be seen, there is a chance of obtaining an improvement of 14.9 per cent by going to 1,200 pounds and reheating. When this is corrected for additional auxiliary

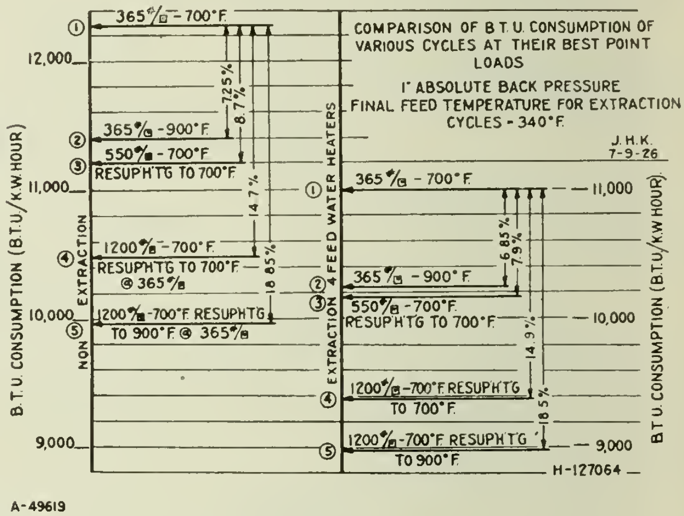

Figure No. 3.—Relation between Costs of Various Parts of a Steam-electric Generating Station.

power, etc., a net improvement of about 12 per cent can be expected.

Comparison of Costs

Many are of the opinion that the cost of a high-pressure station is too great to be justified by the coal saving. To satisfy these "doubting Thomases" let us analyze the cost of a steam-electric generating station and see what the various items which are affected by pressure costs as compared to the whole. Figure No. 3 shows the approximate relation between the costs of the various parts of a steam-electric generating station.

Since a high-pressure boiler will generate more kilowatts than a boiler of the same size operating at normal pressure at same rating, it is obvious that the cost of the main buildings, the preparation of site, coal and ash handling equipment, etc., will be less per kilowatt of generating capacity. Since the turbine-generating unit will use less steam per kilowatt hour it is also obvious that the cost of the condensing plant, including the intake and discharge tunnels, will be less.

The turbines and their foundations will cost more for the high-pressure equipment. The switch house, switch

Figure No. 4.—View of the Edgar Station at the Present Time.

gear and wiring, and auxiliary equipment, should cost about the same. In the boiler plant the pressure parts will cost more while those parts which are not subjected to pressure will cost less.

This, in general, is the picture. The summary of these costs shows that the cost per unit of station capacity is about the same for a 1,200-pound as for a 350-pound plant.

Description of the Station

Taking all of these factors into consideration, the construction of a first-class 350-pound station consisting of two 32-000-kw. turbine-generator units and three 425-pound boilers was undertaken.

Figure No. 4 shows the Edgar station as it stands today, and figure No. 5 a plan of the first section showing the two 32,000-kw. turbine-generator units, the three 425-pound boilers and the high-pressure installation, while a cross-section of the station is shown in figure No. 6.

Outside of the question of pressure, this design of boiler plant is particular to the stations of The Edison Electric Illuminating Company of Boston. By placing the stokers in the outside aisles the major work of the boiler room oper-

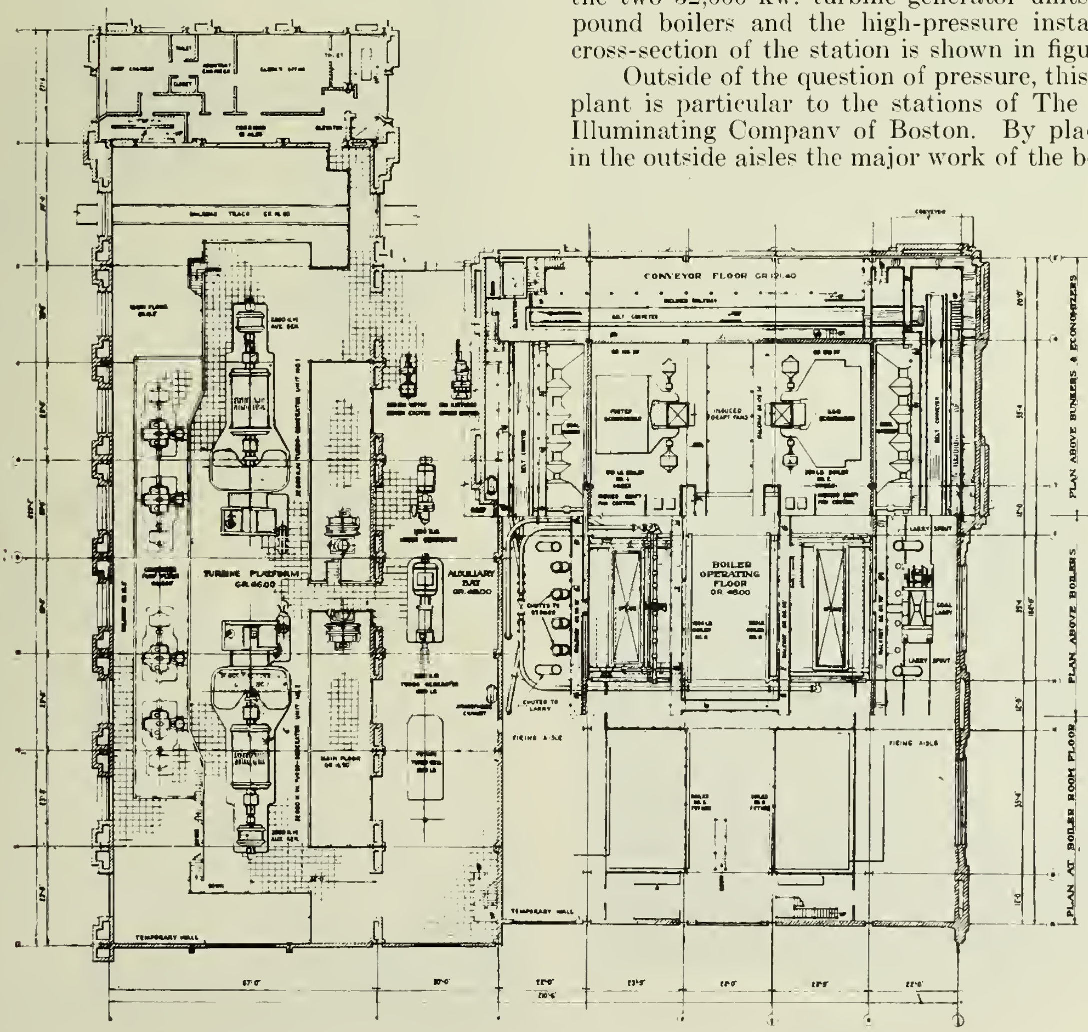

Figure No. 5.—General Plan of the Weymouth Power Station.

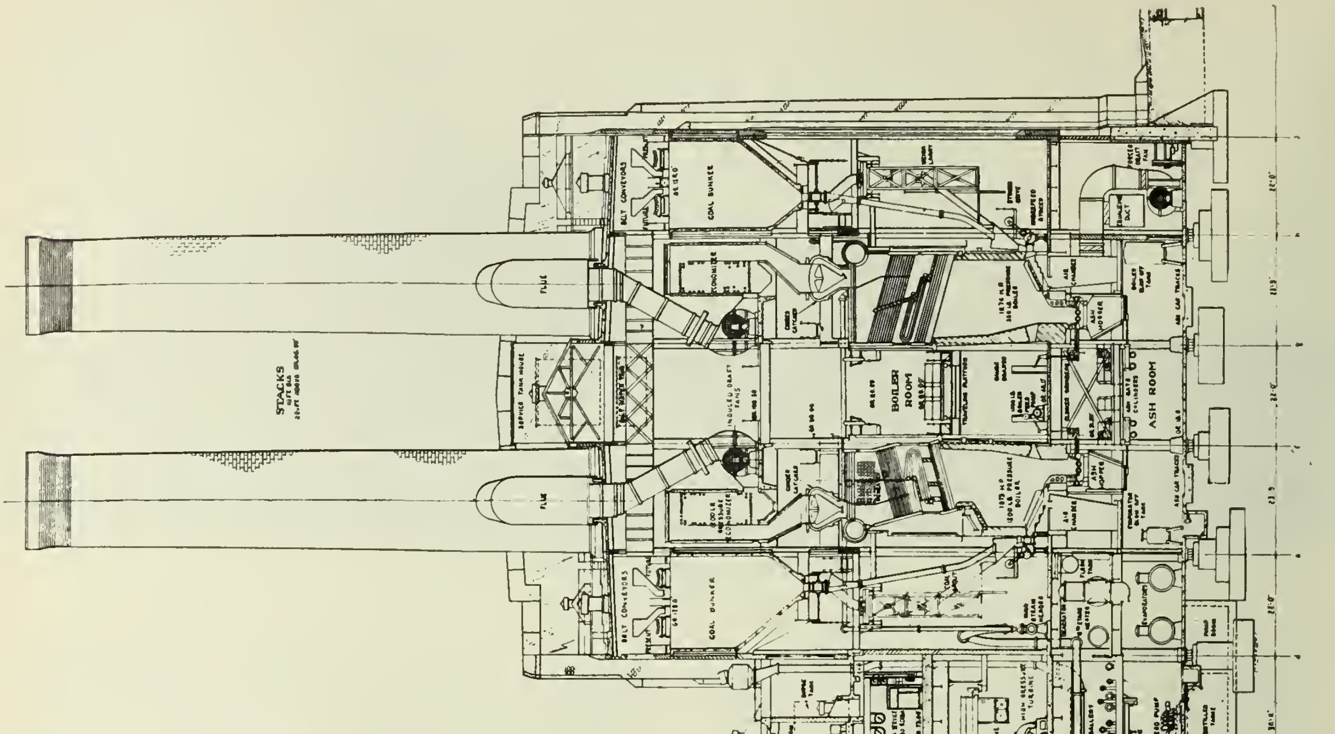

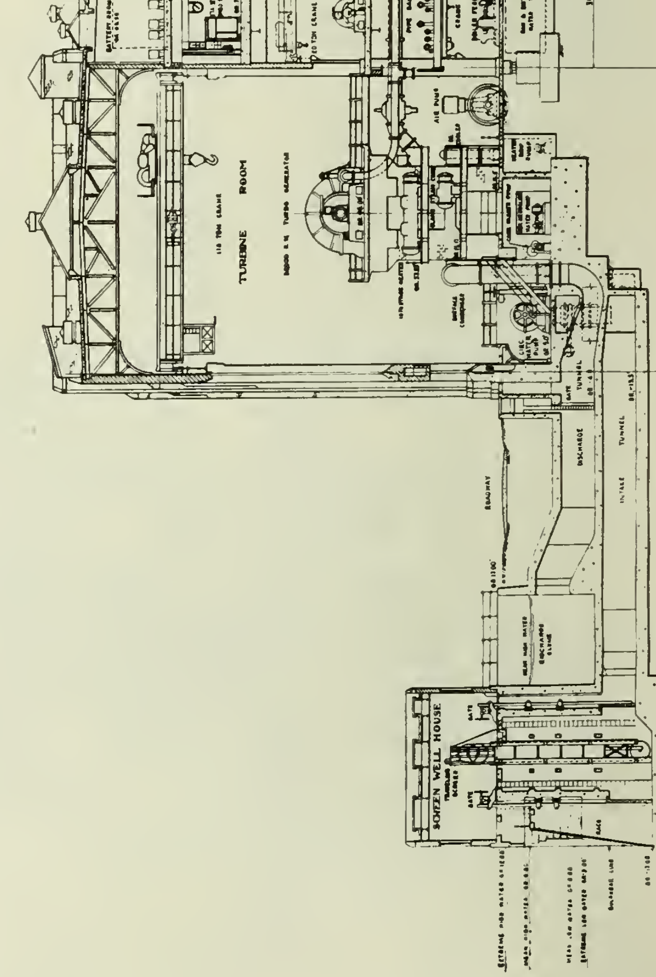

Figure No. 6.—Cross-section of the Weymouth Power Station.

ators is confined to one central aisle. In this aisle are located the instruments for controlling the operation of the boilers and the boiler room operator can supervise the operation of the boilers with the minimum amount of moving around. He can keep in touch with what is going on much better than if the controls were located in several aisles.

The two outside aisles are closed off from the central aisle so that the operating aisle can be kept clean. The roof over the operating aisle is of glass so that the men work in a sunlit, cheerful room instead of the dark aisles so often found in large boiler plants. Plenty of daylight does much to improve the morale of the boiler room operators and makes them better operators.

Figure No. 7 is a cross-section of the first 1,200-pound boiler. It contains 15,732 square feet of water evaporating surface. The tubes are 2-inch O.D., No. 5 B.W.G., and are 15 feet long.

As will be noted, the 1,200-pound superheater is located interdeck above the seventh row of tubes and the 375-pound reheater for the exhaust of the high-pressure turbine is located above the tubes in the first pass. There is a movable baffle in the gas path through the reheater that allows the outlet steam temperature to be regulated. So far it has not been found necessary to use this feature.

The furnace under the boiler is fired by a 15-retort, 29-tuyere underfeed stoker. Due to the short boiler tubes it was necessary to use an arch over the front of the stoker to get in a stoker of sufficient length. Unfortunately, an inclined arch at a wrong angle was installed. The reflection from this arch overheats the rear wall unless it is operated with higher excess air than desirable. It is believed that if the arch was horizontal there would not be this trouble.

The boiler drum was made from a solid forging. It is 48 inches inside diameter, 4½ inches thick, and weighs 96,000 pounds. If it were not for the cost, that is how we would like to have all boiler drums made irrespective of pressure. It would materially reduce the explosion hazard.

Operating Features

This was the first commercial 1,200-pound boiler ever built and many possible troubles were visualized. As it turned out, practically every trouble that was looked for failed to materialize.

No one had had any experience with safety valves at this high pressure and it was feared that when the safety valves operated they might destroy their seats. To guard

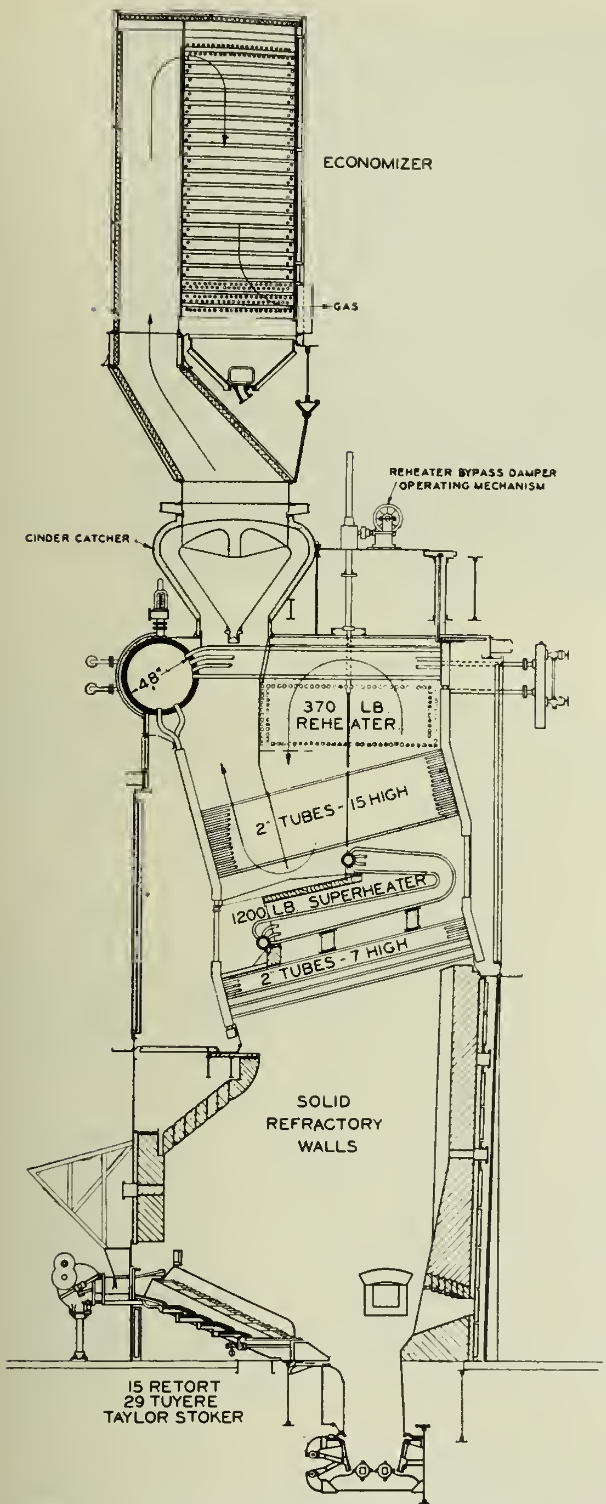

Figure No. 7.—Cross-section of 15,732 square feet, 1,200-pound Boiler, Edgar Station.

against this two small safety valves with shut-off valves between them and the boiler were installed. These valves were set at a pressure below the setting of the main valves. It was thought that these would give warning of the pressure approaching the blowing pressure of the main valves and steps could then be taken to reduce the pressure and prevent the main valves from lifting. It was actually found out that the main valves operate just as satisfactorily as normal pressure safety valves and do not destroy the seats, and it has been possible, therefore, to dispense with the small valves and operate the boiler nearer the pressure setting of the main valves.

A lot of trouble has been experienced with steel castings, in the past, at 200 and 300 pounds. To be sure of sound castings for the 1,200 pounds pressure all castings were examined by means of an X-ray. Some porous ones were found and rejected. As a result there was no trouble with steel castings operating at 1,200 pounds. Some trouble was experienced with the castings for the 350-pound part of the station which were not examined by X-ray.

It was not known how the water level in the 1,200-pound drum would act. No one had manufactured feed water regulators for this pressure so it was arranged for hand control of the feed water. It was found that the water level in the 1,200-pound drum is just as steady as in the 425-pound boilers. The 1,200-pound boiler has been equipped with feed water regulators and they are now operating satisfactorily.

The only thing that has happened to the 1,200-pound boiler, out of the ordinary, is the warping of the boiler tubes exposed to the radiant heat of the furnace. Many of these tubes have warped but some in one direction and some in another. They did not fail and now the warping seems to have stopped.

Another trouble that was experienced is the slagging over of the lower row of tubes. This, it is believed, is due to too close spacing of the tubes exposed to the furnace and to stoker and furnace operation.

Figure No. 8 shows the 3,150-kw., 1,200-pound turbine installed in connection with the boiler just described. It is a 20-stage, 3,600-r.p.m., General Electric Company turbine.

When this turbine was designed it was not known whether its governing characteristics would be such that it could be synchronized easily. Therefore, the generator field was designed so that the turbine could be brought up to somewhere near synchronous speed and the generator put on the bus as induction generator.

When the turbine was finally installed it was found that it responded to its governor just as well as any normal pressure turbine but the special field was the cause of some vibration. The manufacturer therefore replaced the special field with one of standard design and the vibration troubles were cured.

Carbon shaft packing was originally installed outside the labyrinth packing. This packing failed before the machine was placed in commercial operation and was re-

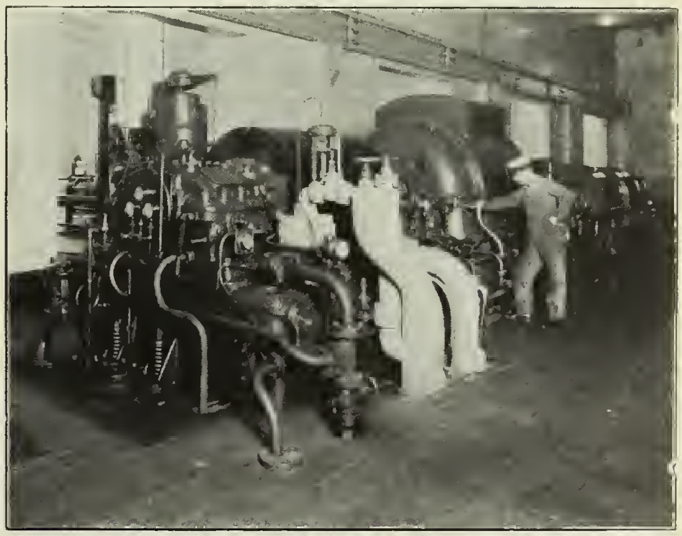

Figure No. 8.—3,150-kw., 1,200-pound Turbine Generator Unit at Edgar Station.

placed with labyrinth packing and no further trouble has been experienced. The thrust bearing was found to be too small and was replaced with a larger one, and has since operated satisfactorily.

The radial diaphragm packing was damaged when the carbon packing failed and has been replaced with axial packing.

Inspection After Operation

In May, 1926, after 1,600 hours of service, the turbine was opened up for inspection. In general the interior of the turbine was as might be expected of a normal pressure turbine with the following interesting exceptions.

The first two rows and the last two rows of buckets on the rotor were bent in as if they had come in contact with some hard object. The nozzles were not injured nor were the other sixteen rows of buckets. So far no satisfactory explanation of this trouble has been advanced. The buckets were trued up and the turbine has operated satisfactorily ever since.

Another thing that was discovered when the turbine was opened up was the fact that the whole interior of the casing and the buckets were covered with a light deposit of iron oxide. This deposit was also found in the valves, fittings, and all the boilers in the station, both normal pressure and high pressure. In certain spots this deposit was built up in little mounds and when these were removed evidence of the start of pitting was discovered.

A motor-driven pump and a turbine-driven pump were installed for boosting the feed water pressure from 450 to 1,350 pounds. These pumps have operated satisfactorily except for some trouble with the hydraulic thrust balancing surfaces of the motor-driven pump.

Taking the plant as a whole, none of the troubles that have been experienced have been due to the pressure.

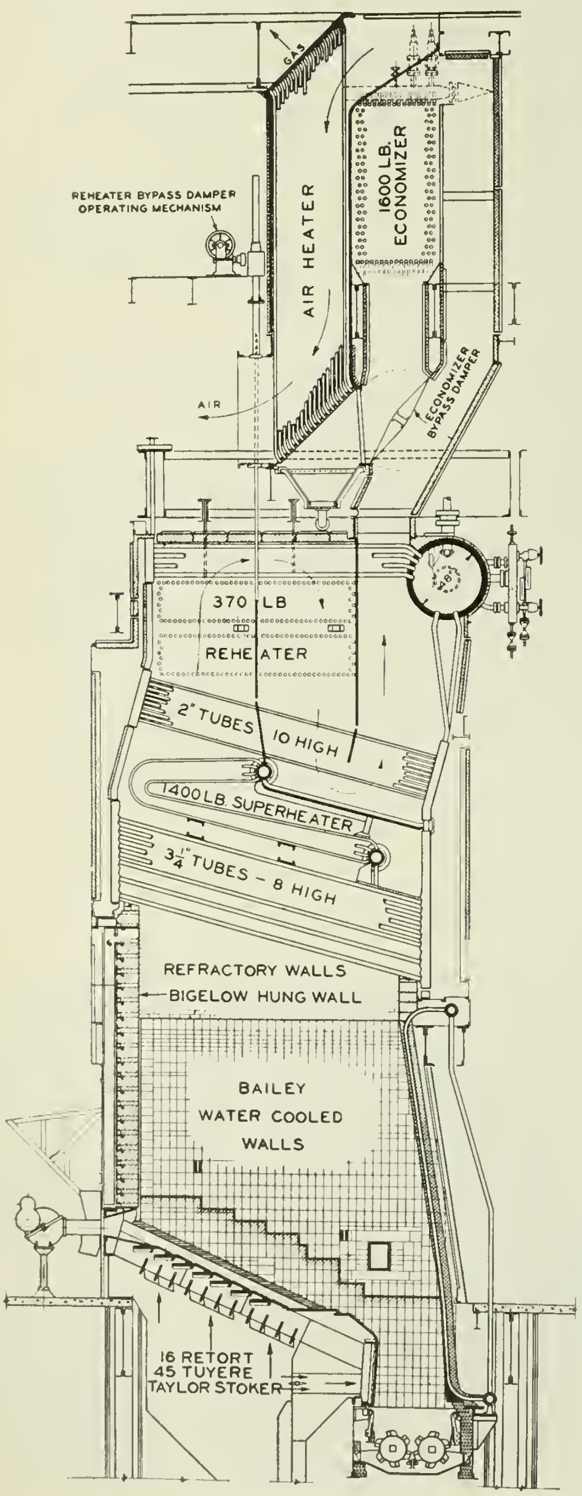

Figure No. 9.—Cross-section of 15,093 square feet, 1,400-pound Boiler, Edgar Station Extension.

Extension to Edgar Station in 1926

In 1926 it became necessary to start an extension to the Edgar station. In the light of our experience with high-pressure equipment an exhaustive study was made to determine the proper pressure for the extension. Three schemes were studied, as follows:

(1) All 350-pound.
(2) All 1,200-pound.
(3) One-half 1,200-pound and one-half 350-pound.

This study showed that the second scheme, all 1,200-pound, would give the lowest cost per kilowatt hour on the station bus when all things are considered. It appears at this time that all boilers in the extension of this station will be built for a maximum working pressure of 1,400 pounds per square inch.

It was also considered going to a steam temperature of 900°F. The turbine manufacturers assured us that they could build a turbine for any temperature steam which could be delivered to the throttle. The problem of handling steam at higher temperatures in the turbine, however, is far simpler than the problem of designing superheaters to deliver the steam. The superheater tubes must be at some temperature above the temperature of the exit steam and "there's the rub." With first pass gases on one side and very hot steam on the other, the superheater tube is subjected to very severe service. However, the investigations of the characteristics of metals at elevated temperatures are bound to produce in time a metal or alloy which will be suitable for the service and salable at a price that will make it economically justified. The superheater manufacturers are ready to supply superheaters designed for a temperature of 900°F., but they are frank in saying that some operating troubles must be expected, the seriousness of which they cannot definitely predict.

The valve and fitting manufacturers have given assurance that they can safely handle steam at 1,000°F. Station designers in the United States, however, seem to feel that 750°F. is about the limit at this time. They feel that those who have gone beyond this limit have not given due consideration to the characteristics of the materials being used when maintained at the high temperatures over long periods.

When it came to the purchase of the two boilers for

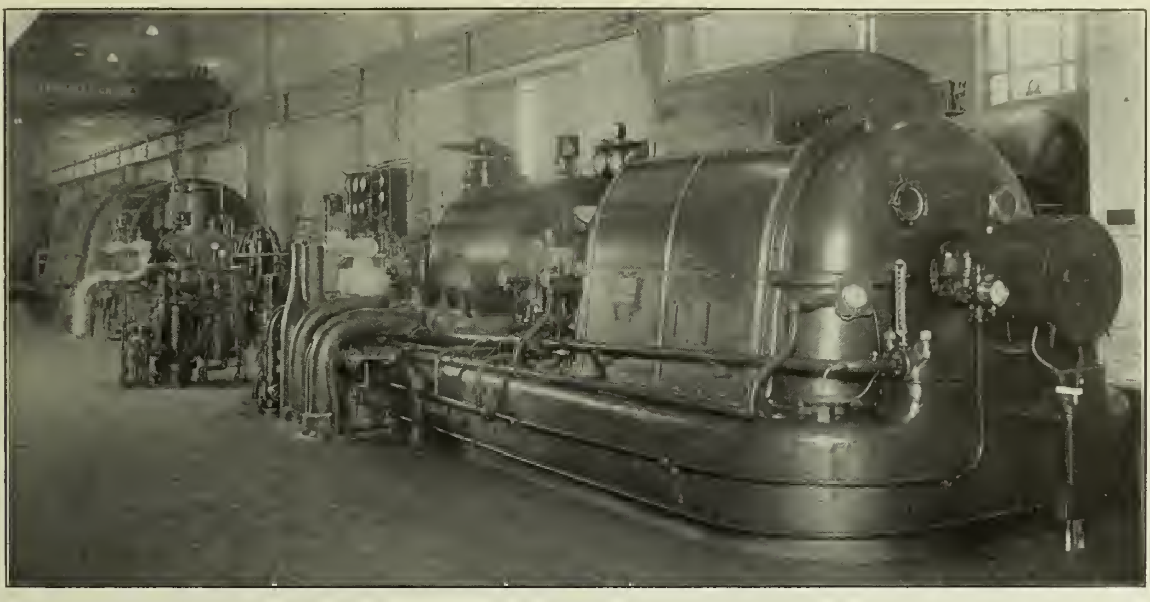

Figure No. 10.—General View of 1,200-pound Turbine Generator Units at the Edgar Station.

the extension to the station it was found that the thickest steel plate that could be forged into headers by the Babcock and Wilcox Company would give a safe working pressure of 1,400 pounds per square inch. As this additional pressure could be obtained at very little increase in cost, the new boilers were designed and built for this pressure. Figure No. 9 shows a cross-section of the new 1,400-pound boilers.

As mentioned previously, the first high-pressure boiler was built with 2-inch tubes throughout. It was found that the tubes were spaced too closely and resulted in slag bridging across between the tubes next to the furnace. The new boilers have eight rows of 3¼-inch tubes in the lower bank and they are spaced 8¼ inches centre line to centre line, giving a space of 5 inches between tubes. No trouble with slag has been experienced with these boilers. The upper bank of tubes is made up of 2-inch tubes and is ten tubes in depth. It was also found possible to use 19-foot 3¼-inch tubes, and 18-foot 2-inch tubes instead of the 15-foot tubes used in the first boiler. The new boilers each contain 15,093 square feet of water evaporating surface. The superheaters are located the same as in the first boiler but are designed for higher outlet steam temperature. The 1,200-pound superheater is designed for an outlet temperature of 725°F., and the 375-pound reheater is designed for an outlet steam temperature of 750°F.

A 5,596-square foot economizer and a 32,032-square foot air heater have been installed in connection with each of the new boilers. The air heater is designed to give an air temperature of 400°F., but the stoker is designed for a maximum air temperature of 600°F. A by-pass for the economizer has been installed so that the performance of the stoker with air temperatures in excess of 400°F. can be studied.

The first high-pressure boiler was fired by a 15-retort, 29-tuyere Taylor underfeed stoker and has a continuous capacity of approximately 121,000 pounds of steam per hour. The new boilers are fired by 16-retort, 45-tuyere Taylor stokers and are designed to generate 270,000 pounds of steam per hour continuously. These stokers are the largest underfeed stokers in service today.

Some trouble has been experienced with the refractories in the furnace of the first high-pressure boiler and

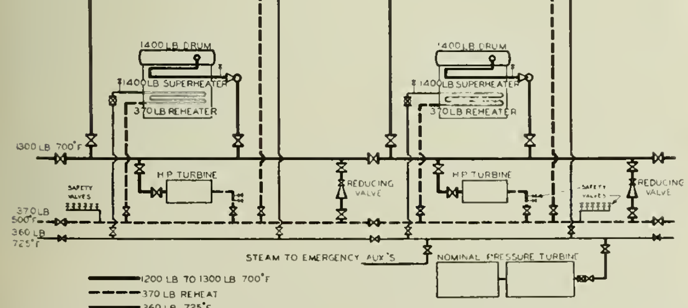

Figure No. 11.—Piping Arrangement at Edgar Station Extension.

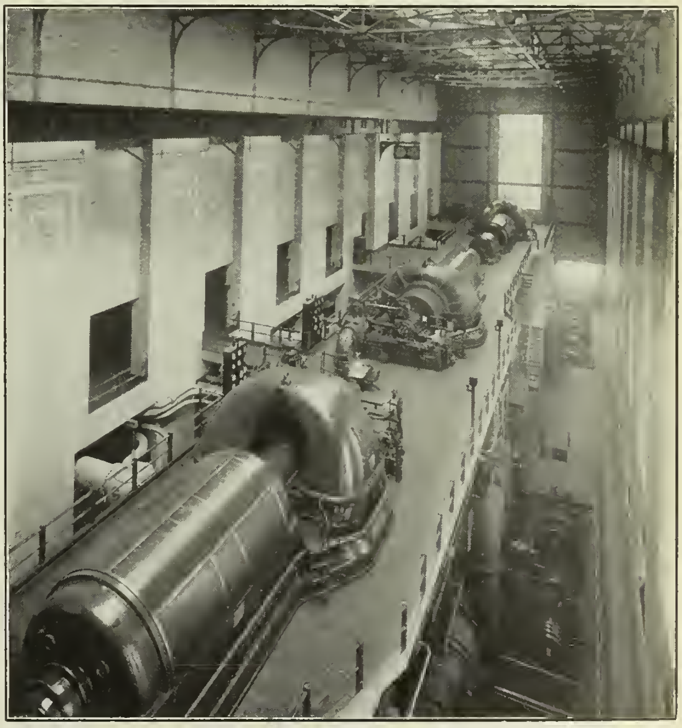

Figure No. 12.—350-pound Turbine Room at Edgar Station.

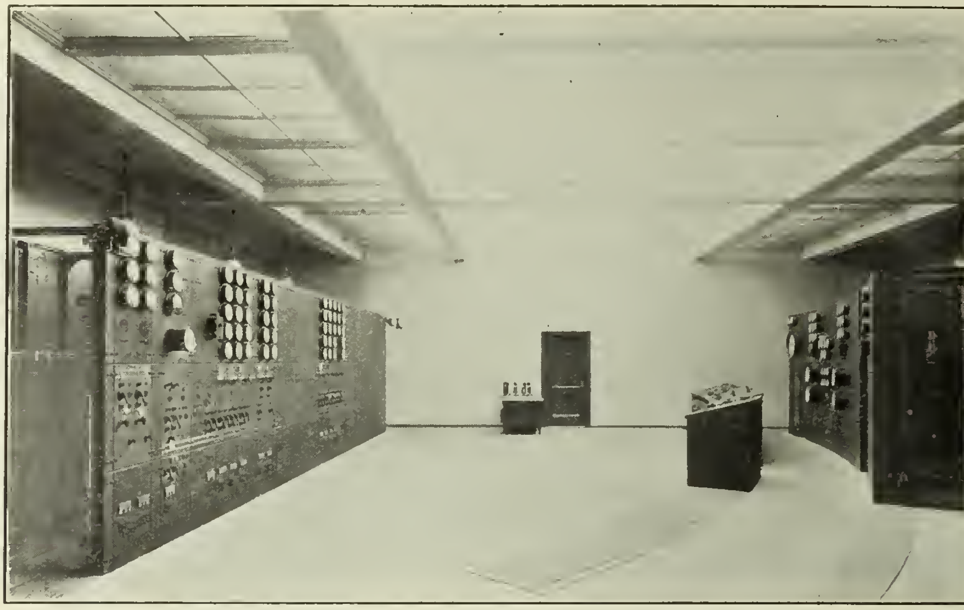

Figure No. 13.—View of Operating Room at Edgar Station.

this has necessitated operation with higher excess air than desirable. With the use of preheated air and such high heat liberation per cubic foot of furnace volume, the problem of a satisfactory refractory furnace seems hopeless and so the new furnaces are provided with water-cooled refractory-faced Bailey water walls on the side and rear walls. The front walls are Bigelow hung walls ventilated in the rear.

From this it will be seen that the problem of lowering the cost of construction by building the furnaces and fuel burning equipment to operate the boilers at higher capacities is being actively attacked. It is believed that in this way the cost of the station per unit of generating capacity is going to be materially reduced.

Equipment of Extension

In the extension to the station a 10,000-kw., 1,200-pound and a 65,000-kw., 350-pound General Electric Company turbine-generator unit has been installed. Both of these units are of special interest. The 10,000-kw., high-pressure unit is the largest 1,200-pound unit in the world and the 65,000-kw., 350-pound unit is the largest single-barrel single-flow 1,800-r.p.m. unit in the world.

The new 10,000-kw. unit is in the background in figure No. 10. As can be seen, it is not much larger than the 3,150-kw. unit which appears in the foreground.

The casing of the new turbine is of forged steel, while the casing of the first turbine was of cast steel. The new turbine has sixteen stages instead of twenty and will have a 4 per cent better water rate than the first one. It is equipped with water-sealed glands outside the labyrinth packings on both the high-pressure and exhaust ends of the shaft.

The governing of this high-pressure turbine presented a problem which was much more difficult than when there was only one boiler and one turbine. The design adopted after careful study is as follows. The turbine will be brought up to speed and synchronized by means of a speed-actuated governor of standard design. After the turbine is on the line a pressure-actuated governor will be put into operation and the speed-actuated governor set for some speed above 3,600-r.p.m., where it will act as an emergency governor. The pressure-actuated governor will control the load on the high-pressure turbine so as to maintain a constant pressure in the 360-pound 725° header supplying steam to the 350-pound turbines.

The problem of piping up several high-pressure boilers and their reheaters in parallel is considerably more complicated than the piping of a single boiler and turbine. Figure No. 11 shows how the new boilers and high pressure turbine have been piped up.

As will be seen, a reducing nozzle is provided between the 1,200-pound header and the reheat header. If the high pressure turbine is out of service the steam can be expanded through this nozzle and the boiler kept on the line.

This system of piping is rather expensive and it is hoped that in the future extensions it can be materially simplified and the cost of construction thereby reduced.

For all of the high-pressure pipe joints the welded Van Stone joint known as the "Sargol" joint has been used. There has not been any trouble experienced with any of these.

The problem of pumping sufficient boiler feed water for a load of 85,000-kw. to a maximum pressure of 1,600 pounds per square inch is a pumping problem such as has never before been encountered in steam-electric generating station design. To accomplish this, three boiler feed pumping units of very interesting design have been installed. Two are motor-driven and will be used for normal operation. The third is turbine-driven and will be used for emergency service. Each unit has a capacity of 900,000 pounds per hour.

Each of the motor-driven units consists of four pumps in series. The first two pumps of each unit are piped in series and are driven by a 625-h.p. motor. The second pump of this unit delivers water at a maximum pressure of 500 pounds per square inch and pumps through the high-pressure bleeder heaters to the suction of the third pump. The third and fourth pumps are piped in series and are driven by a 2,030-h.p. motor.

The motors are all 1,800-r.p.m., 2,300-volt, wound rotor induction motors and their speed is automatically regulated. The 625-h.p. motors are regulated to maintain a constant discharge pressure. The 2,030-h.p. motors are regulated to maintain a constant differential between the discharge pressure and the pressure in one of the boiler drums.

The turbine-driven boiler feed pump is designed for a maximum speed of 3,570-r.p.m., and pumps the water from

Figure No. 14.—Aeroplane View of Proposed Completed Edgar Station at Weymouth, Mass.

approximately 50 to 1,600 pounds in one casing. The turbine is differentially controlled and is also arranged for automatic starting when the pressure in the 1,600-pound boiler feed headers drops below a set pressure. The turbine is rated at 2,450-h.p. This boiler feed pump is the largest one in the world by far from the standpoint of the power required to drive it.

It is hoped that the boiler feed pumps can be materially simplified in the extensions to the station. The limiting factor so far appears to be in the motor. None of the manufacturers to date have manufactured a 3,600-r.p.m. wound rotor induction motor of the size required.

A study of the heat balance of the extension showed that it was economical not only to bleed the 350-pound turbine at three points but also to bleed the exhaust of the high-pressure turbine for heating the feed water. This means that steam at approximately 370 pounds will be used for heating the feed water. The heater is designed so that water at approximately 420° will be fed to the economizers. So far as the writer knows, this is the highest steam pressure used for this purpose.

No doubt some will wonder why the 1,200-pound steam is not used in a live steam reheater to reheat the steam from the exhaust of the high-pressure turbine. The reason for this is that the saturation temperature at 1,200 pounds is about 570°F. If a live steam reheater was used and the 350-pound steam delivered to the normal-pressure turbines at 570°F. there would be lost in economy practically all that is gained by going from 350 to 1,200 pounds. There is a real possibility, however, that a live steam reheater and a tandem compound 350-pound turbine can be used to advantage in extensions to the station. This possibility will be studied when the next 350-pound turbine is installed.

Figure No. 12 shows the three 350-pound turbine-generator units in the main turbine room. The two 32,000-kw. units are in the foreground and the 65,000-kw. unit in the background. The space advantage of the larger unit can easily be seen.

Figure No. 13, made from an architect's picture, shows the general arrangement of the ultimate station on the property. It also shows the location of the station in reference to the coal field and the outgoing 110,000-volt lines. The 14,000-volt and 25,000-volt lines go out underground and under the river through a tunnel.

In reference to the growth of the use of 1,200-pound pressure in the United States, it might be interesting to know that there are now in service 79,362 square feet of boiler surface operating at 1,200 pounds or higher. There is also in service 20,150-kw. of turbine-generator capacity for this pressure. In addition to this, there is 17,000-kw. of turbine-generator capacity on order and no doubt boilers for these units are also on order.

In building a high-pressure steam-electric generating station the question of design is of paramount importance. If the design is correct a high-pressure station will operate just as satisfactorily as a low-pressure station and it will be just as flexible, and will pay a handsome dividend on the money and effort expended. On the other hand, a poorly designed high-pressure station may be very uneconomical and the cause of many operating difficulties. Each project should be carefully studied and the decision made on the merits of the particular case.

The most important facts brought out by the present high-pressure installations in the United States are that in a properly designed station the high pressure does not decrease flexibility or incur any serious operating difficulties; furthermore, that a high-pressure plant of the proper design need not cost any more per unit of generating capacity than a low-pressure plant and will actually show a substantial improvement in thermal efficiency.

The first experience of The Edison Electric Illuminating Company of Boston with high-pressure steam was at the L street station in South Boston. In 1921 the operating pressure of a part of that station was raised to 300 pounds. It took as much courage to go from 200 to 300 pounds as it did to go from 350 to 1,200 pounds. All kinds of troubles were visualized but no troubles due to the pressure were experienced.

Stress has been laid on the economics of the various things that have been done which are different. This has been done purposely in order to emphasize the fact that we are not interested in thermal efficiency that lowers our dollar efficiency. Some one has jokingly said that designing engineers today are getting to be " financial engineers." There is more truth to that statement than the joker probably realized.

Forest Conservation in British Columbia

A Résumé of the Work being carried on by the British Columbia Forest Service

P. Z. Caverhill,
Chief Forester, Forest Branch, Department of Lands of British Columbia.

Paper presented at the Western General Professional Meeting, of The Engineering Institute of Canada, at Vancouver, B.C., June 7th to 9th, 1928

In a province such as British Columbia, with its wide areas and diversified topography, where even preliminary surveys are far from complete, and where topographic, geological, soil, and climatic surveying is yet in its infancy, an accurate statement of the forest resources is impossible. The forest resources of British Columbia not only include those bodies of mature timber now ready for the axe and the saw of the logger, but also the young growth and the qualities of site, soil, and climate which will repeat time and time again the mature forest crop, and which determine whether our annual increment shall be five or two hundred cubic feet per acre per year; and our topography, transportation, and markets, which determine how much of that crop can be used to serve a human need and how much will return a dollar for each one spent thereon. Conservation is the making legitimate use of our natural resources. It is not the spending of $1.25 in the recovery of a product that will command only $1.00 on the market.

A decade ago the Commission of Conservation of Canada made an exhaustive study of the data then available, and published a comprehensive report, "The Forests of British Columbia." This is still the most authoritative general information on the subject.

The Forest Service, in co-operation with timberland owners, licensees, and timber cruisers, is now engaged in compiling a similar estimate based on the information secured during the past decade. This will not only record the stands ready to cut, but the area and age-classes of reproduction, and from the information secured a rough forecast can be made of areas which will be available to cut when the mature timber is exhausted.

The report of the Commission of Conservation gives an estimate of 350 billion feet as the saw-milling timber in the province, and states there is 100,000 square miles of fire-swept areas in various stages of regeneration which, if protected from fire, will be able to produce 6 to 7 billion feet per year.

Present investigations have gone far enough to show

Figure No. 1.—Typical Scene of a Forest Fire.

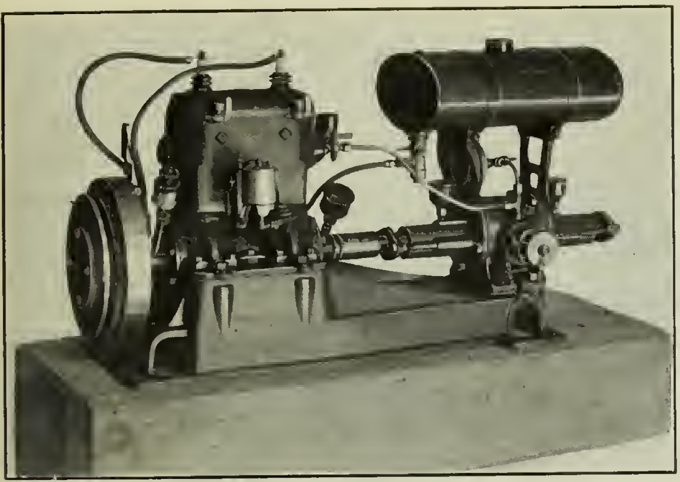

Figure No. 2.—One Type of Portable Gasoline Pump Used in Forest Fire Control.

that in some areas this estimate is excessive and in others very low. On considerable areas young stands forty, sixty, eighty years of age exist, which will produce merchantable material in forty to sixty years. The work has not yet proceeded far enough to state how the total will check with that report.

Forest Protection

H. S. Reynolds, of the Massachusetts Forestry Association, aptly says: "What will it profit us to know how to grow timber if it is to be destroyed by fire?" The forest-fire phase of conservation work was early recognized by the British Columbia Forest Service. It received the earliest attention of the Service and has always occupied a premier place in the working programme. The area now under patrol is approximately 125,000,000 acres in extent, or about 60 per cent of the area of the province, one-half of the area being productive forest land or land capable of producing commercial stands. The expenditure for protection work averages about $600,000 per year, or about one cent per acre.

Forest fires are not new phenomenon on the Pacific coast. The forest-fire menace, however, has unquestionably increased since the advent of the white race, with its land clearing, its machine logging, and other industrial activities in the forest, and it is still increasing. The automobile has opened up a new world—"the forest"—to the city dweller, a world which he thoroughly enjoys, but as yet he does not appreciate the damage his neglected camp-fire, discarded cigarette, or dropped match may do.

The objective of the Forest Protection Division is to counteract this increasing hazard through educating the public and developing in them a forest conscience, and to control fire outbreaks with a minimum of loss and expense.

Forest-fire protection is not the simple problem of a decade or two ago, when a patrolman was sent out on horseback with a shovel and a bucket to patrol and control any forest-fire outbreaks. The saddle-horse and the shovel still have their place in the organization, but portable gasoline pumps with one or two lines of hose delivering water to heights of 250 feet; tank pumps filled with a mixture of water and "no-burno" for mopping up; motor cars; fast gasoline launches with radio equipment in order to speed up communication and transportation; the use of the hygro-thermograph and the forecasting of humidity as an element in fire control; the construction of the mountain lookout, the "eyes" of the Service; and special aeroplane patrols, are developments of the last decade. Some idea of the size of these operations can be gained from the following figures for the British Columbia Forest Service per year:

Distance covered by gasoline transportation	750,000 miles
Hose required for pumps	25 miles
Messages received and sent by radio	9,800
Fires handled (ten-year average)	1,688

In organizing for fire control it is necessary to foresee as far as possible emergencies and to plan in advance for sudden and disastrous outbreaks. In addition to the regular staff of rangers and assistant rangers, patrolmen, lookouts, and smoke-chasers, through co-operation the Service attempts to organize the countryside into a reserve. Honorary fire wardens to the number of 635 have been enrolled and have undertaken to take the first steps to control any outbreak in their vicinity. The man-power of the community is canvassed and assigned, in the organization plans, to their particular jobs,—foremen, strawbosses, shovel men, snag fellers, packers, pump operators, cooks, etc. Tool caches are established, and points where further supplies may be secured are recorded. It is often necessary to expand the organization in a locality from a few men to several hundreds or even thousands, with all machinery for their effective supervision, subsistence and work, and these organization plans are then invaluable.

Figure No. 3.—Second Growth Stand 100 Years Old at Vancouver Island, Now Ready to be Cut.

Figure No. 4.—Douglas Fir Reproduction Amid Debris of Old Logging.

"Does organized forest protection pay?" is a pertinent question and, at the same time, a difficult one to answer. The destruction which has occurred in spite of the best efforts of the Service is known, and it can only be conjectured what it would have been without effort. The chief forester of the United States Forest Service points out, however, that in the United States in 1926, 91,000 fires occurred, burning over 24,000,000 acres, that 63 per cent of the fires and 80 per cent of the area were in states having no organized forest protection. On an average, fire burned 16½ acres out of each thousand acres of forest land in those states having patrols, but 106 acres in the areas without patrol. In British Columbia the area burned out of each thousand acres of timber land was 10 acres in 1926 and 2 acres in 1927. In three years an average of 78 per cent of all fires were controlled under 10 acres and 85 per cent under $100 in damage.

The railways are subject to a natural operating hazard and, in British Columbia, are required to maintain a patrol along their rights-of-way. While the percentage of fires originating from railways remains relatively high, 13 to 17 per cent, the damage from these fires has been reduced to 2.26 per cent in 1926 and 0.93 per cent in 1927.

Again the closer organization for fire control by the British Columbia logging operators, following the disastrous losses in 1923, has brought about a marked reduction in industrial fires as shown by the following percentages:

Year	Fires due to Industry
1923	11.11 per cent.
1924	6.1 " "
1925	5.5 " "
1926	4.84 " "
1927	3.89 " "

In spite of the severe years of 1925 and 1926 this work showed direct results. The question can, therefore, be answered with an emphatic "Yes." Today, there is being spent for protection one cent per acre of productive area. It has been estimated that 3½ cents are required for adequate protection in the Douglas fir belt, and 4 to 8 cents in the mountainous sections of Idaho and Montana. In British Columbia the season is somewhat shorter, and there is little hazard on the north coast. The author believes that 2 cents per acre would, however, be a figure comparable with the above estimate for that area now under patrol. More lookouts, more patrolmen, and especially more roads and trails to permit getting to fires and starting control work while they are still small, are required.

Forest Reserves

It is obvious that if forest crops are to be produced, crops which require seventy-five to one hundred and fifty years to mature, the first step is to select the site and dedicate it to forest production. It is useless to spend money in securing regeneration on areas which will in five, ten or twenty-five years be pre-empted and cleared for cultivation, or used for some other purpose. The Forest Service is now engaged on an active programme of selecting and securing the dedication of Provincial Forests for the perpetual production of timber. These are the socalled "Forest Reserves." There have now been so dedicated eighteen Provincial Forests, totalling 6,500,000 acres, under the jurisdiction of the provincial government, and an additional 1,714,000 acres of national forests have been set aside in the Railway Belt. The programme calls for further dedication at the rate of 1,000,000 acres per year, and by 1950 it is hoped to have 25,000,000 acres so set aside, an area greater than the public forests of both Germany and France.

In selecting these areas an examination has to be made

Table No. 1

	Merchantable		Age Classes—Acres				Present Sustained Yield M.B.M.	Ultimate yield under crude forestry M.B.M.
	Area acres	Timber M.B.M.	80 and over	41 to 80	1 to 40	Not restocked		
Four Coast Forests (Hardwick, The Thurlows, Sonora, Redonda).	63,800	1,221,000	......	2,100	21,700	17,100	18,500	27,800
Four Okanagan Valley Forests	163,900	1,380,000	27,600	204,100	201,000	......	27,000	38,000
Babine	244,000	2,400,000	51,100	210,000	224,000	197,000	In process	of compilation
Nehalliston	101,000	1,070,000	......	61,400	32,700	30,000	In process	of compilation

to determine possible future use and to separate areas chiefly valuable for forest purposes from those capable of supporting agricultural development. A survey is then made of the existing and potential forest crop under the headings of Mature Timber and Young Growth in various age-classes. See Table No. 1.

With this information on record it is possible to determine how much and where the cut can be made without depleting the resource. A sale of 52,000 M. feet in the Little White Mountain Forest has just been completed. This sale not only provides for the re-establishment of a new crop, but it limits the cut not to exceed two million feet per year, the estimated annual growth of the forest at present. Thus, barring accidents, a permanent supply of logs for a local factory is provided, which in turn supplies boxes for the fruit industry of the valley, and the forest asset of the region is in no wise reduced. Insofar as it is possible, without confiscating private interests, all Forest Reserves or groups of Reserves will be brought under sustained yield. It may be well, here, to emphasize that the word "Reserve" does not infer a withdrawal of the timber from legitimate use, but rather an encouragement to use the area to the fullest extent for forest purposes. It is only by such use that it can be hoped to put forestry on a paying and permanent basis.

The Forest Reserve Development Fund, three per cent of the collections from stumpage and royalty, and equalling $65,000 to $70,000 a year, is available for the selection, surveying and development of the Provincial Forests.

Forest Research

This is an age of research. Through agricultural research the wheat belt has been extended hundreds of miles north; rust has been conquered; and many other changes in production brought about. The forest is an even more complex crop and its development is influenced by a multitude of factors. In Europe forest research has been going on for generations. In America, and especially on the Pacific coast, there are new species and rapidly changing environments due to the rugged topography. On every hand unanswered questions await the scientific investigator. It is known that abundant natural regeneration can be obtained in most cases, but not in all. Why? The number and quality of the seed-trees left in logging are of moment to the operator and the land-owner alike, but their interests are directly opposite. Before intelligent contracts can be drawn, providing for such seed-trees, it should be known how far successful seeding will take place, and whether or not a scrubby tree situated on a rocky knoll will make a successful parent for the future crop.

Professor Ralph S. Hosmer of Cornell University says: "It is not difficult to learn how to plant trees well. To bring to maturity a fully stocked forest of high-grade timber is not so easy. But if we are to realize the objective that we have set up as our National Forest Policy, to do just this becomes the duty of the forester. In undertaking it, he needs all the help he can get from specialists working in varied branches of science. Mother Nature uses many servants. The ways in which they do her bidding are secrets that are not easily found out." If our forest conditions are to be assisted or improved these secrets must be known.

The Forest Service is now engaged on the most pressing of our forest problems. For some years market extension work has been carried on, and closely allied to this is the work now going on in connection with the utilization of waste products. The objective of this undertaking is a more complete utilization of the present stands, since the more of the product that can be marketed at a profit, the nearer the goal where it will pay to grow a forest as a paying crop such as wheat or cotton.

More recently the Service has taken up some of the silvicultural problems, more especially those related to the securing of natural regeneration and seed-bed conditions which are responsible for success or failure in securing a crop without the heavy expense of planting. At Aleza lake a demonstration forest has been created where the theories evolved by our research men will be put into practice on a commercial scale.

Forest nurseries for the production of planting material are being developed, one for the coast and one at Aleza lake for the northern spruce areas. These will be small and experimental in nature for the present, but capable of being extended so that, if necessary, any blank spaces which may occur in the natural regeneration on our Provincial Forests can be planted. While forest fires are still taking a toll of 100,000 acres of young stands per year, planting is not only a precarious investment but the money can be spent to better advantage in solving the fire problem.

Figure No. 5.—Hemlock Reproduction Amid the Fire-seared Trunks of the Former Stand.

Figure No. 6.—The Modern Logging Engine.
This equipment not only yards the logs to the track but also loads them on to the railway cars.

The Service is now expending $15,000 to $20,000 per year on markets and waste products, and a like sum on silvicultural research It is the author's opinion that during the next decade money spent on well directed research will return a greater dividend than any other forest investment except fire protection.

Transportation

Transportation is probably the most important single factor in giving value to the forest crop. Dr. Schenck, a forester of international repute, says: "Conservative forestry is more a matter of transportation than of botany." In the intensively managed forests of central Europe, one mile of road for each 200 acres, one-half of which is hard-surfaced, is the objective. And often $1.00 to $1.50 per acre per year is spent on road construction and maintenance.

On the British Columbia coast Nature has provided, in the wonderful system of inlets and channels, the main arteries for transportation, but many of the side valleys and mountain forests are today absolutely closed areas. These areas must be opened up before conservative forestry can be practised or adequate protection given to what Nature provides.

The Public Works Department is today building a system of provincial roads, some of which will serve as arteries for future forest roads. Leading back from these the Forest Service is constructing bridle paths and trails which provide access for fire-crews, but which cannot be used for the transporting of forest material. The abandoned grades of our logging railways would, in many cases, form the basis of an excellent system of forest roads, but would need a certain amount of upkeep each year.

In closing, then, it should be emphasized that there are still, in British Columbia, large stands of mature timber and areas of young growth which will be of commercial size before the mature timber is cut. The quantity of timber that can be removed depends on markets, transportation, and engineering skill.

The policy of the Forest Service for forest conservation is:

(1) Increased forest protection until the losses in forest material, especially in young growth, are reduced to the minimum.

(2) Extension of forest surveys to determine the quantity of material now available; the age-classes, stocking, and annual growth of our young stands; and what areas are more suitable for forest production than for agriculture.

(3) The reservation of areas unsuited for farming but suitable for timber-growing, such reservation to take place at the rate of one million acres per year until some twenty-five million acres are selected and reserved.

(4) The encouragement of the opening up of our forest areas by the construction of roads and trails which will serve as a means of access in case of fire and assist in the transportation of forest material to market.

(5) The building up, through research, of scientific data for use in the administration of the Provincial Forests on the soundest and most economical lines.

(6) The development, as conditions warrant, of forest nurseries for the planting of blank areas in the Provincial Forests. Such planting at the present time will be limited and of an experimental nature, rather than on a commercial basis.

Discussion of Paper on the Lock Gates of the Welland Ship Canal by Frank E. Sterns, M.E.I.C.[1]

J. L. Weller, M.E.I.C.[2]

Mr. Weller remarked that the author had opened up the subject of single leaf versus mitering lock gates, and while this was now a dead issue as far as the Welland canal is concerned, it was important for other canals which might be built in the future; in his opinion the conclusions presented in the paper should not be broadcast without protest. Mr. Weller, after years of experience in handling wrecked mitering lock gates, endeavouring to improve them and to develop something more simple and reliable, was firmly of the opinion that the single leaf gate as originally designed for the Welland canal was the greatest advance in canal engineering that had been suggested in many years. The single leaf was as far ahead of the mitre type as the single span bascule or lift bridge was ahead of the double leaf, and no railway man would accept a double leaf where he could possibly use a single leaf span. The single leaf gate required no meticulous care in construction or fitting, as both ends rested positively on heavy wooden bearings against vertical checks in the lock walls. A single leaf gate might be destroyed by a heavy blow from a ship, but it could not be unseated like a mitre gate. Should an accident warp or twist a single gate even three or four feet out of its true plane, no delay need occur, as the gate could be closed and the water pressure would bring it to a true bearing. This method dare not be attempted with mitering gates; mitre-gate advocates lost sight of the fact that each leaf of their gates was really a complicated single leaf gate which had a precarious toe support, depending as it did upon the friendly resistance offered by its mate instead of a solid abutment, and the best of friends had been known to part. One leaf of Mr. Sterns' gates of much simpler construction would make a good single leaf gate for a lock about forty-five feet in width; one leaf of the Panama lock gates is not much smaller than the single leaf gate for the Welland canal. He presented this discussion in the hope that when other canals are built, single leaf gates would be given more consideration.

E. S. Mattice, M.E.I.C.[3]

Mr. Mattice, as the engineer responsible for the actual building of the steel gates, had been impressed with the great care taken in the preparation of the design and the accuracy of detail. Only two points in the design had seemed to him to involve unknown difficulties. The first of these, (probably caused by the special care taken to secure as much duplication as possible), was the making of all the horizontal girders a uniform depth back to back of angles. The girder angles were riveted at their ends to the continuous vertical ¾-inch angles at the quoin and mitre end post; and the sheathing plates, varying in thickness from 15/16-inch at the bottom to 7/16-inch at the top of the 82-foot girders, were riveted to the girder angles and butted against the toes of the ¾-inch vertical angles. A vertical continuous doubling plate was placed over the sheathing plates and the face of the angle, and passed under the return portion of the continuous end post plate. Sections at the top and bottom of the upstream face of an 82-foot gate for this construction were shown in figure No. 4. This assembly resulted in two series of shims being required to ensure tight rivets, one 3/16-inch thick throughout between the vertical angle and the doubling plate, and one, tapering from zero at the bottom to ¼-inch at the top, between the doubling plate and sheathing plates; an exceedingly difficult job to get together and make watertight.

Before beginning the work he had suggested to the author that all sheathing plates be kept flush outside with the end vertical angle, and that the depth of the girders be varied to enable this to be done. This assembly necessitated the crimping of the girder angles where the sheathing plates were less than ¾-inch thick, and the use of short shims at the girder ends where the sheathing plates were more, and gave good plain caulking edges.

In the final development of this assembly several girders were made of uniform depth and the difference made up by shim plates between the girder flanges and the sheathing plates.

The second point in the original design which he had questioned was the practicability of forging or pressing ¾-inch plates about 92 inches wide and 80 feet long, and weighing about ten tons each, to the form required, with the necessary degree of accuracy. The Hamilton Bridge Works Company, the sub-contractors for the fabrication of the steel work, were loath to undertake the work, and their chief engineer, Mr. Palmer, visited several of the largest steelworking plants in the United States in an effort to have it done. Only one firm would undertake to try the job and they would give no guarantee of tolerance, either for straightness or smoothness. It was, therefore, decided to try welding, with the result that end posts were being obtained which are to all intents and purposes an exact fit.

He believed that some notes on the Chicago boom used in erection might be of interest. This boom was designed for a length of 120 feet, (which was later increased to 130 feet), and was made of four 5 by 5 by 7/16-inch angles latticed 35 inches back to back through the middle lengths.

The heaviest piece in a gate was the mitre post, weighing 20 tons, which was erected near the centre line of the lock, while the quoin post, weighing 10 tons, was erected close to the far wall. The boom is, therefore, designed for a load of 20 tons on a 60-foot radius or 10 tons on an 85-foot radius. The impact was taken at 60 per cent, a wind load of 20 pounds per square foot was allowed for, and eccentric loading was carefully considered. The formula used was as follows:—

$$F = \frac{W}{A} + \frac{Wl^2}{8S_1} + \frac{PW}{P-W} \times \frac{D}{S_2}$$

where

F = Maximum fibre stress, (not to exceed 20,000 pounds per square inch).
W = Total axial load on boom.
A = Area of boom.
W = Resultant dead and wind load at right angles to axis of boom.
S_1 & S_2 = Section moduli at right angles to respective loads.
D = Deflection due to cross bending.
P = Critical load from Euler's formula.

The boom fall has seven parts of ¾-inch steel rope and the load fall eight parts.

Steel Gate Leaf 82 feet High.

D. W. McLachlan, M.E.I.C.[4]

Mr. McLachlan observed that the question of whether single or double leaf gates should be used for locks had been brought up by Mr. Weller, and desired to explain that the arch traitor in going back to the mitre gates from the single leaf gates had been himself.

In the early stages of the Welland ship canal, when its location was being considered, along with many features of its design, he had been engaged on the work with Mr. Alfred Noble, Mr. Bowden and Mr. Sterns in 1912, and the ques-

[4] Department of Railways and Canals, Ottawa.

tion of single leaf and mitering gates had been a subject of argument for a number of years during the different stages of the work.

One point about the single leaf gate had made it attractive to Mr. Bowden, the late chief engineer of the department. This feature was that such a gate could easily be swung to in case of accident. That is, in the event of a ship carrying away a gate so that the lockage was lost, a single leaf gate long enough to swing right across could simply be let free and would slam, and if it could be brought to rest at the free end slowly, the situation would be saved.

At the time single leaf gates were first adopted it was thought that this was quite practicable, but on looking into the details a serious objection was found; a lock gate swings around a circular quoin, and its axis of rotation is not in the centre of that circular quoin, but, in lock practice, is always put slightly to one side, so that the gate does not bring up against the circular support or quoin until it is in its closed position, when the quoin post makes a tight fit against the quoin. Thus in the case of a single leaf gate closing under a considerable head of water, there would be a tremendous leverage tending to make the gate roll out of its quoin, and break the yoke and pintle. For this reason Mr. McLachlan had advised Mr. Bowden and Mr. Grant to go back to the old mitering gate, and he was glad that they had done so.

Mr. Henry Goldmark.[5]

Mr. Goldmark begged to differ with the author of the paper as to one statement made by him on page six, in which he had stated that " gates are rarely, if ever, struck on their down-stream side." One of the most serious accidents on record occurred on the Canadian Soo lock in 1909, when a vessel approaching the lock from below struck the lower operating gate. This accident was described briefly in a paper by Mr. Goldmark read before the American Society of Civil Engineers, December 7th, 1927, which gave photographs showing the flow of water through the locks after the accident.

The author's description of the gates, the method of design, loads, stresses, and also the method of erection, was so complete that he had nothing to add in way of discussion. It was of interest to note, however, the great increase in the cost of these gates over the very similar ones erected in the locks of the Panama canal, which was completed in 1914. The bids for the Panama gates were opened in 1910, the price of the structural steel work being only 3.79 cents per pound of steel erected and painted. The Welland price for corresponding materials was 9 cents per pound.

He noted that the Welland gates were opened and closed by wire cables operated by an electrically driven winch. This form of operating machinery had been used less of late years than other kinds of mechanism, this statement applying to the United States and Europe. Even in 1908 he had been informed by the engineer in charge of the new locks at Avonmouth, near Bristol, England, that no English engineer would think of using rope-driven machinery for lock gates, and he much preferred mechanism which dispensed with ropes or chains.

Professor Peter Gillespie, m.e.i.c.[6]

Professor Gillespie remarked that for an engineer with a penchant for analytical mechanics, the design of the mitering lock gate afforded much opportunity for the exercise of his mathematical bent and for industry also. It was evident that the author had brought both in large measure to the solution of his problem. One was particularly struck with the ingenious way in which the changing lengths of the hauling cables for the lock gates had been determined, how this variation in length had been provided for by slight differences in the diameter of the winding drums and how minor residual differences had been taken care of by compensating springs. It was noted that the hauling ropes passed along the top of the leaf from the quoin to the mitre and down to the bottom along the mitre post. Presumably the designer had considered the comparative merits of this plan and the one in which the cables would pass down the leaf at the quoin, thence horizontally along the bottom of the leaf to the mitre.

(5) Consulting Engineer, New York, N. Y.

(6) Professor of Civil Engineering, University of Toronto, Toronto.

J. B. O. Saint-Laurent, a.m.e.i.c.[7]

Mr. Saint-Laurent asked what means were adopted to prevent the rapid wear of the ropes which are used to open up the gates. These ropes, he understood, passed round curved masonry at the bottom of the locks. Did they go over rollers or did they rub against the masonry?

R. A. Ross, D.Sc., m.e.i.c.[8]

Mr. Ross enquired as to the operation of the safety horns on the gates. When these horns were put together they appeared to resemble the Zip overshoes, fitting very closely together. How was such an accurate joint obtained?

W. J. Smither, m.e.i.c.[9]

Mr. Smither desired to ask the horse power required to move the gates, and the time required for their operation.

Frank E. Sterns, m.e.i.c.[10]

The author, in reply, believed that the point raised by Mr. Weller had been answered by Mr. McLachlan and by the statement as to the relative merits of the two types of gates given in the paper. With regard to Mr. Mattice's discussion, the use of girders of different thicknesses in order to make it easier to take care of shimming at the ends was a very practical detail, but he would have hesitated to put that on the plan in the first place, feeling sure that had this been done, the contractor, whoever he might be, would have wanted to have them all the same depth in order to facilitate construction.

With regard to the bent plates shown on the end posts, enquiries had been made, and assurances had been received that the proposed construction was feasible, but when the point of commercial manufacture was reached, it could not be managed.

With regard to the question by Professor Gillespie, it would be a difficult thing to have the ropes pass down the gate at the quoin, because on account of the gate moving from the open to the closed position the sheaves would move with it, and the ropes would not lead properly, or they would have to be mounted on swivels, which would bring in an objectionable detail. It would also mean that the ropes would be leading along the bottom of the gate under water, where they would be likely to be obstructed with sunken logs or any other debris in the locks. This would be a less reliable arrangement than the one adopted, whereby the ropes go along the top of the gate in the air.

With regard to Mr. Saint-Laurent's question as to rubbing of the ropes against the circular wall, it should be noted that the ropes did not move on the wall, but simply lay against it. As the gate moved the sheave rolled along

Diagram Showing Arrangement and Action of Safety Horns.

the rope, and the rope went up through the gate behind the sheave. The rope was anchored near the end of the wall and pressed against the wall without moving along it, thus avoiding any wear at that point.

In answer to the question asked by Dr. Ross, the author believed that figure No. 3, showing two leaves in a displaced position, would be of assistance. Of course in that position there would be a great deal of leakage through between the bearing faces of the two gates, but that would not be the normal position. Ordinarily, when the leaves are closed, the smooth bearing faces of timber would bear against each other, and make a perfectly water-tight joint, and the castings would simply lie against each other in the triangular spaces left. Only when the gate was moved out of its mitered position would there be any leakage through between the leaves.

Referring to Mr. Smither's question about the horse power required and the time necessary to operate the gates, he might say that the time required to open or close a gate was approximately one and a half minutes. Under the worst conditions, against a high wind with both leaves moving together, fifty horse power was required for the 82-foot gates. For the lower gates, under average conditions, probably half that horse power would be used. However, all the operating machines were made the same and were able to deliver the maximum power.

Professor Peter Gillespie, m.e.i.c.

Professor Gillespie desired to refer again to the eccentricity of rotation of the quoin. He understood that the gates did not revolve about the centre of the quoin, in order that when a gate swung open the friction against the quoin would be relieved, that the eccentricity was about an inch and a half, and that the size of the pintle was sixteen inches. He did not quite see how the pressure would cause the leaf to unseat from a pintle 16 inches in diameter with an eccentricity so small as that.

Frank E. Sterns, m.e.i.c.

The author replied that with the eccentricity provided, the leaf while swinging was not supported on the masonry wall except at the top and the bottom, the support at the bottom being due to its sitting on a 16-inch hemisphere. When the leaf is nearly closed its quoin end comes in contact with the hollow quoin and, as a result of the eccentricity, the further movement of the leaf causes the pintle to slide slightly forward upon the base casting and transfers the horizontal component of its load to the hollow quoin.

Professor C. M. McKergow, m.e.i.c.[11]

Professor McKergow would like to ask what happened if a rope broke when the gate was being opened. Would the gate simply slam back?

Frank E. Sterns, m.e.i.c.

The author remarked that the gate could not slam unless it were moved by something, because the lower part of the gate was immersed 30 feet deep in the water, and great force would be required to move it. Unless the breaking of the rope were caused by the impact of a ship, probably the gate would stay where it was or drift very quietly one way or the other. As to the life of the ropes, they have not yet been in operation, so that no information was available. Where operating ropes were used in a slightly different way, however, they had been found to last about a year or a year and a half.

The statement in the paper, to which Mr. Goldmark had taken exception, that "these gates are rarely if ever struck upon their downstream side," referred to the lower gates of the present Welland canal and not to lock gates in general. The records showed that on the present Welland canal, forty-four accidents in which lock gates were carried away had occurred during the seventeen years 1911 to 1927 inclusive, of which not one had resulted from a lower gate being struck upon its downstream side. It was the fact, however, as Mr. Goldmark had pointed out, that the only accident at Sault Ste. Marie in which lock gates were carried away by a ship had resulted from the lower gate of the Canadian lock being struck upon its downstream side.

As regards the use of wire ropes for operating the gates, wire ropes had been used for many years in the locks at Sault Ste. Marie and had given such satisfaction that they were adopted in the new third and fourth locks of the American canal.

Discussion of Paper on the Uniflow Steam Engine by E. A. Allcut, M.E.I.C.[1]

PROFESSOR E. A. ALLCUT, M.E.I.C.[2]

The author, in presenting the paper, remarked that there were many misconceptions regarding the history of the uniflow engine, which was by no means unusual in engineering work. An inventor occasionally worked on something about a hundred years before his time; then the subject dropped practically out of sight, and afterwards reappeared as the very latest development in that particular field, while the early work was liable to be forgotten. His apology, if any were needed, for including in the paper quite a lot about the history of the uniflow engine was this fact, and in that connection it was interesting to note that the uniflow engine had now almost reached its centenary.

The uniflow engine was first constructed by Jacob Perkins in England in 1827. He also experimented with a compound engine working on the same principle, of which the next example appeared at the Wembley Exhibition in 1924 and was regarded as the very latest word in steam practice. It was also remarkable that at the time when Boulton and Watt were using pressures of 5 and 10 pounds per square inch, Perkins actually used steam at a pressure of about 2,000 pounds per square inch.

The development of the uniflow engine was bound up with the question of cylinder condensation, and he therefore proposed to consider briefly cylinder condensation and the principal influences which affected it. In the ordinary type of engine the steam entered at a temperature of say 400 or perhaps 500°F.; it expanded in the cylinder and went out at a temperature in the neighbourhood of 100° to 150°F., depending on the conditions. That inevitably meant that there must be a considerable variation of temperature in the metal of the cylinder itself, and that the metal which was cooled or partly cooled by the exhaust steam during one part of the cycle must again be raised to a higher temperature during the admission part of the cycle. Therefore, if the steam were dry or only slightly wet at the beginning, it would inevitably be considerably wetter later on. Referring to figure No. 1 in the paper, which applied to an ordinary counterflow type of engine of about the same size as the uniflow engine of which particulars were given in the paper, it would be noticed that the dryness fraction at the point of cut-off was somewhere in the neighbourhood of 55 per cent. When that steam went into the engine it was 99 per cent dry, which meant that between 40 and 50 per cent of the steam entering the cylinder had been condensed, and after that little more condensation had taken place.

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February 15th, 1928, and published in The Engineering Journal, January 1928.

(Figure No. 1 of original paper published in January 1928 Journal.)

Entropy Diagram from 50-h.p. Counterflow Engine.

The next factor was the ratio of surface to volume. If the portion of the cylinder exposed to the steam up to the point of cut-off were large in diameter and very thin, there would be much more chance for the steam to be condensed than if the steam space were comparatively short and thick. Thus, other things being equal, the larger the surface in comparison to the volume present at that time the greater would be the amount of cylinder condensation, and therefore in ordinary steam engine practice an early cut-off contributed greatly to cylinder condensation.

The third factor comprised the various facilities for heat interchange. Among these, of course, would be the extent to which the cool steam or comparatively cool steam from the exhaust process flowed over the surface which had been heated by the previous admission process. Thus in a counterflow engine the cold steam from the exhaust flowed back through the passages previously heated by the live steam, in which case, other things being equal, the heat loss and the mean cylinder condensation would be greater than in cylinders where this reversed movement did not take place.

He had mentioned still another factor which needed stressing rather more than was usually done, and that was the wetness of the steam. Dry steam, of course, was a very poor conductor of heat; superheated steam was poorer still, and consequently the greater the heat conductivity of the fluid actually in the cylinder the greater would be the amount of cylinder condensation, because the heat would be able to get from the interior of the cylinder to the outside with greater facility. These, he thought, were the principal factors in connection with the facilities for heat interchange.

MR. W. CLINTON BROWN.[3]

Mr. Brown desired to call attention to one statement in the paper which he thought liable to be misleading; that was, the sentence reading as follows:—

> "The reduction of mean effective pressure due to the large amount of power used for compression also necessitates the use of larger cylinder diameters than are customary in counterflow engines producing the same powers."

While high compression, especially in atmospheric exhaust engines without auxiliary exhaust valves, did increase the cylinder diameter needed for a given power, the great factor in reducing the mean effective pressure was really the short cut-off used in these engines. On account of the elimination of initial condensation it was possible to operate uniflow engines with very short cut-offs without loss, and get the economical benefit of low terminal pressures, and this was one of the reasons for the remarkable economy of the engine. As the steam consumption of a uniflow engine was even lower than that of a counterflow compound engine, the steam cylinder diameter should be compared to the low pressure cylinder of the compound engine, rather

Rankine Cycle Efficiency Ratios of Uniflow Engines.

than to the cylinder diameter of a single cylinder engine which was not in its class.

Mr. C. C. Trump.[4]

Mr. Trump believed that the chief value of the paper would be found in the rather complete history and bibliography which was presented.

The discussion of the steam jacket was of special interest. Unfortunately the author had not included a complete description of the 40-h.p. engine and other apparatus used in his tests. The engine was possibly defective to some extent, for the Rankine cycle efficiency ratios were not nearly good enough, as would appear on comparing figures Nos. 8 and 13.

In connection with the author's views about end jackets as expressed in his second paragraph on page 6 of the paper, Mr. Trump would refer him to the last paragraph of the discussion of the tests by Barrus, (A.S.M.E. Transactions, paper 1968, May 1925, on page 489, and to Chapter 8 of the Book by Professor Stumpf, 2nd Edition), where it was shown by actual temperature measurements of precision that the heat of compression in the cylinder raises the temperature inside the head as much above that of supply as it falls below. Thus head jackets would not condense steam under full load conditions, in a properly designed uniflow engine. Body jackets were most effective with saturated or wet steam supply, as shown by the author's tests, as well as those by Stumpf and others.

The description in the Appendix of the Stumpf Compound Uniflow Marine Engine showed independent means of jacket supply and drainage.

Single cylinder uniflow engines might be bled for heating steam as easily as compounds, and he was surprised that this was not more often done. Let the engineers of the smaller plants know this and it would help many of them to economies in fuel.

Prof. L. M. Arkley, M.E.I.C.[5]

Professor Arkley considered that in reviewing the development of the steam engine one could easily find certain milestones which indicated its progress.

Perhaps the most important recent step in this connection, and certainly the most important from the standpoint of increasing the efficiency of the engine, had been the development of the uniflow engine by Stumpf in the early years of this century.

The reciprocating steam engine had lately been meeting some severe competition. The steam turbine as applied to marine propulsion and central station work had practically replaced the reciprocating engine, and the development had been so rapid that plants were now being equipped with 75,000-kw. turbines, while still larger ones were being built.

The internal combustion engine, not the steam engine, supplied the millions of horse power in use in the automobile industry, and now had come the Diesel engine with its high thermal efficiency and its ability to use a cheap fuel, decreasing still further the field open to the steam engine.

In view of the above it was natural to enquire as to the necessity for spending the money and time necessary to design and perfect such a unit as the uniflow.

The answer was, that there were still many places where an efficient reciprocating steam engine had advantages over any of the prime movers mentioned above. The steam turbine, while it had many good points, was not at its best unless operating at high vacuum and in large units.

An ideal situation for a uniflow engine would be a manufacturing plant where a large quantity of low pressure steam could be used for heating purposes or in process work. The high economy of such a plant was often overlooked; for example, the highest efficiency yet achieved by condensing plants using high steam pressure and highly superheated steam is about 30 per cent, but a non-condensing plant where all the exhaust steam can be used could reach an efficiency of over 60 per cent.

As indicated in the paper, one of the most important points in the operation of the engine was the question of compression. This also affected efficiency, and while it could be proved theoretically that if compression were carried to the admission pressure of the steam no loss would result, this was not borne out by actual tests. The tests of Professors Jacobus and Carpenter to determine the effect of compression on efficiency as reported in the Transactions of the American Society of Mechanical Engineers, in each case showed a reduction in efficiency as compression increased.

As stated by the author, a series of tests, such as those in this paper, on an engine giving at the most 40 h.p. could have little bearing on the actual performance of the uniflow engine as applied to industry. In the first place it would be difficult to predict from the efficiency of a 40-h.p. engine what might be expected from one of say 400 h.p. Prof. Arkley did not think that it would even be safe to generalize in regard to the use of jackets from such a series of tests, as the size of the cylinder had so much to do with this. The interesting thing to know about the uniflow engine was whether its superiority to the old counterflow type would prove to be sufficient to keep it from being pushed aside by the prime movers mentioned above. The author in table No. 4 had given some interesting information along this line; for example, the quoted steam consumption of 8.8

(4) Merion Station, Pa.

(5) Professor of Mechanical Engineering, Queen's University.

pounds per i.h.p. per hour was quite good considering the low pressure and moderate degree of superheat used. William D. Ennis, writing in Marks and Davis's handbook, reported tests made by Lentz on a 100-h.p., uniflow condensing engine, which, operating at a pressure of 235 pounds per square inch absolute and with superheat of 528°F. had a steam consumption of 6.52 pounds per i.h.p. per hour, which represents 162 B.t.u. per i.h.p. per minute; and operating at 461 pounds per square inch absolute, and 559° superheat, the steam consumption was 5.67 pounds per i.h.p. per hour, or 144 B.t.u. per i.h.p. per minute.

These were remarkable results and showed a thermal efficiency which compared favourably with anything on the market, and would lead us to conclude that the uniflow engine had a useful future ahead.

Prof. Arkley regretted that the author had not included in his paper some of the typical indicator cards from his tests, and desired to ask if the tests were run with the engine operating as a true uniflow, or if the auxiliary exhaust valve had been used to lower compression.

H. A. Wilson, A.M.E.I.C.[6]

Mr. Wilson drew attention to the claim by a manufacturer of uniflow engines that he had designed into his valve gear something which would compensate for the expansion of the cylinder at different loads, claiming that an extremely long cylinder had an expansion that had to be taken into consideration, which would upset the balance of the engine. One side of the piston had been so arranged that it would be delivering more power than the other side, which was claimed as a superior point of his engine. Had that been shown, in the various makes of engines, as an advantageous factor?

He had also been told that unless a certain ratio of expansion was available, the uniflow engine would not show sufficient economy over the counterflow to warrant the extra investment. He would ask whether the field of the uniflow was to be confined to the higher net expansion, did back pressure throw it out of the running, and was a high initial pressure necessary before it really became an efficient engine?

Professor E. A. Allcut, M.E.I.C.

Replying to Mr. Clinton Brown, the author agreed that the diameter of the uniflow cylinder should be compared with the low pressure cylinder of the compound engine. Mr. Brown had said that in the uniflow engine it was possible to use economically an earlier cut-off, and that in itself produced " skinny " diagrams, although it made for efficiency. If on the top of that a high compression curve were superimposed the amount of work would be further reduced, and of course the mean effective pressure would be low in spite of the superior economy.

In reply to Mr. Trump's questions, as was stated in the paper, the diameter of the cylinder in this particular engine was 10 inches, with a stroke of 15 inches, and there were two piston valves. This statement answered one of Professor Arkley's questions also. One valve controlled the admission and the other valve the exhaust, so the engine was not a true uniflow engine, in that the compression was controlled by an auxiliary valve; it should perhaps be regarded as a hybrid of the uniflow and counterflow types. On the other hand, the true uniflow engine, as was pointed out in the paper, could only be used with difficulty without such valves with low vacua or non-condensing operation. The only way to get over that would be by using a larger clearance volume, the inefficiency of which had already been referred to. Earlier compressions had been experimented with but were unsatisfactory. Since the publication of the paper vacua up to 28 inches of mercury had been used but with no improvement of efficiency.

The tests mentioned by Mr. Trump were also referred to in the paper, so that due attention had been paid to the points raised by him.

With reference to the remarks of Professor Arkley, particularly regarding the steam turbine, he would point out that as far as the flow of steam was concerned the steam turbine itself was a uniflow engine, because the steam always moved in one direction. Professor Arkley's reference to non-condensing operation and process work was very timely, and had partly answered the question raised by Mr. Wilson, who asked if the uniflow engine could be used or was used in non-condensing work, and the exhaust employed for process work, or for heating. In that way a combination of exceedingly high efficiency would be obtained. The author considered that the uniflow engine would be efficient when used in that way, if it were possible to provide some device for using efficiently the exhaust heat.

Professor Arkley's remarks about the smallness of the Toronto engine were of course very true, but, unfortunately, as Professor Arkley knew only too well, the expense of a very large unit in a university laboratory would be so great that other equipment could not be obtained, and, further, a large unit could only be run very seldom, so that universities were necessarily confined to the use of small units for experimental purposes. As far as the results were concerned, the Rankine cycle efficiency was certainly lower than he had expected to get with that engine, but efficiencies obtainable with larger units were given in the paper, so that current practice could be referred to.

The value of this particular series of tests was comparative, as all the tests were made under strictly comparable conditions, and therefore reasonable deductions could be made from them.

The reason why the indicator cards were not included was that in his opinion the entropy diagram, for those who were familiar with such diagrams, gave more information from the thermal standpoint than the indicator cards could do. They were simply a means of expressing all that the indicator diagrams did, and more.

The expansion of the cylinder referred to by Mr. Wilson was an important point. In using high temperature steam this expansion, and particularly the resulting distortion, might be a serious matter. He was not aware, however, that the expansion was so great as to make any considerable difference in power between the two sides of the cylinder. Usually the valve gear had a great deal more to do with that matter than the expansion of the cylinder could have.

The 1,500-h.p. three-cylinder marine engine, to which he had referred in the paper, had exhaust ports in the centre of the cylinder which were not cut from a solid liner, but constituted the space between two liners, one inserted from each end of the cylinder. That seemed to be quite a reasonable attempt to get over some of the difficulties of expansion to which attention had been drawn.

As had been stated before, a high ratio of expansion and a low back pressure were essential for economy in the true uniflow engine unless the exhaust steam could be utilized, in which case the economy of the engine was not usually a question of paramount importance. A high steam pressure was not essential, as some of the results tabulated had been obtained with quite moderate pressures.

VOLUME XI JUNE 1928 No. 6

Result of Ballot for Amendments to By-Laws

The report of the scrutineers appointed to canvass the recent ballot for the amendments to By-laws was presented to Council at the meeting held on Friday, May 18th. The report disclosed that all of the proposed amendments, with the exception of that to Section 29, were carried by substantial majorities. The amendment to Section 29, however, was defeated.

The proposals to amend the By-laws, it will be recalled, were made in accordance with Sections 75 and 76 of the By-laws, and adopted by Council and presented to the annual meeting in Montreal on February 14th for discussion. Subsequently, the ballot was mailed to all the corporate members and canvassed on May 12th.

As a result of these changes, which have now become effective, the age limit of the grades of Student and Junior, as provided in Sections 9 and 10, may be extended, if, in the opinion of Council, special circumstances warrant such extensions.

The wording of Section 18 is changed to conform with the deletion of Section 24, which previously provided for an Engineering Sections Committee.

Section 53 is amended by the addition of a paragraph to provide for the formation of Students' Sections in connection with the various branches.

The wording of Sections 68, 69 and 70 is changed for the purpose of clarification, as difficulty had arisen from the use of the words "Officers' Ballot" in these sections.

By the amendment of Section 76, provision is made whereby any proposed modifications or alterations which may be made to the proposed amendments at the time of the annual meeting shall be included in the letter ballot and voted on by the corporate members of The Institute.

The other amendments referred to Sections 74 and 52, and were intended to authorize the present practice in connection with the subscriptions to The Engineering Journal by Honorary Members, Life Members and Members who have compounded their fees, and in connection with the appointment of the secretaries and treasurers of the branches.

The By-laws as they now stand are being prepared for printing and will be available within a short time and will include not only the recent amendments but those which were adopted during 1927.

The Annual Meeting of 1929

The members of The Institute will be interested in the announcement that the Annual General and General Professional Meeting next year will be at Hamilton, Ont., the tentative dates being February 14th to 16th, inclusive. The preliminary work in connection with this meeting has already been commenced and announcements of arrangements will be made through the Journal from time to time.

Institute's Year Book being Revised

The Year Book of The Institute containing the list of members is at present being revised and will shortly be sent to the printers for publication.

At the end of 1927 a special card was mailed to all members requesting information for the membership list. The returns from this request were gratifying, although there are still a number of members who have not replied. In order that the Year Book may be as complete as possible, any member who has not returned his card is requested to forward, without delay, information as to his present position, the name of the firm with which he is connected, his business address and his home address.

In this connection it will not be possible to make any changes in the forthcoming issue of the Year Book after June 30th, 1928.

Institute's Employment Service

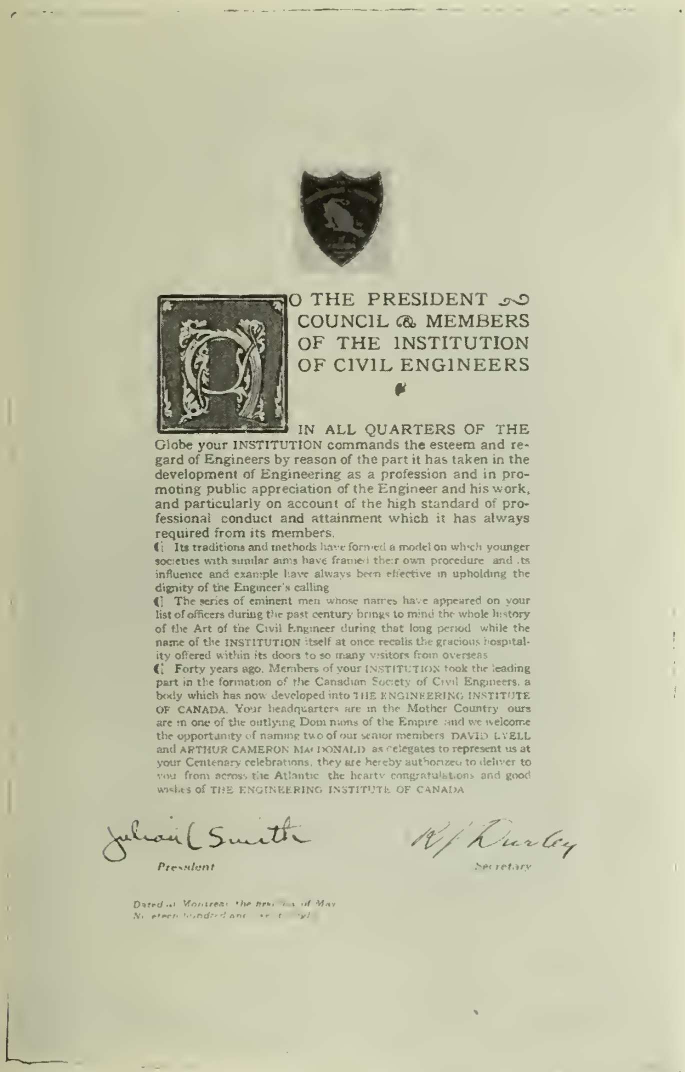
The work of The Institute's Employment Service has grown to such an extent that it has been found necessary to establish a somewhat more elaborate system for handling the applications for positions received, in order that the greatest possible service may be given to the members.

Full particulars of the proposed development of this work will be announced later, but in the meantime it will be of great assistance if all members wishing to register with the Employment Service will advise Headquarters so that the necessary forms and instructions may be forwarded to them. It is proposed that each member upon registering should forward a statement of his professional record on a prescribed form with ten extra typewritten copies of his record of qualifications and experience. He is also requested to attach a photograph of himself to each copy. This is necessary if the fullest advantage is to be taken of the Service, as it will provide material to submit to prospective employers. The provision for ten copies is made in order that a sufficient number may be available to supply various requests which may be received about the same time. The value of supplying photographs with the record is at once evident.

The record sheet with details of the Service and instructions as to requirements will be available about June 15th and every member wishing to register or to have his name retained on the list should communicate with headquarters as soon as possible.

The Centenary of The Institution of Civil Engineers

In the ninth year of the reign of King George the Fourth, or, in other words, in 1828, that monarch granted to "Thomas Telford of Abingdon Street, in our City of Westminster, Esquire, a Fellow of the Royal Societies of London and Edinburgh, and others of our loving subjects" a Charter of Incorporation for a Body Politic and Corporate by the name of The Institution of Civil Engineers. The society



TO THE PRESIDENT COUNCIL & MEMBERS OF THE INSTITUTION OF CIVIL ENGINEERS

IN ALL QUARTERS OF THE Globe your INSTITUTION commands the esteem and regard of Engineers by reason of the part it has taken in the development of Engineering as a profession and in promoting public appreciation of the Engineer and his work, and particularly on account of the high standard of professional conduct and attainment which it has always required from its members.

Its traditions and methods have formed a model on which younger societies with similar aims have framed their own procedure and its influence and example have always been effective in upholding the dignity of the Engineer's calling

The series of eminent men whose names have appeared on your list of officers during the past century brings to mind the whole history of the Art of the Civil Engineer during that long period while the name of the INSTITUTION itself at once recalls the gracious hospitality offered within its doors to so many visitors from overseas

Forty years ago. Members of your INSTITUTION took the leading part in the formation of the Canadian Society of Civil Engineers, a body which has now developed into THE ENGINEERING INSTITUTE OF CANADA. Your headquarters are in the Mother Country ours are in one of the outlying Dominions of the Empire and we welcome the opportunity of naming two of our senior members DAVID LYELL and ARTHUR CAMERON MACDONALD as delegates to represent us at your Centenary celebrations, they are hereby authorized to deliver to you from across the Atlantic the hearty congratulations and good wishes of THE ENGINEERING INSTITUTE OF CANADA

Julian C. Smith
President

R. J. Durley
Secretary

thus formed is accordingly celebrating this year, on the 3rd of June, the one hundredth anniversary of the event above mentioned, and the Council of The Engineering Institute of Canada has forwarded to the Institution an address of congratulation, a facsimile of which is reproduced above.

The occasion is memorable, for the Institution of Civil Engineers is not only recognized as the leading engineering society in the British Empire, but also holds a commanding position owing to its seniority, its high standard of professional attainment, its widespread membership, and the acknowledged eminence of the names to be found upon its lists of officers, past and present. Members of The Institute will join in the message of goodwill which their Council has transmitted to the Institution.

Meeting of Council

Meeting of May 18th, 1928

A meeting of Council was held at 8 o'clock p.m. on Friday, May 18th, 1928. President Julian C. Smith, M.E.I.C., in the Chair, and nine other members of Council being present.

The minutes of the meeting held on April 20th, 1928, were taken as read and approved.

The Financial Statement of The Institute for the period ending April 30th, 1928, was submitted and approved.

The preliminary arrangements for the Annual General Meeting 1929 received consideration, and it was noted that the dates suggested for the meeting, February 14th, 15th and 16th, 1929, met with the approval of the Hamilton Branch Executive Committee.

The programme for the Western Professional Meeting to be held in Vancouver on June 7th, 8th and 9th was approved.

The report of the scrutineers on the voting for the amendments to By-laws closing on May 12th was presented, and in accordance with this report, the amendments proposed to Sections 9, 10, 18, 24, 52, 53, 68, 69, 70, 74, and 76 of the By-laws were declared to be carried, and that proposed to Section 29 was declared to be lost.

It was decided that the question of the changes, if any, which are desirable in the present method for the election and transfer of members in The Institute should receive consideration at the Plenary Meeting of Council to be held in October. Consideration being also given at that time to the changes which are desirable in the present scale of members' annual fees.

A resolution passed by the Alumni Society of the Ecole Polytechnique opposing any change in the present policy of The Institute regarding the qualifications of its different classes of membership was presented, noted, and referred to the Committee which is at present considering the question of Grades of Membership in The Institute.

A letter was submitted from the President of the Royal Architectural Institute of Canada, regarding the proposed standard forms of contract of the Canadian Construction Association, suggesting that the Committee of The Institute at present considering this question co-operate with their own Committee, with a view of arriving at some final decision. After a short discussion the Secretary was directed to express Council's willingness for the two committees to co-operate in the manner suggested, and to notify the Chairman of The Institute Committee accordingly.

The report of the Board of Examiners was approved, showing that of three candidates for admission or transfer to the grade of Junior, who took the examination under Schedule B. on May 1st, two failed and one passed, and of three candidates who took the examinations under Schedule C. all had passed.

A memorandum was presented pointing out that in order to develop the work of the present Employment Service some means of more frequent and regular communication with the members of The Institute and with prospective employers should be available, so that positions can be brought promptly to the attention of the former, and the qualifications of those seeking positions can be placed before employers. The Journal hardly offers a satisfactory medium for this purpose, due to the lapse of time between issues, and it was therefore suggested that a weekly news bulletin, to contain lists of positions available, brief outlines of qualifications of those seeking positions, news items of proposed works, notices of meetings of The Institute and other societies, announcements from Headquarters such as elections and transfers of members, preliminary notices of applications for admission or transfer, etc., should be established.

After a short discussion, on the motion of Fraser S. Keith, M.E.I.C., seconded by Professor C. M. McKergow, M.E.I.C., it was decided to approve the issue of a bulletin, along the lines suggested, for a trial period of six months.

The membership of the Leonard Medal Committee for the current year was approved as follows: L. L. Bolton, M.E.I.C., Chairman, F. W. Gray, M.E.I.C., J. Colin Kemp, A.M.E.I.C., L. H. Cole, M.E.I.C., and J. F. Robertson, M.E.I.C.

Consideration was given to the representations made by the various branches regarding the subject to be chosen for the first competition for the Past-Presidents' Prize for the year July 1928-July 1929.

Council noted with deep regret the death of H. J. Cambie, M.E.I.C., which took place on April 23rd, 1928, and the following resolution was unanimously passed:—

> By the death of Henry John Cambie, The Engineering Institute of Canada has lost one of its oldest members, an engineer of ripe experience, and one of the few survivors of that band of pioneers whose efforts marked out the routes of our present transcontinental railways.
>
> Mr. Cambie served on Council, contributed to the Transactions and throughout his long career lost no opportunity of furthering the interests of his fellow engineers.
>
> The Council of The Engineering Institute of Canada records his death with deep regret, and desires to convey to his family the most sincere condolence and sympathy.

The list of officers of the St. John Branch for the year 1928-29 was submitted and approved.

The Secretary reported that Lt.-Col. A. C. Macdonald, D.S.O., M.E.I.C., and Col. David Lyell, C.B.E., C.M.G., D.S.O., C.deG., M.E.I.C., had consented to act as The Institute's representatives in London on the occasion of the Centenary Celebrations of the Institution of Civil Engineers in June of this year, and was directed to express to these gentlemen Council's thanks for their services. The address which is to be presented to the Institution on this occasion was submitted and approved.

A letter was presented from the American Society of Mechanical Engineers, requesting The Institute to nominate a representative to act on an Advisory Committee which is being formed in connection with a new Engineering Index Service. The Secretary was directed to communicate with the Society asking whether his services on the Committee would be acceptable.

A letter was submitted requesting Council to nominate a representative to attend the Eighth Industrial Chemical Congress which is to be held at Strasbourg on July 22nd-28th, 1928. Council regretted its inability to make arrangements for representation on this occasion.

It was noted that the President and Secretary had received invitations to attend the opening ceremonies of the new library at the University of Louvain, (Belgium), on July 4th, and the Secretary was directed to express Council's appreciation of the courtesy paid to The Institute.

Four reinstatements were effected, seven resignations accepted, and five special cases dealt with.

The following elections and transfers were effected:—

Elections.		Transfers.	
Associate Members	6	Assoc. Member to Member	4
Students	9	Junior to Assoc. Member	5
		Student to Assoc. Member	1
		Student to Junior	3

Twenty-seven applications for admission and transfer were scrutinized and classified for the ballot returnable June 15th, 1928.

The Council rose at 12.05 o'clock a.m.

Recent Graduates in Engineering

Congratulations are in order to the following Students and Juniors of The Institute who have recently completed their course at the various universities.

University of Manitoba

University Gold Medal and Joseph Doupe Gold Medal

Bain, Archie Marcus, B.Sc., (Ci.), Winnipeg, Man.

University Gold Medal

Briggs, Herbert Lee, B.Sc., (El.), Killarney, Man.

Degree of B.Sc.

Borgford, Thorsteinn Bjorgvin, B.Sc., (Ci.), Winnipeg, Man.
Cantlon, Carman Farrar, B.Sc., (El.), Winnipeg, Man.
Cheney, Wayne Putnam, B.Sc., (El.), Winnipeg, Man.
Collins, George Edward, B.Sc., (Ci.), Winnipeg, Man.
Fidler, Frank, B.Sc., (El.), Winnipeg, Man.

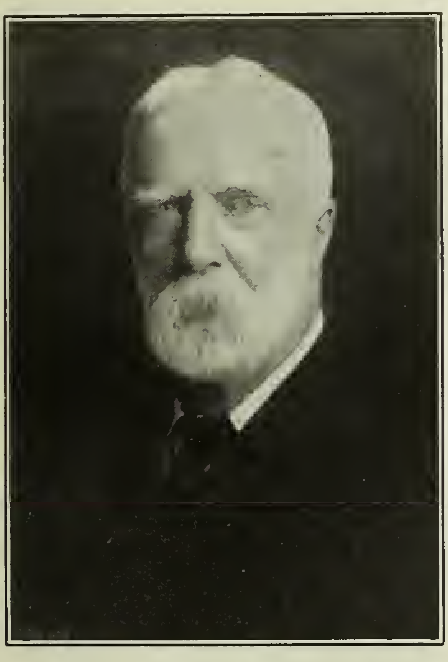
OBITUARIES

Henry John Cambie, M.E.I.C.

Through the death of Henry John Cambie, M.E.I.C., which occurred in Vancouver on April 23rd, 1928, The Engineering Institute of Canada has lost one of its earliest members and staunchest supporters, and Canada, and Vancouver in particular, is the poorer by the loss of an engineer of ripe experience and one of the few survivors of that small group of pioneers, through whose ability, energy and resourcefulness the development of Canada's great transcontinental railway systems was made possible.

Following an illness of little more than a week, from a severe cold which developed into pneumonia, this great pioneer passed away peacefully, in the beautiful setting which he had made his home during his declining years, and with his passing there comes to a close a life of great achievement indelibly inscribed on the pages of Canadian history.



HENRY JOHN CAMBIE, M.E.I.C.

An Irishman who never quite lost a touch of the brogue, Henry John Cambie came from an old Irish family which settled at Castleton, in the county of Tipperary, in Cromwellian times. He was born in Tipperary on October 25th, 1836, and while still a lad of sixteen he emigrated to Canada with his parents and a brother.

Shortly after his arrival in this country he entered the office of the late Walter Shanly, M.E.I.C., of the Toronto and Guelph Railway as an apprentice. From 1853 to 1859 he was with Messrs. Gzowski and Company, contractors for the western part of the Grand Trunk Railway, occupying various junior positions, principally in connection with surveys. For two years after 1860 he was engaged on surveying and exploratory work with the Government of Upper Canada, and from 1863 to 1866 for the Intercolonial Railway of Quebec, New Brunswick and Nova Scotia. Before the age of thirty he was in charge of his first railway construction project, when during the years 1867 to 1868 he was engaged in locating and constructing the Windsor and Annapolis Railway. The three succeeding years found him in charge of some of the most extensive works on the Intercolonial Railway in New Brunswick and Quebec.

When British Columbia entered Confederation one of the conditions was that a transcontinental railway should be undertaken. As nothing had been done three years later the premier of the western provinces complained bitterly to the Federal government. The Hon. Alexander MacKenzie, then head of the Dominion government, dispatched James Edgar to the Pacific coast as mediator with instructions to propose the immediate construction of a railway between Esquimalt and Nanaimo and at the same time sent Mr. Cambie to the coast to take charge of the work. This proposal was not accepted by the western provinces and when the project fell through Mr. Cambie was employed by the Dominion government on explorations and surveys throughout the province of British Columbia and his work resulted in the decision that Burrard Inlet could be made into a suitable deep-water harbour and that a railway could be built through the Fraser canyons. In 1875 he explored the difficult Chilcotin country, seeking a route for a railway to Butte inlet and thence, over Seymour Narrows, to Vancouver island.

In 1876, Sanford Fleming, chief engineer for the Dominion government, began a four years leave of absence. Marcus Smith, who was in charge of surveys in British Columbia, took his place and Cambie was put in charge of surveys in British Columbia, and continued in charge until 1880. In 1876, he and Dr. G. W. Dawson retraced Sir Alexander MacKenzie's route from Bella Coola to the Fraser river.

Next year he directed the survey of the Fraser river route from Yellowhead Pass to Port Moody, and the information gathered on that survey practically determined the selection of Burrard Inlet as the terminal of the new railway.

In 1878, Mr. Cambie was sent by the Federal government to determine the feasibility of a line to the mouth of the Skena river, both by the Peace Pass and the Pine Pass. In this work he was accompanied by Dr. G. W. Dawson, Henry MacLeod and Rev. D. M. Gordon, later principal of Queen's University. On his return from this work he learned that the Fraser route had been selected for the railway and that the contract for the Pacific section had been let.

The work of construction was to be proceeded with at once and Mr. Cambie, whose record in the Eastern provinces had not been forgotten, was placed in charge of operations in the Fraser canyons. After this tremendous work was completed, Mr. Cambie was made superintendent of construction on the section from Savona to Shuswap lake, and after the opening of the line he was appointed engineer to the western division of the Canadian Pacific Railway. In 1902 he was made consulting engineer to the company and he retired from active service in 1920, although his services were retained by the company in an advisory capacity.

Throughout his long and eventful career Mr. Cambie was ever ready to assist his fellow engineers in furthering their interests. He was elected a member of The Institute on February 9th, 1888, and throughout its early days, before its name was changed from the Canadian Society of Civil Engineers, he took a very active part in its affairs, serving on its council during the years 1892, 1896, 1901, 1904 and 1910. He contributed two papers to The Institute which were published in the Transactions; one on the "Fraser River Bridge" in Volume V, 1891, and the other on "Unrecorded Property of Clay" in Volume XVI, 1902. In the fall of 1923 an interesting photograph of three of Canada's railway pioneer engineers was taken at Vancouver, and was published in the February 1924 issue of the Journal. This group consisted of Thomas Henry White, M.E.I.C., the late Henry John Cambie, M.E.I.C., and the late James Henry Kennedy, M.E.I.C.

In its editorial columns the Vancouver newspaper refers to the death of Mr. Cambie in part as follows:—

> " For of Henry J. Cambie, explorer and railway builder, it can be said more than of most men that he died full of years and honour and at the close of a long life so well rounded out that it is not possible to think of any other circumstance that would have made it more complete. Great achievement and the love and esteem of many friends were his and it is doubtful if he had an enemy in the world. What could man desire more and of how few can this be said after ' life's fitful fever ' is passed and the final call has come.
>
> " When ninety-one years ago this contemporary and friend of Strathcona, Mount Stephen and Angus—the three great organizers of the Canadian Pacific Railway—was born in a little hamlet in Tipperary, Ireland, who could have foretold such a career of strenuous endeavour and accomplishment in a country six thousand miles away? Of these four men, all of whom lived to be over ninety, the last to go has been the practical man, the actual builder. Upon three railway systems he left the mark of his constructive genius and the last of these was the greatest, for he was in charge of the mapping out, surveying and building of that stupendous piece of work through the Fraser canyons.
>
> " That was Henry J. Cambie, the practical man, the man of achievement. But there was included in his make-up another man, the man of character, of personal charm, of lovableness, of great modesty regarding his works, and that was the man whom a later generation knew and learned to esteem, and that is the man who will linger in memory. His life was an example to those who come after him. He was a man who did unto others as he would be done by and who did his duty. Can there be finer epitaph than that? "

Alexander Siemens, M.E.I.C.

In the death of Alexander Siemens, M.E.I.C., which occurred at Westover, Milford-on-Sea, Hants, England, on Thursday, February 16th, 1928, at the age of 81, there has passed an engineer whose name has been intimately linked with the development of the electrical industry, and whose name, with that of Sir Charles Siemens and Werner von Siemens, will occupy an honoured place in any history of the progress of this branch of engineering.

Born at Hanover, Germany, on January 22nd, 1847, the late Mr. Siemens received his early education at the schools in Hanover until 1866, when he entered the Polytechnic School. While still a young man of 20 he moved to England to assist his uncle, William Siemens, in the works which he had established and which are still existing at Woolwich for the production of electrical equipment. In 1868 he was called for military service but was rejected on account of bad eyesight, although he afterwards served in the Franco-German war and as a private in an infantry regiment was present at the fall of Metz and received the Iron Cross after being wounded at the battle of Beaune-la-Roland in the Orleans campaign. Prior to his active service, however, he had been engaged on the erection of the Indo-European telegraph line in Persia,* and in laying cables in the Black Sea.

In the autumn of 1871, he returned to Woolwich, and was employed for the next few years in the design and erection of those regenerative furnaces for various purposes with which the name of his uncles will always be connected. In September, 1875, he again took up telegraphy and joined the cable ship Faraday, during the time she was stationed at Halifax, N.S. He was still closely connected with furnace work, however, assisting in the erection of blast and steel furnaces, both for the Steel Company of Canada and at Pittsburgh. He was nationalized as a British subject in 1878. After his return to England in 1879, Alexander Siemens was appointed manager of that branch of the works at Woolwich, which was engaged in the manufacture of dynamos. Machines of this kind, produced under his direction, were used for lighting the Albert Hall, London, the British Museum, and the Albert Docks, while the firm also undertook the contract for lighting the streets of Godalming, in Surrey, this being the first town in which a public supply of electricity was given in this country. He was also connected with the electrification of the tramway between Portrush and the Giant's Causeway, in Ireland.

After the death of Sir William Siemens in 1883, Alexander Siemens assumed a much more important position in the firm, of which he became first a director and subsequently managing director. Soon after his appointment to the latter position, the firm secured the contract for laying the third Atlantic cable for the Commercial Cable Company, and also for a cable which extended 1,000 miles up the Amazon river. At the same time, the use of electricity for power purposes was increasing, and the firm took their full share in these activities, one of the more important contracts undertaken by them, though at a later date, being the complete electrical equipment of the Waterloo and City Railway.

ALEXANDER SIEMENS, M.E.I C.

Soon after the beginning of the century the business of the firm had increased so much that no further extensions

*An interesting historical account of this work appeared on page 209 of the February 17th, 1928, issue of Engineering.

on the Woolwich site were possible, and for this and other reasons it was determined to divide the telegraph and cable work from the manufacture of machinery, and to establish new factories at Stafford for the production of the latter. Further, the firm was divided into two, the Woolwich branch retaining the original name of Siemens Brothers and Company, while the Stafford section became known as Siemens Brothers Dynamo Works. The two, however, worked in the closest co-operation, and Alexander Siemens was the chief permanent director in England of both.

Although this important position claimed a great deal of his time, he did not neglect the technical side of engineering and was particularly interested in the work of scientific associations and was a frequent contributor to their proceedings.

He was a founder member of the Institution of Electrical Engineers and was appointed a member of its council in 1880. He was elected vice-president in 1890, and became president in 1894 and again in 1904, thus following his uncle, who had occupied the same chair in 1872 and 1878. He joined the Institution of Civil Engineers as a student in 1867, soon after his arrival in England. He was transferred to Associate and to Full Membership in 1890. In 1898 he was elected Member of the Council of The Institution and served as its President in 1910-11. He was also a member of the Institution of Mechanical Engineers, the Iron and Steel Institute, the Physical Society and the Society of Engineers. He served as president of the Junior Institute of Engineers in 1894 and was secretary of the Royal Institution from 1913 to 1915. He was a member of the Committee appointed in 1897 to enquire into the desirability of establishing the National Physical Laboratory, and later served on the executive committee of that institution. He was also connected with the formation of the London Association of Engineering and Shipbuilding Employers, and was its first president up to 1901. About the same time he was a member of the British Admiralty Committee to consider the question of utilizing electrical energy on warships, and was subsequently nominated a member of the Railway Conference, which sat during 1908-09 at the Board of Trade. He was also appointed a member of the Departmental Committee on Railway Amalgamations and Agreements which reported in 1911.

His connection with The Institute dates from the early days of the Canadian Society of Civil Engineers, when on June 11th, 1888, he was elected a Member of the Society. On November 21st, 1922, he was made a Life Member of The Institute.

Howard George Kelley, M.E.I.C.

Howard George Kelley, M.E.I.C., former president of the Grand Trunk Railway System and one of the outstanding railway engineers of Canada, died suddenly on May 15th, 1928, at San Diego, California.

At the time of his death Mr. Kelley was in his 71st year, having been born at Philadelphia, Pa., on January 12th, 1858. His engineering training was received at the Polytechnic College of Pennsylvania, following which he entered railway work in 1881. During the first four years he was engaged as assistant engineer on the location and construction of the Northern Pacific Railroad on the Western and Pacific Divisions, but in 1887 he became interested in mining work and accepted the position of mines superintendent in connection with some works in Montana. He returned, however, after three years to railroad engineering and his ability earned for him the position of resident engineer and superintendent of bridges of the St. Louis and Southwestern system.

Rising to the posts of chief engineer on the Minneapolis and St. Louis Railway and the Iowa Central Railway, he finally travelled back to the St. Louis and Southwestern system again in 1898, in the capacity of consulting engineer. By this time his qualities had made him famed throughout the railroad world of the North American continent, and in 1907 he was brought north to Canada as chief engineer of the Grand Trunk Railway system. The late Mr. Charles M. Hays was at the helm of the big Canadian road in those days. Before him, Mr. Hays saw possibilities in the extension of the steel. For location and construction work he could see nobody more qualified than Mr. Kelley and thus it was that the engineer joined the Canadian road. Under him, some ten thousand miles of track, largely in practically unexplored territory, were added to the Grand Trunk Railway mileage. Before the work had been completed the Titanic disaster came and with the huge liner went the late Mr. Hays and over a thousand more of the passengers. The presidency of the Grand Trunk Railway went to Mr. E. J. Chamberlin, and Mr. Kelley was promoted to the post of vice-president in charge of operation, maintenance and construction, one of the most onerous positions in the gift of the system. He had jurisdiction over not only the Grand Trunk lines in Canada, but also those dipping into five states in the Middle West, and traversing New England.

Upon retirement of Mr. Chamberlin the presidency of the Grand Trunk system, comprising the Grand Trunk Railway and the Grand Trunk Pacific Railway, fell to Mr. Kelley. That was in 1917, and he remained in that capacity until the Dominion government took over the consolidated Grand Trunk and Canadian Northern systems. Then he retired from office.

From time to time during his career the services of Mr. Kelley were taken advantage of by United States bankers involved in railroad financing, while his counsel also was sought by governments in several European countries.

The late Mr. Kelley joined The Institute in 1907, when he was elected a Member on December 12th of that year.

HOWARD GEORGE KELLEY, M.E.I.C.

Thomas James McMinn, M.E.I.C.

It is with regret that we record the death of Thomas James McMinn, M.E.I.C., which occurred at Philadelphia, Pa., on September 21st, 1927.

The late Mr. McMinn was born at Port Hope, Ont., on October 8th, 1854. His engineering work was commenced in June 1874 when he was on the construction of the new waterworks for the city of Toronto under the late P. A. Peterson. He remained on this work and its various subsequent extensions until 1879 when he was made assistant engineer to the late R. J. Brough. In 1880 Mr. McMinn was engaged in making surveys, plans, specifications and estimates for the construction of a 6-foot oak conduit to be built and extended for a considerable distance into Lake Ontario. In 1881 he was appointed resident engineer on this work and served in this capacity until the end of 1882.

From that date until 1889 Mr. McMinn was employed as assistant engineer of the waterworks department of the city of Toronto, during which period he made a barometric survey of the country extending to the north of Toronto in connection with the proposed gravitation water supply for the city.

On leaving the employ of the city of Toronto, Mr. McMinn moved to the United States and joined the staff of the late Rudolph Hering, M.E.I.C., who was engaged in the private practice of engineering in New York city. He remained with Mr. Hering until January 1898 when he was elected assistant secretary of the American Society of Civil Engineers, which position he retained until his retirement in 1919. Shortly after retiring he moved to Bridgeport, Conn., and then to Philadelphia, Pa., where he resided until the time of his death. During latter years Mr. McMinn was engaged in editing several technical books.

Some insight into the character and personality of Mr. McMinn may be gained from the memoir recently issued by the American Society of Civil Engineers, which reads in part:—

> "Such, in brief, is an outline record of a useful life. To most members—and Mr. McMinn was widely known in the Society—his most valuable work was comprised within his official term as Assistant Secretary. The duties of this office were varied, especially in the early days, when the smallness of the organization demanded a wide variety of service of each officer. Always, however, Mr. McMinn gave his main efforts to publications.
>
> "At one time he handled the many phases of this work—editing, attending to engraving, proofreading, and supervising the printing. Later, however, as the work expanded, he devoted his time mainly to the editing. In this he was, happily, successful. Endowed naturally with a clear perception of the fitness of expression, he was at once painstaking, well read, and widely versed in engineering methods. Many of the details of style he instituted are still standard practice, to the lasting credit and reputation of the publications. . . .
>
> "During so many years' intimate connection with the Society journals, he gained a wide and close acquaintance among the members. Endowed with a mildness of manner and a gentlemanly bearing, his relations were always pleasant. No one could exchange ideas with him anent engineering matters, especially the details of rhetorical expression, without feeling his innate grasp of such intricacies.
>
> "His qualities of person and character endeared him to his many colleagues at Society Headquarters. He had made for himself a solid place in their esteem. Apparently the feeling was mutual; the several years after his retirement were punctuated by frequent visits to New York, at which times he always made it a point to keep his many friendships in good repair.
>
> "Mr. McMinn was essentially a literary editor and an excellent one. But he was also an engineer; and, above all, a man. His lengthening years of Society work only served to ennoble his character, to bring into stronger relief the qualities of mind and of person that made him revered and loved. His place in the annals of the Society is secure."

The late Mr. McMinn was one of the few remaining original members of The Institute, and while his name does not appear on the list of chartered members it may be found among those who were responsible for its establishment, as his election to membership dates back to January 10th, 1887.

PERSONALS

C. R. Murdock, A.M.E.I.C., town engineer of Timmins, Ont., has resigned to accept the post of town engineer and townsite manager of the town of Kapuskasing, Ont.

J. K. Sexton, S.E.I.C., who graduated from the University of Saskatchewan this year, has joined the staff of the Calgary Power Company at Seebe, Alta.

M. Du Bois, J .E.I.C., formerly marine engineer with the Alex. McKay Company, Limited, Quebec, Que., has been appointed to the staff of the hydraulic department of the Dominion Engineering Works, Limited.

R. S. Baker, A.M.E.I.C., formerly mechanical research engineer for the Canadian International Paper Company at Temiskaming, Ont., is now located at Ottawa with Messrs. Alex. Fleck, Limited.

R. K. Robertson, A.M.E.I.C., factory manager of the Canadian Marconi Company, Montreal, has joined the staff of the Cooksville Shale Brick Company, at Cooksville, Ont. In 1923 Mr. Robertson was with this firm in the capacity of works manager.

William S. Orr, A.M.E.I.C., formerly on the staff of the Hydro-Electric Power Commission, Niagara Falls, Ont., has been appointed works commissioner of the city of Niagara Falls. His appointment combines the positions of city engineer and superintendent of outside construction.

D. G. Geiger, A.M.E.I.C., lecturer in electrical engineering at Queen's University, Kingston, has resigned his position to join the staff of the Bell Telephone Company of Canada at Montreal, where he is in charge of special transmission information, toll circuit testing and transmission surveys in the transmission division of the engineering department.

C. O. Whitman, A.M.E.I.C., has joined the staff of the Foundation Company of Canada and has proceeded to Lake Resignoul in Nova Scotia in connection with the company's work on the Liverpool river. Mr. Whitman is a graduate of Nova Scotia Technical College of the year 1921 and has had extensive experience in various construction works since that date.

J. E. Armstrong, A.M.E.I.C., has been appointed assistant chief engineer of the Canadian Pacific Railway, according to an announcement recently issued by the company. Mr. Armstrong is a native of Peoria, Ill., where he was born in 1886. He is a graduate of Cornell University of the class of 1908. Previous to that date he had been employed in the engineering department of the Toledo, Peoria and Western Railway for some five years.

P. L. Pratley, M.E.I.C., of the firm of Monsarrat and Pratley, consulting engineers, Montreal, has been retained by the city of Grand'Mere, Que., to represent the city and the province on the project for a highway suspension bridge over the St. Maurice river at Grand'Mere. The firm of which Mr. Pratley is a partner has been engaged as consulting engineers by the financial interests behind the project for a highway and railway over the Saguenay river at Chicoutimi, Que., and as designing engineers for the Saguenay river bridge of the Quebec and Chibougamau Railway.

J. B. Carswell, A.M.E.I.C., president of the Carswell Construction Company, Limited, Toronto, has been appointed managing director of the Burlington Steel Company, Limited. Mr. Carswell is a native of Paisley, Scotland, where he received his primary education; his technical training was obtained from the Paisley Technical School and Glasgow University. His first engineering work in Canada was in 1910 when he was on maintenance work in connection with the Grand Trunk Railway. The following year he was with Messrs. John Stewart and Company, railway contractors, and in October 1911 he joined the staff of Messrs. Ross and Macdonald, architects.

Alan H. Munro, A.M.E.I.C., of Peterborough, Ont., has accepted a position with the Alcoa Power Company, Limited, at Kenogami, in connection with the design of the company's new power development on the Saguenay river. Mr. Munro is a graduate of the University of Toronto of the year 1911 and has had extensive experience in various types of construction, his work having been connected mostly with hydro-electric power projects. Prior to his recent appointment he was engaged on a survey in connection with the proposed power development on the upper waters of the Ottawa river, and before that he was with the Ontario Paper Company, Limited, on the construction of the hydro-electric power plant at Outarde Falls, Que.

A. R. Ketterson, A.M.E.I.C., has been appointed assistant engineer of bridges of the Canadian Pacific Railway, with headquarters at Montreal, according to an announcement recently issued by the company. Mr. Ketterson is a native of Greenock, Scotland, where he was born on June 24th, 1881. Mr. Ketterson entered the Canadian Pacific Railway service as bridge inspector in the chief engineer's department, Montreal, in May 1907. In 1910 he was engaged on work as a structural draughtsman of bridges in the same department and in 1912 was appointed assistant engineer until 1916, when he went overseas, where he served with distinction and was awarded the D.S.O. In 1919 he was appointed to the chief engineer's department and is now called to the position of assistant engineer of bridges in that department.

A. J. T. Taylor, M.E.I.C., has been elected to the board of directors of the Sir W. G. Armstrong, Whitworth and Company according to an official announcement recently issued, which also contains the information that the Earl of Verulam has been added to the board. Mr. Taylor was formerly president of Combustion Engineering Corporation until the beginning of 1926, when he was transferred from Canada to England as managing director of the Underfeed Stoker Company of London, England, and as director of International Combustion, Limited. He was also chairman of Ruth Steam Accumulator Company of New York, but has resigned the chairmanship to become managing director of Ruth's Steam Accumulators, Limited, of London, England. Upon his election to the board of Messrs. Armstrong, Whitworth he also resigned from the Underfeed Stoker Company.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 18th, 1928, the following elections and transfers were effected:—

Associate Members

FRY, Albert Edward, general mechanical engrg. work with Dominion Glass Co., Montreal.

GEAR, Sydney Stuart, grad., (Univ. of Toronto), contracting engr., Horton Steel Works, Ltd., Bridgeburg, Ont.

JONES, Robert Bolton, asst. engr., C.P.R. terminal and yard design, valuations rail, etc., Montreal, Que.

MELLOR, Arthur Lees, sr. inspector, Montreal South Shore Bridge, Messrs. Milton Hersey Company, Ltd., Montreal.

SPENCE, William Archibald, B.Sc., (Queen's Univ.), engr. for Thomson & Clark Timber Co., Ltd., Vancouver, B.C.

WALTON, Clarke Gibbs, B.Sc., (Queen's Univ.), constrn. engr., Ford Motor Co. of Canada, Ltd., Sandwich, Ont.

Transferred from the class of Associate Member to that of Member

CARSWELL, John Ballantyne, B.Sc., (Glasgow Univ.), president, Carswell Constrn. Co., Ltd., Toronto, Ont.

HOLLOWAY, Edward S., B.Sc., (McGill Univ.), reporting on various pulpwood operations, wharves, loading plants, etc., i/c for Kerry & Chace, St. Hilaire, Que.

KENNEDY, Howard, B.Sc., (McGill Univ.), mgr. woodlands dept., i/c all woods operations and purchase of pulpwood and match lumber, E. B. Eddy Co., Ltd., Ottawa, Ont.

MILNE, Arthur H., B.Sc., (McGill Univ.), mgr. of mtce. for Protestant Board of School Commissioners, Montreal.

Transferred from the class of Junior to that of Associate Member

BUNTING, William Russell, B.A.Sc., (Univ. of Toronto), power apparatus specialist, Northern Electric Co., Ltd., Montreal.

LeCLAIR, William James, ch. engr. and managing partner of Lawson & LeClair, Dalbeattie, Scotland.

McKAY, Hugh Alexander, B.A.Sc., (Univ. of Toronto), mgr. London Structural Steel Co., Ltd., London, Ont.

VOGAN, George Oliver, B.Sc., (Queen's Univ.), designing engr. for the Alcoa Power Co., Ltd., Arvida, Que.

Transferred from the class of Student to that of Associate Member

DICK, George McKinstry, B.Sc., (McGill Univ.), designing engr. on mine hoists and haulage machinery, Can. Ingersoll Rand Co., Ltd., Sherbrooke, Que.

Transferred from the class of Student to that of Junior

FERRABEE, Francis Gilbert, B.Sc., (McGill Univ.), i/c selling and servicing the Ingersoll Rand Products in the lower half of the state of West Virginia, Huntington, W.Va.

HORSEY, Richard Mountstephen, B.Sc., (McGill Univ.), power cable testing and design, Northern Electric Co., Montreal.

WIGHTMAN, John, B.Sc., (McGill Univ.), mine exploration in N.S., N.B. and Nfld. for Cons. Mining and Smelting Co. of Canada, Ltd., Sydney, N.S.

The Canadian Ohio Brass Company, Limited, announces the removal of its Montreal office from 1188 Phillips Place to 708 Canada Cement Building, effective immediately. This new location provides the company with better facilities for serving the territory covered by the Montreal office.

The Canadian General Electric Company, Limited, announces the publication of their new 1928 Industrial Control Catalogue. This is a 200-page treatise on the latest Canadian General Electric practice in the control of motors. For instance, controllers embodying thermal overload protection, definite time acceleration, time delay, undervoltage protection and other modern features are described in detail. Copies may be obtained through the nearest Canadian General Electric office.

The Engineering Institute of Canada: Transactions, 1887-1911. Royal Commission: Quebec Bridge Inquiry, 1908. Institution of Civil Engineers: Proceedings, 1905-1908, 1911; List of Members, 1908.

EMPLOYMENT BUREAU

Situations Wanted

ENGINEER AND SUPERINTENDENT

First class man, graduate engineer, is looking for a new position. Has ten years experience in big construction work. Apply to Box No. 236-W, The Engineering Journal.

MUNICIPAL AND CONSTRUCTION ENGINEER

Fully qualified engineer with experience in municipal work, paper mill construction and operation, and other industrial work, is available for a position. Experience covers a period of eight years on municipal work, during which the position of city engineer was held, two years on the construction and operation of a paper mill, and six years as engineer, superintendent, and chemist in manufacturing work. Apply Box No. 237-W, The Engineering Journal.

CIVIL ENGINEER

Age 35, A.M.E.I.C. and Regd. Professional Engineer of Ontario, seeks position as town engineer for small Ontario town, Northern Ontario preferred, but other locality considered. Apply box No. 238-W, The Engineering Journal.

Situations Vacant

STRUCTURAL STEEL DETAILERS

A company in Ontario has two openings for experienced structural steel detailers. Apply box No. 195-V, The Engineering Journal.

PULP AND PAPER MILL DESIGNER

A pulp and paper company in Northern Quebec has an opening for a competent designer. Preferably one with pulp and paper mill, or at least industrial experience. Preference will be given to an unmarried, university graduate. Apply box No. 197-V, The Engineering Journal.

INSTRUMENTMEN

Two graduate engineers with experience in survey work as instrumentmen for general survey work in connection with power projects. Apply box No. 203-V, The Engineering Journal.

ARCHITECTURAL DRAUGHTSMAN

With experience in designing, detailing and able to make specifications and estimates. Apply box No. 204-V, The Engineering Journal.

BOOK REVIEWS

The Disposal of Sewage

By T. H. P. Veal, Van Nostrand Company, New York, 1928, Cloth, 8½ x 5½ in., 170 pp., figs., plans, $4.25.

This book, written for the use of engineers, introduces the subject of sewage disposal by giving a short and interesting history of the sanitary conditions in Britain in the early nineteenth century, and traces the gradual development of the method of dealing with sewage and storm water.

Owing to the increasing density of population and the aggravated unsanitary condition of the rivers and streams, drastic measures had to be taken decades ago in an honest effort to improve affairs, and, without doubt, Britain was therefore compelled to lead in the work of sanitation. Broad irrigation of land, which its subsequent modifications, has long had its day and in many places has had to be supplanted by improved methods of treatment.

The collection of sewage and storm water, simple as it appears to many, entails considerable study to obtain the best result. The author traces these conditions and refers to the many differences between British requirements, and, say, North American. The use of water is greater in this country. The climatic conditions are more severe, and the intensity of rainfall is higher. The author also refers to the periodicity and fluctuations of the flow of sewage.

A Canadian student using the book as his text must bear in mind the differences mentioned.

The design of sewers by the Burkli-Zeigler formula is seldom done now in North America with satisfactory results. The rational method, or, more correctly, the synthetical method with the adoption of suitable factors, is largely in use here.

The author describes the various methods of sewage disposal. He deals with screens and grit chambers, also with tanks for sedimentation. If the tank is to be self-cleansing, the slopes should exceed one in ten, as stated on page 55. Interesting calculations are given to estimate the capacity of rectangular settling tanks for continuous flows.

Reference is made to contact beds similar to those built by the reviewer in 1896 and contact beds are still in use where careful supervision is possible, but many changes have taken place since then, and percolating filters have largely supplanted them. The efficient use of percolating filters depends to a great extent upon the proper performance of the operations in the sedimentation tank, for if much fine flocculent sludge is carried forward, the filter will choke. The use of percolating filters is extensive, and where it is under proper control its efficiency is high, hence the desirability of maintaining good sedimentation, the avoidance of septic action, and the adoption of reliable efficient distributors, many of which are illustrated in this book.

In the matter of bio-aeration treatment, the author gives a terse history of its development. On page 115 he states that the detention in bio-aeration tanks varies from six to eighteen hours. This much exceeds the time allowed in this country. Possibly this is due to the more dilute character of the sewage on this side. The interesting method of aeration which originated in Sheffield is described, but this method has not yet been tried on this side. The Simplex Surface aeration whieh was evolved at Bury has been tried in the United States.

The use of combined bio-aeration tanks and trickling filters as tried at Birmingham has considerable promise, for the action in the aeration tank is rapid and it is possible to minimize the time and cost of aeration by completing the purification on trickling filters.

The author mentions the subject of the creation of activated sludge, which by normal aeration is a slow process. The Director of the Engineering Division of the Provincial Board of Health of Ontario has a chemical process of starting the plant which is effective and expeditious.

The disposal of the sludge is a matter of prime importance in eonnection with sewage treatment. Mechanical methods such as centrifuging, pressing, intensive filtration, etc., are not practically efficient. Mr. Watson of Birmingham long ago suggested the process which gives promise of success, namely, by digestion. This is dealt with by the author, but not in a sufficiently comprehensive manner. The policy of reducing the sludge by proper digestion is one which will probably be largely adopted in future. This problem is under investigation today in a number of places, both in Europe and America.

The development of power by using gas generated in digestion tanks is a most interesting one, and the author might discuss this matter more fully in future editions.

The costs of works as given by the author are useful for British readers, but the proportions and expenditures involved are not comparable for use on this continent. Nevertheless, the reader will find much of value.

The disposal of sewage in rural districts is dealt with and many instructive examples are given.

Veal's volume on "Sewage Disposal" will be found useful for reference as to the methods adopted by different engineers in handling various sewage problems, and, if it is borne in mind that the book is intended primarily for British engineers, it will be found valuable by students of sanitary engineering in Canada and elsewhere.

Matter, Electricity, Energy

By Walter Gerlach, translated by Dr. F. J. Fuchs. Van Nostrand, New York, 1928, Buckram, 9 x 5 in., 427 pp., figs., $6.00.

The title of this book, "Matter, Electricity, Energy," does not give as clear a conception of its contents as if the title read "Atoms, Electrons and Quanta," for this is indeed the range of subjects of which the book treats. However, one can well understand that to the author, matter and electricity are practically synonymous with atoms and electrons and that he regards energy as being more worthy of emphasis than theories concerning quanta.

This book, which has only recently been translated from the German, was originally written in 1893 and revised in 1896, and is really a mine of information on the subjects of which it treats. It is written from the experimental standpoint, contains no mathematics and is therefore fairly easy reading. Before reading the book, however, unless one is well versed in physics or physical chemistry, it might be advisable to obtain some slight knowledge of atomic physics by reading some such book as the "World of Atoms," by Haas, recently reviewed in these columns, which treats of many of the same topics but in a more elementary way and much more briefly. We are informed that the book was written for the chemist, the mineralogist and the engineer, and that it has been widely used as a seminar text book for graduate students. This information gives us a good idea of the scope of the book and to the class of reader to which its appeal is made.

To the engineer who wishes to keep abreast of the times, we recommend the book very highly, for, while it treats of many things that are regarded as pure science, we must remember that the pure science of to-day is the source out of which to-morrow's applied science must spring. Some of the pure science in this book is already receiving practical application. For instance, photo-electricity is now fundamental in the new science of television. Certain practical applications of the photo-electric effect are taken up and given considerable attention. There are also chapters on super-conductivity, crystal conduction, photo-chemistry and structure-analysis by means of X-rays. Super-conductive effects are simply marvellous, for we are informed that at very low temperatures,—within a few degrees of absolute zero,—the resistance of certain metals is 10^{12} times as low, or, in other words, one millionth of a millionth as low as at zero degrees centigrade.

The translation is well done, and we are under obligation to Dr. Fuchs for having made available to us in English this important German book.

BRANCH NEWS

Border Cities Branch

Orville Rolfson, A.M.E.I.C., Secretary-Treasurer.
(Reported by R. C. Leslie, A.M.E.I.C.)

This branch held its April meeting in the Prince Edward hotel, Windsor, on Friday the 20th. The meeting was well attended and a good speaker was on hand whose talk was enjoyed by all present. Mr. Herbert W. Walter, superintendent of the Port Colborne plant of the International Nickel Company, was the guest of honour, and he described for us the nickel industry.

Mr. Walter went over some of the history of nickel, telling of its early discovery in Ontario in 1854, and of the difficulties which stood in the way of refining the new metal. The discovery of a suitable process for refining brought with it a realization that there was no market for nickel after it was produced in commercial quantities. The governments of Canada and the United States were both interested in nickel and assisted the producers in developing markets. The United States navy ordered one million dollars worth of nickel steel for armour plate. Gradually other uses became known, and the production of nickel increased.

The members were shown, by means of diagrams, the Creighton mine and the system used there for removing the ore. Then the process of natural roasting takes place before the smelter is reached. The material that is shipped to Port Colborne is a nickel matte, 80 per cent copper and nickel. The Port Colborne plant uses the Orford process for refining nickel, and this was described in detail. Mr. Walter stated that with the electrolytic refining, which is being used more and more, the nickel comes out 99.95 per cent pure.

Before the World War the main use of the metal was in ordnance and armour plate, and during the war the demand increased tremendously. However, with the cessation of hostilities in 1918, followed by the Washington Conference of 1922, the market disappeared. For a time the nickel business was practically non-existent. The company then instituted a vigorous research programme with a view to discovering new uses. They were highly successful in so doing, and today the business is larger than before the war, but the major demand is for peace time purposes. An interesting comparison is to be had in the following table:—

	Uses in 1913	Uses in 1925
Armour plate	52 per cent	3 per cent
Coinage and plating	26 " "	23 " "
Nickel steel	17 " "	50 " "
General	5 " "	24 " "

How intimately nickel has been worked into the life of today was shown by tracing the daily routine of the average man, showing how nearly everything that he uses or comes in contact with during the day has nickel in its composition.

In the discussion which followed Mr. Walter's address, a visitor to the branch, Mr. Cummings, who had been connected with the Nickel Company for some years, gave some additional information that was of great interest.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

Sackville Meeting

On April 4th a combined meeting of Moncton branch and the Engineering Society of Mount Allison was held at Sackville, in the Science building of the university. H. J. Crudge, A.M.E.I.C., building engineer, Canadian National Railways, Moncton, N.B., gave a very instructive address on "Construction Methods." The address was illustrated with slides and motion picture films, showing construction of the immigration building, and new Canadian National Railway hotel and station at Halifax. Prof. F. L. West, M.E.I.C., presided.

Construction Methods

The term "Construction Methods" in reality had reference to handling the material of which the structure was composed. The best and cheapest methods are those which involve as little handling as possible. Strange as it may seem, the lazier the foreman or superintendent, that is, with regard to moving his building materials, the more efficient he may be. Naturally, in avoiding unnecessary physical labour, considerable foresight and planning is required. The mixing of concrete, for example, is an every-day manufacturing operation, but the efficient stacking and handling of the materials of which the concrete consists is a problem that sometimes taxes the skill of the engineer to a considerable extent.

Mr. Crudge described in detail conditions affecting the building operations at Halifax. In the construction of the hotel foundations, the sand and gravel were taken in dump trucks from a central pile, an average distance of 200 feet, and elevated to the mixer. The finished concrete was carried away by a suspended trolley, then dumped into steel buggies and wheeled by hand to the forms. The daily, (8-hour), output averaged 100 cubic yards. It was interesting to note that both dump trucks and buggies were equipped with roller bearings in order that operations should be carried on with maximum speed and minimum effort. In pouring the upper floor of the 1,250-foot immigration building, the mixer was mounted on a travelling tower. The haul away from the mixer was reduced and the daily output increased to 125 cubic yards. Very favourable circumstances existed in connection with the pouring of the lower floor, in that two parallel tracks ran alongside the building for its entire length. The mixer, in this case, was mounted on a flat car on the inner track and the material cars drawn up on the outer. The movement of material, both to and from the mixer, was in consequence reduced to a minimum and the daily output again increased, this time to 140 cubic yards.

In conclusion, Mr. Crudge described briefly the precautions that were taken to protect the concrete in freezing weather.

Following the address, the thanks of the meeting was tendered the speaker by the presiding chairman.

Forestry and Its Relation to Canadian Forests

A joint meeting of Moncton branch and the Gyro Club of Moncton was held in the Palm Room of the Brunswick hotel on April 23rd. This meeting was arranged in connection with the "Canadian Forest Week" campaign for forest protection. H. P. Webb, professor of forestry, University of New Brunswick, delivered an address on "Forestry and Its Relation to the Canadian Forests."

The forestry profession is still very young in Canada. Very little has been done along purely scientific lines of research. However, a start has been made and this phase of the profession has been receiving more attention during the past few years. The day of the old timber cruiser has passed to a great extent, and now private companies, trust companies and banks throughout the Dominion require reports of timber limits made by educated, trained men who can make a systematic survey that is not a casual guess.

The crying need of our forests to-day is protection. Not only protection from fires but protection from too heavy exploitation and protection from insect pests. All of these represent part of a forester's problem. The greatest enemy of our forests has been fire, and unless we can stop the fire fiend from licking up our green timber and young growth the pendulum, which is now swinging to a great era of development and prosperity, will swing in the other direction. Prevention is better than cure, and if every Canadian citizen could be impressed with the value of our great heritage the cure would not be quite so necessary.

The second part of the forester's duty is to prevent depletion from overcutting the annual growth increment. This phase of forestry has been given too little attention in the past. The province of Quebec has enacted legislation whereby lease-holders of Crown Lands are only permitted to cut 80 per cent of the growth increment.

Finally, a forester should have a working knowledge of entomology, especially that branch of it which is known as forest entomology, along with a knowledge of forest pathology. We have, in the past, had serious insect pests in our forests, outbreaks which have cost Canada the loss of millions of dollars.

In Canada to-day we have four forest schools which, it is believed, are adequate to supply the demand for technically trained men. These schools are the University of British Columbia, at Vancouver; the University of Toronto; the Laval Forest School, in Quebec City, and the University of New Brunswick.

The importance of the forest is second only to agriculture, and it produces more than twice the value of the products of the mines. The forests provide 20 per cent of the entire freight hauled on Canadian railways.

The area which is capable of producing timber in Canada, is estimated at about 1,200,000 square miles. Much of this area has suffered from forest fires, and in many instances is covered with young stands of timber. These areas as well as the merchantable stands must be protected from fire, since they represent a great potential value.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
W. McG. Gardner, A.M.E.I.C., Branch News Editor.

St. Lawrence Waterways

On March 29th, the Montreal Branch was favoured with two authentic studies bearing on the most important engineering project of the day when Vice-President Jas. H. Hunter, M.E.I.C., and Councillor O. O. Lefebvre, M.E.I.C., presented papers on the St. Lawrence Waterways.

Paper by J. H. Hunter, M.E.I.C.

In a brief historical review, the author described the discovery of the St. Lawrence river by Jacques Cartier and its subsequent exploration by Champlain, LaSalle and others. Dating from the Treaty of Paris in 1783, when the boundary between the United States and Canada was first defined, the river and Great Lakes assumed a new and international importance. Treaties in 1814, 1842, 1871 and 1909 added to the delimitation of this boundary, established other rights, obligations and interests of both countries along their common frontier and in the national sections of this waterway.

"About one hundred years ago the provinces of Canada started the present canal system, and by the year 1850 a nine-foot draught was available. Later, it was decided to deepen the Welland and St. Lawrence canals and enlarge their locks. The former was completed to a depth of 14 feet in 1887 and the latter in 1901, at a capital cost, to date, exclusive of interest, maintenance and operation, of approximately $65,000,000.

"In 1914, work on the New Welland canal was started. This work will be completed in 1930, at a cost of about $120,000,000. This canal will have eight locks instead of twenty-six and a minimum navigable depth of 25 feet. The time of passage for a boat will be reduced from an average of fifteen to an estimated eight hours. With the opening of this new canal, the largest vessels now operating on the upper lakes of about 10,000 tons will be able to navigate as far as Kingston. With improved channel depth and width throughout the Thousand Island section, these could come as far as Prescott, 110 miles west of Montreal.

"While the present tonnage passing through the St. Lawrence canals is large, the canals are not yet nearly taxed to the limit. It is true that congestion takes place at certain periods of the year, but for the major portion of the time the canals are not operated at anything like their full capacity. Government statistics show it to be less than 50 per cent. The building of the Hudson Bay railway, the ever-growing grain shipments via Vancouver, reduction in eastern railway rates and the opening of the New Welland ship canal will all have their effect on the traffic through the St. Lawrence canals.

"Agitation by the central and western states for improved navigation, combined with the demands of eastern states for a large amount of power at a low rate, culminated during 1919 in the United States government requesting the International Joint Commission which had been created by the Waterways Treaty of 1909 for an investigation of the possibilities of improving navigation and developing power on the St. Lawrence river between lake Ontario and Montreal.

"Two engineers appointed by the Commission at that time to examine the project, after having made extensive surveys and co-ordinated various reports and studies of the whole undertaking, reported in favour of the development of a combined navigation and power scheme in the international section and a navigation scheme in the Quebec national section, estimating the cost of these improvements at $250,000,000. This report was not acted upon.

"Further pressure was brought to bear upon Canada by the United States in 1924, resulting in the appointment of the St. Lawrence River Commission by the United States and the National Advisory Committee by Canada. During the same year the two governments appointed a Joint Engineering Board consisting of three engineers on each side. The Canadian representatives were Messrs. McLachlan, Lefebvre and Mitchell, all members of our Institute. This Board was instructed to investigate and report what improvements would be necessary to make the St. Lawrence river navigable for ocean steamers between Montreal and the head of the Great Lakes, together with the estimated cost of such an undertaking.

"The Joint Engineering Board has now made its final report, in which they come to the conclusion that with specific safeguards the plan is feasible. The estimated cost of the combined project of navigation and power, as recommended by them, is $620,000,000. Of this amount, which does not include the cost of the New Welland canal,—$180,000,000 is chargeable to navigation and the balance of $440,000,000 to the development of some 5,000,000 h.p.

"The proposal, as it now stands, is to dam the river at Lachine and other rapids in the Canadian and international sections; deepen and widen the channel through lakes St. Louis and St. Francis, and the connecting river portion as well as in the international part of the river between Cornwall and lake Ontario.

"The power would be developed as follows:—At the international portion of the river, 2,326,000 h.p.; Soulanges rapids, 1,980,000 h.p.; Lachine rapids, 924,000 h.p. It will be noted that 46 per cent of the power is in the international section, the United States and Canada both being entitled to 23 per cent respectively. As 54 per cent is wholly within the boundaries of the Dominion, Canada is therefore entitled to 77 per cent and the United States to 23 per cent of the total available power.

"From a navigation viewpoint, the success of the whole project depends upon the probability of obtaining return cargoes. Heretofore, owners refuse to take advantage of lower rates by reason of damage in transferring and shipping, delay occasioned in transit, and the proportionate higher rail rate for forwarding from the head of navigation due to short haul.

"From a power standpoint, there can be no question but that the development and sale of such an enormous quantity of power would more than offset the loss suffered on account of transportation. In fact, it is estimated that the sale of power would pay interest, depreciation and maintenance on the total cost and leave a considerable balance towards profit and loss.

"However, if the use of electric power in Ontario and Quebec should grow in the future as it has in the past fifteen years it would be thirty years before we could utilize our portion of the available power, possibly even forty years, taking into consideration the limitations of the specified area between Toronto and Quebec.

"In the author's opinion, there is no objection to an agreement being arrived at between the two countries for the development of power and the improvement of navigation on the international part of the river as and when Canadian requirements may demand. The upper or Morrisburg part of the project could be put through immediately, and the 300,000 h.p. which would be Canada's portion, could readily be absorbed by the Hydro-Electric Power Commission of Ontario. The second development, at the foot of the Long Sault rapids, should only be undertaken when Canada can utilize the power to which it is entitled, about 700,000 h.p. These two developments, with some dredging in the river, would improve navigation as far as Cornwall or throughout the international section of the river. At this point, the United States control of the project in any way, shape or form should terminate.

"The strictly Canadian section should not be undertaken until we are ready to absorb sufficient of the power available to pay for the cost thereof, and it should be controlled and paid for by Canada."

Paper by O. O. Lefebvre, M.E.I.C.

As a member of the Joint Board of Engineers appointed to study the development of the St. Lawrence river for navigation and for the supply of power, it was not to be expected that Mr. Lefebvre would refer to features of the project beyond the scope of the Board's report.

In opening his remarks, the author presented data relating to the Great Lakes which illustrated their ability to serve two great economic uses: as navigation routes of vital concern to the two countries and as an enormous reservoir system to equalize the flow of the St. Lawrence river.

Though the total area of the drainage basins is approximately 300,000 square miles, nearly one-third is occupied by the lake surface itself. So great is the volume of water that a draw down of only one foot on the lake system as a whole would provide the entire average flow delivered to the St. Lawrence for more than four months or a total of 1,008,500 cubic feet per second.

Loss by evaporation is very great, amounting to roughly 40 per cent of the total gross-supply. In fact, the records show months having a negative net supply. Nevertheless, the monthly mean outflow from the lakes during the past sixty-five years has ranged between the narrow limits of 318,000 and 174,000 cubic feet per second, and this minimum was due to ice retardation. The average yearly outflow is even more regular, ranging between 285,400 cubic feet per second in 1861 to 205,500 cubic feet per second in 1895. The average total outflow from 1861 to 1925 has been 246,100 cubic feet per second.

The annual fluctuation of the lake levels in absorbing the seasonal irregularities of supply is also within narrow limits, ranging from 15 to 24 inches, with extreme fluctuations rarely exceeding 36 inches.

Superimposed on the rise and fall of the level surfaces of the lakes shown by the monthly mean levels, there are occasional oscillations due to wind and barometric pressure by which the water is raised temporarily by several feet in a part of a lake and depressed by an equivalent amount in another part. Lake Erie, being shallow as well as long and narrow, is particularly subject to such disturbances. Its fluctuations reach their maximum at Buffalo where, during a western gale, the water has been known to rise eight feet above its monthly mean level, with a corresponding fall of four feet at Toledo. While the systematic recording of the levels of the lakes was not begun until 1860, old records indicate that in 1819 the lakes may have been at substantially the low levels of 1925.

The records of the several water level gauges on the Great Lakes show a gradual steady rise of the earth surface on the northerly shores of the lakes relative to that of the southerly shores. The axis of the present tilting as a whole is approximately twenty degrees north of west and the rate of titling is in the vicinity of six inches per hundred miles per hundred years. If the titling of the earth continues at the present rate, it is to be expected that the depths in the channels of the lower St. Mary's river, where the movement is worst, may be reduced by one foot in a hundred years.

The author presented a discharge formula for the St. Clair river, while ice free, as follows:—

$$Q = 100\ [(H-B) + 0.6\ (h-B)]^{1.8}\ (H-h)^{0.5}$$

Where Q = discharge in cubic feet per second.
H = elevation of Lake Huron (Harbour beach.)
h = elevation of Lake St. Clair (St. Clair flats).
B = a constant of 551.58 at present.

In referring to the diversion at Chicago, the author touched on methods of compensation that would counteract the effect and give results commensurate with their cost. Such means as a series of rock-filled submerged weirs was found to have been satisfactory at other locations.

In opening the discussion, Mr. Geo. Henderson, chairman of the Montreal Board of Trade, expressed his pleasure at being present to obtain information on the engineering problems connected with this project. Though difficult, he observed that these were not insuperable.

Mr. A. L. W. MacCallum, secretary of the Shipping Federation, believed further information was required before it was possible to say where ocean vessels could or could not go.

J. A. Jamieson, M.E.I.C., also felt that further study was required, particularly with regard to the possibility and economics of improving the present system of grain transportation.

Authentic information covering the economic features of the project was greatly needed.

Major C. F. Draper, M.E.I.C., proposed the thanks of the meeting to the speakers which was presented by F. C. Laberge, M.E.I.C., chairman of the Montreal Branch, who presided.

Niagara Peninsula Branch

Walter Jackson, M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

Under the new By-laws, the following officers for the Niagara Peninsula Branch have been elected for the coming year:—

E. G. Cameron, A.M.E.I.C., *Chairman.*
Walter Jackson, M.E.I.C., *Vice-Chairman.*
R. W. Downie, A.M.E.I.C., *Secretary-Treasurer.*

H. M. King, M.E.I.C. C. G. Moon, A.M.E.I.C. N. Bates, A.M.E.I.C.
E. S. Turner, A.M.E.I.C. J. E. Sears, A.M.E.I.C. W. R. Manock, A.M.E.I.C.
R. L. Peek, M.E.I.C. E. P. Murphy, A.M.E.I.C.

Ex-officio

A. J. Grant, M.E.I.C., Vice-President of The Institute.
C. H. Scheman, M.E.I.C., Past-Chairman.
M. B. Atkinson, M.E.I.C., Councillor.

The results of the balloting were made known at a special luncheon meeting, called the "Electoral Meeting," which was held in Thorold on May 4th. Fifty-four ballots were returned out of a total of one hundred and thirteen issued, which is probably as high a percentage as most of the municipal, provincial or federal election returns.

With that spirit of modesty which characterizes the true engineer, a few of the newly-elected officials failed to put in an appearance at this meeting, and in consequence the naming of chairman, vice-chairman and the appointing of a secretary-treasurer was held over until the following Monday.

Therefore, at noon on Monday the newly-elected executive met at the residence of Mr. Grant and prepared to transact this most important business for the branch, and there was very little time wasted. After an excellent meal, prepared under the skilled supervision of a Scottish-Canadian epicure, a motion was tentatively put forward suggesting E. G. Cameron, A.M.E.I.C., as chairman, Walter Jackson, M.E.I.C., as vice-chairman, and R. W. Downie, A.M.E.I.C., as secretary-treasurer.

Much to the surprise of these gentlemen, no question was raised as to this and the motion was then and there adopted unanimously.

The annual meeting was to be held that same Monday evening with Sir Henry Thornton, M.E.I.C., as the principal speaker.

Sir Henry, Lady Thornton and their party, consisting of A. E. Warren, R. H. Fish, T. T. Irving, A.M.E.I.C., E. G. Hewson, M.E.I.C., W. H. Hobbs and H. C. Rochester, arrived in St. Catharines at 2.30 p.m. Members of the executive met them at the station and showed them some of the interesting engineering works in the peninsula, including the lock and harbour of the ship canal at Port Weller and the hydro-electric power plant near Queenston.

Ninth Annual Meeting

Following a policy which had proved successful last year, the executive decided to again invite ladies to be present at this meeting. Lady Thornton had kindly consented to attend and bring Sir Henry, who was to do all the speaking. The combined result was an overflow meeting, with table space at a premium and a severe tax put upon the hotel staff. Some three hundred people, of whom about forty per cent were ladies, attended this meeting, which was held at Niagara Falls on May 7th. Mayor Stevens, of Niagara Falls, welcomed the members of The Institute to his city, and was responded to by Mr. Hewson, who explained that his engineering duties with the National Railways did not always include speech-making, but that he was willing to try anything once and hoped that, if he were successful, it might lead to other invitations and possibly a permanent sinecure as a substitute for Sir Henry.

Alex. J. Grant, M.E.I.C., introduced Sir Henry Thornton, M.E.I.C., as a brother engineer who had also devoted his life to the study of transportation by land instead of by water, and the growth of any large continent such as Canada was insolubly related to the growth of transportation.

Address by Sir Henry Thornton, M.E.I.C.

"This vicinity, which is known as a peninsula, and which probably could be better described as the Garden of Eden, especially in blossom time, has provoked more engineering effort than any other section of Canada. In 1824, the first canal was started, and as the decades passed by that canal, which provided an artery between the Great Lakes and the Atlantic ocean, was increased in size and altered several times until to-day the new Welland canal represents one of the greatest canal works in any quarter of the globe. The locks, I am told, even exceed in some respects those of Panama.

"Not only in the construction of canals has this been a prolific field for engineers, but from Detroit to the Niagara river various lines of railway connect various parts of the United States by a short route to the eastern part. There, too, is a great artery of commerce. To-day there flows across this peninsula and southern Ontario an enormous traffic, not only of the Dominion of Canada, but international. Last year across the Canadian National bridge at Niagara Falls there passed 650,000 loaded and 500,000 empty freight cars, which gives some indication of the importance of this part of Canada. It is singularly appropriate that this branch of The Institute should take pride in the achievements which have and are taking place in the southern part of Ontario and in the Niagara peninsula in particular.

"Engineering is probably one of the most ancient of all professions. There are two distinct features of the work of our ancestors as compared with the modern engineer. The ancient engineer was chiefly concerned with moving masses in two planes, and he had unlimited manual labour. All the great works of antiquity con-

Sir Henry Thornton's Visit to Niagara Peninsula Branch.

sisted solely of hewing blocks of stone and moving them either horizontally or vertically. The accomplishments were extraordinary, not only in the magnitude of the work, but also in the precision. All was carried out and brought to completion by the sacrifice of an enormous number of lives. They went to war to acquire slaves —manual labour. The great works of antiquity were founded on sacrifice of numerous lives.

"After what we saw this afternoon in the inspection of the plant of the Hydro-Electric Commission, I can say that there is a task which vastly exceeds in skill and ingenuity all the accumulated engineering efforts of the ages; and more significant is the fact that this great work was not brought on through the sacrifice of innumerable lives,—was not erected to do honour to some strange god or to protect some great monarch,—but for the development of electrical energy usefully employed in the service of mankind. There we have the difference between the engineers of antiquity and the modern engineers. We, as engineers, should direct our efforts and brain power to the construction of useful works and bring to bear all the science placed at our disposal. However much we may admire the grandeur or with what amazement regard the ruins of ancient days and say that modern engineers could not reproduce the work, I would say that the modern engineer not only exceeds in the monumental character of the work but in the use to which it is put."

Sir Henry then pointed out the opportunities for the engineers to assist in the great national objective to bring into harmonious relations all sections of our country and all our resources, and, after referring to the various resources of the country, concluded his remarks by saying:—

"Certainly the future of Canada is assured,—it only remains for us, as good engineers, to bring into harmonious relationship all the different elements found in this country, both material and social, and if we dedicate ourselves to that purpose and adopt the policy one for all and all for one there would be no country of greater prosperity than the Dominion of Canada, and as the ages roll by our country will become richer and richer and achieve the destiny for which it has been marked by Providence."

At the conclusion of Sir Henry's remarks, C. H. Scheman, who presided, gave out the names of the newly-elected executive and then the meeting adjourned.

Too much credit cannot be given to Messrs. Scheman, Grant and Cameron, and particularly Mr. Jackson, for their hard work and untiring effords towards making this meeting such a success. Owing to the constant demands upon Sir Henry's time, he was unable to give more than one week's advance notice. Dinner arrangements, entertainment, programmes, notices, etc., were prepared in exactly seven days.

MEETING IN HONOUR OF PRESIDENT JULIAN C. SMITH, M.E.I.C.

Another hastily-prepared meeting was responded to in a noble manner by the branch. On a day's notice, some thirty-five members met at luncheon and welcomed the president of The Institute and Mr. Durley.

The luncheon was held at the Lincoln hotel, St. Catharines, on May 17th, and quite a number accompanied Mr. Smith and Mr. Durley to Hamilton afterwards to attend the annual meeting of that branch.

Mr. Cameron introduced Mr. Smith, who spoke briefly and to the point about the affairs of The Institute.

Engineers, said Mr. Smith, were not as highly organized as some of the other professions, and one of the principal objectives of The Institute is to work towards some such organization as exists in the medical profession. To do this, however, it was necessary that engineers should pull together and give of their best towards aiding The Institute.

Ever since branches and provincial organizations had come into being, The Institute had taken on a new lease of life, but he wished to convey a warning that branch affairs might prove to be so absorbing that the parent body would suffer from neglected interest.

There should be some closer amalgamation and understanding; some sort of affiliation with the provincial bodies which would tend to do away with overlapping of effort and bring all engineers upon a uniform basis and working together, but in their respective spheres, towards a common end.

The Engineering Institute of Canada, Mr. Smith pointed out, was the oldest and best-known organization, and as such was logically the nucleus wherein improvements should have their origin. It was governed by a president, vice-presidents and councillors, many of whom gave a great deal of their time and took a lot of trouble with Institute affairs. The old idea that Council at Headquarters ran things for the benefit of a clique in Montreal is exploded.

He and others had sat many evenings from eight until ten going into business details and then from ten to twelve passing on applications for admission. Most councillors, although highly appreciative of the honour, quite willingly step aside when some worthy successor is appointed to take their place.

In conclusion, Mr. Smith pleaded that the greatest latitude be given to Council. Councillors were in touch with the needs of The Institute and could be trusted to judge fairly in the handling of its affairs. The one weakness of our democratic system of government was that men were elected to look after the welfare of the country as a whole, and yet had so little freedom that they thought provincially.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Ottawa Branch was honoured in having as its guest at luncheon at the Chateau Laurier on April 23rd, Mr. F. Handley Page, C.B.E., designer of Handley Page aircraft, who was paying a short visit to Ottawa. Members of the Canadian Club were also invited to attend, with the result that the main dining room of the Chateau was well filled when Chairman Dr. Chas. Camsell, M.E.I.C., rose to introduce the speaker, whom, he stated, it was very gratifying to have as our guest, especially when the attention of the whole world was focussed upon two notable events in aviation,—the crossing of the Atlantic by the Bremen and of the polar regions by Wilkins.

RECENT DEVELOPMENTS IN AVIATION

Choosing as his subject "Recent Developments in Aviation," Mr. Handley Page first spoke of the phases through which aviation has passed in Europe. After the war, he stated, it was thought that every aircraft manufacturer must look to civil development in order to make progress, and some of them started without government subsidies to run aviation lines in Europe. Very soon it was found that in the short distances in Europe such services could not pay, and in the countries where services had been run without subsidy, subsidies were given, and in other countries that had started out with subsidies, the subsidies were increased. As time went on, these subsidies formed a very large proportion of civil aviation companies' receipts, 70 per cent in 1926 in the case of Lufthansa, the big German commercial aviation association, 54 per cent for Imperial Airways in Great Britain, 52 per cent for the Air Union in France and 80 per cent for another French company, the Franco Romaine. In effect, stated Mr. Page, the government of these countries in providing subsidies was virtually running such aviation transport, though under auspices of a civil authority.

This situation led to consolidation of transport interests, so that monopolies were created having the sole subsidy given by the state, such as Imperial Airways in Great Britain and Lufthansa in Germany. In Belgium, there is a single national company which runs services in Belgium and the Belgian Congo; in Holland, a single company; and, in France, more than one company but each assigned one definite route.

Owing to the disparity between what the public is willing to pay for services and the cost of civil aviation, there sprang into being national companies which are in effect nothing more or less than government departments, only conducted under civil auspices. The speaker contended that if such were to continue it would be a very hopeless outlook for aviation for any other purpose than military or naval ends.

The first essential for development of aviation should be a demand for civil air transport and that the people should be willing to pay a price adequate to the cost of the service rendered. The only place where such demands exist are in countries where enormous distances have to be traversed, and in this the speaker believed that no continent offered such wonderful opportunities as North America.

There is here a big demand for quick transport and a great deal of commerce between centres widely separated. Under these conditions, Mr. Handley Page believes that business men will certainly take up flying and be willing to pay prices which in countries of smaller distances are not worth while.

We are seeing such development to-day, he said, in Canada, the United States, Australia and the Belgian Congo. In the latter country a service is run for 1,200 miles over equatorial forests and swamps, covering this distance in two days from the mouth of the Congo on the west side of Africa to Tanganyika on the east. It provides transport into the rich interior mineral area in Tanganyika.

The second essential that will make air transport more widely used, the speaker contended, would be cheaper costs. The 1,000- or 1,200-h.p. plane used enough power to pull a good-sized train and was used merely to transport some fourteen or so passengers. He believed that if sufficient attention is given civil rather than military aviation, the efficiency of aircraft will be increased to where it will be possible to halve the horse power.

The third essential is that flying must be made safe. People should get into their heads that flying is, and can be made, as safe as any other form of transport. The speaker said his own company had been engaged for seven or eight years in developing the device known as the slotted wing, so that safety and security might be given to an aeroplane when it had lost its flying speed and would normally go into a spin and nose-dive into the ground. To make a plane safe it must lift under all conditions, and the slotted wing enables a machine so equipped to continue lifting when the ordinary aeroplane having lost its flying speed would crash to the ground. He believed that with this device a machine could be made absolutely immune from a tail spin or a dive, which are the most fruitful causes of aeroplane disasters.

Along these three lines of greater demand, cheapening of the cost of transport and safety in the air, Mr. Page considered that development would take place. With these requirements satisfied, he believed commercial aviation would go ahead at an enormous rate and would be one of the biggest forms of transportation that the world has yet seen,—a development that would be more important than any other in linking the British Empire together. The greatest need for quick transport was between the Old Country and the new, a route all the way along portions of the British Empire,—Canada, Ireland and Great Britain.

This service Mr. Page commended to the authorities here and in Great Britain. He thought study should be directed toward the development of a flying boat service via Ireland. It will have to be possible to fly for a longer number of hours than is possible to-day. The world's duration record of fifty hours will have to be pushed up to between sixty and seventy, and the corresponding distance that can be flown non-stop increased by a corresponding amount. When this is done and a multi-engine flying boat is capable of doing it, then the day will have arrived when we can see a service between this country and the other side. A greater possibility of demand and a much greater possibility of development, the speaker believed, existed for this great Imperial Airway than exists almost anywhere else. In Ireland and in Canada are the terminal ports through which all transport between the old and the new hemispheres must pass, whether to the United States or Canada.

On this continent, the speaker was glad to see commercial aviation starting to occupy the predominant position, in contrast to Europe, where every country is spending on military aviation more than before the war. He was glad to see on this continent developments taking place which were sure to bring aviation into its real field of usefulness for transport and the general purposes of mankind.

Reclassification of the United States Civil Service

On Friday, May 18th, the Ottawa Branch had as its guest and speaker Colonel E. Lester Jones, director of the United States Coast Geodetic Survey and United States International Boundary Commissioner. Col. Jones selected as his theme, "Reclassification of the United States Civil Service."

"I feel strongly that men who are devoting their lives to the government service and have spent a great number of hard years in college and in research and other preparational works should be well cared for when active and when retired," stated Col. Jones in his opening remarks.

Introduced by Dr. Charles Camsell, M.E.I.C., who presided, the speaker went very fully into the reclassification of the United States Civil Service, which became effective in 1925. Prior to that time, he pointed out, all government employees were underpaid under the system that pertained, of statutory salaries. The type of men who should be sought and retained couldn't afford to stay, and as a result undesirables were hired, there being no others to choose from.

Since the passing of the Reclassification Act, however, the demand for positions was greater and partisanship has disappeared. The act affected 40,000 in the District of Columbia, and a lump sum of $9,000,000 was allocated to deal with cases that were finally passed on by a Reclassification Board after recommendations made by the head of a bureau and the secretary of the department concerned. Whatever action the Board took, in the opinion of Colonel Jones, reflected, as a rule, what the department thought was best. The personnel of the Board was composed of the head of the Civil Service Commission as president, the chief of the Budget and the chief of the Efficiency Bureau. One weakness of the commission, it was pointed out, was its flexibility. Appointments for life, with salaries commensurate with the duties performed by the commissioners, were thought to be desirable by Colonel Jones, who stated that the tasks involved were tremendous, taking literally years to master.

As a result of the 1925 act, statutory salaries were eliminated, and one of the outstanding results was that an average increase of $100 followed, the people who benefitted most being the professional and administrative classes. Chiefs of bureaux who received from $3,500 to $6,000 were increased to $7,500.

Colonel Jones stressed the necessity of giving a man a living wage, which relieved him of worry with a resultant increase in the standard of efficiency. The standard of employees would moreover be raised, because they could all be hand-picked. He did not see why the government couldn't get as much from an employee as a corporation.

Attention was drawn by Colonel Jones to the fact that Congress has just passed another Reclassification Bill, as a result of further study, which aimed to give $2,000 as the lowest professional salary of an entrant in that class; the maximum of a bureau head was likewise raised from $7,500 to $9,000. The latest act affected 135,000 officials, of whom 45,000 were in the District of Columbia and 90,000 in the field.

Carrying the act into effect on July 1st would mean a total expenditure of $20,000,000, or $150 per person. It was aimed to adjust inequalities. Colonel Jones stated that the act had passed both Houses, but it had not as yet received the necessary presidential assent.

D. Roy Cameron, M.E.I.C., president of the Professional Institute of the Civil Service, in a brief and adequate manner, voiced the thanks of The Engineering Institute and the Professional Institute for the illuminating and timely nature of Colonel Jones' interesting talk.

Saint John Branch

E. J. Owens, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Saint John branch was held amid festive surroundings in the Admiral Beatty hotel on the evening of May 3rd, 1928. Supper was served at 6.30 p.m. with twenty-eight persons in attendance and S. R. Weston, M.E.I.C., presiding.

The toast list included "The King," proposed by the chairman and observed in silence; "Our Guests" was proposed by J. L. Feeney, A.M.E.I.C., and responded to by O. J. Fraser, general manager of the New Brunswick Telephone Company, and by F. W. Johnson, of Halifax, Maritime manager for the Northern Electric Company; "The Press," proposed by J. L. Holman, Jr.E.I.C., and responded to by a representative of "The Saint John Telegraph-Journal"; "Other Professions" was introduced by E. A. Thomas, A.M.E.I.C., and replied to by C. F. Inches, K.C.; "The Engineering Institute of Canada" proposed by J. N. Flood, A.M.E.I.C., and replied to by C. C. Kirby, M.E.I.C.

In responding to the toast of The Institute, Mr. Kirby spoke in a reminiscent mood of the early days of his membership in The Canadian Society of Civil Engineers; of the formation of The Engineering Institute of Canada, and the decision to form branches in various centres throughout Canada. Mention was made of steps taken for the formation of the Saint John branch at a luncheon meeting attended by Fraser S. Keith, M.E.I.C., just ten years ago and of the growth of the local branch since then, with its benefits both to members and the community.

Following the toasts, the business meeting was conducted. The report of the auditors was given by J. M. Lamb, Jr.E.I.C., and of the executive by the secretary. The reports from the chairman of various committees were submitted as follows:—Programmes and Meetings, J. N. Flood, A.M.E.I.C.; Entertainment, E. J. Owens, A.M.E.I.C.; Employment, J. A. W. Waring, A.M.E.I.C.; Salaries, A. A. Turnbull, A.M.E.I.C.; Publicity, J. L. Holman, Jr.E.I.C.; Natural Resources and Engineering Industries, Geoffrey Stead, M.E.I.C.; Town Planning, A. R. Crookshank, M.E.I.C.

The excutive report showed that the branch had met ten times during the year and had heard nine addresses delivered before it. Events held in Saint John during that period included four regular meetings for presentation of papers; a joint dinner with the Association of Professional Engineers of New Brunswick; a complimentary dinner for R. J. Durley, M.E.I.C., general secretary of The Institute; a farewell dinner to W. R. Pearce, past chairman of the branch; a joint meeting with the Engineering Society of the University of New Brunswick at Fredericton, and a motor trip to Grand Falls,—distant 200 miles from Saint John. It was also stated that ten members of the branch had attended the annual meeting of The Institute held in Montreal, February 14th to 16th, 1928. Fitting references of regret were expressed regarding the deaths of the late A. W. Wilbur and D. L. Hutchinson during the year.

The total membership at April 30th, 1928, was 78, while the financial statement was satisfactory by showing a surplus.

The report of the scrutineers, F. M. Barnes, A.M.E.I.C., and J. P. Mooney, A.M.E.I.C., showed the following branch officers were elected: Chairman, Geoffrey Stead, M.E.I.C.; Vice-Chairman, W. J. Johnston, A.M.E.I.C.; Secretary-Treasurer, E. J. Owens, A.M.E.I.C.; Member of Executive, J. N. Flood, A.M.E.I.C.

S. R. Weston, M.E.I.C., gave an address thanking the branch officers and members of committees during the past year and escorted Geoffrey Stead, M.E.I.C., to the chair. Short speeches were given by the newly-elected officers expressing appreciation for their election.

A vote of thanks was tendered to the New Brunswick Telephone Company for use of their assembly hall for holding of branch meetings, and to the press for publicity given branch activities.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

River Regulation in Northern Ontario

The regular meeting was held on Friday, April 27th, in the Y.W.C.A. rooms. Following a dinner, W. S. Wilson, A.M.E.I.C., chairman, called upon G. W. Holder, Jr.E.I.C., of the hydraulic department of the Spanish River Pulp and Paper Mills, Ltd., who gave a most interesting talk on "River Regulations Pertaining to Northern Ontario."

River regulation, according to the speaker, might be defined as the science of controlling and regulating the flow of streams so that the most economic use of water may be had for power, irrigation or other purposes or that floods and consequent property losses may be avoided. It consists of levelling off the peaks and filling up the valleys of flow by means of properly located regulating works such as dams and weirs or, as in the case of some rivers in the south, confining the flow to channels where no damage is done.

In order to make an intelligent study of a river to determine its possibilities for regulation, certain records and information must be available, and an outline of the various steps necessary to consummate a storage proposition which is the most common form of river regulation is here given.

1. The study of maps to obtain drainage areas and locate probable reservoirs, etc.
2. The study of existing rainfall and run-off records either for the given drainage area or for one nearby for which there are records. This latter requires good judgment and considerable experience in modifying these records in accordance with good practice.
3. Reconnaissance surveys to get preliminary information on ground as to probable capacity, existence of dam sites, lands which may be flooded, location of roads for construction purposes, etc.
4. Ontario land surveys to locate flood contours; these are required to be filed with the government.
5. Acquisition of storage rights.
6. Topography at dam sites.
7. The design, estimates, specifications of the work. Plans showing the proposed work must be filed with the Minister of Lands and Forests in accordance with "Streams Act 1927" and approved by Lieut.-Governor in Council before construction can start.
8. Location and construction of roads to haul equipment and construction materials to the sites and the construction of the dams themselves.
9. Last and not least is the operation of these dams intelligently to the best advantage of all the interested parties, but with the idea of getting the most economical use of the water, in this case for the mills at Espanola and Sturgeon Falls.

A map of the area covered by Mr. Holder in his work showed clearly the general progress of the development; the location of the precipitation stations and the current metering stations were given, also the location of the various dams that had been constructed during this work. The field work, the design and specifications were handled by Mr. Holder, while Lang and Ross, surveyors and contractors of the Sault, did the contour surveys and the construction of the dams.

The speaker by the use of charts and tables showed how it was possible to calculate the runoff from the data collected at the various stations above mentioned. He said, "We have found the precipitation on these drainage areas to vary from 20 to 33 inches, but the weighted average has been close to 27 inches. The average runoff is about 13.5 inches, of which 8 inches occurs in the average year during the months of April, May and June. This is the refilling period for our storage reservoirs, as about 60 per cent of the runoff occurs then, and it is on this basis that the desired capacity is calculated, providing, of course, that the lake area and surrounding country will admit of impounding all the runoff during these three months. The annual river flow or runoff has been found to be about 45 per cent of the annual precipitation for the Spanish river and 53 per cent for the Sturgeon river.

The monthly average daily flow varies from 5.5 c.f.s. to as low as 0.25 c.f.s. per square mile on the Spanish. Average daily flows as high as 7 c.f.s. per square mile have been experienced in the Sturgeon river, and close to 8 c.f.s. on the Vermillion river. On the Sturgeon river they have some 810 mile-feet of storage and on the Spanish there is about 1,200 mile-feet of storage, of which 20 per cent is controlled by the Spanish River Pulp and Paper Company.

Mr. Holder pointed out that no matter how large an area was used for storage purposes, unless it was properly controlled the efficiency was lost. At each mill there is a water regulation foreman who is responsible for the operation and maintenance of these dams. In general the reservoirs are empty by the middle of March and are ready for the spring refilling. As far as possible, enough storage is carried over to improve flow conditions during January, February and the first half of March.

A very lively discussion followed Mr. Holder's interesting talk and Messrs. Wilson and Speer tendered him a hearty vote of thanks.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

Executive Meeting, April 12th

A meeting of the executive committee of the Hamilton Branch was held in the Royal Connaught hotel at 5.15 p.m. on April 12th, 1928. L. W. Gill, M.E.I.C., was in the chair. Those present included R. J. Durley, M.E.I.C., general secretary of The Institute, and nine corporate members of the Hamilton Branch.

Some routine business was transacted and discussion took place with Mr. Durley regarding general Institute affairs. Letters from Mr. Durley regarding the nominations for the Sir John Kennedy medal and subjects for the Past President's prize were considered. The nomination of candidates for the Sir John Kennedy medal was postponed until the next meeting.

After considerable discussion, several subjects were recommended to Council for the Past President's prize.

The meeting then adjourned for dinner in the same room.

Branch Meeting, April 12th

A meeting of the Hamilton Branch was held in the cafeteria of the Technical Institute on April 12th, 1928, with an attendance of approximately thirty. R. J. Durley, M.E.I.C., general secretary of The Engineering Institute of Canada, was present and addressed the meeting, outlining the functions of Council and explaining some of the difficulties encountered.

The speakers were H. S. Philips, M.E.I.C., who spoke on "Sewage Disposal," and J. R. Dunbar, A.M.E.I.C., who spoke on "A.C. Generators." Both papers were illustrated by lantern slides.

Joint Meeting with A.I.E.E.

The annual joiut meeting of the Toronto section of the American Institute of Electrical Engineers and the Hamilton Branch of The Engineering Institute of Canada was held in the Westinghouse auditorium on April 27th, 1928. L. W. Gill, M.E.I.C., principal of the Technical School aud chairman of the Hamilton Branch, called the meeting to order and spoke a few words of greeting to the Toronto engineers. He announced that word had been received from the general secretary in Montreal that the annual convention of The Engineering Institute would be held in Hamilton next year. The dates would probably be early in February.

C. E. Sisson, M.E.I.C., of the Canadian General Electric Company, chairman of the Toronto section, then took the chair and introduced Mr. G. E. Stolz, manager of industrial engineering for the Westinghouse Electric and Manufacturing Company at East Pittsburgh. His lecture was illustrated by lantern slides and dealt with industrial applications of electricity.

Industrial Applications of Electricity

According to Mr. Stoltz, the manufacturer who was alert and utilized new developments had a great advantage over the manufacturer who continued manufacturing along lines which might have been considered progressive some years ago. He further pointed out that, in general, those who were successful were the ones who were quick to take advantage of new facilities.

During the war, the steel industry responded to the great demand for increased output. After the war, the keen competition which prevailed was met by the introduction of electrical apparatus and rearrangement of machinery to take every advantage of the possibilities of electrification, he said. Mr. Stoltz was well acquainted with electrical conditions in the steel industry, which was his field of concentration with the Westinghouse since 1911.

After the paper, some discussion took place. Mr. E. S. Jefferies, of the Steel Company of Canada, and Mr. C. F. Publo, of the Hydro-Electric Power Commission, contributed to this.

On behalf of the meeting, Mr. Sisson tendered a vote of thanks to the speaker which was heartily applauded. Mr. Gill then took the chair and extended to the Canadian Westinghouse Company a hearty vote of thanks for the use of the auditorium. H. U. Hart, M.E.I.C., general manager of the Canadian Westinghouse Company, replied and announced that the company had supplied refreshments to which all were welcome. The attendance at the meeting was approximately two hundred and fifty; this included about fifty who had motored over from Toronto, several engineers from St. Catharines and neighbouring towns and twenty pupils of the London Technical School under the supervision of J. R. Simpson.

Executive Meeting, May 3rd, 1928

A meeting of the executive committee of the Hamilton Branch was held in Mr. McFaul's office in the City Hall on May 3rd, 1928. Mr. Gill was in the chair and four other members of the executive were present.

Details of the annual business meeting of the branch, to be held about the middle of May, were discussed.

After some discussion, the name of a prominent engineer was submitted to Council for the Sir John Kennedy medal.

A letter from Mr. Durley announcing that Council had accepted Hamilton's invitation to hold the annual meeting here in February 1929 was read. Names of several prominent gentlemen were recommended as speakers for the annual dinner. The dates proposed by Council, namely, February 14th, 15th and 16th, were accepted, subject to later developments which might require the dates to be changed.

D. W. Callander, A.M.E.I.C., and E. M. Coles, A.M.E.I.C., were appointed scrutineers for the election of officers.

Annual Meeting, May 17th, 1928

The annual meeting of the branch for the year 1928 took the form of a dinner-meeting which was held in the Royal Connaught hotel on May 17th. The guests included Julian C. Smith, M.E.I.C., president of The Institute; A. J. Grant, M.E.I.C., vice-president of The Institute; R. J. Durley, M.E.I.C., general secretary of The Institute, and representatives of the Toronto and Niagara Peninsula Branches. Mr. Gill occupied the chair at the opening of the meeting and about forty sat down to dinner.

After dinner, H. U. Hart, M.E.I.C., introduced President Julian C. Smith to the meeting and sketched, briefly, Mr. Smith's career as an engineer. Mr. Smith gave a very inspiring address, which will be more fully reported in next month's Branch News.

Following Mr. Smith's address, E. G. Cameron, A.M.E.I.C., of St. Catharines, introduced A. J. Grant, M.E.I.C., to the meeting. Mr. Gill took the opportunity of thanking the members of The Institute, resident in Ontario, through the Hamilton Branch, for the honour they have done him in electing him vice-president of The Institute. Mr. Grant's address dealt with the Welland ship canal and will be more fully reported in next month's Branch News. R. B. Young, M.E.I.C., spoke briefly on behalf of the Toronto Branch, and expressed the pleasure of the branch at being requested to send a representative to the annual meeting of the Hamilton Branch.

The business portion of the meeting was then proceeded with. W. F. McLaren, M.E.I.C., secretary, presented the secretary-treasurer's report, which is reproduced below.

Report of Secretary-Treasurer, May 17th, 1928

The branch held eight meetings, as follows:—

Sept. 19, 21, 22.—"**The Design and Control of Concrete Mixtures,**" by Rufus S. Phillips, Lewis Institute, Chicago. Attendance, 50.

Oct. 28.—Trip to Welland Canal. Dinner Guests of Niagara Branch. Attendance, 35.

Dec. 12.—"**The Air League of Canada,**" by Maj.-Gen. J. H. MacBrien. Attendance, 50.

Jan. 31.—"**The St. Lawrence Development,**" by F. I. Ker, A.M.E.I.C. Attendance, 120.

Feb. 17.—"**Ontario Highways,**" by R. M. Smith, A.M.E.I.C. Attendance, 20.

Apr. 12.—"**A.C. Generators,**" by J. R. Dunbar, A.M.E.I.C.; "**Sewage Disposal,**" by H. S. Philips, M.E.I.C. Attendance, 30.

Apr. 27.—"**Electric Power in Industry,**" by G. E. Stoltz. Attendance, 220.

May 17.—Final dinner-meeting. Julian C. Smith, M.E.I.C., A. J. Grant, M.E.I.C.

The average attendance was about 70 and the average cost about $25.00.

Membership

Class	Resident	Non-resident	Total
Members	18	6	24
Associate Members	46	13	59
Juniors	7	4	11
Students	34	11	45
Branch Affiliates	28	..	28
Totals	133	34	167

One very carefully-prepared paper has been submitted for Student prize and two papers for Senior prize, but no action has been taken as yet.

The executive held eight meetings, with an average attendance of six out of a possible ten.

At the meeting of January 6th, the first discussion took place regarding the invitation to hold the annual meeting of The Institute in Hamilton. This was finally approved at the branch meeting of January 31st, and presented by our delegates, Messrs. Gill and Darling, at the Montreal meeting in February. The Council accepted our invitation unanimously on April 20th, proposing the dates of February 14th to 16th, 1929.

Financial Statement

Receipts		*Expenses*	
Brought forward	$627.15	Printing	$ 66.24
Branch Affiliates, 26 at $3.00	78.00	Postage and stationery	26.85
Journal subscriptions 1928, 7 at $2.00	14.00	Cafeteria and halls	50.10
Journal subscription 1927, 1 at $2.00	2.00	Telegrams	1.19
Rebates on members fees	56.70	Expenses of speakers	5.00
Branch news	11.71	Delegates to Montreal	62.60
		Journal subscriptions	14.30
		Total	$226.28
		Balance	563.28
	$789.56		$789.56

No rebates or branch news payments received since November 1927.

Expenses of dinner and allowance for stenographer still to be paid.

Election of Officers

The results of the election of officers for the next branch year were then announced. The following will form the Branch Executive for the coming year:—

Chairman	W. L. McFaul, M.E.I.C.
Vice-Chairman	J. A. McFarlane, M.E.I.C.
Secy.-Treas.	W. F. McLaren, M.E.I.C.
Executive	H. A. Lumsden, M.E.I.C.
	G. R. Marston, M.E.I.C.
	F. P. Adams, A.M.E.I.C.
	W. D. Black, A.M.E.I.C.
(Ex-officio)	L. W. Gill, M.E.I.C.

Mr. Gill, before relinquishing the chair to Mr. McFaul, the incoming chairman, remarked that, during the past year, the Hamilton Branch of The Engineering Institute of Canada had proposed to the Hamilton Chamber of Commerce that an engineering committee be formed which would handle matters on which the Chamber of Commerce desired information. He stated that an important matter has been reported to this committee and is, at the present time, under consideration.

Mr. McFaul then took the chair and thanked the branch for the honour in electing him chairman. He requested J. A. MacFarlane, F. P. Adams, A.M.E.I.C., and W. D. Black, A.M.E.I.C., the newly elected members of the Executive Committee, to come forward so that all the members might know them.

On the motion of L. W. Gill, M.E.I.C., seconded by A. H. Munson, A.M.E.I.C., W. D. Black, A.M.E.I.C., was appointed chairman of the main committee to take charge for the Annual General and General Professional Meeting of The Engineering Institute of Canada to be held in Hamilton in February 1929. The appointment of the chairmen of the various committees who will have charge of the detailed arrangements for the meeting will be left to Mr. Black.

Throughout the dinner Kalani's orchestra supplied music. Police Constable Clark interrupted the dinner to bring Mr. Marston to task for certain alleged infringements of the Statutes of the province of Ontario. After a heated discussion, in which Mr. Marston managed to clear his good name, the charge was withdrawn, but the chairman demanded some form of reparation. Mr. Gill first requested a dance, but the constable could not supply this and offered to fight any member present. As a compromise, Police Constable Clark rendered a few of the old favourite songs which were received with applause by the meeting. He repeated the entertainment shortly afterwards.

Preliminary Notice

of Applications for Admission and for Transfer

May 18th, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in June 1928.

R. J. Durley, *Secretary.*

---

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the Council. or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ARNOLD—GUY WALKER, of Hamilton, Ont., Born at Sussex, N.B., July 20th, 1890; Educ., B.Sc., Univ. of N.B., 1912; 1911 (summer), in transformer assembly dept. of C.G.E. Co., Peterborough; 1912-14, apptce. in elec. test dept. of Can. Westinghouse Co.; 1920 (Jan. to Sept.), instructor in elect'l engrg., Dept. of Soldiers' Civil Re-establishment, Fredericton, N.B.; 1921-22, asst. to dist. engr., Can. Westinghouse Co., Montreal; June 1922 to date, with Can. Westinghouse Co., Hamilton, as follows: June to Dec. 1922, designer of induction motors; Dec. 1922 to Sept. 1925, designer of d.c. motors, generators, exciters, railway motors, etc.; Sept. 1925 to date, i/c all elect'l design of d.c. motors, railway motors, d.c. generators and exciters, synchronons, converters and their accessories.

The Cariboo Road

Its Origin, History and Re-construction

Patrick Philip, M.E.I.C.

Deputy Minister and Public Works Engineer, Provincial Government of British Columbia.

Paper presented at the Western General Professional Meeting of The Engineering Institute of Canada, at Vancouver, B.C., June 8th, 1928

Introductory and Historical

On the North American continent there are several highways of outstanding merit and importance, but chiefly because of its historic interest, the Cariboo road occupies a foremost place. The "Lincoln highway" or the "Dixie highway" are longer and traverse a more populous and diversified country, but the Cariboo road with its romanceful history occupies a unique position in highway annals. Mere mention of the name "Cariboo" conjures up stirring tales, reminiscent of the enterprise and endurance of the earliest explorers and pioneers of the province of British Columbia. In fact so insistent was the demand for the retention of the designation "Cariboo road" that the subject was brought up at the 1925 session of the provincial legislature and the following resolution unanimously passed:

> "Whereas it is proposed to change the name of the old Cariboo Road to Fraser Canyon Highway:
>
> "And whereas the name for this old road was derived from the discovery of gold on Williams Creek as far back as the year 1857, and the miners, merchants and also pioneer settlers paid a large amount of tolls towards the building of this road:
>
> "Therefore be it resolved that in respect to the old pioneers of this Province and our native sons especially of Cariboo, and in the interest of the history of British Columbia, this old historic road shall continue to be known as the *Cariboo Road*."

To commemorate the work and worth of the pioneers associated with the conception and construction of the old Cariboo road a huge granite boulder monument was erected in 1925 by the Historic Sites and Monuments Board of Canada, at Yale, on the site of the starting point of the original wagon trail.

Officially, the Cariboo road commences at Hope and is virtually a continuation of the old Yale road, (sometimes known as the Transprovincial highway), which traverses the Fraser valley eastward from New Westminster. Reference to the key map, (see figure No. 1), will show that the Cariboo road proper extends from Hope to Prince George, 432 miles, or a total distance of 536 miles inland from the Pacific coast. With the exception of the portion between Lytton and Clinton, (87 miles), which traverses the Thompson and Bonaparte valleys, this highway approximately parallels the Fraser river throughout its entire length.

This great highway so rich in romance has recently been reconstructed, partly to satisfy the demands of modern traffic conditions and partly to provide transprovincial connection with the Dominion highway system.

To engineers the original opening of the Cariboo road is the story of the first major engineering project in the West. How fortunate the Colony was in having a Colonial Governor possessed with such vision that in the settlement of the Colony his first concern was that the wagon roads should be carefully planned and supervised by competent engineers. Historically the following facts should be of comparative interest:

In 1808, Simon Fraser, the noted explorer, came overland to the Pacific by way of the river which subsequently perpetuated his name. According to his own journals that portion of the journey through the canyon filled him with a deep gloom,—"This country is a series of cascades intercepted with rocks and bounded by precipices and mountains that seem to have no end. I scarcely ever saw anything so dreary and so dangerous. Whatever way I turn my eyes, mountains upon mountains, whose summits are capped with eternal snow, close the gloomy scene. As for the road by land we could scarcely make our way with even our guns, we had to pass where no human being should venture." This is our first introduction to the famous Fraser canyon through which the original Cariboo road was built in the Sixties and later two transcontinental railways running parallel along the gorges of the mighty Fraser and Thompson rivers. The engineering profession may be justly proud of the skill and daring of the engineers who surveyed the routes of the above projects, the Cariboo road in 1858, the Canadian Pacific Railway in 1882 and the Canadian Northern Railway in 1910.

When gold was discovered in the bars of the Fraser in 1857-58, the first route into the Cariboo gold fields was by way of the lower Fraser, (see figure No. 1), up the Harrison river into Harrison lake, thence to the head of the lake over the trail built in 1857, to Little Lillooet lake. From Lillooet lake to Anderson lake, a distance of approximately 24 miles by road, the route continued three-quarters of a mile across a tramway from Anderson lake to Seaton lake, finally reaching the road to Parsonstown on the banks of the Fraser, near to what is now called Lillooet. From this point the road was built on the left bank of the Fraser through to Clinton via Pavilion mountain, and from Clinton through to the Cariboo country.

As will be seen from the map, (figure No. 1), this route was indirect and inconvenient, requiring many portages which added greatly to the cost of hauling supplies. Representations were therefore made to Governor Douglas to construct a road by the Fraser canyon route. Sometimes we are inclined to doubt the wisdom of the present generation of road enthusiasts when they present petitions for roads through seemingly impossible country. What then shall we say of those early pioneers who submitted to their Governor a request for such a vast undertaking? Truly " your young men shall see visions."

Prior to the construction of the wagon road two mule trails were built through the Fraser canyon, but the grades were prohibitive and the trails unsafe for ordinary travel. The trails, however, served to demonstrate the feasibility of this route and the possibility for improvements thereto. In 1862 a party of Royal Engineers built the first six miles of the road north from Yale, (then the head of navigation). Contracts were awarded in sections for the remaining portions of the work as far as Spuzzum or Alexandra bridge, (named in honour of the late Queen Alexandra), and built by Thomas Spence. The section from the bridge to Boston Bar, (16 miles), was built by Joseph W. Trutch; that from Boston Bar to Lytton, (30 miles), by Thomas Spence, and that from Lytton to Cooks Ferry, (24 miles), by Walter Moberley, (the eminent engineer who was later connected with the construction of the Canadian Pacific Railway, and to whom belongs the credit for the most difficult engineering work on that railway through the Selkirk mountains). All the above road construction was undertaken in 1862. Considering the disadvantages and dangers under which these pioneer road builders laboured and the magnitude of the work involved, one can truly affirm that they were real " Empire Builders," men of vision and courage earnestly devoted to their tasks.

From the map, (see figure No. 1), it will be noted that a link remained to be built between Cooks Ferry and the road originally built to the Cariboo via Harrison lake. This section was completed in 1863, a substantial bridge being built across the Thompson river in 1864 by Thomas Spence at Cook's Ferry, subsequently known as Spences Bridge.

Writing in his excellent " History of British Columbia," Judge Howay thus describes early scenes:—

> " The Great Cariboo wagon road—the Appian Way of British Columbia—reaching from Yale to the heart of the mining region, amidst the tumultuous mountain masses of the Cariboo, had not yet, (1860), been dreamed of. The boldest financier might well hesitate and draw back when from the mule trail or the Upper or Lower canyon trails, he surveyed the Little canyon and the Big or Black canyon of the Fraser and estimated the cost of a passable wagon road where a goat could scarce have gained a foothold. We now approach the commencement of that eighth wonder of the world."

Continuing, he further graphically describes the original road thus:—

> " Reaching from Yale, the head of navigation, to the mines of the Cariboo, a distance of nearly 400 miles, and solidly and substantially constructed by our infant Colony in less than three years, this road was the pride of British Columbia and a source of wonder and admiration to its visitors, who were loud in their expressions of surprise at the daring conception and skilful execution of the work. Here the road was supported by piling, there built upon immense masonry ' fills,' sometimes on gigantic crib work, the ruins of which yet remain, sometimes cut through a sheer rock bluff, now almost at the water level, and anon raised to giddy elevations whence the river seemed but a silver ribbon."

Such then is a clear and concise description of the old road, built under careful and competent engineering supervision over sixty years ago. What a tribute to the skill of the engineers and the labours of the pioneers. As engineers we are particularly gratified that the local branches of The Engineering Institute collaborated with the Association of Professional Engineers of British Columbia in the erection of a cairn at the site of the old Alexandra bridge, commemorating the work of the Royal Engineers engaged in the construction of this great road. The following is inscribed on the cairn:—

1858 — 1927

IN COMMEMORATION

of the work of

HER MAJESTY'S ROYAL ENGINEERS

and in respectful admiration of the
skill and energy displayed by them
from 1858 to 1861 in the construction of

THE ORIGINAL CARIBOO HIGHWAY
THROUGH THE FRASER CANYON

This Tablet is Erected and Dedicated

The Engineering Institute of Canada
and
The Association of Professional Engineers
of British Columbia

ANNO DOMINI MCMXXVII

With such a description before us we have a standard of excellence which the modern engineer could well emulate.

Considering the prevailing modes of transportation set amidst such scenic splendor, one can visualize the panoramic scenes of the Sixties.

The stage coaches with their adventurous passengers, the gold escorts with their scarlet trappings, the prairie schooners with their varied freight—all such motley conveyances traversed this grand highway. Someone has said the Cariboo road was the " Symbol of Liberty, Equality and Fraternity." Evidently its construction at comparatively high expenditure in the early life of the Colony was subsequently justified. Over $30,000,000 in gold was transported safely to the coast from the rich placer mines of the Cariboo.

With the advent of the " Iron Horse," the destruction of this highway seemed inevitable, particularly as there was little room for both road and railway in the canyon. The construction of the Canadian Pacific Railway in the early Eighties under the terms of the British North America Act witnessed the " beginning of the end " of the old Cariboo road. After the construction of the railway there was still the semblance of a wagon trail on some portions of the road diverted in terms of the contract. However, as the railway virtually destroyed the road as a continuous highway, and, moreover, offered a quicker and cheaper method of transportation, the highway, through lack of maintenance, lapsed into disuse.

The Alexandra bridge over the Fraser at Spuzzum, (demolished several years ago), suffered through the ravages of the flood of '94, and to complete the destruction of the road, the provincial government, wisely or unwisely, permitted the remainder of the old Cariboo road between Chapman and Cisco to be practically disrupted by the Canadian Northern Railway in 1912,—exactly half a century after the road was built.

Who cared, in 1886, about the cumbersome and costly means of transportation over the highway when a modern railway was built for the express purpose of carrying freight and passengers from the Atlantic to the Pacific. A lethargic public had so little vision in 1912 that it could not foresee the immense potentiality of the old road as the nucleus of a modern motor highway. Although the automobile age had then arrived, the cry was for more railways, and as the Fraser river canyon could not, as in the case of the Canadian Pacific Railway, accommodate within reasonable limits both highway and railways, the former was sacrificed. But in the case of the construction of the Canadian Northern Railway no provision was made for highway diversions, and consequently the Cariboo road, through the Fraser and Thompson canyons, was practically eliminated. Nevertheless the increasing popularity of the automobile emphasized the demand for more motor highways. As an illustration: in 1912 there were 4,289 motor vehicles registered in this province, in 1916 this number had doubled, and rapidly increased to 28,136 in 1920. (In 1927 the figures had reached to over 75,000.) Thereafter travel by road developed to such an extent that representations were made to the provincial government to build a highway from the coast to the interior, and also to provide a direct route through the Dominion for the Trans-Canada highway. Until the reconstruction of the Cariboo road all through highway traffic had perforce to detour at length via the state of Washington.

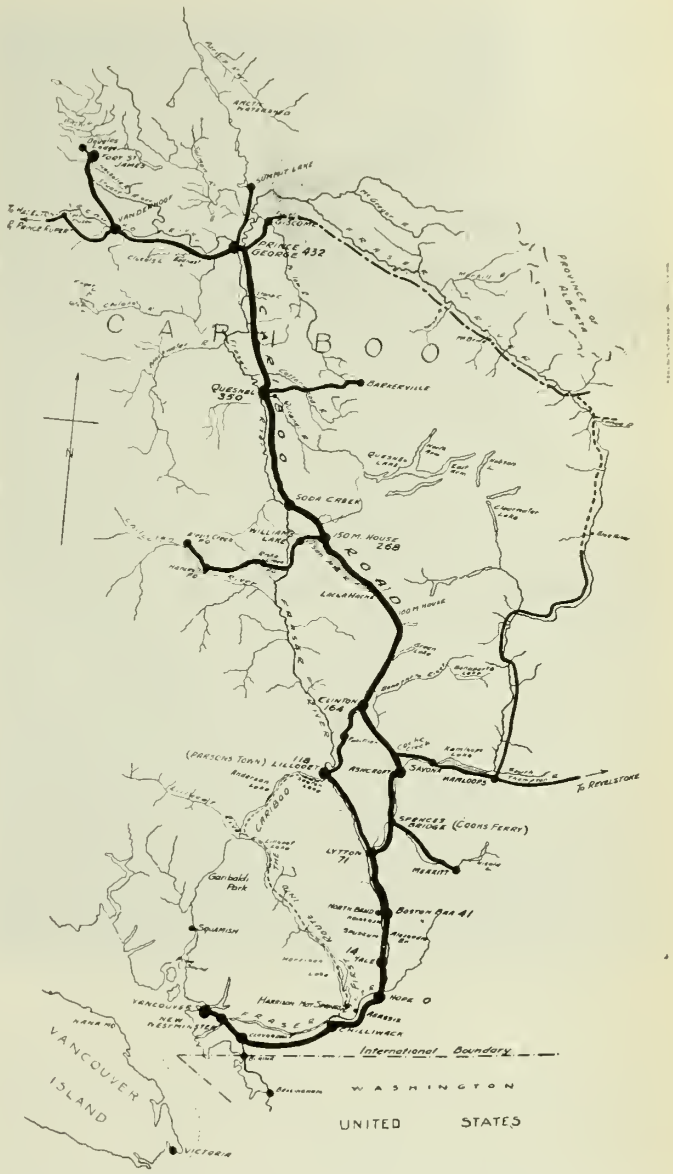

Figure No. 1.—Map showing the Location of the Cariboo Road.

Location

Those familiar with the topography of British Columbia will appreciate the fact that in the selection of a route for a highway from the coast to the interior many economic and engineering factors had to be taken into consideration. While important, initial cost is by no means the only factor in the final analysis. Annual maintenance costs, length of time the road will be open for traffic throughout the year, elevations, grades, alignment, proximity to road surfacing material along the route—all such elements have an important bearing in the choice of a transprovincial highway. Consequently careful preliminary surveys were made of three important routes: (a) the location of the old Cariboo road; (b) the Hope-Princeton route via Allison pass, (elevation approximately 4,450 feet); (c) by Harrison lake to Lillooet, (the first route adopted in 1857 and later abandoned by the pioneers after the Cariboo road was built).

With the foregoing economic and engineering factors prominently in view, publicly supported by sentimental regards for the old Cariboo road, location of the old highway via the Fraser canyon was finally selected.

Following the practice adopted on railway construction, previous to the letting of the contract, the preliminary line was extensively revised, the most important revision being in the vicinity of " Hell's Gate " in the Fraser canyon. Here the old road was " galleried " in the cliff close to high water line. When the Canadian Northern Railway tunnelled through this cliff at the west portal a huge slip occurred during railway construction. Many thousands of yards of rock fell into the Fraser river, causing a blockade, (later removed at great cost), in one of the narrowest channels, in consequence of which it is alleged that the salmon run on the river was adversely affected, causing a serious loss to the fishing industry, which, according to experts, is still suffering from the effects of this blockade. With this catastrophe still fresh in mind, and realizing the possibility of a repetition thereof should extensive blasting be done in the vicinity of the tunnel, careful inspections were made in cooperation with railway officials, which investigation confirmed the decision of the Department's engineers, viz., to locate the road in such a position as to avoid any interference with this section. Hence, following reconnaissance surveys a route was finally located at an elevation of about 650 feet above the Canadian Northern Railway at Hell's Gate. This established a new control point, and necessitated the revision of a considerable portion of the prelimi-

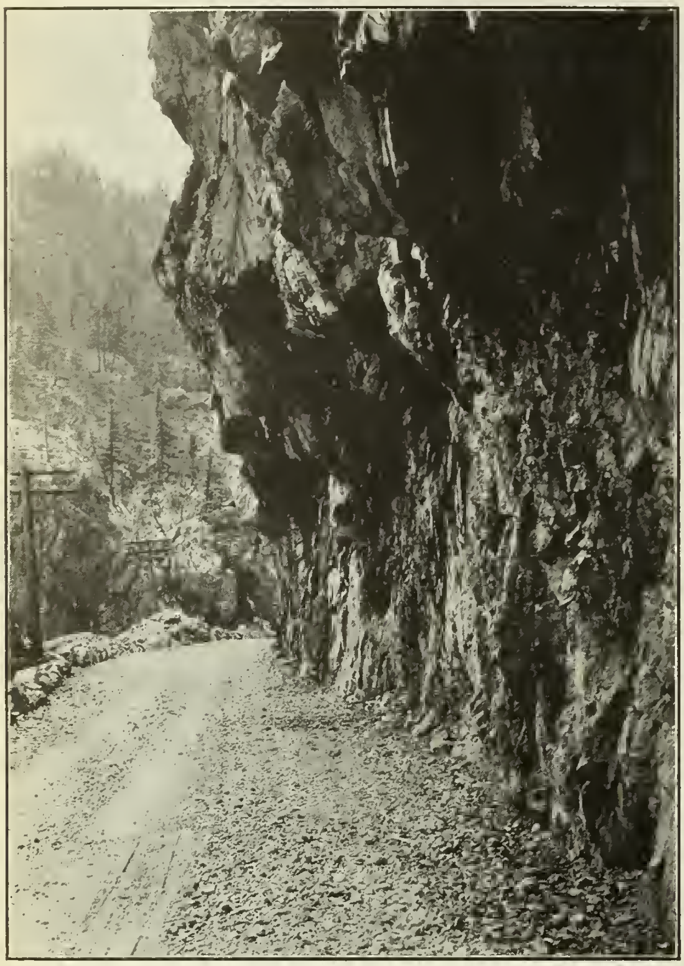

Figure No. 2.—Rock Gallery, one mile East of Yale.

nary location, excellent though it was. By adopting the revised location the engineers were able, (with the exception of one crossing near the east end of the Alexandra bridge), to avoid all level and overhead crossings of the railway through the entire length of the Fraser canyon, a distance of about twenty miles. When it is remembered that there were ten crossings of the old road by the Canadian Northern Railway the merits of the new location will be better appreciated.

As if linking in a bond of sympathy the new with the old, here and there the new road is in close contact with the old one. In fact the massive retaining walls built of random rubble sixty years ago still stand, a fitting tribute to the skill of these early roadbuilders. To the writer it is inspiring to contemplate the old roadbed and reflect on the efficient work of the master builders of 1863.

From an engineering standpoint the following facts concerning the location should here be of considerable interest and instruction:—

Grades:

Except at Jackass mountain, on the old road, where 10 per cent was imperative, the maximum grade was 8 per cent, reduced when possible on curves. At all abrupt changes of grade, vertical curves were introduced.

Curvature:

"Exterior" curves round a rock bluff, minimum radius 100 feet. "Interior" curves round a ravine, minimum radius 60 feet. Wherever feasible, however, 100 feet has been considered a minimum for all curves. A 300-foot clear view was always aimed at.

Super-elevation:

Emphasis was placed on the proper super-elevation, where necessary, of all curves,—a feature which has added both to the safety and comfort in negotiating the numerous curves.

Roadbed:

Minimum width on tangents, 16 feet clear of ditches. Minimum width on curves, 20 feet. In many places, the roadbed is 24 feet wide.

A minimum width of 14 feet 8 inches has been provided for on the timber bridges, the average estimated life of which is fifteen years,—galvanized sheeting having been freely used to protect all chord timbers, etc., from wet weather and overhead drippings. It is not found either necessary or economical to paint timber structures.

Construction

In the winter of 1924 contracts were called for the construction of portions of the road in three sections—(1) Yale to Alexandra bridge, (13½ miles); (2) Alexandra bridge to Boothroyd, (21 2/3 miles); (3) Lytton to Spence's bridge, (24 miles). The sections from Hope to Yale, (14 miles), and Boothroyd to Lytton, (22 miles), were carried out by the provincial government day labour forces under the direction of the district officials. Since in the Hope to Yale section the existing road, built in 1875, was both badly located, having no fewer than nine grade crossings of the Canadian Pacific Railway, and indifferently constructed, it was practically rebuilt. In the relocation of this 14-mile section only one of these crossings was perforce retained, (and even then on an improved location), thus demonstrating the commendable desire of the engineers to make the new highway as safe as possible even at considerably greater initial expenditure. With the "safety first" idea always prominently in view, no fewer than twenty-six Canadian Pacific Railway and ten Canadian Northern Railway crossings were eliminated, and of those remaining, two crossings are overhead, one is a subway and four are protected by automatic safety signalling devices. In constructing this section by day labour the department employed efficient foremen and workmen, chiefly local residents, together with the most modern plant, such as gasoline shovels, compressors, jack hammers, caterpillar tractors, etc.

Section No. 1, between Yale and Alexandra bridge, was built by contract in 1925-26 by W. P. Tierney and Company, Vancouver, on a unit price basis. The excavation was classified under solid rock, loose rock, hardpan and earth, (or common excavation). The following items were also covered by unit prices: dry masonry, retaining walls, timber cribbing, metal pipe culverts, round log curbing and timber trestles. The specification stipulated that the excavation prices included the loosening, removal and disposal of the various materials comprised in the different classifications, together with excavation for cribs, walls, rip-rap, culverts, bridge abutments, trestle bents and galleries. The grading of this section was carried out more substantially than originally intended, timber trestles, (previously planned for economy sake), being subsequently replaced by substantial fills. Careful revision of the preliminary survey of this line added over one mile to the length but with compensating advantages in alignment and grades. Being located adjacent to the Canadian Pacific Railway extreme care had to be exercised, one dollar per minute being the penalty for all delays or holdup of railway traffic. Fifteen trains passed daily over the railway, to safeguard the operation of which the telegraph wires were laid in duplex cables at all hazardous points. For the safety of all trains linemen and watchmen patrolled the track throughout the undertaking. A typical view of the rock gallery excavation on this road is shown in figure No. 2.

An outstanding example of grade separation can be seen

Figure No. 3.—View of River, Road and Rail, between Yale and Alexandra Bridge.

1½ miles east of Yale, where the highway is carried overhead across the railway at the east portal of the tunnel.

Travellers by the Canadian Pacific Railway will notice that as this section continues westerly:—

> " *Where the mountain pass is narrow*
> *And the torrent white and strong,*"

the canyon gradually contracts, thereby leaving little room for a road alongside the railway. Consequently careful location was necessary to obviate encroachment on the railway roadbed. Figure No. 3 shows an interesting and instructive view illustrating this unique feature of construction, viz., river, road and rail approximately paralleling each other. Attention should also be directed to the substantial dry stone wall constructed as a curb at the more dangerous points on the outside of the roadbed.

Practically all of this section was undertaken by station men, one gang doing 3 miles thereof. The excavation was handled partly with light cars and trucks, and partly by wheelbarrows. Around the first two Canadian Pacific Railway tunnels galleries were cut in the rock, (see typical gallery—figure No. 4), and in rock slides care was taken not to disturb " key " rocks. Some of the old retaining walls were used and short stretches of the old road are just as originally constructed, with stones, etc., cleared off the roadbed. Trestles were built between the tunnels at Yale and an unusually long one at Saddle Rock. For surfacing purposes the department was fortunate in procuring excellent limestone gravel adjacent to the right-of-way. This contract was commenced in January 1925 and completed in February 1926.

Inclusive of gravel surfacing, the cost of this 14-mile section averaged roughly $20,000 per mile, certainly not excessive, considering the comparatively large percentage of solid rock work, (about 65,000 cubic yards), or more than twice the yardage of earth work, the proximity of the operations to the railway, and the hazards thereby incurred. The following is the range of unit prices paid on all the contracts for the Cariboo road:—

Clearing	$100.00 per acre
Grubbing	$200.00 to 300.00 " "
Excavation (200 feet free haul)	
(a) Solid rock	$1.75 to $2.00 per cu yd.
(b) Loose rock	0.65 " 0.85 " " "
(c) Hard pan	0.50 " 0.85 " " "
(d) Earth	0.30 " 0.35 " " "
Overhaul	
Per cubic yard per 100 feet	0.04 per cu. yd.
Retaining Walls	
Dry masonry	$4.75 to $5.00 per cu. yd.
Cribbing	
Square timber	$40.00 to $50.00 M. feet B.M.
Metal Pipe Culvert	
12 to 36 inches diameter	$2.25 to $7.55 per lin. ft.
Trestle Bridges	
Square and hewn timber	$55.00 M. feet B.M.
Curbing	
Round logs	$0.20 to $0.35 per lin. ft.
Tunnelling	$100 per lin. ft.

Alexandra Suspension Bridge

About 1.5 miles north of Spuzzum the highway crosses to the east bank of the Fraser river on the Alexandra suspension bridge. This bridge was built practically on the same site as the old bridge but 10 feet higher, and, therefore, beyond possibility of damage by extraordinary floods. This structure was designed with a view to preserving, as far as practicable, the historic features of the former suspension bridge, but at the same time to provide for modern traffic requirements. The piers and wing walls are of 1:2½:5 mass concrete, (aggregating 1,066 cubic yards), faced with random rubble masonry to harmonize with the scenic setting of this structure. The towers, the tops of which are 35 feet above the bridge floor, are of reinforced concrete, (1:2:4), containing 202 cubic yards. The anchor blocks, rendered necessary owing to absence of stable solid rock anchorage, are of mass concrete, (1:2½:5), containing 638 cubic yards.

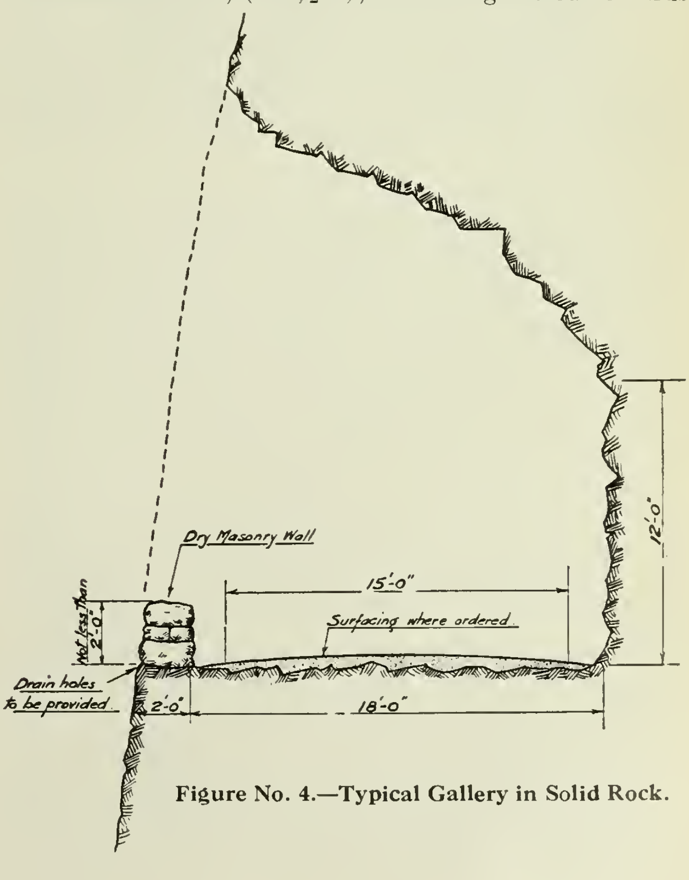

Figure No. 4.—Typical Gallery in Solid Rock.

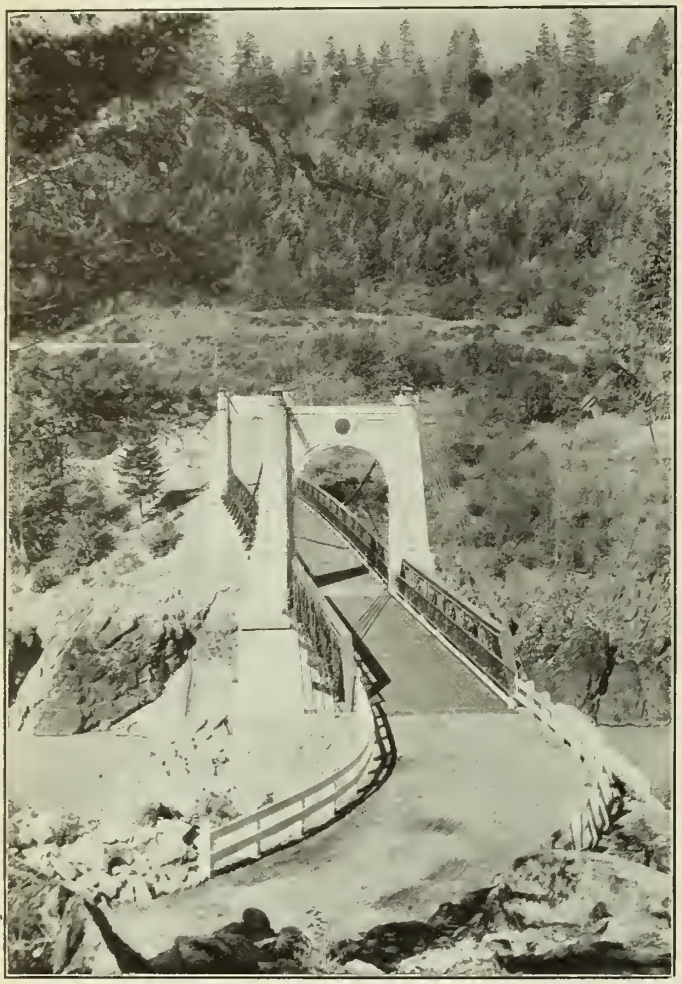

Figure No. 5.—Alexandra Bridge, Yale District.

On Cariboo highway, crossing Fraser river on same site as old Alexandra bridge built by Governor Trutch in 1863-64. One 277-foot steel suspension span and 90-foot steel truss span on concrete towers and piers, with footings faced with stone masonry. Concrete work and steel fabrication done by contract. Erection of all steel done by day labour.

The main suspension span is 270 feet long and is supported by eight 2½-inch diameter steel wire cables. The saddles for carrying the main cables on the towers are of the roller bearing type. The span is a steel stiffening truss with a timber deck having a 16-foot clear roadway. The east approach to the suspension span consists of a 90-foot steel pony truss, containing 124 tons of steel. The timber deck is finished with a bituminous surface and the timber guard rails are painted white in contrast with the black paint of the steel.

The concrete work was satisfactorily carried out by the The A. B. Palmer Company, Vancouver. The Canada Wire and Cable Company furnished the cables and hangers. The steel was fabricated by Coughlan Steel Works, Vancouver, and erected by the provincial day labour forces under competent supervision. The preparatory work in connection with test pits and foundations was commenced in the middle of August, 1925, and the entire structure satisfactorily completed the following August. On completion of the stiffening truss, the bridge was satisfactorily tested at different panel points with six loaded gravel trucks of 4 cubic yards capacity, (aggregate load 72 tons). As a result of measurements taken during construction of the 270-foot span, it was possible to determine the total amount of stretch, (viz., 16⅝ inches), in the main cables. The following summary of tests on concrete work which was undertaken by a "Little Wonder" mixer should prove instructive:—

Cement

Cement used in 1:2:4 mix.... 6.50 sacks per cubic yard
" " " 1:2½:5 ".... 4.80 " " " "

According to laboratory tests, initial set took place in 2½ hours; final set took place in 5 hours; average tensile strength sand briquettes at 28 days, 400 pounds per square inch.

Aggregate

The imported fine aggregate showed a fineness modulus of 2.71; the coarse aggregate 7.22.

Water

The quantity of mixing water used varied somewhat, according to the amount of moisture carried by the aggregates, but it was kept down to a maximum of 4 gallons per sack of cement. After having been analyzed and found suitable, Fraser river water was used.

Results of Tests

Average compressive strength of 1:2:4 mix at 28 days.......... 3,240 pounds per square inch
Average compressive strength of 1:2½:5 mix at 28 days........ 2,308 " " " "

The total cost of this structure was $101,793.58, an analysis of which, together with classified distribution, is shown in table No. 1.

The section of the Cariboo road from Alexandra bridge to Boothroyd, (21 2/3 miles), was undertaken by the A. B. Palmer Company, Vancouver. From the east end of the bridge the road loops up to cross the Canadian National Railway, (meantime for economic reasons on a grade crossing which later may be replaced by a subway), and continues above the railway on an entirely new location except for a short stretch at Chapman's station where the old road is followed.

The road climbs gradually to the summit of this section, (approximately 1,100 feet above sea level), where such was the topography that it was imperative to tunnel the gigantic granite rock bluffs with two tunnels, the first 260 feet, and the succeeding one 90 feet in length, both on tangents. The longer tunnel was made 27 feet wide and 17 feet in height, and since both tunnels were bored through hard rock devoid of seepage, it was unnecessary to line them.

Since the tunnels are the only ones forming part of a highway in the Dominion, they are unique in highway con-

Figure No. 6.—Tunnels 19 miles North of Yale.

Tunnel at right side of picture in background is 260 feet in length.

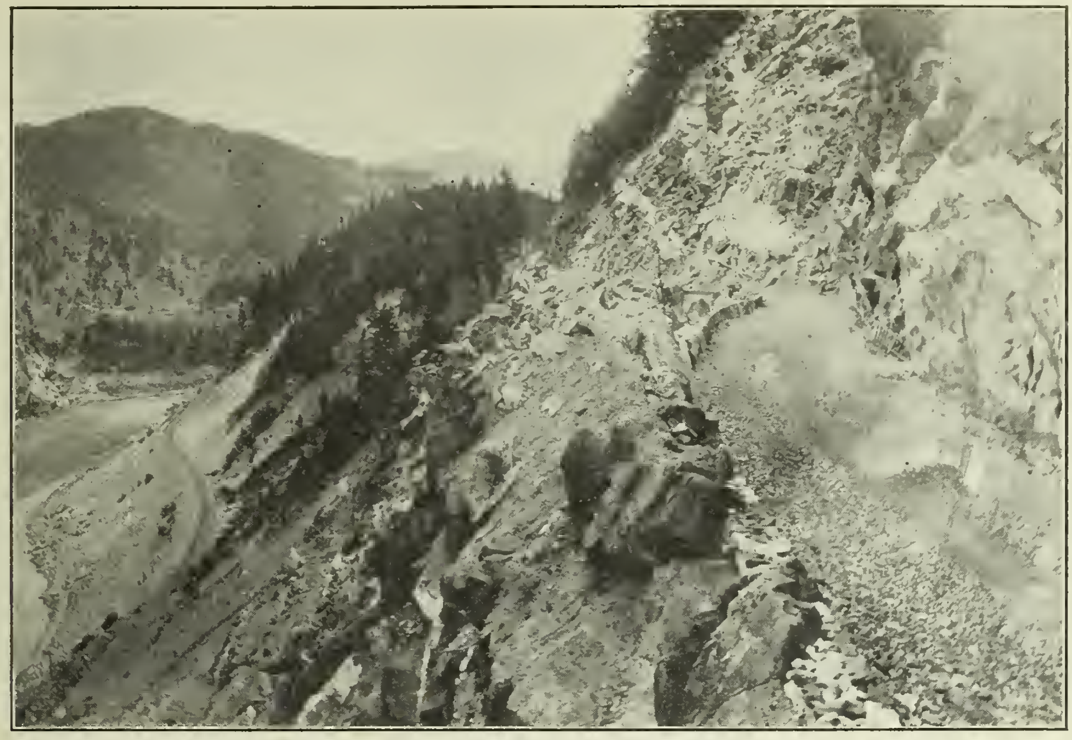

Figure No. 7.—View of Road at China Bar Bluffs—with Railway shown on the Lower Level.

struction. Pioneer bores were commenced simultaneously at each end, air compressors and pneumatic rock drills being the only labour-saving devices utilized throughout the operations, which occupied about four months. Much of the rock excavation was hauled to nearby dumps in cars on light rails, but it was possible to use the larger blocks for the dry rock protection walling which formed a special feature of the construction along the rock bluffs in this vicinity. As will be noted from the unit prices previously referred to, the tunnelling was undertaken at a unit price of $100 per lineal foot of cross-section.

After leaving the tunnels the highway continues, in easy and graceful curves, to wind round the rock bluffs, towering over the Canadian National Railway, which at this point is about 600 feet below the road. Despite the difficult and expensive construction in rock work, the highway was built of ample proportions, the roadbed being everywhere wide enough for two motor vehicles to pass safely, and all curves being widened out and super-elevated. As an added precautionary measure substantial walling, (see figure No. 6), about 2 feet in height and 18 inches wide, was constructed on solid foundations at the outer edge of the roadway, wherever this was deemed necessary. With so much rock conveniently available it was possible to construct dry rock retaining walls of massive blocks, and it is interesting to note that in many places the foundations of such walls were laid directly on the old roadbed and even in some instances on top of old retaining walls, so substantially had they been built in the Sixties. Where rock was not available heavy log protection railing was laid on cradles at the outer edge of the road. Such precautionary measures are illustrative of the care and consideration exercised to add to the comfort and protection of travellers in overcoming hazards, mental or actual.

At difficult points on this section some splendid specimens of peeled log cribwork can be seen, suitable timber being found nearby. The portion known as China Bar bluffs proved exceedingly hazardous,—certainly the most difficult piece of rock work the writer ever experienced in either railway or road construction. These bluffs overhang the Canadian National Railway tracks some 300 feet below, while above are menacing precipices. Hence every yard of rock had not only to be laboriously moved by manual methods, (exclusive of rock drilling and small shots), but also had to be loaded in cars and hauled to safe dumps away from the railway. The engineering problem was not so much to excavate a roadway round the rock bluffs, but to prevent, or rather hinder, material from the overhanging bluffs from damaging either roadway or railway.

Considerable underpinning of the rock above and construction of overhead retaining walls had to be carried out under most dangerous, and, of course, expensive conditions. But, fortunately, this section, unique in highway construction, was successfully and safely negotiated without loss of life or limb, greatly to the credit of the contractors, who had not only to shoulder tremendous responsibility, (on one occasion an eleven-hour delay of trains due to accidental discharge of rock excavation on the Canadian National Railway involved the contractors in a $2,500 renewal and repair bill in addition to the cost of clearing the tracks), but also the expense bill. The fact that an enormous yardage of rock was laboriously handled in this section, which cost the contractors no less than $76,000 for a distance of 2,260 feet, viz., over $33 per lineal foot, should best demonstrate the difficulties and disabilities under which the work was undertaken over a period of fourteen months.

The view in figure No. 7 illustrates the rugged and diversified nature of the country which this highway traverses, at the same time emphasizing the extreme engineering difficulties to be contended with.

To afford a more definite conception of the magnitude of the operations on this contract, (2A), the following is the percentage of classification of excavation:—

Solid rock	35 per cent
Loose rock	18 " "
Hard pan	28 " "
Earth	19 " "

Another outstanding feature of the location of this section of the Cariboo road was the diversion round Nine Mile creek, north of Boston Bar. While this added over one mile

Figure No. 8.—Bridge over Anderson River—160-foot Howe Deck Timber Truss.

to the length of the road it resulted in eliminating an expensive high level crossing, about 500 feet in length, paralleling the Canadian National Railway. This diversion further commended itself in the additional scenic features and auto camp sites it rendered available to the motoring public. Nowadays scenic highways are not fundamentally located on the shortest possible distance consistent with negotiable grades.

The contractors having their organization available, the gravel surfacing between a point 4 miles west of Yale and Boothroyd, (36 miles), was carried out by them on the following unit basis:—

(a) Approved material spread upon the roadbed, as directed by and to the satisfaction of the engineer; free haul three miles; volume of each load to be measured in vehicle of transport at point of loading; cubic yards, more or less. 50,000 at $1.20.....	$60,000
(b) Additional payment for each mile or part of a mile over which each cubic yard is hauled beyond the limit of three miles' free haul; cubic yard-miles, more or less. 10,000 at 35 cents..................	3,500
Total (estimated)	$63,500

So close was the engineer's estimate that the amount paid the contractors was actually $29 less than this estimated total. Exclusive of bridges, the cost of gravelling worked out at, roughly, $1,800 per mile of 14 feet width, road centre depth of 4 to 6 inches unconsolidated gravel. Several splendid gravel and shale deposits either in the larger cuts or in pits adjacent to the road reservation were available, but nevertheless the contractor was obliged to haul materials considerable distances.

In several instances it was necessary to screen the gravel through a "grizzly" erected on the roadway, but generally most of the surfacing material was of such a character as to permit of its being deposited directly on the road. By means of power shovels and 4-yard truck units it was possible to undertake a considerable yardage daily. The contractors were not required to roll the gravel, but motor graders were employed to grade and shape the roadbed to an even and uniform contour. Since the major portion of the road is built of excellent materials with a large percentage of rock, the nucleus of a splendid gravel surface was thereby procured. Subsequently the surface has been materially improved by the sustained efforts of a special day labour patrol gang equipped with mechanical labour saving outfits.

Here it may be mentioned that immediately after the opening of this highway special maintenance gangs were organized, and outfitted with the necessary equipment to deal with the rock slides, "cave-ins," subsidences and other works contingent to a newly constructed mountain highway. Hence, in the course of maintenance operations the roadbed is being widened, surfaced and otherwise materially improved. On this highway, as on other main highways built out of capital funds, the department has continued its policy of conserving, by careful and continuous maintenance, the original type of construction,—an all-important measure so frequently neglected by highway engineers with detriment to the highway and subsequent greater expense to the treasury.

As has been previously mentioned, the original road contracts did not include gravel surfacing, as it was deemed advisable to provide for such work in extended contracts after the bridges had been built. Obviously a mountain road of this description necessitated numerous bridges to negotiate the yawning chasms and span the turbulent creeks emptying into the Fraser river with comparatively wide mouths. While the ordinary bridges were undertaken by the A. B. Palmer Company, being built in systematic succession after the completion of the grading, two larger bridges, namely, those at Anderson creek and Stoyama creek, were constructed by separate contract. The photograph, (figure No. 8), shows that they were Howe deck timber bridges, that type proving most economical in design and æsthetic in appearance. Spans of 160 feet, having a clear roadway of 14 feet 8 inches, were necessary. Since they crossed rocky canyons at an average height of 160 feet from the creek bed, naturally their erection demanded an abnormal amount of falsework. The cost of the two bridges in one contract was about $46,000. Coast fir cost $85.00 per M. in place, and trestle approaches and timber piers $22 per M. in place. All the timber bridges are built to withstand a 15-ton concentrated load and have an estimated life of from fifteen to twenty years.

It is a pleasure to record the generally excellent work undertaken by the contractors, who continuously co-operated with the department's engineers in an earnest endeavour to carry out all work in an efficient and expeditious manner. In the distribution and administration of the necessary construction camps the contractors showed considerable initiative and enterprise, visitors expressing surprise and pleasure at such splendid organization and commissariat. Obviously in mountainous territory with no access roads available the assembling and distribution of plant and material called for considerable labour and ingenuity. On rocky mountain slopes the primitive mode of packing of heavy loads on men's backs had perforce to be resorted to.

Owing to the topography of the country, the ordinary methods of construction of such major highway works, namely, by excavation and other power equipment, had to be dispensed with along rocky mountain slopes. In handling the numerous large boulders and enormous excavated rock work, improvised tripods and hand cranes were used. Air compressors and pneumatic rock drills were also freely utilized to advantage in the abnormally heavy rock work.

So precipitous were the rocky slopes in some sections that the drilling and other work had to be undertaken by men suspended by ropes. Altogether the operations were of an unusual character, calling for resourcefulness and eternal vigilance on the part of the contractors. Consequently it is a fitting testimony to the excellence of their organization and the worth of their superintendents that in a contract of such magnitude involving about a million dollars, there was no loss of life, and even accidents were of minor proportions.

Boothroyd-Lytton Section

Partly because this 24-mile section involved considerable reconstruction of the old Cariboo road, and partly due to the department's desire to utilize its own extensive up-to-date equipment, it was efficiently and economically carried out by provincial day labour under the supervision of District Engineer Major Taylor, thoroughly conversant with such construction work. A half mile diversion involving heavy cuts and fills at Tilton creek was carried out by contract at a cost of approximately $32,000. Other important diversions, to improve both alignment and grades, were carried out by day labour at Kanaka, Falls creek and Cisco. The material handled in those diversions consisted largely of gravel with large round boulders, solid rock and slide rock. On account of the large percentage of rock boulders ploughing was not practicable and some of the hand-moved material cost on an average 50 cents per cubic yard.

However, the bulk of this grading on this section was carried out by the department's gasoline shovels at from 10 to 14 cents per cubic yard for earth. Particularly on the side hills, where slide rock predominated, such excavators were found most practicable, economical and expeditious in the widening out of the former narrow roadbed.

In this 24-mile section, which generally traverses, in a winding and undulating manner, the east bank of the Fraser river alternately above the Canadian National Railway and Canadian Pacific Railway, the strategic point is at Jackass mountain, where, after climbing a considerable distance on a 10 per cent grade, (the greatest on the whole of the Cariboo road), the highest summit, (1,180 feet), is reached.

Since the work at this point was directly over the Canadian National Railway track, heavy blasting was precluded, and practically every yard of rock had to be hauled away, rendering the cost of solid rock excavation about $2.75 per cubic yard.

Some splendid specimens of peeled log timber crib work can be seen at the Jackass mountain summit, where such was the perpendicular nature of the rock that retaining cribs had to be undertaken to permit of the standard width of roadbed, (sixteen feet).

At the east end of Lytton Townsite, where the old road crossed the Canadian Pacific Railway on a dangerous grade crossing, " grade separation " was resorted to. In the entire 24-mile portion there is not a single grade crossing, whereas the old location crossed and recrossed the Canadian Pacific Railway several times. With willing co-operation of the Canadian Pacific Railway Company it was possible thus to eliminate all grade crossings, with resultant improved alignment and grades to the highway generally. Hence it will be observed, and it is hoped, appreciated, that the department concentrated every effort towards obtaining a safe and serviceable location, even at greatly increased expenditure, the vision of heavy motor travel being ever prominently in view.

To permit of a necessary revision of the old Cariboo road at Cisco, Cisco creek had to be bridged over a rocky gorge with precipitous walls. From road level to creek bed is 180 feet, (see figure No. 9). Despite the extremely difficult and dangerous nature of this work and the great expense involved in falsework, the structure was successfully constructed by provincial day labour at reasonable cost, ($18,570). The structure consists of one 150-foot deck Howe truss span and 80 feet of trestle approaches, all on concrete piers and with a concrete retaining wall abutment at the east end.

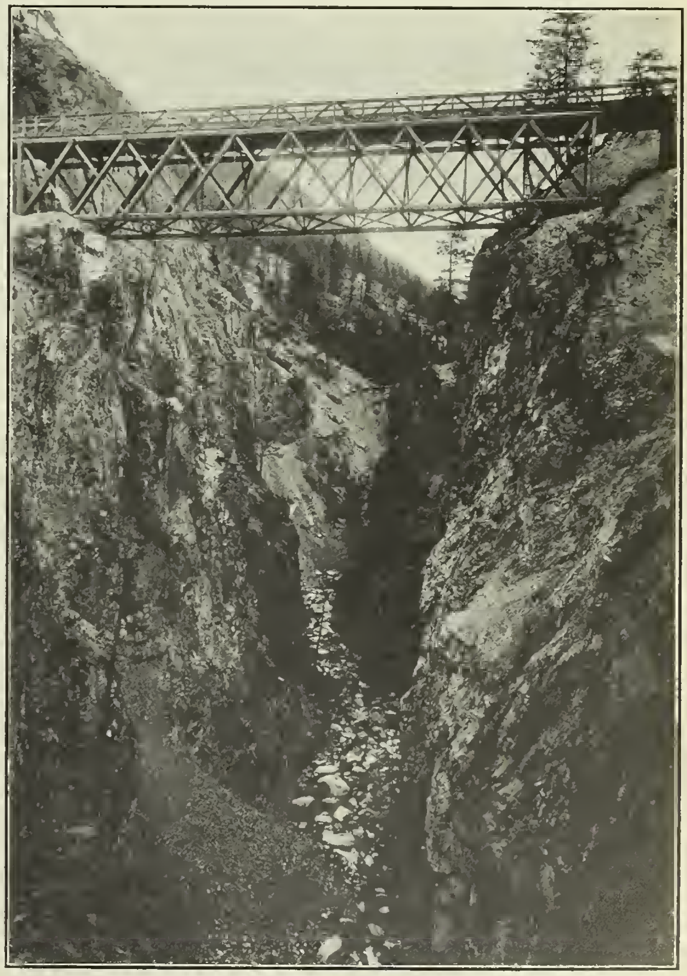

Figure No. 9.—Cisco Bridge—180 feet above bed of Creek—Built by Day Labour.

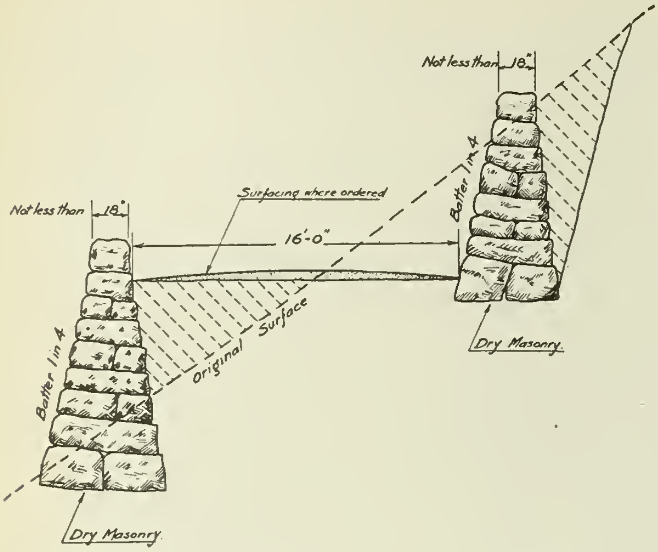

Figure No. 10.—Typical Section with Retaining Walls in Loose Rock or Earth.

Lytton-Spences Bridge

This is the last section of the Cariboo road with which the present article deals. Traversing this territory eastward, particularly for the first time, one is strongly, and even strangely, impressed by the sudden change in the nature of the landscape. Hitherto frowning precipices, the swift flowing Fraser swirling through rock gorges, and sundry cultivated areas, have in succession met the enchanted eye. But after leaving the quaint town of Lytton, situated sentinel-like at the confluence of the Fraser and Thompson rivers, the scenery displays a totally different aspect. Now we are in the " Dry Belt " with sparse timber, (chiefly bull pine), and scant vegetation subsisting on the wide sand benches which chiefly characterize this country, but nevertheless with an attraction and charm peculiarly its own.

Throughout its entire length this section of the highway is located on the left bank of the Thompson river, approximately paralleling the Canadian Pacific Railway for the greater part of the distance. For three-quarters of the length the highway route is located well above the railway, but owing to the precipitous gravel slopes, (points being designated with the weird names " Indictment Hole " and " The Jaws of Death "), it was imperative to locate the line with extreme care. To do so it was necessary to construct retaining walls adjacent to the railway and heavy rock fills into the river. In loose rock or earth, retaining walls, (see figure No. 10 for typical section), had in many places to be constructed. Here also it was possible, by careful revision, to eliminate grade railway crossings so that in the whole of this 24-mile stretch there are only two level crossings.

The country between Lytton and Spence's bridge is very rough, and consists alternately of solid rock, gravel and hard pan bluffs with short stretches of flats intervening. The old Cariboo road followed the left bank of the river and at various points round the bluffs was cut out of the solid rock or hard pan. The construction of the Canadian Pacific Railway completely destroyed the old road at many points, but particularly where the bluffs come down to the river. On account of the destruction of the old road at these points, in the construction of the new road it was necessary to go over the tops of bluffs, or in cases where that was impossible, to adopt costly and difficult means of construction. Following is a general description of the route:—

Leaving Lytton the road crosses the railway on a level crossing and climbs up a hard-pan and gravel side hill through broken country to the flat at Lytton race course, thence the grade generally falls to the two mile slide. The old road at this slide crossed the railway, ran along the bottom of the railway banks close to the river, and after passing the slide climbed up to the railway again and recrossed. The new road does not cross the railway, but comes down to a level of about eight feet above the rail and is taken along past the slide on a bulkhead consisting of round cedar posts anchored back to cedar logs with round iron tie rods, planked up behind the posts and filled with rocks. After leaving the two-mile slide the road rises to clear the tops of long gravel slides, which reach to the railway, and after reaching the summit, about two miles east of the slide, the grade drops through easier country to the flat at Gladwin.

From Gladwin flat the road climbs on solid rock and gravel side hill to get over a summit above the " Jaws of Death," and at this summit it strikes the old road which it follows to a point near Tank creek where the road drops on a steady 8 per cent grade to a level crossing. Thence the road drops on a 6 per cent grade on trestle and then follows practically a water grade between the railway and the Thompson river to Thompson Siding. At Thompson Siding there was an old railway crib approximately 1,400 feet long. This crib has been replaced with a heavy rock fill. The road now passes under the Canadian Pacific Railway Barrack Creek bridge at the west end, and distance is developed in the basin of the creek, so that the grade reaches a point about eight feet above the railway at the east end of Barrack bridge. From this point for a distance of 4,000 feet the road will be constructed parallel to the railway and about eight feet above rail level. The construction will consist of a concrete mass retaining wall.

At the end of this wall the road rises on a steady 8 per cent grade to cross the " Indictment Hole " and from this point follows a rocky side hill for a distance of two miles to an overhead crossing of the Canadian Pacific Railway. The route is then between the railway and the river to Spence's bridge. The construction consists of long cribs where the ground between the railway and the river is limited. There are several good flats where construction costs were light.

At Drynoch slide the road is well clear of the railway, but it is anticipated that trouble will always be experienced in this slide, as the railway, passing through similar ground, has always had trouble at this place. One mile east of Drynoch it was necessary to straighten out the railway to allow room for the highway above steep cut banks to the river.

The construction from this diversion to Spence's bridge consists of side hill, flats, cribs and rock cuts, and is generally of a fairly costly nature.

Owing to the many difficult construction features and the limitations placed on location of the highway by the Canadian Pacific Railway and the Thompson river the whole stretch of approximately 24 miles is costly road construction.

Signing and Patrolling of Highway

Despite the fact that extreme care was exercised both in the location and the construction of this mountain highway so as to render it as safe as possible from a traffic standpoint, careless and indifferent motorists have always to be reckoned with. Consequently, after co-operation with the Automobile Association of British Columbia, an adequate number of warning and directing signs have been placed where considered essential. At the few grade crossings automatic signals have been installed. The following press report should allay any apprehension as to the safety of this highway:

> "One of the outstanding features of the new Cariboo highway, according to the motorists who have reported their impressions of the road to the Automobile Club of British Columbia, is the safety and freedom from mental hazard provided in the Fraser Canyon stretch. Sufficiently wide at all places for two cars to pass, and entirely free from steep grades, the road is also provided, wherever necessary, with outside protection consisting of stone wall construction two feet thick. In addition to these precautions and despite the engineering difficulties presented, practically all level railway crossings have been eliminated, while ample warning signs have been provided at strategic points. These features, together with the splendid scenic offerings and excellent roadbed, have contributed much to the present popularity of the route."

In co-operation with the Department of the Interior, under whom is the control of this Railway Belt, the department is making an earnest effort to prevent the spoilation of this scenic highway by placarding it with commercial signs and alluring advertisements. No permits are being issued for any signs, however apparently attractive. During the motoring season, lasting from May to October, (although the highway will likely be open for through traffic every normal winter), an official of the provincial police, mounted on a motorcycle, will patrol it for the protection and safeguarding of the interests of the travelling public.

Conclusion

Inclusive of the Alexandra suspension bridge, the gravel surfacing, and the engineering costs, (the latter about 6 per cent of the aggregate), the reconstruction of the 100 miles of the Cariboo road, when completed in the fall of 1928, will have cost in the neighbourhood of $2,500,000. Considering the enormous difficulties contended with, the abnormal quantity of solid rock work, and the excellence of the road work done, an average of $25,000 per mile is quite reasonable.

In conclusion, due credit should be given to those engineers who closely co-operated with the writer in the following work, thereby contributing largely to the success of this undertaking, one of the most important in the highway annals of the province:—

Preliminary Surveys: W. K. Gwyer, M.E.I.C., and F. J. Dawson, A.M.E.I.C.

Final Surveys: H. C. Whitaker and R. M. Corning.

Construction Work: Major R. M. Taylor, M.E.I.C. (district engineer at Kamloops), H. C. Whitaker and D. McMillan, M.E.I.C.

Resident Engineers: F. J. Clarke, T. E. Clarke and G. P. Hayman (*deceased*).

Construction Work: Major R. M. Taylor, M.E.I.C., and E. H. Verner, M.E.I.C., district engineers; H. C. Anderson, A.M.E.I.C., and G. N. Stowe, A.M.E.I.C., assistant district engineers.

Bridges: G. M. Duncan, chief draughtsman; A. L. Carruthers, M.E.I.C., bridge engineer; H. L. Swan, A.M.E.I.C., and O. W. Smith, M.E.I.C., resident engineers.

Particularly in the debatable points of location and in the more difficult construction details, great credit is due to G. P. Napier, M.E.I.C., assistant public works engineer, for valuable advice and assistance.

Reference already has been made to the excellent work of the contractors, but special mention should be made of the willing co-operation of Mr. John Boyd of the General Construction Company, (late the A. B. Palmer Company), and also to that fine veteran contractor, Wm. P. Tierney, who carried out the western section of the canyon work so expeditiously and creditably.

Table No. 1.—Analysis of Cost and Classified Distribution of Alexandra Bridge.

:ALEXANDRA BRIDGE:
·COST ANALYSIS·

Item	Quantity	Unit Cost	Cost			
270' Suspension Span — Sub-Structure — Excavation.						
Anchors	1710 cy	$1.59	2721.37			
Piers	608 cy	$2.24	1359.34

Some Engineering Aspects of the Bridge River Project

A Description of the Hydro-Electric Power Development of the British Columbia Electric Railway Company, Limited; the Power Possibilities of the River, the Proposed Programme of the Stages of the Development and the Progress of Construction

E. E. Carpenter, M.E.I.C.
Consulting Engineer, British Columbia Electric Railway Company, Limited.

Paper presented at the Western General Professional Meeting of The Engineering Institute of Canada, at Vancouver, B.C., June 7th, 1928

It is, perhaps, somewhat unusual in technical procedure to present in a formal paper to the engineering profession, as represented by The Institute, a descriptive discussion of a project which has neither the status of a proposal nor of a consummation, but lies midway between, its actual state being that of a proposed project that is just taking on the first stages of fulfilment. In order to avoid any confusion the construction features of the project will, throughout the paper, be spoken of in the future tense, even though some of them may have been carried out to some degree.

It is, perhaps, equally extraordinary to present for review and discussion, plans and details of structures yet unconstructed, in fact, in many cases plans that partake of the nature of studies leading up to the best solution of the problems and the determination of the final plan. This latter point is brought out deliberately in the belief that valuable suggestions may result from the discussions with which the paper may be favoured.

Aside from the technical problems involved, the Bridge River project possesses two features of special interest which make it stand out in comparison with other power development projects in Canada, or elsewhere for that matter. These are, first, the large quantity of water capable of diversion, and, second, the high head available for its utilization. Many plants are more favoured with respect to one of these two features, but it is believed, without positive examination of the records, that few, if any, sites can be named which possess the combination of head and water supply with which this project is endowed.

Imagine a river,—not a mountain stream,—of some 3,700 cubic feet per second average flow, meandering through the flat basins of its middle course with mountain ranges towering on either side, then plunging downward some 1,400 feet in the few miles remaining to be traversed to join it with the Fraser river. Imagine then this river bending southward, before its final plunge to the Fraser, until its

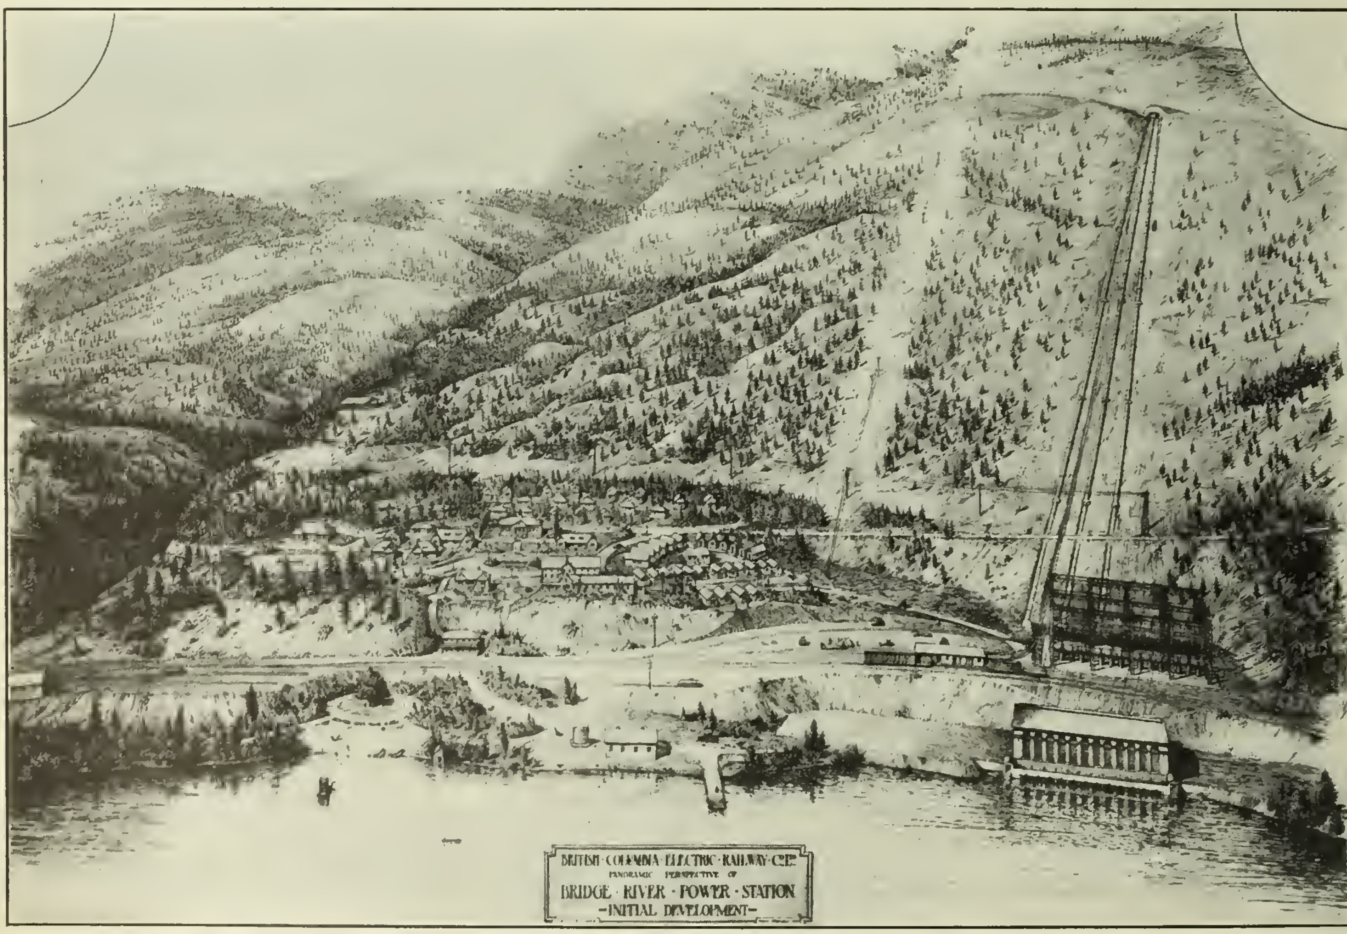

Figure No. 1.—A Sketch of Proposed Initial Development of Bridge River Power Station.

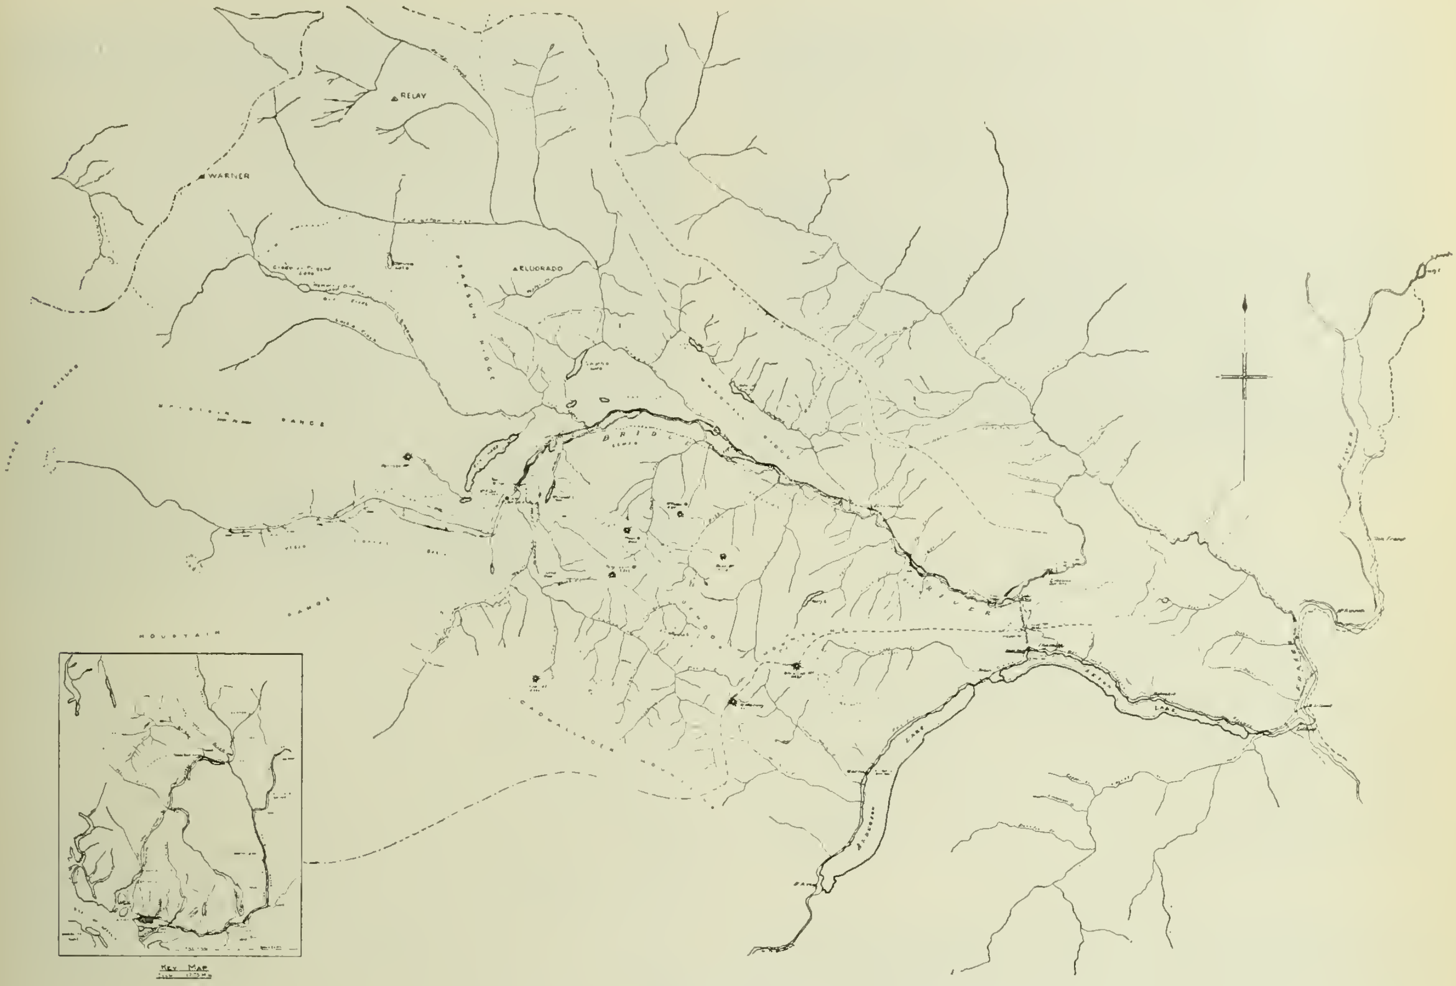

Figure No. 2.—Map of Bridge River Drainage Area.

bed is separated by less than 3 miles from a beautiful lake lying to the south in a parallel rock-bound trough of the mountain chain, but some 1,200 feet lower than the river bed; three miles of mountain mass to be tunnelled to bring the river through the mountain and discharge its mighty waters on the mountain side above the lake, there to be harnessed by the artifices of man, which will wrest from it its huge store of energy and direct it to the beneficial use of a distant community. This is a picture of Bridge river and Seton lake, the water supply and the tailwater basin respectively of the project, which will ultimately afford electric power to the extent of some 600,000 horse power, to be taken off at will, as, and when required by the expanding communities of coastal British Columbia.

History

The power possibilities of the site were first made known by Captain Downton, a land surveyor who discovered the difference in elevations of river and lake and their close proximity to each other. The first applications for appropriation of the waters for power purposes were made in 1912 by a group headed by W. R. Bonnycastle, M.E.I.C., hydro-electric engineer of Vancouver. Preliminary surveys and investigations were carried on at that time,—sufficient to establish the power capability of the project. Subsequently various schemes to promote the development to a construction stage were pursued but none of them were successful owing to a lack of a firm market for the power.

In 1925, the British Columbia Electric Railway Company took an option on the rights and properties of the Bridge River Power Company, Limited, then owners of the project, and after a close investigation of the whole project, acquired the property in September, 1926, by purchase of the stock of the old company.

Location

The site of the development lies some 130 miles transmission distance from Vancouver in a north easterly direction. The Pacific Great Eastern Railway passes the site of the generating plant at Bridge River station on the shore of Seton lake. Transportation to the site is afforded by water carriage from Vancouver to Squamish at the head of Howe sound and thence by rail to the power site. The boat trip is about 45 miles and the railway trip about 104 miles in length.

Watershed

Bridge river, one of the major tributaries feeding the Fraser river from the west, has its source in the eastern flanks of the coast mountains, which rise from 6,000 to 10,000 feet above sea level in rugged snowclad peaks and ridges whose snow fields and glaciers contribute largely to its water supply. In its upper reaches it is a turbulent, fast moving stream, highly erosive in action and carrying a heavy load of glacial detritus which is being deposited in the long flat bottomed valley basins of the meandering middle reaches. The whole picture is one of recent glacial occupation, and a youthful unorganized state of being. These valleys, or basins, two in number, with their newly deposited sand and gravel bars alternating with marshy alluvial flats overgrown with cottonwood, birch and alder,

Figure No. 3.—Gun Lake in Upper Watershed showing High Ridge beyond Bridge River.

are important to the project in that their extremely gentle gradients and flat floors afford excellent storage sites for the future regulation of the stream.

The lower reach of the river plunges downward through a deep box-like canyon, in a series of rapids and falls which dissipate some 1,400 feet of head in the 15 miles distance from the lower basin to the confluence with the Fraser. It is this plunge that makes possible the high head to be obtained by diverting the stream southward through the mountain.

The water shed is largely unmapped but is estimated at about 1,350 square miles.

Water Supply

The water supply of the river is chiefly derived from the higher levels of the watershed, where precipitation is more plentiful and falls largely in the form of snow. The lower elevations receive very limited rainfall and are semi-arid in character. Yellow pine predominates in the park-like forested slopes and benches, and sage brush is often seen on the Seton lake side of the range.

Precipitation records have not been taken continuously. Run-offs have, however, been well established by stream measurements carried on for several years. The limited records of precipitation indicate that the average at Gun lake, in the upper watershed at elevation 2,900, for the three years 1925, 1926 and 1927 was about 18 inches. At Bridge river station, the precipitation for 1927, the only year of observed record, was 20.54 inches.

With the co-operation of the Dominion Water Power and Reclamation Service, and under its supervision, the flow of Bridge river and its principal tributaries has been measured and recorded since June 1913. Thus, an excellent history of the stream is available for a fifteen-year period. The daily discharge records are published in the Water Resources Papers of the Department. A tabulation of the mean monthly and yearly flows is given in table No. 1.

The mean annual yield of the watershed of 3,736 cubic feet per second is at the rate of 2.8 cubic feet per second per square mile of drainage area. It is interesting to compare this with similar data of the company's coastal watersheds, as given in the author's paper on " The Water Power Developments of the Alouette-Stave-Ruskin Group "[1] and its subsequent discussions. The corresponding per square mile yields of the Stave, Alouette and Coquitlam watersheds are shown as 8.6, 11.2 and 8.1 cubic feet per second, respectively.

[1] The Engineering Journal, January 1927.

The stream flow is subject to wide seasonal variations. The low water stage occurs in winter. January, February and March, with minimum temperatures as low as 30° to 40° below zero, register the least discharges. April brings gradually rising waters which increase until late June or early July, when the maximum is reached, and then decrease slowly through August and September, but hold up well until the cold snaps of late December and early January. The seasonal characteristics of the Bridge river run-off differ materially from those of the lake group. This relation is, fortunately, to a degree a complementary one, in that the Bridge river run-off remains comparatively high throughout the late fall months, while the lake group is passing the critical low period of its run-off. A graphic representation of this relationship is shown in figure No. 4.

The extreme low water stages of the river are of the utmost importance in their bearing upon the first stage of the development. It has been found that following the occurrence of an extremely cold period the discharge drops sharply to approximately one-third of the normal winter minimum and remains at this lower value for three to five days, when it resumes its normal proportions, without any material rise of temperature having occurred in the meantime. Normally, this condition is most emphasized only once in a season,—at the first heavy cold snap,—although it may be subsequently repeated in a modified form. Owing to the short duration of these freeze-up discharges, their effect is not so serious and may be overcome with comparatively small forebay storage at the diversion.

This is not an unusual occurrence under similar circumstances, and it is probably largely due to the actual freezing and depositing of the running water in the form of ice in the stream and on the watershed. When this freezing progresses to a certain stage, comparative insulation is set up, and the water flow is resumed, but with the modified hydraulic characteristics imposed by the ice-covered and ice-fringed channels, which quickly settle down to their winter regimen.

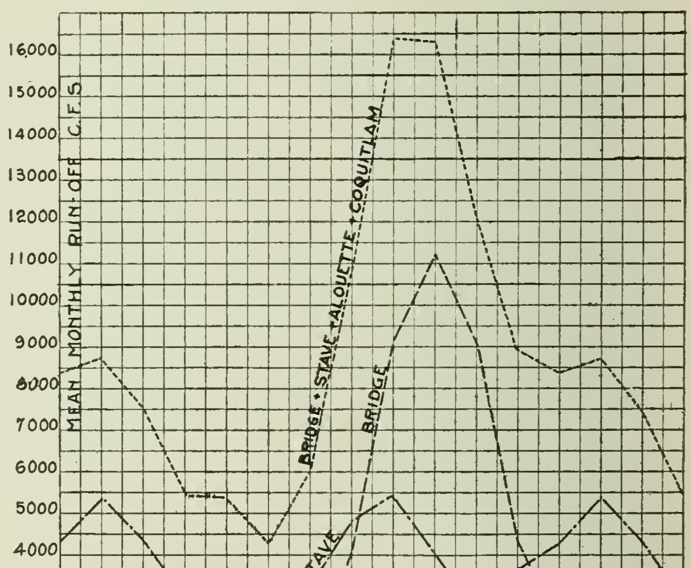

Figure No. 4.—Relation of Bridge River Run-off to that of the Lake Group of Plants.

Figure No. 5.—Testing Machine Used in Bearing Tests at Diversion Dam.

The fifteen-year observed record shows that the maximum flood occurred in June 1917, when the discharge reached 26,000 cubic feet per second, or 19.3 cubic feet per second per square mile of drainage area. The mean of the annual maximum floods for the period is 17,750 cubic feet per second, or 13.15 cubic feet per second per square mile. As a result of frequency studies, a maximum flood of 40,000 cubic feet per second, (29.6 cubic feet per second per square mile), has been set as the basis of design of spillways and other structures involving these problems.

Storage Reservoirs

The known and surveyed reservoir sites for the project are four in number, with a total capacity of 1,293,000 acre-feet, (29.7 square mile-feet). This storage, with due allowance for evaporation and silting of reservoirs, is estimated to be sufficient to regulate the flow to afford a continuous draught at the diversion for power purposes of not less than 3,000 cubic feet per second. This is 80 per cent of the mean discharge, which is considered close to the economic limit of regulation when the cost of storage works is taken into account. The continuous power output resulting from this flow at an average effective head of 1,300 feet is estimated at 354,000 horse power.

The storage sites and their respective capacities and heights of impounding dams are shown in table No. 2.

Proposed Programme of Development

While the full development of the enormous power resources of the Bridge river extends many years into the future and its progressive accomplishment will depend largely upon the economic conditions affecting the demand for power, it has been necessary, in order to study and determine consistently the initial steps in the progression and their relation to the ultimate, to set up a programme of development incorporating the successive stages as nearly as they can be visualized at the present. Three stages of development are indicated, which may be briefly described as follows:—

First Stage

The first stage is essentially the development of the stream flow, *without storage* except minor forebay storage sufficient to regulate against load fluctuations and low river stages resulting from freeze-up conditions. For economic reasons, the first stage is divided into two steps, called, for convenience, the "initial development," now being undertaken, and the "second development."

The principal structural elements involved in the initial development will be a diversion dam on the Bridge river, a 13,200-foot tunnel with intake, surge chamber, penstock tunnel and outlet structures, two penstocks from the tunnel outlet to the power station, a station building to house two 20,000-kw. hydro-electric generating units with outdoor

transformers and switchyard, a single-circuit, 154-kv., 60,000-kw. transmission line connecting the power station to the company's existing system at Vancouver, and a receiving station at Vancouver to handle the input from the new plant.

It is planned to complete the initial installation in the fall of 1931.

The second development of the first stage will follow closely upon the first, being planned for completion in the fall of 1933. It will consist of the addition of a third unit similar to the first two and will involve only the installation of an additonal penstock, an additon to the power house and the installation of the necessary hydraulic and electrical equipment. No additions nor changes in dam, tunnel or transmission line will be required.

With the completion of the third unit, the plant will have an installed capacity of 60,000 kw. The average output, limited by the available stream flow, will be approximately 45,000 kw.

Second Stage

The second stage of the development, as planned, will likely not be the next step of the company's development programme, but will be deferred until about 1938, if present forecasts are borne out, and, in the meantime, the Ruskin plant, on the lower Stave, will be built to come into service about 1935. This plan seems best to fit economic policies and load requirements.

The second stage contemplates the average utilization of 1,650 cubic feet per second of water, and will involve the building of a storage dam at or below the diversion, impounding some 750,000 acre-feet of water to afford the required regulation, the driving of a second tunnel, 14½ feet in diameter parallel to, and approximately 400 feet west of, the initial tunnel, the progressive provision of penstocks, hydro-electric units and power house extensions for additional generating capacity of 180,000 kw., thus bringing the total capacity of the plant at this stage up to 240,000 kw.

A second transmission line at 220 kv., 110,000 kw., paralleling the first, must be provided, and before the full capacity is brought into service the first line must be reconstructed for 220 kv. and its capacity raised to 110,000 kw.

Third Stage

The third, or ultimate, stage of the development is, in point of time, a means of meeting the demands of a long future,—so long, in fact, that no serious attempt has been made to set any definite dates for its accomplishment.

With its consummation, the final and full resources of the stream's regulated flow of 3,000 cubic feet per second will have been utilized. Aside from the hydraulic and electrical machinery, its construction will involve the enlargement and lining of the initial tunnel, (the tunnel now being bored), the boring of a branch tunnel to the east to serve additional units, the development of large additional storage by building dams at La Joie falls, South Fork and Gun lake and the provision of two additional heavy transmission lines, probably following an entirely different route, from the plant to Vancouver.

This stage will add 200,000 kw. to the capacity and will bring the ultimate installed capacity up to 440,000 kw.

In speaking of the second and third stages of the development of the Bridge river project, it is somewhat presumptious to attempt to outline with any definiteness their component parts. So many things may happen to influence their form and arrangement, and the times and order of their installation, that it would be verging upon futility to do so. The load requirements may not grow in conformity with the forecasts; advance in the arts of manufacture may change entirely the sizes, types and characteristics of electrical and hydraulic machinery and many other influences may work to upset present planning for such a distant future.

Initial Development

The planning of the structures of the initial development has now advanced to a middle stage and some of the actual construction work has been started.

The major structures and equipment for the initial development will be described.

Diversion Storage

While it is not the purpose to include in this paper any descriptions of construction features involved in stages two and three, other than the general remarks occurring previously in discussing the programme of development, it would be difficult, in discussing the diversion dam for the initial development, to avoid touching upon some of the features of the storage dam for the second stage, which is planned to occupy the same site, and which, in its problems of design and construction, is rather intimately related to the initial structure.

One of the most difficult problems of the investigation of the Bridge river project was found to lie in establishing a site for a storage dam for the lower basin. The years of investigation before its purchase by the British Columbia Electric Railway Company had failed to solve this most important problem, which so vitally affected the value of the project. Subsequently, two seasons of time and many thousands of dollars were spent in test borings in the box-like canyon below the basin, but no bedrock foundation could be found in the narrow channel flat, although towering bluffs of solid granite shouldered its margins and plunged diagonally below its level.

Many favourable looking sites, extending some four miles down the canyon, were drilled to depths ranging up to 200 feet without bottoming the river wash. As a last resort, the drill was moved up to the quiet waters at the lower end of the basin, and here, although the bedrock quest was not rewarded, there was revealed a massive band of clay underlying the river bed 30 to 50 feet, which joined the solid rock walls of the underground canyon with a barrier almost as impermeable as the bordering rock walls themselves.

After many tests of the permeability and bearing values of the clay bed and its thickness and extent, the proposed plans for the two dams were worked out.

The degree of permeability of the clay,—as determined in the field by casings sunk into it in pits bottomed on the clay bed itself,—was quite satisfactory. Laboratory analyses bore out the field results. The bearing values were, however, a more difficult problem. An elaborate set of tests demonstrated that the clay settled materially under loads as small as ½ ton per square foot, the rate decreasing until rest occurred. Successive additional loads produced more pronounced settlements, which decreased similarly, and, in each case, rest was restored. In each case, the state of rest partook more of the nature of a state of unstable equilibrium; any disturbance causing further settlement. No lateral displacement or bulging of the surface adjacent to the test block was observed.

After considering all the conditions disclosed by the tests, and with due regard for the limitations of the site, the plan of placing the cut-off upstream from the body of the main dam at a point where the clay bed is thickest and most competent to perform its cut-off function, and of placing the heavy dam on on area underlain with the thinning layer of clay with boulder formation predominating in the overburden, thus rendering it more able to withstand the heavy weights without danger of destructive settlements,

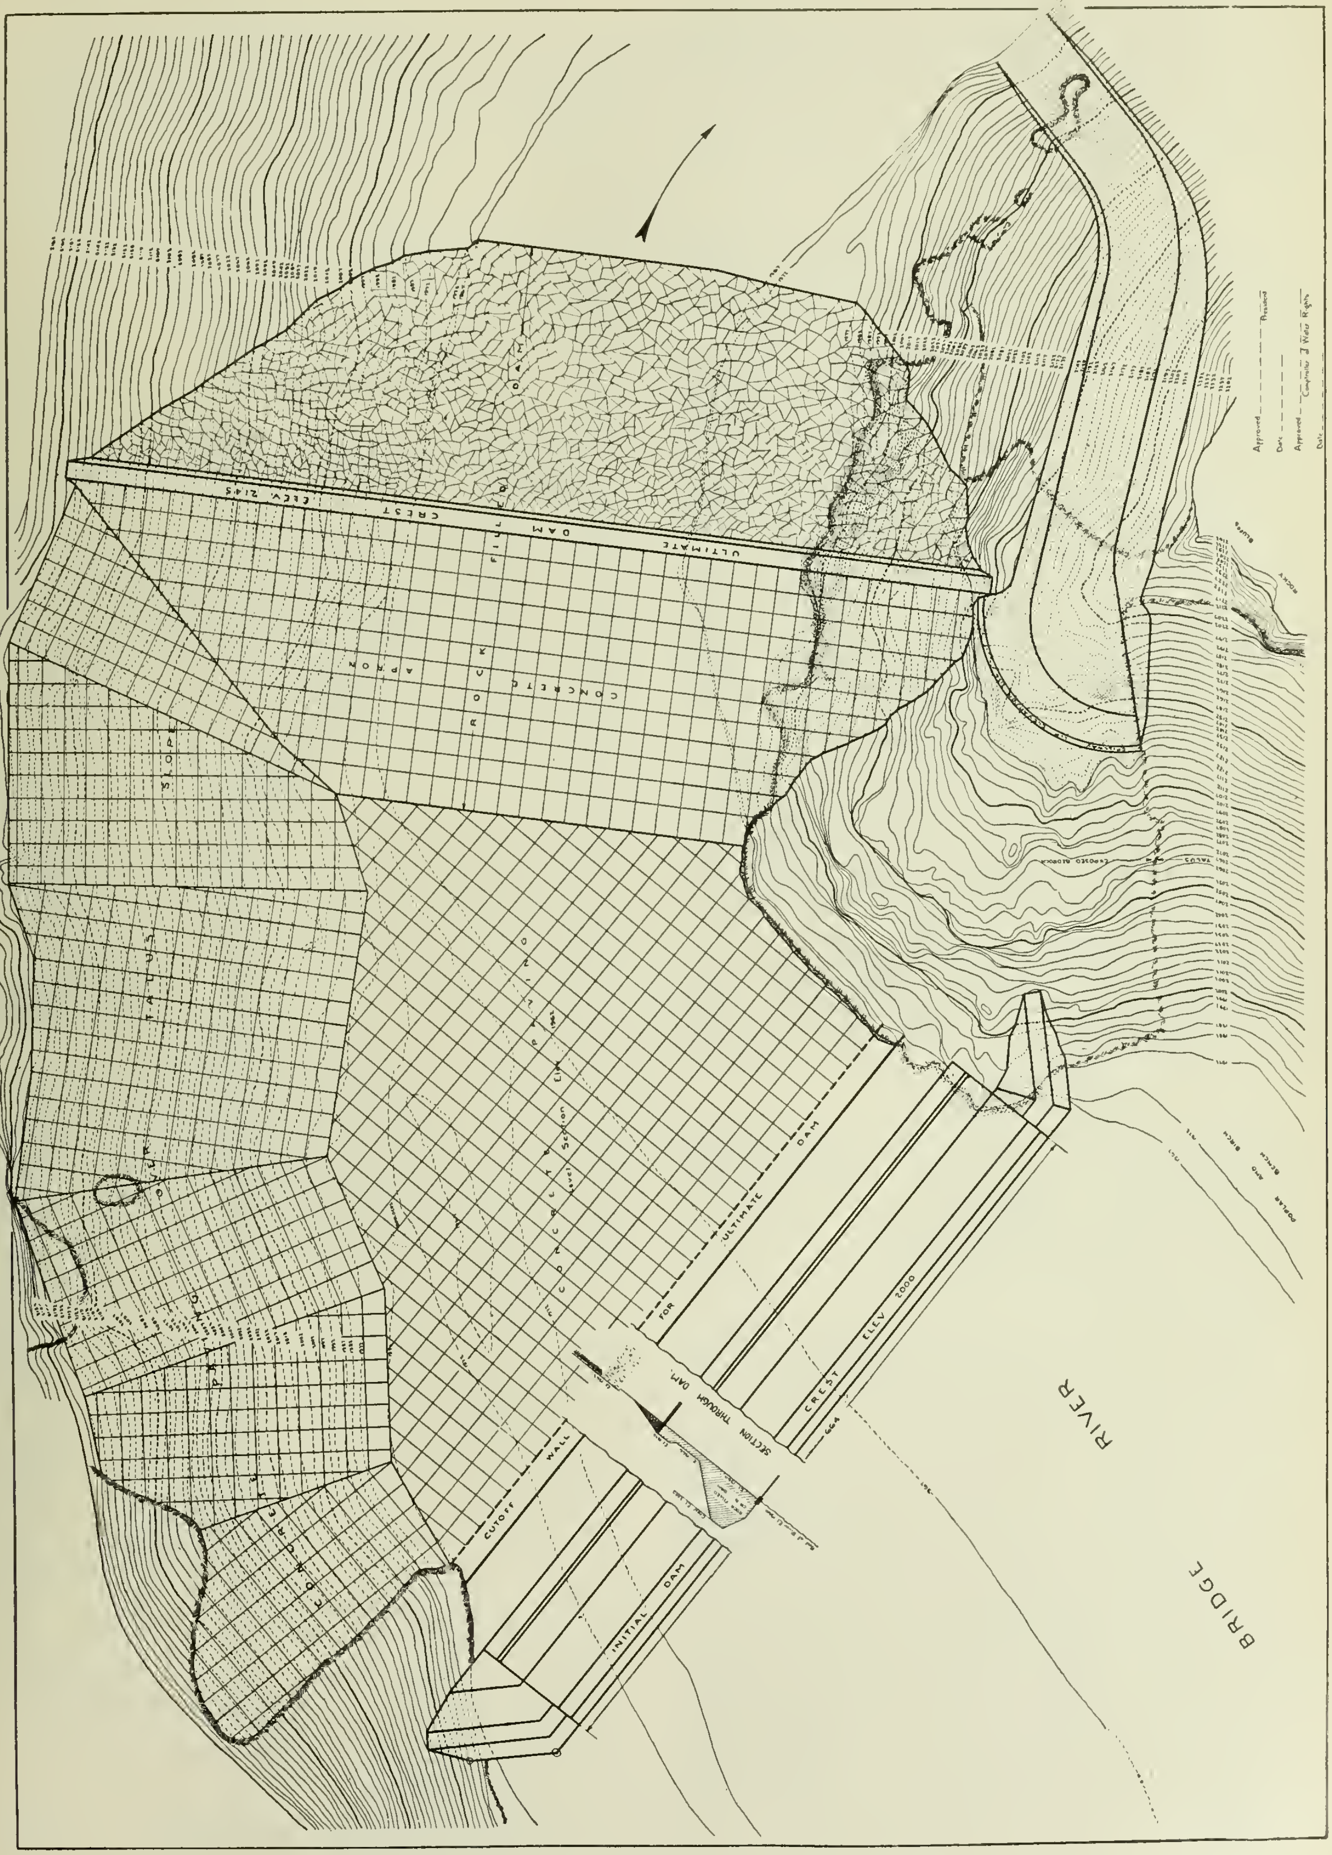

Figure No. 6.—Plan of Initial and Ultimate Dams.

and of connecting the two elements with a water-tight concrete cover extending over the bottom and up the sidewalls of the canyon to solid rock and up the face of the dam to its crest was worked out.

Preliminary plans and some details of the initial diversion dam and the ultimate storage dam are shown in figures Nos. 6 and 7.

Diversion Dam

The first diversion will be accomplished by erecting a log crib rock-filled type dam at the site of the larger storage dam, but located upstream and in such a position that it will not interfere with the ultimate structure but will serve as a cofferdam for its construction.

The log crib dam will be of the overflow type, with crest at elevation 2,000, 40 feet above stream bed. Its crest length is 900 feet. A pool or bucket is provided at the downstream toe to absorb the destructive energy of the descending sheet of water which, at the maximum stages assumed in the design, will have a depth of 7 feet on the crest of the dam. Timber sheet piling will protect the toe from undercutting, and heavy riprap will be used as a further protection.

The timber structure will be of standard round-log construction, with pockets 10 feet square to contain the rock filling. Sheathing will be heavy sawed planks. The upstream sheathing will connect with a curtain of interlocking steel sheet piling driven some 40 to 60 feet below the stream bed into the impervious clay stratum underlying the stream gravels, thus forming a cut-off for the dam.

During the construction period, the river flow will be carried through the dam by means of a series of timber-lined culvert openings which, upon completion, will be closed with flap gates and filled with rock. The closing sections of the dam will be built during the winter months, when high water stages are not above 4,000 to 5,000 cubic feet per second.

The storage afforded by the dam will amount to 13,500 acre-feet, which will amply meet the requirements for daily regulation of draught, to carry over the freeze-up periods previously described and to provide an allowance for silting during the period of its use.

Bridge River Intake

The intake structure to control the diversion will be set on the south bank of the valley, about 2 miles upstream from the diversion dam. Its location is governed both by the considerations of tunnel length and suitable rock structure for its foundations and for the entrance of the tunnel into the mountain. Fortunately, a site was found to meet both these conditions.

The intake tower will be a massive concrete structure circular in form with base spread and buttressed for greater stability and to afford two entrance bays with water passages through the base and leading up into the interior of the tower and thence into the tunnel.

The control gate for the intake will be of the balanced cylindrical wet-pipe type. It consists essentially of a plate steel cylinder or pipe, 20 feet in diameter, with open bottom which sits in an upright position on an annular seat encircling the water opening in the base of the tower. When the gate is in the closed position, the water of the reservoir rises to its level *within* the cylinder, but the annular space surrounding the cylinder and connecting to the tunnel opening remains dry. When the gate is opened, which is accomplished by lifting the pipe, the water flows freely into the tunnel. Since the forces exerted by the water upon the gate are balanced there is little resistance to be overcome in lifting the gate beyond the weight of the cylinder which may be largely offset by counterbalancing weights at the top of the tower.

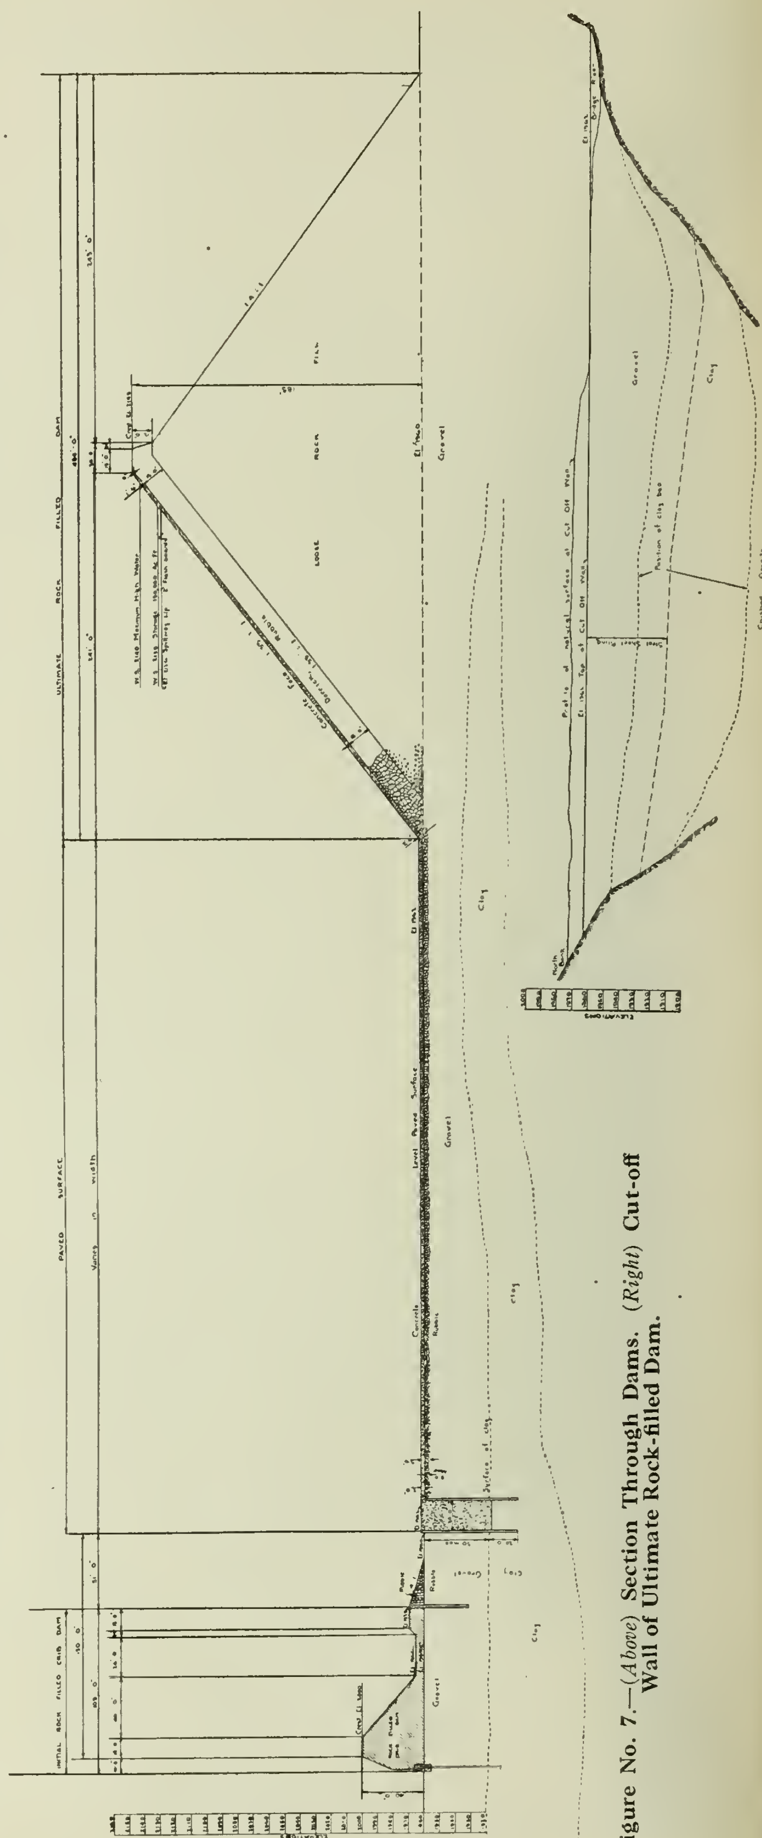

Figure No. 7.—*(Above)* Section Through Dams. *(Right)* Cut-off Wall of Ultimate Rock-filled Dam.

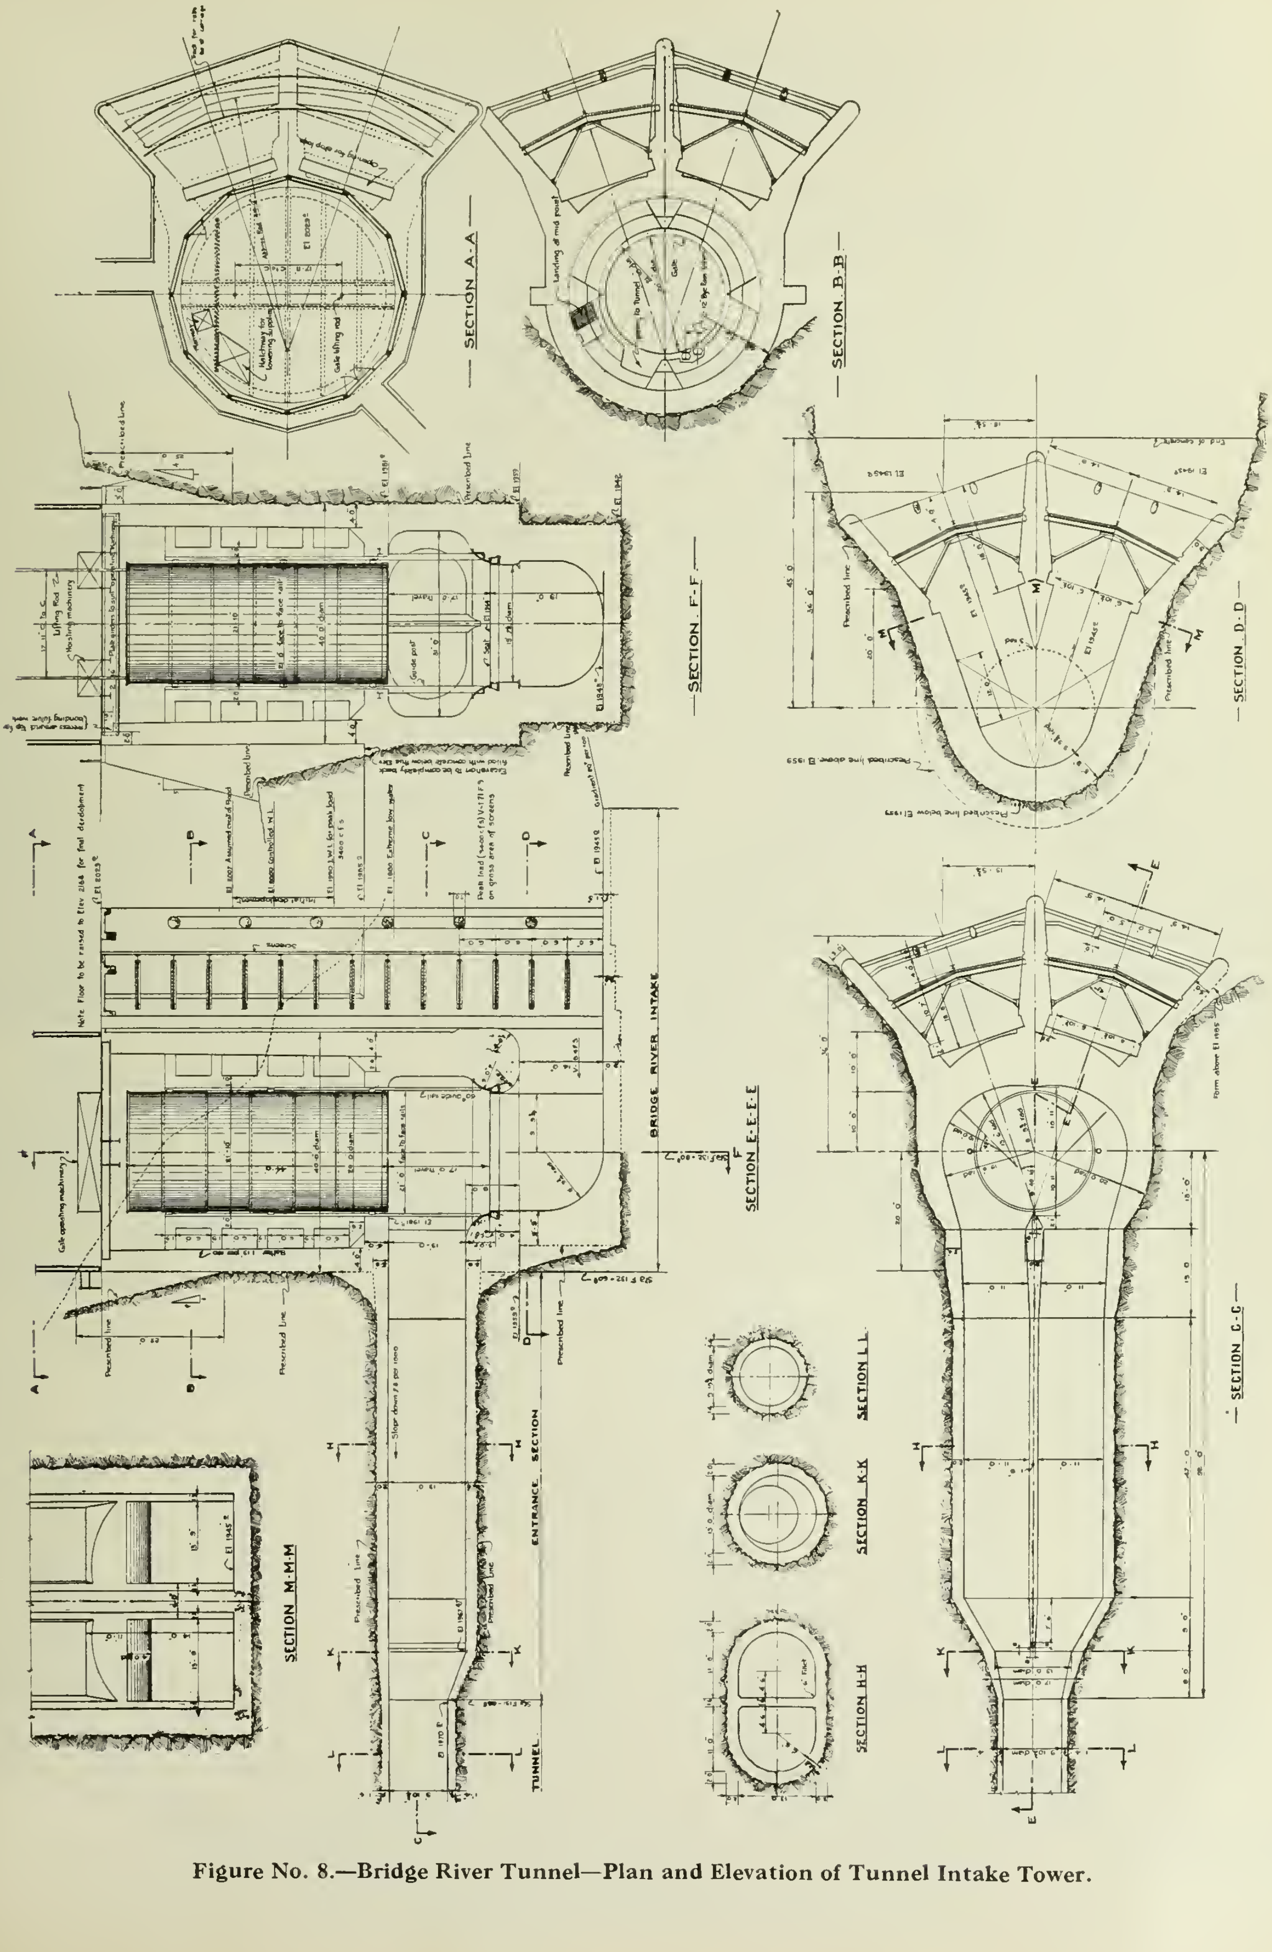

Figure No. 8.—Bridge River Tunnel—Plan and Elevation of Tunnel Intake Tower.

This type of gate is of recent development and has been successfully used on several installations where large quantities of water are to be handled under moderately high heads. Its first use under these conditions was made by the Southern California Edison Company in its Big Creek No. 3 plant.

Screen racks of adequate area to afford entrance velocities at low water, not to exceed 1¾ foot per second on the gross area, will protect the intake openings. Trash rakes and gate operating equipment will be mounted on the deck of the tower.

An outside barrier, upstream from the screens, will be provided by means of a heavy grillage of concrete columns and beams tied to the buttresses of the intake and extending up to the high water level. These are intended to fend off heavy floating ice and other coarse debris and prevent their approach to the screens.

Although temperatures of 30° below zero occur in the valley, observations of ice conditions on the river, indicate that no trouble will be experienced from frazil ice at the intake, which is deeply submerged in an extensive pondage of quiet water.

While the initial structure will only be called upon to control reservoir water levels up to elevation 2,007, the dimensions of water passages, screen areas, etc., and the strength of all the structural features of the intake and gate will be designed to conform to the requirements of the ultimate tunnel after enlargement to 16 feet 6 inches in diameter, and to meet the pressures imposed by the head of the ultimate reservoir level at elevation 2,140.

While the tower structure in its initial stage will be only 84 feet high from base to deck, its broad base and heavy walls are designed to be carried to an ultimate height of 217 feet. Its design was largely influenced by considerations of heavy thrusts which may be imposed by ice formations and floating debris. As the extent of these loads cannot be definitely fixed in advance, the design of these elements of the design becomes largely a matter of judgment.

The general arrangement and details of the intake are shown in figure No. 8.

Tunnel

The main tunnel will be straight in alignment, equivalent to 12 feet in diameter, 13,200 feet in length, with a constant gradient from intake to surge chamber of 7.3 feet in 1,000 feet. It will be constructed from two portals or headings and will traverse in its length rock formations of varying degrees of hardness.

One type of section will be employed throughout in the excavated bore. Normally, it will be unlined, linings only being used where rock conditions or water tightness require. Several types of linings may be employed, depending upon conditions developed in the boring work. The types of lining contemplated in the contract include:—

Type R.—Untimbered and Unlined Rock Section.—This section will be used in solid rock where no timbering is required.

Type S.—Untimbered and Lined Horseshoe Section.—This section will be used in rock that will stand without timbering, but which is lined with plain concrete to secure water-tightness.

Type U.—Timbered and Lined Horseshoe Section.—This section will be used where the rock requires timbering, but where no excessive unbalanced internal or external pressures are likely to occur.

Type T.—Untimbered and Lined Circular Section.—This section will be used where the rock will stand without timbering, but where heavy external pressures are likely to occur.

Type V.—Timbered and Lined Circular Section.—This section will be used where the rock requires timbering and where heavy unbalanced external or internal pressures are likely to occur. Adjacent to the intake or at other locations where heavy external pressures may occur it will be used without reinforcement. Adjacent to the outlet where heavy unbalanced internal pressures may occur it will be used with reinforcement.

The contract stipulates that all concrete linings for tunnel, surge chamber and shaft are to be placed by pneumatic methods and after setting are to be backed up by pressure grouting. Where rock is comparatively sound, the grouting will be relied upon as a final, positive filling or plugging of all spaces between concrete linings and rock walls to enable the linings to withstand the internal pressures. Where rock is not considered fully adequate for support, and particularly adjacent to the outlet, circular bands of reinforcing steel will be employed. The amount of this reinforcing will be proportioned to withstand the full water pressure without stressing the steel beyond its elastic limit. In the surge chamber design, these assumptions lead to the use of 1¾-inch square bars.

Surge Chamber

The surge chamber will take the form of an enlarged tunnel section, circular in form, with its bottom circumference tangent to the tunnel gradient and a vertical shaft extending some 300 feet to the ground surface. The combination of enlarged tunnel section and shaft affords something of a differential action for meeting the hydraulic conditions imposed by variations in load on the waterwheels

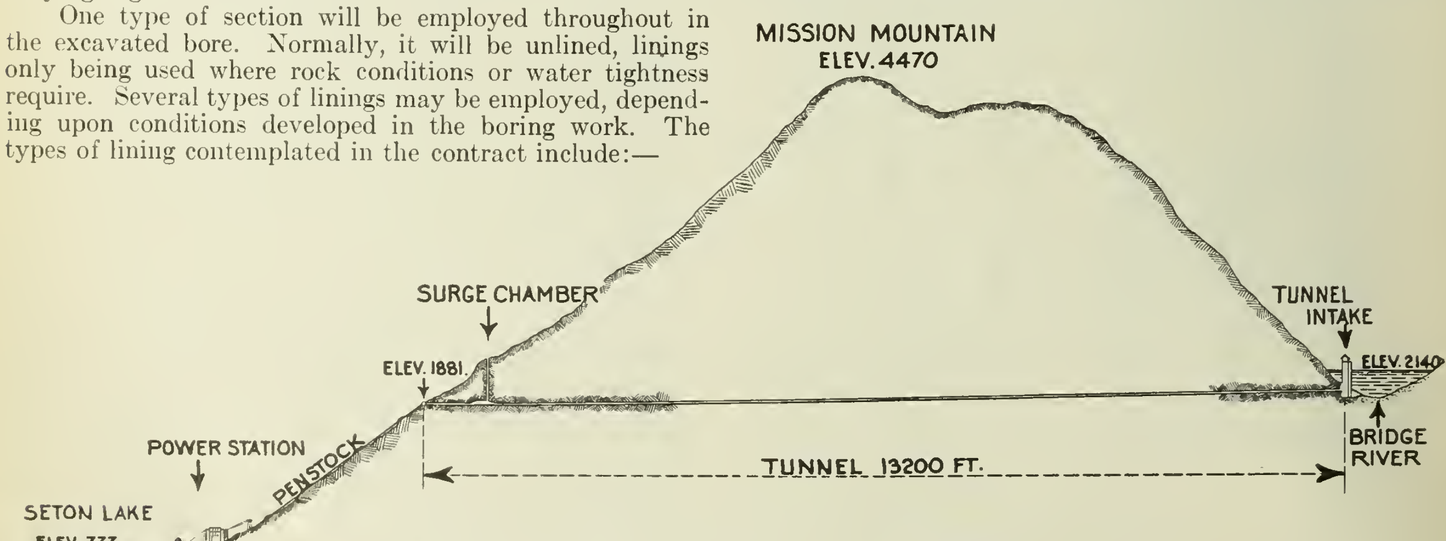

Figure No. 9.—Schematic Profile of Tunnel and Penstock.

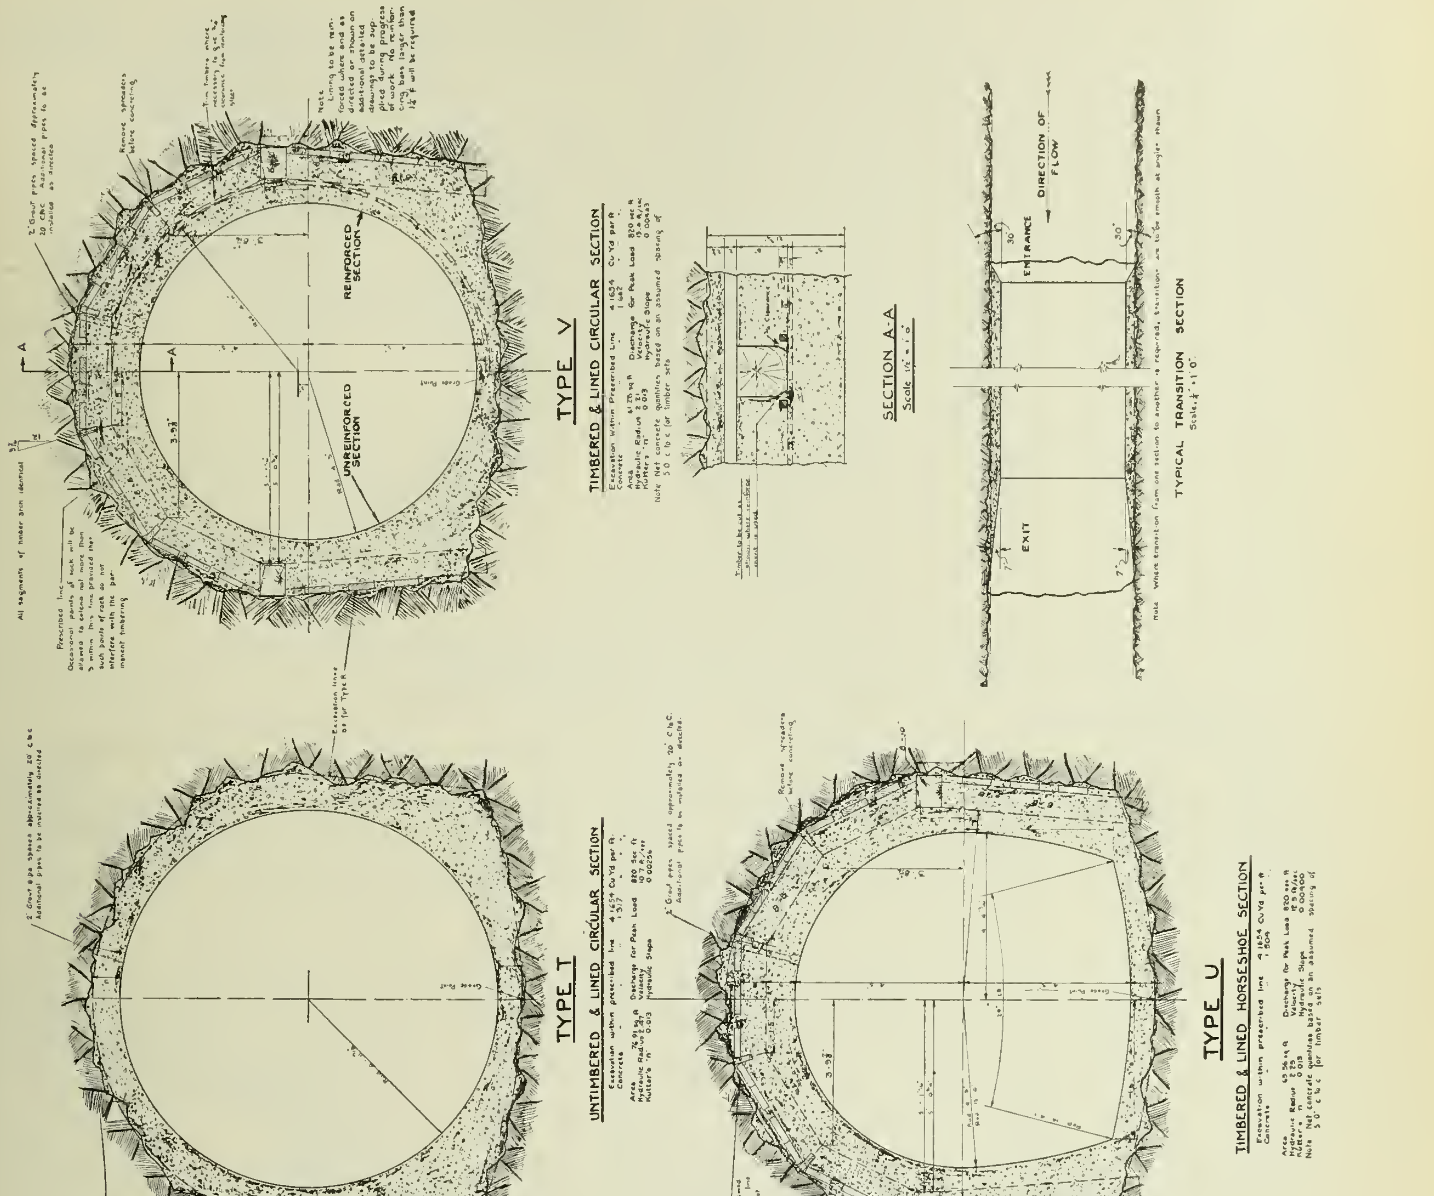

Figure No. 10.—Cross-sections of Main Bridge River Tunnel.

and the consequent varying rates of flow in the tunnel, due account being taken of the changing levels of the head water when the diversion storage dam is built. The shaft serves as well as a relief standpipe and a means of entering the tunnel for maintenance or repair work. The shaft collar is located above the greatest height that will be reached by the surge, thus avoiding overflow which would be very difficult to take care of at the location. Anticipating movements of debris from the floor of the unlined tunnel sections, the surge chamber is provided with a sump to receive any wash of this character which may be then removed through the shaft by means of a hoist and bucket. No means of flushing or blowing off wash material from the tunnel is feasible. A screen, with bars 2 inches clear spacing, is set in the surge chamber just downstream from the sump.

The design of the surge chamber is based upon the following limiting load assumptions:—

¼ load to full load in 22½ seconds—forebay level 1,990. Full load to zero load in 2½ minutes—forebay level 2,140.

Plans and details of surge chamber, shaft, etc., are shown in figure No. 11.

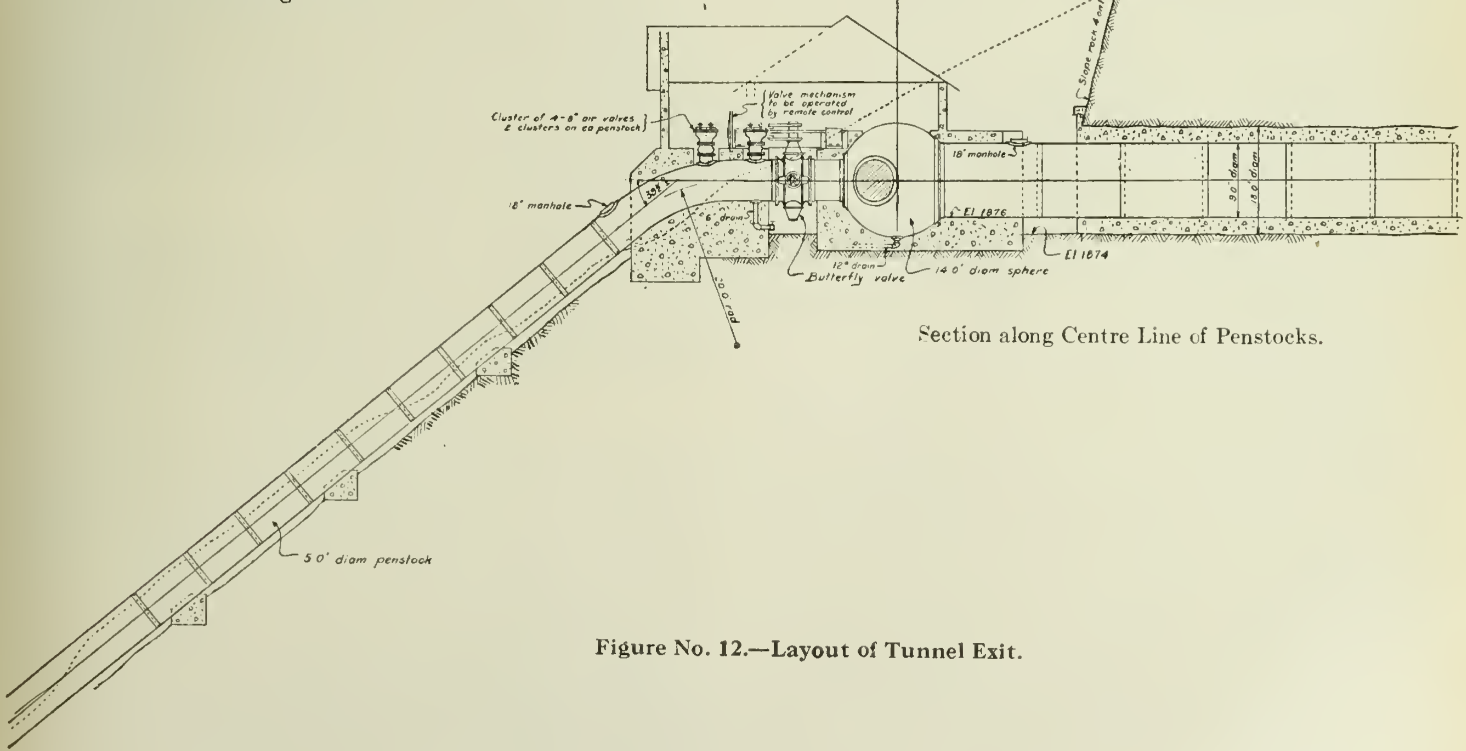
Plan showing Penstocks.



Section along Centre Line of Penstocks.

Figure No. 12.—Layout of Tunnel Exit.

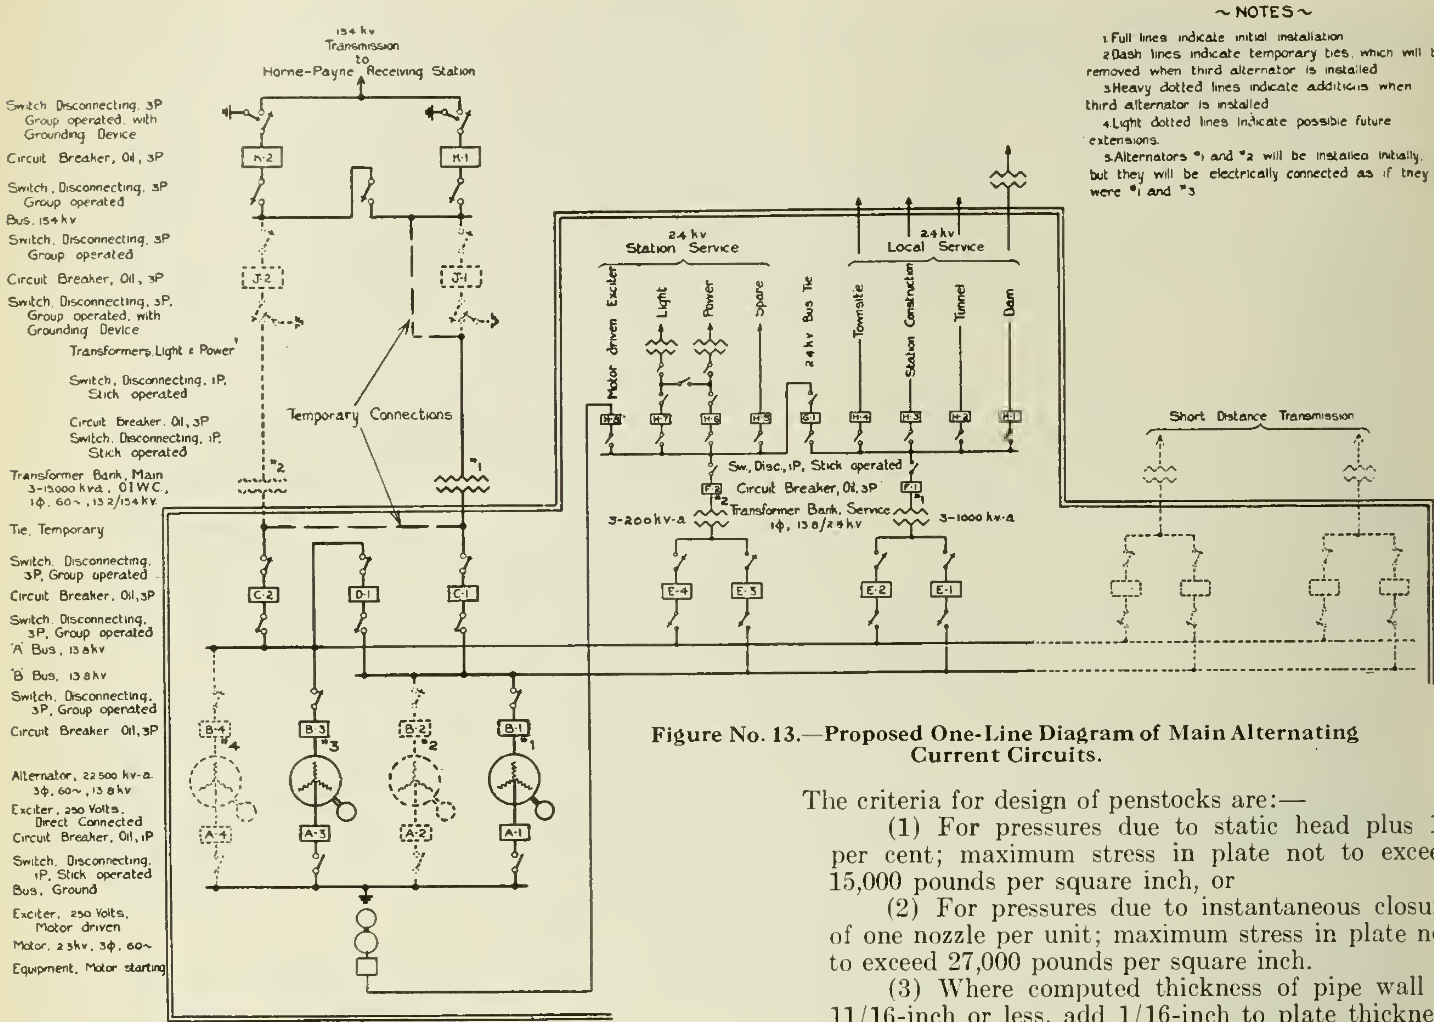


Figure No. 13.—Proposed One-Line Diagram of Main Alternating Current Circuits.

Penstocks

The penstock proper begins at the outlet of the surge chamber. The first section of 9-foot diameter riveted steel pipe, set in tunnel and solidly backfilled with concrete, will terminate just outside the Seton portal, in a spherical riveted steel manifold 14½ feet in diameter. Provision will be made in the manifold for connecting three riveted steel penstocks 5 feet in diameter. Two penstocks only will be built in the present development. A cross-connecting header will be provided at a later date to supply the initial units with water from the second tunnel while the first tunnel is being rebuilt and enlarged for the ultimate stage.

Butterfly valves, motor operated and closed by remote control from the power station, will be set in the penstocks at the gate house immediately below the manifold. No standpipes will be provided, air valves being employed in their stead. From manifold to power house wall,—about 2,200 feet,—two riveted steel penstocks varying in diameter from 60 inches at the top to 51 inches at the bottom and in plate thickness from ⅝-inch to 1 5/16-inch, will be installed. Heavy concrete anchor blocks will be provided at all bends and lighter concrete supporting piers for each section of pipe will be set between the anchors. Generally the pipes will be well above the ground surface. At the crossing of the Pacific Great Eastern Railway tracks the penstocks will be taken through concrete lined culverts which will continue nearly to the power house wall. A cross-connecting header with gate valve between penstocks will be set just upstream from the wye pipes supplying the nozzles.

The criteria for design of penstocks are:—

(1) For pressures due to static head plus 15 per cent; maximum stress in plate not to exceed 15,000 pounds per square inch, or

(2) For pressures due to instantaneous closure of one nozzle per unit; maximum stress in plate not to exceed 27,000 pounds per square inch.

(3) Where computed thickness of pipe wall is 11/16-inch or less, add 1/16-inch to plate thickness to allow for deterioration. Maximum thickness of plate 1 5/16-inch. Minimum thickness ⅜-inch.

In general, criterion No. 1 governs the design for the lower portions of the penstock, and criterion No. 2 for the upper portions. The 15 per cent pressure rise is that due to the mechanical lag of the relief nozzle, and is a condition which will occur in the normal operation of the units, while the condition provided for under criterion No. 2 is of very remote probability.

The annual cost of the pipe in place, (interest, plus depreciation, plus value of lost power), was computed for a number of different diameters and combinations of diameters. As a result of this economic study a penstock consisting of 980 feet of 60-inch diameter pipe and 1,175 feet of 51-inch diameter pipe was decided upon.

Generating Station

While detailed plans for the station can not be carried beyond their preliminary stages until equipment contracts are awarded and manufacturer's drawings are available, studies of a general nature have fixed, with considerable accuracy, the major features of the initial installation. Consideration of the expected intervals between successive stages of development, and the probable changes in equipment design during those periods, early pointed to the inadvisability of attempting to plan a station that would provide for all future extensions. It was decided to limit the design to a station that will reasonably accommodate the initial development, giving due thought in the way of space requirements and structural clearances to the relation of this first station to subsequent stations.

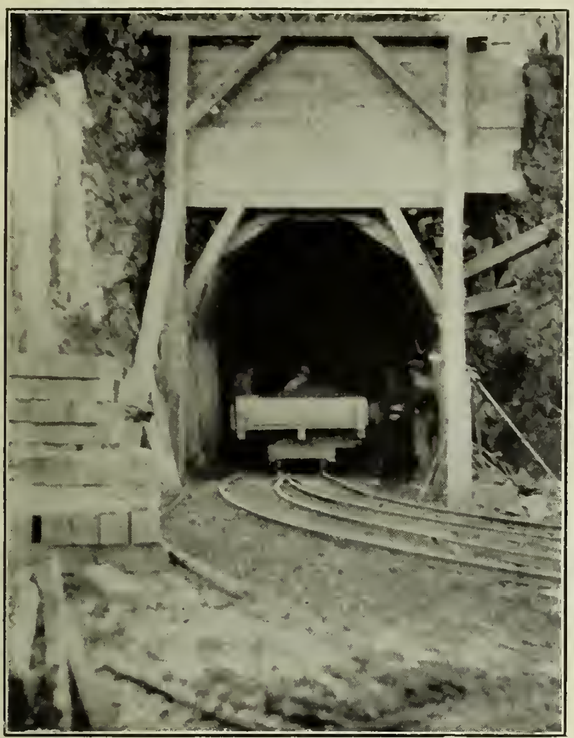

Figure No. 14.—Bridge River Tunnel Seton Portal.

Station No. 1, as planned, will provide for the 60,000 kw. of power to be developed under the first stage. It will be a concrete structure with steel frame, fronting on the lake and situated between the lake and the railway. The generating units will consist of two horizontal shaft alternators rated at 22,500 kv.a., at 90 per cent lagging power factor, 13,800 volts, each driven by a double overhung, single-jet impulse water-wheel designed to develop 28,000 b.h.p. under an effective head of 1,097 feet. The speed is not set but will be between 200 and 260 r.p.m. Each unit will have its own direct-connected exciter, but, for spare and emergency purposes, an additional motor-driven exciter will be provided. A third main unit of the same rating and type will be installed as the second development of the first stage. Structural arrangement will be made for a fourth similar unit, although the plan is not definitely committed to any type of units for the second stage.

The main generating units, exciters, low tension oil circuit breakers, low tension buses, switchboard and other auxiliary equipment will be housed in the station building. The step-up transformers, high tension oil circuit breakers, and high tension buses will be given an outdoor setting, the transformers immediately adjacent to and behind the station building, and the breakers and buses in a high tension switch yard on a bench above the railway tracks.

A one-line wiring diagram, figure No. 13, shows the proposed arrangement of main alternating current circuits.

To provide for the developments under the second stage, a new and separate generating station is visualized. It is expected that larger units may then be used.

Preliminary specifications for the hydraulic and electrical equipment have been prepared, but tenders will not be taken before the early part of 1929.

Transmission Line

The bulk of the power developed will be delivered to the company's system at Horne-Payne receiving station in Vancouver, approximately 130 miles transmission distance from the generating station.

For the first stage, a single circuit transmission line largely supported on H-frame cedar pole structures will be used. For about one half mile at the sending end and for some seven miles at the receiving end, steel towers will be employed. The line voltage will be 154 kv., and the conductor 397,500 c.m. steel core aluminum or its equivalent.

When the second stage is entered upon, the transmission voltage will be raised to 220 kv. Coincidently one or more new circuits of larger conductors, probably 795,000 c.m. steel core aluminum or equivalent, carried entirely on steel towers, will be erected.

Receiving Station

The Bridge River transmission circuits will terminate at Horne-Payne receiving station No. 2. This new station, although constructed adjacent to the existing Horne-Payne station, will be entirely distinct and treated as a separate unit.

The station, including both indoor and outdoor facilities, will be progressively constructed and equipped to provide for the energy produced under the various stages of development. It will contain synchronous condensers and other equipment for controlling and stepping down the transmission voltage to 60 kv., at which voltage the energy will be absorbed into the system.

Construction Progress

It has been attempted, in the above pages, to set out with consistent brevity, a comprehensive description of the engineering aspects of the project. Discussion of details of design and methods of construction has been necessarily limited to a few of the more important points which in their study have proved most interesting to the designing engineers. It is felt, however, that the paper would not be complete without including in it some statement of the status of the construction work.

Preparatory work at the site was started in May 1927. Since that date a permanent headquarters camp has been established on a scale sufficient to meet the requirements of the whole job. Twenty-four bunk houses, each lodging eight men; a community building with dining and kitchen facilities for two hundred and fifty men, and lodging for fifty staff; and fifteen temporary family cottages have been provided. Five permanent cottages, including guest cottage, superintendent's cottage and three operators' cottages have been erected. A water supply system, sewer system with septic tank, and a lighting system are in operation.

A construction power plant, consisting of two 610-h.p. Diesel engines, direct connected to 520-kv.a. generators, furnishes light and power to the main camp, contractor's camps and for driving the tunnel. Roadways over the mountain down to the diversion dam have been built and are being used for hauling supplies by motor truck for the tunnel work. An inclined tramway of standard gauge connects the railway yard with the Seton portal of the tunnel.

The tunnel contract was awarded in October, 1927. Based on the estimated quantities the price amounts to $1,252,000. Good progress has been made by the contractor. Camps and machinery equipment are installed at each portal and the work of boring has progressed about 1,200 feet at the Bridge River portal and about 1,000 feet at the Seton portal.

Transmission line surveys are practically completed and rights-of-way about two-thirds purchased. About 15 miles of clearing has been done.

The Construction of Isle Maligne Transmission Line

General Features of Design, Organization and Construction of a 3-Phase, 60-Cycle, 165,000-Volt Line through 130 miles of Undeveloped Territory

T. M. Montague, A.M.E.I.C.,
Construction Engineer, The Shawinigan Engineering Company, Limited.

Paper read before the Quebec Branch of The Engineering Institute of Canada, March 19th, 1923

The Isle Maligne transmission line was built as a means by which electrical energy generated at the Grande Décharge on the Saguenay river, at the outlet of lake St. John, could be made available for consumption in the city of Quebec and the adjoining territory. It was built by the Shawinigan Water and Power Company and is operated by the company as an integral part of its already extensive transmission system. The terminal station outside the city of Quebec provides a link by which it is interconnected with that system.

Although this paper is written from a construction viewpoint, yet, in order that this may be better understood, it is necessary to give some of the basic features of the design, and also describe to some extent the country through which the line passes.

Features of Design

The line is 130 miles in length, and for over 100 miles it traverses an absolutely undeveloped country, and in that distance crosses the complete range of the Laurentian mountains. This country is for the most part heavily timbered and interspersed with many lakes, rivers and swamps, which tended to make the project much more difficult. It involved, in fact, the cutting and clearing of a right-of-way 150 feet in width by 100 miles in length; the building of a road 100 miles long, with the necessary bridges capable of carrying very heavy loads; and the construction of large camps at frequent intervals as living quarters for the men employed; all of this before the actual construction of the line could be commenced.

The line, as located, probably follows the shortest practical route between the power house at Isle Maligne and the terminal station at Quebec city. Where possible, the location follows along the valleys of the various rivers and chains of lakes, but it was necessary to cross several mountain ranges in order to follow this route. The line was located in as long tangents as the very rough topography of the ground would permit, and it rises at the highest point to an altitude of 3,000 feet above sea level.

The towers are of a square type with three cross-arms each, and are of galvanized steel resting on concrete foundations. All told, there are some eight hundred and twelve towers. Three types of towers are used, each style being designed to meet certain definite conditions. These types were designated as follows:—light, semi-anchor and anchor. Light towers are used on tangents where the span does not exceed 1,000 feet and at angle points where the angle does not exceed 4 degrees. This tower is 85 feet high overall and weighs in the neighbourhood of 5 tons. The concrete foundation for each leg is round, 2 feet diameter at the top and 7 feet at the bottom, and is carried 7 feet 6 inches into the ground. Each foundation requires at least 2 cubic yards of concrete, or 8 cubic yards per tower.

The semi-anchor tower is used where the span is over 1,000 feet and where the angle is less than 20 degrees. It is also used at points of special strain and crossings over roads. These towers are 88 feet high overall and weigh in the neighbourhood of 9 tons. The foundations are similar in shape to those of the light towers, but are 3 feet in diameter at the top and 9 feet at the bottom, and are set 9 feet 6 inches into the ground. Both of these types of towers are held down by eight large anchor bolts extending to the bottom of the foundation.

The anchor towers are used to carry extremely long spans, up to 1,700 feet, or at points where the angle is very large and also at dead end points. In this case, the tower must withstand the unbalanced pull of all the conductors under the worst possible conditions. The foundations are square reinforced concrete spread footings. The large angles forming the tower legs extend to the bottom of the concrete. These towers weigh approximately 10 tons and the foundations require 30 cubic yards of concrete per tower.

The towers and foundations are designed to withstand an 8-pound wind-pressure with a covering of one-half inch of ice on each of the conductors. The line, as built, provides two circuits for 3-phase, 60-cycle current at 165,000 volts. It has a calculated capacity of 100,000 horse power carried on 397,500 C.M. conductors made up of a number of strands of aluminum wire spun on a central core of galvanized steel cable.

The electrical features of this transmission line have been fully covered in a paper by Professor C. V. Christie, M.E.I.C., published in The Engineering Journal for January 1927.

Construction Organization and Equipment

For construction purposes, the transmission line was divided into two sections. Section number one, at the north

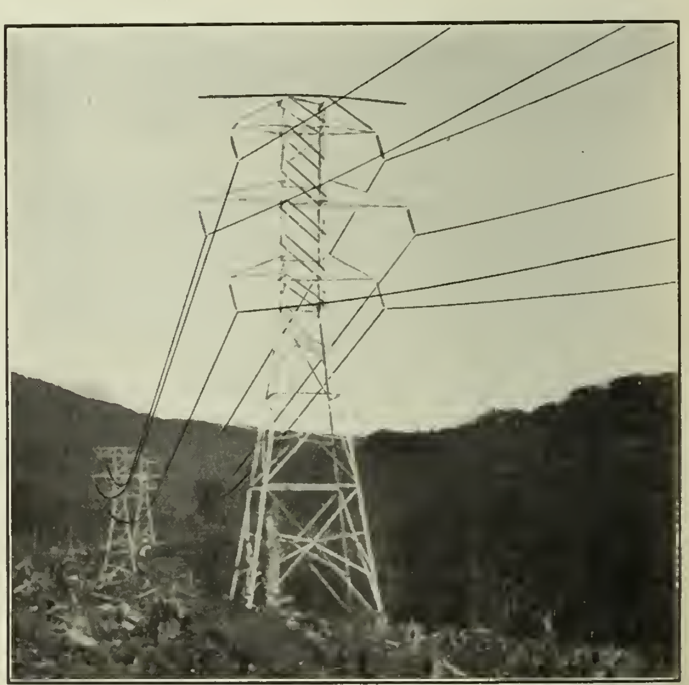

Figure No. 1.—Isle Maligne-Quebec Transmission Line—Standard Towers on Slight Angle.

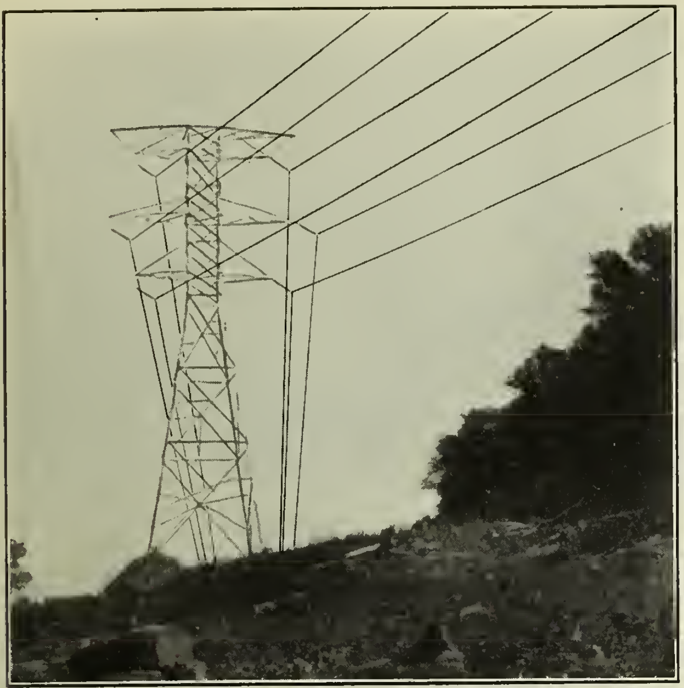

Figure No. 2.—Isle Maligne-Quebec Transmission Line—Semi-heavy Strain Tower on Angle.

end, had headquarters at Hebertville, Que., and section number two, at the south end, had headquarters at Stoneham, Que. This division was necessary because the two ends were obviously the only points from which the work could be carried on, and headquarters of each section were the furthest advanced points to which rail transportation was available. The administration of these sections were entirely separate, but they both were under the supervision of the head office of the company.

There was a superintendent for each section, and under him came the headquarters organization and field organization necessary to accomplish the work. At the outset, it was recognized that one of the greatest problems to solve would be that of transportation, since from rail head to the end of either section was 55 miles.

To take care of this, the following mechanical transport was provided:—twelve Linn tractors, each of which with trailers could haul 20 tons of material over the ruling grade; two 10-ton Holt tractors; four 3-ton trucks; sixteen Fordsons, ten of which were equipped with compressor units; six 1-ton trucks; and automobiles for supervision and inspection. This equipment was kept in repair at garages at each headquarters and at other convenient points along the line.

A good road, capable of sustaining very heavy traffic, was essential, and naturally had to be built first. A large force of men worked on this continuously in order to keep ahead of the other construction crews. Many bridges were necessary to cross the creeks and rivers, and these included several spans of over 50 feet which were designed to carry a concentrated live load of 20 tons. Very little good road material was available immediately adjacent to the location, so that long hauls were necessary, and in places rock crushers were installed and quarries opened to provide this material. The many swamps required a great deal of corduroy as a base. In most places the ground was thickly covered with large boulders which, together with ledge rock, required much drilling and blasting to prepare a foundation.

The construction of the camps followed immediately behind that of the road. These were built at intervals of 6 to 7 miles, and were for the most part of boards covered with tar paper; some, however, were built of logs, while in others a combination of tents and logs were used. They consisted in general of an office, store house, dining room and cook-house, bunk-houses and stables, and were each capable of accommodating one hundred and fifty men and twenty to thirty teams. Altogether, twenty camps were established, in addition to the two headquarters. The foregoing work was only a preparation for the actual construction of the line itself, and yet required considerable time and large crews of men in order that line construction would not be held up.

Construction of Tower Bases

The construction of the tower bases was probably the most difficult part of the whole operation, on account of the nature of the ground encountered, which was for the most part solid rock, swamp or wet sand. The method of putting in these foundations depended altogether on the class of material to be excavated. The ideal condition is that in which the earth will permit opening up the excavation at 2 feet diameter for the light tower and gradually widening out to the full spread of the base of 7 feet. After the setting of the anchor bolts, these excavations are filled with concrete. This method is very economical, in that it saves excavation and forms and also permits the superimposed earth to be developed to the greatest extent as a holding down load.

Where the ground was soft and wet, this method could not be used, and it was necessary to excavate a square hole somewhat larger than the greatest diameter of the base and support the sides with sheet piling. To place the concrete, specially designed collapsible steel forms were used, which were removed when the concrete had set, the sheeting pulled and the excavated ground backfilled.

Where rock was encountered, an excavation was made deep enough and large enough to accommodate the anchor bolts. The hole was then filled with concrete. A great deal of pumping was necessary at all times. This was done with gasoline-driven diaphragm pumps, or, where the amount of water was less, with hand pumps.

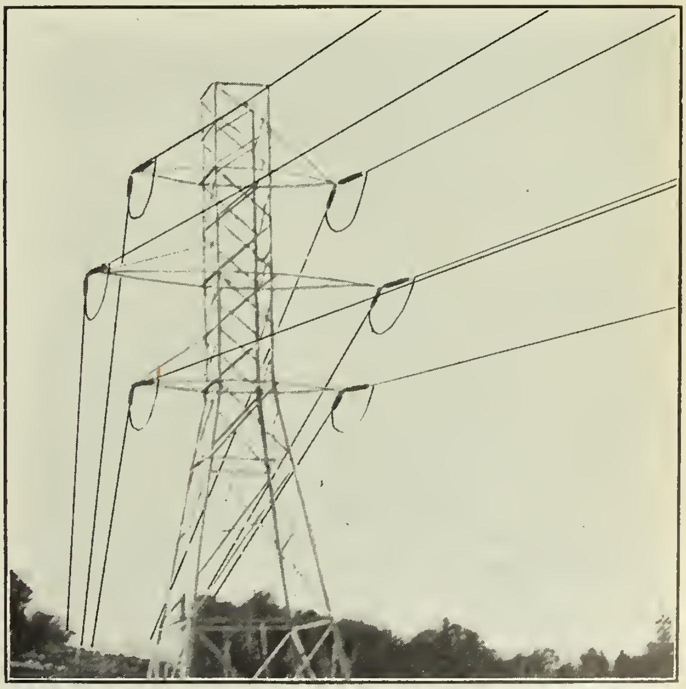

Figure No. 3.—Isle Maligne-Quebec Transmission Line—Heavy Strain Tower on Angle.

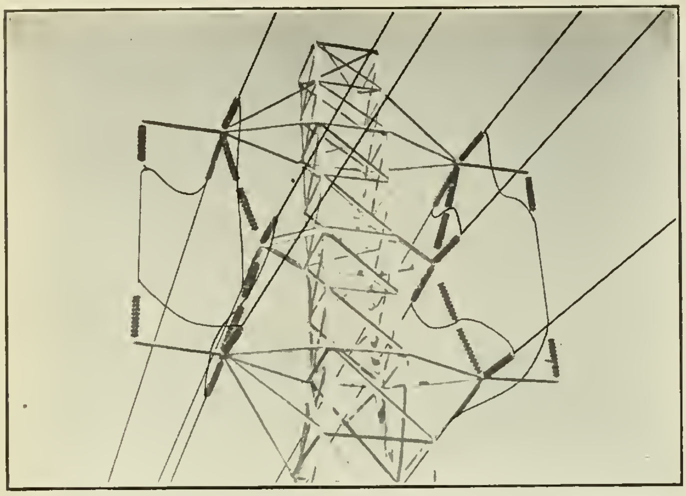

Figure No. 4.—Transposition Tower—One of Two on Isle Maligne-Quebec Transmission Line.

The concrete used for the bases was a 1-2-4 mix. The aggregate employed was both crushed stone and sand or gravel, depending upon the location. At the south end, good aggregate was very scarce and it was necessary to open up eight quarries and instal crusher plants to provide this material. At the north end good gravel was available at convenient locations.

The mixing was done with a gasoline-driven machine of 1/6 cubic yard capacity. Due to numerous steep side hills, together with other transportation difficulties, the weight and quantity of all equipment had to be reduced to a minimum. It must be borne in mind that every time a tower was completed the whole plant had to be moved.

A great many bases were put in during the winter months, and this presented some difficulties on account of the small amount of equipment that could be made useful. The water was heated in large sheet steel tanks mounted on skids. The stone was warmed by fires built around the piles and as close as possible to them. After pouring, any exposed concrete was protected as well as conditions would permit. In cases where forms were used, a small stove was put in each excavation and fired for a day. Where the concrete extended above the ground, fires were built around the foundations, and where they were all below ground the exposed surface was covered with stable refuse and tar paper.

The anchor bolts were held in their exact position during the concreting by means of large steel templates which spanned the four holes. When these were centered and levelled the anchor bolts were in their correct position. These templates were made collapsible for convenience in moving. When the concrete in the foundations was poured, it was kept down 6 inches to permit capping. This was done in order that the foundations might be brought to a dead level after the bulk of the concrete had set. It was found that if one leg of a tower was ¼ inch out of level the tower steel could not be put together.

Erection of Towers

The erection of the steel towers followed closely behind the foundations. The steel was shipped knocked down from the factory in car lots, each car made up of a certain number of complete towers. Each piece of steel was stamped with a number, and a diagram indicated the number of pieces required to complete a tower. It was unloaded at the headquarters and checked and separated into individual towers. These were then hauled up the line to the various camps by the tractors and distributed to the tower sites by teams.

On transmission lines where the steel is lighter, it is customary to assemble the tower completely on the ground and then raise it by means of heavy tackle and sheer legs. This method could not be used on towers of this type, so that a different method had to be developed. This was as follows:—The two sides of each tower, up to the lower cross-arm, were assembled on the ground and raised separately by means of sheer legs. The connecting bracing was then filled in piece by piece. The top portion was then assembled in two sections and the sheer legs were raised to the top of that portion of the tower already erected, when the top sections were lifted into position and bolted fast. The cross-arms were raised separately and connected to the tower. A well-trained crew and foreman could complete one of these towers per day. A crew consisted of one foreman, eight climbers, four ground men, a team and a driver.

A semi-anchor tower was erected in substantially the same manner, but, due to its greater weight and a greater number of bolts, required from two and one-half to three days to complete, the anchor towers required from three to four days, depending on their location.

Stringing of Conductors

The next operation was the stringing of the conductors and ground wire. The conductor came in reels of approximately 4,000 feet, each weighing in the neighbourhood of 1¾ ton. Twelve reels were distributed at every tenth tower and reeled out both ways. The different lengths were united by means of compression sleeves; a steel sleeve for the steel core and an aluminum sleeve for the aluminum covering. These sleeves were pressed on by means of an hydraulic press developing a pressure of 2,000 pounds per square inch.

The wire was reeled out by teams. Specially-made snatch blocks were suspended from each cross-arm, and as the wire advanced from tower to tower it was passed through these blocks. In this way the wire was protected from abrasion and the unreeling expedited. When the wire which was being reeled out met that which had already been completed they were joined with the compression sleeves and that last strung was sagged.

The amount of sag given to the conductors varied with the length of the span and the temperature at the time the work was being done. The method adopted to do this was as follows:—After determining the amount of sag for a particular span from tables provided, targets were placed

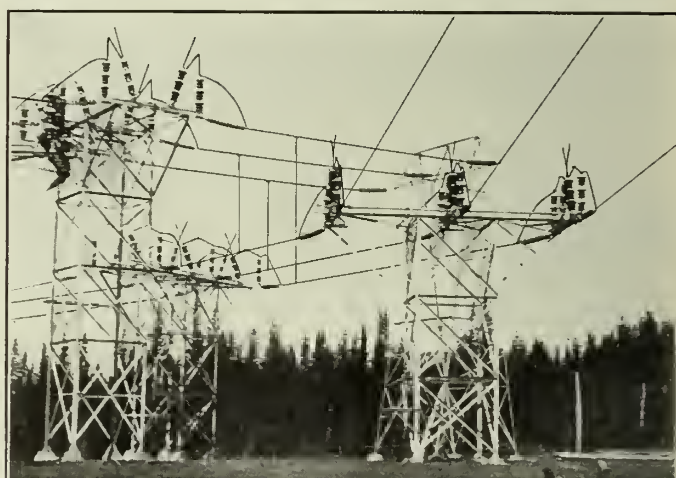

Figure No. 5.—Circuit Opening Switches—Two of these on Isle Maligne-Quebec Transmission Line at First and Third Quarter Points.

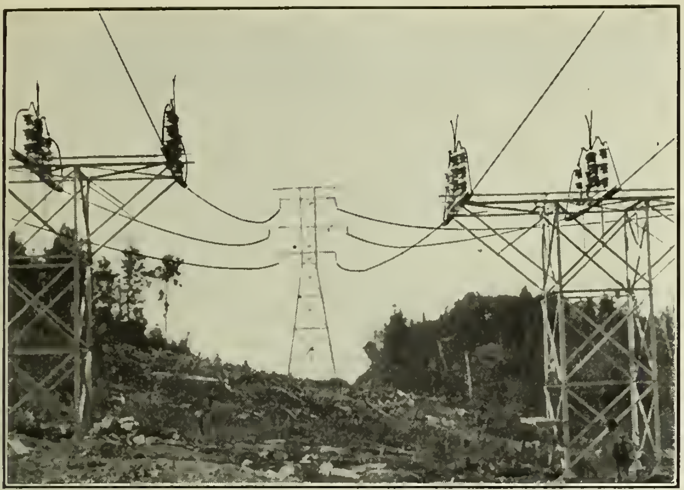

Figure No. 6.—Portion of Circuit Opening and Circuit Crossover Switches—One at Centre Point of Isle Maligne-Quebec Transmission Line.

on the towers at either end at the correct distance beneath the point of suspension of that particular conductor. The conductor was then tightened until it was in line at its lowest point with the targets. As a rule, four or five spans were sagged simultaneously. The conductor was then freed from the snatch blocks, clamped to the insulator, and the armour wire applied, for protection, at the point of suspension.

The ground wires were strung in much the same manner, but were clamped rigidly to each tower.

The final operation on the line was carried out by an inspection crew. Each tower was examined for any missing steel or bolts. The bolts were all tightened and centre punched; that is, a centre punch was driven into the bolt at its junction with the nut to prevent their working loose.

Method of Hauling Tower Material

A short account of the method used to haul the tower material to the site of operations may be of interest. As has been stated, all this material, such as tower steel, anchor bolts, insulators, cement, conductors, equipment and supplies for the camps were all transported to the two headquarters by rail. This material approximated 30 tons per tower. The experience of the summer months was that economical and successful transportation could only be done over snow roads, which were available about the first of January.

The hauling was done exclusively by the Linn tractors, with sleighs replacing the front wheels. Two heavy sleigh trailers were provided for each Linn. The crew consisted of a driver and a helper. As the tractors were loaded, a complete bill of lading was made showing the destination of the load. On section number two there were established two refuelling stations, one 20 miles and one 40 miles above Stoneham. At each of these there was a garage with mechanics capable of making all repairs, and at the upper one relief crews for the tractors were stationed.

The routine was as follows:—A loaded tractor with trailer would leave headquarters routed to the end of the line. At the first filling station a stop would be made, fuel and oil taken, any minor repairs made, and the journey continued. At the next filling station the operation was repeated and the crews changed. The fresh crew would continue on immediately to the destination, where a crew would unload the material, check it and sign the bill of lading, noting any shortages. The tractor would then return direct to headquarters, stopping only to refuel. A fresh crew would take over and the operation be repeated.

A round trip to the end of the line required, on an average, thirty hours, and the average load was 20 tons. The roads remained in good condition for three months, and during that time material weighing some 12,000 tons, exclusive of foundation material, was hauled on the two divisions.

A telephone line of first-class construction was built paralleling the transmission line for operating purposes. This was carried along with the transmission line itself and used for communication during construction. Six well-built houses were also constructed at different points for the use of the patrol men.

Construction was actually started on this transmission line the first part of June 1926. During that summer and autumn, all branches of the work were pushed vigorously, and by the time winter set in the road had been completed. The camps were finished soon afterwards, and a great many tower bases were made. Good progress had also been made in the erection of the steel towers and stringing the wire. During the following winter these construction operations were continued, although on a smaller scale; the chief concern being the hauling and distribution of material. This was advanced so well that when the roads broke up in the spring of 1927 all the material for the construction of the towers was at the sites. This included the sand and stone or gravel, as the case might be, steel, insulators and conductors. The cement was stored in sheds at convenient intervals.

In the spring of 1927, construction operations were again pushed actively, so that by July the transmission line was complete. It was tested out and put into operation on August 7th the same year, fourteen months after the commencement of construction.

Discussion of Paper on the Chippawa Creek Syphon Culvert of the Welland Ship Canal by A. J. Grant, M.E.I.C.[1]

A. J. Grant, M.E.I.C.[2]

The author, in presenting his paper, observed that the maximum discharge of Chippawa creek may reach 10,000 cubic feet per second, under the conditions of a heavy snowfall in the winter followed by heavy rains in the spring. The water surface of the creek, for 27 miles from the Niagara river westward, was practically level in the summer at elevation 562.0 above sea level and west of the canal during spring freshets it rose to about elevation 569.0. The summit level of the present canal was open to lake Erie and its water surface varied between elevations 570.0 and 579.0.

The creek crossed the canal at the city of Welland, about 8 miles from lake Erie. At the site of the culvert the material overlying the rock surface was about 100 feet deep and consisted of soft blue clay with underlying glacial deposits. The clay was mixed with a very fine sand, and some small stones and a few boulders. Immediately over-

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February 15th, 1928, and published in The Engineering Journal, February 1928.

(2) Engineer-in-Charge, Welland Ship Canal, St. Catharines, Ont.

lying the rock they had found a layer of hard boulder clay. In making test borings water was encountered at the surface of the rock immediately after penetrating it. The water in the test pits rose as high as elevation 584.0, or from 8 to 10 feet above the level of the present canal.

Owing to the congested area of the culvert site in the city of Welland it was found practically impossible to locate the syphon culvert for the canal on the south side of the present aqueduct, and in order to make its construction as economical as possible the centre line of the culvert north of the aqueduct made an angle of about fifty-nine degrees with the centre line of the canal. On account of the eastern end of the culvert pit projecting into the present canal about 125 feet, there was at that point a letter *S* turn in the canal which had given some trouble to the captains of ships navigating the canal.

The culvert consisted of six parallel tubes, each 22 feet in diameter and 353 feet long between the end wells of the tubes. The bottom of the culvert pit was about 80 feet below the surface of the ground. Across each end of the tubes a massive concrete wall had been built, the adjacent faces of which are 244½ feet apart. The piers separating the wells of the tubes were provided with stop-log checks, so that in the future, should the tubes become choked, stop-logs can be placed in front of any of the three pairs of tubes, and the latter pumped out to enable them to be cleaned.

The tubes and walls of the structure were carried on timber bearing piles 22 feet long. Under normal conditions, with the water in the canal, the piles under the tubes would carry a load of 9 tons each, and those under the head walls would carry a load of about 35 tons.

In order to permit the construction of the culvert, a cofferdam consisting of twenty-six cells each 36 feet long by 26 feet wide, and built of Lackawanna steel sheet piling, had been driven around the east end of the culvert pit to cut off the present canal. The excavation of the culvert pit had been taken out in two layers, each 40 feet deep. The upper portion of the excavation had been done largely by dredging concurrently with the construction of the cofferdam. The lower half had been done in steel sheet pile trenches or pits braced with timber. It was the construction of these trenches which had made the work so interesting on account of the difficulties encountered.

These pits varied in size from 26 by 43 feet up to 65 feet wide by 111 feet long.

The steel piling used in the construction of the pits had a maximum length of about 83 feet. Owing to the character of the material in which the structure was founded, they had generally been able to drive piling to that depth with considerable accuracy with reference to a vertical plane, although in some cases there were considerable divergencies from those lines.

Owing to the heavy pressures encountered in these pits it had been necessary to use very large timbers; the struts used ranged from 12 by 12 and 14 by 14 to as high as 24 by 24. In the wider pits the struts had been calculated as unsupported columns. They were braced together in pairs, which left every alternate opening free for the working of the machines excavating the material.

It was hoped to complete the main portions of the culvert about July 1st, 1928, barring accidents.

Major A. S. Dawes, m.e.i.c.[3]

Major Dawes remarked that during the execution of the work the manner in which the engineers had handled the difficult problems that had arisen had given the contractors great confidence in the ultimate outcome. He felt that Mr. Grant, as the head of the engineering organization, deserved great credit, and it was gratifying to note that the engineers on the Welland canal are practically all Canadian-born and educated in Canada.

O. O. Lefebvre, m.e.i.c.[4]

Mr. Lefebvre said that he had been fortunate enough to visit the Welland canal work and had found that the problem of laying the culvert or syphon underneath the new Welland canal in order to pass the flow of the Chippawa creek was of great interest.

The size of the culverts and their depth, and so on, had all been planned in the usual manner, and the contractors were asked for a bid on the work. Generally, the contractor was not given any layout as to the method which he should follow in executing a certain work; he was left more or less free to approach the solution of the problem in his own way. But in this instance everything had been planned out ahead; the whole layout and the method of approach had been determined by the engineers in charge of the construction. The only thing that was left uncertain, and for which the contractors were asked to bid a lump sum, was the pumping.

Engineers knew that in most cases when tenders were asked, say for the construction of a dam, it was stated that the site of the dam would have to be unwatered. Decision as to what method should be followed, or which part of the river should be tackled first, and what proportion of the river should be dealt with at one time was usually left absolutely in the hands of the contractors. Everyone bidding on the job could look at the problem in his own way. That system might be a mistake, and in his opinion engineers, when preparing such plans, should also provide for the method which they consider should be followed to unwater the river section, so that the contractor would not be called upon to face the uncertainty which is connected with any unwatering problem.

Another feature, which he had noticed, was the behaviour of the steel sheet piling. The author had mentioned that at a certain depth some steel sheet piling had separated, which meant that such piling is not absolutely dependable when water-tightness is desired.

He would say, further, that while there might be differences of opinion as to the advisability of having built the Welland canal at all, and there might be differences of opinion as to the effects of that work on the cost of transportation, when it came to the engineering features of that great work, there were no differences of opinion regarding the successful and creditable work of the engineers of the Department of Railways and Canals and the engineers of the Welland ship canal in carrying out this large undertaking.

T. Kennard Thomson, m.e.i.c.[5]

Mr. Thomson remarked that from the drawings it appeared as if the culvert tubes were not as heavy as the material displaced, and he enquired whether, if the tubes were unwatered with no water above them, there would be danger of the structure being lifted by the water pressure below them.

The author, in reply, stated that all the tubes could never be unwatered at one time; it was possible to have two tubes unwatered, but not all of them, as that would involve obstructing the flow of the creek, which would be too dangerous to contemplate.

He pointed out further that the steel sheet piles that surrounded the perimeter of the culvert were left in place

[3] President and Managing Director, Atlas Construction Co., Ltd., Montreal.

[4] Chief Engineer, Quebec Streams Commission, Montreal.

[5] Consulting Engineer, New York City.

and that these piles would act as an anchor to keep the structure down. The culvert was constructed with vertical joints at frequent intervals in the length of each tube.

Wm. McG. Gardner, A.M.E.I.C.[6]

Mr. Gardner enquired how the tunnelling was executed under the canal section, why piles were necessary there, and why a depth of 3 feet from the bottom of the canal to the top of the concrete was selected.

Mr. Grant.

The author replied that there was no tunnelling done in constructing the culvert. The excavation was all done in the open. For the upper 40 feet the excavation was all done in one large open pit, and below that the excavation was done in a series of open steel sheet pile trenches.

As regards the proper depth for the concrete below the bottom of the canal, it was a matter of discussion as to whether the upper surface of the concrete should be finished in the plane of the bottom of the canal for 30-feet navigation, or whether it should be carried down a little more. It was decided that in the event of the canal being required for 30-feet draught it would be better to give the ships some water under them over the culvert, and avoid the danger of the ships' keels scraping the top of the concrete and injuring the culvert, so an additional depth of 3 feet was decided upon over the top of the culvert.

The length of the locks had never been questioned, though some engineers had questioned the width and others the depth. One prominent engineer advocated 32 feet of water for 30-feet navigation, but the author thought that was a matter of opinion. Today the depth of navigation was 14 feet, which was used to the last inch; in fact boats in passing through the locks scraped the mitre sill platforms. For 14-feet navigation the locks should have a greater depth of water over their sills than 14 feet.

In regard to Mr. Lefebvre's remarks, he might say that the contractor was not given any option in the type of cofferdam he could use in closing the east end of the pit. One of the main problems had been to maintain uninterrupted traffic in the present Welland canal. If that had been obstructed, even for a few days, the consequences would have been serious; careful plans were therefore made for the cofferdam, and the contractors were informed both by the specifications and the plans how it was to be built. The only question at issue was the amount of pumping necessary to be done.

In order to give some idea of the pressure which had to be dealt with in the lower pits, the author pointed out that all of the 12 by 12, 14 by 14 and 14 by 16 struts were supported at their ends by 1-inch steel plates bolted to the corbels. Some of these steel plates had been bent to such an extent that they had been forced 5 inches into the corbels and had remained there when the corbels were finally removed from the pits.

The 18 by 18 struts had crushed as much as 2½ inches into the oak corbels, which were 8 inches thick and 22 inches wide and had a minimum length of about 6 feet. Those corbels bore against 24 by 24 inch Douglas fir wales, and in many of the pits the corbels had been completely destroyed, especially in pit "*H*" at the northeast corner of the structure.

For the support of the north wall of pit "*E*" it had been necessary to carry across the culvert to the north side of the northern tube 24 by 24 struts which were supported against 24 by 24 wales. The ends of these struts had crushed into the wales 5 inches, and in some cases had practically destroyed the wales themselves, and in doing so had put a bow in the 24 by 24 wales of at least 12 inches in a length of about 6 feet.

Another feature of the case which would perhaps illustrate some of the difficulties more clearly even than the crushing of the timber struts and wales was an occurrence in the southeast corner of the culvert pit. In pit "*F*," which was, roughly speaking, about 65 feet wide and 90 feet long, and contained about 5,500 yards of concrete, this mass of concrete was about 70 feet high. The superintendent on the work at three o'clock one afternoon felt the timber trestle surrounding the east end of the culvert pit shake under his feet, but on looking around nothing seemed to be wrong, so he forgot all about it. The next morning he requested the engineers to lay out some work in an adjacent pit, when it was discovered that the mass of concrete in pit "*F*" had moved 2 feet to the northwest. An examination showed that it had not leaned over and had not gone out of the perpendicular, but had shifted bodily in a horizontal plane. This incident gave some idea of the unstable character of the foundation against lateral pressure.

C. S. G. Rogers, A.M.E.I.C.[7]

Mr. Rogers observed that the author had favoured several of the local branches of The Institute with a broad general outline of the design and construction of the canal itself, and had now shown that some of the details of the work were in their own way as unique as the canal itself.

The problem of opening a large area of ground and building in it a concrete block enclosing a series of underground tunnels to act as a syphon to carry the Chippawa creek under the canal involved pits sunk to a depth of 80 feet,—a work that was rendered exceedingly difficult by the proximity of the excavation to the existing canal. The volume of flow of water into the excavation was the governing factor in deciding the feasibility of such a work. Cofferdams could be made to exclude the water from the canal, but the flow through the underlying rock strata was another problem.

It was very gratifying to note how nearly the results obtained from the borings made at the site confirmed the reasoned opinions based on such geological features as neighbouring water horizons and the direction of rock incline. The borings too had justified the change in design of syphon from that of tunnels through rock some 170 feet below ground to tunnels through the clay just clear of the bottom of the canal. He thought it very doubtful whether the work as originally designed could have been carried to a successful conclusion, except at prohibitive cost, or whether the original scheme would have resulted in a structure capable of the future inspection and maintenance that were provided for in the altered design.

The method of handling the excavation showed a broad grasp of the problem to be met. The first step entailed an open pit excavation, with one end a bank cut to natural earth slope, and the other end protected by a most interesting cellular type steel pile cofferdam. The second step divided the lower half of the excavated area into a number of vertical walled pits of the open steel sheet-piling cofferdam type.

He noted that some of the cells of the cofferdam had tilted inwards and settled on their inner edges, and believed that this was due to a mistaken assumption in design. The design contemplated the distribution of base pressures over the total area of the horizontal cross-section of the cells, but this would be prevented by the fact that the earth filling adjacent to the point of application of side pressures would compress, and so would not pass on the applied force to

(6) Special Trackwork Engineer, Montreal Tramways Company.

(7) Engineering Department, Canadian National Railways, Moncton, N.B.

the area of base covered by the earth fill. On the other hand the transverse walls of the cells would actually carry the pressure across and apply it as a toe pressure, that is, as a downward thrust on the inside pile wall, with the result that settlement actually took place.

The fact, too, that the walls carried practically the total horizontal pressure, and converted it into a downward thrust on the inner walls, accounted for the steel pile walls bursting apart.

He would submit that in designing cofferdams of this kind, either the filling of the cells must be of a nature to transmit the applied pressures to the base, or the inner and outer walls must be figured to resist the downward pressure or the uplift, as the case might be.

If a criticism of this paper might be offered it would perhaps be that the honesty of the engineer had forced him to emphasize the minor failures encountered, particularly in the bracing of the open pit cofferdams,—failures which were relatively unimportant, having regard to the magnitude of the success.

Mr. Rogers would suggest an interesting study which might throw light on an aspect of open cofferdam work that is always a matter of doubt. The author had stated that in designing the bracing for the pits a weight of material of 120 pounds per cubic foot was assumed, with angles of repose of 4 to 1 and 3 to 1. In analysing the failures of struts involved, the computed stress is known, the weight of material is to all purposes correct, and the ultimate strength of Douglas fir timbers is pretty well known. Would it not be possible then from these known factors to work back and find out the actual pressure of earth, and make a check on the assumed angles of repose of 4 to 1 or 3 to 1, as the case might be?

Pits of this depth and length of side were seldom encountered, and data obtained from them would give a real indication of earth pressures, as they would be relatively free from the arching action of the earth walls that occurred in pits of lesser dimensions. The failures of timbers recorded seemed to indicate pressures just producing collapse and no more, so that they would appear to offer a fairly accurate solution of this question.

Might he be permitted to express the very real pleasure and satisfaction he had felt in the study of the paper?

D. W. McLachlan, M.E.I.C.[8]

Mr. McLachlan remarked that in the years which followed the power developments made at Niagara falls between 1902 and 1906, a number of schemes for overland power canals from lake Erie to lake Ontario had been advanced. One of these proposed to carry the level of lake Erie across the country from Wainfleet to Jordon, where almost the full head between lakes Erie and Ontario was to be concentrated in a power house with about one mile of pipe line, and he had been employed on the survey of this project. Other projects had also been considered at this time, notably the Queenston-Chippawa route, afterwards utilized by the Hydro-Electric Power Commission of Ontario.

Further, in 1911 and 1912 the idea of building a deeper navigation canal between lakes Erie and Ontario began to develop, but as the problem of getting down to the lower level with a navigation canal differed from that involved in power development, the engineers connected with the work looked for a route along an obvious depression in the country west of Decew falls. This proposed route followed the Welland canal from lake Erie to Port Robinson, thence west to the Twelve Mile creek, and then down the Fifteen Mile creek to lake Ontario. Borings made on this route showed great deposits of quicksand, and then it was discovered that the route followed a pre-glacial outlet of lake Erie, and solid rock was very far below the surface of the ground. Further light on the situation came from an examination which Mr. McLachlan had made of a report by Dr. Spencer, which was printed in 1905. Dr. Spencer's sketches indicated that the valley could be avoided by following a route directly north from Thorold to lake Ontario, or going west of it, via Jordon. The fall in the country near Jordon or the Twenty Mile creek was too rapid for a canal with ordinary lifts, so borings were made on the Thorold-Ten Mile creek route. These showed the rock surface to drop gradually from about elevation 350 at the foot of the escarpment to about 210 near lake Ontario. This enabled three locks with lifts of 46½ feet to be introduced at intervals of about one mile. At the escarpment some locks had to be placed in flight to follow the ground surface, and in that case they had to be twinned to maintain traffic capacity. The country between Thorold and lake Erie, being flat, geological conditions did not dictate the route to be followed there. In this territory nothing would have been gained by departing from the alignment of the old canal, except where solid rock was encountered in quantity. At these points deviations were made to enable the rock section to be removed in the dry. The flight lock arrangement on the canal had been evolved by Mr. Sterns after he joined the canal staff in 1912.

The two most difficult problems on the canal were the building of lock No. 3 and the Welland aqueduct. In preparing the early plans for the canal, it was thought that the building of the aqueduct could be avoided by taking the Welland river into the summit level of the canal, and discharging flood flows at Port Robinson over a dam there. However, years of study and consideration brought a change, the idea was finally given up, and the new canal, like former canals, crosses the Welland river by an aqueduct without affecting its level.

Mr. McLachlan had had nothing to do with determining the length, width and depth of the locks selected, and did not know how they were arrived at. He did, however, remember the low elevation of solid rock at locks 1, 2 and 3 being advanced as an argument for giving 30 feet depth to those locks. As explained by Mr. Sterns, it was first intended to equip the locks with single leaf gates at both ends. In fact, parts of some of the locks had been built with this scheme in view. However, the practicability of single leaf gates was investigated by Mr. McLachlan early in 1920, and he had succeeded in persuading Mr. Alexander Grant and the late chief engineer of the Department of Railways, Mr. W. A. Bowden, to change back to mitering gates. Single-leaf gates were first adopted because it was thought they could be slammed in case of accident. Later investigations showed that this could not be done without departing from pintle and yoke construction, because the deflection of the gates under load would set up a leverage action by contact with the hollow quoin casing during slamming. Later investigations also showed the single leaf gate to be too heavy to lift by floating pontoon except with the gate in its recess. This was thought to be a dangerous state of affairs to leave for posterity to deal with. The change back to mitering gates was chiefly made because of these difficulties.

In the Welland ship canal, a new type of lock valve was being tried out, and lift bridges were introduced on a large scale for the first time. These were the most important advances from the former works of this kind.

The summit level of the canal was protected by a pair

(8) Department of Railways and Canals, in charge of St. Lawrence Ship Canal and Hudson Bay Railway Terminals.

of guard gates in accordance with the practice established by Page, Munro and others many years ago, double gates at the head and foot of locks standing against traffic whenever large quantities of water are held back.

The Welland ship canal was being built on conservative lines, and estimates showed that it follows the cheapest route for such a canal between lake Erie and lake Ontario. In fact, a canal on the United States side would have cost twenty per cent more than a similar canal on the Welland route.

Discussion of Paper on Bridges over the Welland Ship Canal by M. B. Atkinson, M.E.I.C.[1]

M. B. Atkinson, M.E.I.C.[2]

The author, in presenting his paper, stated that he wished to correct a very unfortunate printer's error on the last page of the paper, in the last paragraph but one, as a result of which the names of the consulting engineers and the Canadian Bridge Company had been omitted from the list of those organizations whose staffs had done so much to ensure the successful completion of the work. He then presented and described a series of lantern slides of views which, for lack of space available, could not be included in the paper. These showed the variety of work required for the bridges over the canal, including, as they did, long reinforced concrete spans for both highway and railroad traffic, substructures, bridge sites at the canal locks, temporary bridges for diverting traffic during the construction of the new substructures and superstructures, reinforced concrete bridge houses and their cantilevering supports, old swing-spans, new bridges built, etc.

W. Chase Thomson, M.E.I.C.[3]

Mr. Thomson remarked that the author was to be complimented on his very complete description of the bridges over the Welland ship canal.

From an aesthetic point of view, the vertical-lift structures were fairly satisfactory; and the double-leaf bascule at Queenston road had very good lines. On the other hand, the best that could be said of the single-leaf bascules with overhead counterweights was that they were more useful than ornamental. They seemed to be necessary evils where located close to lock gates; but, in cases where there was sufficient room, simple bob-tail swings would have been more economical, both in first cost and in operation, and also less offensive to the eye.

The late Mr. W. A. Bowden had been sufficiently impressed with some preliminary sketches for a double-swing design which Mr. Thomson had submitted to suggest that he should design a bridge of this type for the highway crossing at Port Robinson, in accordance with the Welland ship canal specification and the substructure drawings which he provided.

A design was prepared accordingly, in which Mr. Thomson had placed the pivot piers sufficiently far apart to provide the full clearance for navigation required by the specification, the bridge being fully protected, when open, by massive concrete retaining walls on both sides of the waterway, instead of fenders composed of pile clusters or floating booms, as mentioned in the paper. The bridge was counterweighted to balance the dead load; and, when closed, the shore ends were anchored to provide the negative reactions for the live load over the waterway. In all other respects the structure was similar to ordinary swing-spans, and the details were exceedingly simple. The provision of a satisfactory end anchorage, however, required a good deal of study.

In accordance with the requirements of the specification, this bridge had a 20-foot roadway, with two sidewalks, each 5 feet wide in the clear; and it was designed for a live load of 100 pounds per square foot on roadways and sidewalks; or for two 20-ton motor trucks, passing each other on the roadway, with 100 pounds per square foot on the sidewalks. The length of the anchor arms was 60 feet, and that of the cantilever arms 120 feet. The trusses were 23 feet 2 inches centre to centre; and the distance between centres of pivot piers was 243 feet. The counterweights were underneath the floor, and thus out of sight.

Some of the advantages incident to this type of bridge, as compared with others designed to meet the same requirements, might be stated as follows:—

(1) In the event of a collision, the damage to the structure would be less serious than to a bascule or to a vertical-lift bridge; for the applied force would mainly tend to swing the individual leaves in their normal path; moreover, there would be no overhead counterweight to drop. At the worst, the bridge could be cleared away far more readily than any of the other types.

(2) The stresses in all members would be readily determinable, and there would be an entire absence of reversals. Thus the danger of failure due to stresses which might be incalculable and difficult to estimate would be eliminated.

(3) The first cost of this type of bridge would be much less than that of a trunnion-bascule, rolling-bascule or vertical-lift, due to less structural steelwork with simpler details, less counterweight and easier erection.

(4) The cost of operation and maintenance would also be much cheaper, because it could be operated with less than one-half the power required for any of the other types, and because it had no complicated parts likely to get out of order.

(5) A concrete floor could be used with it, an advantage which did not apply to some of the other types.

(6) It could readily be operated by hand-power, should the electric motors and gasoline engines fail.

The cost, in accordance with this design, of the superstructure alone was estimated at the time as follows:—

Structural steel work, 828,000 lbs. at 8c	$66,240
Heavy machinery, 100,400 lbs. at 34c	35,140
Reinforced concrete floor, 175 cubic yards at $40.00	7,000
Concrete counterweight, 187 cubic yards at $10.00	1,870
Electrical equipment with incidental machinery	15,000
Operator's cabin	2,000
	$127,250

being less than one-half the cost of a double-bascule or of a vertical lift bridge.

Mr. Thomson further pointed out that the dependability and low cost of maintenance of swing bridges were well known, for swing bridges were far more common than any other type of movable structures. It was true that double-swing bridges were uncommon. Two were men-

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February 16th, 1928, and published in The Engineering Journal, February 1928.

(2) Structural Engineer, Welland Ship Canal, St. Catharines, Ont.

(3) Designer, Dominion Bridge Company, Limited, Montreal.

tioned in the paper, and, as a matter of interest, he wished to point out that there was another at Mira, Cape Breton, near the line of the Sydney and Louisburg Railway.

Referring to the double-swing bridge at Cleveland, which was built in 1895, and located in the downtown district, where the traffic, consisting largely of motor trucks, was exceedingly heavy, he had reliable first-hand information to the effect that the operation of this structure had been very satisfactory and inexpensive, which the author had admitted in the paper under discussion. In the same sentence, however, he had proclaimed that not another bridge of this type had since been built; and he apparently considered this fact to be an adequate reason for its condemnation.

It might be pointed out that there were fashions in bridges, as well as in clothes and hats. In swing bridges, whether single or double, there were few patentable features. On the other hand, other types of movable bridges had been covered by many patents. Consequently, such structures had been intensely advertised by the holders of such patents. The result had been that many bascule and vertical-lift bridges had been adopted where simple swings would have given far better service at much less cost.

Some criticism of the speaker's design having been made on the ground of excessive cost of substructure, due to the mass concrete guard walls on both sides of the waterway, an alternative design for the substructure only had been submitted subsequently. It was a very substantial reinforced-concrete structure, including a horizontal fender about 5 feet above the water line, supported on bents 30 feet apart. The fenders were 30 inches deep and 48 inches wide, suitably reinforced, and were designed for a horizontal load at the centre of 150,000 pounds. The bents consisted of a vertical member 30 inches square, and a diagonal backstay of the same dimensions. They were designed for a horizontal load at the top of 300,000 pounds. In this case the pivot piers were hollow, and capped by a heavily-reinforced slab 9 feet thick. The estimated cost of this alternative substructure was about $90,000.

J. L. M. Tait, A.M.E.I.C.[4]

Mr. Tait desired to ask whether cast iron gears or racks were permitted in the swing-span bridges, or whether cast steel had been employed. He would also inquire whether any difficulty had been found in providing a satisfactory type of rolling bed for the heavy bridges. In his experience it was difficult to get a satisfactory pier for a rolling-lift bridge, although such bridges had been used for the past twenty or twenty-five years.

Experience had shown that it was practically impossible to get a satisfactory rolling track. In almost every case the track buckled and the rivets sheared off.

Mr. Tait also asked the author to state what considerations had led to the selection of the lift-span type of bridge, for it would seem to the outsider that lift-span bridges were more liable to accident than almost any other type.

S. Blumenthal, A.M.E.I.C.[5]

Mr. Blumenthal referred to the point under discussion, and stated that the Canadian Pacific Railway had a double-track rolling-lift bridge with about 120-foot span at Fort William, which had been in use for fifteen years, and had never experienced any trouble with regard to the rivets shearing along the edges of the segmental girders.

(4) Structural Designer, Dominion Bridge Company, Limited, Montreal.
(5) Assistant Engineer, Bridge Department, Canadian Pacific Railway, Montreal.

Prof. Peter Gillespie, M.E.I.C.[6]

Professor Gillespie observed that the paper described work which displayed a care in design and an excellence in workmanship for which the Department of Railways and Canals was justly well known.

Mr. Tait had drawn attention to the design of the bearing plates for the segmental girders and for the supporting girders upon which they roll in the Scherzer type of bridge, and certain troubles incidental to their operation. In this case the area of contact between roller and girder was relatively small, while the deformation or "biting in" seemed to be proportional directly to the load, and to be independent of the diameter of the cylinder.

The investigations of Mr. Wilson of the Engineering Experiment Station, University of Illinois, and others, had indicated the magnitude of these quantities. While he did not recall the precise figures, they were substantially of this order: a 20-foot diameter cylinder loaded with 75,000 pounds per inch of length contacted over only about 2 inches and the deformation was only about 0.004-inch. Now, while such figures were interesting, there lay in their smallness a potential cause of trouble. If, for example, the upper face of the supports, transversely, were not parallel with the rolling face, the roller must "ride the ridge," and if the lack of parallelism were equal to the figured normal deformation for good contact, the first half of the load would produce the designed stress, and the whole load might occasion stress beyond the yield point. For greater lack of parallelism the undesirable effect would obviously be correspondingly increased. Such lack of parallelism might result from inaccuracies in workmanship, but more likely from errors in setting the supporting girders. The inference just drawn respecting the effect of such errors of course assumed a perfectly rigid support for the bearing plates—a condition never entirely realized.

To prevent the overstressing, to which Mr. Tait had referred, a generous bearing width was the first essential. A second was ample thickness of bearing plates,—not less than 6 inches generally. A third was accurate machine work in the shop and precision in setting the supporting girders. Finally, to produce a little more flexibility and consequently to facilitate the adjustment necessary because of lack of parallelism, it might be advisable to stagger the stiffeners on the rolling girder with those on the supporting girder beneath it.

P. L. Pratley, M.E.I.C.[7]

Mr. Pratley, the chairman, believed that the author had put his finger on the spot when he spoke of workmanship. Today, the vast improvements in methods, the increase in care, and the intelligent use of equipment in our fabricating shops all tended towards the removing of our fear of this high pressure or of these deformations. His present feeling was, that the shearing of rivets on rolling-lifts was caused by a possible lack in careful workmanship, but that with research along that line, with a careful study of the bridges of this type actually operating, and with thorough inspection during fabrication and erection, vast improvements were being effected in the detail construction and in the conditions under which such bridges had to operate. Under modern circumstances, then, it had been possible to re-establish this type in competition with other types such as those depending on lubricated trunnions.

(6) Professor of Civil Engineering, University of Toronto, Toronto, Ont.
(7) Monsarrat and Pratley, Consulting Engineers, Montreal.

Dean H. M. MacKay, M.E.I.C.[8]

Dean MacKay noticed that the figures given, in the list of bridges, as to the power required for operation indicated that the vertical-lift bridges required greater power than other types, other things being equal. Was this impression correct?

M. B. Atkinson, M.E.I.C.

The author, in reply, remarked that Mr. Thomson, in his discussion, had stated the advantages which he considered that the double-swing span had as compared with the other types of movable bridges investigated, but he did not propose to enter into controversy regarding the relative merits of various types of movable bridges, since the purpose of his paper was a description of the work involved in providing the necessary bridges for traffic crossing the canal. It was proper, however, to point out that the estimate of cost made by the Welland ship canal office for the superstructure of a double-swing span designed to the requirements of the Department's specifications was largely in excess of Mr. Thomson's estimate. Mr. Thomson seemed to have received from the paper the erroneous impression that the author was disposed to condemn the use of the double-swing span simply because no more had been built. What the author meant to convey was, that during the past thirty years there must have been many cases where this type of bridge should have received favourable consideration in competition against the many patented bridges that had been built, and he did not understand why this consideration had not been given. Double-swing bridges were unsuitable for railroad traffic, but were suitable for highway traffic. The cost of the superstructure should be less than for the others, but the approval of the use of a double-swing bridge by the engineer for a government, municipality or corporation would depend on what he would accept for protection; the deeper the depth of water required for navigation the greater the cost of the protection. As the locks of the Welland ship canal were built to take a ship of almost 80 feet beam, 800 feet length and 30 feet draught, he believed it would be evident why Mr. Thomson's design for protection had been unacceptable. Pile clusters were used a great deal to protect structures from being struck by large vessels, as their efficiency lay in their elasticity; they were now in use on the canal, and would be used at some of the new bridges. He believed it would be plain that in using, for estimate purposes, pile clusters as a protection to the double-swing span, the estimate of cost for that type had been kept down to the minimum.

In reply to Mr. Tait, the author would decline to discuss the reasons for the selection of the rolling-lift type, as the various designs submitted had been investigated by a board which reported to the chief engineer of the Department. Cast iron had not been permitted in the machinery drive and racks, the pinions were made of forged steel, the gears of cast steel, and all teeth were cut. With regard to the difficulties with the rolling tracks of rolling-lift bridges, there were in the city of Cleveland two double-track railway bridges, one designed for the Nickel Plate Railroad, and another earlier bridge of the same design, which was for another railway.

He believed that the same shop drawings had been used for the two bridges. One bridge had given trouble, but the other had given rise to no difficulty at all. The bridge engineer of the Nickel Plate Railroad had stated that in his opinion the satisfactory results from his bridge had been due to good inspection and good shop work. The two bridges in question were both across the Cuyahoga river and were operated to about the same extent. The tread plates were 2 and 2½ inches thick; the tread plates for the bridges of the Welland canal had a minimum thickness of 6 inches. He would point out that the American Railway Engineering Association's specifications called for a space to be left between the ends of the tread sections. The practice in Cleveland had been followed in the Welland ship canal, that is, the ends of the tread and track sections at the joints had been faced and brought to a bearing.

Mr. Blumenthal's remarks regarding the lack of trouble the Canadian Pacific Railway had experienced with their 120-foot span double-track rolling-lift bridge at Fort William during the fifteen years it had been in operation bore out previous reports regarding this bridge received some years ago by the Department.

Professor Gillespie had referred to the tests with large rollers now being carried on at the University of Illinois under the auspices of the American Railway Engineering Association; when these tests were finally completed and published they would no doubt be the subject of a large amount of discussion pro and con. It might be of interest to note that some of the large bridge companies in Great Britain had been building for some years past large rolling-lift bridges with tread plates only 3½ inches thick, but they cut the tread and track plates across at 45 degrees, thus leaving gaps due to the cuts at intervals of about 5 feet, the cuts in the tread plates being at right angles to the cuts in the track plates, and these British bridge companies had expressed themselves as being very well satisfied with the results obtained.

The author was in hearty agreement in every respect with the remarks of Mr. Pratley, but he would add, that after the structure had been properly fabricated, with the erection equipment now used by Canadian bridge companies, a reasonable amount of careful engineering in the field would ensure the erection of the bridge to the proper accuracy required.

With reference to Dean MacKay's remarks regarding the figures given in the list of bridges as to power required, the author would point out that the normal time of opening under electric power specified for all the vertical-lift bridges and the double-leaf rolling-lift bridge No. 4 was one and one-half minutes, and for all the other rolling-lift bridges it was specified as one minute, on account of their being over the entrances to canal locks. Fifteen seconds was allowed in both cases for the operation of signals and bridge locks, and this must be deducted from the normal time in order to get the actual time for bridge movement. It was therefore apparent that the 80-foot spans moved much faster than they would were the normal time of opening specified for them also one and a half minutes. In general it could be said, that under ordinary working conditions the rolling-lift bridges required much less horse power than did the vertical, but when the former were open against a ten-pound wind the torque required of the motor was greatly increased. It should be noted that the term horse power, when used for bridge motors, was liable to be very misleading, for the torque required of the motor was the quantity which really counted.

In closing, the author desired to express his appreciation of the discussions of the paper which had been presented, and he would also thank the chairman for his kindly remarks.

(8) Dean of Faculty of Applied Science, McGill University, Montreal.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI JULY 1928 No. 7

The Western General Professional Meeting

The success of any meeting rests to a large extent with those in whose hands has been placed the responsibility of planning, arranging and carrying out the details, so that a great deal of credit is due to those western members of The Institute who, as a Committee of the Vancouver Branch, have directed and brought to a successful conclusion the recent Western General Professional Meeting at Vancouver, a meeting which has established a record as one of the most interesting and enjoyable gatherings of its kind.

Only those who have had the responsibility of arranging for such a meeting can appreciate fully the great amount of detail work involved, and the thanks of all members of The Institute are due to the individual members of the Committee of the Vancouver Branch through whose energy and resourcefulness the recent meeting was made possible.

It is, of course, essential to the success of a meeting that there be a good attendance, and in this respect the Vancouver meeting was well supported, particularly since at this time of the year the duties of the engineer are perhaps greater than at any other season.

The report of the meeting, which appears elsewhere in this issue, will give some idea of the features of the programme, but it is not possible in such a statement to record in fitting terms the generous and whole-hearted hospitality extended to the visiting members by those of the local branch.

The E-I-C News—A Weekly News Bulletin

Commencing on July 16th there will be issued by The Institute a weekly news bulletin to be known as the *E-I-C NEWS*, the purpose of which is to afford a means of transmitting information to the members of The Institute at more frequent intervals than is possible at present.

The News will be issued each week excepting that in which the Journal is published; the date of mailing of the latter being fixed as the first Thursday of each month.

This announcement will be of particular interest to members following the notice which appeared in the June number of the Journal relative to the extension of The Institute's Employment Service, as it will be possible through the News to keep the members advised of positions which may be available and at the same time bring to the attention of organizations employing engineers details of the qualifications of members seeking positions.

The publication of the News and the development of the work of the Employment Service Bureau have been undertaken on the recommendation of a committee appointed by Council to consider possible means of rendering greater service to the members of The Institute.

Further details regarding the weekly bulletin and the Employment Service Bureau will be published in the first and subsequent issue of the News. In the meantime, any member interested in the work of the Employment Service can secure full information by communicating with Headquarters.

Subject Selected for Past-Presidents' Prize Competition

The subject selected by Council for the competition for this prize for the year July 1st, 1928 to June 30th, 1929 is "Engineering Education."

The award of this prize is governed by the following rules:—

In recognition of the fund established in 1923 by the then living past-presidents and contributed to by subsequent past-presidents, a prize, to be called "The Past-Presidents' Prize," may be awarded annually according to the following rules:—

(1) The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July first to June thirtieth.

(2) In deciding on the subject to be specified, the Council shall confer with the branches, and use its discretion, with the object of selecting a subject which may appear desirable in order to facilitate the acquirement and the interchange of professional knowledge among the members of The Institute.

(3) The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this commitee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

(4) The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that

value when suitably bound and printed, or engraved, as the case may be.

(5) All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

(6) All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local branch.

(7) The award shall be announced in The Engineering Journal and at the Annual Meeting, and, if possible, the presentation shall take place at that meeting.

In preparing papers for this competition it will be noted that members of The Institute of all grades are eligible to compete, and it is suggested that in preparing their communications, members should be guided by the pamphlet "Suggestions to Authors" issued by The Institute, copies of which can be secured from Headquarters.

The Secretaries of all Branches are being requested to bring this prize competition to the attention of members.

Recent Graduates in Engineering

In addition to the list of Juniors and Students of The Institute who have recently completed their course at the various universities, as published in the June issue of the Journal, congratulations are also in order to the following, results of which examinations were received too late for publishing with the main list last month:—

McGill University

Honours in the Graduating Class, Medals and Prizes

Benjamin, Archie, Outremont, Que.—British Association Medal, (Electrical Engineering); Montreal Light, Heat and Power Cons., First Prize; Undergraduates' Society's First Prize for Summer Essay.

Nightingale, Matt. Simons, Montreal West, Que.—Montreal Light, Heat and Power Cons., Second Prize.

Degree of B. Sc.

Abbott, Harold Felch, B.Sc., (El.), Prince George, B.C.
Benjamin, Archie, B.Sc., (El.), Outremont, Que.
Brain, Cecil, B.Sc., (Mech.), Grand Falls, Nfld.
Buchanan, Edward Trevor, B.Sc., (El.), Montreal, Que.
Budden, Arthur Napier, B.Sc., (El.), Montreal, Que.
Coleman, Sheldon Williams, B.Sc., (Ci.), Montpelier, Vt.
Curtis, Arthur E., B.Sc., (El.), Stanstead, Que.
Dalton, Peter Dudley, B.Sc., (Ci.), Montreal, Que.
Durley, Thomas Richard, B.Sc., (El.), Westmount, Que.
Fong, William Hin, B.Sc., (El.), Canton, China.
Fulton, Fraser Fowler, B.Sc., (El.), Fredericton, N.B.
Gagnon, Elmore Gerald, B.Sc., (El.), Montreal, Que.
Godwin, Harold Brandon, B.Sc., (El.), Ste. Anne de Bellevue, Que.
Groleau, Arnold John, B.Sc., (El.), Westmount, Que.
Hayes, Ronald Abram Hughson, B.Sc., (El.), Niagara Falls, Ont.
Jehu, Walter, B.Sc., (Mech.), Toronto, Ont.
Ketchen, William Arthur, B.Sc., (Chem.), Port Alice, B.C.
Lyons, Walter, B.Sc., (El.), Montreal, Que.
Nightingale, Matt. Simons, B.Sc., (El.), Montreal West, Que.
Palmer, William Henry, B.Sc., (El.), Heart's Content, Nfld.
Rhodes, Donald, B.Sc., (El.), Montreal, Que.
Taylor, Frank Denzil, B.Sc., (Chem.), Golden Ridge, Barbados, B.W.I.

University of Saskatchewan

The Saskatchewan Branch of The Engineering Institute of Canada Prize; the Governor General's Gold Medal

Sexton, Jack Kenneth, B.Sc., (Ci.), Seebe, Alta.

University of Alberta

Award of the Association of Professional Engineers of Alberta

Bowman, Ronald Fraser Patrick, B.Sc., (Ci.), Lethbridge, Alta.

Degree of B. Sc.

Hargrove, Paul, B.Sc., (Ci.), Edmonton, Alta.

Meeting of Council

Meeting of June 15th, 1928

A meeting of Council was held at 8 o'clock p.m. on Friday, June 15th, 1928. President T. R. Loudon, M.E.I.C., in the Chair, and five other members of Council being present.

The minutes of the meeting held on May 18th, 1928, were taken as read and approved.

The Financial Statement of The Institute for the period ending May 31st, 1928, was submitted and approved.

A letter was presented from the Lakehead Branch conveying an invitation to Council to hold the 1929 Annual Meeting at that branch, but as it had been decided at a previous meeting of Council that the next Annual Meeting should be held at Hamilton, Ontario, it was not possible to accept the invitation of the Lakehead Branch.

Professor T. R. Loudon, M.E.I.C., the chairman of the Service Bureau Committee, reported that in accordance with the Council's decision the establishment of a weekly bulletin was being proceeded with, and that arrangements had been made to extend the work of the present employment service at Headquarters.

The resignation of George R. MacLeod, M.E.I.C., as chairman of the Committee on Relations with the Provincial Professional Associations, was received and accepted with much regret, and S. G. Porter, M.E.I.C., of Calgary, was appointed Chairman of this Committee.

Dr. R. W. Brock, M.E.I.C., was appointed a member of the Leonard Medal Committee.

The lists of officers of the Hamilton and Niagara Peninsula Branches for the year 1928-29 were presented and approved.

A report was presented from the Board of Examiners and Education, announcing that a candidate who sat for The Institute's examinations under Schedule A. on May 28th and 29th had been successful in obtaining the necessary percentage for a pass.

Letters were submitted from Colonel David Lyell, M.E.I.C., and Lieut.-Colonel A. C. Macdonald, M.E.I.C., expressing appreciation at being chosen to represent The Institute on the occasion of the Centenary Celebrations of the Institution of Civil Engineers which took place in London, England, in June of this year.

It was decided that Council should not meet during the month of July, but a committee was appointed to canvass the ballot for the election and transfer of members which is to be opened on July 18th.

The ballot for the award of the Sir John Kennedy Medal was canvassed, which showed that the proposal to award the medal to Colonel R. W. Leonard had met with the unanimous approval of the members of Council. J. L. Busfield, M.E.I.C., was appointed Chairman of a Committee to secure a design for the medal to be submitted to Council for approval.

The recommendations of the Finance Committee in connection with four special cases were approved and four resignations were accepted.

The following elections and transfers were effected:—

Elections		Transfers	
Member	1	Associate Member to Member	6
Associate Members	8	Junior to Associate Member	5
Junior	1	Student to Junior	1
Students	2		

Eleven applications for admission and transfer were scrutinized and classified for the ballot returnable July 18th, 1928.

The Council rose at 10.30 o'clock p.m.

The Western General Professional Meeting

The Vancouver Branch of The Institute is to be congratulated on the success of the Western General Professional Meeting of 1928, which was held under their auspices on June 7th, 8th and 9th. The city of Vancouver forms an ideal location for such a meeting, and in framing its programme the local Committee took full advantage of the natural beauties of the neighbourhood and the opportunities for excursions and social events.

The chairman of the branch, W. Brand Young, A.M.E.I.C., presided at the opening session on the 7th, and the proceedings commenced with an address by His Worship the Mayor of Vancouver, who extended a cordial welcome to the city. The president of The Institute, Julian C. Smith, LL.D., M.E.I.C., and the vice-president from the Western Zone, S. G. Porter, M.E.I.C., of Calgary, were unavoidably prevented from attending, and the chairman, in opening the meeting, presented letters of regret from these and other officers of The Institute.

At the commencement of the first technical session, E. A. Cleveland, M.E.I.C., took the chair, and introduced E. E. Carpenter, M.E.I.C., who presented his paper on "Some Engineering Aspects of the Bridge River Project." In doing so, Mr. Carpenter pointed out that when ultimately developed, this would be one of the largest single sources of power in North America, with an effective head of 1,200 feet, at which head one second-foot would give 80-kw. The storage and regulation facilities to be developed would permit the control of the river flow to a minimum of 3,700 second-feet. The two main storage basins would be sufficient to raise the minimum discharge to the above-named figure from the existing minimum of 200 second-feet, which is occasionally experienced in very cold weather. A maximum flood discharge of 40,000 second-feet had been allowed for. The watershed area of about 1,500 square miles had a precipitation of only 18 or 20 inches per year, for it lay in a semi-arid area, and the flow of the Bridge river is largely derived from melting snow.

Mr. Carpenter described the characteristics of the dam site, the bearing tests which had been carried out, the provision against silting, and the arrangements which had been made for the construction of the tunnel now in progress. Preliminary data were given as to the transmission line and the methods to be adopted for its erection in such rugged and mountainous country. An active discussion followed, in which Messrs. Yuill, Webb, MacDonald, Muckleston, Brock, Foreman and others took part. This paper, which appears in this issue of The Engineering Journal, was of special interest, as it is unusual for an engineer to present for criticism and suggestions the details of a scheme, a large portion of which has still to be designed in detail.

The session was followed by a luncheon for members and ladies, at which a very attractive programme of music was given, and in the afternoon members were taken for a cruise on the harbour, by the courtesy of the Vancouver Harbour Commissioners, and through the kindness of G. E. Herrmann, AFFIL.E.I.C., were able to visit the creosoting works of the Vancouver Creosoting Company at North Vancouver, where Douglas fir ties and structural timber were being subjected to preservative methods. The ladies of the party were entertained at tea at the Royal Vancouver Yacht Club at Jericho Beach.

The technical sessions were continued in the evening, under the chairmanship of H. B. Muckleston, M.E.I.C., when it was announced that, owing to the illness of F. W. Groves, M.E.I.C., the paper announced on "Irrigation in Mountainous Country" could not be given. His place was taken at very short notice by K. W. Hicks, S.E.I.C., who read a paper on "The Preservation of Douglas Fir by Pressure Creosoting." After touching on the history of wood preservation, Mr. Hicks pointed out that the ten creosoting plants on the Pacific coast were now treating some 300,000,000 cubic feet per year, and a modern plant such as that visited by the members at North Vancouver was able to treat ties at the rate of seven per minute. He stated that the process there carried out did not materially reduce the strength of the timber as compared with air-seasoned lumber, and that structural timbers and ties should be treated after fabrication and boring, since untreated surfaces and holes in the sticks were always sources of incipient decay. Proper creosote treatment had been found to give practically complete security against the attacks of the teredo and other marine organisms, which are so destructive to timber in sea water on the Pacific coast. He gave illustrations of a number of structures where creosoted material, treated before fabrication, had been used successfully for scows, cribs, bridge timbers and other structural purposes, and had given excel-

View of Vancouver Harbour Taken from Vancouver Hotel.

lent results as regards durability. An active discussion followed, in which the difficulties in treating pipe staves, and the methods of avoiding changes of form and dimensions due to creosote treatment were discussed by Messrs. MacDonald, Yuill, Archibald and others.

The third technical session opened at 10.30 on the morning of Friday, June 8th, with H. B. Muckleston, M.E.I.C., in the chair, when Patrick Philip, M.E.I.C., deputy minister of public works, British Columbia, presented his paper upon " The Cariboo Road." This was profusely illustrated by lantern slides and dealt with the history and construction of this important highway project, commencing in the year 1857 when the influx of miners to the goldfields of the Cariboo began. This paper appears in this issue of The Engineering Journal, and was greatly appreciated as forming a complete record of the history and construction of this main route into the interior of British Columbia. On the conclusion of Mr. Philips' paper, the general secretary gave an informal talk on Institute affairs, outlining the problems before The Institute at the present time and the plans for future development.

In the afternoon, members attending the meeting visited the industrial plant of the Canadian Western Lumber Company, (Fraser Mills), New Westminster, this visit being rendered possible by the courtesy of Mr. J. D. McCormack, vice-president of the company. Those who had never had the opportunity of observing the operation of a large modern wood-working plant were greatly impressed with the great variety of work performed, the efficiency of the modern machinery employed, and the large scale upon which the manufacture is conducted.

In the evening, the ladies were entertained at dinner and at a theatre party, while The Institute Dinner took place at the Hotel Vancouver, over which W. Brand Young, A.M.E.I.C., chairman of the Vancouver Branch, presided. The principal speakers were Mr. Harold Brown, manager of the Union Steamship Company of British Columbia, Past-President George A. Walkem, M.E.I.C., His Worship the Mayor of Vancouver, Dean R. W. Brock, M.E.I.C., of the University of British Columbia, and Mr. Frank Sawford, past-president of the Association of Professional Engineers of British Columbia. A delightful musical programme was

60. R. Martin
61. F. R. Smith, A.M.E.I.C.
62. J. C. MacDonald, M.E.I.C.

rendered during the dinner, which was admitted to be one of the most successful functions of the meeting.

At 10 a.m. on Saturday, June 9th, the fourth technical session commenced, with A. C. R. Yuill, M.E.I.C., in the chair, when P. Z. Caverhill, chief forester, Department of Lands of the province of British Columbia, presented his paper on "Forest Conservation in the West." This paper, which has already been published in the June issue of The Engineering Journal, gave rise to an active discussion, dealing with such important topics as the reforestation of areas damaged by high-lead logging, the expense and possible advantage of artificial planting as compared with natural reproduction, both in the case of Douglas fir and spruce, the experiments which are being made in studying the possibilities of natural re-seeding as compared with replanting, the advantages of selective logging, the possibilities of reforestation by leaving seed trees, the disposition of slash, and other important matters. In the author's opinion, under the conditions now existing in British Columbia, the funds available could be more advantageously spent in giving adequate fire protection than in embarking on extensive schemes of artificial reforestation.

Mr. Caverhill's paper was followed by a paper on "The Study of Transmission Line Power Arcs," by Paul Ackerman, A.M.E.I.C., which was presented by the chairman and was illustrated by a large number of slides and a moving picture film giving a clear idea of the methods adopted in carrying out the experiments described by Mr. Ackerman. This paper has already been published in the May issue of The Engineering Journal, and was recognized as being of outstanding interest, particularly to those concerned in the present development of long-distance power transmission in British Columbia.

After an informal luncheon, the members and ladies were taken on a motor drive round the city and district, stopping at the University of British Columbia, Point Grey, where they were received by Dean Brock and hospitably entertained at tea.

The meeting closed on Saturday evening with a dinner and dance held at Grouse Mountain Chalet, 3,800 feet above the sea, to which point the members travelled in a procession of automobiles, most of which succeeded in negotiating the eight miles of continuous uphill grade without any halt for water or other refreshment on the way.

Few cities are able to show the visitor a view of the extent and beauty of that obtained from Grouse mountain, and this delightful dinner-dance and drive, favoured by splendid weather, formed a fitting climax to the many enjoyable functions of this successful meeting.

Presentation of Plummer Medals

The presentation of the Plummer Medals, which, as announced at the Annual General Meeting in Montreal last February, were awarded to Professor J. W. Shipley and Mr. C. F. Goodeve, was the feature of an executive meeting of the Winnipeg Branch held in the St. Charles Hotel on June 1st, 1928.

In the absence of Mr. Goodeve, who is in London, his father, the Rev. F. W. Goodeve, received the medal for his son.

The presentation was made by R. J. Durley, M.E.I.C., the General Secretary of The Institute, and Professor J. N. Finlayson, M.E.I.C., the chairman of the Winnipeg Branch, presided at the meeting.

OBITUARY

Major Wallace C. Trotter, Affiliate E.I.C.

It is with regret that we record the death of Major Wallace Cuthbert Trotter, Affil.E.I.C., president and managing director of the Standard Clay Products, Limited, St. Johns, Que., and New Glasgow, N.S., which occurred at his home in St. Johns, Que., on June 11th, 1928.

The late Major Trotter was born at Sydney, Gloucestershire, England, on March 26th, 1851. He served with the Montreal Garrison Artillery in the Northwest Rebellion in 1885, and commanded No. 1 Battery as Captain. He was afterwards retired with the rank of Major, and was the holder of the officers' Long Service Medal.

Major Trotter was the founder of the company of which he was president over a period of forty-five years, and was actively engaged in the business of his company up to the time of his death.

On May 12th, 1887, shortly before the incorporation of the Canadian Society of Civil Engineers, he was admitted to the Society as an Associate, which grade was later changed to Affiliate, and throughout the long period of his membership he has been keenly interested in the development of The Institute.

The late Major Trotter had a host of friends amongst engineers throughout Canada by whom the news of his death will be learned with sincere regret. Lt.-Col. H. L. Trotter, D.S.O., M.E.I.C., of the firm of Trotter and Cate, consulting engineers, Montreal, is a son of the late Major Trotter.

View of Vancouver by Night from Grouse Mountain.

PERSONALS

Martin Wolff, A.M.E.I.C., who for the past two years has been on the engineering staff of the Gatineau Power Company at Ottawa, has resigned his position and is at present located in Montreal.

David Humphreys, A.M.E.I.C., hydro-electric engineer and superintendent of power station with the Newfoundland Power and Paper Company at Deer Lake, Newfoundland, and later with the International Paper Company of Newfoundland, has resigned his position.

Charles A. Wakeham, S.E.I.C., of Saint John, N.B., who graduated with the degree of B.Sc. in electrical engineering from the University of New Brunswick this spring, has accepted a position with the Northern Electric Company, Montreal, and is engaged on automatic telephone work.

James B. Nelson, A.M.E.I.C., of McGregor-McIntyre Structural Steel, Limited, Toronto, has been promoted by the company and is now in charge of draughting in the ornamental iron department. Mr. Nelson has been with this company for the past three years, prior to which he was at various times with the A. B. Ormsby Company, Limited, of Toronto; the Standard Steel Construction Company, Limited, of Welland; Canadian Allis-Chalmers Limited, Toronto, and the Trussed Concrete Steel Company, Limited.

W. S. E. Morrison, A.M.E.I.C., who for some time past has been located at the R.C.N. Barracks at Esquimalt, B.C., has been promoted to Lieutenant-Commander (E) and appointed to the new Canadian destroyer *H.M.S.C. Champlain* on the east coast of Canada. In a recent letter from Lieutenant-Commander Morrison he advised Headquarters that it is expected that the *H.M.S.C. Champlain* will arrive in Montreal some time in July, and he extends an invitation to all members of The Institute in Montreal at that time to visit the destroyer.

Viggo Anderson, Jr.E.I.C., formerly on the engineering staff of the Dominion Bridge Company at Lachine, Quebec, has accepted a position with the Southern Canada Power Company. Mr. Anderson is a graduate of the Royal Technical College of Copenhagen, Denmark, in 1923. He came to America in 1924 and spent two years in the United States on engineering work. He returned to Denmark in June 1926. In May 1927 he came to Canada, and has been employed with the Dominion Bridge Company since that time.

A. H. Pattenden, M.E.I.C., has recently resigned from the position of electrical engineer of the eastern and western plants of the Dominion Rubber Company, Limited, and has accepted the appointment of industrial engineer of the new business department of the Montreal, Light, Heat and Power Consolidated at Montreal. Mr. Pattenden joined the Dominion Rubber Company in 1918, prior to which he was engaged for a short time on research work and previously was with the Canadian Pacific Railway in charge of the electrical department at the Angus Shops.

C. Oldrieve Thomas, A.M.E.I.C., formerly with the designing and estimating department of Canadian Vickers Limited, has accepted a position with the Dominion Bridge Company. Mr. Thomas is a native of the Old Country, and since coming to America in 1904 he has had extensive experience in structural steel and other engineering work, having been connected at various times with the Canadian Westinghouse Company, Limited, the Algoma Steel Corporation, the Canada Car and Foundry Company, Fraser and Chalmers of Canada, the Montreal Light, Heat and Power Consolidated, and the Dominion Bridge Company.

G. W. Waddington, A.M.E.I.C., is located at Creighton Mine, Ontario, with the International Nickel Company. Mr. Waddington was formerly mining engineer with the Iron Mask Mine at Kamloops, B.C. He received his engineering education at the University of British Columbia, from which he graduated with the degree of B.A.Sc. in 1927, although prior to his graduation he had been engaged on engineering work for some years, having been on survey work since 1913. In 1920 he was appointed engineer for the Middlesboro Collieries Limited, at Merritt, B.C.

J. E. Thicke, S.E.I.C., of New Liskeard, Ont., is located in Pittsfield, Mass., where he is taking the students' test course with the General Electric Company. Mr. Thicke graduated with the degree of B.Sc. in electrical engineering from Queen's University this year. During the summer months of his university course he was engaged on steel transmission line construction; the first summer as chainman, the next year as assistant to the resident engineer and finally as assistant to the resident engineer and instrumentman on the construction of fourteen miles of railroad for the Abitibi Transportation and Navigation Company, Iroquois Falls, Ont.

J. P. Watson, A.M.E.I.C., formerly of the Dominion Bridge Company, Limited, is now with the Canadian Mead-Morrison Company, Limited, in Montreal. Mr. Watson was for a short time with the engineering department of the Imperial Tobacco Company, Montreal, which he left in September 1920 to accept a position in the engineering department of the Wayagamack Pulp and Paper Company, at Three Rivers. In August 1921 he was appointed to the staff of the mechanical department of the Canadian Pacific Railway, where he remained until the early part of 1924, when he went with the Dominion Bridge Company, Limited.

George F. MacRae, S.E.I.C., who has accepted a position in the underwriting department of Johnson and Ward of Montreal, in connection with which an announcement appeared in the May 1928 issue of the Journal, was formerly sales manager for the Combustion Engineering Corporation Limited for the Maritime provinces and Quebec. As noted in the previous announcement, Mr. MacRae had previously been connected with the Bell Telephone Company, from which he resigned in March 1926 to accept a position on engineering sales with the Combustion Engineering Corporation. His work in his new position will be in connection with the engineering end of financial reconstruction of industrial companies.

V. R. Currie, Jr.E.I.C., has joined the staff of the Abitibi Fibre Company, Limited, at Smooth Rock Falls, Ont. Mr. Currie is a graduate of Queen's University, having received his degree of B.Sc. in civil engineering in 1923. Following graduation Mr. Currie was engaged on land subdivision work in British Columbia and in the same year became connected with the Spanish River Pulp and Paper Company engaged on hydro-electric surveys and dam construction. In 1924 he was offered a position with the Alabama Power Company, which he accepted. His headquarters were at Birmingham, Ala., and for the first year he was engaged on general survey work. From November 1926 until recently he was resident engineer for the same company on investigations and foundations.

William A. Gilmour, A.M.E.I.C., has joined the staff of the Foundation Company of Canada Limited, and is located at Liverpool, N.S., in connection with the company's work on the Mersey river. Mr. Gilmour is a graduate of Edinburgh University at which he received the degrees of M.A.

and B.Sc. in 1911. Immediately after he graduated, he spent a year in Scotland on engineering work. He came to Canada in 1912 where he secured a position with McKenzie, Mann and Company on the construction of the Mount Royal tunnel. He remained with this company until 1917, being engaged on survey work and later as chief inspector on the construction of the tunnel. In 1917 he was appointed to the engineering staff of the Montreal Water and Power Company, later being appointed assistant superintendent in charge of construction with supervision of the pumping stations of the company. He remained in this position until his recent appointment.

A. S. Runciman, a.m.e.i.c., Receives Degree of E.E.

A. S. Runciman, a.m.e.i.c., maintenance engineer of lines with the Shawinigan Water and Power Company, Montreal, received the degree of E.E. at the recent convocation of the University of Toronto. Mr. Runciman was born at Goderich, Ont., in 1890 and graduated from the school of Applied Science, University of Toronto, in 1911. Following graduation he was engaged with the Calgary Power Company at Horse Shoe Falls, and in the following year was appointed assistant superintendent of the light and power department of the city of Prince Albert, where he remained until the end of 1914. During the following year he was with the Canadian Westinghouse Company, located at Grand'Mere, Que., in connection with the construction of the Laurentide Power Company's plant. The next year he joined the staff of the Marconi Wireless Telegraph Company of Canada and was located at the Transatlantic receiving station at Louisburg until July, when he was transferred to the company's plant at Glace Bay, N.S. The following year he was made assistant manager and in 1918 he was transferred to the company's factory, where he was engaged on experimental work. Mr. Runciman joined the Shawinigan Company in May 1920 and has been with this company since that date.

G. B. Mitchell, m.e.i.c., Transferred to Colombia, S.A.

G. B. Mitchell, m.e.i.c., western manager of the Peter Lyall and Sons Construction Company, Victoria, B.C., has been transferred by the company to Bogota, Colombia, S.A. Mr. Mitchell graduated from the Colorado School of Mines in civil engineering in 1896. In 1897 he was associated with Messrs. William Cramp and Son of Philadelphia, Pa., as draughtsman and assistant to the chief engineer. The following year he became assistant engineer with the United States Deep Waterway Commission and was located at Ogdensburg and Detroit. In August 1899 he was located at Nicaragua as assistant engineer with the Isthmian Canal Commission. One year later he became office engineer with the same commission at Washington. In March 1902 he entered private practice as a member of the firm, A. J. Norris and Company, Amsterdam, N.Y., but in September of the same year he accepted a position with the Canadian Pacific Railway Company as assistant engineer at the Angus Shops, Montreal. Two years later he was transferred by the company and placed in charge as assistant engineer of the mechanical work of the company's engineering department at Montreal. In December 1905 he accepted the position of superintendent of buildings with the New York, New Haven and Hartford Railroad at New Haven, Conn. In January 1907 he became associated with the C. E. Deakin Limited, general contractors, as vice-president of the company, with which he remained until September 1916 when he entered private practice as general contractor with headquarters in Montreal. In November 1917 he joined the staff of the Foundation Company of New York, where he was in charge of various works for the company in different parts of the United States and South America until December 1922. In May 1923 he was appointed western manager of the Peter Lyall and Sons Construction Company, with which he has remained ever since.

K. H. Smith, m.e.i.c., Joins Investment Bankers

K. H. Smith, m.e.i.c., who has joined the firm of Harley, Milner and Company, Toronto, investment bankers, graduated from the University of Toronto, Faculty of Arts, Victoria College, in 1908, from which he received the degree of B.A., and the Faculty of Applied Science in 1911.

Mr. Smith was attached to the Dominion Water Power and Reclamation Service, Department of the Interior, Canada, continuously from May 1911 to July 1926, in various capacities from junior field engineer to district chief engineer. During this time he was engaged in all phases of power development from preliminary field and office surveys and investigations to construction and operation. While still connected with the Federal Department he was chief engineer of the Nova Scotia Power Commission from its inception in August 1919 to October 1925, and was responsible for the conception, organization, construction and operation of an extensive electrical generating, transmission and distributing system in the province of Nova Scotia. His work in this connection included not only the technical matters involved, but the draughting of an enabling and administrative legislation.

K. H. SMITH, M.E.I.C.

He was consulting engineer to the New Brunswick Electric Power Commission in connection with water power legislation and the construction of transmission lines from Bathurst to Newcastle and Saint John to Moncton, these being the first long distance high voltage lines in the Maritime Provinces.

In the winter of 1925 Mr. Smith was employed by the Royal Securities Corporation of Montreal to investigate and report upon public utility projects in South America. In December of the same year he was appointed investigating engineer with the Montreal Engineering Company, Limited, the engineering department of the Royal Securities Corporation, Limited, and at the same time was retained in a consulting capacity by the Dominion Water Power and Reclamation Service. He resigned from the

Montreal Engineering Company, Limited, in April 1928, to join the firm with which he is now associated.

While with the Federal Government Mr. Smith was charged with the construction and assembling of the Canadian water power exhibit for the Panama-Pacific Exposition, at San Francisco, in 1915, and during the World Power Conference in London in 1924 he was an official delegate to the Conference.

J. P. McRae, A.M.E.I.C., Appointed General Manager of Sawyer-Massey Company

J. P. McRae, A.M.E.I.C., has resigned his position as manager of the engineering and water works department of the General Supply Company of Canada, to accept the appointment of general manager of the Sawyer-Massey Company, of Hamilton, Ont.

Mr. McRae is a graduate of McGill University, from which he received the degree of B.Sc. in mechanical engineering in 1912. His first work after graduating was in the office of J. B. McRae, M.E.I.C., consulting engineer, Ottawa, where he remained until February 1913, when he went to Moose Jaw, Saskatchewan, on the erection and operation of a Diesel engine unit for the Moose Jaw Street Railway.

He returned to Ottawa in the latter part of the year and was again engaged with J. B. McRae, M.E.I.C., on the design and construction of the High Falls dam on the Livre river. Other work on which he was engaged at this time was the proposed development at Waddington; the power development of the Electric Reduction Company at Buckingham, Que.; the Renfrew Municipal Power Development; the power development for the town of Orillia on Swift rapids on the Severn river, and a number of other investigations of proposed hydro-electric developments. Mr. McRae was also responsible for the reinforced concrete work on the bridge carrying the steel mains for the water supply of the city of Ottawa from Lemieux Island in the Ottawa river to the mainland.

On August 4th, 1915, Mr. McRae enlisted for overseas service, and served with distinction during the Great War. In February 1919 he returned to Canada and in April of that year was appointed to the staff of the Hydro-Electric Power Commission of Ontario, and was engaged on inspection of the Chippawa power units in Cleveland, Ohio.

He returned to Toronto in 1920 as assistant service manager and shop superintendent with the agency for the Cole and Oldsmobile automobiles. The following year he was shop superintendent with the Dodge Brothers' Service in Toronto. He was later technical adviser to the Purchasing Commission of Toronto on the purchase of motor equipment. In July 1923 he accepted the position of manager of the engineering and water works department of the General Supply Company of Canada at Ottawa, and has remained with this company since that date.

ELECTIONS AND TRANSFERS

At the meeting of Council held on June 15th, 1928, the following elections and transfers were effected:—

Member

BUNCKE, Harry Jacob, C.E., (Columbia Univ.), M.S., (Univ. of Maine), chief engineer, Abitibi Power & Paper Company, Ltd., Iroquois Falls, Ont.

Associate Members

BARNES, Frank Harvey, B.Sc., (McGill Univ.), designing engr. and asst. mgr., Northern Foundry & Machine Co., Sault Ste Marie, Ont.

BOURASSA, L. Wilfrid, B.A.Sc., C.E., (Ecole Polytech.), town manager, La Tuque, Que.

EYRE, Robert Thornton, plan examiner, city architect's dept., Toronto, Ont.

FLEISCHMANN, Albert Charles, technical engr., Sewers Commn., Technical Service, City of Montreal.

JACKSON, William, inspecting engr. for three prairie provinces, Dept. of Rlys. and Canals, Edmonton, Alta.

MacLEAN, Charles Salmon, B.A., B.Sc., (Univ. of N.B.), gen. mech'l. engrg., T. McAvity & Sons, Ltd., Saint John, N.B.

MERRIMAN, Horace Owen, B.A.Sc., (Univ. of Toronto), inductive interference engr., under the director of radio service, Dept. of Marine and Fisheries, Ottawa, Ont.

PAPINEAU, Gustave Joseph, B.A.Sc., C.E., (Ecole Polytech.), municipal engrg., Technical Service, City of Montreal.

Junior

DREW, Alfred William, B.Sc., (Univ. of Alta.), office asst. and dftsman. with divn. engr. of constrn., C.N.R., Edmonton, Alta.

Transferred from the Class of Associate Member to that of Member

BEGG, James McGee, B.Sc., (Glasgow Univ.), chief engr., Vancouver and Districts Joint Sewerage and Drainage Board, Vancouver, B.C.

GAMBLE, Clarke William, B.Sc., (McGill Univ.), res. engr. on bridge over Mississippi river at Cairo, for Waddell & Hardesty, Cairo, Ill.

JONES, William Henry, B.Sc., (Univ. of Man.), asst. mgr. i/c of production, Medway Oil and Storage Co., Isle of Grain, England.

LEES, Thomas, Associate, (Royal Tech. Coll., Glasgow), dist. engr., C.P.R., Calgary, Alta.

PATTENDEN, Albert Henry, elect'l engr., eastern and western plants, Can. Cons. Rubber Co., Montreal, Que.

PROCTOR, Edward Moore, B.A.Sc., (Univ. of Toronto), president, James, Proctor & Redfern, Ltd., Toronto, Ont.

Transferred from the Class of Junior to that of Associate Member

FRASER, Isaac Matheson, B.Sc., (McGill Univ.), asst. professor, mech'l engr., University of Saskatchewan, Saskatoon, Sask.

JOB, Stanley Robert, designing engr. and dftsman., L. & P. Manufacturing Company, Niagara Falls, Ont.

KEITH, William Hargreave, B.A.Sc., (Univ. of Toronto), dist. engr., municipal roads, Dept. of Public Highways, Ontario, Islington, Ont.

PAINCHAUD, Francois Benoit, B.A.Sc., (Ecole Polytech.), struct'l engr., Dept. of Public Works, Quebec, Beauport, Que.

PLUMMER, William Elfric, asst. engr., Welland Ship Canal, Humberstone, Ont.

Transferred from the Class of Student to that of Junior

VICKERSON, George Locker, B.Sc., (McGill Univ.), estimator and asst. foreman, G. R. Locker Co., Montreal, Que.

Students Admitted

KLEMPNER, Harold, undergraduate Univ. of Man., at present junior dftsman., Dominion Water Power and Reclamation Service, Winnipeg, Man.

WELSFORD, Jack A., Engrg. Cert., Acadia Univ., senior student, N.S. Technical College, Halifax, N.S.

Outstanding
in the Course of

The Royal York Hotel

The Royal York Hotel of the Canadian Pacific Railway Company, which is being erected on Front street in Toronto, immediately opposite the Union Station, will provide, in addition to the public spaces, one thousand and ten bedrooms of varying sizes and grouping. Special provision has been made in the design for the accommodation of conventions and other private and public functions, which includes the following public rooms: Main dining room, 8,270 square feet; five private dining rooms, varying in size from 700 to 2,208 square feet. The approximate aggregate accommodation of these rooms is, for dining, 2,500 persons; for banquets, 4,300 persons; for conventions, 6,400 persons. The building will occupy 10,000,000 cubic feet of space, and the exterior will be entirely in stone.

The work is being carried on under the direction of J. M. R. Fairbairn, D.SC., M.E.I.C., chief engineer of the Canadian Pacific Railway Company, with J. W. Orrock, M.E.I.C., of the Canadian Pacific Railway Company, as engineer of buildings for the company, and H. S. Bare, A.M.E.I.C., assistant engineer of the Canadian Pacific Railway Company, representing the architects. The general contractors are Messrs. Anglin-Norcross, Limited, of Montreal and Toronto, and the general steel contractors, the Dominion Bridge Company of Montreal. The architects are Messrs. Ross and MacDonald, of Montreal, with Messrs. Sproatt and Rolph, of Toronto, as associate architects.

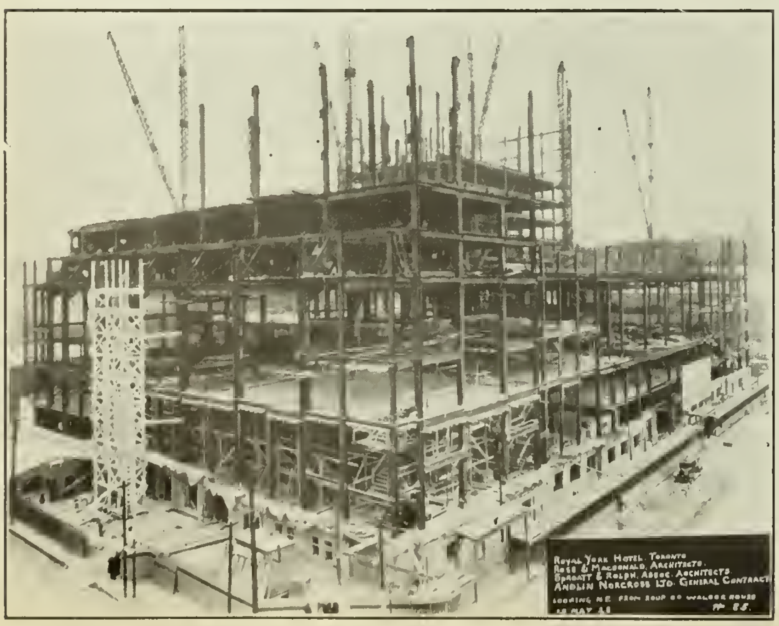
The Head Office of The

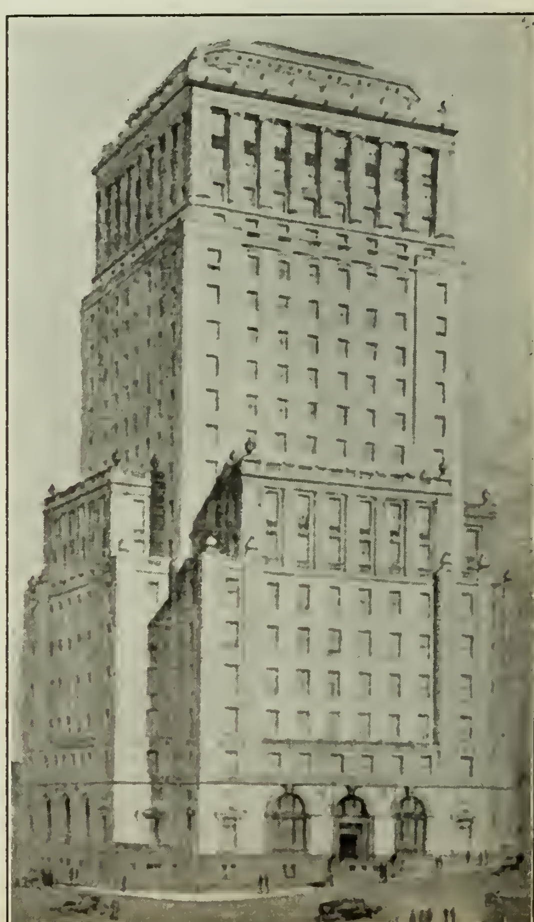
The new Bell Telephone Building at present under construction on Beaver Hall Hill in Montreal, at the northwest corner of the intersection with Lagauchetiere street, will comprise twenty storeys, exclusive of penthouse, machinery room, basement and sub-basement. The height will be approximately 315 feet above the street level, and the foundations were taken to rock. The building will be faced with limestone on all sides and will comprise approximately 5,000,000 cubic feet of space, developing 193,000 square feet of net floor area.

(*Above*) Royal York Hotel of The Canadian Pacific Railway Company, in Toronto, Ont. Sketch of building as it will appear when completed.

(*Below*) Progress photograph of Royal York Hotel taken on May 10th, 1928.

(*Right*) Head Office Building of The Bell Telephone Company of Canada, in Montreal, Que. Sketch of building as it will appear when completed.





Buildings

Construction

The Sun Life Building

The head office building of the Sun Life Assurance Company of Canada, which is at present under construction, is located opposite to Dominion square in Montreal and occupies an area 217 feet wide by 430 feet long, facing on Metcalfe, Dorchester and Mansfield streets. The existing head office building was so designed as to permit of its forming a part of the larger building which is now being constructed.

The completed building, shown on this page, is twenty-one storeys in height and has a total floor area of 1,120,000 square feet exclusive of the basements.

It will comprise approximately 22,000,000 cubic feet of space, and the building will be entirely faced with Canadian grey granite.

The present construction programme contemplates the completing of the building up to the eighth storey over the entire site, the easterly section of which is at present under construction, and it is intended that the work on the westerly section will be commenced during the coming winter. The steel for the entire structure, however, is now being prepared.

The construction of the building is in charge of A. J. C. Payne, staff architect of the Sun Life Assurance Company, and the architects are Messrs. Darling and Pearson, of Toronto, and the general contractors are Messrs. Cook and Leitch of Montreal. The structural engineers are Messrs. Harkness, Loudon and Hertzberg, of Toronto, and the mechanical engineer is E. A. Ryan, M.E.I.C. The Dominion Bridge Company are supplying the steel.

Bell Telephone Company

The building will house the entire headquarters staff of the company now located in Montreal.

The chief engineer is R. V. Macaulay, M.E.I.C., of the Bell Telephone Company, and the engineer representing the Telephone Company and the architects is T. T. Rutherford. The architects are Messrs. Barott and Blackader of Montreal, and the general contractors are the George A. Fuller Company of Canada, Limited. The structural steel is being prepared by the Dominion Bridge Company.

BOOK REVIEWS

The A. C. Commutator Motor

By C. W. Olliver, D. Van Nostrand Co., New York, 1927, Buckram, 6 x 9½ in., 281 pp., diagrs., figs., plates, $7.50.

The author was educated at Eton and in Paris, completing his education in England first and finally in Paris, where, and this is the important part as regards the book, he became the pupil of Marius Latour at the Ecole Supérieure d'Electricité, Paris. Practical engineering experience was obtained first at the Thomson-Houston Company, Paris, and then as a consulting engineer in his own name. Returning to England, the author was first on the editorial staff of the "Power Engineer" and "Colliery Engineering" and is at present on the engineering staff of the London office of the Ateliers de Constructions Electriques de Charleroi, better known as the A.C.E.C., one of the largest of continental electrical manufacturers.

This is the author's second book, the first published in France and in the French language being a detailed study of the potentialities of electrical development and a power station on the Cunene river in Angola, South West Africa.

The author has written a considerable number of technical articles on electrical subjects for various technical papers such as "Power Engineer," "Colliery Engineering," "Railway Engineer," "Marine Engineer," etc., and is regular abstractor for "Science Abstracts."

The book is a plea for the use of the single-phase a.c. commutator type motor, including very large sizes.

The first five chapters deal with theory and the last four with practical applications.

Under theory he treats of commutation, of the analysis of single-phase and repulsion motors, such as the Latour motor, the Deri motor, the Wagner motor, the Schuler motor and the Fynn-Weichsel motor. Polyphase commutator motors are illustrated by the Brown-Boveri type.

The fifth chapter deals with power factor correction by means of induction-commutator type motors. Any rotary machine provided with a commutator or any induction motor used in conjunction with a commutator machine can be made to feed back wattless energy to the mains and thus compensate for low power factor.

Under "Practical Applications" he describes crane and hoisting appliances. Then follows a chapter on single-phase traction. Brown-Boveri machines are illustrated.

One picture shows a 2,960-h.p., 350-v., single-phase commutator type motor used on an express locomotive, German State Railways. The trolley voltage is 15,000. A speed of nearly 70 miles per hour can be obtained. Auxiliary ventilating fans are mounted on the frame. Control is obtained by shifting the brushes.

A description is also given of a single-phase locomotive characterized by the use of a single 3,000-h.p. motor.

Chapter eight deals with rolling mill drives and this application is chosen as typical of the advantages of large commutator machines, the more so since it introduces not only the 3-phase commutator motor as a unit, but also various combinations of induction motors and commutator machines, either in cascade on the same shaft or running as separate auxiliary units, as in the Kramer and Scherbius systems.

The last chapter deals with other applications to which the commutator type a.c. motor is suitable, such as collieries, paper mills and cetera.

The book should prove of great interest to designing engineers, as the subject matter is remarkably well presented.

W. F. McLaren, M.E.I.C.,
Chief Draughtsman,
Canadian Westinghouse Company,
Hamilton, Ont.

The Mathematics of Engineering

By Ralph E. Root, Williams & Wilkins, Baltimore, Md. Buckram, 6 x 9 in., 540 pp., figs., $7.50.

This text is rather unusual, in that it combines in one book explanations of algebraic and geometrical operations together with those of the differential and integral calculus. It is essentially a text for students and for those engineers who from time to time may have recourse to mathematical processes in which they do not possess facility for lack of continuous use.

There is in the book a slight suggestion of the formulism so prevalent in the viewpoint of students on the North American continent. The emphasis on basic operations from which other subsidiary formulæ may be developed is somewhat lacking, as indeed it seems to be in most of the present educational tendencies on this continent.

The first three chapters are devoted to developing the idea of the derivative of a function. General rules for finding derivatives of the usual functions are given.

Chapter four is a concise statement of the idea of integration together with tables of the ordinary integration formulæ.

Chapter five is devoted to a discussion of the solution of equations. It is a well put together chapter, the reason for the location of which is not clear.

Chapter six gives the various processes of integration.

Chapter seven deals with the methods of analytic geometry; and then in chapter eight the methods of the calculus are applied to derive certain information from given equations of curves.

And so the book runs from one chapter to another, not always in the logical order of the usual text, but certainly in much more interesting and exciting forms.

The following are the remaining chapters:—

Chapter IX, Application of Integration; Chapter X, Methods of Evaluating Functions; Chapter XI, Complex Quantities and Periodic Functions—this chapter is well put together; Chapter XII, Functions of Several Variables; Chapter XIII, Treatment of Empirical Data; Chapter XIV, Ordinary Differential Equations, First Order; Chapter XV, Ordinary Differential Equations, Higher Order; Chapter XVI, Ordinary Differential Equations, Several Variables; Chapter XVII, Partial Differential Equations; Chapter XVIII, Differential Equations, Additional Devices.

If one is interested in mathematical exercises, there are problems scattered throughout the book that will enable one to spend many profitable hours.

T. R. Loudon, M.E.I.C.,
Professor of Applied Mechanics,
University of Toronto.

Investigations of Fuels and Fuel Testing, 1925

Report of the Mines Branch, Ottawa, 1927, Paper, 6½ x 10 in., 184 pp., figs., tables.

This report divides itself into three main parts—the first having to do with solid fuels, the second with oils and gasolines, and the third with oil shales.

In Part I, Messrs. Gilmore, Malloch, Strong, Nicolls, Mohr and Baltzar contribute a great deal of interesting and valuable data. From the point of view of the consumer, the paper of Messrs. Malloch and Baltzar is particularly interesting. In their paper, Table V summarizes the relative value to the consumer of twenty-one possible domestic fuels available for Canadian consumption. This table is one that merits the careful study of those who wish to discuss the present fuel problem of Canada.

In view of the future importance of low temperature carbonization, Mr. Strong's paper is a valuable contribution to the literature on the subject. His present investigation is confined to the application of L.T.C. to bituminous coals. The physical examination of domestic cokes by Messrs. Gilmore, Mohr and others is of interest.

Mr. Rosewarne's researches on lubricating oils after use in motor car engines is in the nature of a progress report on a research that may prove to be most valuable.

The report is one that should be on the shelves of all those interested in the questions of fuels and fuel technology.

Lesslie R. Thomson, M.E.I.C.,
Consulting Engineer, Montreal.

CORRESPONDENCE

The Editor, Montreal, June 11th, 1928.
The Engineering Journal.
Sir:—

Referring to my paper on "Viaduct Structure at Toronto Union Station" read before the Toronto Branch on 5th of January and published in the April issue of the Journal.

In discussing the general features, I mentioned in paragraph 3, page 254, that several structures of flat slab type had been built in the United States for railway loading, but in no case, (as far as I was aware), did they exceed the Toronto structure in the size of the normal panel, viz., 26 feet by 25 feet 8¾ inches.

I am in receipt of a letter from Mr. M. Hirschthal, concrete engineer, Delaware, Lackawanna and Western Railway, pointing out that the normal panels of their Buffalo Terminal structure, (of same type), are 27 feet by 27 feet and, therefore, one foot larger than the Toronto structure.

As this point may be significant to those interested in this type of construction for railway purposes, I wish to acknowledge this correction through the Journal.

Yours very truly,
(Signed) A. R. Ketterson, A.M.E.I.C.

Second Generator Started in Paugan, Que., Power House

The second generator has been started in the new Paugan, Que., power house of Gatineau Power Company, one of the largest hydro-electric stations on the North American continent. Designed for 272,000 horsepower in eight generators of 34,000 horsepower each, the plant is located on the Gatineau river, thirty-three miles north of the city of Ottawa. Gatineau Power Company is a subsidiary of Canadian Hydro-Electric Corporation, Limited, which in turn is a subsidiary of International Paper Company.

EMPLOYMENT SERVICE BUREAU

In connection with the announcement which appeared in the June issue of The Journal regarding the reorganization of The Institute's Employment Service Bureau, all members who wish to be registered with this service are requested to secure the necessary Registration Form either from Headquarters or from their local Branch Secretary and forward it, properly completed, to Headquarters.

Situations Vacant

Electrical Designer

Electrical designer required for general wiring layout in connection with pulp and paper mill work by a firm of consulting engineers. The position is temporary at the present time but there is possibility of permanency. Reply with full particulars of experience to Box No. 3-V, The Engineering Journal.

Draughtsmen

Two draughtsmen with experience in structural and mechanical detailing are required by a mining company in northern Quebec for general industrial work. Give full details of qualifications and experience with application. Apply Box No. 4-V, The Engineering Journal.

Electrical Engineer

Industrial company in Ontario requires the services of an electrical engineer, briefly one with experience in electric railway and distribution work. Apply Box No. 7-V, The Engineering Journal.

Mechanical Draughtsmen

A manufacturing company located in Ontario has an opening for two draughtsmen with experience in mechanical work. The company intends that these men should be attached to the staff of the parent company in the United States for training prior to establishment of an engineering office in Canada. Apply with full particulars to Box No. 10-V, The Engineering Journal.

Combustion Engineer

A manufacturing company located in Ontario has an opening for a combustion engineer with experience in the design of coke and gas products. The company intends that this man should be attached to the staff of the parent company in the United States for training prior to establishment of an engineering office in Canada. Apply with full particulars to Box No. 11-V, The Engineering Journal.

Draughtsmen

A large manufacturing company requires the services of two draughtsmen with four or five years' experience. Preference will be given to those having experience with electrical equipment. Give full particulars of qualifications with application. Apply Box No. 15-V, The Engineering Journal.

Recent Graduates

The Institute's Employment Service Bureau has received during the past few weeks a large number of requests for recent graduates and undergraduates in connection with various large construction works, and for general draughting and detailing. Any members of The Institute interested in such positions should register with the Employment Service Bureau as soon as possible.

Situations Wanted

Civil Engineer

Civil engineer, A.M.E.I.C., speaking French and English, with experience in building construction, factory managing and costing, desires a position as chief engineer or manager with a lumber company or as construction or resident engineer on any general construction work. Apply Box No. 1-W, The Engineering Journal.

Civil Engineer

Civil engineer, M.E.I.C., Registered Professional Engineer of Alberta, fully qualified, thirty years experience in railway construction, reconnaissance and highway work, is available for a position. Would prefer position as city engineer, or post of trust and responsibility, in western province. Apply Box No. 3-W, The Engineering Journal.

BRANCH NEWS

Border Cities Branch

Orville Rolfson, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Border Cities Branch was held in the Prince Edward hotel on May 11th. The chairman introduced the speaker of the evening, William Gore, M.E.I.C., of the firm of Gore, Nasmith and Storrie, consulting engineers, of Toronto.

Toronto Water Supply System

Mr. Gore remarked that the population of Toronto is 575,000 and the population, including suburbs, is 675,000, and that there is a difference of elevation of three hundred feet between some parts of the city. There are seven distinct pumping areas in the city's water supply system, and a balancing reservoir is located on the upper level.

In a general way most cities require pumping facilities for twice the average consumption of water, but in Toronto the balancing reservoir is of great value because with it smaller pumps which run more nearly to capacity can be used.

The average demand of Toronto is 73,000,000 gallons per day. The city sewage is emptied into lake Ontario, from which it draws its water. The present filtration plant, using both slow sand and mechanical filters, is located on the Island. The water is chlorinated and pumped through the tunnel under the bay to the John street pumping plant, from whence it is pumped to the city mains.

On account of phenol tastes the water is super-chlorinated on the Island and dechlorinated at the John street station by using sulphur dioxide. During the time of passing from the Island to the John street station the chlorine acts on the impurities in the water. Mr. Gore presented a chart, prepared by the Toronto Board of Health, showing that, by chlorination, sedimentation and pasteurization, the typhoid mortality had been reduced from 44 to 4 per 100,000.

Consulting engineers are working on the problem of increasing the supply of water for the city. The prevailing winds are westward, and the new pumping station and filtration plant will be located at the east side of the city. The new intake will extend 7,500 feet from the shore into 50 feet of water. Because of erosion the first half of the intake will be a tunnel in the shale and the remainder a pipe laid on the bottom of the lake.

The new filtration plant will have a capacity of 200,000,000 gallons per day, and from it the water will be pumped through a 7-foot tunnel in the shale to the existing plant at John street and to Sunnyside. Also two large mains running northerly, and then westerly, will supply another section of the city. A reservoir on St. Clair avenue will be constructed which will have a capacity of 50,000,000 gallons.

The address was illustrated by lantern slides. Also Mr. Gore showed blue prints of several features of the work.

Calgary Branch

W. H. Broughton, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

On Saturday, June 2nd, a golf tournament was arranged between the members of the Calgary Branch and members of the Earl Grey Golf Club and was played on the latter's golf course. Some twenty-four players paired off for the first tournament that this branch of The Institute has participated in locally. A cloudy day proved an advantage, if anything, and the excellent condition of the tees and greens proved conducive to a most enjoyable afternoon. A magnificent view of the snow-capped Rocky mountains is seen from this golf course. The programme was arranged as follows:—

Thirteen holes medal play in competition for prizes of golf balls.

Best net score.
Best gross score.
Hole in one.
Hole in two.
Consolation (highest gross score).
Consolation (highest net score).

The handicap and draw committee were G. P. F. Boese, D. T. Townsend, C. C. Richards, and J. A. Spreckley.

The results of the match were: H. L. High, best net score and best gross score; hole in two, G. P. F. Boese; consolations, Lt.-Col. F. M. Steele and F. K. Beach. Incidentally, no one chanced to make a hole in one. Chairman T. Lees presented the prizes.

Major Duncan Stuart, president of the Earl Grey Golf Club, regaled the players with refreshments at his beautiful residence nearby, which contributed considerably to the ultimate success of the afternoon.

The Programme Committee met under the convenership of J. A. Spreckley, A.M.E.I.C., and a tentative selection of outings and meetings for the year has been arranged, among which are the following: Picnic to P. Burns Ranch; lectures on "Modern Power" by F. J. Robertson, A.M.E.I.C.; "Technical Education" by Dr. W. G. Carpenter; "Aviation" by W. St. J. Miller, A.M.E.I.C.; a visit to Spiller's Flour Mills; a paper on "Steam Plants," and the annual ball, etc.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Moncton Branch was held in the Council Chamber at the City Hall on May 18th. G. C. Torrens, A.M.E.I.C., chairman of the branch, presided. The annual report and financial statement was presented and approved. On motion of F. O. Condon, M.E.I.C., seconded by F. B. Fripp, A.M.E.I.C., a vote of thanks was tendered the retiring chairman and members of the executive for their untiring efforts on behalf of the branch during the past year.

Following the business of the meeting, through the courtesy of Messrs. Stone and Webster, of Boston, Mass., two motion pictures were shown. The first was entitled "From Coal to Electricity" and illustrated the working of an electric power plant, and the second, "Conowingo," which featured a large hydro-electric development on the Susquehanna river, near Conowingo, Md.

Report of the Executive Committee

The Executive Committee held six meetings during the year. There were ten meetings of the branch, one of which was open to the public. At these meetings papers were read, addresses given and business transacted as follows:—

1927

Sept. 9—A meeting, open to the public, was held in the City Hall. Ian M. McLean, of the Canadian General Electric Company, Toronto, gave an address on **"The Progress Made in the Electrical Industry."** The address was illustrated with moving picture films.

Oct. 28—A supper-meeting was held in the Y.M.C.A. Prof. H. W. McKiel, M.E.I.C., of Mount Allison University, gave an entertaining and instructive address on **"The Autobiography of the Earth."**

Nov. 18—A supper-meeting was held in the Y.M.C.A. Dexter P. Cooper gave a very interesting address on **"The Passamaquoddy Tidal Development."**

Dec. 14—A supper-meeting was held in the Y.M.C.A. An instructive paper on **"The Evolution of Industrial Organization"** was read by Prof. Norman M. Guy of Mount Allison University.

1928

Jan. 11—A supper-meeting was held in the Y.M.C.A. P. L. Pratley, M.E.I.C., consulting engineer, Montreal, and councillor of The Institute, gave a very interesting detailed description of the construction of **The Montreal South Shore Bridge.**

Feb. 22—A supper-meeting was held in the Y.M.C.A. E. W. Jeffrey, sales engineer, Northern Electric Company, Halifax, gave an address on **"Illumination."**

Mar. 6—A special meeting of the branch was held for the purpose of discussing Institute affairs with the general secretary, Mr. Durley.

Mar. 30—A meeting was held in the Council Chamber of the City Hall. H. E. Bigelow, Ph.D., Dean of the Faculty of Science, Mount Allison University, gave a very interesting paper on **"Coal, Oil and Wood; Something of Their Past Performance and Future Promise."** Branch officers for 1927-28 were nominated at this meeting.

Apr. 4—A joint meeting of Moncton Branch and the Engineering Society of Mount Allison University was held at Sackville. H. J. Crudge, A.M.E.I.C., building engineer, Canadian National Railways, Moncton, gave a very instructive address on **"Construction Methods."** The address was illustrated with slides and motion picture films.

Apr. 23—A joint supper-meeting of Moncton Branch and the Gyro Club of Moncton was held in the Palm room of the Brunswick hotel. H. P. Webb, M.Sc.F., professor of forestry, University of New Brunswick, read a paper on **"Forestry and Its Relation to the Canadian Forests."**

The following is a statement of our membership at the present time:—

Juniors	4	—	4
Students	6	3	9
	39	14	53

GENERAL

The meetings during the year have been well attended. The branch was fortunate in securing a number of outstanding speakers, and the chairman of the Papers Committee, Prof. F. L. West, M.E.I.C., is to be congratulated on the uniform excellence of the papers presented.

It has been customary each year for the branch to hold at least one open meeting to which the public have been invited. Special care has been taken that the subjects of the addresses should be interesting as well as educational, and slides and motion pictures have always been included in the programme. The attendance on the part of the public, however, has been disappointing. Apparently the average person cannot get away from the idea that it is not possible for a technical address to be entertaining as well as instructive.

In an endeavor to co-operate with the provincial government in the annual "Save the Forest" campaign, a joint meeting was arranged during Canadian Forest Week with the Gyro Club of Moncton. The speaker was H. P. Webb, M.Sc.F., professor of forestry, University of New Brunswick, and his address was later published in full in the local papers.

The thanks of the executive are due Prof. F. L. West, M.E.I.C., chairman of the Papers Committee, Messrs. J. G. Dryden, A.M.E.I.C., and J. A. H. Whitford, JR.E.I.C., of the Entertainment Committee, and the ladies and gentlemen who very kindly furnished the musical entertainment for our meetings.

FINANCIAL STATEMENT

STATUS AND OPINION OF ENGINEERING GRADUATES

An analytical study of the "Occupations and Opinions of McGill Graduates in Applied Science," as expressed in reply to a questionnaire, formed the subject of an address to the branch on April 5th last, by Dean H. M. MacKay, M.E.I.C. The paper, of interest to all engineers and to The Institute in particular, when delivered in the Dean's inimitable manner, attracted marked attention.

In opening his remarks, the Dean pointed out that in view of the general discussion in recent years relating to the training of young engineers, engineering schools had deemed it advisable to carry out some investigation on their own account. That such an investigation is justified by financial considerations is apparent from a survey covering the average cost of producing a graduate engineer. This usually amounts to around $4,000, of which $2,000 is provided by the funds of the school, $1,000 by the graduate and the remainder represents interest on the cost of land, buildings and equipment.

The investigation at McGill University included a questionnaire to all graduates preceding the class of 1924. On some 30 per cent of the recipients responding, the most important features of these replies were carefully summarized.

On the subject of activity of graduates since their graduation, the study revealed some interesting tendencies. Mechanicals lead by a small margin in executive work; metallurgists in superintendence, and miners in management. Civils do more than their share of designing and estimating, while chemicals lead in research. Electricals are to the fore in consulting work and mechanicals reach the happy stage of ownership to a greater extent than their fellows.

As the years elapse after graduating, there was a gradual shifting of the centre of gravity from activities mainly technical to those which are mainly executive or administrative. More than 80 per cent of the graduates in the classes 1920-24 were engaged in work mainly technical, while 49 per cent only of the graduates previous to 1900 were so engaged, leaving more than 50 per cent engaged in executive, administrative or other work mainly non-technical. In the United States, due to greater industrial activity, this figure approaches 70 per cent. While the drift from technical to executive work is entirely satisfactory, the gateway seems likely to be mainly through technical employment.

Sixty-three per cent of civils and forty-five per cent of mechanicals remain in the field into which they were graduated, but on the other hand, only 28 per cent of chemists and miners are constant to their first choice, though both display versatility in entering other fields.

However, some 14 per cent of the work of graduates lay away from engineering altogether. The ownership percentage was small and less than that prevailing among American graduates, nevertheless our clerical percentage was also lower than theirs.

In view of the trend away from the course followed at college, it is evident that Canadian schools must continue to train along broad lines.

A number of interesting conclusions were drawn from the careful analysis of the income figures submitted as derived from earnings. For instance, graduates who enlisted for overseas service have been set back on the average about five years in this respect. University teachers and government employees are the two groups of graduates who earn least eventually, though both start off pretty well.

While these income statistics are rather erratic, due to the smaller representation of Canadian graduates, they are closely parallel to corresponding figures gathered in the United States. Their medium graduate, the man neither more nor less deserving or fortunate than his fellows, begins at nearly the same rate as in this country. Though he seems to advance a little more rapidly for the first five years or so, in the end he hardly holds his own with the Canadian graduate.

A remarkable feature of the study was the indication that, though the initial income following graduation was much higher than twenty years ago, in actual relative purchasing power the new graduate was not much better off than his predecessor.

On correlating income with academic standing, it appeared that after twenty years of graduation, the good and the medium were receiving approximately the same income, with the "low" man considerably behind.

Considerable difference of opinion prevailed in answer to questions on the quality of the engineering training obtained and the product turned out. On the whole, however, both were credited with being good.

The answers relating to the elements that should be included in the course and stressed as being most useful and important to engineers, have been of service in strengthening the curriculum. The majority of the graduates seemed to believe that while it is true that such subjects as foreign languages, accounting, industrial management, psychology, history and political science might be useful, the limited time available renders it difficult to present them in such a way that they would be both interesting and fruitful of result.

Both the general trend of opinion indicated and the individual suggestions and criticisms were proving most useful in adjusting the courses to meet present day circumstances.

In the interesting discussion which ensued, led by D. C. Tennant, M.E.I.C., R. J. Durley, M.E.I.C., P. F. Sise, M.E.I.C., R. A. Ross, D.Sc., M.E.I.C., and Geo. R. MacLeod, M.E.I.C., all stressed the importance of training the young engineer in the fundamentals of his profession.

A. S. Wall, M.E.I.C., moved the vote of thanks which was presented by D. C. Tennant, M.E.I.C., the presiding chairman.

66-K.V. CABLES OF MONTREAL LIGHT, HEAT AND POWER CONSOLIDATED

The recently installed 66-k.v. underground cables of the Montreal Light, Heat and Power Consolidated, representing as it does an almost phenomenal development in cable construction, formed the subject of a most timely address, when on April 19th the branch received a paper on that subject, splendidly illustrated with both slides and picture films, by Humphreys Milliken, M.E.I.C.

This high voltage underground installation came as a result of the economic need of feeding the company's new Vallee Street substation, situated in the heart of Montreal's underground distribution system, with a 66,000-volt system.

Forming part of a protective ring around the city, these 66-k.v. cables, in addition to carrying the load of Vallee Street station, may be called upon to carry the load of one or more adjacent stations in case the ring is temporarily open-circuited.

The present cable system covering the distance from Vallee station to the overhead lines is approximately 4,000 feet long and consists of six single conductor cables constituting two 3-phase circuits. These have been installed in a line of ten ducts, two ducts wide by five high. The duct system has been so arranged that it may receive a third feeder, connected in multiple with either of the two installed circuits.

The conduits are 4½ fibre with sleeve joints.

To provide for unavoidable seepage in the ducts and manholes, some of which are below sewer level, it was necessary to install sump pumps, automatically controlled by a float valve.

Specially large manholes have been constructed at the ends of the line to accommodate three-pole double-throw oil switches, required for connecting the future third feeder in multiple with either of the present circuits.

The cable, a single-conductor 750,000 C.M. copper strand, laid around a spiral steel spring, forming a hollow core, is insulated with a 30/32-inch thickness of paper enclosed in a 9/64-inch lead sheath and manufactured entirely in Canada.

The Simmons joints applied to this line have as their essential feature the application of one wide and long sheet of insulating paper, cut by machine to fit the steps of the joint at the moment of application and bonded by automatic ground shields at the ends formed by long pieces of thin tapering tinfoil applied to the paper in the factory.

The cable was pulled in with a power winch, the maximum tension required to start the cable from rest being 2,780 pounds, and that to keep it in motion 2,020 pounds. The pulling speed averaged from 15 to 20 feet a minute, with an average pull of 308 feet straightaway.

Heavy grease was used for lubricating the cable during the pulling, and in spite of an outdoor temperature of from 16°F. to 42°F. no difficulty was experienced.

This success was largely due to the care taken in ensuring the best working conditions in the manhole. For this reason a shack 10 by 12 feet was built, which could be removed from one manhole to another as the work progressed.

As a further precaution to prevent moisture entering the joints the air in the manhole was dried by passing it through a calcium chloride dryer and warmed against condensation by electric heaters placed in both shack and manhole.

On the completion of the work the two circuits were connected in series, and a short circuit current of approximately 250 amperes, 60-cycle, 3-phase, was put through the two circuits for a period of twenty-eight consecutive days.

The temperature in the adjacent empty ducts was read by a thermocouple, and that of the cables by resistance during the heat run. From these results it has been calculated that the maximum safe operating current will be about 350 amperes at 60°C. with ambient temperature of 20°C.

The heat run served also to test the operation of the sylphon reservoirs and as a result additional precautions have been taken to ensure the operation of an alarm signal should any such reservoir become empty of oil.

All cable sheaths are grounded on either side of each joint and both the cable and joints in the manholes wrapped with three wide asbestos listing saturated after installation with a solution of sodium silicate.

The cable terminals rated at 110-k.v. are oil filled. They have been protected against electrostatic stresses at the base by concentric tubes of micarta terminating in a correctly flaring copper ground shield. Two arresters have been installed to protect the cables against lightning.

Following a successful test with a six-tube Kenotron set, when the cables withstood 219,000 volts d.c. for fifteen minutes, the circuit was put into service on November 13th, 1927, and has been operated successfully ever since, with no troubles in cable or joints.

In the discussion which followed, N. L. Morgan, A.M.E.I.C., gave credit to the Montreal Light, Heat and Power Consolidated for being the pioneers in this development in Canada, and commented on the effect of sheath losses on the current carrying capacity of single conductor cables operating 3-phase with their sheaths bonded.

G. E. Templeman, M.E.I.C., referred to the research and investigation now being conducted on these high voltage underground cables and the problems introduced by their adoption outside of the high cost. W. S. Vipond, M.E.I.C., reported a 220-k.v. underground cable as being considered in New York.

Following the presentation of the vote of thanks by Prof. C. V. Christie, M.E.I.C., presiding chairman, as moved by G. E. Templeman, M.E.I.C., the meeting enjoyed a reel of microscopic studies on minute sea life beautifully illustrated.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary-Treasurer.

At the regular meeting of the branch held Thursday, April 26th, 1928, H. R. Sills, JR.E.I.C., a member of the a.c. design engineering department of the Canadian General Electric Company, Peterborough, gave a paper on the "Starting Characteristics of Synchronous Motors."

THE STARTING CHARACTERISTICS OF SYNCHRONOUS MOTORS

As an introduction the author gave something of the evolution of the induction motor characteristics of self-starting synchronous motors from the rudimentary squirrel cage winding used in early designs of alternators to give them self-starting properties to the modern starting winding which is an integral part of the machine, of as great importance as its synchronous characteristics.

The changes in the design of the pole pieces to accommodate an effective pole face winding, the effect of ratio of pole face to pole pitch, the ratio of stator to rotor ampere turns, and the air gap dimensions, were discussed in some detail. The effect of the resistance and reactance of the pole face winding on the starting characteristics was demonstrated with slides, and the speaker gave a fairly comprehensive discussion of the various phases of full voltage and reduced voltage starting, and showed that motors with special

Visit of Peterborough Branch to Lakefield, Ont.

Plant of Canada Cement Company, Lakefield, Ont.

high reactance windings could be designed to give the same starting characteristics as standard motors starting on 80 per cent voltage by means of a compensator, and further that full voltage starting was one of the best as well as the most economical methods of starting synchronous machines.

The effect of short circuiting the field winding on the inrush kv.a. and torque and the effect of resistance in the field circuit were discussed, followed by the theory and practice of compound windings for full voltage starting.

The speaker then referred to the mechanical design of pole face windings, covering something of their evolution and the reasons for adopting the present design. The end rings are placed against the side of the pole, and the bars are entirely embedded in the iron of the pole, so that the heating of the pole face winding is totally absorbed in the pole body and thus the bars cannot heat sufficiently to burn out. This construction makes the heating constant of the rotor of the same order as those of the stator, and hence the machine as a whole is protected by the overload protective devices.

The bars are silver soldered to the rings and so can operate at high temperatures without trouble. The method of connecting the ring segments between poles and the effect of omitting these connections were then described.

In closing, the author mentioned that the pole motors under discussion included motors that were susceptible to starting as squirrel cage induction machines, and called attention to the demand for a type of synchronous motor that fulfilled the functions of the wound rotor induction motor. A short description was then given of the starting characteristics of the synchronous induction motor; the standard synchronous motor with a magnetic clutch, and the so-called super-synchronous motor in which, when starting, the stator revolves until the motor is synchronized and then is braked to a standstill. Bringing the rotor up to speed in this manner makes use of the pull out torque of the motor to start the load.

The address was well illustrated by slides, both photographs and diagrams, many of which had been made by the author.

An interesting discussion followed the address, particularly amongst the electrical members of the branch, and a hearty vote of thanks was accorded to Mr. Sills for his paper.

Annual Meeting

The annual meeting of the Peterborough Branch was held at the Paragon Tea Rooms on the evening of May 10th, 1928. This took the form of a "ladies' night," commencing with a supper at 6.30 p.m., followed by the business portion of the meeting and concluding with a social hour for amusement and entertainment.

Chairman A. E. Caddy, M.E.I.C., was master of ceremonies, and since by strange coincidence his birthday fell on the date of the annual meeting, a birthday cake was introduced with all due ceremony during the first part of the evening. The toast to the ladies by Secretary W. E. Ross, A.M.E.I.C., and R. L. Dobbin, M.E.I.C., proved brief but humorously interesting, after which a half-hour was taken up with business, including the presentation of reports and the election of the executive committee as follows: G. H. Burchill, M.E.I.C., W. M. Cruthers, A.M.E.I.C., R. C. Flitton, A.M.E.I.C., A. B. Gates, A.M.E.I.C., J. A. G. Goulet, M.E.I.C., B. Ottewell, A.M.E.I.C., R. H. Parsons, M.E.I.C., E. R. Shirley, M.E.I.C.

The retiring chairman, Mr. Caddy, briefly addressed the meeting, giving all credit to the committee rather than to himself for the success of the past year. He thanked the branch for the honour of having been its chairman, made complimentary reference to the new executive committee and expressed the hope that the branch might enjoy a prosperous future.

Following the business meeting, moving pictures, written, filmed and edited by members of the branch, were shown, while the remainder of the evening was spent playing auction bridge.

As a result of the Annual Executive Meeting, May 28, 1928, the following is the list of officers for the season 1928-29:—

Chairman	W. M. Cruthers, A.M.E.I.C.
Secretary	S. O. Shields, Jr.E.I.C.
Treasurer	A. B. Gates, A.M.E.I.C.
	G. H. Burchill, Jr.E.I.C.
	J. A. G. Goulet, M.E.I.C.
	R. C. Flitton, A.M.E.I.C.
	E. R. Shirley, M.E.I.C.
Ex-officio	R. L. Dobbin, M.E.I.C.
	A. E. Caddy, M.E.I.C.
	W. E. Ross, A.M.E.I.C.

Visit to Cement Plant at Lakefield

The annual picnic of the branch was arranged for Saturday, June 9th, and comprised a drive to Lakefield, an inspection trip through the plant of the Canada Cement Company, followed by sports and dinner at the Lakefield hotel. The outing was well organized by a number of sub-committees and a total of fifty-four members and friends took advantage of the trip.

Mr. E. W. Bailey, superintendent of the Lakefield plant of the Canada Cement Company, and his assistants conducted the tour through the works which have recently been completed and have an output of 3,500 barrels per day.

The party first proceeded on two electric locomotives to the limestone shale quarry about half a mile away and inspected the operation of the electric shovel. Power for this railway is furnished by a 200-kw., 600-volt synchronous motor-generator set. Returning to the plant the several guides followed the direction in which the materials pass through the plant, describing the various processes involved.

The shale from the quarry is dumped from the cars into a 36- by 60-inch Allis Chalmers, single-roll crusher, belt driven by a 150-h.p. motor, falling thence into a Fraser and Chalmers "Pennsylvania" crusher driven by a 175-h.p. motor.

From this point the material travels by a long inclined belt conveyor into bins, then into the rock dryers to storage tanks.

The six ball mills and six tube mills were next inspected, the former driven through belt and spur gears, the latter by a 285-h.p. wound rotor induction motors through herringbone gears.

Meantime the coal is carried by conveyor from yard storage to the dryers and pulverizers, and thence to the kilns. There are six kilns, approximately 10 feet in diameter by 250 feet in length, rotated at about 40 revolutions per hour and fed with the ground shale at the upper end, being fired with powdered coal at the lower end. The resultant cement clinkers pass through the coolers and then by chain conveyor to the grinders. Here the material is ground twice before passing through "Hummer" electric screens to the storage silos, of which there are sixteen, each with a capacity of 21,000 barrels.

There are three 3-bag Bates packers which automatically fill and weigh 87½-pound paper bags, the cement being forced through one corner which is subsequently self-sealing.

In the chemical laboratories samples of the raw materials and finished product are taken and tested every two hours so that a close check is kept on quality.

The party next proceeded to the company's new power house on the Otonabee river close by, which furnishes power to the entire mill. This contains a 2,600-kv.a. vertical generator with direct connected exciter, motor-generator exciter set, switchboards, etc. This completed the tour of the mill and the members separated for tennis, softball, etc., rejoining for dinner at 6.30 p.m. After inhaling quantities of cement dust and indulging in more or less strenuous sports, all were most appreciative of the excellent fare provided by Mr. Strickland, mine host of the Lakefield Inn.

Mr. E. W. Bailey and his associates were entertained as guests and were heartily thanked by W. M. Cruthers, A.M.E.I.C., chairman, on behalf of the members, for the interesting trip through the plant.

Quebec Branch

Philippe Méthé, A.M.E.I.C., Secretary-Treasurer.

The St. Lawrence Waterways

A most successful meeting was held on May 7th, when the Lieutenant-Governor of the province of Quebec, Hon. N. Pérodeau, the Prime Minister, the Hon. Alexandre Taschereau, and the Hon. A. Galipeault, minister of public works and labour, attended the regular monthly luncheon of the Quebec Branch, at the Chateau Frontenac, together with a large number of members of the Quebec Board of Trade and of the Rotary and Kiwanis Clubs, who had been invited by the branch to listen to a talk of the utmost importance to the province and the country at large.

The interest aroused by the subject, which was presented by such an authority as O. O. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission, and a member of the Joint Board of Engineers appointed in 1924 to report on the problem of canalizing the St. Lawrence river and of developing its water powers, was well evidenced by the fact that this gathering included over 200 persons.

Beginning with a few general remarks on the geographical features of the St. Lawrence river, the economics and allied aspects of the problem, the very interesting and lucid lecture, delivered in French by Mr. Lefebvre, on the St. Lawrence Waterways may be briefly summarized as follows:—

Is it feasible to improve the St. Lawrence for deep navigation alone? Which is the best way to perform these improvements, and what will be the probable cost?

Is it feasible to improve the St. Lawrence for power alone? Which is the best way and the probable cost?

Is it possible to improve the St. Lawrence for both navigation and power? Which is the best way and the probable cost?

To answer these questions the Board had to study the whole problem of canalizing the St. Lawrence.

For navigation purposes, the river may be divided into three sections:—

First, from the gulf of St. Lawrence to Montreal, 1,000 miles. In this section a depth of 30 feet has been made available by spending $32,000,000, and this depth is being increased to 35 feet.

The second section extends from Montreal to Port Colborne, at the foot of lake Erie, a distance of 368 miles; the difference in level of 552 feet, due to falls and rapids. is at present overcome by lateral canals with locks 14 feet deep. Lachine canal surmounts the 45 feet of the Lachine rapids, between Montreal and lake St. Louis.

The second obstacle in this section is between the head of lake St. Louis and lake St. Francis, a distance of 16 miles with a difference in level of 83 feet, overcome by the Soulanges canal.

The third obstacle is the rapids between Prescott and Cornwall, a total drop of 92 feet in about 50 miles, overcome by canals with locks at Cornwall, Farran's Point, Morrisburg and Cardinal.

The fourth obstacle is the drop of 326 feet between lake Erie and lake Ontario, overcome by the Welland canal. The new Welland canal will be completed in 1930 at a cost of $115,000,000. The depth will be 27½ feet and the locks will be 30 feet deep. The old Welland canal has cost about $40,000,000, and $51,000,000 have been spent in other canals.

The third section is that comprising the Great Lakes system above the foot of lake Erie, navigable for boats drawing 20 feet, due to dredging the channels between the different lakes.

The problem is as follows:—

From the Great Lakes to the gulf of St. Lawrence maritime transportation necessitates two transshipments; first at Port Colborne, and second at Montreal. It is hoped that the St. Lawrence deep waterway would eliminate these two transfers by allowing ocean vessels to reach the Great Lakes. It is generally admitted that the first transshipment can easily be eliminated, but many experts are in doubt about the second.

Between Montreal and the Great Lakes 5,000,000 h.p. can be developed, 2,000,000 h.p. in the International section, and 3,000,000 entirely in the province of Quebec.

Improving the St. Lawrence river for navigation alone is very simple, and the flow would not be affected at all. The problem of developing the water powers is more complicated, as it involves interference with the flow of the river, which must be maintained uniform and regular.

The cost of improved navigation in the section of Lachine rapids is estimated as $53,000,000, and between lakes St. Louis and St. Francis, in the Soulanges section, $33,000,000.

In the International section, the cost of navigation improvements would amount to $79,000,000, and that of harnessing 2,000,000 h.p. available, $213,000,000.

American engineers favour the single-stage development as less expensive, but Canadian engineers insist on having a two-stage development, one at Morrisburg and the second at Cornwall, as affording a better control of the flow.

The total cost of developing all of the water powers would be $533,000,000, or approximately $100.00 per horsepower. The total cost of the improvement for navigation and power combined would be $650,000,000, so that $58,000,000 would thus be saved. To this must be added the $115,000,000 of the new Welland canal.

Mr. Lefebvre emphasized the necessity of maintaining the uniform flow of the St. Lawrence. Very little can be done to further regulate the flow of the Great Lakes, which are 90,000 square miles in area. One inch of water over such an area represents 80,000 cubic feet per second for one month, about one-third of the low water flow of the St. Lawrence.

It has been proposed to have the water power development in the Canadian section bear the cost of the navigation improvements in that section; the province of Quebec cannot agree to such a proposition, as the whole of Canada would benefit by the improvements, but the burden would rest on the shoulders of the consumers of power, for the great majority of whom would be located in the province of Quebec.

The luncheon was presided over by A. B. Normandin, A.M.E.I.C., chairman of the branch, and the vote of thanks presented by Dr. A. R. Décary, M.E.I.C., honorary chairman of the branch.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Sault Ste Marie Branch was held on Friday, May 25th, at 8 p.m., in the Y.W.C.A. rooms, with W. S. Wilson, A.M.E.I.C., chairman.

Mr. D. C. Wright, technical engineer of the Electric Controller and Manufacturing Company, of Cleveland. gave a splendid address on "Advantages Derived from Enclosed and Fully Protected Types of Motor Starting Apparatus."

Commencing with the earliest use of a.c. motors, the speaker gave an interesting paper on the history and development of control apparatus for a.c. motors. The control apparatus originally was of the manual type which frequently gave more trouble than the motors. Later, semi-automatic and complete automatic controllers operated from master switches were developed which still gave more or less trouble, due to the use of more delicate parts.

More attention was then given to providing suitable control rooms to protect the apparatus against dust, fumes, etc. Such rooms are sometimes expensive, requiring extra wiring and conduit work, but are justified wherever they can be provided. In places where it is impossible to provide such rooms the enclosed type of controller is used. The latter type was first introduced about ten years ago and has been well developed for all purposes. They are now in very extensive use, providing greater safety to operation and simplicity of control through simply pressing a button.

These compensators are operated from a master switch, and have automatic features for acceleration and protection against overload and starting. They are mounted in heavy cast iron or sheet steel tanks with tight fitting covers and all operating parts immersed in oil. Different attachments and connections can be made to give the desired flexibility for all purposes for which motors may be required, including provision for quick stopping of motors, when it may be necessary in case of accident, etc.

A more detailed discussion was given of recent developments to controllers to adapt them to use with synchronous motors. By the addition of a field control panel various refinements can be worked out to suit all conditions of starting acceleration and pull-in torque and a more recent development has been worked out whereby automatic power factor correction can be secured by varying the field strength where the synchronous motor is over-size or larger than is necessary to perform the required mechanical work.

A considerable number of lantern slides were shown of the various types and installations of control apparatus, etc.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

Concrete Control

At the May meeting of the Saskatchewan Branch Mr. L. J. Street, vice-president of the National Testing Laboratories, Limited, of Winnipeg, Man., addressed the members on the subject of "Concrete Control." Mr. Street supplemented his remarks by charts illustrating the fineness-modulus, water ratio and compressive strength of tested samples.

Mr. Street stated that for years concrete has been proportioned on a purely volumetric basis. Time of mixing and curing of concrete apparently were not appreciated to the full. Yield of aggregate, bulking due to moisture, percentage of fine and coarse aggregate, fineness-modulus, etc., were either unknown, or viewed as heights of knowledge considered impossible or unnecessary to climb. The allowable quantity of mixing water to a sack of cement was not specified and no restrictions imposed as to any extra water necessitated by reason of excess sand in the mix, lower fineness-modulus of aggregate, or personal whim of the contractor, who might happen to be of the "soup mix" type.

About seven years ago Professor Duff A. Abrams, M.E.I.C., working in the Structural Materials Research Laboratory of the Lewis Institute in Chicago, discovered in his thousands of tests an ordered relation between strength of concrete and the ratio of the water to the cement in the concrete, a relation that persisted through all kinds of aggregate and all kinds of mixes, provided the resultant concrete was what could be called workable, that is, of a consistency that would readily slide from mixers, fill forms and penetrate rod meshes, all without segregation or visible water. There followed soon after suggestions by other investigators for the proper grading of the aggregate, all of which was tied up to the water content in the final determination of the mix.

A year or so ago, however, from various sources it began to be apparent that the rational adaptation of the water-cement ratio was just the one which is discussed by Ahlers, McMillan and Yound, that is, that strength is a function of water-cement ratio and economy a function of aggregate grading and proportioning, and that the two are quite separate. There followed, therefore, the radical proposal that instead of requiring the contractor to proportion his concrete by some arbitrary measure of cement and aggregate, that the engineer merely specify the water content to guarantee the desired strength, and let the contractor put in as much stone as he could actually work with, in such proportions as to insure this workable mixture. Theory indicated, what some experience has since demonstrated, that the resulting concrete would be uniform and strong, which the engineer wanted, and economical, which both the contractor and engineer wanted.

The water-cement ratio theory is that, for given materials and conditions of manipulation, the strength of concrete is determined by the ratio of the volume of mixing water to the volume of cement so long as workable mixtures are obtained. It is common knowledge that, as long as other conditions are maintained constant, the strength of concrete is increased by (1) mixing the concrete drier, (2) increasing the cement content, or (3) using coarser aggregate.

For concrete made under average conditions and cured in the presence of moisture, the compressive strength may be expressed by the equation:—

$$S = \frac{14{,}000}{9x}$$

where S = the compressive strength at 28 days, in lbs. per square inch, and
x (an exponent) = water-ratio, (by volume).

The constant 9 will usually suit our local Portland cement but may vary with the product of different mills. It is necessary therefore to plot a water-cement ratio curve to suit the particular cement being used and evolve a suitable constant.

The practice has so long prevailed of securing increased workability or wet mixes by simply adding water, which practically costs nothing, without putting in additional cement, which would cost money, that a very firm stand will require to be taken to correct these conditions.

Time of mixing, while not of the same direct importance as water content, still has a bearing on the strength of the concrete which cannot be ignored. Tests show that thorough mixing makes a stronger and more uniform concrete and it also increases the plasticity, which means a more workable mixture and less labour in placing. Mixing for two minutes after all the materials are in the mixer should be the minimum, and mixing concrete for five minutes will give a further increase in strength. The revolutions per minute of the mixer drum should also be checked and should not exceed twenty revolutions per minute.

The speaker then referred to a number of precautions to be taken, particularly in curing and in the choice of water to be used, and concluded by saying that concrete made with Portland cement has been used over a period of one hundred years.

High-Pressure Gas Research at the Imperial College, London

The useful work on gaseous combustion at high pressures, which has been carried on under the direction of Professor W. A. Bone, F.R.S., in the department of chemical technology of the Imperial College of Science and Technology, London, is well known. Such work necessitates, among other things, the collection of not a little special, and often of specially designed, apparatus and, frequently, the development, as the result of hard experience, of a new experimental technique. In a word, in new investigations of this kind, the education of the worker is as important as the organization of the work. After seven years, then, the college is in a specially favorable position to offer facilities for training post graduate students in a branch of technology, which is becoming of increasing importance, in connection with new developments in the chemical industry. The position is being still further improved by the provision of two new high-pressure gas research laboratories, one of which is divided into four sections by steel partitions for the accommodation of high pressure explosion bomb installations and two pressure catalytic tube units. The other will be equipped with apparatus for preparing, storing and compressing gases, for determining compressibilities and for testing and calibrating standard gauges. Outside the building there will be an experimental gas generator and gas holders of various capacities from 3,000 cub. ft. downwards. The other equipment will include two compressors, one working up to 200 and the other up to 1,000 atmospheres pressure, a wide range of bombs capable of withstanding pressures of 100, 1,000, 2,000 and 20,000 atmospheres respectively, and catalytic tube units for pressures up to 500 atmospheres at 500 deg. C. It is hoped that most of this equipment will be ready for operation by the end of March 1928. This will enable a limited number of post-graduate research students to undergo a two-years course of systematic training, under the personal direction of Professor Bone and his assistants. As the number of vacancies is limited, early application should be made to Professor Bone at the Imperial College of Science and Technology, London, S.W. 7.—*Engineering*.

Tungsten Reactions in Gas-Filled Lamps

The temperature at which a tungsten filament can be operated in a vacuum is in practice settled by the state of evaporation of the metal which forms a black deposit on the bulb. The loss of metal is reduced by filling the bulb with an inert gas. In ordinary low-watt lamps the inert gas used is argon containing from 10 per cent to 20 per cent of nitrogen; on economic grounds large lamps, of 500 watts and more, are filled with nitrogen only, though they are run at temperatures of 2,850 deg. K. In such lamps a dark brown deposit settles on the bulb very slowly, yet more rapidly than in argon-nitrogen mixtures. That this brown deposit is a tungsten nitride had long been suspected, but had not actually been proved even by Langmuir in his studies of tungsten lamps. When the problem was recently taken up by Messrs. Colin J. Smithells and H. P. Rooksby in the research laboratories of the General Electric Company, Limited, at Wembley, they had to burn a four-litre lamp for 1,000 hours to collect about 10 milligrammes of the brown deposit. Ignited in air this deposit burnt to a greenish yellow oxide. X-ray examination of the deposit, of tungsten metal itself, and of its three oxides, (WO_3 yellow, W_2O deep blue and WO_2 chocolate brown), did not indicate any oxygen compound. Oxidation of the deposit with potassium permanganate in a spectrum tube showed the presence of nitrogen, and the volume relations suggested a nitride WN_2. This formula was confirmed by further experiments; the density of the nitride was of the order 5. In their recent communication on this subject to the Chemical Society, Messrs. Smithells and Rooksby also referred to the action of water vapour, which is difficult to exclude entirely. The reaction between the hot tungsten and the vapour giving oxide and hydrogen is reversible. The hotter parts of the filament, as Dr. Smithells has previously shown, are oxidized, the oxide is reduced again, at lower temperature by the hydrogen, to metal which is re-deposited on the cooler portions of the filament. One would then expect that the brown deposit should also contain oxygen which, however, was not found. There is, however, reason to assume that water vapour does reach the glass walls; but it seems to be reduced again by the atomic hydrogen. That would help to explain how one part of water vapour in 10,000 can burn out a tungsten filament in less than an hour.—*Engineering*.

Preliminary Notice

of Applications for Admission and for Transfer

June 20th, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in July 1928.

R. J. Durley, *Secretary.*

---

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

FIEGEHEN—EDWARD GEORGE, of 8016 Western Avenue, Montreal West, Que., Born at London, England, Jan. 7th, 1875; Educ., Bedford Modern School, technical classes at Bedford, Leeds Univ. and McGill Univ. at intervals during 1895-1913; apptce., 1892-94, Grafton & Co., Bedford, and 1894-98, Bedford Engrg. Co.; 1898-1900, dftsman., and 1900-07, i/c of production, Bedford Engrg. Co.; 1907-09, leading dftsman., Thos. Smith & Sons, Ltd., Rodley, Eng.; 1909-11, i/c of crane dept., estimating, etc., Royce, Ltd., Manchester, Eng.; 1911-13, 2nd mech'l engr., Dominion Bridge Co., Montreal; 1913-27, (with exception of 1914-17, when Major in command of Field Co., R.E., in Gallipoli, Egypt and Palestine), senior partner, Bedford Engrg. Co., Bedford, Eng.; at present in mech'l dept., Dominion Bridge Company, Lachine, Que.

The St. Lawrence River Project

A Review of Existing Conditions and a Discussion of Proposed Improvements

O. O. Lefebvre, M.E.I.C.
Chief Engineer, The Quebec Streams Commission.

Paper read before the Quebec Branch of The Engineering Institute of Canada, on May 7th, 1928 (1)

Previous Surveys

The linking up of the important territory bordering the Great Lakes with the Atlantic ocean by a ship canal has been a subject of discussion during the past thirty years in Canada and the United States. A commission of engineers was appointed in 1899 by the Government of the United States to study this question, and this commission submitted a report in 1900.

Three routes were considered. The route favoured at that time was that of lake Erie to lake Ontario by a canal on the American side, then navigation to Oswego, N.Y., and a deep ship canal from Oswego to the Hudson river.*

No action was taken following this report.

In 1904, the Canadian Government, with the object of facilitating the grain movement from the head of the Great Lakes to Montreal, had a study made of a ship canal scheme by way of the Ottawa river and French river. This is the Georgian Bay canal project.

In 1920, the Government of the United States and the Canadian Government submitted to the International Joint Commission the study of a project which aimed to make the St. Lawrence navigable by deep draught ships. This Commission submitted the technical aspects of the scheme to two engineers, Lieut.-Col. W. P. Wooten, of the United States, and W. A. Bowden, at the time chief engineer of the Department of Railways and Canals. The report of these two engineers is known as the "Wooten-Bowden Report."

In 1921, this Commission made a report which was rather favourable to the undertaking, but it recommended that the problem be submitted to an enlarged board of engineers, and in 1924 the two governments appointed such a board which consisted of six members:—

American Section:—

- Major-General Edgar Jadwin, then assistant chief engineer of the United States Army War Department, Washington.
- Colonel William Kelly, at the time chief engineer of the "Federal Power Commission," Washington.
- Lieutenant-Colonel G. B. Pillsbury, at the time engineer in charge of hydrographic surveys on the Great Lakes.

Canadian Section:—

- D. W. McLachlan, M.E.I.C., engineer in charge of the St. Lawrence in the Department of Railways and Canals.
- Brigadier-General C. H. Mitchell, M.E.I.C., dean of the Faculty of Applied Science, University of Toronto, and consulting engineer.
- O. O. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission.

The two governments submitted to these engineers a certain number of questions regarding the possibility of improving the St. Lawrence as a deep waterway. This commission presented a report in 1927. This is the report which serves as a basis for most of the discussions on the subject.

It should be pointed out, at the outset, that these engineers did not recommend the carrying out of the scheme. They answered certain questions of a wholly technical character which had been submitted to them. The Board stated unanimously that the project was feasible with all guarantees of security. They recommended that, in order to achieve a given result, the best plan to adopt was this or

(1) This paper also formed the basis of Mr. Lefebvre's address to the members of the Montreal Branch of The Engineering Institute of Canada, on the occasion of their excursion on the St Lawrence river from Montreal to Prescott, June 1st and 2nd, 1928.

*(See Deep Waterways Board Report, 1900.)

that one, for such and such a reason, but they did not state that the said plan should be undertaken. It has been wrongly stated in certain quarters that this Commission reported favourably to the scheme.

Actual Conditions

For the purposes of navigation, the St. Lawrence may be divided into three sections: that of the Gulf of St. Lawrence up to Montreal,—a distance of about 1,000 miles, and navigable by ocean-going ships with 30 feet of draught. This navigation has been made possible by dredgings, more particularly above Quebec, which have cost Canada in the neighbourhood of $32,000,000. The work of deepening the river is being continued with the object of increasing the available depth to 35 feet. The harbour of Quebec, whose importance is increasing rapidly, and into which ocean liners of the greatest tonnage may find a berth, is situated in this section. The season of navigation covers, on an average, a period of about seven and a half months,—from April 15th to the beginning of December.

The second section, from Montreal to the foot of lake Erie at Port Colborne, covers a distance of 368 miles. Within this stretch there is a rise of 552 feet,—a rise which is overcome by canals and locks opposite the falls and rapids. The depth of the canals accommodates boats with 14 feet of draught.

The First Obstacle:—The Lachine rapids between Montreal and lake St. Louis, in which there is a fall of 45 feet, are overcome by the Lachine canal, which is 8½ miles in length and has five locks.

The Second Obstacle:—Between the head of lake St. Louis and the foot of lake Francis, a distance of 16 miles, where Coteau, Cedars and Cascades rapids are located. The difference in level between the two lakes is 83 feet and the distance is navigated through the Soulanges canal, which is 14 miles in length and has four locks.

The Third Obstacle:—At Cornwall the river becomes an international waterway. The rapids of the Long Sault, which are overcome by a lateral canal 11 miles in length, with six locks, commence near Cornwall. The fall in the Long Sault rapids is 48 feet. Then there is another lock at Farrens Point, and the length of the canal is 1½ miles.

At Morrisburg, (at Rapide Plat), there is a canal 3 2/3 miles in length with two locks, and finally, between Iroquois and the head of the section of the rapids, at Cardinal, a few miles below Prescott, there is a canal with three locks. From the head of Galop rapids, 110 miles from Montreal, where the control section of lake Ontario is located, there is open navigation for a distance of 225 miles. The Niagara river and Niagara falls are between lake Ontario and lake Erie, where the difference in levels is 326 feet, and is overcome by the Welland ship canal, which is 26¾ miles in length and has twenty-five locks.

The third section is that of the Great Lakes where a depth of 20 feet has been made possible by deepening certain of the channels connecting these lakes, such as the Detroit river between lake St. Clair and lake Erie, a distance of 28⅛ miles; lake St. Clair, 14 miles in length; the St. Clair river between lake Huron and lake St. Clair, a distance of 39 miles; and finally, St. Mary's river between lake Superior and lake Huron, a distance of 64¾ miles. Lake Superior is 600 feet above sea-level, whereas lake Huron and lake Michigan are at 580 feet. The difference of 20 feet is to be found in the slope of St. Mary's river and in the rapid or falls of 18 feet at Sault Ste. Marie. This rapid is overcome by locks, four on the American side and one on the Canadian side. Two of the American locks have a depth of 24½ feet over the sills, and the Canadian lock has a depth of 18 feet.

Therefore, the existing system provides ocean navigation with a draught of 30 feet and more as far as Montreal; navigation at 14 feet from Montreal to Port Colborne, at the foot of lake Erie; and navigation at 20 feet on the Great Lakes as far as the head of lake Superior.

Cost of Canals

The canals mentioned in the second section, (from Montreal to lake Erie), are all located in Canadian territory. They were constructed and are maintained by the government of Canada, and our country made a capital outlay of $69,000,000 for their construction. You are aware that a new Welland canal is under construction, and that it is estimated it will be completed in 1930. It will provide a depth of 27½ feet in the reaches, and a depth of 30 feet in the locks. In 1930, it will be possible for the largest lake boats to enter lake Ontario and to navigate as far as Prescott, 115 miles from Montreal. The cost of the new Welland canal is estimated at $115,000,000.

Improvements in the Great Lakes

If all the canals in the second section have been constructed by Canada, at Canada's expense, it is but fair to say that the improvements in the rivers connecting the Great Lakes were carried out almost exclusively by the United States government, at a cost of about $46,000,000. The improvements include the locks at Sault Ste. Marie. The channels thus improved are not all located in American territory; the Livingstone channel, in the Detroit river, is largely in Canadian territory; the Amherstburg channel in the same section of the Detroit river is wholly in Canadian territory,—the first is used by downbound vessels and the second by upbound vessels. Canadian boats use them on the same basis as American boats, just as the latter make use of our canals. The government of Canada has spent about $6,000,000 for the lock at Sault Ste. Marie.

The present system of navigation requires a transfer of export cargoes at two points; first at the foot of lake Erie, then at Montreal. It is believed that there is an advantage in doing away with this transshipping from one vessel to another if the St. Lawrence were deepened and improved to accommodate vessels of greater draught. This undertaking is what is generally called " The St. Lawrence Deep Waterway."

St. Lawrence Deep Waterway

The problem submitted to the engineers was that of determining if such a project could be carried out; the best plan of carrying it out, and the probable cost of same.

In view of the fact that the falls and rapids on the St. Lawrence have a potentiality of approximately 5,000,000 h.p., of which 3,000,000 h.p. are in the Canadian section and 2,000,000 h.p. are in the International section, and that it is desirable to utilize this power for the industrial development of the two countries, would it be possible to improve the St. Lawrence for the production of that power? The investigation had reference to the following questions: What would be the cost of improving the river for navigation alone, and what would be the cost of improving the river for power alone? What would be the cost of a combined plan of improvement? Would it be advantageous to carry out the combined projects?

The St. Lawrence has, as you know, a drainage basin of about 375,000 square miles at Montreal. It has a flow which is extraordinarily regular. In fact, it is the best regulated river in the world. At the outlet of lake Ontario, the maximum flow registered was 320,000 second-feet, and the minimum flow 180,000 second-feet. The ratio between the extreme maximum and the extreme minimum was less than 2 to 1. On the St. Maurice river, for instance, the ratio is 25 to 1; on the Ottawa river the ratio is 10 to 1.

Navigation Alone

One of the problems to be solved was an improvement of the river above Montreal, and as far as the head of the Great Lakes, for navigation alone.

The problem looking to the improvement of navigation alone is easy enough, since in every case, with the exception of one short section, the depth is secured by means of lateral canals with locks, at an estimated cost of $167,200,000. The exception mentioned is in the reach just above the head of the Long Sault rapids, where it is cheaper to use the river for a certain distance, which would require the construction of a low dam.

All these works for navigation alone do not affect the flow of the river in any way, and do not involve any engineering difficulties whatever.

Water Power

This is not the case when the improvement of the river for power is considered. The concentration of the available heads at given points requires extensive changes in the sections and rather complicated compensating works, if the necessary safeguards against damage claim and disasters are to be provided.

Ice constitutes one of the most difficult problems in the St. Lawrence and creates a situation which calls for very careful study if a definite and effective solution is desired. For instance, the sections of the rapids do not cover with ice. This stretch of open water subjected to the cold air forms frazil which is carried along by the current and gathers in the parts of the river where the surface is smoother, and piles up at the surface if the velocity of the current does not exceed 2¼ feet per second, or which is carried under the ice if the current exceeds 2½ feet per second. This process of ice-formation goes on throughout the whole winter.

The Lachine rapids and the foot of lake St. Louis are responsible for the Laprairie basin and the harbour of Montreal being filled with ice, frazil, (which the French call "glace en sorbet," "sherbet ice"). This ice forms an obstruction and raises the water in the harbour from 10 to 12 feet higher than the summer level. This phenomenon is due solely to the obstruction caused by the ice.

Lake St. Louis, where the sheet of water is smooth, is covered with ice, but the rapids of Coteau and the Cedars always remain open, and the same phenomenon of the production of ice and frazil is repeated, with the result that the surface of lake St. Louis, which should be practically level, rises at the head of the lake as much as 7, 8 and even 10 feet above the normal summer level, so that at a certain time a portion of the water of the St. Lawrence flows into the Ottawa river at Vaudreuil through the lake of Two-Mountains, whereas normally it is the Ottawa river which flows into the St. Lawrence by that channel.

The same ice phenomenon occurs in the international section of the river between Prescott and Cornwall. The ice piles up at the foot of the Long Sault rapids and often causes very damaging floods at Cornwall in the middle of winter. From Prescott to Kingston, the river covers with ice in a normal way. Lake Ontario does not freeze, neither do the other lakes, with the exception of lake St. Clair, which in area might be compared with lake St. John at the head of the Saguenay river.

To ensure the operation during the winter months of hydro-electric power stations erected on the St. Lawrence river, it is essential that the upper reach be covered with a sufficient ice cover to prevent the frazil from reaching the power house. To achieve this object, the section of the river in the rapids must be enlarged to a point where the velocity of the current will not be more than 2¼ feet per second, or, at all events, that the surface water exposed to the air and producing frazil will be reduced to a point where the frazil that is formed may be stored in the deep part of the head-race without retarding the regular flow of the river.

The concentration in generating plants can only be attained by means of dams built across the river, or by the diversion of the waters into lateral head-races excavated for this purpose. At all events, the plan found to be the cheapest was that which uses the river by taking all factors into account; necessary deepening in the rapids, in order to secure a current which would practically eliminate the formation of frazil, and ensuring a regular and uniform flow of water to the various power houses. In summer the enlargements of certain sections are necessary in order to avoid backwater and head losses.

Cost of the Combined Improvements

It has been found that navigation between lake Ontario, at Kingston, and Montreal, for a depth of 25 feet with locks at 30 feet, may be secured at a cost of $167,000,000. It has also been established that in order to improve the river for power alone in the same section the cost would total $533,000,000 for a power house capacity of 5,000,000 h.p. By combining the two improvements, the cost would be $650,000,000, so that an economy of $50,000,000 would be realized. If one adds the cost of the Welland canal, $115,000,000, the cost of deepening the rivers connecting the Great Lakes, and that of the compensating works, estimated at $44,000,000, one reaches a grand total of $799,000,000. Once again, this estimate provides for hydro-electric plants with a capacity of 5,000,000 h.p. Of this quantity of power 2,000,000 h.p. in round figures are situated in the international section from Cornwall upstream, and are to be divided equally between the two countries. The balance, 3,000,000 h.p., is available in the essentially Canadian section of the river, which is wholly in the province of Quebec, namely, 2,000,000 h.p. in the Soulanges section, and 1,000,000 h.p. in the Lachine section. It goes without saying that the installation of the power generating units may be made when the power may be disposed of and our industrial progress demands it.

No Export of Power

It is well understood, and it is a policy approved by the greatest majority,—that is about the only point on which everybody is in agreement,—that the power that will be generated from our section of the St. Lawrence must be utilized at home and will not be exported to the United States. Moreover, the author believes that American opinion accepts this situation with good grace, and that our friends in the United States are not counting on receiving from the St. Lawrence any other electrical power than that which rightfully belongs to them. They desire the improvement of navigation; they want to make it possible for vessels of the Great Lakes to reach Montreal or Quebec, or even enter the gulf, and they believe that ocean steamers will travel up to the head of the Great Lakes; to Chicago, Duluth, Fort William.

Estimates

The estimates prepared by the engineers have caused some criticism. Comparisons have been made. The estimate of $252,000,000 made by Messrs. Wooten-Bowden in 1921 has been compared with the estimate of $650,000,000 mentioned in the last report, and this has led to the statement: " What was to cost $252,000,000 in 1921 is estimated at $650,000,000 in 1927."

In the first place, a comparison is made between two plans which are not comparable because they do not cover the same items. The estimate of 1921 only covers the section between the foot of lake Ontario and Montreal. In addition, the estimate only deals with the development of 1,464,000 h.p. in the International section. It does not include any power development in the purely Canadian section. If the two estimates are placed on the same basis, it will be found that they are not very far apart.

It is generally stated that the engineer's estimates are insufficient. The author is in a position to tell you that the estimates embodied in the report which was submitted last year were prepared with the greatest care. Nothing was overlooked in the way of determining the exact nature of the foundation, the ground which would require excavation, and finally all the factors which would have any bearing on the cost of the works. Strangely enough, it is whispered in certain quarters that the estimates are too high. That is, the unit prices we have used have been stated to be too high.

Maintenance of a Uniform Flow

In considering the problem of the development of the St. Lawrence and its improvement, both for navigation and for power, there are certain guiding principles which must be kept in mind. For instance, the uniform flow of the St. Lawrence must be maintained at all costs; it must be guaranteed. The level of the St. Lawrence river at Montreal is seasonably regular and free from sudden fluctuations because the discharge from lake Ontario is seasonally regular and uniform. On the other hand, the volume of water utilized by hydro-power plants is, with rare exceptions, very variable. It varies directly with the quantity of power supplied to the customers.

The power plants which will be installed on the St Lawrence will be subject to the same conditions. Whatever the power factor may be, it is essential that the flow of the river must not change with the load,—which amounts to this: the maximum to be allowed for the power generating plants must correspond to the power which an average available flow can produce. In this way, when the water is not required at the plant, it will not be stored in a pond formed by a dam or a lake, but it must be allowed to flow out by means of sluice-gates outside of the plant, in a dam constructed for this purpose. It is an exceedingly important principle if one is to retain for our river its navigable character.

All the commissions of engineers were unanimous in laying down this principle, which must be applied not only in the international section but also in the Soulanges section and in the Lachine section.

It is the method to be followed in order to ensure a uniform flow that caused the two sections of the Board to differ with respect to the plan for the international rapids section. The Americans favoured what is known as the " single-stage development," a concentration at one point of all the fall between Prescott and the foot of the Long Sault rapids at Cornwall, by means of a dam located at either the head or at the foot of Barnhart island, but the power plant would in both cases be located at the foot of Barnhart island. This means that the flow from lake Ontario would be controlled by a dam connected to a power station having a capacity in excess of 2,000,000 h.p. The flow in such a plant may vary to a very considerable degree. As the stretch of water above the dam is lake Ontario, which has an area of 7,500 square miles, the flow may be retarded with little effect on the level of this sheet of water, but the effect might be positively disastrous to that section of the river below the dam.

The Canadian section of the Board insisted that the control of the flow from lake Ontario be not connected with a power plant having a capacity of several million h.p. The ideal plan would be the construction of a control dam for flow only, but as this plan would involve the loss of a certain quantity of power which may become very valuable, and which has an important value to-day, it was agreed by the Canadian section to connect this dam with a hydro-electric plant of much lesser proportions, and which can be operated as a basic plant with a uniform load 24 hours a day. It is readily conceivable that this plant may be connected with a system in which the variations in load will be absorbed by other units in the system. For this reason concentration at two points, " the two-stage development," was favoured.

The control dam for lake Ontario would be at Crysler island, a few miles below the town of Morrisburg. The head available would be 24 feet. The other concentration would be at Barnhart island, at the same point favoured by the American section, where the head would be about 60 feet. The dam at the head of Barnhart island will be equipped with a long spillway, and if the volume of water in the plant be reduced, the pond between the two power houses, which is limited to the area of the river, will rise very rapidly, and in a very short while the water will flow over the spillway.

This plan ensures the uniformity of the discharge from lake Ontario, which is the essential thing, not only in the interest of good navigation at Montreal, but also to safeguard the value of the water power in the Canadian section of the river. It is quite true that this plan would involve an outlay of $34,000,000 more than the sum required to carry out the single-stage plan, but the security of the level in the port of Montreal and of the level below Montreal is worth much more than this slight difference. Moreover, control by means of two dams makes provision for greater security against accidents, the chances of which are very remote, but nevertheless quite possible.

" The Joint Board of Engineers, 1924," lays down the following:—

> *Paragraph 109. Fundamental Principles.*—The plans have been prepared in accordance with the recognized principle that the interests of navigation on the St. Lawrence are paramount. A full observance of this principle does not interfere with the beneficial use of the flow of the river for power generation. On the contrary, the improvement of the rapids sections of the river for the joint benefit of navigation and power affords, as a rule, much better navigation than could be secured by the improvement now economically justifiable in the interest of navigation alone.
>
> *Paragraph 116.*—The various power houses have the capacity for the development of the maximum flow which the Board considers as utilizable in the future. The interests of navigation require that the flow down the St. Lawrence be maintained at a high degree of uniformity, and prevent the maximum use of water for power by fluctuating the hourly flow to meet the fluctuating power demand. An installed capacity well in excess of the minimum flow of the river has been provided, however, since the increasing value of power will justify its eventual development from the flow available during high-water periods only.
>
> *Paragraph 218.*—The improvement of the St.

Lawrence river could affect the water levels at and below Montreal to the extent only that the works might be so operated as to modify the rate of discharge of water down the river. The programme for the regulation of lake Ontario recommended by the Board is so drawn as to afford mean discharges during the critical months of September, October and November at least equal to the discharges that occur in nature; and discharges in the half of April, when the river has its maximum flood levels, no greater than those that would occur with equal frequency without regulation. There remains the possibility of the introduction of fluctuations in the discharge of the river through the fluctuations in the discharges through the power plants to meet their changing loads.

Paragraph 219.—Any necessary uniformity of discharge past the various power structures can be secured by opening sluice gates as the power load and power house discharge diminishes. Power can be profitably generated at the various plants recommended by the Board without causing any greater hourly and daily fluctuations in the water levels at Montreal than now occur from natural causes, and suitable government supervision, both over the plants in the international section and over those in the province of Quebec, can assure this result.

Paragraph 234.—Question 5: "To what extent may water levels in the St. Lawrence river at and below Montreal, as well as the river and lake levels generally, be affected by the execution of the project?"

Answer: The irresponsible operation of the power works proposed by the Board, or indeed of any power works, however designed, that develop fully the power resources of any section of the river, would affect injuriously the water levels in the St. Lawrence river at and below Montreal; but it is feasible to operate these works under government supervision in such manner that they will neither lower the summer levels in the lower river nor raise the winter and spring levels. With such control the improvements proposed will have no injurious effect whatever on the water levels of the St. Lawrence at and below Montreal.

Regulation and Control of Discharge from the Lakes

The possibility of regulating the discharge of the Great Lakes with the view of improving it, if possible, has been the subject of a thorough study. This study has shown that no improvement can be carried out which would warrant the extraordinary expenditure it would involve.

Certain interests in the Great Lakes have proposed that the level of the Great Lakes be controlled with the object of maintaining a given minimum. Now, the Great Lakes are the basins which feed the St. Lawrence, which regulate its flow. When the supply of water is very great, the levels of the lakes rise and the lakes retain a large portion of the supply. On the other hand, when the supply is small, the St. Lawrence is fed from the storage in the lakes, the levels of which then recede. If it be planned to install control works that would prevent the level of the lakes from receding during a certain period, this would prevent the lakes from performing their function, that of feeding the St. Lawrence. This is a project which must be opposed every time it is put forward. A calculation based on the conditions that obtained in the month of September, 1925, proves that in order to prevent the level of the lakes from dropping during that month, the discharge would have had to be reduced by 142,000 cubic feet per second. Now, what would be the effect of such a reduction at Montreal? The lake Ontario level would have dropped about two feet, and in the harbour of Montreal the drop would have been greater, since the level of the harbour under normal conditions drops one foot when the discharge is decreased by 23,000 cubic feet per second.

Diversions

Another interesting point is the effect of the diversion of water at Chicago on the level of the lakes and the level of the river. This diversion caused a lowering of about six inches in the level of lakes Huron, Michigan, Erie and Ontario. The level of lake Ontario was restored by the construction of a dam between two islands, at Galop rapids,—which is known as the "Gut" dam. The water diversion at Chicago results in a lowering of the level at Montreal by 4½ inches. This effect does not increase. It is definite and will not increase if the volume of water diverted is not increased. It will decrease if the volume of the diverted water decreases.

The lowering of the level may be remedied by means of compensating works. At the outlet of lakes Michigan and Huron, these compensating works would take the form of submerged weirs in the St. Clair river, which would spread over a great distance the additional slope it is desired to secure. At the outlet of lake Erie in the Niagara river, compensating works that would restore the level of lake Erie could be carried out. The estimated cost of all these compensating works is $3,100,000.

There is one thing, however, which the Chicago diversion causes, and for which there is no remedy. This is the loss of power represented by 8,500 second-feet on the available head. This loss amounts to 161,000 h.p. in the section of the river between Prescott and Montreal. With respect to the loss which this volume of water represents at Niagara falls, Canada may be compensated for same by a distribution of the amount of water authorized to be diverted from the falls. At the present time the volume of water diverted at Niagara falls under the terms of a treaty between the two countries is 56,000 cubic feet per second, of which 20,000 are on the United States side and 36,000 on the Canadian side. There is a proposal to increase this volume to 80,000 cubic feet per second, if it can be proven that such a diversion will not affect the grandeur or mar the beauty of Niagara falls.

There are several water diversions throughout the whole St. Lawrence system, most of them for the purpose of generating power. At the outlet of lake Superior, at Sault Ste. Marie, 50,000 cubic feet per second are diverted, of which 30,000 are on the American side and 20,000 on the Canadian side.

To compensate for this diversion on lake Superior, a dam which serves to control the discharge from the lake was constructed in St. Mary's river. This dam is under the control of the International Joint Commission. This diversion does not affect the levels below.

The most important water diversion outside of Chicago is that at Massena. Between the St. Lawrence river at the head of Long Sault island and Massena, N.Y., on the Grasse river, there is a drop of 42 feet. The river at Massena is three miles from the St. Lawrence. A feeder canal was excavated, whereby 23,000 cubic feet per second are diverted for the generation of 86,000 h.p., used for the manufacture of aluminum. This water again finds its way into the St. Lawrence by the Grasse river and in no way affects the level of the river below.

Grain Carrying Charges

The effect of this improvement on the transportation charges is a matter of discussion. Certain enthusiastic supporters of the project speak optimistically of a reduction of $0.10 per bushel in the grain carrying rates. There are others who assert that there will be no change whatever in the freight rates. During the past few years the cost of grain transportation from Fort William to Port Colborne has been, on an average, $0.03 per bushel. This rate will not be lowered as a result of the proposed improvement.

The distance between Fort William and Port Colborne is 850 miles, and requires a lockage lift of 18 to 20 feet at Sault Ste. Marie. The average time required for this lockage in 1925 was 1 hour and 9 minutes, inclusive of the delay incidental to the entry into the canal and the exit therefrom.(2) If one deducts the delay, the lockage itself took an average of 52 minutes. This demonstrates the importance of the vertical distance.

From Port Colborne to Montreal the distance is 368 miles, but the vertical drop which must be overcome by canals and locks is 540 feet. This vertical distance is equivalent to an horizontal distance of about 300 miles for the average freighters on the Great Lakes. Under present conditions the cost of grain transportation, including the transshipment charges between Port Colborne and Montreal, works out at about $0.06 per bushel. This is the only section of the river where a reduction in transportation costs is anticipated. What will this reduction amount to? The most competent authorities have stated that this reduction may reach a maximum of $0.03. It can only apply to grain tonnage which will be carried mainly by this improved route. On the basis of the cost of wheat, this reduction would equal $1.00 per ton. As the capacity of the projected canal is 24,000,000 tons per year, the maximum amount that could be saved on this basis would be $24,000,000. (Last year, cargoes totalling 7,200,000 tons passed through the Welland canal, so that the economy effected would, therefore, be $7,000,000.) Twenty-four million dollars is the maximum which may be hoped for. Can this maximum be realized? There is reason to doubt whether it will be. Traffic on the Great Lakes in 1926 totalled 121,000,000 tons, divided between four main commodities, namely:—

> Iron ore, from the mines on lake Superior to the harbours on lake Erie, 63,000,000 tons;
> Coal, traffic from the east to the west, return traffic, 31,000,000 tons;
> Crushed stone, 14,000,000 tons;
> Grain, 12,000,000 tons.

These products are carried as bulk cargoes. The balance of the traffic is largely made up of package freight which only represents a very small portion of the total traffic. Iron ore will not be transported by way of the improved canals. It is used in the blast-furnaces in the Pittsburgh district and in the ports on lake Erie. Coal is shipped to us from the ports on lake Ontario. It is doubtful whether the improvement contemplated will have the least effect on the freight charges for this kind of merchandise. Crushed stone and gravel constitute a very important local traffic which, however, will not extend beyond the Great Lakes. Grain is the only article which may increase the traffic on the Great Lakes, and this traffic will probably show a very large increase.

What the package freight to be developed on the St. Lawrence route will amount to is problematical. On the other hand, it must be borne in mind that the fixed charges, interest and maintenance of the canals, will be several million dollars greater than they are to-day. There are no toll charges on the canals, which are free to navigation.

There is another aspect of the deep waterway project to which attention must be called, and that is the necessity of separating the cost of navigation from the cost of power development. The canals of Canada have been declared to be public works, which have been carried out for the greatest advantage of the country, and their cost is paid by the whole country. Water power must be paid in the final analysis by the consumer of electric current. Now, the government is being advised from certain quarters to deviate from this principle, and the following proposal is put forward:—

The St. Lawrence deep waterway may be carried out without entailing any cost to the country, in addition to those expenditures we are committed to, such as the Welland canal. Here is the proposal:—As an offset to our expenditures for the Welland canal and the deepening of the St. Lawrence below Montreal, the United States would be asked to undertake at their own expense the works projected in the International section of the river for the improvement of navigation and the development of power, Canada would take her share of the completed works, including half of the power. As regards the national or Canadian section of the river, the section situated wholly in the province of Quebec, it is submitted that the producers of hydro-electric power, private interests probably, but the principle would be the same in the case of a government organization, would be prepared to provide the country with improved navigation free of charge, in exchange for the privilege of developing the water power, and here you have a completed deep waterway project without any further cost to the federal treasury.

It is, nevertheless, interesting to ponder for a minute and ask oneself who is going to assume the function of the federal treasury, because, after all is said, this improved navigation, whose cost is estimated at from $86,000,000 to $90,000,000, must be paid for by somebody. The canals cannot provide any revenue, as they are free. The only source from which these producers or private interests could derive revenue would be the sale of power. Consequently, it is self-evident that the cost of navigation, which would be added to the normal cost of their power development, would be paid by the consumer of electric current. This mode of procedure would be extremely unfair to the province of Quebec which would be called upon to pay in final analysis the cost of an improved navigation that is designed to benefit and is demanded by interests outside the limits of the province.

This proposal is embodied in the report of the National Advisory Committee. It is stated in this report:—

> "We believe that if a reasonable time were permitted in which to enable the resultant power to be economically absorbed, the development of this national section would be undertaken by private agencies able and willing to finance the entire work, including the necessary canalization, in return for the right to develop the power."

Messrs. Beaudry Leman, A.M.E.I.C., and the Hon. Adelard Turgeon declined to assent to such a proposal, and it is to be hoped that the federal government will not entertain it.

What we require in the province of Quebec is cheap power that will bring large industries in our midst and keep our population at home. The system that is proposed is not designed to give us this result.

The following is the meaning of this proposal in figures:—The cost of the works for deep navigation in the Canadian section is estimated at $86,000,000. About 3,000,000 h.p. can be developed at Soulanges and Lachine at a

(2) See paragraph 139, Appendix "B."

cost of $296,000,000. Now, then, the fixed charges on this capital expenditure of $86,000,000 will amount to at least $7,000,000. Spread over 3,000,000 h.p. it means that there must be added $2.50 per h.p. to the sale price of the power. This is the minimum increase. But 3,000,000 h.p. can only be fully marketed after a long period of years. It is very likely that improved navigation will have to be provided before the 3,000,000 h.p. can be marketed. It is even possible that the additional charge will have to be spread over one million h.p. In that case $7.00 per h.p. would have to be added to the normal selling price in order to cover the costs of navigation. Such a principle will never find acceptance in Ontario, and it is to be hoped that Quebec will not lend it support.

Conclusion

(1) The St. Lawrence can be improved for navigation alone at a cost of $167,000,000 between lake Ontario and Montreal, and at a cost of $44,000,000 in the Great Lakes section, for navigation at 25 feet. This is the deep waterway project proper.

(2) The St. Lawrence can be improved for power alone by retaining the present canals, at a cost of about $533,000,000,—whether there be canalization or not, this water power will be developed some day.

The two proposals are distinct.

(3) It is essential that a uniform flow be maintained down the river and every development scheme must be made to provide for the maintenance of this uniformity.

(4) We must scrutinize the plans which may be proposed with respect to the development of the international section of the river, as well as the plans which may be proposed in regard to the control of the flow from the Great Lakes.

(5) The cost of canalization must be separated from that incidental to the hydro-electric development,—improved navigation should be paid by the country at large, and not by the consumers of power.

Arc Welded Structures

Progress in the Art of Arc Welding and its Application to Structural Engineering

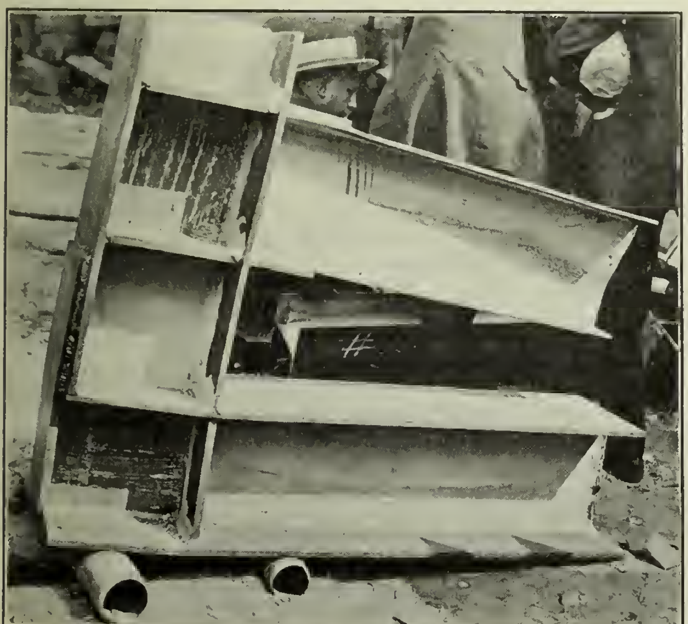
Gilbert D. Fish,
Consulting Structural Engineer, Westinghouse Electric and Manufacturing Company, New York

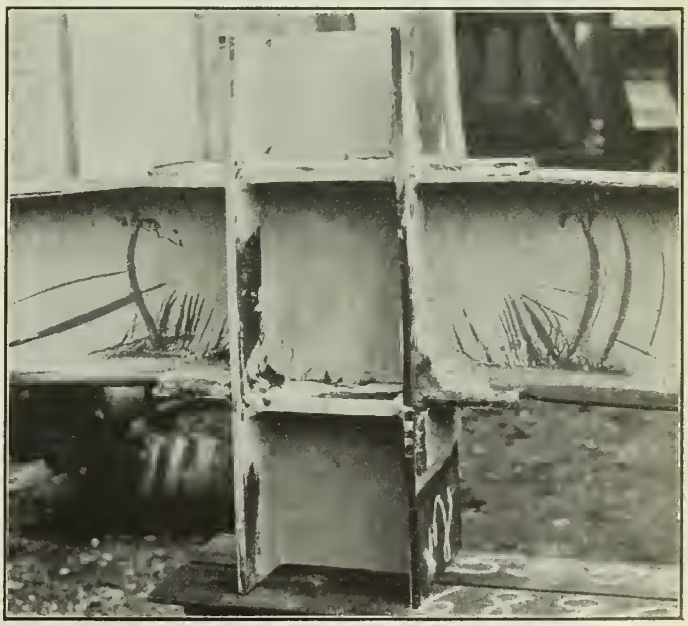
Paper presented before the Montreal Branch of The Engineering Institute of Canada, October 6th, 1927

The integrity of arc welded connections correctly designed and executed under proper control has been established. Wherever structural steel parts are to be joined permanently together, the electric arc process is suitable for the purpose.

The analysis of welded joints, although still in the research stage, is inherently more definite than that of riveted or bolted ones, because of the continuity of metal through the junctions. We know enough about the properties of welded joints at this time to design and detail welded structures economically according to definite standards, and the testing and research now in progress are enabling us from month to month to refine our designing methods and reduce excessive safety factors.

Welded joints will prove more permanent under severe conditions of moving loads and stress reversals than riveted ones, owing to their immovability. Doubt is frequently expressed as to the fatigue and shock resistance of weld





Figures Nos. 1 and 2.—Welded Cantilever Joint Used in Test at Carnegie Institute of Technology in Pittsburgh.

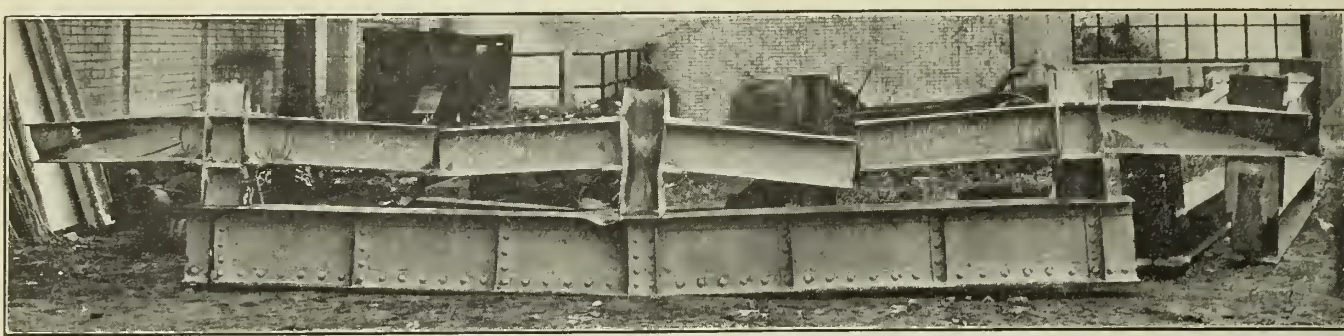


Figure No. 3.—Result of Test of a Riveted Girder.

metal, laboratory tests having shown that the cast steel forming a weld is somewhat inferior to rolled steel in respect to these factors. What counts is that the properly designed welded joint, in which no part suffers strains beyond the elastic limit, has a joint resistance to impact and fatigue far superior to the non-continuous riveted joint in which rivets are stretched and connection angles twisted by sudden and frequently repeated deflections of one or more of the connected members.

Continuity or fixedness of welded joints brings into use the elastic, or " rigid " frame, with its economy of material, elimination of play at joints, minimum deflection and vibration, and reduced cracking of fireproofing material and plaster if used. The elaboration of design calculations for the elastic frame places an extra burden on the designing engineer, but the elimination of rivet holes greatly reduces the work of the detailer and steel shop draughtsman.

The change from riveted to welded construction, now in its early stages but taking place at increasing speed, calls for changes in the instruction of professional engineering students and for study on the part of practising engineers. There is need for a text book covering welded construction in its present state, and steps are being taken to meet this need.

The reasons for preferring welding to riveting in structural work are its comparative economy, its availability for some purposes not served by riveting, its properties whereby the bending and tensile strength of the members joined may be fully developed, its reduction of dead weight and bulk of steel required, and its silence.

Figure No. 4.—Result of Test of Welded Plate Girder (with Plates and Angles).

The Westinghouse tests at the Carnegie Institute of Technology in Pittsburgh in July 1926 proved that arc welded structural joints could be made stronger than any possible riveted joints. Figures Nos. 1 and 2 show cantilever joints which developed the ultimate bending resistance of the cantilever arms, a performance not to be matched by riveted joints regardless of number, size or arrangement of rivets and connecting parts.

These and similar tests paved the way for the first use of fully continuous beams and girders in steel building construction, which occurred in the Sharon building. This statement is made with due respect to the prior use of cantilever beam construction in riveted buildings and the familiar continuous plate girder of turn-tables and deck bridges.

Figures Nos. 3 to 5 show results of testing a riveted plate girder, a welded plate girder made of duplicate parts, and a welded girder of the same depth made of plates only. The welded girder made of plates and angles developed 9 per cent greater ultimate resistance under concentrated centre load than the riveted girder, due probably to the welds connecting the flange angles directly to each other at their heels. The girder made of plates only weighed the same as the riveted girder but developed 55 per cent greater ultimate resistance due to its greater section modulus and its stiffer compression flange.

Figure No. 6 shows the Sharon building of the Westinghouse Company. Figures Nos. 7 and 8 are views of the massive plate girders carrying five tiers of that building across the 45-foot crane runway. Figure No. 9 illustrates a typical interior column joint, with two 15-inch beams and two 20-inch girders fixed by welding to the column so that full continuity is developed in both directions; absence of continuity as in riveted construction would have necessitated 18-inch instead of 15-inch beams and 24-inch instead of 20-inch girders. Welded construction saved 100 tons of steel in this 800-ton structure.

Figure No. 10 is a view of the welded building at Derry, Pa., which was constructed of 135 tons of fabricated steel and 200 tons of plain material shipped directly from mill to job. The purlins were made fully continuous by the welding, but the rafters could not be made continuous because they were at different elevations. The welded design required 10 per cent less steel than the riveted design on which comparative bids were taken, and the cost to the owner was approximately 10 per cent less than the bid of the same contractor on the riveted design.

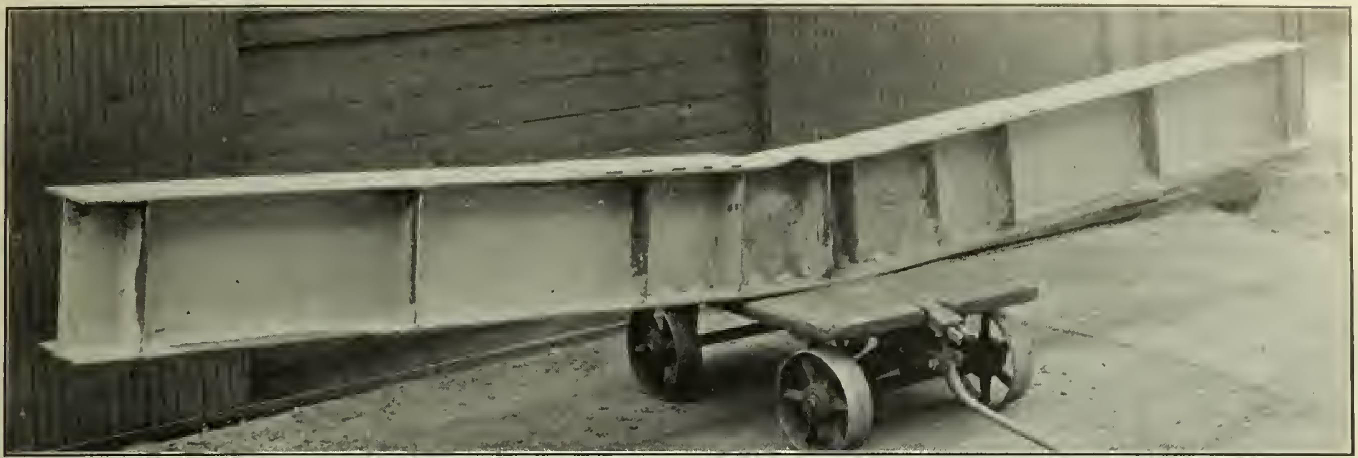

Figure No. 5.—Result of Test of Welded Girder (with Plates only.)

Arc Welding in Railroad Work

The principal uses for arc welding in railroad work are:—

(1) Miscellaneous shop work on locomotives and cars, especially repairs and building up worn parts such as wheels.

(2) Maintenance of way, particularly building up worn frogs and switch rails.

(3) Construction of miscellaneous steel structures such as signal bridges, switch towers, catenary supporting bridges on electric lines, transmission towers, water towers and tanks.

(4) Construction of buildings such as machine shops, tool houses, train sheds and stations.

(5) Constructing steel bridges, trestles, viaducts and turntables.

(6) Reconstruction and reinforcement of bridges to carry increased train loads or to restore original strength after deterioration.

(7) Construction of locomotives and cars.

Arc welding for repair purposes has been going on in railroad shops for some years. It is the author's belief that all railroads have arc welding equipment, and its use for building up worn wheels, repairing cracked cylinders and fireboxes, fastening boiler tubes to tube sheets, and repairing broken parts of locomotives and shop machinery is too well established to require detailed discussion here. The use of arc welding in locomotive boiler construction is being developed. Many welded tanks are in use by railroads.

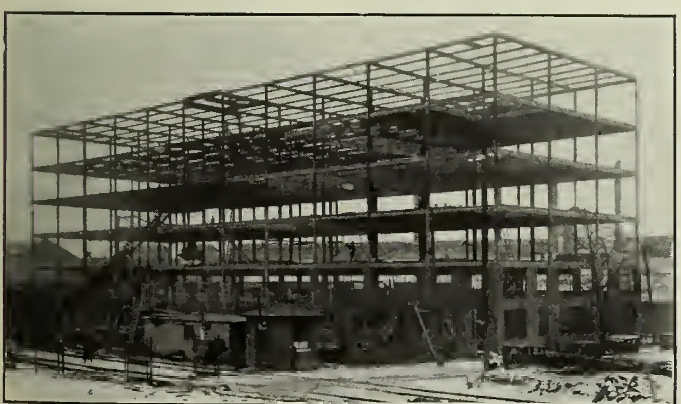

Figure No. 6.—Sharon Building of the Westinghouse Company.

Extensive use of the arc is being made for building up manganese steel frogs in railroad yards. The joining of rails by welding is very common where track is embedded in concrete or pavement, and the arc method is generally employed for this purpose. The C. B. & Q. Railroad has built half a dozen small arc welded buildings; as welded buildings have already been discussed sufficiently for the purposes of this paper, further reference to them will not be made except to point out that railroads are suitably organized to construct welded buildings of unfabricated steel, using their own labour and sometimes drawing on the steel scrap pile.

Light steel structures such as signal bridges and towers are an attractive field for welding. Many parts of such frames, when designed for riveting, are made of angles with legs 2½ inches wide to take ¾-inch rivets and ⅜-inch thick to withstand weathering, where angles of the same

Figure No. 7.—View of the Plate Girders of the Sharon Building.

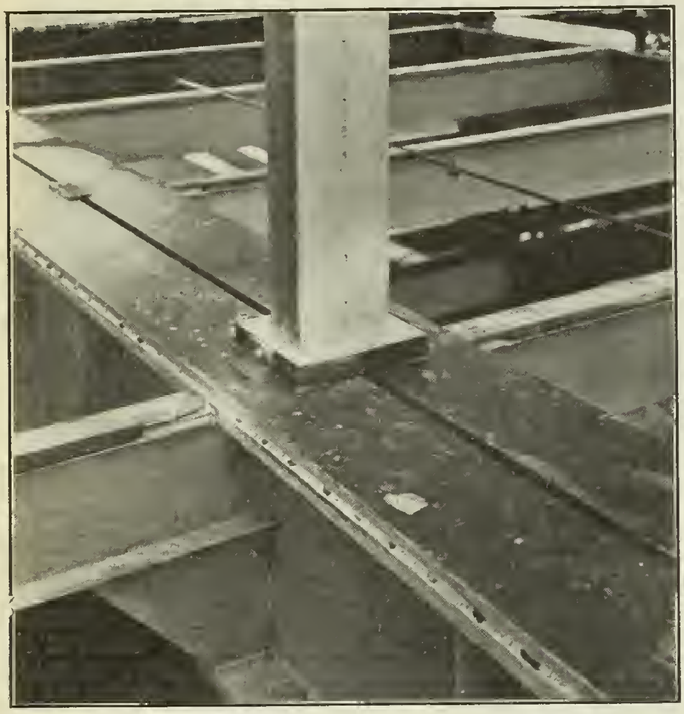

Figure No. 8.—Welded Plate Girders of the Sharon Building.

thickness but with narrower legs or narrow bars ⅜-inch thick would serve the purpose if welded.

Again, the tension value of a small angle or lattice bar connected by rivets in one leg only is very small in relation to its weight, and welded connections for such members save a large percentage of weight. Further, the fabrication cost is relatively high in these light frames when riveted, whereas such structures if welded can be built on the floor of a shop with the use of jigs and entirely without punching.

The author has recently designed for welding a four-track signal bridge which required 25,000 pounds of steel according to the railroad standard for riveted construction; the design for welding required less than 10,000 pounds, although standard working stresses were figured and the ⅜-inch minimum thickness rule was observed; part of the difference was due to many parts of the riveted design being unnecessarily heavy in order to match corresponding parts of the eight-track bridge, but most of the saving in the welded design was due to the economy of material inherent in welded design. Struts and braces carrying slight loads can often be made lighter when connected by welding, because of the superior fixation of the ends. Main compression members of bents and trusses may be reduced by subdividing panels with cross braces welded in place; this procedure being economical in many cases where it would not pay to introduce extra fabricated pieces. Gussets are almost entirely eliminated from truss and bent construction in this class of work. Avoidance of gussets and reduction in cross-section of members reduce both dead load and wind load stresses and in the case of overhead structures on railroads have the additional advantage of improving visibility. Cost of maintenance is somewhat reduced due to saving in the painting item, the surface of metal being less and the absence of rivet heads lowering the labour cost of brush painting and doing away with the points of worst corrosion.

The Pullman Company has effected savings of 50 per cent in cost of electric transmission towers by substituting arc welding for riveting. The Mississippi Valley Structural Steel Company is manufacturing roof trusses by arc welding on the floor of one of its shops and reports cost savings. Within the last month the author has brought together an oil company and a steel shop on a project for shop manufacture of standardized small buildings for erection at scattered points, the building frame to be shop welded in panels and bolted together in the field.

The Westinghouse Company is welding all frames and bases for its transformers built at the Sharon works, and the savings realized at that plant due to replacement of riveting are estimated at $20,000 a month, with further economies in view due to improved designs and extension of automatic welding. Generally, in light steel construction with considerable repetition of pattern, where most of the work can be done in the shop with the aid of jigs, the replacement of riveting by welding can be made to save about half the cost of riveted construction, with increased stiffness of the structures and without any disadvantages.

Reconstruction of Railway Bridges

The most interesting application of arc welding in railroad work are the construction and reconstruction of bridges and viaducts. Few bridges built during the last century were designed for such heavy loads as they now carry; furthermore, most bridges become weakened by corrosion. At present, nearly all railroad bridges except those built within the last few years are overloaded, in many cases 50 per cent beyond standard specifications for new bridges. The more serious cases cannot be remedied by riveted reinforcement, because the cost of such operations would exceed the cost of new bridges and because major alterations would close the bridges to traffic. Less serious cases may be reinforced by riveting, usually at very high expense and rarely without impeding traffic.

Even minor reinforcements usually weaken some of the members temporarily and require interruptions of traffic or reduced speed of trains. On multi-track bridges the floor systems may be reinforced by introducing additional

Figure No. 9.—A Typical Interior Column Joint of the Sharon Building.

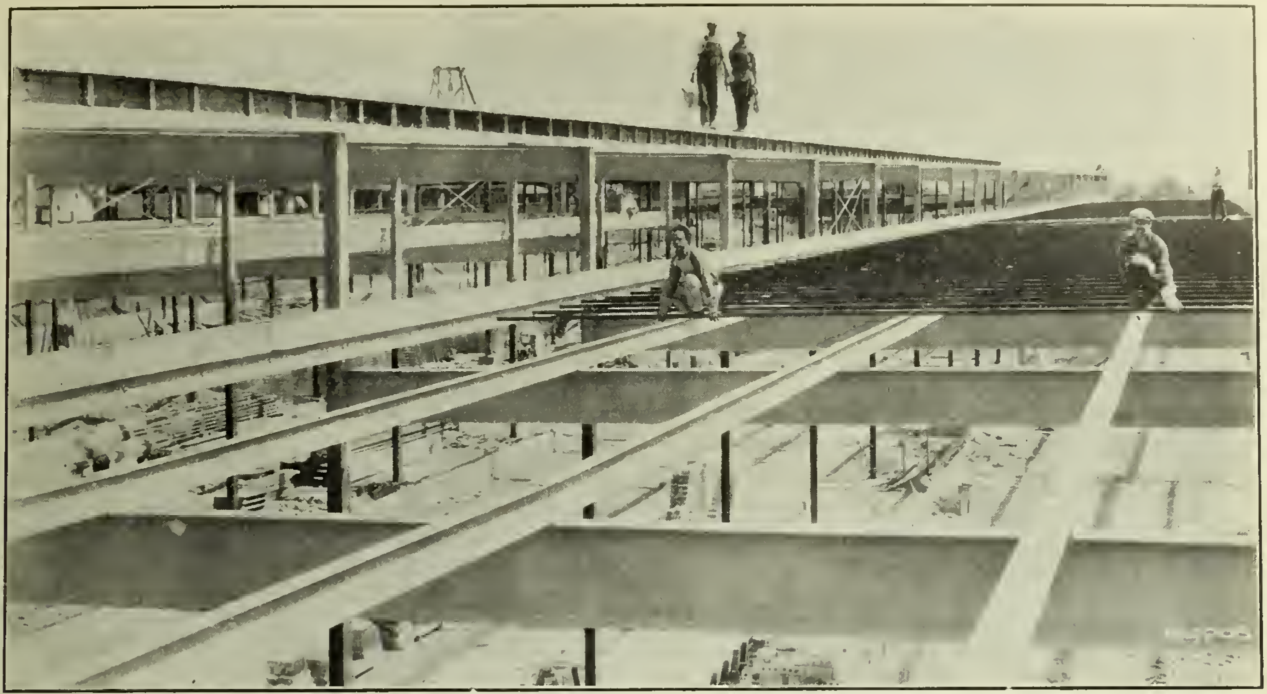

Figure No. 10.—Welded Steel-work of Building at Derry, Pa.

stringers and by riveting extra cover plates to the floor beams, one track at a time being closed to traffic. Where flange angles are badly corroded or cracked, they cannot be restored by riveted reinforcement but must be replaced.

The situation as described to the author by a number of railroad bridge engineers is a serious economic problem for the railroad companies, which are faced with the necessity to replace a majority of their bridges within a limited number of years unless they turn to welding as a means of reinforcing the old structures.

The American Bridge Company recently completed extensive arc welded reinforcement of the Great Western bridge across the Missouri river at Leavenworth. This operation, which saved a large part of the expense which would have been involved according to the original plans, was the first application of arc welding for major alteration of a railroad bridge, at least in this country. Several months earlier the Neeld Construction Company of Pittsburgh reinforced and double-decked the long highway bridge over the Susquehanna river at Havre de Grace, using arc welding exclusively for field connections.

New Bridge Construction

For new bridge construction, welding permits great economy of material for several reasons. Stringers are made continuous, with consequent saving averaging about 20 per cent in weight of stringers. Flexural members other than rolled beams, whether acting as stringers, floor beams, top lateral cross-beams, or main girders in plate girder spans, require less material if designed for welded assembly than otherwise, because the best type of welded plate girder uses plate material only and has a greater section modulus than a plate and angle girder of the same weight and depth.

Tension members of trusses are designed without deductions for rivet holes, such deductions in riveted designs frequently amounting to 15 per cent. The small amount of labour required to weld in place a light brace provides opportunity to reduce the unsupported lengths of long compression members and therefore to reduce their weights. The largest item of material saving is the elimination of most of the connection material, which amounts to 30 per cent of the total weight of steel in many riveted bridges. The lightness of the welded bridge means smaller dead load stresses than for the riveted one, and this is in itself an additional basis for weight saving.

Figure No. 11 shows a welded bridge designed to carry a spur of the Boston and Maine Railroad across a canal into the plant of the Westinghouse Electric and Manufacturing Co., at Chicopee Falls, Mass. The design has been

Figure No. 11.—A Welded Bridge Designed to Carry a Spur of the Boston and Maine Railroad across a Canal into the Plant of the Westinghouse Company, at Chicopee Falls, Mass.

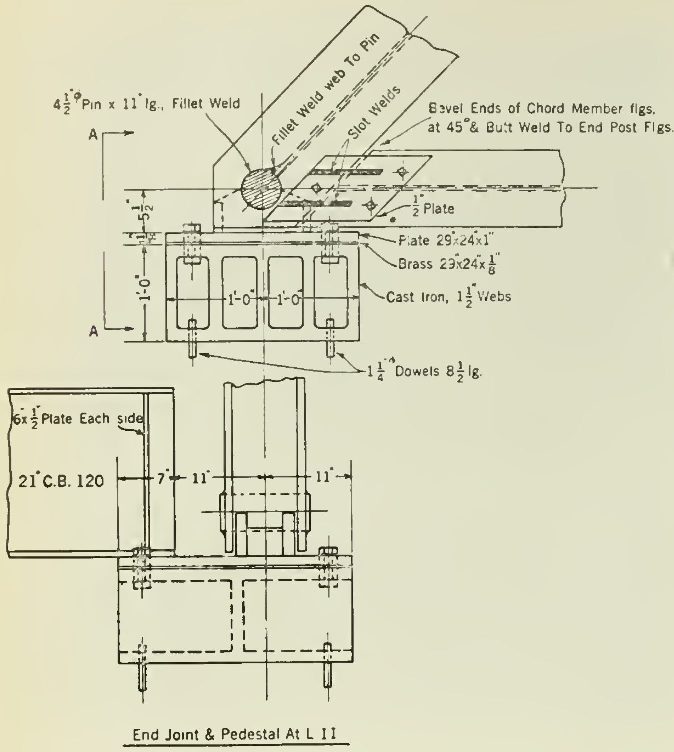

Figure No. 12.—Detail of End Joint and Pedestal of Welded Bridge at Chicopee Falls.

approved by the railroad and proposals for construction are expected this week. This is a single track through span with extreme skew, each truss being 135 feet long. The live loading is Cooper's E-50.

The bridge was first designed for riveting, with Cooper's E-60 loading, this design requiring 140 tons of steel. For E-50, the riveted design would require about 120 tons. The welded design calls for 80 tons, saving one-third in material. The weight saving is due to omitting most of the connection material, utilizing gross section of tension members, 30 per cent reduction of dead load stresses, use of extra brace members to reduce length ratios of compression members, and continuity of stringers. The centre line dimensions were made the same as for the riveted design, but rolled sections of the H-column type have been substituted for built up sections throughout.

It is believed that this is the first welded railroad bridge. Details of the design may therefore be interesting to structural engineers and steel men. Figure No. 12 shows an end joint detail. A 4½-inch pin is set in a hole drilled through the end post H-section and welded in place; both flanges and the web bear on the pin. The pin pedestal is made of two 1½-inch plates having semi-circular notches to carry the full vertical truss reaction transmitted by the pin, with two 1-inch plates welded between the pin plates

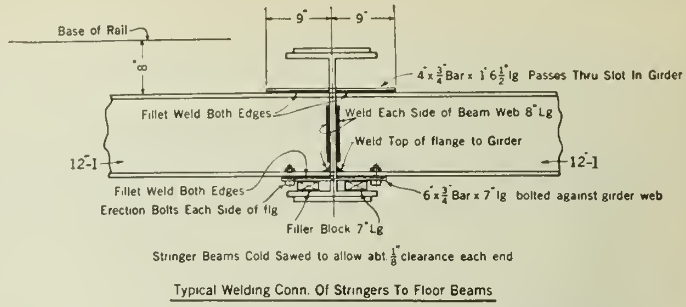

Figure No. 13.—Plan of Typical Stringer-to-Floor-Beam Connection for Chicopee Falls Bridge.

to brace them. All four plates are welded to the 1-inch sole plates.

The sole plates have slotted holes where the anchors go through, and ⅛-inch brass is used between sole plate and cast iron pedestal to permit sliding with temperature change. The pedestal, which is partly embedded in concrete abutment, is made of cast iron to resist rust, the top of the abutment being only a few inches above the water line. The bottom chord tension is developed mainly by butt welding the chord flanges to the flanges of the end post; the ends of the chord flanges are bevelled 45 degrees to facilitate butt welding. The additional tension carried by the web of the chord member is transferred across the joint by the strap plates; these are welded not only along the horizontal edges but also through the slots, which are ½ inch square in section. These plates are bolted to the members for erection purposes.

Figure No. 13 shows a typical stringer-to-floor-beam connection. The continuity is developed by a tension plate passing through a slot in the beam web and welded along its edges to the top flanges of the stringers, and by butt plates below which also serve as erection seats. The web weld is for vertical reaction. If full continuity were not developed it would be unsafe to carry the end reaction by means of a weld between the stringer web and the supporting beam, because the deflection of the stringer under live load would be likely to crack the weld. A safer procedure, in any case where it might be impracticable to develop continuity, would be to use side framing angles with welds at the outer edges, thus providing a flexible element which would accommodate the stringer deflection by yielding slightly in torsion at each application of live load. In riveted work the upper rivets connecting framing angles to supporting beam usually stretch, thus relieving considerably the torsional fatigue in the angles but throwing most of the load upon the lower rivets.

The steady replacement of the rivet by electric arc welding is a great economic movement which cannot be checked by skepticism as to the dependability of the process. The results can be definitely controlled, and failures are as definitely preventable as they are in other engineering operations.

Recent Developments in the Combustion of Fuels

A General Summary of Present Methods of Combustion with Particular Reference to Western Canadian Coals

J. G. Hall, A.M.E.I.C.
Sales Engineer, Combustion Engineering Corporation, Limited, Montreal.

Paper read before the Winnipeg and Lethbridge Branches of The Engineering Institute of Canada, October 27th and October 29th, 1927, respectively.

The question may well be asked by those who have been studying the stock market this last year, "Why is it so important to develop combustion methods, is not hydro-electric power much cheaper?" It is true that during the last twenty-five or thirty years there has been a rapid increase in the use of hydro-electric power, but unfortunately our cheap water power sites are not unlimited. There are, no doubt, many places where owing to natural advantages the actual construction costs of storages and power plants are low, but the cost of getting the power to the customer is in many cases prohibitive. The result is that while the average cost of hydro-power is steadily climbing the cost of coal-power is steadily decreasing, so that in a few years, except in a few fortunate localities, we must look to fuels as the source of electric energy.

According to a statement recently made public by a geological survey of the United States Department of Interior at Washington, the total electric energy produced by public utility plants in the United States in 1926 was 73,791,000,000 kw. hrs., of this 47.5 billion kw. hrs., or 64.5 per cent, was generated by the use of fuels and the rest by water power. Of the 47.5 billion, 90 per cent was obtained from coal and 10 per cent from oil, gas or wood. The average rates of consumption were as follows:—

Coal..................1.94 lbs. per kw. hr.
Oil.....................243 kw. hr. per barrel
Gas...................22 cu. ft. per kw. hr.

while the best fuel rates were:—

Coal...................0.9 lbs. per kw. hr.
Oil.....................450 kw. hr. per barrel
Gas...................13 cu. ft. per kw. hr.

As these latter are roughly one-half the average rates, the consumption of fuel by electric public utility power plants would have been reduced one-half if all electricity had been produced at the best fuel rates and this would have conserved more than twenty million tons of coal in the year, representing a value of approximately $75,000,000.

These figures do not take into consideration the industrial boiler plants where at least a similar saving is possible. Also for every plant burning 500 tons per day there are hundreds of small plants burning from 5 to 20 tons per day. It must not be forgotten, however, that dollar efficiency and not fuel efficiency is the most important factor, and in a great many of the smaller plants it requires careful investigation to show that large expenditures will pay dividends. In making improvements to boiler room equipment considerable saving in labour can sometimes be shown as well as fuel savings, while in other cases labour is already down to a minimum, so that fuel savings only can be taken into consideration.

Some people claim that owing to the fuel reserves being limited, they should be conserved at all costs, while others more interested in the fuel industry are more concerned, say, in coal production at the present time than they are in the necessities of future generations. It is probably true that both these schools of thought are somewhat radical and the general belief is that although waste is regrettable at any time, yet no industry can prosper unless it can show dividends for every dollar expended.

In general there are three methods of firing coal:—(1), hand-firing; (2), automatic stokers; (3), pulverized fuel.

It is only recently that much serious thought has been given to the improvement of hand-firing methods. This type of firing applies to houses, apartment and business blocks, and small industrial plants. Too often the average householder would rather pay $25.00 or thereabouts more per winter than bother about improving his conditions. Also in the smaller industrial plant the executive, in trying to keep down expenses, will not pay the necessary salaries to get competent men. The boiler plant is considered a dirty, messy place, a good place to stay away from, and all the thought he gives to it is when he growls at the monthly coal bill. His men soon get to know this and, not having any incentive to do better, become as lax as their employer.

Another trouble is with the building designers, who forget all about the boiler room until the last minute and then put it down in some corner which is no good for anything else, and too often no good for boilers either. These conditions, of course, do not always apply, but it should be remembered that in any concern, especially in this locality, the boiler room is one of the most, if not the most, important parts of the industry, because no other department can function until it does.

In spite of all these drawbacks, however, big improvements have been made. H.R.T. boilers are being set higher, with furnaces big enough to burn the gases before they reach the relatively cool drums. Some engineers still cling to the old idea of using triangular piers, half way between the bridge wall and the rear wall, to mix the gases still further. Before furnace volumes became adequate this method was very effective, but with modern settings an attempt is made to complete combustion before the gases pass the bridge wall, and in this way eliminate the costly settings made necessary by the almost blow torch action of the piers.

Another big improvement is the use of forced air with proper means of regulation and boiler room instruments, such as CO_2 meters, draught gauges, flow meters, etc. The firemen thus given some encouragement are taking more interest in their work, the effect being as much psychological as anything else. The use of forced draught under proper control means not only higher efficiency, the ability to burn a greater variety of coals and higher combustion rates, but also in some cases it means a considerable reduction in banking losses. In a number of cities in the United States this is found to be true in connection with heating of school buildings. Being able to get up steam in a much shorter time means a saving of several hours of labour after the building has been closed for any period.

These conditions do not always hold true, and it is therefore very difficult to make a general statement as to the particular type of equipment to be used. Each case must be figured out on its own merits, bearing in mind all conditions, including coals available, their cost, particular load conditions, etc.

The question is often asked regarding the advisability of sprinkling coal or using steam jets to aid combustion. From a purely thermal standpoint this means a direct loss, but other factors come into play which in some cases result in a net gain. The most reasonable explanation of this seems to be that the moisture or steam, meeting the excessive temperatures of the fuel bed, is broken up into its original constituents of hydrogen and oxygen and this nascent oxygen seems to be much more efficient in combining with carbon than ordinary air. If this explanation is true it would appear that it would be very effective with coal of ordinary moisture, but it does not seem reasonable to add water to lignites which already contain from 15 to 35 per cent water.

Stokers

Due to natural improvement in design and also the severe competition of pulverized fuel, the tendency has been towards higher ratings and increased efficiencies. This has resulted in compulsory changes in furnace as well as stoker design. Several new stokers for small boilers have been introduced and those already well known have been changed as a result of more experience, and also to meet local conditions.

In the case of the underfeed multiple retort type, in order to reduce the combustible loss in the ash pit, clinker grinders are becoming standard equipment for large installations where high ratings are required. By this means a larger effective grate area can be secured, thus increasing the boiler rating for a given combustion rate and coal. For any given coal each stoker has its own maximum efficient combustion rate, i.e., the number of pounds of coal which can be burned per square foot of grate area per hour to give the maximum efficiency.

High combustion rates and high efficiencies mean higher furnace temperature, and it is this furnace temperature which has complicated matters. Stoker parts must be well protected and provision made to prevent slag formation at the sides where the walls and stoker meet. This is true with both underfeed as well as chain grate stokers. Carborundum bricks and hollow blocks seem to be overcoming this difficulty to a large extent although some companies still report high maintenance. The biggest difficulty seems to be along the side walls, due to the necessity of removing clinkers. Carborundum is extremely hard and somewhat brittle so that a sudden jar such as is sometimes necessary to remove clinker will crack the blocks. Resetting is required at irregular intervals, varying from three months to two years, depending on the coals used and ratings developed.

With chain grate stokers we have an added complication due to the necessity of arches. Very extensive study has been given to this phase of stoker work and important developments have taken place. This is especially true with regard to the burning of anthracite fines, coke breeze and high moisture lignites. Arches are necessary not only to obtain quick ignition but also to maintain ignition and assist in eliminating the stratification of gases. Owing to combustion taking place in several successive stages this stratification becomes a serious menace to high efficiency unless great care is taken. The percentage of CO_2, CO, and O_2, varies quite considerably over the length of the grate and the various gases attempt, if possible, to find their way up through the boiler passes without mixing. Designers use one arch, two arches and sometimes three arches to effect proper mixture and reduce the combustible loss in the ash pit. In some cases, also, a steam or air jet is used through the front arch causing turbulence at the furnace throat, although this is not in very general use.

Although attempts are usually made to obtain a balanced draught or a small negative pressure in the furnace it is sometimes found necessary, especially with coke breeze, to maintain a slight positive pressure. This plays havoc not only with the arches and furnace walls, but also with any parts of the stoker exposed in the furnace. This means that unless the stoker is very well designed and constructed, maintenance costs are very high.

Air Preheater and Water Walls

Two other developments which have influenced stoker work are airheaters and water walls, and it is very difficult to treat these two entirely separately, as the use of the one has a more or less distinct bearing on the other.

Due to the changes in turbine design, including back pressure and bleeder types, also the gradual changes in power plant heat balance, it is often found inadvisable to use water economizers. This brings up the question of utilizing the heat in the chimney gases, because, although the percentage of excess air can be greatly reduced by increasing the CO_2 content, there is still an appreciable flue gas loss. The air preheater was the natural outcome of this situation.

As a result of tests made with air preheaters and Westinghouse multiple retort stokers at Colfax station by Mr. G. W. E. Clark, the following notes were made:—

(1) The fuel bed was much more uniform with preheated air and no holes or disturbances of any kind appeared to break up the uniformity of operation.

(2) The fuel ignited more readily.

(3) The fuel bed burned much more uniformly throughout its depth.

(4) There was less combustible ejected from the underfeed section to the clinker grinder pit.

(5) Less carbon was contained in the refuse discharge into the ash pit.

(6) The refuse in the clinker grinder pit ground out with less trouble, due to the character of the clinker.

(7) No clinker trouble of a serious nature was encountered at any time. The clinker itself was harder and more easily handled.

The three main types of airheaters are the rotary, tubular, and plate. In the rotary type the transfer of heat is obtained by passing the hot flue gases and the air alternately through portions of the equipment. The tubular type is similar to the standard water economizer, except that the heat is transferred to air instead of water. In the plate type the gas and air passages are separated by thin plates which are either bolted or welded together, care being taken to direct the flow of gas and air so as to obtain the greatest transfer of heat and the minimum draught loss.

Advantages are claimed for each type by the various manufacturers but it is not within the scope of this paper to comment on them. Suffice it to say that there are, no doubt, facts to bear out the various statements made and the purchaser should study the claims made very carefully before deciding on the type best suited for his particular conditions.

It is, however, of decided interest to note the effects of preheated air on stokers and furnaces. When the air necessary for combustion is admitted either through the fuel bed or over the fire at a temperature from 200 to 400 degrees in excess of ordinary boiler room temperatures an entirely different set of conditions is encountered. Clearances must be changed to take care of greater expansion. Air passages must be revised owing to the decreased density of the air and provision made to prevent burning out of the stoker parts.

Unfortunately the important moving parts of the stoker are inside the furnace and should anything happen to them it means shutting down the unit, in most cases, to make repairs. Again, preheated air usually means more rapid combustion and therefore higher temperatures. The limits of firebrick and tile are fairly definite and when these are approached troubles begin. Increased slagging on the side walls and on other portions of the furnace are a serious menace to the engineer's peace of mind, and although some companies report the use of air preheated to a temperature of nearly 500 degrees without excessive maintenance this does not seem to be general.

Air cooled arches and furnace walls were tried and this method is still being used with great success up to a certain point of boiler rating and efficiency. A great many engineers realized, however, that this was only a temporary breathing spell in overcoming the trouble, and this brings us to the water or steam cooled walls.

Steam cooled walls are simply radiant heat superheaters placed in the furnace walls with some sort of protection from the direct rays of the flame. It must not be forgotten that the specific heat of steam is approximately one-half that of water, so that there is a grave danger that the steam in the tubes cannot carry away sufficient heat to prevent them from burning.

Generally speaking water walls are composed of vertical tubes placed in the furnace walls and connected into the main boiler circulation. These tubes are also protected to prevent burning and many ingenious devices are used. One method is to shrink pre-cast iron blocks on the tubes, the idea being that the cast iron will absorb the radiant heat and conduct it through the metal to the water. Another method is to surround the tubes with firebrick tile, the advantage claimed being sufficient refractory properties to aid combustion at low ratings. A third type is known as the bifurcated water wall. In this type two tubes are welded together at each end so as to have a common connection to the header. A fourth type is known as the fin tube wall, which consists of tubes with a steel fin electrically welded on each side and diametrically opposite each other. These fins, which are ¼-inch thick and 1 7/16-inch wide, extend the whole length of that part of the tube which is exposed to the heat of the furnace. The tubes are spaced on 7-inch centers and form a continuous water cooled metal surface.

In all cases the tubes are bent out through the furnace wall at the top and bottom and expanded into headers which are connected to the boiler drums by suitable circulating tubes. Great care has been taken in the design of the headers and in the provision of necessary fittings so that this part of the heating surface may be as accessible and as easy to keep clean as the boiler itself.

A great deal of discussion has taken place with regard to the credit for increased steaming capacity which should be given to water-cooled furnace walls. When dealing with this aspect of the question it must be remembered that the steaming capacity of a boiler depends not so much on the amount of heating surface as on the amount of heat generated efficiently in the furnace. Provided that a boiler is properly designed and the tubes kept clean, both inside and outside, its capacity to deliver steam is unlimited within ordinary ranges as long as the proper amount of heat is applied. It is true that at high ratings the exit flue gas temperatures will be higher, but this can be taken care of with either water or air economizers.

The main advantages of water-cooled walls in connection with stoker firing are,—first, they eliminate furnace wall maintenance so that combustion is not limited in this respect; second, they relieve the boiler proper of a great deal of its work, so that draught loss and exit temperatures should be lower.

Pulverized Coal

The idea of burning coal in a pulverized form is not new, but it is only within the last ten, or possibly fifteen, years that it has been developed to any extent in stationary plant work. Previous to that time it had been used in the cement and steel industry, and although considerable success had been achieved it was realized that the problems were not the same as those which would be encountered in the ordinary power plant. The idea was also applied to locomotive work and there is still quite a number of locomotives equipped in this manner and doing good work in Brazil and also in Japan.

The early history of the development of pulverized fuel in power plants is a very interesting study, but time will not permit any comments at this time except to say that great credit is due to the men who had faith in the principles involved and who, in spite of discouragements and criticism, overcame the difficulties and finally succeeded in bringing about its present high standard of efficiency.

There are two distinct methods of burning coal in a pulverized form, namely, the indirect or storage system and the direct or unit system. In the first the coal is pulverized in ball or roller mills and stored in bins convenient to the furnace. From there it is fed through proper mixing chambers where it is mixed with from 10 to 20 per cent of the necessary air for combustion, thence to the burners and into the furnace.

The main advantages of this system are,—first, owing to the type of mill used, power consumption and maintenance costs are lower and, generally speaking, a more uniform fineness is obtained; second, the pulverizing can be done during off-peak periods and, if advisable, at some considerable distance from the boiler room; third, owing to the positive control of the feed and air regulation, a better mixing of the air and coal is possible so that in spite of fluctuating loads a very flat efficiency curve is possible. The big disadvantage is increased first cost.

With the direct system each boiler is a unit in itself. The coal is pulverized in a ball, tube or hammer mill placed directly in front of the boiler. In most cases the primary air, or about 20 per cent of the total air required, goes through the mill with the coal and the mixture blown directly through the burners into the furnace. Some companies admit as high as 90 per cent of the total air into the mill, but this method does not seem to be in very general use.

The disadvantage is a slightly lower overall efficiency and the need of more careful operation with fluctuating loads and changes in size, moisture content and types of coal. The reason for the lower efficiency is that the output from the mill will vary, due to a change in the size of coal, moisture content, or a slight variation in the feed, which means that the mixture of air and coal for maximum efficiency is difficult to maintain. This same variation will be caused by fluctuating boiler ratings.

Designers, realizing the advantages of the two methods, are now endeavouring to work out a simplified storage system with all the advantages and none of the disadvantages of both. The idea is to use, say, for instance, a roller mill and cyclone separator for each unit discharging the pulverized coal into a small bin in front of the boiler, from which a positive feed of air and coal under proper control is admitted to the furnace, and in this way it is hoped to reduce the cost of the storage system without any sacrifice in efficiency.

Burners

Burners are of two types, namely, vertical and horizontal. There is also the inclined type of burner, but it is really a modification of the vertical.

With the vertical type of firing the coal and primary air are fed through an arch into the top of the furnace. Ignition takes place a short distance from the burner tip and the flame sweeps down within a short distance from the bottom of the furnace where it turns upwards and through the boiler passes. Secondary air is admitted through openings in the furnace front and meets the downcoming stream of coal. The result is a long slow burning flame requiring a larger furnace but one which takes full advantage of radiant heat transfer.

With horizontal firing the coal and primary air meet the secondary air either in the burner or at the burner tip. The burner is constructed so as to give a turbulent motion to the mixture, resulting in much more rapid combustion and therefore smaller furnaces.

With the large public utility plants vertical firing still seems to be the most popular, although even here there is a tendency towards the horizontal type. Most of the industrial plants use the horizontal type with either the storage or unit system. The development of the horizontal burner is probably the result of engineers beginning to realize more fully the importance of intensive mixing. They have come to realize that the rate of combustion is determined by the rapidity with which oxygen and carbon are brought together and not by the speed with which they combine after being brought together. The particles of powdered coal, although small in size when compared with the oxygen molecules, are still very large. A very large number of the oxygen molecules must be brought in contact with the coal particles before the latter are completely burned. The surface area of the particles is rather small, so that only a small number of oxygen molecules can be brought in contact at a time. The products of combustion must be continually removed from the surface in order that contact with fresh oxygen molecules can be made. Intensive mixing helps to do this.

Furnace Design

The early installations used ordinary solid wall brick furnaces, the same as were used for stoker work at that time. The main difficulties encountered were the slagging of the ash and rapid erosion of the firebrick lining. The ash fused and accumulated in a molten condition at the bottom of the furnace and was very difficult to remove, resulting in much hard labour and frequent boiler outage.

The trouble was not so much with the high furnace temperatures but rather that the hot molten ash was sprayed on the refractory walls and ran down in a molten condition, eroding the brick on its path to the bottom of the furnace. This washing away of the brick was particularly rapid if the flames were allowed to impinge on it, and in order to overcome this, furnaces were made much larger than was necessary for good combustion. The advantage of turbulence was recognized but could not be made use of, so that the process of combustion was slow, the heat liberation seldom being more than 25,000 B.t.u. per cubic foot per hour.

The manufacturers of refractories co-operated in an attempt to overcome this trouble, but unfortunately the combustion of coal ash varies so much that it was found difficult to obtain a refractory material that would resist each variation in the ash composition. Hollow furnace walls were then tried and considerable success was attained. These walls are still being used under certain conditions, but as the size of steam generating units became larger and the furnace walls had to be built very high and wide, the designer became faced with the problem of making the walls mechanically strong so that they would not collapse before they were worn out by the erosion of molten ash. Expansion and contraction of such large walls was another difficulty and it was difficult to take care of this weakness.

Water-Cooled Furnaces

The steam or water-cooled furnaces as described earlier in this paper were next developed. At first only the bottom portion of the furnace was water-cooled. This created a cooling zone so that the particles of molten ash were cooled below the fusing temperature before they reached the floor. The ash, although at a very high temperature, does not contain a great amount of heat, so that in most cases a single row of tubes is sufficient for this purpose. Next, portions of the side walls and rear walls were added and as no serious difficulty was encountered it soon became apparent that the right way to build a furnace for burning powdered coal was, if possible, to build the boiler around it. Such metallic walls would be both strong and durable and being exposed to the direct radiant heat of the flame would relieve the boiler proper of much of its work. Particularly would it relieve the tubes in the first row of the excessive heat to which they are exposed in refractory furnaces.

In water-cooled furnaces the rate of heat liberation may be very much higher because the walls will not be damaged by high temperatures or even flame impingement. All the combustion space may be effectively utilized and burners, etc., may be so designed as to make use of intense turbulence of gases, thus resulting in thorough mixing and rapid combustion. As a result of this heat, liberation of 40,000 B.t.u. per cubic foot per hour is quite common, with nearly complete combustion, thus permitting the use of a smaller furnace.

When the water-cooled wall was first introduced it was met by a great deal of criticism from engineers all over the country, but up to the present time at least these criticisms have not been justified by actual experience. In a statement made by the Thomas E. Murray Company of New York, more than eighteen months ago, in connection with their experience with water walls at Hell Gate station, the following was said:—

> "It is necessary for us to clean the bottom tubes of our boilers at least once every three to four weeks, or we would lose tubes very rapidly. On the other hand, the side wall tubes are practically in the same condition today as the day they were installed. We have never had to replace a tube in the side walls and some of these boilers have been running for over two years. We consider that the side walls are very much less subject to trouble due to impure water than the ordinary tubes found in a water-tube boiler."

Another criticism was, that owing to so much heat being absorbed by these walls, the furnace temperature would be reduced to such an extent as to affect combustion seriously, especially at low ratings.

It has been proven, however, that the furnace walls only affect the radiation of a relatively thin envelope of the furnace volume and that the interior of the furnace is affected but little, if any, by wall conditions. When a mixture of coal and primary air is introduced into the furnace it must first be heated up before combustion starts. This heating is done in stages; first, any moisture in the coal must be vaporized. This process is heat absorbing, i.e., either the furnace walls or the burning flame must furnish the heat, and although some of it is furnished by the surrounding walls the greater part comes from the flames of burning coal and gases. Next comes distillation, which starts at about 400°F. when gases and volatile vapors are given off, forming smoke. The smoky gases from the coal contain carbon particles which continue to absorb radiant heat until the mixture reaches ignition temperature, and combustion of the gases begins.

The above will explain why it is that we have so much smoke in lighting up a pulverized fuel installation with a cold furnace. However, once ignition takes place the temperature above that point is of minor importance because it does not affect materially the bringing together of oxygen and carbon.

It is frequently observed that rapid combustion is accompanied by high temperatures and the conclusion is sometimes drawn that the rapid combustion is caused by the high temperatures. The true sequence, however, is intense mixing causes rapid combustion and rapid combustion causes the high temperatures. It will be seen from this that water walls will not affect combustion to any extent, but they do mean that combustion can be made independent of furnace limitations. With the usual rates of combustion found in steam boiler practice there is very little danger that water-cooled furnace walls will cause incomplete combustion by excessive cooling of the flame. The temperature of the flame is always high enough for anything to burn that is burnable as long as a supply of air is sufficient and mixed properly with coal particles.

The use of preheated air will greatly hasten the ignition of the coal after it has entered the furnace, because by this means a considerable portion of the heat necessary is supplied from without the furnace. Air preheated to 700°F. has been used in connection with pulverized fuel burning and water-cooled walls with great success.

In order to appreciate more fully the extent to which pulverized fuel units have been developed, it might be interesting to note the general dimensions of some of the larger plants:—

New Unit at Lakeside Plant

The new unit at Lakeside has the following heating surfaces:—

Water heating surface in furnace	1,544 sq. ft.
Water heating surface of boiler	28,532 "
Total water heating surface	30,076 "
Superheating surface	930 "
Reheating surface	933 "
Total heating surface in furnace	3,407 "
Air preheating surface	40,320 "

Steam is generated at 1,200 pounds pressure and a final temperature of 720°F. It is fired with pulverized fuel and has a capacity of 240,000 pounds per hour.

Kip's Bay Station

The arrangement of the heating surfaces in each unit is as follows:—

Furnace surface

Water heating surface in side walls	1,336 sq. ft.
Water heating surface in side walls between boiler tube banks	666 "
Water heating surface in front walls	942 "
Water heating surface in arches	500 "
Water screen	688 "
Total surface in furnace	4,132 sq. ft.
Boiler surface	10,802 "
Total water heating surface	14,802 sq. ft.
Superheating surface	None
Economizer	10,802 "
Air preheater	46,800 "
Total surface	71,682 sq. ft.

Steam pressure is 275 pounds, with no superheat. Vertical firing of pulverized fuel is used, the combustion space is 19,000 cubic feet, and the normal capacity of each unit is 340,000 pounds per hour.

Calumet Station

The heating surfaces are as follows:—

Water heating surface

Rear bank of tubes	3,637 sq. ft.
Side walls	1,710 "
Roof	254 "
Bottom bank of tubes	1,375 "
Total water heating surface	6,976 sq. ft.
Superheating surface ... approx.	3,000 "
Economizer	5,250 "
Air heating surface	25,200 "
Steam pressure	360 lb. gauge
Effective combustion space	5,000 cu. ft.
Normal capacity of unit	125,000 lbs. per hr.
Peak capacity of unit	150,000 " " "

Low Temperature Carbonization

This question has been causing a very great deal of attention on all sides for the last few years. Unfortunately extravagant statements have been made regarding the results obtained by its overenthusiastic friends. The impression should not be taken from this statement that low temperature carbonization has no future. It is generally believed by competent engineers that the time is coming when it will be considered little short of a crime to burn as fuel in the ordinary way those valuable by-products which can be obtained from coal, but, as stated previously in this paper, no industry can prosper unless it can show dividends for every dollar expended.

We hear a great deal regarding the value of by-products, but it must not be forgotten that the value of any article is not what the producer places on it but rather what the consumer can afford to pay, or is willing to pay. It is perfectly true that the by-products in question are valuable under certain conditions and in certain places, but it is foolish to talk of obtaining by-products of a certain value from a ton of coal when their actual market value is only a fraction of this amount and the net result of the whole operation is a loss.

The main difference today between a scientist and an engineer is that a scientist discovers new processes with little regard to their commercial value, while an engineer must apply these discoveries in a practical way to everyday problems. At present some two hundred processes of low temperature carbonization have been listed, while it is doubtful if 10 per cent have been operated on anything approaching the commercial scale. Of these 10 per cent a large number are successful under a definite set of conditions, but if attempted under different circumstances the result would be a failure from a financial standpoint.

There are two main types of low pressure carbonization processes: first, one in which the resulting char is similar in size to coal and is to be used as smokeless fuel in domestic furnaces as well as in power plants; second, one in which the resulting char is applicable to power plant work in a pulverized form.

With the first method probably the most common type of furnace used is the rotary kiln, somewhat similar to the ordinary cement kiln. It is externally heated, and the coal being fed into the upper end of the retort is forced to the lower end by means of the rotary motion and the inclination of the retort. The retort is externally heated and the main difficulty seems to be that the drum, owing to its size, is greatly weakened by the heat to which it is exposed.

A second furnace is the concentric drum type of retort in which an inner and an outer drum are used. The coal is fed in at the bottom of the inner retort, is forced upwards by vanes acting like a screw conveyor. Having reached the top it discharges into the outer drum and because of the rotary motion and declination of the drum flows towards the lower end where it is discharged. During its path upward in the inner drum, the coal is exposed to moderate heat only, which tends to destroy some of its coking properties, so that when followed by the higher heat treatment in the outer drum it is not only distilled but is formed into hard dense lumps.

There are also the vertical stationary types of retort and the horizontal stationary type, and these are also being developed on a commercial scale.

In the second general method of carbonization the coal is first pulverized and fed into the top of a stationary vertical retort. During its fall by gravity it is exposed to sufficient heat to dry it, destroy its coking properties and heat it to approximately 500°F. From this retort it passes into a second similar retort where the carbonization process takes place. The by-products are taken off and the resulting char, still in the form of dust, is fed directly into furnaces and burned in a manner similar to pulverized coal.

Time will not permit a detailed description of the various processes, but in spite of the difficulties to which it is exposed by its own overenthusiastic friends, low temperature carbonization is making rapid strides and it would appear safe to prophesy that in the very near future, as stated previously, it will be considered, if not criminal at least uneconomical, to burn raw coal in large power plants.

Wood Refuse Burning

A development which has taken place in recent years which is of very great interest, although not applicable to all power plant work, is the burning of wood refuse. Where this refuse is dry the problem is a simple one, and there are already in the United States several plants burning a combination of sawdust and other wood refuse in the pulverized fuel type of furnace, either alone or in conjunction with coal. The sawdust burns in suspension while the larger lumps pile up on the water screen where combustion is completed.

In the paper mill industry there is an entirely different set of conditions. The bark and wood splinters come from the barking drums with a high moisture content which amounts to 50 or 60 per cent, even after passing through the bark presses. Not only is this costly to discard, but it must be remembered that one pound of bone dry wood refuse contains nearly 8,000 B.t.u., so that its efficient use is a very important problem.

It has long been realized that not only is the evaporation of this moisture content done at the expense of the heat content of the wood, but also the fact of it being done in the furnace complicates the combustion of other fuels. Many attempts have been made to reduce the moisture content and a process developed in Sweden is now being introduced in this country with considerable success.

The equipment consists of an inner and an outer perforated vertical circular tower with a housing outside of both. The wood refuse is fed in at the top by means of a revolving chute and passes down between the two perforated towers to the bottom where it is discharged and conveyed to the furnace. Waste stack gases are blown into the inner drum at the bottom, pass through the descending bark and out through the stack. If the entering gases are too hot an arrangement is provided by which a portion of the cooler gases, after having passed through the bark, are drawn back to dilute those entering and keep it at the proper temperature. As this process is automatic the operation of the equipment is simple.

At the present time there are two installations on this continent, one of which has been in operation for some months. Although it is admitted that certain refinements are still necessary the results obtained so far appear to have more than justified the necessary installation costs.

Summary

In summarizing, the question comes up of how much interest these developments are to us in the use of our western Canadian coals.

At ordinary combustion efficiencies it requires about 7 per cent of the total heat in Souris coal to evaporate the moisture in it. Besides this direct loss, the moisture complicates furnace conditions so that additional losses appear Any process, therefore, which will remove a portion of the moisture content efficiently outside the furnace will mean a considerable saving in the burning of the coal. There are several methods in the process of development at the present time and considerable success is claimed in each case by those interested. Time alone will prove whether or not these statements are justified, but at present we must consider the proposition from the standpoint of the coal as mined.

With small boilers the only apparent successful method for high ratings is with the use of well designed hand-fired grates and some method of forced draught under proper control.

With medium sized boilers considerable success can be obtained with single retort underfeed stokers, provided continuous ratings of not more than 125 per cent are required. With forced draught chain grate stokers and possibly air heaters 200 per cent continuous rating can be obtained with good efficiency. If higher ratings are necessary or larger boilers are used, pulverized fuel burning is the only method at present practicable.

With the indirect system the difficulty is with storing the undried pulverized coal for any length of time, but if the moisture content is reduced to any considerable extent, no serious difficulty should result.

With the unit system, if properly designed, the biggest difficulty will be the reduced capacity of the mill with undried coal, and this can be easily overcome by the use of larger mills.

Slagging of the lower boiler tubes has been experienced. This has been partly overcome by means of what is called a slag screen. In this method the bottom row of boiler tubes is divided into two rows with increased clearances and the tubes staggered. This has not completely overcome the trouble, so that some means of removing the slag must be used to prevent frequent boiler outage.

Alberta Coals

With the bituminous coals of Alberta all standard types of combustion equipment have been found successful, except that in the case of the highly coking coals the combustible loss in the ash pit is high with chain grate stokers.

With the lignites, the ratings possible are limited somewhat by the combustion rates of the various types of stokers. With pulverized coal equipment no trouble should be encountered in properly designed plants.

With all western coals low temperature carbonization is possible, but it would seem that it can be successful only on a large scale; also careful tests and serious investigation should be made of the amount and properties of the resulting products together with their market value in competition with similar products from other sources.

Discussion of Paper on the Removal of Carbon Sulphur Compounds from Coal Gas by Oil Washing by K. L. Dawson, A.M.E.I.C.[1]

K. L. Dawson, A.M.E.I.C.[2]

The author, in presenting the paper, remarked that in manufacturing coal gas at Halifax the obvious source of the supply of coal would be the well known fields of Nova Scotia, and the Cape Breton mines would be the first to be considered. It was not generally known that the gas-making properties of Cape Breton coal, with regard to the yield of gas per ton, are second to none. On the other hand, some coals from Cape Breton contained a proportion of sulphur, which was not at all desirable when using the coal with the ordinary small gas plant equipment. The sulphur in the original coal manifested itself in the gas in two main forms, in combination with hydrogen alone as sulphuretted hydrogen, and in combination with carbon or with carbon and hydrogen in various carbon-sulphur compounds.

Sulphuretted hydrogen could be removed readily from the gas; it is simply a matter of having sufficient equipment, but in the ordinary course of gas plant procedure, the carbon-sulphur compounds were not touched at all, because from a coal containing less than one per cent sulphur the quantity of carbon-sulphur compounds in the finished gas would have practically no deleterious effect. Most gas plants, particularly in the United States, could obtain coal containing less than one per cent of sulphur, but at Halifax, where native coal containing uniformly and consistently less than two per cent, was not commercially available, the problem of sulphur removal had to be faced.

In the paper he had tried to place on record what had been done towards solving the problem because it would indicate what remained to be accomplished.

He had described the apparatus used for washing the gas and had given the facts concerning the type of oil used.

Certain changes had been found to occur in the molecular weight of the oil following continual use of it and there were indications that the absorptive capacity for the carbon-sulphur compounds decreased with the increase in the molecular weight of the oil.

The paper contained data in connection with the carbon-sulphur compounds which had not been published elsewhere so far as he knew, and which could not be found in standard tables of physical constants.

With regard to the reasons for removing some of the fixed sulphur, he desired to point out that in Halifax the Board of Commissioners of Public Utilities had ruled that 35 grains per 100 cubic feet of gas should not be exceeded. This conclusion was reached after the Board had examined the available data on the subject, and after they had considered the rulings of other similar bodies. They had prescribed a penalty, based on the quantity of gas sold, which at present is equivalent to a fine of $600 per month for every month in which 35 grains is exceeded three times or 45 grains is exceeded once, the tests to be made daily. Thus there was an immediate monetary incentive to deal with the question of its removal in addition to such future benefits as would accrue as increased good-will and sales from a low sulphur gas.

The paper also considered the solutions of sulphur in the oil and in the gas, a chemical problem which he found he must handle mathematically. He had not been able to find a method of determining with sufficient accuracy the small quantities of carbon bisulphide or thiophene which would be left in the oil after that oil had been re-distilled or re-heated to drive off the sulphur which it had accumulated when it was in contact with the gas. Such a method would require exceptional accuracy, but was necessary in order to show whether the formulæ or conclusions worked out in the paper applied with the accuracy demanded by a chemist. From the standpoint of the mechanical engineer operating such equipment as they had in Halifax, they applied with sufficient accuracy to enable the engineer to determine practically what his plant would do under given circumstances.

He had carried out some experiments to show how the theory applied, and to indicate its correctness. For example, figure No. 13 gave the results of various tests of washing gas. The line drawn among the points showing observed results agreed with the projected theory. Remembering that there are at least nine variables in the operation of this oil scrubbing equipment, only one of which could be anchored in their plant at Halifax, while the others were varying, it would be seen that it was necessary to depend on the average of many tests to show the accuracy of the projected theory. The results indicated by scrubbing theory were summed up in figure No. 14.

The influence of temperature on the transfer of the sulphur-compounds was studied and data were given to show that the theory had been supported by actual evidence.

The paper covered the operation of the plant while washing at the rate of about 300,000 cubic feet of gas per day, so that the work was done on a commercial, not a laboratory scale.

It was interesting to note that about 30 B.t.u. were removed from each cubic foot of gas during the washing process. These were found in the crude benzol collected as a by-product. Also, the sulphur taken out of the gas appeared in the crude benzol, and unless the crude benzol was rectified or purified of course the sulphur remained in it.

In general the records of the operation of the oil scrubbing equipment at Halifax showed definitely that it removed carbon-sulphur compounds from the gas and that the efficiency of removal fluctuated widely.

The reason for this fluctuating efficiency of removal was obscured by the number of variables which influence the transfer of sulphur from the gas to the oil, but he believed that further investigation of the operation of the heating column, for the purpose of obtaining greater uniformity in the rate of flow of the oil through it, and more uniform temperature conditions, would bring improvement.

The theory set forth in the paper had served to establish that in connection with the transfer of sulphur from the gas to the oil the sulphur must be considered as existing in at least two forms, which for convenience and with reason have been considered as CS_2 and C_4H_4S; and that the efficiency of transfer, as defined, was the real measure of the efficiency of the scrubbing units; further, that the efficiency of transfer was uniformly high, probably well over 90 per cent under ordinary conditions of operation; and that the solutions of the sulphur compounds in both the gas and the

---

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February 16th, 1928, and published in The Engineering Journal, April 1928.

(2) Superintendent, Gas Department, Nova Scotia Tramways and Power Company, Limited, Halifax, N.S.

oil obeyed closely, if not exactly, the elementary laws for dilute solutions. By means of it, equations had been derived which could be used to predict what the performance of the process would be under given conditions.

Unless the values of R, which had been used for both CS_2 and C_4H_4S, proved to be so much too high that values less than 0.80 could be assumed for the efficiencies of transfer, (Ea and Ec), it would be apparent that there was nothing to be gained from re-circulating the oil in any one or all of the scrubbers.

The development of methods for the accurate and rapid determination of the small quantities of sulphur as CS_2 encountered in the gas, and the smaller quantities of sulphur which, as this study seemed to prove, were carried by the oil from the heating column, appeared to be a necessity before Ea, Ec, R and K could be evaluated, or much further progress could be made in building up a complete set of rules for the operation of the system at Halifax, and in finding the degree of accuracy with which the projected theory applied.

The operating cost of the process itself, without any reference to overhead or depreciation, was given in this paper as about 3¾ cents gross, and about 1½ cent net per thousand cubic feet. That might or might not compare favorably with the cost of the removal of benzol or the absorption of benzol in large coking plants, but it should be remembered that at Halifax they had utilized certain equipment not specially designed for the purpose, and that where only a comparatively small quantity of gas was treated, as compared with the enormous quantity handled in the ordinary coking oven plant, the unit cost would necessarily be greater.

A matter which he thought might be more fully investigated by engineers connected with gas utilities was the relation of the quantity of sulphur in the coal to the amount contained in the gas. From the data collected he thought it possible to predict with reasonable accuracy the mean total quantity of carbon-sulphur compounds which would be found in the finished gas from a given type of equipment when using coal containing a given percentage of sulphur, but this question needs further investigation than he had been able to give it.

Following the gathering of the data on this question which is shown in figure No. 4A the company had decided to change the type of apparatus in the plant from the present inclined slot retorts to continuous vertical ovens, and it was expected that in connection with the oil scrubbing system described in the paper, it would be possible to utilize coal containing from 2 to 2½ per cent of sulphur. At present coal with a sulphur content of less than 1.5 per cent must be used in conjunction with the oil scrubbing system, or with a sulphur content of less than 1 per cent if the oil scrubbing system was not employed.

J. J. Humphreys[3]

Mr. Humphreys observed that the process described by the author absorbed benzol and organic sulphur from the gas by means of heavy oil to the extent of about 50 per cent of the organic sulphur, and on distillation the benzol, and the sulphur which was absorbed as organic sulphur, came off together, leaving the heavy oil ready to be used over again. The benzol was apparently sold with the sulphur still in it.

In his opinion, the author's experiments and theories had shown that the process works, but costs too much, and left the sulphur in the benzol.

(3) Engineer of Gas Manufacture, Montreal Light, Heat and Power Consolidated.

F. W. Sperr, Jr.[4]

Mr. Sperr remarked that the author was to be congratulated on the work he had done on the removal of carbon-sulphur compounds from coal gas by oil washing.

The principle of oil scrubbing for this purpose was fundamentally sound, and he believed that it would come to be more generally applied when gas companies in different parts of the country had to face the use of higher sulphur coals. Fortunately for most people, in the United States at least, such a condition was still in the future.

He desired to compliment the author on the attention he had given to important theoretical considerations, and noted that the author's calculations did not appear to take into account the B.t.u. value of the benzol in the gas.

C. H. Wright, M.E.I.C.[5]

Mr. Wright desired to point out that in Cape Breton, Nova Scotia and across Newfoundland there were coal and iron areas of greater value than similar areas in the Saar valley, which was the economic cause of the Great War, as was well known.

In Nova Scotia, out of a population of about 500,000 people, over 125,000 persons were directly dependent upon the steel and coal activities of that province. As these activities prospered so would these people prosper. They had succeeded in getting the government of Canada to appoint the Duncan Commission, and one of the recommendations of that Commission was to the effect that the coal of Nova Scotia should be used in coking plants, and of course these would have to be established where gas could be used.

One point at which they would naturally expect a gas plant to be constructed was Halifax, and the author had taken the first step, or at least an important step, to make Nova Scotia coal available for the production of gas, such as could be used in our cities.

He did not think the percentage of sulphur compounds in domestic gas fixed by our public utility board was too low. They had in Halifax at one time a brand of gas which was absolutely nauseating; the Public Utilities Board stepped in, and to obtain relief it was then necessary to use American coal. The author had shown that this was no longer required, and he believed that coking plants should be established in all the centres of eastern Canada to use Nova Scotia coal.

A paper such as this was of importance to the economic life of the Maritime provinces, for it struck at the root of a very vital problem facing the province of Nova Scotia. The whole trend of gas-coke development in eastern Canada, including Quebec, would be influenced as a result of work like that of the author.

A. W. McMaster, A.M.E.I.C.[6]

Mr. McMaster wished to draw attention to the great amount of work done by the author in collecting his results and placing them before The Institute. His experiments went back to 1925, and dealt with a question of vital importance and removed a difficulty which had been a source of trouble for a number of years.

Nova Scotia coal had a variable sulphur content, sometimes running a little over two per cent, but the author had discovered a plan which would take care of the problem of

its removal, not only in the Maritimes but in the smaller communities in Quebec, which in another twenty-five years would have their own gas plants.

B. F. C. Haanel, M.E.I.C.[7]

Mr. Haanel, as chief engineer of the Division of Fuels and Fuel Testing at Ottawa, was greatly interested in all problems having to do with the utilization of native coal, especially in the Maritime provinces. While we had been led to believe that in general Cape Breton coals contained a high amount of sulphur, it was also the case that many coals there contained only a small amount of sulphur.

He believed that, unfortunately, the coals containing the largest proportions of sulphur were being mined in the largest quantities, and in view of that fact it should be the business of those conducting research work to see how such coals could be used to the best advantage in competition with coals of higher grade, so far as sulphur content is concerned, which were being imported into this country.

At present, he supposed that the amount of Canadian coal used in gas plants all over the country was small, amounting to only a fractional percentage of the total, and any contribution made by any individual which would lead to the more extensive use of native coal for gas-making merited a great deal of support; the man who did that work should be congratulated.

As far as the Department of Mines was concerned, research work on Canadian coal was being conducted and extended, but as yet they had not occasion or time or the necessary apparatus to deal with the question of sulphur compounds in gas. To a limited extent they had dealt with the question of the kinds of sulphur in the coal and the various methods which might be employed for its reduction, but the author had gone ahead on his own account and reduced the sulphur in the gas itself.

The author was thus responsible for the use of a considerable quantity of Nova Scotia coal instead of American coal in a gas-making plant, which had not been the case formerly, and since Nova Scotia had herself started to solve some of her own problems, Mr. Haanel believed there was a bright future for that province, especially when the rest of Canada extended the necessary assistance.

President Smith Sounds Note of International Accord

In telegraphing his regrets at not being able to attend the Annual Summer Meeting of the American Society of Civil Engineers at Buffalo recently, President Smith sounded a high note of international accord when he said:—

> "Exceedingly regret that matters requiring important attention here before I sail for Europe next week will prevent my attending summer meeting this week of the American Society of Civil Engineers stop I had looked forward to an opportunity to take advantage of this gathering of American engineers so close to Canada and at a point where there has been so much international co-operation in engineering matters to have voiced the satisfaction of The Engineering Institute of Canada for the happy relationship which exists between its membership and that of your Society and to emphasize a personal hope that there might be found some more direct and continuous liaison between their governing bodies in order that the best interest of the engineering profession on this continent might be advanced irrespective of the imaginary boundary which defines but does not separate the spheres of influence of the two societies."

The Annual Summer Meeting of the American Society of Civil Engineers

The annual summer meeting of the American Society of Civil Engineers which was held at Buffalo, N.Y., on July 17th to 20th, 1928, was of particular interest to members of The Institute. The papers presented, in the main, dealt with engineering matters of great international importance and concern to the profession in Canada. These were:—

> "The Engineering Pioneers of the Niagara Frontier," by Walter McCulloh, consulting engineer, Niagara Falls, N.Y.; "The Interim Report of the Special International Niagara Board on the Preservation of Niagara Falls," by Robert S. Thomas, major, Corps of Engineers, U.S.A., district engineer, Buffalo, N.Y.; "The Sanitary Character of the Waters of Lake Erie and the Niagara River"; "Niagara Power," by N. R. Gibson, M.E.I.C., chief engineer of the Niagara Falls Power Company, Niagara Falls, N.Y.; "Regulation of Levels, Flow and Navigation on the Great Lakes," by George B. Pillsbury, lieutenant-colonel, Corps of Engineers, U.S.A., Philadelphia, Pa.

The Interim Report of the Special International Board on the Preservation of Niagara Falls, which has been published by the government, is truly of international interest. This report was discussed at the meeting in Buffalo by prominent engineers from both countries, and the complete proceedings will provide a valuable compendium on the subject.

President Julian C. Smith was to have been present at this meeting, but at the last minute was prevented from attending. However, he was represented by Dr. Arthur Surveyer, M.E.I.C., past-president of The Institute, who, in Dr. Smith's absence, delivered a short address at the banquet on the night of July 19th.

Dr. Smith had been invited also to present a discussion on the Interim Report of the Special International Board, and in his unavoidable absence this was presented by J. B. Challies, M.E.I.C., past vice-president of The Institute.

Discussion on Interim Report of Special International Niagara Board,* by Julian C. Smith, LL.D., M.E.I.C., M.Am.Soc.C.E.

The Interim Report of the Special International Niagara Board on the Preservation of Niagara Falls, dated December 1927, and recently made public, briefly crystallizes the results to date of a comprehensive and well coordinated investigation of the factors involved in the preservation of Niagara for both æsthetic and utilitarian purposes.

By fully summarizing the pertinent data, by frankly exposing its general conclusions, by clearly setting out its reasons therefor, and by making a safe and sane recommendation acceptable to the general public of both countries, the Board has paved the way for international accord upon a complicated situation which might under a less frank and wise exposé of the facts have prompted a deluge of controversial propaganda.

The Board deserves the congratulations of the engineering profession of both countries, and I hope this meeting may be the occasion for some endorsement of the

* Presented at the Summer Meeting of the American Society of Civil Engineers, at Buffalo, N.Y., July 18th, 1928.

Board's conclusions that those in authority will be encouraged to see that not only are the Board's recommendations for remedial measures to preserve and enhance the spectacle of the falls carried out promptly, but that the very important issue of reasonable additional withdrawals is left with the Board for further study and solution.

Perhaps nowhere else is there to be found a situation where commercial considerations are so far-reaching and where at the same time æsthetic interests are of such paramount importance.

Whatever additional withdrawals may be permitted, extreme care must be exercised to insure that further works at the falls and in the gorges below conform to such high standards of architectural treatment that the majesty and beauty of Niagara will not be marred.

While the Niagara district may continue for many years to be the mecca of the engineer bent upon studying the progress of hydro-electric practice on this continent, it might well also be an example for those seeking knowledge and inspiration for the proper treatment of monumental engineering works in important settings. Although excellent results have been achieved in this regard on both sides of the boundary, it is timely and appropriate that attention be focussed upon the need for a comprehensive scheme for beautifying the whole Niagara valley. The preservation of the beauty of the falls both as to colour and volume is a basic necessity, but it should be only the central motif of a major project embracing the district immediately contiguous to the whole river. The Board's duties might therefore be extended to incorporate the evolution of a regional planning scheme which would contemplate the best use of all the falls and rapids of the Niagara river as a world-famous scenic spectacle, coupled with a complete study of ways and means for conserving the usable fall of the river between lakes Ontario and Erie.

With regard to the Board's recommendations, the general character of the proposed remedial works seem to be adequately conceived as a corrective to the impairment of bared flanks of the Horseshoe falls and for a substantial betterment of the " curtain " over the American falls while preserving the volume and deep green colour of the toe of the Horseshoe.

The Board wisely emphasizes the importance of these initial remedial works being carried out gradually and in a manner to permit actual testing of their efficiency both as a corrective for past impairment and as a necessary preliminary to further withdrawals. Cautious " cut and dry " procedure is essential in regard to both the design and the construction of these remedial works, especially with respect to their effect upon ice conditions and their use for seasonal variations in diversions.

The Board aptly calls attention to the contrast between the curtain or fleecy effect of the American falls and the deep rich tones of the Horseshoe as one of the important artistic features of Niagara, and very properly records the opinion that this feature must be retained as contra to the urge from some quarters for uniformity of colour and volume from shore to shore.

The Board considerably corrects the impression which, unfortunately, is generally believed, that the Horseshoe falls is so rapidly " committing suicide " that within measurable time the falls will deteriorate into a series of cascades. It conclusively shows to the contrary that all the factors involved indicate that further recession into the notch of the Horseshoe will be greatly retarded and what recession does occur will but cause these falls to present a superior appearance.

While Niagara is the property of the people of the United States and Canada, in a very real sense it belongs to the millions who visit it from all over the world. It therefore behooves the engineering profession on both sides of the boundary, who appreciate the æsthetic as well as they know the commercial value of Niagara, to emphasize the importance of its preservation. So I am glad, as representing the profession north of the boundary, to take advantage of the summer meeting of the American Society of Civil Engineers to urge that the Niagara problem be studied and solved in the broadest possible way and according to the slogan of one of its largest users*, " The greatest good to the greatest number."

Address by Dr. Arthur Surveyer, M.E.I.C.**

Ladies and Gentlemen:—

I am greatly honoured at having been selected to represent The Engineering Institute of Canada at this convention of the American Society of Civil Engineers. I regret very much, however, that our president, Dr. Julian C. Smith, has been unable to attend this function on account of his approaching departure for Europe. Dr. Smith is one of the pioneers of hydro-electric development on this continent; he began his professional career at Niagara Falls, and it would have been most fitting if he could have addressed you on this occasion.

I bring you to-night the hearty greetings of all the members of The Engineering Institute of Canada. I wish, at the same time, to express to you my personal congratulations on your most successful convention. It is not often that one has the privilege of attending an engineering meeting where the subjects discussed are of such international importance and where the papers presented and the discussions have been of such high character.

The North American continent, taken as one, is probably, from the point of view of natural resources, the most complete economic unit in the world. Divided into the two political units known as the United States and Canada, each country stands separately somewhat impoverished and somewhat dependent upon the other country for some of the raw materials necessary to its industrial life.

A few days ago, an investment survey, prepared by a New York financial house, called attention to the fact that the interchange of products between the two countries was larger than the trade between any other two nations. It mentioned the fact that the merchandise exchanged, last year, between the United States and England had a value of $1,200,000,000 compared with a figure of $1,300,000,000 for the combined trade between the United States and Canada; and this last figure exclusive of what the economists would call the invisible imports represented by the continuous flow of Canadian spirits distributed in the United States by an organization of altruistic bootleggers.

Canada, with a population of less than 10,000,000 inhabitants, has a foreign trade of $2,500,000,000 per year, which is exceeded only by four other countries in the world. Her exports consist not only of raw materials but also of manufactured articles. The building up of these various industries has absorbed large sums of monies which, before the war, were generally supplied from the British Isles. The war, however, has left the United States so wealthy that the flow of American capital into our country has increased to such a large volume that some people have become alarmed at the possible financial conquest of Canada. But, " a fair exchange is no robbery," and I assure you that your capital is most welcomed. You have found

* The Niagara Falls Power Company.

** Delivered at the banquet of the American Society of Civil Engineers' Annual Summer Convention at Buffalo, N.Y., July 19th, 1928.

in our country a safe field for investment and we have found in your money the means of developing natural resources which would otherwise have remained unexploited.

It is the *function of engineers* to develop natural resources and to create wealth, generally for the benefit of others. With the advent of American capital into Canada came also the American engineers, employed by the bankers, to investigate Canadian possibilities or to supervise the expenditure of their funds. Just about that time, the necessity of studying some of our international engineering problems led to the creation of technical boards composed of representatives of the two countries. This co-operation of the American and Canadian engineers in the development of the resources of Canada and in the solution of our international engineering difficulties has brought about a feeling of mutual respect and has led to the formation of very friendly relations between the engineers of the two countries.

I do not think that there are in the world to-day two groups of engineers of different nationality who understand each other so well or who can work together as well as the American and the Canadian engineers. It is to be hoped, therefore, that any work which we may be called upon to undertake in co-operation may be the means of further cementing the existing bonds of friendship.

OBITUARIES

Onésiphore Horace Coté, A.M.E.I.C.

Sincere regret is expressed in recording the death of Onésiphore Horace Coté, A.M.E.I.C., which occurred at Woonsocket, R.I., on October 1st, 1927.

The late Mr. Coté was born at St. Hugues, Que., on November 9th, 1869, and graduated from the Ecole Polytechnique, Montreal, in May 1899.

At the time of his death Mr. Coté was connected with Messrs. Lamoureux Bros., general contractors of Woonsocket, and was superintending the erection of the Wallum Lake new hospital for children. His last completed work was the Woonsocket junior high school, which was opened in September 1927.

Prior to removing to Woonsocket, in 1925, Mr. Coté was industrial commissioner of the Quebec Board of Trade in Quebec city, and before that he had been located in Montreal, having been for some time chief engineer of the Phoenix Bridge and Iron Works.

Mr. Coté joined The Institute as a Student March 16th, 1899, and was transferred to the class of Associate Member April 19th, 1906.

Arthur Philip Holden Tully, A.M.E.I.C.

It is with deep regret that we record the death of Arthur Philip Holden Tully, A.M.E.I.C., who, after an illness of over two years, passed away on December 24th, 1927, at Kentville, N.S.

The late Mr. Tully was born at Kentville, N.S., on April 25th, 1887, and received his early education there, later taking a course at the University of St. Francis Xavier, which he completed in 1908.

Mr. Tully then entered the employ of the National Transcontinental Railway at St. John, N.B., as draughtsman. In 1912 he became attached to the Canadian Pacific Railway as bridge inspector on the reconstruction of the Dominion Atlantic Railway. From 1914 to 1916 he was transitman on the construction of the Windsor and Weymouth bridge; from 1916 to 1917 he acted as bridge and building inspector, including the inspection of stations, and from 1917 to May 1918 he was senior transitman on the Brownville Division.

From May 1918 to the time of his illness Mr. Tully was connected with the engineering staff of the Canadian National Railways in the Maritime provinces.

Mr. Tully joined The Institute as an Associate Member in 1920, and the news of his death will be learned with sincere regret by many of his fellow members.

PERSONALS

Owen F. C. Armstrong, S.E.I.C., who graduated from the Nova Scotia Technical College in 1928, with the degree of B.Sc., is at present attached to the general traffic department of the Bell Telephone Company of Canada, Montreal.

Milton E. Dines, S.E.I.C., who graduated from the University of New Brunswick in June of this year with the degree of B.Sc., is at present connected with the Bell Telephone Company of Canada in Montreal.

J. E. Archambault, S.E.I.C., formerly of Montreal, is at present connected with the North Shore Power Company at Three Rivers, Quebec. Mr. Archambault graduated from the Ecole Polytechnique in 1927, having obtained the degree of B.Sc.

H. Kirsh, Jr.E.I.C., is with the Dominion Reinforcing Steel Company, Montreal, engaged on design. Mr. Kirsh, who is a graduate of McGill University of the year 1925, was formerly on the engineering staff of the St. Regis Paper Company at Deferiet, N.Y.

A. W. Crawford, A.M.E.I.C., who for the past five years has been director of technical education in the Department of Labour, Ottawa, has accepted a position with the Ontario Provincial Government at Toronto as inspector of apprenticeship, his duties being to administer the Apprentice Act of 1928.

W. S. Lawson, M.E.I.C., structural engineer of penitentiaries for the past seven years, has been appointed chief penitentiaries engineer, Department of Justice, Ottawa. Mr. Lawson has been a corporate member of The Institute since 1907, and is a registered Professional Engineer, Ontario, in civil and mechanical engineering.

Wm. O. Scott, Jr.E.I.C., formerly mechanical engineer with Scott Foster and Company of Vancouver, has now joined the staff of Canadian Utilities, Limited, of Calgary. Mr. Scott, who joined The Institute as a Student in 1922, transferring to the class of Junior in 1926, graduated from the University of British Columbia in 1923, having obtained the degree of M.A.Sc.

V. W. G. Wilson, Jr.E.I.C., is laboratory assistant with the Spruce Falls Power and Paper Company, Limited, at Kapuskasing, Ontario. Mr. Wilson is a graduate of McGill University of the year 1926, and received the degree of Master of Science in mechanical engineering from the Massachusetts Institute of Technology in June of this year.

Walter G. Hunt, A.M.E.I.C., who for the past two years has been engaged in general contracting in Montreal, has now formed the firm of Walter G. Hunt Company, Limited, Coronation Building, Montreal, engineers and general contractors. Mr. Hunt, who is a graduate of McGill University of the year 1917, was associated with the firm of Ross-Meagher Company, engineers and general contractors, Ottawa, as engineer and general superintendent for the five years previous to coming to Montreal.

A. H. Pattenden, M.E.I.C., has accepted the appointment of industrial engineer of the new business department of the Montreal Light, Heat and Power Consolidated, Montreal. Mr. Pattenden previously held the position of electrical engineer of the eastern and western plants of the Dominion Rubber Company, Limited, having joined that company in 1918.

S. W. Shackell, A.M.E.I.C., formerly junior engineer with the Department of Railways and Canals at Ottawa, has been appointed to a position on the Trent canal at Washago, Ont., by the same department. Prior to becoming attached to the Department of Railways and Canals, Mr. Shackell was on the staff of the Canadian Pacific Railway Company.

Archibald Cox, A.M.E.I.C., is at present in charge of all construction and mechanical departments with the Corbin Coal Company at Corbin, B.C. Mr. Cox was for several years superintendent engineer of the City of Regina Light & Power Plant, following which, in 1924, he occupied a similar position with the Winnipeg Standby and Central Heating Plant, and in 1926 he was Town Engineer and superintendent of utilities for the Town of Estevan, Sask.

E. T. Harbert, S.E.I.C., has been appointed engineer of pulp and paper research, as assistant to Mr. C. E. Planck, manager of the Pulp and Paper Department of the Canadian Ingersoll-Rand Company, Limited, Montreal. Mr. Harbert is now devoting his whole time to work in connection with the B. I. and S. micro-seal condensate removal system, the Van de Carr thin stock consistency regulator, the Haug refiner and the Shortt trap.

Theodore Kipp, Jr., M.E.I.C., vice-president and managing director of Kipp-Kelly, Limited, and partner in the engineering firm of Sullivan Kipp and Chase, Limited, of Winnipeg, has been elected chairman of the New Industries Committee of the Industrial Development Board of Manitoba. Mr. Kipp brings to the work of the committee wide experience in industrial investigations and promotion. During the War he was consultant to the British Food Board, for whom he designed and built a number of plants in England and Ireland.

J. H. Summerskill, A.M.E.I.C., who has been acting machine and building design engineer for the B. F. Goodrich Company, Akron, Ohio, has been appointed engineer of buildings and construction in charge of all property and building maintenance, new building construction and all machinery or equipment installations. Mr. Summerskill has been with the B. F. Goodrich Company for several years, having occupied the positions of inspector of mechanical insulations and material engineer prior to his appointment as acting design engineer. He is a graduate of McGill University in electrical engineering in 1914 and in mechanical engineering in 1915.

President of the American Institute of Electrical Engineers

The announcement of the election of R. F. Schushardt as President of the American Institute of Electrical Engineers for the year beginning August 1st, 1928, was made at the annual convention of that Institute which was held in Denver, Colorado, on June 25th to 29th. Mr. Schushardt is a graduate of the University of Wisconsin, and has been with the Chicago Edison Company, and its successor, the Commonwealth Edison Company, since 1898.

Colonel C. H. L. Jones, O.B.E., M.E.I.C., Appointed President of Mersey Paper Company, Ltd.

Colonel C. H. L. Jones, O.B.E., M.E.I.C., vice-president and manager of operations of the Spanish River Pulp and Paper Mills Company, Limited, which was recently merged with the Abitibi Paper Company, has severed his connection with that concern, and will shortly remove to Liverpool, N.S., where he will become president of the Mersey Paper Company, Ltd., being constructed there by the Royal Securities Corporation of Montreal.

Colonel Jones was born in Montreal, Que., and attended McGill University during the years 1891 to 1893. After graduation he worked on operation, maintenance-of-way and construction with the Canadian Pacific Railway Company.

During the year 1900 Colonel Jones was connected with the Algoma Central and Hudson Bay Railroad on construction work, in the years 1900-1903 he was associated in an assisting capacity in the planning and carrying out of engineering and construction details of the Algoma Central and Hudson Bay Railroad main line, and from 1904 to 1910 he was assistant general manager of the Lake Superior Corporation with direct responsibility over engineering and construction on the work carried out by that concern.

During the past eighteen years Colonel Jones has been associated with the paper industry, having been connected with the Sault Ste. Marie Pulp and Paper Company, Lake Superior Paper Company, The Spanish River Pulp and Paper Mills, Limited, Fort William Paper Company, Limited, and the Manitoba Pulp and Paper Company.

During the Great War Colonel Jones organized the 227th Battalion, and commanded it until it was absorbed into other units, after which he was transferred to the command of the C. F. C., Central Group in France, which command he held for eighteen months.

Colonel Jones has taken a great interest in public affairs and his departure from Sault Ste. Marie will be greatly regretted by his many friends in that city.

J. H. Wallis, A.M.E.I.C., Appointed Manager, Dominion Welding Engineering Company

J. H. Wallis, A.M.E.I.C., has recently resigned his position as manager and purchasing agent for the Ste. Anne Paper Company, Limited, and the Murray Bay Paper Company, Limited, to take over the management of the newly organized Dominion Welding Engineering Company, Limited, in Montreal. Mr. Wallis has been engaged on engineering work in Canada since 1903, his early work being land surveys, railway surveys and construction. In August 1914 he enlisted for overseas service as a private with the British Expeditionary Force, and throughout the war served overseas with distinction. In July 1915 he received his commission as Lieutenant and in 1916 that of Captain and in the following year that of Major.

Following his return to civilian life in 1919, Mr. Wallis entered the service of the Canadian Pacific Railway Company on maintenance-of-way on the Bowmanville division. In June 1920 he was appointed assistant engineer with the Department of Railways in connection with the Grand Trunk arbitration, and later in that year joined the engineering staff of the Canada Creosoting Company in Toronto. Subsequently, he was appointed supply engineer with the Riordon Pulp Corporation, Limited, at Temiskaming, Que., and, following the acquisition of this company by the Canadian International Paper Company, he was transferred to the construction department in charge of the purchase of equipment and materials for the extension to the mill.

The new company of which Mr. Wallis has been appointed manager is closely associated with the Dominion Bridge Company, Limited, and the Dominion Engineering Works, Limited.

BRANCH NEWS

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

Visit of General Secretary

On July 5th a gathering of thirty members and affiliates welcomed the general secretary, R. J. Durley, M.E.I.C., who visited Lethbridge during his annual western tour. The meeting commenced with a dinner in the new community hotel Marquis, during which the Rainbow Orchestra rendered several selections, later leading the community singing headed by Mr. J. Haimes. A pianoforte selection by C. Constantineau and vocal solos by Messrs. Smith and Meldrum were much appreciated by the members.

Mr. Bradley, chairman, introduced the visitor, who later explained various matters of interest in Institute affairs. Suggestions by members found a ready reception from Mr. Durley, who showed a keen interest in forwarding and helping the smaller branches of The Institute.

On account of the adverse weather conditions (a very heavy rain storm having occurred during the night), it was decided to abandon an auto trip to the Crow's Nest steam plant of the East Kootenay Power Co. Instead Mr. Durley met the executive at lunch and both he and they gained considerable information regarding local conditions concerning The Institute.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
W. McG. Gardner, A.M.E.I.C., Branch News Editor.

Moving Pictures from Coal to Electricity

Early in the year the branch was privileged to entertain a paper of particular interest when Irving E. Moultrop, Esq., chief engineer for the Edison Electric Illuminating Company of Boston, described the construction of the new Edgar power station at Weymouth.

As this plant was equipped with the first commercial 1,200-pound boiler, its development has been watched with considerable interest, and as a consequence the paper was reproduced in full in the June issue of the Journal.

To supplement this detailed description of modern steam power production, the branch was fortunate in receiving through the courtesy of the contractors, Messrs. Stone and Webster, two reels of film which were shown at a meeting on the 26th of April.

The first of these reels opened with a series of historical drawings illustrating the importance of operative power in the growth of civilization. By an ingenious representation of the principles discovered by Faraday in 1831, a simple electrical motor was depicted producing an alternating current of sufficient strength to light a lamp.

Contrasting the potential power of small rivers having a great fall with huge volumes of water at a low head, the Stone and Webster development at Bry creek, California, utilizing 2,062 feet of head was shown in conjunction with the large Keokuk plant on the Mississippi river.

Interesting charts illustrating the wide distribution of water power and coal deposits over the United States brought out the remarkable circumstance that where the former was scarce the latter was often found present in abundance.

The film concluded with clever drawings revealing the simple forces of impulse and reaction discovered in steam discharging jets thousands of years ago and still applied in our many vaned powerful steam turbines.

The second reel presented the operation of a steam plant in four stages. In the first stage of "Coal to Heat," huge piles of coal were unloaded and stored, conveyed from bunkers and hoppers to automatic stokers on which they are converted into ash by a preheated forced draught of air in the furnace.

In the second stage of "Heat to Steam," distilled water after being carefully freed of oxygen and impurities, and warmed in the condensers is passed through the hot tubes of the boiler and superheater till it is converted into hot dry steam at high pressure and temperature.

This high pressure steam, expanded to 500 times its volume in the turbine, generates the mechanical power of the third stage.

The fourth and last stage in which the turbine driven generator converts mechanical into electrical power brought the clever series of illustrating diagrams to a close.

It did not require graphs and charts to indicate why, in the face of rising prices for all other commodities, the cost of electrical power was steadily falling.

C. K. McLeod, A.M.E.I.C., secretary-treasurer of the branch, presided.

Ladies' Tea

The second monthly tea for the ladies of the branch members' families was held in the Prince of Wales salon, Windsor hotel, on Friday, April 27th, the guests being received by the ladies of the temporary committee: Mrs. J. L. Busfield, Mrs. George R. MacLeod, and Mrs. W. C. Adams.

A very enjoyable musical programme was thoroughly appreciated and the artists, pupils of Mr. Merlin Davies, were warmly thanked by Mrs. MacLeod.

A short discussion followed relating to the hour at which meetings should be called during the coming season and it was decided that 3.30 p.m. was the most convenient time for the majority.

The aims and proposed activities of the organization were announced in a brief outline by Mrs. MacLeod, who urged all to show their interest by being present at every meeting whenever possible.

Annual Summer Excursion of the Montreal Branch

The magnitude of the contemplated development of the St. Lawrence waterways has attracted the attention of members of The Institute for many years.

During this time numerous papers and reports have become available for technical study. While of great value, such reports do not always give the clear conception that comes of a personal acquaintance with the site of the undertaking.

Feeling that the development of the St. Lawrence was one of the most important projects facing the profession today and that members of the branch would wish to be well informed on the engineering aspects of the problem and view the scene of the proposed undertaking, the Montreal executive decided to arrange a tour of inspection that would enable the members to study the situation at first hand.

With such as the object, the C.S.L. steamer *Rapids Prince* was chartered by the branch for a two-day trip and invitations were extended to such public bodies as the Montreal Board of Trade, the Chambre de Commerce and others to join in the excursion. In response Mr. George Henderson, president of the Montreal Board of Trade, Hon. Raoul Grothe, president and Mr. J. A. Paulhus, vice-president of the Chambre de Commerce, were welcomed as guests from Montreal, while at Prescott the party was augmented by a contingent from the Ottawa Branch and a delegation from the Cornwall Board of Trade.

On Friday, June 1st, the party, consisting of some one hundred members and guests, left Victoria pier, Montreal, and proceeded up the river to Prescott; with good weather prevailing throughout the trip, splendid opportunity was provided to observe the existing conditions on the waterway and the general interest that was shown in the project by all on board proved to be the feature of the trip.

Following dinner Friday evening, O. O. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission and member of the Joint Board of Engineers, addressed the members of the party on the subject of the contemplated canalizing of the St. Lawrence river and the coincident development of its water powers.

Although principally confining his address to the general engineering features of the project and to interesting descriptions of the methods and costs of development, Mr. Lefebvre clearly expressed his personal opinion on the economic aspect of the subject in a reasonable and farsighted pronouncement.

"While Canada does not yet require an enlargement of the St. Lawrence canals, it would be in her interest to accept the offer of the United States should the latter, in her desire for increased navigational facilities between the sea and the Great Lakes, be willing to pay for the construction of a larger canal section in both the national and international sections of the river. Such an undertaking could be carried out in conjunction with the development of power in the international sections, then, when, and not before, she requires the additional electric energy, Canada can continue with the erection of power plants in her own territory. In view of Canadian expenditures on the new Welland canal and the river channel below Montreal the arrangement would not be unreasonable."

In proposing the vote of thanks to the speaker, Mr. George Henderson expressed the view that since the Joint Board of Engineers had pronounced on the feasibility of the project, it now remained for the taxpayers of Canada to pass on its economic soundness and desirability.

J. L. Busfield, M.E.I.C., was complimented by all present for the able manner in which such a successful trip had been organized.

Arriving at Prescott the party was met by Mayor W. J.

Taugher, who explained to the members the advantage of utilizing Prescott as a transfer terminal for the 600-foot freighters that will be able to descend into lake Ontario on the completion of the Welland canal. A unique advantage of this port would exist in its freedom from ice during the winter months.

Returning down the river Saturday, Mr. Lefebvre pointed out from the ship deck the main items of interest referred to in his address. After what was conceded by all to have been a most successful outing from every viewpoint the party disembarked at Lachine at 9 p.m. Saturday evening.

Peterborough Branch

S. O. Shield, Jr.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

In the report of the annual meeting of the Peterborough Branch, which appeared on page 449 of the July issue of the Journal, several names were omitted from the list of officers for the season 1928-29. The complete list is given below:—

Chairman	W. M. Cruthers, A.M.E.I.C.
Secretary	S. O. Shields, Jr.E.I.C.

Report on Silica Deposits of Western Canada

The Mines Branch, Department of Mines, Ottawa, has recently issued a report entitled Silica in Canada, Part 2—Western Canada, (No. 686), by L. Herber Cole, M.E.I.C. This report describes a number of typical deposits of silica in that part of Canada west of Fort William, Ont., and gives a brief résumé of the latest development in this industry in eastern Canada since the first volume, Silica in Canada—Eastern Canada, (No. 555), was published in 1923. The report comprises 59 pages and is adequately illustrated with photographs, drawings and maps. Copies may be obtained on application to the Director, Mines Branch, Department of Mines, Ottawa.

Important Hydro-Electric Studies under Way in Upper St. Maurice River

Members of The Institute will be interested in watching the progress of the comprehensive engineering investigations that are under way on the St. Maurice river by the Power Engineering Company, of which Sven Svenningson, M.E.I.C., is chief engineer and vice-president. At the recent special meeting of the Shawinigan Water and Power Company Dr. Julian C. Smith, M.E.I.C., made public the terms of a concession that has been recently consummated with the Government of the province of Quebec looking to the early development of the remaining water power resources of the St. Maurice river. The concession granted to Shawinigan covers a 75-mile stretch of the river between the Manouane and La Tuque, within which the river drops approximately 650 feet. The bulk of this fall is fairly well concentrated in three falls and several rapid reaches and it is expected that it will require three or more power developments to utilize the potential power of this section of the river. In the absence of detailed topographic and hydraulic information, the Power Engineering Company has had under way for some time an elaborate engineering investigation. The field work is under the supervision of C. R. Lindsey, A.M.E.I.C., and under the immediate direction of Charles Luscombe, A.M.E.I.C., as resident engineer, with headquarters at La Tuque. A large staff of engineers, technical assistants, etc., is now busily engaged upon this work.

The concession granted to Shawinigan by the Quebec government imposes upon the company important obligations, the principal of which are as follows:—

(a) Complete by January 1st, 1930, a comprehensive engineering investigation of the whole reach of the river leased and to spend thereon at least $100,000.
(b) Commence construction operations on the first development by the 1st of July, 1930, and have 100,000 horse power developed by the 1st of July, 1933, at a cost of $10,000,000.
(c) Carry out the succeeding developments so that the fourth will be started July 1st, 1938.
(d) Spend at least $25,000,000 upon these developments and the necessary transmission lines.

Few members of The Institute appreciate the extent of the huge power reserves on the St. Maurice river within easy economic transmission distance of existing commercial centres. The provincial government engineers concerned with the St. Maurice river confidently predict that it will be producing at least 1,200,000 horse power within ten years. Such a result follows directly upon the wise policy of the government of Quebec through the Quebec Streams Commission in conserving and regulating the flow of the St. Maurice and its tributaries.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

MECHANICAL DRAUGHTSMEN

A manufacturing company located in Ontario has an opening for two draughtsmen with experience in mechanical work. The company intends that these men should be attached to the staff of the parent company in the United States for training prior to establishment of an engineering office in Canada. Apply with full particulars to Box No. 10-V.

COMBUSTION ENGINEER

A manufacturing company located in Ontario has an opening for a combustion engineer with experience in the design of coke and gas products. The company intends that this man should be attached to the staff of the parent company in the United States for training prior to establishment of an engineering office in Canada. Apply with full particulars to Box No. 11-V.

Situations Vacant

DRAUGHTSMEN

A large manufacturing company requires the services of two draughtsmen with four or five years' experience. Preference will be given to those having experience with electrical equipment. Give full particulars of qualifications with application. Apply Box No. 15-V.

MECHANICAL DRAUGHTSMAN AND DESIGNER

A well-known manufacturing company in Ontario has openings for two mechanical draughtsmen and designers, preferably men who have had two or three years' experience in industrial work. The work will be in connection with draughting and design of equipment. Apply Box No. 17-V.

CONSTRUCTION ENGINEER

A large industrial firm in Ontario has an opening for a young graduate engineer. Applications will be considered from men having two or three years' experience in industrial construction work. Apply Box No. 18-V.

Situations Vacant

MECHANICAL DRAUGHTING AND DESIGN

A large pulp and paper company in Quebec has an opening for a recent graduate, preferably in mechanical engineering. The work is in connection with mechanical draughting and design for the company's plant. The position offers possibilities of advancement. Apply Box No. 19-V.

ELECTRICAL ENGINEER

Two graduate engineers for electrical manufacturing development work. Experience in radio engineering desirable but not essential. Location, Quebec province. Apply Box No. 24-V.

INSTRUMENTMAN

Instrumentman required for municipal work in connection with sewer and waterworks construction. Apply Box No. 28-V.

CONCRETE DESIGNER

Reinforced concrete designer required for the Montreal office of a large structural engineering company. Apply Box No. 34-V.

STRUCTURAL DETAILER

A firm of consulting engineers in Montreal has an opening for a young engineer with experience in timber and concrete designing and construction. Apply Box No. 35-V.

(Continued on next page)

Situations Vacant

Sales Engineer

An engineering sales organization in Montreal requires the services of a recent graduate in mechanical engineering for work on the sales and installation of combustion and refrigeration equipment. Applicants must be able to speak French. This position is in Montreal. Apply Box No. 37-V.

Draughtsman

Manufacturing company located in Eastern Ontario requires a draughtsman to lay out plant, buildings and equipment, and to estimate costs of new plant. He must be experienced in the design of foundry, machine shop and metal working plant. Position good for six months at least. Apply with full particulars to Box No. 42-V.

Draughtsman

Chief draughtsman for the City of Winnipeg Engineering Department, Manitoba. Applicant must have experience in mechanical and structural design, including reinforced concrete. Apply, stating qualifications and salary expected, to W. P. Brereton, City Engineer, Winnipeg, Manitoba.

Draughtsman

A large public utility company in Ottawa requires the services of one draughtsman with three or four years' experience. Preference will be given to those having had experience in sub-station layouts and other work in connection with a distribution or transmission department. Apply Box No. 44-V.

Situations Wanted

Construction or Industrial Engineer

A.M.E.I.C., 37 years of age, with experience in industrial and general construction and management of lumber mill, and a knowledge of factory management and costing, desires a position as construction engineer on any large works or as executive with a manufacturing enterprise. Speaks French fluently. Apply Box No. 1-W.

Electrical Engineer

Graduate in electrical engineering, Canadian, 22 years of age, with one year's training with a large electrical equipment manufacturing company, desires a position on sales, design or construction. Speaks German and has a knowledge of French. Apply Box No. 2-W.

Civil Engineer

Civil engineer, M.E.I.C., Registered Professional Engineer of Alberta, fully qualified, thirty years' experience in railway construction, reconnaissance and highway work, is available for a position. Would prefer position as city engineer, or post of trust and responsibility, in western province. Apply Box No. 3-W.

Situations Wanted

Building Superintendent or Sales Engineer

Mechanical engineer, A.M.E.I.C., 41 years of age, with extensive mechanical and combustion engineering experience, wishes to improve his present position by appointment as building superintendent or as sales engineer on power plant equipment. Apply Box No. 5-W.

Mechanical Engineer

Graduate in mechanical engineering of this year, with experience in paper mill operation, would like a position on production or maintenance with a pulp and paper or other industrial company. Apply Box No. 9-W.

Pulp and Paper Mill Engineer

Graduate mechanical engineer, 33 years of age, with extensive and varied experience in pulp and paper mill work, including operation, design, maintenance and construction, occupying during the past three years the positions of mechanical superintendent and resident engineer with a large pulp and paper company on the Pacific Coast, desires a position with opportunities for further experience. Apply Box No. 10-W.

Electrical Engineer

Electrical engineering graduate, 23 years of age, with two years' training with an electrical manufacturing company, wishes to secure a position on design, operation or sales of electrical equipment. Apply Box No. 11-W.

Electrical Engineer

Young electrical engineer, S.E.I.C., 22 years of age, McGill University, wishes to secure a position. Will be available in October. Experience during vacations on electrical conduit construction. Apply Box No. 12-W.

Designing Engineer and Estimator

Graduate of University of Manitoba in civil engineering with degrees of B.A. and B.Sc., 30 years of age, with experience in structural steel and reinforced concrete design and estimating; at present located in Chicago, wishes to secure a position in Canada, preferably in Winnipeg. Apply Box No. 13-W.

Construction Engineer

Construction engineer, 39 years of age, with nineteen years' experience, including municipal work, harbour, power line and dam construction, and townsite and industrial housing development, desires a position as resident engineer or superintendent on construction. Apply Box No. 14-W,

Situations Wanted

Electrical Engineer

Graduate of 1926 in electrical engineering, 24 years of age, with two years' experience with a large electrical manufacturing company, desires a position with an industrial company or on sales work. Apply Box No. 15-W.

Civil Engineer

Graduate civil engineer, 32 years of age, with experience on highway, municipal and construction work, wishes to secure a position as town engineer or with a firm of building contractors as estimator or assistant engineer. Apply Box No. 16-W.

Electrical Engineer

Graduate of the University of New Brunswick in electrical engineering of the year 1926, with two years' experience on the manufacture of electrical equipment, desires position with an industrial organization or on electrical construction. Apply Box No. 17-W.

Construction Engineer

Graduate engineer with seven years' experience on construction work, including municipal, highways, and general building construction, wishes to secure a position on similar work. Knowledge of French, German and Spanish. Apply Box No. 18-W.

Electrical Engineer

Recent graduate of McGill University in electrical engineering, with two years' experience with large electrical manufacturing company, desires a position. Apply Box No. 19-W.

Construction Engineer

Graduate engineer with extensive experience in industrial construction desires a similar position with pulp and paper company or other industrial organization. Apply Box No. 20-W.

Construction Engineer

Engineer, 36 years of age, with considerable experience in power and municipal surveys and municipal construction, is available for a position on similar work, preferably in Quebec or the Maritime provinces. Apply Box No. 25-W.

Chemical Engineer

Chemical engineer, graduate of McGill University of the year 1922, desires a position in the vicinity of Montreal. Apply Box No. 28-W.

Civil Engineer

Graduate of Queen's University of the year 1919 in civil engineering, with experience in construction, lumbering operations and electric railway work. At present located in the United States, wishes to secure a position in Canada. Knowledge of French. Apply Box No. 29-W.

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume XI | Montreal, September 1928 | Number 9

The Preservation of Douglas Fir by Pressure Creosoting

K. W. Hicks, S.E.I.C.
Vancouver Creosoting Company, Limited.

Paper presented before the Western General Professional Meeting of The Engineering Institute of Canada, at Vancouver, B.C., June 7th, 1928

History

Timber was the first structural material used by man, and he early discovered its proneness to decay, but it was with the commencement of the railway age that timber preservation received its greatest impetus, the wooden ties which replaced stone blocks and other solid supports decaying so rapidly that artificial means of prolonging their life was found necessary.

As early as 1756 attempts were made to impregnate wood with vegetable tars. In 1836 Franz Moll took out a patent for impregnating timber in closed iron pots with oils of coal tar.

The year 1838 saw the origin of the so-called creosoting process under pressure, when John Bethel took out a patent in England.

On the Pacific coast, the earliest pressure plants for the creosoting of Douglas fir were established by J. M. Colman in Seattle, Wash., in 1884, and by the Southern Pacific Railway Company at West Oakland, Cal., in 1887.

Today there are ten modern creosoting plants operating in California, Oregon, Washington and British Columbia, all treating Douglas fir exclusively.

A great increase in the use of creosoted timber has been evidenced since the early days of the industry on this continent. In 1909, 75 million cubic feet of timber were processed, while in 1925, 273 million cubic feet were treated, and last year over 300 million cubic feet.

Last year nearly 200 million gallons of creosote oil were used in Canada and the United States.

Creosote Oil

The preservative technically known as creosote oil is described in specifications as: "A distillate of coal gas tar, or coke oven tar," and standard specifications of the American Railway Engineering Association and the American Wood Preservers' Association require it to contain not over 3 per cent of water and not more than 0.5 per cent of matter insoluble in benzol. Its specific gravity at 38° C. compared with water at 15.5° C. must be not less than 1.03. It may distil not more than 5 per cent up to 210° C. for grade No. 1, 8 per cent for grade No. 2, and 10 per cent for grade No. 3. Up to 235° C. not more than 25 per cent may distil for grade No. 1, 35 per cent for grade No. 2 and 40 per cent for No. 3 oil. The residue above 355° C., if it exceeds 5 per cent, must have a float test of not more than 50 seconds at 70° C. The oil may yield not more than 2 per cent coke residue.

Detailed specifications are laid down for the methods of testing.

Creosote oil of the above standards is obtained from Great Britain, Belgium, Germany, the United States, Canada and recently from Japan. Grade No. 1 is most frequently used.

Some twenty years ago experiments were made using petroleum of asphaltic base instead of creosote oil, and others using a mixture of creosote oil and petroleum. Service records of ties so treated indicated a preference for the mixture, and today millions of ties and construction timbers are treated with mixtures varying from 75 per cent of creosote oil and 25 per cent of petroleum, to 50 per cent creosote and 50 per cent petroleum.

Grades of Timber for Treatment

As in untreated structures, the grade of lumber depends upon the use to which the material is to be put. Any standard grade of lumber, No. 1 common or better can be successfully creosoted.

Caps, stringers and important structural members should be at least of select common grade.

Sapwood is no defect, since when sound it is just as strong physically as heartwood, and takes the preservative more easily. This permits the use of less costly grades of lumber for some wood products such as pipe staves, conduit, bridge and culvert timbers, etc., etc., when these are creosoted.

All bark must be thoroughly removed before treatment.

Figure No. 1.—Pre-framed and Creosoted Railway Trestle Approach to Alberta Wheat Pool Elevator, Vancouver, B.C.

Processes

Brush and open tank immersion treatments are sometimes used, but the most economical method, though higher in first cost, is that known as the pressure process, and all of the timber for important uses today is so treated.

Before the preservative can be successfully forced into the timber, the moisture content of the wood must be reduced below the fibre saturation point, which for Douglas fir is about 22 per cent of the oven-dry weight of the wood. Poor results are obtained by endeavouring to impregnate before the timber is sufficiently dry to be receptive of the creosote.

The seasoning of Douglas fir before treatment is best done by what is known as the " boiling-under-vacuum process," although in some instances air seasoning is resorted to.

In the early days of treatment on the Pacific coast, timber was seasoned by steaming or boiling at high temperatures, often resulting in serious injury to the wood structure. In the boiling-under-vacuum process, timber may be seasoned by boiling it in creosote oil under a vacuum at temperatures 60 to 75 degrees lower than were used in steaming and boiling, and practically no injury to the timber results. This process has been used along the Pacific coast during the past fourteen years and now is the only treatment specified by purchasers. Some eastern plants are adapting its use to other kinds of wood with excellent results.

Standard specifications limit temperatures during the artificial seasoning period as follows:—

Piling—220° F. maximum.
Ties—220° F. maximum.
Lumber—200° F. maximum.

All lumber, however, may not be subjected to the maximum temperature of 200° F., and for small dimension lumber, temperatures of 180 to 190° F. should not be exceeded, or injury to the wood will result.

Just as in kiln drying, artificial seasoning in creosote oil must be conducted most carefully, otherwise warping, splitting and reduction in natural strength will result. Timber properly seasoned by boiling in creosote oil under a vacuum checks less than the same timber air seasoned, and the process has numerous advantages, among which are the reduced temperature necessary and consequent freedom from injury to the wood structure; quicker accomplishment of moisture extraction, and the thorough sterilization of the timber from incipient rot, which, authorities claim, is present in most sawn timber today. That complete sterilization does occur in this process has been proved by the Forest Products Laboratory and this is a valuable aid in increasing the useful life of timber.

Immediately following the seasoning period the impregnation with the preservative occurs. Specifications require timber to be treated either by the empty cell process or the full cell, with specified quantities of preservative.

The empty cell treatment consists in thoroughly coating the wood cell walls with the preservative and leaving no free oil in the cavities. In the full cell treatment not only are the cell walls coated, but free oil remains in the cavities.

The empty cell treatment is used for all timber structures to protect them from decay or insect attack and 6, 7 or 8 pounds of creosote oil per cubic foot of wood is commonly specified. For the prairie provinces, where decay does not occur quite so rapidly as on the Pacific coast, a 6-pound empty cell treatment for superstructure bridge timbers is considered sufficient, with 8-pound empty cell treatment for the piling and other sub-structures. In British Columbia it is advisable to use 7- or 8-pound empty cell treatment, depending upon the importance of the structure.

This treatment is accomplished by subjecting the wood, after seasoning, to air pressure of 50 to 65 pounds per square inch, after which, and without releasing pressure, creosote oil is forced into the timber in sufficient quantity to insure, when pressure is released and the " kick back " of creosote by the air imprisoned in the wood occurs, the specified net retention of preservative per cubic foot of wood remaining in the wood at the end of treatment. For example: for an 8-pound empty cell treatment, the gross absorption would be 11 to 12 pounds, of which 3 to 4 pounds is ejected after release of pressure.

After pressure is released, the treating cylinder is speedily emptied of the preservative and a vacuum of at least 20 inches promptly created and maintained until the lumber can be removed from the cylinder free of dripping preservative. Or, after pressure is completed and before removal of preservative from the cylinder, the preservative surrounding the lumber may be reheated to a maximum of 210° F., the steam being turned off the heating coils within thirty minutes after the maximum temperature is reached. The total time consumed, until the steam is turned off the coils in this expansion bath, must not exceed two hours. The preservative is then removed from the cylinder and the vacuum applied as noted above. Or, after the pressure is completed

Figure No. 2.—Creosoted Scow under Construction—Timbers Framed before Treatment.

and before removal of preservative from the cylinder, the preservative surrounding the lumber may be reheated to a maximum of 210° F. and a vacuum created during this heating period to assist further in expelling excess preservative from the lumber, the steam being turned off the heating coils within 30 minutes after the maximum temperature is reached. The total time consumed until the steam is turned off the coils in this expansion bath must not exceed two hours. The preservative is then removed from the cylinder and the vacuum applied as specified above.

The effect of these final periods in the treatment is to free the timber of dripping preservative and render its surface dry, and afford a better diffusion of the preservative in the wood.

Compressed air is sometimes used on the timber in the cylinder after the oil has been removed, which has the effect of driving surplus preservative into the wood and thus further drying the surfaces.

For timber to be used in salt water infested by marine borers, full cell treatment with 12, 14 and 16 pounds of straight grade No. 1 creosote oil is desirable, depending upon the probable intensity of the borer attack. In our Canadian waters a 12-pound full cell treatment is usually considered sufficient.

The desired physical result of creosoting is that all of the sapwood and as much of the heartwood as possible shall be impregnated without material loss in strength of the wood. It is the sapwood that rots first and the decay carries into the heartwood, therefore it is absolutely essential that there be complete saturation of all sapwood by the preservative.

The depth of penetration into the wood for the various treatments with creosote oil has been laid down as follows:—

For Piling

12-pound	full	cell	process—a	minimum	of	¾-inch	penetation
14	"	"	"	"	"	⅞	"	"
16	"	"	"	"	"	1	"	"

For Sawn Lumber

Average penetrations of	½-inch	for	6-pound	empty	cell	treatment
	⅝ "	"	7 "	"	"	"
	¾ "	"	8 "	"	"	"

It will be noted that specifications call for only *average* penetration for sawn lumber. It is obvious that the superficial area in lumber of small dimensions is much greater than in large timber, therefore the smaller dimension material will receive less depth of penetration than will the large timbers with the same quantities of preservative.

Creosoters naturally desire to turn out a product whose long life will warrant the continued and increased use of their product, and it is desirable that, where possible, engineers consult with creosoters as to the best treatment to be given any certain lot of timber required for specific purposes, thus obtaining their recommendations based upon the experience of a great many users and also upon service records.

There are available standard specifications of the American Wood Preservers' Association for the preservative treatment under pressure of Douglas fir piling, ties and sawn lumber.

Both the Bureau of Public Roads of the United States Government and the American Railway Engineering Association have concluded, after full consideration that, properly treated, the strength of timber is not materially reduced, and the same working stresses may be used as in untreated timber.

Plant Required

A modern creosoting plant for the treatment of Douglas fir by the boiling-under-vacuum process must include one or more steel treating cylinders 7 to 8 feet in diameter and 130 to 150 feet long made of at least ¾-inch plate, fitted with tracks, and efficient steam heating coils. In addition to these, vapour drums, condensers and drip tanks must be installed to permit the ready escape of the moisture in the form of vapour from the timber, followed by its condensation and measurement in order that the progress of the artificial seasoning may be noted hour by hour and the fact known when the timber is sufficiently dry to be properly receptive to the preservative.

Recording gauges for temperature, vacuum and pressure are used and records are carefully kept of the treatment of each charge.

A sufficient power plant for steam generation is essential together with air compressors, vacuum pumps, pressure pumps, etc.

Steel tanks are necessary for the storage of preservatives so that accurate measurements may be taken of quantities of preservative injected into each charge of timber.

Other equipment may include several miles of standard and narrow gauge trackage, together with 100 or more steel retort trams to convey the materials into the cylinders, also locomotive cranes, travelling derricks and other elevating and carrying devices, together with large booming grounds.

The most modern plants are equipped with a mill for the incising, adzing, boring and branding of railway ties before treatment. Such mills are expensive installations capable of putting through seven ties per minute. All railways today require their ties to be so machined before treatment, and this adds materially to the length of useful life.

Framing and Boring Before Treatment

It is now becoming usual to fabricate timber structures

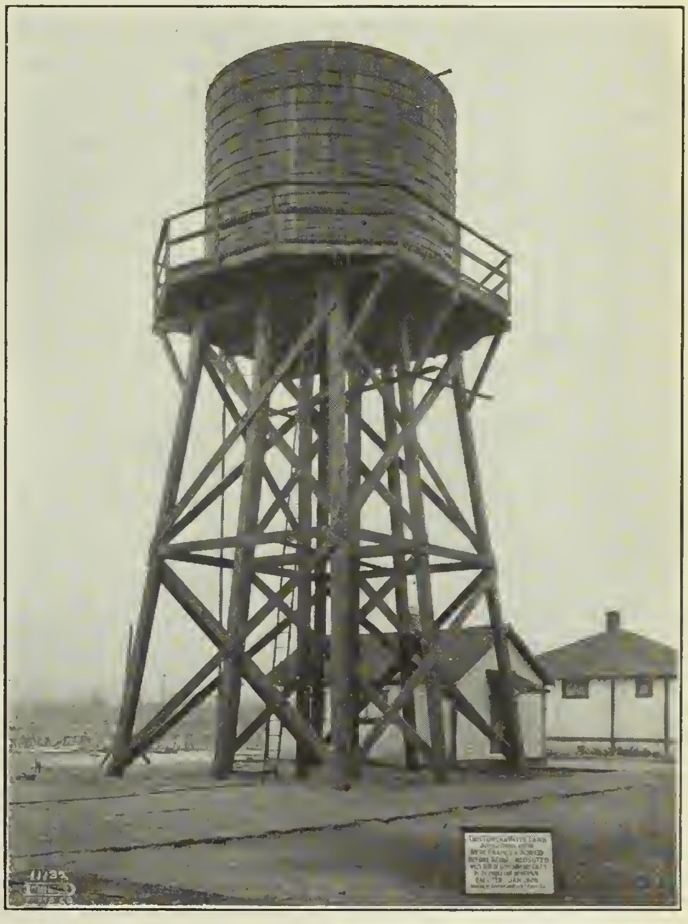

Figure No. 3.—Creosoted Water Tank and Tower.
All members framed and match marked for erection before creosoting.

Figure No. 4.—Creosoted Deck—Howe Truss Railroad Bridge, Vancouver, B.C.
All chords and web members were framed and then creosoted.

completely before treatment is given, therefore a framing mill is essential at a modern plant to permit of boring holes, cutting to length, dapping, etc.

Such fabrication of timber structures in accordance with detailed blue prints so that all parts in the structure "in contact" may receive the greatest benefit from the preservative treatment, is a matter to which too much attention cannot be paid.

It is the parts in actual contact in a timber structure which fail from decay, therefore it is absolutely essential that all possible framing and boring of holes be done before treatment.

In cases where timber has unavoidably to be cut after treatment the exposed untreated surfaces should receive three brush coats of hot creosote oil, and holes through untreated timber should be thoroughly swabbed out with hot creosote oil. These precautions will pay dividends.

Large users of treated timber have been a little slow to benefit by pre-fabrication, but much greater interest in this question has been shown during the past three years, and it received attention at the last annual convention of the American Wood Preservers' Association held in Montreal in January 1928.

Engineers having occasion to demolish a decayed wooden structure, such as a bridge, will discover, on careful examination, that practically all of the decay happens at points in contact and where bolts pass through the timbers, frequently leaving the remainder as sound as the day it was installed in the work. Millions of feet of one of our greatest natural resources are thus wasted because of the decay of about only 25 per cent of the wood used.

Reference may be made here to the incising of timber. This consists of running each stick through a machine having top, bottom and two side rolls studded with knife-like teeth which make incisions in the four faces of each timber, so spaced as to afford the deepest and best diffused penetration to the depth permitted by the quantity of preservative specified to be injected.

In sawn timber, where a great many varieties of surface grain exists and where we may have heartwood on one corner and sapwood diagonally opposite, it is impossible to get a uniform penetration. Incising tends to correct this, and does not reduce the strength of the timber more than two or three per cent, and the added protection of the deeper penetration of the preservative more than compensates for this small reduction.

Full size tests recently made on a number of incised, boiled-under-vacuum, pressure-creosoted stringers, size 6 inches by 12 inches, 12 feet span, and on full size ties, have shown an average modulus of rupture of 5,967 pounds per square inch, or 97 per cent of the untreated, not incised specimens.

Just as bridge, culvert and other structural timbers should be pre-framed, so railway ties should be adzed and bored for spike holes before treatment. Adzing is necessary only where hewn ties are used. The boring of the spike holes is essential to long life, and railways have, during the past five years, adopted this as standard practice.

Handling After Treatment

The following suggestions for the proper handling of creosoted material should be given attention:—

Creosoted timber is entitled to the same respect and care as steel, concrete or any other construction material, for its value can be greatly reduced or totally destroyed by improper handling.

Creosote does not penetrate the entire volume of the stick, but if no puncture or cut is made which will expose untreated wood, the stick is permanently protected against the attack of decay-fungi, marine borers, white ants, or other wood-destroying agency.

If cuts exposing white wood are unavoidable, always give exposed surface two brush coats of hot creosote.

Do not chop, drive dogs, peavies or other sharp tools into creosoted piles or timbers. If holes are unavoidably made, fill them with thoroughly creosoted, tight-fitting wooden plugs. This is particularly important with timbers used in sea water.

Protect creosoted material from chafing.

Apply at least two brush coats of hot creosote to the tops of piles after cut-off.

Bore all holes for bolts sufficiently small to give a driving fit.

Creosoted piles stand driving as well as untreated piles, but their additional value justifies greater precaution in protection against damage.

Use a follower or other means for avoiding injurious brooming or slivering of pile heads. Do not pound a creosoted pile longer than necessary.

Snipe the edge of butts before driving so that the hammer will strike on the heartwood in the centre of the pile.

Why Preservative Treatment is Desirable

Many records exist of the material increase in life of timber structures secured by creosote treatment and the corresponding reduction in the cost of the structure per year of life.

Decay in timber is only too familiar to engineers, whether due to infection by dry-rot, fungus, or the action of marine borers which, of course, affect timber used in sea water.

In tropical countries and throughout the southern half of the United States from one coast to the other, timber is quickly destroyed by termites; the white ant in the tropics, which operates in the dark and in moist soil, and the winged ant which attacks structures above the ground level.

Information has come to light during recent years of the serious depredations of this insect in North America, and users of telephone and telegraph poles in California have found it necessary to install full length treated poles in their service lines. The termite has been found as far north as Vancouver, particularly in telephone poles.

Alkali in the soil is another cause of failure of untreated wood. In certain districts in British Columbia where the soil is highly alkaline, untreated railway ties have been rendered unserviceable in four to five years.

Records of Long Life

Records of the long life of creosoted timber structures can now be found among the files of governments, railways, telephone, telegraph and power companies, the American Railway Engineering Association and the American Wood Preservers' Association.

Creosoted piling exists today in San Francisco harbour after thirty-seven years' use, and is still in good condition.

Seattle and Vancouver harbours contain many creosoted piles that have been in service for twenty-five years and are still sound.

The Southern Pacific Railway Company has records of many treated timber culverts that have been in service for thirty to thirty-five years, and any partial failures observed are reported as entirely due to cuts having been made in the creosoted wood and not properly brush treated.

The same railway has numerous creosoted bridges and trestles that have been in service thirty years and, quoting from the report of the engineer of bridges, " they have been using creosoted material for thirty years and the repairs to their structures have been very small." Their " average maintenance cost of treated timber trestles is about $1.00 per foot per year, which includes renewals as required from time to time due to mechanical causes."

He goes on to state that " from the standpoint of economy there is no structure that can compete with a creosoted wooden structure, where such a structure is at all suitable. We have not found the fire hazard of creosoted timber trestles to be any greater than that of the untreated structures, and our fire loss is extremely small."

Treatment of railway ties needs no further recommendation than that all of the railways on this continent and in England are practising this economy as well as in India and the Sudan.

Mine timbers that have been creosoted have been found to last five to nine times the life of the untreated.

Back in 1854 the London Port Authority installed at the Victoria docks, London, England, a creosoted wooden fence consisting of posts, stringers and palings. This fence is still in service after seventy-four years.

The United States Corps of Engineers some twenty-eight years ago commenced the use of creosoted timber barges and scows on the Mississippi river. There are now over one hundred in daily operation. The condition of a number of these that have seen twenty-seven years' continuous service, fully warrants the expectancy of thirty to thirty-five years' useful life.

The economy of their use is indicated by the very low maintenance expense over a period of years, which averaged (all repairs included) $59.00 per barge per year. Steel barges require docking for repainting about every three years, and this costs approximately $1,100 per barge.

In 1923 a pre-framed creosoted timber scow was built for use in Vancouver harbour and over a period of five years this scow has not cost one penny for maintenance or repairs.

Economics

The question of economics can only be touched on here.

Curves have been plotted by R. H. Rawson which show the relation of strength to years in service of not-incised untreated timber and incised creosoted timber. They give modulus of rupture in pounds per square inch as ordinates and time in years as a base, and show that for the first five years the not-incised untreated material has a slightly greater strength. During the next nine years the strength of the not-incised untreated material decreases rapidly to the low strength value at which it must be replaced, whereas it takes the incised treated material a further thirty-six years to reach the same low strength condition. The net

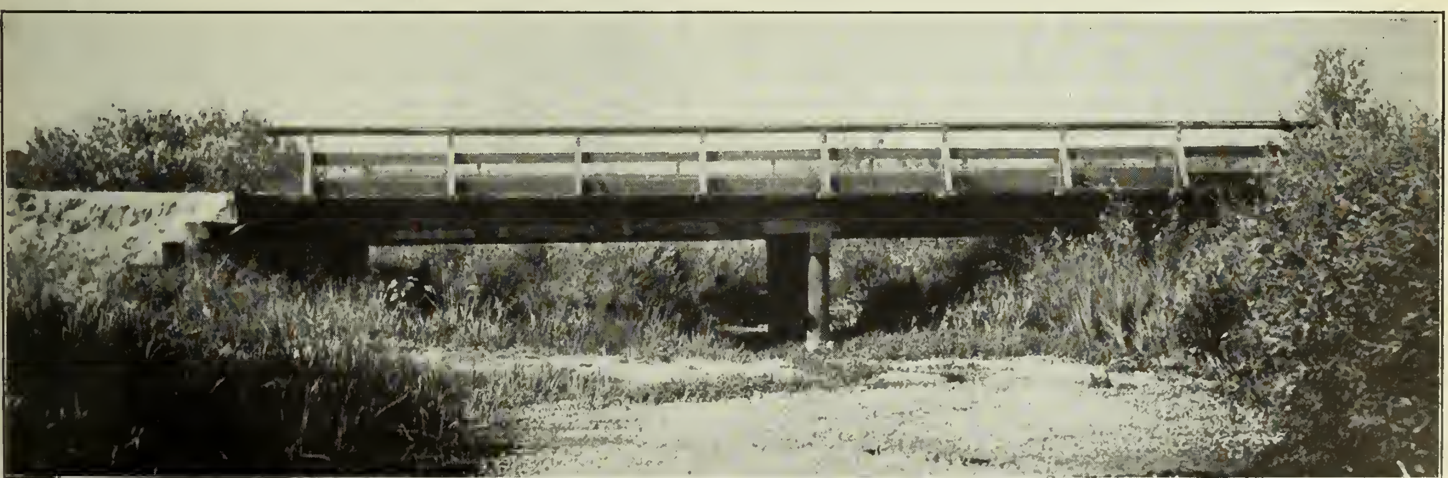

Figure No. 5.—Creosoted Highway Bridge.
Members framed before being creosoted.

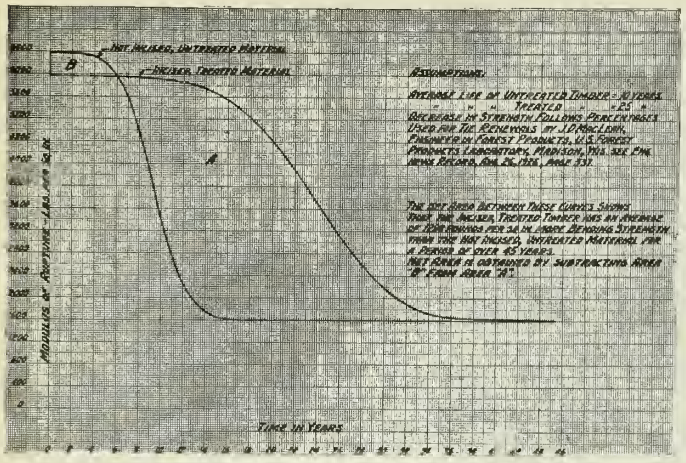

Figure No. 6.—Diagram showing the Relation of Strength to Years in Service of Not-incised Untreated Timber and Incised Creosoted Timber.

area between the two curves shows an average of 1,288 pounds per square inch greater strength for forty years in favour of creosoted material.

A diagram published on page 407 of bulletin No. 293, dated January, 1927, of the American Railway Engineering Association, shows the annual charges for timber trestles of various relative costs and for various periods of life, and is included in the report of the Committee on Wooden Bridges and Trestles. These charges are based on an interest rate of 6 per cent on the invested capital, a sinking fund providing for renewal at the end of the life of the structure, and a maintenance charge equal to one-half of the total cost of the structure spread over the life of the structure. The maintenance charge will naturally be small during the earlier years of the life of the structure and increased during the later years, but for the purpose of comparison it is assumed to be spread over the period of useful life uniformly.

Assuming a cost of untreated structures in place as unity,—for this example $75.00 per M. ft. b/m,—and of a similar creosoted structure in place, the 7-lb. creosote treatment adds about $29.00 per M. feet, b/m, making a total of $104.00 per M. feet, b/m, which is about 1.4 times the cost of the untreated structure. Allowing a life of twelve years for untreated and thirty-five years for creosoted, then the annual charges for untreated structures will be 0.173 times the cost as against 0.112 for creosoted structures.

The untreated structure, at $75.00 per M. feet b/m in place, at an annual charge of 0.173, thus results in an annual charge of $12.98 per M. feet b/m, while for the creosoted structure, costing $104.00 per M. feet b/m in place, at an annual charge of 0.112 results in an annual charge of $11.65 per M. feet b/m. This shows a saving of $1.33 per M. feet b/m. On one million feet b/m of timber the saving would be $1,330.00, which equals the interest charges at 6 per cent on $22,000.00.

If we take the annual charges on the untreated structure mentioned in the foregoing as unity, with a life of twelve years, and if a similar creosoted structure is 1.4 times as costly, then for the same cost per year as the untreated, the creosoted structure would have to last eighteen years in order to equal the cost of the untreated structure. As already mentioned, a life of thirty-five years is conservatively given as the estimated useful life of creosoted structures. Many such are in position today under much heavier loads than when originally built thirty years ago.

The same committee of the American Railway Engineering Association arrived at the following conclusions:—

1. Treated timber is more economical than untreated timber in wooden bridges and trestles and should be used for these structures except when the construction is temporary.

2. Timbers which are to be creosoted should be completely framed before treatment. If it is necessary to cut or damage the surfaces after treatment, they should have several coats of hot creosote applied to protect them.

3. If properly handled in the creosoting plants, the strength of the timber is not materially reduced and can be used with the same working stresses as untreated timber.

4. The fire hazard is somewhat reduced, and if ballasted deck bridges are constructed of treated timber, the hazard from inflammatory material dropped from trains is nearly eliminated.

5. Creosote in timber is not injurious to the metal fastenings.

6. Sapwood when treated is preferable to heartwood. It is inherently as strong and takes the creosote more readily.

Discussion

Mr. Durley enquired as to the effect of incising the timbers, and asked whether the incisions were specially arranged so as to avoid unnecessary loss of structural strength. The author replied that tests on incised timbers show only a very slight decrease in the natural strength of the timber due to incising, and that this decrease—amounting at the most to not over 2 per cent—was negligible in consideration of the greater and better diffused depth of penetration of the preservative into the wood. He explained that the incisions were so arranged, after a great deal of experimenting, as to afford the deepest and most uniform penetration of the preservative that could be obtained with the amount of the latter specified.

Colonel W. S. McDonald drew attention to a case of failure of pipe staves, which he had observed, due to the separation of the annular rings of the wood, and enquired whether that was due to any effect of the preservative treat-

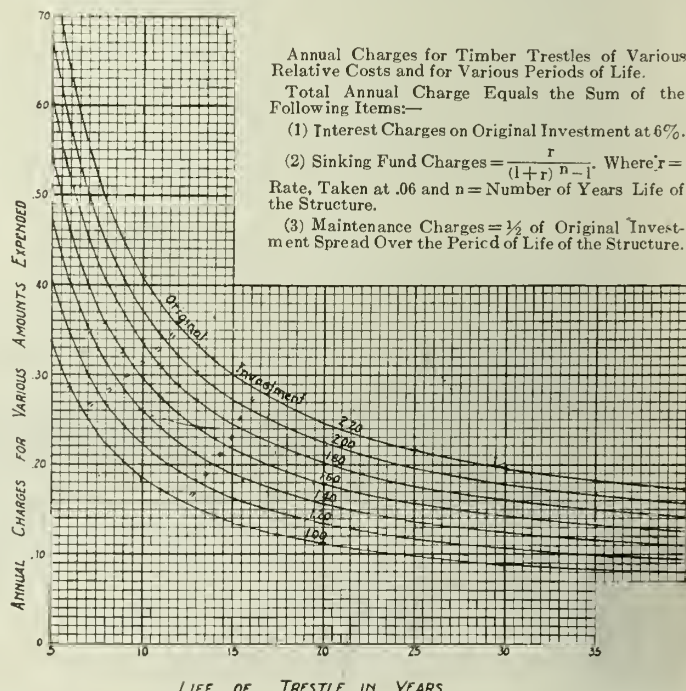

Figure No. 7.—Diagram showing the Annual Charges for Timber Trestles for Various Periods of Useful Life.

ment. The author replied that he was familiar with this particular complaint which had occurred in wood stave pipe under a 150-pound water pressure, and in discussing the matter with the companies which manufactured the pipe staves he had been informed that this same failure occasionally happened in untreated pipe where flat or slashed grain staves were used, being caused by the cinching of the pipe bands during erection of the pipe. The same fault is found in other untreated timber, such as slashed grain surface of planking.

The staves are received by the creosoting works either entirely seasoned or practically so, and therefore require but little artificial seasoning, during which hot treatment is necessary. With such staves as are artificially seasoned great care in the application of the seasoning temperatures is used, particularly so that the butts of the staves will not shrink unequally with the central portions. No greater shrinkage is found with creosoted pipe staves than with pipe staves that are air dried. For satisfactory results pipe staves should be milled from dry timber, because if they are not thoroughly dry when milled they will show greater shrinkage at the butts than in the middle, such difference in shrinkage occasionally being as much as 1/16 of an inch, and this happens whether the staves are creosoted or not.

Where partially dry stave lumber is milled and subsequent butt shrinkage occurs, it is difficult to obtain a thoroughly water-tight job until the butts have taken up considerable water. It was further stated by the author that it had been reported to him by the wood stave pipe companies that the creosoted pipes show materially less leakage than untreated staves.

Mr. H. P. Archibald had noted that creosoted staves were now being largely used for silos, and asked whether any effect from the creosote had been noticed in regard to tainting the silage. The reply was made that in order to determine and give the public the unbiased facts relating to this point, the U. S. Forest Service Laboratory at Madison, Wisconsin, recently conducted an investigation on this subject, and the following extract is taken from the report:—

> While but few of the experiment stations had had any experience with creosoted silos, and only a small number of owners of such silos could be located, not a single case was reported where the silage had been damaged or the health or appetite of the stock affected. It was the general opinion of the experiment stations that no danger need be anticipated on this account.
>
> With the present perfected methods of treating lumber, which remove all excess or free oils, the last doubt as to the value of a creosoted silo has vanished.

Mr. G. E. Herrmann remarked that the preservative treatment described in the paper—while not new and while thoroughly effective—was still in the process of development through experiments and tests, just as in the case of steel, concrete and other construction materials, and that considerable investigation and experimenting is constantly under way to better the methods employed and increase their efficacy.

In conveying to the author a hearty vote of thanks for the presentation of his paper, the chairman of the meeting stated that while he had always been thoroughly conversant with the preservation of timber with creosote oil, it had never been so forcibly brought home to him before that it is highly desirable to do all framing and boring of holes, in fact, complete fabrication, before the creosote treatment was applied.

Discussion of Paper on the Effect of Steam Treatment of Portland Cement Mortars on their Resistance to Sulphate Action, by T. Thorvaldson and V. A. Vigfusson, and on Appendices A and B of the 1927 Report of the Committee on the Deterioration of Concrete in Alkali Soils.[1]

A. G. Fleming[2].

Mr. Fleming wished to draw attention to some details of the expansion experiments described in the paper on the Effect of Steam Treatment of Portland Cement Mortars on Their Resistance to Sulphate Action, by Messrs. Thorvaldson and Vigfusson, which had been made with a lean mix, standard sand being used in the aggregate with certain water content. The consistencies stated for the two cements, (Nos. 126 and 555), were respectively twenty-four per cent and twenty-two and a half per cent, but in making up the mortar bars more water had been used with the cement of dry consistency than with the wet.

He believed that a very practical application of the lean mortar bar test might be made by standardizing it as a method of testing the alkali resistance of various brands of cements by exposing these bars to the action of sulphate solution under well defined conditions. This appeared to be a workable method of determining, in a general way, and with considerable saving of time, the relative resistance of different brands.

The work of the authors, though different in method and procedure from that being conducted by D. G. Miller[3], had led to very similar conclusions as regards the efficacy of steam-curing in increasing resistance to alkali action.

B. Stuart McKenzie, m.e.i.c.[4]

With reference to Appendices A and B of the Committee's Report, Mr. McKenzie stated that he had no intention of going into detail with regard to the early days of this committee, but it was a fact that its operations had met with very unsympathetic criticism in some quarters. This criticism came mainly from those who had fully developed theories of their own, but who refused to face actual conditions, as found, with an open mind.

There had been serious trouble in the sewers of Winnipeg, and chemicals in the sewage itself had been blamed. In the foundations of buildings in that city the same conditions had been found, accompanied by the smell of sulphur compounds, and the same theory had naturally been applied at first. Further investigation, however, indicated other reasons for the decay of the concrete. Conditions in an aqueduct had been remedied by draining the ground water

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February 16th, 1928, and published in The Engineering Journal, March 1928.

(4) Secretary, Canadian Engineering Standards Association, Ottawa.

away from the outside of the concrete pipe, as it had been found that serious damage had been done by chemicals carried in solution by the ground water.

Conditions all through the West had been very serious, and many officials had spent sleepless nights over the work in their charge. It was a matter of great satisfaction and of personal interest to see how far the committee had gone in solving this problem. There had been sufficient evidence accumulated to indicate that the problem should be attacked from a chemical standpoint.

Mr. McKenzie believed that the committee was working in the right direction and had made remarkable progress. He wished them every success in their efforts, and was optimistic enough to make a personal prediction that the committee would reach its objective.

E. Viens, M.E.I.C.[5]

Mr. Viens observed that in order to appreciate these papers fully one should be familiar with the results of this research which had already appeared from time to time in different technical journals. He hoped that when the investigations were completed, the resulting information would be collected and be published in one book.

He felt justified in saying that the researches carried out at the University of Saskatchewan had gone further than any other known experiments in shedding light on the real cause of so many concrete failures in the sulphate waters of the alkali soils.

Some knowledge of the effects of steam curing at various temperatures and durations of exposure on the strength of cement and concrete had been obtained through the researches carried out by R. J. Wig at the Bureau of Standards of the United States. It had also been known for some years, through the researches of Dalton G. Miller, carried out at University Farm, St. Paul, Minnesota, that steam curing increased very materially the resistance of Portland cement mortars and concretes to the action of sulphate solutions.

The authors of the paper under discussion, however, were not content to know that the strength of concrete is increased, in some cases over one hundred per cent, and that it is rendered more resistant to the sulphate solutions by as many as thirty-fold, but they wanted to know why, hoping that in this research they might find a new clue leading to the cause for Portland cement failure in sulphate waters. So they had endeavoured to find out what constituent or constituents of Portland cement were affected by this treatment, and they "suggested the theory that it is primarily due to the action of steam on the tricalcium aluminate." This was a very important discovery, in that it proved conclusively that alumina in cement is present in the form of tricalcium aluminate, and also that this constituent of Portland cement is the weakest in the presence of sulphate solutions.

So far, commercially, the steam treatment of concrete must of necessity be limited, as it could only be applied to comparatively small units such as drain tiles and possibly other small building units. The difficulty in using precast building units treated in this way would be that one would still have to contend with the cement mortar for the joints of such units.

He hoped that the researches under way would find a solution to this perplexing problem. But in the meantime what was to be done? As far as tests had gone on admixtures and surface coatings for concrete, they had proved unsatisfactory; in fact, some had actually been found detrimental instead of being beneficial.

[5] Director, Testing Laboratories, Department of Public Works, Ottawa, Ont.

However, if the investigators had not yet found a remedy to render Portland cement immune, they had at least discovered that it is possible to make concrete that will endure for a reasonable time under ordinary alkali soil conditions and that there is considerable difference in the resistance to sulphate action of cements manufactured in different mills.

D. G. Miller had experimented with cements from thirty different mills of the United States as to their respective resistances to sulphate action, and had found a very wide variation between mills. He had pointed out that this fact should be taken into consideration in choosing cement for use in alkali soils, and was now working on an accelerated test whereby the most resistive cement could be detected.

The Committee on Deterioration of Concrete in Alkali Soils of this Institute in its Annual Report for 1927, (see The Engineering Journal, March 1928, pp. 200-202), had brought out very clearly this difference between the cements from different mills.

Mr. Viens considered that among other factors playing a part in the ability of concrete to resist sulphate action were: (1) The quantity of cement used. Experiments by many investigators had shown that only rich mixes should be used, while our committee was of the opinion that there is an optimum richness at which concrete is most durable; with richer and leaner mixes than this the concrete becomes less resistant. (2) The amount of water used. There was also an optimum quantity of water for the best results, which seemed to be at a relative consistency of about 1:1. (3) The quality and graduation of the aggregate. Naturally, the aggregate should be composed of the densest rock and one that is unaffected by the sulphates. (4) Time of mixing. Concrete for such purposes should be mixed for at least two minutes. (5) Proper curing. It is now known that for the best results concrete should be cured for as long as possible under moist conditions, at a sufficiently high temperature, and out of contact with sulphates. Finally, for the most severe conditions of sulphate action, he believed that the only reliable method of protecting the concrete was to drain it properly.

A. G. Larsson[6]

Mr. Larsson considered that the problem of protective treatments of concrete in alkali water would be best approached by a study of the composition of the hardened cement and of the main reactions of alkali water, and his views could be summarized as follows:—

(A) The Main Products in Hardened Portland Cement

The most important compounds in hardened Portland cement are:—hydrate of lime ($Ca\,O.H_2O$), hydrated dicalcium silicate ($2\,CaO, SiO_2\,.n\,H_2O$), hydrated monocalcium silicate ($CaO.\,SiO_2.nH_2O$) and hydrated tricalcium aluminate ($3\,CaO.\,Al_2O_3.5.5\,H_2O$). These make up the substance which cements the aggregates together. This being the case, it is evident that the strength and durability of the concrete will suffer if either or all of them are destroyed. The injurious effect of alkali waters must therefore be studied by observing their reactions on the four compounds contained in hardened cement.

(B) The Action of Alkali Waters

The alkali waters contain varying amounts of sulphates and chlorides of calcium, magnesium and sodium Investigations have proved that the injurious action of these salts on concrete is caused mainly by the ions of magnesium and sulphuric acid, and only seldom by chlorine.

[6] Chief Chemist, St. Mary's Portland Cement Company.

An investigation of the effect of alkali waters, which evidently should precede the one of protective treatments, must therefore be divided into two parts.

(1) The actions of magnesia on the hydrated products of cement.

(2) The actions of sulphuric acid on the hydration products of cement.

(1) The Action of Magnesia on Hardened Portland Cement

Careful studies of this subject have proved that magnesia (MgO) replaces the lime (CaO) in each one of the four compounds constituting the hardened cement. The final products of the reactions are a non-hydraulic magnesium silicate and colloidal hydrates of magnesia ($Mg(OH)_2$) and alumina ($Al(OH)_3$).

The two hydrated silicates, $2CaO.SiO_2.2n\,H_2O$ and $CaO.SiO_2.n\,H_2O$ are of vital importance for the strength of the concrete, as they act like glue in cementing the aggregates together. The injurious effect of their destruction is therefore evident. But the formation of the two hydrates $Mg(OH)_2$ and $Al(OH)_3$ marks also the beginning of trouble.

As both are colloidal, they will, when exposed to water, absorb large quantities and expand. This will be followed by contraction when the water is removed. It is, however, evident that repeated expansions and contractions will tend to destroy the concrete, already weakened by the action of the alkali water.

(2) The Reaction of the SO_2 ion or of Soluble Sulphates on Hardened Cement

The sulphate action is different from the one just described. The hydrated aluminates in the cement are now the most affected. Different reactions take place, depending on the different sulphates contained in the water. Suffice it to say that they tend to form calcium sulpho-aluminate. The building up of this compound is accompanied by considerable expansion, caused by the high percentage of water contained in the molecule. If, therefore, enough of this material is formed, it will result in cracking and crumbling of the concrete.

(C) Protective Treatment

Having thus made clear the composition of the hardened cement, together with the main reactions of the alkali waters, we are in position to consider the possibility of protecting the concrete. The problem may advantageously be studied by applying separately the two main reactions of alkali water, i.e., the actions of the magnesia salts and the actions of the sulphates on the hydration products of Portland cement.

(1) Protective Treatment Against Magnesia in Alkali Water

As has been pointed out under (A), hardened Portland cement contains hydrated lime, hydrated dicalcium silicate, hydrated monocalcium silicate and hydrated tricalcium aluminate. We have also seen that each one of these compounds is subject to the destructive action of magnesia salts. It does not seem possible that any treatment can prevent the magnesia from replacing, according to well-known chemical laws, the lime in the just named hydration products. The best we can hope to accomplish is to retard more or less the destructive action.

This may be done by neutralizing the free lime with silica. This has been done in Europe for over thirty years by adding trass and other materials to concrete in sea water. These additions increase the strength at later periods. The beneficial effect found by Professor Thorvaldson on steamed test-pieces exposed to magnesium sulphate solutions may be explained by comparing this treatment with the one used in the manufacture of sand-lime-bricks. Owing to the hydrolyses of the cement compounds at the higher temperature, part of the free lime would be in a very reactive state, so that the lime silicate could form at a much lower temperature than is required for the sand-lime bricks. The observed improvement was caused by the formation of silicates.

(2) Protective Treatment of Concrete Against the Action of Sulphates in Alkali Water

We have already seen that calcium sulpho-aluminates are formed by the reaction of sulphates in alkali water on the calcium aluminates in the hardened cement. The injurious effect of this compound has also been described. It is evident that in order to prevent its formation we must either remove the aluminates, or destroy them, and make the alumina less reactive. The first suggestion is evidently not feasible. We know, however, that it would be effective, as it has been found that cements in which the alumina (Al_2O_3) has been replaced by oxide of iron (Fe_2O_3) resist the sulphate action. In this connection, good results in sea water structure are claimed for the Krupp cement.

The improved resistance against the sodium sulphate solutions found by Professor Thorvaldson on steam-treated test-pieces may be explained by the second possibility, the destruction of the hydrated calcium aluminate. The comparatively high temperature of the steam reduces the solubility of the lime, thus destroying the equilibrium. In order to restore the latter, hydrolysis sets in. Lime is now liberated, and either precipitated or, as was pointed out under C(1), united with silica from the aggregate to form calcium silicate. The hydrolysis increases with the temperature. When equilibrium is finally restored, the hydrolysis products will contain various amounts of lime, aluminates and alumina. The heat of the steam had reduced the reactivity of the latter very much, and the possible amount of calcium sulpho-aluminate that can be formed is proportionally decreased. The hotter the steam and the longer the treatment the better the results will be.

(D) Summary

The study of the composition of hardened Portland cement, together with the injurious reactions of alkali waters, makes it evident that no really effective treatment of concrete and mortar is possible. It also teaches us that to get entirely satisfactory results we must produce and use cement of a very different composition. On the other hand, it also indicates that we may increase the resistance of the present product in various ways. Professor Thorvaldson's experiments, for instance, suggest one method useful for small units.

The care taken in making the concrete is of great importance. In a general way, we may state this as follows:—

The lower the strength the less is the resistance against alkali waters; or, the higher the water-cement ratio the lower the resistance. A relative consistency of 1:10 has been found best. Anything that tends to increase this ratio is therefore injurious. The grading of the aggregates is for this reason most important. The fineness modulus should for the best results be about 5:5 and concrete for the best resistance should contain about ten per cent more water than is required for the highest strength.

The richer the mix the better will the concrete withstand the alkali salts. Any admixture to Portland cement which decreases the strength should be avoided. In this case may be counted natural cement, lime, clay and kaolin. Substances like trass, containing soluble silica, have been found beneficial up to about 25 per cent for sea water construction in Europe. In this connection, it is a peculiar fact that in certain experiments with concrete in alkali waters it was found that the so-called alkali-proof compounds used assisted, instead of resisted, the destruction of the test pieces.

Robert S. Stockton, m.e.i.c.[7]

Mr. Stockton remarked that the very careful and thorough research work described by the authors promised to have very important and far-reaching results in the practical field.

While much remained to be done in adapting means of applying the information obtained, there would seem to be by this method a nearly complete protection from the action of sodium sulphate, and the action of magnesium sulphate was so much delayed that some further precautions could probably be devised which would insure a reasonable life to structures subjected to the action of magnesium salts. Since these were the alkaline salts that did most of the damage, the steam treatment constituted a great step forward. It was, of course, possible that further chemical research would discover some easier and cheaper way of bringing about the reactions that affect the aluminates, and so change the mortar that it is little or not at all affected by the sulphate solutions.

He believed that in this case it was the duty of the practising engineers of the West to try to devise economical and practical methods of steam-treating foundations and canal structures where concrete is subject to the attack of alkali water, and thought it would not be very expensive, on fairly large work, to devise coffer-dams that would be sufficiently steam-tight to allow of treating the surface of heavy structures to an extent that would furnish protection. Tile pipe and small slabs could be treated at the point of casting.

Those who had been responsible for the construction and maintenance of moderate-sized concrete structures in the canals and ditches of the Western irrigation systems had had a good deal of experience with alkali action on concrete and had learned to make better concrete, to provide drainage and to remove ground water. They had tried with some success surface protection with hard-burned glazed tile slabs set in the forms just before the concrete is poured. Possibly the same protection could be obtained, especially in sodium sulphate waters, by using steam-treated concrete slabs.

The study of alkali action on concrete in irrigation system structures had been particularly identified with the name of A. S. Dawson, m.e.i.c., chief engineer, Department of Natural Resources, Canadian Pacific Railways, who at an early date had initiated a large number of tests and investigations, all of which had helped The Institute Committee in laying out the most productive lines of investigation.

The authors had laid a broad foundation in this research, particularly along chemical lines, and it was most desirable that this work be continued by the men who are now in such favourable position to build on that foundation.

John R. Baylis[8]

Mr. Baylis was of opinion that, since disintegration is due largely to chemical changes, any comment should stress the need for more information on the chemical reactions taking place.

The rate of disintegration for submerged concrete depended largely on the rapidity with which the salts can get to the concrete, which, of course, meant the rate of diffusion through the pores of the concrete. It was also evident that the concentration of the salts in the solution affected this rate of diffusion. The tests performed by the authors would seem to indicate that failure due to union of the cement compounds with the SO_3 takes place somewhere near the point where 1.5 per cent additional SO_3 unites with the cement compounds after concrete sets. This 1.5 per cent meant the percentage of the total cement before water is added.

Mr. Baylis had conducted experiments in which sulphates were added to the concrete in various ways and amounts, but had never been able to determine the amount of SO_3 that actually caused failure. In experimenting on the addition of gypsum to the cement before mixing with water, he had used $CaSo_4,2H_2O$ to the extent of ten per cent of the weight of the dry cement, in addition to that already in the cement, and the sample was used for making 1:2 mortar blocks.

The time of setting was slow, but hard pieces of concrete were eventually formed. After standing for a few weeks, protected from the air, one of the blocks was submerged in a solution saturated with sodium sulphate. The submerged piece disintegrated within a year. Another piece had been alternately submerged in distilled water and then allowed to dry, and so far no deterioration had taken place.

He was of the opinion that disintegration was due to the formation of calcium sulpho-aluminate. It was thought that the addition of ten per cent additional calcium sulphate would furnish enough SO_3 to have an excess over the amount that would unite with certain of the cement compounds. This apparently was not the case. The purpose of the experiment was to see if concrete could be produced which would not unite with additional SO_3. The tests performed did not prove that this could not be done, but with cements so high in alumina as are most of the brands of Portland cement, the gypsum required for a saturated equilibrium of calcium, aluminum and SO_3 is so great that it probably would not be practical for making concrete.

There were indications that iron might be substituted for much of the alumina in Portland cement without sacrificing strength and other durable qualities. If this were the case, a cement might be developed containing so little alumina that concrete could be produced which would not unite with additional SO_3. Probably concrete made from such cement would be very resistant to the sulphate-bearing waters.

He thought that efforts to produce concrete which will withstand the so-called alkali waters should be continued along two lines of attack. One was to take the cement as now being manufactured and try to make it impervious. The other would be to develop a cement which, when it was hydrated, will not unite to any material extent with the compounds occurring abundantly in the waters of the regions where concrete disintegrates so seriously.

E. W. Reed-Lewis, m.e.i.c.[9]

Mr. Reed-Lewis remarked that in the first paragraph of Appendix A it was conceded that "the resistance of a concrete structure to the action of alkali water is determined by a number of factors, one of which is the natural resistance of the cement itself to the action of sulphates," and that that paper dealt almost wholly with this one factor, namely, "the natural resistance to sulphate action possessed by the cement when exposed under conditions where the sulphate water has free access to the cementing material."

Later, the appendix referred to the nature of the test pieces employed as being such that "the sulphate has then almost as free an access to each particle of cement as if the cement, in finely powdered condition, were shaken with the solution."

Employing test specimens of this nature, the "natural resistance" to sulphates of various cements was compared,

Expansion of 1:10 Cement Mortar Bars in Solutions of Na_2SO_4.

Expansion of 1:10 Cement Mortar Bars in Solutions of $Mg.SO_4$.

and certain differences found, as shown graphically in figures Nos. 1 and 2 of Appendix A.

No evidence had been offered in the committee's report that any relation whatever existed as between the " natural rsistance " of a cement determined by these laboratory experiments and the actual resistance developed in the field by concrete produced with it.

On the contrary, it was stated that " the variation in sulphate resistance, (laboratory), between different brands of high-alumina cement was found to be greater than the variation with different brands of Portland cement," and further that " the resistance of all the samples of high-alumina cement in moderately rich mixes was found to be greater than that of any Portland cement."

Yet reference to the tabulation of field test specimens of concrete in Appendix B indicated that the high-alumina cement which showed the greatest laboratory resistance failed to produce concrete that was materially more resistant to field exposure than that produced with a Portland cement which ranked lowest of all Portlands in the laboratory tests.

Moreover, this same high-alumina cement concrete had proved in the field tests to be very definitely inferior in resistance to that produced with Super cement, though it was shown that a Super cement and a Portland cement produced, from the same clinker exhibited, essentially the same " natural resistance " as measured by Dr. Thorvaldson's laboratory technique.

It might be well to study these laboratory differences in " natural resistance " in the light of a previous paper by Dr. Thorvaldson entitled " The Expansion of Portland Cement Mortar Bars During Disintegration in Sulphate Solutions." This paper appeared in the April 1927 issue of The Engineering Journal, and described in some detail the laboratory methods on which Appendix A was based.

Quoting from this paper, we had the following statement:—" Each increase of 10° C. in the temperature, (of the sulphate solution), reduces the time necessary for equivalent expansion by about one-third."

This quotation referred to 1 to 5 mortar bars, and was followed by the statement that " experiments with 1 to 7½ mortar bars gave a somewhat larger effect for temperature."

It would be noted that the differences in " natural resistance " of various cements shown in figures Nos. 1 and 2 of Appendix A were based on expansion measurements of 1 to 10 mortar bars, which would presumably be influenced by temperature changes of the solution to an even greater extent than the 1 to 7½ mortar bars above referred to.

It would seem, then, by reference to figures Nos. 1 and 2 that the greatest difference found between the " natural resistances " of any two Portland cements was of the same order as the difference in resistance that would result with any one of them by varying the temperature of the solution to which it is exposed, a matter of something less than 10° C.

Without very convincing proof to the contrary, it would seem rational to conclude that such differences could have but little influence on the life of concrete which in the course of its field exposure to sulphate action would possibly encounter ten times such a temperature variation.

In the total absence of any evidence that the " differences " as between cements observed in the laboratory are reflected in their field behaviour, the data submitted in Appendix A would seem to warrant only one conclusion, viz.:—that, with the cements investigated, the " natural resistance " of a cement to sulphate action is an entirely negligible factor in respect to its ability to produce concrete that will endure exposure to such action in the field.

He considered this a significant fact which should be welcomed by the engineering profession; if we had to rely for the permanence of our concrete structures on such nebulous characteristics as those which appear to influence the " natural resistance " of cements to sulphate action, we would indeed be in sad case.

For we had been informed in Appendix A that, in respect to this " natural resistance," one Portland cement might show greater resistance than another to solutions of sodium sulphate, but the reverse under exposure to magnesium sulphate. Also, that while one cement might disintegrate faster in concentrated than in dilute solutions of sodium sulphate, a second cement might disintegrate at the same rate in both, and a third cement might disintegrate much more rapidly in the dilute solution.

As the sulphates present in ground waters were almost invariably a combination of at least two salts in proportions and concentrations that vary widely, not only from place to place, but also from time to time at the same place, (see Appendix B, table No. 1, Committee's report), it would take a wise man, indeed, to select the right brand of Portland cement if " natural resistance of the cement " were the controlling factor or even a significant factor in determining the field resistance of concrete.

" Natural resistance," or, in other words, the chemical stability of a cement under free exposure to the action of sulphate solutions, could be considered a factor of practical significance only when it existed to a degree that could be measured in years, not days, and under exposure to a variety of combinations and concentrations of salts such as one could expect to encounter in the field in any particular area over a period of time.

Even if such a degree of " natural resistance " could be found to exist in any present-day cement, or could be developed in the future, it would still be of paramount importance to have assurance that in attaining this characteristic those other qualities had not been impaired which have enabled existing cements of negligible " natural resistance " to develop in concrete an actual resistance which is apparently unimpaired after six years of the most rigorous field exposure.

Passing to Appendix B, Mr. Reed-Lewis drew attention to the suggestion there made that " in order to avoid reaching unwarranted conclusions from observations of the field specimens, all field tests should be considered in the light of the finding of the laboratory research as set down in Appendix A of this report."

Instead of confusing the issue by seeking to qualify the direct evidence of the field tests of concrete by reference to unrelated laboratory experiments of doubtful significance, he believed that it would seem more logical if the two were considered entirely independently, until they could be rationally and conclusively co-ordinated.

Appendix A showed one thing clearly, viz., that the various cements experimented with were chemically unstable when freely exposed to the action of sulphate solutions. Meticulous refinements of control and measurement had apparently indicated that degrees of chemical instability existed, but no evidence was offered to show that these variations had practical significance.

In referring to the superiority exhibited by the Super cement specimens over the Portland cement specimens in the field tests, it was therefore a statement neither of fact nor of warrantable assumption that by reference to Appendix A " we now know that different Portland cements show equally great variations in their resistance to sulphate action."

Since every effort was apparently made to control the field tests along lines directly comparable with the practical field use of the cements tested, the results of these field tests should be deserving of more careful consideration than had been given in the summary and conclusions of Appendix B.

It would seem to be at least a rational theory that the actual resistance developed by concrete to sulphate action in the field, in contrast to the negligible " natural resistance " of cement as determined in the laboratory, might be credited to whatever degree of impermeability the cement is able to develop in concrete.

Accepting that theory, in the absence of a better one, a finer distinction as between the behaviour of various field specimens seemed desirable than the committee's broad classification of "Affected " or " Unaffected " after six years of exposure.

On page 4 of Appendix B, for instance, under the heading of Super cement, it was stated that " of a total of forty-two Super cement specimens installed, twenty-three have been found unaffected."

Reference to table No. 7 of the same appendix would show that this broad classification would place in the same category specimen 5-3 of Super cement concrete, the condition of which after six years' exposure was reported as " Good, except for slight surface roughening at ground," and specimen 81-3 of Portland cement concrete which was reported as " Rapidly disintegrating " after three years, and " Completely disintegrated " after four years' exposure.

Without further detailed criticism of the committee's summarization of the field test data embodied in their report, and without suggesting that the scope and duration of the tests had been sufficient to warrant final conclusions, it might be stated that a study of the test data in detail would show that of the twenty different cements and supplementary treatments covered by these field tests, Super cement had alone consistently demonstrated its ability to produce concrete that had shown no action after six years' exposure to the severe conditions involved at the three sites.

This appeared to be true in spite of the fact that at least one of the cements included in the field tests showed in the laboratory a much higher " natural resistance " or chemical stability under free exposure to sulphate action than did the Super cement employed.

The lack of stability, under free exposure to sulphate waters and other disintegrating influences, of the substances composing hydraulic cements had been well-known for many years, and chemists had been endeavouring to follow this through to the development of a cement which would be chemically immune.

The attainment of this ideal, not only in the laboratory, but also within the field of commercial economics, would, of course, solve the problem of this type of concrete disintegration.

But, in the meantime, as our present-day cements lacked the necessary " natural resistance " that would render our concrete immune, at least it would seem reasonable to avail ourselves of the demonstrated superiority of any existing material, and thus ensure, to the best of our present ability, a longer life for our structures; and it should be remembered that, while the life of all other concrete under exposure to alkali ground waters might have been determined, time had yet to show that the life of well-made Super cement concrete fell short of eternity.

Author's Reply, by Dr. T. Thorvaldson.

Dr. Thorvaldson, in reply to the various points raised, stated that, as Mr. Fleming had suggested, lean and watery mortars were used in the early experiments on steam treatment for the purpose of obtaining in the shortest time possible an idea of any beneficial effect of steam on the stability of the hydrated cement itself when exposed to sulphate solutions. Considering the low resistance of the mortar used, the results seemed all the more conclusive, at least as far as solutions of sodium sulphate were concerned. If the expansion method were to be adapted to cement testing for the determination of the relative sulphate resistance of cements, it would be necessary to standardize the procedure along the lines which Mr. Fleming had suggested.

Mr. Larsson had taken a very optimistic position as to the extent of our knowledge of the exact chemical composition of the products present in hardened Portland cement.

It had been shown, [10]that solutions of magnesium sulphate acted slowly on the hydration products of the two silicates, tricalcium silicate and beta-dicalcium silicate, supposed to be present in Portland cement clinker. It had also been shown that the action of solutions of magnesium sulphate on hydrated tricalcium aluminate, (which was supposed to be the third main component present in set cement), was very rapid, compared with the rate of action on the hydrated silicates. On the other hand, mortar bars made from either di- or tricalcium silicate had proved completely resistant to the action of solutions of sodium sulphate, while the addition of tricalcium aluminate to the silicates rendered the mortar vulnerable. Since mortar bars made from a normal Portland cement and properly steam-treated acted towards solutions of magnesium and sodium sulphate exactly as mortar bars made from the calcium silicates without any steam treatment, the assumption that the steam treatment renders the aluminum compounds in the cement unreactive towards sulphates was reasonable and in accord with the facts at hand. Difficulties were, however, met with when attempts were made to explain the mechanism of the reaction on the generally-accepted assumption that the alumina was present as the hydrated tricalcium aluminate and that the steam treatment rendered this compound unreactive. While the theory of destruction through hydrolysis seemed most plausible, no free lime could be detected after hydrated tricalcium aluminate in the pure state had been treated with steam under conditions similar to those which rendered Portland cement resistant. Further work on this point was in progress.

With reference to the discussion by Mr. Viens, the authors wished to state that they did not consider that the experiments described in this paper presented a proof that the alumina was present in the form of tricalcium aluminate in normal Portland cement clinker. On the contrary, the failure of the steam treatment to render a mortar made from a cement to which tricalcium aluminate had been added immune to the action of sodium sulphate would have

[10] Thorvaldson, Vigfusson & Larmour, Proc. Royal Soc. of Can., 1927.

to be explained before one could accept without question the statement that the alumina occurred in normal Portland cement as tricalcium aluminate.

In his discussion of Appendix A, Mr. E. W. Reed-Lewis had mainly expounded the thesis that the resistance of a Portland cement in the form of lean mortar exposed to the action of sulphate solutions had no relation to the resistance to sulphate action developed in the field by concrete made from the same cement. It seemed that this hypothesis, which inferred that the chemical stability of a hydrated cement in a lean and permeable test piece had no relation to the chemical stability of the same cement in a less permeable test piece, required some supporting experimental evidence before it could be accepted.

Even in the case of the most impermeable concrete test piece, the surface was exposed. When the test piece was placed in contact with sulphate solutions, action on the cement took place progressively from the surface. The rate of the chemical action between the sulphate and the hydrated cement in the surface layer, or the stability of the cement in sulphate solutions, was one of the factors determining the rate at which the action progressed inwards from the surface.

Using very lean mortars, and thus allowing the solutions free access simultaneously to all the cement particles in the specimen, instead of to a very thin layer on the surface, gave one an accelerated test, and in such a test it was the ratio of the time intervals required to disintegrate two specimens rather than the actual time required which was significant.

That this was the case, had been confirmed by many laboratory studies on the resistance of mortars varying in richness of mix between 1:10 and 1:3. Thus, as the richness of mix was increased, with corresponding decrease in the permeability of the specimen, the ratio of the expansion of specimens made from a cement high in resistance, as determined by the accelerated test, to the rate of expansion of specimens made from a cement low in resistance was actually increased.

In view of the above, and the fact that sulphate action in the case of fairly impermeable concrete specimens proceeded progressively inwards from the surface, it would be seen that the observations of Mr. Reed-Lewis, (based on Figures Nos. 1 and 2), on the significance of the effect of temperature on the rate of sulphate action were entirely beside the mark.

After a study of tables Nos. 6, 7 and 8 of Appendix B, Dr. Thorvaldson was unable to agree with the deductions made by Mr. Reed-Lewis in his discussion of Appendix A as to the inferiority of high-alumina cement, assuming that the reference by Mr. Reed-Lewis was to the resistance of specimens to sulphate action. In tables Nos. 6, 7 and 8, it was reported that high-alumina cement test-specimens were weathered or cracked above the ground line, while all the specimens, except those in the Grandora test plot, were reported not acted on below the ground line, which was the portion exposed to the " alkali " soil. In the absence of any proof that the weathering above the ground was due to sulphate action, there was no direct evidence of such action on any of the high-alumina cement specimens exposed at the Manitoba and Alberta test plots and reported in tables Nos. 6 and 8. At the Saskatchewan test plot, action below the ground line on all the high-alumina cement test-pieces was reported. Reference to table No. 1 of Appendix B showed that the soil water at the Grandora site, in addition to being extremely high in sodium sulphate, contained a considerable quantity of sodium carbonate, which, as stated in the paragraph of high-alumina cements in Appendix A, was found to cause rapid disintegration of test-pieces of this cement. There was no evidence to indicate to what extent the action reported below the ground line at Grandora was due to sulphate action and to what extent it was due to the action of sodium carbonate.

The statements quoted by Mr. Reed-Lewis from the section of Appendix A dealing with high-alumina cements referred to the laboratory findings as to the resistance of the cements to sulphate action only, and there was no evidence that these were at variance with the results of the field tests.

Reply by Dean C. J. MacKenzie, M.E.I.C.

Professor Mackenzie remarked that in his discussion of Appendix B, Mr. Reed-Lewis had suggested:—

(1) That the great differences in " natural resistance " to sulphate action of different Portland cements as found by Dr. Thorvaldson in the chemical laboratory were a negligible consideration under field conditions.

(2) That in reaching conclusions, evidence from field tests only should be used.

(3) That the greater resistance shown in the field tests by the particular brand of Super cement used. as compared with the particular brand of plain Portland cement used, should be credited to differences in permeability of the two concretes.

Professor MacKenzie believed that few engineers would agree that the results of the experiments on the " natural resistance " of different cements, as reported in Appendix A, had no bearing on field tests. However, for those who believed, as Mr. Reed-Lewis did, that evidence should be drawn only from field tests such as reported, the following information might be offered. There were exposed at the " alkali test sites " referred to in Appendix B many other specimens which, not having been part of the committee's programme were not reported upon by the committee, but were inspected and any deterioration noted, just as and when the committee's blocks were inspected and reported. There were, at the Grandora site, concrete blocks made from certain American Portland cements and comparable in mix and cement content, which after the same length of time were found to be as little affected as those made from the particular Super cement used in their investigations. At another one of the sites there were three sets of similar specimens made from the following cements:—(a) A certain brand of Canadian Portland cement; (b) a certain brand of American Portland cement; (c) a Super cement. After six years' exposure, specimens (a) and (c) were found to be standing up well, while specimen (b) was completely disintegrated. Many such experiences might be cited, including the findings of Mr. Dalton G. Miller, drainage engineer, United States Department of Agriculture, who had found a very great difference in the rates of disintegration of high quality concretes made from different brands of Portland cement.

Consideration, then, of field tests only led to the inevitable conclusion that normal Portland cements differ very greatly in their resistance to alkali action.

As to the great difference in resistance between the Portland cement and Super cement in the field tests reported in Appendix B, when it was realized that similar differences had been noted between different brands of Portland cement, Professor MacKenzie felt that until field tests were available, giving a comparison between a Super cement and a Portland cement from the same clinker, the only logical and scientific conclusion warranted was that made by the committee, i.e., " That as our field investigation did not include tests with Portland cement and Super cement from the same clinker, we have no evidence that one is more resistant to alkali action than the other when subjected to the same field conditions."

Discussion of Paper on The Requirements for a Durable Concrete as Observed from Structures in Service, by R. B. Young, M.E.I.C.[1]

W. S. Lee, M.E.I.C.[2]

Mr. Lee remarked that the author had made comparisons between the expansion of concrete due to change of temperature and due to moisture, expressing the opinion that the expansion due to moisture was much the greater. He hoped that the author would discuss this point further, as comparatively little was known about the expansion of concrete due to moisture. It was well-known that in concrete which is porous, the voids would take up water which would reach into the mass due to capillary action. He believed that in the case of a concrete wall in a hydraulic plant subject to a continuous flow of water, very disastrous cracks might result. He was of the opinion that the cracks experienced in such structures were due to porous or bad concrete rather than to temperature expansion.

The author, in reply, stated that it was well established that concrete expands when wetted and contracts when dried, but the data available did not permit a person to compute accurately the amount of the changes in any given case, although it was known that they might be several times the volume changes caused by the usual variations in temperature. Further, it was known that expansion due to wetting took place relatively rapidly, while contraction due to drying took place much more slowly, as might be expected since the drying out of the concrete was a slower process.

As an indication of the rate at which concrete would absorb moisture, the author cited certain experiments made on the capillary pore determinator mentioned in the paper. A concrete, approximately 1:2:4, cured for two days, dried out and then tested, absorbed water at such a rate that it penetrated the specimen an inch an hour for twelve hours, and the total absorbed water amounted to approximately ten per cent of the volume of the specimen. One could imagine what must happen to a similar concrete in service when subjected to a heavy rain. The surface layers would expand rapidly and the concrete would be very unevenly stressed, and it was possible that such stressing is the cause of some of the map cracking found on certain concretes.

L. J. Street, Affiliate E.I.C.[3]

Mr. Street drew attention to certain compression test results obtained on set concrete test cylinders left out in the open over night in zero weather and tested immediately after being brought into the laboratory.

The result of such tests so far made seemed to indicate that when concrete that had reached its normal strength was exposed to low temperature it developed abnormal compression strength if tested at or approaching the low temperature to which it had been exposed. The abnormal strength seemed to be a function of the temperature at the time of testing, as when companion test specimens were similarly exposed and allowed to return to normal temperature before testing, the concrete resumed its normal strength.

He had not yet determined whether the increase of strength varied with the temperature to which the concrete had been exposed or whether it was constant at all low temperatures.

He believed, however, that the test results obtained so far, as shown on the accompanying table, would prove of interest to the members of The Institute.

John R. Baylis.[4]

Mr. Baylis agreed fully with the author's conclusions, and desired to stress the advice that engineers should be sceptical about the addition of substances to concrete to protect it against sulphate-bearing waters. The only thing that could be of help in such cases was to keep the water from getting to the concrete. He believed that any concrete manufactured from Portland cement containing more than one or two per cent of aluminum oxide would disintegrate if sulphates could get to the concrete; unless the hydrated cement compounds had been almost completely carbonated, that is, the $Ca(OH)_2$ converted to $CaCO_3$. The failure in such cases was considered to be due largely to the production of calcium sulpho-aluminate.

A certain hydrogen-ion concentration of the solution within the pores of the concrete was essential before calcium sulpho-aluminate could be produced, consequently, if the alkaline compounds in the concrete were carbonated to the extent that this concentration could not be produced, deterioration would not take place to any great extent. The chief danger of failure in this case would be at points where the certain salts were being concentrated due to moisture being evaporated from the surface of the concrete. However, it was not desirable to manufacture concrete in which all the high calcium compounds can be carbonated after the concrete has set. Such concrete would have to be so porous that it would not be likely to withstand the weathering agents, even though no sulphates were present.

Spalling Caused by the Decay of Unsound Stone. Moisture Reached the Stone Through the Porous Concrete Causing it to Swell.

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February 16th, 1928, and published in The Engineering Journal, March 1928.

(2) Vice-President and Chief Engineer, Duke Power Company, Charlotte, N.C.

(3) Vice-President, National Testing Laboratories Limited, Winnipeg.

Figure No. 21.—Spalling Caused from a Piece of Aggregate Containing Considerable Sulphates.

The author had shown an example of spalling caused by the decay of unsound stone, (see figure No. 4), and this recalled another interesting case of spalling inside of a building over water filters, as shown in figure No. 21. Under certain temperature conditions there had been considerable sweating on the surface of this concrete, but the concrete did not come in contact with other water. The stone causing the spalling was so soft and porous that it seemed impossible that it could have exerted much pressure, if any, on the surrounding concrete. The fact that the pores of the concrete near the piece of stone were filled with calcium sulpho-aluminate indicated that the soft stone had caused the flaking-off of the concrete by giving up sulphates to it and causing the surrounding concrete to expand. There were several spalled-off places in the building, this one being the largest, and the actions occurred after the building was twelve years old. The material remaining in the soft piece appearing dark in the photograph was found to contain 16 per cent of SO_3.

Volume changes due to moisture might be more serious than is generally believed. He had filled a glass tube about ¾ inch in diameter with neat cement mortar and allowed it to stand a few months tightly stoppered. When the glass was broken from around the mortar, the surface was very smooth. The piece was dried for a day at about 100° C. to be used in making a water absorption test. After cooling to room temperature and weighing it was immersed in water. The cracking of the surface could have been heard 10 to 15 feet away. When removed from the water two or three minutes afterwards, it was found that there was no place on the surface over one-half inch which did not have a noticeable crack. The conditions may have been ideal for crazing, but the experiment tended to confirm the author's views as to the cause of these cracks.

The "capillary pore determinator" deserved careful consideration. Mr. Baylis had given considerable thought to methods for measuring the pores in concrete that would not also measure the larger voids, such as spaces produced by air-bubbles in the concrete.[5] The method he had used was somewhat different from that given in the paper, but the results would be largely the same. It was found that when a piece of concrete was submerged in water the larger voids were not filled within 24 hours, and that this test gave a very good indication of the power of the concrete to resist the weathering agents. Due to the possibility of uneven distribution of the coarse aggregate in the mortar, the samples of concrete were crushed and all aggregate retained on the No. 8, (8-mesh), sieve excluded from the mortar measurement. By this method, the mortar volume

and the voids within the mortar were determined, which was the information desired.

He wished particularly to emphasize the importance of the author's statement:—"It is seldom that the deterioration of a concrete is caused by a single agency, for if it is of such poor quality that it is susceptible to one form of attack it is usually susceptible to others. . . . It is seldom possible to protect an exposed concrete from freezing temperature, but it is possible to build one in which the porosity has been reduced to a point where it is no longer damaged by frost action." Many erroneous conclusions had been formed as to the causes of concrete deterioration, and failure to realize the importance of porosity was causing the production of much concrete which would undoubtedly disintegrate in the near future. Surely this excellent paper would have some influence on the production of better concrete.

G. M. Williams, a.m.e.i.c.[6]

Professor Williams observed that, in spite of porosity and absorption, impermeable concretes can be made if proper attention is given to cement, aggregate and water. He would define the terms porosity, absorption and impermeability in much the same manner as the author had done, but would distinguish between porosity and absorption on the one hand and permeability on the other. As would be shown in the following tabulations, concretes varying from the richest to the leanest had almost identical total pore space, yet the degree of impermeability varied directly as the cement content. There were two methods in general use, both adapted to laboratory study, and one adapted only to field tests of concrete, by means of which a fairly accurate determination of total pore space in a concrete or mortar specimen could be made.

The method of absorption, used both in laboratory tests and in tests of set concrete samples obtained from structures, was not generally considered to be reliable, but he believed that this method permitted of a fairly accurate determination of total pore space. Unfortunately, as indicated by the test data, there was apparently little relation between pore space and concrete quality.

The computation of density or solidity ratio was especially adapted for obtaining this value for laboratory concretes, where the actual weights and specific gravities of all of the ingredients in a batch of concrete of known volume could be measured, but was of no value in the study of field concretes. The sum of the absolute volumes of dry materials in a unit volume divided by the unit volume was a measure of the density. For concrete mixtures, this was always less than unity and usually varied between 0.70 and 0.85. Porosity was computed by subtracting the density from unity.

Generally, in computing solidity ratio the specific gravity of the ground clinker was employed to obtain the absolute volume of the cement. This figure might vary from 3.08 for old storage cement to as high as 3.16. He used, and would suggest as a more accurate value, the specific gravity of hydrated neat cement. This figure is considerably less than that of the clinker, and for the tests reported below was 2.42. Such a figure resulted in a density which was more nearly the true solidity ratio of the hardened concrete.

Permeability was usually determined by applying water under pressure to one side of a test slab and noting the time required for water to appear on the opposite face, or the amount per unit area passing through in a given time, but the determination of the permeability of specimens of neat cements or rich concretes was very difficult, owing to the high water pressure required and the tendency to overstress the test specimen. For example, he had found that under certain conditions test slabs 2½ inches thick, when made of concretes of medium to dry consistencies, were impermeable for an indefinite time to a head of 80 feet when the cement content was more than 375 lbs. per cubic yard. Such a concrete with local materials having the proper

aggregate gradation had about a 1 to 6½ volume proportion. It had been fairly well established that, with other factors the same, permeability decreased with increase in cement content.

To illustrate the relations between strength, porosity, absorption and permeability, he gave the results of several groups of tests employing local aggregates, the results being typical of those obtained with the same materials and conditions of these tests, but quite consistent with the range in values found for aggregates, differing rather widely in gradation, from other sources. " Density " in the tabulations was the computed value for solidity ratio in which the specific gravity of the cement in the hydrated form was found to be 2.42.

" Porosity " is equal to unity minus the density. " Cement density " was obtained by dividing the absolute volume of hydrated cement by the sum of absolute volume of cement and void space. " Per cent absorption by volume " was obtained by immersion to practically constant weight. " Solids plus absorption " was the sum of the absolute volumes of solids in a test piece plus the volume of the absorbed water. When this value was divided by the volume of the test specimen a value of approximately unity was usually obtained.

Table No. I gave tests of mixtures ranging from neat cement to 1-3 mortar.

These figures indicated that the computed porosity was practically the same for 1-1 or 1-3 mortars, and slightly less than for neat cement. The slight differences found for absorption were not sufficient to distinguish differences in cement content.

For concrete, at an early age, the computed volume of solids in a specimen plus the absorption by volume was practically equal to the volume of the specimen. Disregarding the small volume of water absorbed by the aggregate particles, the absorption by volume appeared to be a measure of pore space in a mass. Tests made on the same specimens after they had been exposed to the air of the laboratory for about one year indicated an appreciable increase in dry weight, no doubt due to the carbonization of free lime, and when again immersed they attained practically their original wet weights, so that the percentage absorption by volume was less when determined with old specimens.

Permeability of the mortars increased as cement content decreased. The neat cement would be impermeable under all pressures, while the 1-3 mortar would be least water-tight under any given condition of test. Compressive strength and cement density decreased in the same order. Apparently there was no relation here between permeability and density or absorption.

Similar test data for concretes were shown in table No. 2. In this group the cement, aggregates and flowabilities were constants and cement content was the variable.

Compressive strengths, as would be expected, increased with cement content. Permeability tests showed permeability to decrease as cement content increased. The same relation held for durability in sulphate waters. The 1-4 mixture would rank highest, and the 1-6 lowest, with relation to these three important properties. Porosity and absorption seemed to have no relation to these properties, since pore space calculated as well as measured by absorption was a constant. The figures for cement density appeared to bear some relation to quality of concrete for this single aggregate gradation.

In tables Nos. 1 and 2 had been shown mixtures differing in richness or cement content, and no definite relation was apparent between quality of mortar and concrete, and pore space and absorption in the mass as a whole. The computed cement density was the one density figure which seemed to bear any relation to concrete quality. It should be noted here that whereas engineers to-day generally speak of density regardless of cement content, the earlier methods of proportioning concrete by the maximum density theory restricted the density comparison to concretes of equal cement content.

In table No. 3 were shown tests of three concretes of the same cement content, differing only in flowability which varied from dry plastic to wet; slumps from nil to about eight inches.

As would be expected, the mixture of lowest flow was the strongest; approximately 80 per cent stronger than the 206 flow concrete. Permeability tests indicated the times required for penetration through a 2½-inch test slab to be approximately 36, 24 and 12 hours respectively. Porosity and absorption both showed appreciable increases as flowability increased. These results indicated that variation in consistency may result in much greater variations in density than variation in cement content. Cement density, as in the previous tables, showed appreciable decrease as consistency increased.

It would be seen from the foregoing results that porosity may appear to be a criterion for quality when the comparison is restricted to concretes of the same cement content and containing the same aggregate gradation. For the same concretes, the compressive strength would appear to be just as satisfactory a measure.

He had not included any data to show the variation in physical properties with (*a*) change in gradation of fine aggregates or (*b*) change in relative proportions of fine and coarse aggregate. In general, coarser sands would increase the computed density and finer sands would lower the density, other factors being the same. In the same manner, reduction in sand content of the aggregate increased density while an increase tended to lower density. He had also found that with cement contents and flowabilities constant, highest strengths and most impermeable mixtures resulted from aggregate combinations somewhat lower in density than the maximum. Nor did it appear, when comparing aggregates from different sources, with cement content and flow constant, that the mixture of highest density was the concrete of best quality, as measured by strength or permeability tests.

The quality of the cement itself was no doubt an important factor in establishing the life of concrete. Studies had shown that different brands of Portland cement differed greatly in their resistance to sulphate action. It was possible that these same characteristics, which resulted in short life under such conditions, might also contribute to earlier breakdown where exposed to normal atmospheric conditions. For example, it had been noted that a Portland cement, meeting the requirement of the standard soundness test, but unsound when exposed to high-pressure steam, when made up into mortars and exposed to the dry air of the laboratory might crumble away in a few years, whereas the same brand of a cement, sound in high-pressure steam, was unaffected when exposed as a mortar to the same conditions.

He believed that there was no accurate measure of durability or life of concrete, but it seemed that exposure to sulphate waters should in some measure serve to classify mixtures in this respect. Experience had shown that concretes of high cement content were more resistant to sulphate action than those of low cement content; also, that medium dry, plastic mixtures were more resistant than wet flowable mixtures. Laboratory tests indicated those concretes most resistant to be more impermeable than less durable ones. It should be noted, however, that neat cements were less resistant to sulphates than very rich mortars or concretes.

He was of the opinion that the factors of porosity and absorption would give little or no indication of possible life of concrete, whereas strength and permeability, together with "cement density," whenever it was practicable to determine this factor, were fairly good measures of durability.

No doubt as progress was made in the study of cement itself, the engineer could build with greater assurance of permanence. As the author had pointed out, the majority of concrete structures were probably giving good service with ultimate life undetermined and probably sufficiently great to justify the continued use of concrete under most exposure conditions. In the meantime, long life could most certainly be assured by the use of rich plastic mixtures without the addition of more mixing water than is required for placing with a reasonable amount of labour.

Discussion of Paper on a Study of Transmission Line Power-Arcs by Paul Ackerman, A.M.E.I.C.[1]

A. E. Davison[2]

Mr. Davison observed that a feature which had an important bearing upon the protection of apparatus involved in power-arcs was the observation that arcs spread horizontally in a more marked way than they do vertically. This was to be noticed especially in the later pictures, where two post-type insulators separated possibly three or four feet from one another were used to support the lead which carried the loops between which the power-arc was to play and to be studied.

A review of the paper indicated that the performance of the arc between the loops was given much attention as follows:—

(a) Early bending of the arc.
(b) Marked chimney effect.
(c) Change in the resistance of the arc due to short-circuiting of the chimney effect and to various offshoots or irregularities.

Without having a further opportunity to study the films and photographs he had carried away from the meeting, the above impression was regarding the performance of these arcs, namely, that each arc seemed to be cut off about the time that the base of the arc had travelled laterally down the loops, over the first, or nearest insulator, across the lead between the two units, and until it reached the lead outside the second insulator from the loop. At this point the circuit was opened. These arcs did not travel down the loops and across the lead between the two supporting insulators uniformly on each side of the gap, possibly because of a slight wind or other similar irregularity.

If this observation were correct, he wondered whether the author was impressed at the time the work was done with the difficulty of controlling these arcs insofar as they involved the leads.

Was it not an observed fact, that whereas the distance from the top of the horn to the top of the arc was, say, six feet, the distance out to out of the arc horizontally at the close of each experiment must have been of the order of three times that dimension. Doubtless there was in this experiment some repulsion of the two arc columns; however, there seemed to be considerable evidence that once arcs of the type with which the author had experimented were set up long enough to burn appreciably any conductor with which they are connected, then it might be expected that they could not be confined to a reasonably limited part of the apparatus or equipment.

He believed that the author had done the electrical industry a great service in his work on arcs, and should be complimented on his experimental work and his thoroughly modern methods of recording it.

C. R. Reid[3]

Mr. Reid desired to congratulate the author on the adoption of such a bold method for obtaining the desired information, and for the thorough and systematic manner in which his experiments were carried out. The results obtained confirmed operating experience to a great extent, and shed a good deal of light on the limitations of air break switching in particular. In this connection the formula for critical arc length and data given in table No. 4 should be of especial value to the designer and operating engineer in determining the conditions under which a circuit may be safely interrupted on an air break switch.

There might be some difference of opinion in regard to the conducting medium of the arc. In some quarters this medium was regarded as the metallic vapour derived from the arcing surfaces. This question, however, had no bearing on the practical value of the paper. The author had pointed out the sensitiveness of the arc to air currents. This was of importance in connection with the design of bushings and insulators, and was a point that the manufacturer might study more carefully. During a recent flash-over test of a 220,000 volt bushing the break-down arc formed as a true geometrical arc between the top and collar mounting of the bushing. However, the lower part of the arc was immediately carried up against the surface of the bushing by the rising current of heated air. It should not be forgotten, however, that if a power-arc had been present, the magnetic flux set up by it might have been sufficient to hold the arc out away from the bushing surface.

Discussion on "Forest Conservation in British Columbia," by Mr. P. Z. Caverhill[1]

A. C. R. Yuill, M.E.I.C.[2]

Mr. Yuill enquired as to the relation between the cost of reproduction of the forest and the revenue derived from stumpage.

The author replied that it was difficult to give a specific answer, since the cost of reproduction depended on the method of reforesting and on the damage done to the forest during the process of logging. High-lead logging, which came into use ten years ago, was, of course, economical mechanically and enabled large areas to be dealt with which could not be logged by other methods; the apparent destruction in small material was largely offset by taking timber from steep slopes. Notwithstanding the débris left, many extensive areas, as, for example, spruce forest in the Queen Charlotte islands, had been logged by this method and had shown satisfactory natural reproduction. Similar experience had resulted in the case of Douglas fir, where eight or nine years after logging, young trees in excess of five hundred per acre had been found on 60 per cent of the areas examined and on 87 per cent of the areas where fire had been kept out. All factors governing the natural seeding of Douglas fir were not thoroughly understood, though it appeared that while Douglas fir seed will easily travel a quarter of a mile, cases had been observed of seedlings starting as far as three-quarters of a mile from the parent tree. It was, however, true that some areas, when burnt or logged, would be seedless unless seed trees had been left. An important problem was the protection of such seed trees, which are particularly liable to be blown down owing to their exposed situation and are open to damage from slash fires and other causes. Replanting would have to be employed to fill up spaces where natural seeding cannot be obtained. As to the cost of forest reproduction in British Columbia, he observed that planting might cost from $15.00 to $20.00 per acre, and no return could be expected from this outlay for fifty or more years. He deprecated the practice of estimating the cost of artificial planting by assigning compound interest to the original cost of planting, as even if the planting cost were as low as five cents per tree, this sum at compound interest for seventy-five years would reach a prohibitive value.

Major McHugh enquired as to the method adopted in the Okanagan district, where it appeared to him that selective logging would be necessary.

The author replied that such selective logging would probably be advisable in the future in districts where conditions were such as to make it possible. He observed that the selective system, as carried out in Europe, is applied successfully where the timber is small and transportation facilities are good, these conditions being characteristic also of certain localities in the Okanagan. He looked forward to the time when, in the somewhat distant future, selective logging would be possible over a great part of the second growth forests of the province.

Major McHugh was glad to hear this and hoped that in deciding upon the logging methods to be permitted, due consideration would be given to the effect of the removal of the forests on the natural flow of streams and rivers, particularly with regard to the fisheries of the province. He hoped also that it would be possible to pay more attention to the disposal of slash.

The author replied that the cost of piling and burning slash might run to $1.25 per acre, and that at present money for this purpose was not available. On the other hand, if the slash were allowed to remain upon the ground, it not only increased the fire hazard, but endangered the neighbouring standing timber, because it afforded a breeding place to certain bugs and wood-eating beetles which attacked neighbouring trees.

In conclusion, the author pointed out that there were three practical methods of artificial reforestation:—(a) The raising of seedlings from seeds in nursery beds, these being transplanted and finally placed in position in the woods when three or four feet high, the number planted ranging from 500 to 5,000 per acre, depending on the class of timber desired. If not planted sufficiently close, the development of limbs would be encouraged, and the resulting timber would have too many knots. If planted too close, subsequent thinning was necessary. (b) Broadcast seeding, the disadvantage of this being the high cost of seed, which may range from $1.00 to $10.00 per pound. As a rule, the results had not been encouraging, as small rodents busily collected the seed as soon as it was scattered and stored it up for their winter use. When seeding took place under natural conditions, the trees did not drop their seed all at one time, and the period of scattering of the natural seed extended over several months. In this way, the forest animals had not so much chance for collecting and wasting this valuable material. (c) The third method was spot-seeding, where small spots were prepared as beds to receive seed at regular intervals; this had proved more successful than broadcast seeding.

Memories of the Cariboo Trail

Busy with the affairs of today, we are apt to forget the achievements of our predecessors, and often take as a mere matter of course the advances they made in opening up the country, and in making it possible to provide the facilities for transportation and the conveniences of life which we now enjoy.

Much of our progress in Canada is based on the work of the "old-timers," as they are affectionately termed in the west. Their lives, whether spent in pioneer exploration, construction, or development, were tinged with a romance of which they never dreamt. We need only recall, for example, the picturesque scenes which must have occurred along the Fraser river in the sixties, when, as Patrick Philip, M.E.I.C., told us in describing the old Cariboo Road at the recent Professional Meeting in Vancouver,* stage coaches, gold escorts, prairie schooners, and travellers of all kinds thronged that rugged highway, a road which had been developed from a mule trail, and then formed the only means of through communication between the coast and the rich mining region four hundred miles in the interior of British Columbia.

Appreciation of such pioneer spirit as that which actuated the builders of the Cariboo Road is a very proper function of The Engineering Institute of Canada. Much has been done towards the recognition and marking of our historic sites in Canada, and this work is carried on by a number of public bodies, such as the Historic Sites and Monuments Board, but in many cases the people and events commemorated are connected with war-like or political events rather than with industrial progress, and The Institute can fitly associate itself with movements drawing attention to the peaceful work of the early engineers and constructors.

It is not often possible to erect a monument recording at the same time both the accomplishment of an arduous task, and the admirable qualities of the body of men who carried it out, but an opportunity of this kind has recently occurred on the completion of the new motor road through the Fraser canyon.

On Dominion Day, this year, there was unveiled at Spuzzum, on a cairn near the new Alexandra suspension bridge across the Fraser river, a bronze memorial tablet to the memory of the detachment of Royal Engineers who founded New Westminster and built much of the original Cariboo Road. The Chairman of the Vancouver Branch of The Engineering Institute, in his address on that occasion, suggested that there was something of Imperial significance about the day's ceremony. In using this phrase the word Imperial was not used in any boastful sense, but because the event commemorated, and the body of men to whom honour was rendered, may be regarded as typical of the agencies which give the widely separated constituent portions of the Empire their mutual interests. Such links do not necessarily depend on written treaty or act of parliament, but their effectiveness is due to the memory of past achievement and the possession of common traditions.

The Engineering Institute of Canada and the Association of Professional Engineers of British Columbia have joined in erecting this memorial cairn and tablet, and in doing so have placed a memorial to a body of men belonging to a distinguished corps, who, as the event proved, exemplified the qualities of idealism, practical ability and sound common sense, combined with a love of the Old Land from which they came and the New Land to which their duty led them.

The majority of our historic memorials have been erected to the memory of individual pioneers, explorers, soldiers or statesmen, thus the Fraser canyon monument is somewhat unusual in being dedicated to a body of men and their joint contribution to the welfare of the country.

The tablet was unveiled by Judge Howay, of Vancouver, well known as an authority on the history of British Columbia, who pointed out that this party of Royal Engineers, sent out by Lord Lytton, and chosen for this duty from among hundreds of volunteers, were the first builders of roads through the wilds of the lower mainland of British Columbia, and that they developed such an attachment for their adopted country that none of them, except the officers, elected to return to England when their task was finished.

The road, of which these Royal Engineers built the original portion through the Fraser canyon, has now been developed by the provincial government as a portion of the main highway from Vancouver to Prince George, and many miles of it will, before long, form an integral part of the trans-Canada highway. The scenery through which it

* See The Engineering Journal, July 1928, p. 399.

passes, the engineering difficulties which have attended its construction, and the road as finally completed, were fully dealt with in the address by Mr. Philip, to which reference has already been made. The motorist will now travel with speed and comfort through the canyon where, in the days of the gold rush, the slow-moving wagons struggled with the difficulties of the way.

The contrast between the modes of travelling then and now reflects the change in the spirit of the age. It is true that for a time, the old trail having grown into disuse, everyone supposed that the place of highway traffic had been taken for all time by the railways, and indeed portions of the original Cariboo trail were destroyed, either by the construction of the Canadian Pacific on one side of the canyon or the Canadian Northern on the other. With the coming of the motor, however, this was all changed, the necessity of road transport was recognized anew, and the Cariboo road now stands as a monument, not only to its original builders, but also to the far-sighted highway policy of the government of British Columbia.

Recent Progress in Aeronautics

A very complete periodical review of recent progress in aeronautical science is to be found in the Annual Report of the British Aeronautical Research Committee. This Committee's report for 1927-28, which has just been issued,* covers an extremely wide field of work and investigation, ranging from the standardization of symbols to the solution of theoretical and experimental problems in hydrodynamics.

An important decision taken by the Committee, following an interchange of information between the Aeronautical Research Committee and the United States National Advisory Committee for Aeronautics, has been the establishment of a compressed air tunnel at the National Physical Laboratory, which will have a working section five feet in diameter, and in which experiments can be made under air pressures as high as twenty-two atmospheres. The necessity for this equipment arises from the fact that it is impossible to test small aeroplane models in conditions really corresponding with those experienced by the full sized machine, since the Reynolds Law of Comparison, on which model experiments are based, breaks down if the speed of flow approaches the velocity of sound. Fortunately, tunnel experiments carried out under pressure remove this difficulty, since at high air-pressures conditions of dynamic similarity between model and aeroplane can be secured without requiring excessive air speeds. It is expected that work with this tunnel will be particularly valuable in making researches on the thick winged sections from which so much has been expected. The Committee points out, however, that ample facilities must still be provided for full scale experiments as an ultimate standard of reference.

It is interesting to note that a number of British models have been tested in the United States variable density wind tunnel, and the Committee acknowledge their indebtedness to the United States authorities in this connection, the American tests affording a notable example of international scientific co-operation.

Airscrews have been the subject of much study during the past year, particularly with regard to the conditions necessary for operation with high tip speeds. There seems no doubt that consultation between research workers and designers in Britain had much to do with the Schneider Cup victory last year, for a great deal of the research work on which the design of the successful machine was based was carried out at the National Physical Laboratory, under the auspices of the Committee. Further work on sea planes is in progress, and a high speed tank for hull and float-resistance work is being constructed.

Considerable advances have been made in the study of the effect of lead ethyl and similar substances in stopping detonation in engines, the Committee's work being directed towards ascertaining the physical principles on which the prevention of knock must be based.

In connection with the proposed extensive flights of the large airships now being constructed in Britain, there has been further inquiry as to the stresses to which such vessels may be subjected in flight or when moored to a mast, and for this purpose a research on wind structure has been commenced, with a view of obtaining some indication of the forces that may be experienced by a moored airship.

The Committee is of the opinion that during the next few years the most important requirements for successful commercial air transport will be an engine of large horsepower, burning a heavy fuel-oil and economical in fuel, thick-winged monoplanes, all-metal structures, and the use of pusher airscrews and geared engines, with a view of decreasing the discomfort to passengers from noise.

In regard to stability and control, various methods of using slots at the wing tips to improve stability and control are being extensively tried, and a scheme of standard tests for balance, stability, and controllability to be applied to every new type of aeroplane is being worked out. Progress is also being made in the study of the spinning of aeroplanes. The Committee has paid considerable attention to problems of fluid motion, both theoretically and by experiment.

An interesting series of investigations is being carried out on the effect of small obstacles or projections on the drag of an aeroplane body, this having been rendered necessary by lack of precise knowledge as to the extent to which, for example, the projecting cylinders of air cooled engines give rise to unnecessary resistance to the rush of air.

The study of compression-ignition engines is being proceeded with. The advantages offered by an engine of this type would include the diminution of fire risk by using a fuel of high flash-point; a fuel consumption as low, if not lower, than that of a gasoline engine; a cheap fuel, and the elimination of electrical ignition. On the other hand, difficulties due to starting, and the greater ratio of weight to horse-power of the engine would have to be overcome.

Among other topics dealt with in the report of the Committee are the use for fuel of hydrogen withdrawn from the ballonets of an airship, thus utilizing some of the gas which has, in the past, had to be wasted when the airship's lift has to be reduced to correspond with the gradual reduction in load; methods of securing more efficient control of aeroplane carburetors in flight; the fatigue of metals when subjected to corrosive agencies and to alternations of stresses of very high frequency up to 15,000 cycles per second; the torsional vibration and critical speed of crankshafts; and problems connected with the prevention of fire in aircraft resulting from a crash.

During the year over sixty important reports have been approved for publication, and last, but not least, the work of the Committee has been carried out after discussion of its programme with representatives of the Society of British Aircraft Constructors. It is satisfactory to note such close co-operation between a technical and scientific body, and the manufacturers who are particularly interested in its work.

OBITUARIES

William Boyd Davis, A.M.E.I.C.

It is with deep regret that we record the death of William Boyd Davis, A.M.E.I.C., which occurred at the Western Hospital, Toronto, on July 26th, 1927, after a long illness. The late Mr. Davis was born at Ivy, Ontario, on August 9th, 1889, and graduated from the University of Toronto with the degree of B.A.Sc. in 1912. Immediately on graduation Mr. Davis became a leveller on the Trent canal, and continued in this capacity until 1914 when he was made assistant engineer, which position he held up to the time of his death, being at that time in charge of the Severn division. Mr. Davis joined The Institute as an Associate Member on June 27th, 1922.

Charles Napier Wylde, A.M.E.I.C.

Members of The Institute will learn with regret of the untimely death of Charles Napier Wylde, A.M.E.I.C., which occurred on August 26th, 1928, as a result of injuries received at the plant of the Dryden Paper Company at Dryden, Ontario. Mr. Wylde, who was born at Montreal on November 13th, 1898, was educated at Lower Canada College, afterwards proceeding to the Royal Military College, Sandhurst, England, where he was trained for the Imperial army. Following graduation he was granted a commission in the Royal Fusiliers and proceeded overseas with his unit. When unable to serve further in France on account of his wounds, he was returned to England, and later served in Ireland.

In 1921 Mr. Wylde returned to Canada, and in 1923 graduated from McGill University with the degree of B.Sc. On graduation he became identified with the firm of Charles Walmsley and Company, Limited, but severed his connection with that firm in 1925 to join the Dryden Paper Company, Limited, where for two years he was in charge of the steam plant and electrical equipment. In 1926 he was placed in charge of mill maintenance and new construction work, and in June 1927 he was appointed chief engineer of the company, which position he occupied at the time of his death.

Mr. Wylde joined The Institute as a Student in 1921, and was transferred to the class of Associate Member in 1927.

PERSONALS

Elbert H. Hayes, S.E.I.C., who graduated from the University of New Brunswick in 1928, is now connected with the engineer division of the Northern Electric Company at Montreal.

F. D. Taylor, S.E.I.C., is now connected with the Canadian International Paper Company at Hawkesbury, Ont. Mr. Taylor graduated from McGill University this Spring, with the degree of B.Sc.

H. J. Racey, S.E.I.C., is at present field engineer on the investigation of the St. Maurice river with the Shawinigan Engineering Company, Limited, at La Tuque, Que. Mr. Racey graduated from Queen's University this Spring with the degree of B.Sc.

Marc Boyer, S.E.I.C., who graduated from the Ecole Polytechnique in 1928 with the degree of B.Sc., is now connected with the Consolidated Mining and Smelting Company at Trail, B.C. During the summers of 1925, 1926 and 1927, Mr. Boyer acted as transitman for the Quebec Streams Commission.

A. W. Swan, A.M.E.I.C., formerly assistant editor of this Journal, and now publicity manager for Evershed and Vignoles Limited, electrical engineers, London, England, has recently been on a visit to Canada. While here Mr. Swan was married at Magog, Quebec, on August 14th, and has returned with his wife to England, where he will reside.

Syd. H. Davis, A.M.E.I.C., who graduated from McGill University in 1923, is now field engineer with J. M. Forbes, consulting mining engineer of Sudbury, Ontario. Mr. Davis was formerly connected with the Gatineau Power Company as resident engineer for highways and bridges and later as engineer with the development department.

Captain C. R. S. Stein, R.C.E., A.M.E.I.C., is at present stationed at Military District No. 5, Quebec, Que. Captain Stein has just returned from England, where he has been attached to the Royal Military College at Woolwich. Prior to going to England, Captain Stein was district engineer officer for Military District No. 10 at Winnipeg, Man.

E. G. Cullwick, Jr.E.I.C., has accepted a position as assistant professor of electrical engineering in the University of British Columbia. Mr. Cullwick, who graduated from Cambridge University in 1925 with the degree of B.A. in engineering, was for some time connected with the Canadian General Electric Company, Limited, at Peterborough, Ontario.

Thomas Foulkes, S.E.I.C., has accepted a position in the electrical department of the Spruce Falls Power and Paper Company at Kapuskasing, Ontario. Mr. Foulkes graduated from the University of New Brunswick in 1926 with the degree of B.Sc., and was formerly connected with the Canadian General Electric Company at Peterborough, Ont.

Gordon H. Kingan, Jr.E.I.C., who graduated from McGill University in 1925 with the degree of B.Sc., has resigned from the staff of the Riordon Pulp Corporation, Limited, at Temiskaming, Que., to which he has been attached since graduation, to accept the position of designing engineer on the Montreal staff of the Fraser Brace Engineering Company, Limited.

A. S. Rutherford, S.E.I.C., is at present acting in the capacity of superintendent with the George A. Fuller Company of Canada, Limited, on the construction of the new Dominion Square Block in Montreal. Mr. Davis, who graduated from McGill University with the degree of B.Sc. in 1922, was formerly with the Church Ross Company, Limited, as superintendent of construction and had been connected with that firm since 1923.

H. W. R. Shepherd, A.M.E.I.C., recently severed his connection with the James Ruddick Construction Company in Quebec to accept the position of resident engineer with the Foundation Company on the construction of the Ghost river dam for the Calgary Power Company. Mr. Shepherd was formerly resident engineer for the highway department of the province of Alberta, and from 1914 to 1919 was overseas with the Alberta Dragoons and the Second Battalion of Canadian Engineers.

Stanley R. Job, A.M.E.I.C., of Niagara Falls, Ontario, is at present connected with the Herbert Morris Crane and Hoist Company on the design and detailing of cranes. From 1920 to 1922, Mr. Job was designer in the hydraulic department of the Hydro-Electric Power Commission of Ontario, and in 1924 he was assistant mechanical engineer and resident engineer on construction of an elevator at Port Colborne for the Department of Railways and Canals. In 1925, he was assistant designer of mill buildings for the Acheson Graphite Company at Niagara Falls, N.Y., during 1926-27, he was assistant designing engineer on the building of the Canadian Shredded Wheat Company, and prior to accepting his present position he was designing engineer and draughtsman for the Light and Power Manufacturing Company at Niagara Falls.

J. L. Bieler, S.E.I.C., has recently accepted the position of assistant engineer with the Dominion Oilcloth and Linoleum Company in Montreal. Subsequent to his graduation from McGill University with the degree of B.Sc. in 1923, Mr. Bieler took an engineering course with the Bailey Meter Company in Cleveland, Ohio, and remained with that firm until 1925, being on the sales and service staff and in the research department. In 1925, Mr. Bieler was in charge of a party on a Gatineau river power survey, and from January to June 1926 he was engineer with the Consolidated Pipe Company. During the years 1926 to 1928 he was sales engineer and later chief engineer of Industrial Combustion Engineers, London, England.

K. G. Cameron, A.M.E.I.C., has been promoted to the position of assistant chief engineer of the Canada Sugar Refining Company, Limited. Mr. Cameron, who is a graduate of Edinburgh University of the year 1912, was designing engineer with this company until his recent promotion. He came to Canada immediately after graduation, and was on the engineering staff of the bridge department of the Grand Trunk Railway from 1912 to 1916. He was for a number of years located in Nova Scotia, and occupied the position of chief draughtsman in the mechanical department of the Dominion Iron and Steel Company at Sydney, N.S. While located at Sydney, Mr. Cameron was secretary-treasurer of the Cape Breton Branch of The Institute.

A. L. Morgan, A.M.E.I.C., formerly assistant chief engineer of the Canada Sugar Refining Company, Limited, has been appointed chief engineer of that company. Mr. Morgan is a graduate of Queen's University, from which he received the degree of B.Sc. in mechanical engineering in 1912. Prior to entering the university, he had considerable machine shop and draughting experience, and upon graduating he became designing engineer with the mechanical equipment department of the locomotive plant and power house of the Canadian Locomotive Company at Kingston, Ontario. Subsequently, he occupied various positions with industrial manufacturing concerns until March 1st, 1923, when he was appointed assistant chief engineer of the company with which he is now engaged.

Captain W. A. Irvine Grim, M.E.I.C., is at present connected with the Lago Petroleum Company at Tampico, Tamps, Mexico. Captain Grim has been located in Mexico for a number of years, having been engineer in charge of standard gauge railways and irrigation system for the United Sugar Companies at Los Mochis; with the Rockefeller Foundation of New York as secretary to the commission at Colima, Col.; and with the Huasteca Petroleum Company at Tampico. Captain Grim was on active service overseas from 1914 to 1919, being attached to the 16th Battalion of the Canadian Scottish from 1914 to 1917 and to the Canadian Engineers from 1917 to 1919. He enlisted as a private, was commissioned lieutenant in 1915 and was made a captain in 1917 when he was transferred to the Canadian Engineers.

Harry J. Buncke, M.E.I.C., has been appointed chief engineer of the Abitibi Power and Paper Company for the entire group of mills. Mr. Buncke graduated from Columbia University with the degree of C.E. in 1915, and, in 1916, having taken a special course in pulp and paper manufacture at the University of Maine, obtained the degree of M.S. from that institution. In 1916, Mr. Buncke joined the staff of the Abitibi Power and Paper Company as draughtsman and general assistant to the master mechanic, and in 1917 he was appointed superintendent of the groundwood mill. In 1918, he served as first lieutenant in the United States Engineers. In 1919 he became technical assistant to the manager of the Abitibi Power and Paper Company. In 1921, he was promoted to the position of plant engineer, and from 1923 onwards was chief engineer of the Iroquois Falls division of the company. Mr. Buncke was the author of the section on groundwood pulp in " The Manufacture of Pulp and Paper," and is the present chairman of the technical section of the Canadian Pulp and Paper Association.

Charles C. Ross, M.E.I.C., Receives Appointment

Charles C. Ross, M.E.I.C., who was recently appointed by Hon. Charles Stewart, Minister of the Interior, to set up departmental administrative machinery in northern Manitoba and northern Saskatchewan in connection with the mining development which is taking place there, is a well-known member of the Calgary Branch of The Engineering Institute of Canada, where for the past ten years he has been in charge of the department's administrative work in Alberta relating to mineral development.

The appointment of Mr. Ross to set up the local administration in the new mining fields of Manitoba and Saskatchewan and to recommend to the government such changes in the mining laws and regulations as will speed up development and place the industry on a sound basis for future expansion, is a popular one which has brought forth commendation from the press in the prairie provinces. The Calgary *Herald*, in commenting on Mr. Ross' promotion to a larger field of activity, sees much reason for satisfaction in the announcement that the appointment does not mean that his supervision of Alberta's resources will cease, and that, on the contrary, one of his important functions will be the continued administration of all mining and oil regulations in that province.

Mr. Ross, who graduated from McGill University in 1909, went to Calgary in 1916. As senior mining inspector and later as supervisory engineer for the Department of the Interior, he accomplished noteworthy results in the evolu-

CHARLES C. ROSS, M.E.I.C.

tion and harmonious operation of the regulations for the development of the mineral resources of the prairie provinces. He has been chosen to organize the administrative machinery necessary to perfect a similar satisfactory service in northern Manitoba and northern Saskatchewan and also in the Northwest Territories as development may proceed.

Mr. Ross has lately returned from a trip of inspection of the Flin Flon, Cold Lake, Lac La Ronge and other mining regions which come under his new jurisdiction. One of his first and most important undertakings will have to do with alteration of the Quartz Mining Regulations, revision of which is under consideration by the federal government, which administers the resources of the western provinces. The solution of the problems arising in the development of the new mining areas of northern Manitoba and northern Saskatchewan will devolve on Mr. Ross, and those who know him feel that the undertaking is one for which the former Ottawa and McGill hockey and rugby star is adequately equipped.

John Grieve, M.E.I.C., Joins Brandram-Henderson, Limited

John Grieve, M.E.I.C., is now connected with Brandram-Henderson, Limited, Montreal, as general sales manager of industrial sales. In order to accept this position Mr. Grieve resigned from the Dominion Paint Works, Limited, with which firm he had been connected since 1914, and of which he was director and general manager of sales, and from the Detroit Graphite Company of New York, N.Y., with which firm he has been connected for some time. Mr. Grieve's early education was obtained at the Heriot Watt College, Edinburgh, Scotland, and as apprentice to Messrs. Carrick and Ritchie, crane and hydraulic engineers, after which he was draughtsman for Messrs. George Russell and Co., Ltd., Motherwell, Scotland, chief draughtsman for the Steel Company of Scotland, Hallside works, Newton, draughtsman and resident engineer in charge of mill equipment, Lanarkshire Steel Company, Limited, Motherwell, and on coming to Canada in 1911 was connected with the Dominion Bridge Company on designing and estimating.

Leonard E. Schlemm, M.E.I.C., Elected Director of Algoma Steel Corporation

Leonard E. Schlemm, M.E.I.C., who was recently elected a director of the Algoma Steel Corporation, Sault Ste. Marie, Ont., is a consulting landscape architect and town planner, practising in Montreal. He is also a director of the Lake Superior Corporation, and more recently was elected to the boards of the Lake Superior Coal Company, the Cannelton Coal and Coke Company and the Algoma Eastern Railway Company. Mr. Schlemm graduated from the Massachusetts Institute of Technology in 1903, and commenced his professional career as topographer and instrumentman with the Gulf, Colorado and Santa Fe Railway on location surveys, and was later connected with the engineering department of the Chicago North Western Railway on reconnaissance and location surveys. From 1908 to 1910 Mr. Schlemm was connected with Brett and Hall, landscape architects of Boston, being in responsible charge of all construction, and from 1910 to the present time he has been in private practice as consultant in landscape architecture and town planning. Mr. Schlemm is a member of the Boston Society of Civil Engineers, the Town Planning Institute of Canada, and the Corporation of Professional Engineers of the Province of Quebec, and is also a member of various town planning organizations such as the International Cities and Town Planning Association, National Housing Association, and the Town Planning Board of the Metropolitan District of Montreal. Mr. Schlemm is a member of the advisory board of engineers of the Metropolitan Commission for the Island of Montreal.

Canadian Engineering Standards Association Progress of Work

(*First half year 1928*)

Branch of Industry and Subject

Subject	Specification No.	Stage of Progress
A—Civil Engineering and Construction		
Steel Railway Bridges	A1—1928	6

Stages of Progress:—

1. Decision made to undertake standardization.
2. Draft proposal under consideration.
3. Sent out for criticism.
4. Submitted for approval.
5. Approved for publication.
6. Published.

The letter R following the number of stage of progress indicates that the respective specification is under revision.

Link-Belt Limited has just issued Crawler Crane Book No. 995, entitled "Built for Service," which is one of the most attractive and complete of its kind ever published. It covers the complete Link-Belt line of gasoline, Diesel and electric crawler cranes of capacities up to and including the 2 cu. yd. heavy duty machine, as well as standard locomotive cranes.

The Northern Electric Company, Limited, has just issued Bulletin No. 121, describing a wide assortment of standard designs of double deck bus bar supports, which have been produced through the enterprise of the manufacturers, The Electrical Engineers' Equipment Company, and are now available in Canada from the Northern Electric Company. Copies of this booklet may be obtained from the Power Apparatus Department, Northern Electric Company, Limited, 121 Shearer street, Montreal, Que.

W. McG. Gardner, A.M.E.I.C., Branch News Editor.

PRELIMINARY FALL PROGRAMME

The Papers and Meetings Committee are now able to release a tentative programme of branch activities for this autumn. The high professional standing of the prospective speakers, coupled with their comprehensive knowledge of the subjects chosen for their addresses, promise a programme of exceptional interest to all members whatever their specialty. Attendance at these meetings, whether or not the subject is representative of the field of our own particular endeavour, will broaden and intensify individual opinion and interest in the vast expanse of our great profession, create and renew enthusiasm in its far reaching accomplishments, extend and strengthen our contacts with fellow members.

Membership in The Institute is an honour and privilege charged with responsibility. We have each undertaken to facilitate the acquirement and interchange of professional knowledge, encourage original research, promote the interests of the profession by developing and maintaining high engineering standards and to enhance the appreciation of the public for our work by the notable character of our service.

By their presence at these meetings senior members add prestige and dignity to the proceedings, extend honour to the speaker, who by reason of this appreciation will more usually be a leader in the profession. The example set by their attendance will draw the attention and interest for personal improvement of the junior members to whom the opportunities will be self-evident.

Oct. 4—Water Turbines....by H. A. Van Patter, A.M.E.I.C.
" 11—Ville Emard Sewer...by G. R. MacLeod, M.E.I.C.
" 18—Lap Pipe Joints..................by A. M. Houser
" 25—Anticosti Development, by J. H. Valiquette, A.M.E.I.C.

" 20—Annual Meeting.

The Committee responsible for this programme would welcome any suggestions for future meetings that may be sent to any one of their number as follows:—

Chairman ....H. Massue, A.M.E.I.C.
Vice-Chairman ....J. L. T. Martin, A.M.E.I.C.
Civil Section:—Chairman.........A. Plamondon, A.M.E.I.C.
Vice-Chairman ....L. L. O'Sullivan, A.M.E.I.C.
Electrical Section:—Chairman....N. L. Morgan, A.M.E.I.C.
Vice-Chairman ....A. S. Runciman, A.M.E.I.C.
Mechanical Section:—Chairman..G. H. Dickson, A.M.E.I.C.
Vice-Chairman ....H. G. Thompson, A.M.E.I.C.
Municipal Section:—Chairman...J. F. Brett, A.M.E.I.C.
Vice-Chairman ....P. E. Jarman, A.M.E.I.C.
Railway Section:—Chairman....F. F. Clarke, A.M.E.I.C.
Vice-Chairman ....H. B. Montizambert, A.M.E.I.C.

TRANSOCEANIC WIRELESS TELEGRAPHY BY THE BEAM SYSTEM

Notable achievements accomplished by recent developments in wireless transmission were vividly presented before the branch on May 3rd, when in an enjoyable illustrated lecture and demonstration J. H. Thompson, A.M.E.I.C., chief engineer of the Marconi Wireless Telegraph Company, described "Transoceanic Wireless Telegraphy by the Beam System."

The continuous application of electrical discoveries to the wireless transmission of sound has been so remarkable, it is difficult to believe that hardly more than forty years have passed since Hertz announced the results of his scientific investigation on the production of electric or Hertzian waves. Yet today the development of electric waves telegraphy has revolutionized our means of communication across land and sea.

In the earliest stages the apparatus employed consisted of a simple transmitter and a receiver or coherer. Later huge reflectors were employed to collect the waves and concentrate them on the coherer.

The introduction of the aerial by Marconi, the first investigator to realize the practical possibilities of wireless, opened a wide field of application. Late in 1901 by suspending aerials from box-kites he succeeded in sending wireless signals across the Atlantic from Newfoundland to Cornwall, England. His success encouraged many other inventors and from that time onward progress has been rapid.

Wooden towers were subsequently substituted for the uncertainty of kites and ship stations were utilized to relay messages to distant destinations.

These early installations transmitting through the medium of an intermittent spark which dispersed waves equally in all directions proved inefficient under heavier service. As a consequence it was not long before the process of wave production was greatly improved by a method which placed the transmitting arc in an atmosphere of hydrogen, coal gas or other non-oxidizing gas, and at the same time subjecting it to the influence of a strong magnetic field. By this means an apparatus was developed capable of propagating continuous waves of an oscillation better suited to wireless purposes. With its introduction wider range and sharper tuning became possible.

This notable achievement was, however, hardly in use before the remarkable improvement in the construction of the vacuum or thermionic tube and the development of the Alexanderson high frequency alternator made their immediate installation desirable.

So effective was the latter device in creating waves of great power that its introduction made possible the equipping of long distance stations capable of transmitting directly across the world. Nevertheless the development of these long wave installations was impeded by the ohmic resistance of the atmosphere which in contrast with the radiation resistance is high. The great masts and heavy antennæ proved a source of heavy expense while the problem of adequate insulation for such high voltages provided another serious limitation. In illustration a station in France was equipped with an 820-foot mast supporting an antennæ weighing 3½ tons of 1,000-k.w. capacity and 200,000 volts pressure. Due to frequent fires Oregon pine masts were found unsuitable under such circumstances and very light triangular steel columns were substituted in their place.

Long wave transmission is further handicapped by the difficulty experienced in attempting to concentrate the radiated energy in any one direction. While this may be achieved by ranging parabolic reflectors round the antennæ at the centre the device is awkward to build and almost prohibitive as to cost.

A far simpler method of controlling the direction of propagation is found in the erection of two parallel aerial curtains situated at right angles to the desired transmission.

The forward curtain, made up of antennæ coils suspended in double triangles as a check against windsway, is placed a half wave length in advance of the second or reflector coil curtain. Both hang vertically in space with the reflector coils directly to the rear, in which location they serve to reflect the energy emanating from the antennæ curtain, returning it in place to be projected forward as one solid sheet of current.

The utilization of such a device is so advantageous that employing the same energy of transmission it has been found possible to increase the field strength 200 times.

Many auxiliary appliances, such as wave suppressors, phase shifters and condensers, assist in the attainment of this accomplishment while the feeder distribution system creates problems of tube insulation and expansion besides the usual necessity of being electrically balanced as regards to distance from the transmitter. When the station is not sending, absorbing valves utilize resistances to soak up the current.

In order to detect the signals broadcasted from these very high frequency continuous wave beam stations, it is necessary to resort to heterodyning. By this process a second current is superimposed on either the transmitting but more usually upon the receiving current of almost an identical frequency, when it becomes possible by making suitable adjustments to obtain a beat within the audible frequency.

In commercial electric wave telegraphy where continuous reception at all times is of primary interest the heterodyning and superheterodyning appliances become a very essential feature of the installation.

In describing the construction of the new short wave beam wireless station at Drummondville, P.Q., with its 25-kw. capacity and 300-foot masts, the speaker not only illustrated his remarks with lantern slides but demonstrated a machine used in transmitting messages.

This machine, controlled from a typewriter keyboard, punches paper tape before feeding it to a high speed key operating an oscillator where the current is modulated in preparation for the transmitter. This automatic modulator handles 120 words a minute. Samples of tape bearing "Greetings to The Engineering Institute" were distributed to the members.

The speaker referred to the advantage of high frequency transmission in the field of television and illustrated a new development whereby it is possible with paper made sensitive to hot and cold air currents to photograph these radio pictures.

In moving a vote of thanks, N. L. Morgan, A.M.E.I.C., while taking note of the rapid development, looked to even greater progress in the enormous field for advancement lying ahead where 2,000 words a minute will be attained.

G. A. Wallace, A.M.E.I.C., presided.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer

Visit of General Secretary

A special dinner meeting was held on Thursday, July 26th, at 6.45 p.m., to welcome R. J. Durley, M.E.I.C., the general secretary of The Institute.

Following the dinner two 400-foot films of Algoma were shown. These films gave a most vivid close-up view of the splendid fishing and hunting in this part of the country. As numerous speckled beauties were seen landed safely in the angler's net, the followers of Isaac Walton present began to get the fever, and it was only the lateness of the hour that prevented them hiking out to the nearby streams. But, oh boy! when a large bull moose came on the scene real excitement prevailed, but, thanks to the presence of Mr. Durley and the treat ahead, (as he had yet to address the branch), the members did not run home for their shooting irons.

In his remarks Mr. Durley expressed his pleasure at being back with the members of the Sault Branch. He outlined the year's work at headquarters and gave a general talk on his visit to the other branches. He expressed his satisfaction at the way the branches were increasing in membership and becoming stronger, and predicted a bright future for the Canadian engineer in Canada and, as he pointed out, that between 70 and 80 per cent of our graduates in the past ten years were still in Canada and not in foreign countries, as some people would like to believe.

The new venture of the council in getting out the E-I-C News was discussed and the reasons for getting this weekly bulletin was explained, and also the manner in which the branches could help in this venture.

A general discussion followed and many interesting points were brought out in regard to the relationship of the branches to headquarters and also in the way that branches and members could make it easier for the council.

Mr. Wilson expressed the feeling of all present when he said it was a pleasure to have Mr. Durley at the meeting and to hear him speak. He moved a hearty vote of thanks to Mr. Durley, which was unanimously supported.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

At a regular meeting of the branch, held on May 22nd, a very interesting paper was given by Nathan A. Bowers, Pacific coast editor of the Engineering News Record, on "The St. Francis Dam Failure." An attendance of seventy at a summer meeting testified to the interest taken by the members in Mr. Bowers' paper. Mr. Bowers was on the scene the day following the catastrophe, and his address was illustrated by lantern slides, the material for which was obtained by himself on the ground.

From samples of the material below the foundations, actually taken on the ground, and from photographs of the laying of the foundations and of the excavation prior thereto, the speaker maintained that the surprising thing was not that the dam had failed, but that it had stood as long as it did. The dam failed because the material under the foundation was not suitable for the purpose for which it was used. The loss of life and destruction of property was deplorable; but to offset that the work of rescue and of rehabilitation was swiftly and admirably organized and carried through.

On June 7th, 8th and 9th the General Western Professional Meeting was held in Vancouver. Full descriptions of this successful convention have already been given in The Journal. At a meeting of the Executive, held on July 18th, the Secretary-Treasurer submitted audited accounts of the convention, showing that the excess of receipts over disbursements amounted to $4.63.

Memorial to Royal Engineers, Dedicated at Spuzzum, B.C., July 2nd, 1928

On Monday, July 2nd, 1928, a party of engineers travelled from Vancouver to Spuzzum, B.C., for the purpose of dedicating a cairn that had been erected jointly by The Engineering Institute of Canada and the Association of Professional Engineers of the Province of British Columbia, to commemorate the work of the Royal Engineers in the construction of the original Cariboo road.

Unveiling of Memorial to Royal Engineers.

The cairn has been erected on the highway at the north approach to the Alexandra suspension bridge, which spans the Fraser river about one and one-half miles above Spuzzum, and is in a setting of wonderful beauty; the magnificence of the mountains and the rushing Fraser river combine to unite with the memorial as a lasting tribute to the skill and energy displayed by the Royal Engineers in the pioneer work of the early days.

His Honour Judge Howay, of New Westminster, B.C., accompanied the party and performed the unveiling ceremony.

W. Brand Young, A.M.E.I.C., chairman of the Vancouver Branch of The Engineering Institute of Canada, acted as master of ceremonies and in introducing Judge Howay paid tribute to his honour's services as historian of the province and to the splendid qualities of the Royal Engineers. He suggested that there was something of Imperial significance about that day's proceedings, and this simple ceremony would be the means of pulling just a little closer the common ties which bound us together. J. F. Frew, M.E.I.C., president of the Association of Professional Engineers of the Province of British Columbia, associated himself with Mr. Young in his introductory remarks.

Judge Howay dealt at some length with the early trading days, and spoke of the difficulties of transportation through this undeveloped section of British Columbia. He paid glowing tribute to the work of the Royal Engineers and to the calibre of the two companies of engineers who were sent out by Queen Victoria to this outpost of the Empire to assist in its early development.

His Honour recited the following well-known passage from the address delivered to them by Bulwer (Lord) Lytton, colonial secretary, before they left England:—

> Farewell! Heaven speed and prosper you. The enterprise before you is indeed glorious. Ages hence industry and commerce will throng the roads that you will have made. Travellers from all nations will halt on the bridges that you will have first flung over solitary rivers, and gaze on orchards and cornfields that you will have first carved from the wilderness. Christian races will dwell in the cities of which you will map the sites and lay the foundations. You go not as enemies but as the benefactors of the land you visit, and children, yet unborn, will, I believe, bless the hour when Queen Victoria sent forth her sappers and miners to found a second England on the shores of the Pacific.

George A. Walkem, M.E.I.C., past president of The Engineering Institute of Canada, proposed the vote of thanks to Judge Howay, following which refreshments were enjoyed picnic fashion.

The cairn is built of rough granite and is located at the end of a bend in the roadway as it approaches the suspension bridge. A bronze tablet has been built into the cairn, which bears the following inscription:—

> In commemoration of the work of His Majesty's Royal Engineers and in respectful admiration of the skill and energy displayed by them from 1859 to 1863 in the construction of the original Cariboo highway through the Fraser canyon, this tablet is erected and dedicated by The Engineering Institute of Canada and the Association of Professional Engineers of British Columbia.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

Structural Detailer

A firm of consulting engineers in Montreal has an opening for a young engineer with experience in timber and concrete designing and construction. Apply Box No. 35-V.

Sales Engineer

An engineering sales organization in Montreal requires the services of a recent graduate in mechanical engineering for work on the sales and installation of combustion and refrigeration equipment. Applicants must be able to speak French. This position is in Montreal. Apply Box No. 37-V.

Designing Draughtsman

A sales organization in Montreal requires the services of a draughtsman with experience in the design of concrete structures. Apply with full particulars to Box No. 41-V.

Sales Engineer

A large manufacturing company in Montreal has an opening for a graduate engineer on its engineering sales staff. The company manufactures pulp and paper machinery, and preference will be given to those having pulp and paper mill experience. Apply with full particulars to Box No. 55-V.

Mechanical Engineer

A Montreal company has an opening for a recent graduate in mechanical engineering for work in Ontario. The position is permanent. Apply with full particulars of qualifications to Box No. 56-V.

Resident Engineer

A public utility company which contemplates the construction of a large hydro-electric power development in the near future may shortly have an opening for a competent resident engineer with extensive experience on work of a similar nature. The date of commencement of the work is not yet decided, but applications will now be received for consideration. Apply Box No. 57-V.

Electrical Designer

A public utility company, which contemplates the construction of a large hydro-electric power development in the near future, may shortly have an opening for an electrical designing engineer with experience on work of a similar nature. The date of commencement of the work is not yet decided but applications will now be received for consideration. Apply Box No. 58-V.

Hydraulic Engineer

A public utility company which contemplates the construction of a large hydro-electric power development in the near future, may shortly have an opening for a competent hydraulic engineer with experience on work of a similar nature. The date of commencement of the work is not yet decided, but applications will now be received for consideration. Apply Box No. 59-V.

Situations Vacant

Supplies Engineer

Competent man familiar with up-to-date store keeping methods, to take complete charge stores department large public utility Brazil. Must be thoroughly experienced, good organizer, with sound knowledge material and equipment. Knowledge Portuguese or Spanish desirable but not essential; give full details education, experience and references. Apply Box No. 60-V.

Field Engineer

Recent graduate engineer wanted for laying out construction work and inspecting for large industrial and mining company in northern Quebec. Apply Box No. 61-V.

Designing Engineer

An engineer required to design reinforced concrete and structural steel for hydraulic structures. Location, Nova Scotia. Apply Box No. 62-V.

Railway Construction Engineer

A construction company in Montreal has an opening for an engineer with experience in railway construction. Applicants must be able to speak Spanish, as work is in Colombia. Apply with full particulars to Box No. 64-V.

Mechanical Designer

A well-known manufacturing company in Montreal has an opening for a young mechanical engineer for draughting and designing of mechanical equipment. Apply Box No. 68-V.

Electrical Engineer

Recent graduate required by a large electrical manufacturing concern for work on factory methods and manufacturing problems. Please state in first instance, education, full qualifications, references, salary required, age, and when available. Apply Box No. 69-V.

Railway Construction Engineer

A construction company with headquarters in Montreal has an opening for a young civil engineer with experience in railway location and layout. This position has a possibility of permanency, and the work will be in eastern Canada and the middle west. Apply Box No. 71-V.

Reinforced Concrete Designer

There is a permanent position available for a reinforced concrete designer with a large public utility organization in the province of Quebec. The work is in connection with structures for water supply systems. Apply Box No. 72-V.

Draughtsman and Designer

Experienced draughtsman and designer on railway location and construction in the province of Quebec. Applications must contain full details of experience and samples of drawings. Apply Box No. 73-V.

Situations Vacant

Assistant Distribution Engineer

Wanted by a large public utility in Brazil. Must be a university graduate with at least five years operating and construction experience after graduation, including underground and overhead light and power and tramway distribution combined with terminal station and substation operation. Apply, giving details of education, experience and salary, to Box No. 74-V.

Meter Engineer

Must be a graduate engineer with wide experience in various types of meters, particularly General Electric and Westinghouse, and competent to assume charge of meter department of a large utility in Brazil. Apply, giving details of education, experience and salary, to Box No. 75-V.

Municipal Engineer

Graduate engineer experienced in municipal work with a knowledge of sewer design and sewage disposal. Salary dependent upon qualifications. Permanent position. Apply, giving full details of experience, to Box No. 76-V.

Town Engineer

Town engineer for a town in the Maritime Provinces. Applicants must give full particulars as to qualifications, experience and salary expected. Apply to Box No. 77-V.

Crane Estimator and Designer

A Canadian manufacturing company, near Montreal, has a permanent position for a good crane estimator and designer. Apply, giving full particulars, to Box No. 80-V.

Situations Wanted

Electrical Engineer

Electrical engineering graduate of McGill University, age 27, single; five years public utility experience, including G. E. test course, extensive design of power stations and substations and industrial sales. Apply Box No. 8-W.

Electrical Engineer

Graduate of the University of New Brunswick in electrical engineering of the year 1926, with two years experience on the manufacture of electrical equipment, desires position with an industrial organization or on electrical construction. Apply Box No. 17-W.

Electrical Engineer

Recent graduate of McGill University in electrical engineering, with two years experience with large electrical manufacturing company, desires a position. Apply Box No. 19-W.

Construction Engineer

Construction engineer, 36 years of age, with considerable experience in municipal and power surveys, and municipal construction, is available for a position on similar work, preferably in Quebec or the Maritime provinces. Apply Box 25-W.

Chemical Engineer

Graduate McGill University '22, desires a position in the vicinity of Montreal. Apply Box No. 28-W.

Situations Wanted

MECHANICAL ENGINEER

Graduate of McGill University in mechanical engineering of the year 1912, with experience in hydro-electric work, development and nine years experience as manager in charge of a large industrial plant, and at present engaged in industrial consulting work, is available for a position with an industrial organization as plant manager, superintendent or assistant engineer, or as sales engineer on mechanical or construction equipment. Apply Box No. 31-W.

CIVIL ENGINEER

Graduate of the University of Toronto of the year 1911, with extensive experience in industrial development work, including preliminary survey, design and construction, is available for a position with a pulp and paper or power company as resident engineer or construction superintendent, or with engineering staff of some other industrial organization. Apply Box No. 33-W.

ELECTRICAL DESIGNER

Advertiser wishes to connect with contractor or consulting engineer who can offer part time electrical design work. Electrical engineer, B.Sc., M.Sc., P.E.Q., M.E.I.C. Advertiser, having considerable time available, would like to submit industrial power and lighting design and layouts to contractor or engineering firm. Experience includes design construction and testing of electrical equipment, supplemented by extensive installation, operation and maintenance practice. Apply Box No. 40-W.

ELECTRICAL ENGINEER

Young electrical engineer, graduate of University of British Columbia '25; fifteen months' electrical test course, C.G.E.; two years junior assistant engineer switchboard engineering department with large electrical manufacturing company; experience with all types of switching equipment and supervised the construction of all types of switchboards. At present available. Apply Box No. 68-W.

DESIGNING AND CONSTRUCTION ENGINEER.

Fully qualified designing and construction engineer with extensive experience in building and industrial construction, harbour, railway, hydro-electric work and public utility valuation, until recently engaged on general construction and harbour work in the Far East, now wishes to relocate in Canada; at present in Montreal and available immediately. Apply Box No. 70-W.

CIVIL ENGINEER

The advertiser has had seven years experience on surveys as instrumentman and party chief. At present employed, but would like to secure a position with construction company offering a future to one who is willing to work for it. Will go anywhere and willing to start at the bottom. Apply Box 71-W.

DESIGNING ENGINEER

Graduate R.M.C. '25 and McGill University '27, desires new location with promise of advancement. Experience includes maintenance and installation draughting and designing in paper mill work. Apply Box No. 72-W.

CIVIL ENGINEER

Graduate University of Toronto '21, experience including instrumentman on location of railways, inspector on railway and other materials, plan examiner and road superintendent, is open for a position. Apply Box No. 74-W.

MECHANICAL ENGINEER

Young mechanical engineer, graduate McGill University '23, with two years' experience in designing layouts and care of installation of new equipment; two years as efficiency engineer; draughtsman on maintenance work; at present draughtsman on building and equipment in connection with industrial plant, wishes to locate with company where there is promise of advancement. Apply Box No. 80-W.

DESIGNING AND CONSTRUCTION ENGINEER

A.M.E.I.C., with experience in the design, field supervision and organization of the construction of reinforced concrete, reservoirs, filter plants, pumping, underground conduit system, and various types of buildings, wishes to locate with a construction company. Apply Box No. 81-W.

MECHANICAL ENGINEER

A.M.E.I.C. experienced in drawing office, production and plant maintenance; four years as engineer-in-charge of works plant installation and maintenance, mechanical and electrical; three years as sales engineer; conversant with wide variety of machinery; recently mainly on pneumatic plant; having just returned from residence abroad is open for engagement in suitable capacity. Apply Box No. 84-W.

ELECTRICAL ENGINEER

Grad. Queen's Univ. '27, with experience in various departments of manufacturing company, desires a position in sales, hydro-electric development, or industrial organization. Apply Box No. 85-W.

CONSTRUCTION ENGINEER

A.M.E.I.C., with twenty-six years' experience, including ten years railway construction and sixteen years on reinforced concrete bridge, as resident engineer in Canada and United States, desires position. Apply Box No. W. 93-W.

According to a statement made by the Hon. J. E. Perreault, Minister of Colonization, Mines and Fisheries, the Tache bridge at St. Joseph d'Alma, which was carried away by the floods in the early spring, and the St. Felicien bridge which was also seriously damaged, will be reconstructed immediately.

It has been announced that the contract for the construction of the new Canadian National Railways station and hotel at Halifax, N.S., has been awarded to the Foundation Jupiter Company, Limited, Halifax, a subsidiary of the Foundation Company of Canada of Montreal. The contract for the steel has been awarded to the Dominion Bridge Company.

A contract for the construction of a large trunk sewer at Three Rivers, Que., has been awarded to Robertson and Janin Limited, Montreal.

Tenders are being called by the Department of Public Works, Canada, for the construction of an earthen mound and timber superstructure control dam across the Okanagan river at Penticton, Yale District, B.C. Tenders will be received until noon, September 18th, 1928.

Announcement has been made of the award of a contract to Canadian Vickers Limited, Montreal, for the building of a new seventeen knot cruiser to be used in customs preventive service in the Atlantic division. The new vessel, which is required to be delivered at Halifax within nine months, will be 165 feet long, and will be powered by three 500-h.p. oil burning engines.

According to a Bureau of Statistics bulletin, total traffic on the Welland canal exceeded a million tons in June for the first time. The chief increases were in wheat and oats.

The contract for dock construction in the Owen Sound harbour has been awarded to the Jackson Company of Seaforth, Ontario.

A recent report states that Messrs. Lang and Ross, of Sault Ste. Marie, Ontario, have commenced work on the construction of the power line to the Montreal river in connection with the large power development being undertaken by the Great Lakes Power Company, Limited, near Sault Ste. Marie.

Preliminary Notice

of Applications for Admission and for Transfer

August 22nd, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September 1928.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in of Student after he has attained the age of twenty-seven years, unless in the opinion of council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BLAIR—DONALD, of 173 Daly Ave., Ottawa, Ont., Born at Fredericton, N.B., Oct. 14th, 1887; Educ., 3 years Applied Science, McGill Univ., 1908-10; 1909-10 (summers), constrn., G.T.P. Ry.; 1911-12, asst. engr., engrg. dept., Moose Jaw, Sask.; 1912-13, dftsman., land survey, Peace River Block, B.C.; 1916-17, asst. engr., Fraser, Brace & Co., smokeless powder plant, Trenton, Ont.; 1918-21, sanitary engr., Public Works Dept., Ottawa, Architect's Branch; 1922-23, mgr., Gilmour Construction Co., Ottawa; 1923-24, chief clerk and dftsman., div'l office, T. & N. FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER GRADE

COOPER—PAUL EMERSON, of 141 Brinkerhoff St., Plattsburg, N.Y., Born at Ottawa, Ont., Feb. 8th, 1900; Educ., B.Sc. (C.E.), McGill Univ., 1923; 1916-17, rodman and precise leveler, International Boundary Survey; 1918-20, inst'man for Grand Trunk lines in New England; 1921, instr'man, Manitoba-Ontario Boundary Survey; 1922, highway inspr. and engr. on highway constrn., Village of Carp, Ont.; 1923, field engr., Barometric Topographical Survey and mapping for Singer Mfg. Co. on Blanchard Nation Limits; 1924-25, office engr., railroad location and constrn. of Thurso & Nation Valley Railroad for Singer Mfg. Co.; 1926-27, asst. engr., paper mill constrn. at Gatineau, and 1927 to date, res. engr. on constrn., hydro-electric development at Kent Falls, N.Y., for International Paper Company.

References: A. H. White, A. I. Cunningham, H. M. MacKay, S. H. Davis, L. Rochester.

NENNIGER—EMIL, of 564 Notre Dame de Grace ave., Montreal, Que., Born at Berne, Switzerland, July 4th, 1901; Educ., struct'l. engr., Technical School at Burgdorf, 1921; 1917-19, supervision of bldg. constrn. for G. Rieser, gen. contractor, Berne; 1921-23 designing engr., office of W. Schreck, reinforced concrete design of pulp & paper mill and pulp & paper printing plant, struct'l. design of apartment house, all in Switzerland; July 1923 to date, designing engr., office of Dr. Arthur Surveyer, M.E.I.C., Montreal, responsible for design of many large projects.

References: A. Surveyer, J. Labelle, H. Massue, J. B. Challies, O. O. Lefebvre.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER GRADE

ARCHER—AUBREY CLIFFORD, of 534 Notre Dame st., Lachine, Que., Born at Barbados, B.W.I., Feb. 18th, 1901; Educ., B.Sc., (Mech. Eng.), McGill Univ., 1924; 1924-25, production dept., Northern Electric Co.; 1925, time clerk & mapping of pipe line extensions, Montreal Light, Heat & Power Co.; Jan. 1926 to date, medical dept., Sun Life Co. of Canada, selection of risks, in charge of appointments of medical examiners.

References: H. M. MacKay, C. M. McKergow, A. R. Roberts, E. Brown, J. A. Coote.

BIELER—JACQUES LOUIS, of 223 Milton St., Montreal, Que., Born at Chexbres, Switzerland, Aug. 17th, 1901; Educ., B.Sc., McGill Univ., 1923; 1920 (summer), constrn. work for Canadian Explosives; 1922 (summer), and after graduation, cadet engrg. course, Bailey Meter Co., Cleveland, Ohio; with same company on sales and service staff from Oct. 1923 to Nov. 1924, and in research dept., Nov. 1924 to Sept. 1925; 1925 (Sept.-Dec.), i/c of party, Gatineau River Power Survey; 1926 (Jan.-June), engr., Consolidated Pipe Co., Montreal; 1926-28, sales engr., and subsequently chief engr., Industrial Combustion Engineers (Bailey Meter Licencees), London, Eng.; at present asst. engr., Dominion Oilcloth & Linoleum Co., Montreal, Que.

References: C. M. McKergow, A. R. Roberts, F. T. Kaclin, C. J. Desbaillets, L. R. Thomson, W. E. Blue.

COCKSHUTT—CLARENCE FOSTER, of 172 Chatham st., Brantford, Ont., Born at Brantford, July 16th, 1901; Educ., B.A.Sc., Univ. of Toronto, 1923; 1920-21 (summers), labourer, mine & mill of Coniagas Mines, Ltd.; 1922-23 (summers), asst. on geol. survey parties, Ont. Dept. of Mines; 1924 (Apr.-Dec.), and 1925 (May-Nov.), field engr. for Victoria Syndicate, Ltd.; 1926 (Jan.-May), field engr. with Dome Mines, Ltd.; 1927 (Jan.-Mar.), instr'man. on storage basin survey with Land & Ross; Apr. 1927 to date, res. engr., in charge of all work on properties of Grover Daley Mines, Ltd., Amos, Que.

References: H. E. T. Haultain, H. G. Thompson, H. A. Lumsden, deG. Beaubien.

EMERSON—THEODORE ROOSEVELT, of 3 Algonquin Ave., Toronto 3, Ont., Born at Buffalo, N.Y., June 12th, 1901; Educ., B.A.Sc., Univ. of Toronto, 1924; 1924-25, Bell Telephone Co. of Canada; 1926 (6 mos.), Acton Tanning Co., Acton, Ont.; Aug. 1926 to date, on terminal engr.'s staff, C.N.R., Toronto, to May 1927 as concrete inspr., and May 1927 to date, instr'man, with experience in field and office.

References: C. R. Young, P. Gillespie, S. B. Wass, H. L. Currie, J. R. W. Ambrose.

FAIRBAIRN—RHYS AIKINS, of 290 Lincoln Road, Brooklyn, N.Y., Born at Brantford, Ont., April 16th, 1901; Educ., B.A.Sc., Univ. of Toronto, 1923; 1921-22 (summers), machine shop work with Dodge Manufacturing Co. of Canada; 1923-27, engrg. dept., Bell Telephone Co. of Canada, as equipment mtce. engr., and later as dial system equipment engr.; March 1927, transferred to American Telephone & Telegraph Co. (New York), Dept. of Development and Research, on development work for step-by-step dial system central offices.

References: J. M. R. Fairbairn, C. A. Norris, A. E. K. Bunnell, E. L. Cousins, H. E. T. Haultain, C. H. Mitchell.

GRINDLEY—FRANK LLEWELLYN, of 10942 80th ave., Edmonton, Alta., Born at Douglas, Isle of Man, Eng., Mar. 21st, 1904; Educ., B.A., B.Sc. (Ci.), Univ. of Alberta, 1926; 1925 (May-Sept.), rodman on constrn., Alta. Govt. Rys.; 1926 (May-Sept.), transitman on location, C.N.R.; Oct. 1926 to May 1927, instr'man., Aluminum Co. of Canada; 1927 (May-Sept.), transitman, C.N.R. location; Oct. 1927 to Apr. 1928, mtce., C.N.R., and, at present, res. engr. on constrn., C.N.R. Western region.

References: R. W. Boyle, R. S. L. Wilson, H. R. Wake, R. W. Ross.

KILLAM—DONALD ALEXANDER, of 3647 University St., Montreal, Que., Born at Weymouth, N.S., June 16th, 1901; Educ., B.Sc., McGill Univ., 1927; 1925 (summer), instr'man on hydrographic survey for Ottawa-Montreal Power Co.; 1926 (summer), engrg. staff, W. I. Bishop Co., Ltd., paper mill constrn.; 1927-28, designing, dftng. and field work for Abitibi Fibre Co., Smooth Rock Falls, Ont.; March 1928 to date, paper mill designing for Canada Power & Paper Co., Ltd., Montreal.

References: J. A. Dickinson, B. S. McKenzie, A. B. McEwen, H. J. Buncke, H. M. MacKay.

LAYNE—JOHN GRAHAM, of Lime Ridge, Que., Born at Barbados, B.W.I., Nov. 28th, 1894; Educ., B.Sc. (Met. Eng.), McGill Univ., 1923; 1913-14, asst. to land surveyor; 1914-19, H. M. Navy, wireless telegraphy and fire control; 1919 (Apr.-Sept.), asst. to land surveyor; two summer vacations with Mond Nickel Co., Coniston, Ont.; 1923-25, asst. chemist and assayer, and 1925-26, chief chemist, American Smelting & Refining Co., Mexico; 1926-27, acting supt. and later supt., Continental Mexican Rubber Co., Torreon & Cedral plants; April 1928 to date, plant investigation work for J. T. Donald & Co., Ltd., Montreal.

References: J. R. Donald, G. Sproule, N. F. McCaghey, G. F. Layne, A. Stansfield.

McCORMACK—DONALD NEILL, of 712 Union St., Fredericton, N.B., Born at Fredericton, N.B., Feb. 16th, 1905; Educ., B.Sc. (E.E.), Univ. of N.B., 1928; 1925 (Aug.-Sept.), field dftsman., N.B. Electric Power Commission; 1926-27 (summers), dftsman. and instr'man, city engr.'s office, Fredericton; at present dftsman. with the Dexter P. Cooper Co., Inc., Welchpool, Campobello, N.B.

References: A. F. Baird, J. Stephens, E. O. Turner, W. L. Ball, B. T. Weston.

PEAL—EDWARD JAMES, of 14 MacLean Blvd., Toronto, Ont., Born at Rockwood, Ont., June 2nd, 1901; Educ., B.Sc., Queen's Univ., 1924; 1921-22 (summers), asst. to city engr., Guelph, Ont.; summer of 1923 and May 1924 to July 1926, sales service engr., Bailey Meter Co.; July 1926 to Sept. 1927, steam engr., Canada Sugar Ref. Co., Montreal, full charge of installation, upkeep & use of all instruments, and directing use of steam & power; Sept. 1927 to date, asst. supt., Dominion Envelopes & Cartons, Ltd., Toronto, in charge of upkeep on machines & designing and constrn. of new machines.

The Rivers of the Province of Quebec in their Legal Aspect

Features of the Laws of the Province of Quebec as they Affect the Public Rights, Ownership and Administration of Rivers within the Province

J. M. Hector Cimon, A.M.E.I.C.,
Engineer, Price Brothers and Company Limited.

Paper presented before the St. Maurice Valley Branch of The Engineering Institute of Canada, March 17th, 1928

The rapid growth of the pulp and paper industry concurrently with the widespread development of water power in the province of Quebec during the past decade has greatly increased the commercial use which is being made of our rivers. The latest census of these industries shows that nearly 1,700 million feet board measure, or 3 1/3 million cords of wood, are being taken from the forests of Quebec annually, and it is safe to say that over 80 per cent of this large amount of raw material is taken to mills or market, for part of the way at least, by being floated down rivers and streams.

It is also known that turbines of some 2,200,000 h.p. are now installed on the rivers of the province of Quebec. We find during the last ten years our hydraulic power plants have reached their present-day capacity at an average rate of increase of 130,000 h.p. annually, while the increase in the last three years alone has been nearly 900,000 h.p.

Hundreds of millions of dollars have been invested in timber lands, wood-using mills and river improvements, as well as in water power developments and flow regulation works, while considerable sums of money are spent every year by the two basic industries which make use in common of our running streams.

The interests involved are large, as one can well realize; the common law and special legislation by which they are governed in practice are, therefore, of importance, not only to the lawyers who pass upon and approve of the title deeds, etc., for the bankers who finance those enterprises, but also to the engineers responsible for or connected with the projects, and to their colleagues and the public, who are interested in the use and development of the rivers and water powers of the province.

Rights of the Public

According to the common law, running water, like the air and the sea, is considered as belonging to every one. " Equidem maturali jure communia sunt omnium, aer, mare et aqua profuens " was the formula used by the Romans some 1,400 years ago, (Code of Justinian), and the French laws, whence our Quebec laws concerning water courses are derived, also admitted this principle.

Rivers are, by nature, public highways, and everybody has a right to use them as such; it follows, therefore, that the works, of whatever nature they may be, erected in or over any river must not destroy this character of suitability for traffic in the way of navigation and the floating of logs.

To quote from " The Law of Waters " by Coulson and Forbes: " A navigable river is a public highway navigable by all His Majesty's subjects in a reasonable way and for a reasonable purpose. The public right of free passage extends to the whole of the navigable channel, which it appears may be used as a highway by the public whenever it suits their convenience, whether such navigation be valuable or not."

Various texts of our Quebec law may be cited, as for example, (Art. 3, Ch. 264, R.S.Q. 1925), " It shall be lawful to make use of any river or water course, lake, pond, ditch, drain or stream in which, or to the maintenance of which, one or more persons are interested or bound, and the banks thereof, for the conveyance of all kinds of lumber, and for the passage of all boats, ferries or canoes, subject to the charge of repairing, as soon as possible, all damages resulting from the exercise of such right, and all fences, drains or ditches damaged."

It results therefrom that a legal servitude, (Art. 507 C.C.), is established in favour of the public at large for navigation and log driving purposes, not only over all rivers and bodies of water, but also on the shores or banks thereof.

Article 31, div. V., Ch. 46, R.S.Q. 1925, provides that any person, firm or company may, during the spring, summer and autumn freshets, float and transmit timber rafts and craft down all rivers, lakes, ponds, streams and creeks in this province."

Article 516 of the Municipal Code also recognizes this same right in connection with municipal water courses which are defined under Article 499 of this Code as being, "every water course draining several pieces of land with the exception of road and boundary ditches, and every river or natural water course in the parts thereof which are neither navigable nor floatable in the technical sense."

Article 516 reads as follows: "Any person may use any municipal water courses, as well as the banks thereof, for the conveyance of all kinds of timber or wood, and for the passage of all boats, ferry boats, and canoes, subject always to the obligation of repairing, without delay, all fences, drains or ditches damaged thereby, and to the payment of all damages resulting from the exercise of such right."

Private Rights

Although streams are not susceptible of ownership as such, their banks or shores, and the bed in some cases, may be private property, and he who possesses them is in a position to enjoy certain exclusive rights which will be dealt with later on.

Width of Rivers

With regard to the division line between the bed of a river and the riparian lands bordering thereon, or, in other words, to define the width of rivers, we still have no law by which these boundaries may be fixed, but our jurisprudence clearly admits that everything which is included within the limits of the highest water level without overflowing or flooding forms part of the bed. It is, therefore, the high water marks when a stream is flowing full but not overflowing which separate it from the adjacent land. This rule applies to all rivers and streams whether navigable and floatable or not.

Navigability and Floatability

Rivers and lakes, in the province of Quebec, are classed either as navigable and floatable, or as not navigable and not floatable in the same manner as they were in France.

Navigability is a matter of fact. In principle a stream is navigable which can be used for transportation in a practical and profitable manner, either downstream or upstream, so that it can properly be said to be a natural highway.

When logs and timber, (en trains ou radeaux), can be driven down a river in rafts or in the form of cribs, this stream is said to be floatable, and is considered as being in the same class as a navigable one.

All other water courses, even those down which large quantities of loose logs can be driven, are said to be unnavigable and not floatable.

Although the government of this province could rule and declare which streams are navigable and floatable and which others are not, the decision in any particular case has always been left with the courts. Several judgments of our courts have already defined the general character of some rivers, seemingly setting forth the principle that a stream does not cease to be navigable by the fact that, in certain places, navigation is interrupted, due to the presence of falls and rapids, provided that the general characteristics of this river be such as to make it navigable.

According to this formula, tributaries are treated each on its own merits, and may be classed irrespectively of the general character of the main river, but channels forming part of a navigable stream must also be considered as such whether they be navigable in fact or not.

Let us note that the Ottawa and St. Francis rivers were declared by the courts to be navigable and floatable in rafts, while the rivers Jacques Cartier, Rouge, (County of Labelle), Chaudiere and Gatineau were classed as non-navigable and not floatable in rafts.

As regards the Gatineau river, however, by a subsequent judgment, the Supreme Court held that this river was navigable from its mouth to the first rapids which interrupt navigation, the river thus being navigable over a distance of a few miles only. This ruling enunciated a different theory from that which had heretofore been adhered to, and this interpretation might have very far reaching effects in the future if it ever were confirmed by the Privy Council.

Rights of Ownership Upon Navigable Streams

Navigable and floatable rivers and streams are considered as being dependencies of the Crown domain according to Art. 400 of our Civil Code. They are the property of the province, in view of the fact that they are part of the territory included within its boundaries. This right of ownership by the province or its grantees implies, as accessories to the bed, certain useful rights, amongst which the most important is the right to water powers. It must be remembered, however, that, to quote again Coulson and Forbes, "The right of navigation is paramount to the right of property of the Crown and its grantees in the bed of the river, and such property cannot be used in any way so as to derogate or interfere with the public right of navigation."

Federal Authority

On account of this public right of navigation and in virtue of clause 10, section 91 of the British North America Act 1867, the Parliament of Canada, having full legislative authority in matters concerning navigation, can declare what must be considered as an obstacle to navigation and can exercise the necessary control over all works built or placed in navigable water; this federal jurisdiction is such that the refusal of the Governor General in Council to authorize the erection of any proposed works would ipso facto cause the provincial grant regarding the part of the bed upon which the said works would have been built to be of no practical effect.

By the 1867 Act, the federal government was also awarded the property of all recognized public harbours and that of certain water powers derived from navigation canals. This matter being "sub judice" at the present time, any comments must be avoided.

Riparian Ownership Along Non-Navigable Streams

Riparian ownership along navigable streams extends to lands above the high water mark only. As stated previously, the shores, banks or riparian lands are subject to a legal servitude in favour of the public, but, on the other hand, they benefit by their proximity to water courses and their owners can enjoy many useful rights.

The right of alluvion is that by which "deposits of earth and augumentations which are gradually and imperceptibly formed on land contiguous to a stream or river," (Art. 420 C.C.), become the property of the owners of the adjacent land. In a like manner, "the ground left dry by running water which insensibly withdraws from one of its banks by bearing in upon the other" accrues to the proprietor of this bank, but "the proprietor of the opposite bank cannot reclaim the land he has lost." (Art. 421 C.C.)

It may be noted also that "Islands, islets and deposits of earth formed in the beds of navigable and floatable rivers or streams belong to the Crown, if there is no title to the contrary." (Art. 424 C.C.)

The other outstanding privilege is the right of access and egress on to the river which inures to the riparian owners and which, if interfered with, gives grounds for compensation.

Riparian Ownership Along Navigable Streams

In regard to unnavigable or not floatable rivers, the jurisprudence has set the rule in this province, that the bed belongs to the riparian proprietors; that when one holds property on one side of an unnavigable river, his rights of ownership extend to the middle thread of the stream, (usque ad medium filium aquæ), and that, should he be the proprietor of both sides, he owns the bed entirely, subject, however, to the general right of the public for navigation and the floating of logs.

In a judgment " Re the Queen *vs.* Robertson by Judge Strong," it is stated:—

" No principle of Law can be better established, both in England and America, than the rule which ascribed the ownership of the soil and bed of a non-navigable river prima facie to riparian proprietors of the opposite banks, each to the middle of the stream. It results from the proprietorship of the riparian owner of the soil in the bed of the river that he has the exclusive right of fishing in so much of the river as belongs to him, and this is not a riparian right in the nature of an easement, but is strictly a right of property," (R.C. Sup. 6, p. 114). This also applies to water powers.

In accordance with this rule, which is based on the old French law as well as on the English Common law, all rivers, which are not navigable or floatable, located within the Seigniories, are privately owned. In the townships, the bed of all such rivers is also private property whenever it is adjacent to lands alienated from the Crown before June 1st, 1884, when a law was passed whereby all sales and free grants of Crown lands bordering on non-navigable rivers and lakes were to be made subject in the future to a reserve three chains, (198 feet), in depth along the water's edge.

Doubts arose as to the extent of this three-chain reserve, which, it was claimed, in some cases, was subject to a mere servitude for fishing purposes. As a matter of fact, in the cases of McLaren *vs.* Hansen and the Attorney General intervening, the Superior Court, (Champagne J.), held that the three-chain reserve did not imply a right of ownership in favour of the Crown but only a servitude for fishing purposes, and that the strip was the property of the owner of the lot. The Privy Council confirmed the judgment, (Paugan Falls, Gatineau river). The matter was finally settled, for the future at least, by an act passed in 1919, (9 Geo. V. Ch. 31, Sec. 1), which declares that this strip of land remains in full ownership by the Crown.

These two enactments are now recorded in Art. 7 of Ch. 83, R.S.Q. 1925, which reads as follows: " Sales and free grants of lands belonging to the Crown are and have been since June 1st, 1884, subject to a reserve, in full ownership by the Crown, of three chains in depth of the lands bordering on non-navigable rivers and lakes in the province."

Moreover, by an enactment of 1918, (8 Geo. V. Ch. 72, Sec. 1), all lakes and non-navigable and non-floatable rivers and streams and their banks bordering on lands alienated by the Crown after February 9th, 1918, are declared to be dependencies of the Crown domain, so that, since that date, all rivers, streams and lakes, of whatever class they may be, are retained by the province in the meaning of Art. 400 C.C. The Courts having not yet determined the effect of the Act of 1919, (9 Geo. V. Ch. 31), above referred to, the situation as regards water powers or non-navigable rivers contiguous to lands granted between June 1st, 1884, and February 9th, 1918, is at the present time uncertain.

Riparian ownership along rivers and streams which are not navigable or floatable in rafts, besides revolving the strict right of property of the bed to the middle of the stream, implies also many useful rights, such as those of developing water powers, fishing, alluvion, etc.

" Islands and deposits of earth which are formed in rivers which are not navigable or floatable, belong to the proprietors of the banks of the side where the island is formed. If the island be not formed on one side only, it belongs to the proprietors of the banks on both sides, divided by a line supposed to be drawn in the middle of the river," (Art. 425 C.C.).

Referring again to the three-chain reserve, it is important to mention the fact that the holders of location tickets or patents are tacitly allowed by the Crown to occupy these three chains, and, " if we flood them and destroy their improvements or their crops they would probably be successful in collecting damages from us before the Courts, not as owners, but merely as persons being occupants by sufferance and being entitled as such to the protection of the Courts against the acts of others having no better title than themselves. They are in possession, in fact, and if we disturb them they could proceed against us by possessory action and they could probably recover the damages caused them in their possession though they could not recover anything for injury to the land itself as there could be no claim for erosion of the soil," (Opinion from Mr. L. St. Laurent, K.C., Nov. 23rd, 1926).

This is a case which is often met with in log driving operations, and the situation is somewhat similar to that which prevailed in the lake St. John district, where the riparian proprietors owned only down to the high water mark, but because they were in fact occupants by sufferance between high water and low water marks, they had to be indemnified for the damages caused by permanent or semi-permanent flooding between these two points. Another typical example presented itself along the Little Discharge of lake St. John, when the mill pond at Riverbend was created by the construction of a dam which controls the water level permanently at the elevation reached by ordinary freshets, so that the lands included between high water and low water marks had to be practically purchased.

Water Powers

From the foregoing brief exposé of the principles and rules which form the backbone of the legal status in regard to our rivers, it will be understood that water powers are owned by the province, except those situated on non-navigable streams within the Seigniories and the townships where lots were sold or granted to individuals or companies prior to June 1st, 1884, or possibly February 9th, 1918. A number of water power sites in navigable waters and in unnavigable rivers alienated by the Crown since June 1st, 1884, are also privately owned as having been specially conceded by letters patent or notarial deeds of sale. No less than ninety grants were made in this manner and it may be interesting to note here that very important water powers are held in virtue of such titles, namely, the following: the power sites of the Saguenay river and Grand Discharge of lake St. John; several falls and rapids on the rivers St. Lawrence, Ottawa, Gatineau, St. Maurice, Quinze, Lievre, Chicoutimi, etc.

These concessions, in whichever form they were made in the past, were confirmed in 1916 by an enactment which is recorded in the Revised Statutes of Quebec of 1925 under section 1 of chapter 46 which reads, " 3—It has always been lawful, before the 16th of March, 1916, whatever may have been the system of government in force, for the authority which has had the control and administration of public lands in the territory now forming the province of Quebec, or any part thereof, to alienate or lease to such extent as was deemed advisable, the beds and banks of navigable rivers and lakes, the bed of the sea, the seashore and lands reclaimed from the sea, comprised within the said territory and forming part of the public domain.

From and after the 16th of March, 1916, every alienation or lease of one or more of the properties mentioned in the foregoing paragraph may be effected solely with the express authorization of the Lieutenant-Governor in Council, and on such conditions and under such restrictions as he may determine."

The practice of the government of selling outright water powers of importance has now been abandoned. Water powers are now generally granted by public auction, and the right and obligation to develop them are now combined in emphyteutic leases under the following main conditions:—

(1) The term of the lease varies from twenty to ninety-nine years. The most usual terms are fifty to seventy-five years.

(2) The annual rental to be charged for the use of Crown lands occupied, during the whole term of the lease, is in accordance with the accepted bid or tender.

(3) An annual royalty of 50 cents or more per horse power developed is charged based upon the installed capacity of the turbines, and, in some cases, an additional royalty of 50 cents or more per horse power is charged on the amount of power permitted to be exported out of the province.

(4) The royalty is to be revised, usually every ten years, and provision is made for a settlement of this matter in case of disagreement.

(5) A money guarantee must be deposited by the lessee, which is to be returned to him when the initial development is completed.

(6) A definite amount of power must be produced within a given time. Usually two years are allowed, within which the works are to be begun, and two years more for their completion.

(7) Conditions are provided for the sale of surplus power.

(8) A special tariff can be charged for the use of stored water in case reservoirs are created.

(9) The lease may be cancelled by the Lieutenant-Governor in Council, without legal proceedings, for non-payment of rental or royalties or for neglect or failure to carry out the conditions of the lease.

(10) When the lease terminates or is cancelled, the power and lands covered by the lease revert to the Crown, together with all works, buildings and immovable properties thereon, with or without compensation as the case may be. The lessee is to be given a reasonable time in which to remove his machinery, failing which, this also becomes the property of the Crown without compensation.

(11) Provision is also made for the filing of plans, inspection, maintenance, annual statement of operations, transfer of lease and the protection of other interests using the stream.

With reference to water powers in non-navigable rivers adjoining riparian lands conceded before June 1st, 1884, or February 9th, 1918, the right to develop these is given to the riparian owner in virtue of Art. 503 C.C. " He whose land borders on a running stream, not forming part of the public domain, may make use of it as it passes, for the utility of his land, but in such manner as not to prevent the exercise of the same right by those to whom it belongs, etc. He whose land is crossed by such stream may use it within the whole space of its course through the property, but subject to the obligation of allowing it to take its usual course when it leaves his land."

As to both navigable and non-navigable rivers and streams, the owner of the bed and banks thereof has always had the right to turn them to account by the construction of mills, manufactories, flood gates, flumes, dams, booms, dikes and the like, subject to the payment of all damages resulting from the construction and operation of his works, whether by excessive elevation of the flood gates or otherwise. (Div. 11, Ch. 46, R.S.Q. 1925.)

Of course, if these works mean building over or obstructing navigable waters, he has to have his plans approved by the Governor General in Council under Ch. 140, R.S.Q. 1927. Moreover, if works for the development of power are likely to affect public property or the property of third persons or public or private rights, he who wishes to erect them must have his plans approved by the Lieutenant-Governor in Council. Notice of the application for the approval of the plans is to be given and any party interested can be heard and the government may approve purely and simply the plans submitted, or give its approval subject to such modifications and conditions as may be deemed useful or expedient. (Div. 11, Ch. 46, R.S.Q. 1925.)

As an example we may take the conditions under which approbation of the Lieutenant-Governor in Council was given for the erection, maintenance and operation of a power dam on the Chicoutimi river owned by Price Brothers and Company, Ltd.

(1) The authorization is given without prejudice to the right of any third parties who may be affected prejudicially by the said works.

(2) The present authorization shall be valid for fifty years to be computed from December 1st, 1923, and subject to a fee of $100 to be paid to the Department of Lands and Forests before January 1st, 1924.

(3) The applicant shall be responsible for all damages resulting from the erection, operation and maintenance of the said works, and he shall perform his operations at all times in such a way as to conciliate the different interested parties having the right to utilize the said river.

(4) The applicant shall, if requested by the competent authority, erect and maintain in good condition the proper fishways, and he shall also erect and maintain suitable log-slides and sluiceways in the dam, to meet the requirements of all interested parties.

(5) The present authorization is subject to the federal and provincial laws and regulations concerning the navigation, floating of logs, mines and fisheries.

In this case the power site was held in fee simple in virtue of Letters Patent.

The Floating of Logs

There is in all rivers and streams, as was mentioned, in favour of whomsoever may have occasion to use them, a general right of floating logs and timber, either in rafts or loosely, (a buches perdues). This right is subject to payment by him who exercises it of such damages as he may cause in doing so, " except in regard to such as cannot be avoided by the exercise of reasonable care and skill, and those in respect of which the riparian proprietor himself may have contributed or which have been occasioned by his own fault." (Dumont *vs.* Fraser, Supreme Court, 1913—48, S.C.R., p. 137.)

This right to use rivers and streams for floating and driving purposes would seem to be restricted to the spring, summer and autumn freshets in the wording of Art. 31 of Ch. 46, R.S.Q. 1925, but the jurisprudence of our courts is not established in that sense, and it may be construed that the right to drive timber could be exercised at all times when it was physically possible to exercise it.

As to whether or not artificial aids by means of storage reservoirs could be used at other times than during the spring, summer and autumn freshets, the Supreme Court were equally divided in the case of River Ouelle Pulp and Lumber Co. *vs.* The Ste. Anne Fish and Game Club in 1910. The Court below had held that the right to aid the floating of logs by artificial means authorized by the law, (Art. 32, Ch. 46, R.S.Q. 1925), may be exercised at all seasons of the year.

Since February 9th, 1918, (8 Geo. V. Ch. 69, now 33, Ch. 46, R.S.Q. 1925), no work or improvement of which the construction, execution or maintenance necessitates the taking possession or occupation of any public or private property, or prejudicially affects either of such properties, or any rights, public or private, either by the backing up of the water or otherwise, may be constructed, executed or maintained, unless the plan and specifications relating thereto have previously been approved by the Lieutenant-Governor in Council. If the construction and maintenance of any such work necessitates the taking possession, or occupation and/or the flooding of any public lands, or will affect any other rights of the province, it is necessary to obtain from the government a concession of such lands or public rights so affected.

We need not enter into the details of the procedure, (35 to 40 Ch. 46, R.S.Q. 1925), to be followed in order to obtain these authorizations and concessions which are made by notarial leases, for a term of usually twenty years and under certain general conditions. Let us note, however, that a small fee is charged for the authorization, $20 in ordinary cases, and that an annual rental must be paid for the use of the Crown lands or rights affected based on the following rates, in the case of driving dams: 25 cents per acre of lands flooded or subject to flooding plus 25 cents per million cubic feet of water of storage capacity.

The owner of river improvements for the driving of timber or logs, even if they stand on private property, does not have the exclusive right to the use of the river or of such works or improvements, but any other person may use them for the same purposes by paying to the proprietor of such constructions or improvements the tolls determined by order of the Lieutenant-Governor in Council upon a petition to that effect presented by the owner or other parties interested. (41, 42 Ch. 46, R.S.Q. 1925.)

Driving and booming companies are governed by a special act, (Ch. 47, R.S.Q. 1925).

Water Powers and Log Driving Depend on Co-existing Rights

Water power operators and log drivers have co-existing rights, but their interests may often conflict. A power dam is an obstruction to log driving to a certain extent, while the floating of logs and navigation have always been considered as outstanding public rights.

In the case of McBean *vs.* Carlisle, (19 J.P., p. 276), in 1874, the Court held that the dam owners in damming up the river for the purposes of their mill, " were bound to provide for and secure to the public facilities for the floating of their lumber equal to those which the natural flow of the river, before the erection of the dam, would have afforded them."

With reference to this judgment it will be interesting to many a power dam owner or operator to listen to the following opinion of Mr. L. St. Laurent, K.C.:—" I am of opinion that this language goes beyond what would now be required from the owners or lessees of power dams. I think that our Courts would now hold that when power dams are erected in accordance with plans approved by the government, and are provided with all the reasonable facilities which can be made to facilitate the driving of logs, the owners would not be responsible because the floating facilities were not equal to those which the natural flow of the stream before the erection of the dams would have afforded. I think it would be held that both power users and those having occasion to use the streams for driving purposes, have rights in common, and that each must use his rights in such a manner as to cause the least possible inconvenience to the other, and is responsible only if he is making an unreasonable use of this right which he thus has in common with others. I think the Courts would now assimilate this common right to those which all enjoy in the public highway. Everyone is entitled to use the public highway, but he cannot complain if somebody else is using it in a reasonable way at the same time he is. It may be inconvenient to him not to have the free use of it alone. He may be delayed because of the congestion of other traffic, but if the others are not making an unreasonable use of it, he cannot recover from them the damages he may suffer by being thus subjected to some delay."

In case of disagreement between users as to the manner in which they should both exercise their rights, the Public Service Commission has jurisdiction to decide between them. (Ch. 17, R.S.Q. 1925, Art. 28, Sub-sec. 10.) The terms of the provincial authorization, in this particular respect, are ordinarily as follows:—

" If so requested by competent authority, the lessees shall erect and maintain in good condition the proper fishways and they shall also erect and maintain suitable log slides and sluices in the dam to meet the requirements of all interested parties." (Chicoutimi Power Dam, Price Brothers and Co., Ltd.)

A dam owner is not supposed, apparently, to furnish any booms to direct the logs to the sluiceways, but piers and other permanent structures required to hold these booms in position are generally considered as falling to his lot, according to the interpretation of the provincial hydraulic service. However, when authorization must be obtained from the federal authorities under the " Navigable Waters Protection Act," the owner of the dam is often obliged to supply the necessary booms and other requisites.

Storage Reservoirs

It is only since 1918 that we have had a definite law concerning the creation, maintenance and operation of reservoirs, the use of which serves " to impound and to keep stored up, in all seasons, the waters of lakes, ponds, rivers and streams, with the object of conserving them so as to regulate their flow, either by their natural outlets or by a deviation therefrom, and thus to ensure a uniform supply to water works systems and mills and a constancy of hydraulic power." (Div. VI. Ch. 46, R.S.Q. 1925.)

This law provides for the authorization of the works required for the purpose of storing water, as well as for the acquisition of the necessary lands and rights and for the establishment of a tariff of tolls where several parties benefit by the regulation of the flow.

Where the lake or reservoir is on Crown land it is the policy of the government, as in the case of water powers, to grant the applicant the necessary lands and privileges by emphyteutic leases, for a term of fifty years and under certain conditions, amongst which it may be interesting to note the following:—

An annual rental is charged, based on the area of the lands affected, at the rate of 25 cents per acre per annum in ordinary cases.

A supplementary charge or royalty must also be paid over and above the rental mentioned which is calculated at the rate of 50 cents or more per additional horse power year resulting from the water of the storage reservoir at the power plants benefitting by the regulated flow. This royalty is subject to revision every ten years. The government reserves the right to expropriate the works within the term of the lease.

It is useless to even mention the fact that storage reservoirs are of the utmost importance in many respects. It may be pointed out, however, that they afford the means of legally diverting water from its natural course to a certain extent at least, and they therefore permit of operating flumes, for instance, for the transportation of logs and timber from one watershed to another.

Conclusion

This sketch of the work, salient legal principles and requirements affecting the rivers of the province of Quebec, is necessarily incomplete. May it suffice to show that although legal rules are based as common sense, a variety of particular circumstances often renders this application complicated and that, in problems dealing with the utilization of natural forces, legal difficulties as well as physical ones are within the scope of the work of the engineer lest the success of the enterprise may be economically handicapped.

Discussion of Paper on Some Engineering Aspects of the Bridge River Project by E. E. Carpenter, M.E.I.C.[1]

A. C. R. Yuill,[2] M.E.I.C., enquired as to the purpose of the depression at the foot of the surge chamber which he had noticed.

The author, in reply, explained that this was to act as a sump for the purpose of collecting rock fragments eroded from the floor and walls of the unlined tunnel, and preventing them from entering the penstock. At intervals, it would be necessary to clear this sump out, for which purpose an orange peel or clamshell bucket would normally be used.

H. B. Muckleston,[3] M.E.I.C., remarked that in the diversion dam, which was placed 500 feet upstream from the final dam, he noticed that the space or apron had been filled with concrete in squares. Had a puddle blanket of clay been considered for this purpose? From his experience he would fear that the concrete might open up. In a case known to him in India, with about 60 feet head upon the dam, a blanket of 15 feet of clay had been used with success. This was in Jaipur, Rajputana.

The author, in reply, remarked that in the case under consideration the head was considerably greater than that spoken of by Mr. Muckleston, being 160 feet, but he believed that clay would have answered the purpose very well had it been possible to obtain a supply of suitable material within reasonable distance. An hydraulic fill dam would have been suitable for this location, but it had been felt that with this type of structure the control of flood conditions during the construction period would be too difficult, and the cut-off problems too hard to solve.

Col. J. C. MacDonald,[4] M.E.I.C., remarked that the British Columbia Electric had just let contracts for a 100,000 hp. steam plant, and enquired what relation the operation of this plant would have to that of the Bridge river installation.

The author replied that the steam plant would be used for taking care of a certain amount of seasonal peak load, but in its principal function would be that of a regular operation standby plant to take up load in case of interruption to the hydro service. Dean R. W. Brock,[5] M.E.I.C., asked whether tests had been made regarding the hot weather flow of the river and the probable evaporation losses from the lakes used for storage. Mr. Webb observed that information regarding this matter was not yet available. The Provincial Water Rights Branch had established two evaporation test stations on which observations were being made. Investigations made recently at Vernon had indicated that the summer average loss in the arid belt was approximately one-eighth of an inch per day.

Dean Brock remarked that the views shown by the author indicated valleys of a form typical of those which had carried large glaciers. During the period of glaciation, the transverse valleys in many cases had filled with ice, which had formed a bridge over which the main ice sheet had passed. Later, the action of the ice had resulted in the conversion of the normal V-shaped valley into one of a U section. At the points where transverse valleys entered the main valleys, this had resulted in the formation of depressions or even of lake basins in the valley floor, such deepenings being characteristic of the junction between tributary valleys and main valleys. Such ice-conditions belonged, of course, to a comparatively recent geological age. He would ask the author what kind of material had been found under the clay bed of which Mr. Carpenter had spoken.

The author replied that the clay was underlain not by sand, but by fragments of granite, ranging in size from that of a pea down to sand grains. This material was tolerably watertight. Similar material had also been found when drifts had been run into the talus slopes at the sides of the valleys when exploring for a suitable dam site.

A. E. Foreman,[6] M.E.I.C., remarked that he had observed no provision for removing silt and asked why scouring valves had not been installed.

The author, in reply, pointed out that any silt brought in would probably be deposited at the upper end of the lake, in which case scouring valves at the dam would not be of much use. In his experience, the use of scouring valves had proved disappointing, because even when silt was deposited in their vicinity, it was only removed locally in the immediate proximity of the valves, the main body of the silt remaining in situ.

C. E. Cartwright,[7] M.E.I.C., enquired whether the silt in the Bridge river was not largely due to volcanic ash. The author replied that this was possibly the case, since many of the upper hillsides were covered with ash.

On the conclusion of the discussion, a very hearty vote of thanks was accorded to Mr. Carpenter.

The Forest Products Laboratory of Vancouver

The Value of Forest Products in Canada; the Work of the Vancouver Laboratory and Results Attained

J. B. Alexander,
Forest Products Laboratory, Vancouver, B.C.

Paper presented before the Vancouver Branch of The Engineering Institute of Canada, January 18th, 1928

In order to give a proper setting for the subject, it is desirable to review the economic importance of forest products in the Dominion and in British Columbia, confining it entirely to official statistics compiled and released by federal and provincial departments.

The Economic Importance of Forest Products

There are four great primary industries or occupations: agriculture, lumbering, mining and fishing. In practically every country in the world agriculture far outranks any of the other three, both in value of its product and in the number of its employees. For Canada as a unit that is true. Comparative statistics for 1925, the latest available, show agricultural production valued at more than one and one-eighth billion dollars, with exports, chiefly to Great Britain, of $562,000,000. Ranking next in value, the forests of this Dominion produced material to the value of more than $1,000,000 per day, a total for the year of $368,000,000.

After supplying all her own needs in domestic woods, in 1926 Canada exported lumber, pulp and paper, and other wood products to the value of more than $284,000,000, or 22.7 per cent of the total export trade.

The United States received agricultural products, including animals and animal products, to the value of nearly $145,000,000, while she received forest products to the value of more than $242,000,000.

Since Confederation, 18.5 per cent, in value, of all Canadian exports have been of forest origin. Every fifth railway freight car loaded in Canada contains wood or wood products.

Let us examine briefly the situation in British Columbia. Here the ranking of the four basic industries is: lumber, 1926 valuation, $85,000,000; agriculture, $71,000,000; mining, $67,000,000; fishing, $27,000,000. So, at the outset, it can be seen that lumbering occupies the premier position. To her magnificent forests more than to any other resource, either natural or industrial, the people of British Columbia look for their livelihood.

Logging, sawmills, lath, shingle, pulp and paper mills, veneer mills, box factories, and allied primary wood-working industries employ about 40,000 men, roughly one-third the total working male population of the province, and return in wages more than $43,000,000 annually.

Last year, by boat, more than 1,000,000 tons of sawed lumber left British Columbia, 40 full cargoes for the biggest boat on the Pacific, the Empress of Canada; 75 per cent as much tonnage went out in the log, some by cargo, more in raft; 187,000 tons of pulp and paper required shipment and partial trans-shipment. The Canadian National, Canadian Pacific, and Great Northern railways moved more than 2,000,000 tons of export forest material. Every second railway freight car loaded in the province contains material originating in the forests.

These forests contribute annually one-fifth of the total provincial revenue; in 1926 more than $4,000,000.

These facts substantiate the previous statement that to the forests of British Columbia more than to any other resource, either natural or industrial, the citizens of the province look for their livelihood.

Early Investigations

From the earliest times a few basic facts were undeniably known by experience. It was known, for example, that stone was stronger than wood in compression, and, later, that metals are still stronger. No quantitative results appear to have been determined and recorded until about the middle of the eighteenth century.

Galileo, in 1638, experimented upon beam failures, but regarded all fibres as inextensible. It was another hundred years before tests of the strength of bars were made, and these tests were with regard to ultimate load only, the elastic limit being unknown. In 1678, Hook, in England, announced the theory of "springy bodies," stating that "elongation is proportional to force."

Early in the nineteenth century, Young introduced the Modulus of Elasticity, quite commonly called Young's Modulus, in his book "Lectures on Natural Philosophy," but he does not mention that it can be deduced and applied only to stresses below the elastic limit. Tredgold and Barlow a few years later, in conducting a series of experiments on cast iron bars, noted a permanent set.

It was not until about 1830, when metallic bridges came into demand by reason of railway building, that exhaustive tests were made and recorded and definite conclusions drawn with respect to ultimate load and factors of safety, having especial reference to wrought and cast iron.

With rapid expansion in railway, highway, and building construction, imperative demands arose for accurate determination of strength values for all structural materials. Societies, national and international, governments, steelworks and universities, established testing laboratories and vied with one another in experimental work and compilation of results, until today the literature dealing with experimental results is of enormous volume and corresponding value, while the end is not yet. As a matter of fact, there will be no end so long as this world endures.

The Establishment and Work of the Vancouver Laboratory

The Forest Products Laboratory at Vancouver is a product of the Great War. As you all know, Britain and her allies were almost wholly dependent upon the Sitka spruce forests of the Pacific coast, more particularly those of the Queen Charlotte islands, for airplane material. Only the very highest quality of spruce was acceptable, so that an inspection service was instituted at Vancouver to cull out all material having the slightest blemish, in order to conserve cargo space.

In 1918, testing machinery was installed and comprehensive research work begun on Sitka spruce under the direction of the Forestry Branch, Department of Interior. From the outset the value of the laboratory was recognized by progressive lumbermen, and when the war closed representations were made at Ottawa citing the desirability of continuing its operation as an outpost of the central laboratory, then situated at Montreal, (the central laboratory, by the way, has just been removed to Ottawa, with the exception of the pulp and paper division which remains at McGill University in a building erected by the Canadian Pulp and Paper Association for this division, for the Department of Cellulose Chemistry of McGill University and for its own general offices).

Recognition of the peculiar problems facing the lumber industry in the province of British Columbia, with its 40 per cent of Canada's timber reserve, 70 per cent of Canada's saw-log material, and the great advantage accruing to manufacturer and consumer alike from the establishment of a technical investigative service locally, led to the decision to continue the laboratory as a unit in the Forestry Branch of the Department of the Interior. It is now located at the University of British Columbia, Point Grey, under a working agreement with the university, whereby the university supplies accommodation, while the personnel and equipment are provided by the Forestry Branch. The testing equipment is at the disposal of the Faculty of Applied Science of the University of British Columbia for instruction of students in engineering during their laboratory periods in construction materials.

The laboratory is housed in three buildings, the main building containing the executive offices, photographic dark room, pathological laboratory, testing laboratory, and carpenter shop, with dry kiln and air drying shed in separate buildings adjoining.

Equipment, at present, comprises two 30,000-pound Olsen universal testing machines; a 200,000-pound Olsen universal testing machine capable of testing sections up to 16 feet in length, either in end compression or cross bending; a Turner-Hatt impact testing machine; electric drying ovens; auxiliary apparatus for complete timber tests; tools for machine driving and pulling nails, and for pulling screws.

The purpose of the Forest Products Laboratory might be defined in some way such as this: "To conserve Canadian forests by developing the most economical methods of converting standing trees into finished products; to make the growing of timber more profitable by increasing the possibilities of utilization of both used and unused species, to find new uses for old materials and new materials for old uses." In other words, the object is to give practical assistance to both manufacturer and user of wood and wood products, and, in conjunction with them, to promote forest conservation.

Every Canadian industry and class of citizen that grows wood or uses it, or any of its derived products, may thus directly benefit by the research of the laboratory, and the value of the laboratory to any wood-using industry, class of consumer, engineer, or architect, depends almost wholly upon the use any of them makes of it. Any citizen of Canada has perfect freedom to correspond with the laboratory about particular problems dealing with utilization of wood, and will receive prompt answers, based upon whatever information is available upon the subject.

The laboratory is in charge of a superintendent, an assistant engineer, and staff. The work of the laboratory is distributed between two technical sections:—*Timber mechanics*, strength of wood and manufactured articles, computation; *timber products*, experimental and practical kiln drying, physical properties, mill studies, industrial investigations, pathology of timber products.

In addition, there is the section which handles accounts, photography, records and supplies. It is thus evident that the laboratory is well organized to render effective service to those requiring aid in the solution of problems coming within the range of its organization, and any lying outside its range will be immediately transmitted to the central laboratory at Ottawa, which has a very much larger number of technical sections.

Each year shows a very greatly increased total of requests for technical information over the preceding year, and it is to be expected that very shortly the entire time of one technical man will be required to attend to answers to these requests.

Timber Products

The timber products section of the laboratory operates the dry kiln, prepares kiln drying schedules for different species and thicknesses of stock, and offers expert advice upon the operation of commercial dry kilns. The necessity for this advice was recognized after a study of kiln drying losses in the dry kilns on the lower mainland in Victoria and at Nanoose, where the average loss in degrade and destroyed lumber was shown to be $2.62 per thousand feet board measure of lumber run through the kiln, representing in this area a yearly loss, (much of it preventable), of about $1,250,000. Mill studies of degrade, due to injuries in manufacture, and of methods of reduction or elimination, have been made. The resulting information placed at the disposal of local mills has materially reduced losses from the various causes.

Studies of absorption of moisture, and of piling methods for air seasoning, have also been carried out with resulting improvement in storage after kiln drying, and better piling methods. When all is said and done, only about 35 per cent of the wood in a forest emerges as rough lumber on the grading table at the mills, so that it behooves any lumber manufacturer to stop every leak within his power where such stoppage shows increased financial returns.

There is a huge undertaking ahead in developing ways and means of reducing to a minimum the losses in logging and milling and in discovering fields for profitable utilization of low-grade material.

Pathology

Cultures, of stains, moulds and wood-destroying fungi, are constantly being made and the organisms identified. Advice as to the control of these harmful organisms is frequently sought and supplied. There is a tremendous field ahead for research in these problems. Dry rot alone is responsible for losses running into millions annually.

Tree Growth

For an intelligent discussion of the physical and mechanical properties of wood, some slight knowledge of tree growth and structure are essential. Wood is a complicated structure, built more or less irregularly by the tree to serve the tree's ends; irregularly, because there are dozens of variable factors affecting the tree over which it has no control. A tree must grow where the seed germinates, or it must die there through lack of suitable growth conditions. Sun and wind, heat and frost, abundant moisture and drought, rich soil and poor, high and low altitude, all these and many other factors influence the character of the structure and leave legible records which they, who understand, may read.

In the light of the preceding statement, it is easy to see why there is such an infinite variety of wood and why there is such variation in quality between trees of the same species, even great variation between different logs cut from one tree and between different cuts from one log.

A tree has three major divisions: root system, trunk, and branches. The root system serves to anchor the tree in place and to collect from the soil the slight quantities of mineral matter, together with the large quantities of moisture, essential to tree growth. Incidentally, it contains the lightest wood in the tree, for its only stresses are tensile or compressive, in which wood has high strength values. The trunk supports the crown, conveys the raw sap, sent forward by the roots to the leaves, and serves as a store-house for food manufactured in excess of current needs. The branches are merely leaf bearers.

The majority of people think of a tree as a product of the soil. In a sense it is, but mainly it is not. Burn a piece of wood; on an average about one per cent by volume remains as ash. That is mineral matter which, with the moisture in the tree, represents the entire contribution of the soil to tree structure. The main source of food supply is the air from which the tree obtains carbon in the form of carbon dioxide. Growth takes place at the tips of roots, stem and branch, and at their circumferences under the bark. Wood formed previous to the current year does not increase in volume. Its only change, in normal growth, is a gradual one from sapwood to heartwood, as successive annual layers are laid on.

Heartwood is really dead wood. The only living cells in a tree are in the sapwood, and of these few are active. These cells or fibres are roughly either circular or rectangular in cross-section, and in length from twenty-five to several hundred times their diameter. The average length of fibre in our Pacific coast softwoods is about one-eighth of an inch. Hardwood fibres are much shorter. There is an almost incredible number of them in a cubic foot of wood. A single sheet of newspaper contains enough of them, if laid end to end, to reach from Vancouver to well beyond Kamloops.

The age of a tree can be determined by counting the rings in a cross-section. Each ring consists of two parts, a band of thin-walled weak cells grown in the spring and early summer, known as spring wood, and a band of thick-walled very much stronger cells grown in the late summer and early fall, called summerwood. Summerwood gives strength and hardness to any wood and, other factors being equal, is a direct indication of the strength of a piece of timber. The higher the percentage of summerwood shown in a cross-section, the stronger the specimen. This fact is so well recognized that specifications for the highest quality of structural material for Douglas fir and southern yellow pine contain definite statements of the percentages of summerwood required, 33 1/3 per cent for timbers having between six and twenty-five annual rings per inch, and 50 per cent for timbers having less than six rings per inch.

Timber Mechanics

Knowledge of the mechanical properties of woods and wood products is essential for their intelligent and economic use, whether in the factory, in the home, on the railroad, in the mine, or in the air. Thus, development of the airplane and progress along many other lines depend to a great degree upon accurate information as to the strength, toughness, elasticity, and other mechanical properties which determine the suitability of different woods for different purposes. There is a right wood for every use and a right use for every wood. One would hardly use cedar for handles, or oak for shingles. Uses of certain woods for specific purposes have frequently resulted from unreasoning prejudice or from custom handed down from one generation to the succeeding one. For example, it was long held that hickory heartwood was much inferior to sapwood for handle stock, an opinion based solely upon appearance without a vestige of truth for foundation, as mechanical tests showed.

Tests may be made either upon small clear specimens, or upon structural sized timbers. In the first case, the strength value of the wood itself is obtained, free from any defect which would vitiate the results as values directly comparable for different species. In the second case, every defect exerts a weakening influence upon the specimen and thus the total effect of knots, shakes, checks, pitch pockets, cross-grain, and other defects, natural or of manufacture, or of any of them, can be determined.

There are ten standardized tests of small clear specimens used today in determining the mechanical and physical properties of wood:—

(1) Static bending;
(2) Impact bending;
(3) Compression parallel to grain;
(4) Compression perpendicular to grain;
(5) Hardness;
(6) Shear;
(7) Cleavage;
(8) Tension;
(9) Shrinkage—radial, tangential and volumetric;
(10) Specific gravity.

These standardized tests are in use by government laboratories in the United States, Great Britain, Canada, India, Australia, and New Zealand, so that values obtained in any of these countries are directly comparable with those obtained in any other country.

Publications of the Vancouver laboratory are now in circulation dealing with Douglas fir, Sitka spruce, western hemlock, western yellow pine, western larch, Englemann spruce, amabilis fir, western red cedar. It is not intended to launch a discussion on these standardized tests, but it is desired to go somewhat fully into the discussion of moisture in wood and its effect.

The structure of a tree is built by the tree to serve its own ends. The tree wants its wood wet; man wants it dry. It is quite within his power to produce dry lumber, but he must exercise care in its production, or inevitably much material is spoiled in the process.

It is popularly supposed that trees contain a much larger quantity of moisture in spring and summer than in winter. One hears constantly the expressions "when the sap is up" and "when the sap is down." Such expressions have no meaning whatever, for actual tests on many different specimens from different localities have shown no appreciable differences in moisture content at any season of the year. A very simple analogy to the water service-pipes of a house will give a good illustration. Like the water pipes, the tree can contain only a certain maximum amount of water, (according to Tiemann, for wood of a given specific gravity there is a definite maximum moisture content). When the water taps are opened, circulation begins, and more and more water passes through in a given time as the taps are opened wider and wider. So with the tree. As the warmth of sun and wind wakens it from winter's dormancy and the leaves are opened, sap circulation starts and speeds up. More and more water passes through the tree in a given time without increasing measurably the quantity present at any given instant.

Moisture in a piece of green wood saturates the cell walls and fills, or partially fills, the cell cavities. As you are aware from observation, a piece of dry wood is much stronger than the same piece when green. It will support a greater load when used as a beam or as a column, and will withstand a greater shock. Also as wood dries, it shrinks. This increase in strength does not commence, nor does any shrinkage take place until the cell cavities have been emptied of moisture and the cell walls have begun to dry out. From this point, known as "fibre saturation point," increases in strength is rapid.

In dealing with wood, there is only one moisture content that can be definitely fixed. That is the condition which we call "oven dry," which is defined as being the weight that remains constant when held in an oven at 212°F. That weight can always be exactly determined and all moisture percentages, when dealing with wood, are expressed in terms of this "oven dry" weight.

Moisture in a tree is exceedingly variable. It varies from point to point along the trunk, and from pith to bark, the sapwood having the greatest quantity. Many specimens have shown, at the Forest Products Laboratory, moisture content in excess of 200 per cent. That is, the weight of water evaporated at 212°F. has been more than double the weight of the dry wood.

There are two critical moisture percentages, green and air-dry, green being defined as any percentage higher than fibre saturation point, which varies slightly for different species and lies between 20 and 30 per cent for all British Columbia species so far determined.

Air-dry condition varies slightly from month to month; an average for Canada for the summer months would be about 12 per cent, while for winter it would stand higher at 14 or 15 per cent.

Now the method of determination of "fibre saturation point" may prove of interest. It is probably not susceptible of absolute fixation, but may be closely approximated. Standard specimens are tested in static bending and compression parallel to grain at a predetermined range of moisture content; say, from 20 to 30 per cent, by one degree intervals. The rough green sticks are weighed and their moisture content determined from a moisture disc. Then the weights of the sticks at the assigned moisture contents are computed, marked on the sticks, and the sticks carefully air-dried. From time to time these are check-weighed, until they come to the computed weights. They are then dressed to standard size, and the moisture content of the dressed test pieces re-determined. The weight of each test piece and its computed weight at the assigned moisture content are compared. If they agree, the specimen is immediately tested. If they do not, it is brought to the correct moisture content by drying or adding moisture, as may be necessary, and tested when in the series of check-weighings it shows the computed weight at the assigned moisture content. Moisture discs are then taken from each test piece and its moisture content accurately determined.

Typical moisture strength curves for western larch, western hemlock, western yellow pine, Sitka spruce, and Engelmann spruce, as determined by the Forest Products Laboratory, Vancouver; the first is for the static bending and the second for compression parallel to grain. These curves are subject to minor corrections as more trees are tested, and the values derived enter into the averages from which these curves have been plotted. It will be noted that the strength remains constant until a moisture content of, roughly, 25 per cent is reached, when a sudden and sharp increase in strength occurs. This is the "fibre saturation point." It may also be fixed by plotting shrinkage—moisture curves.

When analyzing the results, obtained experimentally, for strength values of small clear wood specimens, one cannot fail to be impressed by the fact that strength and stiffness depend very largely upon the moisture content of the wood. In general terms, strength is the ability to sustain loads without failure, while stiffness is the ability to resist distortion.

It is apparent that these experimental values hold only for the percentage of moisture content at which the tests were made. As such a comparatively weak wood as Engelmann spruce shows much higher strength values at 12 per cent moisture content, (air-dry), than green Douglas fir in fibre stress at elastic limit and in modulus of rupture, static bending, in crushing strength, compression parallel to grain, and in fibre stress at elastic limit impact bending, it is obvious that tables of strength values are of no use for comparison unless they show the corresponding moisture percentages.

It is not feasible, indeed it is not possible, to bring test specimens to an exact, pre-determined moisture content. The three moisture percentages particularly of interest in the laboratory are green—any percentage above the fibre saturation point; air-dry—roughly 12 per cent; and oven-dry—about 0.5 per cent. Comparison of strength values for different trees of one species at any one of these moisture contents is a very simple matter. But when a specimen is tested and its moisture content, as determined, lies somewhere in the range between oven-dry and green, an immediate difficulty arises in making comparison, and some adjustment is necessary to reduce the observed value to an equivalent value at a standard percentage, usually 12 per cent.

The problem is to find some mathematical law connecting strength value and moisture content. Moisture strength curves, plotted upon cross-section paper, are smooth curves, very regular in form. A study of these curves has resulted in an empirical formula, the so-called "exponential formula," by means of which, given the moisture percentage at fibre saturation point, the green strength and the strength and corresponding moisture content anywhere in the range from oven-dry to green, the strength at any other moisture content can be closely approximated.

As an indication of how the results of research sometimes find immediate application three recent instances are cited. During the past year the results of tests on western hemlock, conducted in the Vancouver laboratory, were largely responsible for defeating a proposed ordinance against the use of western hemlock for certain types of construction in some of the boroughs of New York City. The outcome of the investigation, conducted by New York engineers on the Pacific coast, was that instead of lowering the former rating, the new rating showed a material increase in allowable stresses and a large and valuable market for western hemlock thereby established.

A report was made recently that the Japanese market was inclined to believe that Washington and Oregon hemlock exceeded British Columbia hemlock in strength. Strength values determined by the Vancouver laboratory showed that the reverse is true and their presentation to the Japanese dealers through the Canadian Trade Commissioner in Japan successfully held the Canadian market there.

Some three years ago an enquiry came to the laboratory from the district forest inspector's office at Kamloops as to the relative strength of green-cut and fire-killed cedar, and as to whether the complete exclusion of fire-killed poles from acceptance under the current pole specifications had sufficient justification. As frequently happens, an enquiry of this kind opened up unexpected phases. It was found that the provincial Forest Service was greatly concerned on this matter. Information came in to the effect that in some districts at least one-half the cedar of pole size had been fire-killed.

Enquiry at the United States Forest Products Laboratory at Madison, Wisconsin, elicited the reply that such tests as had been made there on fire-killed material did not include western red cedar. However, a working plan for tests of this species had been prepared, and, in a very generous spirit of co-operation, this working plan, together with valuable suggestions for improvements in testing methods, was supplied to the Vancouver laboratory.

Two shipments of poles, one from near Cloverdale and one from near Kamloops, were secured for investigation.

Each shipment was composed of four groups of fifteen each:—

(1) 15 green-cut poles of merchantable grade.
(2) 15 poles fire-killed less than two years.
(3) 15 poles fire-killed from five to ten years.
(4) 15 poles fire-killed more than fifteen years.

When this project was initiated, the sole purpose was to establish the relative strengths of green-cut and fire-killed material. But now an unexpected phase developed. The research division of the Western Red Cedar Association at Chicago, vitally interested in any investigation relative to cedar, drew the attention of the laboratory to the fact that the Engineering Standards Association had a committee at work for the purpose of recommending allowable fibre stresses in pole line design for white cedar, western red cedar, southern yellow pine, and chestnut, and that the American Telegraph and Telephone Company had carried out a series of tests on full-sized poles of all species.

It soon became evident that the members of the Engineering Standards Committee were not of one opinion as to the methods to be adopted in reaching a decision. Some of the members were inclined to base permissible stress on the strength values shown by standard tests on green material cut from mature trees. Others were of the opinion that these tests from mature trees did not show as high strength values as would be shown by tests on specimens from pole-sized trees. This laboratory held the latter view, and the difference of opinion led to a decision to postpone recommendation of the allowable fibre stress until the completion of the tests at Vancouver. These tests, both upon full-sized poles and upon small clear standard test pieces, confirmed the contention that higher allowable stresses were practicable for pole-sized than for mature timber. It is expected that the figure now under consideration will be finally adopted. This figure, which is still confidential, will be very satisfactory to the Vancouver Forest Products Laboratory.

An analysis of results of the investigation of the relative strength of green-cut and fire-killed poles shows:—

(1) Rigid inspection of fire-killed poles is a necessity.

(2) A large percentage of standing fire-killed poles may be safely marketed under rigid inspection service.

(3) Fire-killed poles, acceptable under the commercial specifications for green-cut poles, show a maximum reduction in strength of 8 per cent as compared with green-cut. In one group of poles, fire-killed thirteen months, the modulus of rupture showed a higher value than for green-cut. Another group, fire-killed six years, showed only two-tenths of one per cent lower modulus of rupture than the green-cut poles.

There have been rumors of coming shortage of lumber. It is freely predicted that the first shortage to be felt will be in poles, and that this shortage will be noticeable within the next fifteen years. Meanwhile, any modification of specifications so as to permit the use of found fire-killed poles will help materially to postpone this anticipated shortage.

Projects on Hand

Projects under investigation at the present time include "The holding power of nails in wood," "The holding power of screws in wood," and "Deterioration of black cottonwood in storage, both in the air and in water." These have not progressed sufficiently to render any report possible at present. The above covers fairly well the routine work of the laboratory. The laboratory is continually conducting special industrial investigations such as: strength of wooden containers, strength of plywood, strength of glued joints, moisture content of kiln dried woods.

Now it will be quite in order to indicate a matter that will eventually, perhaps even almost immediately, require extensive and exhaustive enquiry. This is in connection with standardized building codes with which lumber grades are inseparably linked. It will involve an extensive programme of tests of structural sized timbers covering all grades and all structural species. A working plan has been prepared and can be put into immediate operation as soon as authority is granted.

An examination of the allowable stresses for timber of different species shown by the building codes of various cities reveals wide variations in these values. So far as structural safety is concerned, the purpose of a building code is, or ought to be, to provide for safe, allowable stresses, and also to maintain a reasonable economy in costs. Manifestly the maximum safe stresses are desirable. It is upon this point that variations occur; but the stress that is safe in one city is certainly safe in another city, for the same loading conditions, and there seems no sufficient reason to prevent the adoption of a uniform set of values.

With finishing lumber, appearance is the dominant factor, but with structural material the criteria are size, position, and number of defects. For example, in a beam, a knot on the underside at the centre of the span is in the worst possible position, and the larger the knot the greater the weakening; so, too, the knot has less weakening effect as it approaches the neutral axis of the beam.

A few years ago the city of Vancouver made certain changes in its building code. This laboratory was asked to recommend allowable stresses for Douglas fir, western hemlock, western red cedar, and Sitka spruce. Considerable criticism has been directed against the values adopted for Douglas fir, more particularly that of 1,500 pounds per square inch for extreme fibre stress in bending, which has been considered too low.

Lumber in British Columbia mills is graded according to the grading rules of the British Columbia Lumber and Shingle Manufacturers' Association, whose highest grade in structural material is "Selected Common." This grade is slightly lower than the "Structural" grade of the West Coast Lumbermen's Association, for which the United States Forest Products Laboratory recommends an allowable stress of 1,600 pounds per square inch. There is a higher grade recognized than this, "Dense Structural," for which the recommended stress is 1,800 pounds per square inch in extreme fibre stress. Now these two higher grades are selected from material falling in the "Selected Common" grade of British Columbia. It would be a manifest absurdity to specify 1,800 pounds per square inch for "Selected Common" grade and run the certain risk of material barely passing this grade being incorporated in an important structure.

A very grave defect in structural timber is spiral or diagonal grain. C. J. Hogue, field manager, West Coast Lumber Trade Extension Bureau, referring to structural material, states: "There is not much reduction in strength from cross-grain until an angle of 1 in 40 is reached. From that slope, in a beam, an angle of grain of 1 in 20 reduces the strength about one-eighth; 1 in 15, about one-fourth; 1 in 11, three-eighths; and 1 in 8, one-half. In a post or column this reduction is about one-eighth for an angle of 1 in 15; one-fourth for 1 in 11; three-eighths for 1 in 8, and one-half for 1 in 6." These conclusions are based upon experimental data determined by the United States Forest Products Laboratory, Madison, Wisconsin.

Defects in structural timber, their effect upon its mechanical properties, and safe allowable stresses for recognized grades of structural species, open up an alluring field for discussion which it is hoped may be entered upon at some future date when these subjects may be given consideration under the general caption of "Structural Timber."

Public Address Systems

A General Outline of the Principle, Equipment and Application of such a System

A. A. Turnbull, A.M.E.I.C.,
Plant Engineer, New Brunswick Telephone Company, Limited, Saint John, N.B.

Paper read before the Saint John Branch of The Engineering Institute of Canada, April 3rd, 1928

The public address system is a development of the communication art. It has been developed in order to enable a speaker to address an audience of much greater size than possible without artificial means of increasing the volume of his voice.

In a small hall of poor acoustic properties, it is probable that not more than two or three hundred people could hear the speaker. With the aid of the public address system, an indoor gathering of 15,000 people have been able to hear the speaker. Ordinarily, it is difficult to speak to more than 5,000 people, either indoors or outdoors, and be heard, but by artificial means this audience can be enlarged to crowds of over 100,000, the outskirts of which may be 1,000 feet from the speaker.

Besides the public address system proper, and its general or most common use, it may be used in stations for announcing the departure of trains; on battleships for centralized fire control; in telephone work to assist the wire chief in clearing troubles in the terminal room, and in connection with wire telephony on the toll lines to enable a speaker to address audiences at distance points.

The requirements of such a system can be divided into three main parts—the " pick up " of a speaker's voice, the amplification of the " picked up " voice and projection of the amplified " pick up," so that the speaker may be easily heard by a much larger audience than otherwise possible.

The " picking up " of some of the energy from the speaker's voice in such a way that his usual actions are not unduly hampered is the first consideration. This " picked up " energy must then be converted into electrical energy of the same characteristics as that of the voice. The instrument used to perform this work of converting sound waves into electrical waves is called the microphone or transmitter.

The small amount of energy " picked up " by the microphone or transmitter must now be greatly amplified and this is done by the amplifying unit and associated equipment.

The amplified electrical energy must now be properly directed and controlled so as to be projected in the form of sound waves in such a way that the entire audience can distinctly hear what the speaker is saying and so that there will be no interference experienced by those who are near to the speaker and hear him distinctly. This is accomplished by means of loud speaking receivers and projectors, properly distributed, the function of these receivers being to convert the electric waves into sound waves.

The Transmitter or Microphone

A high quality transmitter has now been developed which permits of excellent quality speech sounds being reproduced. This transmitter consists of two carbon buttons, one on each side of the diaphragm. Distortion in one button is counteracted by distortion in the other. The diaphragm is stretched so that its natural frequency is above the range of frequencies encountered in speech and music. It is less efficient from a volume point of view than the ordinary transmitter of a subscriber's telephone set, but produces far better quality of speech or music.

The transmitter mounting consists of a drum shaped cage perforated on all sides and covered with a fine brass wire mesh. Inside are four hooks from which the transmitter is suspended by means of coil springs. Sometimes a felt lined wooden box is used for holding one or two transmitters, the transmitters being suspended in the same manner from hooks by means of coil springs. The face of the box of course has one or two openings.

Adjustable pedestals are sometimes used in connection with the transmitted mountings. The transmitter has a very uniform efficiency over the entire voice range of frequencies, i.e., from about 200 to 2,000 cycles; and it is also quite efficient as high as 5,000 cycles, which is about the practical limit required for good reproduction of musical instruments. Distortion of the voice waves is reduced considerably by the " push-pull " effect of the two carbon buttons.

The Amplifier

The usual input impedance of an amplifier may be around 200 ohms with an output impedance of 500 ohms or 2,000 ohms, depending on where the output is to be directed. If the amplifier is used in connection with long lines, an output impedance of 500 ohms will usually be required. If directly connected to three or four receivers or projectors, then a 2,000-ohm output impedance is more desirable. There are several types of amplifiers suitable for various purposes, but their general principles are the same. Large systems or systems used in connection with radio broadcasting have also transmitter control, volume indicator and volume control apparatus, in addition to the amplifier unit.

One type of three stage amplifier used in connection with a high quality microphone is capable of a maximum energy amplification of one hundred million and a minimum of one hundred. Power amplifiers used in connection with this three stage amplifier are capable of increasing the energy an additional twenty-five times. This amplification would be suitable for a large auditorium.

For large out-door gatherings a power amplifier capable of increasing the energy of the three stage amplifier three hundred times could be used.

The 32-A amplifier used in the Western Electric No. 4-A public address system consists of four stages of audio amplification. The first three stages consist of resistance coupled amplification using No. 231-D vacuum tubes. The fourth stage of amplification is obtained with the use of a transformer coupled No. 250-D vacuum tube. The filament current for the first three stages is supplied from a 12-volt storage battery or No. 6 dry cells; these tubes require only 60 milliamperes at 3.3 volts. The filament current of the fourth stage is supplied from a step-down transformer connection to the 110-volt lighting circuit. Plate current is supplied to all the stages by means of half wave rectification of the 110-volt lighting circuit and using a No. 205-D vacuum tube for this purpose, the filament of which is supplied from the alternating current source. The gain of the amplifier is controlled by means of a potentiometer which may be varied in steps of 3 T.U.* for each of the twenty-two steps. The input of the amplifier is of 200 ohms impedance while the output impedance can be made 500 ohms or 2,000 ohms.

Projectors and Receivers

A projector consists of a receiver, receiver housing and horn of one design or another, depending on what the conditions require. The amplified electrical waves are converted into sound waves by means of a receiver consisting of magnets, armature and diaphragm. The magnet and armature of this receiver combine to give a "push-pull" effect to the vibrating of the diaphragm, thus tending to minimize distortion in the wave shape and giving maximum amplitude of vibration.

The horns most commonly used for auditoriums and for small out-of-door gatherings are usually of wood fibre, about 3 feet in length and about 1½ feet at large end. Horns for large out-of-door audiences are sometimes 10 feet long and 2 feet at the large end.

The cone type loud speaker lacks the directive effect of the horn of a projector and is never used except for monitoring.

Power Equipment

For large installations, more or less permanent and elaborate means of control and power supply equipment are utilized.

Sound Transmission and Acoustics

Sound is transmitted through the air by waves and only part of the sound reaches the listener directly from the original source. The remainder comes by reflection from the walls, ceilings or other bodies in the room. In some cases this reflected sound is very small, due to the direct sound waves being absorbed by the reflecting surface. This happens when the reflecting surface is soft and yielding. If the reflection comes from a hard smooth surface this energy will form quite a large part of the total received by the listener.

An overlapping of reflections in a room or auditorium is called reverberation, while the lagging of reflections cause echoes. Some rooms have both reverberation and echo effects and in order to reduce or overcome these annoying conditions it was usually necessary to pad the room with absorbent material. Sometimes a large audience will have the same result.

Reverberation and echoes can be eliminated by the use of the public address system. The speaker can lower his voice and there is not the same opportunity for producing reverberation and echoes. The sound is carried directly where it is needed and where it will be absorbed most efficiently by the audience.

Operation

The success of a system largely depends upon the operation of the apparatus and suitable location of all units.

A local programme will probably be direct from the transmitter to the amplifier, to the projectors. For a programme from some distant point the input to the amplifier will be from a wire line. Local inputs may be picked up by means of transmitters located at different points, a means of switching to the desired transmitter being available.

Transmitters must be properly located. This is best determined by trial. They should be placed 2 to 6 feet from the source of sound in the case of speakers or soloists; facing the piano and for piano music, a little to one side of the keyboard; suspended over an orchestra and to the front, somewhat in a position nearer to the stringed instruments and bass than to others; diagonally in front of phonographs, and in all cases so placed that it will not have the sound from a projector directed toward it. Sounds from projectors entering a transmitter will cause the transmitter to "howl" or "sing."

Above all things, the audience must not experience anything unnatural in the quality of sound from the speaker. The system must operate so successfully that the audience will not realize that hearing is being mechanically aided.

---

*The transmission unit, abbreviated T.U., is an arbitrarily selected unit which is used to measure gain and loss. For practical purposes it may be considered that a gain of 3 T.U. indicates that the output power at speech frequencies is approximately twice the input power at speech frequencies, a gain of 6 T.U. four times the input power, a gain of 9 T.U. eight times, etc. Conversely, a loss of 3 T.U. indicates that the output power is approximately one-half the input power, a loss of 6 T.U. one-quarter the power, a loss of 9 T.U. one-eighth, etc.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME XI   OCTOBER 1928   No. 10

Success and Education

From the time of its original formation as The Canadian Society of Civil Engineers, The Engineering Institute of Canada has laid stress on the importance of educational qualification as a condition for admission to its membership. Further, our records and publications, like those of other engineering societies, contain many papers, discussions and articles on Engineering Education, and there are, in fact, societies which have for their main purpose the promotion of engineering education. It is thus evident that engineers, as a body, appreciate the importance of the subject, and it is natural to inquire whether the results obtained in the way of material success are commensurate with the expense and time involved in obtaining a professional education of the highest class.

The laborious investigations of the Society for the Promotion of Engineering Education have provided us with a mass of data, from which, however, it is difficult for a reader, who is not himself an educational authority, to judge how far our present system of engineering education is really satisfactory. The individual naturally asks whether his own training has been effective in securing his present success. The employer, often a large corporation employing engineers' services, would like to ascertain whether it is worth while to give the preference to engineers who have taken an adequate professional course, or have distinguished themselves during their undergraduate career.

An interesting analysis of the situation recently appeared in Harper's Magazine, May 1928, from the point of view of the president of one of the largest industrial companies in the United States, under the title, "Does Business Want Scholars?" the information used in the article being based on the university records of over four thousand graduates from over a hundred colleges, and their success or otherwise in the company's service. These men were, of course, not all engineers, but it is interesting to note that the proportional results for the engineering graduates taken by themselves were almost exactly the same as those for the whole group studied, or for the graduates in Arts and other faculties taken separately.

In default of a better criterion, success was taken to be measured by salary, which is perhaps the best, if not the only possible gauge to be applied in studying a body of men who all work in the same business organization. The writer points out the tendency, so noticeable in the present-day undergraduate, for the student to think that his athletic or social activities, and his work on the college paper or in the dramatic club, for example, are a better training for the future than his academic course, and this is an opinion which is also held by many outside of university circles. It is, therefore, a very live question as to whether industry should seek students who have a high academic record, or should give the preference to those who have distinguished themselves at the university in athletic or social activities, and the results of the inquiry certainly have some bearing on this point. There is no question that in Law or Medicine those who have stood well in their professional classes are more likely to attain high standing in their professional work in later years, but does this hold good to the same extent in industrial or business life, and particularly in the work of engineers?

The data so far available from other sources are largely confirmed by the results of the inquiry now referred to, and there seems no doubt that it is not so much the special knowledge acquired by the men of high academic standing which makes them valuable when they leave the professional school, but the fact that they have acquired the "habit of successful mental accomplishment."

It is well known that many graduates of our engineering schools do not take up engineering after graduation, but deliberately elect to follow a non-technical or business career, and it is for this reason that Mr. Gifford's inquiry has particular interest for us. It is true that a great number of the higher positions in the Bell organization are held by men who have not gone to college, and the inquiry has not yet been extended to the scholastic and business records of these men. The conclusions drawn should, therefore, be applied only to those who have received a college education. In general it was found that the men who had taken high standing in their university courses had been correspondingly successful in the company's work, and in fact that "men in the first third of their college classes are most likely to be found in the highest third of their group in salary, those in the middle third in scholarship to be in the middle third in salary, and those in the lowest third in scholarship to be in the lowest third in salary." This applied to graduates in the service who had been over five years out of college. Further, it was found that "the longer the best students are in business the more rapidly their earnings rise. The longer the poorer students are in business, the slower their earnings rise."

"If studies by others," says Mr. Gifford, "corroborate the result of this study in the Bell System, and it becomes clear that the mind well trained in youth has the best chance to succeed in any business it may choose, then scholarship as a measure of mental equipment is of importance both to business and to business men."

Recent Progress in Oil- and Gas-Power Engineering

Twenty years ago the small power user naturally turned his thoughts to the four cycle gas-engine, often using producer gas, but the manufacture of such small and medium sized gas-engines has largely lost its relative importance since the development of gasoline and Diesel type engines. The large gas-engine holds its own where industrial gas is available as a by-product of blast furnace or steel-mill operation, and such engines under these circumstances are still the most economical generators of power, particularly in the larger sizes up to 4,000 h.p. capacity.

Of recent years the tendency of oil-engine development has been towards the increase of compression pressures, not only with the aim for higher output, but also for the sake of convenience in starting cold, and economy in operation. In gasoline engines progress in this direction has also taken place but has been limited by detonation troubles, and the problem has not yet been fully solved, even when fuels containing lead ethyl and other anti-knock compounds have been used. Higher rotative speeds are being employed, and the satisfactory results thus obtained have been largely rendered possible by the experience gained with high speed automotive and aircraft engines. It is thus probable that we are only at the beginning of a period of development of higher speed internal combustion engines.

The use of higher compression pressures has been particularly noticeable in oil-engine practice, and as a result the importance of the low compression or semi-Diesel-engine has distinctly diminished during the last few years. Much, however, remains to be done before the heavy oil-engine will become as supreme in the automotive field as it is for stationary and marine work. Perhaps the greatest progress has taken place in connection with the Diesel-locomotive, on which a great deal of work has been done in Europe, where no less than nineteen companies are engaged in the construction of Diesel-engine locomotives and railway cars. Amongst others, the Canadian National Railways have been pioneers in this line of work, and it is understood that very satisfactory operating results have been obtained from the Beardmore engines with electric transmission as fitted in their cars.

Of the many different systems of transmission which are being tried for oil-engine locomotives, the electric drive has so far had the best opportunity to prove its success, and operating experience gained in the last two years shows that the Diesel-locomotive is capable of high economy in its particular field. Considerable progress has been made in the successful employment of Diesel-engines for automotive work, largely in connection with trucks, and great efforts are being made by various governments to develop the heavy-oil compression-ignition engine so that its engine weights may be brought down to figures comparing favourably with those of gasoline engines; success in this direction will mean much to the aircraft and automobile designer. It is understood that heavy-oil engines are being used in one of the two great airships of five million cubic feet capacity now being constructed by the British Government.

In high power Diesel-engines, the principal field of employment is now at sea, Lloyd's figures for last year showing over 1,000,000 h.p. of oil-engines under construction, as against about 900,000 h.p. of steam machinery. The largest cylinder output so far obtained, (from an experimental one-cylinder engine), is 2,900 indicated h.p., but in multi-cylinder engines several are working successfully while developing 1,200 h.p. per cylinder.

It seems an established fact that unless favoured by local conditions the Diesel-engine cannot compete with steam and water turbines for large power generating units. Their combination, however, with steam and water power for peak use offers decided advantages.

The successful operation of Diesel-engines depends so largely on good design, and particularly on accurate workmanship of a high grade, that it is not surprising to find more and more engineering skill applied to their production. Careful and elaborate finishing methods are found to bring good results, and such expensive operations as the grinding and honing of cylinders and lapping of pump plungers and valve seats have proved worth while.

As in the case of aircraft and automobile work it has been necessary to devise and manufacture a number of special accessories, and the development of the heavy-oil engine has accordingly led to the construction of satisfactory air and oil filters, supercharging blowers, distant-reading thermometers, and high-speed indicators. The development of supercharging has been a particularly interesting feature, in some cases the rating of a four-cycle engine being increased no less than fifty per cent by the adoption of this device.

So far as economy is concerned, considerable progress is to be noted, a fuel consumption of less than four-tenths of a pound of oil per B.H.P. per hour having been recorded.

One of the principal handicaps to the successful use of heavy-oil high-compression engines for commercial work is being gradually removed owing to the availability of more trained men. A skilled operator, familiar with Diesel work and practice, is just as necessary for success as a competent man would be in a steam-plant. There seems every reason to anticipate further continued and satisfactory development in heavy-oil power engineering.

OBITUARIES

Alexander Charles Dogherty, A.M.E.I.C.

It is with regret that we record the accidental death by drowning on August 10th, 1928, of Alexander Charles Dogherty, A.M.E.I.C., in Brome lake, Quebec, where he was spending his vacation with his family.

The late Mr. Dogherty was born in Montreal on September 6th, 1891. At the age of seventeen he entered the employ of the Northern Electric and Manufacturing Company and spent two years in their shops and drafting room. This was followed by a year with the Allis-Chalmers Bullock Company at Rockfield, Que., on the erection and drafting connected with switch-boards. During his early years he successfully completed a course in electrical engineering with the International Correspondence Schools at Scranton, Pa.

In February 1911 he joined the staff of T. Pringle and Son, Limited, of Montreal, engineers and architects, with whom he was connected until the time of his death, with the exception of the years he spent overseas with the C.E.F. and part of 1918 in Three Rivers, Que., when his services had been loaned to the Wayagamack Pulp and Paper Company for the reorganization of their electrical equipment.

In 1914 he designed and supervised the construction of pumping and electrical equipment for the Corby Distillery Company at Corbyville, Ont. Towards the end of the year he enlisted in the C.E.F. and in 1915 went overseas with the 27th Battery, C.F.A. Severely wounded at the battle of the Somme in 1916 he underwent thirteen operations before being returned to Canada in 1917. Upon resuming his connection with T. Pringle and Son, Limited, he spent eight months as resident engineer for them on an hydro-electric development at Coaticook, Que., for Penmans Limited. From 1919 until the time of his death he had charge of the electrical, mechanical, heating and ventilation work for this firm.

Mr. Dogherty joined The Institute as an Associate Member in May 1925. The news of his untimely end will be learned with regret by his many friends and business associates by whom he was held in the highest regard.

Hugh David Lumsden, M.E.I.C.

The death of Hugh David Lumsden, M.E.I.C., at Orillia, Ontario, on Wednesday, August 29th, 1928, at the age of eighty-four, takes from among us a prominent member of the band of engineers who, in the seventies and eighties, did the pioneer work on the great railway transportation systems of this country. With the exception of Prince Edward Island there is not a province in Canada in which he did not contribute to the upbuilding of the country.

Born on September 7th, 1844, at Belhelvie Lodge, Aberdeenshire, the youngest son of Colonel Thomas Lumsden, C.B., he belonged to a family whose members distinguished themselves in many parts of the world and in many spheres of activity. In India his eldest brother, General Sir Harry Lumsden, raised the Queen's Own Corps of Guides, (Lumsden's Guides), in 1846 for service on the North West Frontier, and clothed that famous corps in khaki, introducing for the first time the uniform which was later adopted throughout the Indian Army and in almost every army in the world. Another brother, General Sir Peter Lumsden, rendered important services on the Afghan Boundary; another, William, was killed at the gates of Delhi during the Indian Mutiny. Another, John Lumsden, came to Canada, settling at Galt, of which city he was mayor, and represented that constituency in the old Legislature of Upper Canada.

HUGH DAVID LUMSDEN, M.E.I.C.

Hugh David Lumsden received his early education in Aberdeen and at Wimbledon, coming to Canada in 1861. He served his time as Provincial Land Surveyor at Woodville, Ontario, and was admitted to practice as such in January 1866. From 1866 to 1870 he was in private practice as a Provincial Land Surveyor at Woodville.

In 1870 he was elected Reeve of the township of Eldon in Victoria County. In 1871, under Edmond Wragge, M.E.I.C., he had charge of the location of the Toronto and Nipissing Railway, through Orillia, Gravenhurst and northward. From this time onward he was almost continuously employed in the location or construction of railways. To mention but a few of these: Portions of the Credit Valley Railway; Toronto, Grey and Bruce; the Georgian Bay Branch of the Canadian Pacific Railway; location and construction of the Ontario and Quebec Railway; Toronto to Perth; and the Canadian Pacific Railway, Smith's Falls to Vaudreuil, St. Johns, Que., to Lennoxville, Holeb to Mattawamkeag, and Rigaud to Ottawa. In the west he was for a short time on some of the first surveys for the Canadian Pacific Railway. Later he was supervising engineer for the location and construction of the Qu'Appelle, Long Lake and Saskatchewan Railway; the Calgary to Edmonton Railways; and was locating engineer on the Crow's Nest Pass Railway, Kootenay Landing to Lethbridge.

On the commencement of the National Transcontinental Railway in 1904, he was appointed chief engineer, which position he held until 1910. By this date the location and much of the construction was completed, but being unable to agree with the policy of the commission of that time, he resigned. He carried on some consulting practice for a number of years, but after 1914 did little active engineering work. In this connection it is of interest to note that from 1861 up to the day of his death, he never failed to write up his diary. Throughout his life he was a keen fisherman and an excellent shot. He also made a hobby of photography, and many of his pictures of the west in the early days are of historical interest.

In 1887 he joined The Canadian Society of Civil Engineers, now The Engineering Institute of Canada, serving on the Council for some years, becoming a vice-president in 1898 and president in 1906. He was for many years a Member of the Institution of Civil Engineers (Great Britain).

In 1885 he married Mary Whitney, of Toronto, who died in 1926. He leaves four sons, the eldest, Hugh Allan, being County Engineer of Wentworth; Harry Bruce, Assistant Director of Development, Canadian Pacific Railway, Winnipeg; Gordon Leith, with Robins Ltd., Toronto; and Peter Vernon, in Bagdad, Mesopotamia.

Hugh David Lumsden was almost the last survivor of the engineers who were responsible for the original formation of The Canadian Society of Civil Engineers, of which he was a charter member. In addition to great technical skill in his profession, he was characterized by a keen sense of honour, and a markedly independent spirit. The loss of such a man leaves a vacant place in the ranks of The Institute which cannot readily be filled.

PERSONALS

C. A. W. Grierson, S.E.I.C., has accepted a position with the Bell Laboratories, Inc., in New York City. Mr. Grierson, who formerly resided at Weymouth, N.S., is a graduate of Dalhousie University of the year 1925.

W. C. Macdonald, A.M.E.I.C., secretary-treasurer of La Societe Generale de Ponts et Chaussees, Limitee, at Montreal, is at present located at the company's office at Kingston, Jamaica.

V. E. North, S.E.I.C., is at present attached to the apparatus sales department of the Canadian General Electric Company, Limited, at Toronto. Mr. North was formerly attached to the company's Montreal office.

B. H. Zwicker, S.E.I.C., has joined the students' course of the Canadian General Electric Company, at Peterborough, Ont. Mr. Zwicker graduated from the Nova Scotia Technical College with the degree of B.Sc. this spring.

G. W. Babbitt, S.E.I.C., formerly of Fredericton, N.B., is at present located at Peterborough, where he is taking the students' course at the plant of the Canadian General Electric Company. Mr. Babbitt graduated from the University of New Brunswick in 1928, with the degree of B.Sc.

Cecil Brain, S.E.I.C., who graduated from McGill University in the spring of this year with the degree of B.Sc., is now a member of the staff of the International Paper Company at Corner Brook, Newfoundland.

L. McGill Allan, A.M.E.I.C., who has been local manager for Wells and Gray, Limited, general contractors, Windsor, Ontario, for the past fifteen years, has organized a company to carry on a similar business, with Charles Earl, under the name of Allan and Earl Limited.

Sheldon W. Coleman, S.E.I.C., formerly of Montpelier, Vermont, is at present located in Montreal, having joined the staff of John S. Metcalf Company, Limited. Mr. Coleman graduated from McGill University in the spring of this year, with the degree of B.Sc.

R. P. Freeman, A.M.E.I.C., who was construction engineer with the International Paper Company at Three Rivers, Que., is now at Dalhousie, N.B., where he will be located with the International Paper Company for a year or more.

C. A. Wakeham, S.E.I.C., is now taking a student course with the Canadian Westinghouse Company at Hamilton, Ontario. Mr. Wakeham graduated from the University of New Brunswick in the spring of this year with the degree of B.Sc.

George F. Binns, S.E.I.C., has been appointed to the engineering staff of the Canada Starch Company, Limited, Montreal. Mr. Binns is a graduate of McGill University of the year 1923, and was until lately mechanical draughtsman with the Laurentide Company, Limited, at Grand'Mere, Que.

C. C. Langstroth, A.M.E.I.C., has been appointed flying instructor for the Saint John, N.B., Aero Club. Mr. Langstroth, who is on the staff of the Atlantic Sugar Refineries Limited, and a graduate of McGill University of the year 1921, has had considerable previous experience in flying while instructor at one of the training schools of the Royal Flying Corps, in England, during the War.

W. L. Mackenzie, A.M.E.I.C., has resigned his position as assistant engineer on the Welland ship canal at St. Catharines, Ont., to become designing engineer on the new Hudson Bay terminus which the Department of Railways and Canals is erecting at Fort Churchill, Man. Mr. Mackenzie, who is a graduate of McGill University of the year 1917, had been on the staff of the Welland ship canal since 1921, first as senior draughtsman and from 1923 to the present time as assistant engineer.

John Lee, A.M.E.I.C., has been appointed works manager of the Winnipeg shops of the Canadian Pacific Railway Company. Mr. Lee has been connected with the Canadian Pacific Railway Company since 1911, when he joined the staff as assistant foreman. He became assistant shop engineer, and later shop engineer, and in 1920 was promoted to the position of engineer of tests and chief draughtsman at the Canadian Pacific Railway depot, mechanical department, at Winnipeg, which post he has held up to the present time.

K. O. Elderkin, Jr.E.I.C., is now chief engineer of the new Mersey Paper Company at Liverpool, N.S. Following his graduation from McGill University in 1920, Mr. Elderkin joined the staff of the Nova Scotia Steel and Coal Company Limited, New Glasgow, N.S., as draughtsman, later being on the staffs of the St. Lawrence Paper Mills at Three Rivers, Que., and of Price Brothers and Company Limited at Kenogami, Que. In 1925 he accepted the position of assistant chief engineer with the Abitibi Power and Paper Company at Iroquois Falls, Ont., with which firm he remained up to the time of his present appointment.

Wing Commander L. S. Breadner, A.M.E.I.C., has returned from London, England, where he was attached to the Royal Canadian Air Force at the Air Ministry, and is at present in Ottawa at the headquarters of the R.C.A.F. During the Great War he served continuously in the Royal Naval Air Service and the Royal Air Force, having joined the former as Flight Sub-Lieutenant. He was discharged with the rank of Major in April 1919, and was appointed to the Air Board in Canada in April 1920 and has been with the Air Board and Royal Canadian Air Force since that date.

J. A. MacGillivray, A.M.E.I.C., until recently resident engineer for the Manitoba Power Company, Limited, at Great Falls, Man., is now construction engineer at Point du Bois, Man. Mr. MacGillivray was previously located at New Glasgow, N.S., but was also for a number of years in Manitoba on various engineering works, including sewer construction, bridge work in connection with the highways system of the province and power house construction for the city of Winnipeg. He was later on the staff of the Manitoba Public Utilities Valuation Board, engaged on work in connection with the Winnipeg Electric Railway.

Frank O. White, M.E.I.C., who, since the establishment of the St. Lawrence Paper Mills in 1922, had been chief engineer of the plant in Three Rivers, Que., left on September 1st to assume the duties of chief engineer for the Fraser Companies, having his headquarters at Edmundston, N.B. Mr. White, who is a graduate of the University of Maine of the year 1905, was formerly chief engineer of the Kipawa Company, Limited, at Temiskaming, Que., and of the Brompton Pulp and Paper Company, Limited, at East Angus, Que., and prior to his accepting the appointment with the St. Lawrence Paper Mills in 1922, was located at Orone, Maine.

G. H. Burchill, Jr.E.I.C., is leaving the employ of the Canadian General Electric Company, at Peterborough, Ont., to assume the position of assistant professor of electrical engineering at the Nova Scotia Technical College, Halifax, N.S. Mr. Burchill has been connected with the Canadian General Electric Company since he graduated from the Nova Scotia Technical College with the degree of B.Sc., in 1923, being attached to the testing department during 1923 and 1924, and assistant engineer in the alternating current engineering department from 1924 to the present time. Mr. Burchill was overseas with the Canadian Artillery from May 1917 to May 1919.

N. H. Kearns, A.M.E.I.C., is now connected with the International Nickel Company at Copper Cliff, Ont. On graduation from the University of Toronto in 1919, Mr. Kearns became assistant to the city engineer of Niagara Falls, Ont. In 1920 he went to Brazil as field and office engineer with the Sao Paulo Electric Company at Sorocaba Falls on the erection of a 50,000-h.p. hydro-electric plant, and later became construction engineer in charge of construction of an additon to the same plant. In May 1925 he became attached to the Chile Exploration Company at Chuquicamata, Chile, where he was first assistant superintendent of construction and later general superintendent of construction on a $15,000,000 extension to the reduction plant of the company.

G. Alan Johnson, A.M.E.I.C., joins Sawyer-Massey

G. Alan Johnson, A.M.E.I.C., has been appointed recently to the staff of the Sawyer-Massey Company. On graduating from McGill University in 1912, Mr. Johnson was for a time employed on the design of hydro-electric power developments in Ottawa, and 1913-14 he was resident engineer on the construction of a dam and log slide at High Falls on the Lievre river near Buckingham, Que. The following year Mr. Johnson was resident engineer for the Amburson Hydraulic Construction Company on a storage dam built for the Hydro-Electric Power Commission of Ontario at Eugenia Falls, Ont. In 1915 he was employed by the Robert Mitchell Company Limited for the equipping and manufacturing of 4.5 shell parts, gauges, etc., and from 1916 to 1918 he was with the C.E.F. as a lieutenant in the 11th Field Company, Canadian Engineers. From March 1918 up to the present time Mr. Johnson has been factory manager for the Robert Mitchell Company, Limited.

H. L. Cairns, A.M.E.I.C., now connected with Canadian Pacific Railway Company

H. L. Cairns, A.M.E.I.C., who was formerly engaged in private practice at Shaunavon, Sask., is at present resident engineer on construction with the Canadian Pacific Railway Company at Cardston, Alta. Mr. Cairns came to this country from Scotland in 1910 and from that time to 1915 he was connected with the Canadian Pacific Railway Company as topographer and draughtsman on location and draughtsman and instrumentman on construction. In 1915, he enlisted as a sapper in the Royal Engineers, was commissioned in 1916, served in France with the 205th and 83rd Field Companies, and in 1918 was an instructor in military engineering to N.C.O. classes, and O.C. training D Company, Royal Engineers, Newark Training Centre. From September 1918 to July 1919, Mr. Cairns was with the North Russian Expeditionary Force on construction and maintenance of roads and bridges, and for two months was Acting O.C. with the Royal Engineers, (Dvina Force). On his return to Canada in 1920 he again became connected with the Canadian Pacific Railway Company.

J. A. H. WHITFORD, Jr.E.I C.

J. A. H. Whitford, Jr.E.I.C., Awarded Prize

J. A. H. Whitford, Jr.E.I.C., architectural draughtsman with the Canadian National Railways, Moncton, has been advised that he is a prize winner in the competition offered by Lord Beaverbrook to architects submitting the best designs for the new Lady Beaverbrook Residency at the University of New Brunswick, Fredericton. This contest was open to architects from Halifax to Vancouver, many of whom competed for the substantial cash prizes offered. Mr. Whitford, together with a well-known firm of Saint John architects, was bracketed for second prize, and his success is all the more remarkable in that his design was prepared entirely during spare time.

A. I. Cunningham, A.M.E.I.C., becomes Resident Engineer, N.B. International Paper Company

A. I. Cunningham, A.M.E.I.C., has recently accepted the position of resident engineer with the New Brunswick International Paper Company at Dalhousie, N.B. On graduation from McGill University in 1914, Mr. Cunningham was for a year with the Bathurst Lumber Company as instrumentman, following which he was on the staff of the Grand Trunk Railway on surveys and design of car sheds at Port Huron, Mich., from 1915 to 1919 he was in the Canadian Siege Artillery with the rank of captain. Following the war, and until 1922, Mr. Cunningham was field engineer for the St. Maurice Lumber Company at Three Rivers, Que., later joining the staff of the Parklap Construction Corporation as field engineer on the Sherman Island hydro-electric development at Glen Falls, N.Y. In 1923-1924 he became attached to the Moreau Manufacturing Corporation, Glen Falls, N.Y., as resident engineer on the construction of the Feeder Dam hydro-electric development. From 1924 to 1927 Mr. Cunningham was in charge of construction of an extension to the St. Maurice Lumber Company's paper mill at Three Rivers, and in 1927 was resident engineer for the Canadian International Paper Company at Gatineau, Que.

Charles A. Magrath, M.E.I.C., reappointed Chairman of the Canadian Section of the International Joint Commission

Charles A. Magrath, M.E.I.C., has been reappointed chairman of the Canadian section of the International Joint Commission. Mr. Magrath will retain the chairmanship of the Ontario Hydro-Electric Power Commission, to which office he was appointed in 1925 in succession to the late Sir Adam Beck. Mr. Magrath's professional experience has been varied and to a marked degree of a public nature. In early days he practised the profession of land surveyor in the North West Territories, holding the titles of Provincial and Dominion Land Surveyor and Dominion Topographical Surveyor. He was land agent for the Alberta Railway and Coal Company and later played an important part in the development of the sub-arid districts of Southern Alberta as manager of the Canadian North West Irrigation Company. Mr. Magrath entered politics in 1891 as member for Lethbridge, holding the post of minister without portfolio in the Haultain Ministry in Saskatchewan from 1898 to 1901. He also represented Medicine Hat in the House of Commons from 1908 to 1911. From 1911 to the present date Mr. Magrath has occupied with distinction the chairmanship of the Canadian section of the International Joint Commission. This body, which has dealt with many important international questions, such as the Lake of the Woods levels and the St. Lawrence deep waterways schemes, owes much to his indefatigable energy and executive ability.

Norman D. Wilson, M.E.I.C., receives Appointment with Advisory Town Planning Commission, Toronto

Norman D. Wilson, M.E.I.C., has been appointed general director of the Advisory Town Planning Commission for Toronto. Mr. Wilson, who is a member of the firm of Wilson, Bunnell and Borgstrom, Limited, consulting engineers and town planners, Toronto, is a graduate of the University of Toronto of the year 1904. After graduation Mr. Wilson spent four years on railway location and construction and Dominion land surveys, but in 1908 he formed a partnership with Mr. J. C. Gardner at Niagara Falls, Ontario, and for a time was engaged in municipal work in the Niagara peninsula. From 1910 to 1912 he was engaged in private practice as a land surveyor in Toronto, and in February 1912 he was appointed engineer of surveys and lands for the Toronto Harbour Commission, which position he held until 1923. In 1915 Mr. Wilson was on the staff of the Civic Transportation Committee in its study of the general transportation in the city, particularly with regard to the question of radial entrances into the city. When the Toronto Transportation Commission was formed in 1920, Mr. Wilson's services were requested to assist in the investigation preliminary to taking over the Toronto Railway, later being appointed engineer of traffic study. In June 1923, when he resigned from the Harbour Commission, he joined A. E. K. Bunnell, M.E.I.C., in partnership as engineers and city planning consultants, and two years later the firm became Wilson, Bunnell and Borgstrom, Limited.

Additional Vice-Presidents for Canadian Westinghouse

H. U. Hart, M.E.I.C., has been appointed vice-president and chief engineer, and George R. Kerr, vice-president and treasurer, of the Canadian Westinghouse Company Limited, according to an announcement made by Paul J. Myler, president of the company.

In 1893 Mr. Hart enrolled as a student-apprentice of the Westinghouse Electric and Manufacturing Company at Pittsburgh. His advancement in the different branches of the works and engineering department was rapid, and in 1899 he was sent to the French Westinghouse Company as designing electrical engineer, and was later appointed chief engineer. During this period Mr. Hart had charge of the design of some very large generators then being built for water power developments in France and Italy.

H. U. HART, M.E.I.C.

In 1905 he was secured by the Canadian Westinghouse Company as chief engineer, which position he has held for the past twenty-three years, where his guidance in engineering and manufacturing has contributed to the remarkable growth of this organization.

Mr. Hart's executive ability resulted in his appointment as general manager in 1923. He has established many new lines of manufacture, such as radio, electric ranges and improvements and larger ratings of generators, motors, transformers and other applications of electricity to various industries.

Mr. Hart is a Fellow of the American Institute of Electrical Engineers.

Mr. George R. Kerr was one of the original members of the Westinghouse Manufacturing Company Limited, manufacturers of air brakes, and destined to hold later on one of the most important positions in the entire electrical industry. When the Canadian Westinghouse Company Limited was organized in 1903, Mr. Kerr was placed in charge of the accounting end of the business and has been identified with the remarkable progress made by this company since its inception.

Mr. Kerr's appointment as treasurer dates back upwards of ten years, and throughout that period his advice and insight into the future possibilities of Canadian electrical development and prosperity have undoubtedly had a great influence on the enterprise and leadership for which the Canadian Westinghouse Company is famous.

During his service as an officer of the company vast amounts of capital have been required for the undertakings of this large industry, and his foresight, executive ability and control of the assets and finances have contributed much to the fact that the Canadian Westinghouse Company Limited experienced no financial difficulties during the post war period and finds itself today one of the largest and most successful enterprises in the Dominion.

Meeting of Council

Meeting of September 11th, 1928

A meeting of Council was held at 8 o'clock p.m. on Tuesday, September 11th, 1928, Past-President A. R. Decary, M.E.I.C., in the Chair, and six other members of Council being present.

The minutes of the meeting held on June 15th, 1928, were taken as read and approved.

The Financial Statement of The Institute for the period ending August 31st, 1928, was submitted and approved.

The Nominating Committee's report was presented, and was held over for consideration at the Plenary Meeting of Council.

The membership of the Gzowski Medal Committee was approved as follows: W. G. Mitchell, M.E.I.C., Chairman; Messrs. O. O. Lefebvre, M.E.I.C., F. C. Laberge, M.E.I.C., Ernest Brown, M.E.I.C., and W. C. Adams, M.E.I.C.

The attention of Council was drawn to the desirability of further publicity with regard to the new regulations for the Past-Presidents' Prize, and the Secretary was directed to make a further announcement regarding this matter in the publications of The Institute, and also to draw the attention of all members to the fact that the subject selected for the first award of the prize for 1928-1929 is Engineering Education.

It was noted that S. G. Porter, M.E.I.C., has accepted the chairmanship of the Committee on the Relations of The Institute with the Provincial Professional Associations, and that an interim report from this committee may be expected in time for the Plenary Meeting of Council. A resolution passed at the last meeting of the Association of Professional Engineers of the Province of Alberta was communicated to the Council and the appointment of a committee by that Association to study this question was noted with appreciation.

P. L. Pratley, M.E.I.C., chairman of the Committee on Standard Forms for Construction Contracts, presented an interim report, and a resolution passed by the Royal Architectural Institute of Canada regarding this matter was also presented and noted.

A tender and preliminary design for the Sir John Kennedy Medal was submitted and the design approved.

Council noted with deep regret the death of Hugh David Lumsden, a Charter Member, which took place on August 29th, 1928, and the following resoution was unanimously passed:—

"The death of Hugh David Lumsden removes from the membership list of The Engineering Institute of Canada almost the last of those whose efforts resulted in the formation of the Canadian Society of Civil Engineers in January 1887.

For many years a member of Council, he was President in 1906, and took a prominent part, not only in the affairs of The Institute, but also in the construction and development of the railways of the Dominion.

His professional eminence and the wealth of experience acquired during his long life indicate the loss which The Institute now sustains, and the Council desires to place on record its deep regret, and to convey to the members of his family its condolence with them on their bereavement."

A letter was read from Hugh A. Lumsden, M.E.I.C., expressing appreciation to Council for the floral tribute received.

J. B. McRae, A.M.E.I.C., reported that he had represented The Institute at the C.E.S.A. conference on the Standardization of Fire Hose Connections, at which meeting it was unanimously decided that a C.E.S.A. committee be appointed to go into the question. The Council approved this decision, thanked Mr. McRae, and will welcome any progress made towards standardization of fire hose connections in Canada.

A complimentary copy of a brief history of the Institution of Civil Engineers, with an account of the Charter Centenary Celebrations of June 1928, was received, and the Secretary was directed to acknowledge receipt of this to the President and Council of the Institution.

A letter was received from the Administrator of the House of Chemistry, Paris, erected as a monument to the honour of the illustrious chemist, Marcelin Berthelot, requesting that The Engineering Journal and the publications of The Institute might be given for the Library which is being established in connection with this House of Chemistry; it was unanimously resolved that this request be granted.

A letter was submitted from Colonel Leonard's secretary expressing to Council his appreciation of the honour conferred upon him in the award of the Sir John Kennedy Medal.

Eight special cases were dealt with, six resignations accepted, and one reinstatement was effected.

The committee appointed to open the ballot on July 18th, 1928, reported that it had been duly opened and the following elections and transfers effected:—

Elections		Transfers	
Members	1	Student to Assoc. Member	1
Associate Members	2	Student to Junior	3
Juniors	2		
Affiliate	1		

Twelve students were admitted.

Twenty-four applications for admission and transfer were scrutinized and classified for the ballot returnable October 15th, 1928.

The Council rose at 10:45 o'clock p.m.

BOOK REVIEWS

Probability and Its Engineering Uses

By T. C. Fry, D. Van Nostrand Company, New York, 1928, buckram, 6½ x 9¼ in., 500 pp., diagrs., $7.50.

The word probability suggests to most of us the kind of question primarily interesting to gamblers rather than engineers—how likely is it that a certain event will occur when coins are tossed, dice are thrown, or cards dealt. To the uninitiated it is a revelation to find that the subject has wide ramifications, and that its mathematical treatment has an important practical bearing on many phases of our daily life and industry, a fact amply demonstrated by Dr. Fry's book. The work is not one designed for the casual reader, and its scope may be judged from some of the topics mentioned in its problems and section headings. The design of locks for master-key systems, the probable percentage of defective lamps in a shipment, only a portion of which have been inspected (and many other questions concerning the testing of factory output), the distribution of velocities in the molecules of a gas, the amount of dog-biscuit (or other given commodity) which a store should stock on Monday mornings in order not to lose more than one sale per hundred during the week, the results to be expected from advertising, are examples taken at random.

An important section deals with problems of congestion, particularly as regards telephone exchange operation and telephone engineering. Dr. Fry's book was, in fact, the outgrowth of the mathematical work he has carried out for the Bell Telephone Laboratories, for telephone service requires the solution of many problems for which the theory of probability and its applications must be employed.

For the engineer of sufficient mathematical training the volume can be recommended as a mine of information on a somewhat abstruse but important subject.

Solubilities of Inorganic and Organic Compounds

A. Seidell, Volume 2, D. Van Nostrand Company, New York, 1928, buckram, 6 x 9½ in., 1,569 pp., tables, $8.00.

This volume forms a supplement to the second edition and contains data published during the years 1917-1926. It is essentially a work of reference, and contains a large amount of clearly tabulated data regarding the solubilities of all the familiar chemical compounds and many of the more unusual ones. The sources of information are stated in each case, and there is an index of authors as well as a subject index.

American Chemistry

By Harrison Hale, Second Edition, D. Van Nostrand Company, 1928, buckram, 5½ x 8 in., 255 pp., plates, $2.50.

The author's principal object has been to call attention to the fundamental importance of chemistry in the development of the world today, particularly referring to the "record of the American chemist." The book is not a lengthy one, and is intended for students in science as well as for the general reader. Topics such as sanitation, food, fertilizers, textiles, fuels, paints and varnishes, rubber, electrochemistry, and others are succinctly treated, each chapter being followed by a list of references for more extended study. The work can be recommended as a source of general information and an incentive to further enquiry on the part of the reader.

Théorie Calcul et Construction des Cheminées D'usine

By E. Lefon, Librairie Polytechnique Ch. Béranger, Paris, 1928, Buckram, 6 x 9½ in., 176 pp., diagrs., $2.25.

The author has written many papers on the design of chimneys, either as contributions to scientific reviews or to technical societies, and the present book is a development of his previous studies.

The treatise begins with a brief review of the various empirical formulæ, points out their deficiencies in neglecting important factors and suggests that although they were sufficiently accurate for small and simple grates, the industrial developments of today require a better analysis of the phenomena.

After a general exposition of the principles upon which the design of chimneys should be based, the author proceeds to analyze the various theories of design that have been put forward, seven chapters being devoted to the analysis of as many theories. He then continues by expounding his own theory, which takes into consideration both the maximum velocity and the temperature of gases. The whole problem lies in the determination of the maximum possible velocity of the gases.

Chimneys of the same capacity may vary widely according to the formulæ used, and the author discusses an example of chimneys used for 50-ton Martin furnaces, varying in the ratio of 3½ to 1 in section. Such errors have led to the use of forced draft, which uses about one per cent of the coal burnt on the grates.

Boilers with numerous changes of direction of gases are detrimental to good draft. The ideal boiler would provide a straight path to the gases with an increasing velocity towards the stack. In practice all the variations of section and of direction should be smooth and gradual. Sections of flues should not be constant, the velocity varying with the distance from the grate.

The next chapter deals with the stability of chimneys. The effect of wind and also earthquakes is considered, and the regulations in force in France and Germany are discussed.

Practical details of the building of chimneys are next given. Materials used in their construction are compared as to cost, durability, stability, maintenance, etc.

A comparative study of the merits of natural and mechanical drafts is presented at the end of the book, and the author believes in the superiority of the natural draft.

This book gives good and easy methods of chimney construction, based on scientific principles and on good practice. It should prove valuable to the student who wishes to acquire a general knowledge of the methods used in designing chimneys. It is equally interesting to the technician who wants a practical and sound method of economical construction.

Armand Circé,
Professor of Strength of Materials,
Ecole Polytechnique, Montreal.

Ice Engineering

By Howard T. Barnes, M.E.I.C., Renouf Publishing Company, Montreal, 1928, buckram, 6 x 9½ in., 364 pp., figs., tables, diagrs., $5.00.

This work may be regarded as an amplification of the author's former book on Ice Formation, with the addition of accounts of his more recent work and investigations on river and sea ice. It treats of a multitude of topics connected with the formation and destruction of various types of ice, and the difficulties to which they give rise in connection with the engineering work and navigation on our streams and lakes and at sea.

Some of the material presented has been previously published in various technical papers, but Dr. Barnes now gives collected accounts of the various methods which he has employed in his so-called "ice remedial work." The later portion of the book contains a statement of his views in connection with the conservation of heat in lakes and rivers for ice prevention, and the possible employment of this principle for the improvement of navigation in such channels as the St. Lawrence, above Montreal.

The volume includes much useful information on the physical constants of ice and water, and on the tests which have been made on the physical strength and structure of various types of naturally formed ice.

Those interested in ice navigation will find collected in chapter VIII many particulars connected with the dimensions, design and operation of ice-breaking steamers. A full and detailed bibliography adds to the utility of the work.

The Geology of Petroleum and Natural Gas

By E. R. Lilley, D. Van Nostrand Company, New York, 1928, buckram, 6 x 9½ in., 524 pp., figs., tables, diagrs., $6.00.

Interest in this subject has recently increased greatly in Canada, owing to the development of the Alberta oil fields, and the commencement of commercial production in the Turney valley. Much of the information available regarding the geology of petroleum and natural gas is scattered and contained in technical papers and reports, and is therefore not in an easily accessible form for reference. A book like the volume under review is therefore welcome, for it not only presents basic information on the properties of petroleum and its allied products, and the theories regarding the origin of petroleum, but covers the essential geological conditions limiting the occurrence of oil.

Geologic history and the occurrence of oil, the various types of folded and faulted structures, salt core structures, and the effects of sedimentation and folding are adequately treated, and the utility of the book is greatly increased by the inclusion at the end of each chapter of a selected bibliography stating the sources of additional information, should this be desired in connection with any particular point.

The book can be recommended as a useful reference work for engineers and others connected with the petroleum industry.

A Treatise on Chemical Engineering

By G. Martin, Crosby, Lockwood & Son, London, 1928, buckram, 7 x 10 in., 448 pp., figs., tables, diagrs., $15.75.

This book represents a serious attempt to gather into one volume a large amount of data and information regarding the flow of fluids. It will receive a real welcome from those who, having had to deal with the problem of handling large volumes of gases on a works scale, have had difficulty in locating quickly the necessary formulæ and, what is more important, in reconciling divergent results.

The book commences with a series of calculations of volumes of air supply to cement kilns as an example of many similar industrial operations. A series of tables relating to the pressures and volumes of various gases are given.

Chapters II to VI deal with the measurement and calculations of the speed and quantities of gases. A very complete description with illustrations is given of the Pitot tube method for determining these factors.

Chapters VII to XIV deal with viscosity and friction, and include a discussion on the behaviour of gases flowing in pipes at different speeds.

Chapters XV and XVI give details of pressure heads and calculations of horse-power as an introduction to several chapters on Bernoulli's theorem followed by a description of Venturi meters.

The remainder of the book contains chapters on the discharge and flow of gases, etc., a description of the various meters in ordinary use, a series of tables of the volumes and weights of gases, and a discussion of the rate of fall of particles in moving fluids. The last chapter is devoted to calculations on the pneumatic transport of granular materials.

As will be seen, the book is comprehensive and is probably the first to gather into one volume such a large mass of theoretical and practical data. One criticism might be offered in connection with the tables in chapter XXIX, which do not include figures for sulphur dioxide. In view of the extensive use of this gas in the chemical industry, it might well be included in future editions.

Of interest to Canada is the dedication of the book to Sir Percy Girouard, a Canadian and an Honorary Member of The Institute.

W. H. DeBlois, M.E.I.C.,
Engineer, Chemical Division,
The Mond Nickel Company, Limited.

BRANCH NEWS

Winnipeg Branch

E. W. M. James, A.M.E.I.C., Secretary-Treasurer.

International Meeting at Winnipeg

At a meeting of the executive of the Winnipeg Branch on May 1st, it was decided to invite the Minnesota Federation of Architectural and Engineering Societies and other technical groups to attend an international meeting in Winnipeg during the summer of 1928. In furtherance of this a general committee was formed composed of two members from each of the following bodies:—

- Winnipeg Branch of The Engineering Institute of Canada.
- Association of Professional Engineers, province of Manitoba.
- Manitoba Electrical Association.
- Association of Manitoba Land Surveyors.
- Manitoba Association of Architects.

The dates set by the committee were August 24th and 25th. The programme decided upon and which was carried out was as follows:—

- Registration at the Royal Alexandra hotel, Friday morning, August 24th.
- Civic luncheon at Kildonan park, at 12.30 p.m. Friday, when there were 250 present.
- Technical session, 3.00 p.m. Friday.

Papers

"**Highways,**" by C. M. Babcock, commissioner of State Highways, Minnesota.

"**Steam Power Development in Minnesota,**" by J. A. Colvin, superintendent of generation, Northern States Power Co., Minneapolis.

"**International Relationships,**" by Prof. F. W. Kerr, Manitoba College.

"**An Adequate Wire Installation,**" by F. A. Cambridge, city electrician, Winnipeg.

During the technical session, the ladies of the group were entertained at tea at historic lower Fort Garry on the banks of the Red river. Some eighty ladies were present at this function.

Dinner-dance at the Royal Alexandra hotel at 8.30 p.m. Friday, August 24th, at which there were 250 present.

On Saturday morning a special train conveyed the party to Great Falls, on the Winnipeg river, where those present were the guests at luncheon and tea of the Manitoba Power Company, and where they had an opportunity of inspecting the 168,000 h.p. hydro-electric plant of the company, and saw the installation of the fifth and sixth units, each of 28,000 h.p.

Interest was added to the Saturday programme by the arrival in Winnipeg of some ninety members of the American Society of Mechanical Engineers from the eastern states, who spent Saturday and Sunday in Winnipeg as guests of the branch, and many of whom took advantage of the trip to Great Falls. On the return of the train to Winnipeg, an impromptu supper-dance was held at the Royal Alexandra hotel, which was attended by many members of the American Society of Mechanical Engineers. These visitors proceeded at 6.00 p.m. Sunday, August 26th, to St. Paul, in which city the Annual Convention of the society was to be held on August 27th to 30th.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

A Letter from the Chairman

To the members of the Montreal Branch of The Engineering Institute of Canada:

Gentlemen:—

It is a pleasure to extend to every member of the Montreal Branch a special invitation to attend and take part in the various activities of the branch during the coming season.

The papers, which have been arranged for by your committee for presentation at our meetings, deal with a variety of subjects and I feel sure that these will be of considerable interest to the members.

These papers are prepared by engineers, each of whom is a specialist in his own particular field, and the members of the branch should welcome the opportunity of acquiring further knowledge of recent developments within the profession.

These meetings afford an excellent opportunity for each member to become acquainted with his confreres, which in itself is perhaps one of the most valuable functions of an institute such as ours.

The efforts of your executive on behalf of the branch are deserving of your fullest support, and it is sincerely hoped that the meetings this year will be largely attended.

I have the honour to be,

Yours very truly,

(Signed) F. C. Laberge, B.A.Sc., M.E.I.C.,
Chairman Montreal Branch.

Television

Reported by A. B. Rogers, A.M.E.I.C.

A vivid description of the principles underlying recent improvements in the practice of "Television" formed the background for a fascinating address, when on April 12th last Dr. Robert W. King, assistant director of Bell Telephone Laboratories' Publications, in discussing possible applications of this interesting development before the Montreal Branch dispelled some of the popular misconceptions surrounding its probable utilization.

Referring to prevailing anticipation looking toward the speedy adaptation of television for home use in conjunction with residence phones, the speaker pointed out that the quantity, intricacy and cost of even such equipment as would be required to present crude reproduction of distant views, made the realization but a remote possibility. Notwithstanding the limitations, it was possible, however, to conceive of using the means for simultaneous presentation before large gatherings assembled in distant stadiums or auditoriums of popular sporting events.

Diagrams and illustrations supporting these illuminating conclusions were splendidly produced on slides and films, while the principle governing the essential action of the neon tube was beautifully demonstrated with some simple equipment.

This latter tube, while corresponding in function to the photo-electric cell as a medium for conversion between electricity and light, responds in exactly the reverse order, for whereas the photo-electric cell interprets the intensity of the light falling upon it in terms of a varying current frequency the latter glows bright or dim with an intensity proportioned to the varying frequency of the controlling current.

Possessing then the means for readily transforming light intensities into variable current frequencies it is now only necessary to scan with this sensitive cell the picture or object to be transmitted, unit by unit in regular sequence to record a series of light gradations representative of the definite form viewed.

For the purpose the picture may most conveniently be divided into some 2,500 units, while additional units are desirable for clarity of definition, but the cost of the apparatus would thereby be greatly augmented. On the other hand, fewer units would obscure the reproduction. On selecting therefore 2,500 equal units, each must then be scanned in regular rotation to register a current frequency representative of the light intensity reflected from its surface. As a result a sequence or series of 2,500 light registrations will be available for transmission by the carrying circuit.

Arriving at the receiving end suitably strengthened by amplifiers each series of light gradations is rapidly reproduced and regrouped into a replica of the original scene. This is accomplished by apparatus reversing the process utilized in the scanning device with its photo-electric cell. Whereas in this instance a neon tube is employed to interpret current in terms of light.

The important apparatus required first to scan the scene and later to reverse the process for presentation at the distant studio was realistically demonstrated in principle by a cleverly contrived model. This consisted of a small metal disc accurately perforated by a series of minute holes, arranged in spiral form around its outer edge.

A portrait of a man was then projected upon the screen, and the scanning disc placed before it to cut off all but a small spot of light emanating from a point directly behind the first hole. On the disc being turned slowly by hand the spot traversed the portrait from top to bottom, eventually passing off the picture at the lower right hand corner. At the same instant the second hole in the disc appeared as a spot at the upper edge, but slightly to the left of its predecessor. Thus the spots continued to move down across the portrait, one following the other in regular succession, till on the completion of one revolution the entire picture had been scanned unit by unit.

At this stage a characteristic of the human eye, known as persistence of vision, became an important advantage, for by its presence the observer is enabled to retain the visual sensations created by each spot in turn till a cycle has been completed. Thus it transpired that a rapid rotation of the disc was at once sufficient to produce the entire picture.

So in television the speed of the scanning disc may not only be adjusted to blend the many dots composing a picture into a distinct reproduction of the original, but may simultaneously be adjusted to present complete pictures in such rapid succession that the effect is the equivalent of a moving picture. As a consequence changes of expression and movement are transmitted with an ease approaching that of still subjects.

The function of the scanning disc at the sending end, therefore, consists in throwing the scene spot by spot upon the photo-electric cell, while that at the receiving end throws the light from the neon tube spot by spot to the eyes of the observer. However, in order that the reproduction may conform with the original, it is essential that both the discs be held at the same speed of rotation within very close limits. For this purpose a special synchronous motor has been designed to control their operation within one ten thousandth of a revolution.

The scene viewed through the disc of the receiver is necessarily small. Where large audiences are assembled to view the presentation enlargement becomes imperative. For this purpose a special neon lamp, prepared in the form of a long tube bent back and forth into parallel sections, is able to produce a picture some two feet square. Within the tube some 2,500 cathode elements, spaced at equal intervals, correspond to the elemental areas into which the scene is being split by the scanning disc. These elements are made to glow successively by a distributor driven in synchronism with the scanning disc at the sending end.

The synthesizing action of the observer's eyes is once again utilized to unite the elemental units into a replica of the original.

After a short discussion had ensued, J. T. Farmer, M.E.I.C., in well chosen remarks, moved a vote of thanks to the speaker, which was passed unanimously.

Councillor W. C. Adams, M.E.I.C., presided in the chair.

A new bulletin on electric steam generators has recently been published by the Canadian General Electric Company, Limited. This interesting publication, which is known as Bulletin ASD-4022, describes in detail the construction, control and application of electric steam generators as manufactured by the Canadian General Electric Company. Copies may be obtained upon request.

De Laval Steam Turbine Company, Trenton, N.J., has issued a leaflet known as bulletin E-1107, describing their centrifugal blowers and compressors as used in blast furnaces, steel plants and by-product coke oven plants. The bulletin contains a large number of illustrations of the installations of the company's equipment.

EMPLOYMENT SERVICE BUREAU

This service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All Correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

Supplies Engineer

Competent man familiar with up-to-date store keeping methods, to take complete charge stores department large public utility Brazil. Must be thoroughly experienced, good organizer, with sound knowledge material and equipment. Knowledge Portuguese or Spanish desirable but not essential; give full details education, experience and references. Apply Box No. 60-V.

Field Engineer

Recent graduate engineer wanted for laying out construction work and inspecting for large industrial and mining company in northern Quebec. Apply Box No. 61-V.

Electrical Engineer

Recent graduate required by a large electrical manufacturing concern for work on factory methods and manufacturing problems. Please state in first instance, education, full qualifications, references, salary required, age, and when available. Apply Box No. 69-V.

Assistant Distribution Engineer

Wanted by a large public utility in Brazil. Must be a university graduate with at least five years operating and construction experience after graduation, including underground and overhead light and power and tramway distribution combined with terminal station and substation operation. Apply, giving details of education, experience and salary, to Box No. 74-V.

Meter Engineer

Must be a graduate engineer with wide experience in various types of meters, particularly General Electric and Westinghouse, and competent to assume charge of meter department of a large utility in Brazil. Apply, giving details of education, experience and salary, to Box No. 75-V.

Town Engineer

Town engineer for a town in the Maritime Provinces. Applicants must give full particulars as to qualifications, experience and salary expected. Apply to Box No. 77-V.

Estimator and Designer

Largest Canadian firm manufacturing material handling machinery such as cranes and hoists, also a variety of heavy mechanical work, including sluice gates, has an opening for a man with experience in design and estimating along these lines. Apply to Box No. 80-V.

Designer and Draughtsman

Experienced designer and draughtsman on structural design, preferably in both concrete and steel building construction. Remuneration depends on capacity of applicant. Apply giving full particulars to Box No. 82-V.

Draughtsman

A firm of contractors in northern Ontario has an opening for a draughtsman, which would lead to instrumentman on field work. Apply to Box No. 83-V.

Situations Vacant

Sales Engineer

A large manufacturing company in Montreal has an opening for a graduate engineer on its sales staff. The company manufactures compressed air machinery. A man familiar with pneumatic tools, portable compressors is one whose application will be given most serious consideration. Apply to Box No. 84-V.

Sales Engineer

A large manufacturing company in Montreal has an opening for a graduate engineer on its engineering sales staff. The company manufactures compressed air mining machinery and oil engines. Preference will be given to those having some experience in these lines. Apply with full particulars to Box No. 85-V.

Sales Engineers

Two graduates of two or three years for sales and demonstration of construction of (road) machinery. Would be given experience and instruction on operation. Apply Box No. 86-V.

Industrial Designers and Draughtsman

College graduates with three or four years experience in pulp and paper industry. Salary $200 a month. Apply to Box No. 88-V.

Junior Engineer

Preferably college graduate, as assistant to field engineer, for a large paper mill in the province of Quebec. Salary $150 a month. Apply to Box No. 89-V.

Superintendent of Construction

A large paper mill in the province of Quebec has an opening for a thoroughly competent engineer for machinery installation. Preferably Canadian or one familiar with Canadian construction practice and labour conditions. Must be able to supervise installation of equipment and produce accurate work at lowest cost. Apply to Box No. 90-V.

Sales Engineer

A well known building supplies sales organization in Montreal has an opening on their sales staff for a recent graduate in engineering, to specialize in a particular branch of the company's work. Apply to Box No. 92-V.

Promotion Engineer

A large Canadian industrial company, distributing a construction material from coast to coast, has an opening for a graduate engineer between the age of 25 and 30 to carry on promotional work in the western provinces from the head of the Great Lakes to British Columbia. Apply to Box No. 93-V.

Draughtsman and Junior Designer

Recent graduate in civil engineering for position as draughtsman and junior designing engineer on hydro-electric developments. One with experience preferred, but experience not essential. Give education, experience and reference and state salary required for engagement of one year. Location, Nova Scotia. Apply to Box 97-V.

Situations Vacant

Instrumentman

A pulp and paper company in northern Quebec wishes to secure the services of a graduate engineer for power surveys. Preferably one who has had hydrographic experience. Apply to Box No. 99-V.

Pulp and Paper Engineer

A pulp and paper company in Ontario ha an opening for a young mechanical enginee who has had pulp and paper mill experience Apply, giving full particulars of qualification and experience, to Box No. 100-V.

Junior Electrical Engineer

A recent graduate in electrical engineering i required by a pulp and paper company. Pre vious experience unnecessary. The positio offers excellent opportunities for advancemen Apply to Box No. 103-V.

Draughtsman

Draughtsman with some architectural expe rience required for municipal work. Applicar must state age, experience, salary expected an submit sample of drawing. Apply Box N 105-V.

Steam Plant Designer

A thoroughly experienced man familiar wi modern practice in the layout of boilers, tu bines, piping and the usual accessory equi ment. Apply giving full details of experien to Box No. 106-V.

Mechanical Designer

A man with several years' experience in t layout of mechanical equipment, shafting, pi ing and generally familiar with industrial pla practice. Apply giving full details of expe ence to Box No. 107-V.

Structural Designer

A man fully competent to design and det simple structures in steel, timber and reinforc concrete. Apply to Box No. 108-V.

Factory Manager

Required by progressive and growing Car dian company engaged in the manufacture a wide range of material handling machine factory manager capable of assuming entire sponsibility for maximum production at low cost. Position offers unlimited scope to am tious and energetic man. Apply giving det of training, experience, and salary required Box No. 109-V.

Electrical Engineer

An electrical draughtsman for maintena and construction design in a large steel pl University graduate preferred. State age, e cation, experience, and salary to Box No. 110

Electrical Designer

Electrical designer with at least five ye experience in designing electrical sub-stati s for power companies. Applicant must thoroughly familiar with latest types of swit board equipment. Give full detailed infor tion in first letter, including age, salary pected, names of references, recent photogra and samples of drawings made. Perman t work with good future for the right man w large power company in eastern Can Apply Box No. 111-V.

Industrial Designer and Draughtsman

Young engineer with electrical training, r an industrial firm in Montreal, preferably e with experience after graduation, on electr heating and ventilating layouts. Must b a good draughtsman. Remuneration depend n capacity of applicant. Apply, giving full ticulars, to Box No. 112-V.

Situations Vacant

JUNIOR DRAUGHTSMAN

Junior draughtsman, for a firm in western Ontario, with experience on structural steel. Apply to Box No. 113-V.

MECHANICAL DRAUGHTSMAN

Mechanical engineer and draughtsman, between twenty-five and thirty-five years of age, preferably experienced in paper mill engineering. Apply, stating past experience, education, married or single, salary expected and when services available, to Box No. 115-V.

Situations Wanted

RECENT GRADUATE

Graduate of Univ. of B.C. '28 with the following experience is open for a position: Instrumentman and designer on the construction of roads; resident engineer on construction of buildings; structural designer and inspector on construction of a concrete warehouse. Apply Box No. 49-W.

PULP AND PAPER MILL ENGINEER

A.M.E.I.C., R.P.E., Ontario, civil and mechanical branches, 28 years' experience in pulp and paper mill work, both operating and engineering; 16 years' engineering experience. Has successfully held position of chief engineer with large Canadian company. Good executive. Apply Box No. 53-W.

CIVIL ENGINEER

Young engineer, graduate of the Univ. Toronto '27, would like to secure a position. Experience includes field draughtsman and instrumentman on hydro-electric development, making plans, estimates on excavation and concrete required, progress reports, etc. At present in charge of survey party. Apply Box No. 54-W.

ELECTRICAL AND MECHANICAL ENGINEER

Canadian, 30 years of age, graduate engineer, at present located in New York city, wishes to return to Canada and is available for a position in research, testing or mechanical work, with an industrial company. Experience includes machine design and layout, and the preparation and executing of patent drawings in connection with mechanical and electrical apparatus. Apply to Box No. 57-W.

ELECTRICAL ENGINEER

Young electrical engineer with experience as efficiency engineer compiling reports on operation of newsprint, groundwood and sulphite mills, and steam plant; meter engineer, in charge of upkeep and installation of all meters and recording machines; and assistant control engineer, handling investigation, control of process and cost. Apply to Box No. 58-W.

Situations Wanted

CHEMICAL ENGINEER

Graduate of Mass. Inst. of Tech. '27, age 28 years, with experience in paper and paper size manufacture, and industrial plant layout and construction, desires a position with a pulp and paper company or other industrial organization, either on operation or as chemical, combustion or mechanical engineer. At present located near Montreal. Apply to Box No. 76-W.

MECHANICAL ENGINEER

A.M.E.I.C. experienced in drawing office, production and plant maintenance; four years as engineer-in-charge of works plant installation and maintenance, mechanical and electrical; three years as sales engineer; conversant with wide variety of machinery; recently mainly on pneumatic plant; having just returned from residence abroad is open for engagement in suitable capacity. Apply Box No. 84-W.

CIVIL ENGINEER

B.A.Sc. '23, D.L.S., with experience in railroad switch work, pipe lines, sewers, setting mill machinery, motors, pumps, layout of foundations and concrete form work for reinforced concrete, erection of steel reinforced concrete, brick and wooden structures, surveys and topographic surveys, at present in United States, would like to secure work in Canada. Apply Box 86-W.

CONSTRUCTION ENGINEER

A.M.E.I.C., with twenty-six years experience, including ten years railway construction and sixteen years on reinforced concrete bridge, as resident engineer in Canada and United States, desires position. Apply Box No. W. 93-W.

AIRPORT ENGINEER

Civil engineer with two years surveying and five years general construction wishes to join an engineering firm specializing in or wishing to commence a department for location, design and construction of airports. Location Montreal or in Ontario. Apply Box No. 99-W.

SPARE TIME WORK

Graduate of this year, at present employed in Montreal, wishes to secure some spare time employment in the city; either draughting or clerical work associated with engineering. Available three or four evenings each week. Apply Box No. 100-W.

ELECTRICAL ENGINEER

Graduate of N.S. Tech. Coll. '25, age 27, single, two years Westinghouse test course, one year assistant electrical superintendent of a large mining concern, desires position in public utility work. Available at reasonable notice. Apply Box No. 101-W.

Situations Wanted

CIVIL ENGINEER

A graduate of McGill Univ. '24, with some knowledge of French, wishes to return to Canada from the U.S.A. His experience includes instrumentman on railway construction, resident engineer on railway construction, instrumentman on general maintenance, and transitman on preliminary surveys. Apply to Box No. 103-W.

CIVIL ENGINEER

Civil Engineer, graduate of Toronto University '22. with experience in hydraulic work, buildings, roads, docks, open for engagement in executive or technical capacity; any locality, preferably Montreal. Excellent references. Apply to Box No. 109-W.

ELECTRICAL ENGINEER

University graduate, with seven years' experience in the design and application of all varieties of switching equipment, including the design and layout of power stations and substations, desires to become connected with operating or industrial company, or with a firm of consulting engineers. Apply to Box No. 113-W.

Tenders

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for repairs to North Jetty, Steveston, B.C." will be received until **12 o'clock noon, Wednesday, October 24, 1928,** for repairs to Fourth Section of the North Jetty, at Steveston, Fraser River, New Westminster District, B.C.

Plans and form of contract can be seen and specification and forms of tender obtained at this Department, at the offices of the District Engineer, Post Office Building, New Westminster, B.C.; Victoria Builders Exchange, 2509 Prior Street, Victoria, B.C.; The Building and Construction Industries Exchange, 615 West Hastings Street, Vancouver, B.C., also at the Post Office, Steveston, B.C.

Tenders will not be considered unless made on printed forms supplied by the Department and in accordance with conditions contained therein.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Minister of Public Works, equal to 10 per cent of the amount of the tender. Bonds of the Dominion of Canada or bonds of the Canadian National Railway Company will also be accepted as security, or bonds and a cheque if required to make up an odd amount.

NOTE.—Blue prints can be obtained at this Department by depositing an accepted cheque for the sum of $20.00, payable to the order of the Minister of Public Works, which will be returned if the intending bidder submit a regular bid.

By order,

S. E. O'BRIEN,
Secretary.

Department of Public Works,
Ottawa, September 29, 1928.

Foster Wheeler Corporation has issued Superheater Catalogue No. 304. This catalogue consists largely of illustrations of notable superheater installations so that the reader may grasp the manner in which installations are made. Short statements are given covering the history of Foster superheaters and their application to many types of boilers. The types of superheaters particularly emphasized are convection, radiant heat, combination, separately fired, waste heat and portable. The catalogue is completed with a steam table extending up to 1,500 pounds absolute pressure and 300° superheat.

Power Corporation of Canada, Limited, Montreal, Que., has published an attractive booklet entitled "Power Corporation of Canada—What It Is and What It Does," describing its organization with particular reference to its engineering and construction service. The booklet contains illustrations of the plants of various companies in the Power Corporation group.

American Institute of Steel Construction, Inc., 285 Madison avenue, New York city, through a committee of engineers under its auspices, have prepared and published a specification for the fireproofing of structural steel plants. The specification is divided into seven sections:—1, Purpose and Scope; 2, Fires; 3, Fire Hazards; 4, Steel; 5, Fireproofing Materials; 6, Tests; 7, Safety Factor. Copies of this booklet may be obtained upon application to the American Institute of Steel Construction, Inc.

The Superheater Company has issued a new booklet entitled "The Elesco Superheater for Power Plants," which contains fifty-one pages and ninety-five illustrations describing the design, construction and application of the Elesco superheater to the power plants. Copies may be obtained from the company at 276 St. James street, Montreal, Que.

Preliminary Notice

of Applications for Admission and for Transfer

September 21st, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October 1928.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ADLINGTON—WILFRED ERNEST, of Chambly Canton, Que., Born at Durban, Natal, South Africa, Nov. 6th, 1900; Educ., B.Sc., Mass. Inst. Tech., 1927; June 1918 to June 1919, Hope & Co., Johannesburg, S.A., install'n of elect'l equipment and various types of machines; June 1927 to date, chem. engr. with Bennett Ltd., Chambly Canton, Que., mfrs. of papermakers' size, papers and boards, operation and control of driers, design of equipment and layout of same, including electric motors, pumps, heating units and special machinery, design and plant for bldg. constrn., etc.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

MARR—NORMAN, of 81 Metcalfe Street, Ottawa, Ont., Born at Walkerton, Ont., June 29th, 1890; Educ., B.A.Sc. (C.E.), Univ. of Toronto, 1912; 1907-09 (summers), chaining, rodding, levelling on Dominion land surveys, rly. location and city waterworks extensions; 1910-11, instr'man constrn., Nat. Transcont. Rly.; 1912-13, asst. engr., C. H. & P. H. Mitchell, consltg. engrs., on constrn. of Lacolle Falls hydro-electric development for City of Prince Albert, Sask.; 1913-18, asst. engr., Dept. Rlys. and Canals, i/c constrn., sections 4 and 5, Trent Canal; 1918-26, senior hydraulic engr., and 1926 to date, chief hydraulic engr., Dom. Water Power and Reclamation Service, Dept. of Interior, Ottawa, Ont.

References: J. B. Challies, T. H. Hogg, J. T. Johnston, R. S. Lea, D. W. McLachlan, S. S. Scovil.

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER GRADE

GILBERT—EDGAR VALENTINE, of Montreal, Que., Born at Liverpool, Eng., Sept. 3rd, 1896; Educ., B.Sc., McGill Univ., 1923; 1915-19, sapper, Can. Engrs.; 1923-24, inspr., R. W. Hunt Co.; 1924-25, dftsman. and asst. field engr. at Hemmings Falls power house, and 1925-26, field engr. on constrn. of Drummondville power house, Southern Canada Power Co.; Feb. 1926 to date, with Foundation Co. of Canada, Ltd., as follows: Feb. 1926 to July 1927, asst. to dist. engr. and dist. engr. for Gatineau storage dams; July 1927 to April 1928, i/c of parties on exploration of dam sites on Desert and Trinity rivers, locating flume line and rly. at Trinity Bay, and April 1928 to date, engr. and works clerk on inclined tunnel, Thetford Mines, Que.

References: R. E. Chadwick, W. Griesbach, H. V. Serson, W. N. Cann, F. F. Griffin, T. C. Connell.

PROCTOR—WILLIAM DOUGLAS, of 32 Winnett Ave., Toronto 10, Ont., Born at Sarnia, Ont., July 25th, 1895; Educ., B.A.Sc., Univ. of Toronto, 1921; 1913-14 (summers), city engr.'s staff, Sarnia; June 1915 to Apr. 1916, on shell parts, Can. Inspection Co., Sarnia and London, Ont.; 1916-19, overseas, Lieut., Can. Engrs.; 1919 (summer), res. engr. on pavements at Strathroy, Ont., for James, Loudon & Hertzberg; 1920-21 (summers), res. engr. on Scarboro water system, for E. A. James & Co.; 1921-22, res. engr. on various constrn. works for James, Proctor & Redfern, Ltd.; 1923 (Jan.-July), struct'l detailer, McGregor-McIntyre, Ltd.; Sept. 1923 to date, with James, Proctor & Redfern, Ltd., as follows: 1923-24, on designing staff on reservoirs, etc.; 1925, res. engr., York Twp. sewage disposal plant; 1926-27, design and charge in field of constrn. of sewerage system for Village of Forest Hill, Ont.; at present, designing engr. in charge of dfting. room.

References: O. M. Falls, E. M. Proctor, O. L. Flanagan, W. B. Redfern, C. R. Young, P. Gillespie, A. R. Robertson, E. T. Bridges.

ROSE—HUGH GRANT, of 337 40th St., Fairfield, Ala., Born at Ottawa, Ont., Jan. 25th, 1898; Educ., M.A., Queen's Univ., 1920, B.A.Sc., Univ. of Toronto, 1923, D.L.S., 1921; 1916-20 (summers), asst. on geodetic survey parties; 1921 (summer), geod. engr., i/c party observing for Geod. Survey in Ont.; 1922 (summer), geod. engr. on reconnaissance in Quebec, and 1923 (summer), geod. engr. i/c party observing in Quebec for Geod. Survey of Canada; 1924-25, geod. engr. with R. H. Randall & Co., geod. and topographic engrs., making a topographic map of the city of Pittsburg; Aug. 1925 to date, field engr., Ensley Works, Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., gen. industrial work, mtce. and constrn. in large steel plant.

References: J. L. Rannie, N. J. Ogilvie, W. M. Tobey, C. Brady, P. Gillespie, W. M. Dennis, W. C. Murdie.

WIMBERLEY—ARTHUR CECIL, of 116 Brighton Ave., Ottawa, Ont., Born at High Bluff, Man., July 5th, 1895; Educ., Toronto Matric., I.C.S. diploma, municipal engrg.; passed E.I.C. exam. for Junior, May 1922; 1912 (3 mos.), survey with Dept. of Militia; 1913-22 (except 1916-19, when overseas), dfting., etc., irrig. branch, Dept. of Interior, Ottawa; 1916-19, sgt., Can. Art'y, D.C.M.; 1923-26, junior engr., and 1927 to date, asst. engr., reclam. service, Dept. of Interior, Ottawa, Ont.

References: J. T. Johnston, V. M. Meek, G. F. Richan, M. F. Cochrane, J. S. Tempest, G. F. Horsey.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER GRADE

CLEVELAND—HARRY ROLAND, of Montreal, Que., Born at Danville, Que., Jan. 9th, 1899; Educ., B.Sc. (E.E.), McGill Univ., 1924; 1923 (summer), electr'n's helper, Canadian Johns-Manville Co.; Jan. 1926 to date, cable design and sales engrg., Northern Electric Company, Ltd., Montreal.

References: W. S. Vipond, N. L. Dann, T. Eardley-Wilmot, N. L. Morgan, C. V. Christie.

GRAHAM—WALTER WHITE, of 792 Decarie Blvd., Montreal, Que., Born at Glasgow, Scotland, Aug. 29th, 1901; Educ., B.Sc. (Mech.), McGill Univ., 1925; 1922 (summer), rodman on constrn., Intercol. and James Bay Rly., C.P.R. branch line; 1923 (summer), concrete inspr., Steel Co. of Canada, Montreal; 1924 (summer), install'n of H. V. disconnecting switches, motor operated, H.V. bus and lighting conduits, La Gabell dev., Shaw. Water & Power Co.; 1925 to date, with Power Engineering Co., on elect'l and hydro-electric design.

References: A. L. Patterson, J. A. McCrory, S. Svenningson, J. S. Brisbane, J. D. Stott, G. J. Dodd, A. B. Rogers.

KETCHEN—WILLIAM ARTHUR, of 49 Brock Ave., Montreal West, Que., Born at Montreal, Que., July 18th, 1903; Educ., B.Sc. (Chem.), McGill Univ., 1928; 1924 (summer), machinist, and 1925 (summer), millwright, B.C. Pulp and Paper Co., Port Alice, B.C.; 1926 (summer), asst. chemist, Niagara Ammonia Co., Niagara Falls, N.Y.; 1927 (summer), asst. chemist, Port Alice plant, B.C. Pulp and Paper Co.; at present, operator, Electro Products, Shawinigan Falls, Que.

References: H. M. MacKay, C. M. McKergow, G. A. Wallace, J. B. Bladon, W. L. Ketchen.

REAPER—CLARENCE PAUL, 3649 Durocher St., Montreal, Born at Montreal, June 15th, 1901; Educ., B.Sc., McGill Univ., 1924; 1923 (summer), pulp and paper testing, Abitibi Power & Paper Co.; 1924-26, with Newfoundland Power & Paper Co., as follows: 1924 (June-Dec.), dfting., Dec. 1924 to June 1925, supervising part of elect'l install'n in Nfld.; June 1925 to Feb. 1926, i/c of testing labs.; 1926 (Mar.-Dec.), field engr. i/c of erection of paper mill divn. at Port Alfred for H. S. Taylor, M.E.I.C.; Dec. 1926 to Jan. 1928, paper mill design, and Jan. to March 1928, installed testing labs. and started the service divn. at Lake St. John Power & Paper Co.; at present life underwriter with the Imperial Life Assurance Co., Montreal.

References: J. Stadler, H. S. Taylor, R. L. Weldon, H. C. Brown, J. C. Day, C. Bang.

SHIER—BRUCE BANKS, of Montreal, Que., Born at Westmount, Que., July 3rd, 1901; Educ., B.Sc. (E.E.), McGill Univ., 1923; 1920-22 (summers), timekpr., material clerk and inspr. with Shawinigan Engrg. Co.; 1923-24, graduate student course, Can. Westinghouse Co., Ltd., Hamilton, Ont.; 1924 to date, engr., inspection engrg. dept., Northern Electric Co., Ltd., Montreal.

References: W. C. Adams, A. J. Lawrence, W. C. M. Cropper, H. J. Vennes, N. L. Dann, N. L. Morgan.

SINCLAIR—ARCHIBALD BEAIRSTO, of Kenogami, Que., Born at Truro, N.S., Apr. 3rd, 1902; Educ., B.Sc. (E.E.), Univ. of Man., 1927; 1920 (May-Sept.), rodman, Reclam. Branch, Dept. Public Works, Man.; 1921 (May-Sept.), mechanician, Can. Aircraft Co., Winnipeg; May 1922-Sept. 1923, instr'man, Manitoba Power Co., Great Falls, Man.; 1924 (May-Sept.), electr'n, Foundation Co., Mishawaka, Ind.; 1925 (May-Sept.), storekeeper and material checker, Foundation Co., West Pittston, Pa.; 1926 (May-Sept.), dftsman., Western Engrg. Co., Winnipeg; May 1927-May 1928, student course, Canadian Westinghouse Co., Hamilton; June 1928 to date, asst. to gen. elect'l supt., Price Bros. & Co., Ltd., Kenogami, Que.

References: N. D. Paine, J. N. Finlayson, N. M. Hall, E. P. Fetherstonhaugh, B. S. McKenzie.

WELSH—DEAN THOMAS, of Hamilton, Ont., Born at Port Colborne, Ont., Sept. 26th, 1900; Educ., B.A.Sc., Univ. of Toronto, 1924; with city engr.'s dept., Hamilton, as follows: 1920 (summer), chainman and rodman; 1921 (May-Dec.), instr'man on bridge and pavements and concrete inspr. on sewer pipe; 1922 (Jan.-Aug.), instr'man and dftsman. on pavement surveys and constn.; 1923 (May-June), instr'man on pavements; May 1924-June 1926, instr'man and dftsman. on pavement surveys and constrn., also some sewer design; 1923 (Aug.-Sept.), asst. to Etobikoke Twp. engr., on watermains and sidewalks at Islington; June 1926 to date, with Dept. of Northern Development, Ontario Government, as follows: 1926 (June-Nov.), asst. engr. in Thunder Bay District on road location and bridge surveys; Dec. 1926-Oct. 1927, asst. to chief of party on Fort Francis-Kenora Road location survey; Oct. 1927-Mar. 1928, asst. engr. on re-location survey, Ferguson Highway, Severn Bridge to Burk's Falls; 1928 (Mar.-Aug.), res. engr., Ferguson Highway, Falkenburg-Huntsville Divn. (i/c of 5 miles); Aug. 1928 to date, res. engr. i/c of constrn. of Driftwood-Smooth Rock Falls Road (17 miles).

TREASURER
F. P. SHEARWOOD, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

ASSISTANT SECRETARY
N. E. D. SHEPPARD, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, J. F. LUMSDEN
Sec.-Treas., R. R. MURRAY, 4 Carleton Street, Halifax, N.S.
Executive, W. J. DeWOLFE, W. B. MacKAY, H. W. MAHON, A. R. CHAMBERS, H. C. BURCHELL, C. B. McDOUGALD, O. S COX
(Ex-Officio) C. A. D. FOWLER, H. W. L. DOANE

CAPE BRETON
Chairman, W. E. CLARKE
Vice-Chair., M. DWYER
Sec.-Treas., E. L. GANTER, P.O. Box 310, Sydney, N.S.
Executive, S. C. MIFFLEN, W. J. RIPLEY
(Ex-Officio) W. E. CLARKE, W. S. WILSON

SAINT JOHN
Chairman, GEOFFREY STEAD
Vice-Chair., W. J. JOHNSTON
Sec.-Treas., E. J. OWENS, P.O. Box 820, St. John, N.B.
Executive, J. R. FREEMAN, J. P. MOONEY, J. N. FLOOD
(Ex-Officio) S. R. WESTON, J. STEPHENS

MONCTON
Chairman, H. J. CRUDGE
Vice-Chair., M. J. MURPHY
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, E. T. CAIN, J. R. FREEMAN, L. H. ROBINSON, G. E. SMITH, H. B. TITUS, F. WILLIAMS
(Ex-Officio) F. O. CONDON, G. C. TORRENS, F. L. WEST

SAGUENAY
Chairman, G. F. LAYNE
Vice-Chair., N. D. PAINE
Sec.-Treas., J. F. PLOW, P.O. Box 26, Riverbend, Que.
Executive, C. N. SHANLY, J. M. GILCHRIST, R. E. PARKS, H. R. WAKE
(Ex-Officio) N. F. McCAGHEY

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, A. B. NORMANDIN
Vice-Chair., S. L. deCARTERET
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive H. CIMON, T. J. F. KING, L. C. DUPUIS, A. LARIVIERE
(Ex-Officio) W. G. MITCHELL

ST. MAURICE VALLEY
Chairman, ELLWOOD WILSON
Sec-Treas., R. MORRISSETTE, City Engr., Cap de la Madeleine, Que.
Executive, H. DESSAULLES, B. GRAND MONT, S. W. SLATER

MONTREAL
Chairman, F. C. LABERGE
Vice-Chair., J. A. McCRORY
Sec.-Treas. C. K. McLEOD, 698 St. Catherine St. W., Montreal, Que.
Executive, J. G. CARON, R. deL. FRENCH, D. HILLMAN, H. MASSUE, D. C. TENNANT, E. A. RYAN
Ex-Officio, C. V. CHRISTIE, P. L. PRATLEY, C. M. McKERGOW, J. H. HUNTER, W. C. ADAMS, J. L. BUSFIELD, FRASER S. KEITH, O. O. LEFEBVRE, ARTHUR SURVEYER

OTTAWA
Chairman, C. CAMSELL
Sec.-Treas., F. C. C. LYNCH, Nat. Resources Intelligence Service, Dept. of the Interior, Ottawa, Ont.
Executive, A. K. HAY, W. BLUE, F. H. PETERS, V. M. MEEK, G. A. BROWNE
(Ex-Officio) N. CAUCHON, A. F. MACALLUM, J. D. CRAIG

PETERBOROUGH
Chairman, W. M. CRUTHERS
Secretary, S. O. SHIELDS, 2 Chester St., Claraday, Ont.
Treasurer, A. B. GATES
Executive, H. O. FISK, J. A. G. GOULET, B. OTTEWELL, R. H. PARSONS, E. R. SHIRLEY, R. C. FLITTON
(Ex-Officio) A. E. CADDY, R. L. DOBBIN, W. E. ROSS

KINGSTON
Chairman, D. S. ELLIS
Vice-Chair., W. L. MALCOLM
Sec.-Treas., D. G. GEIGER, Fleming Hall, Kingston, Ont.
Executive LeR. F. GRANT, A. G. MacLACHLAN, L. F. GOODWIN
Ex-Officio L. T. RUTLEGDE, G. J. SMITH

TORONTO
Chairman, L. W. WYNNE-ROBERTS
Vice-Chair., T. TAYLOR
Sec.-Treas., J. J. SPENCE, Eng. Bldg., Univ. Toronto, Toronto, Ont.
Executive, G. H. DAVIS, A. B. CREALOCK, H. N. MASON, J. W. FALKNER, J. J. TRAILL, C. S. L. HERTZBERG
(Ex-Officio) R. B. YOUNG, W. B. DUNBAR, J. G. R. WAINWRIGHT, T. R. LOUDON, J. M. OXLEY

HAMILTON
Chairman, W. L. McFAUL
Vice-Chair., J. A. McFARLANE
Sec.-Treas., W. F. McLAREN, Can. Westinghouse Co. Ltd., Hamilton, Ont.
Executive, F. P. ADAMS, W. D. BLACK, G. R. MARSTON, H. A. LUMSDEN
(Ex-Officio) L. W. GILL

LONDON
Chairman J. A. VANCE
Vice-Chair., G. E. MARTIN
Sec-Treas., FRANK C. BALL, City Engineer's Dept., London, Ont.
Executive, J. A. COOMBS, R. W. GARRETT, W. C. MILLER, W. P. NEAR, W. M. VEITCH
Ex-Officio, J. R. ROSTRON, W. P. NEAR

NIAGARA PENINSULA
Chairman, E. G. CAMERON

The Influence of Various Factors on the Power and Economy of a Gasoline Engine

E. A. Allcut, M.E.I.C.

Associate Professor of Mechanical Engineering, University of Toronto, Toronto.

Paper to be presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, Hamilton, Ont., February 13th-15th, 1929

The tests recorded in this paper were performed on a six-cylinder Durant Continental engine (No. 15-L-10045), equipped with Tillotson carburettor, and both hand and automatic spark advance. The bore and stroke were 2⅞ and 4¾ inches, respectively, the firing order 153624, and compression ratio 5.35. The cranks were 120 degrees apart, Nos. 1 and 6, 2 and 5, 3 and 4 being together. The speed range investigated was 850 to 2,800 revolutions per minute, and in each case the throttle was fully open and the ignition advance adjusted to give maximum power.

The engine was mounted on a frame, as shown in figures Nos. 1 and 2, and was connected through the gear box to a Froude water dynamometer, by means of which the power developed was calculated for each test. The speed was taken with a speed counter, the exhaust temperatures with a calibrated Chromel Copel thermocouple, and the exhaust pressures with a mercury gauge. The fuel consumption was observed by weight at intervals during each test, so that the time taken for the consumption of each pound of gasoline was accurately known, and no test was started until the conditions became constant. The cooling water was weighed and inlet and outlet temperatures were measured in each case.

The tests resolve themselves into four series:

(1) Tests made with the same fuel but different mixture strengths.

(2) Tests made with different fuels but the same carburettor setting.

(3) Tests made with different cooling water temperatures.

(4) Tests made with patent lubricants mixed with the fuels.

Variable Mixture Tests

In these tests the first series, (*A 1-5*), was made with the main jet needle open 2½ turns, so that the analysis of the exhaust gases showed a CO_2 content of approximately 8 per cent, (table No. 1), and a CO content of approximately 8 per cent. This corresponds to a fuel supply about 15 per cent in excess of that required for perfect combustion. The second series, (*A 8-12*), gave a CO_2 content of about 10.5 per cent, and CO approximately 3 per cent, (table No. 2). The third series, (*A 13-17*), was made with what was practically a correct mixture, the exhaust analysis being about 13 per cent CO_2 and 0.4 per cent free oxygen, (table No. 3).

The curves showing the results obtained at different speeds are given in figures Nos. 3-5. In some cases, (as in the power curve), the various lines are so close together that only one curve can be drawn.

The results, as far as power and economy are concerned, are given in figure No. 6. For the purpose of extending the mixture range, a set of points obtained with 15 per cent excess air on a similar engine, (No. 15-L 5057), is included, and it is evident that for all speeds, the most economical figures are obtained with about 2 per cent of free oxygen in the exhaust gas. This corresponds to about 9 per cent excess air in the mixture.

Many tests have been made, and several papers have been published dealing with the effect of mixture strength on power and economy. The experiments of Ricardo[1] indicate that with gasoline the minimum fuel consumption is obtained with 10-15 per cent of excess air in the mixture, and maximum power with about 20 per cent excess fuel.

Berry[2] shows similar curves with maximum economy at about 5 per cent excess air, and maximum power at about 16 per cent excess fuel. A paper read by H. M. Jacklin[3] includes a series of curves with different spark plug combinations, and the following figures are taken from the curves with one spark plug:—

(1) "The Internal Combustion Engine," Ricardo, vol. II, p. 46.

(2) "More Car Miles per Gallon of Fuel," Society of Automotive Engineers Jrl., August 1922.

(3) "Improving Engine Performance," Society of Automotive Engineers Jrl., March 1928.

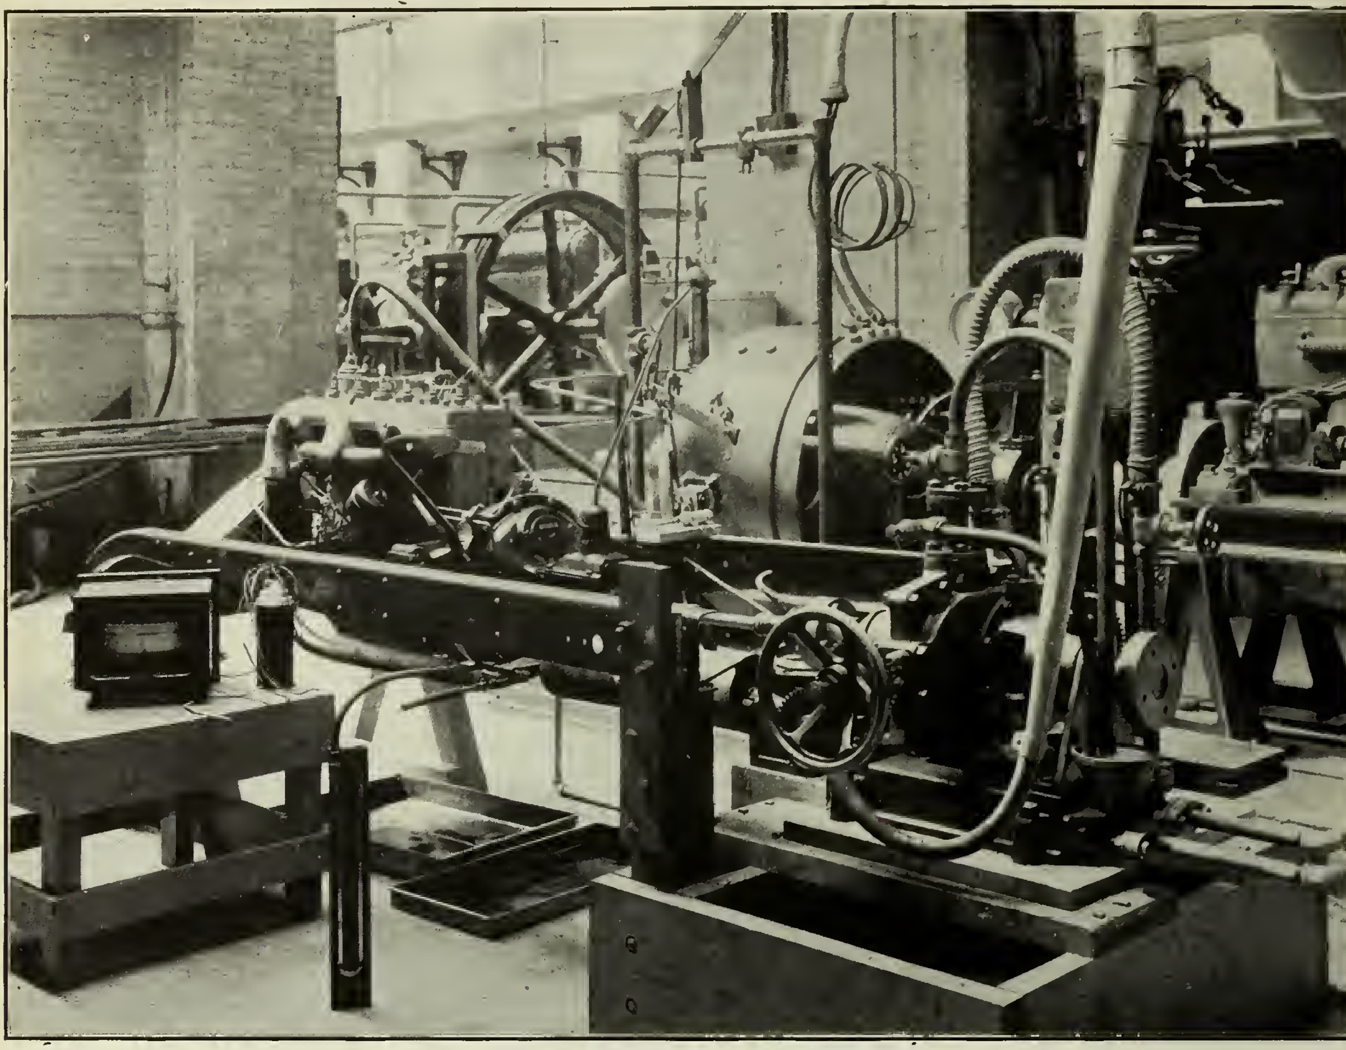

Figure No. 1.—Arrangement of Engine for Test.

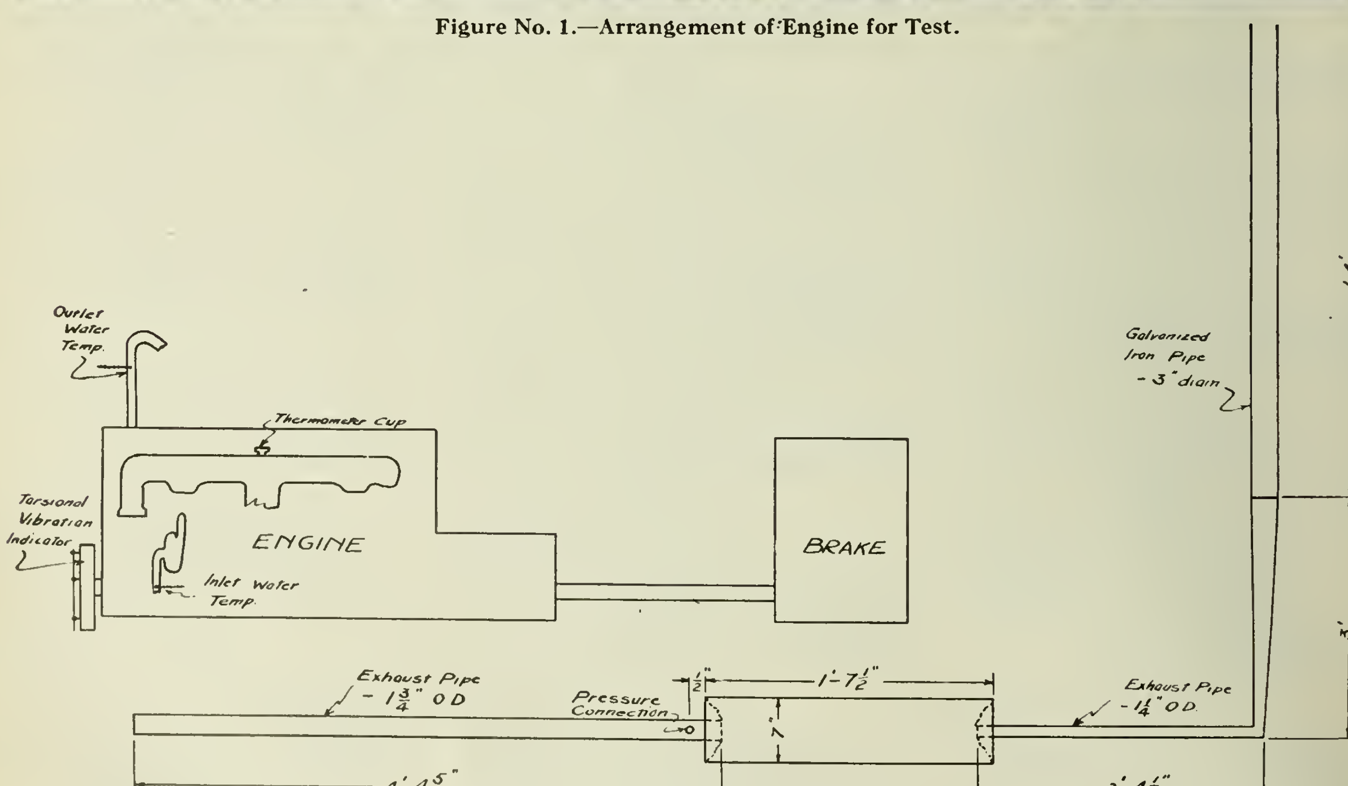

Figure No 2.—Diagram of Test Layout.

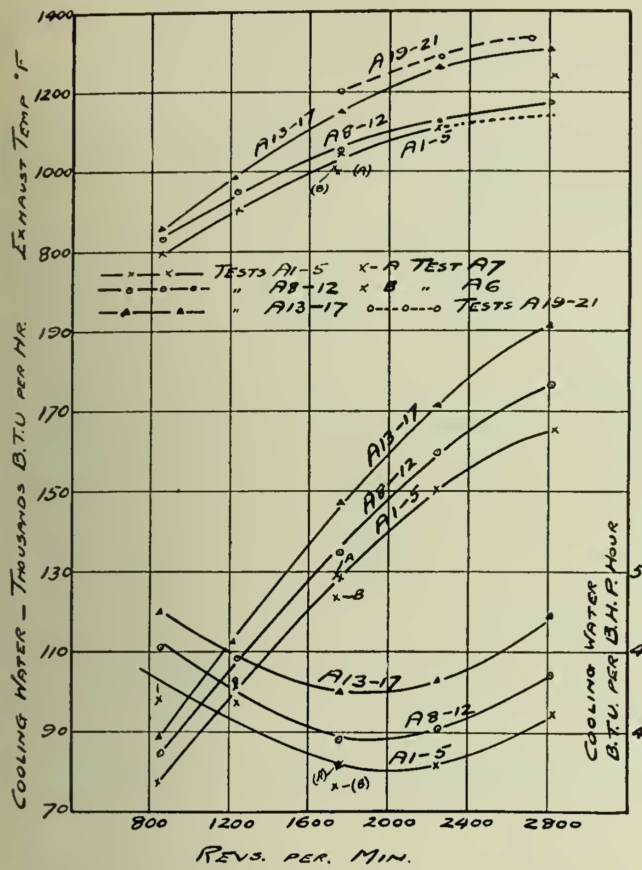

Figure No. 3.—Results of "A" Tests with Different Mixture Strengths.

Spark Advance	Max. B.H.P.	Mixture Ratio Air/Fuel	Max. I.H.P.	Mixture Ratio Air/Fuel
10°	1.14	14.5	1.92	14.0
20°	1.26	13.5	2.02	13.0
30°	1.21	10.5	1.97	12.5

Taking the correct mixture ratio for complete combustion as 15:1, it is evident that all of these maxima are obtained with rich mixtures. This paper also indicates a decrease of mechanical efficiency as the mixture increases in richness.

A summary of the situation, given by S. W. Sparrow,[4] points to the same conclusions, that the maximum economy is obtained with the leanest mixture upon which the engine will run regularly, and the maximum power with a mixture 10 to 20 per cent richer than that required for complete combustion.

The reason for the former is not far to seek. Excess air is required for maximum efficiency, because the air and fuel are never completely mixed in the cylinder, and therefore there must be sufficient oxygen present at all points to burn the fuel available, otherwise some incomplete combustion will result. With this conclusion the present series of results is in agreement.

The case of the power curve, however, is different. In the tests cited above, the power curve rises rapidly to a maximum on the rich side, and then slowly decreases as the quantity of fuel is increased. The present tests, (figure No. 6), indicate no appreciable difference in power over the range of mixtures investigated. It is reasonably certain that weaker mixtures than those given in figure No. 6 would show progressive decreases in power, but at each of the speeds indicated the power curves were practically flat, thus differing from those obtained in the experiments described above. In several of those cases, the engine experimented on was a single cylinder variable compression engine, and the question arises whether the results obtained on such engines are generally applicable to multi-cylinder engines. This series of tests, made on a six-cylinder engine manufactured under commercial conditions, indicates that there is some doubt on that point.

The fuel consumption curves are fairly flat, reaching a minimum in each case between 1,200 and 2,000 r.p.m.

In all cases the curves representing the percentage of CO_2 in the exhaust gases were very flat. It is notable that the tests made at 850 r.p.m. in all cases gave a lower percentage of CO_2 and more CO and O_2 than those made at higher speeds.

Warner[5] states that with 7 per cent of CO_2 in the exhaust gases, combustion is about 57.5 per cent complete, and with 14 per cent CO_2 combustion is 97 per cent complete. Between the two, (according to Fieldner and Jones), there is a straight line relationship. As in the present series, 13-14 per cent CO_2 was obtained in many tests, it is evident that the combustion efficiency was high.

(5) "Instruments for Automotive Research," Society of Automotive Engineers Jrl., June 1925.

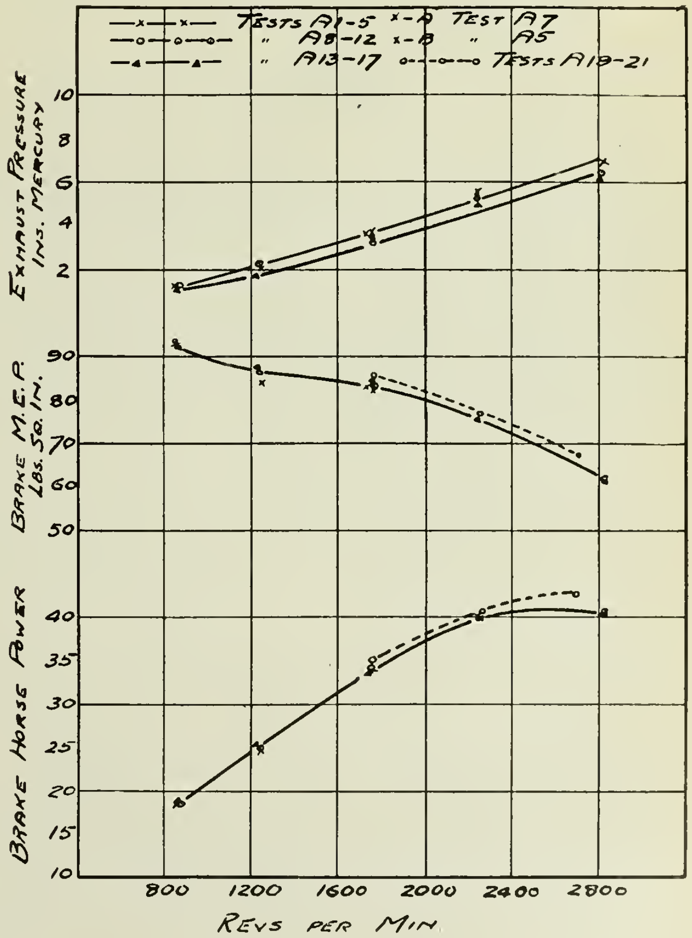

Figure No. 4.—Results of "A" Tests with Different Mixture Strengths.

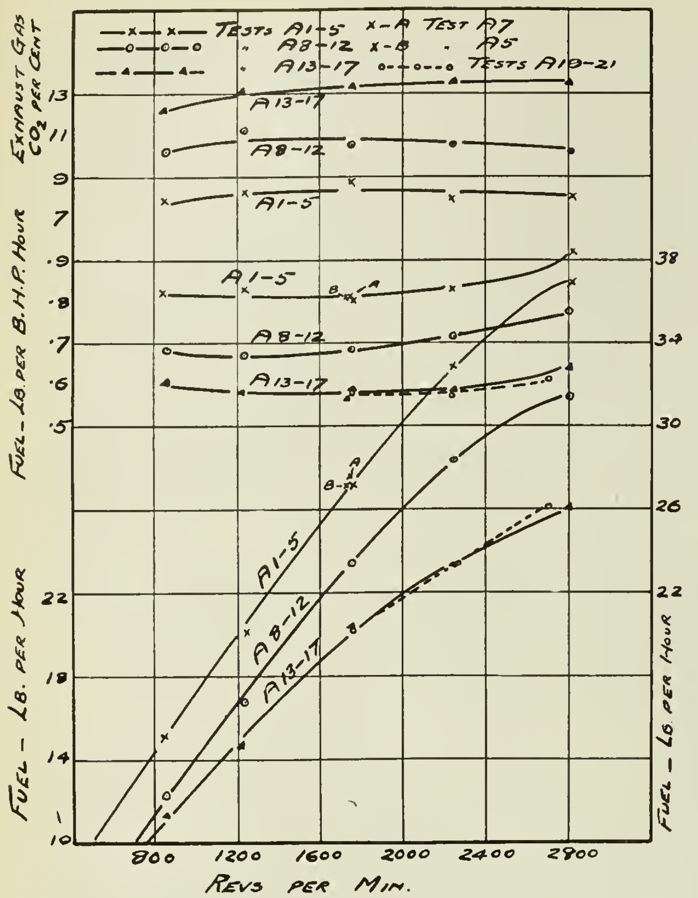

Figure No. 5.—Results of "A" Tests with Different Mixture Strengths.

The cooling water losses decreased as the speed increased, and increased as the mixture strength was decreased. That is to say, the weak mixtures which developed the highest exhaust temperatures also rejected to the cooling water approximately 40 per cent of the heat generated, as against 25 per cent in the case of the rich mixtures.

In all cases the thermal efficiencies were calculated on the higher calorific values of the fuels as obtained in the Parr calorimeter. In these tests, Blue Sunoco gasoline was used throughout, and brake thermal efficiencies up to 23 per cent were obtained. In a previous series made with engine No. 15-L 5057, efficiencies of over 24 per cent were obtained on several occasions.

A further series of tests was made on this engine to determine the effect of the muffler and air cleaner on the power and economy obtained. The air cleaner was removed and the muffler and tail pipe were replaced by 21 feet of 1½- to 1¾-inch exhaust piping. The carburettor setting was approximately that used in tests *A 13-17*, and the mixture was practically the same as indicated by the exhaust analyses for tests *A 19-21*, (table No. 13). At 1,760 r.p.m. the power was increased from 34.7 to 35.0 b.h.p. At 2,260 r.p.m. the increase was from 39.7 to 40.6, and at maximum speed the power was raised from 40.6 to 42.6 b.h.p. The economy was unaltered, but the exhaust temperatures were higher than those in the previous series. The results obtained are indicated by dotted lines in figures Nos. 3-6.

Advantage was taken of this opportunity to check the results obtained with different mixture strengths, and therefore tests *A 22* and *23* were performed under exactly the same conditions as test *A 21*, but with the main jet of the carburettor opened ¼ turn between each pair of tests.

Again, it is evident that the power is practically unaltered as the mixture is made richer than the chemically correct mixture.

Different Fuels

During the past ten years considerable attention has been paid to the nature of the fuel used in gasoline engines, and the various characteristics that conduce to satisfactory performance on the road.

The desirable features are:—

(a) Easy starting.
(b) Good acceleration.
(c) High anti-detonation, or anti-knocking value.

Easy starting from cold requires a comparatively large percentage of constituents with low boiling points. In this connection it was pointed out by Professor G. G. Brown[6] that fuels giving easy starting and having low boiling points are liable to vapourise in the carburettor under road conditions, and also that the mixture is liable to be superheated in the intake manifold in some cases. This causes a loss of power and economy, particularly at part throttle. Figures Nos. 7 and 8 give the distillation curves for the fuels under consideration. Figure No. 7 was taken from the Dominion Survey,[7] and figure No. 8 contains the actual distillation curves obtained from samples of the fuels used in the tests.

Detonation is a complex subject and has been the sub-

[6] "Present Tendencies in Motor Fuel Quality," Society of Automotive Engineers Jrl., May 1928.

[7] "Gasoline Survey for 1927," Rosewarne and Offord, Dept. of Mines, Ottawa, April 1928.

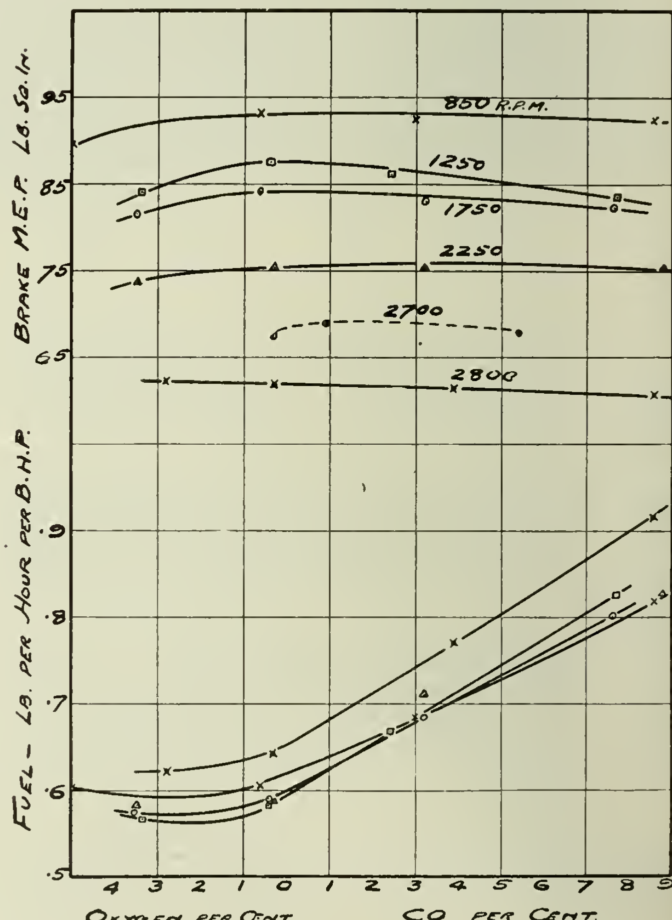

Figure No. 6.—Results of "A" Tests with Different Mixture Strengths.

ject of numerous papers: Brown[8] has investigated the relationship between volatility and detonating properties of fuels, and Ricardo has established the importance, from a detonation standpoint, of the relative proportions of paraffins, aromatics and naphthenes in the fuel. Numerous papers have appeared, and the Society of Automotive Engineers has held symposiums on volatility and detonation,[9] so that the subject has been well considered. However, there is no finality of opinion, either on the nature of detonation, or on the method of measuring it, so that these matters will not be considered here.

Anti-detonating fuels, however, are in common use, and various claims of increased power, economy and carbon removal are made for them. The advantage of ethyl and similar gasolines in increasing the possible compression ratio, (and therefore the power and economy of engines), may be conceded, but the question arises whether any benefit is derivable from their use in engines having compression ratios less than 5½ to 1, and well designed combustion spaces where detonation would not normally occur. The present engine, having a compression ratio of 5.35:1, was well suited to such an investigation, and the fuels were chosen with this idea in view.

In these tests the engine was run with the same carburettor setting throughout. The " A " series was run on Blue Sunoco gasoline, and the carburettor setting, (1½ turns), corresponding to tests *A 13-17*, was chosen as a standard, because the exhaust analysis showed that under

(8) "The Relation of Motor Fuel Characteristics to Engine Performance," University of Michigan Bulletin, May 1927.

Figure No. 7.—Fractional Distillations for 1926-27 from Dominion Report.

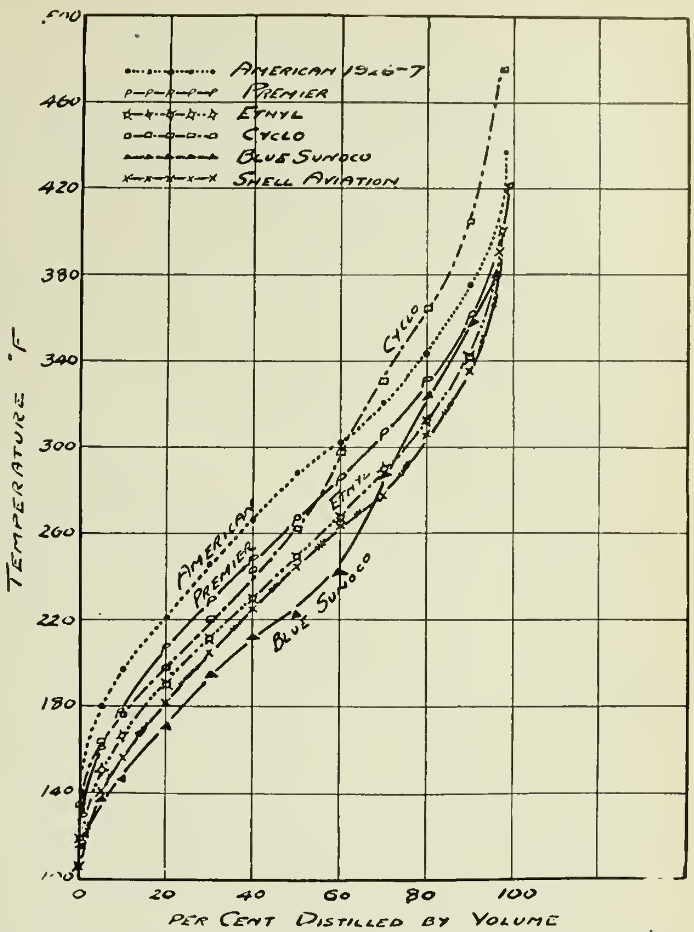

Figure No. 8.—Fractional Distillations of Samples Taken During Tests.

these conditions the mixture was very nearly chemically correct. Table No. 3 indicates that in this series there was no CO in the exhaust gases and the free oxygen content was about 0.4 per cent.

Tests *B 1-5* were made under the same conditions with Imperial ethyl gasoline, but it was found that the exhaust gases contained about 2.5 per cent of CO, (table No. 5). A further series of tests was then made with the carburettor jet closed ⅛ turn. The results obtained are given in table No. 6, (tests *B 8-12*), and under these conditions the fuel consumption at the most economical speed was cut down from .615 to .578 lbs. per b.h.p. hour.

Allowing for the slight difference in speed in tests *B-1* and *B-8*, respectively, the power of the engine again was not affected by the change of mixture. The lower and higher speeds in this case showed a slight loss of power with the leaner mixture.

Tests *C*, (table No. 7), with Shell Aviation, *D*, (table No. 8), with "Cyclo," and *E*, (table No. 9), with Premier gasoline, were all made under the same conditions as tests *A 13-17* and *B 1-5*. The results are plotted in figures Nos. 9, 10 and 11.

Figure No. 9 indicates that the minimum consumption in pounds per b.h.p. hour was obtained over the entire speed range with Blue Sunoco gasoline. The hourly consumption of Shell Aviation fuel was less with the same carburettor setting, but the power obtained was also less. Figure No. 12 gives the fuel consumption curves on a volumetric basis, as this is the condition under which each fuel is sold; and, taking into account the retail prices as on July 14th, 1928, table No. 10 shows in cents per b.h.p. hour the cost of running at 1,750 r.p.m., (35 miles per hour), and full load.

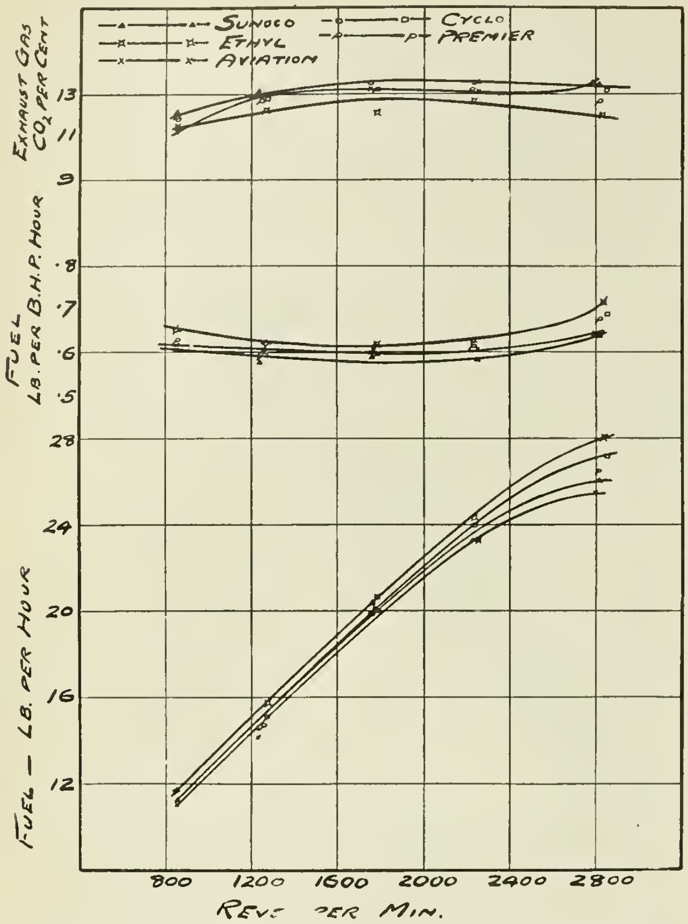

Figure No. 9.—Chart showing Results of Tests on Different Fuels.

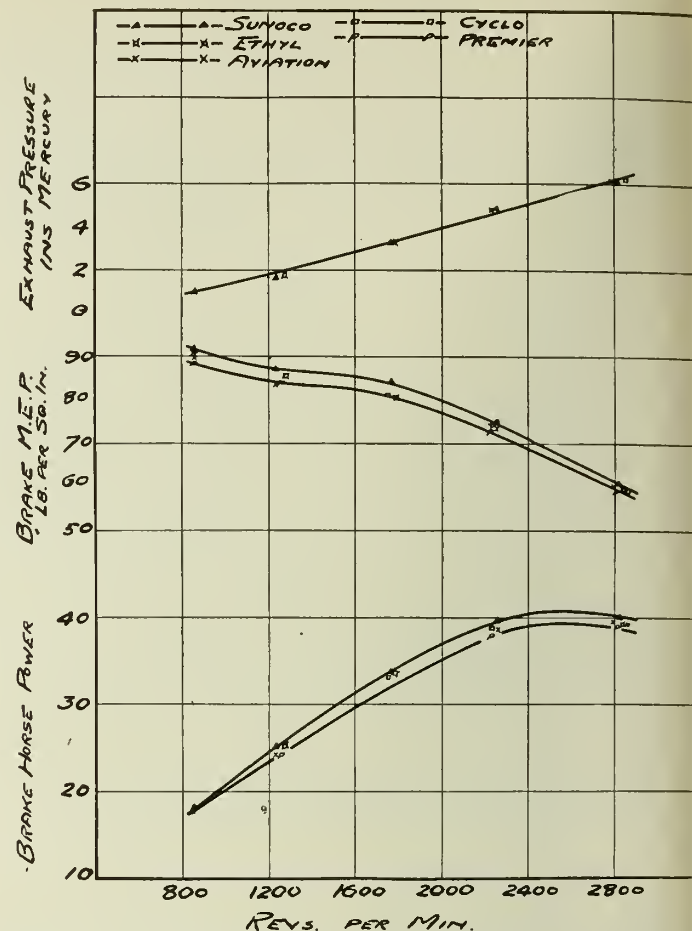

Figure No. 10.—Chart showing Results of Tests on Different Fuels.

This, of course, does not take into account variations in actual running conditions, but it is the only basis of comparison available. The minimum cost of running varies from 1.99 cents per b.h.p. hour on Blue Sunoco to 2.433 cents on Shell Aviation. The latter figure is due to the low specific gravity of this fuel, which is .717, as compared with .74 for most of the other gasolines tested. The cooling water losses do not vary very greatly for the different fuels. In each series the water outlet temperature was adjusted to 160-170°F., so that variations from this cause should not affect the results.

The general conclusion to be drawn from these figures is identical with that of Professor Brown,[10] who states that there is no economic advantage in buying anti-knock fuels at a 3-cent premium, (about 11 per cent on the selling price), if an engine having a compression ratio of 5½ to 1 can be operated satisfactorily on an ordinary gasoline.

Cooling Water Temperatures

At the end of each series of tests described above, further experiments were made with the maximum and minimum quantities of cooling water available, so that the influence of cooling water temperature on the power and economy of the engine might be studied at different speeds. The temperature range obtainable was not the same in each case, because the cooling water for the brake was taken off the same inlet pipe, and this could not be reduced below a certain quantity. However, the outlet temperature range in all cases was varied sufficiently to indicate any differences that might exist on this account.

The jacket temperature may be expected to influence five factors in engine economy and operation. These are:—

(a) Cooling loss during combustion.
(b) Volumetric efficiency.
(c) Piston friction.
(d) Crank case dilution.
(e) Starting difficulties.

Ricardo[11] states that in all cases the cooling water loss during the combustion period does not exceed about 13 per cent of the heat in the fuel, and therefore the saving achieved by using high water temperatures can only be a portion of this amount. Also, as the difference in temperature between the hot gases and water is in the neighbourhood of 3,500°F., the greatest possible difference in water temperature can only be small by comparison, and therefore the difference in (a) is probably negligible.

On the basis that the change in temperature of the entering gases is about 1/6 that of the cylinder walls, and that the power output is proportional to the absolute temperature of the gases, Ricardo also calculates an advantage of 2½ to 3½ per cent in power in favour of a low cooling water temperature. This is confirmed by Taub,[12] who found that with a water outlet temperature of 110-140°F., the volumetric efficiency of an engine was 81 per cent. From 140-180°F. the volumetric efficiency fell, until at 180-200°F. it was 77 per cent.

As the wall temperature rises, the viscosity of the lubricating oil falls, thus improving the mechanical efficiency,

[10] "Present Tendencies in Motor Fuel Quality," Society of Automotive Engineers Jrl., May 1928.

[11] "The Internal Combustion Engine," vol. II, p. 72.

[12] "High Average Operating Temperature," Society of Automotive Engineers Jrl., March 1926.

so that the power output may be increased as much as 3-8 per cent, due to this factor alone.

It follows, therefore, that factors (b) and (c) work in opposite directions, and according as the change in (c) is large or small, the use of high outlet temperatures may have a beneficial effect, or no effect at all, on the actual power produced.

It is certain, however, that a low cylinder temperature will increase crank case dilution. This is confirmed by Sparrow and Eisinger,[13] who indicate a reduction of dilution from 5 per cent to 0 as the jacket temperature increases from 50° to 212°F. Taub states that 16 per cent crank case dilution is necessary to facilitate starting with a cold engine, but this would appear to be dependent on the kind of oil used and its temperature.

Cold cylinder walls obviously make it more difficult to get sufficient fuel into the cylinder when starting the engine, on account of the precipitation of fuel in the liquid state.

The question of cylinder wall temperature and its influence on power and economy is important in connection with the proposed adoption of steam cooling, which produces a uniform temperature of 212°F. Numerous papers have been written on the advantages of this system to prove the benefits obtainable in practical operation, but steam cooling is advancing very slowly, if at all.[14]

In connection with this investigation a previous series of tests on a tractor engine had indicated little or no difference in power and economy when the cooling water outlet temperature was varied from 100 to 200°F. In the present case tests were made at 1,750, (*A* and *B* series), 1,250, (*C* series), 855, (*D* series), and 2,250 r.p.m., (*E* series), so that

[13] "Recent Co-operative Fuel Research Progress," Society of Automotive Engineers Jr., February 1925.

[14] Except in aircraft work. Steam cooling is being used on the "Tornado" engine used in the large British airship R-101 for Trans-Atlantic work. (Wing-Commander Cave-Browne-Cave, on "The Evaporative Cooling of Aircraft Engines."—British Association, Section G, September 10, 1928.

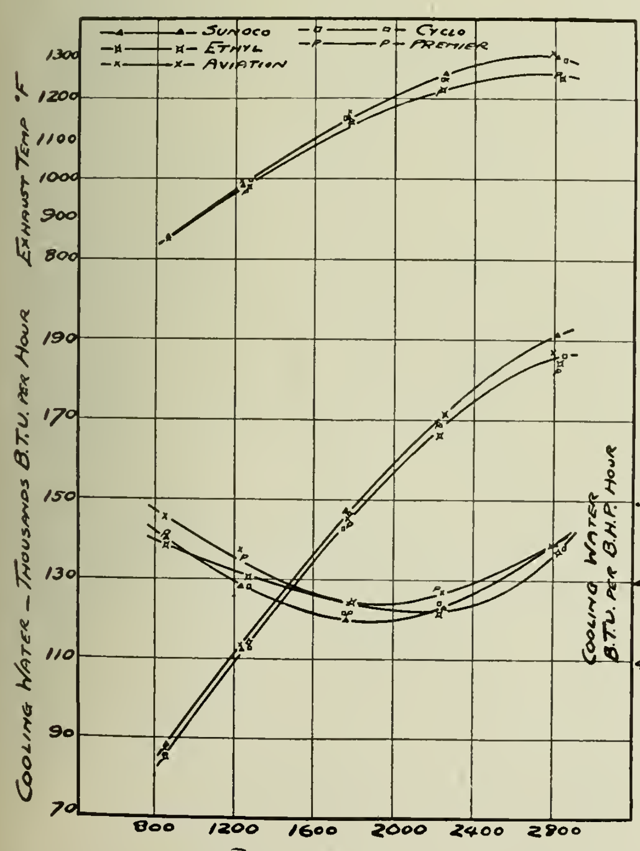

Figure No. 11.—Chart showing Results of Tests on Different Fuels.

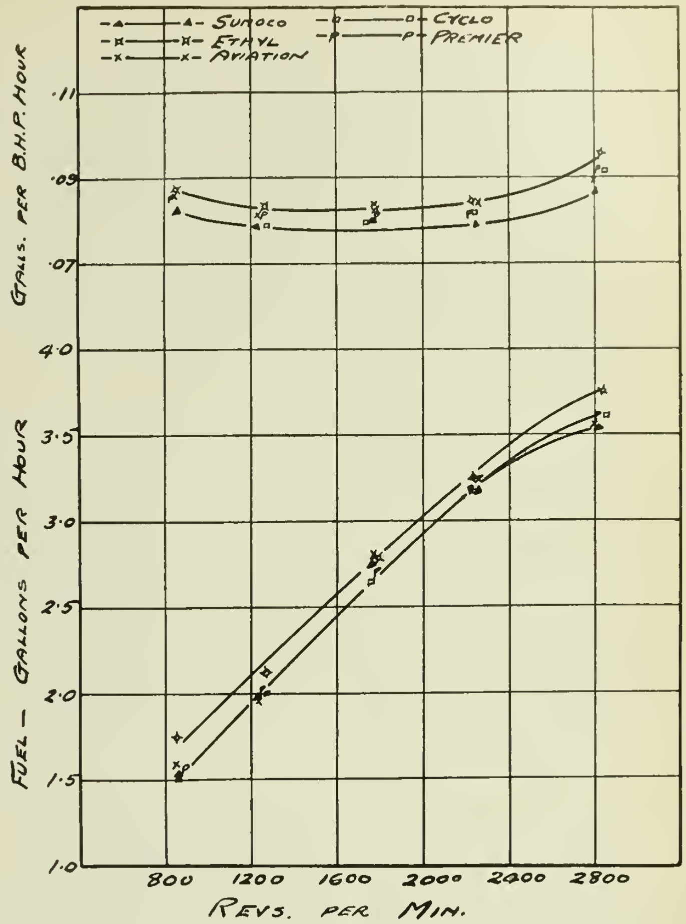

Figure No. 12.—Chart showing Results of Tests on Different Fuels (Volumetric Bas's).

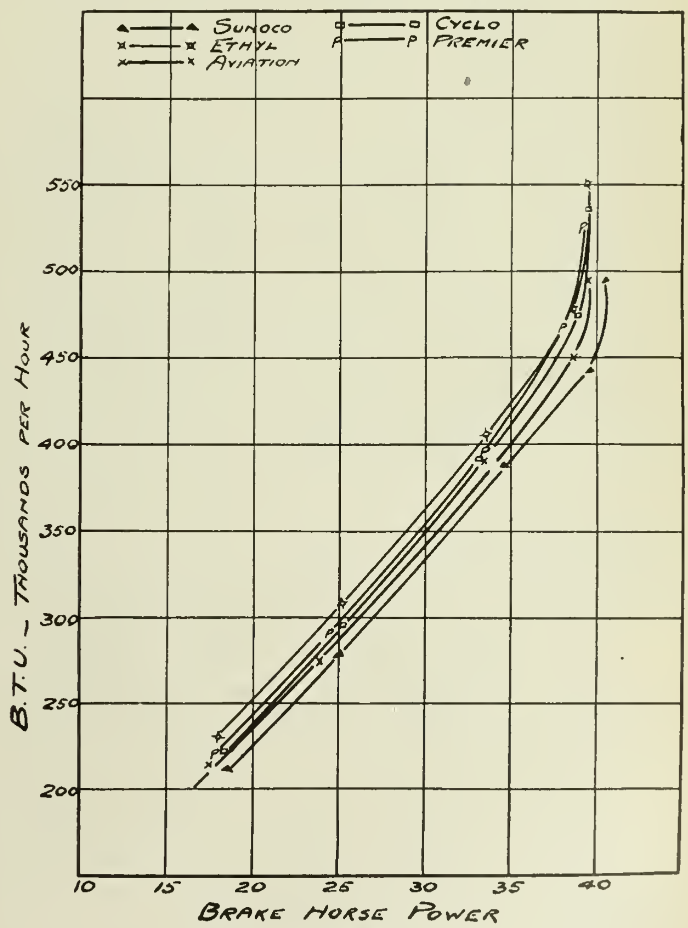

Figure No. 13.—Chart showing Hourly Heat Consumption of Different Fuels.

different fuels were investigated, as well as different speeds. The results are given in table No. 11.

In most cases a slight fall of power was observed at the higher temperatures, and at 855 and 2,250 r.p.m. there was a slight increase of economy, but this did not hold good for the other speeds, at which the economy was unaffected.

The total heat lost per hour to the cooling water decreased generally as the temperature increased, but the cooling loss expressed as a percentage of the total heat entering the engine remained very nearly constant, and did not show any progressive decrease. The figures are so close that it may be said that the cooling water temperature has no appreciable effect on the brake horse power, or on the brake thermal efficiency.

Special Lubricants in Fuel

Various special lubricants are now on the market, and it is claimed that if these are mixed with the fuel entering the carburettor, remarkable benefits in power, economy and mechanical running will be obtained. The *F* series, (table No. 12), was therefore devoted to an investigation of these claims. The running time was not sufficiently long to test the influence of these lubricants on the life or wear of the running surfaces, but it enabled the power and economy claims to be investigated.

Test *F-1* was run at nearly 1,800 r.p.m. with Premier gasoline, and at the end of this test the quantity of Mixtrol, prescribed in the instructions, was added to the fuel and the engine allowed to run for some time before test *F-2* was made. The power was unaltered, but there was a fall of about 2½ per cent in fuel consumption. The comparative costs are shown in table No. 10, from which it is seen that although the actual fuel cost per unit of power is reduced, the extra cost of the oil more than swamps the economy obtained.

A similar series, (*F-3* and *F-4*), with Aviation and Aviation + Mix-Ur-Oil, produced similar results. It would appear, therefore, that there is no gain in power or economy by using these lubricants, but there may possibly be beneficial results, as far as the running surfaces are concerned.

The thanks of the author are due to the Durant Company of Canada, who supplied the engine; to Messrs. G. H. Harlow, B.A.Sc., and R. A. Westervelt, B.A.Sc., who assisted in taking observations and making the necessary calculations; and to Mr. F. Hickey, who erected the test apparatus, and was in charge of the engine while the tests were in progress.

The Saint-Paul Ward Main Sewer in the City of Montreal

Features Governing the General Plan and Design, and Details of Construction

Geo. R. MacLeod, M.E.I.C.
Chief Engineer, Technical Service, City of Montreal.

Paper read before the Montreal Branch of The Engineering Institute of Canada, October 11th, 1928

The Saint-Paul ward main sewer is so called because it drains the greater part of Saint-Paul ward, but the drainage area, 1,135 acres, includes also a part of the town of La Salle.

As may be seen from the accompanying map, figure No. 1, the easterly boundary of the area is not a natural "height of land" but an artificial barrier formed by the aqueduct canal of the city of Montreal. The same is true of a portion of the northerly boundary, where the Lachine canal prevents a certain amount of drainage towards the valley of the Little River Saint-Pierre.

The point of final concentration for the area under discussion, so far as the new sewer is concerned, is at the intersection of Pitt and Dunn streets, where the new sewer discharges into a circular brick sewer of 6 feet diameter built in 1914-15. The latter sewer follows Pitt street and St. Patrick street, passes under the Canadian National Railway and discharges into the Little River Saint-Pierre at a point near the old water works tailrace.

It should be stated here that the capacity of this 6-foot brick sewer is less than that of the new 10-foot St. Paul Ward sewer, but as the area to be drained by the latter will not be fully developed for some years, the 6-foot sewer will adequately take care of the flow for the present, and when the run-off shall have become too great for this arrangement, a new auxiliary sewer to take care of the extra flow will be built from the intersection of Pitt and Dunn streets to a junction with the very large Saint-Pierre river collector, which is proposed to be built next year. This junction with the Saint-Pierre river collector will be near Atwater avenue and the tailrace.

Commencing at Pitt and Dunn streets, the new Saint-Paul ward sewer runs parallel to and close to the aqueduct canal as far as Raudot street, a distance of 7,090 feet, composed of 1,029 feet of 10-foot diameter, 2,677 feet of 9½-foot diameter and 3,384 feet of 9-foot diameter, all of horseshoe section. Thence the sewer runs along Raudot street, (a southwesterly direction), and this part is composed of 1,325 feet of circular brick of 6-foot diameter, 1,075 feet of 5½-foot diameter, and 350 feet of circular 5-foot diameter, which brings it to the intersection of Jogues street, from whence it turns almost due west along the north line of the unsubdivided farm, (cadastre 4684), with gradually decreasing diameters of 4.5, 4, 3.5, and finally 3 feet, terminating for the present at the boundary between Montreal and La Salle; the total length of this branch being 4,075 feet.

Determination of Drainage Areas

The drainage area, for the purpose of determining the

Figure No. 1.—General Plan of St. Paul Ward Drainage District.

coefficient of run-off, which varies from place to place, is divided into ten areas of different sizes, according to the local conditions of the soil, the slope, the character of the surface, and the minimum time of concentration.

In designing sewers, more especially trunk sewers, the first step is to determine the outermost limit or boundary of the whole area. The next is to subdivide this into sections or areas over which the conditions named above are fairly uniform. Then, taking a given area with a given intensity of rainfall, the total quantity of water falling on the area under study, in a given time, is easily arrived at. Next by applying the run-off coefficient adopted for the local conditions, the proportion of the water finding its way into the sewers is calculated, and hence the total quantity that must be taken care of at the point of concentration on that particular portion of the trunk sewer.

The formulæ governing the intensities, and the considerations determining the run-off factor which were used in designing the Saint-Paul ward main sewer, being the result of years of study and research in the Technical Service of the city of Montreal, were very fully discussed and explained in the paper presented before the Montreal Branch of The Institute by J. G. Caron, A.M.E.I.C., on April 16th, 1925, and later printed in The Engineering Journal of June 1925, and for that reason need not be repeated here.

Run-off Factors

It is sufficient to give some idea of the variation in the run-off factor from one division of the drainage area to another. For example, referring to figure No. 1, the division of 430 acres at the extreme or south end of the district is given a run-off factor of only 39.3 per cent; this area is all composed of open fields without streets or urban development of any kind. The slope is fairly flat and it is known that a large part of the area has been reserved for a park. Incidentally, it should be mentioned that this area will be served later by an extension of the trunk sewer along the aqueduct from a junction at Raudot to whatever distance may be required. The diameter of this extension will be 7 feet 4 inches, and, of course, the discharge from this future sewer was taken into account in designing the main trunk from Raudot to Pitt street.

The next area, 312 acres, is given a run-off factor of 60 per cent chiefly because the streets are very close together, indicating a large proportion of paved surface per acre, and the subdivision consists of narrow lots, with not a very great depth, which indicates a very large proportion of roof area per acre.

An even higher factor, 64 per cent, is given to the 34 acres north of Rielle street, between Wedgewood and De-Villiers streets.

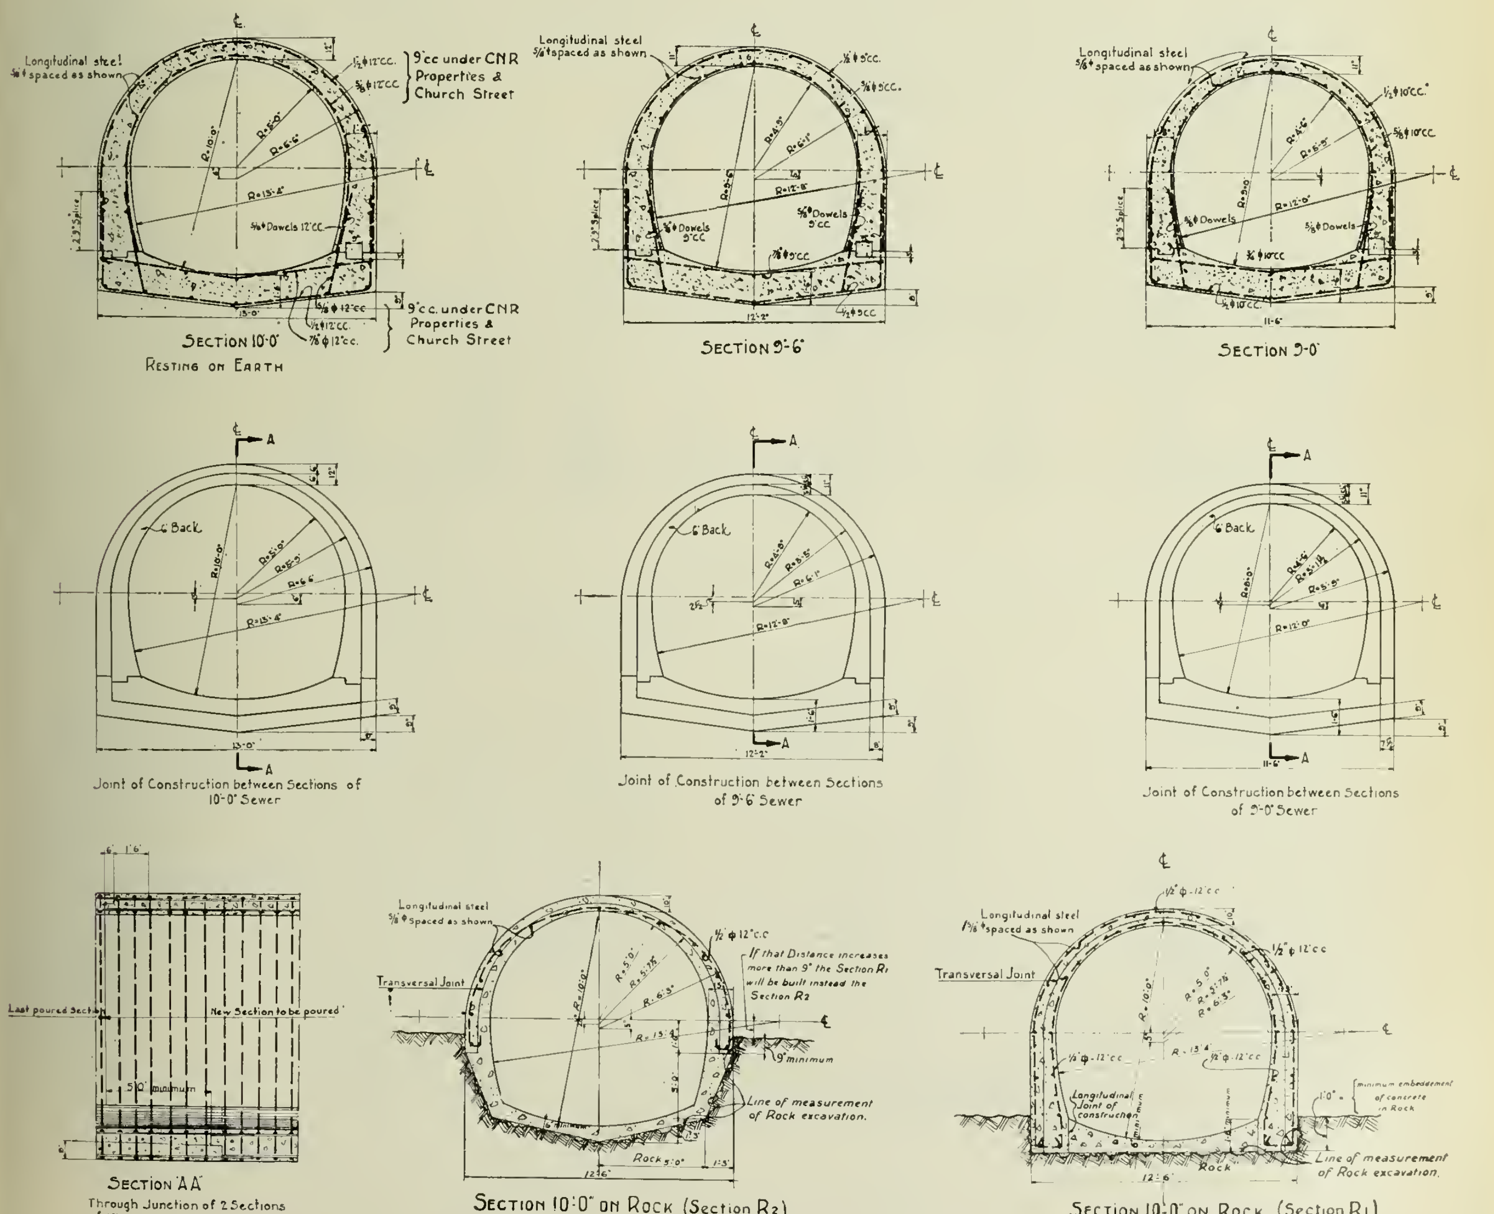

Figure No. 2.—Typical Cross-sections for 10′ 0″, 9′ 6″ and 9′ 0″ Sewers.

Other examples of the run-off factor on the diagram, figure No. 1, are:—144 acres, 50 per cent; 13.5 acres, 40 per cent; 42 acres, 52 per cent.

Another feature of this trunk sewer not yet mentioned is the branch of circular brick sewer, 4 feet in diameter, on DeMaricourt street, connecting with the 9.5-foot trunk at the aqueduct and extending along DeMaricourt and Rielle streets, a distance of 2,000 feet. This branch is now under construction and as soon as it is completed it will be possible to discontinue operating the sewerage pumps, which have been handling the sewerage from an area of about 130 acres in the vicinity of Rielle street, this area being too low to drain by gravity into the existing system of old sewers in the northern part of the district.

The total length of trunk sewer, including the branches of circular section, is 13,165 feet.

As there is nothing unusual connected with the size or the design of the circular brick sewers on Raudot street and on DeMaricourt street, the data given below refers only to the reinforced concrete section, 7,090 feet long, parallel to the aqueduct canal.

As the fall between the foot of Raudot street and the

Figure No. 3.—Detail Plan for Snow-chute and Boat Entrance.

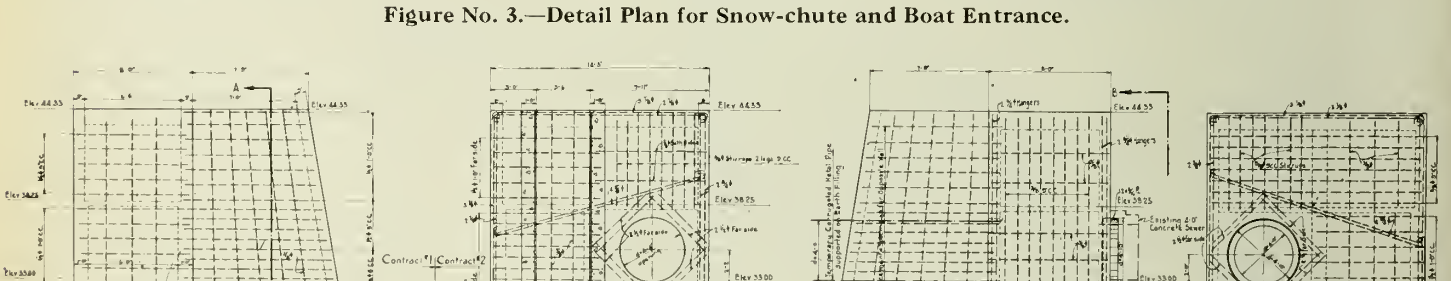

Figure No. 4.—Detail Plan of Chamber Connecting with Syphon under Aqueduct Canal.

intersection of Pitt and Dunn streets is nil at the surface, the rate of grade of the sewer is the minimum allowable, 0.10 feet per 100 feet. This very flat grade of course gives a very low velocity and hence necessitates a large sectional area of sewer.

Hydraulic Elements of Sewer

The hydraulic elements of the Saint-Paul ward main sewer have been computed from the invert to the crown and have been plotted on cross-section paper, taking as unity the height of the section, and from this diagram the ratio of each of the three hydraulic elements, area, mean velocity, and discharge, of the filled segment to that of the entire section, corresponding to any ratio of depth of flow to the vertical diameter may be obtained. This diagram gives also the ratio of the wetted area and mean hydraulic radius of the filled sections, in terms of the vertical diameter.

A slope of $S = 0.001$ and $n = 0.015$ has been used in the preparation of the diagram and the following constants have been derived:—

Diameter of equivalent circle	$= 1.0326\ D$
Wetted perimeter	$= 3.2895\ D$
Area	$= 0.8358\ D^2$
Hydraulic radius	$= 0.2542\ D$

According to this the maximum discharge occurs when the wetted area reaches 93 per cent of the whole section, and such discharge is then increased 0.07 per cent more than the sewer flowing full.

Details of Design

For details of design of the reinforced concrete sections, see figure No. 2. Before adopting this horseshoe section, complete calculations and designs of a section with semi-elliptical arch were made; a comparison of the elements of the latter with those of the horseshoe type resulted as follows:—

Comparison of a Horsesh e and Semi-elliptical Sections.

	Horseshoe	Semi-elliptical
Section	83.60	76.509
Perimeter	32.87	32.038
Hydraulic radius	2.543	2.388
Height	10 ft.	10 ft.
Width	10 ft.	10 ft.
Grade	0.001	0.001
Velocity	5.82	5.637
Discharge	486 c.f.s.	431 c.f.s.
Concrete	2.01 cu. yds.	1.6 cu. yd.
Steel	140.66 lbs.	112 lbs.

In construction, the invert was, of course, laid first, and allowed to stand untouched for at least 24 hours before beginning to place arch forms or doing any work which might crush or distort the newly poured invert. It is noted that there must be a space of at least 5 feet between the lap joint of invert, (section "A-A"), and the lap joint of side wall and arch sections. After construction commenced, the contractor was permitted to pour along with the invert

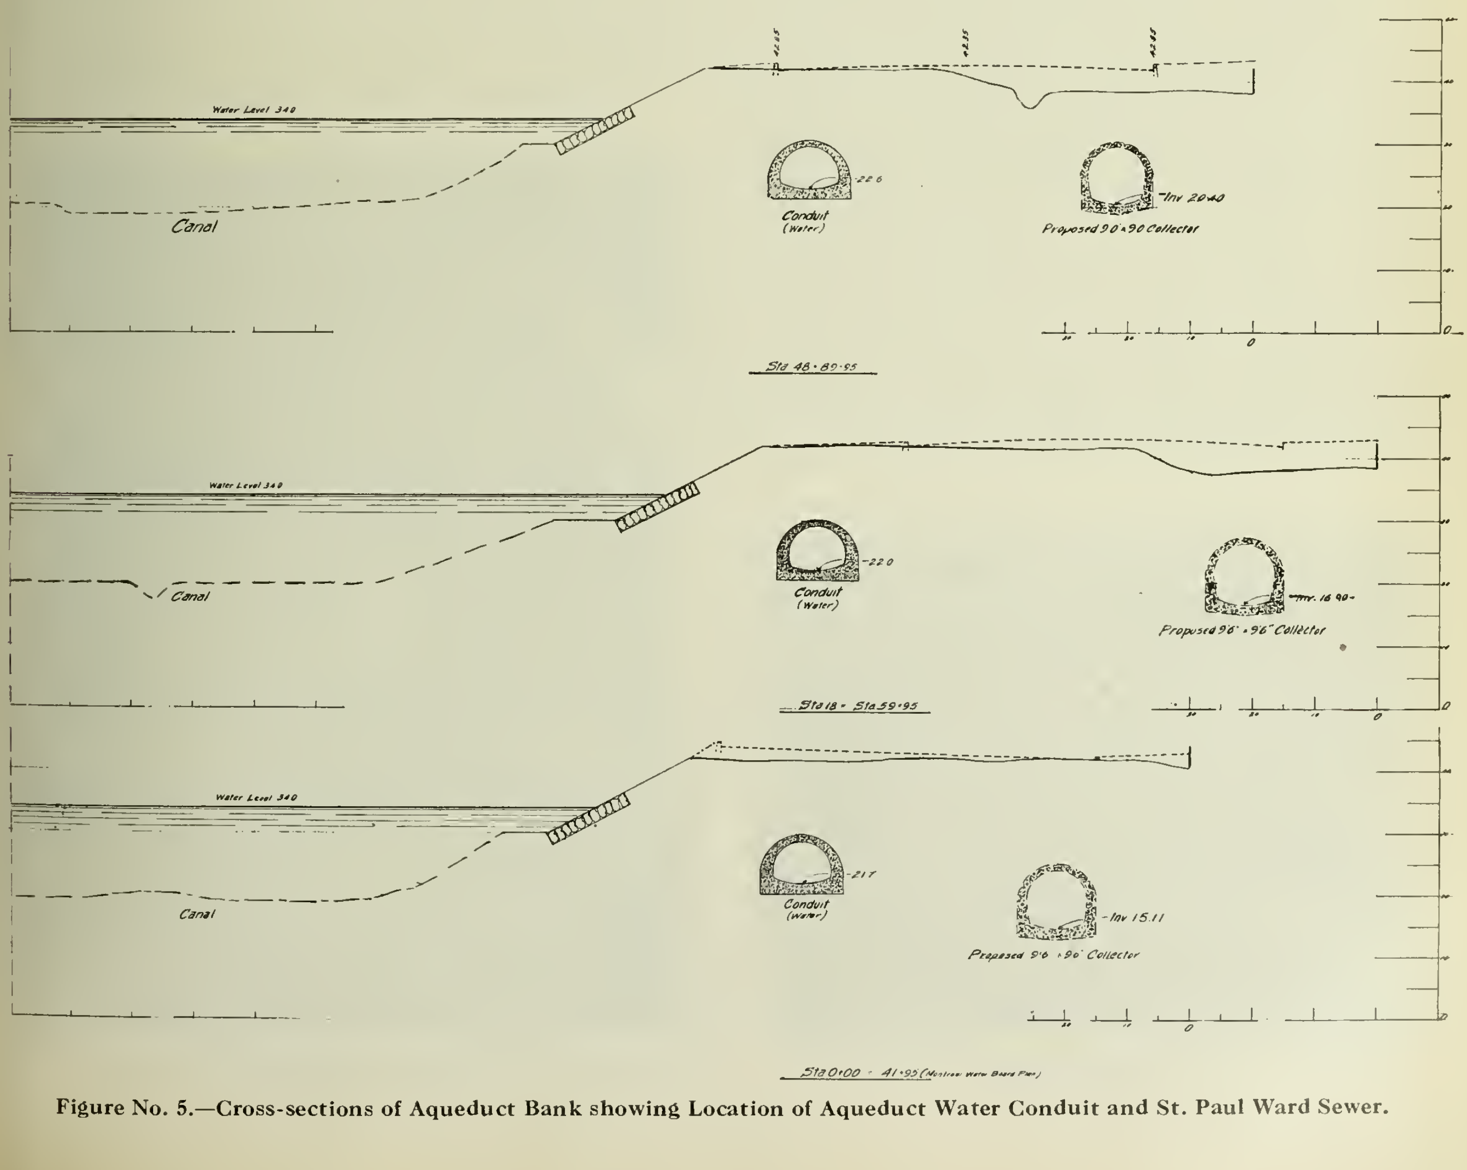

Figure No. 5.—Cross-sections of Aqueduct Bank showing Location of Aqueduct Water Conduit and St. Paul Ward Sewer.

Figure No. 6.—General View of 10′ 0″ Sewer, Looking Eastwards from Intersection of Canadian National Railway.

Figure No. 8.—Interior of Sewer, Looking Westwards, from Junction Chamber, Station 0 + 00.

a height of six inches of side walls, the object being to provide a face to hold the lower edges of the collapsible steel forms for the arch.

Figure No. 5 shows two cross-sections of the aqueduct canal, with a reinforced concrete water conduit in its " north " bank, and the space between this conduit and the sewer. The upper section shows practically the maximum distance between sewer and water conduit, and the lower section the minimum, which occurred for a distance of about 600 feet east of Church avenue. The average distance between sewer and conduit for the greater part of the work was about the mean between the maximum and minimum.

It turned out, however, that most of the rock excavation occurred on the stretch of sewer which was nearest the conduit. Before any rock blasting was permitted, the water conduit was emptied and remained empty during the whole period of blasting. Careful inspection of the conduit was made before and after blasting, and it was seen that no damage whatever was caused to the water conduit from that cause. It was feared that if any accident should occur with the conduit full of water, (under pressure), a very large area of that part of the city would be flooded, but happily such accident was entirely avoided.

The rock extended from station 0+00 to station 16+80, the maximum depth of rock excavated being 13.7 feet, the average depth 5½ feet, and the total quantity 3,954 cubic yards.

Before designing the cross-section, test pits and borings were made along the route of the sewer, so that the profile of rock above grade and the character of the soil were fairly well known in advance. In view of the proximity of the aqueduct and certain areas of a swampy nature, care was taken to provide a fairly substantial invert, and clauses were embodied in the specifications in case special foundations of crushed stone, plank flooring, class C concrete, or

Figure No. 7.—View of Bracing under Canadian National Railway Tracks.

Figure No. 9.—Interior of Sewer, Station 3 + 78, Looking Westwards, showing 120 ft. of Blaw Knox Steel Forms.

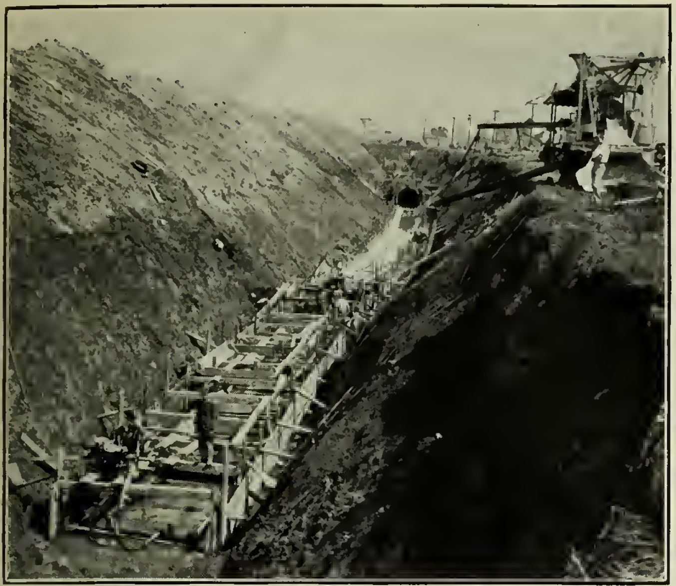

Figure No. 10.—General View of Works from Station 15 + 00, Looking Westwards.

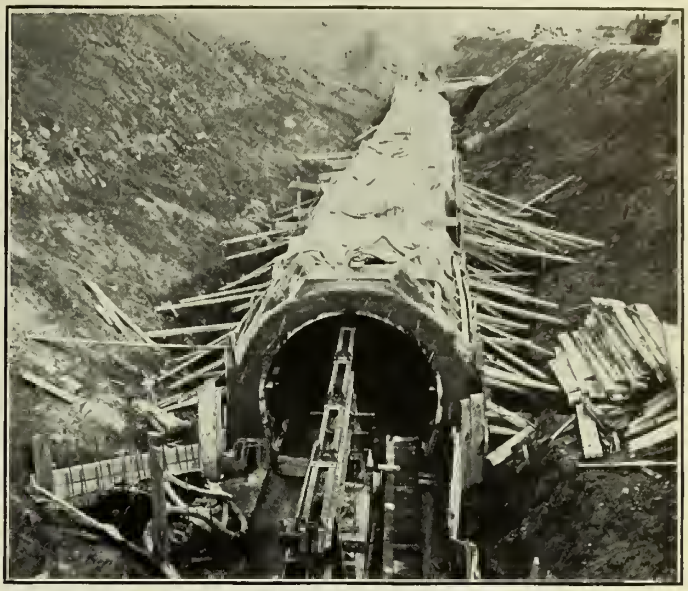

Figure No. 12.—View of End of 9′ × 9′ Sewer (Station 70 + 77.5) and Invert of Junction Chamber.

piles might be required. During actual construction no piles or class C concrete were required under the invert.

SPECIAL FOUNDATIONS

Special foundations were required from stations 33+50 to 33+77 and stations 39+08 to 39+50, representing a total length of 69 feet. These foundations consisted of eight rows of 2-inch planks about 2 feet apart, parallel to the axis of the sewer driven to a depth of from 5 to 6 feet below the sub-grade and covered with a layer of broken stone 9 to 12 inches thick. In other sections where the bottom of the trench was not firm and dry the sewer was built on a layer of broken stone and a 2-inch plank flooring with a layer of broken stone on top. For this purpose the quantity of wood used was 18,834 f.b.m. and the broken stone 522½ cubic yards.

The surveys, studies and plans for this trunk sewer were all worked out by engineers in the Technical Service of the city, under the general direction of the Montreal Sewers Commission, the personnel of which is as follows:—

Chairman:—The chairman of the Executive Committee of the city of Montreal.

Members:—H. A. Terreault, M.E.I.C., director of public works of the city; W. S. Lea, M.E.I.C., consulting engineer; T. J. Lafrenière, M.E.I.C., chief sanitary engineer, Provincial Bureau of Health.

Member and secretary:—Geo. R. MacLeod, M.E.I.C., engineer in charge of Technical Service.

It will be noted that the commission includes the chief executive officer of the city, the head of the Public Works Department, and the head of the engineering department, thus giving close intercourse between the commission and the engineering staffs in charge of design and construction, while the two consultant members are available at any time, and actually did come in for direct consultation on many special problems connected with the designs and during construction.

The inspection and testing of the materials, (cement, sand, stone, reinforcing steel, etc.), was performed by J. T. Donald and Company.

The construction contract was executed by the Atlas Construction Company, Limited. Work commenced on December 15th, 1926, and was completed in December 1927, while the official inspection and provisional acceptance took place on December 22nd, 1927.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI NOVEMBER 1928 No. 11

Annual General and General Professional Meeting

Hamilton, Ont., February 13th, 14th and 15th, 1929.

List of Nominees for Officers

EXTRACT FROM BY-LAWS

Section 68—Not later than the seventh day of November, the Secretary shall mail to each corporate member of The Institute the list of nominees for officers, as prepared by the Nominating Committee and the Council.

Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot. The words "Special Nomination" shall be printed conspicuously near such names, and the names of the members making such nominations shall be printed on some part of the officers' ballot.

Section 74—Notices shall be deemed to have been mailed to members as prescribed by the By-laws if such notices are printed in the Journal of The Institute and mailed by the dates prescribed in the By-laws.

NOMINATIONS

The report of the Nominating Committee was presented to and approved by Council at the meeting held on October fifteenth, nineteen hundred and twenty-eight. The following is a list of the nominees as prepared by the Nominating Committee and now published for the information of all corporate members, as provided by Sections 68 and 74 of the By-laws:—

The Second Plenary Meeting of Council

The second Plenary Meeting of the Council of The Institute was held on Monday, Tuesday and Wednesday, October 15th, 16th and 17th, 1928, the following members being present:—

President Julian C. Smith, M.E.I.C., in the chair; Past-President A. R. Decary, M.E.I.C.; Vice-Presidents J. H. Hunter, M.E.I.C., W. G. Mitchell, M.E.I.C., and S. G. Porter, M.E.I.C.; Councillors W. C. Adams, M.E.I.C., M. B. Atkinson, M.E.I.C., A. J. M. Bowman, A.M.E.I.C., W. E. Clarke, M.E.I.C., E. Davis, M.E.I.C., H. W. L. Doane, M.E.I.C., R. L. Dobbin, M.E.I.C., R. J. Gibb, M.E.I.C., B. GrandMont, A.M.E.I.C., P. J. Jennings, M.E.I.C., Fraser S. Keith, M.E.I.C., O. O. Lefebvre, M.E.I.C., T. R. Loudon, M.E.I.C., H. R. MacKenzie, A.M.E.I.C., N. F. McCaghey, A.M.E.I.C., C. M. McKergow, M.E.I.C., W. F. McLaren, M.E.I.C., W. P. Near, M.E.I.C., W. H. Powell, M.E.I.C., P. L. Pratley, M.E.I.C., L. T. Rutledge, M.E.I.C., J. Stephens, M.E.I.C., J. G. R. Wainwright, A.M.E.I.C., F. L. West, M.E.I.C., and Treasurer F. P. Shearwood, M.E.I.C.

Letters of regret were read from Past-President George A. Walkem, M.E.I.C., Vice-President F. O. Condon, M.E.I.C., and Councillor J. L. Busfield, M.E.I.C.

Monday, October 15th

Morning Session

The president took the chair at the morning session of October 15th, and welcomed the visiting councillors, after which the report of the Nominating Committee for 1928, containing the list of nominees for officers for the year 1929, was presented and approved for communication to the membership. This list accordingly appears on page 566 of this issue of The Journal.

The design for the Sir John Kennedy Medal, which was approved at the last meeting of Council, was submitted for the information of councillors present, and the quality and weight of the medal were decided upon.

The attention of Council was drawn to the forthcoming World Engineering Congress to be held in Tokyo, Japan, in October 1929. The secretary reported that The Institute had been requested to send delegates, and also to contribute papers. The secretary was directed to obtain further information regarding this event and bring the matter up for consideration at a later meeting of Council.

The financial statement to September 30th, 1928, was submitted and approved, and the recommendations of the Finance Committee with regard to special cases, resignations, and Students in arrears were accepted.

The following elections and transfers were effected:—

Elections		Transfers	
Members	4	Associate Member to Member	2
Associate Members	4	Junior to Associate Member	2
Juniors	1	Student to Associate Member	4
		Student to Junior	7

F. P. Shearwood, M.E.I.C., the chairman of the Committee on Grades of Membership, presented a report of that committee's work, from which it appeared that the matter of the grades of membership would require further consideration, the opinion of the committee being strongly divided as to the policy which it is desirable for The Institute to adopt. Two main questions had been considered by the committee, the first being whether the scope of The Institute's membership should be widened so as to admit in some capacity men who cannot be considered fully and broadly educated engineers, but whose experience in engineering work or allied occupations has given them technical knowledge which could contribute materially to the principal object of The Institute, the dissemination of professional knowledge. Among these men would be included, for example, engineers holding responsible positions requiring exceptional engineering experience, but whose work is of a technical rather than a scientific nature.

The second point before the committee, dealt with the desirability of making any changes in the nomenclature and arrangement and qualifications of the present grades of membership.

From Mr. Shearwood's report it appeared that the committee had been unable to arrive at any definite recommendations, on account of fundamental differences in the points of view of the various members.

During the discussion which followed several members expressed the hope that in any changes that might be recommended there would be no tendency to lower the educational standard for admission to The Institute, and a suggestion was made that the Council's power of waiving the requirement for examination, as set forth in the concluding sentence of Section 8 of the By-laws, should perhaps be taken away or limited.

Further discussion on this report was held over until a later point in the meeting.

Afternoon Session

During the afternoon session the chair was taken by Vice-President S. G. Porter, M.E.I.C., and nearly the whole period was taken up with the consideration of a number of applications for admission and transfer, from which the members of Council present were able to judge of the difficulties which are experienced in classifying applicants whose training has not been exactly that contemplated in the By-laws. A number of special cases were also discussed. Eight Students were admitted.

Following this, the report of the Library and House Committee was presented, and in connection with this report it was decided to approve the expenditure necessary to change the swing of the various doors in the Headquarters building from inwards to outwards, so as to comply with the city building By-laws, and certain other necessary repairs were authorized.

Tuesday, October 16th

Morning Session

On the morning of Tuesday, October 16th, a set of rules governing the award of the Plummer Medal were submitted and approved, these rules being generally similar to those in force for the Leonard Medal. They are printed on page 571 of this issue of The Journal.

The newly elected officers of the Edmonton Branch were noted and approved.

Vice-President S. G. Porter, M.E.I.C., presented the report of his Committee on the Relations of The Institute with the various Provincial Professional Associations, and stated that this committee had considered the following questions:—

(1) Considering the welfare of the profession in its broadest sense, what relationship should exist between The Engineering Institute of Canada and the various provincial associations?

(2) What obstacles are there in the way of attaining the desired end?

(3) What procedure do you suggest for overcoming them?

While the committee was not yet in a position to make a definite recommendation, it appeared that a considerable number of its members believed that the ultimate integration of all provincial organizations or their amalgamation into one body was attainable, but the committee had not been able to define the action which in its opinion The Engineering Institute should take in this movement.

Mr. Porter suggested that the committee be continued, and asked to present at the next Plenary Meeting of Council as definite a recommendation as it is possible to make on the whole subject; this report to be made after informal discussion with the various provincial associations. He reminded the members of Council present that The Institute had taken a leading part in connection with the original organization of the various provincial associations, a model act having in fact been drawn up in 1919 by a committee of The Institute. He felt that a certain amount of responsibility remained with The Institute to assist and to aid in harmonizing the efforts of the provincial associations for the best interests of the profession as a whole. He pointed out that where there are two or more distinct organizations functioning entirely on their own accounts without any interchange of views, there is always a tendency to diverge gradually in their procedure, which is what appeared to be happening three or four years ago when The Institute offered its facilities and a conference of representatives of the various associations was held with the view of discussing these divergences and securing more uniform practice.

He stated that this matter had recently been discussed very fully in Alberta, both at meetings of the Alberta Association of Professional Engineers and at Branch meetings of The Institute. He further presented a resolution passed at the last annual meeting of that Association appointing a committee to study the problems involved in coördinating the activities of the various engineering organizations in Canada, and to work in conjunction with similar committees from other organizations, looking forward to the ultimate integration of all these bodies into one national organization.

He believed that sooner or later there would necessarily be some Dominion-wide organization of these provincial bodies, and thought that if The Institute did not suggest some means of providing for this amalgamation, the associations themselves would eventually have to do so.

During discussion, which was participated in by councillors from the Maritime provinces and British Columbia, it was noted that this topic was receiving careful consideration from the Councils of a number of the professional associations, and that in some places it had been suggested that the provincial associations might possibly function as provincial divisions of The Institute.

Past-President A. R. Decary, M.E.I.C., pointed out that the legal functions of the professional associations must be exercised by bodies deriving their authority from the several provincial governments, (this following from the provisions of the British North America Act), and in discussing any scheme of closer relationship between The Institute and any of the associations this feature must always be borne in mind.

At the unanimous request of Council, Mr. Porter accepted the chairmanship of this committee for the coming year, and the committee was accordingly continued with the same personnel as last year.

Professor T. R. Loudon, M.E.I.C., presented a report of the work of the Service Bureau Committee which had been appointed in March 1927 as a result of a discussion as to ways and means of stimulating interest among the members of The Institute. A progress report had been presented at the last Plenary Meeting of Council, at which time the recommendations of the Committee had been approved. These recommendations included the further development of the Employment Service, and the publication of a weekly bulletin to aid in this work. The E-I-C News had accordingly been started, its primary purpose being to serve the members in the matter of employment and bring The Institute membership in touch with employers. Prof. Loudon stated that although he could not yet present a definite report on the results obtained, the progressive increase in the enquiries from both those seeking positions and those seeking men have been most encouraging.

He pointed out that to carry on successfully the work of The Institute's Employment Service Bureau, the active and whole-hearted support of the members of The Institute was a necessity, and he felt that every member of Council present should use every opportunity to impress upon the members in his own particular Branch of The Institute the fact that The Institute is endeavouring to be of real service to its members, particularly in bringing the Employment Service to the notice of employers.

In connection with the E-I-C News similar assistance was essential to the success of the publication. This coöperation should take the form of supplying interesting news items or information regarding works in progress in various localities; of bringing the publication to the attention of the proper officials of industrial and other organizations who employ technically trained men, and of aiding to secure official notices of calls for tenders from the provincial and municipal governments for publication in the News.

To this end it was thought that each Branch might have a small Service Committee to advance the interests of this part of The Institute's work.

The report was received and the committee was continued with the same personnel.

The next subject dealt with was the report of the Legislation and By-laws Committee, the chairman, O. O. Lefebvre, M.E.I.C., presenting certain recommendations regarding amendments to the By-laws to be proposed by Council concerning the compounding of fees, Students' subscriptions to The Journal, and the schedule of fees.

It was decided to take no action at the present time regarding the compounding of fees, and discussion followed on the question whether the present obligation of Students to subscribe to The Journal should be continued. It was pointed out that in many cases this requirement militated strongly against the formation of Students' Sections, and in fact tended to deter Students from joining The Institute, and after considerable discussion it was decided to propose an amendment to Section 73 of the By-laws providing that the subscription to The Journal be optional to all Students.

Afternoon Session

At the afternoon session the recommendations of the Legislation and By-laws Committee regarding the suggested increase in members' annual fees were considered, and it was noted that the proposal decided upon at the plenary meeting of Council in 1927 for an increase applying to the fees of Members, but not to other grades, had been withdrawn, since it had become apparent that the limitation of the increase to one grade of membership did not meet with the approval of the membership at large.

After considerable discussion it was decided to propose an amendment to Section 34 of the By-laws for the consideration of the next annual meeting providing for an increase in fees of $3.00 for Members, $2.00 for Associate Members, and $1.00 for Juniors; this, if it becomes effective, would result in an increase in the revenue of The Institute which would enable its increased activities to be adequately financed.

In connection with the work of the Papers Committee a letter was read from the Chairman, J. L. Busfield, M.E.I.C., in which he suggested that the work of his committee in arranging for speakers for outlying Branches would be much facilitated if the smaller Branches would get together themselves, arrange a tentative series of dates, and then call upon Headquarters for assistance in making the final arrangements. The opinion was generally expressed that more work could be accomplished by this committee if the Branches would take the initiative, and it was decided to ask all councillors present to bring this matter strongly before the executive committees of their Branches.

The next item of business concerned the report of the Committee on Method of Admission of Members, this committee having been appointed by Council in July last to study the desirability of changing the present method of dealing with applications for admission and transfer. The report recommended certain modifications in Sections 27 and 28 of the By-laws, and outlined a method of procedure in which all members of Council would have the opportunity of submitting a written opinion on the eligibility of a candidate before his admission or transfer is definitely voted upon by Council.

The report also recommended the abandonment of the present method of councillors voting by letter ballot, and

Second Plenary Meeting of Council, Montreal, Oct. 15-17th, 1928.

24. W. F. McLaren, M.E.I.C., (Hamilton Br.).
25. W. C. Adams, M.E.I.C., (Montreal Br.).
26. W. H. Powell, M.E.I.C., (Vancouver Br.).
27. R. L. Dobbin, M.E.I.C., (Peterborough Br.).
28. J. G. R. Wainwright, A.M.E.I.C., (Toronto Br.).
29. W. E. Clarke, M.E.I.C., (Cape Breton Br.).
30. F. P. Shearwood, M.E.I.C., Treasurer.

proposed that five negative votes should be required to exclude from membership.

O. O. Lefebvre, M.E.I.C., pointed out that the objects of the committee were to find a more satisfactory method than the present one of dealing with applications for admission or transfer, and also, if possible, to devise a means of reducing the time spent by Council in dealing with applications. It was pointed out that the procedure suggested by the committee required every councillor to give consideration to each application before it came before the Council meeting, and general approval was expressed of this feature.

After considerable discussion it was resolved to accept the report of the committee, that Council was generally in accord with the proposed change in the method of election, and that the report be referred to the Legislation and By-laws Committee for further consideration of the details of the proposed procedure, and the effects of the proposed changes in connection with other suggested amendments.

In regard to the report of Mr. Shearwood's Committee on Grades of Membership, Mr. Lefebvre suggested the desirability of modifying the concluding sentence of Section 8 of the By-laws, with the view of simplifying procedure and saving the time of Council in dealing with applications. He proposed that the last sentence of the second paragraph of Section 8 of the By-laws should be amended to read, "Any or all of these examinations may be waived at the discretion of Council if the candidate is forty-five years of age or over, and has held a position of professional responsibility for ten or more years."

It was pointed out that this amendment, without taking away the power of Council to waive the examination requirement, would limit this power, and would considerably reduce the number of debatable cases to be considered by Council.

After considerable discussion as to the desirability or otherwise of requiring all candidates who have not had university training to pass an examination, Mr. Lefebvre's suggestion was approved, and it was decided to propose an amendment to Section 8 at the annual meeting in accordance with this recommendation.

The attention of Council was drawn to the fact that the first award of the Past-Presidents' Prize for a paper on the subject of Engineering Education would take place next year, for essays to be submitted during the prize year from June 1928 to June 1929. In view of the importance of this subject, members of Council present were asked to bring this matter to the attention of members of their Branches in order that a number of papers worthy of the importance of the subject might be secured for the competition.

The secretary reported that the Board of Examiners and Education had a revised examination syllabus in course of preparation, which would shortly be printed and issued, and which called for more uniform requirements in the different branches of engineering, resulting in a simpler and more logical examination system. This document, in draft form, had been communicated to the Examining Boards of the various provincial associations with a request for their criticism and comment.

With regard to Section 3 of the By-laws defining the classes of membership in The Institute, it was pointed out that on several occasions different Branches of The Institute had suggested changes in the present grades of membership, and that this question had been discussed by Mr. Shearwood's committee. In view of the fact, however, that this committee had presented no definite recommendation, it was decided that no action should be taken at the present time, but that the matter should be fully discussed during the coming year and taken up again at the next plenary meeting of Council.

Letters were read from the Moncton and Lethbridge Branches indicating that there is some dissatisfaction on the part of the smaller Branches at the present scale of rebates, and the feeling of the meeting was that some increase should be made in the rebates to the smaller Branches, but it was decided that no action should be taken until after the annual meeting and until some decision had been reached as to the increase of fees.

Consideration was given to the desirability of Council paying the expenses of delegates from the various Branches to each annual or regional meeting, as is done by certain of the American Engineering Societies, but in view of the financial position of The Institute at the present time it was decided that no action should be taken. It was suggested that the matter might be referred to the various Branches with a request for an expression of opinion.

A tentative programme of the Annual Meeting Committee of the Hamilton Branch was submitted and approved, and it was noted that the dates had been changed to February 13th, 14th and 15th, 1929.

The question of holding other professional meetings during 1929 was discussed, but as no requests had yet been received from any of the Branches, it was decided that each councillor should take the matter up with his Branch Executive Committee, and forward any suggestions to Council for consideration at an early meeting.

Wednesday, October 17th

At the morning session of Wednesday, October 17th, the president in the chair, M. B. Atkinson, M.E.I.C., presented a memorandum to Council expressing the opinion that The Journal in its present form did not meet the requirements of the members, in that it was too large to be conveniently filed away; he considered that it should either be reduced to 6 by 9, or continued in its present form and transactions issued in addition without charge to members, containing the most important papers presented to The Institute.

The secretary stated that if the size of The Journal were reduced as suggested, very serious difficulty would be experienced in connection with advertising, upon which The Journal depends for its main revenue. At the present time industrial advertising is so standardized as to make it almost impossible to sell advertising for any magazine of a size differing materially from 9 by 12.

With regard to transactions, the Secretary drew attention to the fact that when the last volume of transactions was issued, as a result of some demand, only approximately three hundred copies, at a cost of $3.00 each, were disposed of out of one thousand printed.

After further discussion, it was resolved that the officers of The Institute should give this matter study, and present it for further discussion at a later meeting.

The secretary presented a communication from A. D. Swan, M.E.I.C., requesting an opinion as to the liability of engineers in the province of Quebec during the period of five years after the completion of a piece of work, as the revised statutes of the province do not specifically mention engineers, although they do mention architects and contractors.

It was pointed out that the courts in the province of Quebec have in the past held engineers responsible in the same way as contractors and architects, but that this matter, having to do with legal responsibility, was one which should really be dealt with by the Corporation of Professional Engineers of Quebec, and it was accordingly referred to that body, with a request for an opinion on the subject.

At the request of the Canadian Construction Association a joint conference between representatives of the Royal Architectural Institute of Canada, The Engineering Institute of Canada, and the Canadian Construction Association, was approved, for the purpose of discussing the Canadian

Construction Association's proposed Standard Forms for Contracts.

A request having been received from the Ecole Centrale des Arts and Manufactures for a representative of The Institute at their Centenary Celebrations in Paris in 1929, the Secretary was directed to arrange, if possible, for The Institute to be represented on this occasion.

The secretary presented a table showing the numerical changes which had taken place in the membership list during the past six years, through admissions, removals, transfers, etc., which showed that at the present time the membership is increasing somewhat slowly. The opinion was expressed that this condition was to be expected in view of the fact that many engineers found that they could not belong to two societies, and as it was compulsory for them to belong to a Provincial Association, refrained from joining The Institute. The president felt that this only emphasized the desirability of working out some friendly arrangement with the Provincial Associations.

The president stated that he felt that the work of The Institute as a whole, and the work and activities of the Branches and their members, should receive all the publicity possible, and asked for a discussion as to possible ways and means of accomplishing this.

M. B. Atkinson, M.E.I.C., pointed out that the engineer is naturally a reticent person, and thought that some endeavour should be made by The Institute to promote publicity in connection with the large number of important engineering works being carried on throughout the Dominion, and about which very little is now being said in the non-technical press, arranging that full credit should be given to the engineer, who is so largely responsible for the prosperous condition of Canada today.

Vice-President S. G. Porter, M.E.I.C., stressed the fact that not only could publicity be secured through the press, but by engineers taking an active part in public affairs, serving on public committees, city councils, and on legislative committees, and in that way giving advice and pointing out to the various bodies that govern communities and provinces the necessity for securing proper engineering advice.

The president agreed that good work was being accomplished by the Branches, but felt that a small committee at Headquarters, of possibly three members, could aid in coordinating the efforts of the Branches, although in no way taking away from them their initiative in connection with local publicity.

After some further discussion it was resolved that a Publicity Committee of three be appointed by the president, more particularly for the purpose of aiding and coordinating the work of the various Branches as regards publicity. The committee was accordingly appointed, consisting of Fraser S. Keith, M.E.I.C., chairman, W. G. Mitchell, M.E.I.C., and W. C. Adams, M.E.I.C.

There being no further business, a hearty vote of thanks was unanimously accorded to the president, in acknowledgment of his services as presiding officer, which had done so much to ensure the success of the second Plenary Meeting of Council.

Rules Governing the Award of the Plummer Medal

The following rules governing the award of the Plummer Medal were adopted by Council at the Plenary Meeting on October 16th, 1928:—

A gold medal, to be called "The Plummer Medal," shall be struck each year and paid for from the annual proceeds of the fund provided for that purpose by Mr. J. H. Plummer, D.C.L., which medal shall be awarded according to the following rules for papers on chemical and metallurgical subjects presented to The Institute.

1. Competition for the medal shall be open to those who belong to The Engineering Institute of Canada, and to non-members if their papers have been contributed to The Institute and presented at an Institute or Branch meeting.
2. Award shall be made not oftener than once a year, and the medal year shall be the year ended June last previous to the year in which the award is made.
3. The medal shall be presented at annual meetings of The Engineering Institute of Canada.
4. A committee of five shall judge the papers entered for competition, all of whom shall be members of The Engineering Institute of Canada, and shall be appointed by the Council of The Institute.
5. All papers presented shall be the work of the author or authors and must not have previously been made public, except as part of the literature of The Engineering Institute of Canada.
6. Should the committee not consider the papers presented in any one year of sufficient merit, no award shall be made, but in the following year, or years, the committee shall have the power to award the accumulated medals or to award a second prize in the nature of a silver medal, or a third prize of books to be selected by the committee.
7. The medal shall be suitably engraved, containing the name of The Engineering Institute of Canada, and the words, "The Plummer Medal," together with the adopted design, and on the reverse side the name of the recipient, the date and any other inscription that may be decided upon by the committee.

OBITUARIES

Robert Fowler, M.E.I.C.

Members of The Institute will learn with regret of the death of Robert Fowler, M.E.I.C., which occurred at Victoria, B.C., on September 19th, 1928. Mr. Fowler was born in Cobourg, Ont., on September 30th, 1857, and began his professional career on the Temiscouata Railway construction. Later he was transferred to the Canadian Pacific Railway line construction along lake Superior and between Fort William and Winnipeg under both the government and the Canadian Pacific Railway Company. Upon completion of that work he returned to Ontario and was engaged upon construction of Canadian Pacific Railway lines in that province and subsequently in Manitoba and Saskatchewan.

In 1905 Mr. Fowler moved to Victoria, B.C., and in 1907 he became engineer for Oak Bay, and under his direction the public works of the municipality were largely constructed. He retired from active practice in 1927 on account of ill health but was retained by the municipality as consulting engineer.

Mr. Fowler joined The Institute as an Associate Member at the time of its inception in 1887, and transferred to the class of Member in 1912. He was always keenly interested in the affairs of The Institute and was a staunch supporter of the Victoria Branch. He was also a member of the Association of Professional Engineers of British Columbia, having joined at the time of its establishment.

Alexander Pringle, M.E.I.C.

In the death of Alexander Pringle, M.E.I.C., which occurred at the Medical Arts Hospital, Montreal, on October 5th, 1928, there has passed a member of The Institute who for years was prominent in engineering circles in eastern Canada, and one whose membership in The Institute dates from the day of the Canadian Society of Civil Engineers, to which he was elected Member in 1899.

Born in Montreal on July 9th, 1864, Mr. Pringle received his education at Bishop's College, Lennoxville, Que., and in 1892 joined his father, the late Thomas Pringle, forming a partnership known as T. Pringle and Son. About this time they collaborated with the late Mr. W. McLea Walbank in connection with the development of power known as the Lachine Rapids Hydraulic and Land Company's plant, near Montreal, which passed into the control of the Montreal Light, Heat and Power Company in 1903.

In 1898, Mr. Thomas Pringle retired from the business, and from that time the firm was continued as T. Pringle and Son, and managed by Alexander Pringle alone. Among other works, Mr. Pringle carried out the surveys and original development of the Shawinigan Water and Power Company's plant at Shawinigan Falls, Que.; the plant for the Canadian Electric Light Company at Chaudiere Falls, Que., and a water power development near Mille Roches on the Cornwall canal; mills for the Montmorency Cotton Mills at Montmorency Falls, Que., and various buildings for the Dominion Cotton Company. In 1907, the company was incorporated and known as T. Pringle and Son, Limited, Mr. Pringle being elected president, which office he held until the time of his death. Some years ago he was vice-president of the Wayagamack Pulp and Paper Company, Ltd., and a director of the Wabasso Cottons Company, Ltd.

Mr. Pringle resided at Chateauguay Basin, Que. He was a member of the Engineers' Club, the Kanawaki Golf Club, the Montreal Amateur Athletic Association, and was a governor of the Montreal General Hospital.

Kenneth Grahame Polyblank, M.E.I.C.

It is with regret that we record the death of Kenneth Grahame Polyblank, M.E.I.C., which took place at Rouyn, Que., on October 17th, 1927. Mr. Polyblank, who at the time of his decease was assistant chief engineer of the National Transcontinental Railway Branch Lines Company at Taschereau, Que., was born at Bristol, England, on August 17th, 1884. Mr. Polyblank was connected with the Canadian Northern Railway and later with the Canadian National Railways from 1911 to 1924, at which time he became assistant chief engineer of the Rouyn Mines Railway. He was overseas from 1915 to 1919, seeing service with the infantry and with the Canadian Engineers. Mr. Polyblank joined The Institute as an Associate Member in 1923, and transferred to the class of Member in 1926.

PERSONALS

L. McGillis, S.E.I.C., formerly of the staff of the Tramway Light and Power Company, Rio de Janeiro, Brazil, is now connected with the North Shore Power Company at Three Rivers, Que.

V. R. Currie, Jr.E.I.C., is at present assistant engineer on the Trent canal at Peterborough, Ont. Mr. Currie, who is a graduate of Queen's University of the year 1923, was formerly on the staff of the Abitibi Fibre Company, Ltd., at Smooth Rock Falls, Ont.

R. F. Howard, M.E.I.C., manager of power sales, Gatineau Power Company, attended the opening ceremony of the new Toronto-Leaside 220 kv. terminal on October 1st, as the official representative of the Gatineau Power Company.

I. S. Patterson, S.E.I.C., has joined the students' course at the plant of the Canadian General Electric Company at Peterborough, Ont. Mr. Patterson graduated from the Nova Scotia Technical College this year with the degree of B.Sc.

Darrel D. Steeves, Jr.E.I.C., who was formerly chief estimator with Messrs. Martin and Krausman, general contractors, Detroit, Mich., is now connected with Messrs. Gannett, Seelye and Fleming, Inc., public utility engineers, Harrisburg, Pa.

Edward M. Van Koughnet, S.E.I.C., is now connected with the Sao Paulo Tramway Light and Power Company, Limited, at Sao Paulo, Brazil. Mr. Van Koughnet, who was formerly employed by the Canadian and General Finance Company, Ltd., Toronto, as estimator on transmission lines design and cost, is a graduate of the Royal Military College of the year 1922.

G. F. O'Connor, A.M.E.I.C., who has been in private practice at Niagara Falls, Ont., is attending the graduate school at the University of Michigan, Ann Arbor, Mich., has been awarded a Roy D. Chapin Fellowship in highway engineering, and is taking a course of studies leading to a Master's Degree. Mr. O'Connor graduated from Queen's University with the degree of B.Sc. in 1921.

Dr. H. G. Acres, M.E.I.C., consulting engineer, Niagara Falls, Ont., Walter Blue, A.M.E.I.C., manager of development, Gatineau Power Company, and R. L. Hearn, M.E.I.C., chief engineer, H. G. Acres Company, were present on September 30th, at the inaugural and technical tests when power was first turned on at the Grand Falls, N.B., generating station of the International Power Company.

A. T. C. McMaster, M.E.I.C., is now with the McMaster-Jacob Engineering Company, Limited, consulting, designing and supervising and sales engineers, Toronto. Mr. McMaster, who is a graduate of the University of Toronto of the year 1903, was formerly senior power house engineer in connection with the Welland ship canal at St. Catharines, Ont.

D. C. Macpherson, S.E.I.C., of the staff of the Dominion Bridge Company, Ltd., has been transferred from Toronto, where he was employed on the Royal York hotel, to Halifax, where work is proceeding on the combined new terminal and Nova Scotia hotel for the Canadian National Railways. Mr. Macpherson graduated from Queen's University in 1924 with the degree of B.Sc.

J. Saint John, Jr.E.I.C., has undertaken the management of La Mouche Mine, Newfoundland. He was at one time efficiency engineer with the Nova Scotia Steel and Coal Company at West Wabana, Newfoundland, and has also been connected with the Newfoundland Power and Paper Company at Deer Lake, and the Buchans Mining Company, Buchans, Newfoundland.

C. H. McL. Burns, A.M.E.I.C., is now with the engineering department of the International Nickel Company at Copper Cliff, Ont. Mr. Burns was at one time chief engineer with the Maritime Coal, Railway and Power Company, following which he resided in Philadelphia, Pa., specializing on the mechanical equipment of mines and the preparation of coal. Prior to his present move, Mr. Burns was located at North Glenside, Pa.

G. Ernest Booker, A.M.E.I.C., has joined the engineering staff of the Power Corporation of Canada with headquarters in Montreal. Until recently Mr. Booker was on the staff of the Metabetchouan Sulphite and Power Company, Ltd., at Desbiens, Que. He was for a time with James Ruddick, M.E.I.C., consulting engineer, Quebec city. Mr. Booker was at one time in private practice in Halifax, and subsequently accepted a position as mechanical engineer with the British-American Nickel Corporation at Deschenes, Que.

H. E. Mott, A.M.E.I.C., has accepted the position of chief engineer with the Standard Radio Manufacturing Corporation, Limited, Toronto. Mr. Mott graduated from McGill University with the degree of B.Sc. in electrical engineering in 1922, and following graduation joined the staff of the Canadian Marconi Company as test engineer, subsequently occupying the positions of engineer of test room, superintendent of works, and works engineer until 1927, when he resigned in order to become connected with the DeForest Radio Corporation, Toronto, as chief engineer.

V. Pearson, A.M.E.I.C., formerly superintendent of power plants for the government of Alberta, Edmonton, Alta., has resigned to take charge of the Edmonton branch of Electrical Engineers Limited. From 1914 to 1917, Mr. Pearson was in charge of the electrification of the Canmore Coal Company property at Canmore, Alta., later becoming chief engineer of that company. In 1919 he became superintendent of public utilities for the town of Macleod, and remained in this position until 1923, when he entered the employ of the provincial government of Alberta.

Walter Griesbach, A.M.E.I.C., has recently been appointed chief engineer of the Foundation Company of Canada, Limited, Montreal. Following his graduation from Queen's University with the degree of B.Sc., in 1912, Mr. Griesbach became attached to the Department of Public Works of Canada, and while with the department he was assistant engineer and resident engineer on breakwater construction and in charge of surveys of various harbours and rivers. In 1918 he joined the staff of the Foundation Company of Canada, Limited, as office engineer, which position he has held to the present time.

Harry B. Dickens, A.M.E.I.C., is at present connected with Messrs. Lang and Ross, on transmission line survey in connection with the Flin Flon mine. Mr. Dickens, who was surveyor and assistant manager at the Amiri tin mine, Nigeria, West Africa, during 1913-1915, was on active service in the Cameroons and Nigeria, West Africa, from May 1915 to September 1919, for the greater part of 1917-1919, being in charge of the Mama and Mada patrols in Nigeria. After the war, Mr. Dickens was engaged on timber limit surveys in northern Ontario, later joining the engineering staff of the Underwriters' Survey Bureau, Toronto. In 1923 he was employed by Frank Barber and Associates, and in 1924 he was employed with the township of East York. Prior to accepting his present position, Mr. Dickens was on the staff of the Welland ship canal at Port Colborne, Ont.

Charles H. Jackson, Jr.E.I.C., formerly assistant superintendent on paper mill construction with Price Brothers and Company, Ltd., at Riverbend, Que., is at present connected with Messrs. Ross and McDonald, architects, on the construction of the new Dominion Square Building, Montreal. Mr. Jackson is a graduate of the University of Toronto of the year 1923 and has had varied experience, having been engaged in surveying mining claims in Rouyn, Que., clerk in charge of stores, materials, payroll, etc., on conduit construction with J. A. Mercier Company, Detroit, instrumentman and field engineer on paper mill construction with W. I. Bishop Company, Ltd., and Price Brothers and Company, Ltd., at Riverbend, Que., and assistant to resident engineer paper mill construction at Pine Falls, Man., with the Carter-Halls-Aldinger Company, of Winnipeg.

G. A. Browne, A.M.E.I.C., is now assistant general superintendent of the engineering division of the Department of Pensions and National Health, Ottawa. Prior to his present appointment Mr. Browne was assistant general superintendent of the engineering division of the Department of Soldiers' Civil Re-establishment at Ottawa. From November 1915 to March 1917 he was with the Canadian Engineers, Second Tunnelling Company, C.E.F., and served in France with the rank of lieutenant. On being discharged, Mr. Browne became resident superintendent, engineering branch of the Military Hospital Commission, following which he was made western district superintendent of the engineering branch of the Military Hospitals Commission-Invalided Soldiers' Commission, which was later changed to the Department of Soldiers' Civil Re-establishment.

F. M. Dawson, A.M.E.I.C., is at present professor of hydraulics at the University of Wisconsin, Madison, Wis. Professor Dawson, who graduated from the Nova Scotia Technical College in 1910, with the degree of B.Sc., and from Cornell University in 1913 with the degree of M.C.E., was formerly Dean of Men of the College of Engineering at the University of Kansas, Lawrence, Kansas, and prior to that was professor of hydraulics at the College of Civil Engineering, Cornell University. Professor Dawson was overseas with the C.E.F. from 1915 to 1919, being attached to the 40th Battalion in 1915 with the rank of lieutenant. He was transferred to the Canadian Engineers in 1916, mentioned in dispatches in 1918, and was awarded the Military Cross in 1919. He was promoted to captain in 1918, and was adjutant of the 8th Battalion for ten months, being discharged in April 1919. Following his return to this country he was a partner with the firm of Monks, Manhard and Dawson, engineers, agents and contractors, Montreal.

W. A. Spence, A.M.E.I.C., is now located at Fort Churchill, Man., with Dominion Explosives, Limited. After graduating from Queen's University in 1917, with the degree of B.Sc., Mr. Spence became a pilot in the Royal Air Force and served until 1919, following which he was an assistant on the survey of a portion of the interprovincial boundary between Manitoba and Saskatchewan for the Dominion government. In 1920 he was engaged on development work on mining properties in northern Manitoba, and in 1921 and 1922 he was in charge of reconnaissance, location and construction of roads and highways for the Colonial Government in British Honduras. On his return to Canada, Mr. Spence was in charge of plant maintenance and construction for the Whalen Pulp and Paper Company, Limited, at Port Alice, B.C., and was later in charge of surveys on investigation of the Bridge River power project and location of transmission line for the British Columbia Electric Railway Company. During 1926 he was engineer on construction of sidewalks, sewers, retaining walls, etc., for the municipality of South Vancouver, B.C., and later was engineer for the Thomsen and Clark Timber Company, Limited, in charge of logging, railway location and construction. Prior to accepting his present position, Mr. Spence was located at Jordan River, B.C.

Recent Additions to the Library

Proceedings, Transactions, etc.

Presented by the Societies:

The Mining Institute of Scotland: List of Members, 1928.
The Society of Naval Architects and Marine Engineers: Year Book, 1928.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 11th, 1928, it was reported that, in accordance with Council's instructions, a ballot had been opened on July 18th, 1928, and the following elections and transfers were accordingly effected:—

Member

SMALL, Herbert W., Jr., chief engr., Alcoa Power Company, Arvida, Que.

Associate Members

ARNOLD, Guy Walker, B.Sc., (Univ. of N.B.), i/c all elect'l design of d.c. motors, etc., Canadian Westinghouse Company, Hamilton, Ont.

LANGLOIS, Raoul, C.E., (Ecole Polytech.), asst. chief engr., Montreal Tramways Commission, Montreal, Que.

Juniors

HAYES, Roland Earle, B.Sc., (McGill Univ.), sales engr. & mgr., water works dept., General Supply Company of Canada, Ottawa, Ont.

MUMFORD, Patrick Foster, M.E., (Stanford Univ.), Canadian Westinghouse Company, Hamilton, Ont.

Affiliate

MURPHY, Maurice Edward, mech'l supt., Dominion Coal Company, Glace Bay, N.S.

Transferred from the class of Student to that of Associate Member

BUTTERWORTH, John Victor, B.Sc., (N.S. Tech. Coll.), topographical engr., Geological Survey of Canada, Ottawa, Ont.

Transferred from the class of Student to that of Junior

CARTEN, Francis Tracy, B.Sc., (Univ. of N.B.), with H. G. Acres Co., Grand Falls, N.B.

ELKINGTON, Gerald Erlam, B.Sc., (McGill Univ.), erecting engr., Canadian General Electric Co., Ltd., Toronto, Ont.

GAUVIN, Herve Alfred, B.Sc., (Univ. of Sask.), sec.-treas., and i/c design & estimates, Gauvin, Ltd., Ottawa, Ont.

Students Admitted

BRAKE, Erie Charles, B.Sc., (Queen's Univ.), Canadian General Electric Co., Ltd., Peterborough, Ont.

CLARK, James E., B.Sc., (Queen's Univ.), Canadian General Electric Co., Ltd., Peterborough, Ont.

CRUMP, Norris R., 971 Dominion street, Winnipeg, Man.

DODDRIDGE, Paul William, B.Sc., (Univ. of N.B.), Canadian General Electric Co., Ltd., Peterborough, Ont.

DUNCAN, John Daniel, B.A.Sc., (Univ. of B.C.), Canadian General Electric Co., Ltd., Peterborough, Ont.

FELLOWS, Geoffrey Meysey, Imperial Bank of Canada, St. James & McGill streets, Montreal, Que.

HAGGERT, Gordon J., B.A.Sc., (Univ. of Toronto), Canadian General Electric Co., Ltd., Peterborough, Ont.

HALL, Thomas Leonard, B.Sc., (Univ. of N.B.), Canadian General Electric Co., Ltd., Peterborough, Ont.

MORRISON, J. Alexander, B.A.Sc., (Univ. of Toronto), Canadian General Electric Co., Ltd., Peterborough, Ont.

MORRISON, Gilbert Rutter, P.O. Box 561, North Sydney, N.S.

MURRAY, Victor Stuart, B.Sc., (Queen's Univ.), 1139 Parent avenue, Windsor, Ont.

TAYLOR, John Joseph, B.Sc., (Univ. of Alta.), Canadian General Electric Co., Ltd., Peterborough, Ont.

At the meeting of Council held on October 15th, 1928, the following elections and transfers were effected:—

Members

FIEGEHEN, Edward George, mech'l dept., Dominion Bridge Company, Lachine, Que.

FLEMING, Alexander Greig, B.A., (Queen's Univ.), chief chemist, Canada Cement Company, Montreal, Que.

HAVILAND, Frank Leslie, Grand.S.P.S., (Univ. of Toronto), chief engr. & sales mgr., Standard Steel Construction Company, Welland, Ont.

RICKER, Herbert A., B.A.Sc., (Univ. of Toronto), mech'l engr. on a.c. generator design, Canadian Westinghouse Company, Hamilton, Ont.

Associate Members

COMETTE, Romeo, C.E., (Ecole Polytech.), engrg. office work, estimator, etc., Lake St. John Power & Paper Co., Montreal, Que.

FREGEAU, John Henry, B.Sc., (McGill Univ.), supt., North Shore Power Company, Three Rivers, Que.

LEGATE, Robert Moorhead de Comlay, B.Sc. (E.E.), M.Sc. (E.E.), (Univ. of N.B.), engrg. dept., Montreal Light, Heat & Power Cons., Montreal, Que.

MANSON, George James, S.P.S. 1904, M.E. 1913, (Univ. of Toronto), managing director, Manson's, Ltd., Hawkesbury, Ont., and president, Manson Chemical Co., Montclair, N.J.

Junior

McMAHON, John Leonard, B.Sc., (Univ. of Man.), dftsman., C.N.R., Winnipeg, Man.

Transferred from the class of Associate Member to that of Member

BLACK, William Duncan, B.A.Sc., (Univ. of Toronto), vice-president & managing director, Otis-Fensom Elevator Co., Ltd., Hamilton, Ont.

DAY, Joseph Charles, B.Sc., (McGill Univ.), designing engr., Lake St. John Power & Paper, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

COOPER, Paul Emerson, B.Sc. (C.E.), (McGill Univ.), res. engr. on constrn., at Kent Falls, N.Y., for International Paper Co.

NENNIGER, Emil, struct'l engr., (Technical School of Burgdorf), designing engr., office of Dr. Arthur Surveyer, M.E.I.C., Montreal, Que.

Transferred from the class of Student to that of Associate Member

ANTLIFF, James Cooper, B.Sc., (McGill Univ.), asst. to gen. supt., elect'l dept., Montreal Light, Heat & Power Cons., Montreal, Que.

BREHAUT, Harry Baker, B.Sc., (Univ. of Sask.), res. engr. on C.N.R. constrn., Edmonton, Alta.

RUTHERFORD, Andrew Scott, B.Sc., (McGill Univ.), supt. on new Dominion square block, Montreal, for George A. Fuller Co. of Canada, Ltd.

STEWART, William Lewis Reford, Grad., (R.M.C.), managing director, Stewart Construction Co., Ltd., Sherbrooke, Que.

Transferred from the class of Student to that of Junior

BENJAMIN, Abraham, B.Sc., (McGill Univ.), engr., Electrical Commission of Montreal, Montreal, Que.

HENDERSON, Ian Gordon, B.Sc., (McGill Univ.), field engr. & struct'l dftsman, Dominion Bridge Co., Montreal, Que.

HICKS, Ben Church, B.Sc. (E.E.), (McGill Univ.), relay mtce. & inspection, Shawinigan Water & Power Co., Montreal, Que.

McBRIDE, Ernest Willard, B.A.Sc., (Univ. of Toronto), i/c control dept., Abitibi Power & Paper Company, Iroquois Falls, Ont.

McCLURE, Lindley Wilberforce, B.Sc., (McGill Univ.), cable engrg. research, Northern Electric Co., Ltd., Montreal, Que.

THWAITES, Joseph Taylor, B.Sc., (Queen's Univ.), i/c service dept., Wentworth Radio & Auto Supply Co., Hamilton, Ont.

VERNOT, George E., B.Sc., (McGill Univ.), engrg. dept., Fraser Brace Company, Montreal, Que.

Students Admitted

BERGER, Bernard A., Undergrad., (McGill Univ.), 796 Champagneur avenue, Outremont, Que.

BERRY, Melville Douglas, Undergrad., (Univ. of Manitoba), 521 Newman street, Winnipeg, Man.

BROWN, Edward Daw, Undergrad., (N.S. Technical College), 72 South street, Halifax, N.S.

COOPER, Lawrence O'Toole, Undergrad., (McGill Univ.), 3483 Peel street, Montreal, Que.

TAGGART, E. McKay, Undergrad., (McGill Univ.), 825 University street, Montreal, Que.

MOFFATT, Harold Seymour, B.Sc., (Queen's Univ.), with Frank Barber & Associates, Ltd., Toronto, Ont.

SMITH, Gordon Carington, Grad., (R.M.C.), Undergrad., (McGill Univ.), 79 Grande Allee, Quebec, Que.

YEOMANS, Richard Henry, Undergrad., (McGill Univ.), 55 Wolseley Ave., Montreal West, Que.

BOOK REVIEWS

Mechanics for Engineers

By J. C. Smallwood and F. W. Kouwenhoven. D. Van Nostrand Company, New York, 1928, buckram, 6 x 10 in., 185 pp., tables, diagrs., $2.50.

This book, as the preface states, is the outcome of an attempt by the authors to write a brief text suitable for engineering students taking a course in mechanics limited to about 60 or 80 classroom hours. The principal reasons advanced for adding to the list of textbooks on mechanics are that applied mechanics is not an easy science to teach that the average ,student finds it difficult to learn and apply, and that the more comprehensive treatises are not easy to assimilate by those taking a course of limited duration. The authors claim nothing new except in the arrangement and selection of material, the choice of problems and in the emphasis laid on principles of special importance to engineering students. The book treats the conventional problems of statics and dynamics, and numerous well-chosen examples are worked out and set as problems in each chapter. It would be unfair to be too critical of a book which is evidently intended to be used concurrently with a short lecture course, as the explanation of an instructor would help out the text where basic principles are not set forth as fully as many teachers would consider to be desirable. The purpose of such a book places limitations on the treatment of the various topics, and restricts its usefulness in the case of students who may have to study the subject apart from a concurrent lecture course. In a brief chapter of four pages on units of measurement of force and mass, it is stated that "the absolute system is not used in English units, being confined to the metric system." In the preceding paragraph, the authors have defined a certain unit of force, viz., 1 ÷ 32.174 of a pound, which, they state, "has been given a definite name and subjected to use in scholastic circles. Since it has never been used in any commercial physical laboratory or in engineering literature or practice, its only function being to confuse the student of mechanics, it will not be named here. It is mentioned only in order to encourage other writers and teachers to join the present tendency to discard it." The poor "poundal",—for such is the name of this disreputable unit,—is evidently in the worst possible odour. The reviewer is sufficiently old-fashioned to believe that some of the difficulties in connection with the teaching of mechanics are in a measure due to this attitude towards the absolute system of units, which, he believes, may be made to serve other purposes than "to confuse the student." The book is clearly illustrated, and within well recognized limits can be made to serve its purpose in a short lecture course in mechanics.

E. Brown, M.E.I.C.,
Prof. Applied Mechanics & Hydraulics,
McGill University.

Fixation of Atmospheric Nitrogen

By Frank A. Ernst. D. Van Nostrand Company, New York, 1928, buckram, 6 x 9 in., 154 pp., figs., tables, $2.50.

For the past thirty years, chemical engineers have been actively developing methods of utilizing the stores of nitrogen in the atmosphere and converting the gas into compounds which can be used for the manufacture of explosives, fertilizers, photographic films, artificial leather and silk, and a multitude of other purposes. This book tells the story of their success.

It is no longer necessary to depend for our nitrogen supply on the sodium nitrate deposits of Chile, for of nearly one and a half million tons of nitrogen consumed in 1927, some 807,000 tons were obtained from the air by the three processes which are now commercially successful, while 341,000 tons were derived from coke-oven by-products and 298,000 tons from Chilian nitrate.

The demand for explosives during the war, particularly in Germany, gave a great impetus to the nitrogen industry, but the most important developments have taken place since 1918, indicating that the main source of fixed nitrogen will be the direct synthetic ammonia process, in which a compressed mixture of hydrogen and nitrogen is passed at high temperature over a catalytic agent. This process now supplies over 70 per cent of the total nitrogen fixed.

Direct combination of the nitrogen and oxygen of the air can be effected by the arc process, by passing air through a zone of high temperature in an electric furnace, thus forming nitric oxide, which is then absorbed in water and utilized as nitric acid. This was actually the first method to be employed commercially, but its high power consumption has militated against its wide development.

The third method, in which calcium carbide and pure nitrogen are made to react at a red heat, yields calcium cyanamide, and was first carried out commercially on this continent at Niagara Falls, Ontario, in 1909. It is still responsible for about 30 per cent of the world's production.

These processes, with their many developments, are well described in Mr. Ernst's book, which possesses the virtue, somewhat rare in a work dealing with so technical a subject, of being easy to follow even for a reader who knows but little chemistry. It can be recommended, not only as giving a readable and adequate treatment of the main chemical and engineering features of the industry, but also describing the conversion products and discussing the economic and historical aspects of the subject. Statistical appendices and an excellent bibliography add to its usefulness.

Chemical Encyclopædia

By C. T. Kingzett, F.I.C., F.C.S., Fourth Edition, D. Van Nostrand Company, New York, 1928, buckram, 6 x 9 in., 807 pp., tables, $10.00.

The object of this encyclopædia is to serve as a work of reference for use not only by professional chemists, chemical engineers, manufacturers, students, merchants and brokers, but also by other professional and business men in general. The subject matter comprises pure, physical and applied chemistry, a description of the elements and their chief compounds, brief accounts of ore and other natural products, and also the more important chemical terms and theories.

To compile a book of this type is an extremely difficult task and Mr. Kingzett is to be congratulated on the masterly manner in which he has gathered together such a vast number of facts appertaining to chemistry and its applications.

A careful examination of this book has served to show that there are few materials or subjects relating to chemistry, theoretically or industrially, for which some reference will not be found. It is particularly valuable in abounding in references for the convenience of those requiring further information than is contained in this encyclopædia. This book will be found particularly valuable by those coming in contact with chemistry, industrially or professionally, and possesses the great advantage of being written in simple, non-technical language, easily understood by those who are not chemically trained.

J. R. Donald, M.E.I.C.,
Managing Director, J. T. Donald and Co., Limited, Montreal.

Principles of Highway Engineering

By Carroll Carson Wiley, C.E., McGraw-Hill Book Company, New York, 1928, buckram, 6 x 9¼ in., 510 pp. tables, figs., illus., $4.00.

There is perhaps no branch of engineering in which the public is so directly interested as that dealing with the construction and maintenance of highways. The highway engineer finds himself in direct contact with the people of his locality, and occasionally has to display a degree of tact and diplomacy greater than that called for in almost any other line of engineering work.

The rural roads of the United States in 1926 had a total length of over 3,000,000 miles, of which about 500,000 miles had been surfaced. When we add to these the 500,000 miles of city streets, and imagine these traversed by 23,000.000 automobiles, some idea of the extent and importance of the field of the highway engineer may be gained.

The book under review, while designed primarily as a textbook on the subject, includes within its five hundred pages discussion on practically all the important topics connected with highway engineering, and will be found useful as a reference book by any engineer whose work touches on this subject matter. Materials, drainage, methods of construction, road surfaces, repairs and maintenance, surveys and location, finance, traffic and operation, are all treated, and while the practice described is, of course, that usual in the United States, Mr. Wiley's conclusions will be found largely applicable to Canadian work.

As might be expected in view of the special climatic and local conditions occurring in different parts of Canada, some of the followed methods in this country differ from those described in Mr. Wiley's book. For example, in concrete roads Canadian practice in many localities tends towards a wider pavement, a somewhat stronger section and a richer mix of concrete than those suggested by the author, while in asphaltic material a somewhat softer quality than that proposed by him is usual, thus permitting of a plasticity very desirable in a cold climate.

The book can be recommended, and its usefulness is increased by excellent illustrations and a good index.

BRANCH NEWS

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.

The London Branch has been following the policy of substituting motor trips to accessible points of interest in the place of regular meetings during the summer months. The trips have become a valuable part of the Branch activities, having stimulated the interest of friends of the members as well as proving instructive to the members of The Institute.

Summer Excursions

There have been three trips during the past summer, one to the gravel plants of the John E. Russell Company at Paris and Waterford, a second to the Welland ship canal and a third to the plant of the St. Mary's Cement Company.

On June 9th, a party from London and neighbouring towns gathered at Paris in the morning and inspected the gravel plant of the John E. Russell Company. Members were the guests of the company for lunch at Brantford and then drove to the plant at Waterford. Members of the company were generous with their time and information in conducting the group over the plants. About thirty-five men were present, including many who were not members of The Institute.

The main trip of the season was to the Welland ship canal. Cars left London on the morning of Saturday, July 21st, and arrived at Port Colborne in time for an inspection of the work there. After lunch the party was conducted along the canal by members of the canal staff, to whom the London Branch is very grateful for their kindness. Supper was provided at Port Dalhousie. To those who were able to attend, the trip provided new items of interest. The members of the London Branch have found that there is sufficient new construction work on the canal each year to warrant annual trips of inspection, and members of the staff have always been very kind in making the visit really worth while.

A shorter motor trip, coupled with a supper-meeting, was held on Saturday, September 29th, to the plant of the St. Mary's Cement Company. The afternoon was spent in an inspection of the plant, under the guidance of the plant superintendent and the chemist, Mr. G. Larsson. The two groups were conducted over the property, from the quarry to the bagging of the finished product, following the progress of the material through its various processes. Each process was carefully described at the plant and in an address by Mr. Larsson in the evening. To learn of the manufacture of cement under the generous hospitality of the St. Mary's Cement Company proved a treat to the members of the party.

London Branch plans for the near future include a trip through the Bell Telephone exchange, with an address by one of the local Bell Telephone officials, on October 24th, and an address by Deputy Minister of Highways R. M. Smith, A.M.E.I.C., on November 21st, 1928.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
W. McG. Gardner, A.M.E.I.C., Branch News Editor.

St. Paul Ward Main Sewer

The complexity of modern life in large cities and the important role which the engineer is playing in the improvement of public services was strikingly portrayed in an illustrated paper on "St. Paul Ward Main Sewer," presented before the Montreal Branch on October 11th by Geo. R. MacLeod, M.E.I.C.

The speaker, in opening his address, emphasized the absolute necessity in present municipal sewer design of clearly visualizing future developments within the respective drainage areas. In the present instance, the 1,135 acres drained by the trunk sewer under consideration would probably not be fully developed for some years, yet it was economical to provide a section of 9 to 10 feet diameter. This large sectional area followed as a consequence of the street elevations at the terminals being practically at a dead level. With the flow of the St. Lawrence controlling the height at the discharge and the ground topography setting the depth of the intake, the minimum allowable rate of grade, namely, 0.10 feet per 100 feet, was all the fall obtainable.

While a careful comparison of the semi-elliptical with the horseshoe design indicated the superiority of the former as regards strength per unit of weight, this advantage was offset by the required increase in the width of the cut for an equivalent capacity, a preponderant factor where a considerable depth of excavation is involved. Furthermore, the horseshoe section has a greater capacity for the same diameter in width.

An interesting feature of the construction was an indicated economy in the drag line, slope sides method of handling this large excavation.

As the size of the sewer in this case rendered periodic inspection in the usual manner hazardous, a special manhole of sufficient size was provided to permit the introduction of a small boat.

In the interesting discussion which followed, led by Major W. H. Wardwell, M.E.I.C., the speaker favoured a large and attentive audience with careful and explicit replies.

The complete paper is published in another part of this issue.

In introducing the speaker of the evening, the branch chairman, F. C. Laberge, M.E.I.C., welcomed the members to the opening of the fall session. On the conclusion of the address and following the expression of a hearty vote of thanks, moved with enthusiasm by Alderman Stewart F. Rutherford, A.M.E.I.C., the meeting adjourned for a friendly chat around the refreshment table.

Lapped Pipe Joints

The tremendous increase in the pressures and temperature employed in steam plants and oil refineries during the past ten years has been of necessity accompanied by the development of a safe and durable type of pipe joint. The interesting engineering evolution and the improved manufacturing process which have effected this reliability under severe operating conditions provided the subject for an admirable paper on "Lapped Pipe Joints" by Mr. A. M. Houser, engineer of products, Crane Company, Chicago.

In his inability to be present before the branch on October 18th, Mr. Houser entrusted the delivery of his well-illustrated paper to the capable offices of his confrère, Mr. J. O. Lange.

In the excellent discussion which followed, F. A. Combe, M.E.I.C., referred to the very few existing high pressure plants now operating in Canada, while E. A. Ryan, M.E.I.C., brought out the fact that little difference existed in the nature of test fractures produced in either lap welded pipe or seamless tubing.

In reply to questions, the speaker mentioned the strength requirements of the American Standards Association and the division of the bolting materials into three classifications. In closing, Mr. Lange, responding to L. Cowan, S.E.I.C., described a method of case hardening nuts by the cyanide process.

E. A. Ryan, M.E.I.C., closed the meeting by proposing a hearty vote of thanks. H. G. Thompson, A.M.E.I.C., sub-chairman of the Papers Committee, presided.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

The first fall outing of the season took place on the afternoon of September 27th, 1928.

For the last two years, the members of this branch have been promised the pleasure of visiting the modern filtration plant which supplies St. Catharines with water and which was constructed under the supervision of a past-chairman of the Branch, Alex. Milne, A.M.E.I.C.

Mr. Milne is very proud of his plant, and justly so, for it embodies the very latest improvements in mechanical equipment and the architectural treatment is rather better than usual for this type of structure.

This year, the Entertainment Committee, in response to various requests, decided to combine other features with the visit to the filtration works and thus make a full afternoon; in consequence, arrangements were made whereby the Scots could have a round of golf at the Lookout course and the technically-minded engineers could visit the Ontario Paper Mills, both of which are within a radius of three miles.

Some seventy-five members availed themselves of the privileges thus granted and enjoyed themselves thoroughly, twenty-four meeting at the Golf Club and the balance at the paper mill.

The output of this large mill, some 315 tons per day, goes exclusively to the making of only one newspaper, the Chicago Tribune.

The pulpwood is obtained mainly from the north shore of the St. Lawrence river, below Quebec city, and carried by steamer up the present Welland canal to the storage grounds. A sight that always impresses itself upon visitors to this district are the great mounds of stored pulpwood, some two hundred feet high and visible for several miles.

Both sulphite and ground pulp are made in this mill and mixed in the proportion of 15 per cent sulphite to 85 per cent ground pulp for the production of newsprint. One of the features which impressed itself upon the party was the adeptness with which the men broke the paper strip by means of a compressed air hose and started a new roll without stopping the machinery. The plant covers some seventy acres of ground and employs about six hundred and thirty men. The newsprint rolls each weigh about one thousand pounds and are shipped by train to Chicago.

An approximate analysis of one ton of this paper gives the following interesting figures:—

1.22 chords of wood
15 horse power
1,500 pounds coal
4 man-days.

About 4.30 p.m. the two groups, golfers and paper men, joined forces at the filtration plant. Alex. Milne, A.M.E.I.C., superintendent of water works, and G. F. Peterson, chairman of the Water Works Commission, met and accompanied the party.

The total capacity is ten million gallons per day, with five million storage reservoir and provision for a future duplication. It stands near the brink of the Niagara escarpment and draws water from lake Erie, via the Welland canal. After coagulation and filtration, the flow is by gravity down the escarpment and across the flat some three and one-half miles to the city of St. Catharines, with a head of about 180 feet, giving a city main pressure of about 70 pounds.

Three electrically-driven Crocker-Wheeler motors, directly connected to DeLaval pumps, give four, six and ten million gallons respectively for the low lift from the forebay to the coagulating basin. There is also an emergency generator set consisting of a 250-h.p., 8-cylinder Sterling gas engine connected to a 125-k.v.a. Lancashire generator. All valves are hydraulically operated under a constant pressure of 75 pounds maintained by a separate electrically-driven pump.

Each of the six double unit rapid sand filters is 14 by 28 feet and has a capacity of two million gallons.

Mr. Milne flushed out one of these units for the benefit of the visitors, and then invited the party to partake of the refreshments which the commission had very thoughtfully provided. As it was then nearly six o'clock, these were welcomed with enthusiasm and partaken of freely.

Chairman E. G. Cameron, A.M.E.I.C., then proposed a vote of thanks and mentioned incidentally that Mr. Milne and Mr. Peterson were too modest, particularly about the method of financing the whole project. He understood on good authority that the plant had been constructed with practically no added cost to the ratepayers or water users beyond the regular water rates. Due to great far-sightedness, a reserve fund for this work had been started quite a number of years ago. The total expenditures had been about $434,000, but, due to this reserve fund, only $275,000 worth of debentures had to be issued, and these were being retired in thirty equal annual instalments and were quite easily taken care of by means of the present rate, which is comparatively low, some $10.50 per annum for an eight-room house. S. R. Frost, M.E.I.C., and Roy Beatty, of Welland, also expressed their appreciation of the quality of the work.

On leaving the building, the visitors were shown an added feature, a visual proof that the plant was functioning properly. In the entrance hall, a well had been built over one corner of the clear water storage basin. The basin was floored with white tile at this point and lights placed so that on looking down through the plate glass cover and some 20 feet of water they could clearly distinguish the four five-cent pieces which had been dropped there.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary-Treasurer.

At a meeting of the Executive Committee of the Branch on September 6th, 1928, M. W. Cruthers, A.M.E.I.C., chairman, expressed regret that G. H. Burchill, JR.E.I.C., was leaving to accept a position as assistant professor of electrical engineering at Nova Scotia Technical College. It was moved and seconded that H. O. Fisk, M.E.I.C., be appointed to the executive, replacing Mr. Burchill. B. L. Barns, A.M.E.I.C., subsequently agreed to carry on Mr. Burchill's duty on the Meetings and Papers Committee.

Roller Bearings

The first meeting of the Peterborough Branch for the season was held on September 28th, 1928, the speaker being Mr. S. C. Partridge, district sales manager of the Timken Roller Bearing Company. Taking as his subject "The Alloy Steel Mill of the Timken Company," Mr. Partridge briefly sketched the equipment installed and the processes involved in the production of the steel used in roller bearings.

Electric furnace steel is used for the purpose, a 60-ton furnace requiring 10,000 k.w., and the largest in the world, being employed. Open-hearth furnaces of various capacities are also installed for other purposes to give the mill rolling capacity.

Two reels of moving pictures illustrated the address and well depicted the progress of the material from the stock pile, through the furnace, the soaking pits, the various rolling mills and saws until it emerged as bars or tubes of the necessary shape and size for the manufacture of the bearings. The production of seamless steel tubing for the raceways by the Mannesman process was especially interesting.

An active discussion followed the address, during which a large number of questions drew from the speaker much additional information on the actual manufacture and application of roller bearings. It was stated that the Chicago, Milwaukee and St. Paul Railway had 2,000 bearings in service and the Pennsylvania has 400

St. Catharines Water Works Filtration Plant.

cars so equipped. Several speakers gave instances of the reduction in losses by the use of anti-friction bearings on large machinery, such as the dryer sections of paper machines. On railway equipment, a saving of 7 or 8 to 1 on draw bar pull was obtained and 15 per cent when running.

While oil lubrication was recommended, the speaker stated that grease was permissible up to 2,000 r.p.m.

V. S. Foster. A.M.E.I.C., acted as chairman for this meeting. A cordial vote of thanks was moved by R. C. Flitton, A.M.E.I.C., and tendered to Mr. Partridge for his address.

ENGINEERING EDUCATION

In the absence of Chairman W. M. Cruthers, A.M.E.I.C., B. L. Barns, A.M.E.I.C., presided at the meeting held October 11th, 1928, and introduced Mr. R. E. Doherty, consulting engineer of the General Electric Company, Schenectady, N.Y., whose subject was entitled "The Effect of Present Engineering Education As It Is Reflected In the Young Men Who Come to the General Electric Company."

Through his experience in the A.C. Engineering Department, as a consulting engineer and co-worker with the late Dr. C. P. Steinmetz, and later by his connection with the General Electric Student Course, Mr. Doherty is well qualified to speak on this subject.

The opinions he expressed were based on careful observation and records of the 250 to 300 graduates from 120 colleges who annually join the company. While pointing out that the university courses in engineering had been gradually evolved to meet the needs of many industries, and could not suddenly be changed, he criticized mainly the large number of semester hours compared with other professional courses, the ratio being on the average about 150 to 125.

The result was that the student had no time for other interests and tended to become a bookworm. He was good at inductive reasoning and had a great knowledge of formulæ, but could not reason deductively and was lost when on the frontier of new things where no formulæ exist.

The speaker's remedies for this condition were a reduction in semester hours by cutting out some of the shop and laboratory work and greater emphasis on the fundamentals of physics, chemistry, etc., throughout the course. In view of the fact that only 30 per cent of students graduates, he thought there should be a "getting-off place" at two years for students unsuitable to the four years course and graduation. It was claimed that the present courses, with long hours, were driving young men away from engineering to other professions, such as commerce.

Considerable discussion followed the address, and the speaker's opinion was asked on many other aspects of the subject; for example, the "Sandwich system" of college and factory training, post-graduate work, the value of technical high schools, etc.

A hearty vote of thanks to Mr. Doherty for his address was proposed by E. R. Shirley, M.E.I.C., and cordially approved by those present. Besides a large turnout of branch members, there were present at this meeting the city clerk and representatives of the local Board of Education.

St. Maurice Valley Branch

Romeo Morrissette, A.M.E.I.C., Secretary-Treasurer.

THE PUBLIC SERVICE COMMISSION'S DEBT TO THE ENGINEERING PROFESSION

The first meeting of the season of the St. Maurice Valley Branch was held at the Laurentide Club, Grand'Mere, Quebec, on Saturday, October 20th. The members gathered at the Laurentide hotel, where dinner was served at six o'clock.

The speaker of the evening was Alex. Lariviere, A.M.E.I.C., chief engineer of the Quebec Public Service Commission, who chose for his subject "The Public Service Commission's Debt to the Engineering Profession."

In his opening remarks, Mr. Lariviere stated, "Engineers originated, designed, constructed and operate public utilities, and it is not strange that the engineers' place in the field of their regulation is an important one." The speaker referred briefly to the work of the commission engineers, but dealt principally with the part played by other engineers who have to appear before the commission on behalf of public service to advise upon technical matters in dispute. He also outlined the organization, jurisdiction and procedure of the Public Service Commission and the principles followed by the commission.

At the conclusion of Mr. Lariviere's address, a hearty vote of thanks was tendered by Bruno Grand Mont, A.M.E.I.C., Councillor.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

RAILWAY CONSTRUCTION ENGINEERS

There are openings for experienced railway construction engineers in connection with the construction of a large railway being carried on by a Canadian company in Colombia. Applicants must have a fairly good knowledge of the Spanish language. Apply to Box No. 64-V.

ESTIMATOR AND DESIGNER

Large Canadian firm manufacturing material handling machinery such as cranes and hoists, also a variety of heavy mechanical work, including sluice gates, has an opening for a man with experience in design and estimating along these lines. Apply Box No. 80-V.

SALES ENGINEER

A large manufacturing company in Montreal has an opening for a graduate engineer on its sales staff. The company manufactures compressed air machinery. A man familiar with pneumatic tools, portable compressors is one whose application will be given most serious consideration. Apply to Box No. 84-V.

SALES ENGINEER

A large manufacturing company in Montreal has an opening for a graduate engineer on its engineering sales staff. The company manufactures compressed air mining machinery and oil engines. Preference will be given to those having some experience in these lines. Apply with full particulars to Box No. 85-V.

SALES ENGINEERS

Two graduates of two or three years for sales and demonstration of construction of (road) machinery. Would be given experience and instruction on operation. Apply Box No. 86-V.

PROMOTION ENGINEER

A large Canadian industrial company, distributing a construction material from coast to coast, has an opening for a graduate engineer between the age of 25 and 30 to carry on promotional work in the western provinces from the head of the Great Lakes to British Columbia. Apply to Box No. 93-V.

JUNIOR ELECTRICAL ENGINEER

A recent graduate in electrical engineering is required by a pulp and paper company. Previous experience unnecessary. The position offers excellent opportunities for advancement. Apply to Box No. 103-V.

DRAUGHTSMAN

Draughtsman with some architectural experience required for municipal work. Applicant must state age, experience, salary expected and submit sample of drawing. Apply Box No. 105-V.

STEAM PLANT DESIGNER

A thoroughly experienced man familiar with modern practice in the layout of boilers, turbines, piping and the usual accessory equipment. Apply giving full details of experience to Box No. 106-V.

MECHANICAL DESIGNER

A man with several years experience in the layout of mechanical equipment, shafting, piping and generally familiar with industrial plant practice. Apply giving full details of experience to Box No. 107-V.

STRUCTURAL DESIGNER

A man fully competent to design and detail simple structures in steel, timber and reinforced concrete. Apply to Box No. 108-V.

FACTORY MANAGER

Required by progressive and growing Canadian company engaged in the manufacture of a wide range of material handling machinery, factory manager capable of assuming entire responsibility for maximum production at lowest cost. Position offers unlimited scope to ambitious and energetic man. Apply giving details of training, experience, and salary required to Box No. 109-V.

ELECTRICAL ENGINEER

An electrical draughtsman for maintenance and construction design in a large steel plant. University graduate preferred. State age, education, experience, and salary to Box No. 110-V.

ELECTRICAL DESIGNER

Electrical designer with at least five years experience in designing electrical sub-stations for power companies. Applicant must be thoroughly familiar with latest types of switch-

Situations Vacant

board equipment. Give full detailed information in first letter, including age, salary expected, names of references, recent photograph, and samples of drawings made. Permanent work with good future for the right man with large power company in eastern Canada. Apply Box No. 111-V.

Industrial Designer and Draughtsman

Young engineer with electrical training, for an industrial firm in Montreal, preferably one with experience after graduation, on electrical heating and ventilating layouts. Must be a good draughtsman. Remuneration depends on capacity of applicant. Apply, giving full particulars, to Box No. 112-V.

Junior Draughtsman

Junior draughtsman, for a firm in western Ontario, with experience on structural steel. Apply to Box No. 113-V.

Electrical Engineer

Electrical engineer wanted for design and construction work on hydro-electric power house. At least three years experience desirable. Position probably permanent on completion of work. Apply to Box No. 114-V.

Mechanical Draughtsman

Mechanical engineer and draughtsman, between twenty-five and thirty-five years of age, preferably experienced in paper mill engineering. Apply, stating past experience, education, married or single, salary expected and when services available, to Box No. 115-V.

Construction Engineer

Young engineer, preferably one with two or three years experience in general construction, for design and detailing work. Location, Montreal. Apply to Box No. 116-V.

Draughtsman

Must be capable of working up reinforced concrete structures and power house substructure design for a power development in the middle west. Apply to Box No. 119-V.

Hydro-Electrical Engineer

There is an opening for an expert hydro-electrical engineer in the Irrigation Branch of the Public Works Department, United Provinces, India. The applicant must be a university graduate, with practical experience in the design, construction and control of reaction-turbine-stations, high voltage transformation and transmission systems. The applicant must be not less than 36 years or more than 42 years of age. The appointment will be made for five years in the first instance. Full particulars may be secured upon application to Box No. 122-V.

Assistant to Superintendent

Technical superintendent to act as assistant to superintendent of steam plant for large newsprint mill. Graduate engineer essential. In reply, state age, experience and salary expected. Position permanent. Apply to Box No. 123-V.

Designer and Detailer

A structural steel company requires a designer and detailer. Good living conditions and good prospects. Interesting variety of work. Apply, giving full particulars and references, to Box No. 124-V.

Civil or Mechanical Engineer

Civil or mechanical engineer for office and field work on hydro-electric power plant. At least three years experience desirable. Apply to Box No. 125-V.

Structural Designer

Experienced structural designer for the design of factory buildings required for a large industrial company in Montreal. The position is permanent, and preference will be given to applicant who has had experience on architectural work or building design. Apply to Box No. 127-V.

Mechanical Draughtsman

Mechanical draughtsman required for the layout of mechanical equipment, including heating and ventilating, and electrical equipment. Position permanent. Apply to Box No. 129-V.

Draughtsmen

Large power company requires several draughtsmen with experience in topographical survey work or on general design. Apply to Box No. 130-V.

Designer and Draughtsman

Experienced man for general structural and mechanical work in connection with mine, mill and smelter construction and maintenance. Offer $225.00 per month and transportation from Montreal or Toronto to location in Northern Quebec. Apply Box No. 131-V.

Mechanical Draughtsman

Young mechanical draughtsman for a pulp and paper company in Northern Quebec. This position will develop into operating engineer. Apply to Box No. 132-V.

Mechanical Draughtsman

Wanted by a large public utility company in Montreal, a young engineer with experience on civil engineers' plans. Must be neat daughtsman. Apply to Box No. 134-V.

Mechanical Superintendent

First class mechanical superintendent with experience and capable of taking complete charge of machine shop employing approximately 300 men, manufacturing brass and iron valves, plumbing goods, locomotive specialties, also large steel and bronze fittings and specialties for pulp mills. Apply giving full particulars as to qualifications, past experience and salary expected to Box No. 137-V.

Electrical Salesman

A company in the province of Quebec, has an opening for an electrical engineer to take charge of their merchandise sales department. The applicant must speak French and English, and must have had previous experience in salesmanship, and be able to conduct sales campaigns and supervise sales staff. He must also be able to direct the advertising and must have a personality necessary for such a position. Apply giving full particulars regarding qualifications to Box No. 138-V.

Traffic Superintendent

Traffic superintendent wanted on South American tramway property. Require man with experience in actual operation of street cars and buses on modern city property. Preference given to young man and to technical graduate if with necessary practical experience. Applicants please state full details of education, experience, present salary and give references. To right man this opening presents great opportunities. Apply to Box No. 139-V.

Mechanical Designer and Estimator

A company in Montreal has an opening for a mechanical engineer with experience in the design of digester and acid plants for sulphite pulp mills. The work will be designing and estimating special equipment, and the position offers excellent opportunities for advancement. Apply giving full details to Box No. 140-V.

Mechanical Draughtsman

A manufacturing company in central Ontario has an opening for a mechanical draughtsman with several years experience. The work is in connection with the extension and alteration of the company's manufacturing plant. Apply giving full details of experience to Box No. 141-V.

Mechanical Draughtsmen

Several good mechanical draughtsmen with paper machine experience preferred. Apply giving age, past experience, salary expected and when services are available, to Box No. 142-V.

Combustion Engineer

A manufacturing company specializing in the domestic heating field, has an opening on its sales staff for a young engineer with knowledge of heating and combustion systems. Salary and commission basis. Apply to Box 143-V.

Situations Wanted

Construction Engineer

Electrical engineer, B.Sc., M.Sc., wishes to locate in Montreal on electrical construction or installation work involving power and distribution equipment. Experience covers design, testing, operation, maintenance and installation of power equipment. Can handle men successfully and show results. Now employed in Quebec. Apply Box No. 40-W.

Recent Graduate

Graduate of Univ. of B.C. '28 with the following experience is open for a position: Instrumentman and designer on the construction of roads; resident engineer on construction of buildings; structural designer and inspector on construction of a concrete warehouse. Apply Box No. 49-W.

Mechanical Engineer

A.M.E.I.C. experienced in drawing office, production and plant maintenance; four years as engineer-in-charge of works plant installation and maintenance, mechanical and electrical; three years as sales engineer; conversant with wide variety of machinery; recently mainly on pneumatic plant; having just returned from residence abroad is open for engagement in suitable capacity. Apply Box No. 84-W.

Civil Engineer

B.A.Sc. '23, D.L.S., with experience in railroad switch work, pipe lines, sewers, setting mill machinery, motors, pumps, layout of foundations and concrete form work for reinforced concrete, erection of steel reinforced concrete, brick and wooden structures, surveys and topographic surveys, at present in United States, would like to secure work in Canada. Apply Box 86-W.

Construction Engineer

A.M.E.I.C., with twenty-six years' experience, including ten years railway construction and sixteen years on reinforced concrete bridge, as resident engineer in Canada and United States, desires position. Apply Box No. 93-W.

Airport Engineers

Civil engineer with two years surveying and five years general construction wishes to join an engineering firm specializing in or wishing to commence a department for location, design and construction of airports. Location Montreal or in Ontario. Apply Box No. 99-W.

Spare Time Work

Graduate of this year, at present employed in Montreal, wishes to secure some spare time employment in the city; either draughting or clerical work associated with engineering. Available three or four evenings each week. Apply Box No. 100-W.

(Continued on next page)

Situations Wanted

Electrical Engineer

Graduate of N.S. Tech. Coll. '25, age 27, single, two years Westinghouse test course, one year assistant electrical superintendent of a large mining concern, desires position in public utility work. Available at reasonable notice. Apply Box No. 101-W.

Civil Engineer

A graduate of McGill Univ. '24, with some knowledge of French, wishes to return to Canada from the U.S.A. His experience includes instrumentman on railway construction, resident engineer on railway construction, instrumentman on general maintenance, and transitman on preliminary surveys. Apply to Box No. 103-W.

Civil Engineer

McGill graduate with eleven years experience on the construction of hydro-electric developments and industrial buildings desires a position as resident engineer. Open for engagement at very short notice. Apply to Box No. 117-W.

Civil Engineer

Toronto Univ. graduate '25 desires permanent position, preferably but not necessarily on hydro-electric development. Most recent experience, design of bridges, culverts, etc., two years; river control studies and open channel hydraulics for hydro developments, two years; draughtsman and detailer on hydro development, three years; mechanical draughtsman on steam power plant work, two years; at present in Southern California, but available on short notice. Apply to Box No. 119-W.

Sales Engineer

A graduate mechanical engineer resident in Toronto, experienced in the design and construction of industrial plants and smaller work, would like to represent manufacturing concerns in this territory. Remuneration could be adjusted after a reasonable trial. Apply to Box No. 123-W.

Civil Engineer

A graduate civil engineer with over 15 years varied experience, mostly in the construction field, desires a position on construction as superintendent or resident engineer, or on editorial or publicity work, with which he has had experience. Apply Box No. 124-W.

Structural Designer and Draughtsman

Structural designer and draughtsman, graduate engineer with 16 years experience in Canada and in the city of New York, on all types of structures, including tall buildings, apartments, hotels, warehouses, factories and industrial buildings. At present in Montreal, desires spare time employment, evening, Saturday afternoons, etc., at home or office, designing, laying out, figuring, checking or estimating. Apply to Box No. 127-W.

Electrical Engineer

Graduate of McGill Univ. '27 in electrical engineering, age 24, single, desires a position which will give him experience in construction or design along this line. Employed since graduation by a large public utility on pole line work. Has also had considerable experience in surveying. Apply to Box No. 129-W.

Canadian Electrical Code Requires Second Edition

Under the auspices of the Canadian Engineering Standards Association, Committees have just completed a five-day session in Montreal, at which consideration has been given to proposed revisions for the second edition of the Canadian Electrical Code. Two days were spent by a special Committee of provincial representatives in a preliminary discussion of comments and suggestions for revisions made by various provinces with the object of attaining provisional agreement. This meeting was attended by the following provincial representatives: F. W. W. Doane, Doane Engineering Company, Halifax, Nova Scotia; F. P. Vaughan, Electrical Contractor, Saint John, New Brunswick; J. N. Mochon, Board of Electrical Examiners, Quebec; A. G. Hall, Hydro-Electric Power Commission, Toronto, Ontario; J. H. Schumacher, Electrical Contractor, Winnipeg, Manitoba; S. R. Parker, Department of Railways, Labour and Industries, Regina, Saskatchewan; D. Donaldson, Electric Light and Power Department, Edmonton, Alberta; and H. L. Taylor, Provincial Inspector of Electrical Energy, Vancouver, British Columbia; and also Mr. Dobson, chairman of the C.E.S.A. Code Committee; A. S. L. Barnes and H. F. Strickland, code editors, and B. Stuart McKenzie, C.E.S.A. secretary.

It was reported that the code had been adopted by legislation in five provinces and special provincial editions had been issued. In Nova Scotia the code is administered by the Nova Scotia Fire Prevention Board, in Quebec by the Board of Electrical Examiners, in Ontario by the Hydro-Electric Power Commission, in Saskatchewan by the Department of Railways, Labour and Industries, and in British Columbia by the provincial Department of Electrical Energy. In New Brunswick the code has been officially adopted in the cities of Saint John and Campbellton, and the provincial commitee is endeavouring to have the code adopted by other cities before obtaining provincial legislation. In Alberta a bill has been drafted with the object of securing provincial legislation and it is expected that this will be favourably received at the next session of the legislature. In Manitoba the question of legislation is being carefully considered by the C.E.S.A. provincial committee on the code.

The meeting of the provincial representatives was followed by the meeting of the C.E.S.A. Committee on Canadian Electrical Code, which was held in the Ministers' room at the Court House under the chairmanship of W. P. Dobson, chairman of the C.E.S.A. Committee on Canadian Electrical Code, and the attendance at this meeting was particularly representative and was well maintained throughout the sessions.

Suggestions for revisions to Canadian Electrical Code were thoroughly discussed using as a basis the recommendations from Committee of Provincial Representatives. As a result of the discussion many recommended revisions were approved, particularly with regard to grounding, motor rules, demand factors, wattage of outlets and other matters; and full advantage was taken of the experience gained since the publication of the first edition of the Canadian Electrical Code in October 1927. Revisions appearing in the National Electrical Code for 1928 were considered, much of the material therein contained being approved for adoption and a certain amount of the material from provincial rules will be incorporated in the new edition of the Canadian code. One particular feature of the discussion was the active part taken therein by manufacturers and utility companies.

Part 2 of the Canadian code covering specifications was considered and it was decided to proceed with the drafting of specification for electrical apparatus in preparation for the establishment of an approvals laboratory for electrical apparatus in connection with the National Research laboratories at Ottawa. It was felt that these specifications should cover minimum standards and that they be modelled mainly on specifications now being used by the Hydro-Electric Power Commission laboratories at Toronto and Underwriters' laboratories at Chicago, also any available British specifications.

With reference to Part 3 of the Canadian code covering outside wiring rules it was felt that the drafting of rules be proceeded with at once. A definite recommendation to this effect was made to the committee by the Grounding Panel and requests have also been received from the C.E.S.A. provincial committees, communication companies, power companies, Quebec Power Commission and other interests. It was finally decided that a committee be formed to draft a set of rules covering minimum requirements, taking as a basis rules now in force in many of the provinces, also rules being prepared by the various electrical associations.

The revisions approved at the meeting of the code committee will be issued in draft form and sent out to the various provincial committees for final endorsement. Thereafter preparation will be made for the publication of the second edition of the Code and it is hoped to issue this in the spring of 1929. It was the consensus of opinion that this second edition should not need revision for at least two years and it was proposed that the next meeting of the C.E.S.A. Committee on Canadian Electrical Code be convened in 1930.

Reports from all provinces indicate the successful progress of the Canadian Electrical Code since its publication by the Canadian Engineering Standards Association and it is felt that much has been accomplished in the attainment of uniform wiring rules throughout Canada.

The Kerr Engine Company, Ltd., Walkerville, Ontario, have issued a new booklet entitled "Valves and Hydrants," containing illustrations and price list of brass and iron valves, fire hydrants, indicator posts, etc. The Kerr Company will be pleased to send copies of this publication to any persons interested, upon request for Catalogue No. 6.

Horton Steel Works Limited have just issued a booklet entitled "Johnson Differential Surge Tanks," which was prepared under the direction of Mr. Raymond D. Johnson, and which points out the particular advantages gained by using the differential surge tank for hydraulic power plant regulation. The pages are profusely illustrated with installations made by the company, including pipe lines, penstocks, tees, manifolds, wyes, etc. Chile and Japan, as well as the United States and Canada, are represented. Copies may be secured from the company by request.

Preliminary Notice

of Applications for Admission and for Transfer

October 22nd, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November 1928.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

GILES—BEVANS HENRY DRUMMOND, of Montreal, Que., Born at Montreal, April 20th, 1903; Educ., B.Sc. (Met. Eng.), McGill Univ., 1927; 1923-24, lab. asst., Canadian Laco Lamps; 1927 to date, engr. with the Canadian SKF Co., Ltd., covering eastern Canada, on installn., service, inspection, etc., ball and roller bearing in pulp and paper mills, textile mills, woodworking plants, steel mills, etc.

References:—G. Janes, E. Klein, C. V. Christie, A. J. Grant, C. M. McKergow, R. DeL. French.

GRAY—ROBERT BALFOUR, of 19 Salisbury Road, Pointe Claire, Que., Born at Glasgow, Scotland, Jan. 3rd, 1892; Educ., 1914 and 1919-20, design of structures, Glasgow Technical College; 1909-14, struct'l training in templet shop, fabrication shops and field work, Sir W. Arrol & Co., Glasgow; 1915-18, supervision work on constrn. of Sinai Desert Railways, roads, waterworks, with the Royal Engineers; 1919-20, dfting., office work, on boilers, stationary and marine, Babcock & Wilcock, Ltd., Scotland; 1919-24, dfting., office work on structures and tank work, and 1925-27, squad leader i/c of struct'l detailing and plate work, Dominion Bridge Company, Lachine; at present district sales engr. for Montreal, with the Robb Boiler Works, Amherst, N.S.

Resident Engineer, Anticosti Corporation, Anticosti, Que.

Paper read before the Montreal Branch of The Engineering Institute of Canada, October 25th, 1928

Development of Anticosti Island—Part I.

Geographical Location and Size

The island of Anticosti is situated in latitude 49 north, and longitude 63 west, in the gulf of the St. Lawrence, 360 miles below the city of Quebec. The closest point to the mainland on the south shore is the Gaspé coast 40 miles distant and on the north shore Mingan, which is 21 miles distant.

The island has a length of 135 miles and a width of 35 miles, the area being 3,100 square miles or approximately one and one-half times the size of the province of Prince Edward Island.

Discovery and History

On August 15th, 1534, Jacques Cartier, the noted French explorer, entered what we now know as the gulf of St. Lawrence and discovered the island to which he gave the name " Ile de l'Assomption " as the discovery was made on Assumption day. At a later date the island was visited by another explorer, the Marquis de Roberval, and as his visit took place on Ascension day the name was changed to " Ile de l'Ascension." Later, however, the name Anticosti was adopted, which it is thought has its origin in the Montagnais Indian word natikoteck, meaning " the land of bears."

It was only in 1680 that the real history of Anticosti began, when King Louis XIV of France ceded the island to Louis Jolliet, his hydrographer, in recompense for his services in exploring the Mississippi river and Hudson bay. Jolliet took possession of his seigneurie, established his family there and centred his activities on seal hunting and fishing. Jolliet's peaceful tenantry was disturbed when Admiral Phipps on his way to besiege Quebec in 1690 took Jolliet, together with his wife and family, prisoners. This misfortune, however, did not discourage Jolliet, whom we see again in 1697 carrying on a fur trading business on the Mingan coast. In the following year, availing himself of his knowledge of hydrography, he published a map of the island of Anticosti. The exact date of Jolliet's death is not known, but it is thought to have been between 1699 and 1701. The place of his burial, too, is uncertain, but is considered to be somewhere on the island.

Following Jolliet's death the ownership of the island passed into the hands of his three children. Succeeding them, we learn that until the year 1874 the ownership was more or less complicated, when an attempt was made by the Forsyth Company of Newfoundland to colonize it. This attempt proved unsuccessful and disaster to the settlers was only averted by the government's timely intervention. In the following ten years we see further changes, and in 1884 Anticosti was sold by sheriff's auction to T. W. Stockwell, who disposed of it in 1888 to a company known as " The Governor and Company of the Island of Anticosti." Finally in 1895 this company's trustees sold Anticosti to Mr. H. E. A. Menier, of Paris, France, for the sum of $125,000.

With Mr. Menier's acquisition of the island came the

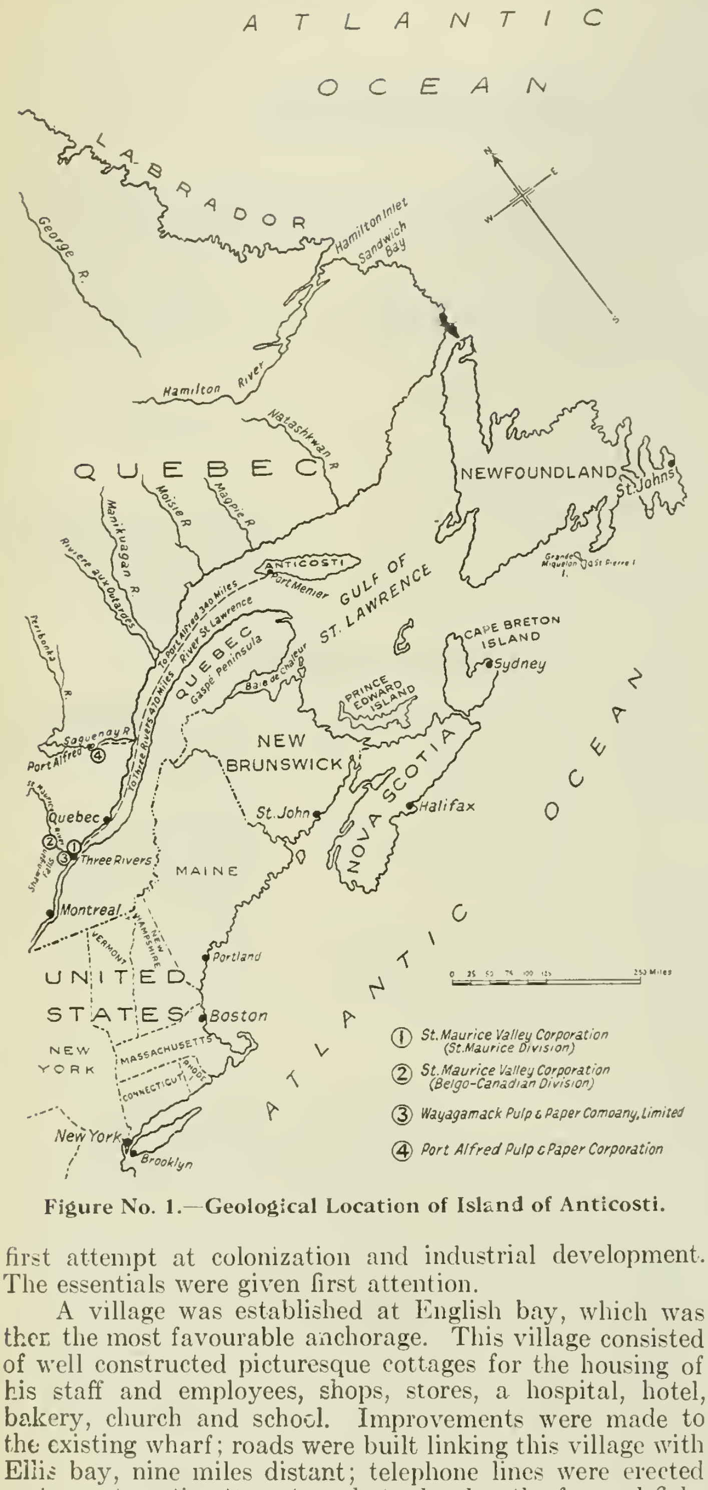

Figure No. 1.—Geological Location of Island of Anticosti.

first attempt at colonization and industrial development. The essentials were given first attention.

A village was established at English bay, which was then the most favourable anchorage. This village consisted of well constructed picturesque cottages for the housing of his staff and employees, shops, stores, a hospital, hotel, bakery, church and school. Improvements were made to the existing wharf; roads were built linking this village with Ellis bay, nine miles distant; telephone lines were erected and a systematic attempt made to develop the fur and fishing industries.

In addition to this, a farm was developed adjacent to the village to meet the needs of the inhabitants and to experiment with the agricultural possibilities of his new territory.

In 1899 Mr. Menier, realizing that valuable timber resources were at his command, saw that his efforts towards developing them were greatly restricted by continuing operations at English bay owing to its limited depth of water for harbourage. With a view of obtaining a deep sea port he commenced the construction of a wharf at Ellis bay, which provides the finest protection for ships in the island. The reef here, as at other points, is long and shallow, necessitating the construction of a wharf 3,500 feet in length, in order to reach a depth of 12 feet of water at low tide.

The harbour established, his next step was to construct an entirely new village at Ellis bay, which point was now to be the new centre of his activities. The new village was given the name of Port Menier. Profiting by his experience at English bay, he proceeded with the construction of more substantial and commodious buildings, aiming at larger industrial developments. Having established his new capital he erected for himself a villa modelled along the lines of a French chateau, upon which he spared no expense either in the construction or its sumptuous furnishings.

In 1910 he entered upon an extensive programme of pulpwood logging. He constructed a rossing plant, consisting of 20 knife barkers, together with a steam generating power plant to furnish the necessary power. A slasher, conveyor and loading equipment formed a part of the scheme. A standard gauge railroad was built to transport the wood from the logging area to this plant. This was finally extended about thirty miles down the island.

In 1913 an important event occurs in the history of the island, when its owner, Mr. H. Menier, died and was succeeded by his brother, Mr. Gaston Menier, who continued the operations then under way.

Pulpwood logging activities were carried on until 1918, to which date 500,000 cords of barked wood had been shipped. Encountering financial difficulties through the fall of the French currency, the owner decided to discontinue logging operations and a period of quiet ensues between that date and the sale of the island to the present owners.

The Anticosti Corporation

In the spring of 1926 negotiations were opened between the Wayagamack Pulp and Paper Company, the St. Maurice Valley Corporation and the Port Alfred Pulp and Paper Corporation and Mr. Gaston Menier for the purchase of the island. In May of this year the late Mr. H. R. Wickenden, then chief forester for the Wayagamack Pulp and Paper Company, proceeded to the island together with a party of timber cruisers to conduct an exploration. Following this the island was visited by several of the directors of the above companies and in July the island passed into the hands of the present owners. A limited company was formed known as The Anticosti Corporation, controlled jointly by the three paper companies. An agreement was made by which these companies would purchase the entire annual timber output of the island at a figure sufficient to provide for the expenditures, including operating expenses, bond interest, sinking fund, etc.

Transportation

Freight, passenger, mail and transportation of men, materials and supplies is handled by a joint company known as The Anticosti Shipping Company.

Two vessels, the "Fleurus" and the "Sable I," operate between Montreal, Quebec and Anticosti on a schedule of sailings drawn up to cover the season's operations. The "Fleurus," which was built at Le Trait, on the Seine, in 1926, is an oil burning steam vessel of 1,100 gross tons, having accommodation for forty first-class passengers and seventy-five second-class passengers, and has a speed of 12 knots. The "Sable I," built in England in 1914, also is a steam vessel of 734 gross tons, with accommodation for one hundred passengers and commodious freight capacity. She has a strongly constructed hull, with an ice breaking bow, and is capable of a speed of 11 knots.

For the distribution of materials and supplies along the coast, two auxiliary schooners are used as well as a fleet of small motor launches. The larger of the schooners, the "Jolliet," is equipped with a 150-h.p., semi-Diesel Fairbanks-Morse engine and has a speed of 10 knots.

A regular boat service has been maintained without difficulty between the months of April and December. During the winter, the government ice breakers, the "Montcalm" and "Mikula," make a monthly trip to the island. Supplies are discharged on the ice about two miles off shore and transported to the depot by tractors and teams.

During the past winter, arrangements were made with the Transcontinental Airways, Ltd., to transport mail from Murray Bay to points along the north shore of the St. Lawrence and to Anticosti. A light Fairchild monoplane, using skii for a landing gear, was used for this service, and its landing performance, even in severe weather, was remarkable. By this means an unbroken mail service has been established throughout the year. This, combined with wireless and cable service, keeps the inhabitants in constant touch with the mainland.

Natural Resources

The principal natural resources of the island may be said to be timber, farming, fur, fish and game. Of these only timber and fur are exploited by its present owners for commercial gain. The remaining resources are developed on a small scale, sufficient to meet local needs. The development of the timber resources is primarily the object of The Anticosti Corporation.

Timber

An idea of the vastness of the timber area may be had from the carefully prepared estimates of the Corporation's forestry engineers which show that there is a quantity of 14,400,000 cords of standing timber, of which about 40 per cent is spruce and 60 per cent balsam. This would represent sufficient raw material to manufacture about 11,000,000 tons of newsprint.

Forest Resources

The forest producing capacity can be determined in a general way by considering two dominant factors, namely, the climatological conditions and the geological origin and structure of the soil. The climate of the island is characteristic of that of the northern regions of the temperate zone, although greatly influenced by the surrounding sea. The period of vegetation is brief but intense, while the winter is of long duration. The summer heat and the winter cold are, however, less extreme than in the interior of the Laurentians of a more southerly latitude. The rainfall is moderate, and in comparison less than in the Quebec-Montreal region during the vegetation season. The predominating winds are southeasterly and northwesterly and have an apparent influence on the tree growth of the island which shows itself by the shore belt being of stunted and scrubby trees, while the protected localities show an excellent growth.

The geological properties of the soil are next in importance. The island of Anticosti is a remainder of the silurian deposit that in an early epoch formed a large part of northern Canada.

The disintegration of this rock forms a very rich top-

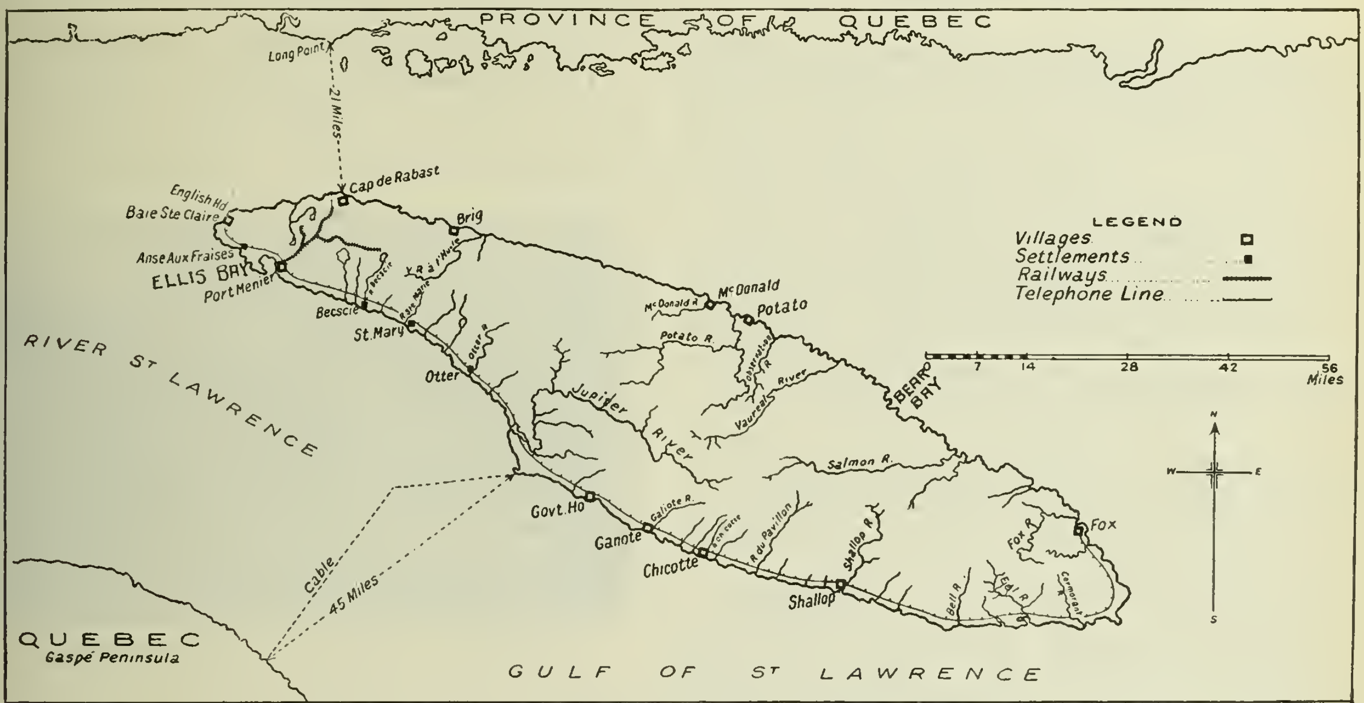

Figure No. 2.—Map of Island of Anticosti.

The most important part of the transportation arrangements is that provided for the shipping of pulpwood to the mainland.

During the season of open navigation, i.e., from May 1st to October 10th, a continuous service for the transportation of pulpwood has been maintained by the Water Transports Limited and the Canada Steamship Lines. The former company built and equipped six boats specially for this service, while the latter has placed at the disposal of the company sufficient additional boats to meet the balance of their requirements. These boats are of the lake type, 252 feet in length, with 42-foot beam and a bale capacity of 123,000 cubic feet under deck and when fully loaded to a mean draft of 16 feet carry 800 cords of wood in the hold and 600 cords on deck. Their speed is 9 knots.

To suit the loading and unloading plants the hatches have been made especially large, having a clear opening of 14 by 30 feet. This type of boat is well adapted to the pulpwood trade and has the added advantage of being a suitable grain and coal carrier, ensuring its continuous demand at all seasons.

Figure No. 2a.—View from Loading Plant Looking Across Ellis Bay.

Typical loose wood raft (centre); storage boom (right); and steamer "Fleurus" (foreground).

crust of gravel and clay and covers almost the entire island. Wherever these quarternary formations occur and the natural drainage of the soil is satisfactory, the timber thrives perfectly. Mentioned here is the drainage of the soil, which indeed is the factor that greatly promotes or limits the forest growth of the island. The limestone soil, whereof the clay is a component, is rather impermeable. This quality added to the effect of water in localities of flat topography, results in more or less extensive areas of swampy ground, often real peat bogs, called muskegs. This is, however, a characteristic of the northern part of the province and is also a result of the reaction on the soil of a comparatively cold climate. The rapid development of the timber on sloping land where drainage conditions are favourable is a striking contrast to the poor growth of timber on the above mentioned saturated areas. It is evident that if the future value of pulpwood would allow the expense of trenching swampy land many a square mile of now non-merchantable growth could be converted into a good timber in a reasonable time.

The timber of Anticosti is found in a virgin state, the balsam predominating. The balsam reproduces itself readily in protection and shadow. It has been observed that in a partly wind fallen stand the young regrowth of balsam starts to sprout rapidly. In the virgin forest, by the time the overmature balsam fails, there is generally a new generation well under way.

Forest fires are aiding the regeneration of spruce rather than that of balsam. A fire provides space and light necessary for the young spruce plant to thrive successfully. On the west end of the island the evidence of this may be seen where a forest fire has burnt over most of the old cutover areas and a young generation of spruce predominates. Along the Jupiter river, this is again evident, where a young forest of spruce has grown up after a fire of sixty years ago.

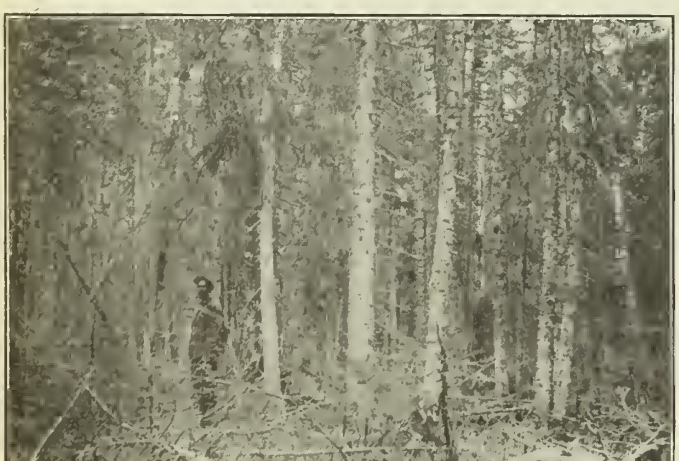

Figure No. 3.—Typical Spruce-Balsam Stand, near Potato River.

Where the spruce-balsam type grows to best advantage it yields as high as 50 cords per acre. Over large areas of the coastal regions of the island an average of about 10 cords per acre is found.

In swampy localities or dry and poor soil one finds the black spruce type in evidence. Where conditions are favourable this type yields up to 15 cords per acre. On the other hand, wherever the soil conditions are very poor, or on swampy ground, this type turns to so-called scrub spruce of a stunted appearance that seldom reaches a merchantable size.

Of leaf trees there is not a great variety. Birch always occurs on the better soil and poplar is frequent in certain localities on the north shore.

Reforestation, Annual Regrowth and Annual Decay

It may be stated that conditions for natural reforestation of the island are very favourable. The rate of the annual increment may be judged by the fact that it takes 60 to 70 years for the spruce-balsam type on average soil conditions to grow to a merchantable size and at that time it will yield about 11 cords to the acre.

Figure No. 4.—Potato River Looking Towards Sea.

It is believed at the present time the natural regrowth more than offsets what is cut and lost by decay and windfall.

The Anticosti Corporation are organizing to direct their exploitation in the more matured wood which will have the effect of deriving more benefit from the yearly regrowth of the young trees.

Fire Hazard

On account of its isolation as an island, Anticosti is not exposed to outside hazard, as are other limits on the mainland. However, on account of the highly inflammable nature of the soil in extended dry periods a constant enforcement of fire protection measures is necessary.

Fur

The principal fur bearing animals existing at present on the island are the fox and the beaver. The fox is native to the place, but through the efforts and research of Mr. Menier's botanist the strain was much improved and this fine little animal became very abundant. The trapping of the fox has been carried on for a great many years. The 1925-1926 catch of fox reached 1,600, 15 per cent of which were silver, the balance being cross and red.

Beaver were imported around the year 1900 and have multiplied very rapidly ever since. Fisher and mink were also imported, but are rarely seen today. Otter and marten, which are native, are found occasionally. Seals are taken on the reefs and shoals around the island.

Game

In 1897 and 1898, Mr. Menier imported about 300 couples of Virginia white tail deer. This interesting inhabitant of the forest has become so numerous that one must visit the place in order to see for oneself how plentiful they really are. It has been estimated that the island contains probably 100,000 deer. The deer is a meat resource of no small value. In the western portion of the island, in the vicinity of the settlements and in logging districts, close to 1,000 deer are killed annually for immediate consumption.

A herd of reindeer and a pair of elk were imported a few years ago. Both these animals appear to be thriving.

Wild fowl are in abundance during the migration season, the Canada goose being one of the most popular visitors. Partridge have confined themselves to the west end of the island but here they are steadily increasing in numbers.

Fish

In the larger rivers of Anticosti one finds excellent salmon and trout fishing. The disciple of Isaac Walton can find great opportunities for practising the noble art on the island. Mr. Menier had constructed at eight of the river mouths camps suitably equipped for the reception of sports and anglers.

Figure No. 5.—Commencement of Drive on Canard River.

The coast waters abound with cod, halibut and lobster. These are taken in sufficient quantity to supply the local needs.

Logging Methods

Logging

The cutting operations may be described as being carried on in two distinct manners, by company operated camps and by contract. The 12-foot log has proved to be the most suitable for driving and towing. The corporation at present operates two logging camps manned by their own forces and under the direct control of the superintendent of one of their logging districts. The larger of these camps this year has started on a cut of 15,000 cords and the smaller 7,000. The men in these camps are working on a piece work basis, being paid so much per log. The above operation represents only a small proportion of the total cut, which, during the past winter, amounted to 175,000 cords.

Cutting by contract is the usual practice in the logging of the island. Contracts vary from 6,000 to 30,000 cords. The contractor binds himself to deliver the wood at a certain price per 1,000 FBB on driving streams, at tractor roads or railway. The work of the contractor is under the constant check and supervision of the superintendent of the logging district in which he operates.

Figure No. 6.—Reindeer on Island of Anticosti.

In suitable locations, the cut is commenced early in summer, and usually finishes before the snow falls. Generally, however, the bulk of the cutting is done in winter, commencing early in the fall, and is brought to an end in the late winter when snow gets deep.

Logging conditions during the winter are very similar here to points on the mainland. The snowfall is not greater than elsewhere throughout the province of Quebec.

Driving

Wherever possible the wood is delivered on streams and driven into holding booms at the sea or direct to the main storage area at the shipping point.

The driving operation is carried on either by contract or by day labour. Preparation for the storage of water necessary for driving must be made the previous fall. Timber rock-fill dams are used for a head exceeding 8 feet. For dams with a lesser head, a round timber structure with an inclined sheeted face on the up-stream side is used. This is commonly known among lumbermen as a " charge d'eau " dam. A slope of 2 to 1 on the upstream face is found satis-

Figure No. 8.—Tug "George M. McKee," with Raft in Tow.

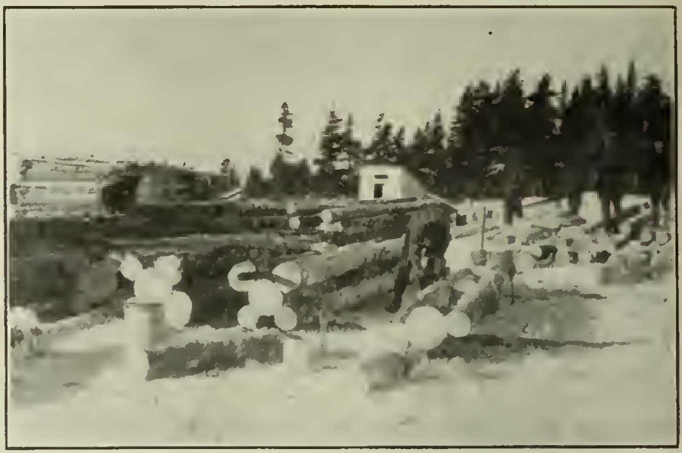

Figure No. 9.—Construction of Four-Piece Towing Boom.

factory, when the timber work is well set into the ground or anchor bolted to rock.

The natural run-off in Anticosti is rapid and without artificial water storage; driving can be carried on for a period of two to three weeks.

The driving capacities of the rivers depend, more or less, on the extent of improvements made. The average stream is capable of floating about 35,000 cords of wood during the months of May and June, when proper water storage is provided.

Towing

Wood driven on rivers other than those discharging into Ellis bay must be delivered into holding areas at the river mouths and held by booms, to be later made up into rafts and towed to the loading plant at Ellis bay. So far, the estuaries of three drivable streams discharging to the south shore have been developed into storage basins protected by cribs and booms, offering facilities for the storage of 70,000 cords.

For the rafting of wood heavy towing booms have been constructed. These consist of four pieces of round timber, bolted securely to 12 by 12 British Columbia fir blocks, one round timber being bolted to each face of the block. The average length of the boom sticks is 22 feet. These are joined with one-inch double chain locked with shackles. When floating they draw about 20 inches of water, leaving 10 inches exposed. The average raft towed during the past summer contained 800 cords of wood. This requires approximately 100 pieces of boom stick. The method employed in the making of rafts at the river mouths is as follows: The holding boom is opened on the falling tide, allowing the wood to enter the towing boom already placed at the opening. Cribs are located at each side of these openings to which the ends of the towing boom are securely fastened. When the boom is filled, it is towed to the awaiting tug by a shallow draft gasoline boat called an alligator. The raft is then taken in tow by the tug and delivered to the loading plant where it is floated into the holding area on a rising tide.

The tugs used for this work were the "Geo. M. McKee" and the "Hullman." The "Hullman" is a steam vessel of 171 gross tons, with a speed of 11 knots. She is powered with 650-h.p. triple expansion engines. The "Geo. M. McKee" is a Diesel oil tug of 720-h.p., capable of a speed of 11.3 knots. These two tugs towed a total of 73,000 cords of wood between the months of May and October. The average towing distance was eleven miles and the average raft towed was 800 cords.

To carry on a towing operation successfully in the gulf of the St. Lawrence the weather and tides must be studied closely. The tidal stream sweeping the southern coast of Anticosti has a speed of 1½ to 3 knots. This combined with a head wind is sufficient to force a tug to lose ground, even with a comparatively small raft. From the experience gained so far, it may be said that if accurate local weather forecasts can be procured, coastal towing is a success.

Tractor Hauling and Railroading

Tractor hauling, as a means of pulpwood transportation, is proving its worth in the logging operations of the island. Three Lynn tractors and two Holts have been used for the past two winters. On an average haul of six miles, 18,500 cords were transported during the past season. The main haul road was iced and on this road each of the larger

Figure No. 10.—Lynn Tractors Hauling Pulpwood.

Figure No. 11.—Caterpiller Tractor Hauling Pulpwood.

tractors were able to handle an average load of 35 cords. The coming winter's operations will include the hauling of 21,000 cords of wood a distance of six miles. Where this cut is being taken out, it was found impossible to skid during the summer with horses. To overcome this difficulty several spurs of Decauville track of 19-inch gauge have been used to bring the wood to the main haul road. Depending on the grade of the track, a train of 10 to 20 cars, each carrying ½ to ¾ of a cord, is handled by a team of two horses. The whole equipment is light and portable and is readily moved along as the cut progresses.

Logging operations are again being commenced on a small scale along the railway laid down by the Menier organization. A cut of 20,000 cords will be landed on a lake adjacent to the track. From the water, the wood will be jack laddered into flat cars and hauled to the loading plant.

Development of Anticosti Island—Part II.

Ellis Bay Harbour

Ellis bay is situated on the south coast of Anticosti, 7 miles from its western extremity. Extending inland for a distance of 3 miles, with a width of 1¾ miles, the bay forms the best natural harbour on the island. On either side of the mouth of the bay shallow limestone reefs extend into the sea, affording good protection. A reef 3,000 feet long borders the entire shore, being totally exposed at low-tide, but covered by from 3 to 5 feet of water at high-tide.

Figure No. 12.—Log Jammer Loading a Lynn Tractor.

The channel follows the centre line of the bay, running north 7° east. At the inner end and about 1,000 feet distant from the reef, a natural depth of 12 feet at low-water is obtained. This increases seaward to 22 feet at the mouth of the bay, being constant for approximately 1,000 feet on either side of the centre line. The tide rise at Ellis bay is 7½ feet springs and 5½ feet neaps.

In Part I of this paper it has been stated that Mr. Menier constructed a wharf 3,500 feet long, commencing at the east side of the bay and extending westward to the channel. This jetty has a width of 13 feet, extending from the village to the reef, which at this point is 2,800 feet from the shore. Here it widened out into a timber rock-filled wharf 35 feet wide and 900 feet long. A standard gauge railway runs the full length of the wharf and jetty.

When the corporation acquired the island, it was seen that this wharf was not sufficiently large, and that there was not a depth of water necessary for the type of vessel to be used in their pulpwood service. With a view to providing the proper facilities for the loading of their wood, the corporation embarked on the extension of this wharf. They also found it necessary to construct a general cargo wharf for the loading and discharging of men, supplies and equipment. For this work the services of the Foundation Company of Canada were secured, and construction operations commenced in November 1926. About this time the Department of Marine and Fisheries for the province of

Submarine drive and widening cribs at right side.

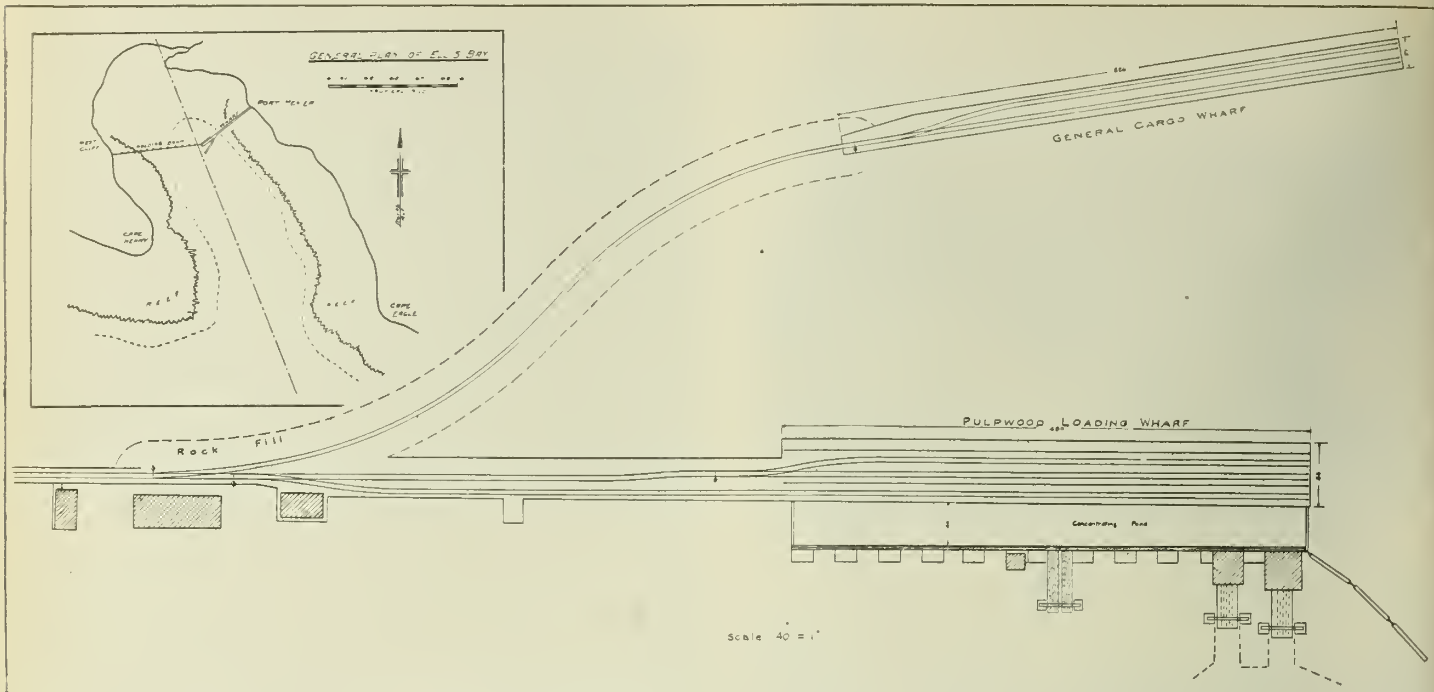

Figure No. 14.—General Plan of Ellis Bay; General Cargo Wharf and Pulpwood Loading Wharf.

Quebec became interested in the developments under way at this port, and a dredging programme was decided upon to provide sufficient depth of water in the harbour for sea-going vessels. Soundings showed that to obtain a depth of 20 feet at low-water, it would be necessary to excavate 34,000 yards of rock and 467,000 yards of gravel and clay. This work was commenced in June 1927 by the Canadian Dredging Company. A dipper-stick dredge, with an eight-yard bucket was employed on this work.

The outer 500 feet of the old wharf, which rested on clay, was widened from 35 feet to 55 feet by means of timber rock-fill widening cribs and their foundation excavated to solid rock at a depth of 20 feet at low-water. The opposite side of the wharf was piled to natural rock surface, to prevent the clay underlying the old structure from sliding. An additional length of 100 feet was built to the old wharf, being excavated to rock. At the time of the extension to the loading wharf, the construction of a new cargo wharf was also commenced. This structure has a rock-fill approach 660 feet long, which diverges from the jetty at a point 1,000 feet from its end. The end of this approach is 250 feet distant from, and at right angles to the main wharf, at which point the timber structure of the cargo wharf commences. This is 520 feet long and 27 feet wide and is made up of timber rock-filled cribs taken to rock. The clear distance between the outer ends of these wharves is 350 feet, so that the ship basin has an average width of 300 feet and is 500 feet in length. There is berthing space at each wharf for two boats and a dredged depth over the entire basin of 20 feet at low-water.

A line of booms and round timber cribs extending 5,000 feet from the end of the pulpwood wharf to the west side of the bay were also built. These, together with the wharf and jetty, block off the inner 1¾ square mile of the bay from the sea. This forms the principal storage area from which the wood for the season's operations is taken. A concentrating basin was also built at this time, but is described in connection with the loading plant.

Construction work was completed in July 1927. The chief difficulty encountered while carrying on this work was severe weather conditions during the winter, the bay being exposed to the northwest winds. A total of 35,000 cubic yards of rock-fill, 100,000 lineal feet of round timber and 3,000,000 F.B.M. of British Columbia fir were used. Owing to the shortage of men during the winter, the work was retarded somewhat. To overcome this, it was decided that the cribs for the cargo wharf would be built in Gaspé and towed to Ellis bay in the spring. The five cribs, each 90 by 27 feet, were landed at Ellis bay without any difficulty.

New Method of Handling Pulpwood

Loading Plant

The most popular methods employed at present in the loading of 4-foot pulpwood into boats is by conveyor or flume. Both of these methods involve the dropping of wood into the ship's hold from a height of 40 feet. This invariably results in considerable damage to the ship's tank tops and is also a menace to the safety of the stowers.

To overcome these difficulties, the Canadian Mead-Morrison Company devised a type of bucket, known as a "Pulpwood Trapper," to be used as an attachment to their standard type of straight line coaling crane for the purpose of transferring wood from the water to the ship's hold. The trapper is an oblong box-like structure of steel and wood, open planked and perforated, which by reason of its weight penetrates the floating wood. The floor of the box is formed by two gates, which are opened before descending into the wood and closed before the trapper is hoisted with its load. It has a capacity of 400 cubic feet, being 10 feet long by 8 feet wide by 5 feet high. With the wood maintained at a depth of 4 or 5 feet, the trapper is capable of taking ¾ cord or 80 sticks of 4-foot wood. When lowered into the boat, the gates are opened and the load is discharged at any desired point on the ship.

To assist this operation, the wood had to be concentrated in an enclosed pond to a depth of 4 feet. This pond, which is known as the concentrating basin, has a minimum depth of 12 feet of water at low-tide, is 40 feet in width and extends along the full length of the loading wharf.

The Mead-Morrison loading towers, of which there are two, are typical straight-line cranes, with a rail travel of

Figure No. 15.—Construction of Timber Crib for Wharf.
Crib, 100 by 27 feet, constructed on three small piers prior to overturning and floating into place.

490 feet, or the lengths of the two loading berths, so that one tower may be used on each ship or the two towers utilized on the same ship. The towers are steel structures, by Dominion Bridge Company, powered with Mead-Morrison engines, the main hoisting engine being 7 by 14½. The trolley has a travel of 140 feet, or sufficient to reach from the extreme farther side of the concentrating basin to the farther side of the boat. The portals of the cranes are designed to allow trains to pass under on the double track, so that the cranes may be utilized for unloading coal.

To maintain a proper, evenly distributed depth of wood in the concentrating basin is one of the most important factors governing the successful operation of the towers. The following is a description of how this is accomplished. From the main storage area the wood is jack-laddered in 12-foot lengths up inclined hauls, passing through the two slasher mills, from whence it is delivered in 4-foot lengths to a six-chain conveyor, located on cribs forming the back wall of the concentrating basin. This conveyor is built in two sections with independent drives, one section being reversible to suit the delivery of wood from two 6-chain jack-ladders, fed from a 4-foot wood storage, and located at the junction of these two sections. By this means wood from the jack-ladders can be distributed to one loading berth or to both as required.

Figure No. 16.—Launching Timber Crib.
Showing crib in act of overturning.

During the past season it has been the practice to load two boats simultaneously, using one tower on each boat. The towers are capable of averaging one trip per minute, the trapper taking ¾ cord per trip. This gives each tower a capacity of 50 cords per hour, under favourable conditions.

Loading commenced this year on May 15th, and ended October 10th, 120,000 cords of wood being shipped. The second slasher mill was not completed until August 1st, so that the plant was running at about 60 per cent capacity until that time. The average cargo carried was 1,375 cords of green wood. The return trip to Three Rivers, including unloading, occupied 5½ days; to Port Alfred, 4 days.

The electrical energy of the plant is developed in a steam-electric power plant on shore. This consists of a 500-h.p. horizontal steam engine belted to a 500-kv.a. generator. Power is transmitted to the wharf sub-station at 2,200 volts, where it is stepped down to 550 and 220 volts for distribution to motors, etc. The total power consumption of the town and loading plant is 450 h.p.

Unloading Plant

A variation from the common practice of unloading has been made at Port Alfred, Cap de la Madeleine and Wayagamack, these being the points to which Anticosti wood is shipped. At these places electrically-driven unloading towers, similar to the loading towers at Anticosti, have been installed. At Port Alfred and Cap de Madeleine the wood is loaded by men into steel opened-ended skips of 1½ cord capacity.

At the discharge end of the boom the forward wheels of the trolley descend in the trackway and the rear wheels ascend, this accomplishing the tipping of the skip to rapidly and automatically discharge the wood. The towers each have a capacity of 40 cords per hour.

The Wayagamack Company have equipped their towers with a new type of steel clam, which removes the wood directly from the boat without being handled by men. The clam is 4 feet wide, weighing 10 tons, and when dropped and closed on the piled tiers, forces its way through the wood, taking about ½ cord. Each tower handles 30 cords per hour by this method.

Future Developments

Harbours

Anticosti presents a complex problem for the logging engineer. It would seem that with the abundance of timber and many swift running streams, this island would lend itself readily to development as a pulpwood limit.

The coast line, however, offsets the fine driving facilities to quite some extent. The island is fringed practically the whole way around with a limestone reef, extending from 500 feet to 2,000 feet in length, this being exposed at ebb tide. Beyond this, a depth of 20 feet at low water is not usually obtained within another 1,500 feet, so that a close approach to the shore by a large vessel is out of the question in many cases. There are indentations in the reef at several of the river mouths, but these are too small and too shallow for anything larger than a small schooner. The three natural harbours of the island are Fox bay, Ellis bay and Bear bay. Each of these bays is protected on three sides and form a natural basin in which to anchor ships, unless the wind is from the unprotected quarter.

Of these three bays, however, Bear bay is the only one with a natural depth of water sufficient to accommodate a 3,000-ton vessel in the protected portion of the bay. Fox bay has a depth of 12 feet at low water in the harbour, Ellis bay has a natural depth of 12 feet at the wharf, but this was increased to 20 feet at low water by dredging.

Figure No. 19.—Pulpwood Trapper being Raised from Concentrating Basin with Load of Pulpwood.

Referring to the map, figure No. 2, it will be seen that, unfortunately, none of the above-mentioned harbours occur at the mouth of one of the large rivers; in fact, Ellis bay is on the western extremity of the island and Fox bay is on the eastern extremity, so that the drainage to these points must naturally be very small. Besides this, the timber is much more dense in the wider central portion of the island. Of the 14,000,000 cords standing there are but 1,500,000 cords of wood within a radius of 25 miles of Ellis bay, and less than 1,000,000 within a radius of 25 miles of Fox bay. To utilize either of these places means extensive towing around the coast or transportation by railroad. It was decided that before going further, both of these methods would be given a fair trial on a working scale.

From experience so far, it would appear that towing wood loosely in raft is practical up to a distance of 25 miles. This may be increased by the use of solid wood rafts, such as are used on the coast of British Columbia. The railroading of pulpwood is being carried on economically up to this distance by several concerns in Canada. The topography and nature of the ground surface on the western portion of the island is very favourable for the construction of logging railroads, and at present a survey is being carried on to determine possible location and estimate the economical advantage of extending the present railway further down the island.

The central portion of Anticosti, with 12,000,000 cords of standing timber, is the section in which we are particularly interested. The logging of this portion will require the construction of two loading plants, one on the north

Figure No. 20.—Pulpwood Trapper Discharging Load of Pulpwood into the Ship.

shore and one on the south shore. Bear bay offers the most favourable harbour site on the north and undoubtedly will be developed in connection with a future programme. The south coast has no natural harbours, apart from Ellis bay. However, the Jupiter river entering the sea 50 miles from the west end of the island affords a favourable site for the development of an artificial harbour. By constructing a breakwater 1,200 feet long and dredging a ship basin ample protection can be secured. Three-quarters of a mile from the sea the wide valley of this river narrows down to 700 feet. Here a dam with a 30-foot head will provide a log storage of 100,000 cords. From this point the wood may be conveyed by flume directly to the ship.

Water Powers

In connection with the preliminary survey of harbours it has been thought advisable to examine any available water power which might be used for the operation of a mechanical loading plant.

Fifteen miles from Bear bay, on the Vaureal river, is found an interesting site for a small hydro-electric plant. Ascending the river 7 miles, one finds it running in a limestone canyon, about 500 feet wide, with perpendicular walls 200 feet high on either side. A mile up this canyon is situated Vaureal falls, having a perpendicular drop of 170 feet. The rapids above have a combined drop of 30 feet, so that the total available head is 200 feet. Visiting the falls in December, the river was found to be discharging 200 second-feet. The minimum low water flow is not known.

The Quebec Streams Commission have measured the flow of many of the rivers along the north shore of the St. Lawrence, and their experience has led them to use the figure 0.33 cubic feet per second per square mile when estimating the probable extreme low water flow for those rivers, on which records have not yet been established and which lie in approximately the same longitude as Anticosti.

Extreme low water conditions occur in the season between December 1st and April 1st, and are due to extreme cold and the fact that precipitation in the form of snow does not act to augment the flow of the river until the thawing season begins. For the purpose for which this power would be required during the loading season, the basis of estimating the power available should be the probable minimum rate of flow for the rivers between April 1st and November 1st. No data is available for establishing this except as before stated, by comparison with other rivers on the mainland whose records have been kept. From such a comparison a minimum flow during this period of 0.8 cubic feet per second per square mile has been assumed.

Without artificial storage, this flow with a head of 200 feet would give a continuous output of 600 h.p., or with a load factor of 40 per cent would warrant the installation of 1,500 h.p. of hydraulic machinery. It may be said that the river above the falls is not suitable for the construction of storage dams. The headwaters rise in a flat muskeg which is favourable to the retention of water and which will prevent the disappearance of the river during a long spell in the summer.

The Jupiter river is approximately 50 miles long, rising in shallow lakes at the centre of the island. It is estimated that its extreme low water flow between April 1st and November 1st is 200 second feet. By the construction of a dam on lake Wickenden, a storage of 368,000,000 cubic feet could be obtained, which would serve to augment low water flow, adding to it 66 second feet over a period of two months. A dam site for a power development on the Jupiter river is located 5 miles up from the sea. A head of 20 feet can be obtained, with a dam 400 feet long. The river bed is exposed limestone ledge. With this head and a regulated flow of 266 cubic feet per second, 475 h.p. could be developed, at 80 per cent efficiency, allowing an installation of 1,180 h.p. on 40 per cent load factor.

Lapped Pipe Joints

An Outline of the Evolution of the Pipe Joint and Its Development to Meet the Increase in Pressure in Modern Pipe Lines

Arthur M. Houser,
Engineer of Product, Crane Company, Chicago, Ill.

Paper read by J. O. Lange before the Montreal Branch of The Engineering Institute of Canada, October 18th, 1928

It seems appropriate before discussing the details of the subject of the lapped joint, or the Van Stone joint as it is probably more popularly known, to sketch briefly the engineering evolution of this type of pipe joint now so universally recommended for high pressure work in the power plant, oil industry, and in manufacturing processes in general.

Larger boiler units and prime movers have been consistently producing higher steam pressures and temperatures and thus have introduced many perplexing problems to the valve, fitting and piping designers. Today a leaky piping system or a blown gasket, causing a shutdown, is a very serious and costly matter as compared to that of former times. We can appreciate the importance of this last statement when we realize the increase in " commercial " steam pressures from perhaps 35 pounds per square inch in 1855 to and in excess of 1,400 pounds at present.

A brief historical review of the increase in steam pressures and temperatures will add background to the story of the development of pipe joints designed to hold these pressures. In the following statements no attempt has been made to record the early experimental development. In most cases the references are to installations typical of the advanced practice in their day, and this historical résumé, except for later modifications, is taken from the July 1925 issue of " The Valve World," the house organ of the Crane Company.

From 1855 to 1865 the meagre available records indicate that steam pressures ranged from 30 to 50 pounds. From an early issue of Harper's Weekly, dated August 31st, 1861, we find the following headline:—

> " Twenty-three gun boats to be built for the Government. Each boat to have two boilers, of Martin's patent, placed side by side. The boilers will be furnished with draught from a blower engine and a Dumphel blower.
>
> " Each boiler will be complete in itself so that they can furnish steam to both or either of the engines. A working steam pressure of 30 pounds above the atmosphere is required of them . . ."

In 1857 some experimental work was done with steam at 35 pounds and with superheat temperatures ranging from

Table No. 1.—Physical Qualities of Metal before and after Lapping.

PERCENT REDUCTION OF AREA	67.7	69.0

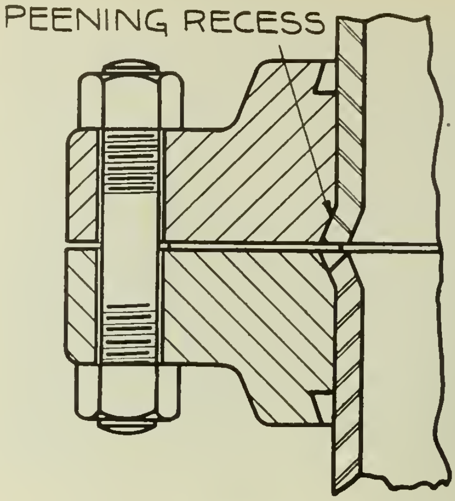

Figure No. 4.—Shrunk and Peened Joint.

410 to 490°F.; but in 1883, the use of superheated steam was discontinued, and the reason given was that the pressures had gone beyond 60 pounds. The Adams street station of the Commonwealth Edison Company, Chicago, was built in 1888, and operated at 125 pounds. About 1890, the Pennsylvania Railroad completed a power plant at Altoona, Pennsylvania, operating at 150 pounds.

Perhaps the next evidence of the increasing pressures was the Wabash avenue station, Chicago, of the Commonwealth Edison Company, built in 1891 and operating at 175 pounds. Other stations were erected by the same company in 1903 and 1912, to operate at 200 and 250 pounds respectively. A pressure of 285 pounds was used at a plant built by the Buffalo General Electric Company in 1917. The Joliet plant of the Public Service Company of Northern Illinois, built in 1917, and the Calumet station of the Commonwealth Edison Company, Chicago, built in 1922, operated at 325 pounds.

Several central stations were constructed during 1923 to operate at pressures ranging from 375 to 400 pounds. Notably among these are the Weymouth, (Edgar), station of the Edison Electric Illuminating Company, of Boston; the Waukegan station of the Public Service Company of Northern Illinois; the Saginaw river station of the Consumers Power Company, and the Grand Tower station of the Midwest Utilities Company. In 1925, the Crawford station of the Commonwealth Edison Company of Chicago and the Philo station of the Ohio Power Company were operating at 600 pounds. The highest pressures used on a large scale today are in the neighbourhood of 1,400-pound installations at the Lakeside station of Milwaukee Electric Company; Northeast station of the Kansas City Power and Light Company, and the Edgar station of Edison Electric Illuminating Company of Boston. Consideration is being given to the use of 2,000 pounds per square inch for central station work.

The use of superheated steam, which was discontinued about 1883, again became commercially successful about 1898 and since that time the temperature has increased to 750°F., which is the total temperature at the 1,400-pound stations operating today.

The great rise in pressures and temperatures has been by no means confined to the field of steam engineering, for there has been a more rapid and greater increase in the pressures and temperatures in the oil refineries and cracking plants. It was only about ten years ago that oil processes required pressures slightly above atmospheric pressure and temperatures up to 550°F. This was followed by pressure increases to 25, 80 and 110 pounds with temperatures running to 700, 800 and 900°F. New processes were developed, causing the rise in pressures to be very pronounced, starting from 150 and 250 pounds to 500, then 1,000 pounds, and today 1,500 pounds is popular practice. The extreme pressures found in process in the oil industry today approximate 1,500 pounds with attendant temperatures of 1,000°F. Serious consideration is in effect at present of using 3,500 pounds per square inch at 900°F.

In the earlier days of steam engineering, when 125 pounds per square inch was considered a relatively high pressure, the screwed or threaded pipe joint was in common use and was considered safe and reliable for any pressure

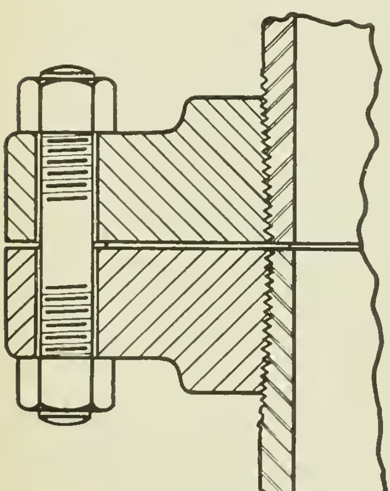

Figure No. 1.—Plain Screwed Joint.

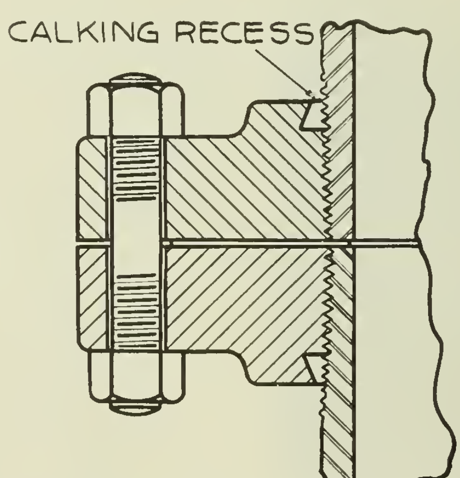

Figure No. 2.—Screwed and Calked Joint.

Figure No. 5.—Rockwood Joint.

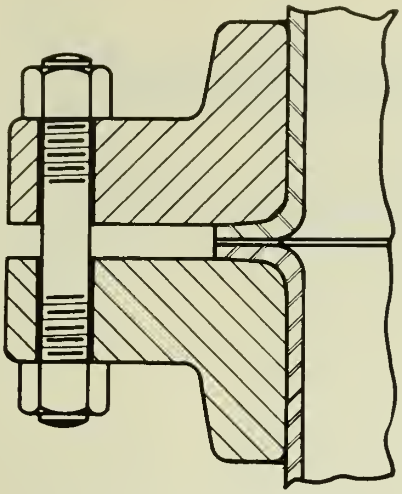

Figure No. 6.—Van Stone Joint.

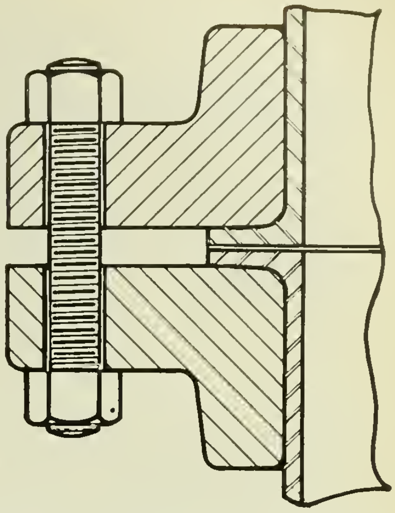

Figure No. 7.—Plain Face Cranelap Joint.

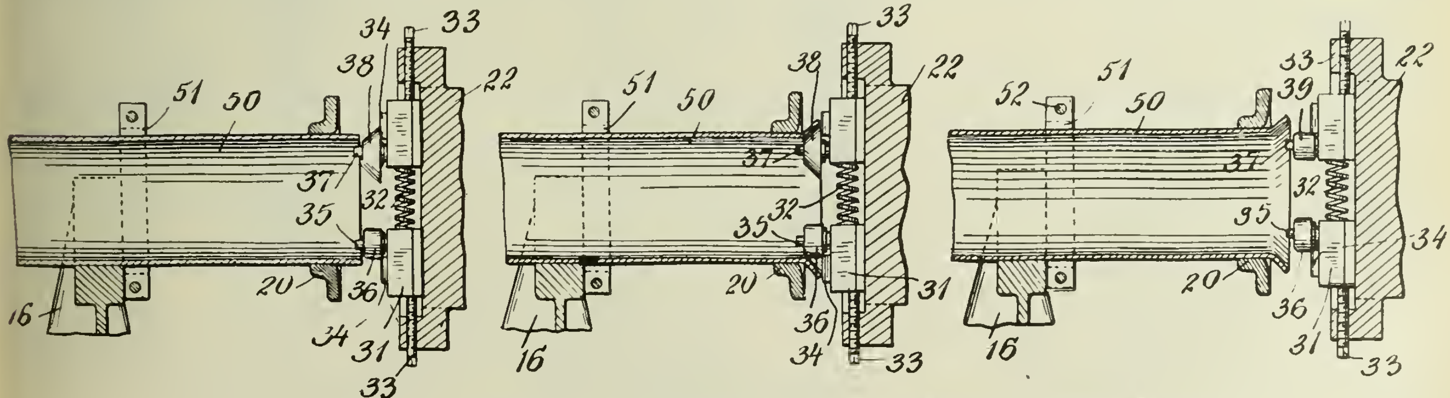
range then carried on the boilers. Originally the screwed flange was simply a flat ring tapped to fit the threaded pipe and provided with drilled holes for bolts. Later the hub was added to the flange for strength. (See figure No. 1 for typical joint with hubbed flange.)

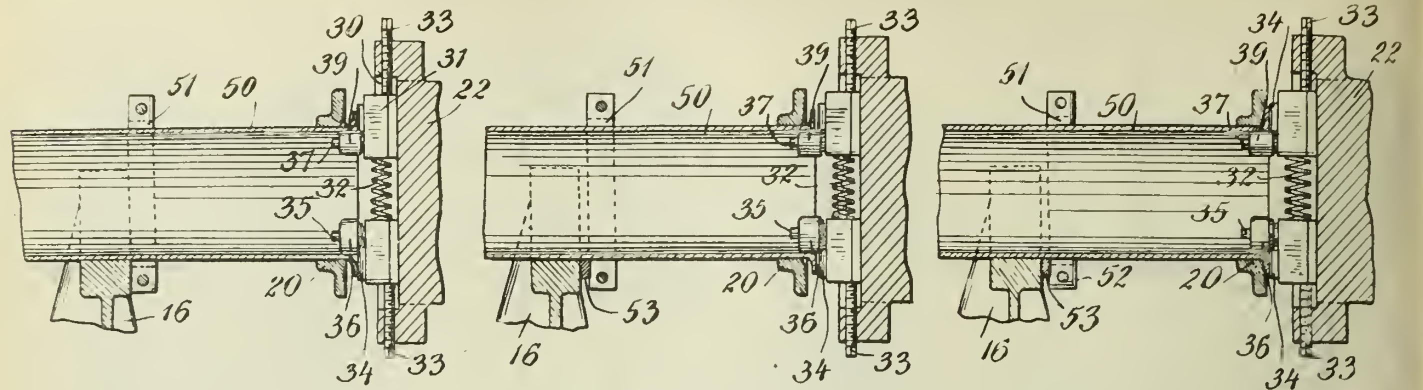
Originally the screwed joint differed from that shown in the illustration in that full face gaskets were used, extending from the inside edge of the pipe to the outside edge of the flange, covering the entire area of the face of the flange and end of pipe except for the bolt holes. This practice, according to records, seems to have been evolved from old time marine work. During the early nineties when higher pressures were considered, it was thought wise to reduce the gasket area. At that time it was felt that with these higher pressures the resultant load per square inch of the full face gasket would be small; and that a slight transverse stress produced by expanding pipes would open the joint on one side, thereby causing a leaky joint. The tongue and groove joint, which will be illustrated later, was introduced at this time. The groove also has the merit of protecting the gasket from displacement or being forced out in part by the pressure of the bolts. The gasket is also protected from being blown out if slightly relieved on one side. The disadvantage of the tongue and groove is that the gasket is not readily renewable without opening the space between the pipes several inches, which is not always possible.

The 1/16-inch raised face, which is very common practice today, also has its history. The raised face of extra heavy iron flanged material, as made today, has its diameter just inside of the bolt hole and is raised 1/16-inch above the remainder of the face of the flange; ¼-inch raised face of a lesser diameter is used on the higher pressure steel flanges to take care of interchangeability with male and female face. About 1896 and 1899 the raised face was a live subject among leaders in steam engineering. The tongue and groove was in practice for some time before the raised face was considered. The flat face joint with full gasket was the most popular joint in those days. Heretofore, the flat face joint was made on the lathe and boring mill without any subsequent grinding of any kind, and without any special tooling or pains whatever to make sure of a true bearing surface. Some joint faces were made about 3/16-inch wide, and by making the flange heavy enough to insure stiffness, the bolt pressure would come on the joint and not at the outer edge of the flange. The trouble experienced with this practice was that the outer edges were drawn together and sprung when the bolts were pulled up to make a joint on the outside edge, thereby causing leakage through the bolt holes. These excessively heavy flanges overcame this difficulty in that the rough faces would knit without springing the flanges, but this was costly and remedied the condition only partially. The raised face came into common practice about 1904 to overcome the use of these excessively heavy flanges and to insure a tight joint to take care of the pressures of the time, (250 pounds). The raised face was introduced in the form of a " narrow Chipping strip " as wide as deemed necessary for all pipes; the joint was so designed that the surfaces in contact were inside the bolt holes. It became regular practice to use 1/32-inch raised face and this was used almost exclusively until the adoption of the 1914 iron standards for flanges, when the 1/16-inch face became standardized.

With the advent of larger central stations and the



Figures No. 8, 9, 10.—Consecutive Operations Performed on Pipe during Flanging Process.



Figures No. 11, 12, 13.—Consecutive Operations Performed on Pipe during Flanging Process.

steadily increasing demand for superheated steam at higher pressures, manufacturers were called upon to furnish pipe joints that would insure a higher all around factor of safety than was previously possible with the screwed joint. The trouble experienced with screwed joints might be traced to the fact that when the pipe, which is screwed into the flange, expands circumferentially, it tends to return again to its original dimensions when cooled, but the flange in time, due to other strains, structural, for example, takes a permanent set and does not return again to its original dimensions, increasing slowly on the inside diameter. This space between the threads on the pipe and the threads on the flange results in slight leakage, which is increased, as time goes on, by the oxidizing and erosive action of the steam and water.

Several novel and fairly successful methods have been devised to guard against this leakage through the threads in an effort to make good the screwed joint for the increasing higher pressures. Favourable results for that time have been obtained by cutting a caulking recess in the hub of the flange. (See figure No. 2 for this type of joint.)

This type as illustrated has stood the test of time quite well. The pipe is screwed into the flange to a steam-tight bearing, and the recess is then filled with soft copper or other suitable metal, which is caulked firmly in place.

Another method of making screwed joints, to guard against leakage through the threads, is to roll or peen the end of the pipe into a peening recess at the face of the flange after making the flange tight on the pipe. Such a joint is known as a screwed and peened joint, as shown in figure No. 3.

A step nearer the Van Stone joint was made when the shrunk and peened joint was first used. In making this type of joint, the flange is accurately bored out to a diameter slightly less than the outside diameter of the pipe. When heated to a proper temperature the flange expands and is forced over the end of the pipe. In cooling the flange contracts and grips the pipe all around its outside circumference with tremendous force. The end of the pipe is allowed to project slightly beyond the face of the flange and is peened over into the recess. If so desired, a caulking recess can also be provided; if a slight leak occurs the recess can be caulked with soft copper. Figure No. 4 shows this form of joint.

As far back as June 20th, 1895, an article appeared in the magazine, "Engineering Record," in which Mr. George I. Rockwood describes, in a letter to the editor, his joint for higher steam pressures. This is the first written information we have found on the joint known today as the Van Stone joint. This letter brings out many interesting features that are used in the present day:—

Pipe Fitting for Heavy Steam Pressure

Worcester, Mass.,
June 18, 1895.

To the Editor of the Engineering Record:

Sir: Believing it would be of interest to your readers, I send you a sketch showing a form of pipe fitting that I have used successfully in some large sized steam piping subjected to a steam pressure of 150 pounds per square inch. The greater part of the piping now in use has, I believe, the flanges screwed

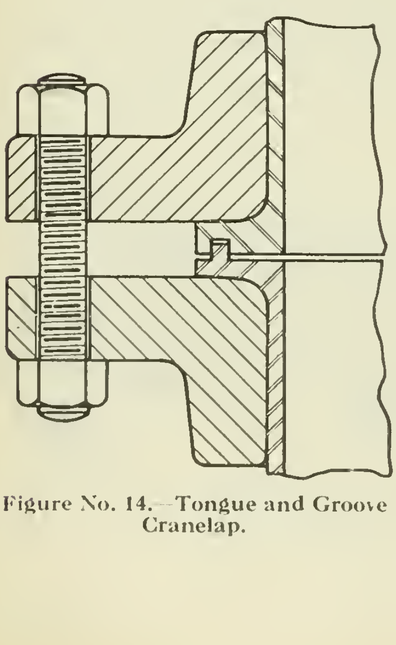


Figure No. 14.—Tongue and Groove Cranelap.

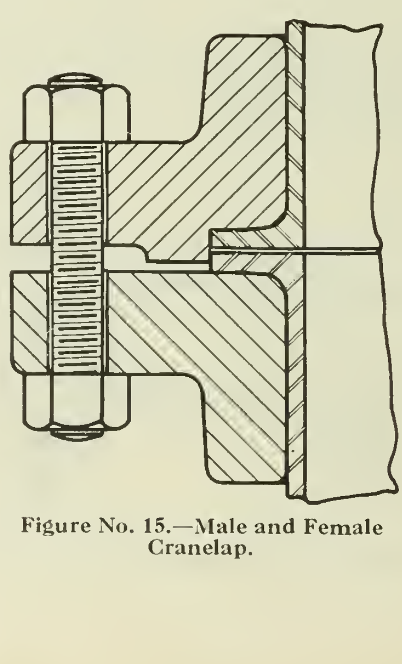

Figure No. 15.—Male and Female Cranelap.

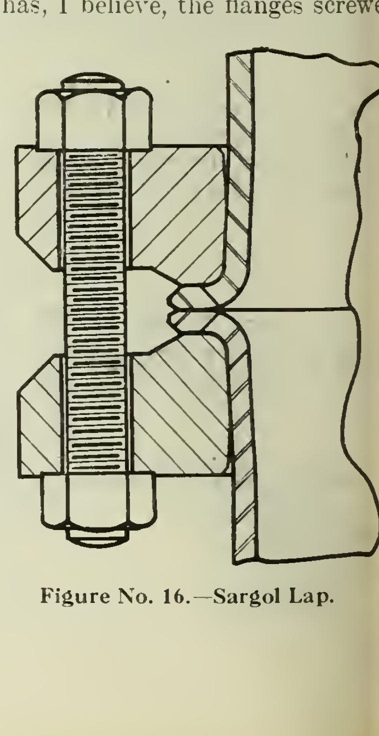

Figure No. 16.—Sargol Lap.

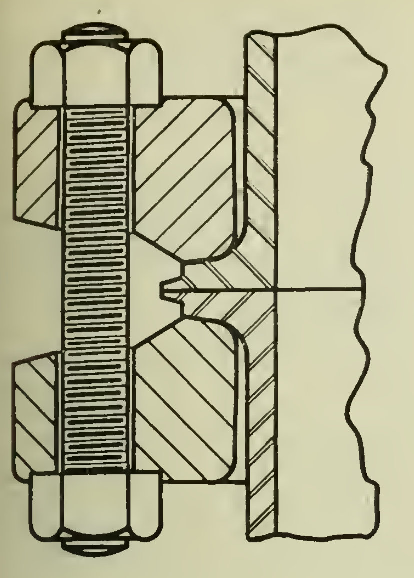

Figure No. 17.—
Square-corner Joint.

or riveted onto the ends of the lengths of pipe. Either method of fastening leaves something to be desired, as if any leakage occurs after the pipe is erected and the pressure on, the flange has to be removed and thrown away if screwed on, and if the rivet fastening be adopted and caulking is relied upon to make the joint then the pipe must at least be taken down before the leakage is stopped.

With the idea of partly overcoming these difficulties I made use of the flange shown in the accompanying sketch. A cast iron flange is bored out a rather close fit to the pipe, its face is turned to the section shown and the flange is then slipped onto the pipe and temporarily left some distance on from the end. The blacksmith then heats and flanges over the end of the pipe, (which must be a steel boiler flue, as iron pipe will not permit this flanging process), and moving the cast flange up to the heated end he moulds the two flanges together.

A very few ⅞-inch rivets are used to make the cast flange fast to the pipe, enough only to take any subsequent strains from the flanged end, it being thought unwise to allow the push and pull of the line to come upon the metal of the pipe after being so roughly treated as in the flanging process. I put six rivets into 10-inch pipe.

A length of tubing, after being thus flanged on each end, is placed in a lathe, straightened and faced. The outside portion of the face of the cast flange is beveled off as shown in order that a caulking tool may be inserted between the two faces to close up the joint made by abutting ends of pipe. Although I used corrugated copper gaskets, painted on each face with red lead and boiled oil to insure against leakage, yet if at any future time the joint gives any trouble, the mild steel edges of the pipe flanges are there and can be caulked.

A diameter of 10 inches is about as small as is practical to join together in this manner, although I have used the joint on 8-inch piping. The main object of the design is to avoid the possibility of a leak under the cast flange.

(Signed) George I. Rockwood.

Mr. Rockwood's pipe joint was patented in the United States April 6th, 1897. The joint as patented differs slightly from the original idea in that a bead is formed in the pipe, fitting a groove in the flange instead of the rivets. This was used to prevent longitudinal movement of the flanges in the process of making the joint. In the discussion of Mr. A. F. Nagle's article, "Pipe Flanges and Their Bolts," which is recorded in the 1899 Transactions of the American Society of Mechanical Engineers, Mr. Geo. I. Rockwood refers to his joint and mentions Mr. Van Stone in connection with the making of these joints.

The Rockwood joint, minus the bead or rivets, is in principle the "Van Stone joint" of today.

The differences between the Van Stone and Cranelap joints can be seen from figures Nos. 6 and 7. The improvement of the Cranelap joint consists in rolling the joint to a square corner surface at the inside edge of the lap, giving wider bearing surface for the gasket and at the same time eliminating a water pocket at the joint. The elimination of this pocket, which is always present with round cornered joints, means more even and uniform expansion and contraction throughout the joint. Corrosion is more apt to set in with the round cornered joint, due to lodging of sediment and condensate, which is present in all lines.

In making the Cranelap joint the flange is bored out to fit loosely over the outside diameter of the pipe and is placed some distance from the end. The end of the pipe is heated to the required temperature and then placed in a special machine where the rolling is done. The end of the pipe is flared out in the lapping process, the rollers forcing the pipe over and at the same time forming a square corner at the inside edge of the lap. The face to face dimension is then checked and if inspection shows that the lap is satisfactory the pipe is allowed to cool slowly. The face of the lapped over pipe is machined to a true gasket bearing surface, which will insure a steam tight joint.

Figure No. 8, taken from one of our basic pipe-flanging machine patents, shows the consecutive operations performed on the pipe while in this special constructed mechanism. As shown in this illustration, the pipe is set in the machine, projecting the end of the pipe, through the forming die, the correct amount to form the lap. The strap collar (*51*) is securely fastened to the pipe, abutting the collar against the stop-bracket (*16*). All the parts are so adjusted that the pipe will be held with its axis in alignment with the axis of the rotating disc (*22*). After the end of the pipe is heated to a good forging temperature it is placed in the machine with the heated end projecting through the forming die and the strap collar abutting the stop-bracket. The pipe is securely held to prevent turning.

The operator forces the carriage toward the rotating disc to make sure that the strap collar is securely held against the stop-bracket. The conical flaring roller is forced against the heated end of the pipe, bending the pipe outwardly as shown in figure No. 9.

As soon as the flaring of the pipe is done the carriage is drawn back away from the rotating disc and the conical roller is removed, putting in its place a cylindrical roller (*39*). Figure No. 10 shows the parts ready for the next step.

Again the carriage and pipe are forced toward the rotating disc. This time all of the rollers (*34, 36* and *39*) will act upon the pipe, forcing its heated end against the forming mould as shown in figure No. 11. A flange of desired shape and size will thus be formed.

But in order to perfect the flange and to increase its strength the process is carried on further. The carriage is again withdrawn and the mould (*20*) is loosened so that the flanged end of the pipe may be moved through the mould into the position as shown in figure No. 12. It will be noticed that a wedge (*53*) is thrust between the strap collar and the stop-bracket, the mould is tightened and the carriage is again advanced toward the rollers in the rotating disc.

The metal is forced between the mould and the rollers,

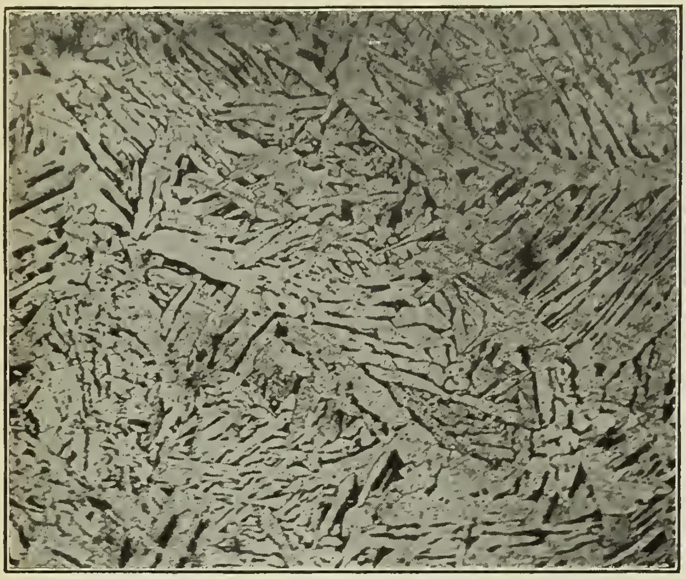

Figure No. 18.—Open Hearth Pipe before Lapping Operations.

thereby increasing the density and strength, as illustrated in figure No. 13. The pipe is removed from the machine and allowed to cool slowly.

The faces of these laps are made in several different ways. The best method of attaching flanges to piping used in power plants is so much a matter of individual preference that it is necessary to furnish pipe work with various styles of joints to conform with the ideas and experience of different engineers.

The square cornered Cranelap joint, (figure No. 7), was first introduced in 1911. In 1921 the full thickness lap was developed, which is made much stronger than the pipe even after refacing for the gasket bearing surface. A gasket is regularly furnished with this joint, although the manufacturer is prepared to furnish the faces with a smooth lathe finish ready for grinding to a metal-to-metal or ground joint if so desired by a customer. This joint with full metal thickness at the lap can be used successfully on the present day high pressures. The plain straight face Cranelap is in reality a raised face joint. The diameter of the lapped over pipe was not standard until in 1920 when it was suggested to use the diameter of the raised face as given for flanges approved by the American Engineering Standards Committee. Today this is regular practice.

Some engineers prefer the tongue and groove joint, (see figure No. 14). The dimensions for the small tongue and groove in the steel standards approved by the American Engineering Standards Committee are applied to the tongue and groove Cranelap, the lapping process of which has been developed to make the lap one and one-half times full pipe thickness, thereby insuring at least full metal thickness from the bottom of the groove to the back face of the lap. A flat metallic ring gasket is used.

Some of the present day piping is made with male and female joints. (See figure No. 15.)

Weld-sealed pipe joints without the interposed gasket have been used in many of the high pressure, high temperature central stations. Practically all the weld-sealed joints were made under the Sargol patent license until its recent expiration. The Sargol patented idea is shown in figure No. 16.

Welding lips on the Sargol joint are formed by machining the adjoining edges of the laps to a V-shape, into which additional metal is welded to form a seal. The back face of the lap is not machined in order to keep the " skin tension " of the material. A slight clearance is maintained between the outside diameter of the pipe and the inside diameter of the flange to permit swiveling around to line up the bolt holes. It will be noted from figure No. 16 that the Sargol joint has the round corners at the lap, and also that the pipe tapers; the object being to prevent complete rupture should the lap fail.

Some difficulties were encountered when welding the joint as shown in figure No. 16. In welding the Sargol joint, a filler rod is necessary to fill the V-shape gap. The welding requires a large amount of heating, and this intense heat concentrated at the extremities of the lap causes uneven expansion and contraction, thereby separating the flanges around their inner circumference.

In order to overcome this difficulty a thin lip, weld-sealed pipe joint was introduced about two years ago, as illustrated in figure No. 17. This lap is rolled in the flanging process similar to Cranelapping as described before.

No additional metal is required for welding as the long thin lips are simply fused together. This seal is very narrow and thin, thereby requiring little heat in the welding operation. These weld-sealed joints are usually tested under the full pressure intended before the welding takes place, the joint being metal-to-metal.

In all Cranelap flanges, whether it be the plain face, male and female, tongue and groove, or the thin lip-weld sealed joint, the flange is machined with a tapered bore three-quarters of an inch per foot to furnish clearance between the flange and the pipe when the flange is backed off, allowing for swiveling to line up the bolt holes. This is an advantage over the screwed joint. There is another significance and important purpose for this tapering; that is, in the lapping operation when the metal is being worked, the taper aids in drawing out the point of crystallization, giving a much finer grain structure to the lap.

Pipes from 2½ inches to 30 inches are lapped regularly. Pipe as small as ¾-inch and as large as 48 inches have been lapped on orders. The weights of the pipe depend upon the type of service and the pressures to which these pipes will be subjected. Standard, extra strong and double extra strong pipe can be lapped, and so can copper, wrought iron, wrought steel and some alloy steels, while chrome-vanadium and molybdenum steel tubing have been lapped successfully.

As to temperatures, it is necessary to obtain a good forging heat in order to upset and roll the ends of pipe to a square cornered lap.

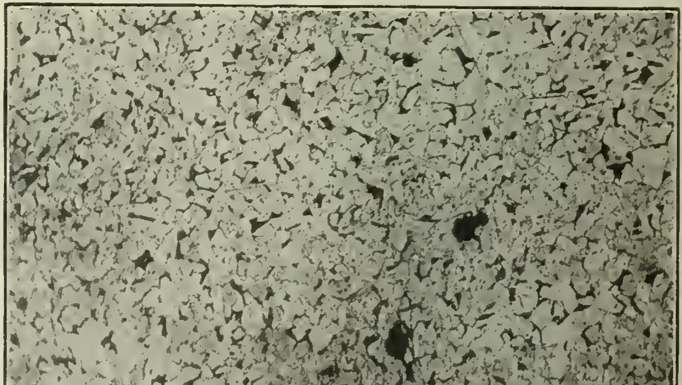

Figure No. 19.—Structure at Crotch of the Lap after Lapping Operations.

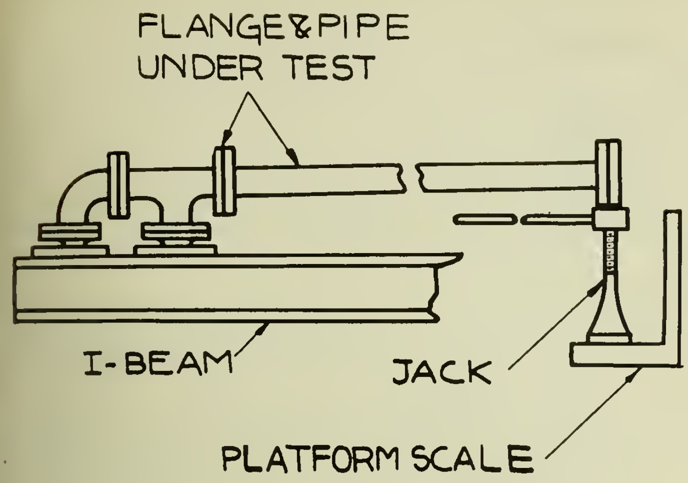

Figure No. 20.—Pipe Joint Flexibility Test.

Some years ago when the standardizing of fittings and flanges was a live subject, some question was raised as to the effect on the metal of the pipe at the lap and immediately adjacent thereto when considering the Van Stone joints. For years it has been our experience in general that the metal of the pipe is materially improved. In order to produce actual facts the Crane Company made a thorough study of the Cranelap joint from the physical and metallurgical aspect. The photomicrographic illustrations show the metal before and after lapping.

The section shown in figure No. 18 represents open hearth pipe as received before any lapping operations are performed. The crystals are somewhat needle shaped, irregularly arranged and not uniform. It is of particular interest to note the arrangement of the elements of the structure, its fineness and uniformity, as compared with that shown in figure No. 19.

The structure at the crotch of the lap, (figure No. 19), after the lapping operation, shows considerable improvement. The grain is finer and more uniform. The black spots in the lower right hand corner are not a result of working during the lapping operation but is the condition of the pipe as received. There is very little evidence, if any, of slag inclusion.

In order to further convince ourselves that the lapping operation does not injure the metal, but actually improves the condition at the joint, let us investigate the physical qualities before lapping and effects after. Tensile test bars per American Society for Testing Materials' Standard of 0.505-inch diameter were taken from a section of the lapped pipe shown in figure No. 19. The results as shown in table No. 1 are representative of the pipe metal shown in the photomicrographs.

The pipe is increased in strength at the lap but a short distance from the lap it is not affected by the lapping operation. The pipe appears to be slightly stiffer, as evidenced by the elongation figures. The fractures indicated a well worked metal and considerable ductility. The yield point is raised considerably.

To permit of a better understanding of the condition of the metal after Cranelapping the other tests will be briefly explained.

Brinell hardness tests indicated that lapping does not change the hardness of the metal as compared with the original condition of the pipe. Indentations were made respectively at the crotch of the lap, adjacent to the lap and some distance from the lap. These readings were taken to study across the section as well as the outside of the pipe.

Piping, no matter what the service may be, is subject to shock in some form. It is most essential that the joints be so designed and constructed as to resist shock. Some time ago a test was made in which several joints, namely, the screwed joint, the shrunk and peened joint, and the Cranelap joint, were made up on the end of respective pipes. Severe blows were applied with a sledge hammer to these joints; the Cranelap joint stood the test, holding its place, while the other two types were knocked off the pipe without much difficulty.

The material that goes into this lapped design should also resist shock. Therefore, an Izod impact machine was used to investigate the material of these various laps to resist shock; incidentally the homogeneity and ductility is also revealed in a qualitative and comparative sense only. The lapping affects the Izod impact value for a distance of six to nine inches back of the lap. Lapping increases the ability of the material to resist shock as much as three-fold in some cases.

To test pipe laps in a way equivalent to the service they are put to, when contracting or expanding forces are steadily pulling the pipe from its flanges, would necessitate the bolting of two lapped pipes together with flanges and applying a transverse or longitudinal force at the end of the pipes.

In reality, the type of joint that lends itself to the greatest flexibility under maximum strain is the safest and most preferable for high pressure and high temperature work. A test of this kind was made some time ago. Sixteen-foot lengths of pipe, having flanges screwed on, shrunk on, welded on and Cranelapped, were bolted to a well braced tee on a test rig, as best shown in figure No. 20.

An extra length of pipe was bolted to the length to be tested. A scale was used in connection with the jack screw in order to see just what effect a side strain or throwing out of line would have on the various joints. Thirty pounds per square inch of internal hydrostatic pressure was used in all cases.

Summarizing the results of this test we find that screwed joints failed before the other types, this failure taking place at the threads, due to a weakened section exposed outside of flange. Shrunk and welded joints, being rigid on the pipe, offer practically no flexibility if the pipe line is subjected to transverse strains, practically all the movement being taken care of by the stretch of bolts, compression of the gasket or actual bending of the pipe. Welding of pipe joints does not materially weaken the pipe back

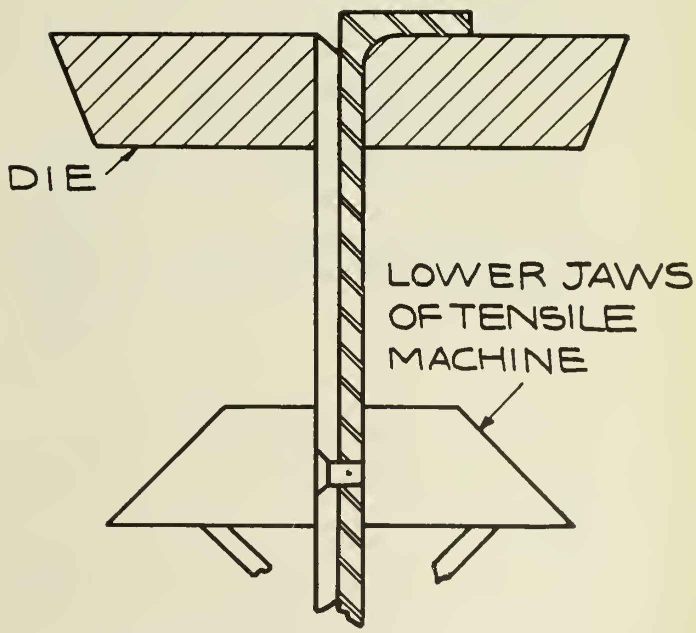

Figure No. 21.—Die Straightening Test.

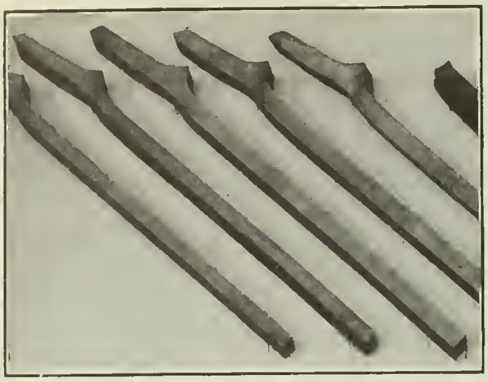

Figure No. 22.—Tensile Test Bars per A.S.M.E. Standard Taken from Section of Lapped Pipe.

of the flanges by the process in the Cranelap joints as our tests showed no signs of failure until the pipe was subjected to strains well beyond those which would occur in service.

In order to further study the effects on lapped joints by applying extremely large longitudinal forces, and yet make this test complete by accurately measuring the forces applied, strips were cut from the laps, machined to 1¼ inch wide and pulled in a tensile testing machine through a die, as shown in figure No. 21. The results are best explained by figure No. 22.

From this die straightening test it is only evident that the lapping leaves the pipe in a very satisfactory condition, permitting straightening without tearing the lap at the crotch.

Last year when the Crane Company was making certain investigations on lap welded pipe, numerous pipes were burst. The pipes were made up with the square corner Cranelap and bolted to blind flanges. Internal hydrostatic pressures as high as 5,000 pounds per square inch were reached before the bursting took place.

It can be seen from figure No. 23 that the break did not occur at the lap or adjacent thereto. The break in all cases had the same characteristic shape. This should be conclusive proof that the lapping operation does not put the pipe in a poorer condition.

Incidentally, an article that relates to this talk appeared in the June 12th, 1928, issue of " Power," written by Mr. I. W. Whittle of the Southern California Edison Company on " Pipe Joints That Will Hold at High Pressures and Temperatures." Mr. Whittle gives the advantages of the different present day welded pipe joints. The following is quoted from his statements on the square-corner joint:—

> " The square corner type joint is manufactured by upsetting and forming the lap against dies in a machine. The heels of the two laps form a continuous inner wall in which there will be no pockets for collecting sediment and condensate. This forms a rigid joint with no possibility of bellows action due to expansion in the pipe. There is also more metal in this joint to form a bearing surface for the abutting laps.
>
> " It is the opinion of engineers who favour the square-lap joint that the fibre structure of the metal will not be ruptured, and that there will be no slag inclusions in forming this square-lap joint when the metal is worked at the correct temperatures. The back of the lap, forming a bearing surface for the flange, is slightly tapered and faced off to insure the flange bearing first on the innermost part of the back face of the lap.
>
> " Relatively long tapered lips are provided on the outer edges of the adjoining flanges, and no additional metal is required for the first welding, as the metal lips simply are fused together. It is the contention of users of this method of welding that the thin section welding lip prevents uneven heating of the lap and a separation of the flanges around their inner periphery."

In concluding, it may be said by summing up all the results of the tests given herein, that Cranelapping pipe improves the condition of the metal at the lap and adjacent thereto. Further, that continuing widespread usage for severe service and exceedingly high pressures and temperatures has proven the reliability and safeness of the square-lap joint.

66-kv. Cables of Montreal Light, Heat and Power Consolidated

Humphreys Milliken, M.E.I.C., Chief Engineer,
L. A. Kenyon, A.M.E.I.C., Assistant Chief Engineer,
Electrical Department, Montreal Light, Heat and Power Consolidated,
and
D. M. Simons, Development Engineer,
Standard Underground Cable Company.

Paper read before the Montreal Branch of The Engineering Institute of Canada, April 21st, 1927

The Montreal Light, Heat and Power Consolidated has recently completed a 4,000-volt distribution substation in the heart of the city of Montreal where the density of the load is such as to require an ultimate station capacity of approximately 90,000 kv.a. two-hour rating. This station is known as the Vallee Street substation. In order to feed this station economically, it was found advisable to adopt a voltage of 66,000. This necessitated underground cables of this voltage, as the station is located in the underground district of the city.

A general diagram of this 66-kv. system is shown in figure No. 1. There is a double 66-kv. ring around the city consisting of two overhead 66-kv. circuits. One of the 66-kv. circuits is looped into each important substation in the city and, in certain cases, both of the 66-kv. circuits are carried into the same station. Each of the two rings is thus sectionalized at a substation and relayed so as to provide selective protection of the different sections, i.e., a fault on one section of the ring will open only the circuit breaker at each end of the faulted section, thus clearing only the section of the line which is faulted. The power will then flow around the ring in the other direction and there will be no interruption of supply to any substation.

The 66-kv. cables form a part of this ring and are therefore required to carry the load of Vallee station and, in addition, the load of one or more adjacent stations in case the ring is temporarily open circuited.

The length of the cable system is approximately 4,000 feet, the distance from the Vallee station to the overhead lines. The duct system so far constructed provides a duct space for three three-phase circuits, with one spare duct. The cables installed up to the present time consist of six single-conductor cables, constituting two three-phase circuits. When the third circuit is installed it will be arranged for connection in multiple with either of the two present circuits, according to which of the two present circuits is carrying the heavier load. (A diagram of connections is shown in figure No. 2.)

The cables at present installed are intended to supply the first half of the ultimate capacity of Vallee station. When the second half of the station is built the present cable system will be duplicated and connected to the second overhead ring.

Ducts and Manholes

The present 66-kv. duct system consists of ten ducts, two ducts wide by five ducts high, as shown in figure No. 3, which also shows a typical manhole and certain details. The conduits are 4½-inch fibre, with sleeve joints.

The station is located in an old section of the city

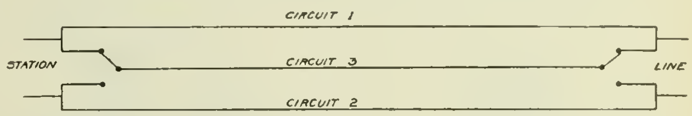

Figure No. 2.—Connections for Third 66-kv. Cable Circuit.

where the streets are very congested with existing underground obstructions. It was therefore necessary to place the 66-kv. ducts at an unusual depth to avoid obstructions. At some points it was necessary to go below the sewer levels. The deepest manhole is shown in figure No. 4.

The soil in several locations is very wet and, to take care of the unavoidable seepage, it was necessary to install sump pumps. These are arranged to operate automatically by means of a float valve, and are successfully preventing water from rising in the manhole. There are two corner

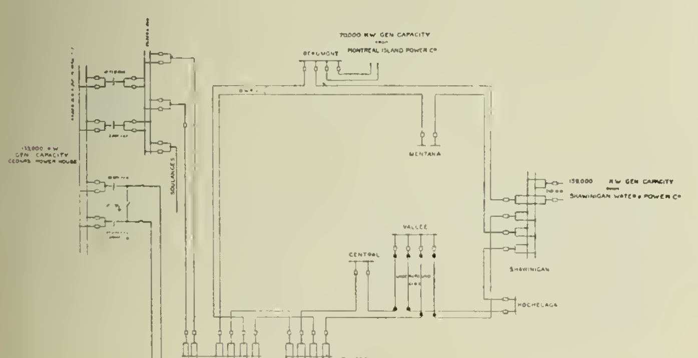

Figure No. 1.—Schematic Outlay for City of Main Transmission System and Substations.

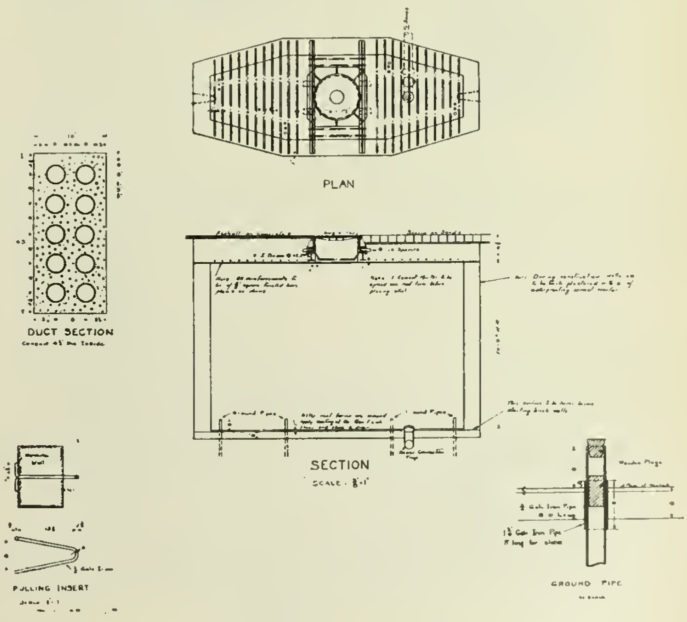

Figure No. 3.—Typical 66-kv. Manhole Details.

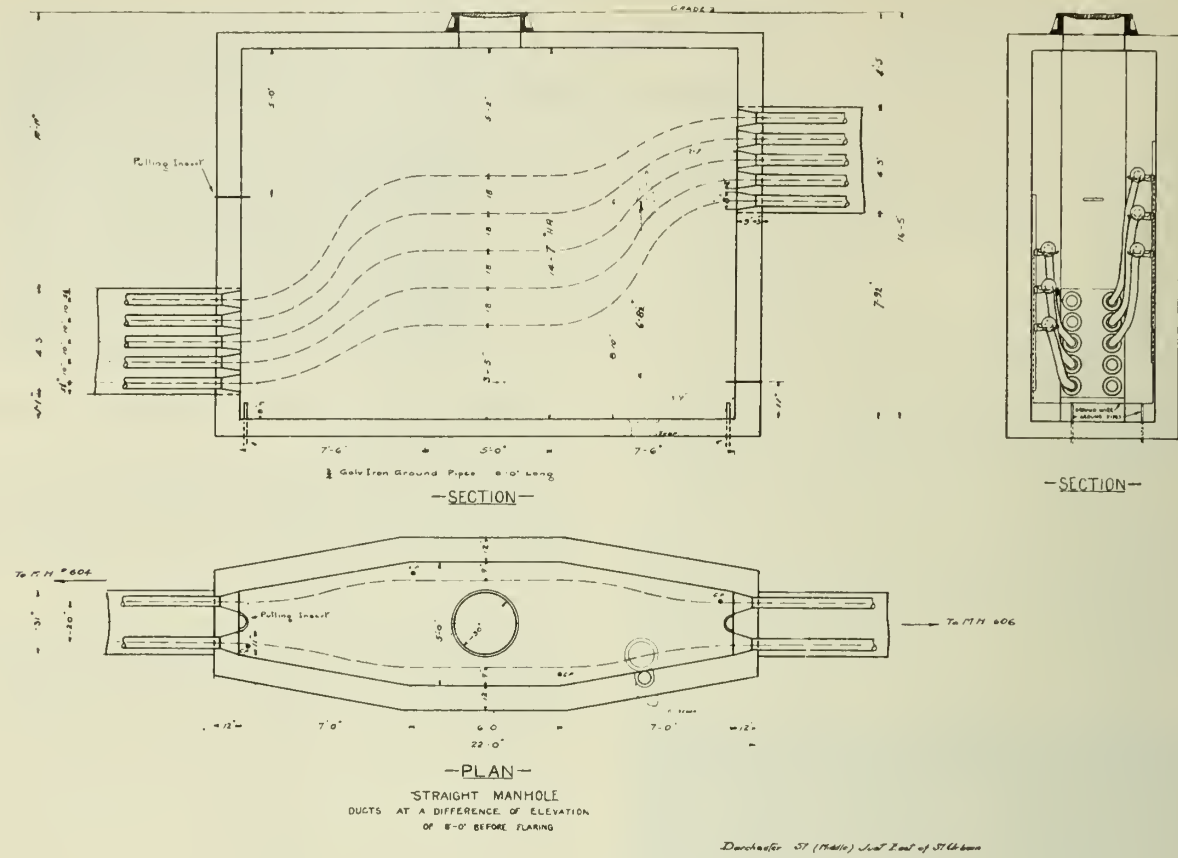

Figure No. 4.—Plan and Elevation of 66-kv. Manhole.

manholes in the system, one of which is shown in figure No. 5.

At the two ends of the line are specially large manholes, (see figures Nos. 6 and 7), to accommodate three-pole double-throw oil switches required for switching the future spare circuit in multiple with either of the two main circuits. Provision is made for operating these two switches electrically from Vallee substation.

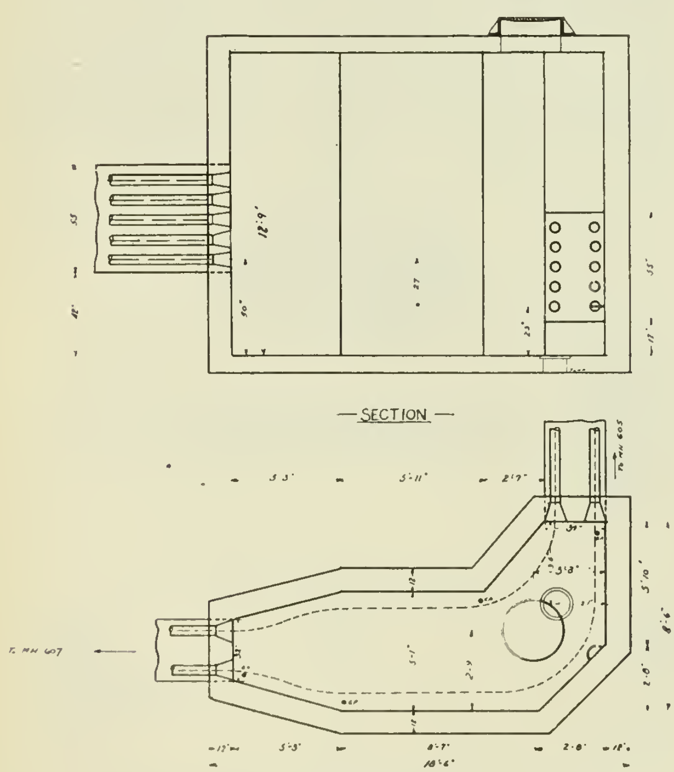

Figure No. 5.—Typical Corner 66-kv. Manhole.

66-kv. Cables

The cable is a single conductor, 750,000 c.m. strand, the conducting strands being laid around a spiral steel spring to assist in impregnation and in maintenance. The insulation thickness is 30/32-inch paper, surrounded with a 9/64-inch lead sheath.

Installation

Each length of cable was equipped in the factory with a pulling eye on one end, which saved considerable time in attaching pulling connections in the field. The cable was pulled in with a power winch on the regular cable truck. The maximum tension required to start a cable from rest was 2,780 pounds. The maximum tension to keep the cable in motion was 2,020 pounds. The average speed of pulling cable was 15 to 20 feet per minute. The length of pull was 308 feet straight away. A heavy grease was used for lubricating the cable during the pulling. The work was done during the month of December, 1926, with an outdoor temperature from 16°F. to 42°F. Each cable was pulled in within three hours after removal from the store room.

66-kv. Cable Joints

The line was completely jointed by the construction department of the Standard Underground Cable Company, using the design of joint developed by Mr. D. M. Simons, development engineer of the company.

As a preliminary to making the seventy-two joints on

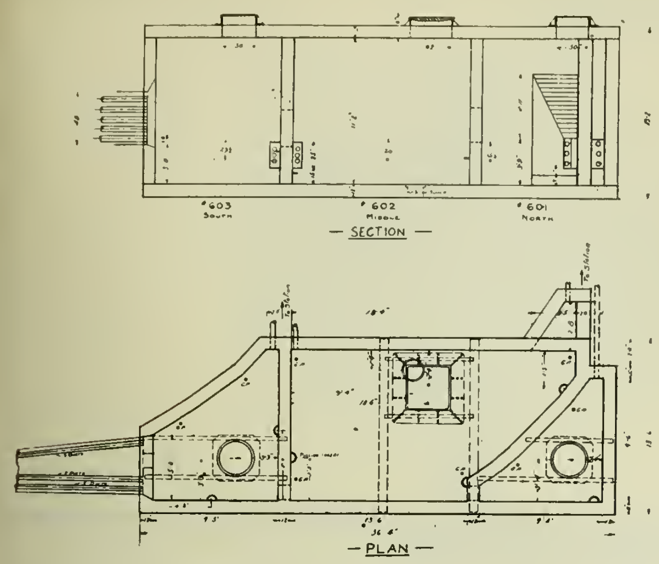

Figure No. 6.—66-kv. Manholes at Station End of Duct Line.

this cable the air in the manholes was heated and dried to a humidity of from 55 to 85 per cent. The heating was accomplished by means of an electric heater and gasoline furnaces and the air dried by passing it over calcium chloride crystals resting on shelves in a specially designed container. (See figure No. 8.)

Figure No. 9 shows the joint and indicates the various operations involved in its construction.

The ends of the cable to be spliced were trained to position and cut to length, after which the lead and paper for a distance of 1½ inches was squarely cut away by a special machine.

The two-piece lead sleeve was then slipped over the ends of the cable and a ⅜-inch cold rolled steel rod 18 inches long was pushed into each end of the hollow core cable for the purpose of preventing the compound from flowing out of the core during jointing.

The two ends of the cable were then joined together by

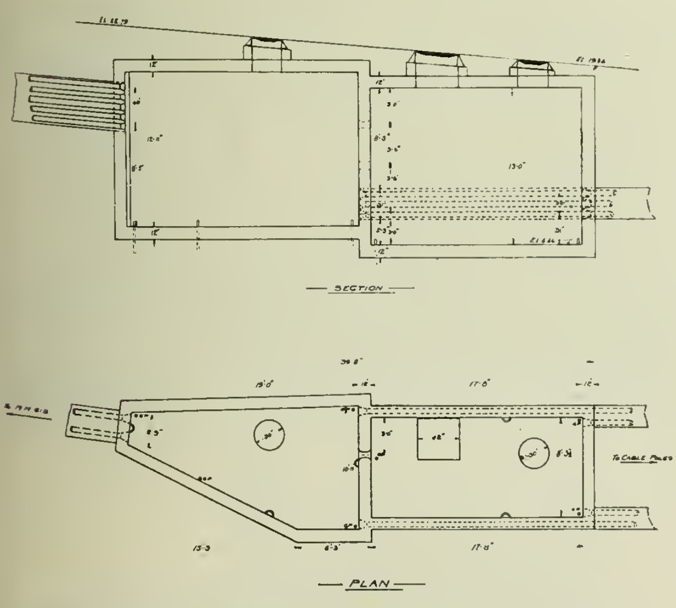

Figure No. 7.—66-kv. Manholes at End of Duct Line Connecting with Overhead System.

a slotted connector soldered into position and the lead sheath removed to a total length of 18½ inches from the centre of the joint.

The factory paper insulation was then removed to form nine 1½-inch steps and one 3½-inch step when a perforated metallized strip of paper 2⅜ inches wide was wrapped around the factory insulation and slipped under the lead sheathing for a distance of ¼-inch from the lead sheath.

Impregnated flax twine was used to fill up the small space between the connector and the paper insulation and form a smooth surface, after which impregnated paper tape was hand wrapped over the connector to a thickness approximately midway between the diameter of the second and third steps.

The remainder of the insulation was applied with a machine designed by the Standard Underground Cable Company and the lower half or frame of this machine was then fitted in place and bolted to the cable racks. Special impregnating compound at a temperature of 300°F. was poured over the joint to remove any trace of moisture from the insulation. The upper half or rotating part of the insulating machine was then installed, equipped with knives to cut the insulating paper to a proper width to fit the stepping as the machine rotated around the cable. This insulating roll of paper was 35½ inches long and the two strips of metal foil were attached to the roll of paper so that as the paper was wound on the joint, these metal strips made con-

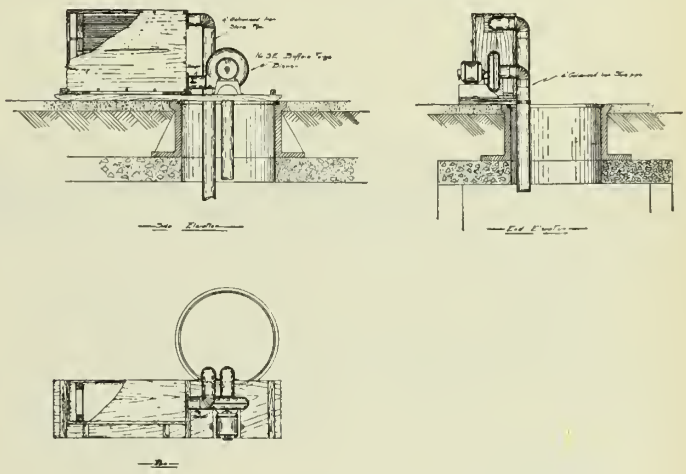

Figure No. 8.—Calcium Chloride Air Dryer.

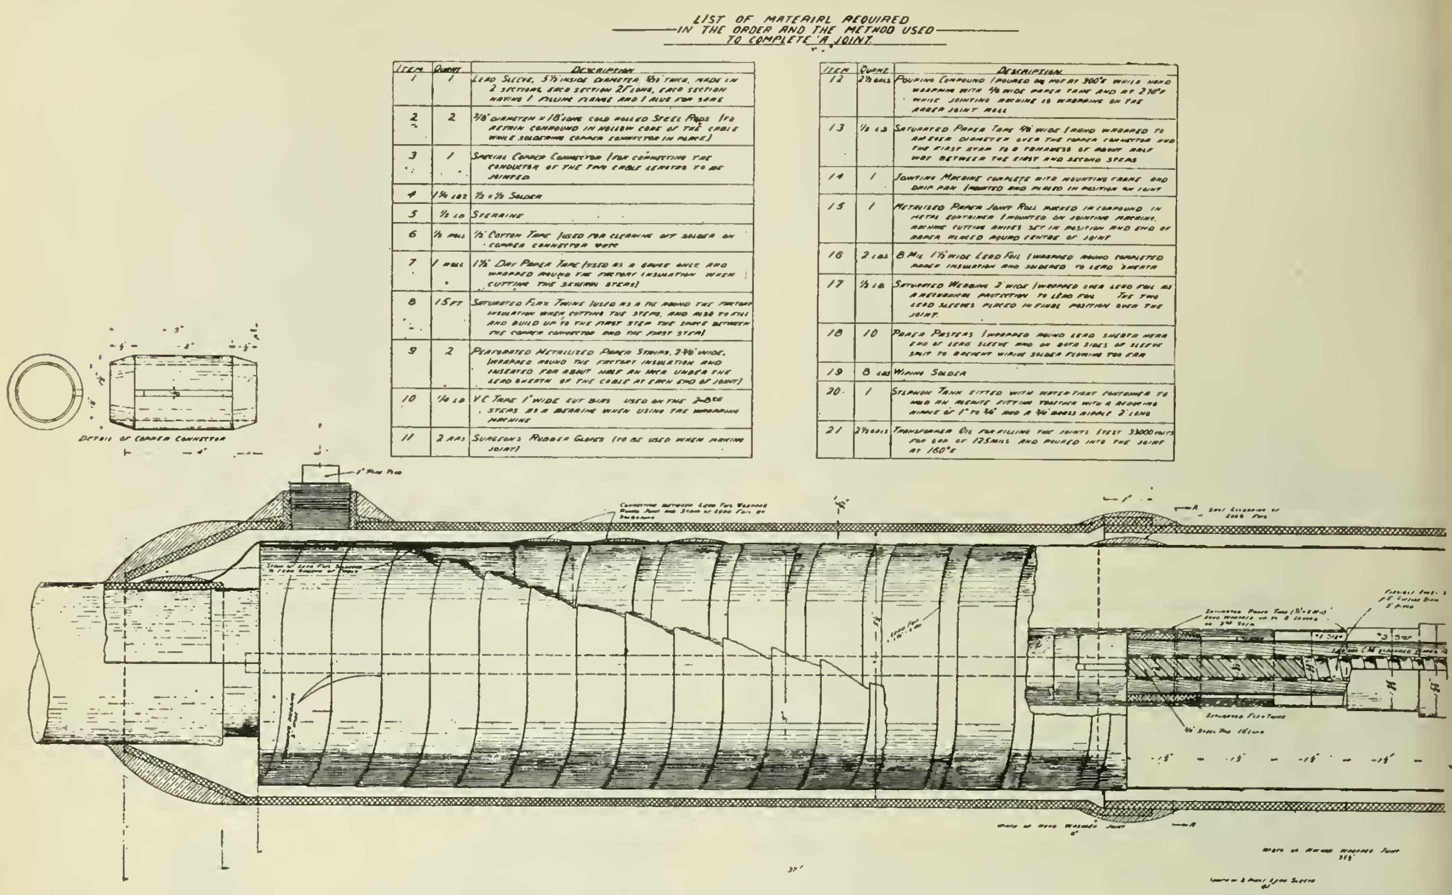
tact with the perforated metallized strips of paper and gradually worked in toward the centre of the joint to a distance of about 10 inches from the edge of the paper. This had the same effect as a metallic cone shield, and reduced electrical stresses on the insulation.

During the process of wrapping, impregnating compound, at a temperature of 270°F., was poured on the joint at each revolution of the machine and, when the wrapping was completed a metal foil ribbon was placed in contact with the two strips of metal foil and wrapped around the joint and connected to the lead sheath by soldering. This removed all electric stresses from the oil surrounding joint.

A layer of impregnated webbing was wrapped around the joint to protect the metal foil. The two sections of the lead sleeve were then fitted together over the joint and a wiped joint made at each end of the sleeve and at the



Item	Quant.	Description
1	1	Lead Sleeve, 5½" inside diameter ⅜" thick, made in 2 sections, each section 21" long, each section having 1 filling flange and 1 plug for same
2	2	⅜" diameter × 18" long cold rolled Steel Rods (to retain compound in hollow core of the cable while soldering copper connector in place)
3	1	Special Copper Connector (for connecting the conductor of the two cable lengths to be jointed)
4	1¼ lbs	½ + ½ Solder
5	½ lb	Stearine
6	½ roll	½" Cotton Tape (used for cleaning off solder on copper connector note)
7	1 roll	1½" Dry Paper Tape (used as a gauge once and wrapped round the factory insulation when cutting the several steps)
8	15 ft	Saturated Flax Twine (used as a tie round the factory insulation when cutting the steps, and also to fill and build up to the first step the space between the copper connector and the first step)
9	2	Perforated Metallized Paper Strips, 2⅜" wide. (wrapped round the factory insulation and inserted for about half an inch under the lead sheath of the cable at each end of joint)
10	¼ lb	V.C. Tape 1" wide cut bias used on the 2-8th steps as a bearing when using the wrapping machine
11	2 prs	Surgeon's Rubber Gloves (to be used when making joint)
12	2½ gals	Pouring Compound (poured on hot at 300°F while hand wrapping with ⅛ wide paper tape and at 270°F while jointing machine is wrapping on the paper joint roll
13	½ lb	Saturated Paper Tape ⅛" wide (hand wrapped to an even diameter over the copper connector and the first step to a thickness of about half way between the first and second steps
14	1	Jointing Machine complete with mounting frame and drip pan (mounted and placed in position on joint
15	1	Metallized Paper Joint Roll packed in compound in metal container (mounted on jointing machine, machine cutting knives set in position and end of paper placed round centre of joint
16	2 lbs	8 Mil 1½" wide Lead Foil (wrapped round completed paper insulation and soldered to lead sheath
17	½ lb	Saturated Webbing 2" wide (wrapped over lead foil as a mechanical protection to lead foil. The two lead sleeves placed in final position over the joint.
18	10	Paper Pasters (wrapped round lead sheath near end of lead sleeve and on both sides of sleeve split to prevent wiping solder flowing too far
19	8 lbs	Wiping Solder
20	1	Sylphon Tank fitted with watertight container to hold an ebonite fitting together with a reducing nipple of 1" to ¾" and a ¾" brass nipple 2" long
21	2½ gals	Transformer Oil for filling the joints (test 33000 volts for gap of 125 mils and poured into the joint at 160°F

Figure No. 9.—Details of

middle where the two sections joined together. The sleeve was then filled with insulating oil and made watertight by screwing down a plug in one flange at one end of the joint and installing a sylphon tank at the other end of the joint. This sylphon tank was also filled with oil and acted as a storage tank to replace any oil absorbed by the joint.

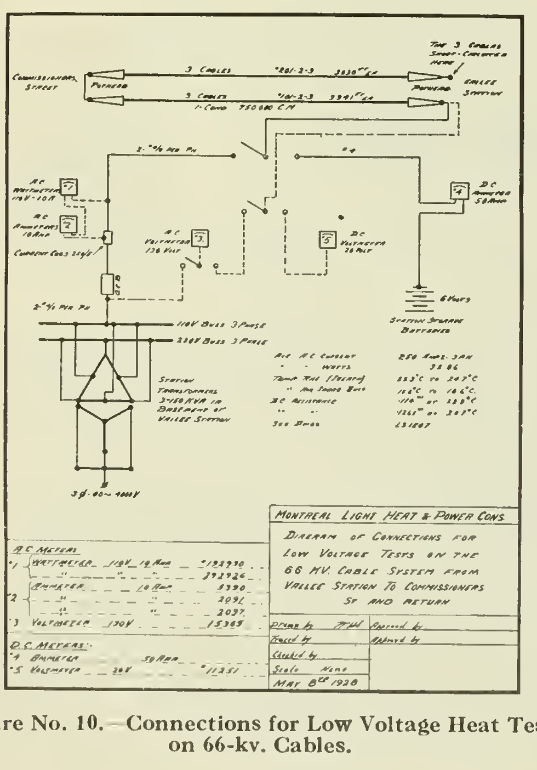


Figure No. 10.—Connections for Low Voltage Heat Tests on 66-kv. Cables.

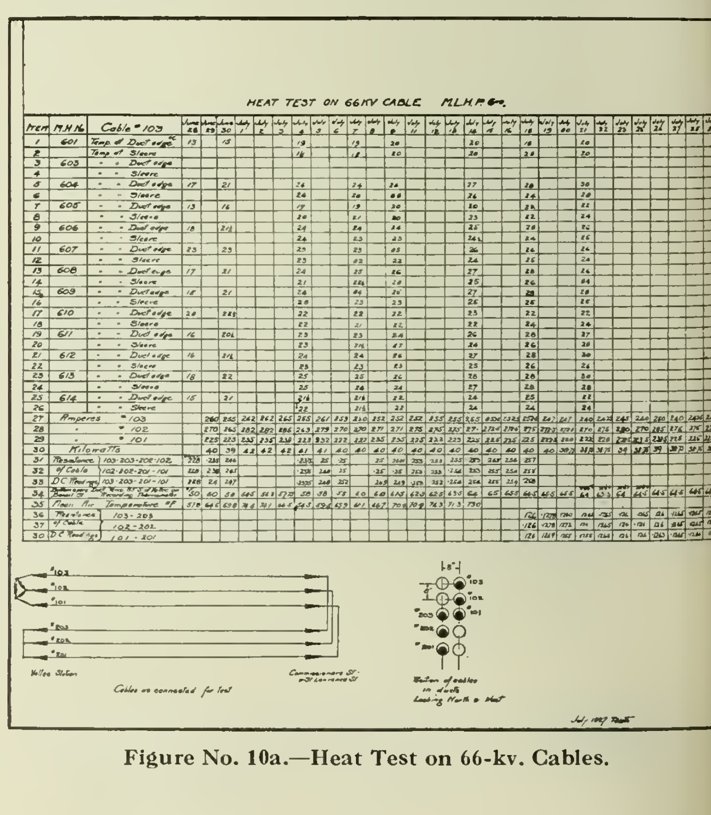

Figure No. 10a.—Heat Test on 66-kv. Cables.

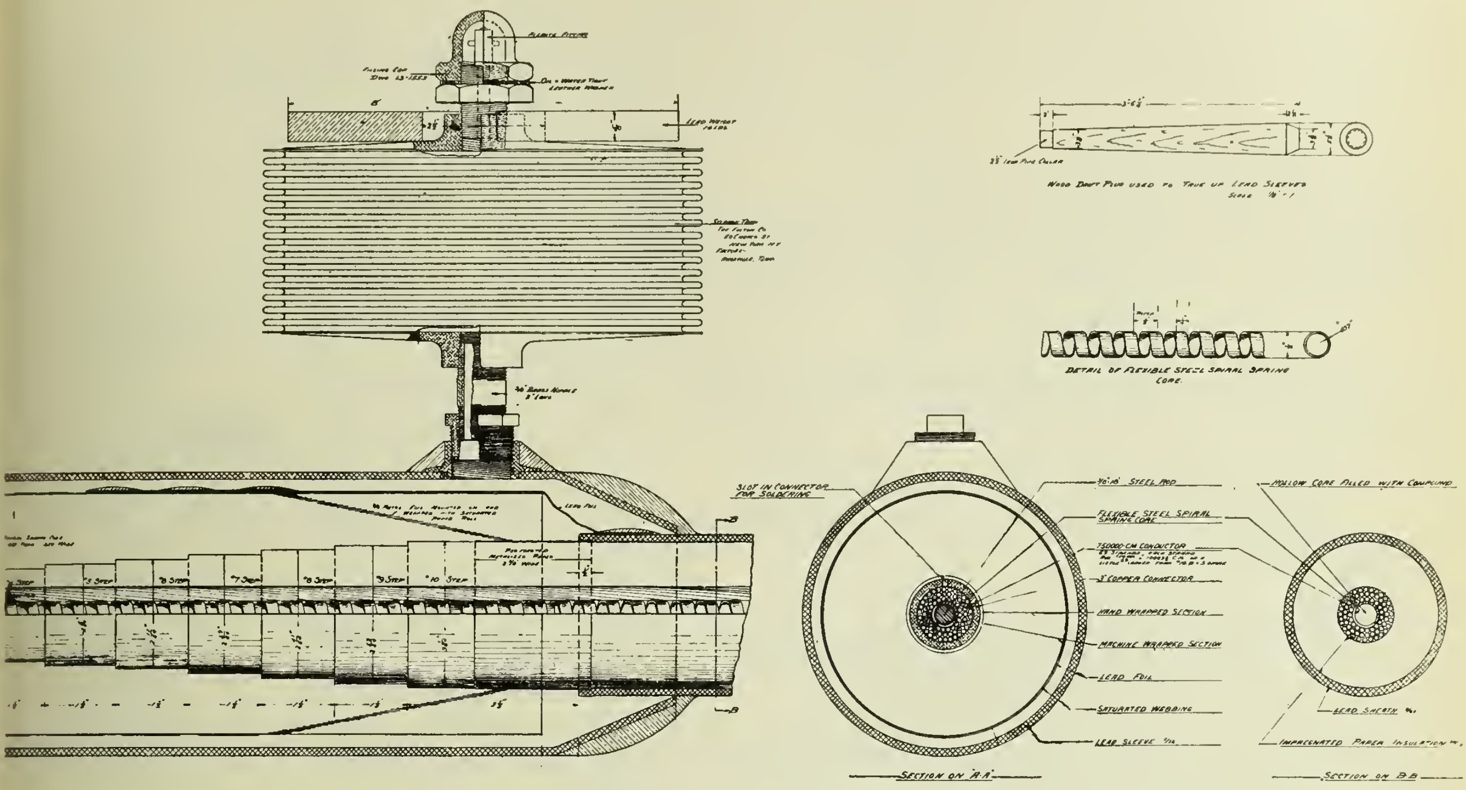

66-kv. Cable Joint.

After the completion of the installation, a short circuit current of approximately 250 amperes, 60 cycles, 3-phase was put through the two circuits of cables in series for a period of twenty-eight days. The temperature in the adjacent empty ducts was read by a thermocouple during the heat run and the temperature of the copper in the cables was read by resistance during the heat run. (See figures Nos. 10 and 10A.) From the rise in temperature observed, calculations were made to determine the maximum safe current which these cables will carry in operation. This current was estimated at 350 amperes, which corresponds to the specified maximum operating temperature of 60°C., either circuit would be able to transmit the entire capacity with an ambient temperature of 20°C. This maximum operating current of 350 amperes corresponds to a continuous rating of 40,000 kv.a. for each of these circuits. This indicates that in case of a fault in one section of the ring either circuit would be able to transmit the entire capacity of 45,000 kv.a. for a period of time depending largely upon the load conditions which existed before the occurrence of the fault.

The heat run also served to give an indication of the behaviour of the sylphon reservoirs under rise of temperature. It was found that almost no movement of these reservoirs took place between the cold and warm temperatures of the cable. It was found, however, that several of the reservoirs had emptied, creating a considerable vacuum. The sylphons have been filled to a slightly higher level than previously and a leaden weight of 14 pounds has been placed on each sylphon. Arrangements have been made so that if oil again flows out of a reservoir the weight will ensure a sufficiently definite downward movement to close a signal switch and operate a signal in the substation which will inform the operator that a sylphon reservoir has emptied in a certain manhole. Immediate inspection will then be made to determine the cause of the reservoir empty-

ing. In this way it is intended to detect any oil leak which may occur in a lead sheath of a joint or at any point in the lead sheath of the cable.

In order to fill a sylphon reservoir under pressure, each reservoir is equipped with an Alemite connection and the oil is pumped into the reservoir by a portable outfit. A brass cap is screwed over the Alemite connection to protect it from dirt.

Grounding of Cable Sheaths

All sheaths are grounded at each side of each cable joint so as to reduce to a minimum any current which might flow through the lead sheath of the joint. (See figure No. 11.) A diagram of the ground connections is shown in figure No. 12.

Description of Fireproofing Cables

The cables and joints in the manholes were wrapped half lap with asbestos listing 3 inches wide and 1/16-inch thick, saturated after installation with a solution of silicate of soda.

Cable Terminals

The cable terminals are rated at 110 kv., this extra rating seeming advisable on account of the importance of the line. They are oil-filled terminals with no auxiliary wrappings. The stresses at the base of the terminal are taken care of by concentric tubes of micarta which terminate in a correctly flaring copper ground shield.

At the substation the cables terminate on the fifth floor at a height of 62 feet above the cables in the street.

The weight of cable extending up to the fifth floor is supported at four points by a wooden clamp at each point, resting on steel springs for the purpose of evenly distributing the weight at the several points. (See figure No. 13.)

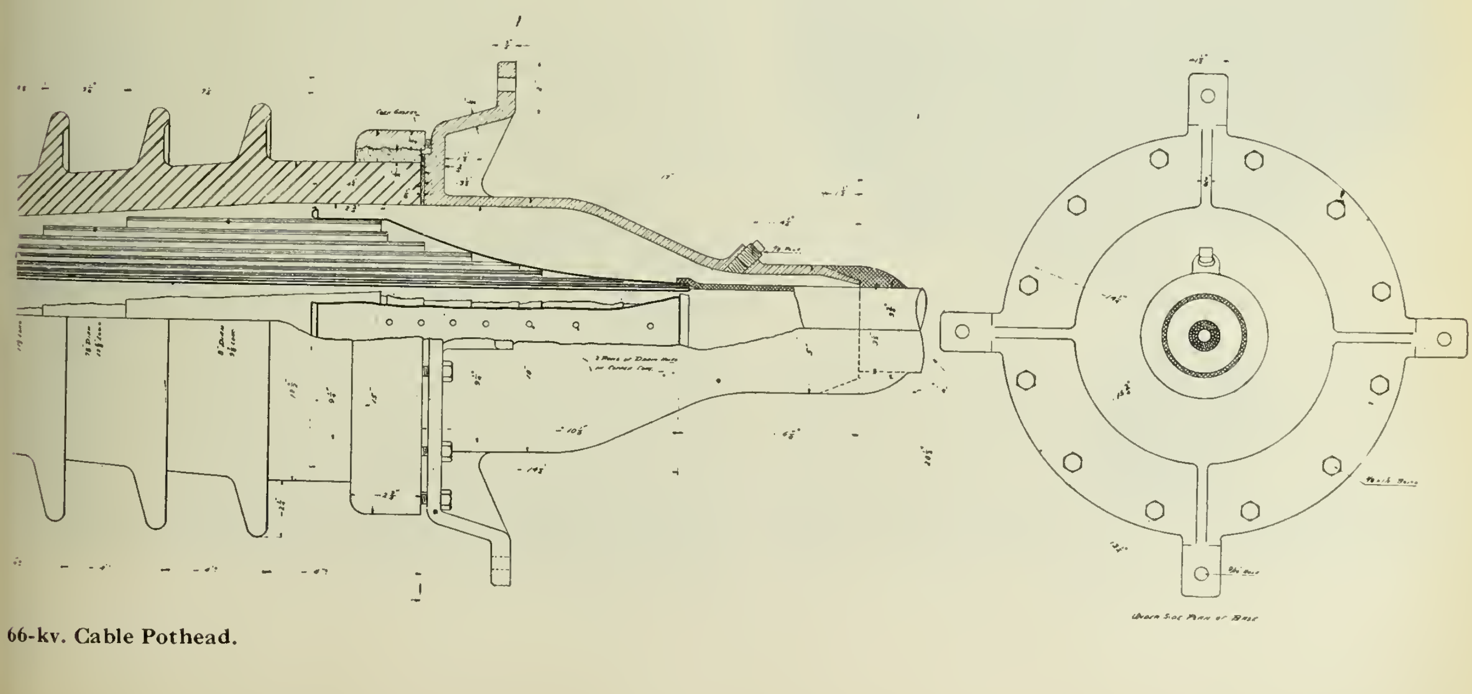
Where the cables join the overhead line the terminals are located at the top of pole, as shown in figure No. 14.

The underground fibre conduit extends with a 10-foot radius bend up to an elevation of 5 feet above the ground, protected by a concrete pier. From this point up the cables are supported by wooden clamps spaced an average of 24 inches apart and are protected from mechanical injury by galvanized sheet iron housing.

Tests

The cable specifications required a test of 219,000 volts d.c. for 15 minutes. All of the cables successfully stood this test.

The testing apparatus consisted of a 6-tube Kenotron set built by the General Electric Company, the wiring diagram of which is shown in figure No. 16.



66-kv. Cable Pothead.

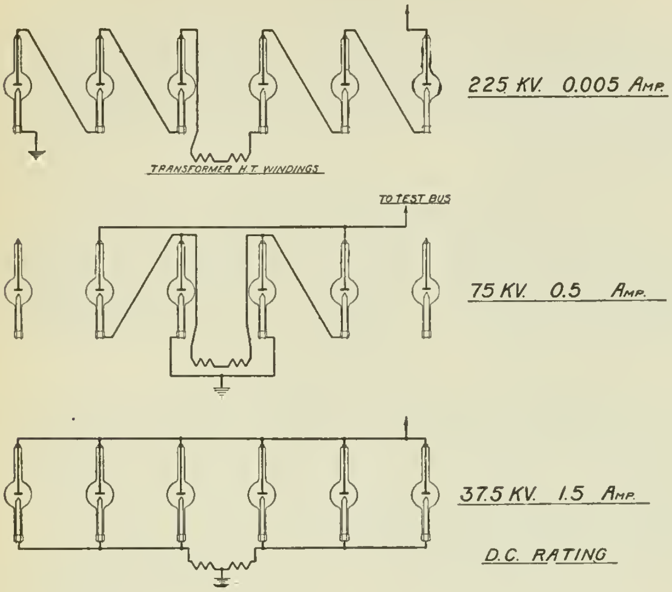


Figure No. 16.—Connections for Kenotron Test Set.

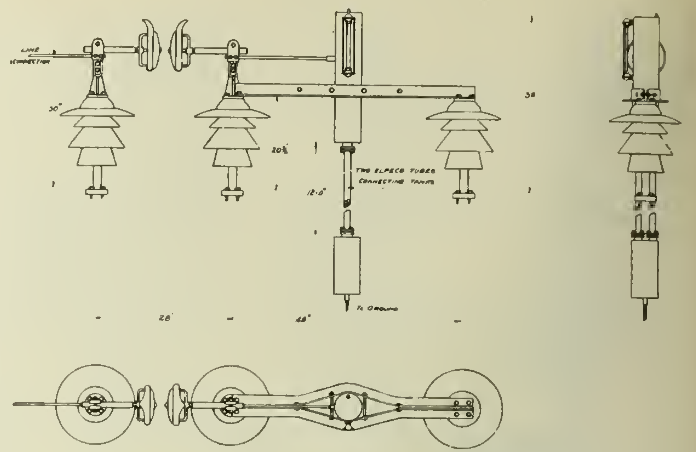

Figure No. 17.—Bennett Lightning Arrester.

Lightning Arresters

In order to protect these cables against possible damage from lightning, two arresters have been installed, one on each pole adjacent to the terminal poles. These are Bennett arresters supplied by the Electric Power Equipment Company of Montreal. (See figure No. 17.)

Operating Record

These cables have been in operation continuously since November 13th, 1927. No trouble of any kind has occurred on the cables or joints during the tests or in regular operation under load in the conduit construction in its entirety.

Waterwheel Driven A. C. Generators

The Effect of Operating Requirements on Design

John R. Dunbar, A.M.E.I.C.
Engineering Department, Canadian Westinghouse Company.

Paper read before the Hamilton Branch of The Engineering Institute of Canada, April 12th, 1928

An electric generator is a rotating machine which transforms mechanical energy, derived from a prime mover, into electrical energy. It consists, essentially, of a system of electro-magnets, known as the field, moving with relation to a laminated structure of low reluctance iron in which copper conductors are embedded, known as the armature. The magnetic flux from the field, cutting the armature conductors, induces in them an alternating voltage. This voltage appears at the terminals of the machine as an alternating or as a direct voltage, depending on the design of the generator. In d.c. generators and some very small a.c. generators the field is stationary and the armature revolves. The great majority of a.c. generators are now built with stationary armature and revolving field.

Type of Prime Mover Influences Design

Although it is not very generally recognized by users of electrical equipment, the type of prime mover that is to drive a generator has a considerable effect on the design of the generator, due to the inherent differences in the prime movers. A steam turbine runs at a high speed, usually 1,800 or 3,600 r.p.m., and this high speed requires a very special type of construction with cylindrical rotors. Steam engines and internal combustion engines operate at lower speeds, which permit the salient pole type of rotor to be used. The runaway speed is about 25 per cent above normal speed. With internal combustion engines it is necessary to supply an amortisseur winding on the generator, on account of the large fluctuations in the crank effort. In the case of waterwheel driven generators, the normal speeds are of the same order as for steam engines, but the runaway speed is from 85 to 125 per cent above the normal speed. This requires special provision to be made in the design of the generators. Thus each kind of prime mover introduces its own problems and, in order to supply machines suitable for various drives, it is necessary to use several types of construction.

Waterwheels may be divided into two general classes, horizontal shaft and vertical shaft. In turn, the generators may be driven from the waterwheel by means of belts, chains, gears, or by direct coupling to the shaft of the waterwheel. All generators which are to be driven from horizontal shaft waterwheels are horizontal shaft themselves, and belted units are usually horizontal shaft whether driven by horizontal or vertical shaft turbines. Generators geared to vertical shaft turbines may be horizontal or vertical, but those direct coupled to vertical shaft turbines must be of the vertical type. Thus there are the following types of waterwheel driven alternating current generators: horizontal shaft, either belted, chain driven, gear driven, or coupled, and vertical shaft, either gear driven or coupled.

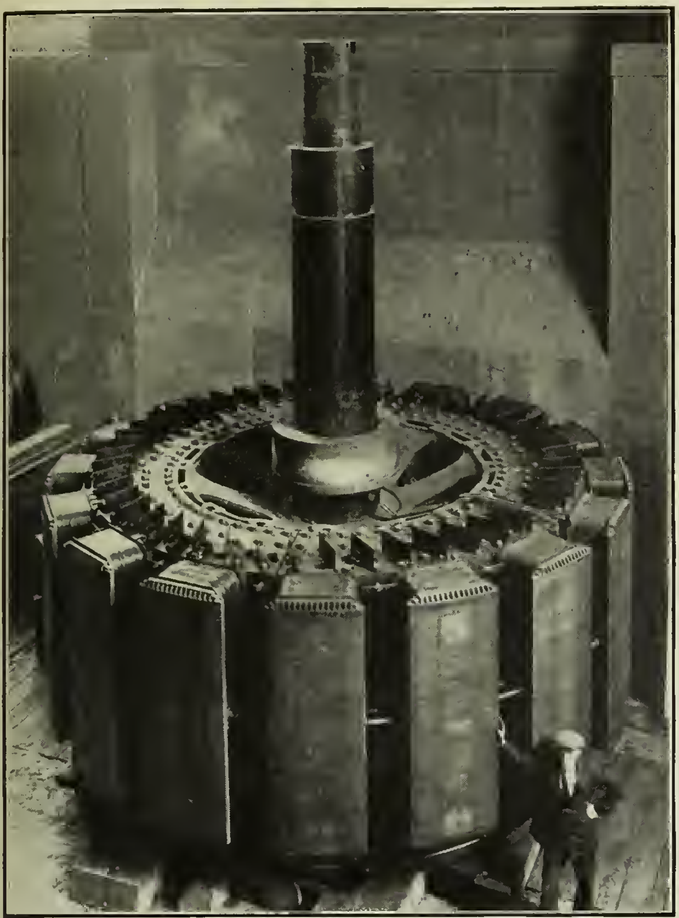

Figure No. 1.—Laminated Rim Rotor for Large High-Speed Waterwheel Generator.

The type of drive has no effect on the electrical design, provided the other characteristics are suitable; that is to say, the electrical parts of a generator rated at 500 kv.a. 6,600 volts, 450 r.p.m., and originally designed to be direct connected to a high speed vertical shaft waterwheel, may be used for belt drive from a low speed horizontal shaft waterwheel, to give the same rating. Of course, the mechanical parts would be different.

Rating Requirements

Before the electrical design of a generator can be proceeded with, it is necessary to know the rating, together with any special conditions which have to be met. The rating includes kilovolt-amperes, power factor, volts, phase, cycles, revolutions per minute and temperature rise. Of these the temperature rise and power factor are the only ones that require further comment.

The permissible temperature rise is determined by the insulating material and by the kind of rating. The normal kind of rating is the continuous rating without overload capacity, but frequently it is advisable to use a different kind of rating; for example, if the load is of such a nature that it would be 25 per cent greater during a two-hour period than it is during the rest of the day, a slightly smaller generator could be used, by using a continuous rating with an allowance for 25 per cent overload for two hours. In some cases the consulting engineer feels that it would be advisable to use a lower temperature rise than the maximum permissible for the type of insulation. The kind of rating and the margin between the actual guaranteed rise and the maximum permissible rise is a matter for the consulting engineer to determine, but the maximum permissible rise depends on the kind of insulation used and is determined by the designing engineer.

Insulation

Two kinds of insulation are used, class "A," which consists of cotton, paper and similar materials, impregnated with a varnish, and class "B," which consists of mica, asbestos and similar materials, which are held together by organic materials for binding purposes only.

When class "B" insulation is used on armature or field coils an observable temperature rise of 80°C. is permissible, when measured by embedded detectors or by the change of resistance method in the case of field coils. For class "A" insulation the permissible observable rise is 60°C. If thermometers are used, then the permissible observable rise is 10° less than the above, except in the case of bare strap field coils when the thermometer is actually in contact with the copper. In some cases class "A" insulation is used in the armature and class "B" in the field, so that it is quite reasonable to have different temperature guarantees on the armature and on the field.

Effect of Power Factor on Design

The power factor of the generator has two effects on the size of the machine. First, for a certain rating of waterwheel the generator kv.a. rating is higher for a lower power factor; for example, a 10,000-h.p. waterwheel would require

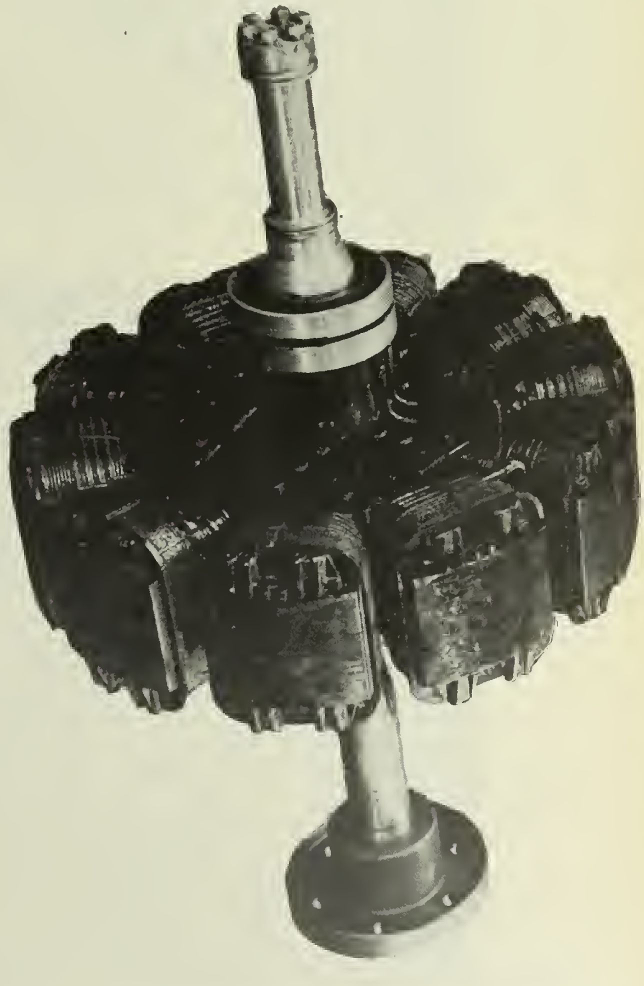

Figure No. 2.—Laminated Spider Rotor for Small Waterwheel Generator.

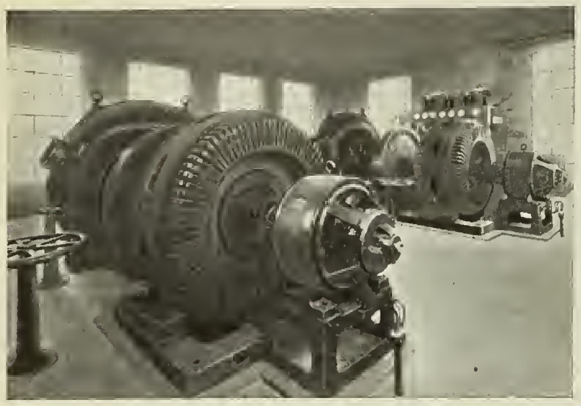

Figure No. 3.—Two 1,000-kva., 60-cycle, Horizontal Shaft Generators in Windsor Power House of Avon River Power Company.

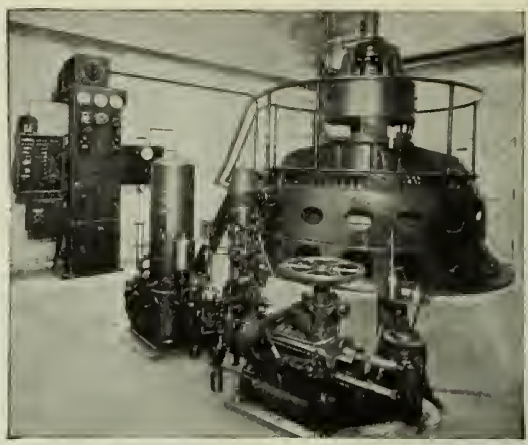

Figure No. 5.—Small Vertical Shaft Automatically Controlled Generator.

an 8,000-kv.a. generator at 90 per cent power factor, but the rating would be increased to 9,000 kv.a. if the power factor were reduced to 80 per cent. In addition, the field current for a certain kilovolt-ampere output is higher for a lower power factor. Both these results combine to require a larger machine for a lower power factor.

Special Conditions

Some of the special conditions which affect the electrical design are: Special requirements for operation or tests, high values of fly wheel effect, and special requirements regarding regulation, short circuit currents or stability.

Naturally if higher values of test voltage than standard are specified, then extra insulation must be added to take care of the special requirements.

A normal design of generator gives a certain value of fly wheel effect. It is possible to increase the fly wheel effect by adding weight to the rotating field up to a certain point, but above that point it becomes uneconomical to attempt to increase the fly wheel effect by adding weight. If this point is reached then it is necessary to redesign the generator completely, using larger diameters and narrower widths. That is, exceptionally high fly wheel effect requirements affect the electrical design by increasing the diameters necessary.

The characteristics which are included under regulation, short circuit currents and stability, depend on the reactance of the generator and upon the air gap. If good regulation is required, so that the change in voltage will be small when there is a variation of load, then a low reactance machine with a large air gap is required. If the short circuit currents are to be kept low, then a high reactance generator is required. If the generator is to feed a long transmission line and there is likely to be trouble from the ends of the transmission line falling out of synchronism, or if it will be required to operate on an unloaded transmission line, which would draw leading current from the generator,

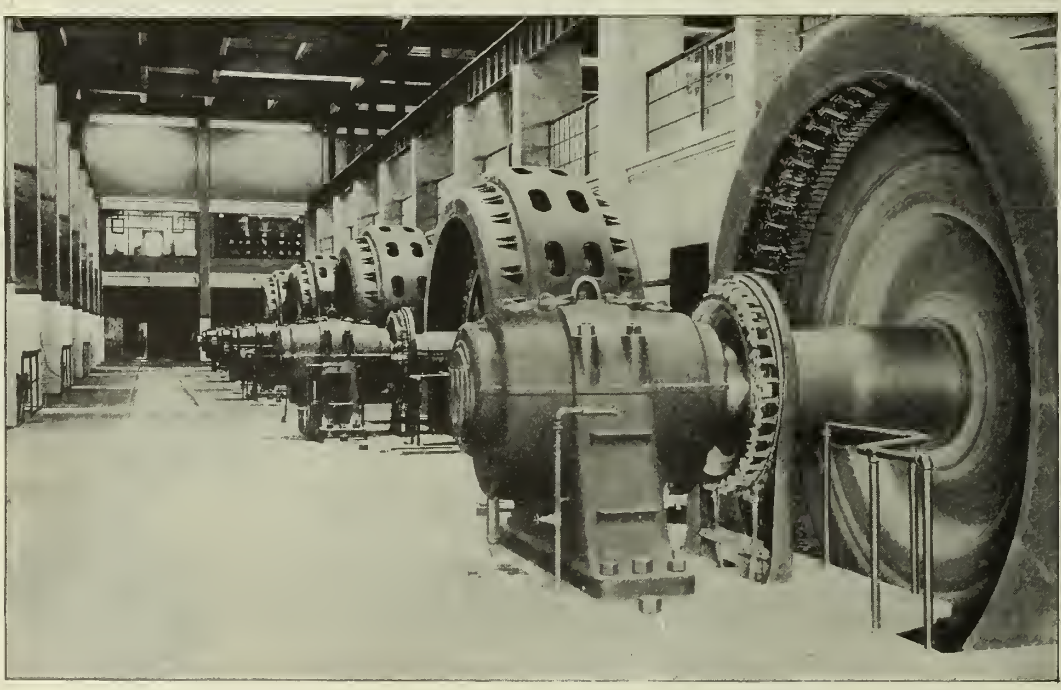

Figure No. 4.—Five 15,000-kva., Horizontal Shaft Generators in Shawinigan Water and Power Company's Plant on St. Maurice river, Shawinigan, Que.

then a low reactance generator with a large air gap is necessary. If, however, it is desired to operate the generator at times of light load as a synchronous condenser to increase the power factor of the load on other generators, then a small air gap is required.

Features of Mechanical Design

The details of the mechanical design are, of course, interlinked with the electrical design, but there are some features that affect the mechanical design more than they do the electrical design.

The peripheral speed of the rotor has a considerable bearing on the rotor design. The speed for which the rotor must be designed is the speed at the maximum possible overspeed. The field poles may be fastened to the spider by means of bolts or dovetails, bolts being used for the lower speeds and dovetails for the higher speeds. The type of spider construction is also affected by the speed. At low speeds cast iron or cast steel may be used. As the speeds get higher castings are too unreliable and it is necessary to adopt a different construction. For some of the smaller generators the spider may be forged integral with the shaft. On slightly larger generators the spider may be built up of thin laminations or of boiler plate and on still larger generators a cast steel or boiler plate centre may be used with a rim built up from thin steel laminations.

Occasionally it is found that the overspeed is so high that no suitable rotor design can be devised. When this is the case it is necessary to distort the electrical design so as to use a less economical machine on a smaller diameter.

The above discussion will show how various operating requirements affect the design of the generator and in some cases how different requirements are conflicting. It assists the designing engineer materially if he has full information regarding the operating conditions, but if no data are available it is necessary for him to assume reasonable values and design the most economical generator, taking into consideration only such data as he has available.

Aeroplane Flight

Types of Aircraft, Forces Effecting Flight, and Factors Governing Stability

C. C. Langstroth, A.M.E.I.C.
Atlantic Sugar Refineries, Saint John, N.B.

Paper read before the Saint John Branch of The Engineering Institute of Canada, October 18th, 1928

Aeroplanes are the most highly developed type of the "heavier than air" type of aircraft. Others of this type are the helicopter and the orthinopter. All these are distinguished from the "lighter than air" ships by the fact that they depend upon dynamic forces for their sustention in the air, while the latter type are sustained by the flotation of a light gas.

Lighter than air craft are divided into classes according to structural differences and are known as rigid, semi-rigid and non-rigid.

The rigid type is distinguished by an aluminum alloy frame covered with fabric and supporting the several gas balloonettes inside. Passenger, cargo and engine compartments are either contained in the frame or rigidly suspended from it. The German Zeppelins, the English R-33 and the American Los Angeles are examples of the rigid type. The rigid airship is the liner of the near future and both England and Germany have ships now that will, within a matter of months, attempt regular trans-Atlantic passenger services.

The semi-rigid type of airship has a metal framework along the bottom of the gas bag. This frame acts as a ship's keel and the accommodation is affixed rigidly. The ships of the Italian Arctic expeditions were of the semi-rigid type.

A non-rigid airship is a really self-propelling balloon held in shape only by the pressure of the gas that floats it, and carrying its useful load slung beneath it by ropes. It was used in the war for patrol duty and known as a "Blimp."

In common with "heavier than air" craft the "lighter than air" ships depend upon the thrust of air screws for their forward motion and upon planes for manoeuvring at least in part.

Airships require large crews to navigate and land them and are difficult to handle near the ground. Hydrogen, the first widely used flotation gas, is highly inflammable and an ever present hazard. The post war development of the mooring mast and the war time discovery of new sources of the uninflammable light helium will probably do much to make the airship a practical means of transportation.

Of the "heavier than air" machines, the orthinopter is an attempt to imitate mechanically bird flight with flapping wings. This type has so far been shelved by the simpler structures of the aeroplane and the helicopter.

The helicopter has for its distinguishing characteristic airscrews on vertical axes that support the machine in the air while other airscrews working normally on horizontal axes impart forward motion. Experiment with the helicopter has persisted in spite of many disappointments on account of the advantages of nearly vertical ascent and descent in alighting on and leaving restricted areas.

Aeroplanes are classified by the following characteristics:—

(1) "Tractor" or "pusher" depending on whether the machine is drawn by the airscrew or pushed by it. In multi-engined machines both types of airscrews may be used.

(2) "Monoplane," "biplane," "triplane" and so forth by the number of main lifting planes.

(3) A land machine normally alights on the ground.

(4) A seaplane is one that normally comes to rest on the water and takes the form of a land machine with floats in place of wheels on the landing gear.

(5) A flying boat is a seaplane whose fuselage has the function of a float when resting on the water.

(6) An amphibian is an aeroplane fitted for alighting on both land and water.

A Spanish engineer has lately brought a helicopter, which he calls an "Autogiro," to a stage of development that allowed him to fly it from London to Paris. This event has been hailed by some authorities as one comparable to the first flight of a plane across the English channel.

The aeroplane depends, for its suspension in the air, on the reaction of the airstream caused by the machine's forward motion, on fixed planes or aerofoils. The forward speed necessary to give the machine lift sufficient to sustain it is so great that a run on the ground, (or water), is necessary to accelerate the machine when taking off, and on alighting to reduce its momentum.

The word "airship," according to English and Canadian authorized practice, refers to a self-propelled lighter than air craft and cannot be properly applied to an aeroplane.

Both land machines and seaplanes have been fitted with skiis for alighting on snow and have been successfully used.

Forces Effecting Flight

Successful aeroplane flight is accomplished by maintaining in equilibrium four primary forces: thrust, drag, lift and gravity. Thrust is the force exerted by an airscrew when turned by the engine. An airscrew follows generally the same aerodynamic principles as any other aerofoil and is really a pair of rotary planes. An important characteristic of the airscrew is the helical wake of turbulent air that it heaves when working.

Drag is the head resistance of an aerofoil or aeroplane as it moves through the air. In an aeroplane drag has three components:—

(1) The "passive" drag of the surfaces at right angles to the air flow.

(2) The "active" drag caused by the reaction of the lift and control surfaces.

(3) The "skin friction" of all surfaces exposed to the flow.

Drag represents a direct power loss and its reduction is important in aeroplane design. The passive resistance is reduced to a minimum by a device known as stream lining.

When a stream of fluid flowing against a body is parted and brought together in such a way that the fluid flows smoothly, setting up the least possible turbulence, the body offers minimum of resistance to the fluid flow. The bodies of birds and fish are natural examples of this principle. In a properly streamlined body it is possible to reduce the air resistance to one-quarter that of a thin flat plate representing the same section to the air stream.

Abrupt changes in shape in aeroplane structures tend to make the air turbulent when the machine is in flight. To reduce the passive head resistance all the structure possible is kept inside the fuselage and wing structures while all bracing wires and struts are carefully streamlined.

Lift is the reaction on a plane or aerofoil of the airflow past it, the lift being measured normal to the airflow. The ratio of the lift to drag or drift forces are the measure of aerofoil efficiency. This ratio decreases as the angle of the plane to the direction of the airflow is increased; the angle between the plane and the direction of the airflow being known as the angle of incidence. Flat planes were early abandoned for lifting on account of their low lift drift ratio, experiment having shown that a curved or combered wing section gave greater lift for the power expended.

It is a fact that the upper surface of a combered aerofoil section has more influence than the lower on the lift, in good aerofoil sections as high as 70 per cent of the lift being obtained on the upper surface of the wing.

The flying angle of incidence of a plane varies between a minimum and a maximum, where other conditions being equal horizontal flight may just be accomplished; between these angles, about midway, lies the optimum angle or that of greatest climb and efficiency.

When the maximum angle of incidence is exceeded in an aeroplane, the plane stalls. That is, the machine loses flying speed to the extent that it becomes uncontrollable and falls. It will continue to fall out of control until enough speed has been attained to make the control surface effective. Stalling is not the direct result of engine failure; a machine may be kept under control without the engine running by setting it at its gliding angle, giving a scope of six times the machine's height in the air in all directions to make an emergency landing.

One of the most important recent developments for aeroplanes is a device that hinges on the leading edge of the wings and prevents the machine from being lifted above its maximum flying angle, so that the machine must stay under control.

The useful component of lift is that which works against gravity and is known as the horizontal equivalent.

Stability

An aeroplane must have its lifting and control surfaces so arranged that in flight it has a measure of inherent stability; that is, it must tend to fly straight on an even keel without pitching. The extent of the stability designed into a machine depends upon the purpose of the machine. A large weight carrying plane would have a strong tendency to right itself while a small fighting machine must be balanced on a pin point.

For the purpose of discussing the factors governing stability, an aeroplane may be considered as turning about three axes each at right angles to the others and all running through the centre of gravity. The longitudinal axis is considered as being parallel to the axis of the airscrew. The lateral parallel to the general line of the wings and the normal axis is vertical when the machine is in flying position.

Combered aerofoils have no longitudinal stability, but when the angle of incidence is increased or decreased by a change in the direction of the airflow against them they tend to keep on increasing or decreasing the incidence angle.

This tendency on the part of the main planes of an aeroplane is offset by a smaller surface placed behind the main plane and known as the tail plane. The spars of the tail plane are parallel with those of the main planes but the tail plane has a different angle of incidence from the main planes.

All tail surfaces are affected by the slip stream of the airscrew, when the engine is on; the wash from the airscrew causes the air to flow by the tail surfaces with a greater velocity and in a different direction from that which it takes when the power is off. This makes the rudder and elevator control less sensitive in a glide than when under power.

Lateral stability is attained by five devices:—

(1) The wings are set at an angle to each other in such a way that the horizontal equivalent of the low wing is greater than that of the upper when the machine rolls. This practice is not altogether successful, as in order to get enough difference on the lift of the two wings considerable lift is sacrificed when the machine is level.

(2) The incidence of the planes is decreased toward the ends, resulting in more effective aileron control.

(3) The tendency of the airscrew to turn the machine in the opposite direction to the airscrew is offset by increasing the incidence on the wing that tends to fall.

(4) The keel surface is arranged so that it is divided about the longitudinal axis in such a way that a side gust will not tend to make the machine roll.

(5) The relation of the centre of gravity and the centre of lift must be such that neither a pendulum or a top heavy effect is obtained.

Stability about the normal axis is a matter of disposal of the keel surface. When an aeroplane is turned about the normal axis the keel surface is not large enough to keep the machine from side slipping outwards and this may alter the attitude of the wings so that there is not sufficient lift to sustain the machine. To overcome this outward side slip, a machine is tipped inward or banked so that the lift aids the keel surfaces and keeps the machine in equilibrium.

To obtain a stable machine both flying and gliding, the centre of thrust in an aeroplane should be placed below the centre of drag and the centre of gravity ahead of the centre of lift. These four forces form two couples that neutralize each other when the machine is in flight and when the thrust is removed by throttling the engine make the machine tend to assume a gliding position.

The control surfaces of an aeroplane are the ailerons, the elevators and the rudder; these, with the engine, are used in the manoeuvring of the machine.

The ailerons are flaps hinged to the trailing edge of the main planes, usually near their ends. They give control about the longitudinal axis of the aeroplane. As the ailerons on the right wings turn up, those on the left turn down, causing the plane to bank toward the upturned aileron.

The elevators are a pair of flaps hinged to the trailing edge of the tail plane. By changing the effective incidence of the tail plane the elevators cause the nose of the aeroplane to rise or fall.

Both ailerons and elevators are manipulated by a control column which has a universal joint at its lower end, allowing it free motion in all directions through a small angle. This control column is so arranged that the plane tends to follow its direction of movement.

The rudder is a plane hinged to turn on an axis at right angles to the tail plane. The rudder controls turns of the aeroplane about its normal axis. It is operated by the feet through a rudder bar pivotted at the centre and secured to the floor of the cockpit of the machine.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XI DECEMBER 1928 No. 12

Proposed Amendments to By-laws

In accordance with Sections 74 and 75 of the By-laws, the following amendments, proposed by Council, are presented for consideration by corporate members of The Institute, and will be discussed at the Annual General Meeting:—

Section 8 (Waiving of Examinations for the Class of Associate Member)

It is proposed to amend the last sentence of the second paragraph of Section 8 as follows:—

As at present " Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years."

Amend to read " Any or all of these examinations may be waived at the discretion of the council if the candidate is forty-five years of age or over, and has held a position of professional responsibility for ten or more years."

Sections 27 and 28 (Consideration of Applications for Admission or for Transfer)

In accordance with the recommendations of the Committee appointed by Council to study and report on the question of changing the present method of dealing with applications for admission or for transfer, it is proposed to amend Sections 27 and 28 to read as follows:—

Section 27. " Immediately upon receipt of an application the secretary shall forward a copy thereof to the secretary of the branch, if any, to which the applicant belongs. The executive committee of the branch shall thereupon make such inquiries concerning the applicant as it deems to be advisable, and shall recommend to the council the action that it considers should be taken with reference to the application.

" At stated periods to be determined by the council there shall be issued to corporate members whose addresses are known a list of new applicants for admission or for transfer, containing a concise statement of the record of each applicant and the names of his references, with a request that members transmit to the secretary any information in their possession which may affect the classification or eligibility of the applicant.

" The secretary shall also forward to each member of council a concise statement of the record of each applicant and the names of his references on a form on which space shall be provided for each councillor to make his recommendation regarding the applicant. The forms shall be mailed to councillors at least thirty days before the applications referred to are dealt with by council. Each form must be signed by the councillor returning it, but it is not necessary that he should express a recommendation regarding all or any of the applicants."

Section 28. " The council shall consider all the information with reference to each application, making further inquiries if deemed expedient, and shall then decide whether the application shall be accepted, and if so, to what class of membership the applicant shall be admitted. Before reaching this decision, however, not less than twenty-five of the forms referred to in Section 27 must have been returned to the secretary, and the recommendations contained in these forms must be placed before council. If five or more members of council oppose the admission or transfer of an applicant he shall not be elected, otherwise a majority of three-quarters, or more, of those present at a council meeting shall determine the classification of the applicant, with or without examination, and thereby constitute his election, subject to examination if so required.

" A rejected candidate shall be notified promptly that his application has not been accepted, and he may renew his application for admission or transfer at any time after the expiration of one year from the date of his notification.

" Application for membership in the class of Student shall be passed upon by council without the formality of notification to all councillors."

Section 29 (Notification of Election)

It is proposed to amend this Section by substituting the word " election " for " admission " in lines one and three, the section then reading as follows:—

Section 29. " On the election of a candidate, he shall be notified by the secretary and he shall then be entitled to the privileges of membership. Membership shall date from the date of election."

SECTION 34 (SCHEDULES OF FEES)

In accordance with a resolution passed at the Plenary Meeting of Council, it is proposed to increase the annual fees payable by Members by $3.00, Associate Members by $2.00, and Juniors by $1.00, the amended Section 34 to read as follows:—

Section 34. "The annual fees payable by Montreal Branch residents shall be as follows:—

		If paid on or before March 31st.
Members	$17.00	$16.00
Associate Members	13.00	12.00
Juniors	8.00	7.00
Students	2.00	1.00
Affiliates	11.00	10.00

"The annual fees payable by all other branch residents shall be as follows:—

Members	$14.00	$13.00
Associate Members	11.00	10.00
Juniors	6.00	5.00
Students	2.00	1.00
Affiliates	11.00	10.00

"The annual fees payable by branch non-residents and non-residents shall be as follows:—

Members	$12.00	$11.00
Associate Members	9.00	8.00
Juniors	5.00	4.00
Students	2.00	1.00
Affiliates	11.00	10.00

"Honorary Members shall be exempt from annual fees.

"In accordance with the above schedules, if paid on or before March 31st of the current year, a deduction of one dollar will be allowed on the annual fees of all grades."

SECTION 73 (JOURNAL OF THE INSTITUTE)

In order to give effect to Council's decision to make The Journal subscription optional to Students it is proposed to amend Section 73 to read as follows:—

Section 73. "The annual subscription for The Journal of The Institute for members of The Institute shall be two dollars, and shall be paid by members of all classes, with the following exceptions:—Honorary Members, Life Members, and members who have compounded their fees, who shall receive The Journal gratis, and Students who shall have the option of subscribing to The Journal at the above rate. The annual subscription to The Journal for non-members of The Institute shall be three dollars. All subscriptions shall be payable on the first day of January in each year."

Meeting of Council

A meeting of Council was held at eight o'clock p.m. on Friday, November 16th, 1928, with President Julian C. Smith in the Chair, and nine other members of Council present.

The minutes of the meeting held on October 15th, 16th and 17th, 1928, were approved with two amendments.

The financial statement of The Institute for the period ending October 31st, 1928, was submitted and approved.

The attention of Council was drawn to the importance of the World Engineering Congress which is to be held in Tokyo in October 1929, and to the fact that the leading engineering societies of the world are taking measures to be represented at this Congress. A small committee was appointed to consider a desirable course to be adopted by The Institute in this connection.

A progress report was presented by the Publicity Committee suggesting that the matter of publicity be brought particularly to the attention of the Branches, and that the Branches be requested to submit suggestions.

Arrangements were made for a delegate to represent The Institute at the inauguration of the new President of the Stevens Institute of Technology, Hoboken, N.J.

Discussion followed as to the amendments to the By-laws which are to be proposed by Council for the consideration of the membership at the Annual Meeting. Proposals to amend Sections 8, 27, 28, 29, 34 and 73 were approved for this purpose. These are printed elsewhere in this issue.

One resignation was accepted and three special cases were dealt with.

The following elections and transfers were effected:—

Elections		Transfers	
Associate Members	8	Assoc. Member to Member	3
Juniors	4	Junior to Assoc. Member	3
Students Admitted	158	Student to Assoc. Member	4
		Student to Junior	15

Twenty-two applications for admission and transfer were scrutinized and classified for the ballot returnable December 18th, 1928.

The Council rose at eleven-thirty p.m.

THE ANNUAL GENERAL AND GENERAL PROFESSIONAL MEETING

HAMILTON, Ont.

WEDNESDAY, THURSDAY AND FRIDAY, FEBRUARY 13th, 14th and 15th, 1929

PRELIMINARY PROGRAMME ANNOUNCEMENT

WEDNESDAY, FEBRUARY 13TH:
- 9:00 a.m.—Registration.
- 10:00 a.m.—Annual General Meeting.
- 1:00 p.m.—Luncheon.
- 2:30 p.m.—Annual General Meeting Continued.
- 4:30 p.m.—Ladies' Tea.
- 8:00 p.m.—Illustrated Lecture and Smoking Concert.

THURSDAY, FEBRUARY 14TH:
- 9:30 a.m.—Technical Sessions.
- 1:00 p.m.—Informal Luncheon.
- 2:30 p.m.—Visits to Engineering Works.
- 8:45 p.m.—Reception and Supper-Dance.

FRIDAY, FEBRUARY 15TH:
- 9:30 a.m.—Technical Sessions.
- 2:30 p.m.—Technical Sessions.
- 7:30 p.m.—Annual Dinner of The Institute.

PRELIMINARY LADIES' PROGRAMME ANNOUNCEMENT

WEDNESDAY, FEBRUARY 13TH:
- 9:00 a.m.—Registration.
- 1:00 p.m.—Luncheon.
- 4:30 p.m.—Tea.
- 8:00 p.m.—Illustrated Lecture.

THURSDAY, FEBRUARY 14TH:
- 1:00 p.m.—Informal Luncheon.
- 8:45 p.m.—Reception and Supper-Dance.

FRIDAY, FEBRUARY 15TH:
- 7:30 p.m.—Ladies' Dinner.

OBITUARIES

John Frederick Flint Cahan, M.E.I.C.

It is with deep regret that we record the death of Captain the Hon. J. F. Cahan, M.E.I.C., assistant minister of highways in the Nova Scotia government, and son of C. H. Cahan, K.C., M.P., for St. Lawrence-St. George ward, Montreal, which occurred at Halifax, N.S., on November 8th, 1928, from complications arising out of spinal injuries received during the war.

The Hon. J. F. Cahan was born at Halifax, N.S., in 1889, and after receiving his early education at the high school of that city he entered Dalhousie University, from which he received his degree of Bachelor of Engineering. Subsequent to completing a post-graduate course in engineering at McGill University, in 1910 he was appointed resident engineer of the building of the University of Saskatchewan, which post he occupied until 1912. In 1912 he was superintendent and construction engineer for the Western Canada Power Company, Ltd., engaged on pumping installation, construction of dams and extension of the company's power house. In 1915 he enlisted for overseas service as lieutenant in the first Canadian Pioneer Battalion and was promoted to the rank of captain. At Courcellette, in 1916, Captain Cahan received severe wounds, as a result of which he was confined to the hospital for several years. Like his father, Captain Cahan was a Conservative in politics. He was elected to the Legislative Assembly of Nova Scotia on June 25th, 1925, becoming a member of the Executive Council without portfolio in the Rhodes Cabinet. He served under the Hon. Percy Black, Minister of Highways. Captain Cahan joined The Institute as an Associate Member in 1914.

An Appreciation

by

The Hon. Percy C. Black

Minister of Highways, Province of Nova Scotia

The Honourable John F. Cahan was born in Halifax thirty-nine years ago. Here he spent his boyhood and attended Dalhousie University. From there he proceeded to McGill University where he continued his study of engineering. After his graduation as an engineer, he became interested in engineering development in western Canada. It was by reason of the practical experience and training he there received that he was so eminently qualified to take the positions he held in the Highways Department and the Power Commission of Nova Scotia since 1925.

When the Great War broke out in 1914 Captain Cahan was amongst the very first Canadians to enlist. For he belonged to that noble company of mankind whose ears are attuned to the high call of service and his response was as immediate as it was eager. In a memorial address to our Soldier Dead, delivered by him at Yarmouth in 1923, he said:—

> "Of what like were these men whose names we find written here? They were youths standing on the threshold of opportunity, with the whole enticing panorama of life spread before their eager eyes. And what an enchanting vista life presents to youth! But for these men this was but a vision of desire which was ever to remain unfulfilled. Harshly insistent struck the note of war, and by a deep stirring within, each one knew that the call would be for him. And so they donned the irksome equipment of war, gave up their personal liberty that we might be free, and with but 'one longing, lingering look behind' bade goodbye to all that they held most dear, and turned their faces to the unknown. Then they endured all things bravely; the terrible hardships of war, things heard that man should not hear, things seen that human eye should not look upon; and at last drank the bitter cup to its very dregs. Think of it, the splendid unutterable pity of it! and let no heart be too worldly to be touched, nor any eye too proud to shed a tear."

JOHN FREDERICK FLINT CAHAN, M.E.I.C.

It was at the battle of Courcellette in 1916 that Captain Cahan received a terrible wound which inflicted an irreparable injury to his spine. The wound caused intense suffering which he bore unflinchingly for six long years, displaying during that period of pain a patience and even a cheerfulness that demonstrated the splendid fibre of the man. An intimate friend of the family writes:—"Three times he was practically given up for dead, but that same valiant spirit which was planted deep in his breast made him fight on and he came back as it seemed by sheer force of a determination to live and get well."

In 1922 a surgical operation brought some measure of relief from pain. His anguish was assuaged to the point where he could once more make use of his mental powers. He turned his mind to public life as he saw there an opportunity to put his fine mental gifts to excellent service. He welcomed the nomination of Yarmouth county in 1925, and on being elected he joined the government of Nova Scotia and thus became my colleague in the Department of Highways.

In his address at Yarmouth from which I have already quoted, Captain Cahan said:—

"He who would say 'I love my country' must be willing to die for it, knowing that life without liberty is a curse. But also he must be willing to live for it, and to him whatsoever affects its welfare must be of paramount interest and concern. The village, the town, the province are the nuclei of the nation, and he who has added one iota to their betterment is in very truth a patriot, and has been of service to the commonwealth at large. All men cannot be great, but every man can be a patriot. Each one must see that nothing in the communal life of the village is neglected, that education is fostered in every way, that civic affairs are never viewed with indifference, and that no one is chosen for public office, whether municipal, provincial or federal, whose chiefest concern is not the public good."

Now, after close association with John F. Cahan over a period of more than three years, I wish to testify that every official word spoken and official action taken by him were directed by a single aim—the public good. Nothing else mattered. His devotion to duty, which flamed out in him at the commencement of the war, continued to burn just as brightly when he volunteered for peace-time service in 1925. I never saw a man throw himself more wholeheartedly into his work. It became almost a passion with him. His trained mind readily grasped the essential details of his office. Having mastered these he grappled with the various problems and difficulties that always confront responsible heads of government departments, and his acute discernment and sound judgment proved to be well-nigh invaluable assets.

Now we who were closely associated with this man had two main reasons for satisfaction. One was that Nova Scotia had obtained so fine a type of public servant; the other that his work was re-acting so favorably on himself. His health improved as his interest grew. Soon it absorbed him to the point where for hours at a time he could forget his physical ills and the irksomeness of a wheel chair. At length it was apparent to us that Cahan lived in and for his work. It meant vastly more to him than just a means of livelihood. It was his life.

That was the situation with him when with high spirits he entered upon the political campaign of last September, satisfied that he had put his utmost effort into the advancement of his county and his province. He fought with amazing vigour and those of us who realized his circumstances hoped with all our hearts for his success. He did not complain at the result. His indomitable will, too strong for his broken body, held to the fixed purpose of again serving his county. We who knew and loved and honoured him find it difficult to understand the viewpoint of those who were primarily responsible for his tragic defeat. He, on the other hand, realized with clear vision that in the public service, as on the field of battle, the real reward comes not in personal advancement but in the realization of duty well done.

Let us keep steadfastly in mind that it is to men like the late Captain J. F. Cahan that we owe the freedom we now enjoy. He leaves behind him a record of unswerving devotion to his country at whose feet he laid his youth, his health, his talents and his life. It is our high privilege in so far as in us lies to emulate the example of this great Nova Scotian. In his own words:—

"This freedom to which you have fallen heir has been obtained at a great price; the price of unselfish devotion and self-sacrifice, and if you in your turn would hand it on, it demands the same from you."

Edward V. Johnson, M.E.I.C.

Members of The Institute will learn with regret of the death of one of The Institute's earliest members, Edward V. Johnson, M.E.I.C., which occurred at his home in Ottawa on October 5th, 1928.

Mr. Johnson was born at Fredericton, N.B., on October 7th, 1845, and was a son of the late James Johnson, commissioner of customs. He received his education at Fredericton, N.B., and at a college in the United States. His first engineering work was as chainman with the Intercolonial Railway, with which he became connected in May of 1869. Two years later he joined the engineering staff of the Canadian Pacific Railway as assistant leveller, and in 1872 was transferred to the company's head office, where he was

EDWARD V. JOHNSON, M.E.I.C.

placed in charge of the draughting office. Shortly after this he was appointed to the staff of the Department of Railways and Canals at Ottawa, where he was again in charge of the draughting office. In 1900 he was promoted to the position of assistant inspecting engineer, and two years later he became inspecting engineer.

On retiring from the department in 1921 after over fifty years service, Mr. Johnson took up his residence in Oakville, Ont., but returned to Ottawa in 1926.

Mr. Johnson was present at the first organization meeting of the Canadian Society of Civil Engineers, and is entered on the membership roll of The Institute as having been admitted as a Member on February 24th, 1887. He was a member of Council during the years 1902 and 1907, and was made a Life Member of The Institute by Council on November 25th, 1924.

PERSONALS

George W. Fuller, M.E.I.C., consulting engineer, of the firm of Fuller and McClintock, New York City, was elected president of the American Public Health Association at the annual meeting of that association held recently in Chicago.

Wm. Smaill, M.E.I.C., chief engineer of the Northern Construction Company and J. W. Stewart, has assumed the direction of the work which his company is doing in connection with the construction of the Windsor-Detroit tunnel.

A. B. Cooper, M.E.I.C., general manager of Ferranti Electric, Ltd., has just returned from a trip to the west coast. As a vice-president of the American Institute of Electrical Engineers, Mr. Cooper was the guest of the Regina and Vancouver sections of that institute.

D. H. McDonald, A.M.E.I.C., engineer in the Department of Public Works, Canada, Halifax, N.S., has been granted leave of absence for six months to take charge of the construction of a highway on the Island of Montserrat, British West Indies.

A. R. Greig, M.E.I.C., professor of mechanical engineering at the University of Saskatchewan, was reappointed as representative for the senate of the University at the meeting of the Saskatchewan Association of Architects which was held at Saskatoon, Sask., on October 29th last.

A. M. Moon, S.E.I.C., who graduated from the University of Toronto in 1924 with the degree of B.A.Sc., is now connected with the Vocational School, Peterborough, Ont. Mr. Moon was formerly at the Technical School, Niagara Falls, Ont.

J. G. Schaeffer, A.M.E.I.C., formerly a member of the city engineer's staff of Regina, Sask., has been appointed resident engineer for Underwood and McLellan, in connection with the new townsite of Flin Flon, Man. Mr. Schaeffer graduated from Queen's University in 1923, with the degree of B.Sc., and has been connected with the city engineer's department at Regina since that time.

W. L. Dawson, A.M.E.I.C., has severed his connection with the Northern Electric Company, Ltd., Montreal, and has accepted a position as patent attorney with the Bell Telephone Laboratories, Inc., New York City. Mr. Dawson, who is a graduate of Queen's University of the year 1913, has been with the Northern Electric Company since 1919, occupying in turn the positions of telephone switchboard engineer, research engineer and communication engineer. He was on active service overseas from 1915 to 1919, having the rank of Major, and being wounded in July 1916.

G. A. Gaherty, A.M.E.I.C., formerly manager of the Calgary Power Company, has been made president of that organization, and will move his headquarters from Montreal to Calgary. Mr. Gaherty will, however, retain his post as chief engineer of the Montreal Engineering Company, the parent organization of the Calgary Power Company. Mr. Gaherty, it is understood, will also have an office at Regina, Sask., where he will act for the Royal Securities Company in connection with the acquisition of power franchises and construction of power transmission lines on the prairies.

A. G. Moore, S.E.I.C., who was formerly on the staff of the electrical department of the Asbestos Corporation of Canada, Thetford Mines, Que., has recently entered the employ of the Shawinigan Water and Power Company, Ltd., at Shawinigan Falls, Que. Mr. Moore, who graduated from the Nova Scotia Technical College in 1925 with the degree of B.Sc., was for a time located at Wilkinsburg, Pa., with the Westinghouse Electric and Manufacturing Company, on their students' test course, and was later attached to the engineering staff of the Bell Telephone Company of Canada, at Montreal, Que.

C. Oldrieve Thomas, A.M.E.I.C., a member of the staff of the Dominion Bridge Company, Montreal, has been granted patents on a metal-to-metal flexible shaft coupling without springs or back-lash. Since coming to America from the Old Country in 1904, Mr. Thomas has had extensive experience in structural steel and other engineering work, having been connected at various times with the Canadian Westinghouse Company, Ltd., the Algoma Steel Corporation, the Canada Car and Foundry Company, Fraser and Chalmers of Canada, the Montreal Light, Heat and Power Consolidated and Canadian Vickers Limited.

Burton M. Hill, M.E.I.C., has been appointed manager of the Maritime provinces for F. J. Fairhall and Associates, Limited, Investment Trust Bankers. Mr. Hill will make his headquarters at Saint John, N.B. He is a graduate of

BURTON M. HILL, M.E.I.C.

civil engineering of the University of New Brunswick, and has had twenty years of experience in construction and consulting, railway, highway and bridge engineering. He was formerly Minister of Public Works of the province of New Brunswick and is president of Lewis-Connor and Sons, and a director of Connor Bros., Black's Harbour, N.B.

H. W. R. Shepherd, A.M.E.I.C., formerly resident engineer with the Foundation Company on the construction of the Ghost river dam for the Calgary Power Company, is now connected with the Northwestern Power Company at Whitemouth, Man. Mr. Shepherd, who was formerly connected with the James Ruddick Construction Company in Quebec City, and at one time resident engineer for the highway department of the province of Alberta, was overseas with the Alberta Dragoons and the Second Battalion of Canadian Engineers from 1914 to 1919.

Horace L. Seymour, M.E.I.C., who for the past two years has been resident engineer for the Town Planning Commission of Vancouver, B.C., has been appointed as director of town planning for the province of Alberta, and will undertake his new duties on January 1st, 1929. A provincial town planning board has been appointed in Alberta, and Mr. Seymour will be the engineering executive official of this board. Mr. Seymour, who obtained the degree of B.A.Sc. from the University of Toronto in 1913, was at one time special lecturer in town planning in the Department of Civil Engineering at that university, and prior to leaving for Vancouver, was engaged in consulting work in Toronto.

W. H. Riehl, A.M.E.I.C., City Engineer of Stratford, Ont.

W. H. Riehl, A.M.E.I.C., was recently appointed city engineer of Stratford, Ont. Following his graduation from the University of Toronto in 1920, with the degree of B.A.Sc., Mr. Riehl was for several months connected with the Grand Trunk Railway, but in October 1920 he became assistant engineer of the city of Stratford, where he remained until 1925 when he was appointed engineer of the town of Brampton, Ont., which post he has held up to the present time.

F. W. Gray, M.E.I.C., Receives Appointment

F. W. Gray, M.E.I.C., has been appointed assistant general manager of the Dominion Coal and Dominion Iron and Steel Companies. From the time of his arrival in this country from England, in 1904, until 1918, Mr. Gray was connected with the Dominion Coal Company, acting as assistant to various general managers, later becoming assistant to the president of the Nova Scotia Steel and Coal Company. From 1919 to 1921 he was editor of the Canadian Mining Journal and Iron and Steel of Canada, and in 1921 he became assistant to the vice-president of the British Empire Steel Corporation. From 1923 to the present time Mr. Gray has been assistant to the president of the British Empire Steel Corporation.

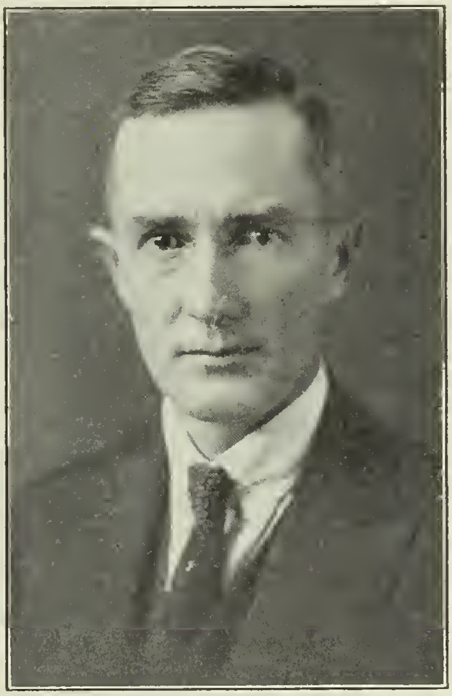
F. W. GRAY, M.E.I.C.

Appointed Chief Engineer of Dryden Paper Company

Selwyn H. Wilson, A.M.E.I.C., is now chief engineer of the Dryden Paper Company, Ltd., at Dryden, Ont. Mr. Wilson, who was overseas with the Canadian Engineers and Artillery from 1915-19, is a graduate of McGill University of the year 1922. On graduation he was employed by the Department of Railways and Canals at Cornwall, Ont., with a precise levelling party, and in December 1922 became attached to the Riordon Pulp Corporation at Temiskaming, Que., on draughting and designing work. From 1923 to 1925 he was assistant to the chief forester of the St. Maurice Pulp and Paper Company, Ltd., at Montreal, following which he joined the staff of the Riordon Pulp Corporation, Ltd., at Hawkesbury, Ont., as maintenance engineer, later becoming assistant to the chief engineer, and in 1927 he accepted the position of mechanical engineer with the Canadian International Paper Company at Hawkesbury.

A. Ross Robertson, A.M.E.I.C., Appointed to Dominion Bridge Company

A. Ross Robertson, A.M.E.I.C., has been appointed manager of the Ontario division of the Dominion Bridge Company. Following his graduation from the University of Toronto in 1909 with the degree of B.A.Sc., Mr. Robertson joined the engineering staff of the old Canada Foundry Company, Ltd., later taken over by the Canadian Allis-Chalmers, Ltd. In 1912 he became sales engineer for Messrs. McGregor and McIntyre, Ltd., Toronto, with which firm he has been connected up to the present time with the exception of the period 1915-1919, when he was overseas with the Canadian Expeditionary Force, having the rank of lieutenant and later captain. When the company was reorganized last March, and the name changed to McGregor-McIntyre Structural Steel, Ltd., he was appointed vice-president, following the retirement of J. H. McGregor, and R. L. McIntyre assumed the presidency.



A. G. TAPLEY, A.M.E.I.C.

Chief Engineer of Halifax Harbour Commission

A. G. Tapley, A.M.E.I.C., assistant engineer in the Department of Public Works, Canada, at Halifax, N.S., has been appointed chief engineer of the Halifax Harbour Commission. Mr. Tapley will have charge of all the engineering work recommended by the commission in connection with harbour construction and maintenance. His early engineering work was with the Intercolonial Railway, with which he became connected in 1898, and between that date and August 1905 he occupied the positions of draughtsman, transitman and engineer in charge of construction. During the following two years he was with the National Transcontinental Railway as leveller, draughtsman, instrumentman and resident engineer. During 1908 he again became connected with the Intercolonial Railway. From 1909 until the present time he has been with the Department of Public Works of Canada as assistant engineer, having previously been located in Saint John, N.B. It will be recalled that Mr. Tapley was awarded the Gzowski Medal for his paper entitled "Concrete in Sea Water," which was published in the November 1924 issue of The Journal. Mr. Tapley has been most active in the affairs of The Institute, having served on the executive of the Saint John Branch in 1921, and as chairman of the branch in 1922.

ELECTIONS AND TRANSFERS

At the meeting of Council held on November 16th, 1928, the following elections and transfers were effected:—

Associate Members

ANDERSON, Charles, mech'l and struct'l dftsman., Hamilton Bridge Co., Ltd., Hamilton, Ont.

FULTON, Edward Arthur, B.Sc., (C.E.), (Univ. of Man.), res. engr. on constrn. of waterworks plant for City of Kingsport, Tenn.

FORD-SMITH, Percy, gen. mgr. and president, Ford-Smith Machine Co., Ltd., Hamilton, Ont.

McFADYEN, Andrew James, B.A.Sc., (Univ. of Toronto), 59 Alloway avenue, Winnipeg, Man.

McGEE, Thomas Aloysius, M.E., (Polytech. Inst. of Brooklyn), res. engr. of Furnace Engineering Co. of Canada, and vice-president and chief engr., F. W. Pennock & Co., Montreal, Que.

MIESCHER, William Albert, C.E., (Polytech. Inst., Zurich), asst. engr., Alcoa Power Co., Ltd., Arvida, Que.

PARKER, John Spence, B.A.Sc., (Univ. of Toronto), gen. mgr., The Gatineau Electric Light Co., Ltd., Ottawa, Ont.

ROBSON, William Gordon, B.Sc., (E.E.), (Univ. of Man.), sales engr., Otis-Fensom Elevator Co., Ltd., Hamilton, Ont.

Juniors

ADLINGTON, Wilfred Ernest, B.Sc., (Mass. Inst. Tech.), with J. T. Donald & Co., Ltd., Montreal, Que.

GELDARD, Percy Walter, (completed third year, Applied Science, Univ. of Toronto), 93 Boon avenue, Toronto, Ont.

GRUNSTEN, Arne William, B.A.Sc., (Univ. of Toronto), struct'l designing engr., H.E.P.C. of Ontario, Toronto, Ont.

WRIGHT, Noel Mithsdale, B.Sc., (Univ. of Illinois), sales engr., Ferranti Electric, Ltd., Montreal, Que.

Transferred from the class of Associate Member to that of Member

STAIRS, Gordon Salter, B.Sc., (N.S. Tech. Coll.), sales mgr. and engr., L. E. Shaw, Ltd., Avonport, N.S.

SWAN, Hamilton Lindsay, asst. engr. i/c Yale District, Dept. Public Works, B.C., Merritt, B.C.

WEBB, Christopher Everest, B.A.Sc., (Univ. of Toronto), district chief engr., Dominion Water Power & Reclamation Service, Vancouver, B.C.

Transferred from the class of Junior to that of Associate Member

GAUTHIER, Paul Gillies, B.Sc., (McGill Univ.), Alcoa Power Co., Ltd., Kenogami, Que.

ROSE, Hugh Grant, B.A.Sc., (Univ. of Toronto), field engr., Ensley Works, Tennessee Coal, Iron & Railroad Co., Birmingham, Ala.

WILLIAMS, Arthur Samuel, B.Sc., (Univ. of Man.), chief operator, Manitoba Power Co., Ltd., Great Falls gen. station, Great Falls, Man.

Transferred from the class of Student to that of Associate Member

LAWTON, Frederic Lewis, B.A.Sc., (Univ. of Toronto), asst. to supt. of operation, Duke-Price Power Co., Isle Maligne, Que.

LAYNE, John Graham, B.Sc., (McGill Univ.), plant investigation work for J. T. Donald & Co., Ltd., Montreal, Que.

MacKENZIE, Donald Gordon, B.Sc., (McGill Univ.), consultg. and contracting engr., Montreal, Que.

WELSH, Dean Thomas, B.A.Sc., (Univ. of Toronto), res. engr. i/c of constrn., Driftwood-Smooth Rock Falls Road, Dept. of Northern Development, Ontario Govt.

Transferred from the class of Student to that of Junior

BIELER, Jacques Louis, B.Sc., (McGill Univ.), asst. engr., Dominion Oilcloth & Linoleum Co., Montreal, Que.

CREIGHTON, Thomas Whitelock, (Diploma, R.M.C.), transitman, Kenora Divn., C.P.R., Kenora, Ont.

EMERSON, Theodore Roosevelt, B.A.Sc., (Univ. of Toronto), instr'man, terminal engr.'s office, C.N.R., Toronto, Ont.

GRINDLEY, Frank Llewellyn, B.Sc., (Univ. of Alta.), res. engr. on constrn., C.N.R., western region, Edmonton, Alta.

HARBERT, Edward Thomas, B.Sc., (McGill Univ.), engr. to sales dept., Canadian Ingersoll-Rand Co., Ltd., Montreal, Que.

HARRIS, Arthur Clifford, B.Sc., (N.S. Tech. Coll.), struct'l bridge and machine detailing, Nova Scotia Steel & Eastern Car Co., New Glasgow, N.S.

KILLAM, Donald Alexander, B.Sc., (McGill Univ.), paper mill designing, Canada Power & Paper Co., Ltd., Montreal, Que.

KURTZ, Harold John, B.Sc., (Queen's Univ.), dftsman., Tropical Oil Co., El Centro, Colombia, S.A.

McCORMACK, Donald Neill, B.Sc., (Univ. of N.B.), dftsman., Dexter P. Cooper, Inc., Welchpool, Campobello, N.B.

McGILLIS, Lester, B.Sc., (McGill Univ.), operating engr., Brazilian Hydro-Electric Co., Parahyba development, Rio de Janeiro, Brazil.

MOON, George Douglas, B.A.Sc., (Univ. of Toronto), asst. field engr., Bell Telephone Company, Quebec, Que.

ROBERTS, Frederic Morley, B.Sc., (Queen's Univ.), asst. to engr. on pulp and paper mill electrification, also cement mill electrification, General Electric Company, Schenectady, N.Y.

SMYE, Gordon Renfrew, B.A.Sc., (Univ. of Toronto), asst. to chief chemist, Firestone Tire & Rubber Co., Hamilton, Ont.

TAMES, John Alexander, B.Sc., (Univ. of Alta.), salesman on power apparatus and service, Canadian Westinghouse Co., Ltd., Vancouver, B.C.

VAN KOUGHNET, Edward Matthew, (Diploma, R.M.C.), estimates on transmission lines, design and const., hydrology, Canadian & General Finance Co., Ltd., Toronto, Ont.

Students Admitted (Undergraduates)

ABBOTT, Donald S., (Queen's Univ.), 131 Union street, Kingston, Ont.

ACTON, William Arthur, (Queen's Univ.), 78 Wellington street, Kingston, Ont.

ADAMS, Herbert Wallace, (Queen's Univ.), 2024 McIntyre street, Regina, Sask.

AGNEW, Thomas Charles, (Queen's Univ.), 7 Aberdeen street, Kingston, Ont.

AITKENS, John Currie, (Univ. of Man.), 563 Broadway avenue, Winnipeg, Man.

AMES, Horace Lyall, (Queen's Univ.), 380 Brock street, Kingston, Ont.

ANDERSON, Roderick Victor, (Univ. of B.C.), 3520 13th avenue west, Vancouver, B.C.

ARMSTRONG, William Harrison, (Queen's Univ.), 380 Brock street, Kingston, Ont.

BAKER, Clifford M., (Queen's Univ.), 309 Frontenac street, Kingston, Ont.

BAKER, John Hyatt, (Queen's Univ.), 135 Centre street, Kingston, Ont.

BARTON, Edward Allen, (Queen's Univ.), 557 Johnston street, Kingston, Ont.

BELL, George Moore, (Univ. of Man.), 235 Colony street, Winnipeg, Man.

BENARD, Frederick, (McGill Univ.), 4877 Park avenue, Montreal, Que.

BENJAFIELD, Philip Grant, (Queen's Univ.), 120 Earl street, Kingston, Ont.

BISHOP, Joseph William, (Univ. of B.C.), 1226 13th avenue west, Vancouver, B.C.

BLACKETT, Harold Wilfrid, B.A., (Univ. of B.C.), 4487 13th avenue west, Vancouver, B.C.

BOOK, Clarence F., (Queen's Univ.), 102 Clergy street east, Kingston, Ont.

BULMER, Harold, B.A., (Queen's Univ.), 556 Princess street, Kingston, Ont.

BURBANK, Ellsworth Frederick, (Queen's Univ.), 142 Bagot street, Kingston, Ont.

BURGESS, Thomas John, (Queen's Univ.), 517 Johnston street, Kingston, Ont.

BUSHLEN, Harvey E., (Queen's Univ.), 416 Earl street, Kingston, Ont.

CAIRNCROSS, Alexander T., (Queen's Univ.), 560 Princess street, Kingston, Ont.

CAMERON, Gordon Alan James, (Queen's Univ.), 347 2nd street, Brandon, Man.

CAMPBELL, James Stouffer, (Queen's Univ.), 560 Princess street, Kingston, Ont.

CARPENTER, Robert Burton, (Univ. of B.C.), 1107 33rd avenue west, Vancouver, B.C.

CLIMO, Percy Lloyd, (Queen's Univ.), 72 Division street, Kingston, Ont.

CORNEIL, Ernest R., (Queen's Univ.), 1 Mack street, Kingston, Ont.

CORNEIL, Robert B., (Queen's Univ.), 1 Mack street, Kingston, Ont.

CORNISH, Charles Rischman, (Univ. of B.C.), 323 26th street east, North Vancouver, B.C.

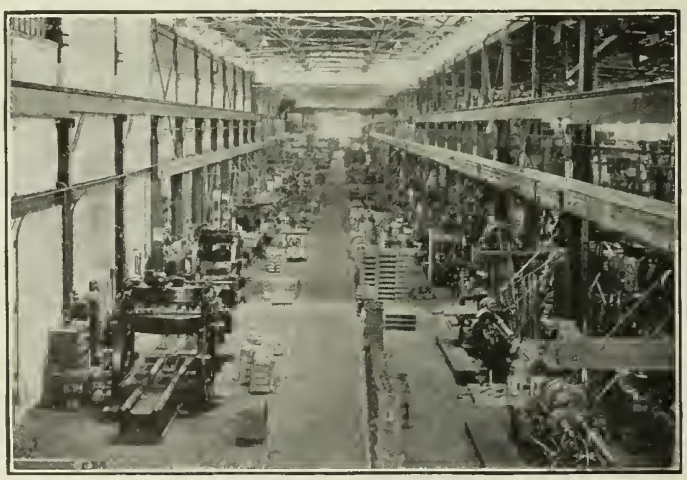
The Annual General Professional Meeting

at HAMILTON, ONTARIO

February 13th, 14th & 15th, 1929



Machine Shop of One of the Manufacturing Plants to be Visited.

Plan now to be present

The following are some of the industrial plants which may be visited during the Annual Meeting in Hamilton.—

Hamilton Bridge Company, Limited
Steel Company of Canada Limited
Hamilton By-Product Coke Ovens Limited
Canadian Westinghouse Company, Limited
Otis-Fensom Elevator Company, Limited
Dominion Foundries & Steel Limited
Sawyer Massey Company, Limited
National Steel Car Corporation Limited
Frost Steel & Wire Company, Limited
B. Greening Wire Company, Limited
Steam Plant of Dominion Power and Transmission Company, Limited
City Sewage & Water Works Pumping Station

Full details of the Programme will be published in the next issue of the Journal.

BOOK REVIEWS

Impurities in Metals, Their Influence on Structure and Properties

By Colin J. Smithells. Chapman and Hall, London, 1928. Buckram, 6 x 9½ in., 157 pp., figs., tables, plates, $4.50.

The author considers the influence of "impurities" or "minor constituents" on the structure and physical properties of metals and alloys. His method is fundamental and scientific. He begins by describing the structure of pure metals and alloys as revealed by the microscope and by X-ray analysis; he then shows the changes in structure that result from the presence of minor constituents, which may be small amounts of other metals, non-metallic solid elements such as sulphur and carbon, gases such as oxygen, hydrogen and nitrogen, slag and other non-metallic inclusions. In connection with the changes of structure, the author discusses the influence of these impurities on the mechanical properties, the electrical properties and the corrosion of metals and alloys.

The book is clearly written; it contains a large amount of valuable information regarding the effect of impurities, and this information is arranged to show the underlying principles instead of being a catalogue of unrelated facts. The book is well printed and illustrated, and it will be very useful to engineers and others who wish to make a thorough study of the influence of impurities on metals and alloys.

A. Stansfield, M.E.I.C.,
Professor of Metallurgy,
McGill University.

The Falls of Niagara

By Glenn C. Forrester. D. Van Nostrand Company, New York, 1928, buckram, 9 x 6 in., 155 pp., maps, plates, diagrs., $2.50.

Mr. Forrester in this compact volume of one hundred and fifty-five pages gives in a very readable form the story of Niagara falls. He does not claim to put forward any new facts, but he has gathered together from the scattered papers written by the many distinguished geologists who have made exhaustive studies of the region a great body of most interesting information, and he presents in the form of a continuous narrative, free from all confusing technicalities, the life history of the falls from their birth to the present day. The story thus unfolded is of striking interest, but the reader can from it form but little idea of the immense amount of detailed and painstaking research which had to be carried out before this simple narrative could be written.

The Niagara river flows out of lake Erie at Buffalo and into lake Ontario at Youngstown. As it leaves lake Erie it is about 600 feet above sea level, but where it enters lake Ontario it is somewhat less than 300 feet above the sea, so that during its course from one lake to the other it falls about 300 feet. This descent is made in a series of rapids and falls with one great vertical drop,—that at Niagara falls, which are 160 feet high.

The chief interest of Niagara falls from a scientific standpoint was concentrated in the fact that it was expected that they would prove to be a sort of geological time-clock,—one that would furnish, to a certain extent, a means of measuring geological time in terms of human years.

In the time immediately preceding the advent of man in North America the continent was covered by a great ice sheet, such as that which now spreads over Greenland. The thickness of this ice sheet is conservatively estimated at 3,000 feet. At that time the surface features of practically the whole northern portion of our continent were completely hidden beneath this great mantle of glacial ice. This period is known as the "glacial age."

In the glacial age the Niagara river was, of course, nonexistent. There came a time, however, when the intense cold commenced to ameliorate and the ice gradually melted away, commencing at the southern border where the climate was mildest. The ice sheet thus commenced to recede,—the water from the melting of this enormous mass of ice gathered itself together in a series of lakes and rivers and established a new drainage system on the land area which was thus laid bare. The waters of this system first discharged southward into the Ohio river. When, however, the ice receded as far as the shallow depression in which the Niagara river now runs out of lake Erie, the present Niagara river came into being and ran out of lake Erie into lake Ontario, larger then than at present and in its larger extension known as lake Iroquois, falling down into this lake over the Niagara escarpment at Lewiston. The river at once began to cut its way back through the plain, thus starting the Niagara gorge. This process it has continued from that remote period to the present time. During this period the river has cut its way back for a distance of seven miles. The International Niagara Control Board has found by very careful measurements that the average rate of recession of the falls at the active part of the crest of the Horseshoe has been 3.7 feet per year since 1842, when the first accurate survey of the crest of the falls was made. It might seem a mere matter of simple arithmetic to divide the distance of seven miles by the amount of the annual recession,—namely, 3.7 feet,—and thus ascertain the number of years which have elapsed since the great glacial ice sheet retreated from southern Ontario.

But this, like many other problems, is much less simple than it looks. The late Mr. G. K. Gilbert, after a careful study of the falls many years ago, stated that there were some twenty-three factors which affected the result and for which corrections would have to be made before the number of years which had been occupied by the recession could be determined. Thus it has been ascertained that the volume of water precipitated over the fall has varied greatly at different times, and thus the recession has been much more rapid at some times than at others. The river runs over strata that are not horizontal but are gently inclined upstream. Some of these strata are softer and therefore more quickly eroded than others. During the recession, the river has thus encountered a varying degree of resistance to its task. Again, when the river reached the locality where the whirlpool is situated it encountered the old filled up valley of a Niagara river, which in pre-glacial times had run across the country in a course which is transverse to that of the present river. The falls, when they reached the soft alluvial deposits in this old valley, cut through them very quickly, but how quickly cannot be determined. In the present state of our knowledge accurate corrections for these and for all the other factors which complicate the problem cannot be made, and hence the study of Niagara falls has not given, as was hoped at one time, an accurate measurement of the time which has elapsed since the close of the glacial age in southern Ontario, a problem which has, however, been more recently solved by attacking it from quite another direction.

This interesting subject cannot, however, be pursued further in this brief review; the reader must go to the book itself, where he will also find an interesting account of some of the geological agencies which have been at work in shaping the Niagara story, then an account of the great ice sheet and of the birth and development of the Great Lakes, which were incidents in its retreat; of the various companion falls which at first were associated with Niagara and which were gradually dispossessed by the latter and dried up by the lowering of the waters, and finally a discussion of the question of the future recession of the falls and what old age has in store for them.

F. D. Adams, Hon.M.E.I.C.,
Montreal, Que.

Distribution of Electricity by Overhead Lines

By William T. Taylor, Charles Griffin & Company, Ltd., London, 1928, buckram, 6 x 9½ in., 265 pp., tables, diagrs., illus., $6.50.

The author in his preface clearly states that it is "general overhead distribution practice" which is covered by this book. The book will be found to treat this subject in an interesting manner, and bears much internal evidence of an intimate acquaintance with the actual conditions met with in the operation of such systems. It discusses in a pleasant argumentative fashion the necessity of the design being carried out so as to give a convenient and safe system at a cost reasonably related to its earning power.

The author, it appears, is an enthusiastic advocate of the three-phase four-wire system and claims its superiority over all other systems for a very wide range of service. He advises its use for secondary distribution at lamp voltage, as well as for primary distribution at moderate voltage, and the inference is to be drawn that its field of usefulness extends to the extra high voltage networks, which are engaging much public attention in Britain owing to the projects of the Electricity Commission. In his preface the author speaks of this system as "a *novel* line distribution system." Its novelty may be apparent to the British reader not acquainted with practice on this side of the Atlantic, but it is quite generally employed for primary distribution in Canada; and in the United States its use for this purpose nearly equals that of all other systems combined.

The book contains chapters on the structural features, design and installation of wood pole lines, and also on the operation and maintenance of such lines. The seeker after information on these matters will find here a far more complete and authoritative treatment of this part of the problem than is usually found in books of this comprehensive type.

E. G. Burr, A.M.E.I.C.,
Assistant Professor of Electrical Engineering, McGill University.

Practical Designing in Reinforced Concrete

By M. T. Cantell, Part I. E. & F. N. Spon, Ltd., London, 1928, buckram, 6 x 9 in., 277 pp., illus., $3.75.

In the present book, which is the first volume of a two-volume work, the author presents an elementary discussion of reinforced concrete design and practice to suit more particularly those whose mathematical training has not been very extensive. While the author presents the work as a possible engineering college text book, it is scarcely so suitable for that purpose as numbers of other books that might be named. It is rather more a volume for a technical high school, as we know such in this country.

The book, which is not divided into chapters and therefore lacks somewhat in convenience, contains a large number of unnumbered articles on varieties of topics connected with concrete and reinforced concrete. At the outset there is a discussion of the properties of the materials involved, resistance to earthquake, hurricane and fire, mixing and depositing, removal of forms, deterioration of concrete, waterproofing and many allied subjects. There then follows a presentation of the elements of design of reinforced concrete beams, slabs, floors and columns. A small amount of space is given to the subject of concrete piles. The work concludes with a statement of the formulæ employed with demonstrations of their derivation.

While the volume is well printed, there are certain errors, typographical and otherwise, which no doubt will disappear in a second edition. For example, the reinforced concrete railway viaduct illustrated on page 243 is not located at Richmond, England, but at Richmond, Virginia. The illustrations are legible but lack the perfection of detail that characterizes the illustrations in technical books published on this continent.

C. R. Young, M.E.I.C.,
Professor of Structural Engineering, University of Toronto.

Reinforced Concrete Bridges

By W. L. Scott, assisted by C. W. J. Spicer, 2nd Edition. Crosby, Lockwood & Son, London, 1928, buckram, 6 x 9 in., 220 pp., tables, diagrs., plates, $6.25.

In this, the second, edition of a work published in 1925, the author has made some slight additions at the end of the volume, consisting of seven figures and an addendum to the Appendix the book has not been changed, with the possible exception of correcting typographical errors.

The work as it stands is a useful discussion of reinforced concrete bridge work. Chapters are devoted to loading and wind pressure, temperature and shrinkage effects, influence lines, arch bridges, girder bridges, bow-string girder bridges, temporary and permanent hinges, foundations and abutments, description of bridges and an appendix.

The book is a judicious blending of the mathematical and practical aspects of the design of the structures forming the subject matter. Illustrations are drawn entirely from European examples, and more especially from the particular works undertaken by the author's firm, Considère Constructions, Limited. It is regrettable that in a book which purports to deal with the general subject of reinforced concrete bridges, there is no mention of such epoch-making structures as the great arch at St. Pierre du Vauvray and the still more remarkable three-arch bridge at Plougastel, not to mention the Cappelen memorial bridge at Minneapolis.

While every engineer having to do with reinforced concrete bridges should possess a copy of this work, there is not sufficient difference between the second edition and the first to warrant the purchase of the later edition if the earlier one is available.

C. R. Young, M.E.I.C.,
Professor of Structural Engineering, University of Toronto.

Exemples de Calculs des Constructions en Béton Armé

Léon Cosyn, Librairie Polytechnique, Ch. Béranger, Paris et Liege, 1928. Buckram, 6 x 8½ in., 454 pp., diagrs., $2.60.

The author, who is well-known in France and Belgium as principal architect of the Belgian state railways, has compiled a handbook covering the designing and detailing of reinforced concrete structures. Particular attention is given to the various members making up the framework of multistorey buildings.

Retaining walls, bridges, hydraulic structures and bins are also treated in a general way.

The influence of framing arrangements upon the cost of the finished structure is stressed, and several chapters are devoted to the development of the economical design of floor panels. Although the relative costs of materials and labour are different in this country, the methods of analysis presented should be valuable to engineers engaged upon commercial designing anywhere.

The seven divisions of the book are as follows:—

- First Part:—Lay-out, design and cost of falsework and forms.
- Second Part and Third Part:—Tension and compression members.
- Fourth Part and Fifth Part:—Simple bending, bending and direct stress.
- Sixth Part:—Miscellaneous structures.
- Seventh Part:—Tables.

In part four, an exhaustive study is made of concrete foundations on piles. The rather involved action of stirrups in such members is clearly explained. Footings comprising from one to seven piles are treated by means of worked-out examples, where material will be found which is seldom available in current text-books.

The numerous examples given throughout the book are similarly worked out, and one is impressed with the attention given to the detailing of each reinforcing bar with reference to anchorage, bond stress, crushing of the concrete, etc. Such points, affecting the ultimate strength of structures, are often neglected or overlooked in some of the modern treatises.

J. F. Brett, M.E.I.C.,
Designing Engineer, Montreal Water Board.

Correspondence

Zaria, Nigeria, October 28th, 1928.

The General Secretary,
The Engineering Institute of Canada,
Montreal, Que.

Dear Sir:—

I am sending you three photographs which may be of interest to railway construction men in Canada.

No. 1 shows part of the track-laying train, which consists of four wagons of rails, four of sleepers, one of fittings, one tank wagon, one wagon of telegraph material and one tool van.

No. 2 shows rails and sleepers being carried out from train—the rails are B.S. 60-lb., 33 feet long and the sleepers are South African pattern steel.

No. 3 shows rails being bolted to the sleepers. This is done with T-bolts and clips. The clips are two sizes to enable gauge to be widened on curves.

The Zaria-Gusau branch construction is 140 miles in length and taps an excellent cotton growing country. It runs from Zaria in a northwesterly direction to within a short distance of the French Sudan.

The labourers are Mohammedan and pagan natives and supervision is carried out by European engineers and foremen and native overseers and gangers.

With best wishes, I remain,

Faithfully,

R. D. Thexton, A.M.E.I.C.,
Engineer-in-charge,
Zaria-Gusau Construction.

Map of Southwestern British Columbia

A geological map of interest to the people of British Columbia has just been issued by the Geological Survey, Department of Mines, Canada. It is published on a scale of eight miles to one inch and covers an area in the southwestern part of the province of British Columbia extending from the coast, including Vancouver island, east as far as Lillooet and from the International boundary north to some distance beyond Chilko lake and Fitzhugh sound. The main geographical features are shown, the geology is indicated in colours, and the localities in which the most important economic mineral deposits have been found are shown by legible symbols.

Geological Maps of Northern Manitoba

Reprints of two geological maps of parts of northern Manitoba have been published. One is a map on a scale of three miles to one inch of the Athapapuskow lake region and covers a section of country extending from Amisk lake in Saskatchewan to Elbow lake in Manitoba, including the Flin Flon and Mandy mines. The other is a map on a scale of two miles to one inch of the Reed and Wekusko lakes region and covers a section of country extending from Reed lake east to some distance beyond Herb or Wekusko lake. Copies of these maps may be had on application to the director, Geological Survey, Ottawa.

A compact and yet comprehensive handbook on reinforced concrete building design has been issued by the Portland Cement Association under the title of "A Handbook of Reinforced Concrete Building Design." The tentative building regulations for reinforced concrete of the American Concrete Institute, appearing in the 1928 proceedings of that body, and Mr. Arthur R. Lord's paper on "Design and Cost Data for the 1928 Joint Standard Building Code," which was presented before the above-mentioned institute this year, have been reprinted to form this handbook. In presenting to the engineering profession the first edition of this publication, its sponsors have endeavoured to eliminate variables which limited the utility of former publications in this field. The handbook embodies tables and diagrams for the design of structural members of buildings in accordance with the provisions of the Joint Code, and the design practice which is presented offers a means of obtaining a degree of economy consistent with the quality of the concrete used. Copies of this handbook may be obtained from the Portland Cement Association, 33 West Grand avenue, Chicago, Ill., at a cost of $1.00 each.

The Canadian Ohio Brass Company, Limited, Niagara Falls, Canada, has just published a sixteen-page booklet with complete descriptions and illustrations of the new 250- and 600-volt lightweight portable electric arc welding machines for use on mine track circuit bonding and general repair work. The principle of unit construction of the resistance elements in these machines is fully described. Besides ordering information, brief illustrated reference is made to the various types of rail bonds manufactured by that company. Copies of the welder booklet will be furnished upon request.

Canada Gypsum and Alabastine, Limited, have issued a new booklet on Gypsum Partition Tile and its many uses in modern construction. It is believed that this booklet, which has been designed to serve as a reliable and handy reference on the subject, will fill a long-felt want, on the part of architects and engineers of to-day, for a comprehensive study of the many phases of gypsum tile construction. Copies of this booklet may be obtained upon request from the head office of Canada Gypsum and Alabastine, Limited, at Paris, Ontario.

Railway Construction Work in Nigeria.

BRANCH NEWS

Border Cities Branch

Orville Rolfson, A.M.E.I.C., Secretary-Treasurer.
R. C. Leslie, Jr.E.I.C., Branch News Editor.

The speakers of the evening at the October meeting of the Border Cities Branch were O. E. Fleming, K.C., president of the Canadian Deep Waterways Association, and Mr. E. G. Odette, member of parliament for East Essex.

The St. Lawrence River Development

Mr. Fleming was the first speaker. He traced the development of the St. Lawrence canal systems from the earliest times, pointing out how inevitable further development was. The Canadian Deep Waterways Association is engaged in the business of assisting the government in its study of the St. Lawrence question, by collecting relative information and by broadcasting the same to the public.

Mr. Fleming set forth the main points which are raised in objection to Canadian participation in an international project for the improvement of the St. Lawrence. One of the objections is that because the city of Chicago is diverting water from the Great Lakes system we should not make any move toward mutual canalization. The answer to this is that because of an agreement entered into in 1909 by the International Joint Commission we granted the right to withdraw a certain amount of water. However, the amount has been greatly exceeded and has been the subject of litigation in the United States Supreme Court, and Chicago has been ordered to cease the excessive diversion. Because of sanitary considerations it is impossible to stop it at once without serious consequences, and therefore a gradual scaling down of requirements is in progress. The War Department receives a report at the end of each year on the steps taken to treat the Chicago sewage. To date the city has lived up to the schedule, and it is confidently expected that even before the St. Lawrence canal system is begun the excessive diversion at Chicago will be stopped.

A second objection raised is that there should be no foreign capital, that is, foreign government capital, invested in Canadian waterways, as would be the case if the recommendation of the Canadian National Advisory Committee were followed. The committee has recommended that the purely Canadian section of the river be developed by Canadian money and the international section by the United States. The objection to this is overruled by the two precedents which we have for similar action. The Livingstone channel in the Detroit river and the St. Clair Flats canal were built and are maintained by the United States, and yet Canada has lost no police rights over her part of these waters.

Mr. Odette followed Mr. Fleming and gave some interesting thoughts on the subject. He showed that the provinces of British Columbia and Alberta were turning to Vancouver as an outlet for their products, while Manitoba was interested in the Hudson Bay route. The government, he thought, was generally in favour of the scheme, but could not, of course, proceed without feeling that public sentiment was strong for the work. Mr. Odette thought that the offer of the financiers to construct the canal should be accepted. In his opinion, whatever disadvantages there might be in granting such rights to a private corporation were more than offset by the industrial advancement which would follow quickly upon the building of the canal and which would benefit all concerned.

The Hydro-Electric Power Commission of Ontario

Dr. F. A. Gaby, M.E.I.C., chief engineer of the Hydro-Electric Power Commission of Ontario, was the speaker at the November meeting of this branch, held on Friday, November 9th, in the Prince Edward hotel, Windsor.

Dr. Gaby explained the structure of the Hydro organization and traced its growth from its inception in 1906 to its present standing as a great distributor of power. The system is a co-ordination of power developments serving some 550 municipalities in Ontario, 233 of which are rural townships. There are five main points of note about the system, as follows:—

1. The wholesale generation of electricity is under the Hydro-Electric Power Commission, a body appointed by the government and whose engineering staff is entirely free from political interference.
2. Distribution within the bounds of a municipality is taken care of by a local commission appointed by the electors of the town.
3. The commission is financed by a provincial government loan, paid back over a period of forty years.
4. Municipal commissions financed by municipal debentures or loans from the provincial commission.
5. The cost of supplying electricity is proportioned to the various units each year and the rates for the ensuing year set.

In 1912 the system served twelve municipalities, with a supply of 10,000 horse power and a total investment of $10,000,000. By the acquisition of the plants of the Ontario Power Company and the Electrical Development Company, the development at Queenston and a contract with the Gatineau Power Company for 260,000 horse power and other developments throughout Ontario, the available developed horse power has been increased until it now stands at about one million. Of this total, 870,000 horse power is in the Niagara system, the remainder being made up by the other seven systems operated by the Commission. The total investment in local systems is $97,000,000, in the provincial system $212,000,000, making a grand total of $309,000,000. The number of consumers of hydro-electricity in 1912 was 34,000, as against 526,000 users in 1928.

Dr. Gaby showed views of the transmission lines, the Niagara and Queenston power plants, the Chippawa canal and the huge switching station recently completed at Leaside. This switching station receives the power over the 230-mile transmission line from the Gatineau river at 220,000 volts and feeds it into the Niagara system, stepping the voltage down to 110,000 in the process. A reel of moving pictures was shown illustrating the type of country through which the Gatineau-Toronto line was built, the methods of transporting steel to the site, sometimes as much as twenty miles from a railroad, and also the method of erecting the towers. The method used in locating this line was a great success. An airplane flew the length of the proposed line taking pictures of the country for a width of five miles. These pictures were then put together and the line plotted in the office. The line is so straight that in its whole length there are only two angles, both of which are less than four degrees.

The Detroit section of the American Society of Mechanical Engineers joined with us in this meeting, and the occasion was one of good-fellowship. A hearty invitation was extended to our members to attend the meetings of the A.S.M.E. in Detroit.

On Saturday afternoon, November 10th, the members of the branch visited the property of the Canadian Steel Corporation at Ojibway to see the first of the tubes for the Detroit-Windsor subway. These tubes are being built by the Canadian Bridge Company, of Walkerville.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The first meeting of the season under the auspices of the Lethbridge Branch was held in the Marquis hotel on Saturday evening, October 20th. Dinner was served at 6.30 p.m. when over forty members and visitors were present.

During the dinner the Rainbow orchestra contributed selections which were much appreciated. Mr. George Brown, A.M.E.I.C., gave a violin solo, assisted by Mrs. Brown at the piano. The popularity of these well-known artists was demonstrated by the repeated encores they received from those who were fortunate enough to hear them. The solos sung by Mr. William Stott were beautifully rendered, and those present extended their hearty thanks to the soloist, also to all those who so generously and unselfishly gave of their time and talent.

In introducing the speaker of the evening, Mr. J. D. Baker, who is plant superintendent of the Alberta Government Telephones, mention was made of the part Mr. Baker played in the development of telephone communication in Alberta, and particularly of the high class standard of service given by the department. Mr. Baker was associated in the early days of Alberta's development with the Bell Telephone Company, which was purchased by the provincial government and which has been successfully equipped, maintained and operated since. The popularity of the speaker among the members of his staff was stressed, and which is the envy of other operating companies.

Recent Development in Telephone Communication

Mr. Baker's subject, "Recent Development in Telephone Communication," was highly technical at times, but with the aid of lantern slides and the public address system which was operated by Mr. Mason, assistant transmission and equipment engineer, his hearers were able to follow in detail the problem of voice transmission. In part, the speaker drew attention to the wave structure of certain notes produced by various instruments, also by the voice. These wave structures were demonstrated by oscillograms. In comparing the values of power used, the speaker made reference to power men, calculating in terms of kilowatts, whereas telephone engineers had to contend with power values in micro-watts and milliamperes.

The elementary stages of sound wave production in front of a transmitter was illustrated, whereby varying electrical currents created by the carbon of the microphone flowed to the receiver at the other end of the circuit and there reproduced by the diaphragm to the original sound of the voice.

The introduction of repeating coils increased the economic value of physical lines, thereby creating extra circuits without the necessity of stringing additional wires.

Further development was made possible by the introduction of composite apparatus which further increased the number of derived circuits. By its use three telephone and four telegraph circuits were obtained over two pairs of line. Until the advent of the vacuum tube, telephone communication was retarded on account of the excessive high line attenuation. Long distance operation was not commercial over what is termed thirty standard cable miles. By the use of telephone repeaters, space, as far as telephone transmission is concerned, has been annihilated, speech being now possible throughout the entire globe. The carrier system, or wired wireless, is a further development in the art of communication. A carrier current circuit is a method of communication in which voice currents are modulated on a high frequency channel, and after amplification are transmitted over the physical toll line to the distant station, where the feeble currents arriving are again amplified, demodulated and directed into their respective circuits by means of electrical filters. The existing carrier operating between Calgary and Edmonton was the first installed in the British Empire and the fifth in existence. Lethbridge will become a carrier terminal point early in 1929. The use of this carrier will then make possible to transmit over two physical lines to Calgary; three regular telephone circuits; four telegraph, and two carrier telephone circuits.

Long distance lines are now used on large " hook-ups " in connection with radio broadcasting. A recent example of this was demonstrated on July 1st, 1927, when all the principal radio stations in Canada were connected with broadcast from Ottawa parliament buildings. The power level was maintained by use of one-way amplifiers distributed at strategic points along the circuit.

A further up-to-date service has been provided for the people of this province in the purchase of a public address system, by means of which large audiences may be addressed without effort on the part of the speaker. This apparatus was successfully used on the occasion of the recent visit to the province of His Royal Highness the Prince of Wales, when he spoke to a crowd of 10,000 people in Calgary.

The lecture was very much appreciated by the audience, and a hearty vote of thanks was accorded to Mr. Baker for the valuable information " broadcasted " to his hearers.

November Meeting

A well-attended meeting of the Lethbridge Branch assembled at the Marquis hotel on November 3rd, when the members met their old friend, J. T. Watson, A.M.E.I.C., who later in the evening gave them a splendid description of the steam plant of the East Kootenay Power Company, at Sentinel, Alberta.

During the dinner, the Rainbow Orchestra rendered delightful selections and helped in the community singing led by Mr. F. Teague, who also entertained with two well rendered vocal solos.

After the general business was concluded, Mr. Watson was accorded a welcome on his return to active participation in the affairs of the branch, and he then proceeded to explain the details of the stand-by plant, as given in the following paper.

The Steam Stand-by Plant of the East Kootenay Power Co.

The East Kootenay Power Company, Ltd., having their head office at Fernie, B.C., supplies power and light to the industries and towns from Kimberley, B.C., to Hillcrest, Alberta, the consumers including several of the large collieries of the Crow's Nest field. With rapid developments around Kimberley and the mining districts of the Crow's Nest pass, it became evident early in 1926 that additional power would be required to augment the supply from the company's two hydro-electric stations located at Aberfeldie, on the Bull river, and Elko, on the Elk river.

After careful consideration by the engineering department of the Power Corporation of Canada, Ltd., the holding company, it was decided to construct a steam plant as an auxiliary source of supply during periods of low water at the hydro-electric stations. The design and construction were carried out by the Power Corporation of Canada, Ltd., and ground broken for the construction camp in August 1926. The plant started operation in July 1927, slightly under one year from the commencement of the work.

The site chosen was at the eastern end of Crow's Nest lake, about one mile west of Sentinel flag station on the Crow's Nest branch of the Canadian Pacific Railway. This has proved to be an ideal location for a plant of this kind, having an ideal supply of clean cold water for condensers and boilers, convenient access to the above-mentioned railway for coal delivery, and the close proximity to the Crow's Nest pass steam coal fields, no doubt being deciding factors in the choosing of the site.

The building is of steel frame and brick construction and large enough for two 5,500 continuous maximum rating steam turbo generators, only one being at present installed, and served by an overhead crane of 20 tons capacity with electrically operated hoist. The turbine and alternator with direct connected exciter were built by C. A. Parsons and Company, Newearth-on-Tyne, England, the turbine being a single-cylinder reaction type exhausting into a surface condenser.

The ventilation of the alternator is known as the closed system, contained wholly within it and the foundation, the air being re-circulated through cooling units of the radiator type, provision being made through emergency air inlet and discharge doors for ventilation from outside should any accident happen to the closed system.

Auxiliaries such as circulating pump, service air and oil cooling and fire pumps are located in a pump pit to the east of the present unit and midway between this and the future unit. The pump room is below normal low water level in the lake, consequently the pumps are primed at all times.

The boiler room adjoins the turbine room and contains two Robb stay-bolt header, cross-drum water tube boilers rated at 665 h.p. each. Space is provided for a third boiler which is being installed at the present time.

The boilers are fired by powdered coal supplied by Simplex unit pulverizers of the impact type. This, the writer believes, is the first plant in the province of Alberta to use powdered coal and probably the only one west of Winnipeg. Experience gained during sixteen months at this station proved that this is an ideal system for burning high ash coal, providing the fusive point of the ash is not too low to cause slagging. Ratings up to 225 per cent could be maintained from coal having an ash content of 24 per cent and 10,800 B.t.u.

The necessary steam flow meters, recording and indicating thermometers, CO_2 meters, draught gauges and damper control are mounted on instrument boards located in the firing aisle and are necessary for the economical operation of the boiler plant.

All 6,600-volt breakers are installed in the basement of the turbine room; the transformer banks and high tension breakers being located outside, forming an outdoor substation. Here the voltage is stepped up from 6,600 to 66,000 volts and tied into the two-system transmission lines running from Kimberley to Hillcrest.

The operation of this plant has proved to be all the engineers responsible for its design anticipated, being efficiently reliable and well adapted for stand-by service. The powdered fuel equipment burners and furnaces are a very interesting feature of the installation. A large number of outside engineers interested in steam plant design have visited this plant since its installation, and invariably devote most of their attention and remarks to the fuel and furnace equipment.

The heat balance of the station is adequate, and provision has been made to take care of this important part of plant economy for any addition that may be necessary.

At the close of the paper, Mr. Watson was asked numerous questions, and the ready replies showed the speaker to be well versed in his subject. A hearty vote of thanks was accorded Mr. Watson for his good spirit in filling, at short notice, a breach occasioned by the absence of the speaker originally arranged for.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

An extremely lucid and comprehensive address on " Some Legal Aspects of Railway Engineering " was given before the branch by the Hon. Ivan C. Rand, regional counsel, Canadian

National Railways, Moncton, on the occasion of the first supper-meeting of the season, held in the Y.M.C.A. on October 25th. H. J. Crudge, A.M.E.I.C., chairman of the branch, presided. During the evening several very enjoyable vocal solos were rendered by Mr. Roy B. Metzler.

Some Legal Aspects of Railway Engineering

In his opening remarks, Mr. Rand confessed to a certain envy of the engineering profession. The lawyer is concerned solely with man-made regulations, which are constantly changing with the ever-changing social and economic standards of the people. The engineer, however, deals with, and is always striving to discover, the fixed and immutable physical laws of the universe, a fact which tends, more than anything else, towards intellectual honesty.

Railway law in Canada, and especially in the Maritime provinces, is very complicated. This is due in large measure to the varied character of the original ownership of the roads. In the case of government railways the ownership was vested in the Crown, and numerous immunities pertaining to Royalty were enjoyed by these lines. For example, previous to 1887, no government railway could be held responsible for loss of life or other accident due to negligence of its employees.

Referring to expropriation, the speaker said that, not withstanding the basic right of the individual to hold what is his own, the law gives the railways the somewhat arbitrary power to seize, at will, land required for their operation. The regulations under which this may be done are, however, very strict. The higher courts are always sympathetic to the rights of private ownership, and cases were cited where the finest legal technicalities were invoked to protect the individual from loss.

As a general rule, it is possible to collect land damages due to railway construction but not to railway operation. A continued trespass for more than twenty years raises the presumption that some legal right was granted in the beginning. This is known as prescriptive right. As an example, the presence of a railway embankment might cause the annual flooding of waste land. Should this continue without protest for twenty years, the owner, deciding later to cultivate the land, would have no legal recourse against the railway for any damage he might suffer by reason of the flooding.

The question of easements, or the effect which the expropriation of land may have on adjoining properties, was treated in detail by the speaker. In conclusion, an explanation was given of the relationship that exists between the railways and the public in the matter of highway crossings.

A hearty vote of thanks, moved by G. C. Torrens, A.M.E.I.C., and seconded by G. E. Smith, A.M.E.I.C., was tendered Mr. Rand by the chairman.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
Wm. McG. Gardner, A.M.E.I.C., Branch News Editor.

Anticosti Island Development

A romantic representation, illustrative of the marvellous possibilities that exist within our great Dominion, was ably described in two splendid papers on the "Anticosti Development," when on October 25th the branch was addressed by J. H. Valiquette, A.M.E.I.C., manager, Anticosti Corporation, and T. B. Fraser, S.E.I.C., resident engineer.

Opening with a narrative of the discovery and history of Anticosti, Mr. Valiquette proceeded to sketch the extent of its natural resources, referring especially to its wealth of timber.

In this respect the geological characteristics have favoured a dense growth amounting to possibly some 14,000,000 cords; a fine forest which the natural isolation of the island has saved from the ravages of fire.

Many interesting means have been developed for bringing out the cut and preparing it for shipment. These are fully presented elsewhere in this issue.

Fur, fish and game abound, the latter mainly deer, having increased to such an astounding extent during the past thirty years that today the 100,000 available constitute a valuable meat resource.

In expressing his appreciation of the large assembly present to hear the papers, Mr. Valiquette referred to the weekly meetings of some twenty years ago when twenty members constituted a normal attendance.

Mr. Fraser followed with a paper on the fine development of the harbour at Ellis bay to serve the larger undertaking assumed by the corporation. This has been likewise produced in this issue.

In opening the discussion Councillor O. O. Lefebvre, M.E.I.C., complimented the supervising engineers on the achievement of transferring the heavy wooden cribs from the mainland to the island without the slightest mishap.

Chairman F. C. Laberge, M.E.I.C., attested the pleasure and appreciation of the meeting in a vote of thanks, closing with a wish to view the development at closer range.

The meeting was presided over by A. Plamondon, A.M.E.I.C.

Heat, Rust, and Acid Resisting Steels

On October 30th members of the branch were the guests of the American Society for Steel Treating, Montreal Chapter, at a meeting in the chemistry building, McGill University, when an excellent lecture on "Heat, Rust and Acid Resisting Steels" was delivered by Dr. W. H. Hatfield, director, Brown-Firth Research Laboratories of Sheffield, England.

Prospecting by Physical Methods

What might well be described as a most informing and delightfully scientific lecture provided the branch with a profitable evening's enjoyment when, on November 1st, Dr. A. S. Eve, F.R.S., presented a splendid address and demonstration on devices for "Prospecting by Physical Methods."

After touching briefly upon several excellent magnetic and gravitational balances now in use to detect the presence and location of salt domes and ore bodies, the speaker described a process of discovering these same deposits with considerable accuracy by means of the vertical oscillogram or seismograph.

In this process some 300 pounds of t.n.t. explosive are fired at a depth of twelve to twenty feet below ground. The resultant shock is registered on a battery of these seismographs situated three to four miles away upon which the time of the explosion has already been recorded by radio signal. Subsequent study of the varying time intervals at each seismograph serves to indicate the nature of the medium through which the sound was transmitted. This method, based upon the density and elasticity of the intervening material, has been developed to such high precision that experienced companies are now spending up to $30,000 a month on explosions alone.

Of several electrical methods available for ore prospecting, one of the oldest is the Stronsberg process. This process depends for its success on the fact that surface water in the neighbourhood of sulphur bearing ores transmits the galvanic currents created by these ore bodies to a delicate potentiometer capable of measuring small variations in voltage. A very realistic demonstration of this simple and inexpensive method was given by Dr. Eve, using porous pots containing copper sulphate as the ground terminals.

Another good method is known as Lundberg's parallel wire process. In this method two wires are pegged down, parallel to each other but some distance apart. Current supplied to one will flow through the ground toward the other, but at any point the fall of potential will be related to the character of the transmitting material. An interesting experiment thereupon illustrated lines joining points of equal potential diverging from each other to pass round an ore body. A variation of this process developed by Dr. Eve and his associates known as the leap-frog method, is a simpler and easier version, giving splendid results.

A peculiar coincidence noticed with these methods that must be guarded against is the ability of water to simulate ore.

Another electrical process known as the horizontal loop or geophysical method depends upon the possibility of detecting re-radiation. Still another device described as Lundberg's two-coil method, consisting in grounding two coils and listening in on the connecting telephone circuit.

An interesting development resulting from research on terrestrial magnetism by the Carnegie Institute is a successful process for detecting ore bodies located at a considerable depth below the surface. This was described by Dr. Eve as a joyful method in that it merely consists in winding the handle of a megger and measuring the drop of potential across the middle third intervals of four equidistant ground stakes. A deduction from this resistivity method by Romney places the depth of the ore body as equal to the stake interval.

Simple surveys carried out by these methods at a cost of a few hundred dollars may yield results which will save many thousands of dollars in diamond drilling for ore bodies, oil deposits, and rock foundations for dam sites.

A hearty vote of thanks, proposed by Councillor Fraser S. Keith, M.E.I.C., was presented to Dr. Eve by N. L. Morgan, A.M.E.I.C., the presiding chairman.

REMAKING THE MAP OF CANADA WITH THE AERIAL CAMERA

The remarkable progress in the science of aerial photography as applied to the mapping of unexplored regions proved itself an intensely interesting topic when presented by the student section of the branch on November 15th. On that occasion the speaker of the evening Flying-Officer J. Moar, R.C.A.F., in a splendidly illustrated paper, discussed the methods now being employed to "Remake the Map of Canada with the Aerial Camera."

Due to the prevalence of lakes and water courses in the undeveloped north country and to the obvious advantage of an unobstructed view, a powerful seaplane of the pusher type is now employed on the majority of these aerial surveys.

This class of plane is well suited to photograph from the air by the oblique method, which method lends itself to the photographing of areas having little or no control; also it is the most economical, and therefore has been the method used most extensively in Canada up to the present. To facilitate the work the camera has been mounted on the combing of the cockpit in such a manner that it may be quickly moved in the arc of a semicircle to take successively, one picture directly on the line of flight and one to each side, at approximately 45 degrees with that line.

In spite of the skill of the pilot and the accurate calibration of the navigating instruments, the operating conditions are such that it is necessary to run periodic ground traverses which can be utilized to control the scale of the maps prepared from the photographs.

The compilation of these maps has been facilitated by the preparation of ingenious grids or perspective diagrams that may be superimposed upon the prints.

Chief among the difficulties encountered in the prosecution of this work is unsuitable weather. Often it becomes necessary to wait patiently for several weeks to obtain one photographic day. Haze caused by the refraction of light from water vapour, smoke from forest fires, or dust in the atmosphere reduces the sensitiveness to detail by diminishing the light contrasts of distant objects on the earth's surface.

To remedy this condition it has been found possible to employ filters of dyed gelatine which eliminate the components of light particularly responsible for this disturbing influence.

For such exacting conditions, the care and choice of high-grade films is of primary importance and considerable experience is essential in their selection.

Where possible, the aerial party consists of three men, the pilot, giving all his attention to maintain the plane on the desired line at a constant altitude; the navigator meanwhile determines the drift and ground speed, times the pictures and selects the control points used in guiding the plane, while the mechanic, acting as the camera man, takes the pictures.

Complete supplies are taken in on the plane, with the exception of the gasoline which must usually be sent in by canoe considerably in advance of the aerial party.

An interesting discussion ensued, led by Prof. A. Kelly, M.E.I.C., and Councillor Geo. R. MacLeod, M.E.I.C., in which the relative merits of the oblique and vertical methods were compared and the accuracy and cost of the photographic survey cited.

Chairman H. R. Montgomery adjourned the meeting with a rising vote of thanks.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

In conjunction with the Buffalo Engineering Society and the Buffalo section A.I.E.E. this branch enjoyed an afternoon and evening meeting on October 25th. Members met at the plant of the Lackawanna Steel Company about 3.00 p.m., and were shown around by courteous officials or allowed to roam at will. There was plenty to see; in fact an afternoon was all too short a period of time in which to properly absorb the details of such an immense enterprise.

There were seven blast furnaces, twenty-four open hearth furnaces, four Bessemer converters and twelve rolling mills in which all kinds of structural shapes and plates were being manufactured, light rails, heavy rails, sheet piling and special shapes, including the B-section 36-inch I-beams, G-section 290 lbs. per foot, and H-16, 427 lbs. per foot.

Then there were the repair shops, the nut, bolt and spike shops, and the drive motors, eight or ten feet in diameter, which reversed themselves and their directly-connected rolls with the ease that a child spins a hoop.

The grounds must be a mile or so in length and quite a few members stated that they had had a good afternoon's exercise by the time they got back to the cars.

Just at present the plant is running close to capacity, which is about 160,000 long tons of open hearth a month.

After a well-earned and appreciated meal at the Statler the meeting was addressed by Mr. G. A. Richardson of the U. S. Steel Company, who accompanied in a versatile and truly remarkable manner a series of moving pictures which gave the story of steel from the ore-fields to the finished product. "Accompanied" is the right word to use, for he carried along his explanations coincidently with the film views, and thus gave his audience a splendid conception of the various processes and many of the involved but interesting details.

A few miscellaneous facts were jotted down as likely to prove of interest in the record. For instance, one of their ore boats loaded 10,000 tons of ore in fourteen minutes and took two and one-half hours unloading the same quantity. Ten to twelve million tons of ore are mined and used every year in the United States. The average capacity of a blast furnace is from 500 to 700 tons in twenty-four hours. Eight tons of material (including four tons of air) go to the making of one ton of iron. Bessemer converters carry from twelve to fifteen tons of steel, the manganese and silicon burn off with the low flame which is first seen and the later flame, thirty or forty feet in height, indicates the period when carbon is being consumed. All structural steel shapes and rails are now being made with the open hearth process, the furnaces of which carry from 100 to 250 tons each. The U. S. Steel plant at Coatsville manufactures a grade of charcoal iron which has many special uses. The maximum width of plates obtainable is now 152 inches.

After Mr. Richardson there were two other speakers, Mr. A. F. Kenyon and Mr. L. A. Umansky, but the St. Catharines members had a forty-mile drive ahead of them and therefore were forced to forego the latter part of a most enjoyable session.

VISIT TO WESTINGHOUSE AND STEEL COMPANY'S PLANTS

The branch is developing a delightful faculty of availing itself of neighbouring goodwill and kindliness. A faint hint is more than sufficient, in fact, if there is some particular plant we wish to visit our well trained executive sometimes has been known to hint for a hint. Be that as it may, the fact remains that we called upon the Buffalo society to entertain us last month, and on November 14th we invaded Hamilton in the other direction, and they both responded so nobly that they can count upon remaining permanently on our lists.

The East End works of the Westinghouse Electric Company and the adjacent plant of the Steel Company of Canada were our double-barrelled aim, and for good measure the Hamilton Branch were somehow able to convince Brigadier-General C. H. Mitchell, M.E.I.C., that he should journey all the way from Toronto to tell us about, and show pictures of, the latest engineering achievements in Europe.

Due to accidental misunderstanding some of the members who wished to visit the steel plant were beguiled into following an electric leader and once inside the Westinghouse plant they were lost and had to follow along.

The work, however, was absorbing, motors, generators, transformers, circuit breakers and even radios in all stages of the making and the afternoon was well spent. A few, nevertheless, did break away and get to the Steel Company, and the report of their reception and consequent inspection has started a movement to make another trip some afternoon for the purpose of visiting that one plant alone.

BRIG.-GEN. C. H. MITCHELL, M.E.I.C., ADDRESSES BRANCH

Dinner was held at the Royal Connaught hotel with Chairman W. L. McFaul, M.E.I.C., presiding, and after the tables were cleared General Mitchell held the complete attention of his audience while he described some of the engineering triumphs which he noticed whilst on a recent trip to Europe.

General Mitchell reviewed some of the outstanding activities in four distinct fields: railways, road transportation, aerial transportation and hydro-electrics.

"Canadian conditions are different from those in Europe," said the General, "and Canadian engineers do not lack in initiation or resourcefulness, but in quite a few things the Europeans are advancing with great strides and we might do worse than to study their methods and adopt those which may be deemed suitable."

Firstly, the railways have not been paying for some years. Three things have contributed to this condition (a) strikes, (b) increased taxes and (c) motor competition. They are meeting the difficulties and surmounting them by means of amalgamation—most of the railroads are now combined into four groups. Then they are improving the accommodations and adding fleets of their own motors to draw traffic to the railways from the surrounding districts. They are also electrifying largely; nearly all the main railway lines in the London area are electrified and all of the eighteen tracks running into Liverpool Street station. France also is going in largely for electrification, particularly that district south of Bordeaux and west of Toulouse, which can obtain easy hydro power from the Pyrenees.

General Mitchell was also particularly interested in some of the experiments which are being made at Greenwich on the liquefaction of coal under some 3,000 lbs. per square inch pressure. It is not yet at a commercial stage, but some of the results are startling enough—30 gals. Naptha oil, 60 gals. heavy oils and 30 gals. fuel oil at a cost of about 45 cents a gallon from a ton of coal carrying 13,500 B.t.u.

Most of the notable docks are being or have been recently enlarged. Pictures of the Gladstone dock at Liverpool, the Tilbury and West India docks at London were shown and attention was particularly drawn to some of the peculiar details necessitated by a very yielding foundation subsoil. These docks will now have 110 feet width or more and a least draft of 37 feet 6 inches over the sills, while the new French dry-dock at Toulon will be 1,460 feet long and 165 feet in width and 40 feet in depth.

Motor traffic in England has grown tremendously, the old Roman roads are coming back to their own again. Day and night trips can be arranged to almost any part of the island and the accommodation, consisting sometimes of a reclining chair-couch, are excellent. Timetables similar to those in use on the railway systems are printed and given out.

Aerial navigation is an everyday occurrence and practically part of European life now. It is accepted and has come to stay. The record of commercial accidents is negligible and is comparable with that of railways or other means of transport.

General Mitchell showed some very good views of the new airships R-100 and R-101 and described a most interesting afternoon spent in the control room at the Croydon airport. Wireless communication is kept up incessantly with every airplane, either going or coming, within range. One French plane lost its bearings in a fog that afternoon and got nearly to Southampton, which was many miles off its course. By means of direction-finders they were able to locate its exact position and give directions which enabled it to land safely at the airport. A new Goliath-Farman was at the field that day—a plane having 500 h.p., capable of 125 m.p.h., and carrying twenty-four passengers.

Most of the electric power in England is steam-generated, but in the Pyrenees and the French Alps advantage is taken of nearly every little stream. High heads predominate as needs be in countries where the volume of water is limited, but 400- to 700-foot heads are common, while one plant operated under 3,100 feet. The Romanche river, near Grenoble in the French Alps, is a beautiful example of conservation of power. There are about twenty hydro-electric plants generating some 50,000 h.p. located on this one little stream of about 1,500 c.f.s., and not an ounce of energy is wasted.

General Mitchell finished by showing some beautiful examples of bridge design, both ancient and modern, the famous Carcaconne bridge, some 2,000 years of age, and the old bridge at Avignon, both in an excellent state of preservation. The French are still past masters in the use of reinforced concrete and the boldness of design and audacity of construction may in a very great part be attributed to the care with which they inspect every bit of steel and every yard of concrete while erection is in progress. A 600-foot reinforced concrete arch span is now under construction in France and a rather remarkable lattice truss bridge, with 250-foot spans and trusses 33 feet deep, has just been completed. In England they have just opened their longest steel arch bridge, 540-foot span, with a parabolic arch, at Newcastle-on-Tyne.

Our chairman, E. G. Cameron, A.M.E.I.C., expressed the very great appreciation of the members to General Mitchell for the pleasure experienced and knowledge gained through his valuable address, and then tendered the thanks of the Niagara Branch to Chairman McFaul of Hamilton for having arranged so successful a day.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Addressing the members of the Ottawa Branch at a luncheon held at the Chateau Laurier, Mr. Frank P. McKibben, consulting engineer to the General Electric Company of Schenectady, N.Y., outlined the progress being made in electric welding as applied to the erection of buildings, bridges and other structures.

Electric Welding of Buildings and Bridges

Introduced by Dr. Charles Camsell, M.E.I.C., chairman of the Ottawa Branch, Mr. McKibben said that it was incumbent on the engineer to make haste slowly in the adoption of new ideas. He did not advocate electric welding to replace entirely the pin joint and the rivetted joint for every purpose. As the pin joint had given way many years ago to the rivetted joint for many purposes, so was the rivetted joint now being replaced in building construction and to a considerable extent in bridge building by the electrically welded joint.

Some sixty or sixty-five buildings, the speaker said, have now been erected with all or the major part of the steel work electrically welded. Electric welding has also been used on some fifteen bridges and on fifteen barges or ships, as well as on innumerable pipe lines.

The highest welded steel building to date is one of twelve storeys, Mr. McKibben said, and at Atlantic City there is a power house six storeys in height in which electric welding was used.

Revision of the building codes is necessary before electric welding can come into general use, the speaker stated, though it is now permitted in New York, Buffalo and many other large cities in the United States. Specifications for electric welding, he stated, are now available as the result of five or six years experience, and the strength of the welded joints is now well established as the result of many tests.

The General Electric Company, Mr. McKibben stated, is now using electric welding on 30,000,000 to 40,000,000 pounds of steel per annum and instructions have been issued that there were to be no more rivetted buildings. Engineers should go slow, however, he said, in adapting electric welding to structures where the impact stresses were very great. In bridges where the floor structure was such as to absorb impact shocks, electric welding would be all right, and he pointed out that there had been only one failure of an electrically welded joint that he knew of,—this in a tension member in a bridge joint.

Dealing with the advantages of electric welding, Mr. McKibben pointed out the saving in steel which results, particularly from the elimination of gusset plates and other parts which are necessary in rivetted joint construction. In electric welding the members of trusses are welded directly to one another. Trusses with electrically welded joints used in a General Electric building weighed 5,000 pounds, against 6,800 for similar trusses in our older building with rivetted joints. There was a 10 per cent reduction in the tender for electric welding from that for a rivetted steel job. Part of the saving in electric welding was due to an economy in labour, as two men took the place of nine to twelve men on a rivetted job. In shop practice, automatic electric welding machines were coming into use and trusses were largely built in jigs, with the welding machines quickly completing the work of permanently joining the various members.

Through the screening of a series of slides, Mr. McKibben illustrated the work of electric welding and how the various joints are made, also the results of testing the fillet joints which are made with the electric arc. Shearing tests establish the strength of the electrically welded joint at 11,000 pounds per lineal inch of the fillet, according to the tests sheets, but the speaker stated that this represented the minimum and there is a variation of about 25 per cent in the strength of the welding as performed by good or indifferent workmen.

In conclusion, Mr. McKibben stated that the General Electric Company recommends electric welding where adaptable and hopes it will not be used where not adaptable.

Meeting of November 15th

Speaking under the auspices of the Ottawa Branch at a luncheon which took place at the Chateau Laurier on November 15th, J. Ivon Graham, M.A., M.SC., F.R.C.SC.I., A.I.C., M.I.M.E., assistant director of the mining research laboratory of the University of Birmingham, outlined in a general way the work going on in fuel research in Great Britain.

The distinguished speaker, introduced by Dr. Charles Camsell, M.E.I.C., in the chair, was on his way to the International Fuel Congress at Pittsburgh.

Fuel Research in Great Britain

There were three separate organizations in Great Britain dealing with fuel research, stated Mr. Graham, namely, the Department of Scientific and Industrial Research, formed during the Great War and financed jointly by individual industries and the British government; the Safety in Mines Research Board, financed from the $25,000,000 mines welfare fund representing a five-year levy on coal output by tonnage; and the British Collieries Association Research Board, also financed by levy. This last-mentioned, which was purely a coal owners' association, Mr. Graham pointed out, largely financed the Birmingham research laboratory, where extensive research work was being carried out on hydrogenation of coal.

The fact was stressed by the speaker that the Fuel Research Board, formed as a section of the Department of Scientific and Industrial Research, was doing very good work on low temperature carbonization of coal. Experiments in this respect, said Mr. Graham, had indicated that low temperature carbonization not only yields smokeless fuel but more oil than high temperature carbonization. Another phase of research being carried out, he added, was a physical and chemical survey of structures of coal seams.

Alluding to the investigations being carried out by the University of Birmingham in connection with the hydrogenation of coal, Mr. Graham pointed out that he first became interested in this phase of research following a visit to Mannheim, Germany, where Dr. Bergius had made important tests. Five years of research in England, stated Mr. Graham, had substantiated Dr. Bergius' claims. Certain coals, said Mr. Graham, are much more amenable to hydrogen treatment than others. This was the case, he pointed out, with brown coals, owing to their high oxygen content. Some bituminous coals, he stated, are very readily hydrogenated and yield large oil content.

Mr. Graham spoke at some length of the use of catalysts in the hydrogenation process. By the use of a catalyst, he said, much higher percentages of oil were obtained. In one test at Birmingham using a catalyst there was a production of 25 gallons of petrol and 150 gallons of crude oil per ton of coal. The German Chemical Trust, the I.G., had recognized the importance of using a catalyst and had covered the process by patents. With a catalyst there was a very much greater yield of oil than by any low temperature process.

The general opinion, said Mr. Graham, was that 10,000,000 tons of coal could be utilized annually in Great Britain if hydrogenation of coal could be made a commercial success. This, he added, would be a wonderful help to the British coal industry. Imperial Chemical Industries, continued the speaker, are taking an active interest in hydrogenation, and if anybody can solve this problem on the commercial side, he thought they were the people to do so.

At the present price of gasoline in Canada, Mr. Graham thought that hydrogenation of coal as a method of producing motor fuel would not be commercially feasible. He pointed out, however, that cheap hydrogen is one of the things necessary for this method in liquefaction of coal, and Canada, with its cheap water power, is in an enviable position in this respect for the synthetic production of hydrogen.

The speaker also referred to experiments going on in partial hydrogenation. Certain coals which are non-coking in the ordinary way can be converted into coking coals by partial hydrogenation. Even with anthracite, the Fuel Research Board has obtained a strongly coking coal. The only satisfactory return, however, in Mr. Graham's view, was to carry out the complete conversion into oil.

At the conclusion of the address, Dr. Camsell expressed the hope that Great Britain and Canada would eventually co-operate in fuel research. This might take the form, he thought, of the interchange of technologists, as at present is being done between London and Washington.

Referring to Canada's new fuel research laboratory now nearing completion in Ottawa, Dr. Camsell stated that it was already attracting attention outside, and its sphere of usefulness was to be seen from the fact that he had already received an inquiry from the Portuguese Consul-General asking if the Canadian laboratory could undertake investigations on Portuguese lignites.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.

A meeting of the Peterborough Branch was held on October 25th, 1928, at which W. Gore, M.E.I.C., of Gore, Nasmith and Storrie, consulting engineers, Toronto, gave an address entitled "Astronomy in an Engineer's Life." The talk was of a popular nature and covered a very wide range of subjects in the history and science of the universe.

Pointing out that while it had been said that engineering was the most useful of the sciences, whereas astronomy was the most useless, the speaker emphasized the interdependence of the two in many ways. Both dealt with such fundamental concepts as time, distance and speed, and progress in engineering enabled the astronomers to make new discoveries.

The great Pyramid was built by the association of engineering and astronomical knowledge. The purpose of the Pyramid has long been the cause of discussion, said the speaker. There were seven million tons of rock used in the construction, and all indications point to the fact that there was formerly a limestone covering which reflected the sun's rays and made it act in some form of a sun dial.

The Egyptians had great difficulty with their seasons and calendar, explained the speaker, but the Pyramid gave them a means of correcting their calendar. The age of the Pyramid can be definitely set at about five thousand years, by calculating the movement of Alpho Draco, a star at which one of the passages formerly pointed. The speaker went on to mention many ancient methods of measuring time, and the importance of the knowledge of telling the time and season to mankind.

Tides form another means of telling the time and the speaker explained the interesting phenomenon of the tidal bore, where the incoming rush of water makes a stream flow uphill. The bore or crest is formed because the water coming up behind travels faster than the water in front.

On the subject of tides, the speaker said, many would be surprised to learn that Lake Ontario had a tidal rise and fall, although difficult to find. The neap tide at Toronto is three-eighths of an inch and the spring tide about an inch.

Going on to the movements of the universe, the speaker spoke of the meteorites, those small pieces of metal which reach the earth and are called shooting stars by many people, and he explained that because the Romans discovered the meteorites contained a good deal of iron, they had a theory that the heavens was a roof of iron.

Dealing with the sun and its radiant energy, the speaker said it has been a question of how and where did the sun get all the radiant energy. The earth receives two thousand million horsepower per second from the sun, and yet we receive only a small particle of the energy the sun sends off. Many geologists claimed that the sun would burn itself out in ten million years (a comparatively short time in speaking of time in relation to the universe).

But now, according to the Einstein theory and greater knowledge gained, astronomers believe that the sun is getting hotter and not colder. This theory explains that the mass of the sun is breaking up into radiant energy in the form of electrons. The mass of the sun is getting smaller, but it is sending out as great or greater heat than it did formerly. Some scientists further advance the theory that the radiant energy forms back again somewhere else into mass and therefore is not lost. This disproves the old idea that the universe was slowly running down and we are in a fair way to believe that the universe will go on forever, said Mr. Gore.

The interesting feature of the moon is its craters, said the speaker, and went on to deal with some of the theories in regard to their formation.

The planet Mars is interesting because the lines seen on its surface are claimed to be canals, said Mr. Gore. These seemed to have been made by intelligent beings because of their straightness and their intersections, not haphazard but purposeful.

Mr. Gore then discussed at some length the theories regarding conditions on Mars.

Following an active discussion Mr. Gore was accorded a hearty vote of thanks for his interesting address.

Annual Banquet

The Divine Insanity of noble minds
That never falters nor abates,
But labours and endures and waits
Till all that it foresees, it finds,
Or what it cannot find, creates.

Thus, one of the speakers lauded the spirit of the engineering profession during the annual dinner of the Peterborough Branch, held in the Empress hotel on November 20th. Graced by the presence of prominent officials of The Institute from Montreal and Toronto, and featured by an impressive programme of toasts and addresses by members of the engineering as well as representatives of sister professions, the annual dinner crowned with success the labours of an energetic executive and afforded fresh impetus to the season's activities of the local branch.

Among the guest speakers were Julian C. Smith, M.E.I.C., president of The Engineering Institute of Canada and vice-president and general manager of the Shawinigan Water and Power Company; R. J. Durley, M.E.I.C., general secretary of The Institute; Fraser S. Keith, M.E.I.C., member of the Council of the E.I.C., of Montreal; Professor P. Gillespie, M.E.I.C., representative of the Toronto Branch and a past vice-president of the E.I.C.; V. J. McElderry, K.C., president of the Peterborough Law Association; Dr. F. P. McNulty, president of the Medical Association; Rev. J. L. Hughes, president of the Peterborough Ministerial Association; G. S. Mattice, of the Teachers' Association; and F. H. Dobbin.

Presiding over the dinner meeting, Chairman W. M. Cruthers, A.M.E.I.C., proved a capable master of ceremonies. Following the banquet, he introduced the programme by a short address, in which he reviewed the aims of The Engineering Institute, and the possibilities that the future holds for the profession.

"In agriculture, lumbering, mining, and the manufacturing industries, mechanically inclined men are destined to play a great part," he declared.

Toast to The Institute

"The Engineering Institute of Canada is unique among other national organizations, in that it includes in its membership, engineers practising all branches of the profession," said R. L. Dobbin, M.E.I.C., in proposing the toast to The Engineering Institute. "It was formed in 1887 as the Canadian Society of Civil Engineers, and in 1918 the name was changed to its present form. We have now 4,700 members of all classes, located in every part of the Dominion," he continued.

"The Institute has been fortunate in having many distinguished engineers as its presidents. Notable among them have been the late Walter J. Francis, Dr. R. A. Ross, M.E.I.C., and Dr. J. M. R. Fairbairn, M.E.I.C., all of whom we claim to have been Peterborough men; yet not the least of the engineers who have occupied that high office is the present incumbent, Julian C. Smith, M.E.I.C., who has honoured us by his presence tonight. This is not his first visit to the Peterborough Branch, for he came to us at our banquet in 1920. Gentlemen, is not The Institute in good hands? Let us drink to The Engineering Institute!"

President Julian C. Smith

Mr. Smith, responding, complimented the local branch on the evening's gathering. "As you know, The Institute has grown from a small beginning until now it boasts thousands of members," said he.

"One might speak of the past, present, or future of The Institute, but I do not choose to speak of the past. While in England last summer I met Rudyard Kipling, the first man to use the term 'cold iron.' Mr. Kipling was very much interested in The Engineering Institute, particularly in Canada.

"The future of The Institute is that thing in which we are most interested, for we must maintain the influence of it to keep the members of the profession joined together. This will be difficult because of geographic conditions, and the branch must necessarily play a great part.

"No man can get out more than he puts into The Institute, which has been organized for the mutual benefits to be derived—one member from the other."

The speaker dealt with membership fees as applied to Students of The Institute and regular members, as well as with proposed changes in the method of accepting members into The Institute.

Greater Work Ahead

"As regards the future, it is obvious that the work to be done by engineers will be greater than in the past in the development of electrical power with all branches of work incidental thereto," he continued. "With the development of Canada agriculturally and industrially, the work to be demanded of the engineering profession will be greater and more important. Therefore, engineers will have to be better prepared, and the co-operation and confidence that the Institute develops will be necessary."

The General Secretary

The general secretary of The Engineering Institute, R. J. Durley, M.E.I.C., expressed a desire to speak of the general affairs of The Institute. He, too, touched briefly on the changes in membership fees. Running over a few suggestions for further expenditures by the council in case a surplus is realized, in the future, he mentioned the Employment Service Bureau and urged co-operation in this work. He felt that more money could be spent on The Institute publications. The branch activities, he intimated, could sometimes be assisted by further assistance from the council, while the importance of the branch secretaries' work was stressed.

Entertainment

W. E. Ross, A.M.E.I.C., was called upon to show "what it means to look backward" to what The Institute was, particularly the Peterborough Branch. He then had thrown on the screen slides of members and conducted a "who-is-it" contest that provoked much merriment. The presentation of a silk hat prize by E. R. Shirley, M.E.I.C., to the winner, A. L. Killaly, A.M.E.I.C., followed.

The branch orchestra of three violins, piano and banjo was heard on several occasions, rendering popular numbers in commendable manner. In addition, there was community singing that added to the enjoyment of the evening.

Toast to the Branches

A. L. Killaly, A.M.E.I.C., proposed the toast to "The Branches." In so doing he referred to the mission and benefits of the branch as a unit in promoting the interests of The Engineering Institute of Canada as well as of individual members.

He went back in The Institute's history to the time when it began under its present name, and touched on the increase in the number of branches. "To those branches the Peterborough body now extends its good will," he concluded.

The representative of the Montreal Branch, Fraser S. Keith, M.E.I.C., responded to what he termed "one of the most important toasts of the evening."

"Today the branches of The Institute are the shining lights of the engineering profession," declared Mr. Keith, "for your mission is to interpret the engineer to the public and make it appreciate him and what he has done."

Declaring that engineers have built for posterity; that all the Titans of engineering do not live at the present time, and that engineering is a progressive science standing for the removal of materialism from human life and human affairs, Professor Peter Gillespie, M.E.I.C., was the second speaker responding to the toast to The Institute.

Professor Gillespie arose to speak as many of those present burst into the old School of Science yell. He thanked them for the enthusiastic reception and extended the best wishes of the Toronto Branch. Then, going back to the days of early history, he spoke of the Hadrian aqueduct, built to supply the city of Athens with water. Though without the more recently conceived engineer's transits, the methods used were necessarily crude, the job was a marvel of engineering, as was the Menai bridge, built hundreds of years later, with its 600-foot suspension. The third example quoted was the Stevenson creek experimental dam, built in California, and from which very valuable theories had been evolved.

"It has been heard from many quarters," said Professor Gillespie, "that we live in a materialistic age, but it seems to me that we are not nearly so materialistic when we worship in comfortable churches as the native who sat in filth and poverty, contemplating the problems of the universe. The profession of engineering has lifted us above that," he concluded.

A skit, depicting a meeting of the local branch, was put on by a group of Canadian General Electric Company students, who cleverly imitated well-known local members. It proved decidedly entertaining and laughter-provoking.

Toast to the Sister Professions

Recalling college days when rivalry between students of the various courses is keen, only to decrease as graduation brings common problems, W. T. Fanjoy, S.E.I.C., proposed the toast to the sister professions. Replying were four representatives of the four other professions, ministerial, law, teaching and medical, all of whom indicated in brief but well ordered addresses, the relations of their respective professions to the others. The Rev. Mr. Hughes, Mr. McElderry, Mr. Mattice and Dr. McNulty represented the sister professions.

Previous to the close of the meeting, Chairman Cruthers spoke of the Old Boys' Re-union to be held in Peterborough next year. Since next year will be the tenth anniversary of the branch and the dates of the re-union and of the annual dinner do not coincide, he urged the local branch, and thought that the members should catch the spirit of the re-union and co-operate in bringing back many of the old members to the annual dinner.

Saguenay Branch

J. F. Plow, Jr.E.I.C., Secretary-Treasurer.

Town and Hexagonal Planning

On October 23rd, at Arvida, the Saguenay Branch was favoured with a lecture from J. E. Nolan Cauchon, A.M.E.I.C., the government expert on town planning.

Mr. Cauchon's subject was "Town Planning and Hexagonal Planning," which he placed before his audience in a very clear and interesting manner, admirably illustrated by a series of diagrams. The lecturer covered the subject in a general way and gave the numerous advantages under which the inhabitants lived when their town was laid out according to town planning ideas. He laid stress, however, on the engineering viewpoint and its application to new and existing towns and cities.

The lecture was attended by nearly one hundred members and friends, Arvida, Chicoutimi, Kenogami, Isle Maligne and Riverbend being represented.

In introducing the speaker the chairman, G. F. Layne, A.M.E.I.C., said that though the branch had been very inactive of late, in future he hoped to be able to have a number of lecturers address the members: Mr. Cauchon being the first; and O. O. Lefevre, M.E.I.C., had consented to give an address on the St. Lawrence waterways, in the near future.

R. E. Parks, A.M.E.I.C., proposed a vote of thanks to Mr. Cauchon for his very interesting lecture, which he knew was heartily appreciated by all.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held in the Y.W.C.A. rooms, at which W. S. Wilson, A.M.E.I.C., chairman, introduced Mr. Chas. A. Price, of the Precise Water Level Division, Canadian Hydrographic Service Department of Marine, Ottawa, the speaker for the evening.

He gave an illustrated talk on "Recording Water Levels of the Great Lakes and the St. Lawrence River." The Great Lakes were more fully dealt with, as they were in our own district. "The centralization of this work, for such a large territory, eliminates duplication, reduces overhead expenditure, and, most important of all, from an engineering point of view, the resulting data are reduced to a common basis of reference, to a precise standard in compilation. The reference datum now in general use is the U.S. Lake Survey levels of 1903 adjustment," he said.

The subject was considered by Mr. Price under the following nine main points:—

(1) *Territory involved.*—a general chart of the Great Lakes from Port Arthur to Kingston was shown giving the gauge locations.

(*a*) Lake Superior—seven gauges being operated.
(*b*) Lake Huron—five gauges being operated.
(*c*) Lake Erie—four gauges being operated.
(*d*) Lake Ontario—three gauges being operated.

In all, nineteen gauges are being maintained on the Great Lakes, while on the St. Lawrence river twenty-five gauges are being maintained, as follows:—

(*e*) The International section,—from lake Ontario to lake St. Francis, where the fall is approximately 94 feet in 105 miles, there are eight gauges in operation.

(*f*) The purely Canadian section,—from lake St. Francis to Montreal harbour, where the fall is approximately 132 feet in 68 miles, there are seven gauges being operated.

(*g*) The Montreal-Quebec section,—which is related to true deep sea navigation and which in the lower portion comes under tidal influence, and where the fall is approximately 19 feet at low water in 176 miles.

(2) *Types of gauges.*

(*a*) The Haskell self-registering graphic; thirty-six being used in 1928.

(*b*) The Gourley printing register No. 630; eight being used in 1928.

(*c*) Standard staff gauges.

(*d*) Levels used,—the Zeiss level, model 111, being used for all precise levelling in setting gauges and tieing in with other surveys, etc.

(3) *Installations of gauges for operation,*—slides were shown giving the location, type and general characteristics of the different gauges in use.

(4) *Types of records obtained.*
(*a*) Printed records.
(*b*) Graphic records.

(5) *Methods of compilation,*—the compilation of the July 1928 chart from the Upper Soo gauge resulted in 818 sets of figures, which gives a very fair idea of the amount of work to be done in handling all the charts.

(6) *Uses and requests for data.*—Mr. Price emphasized the remarkable increase in the demands for the data that his department is able to furnish. He estimates that they will issue over 30,000 sheets of data in 1928. Requests come in from all over the world.

The 1928 compilations will include approximately 500,000 sets of water surface elevations and will entail handling approximately 1,500,000 sets of figures.

(7) *Seiches and storms,*—the word seiche is given in the encyclopædia as being "An irregular fluctuation of the water level of lakes, first observed and so named in Switzerland. First noted in 1730." The first reference to seiches in the Great Lakes was made by Sir Alexander MacKenzie in regards to water action at Grand Portage in lake Superior about 1790.

On August 27th, 1917, at Michipicoten harbour, according to Mr. Price, seiches in five hours gradually increased until the first large change was:—

a fall of 1.00 feet in 10 minutes
rise " 2.56 " " 9 "
fall " 1.84 " " 8 "

The seiches continued for fourteen hours before action of water level again became normal. There were heavy south west winds during the seiche period.

Several charts and slides were shown giving comparisons at different stations during a seiche period or a storm period. Mr. Price pointed out how they could pick out a storm period on a chart. He said that a storm showed a steady banking up of the water in the direction of the wind, and the level will remain banked up until the velocity of the wind lessens, and then it recedes gradually. The progress of a storm can be followed down the lakes by the water levels registered on the different gauges.

(8) *General data relating to each of the Great Lakes,*—comparison charts were given showing general data of the Great Lakes.

(9) *Results derived by the use of data.*—A general discussion followed Mr. Price's address, and a hearty vote of thanks was tendered to him by the chairman.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
(Reported by H. Neville Mason, A.M.E.I.C.)

New Engineering Projects in England and France

The first meeting of the season 1928-1929 of the Toronto Branch of The Engineering Institute of Canada was held in the Mining building, University of Toronto, on Thursday evening, October 18th, at 8.15 p.m. The speaker of the evening was Brigadier-General C. H. Mitchell, M.E.I.C., Dean of the Faculty of Engineering, University of Toronto.

Previous to the meeting dinner was served at Hart House. The meeting was well attended, ninety-one people being present, including Mrs. Mitchell and Mrs. Wynne-Roberts. The substance of the speaker's address was based upon a tour of Europe, which he had made during the previous summer.

The effect of motor coach transport on steam railway operation was indicated in terms of reduced revenue, which, combined with higher wages and heavy taxes, had caused the railway companies to seek relief in electrification of the roads, and in some cases the organization of motor coach services of their own. A complete guide giving all the motor coach routes, times and fares is obtainable, some of these routes traversing the same roads and passing through the same towns and villages as was the custom a hundred years ago.

The speaker described some of the most modern achievements in automobile construction in Great Britain, including a 25,000-mile test of a car without either clutch or gear-shift.

A further highly interesting topic was introduced by the description of the liquefaction of coal, which, if successful on a commercial scale, would create a use for our great deposits of low grade coal in the north and west.

Several very interesting slides were shown indicating the remarkable increase in shipping facilities at Liverpool and London; and peculiar features of construction in the latter area, due to the soft nature of the ground, were emphasized. At Toulon, in France, the largest dock in the world, now nearing completion, will be 1,460 feet long, 165 feet wide and 40 feet deep.

In aerial navigation, contrary to the general idea, Great Britain still leads the way. The Croydon aerodrome, with its visual synchronous control, reporting and despatching facilities, was romantic evidence of the great strides which had been made in recent years. The speaker described the facility by which a new pilot on a French air liner had been directed to the aerodrome after losing his way on the British coast. The total area covered by the air port is 360 acres, and the equipment includes control rooms, customs and immigration halls, express and freight rooms, police and hospital quarters, as well as a residential hotel and restaurant.

The speaker paid a visit to the government works at Cardington, near Bedford, where the new British air ship R101 is being built. This ship, when completed, will be about one and one half times the size of the "Graf Zeppelin," which but recently crossed over to America and back.

Hydro-electric power is making substantial progress, especially in the Pyrenees. One plant recently installed operates under a head of 3,100 feet. Reinforced concrete structures, sometimes as high as 60 feet, are used to carry the transmission wires. The development of the Romanche river was described as being of peculiar intensity. Fifteen plants are operated successively over a distance of 20 miles, the tail-water of one becoming the head-water of the next below it. When the development works are completed, the river will yield a total of 150,000 h.p.

One of the most interesting slides shown was of the new high level bridge at Newcastle-on-Tyne, recently opened by His Majesty the King. It has a clear span of 540 feet and permits a clearance for vessels of 100 feet. It is of an arch type, very high in the centre, and cost approximately $6,250,000 to build.

France continues to lead the world in boldness of design, ingenuity and care in workmanship where reinforced concrete is concerned, two notable examples being a reinforced concrete highway bridge in Paris, consisting of two 250-foot truss spans, continuous over the centre support, the trusses being 33 feet high and providing for a 66-foot roadway; and a 600-foot arch span, carrying a railway, now nearing completion at Brest.

In conclusion, the speaker displayed a number of beautifully coloured slides showing types of old bridges in the south of France, built centuries ago but still in a wonderful state of preservation. Some of the bridges shown dated back as far as 1180 A.D. The inclusion of these photographs made one appreciate to the full the privilege of accompanying the speaker on his wonderful holiday.

Wm. Gore, M.E.I.C., moved a hearty vote of thanks, seconded by Peter Gillespie, M.E.I.C., in which the gathering heartily concurred.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

Executive Meetings

Since August 15th, three meetings of the Branch Executive have been held, on September 5th, October 12th and October 25th. The main item of business at the September 4th meeting was to discuss with Mr. Powell, Branch Councillor, the feeling of the branch on various matters which were to arise at the Plenary Meeting of Council in Montreal on October 15th to 17th. The October 12th meeting was in the nature of a "send-off" to the Branch Chairman, W. B. Young, M.E.I.C., who left the following day on a two-months trip via the Panama canal to the West Indies. The strain on Mr. Young occasioned by the death of Mrs. Young, following a long severe illness, had told on his health, and it was the hearty wish of the members that the change might be of benefit to him, restoring him to his usual good health and spirits.

At the meeting on October 25th, Mr. Powell reported to the executive the result of his trip to Montreal, explaining the attitude of Council on the various matters brought before it, together with the recommendations which will be put by it before the annual meeting early next year.

Aerial Surveying

At the first regular meeting of the branch this winter, on November 7th, a very interesting paper was given by C. H. Taggart, A.M.E.I.C., on "Aerial Surveying." Mr. Taggart outlined the development of aerial surveying in Canada, making particular reference to the experimental operations carried out during the past season in British Columbia. His address was illustrated by lantern slides, and the attendance of fifty members and friends attested the interest aroused in his subject.

Following a short introduction by the vice-chairman, W. B. Greig, A.M.E.I.C., Mr. Taggart sketched the development by the Dominion government of aerial surveying, supplying, through the Royal Canadian Air Force, the planes, equipment and personnel; and, through the Department of Interior, Topographical Surveys Branch, the photographers and surveyors. The inception of this work in Canada was some seven or eight years ago, the first flights being made over The Pas mineral area in northern Manitoba.

The two methods of photography were then described, the "oblique" method, the first used, and one suitable for work in the flat country with a definite even horizon, and later the "vertical" method, suitable for work in a hilly or mountainous country like British Columbia. In the first method, cameras were mounted in the nose of the machine and photographs taken obliquely to the horizon and through a horizontal angle of 180°. In the second method, photographs were taken through a hole in the floor of the machine, using the plumb bob as a base line.

Already by the photographic method 300,000 square miles of Canada have been photographed, reproduced and the finished maps issued.

Until the delivery this spring from New York of two Fairchild monoplanes, the Royal Canadian Air Force had no plane capable of being used in British Columbia, as a seaplane of high power is necessary for work there.

The general outline of the work done this year in British Columbia was then given, consisting of the Fraser valley, Vancouver to Lytton; the Thompson valley, Lytton to Kamloops, 3,200 square miles in the Shuswap lake area; the Fraser valley, Lytton to Prince George; and, finally, some 2,000 square miles in the Ootsa and Babine lake areas.

The Fairchild monoplanes used in this work were fitted with a nine-cylinder Wasp engine of 420 h.p., capable of flying at an altitude of 19,000 feet. With the 12-inch focal lens Fairchild camera, the first photos were taken at an altitude of 17,000 feet. Working at this altitude was difficult, and, as good results could be obtained at 15,000 feet, this altitude was later adopted, the latter part of the season's work all being done at an altitude of 15,140 feet, or, roughly, three miles. Even at this altitude, owing to "bumps" it was difficult to keep the planes on an even keel, only 2° out of plumb being allowed in taking photographs.

In all, 15,000 photographs had been taken, and of this number only 25 were classed as other than excellent. The photos were taken in strips one mile apart, allowing an overlap, and this required skilled pilots. From the flying standpoint, the season's work had been a success, and from the scientific standpoint as yet a trial, but success was expected.

Mr. Taggart showed forty-one slides during his address, and at the conclusion exhibited plotted flight lines, views of machines used, oblique views, views with grid used for plotting, the members viewing photographs through stereoscopes.

T. A. McElhanney, A.M.E.I.C., moved and A. S. Wootton, M.E.I.C., seconded a very hearty vote of thanks to the speaker.

STUDENT SECTION

The opening of the University of British Columbia on September 25th marked the beginning of the second year of the Students' Section of the Vancouver Branch. During the summer months, the executive carried on a correspondence among themselves, the object of which was to plan a programme of activities for the winter session at the university. A tentative constitution for the section was prepared, to be placed before the members when they met in the fall. The secretary also made numerous enquiries for a hall and caterers, with the intention of arranging for a dinner immediately the university opened.

The first executive meeting for the session was held on Friday, September 29th. The activities for the coming months were discussed and tentative plans for a programme were prepared. Due to the resignation of J. H. Legg as vice-president, it was decided that a new vice-president would be elected at the first meeting of the members. A drive for new members was planned and a circular letter to Applied Science students was prepared and sent to the branch for printing. The letter follows:—

Circular Letter to Applied Science Students

> The U.B.C. Students' Chapter of The Engineering Institute of Canada is commencing its second year at the university. An extensive programme is planned for the session. Plans include lectures by prominent men of various professions, trips to engineering and industrial works in the vicinity of Vancouver and a students' night, when members will have an opportunity to present papers before students and visiting engineers. A get-together dinner will be held in the fall term. Students are invited to join the section and take advantage of the benefits derived from membership. Students in 2nd, 3rd and 4th years of Applied Science are eligible.
>
> A. Peebles, *President.*
> R. Morrison, S.E.I.C., *Secretary-Treasurer.*

It was then decided to hold a dinner as soon as possible. This dinner was for the purpose of introducing new members to members of the branch and to create a keener interest in The Institute among the students. A postcard with suitable blanks was devised for circulation amongst the members, announcing meetings and trips.

Address by Prof. W. E. Duckering

The first meeting of the members was held at noon, October 10th. The president, A. Peebles, was in the chair. The first business brought before the meeting was the election of a new vice-president. W. W. Blankenback, S.E.I.C., and J. Hadgkiss were nominated; Mr. Blankenback being elected. Professor Duckering, honorary president, gave a short address. He first pointed out the numerous reasons for the origin of societies and reasons why the members of the various professions should band themselves together. The speaker then gave numerous concrete examples of how the societies protected the engineers from incompetent competition. Coming closer to home, he went on to point out the difference between The Institute and the Association of Professional Engineers. In closing, he pointed out many reasons for students becoming members; the benefits to be obtained by association with engineers in practice; the information to be obtained and broadening of the student outlook on life by listening to outside speakers and the insight to industrial methods obtained by visits to the various centres of industry. Professor Duckering's remarks were enthusiastically received by those present.

Ancient Irrigation and Some Modern Aspects

The second meeting of the year was held at noon on Wednesday, October 23rd, with A. Peebles in the chair. The speaker for the meeting was H. B. Muckleston, M.E.I.C., consulting engineer. He chose as his subject, "Ancient Irrigation and Some Modern Aspects." The speaker pointed out how man had always preferred the arid, desert lands, where irrigation was necessary. He went on to show how the water was put on the land; how it was first carried in gourds. Later they learned by experience that by flooding the land at high water a limited amount of moisture may be put into the ground. As time went on, men learned to make improvements and canals were built. Mr. Muckleston showed that irrigation was the beginning of modern civilization. Canals were built, then cities grew up on their banks. Man was progressing from the stage of nomads and seasonal habitations to permanent dwellings, all very largely as the result of irrigation becoming possible. The speaker then gave a brief history of various irrigation projects of ancient Egypt and in the vicinity of the Euphrates and Tigris rivers. He paid tribute to the engineers of ancient times in their design of large canals, some of which were several hundred miles long. In closing, he pointed out some of the modern problems of irrigation, how there were many details of irrigation as yet unsolved, but all of which were capable of solution.

Mr. Muckleston gave an exceptionally interesting and instructive talk and one which was very much appreciated. Mr. Blankenback moved the vote of thanks.

Visit to Creosoting Works

On Saturday, October 20th, the members took a trip to the Vancouver Creosoting Works. The plant handles ties, piles and timbers for small trestles and bridges.

Ties to be creosoted first enter the tie mill on the tie machine, where ¾-inch slits are incised in them. This gives a uniform penetration of the creosote into the wood. A conveyor then takes them to another machine, where they are adzed and holes bored into them, so that the railway spikes may be driven in without splitting the wood. They are then loaded on to a retort carrier and taken into the retort cylinder, where they are creosoted. Large timbers, for structures, etc., are cut to the required length in the framing mill before entering the retort.

Piles to be creosoted are seasoned for about two months before being treated, as this shortens the time required for treatment in the retort. Seasoned piles require 16 hours treatment, whereas the wet ones take from 35 to 40 hours.

The carrier, with its charge, is run into the retort, which is simply a long cylinder, and the end is sealed. The retort is then filled all but about 6 inches from the top with creosote; the valves are closed and a vacuum produced in it. The oil is now heated by means of steam coils underneath the retort; the temperature to which it is heated depending on the moisture content and the timber itself. This is known as the "boiling under vacuum" process.

The moisture which is thus taken out of the wood is drawn off into another tank.

A pressure of 150 pounds is then applied, forcing the oil into the wood. What oil is left in the cylinder is drawn off and the vacuum pump started again to take some of the oil out of the wood. The idea of this is to give a deeper penetration into the wood. If 6 pounds of oil per cubic foot of wood is to be used, then 9 pounds is pressed into it and 3 pounds drawn off; 6 pounds of oil giving a ⅝-inch penetration.

First Annual Dinner

On Friday evening, October 19th, the Section held its first annual dinner. Forty-three students and members of the branch gathered to enjoy a most excellent dinner. Due to the unavoidable absence of Mr. Young, chairman of the branch, W. B. Greig, A.M.E.I.C., vice-chairman of the branch, was called on as the principal speaker of the meeting.

Mr. Greig expressed the interest that the branch was taking in the students, the wonderful opportunity that the movement was giving to both members and Students to become better acquainted and have a better understanding of one another.

Mr. Greig was followed by Ted Hay, who gave the gathering two splendid piano solos. The meeting was fortunate in having two prominent engineers from Montreal, J. M. R. Fairbairn, M.E.I.C., chief engineer of the C.P.R., and P. B. Motley, M.E.I.C., engineer of bridges for the C.P.R. Both gentlemen had an interesting message for the students. Mr. Fairbairn encouraged the students to study the problems of government, to interest themselves in others and to make the most of their opportunities as students.

The chairman introduced the other members of the branch present. Those present were H. B. Muckleston, M.E.I.C., A. E. Foreman, M.E.I.C., H. P. Archibald, A.M.E.I.C., W. B. Greig, F. P. V. Cowley, E. A. Wheatley, F. W. Alexander, S. F. Ricketts and Professor Duckering.

The Science Men's quartette entertained the gathering for a few minutes. Then Professor Duckering, honorary president of the Section, had a few words to say to the students. He stressed the difference between a professional man and a technician. In conclusion, he advised the student to stick with whatever he has to do and make a good job of it.

The remainder of the evening was spent in playing bridge. An orchestra added the necessary melody. The evening was declared by all as an entire success. The menu was excellent and the entertainment, which was provided entirely by Students, was the crowning success of the evening.

The executive for the session of 1928-29 is as follows:—

Honorary President	Professor W. E. Duckering.
President	A. Peebles, S.E.I.C.
Vice-President	W. Blankenback, B.A., S.E.I.C.
Secretary-Treasurer	R. L. Morrison, B.A., S.E.I.C.
Assistant Secretary	W. R. Workman, S.E.I.C.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

The Design and Construction of the Victoria Grain Elevator

A. L. H. Sommerville, resident engineer on the new Victoria grain elevator, addressed the members of the Victoria Branch at a meeting on October 30th.

Mr. Sommerville described in detail the construction of the plant and expressed a very high opinion of the way in which it was done. Considerable interest attached to his description of the method of constructing the cement tanks, where the system was employed of raising the moulds as the work proceeded so that the cement was kept pouring continuously for the full twenty-four hours of the day for each succeeding day.

The process was described in handling the grain from the time that the cars arrived and were dumped into the hoppers until it was carried along continuous belts and through the dryers into the various compartments, and eventually carried into the ships for transport across the sea.

The drying is accomplished by dropping the grain through compartments where, by means of fans, hot air is kept circulating. The grain in its descent is made to follow a broken course, so that it is being constantly subjected to the air currents. The dryer is capable of handling some 5,000 bushels an hour.

The piling was described, and Mr. Somerville said that nothing was left to chance. Every pile placed in position was definitely recorded, and it was known exactly the position of it and full particulars, together with the estimated load which it would carry. In order that the piers might not suffer any damage from the driving of the piles, the jets of water were used under pressure, so that the way for the pile was made easy. Some of the piles were put down fifty feet.

Following the address a general discussion took place.

Aids to Navigation

"Although trans-Pacific travellers feel comparatively safe out on the ocean with plenty of water under them, they breathe sighs of relief when they sight land," said Col. W. R. Wilby, C.B.E., agent for the Department of Marine, in a paper on "Aids to Navigation," delivered before the Victoria Branch of The Engineering Institute of Canada, on November 12th.

"You can imagine what navigators of ships think of obscuring fog and snow," he continued, showing views of the rocky formation of the west coast of Vancouver island, including Pachena point.

"The first requirement of safety for vessels is location of danger points, which must be marked. In this connection the Hydrographic Survey vessel Lillooet is kept busy charting the British Columbia coast.

"Lighthouse construction requires patience, tenacity and obstinacy beyond description," said Col. Wilby, showing views of C.G.S. Lillooet and foam-covered rocks on the coast of Vancouver island.

"In the old days we had beacon fires to guide vessels on their courses; now we have fog alarm signals, radio beacons and powerful lights. I can remember the days when C.P.R. steamers were guided out of Victoria harbour during foggy weather by persons on shore beating tin pans," he continued, showing views of modern whistling buoys and the Pachena lighthouse.

At this point a view of the old wireless station and lighthouse at Triangle island was thrown on the screen. Col. Wilby explained that the wind on the barren rock was so fierce that ropes had to be laid to enable persons stationed there to move from one part to another. The station was moved to Bull harbour, at the north end of Vancouver island, several years ago. Other views shown included Portlock point, Quatsino sound light and Ivory island light.

"Navigation aids include unwatched lights and watched lights," said the colonel, "the earliest form of light was a wood fire on top of a tall tower, its visibility depending upon the direction of the wind. If there was an off-shore wind the light would show brilliantly, but not otherwise.

"Metal reflectors, candles, fish oil, coal oil and gasoline were later used for lights. In 331 B.C. a light was established in Greece on top of a 400-foot tower and it burned for 1,600 years. On the coast of Spain, off Finisterre and on the Bay of Biscay, two of the world's oldest lights are still burning," he said.

"The Biscay light was built by a tax levied upon all ships passing in and out, and included a chapel and royal residence on a 134-foot circular base. Wrecked during the French Revolution, the lighthouse was reconstructed.

"Started in 1695 and finished in 1698, the Eddystone lighthouse in England is another famous navigation aid. After it was swept away in a tremendous gale in 1706 another was started and survived until 1755, when it was destroyed by fire. It was replaced in 1756 by Smeaton's tower, built of stones weighing a ton each. In 1877 the foundation became insecure and the site of the light was moved.

"The fourth light was built 133 feet high and with walls from two feet three inches to eight feet six inches in thickness," said the speaker.

"The first lighthouse on the British Columbia coast was at Race Rocks. It was constructed in England and sent out in pieces in 1861 by the Imperial government. The son of the first keeper is still in the service, being stationed at Pachena. Cape Beale, one of the worst spots on the west coast, was the first station constructed by the Canadian government."

Following a description of the action of a radio compass, fog signals and automatic flashing buoys, Colonel Wilby said that the Department of Marine now maintained 24 lighted buoys, 124 beacons and 203 unlighted buoys, a large increase over the number in 1921.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

Electrical Engineer

Recent graduate required by a large electrical manufacturing concern for work on factory methods and manufacturing problems. Please state in first instance, education, full qualifications, references, salary required, age, and when available. Apply Box No. 69-V.

Civil or Mechanical Engineer

Civil or mechanical engineer for office and field work on hydro-electric power plant. At least three years experience desirable. Apply to Box No. 125-V.

Mechanical Superintendent

First class mechanical superintendent with experience and capable of taking complete charge of machine shop employing approximately 300 men, manufacturing brass and iron valves, plumbing goods, locomotive specialties, also large steel and bronze fittings and specialties for pulp mills. Apply giving full particulars as to qualifications, past experience and salary expected to Box No. 137-V.

Electrical Salesman

A company in the province of Quebec, has an opening for an electrical engineer to take charge of their merchandise sales department. The applicant must speak French and English, and must have had previous experience in salesmanship, and be able to conduct sales campaigns and supervise sales staff. He must also be able to direct the advertising and must have a personality necessary for such a position. Apply giving full particulars regarding qualifications to Box No. 138-V.

Traffic Superintendent

Traffic superintendent wanted on South American tramway property. Require man with experience in actual operation of street cars and buses on modern city property. Preference given to young man and to technical graduate if with necessary practical experience. Applicants please state full details of education, experience, present salary and give references. To right man this opening presents great opportunities. Apply to Box No. 139-V.

Mechanical Designer and Estimator

A company in Montreal has an opening for a mechanical engineer with experience in the design of digester and acid plants for sulphite pulp mills. The work will be designing and estimating special equipment, and the position offers excellent opportunities for advancement. Apply giving full details to Box No. 140-V.

Mechanical Draughtsman

A manufacturing company in central Ontario has an opening for a mechanical draughtsman with several years experience. The work is in connection with the extension and alteration of the company's manufacturing plant. Apply giving full details of experience to Box No. 141-V.

Mechanical Draughtsmen

Several good mechanical draughtsmen with paper machine experience preferred. Apply giving age, past experience, salary expected and when services are available, to Box No. 142-V.

Transitmen

A pulp and paper company in Quebec have openings for several transitmen for general surveying work. Apply to Box No. 144-V.

Civil Engineer

A large utility company in Ontario require a civil engineering graduate, about 30 years of age, having practical experience covering building construction to a large degree, with some experience in the installation of electrical apparatus, heating, plumbing, fire protection systems, and the layout and construction of sewers, water mains, roads and railways. This position will eventually lead to position of plant engineer. Apply giving full particulars to Box No. 145-V.

Chemical or Metallurgical Engineer

Wanted a recent chemical or metallurgical engineering graduate, with Italian background. Must be able to read and write Italian fluently. Position open contemplates an indefinite training period at a metallurgical plant in Canada for possible future transfer to plant located in Italy. Apply to Box 150-V.

Structural Draughtsman

Structural steel detailer for small firm, with at least five years experience making and checking shop details on bridge and building work. Knowledge of design desirable but not essential. Position permanent to man who can fill the position satisfactorily, with splendid opportunity for advancement. Apply to Box 151-V.

Architectural Draughtsman

Young architectural draughtsman with a knowledge of strength of materials for a young and growing company in Montreal, engaged in the chemical industry. Permanent position. Apply to Box No. 153-V.

Situations Vacant

Chemical Engineer

Recent graduate in chemical engineering for general chemical laboratory and test work. Apply to Box No. 155-V.

Mechanical Engineer

Mechanical engineer, age about 30, technical graduate with six to seven years' experience, including hydro-electric power plant design and construction. Prefer applicant with knowledge of French and German. Ultimate location South America. Please give full details age, education, experience and references. Apply Box No. 157-V.

Power Sales Engineer

Power sales engineer required by a large electric light and power utility in South America. Must be capable of investigating and encouraging development of new business of wide variety utilizing electric power. Should be a technical graduate with five to ten years' sales experience and possess ability to learn foreign languages. Applicants please give details of age, education, experience and references. Excellent opportunities for right man. Apply to Box No. 158-V.

Manager for Cold Storage Terminal

Wanted, a man with engineering and sales experience to take charge of the management and operation of a large modern cold and general storage terminal in New Brunswick. Must be able to sell storage to a wide clientele and have mechanical, organizing and operating ability. Apply giving full particulars regarding qualifications to Box No. 159-V.

Designing Draughtsman

Designing draughtsman for newsprint mill. Must be neat and accurate, capable of designing structural steel and reinforced concrete structures and handling mechanical details for plant equipment installations. Industrial plant experience necessary, preferably paper mill. State age, education, experience, salary expected, if married or single, and notice required. Send samples of design calculations and draughting work, also photograph. Apply to Box No. 160-V.

Structural Draughtsmen

Two structural draughtsmen required who have had experience in steel plate and tank work, if possible. Apply stating past experience, education, whether married or single, salary expected and when services available. Apply to Box No. 161-V.

Recent Graduate

Recent graduate in chemical or mechanical engineering for process work in large newsprint mill. Reply giving full details of experience, education, salary expected and nationality to Box No. 163-V.

Mechanical Engineer

Young graduate Canadian engineer experienced in air moistening and conditioning for the Canadian plant of an American blower concern. Business also comprises artificial heating and ventilation. Position, which is with large bona fide concern, calls for an investment of $1,000 to $2,000 as evidence of good faith. State salary and full particulars of experience to Box No. 164-V.

Chemist

Wanted, experienced chemist for high-grade bleached sulphite mill. In reply, state age, past experience whether on control or research work. Apply to Box No. 165-V.

Mechanical Draughtsman

Competent draughtsman, preferably a graduate in mechanical engineering, with experience in paper mill maintenance and alteration work. Apply to Box No. 166-V.

Situations Vacant

Sales Engineer

An engineering company manufacturing power plant and materials handling equipment requires a graduate engineer with experience in the power plant field and interested in sales engineering work for assistant in sales department. Sales experience desirable but not essential. Excellent opportunity for qualified man. Apply to Box No. 167-V.

Mechanical Engineer

A recent graduate in mechanical engineering interested in sales work to start in erection or draughting office of engineering company manufacturing power plant and materials handling equipment, to fit him for sales department. Apply to Box No. 168-V.

Assistant Engineer

Wanted immediately, assistant engineer experienced in the design of structural steel work and reinforced concrete, stating age, salary expected, experience and earliest date on which service available. Apply to Box No. 169-V.

Sales Engineer

A graduate engineer with wide experience in sales work, for a company manufacturing power plant and materials handling equipment. Apply to Box No. 170-V.

Mechanical Engineer

Young mechanical engineer about 25 to 30 years of age, with technical training and several years shop experience, for draughting and designing department of a company in western Ontario, where there is ample opportunity for advancement. Position permanent. Apply to Box No. 171-V.

Electrical or Mechanical Engineers

Vacancies exist for commissioned officers in the Royal Canadian Signals, Permanent Forces of Canada. Applicants must be British subjects, be under 25 years of age, physically fit and unmarried, and hold degree of electrical or mechanical engineering from a recognized university. Apply Box No. 172-V.

Production Engineer

A manufacturing company near Toronto has an opening for a young graduate engineer with experience in estimating and also preferably with experience in actual machine shop work. Apply Box 173-V.

Chemical or Metallurgical Engineer

A company with headquarters in the state of West Virginia requires the services of an experienced chemical or mechanical engineer for work in connection with the development of sodium sulphate deposits. The work in the first instance will be in West Virginia and later in western Canada. Apply Box 174-V.

Construction Engineer

A graduate engineer with five or six years experience on concrete and steel construction, required by a firm in Montreal. Apply with full particulars to Box 175-V.

Draughtsman

Wanted, a structural draughtsman with some experience in power plant and machinery layout. Location Montreal. Apply to Box No. 176-V.

Assistant Engineer

Wanted, an assistant engineer, preferably with some experience in connection with pulp and paper mills. Apply, stating age, experience, salary expected, and when available to Box No. 178-V.

Situations Vacant

Chemical Research Engineer

A young chemical graduate with a good academic record required by the research department of a large pulp and paper company in the province of Quebec. Apply to Box No. 179-V.

Recent Graduate

A paper company in Quebec has an opening for a recent graduate in mechanical, civil or electrical engineering. This position offers an opportunity for experience in the manufacture of pulp and paper. Apply to Box No. 180-V.

Salesman

An established, rapidly growing manufacturing business with branch offices in principal Canadian cities, distributing roofing and allied building materials, has an opening for a salesman in the Toronto office for promotion work with architects. This position requires a young ambitious man of irreproachable character, preferably with experience in engineering and building construction. Apply, stating age, education, experience, and give references to Box No. 181-V.

Draughtsman

Draughtsman wanted for general engineering in industrial plant in Montreal. Must be graduate engineer with at least five years experience, and with initiative and some ability to design. Permanent position. Apply to Box No. 182-V.

Situations Wanted

Designing Engineer

Electrical engineer, five years' experience in design and construction of hydro-electric plants and H.T. sub-station work, seeks position in or around Montreal. Experienced in all phases of electrical power house and sub-station design. B.Sc. '24, M.Sc. '28, age 30 years. A.M.E.I.C. Apply Box No. 7-W.

Construction Engineer

Electrical engineer, B.Sc., M.Sc., wishes to locate in Montreal on electrical construction or installation work involving power and distribution equipment. Experience covers design, testing, operation, maintenance and installation of power equipment. Can handle men successfully and show results. Now employed in Quebec. Apply Box No. 40-W.

Mechanical Engineer

Graduate mechanical engineer, aged 30 years, of good standing and integrity, with several years experience in paper mill design, construction, operation and records department, also good knowledge of cost accounting, desires responsible position. Apply to Box No. 45-W.

Civil and Mechanical Engineer

Civil and mechanical engineer with long and varied experience on design, construction, and operation of pulp and paper mills, desires position of responsibility. Specialty is reduction of conversion costs. Apply to Box No. 53-W.

Civil Engineer

Young graduate civil engineer with experience as field draughtsman and instrumentman on hydro-electric power developments, making plans, estimates on excavation and concrete, would like to secure a position. Apply to Box No. 54-W.

(Continued on next page)

Situations Wanted

Civil Engineer

A graduate of McGill Univ. '24, with some knowledge of French, wishes to return to Canada from the U.S.A. His experience includes instrumentman on railway construction, resident engineer on railway construction, instrumentman on general maintenance, and transitman on preliminary surveys. Apply to Box No. 103-W.

Civil Engineer

McGill graduate with eleven years experience on the construction of hydro-electric developments and industrial buildings desires a position as resident engineer. Open for engagement at very short notice. Apply to Box No. 117-W.

Civil Engineer

Toronto Univ. graduate '25 desires permanent position, preferably but not necessarily on hydro-electric development. Most recent experience, design of bridges, culverts, etc., two years; river control studies and open channel hydraulics for hydro developments, two years; draughtsman and detailer on hydro development, three years; mechanical draughtsman on steam power plant work, two years; at present in Southern California, but available on short notice. Apply to Box No. 119-W.

Sales Engineer

A graduate mechanical engineer resident in Toronto, experienced in the design and construction of industrial plants and smaller work, would like to represent manufacturing concerns in this territory. Remuneration could be adjusted after a reasonable trial. Apply to Box No. 123-W.

Structural Designer and Draughtsman

Structural designer and draughtsman, graduate engineer with 16 years experience in Canada and in the city of New York, on all types of structures, including tall buildings, apartments, hotels, warehouses, factories and industrial buildings. At present in Montreal, desires spare time employment, evening, Saturday afternoons, etc., at home or office, designing, laying out, figuring, checking or estimating. Apply to Box No. 127-W.

Electrical Engineer

Graduate of McGill Univ. '27 in electrical engineering, age 24, single, desires a position which will give him experience in construction or design along this line. Employed since graduation by a large public utility on pole line work. Has also had considerable experience in surveying. Apply to Box No. 129-W.

Recent Graduate

Electrical engineer, graduate '27, with experience in electrical construction, Diesel engines operation and eighteen months tests course, wishes to secure position with promise of advancement. Location immaterial. Apply to Box No. 132-W.

Civil Engineer

Graduate R.M.C., eighteen years' experience on hydraulic construction, building construction and design, dredging, manufacturing, steel fabrication, and plant maintenance, desires position as resident engineer, maintenance engineer, or dredging manager. Apply to Box 136-W.

Mechanical Engineer

Graduate mechanical engineer with 8 years experience, including 2 years on hydro-electric power construction and 6 years design and installation of equipment with a pulp and paper company and a large industrial manufacturing plant, desires a position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

Mechanical Engineer

M.E.I.C., with exceptional experience in the design, manufacture and sale of cranes of all types. Can organize economical production throughout, accustomed for many years to full responsibility. Apply to Box No. 148-W.

The Training of Young Engineers

Each year at this season, a certain number of engineers have claim to a good deal of sympathy from their fellows. The call to the high office of president of our leading technical institutions carries with it, among other responsibilities, that of delivering an address, which everybody, author, secretary and audience included, devoutly hopes and prays may be found to be not without interest. Each year a number of such addresses are delivered, and as the number of our important institutions is not small, the rate at which topics are thus dismissed is considerable. There is indeed little hope of anyone nowadays striking one that is really novel. The circle, in spite of the wider fields into which engineering is ever extending, tends to become relatively narrower. The philosophical type of address will remain the exception. There are few engineers in these days with leisure during their working lifetime sufficient to devote to erudite scholarship, much as many would like to crowd it in, and addresses on the more abstract side of what the profession stands for are better left to the gifted few than attempted by many. More often the best address, as Mr. Richard W. Allen suggested on Friday last, is made out of a man's own experience.

On the occasion to which we have alluded, Mr. Allen delivered his presidential address to the Institution of Mechanical Engineers, and in more than one respect was fortunate above his fellows. Both he and his firm have been closely connected with a special branch of engineering work not previously dealt with so far as memory serves, in addresses before the Institution. In any case the review given by Mr. Allen of the development of marine auxiliaries was not only permissible but welcome, covering as it did stages on which he is qualified to speak better than most engineers. Secondly, his remarks on training, in view of the attitude for so long adopted by his firm, cannot fail to carry the conviction that they are the outcome of a very practical experiment. And, we may add, thirdly, Mr. Allen's address was delivered in a manner which, without exaggeration, made listening a delight.

We have already referred to the place which the training of young men occupies in the economy and organization of the Queen's Engineering Works, Bedford. The stress laid upon the importance of this has been brought before engineers, on occasions, since the system was first adopted under the late Mr. W. H. Allen, who, it will be remembered, signified his interest in the younger men in the Institution by presenting to it not many years ago two valuable scholarships. In respectively proposing and seconding a vote of thanks to the president for his address, both Sir John Aspinall and Dr. H. S. Hele-Shaw referred to this matter of training. Sir John asserted that much of the success which Messrs. Allen had achieved was undoubtedly due to the care taken with regard to training. The company has never allowed itself to be exercised by the fear, so often expressed, that if a firm educates lads they will leave it as soon as possible for jobs at more attractive pay with its competitors. While this may be sometimes the case, taken by and large the care bestowed upon them is worth while. In many cases it results in a sincere attachment between the members of the staff and the firm, while we may be sure the latter has few regrets if, of the multitudes passing through its hands, some must inevitably ultimately become detached to follow the profession in the Dominion overseas, or elsewhere, provided that, as will most certainly be the case with the majority, the Allen traditions are maintained. With such a training coupled with the development of healthy social spirit, the Empire will certainly gain if at times men leave Bedford for more distant spheres.—*Extract from Engineering, October 26th, 1928.*

Preliminary Notice

of Applications for Admission and for Transfer

November 20th, 1928.

The By-laws now provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in December 1928.

R. J. Durley, *Secretary.*

* The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BROWN—HILTON ORLAND, of Iroquois Falls, Ont., Born at Port Sydney, N.S., July 28th, 1890; Educ., B.A.Sc., Univ. of Toronto, 1912; 1911 (summer), asst. on stream measurements, Dept. Interior, Calgary; 1912-14, engr. on hydrographic surveys and irrigation inspections, Dept. Interior, Calgary; 1914-15, supervising house constrn. work (personal); 1915-17, dftsman. and asst. engr. on constrn. at McIntyre Mines, Ontario; 1917-19, overseas, Can. Engrs.; 1919-20, field engr. on constrn., E. A. James Co., Toronto; 1920-21 (5 mos.), designing dftsman., Riordon Paper Co.; 1921-25, designing dftsman., and 1925 to date, engr. in charge of dfting., Abitibi Power & Paper Co., Iroquois Falls, Ont.

References: H. J. Buncke, C. B. Shaw, E. M. Proctor, W. B. Redfern, P. M. Sauder, F. H. Peters.

CALDWELL—FREDERICK WILLIAM, of 17 Marlowe Ave., Montreal, Que., Born at Lawrence, Mass., Nov. 12th, 1875; Educ., S.B., Mass. Inst. Tech., 1899; 1897-1902, periods of six mos. to two years, with United Shoe Machy. Co., American Soda Fountain Co., Mass. Highway Commn. (res. engr. i/c of constrn. of Reading & Woburn Rd.), Penn. Steel Co. (designed special milling machine and machy. for wall cranes in bridge shop); 1902-27, with General Electric Company, Schenectady, N.Y., engr. in office of vice-president, i/c of engineering and manufacturing, duties of a general engineering and executive nature; at present consltg. engr., Montreal, Que.

References: H. O. Keay, L. DeW. Magie, F. Newell, G. Kearney, W. M. Cruthers, V. S. Foster.

GRAVEL—ARTHUR L., of 451 Clarke Ave., Westmount, Que., Born at Montreal, July 4th, 1904; Educ., B.Sc., McGill Univ., 1924; 1922-23 (summers), elect'l mtce. work, Hollinger Cons. Gold Mines, Ltd.; 1924-25, student course, and part of 1925, switchboard engrg. dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh; 1925, elect'l engr., Quebec Development Co., Isle Maligne, Que., power plant mtce. and transmission line design and field location; 1926-27, educational work under H. M. Morris, Bell Telephone Co. of Canada; 1928, paper mill design and layout, Canada Power & Paper Corpn., Montreal, Que.

FOX—EDWARD CECIL EVANS, of 94 Duplex Ave., Toronto, Ont., Born at Coaticooke, Que., Nov. 29th, 1899; Educ., diploma, mech'l engr., I.C.S., 1922; qualified as Capt. in Military Engrg., R.M.C., 1924; 1918-20, app. engr., Canadian Ingersoll-Rand, Sherbrooke, Que.; 1920-21, app. instr'man and civil engrg. dftsman., Q.C. Rly.; 1921-24, instr'man and app. struct'l engr., McGregor & McIntyre; 1924-27, instr'man and app. struct'l dftsman., Bethlehem Steel Co.; 1927, asst. res. engr., T. & N.O. Rly., constrn. on James Bay Extension; 1928, asst. res. engr., Dominion Bridge Co., on erection of steel of Royal York Hotel; at present on leave of absence.

References: C. S. L. Hertzberg, E. T. Bridges, J. Robertson, S. B. Clement, A. W. Robinson.

GATES—GRANT GORDON, of 198 Fairleigh Ave. South, Hamilton, Ont., Born at Fairground, Ont., July 18th, 1894; Educ., 1916-17, first year, applied science, McGill Univ.; 1915, 1918-19, rodman and instr'man with J. W. Tyrrell & Co., and 1920-22, municipal, survey and subdivision work for same company; 1923-24, partner with O. R. Blandy, gen. engrg. and survey work, design of coal handling plant for Barton Coal Co.; 1926, res. engr. on constrn. of sheet mill and galvanizing plant; 1927, constrn. of new power house, and at present constrn. engr. for Steel Co. of Canada, Ltd., Hamilton, Ont.

References: J. W. Tyrrell, E. G. MacKay, J. E. Jackson, J. E. Grady, W. F. McLaren, J. J. MacKay, F. W. Paulin.

McCURDY—LYALL RADCLIFFE, of 227 Milton St., Montreal, Que., Born at New Glasgow, N.S., July 16th, 1897; Educ., B.Sc. (Mech.), 1921, M.Sc., 1927, McGill Univ.; 1918-20-22 (summers), dfting, freighting-car layout, estimating, etc., engrg. dept., Eastern Car Co., Ltd., New Glasgow, N.S.; 1922-27, sessional lecturer and demonstrator, dept. mech'l engrg., McGill University, and from 1927 to date, full time lecturer in same dept.; 1924-25 (summers), lab. experimentation on artificial stone, with Prof. R. DeL. French, M.E.I.C.; 1926 (summer), prepared new manual for mech'l drawing course, 1st and 2nd years, McGill Univ.; 1927 (summer), conducted investigation into efficiency and operating costs of fleet of 25 tow-boats on Upper Ottawa River; 1928 (summer), assting. Prof. A. R. Roberts, A.M.E.I.C., in research on Journal Bearing Friction.

References: H. M. MacKay, C. M. McKergow, A. R. Roberts, R. DeL. French, J. A. Duchastel, A. S. Wall, R. B. Stewart.

MUELLER—VICTOR LEO AUGUST, 49 Radford Ave., Toronto 3, Ont., Born at Hamilton, Ont., Jan. 26th, 1895; Educ., 1916-18, Buffalo Tech. School; 1912-16, ap'tice, Hamilton Bridge Works; 1916 (6 mos.), checker, Ferguson Steel & Iron Works, Buffalo; 1917, designing, Essenwein & Johnston, Buffalo; 1918 (6 mos.), checking and designing, Peck Bros., Buffalo; 1918-28, checking and designing, Dominion Bridge Co., Ltd., Toronto; March 1928 to date, engr. for Canadian & General Finance Co., Toronto—work covers power, gas, rlys., tramways, transmission lines.

References: A. H. Harkness, W. W. Gunn, G. L. Wallace, D. C. Tennant, C. S. L. Hertzberg.

SCOTT—WILLIAM BEVERLY, of Grand'Mere, Que., Born at Dalhousie, N.B., Oct. 26th, 1895; Educ., B.Sc., McGill Univ., 1920; 1920 to date, with Laurentide Co., Ltd., as follows: 1920-21, erection foreman; 1921-22, asst. master mechanic; 1922-27, master mechanic; 1927 to date, master mechanic and steam plant supt.

References: A. R. Roberts, C. M. McKergow, E. Brown, H. O. Keay, E. Wilson, H. E. Bates.

SHAW—GERALD EDISON, of 772 Sherbrooke St. West, Montreal, Que., Born at Windsor, Ont., May 5th, 1901; Educ., B.Sc., 1924, M.Sc., 1925, McGill Univ.; Sept. 1919-Sept. 1920, dftsman.; 1921 (summer), finish shop, assembling, etc.; 1922-23-24 (summers), dftsman., detailing bridges and towers, Canadian Bridge Co., Ltd.; 1925 to date, engr. in bridge dept., C.P.R., Montreal; work mainly on Toronto grade separation, designing steel and concrete structures.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of the engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service wil be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N.Y.

A

AIR COMPRESSORS

PORTABLE. Portable Air Compressors (Gleisfahrbare Untertage-Elektro-Kompressoren). Bergbau, vol. 40, no. 40, Oct. 6, 1927, pp. 553-556, 9 figs. Description of DEMAG air compressors travelling along narrow-gauge tracks, suitable for mining work; also compressed air locomotives.

AIR CONDITIONING

HIGH AIR TEMPERATURE. The Physiology of Work Under High Air Temperature Conditions, K. Neville Moss. Jr. Instn. Engrs.—Jl., vol. 37, part 11, Aug. 1927, pp. 541-547. Notes based on experimental work carried out for mining industry in mining department of University of Birmingham with view to obtaining information about work done by human body under varying conditions of air temperature and humidity; tests referred to have distinct practical value, apart altogether from their physiological interest.

AIRPLANE ENGINES

COMBUSTION IN. Combustion Time in the Engine Cylinder and Its Effect on Engine Performance, C. F. Marvin. Jr. Nat. Advisory Com. for Aeronautics—Report, no. 276, 1927, 16 pp., 16 figs.

AIRPLANES

PERFORMANCE. A Simple Theoretical Method of Analyzing and Predicting Airplane Performance, I. H. Driggs. Flight, vol. 19, nos. 34, 38 and 43, Aug. 25, Sept. 22 and Oct. 27, 1927, pp. 596a-596d, 668d-668f and 750a-750b. Gives formulas to show relation of certain fundamental variables to absolute ceiling and to rate of climb, and to allow estimate to be made for these quantities with but minimum of calculation.

STRUCTURAL DESIGN. Some Further Practical Points in the Structural Design of Aircraft. Inst. Aeronautical Engrs.—Jl., vol. 1, no. 9, Sept. 1927, pp. 5-14 and (discussion) 14-19, 9 figs.

WINGS. Pressure Distribution Tests on PW-9 Wing Models Showing Effects of Biplane Interference, A. J. Fairbanks. Nat. Advisory Com. for Aeronautics, no. 271, 1927, 13 pp., 14 figs.

ALLOY STEELS

MOLYBDENUM. Facts and Principles Concerning Steel and Heat Treatment, H. B. Knowlton. Am. Soc. Steel Treat.—Trans., vol. 12, no. 5, Nov. 1927, pp. 814-826, 3 figs.

ALLOYS

ALUMINUM. *See Aluminum Alloys.*

BRASS. *See Brass.*

COPPER. *See Copper Alloys.*

CORROSION-RESISTANT. Selection of Corrosion-Resistant Alloys, W. M. Mitchell. Blast Furnace & Steel Plant, vol. 15, no. 9, Sept. 1927, pp. 427-434. Causes of corrosion are explained; elements which increase resistance of steel are silicon, copper and chromium; non-ferrous alloys effective under certain conditions.

ALUMINUM

COMMERCIAL. Commercial Forms and Applications of Aluminum and Aluminum Alloys, P. V. Faragher. Am. Inst. Min. & Met. Engrs.—Tech. Publication, no. 33, 1927, 28 pp., 5 figs. Commercially pure metal containing from 99.0 to 99.4 per cent aluminum, remainder consisting largely of iron, silicon and copper, introduced in process of electrolytic reduction is called "pure aluminum" when it is desired to distinguish it from its alloys; effect of impurities in aluminum of high purity; uses for commercially pure aluminum; strong alloys; heat treatment; casting alloys; types of casting processes; sand-casting alloys; effect of heat treatment on strength; permanent-mould castings; die castings; aluminum-alloy forgings and aluminum cable.

MACHINING. Machining Aluminum, R. L. Templin. Am. Inst. Min. & Met. Engrs. —Tech. Publication, no 31, 1927, 15 pp., 10 figs. Comparison of tools more commonly used in machining brass and mild steel with tools most suitable for machining aluminum, and specific discussion of individual tools.

SAND CASTING. Some Notes on Sand Casting Aluminum. Mech. World, vol. 82, no. 2128, Oct. 14, 1927, pp. 290-291. Light weight of aluminum has always to be borne in mind, hence it must be fluid and poured quickly, and it must not meet much resistance from steam or air in mould; moulds should be as dry as possible while still remaining workable, and they must be well vented in places where gases of any kind would otherwise be able to form pockets.

ALUMINUM ALLOYS

ALUMINUM-COPPER. Industrial Utilization of Aluminum Alloys (A propos de l'utilisation industrielle des alliages d'aluminium), H. Pommerenke and P. Herman. Revue de Métallurgie, vol. 24, no. 6, June 1927, pp. 297-306, 8 figs.; and translated abstract in Metallurgist (Supp. to Engr.), Oct. 28, 1927, pp. 154-155, 2 figs.

ARCHES

STRESSES IN. A Graphic Method for Determining the Stresses in Circular Arches Under Normal Loads by the Cain Formulas, F. H. Fowler. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1893-1917, 13 figs. Presents series of curves for determining stresses, in pounds, per square inch, at extrados and intrados of crown and abutments of circular arches under normal loads.

AUTOMOBILE ENGINES

CARBURETORS. The Function of Carburetors, with Special Reference to Automobile Engines (Le fonctionnement des carburateurs des moteurs à explosion, envisage principalement au point de vue de leur application à l'automobile), A. Coppens. Chaleur & Industrie, vol. 8, nos. 87 and 90, July and Oct. 1927, pp. 424-428 and 603-610, 17 figs. July: Deals with control of carburetors. Oct. Construction of curves and diagrams.

VARIABLE-COMPRESSION. A New Automobile Engine, Nau-Touron (Un nouveau moteur à courses inégales à faible obliquité de bielle et à compression variable), E. Marcotte. Arts & Metiers, no. 83, Aug. 1927, pp. 277-288, 23 figs. Theory and construction of engine of unequal stroke, slightly oblique, connecting rod and variable compression; points out its special economic value for France in permitting use of various fuels, and its significance for aviation by making possible a wider range of flight.

AUTOMOBILE MANUFACTURING PLANTS

HEAT PROCESSES. Heating Processes Synchronized in Straight Line Production, J. B. Nealey. Iron Trade Rev., vol. 81, no. 10, Sept. 8, 1927, pp. 584-587, 5 figs. Methods and equipment of Ford Motor Co.; heating steel ingots.

AUTOMOBILES

BRAKE-TESTING MACHINES. Brake-Testing Machine Simulates Road Operating Conditions. Automotive Industries, vol. 57, no. 19, Nov. 5, 1927, pp. 684-685, 4 figs. Synchrometer automatically makes record of decelerating characteristics of each wheel, plotting speed for each foot of travel from time brake is applied to complete rest.

PROGRESS. Progress in Design. Autocar, vol. 59, no. 1668, Oct. 21, 1927, pp. 816-870. Notes on development based upon characteristics of 312 different types of cars available on British market.

AUTOMOTIVE FUELS

DEVELOPMENT. Motor Fuels, J. B. Hill. Indus. & Eng. Chem., vol. 19, no. 10, Oct. 1927, pp. 1114-1115. Chemistry's contribution to quantitative production and quality of motor fuels; substitutes for gasoline.

B

BALANCING

PRINCIPLES. Balancing of Rotating Bodies, C. R. Soderberg. Tech. Eng. News, vol. 8, no. 5, Oct. 1927, pp. 212-216 and 246, 18 figs. Principles involved in mechanical balancing, with description of various types of balancing machines.

BEAMS

REINFORCED CONCRETE. Experiments on Shearing Strength of Reinforced Concrete Beams, J. Gilchrist. Engineering, vol. 124, no. 3224, Oct. 28, 1927, pp. 563-566, 8 figs. Experiments made to find out how shearing strength of beams varied with strength of concrete.

BEARING METALS

SELECTION. Choosing White Bearing Metals, E. R. Thews. Am. Mach., vol. 67, no. 20, Nov. 17, 1927, pp. 759-760. Great number of combinations possible in white bearing-metal alloys makes it desirable for designer and shop man to have clear understanding of effects of each element entering into alloy on final bearing qualities of metal to be selected for bearing.

BEARINGS, BALL

MANUFACTURE. The Manufacture of Ball and Roller Bearings, G. James. Eng. Jl., vol. 10, no. 11, Nov. 1927, pp. 487-493, 22 figs. Details of major manufacturing operations.

BOILER FEEDWATER

TREATMENT. Boiler Feed Water Treatment, E. Caldwell. Indus. Power, vol. 8, no. 4, Oct. 1927, pp. 54-58 and 94 and 96, 5 figs. Discusses necessity for treating boiler feed water and various methods of treating.

Boiler Feed Water Treatment from a Manufacturer's Viewpoint, J. B. Romer. Am. Ry. Eng. Assn.—Bul., vol. 29, no. 298, Aug. 1927, pp. 64-69. Deals with scale, corrosion, embrittlement and priming and foaming.

Treating Boiler Feed Waters, M. H. Watson. Power House, vol. 21, nos. 18 and 19, Sept. 20 and Oct. 5, 1927, pp. 17-20 and 117-121. Discussion of common impurities found in boiler feed water, chemical treatment to prevent corrosion and foaming and explanation of chemical reactions involved, with reference to external purification.

BOILER FURNACES

Combined Pulverized Coal and Stoker Firing. Pulverized Coal Takes Fluctuations in a Stoker Fired Plant. Power, vol. 66, no. 20, Nov. 15, 1927, pp. 733-735, 6 figs. Application of pulverized-coal burners in combination with existing stoker equipment.

Gas-Fired. Gas-Fired Steam Boilers, A. B. Greenleaf. Chem. & Met. Eng., vol. 34, no. 9, Sept. 1927, pp. 566-568, 8 figs. Study of economics involved; there are two principal types of gas-fired boilers in general use; cast iron type is limited to use for comparatively low pressures, while steel firetube type can be used over practically entire range of working pressures.

Water Walls. Boilers with Water Walls for Industrial and Isolated Power Plants, K. Toensfeldt. Combustion, vol. 17, no. 5, Nov. 1927, pp. 293-297, 4 figs. Shows how presence of water walls in furnace not only makes possible higher ratings than may be obtained with old firebrick-lined furnaces, but also how their presence betters relative performance of boiler at same steaming rates.

BOILER PLANTS

Instrument. Automatic Volume Control of Steam and Air, J. Wolfe. Chem. & Met. Eng., vol. 34, no. 9, Sept. 1927, pp. 562-565, 17 figs. Cites two examples: first is one in which continuous control of air for combustion in steam raising is used, while second is example of intermittent or cyclic control of air and steam for manufacture of blue gas or carburetted water gas.

BOILERS

Heat Transfer in. Large Boiler Units and Heat Transfer, A. Page. Power Engr., vol. 22, nos. 259 and 260, Oct. and Nov. 1927, pp. 377-380 and 425-427, 2 figs. Oct.: Thermal losses of modern boiler unit are analyzed. Nov.: Novel method of boiler construction by which chimney and radiation losses are claimed to be greatly reduced.

Marine. *See Marine Boilers.*

Selection. The Selection of Steam Boilers, W. A. Shoudy. Combustion, vol. 17, no. 5, Nov. 1927, pp. 285-288 and 302, 2 figs. Whether waste-heat or direct-fired boilers are to be installed, there is no rate which will completely govern their selection; author has attempted to point out certain paths of approach to problem and to offer few words of warning; there is not now, nor will there be, a universal type suitable for all needs.

Settings. Boiler Settings, G. E. Dignan. Engrs'. Soc. West. Pa.—Proc., vol. 43, no. 6, July 1927, pp. 279-302 and (discussion) 303-305, 12 figs. Points out how conditions can be met in practical and commonsense manner; deals more with larger installations, as conditions are more severe and lessons learned can be applied with profit and discrimination to smaller installations.

Increasnig Height of Boiler Settings, H. B. Singleton. Power House, vol. 21, no. 20, Oct. 20, 1927, pp. 20-21, 3 figs. View is expressed that when boilers are set higher than it is customary and careful firing methods adopted they can be run with practically clean surface if tubes are cleaned every 10 or 12 hours.

Waste-Heat. Raising Steam by Waste-Heat, F. J. Taylor. Colliery Guardian, vol. 135, no. 3485, Oct. 14, 1927, pp. 617-621, 9 figs. Deals with facilities available for producing steam by gas-fired or waste-heat boilers, and certain other means of turning waste-heat to good account.

The Production of Steam from Waste-Heat, A. J. Ebner. Chem. & Met. Eng., vol. 24, no. 9, Sept. 1927, pp. 572-574, 6 figs. Although waste-heat boilers of firetube type have been installed to operate at steam pressures up to 250 lb., greater number are in service at 150 lb. or less; combination of better heat recovery and low initial cost of equipment in an operation at moderate pressure usually outweighs benefits to be derived from high-pressure steam.

Waste-Heat Boilers, J. B. Crane. Combustion, vol. 17, no. 5, Nov. 1927, pp. 303-306 and 310, 6 figs. Boilers for waste-heat purposes are horizontal return-tubular, horizontal or vertical water-tube; settings should be made heavier and more substantial with waste-heat than with regular boilers.

BOLTS

Heat-Treating. Low-Carbon Bolts Show Uniformly High Strength, E. F. Ross. Iron Trade Rev., vol. 81, no. 17, Oct. 27, 1927, pp. 1025-1027, 2 figs. That tensile strengths of low-carbon steel, containing up to 0.15 per cent carbon, could be increased 30 per cent simply by making extremely rapid quench was discovery of Roy H. Smith, of Lamson & Sessions Co., at Kent, Ohio; numerous improvements which have been made during past two years are described.

BRASS

Hot Rolling. Problems of Hot Rolling Brass, L. Kroll. Brass World, vol. 23, no. 10, Oct. 1927, pp. 325-326. Larger heats in casting shop result in more accurate mixing and easier work with moulds; critical review of hot-rolling literature.

BRIDGES, HIGHWAY

Concrete. Concrete Arch Bridge Over the Mississippi, M. S. Grytrak. Eng. News-Rec., vol. 99, no. 19, Nov. 10, 1927, pp. 754-758, 7 figs. Design of bridge on Twin City highway; arch ribs with spandrel bents; foundation work; cableway for concreting; steel centering.

BRIDGES, MOVABLE

Specifications. Standard Specifications for Movable Bridges. Can. Eng. Standards Assn., Sept. 1927, 70 pp., 2 figs. Specification is intended to include technical provisions necessary for supply of article herein referred to, but does not purport to comprise all necessary provisions of a contract.

BRIDGES, STEEL

Highway. Victoria Bridge, Ridout Street, London, Ont., J. R. Rostron. Can. Engr., vol. 53, no. 17, Oct. 25, 1927, pp. 474-478. New steel pony-truss bridge erected over south branch of river Thames to replace old structure; two spans, each 126½ feet, accommodate 31-ft. asphalt roadway and two 6-ft. concrete sidewalks.

BUILDING CONSTRUCTION

Wind-Bracing Connection. Wind-Bracing Connection Combines Welding and Riveting, W. A. Hakin. Eng. News Rec., vol. 99, no. 19, Nov. 10, 1927, p. 752, 2 figs. Tests were completed by Detroit Structural Welding Committee on a combined arc-welded and riveted wind-bracing connection between floorbeam and column.

Winter Inclosure. Winter Construction Methods and Plant, C. S. Hill. Eng. News-Rec., vol. 99, no. 17, Oct. 27, 1927, pp. 674-679, 11 figs. Winter inclosure in building construction.

BUILDINGS

Wind Connections. Details for Wind Connections in Tier Buildings, W. H. Weiskopf. Eng. News-Rec., vol. 99, no. 10, Sept. 8, 1927, pp. 396-399, 7 figs. Connections using angles and I-beams; several types of bracket; connections for double girders.

C

CABLES, ELECTRIC

Conduits for. Determining the Size of Conduit Required for Cables. Elec. World, vol. 90, no. 16, Oct. 15, 1927, p. 787. Proper allowances for conductor placement to avoid expensive alterations and rearrangements may be made by preliminary survey and analysis of specifications.

CABLEWAYS

Aerial. Aerial Tramways, F. C. Carstarphen. Am. Soc. Civ. Engrs.—Proc., vol. 53, no. 9, Nov. 1927, pp. 2101-2182, 22 figs. Author aims at outline classification, together with such comments and formulas that may be of service to engineers in determining elements of aerial ropeway for their needs; these formulas have been derived, checked and used by author and are believed to be in correct and convenient form.

CANALS

Automatic Head Works. Side Spillways for Regulating Diversion Canals, W. H. R. Nimmo. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1869-1892, 10 figs. Deals with design of automatic head works for Ouse-Great Lake canal in Tasmania; as head works are likely to become coated with ice for several weeks at a time, forces applied to move gate must be large, and for this reason gates operated by floats were found to be unsuitable; writer investigated theory of flow in side spilling channel with a view to devising a type of regulator without moving parts; paper presents theory developed, describes experiments carried out to test it, and adaptation of theory to design of automatic head works for Ouse-Great Lake canal.

Head Works. The Head Works of the Imperial Canal, C. E. Grunsky. Am. Soc. Civ. Engrs.—Proc., vol. 53, no. 9, Nov. 1927, pp. 2183-2187, 2 figs. In 1916 it became necessary to make considerable improvements, which included an upstream extension of canal for about 1 mile and building of intake structure which is known as Rockwood Gate; this gate was designed for erection on sand foundation; it has 75 openings between piers and extends for more than 600 ft. along bank of river; there has been no trouble with settling during eight years since its completion.

CARS FREIGHT

Braking Power. Proposed Revision of Braking Power for Freight Cars, F. K. Vial. Ry. Mech. Engr., vol. 101, no. 11, Nov. 1927, pp. 714-719, 5 figs. Irregularities are principal cause of wheel failures; simple remedy suggested.

CARS, PASSENGER

Aluminum. Aluminum Used Extensively in New C. & N. W. Suburban Cars. Ry. Mech. Engr., vol. 101, no. 10, Oct. 1927, pp. 665-667, 6 figs. Affords saving in weight of 5,700 lb. per car; 120 cars equipped with Melcher-Hyatt roller bearings.

CASE HARDENING

Practice. Practice in the Carburization of Steel, J. D. Gat. Forging—Stamping—Heat Treating, vol. 13, no. 10, Oct. 1927, pp. 393-396. Factors which exert an influence on final product such as manner of packing, carburizing agents, energizers, etc.

CAST IRON

Strength of. The Strength of Cast Iron, J. E. Fletcher. Foundry Trade Jl., vol. 36, no. 570 and 571, July 21 and 28, 1927, pp. 69-72 and 89-92, 5 figs. Presents deflection in transverse tests; dominating influence of silicon and total carbon together, and importance of carbon and silicon proportions in (T. C. + Si) factor must have first attention when attempting to interpret analysis of cast iron in terms of its mechanical strength.

CASTING

Centrifugal. Centrifugal Castings for Locomotive Piston-Valve Bushings. Engineering, vol. 124, no. 3225, Nov. 4, 1927, pp. 580-581, 4 figs. Importance attached by locomotive engineers to centrifugal castings for piston-valve liners is shown by fact that they are now frequently specified; process known as Spun-Sorbitic is new development of Hurst-Ball process; it enables casting, having relatively low silicon contents, ranging from 0.75 to 1.5 per cent to be produced without incurring danger of chilled surfaces or hard spots; important feature of process is that casting is cooled from temperature immediately below solidification point by means of special type of wet-air blast; immediate effect of this special cooling treatment is to convert pearlite into sorbite.

CEMENT

Proportioning Raw Materials. Proportioning Raw Cement Materials, E. S. Ernst, W. S. Ernst and W. A. Ernst. Rock Products, vol. 30, no. 21, Oct. 15, 1927, pp. 73-77, 4 figs. Use of system of triangular co-ordinates compared with algebraic methods.

CEMENT MILLS

Electric Drive. Application of Electricity in Cement Mills, W. E. North. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 881-884, 5 figs. Advantages of electric drive for cement mills are enumerated and general pointers on installing electrical equipment are given.

CHAINS

Manufacture. Heavy-Duty Chain Made by New Method. Iron Trade Rev., vol. 81, no. 15, Oct. 13, 1927, pp. 897-898 and 908, 3 figs. Drop-forging company in Worcester, Mass., has started production of weldless heavy-duty chain, patterned after design first worked out in connection with anchor chain for U.S. navy; this new weldless chain develops on testing machine strength considerably greater than usual type of forged welded chain.

CHIMNEYS

Flue Lining. A Study of Flue Lining, R. A. Hart and H. W. Clark. Am. Ceramic Soc.—Jl., vol. 10, no. 10, Oct. 1927, pp. 795-803, 4 figs. Investigations conducted on various types of flue lining following failure of several lengths in a chimney; standardization on a round tile lining with minimum area of 95 square inches, and having modified tongue and groove joint is recommended.

CIRCUIT BREAKERS

Control. The Use of High-Frequency Currents for Control, C. A. Boddie. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 763-769, 11 figs. Details of high-frequency system installed at Tipton, Indiana. See also discussion in no. 10, Oct. 1927, pp. 1128-1129.

High-Voltage. High-Voltage Oil-Circuit Breakers, R. Wilkins and E. A. Crellin. Elec. World, vol. 90, no. 17, Oct. 22, 1927, pp. 833-835, 3 figs. Functional requisites of equipment for high-tension transmission networks; contact designs and operating speeds bear close relation to improved performance.

COAL

CARBONIZATION. Coal Utilization. World Power, vol. 8, no. 46, Oct. 1927, pp. 185-187. Papers read before British Assn. urge importance of pretreatment and chemical additions before or during coking, and need for further research toward improved methods of heat transmission in carbonization.

Low Temperature Carbonization. Can. Engr., vol. 53, no. 15, Oct. 11, 1927, pp. 447-448. These processes described; appendix to report on proposed coke ovens for Toronto; estimate of cost.

PULVERIZED. *See Pulverized Coal.*

COAL MINING

ALBERTA. Operations of the Cadomin Coal Co., W. J. Dick. Can. Min. Jl., vol. 48, no. 43, Oct. 28, 1927, pp. 852-854. Mine is situated at Cadomin, Alberta; method of extracting pillars; rock-tunnel isolated-panel system of mining; ventilation and haulage.

COLD STORAGE

INSULATION. Insulation of Fruit Storage Houses, F. G. Hechler. Agric. Eng., vol. 8, no. 9, Sept. 1927, pp. 249-251, 1 fig. Insulating materials and methods of heat transfer; gives tabular data on thermal conductivity of materials and relative insulating value of some air storage constructions.

PERISHABLE-PRODUCTS TERMINAL. The New Philadelphia Perishable Products Terminal, H. D. Peltier. Ice & Refrigeration, vol. 73, no. 4, Oct. 1927, pp. 193-198, 13 figs. Description of modern plant erected at Philadelphia, Pa., by Baltimore & Ohio and Reading Railroad companies; equipped with latest improvements in cold-storage equipment; ample facilities provided for storage of perishable products of markets and general consumers.

COMBUSTION

CONTROL. Operating Principles of the Smoot System of Combustion Control, D. L. Fagnan. Nat. Engr., vol. 31, no. 11, Nov. 1927, pp. 523-527, 5 figs. Fundamental operating principles of centralized combustion control; functions of different parts of apparatus and construction details; applications and operation under various service conditions.

COMPRESSED AIR

LEAKAGE. New Method for Measuring Compressed Air Leakage (Sur une nouvelle méthode de mesure des fruites d'air comprimé), G. Levy. Revue de l'Industrie Minérale, no. 163, Oct. 1, 1927, pp. 401-407, 6 figs. Reviews common methods of determining leakage from centrifugal and displacement compressor systems and proposes new grapho-analytic method of parallel tangents.

MEASUREMENT. Measurement of Compressed Air by the Air Orifice Method, G. J. Heimel and W. Z. Lidicker. Wis. Engr., vol. 32, no. 1, Oct. 1927, pp. 10-11 and 32, 3 figs. In making a thesis investigation of an air-lift pump, writers found it necessary to measure compressed air used in operation of pump; standard orifice method was used with 6-in. drum.

CONDENSERS, STEAM

SURFACE. Final Devaporization of Steam in Surface Condensers, W. J. Dana. Power, vol. 66, no. 20, Nov. 15, 1927, pp. 747-749, 2 figs. Shows how to calculate surface necessary to condense remaining steam.

CONDUITS

PRESSURE. Steel Penstock Design by a Graphical Method, P. Bier. Eng. News-Rec., vol. 99, no. 16, Oct. 20, 1927, pp. 629-634. Charts used to determine proper thickness of steel plates, most efficient type of joint; weight and cost of pipe; both riveted and welded pipe included, also various working stresses.

CONSTRUCTION WORK

WINTER. Winter Construction Methods and Plant, C. S. Hill. Eng. News-Rec., vol. 99, nos. 9 and 10, Sept. 1 and 8, 1927, pp. 332-336 and 391-394, 7 figs. Planning and servicing winter construction. Sept. 8: Winter care and servicing equipment.

COOLING TOWERS

DESIGN AND OPERATIONS. Construction and Operation of Cooling Towers (Construction des refrigérants, et sur leur fonctionnement), T. J. Gueritte. Société des Ingénieurs Civils de France—Mémoires et Compe Rendu, vol. 80, nos. 3-4, Mar.-Apr. 1927, pp. 388-415, 13 figs. Covers elements of theory with use of psychometric charts, describing construction of hyperbolic and rectangular types and showing performance of a few installations.

COPPER ALLOYS

COPPER-ZINC. Physical Characteristics of Commercial Copper-Zinc Alloys, W. H. Bassett and C. H. Davis. Am. Inst. Min. & Met. Engrs.—Tech. Publication, no. 26, 1927, 16 pp., 12 figs. Data and plots are arranged to constitute summary, enabling one at glance to see physical properties of copper-zinc alloys to 62 per cent; characteristics shown are tensile properties, hardness and grain size, both in picture and in numerical values.

COPPER METALLURGY

CONCENTRATES, DEWATERING. Dewatering Concentrates at Chino, J. T. Shimmin. Eng. & Min. Jl., vol. 124, no. 19, Nov. 5, 1927, pp. 726-729, 2 figs. Describes filtration problem; steps taken to solve it by making changes in existing equipment and development at Chino of new type of filter which not only demonstrated its ability to handle flotation concentrates with ease, but also handled mixture of flotation and table concentrates.

CORROSION

THEORY OF. The Theory of Metallic Corrosion in the Light of Quantitiative Measurements, G. D. Bengough, J. M. Stuart and A. R. Lee. Roy. Soc.—Proc., vol. 116, no. 774, Oct. 1, 1927, pp. 425-467, 11 figs. Object of research is discovery of satisfactory way of measuring corrosion of metals in water and dilute salt solutions, and use of it to test adequacy of newer electrochemical theory of corrosion as applied to such media.

D

DAMS

ARCH. Semi-Circular Arch Dam Model Tested in Italy, C. Cuidi. Eng. News-Rec., vol. 99, no. 17, Oct. 27, 1927, pp. 668-669, 2 figs. Dam forming inner wall of ring-shiped tank tested under pressure; other tests on concrete structures.

CONSTRUCTION. Construction Features of Bull Run Dam, B. E. Torpen. Modern Irrigation, vol. 3, no. 9, Sept. 1927, pp. 40-41, 4 figs. New and unusual construction methods are being utilized by builder of Exchequer Dam in new project; manufacture of concrete aggregates, dam excavation and dam concrete operations will be continuous throughout period of construction.

MODEL EXPERIMENTS. Baffle-Pier Experiments on Models of Pit River Dams, I. C. Steel and R. A. Monroe. Am. Soc. Civ. Engrs.—Proc., vol. 53, no. 9, Nov. 1927, pp. 2189-2218, 27 figs. Results obtained from series of experiments made on one-twentieth scale models of diversion dams for Pit No. 3 and Pit No. 4 hydro-electric projects of Pacific Gas & Elec. Co.; object to determine most satisfactory means of controlling or destroying energy from overpour water at foot of dams in order to prevent erosion of downstream banks and bed of stream; several types of stilling devices were experimented with; most satisfactory results were obtained by use of two rows of baffle piers resting on concrete apron below bucket of dam, upper row of piers being truncated prisms serving as splitters and lower row having curved upstream faces to act as deflectors and baffles.

DIELECTRICS

ELECTRIC STRENGTH. Electric Strength of Solid and Liquid Dielectrics, W. A. Del Mar, W. F. Davidson and R. H. Marvin. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1002-1006 and (discussion) 1127. Summary of existing literature; consideration of general subject of instability in electric circuits, and explanation of instability in case of dielectrics, in terms of stress and strain characteristic; distribution of stress and strain in non-uniform fields, and their relation to breakdown; reversible and non-reversible phenomena of dielectric failure; relation of breakdown voltage to various factors, such as insulation thickness, insulation area, electrode form, heterogeneity, temperature, rate of voltage, variation, pressure, etc. Bibliography.

DIESEL ENGINES

AIRLESS-INJECTION. A 1,500-Horse Power Diesel of the Solid-Injection Four-Stroke Cycle Type. Power, vol. 66, no. 19, Nov. 8, 1927, pp. 695-697, 5 figs. Among other unusual features is speed of 300 to 350 r.p.m.; eight cylinders are 18 in. diameter by 22-in. stroke, giving piston speed of 1,283 ft. at 350 r.p.m.

DESIGN. Modern Trend of the Diesel Engine with Respect to Low Weight Per Horse Power, High Revolutions Per Minute and High Mean Effective Pressure, O. D. Treiber. Soc. Naval Architects & Mar. Engrs.—Advance Paper, no. 13 for mtg., Nov. 10-11, 1927, 13 pp., 16 plates.

M.A.N. Test of a Two-Cycle Double-Acting Marine Diesel Engine, E. Nibbs and S. A. Gardner. Soc. Naval Architects & Mar. Engrs.—Advance Paper, no. 10, for mtg., Nov. 10-11, 1927, 12 pp., 14 figs. Tests carried out on M.A.N. type engine built for U.S. Shipping Board by New London Ship and Engine Co. to be installed in S.S. Wilscox, 9,500-deadweight ton vessel of Oscar Daniels type.

POWER COSTS. Diesel Oil Engine Power Costs. Elec. News, vol. 36, no. 19, Oct. 1, 1927, pp. 30-33. Collection of data over several years from 98 plants having combined annual output of over 223,000,000 kw.-hr. may be used to estimate cost per kw.-hr. of a proposed plant.

POWER PLANTS. How to Figure Diesel Plant Initial Costs, E. J. Kates. Power, vol. 66, no. 19, Nov. 8, 1927, pp. 697-698. Initial cost of 1,000-kw. Diesel generating plant for industrial use and of 1,000-kw. Diesel electric central station in dollars per kilowatt capacity.

U.S. SHIPPING BOARD. The Engines of the U.S. Shippnig Board Diesel Conversion Programme, R. D. Gatewood. Soc. Naval Architects & Mar. Engrs.—Advance Paper, no. 12 for mtg., Nov. 10-11, 1927, 6 pp. Diesel conversion programme includes engines of all variations and, in addition, special features of design which are described, together with shop-test results and operating results at sea on such engines as are in service at time of writing.

E

EDUCATION, ENGINEERING

CURRICULUM. The Engineering Curriculum, H. P. Hammond. Jl. Eng. Education, vol. 18, no. 1, Sept. 1927, pp. 57-84, 9 figs. Summarizes number of more significant facts and conclusions concerning curriculum which have been gathered in course of investigation.

GRADUATE STUDY. Graduate Study in the Engineering Schools, D C. Jackson. Jl. Eng. Education, vol. 18, no. 2, Oct. 1927, pp. 125-147 and (discussion) 148-158. See also contribution by G. M. Butler, pp. 136-143, giving account of experiment in engineering education that University of Arizona is making; and contribution by C. S. Coler, pp. 144-147, on method employed by University of Pittsburgh; and discussion, pp. 148-158.

TEACHERS. A Brief Report and Impressions of the Summer School for Engineering Teachers at Cornell University and University of Wisconsin, H. P. Hammond. Jl. Eng. Education, vol. 18, no. 1, Sept. 1927, pp. 11-36. Brief comments, supplemented by excerpts from some of statements received from those who attended; general impression of those who attended or observed schools seems to be that work may be pronounced successful.

ELECTRIC CIRCUITS

MECHANICAL FORCES. Experimental Measurement of Mechanical Forces in Electric Circuits, J. W. Roper. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 913-915, 6 figs. Simple laboratory method of measuring mechanical forces exerted on parts of complete circuit due to current flowing in circuit; tests, using method, show that "classic" methods of computing such forces are reliable.

Mechanical Forces Between Electric Currents and Saturated Magnetic Fields, V. Karapetoff. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 897-903, 2 figs. General case considered is that of N independent electric circuits placed in medium of variable permeability and subject to saturation, in parts or as whole; problem is to determine component (in given direction) of mechanical force acting upon one of electric circuits, upon group of circuits, or upon group of circuits with part of magnetic medium rigidly attached to them; it is believed that problem has not been solved in this general form heretofore.

ELECTRIC CONDUCTORS

PROXIMITY-EFFECT CALCULATIONS. Proximity-Effect in Groups of Round Wires, H. B. Dwight. Gen. Elec. Rev., vol. 30, no. 11, Nov. 1927, pp. 531-536, 7 figs. Formulas to determine division of current; impedance drop; watts loss; five types of conductor grouping with examples.

ELECTRIC CURRENTS, A.C.

NON-HARMONIC. Non-Harmonic Alternating Currents, F. Bedell. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1057-1064. Certain principles are presented for solving non-harmonic a.c. problems. Bibliography.

ELECTRIC CURRENTS

SHORT CIRCUITS. Short Circuits Currents, R. C. R. Schulze. Elec. Light & Power, vol. 5, nos. 10 and 11, Oct. and Nov. 1927, pp. 21-25 and 27-30, 11 figs. Author shows that there are number of uses for knowledge of short circuit currents that may flow in various parts of system, and illustrates just what the calculations represent; shows ways by which calculations can be made and procedure when making study of the fault currents; sources of error are pointed out, with their approximate magnitude and possible effect.

ELECTRIC DISTRIBUTION SYSTEMS

EQUIPMENT. Equipment for 220-Kv. Systems, J. P. Jollyman. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 877-880. Characteristics of equipment which have been found most suitable for use on 220-kv. systems or on extensive lower-voltage systems; consideration is given to general system design, governors of prime movers, generators, excitation systems, transformers, high-voltage oil circuit breakers, transmission line and equipment of sub-stations.

ELECTRIC FURNACES

BRITISH PRACTICE. British Electric Furnace Practice, H. C. Dews. Elec. Times, vol. 72, no. 1876, Oct. 6, 1927, pp. 416-419, 5 figs. Operating costs; power supply; steel melting; melting mild steel; arc furnaces; electric pig iron; induction-type furnaces; Ajax Wyatt furnace; Ajax Northrup.

MELTING. High-Frequency Induction Melting, D. F. Campbell. Elec. Rev., vol. 101, no. 2602, Oct. 7, 1927, pp. 607-609. 5 figs. Details of Ajax-Northrup high-frequency furnace. Abstract of paper read at Iron and Steel Inst.

ELECTRIC GENERATORS, A.C.

SYNCHRONOUS. A Study of Transverse Armature Reaction in Synchronous Machines, R. A. Schaefer. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 811-814, 5 figs. Results of tests by means of second machine with adjustable stator.

ELECTRIC MEASURING INSTRUMENTS

SHORT-CIRCUIT TORQUE. An Instrument for Measuring Short-Circuit Torque, G. W. Penney. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1151-1159, 10 figs. Small instrument which can be attached to end of shaft of machine to be tested; it records instantaneous acceleration of rotor, corresponding torque being calculated; acceleration is measured by two separate methods; first method gives points on acceleration time curve, and second gives continuous record of torque; acceleration is recorded on oscillogram, so that by using six-element oscillograph simultaneous record can be obtained showing both acceleration and short-circuit currents; it can also be used for measuring sudden shocks on motors and other rotating machinery.

ELECTRIC MOTORS, A.C.

INDUCTION. Recent Improvements in Large Induction Motors, D. F. Alexander. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1167-1175, 6 figs. Deals with ventilation, insulating, coil design and bracing, collectors, bearings and manufacturing improvements.

SYNCHRONOUS. The Automatic Control of Synchronous Motors, J. H. Hall. Iron & Steel Engr., vol. 4, no. 10, Oc.t 1927, pp. 427-434 and (discussion) 434-435. Describes several of methods in use for closing field contactor automatically at proper moment; operation; protective devices; electrical interlocks; instruments; automatic power-factor regulation.

Starting Performance of Synchronous Motors, H. V. Putman. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 794-801 and (discussion) 830-832, 13 figs. Deals with theory underlying starting performance of salient pole synchronous motor equipped with damper windings; method for calculating speed torque curve from standstill to synchronous speed.

ELECTRIC MOTORS, D.C.

PARALLEL OPERATION. Operation of Series Motors in Parallel When Rigidly Coupled to the Same Load, J. A. Jackson. Iron & Steel Engr., vol. 4, no. 10, Oct. 1927, pp. 423-427, 11 figs. Occasionally economy in selecting control equipment leads to error of using common reversing contactors or drum switches with single reversing segments for motors mechanically connected to same load which frequently results in unsatisfactory operation; author analyzes this connection and shows why such control connection is dangerous.

ELECTRIC SWITCHES

AUTOMATIC. Development of Automatic Switching Equipments in the United States and Europe, A. H. de Goede. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1209-1214, 8 figs. Outline of history and general development as applied to power equipment; comparison based on personal observation between conditions in United States and Europe, which accounts for less rapid development and less extensive applications of automatic equipments in Europe; mercury arc rectifiers and supervisory-control systems.

ELECTRIC TRANSMISSION LINES

CARRIER-CURRENT PILOT SYSTEM. A Carrier-Current Pilot System of Transmission Line Protection, A. S. Fitzgerald. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1015-1021, 14 figs. Term carrier current is employed as descriptive of a.c. energy generated at frequencies which lie, roughly, between 10 and 200 kilocycles; at these frequencies, transmission of electrical energy exhibits special characteristics due to which it is possible to superpose carrier-current-control circuits on transmission lines or cables. See abstract in Elec. World, vol. 90, no. 18, Oct. 29, 1927, pp. 889-891, 2 figs.

COUPLING FOR CARRIER-CURRENT. Coupling Capacitors for Carrier-Current Applications, T. A. E. Belt. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1051-1056, 8 figs. Approximate method for determining effectiveness of coupling wires and coupling capacitors.

ELECTRIC OSCILLATIONS. Electric Oscillations in the Double-Circuit Three-Phase Transmission Line, Y. Satoh. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 868-875 and (discussion) 875-876, 6 figs. Shows that there are three kinds of travelling waves, and describes nature of these waves, and some of important results of induced transients; in appendices, it is shown how these results were derived and how to calculate line constants from construction data of lines; numerical examples.

GROUND PROTECTION. Ground Relay Protection for Transmission Systems, B. M. Jones and G. B. Dodds. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1089-1094, 5 figs. Discusses different schemes for ground protection.

HIGH-VOLTAGE FEEDERS. Serving Large Power Blocks with 24-Kv. Feeders, W. H. Colburn. Elec. World, vol. 90, no. 17, Oct. 22, 1927, pp. 845-847, 4 figs. Limitations of 13.8-kv. system dictate use of higher voltage feeders; simplification of substation design and improved testing arrangements are achieved.

OPERATION. Recent Investigation of Transmission Line Operation, J. G. Hemstreet. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1221-1229, 8 figs. Operating experience on 140,000-volt isolated neutral system of Consumers Power Co., Michigan; tests to determine conditions existing relative to insulator flashover.

RELAY PROTECTION. Directional Ground Relay Protection of High-Tension Isolated Neutral Systems, J. V. Breisky, J. R. North and G. W. King. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1184-1192, 14 figs. Problem of obtaining selective relay protection in case of accidental grounds; relay was developed whose overcurrent element operates on residual charging current which exists when ground occurs on such system, and whose directional element is operated by residual charging current and residual voltage.

TOWERS. Transmission Tower Diagonal Bracing, C. R. Young, W. B. Dunbar and E. B. Allan. Can. Engr., vol. 53, no. 15, Oct. 11, 1927, pp. 441-444, 7 figs. Effective length of diagonal bracing struts; tests made in laboratory of University of Toronto; average slenderness ratio for struts supported in one direction 81.6 per cent of that for unsupported struts.

TRANSIENTS DUE TO SHORT CIRCUITS. Transients Due to Short Circuits, R. J. C. Wood, L. F. Hunt and S. C. Griscom. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 985-994, 22 figs. Study of tests made on Southern California Edison 220-kv. system.

ELECTRIC WELDING, ARC

CRANE CONSTRUCTION. Arc Welding Applied to Crane Construction. Elec. World, vol. 90, no. 19, Nov. 5, 1927, pp. 934-935. 10-ton, 60-ft. span electric overhead travelling crane, fabricated entirely by means of arc welding, has been constructed by Cleveland Crane & Eng. Co., Wickliffe, Ohio.

RAILWAY STRUCTURES. Arc Welding for Railway Structures, G. D. Fish. Ry. Club of Pittsburgh—Official Proc., vol. 26, no. 8, Sept. 22, 1927, pp. 186-206 and (discussion) 206-208, 16 figs. Author claims that steady replacement of rivet by electric arc is a great economic movement which cannot be checked by skepticism as to dependability of process; results can be definitely controlled, and failures are as definitely preventable as they are in other engineering operations.

ROLLED-STEEL FABRICATION BY. Rolled-Steel Fabrication by Welding Displaces Castings in Machine Construction, R. H. Rogers. Universal Engr., vol. 46, no. 4, Oct. 1927, pp. 27-29. Rolled-steel is stronger pound for pound; readily fabricated by metallic arc welding; greater freedom in machine design; quicker production; final product superior.

ELECTRIC WELDING, RESISTANCE

PERCUSSION. On Electric Resistance and Percussion Welding, T. Okamoto. Inst. Elec. Engrs. of Japan—Jl., no. 469, Aug. 1927, pp. 874-894, 24 figs. Solution of a differential equation expressing temperature at any time and distance along bar in butt welding is obtained; theory of percussion welding is developed; percussive welded joints of various metallic wires are drawn through dies several times and tested to show how they behave under this operation. (In Japanese.)

ELECTRICAL APPARATUS

PROTECTIVE DEVICES. Protective Devices. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 779-785, 12 figs. Annual report of committee as follows: development of automatic switching equipments in United States and Europe, by A. H. de Goede; subcommittee on lightning arresters; subcommittee on oil circuit breakers; subcommittee on protective relays; report of subcommittee on current and potential transformer characteristics, by H. M. Rankin. See also discussion in No. 10, Oct. 1927, pp. 1123-1124.

SHORT-CIRCUIT TESTS. Removing Errors from Short-Circuit Tests, C. L. Kasson. Elec. World, vol. 90, no. 18, Oct. 29, 1927, pp. 883-884, 2 figs. Miscalculations of energy and power values in many computations; oscillographic methods provide correct data.

ELECTRICAL MACHINERY

PROGRESS AND PROBLEMS. Annual Report of Committee on Electric Machinery. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1241-1262, 23 figs. Attempt has been made to include more important articles that have appeared in domestic and foreign journals in several bibliographies; deals with research, standards, ventilation, turbo-alternators, transformers, induction and synchronous motors; d.c. machines.

ELECTRICAL MEASUREMENT

HIGH-FREQUENCY. High-Frequency Measurements. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1033-1040. Report of committee on instruments and measurements. Bibliography.

HIGH-VOLTAGE. High-Voltage Measurements on Cables and Insulators, C. L. Kasson. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1065-1073, 31 figs. Results of series of high-voltage tests on cables and insulators, extending over period of eight years, determining electrical characteristics of insulation; leakage current, insulation resistance and watt input tests were made with direct and alternating current.

ELECTRICITY SUPPLY

DOMESTIC. The Use of Electricity in the Homes of Canada, S. L. Barnes. Elec. Rev., vol. 101, no. 2604, Oct. 21, 1927, pp. 665-666. Low charges accelerate rate of domestic development.

ONTARIO, RURAL. Canadian Electrical Development, F. A. Gaby. World Power, vol. 8, nos. 45 and 46, Sept. and Oct. 1927, pp. 145-152 and 203-210, 3 figs. Better legislation and government support during past five years has stimulated rural electrification in Ontario; present indications promise unprecedented development of service following extensions being made in main transmission and distribution lines; rural dwellers recognize electrification as blessing which is revolutionizing domestic and farm labour. Oct.: Methods used for rural electrification; tables illustrate estimated costs of power service in rural districts.

ELECTROPLATING

CHROMIUM. Electrodeposition of Chromium from Chromic Acid Baths, H. E. Haring and W. P. Barrows. U.S. Bur. Standards—Technologic Papers, no. 346, June 10, 1927, pp. 413-449, 9 figs. Study of chromic-acid plating solution and of conditions for its operation and control; three principal types of chromic-acid bath which have been developed during past 70 years are shown to be identical not only in initial behaviour, but also in ultimate composition; recent commercial success of chromium plating is attributed not to any changes effected in composition of bath, but to its more careful operation and control; it was found that minor improvements could be effected in throwing power of chromic-acid baths, but that there appears to be little possibility of improving this property which has hindered more general adoption of chromium plating.

ENERGY

THERMAL, FROM TROPICAL SEAS. The Utilization of Thermal Energy from Tropical Seas (L'utilisation de l'énergie thermique des mers tropicals). Génie Civil, vol. 91, no. 9, Aug. 27, 1927, pp. 215-216. Outline of new scheme by C. Boggia for subterranean power station utilizing thermal energy of tropical seas; project involves a 100,000-kw. plant capable of producing 800 million kw.-hr. per year; 70 boilers would be required.

F

FANS

CENTRIFUGAL. Characteristics of Centrifugal Fans, T. G. Estep and C. A. Carpenter. Engrs'. Soc. West Pa.—Proc., vol. 43, no. 6, July 1927, pp. 306-316 and (discussion) 317-332, 16 figs. Information based on tests and manufacturers' data to show existing relationships which limit performance of a fan or blower of any given design; effects of some simple variations in this design; different operating characteristics of more prevalent types of fan, and effects of incorrect applications of fans.

The Theory and Design of the Modern Centrifugal Fan, S. C. Martin. Nat. Engr., vol. 31, no. 11, Nov. 1927, pp. 513-519, 8 figs. Relations of velocity and pressure; volume and horse power; efficiencies; fan blades and casings; cut-off point; fan inlet; blast area; fans for mechanical draught.

FILTRATION PLANTS

Aerators. Effluent Aerators Control Mechanical Filters, M. Pirnie. Eng. News-Rec., vol. 99, no. 10, Sept. 8, 1927, pp. 376-380, 6 figs. Plants at Providence, West Palm Beach, Poughkeepsie and Rahway utilize head between filters and clear well.

FLIGHT

Test-Data Reduction Chart. The Reduction of Flight Test Data to Standard Atmosphere Conditions, J. D. Blyth. Flight, vol. 19, no. 43, Oct. 27, 1927, pp. 750b-750d, 2 figs. Presents reduction chart prepared with object of providing rapid and simple method of reducing data obtained on flight tests to conditions of standard atmosphere.

FLOOD CONTROL

Mississippi River. Civil Engineers Consider Mississippi Floods. Eng. News-Rec., vol. 99, no. 16, Oct. 20, 1927, pp. 636-640. Review of efforts to control Mississippi river; commission severely criticized; definite proposals for flood relief.

FLUE-GAS ANALYSIS

Combustion-Air and CO_2 Determination. Alignment Chart for Determining Minimum Combustion-Air and Maximum CO_2, C. A. Kulmann. Power, vol. 66, no 19, Nov. 8, 1927, pp. 710-711. Chart is based upon equation for amount of CO_2 in waste gases when minimum amount of air is supplied and composition of fuel is known.

FLUMES

Hydraulic Design. The Hydraulic Design of Flume and Siphon Transitions, J. Hinds. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1805-1841, 23 figs. Summary of rules established by U.S. Bur. of Reclamation for proportioning of important structures; although discussion is generally confined to inlets and outlets to and from inverted siphons and flumes, principles established may be applied to any structure designed to change shape or cross-sectional area of open stream of water.

FORESTRY

Drainage. The Marginal Ditch and Swamp Drainage for Forestry, A. E. Wackerman. Jl. of Forestry, vol. 25, no. 7, Nov. 1927, pp. 848-851, 1 fig. " Marginal ditch " usually surrounds northern swamps where they come in contact with upland, mineral soil; this ditch is depression in peat from 10 to 20 ft. wide at edge of swamp in which free water frequently stands and which supports distinct type of vegetation which thus rings swamp and isolates it from upland; drainage of forest swamps to be practical must be as cheap as possible and minimum amount of ditching necessary to bring about desired benefits is what is sought in forest ditching.

FOUNDATIONS

Science of. The Science of Foundations—Its Present and Future, C. Terzahi. Am. Soc. Civil Engrs.—Proc., vol. 53, no. 9, Nov. 1927, pp. 2263-2294, 16 figs. Reviews present state of science of foundations, its principal shortcomings and possibilities for its improvement; effect of type of building on admissible settlement; relation between settlement, size of loaded area and depth of foundation; distribution of soil reactions over rigid, loaded slabs; bearing capacity of individual piles; bearing capacity of a pile foundation; effect of freezing on foundations; soil classification based on elastic constants of soils.

FOUNDRIES

Automobile Plants. Foundry Effects Substantial Savings, C. H. Vivian. Automotive Mfr., vol. 69, no. 7, Oct. 1927, pp. 5-9. At shop of Campbell, Wyant & Cannon Foundry Co., Muskegon, Mich., most modern methods are utilized to produce 400 tons of motor castings daily; details of procedure in casting room.

French Automobile Foundry Employs Continuous System, V. Delport. Foundry, vol. 55, no. 19, Oct. 1, 1927, pp. 748-750 and 752, 6 figs. Details of continuous system of Citreon foundries at Clichy, France.

Future Design. An Engineer Visualizes Foundries of the Future, E. A. Custer, Jr. Foundry, vol. 55, nos. 20 and 21, Oct. 15 and Nov. 1, 1927, pp. 791-792 and 815 and 844-846. Oct. 15: Account of imaginary tour of plant where castings are made in manner radically different to methods which prevailed up to 1927; melting apparatus and control mechanism based upon modern ingenious theory. Nov. 1: Methods and equipment connected with handling sand, moulds and cores, theory and practice of pouring iron and cleaning castings.

Westinghouse Manufacturing Co., Hamilton, Ont. Foundry Methods in Westinghouse Plant, E. G. Brock. Can. Foundryman, vol. 18, no. 10, Oct. 1927, pp. 7-11, 6 figs. Up-to-date foundry equipment and efficient methods enable Hamilton ferrous and non-ferrous foundries to economically turn out castings varying from an ounce to many tons.

FRICTION

Contact of Flat Surfaces. Contact of Flat Surfaces, F. H. Rolt and H. Barrell. Rol. Soc.—Proc., vol. 116, no. 774, Oct. 1, 1927, pp. 401-425, 10 figs. Measurement of film thickness has been made by two methods; first, called area method, depends upon measurement of area attained by known volume of liquid placed between two flat surfaces which are wrung together and therefore gives average thickness of a wringing film; second, called interferometer method, is based upon comparison of length of wrung combination of block gauges with sum of their individual lengths.

FUELS

Coal. *See Coal; Pulverized Coal.*
Oil. *See Oil Fuel.*

FURNACES, INDUSTRIAL

Gas-Fired. Furnaces Burning Manufactured Gas, A. J. Smith. Forging—Stamping—Heat Treating, vol. 13, no. 10, Oct. 1927, pp. 403-404, 2 figs. Experiments on application of reversible regeneration as employed on gas-fired furnaces, give results showing high efficiency.

FURNACES, MELTING

Air Furnaces. Air-Furnace Practice, C. Kluijtmans. Foundry Trade Jl., vol. 36, nos. 576 and 577, Sept. 1 and 8, 1927, pp. 197-198 and 213-219, 25 figs. Results of experience with 15-ton hand-fired air furnaces; air furnace design; composition of charge, and melting practice; oxidation of constituents; influence of constituents on iron as cast; and on annealing; melting practice; temperatures, fractures and procedure; accidents.

G

GAS TURBINES

Heat-Regenerative Cycles. Heat Regeneration and Regenerative Cycles, W. J. Walker. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Science, vol. 4, no. 22, Sept. 1927, pp. 526-530, 2 figs. Investigates possibilities in heat-regenerative cycles, particularly in relation to internal-combustion turbine development; new type of regenerative cycle is proposed, analysis of which indicates independence of turbine thermal efficiency on compression ratio.

GEARS

Manufacture and Heat Treatment. The Manufacture and Heat Treatment of Gears, F. A. Brooks. West. Machy. World, vol. 18, no. 10, Oct. 1927, pp. 471-475, 3 figs. Gear-tooth stress; manufacture of case-hardened gears; characteristic failures due to overstrain; microstructure; fracture at root of tooth.

Progress and Problems. Standardization of Gear Hobs Next on A.G.M.A. Programme, P. M. Heldt. Automotive Industries, vol. 57, no. 18, Oct. 29, 1927, pp. 660-662, 2 figs. Project is inaugurated at meeting in Montreal; broadening of association's studies urged by President; review of technical paper presented.

Tooth-Rounding Machine. A New Automatic Gear Tooth Rounding Machine. Brit. Machine Tool Eng., vol. 4, no. 47, Sept.-Oct. 1927, pp. 653-655, 2 figs. Work is carried in special fixture on knee, and is indexed in front of cutter by means of special indexing arrangement, which provides for all sizes of gears having same pitch.

Worm. Worm Gear Inspection and Testing, G. H. Acker. Automotive Industries, vol. 57, no. 18, Oct. 29, 1927, pp. 662-663, 1 fig. Potential sources of error in worm gearing that must be guarded against by suitable inspection are: eccentricity and correct sizing of worm, index, head and profile of worm thread, angle of gear, eccentricity of gear and silence.

GRINDING

Cylindrical. Speeding Up the Grinding Operation, H. Rowland. Can. Machy., vol. 38, no. 17, Oct. 27, 1927, pp. 15-17, 4 figs. Presents illustrations dealing with cylindrical grinding and covering wide variety of grinding machines; standard machines are used in practically every instance, but in many cases these have been slightly changed in order to adapt them to particular operation on production basis.

H

HEAT

Ambient, Utilization of. Utilization of Ambient Heat as a Motive Force (L'utilisation de la chaleur ambiante comme force motrice au moyen de la machine frigorifique), E. Guarini. Houille Blanche, vol. 26, no. 206, May-June 1927, pp. 73-77. Report to Fifth International Refrigeration Congress, in which author proposes utilizing heat of atmosphere, oceans, etc., by means of refrigerating machines, in manner similar to the Dornig-Boggia and Romagnoli schemes.

Flow of. The Flow of Heat in a Body Generating Heat, J. H. Awberry. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Science, vol. 4, no. 22, Sept. 1927, pp. 629-638. Problem of temperature of all points and times, in sphere generating heat, is solved in detail, when constant initial temperature is given, surface being held at definite temperature from time-zero onwards, and also for more elaborate case where initial temperature distribution is an equilibrium one, and boundary condition is Newton's law of cooling.

HEAT TRANSMISSION

Cylinder Walls. The Transfer of Heat in Cylinder Walls, A. Nägel. Engineer, vol. 144, nos. 3744, 3745, 3746 and 3747, Oct. 14, 21, 28 and Nov. 4, 1927, pp. 420-421, 459-460, 480-482 and 506-507, 13 figs.

Insulating Materials. Effect of Moisture on the Heat Transmission in Insulating Materials, L. F. Miller. Refrig. Eng., vol. 14, no. 5, Nov. 1927, pp. 141-144, 7 figs. Experimental results on insulating value of wood, cane, flax and rag felt as it is influenced by degree of moisture.

Prandtl Theory. Heat Transmission Between Fluid and Wall (La transmissione del calore tra fluidi e pareti secondo la teoria moderna), A. Bernini. Nuovo Cimento, vol. 4, no. 5, May 1927, pp. 201-213, 2 figs.

HEATING, STEAM

Over-Heating, Reduction of. Control Steam to Reduce Over-Heating, C. A. Thinn. Power House, vol. 21, no. 18, Sept. 20, 1927, pp. 30-34, 4 figs. Differential vacuum system proves solution of endeavour to reduce great loss of heat in buildings due to over-heating in mild weather, bringing tangible savings in fuel consumption.

HYDRAULIC TURBINES

Relief-Valve Operation. Operation of Relief-Valves in Hydro-Electric Plants. Power, vol. 66, no. 20, Nov. 15, 1927, pp. 761-762. Two general types are in use for relief-action turbines, governor-operated type and type which operates due to pressure rise in penstock; size of relief-valves; closing time.

HYDRAULICS

Formulas and Theories. Comparison of Hydraulic Formulas and Theories. Mech. Eng., vol. 49, no. 11, Nov. 1927, pp. 1219-1227, 3 figs. Discussion of specific characteristics for hydraulic turbines, and comparison and limitations of various water-hammer theories.

Law of Similitude. Application of the Law of Similitude to Hydraulic Laboratory Research, G. De Thierry. U.S. Nat. Academy of Sciences—Proc., vol. 13, no. 9, Sept. 1927, pp. 684-688. While Froude began by applying laws of similitude to problems of naval architecture, Engels, of Tech. Univ. of Dresden, developed methods of research of constructions by hydraulic engineering; Krey, of Prussian Nat. Experimental Instn. for Hydraulic Eng. and Shipbldg., has extended Engels' investigations in applying methods of laboratory to special problem on the river Elbe; most valuable results obtained are his finding out, for special case he examined, relations between water and débris discharge.

HYDRO-ELECTRIC DEVELOPMENTS

Ontario. Hydro-Electric Progress in Ontario. Can. Engr., vol. 53, no. 16, Oct. 18, 1927, pp. 465-469. Annual report of Ontario Hydro-Electric Power Commission deals with progress in electrical development in province; extensions and improvements in various systems; extension of rural distribution systems.

Quebec. Development of Coaticook River, Que., E. E. Akhurst. Elec. News, vol. 36, no. 19, Oct. 1, 1927, pp. 27-30, 5 figs. Concrete-lined tunnel, 1,550 feet long, driven through rock under town delivers water to two 1,000-h.p. units with head of 143 feet.

HYDRO-ELECTRIC PLANTS

Automatic. Automatic Hydro Holds Lake Level. Elec. World, vol. 90, no. 19, Nov. 5, 1927, pp. 948-949, 2 figs. Electricity generated to carry investment charges on dam; energy sold on dump-power basis to Blue Ridge utility; resort expected to consume output ultimately.

Small. Small Water Powers, F. J. Taylor. Elecn., vol. 99, no. 2575, Oct. 7, 1927, pp. 432-433. Suggestions for economical development; plant under 1,000 h.p.; preliminary surveys of sites; choice of turbines.

South Africa. The Sabie River Hydro-Electric Power Station, A. M. Jacobs. S. African Engr., vol. 17, no. 112, Aug. 1927, pp. 3-11, 5 figs. Works comprise the dam and intake works; system for conveying water to power station, including three tunnels; two aqueducts with outdoor high-tension switchgear; 22,000-volt transmission line and telephone line; substation with outdoor high-tension switchgear at Sabie township; 2½ miles of 3,300-volt distribution line at Sabie, etc.

I

ICE FORMATION

Control. How Can Ice Formation Be Controlled? H. T. Barnes. Contract Rec., vol. 41, no. 43, Oct. 26, 1927, pp. 1085-1087. Methods by which ice jams can be relieved; cognizance must be taken of underlying causes of ice formation; jams successfully removed.

ICE PLANTS

Oil-Engine Drive. Efficiency in the Oil-Engine Driven Ice Plant, E. J. Kates. So. Power Jl., vol. 45, no. 10, Oct. 1927, p. 45. Points out that there is no reason why ice plant to be driven by oil engine cannot be made just as economical in its power requirement as that equipped with motor drive.

INDICATORS

Electric. Electrical Indicators for High Speed Internal Combustion Engines, J. Obata. Imperial Academy—Proc., vol. 3, no. 7, July 1927, pp. 426-429, 3 figs. Devised for purpose of serving for general uses in laboratories, they contain no mechanical part which exhibits appreciable friction or inertia, and they are entirely free from influence of natural vibration of any part of system, so that they are especially suited for high-speed engines, in which ordinary indicators fail to give correct diagrams.

INSULATING MATERIALS, ELECTRIC

Electrical Resistance. The Electrical Resistivity of Insulating Materials, H. L. Curtis. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1095-1103. Review of literature on conduction through insulators; every dielectric has definite resistivity when potential gradient is below certain value, different for each substance; if potential gradient is continually increased, a point is reached where increase in voltage does not affect current; this is called saturation current. Bibliography.

INSULATION, ELECTRIC

Puncture Voltage. A Precision Measurement of Puncture Voltage, V. Bush and P. H. Moon. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1007-1014 and (discussion) 1124-1127, 16 figs. Describes apparatus for automatic determination of dielectric strength of thin sheet insulation; machine makes about 1,000 breakdown tests in day; almost no attention is required, thus reducing human element to minimum; results of over 1,000,000 punctures are given.

INSULATION, HEAT

Thermal Constants, Measurement of. A Method for the Measurement of Thermal Constants of Heat Insulating Material, K. Kumabe. Soc. Mech. Engrs. of Japan—Jl., vol. 30, no. 125, Sept. 1927, pp. 395-399, 2 figs. On applying a sine-wave heating method for measurement of thermal constants of heat-insulating material, authors point out that pure sine thermal wave form on plane surface of sample is not necessary condition for application of this method, and only periodic wave is sufficient; they propose simple method on this principle for industrial purpose, and experiment result is given. (In English.)

INTERNAL COMBUSTION ENGINES

Efficiency of. The Ideal Efficiency of Internal Combustion Engines, W. T. David. Gas Jl., vol. 179, no. 3357, Sept. 21, 1927, pp. 695-696. Two suggestions are put forward in this paper—first, that ideal efficiencies of internal-combustion engines calculated upon basis of generally accepted specific heat and dissociation data are too low; and second, that ideal efficiencies increase with compression ratio at rate not only greater than that indicated by air standard, but also greater than that indicated by ideal efficiency calculations based upon usual specific heat data.

IRON AND STEEL

Bend Test. A Critical Study of the Bend Test as Applied to Iron and Steel, A. B. Kinzel. Am. Soc. Steel Treat.—Trans., vol. 12, no. 5, Nov. 1927, pp. 778-791 and (discussion) 791-793, 10 figs. Theoretical study of strains produced on bending a rectangular bar; from theory there is deduced a method for quantitative evaluation of a bend test; phenomena of inside crack is investigated and relation between tensile and bend elongation is discussed; specifications for routine quantitative bend testing.

IRON CASTINGS

Direct Metal for. How Ford Uses Direct Metal for Motor Castings, P. Dwyer. Iron Trade Rev., vol. 81, no. 12, Sept. 22, 1927, pp. 711-714, 8 figs.

IRON, PIG

Specifications. Propose Specification for Foundry Iron. Foundry, vol. 55, no. 21, Nov. 1, 1927, p. 846. Specification for foundry pig iron proposed by Federal Specifications Board.

L

LATHES

Turret. Heavy-Duty Turret Lathes. Iron Age, vol. 120, no. 19, Nov. 10, 1927, p. 1314. Rugged construction, intended to assure continued accuracy of entire machine, is among features of new Libby lathe which has been added to line of Int. Machine Tool Co., Indianapolis.

LIGHTING

Production and Application. Production and Application of Light. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1022-1029. Report of committee as follows: incandescent filament lamps; residence lighting equipment; ultra-violet radiation; street lighting; signal lights for traffic control; lighting of exteriors; electric signs for daylight use; illuminated bulletin boards; subterranean lighting; railway lighting; illumination of outdoor substations; related topics.

Progress. The Year's Progress in Illumination, 1926-1927. Illum. Eng. Soc.—Trans., vol. 22, no. 7, Sept. 1927, pp. 689-819. Review of developments, includes bibliography and index.

LOCOMOTIVES

Cylinder Losses. An Investigation Into the Cylinder Losses in a Compound Locomotive, E. L. Diamond. Instn. Mech. Engrs.—Proc., no. 2, 1927, pp. 465-479 and (discussion) 480-517, 10 figs. Investigation to ascertain what proportions of available energy of steam between boiler and atmospheric pressures are accounted for by various known sources of loss in engine, and to discover relationship between variation of these losses and conditions under which they occur.

4-8-4. New 4-8-4 Type Locomotives in Canada. Ry Engr., vol. 49, no. 573, Nov. 1927, pp. 422-424. Engines placed in service on Canadian National Railways system represent advance of 20 per cent in tractive power over those of "6000" class, which, at time of their introduction, were largest passenger locomotives in world.

High-Pressure. High-Pressure Steam Locomotives, J. M. Taggart. Boiler Maker, vol. 27, no. 10, Oct. 1927, pp. 278-281, 3 figs. Discusses type of power best suited economically to utilize pressures of 800 pounds and over; the boiler of the future locomotive.

Power Blow-Off. A Power Blow-Off for Locomotives. Ry. Age, vol. 83, no. 18, Oct. 29, 1927, pp. 838-839, 3 figs. Bird-Archer Co. introduces attachment for operating locomotive blow-off cocks by power; device has two parts: power attachment proper and cab-operating valves.

LUBRICATING OILS

Properties. Lubricating Oil from an Engineer's Point of View, with a Note on Fuel Oil, F. G. Martin. Liverpool Eng. Soc.—Trans., vol. 48, 1927, pp. 65-75 and (discussion) 76-81, 2 figs. Notes on properties of fuel and lubricating oils and results.

LUBRICATION

Surfaces Under High Loads. Lubrication. World Power, vol. 8, no. 46, Oct. 1927, pp. 184-185. Important outcome of investigations of National Physical Laboratory is fact that certain mineral oils will maintain themselves in film condition at temperatures in excess of limiting temperature of castor oil.

M

MALLEABLE CASTINGS

Cupola. Metal for Malleable Iron Fittings Melted in the Cupola, L. E. Gilmore. Foundry, vol. 55, no. 31, Nov. 1, 1927, pp. 840-843, 4 figs. Production of desired quality in cupola malleable requires careful control over details of cupola construction and daily preparation; blast used; quality and quantity of fuel; raw materials; mixtures; control of sands for moulds and cores; details of annealing operation and effect of temperatures, time and rate of cooling.

Properties. Malleable Cast Iron (La fonte malléable), M. Guedras. Fonderie Moderne, vol. 21, Mar. 25, Apr. 10, June 25 and July 10, 1927, pp. 30-32, 58-61, 185-190 and 210-213, 8 figs.

MARINE BOILERS

Pulverized Coal Fired. Pulverized Coal Tests of a Marine Water Tube Boiler, T. B. Stillman. Soc. Naval Architects & Mar. Engrs.—Advance Paper, no. 9 for mtg., Nov. 10-11, 1927, 12 pp., 12 plates. Babcock & Wilcox Co. has conducted series of experiments at its Bayonne plant using pulverized coal under marine boiler; gives results to date, and general statements of advantages and disadvantages of this method of firing coal as observed during these tests.

Test of Pulverized Coal as Applied to Scotch Marine Boilers, E. Jefferson and J. S. Evans. Soc. Naval Architects & Mar. Engrs.—Advance Paper, no. 8 for mtg., Nov. 10-11, 1927, 17 pp., 9 plates.

MATERIALS HANDLING

Brick Factories. Cutting Costs to Third by Improved Methods of Handling Materials, J. Stuber. Mfg. Industries, vol. 14, no. 5, Nov. 1927, pp. 357-360, 7 figs. Camp Bros'. modern brick and hollow-tile plant shows how big savings can be made.

Ford Organization. Organizing for Effective Transportation Within the Plant, H. J. Payne. Indus. Mgmt. (N.Y.), vol. 74, no. 4, Oct. 1927, pp. 212-217, 6 figs. Points out proper management is as essential in work of handling as in contact of other operations within plant; demand upon transportation equipment can only be made upon establishment of orderly, systematized flow of materials embracing needs of entire plant.

Tendencies. Tendencies in Material Handling, S. G. Koon. Iron Age, vol. 120, no. 19, Nov. 10, 1927, pp. 1293-1296, 2 figs. Combination of systems needed to fit most cases; increasing size of units; financial aspect.

METALS

Structure. Crystallization and the Structure of Metals and Alloys (La cristallisation et la structure des metaux et alliages), A. Portevin. Société Chimique de France—Bul., vol. 41, no. 8, Aug. 1927, pp. 961-987, 40 figs. Solidification structures of commercial and other alloys; number and size of crystals; structural effect of cold hammering and subsequent reheating.

METEOROLOGY

Weather Forecasting. Two Contrasting Examples Wherein Radio Reception Was Affected by a Meteorological Condition, E. H. Kincaid. Inst. Radio Engrs.—Proc., vol. 15, no. 10, Oct. 1927, pp. 843-868, 15 figs. Shows that static has sufficiently definite relationship to distribution of atmosphere as plotted on daily weather map to enable one by proper observations to make use of static in weather forecasting, and to make use of present knowledge of atmospheric distribution and movement in static forecasting; includes abstracts of papers on meteorological relations of atmospheres.

MINE TIMBERING

Preservation. How Should a Mine Preserve Its Timbers? H. B. Carpenter. Coal Mine Mgmt., vol. 6, no. 10, Oct. 1927, pp. 35-36, 1 fig. It has been well-established that creosote is unsuitable for mine work; use of pressure plants.

MOTOR BUSES

Maintenance and Desiggn. Bus Maintenance and Design, P. V. C. See. Ry. Age (Motor Transport Sec.), vol. 83, no. 17, Oct. 22, 1927, pp. 814-817. Unusual methods of large electric railway operator; improvements in construction proposed.

N

NICKEL

Annealing. Nickel and Monel Metal, with Especial Reference to Annealing, C. A. Crawford. Am. Inst. Min. & Met. Engrs.—Tech. Publication, no. 35, 1927, 21 pp., 4 figs. Chemical composition; physical and mechanical properties; working and fabricating of nickel and monel metal; annealing; includes appendix on details regarding different classes of commercial nickel and monel-metal products.

NUTS

Standard. Standard Bolt Heads and Nuts. Am. Mach., vol. 67, no. 19, Nov. 10, 1927, p. 747. Standards for bolt heads and nut sizes approved by Am. Eng. Standards Committee and intended to introduce national uniformity and to supersede all existing standards of bolt heads and nuts. Reference-book sheet.

O

OIL FUEL

Burners. Low Pressure Fuel Oil Burning Systems, H. L. Schultz. Indus. Mgmt. (N.Y.), vol. 74, no. 5, Nov. 1927, pp. 263-269, 6 figs. Practical suggestions for better efficiency; types of systems and their merits; fuel-oil specifications vs. system; location of pumps, blowers, etc.

OIL STORAGE

Lightning Protection. Lightning Protection for Oil Reservoirs, J. T. Lusignan, Jr. Elec. World, vol. 90, no. 16, Oct. 15, 1927, pp. 775-779, 3 figs. Views of leading authorities and experiments discussed to show existing theories of lightning and lightning protection: protective systems described.

OIL TANKS

LIGHTNING PROTECTION. Lightning Protection for Oil Storage Tanks and Reservoirs, R. W. Sorensen, J. H. Hamilton and C. Hayward. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 859-868, 15 figs. Work done in connection with planning protection scheme for oil-storage-tank farms of Gen. Petroleum Corp. of Cal. shows that average annual number of storms at given location is constant; dielectric property of oil has no influence in causing lightning or inducing it to strike oil in storage; tests show that excellent protection can be obtained by towers properly installed, but they do not indicate absolute immunity against hits. Bibliography.

OIL WELLS

DRILLING. Electricity in the Drilling of Oil Wells, L. J. Murphy. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 805-811, 10 figs. It is claimed that satisfied drillers, easy operation, low maintenance, low power bills, fewer shut downs, perfect motion, faster drilling, heavier pulling, no standby losses have contributed to make electricity the coming accepted standard by which all other forms of oil-well drilling will be judged.

OPEN-HEARTH FURNACES

MODERN TYPES. Modern Open-Hearth Furnaces (Les fours Martin modernes), J. Seigle. Technique Moderne, vol. 19, no. 20, Oct. 15, 1927, pp. 641-647, 12 figs. General review of recent practice in design and operation of open-hearth furnaces in France, Germany and America.

ORE DRESSING

GRINDING MEDIA. Theory and Practice in Selecting Grinding Media, H. Hardinge. Eng. & Min. Jl., vol. 124, no. 18, Oct. 29, 1927, pp. 695-698, 7 figs. Outlines factors that affect both theoretical and practical side of this question; weight per unit of volume.

OVERVOLTAGES

PROTECTION AGAINST. Protection from Overvoltage Due to Voltage Regulators, J. H. Ashbaugh. Elec. Jl., vol. 24, no. 11, Nov. 1927, pp. 551-553, 5 figs. Discusses methods available to prevent overvoltage; scheme is now available for protection of small stations whereby they can be assured of continuity of service without any hazard of overvoltage due to failure of regulator contacts.

OXY-ACETYLENE WELDING

AIRPLANE-FRAME MANUFACTURE. Fabricating Frames for Airplanes by Oxy-Acetylene Welding. Iron Trade Rev., vol. 81, no. 15, Oct. 13, 1927, pp. 903-904, 2 figs.

P

PIPE, CAST IRON

CENTRIFUGALLY CAST. Cast Iron Pipe Centrifugally Made Sand Moulds, J. T. MacKenzie. Am. Iron & Steel Inst.—Advance Paper for mtg., Oct. 28, 1927, 13 pp., 4 figs. Presents tabulation or results obtained by Professor Talbot on pit-cast and centrifugally sand-cast pipe. See also Iron Age, vol. 120, no. 19, Nov. 10, 1927, p. 1302.

PLATES

RECTANGULAR. An Optical Determination of Axial Stresses in Long Rectangular Plates Under Torsion, I. A. Balinkin. Phys. Rev., vol. 30, no. 4, Oct. 1927, pp. 520-526, 5 figs. New photometric method for measuring stress intensities was employed.

POLES, CONCRETE

TESTING. Testing Concrete Poles Under Load, F. G. Welsch. Can. Engr., vol. 53, no. 15, Oct. 11, 1927, pp. 451-453, 7 figs. Tests show that concrete poles can be designed for definite loads and with uniform results. Reprinted from Concrete Highways and Mun. Improvements.

POWER FACTOR

CORRECTION. Correcting Power Factor with Static Condensers Reduces Power Costs, J. E. Trostle. Power, vol. 66, no. 20, Nov. 15, 1927, pp. 736-739, 3 figs. By addition of static condenser to improve power factor, certain power companies and industrial plants have been able to carry their regular load with less equipment in operation, while others have made it possible to take on more load without purchasing additional generating equipment.

Power Factor Correction, Effective Power and Reactive Power, W. H. Feldmann. Iron & Steel Engr., vol. 4, no. 9, Sept. 1927, pp. 389-395, 3 figs. Disadvantages of poor power factor and savings to be effected when power is purchased and when it is generated; static and synchronous condensers, and synchronous motors.

DISTRIBUTION CIRCUITS. The Most Economical Power Factor, H. S. Litchfield. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 904-9.2, 4 figs. Practical design formula for distribution circuits.

POWER GENERATION

PROGRESS IN. Progress in Power Generation. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 916-933. Annual report of committee as follows: Steam turbine generator units; condensers; boilers, superheaters and economizers; stokers and furnaces; pulverized fuel; automatic combustion control; ultra-high-pressure steam turbine generator installations; mercury-vapour installation; hydro-electric development; power station auxiliaries; power production economies.

POWER TRANSMISSION

LUBRICATION. Lubrication of Power Transmission Equipment, A. F. Brewer. Indus. Engr., vol. 85, no. 10, Oct. 1927, pp. 471-476, 6 figs. Lubrication of anti-friction bearings, gears, chain drive, etc.

PULSATING LOADS. Methods of Handling Shock or Pulsating Loads. Indus. Engr., vol. 85, no. 10, Oct. 1927, pp. 477-480, 6 figs. Presents examples showing how interesting problems were solved in transmission of power when shock or pulsating loads were important factor to be considered.

PSYCHOLOGICAL TESTS

APTITUDE TESTS. Determination of Vocational Aptitudes, H. D. Kitson. Personnel Jl., vol. 6, no. 3, Oct. 1927, pp. 192-198. Author is critical of methods of validation which rely on correlations between test score and proficiency on job, without consideration of scores made by a comparable but vocationally unselected group.

PULVERIZED COAL

BOILER FIRING. Pulverized Fuel and Its Application to Boilers, R. B. Potter. Instn. Mech. Engrs.—Proc., no. 2, 1927, pp. 549-554. Summarizes advantages of pulverized fuel; discusses apparatus needed.

PUMPS, CENTRIFUGAL

AXIAL-FLOW. Low-Lift Axial-Flow and Centrifugal Pumps, H. R. Lupton and J. H. W. Gill. Engineering, vol. 124, nos. 3223 and 3224, Oct. 21 and 28, 1927, pp. 534-536 and 566-568, 13 figs. Investigation of relative incidence of losses in centrifugal and axial pumps are examined; determination of characteristics and losses in axial-flow and centrifugal pumps.

GUARANTEES. Determining Centrifugal Pump Guarantees, G. H. Gilson. Power House, vol. 21, no. 18, Sept. 20, 1927, pp. 23-24. Meaning of velocity head in centrifugal pump guarantees is explained and methods of making velocity head corrections outlined, where areas of suction and discharge nozzles differ.

THEORY. New Theory for the Centrifugal Pump, A. F. Sherzer. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1775-1803, 18 figs; and abstract in Power, vol. 66, no. 17, Oct. 25, 1927, pp. 645-646. Outlines programme of research and experiment on centrifugal pumps conducted in hydraulic laboratory of Univ. of Mich.; this study has resulted in (1) discovery of number of errors in present accepted theories; (2) development of entirely new theory; and (3) successful application of new theory in increasing the efficiency of centrifugal pump.

PYROMETERS

OPTICAL. Optical Pyrometer and Distance Thermometers. Engineering, vol. 124, no. 3224, Oct. 28, 1927, p. 550, 2 figs. Instruments made by Siemens Bros. & Co., Woolwich, England; portable pyrometer is of disappearing-filament type.

R

RADIOTELEGRAPHY

AERIAL SYSTEMS. Calculation of the Polar Curves of Extended Aerial Systems, E. Green. Experimental Wireless, vol. 4, no. 49, Oct. 1927, pp. 587-594, 9 figs. Case considered is that of a line of aerials, the adjacent ones separated by small fraction of a wavelength, and whole system extending in straight line several wavelengths long.

RAILS

SURFACE CRACKING. Surface Cracking of Rails in Service (La fissuration superficielle des rails en service Technique d'étude des rails fissurés), A. Portevin. Revue Générale des Chemins de Fer, vol. 46, no. 9, Sept. 1927, pp. 263-275, 19 figs. Chemical and physical tests for determining character of temper and cold rolling of rails with view of correlating with surface cracking of rails in service.

RAILWAY REPAIR SHOPS

LOCOMOTIVE. Steel-Frame Repair Shop for Locomotives, C. I. & L. Ry. Eng. News-Rec., vol. 99, no. 19, Nov. 10, 1927, pp. 759-761, 4 figs. Pit tracks served by 200-ton travelling crane and transfer table; heavy column design; transverse monitors.

RAILWAY SIGNALLING

COLOURED-LIGHT SIGNALS. Denver & Rio Grande Western Installs Its First Automatic Signals, B. W. Molis. Ry. Signalling, vol. 20, no. 11, Nov. 1927, pp. 415-417. Signal department organization established and 104 miles of single-track colour-light signals completed during first year.

RAILWAY TRACK

CURVE RESISTANCE. Freight Train Curve Resistance on a One-Degree Curve and a Three-Degree Curve, E. C. Schmidt. Am. Ry. Eng. Assn.—Bul., vol. 29, no. 298, Aug. 1927, pp. 1-30, 14 figs. Tests made with five freight trains; results relate exclusively to resistance of cars composing train and apply only to freight trains with four-wheeled trucks.

RECTIFIERS

MERCURY-ARC. Mercury-Arc Rectifier Characteristics, E. B. Shand. Elec. Jl., vol. 24, no. 10, Oct. 1927, pp. 486-493, 12 figs. Describes number of features adopted in a large rectifier which has recently been developed.

Automatic Switching Control for Mercury-Arc Rectifier, M. E. Reagan. Elec. Jl., vol. 24, no. 10, Oct. 1927, pp. 496-499, 2 figs. Shows that use of automatic switching has not greatly complicated handling of a rectifier substation.

Mercury-Arc Power Rectifiers, O. K. Marti and H. Winograd. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 818-826, 13 figs. Their applications and characteristics.

Papers on Mercury-Arc Rectifiers. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 10, Oct. 1927, pp. 1104-1105, 3 figs. Discussion of papers published in previous issues of Journal.

REFRACTORIES

MAGNESIA. Magnesia Refractories for Steel Furnaces, G. M. Currie and C. F. Pascoe. Can. Min. & Met. Bul., no. 186, Oct. 1927, pp. 1186-1272. Outlines occurrence of raw materials and indicates conditions under which finished product operates; nomenclature; uses; refractories available; applications; bibliography.

REFRIGERANTS

METHYL CHLORIDE. Certain Physical and Chemical Properties of Methyl Chloride, H. J. Macintire, C. S. Marvel and S. G. Ford. Refrig. Eng., vol. 14, no. 4, Oct. 1927, pp. 115-120 and 138, 2 figs. Summarizes facts about this refrigerant pertinent to present uses; physical and chemical properties.

REFRIGERATING MACHINES

AUTOMATIC. Hazards of Automatic Refrigerators, W. R. Rilling. Contract Rec., vol. 41, no. 42, Oct. 19, 1927, pp. 1068-1069. Possibilities of danger that should be considered by every architect and contractor responsible for specifying or installing electric or gas cooling devices.

MANUFACTURING COST. Manufacturing Cost, E. S. Schenck. Refrig. Eng., vol. 14, no. 5, Nov. 1927, pp. 139-140. Fundamentals apply to any variety of product, but special reference is given to refrigerating machinery.

REFRIGERATION

COMPRESSION AND ABSORPTION. Compression and Absorption Cycles Combined, M. Pohlmann. Refrig. Eng., vol. 14, no. 5, Nov. 1927, p. 162, 2 figs. Presents theoretical card for combined process and diagrammatic arrangement of possible combined cycle. Translated from Kälte-Industrie, Aug. 1927.

DOMESTIC. Household Refrigeration, C. C. Spreen and L. A. Philipp. Refrig. Eng., vol. 14, no. 5, Nov. 1927, pp. 145-149, 4 figs. Effect of compressor speed upon refrigerating capacity and efficiency in the case of small compressor.

REGULATORS

INDUCTION. Induction Regulators, N. D. Seaton. Eng. Jl., vol. 10, no. 11, Nov. 1927, pp. 481-486, 4 figs. Theory of induction regulators, special features of their design and construction, with note on their selection, operation and application.

RELAYS

PROTECTIVE. Ratio-Differential Relay Protection, H. P. Sleeper. Elec. World, vol. 90, no. 17, Oct. 22, 1927, pp. 827-831, 8 figs. By using relays that automatically exert reverse torque and raise pick-up on through faults, drawbacks of ordinary differential protection are avoided; characteristics and performance.

RIVERS

MISSISSIPPI. Work of Mississippi River Commission Outlined, C. W. Kutz. Eng. News-Rec., vol. 99, no. 17, Oct. 27, 1927, pp. 670-673. Reviews its history and limitations; studies for extensive flood-control programme based upon effects of 1927 flood.

ROAD CONSTRUCTION

Contract Control. Road Construction Contract Control, L. R. Ames. Can. Engr., vol. 53, no. 14, Oct. 4, 1927, pp. 159-260. Verbatim report of proceedings, tract control elevates standard of performance in contracting industry.

ROADS

Asphaltic Oil Surfaces. Light Asphaltic Oil Road Surfaces, C. L. McKesson and W. N. Frickstad. Pub. Roads, vol. 8, no. 7, Sept. 1927, pp. 125-158, 30 figs. Investigation to determine service value that may be expected of fine crushed rock and gravel surfaces to ascertain what methods might be employed to conserve material and increase serviceability by use of bituminous material; fine crushed rock and gravel roads; surface oiling of California state highways; bituminous treatment of crushed rock and gravel roads by surface mixing process; selection of method and oil for treatment; treatment of earth roads with oil.

Problems and Developments. Road Convention at Niagara Falls, Ont. Can. Engr., vol. 53, no. 14, Oct. 4, 1927, pp. 159-206. Verbatim report of proceedings, papers and discussions at fourteenth annual convention of Canadian Good Roads Assn., Niagara Falls, Ont.

ROADS, CONCRETE

Design. Design of Concrete Roads—Curing of Concrete, H. F. Clemmer. Boston Soc. Civ. Engrs.—Jl., vol. 14, no. 7, Sept. 1927, pp. 398-419 and (discussion) 419-423, 12 figs. Deals with actual factors affecting life and load-bearing qualities of pavement slab; fatigue of concrete, resistance to repeated stresses; use of centre longitudinal joint; internal stresses due to temperature and moisture changes; expansion joints; formula for design of cross section; curing of concrete; calcium chloride used integrally.

Sand Gravel as Aggregate. Sand Gravel as Total Aggregate for Concrete Roads, W. V. Buck. Eng. News-Rec., vol. 99, no. 19, Nov. 10, 1927, pp. 749-751, 4 figs. In many localities of Kansas, sand and sand-gravel deposits occur in abundance, both in stream beds and in banks or pits; method of utilizing fine aggregate deposits in concrete-road construction.

ROADS, EARTH

Corrugations. What Causes Corrugations in Traffic-Bound Roads, J. P. McMarin. Eng. News-Rec., vol. 99, no. 10, Sept. 8, 1927, pp. 384-386, 2 figs. Rain water and wind action start chatter bumps which motor vehicle traffic develops into a nuisance.

Sand-Clay and. Sand-Clay and Earth Roads, H. R. Mackenzie. Contract Rec., vol. 41, no. 42, Oct. 19, 1927, pp. 1069-1070. Two types that comprise greater part of Saskatchewan's highway system; methods used in that province to build and maintain these roads; cost data.

Alberta's Sand-Clay and Earth Roads, C. A. Davidson. Contract Rec., vol. 41, no. 43, Oct. 26, 1927, pp. 1089-1090. Procedure followed in connection with building 2,500-mi. main highway system; features of design, quantities and cost; sand-clay specification.

ROADS, GRAVEL

Asphaltic-Oil. Surface-Mixed Oiled-Gravel Road on Wyoming Plains, C. H. Bowman. Eng. News-Rec., vol. 99, no. 18, Nov. 3, 1927, pp. 703-704. New type of asphaltic-oil road construction for fine crushed surfaces; working force, plant and cost itemized.

Nova Scotia. Nova Scotia's Experience with Gravel Roads, R. W. McColough. Contract Rec., vol. 41, no. 42, Oct. 19, 1927, pp. 1071-1073. 5,000 miles of highway system surfaced with gravel; methods which are used by Nova Scotia Department of Highways to maintain these roads in good condition.

ROLLING MILLS

Bar Mills. Bar Mill Designed Essentially for Alloy Steel Sections. Iron Trade Rev., vol. 81, no. 11, Sept. 15, 1927, pp. 662-666, 4 figs. Barpiling device at hot bed retards cooling of material and permits stack annealing.

Bearing Pressures. Measuring Pressures on Bearings of Rolling Machinery. P. H. Frank. Iron Trade Rev., vol. 81, no. 16, Oct. 20, 1927, pp. 965-967, 3 figs. Two methods have been developed to determine loads which anti-friction bearings must withstand.

Electric Drive. Electric Drive for the Reversing Mill at Margam Works. Iron & Coal Trades Rev., vol. 125, no. 3111, Oct. 14, 1927, pp. 563-564, 5 figs. Equipment consists essentially of 8,000 18,000-h.p. d.c. motor driving mill; Ward-Leonard motor-generator set for control of mill motor; exciter set; high- and low-tension switchboards; switchgear for operation platform, and automatic slip regulator for a.c. motor of Ward-Leonard set.

Recent Developments in Electric Drives for Rolling Mills, L. A. Umansky. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 885-892, 12 figs. Electric drives, of capacities larger than encountered elsewhere, are usually designed to fit individual cases; special machines or special combinations of them are frequently used; several representative cases are outlined and methods of solving encountered problems are analyzed.

Four-High. Developments in Four-High Rolling, F. C. Biggert, Jr. Iron Age, vol. 120, no. 20, Nov. 17, 1927, pp. 1367-1370. Mill and roll design matured rapidly; roller bearings large factor; high tonnage output. Paper read before Iron & Steel Division of Am. Soc. Mech. Engrs.

Refractories for. Refractories and Four-High Mills. Iron Age, vol. 120, no. 20, Nov. 17, 1927, pp. 1370-1371. Review of papers read before iron and steel division of Am. Soc. Mech. Engrs.

Soaking Pits. Soaking Pit Operates on Recuperative Principle. Iron Trade Rev., vol. 81, no. 9, Sept. 1, 1927, p. 501. Because of success of this type pit in France, trial installation was made at Donner Steel Co., Buffalo; it was designed and built by Chapman-Stein Furnace Co.

Wire and Rod. Study of Wire-Rod Rolling Mills (Etude sur les trains à fils), E. Richarme. Revue de Métallurgie, vol. 24, nos. 4, 5, 6 and 7, Apr., May, June and July, 1927, pp. 161-178, 255-277, 307-316 and 405-407, 3 figs.

S

SEWAGE DISPOSAL

Pumping Station. Wellpoint Method for Handling Excavation of Foundation Pit at New Sewage Pumping Station, Lynn, Massachusetts, C. Terzaghi. Boston Soc. Civ. Engrs.—Jl., vol. 14, no. 7, Sept. 1927, pp. 389-397, 3 figs. In spring of 1927 rather delicate piece of excavation work was performed for foundation of new pumping station; work included an open excavation, 30 ft. deep, through quicksand, at short distance from both seacoast and incinerator plant with shallow foundation; by using wellpoints for lowering ground-water level contractor succeeded in keeping quicksand almost perfectly undisturbed; description of work and brief review of difference between American and European method of handling similar construction problems.

SHEARS

Combined Punching and Shearing. Cleveland No. 2 Combination Punching and Shearing Machine. Am. Mach., vol. 67, no. 19, Nov. 10, 1927, p. 751, 2 figs. Punching, notching, shearing and splitting can be performed on this machine; attachment is also supplied for twisting bars.

Continuous Automatic. Machine Trim Sheets Automatically. Iron Trade Rev., vol. 81, no. 17, Oct. 27, 1927, p. 1031, 1 fig. Substantial reduction in labour cost and increased production are made possible in sheet and tin plate mills by means of continuous, automatic shearing machine placed on market by Streine Tool & Mfg. Co., New Bremen, Ohio. See also Iron Age, vol. 120, no. 117, Oct. 27, 1927, pp. 1160-1161, 3 figs.

SIGNALLING

Traffic Control Lights. Traffic Control by Electric Signal Lights, M. O. Eldridge. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1989-1994, 3 figs. One of more difficult traffic centres of Washington, D.C., is Scott Circle; situation is complicated because it is intersection of six streets (three directions), the main traffic being north and south in Sixteenth street; there is a considerable rotary as well as through movement, but signal lights have fairly well succeeded in solving difficulties; essential features of this plan are division of circular street with inner zone for through north and south traffic and outer zone for rotary traffic; and treatment of both diagonal avenue simultaneously as cross streets.

SMOKE

Abatement. Organizing a Smoke-Abatement Campaign, E. Ormsby. Mech. Eng., vol. 49, no. 11, Nov. 1927, pp. 1216-1218. Technical division of city's engineers first essential in smoke-abatement campaign; major activities of technical division; research-publicity work; smoke surveys; educational work; conduct of campaign; appalling monetary loss caused by smoke.

Some Hints on Securing Smokeless Combustion with Bituminous Coal, T. E. Landvoigt. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 33, no. 10, Oct. 1927, pp. 607-611. If suitable equipment is used, and intelligently operated, smoke is unnecessary; if well-known principles of combustion are applied in practice, satisfactory results are readily obtainable with bituminous coal; three things necessary for complete combustion are air properly introduced and controlled, a suitable temperature, and a properly proportioned combustion chamber.

SPRINGS

Steel, Corrosion of. Protection of Steel Springs Against Corrosion. Mech. World, vol. 82, no. 2127, Oct. 7, 1927, p. 269. Discusses various methods for protecting springs, including: (1) painting; (2) oil finishing; (3) coating by molten metal, chiefly by tin; (4) electroplating; (5) non-metallic coating produced by boiling in special chemical solution often sold under trade name.

STEAM ACCUMULATORS

Application. Application of Steam Accumulators, G. Keeth. Chem. & Met. Eng., vol. 34, no. 9, Sept. 1927, pp. 560-561, 2 figs. Writer's impression and observations on application of accumulators to industrial power plants.

Ruths. Ruths Accumulator in the Paper Industry. Paper Trade Jl., vol. 85, no. 17, Oct. 27, 1927, pp. 74-76, 5 figs. Far-reaching effect of accumulator upon operation of pulp and paper mill shown to good advantage at new plant of Price Bros. & Co., Ltd., at River Bend; other installations in United States and Canada.

STEAM ENGINES

Extractions. Extraction Engines. Power Engr., vol. 22, no. 260, Nov. 1927, pp. 412-414, 5 figs. Describes control systems in use in connection with extraction engines, with references to economies obtainable by engines of this type.

Single-Cylinder Extraction Engine. Engineering, vol. 124, no. 3224, Oct. 28, 1927, p. 550, 6 figs. on p. 554. Engine designed to meet wide variation in conditions; made by Maschinenbau, A.G., Silesia.

STEAM GENERATION

Submerged Combustion. Steam Generation—Submerged Combustion, N. Swindin. World Power, vol. 8, nos. 45 and 46, Sept. and Oct. 1927, pp. 128-132 and 189-196, 14 figs. Submerged combustion is inversion of present-day practice in steam generation and evaporation; history and development of burners in which fuels can be consumed in contact with water and other liquid. Oct.: Brunler and Hammond systems; influence of law of partial pressure on temperature and pressure of mixture of steam and gas; behaviour of steam-gas mixture when expanding in steam-engine cylinder; thermodynamics; difficulties in adapting submerged combustion boiler to steam power.

STEAM METERS

Control. Steam Metering and Control, H. M. Hammond. Chem. & Met. Eng., vol. 24, no. 9, Sept. 1927, pp. 569-571, 5 figs. Meters recording steam flow and air flow should be installed on each boiler not only to show distribution of load on boiler, but to guide firemen in controlling rate of fuel feed, air supply, etc., to generate required amount of steam most efficiently.

STEAM PIPES

Developments. Modern Developments in the Steam Piping Field, A. B. Williams and C. W. Welch. Chem. & Met. Eng., vol. 34, no. 9, Sept. 1927, pp. 547-550, 4 figs. Design of high-pressure plants; flow diagram; standards for fittings and pipe flanges; materials.

STEAM POWER PLANTS

Combined Power and Process. Balancing Process Steam and Power in a Coated-Fabric Plant, L. C. Cooley. Chem. & Met. Eng., vol. 34, no. 9, Sept. 1927, pp. 551-553, 3 figs. Story of production and use of steam for process and power; unique arrangement developed and applied to control of steam and power generation.

Turbine Loading Schedules. Large Economies Result from Using Steam-Turbine Loading Schedules, A. R. Haynes. Power, vol. 66, no. 13, Sept. 27, 1927, pp. 462-465, 5 figs. Study of operating schedule built up from water rates of units; typical case of station with four units is assumed, and operating data plotted to show characteristics of units and most efficient combination of loads.

STEAM TURBINES

By-Product Power from. By-Product Power from Steam Turbines, C. B. Campbell. Chem. & Met. Eng., vol. 34, no. 9, Sept. 1927, pp. 554-559, 10 figs. Most of larger process industries can develop their own power at favorable unit cost by taking advantage of possibility of co-ordinating generation of steam for power and process.

Extraction. The Field and Limitations of Extraction Turbines, C. B. Campbell. Elec. Jl., vol. 24, no. 11, Nov. 1927, pp. 553-556, 2 figs.

Loading. Efficient Loading of Steam Turbines, A. R. Haynes. Power, vol. 66, no. 20, Nov. 15, 1927, pp. 730-732, 1 fig. Minimum water-rate curves; total steam and water rates for different combinations of units; when auxiliary valve may be opened.

Small. Small Steam Turbines, G. A. Orrok. Engrs'. Soc. of West Pa.—Proc., vol. 43, no. 6, July 1927, pp. 267-272 and (discussion) 273-278, 4 figs. Author claims that small turbine is most advantageous; it is light and occupies very small space; rugged in construction and automatic in operation; economical in use of steam in proportion to price paid for it; requires little attention, and uses little oil; maintains its economies over a series of years.

The Small Steam-Turbine Unit for Industrial Requirements, G. Arrowsmith. Instn. Mech. Engrs.—Proc., no. 2, 1927, pp. 555-566, 1 fig.

STEEL

ALLOYS. *See Alloy Steels.*

ETCH TESTS. Deep Etch Test for Iron and Steel, H. G. Keshian. Am. Soc. Steel Treat.—Trans., vol. 12, no. 5, Nov. 1927, pp. 689-727 and (discussion) 727-736, 30 figs. Describes types of structure revealed by method; factors influencing results, such as method of melting, chemical composition, reduction of area, heat treatment, direction of fibre in steel, etc.; points out value and limitations of method based on relation of various etch structures to performance of steel in service as observed by author.

HIGH TEMPERATURES, EFFECT OF. The Properties of Steel at High Super-Heat Temperatures, A. McCance. Liverpool Eng. Soc.—Trans., vol. 48, 1927, pp. 205-224 and (discussion) 225-240, 11 figs. Examination of temperature-strength curves for various steels; secondary effects of prolonged high temperature.

PROPERTIES. On the Properties of Steels, J. E. Howard. Am. Soc. Steel Treat.—Trans., vol. 12, no. 4, Oct. 1927, pp. 622-629 and 650. Discusses various physical properties of steel and their behaviour under different conditions; some of points discussed are Poisson's ratio, Hooke's law, elastic limit, elongation and contraction of area, modulus of elasticity, coefficients of expansion.

The Relations Between the Properties of Materials and Their Structure, A. Pomp. Eng. Progress, vol. 8, no. 10, Oct. 1927, pp. 263-264, 2 figs. Points out that nature of structure is of great moment as regards machining of steel with cutting tools; original structure of steel is also of decisive importance for results obtained in hardening; influence of cementite structure on result of hardening; favorable results achieved with tempering.

COMPRESSION AND BREAKING ENERGY. Influence of Compression Upon the Breaking Energy of Steel (Influence de la compression sur la fragilité de l'acier—existence d'une limite de fragilité), P. Dejean and H. Le Chatelier. Académie des Sciences—Comptes Rendus, vol. 184, no. 4, Jan. 24, 1927, pp. 188-189. See brief translated abstract in Mech. World, vol. 82, no. 2128, Oct. 14, 1927, p. 295.

STEEL, HEAT TREATMENT OF

AUTOMOBILE PARTS. Heat Treating 20,000 Hubs and Piston Pins Daily, S. Thompson. Iron Trade Rev., vol. 81, no. 19, Nov. 10, 1927, pp. 1160-1161, 3 figs. Details of heat treating department of Defiance Screw Machine Products Co.

DEFINITIONS AND FUNCTIONS. Some Facts About Heat Treatments, S. Dunn. Ry. Mech. Engr., vol. 101, no. 11, Nov. 1927, pp. 745-747. Definition; difference between iron and steel; function of heat treating; heat treating billets for forging, and in blacksmith shop; heating steel to critical temperatures; importance of accurate heat treatment.

DESIGN PROBLEMS. Design from the Heat Treating Standpoint, G. M. Eaton. Am. Soc. Steel Treat.—Trans., vol. 12, no. 5, Nov. 1927, pp. 794-811 and (discussion) 811-813, 7 figs. Author stresses need for closer co-operation between metallurgist and mechanical engineer; gives some typical problems still unsolved because of lack of union; freight car bolster spring is discussed, and suggestions offered for possible elimination of it.

ELECTRIC. Benefits Obtained from Electric Heat Treatment. Elec. World, vol. 90, no. 19, Nov. 5, 1927, pp. 927-934. Annealing, carburizing, hardening and drawing in automatic electric furnaces speed-up production in Detroit automobile plants; heat-treating costs reduced and quality improved.

RAILWAY-SHOP TOOLS. Heat Treating Methods and Equipment Recommended for Railroad Shops. Ry. Jl., vol. 33, no. 10, Oct. 1927, pp. 21-23. Report of Committee on Am. Ry. Tool Foremen's Assn. on handling of railway repair tools requiring heat treatment; manufacture of and repairs to chisels, caulking tools, etc., high-speed machine tools, and reamers, taps, rivet sets, etc.

RATE OF HEATING. Heat Treatment and Metallography of Steel, H. C. Knerr. Forging—Stamping—Heat Treating, vol. 13, no. 10, Oct. 1927, pp. 420-422, 5 figs. Rate of heating.

THEORY. The Constitution of Steel and Cast Iron, F. T. Sisco. Am. Soc. Steel Treat. Trans., vol. 12, no. 4, Oct. 1927, pp. 651-666, 10 figs. Study of theory of heat treatment; review of constitution of steel and cast iron from standpoint of stable equilibrium; solid solution of carbon in gamma iron, or austenite; discussion of grain growth of austenite above critical range.

STEEL, HIGH-SPEED

TESTS. Comparisons of Impact and Slow Bend Tests of High Speed Steel, R. K. Barry. Am. Soc. Steel Treat.—Trans., vol. 12, no. 4, Oct. 1927, pp. 630-634, 1 fig.

STEEL WORKS

ENGLAND. The Works of William Beardmore & Co., Limited, Mossend Steel Works. Foundry Trade Jl., vol. 37, no. 584, Oct. 27, 1927, pp. 61-62, 3 figs. Details of melting shop; section mills, cogging mill, bail-finishing plant; power station; plate mill; shearing plant, etc.

POWER APPLICATION. Power Application in Steel Plant. Elec. World, vol. 90, no. 18, Oct. 29, 1927, pp. 877-882, 9 figs. New merchant mills in Gary works of the Illinois Steel Co. exemplify modern practice; highly developed methods speed production and improve quality of product.

STREET RAILWAYS

CARS, ONE-MAN. London, Ont., Cars Converted to One-Man Safety Operation, L. Tait. Elec. Ry. Jl., vol. 70, no. 13, Sept. 24, 1927, pp. 557-559. Two-man, single-truck cars converted to safety type, with double doors in front and treadle exit door in rear.

STRESSES

FILLETS AND HOLES, PRODUCED BY. Stress Concentration Produced by Fillets and Holes, S. Timoshenko. Int. Congress for Applied Mechanics—Proc., 1926, pp. 13-20, 13 figs. Study can be carried out either by analysis, photoelasticity, Lüders' lines or by fatigue test; all these methods are discussed.

SUBSTATIONS

AUTOMATIC. A 21,000-Kva. Automatic Substation, D. W. Ellyson. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 802-804 and (discussion) 832-834, 4 figs. Summary of apparatus and control equipment, general scheme of operation, together with floor plans of building, one-line diagrams illustrating operation, and view of portion of single-phase regulator equipment; shows total kva. capacity of apparatus that is automatically controlled.

SUPERHEATED STEAM

INDUSTRIAL APPLICATIONS. Application of Superheated Steam in Industrial Processes, F. G. Page. Chem. & Met. Eng., vol. 24, no. 9, Sept. 1927, pp. 575-576, 2 figs. Specific results are cited which constitute example of how superheat may be important factor in process work.

SURVEYING

BOUNDARY. Boundary Surveys, C. T. Johnston. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 2013-2020. Cadastral surveys; political and riparian boundaries

SWITCHBOARD

PANEL MATERIAL FOR. Panel Material for Switchboards, E. G. Bern. Gen. Elec. Rev., vol. 30, no. 11, Nov. 1927, pp. 541-543, 3 figs. Marble used chiefly for architectural effect; slate is better adapted to service requirements; synthetic material for panels; metal panels; panel beveling.

T

TELEPHONY

AUTOMATIC. Automatic Telephony, G. W. Stubbings. World Power, vol. 8, no. 46, Oct. 1927, pp. 197-199, 2 figs. After brief account of rudimentary automatic exchange, author describes problems which arise in application of automatic principle to groups of exchanges in large cities; differences between "controller" and "director" systems; statistics regarding relative operation costs of manual and automatic exchanges.

TEXTILE MACHINERY

ELECTRIC DRIVE. Applying Electric Drives to Textile Finishing Machines Where Speed Adjustment is Required, W. H. Tate. Textile World, vol. 72, no. 16, Oct. 15, 1927, pp. 43-47, 4 figs. Machines may be operated as single units or in tandem; five driving systems available.

TEXTILES

RESEARCH. Résumé of the Year's Textile Research at the Bureau of Standards, C. W. Schoffstall. Textile World, vol. 72, no. 19, Nov. 5, 1927, pp. 103-107, 3 figs. Work extended into new fields. Publication approved by Directors of Bur. of Standards.

TRAFFIC

CONTROL. Traffic Control in New York, N.Y., P. D. Hoyt. Am. Soc. Civil Engrs. —Proc., part 1, Oct. 1927, pp. 1995-2001. Complexities of problem are increased not merely in proportion to its great population but also because of many other factors, some of them peculiar to city; widening of highways and elevated roadways have been recognized as essential to future needs of city.

TRANSFORMERS

BANKS, INSTABILITY. Instability in Transformer Banks, K. E. Gould. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1160-1166, 15 figs. Considers instability which sometimes occurs in banks of transformers supplying capacity load when certain harmonics in primary current are suppressed, either by type of transformer connections or by resonant circuit in series with primary of transformer, and similarity between several unstable circuits is pointed out.

COOLING. Auxiliary Cooling for Transformer Units, W. R. Farley. Elec. World, vol. 90, no. 18, Oct. 29, 1927, p. 885, 1 fig. Temperature controllers operate apparatus for protection of one or more transformers subject to heavy overloads.

EXCITING CURRENT. Reduction of Transformer Exciting Current to Sine-Wave Basis, G. Camilli. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 9, Sept. 1927, pp. 892-896, 7 figs. Describes two methods developed for reduction of exciting current to sine-wave basis.

LOAD-RATIO CONTROL. Application and Design of Load Ratio-Control Equipment, A. Palme. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1202-1206 and (discussion) 1269-1273, 9 figs. Gives various possible applications and details of electrical and mechanical design of apparatus.

RADIO-FREQUENCY. Radio-Frequency Transformers, N. W. McLachlan. Experimental Wireless, vol. 4, no. 49, Oct. 1927, pp. 597-600, 4 figs. Their application to screened valves.

REPAIR VS. REPLACEMENT. Repair vs. Replacement of Old Transformers, M. D. Smith. Power, vol. 66, no. 15, Oct. 11, 1927, pp. 552-554, 8 figs. Method for determining which is more economical, to repair an old transformer that has failed or replace it with new one.

TAP CHANGING. Transformer Tap Changing Under Load, L. H. Hill. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 11, Nov. 1927, pp. 1214-1221 and (discussion) 1269-1273, 12 figs. Methods of changing taps under load; equipment for obtaining smooth curve voltage control; combination voltage and phase-angle control.

MECHANICAL FORCES. Mechanical Forces in Transformers, J. E. Clem. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 8, Aug. 1927, pp. 814-817, 8 figs. Method of calculating mechanical forces based on mutual reactance between coils, formula for mutual inductance between coaxial solenoids is developed and from this expression formula for mechanical force between concentric cylindrical transformer coils is derived. See discussion in no. 9, Sept. 1927, pp. 961-963, 1 fig.

TUNNELING

STREET RAILWAY TUNNELS. Tunneling Under San Francisco's Hills, C. W. Geiger. Explosives Engr., vol. 5, no. 11, Nov. 1927, p. 429. Construction methods employed on 4,232-ft. street railway tunnel now being constructed.

TUNNELS

RAILWAY. Cascade Tunnel Commission Favours Route Near Great Northern, F. W. Harris. Eng. News-Rec., vol. 99, no. 18, Nov. 3, 1927, p. 715. Construction of twin railroad tunnels 29 miles long under Cascade mountains to provide low level route for both highway and railway traffic between eastern and western parts of state of Washington has been recommended by Cascade Tunnel Commission in its report to 1927 legislature.

V

VIADUCTS

CONCRETE AND STEEL. East York-Leaside Bridge, Toronto, W. Snaith. Can. Engr., vol. 53, no. 17, Oct. 25, 1927, pp. 483-486. Long concrete and steel viaduct crossing Don Valley; steel superstructure erected by cantilever method; tall concrete piers built during winter and protected against frost. See also Contract Rec., vol. 41, no. 43, Oct. 26, 1927, pp. 1080-1081, 4 figs.

W

WAREHOUSES

TERMINAL. New Terminal Warehouse at Montreal, J. J. Shea. Can. Engr., vol. 53, no. 16, Oct. 18, 1927, pp. 457-461. Large warehouse with facilities for dry and cold storage erected adjacent to Place Viger yards; entire building of reinforced-concrete construction with slab-type floors; bulk of concrete was poured in winter.

WATER POWER

APPRAISALS. Water Power Appraisals, W. H. Cushman. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1843-1850. Calls attention to lack of uniformity in methods now used in appraising water power property; attempt is made to outline a logical method of procedure that will eliminate several factors which, under some of current methods, are difficult to determine, or which lead to erroneous conclusions.

WATER SUPPLY

SURFACE, CANADA. Surface Water Supply of Canada. Can. Dept. Interior—Water Resources Paper, no. 52, 1927, 91 pp. Atlantic drainage (south of St. Lawrence river), New Brunswick, Nova Scotia, Prince Edward Island, climatic years 1924-25 and 1925-26.

WATER TREATMENT

CARBON DIOXIDE. Carbon Dioxide Treatment at St. Louis Water Works, A. V. Graf. Eng. News-Rec., vol. 99, no. 16, Oct. 20, 1927, p. 643. Each carbon dioxide plant will consist of gas producer burning coke; combined washer, scrubber and drier; gas burner, compressor or blower, and necessary gauges for control of operation.

COLOUR REMOVAL. Notes on Colour Removal from Water, R. S. Weston. Can. Engr., vol. 53, no. 17, Oct. 25, 1927, pp. 479-482. Results of observations on treatment of soft coloured waters; various methods of colour removal employed. Paper presented at Am. Water Wks. Assn.

WATERWAYS

ENGINEERING PROGRESS. Advances in Waterways Engineering During a Half Century, W. M. Black. Am. Soc. Civil Engrs.—Proc., part 1, Oct. 1927, pp. 1937-1959, 8 figs. Shows some of progress made in waterways engineering in United States.

WATT-HOUR METERS

ARRESTER PROTECTION FOR. Arrester Protection for Watt-Hour Meters, C. J. Fuhrmann. Elec. World, vol. 90, no. 17, Oct. 22, 1927, pp. 831-832, 1 fig. Points out that watt-hour meter failures caused by electrical storms can be materially decreased by installation of secondary lightning arresters of proper voltage rating at properly chosen locations on 3-phase power secondary circuits.

WIND POWER

MOTORS. Wind Motors (Fonctionnement des roues coliennes), F. Verdeaux. Revue Générale des Sciences, vol. 38, no. 19, Oct. 15, 1927, pp. 541-548, 7 figs. Mathematical theory of air motors and windmills with horizontal axis, their maximum and average mechanical efficiency, methods of operation, energy losses, etc.

WIRE DRAWING

PROFILE AND SHAPED WIRE. The Drawing of Profile and Shaped Wire, J. D. Brunton. Wire, vol. 2, no. 11, Nov. 1927, pp. 379-382, 10 figs. It has been found that a straight carbon steel, when properly treated and subsequently cold worked to correct degree, compares very favorably in physical properties with a heat-treated alloy steel, and fulfills entirely requirements specified for a certain purpose; for mass production there is undoubted saving in getting profiles drawn.

WOOD PRESERVATION

PAINT TESTS. Some New Paint Tests on Wood in Florida and in Washington, H. A. Gardner. Am. Paint & Varnish Mfrs'. Assn.—Scientific Section, no. 315, Aug. 1927, pp. 439-446. Discussion of paints with raw linseed oil or small percentages of heavy bodied oils as bases; observations on exposure tests in Washington and Florida on varnish and bodied oil paints; lacquer tests; formulas used in tests, etc.

WOODWORKING PLANTS

DRY KILNS. Improving Conditions in Drykiln Equipment, E. F. Werner. Wood-Worker, vol. 46, no. 8, Oct. 1927, pp. 41-42. Heart of woodworking factory is the drykiln; life of lumber, percentage of cutting value, returns on money invested, all depend upon condition of lumber as it comes from the kiln.

MATERIALS HANDLING. Receiving and Handling Lumber at the Plant. Wood-Worker, vol. 46, no. 8, Oct. 1927, pp. 44-45, 4 figs. How costs of receiving, moving and storing factory lumber have been reduced through use of various types of mechanical equipment.

Z

ZINC

WROUGHT. Wrought Zinc, C. S. Trewin. Am. Inst. Min. & Met. Engrs.—Tech. Publication, no. 34, 1927, 4 pp. Zinc, in its wrought form, is produced commercially in rolled strip, sheet, wire, rod and tubing; wire has been made periodically, but, due to fact that slight draughts are necessary, cost of production is greater than for more common non-ferrous metals which are made into wire.

ZINC DEPOSITS

CANADA. Zinc and Lead in Canada, T. W. Bingay and F. J. Alcock. Am. Zinc Inst.—Bul., vol. 10, no. 9-10, Sept.-Oct. 1927, pp. 14-25 and 66-67. Production of both zinc and lead in Canada has steadily increased during recent years.

ZINC METALLURGY

ELECTROLYTIC PRODUCTION. Electrolytic Zinc Production. Elec. World, vol. 90, no. 17, Oct. 22, 1927, pp. 837-840, 7 figs. Anaconda copper mining company uses 50,000 kw. at Great Falls zinc plant; heavy currents constitute chief problems at present.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of the engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N.Y.

A

AIRPLANE ENGINES

Superchargers. Supercharged Engine Performance, Calculated and Actual, O. Chenoweth. Soc. Automotive Engrs.—Jl., vol. 21, no. 5, Nov. 1927, pp. 508-515, 11 figs.

AIRPLANES

Airfoils. Experiments on Airfoils with Aileron and Slot, A. Betz. Nat. Advisory Committee for Aeronautics—Tech. Memorandums, no. 437, Nov. 1927, 6 pp., 4 figs. Results of experiments on three airfoils to which rear portions, having chords respectively ¼, 1/3 and 2/5 or total chord, are hinged so as to form ailerons, especial attention being given to shape of slot between aileron and main portion of airfoil.

Alignment. Alignment and Checking of Components, R. C. Taylor. Roy. Aeronautical Soc.—Jl., vol. 31, no. 203, Nov. 1927, pp. 1037-1049, 13 figs.

Defects and Deterioration. Defects and Deterioration, W. G. Gibson. Roy. Aeronautical Soc.—Jl., vol. 31, no. 203, Nov. 1927, pp. 1050-1060. Deals with general defects and deterioration encountered during normal life of aircraft without reference to actual breakages caused by crash, together with more general methods of overcoming or repairing such defects and deterioration.

Design Control. Control of Aircraft Design, E. W. Stedman. Soc. Automotive Engrs.—Jl., vol. 21, no. 5, Nov. 1927, pp. 516-518. Difficulties experienced in regard to engineering features of control of civil aviation during period of 7 yr. are summarized; outline of formation of International Commission for Air Navigation subsequent to Great War; Canadian Air Board Act of 1919; I.C.A.N. minimum requirements of aircraft and engines for air-worthiness which are being worked to in Canada as closely as possible; suggestion is then made that regulations must make minimum requirements for strength and performance sufficiently great to allow for reasonable deterioration of structure and loss of engine power; effect of increasing load factors.

Metal. Metal Aircraft Co. Construction at Vickers. Flight, vol. 19, no. 37, Sept. 15, 1927, pp. 646-649. Vickers, Ltd., at their Weybridge works, have carried out long series of experiments, and evolved forms of duralumin construction; simplicity is keynote of design; forms of construction evolved are such that resulting structure is considerably lighter than corresponding wood structure for same strength; basis of system is novel form of spar web. See also Nat. Advisory Committee for Aeronautics—Tech. Memorandums, no. 440, Dec. 1927, 5 pp., 5 figs.

ALLOYS

Aluminum. *See Aluminum Alloys.*

Copper. *See Copper Alloys.*

Corrosion-Resisting. Control of Corrosion—New Alloys, W. M. Mitchell. Indus. & Eng. Chem., vol. 19, no. 11, Nov. 1927, pp. 1253-1256.

Nickel. *See Nickel Alloys.*

ALUMINUM ALLOYS

Aluminum Bronze. *See Aluminum Bronze.*

Casting. Observations on Casting Aluminum and Its Alloys, W. J. Clark. Foundry, vol. 55, nos. 21 and 22, Nov. 1 and 15, 1927, pp. 847-849 and 891-893, 9 figs. Views of practical moulder on his experience with aluminum and its alloys; importance of gating.

Heat Conductivity. Heat Conductivity of Light Alloys (Sur la conductibilité thermique des alliages légers), C. Grard and J. Villey. Académie des Sciences—Comptes Rendus, vol. 185, no. 17, Oct. 24, 1927, pp. 856-858, 2 figs. Experimental study of aluminum-copper and magnesium-copper-aluminum alloys which may be used in engine construction, at various temperatures; calls attention to magnesium alloys.

ALUMINUM BRONZE

Properties. Aluminum Bronze, R. C. Reader. Foundry Trade Jl., vol. 37, no. 588, Nov. 24, 1927, p. 143. Deals with general properties; its tensile strength and elongation and further useful properties; aluminum-bronze golf clubs.

ARCHES

Masonry. The Philosophy of Masonry Arches, E. O. Williams. Instn. Civil Engrs.—Eng. Paper, no. 56, 1927, 34 pp., 6 figs. Design formulæ for various types of arches for spans up to 300 ft.; treatment of filled and open arch construction and comparison of rules with various authorities; economics of masonry arches.

ASH DISPOSAL

Power Plants. Disposal of Ashes and Flue Dust in Power Houses. Indus. Mgmt. (Lond.), vol. 14, nos. 7 and 11, July and Nov. 1927, pp. 237-242 and 403-406 and 408, 14 figs. Collection and removal of furnace ashes and clinkers is carried out by well understood methods, while removal of finer flue ashes has only come to fore with use of small low-quality fuel and extensive employment of pulverized fuel.

AXLES

Fatigue Cracks in. A Study of Fatigue Cracks in Axles, H. F. Moore. Forging—Stamping—Heat Treating, vol. 13, no. 11, Nov. 1927, pp. 447-449. Axles which had been in service were subjected to special test devised to indicate presence of cracks before rupture was complete; method of testing. Abstracts from Bul. No. 165, Eng. Experiment Station, Univ. of Ill.

B

BEARINGS, BALL

Standard Specifications. Ball Bearings and Parallel-Roller Bearings. Brit. Eng. Standards Assn., no. 292, Sept. 1927, 53 pp., 36 figs. Tables of permissible errors due to eccentricity and wobble; tables of tolerances; dimension nomenclature for component parts of ball bearings and parallel-roller bearings; explanation of formation of code of reference symbols.

BEARINGS

Anti-Friction. Machine Tool Precision Improved by Anti-Friction Bearings, R. F. Runge. Automotive Industries, vol. 57, no. 21, Nov. 19, 1927, pp. 762-763, 5 figs. Their use reduces wear and thus makes for greater accuracy and efficiency in production; many new applications have been found in last few years.

BLAST FURNACES

Excess-Gas Generation. The Use of the Blast Furnace as a Gas Producer, R. Franchot. Fuels & Furnaces, vol. 5, no. 11, Nov. 1927, pp. 1451-1454. Discusses generation of excess gas in blast furnace; its use; provision for, and effect of, excess gas outlet on blast-furnace operation.

BLOWERS

Rotary. Characteristics and Operating Requirements of Positive Pressure Rotary Blowers, G. Fox. Fuels and Furnaces, vol. 5, no. 11, Nov. 1927, pp. 1481-1484 and 1501. Various types of rotary blowers; their characteristics; power required and motor drive.

BOILER FEEDWATER

Salinity Determination. Salinity or Impurity Determination of Boiler Feed Water, C. Huey. Am. Soc. Naval Engrs.—Jl., vol. 39, no. 4, Nov. 1927, pp. 658-692.

Treatment. Water and Its Importance in Modern Steam Power Stations. Brown Boveri Rev., vol. 14, no. 11, Nov. 1927, pp. 291-301, 8 figs. New points of view relating to action of feedwater on material used in constructing boiler and suitable treatment of water; research work carried out in Brown Boveri laboratories.

BOILER OPERATION

Control. Automatic Control Regulates Seventy-Two Boilers as a Single Unit, J. A. Ingalls. Power, vol. 66, no. 21, Nov. 22, 1927, pp. 770-774, 9 figs. 72 boilers in double-deck installation are divided into four groups, each under control of master regulator, and four group masters are controlled by station supermaster regulator.

BOILER PLANTS

Design. Rational Boiler Plant Design for Low Cost Steam, F. A. Combe. Power, vol. 66, no. 23, Dec. 6, 1927, pp. 875-878, 3 figs.

Maintenance Costs. Maintenance Costs of 54,000-Kw. Boiler Plant. Elec. World, vol. 90, no. 24, Dec. 10, 1927, pp. 1197-1198, 1 fig. From data sheets of New England central station, costs are given for 32 months ended Aug. 31, 1927.

BOILERS

Fusion Welding. Fusion Welding on Boilers and Pressure Vessels, S. W. Miller. Boiler Maker, vol. 22, no. 11, Nov. 1927, pp. 319-321. Tests developed to insure good welds; suggestions for inspectors to follow in acquiring knowledge of welding processes.

High-Pressure. The Strength of Extra High-Pressure Steam Drums. Power Engr., vol. 22, no. 261, Dec. 1927, pp. 461-463, 4 figs. Deals with strength of steam drum which has dimensions equal to those of boiler at Weymouth station, Mass. (Edison Illuminating Co.), working at 1,200 lb. per sq. in.; drum length, 34 ft.; internal diameter, 4 ft.; and thickness, 4½ in.

Return-Tubular. Film Evaporation Applied to Return-Tubular Boiler Increases Capacity 75 Per Cent. Power, vol. 66, no. 21, Nov. 22, 1927, p. 781, 2 figs.

Steam Purifiers. Steam Purifiers Solved the Problem, J. P. Freund. Indus. Power, vol. 8, no. 6, Dec. 1927, pp. 58-61, 2 figs. On account of long steam-distribution lines a large amount of condensation was encountered; problem was met by installation of steam purifiers in steam drums of boilers.

BRASS

Ingot Melting. Some Practical Notes on the Manufacture of Brass Ingots or Strip, N. F. Fletcher. Metal Industry (Lond.), vol. 31, no. 19, Nov. 11, 1927, pp. 441-442. Describes methods whereby metals which form brass are melted and cast into ingots for subsequent rolling into strips. Paper read before Midland Section of Junior Instn. of Engrs.

Practice. The Fundamentals of Brass Foundry Practice, R. R. Clarke. Metal Industry (N.Y.), vol. 24, nos. 7, 8, 9, 10 and 11, July, Aug., Sept., Oct. and Nov. 1926, pp. 283-284, 318-320, 365-366, 417-418 and 453-454, and vol. 25, nos. 1, 2, 3, 4, 5, 8, 9, 11 and 12, Jan., Feb., Mar., Apr., May, Aug., Sept., Nov. and Dec. 1927, pp. 6, 63-64, 105-106, 146-148, 194-195, 327, 369-370, 455-456 and 493-494, 51 figs. Description of basic laws which control melting and casting of metals and their application to practical foundry operations.

BRIDGE DESIGN

SELECTION. Suitability of the Various Types of Bridges for the Different Conditions Encountered at Crossings, J. A. L. Waddell. West. Soc. Engrs.—Jl., vol. 32, no. 9, Oct. 1927, pp. 313-329. Enumerates many factors that must be considered in selecting design; foundation conditions; methods of pier sinking; preliminary studies for proposed bridges; right-of-way.

BRIDGE ERECTION

ARCH CENTERING. Unusual Arch Centering, J. S. Crandall. Boston Soc. Civ. Engrs. —Jl., vol. 14, no. 9, Nov. 1927, pp. 505-506, 2 figs. Progress and completion of bridge and dam; solution proposed.

BRIDGE PIERS

CENTRE, ENLARGING. Foundation Problems in Enlarging Centre Pier of Swing Bridge at Providence, G. W. Maker. Eng. News-Rec., vol. 99, no. 23, Dec. 8, 1927, pp. 927-929, 3 figs. Plant to enclose old pier, Point street bridge, in steel cofferdam driven into quicksand, and to concrete in dry proves unsuccessful; experts' reports and recommendations; final adopted plan discontinued driving of steel sheeting enclosing old pier; provided for dredging 1,000 yd. material and for cutting off new wooden piles by divers; specified pouring of lower 12 ft. of reinforced concrete by tremie.

BRIDGES

HIGH LEVEL. High Level Fixed Bridges Over Navigable Waters, R. Modjeski. World Ports, vol. 16, no. 1, Nov. 1927, pp. 38-52. Tables showing clearances provided over more important waterways in United States and also in foreign countries.

BRIDGES, HIGHWAY

FLOOR SLABS. Tests of the Delaware River Bridge Floor Slabs. Pub. Roads, vol. 8, no. 8, Oct. 1927, pp. 159-178, 47 figs. Concrete floor slabs of special and unusual design have been subjected to complete set of tests by Bur. of Public Roads in co-operation with Delaware River Bridge Joint Commission; slabs were designed to reduce to minimum weight of floor of bridge.

WINTER CONSTRUCTION. Winter Construction of Road Bridges in Michigan. Eng. News-Rec., vol. 89, no. 23, Dec. 8, 1927, pp. 914-916, 3 figs. Standard field practices and engineering control followed in building some 50 structures during last four winters; it should be undertaken without hesitation whenever time gained in putting road into service equals or exceeds in value extra cost of doing work in winter; for concrete, this extra cost runs from $3 to $6 a cubic yard.

BRIDGES, MOVABLE

CONTROL. Santa Fe Installs Low-Voltage Plant on New Mississippi Bridge. Ry. Signalling, vol. 20, no. 12, Dec. 1927, pp. 457-461. Special locking circuits for controlling operation of bridge, indication lights on machine and submarine cable, features of job for operation of signal facilities at draw span and for operation of two cross-overs and three passing track switches located at point 1.2 miles from Mississippi river bridge tower.

BRIDGES, STEEL

CONCRETE VS. Steel vs. Reinforced Concrete for Bridges, R. Modjeski. Iron Age, vol. 20, no. 22, Dec. 1, 1927, p. 1511. Advantages of steel include known durability, rapid erection and use of materials tested beforehand.

BRIDGES, WOODEN

HIGHWAY. Creosoted Timber Highway Bridge at Minocqua, Wis., C. H. Kirch. Roads & Streets, vol. 67, no. 10, Oct. 1927, p. 457. Wisconsin Highway Commission has completed Federal Aid Project No. 431-B, which consists of bridge over lake Minocqua, Oneida county; structure is 831 feet long, and is made up of 54 spans with bents at 15-ft. centres and one 21-ft. span at centre of bridge to allow for passage of boats.

MACADAM DECKS. Successful Macadam Bridge Decks, W. W. Shelby. Roads & Streets, vol. 67, no. 10, Oct. 1927, pp. 425-426, 4 figs. Los Angeles County Road Dept. is paving wooden bridges with bituminous macadam.

C

CABLES, ELECTRIC

POWER PLANT CONTROL. Standard Specification for Control Cable for Electrical Power Plant Equipment. Can. Eng. Standards Assn., no. C21, Aug. 1927, 10 pp. Particular attention is drawn to provision for use of uniform design and only two colours at any one time in conductor braid of multiple conductor cable.

TESTING. Proof Testing High Voltage A.C. Cables. C. L. Dasson. Elec. Light & Power, vol. 5, no. 12, Dec. 1927, pp. 28-29 and 93, 5 figs. Results of proof tests on 13,200-volt a.c. cable system of Boston Elevated Street Railway Co.; cable to be tested is taken out of service and connected by suitable insulated jumper cables to test set parked outside of station in street or driveway.

33,000-Volt Cable Testing, M. Hochstadter and E. Bowden. Elec. Rev., vol. 101, no. 3609, Nov. 25, 1927, pp. 894-895. Review of present-day testing practice and suggested specification of factory and installation tests embodying combination of usual methods.

CAMS

SPECIAL, MACHINING. Milling Cams of Unusual Outline, C. O. Herb. Machy. (N.Y.), vol. 34, no. 4, Dec. 1927, pp. 273-277, 11 figs. Typical methods of machining special cams ordered in small lots.

CARS. REFRIGERATOR

PALESTINE RAILWAYS. New Perishable and Refrigerator Cars, Palestine Railways. Ry. Engr., vol. 48, no. 575, Dec. 1927, pp. 451-455. These vehicles incorporate special features of design, particularly in respect of method of insulation; ice tanks carrying 2 tons of ice are fitted in roof; doors perfectly air and watertight.

CASE-HARDENING

GAS CARBURIZATION. Gas Carburization of Steel, R. G. Guthrie and O. Wozasek. Am. Soc. Steel Treating—Trans., vol. 12, no. 6, Dec. 1927, pp. 853-868 and (discussion) 868-870, 10 figs. Deals with use of so-called city or manufactured gas for carburizing medium and considers certain inconsistencies heretofore encountered in its use: (1) variation in depth and concentration of case from day to day; (2) what constituent in gas is responsible for carburization of steel; (3) mechanism of carburization; (4) factors affecting this mechanism; results show advantages to be gained from treatment of carburizing gas at furnace, and catalyzing steel in furnace at beginning of run.

NITRATION-HARDENING. Surface Hardening by Nitrogen. Foundry Trade Jl., vol. 37, no. 588, Nov. 24 1927, pp. 135-136. New process of Dr. Fry, of Research Laboratories of F. Krupp of Essen, consists of subjecting parts to be hardened to action of ammonia gas at temperature of 500 deg. cent. for period of time varying from 40 to 120 hr.; ammonia is dissociated, and portion of nitrogen thus formed passes into solid solution in outer layers of parts; one of most valuable features of process is small amount of distortion which parts undergo during nitrogen treatment; electric furnaces essential.

SOFT STEEL. Case-Hardening of Soft Steel. G. A. Nelson. West. Machy. World, vol. 18, no. 11, Nov. 1927, pp. 532-533, 7 figs. Operations in heat-treatment department of Pacific Gear & Tool Works; results obtained with soft steel heat-treated in electric furnace.

CAST IRON

HIGH-STRENGTH. Makes High Test Cast Iron, M. E. Greenhow. Foundry, vol. 55, no. 23, Dec. 1, 1927, pp. 919-920. Castings with varying sections require close-grained, high-strength, wear-resisting iron which is obtained by nickel additions; gives results and data on method followed.

CENTRAL STATIONS

HIGH-PRESSURE. Operating Experiences with 1,300-Lb. Steam Pressure, J. Anderson. Engineer, vol. 144, no. 3750, Nov. 25, 1927, pp. 605-607, 2 figs. Lakeside station operation; desirability of 1,300-lb. pressure; tells of major troubles experienced.

NEW YORK CITY. Analysis of System Conditions, J. W. Lieb. Elec. World, vol. 90, no. 24, Dec. 10, 1927, pp. 1187-1191, 13 figs. Study of load durations, other utility load characteristics, seasonal and weather effects, output, demand, load and coal-consumption trends, load densities and system layout.

CHROMIUM STEEL

HIGH TEMPERATURE. Steel for High Heat and Loads. Iron Age, vol. 120, no. 24, Dec. 15, 1927, pp. 1662-1663, 3 figs. Chromium steel and chrome-nickel steels have best combination of properties; huge seamless drums now forged for petroleum stills, chemical cells and boilers; advanced construction of values. Address before N.Y. Chapter, Am. Soc. for Steel Treating.

CIRCUIT BREAKERS

OIL. High-Voltage Oil Circuit Breakers for Transmission Networks, R. Wilkins and E. A. Crellin. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1340-1348, 14 figs. Oil circuit breaker as limiting feature to securing best operating results in electric transmission developments; essential fundamental requirements brought out by investigation.

CLUTCHES

MACHINING. Machining Friction Clutch Parts, R. Mawson. Can. Machy., vol. 38, no. 18, Nov. 3, 1927, pp. 17-18, 6 figs. Methods employed by clutch manufacturer in machining various components of particular type of friction clutch, on production basis, without recourse to expensive jigs and fixtures.

COAL

ANALYSES. Analyses of Solid Fuels, J. H. H. Nicolls. Can. Dept. Mines—Investigations of Fuels and Fuel Testing, no. 671, 1927, pp. 106-136. Deals with solid fuels occurring in Canada; coal samples submitted by Dept. of Soldiers' Civil Re-establishment; miscellaneous solid fuels.

CARBONIZATION. The K.S.G. Process of Low-Temperature Carbonization, W. Runge. Am. Soc. Mech. Engrs.—Advance Paper, for mtg. Dec. 5-8, 1927, 7 pp., 2 figs.

Low-Temperature Carbonization of Bituminous Coals, R. A. Strong. Can. Dept. Mines—Investigations of Fuels and Fuel Testing, no. 671, 1927, pp. 64-100, 12 figs. Altogether, 32 carbonization tests were carried out, duplicate runs being made on same coal at same temperature by same method of carbonization; results are given as series of tables.

FRIABILITY. Effects of Continued Weathering Upon the Friabilities of Various Fuels, J. H. H. Nicolls. Can. Dept. Mines—Investigations of Fuels and Fuel Testing, no. 671, 1927, pp. 101-105. Tables showing results of continuation of tests upon fuels which have been subjected to open shed exposure; summary of completed friability tests, particularly as regards effects of weathering.

PULVERIZED. *See Pulverized Coal.*

COKE

METALLURGICAL. Properties of Metallurgical Coke, R. P. Hudson. Blast Furnace & Steel Plant, vol. 15, no. 11, Nov. 1927, pp. 526-527. Recital of properties and characteristics coke should possess in order that it may serve most efficiently as a fuel in blast furnace.

CONCRETE

AGGREGATE MOISTURE. Determination of Moisture in Aggregate. Pub. Wks., vol. 58, no. 12, Dec. 1927, pp. 457-458, 1 fig. When accurate control of mixing water for concrete is to be maintained, quick, simple method of determining moisture content of aggregate is desirable; laboratory of Portland Cement Assn. has developed special apparatus for making test.

CALCIUM CHLORIDE TESTS. Tests Show Shrinkage Effect of Calcium Chloride in Concrete, A. S. Levens. Eng. News-Rec., vol. 99, no. 23, Dec. 8, 1927, p. 912, 2 figs. $CaCl$ up to 6 per cent increases shrinkage; relative shrinkage over plain concrete decreases with setting time; results of five series of tests conducted at experimental laboratory of Univ. of Minnesota.

VIBROLITHIC. Further Tests of Vibrolithic Concrete. Pub. Roads, vol. 8, no. 8, Oct. 1927, pp. 179-189, 7 figs. Comparative transverse bending tests on normal and vibrolithic concrete were carried on at Arlington Experimental Station; object of investigation was to obtain data on resistance to rupture by bending, of specimens of different mixes fabricated by each of two methods.

CONCRETE CONSTRUCTION

RIGID-FRAME DESIGN. The Essentials of Rigid-Frame Design, E. H. Harder. Concrete, vol. 31, nos. 4, 5 and 6, Oct., Nov. and Dec. 1927, pp. 13-15, 43-45 and 37-42, 10 figs. Rigid-frame construction, practically non-existent in America, is widely used in Europe; advantages of this type of structure; what it is and how it is used; examples of rigid-frame design.

CONCRETE CONSTRUCTION, REINFORCED

FUTURE. The Future of Reinforced Concrete, F. R. McMillan. Eng. & Contracting, vol. 66, no. 11, Nov. 1927, pp. 513-516. Records of past and possible developments of future; rationalization of design; more attention to durability; volume changes in concrete; inelastic deformation in concrete. Address before Concrete Reinforcing Steel Inst.

PLASTIC YIELD AND SHRINKAGE. Plastic Yield, Shrinkage and Other Problems of Concrete and Their Effect on Design, O. Faber. Engineering, vol. 37, no. 3227, Nov. 18, 1927, pp. 661-663. It is shown that structures of reinforced concrete with stresses inside those allowed in good practice continue to deflect without change of load of temperature, result due partly to shrinkage and partly to plastic yield; consequently, absence of permanent set or deflection must not be insisted on as necessary criterion of safety where test involves appreciable time element; this yield and shrinkage produce large, though gradual, redistribution of stress between steel and concrete in reinforced-concrete structure, of such nature generally as to relieve concrete and add to steel stress; present regulations, which take no account of these matters, leave much to be desired; modulus of elasticity of concrete is much greater than specified in most regulations, but yield and shrinkage, in some cases, produce results similar to those obtained with very low modulus. Abstract of paper read before Instn. Civil Engrs.

CONDENSERS, ELECTRIC

RESONANCE IN CIRCUITS. Resonance in Series and Parallel Circuits, H. J. Boyland. Experimental Wireless, vol. 4, no. 50, Nov. 1927, pp. 675-683. Analyzes certain combinations of inductance, capacity and resistance in order to derive relationship which must exist in certain quantities to satisfy various conditions.

SYNCHRONOUS. Synchronous Condensers, P. L. Alger. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1330-1338, 8 figs. Characteristics of large synchronous condensers, greater standardization in condenser specifications; ratio of lagging to leading kv.a. capacity; advantages of reactors where extra lagging capacity is needed; starting and stability characteristics; recent improvements in design; asynchronous condensers.

CONDUITS

Low-Pressure. The Design of Large Low-Pressure Water Conduits, H. H. Burness. Engineering, vol. 124, no. 3226 Nov. 11, 1927, pp. 632-634, 5 figs. Since height of free water surface, and consequently pressure at various points in shell of conduit, is likely to vary between certain limits once structure has been erected, bending moments will be induced in shell due to its efforts to adjust its shape to altered conditions; method of calculating these moments has therefore been given which can also be applied to determine stress conditions due to earth pressure on outside of conduit when latter may have to be buried at various depths; special case of free water surface coinciding with crown of conduit is dealt with separately; economic justification for use of this type of conduit is shown by comparing estimated cost of actual design with cost of alternative open channel.

CONVEYORS

Belt. Handling Bulk Materials with Belt Conveyors, H. F. Geist. Chem. & Met. Eng., vol. 34, nos. 11 and 12, Nov. and Dec. 1927, pp. 664-667 and 744-748, 8 figs. Presents tables which enable engineer or initiated layman to select width and ply of belt required, effective pull required for haul, speed, horse power, maximum permissible haul, and size of drive pulley and its shaft for either plain grease-bearing type or anti-friction-bearing type belt carriers. Dec.: Practical design; tables which permit of ready solution to any conveyor problem.

Control. How a Complex Conveyor System Was Magnetically Controlled, P. T. Van Bibber. Indus. Eng., vol. 85, no. 11, Nov. 1927, pp. 507-508, 2 figs. Sets forth unusual method of making magnetic type of switch serve also as sort of automatic block-control system on conveyor installation.

Drives and Gearing. Conveyor Drives and Gearing, E. C. Hatcher. Chem. & Industry, vol. 46, no. 46, Nov. 18, 1927, pp. 1063-1064, 2 figs. Deals with belt, chain, open-gear and totally enclosed gear drive; open spur-gear drive is probably most generally used form of conveyor drive; H-R gear manufactured by J. Stone & Co., combines advantages of all types, being standard form of gear box in which any speed ratio from 6 to 1 to 100,000 to 1 can be provided; because of its special construction, only smallest number of teeth are necessary on final driving wheel.

Portable. Portable Loaders. L. I. Thomas. Indus. Power (Indus. Handling), vol. 13, no. 5, Nov. 1927, pp. 137-142. This type of equipment will load from 20 to 60 tons an hour; consists of section of belt or bucket conveyor supported at incline on wheels or on crawler type of mounting.

COPPER ALLOYS

Adnic. Physical Properties of Adnie, W. B. Price. Min. & Met., vol. 8, no. 251, Nov. 1927, pp. 474-475, 2 figs. New corrosion and heat-resisting white-metal alloy, having composition of copper, 70 per cent; nickel, 29 per cent; tin, 1 per cent.

Brass. *See Brass.*

Phosphor-Copper. Phosphor-Copper. Foundry Trade Jl., vol. 37, no. 585, Nov. 3, 1927, p. 86. Claim is made that by method described, no loss of phosphorus is sustained and that uniform phosphor-copper is produced with introduction of 15 per cent phosphorus.

CUPOLAS

Practice. Hints on Cupola Practice, A. Sutcliffe. Foundry Trade Jl., vol. 37, no. 588, Nov. 24, 1927, p. 146. Principal causes of bad melting are faulty quantity and faulty delivery of blast, associated with poor arrangement of charge in furnace; author is of opinion that where adjustments are required in quantity of iron which founder requires to be delivered to him at commencement of his casting operations, they cannot be made satisfactorily by alterations of blast or of weight and disposition of charges in one cupola except within inconsiderable limits; ascertaining blast requirements; numerous large tuyeres advocated.

COPPER METALLURGY

Leaching. Development of Some Fundamentals in the Ferric Sulphate-Sulphuric Acid Process, F. S. Wartman and H. E. Keyes. U.S. Bur. Mines—Reports of Investigation, no. 2839, Nov. 1927, 11 pp. This process, developed by staff of Bureau of Mines, is method of making mixed solutions of ferric sulphate and sulphuric acid suitable in quantity and composition for leaching certain types of low-grade oxide-sulphide copper ores.

CORONA

Formation and Loss. The Law of Corona and Dielectric Strength of Air, F. W. Peek. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1390-1398, 19 figs. Mechanism of corona formation and loss; loss following quadratic law above visual critical voltage; loss on polished wires, cables and imperfect conductors; irregularity factor for weathered conductors important; visual critical corona voltage calculated with great accuracy; artificial corona readily produced.

Loss Investigation. Methods Used in Investigating Corona Loss by Means of the Cathode Ray Oscillograph, W. L. Lloyd, Jr., and E. C. Starr. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1322-1329, 14 figs. Photographic records of figure representative of loss; calculating accurate values of power expended; formulas of "critical disruptive gradients" and "visual disruptive "gradients" checked; practical effect of condition of conductor surface.

Space Charge. The Space Charge That Surrounds a Conductor in Corona, J. S. Carroll and J. T. Lusignan. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1350-1357, 15 figs. Qualitative analysis of nature of space charge created about conductor in corona, particularly with respect to relative magnitudes and polarities, rather than actual quantitative measurement.

D

DAMS

Arch. Experimental Work on Small-Scale Models of Arch Dams Begun by Reclamation Bureau, I. E. Houk. Hydraulic Eng., vol. 3, no. 10, Oct. 1927, pp. 16-17 and 30-31, 2 figs. Miniature models of arch dams, built to exact scale, loaded with mercury, provide data required in design of full-size structures; models of different materials. See also Eng. & Contracting, vol. 66, no. 11, Nov. 1927, pp. 521-523, 2 figs.

Concrete. Ambursen Dam at Junction Brook, Nfld., A. B. McEwen. Can. Engr., vol. 53, no. 21, Nov. 22, 1927, pp. 541-545, 7 figs. Hollow reinforced-concrete dam built by W. I. Bishop, Ltd., for Newfoundland Power & Paper Co.; dam carries Newfoundland Government railway; depth below water level, 68 ft.; Grand Lake area increased from 135 to 215 sq. mi.

Multiple Arch. Multiple Arch Dam Construction. Concrete, vol. 31, no. 6, Dec. 1927, pp. 43-45, 4 figs. Overall length 585 ft. and 104 ft. high; among interesting practices employed was use of excavated rock for coarse aggregate; 3 distinct types of dam construction are employed; multiple arch, gravity-type arch for spillway and hydraulic core beyond concrete wind built on one end of dam.

Sand Impounding. Sand Embankment Impounding Dam at Chicopee, Mass., M. G. Mansfield. New England Water Wks. Assn.—Jl., vol. 41, no. 3, Sept. 1927, pp. 244-260, 4 figs. Dam is of embankment construction forming reservoir with surface area, at normal water level, of approximately 30 acres and maximum depth of 42 ft.; it consists almost entirely of sand and very small percentage of silt and loam, 550 ft. long at top, with maximum height above bed of stream of 48 ft.

DIELECTRICS

Solid. A Theory of Imperfect Solid Dielectrics, M. G. Malti. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1373-1380, 12 figs. Hypotheses for observed behaviour of solid dielectrics; definitions of resistivity, permittivity, electric charge and electric strength under both continuous and alternating potentials; energy losses traced to sources and subdivided into hysteresis, viscosity and resistance losses; methods devised for separating total dissipated energy into its three component parts.

DIESEL ENGINES

Air Cleaners. New Development in Air Intake Protection. Oil Engine Power, vol. 5, no. 11, Nov. 1927, p. 762, 2 figs. Well known type of centrifugal air cleaner adapted to Diesel requirements.

Cylinder Wear. The Probable Causes of Cylinder Wear in Marine Oil Engines. Mar. Engr. & Motorship Bldr., vol. 50, no. 603, Nov. 1927, pp. 412-414, 1 fig. Considers possible principal causes of cylinder wear in Diesel engines and remedies.

Heat Transmission. Transmission and Removal of Heat by the Cooling System of Diesel Engines, W. Wakefield. Am. Soc. Naval Engrs.—Jl., vol. 39, no. 3, Aug. 1927, pp. 514-532, 5 figs. Transfer of heat from time of combustion until it reaches cooling medium is biggest problem that confronts designer of large Diesel engines; question has two phases: (1) transfer of heat of combustion to metal walls of combustion chamber; (2) transfer of heat through combustion chamber walls to cooling medium.

Lubrication. Cylinder Lubrication of Diesel Engines, C. G. A. Rosen. Pac. Mar. Rev., vol. 24, no. 12, Dec. 1927, pp. 568-569 and 41, 3 figs. Kinds of oil used, methods of application and distribution and combustion processes.

DROP FORGING

Die Rolling vs. Drop-Forging and Die-Rolling. Iron & Steel World, vol. 1, no. 2, Mar. 1927, pp. 145-146, 3 figs. Discussion of various factors which determine whether particular shape can best be made by drop-forging or die-rolling.

Fin Formation. Influence of Fin Formation on the Internal Structure of Drop Forgings, E. Decherf. Iron & Steel World, vol. 1, no. 7, Aug. 1927, pp. 489-492, 8 figs. Factors influencing position and formation of fins in drop forging; value of macroscopic tests in determining flow and internal tension of metal. Translated from Revue Universelle des Mines.

DYNAMICS

Newton's Law of Motion. A Suggested Method of Presenting Newton's Second Law of Motion, N. P. Bailey. Jl. Eng. Education, vol. 18, no. 3, Nov. 1927, pp. 176-177. Failure to grasp completely Newton's Second Law of Motion is one of worst stumbling blocks of average undergraduate student in dynamics; past observation has convinced writer that this trouble is primarily caused by introduction of thoroughly intangible quantity, mass, as fundamental unit in statement of familiar law, $F=Ma$.

E

ELECTRIC ARC

Mercury. New Type of Low-Voltage Mercury Arc, A. Bramley and W. B. Nottingham. Franklin Inst.—Jl., vol. 204, no. 4, Oct. 1927, pp. 487-490, 1 fig. New type of arc in which both anode and cathode are of mercury, but conditions at cathode or anode are controlled by special device, the mercury dropper, which simplifies mechanism of arc.

ELECTRIC CIRCUITS

Safety. Grounding Devices and Equipment, S. W. Borden. Elec. News, vol. 36, no. 22, Nov. 15, 1927, pp. 26-29, 2 figs. Term "safety circuit" has been suggested as practical and appropriate designation; it includes not only circuits used for grounding at main switch on customer's premises, but properly includes circuits for grounding all equipment such as motor frames, hand lamps, portable tools and appliances, etc., as well as protective grounds for fire alarm and police boxes, etc.

ELECTRIC CURRENTS, ALTERNATING

High-Frequency. High-Frequency Currents, E. W. Marchant. Instn. Elec. Engrs.—Jl., vol. 65, no. 371, Nov. 1927, pp. 977-988, 8 figs. Treats of phenomena of specific inductive capacity and dielectric loss, dielectric straight and magnetization at high frequencies; effect of distribution networks and overhead lines by high frequency currents.

ELECTRIC FURNACES

Melting. Electric Melting Furnaces Used in Making Steel for Bearings. Fuels & Furnaces, vol. 5, no. 11, Nov. 1927, pp. 1459-1462, 3 figs. Unique design of electric-arc melting furnaces proves very efficient in production of steel for bearings.

ELECTRIC GENERATORS, A.C.

Synchronous. Synchronous Machines, R. E. Doherty and C. A. Nickle. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, p. 1339. Torque-angle characteristics under transient conditions. Synopsis.

ELECTRIC LAMPS, INCANDESCENT

Internal Frosting. Chemical Engineering Contributes to Better Lighting, M. Pipkin. Chem. & Met. Eng., vol. 34, no. 11, Nov. 1927, pp. 660-663, 6 figs. Inside frosting of incandescent lamp bulbs has results not only in better but in cheaper light. See also Glass Industry, vol. 8, no. 12, Dec. 1927, pp. 285-288, 6 figs.

ELECTRIC LOCOMOTIVES

Storage-Battery. Performance of 120-Ton Storage Battery Locomotive, E. Taylor. Ry. & Locomotive Eng., vol. 40, no. 11, Nov. 1927, pp. 319-324, 1 fig. Summary of operation in three terminal freight yards in Chicago; advantages; tractive effort, 71,000 lb., maximum speed, 30 m.p.h.

ELECTRIC MOTORS

Small. Small Appliance Motors, G. I. MacKenzie. Elec. Light & Power, vol. 5, no. 12, Dec. 1927, pp. 30-32 and 92-93, 9 figs. Effect of secondary voltages of motor driven appliances; methods of preventing voltage drop in lighting circuits when small motors are started; compares 115-volt with 230-volt motors.

ELECTRIC POWER

Combined Light and Power Systems. Combined Light and Power Systems for A.C. Secondary Networks, H. Richter. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1436-1441, 3 figs. Standardization suggested to fit most important requirements of industry; present status of application; qualitative analysis for apparatus connected to secondary system; quantitative analysis; relation of trends in industry to problem.

ELECTRIC RAILWAYS

Overhead Contact Design. Railway Inclined Catenary Standardized Design, O. M. Jorstad. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1307-1313, 9 figs. Ideal inclined catenary based on originally discovered tension and weight relation formula; data of railroads using inclined catenary compared with ideal; standardization of overhead systems.

ELECTRIC TRANSMISSION LINES

CONSTRUCTION COSTS. Control of Construction Costs, O. W. Gatchell. Elec. World, vol. 90, no. 24, Dec. 10, 1927, pp. 1193-1195. Detailed cost reports lead to economies in construction of 150-mile steel tower line; foremen rated according to results of labour-charge analysis; supervision simplified and efficiency improved.

ISLE MALIGNE-QUEBEC. Isle Maligne-Quebec Power Line. Can. Engr., vol. 53, no. 21, Nov. 22, 1927, p. 550. Canadian 135-mile line with double circuit steel tower construction towers spaced 900 ft.; maximum voltage delivered 160,000, giving 100,000 h.p. available at Quebec.

OVERHEAD. Overhead Electric Line Design, W. T. Taylor. Elec. Rev., vol. 101, no. 2607, Nov. 11, 1927, pp. 810-811, 1 fig. Aspects of safety and standards of construction: review of latest American practice.

PROTECTION. Ground Relay Protection. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1443-1447. Discussion of following papers: Ground-Relay Protection for Transmission Systems, Jones and Dodds; Directional Ground-Relay Protection, Breisky, King and North, published in Oct. and Nov. issues of Journal respectively.

QUEBEC. Quebec-Isle Maligne Line Operating, C. V. Christie. Contract Rec., vol. 41, no. 46, Nov. 16, 1927, pp. 1167-1170, 6 figs. 160-kv. transmission line of Shawinigan Water & Power Co. that supplies 100,000 h.p. over distance of 135 miles; topography; towers, conductors, transformers and generators.

RURAL. Rural Electric Lines, S. E. Britton. Elec. Rev., vol. 101, no. 2608, Nov. 18, 1927, pp. 849-851. Symposium of opinions of electrical engineers experienced in construction of overhead lines in rural areas, with examples of methods that have been, or are to be, adopted for distribution of electricity at low and medium pressures.

STABILITY, STATIC LIMITS OF. Static Stability Limits and the Intermediate Condenser Station, C. F. Wagner and R. D. Evans. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1423-1430, 25 figs. In static stability calculations, loads represented by equivalent constant admittances and synchronous machines replaced by equivalent impedances; criterion with formulas for calculation of two- three- and four-machine cases; calculations of stability of practical transmission lines; improvements due to intermediate condenser.

ELECTRIC WELDING, ARC

APPLICATIONS. The Electric Arc and Its Function in the New Welding Processes, P. Alexander. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1404-1410. Application to welding of metals; atomic-hydrogen process; shielded-arc process; deposition of metal; physics and chemistry of crate; welding in mixed gases; possibilities of electric arc and gas flame as replacing rivet cutting tools and foundry moulds.

ARC LENGTH. Correct Arc Length, J. B. Green. Welding Engr., vol. 12, no. 10, Oct. 1927, pp. 37-38, 2 figs. Study of metal transfer furnishes basis for determining proper length and practical means for maintaining it. See also Can. Machy., vol. 38, no. 20, Nov. 17, 1927, pp. 21-22.

DEVELOPMENTS. Electric Welding. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1431-1435. Locomotive-boiler repairs; shipbuilding; welding structural steel for buildings; pipe lines; welding to replace castings; resistance welding. Report of committee on electric welding.

OIL-CRACKING VESSELS. Welding Oil Pressure Cracking Vessel, R. Stresau. Nat. Petroleum News, vol. 19, no. 47, Nov. 23, 1927, pp. 64-71, 8 figs. Type of design required for stills operating at 900 deg. Fahr. and pressures of 1,000 lb. per sq. in. or more must also be such that material used in every part of vessel is equally stressed; process developed by A. O. Smith Corp. in manufacturing pressure stills.

RAILS. Building Up Battered Rail Joints by Electric Arc Welding. Ry. Eng. & Maintenance, vol. 23, no. 12, Dec. 1927, pp. 522-524.

TANK SEAMS. Arc Welding Tank Seams at High Speeds, R. E. Kinkead. Boiler Maker, vol. 22, no. 11, Nov. 1927, pp. 307-308. Physical tests by E. V. Kesinger, of Empire Companies of Bartlesville, Okla.; both average and maximum strength of welds was increased in going from 120-160 amperes to 200 amperes.

ELECTRICAL MACHINERY

WINDINGS, HEATING OF. Heating of Windings Determined from Tests of Short Duration, J. Basta and F. Fabinger. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1399-1403, 5 figs. Calculation of "hot spot" temperature rise in electric machine from data obtained by load test of short duration.

ELECTRICITY, APPLICATIONS OF

IRON AND STEEL INDUSTRY. Iron and Steel Industry. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1348-1349. Electric lighting, heating main roll drives, auxiliary mill drives, welding, safety; measurements and instruments; replacing steam by electric drives. Annual report of committee on applications to iron and steel production.

ELECTROPLATING

CHROMIUM. The Theory of the Deposition of Chromium, E. A. Ollard. Metal Industry (Lond.), vol. 31, no. 19, Nov. 11, 1927, pp. 437-439, 3 figs., and discussion in no. 21, Nov. 25, 1927, pp. 485-486. Chemistry of chromium in relation to its deposition; ionization of chromium compounds; composition of chromium plating solutions.

EXCAVATION

CHANNEL DEEPENING. Deepening a Rock-Filled Channel, W. H. Abbott. Eng. & Contracting, vol. 66, no. 10, Oct. 1927, pp. 449-451. How slackline cableway with travelling head tower solved difficult excavating problem.

F

FACTORIES

DRIVEWAYS. Factory Streets and Lower Handling Costs, L. K. Urquhart. Factory, vol. 39, no. 5, Nov. 1927, pp. 827-834. Ideal driveway surface is one that is most nearly permanent so that heaviest and most destructive traffic will have little or no effect upon it; it also presents least resistance to load movements, is not slippery in wet weather, is dustless, drains quickly, is not excessive in first cost, and does not require frequent and expensive maintenance.

FANS

CHARACTERISTICS. Tests to Determine the Effects of Throttling the Inlet on the Characteristics for a Fan, H. Mawson. Instn. Civil Engrs.—Eng. Paper, no. 51, 1927, 16 pp., 9 figs. Object was to ascertain effects of altering suction pressure at eye of fan by throttling inlet; experiments were made on "Sirocco" ventilating fan.

FILTRATION PLANTS

RAPID SAND. Five Years of Rapid Sand Filtration at Cambridge, Mass., M. C. Whipple and H. C. Chandler. New England Water Wks. Assn.—Jl., vol. 41, no. 3, Sept. 1927, pp. 218-243. Operation and performance of plant, at time of its opening largest rapid sand filter plant in New England and at present only one municipally operated in state; some of its problems have been pioneer ones in this part of country; they may serve to furnish guidance for other similar plants that are bound to follow.

FLOORS

CONCRETE. Concrete Floors for Homes, A. Foster. Bldg. Age, vol. 49, no. 12, Dec. 1927, pp. 90-92, 6 figs. Advantages and disadvantages of various kinds; finish of surface to imitate wood, cork, etc.; places where they are of great advantage; fire protection, soundproofing.

FLOW OF WATER

CONTROL. Methods of Controlling Flow of Water, F. J. Taylor. Can. Engr., vol. 53, no. 18, Nov. 1, 1927, pp. 489-493, 7 figs. Types of apparatus employed in dams for regulating flow of water; limitations and hydraulic conditions of solid weir; multiple arch dams; stoney roller sluice; movable weirs; irrigation barrages.

FORGING

DIE DESIGN. Forging Machine Die Design for Deep Piercing, E. R. Frost. Am. Soc. Steel Treating—Trans., vol. 12, no. 6, Dec. 1927, pp. 954-967, 43 figs. Method and die design for producing upset machine forgings having deep holes pierced through them, procedure to be followed in design of dies and piercers, as well as pitfalls to be avoided; kind of material that can be forged; working temperatures and kind of steel and treatment for piercer tools.

Improved Die Design Increases Production, R. Henry. Iron & Steel World, vol. 1, no. 9, Oct. 1927, pp. 637-638. Savings in labour and material result from application of gang forging methods to manufacture of forgings of varying cross-section.

SAFETY CODE. Safety Code for Forging and Hot Metal Stamping. U.S. Bur. Labour Statistics—Bul., no. 451, Aug. 1927, 32 pp., 31 figs. Code applies to all classes of power-forging machinery for both drop forging and flat-die forging, including steam hammers, pneumatic hammers, mechanically operated hammers, hydraulic presses, trimming presses, bulldozers, upsetting, machines and bolt-heading and rivet-making machines, hot saws; and incidental operations in connection with such machinery.

FORGINGS

HEATING AND HANDLING. Furnace Aids in Modernizing Forgings, F. W. Manker. Forging—Stamping—Heat Treating, vol. 13, no. 11, Nov. 1927, pp. 431-432, 2 figs. Equipment used for heating and handling forgings at plant of Willys-Overland Co.

FOUNDRIES

FARM-IMPLEMENT PARTS. Casting Parts for Agricultural Implements, E. G. Brock. Can. Foundryman, vol. 18 no. 11, Nov. 1927, pp. 7-10, 7 figs. Efficient production of plows and other farm implements is achieved at Cockshutt Plow Co.'s plant at Brantford, Ont., by a minimum of skilled labour through simplification of operations and use of modern equipment. See also Can. Machy., vol. 38, no. 22, Dec. 1, 1927, pp. 20-23, 6 figs.

FUTURE PROSPECTS. Grey Iron Foundry Faces a New Era, E. A. Custer, Jr. Iron Age, vol. 120, no. 21, Nov. 24, 1927, pp. 1447-1449. Author declares that new methods in preliminary stages of development will make possible "come back" commercially and scientifically. See also Iron Trade Rev., and vol. 81, no. 21, Nov. 24, 1927, pp. 1294-1295.

MECHANICAL ORGANIZATION. The Mechanical Organization of Foundry Work, M. H. Magdelenat. Foundry Trade Jl., vol. 37, no. 585, Nov. 3, 1927, p. 88. Points out that French markets are not adapted for mass production; in industry in France men are more to be desired than machines, but as this desire is not likely to be fulfilled soon they must resolutely take up mechanical organization of foundry work, preceded by standardization.

RADIATOR. Radiator Foundry Requires Exacting Sand Control, F. G. Steinbach. Foundry, vol. 55, no. 23, Dec. 1, 1927, pp. 912-918 and 931, 11 figs. Radiators, burners, regulators and flues are manufactured complete at Newcomerstorn, O., plant of James B. Clow & Sons; special foundry in which cast parts of unit are made, contains number of interesting features, including special sand-handling and preparing unit, special rigs for pouring and shaking out castings, special moulding equipment, etc.

FOUNDRY EQUIPMENT

CONVEYORS. Piston Moulding Conveyor Units. Iron Age, vol. 120, no. 23, Dec. 8, 1927, pp. 1582-1583, 3 figs. Mould conveyors, hooded cooling conveyors and sand-handling system result in much labour saving in automobile foundry of Buick Motor Co., Flint, Mich.

CRANES. Modern Crane Equipment for a Foundry. Elec. Engr. of Australia & New Zealand, vol. 4, no. 7, Oct. 15, 1927, pp. 245-246, 3 figs. Recent installation at Yarraville, Victoria.

SAND-HANDLING. Foundry Output Increased by Sand-Handling Equipment, G. A. Gunther. Iron Age, vol. 120, no. 24, Dec. 15, 1927, pp. 1645-1649, 8 figs. Deals with continuous moulding and sand-conditioning unit at South Bend, Ind., plant of Studebaker Corporation; equipment is combination of conveying, elevating and sand-conditioning units so arranged that none of sand entering into making of castings is handled by hand, nor is any of heavy lifting, so typical of foundry work, done at man power.

Sand-Condition Plant Saves Labour. Iron Age, vol. 120, no. 22, Dec. 1, 1927, pp. 1512-1513, 3 figs. Combination of conveyors and elevators reduces time 20 per cent; smoother castings reported.

FUELS

COAL. *See Coal; Pulverized Coal.*

OIL FUEL. *See Oil Fuel.*

FURNACES, FORGING

ELECTRIC. Electrically Heated Forging Furnace, H. G. D. Nutting. Elec. World, vol. 90, no. 24, Dec. 10, 1927, pp. 1201-1202, 2 figs. Installed in Detroit automobile-parts plant to heat steel for upsetting purposes; known as Berwick metal heater and made by Am. Car & Foundry Co.

FURNACES, HEAT-TREATING

OIL-BURNING. Burning Oil in Heat-Treating Furnaces. Fuel Oil, vol. 6, no. 6, Dec. 1927, pp. 27-28 and 140. There is no one type of burner suitable for all heating requirements; essential features are that it be properly proportioned to oil and air, or steam pressures available, and so designed that all parts are accessible and permit of close adjustment, cleaning and convenient removal from furnace, without affecting operation of any other burner served by same piping system.

FURNACES, INDUSTRIAL

DESIGN. Practical Industrial Furnace Design, M. H. Mawhinney. Forging—Stamping—Heat Treating, vol. 13, no. 11, Nov. 1927, pp. 452-455, 3 figs. Furnace construction as it relates to members which are either castings or structural steel; physical characteristics of metals.

FURNACES, MELTING

DESIGN. A Note on Foundry Equipment, with Special Reference to Furnaces, C. A. Otto. Mech. World, vol. 82, no. 2133, Nov. 18, 1927, pp. 378-379. Review of developments in brass foundries ordinary; crucible furnaces are gradually being displaced by other furnaces of more up-to-date type, which are capable of dealing with much larger quantity of metal in considerably less time, taking up less space and requiring comparatively less labour to prepare metal; electric furnaces.

G

GAUGES

METALS FOR. Recent Experiments Relating to the Wear of Plug Gauges, H. J. French and H. K. Herschman. Am. Soc. Steel Treating—Trans., vol. 12, no. 6, Dec. 1927, pp. 921-945 and (discussion) 945-953. Results of tests made in laboratory wear tester in gauging file-hard high-carbon steel, an aluminum "piston alloy" and cast iron; in tests made in file-hard high-carbon steel in presence of non-metallic abrasive, stellite, high-carbon high-chromium iron alloy and chromium-plated gauges showed better resistance to wear than customary high-carbon steels or Nitralloy.

GARBAGE DISPOSAL

INDIANAPOLIS. Indianapolis Reaps Profit in Garbage, E. M. Reid. Am. City, vol. 37, no. 6, Dec. 1927, pp. 753-757. Garbage reduction plant designed to extract every saleable product possible by use of McCullough system; garbage collection.

GASOLINE

CRACKING PROCESSES. Gasoline, by Pressure Cracking of Canadian Shale Oil and Bitumen, R. E. Gilmore. Can. Chem. & Met., vol. 11, no. 11, Nov. 1927, pp. 289-291. Samples of Canadian crude shale oil and bitumen from bituminous sands were submitted to Universal Oil Products Co. and to Kansas City Testing Laboratory for pressure cracking tests, according to Dubbs and Cross processes respectively; results are summarized and will serve purpose of helping to decide value of crude shale oil and bitumen on comparative basis with crude petroleum and fuel oils now used as sources of motor fuels by pressure cracking processes.

GEAR CUTTING

HOBBING. Hobbing Brass Worm-Gears. Machy. (N.Y.), vol. 34, no. 4, Dec. 1927, p. 298, 2 figs. Describes fixture for hobbing worm gear on drilling machine.

HOBS. Cutting and Heat-Treating Gear Hobs, D. M. Duncan. Can. Machy., vol. 38, no. 22, Dec. 1, 1927, pp. 17-19. Discussion of problems incident to production of accurate gears and gear-cutting tools, together with description of methods of machining and heat-treating employed by Ontario concern.

INDEXING SEGMENT GEAR. Sine Bar Indexing Device for Segment Gear. Machy. (Lond.), vol. 31, no. 786, Nov. 3, 1927, pp. 137-138, 2 figs. Method of indexing by angular measurements devised by writer after regular indexing equipment had failed to give accuracy required in cutting segment gear and pinion for model of new machine; gears having prime numbers of teeth that cannot be readily spaced by dividing head can easily be cut by this method.

GEARS

NOISE TESTING OF GEAR BOXES. Gear Box Noise-Testing Machine. Machy. (Lond.), vol. 31, no. 786, Nov. 3, 1927, pp. 142-145, 8 figs. Apparatus for indicating and comparing magnitude of sound; by its use all kinds of gear units can be tested as simple production operation.

TOOTH-HARDNESS TESTING. Testing the Hardness of Gear Wheel Teeth. Engineer, vol. 144, no. 3751, Dec. 2, 1927, p. 635, 3 figs. Describes appliance produced by Vickers, Ltd., as adjunct to their diamond hardness-testing machine; in new attachment, mount of diamond is cut away so as to permit diamond to reach pitch line of tooth without interference from next succeeding tooth.

VARIABLE-SPEED. Novel Variable Gear. Autocar, vol. 59, no. 1674, Dec. 2, 1927, pp. 1166-1167, 6 figs. Two helical gear wheels and swashplate control mechanism, constituting multi-speed gear; operation; transverse-cam-rotation; obtaining reverse; clutch optional fitting.

GOLD MINES

QUEBEC. Developments in the Rouyn District, R. C. Rowe. Can. Min. Jl., vol. 48, no. 48, Dec. 1927, pp. 957-960, 3 figs. Real nature of district as gold-copper-zinc field was not realized until 1924; discusses origin of ores, Horne mine, Waite mine and prospects.

GOLD MINING

NOVA SCOTIA. Gold Mining in Nova Scotia, J. C. Murray. Can. Inst. Min. & Met.—Trans., Mar. 1926, 16 pp., 5 figs. Historical; Nova Scotia offers promise of large bodies of low- and medium-grade ore, and further assurance of abundant cheap power; super-added inducement of low working costs is due in part to cheap power, in part to character of ore deposits and in part to unusual accessibility of Nova Scotian gold fields.

GRINDING

AUTOMOBILE PARTS. Development in Cylinder Grinding, M. C. Hutto. Soc. Automotive Engrs.—Jl., vol. 21, no. 6, Dec. 1927, pp. 669-677, 13 figs. Manufacturing of more accurate pistons necessitated better cylinders; problem was to develop new grinding methods which would have four distinct improvements; greater accuracy, greater speed, better finish and lower cost; grinders recently developed have surpassed in performance expectations of designers.

External Grinding in Automotive Production, O. A. Knight. Soc. Automotive Engrs.—Jl., vol. 21, no. 6, Dec. 1927, pp. 708-712, 8 figs. Describes progress being made in machines and methods for external grinding, including plain cylindrical work, crankshafts, camshafts and other irregular work, and simultaneous grinding of two surfaces; classification of grinding finishes.

GRINDING MACHINES

CAM-GRINDING ATTACHMENT. Norton Automatic Indexing Cam-Grinding Attachment. West. Machy. World, vol. 18, no. 11, Nov. 1927, p. 552, 2 figs. Applied to Norton type A and type BA cylindrical grinding machines and used for grinding cams integral with shaft.

FACE-MILL. Oliver Face-Mill Grinder. West. Machy. World, vol. 18, no. 11, Nov. 1927, p. 551, 1 fig. For sharpening face-milling cutters; grinds face and periphery of cutting blade at one pass of wheel and forms circular corner joining two; adaptable to grinding requiring radial motion of grinding wheel or combination of straight and radial grinding.

SURFACE. Vertical Spindle Internal and Surface-Grinding Machine. Machy. (Lond.), vol. 31, no. 788, Nov. 17, 1927, pp. 206-207, 2 figs. Specially designed for internal grinding of laminations in stator cases, though it may be equally well employed on general internal-grinding operations, where work can revolve.

TOOL-SPINDLE. Heavy Duty Self-Contained Machine Tool Spindle Grinding Machine. West. Machy. World, vol. 18, no. 11, Nov. 1927, pp. 552-553, 1 fig. Developed by Cincinnati Grinders, Inc., for giving good finish and accurate surface to large machine-tool spindles; massive wheel slide; forced lubrication of tableways.

H

HEAT, CEMENT

HEAT CHANGES DURING SETTING. Heat Changes During Setting of Alumina and Portland Cements, A. A. Jakkula. Eng. News-Rec., vol. 99, no. 24, Dec. 15, 1927, pp. 955-956, 3 figs. Tests show temperature of alumina cement mix four times that of portland and heat generated twice as great.

HEATING AND VENTILATION

OFFICE BUILDINGS. Saving Heat in Skyscrapers, F. C. Houghten and M. E. O'Connell. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 33, no. 11, Nov. 1927, pp. 639-652, 16 figs. Air-leakage studies on metal windows in modern office building reveal effectiveness of weather-stripping in reducing heat losses. See also Dom. Eng. (N.Y.), vol. 21, no. 10, Dec. 3, 1927, pp. 23-25 and 43, 45, 47-48 and 51, 16 figs.

HEATING, HOUSE

FUELS FOR. Tests of Various Fuels Made in a Domestic Hot-Water Boiler at the Fuel Testing Station in Co-operation with the Dominion Fuel Board, E. S. Malloch and C. E. Baltzer. Can. Dept. Mines—Investigations of Fuels and Fuel Testing, no. 671, 1927, pp. 33-63, 7 figs. Investigation to ascertain relative value of various fuels for domestic heating; this was accomplished by comparing behaviour of each fuel, when burned in standard type of domestic heater, with that of typical sample of American anthracite coal.

HIGH VOLTAGES

HAZARDS PREVENTION. Prevention of High-Voltage Hazards in Industrial Substations, W. C. Wagner. Indus. Eng., vol. 85, no. 11, Nov. 1927, pp. 525-526, 3 figs. Reviews present problems, indicates progress of recent developments, and outlines trend of rules and regulations upon which to depend for guidance.

HIGHWAYS

CALCIUM CHLORIDE, USE OF. Use of Calcium Chloride for Highways, H. F. Clemmer. Can. Engr., vol. 53, no. 18, Nov. 1, 1927, pp. 495-497. Elimination of dust nuisance on gravel roads; method of application; curing concrete and accelerating setting. Paper presented at Southwest Road School and Show, Wichita, Kansas.

HYDRAULIC PRESSES

WELDED. Welded Press Has 1,000-Ton Capacity. Welding Engr., vol. 12, no. 10, Oct. 1927, pp. 29-31, 7 figs. When Pacific Steel Boiler Corp. needed new heavy-duty hydraulic press, conventional designs were discarded and new and unique construction was devised in order to take fullest advantage of strength and economy of welded joints.

HYDRAULIC TURBINES

DESIGN. A Method of Obtaining the Leading Dimensions and of Setting Out the Blade-Forms for Hydraulic Turbines of the Francis Mixed-Flow and Propeller Types, H. Mawson. Inst. Civil Engrs.—Eng. Paper, no. 48, 1927, 22 pp., 8 figs. Conditions under which turbines are required to operate differ widely, and it is necessary to prepare designs for wide range of specific speeds; configuration of runner and shape of blades alter for different conditions; shows how these may be adjusted to satisfy various requirements.

HYDRAULICS

EROSION, NIAGARA FALLS. Experimental Work at Niagara Falls. Can. Engr., vol. 53, no. 20, Nov. 15, 1927, pp. 523-524. Erosion at centre of Horseshoe Falls proceeding at rate of 6 ft. per year; construction of islands proposed to distribute flow over entire length of crest; large model of falls built for experimental purposes.

HYDRO-ELECTRIC DEVELOPMENTS

NEW BRUNSWICK. Construction Methods on Grand Falls, N.B., Hydro-Electric Development. Contract Rec., vol. 41, no. 47, Nov. 23, 1927, pp. 1187-1192, 14 figs. Construction details of dam, tunnel, intake, power house and penstocks.

CANADA. Canadian Electrical Development, F. R. Ewart. World Power, vol. 8, no. 47, Nov. 1927, pp. 246-252. Explains financial basis of Hydro-Electric Power Commission of Ontario; influence of cheap electricity on development of mining, pulp and papermaking industries in Northern Ontario; effects of policy of service in development of domestic load is evidenced by citation of few convincing statistics; possibilities of power development.

Hydraulic Power Developments in British Columbia. Engineer, vol. 144, no. 3751, Dec. 2, 1927, pp. 622-623, 4 figs. on p. 630. Account of Bridge river project; Alouette, Stave Falls and Ruskin development.

The Alouette Power Project of the British Columbia Electric Railway Co. Contract Rec., vol. 41, no. 46, Nov. 16, 1927, pp. 1160-1164, 7 figs. Construction of dam, tunnel, power house and transmission line at Alouette lakes near Vancouver.

HYDRO-ELECTRIC PLANTS

GRAND FALLS, N.B. Power Development at Grand Falls, N.B., A. C. D. Blanchard. Can. Engr., vol. 53, no. 22, Nov. 29, 1927, pp. 559-562, 6 figs. Constructional features of hydro-electric development for St. John River Power Co. Paper presented before Toronto Branch of Eng. Inst. of Canada.

I

INDUSTRIAL MANAGEMENT

COMPLAINTS, HANDLING. How to Handle Complaints, A. J. Smith. Indus. Mgmt. (Lond.), vol. 14, no. 11, Nov. 1927, pp. 412-413. Vital importance of complaints and their possible effect upon future business is in many works sufficient to justify appointment of special executive to deal with all such matters; where such procedure is not possible it will be found on whole that subject can better be dealt with on sales side of organization rather than production side.

DEPRECIATION. Depreciation, J. C. Rath. Soc. Indus. Engrs.—Bul., vol. 9, no. 10, Oct. 1927, pp. 9-17. Its meaning and importance in present-day business practice.

MANUFACTURING OPERATIONS, ANALYSIS OF. How to Analyze Manufacturing Operations, A. B. Segur. Soc. Indus. Engrs.—Bul., vol. 9, no. 10, Oct. 1927, pp. 3-8. To author's mind, most accurate method, in every way, is calculation of rate from time laws of motion and from motion required to obtain quality desired on that particular operation.

NON-PRODUCTIVE PLANNING DEPARTMENT. Linking Maintenance with Production and Costs, C. L. Bonnett. Indus. Mgmt. (N.Y.), vol. 74, no. 6, Dec. 1927, pp. 343-349, 4 figs. Non-productive work as referred to covers that phase of work involved in furnishing and maintaining buildings, machinery, tools, gauges miscellaneous equipment and all items that make up plant and property.

PLANT-ENGINEERING DEPARTMENT. Management and the Plant Engineer, K. D. Hamilton. Factory, vol. 39, no. 5, Nov. 1927, pp. 815-817 and 854. Points out that management too often overlooks direct relation which exists between operation or production expense and low maintenance costs; plant-engineering department, while not actively engaged in production, maintains and operates equipment to keep machinery in continuous production.

PRODUCTION CONTROL. Simplified Production Control, K. R. Wood. Indus. Mgmt. (N.Y.), vol. 74, no. 6, Dec. 1927, pp. 350-353, 5 figs. Describes signaling system for directing work in various divisions of plant, that brings in close touch control department and production departments, all centralized so as to be under one-man control.

PRODUCTION PLANNING. Planning for the Small Manufacturer, F. A. R. Paton. Indus. Mgmt. (Lond.), vol. 14, no. 11, Nov. 1927, pp. 409-411. Shows how schemes may be advantageously applied to small works, and how they may be introduced.

TIME STUDY. *See Time Study.*

INDUSTRIAL PLANTS

MECHANIZATION. Mechanizing of Industrial Establishments, G. F. Zimmer. Indus. Mgmt. (Lond.), vol. 14, no. 11, Nov. 1927, pp. 397-399, 3 figs. Demonstrates that while mechanizing of industry was successfully accomplished half a century ago when labour was inexpensive, logical conclusion of that fact should be universal application of such mechanizing to-day, when labour is so much more expensive.

INTERNAL-COMBUSTION ENGINES

CONNECTING RODS, SHOCKS. Shocks in Connecting-Rod Heads (Contribution à l'étude des chocs dans les têtes de bielles), A. Planiol. Technique Automobile et Aérienne, vol. 18, no. 138, May 30, 1927, pp. 76-84, 12 figs. Importance of subject; theoretical analysis on basis of old Bertin theory; experimental study of a Winterthur engine.

CORROSION. Corrosion Detected by D.O.C. Test, H. J. Young. Oil & Gas Jl., vol. 26, no. 27, Nov. 24, 1927, pp. 146-148. Severe corrosion having occurred on pins and journals of crankshafts of two motorships it fell to author to ascertain cause and if possible to find remedy; he devised what he calls direct oil-corrosion test, performed by means of apparatus whereby warm oil is run continuously over warm steel, white motal, brass, copper or any other metal.

EXHAUST-GAS ANALYSIS. Interpretation of Exhaust Gas, C. C. Minter. Soc. Automotive Engrs.—Jl., vol. 21, no. 5, Nov. 1927, pp. 573-575. Author explains chemistry involved in combustion in effort to arrive at more accurate knowledge of constituents of exhaust gas; sets forth simple stoichiometric relations that exist between products of combustion of hydro-carbon fuel; correction factors that must be introduced in applying these ideal relations to combustion under actual engine conditions.

ITALIAN CONGRESS. Italian Engineers Hold Internal Combustion Engine Congress. Automotive Industries, vol. 57, no. 25, Dec. 17, 1927, pp. 900-901. Motor fuels, detonation, control of combustion in cylinders; flexibility of engine operation and vibration discussed; tribute paid to Bernardi; transformation of gaseous mixture during working stroke; inertia phenomena in intake systems.

See also Airplane Engines; Diesel Engines; Oil Engines.

L

LAKES

LEVELS, CHANGING. Conservation or Confiscation. Minn. Federation Arch. & Eng. Soc.—Bul., vol. 12, no. 11, Nov. 1927, pp. 11-24. International Joint Commission is investigating and preparing to report as to whether levels of certain lakes forming boundary between Minnesota and Ontario shall be changed; plan is to make certain changes in dams and to build seven new storage dams.

LEAD METALLURGY

EXTRACTION. Lead—Its Extraction and Application, R. C. Rowe. Can. Machy., vol. 38, no. 20, Nov. 17, 1927, pp. 15-18. Discussion of utility of lead in every-day life from earliest times to present day; past and present processes for extracting lead from its ores.

LOCOMOTIVES

OIL-ELECTRIC. Oil-Electric Locomotive Shows Fitness for Passenger Service. Compressed Air Mag., vol. 32, no. 12, Dec. 1927, p. 2251. Results of test which consisted of run of 183.7 miles on Erie Railroad from Hornell, N.Y., to Meadville, Pa.; performance was outstanding success.

STOKER FIRING. Stoker Firing of Engines. Ry. Jl., vol. 33, no. 12, Dec. 1927, pp. 33-34. Subcommittee's report before Ry. Fuel Agents' Convention. There is still, without doubt, great opportunity on most railroads to effect further reduction in fuel consumption on locomotives through improved firing practice.

LUBRICATION

SYSTEM FOR MACHINES. Dot Centralized Lubricating System. Am. Mach., vol. 67, no. 24, Dec. 15, 1927, pp. 953-954, 2 figs. Number of bearings upon machine or group of machines or upon line and countershaft oiled simultaneously from central point; comprises pump or means to introduce oil, metering valve, knuckle relief valve, pipe and fittings; hand or power operation.

LUMBER

DRYING. The Practicability of Drying Green Lumber, W. I. Willard. Woodworker, vol. 46. no. 9, Nov. 1927, pp. 35-37, 2 figs. Drying of green or nearly green stock is phase of lumber treatment which is receiving more and more attention; lumber should be thoroughly dried at point of production, and in most economical manner; emphasizes practicability of drying green stock successfully. Offsets erroneous impression that air seasoning is essential factor in successful drying of lumber.

M

MACHINE SHOPS

POWER DISTRIBUTION. Power Distribution in a Large Machine Shop, F. E. Gooding and C. E. Brown. Indus. Eng., vol. 85, no. 11, Nov. 1927, pp. 520-522, 8 figs. Cincinnati Milling Machine Co.'s layout for power and lighting; a.c. and d.c. used purchased from outside; 150 kw. of a.c., 150 kw. of d.c. is maximum power requirement.

MACHINE TOOLS

LUBRICATION. Lubricating Machine Tool Bearings, F. Horner. Can. Machy., vol. 38, no. 21, Nov. 24, 1927, pp. 15-18, 11 figs. Discusses and illustrates variety of ways in which machine-tool lubrication may be accomplished for preservation of bearing surfaces against frictional deterioration or seizure.

STANDARDIZATION. Tool Standardization. Soc. Automotive Engrs.—Jl., vol. 21, no. 5, Nov. 1927, pp. 576-578, 4 figs. Tools and details of jigs and fixtures standardized in Beloit plant.

SWAGING. Dayton-Torrington Improved 4-Die Swaging Machine. Am. Mach., vol. 67, no. 23, Dec. 8, 1927, pp. 921-922. Increased capacity for No. 3 size.

MACHINING METHODS

LOBE-SHAPED BORES. Machining Casting with Lobe-Shaped Bore. Machy. (Lond.), vol. 31, no. 787, Nov. 10, 1927, pp. 180-181, 4 figs. Fixtures and tools designed for machining operations on exhaust-pump castings.

MAGNETIC FIELDS

GRAPHICAL DETERMINATION. Graphical Determination of Magnetic Fields Theoretical Considerations, A. R. Stevenson, Jr., and R. H. Park. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, p. 1389. History; ordinary rules for plotting magnetic flux in air and in current-carrying copper; additional rules for checking accuracy of field plots; theoretical methods for mathematically calculating distribution of field in certain cases.

INTERPOLAR. The Interpolar Fields of Saturated Magnetic Circuits, T. Lehmann. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1411-1414, 4 figs. Effect of assuming infinite permeability in iron on accuracy of calculations of interpolar fields in electric machines; direct development of sketch in air gap in interpolar space and in slots when magnetic circuit is saturated.

MANGANESE STEEL

LOW-CARBON. Some Characteristics of Low-Carbon Manganese Steel, V. N. Krivobok, B. M. Larsen, W. B. Skinkle and W. C. Masters. Am. Inst. Min. & Met. Engrs. Tech. Publication, no. 24, Nov. 1927, 30 pp., 32 figs. It can be manufactured in either basic or acid open-hearth or electric furnaces, available manganese alloys giving any desired composition; finishing of manganese heat in furnace, and use of silico-manganese for making low-carbon heats involve special problems in furnace operation which are not yet entirely solved and deserve further study; it may be useful chiefly in field of cheaper alloy steels, where large tonnages are desired of steel with properties superior to those of ordinary open-hearth carbon steels; double heat treatment is necessary to bring out best properties.

MATERIALS HANDLING

DUMPING MACHINERY. Mechanical Dumping (Maschineller Kippbetrieb), F. Heintze. Bautechnik, vol. 5, no. 48, Nov. 4, 1927, pp. 695-698, 8 figs. Construction and operation of Krupp and other German elevating and dumping belt conveyors, on booms as long as 72 m., combined with bucket excavators; uses in mining, dam construction, earthwork, etc.

METALS

COLD-ROLLED. The Structure of Cold-Rolled Metals (Beiträge zur Kenntnis der Struktur kaltgewalzter Metalle), F. Wever and W. Schmidt. Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung zu Düsseldorf, vol. 9, no. 17, paper no. 90, 1927, pp. 265-272, 39 figs., partly on supp. plates. Deals with structure analysis of rolled aluminum, copper and silver; recrystallization process of aluminum.

IMPURITIES. Impurities. Metallurgist (Supp. to Engineer), Nov. 25, 1927, pp. 162-163. In cases mentioned effects of impurities are most important from point of view of mechanical properties of metals and alloys concerned; from viewpoint of electrical industry, however, electrical and magnetic properties are even more important, and this opens up wider field of research and one involving study of much more minute quantities of impurity as affecting properties of high-purity metals.

MICROSCOPIC EXAMINATION. The Microscopic Examination of Engineering Materials, A. B. Everest. Rugby Eng. Soc.—Proc., vol. 21, 1926-1927, pp. 15-36, 31 figs. Demonstrates how microscope is becoming more and more basis of testing of many engineering materials; microstructure of metals, and its relation to thermal and mechanical treatment; in special case, relation between microstructure and physical properties of series of alloys is discussed, showing how, within limits, microscope can form basis of investigation of such series; micro-examination of some special materials, notably of electrical insulators.

MINING INDUSTRY

BRITISH COLUMBIA. Mining Conditions in British Columbia, H. Browning. Can. Min. Jl., vol. 48, no. 48, Dec. 1927, pp. 963-965. Mining companies still find many attracting propositions; copper, gold, lead and non-metallic production statistics.

MOULDING METHODS

AMERICAN PRACTICE. American Foundry Practice. Foundry Trade Jl., vol. 37, no. 586, Nov. 10, 1927, p. 102, 3 figs. Moulding methods in America are very different from British, and this difference is constituted of many items, such as extended use of wooden moulding boxes; large number of snap-flask boxes; varying qualities of moulding sand; different bonds used in sand; and many small items which tend to create speed.

MOULDS

DRIERS. Electric Mould-Drying Unit. Iron Age, vol. 120, no. 21, Nov. 24, 1927, p. 1456. Heating unit for drying large sand moulds in brass, steel or iron foundries, designed by Gen. Elec. Co. to obviate attention required by kerosene lamps, stoves, coke or coal fires usually employed.

WATER-COOLED. Water-Cooled Moulds in Brass Foundries. Metal Industry (Lond.), vol. 31, no. 20, Nov. 18, 1927, pp. 465-466, 7 figs. Probably most serviceable and convenient type of chill mould is Junker water-cooled mould; these moulds are scientifically designed and calculated to give continuous and effective service of precisely the nature to give best physical structure, density and condition in resulting slabs, and therefore to produce ultimately far better and more uniform sheets than can be obtained by use of old-fashioned cast-iron chill moulds.

MOLYBDENUM

USES. Molybdenum and Its Uses, W. H. Phillips. Can. Machy. & Mfg. News, vol. 38, no. 18, Nov. 3, 1927, pp. 23-24. Forging and rolling; ease with which molybdenum can be added to iron or steel insures good results in melting operation; alloy recovery is exceptionally high, running up to 98 to 99 per cent; molybdenum in all scrap can be fully recovered; its use in iron. Abstract of lecture presented before Montreal Chapter of Am. Soc. for Steel Treating.

MOTOR BUSES

DESIGN. Motorcoach Design, K. J. Ammerman. Soc. Automotive Engrs.—Jl., vol. 21, no. 6, Dec. 1927, pp. 653-659, 6 figs. Topics discussed include effects of excessive overhang, importance of proper weight distribution, baggage problem, value of sturdy appearance, economy of standard body building and costs imposed by deviations from standardized design; methods of construction; views of several leading types of motor coach.

GENERAL MOTORS CO. New General Motors Buses Powered with Buick Engines, A. F. Denham. Automotive Industries, vol. 57, no. 23, Dec. 3, 1927, pp. 834-835. Two chassis, designed for city and school service respectively, are announced; former has wheelbase of 162 in.; school bus seats 42, city 21, balloon tires used dual on rear.

OLYMPIA SHOW, ENGLAND. The Commercial Vehicle Exhibition at Olympia. Engineering, vol. 37, nos. 3227, 3228 and 3229, Nov. 18, 25 and Dec. 2, 1927, pp. 655-658, 694-696 and 703-705, 55 figs. partly on supp. plates. Tendency in design as featured by exhibits; it is considered essential that commercial vehicles, particularly those of passenger type, should be capable of relatively high speeds, and this has led to adoption of highly efficient engines; employment of low-level frames. See also Elec. Ry. & Tramway Jl., vol. 57, no. 1426, Nov. 18, 1927, pp. 324-340, 34 figs.. and Engineer, vol. 144, nos. 3749 and 3750, Nov. 18 and 25, 1927, pp. 566-568 and 596-598, 13 figs.

STREET-CAR TYPE. Will New Street Car Models Extend Economic Field of the Bus? D. Blanchard. Automotive Industries, vol. 57, no. 25, Dec. 17, 1927, pp. 894-897, 5 figs. Increased carrying capacity to give wider field without offsetting increase of operating costs; three makes on market; body maintenance uncertain; reduced storage costs.

MOTOR TRUCK TRANSPORTATION

FLEET-OPERATING COSTS. Using Truck-Opreating Costs to Increase Delivery Efficiency, A. W. Herrington. Soc. Automotive Engrs.—Jl., vol. 21, no. 5, Nov. 1927, pp. 535-538, 2 figs. In line with devising standard method of recording fleet operating costs so that they can be utilized comparatively, author cites supposed company in retail dairy business which has fleet of 30 vehicles, assumes definite monetary values for several factors constituting total cost, and analyzes entire problem in way to demonstrate fundamental principles of comprehensive system of accounting that will make evident all information sought.

RAILWAY AND. Co-ordinated Rail and Motor Truck Transportation, G. W. Dixon. Soc. Automotive Engrs.—Jl., vol. 21, no. 6, Dec. 1927, pp. 680-681. Five principal uses for motor truck and two secondary uses are cited; analysis is made of each of motor truck usages mentioned; it is stated that motor truck and semi-trailers bid fair to become economical auxiliaries to all-rail transportation.

N

NICKEL ALLOYS

NICKEL CAST IRON. Nickel Cast Iron, A. E. Hanson and E. J. Bothwell. Tech. Eng. News, vol. 8, no. 6, Nov. 1927, pp. 258-259 and 278, 4 figs. Description of properties of this new alloy, with reference to its economical use as engineering material.

NUTS

DRIVING MACHINES. Reynolds Nut-Driving Machine. Am. Mach., vol. 67, no. 32, Dec. 1, 1927, pp. 872-873, 2 figs. Such work as assembling of bearing caps; valve bonnets, motor end plates, connecting rods preparatory to reaming, or any work that requires nuts or caps to be driven and tightened in pairs; can be performed on two-spindle machine made by Metalwood Mfg. Co. See also Automotive Industries, vol. 57, no. 24, Dec. 10, 1927, pp. 874-875, 1 fig.

O

OIL ENGINES

DEVELOPMENTS. Oil Engines, J. F. Alcock. Instn. Petroleum Technologists—Jl., vol. 13, no. 63, Aug. 1927, pp. 601-607. Chief feature of year is construction of high-powered engines, mostly for passenger liners; high-speed engines; two-stroke engines; fuel injection; supercharging; hot-bulb engines.

HEAVY OIL. Economics of the Crude Oil Engine Plant, J. H. Dodd. Commonwealth Engr., vol. 15, no. 2, Sept. 1, 1927, pp. 54-56, 1 fig. During past five years considerable progress has been made in Australia in connection with installation of crude-oil engine plants; these installations have been mainly for generation of electrical energy.

LUBRICATION. How Lubricating Oil Can Retain Its Youth, B. C. Oldham. Power, vol. 66, no. 21, Nov. 22, 1927, pp. 788-791, 3 figs. At least three problems are involved in lubrication of oil engines; one is method employed, another is selection of suitable grade of oil, and third is manner in which oil is handled; lubrication within crankcase; trunk-piston engine lubrication; carbon troubles.

SUPERCHARGING. A New System of Supercharging. Mar. Engr. & Motorship Bldr., vol. 50, no. 603, Nov. 1927, pp. 415-416, 2 figs. With object of obtaining more power from given cylinder volume than is possible with their standard system of scavenging with double row of superimposed parts, Sulzer Bros., Switzerland, have developed new method of supercharging two-stroke cycle heavy-oil engines of their design, whether of land or marine type; essential feature of new method consists in introducing certain quantity of charging air at about 0.8 atmos. pressure into working cylinder immediately after termination of normal scavenging process.

OIL FIELDS

BRITISH EMPIRE. Progress and Prospects of Production, E. H. Cunningham-Craig. Empire Min. & Met. Congress—Advance Paper, Aug. 22-Sept. 29, 1927, 18 pp. Possibilities of future production from (1) producing fields, (2) probable fields, (3) areas of retortable material in India, Trinidad, Canada, Barbados, Australia, New Zealand, South Africa, Great Britain, etc.

CANADA. Petroleum and Natural Gas in the Dominion of Canada, J. Ness. Empire Min. & Met. Congress—Advance Paper, for mtg. Sept. 20, 1927, 127 pp., 15 figs. Review of Dominion's proved, possible and probable oil fields; oil and gas in Maritime provinces, Ontario, great plains of western Canada, foothills belt of Alberta and British Columbia and Mackenzie river area.

OIL FUEL

AUTO-IGNITION TEMPERATURE. Study of Auto-Ignition Temperatures, H. J. Masson and W. F. Hamilton. Indus. & Eng. Chem., vol. 19, no. 12, Dec. 1927, pp. 1335-1338, 1 fig. Study of various factors affecting auto-ignition temperatures; as result new form of apparatus has been developed of high accuracy and sensitivity together with simplicity of construction and operation; apparatus and technic may be modified to determine auto-ignition temperatures of solids and gases in any surrounding atmosphere at ordinary or increased pressures.

HOUSE HEATING. Mercoids Features Forecast of Oil-Burner Development, P. E. Fansler. Heat. & Vent. Mag., vol. 24, no. 11, Nov. 1927, pp. 110-111. Author conceives of home having in its cellar, or buried in ground, machine that will make from common oil fuels, stable gas, in quantities and at times wanted; machine might be of instantaneous type, making gas exactly as required, or it might incorporate small storage, maintaining this reserve always at definite minimum; this stable gas can be piped into and through home, supplying heat from combustion taking place in a specially designed heating plant that conceivably might show overall efficiency of 90 per cent; gas from same source would supply kitchen stove, domestic water heater, refrigerating unit, air-conditioning plant, etc.

MEASURING. Measuring Fuel Oils, A. F. Brewer. Indus. Power, vol. 8, no. 6, Dec. 1927, pp. 56-58, 3 figs. In fuel-oil burning systems both horizontal and vertical shortage tanks are encountered; to gauge or measure amount of fuel in such tanks, depth of oil can either be measured directly or distance from a fixed or gauging point at top of tank to surface of oil can be taken; by first method so-called "innage" is determined; second method is termed measuring "outage."

SYNTHETIC. Synthetic Fuels, A. W. Nash and O. C. Elvins. Instn. Petroleum Technologists—Jl., vol. 13, no. 63, Aug. 1927, pp. 597-601. Review of progress; pressure process for methyl alcohol is commercial success; it can be modified to yield liquids suitable for use as fuels, but evidence is not yet forthcoming that such modifications will be economic success; hydro-carbon formation at atmospheric pressure holds much promise for future of synthetic gasoline.

OPEN-HEARTH FURNACES

REFRACTORIES. Open-Hearth Steelworks Refractories, A. T. Green. Foundry Trade Jl., vol. 37, no. 583, Oct. 20, 1927, pp. 50-52. Bricks for port and top courses; highly converted silica unsuitable for open hearth; corrosion and erosion of open-hearth silica bricks; mechanism of corrosion and erosion; bricks from furnace roofs; thermal characteristics of chequerwork; materials for regenerators.

OIL INDUSTRY

LIGHTNING PROTECTION. Lightning Protection for the Oil Industry, E. R. Schaefer. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1358-1364, 11 figs. Design of system to offer high degree of protection for storage tanks in actual use; record of several hundred installations; network of pipe lines as ground for towers compared with single shaft driven vertically downward; their advantages.

OIL SHALES

DISTILLATION. Distillation of Oil Shale with Circulation of Uncondensed Gases, A. A. Swinnerton. Can. Dept. Mines—Investigations of Fuels and Fuel Testing, no. 671, 1927, pp. 176-184, 1 fig. Three runs at different rates of circulation were made on standard oil shale sample for purpose of determining comparative value of distilling oil shale with circulation of hot uncondensed gases.

OILS

ANALYSIS. Analyses of Oils and Liquid Fuels, P. V. Rosewarne. Can. Dept. Mines—Investigations of Fuels and Fuel Testing, no. 671, 1927, pp. 167-175. Results obtained from analyses of miscellaneous samples of oils and liquid fuels submitted to fuel testing laboratories for examination by various departments of government, by corporations and by private individuals.

OXY-ACETYLENE CUTTING

ECONOMICAL APPLICATIONS. Economical Oxy-Acetylene Cutting Needs Intelligent Supervision. J. L. Anderson. Iron Trade Rev., vol. 81, no. 23, Dec. 8, 1927, pp. 1421-1423 and 1428, 3 figs. Calls attention to importance of oxy-acetylene cutting process from oxygen-consumption standpoint; factors that enter into economical application of this process.

OXY-ACETYLENE WELDING

ANNEALING PIPE JOINTS. Annealing Welded Pipe Joints. Acetylene Jl., vol. 29, no. 5, Nov. 1927, pp. 195-196, 3 figs. High-pressure steam main, 18 in. in diameter with steel wall ½ in. thick was constructed with chamfered edges for oxy-acetylene welding of joints; following completion of each weld, all joints were annealed six inches on each side of weld, being heat treated with use of McKneat atomizing burner.

ENGINE CASTINGS. Oxy-Acetylene Welding of Oil Engine Castings. Oil Engine Power, vol. 5, no. 12, Dec. 1927, pp. 829-830, 1 fig. Problems involved in welding large complicated grey iron castings such as are used in oil engines consist mainly in controlling heat of welding operations so that there will be no warping out of true nor cracking due to internal stresses.

PIPE LINES. 500,000 Ft. of Welded Piping in One Building, C. Kandel. Acetylene Jl., vol. 29, no. 5, Nov. 1927, p. 202. In erection of new 16-storey Nurses' Home forming part of Mt. Sinai Hospital, New York, all steam, brine and hot-water pipe lines are welded.

PRACTICAL APPLICATIONS. Practical Oxy-Acetylene Welding, R. Granjon, P. Rosemberg and A. Desgranges. Welding Jl., vol. 24, nos. 284, 285, 286, 287, 288 and 289, May, June, July, Aug., Sept. and Oct. 1927, pp. 140-143, 174-176, 208-211, 237-239, 264-266 and 319-321, 142 figs. May: Welding of cast iron. June: Special and malleable cast iron; welding of aluminum. July: Light alloys of aluminum. Aug.: Duralumin and special alloys; welding of copper. Sept.: Welding of brasses. Oct.: Bronzes and miscellaneous metals and alloys.

PRESSURE VESSELS. Searching Tests of Welded Joints. Iron Age, vol. 120, no. 21, Nov. 24, 1927, pp. 1445-1446. Sponsored by International Acetylene Assn. in study of pressure vessels; value of various gases for cutting flame compared.

STEAM PIPES. Built for the Ages. Oxy-Acetylene Tips for the Linde Ox-Welder, vol. 6, no. 4, Nov. 1927, pp. 61-62, 4 figs. Welded steam piping for heating and snow removal sealed permanently in masonry walls of great cathedral on Morningside Heights in New York City.

P

PAVEMENTS

STEEP GRADES. Types and Costs of Paving on Steep Grades. Am. City, vol. 37, no. 6, Dec. 1927, p. 730. New York states practice where grades are 5 per cent or greater.

PAVEMENTS, ASPHALT

MAINTENANCE MACHINE. Welding Pavements with Oil Heat, C. M. Perkins. Fuel Oil, vol. 6, no. 6, Dec. 1927, pp. 19-20. Luts surface heater consists of oil flame generator contained in hood, by means of which heat can be applied to spot seven feet square; hood is attached by two hinged steel members to frame of rugged truck, and two cables, actuated by hydraulic cylinder using oil from power-driven pump, raise or lower hood when desired.

MIXTURES. The Theory and Practice of Asphalt Paving Mixtures, A. W. Dow. Good Roads, vol. 70, nos. 9 and 10, Sept. and Oct. 1927, pp. 390-392 and 436-437. Sept.: Investigations to determine general formula for asphalt paving mixtures; studies of void determinations on mineral aggregates; surface mixtures. Oct.: Selective absorption; stability vs. pliability.

PAVEMENTS, BRICK

BASES. Bases for Brick Pavements. Highway Mag., vol. 18, no. 12, Dec. 1927, pp. 318-320. Deals with concrete and rolled-stone bases; resurfacing old pavements.

PIPE, CAST-IRON

BRONZE-WELDED JOINTS. New High-Strength Joint. Oxy-Acetylene Tips, vol. 6, no. 4, Nov. 1927, pp. 72-76, 5 figs. Shear-vee type joint for bronze-welding cast-iron pipe develops practically full strength of pipe.

An Improved Joint Design for Bronze-Welded Cast Iron Pipe, T. W. Greene and F. G. Outcault. Gas Age-Rec., vol. 60. no. 20, Nov. 12, 1927, pp. 741-742, 4 figs. Average results of tests indicate that strength of bronze collar joint is only about 55 per cent of strength of pipe.

PNEUMATIC TOOLS

RIVETING AND DRILLING. Pneumatic Tools for Riveting, Drilling and Other Operations. Iron Age, vol. 120, no. 23, Dec. 8, 1927, p. 1596, 1 fig. Semi-portable radial pneumatic general-purpose tool of Guardian Products Co., Cleveland, consists of frame that swings on wall bracket, air-operated mechanism and pneumatic hammer that is clamped to two arms that form outer end of frame.

USES OF. Some New Uses for Pneumatic Tools, A. P. Darcel. Can. Engr., vol. 53, no. 22, Nov. 29, 1927, pp. 569-572, 5 figs. Brief survey of air tools used in timber construction work; records of performance; labour-saving features; where air tools are used; use of tools on dock construction at Wolfe's Cove, P.Q.

POLES

STEEL-CONCRETE. Fabricated Pole Requires No Skilled Labour. Elec. World, vol. 90, no. 22, Nov. 26, 1927, p. 1085. Steel-concrete poles for transmission lines have been developed for use in Australia in endeavour to produce pole that is strong, cheap and readily assembled; they consist essentially of two standard rolled steel channel sections, which form basis for pole construction and may be shipped in quantities to field and when bolted together filled with mixture of concrete, stone and sand.

PRODUCER GAS

BOILER FIRING. The Application of Producer Gas Firing to Waste-Heat Boilers, C. F. W. Rendle. Gas World, vol. 87, no. 2258, Nov. 12, 1927, pp. 450-457 and (discussion) 457-458, 7 figs. Describes new plant working on such lines which has been installed at Redditch; reasoning which led to adoption of boiler dealing jointly with flue gases from retort settings and products from combustion of producer gas made in separate producer. See also Gas Jl., vol. 180, no. 3365, Nov. 16, 1927, pp. 451-457, 8 figs.

PULLEYS

COMPRESSED SPRUCE. Compressed Spruce Pulleys and Gears. Chem. & Met. Eng., vol. 34, no. 12, Dec. 1927, p. 766, 2 figs. Laminated spruce blocks are being used in manufacture of wide variety of sizes of gears and pulleys.

PULVERIZED COAL

CENTRAL STATIONS. Pulverized Fuel Plants, L. C. Harvey. World Power, vol. 8, no. 47, Nov. 1927, pp. 262-270, 12 figs. Economic possibilities of pulverized fuel for power-house applications lie not alone with central system, but with recently developed self-contained unit system; for superpower-station purposes, central system is advocated, but for lesser power station examples are cited in evidence of advance made with unit pulverized equipment; progress has been due to reduction in equipment cost, cost of maintenance of mill parts, power consumption and by introduction of turbulent mixing of fuel and air supplies.

MARINE BOILERS. Pulverized Coal Tests of Marine Watertube Boiler, T. B. Stillman. Mar. Eng. & Shipg. Age, vol. 32, no. 12, Dec. 1927, pp. 669-675, 12 figs. Results of tests with standard Babcock and Wilcox watertube boiler show that pulverized coal can be burned efficiently at high rates of combustion; directly comparable tests using oil, pulverized coal and hand-fired coal were made on this same boiler; efficiency curve of these three methods of firing are shown.

PULVERIZERS. The Rema Pulverizing Mill. Eng. & Boiler House Rev., vol. 41, no. 5, Nov. 1927, p. 239, 2 figs. Low-speed pulverizing mill embodies free-running grinding ring made of manganese or other very hard steel, inside which three specially hard crushers revolve, top crusher being mounted on driving shaft and forms driver.

TURBULENT BURNERS FOR. Turbulent Burners for Pulverized Coal, S. C. Martin. Power Plant Eng., vol. 31, no. 22, Nov. 15, 1927, pp. 1181-1185, 12 figs. To secure proper mixture of pulverized coal and combustion air and to shorten flame travel, thus decreasing furnace volume, various types of burners have been developed.

PUMPING STATIONS

STANDBY UNITS. Standby Units for Pumping Stations, R. C. Dennett and G. L. Swan. Can. Engr., vol. 53, no. 22, Nov. 22, 1927, pp. 547-549. Reliability features of electrically-operated pumping stations; storage tanks, steam pumps, internal combustion engines and electric motors are some of units. Paper presented to New England Water Wks. Assn.

PUMPS

AIR-JET LIFT. The Air-Jet Lift, S. C. Martin. Indus. & Eng. Chem., vol. 19, no. 12, Dec. 1927, pp. 1346-1348, 4 figs. Device comprises arrangement of piping and valves connected by foot piece which constitutes pump proper, together with compressed-air supply pipe and eductor or discharge pipe; equipment required for operation of lift consists of compressor, air receiver, necessary pipe lines and discharge piece or fitting.

R

RADIATORS

TESTING. Proposed Methods for Testing Radiators, F. C. Haughton and S. R. Lewis. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 33, no. 12, Dec. 1927, pp. 697-706, 1 fig. Defines radiators, castings, relation of radiator room and occupant and describes ideal and practical test room with methods of testing.

RADIOTELEGRAPHY

ANTENNAS. Directional Radiation with Horizontal Antennas, A. Meissner. Inst. Radio Engrs.—Proc., vol. 15, no. 11, Nov. 1927, pp. 928-934, 7 figs. Attempt was made to concentrate radiation energy by combining several antennas.

RADIOTELEPHONY

AMPLIFIERS. A Compact Direct-Current Amplifier, H. C. Curl. Bell Laboratories Rec., vol. 5, no. 2, Oct. 1927, pp. 46-48. 6031-A amplifier made by West. Elec. Co.

RECEIVERS. The Power Supply of Wireless Sets. Elec. Rev., vol. 101, no. 2608, Nov. 18, 1927, pp. 856-857, 1 fig. "Batteryless" receiver; experience of engineer who constructed a set which incorporates three thermionic valves with indirectly heated filaments.

RAILS

TRANSVERSE FISSURES. Transverse Fissure Still a Mystery. Iron Age, vol. 120, no. 21, Nov. 24, 1927, p. 1435. There is no inherent reason for attaching responsibility for display of transverse fissures in rails to manufacturing conditions, either in making or rolling of steel, according to conclusions reached by Bur. of Safety, Interstate Commerce Commission, on basis of investigations it has conducted.

RAILWAY MOTOR CARS

DIESEL-ELECTRIC. The First All-American Diesel Rail Car. Oil Engine Power, vol. 5, no. 12, Dec. 1927, pp. 839-855, 13 figs. Description of Foos Diesel replacing old gasoline engine; also electric drive and its advantages; after month of operation on run between Monticello and Calmar, Iowa, indications are that on 200-mile trip per day there will be saving of from $3,500 per year for fuel alone.

STEAM. Rail Car Driven by Steam. Ry. Mech. Engr., vol. 101, no. 12, Dec. 1927, pp. 768-771. International Harvester high-pressure power plant, also adaptable to switch-engine drive, is distillate-burning, direct mechanical-drive unit designed to be noiseless, smokeless and easy riding, with ample power for hauling additional trailer tonnage; known as "Locomotor"; but one operator is required; passenger-baggage car 73 ft. long for 63 passengers. See also Fuel Oil, vol. 6, no. 6, Dec. 1927, pp. 54 and 56, 1 fig.

STREET-RAILWAY SERVICE. Mexican Street Cars Are Powered with Automobile Motors, T. Croft. Elec. Ry. Jl., vol. 70, no. 21, Nov. 19, 1927, pp. 933-935. In Merida, Yucatan, cars are all driven by standard Ford automobile engines; standard Ford parts are used wherever feasible; Ford gasoline tank is installed either horizontally under car seat or vertically in vestibule.

RAILWAY OPERATION

TRAIN CONTROL. Train Control Equipment on the C. & O. Ry. Elec. Engr., vol. 18, no. 11, Nov. 1927, pp. 373-379, 2 figs. Intermittent inductive type used on greater portion of line; testing device and methods for checking operation of apparatus.

RAILWAY SIGNALLING

AUTOMATIC. Buffalo, Rochester & Pittsburgh Has High Standard of Signal Maintenance. Ry. Signalling, vol. 20, no. 12, Dec. 1927, pp. 463-468. Signals are G.R.S. Model 2A, top-post mechanism except for distance of 24.91 mi., where Model 2A a.c. signals are in use; signals have been in service about 14 years; explanation of methods followed in signal department maintenance programme.

AUTOMATIC BLOCK. Colour-Light Automatic Block Signals Installed on the New York Central. Ry. Signalling, vol. 20, no. 12, Dec. 1927, pp. 451-455. Line control employed with centre-fed track circuits; special switch relays used to eliminate necessity of carrying line wires through switch boxes; equips West Shore line on section of West Shore from Selkirk, N.Y., to Utica and from Syracuse west to Buffalo.

RECTIFIERS

CUPROUS-OXIDE. Cuprous-Oxide Rectifier for Alternating Current. Engineering, vol. 124, no. 3226, Nov. 11, 1927, pp. 615-616, 6 figs. Consists essentially of disk of copper, on one face of which a layer of cuprous oxide has been formed at high temperature; it has been found that plate of this kind is unsymmetrical conductor of electricity; that is, resistance to passage of current in direction from oxide to copper to passage of current in opposite direction is in ratio of about 1:1,000 or even higher.

METAL. Westinghouse Metal Rectifiers. Elec. Times, vol. 82, no. 1883, Nov. 24, 1927, pp. 667-668, 4 figs. It has no contacts, moving parts or other features requiring maintenance; it is electronic device depending for its operation on electronic action at permanent junction between copper and copper oxide.

RAILWAY YARDS

CAR-REPAIR TRACKS. Modern Car Repair Tracks. Ry. Mech. Engr., vol. 101, no. 12, Dec. 1927, pp. 789-791. Central of New Jersey improves facilities at its Penobscot classification yard; Ashley planes unique feature in railroad operation; short time in which cars containing rush shipments can be repaired and returned to service is one of features in operation of repair tracks.

CAR RETARDERS. Modern Yard Operation, W. B. Rudd. Can. Ry. Club—Official Proc., vol. 26, no. 7, Oct. 1927, pp. 21-29. Points out advantages of car retarder for hump-yard operation.

RELAYS

OVERLOAD. Thermal Overload Relays. Power Engr., vol. 22, no. 261, Dec. 1927, pp. 446-447, 1 fig. Notes on protective devices for motors, based on thermal rather than electromagnetic principles; thermal overload relay is one of most pronounced advancements recently made for protecting motors in industrial service.

RESEARCH

FUNCTIONS. The Functions of Research, C. F. Kettering. Indus. & Eng. Chem., vol. 19, no. 11, Nov. 1927, pp. 1212-1216. Interpretation of science to public; one great function of research is determination of facts in terms of commercialism; translation of technical details into results; research organization.

PROFITABLE RESULTS FROM. Research—Source of New Profits, L. A. Hawkins. Factory, vol. 39, no. 5, Nov. 1927, pp. 796-799. Engineer of Research Laboratory of Gen. Elec. Co., Schenectady, gives numerous examples of benefits accruing from research; result of research competently carried on is often new product; two things are needed to make research laboratory successful; competent director, and adequate support from management; best results are attained with close co-operation, but complete independence of responsibility.

SCIENTIFIC. Specialization and Co-operation in Scientific Research, K. T. Compton. Science, vol. 66, no. 1715, Nov. 11, 1927, pp. 435-442. Suggests accomplishments and opportunities of research and indicates directions in which to bring about even more fruitful service of science to society in future.

RESERVOIRS

CONCRETE. Movable Forms Used in Construction of Concrete Reservoirs, E. F Rockwood. Boston Soc. Civ. Engrs.—Jl., vol. 14, no. 9, Nov. 1927, pp. 502-504, 2 figs. Wall and roof forms used in construction of covered reservoir on Neutaconkanut Hill and covered reservoir at Longview.

MERCIER RIVER, CANADA. The Mercier Reservoir on the Gatineau River. Contract Rec., vol. 41, no. 47, Nov. 23, 1927, pp. 1182-1185, 10 figs. Storage area created for benefit of power plants at Chelsea, Farmers and Paugan; features of project of impounding 95 billion cu. ft. of water in one lake by 10 dams; lake surface, 64,000 acres.

RIVETS

TENSILE STRESSES. Tensile Working Stress for Rivets, C. R. Young. Can. Engr., vol. 53, no. 18, Nov. 1, 1927, pp. 505-512, 12 figs. Results of tests conducted at Univ. of Toronto and other researches. Paper presented at Am. Inst. of Steel Construction.

WORKING STRESS. Tensile Working Stress for Rivets, C. R. Young. Can. Machy., vol. 38, no. 19, Nov. 10, 1927, pp. 34-37, 12 figs. Author emphasizes that determination of proper working stress for rivets is matter demanding serious consideration. Paper presented at Am. Inst. of Steel Construction.

ROADS

ASPHALTIC OIL SURFACES. Preserving Road Investment by Asphalt Surfacing. Eng. News-Rec., vol. 99, no. 23, Dec. 8, 1927, pp. 923-925. Growing field for bituminous secondary-type roads and for utilizing old surfacing as bases for asphaltic surfacing, discussed by Asphalt Road Conference; it has been found that rigid pavements nearing end of their service life can be preserved and made component part of new pavement by asphalt surfacing. Reviews four papers, as follows: Dimensions of America's Public Roads Undertaking, T. H. MacDonald; Gravel and Stone Bases for Asphalt Wearing Courses, K. N. Seymour; Cost and Service of Asphalt Surfacing on Low Cost Roads, C. N. Conner; Asphalt Surfaces for Reclaiming Concrete Roads, V. L. Ostrander.

CORRUGATIONS. Rhythmic Corrugations in Highways. State College of Wash. Eng. Bul., vol. 19, no. 9, Feb. 1927, 29 pp., 15 figs. Results of studies based on experiments carried out with oscillographic recorder in tonneau of car which gives record of variation in distance between rear axle and body while going over "washboards" and various other obstructions; tests show that rear axle frequently vibrates through vertical amplitudes many times greater than depth of corrugations; laboratory model of rear end of automobile was built; curves taken show relationship in time between rear axle and road surface and that at certain speeds greatest pressure of tire on road comes in trough of corrugation.

ROADS, EARTH

SURFACE TREATMENT. Surface Treatment of Topsoil Roads, J. T. Pauls. Pub. Roads, vol. 8, no. 9, Nov. 1927, pp. 191-202, 16 figs. Exposition of materials and methods to be used in surfacing top soil roads in South Carolina; experiments on 8 miles of road in Anderson county.

ROADS, GRAVEL

OILING. "Turnover" Method of Road Oiling. Pub. Wks., vol. 58, no. 10, Oct. 1927, pp. 377-381. California Highway Dept. has developed method of applying asphaltic oil to gravel road surfaces which has been given name of "turnover" method, and which is considered to produce excellent road at low cost. See also description, by E. B. Bail, in Roads & Streets, vol. 67, no. 10, Oct. 1927, pp. 429-432.

ROADS, MACADAM

CONSTRUCTION. Roads and Road Construction, J. A. Ryan. Instn. Civil Engrs. of Ireland—Trans., vol. 52, 1927, pp. 68-82. Water and tar-bound macadam; Trinidad asphalt macadam; bitumen-grouted roadway; cement-grouted macadam.

ROLLING MILLS

BLOOMING MILLS. Reversing-Blooming-Mill Practice, G. A. Russell. Mech. Eng., vol. 49, no. 12, Dec. 1927, pp. 1331-1334. Résumé of current practice, dealing with cogging, draughting practice, driving main rolls, reversing steam engines and motor drives, mill-train design, etc.

CALCULATIONS. Rolling Mill Calculations, J. D. Keller. Iron & Steel World, vol. 1, nos. 1, 2, 3, 4 and 5, Feb., Mar., Apr., May and June, 1927, pp. 37-42, 127-130, 199-200, 271-276 and 343-346, 20 figs. Analysis of stresses in 44-in. blooming mill for determining constants for use in design of new mills. Feb.: Gripping or biting of steel by rolls; stresses in rolls. Mar.: Maximum bearing pressure on roll necks; stresses in housings, screws and screw box. Apr.: Torsional strength of spindles and wobbler; stresses in pinions. May: Means to prevent overheating of motors. June: Time in mill approximately equals time on tables.

ELECTRIC DRIVE. Cold Rolling Mill of Recent Design, E. W. Duston. Blast Furnace & Steel Plant, vol. 15, no. 11, Nov. 1927, p. 551, 1 fig. Special design of electrically driven mill of six units which offers several distinct advantages, especially in manufacture of bolts and nuts.

Main Drives 10" Merchant Mill at McKinney Steel Company, A. F. Kenyon. Iron & Steel Engr., vol. 4, no. 11, Nov. 1927, pp. 455-457, 7 figs. Mill has roughing train driven by 1,000-h.p., 200/600-r.p.m. motor, intermediate train driven by 2,000-h.p., 137/275-r.p.m. motor and four finishing stands driven by 1,200-h.p. 300/550-r.p.m. motor.

ROPE DRIVE

CALCULATIONS FOR. Rope Transmission, L. T. Rutledge. Can. Machy., vol. 38, no. 23, Dec. 8, 1927, pp. 15-16. American or continuous drive; English or multiple-rope drive.

S

SAND, MOULDING

CONTROL. Practical Moulding Sand Control, N. D. Ridsdale. Foundry Trade Jl., vol. 37, no. 585, Nov. 3, 1927, pp. 79-82, 9 figs. Deals mainly with green sands such as are used for iron and brass founding, and indicates nature and value of small-scale tests both within and without laboratory for assisting practical moulder to use his sands to best advantage.

SEWAGE

CHLORINATION. Recent Developments in Sewage Chlorination. Pub. Works, vol. 58, no. 12, Dec. 1927, pp. 465-468. Effects and advantages, determination of amount required and point of application to secure best results.

SEWAGE DISPOSAL

ACTIVATED SLUDGE. Activated Sludge Digestion Characteristics, G. M. Fair and C. L. Carlson. Boston Soc. Civ. Engrs.—Jl., vol. 14, no. 9, Nov. 1927, pp. 487-494, 2 figs. Reports on certain experiments that were undertaken with view of determining digestion characteristics of activated sludge that might be manifested under different conditions of digestion; experiments discussed are results of digestion under six different conditions being given for purposes of comparison.

AERATION. Note on the Aeration of Water, G. J. Fowler and S. N. Chatterjee. Surveyor (Lond.), vol. 72, no. 1855, Aug. 12, 1927, p. 139. 1 fig. Results recorded show clearly truth of contention expressed by C. H. Hurd in Eng. News-Rec., Aug. 16, 1923, p. 248, that advantage of air circulation over mechanical agitation lies in fact that with equal opportunity for economy due to surface absorption of oxygen, there is assurance of always having sufficient quantity of entrained air to give positive oxidation throughout sewage mass. See also Eng. News-Rec., vol. 99, no. 23, Dec. 8, 1927, p. 922, 1 fig.

MIXING CHANNELS. Design of Mixing Channel Having Small Loss of Head, G. N. Cox. Pub. Works, vol. 58, no. 11, Nov. 1927, pp. 426-428, 3 figs. Experiments to determine type of baffled channel giving most thorough mixing with least loss of head.

PUMPING STATIONS. Future Pumping Station Used for Sewage Treatment, H. Burdett. Pub. Wks., vol. 58, no. 10, Oct. 1927, pp. 373-374, 1 fig. Plant designed for treatment by sedimentation and chlorination provides for present necessities, but when desirable can be converted in sewage pumping station serving six times area.

SCREENING. Digestion of Sewage Screenings, H. Heukelekian. Pub. Wks., vol. 58, no. 12, Dec. 1927, pp. 455-457, 3 figs. Digestion of screenings from fine screen, seeded with ripe sludge, was tried out with and without fresh solids; frequent gas measurements and occasional gas analyses were made; results indicate that digestion of screenings, either separately or in conjunction with fresh solids, is feasible.

TREATMENT PLANTS. Operating Sewage Treatment Plants. Pub. Works, vol. 58, no. 1, Nov. 1927, pp. 431-432. Reasons for unsatisfactory results; suggested operating details for septic and Imhoff tanks, sprinkling filters, contact filters and sand beds.

Two Years' Operation of the Sewage Treatment Plant at Worchester, Mass., R. S. Lanphear. Boston Soc. Civil Engrs.—Jl., vol. 14, no. 8, Oct. 1927, pp. 450-460. Plant consists of two grit chambers, each having a bar screen at outlet end, twelve double Imhoff tanks, four pairs of dosing tanks, 13.68 acres of trickling filters and four final settling basing; designed to care for daily average flow of 28 million gallons of sewage, or estimated population of 242,000 in 1934.

SEWER CONSTRUCTION

SWAMPS. Laying Water-Tight Sewer in Swamp, J. O. Miller. Pub. Wks., vol. 58, no. 10, Oct. 1927, pp. 372-373. Sewer laid in cradles through swamp; asphaltic jointing material used; methods of handling pipe and making joints.

SEWERS

INFILTRATION INTO. Infiltration Into Sewers. Pub. Wks., vol. 58, no. 10, Oct. 1927, pp. 363-366, 1 fig. Reports from large number of engineers from all parts of country describing their experiences and observations.

SHEARS

SHEET MATERIAL. Capacity of Sheet Shear Increased, P. J. Edmonds. Forging—Stamping—Heat Treating, vol. 13, no. 11, Nov. 1927, p. 443. By addition of mechanical contrivance output of shear is raised to 30 tons daily; sheet steel sheared.

SMOKE

ABATEMENT. The Gas Industry's Contribution to Smoke Abatement, F. W. Goodenough. Gas World, vol. 87, no. 2259, Nov. 19, 1927, pp. 484-488. General conclusion is that while gas industry has already materially reduced industrial smoke there is every prospect of great and early extension of this process through far more widespread use of gas; ultimate aim for great majority of industrial purposes must be elimination of solid fuel altogether. Abstract of paper presented to Public Works, Roads and Transport Congress. See also Gas Jl., vol. 180, no. 3365, Nov. 16, 1927, pp. 465-469.

SNOW REMOVAL

METHODS AND EQUIPMENT. Snow Removal and Snow Problems, H. G. McKelvey. Highway Engr. & Contractor, vol. 17, no. 5, Nov. 1927, pp. 28-32. Snow fence; effect of trees; programmes for winter miantenance; equipment for snow removal; operating costs; handling deep drifts.

NORTH DAKOTA. Snow Handling in North Dakota. Pub. Works, vol. 58, no. 12, Dec. 1927, pp. 454-455. Snow prevention more effective than removal; four prevention methods; experience in different parts of state led to certain conclusions which are given.

STEAM ENGINES

BLEEDING. Bleeding Steam Engines (Le soutirage dans le fonctionnement des machines à vapeur), H. Tripier. Chaleur & Industrie, vol. 8, no. 91, Nov. 1927, pp. 625-635, 14 figs. Theoretical foundations of increasing thermodynamic efficiency by single or multiple bleeding.

HIGH-PRESSURE. The Application of High-Pressure to the Reciprocating Marine Steam Engine, S. G. Visker. Shipbldg. & Shipg. Rec., vol. 30, no. 21, Nov. 24, 1927, pp. 583-587, 4 figs. Conversion of machinery of steamer "Borneo" from ordinary triple-expansion installation working with superheated steam of 180-lb. pressure into high-pressure one of 500 lb.

STEAM PIPES

RISERS. Engineers and Contractors Agree on Steam Riser Capacities. Heat. & Vent. Mag., vol. 24, no. 11, Nov. 1927, pp. 61-65 and 87, 6 figs. Critical velocities obtained in research laboratory tests offer basis for figuring capacities of upfeed risers for one- and two-pipe systems.

STEAM POWER PLANTS

HIGH-PRESSURE. 12-lb. Turbine Shows 80 Per Cent Efficiency. Power Plant Eng., Paper Industry, vol. 9, no. 8, Nov. 1927, pp. 1323-1331, 6 figs. Productive capacity increased and great savings effected by reconstruction of plant.

STEAM TURBINES

HIGH-PRESSURE. 12-Lb. Turbine Shows 80 Per Cent Efficiency. Power Plant Eng., vol. 31, no. 22, Nov. 15, 1927, pp. 1186-1188, 3 figs. 7,000-kw. unit is 10 per cent more efficient than 300-lb. equipment with which it operates, of which there is installed capacity of 160,000-kw.; turbine improves station economy 3 per cent.

MANUFACTURE AND TESTING. The Manufacture and Testing of Steam Turbines in the Brown-Boveri Works. Mech. World, vol. 82, no. 2132, Nov. 11, 1927, pp. 365-366, 2 figs. Firm has developed a number of special devices and processes of great interest, which have been incorporated in normal manufacturing system; testing and treatment of materials receive special attention; investigations into vibration of disks.

MARINE. Installation of Dummy Piston and Cylinder in Main High Pressure Turbine of U.S.S. Leviathan, H. J. Reuse. Am. Soc. Naval Engrs.—Jl., vol. 39, no. 4, Nov. 1927, pp. 624-635, 9 figs. Installation of new piston and cylinder has resulted in more even distribution of load on four shafts and marked increase in fuel economy.

STEEL

FRACTURE. The Cause of Cup-Shaped Fractures in Tensile Test Pieces, Fremont. Int. Ry. Congress Assn.—Bul., vol. 9, no. 10, Oct. 1927, pp. 821-828, 48 figs. Phenomenon of deformation makes it clear that beginning of breakage of test piece takes place at centre after which it continues by peripheral tearing following interior curve of crescent section ring; complete or partial collar is due to striction of metal in groove, which in drawing down, by opposing any local extension, makes crescent section ring at bottom of groove more ductile. Translated from Génie Civil.

HIGH TEMPERATURES, EFFECT OF. Properties of Materials at High Temperatures, H. J. Tapsell and W. J. Clenshaw. Eng. Research—Special Report, no. 2, July 1927, 16 pp., 8 figs. Mechanical properties of 0.51 per cent carbon steel and 0.53 per cent carbon cast steel. See abstract in Metallurgist (Supp. to Engineer), Nov. 25, 1927, pp. 172-174.

MANGANESE. *See Manganese Steel.*

TESTING. Notes on the Spark Testing of Steel, G. M. Enos. Am. Soc. Steel Treating—Trans., vol. 12, no. 6, Dec. 1927, pp. 976-981. Sparks given off when ferrous materials are touched to rapidly revolving grinding wheel are characteristic of composition and type of iron or steel in question; author describes technique of making such test and spark characteristics typical of selected group of irons and steels.

STEEL CASTINGS

CUTTING. Cutting of Stainless Steel Castings, C. J. Holslag. Welding Engr., vol. 12, no. 10, Oct. 1927, p. 48, 1 fig. In general, as to electric welding, d.c. is best with copper-base rustless alloys and a.c. for chrome- and nickel-base alloys. See also Machy. (N.Y.), vol. 34, no. 4, Dec. 1927, p. 289.

FOUNDRY PRACTICE. Steel Foundry Practice, A. D. Kirby. Foundry Trade Jl., vol. 37, no. 588, Nov. 24, 1927, pp. 144-146, 1 fig. Deals with sands used; method of moulding and manufacture of steel; methods of strickle work.

MANUFACTURE. Steel Making, with Special Reference to the Manufacture of Steel Castings, J. Deschamps. Foundry Trade Jl., vol. 37, no. 587, Nov. 17, 1927, pp. 125-127. Describes various processes used at present in steel foundries for production of plain carbon steels and discusses their respective merits and disadvantages. See discussion in Foundry Trade Jl., vol. 37, no. 588, Nov. 24, 1927, pp. 141-142.

STEEL, HEAT TREATMENT OF

HARDENING. Electrifying the Hardening Room. Iron Age, vol. 120, no. 23, Dec. 8, 1927, pp. 1584-1586. 100 per cent electric heat treatment of steel practised in some plants; economic and other advantages brought out at Yale Conference, New Haven, Conn.; Pratt & Whitney hardening-room equipment; production costs reduced by electricity.

The Water Hardening of Tool Steels, A. Mumper. Forging—Stamping—Heat Treating, vol. 13, no. 11, Nov. 1927, pp. 444-446, 3 figs. Author's experiences in handling steel of various descriptions; suggestions for improving practice.

STEEL WORKS

POWER GENERATION IN. Power Generation in the Steel Industry, G. Fox. Power, vol. 66, no. 22, Nov. 29, 1927, pp. 819-822, 3 figs. Heat balance in American type of steel plant and total by-product heat available to meet demands; electric power system in steel plant can be made effective pool for by-product fuel utilization only if there is sufficient load at all times to absorb power resulting from fuels not feasible of storage, notably from blast-furnace gas.

STREAM POLLUTION

INDUSTRIAL WASTES AND. Industrial Wastes, a Forward View of Their Disposal, A. E. Fales. Factory, vol. 39, no. 5, Nov. 1927, pp. 810-811, 9 figs. Liquid wastes are generally discharged into near-by streams from industries and result in serious pollution; public opinion is becoming more insistent on abatement of such pollution.

STRESSES

WIRE MODEL ANALYSIS. Brass Wire Models Used to Solve Indeterminate Structures, A. Bull. Eng. News-Rec., vol. 99, no. 23, Dec. 8, 1927, pp. 920-922, 5 figs. Calibrated stock of wire facilitates easy and cheap preparation of models; deflections measured with ordinary scale; brass calibrated wire used in place of cardboard celluloid sheet on tempered steel splines; mechanical method of stress analysis devised by G. E. Beggs, of Princeton Univ.

STRUCTURAL STEEL

CONCRETE VS. Steel and Concrete Engineering, R. Modjeski. Can. Engr., vol. 53, no. 22, Nov. 29, 1927, pp. 573-574. Relative merits of steel and reinforced concrete construction. Paper presented before Am. Inst. Steel Construction.

CONSTRUCTION DEVELOPMENTS. Steel Construction Developments in 1927, L. H. Miller. Can. Machy., vol. 38, no. 22, Dec. 1, 1927, pp. 27-29. Outlines progress in fireproofing of structural steel; welding to replace riveting; study of wind stresses; and standardization of light steel floor construction.

SUBSTATIONS

AUTOMATIC. Automatic Mercury Arc Rectifier, G. Rogers. Elec. Times, vol. 72, no. 1881, Nov. 10, 1927, pp. 588-590, 4 figs. Examples of recent automatic substation plant.

OUTDOOR. Modern Outdoor Stations of High Voltage, P. G. Groodinsky and J. M. Ioffiev. Electritchestvo, no. 10, 1927, pp. 334-342, 22 figs. Historical review of development; plans and description of operating stations in Russia and projects of new substations for Moscow.

PORTABLE. 1,000-Kw. Complete Automatic Portable Substation for B.C.E.R. Company. Elec. News, vol. 26, no. 22, Nov. 15, 1927, p. 25. Can substitute for full automatic stationary substation supplying either 11,500 volts a.c. or 600 volts d.c., operates on load demand, has service-restoring feeders and is fully protected.

SURVEYING

QUANTITY. Quantity Surveying and the Architect, C. L. Weeks. Can. Engr., vol. 53, no. 20, Nov. 15, 1927, pp. 529-530. Presentation of principles of quantity surveying to owner with assistance of architect. Paper presented at Am. Inst. Quantity Surveyors.

T

TAPS

DESIGN. Design and Construction of Taps, A. L. Valentine. Machy. (N.Y.), vol. 33, nos. 8, 9, 10, 11, 12, and vol. 34, nos. 1 and 4, Apr., May, June, July, Aug., Sept. and Dec. 1927, pp. 561-565, 648-652, 767-770, 835-839, 910-914, 57-61 and 284-286, 23 figs. With special reference to taps having ground threads. See also Machy. (Lond.), vol. 30, nos. 771 and 778, July 21 and Sept. 8, 1927, pp. 489-493 and 705-709, 9 figs.

TELEGRAPHY

PRINTING TELEGRAPHS. Printing Telegraphs on Non-Loaded Ocean Cables, H. Angel. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1381-1389, 13 figs. Improvements in apparatus and operation; telegraph codes, relation to speed and applicability to printer operation; transmission methods, shaping of signals, variable lag and effect of earth currents; manual, semi-automatic and full automatic operation of long ocean cables; regenerative repeaters; operation of printers.

TELEPHONY

COMBINED LINE AND RECORDING. Combine Line and Recording Method, S. B. Cousins. Telephony, vol. 93, no. 21, Nov. 19, 1927, pp. 27-28. Method contemplates recording call and establishing connection immediately while subscriber remains at telephone; this method eliminates special recording team, combining outward and recording work at line positions.

TEXTILE MILLS

TRANSPORT SYSTEM. Selecting a Plant Transport System, A. H. Church. Indus. Mgmt. (N.Y.), vol. 74, no. 6, Dec. 1927, pp. 368-371. Advantages of runways and ramps, served by tractors with trailers, elevating trucks, etc., in textile plant; system described not only facilitates transport within plant, but " ties in " conveniently with storage of goods, in process or finished.

TIME STUDY

NEGLECTED VALUES. Neglected Values of Time-Study, J. C. Mottashed. Soc. Automotive Engrs.—Jl., vol. 21, no. 6, Dec. 1927, pp. 691-692. Time study should touch organization at many points; author discusses some neglected points of contact.

RATE SETTING. Time Study for Rate Setting, E. C. Van Orsdell. Indus. Mgmt. (N.Y.), vol. 74, no. 6, Dec. 1927, pp. 330-333. Team work by foremen and operatives essential to success.

TRACTORS

TRAILERS. Tractor-Trailer Express-Transfer Operation, M. T. Hanrahan. Soc. Automotive Engrs.—Jl., vol. 21, no. 6, Dec. 1927, pp. 678-679. Transport of solid loads of express between various railroad terminals in Chicago by eliminating waiting time of both power plant and chauffeur, fleet of tractors and semi-trailers has proved to be prompt, economical and satisfying for this work.

TRANSFORMERS

CHARACTERISTICS. Characteristics Govern Transformer Choice, D. R. Dalzell. Indus. Eng., vol. 85, no. 11, Nov. 1927, pp. 513-516, 4 figs. In selection of transformers for industrial installation it is advisable for operator to obtain benefit of central stations' experience with this class of apparatus; certain characteristics must be definitely established for manufacturer to fill order at minimum expense; many characteristics are set forth.

RATIO CONTROL FOR INTERCONNECTED SYSTEMS. Characteristics of Interconnected Power Systems as Affected by Transformer Ratio Control, L. F. Blume. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1365-1372, 13 figs. Operation of systems, in which constant voltage is maintained by varying generator fields, compared with operation when in addition transformers equipped with ratio control are used; comparison with synchronous condensers for improving regulation; conditions governing current distribution in transmission line loop.

SHORT-CIRCUIT EFFECTS. Short-Circuit Effects Upon Current Transformers, G. L. E. Metz. Elec. Rev., vol. 101, no. 2609, Nov. 25, 1927, 892-894, 3 figs. Author suggests that time has come when current transformers, like oil circuit breakers, should be designed for definite short-circuit ratings, and gives suggestions to that end.

TUNNELS

VEHICULAR. Holland Tunnel Between New York and New Jersey Opened—November 12. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 33, no. 12, Dec. 1927, pp. 726-734, 8 figs. Gives details and dimensions; ventilation, lighting, lining and fire-fighting equipment.

VENTILATION. Ventilation Experiments in the Moffat Tunnel, G. E. McElroy and C. A. Betts. Eng. News-Rec., vol. 99, no. 24, Dec. 15, 1927, pp. 956-959, 4 figs. Determination of air-flow friction factors as basis for design of plant for removing gas and smoke discharged by locomotives.

TUNNELLING

CLAY TUNNEL. Driving 2,000-Ft. Clay Tunnel, C. Christianson. Eng. & Contracting, vol. 66, no. 10, Oct. 1927, pp. 471-472. Use of portable air compressors and compressed-air tools.

PLASTIC CLAY. Tunnelling Methods in Plastic Clay at Detroit. Eng. News-Rec., vol. 99, no. 24, Dec. 15, 1927, pp. 948-954, 12 figs. Tests of half-diameter concrete and brick rings determine lining design for 10-mile tunnel; contract conditions, construction methods and plant.

V

VACUUM TUBES

AMPLIFIERS. On the Values and the Effects of Stray Capacities in Resistance—Coupled Amplifiers, M. von Ardnenne and W. Stoff. Inst. Radio Engrs.—Proc., vol. 15, no. 11, Nov. 1927, pp. 895-901, 4 figs. General theory of stray capacities is developed with due consideration to phase conditions mentioned, and values and effects of stray capacities are discussed for 3-stage amplifier of practical dimensions.

OSCILLATORS. The Short Wave Limit of Vacuum Tube Oscillators, C. R. Englund. Inst. Radio Engrs. Proc., vol. 15, no. 11, Nov. 1927, pp. 914-927, 17 figs. Investigation has indicated that physical limits for ordinary commercial tubes lie between 3.5 and 1.5 m., depending on type of tube used. Bibliography of short-wave vacuum-tube oscillator work is attached.

THERMIONIC VALVES. The Performance of Valves in Parallel, R. P. G. Denman. Experimental Wireless, vol. 4, no. 50, Nov. 1927, pp. 669-674, 6 figs. Examines general case of number of valves operating in parallel on common load, in order to judge extent of losses which are liable to occur in practice, and decide how far it may be necessary or possible to redress balance by means of separate grid bias, etc., for individual valves.

VENTILATION

SCHOOLS. School Ventilation Studies in Toronto, R. F. Heath and J. S. Patterson. Am. Soc. Heat. & Vent. Engrs.—Jl., vol. 33, no. 12, Dec. 1927, pp. 715-725, 3 figs. Alexander Muir school in Toronto; observations on temperature, humidity and air velocity in inlets and outlets.

VOLTMETERS

SPHERE-GAP. The Relation Between Frequency and Spark-Over Voltage in a Sphere-Gap Voltmeter, L. E. Reukema. Am. Inst. Elec. Engrs.—Jl., vol. 46, no. 12, Dec. 1927, pp. 1314-1321, 4 figs. Test of sphere-gap as possible standard for measuring peak values of voltage at high frequencies; experimental data and calibration curves for sphere-gap voltmeter plotted for frequencies from 28,000 to 425,000 cycles per sec.; effect of high frequency.

W

WAGES

PIECE RATES VS. BONUS. Piece Rates or Bonus—Which? Factory, vol. 39, no. 5, Nov. 1927, pp. 803-805. Report of vice-president of manufacturing to his board of directors at board's request.

WATER MAINS

RECONSTRUCTION. Reconstruction of Inadequate Water Distribution Systems, C. E. DeLeuw. Am. Water Wks. Assn.—Jl., vol. 18, no. 5, Nov. 1927, pp. 548-556. Writer has prepared plans for improvement of existing systems in three Illinois municipalities: Riverside, Taylorville and Libertyville, which are described.

WATER PIPES

FRICTION IN ELBOWS. The Friction of Water in Elbows, F. E. Giesecke, C. P. Reming and J. W. Knudson, Jr. Domestic Eng. (Chicago), vol. 121, no. 11, Dec. 10, 1927, pp. 30-34 and 66, 5 figs. Results of investigation to determine friction of water in standard 90-deg. elbows. Method of testing.

WATER POWER

MANITOBA. Water Power Resources of Manitoba. Can. Engr., vol. 53, no. 21, Nov. 22, 1927, pp. 553-556, 4 figs. Industrial Development Board of Manitoba issues report dealing with developed and undeveloped water powers in province; over three million horse power available at minimum flow; present turbine installation is 225,800 h.p.; description of more important rivers and head, and power available at more important undeveloped power sites.

WATER SOFTENING

PRACTICE. Water Softening Practice Developments, C. P. Hoover. Can. Engr., vol. 53, no. 20, Nov. 15, 1927, pp. 531-534, 5 figs. Respective merits of various processes employed. Paper presented at Am. Water Wks. Assn.

WATER TREATMENT

CHLORINATION. Chlorination Control in Chicago, A. E. Gorman. Am. City, vol. 37, no. 5, Nov. 1927, pp. 613-621, 9 figs. During last three years there has developed system of chlorination control in Chicago in connection with which many interesting practical problems have been encountered and solved.

PROCESSES. Studies of Efficiency of Water-Purification Processes, H. W. Streeter. Pub. Wks., vol. 58, no. 12, Dec. 1927, pp. 473-474. Undertaken as part of stream pollution investigations of Public Health Service; relationships between bacterial quality of raw water and quality of effluents from purification plants. Report issued as Public Health Bul., no. 172.

WATERWAYS

BULKHEADING. Bulkheading on Inland Waterways in Hollywood, Fla., J. G. Rakowsky. Eng. & Contracting, vol. 66, no. 10, Oct. 1927, p. 452. Gravity masonry wall made of native Ojus rock boulders.

WELDING

MOTOR FRAMES. Welded Steel for Motor Frames, K. F. Rauderbaugh. Iron Age, vol. 120, no. 22, Dec. 1, 1927, pp. 1507-1508 and 1567, 3 figs. History of application to induction motors; findings in costs of material, labour, inventory, toolroom expense and overhead.

OXY-ACETYLENE. *See Oxy-Acetylene Welding.*

PIPE FITTINGS. Templets for Welded Pipe Fittings. Domestic Eng. (Chicago), vol. 121, no. 8, Nov. 19, 1927, pp. 18-20 and 72, 10 figs. Brings up question of pipe patterns or templets and gives suggestions; clements of templet construction; development of pipe surface; templet for 45-degree intersection; metal templets.

PRESSURE VESSELS. Welding Pressure Vessels, T. M. Jasper. Welding Engr., vol. 12, no. 11, Nov. 1927, pp. 35-37, 8 figs. Examples of products in service which show dependability of welding and a few tests to show sort of research work back of these products.

PROTECTIVE GLASSES FOR. Protective Glasses for Gas and Electric Welding, J. W. Forrest. Am. Mach., vol. 67, no. 23, Dec. 8, 1927, pp. 893-894. Recent research has produced glass with ultra-violet absorption to eliminate external effects of short-wave radiation; visible absorption to take away glare and retinal fatigue, and infra-red absorption to prevent retinal or corneal effect; typical specifications for various shades.

STEEL CASTINGS. What Are the Justifiable Uses of Welding in Production of Steel Castings? R. A. Bull. Iron Trade Rev., vol. 81, no. 24, Dec. 15, 1927, pp. 1475-1477 and 1488, 4 figs. Deals with policy on welding adopted by group of electric steel foundries.

WELLS

DEPTH MEASUREMENT. Machine for Measuring the Depths of Deep Wells, C. E. Van Ostrand. Wash. Acad. Sciences—Jl., vol. 17, no. 19, Nov. 19, 1927, pp. 481-487, 4 figs. Apparatus described is intended primarily for use while lowering cable into well.

WHARVES

NEW ORLEANS. Types of Wharves in the Port of New Orleans, S. M. Young. World Ports, vol. 16, no. 1, Nov. 1927, pp. 17-37, 10 figs. Describes old wharves in use prior to 1901, new wharves of wood and of steel, railroad facilities and inner harbour canal. Paper presented before Am. Assn. of Port Authorities.

WIND TUNNELS

STANDARDIZATION TESTS. Standardization Tests in the Wind Tunnel, E. N. Fales. Soc. Automotive Engrs.—Jl., vol. 21, no. 5, Nov. 1927, pp. 497-507, 15 figs. Points out that two defects in technique of wind-tunnel testing have not yet been overcome; first, aeronautical engineering coefficients derived from tests of small-scale models often require correction for scale effect before they can be applied to full-size design; use of this scale-correction factor has not been standardized; secondly, results obtained from different wind tunnels do not always check, and uncertainty regarding correctness of coefficients may result.

WALL INTERFERENCE. The Effect of the Walls in Closed Type Wind Tunnels, G. J. Higgens. Nat. Advisory Com. for Aeronautics—Report, no. 275, 1927, 18 pp., 30 figs. Series of tests has been conducted during period 1925-1927 in variable-density wind tunnel on several airfoil models of different sizes and sections to determine effect of tunnel-wall interference and to determine correction which can be applied to reduce error caused thereby; Prandtl theoretical corrections give best results, and their use is recommended for correcting closed wind tunnel results to conditions of free air; in appendix experimentally determined effect of walls on tunnel velocity very close to their surface is given; this is of special interest because a " scale effect " was found in boundary layer with change in density of tunnel air.

WIRE ROPE

OIL FIELDS. Oil Country Wire Rope, Its Use and Care, M. G. Ensinger. Nat. Petroleum News, vol. 19, no. 46, Nov. 16, 1927, pp. 85-87. Rope records should be religiously kept so that each manufacturer's product can be correlated and compared with producer's service record so that he can determine which is best construction for service required; type of report is suggested by writer as practical to most users' conditions; this report stays with same reel of rope throughout its life; its success depends upon field man.

WOODWORKING MACHINERY

PLANING AND MATCHING. Four-Roller High-Speed Planing and Matching Machine. Ry. Gaz., vol. 47, no. 22, Nov. 25, 1927, pp. 654-655, 1 fig. Suitable for large planing mills; railway car works and shipbuilding yards; planes up to 250 ft. per hour.

WOODWORKING PLANTS

CHAIRS. Methods of a Specialized Chair Factory, C. C. Campbell. Wood-Worker, vol. 46, no. 9, Nov. 1927, pp. 30-32, 10 figs. Marble & Shattuck Chair Co., Cleveland, O., was able to increase its production by 25 per cent on 44-hr. week over what is formerly produced on 60-hr. schedule with only small increase in size of plant.

Z

ZINC METALLURGY

LEACHING. Recent Developments in Ammonia Leaching for Zinc Ores, H. M. Lawrence. Univ. Missouri School of Mines & Metallurgy—Bul., vol. 10, no. 3, May 1927, pp. 3-12. Ammonia leaching, as process for extraction of zinc from complex ores or other zinc bearing materials, has certain possibilities that are pointed out.

Engineering Index

This Index is prepared by the American Society of Mechanical Engineers.

In this department will be published from month to month the titles of current engineering papers with the authors and source and a brief extract of the more important. It is designed to give the members of The Institute a survey of all important articles relating to every branch of the engineering profession.

PHOTOSTATIC PRINTS

Photostatic copies of the articles listed in this section, or others on engineering subjects, may be obtained from the Engineering Societies Library.

Price of each print (up to 11 by 14 in. size) 25 cents, plus postage. Where possible, two pages, up to 7 by 9 in. size, will be photographed on one print. Larger magazines require a print per page. Bills will be mailed with the prints.

The Library is also prepared to translate articles, to compile lists of references on engineering subjects and render assistance in similar ways. Charges are made, sufficient to cover the cost of this work. Correspondence is invited. Information concerning the charge for any specific service will be given those interested. In asking for information please be definite, so that the investigator may understand clearly what is desired.

The Engineering Societies Library is under the management of the United Engineering Society, which administers it as a public reference library of engineering. It is maintained jointly by the American Society of Civil Engineers; the American Institute of Mining and Metallurgical Engineers; the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. It contains 150,000 volumes on engineering and allied subjects, and receives currently most of the important periodicals in its field.

Orders and correspondence should be addressed to

Harrison W. Craver, Director,
Engineering Societies Library,
29 West Thirty-ninth Street. New York, N.Y.

A

AIR CONDITIONING

HEATING ONLY OR. What Will the Engineer Choose—Heating Only or Air Conditioning for the Modern Plant? H. P. Grant. Am. Soc. Heat. and Vent. Engrs.—Jl., vol. 34, no. 1, Jan. 1928, pp. 1-10, 8 figs. Comparison of first cost and operating expense of various types of heating as well as air-conditioning systems for industrial plants; plans shown of actual building in which air-conditioning system is to be installed.

AIR PREHEATERS

UTILITY. Air Preheaters and Their Utility, C. F. Wade. Colliery Eng., vol. 4, no. 46. Dec. 1927, pp. 494-495. Economies and advantages of air preheaters for combustion and process work; while they cannot compare with exhaust-steam systems of air heating when air is required for manufacturing processes, direct heating of air for such work from sensible heat of waste gases is much more economical than employment of live steam coils; integral type of preheater; as compared with economizers, air heaters occupy less space, require no insurance premiums against explosion and are generally lower in first cost.

Preheated Air for Boiler Furnaces, P. H. N. Ulander. Eng. and Boiler House Rev., vol. 41, no. 6, Dec. 1927, pp. 274-276, 2 figs. Reviews reasons why air preheater has become apparatus of general importance to modern boiler-house practice, and problems arising from use of preheated air.

AIRCRAFT

RADIO DIRECTION FINDING. Radio Direction Finding, L. A. Hyland. Aviation, vol. 24, no. 1, Jan. 2, 1928, pp. 30-33, 5 figs. Fifth of radio series; aims of radio direction finding to direct aircraft along dark airways, to determine accurately limits of airport and to effect landing regardless of visibility; rotating coil compass not suitable; radio compass valuable on isolated routes; radio beacon; comparison of three types of direction finders; development of beam transmitters; no known remedy for "night effect"; beacon emergency landings possible; airplane direction finding by radio not automatic.

SPECIFICATIONS. Manufacturers' Specifications on American Commercial Airplanes and Seaplanes, as Compiled by Aviation. Aviation, vol. 24, no. 1, Jan. 2, 1928, pp. 42-43.

AIRPLANES

AIRFOILS. The Characteristics of the N.A.C.A. 97, Clark Y, and N.A.C.A. -M6 Airfoils, with Particular Reference to the Angle of Attack, G. J. Higgins. Nat. Advisory Committee for Aeronautics—Tech. Note, no. 270, Dec. 1927, 4 pp., 8 figs. Aerodynamic characteristics as determined in variable-density wind tunnel at Langley Field; differences in geometric and absolute angles of attack; drag-coefficient curves and lift curves; polar curves and curves of profile-drag coefficient plotted against lift coefficient; curves of induced-drag coefficient.

WELDING. Airplane Construction and Welding, R. M. Mock. Acetylene Jl., vol. 29, no. 7, Jan. 1928, pp. 284-289, 7 figs. Discussion of advantages of welded construction and some of important joints in which welding is essential; welding is now practically confined to tubular members, though there is some tendency towards building trusses of pressed sheeting.

ALLOY STEELS

HEAT TREATMENT. Nitralloy and the Nitriding Process, H. A. DeFries. Machy. (N.Y.), vol. 34, no. 5, Jan. 1928, pp. 358-359. Special alloy steels which can be surface-hardened by being subjected to action of ammonia gas for from two to ninety hours, while material is heated to 875 deg. Fahr. without subsequent quenching; standard electric furnaces easily adaptable; composition, properties and uses; heat treatment previous to nitriding; nitriding process and equipment; depth and hardness of case.

PRODUCTION AND USES. The Production and Uses of Ni-Cr-Fe and Co-Cr-Fe Castings, J. F. Kayser. Iron and Steel of Can., vol. 10, no. 12, Dec. 1927, pp. 367-369. Treats of alloys made with Ni, Cr, Fe and Co, and used for high-grade steel as well as stainless or non-corrosive steels; composition of alloys used in United States and England is given.

ALLOYS

DIE CASTING. *See Die Casting.*
LEAD. *See Lead Alloys.*

PROPERTIES. Alloys for Casting Under Pressure (Les alliages pour la coulée sous pression). Fonderie Moderne, vol. 21, Dec. 10, 1927, pp. 502-503. Alloys with lead, tin, zinc and aluminum bases; gives physical properties, uses of each and advantages for particular cases; maximum weight possible to cast for each alloy.

ALUMINUM

MELTING. Melting Pot and Crucible Furnaces in the Aluminum Industry, E. R. Thews. Metal Industry (Lond.), vol. 31, no. 26, Dec. 30, 1927, pp. 597-599, 1 fig. Great hope is being placed upon suitability of electric furnaces, but it appears that for time being satisfactory results can only be obtained with fuel-fired furnaces, with reverberatory, crucible and melting-pot furnaces; disadvantages of last-named is strong affinity of molten aluminum for iron, which causes rapid wear of pots and inevitable contamination of aluminum with iron; results of corrosion experiments; corrosion of pot walls.

METALLURGY. Aluminum and Its Alloys Feature Meeting of Institute of Metals. Can. Chem. and Met., vol. 11, no. 12, Dec. 1927, pp. 313-316. Review of papers presented before Institute of Metals of Great Britain, dealing with protection of aluminum and its alloys against corrosion; constitution of alloys of aluminum with silicon and iron; constitution and physical properties of some alloys of copper, zinc and cadmium; effect of work and annealing on lead-tin eutectic; reaction between solid magnesium and liquid tin.

AMMONIA COMPRESSORS

DESIGN. Developments in the Design of Refrigerating Compressors, O. Henckel. Refrig. Eng., vol. 14, no. 6, Dec. 1927, pp. 186-187, 2 figs. Contribution from chief engineer of Sulzer Brothers, Wintertur, Switzerland; discusses in general terms history which has had its parallel in American practice; deals with valves, bearings and frames, packing, dry and compound compression.

ELECTRIC DRIVE. Driving Two Compressors with One Motor. Power, vol. 67, no. 2, Jan. 10, 1928, pp. 65-66, 1 fig. Discusses plan of connecting two machines to one motor; machines are placed with shafts end to end, in a straight-line pattern, with motor mounted between them; this may be properly termed duplex-coupled arrangement, and is usually called simply "duplex" for short.

AMPLIFIERS

RADIO. The Amer Tran Amplifier, L. M. Cockaday. Popular Radio, vol. 13, no. 1, Jan. 1928, pp. 20-22 and 77, 3 figs. Unit described, it is claimed, not only furnishes ideal form of distortionless low-frequency amplification for any high-frequency pack, but supplies all operating voltages for any set that employs AC valves.

ARBORS

VERTICAL. Uses of the Vertical Work Arbor. Can. Machy., vol. 38, no. 25, Dec. 22, 1927, pp. 15-16, 12 figs. Describes vertical work arbors for tables of milling, slotting and gear-cutting machines and some grinding machines; uses loose base and overhead support if necessary; methods of using arbors for various kinds of work and advantages of each.

ARCHES

LONG-SPAN. Hooped Cast-Iron and Long-Span Arches. Concrete, vol. 22, no. 12, Dec. 1927, pp. 692-707, 24 figs. Treats of long-span arches where hooped cast iron has reduced size of members and economized material cast.

ARSENIC DEPOSITS

CANADA. Arsenic-Bearing Deposits in Canada, M. E. Hurst. Geol. Survey—Economic Geology Series, no. 4, 1927, 172 pp., 21 figs. Mineralogy of arsenic; general geology; description of occurrences; principal sources of arsenic at present time are: silver-cobalt ores of Cobalt, South Lorrain and Gowganda, Ontario; arsenopyrite-gold ore of Hedley Gold Mining Co., Hedley, B.C.; concentrates from gold-quartz veins and slate belts in Nova Scotia.

ASBESTOS

STATISTICS. Asbestos, B. H. Stoddard. U.S. Bur. Mines—Mineral Resources, no. II:19, 1927, pp. 195-201. Production, review by states, prices, uses, imports and exports and world's production.

ASBESTOS PRODUCTS

MANUFACTURE. Manufacture of Mixtures of Asbestos and Cement (La fabrication des agglomerés d'amiante et de ciment). Revue Industrielle, vol. 58, no. 2222, Jan. 1928, pp. 1-8, 20 figs. How mixtures of cement and asbestos are made in corrugated sheet form and as shingle for walls and roofs, also as sheet for partitions; composition and fabrication machinery described.

ASPHALT

MATERIALS. Use of Asphaltic Materials, W. L. Hempelmann. Elec. Traction, vol. 24, no. 1, Jan. 1928, pp. 35-36, 2 figs. Asphaltic materials have numerous uses in track construction, for floor and roof coverings, and for waterproofing and general protective purposes on electric railways.

AUTOMOBILE PLANTS

CADILLAC. Cadillac Doubles Plant Output, L. P. Fisher. Mfg. Industries, vol. 14, no. 6, Dec. 1927, pp. 411-414, 4 figs. During past two years company has made far-reaching changes in plant and product involving creation of entirely new car, the LaSalle, and change of Cadillac model; new models were put into production with increase in annual output of from 22,000 to possible 50,000 to 60,000 cars; more efficient use of production equipment, improved types of machinery, rearrangements of plant layout, and better methods of materials handling have effected increased output with addition of 24% to working force.

AUTOMOBILES

BODIES, MANUFACTURE. The All-Steel Automobile Body as a Manufacturing Problem, J. W. Meadowcroft. Am. Mach., vol. 68, no. 1, Jan. 5, 1928, pp. 9-11, 7 figs. Present-day streamline design and large quantities making necessary use of expensive dies and extensive welding equipment; early history and underlying principles; progressive assembly line as pace setter and problems arising from it; materials selection.

ELECTRIC. Electrical Equipment of Electric Road Vehicles, L. W. de Grave. Elecn., vol. 99, no. 2584, Dec. 9, 1927, pp. 719-720, 5 figs. Battery vs. resistance control; controllers with shunted or parallel fields; permanent series field and shunts of 50 per cent and 10 or 20 per cent best; objections to controllers which interlock with brake; regenerative control; electric brakes; controller contacts and fingers; ampere-hour meters should read level.

MANUFACTURE. Efficient Production, with Particular Reference to the Motor Car Industry, H. E. Taylor. Machy. (Lond.), vol. 31, no. 790, Dec. 1, 1927, pp. 265-275, 13 figs.

TIRES, IMPROVEMENTS IN. Another Step in Tire Evolution. Motor Transport, vol. 46, no. 1190, Jan. 2, 1928, pp. 7-8, 3 figs. Startling development in pneumatic-tire construction; how low-pressure tire can be improved and new oval tire with less height and abnormal width affording maximum width of air cushion and tread without changing diameters of wheels or brake drums; tire can be made at less cost and 33 to 40 per cent lighter.

AUTOMOTIVE FUELS

KNOCK CHARACTERISTICS. Comparison of Methods of Measuring Knock Characteristics of Fuels, G. Edgar. Soc. Automotive Engrs.—Jl., vol. 22, no. 1, Jan. 1928, pp. 41-48, 4 figs. Analysis of data obtained from nine laboratories and methods used; rating of fuels in terms of quantity of tetraethyl lead needed to make fuels equal to standard better than they are; rating of fuels themselves in terms of some other standard fuel to which anti-knock or benzol has been added; discussion of experimental results.

AXLES

FATIGUE. Fatigue Cracks in Axles. Metallurgist (Supp. to Engineer), Dec. 30, 1927, pp. 181-183. It is desirable that simple and practical methods of inspection be devised whereby fatigue cracks might be detected at early stage; refers to work of H. F. Moore (Bul. No. 165, Univ. of Ill. Eng. Experimental Station, June 1927), describing series of experiments made on small laboratory specimens to obtain data regarding efficacy of "oil and whiting" method; mentions work carried out at Bureau of Standards in connection with somewhat analogous problem.

B

BELTS AND BELTING

SPECIFICATIONS. A.P.I. Belt Specifications and Results of Use, F. O. Prior. Oil Weekly, vol. 48, no. 2, Dec. 30, 1927, pp. 47-50 and 52, 8 figs. Specifications have provided belts better suited for particular needs and code for care has increased term of usefulness; fatigue or endurance tests; belt records; elastic properties of belting.

BLAST FURNACES

AIR DRYING. Use of Silica Gel for Air Drying in Blast Furnaces (L'emploi du gel de silice pour dessecher le vent des hauts fourneaux), A. Bidault des Chaumes. Génie Civil, vol. 91, no. 27, Dec. 31, 1927, pp. 661-664, 7 figs. Installation at steel works in Scotland of new process of air drying originating in America; results of test since April 1927.

FUELS. The Effect of Varying Ash in the Coke on Blast-Furnace Working, C. S. Gill. Iron and Steel of Can., vol. 10, no. 12, Dec. 1927, pp. 374-376, 2 figs. Gives quantities of ash found in coke used in blast-furnace operation and sulphur in pig iron and analyzes effect of ash on pig obtained from furnace 55 ft. high, 18 ft. diameter; considered a small furnace.

OPERATION. Pig Iron Quality Is Affected by Scrap Additions to Blast Furnace, J. L. Jones. Foundry, vol. 56, no. 1, Jan. 1, 1928, pp. 32-34, 4 figs. Specifications for scrap for use in blast furnaces; increasing tendency of large castings to crack and difficulties in machining may be expected as consequence of lack of uniformity of pig iron made by adding scrap to blast furnace; use of forehearths or large mixing ladles, in connection with cupola or electric-furnace melting, should give more uniform product even if heterogeneous material must be charged.

BOILERS

CONTROL. Modern Boiler Room Control, J. M. Drabelle. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 34-35. Automatic control as applied in modern plants; it is function of automatic boiler-control equipment to duplicate as closely as possible results obtained under test conditions.

DESIGN. Modern Boilers, Their Design and Construction—Methods of Increasing Power Plant Efficiency, E. R. Fish. Steam Coal Buyer, vol. 8, no. 5, Nov. 1927, pp. 38-41. How boilers are made to stand present high pressures; great demand for new boilers of large sizes; water walls are necessary; chimney losses are reduced; superheaters used, necessary to select right equipment for case at hand.

BOILER FEEDWATER

REGULATION. Measurement and Regulation of Feedwater. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 32-33. Measurement of quantity of water is most accurately made by weighing it in tanks where quantity to be measured is not too large and short time determinations are not required; where it is desirable to have continuous observations, some form of meter is advisable; types of meters; feedwater regulators.

TESTING. Testing Treated Feedwater. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 30-31, 1 fig. Regular routine tests are made and records kept as guide to operation; titration provides simple method; control of blowdown secured by tests.

Tests of Raw Water Involve Many Processes. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 26-27, 1 fig. Following careful analysis of water, regular routine tests are made by power-plant personnel and records kept; tests should be made for following: Total alkalinity, carbonate, bicarbonate and hydrate alkalinity, hydrogen-ion concentration, chlorides, dissolved oxygen, total solids, suspended solids, turbidity and total hardness.

TREATMENT. A Method of Feedwater Treatment. Gas Engr., vol. 43, no. 620, Dec. 1927, pp. 323-324. Non-chemical method called "Filtrator" system used at Weston-super-Mare, England; introduces small stream of colloid substances into feedwater or boiler; source of "colloid" is commercial uncrushed linseed; cost very small compared to water-softening plant, and effect as good.

Purification and Treatment of Feedwater, S. T. Powell. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 24-26. Present tendencies in methods of testing feedwaters and their subsequent purification and treatment for use in modern power-plant boilers are toward combination of systems; continuous blowdown methods and adoption of zeolite process increasing in use; electrolytic methods have possibilities.

Treat Feedwater for Its Specific Duty. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 27-30, 5 figs. It is claimed that treatment methods should be individually determined; factors involved in choice of filter; concentration control; corrosive action reduced by degasification.

FURNACE GASES, STRATIFICATION OF. Effect of Stratification of Furnace Gases on Steam Boiler Losses, F. M. Marquis, P. Bucher and H. M. Faust. Ohio State Univ. Studies—Bul., no. 34, Nov. 1927, 82 pp., 44 figs. Investigation of combustion conditions and of interrelations of boiler losses in boilers located in Ohio State University power plant; description of boiler units on which tests were run; method of conducting tests; programme of tests, and discussion of some of more important results, together with their graphical presentation.

FURNACE TUBES. Designing Furnace Tubes for Horizontal Internally-Fired Land Boilers. Boiler Maker, vol. 22, no. 12, Dec. 1927, pp. 354-355, 16 figs. Defects caused by expansion and contraction of furnace tubes of internally-fired boilers have brought about many changes in design of these tubes, which are discussed; modifications of Adamson furnace; cone-shaped furnace rings.

FURNACES—OPERATION. Continuous Combustion at High Pressures, E. C. Wadlow. Engineer, vol. 144, no. 3754, Dec. 23, 1927, pp. 704-705, 5 figs. Description of experimental furnace which writer constructed to supply quantity of gas at elevated temperatures and pressures; experiments show that satisfactory continuous combustion can be maintained in chamber of small capacity; heat losses are considerable; statements are based upon experience gained during about 150 hours running with combustion taking place.

LOCOMOTIVE. *See Locomotive Boilers.*

RATING. Is Boiler Rating an Engineering or a Trade Problem? Heat. and Vent. Mag., vol. 25, no. 1, Jan. 1928, pp. 89-90. Analysis of boiler rating code problem by well-known consulting engineer approaches subject from new point and suggests that, after all, matter is industrial rather than engineering.

BRASS FOUNDRIES

METALLURGICAL CONTROL. Brass Foundry Tests Every Heat, E. Bremer. Foundry, vol. 56, no. 1, Jan. 1, 1928, pp. 2-6 and 14, 6 figs. Modern brass foundry that maintains most complete metallurgical and chemical department according to present-day standards is Mueller Brass Co., Port Huron, Mich.; details of labour-saving devices and methods employed.

BRIDGES

CONCRETE. Concrete Bridges Unite St. Petersburg Island, J. Ludwick. Concrete Products, vol. 33, no. 6, Dec. 1927, pp. 49-51, 3 figs. Bridges total 1,400 ft. in length; construction methods described; system requires three bridges; approximate quantities of materials used are shown in table.

The Aulon Viaduct, Memphis, W. G. Stromquist. Pub. Wks., vol. 59, no. 1, Jan. 1928, pp. 29-32, 4 figs. Construction of concrete viaduct with approaches, totalling nearly 3,000 feet, over three sets of railroad tracks; slab instead of girder and beam construction.

DESIGN. Bridge Design for Various Conditions, J. A. L. Waddell. Can. Engr., vol. 54, no. 2, Jan. 10, 1928, pp. 129-130. Suitability of various types of bridges for different conditions encountered at crossings; concrete vs. timber piles; erection methods; cantilevering and semi-cantilevering; temporary spans for erection; types of bridges; reinforced-concrete or timber trestles; reinforced-concrete arch bridges; steel trestles; cantilever bridges. Paper read before West. Soc. Engrs. (To be continued.)

Bridge Design for Various Conditions, J. A. L. Waddell. Can. Engr., vol. 54, no. 1, Jan. 3, 1928, pp. 105-108. Suitability of various types of bridges for different conditions encountered at erossings. Reprinted from Jl. of Western Society of Engineers. (To be continued.)

HIGHWAY. Grade Line Treatment for Highway Bridges, C. B. McCullough. Roads and Streets, vol. 67, no. 11, Nov. 1927, pp. 494-496, 7 figs. General considerations of grades on and approaching bridges; requirements of camber and grade-line treatment; concave and convex intersections; structures on curves; need of following certain rules to prevent appearance of sag on bridge railing.

Highway Bridge Destruction Tests, N. C. Mcloud. Concrete, vol. 32, no. 1, Jan. 1928, pp. 34-36, 3 figs. Water-power developments present opportunity for making unusual series of tests on concrete arch bridge in North Carolina; bridge to be tested to destruction; will study concrete arch stresses; scope of tests; method of making tests; engineering societies co-operate; 1,069-ft. bridge over Yadkin river between Albemarle and Mt. Gilead, erected in 1922.

SURVEYS. Bridge Surveys for New Structures, W. W. Hadley. Purdue Univ.—Bul., vol. 21, no. 3, May 1927, pp. 22-38. Enumerates various points to be investigated by engineer previous to establishing location of new bridge, necessity for care in such work and recommendations to be made previous to final choice of location and structure.

BRONZE FOUNDING

PROGRESS IN. Developments in Engineering Bronze Founding. Metal Industry (Lond.), vol. 31, no. 22, Dec. 2, 1927, pp. 511-512. Progress in bronze castings; tilting furnaces; electric furnace for foundry work; gas absorption in bronze; grain size and strength; worm-wheel blanks; tin and tin substitutes. Paper read before joint meetings of Inst. of Metals & Inst. of Brit. Foundrymen. See also Foundry Trade Jl., vol. 37, no. 591, Dec. 15, 1927, pp. 195-198, 2 figs.

BUILDINGS

STEEL. Windbracing for Steel Structures, C. T. Morris. Contract Rec., vol. 41, no. 51, Dec. 21, 1927, pp. 1285-1289, 3 figs. Ross method of analyzing stresses recommended as more satisfactory than any of approximate methods now in common use; no definite data as to proper wind-pressure figures; refers to various papers on this subject with comments; analysis of wind stresses in 48-storey office building in Columbus, O.; mention of effects of Florida hurricane on several steel-framed buildings in Miami.

WELDED STEEL. Fabrication Costs for an Arc-welded Steel Frame Building. Elec. News, vol. 37, no. 2, Jan. 15, 1928, pp. 45-46. Power, wire and labour costs per net ton given for various steels; Sharon building of Westinghouse Co. largest building ever constructed by arc-welding method of fabricating steel; presents some useful data on arc-welding; welding process.

C

CARBON DIOXIDE COMPRESSORS

DEVELOPMENT. The Progressive Development of Carbon Dioxide Refrigerating Methods, J. C. Goosmann. Refrig. Eng., vol. 14, no. 6, Dec. 1927, pp. 188-189. History of development of CO_2 machines; nearly all of European CO_2 compressors are designed along standard lines, either horizontal or vertical, single or double acting; condensers, valves and other auxiliary parts show very little deviation from conventional forms; there are two distinct types of fully enclosed rank-case machines, distinguished as "step-piston" and "straight-piston" type; advantages and disadvantages of each.

CARBURETORS

AIR CLEANERS. Air-Cleaning Mountings. Soc. Automotive Engrs.—Jl., vol. 22, no. 1, Jan. 1928, p. 107, 1 fig. Series of carburetor air-horn dimensions developed for air-cleaner mountings; table including sizes of carburetor larger and smaller than those used at present for attachment of air cleaners.

FLANGE STANDARDS. New Duplex-Carbureter Flanges. Soc. Automotive Engrs.—Jl., vol. 22, no. 1, Jan. 1928, p. 106, 1 fig. Dimensional specifications for five standard sizes developed by subdivision; four-bolt mounting; two centre holes optional; distance between centres of centre holes increased by ⅛ in.; some holes have been moved 1/16 in. away from barrel for wrench clearance; spacing between barrels increased in 1¼-in. size.

CARS, TANK

GLASS-LINED. Conveyance of Milk in Glass-Lined Tank Wagons. Ry. Gaz., vol. 47, no. 24, Dec. 9, 1927, pp. 723-727, 9 figs. Design of vehicles for this traffic co-operation between United Dairies, Ltd., and Great Western and L.M.S. Railways; collecting and filling plants; economics of bulk transport of milk; hygienic advantages.

CASE-HARDENING

PRINCIPLES. Facts and Principles Concerning Steel and Heat Treatment, H. B. Knowlton. Am. Soc. for Steel Treat.—Trans., vol. 13, no. 1, Jan. 1928, pp. 142-154. Explains what case-hardening is, reviews history; reasons for case-hardening; selection of steels; S.A.E. specifications for plain carbon case-hardening steels; presents table giving chemical composition of alloy steels commonly used for case-hardening.

CAST IRON

FATIGUE. Fatigue of Cast Iron, C. H. Bulleid and A. R. Almond. Engineering, vol. 124, no. 3232, Dec. 23, 1927, p. 827, 6 figs. Data on an iron suitable for light castings and typical cylinder iron; from results of these two irons and those obtained previously, it appears that ratio of fatigue stress to transverse stress varies greatly in different irons, and may be very low.

MACHINABILITY. Effects of Nickel on the Machinability of Cast Iron. West. Machy. Wld., vol. 18, no. 12, Dec. 1927, pp. 591-592, 2 figs. Brief article with purpose of examining difficulties encountered in machining grey cast iron, and by means of metallurgical laws. microscope and chemical analysis pointing out causes; effect of combined carbon; hard spots and remedy; high silicon content and slow cooling promote internal shrinks; nickel in grey iron supplements silicon without inducing internal shrinking; nickel makes pre-annealing unnecessary.

MECHANICAL PROPERTIES. Some Mechanical Properties of Cast Iron. Metallurgist (Supp. to Engineer), Dec. 30, 1927, p. 188. Review of report by Moore, Lyon and Inglis (Bul. No. 164, Univ. of Ill. Eng. Experimental Station); material was drawn from following sources: 6-in. pipe cast by centrifugal process; hollow cylinders cast in green-sand moulds with dry-sand cores; and inner wall of double-walled cylinder casting.

CASTINGS

DESIGN. Some Faults in the Design of Castings, W. J. May. Mech. Wld., vol. 82, no. 2137, Dec. 16, 1927, pp. 447-448, 7 figs. Suggestions for castings made with cast-on flanges and other projections; castings in which ribs are introduced for purposes of stiffening and adding extra strength; designing of machines having parts awkward to mould or cast; question of suitability of metal for particular purposes.

CHAIN DRIVE

LIMITATIONS. Limitations of Silent Chain Drives, A. B. Wray. Indus. Engr., vol. 85, no. 12, Dec. 1927, pp. 589-591, 4 figs. Maximum horse power using chain drive; ratios of sprockets in train, proper centre distances, number of teeth in sprockets; installation economies in chain-drive gearing shown by examples.

CHIMNEYS

REINFORCED CONCRETE. Design and Construction of Tapering Reinforced Concrete Chimneys, W. A. Jassoy and H. B. Schneider. Contract Rec., vol. 42, no. 1, Jan. 4, 1928, pp. 2-4, 5 figs. Designing methods, forms for construction, methods of constructing foundation and chimney itself; list of chimneys erected in Canada of reinforced concrete by one company, maximum height 250 ft.

CHROMIUM PLATING

ANODES FOR. Anodes for Chromium Plating, O. P. White. Metal Industry (Lond.), vol. 31, no. 24, Dec. 16, 1927, pp. 563-565. Tests of effect of anode materials upon solution and upon deposit; anodes used were chromium, lead, iron and steel, nickel and iron silicon, iron-chromium, nickel-chromium, nickel-silicon and nickel-chromium-silicon alloys. Paper read at Am. Electrochem. Soc.

CORROSION PREVENTION. Chromium as a Corrosion Preventative, L. Wright. Metal Industry (Lond.), vol. 31, no. 25, Dec. 23, 1927, pp. 577-579, 16 figs. Early hopes for production of permanent corrosion-resistant coating of chromium have been hardly realized; failure of carefully stored chromium-plated brass articles in about fortnight forced author to conclusion that many factors, other than corrosion, were at work in causing breakdown of chromium; it has become apparent that failure is not haphazard; discusses number of definite types of failure and attributes to each article definite cause for its breakdown.

CHUCKS

HYDRAULIC. Gridley Hydraulic Unit to Operate Chucks. Am. Mach., vol. 67, no. 26, Dec. 29, 1927, pp. 1033-1034, 2 figs. To operate chucks of screw machines, chucking machines, automatic lathes and other production machinery hitherto actuated pneumatically; consists of tank to hold quantity of oil, cover with motor-driven pump, accumulator for building up air pressure, gauges to indicate pressure and valves to regulate oil flow.

PNEUMATIC. Air Chucks and Fixtures. Machy. (Lond.), vol. 31, nos. 791 and 793, Dec. 8 and 22, 1927, pp. 289-291 and 381-384, 12 figs. Pneumatically operated equipment designed to save time and labour in quantity production; air-operated clamping unit, incorporated in various types of work-holding fixtures and jigs; chucks with pressure-equalizing mechanisms; expanding mandrels used in gripping both ends of long housings during lathe operation; fixture for vertical machine; simple drill jig; line cuts showing details of devices.

CITIES AND TOWNS

PLANNING. Civic Developments at Montreal. Can. Engr., vol. 54, no. 1, Jan. 3, 1928, pp. 115-116. Town-planning activities; work accomplished; several boulevards planned; financing municipal improvements; other cities co-ordinated; working on system; boulevard plans.

STREETS. Arterial Roads in Relation to Town Planning, W. R. Davidge. Roads and Road Construction, vol. 5, no. 60, Dec. 1, 1927, pp. 377-379. Function of by-pass; for by-pass to fulfill its purpose there are two salient things it must do: to skirt town situated on highway so that capacity of streets in town is not unnecessarily strained, and to serve as swift and direct route past town. (Concluded.)

COAL

SPONTANEOUS COMBUSTION. The Reactions Between Oxygen and Coal, W. Francis and R. V. Wheeler. Chem. Soc.—Jl., Dec. 1927, pp. 2958-2967, 3 figs. Work forms part of research on spontaneous combustion of coal which is being carried out for Safety in Mines Research Board; studies more particularly behaviour of hydrogen-containing groupings of ulmin molecule during oxidation of coal, as disclosed by formation of water.

COAL MINES AND MINING

EXPLOSIONS. Explosion in Hillcrest Mine, Alberta, Sept. 19, 1926, G. S. Rice. Can. Min. and Met. Bul., no. 189, Jan. 1928, pp. 121-150, 2 figs. Writer was invited to conduct an investigation into causes of disaster, and to make such recommendations as seemed advisable with view to minimizing as far as possible chance of future explosions.

POWER SUPPLY. The Power System of the Dominion Coal Company, Limited, S. C. Mifflen, A.M.E.I.C. Can. Min. Jl., vol. 48, no. 49, Dec. 9, 1927, pp. 986-990 and 999, 4 figs. Until recent years, power supply in mines proper consisted almost entirely of compressed air; within past five years electrification of all main pumping plants of all collieries together with some auxiliary pumps has been effected; unlikely that electric coal cutters will predominate due to more or less gaseous nature of coal seams.

VENTILATION. The Measurement of Air Quantities and Energy Losses in Mine Entries, A. C. Callen and C. M. Smith. Univ. of Ill. Bul., vol. 25, no. 14, Dec. 6, 1927, 73 pp., 17 figs. Object to see whether pitot-tube traversing methods could be applied with reasonable accuracy at any desired location in mine entry without building measuring station and without special preparation of section.

GEOLOGY. Prospecting Strip Coal Areas, W. J. Borries. Min. Congress Jl., vol. 14, no. 1, Jan. 1928, pp. 48-50, 2 figs. Investigation of successful coal-strip property involves principles of engineering and prospecting and geological study of conditions embodying property; procedure advocated.

COLUMNS

DESIGN. A Simplified Column Formula of the Secant Type, J. B. Hunley. Am. Ry. Eng. Assn.—Bul., vol. 29, no. 300, Oct. 1927, pp. 197-226, 22 figs. Study of effect of various terms of secant formula has suggested another form which is quite simple and yet retains to remarkable degree all desirable features of original formula.

COMBUSTION

CONTROL. Combustion Control Formulas, E. A. Uehling. Power, vol. 67, no. 1, Jan. 3, 1928, pp. 12-14, 2 figs. Application of formulas to test data; heat-loss formulas; it is evident that per cent of CO_2 and CO, temperature of gas on leaving boiler and square root of boiler draught are fundamental data required for intelligent and effective control of boiler operation.

COMPRESSED AIR

AUTOMOBILE MANUFACTURE, USE IN. Compressed Air in an Automobile Plant, C. H. Vivian. Compressed Air Mag., vol. 33, no. 1, Jan. 1928, pp. 2295-2301, 23 figs. Tools driven by compressed air for automobile production are explained; their advantages discussed; applied to plant at Elizabeth, N.J., making Star cars; tires are inflated automatically; air compressors described.

CONCRETE

CONSTRUCTION. Contractor Saves 30 Per Cent Through Quality Control, L. Charron. Concrete, vol. 32, no. 1, Jan. 1928, pp. 37-40, 3 figs. Quality control permitted reducing cement content per cubic yard of concrete in building foundations for greater Penobscot building in Detroit, Mich.; building 47 stories high; description of concrete-plant layout, aggregates and mixes used.

CURING. Curing Concrete, J. Singleton-Green. Concrete, vol. 22, no. 12, Dec. 1927, pp. 687-691, 1 fig. Sixteen conclusions regarding curing of concrete, with diagram for relative compressive strengths for mortars and concretes of any age.

MIXING. Comparison of Water-Cement Ratio Mixes and Ordinary Mixes, C. F. Dingman. Concrete, vol. 32, no. 1, Jan. 1928, p. 24. Effect of workability requirements on amount of cement needed per cubic yard of concrete; mixture must be plastic and workable; comparison is shown of certain mixes, with strengths assumed for them according to Boston building law.

The Modern Idea in Concrete Mixing, J. E. Foster. Contract Rec., vol. 41, no. 52, Dec. 28, 1927, pp. 1330-1331. Water-cement ratio law interpreted in terms of Canadian sacks of cement and imperial gallons; class of concrete to use; calculating quantity of concrete.

PROPORTIONS. Estimation of the Proportions for Concrete, H. W. Coultas. Concrete, vol. 22, no. 12, Dec. 1927, pp. 727-744, 8 figs. Shows how various factors in connection with water-cement ratio theory of specifying quantities for concrete can be put to practical use; expresses mathematically relations between various factors; and shows how to specify use of this theory in practice.

CONCRETE, REINFORCED

STRESSES. Chart Showing Stress Characteristics of Reinforced Concrete Under Bending and Direct Compression, and Notes of Their Construction, S. M. Cotten. West. Constr. News, vol. 2, no. 24, Dec. 25, 1927, pp. 49-51, 2 figs. Writer recently engaged upon some analyses which warranted preparation of series of similar diagrams, two of which are presented herewith; facts are of two different varieties, one group with respect to stress behaviour, and another with respect to methods which were found adapted to preparation of diagrams.

CONDENSERS, STEAM

AIR AND STEAM MEASUREMENTS. Air and Steam Measurements Most Difficult. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 59-62, 10 figs. Instruments showing air and steam conditions in condenser moisture in steam cannot be measured; various methods of measuring air discharged are used, most accurate being bell or gasometer.

DESIGN. Condenser Design and Construction Progress, G. A. Orrok. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 55-56, 2 figs. Decreased surface and high heat transfer are results of improved design of condensers and auxiliaries; water-side problems remain to be solved.

PROBLEMS OF. Condensate Handling Presents Many Problems. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928. pp. 62-64, 6 figs. With surface condensers return of condensed steam to boiler-feed system offers many possibilities which should all be analyzed; on method of measurement which offers no possibility of argument is direct measurement of weight with calibrated scales.

WATER SUPPLY FOR. Circulating Water Supply Extremely Important. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 64-66, 7 figs. If natural supply is not available, spray pond must be provided entailing additional investment and auxiliary power; quantity of circulating water can be found from heat balance.

CONTAINERS

FREIGHT, THEORY OF USE. The General Theory of Container Use, B. Allen. Soc. Automotive Engrs.—Jl., vol. 22, no. 1, Jan. 1928, pp. 74-76. Unit containers for transportation of freight by rail and highway; container operation in United States; full benefit dependent on general use; benefits to railroads; advantages to be gained by shippers; two container sizes seem logical; rquirements to be met in design; field for container use.

CONVEYORS

CHAIN. Carrying Engines on 1½-Mile Conveyor. Iron Age, vol. 120, no. 26, Dec. 29, 1927, p. 1784, 1 fig. Chain-type conveyor said to be longest installed in any industrial plant is being used by Buick Motor Co., Flint, Mich., for taking engines from test room to car-assembly plant.

ROLLER BEARINGS IN. Roller Bearings in Conveyors, M. Weckstein. Indus. Engr., vol. 85, no. 12, Dec. 1927, pp. 575-577 and 591, 12 figs. Application of anti-friction bearings to conveyor rolls and drive mechanism; this covers horizontal and inclined rollers for belt conveyors and conveyor wheels; analyzes loads and oiling methods for roller bearings only.

CORES

MACHINES FOR MAKING. Makes Changes in Design of Core Machine. Foundry, vol. 56, no. 1, Jan. 1, 1928, p. 41, 1 fig. American Foundry Equipment Co., Mishawaka, Ind., has made number of changes in its extrusion-type core machine; new machine is equipped with force-feed rod and mixer to insure uniform sand for all sizes of cores.

CRANES

ELECTRIC TRAVELLING. Some Modern Types of Steel Mill Cranes, W. D. Keller. Iron and Steel Engr., vol. 4, no. 12, Dec. 1927, pp. 506-508. Describes features of overhead travelling cranes; 4-girder type used for ladles; one-piece trolley and use of worm gears advocated; anti-friction bearings used and interlocked gear type of trolley.

JIB. Dock Cranes with Inclinable Overhang (Grue de quai, a volée inclinable). Bul. Technique de la Suisse Romande, vol. 53, no. 26, Dec. 31, 1927, p. 317, 1 fig. Jib crane mounted on movable frame rolling on track; overhand of jib variable, load at maximum overhang of 20 m. is 3 tons; minimum overhang, 8 m. movements of crane are all by electric motors.

CULVERTS

DESIGN. The Design of Deep Culverts, C. S. Chettoe. Surveyor (Lond.), vol. 73, no. 1876, Jan. 6, 1928, pp. 5-8, 9 figs. Treats of external forces on deep culvert, resolves them and applies elastic theory to design of deep sizable culverts with and without invert; outlines method of obtaining stresses on cross-section. (To be concluded.)

CUPOLAS

Control. Control of Cupolas (Controle des cubilots), H. Carra and R. Fric. Chaleur et Industrie, vol. 8, no. 92. Dec. 1927, pp. 673-678, 2 figs. Discusses heat radiation, specific heat of gases, measurement of gas pressure, analysis of gas, CO and CO_2 and amount of air necessary for combustion; relation between real and calculated percentages of CO and CO_2.

D

DAMS, ARCH

Design. Analysis of Arch Dams by the Trial Load Method, C. H. Howell and A. C. Jaquith. Am. Soc. Civ. Engrs.—Proc., vol. 54, no. 1, Jan. 1928, pp. 61-95, 16 figs. Method based on assumption that arch dam is composed of systems of horizontal arches and vertical cantilevers, that each system carries proportion of total load, and that deflections of two systems are equal; series of assumed proportional loads applied; deflections computed when proportionate loading found that gives equal deflections at all points for both systems.

Gravity. Notes on Arched Gravity Dams. Discussion by P. Bauman of paper by B. F. Jakobsen. Am. Soc. Civ. Engrs.—Proc., vol. 54, no. 1, Jan. 1928, pp. 219-232, 12 figs. States that there is insufficient justification for ignoring effect of arch action in case of curved gravity dam, such as Exchequer dam; contributes analysis of stresses in Exchequer dam; shows effect of arch support, and that no tensile stresses exist at upstream face, but that appreciable compressive stresses occur, especially in lower portions of dam.

DIE CASTING

Alloys for. Die-Casting Alloys. Machy. (Lond.), vol. 31, no. 793, Dec. 22, 1927, pp. 397-398. Alloys can be conveniently divided into three groups, namely, those of low melting point, which include tin-base, lead-base and zinc-base alloys; aluminum-base alloys; and copper-base alloys, which include 60/40 brass, aluminum bronze, high-tensile brass and aluminum-brass, each of which is discussed.

DIES

Punching. Die for Producing Hunting Tooth Gear. Machy. (Lond.), vol. 31, no. 793, Dec. 22, 1927, p. 390, 2 figs. Punch and die employed in production of two-tooth hunting gears commonly used in mechanical accounting devices; die is of progressive type, having three positions.

DIESEL ENGINES

Ignition. Diesel Engine Ignition Lag Largely Influenced by Preheating, P. M. Heldt. Automotive Industries, vol. 57, no. 26, Dec. 24, 1927, pp. 936-938, 5 figs. Density of air also factor; development of high-speed ignition-compression engine for automotive service in Europe; several new models.

Lubrication. Lubricating Power Cylinders of Diesel Engines, W. C. Northcutt. Eng. World, vol. 32, no. 1, Jan. 1928, pp. 26-29. Purpose of this paper is to offer constructive criticism of present methods of applying lubricating oil to power cylinders of Diesel engines, and to recommend method which is believed to be improvement; discussion, data and conclusions based on experimental study of this phase of Diesel-engine lubrication.

DRILLS, TWIST

Grinding. Remarks on Grinding of Twist Drills, W. M. Gladding. Abrasive Industry, vol. 9, no. 1, Jan. 1928, p. 3. Brief account of important features in drill-point grinding; tables of drill clearance angles and of point-pressure and torque data; standard drill angles; disadvantages in too much or insufficient lip clearance.

DRY KILN

Steam-Jet-Blower. Design of Lumber Dry Kilns, H. L. Alt. Heat. and Vent. Mag., vol. 25, no. 1, Jan. 1928, pp. 101-102, 2 figs. Describes new type of steam-jet-blower dry kiln with chart showing air and moisture conditions during ordinary lumber-drying process.

DURALUMIN

Properties. "Duralumin," L. Atchison. Metal Industry (Lond.), vol. 31, no. 26, Dec. 30, 1927, p. 602. Discusses its properties and heat treatment; it is produced and used in all known forged forms; it is most conspicuous nonferrous material which has to be completely heat-treated, that is, hardened by quenching and tempered; it is subject to corrosion to certain extent, but is less corrosive than steel. Lecture given before Co-ordinated Societies in Birmingham, England.

E

ECONOMIZERS

Corrosion. Internal Corrosion of Fuel Economizers, E. Ingham. Mech. Wld., vol. 82, no. 2138, Dec. 23, 1927, p. 467. Corrosion caused by pure water is generally believed to be due to presence in water of dissolved gases, oxygen or carbonic acid; corrosion may be avoided by using pure water entirely free from dissolved gases; a great deal may be done to prevent corrosion due to presence of dissolved gases in feedwater by introducing with feed certain reagents; remarks are confined to ordinary cast-iron economizer.

ELECTRIC CABLES

High-Tension. Influence of Internal Vacua and Ionization on the Life of Paper Insulated High-Tension Cables, A. Smouroff and L. Mashkileison. Am. Inst. Elec. Engrs.—Jl., vol. 47, no. 1, Jan. 1928, pp. 24-28, 9 figs. Results of experimental research undertaken at high-voltage laboratory of Electrotechnical Institute in Leningrad; aim of research was to clear up causes in formation of internal vacua, then to determine values of those vacual and decrease of life duration of cable under influence of latter; research is not yet finished and only preliminary results are reported.

Underground. Underground System Temperatures, T. G. Hieronymus. Elec. World, vol. 90, no. 26, Dec. 24, 1927, pp. 1299-1300, 3 figs. Studies are in progress on system of Kansas City Power & Light Co. to determine definite carrying capacity of lead-covered, paper-insulated cables under local conditions of climate and construction practice; conditions so far discovered are related.

ELECTRIC CIRCUIT BREAKERS

Oil. High-Voltage Oil Circuit Breakers for Transmission Lines. Am. Inst. Elec. Engrs.—Jl., vol. 47, no. 1, Jan. 1928, pp. 57-64. Discussion of paper by Wilkins and Crellin published in Dec. 1927 issue of Journal.

ELECTRIC CIRCUITS, SAFETY

Safety. Electrical Safety Circuits—Their Uses and Construction, W. M. Runyon. Iron and Steel Engr., vol. 4, no. 12, Dec. 1927, pp. 508-512, 2 figs. Safety circuit defined; its need, point of installation, features of design and points to observe for high- and low-voltage circuits.

ELECTRIC CONDENSERS

Synchronous. Synchronous Condensers. Am. Inst. Elec. Engrs.—Jl., vol. 47, no. 1, Jan. 1928, p. 54. Discussion of paper by P. L. Alger published in Dec. 1927 issue of Journal.

ELECTRIC CONDUCTORS

Direct-Current. Chart for Selecting Direct-Current Conductors, C. A. Kuhmann. Power, vol. 67, no. 2, Jan. 10, 1928, pp. 68-69, 1 fig. Presents alignment nomograph based on resistance per mil-foot of copper conductor, and value used is 10.37 ohms, as given by Copper and Brass Research Association.

ELECTRIC CONVERTERS

Rotary. Small Inverted Rotary Converters, B. H. Chatto. South Power Jl., vol. 46, no. 1, Jan. 1928, pp. 42-44, 5 figs. Recent increase in demand for small quantities of alternating current in localities served by direct current has resulted in development of small inverted rotary converters of design which has overcome many faults usual to such units.

ELECTRIC FURNACES

High-Frequency. Crucible Steel Production in a High-Frequency Electric Steel Furnace. Ry. Engr., vol. 49, no. 576, Jan. 1928, pp. 10-15, 6 figs. Ajax-Northrup high-frequency electric steel furnace effects revolution in production of tool steel by increasing capacity of crucible from 60 to 450 lb., and reducing time of melting from 4 to hours to 1 hour, while also affording better control.

High-Frequency Induction Melting, D. F. Campbell. Iron and Steel of Can., vol. 10, no. 12, Dec. 1927, pp. 363-366, 5 figs. Describes high-frequency furnace used in Sheffield Steel Works for melting lots of 400 to 500 lb. of steel; 18 per cent tungsten steel in 300-lb. lots can be melted in 45 min.; very low-carbon alloys can easily be made; 150-kva. generator used.

ELECTRIC GENERATORS

Alternating Current. Maintaining Correct Voltage and Frequency. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 67-69, 5 figs. Proper operation of a.c. generators demands accurate knowledge of factors which affect voltage and frequency; voltage variation is accomplished either by hand or by means of automatic voltage regulator; in latter case, Tirrill-type regulator is customarily used, although motor-operated face-plate rheostat is also used.

Alternating Current, Design. Alternator Characteristics Under Conditions Approaching Instability, J. F. H. Douglas and E. W. Kane. Am. Inst. Elec. Engrs.—Jl., vol. 47, no. 1, Jan. 1928, pp. 24-28, 9 figs. Comparatively recent discovery of generator instability is discussed; method of testing synchronous machinery in unstable as well as in stable range; results of test performed on two machines; conclusion is drawn that design of customary machines will have to be improved, synchronous condensers installed on many long lines or inefficient underloading of units will have to be tolerated.

Alternating Current, Short Circuits. Calculation of Sustained Short Circuits, H. B. Dwight. Elec. World, vol. 90, no. 25, Dec. 17, 1927, pp. 1243-1245. Practical method for use with alternators to calculate 3-phase and single-phase short circuit currents; simple formulas are given; methods of utilizing generator characteristics in calculation of sustained values of current for short circuits of several types.

Operation. Load, Power Factor and Temperature Control. Power Plant Eng., vol. 32, no. 1, Jan. 1, 1928, pp. 69-72, 6 figs. Economical loading of electric generators demands consideration of individual and grouped efficiencies of units; effect of power factor is important.

ELECTRIC INDUSTRIES
