From station 11 + 74 to the north shaft the grouting was carried on by first doing the main mass at 100 pounds per square inch and then following up later at 200 pounds per square inch. The grout holes at the quarter bends where special water conditions were encountered were panned and grouted from one to the other in the regular way.

Those joints that had not been welded until after the backing was placed were exceedingly difficult to get dry, frequently they were drilled and tapped and before putting the plugs in the tapped holes grout was forced in with a small pump.

In the shaft one grout hole was placed about two inches lower than the other, the horizontal distance apart being about two feet. In placing the backing the concrete was brought up to the top of the higher hole. After about four hours a sheet of No. 18 gauge galvanized iron was forced down into the hardening concrete about five inches. Concrete between this sheet and the original concrete shaft lining was removed so as to make a trench on a grade between one hole and the other around the shaft but not across the 2-foot intervening space, where a solid dam was left. Before next concreting started this drainage trench was filled with 1½-inch to 2-inch gravel and carefully covered with two layers of burlap snugly tucked at sheet and concrete face so that when the next concrete was placed this gravel drain carried away what water might collect in it, preventing the water from rising up through the green concrete.

The grouting of the shaft then consisted in forcing in grout at the lower hole and continuing the pressure until it flowed freely from the upper one. Only a small quantity was taken but it very effectively shut off the seepage water.

After the grout was set the plugs were screwed in and the aperture in the inner lining filled up with concrete and smoothly finished.

The operation of grouting may be described as particularly tedious, and uninteresting, but results are definite and satisfactory if the work is properly performed.

Where the welding was performed before the backing was placed, any porosity was disclosed before the concrete set by a dampness on the metal. A caulker attended to this and a watertight joint was the result. No finishing was placed until the finisher was sure of that watertightness. The joint finisher roughened the ends of the 2-inch concrete lining, set a reinforcing band of mesh 2 inches by 2 inches of No. 12 gauge and then plastered in the joint cavity, which was 4 inches wide, with 1 to 2 cement sand mortar. It was screeded to perfect alignment, finished with steel trowel and the joint can hardly be detected from the spun portion of the inner lining.

At the south valve chamber the connecting pipes were kept at an even temperature by a system of internal spray pipes and in this even temperature the pipes were grouted into their permanent positions through the north wall of the south chamber. The spray pipes were kept going until the tunnel was filled.

Fig. 14—Grout Holes Discharging Water.

At the north chamber the valve and heads were bolted into position and after the water had risen to the proper elevation to keep them full the grouting into the south wall of the north chamber was completed. Circulation was kept going throughout the period of grouting and setting.

The lead joints connecting the tunnel pipes to the north and south mains were poured and the wall castings grouted to final positions and the tunnel construction was ready for hydrostatic test.

### Hydrostatic Test of Tunnel

The pressure used was 210 pounds per square inch at pipe level in the south valve chamber and was maintained for thirty-six hours, the leakage water being measured.

For the last fourteen hours the total rate of pumping was at the rate of 288 gallons per twenty-four hours. The main south of the south valve was opened and the valve was drop-tight, likewise the blow-off valve in the south chamber. But the valve in the north chamber had not been as carefully closed and it was surmised that some water was passing it. A check was made which was not entirely conclusive but an estimate of 110 gallons per twenty-four hours was arrived at as escaping the valve. This was considered satisfactory under the specifications, and under the peculiar conditions then existing it was impossible to inspect that side of the valve. At a later time the test will be repeated and results noted.

During the test not a drop of water was visible at any exposed bolted joint. Three sand holes were discovered in the steel castings and were caulked and welded.

On June 3rd, after a final inspection was made, the tunnel was swept and washed. After baling out the washing water from the north shaft sump, the tunnel and shafts were filled with chlorinated water containing about 15 parts per million of free chlorine. Afterwards the tunnel was flushed for ninety-six hours before any water was turned into the distribution system, which was only done after the Medical Health Officer had reported the water free both from chlorine and from contamination.

On June 15th water was turned through the city pressure regulating valves into the distribution system and on June 30th the valves were fully opened and normally operated.

The contractors finished their work and removed all plant and equipment on July 8th, just two years after the award of the contract.

After the completion of the work done under the general contractors, the area used for construction purposes around the valve chambers and the access chamber in Stanley Park was filled, graded and seeded, and trees and shrubs planted. On the north shore an access house, octagonal in form, was built of reinforced concrete and located over the shaft.

The north and south pipe line connections to the tunnel were laid by the District's own forces, the mains across the Indian Reserve and across Stanley Park having been installed under separate contracts.

The whole construction work was, fortunately, very free from accidents, only four being at all serious.

The Greater Vancouver Water District was represented as follows: Mr. E. A. Cleveland, M.E.I.C., chief commissioner; the late Mr. J. Waldo Smith, M.Am.Soc.C.E., of New York City, consulting engineer, while Messrs. Sanborn and Bogert, also of New York City, represented him in detail studies; Mr. W. H. Powell, M.E.I.C., engineer; and Mr. Fred Stewart, resident engineer, from whom many of the details of this paper were obtained. Mr. Wm. Smaill, M.E.I.C., was chief engineer for the contractor.

The total cost of the work was $1,249,641.85, which for purposes of analysis may be thus detailed:

| | | |
|---|---|---|
| Preliminary investigations and bedrock exploration.... | | $ 91,540.17 |
| Northern Construction Company and J. W. Stewart, Ltd | | 924,715.64 |
| Ross and Howard Iron Works (steel pipe and bends).... | | 16,172.11 |
| Dominion Engineering Works—valves..... | $ 6,876.00 | |
| shaft caps.. | 19,756.89 | |
| | | $ 26,632.89 |
| Dominion Bridge Company (steel pipe)............... | | 5,464.40 |
| Vancouver Engineering Works (steel flanges, etc.)..... | | 3,043.72 |
| District's own forces.............................. | | 32,989.06 |
| Administration, engineering, testing and inspection. .. | | 78,340.10 |
| Interest during construction up to June 30th, 1933.... | | 70,743.76 |
| | | $1,249,641.85 |

## APPENDICES

Night shift... 40.00
Grave yard shift... 35.00

II

TABULATION OF TENDERS

| Tenderer | Total | Remarks |
|---|---|---|
| Northern Construction Co. and J. W. Stewart Ltd. | $ 957,144.50 | If Bonna pipe used in contracts Nos. 35 and 36, deduct $15,000.00. |
| | $1,003,584.50 | If air locks required as called for in specifications add $50,000.00. |
| Smith Bros. and Wilson Limited. | $ 926,804.83 | If Bonna pipe used in contracts Nos. 35 and 36, deduct $15,000.00. |
| | $ 925,639.59 | Three qualifications of specifications: (1) Relief in event of impossibility of completion. (2) Payment of progress estimates. (3) Arbitration. |
| | $ 981,680.52 | No experience sheet. |
| Pacific Engineers Ltd. | $1,020,447.50 | If Bonna pipe used in contracts Nos. 35 and 36, deduct $15,000.00. |
| | $1,026,827.50 | Three qualifications of specifications: (1) Relief in event of impossibility of completion (2) Payment of progress estimates. (3) Arbitration. No experience sheet. |
| Stuart Cameron Ltd. | $1,320,540.21 | If Bonna pipe used in contracts Nos. 35 and 36, deduct $15,000.00. |
| | $1,371,677.53 | |
| | $1,348,488.13 | |
| | $1,385,493.25 | |

NOTE: Contract No. 35—First Narrows pressure tunnel.
Contract No. 36—Stanley Park pipe line.

VII

Concrete Lining of Steel Cylinder Reinforced Concrete Pipe
Typical Test of Sand and Gravel

| Sand | Fine | Coarse |
|---|---|---|
| Retained on No. 4 mesh | Nil | Nil |
| Retained on No. 8 mesh | 1.0 per cent | 9.0 per cent |
| Retained on No. 16 mesh | 3.0 per cent | 27.5 per cent |
| Retained on No. 30 mesh | 15.0 per cent | 55.0 per cent |
| Retained on No. 50 mesh | 61.5 per cent | 86.0 per cent |
| Retained on 100 mesh | 92.5 per cent | 99.0 per cent |
| Fineness modulus | 1.73 | 2.77 |
| Moisture | 3.8 per cent | 3.6 per cent |
| Organic | O.K. | O.K. |
| Weight per cubic feet (damp loose) | 78 pounds | 89 pounds |

| Gravel | No. 1 | No. 2 |
|---|---|---|
| Retained on ¾-inch | Nil | Nil |
| Retained on ⅜-inch | 0.7 per cent | 1.3 per cent |
| Retained on ¼-inch | 53.0 per cent | 84.8 per cent |
| Retained on 8 mesh | 89.2 per cent | 97.7 per cent |
| Retained on 16 mesh | 98.1 per cent | 99.2 per cent |
| Retained on 30 mesh | 99.9 per cent | 99.8 per cent |
| Retained on 50 mesh | 100.0 per cent | 100.0 per cent |
| Retained on 100 mesh | 100.0 per cent | 100.0 per cent |
| Fineness modulus | 5.41 | 5.83 |
| Weight per cubic feet (damp loose) | 98 pounds | 102 pounds |

The weight per cubic foot of the two mixtures of 1½ cubic feet of coarse sand and 1½ cubic feet of each of the gravels dry rodded was the same, namely 122 pounds per cubic foot, using the above fine sand in each case.

By using less of the finer sand with sufficient No. 1 gravel to bring the total aggregate to three separate volumes, a much denser mixture was obtained, namely 132.5 pounds per cubic foot.

After adding 1 cubic foot of cement and making mixes of the same slumps, the weight per cubic foot was practically the same in each case.

After a few preliminary adjustments of size of batches, the following was adopted:

| | |
|---|---|
| Gravel .................. | 6 cubic feet |
| Sand .................. | 6 cubic feet |
| Cement .................. | 3½ sacks |
| Water .................. | Gauged by eye and checked on each mixer for slump of 2 to 3 inches. |
| Length of mixing time .... | 4 to 5 minutes. |

For each length of tunnel pipe it required 2 batches to fill a trough and about 4 troughs per pipe; a total of slightly over 2 cubic yards in all.

Spinning time while pouring—20 minutes approximately.

Spinning time after pouring at increased speed—45 minutes.

Speed of pipe 113 r.p.m. or 2,700 feet per minute.

Mix: 9 sacks cement per yard—1 sack to 3 volumes, dry rodded mixed aggregate $\frac{3.00}{.92}$ = 3.26 volumes, measured separately.

$$\left.\begin{array}{l} 3.26 \times .68 = 2.20 \\ 3.26 \times .32 = 1.04 \end{array}\right\} \text{Nominal mix: 1-2.20-1.04}$$

$$\left.\begin{array}{l} 2.20 \times 1.24 = 2.73 \\ 1.04 \times 1.14 = 1.19 \end{array}\right\} \text{Field mix: 1-2.7-1.2}$$

For 4 sack batch cement—Birdseye gravel— 4.76 cubic feet
Sand —10.92 cubic feet

1 pint of Vasso per yard was used with this mix.

# The Operation of a Hydro-Electric Power System

## A SYMPOSIUM

*by*

*C. R. Reid, Assistant General Superintendent, W. R. Way, Superintendent of Operation, and E. W. Knapp, A.M.E.I.C., Service Research Engineer, The Shawinigan Water and Power Company, Montreal.*

**Papers presented before the Montreal Branch of The Engineering Institute of Canada, March 22nd, 1934.**

Foreword

*Due to the familiarity of the writers with the operations of the Shawinigan Water and Power Company, the following papers have been based mainly on the physical set-up and operating data of that organization. It is not desired to give any impression that these operating practices are considered superior to those of other similar organizations. Such practices are largely standardized and much of what follows will no doubt be familiar to other operating men.*

*An exhaustive treatment of the subject would require more time than is available, consequently the papers deal only with those features which were thought to be of particular interest to the members of The Engineering Institute.*

## The Operation of a Hydro-Electric Power System

*C. R. Reid*

The water flowing in a stream at a given point and time, as is well known, originated as rainfall on the watershed of the stream. Since rainfall is intermittent in character, it is only to be expected that the stream flow will be of the same nature. Fortunately, the natural storage capacity of the watershed serves to decrease the maximum run-off after a heavy rainfall and to supply ground water to the stream for long periods when there is no rainfall. Notwithstanding this equalizing effect exerted by the absorptive nature of the watershed, the seasonal variation in flow on practically all streams is considerable and must be taken into account in the development and operation of a power site.

A map of the St. Maurice river basin, some 16,000 square miles in area, is given in Fig. 1, on which there are also shown the various storage reservoirs which have been provided for regulation purposes. Figure 2 gives the hydrograph for the unregulated portion of the watershed for 1931 (curve $B$) with an addendum giving the total regulated flow (curve $A$) which of course shows a considerably greater degree of uniformity.

The consumption of energy on a power system undergoes a considerable seasonal variation. This can be attributed to variation in daylight hours affecting the lighting load, additional tramways' load during the winter, electric heating and other causes of minor importance.

The diagram of Fig. 3 shows the annual curve of weekly kilowatt-hour primary power output on the Shawinigan system for 1931 (curve $D$) with the secondary power curve superimposed (curve $C$).

From the above it is apparent that the natural flow of streams in eastern Canada does not conform very well to the annual load curve of a power system. By the use of stored water a much greater conformity may be secured. If a secondary power load is available, it may be utilized to fill the valleys of the primary power load and to make it correspond to the power available as represented to a certain extent by the modified hydrograph of the stream.

In addition to the general management and utilization of the stream flow, a certain amount of control may be exercised at the individual power developments. Thus, if there is a considerable amount of pondage available at the site, this may be utilized on a weekly basis by carrying an excess load during the week and drawing down the pond level. The Sunday load on the system, being of the order of 50 per cent of the week-day load, will permit the pond levels to be restored to a maximum. In the case of a power development with small pondage, this may be used to carry excess load during the daytime and be replenished at night. The results of such control are shown in Fig. 4, in which curves *A*, *B* and *C* give the headwater levels during a week when no spill occurred, at Grand'Mere, Shawinigan Falls and LaGabelle, respectively. The lower curve *D* is a record of the hourly rate of flow through the power house at Grand'Mere.

It is of importance to arrange the loading of the units in a power house so as to obtain the maximum efficiency in the use of the water passing through the plant. It will be noted from Fig. 5 that the propeller type of hydraulic turbine attains its maximum efficiency at full load or close to it. Consequently, in a plant containing this type of unit only, an attempt is made to operate the units at full load by shifting load between plants and by shutting down units a part of each day. Since the efficiency of the Francis type unit is high over a wide range, these units are best adapted to take care of load variations on the system and to adjust the load to best efficiency on the propeller type units.

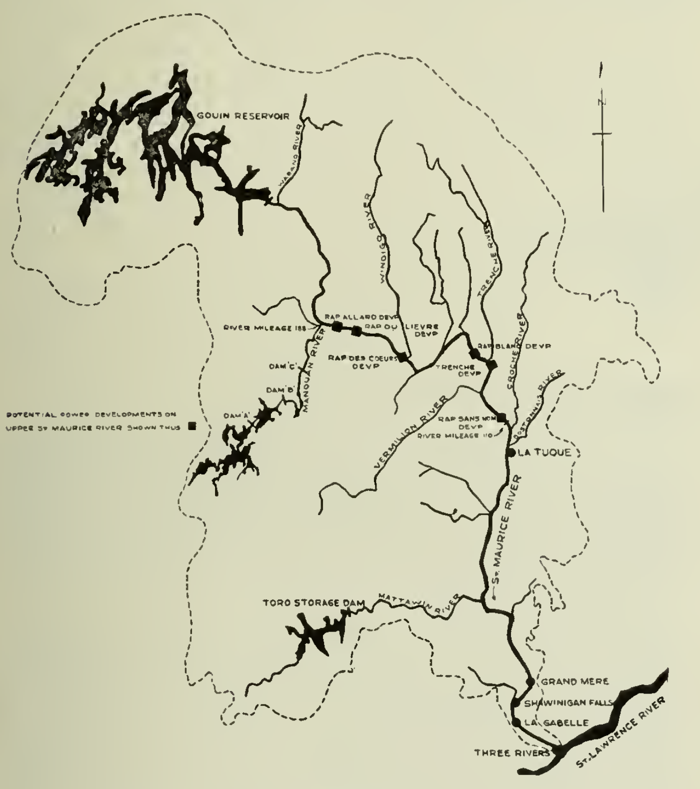

**Fig. 1—Map of St. Maurice River Basin.**

In case a power system consists of a single development containing propeller type units, it is desirable to install one or more Francis type turbines in order to obtain the most efficient use of the water.

A system of lines for the transmission of power is, as a usual thing, planned in its ultimate completeness, but tends to grow more or less as the branches of a tree spread out from the stem. Whenever a new load is available to add to the system, the tendency is to connect it to the existing lines at a minimum cost.

With the growth of load on a system, additional main lines must be built from time to time. At such times, as indeed at any time when extensions are undertaken, an effort is made to forecast future growth and to make extensions and alterations to the system in such a way that they will have the greatest permanent usefulness.

**Fig. 2.**

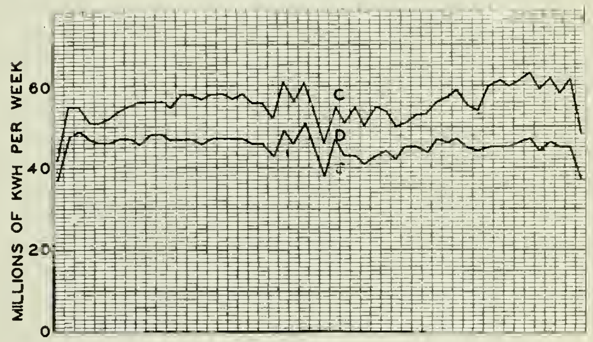

**Fig. 3.**

In order to supply to the customer the best service consistent with a reasonable cost, various devices have come into general use on power transmission systems. On radial lines in which circuit breakers are installed, in series so to speak, at varying distances from the power house, it is found desirable to make use of what is known as distance relaying. This is an arrangement whereby line troubles beyond the second switch will not cause the first switch

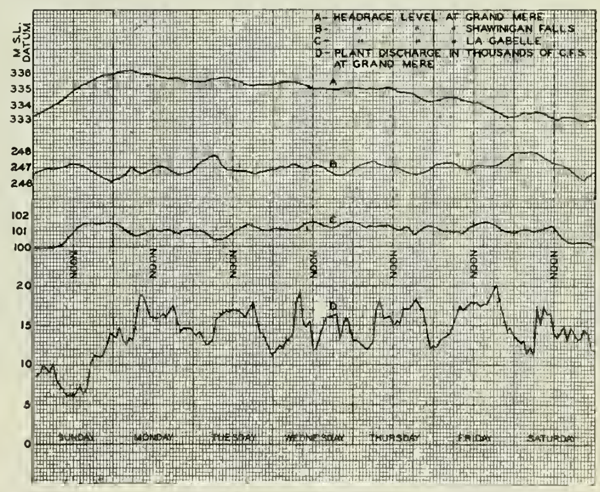

**Fig. 4.**

to open, and so on to the farthest point on the line. This means that a trouble on a radial branch of the line will be cleared off that branch only and not interrupt service as a whole. Radial lines are also well adapted to automatic reclosing. Unfortunately, it is not often that automatic reclosing can be utilized without certain changes to the control equipment on the customer's premises.

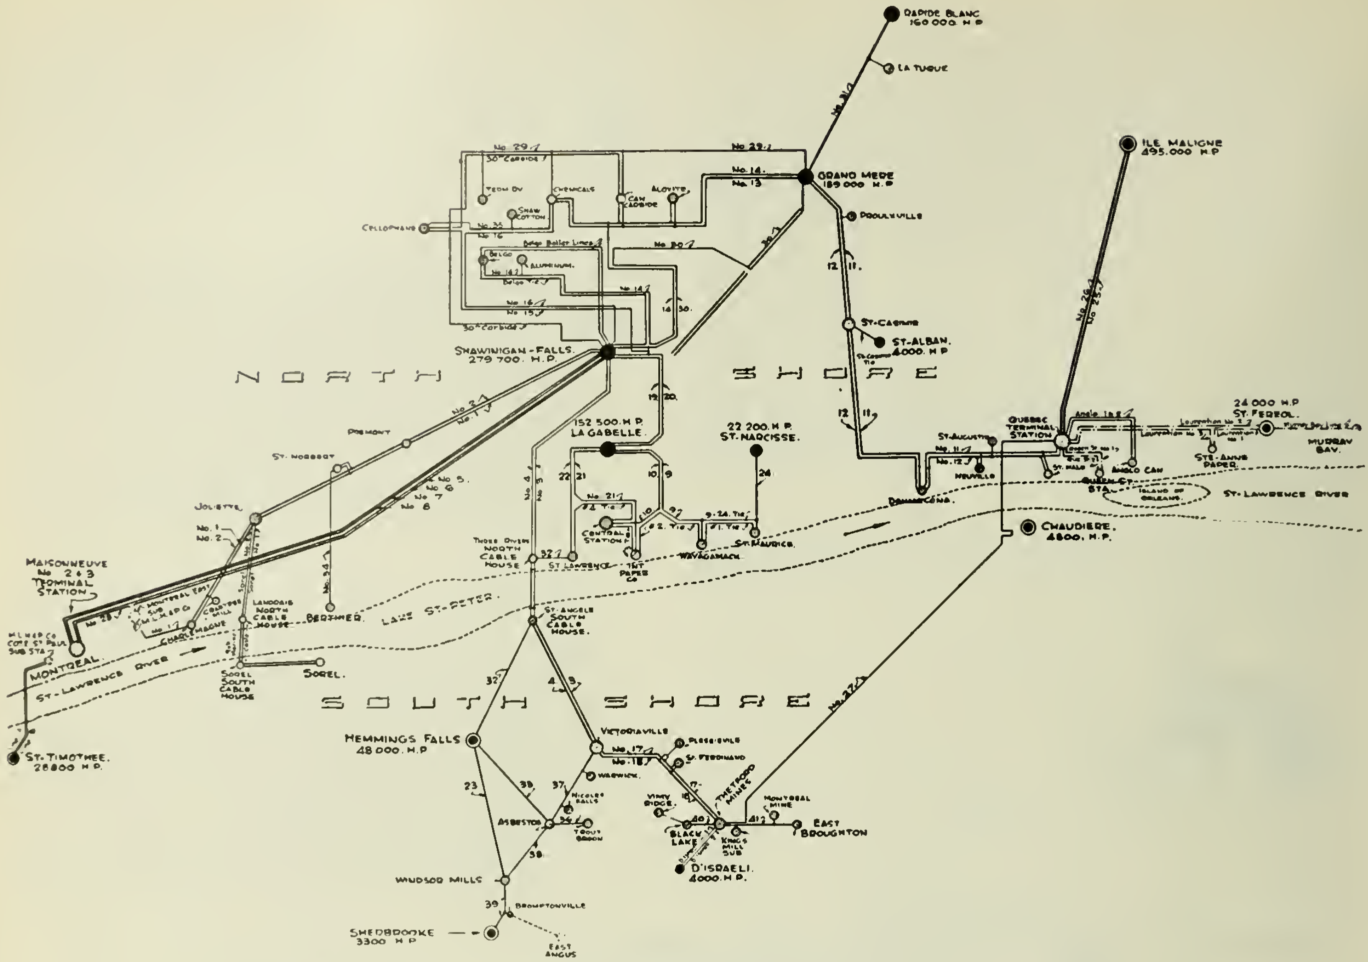

Fig. 6—Main Transmission Lines of The Shawinigan Water and Power Company.

The continuity of service to a customer is safeguarded by multiple feed. This ordinarily takes the form of parallel lines running to or past the customer's premises. Reasonable freedom from interruption may be secured by providing automatic circuit breakers with selective relaying.

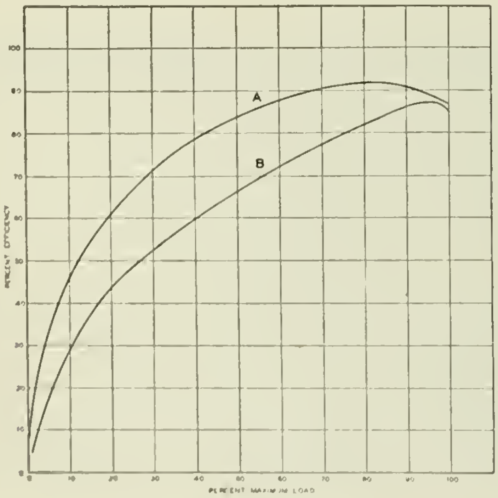

Fig. 5.

Hand operated switches will insure prompt resumption of service by transferring from one line to another.

An alternative to the parallel line system of multiple feed is secured by the network system. The relaying of such a system is apt to be more complicated than in the case of parallel lines. However, such a system is well adapted to cover a large territory where there are no concentrated heavy loads.

A combination of the radial and network systems of transmission consists of a direct line from the powerhouse to each of several large customers together with loop lines between customers. If the customer's plants are not too far apart, the loop lines can be economically protected by pilot wire installation.

Due to the desire on the part of the customer of late years to obtain low cost power even at the expense of continuity, there is an increasing tendency to rely on single lines for carrying loads of considerable importance and magnitude. A special effort is made to render such lines as proof against interruptions as possible. In this connection there has been great progress of late in constructing lines that are reasonably lightning proof. The other causes of interruptions are also being overcome to a great extent.

A plan of part of the main transmission system of the Shawinigan Water and Power Company is given in Fig. 6, and illustrates some of the points mentioned above.

With the growth of a power system, certain difficulties arise which tend to limit the complete flexibility of system set-up which might be desirable from the system operator's standpoint. One of these difficulties is that, with increasing generating capacity, the rupturing capacity of the switch gear originally installed may be exceeded. This must either be provided for by installing heavier switch gear or by a certain amount of segregation in the system set-up.

Another difficulty which may arise with system growth is that transmission lines which were originally used to tie together parts of the system may not have the transmitting capacity to hold together large generating stations. This may require the system to be split into sub-systems for parallel operation.

It will be apparent from the foregoing, that operating conditions on a hydro-electric system are continuously changing. Constant study and care are required to provide adequate service and at the same time to obtain the maximum output available.

## Load, Frequency and Time Control on Interconnected Systems

*W. R .Way*

Regulation and control of load, frequency and synchronous time on a large interconnected electric system is a matter requiring constant supervision. These three factors are closely interrelated, but very often this interrelation is not fully appreciated, since the problem must be viewed from a system standpoint, rather than from a company standpoint.

By load control is meant the regulation of the kilowatt load between units, generating stations and systems. On any one system, load regulation between units or plants is necessary so that efficient operation may result. This is especially true where two or more plants are located on the same river with limited pondage. Load regulation between systems is also very important, since where one company is purchasing power from another, it is advisable and economical to obtain as many kilowatt-hours as possible, and load must be regulated with this end in view.

Good frequency is essential on an electric system primarily to enable motors to be operated at correct speeds for manufacturing processes, and to allow accurate control of the transfer of power between units, stations and systems. Motor-driven centrifugal pumps, for instance, are very sensitive to speed changes, and their output will vary at a far greater rate than the frequency.

In regard to frequency, many terms are used, and proper definitions must be made. Consider a 60-cycle system, for instance; the term "constant frequency" would indicate any fixed frequency, such as 59.8 cycles, which would not be desirable. An "average" frequency of exactly 60 cycles might be obtained over a day's run, but during the day, many swings might have occurred, either continuously or at numerous periods, and this could not be considered good frequency regulation. The aim should be, therefore, to obtain correct average frequency, limiting the departures from normal at any instant to as small a value as possible. If this latter condition can be obtained, synchronous time regulation will disappear, and correct synchronous time will be obtained as a natural result of good frequency. Synchronous time is that indicated on the so-called electric clocks which are directly driven from alternating current systems. It bears a direct relation to system frequency, and shows any cumulative error from normal. On a system which is regulating synchronous time, correct average frequency should coincide with correct standard time.

In the early days of the electrical industry, the matter of voltage regulation was generally considered of more importance than frequency. Regulation of voltage by hand soon gave place to the many devices for controlling voltage automatically. Lighting load predominated, as only a comparatively small percentage of the load used rotating machinery. As the various classes of industry became motorized, manufacturers demanded better frequency, so that they could turn out uniform products at a steady rate of production. Textile firms were particularly interested, since variations in frequency resulted in the fabrics being of uneven colour and texture.

As the years progressed, the large increase in industrial load involving rotating machinery exerted a steadying influence on the system frequency, due to the fact that the inertia of the system, or fly-wheel effect, increased at a greater rate than did the normal load variations. Coincident with this growth of load, additional generating stations were built, systems were interconnected, and governors were improved, all of which tended to increase the normal system stability from a frequency-regulating standpoint.

The interconnection of large electric systems, however, brought out new problems of load control between systems

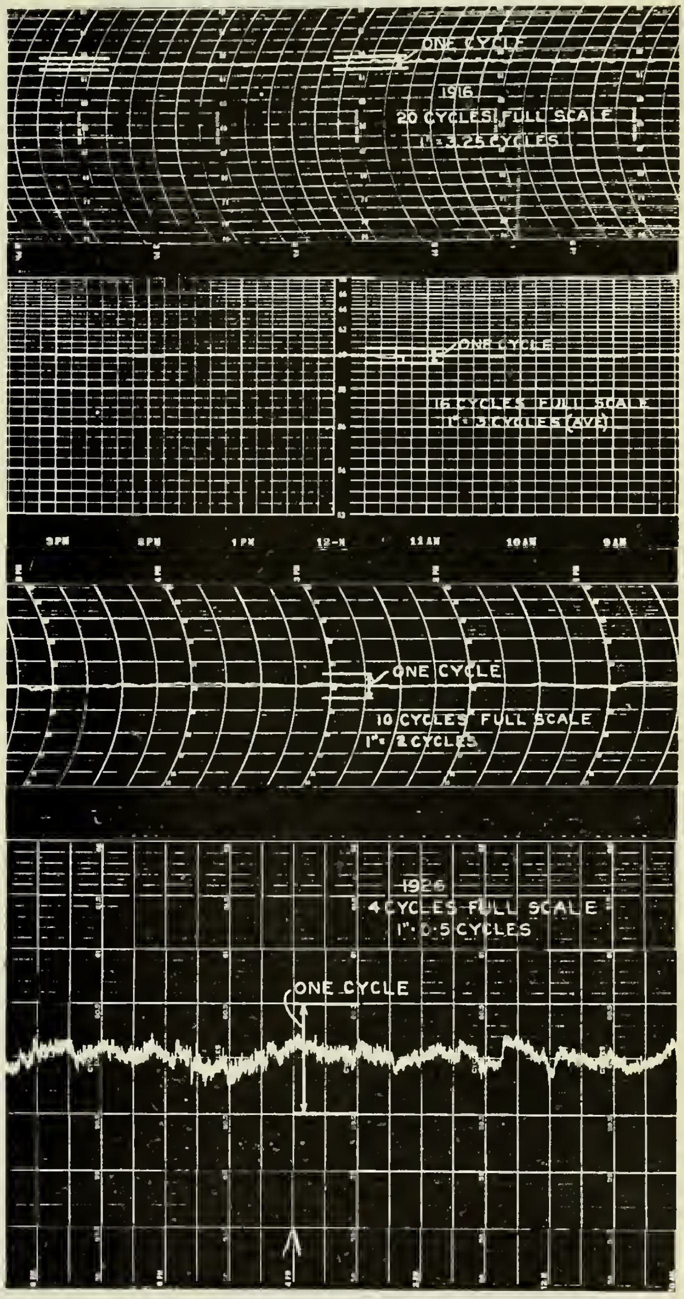

Fig. 7—Improvement in the Sensitivity of Graphic Frequency Meters.

which affected frequency control, and during the past eight or ten years, resulted in the development of commercial frequency meters which permitted an accurate large scale graph of the frequency variations to be recorded.

The introduction of the modern type of frequency meter, sensitive to .01 cycle, made it possible for the problem to be studied more fully, and allowed a great improvement in frequency control to be made over that which had previously existed. Figure 7, which reproduces sample records, indicates the greatly increased sensitivity of the present frequency meter as compared with earlier models.

Among the many new devices brought out, one of the most important was the Warren master clock. The introduction of the master clock was a distinct step forward, since it provided a means whereby the integrated departure of frequency from normal was visible at all times to the operating staff.

Fig. 8—Type "A" Warren Master Clock.

The type "A" Warren master clock, in its simplest from, consists of an instrument having a large dial, in front of which are two concentrically mounted hands of different colours. The gold hand is operated by means of a synchronous motor connected to the system to be regulated, and is suitably geared to denote exact time based on normal frequency. The black hand is actuated from an extremely accurate pendulum clock, which is checked for accuracy twice daily, using observatory time signals. Having once been properly set, the two hands move together around the dial, and remain one over the other as long as the frequency is correct. Any variation in average frequency from normal can immediately be noted, and corrective measures applied, since it will cause the gold hand to lead or lag behind the black hand, according to whether the integrated departure from normal is above or below the normal value. On a 60-cycle system, an average departure above normal of 1/10 cycle for one hour results in the synchronous clocks gaining six seconds during the period.

As electric systems installed master clocks, and average frequency was held within fairly close limits, advantage was taken of the fact to develop synchronous clocks for general use. Due to the fact that such clocks consume power of the order of only 2 watts, no great increase in load resulted for the power company, the maintenance of correct time simply being an additional service rendered to the consumer. One of the advantages of the synchronous clock over the pendulum or spring-wound clock is that the error is non-cumulative, and the accuracy is much better than usually obtained by non-electric clocks.

Turning now to the practical aspects of the problem, due consideration must be given to some of the characteristics and limitations of the hydraulic turbine governor.

It is well known that any prime mover requires some governing device to control speed under various load conditions. The governors used in hydro-electric units are of the centrifugal head type, driven either electrically or mechanically from the respective units. In order to secure satisfactory and stable parallel operation of alternating current generators, it is essential that the governors should have a drooping speed-load characteristic, so that the speed drops as the load increases. If this is the case, and there is a definite relation between load and speed, it is possible to obtain a proper division of load among the many units of different makes and capacities which are operating in parallel. The drop in speed from no load to full load, expressed as a percentage of the no load speed, is called the inherent speed drop, and usually lies between the limits of 2 and 5 per cent. Such drooping characteristics are shown in Fig. 9, where curves *A* and *B* refer to two generators having respectively 2 per cent and 4 per cent inherent speed drop.

On this basis, therefore, during load changes, if no adjustment were made to the governors, the speed, and, therefore, the frequency, would vary inversely as the load, to the extent of possibly 3 cycles, from no load to full load, on a 60-cycle system. Since load changes are almost continually taking place, causing temporary changes in frequency, some adjustment must be made to the governor setting from time to time, either manually or automatically, to insure correct frequency being obtained. The governor synchronizing motor provides this means of adjustment. The operator may bring the frequency back to normal by actuating the governor synchronizing motor control when necessary. This has the effect of raising or lowering the speed-load characteristic curve of the governors, and causes the unit or units to pick up or drop off load as the case may be.

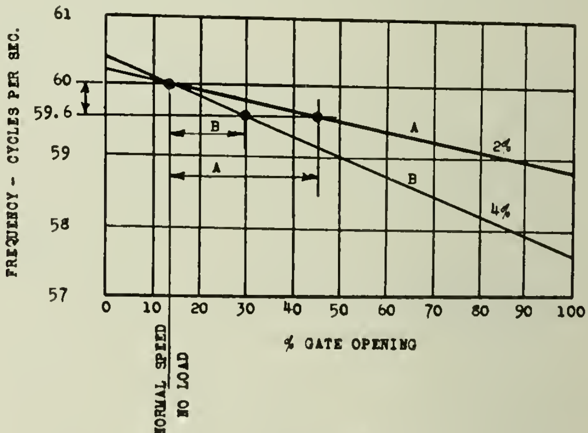

Fig. 9—Typical Inherent Speed Drop Curves.

This is done by changing the linkage between the floating lever and restoring mechanism of the governor, when the inherent speed drop curve is raised or lowered, as shown in Fig. 10, while retaining the same percentage drop. Thus a unit can be made to carry any desired proportion of its full load while running at normal speed.

From the above, the conclusion may be drawn that the governors only tend to maintain constant frequency if no load change has taken place, or conversely, *the governors themselves cannot maintain constant frequency during load changes.*

Most modern governors for hydro-electric units are equipped with a load-limiting device which can be set so that normally the load on the unit will be automatically maintained at any selected maximum figure. The load-limit control furnishes a very stable means for base load adjustment, but obviously cannot be used if the governor is required for frequency-regulating purposes.

Where load-limiting control is not available or not used, the tendency of the operating staff is often to operate a number of the units wide open by adjusting the governor motors, and leave one unit operating at partial gate opening, since it is much easier for the operator to watch and adjust one unit than several. This results in inefficient plant operation, at the same time tending to aggravate the difficulties of frequency regulation.

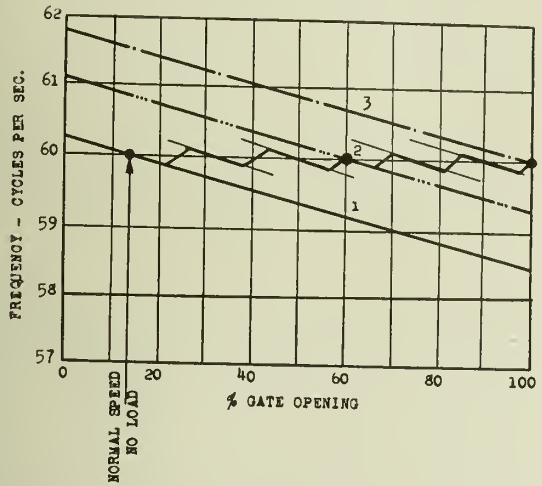

Fig. 10—Effect of Raising Speed-Load Curve.

To bring out some of the practical operating problems involving the interrelation between load and frequency, consider for the moment two power systems, each supplying a load area, and tied together through a tie line. Any change in load in either area will cause a corresponding change in frequency, and if all units are on governor control, the effect of the change in frequency will be felt on all power stations. Should no understanding exist as to frequency-control, the operators on either system may attempt to restore normal frequency. If one system succeeds in restoring normal frequency, power will flow over the tie line, and possibly upset interchange agreements, which the operators of the other system will immediately attempt to correct. By correcting the tie line loading, the frequency would be abnormal again, and the whole process might have to be repeated several times, with many adjustments being made, until normal conditions prevailed.

The result would be, therefore, a constant conflict between systems, with large swings in frequency and tie line load, and inability to maintain contractual relations.

To overcome such occurrences, the system having the greatest proportion of the system generating capacity generally must bear the responsibility of frequency regulation, the other systems regulating their plants to hold tie line loading within definite limits, both between plants and between systems. Ordinarily very little attention is paid to the variations on tie line loading between plants on the same system until some physical limitation of the tie line is reached. At interchange points between systems, however, changes in power flow affect contractual agreements, and care must be taken to regulate the load so that maximum benefits are obtained from the contract without exceeding its provisions.

With one system regulating frequency, and the remaining systems regulating tie line loading, fairly good results are obtained, but some degree of co-ordination between systems is still necessary, particularly if major load changes are made either too quickly or without the frequency-regulating system being advised beforehand. It would seem, however, that this method imposes a rather undesirable obligation on the frequency-controlling system for at least two reasons:—

1. The system controlling frequency must keep sufficient excess active generating capacity available to handle the major part of all the instantaneous load changes that may occur on the entire interconnected network.

   This may result in very inefficient plant operation under normal water conditions, as well as loss of revenue during periods of excess water, especially where off-peak power, such as electric boiler power, is being sold.
2. A considerable burden must be carried by the operating staff of the frequency-regulating system, since they must be making adjustments continually, and are at all times subject to criticism for poor frequency, irrespective of the cause. This is often difficult to determine without making a complete investigation.

   In this connection, it should be kept in mind that load regulation is primarily a local system problem, while frequency control affects the whole interconnected network.

To obtain satisfactory results using the hand-control method just reviewed, certain essential requirements stand out:—

1. All governors should be kept in good repair and adjustment, particular attention being paid to the elimination of lost motion in the linkage.
2. As far as possible, the percent inherent speed drop of all governors should be approximately the same. This is desirable so that all plants and units may share equally when load variations occur.
3. On the frequency-regulating system, load limit devices should not be excessively used, since addi-

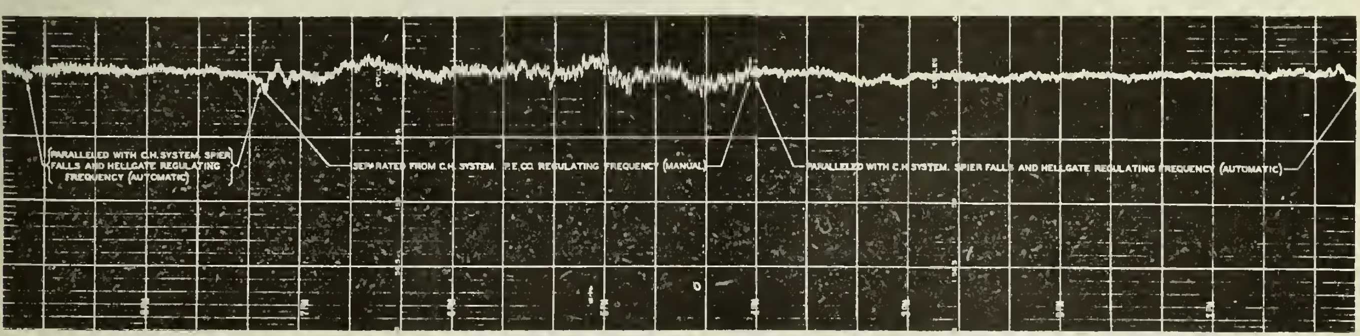

Fig. 11—Manual and Automatic Frequency Control on Large Interconnected System.

tional duty is imposed on all other governors used for speed-regulating purposes.

4. An approved set of operating instructions should be made up so that complete co-ordination may exist between the operating departments of the various companies forming the interconnection.
5. Each power station should be equipped with a modern, large scale type of frequency meter, located in the station in such a position that the indication may be readily observed by the operator when adjusting the governor motor of any unit.

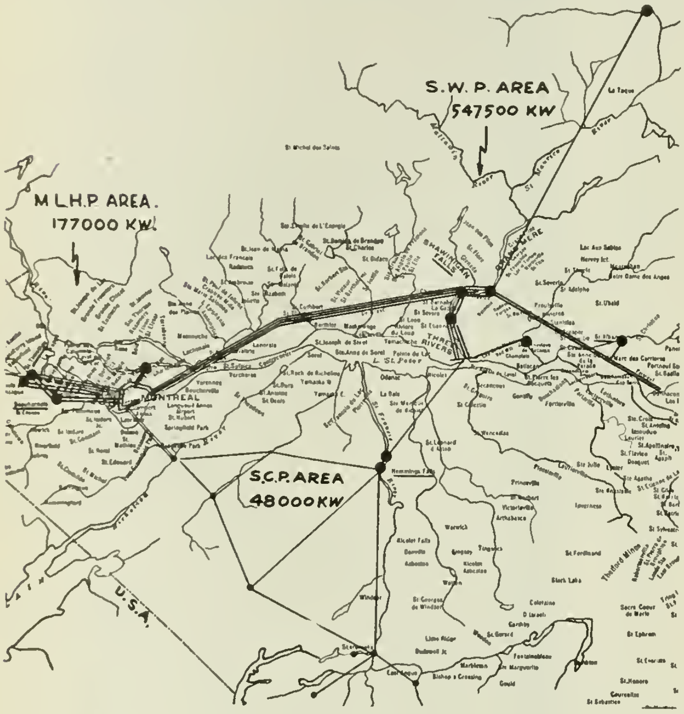

Fig. 12—Maximum Generator Capacity, Location of Generating Stations and Main Transmission Lines of S.W. & P. Co.

To obtain this result, in some stations it may be necessary to provide a large scale secondary frequency meter actuated by Selsyn motor control, or other similar means, from the switchboard meter.

6. In case of extreme or continued departure of frequency from normal, an understanding should exist that *all* stations should immediately assist to some extent in restoring normal frequency. Load adjustments may be made later when the cause of the trouble has been located.
7. The load-regulating systems controlling tie line loading should at any time adjust their governors to maintain correct frequency, if such adjustment will tend to correct tie line loading.
8. If synchronous clocks are being extensively used, each company should be provided with necessary apparatus to regulate time on its own system during periods when tie connections are open for any reason.
9. Frequency meters on the various systems should be checked periodically, and the understanding exist that the meters of the system controlling frequency and time be considered as standard to avoid discussion between company system operators as to whose meters are correct.

In concluding this phase of the subject, it may be said that it has always been the aim of public utility companies to provide an improved service to the customer. It would seem that the hand-control method of regulation has definite limits, and eventually must give way to more modern methods. If the frequency band can be regulated very closely, good synchronous time is obtained, there are less unnecessary power swings between systems, and load control is considerably simplified.

Automatic load and frequency control offers considerable promise as a final solution, and several manufacturers have developed devices for this purpose. The main function of all automatic frequency control devices is the sending of impulses at intervals to the governor motor to raise or lower the frequency, and thus obviate the necessity of the operating staff having to be continually watching the frequency meter. If, however, automatic frequency control exists on only one system, all the load changes will finally be taken up on the units or plants so controlled, and the problem of load changes between systems is not solved. Automatic frequency control on each system might be worked out successfully, or possibly combined with automatic tie line control between systems. The selection of the proper scheme will probably be dictated by the system characteristics.

In the case of automatic tie line control, whereby the governor motors of a selected plant are actuated from a wattmeter element on the tie line, the frequency-regulating system is relieved of the major load changes on the other system. This results in each company forming the interconnection controlling its own load variations to a great extent, and combined with automatic frequency control, makes it possible to maintain frequency and time with negligible errors, at the same time accurately controlling the flow or power between systems. Using these principles, several of the large interconnected systems in the United States normally hold frequency to ± .05 cycles on 60-cycle systems, and synchronous time to a maximum daily error of ± 2 seconds. (See Fig. 11.)

The foregoing touches briefly on a few of the outstanding points on the general subject. It might be of interest to outline the status of the subject as it affects the interconnected network shown in Fig. 12.

This interconnected system is entirely a hydro-system comprising the plants controlled by the Montreal Light Heat and Power Consolidated, Southern Canada Power Company and the Shawinigan Water and Power Company, with a maximum connected generator capacity of the order of 772,500 kw., and consisting of some 59 units.

On the Montreal Light Heat and Power system, there are usually connected to this system two 37,000-kw. units at Beauharnois, six 8,000-kw. units at Cedars and five 7,000-kw. units at the Back River plant. In addition, the Shawinigan Water and Power Company operates the Canadian Light and Power Company's plant at St. Timothee, consisting of four 5,000-kw. units, which ties in with the Montreal Light Heat and Power system at Montreal. This group of plants is tied in with the Shawinigan Water and Power Company's main system through two 30,000-kv.a. transformer banks at Montreal. From here, the tie connection to Shawinigan Falls consists of four nominal 110-kv. circuits 90 miles long.

The Shawinigan Water and Power Company main system consists essentially of the four plants, namely, Shawinigan Falls, Grand'Mere, LaGabelle and St. Narcisse stations, consisting of a total of twenty-four units and 451,500 kw. rating, all of which are located within a radius of 20 miles of Shawinigan Falls. To this must be added the recently constructed plant at Rapide Blanc 100 miles from Shawinigan, consisting at present of three 32,000-kw. units. The Southern Canada Power Company's system has a maximum generator capacity of approximately 48,000 kw., consisting of some fifteen generators, and is tied in with the Shawinigan Water and Power Company's 60-kv. system at Hemmings Falls about 50 miles from Shawinigan Falls, through a 15,000-kv.a. tie bank.

The load supplied on the interconnection is made up principally of lighting, industrial and miscellaneous loads in the metropolitan and rural areas, while a substantial portion of the Shawinigan Water and Power Company's load consists of grinder motors and large induction motors in the paper mills. In addition, there is a considerable number of resistance type loads, such as carbide and carborundum furnaces and electric steam generators. This latter group have a comparatively low speed characteristic in that they are not materially affected by frequency changes. They also have a comparatively low variation characteristic as distinct from loads having high variation characteristics, such as electric steel furnaces or large electric railway loads.

The monthly load factor of the Shawinigan Water and Power Company's *prime load only* is of the order of 75 per cent, while daily load factors of the *total load* often exceed 90 per cent. On several of the paper mills, automatic load control is used, so that daily load factors of the order of 98 per cent are often attained.

The result of having such high load factors and low variation characteristics is that normally there are no excessive load changes. There are, of course, the week-end periods when the paper mills are starting up or shutting down, and the normal load changes in the morning, noon hour and evening, due to the large Montreal load with a daily load factor of 65 to 70 per cent, but the times when these occur are known to the operating staff, and can be taken care of as routine matters.

As to control, it has been customary for the Shawinigan Water and Power Company to regulate frequency and time, the other companies operating their power stations so as to regulate load at the interconnected points. The Shawinigan Water and Power Company's system operator at Shawinigan is in control of the frequency and time regulation, the hand method of regulation being used. He designates the station to be responsible for frequency regulation, and changes the point of designation from time to

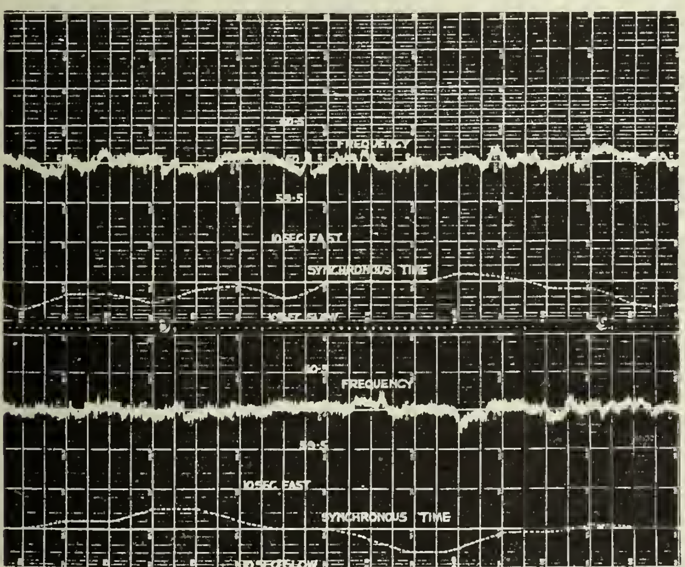

Fig. 13—Typical Frequency and Synchronous Time Regulation.

time, as may be required, for river flow regulation or for other purposes. With this method of regulation, normal frequency deviations are kept to the order of a maximum daily figure of ± .25 cycles.

A typical frequency record is given in Fig. 13, showing the actual variation in frequency and the deviation of synchronous time from normal (manual control).

While the various companies do not sell time, nevertheless, use is made of type "A" and "B" Warren master clocks as a guide to the regulation of frequency, with the result that synchronous time is available to the various customers with a maximum monthly error of ± 15 seconds. During the months of January and February, the average of the maximum daily departures of synchronous time from normal was 7.4 seconds fast and 7.6 seconds slow, which it is believed is quite satisfactory to the average clock user.

Fig. 14—High Sensitivity Frequency Meter.

As far as the Shawinigan Water and Power Company is concerned, their engineers have followed the progress of improved frequency control very closely during the past few years with considerable interest. In 1932, this company installed at LaGabelle station a modern type of automatic frequency and load-controlling apparatus for experimental purposes. This experimental work was temporarily dropped for various reasons, but it is anticipated that in the near future more conclusive tests will be made. In addition, this company is equipping additional power stations with a most modern type of frequency meter (see Fig. 14). As time goes on, it is hoped to still further improve the system frequency and time regulation at a comparatively small expense. This will be done mainly to give the best possible service to those customers who require close speed regulation in their manufacturing processes, and from the power company's standpoint, closer frequency regulation will facilitate the ability to transfer load between units, stations and systems.

To sum up, it may be said that under existing conditions the present degree of frequency regulation on this interconnected network is satisfactory to the various types of connected customers, and complaints, on this account, are very rare.

While the question of providing extremely accurate frequency and time regulation in this area may not be acute at the moment, future growth and additional interconnection will probably demand it. When the problem does become a major one, the use of some form of automatic control will no doubt be necessary, and the problem must become a common one to all interconnected companies, each sharing in the advantages and responsibilities.

## Service Problems on the Power System

*E. W. Knapp, A.M.E.I.C.*

Service problems on a power system are many and varied, and a consideration of service enters into practically every phase of system operation. This paper will, in general, deal with the service reliability of various units of the Shawinigan Water and Power Company high voltage system, including brief references to special problems.

In order to study, analyze and extend service improvements, it is essential to keep accurate and complete records of operating and service conditions. It is good practice to obtain a field report giving a complete story for every trouble on the power system. These reports are forwarded to the head office, where the data are transcribed on forms suitable for study. Each operation is then studied and analyzed, and the results compiled for ready reference. Executive and department heads are then informed of general service conditions by means of weekly, monthly and yearly reports, and special reports are made up as required, concerning special problems. In this manner, responsible parties are kept fully advised as to service conditions on the power system.

One effective method of obtaining data quickly and accurately is by means of oscillograph tests. A few years ago, power company engineers were reluctant to submit power systems to the uncertain shocks and possible hazards of the staged test. To-day staged tests are quite common, and in many cases are part of the regular routine when placing new stations or systems into service. This policy, combined with careful checking of circuits, instruments and equipment, has been found a great help in preventing faulty installations and subsequent service interruptions.

Solidly grounded and isolated neutral systems each have certain advantages and disadvantages from a service standpoint. The solidly grounded neutral system automatically provides plenty of current to actuate protection relays during faults from one conductor to ground (usually known as Lg faults), and no serious overpotential to ground takes place on the sound phases. Ground faults, however, create a more serious disturbance on this system than corresponding faults on the isolated neutral system. The inability to operate open delta when one transformer of a bank is out of service may, at times, prove a disadvantage on this type of system. One problem on the isolated neutral system is to effectively and selectively clear Lg faults before cross-shorts occur. On some systems, the overpotential to ground on the sound phases during Lg faults becomes a service hazard, and it is imperative that this form of fault be isolated as quickly as possible.

One scheme of clearing Lg faults on the isolated neutral system consisted in automatically closing a sound phase to ground on the occurrence of an Lg fault, thus producing a single phase short-circuit through ground. This provided ground fault current to actuate the relays. Unfortunately, however, there was considerable delay in clearing Lg faults, and an overpotential to ground was left on the two sound phases for 1.5 seconds or more for each Lg fault on the system. This often resulted in cross-shorts, sometimes between widely separated parts of the system. This was a serious situation, not only from the power company standpoint, but also as regards adjacent communication circuits.

The next step consisted in reconnecting a 33,000-kv.a. transformer bank, normally operating delta/delta, on one of the larger 60-kv. systems, to delta/star, and solidly grounding the neutral point. This arrangement was successful in providing an effective means of clearing Lg faults, keeping overpotential on the sound phases to a nominal value, and eliminating cross-shorts. The experience with this installation seemed to indicate that a smaller grounding bank might be used as a grounding medium with success.

Finally, the large transformer bank was returned to normal service, and replaced with a small bank located at the same station. Two other 60-kv. systems were likewise provided with small grounding banks. In each case the grounding bank served the dual purpose of supplying load and acting as a grounding medium.

During the year 1933, a large number of Lg faults were cleared successfully by the action of the various grounding mediums. A small grounding bank for high voltage isolated neutral systems would appear to be a satisfactory medium for clearing Lg faults. The size of bank required will depend to some extent upon the system insulation, generator capacity and type of relay protection on each individual system.

The importance of an adequate relay protection cannot be overestimated. It would be impossible to maintain a satisfactory service to load centres, with present-day network and interconnected systems, without an effective and selective protection. In general, quick clearance of faults is important in reducing power arc damage, the chances of oil fires and system instability. Selective clearance of faulted circuits, however, is equally as important as quick clearance, from a service standpoint.

Considerable progress has been made in the protection art during the past few years. The relay organization of the Shawinigan Water and Power Company consists of sections to deal with engineering, experimental testing of instruments and circuits, secondary checks of installations, maintenance of equipment, primary testing on the power circuits, and analysis of all relay operations. This policy has resulted in a steady improvement in the relay situation. Table I indicates the general trend during the past three years, and in addition to showing progress, reveals that there is still room for further improvements.

Table I

Action of High Voltage Line Protection Equipment 1931-1933

| Year | Lines Effectively Cleared | Lines Failed to Clear Properly | Lines Cleared Non-Selective During Faults |
|---|---|---|---|
| 1931 | 81 per cent | 7.3 per cent | 11.7 per cent |
| 1932 | 85.5 per cent | 3.7 per cent | 10.8 per cent |
| 1933 | 92.0 per cent | 2.3 per cent | 5.7 per cent |

The above tabulation covers a total of 40 high voltage lines with a mileage in excess of 1,500 miles.

From a service standpoint, generator breakdowns are not a serious problem. A faulted generator can usually be cleared from the power system with nothing more than a momentary disturbance, and possibly a period of lowered frequency and voltage. Moreover, generator breakdowns are relatively infrequent, representing only about 12 per cent of station equipment breakdowns. There are far more transformers than generators on the power system, and transformer breakdowns are somewhat more frequent. However, if high voltage bushing failures are excluded, transformer troubles are only slightly more frequent than generator troubles. A transformer breakdown may create the more serious service condition, however, depending upon the location of the transformer, and facilities for resuming service and making repairs.

High voltage bushings are a potential cause of service interruptions. There are a great number of these on a power system, and it is, therefore, essential that this form of insulation be as free from breakdown as possible. This is particularly true in view of the large proportion that are located within the zone of high voltage bus protections where a fault may result in a total shutdown to the station concerned.

Table II will serve to illustrate the general situation with regard to frequency of station equipment breakdowns. This record is for the year 1933, and covers all high voltage stations on the system. There is considerable variation from year to year, but the record shown is fairly representative of existing conditions. There was a total of eighty failures at sixty-nine stations during 1933. In view of the large amount of equipment at these stations, this figure does not appear to be unduly high. The tabulation does indicate, however, where weaknesses exist, with possibility of improvement in certain sections.

Table II

Station Equipment Breakdowns (1933)

| High voltage bushings | Number | Per cent |
|---|---|---|
| Oil circuit breaker bushings | 8 | 10 |
| Power transformer bushings | 20 | 25 |
| Potential transformer bushings | 2 | 2.5 |
| Entrance, roof, wall and floor bushings | 19 | 23.5 |
| Total bushings | 49 | 61 |
| Other equipment | | |
| Generator breakdowns | 10 | 12 |
| Power transformer breakdowns | 12 | 15 |
| Bus and switch insulators | 2 | 2.5 |
| Low voltage cable breakdowns | 2 | 2.5 |
| Miscellaneous breakdowns | 5 | 7.0 |
| Total equipment | 31 | 39 |
| Grand total | 80 | 100 |
| Total high voltage stations involved in breakdown | 32 | 46 |
| Total high voltage stations not involved in breakdown | 37 | 54 |
| Total high voltage stations concerned | 69 | 100 |

Table III shows an interesting example of service conditions on two wood pole lines, as construction and operating conditions were changed. These lines are of 5-foot triangular construction, 60-kv. pin type insulators, and no overhead ground wires. Originally the pins and crossarms were wood, and about 85 per cent of the poles were provided with vertical ground wires. Some years ago it was found that the older insulators were not standing up very well, and it was decided to gradually replace existing insulators by some of improved design. Wood pins and crossarms were also deteriorating, and these were to be gradually replaced in steel.

Table III

Troubles on Two 60-Kv. Pin Type Wood Pole Lines

| Condition | 1927 | 1928 | 1929 | 1930 | 1931 | 1932 | 1933 |
|---|---|---|---|---|---|---|---|
| | Per cent | Per cent | Per cent | Per cent | Per cent | Per cent | Per cent |
| Wood pins and cross-arms | 48 | 30 | 19 | 10 | 4 | 0 | 0 |
| Steel pins and cross-arms | 52 | 70 | 81 | 90 | 96 | 100 | 100 |
| Improved type insulators | 28 | 56 | 72 | 76 | 79 | 80 | 81 |
| Gaps in pole down leads | 15 | 15 | 15 | 15 | 65 | 65 | 95 |
| Number of | | | | | | | |
| Lightning outages | 72 | 50 | 160 | 150 | 67 | 72 | 72 |
| Line material breakdowns | 100 | 205 | 145 | 100 | 67 | 22 | 11 |
| Cross-shorts | 135 | 170 | 320 | 55 | 0 | 0 | 0 |

1—The tabulation shows service conditions on the lines as construction and operating conditions changed.

2—All service percentages are based on the seven year average.

3—This system operated isolated neutral until March 1930, and since then, solidly grounded star.

From 1927 to 1930 line outages due to lightning, line material and cross-shorts showed a decided tendency to increase. This was apparently due to changing pins and crossarms from wood to steel. In 1930 these two lines were cut over to a separate system, and operated solidly grounded star. This immediately reduced line outages due to line material failures and eliminated cross-shorts, but did not appear to make the lines less susceptible to lightning flashover. During 1931 the vertical ground wires on one line were provided with 20-foot gaps, thus taking advantage of this section of the wood pole to increase the line insulation. This appeared to reduce insulator outages still further, and also reduced lightning outages. By 1933, practically all vertical ground wires had been provided with gaps, and wood pins and crossarms had been entirely replaced by steel.

Based on the seven year average, lightning outages in 1933 were down to 72 per cent, although that was a very bad lightning year. Line material outages were down to 11 per cent, and cross-shorts were down to zero, although in 1929, cross-shorts had reached 35 per cent of the total line troubles. This seems to indicate that the recent policies are having a beneficial effect.

Table IV shows 60-cycle high voltage line troubles per 100 miles of line for the past five years. Lightning outages have varied considerably from year to year, and it is difficult to indicate any definite trend towards fewer flashovers. A careful survey of troubles on individual lines does reveal, however, that considerable progress has been made towards making these lines less susceptible to lightning flashovers. Wind, snow and sleet troubles have become less frequent due partially to careful checking of conductor sags and better maintenance, etc. Line material, cross-shorts, unknown and miscellaneous outages have each shown rather a remarkable reduction during the five-year period. The table shows that line outages in 1933, due to these four causes, were only 7.5 per cent of the 1929 figures. During the same period, the total line outages per 100 miles of line were reduced from 42 to 15.5, or 37 per cent of the 1929 figure.

Table IV

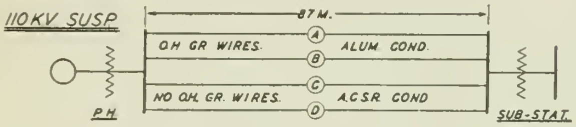
60-Cycle High Voltage Line Troubles Per 100 Miles of Line

| Cause of Line Trouble | Year Miles Lines | 1929 1046 28 | 1930 1380 34 | 1931 1491 39 | 1932 1508 40 | 1933 1508 40 | Ave. 1386 37 |
|---|---|---|---|---|---|---|---|
| Lightning | | 13.5 | 9.9 | 10.0 | 7.6 | 11.5 | 10.3 |
| Wind, snow and sleet | | 3.5 | 4.0 | 2.2 | 0.8 | 1.9 | 2.4 |
| Line material | | 6.0 | 2.9 | 1.9 | 1.3 | 0.7 | 2.3 |
| Cross-shorts | | 10.0 | 2.5 | 1.3 | 0.5 | 0.2 | 2.4 |
| Unknown | | 3.5 | 1.9 | 1.1 | 1.1 | 0.5 | 1.6 |
| Miscellaneous | | 5.2 | 1.8 | 2.5 | 1.0 | 0.4 | 2.0 |
| Total per 100 miles of line | | 42.0 | 23.0 | 20.0 | 12.4 | 15.5 | 21.0 |

In reviewing the situation with regard to improvement in line service, it is obvious that this improvement has been due to a number of causes. Improved maintenance, improved line insulation, more effective relay protection, better grounding mediums, and using part of the wood to increase line insulation, have all contributed to the general service improvement.

Figure 15 refers to four 110-kv. lines of two double circuit tower lines on the same right-of-way. These lines are each 87 miles in length. Lines *A* and *B* have two overhead ground wires, but there are no overhead ground wires on lines *C* and *D*.

The following records of lightning outages on these lines cover a twelve-year period:



| | | | | |
|---|---|---|---|---|
| Single line lightning shorts, line $A$ | 12 | = | 12.8% | |
| Single line lightning shorts, line $B$ | 7 | = | 7.5% | |
| Single line lightning shorts, line $C$ | 7 | = | 7.5% | |
| Single line lightning shorts, line $D$ | 68 | = | 72.2% | 65% |
| Total | 94 | = | 100 % | |
| Double line lightning shorts, line $A$/$B$ | 18 | = | 35 % | |
| Double line lightning shorts, line $C$/$D$ | 33 | = | 65 % | |
| Total | 51 | = | 100 % | 35% |
| Grand total | 145 | | | 100% |

$A$ and $B$ lines $\frac{\text{Double line shorts}}{\text{Total shorts on } A \text{ and } B} = \frac{18}{37} = 49\%$

$C$ and $D$ lines $\frac{\text{Double line shorts}}{\text{Total shorts on } C \text{ and } D} = \frac{33}{108} = 30\%$

Fig. 15.

From the above it will be noted that line $D$, farthest from the overhead ground wires, had far more lightning outages than the other lines. This seems to indicate that overhead ground wires do have a shielding effect, and tend to reduce lightning flashovers. The greatest ratio of double to single line faults occurred on $A$ and $B$ lines, but double and single line faults were much more frequent on lines $C$ and $D$.

Figure 16 shows a curve of service interruptions to representative customers of a large load centre since 1921. During the thirteen-year period, several changes took place with regard to the system set up. The system has been operating at 60-kv. during the period, but is largely insulated for 110-kv. operation.

From 1921 to 1924 the system was supplied with power over two radial lines approximately 30 miles in length. The outages per customer averaged 12.5 per year. During

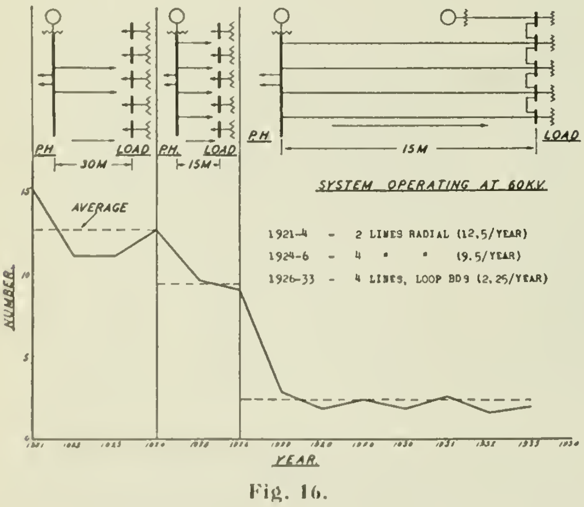


Fig. 16.

1924 a new power house was placed in service, and for the next two years, the system had four radial lines approximately 15 miles in length. During this period, the outages per customer averaged 9.5 per year, only a slight improvement over the previous period. During 1926, the various tie lines at the load centre were connected together to form a loop bus system. This arrangement immediately resulted in a reduction in customer interruptions to an average of 2.25 per year. There are other factors that have contributed to the improvement of service to the load centre, but undoubtedly the loop bus system has played an important part in this improvement.

Figure 17 indicates service conditions to a load centre supplied with power over four parallel lines, each 87 miles in length. There are two double circuit steel towers on the same right-of-way. The line insulators are 7 disc suspension, and the system is operating at 110 kv. The system is capable of supplying upwards of 200,000 kv.a to the receiving stations.

The curves are primarily for the purpose of showing the inherent service to be expected from a system of this nature. Stations and lines have each contributed to interruptions to the load centre during the past twelve years. It is interesting to note the gradual improvement in service for the first six years. From 1928 to 1933 there was an average of two interruptions per year, 1.3 due to lines and 0.7 due to stations. The curves would appear to indicate that this is inherently the average number of interruptions per year which may be expected from this system.

In many cases the customer can do much to make mill loads less susceptible to interruptions during momentary voltage and frequency variations on the power system. In many of the paper mills, a partial drop of mill load is almost as serious a condition as a total interruption. A recent survey of a number of large paper mills indicated that cases of dropping a considerable block of load, due to momentary disturbances on the power system, were more

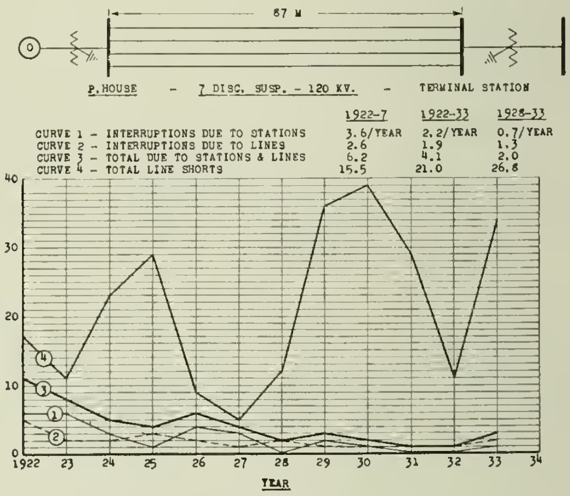

Fig. 17.

frequent than total interruptions, and the actual loss of production was greater due to this cause. In many cases these partial interruptions were due to instantaneous undervoltage releases on induction motors. It is important that mill equipment be as free as possible from interruption during momentary disturbances on the power system; otherwise, loss of production may occur which could be avoided.

In conclusion, it should be noted that the field of service improvement has by no means been exhausted. Many things can be done by both the power company and the customer to reduce service interruptions. Improved service is a matter of correlating engineering knowledge and experience, relative costs and available funds. Improved insulation and line construction, lightning protection, multi-lines, quick and effective clearing of faults, instantaneous reclosing of faulted circuits and customer equipment less susceptible to interruption during momentary disturbances, are all factors which will, in the future, tend to insure improved service to load centres. In order to insure proper co-ordination of the above factors, a careful analysis of service conditions is essential, combined with co-operation of power customers.

# Contribution of the Aeroplane to Canadian Industrial Development

*W. B. Burchall,*
*Publicity Manager, Canadian Airways Limited, Montreal*

**Paper presented before the Montreal Branch of The Engineering Institute of Canada on March 1st, 1934, and later before the Halifax, Saint John, Moncton, Peterborough and Toronto Branches.**

**SUMMARY.—The author gives an outline of the manner in which aerial transportation has developed under Canadian conditions, and discusses such activities as forest protection, communication with remote districts and mapping of areas previously unsurveyed.**

---

When, twenty-five years ago, mechanical flight in heavier-than-air machines first was achieved, it is likely that in the minds of those interested, the field of utility to which the aeroplane appeared peculiarly adapted was as an aid to observation, and particularly, observation for military purposes. Its use as a speedy vehicle of transportation was not at first realized, as the first aeroplanes were comparatively slow.

In 1913 a fast scout type aeroplane was produced which had the then remarkable top speed of 92 miles per hour. This factor of "speed" was a welcome addition in its military application to observation duties.

During the war period 1914-1918 aeroplanes were flown by men drawn from every branch of industry, so, with cessation of hostilities instinctively many of these men thought of the application of this new machine to the solution of the various problems with which they had been confronted in commercial life.

The advantages of aerial observation to the work of the surveyor, the forester and mining engineer, were at once apparent, and it was natural that the use of the aeroplane in Canada should be directed to problems where observation from the ground was restricted or where territory was inaccessible. So it was that from 1919 to 1923 flying was used almost entirely for inspection and observation in the heavily timbered areas of the eastern provinces. Transportation work for personnel and supplies was a secondary development and undertaken only when surface facilities were lacking or natural obstacles had to be overcome.

Quoting from the Dominion Government Report on Civil Aviation for 1924,—"It was therefore decided to concentrate on the development, in the first place, of those services for which there was an immediate need; in forestry and aerial surveying; in transportation to the remoter parts of the country; and leave for the time being, the development of air routes to countries where the natural conditions were easier, the population and traffic denser, and conditions altogether more favourable for experimental work."

This statement will suffice to determine the period with which it is proposed to deal in this paper, when considering the contribution of the aeroplane to industrial development. It will be noted that the period of general application of aerial activity to industry is less than ten years.

The aeroplane as a tool is yet a novelty. Definite types have been evolved to suit military requirements but most of the aircraft employed on commercial work are of the general purpose type. It follows that until types are evolved for particular kinds of work, maximum applicability and efficiency are not possible.

The operations which the aeroplane has been called on to perform may be divided into two classes:—(1) Those which are made possible only by the use of the aeroplane such as aerial sketching and photography, dusting and aerial prospecting. (2) Those in which it has entered into direct competition with existing methods of transportation.

No attempt will be made here to deal with operations which have not been conducted on a commercial scale. This is the broad interpretation of what is a direct contribution to industrial development.

## Forestry

### *Aerial Sketching*

The pioneer application of aircraft to industry in Canada was in connection with timber cruising, aerial sketching, and forest fire detection and suppression. Commencing with a series of experiments in the Saint Maurice valley in the summer of 1919, each subsequent year has seen a steadily increasing use of aircraft for these purposes, by the Dominion authorities, by the provincial governments, and by the great wood using industries, who in some cases established their own patrols and in others employed commercial firms to carry out the necessary flying.

To bring before the public the need of sane forest utilization, it is necessary to show how much raw material is available, also the annual growth and consumption.

A forest inventory is the first requirement and it follows that an aerial forest sketch map, quickly produced at low cost, is a primary need.

Such sketching is done by a specially trained forester during flights, and the detail is inserted on the best available map of the district, enlarged to convenient scale.

These sketch maps have proved of value for the following uses: Exploring the timber resources of unknown districts, mapping boundaries of recently burnt areas, checking up on areas cruised in previous years, to provide maps for forest protection purposes, as preliminary to a ground reconnaissance or forest survey, to check up cut-over areas. There are variations in the intensity of surveys of different localities.

(1) General or preliminary reconnaissance: This is the quickest, cheapest and least detailed. No detail of waterways or types is attempted, but only general classification of areas—whether burned over, timbered, or muskeg,—and of the merchantable types of softwood, hardwood and mixed.

(2) Aerial reconnaissance: This provides greater detail such as the main waterways, and drivable streams, the larger lakes and general forest types.

(3) Aerial forest survey: On this type detail is intensified. All drivable waterways and forest types are shown in detail comparable to that obtained by forest survey on the ground.

Up to the present time about 250,000 square miles have been sketched. This does not include territory that has been photographed for detailed maps. Both vertical and oblique photographs of forest types have been used, Canadian Airways alone having photographed 40,000 square miles. If the photographs are for forest estimating and logging purposes, those taken in the spring, fall or winter, are more satisfactory than those obtained in summer.

*Forest Fire Patrol*

Aircraft have been and are at present regularly employed on forest patrol throughout the heavily wooded portions of the Dominion. They may co-operate with ground organization, or act as independent patrol units.

Until the advent of the aeroplane in this phase of aerial activity, observation of the areas under supervision was confined to the efforts of lookouts posted on towers erected at strategic points across the country. Under ideal conditions these towers were in telephonic or radio communication with the base or central control station, but in the majority of cases they were entirely isolated, and the messages had to be forwarded on foot or by canoe.

Under this system, it was very difficult to locate a fire accurately, and after detection and location of the fire, the transportation of fire fighting equipment and personnel was extremely tedious and often the efforts of the fire fighters, through delay in commencing operations, were abortive.

It will be realized that a fire must of necessity have attained considerable proportions before the smoke can be seen from a distant lookout and it cannot be stressed sufficiently that all success in fire fighting is dependent on one factor—speedy attack.

Aerial transport alone can provide this. Independent of all land conditions and dependent only on the lakes and waterways with which the forest areas are interspersed, the aeroplane has proved the most efficient tool with which to meet the exigencies of the fire fighting service.

By a systematic series of aerial patrols at definite intervals—preferably, at least, every day in times of extreme hazard—fires may be discovered and accurately located at their inception.

Aircraft are used on:

1. Fire detection patrols.
2. Flights to report on fires under suppression and to keep deputies informed as to progress, disposition of crews and equipment.
3. Transportation of rangers, equipment and food supplies.

The work is carried out under the direction of the chief forest ranger, who issues instructions for each flight, and reports are made direct to him. Orders may call for a definite patrol of a certain area or line. In the case of a new fire being detected, the pilot will usually be instructed to fly to the nearest rangers' camp, collect such men and equipment as are considered necessary to fight the fire, and place them at the nearest possible point of attack. Once the pilot knows his area, the detection and suppression of any fire within a radius of fifty miles may be a matter of only two or three hours, provided that the fire is caught in its incipient stage.

The machines used on forest patrol should be able to take-off from small lakes with an "operating" load including pilot and kit, and "payload" of two rangers with their kit, tent, blankets, emergency rations, fire pump, hose, gasoline for pump engine, shovels, axes, jacks, etc.

The following is a typical report filed by a pilot when engaged on forest patrol.

"The machine was at Fort Francis from August 5th to September 15th except for three days at Sioux Lookout—thirty-seven calendar days, seven days rain, one day fog, twenty-nine flying days. During this time 124 passengers and 34,860 pounds of freight were carried, 198 flights were made—a distance of 11,650 miles, in all 149 hours and 22 minutes were flown (400 miles per flying day)."

This report also included details of landings at thirty-nine different points with special mention of hazards and general flying conditions.

It has been authoritatively stated that one single forest fire in the Fort Francis area cost the provincial government $70,000 to extinguish. For more than thirty days, two hundred and forty-nine men, two hundred tons of equipment, numerous planes and a chain of wireless sets were used. It is unfortunate that the credit side of this statement can only be hypothetical, but some idea of what it might be may be formed from the following illustrations.

A valuable stand of timber in a remote area was threatened by several fires. By means of aircraft, the fire fighting crews were rushed to the job and the fires put out. Experienced timber cruisers then estimated the value of the limits which, but for the aerial service rendered, undoubtedly would have been destroyed. This estimated value exceeded the total cost of the aerial forest patrol in this area for the entire season.

*Dusting*

Millions of cords of fir and spruce have been destroyed by the ravages of the spruce budworm, a caterpillar that feeds on the foliage of these trees with the result that the trees are killed.

Experiments were carried out in eastern Canada in 1927 to determine whether dusting of afflicted areas would destroy the budworm or even check the development of outbreaks and in 1930 dusting of forest areas was carried out on a commercial scale in areas adjacent to the city of Vancouver.

An attack of "hemlock loopers" threatened to destroy the forest growth in the Seymour creek area. Stanley Park, noted for its natural beauty and magnificent stands of timber, was also seriously defoliated. It was decided, therefore, to dust both of the afflicted areas with a calcium arsenate mixture. For this purpose three flying boats were employed. The areas had been plotted in strips and each pilot carried a plan.

The operation over the Stanley Park area—850 acres—was carried out early in the morning when there was little

**Fig. 1—Dusting, Seymour Creek Area.**

or no wind and took four and three-quarter hours. Seven and a half tons of calcium arsenate were loaded into the flying boats from a scow anchored in the harbour and distributed over the area.

Advantage was taken of previous experience in the use and distribution of this dust to incorporate certain improvements to the twin pack-saddle hoppers used on the flying boats and each hopper of four hundred pounds capacity had its own discharge directed below the bottom planes—

port and starboard respectively. The throats of the orifices were designed to allow a discharge of six hundred pounds in one and a half minutes. This ensured the specified amount of dust per acre being deposited on the trees.

In order to avoid packing and the necessary construction of an agitator in the discharge opening a tilting floor was arranged on the slope of the hopper. As the dust commenced to flow heavy springs raised the floor, so that as the quantity and weight in the hopper decreased the slope of the floor increased. In this way a constant flow was obtained to the hopper opening, which in turn led into the side of a venturi throat which discharged to the rear.

Later in the day the paths in the park were covered with a layer of loopers one to two inches thick. Examination of the area a week later proved that infestation had been entirely destroyed and two weeks after the operation the trees were once more assuming a green appearance.

Dusting of Seymour creek watershed commenced about a week after the Stanley Park operation. The area which was to be dusted, some 800 acres, lies about seven miles inland from salt water and it was necessary to climb 2,000 feet before discharging the dust.

The amount of dust discharged was approximately the same as in the previous operation, seven and a half tons, but the time taken was longer owing to the distance which had to be covered when travelling to and from the loading barge.

As it was not possible to maintain good formation, tactics were changed so that each aircraft dusted a certain predetermined area. About two weeks later it was apparent that this infestation had also been thoroughly eradicated.

Mr. G. R. Hopping, assistant forest entomologist, Department of Agriculture, who was in charge of the operations described, states that when an infestation of defoliating insects is controlled by dusting there is no assurance that another infestation will not occur within a few years. However, it is unlikely that this will occur until the infestations (e.g. hemlock looper) rise again over the entire region. In other words, there are series of years when factors (mainly climatic, or meteorological) are favourable for the rise of epidemics and in between there are

**Fig. 2—Trapper Shipping Winter Outfit of Dogs and Supplies.**

years when these factors cease to be favourable and the epidemics decline.

Following the dusting of the areas of Stanley Park and Seymour creek, the former in particular, was in better shape from the standpoint of defoliating insects and general tree health than for many years. The maintenance of green healthy trees bordering the line of the big conduit on Seymour creek (water reservoir) undoubtedly prevented the development of a serious fire hazard.

### Fur Trade

Today the old fur trading post, as such, only exists in the four western provinces, north of latitude 55 N. In Ontario and Quebec the territory north of the Canadian National Railway is dotted with trading posts. It is in these territories that the aeroplane has proved of most benefit to the fur trade.

The value of ranch bred pelts now represents about 26 per cent of the total raw fur production of Canada,

**Fig. 3—White Fox Skins Flown from Coppermine to Edmonton.**

valued during the past few years at approximately $12,500,000. With such an increase of ranch bred pelts, the trapper is faced with ever-increasing competition. His handicaps are, distance from rail head to trapping ground, with consequent loss of time and heavy expenditure for travelling, also if water transport be used possible loss or damage in transport. Lastly the trapper, even though he be familiar with prices by means of his radio, is unable to reach the market quickly and avail himself of favourable prices for disposal of his catch.

Like other riches of our Dominion the most valuable furs lie farthest from civilization. And so trappers have for years made their way to the Upper Thelon river, 150 miles east from Fort Reliance.

Heretofore, the trapper reached his trap-line in this region by an arduous water route, via Artillery lake and the maze of shallow streams on the water-shed to the east. His winter's outfit, including his five or six dogs, weighed a full fifteen hundred pounds. All had to be relayed, bit by bit, over more than thirty long hard portages. In order to have time remaining to secure supplies of caribou meat from the migrating herds before they passed on to the south, it was necessary to reach the trapping grounds by September 1st, and to accomplish this meant setting out from Reliance on July 1st. Then followed two months of the most exacting toil to cover but one hundred and fifty miles air-line distance.

The long months of winter trapping over, the very short "open water" season made a return to Reliance by canoe impossible, without the loss of a year's trapping as the price of each trip. So, late in April, camp was broken, and the season's fur catch hauled to the nearest trading post by dog team. By this method the trapper might spend six weeks of his year on the fringe of civilization before being forced to return to his work once more. Further, each year's trapping meant the loss of the good canoe by which he had made his incoming trip.

The late summer of 1930 saw two enterprising trappers on their way to their winter homes at Eileen lake in the first practical application of air freighting to the trapping industry.

In the autumn of 1931, four separate "outfits" went by air from Reliance to the head of the North Thelon river, where a much-desired but hitherto-unattainable trapping area lay. In 1932 trappers flew not only from the Reliance base, but also from the Lake Athabasca side of the watershed, and in 1933 were met, on their outward journey, by aircraft which flew them with their furs through to the railhead. Lowered flying costs have lessened expense to the trapper, and today he may be flown to his trap-line in one of the most obscure parts of the north and back again for less than the actual cash outlay necessary for the purchase of a canoe, outboard engine and fuel.

The fur trading companies, too, have realized the advantages of air transportation and ship furs in bulk from the trading posts to railhead. In northern Quebec furs are shipped by air from the posts at Mistassini, Chibougamau and Waswanapi to Oskelaneo or Senneterre on the Canadian National Railway. From north shore points they are shipped to Quebec. From the posts lying on the eastern shore of the Hudson Bay, Great Whale, Port Harrison and Povungnituk, bales of fur are transported to Moosonee.

Throughout northern Manitoba and in the territory adjacent to the Hudson Bay west coast, shipments are made to Sioux Lookout, The Pas and Winnipeg. From the far north, Coppermine river, Thelon river and the eastern slopes of the Rockies, the aeroplanes fly with their cargoes of pelts to railhead at McMurray or even to Edmonton.

The value of these shipments, which may range from 60 pounds to 1,500 pounds in weight, is difficult to ascertain. A small shipment of marten may be worth $36,000 or a load of 1,000 pounds may be valued at $20,000. There is a steady flow of fur traffic southward all the time, and as mining requirements provide only one way cargoes the contribution of the fur trade towards providing return cargoes cannot fail to have its effect in bringing about lower transportation charges.

Fig. 4 Seiner with Nets out in Prohibited Area off B.C. Coast.

It was estimated that during the 1932-1933 season these shipments exceeded 400 bales of raw fur. In 1929 these 400 bales would have been worth fully $1,500,000.

Fisheries

The production of the British Columbia fisheries in 1932 had a value of nearly $10,000,000 of which salmon contributed seven and a half million. This represents the value of fish marketed.

The aerial fishery patrol, which was instituted in 1923, is designed to assist in the conservation of salmon and to safeguard against the wholesale cleaning out of "schools" and heavy runs of fish in confined areas. Previous to the institution of the aerial patrol illegal fishing was common along the British Columbia coast. The deeply indented and irregular coast line favoured the "seiners" while the inspector's boat gave ample warning of its approach.

The purpose of the patrol embraces three main functions:

(1) Detecting violations in respect of fishing within boundary limits, or within specified distance from mouths of streams.
    Fishing within closed season (Friday 6 p.m. to Sunday 6 p.m.).
    Use of excessively long nets and carrying of extra web—the limit being 1,200 feet of web.

(2) Transportation of fishery officers, supervisors, inspectors, overseers and patrol men.

(3) Inspection of spawning areas—streams and lakes. (These streams may connect a chain of lakes and must be cleared to allow salmon to run. Many of the lakes are practically inaccessible except by air.)

The patrol commences during the latter part of June and continues until October 31st.

Detection is the chief function of seaplanes employed by the Fishery Department, and the advantage of aircraft over motor-boats for this purpose is apparent when inlets, sometimes not more than 10 miles apart, necessitate a water route of between 60 to 80 miles. This mobility of aircraft, combined with their ability to glide silently from high altitudes to a distant point, has made the fishermen distinctly careful and in the heavy fishing districts like Swanson Bay and the Charlotte Islands, it is now not unusual to go through a whole season without observing any violations whatsoever.

Usually after the pressure of heavy fishing begins to slacken off, the fishery officers find time to visit streams and lakes to see whether the salmon have actually spawned and if the spawn is in good condition.

In June and July, 1931, over forty-four thousand pounds of fresh fish were carried by air from Frobisher lake to Cheecham, Alta., on the Northern Alberta Railway. The fish was packed in ice for the 90-mile journey. This was one of the first applications of air transport to the freighting of fish in bulk. During February, March and April, 1933, aeroplanes were employed in northern Manitoba to carry fresh fish from Moose, William and Burntwood lakes to Cormorant lake on the Hudson Bay Railway. The fishing on the northern Manitoba lakes is done in winter time and the catch must not be frozen before reaching market. Snow was so deep that trucks or teams could not cope with the work, so aeroplanes with heated cabins were employed and nearly eighty thousand pounds of fish were carried an average distance of 40 miles. Figures for the winter 1933-1934 are not yet available, but there has been already a notable increase in the use of aeroplanes for the transport of fish from our northern lakes to railroad.

Aerial Survey and Mapping

Perhaps one of the most valuable branches of endeavour in which the aeroplane has been engaged is that of aerial survey. The oblique system of aerial photography was inaugurated and developed in Canada and this system has proved extremely satisfactory for the heavily-timbered areas of the provinces and the mining areas of the north.

Vertical photography has been developed to a high state of efficiency and has supplanted the oblique system of aerial survey wherever detail and accuracy, on a reasonably large scale, are required. This work can be and is being extended to municipal and private enterprise, thereby solving many civic and industrial problems at a reasonable cost.

Also, by means of the stereoscope certain areas can be mapped in relief so that every projection or apparent projection and its elevation can be readily discerned.

Aerial mosaics of any area can be completed in weeks. Large scale mosaics of city properties can be produced on which taxable detail shows up clearly. Property boundaries may be superimposed directly on this photograph so that every feature inside a boundary line can be recorded. Again the photographs composing a mosaic can be used in the field as plane table sheets.

**Fig. 5—Freight Awaiting Air Transportation between Norman and Old Fort Franklin.**

Stereoscopic study also gives the engineer full reconnaissance information in regard to filling and grading.

Aerial survey is particularly applicable to planning and zoning. All conditions effecting municipal improvement and civic problems are seen in photographic detail. By use of transparent colours on map copies, the zones are not only established, but even the non-technical citizen can readily read what lies within these zones and why changes are advocated. When the engineer is presenting recommendations to a non-technical board or committee, he is assisted greatly by being able to demonstrate his plans on readily understandable photographs. Many engineers now attach air photographs to their reports and recommendations, thereby saving many words of explanation and economizing the time of those attending the meeting.

Aerial maps, reduced to a convenient and economic scale, are often used to show the advantages of manufacturing sites. An air map, showing clearly the whole city with the available sites for factories blocked off, affords the prospect a splendid opportunity to choose his location in relation to distribution facilities which also are apparent. These aerial maps are usually supplemented by close-up oblique photographs.

The well-informed civil engineer has come to recognize the aerial survey as the most speedy and also one of the most reliable solutions to many a topographical engineering problem. New applications of it to industrial projects are discovered each year.

It is steadily gaining favour as a time and money saver, and it is extremely probable that ultimately, with the resumption of public works on a more extended scale, its application will be extended to all large developments where survey is involved.

### Mining

In 1924 the first air route for the regular conveyance of passengers, mails and freight was undertaken to serve the new gold field at Rouyn. Aerial transportation was applied later to the requirements of western mining at Red lake, Ont., in 1926 and these services are still in operation. In the years that followed air transport contributed to the primary development of mining territory in the following areas: northern Quebec, Ontario, northern Manitoba, northern British Columbia and finally Great Bear lake, N.W.T.

The extensive prospecting operations carried out in northern Canada during the past six years were made possible only by the use of aircraft, and the districts examined, the discoveries made, and the development accomplished by the aid of the aeroplane have been in territory that otherwise would not have received attention for at least another ten years.

Unfortunately, it is not possible to segregate the figures relating to work accomplished at this stage from those relating to subsequent performance. (See Tables I to IV.)

Some mining areas that became productive previous to 1929 were fortunate enough to obtain railroad and highway facilities, but other mines have had to carry on with water transport and air services. The Red lake and central Manitoba areas still rely on this combination and as lakes are frozen over for about seven months of the year air transport is relied on to provide the year round mail service.

Water routes have been improved and are used for heavy machinery and supplies that will keep over the winter, but for passengers, mail, fresh meat and vegetables, emergency requirements and transport of bullion, the aeroplane holds its own.

For a time it appeared that the sphere of utility for airçraft would slowly recede as the frontiers were thrust back, but with continued improvement in design and operation of aircraft, and with steadily increasing return loads, it appears probable that the aeroplane will continue to occupy a permanent position in the transportation schemes of these and other remote mining areas. Railways may be desired but the initial cost may be prohibitive. It is interesting to note the trend of development of transportation facilities at Great Bear lake, where the open water season is shorter even than in Ontario. With the water power available and with the Norman oil wells as an accessible source of fuel supply, it may be that only concentrates will be shipped out and this can be done by air as the relative cost of air transport to value of cargo transported is low. Notwithstanding the fact that development in this area is of such recent date and that the nearest railway is nearly 1,000 miles distant, a photographic mosaic covering 150 square miles in the vicinity of Echo bay was prepared and has been available by mining engineers for the past two years.

**Fig. 6—Break-up, Levine Point, Great Bear Lake.**

The appended tables show what has been achieved by one air transport company alone, in the following areas: Flin Flon and Sherridon, Central Manitoba, Red Lake, and Great Bear. The contribution of the aeroplane is increasing yearly as may be gauged from the fact that whereas all freight and express carried by Canadian Airways in 1931 amounted to 764,449 pounds, the total had more than trebled in 1933 amounting to 2,522,233 pounds, exclusive of 328,618 pounds of mail.

The following tables refer to work accomplished by this company alone.

TABLE I

| Totals | 6,884 | 740 | 284,012 |

This picture would be incomplete if mention were not made of the contribution of the aeroplane to industrial life as regards health, bodily and mental recreation and the maintenance of adequate standards of living.

Obviously, it would be impossible to arrange for doctors, nurses, or hospital facilities at all northern communities, but in emergency, if aeroplanes are available, air transport is at once employed. In twelve months Canadian Airways' planes made over eighty humanitarian flights.

Federal officials, judges, police officers travel by air. This method of travel combined with the instantaneous communication offered by radio, has revolutionized the control exercised over these vast northern territories.

The fathers of the church and sisters of the religious orders are regular travellers on the 'planes that operate on schedule from McMurray to the Arctic ocean.

Bishop J. D. Anderson, of Moosonee, travelled nearly 1,000 miles throughout his diocese last summer in one week. During the coming summer, 1934, Right Rev. A. L. Fleming, Bishop of the Arctic, hopes to call at every mission, except four, in his diocese, which has a territorial area of 2,250,000 square miles, and extends from Ungava in the east, to Alaska in the west.

It is not too much to say that the possibility of journeys of this kind has made a complete change in the conditions of life in the more remote and previously inaccessible regions of the Dominion.

# The Reflecting Telescope for The David Dunlap Observatory

*by R. K. Young, Ph. D.*[1]

## DISCUSSION

Professor L. M. Arkley, m.e.i.c.[2]

Professor Arkley enquired how the measurements of the mirror surface were obtained to the required limits of accuracy, which approached 1/1,000,000 of an inch.

R. K. Young, Ph.D.[3]

Dr. Young replied that this was done by optical measurement. A parallel beam of light was directed on to the mirror, and the eye placed at the focus of the reflection. Then a razor was moved across the beam at the focus. If the surface was perfect it would blink all the light out from the eye; otherwise shadows would gather over the faulty part, due to the "hills and depressions."

Geo. E. Newill, m.e.i.c.,[4]

Mr. Newill enquired of what material the polishing tool was made, what kind of polish was used, and what was the life of the coating.

R. K. Young, Ph.D.

The author in reply stated that for the rough grinder cast iron was used; for the fine grinder, glass; and for the polish, cast iron covered with a compound of beeswax and rouge, which was allowed to set for some time on the mirror before polishing began. The life of the coatings depended upon the situation; when the mirror was near a city, it required resilvering three or four times a year; but if located in a desert, the coating would last for about a year. Lacquers were now being successfully used on mirrors as was also an aluminum coating.

A. W. Whitaker, Jr., a.m.e.i.c.[5]

Mr. Whitaker wished to know the reflecting power of the silver coating and if the mirror was repolished when resilvered.

R. K. Young, Ph.D.

Dr. Young observed that in the blue green region, from 90 per cent to 95 per cent of the light was reflected. Below that region only about 65 per cent of the light was reflected. With the aluminum coating there was about 75 per cent of the light reflected, but this was constant over most of the wavelengths, and so was more effective than the silver coating. The mirror was not mechanically repolished after it had been resilvered, only rubbed.

Brig.-General C. H. Mitchell, c.b., c.m.g., c.e., d.Eng., m.e.i.c.[6]

General Mitchell requested information on the operation and maintenance of the equipment, and also on temperature effects and the precautions taken in this respect.

R. K. Young, Ph.D.

The author replied that a trained mechanician was needed, but operators should have a slight knowledge of the operating equipment in order to prevent foolish blunders. All the electrical equipment was interlocking, however, and so protected from damage should an operator make a mistake.

With regard to the temperature, while the instrument was surrounded by a heating case, to keep the temperature range within the limits of from 1/100 degree to 1/10 degree, the larger mirror was uncontrolled. The only precautions which could be taken with it were to see that the design of the building was such that proper ventilation ensured that there was no difference between the inside temperature and the surrounding outside temperature, and further to wrap the mirror during the day and thus try and keep it as nearly as possible equal to the temperature of the following night. However, great caution must be used in doing this, due to moisture and various other atmospheric conditions.

J. A. Pearce[7]

Mr. Pearce stated that the new 74-inch reflector was similar to the 73-inch reflector of the Dominion Astrophysical Observatory, Victoria, B.C. It differed from the 73-inch only in minor details, some of which might be regarded as improvements over an instrument which had been designed nearly 20 years ago. The more important of these differences were:

1. A lighter observing platform to reach the principal focus.
2. The method of attaching the tube to the declination axis, to minimize the flow of heat from the more massive parts of the telescope to the mirror cell, which resulted in a temperature gradient across the mirror, producing astigmatism.
3. The motor to focus the secondary mirror, instead of a hand wheel was a difference, rather than an improvement, as the latter method had been quite satisfactory.
4. The iris diaphragm replaced a shutter. The shutter consisted of 12 sector-shaped steel leaves attached at their bases to 12 short shafts connected together by universal joints and a worm wheel rotated by a worm and shaft geared to a worm wheel attached at the lower side of the mirror cell. The hand wheel quickly raised or lowered the leaves simultaneously. When closed the leaves stood at an elevation of 30 degrees forming an arch and giving perfect protection to the mirror.
5. The clock controlled drive, favoured by the Grubb Parsons Company and adopted for the 74-inch telescope would ensure that the telescope was driven at accurate sidereal time. The 73-inch reflector was driven by the ordinary governor but so perfectly did it work that the need for a controlling device had never been felt. Indeed, for spectrographic work, for which the Victoria telescope was designed, it was desirable to have the stellar image drift along the slit of the spectrograph. For photographic work, however, the clock control drive was greatly to be preferred.

The very efficient performance of the 73-inch Victoria telescope during the 15 years, 8 months of its life had proved that the general design left little to be desired. More than 21,800 stellar photographs (spectrograms) had been secured in the 19,100 working hours, an average of 7 plates per night having been obtained. During the past 10 years the telescope had been almost exclusively employed in the investigation of stars fainter than the 6th magnitude, i.e., stars fainter than could be seen with the naked eye. The telescope might be easily handled by one observer, the average time consumed in changing from star to star and rotating the dome between photographs was only 4 minutes. With the engineer assisting the astronomer, this lost observing time was reduced to 2½ minutes. The ease of handling the 45 ton telescope (movable parts) was remarkable evidence of the perfection of mechanical design and workmanship.

It might confidently be anticipated that the Dunlap telescope would duplicate the performance of the Victoria telescope and before many months would be engaged in important astrophysical investigations and researches. Much credit was due to Professors Chant and Young for the construction and successful completion of this splendid instrument and the establishment of an excellent observatory.

## Aptitude and Professional Success

The qualifications for success in life are not usually thought of as a suitable subject for laboratory investigation, but of recent years psychologists have begun to direct their inquiries along this line. It is not without interest to inquire, for example, what are the personal characteristics that make for success in engineering work, and what is their relative importance. How can their existence in a given individual be ascertained, and, if he does not possess them, how far is it possible to develop any of them by early training and professional education.

It is comparatively easy to determine in the laboratory the capabilities of a material or the suitability of a machine for its work, but can similar methods be applied to the estimation of personality? The problem of selecting a suitable man for a given position has to be faced by individual employers, as well as by large corporations and governments. Some form of inquiry or examination has to be adopted, and such investigations take the most varied forms, depending on the point of view of the authority employing them. For instance, in selecting youngsters as cadets for the Royal Navy, if stories are to be believed, far less emphasis has been placed on book learning than on quickness, intelligence and powers of observation. When one embryo naval cadet was asked by the examining officer, "How did you get here this morning from the hotel at which you were staying?" he replied, "In a cab, Sir." "What was the number of the cab?" "Number 41868, Sir." "Good," said the officer who had asked the question. Another member of the board asked the presiding examiner, "How do we know that he gave the right number?", and the reply was, "I don't care a hang whether it was the right number or not. He answered quickly and smartly, and that is what we want."

The satisfactory results presumably obtained by such methods in this particular case would hardly commend them to people who base their opinion of a candidate's fitness upon his ability to make high marks on a carefully set written examination, the method of selection adopted in many branches of the public service in England. The world-wide reputation of the British Civil Service rests largely on the character of its higher officials, who are selected by open competitive examination. Over a period of years this procedure has resulted in the appointment of officers who reach an extremely high average of administrative ability, as exemplified by their work in such branches as the Colonial Service and the Civil Service of India. The examinations, however, are not of a technical or specialized character, but cover a wide range of cultural subjects and contain questions which can only be answered successfully by men of exceptional capacity and wide general reading. Thus it is interesting to note that these appointments leading to high administrative positions depend on the study of subjects largely unconnected with the ultimate life work of the candidates, and that the examinations test general ability rather than special knowledge.

As a contrast to the method of selection by competitive examination, psychologists are now urging the value of vocational analysis as a preliminary to vocational training.

It is evident that in approaching this subject there are two features to be considered, namely, the suitability of any given individual for a given calling, and then, the kind of training which he should afterwards receive to develop the special aptitudes which he possesses.

Some interesting general results of such analyses, as applied to engineering work, have been published recently,* and are based on studies carried out at one of the leading engineering schools in the United States. As a result of the psychological examination of a large number of business executives, engineers, scientists, doctors and lawyers, the broad fact emerged that the subjects of the investigation could be classed in two groups, having respectively the objective and subjective type of personality. These types are not sharply divided, because individuals range over the entire length of the scale from the extremely objective to the extremely subjective. The objective person is naturally interested in matters external to his own mind. He is a group worker and rejoices in contact with others. One hundred successful salesmen averaged "extremely objective," while one hundred business executives were distinctly "less objective." Subjective persons, on the other hand, tend rather to be absorbed in their own intellectual activities. The designing engineer, the successful research worker or inventor, are examples of this type. From the observations made it is apparently very unusual for a markedly subjective person to become more objective in outlook, or vice versa. In other words, this characteristic seems part of one's personality and is little affected by training or environment.

Apart from classification according to this important mental attitude, evidence was secured of the existence of a considerable number of other qualifications each having a more or less decisive influence on a man's fitness for engineering work. One of the chief of these is the gift of visualizing three-dimensional structure, which is indispensable for success in engineering, architecture and surgery. Curiously, women, as a group, have been found markedly inferior to men in this respect. Then there is creative imagination, which enables the possessor to develop new methods or contrivances for engineering work. We are not told whether, as a compensation, women excel in this. Next in importance is the faculty of inductive reasoning, which was found difficult to evaluate. It is the kind of power possessed, for instance, by an automobile trouble

*C. W. Squier, "Measuring Our Capabilities," *Mechanical Engineering*, October, 1933.

man, who takes a car out on the road or examines it in the shop and finds the cause of its failure or defective performance. This is probably the same characteristic as that of the successful diagnostician in medicine. It is used in gathering results and drawing conclusions from the data obtained, and is quite distinct from the ability to break down a problem into its components, which is so necessary for analytical work; it is synthetic, rather than analytic.

Among aptitudes considered of lesser importance in engineering work we find manual dexterity, visual memory and tonal memory—the powers of remembering things seen and heard. In the psychological work referred to studies have also been made of what is termed "accounting aptitude." This is the power of handling clerical details rapidly and accurately, and is a characteristic possessed by successful bankers, accountants, bookkeepers, stenographers and private secretaries. Accounting aptitude is apparently an inherent quality, perhaps inherited, certainly fixed in early youth, and as far as can be seen but little affected by environment and experience.

It will be noted that in the estimate of these aptitudes the value of memory is not strongly emphasized. It was found, however, that there was one very important feature depending on memory, which was possessed by all the persons studied who scored highly in the psychological tests. Practically all of the successful people examined had a large English vocabulary, and it seemed evident that this characteristic, more than any other which could be measured, separated the successful man from the unsuccessful. It does not distinguish one type of worker from another, and is possessed equally by the extremely objective and the extremely subjective types. A large vocabulary is, however, an acquired characteristic. It is within the reach of anyone willing to work sufficiently hard, although there were indications that those whose predominating characteristic was "engineering aptitude," namely, the gift for visualizing three dimensional structure, found it more difficult to obtain an extensive vocabulary than was the case with the average person, this deficiency being due possibly, to the lack of stress laid on English in the average American engineering school.

In regard to the nine or ten aptitudes or characteristics which were the subjects of study, it was noted that successful executives obtained high scores in a wide range of different tests. It seems, therefore, that range of aptitudes, rather than a high rating in any one aptitude, is characteristic of the type of man who becomes successful in administrative work.

In general, it was found that about one person in four scored "A" in one aptitude, while only one in sixteen excelled in two, and only one in sixty-four in three. Taking seven of the characteristics most easily measured, it appeared that only one person in about sixteen thousand would reach the upper twenty-five per cent of the list, whereas one in about one hundred and twenty-five was able to score above the average.

The results of inquiries like these are useful as a guide for the individual who desires to choose the life work for which he is best qualified. They will no doubt be studied by those in charge of the selection of personnel for large industrial and engineering organizations. It seems doubtful, however, whether they can be applied to any great extent by the individual employer in his task of interviewing applicants and using his own common sense and knowledge of human nature in appraising their character and personality.

---

## Western Professional Meeting of The Engineering Institute of Canada July 11th to 14th, 1934

**VANCOUVER, B.C., where The Engineering Institute of Canada will hold a joint meeting with the members of the American Society of Civil Engineers.**

**An ideal place to visit this summer. Why not plan to include the convention in your holiday trip?**

*(Details of the programme appeared in the May issue of The Journal.)*

# OBITUARIES

## Bertram Scott Ashley, A.M.E.I.C.

Deep regret is expressed in recording the death in an aeroplane accident in December, 1933, of Bertram Scott Ashley, A.M.E.I.C. The wreck of Mr. Ashley's plane has now been found, and hope for his safety has reluctantly been abandoned.

Mr. Ashley was born in Leitholm, Scotland, on October 27th, 1889, and he received his early education in that country.

He was one of the best known mining engineers and prospectors in Ontario and Quebec. For many years he was with the O'Brien Company at their properties in Cobalt and Gowganda, and later he became associated with the Victoria Syndicate of the Mond Nickel Company. Mr. Ashley also acted as Canadian representative for various British mining firms. He was, perhaps, best known for his discovery of the gold mine in the Matachewan area which bears his name. In 1928 Mr. Ashley became manager of the Telluride Gold Mines Limited, at Englehart, Ontario, and in recent years he had devoted his attention almost entirely to prospecting, and it was only natural that, with his war experience as a pilot, he should have turned to the aeroplane as an aid in carrying on this work.

Mr. Ashley joined The Institute as an Associate Member on May 26th, 1920.

## William John Cunningham, A.M.E.I.C.

Deep regret will be felt at the announcement of the untimely death at Edmonton, Alta., on May 13th, 1934, of William John Cunningham, A.M.E.I.C.

Mr. Cunningham was born at Altrincham, England, on August 29th, 1886, and received his early education at the Altrincham Technical School. Later on he attended the College of Technology affiliated with the University of Manchester, and graduated from that institution.

During the years 1901-1907 Mr. Cunningham was apprentice and assistant engineer with the Altrincham Electric Supply Company, and, coming to Canada in 1907, was engaged on fitting and erecting in the electrical assembly shops of Allis-Chalmers Bullock Limited at Montreal for six months. In 1908 he entered the service of the city of Calgary as electrician and assistant chief engineer on power house and sub-stations, and in 1912 was appointed assistant superintendent. In 1915 Mr. Cunningham went overseas for the department of munitions. He first represented the firm of Vickers Limited, and for four months was with H.M.S. *Valiant*. He was then appointed to the Royal Arsenal at Woolwich, and remained there as inspector and on fitting naval and field guns until 1918. After the war, Mr. Cunningham returned to Calgary and resumed his former position. In 1919 he was appointed superintendent of the Edmonton power plant, and in 1925 he was named in addition, head of the street railway department of the city, and in the succeeding years Mr. Cunningham had much to do with the development and expansion of both utilities.

Mr. Cunningham became an Associate Member of The Institute on June 7th, 1924, and was an active member of the Edmonton Branch, having served on the executive committee on several occasions, and at the time of his death was convenor of the Branch committee on Engineering Education.

All members are again reminded that papers entered in competition for the Past-Presidents' Prize must be received previous to June 30th, 1934, by the General Secretary of The Institute.

Papers for the Students' and Juniors' Prizes must be received by the Branch Secretaries previous to June 30th, 1934.

# PERSONALS

Dr. A. Surveyer, M.E.I.C., consulting engineer, Montreal, has accepted the appointment as seventh member of the Advisory Finance Board of the City of Montreal. Dr. Surveyer has specialized in semi-financial and technical investigations and in these fields his work has been highly successful.

Dr. Surveyer graduated from Laval University with the degree of B.A. in 1898 and from the Ecole Polytechnique with the degree of B.A.Sc. and C.E. in 1902. The following year was spent taking a post-graduate course at the Ecole Speciale d'Industrie et des Mines du Hainaut, at Mons, Belgium. Dr. Surveyer commenced his professional career with the Public Works Department of Canada in 1904, and remained with the Department until 1911 when he entered private practice in Montreal. In August of the same year he was appointed by the Federal government a member of the St. Lawrence River Commission to judge difficulties arising between the hydro-electric companies and the ship-owning companies. In 1912 he reported to the Federal government on the effect of the Chicago Drainage Canal diversion on the harbours of the St. Lawrence river and the Great Lakes. He was later associated in making a joint report on the opportunity of the government guaranteeing the bonds of the Montreal Tunnel Company and the Montreal Central Terminal Company. During his career Dr. Surveyer has been employed in a consulting capacity by all the important cities in the province of Quebec as well as the Department of Public Works, Canada, the Department of Lands and Forests, Quebec, and the Quebec Streams Commission.

Dr. A. SURVEYER, M.E.I.C.

Dr. Surveyer takes an active interest in educational matters, and has rendered voluntary service for a number of years on the Research Council of Canada. He is a member of the Corporation of Professional Engineers of Quebec, the Institution of Civil Engineers, and the Société des Ingénieurs Civils de France.

Dr. Surveyer joined The Institute (then the Canadian Society of Civil Engineers) as a Student on March 16th, 1899, became an Associate Member on October 24th, 1907, and a full Member on June 22nd, 1912, and has always taken a keen interest in its affairs, having been a member of many important committees, including not only the standing committees of Council, but special committees dealing with the welfare of The Institute. He was elected to Council in 1915, on which he served continuously until the end of 1921. He was then elected vice-president, and filled that office for more than two years. He became President in 1924 on the death of W. J. Francis, and served until the end of 1925.

R. G. Bangs, A.M.E.I.C., formerly assistant engineer on the Welland Canal at St. Catharines, Ont., is now attached to the Transportation and Public Utilities Branch, Bureau of Statistics, Department of Trade and Commerce, Ottawa, Ont.

Kenneth Moodie, M.E.I.C., has entered the service of the Government of British Columbia as combustion engineer in the Department of Public Works, and is located at Vancouver, B.C.

P. A. Beique, A.M.E.I.C., consulting engineer, Montreal, has been appointed vice-president of the Montreal Tramways Commission. Mr. Beique has been a member of the Tramways Commission since 1926, and has for a number of years been prominent in engineering circles.

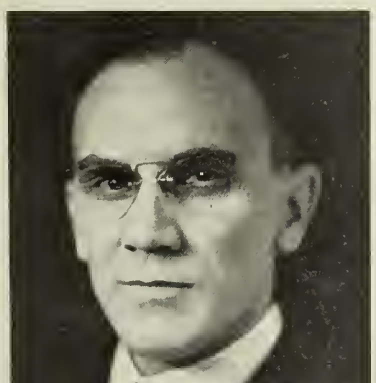
Norman G. McDonald, A.M.E.I.C., has been admitted to partnership in the firm of Gore, Nasmith and Storrie, consulting engineers, Toronto. Mr. McDonald, who graduated from the University of Toronto in 1918 with the degree of B.A.Sc., has been connected with his firm for the last twelve years.

J. L. Wickwire, Jr.E.I.C., is now division engineer with the Nova Scotia Department of Highways, and is located at Middleton, N.S. Mr. Wickwire, who graduated from McGill University with the degree of B.Sc. in 1924, was for a time with C. D. Howe and Company at Port Arthur, Ont.

H. A. Thompson, A.M.E.I.C., is now connected with the E. B. Eddy Company at Hull, Que. Mr. Thompson, who graduated from the University of Saskatchewan in 1927 with the degree of B.Sc., was at one time construction engineer with Morrow and Beatty Ltd., at Fitzroy Harbour, Ont., and in 1932 was on the staff of the Abitibi Power and Paper Company Limited at Smooth Rock Falls, Ont.

James F. MacLaren, A.M.E.I.C., has been admitted to partnership in the firm of Gore, Nasmith and Storrie, consulting engineers, Toronto. Mr. MacLaren, who has been associated with that firm for the past seven years, was at one time superintendent of construction with the Water Supply Section, Department of Works, Toronto, and later was connected with John Inglis Company Limited, Toronto.

John G. Hall, M.E.I.C., formerly vice-president and general manager of the Combustion Engineering Corporation Limited, Montreal, has been appointed general manager and director of the same company. Following



JOHN G. HALL, M.E.I.C.

graduation from McGill University in 1921 with the degree of B.Sc., Mr. Hall was engineer and assistant superintendent of the Back River Power Company until 1924, when he joined the staff of the Combustion Engineering Corporation as manager of the Winnipeg office which position he held until 1927 when he was transferred to Montreal to take over the appointment which he has held up to the present time. Mr. Hall is a member of the Associations of Professional Engineers of Quebec and Manitoba.

W. I. Bishop, M.E.I.C., president and managing director of W. I. Bishop Limited, construction engineers, Montreal, has been appointed a member of the Montreal Tramways Commission. Mr. Bishop is also president and managing director of the Raymond Concrete Pile Company Limited, president and managing director of Ambursen Hydraulic Company, vice-president of the Pacific Construction Company, vice-president of the Pacific Dredging Company.

Philip N. Libby, A.M.E.I.C., is on the staff of the engineering department of the Tennessee Eastman Corporation, and is located at Kingsport, Tenn. Mr. Libby was at one time chief draughtsman with the Riordon Pulp Corporation at Temiskaming, Que., and later was with the Canadian International Paper Company in the same capacity and as assistant to the construction manager. In 1930 he was superintendent of construction for Atwood Limited at Temiskaming, Que., and in 1931 was with the E. B. Eddy Company Limited at Hull, Que. Mr. Libby is a graduate of the University of Maine of the year 1917.

L. H. D. Sutherland, M.E.I.C., has recently incorporated the Sutherland Construction Company, Montreal, to engage in general contracting and engineering. Mr. Sutherland graduated from McGill University in 1909 with the degree of B.Sc., and following graduation was until 1911 with the Canadian Pacific Railway Company as inspector on caisson foundations for an addition to Windsor Station and clerk on construction of additions to several hotels. In 1911 he joined the staff of E. G. M. Cape and Company, and has continued this connection up to the present time, with the exception of the period 1915-1918 when Mr. Sutherland was overseas with the Canadian Engineers and Canadian Railway Troops.

H. Ross MacKenzie, A.M.E.I.C., who was recently elected president of the Association of Professional Engineers of the Province of Saskatchewan, is chief engineer in the Saskatchewan Department of Highways. He graduated from the University of Toronto in 1913 with the degree of B.A.Sc. Following graduation Mr. MacKenzie was appointed inspector with the Saskatchewan Board of Highway Commissioners and in 1917 was promoted to the position of field engineer in the Department of Highways. In 1929 he received the appointment which he now holds. Mr. MacKenzie takes an active interest in the affairs of The Institute, having represented the Saskatchewan Branch on the Council in 1926, 1927 and 1928, and was chairman of the Branch in 1929. In 1919 he represented the Saskatchewan Branch of The Institute at a conference held in Montreal for the purpose of preparing a draft of a model bill providing for the incorporation of provincial associations of professional engineers. In 1929 he was chairman of the Northwest International Highway Association.

E. Winslow-Spragge, A.M.E.I.C., was recently appointed first vice-president of the Canadian Ingersoll-Rand Company Limited. Following graduation from McGill University in 1908, Mr. Winslow-Spragge was for a year at Sault Ste. Marie and Fort William, Ont., with Robert W. Hunt and Company. He then joined the staff of the Canadian Ingersoll-Rand Company at Toronto, and shortly after that was transferred to northern Ontario in charge of the Cobalt office. In 1911 he was transferred to the Montreal office. During the war, Mr. Winslow-Spragge was engaged on the development of munitions manufacture in Canada, and subsequently became chief inspector and manager of the munitions department of his company. Following the armistice, he was appointed general sales manager, and in 1925 he became assistant general manager, in which capacity he has continued until the present. Mr. Winslow-Spragge is a member of the Canadian Institute of Mining and Metallurgy, and was recently elected to the executive council of the Montreal Branch of the Canadian Manufacturers Association.

T. W. Toovey, A.M.E.I.C., formerly chemical engineer with the B.C. Pulp and Paper Company Limited, Port Alice, B.C., has accepted a position with Dr. L. Rys, Harmanec, near Banske Bystrice, Czechoslovakia, in an advisory capacity. Mr. Toovey received his early education at the Royal Grammar School at Newcastle, England, and attended the Rutherford and Armstrong Colleges in the years 1914-1920. From 1914 to 1917 he was an apprentice in the chemical and metallurgical laboratories of Messrs. Sir W. G. Armstrong Whitworth and Company at Newcastle-on-Tyne. Coming to Canada, Mr. Toovey was from 1923 to 1928 in the Research Department of the Canadian International Pulp and Paper Company Ltd., at Hawkesbury, Ont.

C. E. Hogarth, A.M.E.I.C., has recently acquired an interest in the firm of J. D. Armstrong Construction Company Limited, sewer and excavating contractors, Hamilton, and has joined the staff as engineer. Following graduation from the School of Practical Science, University of Toronto, in 1915, with the degree of B.A.Sc., Mr. Hogarth was overseas until 1919 as a lieutenant with the Canadian Engineers. From April until October 1919 he was field engineer on the Welland Ship Canal, and later until July 1920 was field engineer and general foreman with the Austin Company at Cleveland, Ohio. In 1920 Mr. Hogarth was engaged with the Foundation Company of N.Y. as field engineer and in 1921-1925 he was sales engineer with the Refinite Company of Canada, and the Canadian International Filter Company at Toronto. In 1926 Mr. Hogarth was acting assistant superintendent on power house construction for the Detroit Edison Company at Detroit, Mich., and subsequently until 1931 he was engineering assistant with the Michigan Bell Telephone Company at Detroit. In 1931 Mr. Hogarth returned to this country as engineer with Christman-Burke Limited, Toronto.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on April 24th, 1934, the following elections and transfers were effected:

### *Members*

COLLITT, Bernard, F.I.C., metallurgist, Jenkins Bros. Ltd. Montreal, Que.

GERMAN, Alan Macdonnell, B.A.Sc., (Univ. of Toronto), asst. mgr. and gen. supt., Canadian Dredging Co. Ltd., Toronto, Ont.

### *Associate Members*

HOLMAN, Clive Whelpton, (Assoc. Member, Inst. M.E.), teacher of mech'l. drawing, Technical and Commercial High School, Sault Ste Marie, Ont.

MATTSON, Ragnar John, C.E., (Royal Coll. of Engrg., Stockholm), engr., Foundation Company of Canada Ltd., Montreal, Que.

McARA, Peter Graham, B.Sc., (Univ. of Sask), asst. supt., water works dept., City of Regina, Sask.

McDERMID, George, B.Sc., (Univ. of Man.), acting asst. engr., way and structure dept., Winnipeg Electric Company, Winnipeg, Man.

McMILLAN, James, B.Sc., (Univ. of Alta.), purchasing agent, Calgary Power Co. Ltd., Calgary, Alta.

MORGAN, Philip Harold, constrn. supt., Beauharnois Construction Company, Beauharnois, Que.

PEELE, Percy Frederick, B.A.Sc., (Univ. of B.C.), sales engr., Canadian General Electric Co., Calgary, Alta.

TUCKER, Edward Francis, B.S., (Chem.), and Chem. Engr., (Clarkson College of Technology), vice-president and manager, Canadian Stebbins Engrg. and Mfg. Co. Ltd., and secretary and technical director, Stebbins Engrg. and Mfg. Co., Montreal, Que.

### *Juniors*

DuCHENE, Andrew Hubert, B.Sc., (Univ. of N.B.), asst. foreman on tests, Canadian General Electric Co., Peterborough, Ont.

EVANS, Owen Allen, B.Sc., (Queen's Univ.), assayer for the Algoma Central Railway, Sault Ste Marie, Ont.

FULLER, Allan Frederick Samuel, B.Sc., (Univ. of Sask.), 2345 Smith St., Regina, Sask.

LAMOUREUX, Marcel, B.Eng., (McGill Univ.), junior engr., Lake St. Louis Bridge Corporation, St. Guillaume, Que.

### *Transferred from the class of Junior to that of Associate Member*

LEITCH, Hugh James, B.Sc., (McGill Univ.), mgr., warehouse dept., Dominion Bridge Co. Ltd., Montreal, Que.

MacKINNON, William Duncan, B.Sc., (Queen's Univ.), supt. of board mill and steam plant, Donnacona Paper Co. Ltd., Donnacona, Que.

MOON, George Douglas, B.A.Sc., (Univ. of Toronto), dist. engr., Bell Telephone Company of Canada, Quebec, Que.

### *Transferred from the class of Student to that of Associate Member*

ADAMS, George Ronald, B.Sc., (Queen's Univ.), road engr., Veraguas Mines Ltd., Colon, Republic of Panama.

KENT, George Edward, B.Sc., (N.S. Tech. Coll.), asst. to refinery supt., plant No. 2, Imperial Oil Refineries, Ltd., Sarnia, Ont.

NICKERSON, Allan Douglas, B.Sc., (N.S. Tech. Coll.), transmission engr., Maritime Telegraph and Telephone Co. Ltd., Halifax, N.S.

WILFORD, John Richard, (Univ. of Toronto), asst. mgr. and secretary, F. R. Wilford & Co. Ltd., Lindsay, Ont.

### *Transferred from the class of Student to that of Junior*

CHISHOLM, Donald Alexander, B.Sc., (N.S. Tech. Coll.), miner, McIntyre Porcupine Mines, Schumacher, Ont.

CLIMO, Percy Lloyd, B.Sc., (Queen's Univ.), P.O. Box 215, Cobourg, Ont.

MADELEY, W. Arthur, B.A.Sc., (Univ. of B.C.), 4359 West 11th Ave., Vancouver, B.C.

MELLOR, John Harold, B.Sc., (McGill Univ.), field engr., mill constrn., Canadian Copper Refiners, Montreal East, Que.

PEFFERS, William Oswald, Capt., R.C.C.S., B.Sc., (Univ. of Alta.), District Signal Officer, Mil. Dist. No. 3, Kingston, Ont.

TAYLOR, William Russell Coates, B.Sc., (Univ. of Man.), operator, Moose Lake Power Plant, Atikokan, Ont.

### *Students Admitted*

ARTHEY, George Clayton, (Queen's Univ.), 206 Florence St., Ottawa, Ont.

BUBBIS, Nathan S., (Univ. of Man.), 406 Andrews St., Winnipeg, Man.

CLARKE, Bruce Porteous, (McGill Univ.), Lennoxville, Que.

COLPITTS, Henry Gardner Moore, (Univ. of N.B.), P.O. Box 344, Sussex, N.B.

CROSS, Douglas Henry, (McGill Univ.), 3581 University St., Montreal, Que.

DAVENPORT, Ralph Frederick, (Univ. of N.B.), 716 Charlotte St., Fredericton, N.B.

DeBLOIS, Howard Crawford, (R.M.C.), Ile Bizard, Que.

DUNLOP, Duthie MacIntosh, B.Sc., (Univ. of Man.), 128 Arlington St., Winnipeg, Man.

DYER, Edmund Gerald, B.Sc., (N.S.T.C.), 16 Merkle St., Halifax, N.S.

FRASER, Allan Donald William, (McGill Univ.), 1239 Van Horne Ave., Outremont, Que.

FRENCH, Philip Bemis, (McGill Univ.), 456 Pine Ave. West, Montreal, Que.

GOODSPEED, Herbert Newcombe, (Univ. of N.B.), 745 George St., Fredericton, N.B.

GORMAN, David Donald, B.Sc., (Univ. of N.B.), 188 O'Dell Ave., Fredericton, N.B.

HANKIN, Edmund Alfred, (McGill Univ.), 648 Murray Hill, Westmount, Que.

HARRISON, Ronald Dex, (McGill Univ.), 4902 Grosvenor Ave., Montreal, Que.

HURTUBISE, Jacques Edouard, (Ecole Polytechnique), 1430 St. Denis St., Montreal, Que.

LAPLANTE, Joseph Hormisdas Arthur, B.A.Sc., C.E., (Ecole Polytechnique), 2009 Marie Anne St., Montreal, Que.

LEVINTON, Zusse, B.Sc., (Univ. of Sask.), Ridgedale, Sask.

MacPHERSON, John Miles, B.Sc., (Univ. of N.B.), North Devon, N.B.

MICHAUD, Joseph Sylvia Andre, (Ecole Polytechnique), 3582 St. Famille St., Montreal, Que.

McMATH, Andrew Allan Brown, (McGill Univ.), 129 Edison Ave., St. Lambert, Que.

PAQUET, Jean M., (Ecole Polytechnique), 62 de Salaberry, Quebec, Que.

ROSS, Oakland Kenneth, (McGill Univ.), 1627 Selkirk Ave., Montreal, Que.

SAWLE, Ross Tregerthen, (Queen's Univ.), 23 Fraser St., Welland, Ont.

STEVENSON, Charles Lester, (Univ. of N.B.), c/o J. H. Stevenson, Esq., Bank of Nova Scotia, Saint John, N.B.

STURDEE, Charles Parker, (McGill Univ.), 3454 Peel St., Montreal, Que.

TANNENBAUM, Joseph, (McGill Univ.), 5344 Jeanne Mance St., Montreal, Que.

At the meeting of Council held on May 18th, 1934, the following elections and transfers were effected:

*Associate Member*

MAUDE, John Henry, (Assoc., Coll. of Technology, Manchester, Eng.), mech'l. engr., Dominion Bridge Company, Lachine, Que.

*Affiliates*

ALEXANDER, Stanley George, (Chicago Tech. School), chief operating engr., steam power plants, Canadian General Electric Co., Peterborough, Ont.

ROBERTS, Everett H., Director of Forests, Dept. of Natural Resources, Prov. of Sask., Regina, Sask.

WHITE, Robert John, (St. Francis Xavier Coll.), foreman, Project No. 123, Fredericton, N.B.

*Transferred from the class of Junior to that of Associate Member*

McCRONE, Donald Gordon, B.A.Sc., (Univ. of Toronto), chemist, The E. B. Eddy Co. Ltd., Hull, Que.

SAUVAGE, Robert, B.A.Sc., C.E., (Ecole Polytech.), bridge designing senior engr., Dept. of Public Works, Quebec, Que.

WILLIAMS, Edward Clifford, (Final Pass Cert. in Elec. Engrg., City and Guilds of London Institute), industrial heating specialist, Canadian General Electric Co. Ltd., Toronto, Ont.

*Transferred from the class of Student to that of Associate Member*

DECHMAN, Walter Fairchild, B.Sc., (N.S. Tech. Coll.), 19½ South St., Halifax, N.S.

FULTON, Fraser F., B.Sc., (McGill Univ.), 452 Stanstead Road, Town of Mount Royal, Que.

McCORMICK, Archibald Thomas, B.Sc., (Univ. of Man.), special products engr., Northern Electric Co. Ltd., Winnipeg, Man.

WOOD, Robert, B.Sc., (McGill Univ.), executive assistant, Quebec Power Company, Quebec, Que.

*Transferred from the class of Student to that of Junior*

AITKENS, John Currey, B.Sc., (Univ. of Man.), inspecting engr., Project No. 51, Hudson, Ont.

BUNTING, William Lloyd, B.Sc., (Univ. of Man.), supt. of public utilities, Flin Flon, Man.

FRANKLIN, Robert Lawrence, Lieut., R.C.O.C., B.Sc., (Queen's Univ.), Military College of Science, Woolwich, England.

HARDY, Robert McDonald, B.Sc., (Univ. of Man.), M.Sc., (McGill Univ.), lecturer, dept. of civil engrg., University of Alberta, Edmonton, Alta.

STEWART, John R., B.Sc., (McGill Univ.), service engr., Canadian Liquid Air Co. Ltd., Montreal, Que.

*Students Admitted*

BURKE, John Abel, B.Sc., (Univ. of Alta.), 628-15th St. South, Lethbridge, Alta.

CROWE, Frederick Ernest, B.Sc., (Univ. of N.B.), Jeffry, N.B.

DAVIDSON, George Ross, (R.M.C.), Kingston, Ont.

FAURE, Marcel A., (Ecole Polytech.), 32 Elmwood Ave., Outremont, Que.

KAUTH, Carl Gladstone, (Queen's Univ.), Gowanstown, Ont.

KINGSTON, Edgar Lloyd, (McGill Univ.), P.O. Box 149, Prescott, Ont.

LUPTON, Mac Joseph, B.Sc., (Univ. of Man.), 308 Niagara St., Winnipeg, Man.

MANZER, Ronald Wendell, B.Sc., (Univ. of N.B.), South Devon, N.B.

MITCHELL, William Reg., B.Sc., (Univ. of Man.), 344 Overdale St., Deer Lodge, Winnipeg, Man..

PEPALL, James Edward, (R.M.C.), 124 Heath St. W., Toronto, Ont.

PISTREICH, Archie Loebel, (McGill Univ.), 5638 Waverley Ave., Montreal, Que.

SWARTZ, Joseph Norman, (McGill Univ.), 1401 Ford St., Fort William, Ont.

VERGE, Gerard Arthur, (Leaving Cert., St. Patrick's High School, Quebec), 109 Murray Ave., Quebec, Que.

## Dominion Government Relief Camps and Unemployment

Permission has kindly been granted by The Hon. W. A. Gordon, Minister of Labour, to publish the following letter which he addressed to the President of The Institute, commenting on the assistance which The Institute has been privileged to give in connection with the Department of National Defence Relief Camps.

Ottawa, February 26th, 1934

Dear Sir:—

I have before me a report of the Committee on Unemployment organized by The Engineering Institute of Canada, which has been forwarded to me by General McNaughton, Chief of General Staff, Department of National Defence. In forwarding this report General McNaughton indicates to what a great degree your Institute has been co-operating with his Department in their efforts to handle the problem of the relief camps set up under the National Defence Department.

I have no doubt that the success which has marked the General's efforts and those of his staff in meeting this very difficult situation has, in a very great measure, been made possible by the loyal and effective service which has been rendered by the highly trained and experienced men which your Institute has supplied.

It has, however, been a worth-while undertaking and your Institute will, I am sure, draw much satisfaction, and justly so, from the knowledge that they have played a really important part in our combined effort. I desire to express to yourself and to your Institute my sincere appreciation of the very valuable co-operation which you have given the Government in this matter.

Yours faithfully,
(Sgd.) W. A. Gordon,
Minister of Labour.

The President,
The Engineering Institute of Canada,
Montreal, P.Q.

# BOOK REVIEWS

## Treatise on Geodesy

*By Captain P. Tardi, with preface by General G. Perrier. Gauthier-Villars, Editors, Paris. Paper binding, 7 by 10 inches; 732 pages; illustrated, Vol. 1, 80 francs; Vol. 2, 70 francs.*

This treatise is an extensive review of the various phases of geodesy considered as the science dealing with the accurate measurement of areas of such size that the curvature of the earth must be taken into consideration. In this respect, it is of particular value to the experienced geodesist and engineer, and to others for the purpose of scientific reference.

The subjects have been treated under five main divisions:—

(1) General Principles of Geodesy;
(2) Mathematics of Geodesy and Triangulation;
(3) Geodetic Astronomy of Position;
(4) Dynamical Geodesy;
(5) The Figure of the Earth.

The first division is an historical summary of geodetic operations, for which the material was largely gathered from special monographs. In the second division, invar apparatus for base line measurement has been brought to the front in keeping with its increasing use in modern practice. The calculation of triangles and geographical co-ordinates is treated with special care. In his treatment of the representation of the terrestrial ellipsoid on a plane, the author has been inspired by the most recent researches of Roussilhe and Laborde. The adjustment of first order triangulation is outlined for the usual method of directions, and also for the more recent method of variation of co-ordinates, both geographical and rectangular. A feature of the chapter on secondary triangulation is a graphical method of adjustment.

In Volume II, the determination of time and the difference of longitude is the subject of a thorough analysis, justified by the importance which the question has commanded during the last twenty years, due to the more general use of impersonal micrometer meridian instruments and to radio time signals.

In the chapter on Latitude and Azimuth, there are set forth, apart from the recognized methods of meridian and circum-meridian observations, those of Littrow for observations on circum-polar stars and of Struve for stars in the prime vertical.

With regard to the simultaneous determination of local time and latitude, the chapters on the general method or perpendiculars of altitude and the prism astrolabe, consider a means of determination, unknown some thirty years ago, which is of great service at the present time.

In the section on Dynamic Geodesy and the Figure of the Earth, the most advanced theories in modern higher geodesy are presented in a brief and methodical form. Detailed descriptions of the gravity apparatus of Holweck-Lejay and of Venig Meinesz are given. These instruments are innovations of extreme importance, opening, as they do, new horizons to geodesy. Finally, the consideration of the results obtained through triangulation and gravity measurements, the explanation of the Isostatic Theory, by Pratt's method and also by Airy's, the newer method of areas in determining the elements of the terrestrial ellipsoid, are fully treated, and the volume closes with a chapter on the rigidity of the terrestrial globe, containing the most essential ideas on ocean tides, periodic deviation from the vertical, and variations of latitude and tides on the earth's crust.

The volumes are well printed, amply illustrated, and the whole constitutes a record of the science brought up to date. Although the text is in French, the investigator is relieved of the difficulty of reading either in German or French, through various volumes and authors, the many subjects succinctly dealt with by Captain Tardi in two volumes.

## The Young Man in Business

*By Howard Lee Davis, Director of Tech. Emp. and Training, N.Y. Tel. Co., published by John Wiley & Sons Inc. Price $2.00.*

As stated in the preface, this book is for all men and women now in business as well as for those about to seek their first position. With this in view, an effort has been made to take the viewpoint of the young man, and various phases of possible business activity are covered in the twelve chapters. The intention throughout is to help the reader to determine the line of action best suited to himself.

The author points out the importance of fundamental knowledge and the ability to think gained through study, these being indispensable for success. A man should, in fact, acquire early and then keep up throughout the whole of his career the habit of reading and studying.

Mr. Davis considers that in general the attitude of the young man in search of a job is too casual; he should have a definite plan in view, and as far as circumstances permit, should select his own work along the lines for which his aptitudes are the strongest. He would do well to remember that all vocations offer an opportunity for success.

The possible lines of thought of the interviewer and the applicant are also well discussed and methods of approach suggested.

The chapter on "Why Save from the Start" brings out the results of failure to save and the many advantages to be gained and opportunities that may be accepted if some funds are available to the young business man.

The possible behaviour of a man towards his work and his supervisor are considered, and later the seventh chapter on "The Preparation for Responsibility" states that the most important part of his work is when he is fitting himself for the future he desires and for which he has formulated his plans.

For this purpose the author recommends adequate preparation, driving force, attention to detail in both tangible and intangible work, and patience.

The rather unimpressive title of "Educate the Boss" heads a chapter which contains the procedure suggested when placing a plan before a superior for acceptance. Careful and thoughtful study from all viewpoints before presentation is advocated, and in some cases gradual attempts at approval, particularly where any radical change is proposed.

The section devoted to the writing of letters and reports is excellent, but somewhat brief. The factor which most frequently impedes the young man is the inability to express himself adequately in writing, to collect and arrange his thoughts, to give expression verbally. The suggestions made are very much to the point.

The last two chapters are on supervision and leadership, and the factors that are influential in securing promotion and in helping a man to be successful in supervisory work. The duties of a supervisor are outlined and a number of examples are given to illustrate the main points presented. The chapter closes with an outline of the four main functions of supervision.

The purchase of this book by any young business man is recommended as there will be very few who cannot acquire some useful knowledge from Mr. Davis' remarks.

## C.E.S.A. Specifications

The Canadian Engineering Standards Association announces the publication of three more approval specifications under Part II of the Canadian Electrical Code. These constitute specification No. 5, "Construction and Test of Service Entrance and Branch Circuit-Breakers," No. 11, "Construction and Test of Fractional Horsepower Motors," and No. 12, "Construction and Test of Electric Portable Lighting Devices."

These specifications outline conditions which must be met to secure approval for the sale in Canada of these types of electric equipment, and it is suggested that manufacturers secure copies from the C.E.S.A. at Ottawa, so that they may be properly informed. These specifications can be obtained at 25 cents per copy, on application to the Secretary, Room 3064, Research building, Ottawa.

## Erratum

The review of "Arc Welded Steel Frame Structures" by Gilbert D. Fish, which appeared on page 242 of the May, 1934, issue of The Journal, was prepared by H. M. Lyster, A.M.E.I.C., general manager, Dominion Welding Engineering Company, Limited, and not by C. M. Goodrich, M.E.I.C., as was stated when publishing the review.

# BULLETINS

*Tube Couplings*—The Parker Appliance Company, Cleveland, Ohio, has issued Bulletin No. 35, a 36-page booklet containing particulars of tube couplings of the threadless flaired tube type for industrial and domestic plumbing. The booklet also contains a resume of the company's products with specifications and uses.

*Double Reduction Worm Units*—An 8-page folder received from the Hamilton Gear and Machine Company, Toronto, Ontario, contains details of specifications and materials of construction together with motor and load rates of the type D-W small double reduction worm units. A table of the various ratios which can be obtained and the dimensions of the units which are made in seven sizes are included.

*Motor Compressor*—A 4-page leaflet received from Canadian Ingersoll-Rand Company Limited deals with a two-stage air-cooled compressor unit with built in motor, which it is claimed has a number of advantages over the usual unit. It is manufactured in a number of sizes and ratings.

*Surface Condensers*—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued a 4-page folder giving details regarding the folded tube layer type surface condensers. These are of welded steel shell design, and are manufactured in a number of different sizes.

*Refrigeration Compressors*—A 6-page folder received from the Worthington Pump and Machinery Corporation, Harrison, N.J., gives particulars regarding the horizontal duplex type single-stage and two-stage refrigeration compressors. These are belt-driven and direct-connected to a synchronous motor, and are fitted with feather valves. They are manufactured in seven sizes.

*Soot Blowers*—The Diamond Power Specialty Corporation, Detroit, Mich., has issued a 4-page folder giving a short comparison of three types of soot blowers.

## Corrected Acknowledgment

In our issue for April, 1934, the photographs Figs. 1 and 2 appearing with Dr. D. F. Kidd's article "Mineralization in the Great Bear Lake District" were acknowledged incorrectly. The credit line "By courtesy of the R.C.A.F." should have appeared under each of these reproductions.

## File of The Journal Available

A member of The Institute is willing to donate to any institution or person desiring it a complete file of The Engineering Journal, with the exception of the year 1922, which could be supplied by Headquarters. These copies are stripped of the advertising pages, but are in good condition. Enquiries regarding this matter should be addressed to Headquarters, 2050 Mansfield Street, Montreal.

---

*Foster Wheeler Limited*, Montreal, has secured from the Riley Corporation of Worcester, Mass., the exclusive right to manufacture and sell Riley fuel burning apparatus for use in the Dominion of Canada. The Riley Engineering and Supply Co. Ltd., of Toronto, is discontinuing the manufacture and sale of power plant equipment.

This firm has also taken over exclusive rights for the sale and manufacture of the Ruths Steam Storage Systems in Canada.

## The Effect of Construction on General Prosperity

We are permitted to publish the following figures which illustrate the widespread influence of expenditure on a typical construction job, in giving employment in a great variety of different lines of manufacturing and transportation. It will be seen that the effect of such an undertaking in reviving business is felt by a large number of people who are only indirectly connected with the construction industry itself.

The example taken is the new addition to the rayon plant of Courtaulds (Canada) Limited, recently constructed at Cornwall, Ontario, by the Foundation Company of Canada Limited who were the general contractors.

The officers of that company desired to obtain figures showing the value of construction work in material and in labour, both direct and indirect, and they accordingly requested their subcontractors to supply the following information, stating that the intention of the survey was to show that construction work actually had a more widespread effect than is generally supposed:

(*a*) Number of man hours entering into the manufacture of your materials—Canadian.

(*b*) Number of man hours assembling in your shop.

(*c*) Number of man hours in the installation on the job including handling to and from cars or trucks.

(*d*) Number of ton miles handled: divided into rail, boat and truck.

The contract was commenced in October, 1933, and the plant was scheduled to be manufacturing silk by May 7th, 1934. The additions consisted of the following buildings which were steel frame, with brick walls, concrete footings and floor slabs, and precast Haydite roofs.

Mill—507 feet by 135 feet by two storeys.

Storage and shipping building—100 feet by 150 feet by two storeys.

$CS_2$ building—40 feet by 75 feet.

New office building—60 feet by 80 feet.

Addition to churn and mixer building—75 feet by 35 feet by four storeys.

Addition to soda settling building—20 feet by 75 feet.

Addition to pump house—30 feet by 25 feet.

New fume stack—200 feet high.

Underground traffic tunnels connecting new buildings with former buildings.

| | | |
|---|---|---|
| Total cost of new addition including machinery...... | | $2,500,000 |
| Expended on Canadian machinery.................. | | 750,000 |
| Expended on British machinery of a kind not made in Canada.......................................... | | 750,000 |
| Number of man hours in direct labour on the work: | | |
| By general contractor................ | 950,233 | |
| By subcontractors................... | 124,536 | |
| Total.......................... | 1,074,769 | |

From the replies received it was found that indirect labour would run into very large figures and further that it would be impossible to obtain the information from the different manufacturers without putting a large staff on securing the data. However, enough work was done to discover that *more than two million hours of labour* had been provided indirectly throughout Canada in mines, quarries, refineries, transportation systems, manufacturing plants and harbours from British Columbia to Nova Scotia.

As an illustration of the impetus given to business by this one contract the following quantities will be of interest:

37,500 tons of construction material were incorporated in the work.

Over 2,000 tons of common brick were shipped from Delson, Quebec, to the work.

1,200 tons of structural steel were shipped to Lachine, Quebec, from Europe and the United States, fabricated, shipped to the work and erected.

Over 1,000 tons of Haydite partition blocks were made in Montreal from aggregate shipped from Cooksville, Ontario, then shipped to the work.

745 tons of precast Haydite roof slabs were cast in Cooksville, Ontario and shipped to the work

430 tons of asphalt was shipped from Montreal.

200 tons of lead, mined and refined in British Columbia, was consumed in the work.

142 tons of corkboard were shipped from Spain through the harbour at Saint John, N.B.

6,852,181 ton miles of freight was hauled by rail to the work.

90,990 ton miles of freight was hauled on the highways to the work.

3,138 tons of freight was shipped by boat and handled through the different harbours of Canada.

17,725 hours of work was given to farmers' teams.

It is exceedingly difficult to visualize the hours of indirect labour given through the acquiring, manufacture and transportation of the above quantities but possibly an example will be of assistance.

The Otis Fensom Elevator Company of Hamilton, Ontario, supplied equipment consisting of machinery weighing 7½ tons. This was shipped by truck from Hamilton, the transportation amounting to 3,150 ton miles, approximately 1,580 man hours were required for manufacture and 945 hours for installation at the job. However, the company stated that these figures did not include the labour expended by the vendor in the production of the following materials purchased and used by the manufacturer: Rails, pig iron, coke, wiring, conductor cables, conduits and fittings, wire ropes, sheet and structural steel, steel bar stock, bronze, lumber, lead, copper, tin, bolts, screws, nuts, paint, carbons, springs, forgings, controller slates, mica, asbestos, babbit, solder, oils, greases, nails, cotton, friction and rubber tape.

# BRANCH NEWS

## Halifax Branch

*R. R. Murray, A.M.E.I.C., Secretary-Treasurer.*
*C. Scrymgeour, A.M.E.I.C., Branch News Editor.*

Departing from the customary monthly supper meeting, the Halifax Branch of The Engineering Institute of Canada accepted the invitation of its chairman, R. L. Dunsmore, A.M.E.I.C., superintendent of the Imperial Oil Refinery at Dartmouth, N.S., to visit and inspect the large Imperial Oil refining plant on Friday, April 27th, 1934.

That much interest and importance was attached to the proposed inspection of an oil refining plant was evidenced by the large percentage of local members who made up a group totalling sixty-five, and which were augmented by an additional ten members connected with the refinery, these latter assisting in the tour of inspection by acting as guides.

The Branch members met at the Halifax wharf of the Imperial Oil Limited at 2.30 p.m. and were conveyed across the harbour by the Imperial lighter, the *Novalite*, being met at the refinery docks by the superintendent and members of the engineering staff. Before inspecting the plant, the visitors were given two short talks on refinery engineering and refinery processing by Charles Scrymgeour, A.M.E.I.C., plant engineer, and R. L. Dunsmore, A.M.E.I.C., refinery superintendent—the first of these talks outlining the principal problems affecting the construction and maintenance of the plant units, and the latter, a graphic description of the processing of petroleum oils.

Although only two hours were available for a tour of the plant, a complete cycle of all the refining operations, the mechanical shops and the steam and electric power plants was possible, at the conclusion of which The Institute members were taken to the plant town site of Imperoyal where, much to the appreciation of the visitors, light refreshments were served at the club house.

A vote of thanks and expression of appreciation to Mr. Dunsmore and the Imperial Oil Limited, moved by H. S. Johnston, M.E.I.C., concluded a very interesting and instructive meeting, and the members again boarding the *Novalite*, were conveyed back to the city.

## London Branch

*H. A. McKay, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

Somewhat of an innovation was adopted for the regular April meeting, as a speaker was not available. At the kind invitation of E. V. Buchanan, M.E.I.C., the meeting, limited to corporate and affiliate members, was held at his residence. About sixteen members were present and J A. Vance, A.M.E.I.C., Branch councillor, gave a report on the activities of the plenary meetings of Council at Headquarters. A discussion then followed on the constitution of The Institute. It had been felt for sometime that it was desirable to hold a conference on the standing of the professional engineer at the present day both with regard to The Institute and the Provincial Associations. This was taken full advantage of and several suggestions were made which may be brought forward later.

Following the discussion, refreshments, provided by our host, were much enjoyed and the balance of the evening was spent at cards or in social intercourse.

The evening concluded with a hearty vote of thanks to our host, Mr. Buchanan, proposed by the chairman, Frank Ball, A.M.E.I.C., and which was unanimously carried.

## Moncton Branch

*V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.*
*(Reported by T. H. Dickson, A.M.E.I.C.)*

The regular meeting of the Moncton Branch was held in the City Hall on Tuesday, April 17th, 1934, the speaker being H. E. Bigelow, Ph.D., F.R.S.C., Professor of Chemistry, Mount Allison University. The subject of the address was "Chemistry in Industry," which contained a vast amount of useful information concerning the manufacture of many chemical products which are much better known than is their process of manufacture.

### Chemistry in Industry

In his opening remarks, Dr. Bigelow commented on the scarcity of Canadian books on chemical subjects and cited this as the principal reason for the unfamiliarity of Canadians with what has been done in industrial chemistry in Canada.

In illustrating the importance of the chemical industry, Dr. Bigelow stated that the mineral production of Canada for 1929 amounted to $310,000,000. The capital invested in plant $867,000,000 and the products of the industry were valued at $140,000,000 and since 1929 there have been numerous expansions but later figures are not yet available.

As Canadian Industries Limited manufacture a very wide range of chemical products, most of the address concerned the various interests of this company which originated with the Hamilton Powder Works about 1870 and was founded by Mr. Brainerd. Canadian Industries is associated with British Industries Limited, and also with the E. I. DuPont de Nemours and Co. Inc., for the interchange of patented processes.

They have plants in various parts of Canada generally located at points where the required raw materials can be obtained in abundance.

Some plants deal with wood, not as timber, but in the pulp or cellulose state.

Air is a raw material from which is extracted nitrogen and oxygen both of which have many uses.

Sulphur dioxide is obtained as a waste product from various smelters and converted into valuable fertilizers.

Salt is another common raw material which can be used as one of the materials to produce numerous chemical products. The speaker mentioned in passing, the very extensive salt beds near Moncton which will no doubt be the location of a chemical industry sometime in the future. Sandwich, Ontario, also has large supplies.

From water the cheapest and most common raw material is obtained, hydrogen and oxygen. Gun-cotton, an explosive, is obtained by treating cellulose with nitric acid, and about one-half of the nitric acid used is made from nitrogen obtained from the air.

Nitroglycerine is made by treating glycerine with nitric acid, the glycerine being obtained from fats. Cordite is manufactured by dissolving nitroglycerine in nitro-cellulose and dynamite is nitroglycerine diluted with an earth or powder to make it stable.

Gun-cotton mixed with camphor and pressed to a particular shape and heated to a set temperature forms cellulose which is marketed under various trade names, that used by Canadian Industries being Pyralin.

At Sandwich, Ontario, water is pumped into a salt bed 1,600 feet under ground, this dissolves the salt which is then pumped to the surface and evaporated. This salt solution can also be electrolized to produce hydrogen gas, chlorine gas and lye.

Cellulose treated with sodium hydroxide makes a parchment paper, but if carbon disulphide is added, a thick viscous liquid results. If this is passed through orifices and run into a solution viscose silk results.

Courtaulds at Cornwall manufacture another type of artificial silk from cellulose and acetic acid which is called celanese, the highest grade of artificial silk.

Dr. Bigelow's address showed how closely the various industries and products are allied and the many uses to which the products can be put.

In closing, he stated that most of the fundamental substances used in chemistry are found in Canada and that the development of chemical industries in Canada is just beginning and rapid development should take place in the future.

Professor H. W. McKiel, M.E.I.C., made a few remarks in connection with the address, stressing the importance of the chemist in the present scheme of industry.

H. B. Titus, A.M.E.I.C., a former student of Dr. Bigelow's, moved a hearty vote of thanks, which was seconded by G. E. Smith, A.M.E.I.C.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*

A dinner meeting was held on April 11th, 1934, at the Lincoln hotel, St. Catharines. Forty members were in attendance, including H. B. Stuart, A.M.E.I.C., chairman of the Hamilton Branch, and A. Love, A.M.E.I.C., the Secretary-Treasurer.

Chairman W. R. Manock, A.M.E.I.C., introduced the speaker, Mr. F. A. Nagler, chief engineer of the Canadian Allis-Chalmers, Limited, and took occasion to felicitate the Branch upon the honour lately bestowed by The Institute to several of the members, namely: A. J. Grant, M.E.I.C., as recipient of the Sir John Kennedy Medal, E. G. Cameron, A.M.E.I.C., as the new Vice-President for Ontario, W. Jackson, M.E.I.C., as Branch Councillor and Mr. C. G. Cline, A.M.E.I.C., for having received honourable mention in the Past-Presidents' prize competition.

Mr. Nagler is a believer in full size tests wherever possible, and he spoke with the authority of an engineer who had made many of the standard tests on materials only to see some of them fail when subjected to actual working conditions with no acceptable theory to account for such failure.

Tension, elongation and hardness tests are valuable up to a certain point, but they do not always tell the whole story, said Mr. Nagler, and in machines which are subjected to shock, high speeds and reversals the story is particularly inadequate.

Wood, bakelite, aluminum are typical of materials which are forcing their way into the steel field by reason of their strength per pound of weight in cross sectional area.

Cavitation of ship propellers and pitting of water wheel runners are common defects about which there is not complete agreement among research engineers. In answer to questions, Mr. Nagler went into this point more fully and explained that Allis-Chalmers had built a large scale testing plant for the observation of pitting under heads as great as 100 feet. Observations had indicated that pitting was purely a mechanical function and was due to the sudden collapse of nucleii in the small vortexes which are formed at certain speeds and are set up primarily by surface irregularities. For that reason a polished surface is more desirable at all points where a vortex may form than a hard skin which may be rough. Even polished glass will pit, however, and the action may be observed 2 or 3 inches back of the normal surface. Mr. Nagler stated that these actions and effects had been photographed and reproduced under slow motion so that there was very little doubt about the cause.

Some examples of the forward march in welding as applied to pipes, boilers, cylinders and spheres were followed by a moving picture reel showing some of the beautiful scenery in northern British Columbia where Mr. Nagler had hunted big game with a bow and arrow. The picture illustrated a material that was nearly perfect for the duties which it had to perform; namely the Oregon Yew, which went into making the bows. This wood will test to 30,000 pounds per square inch in tension and is five times as strong as steel, per pound of section. The arrows can be driven some 300 yards and will go through the larger game animals such as bear and moose.

### Electoral Meeting

The electoral meeting for the year was held at Erie Downs Golf Club on May 9th, 1934, with sixteen members and their friends as the guests of chairman W. A. Manock, A.M.E.I.C.

This meeting, which seems to have developed into an annual institution, is looked forward to by all the members of the executive as an opportunity for meeting the new officials and extending the courtesies to those who have served so faithfully in the past. At it the ballots are checked, counted and reported by the scrutineers and the personnel of the new executive is made known for the first time. They then hold a short session to appoint their chairman, vice-chairman and secretary-treasurer for the coming year.

The old executive, which carries on until the end of May, then discusses the final arrangements for the annual meeting, and an adjournment is made about 2.30 p.m. for a game of golf.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

At a noon luncheon of the Ottawa Branch at the Chateau Laurier on March 22nd, 1934, W. P. Dobson, M.E.I.C., of Toronto gave an address upon "The Hydro Electric Power Commission Laboratories." Mr. Dobson is in charge of the Testing and Research Department and the Electrical Inspection Department of the Ontario Hydro Electric Power Commission.

Alan K. Hay, A.M.E.I.C., chairman of the local Branch, presided and in addition head table guests included: Group Captain E. W. Stedman, M.E.I.C., J. T. Johnston, M.E.I.C., Commander C. P. Edwards, A.M.E.I.C., A. B. Lambe, A.M.E.I.C., Dr. Frank Allan, Dr. R. W. Boyle, M.E.I.C., B. Stuart McKenzie, M.E.I.C., J. H. Ralph, John Murphy, M.E.I.C., and H. E. M. Kensit, M.E.I.C.

### Ontario Hydro Electric Laboratories

The first work of the laboratories, stated Mr. Dobson, was the testing of meters. Shortly thereafter lamps were tested, the laboratories acting as a sort of central purchasing bureau responsible for a very large amount of testing of lamps for different municipalities.

The laboratories then extended their operations so that now the testing work covers practically every field, its purposes briefly being two-fold: first, to obtain good quality products used in the Commission's equipment, and second, to maintain this good quality.

Mr. Dobson then, by way of example, traced the course of various items of equipment throughout their period of test, the first item considered being the prime mover of a power unit. Other items touched upon were, in turn, electric generators, concrete structures, rubber gloves, safety belts, transformer oil, wood poles, paints, insulating oil, lamps, transmission lines, cable conductors, and so on.

With regard to large generators, the actual tests are usually made in the field after the generators are completed. This is a work of some magnitude often requiring many weeks.

The immense amount of concrete entering into the field structures of the Commission has resulted in new scientific methods for studying the properties of concrete, ways of mixing, and so on.

After construction, the concrete structures are carefully examined every two years by laboratory experts. Sometimes, as a result of these examinations, extensive repairs are made. At the same time, valuable knowledge is accumulated regarding the behaviour of concrete structures under varying conditions.

Considering the question of research, the speaker stated that problems of a more or less scientific nature are constantly arising in the design, construction and operation of the system. A research committee has recently been formed, with suitable subcommittees, to look after problems relating thereto, to discover research talent, to receive suggestions from the staff and to undertake the development of equipment in a more systematic way than in the past. Some problems had been suggested to the National Research Council at Ottawa to whom the speaker paid a high tribute for their work "in producing results in pure and applied science of immense value to utilities."

The investment in the laboratories is less than one-tenth of one per cent of the investment of the Commission. The operating expense is much less, so that as a result the burden on the cost of power is really negligible.

In speaking about the "approval laboratory," one of the laboratories of the Commission, Mr. Dobson stated that it was begun nearly twenty years ago as a result of Ontario legislation aimed at maintaining the safety of electrical equipment. There has since been a gradual evolutionary development so that there is now a Canadian Electrical Code which was issued in 1927 by the Canadian Engineering Standards Association, and is effective in all the provinces of the Dominion. Inspection and approval is carried out under this Code, and the products of some 1,500 manufacturers are on the approved list.

### Canada at the World's Fair

How the Canadian exhibit at the recent Century of Progress exhibition at Chicago drew two and a half million visitors, the interest displayed in the exhibit by the American tourist and business man, and the efficient manner of supplying information to all who asked for it, were a few of the points brought out in an outstanding noon-luncheon address at the Chateau Laurier on April 20th, 1934, before the Ottawa Branch of The Engineering Institute of Canada. C. W. Wright, Honorary President of the Northern Ontario Boards of Trade, who had been appointed to the Dominion government staff for the course of the exhibition, was the speaker.

The Canadian exhibit, jointly sponsored by the Dominion government, the Canadian National Railways, and the Canadian Pacific Railway, portrayed a cross-section of the natural resources of Canada and included the largest map of the Dominion ever prepared. This map measured 130 feet in length by 30 feet in width, was electrically illuminated and was designed and assembled under the direction of F. P. Cosgrove, of the Department of Trade and Commerce, who also had charge of the exhibit.

Canada's participation in the Century of Progress exhibition, in addition to the interest aroused and the information given out at the exhibition itself, also resulted in some seventy-one hundred detailed requests for information which were referred to Ottawa and answered by the various government departments concerned. One noteworthy feature was the fact that twenty-five hundred school teachers asked for literature to aid in the teaching of geography.

Alan K. Hay, A.M.E.I.C., chairman of the local Branch of The Engineering Institute of Canada, presided, and other head table guests included: Dr. Charles Camsell, M.E.I.C., Watson Stellar, Capt. T. Magladery, C. A. Bowman, A.M.E.I.C., Group Captain E. W. Steadman, M.E.I.C., J. G. Parmalee, L. L. Bolton, M.E.I.C., J. B. Harkin, John Murphy, M.E.I.C., Noulan Cauchon, A.M.E.I.C., F. C. C. Lynch, A.M.E.I.C., and C. McL. Pitts, A.M.E.I.C.

## Quebec Branch

*Jules Joyal, A.M.E.I.C., Secretary-Treasurer.*

### Visite du Président

A un lunch qui eut lieu au Château Frontenac le 6 avril 1934, la Section de Québec avait comme invité d'honneur Monsieur F. P. Shearwood, M.E.I.C., Ingénieur en Chef de la Dominion Bridge Company of Montreal et Président de l'Institut des Ingénieurs du Canada pour l'année 1934.

Le lunch était sous la présidence de Monsieur Hector Cimon, M.E.I.C., qui, en termes très élogieux, présenta Monsieur Shearwood à l'assistance.

Le Président de l'Institut se leva au milieu des applaudissements et fit une brève causerie traitant plus particulièrement des différents problèmes auxquels l'Institut doit faire face. Monsieur Shearwood a d'abord déclaré que l'Institut avait fait beaucoup pour le développement de la science au Canada et que le public lui en doit une reconnaissance de tous les instants; cette organisation étend ses ramifications dans toutes les parties du pays et elle se doit de continuer l'œuvre qu'elle a commencée.

Monsieur Shearwood passa en revue diverses questions importantes concernant l'Institut et insista sur la nécessité pour chacun de ses membres d'exprimer leur opinion sur les amendements proposés et ce en exerçant leur droit de vote.

Monsieur A. R. Decary, M.E.I.C., Président-Honoraire à vie de la Section de Québec et ancien Président de l'Institut remercia Monsieur Shearwood puis Monsieur E. A. Evans, M.E.I.C., l'un des fondateurs de notre association et le doyen de la Section de Québec dit aussi quelques mots.

### Difficulties Met With in the Operation of a Hydro-Electric Power System

Summary of a paper delivered by E. Gray-Donald, A.M.E.I.C., superintendent, Power Division, Quebec Power Company, at a meeting of the Quebec Branch held at Palais Montcalm on February 12th, 1934.

It seems to be a very common idea that once a hydro-electric plant, with its transmission lines, substations and distribution lines, is built all that is left to do is to sit back and enjoy life.

A power system, such as that of the Quebec Power Company, is generally roughly divided into three broad divisions: generation, transmission and distribution.

The whole spirit of a hydro-electric generating plant is the river; things happen to rivers: they are flooded at certain times and at others nearly dried up. The ratio of maximum to minimum flow, which is about 2 to 1 for the St. Lawrence river, is about 125 to 1 for the rivers on the north shore near Quebec.

The minimum flow of a river can be increased by regulating works, such as dams.

Frazil ice, blockage of racks by logs, stumps and trash brought down by the river offer difficulties often met with.

Inside the power house an eternal vigilance is required. Temperature of thrust bearings must be watched carefully and all sorts of electrical troubles may occur.

The chief trouble with transmission lines is lightning. On long spans vibration often damages conductors at the support. Insulators are damaged by stones or more frequently rifle bullets. Other causes of trouble are ice, birds, cats, squirrels and sometimes human beings.

Underground transmission and submarine cables are another cause for worry.

Only mechanical damage has been spoken of, but there is also the ever-present danger of electrical breakdown.

Substations may be large or consist only of one bank of transformers. In a fair-size substation there are transformers, switches, bus bars, cables, voltage regulators, motor generator sets, constant current transformers and rectifiers, and a host of other things, then there is all the control and protective equipment.

The ordinary transformer is a fairly simple piece of apparatus to operate, yet it is surprising what can go wrong.

Outdoor switchgear must be carefully maintained so that they will at all times operate freely, these require a great deal of attention and all their mechanism must be watched constantly. Rotating equipment is the cause of endless worry.

The nerves of a substation lie in the control or protective equipment. Nowadays nearly everything is done from the control room.

To the uninitiated a distribution system is merely an unsightly jumble of poles and wires spread over the beautiful streets of our fair cities.

The proper design of a distribution system for a city like Quebec required a lot of technical knowledge and a great deal of thought. Loads increase and decrease; part of the population moves to new residential districts, their old quarter is built up with shops and the old shopping district becomes devoted to manufacturing. This shift of population is continuous and the distribution system is constantly changing to meet new conditions.

Trees are a cause of trouble for the distribution system and another is complaints of low voltage.

## Saint John Branch

*S. Hogg, A.M.E.I.C., Secretary-Treasurer.*
*C. M. Hare, S.E.I.C., Branch News Editor.*

### Operation of a Lobnitz Rock Breaker

C. S. MacLean, A.M.E.I.C., of this Branch, was the speaker at the monthly meeting held in the Admiral Beatty hotel on March 27th, 1934.

The subject chosen for the address was "The Operation of a Lobnitz Rock Breaker."

The speaker opened his remarks by describing in detail and showing slides of the apparatus operating from the scow "Glenbuckie" which has been at work in the main channel of the Saint John Harbour during the past two years.

The apparatus was developed by Lobnitz and Company Ltd., of Renfrew, Scotland. It consists essentially of a heavy chisel that is lifted and dropped on the rock, chopping pieces off the face of the cut, as you might cut pieces from the end of a board with a carpenter's chisel. The chisel of the "Glenbuckie" is a steel cylinder twenty-seven feet long by twenty-two and a half inches diameter and weighing fifteen long tons. It has an alloy steel point with a shank fitting into a hole in the end of the body. The point is renewed when worn. The chisel works in a tube of heavy plate lined with a wooden bushing that serves to guide and restrain it, and through which a descending chisel expels the water with some force to wash away the broken rock at the spot being worked. The apparatus is mounted on a steel hull one hundred and sixty feet long by forty-five feet beam.

The speaker went on to describe the deck machinery, especially a rather unusual clutch on the main winch which operates the chisel. Steam is furnished by a Scotch marine boiler to the main winch, the manoeuvring winch, a winch to handle the tube, and auxiliary apparatus. In operation three blows per minute may be struck, the chisel being hoisted and dropped fourteen feet each time.

The types of rock encountered were next described. At one place rock was so hard that the chisel point had to be replaced every three days.

It is necessary to know the height of the tides at all times when working. The speaker described the complex analysis required, and presented some original thoughts on the causes of currents and undertow in the harbour.

At the conclusion of the address a vote of thanks was moved and seconded and tendered to the speaker by the chairman.

## Toronto Branch

*W. S. Wilson, A.M.E.I.C., Secretary-Treasurer.*
*O. Holden, A.M.E.I.C., Branch News Editor.*

The regular meeting of the Toronto Branch was held on Friday, April 13th, 1934, in the Debates room, Hart House, with Lieut.-Col. R. E. Smythe, A.M.E.I.C., occupying the chair.

Several distinguished visitors were present, including Mr. W. A. Curtis, president of the Toronto Flying Club; Mr. L. C. L. Murray, manager of de Havilland Aircraft; Mr. W. Alan Scott of Canadian Airways and Mr. P. W. Reynolds, M.E.I.C., of the Shell Oil Company.

The speaker of the evening was Mr. William B. Burchall, advertising publicity manager, Canadian Airways, Limited, whose subject was "The Contribution of the Aeroplane to Canadian Industrial Development."

Mr. Burchall said that the use of the aeroplane for non-competitive activities, such as aerial photography and surveying, commenced immediately after the war. Its use in general transportation commenced about ten years ago, the first regular service in Canada being instituted at Haileybury in 1924.

In Canada air transportation has not yet proved a serious competitor to the railroads, but has been a beneficial auxiliary. As 75 per cent of the country is not served by road or rail, the aeroplane is proving an admirable instrument in opening up rich but inaccessible districts.

The aeroplanes most commonly used in commercial pursuits are of the general service type adaptable to a wide variety of loads. For instance, the Canadian Airways have a freighter which has such excellent aeronautical characteristics that it can carry a pay load of three tons a distance of 100 miles at a fuel cost of $10.00, or 3⅓ cents per ton mile.

As used in forestry the aeroplane has been found invaluable in timber cruising. About 250,000 square miles of timber land have already been sketched from the air, and about 40,000 photographed. Aerial photographs show very clearly the type and density of growth and the cut areas.

In combating insect pests, "dusting" from the air allows great areas to be treated in a short time, and is very cheap and effective.

The trapper is taking to the air and the aeroplane is now used by the Pacific Coast fishery patrols to replace the fast motor boat which was at a disadvantage in law enforcement due to the indented and tortuous nature of the coast line.

Aerial photographs have proved useful in city and harbour planning, and make useful progress records and attractive illustrations for advertisements. Accurate contour maps may be plotted from them, and they often remove the necessity for expensive surveys.

It is in the mining industry that the aeroplane has found its greatest field of endeavour and the freight and passenger traffic in connection with this industry has risen to large proportions.

In answer to a query, the speaker gave some statistics regarding risk attending travel by air, notable figures being that the Canadian Airways passenger fatality rate to the end of 1932 was one per 1,231,887 miles, and that the last 8,500,000 miles of daylight service had been flown without a single fatality.

The lecture was illustrated by many slides, which served to drive home the point that aerial photographs are useful and interesting.

A vote of thanks was moved by W. G. Chace, M.E.I.C., and seconded by Mr. Reynolds.

The meeting was brought to a close by Mr. Curtis, with an appeal to members of The Institute to aid in the effort to procure for the city of Toronto an adequate municipal airport. He pointed out that, as Toronto is at present the financial centre of the Ontario mining industry, which makes great use of aerial transport, the lack of aerial facilities is likely to prove costly. The city needs a port for transfer from planes equipped with wheels to those equipped with skis or floats, such as are used exclusively for northern travel.

## Vancouver Branch

*A. I. E. Gordon, Jr.E.I.C., Secretary-Treasurer.*

### The Preservation of Timber

An open meeting of the Vancouver Branch, held on Monday, March 12th, 1934, at 8.15 p.m., in the auditorium of the Medical-Dental building, was addressed by H. N. MacPherson, A.M.E.I.C., on "The Preservation of Timber." The address was illustrated with motion pictures showing every phase of the wood preserving industry. The speaker dealt principally with the creosoting of fir on the Pacific coast and stressed the importance of framing timber structures before treatment in order that the protective coating may remain intact during and after construction. The chairman, P. H. Buchan, A.M.E.I.C., introduced Mr. MacPherson, and following a long and interesting discussion, E. C. Thrupp, A.M.E.I.C., moved a vote of thanks.

Before adjournment, P. L. Pratley, M.E.I.C., on a visit from the east, spoke briefly on the Annual General Meeting.

### The Scientific Side of Flight

The April meeting of the Branch was held on the evening of Thursday, the 12th, in the Medical-Dental auditorium. The speaker was Mr. R. Rolleston West of the Department of Mechanical Engineering of the University of British Columbia, who chose as his subject "The Scientific Side of Flight," and dealt in some detail with the special problems presented in aeroplane design and model and full scale tests of new types.

### Canadian Automobile Industry

In co-operation with the Victoria Branch, the Vancouver Branch of The Institute was fortunate in securing a very interesting motion picture entitled "From the Ground Up" from the Motion Picture Bureau of the Dominion government. This dealt with the Canadian automobile industry and was shown at a meeting held in the auditorium of the Medical-Dental building on the evening of Thursday, May 10th, 1934. The film showed many interesting close-ups of the modern machinery used in Canadian plants, as well as many processes in subsidiary industries. Emphasis was laid on the fact that automobiles are one of Canada's leading exports and nearly two hundred thousand Canadians are dependent directly or indirectly on the industry for employment.

A request that the film be held over for exhibition in Vancouver schools was received by the Branch.

## Victoria Branch

*I. C. Barltrop, A.M.E.I.C., Secretary-Treasurer.*
*Kenneth Reid, Jr.E.I.C., Branch News Editor.*

On Wednesday evening, April 25th, 1934, the Victoria Branch entertained about eighty of its members and friends in the K. of C. hall, when motion pictures were shown depicting the manufacture of automobiles in Canada. The films were obtained through the courtesy of the Dominion Government, Department of Trade and Commerce. In the absence of the Branch chairman, J. N. Anderson, A.M.E.I.C., presided. Invitations were sent to members of the local automotive trade and to the students of Victoria College, which is affiliated with the University of British Columbia.

Aerial views of the automobile manufacturing plants in Canada were shown. These plants occupy over 300,000 acres of ground, in value $98,000,000 in plant investment, employ 16,000 direct employees in normal times, and average an output of over 385,000 cars per year. They absorb raw products taken from over six hundred sources of supply.

The various steps in the manufacture of automobile steel, through furnaces, rolling mills, foundries, etc., were shown, and also the manufacture of machined parts such as blocks, gears, pistons, shafts, etc.

The film then continued to show the manufacture and assembly of many separate articles all of which are combined to make up the finished car. From these smaller units the picture transferred to the manufacture of rubber and rubber products.

After the completion of the chassis assembly, the picture again transferred to the building of the automobile body, both wooden and all-steel. This was followed by the painting of the assembled body. The upholstery for the body and its manufacture in the textile mills of Canada were next shown.

This was followed by the manufacture of storage batteries and finally the assembly of the body to the finished chassis.

Canada is the second largest exporter of automobiles in the world. The packing and shipping departments of the automobile factories were also visited, showing the crating and shipping facilities.

A film of this nature clearly shows the vast number of industries that become related in the manufacture of a single car.

## Winnipeg Branch

*E. W. M. James, A.M.E.I.C., Secretary-Treasurer.*
*E. V. Caton, M.E.I.C., Branch News Editor.*

A meeting of the Winnipeg Branch of The Engineering Institute of Canada was held in the University building, Broadway, Thursday evening, April 5th, 1934, Major A. J. Taunton, A.M.E.I.C., in the chair. After the general business was completed, the meeting was handed over to the junior engineers, their chairman, Mr. Stevens, presiding.

Three papers were presented by the junior engineers, as follows:

"The Beauharnois Project"—Mr. E. A. Grasby.
"Aerial Navigation" —Mr. Walter M. Murray, S.E.I.C.
"Public Works Projects" —Mr. Wallace Walkey.

### The Beauharnois Project

Mr. Grasby dealt with the general engineering features of the Beauharnois project, paying particular attention to certain engineering problems and describing methods which had been used to overcome the difficulties. He gave a very interesting summary of the main constructional features, and his detailed explanation of certain of the methods of construction was of great interest.

### Aerial Navigation

Mr. Murray gave a paper on "Aerial Navigation" and dealt very completely with the methods and instruments used. The interest of the meeting in this paper was indicated by the suggestion that sometime during the coming year he be asked to give a paper to The Engineering Institute on this subject.

### Public Works Projects

Mr. Walkey then presented a paper on "Public Works Projects." He pointed out that among the junior engineers were a large number of men who at present were unemployed and these men had taken on themselves the job of listing all proposed public works which had been suggested by various bodies to relieve the present unemployment situation. He stressed the fact that practically no work had been done towards a proper consideration of the economics and engineering features of any of these schemes; that there was an entire absence of plans and designs, and even if the money were found tomorrow it would be several months before it was possible for any construction work to be gone ahead with owing to the absence of such plans and designs. This being so, the junior engineers had decided to look carefully into all the various plans suggested, both from the engineering and economic view points, to make approximate preliminary designs and estimate of the cost, and now asked the assistance and co-operation of the members of The Engineering Institute and Professional Association in the work. It was stated that office accommodation had already been provided for this work by the senior organizations.

An active discussion followed, during which many members of the senior organizations promised their full support, and congratulated the junior engineers on their public spirited action in this matter.

At the close of the meeting, T. C. Main, A.M.E.I.C., moved a resolution, which was unanimously adopted:

"That a suitable petition be forwarded to both the Dominion and provincial governments, urging them to give serious consideration to the time and effort required for technical investigation to the end that as little delay as possible will result in commencing construction in any public works programme after its authorization."

# EMPLOYMENT SERVICE BUREAU

**The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.**

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situation Vacant

PATENT ATTORNEY'S OFFICE. Opening for a young and ambitious man with technical training, where immediate salary is not important. Excellent future prospects. Apply to Box 1031-V.

## Situations Wanted

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, French, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

INDUSTRIAL ENGINEER, B.Sc., McGill Univ. Age 29. Married. Mechanical and electrical engineering experience with four large Canadian companies; including supervision of manufacture of various products, reduction of manufacturing costs, factory planning and investigation of piece work systems. Available on short notice. Apply to Box No. 132-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian, married, 34 years of age, with 13 years' experience in the industrial field, including design, construction and operation, 8 years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details upon request. Apply to Box No. 161-W.

CIVIL ENGINEER, age 44, open for employment anywhere, experience covers about 20 years' active work, including 7 years on municipal engineering, 2 years as Town Manager, 3 years on railway construction, 3 years on the staff of a provincial highway department, 2 years as contractor's superintendent on pavement construction. Apply to Box No. 216 W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257 W.

ELECTRICAL ENGINEER, B.Sc., '28, Canadian. Age 25. Experience includes two summers with power company; thirteen months test course with C.G.E. Co; telephone engineering, and the past thirty months with a large power company in operation and maintenance engineering. Location immaterial and available immediately. Apply to Box No. 266-W.

MECHANICAL ENGINEER, age 28, nine years all round experience, Grad. Inst. of Mech. Engs. England, S.E.I.C. Technical and practical training with first class English firm of general engineers; shop, foundry and drawing office experience in steam and Diesel engines, asphalt, concrete machinery, boilers, power plants, road rollers, etc. Experience in heating and ventilation design and equipment; 18 months designing draughtsman with Montreal consulting engineers. 2½ years sales experience, steam and hot water heating systems, power plant equipment, machinery, oil-burning apparatus. Canadian 4th class Marine Engineers Certificate; C.N.S. experience. Available at short notice. Apply to Box No. 270-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

PLANE-TABLE TOPOGRAPHER, B.Sc., in C.E. Thoroughly experienced in modern field mapping methods including ground control for aerial surveys. Fast and efficient in surveys for construction, hydro-electric and geological investigations. Apply to Box No. 431-W.

ELECTRICAL ENGINEER, B.Sc., A.M.E.I.C., Am.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.Sc., and C.E., A.M.E.I.C., age 30, married. Experience over the last ten years covers construction on hydro-electric and railway work as instrumentman and resident engineer. Also office work on teaching and design, investigations and hydraulic works, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

## Situations Wanted

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

MECHANICAL ENGINEER, B.Sc. Age 28, married. Four and a half years on industrial plant maintenance and construction, including shop production work and pulp and paper mill control. Also two and a half years on structural steel and reinforced concrete design. Available at once. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years' technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Sc., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

### Employment Situation Slightly Improved

During recent months a definite upswing has occurred in the employment of engineers in the following lines: chemical, metallurgical, mining and mechanical, with a very slight improvement in civil in some parts of the country.

Since the first of the year it has been possible to remove eighty-one names from our roll of unemployed as having obtained either temporary or permanent positions.

This is decidedly encouraging but it is still far from satisfactory and is likely to remain so until some more definite improvement in employment is registered for engineers in the civil and electrical fields and for recent graduates.

CIVIL ENGINEER, age 25, single, graduate. Creditable record on responsible hydro and railroad work in both Eastern and Western Canada. Apply to Box No. 567-W.

MECHANICAL ENGINEER, A.M.E.I.C., with twenty years experience on mechanical and structural design, desires connection. Available at once. Apply to Box No. 571-W.

MECHANICAL ENGINEER, B.A.Sc., '30, desires position to gain experience, and which offers opportunity for advancement. Experience in pulp and paper mill and one year in mechanical department of large electrical company. Location immaterial. Available immediately. Apply to Box No. 577-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building. Location immaterial. Available at once. Apply to Box No. 601-W.

CHEMICAL ENGINEER, S.E.I.C., B.Sc., University of Alberta, '30. Age 31. Single. Six seasons' practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years' experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

## Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box No. 651-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing office. Office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., 29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.Sc., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

## Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, graduate '29. Married. One year building construction, one year hydro-electric construction in South America, fourteen months resident engineer on road construction. Working knowledge of Spanish. Apply to Box No. 744-W.

SALES ENGINEER, B.Sc., McGill, 1923. A.M.E.I.C. Age 33. Married. Extensive experience in building construction. Thoroughly familiar with steel building products; last five years in charge of structural and reinforcing steel sales for company in New York state. Available at once. Located in Canada. Apply to Box No 749-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER. Specializing in power and illumination reports, estimates, appraisals, contracts and rates, plans and specifications for buildings. Available on interesting terms. Apply to Box No. 795-W.

MECHANICAL AND INDUSTRIAL ENGINEER, S.E.I.C., B.Sc. in Mech., (Queen's, '32) and M.Eng. in Indust., (McGill, '34). Age 25. Single. Forty months as moulder's helper, machinist, etc. in foundries, machine shops, and on hydro-electric construction. Now completing two-year Rockefeller Foundation Fellowship at McGill. Good references. Available on short notice. Apply to Box No. 797-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with fifteen years experience mostly in pulp and paper mill work, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

ELECTRICAL ENGINEER, S.E.I.C., grad. '29, age 24, married; experience includes one year Students Test Course, sixteen months in distribution transformer design and eight months as assistant foreman in charge of industrial control and switchgear tests. Location immaterial. Available at once. Apply to Box No. 828-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W.

## Situations Wanted

MECHANICAL ENGINEER, Jr.E.I.C., technical graduate, bilingual, age 30. Two years as designing heating draughtsman with one of the largest firms of its kind on this continent handling heating materials; three years designing draughtsman in consulting engineers' office, mechanical equipment of buildings, heating, ventilation, sanitation, power plant equipment, writing of specifications, etc. Present location Montreal. Available at once. Apply to Box No. 850-W.

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years' experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

CIVIL ENGINEER, B.Sc., Montreal 1930, age 26, single, French and English, desires position technical or non-technical in engineering, industrial or commercial fields, sales or promotion work. Experience includes three years in municipal engineering on paving, sewage, waterworks, filter plant equipment, layout of buildings, etc. Available immediately. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.Sc., '25, McGill Univ., Jr.E.I.C., P.E.Q., age 32, married. Experience as rodman and instrumentman on track maintenance. Seven and one-half years with Canadian paper company, as assistant office engineer handling all classes of engineering problems in connection with woods operations, i.e., road buildings, piers, booms, timber bridges, depots, dams, etc. Apply to Box No. 933-W.

ELECTRICAL ENGINEER, Dipl. of Eng., B.Sc. (Dalhousie Univ.), S.B. and S.M. in E.E. (Mass. Inst. of Tech.), Canadian. Married. Seven and a half years' experience in design, construction and operation of hydro, steam and industrial plants. For past sixteen months field office electrical engineer on 510,000 h.p. hydro-electric project. Available at once. Apply to Box No. 936-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street, improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

## Situations Wanted

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's 14), A.M.E.I.C., Dominion Land Surveyor, 5 months' special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, age 27, graduate 1930, single. Experience includes detailing, designing and estimating structural steel, plate work and pressure vessels; also hydrographic surveying. Available at once. Apply to Box No. 1111-W.

ELECTRICAL ENGINEER, B.Sc., in E.E. (Univ. of N.B. '34), S.E.I.C. Experience in bridge and road construction and auto repairing, desires position in industrial or power plant. Any locality. References on request. Apply to Box No. 1114-W.

CIVIL ENGINEER, B.Sc. Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C.), M.S. (Univ. of Pittsburgh). Canadian. Age 26. Single. One year graduate student course, W.E. and M. Co., East Pittsburgh. Three and a half years engineering research in mechanics with the same company. Location immaterial. Available at once. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25, Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

# for SCALES

Fairbanks Scales meet the basic requirements of modern production—speed and accuracy. Total load shown instantly by unwavering indicator. No calculating. No poise juggling. Loads weighed as fast as they can be handled. Dial markings easily read. Lasting accuracy is assured by Fairbanks construction—the culmination of 100 years of scale building.

From tiny delicate balance to huge railroad track scale, there is a 'Fairbanks' for every weighing purpose.

Fairbanks Scales are made in the only complete scale manufacturing plant in Canada, and the wide acceptance of these famous weighing machines has earned for them a reputation for all that is modern and best in scale manufacture.

Write for our Scale Catalogue No. 3100.

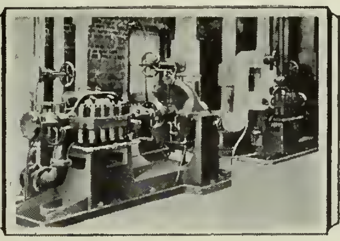
# CAMERON PUMPS



## *For Every Industry*

Around the mines, in chemical works and steel mills, in central stations, paper mills and industrial plants of every description, the name "Cameron" is synonymous with the most modern practice in steam and centrifugal pump design. For boiler feeding, general service, handling acids, viscous and gritty fluids, hot liquids, etc., there is a "Cameron" Pump to suit . . . single- or multi-stage units for all capacities and pressures.

# Ontario Hydro's New Building will have

**Sturtevant** (TRADE MARK)

**Ventilating and Air Conditioning Systems Throughout**

A modern building becomes *thoroughly* modern when it is equipped with the newest system for ventilating and air conditioning.

In the new and imposing building now under construction for the Ontario Hydro Commission in Toronto, a complete Sturtevant system will be installed that will be the largest of its kind in Canada.

A pioneer in the field of air-conditioning, Sturtevant is exceptionally well equipped to provide competent advice, engineering service and equipment. Our catalogue should be in your files—send for it.

CANADIAN chemists, through their national, professional organization, invite professional engineers to consult with them in the selection of staff and the maintenance of the highest standards of professional chemical competency.
Standards of Institute membership will be sent on request.

CORRESPONDENCE on the selection of chemists or chemical engineers for general or highly specialized work will be given most careful consideration. Consultation, without obligation, on any matter relating to the creation of a chemical control or research laboratory will be welcomed.

**CANADIAN INSTITUTE OF CHEMISTRY**
(*Incorporated by Dominion Charter 1921*)
366 ADELAIDE ST. WEST, TORONTO 2, ONT.

## The Institute Badge

Member's gold badge - - $3.75
Associate Member's silver badge - - - - - - - - $2.25
Junior's and Student's bronze badge - - - - $1.50

These Badges may be secured from The Secretary, 2050 Mansfield Street, Montreal

Available in three designs: Clasp Pin, Button, Watch Charm.

## WATER FILTRATION

*Industrial water rectification—Air conditioning.*

During 1931-32 we have been commissioned to install municipal filtration systems totalling a daily supply of 180,000,000 imperial gallons.

# Electric Vibrating Screens by Jeffrey

Great capacity. . . High screening efficiency. . . Low operating cost. . . Dependability. . . Compactness. . . are a few of the outstanding features of Jeffrey-Traylor Vibrating Screens.

Supplied in single or multi-decked styles and in sizes ranging from two to forty square feet, Jeffrey-Traylor Screens are being used in many industries for sizing both coarse and fine materials in both wet and dry conditions.

Jeffrey-Traylor Screens embody the Traylor patented principle of Controlled Vibration. . . they are suspended from vibration absorbers so that all vibration is confined to the screen. No heavy supporting structure is necessary as the installation is a simple and permanent one.

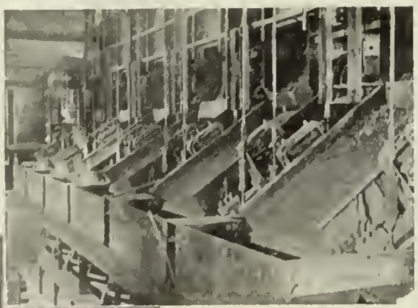
If you want positive control over tonnage. . . a unit that has no mechanical striking and wearing parts, providing low maintenance. . . then investigate this Jeffrey-Traylor Electric Vibrating Screen.

*Complete information and data sent on request.*

## JEFFREY MFG. CO., LTD.

Head Office and Works: Montreal
Branch Offices: Toronto—Calgary—Vancouver

*A double deck vibrating screen (type FB-2) is shown above. A battery of single deck screens are shown at the right.*



*Left—a single deck Jeffrey-Traylor Screen with roll feed.*

•

*Jeffrey-Traylor also makes electric vibrating Conveyors, Feeders, Dryers and Coolers. Send for data.*

SINGLE track concrete roads, so readily converted into full-width highways as traffic growth warrants, are solving the paving problems of many communities. They keep expenditures within scope of limited budgets; yet give the taxpayer what he wants—permanent, car-saving driving surfaces that eliminate costly upkeep. Write our Service Department for full information.

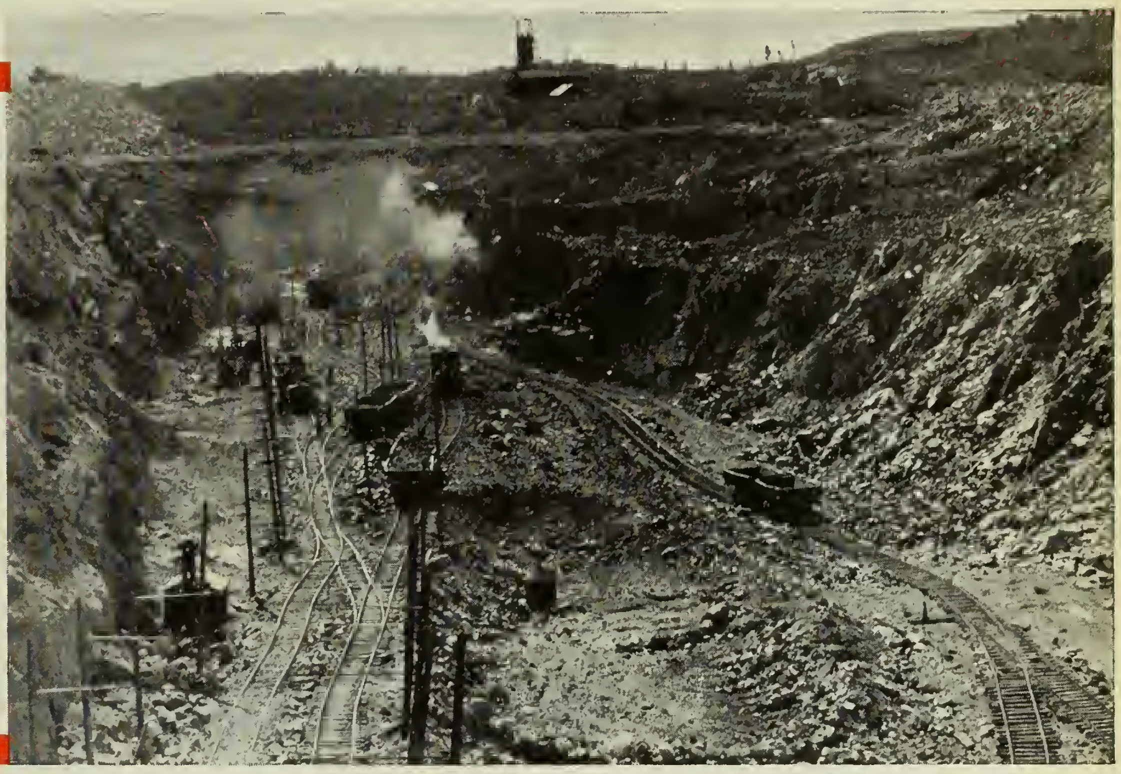
# The Romance of Mining in Canada

In the early days of locating his claim the mining prospector suffered untold hardships. To-day the prospector goes out equipped to meet practically all emergencies.

## COPPER PRODUCTION IN 1932 WAS 247,679,070 POUNDS



*The Flin Flon Mine*

ALTHOUGH Louis XIV granted a concession to Nicholas Denys to mine copper on Cape Breton Island in the year 1654, over 250 years elapsed before refined copper was produced commercially in quantity—by the Consolidated Mining & Smelting Company, at Trail, B.C. Copper mining is still one of the most important divisions of the mining industry in this Province.

Another of the earlier important copper mines in Canada was the Eustis property in the township of Ascot, Que., where over sixty years ago copper matte was produced. The Eustis mines are still producing both copper and iron sulphide concentrates.

Much development has been carried on in the last ten years in the Flin Flon district of Manitoba, on the Saskatchewan boundary. The Flin Flon mine, which is operated by the Hudson Bay Mining and Smelting Company, produced 31,068,556 pounds of copper in 1931. In the production of copper—as in all other Canadian mining projects—C-I-L Explosives have played an important part in speeding production and lowering labor costs.

# EVERYTHING
## for your Pole Line

Whatever your line requirements, Northern Electric can supply them. For more than thirty years we have specialized in this field, always keeping abreast of the times with new and improved devices. From the ground to the top of the pole, you can standardize on Northern Electric material. Our General Catalogue lists all items required to build a safe and highly efficient line: poles, galvanized hardware, cross-arms, steel pins, insulators, guy strand, specialties and tools. Quality, prices and deliveries are in keeping with Northern Electric Company's position — "A national electrical service".

## ..Read what that means *to you*

HOW does the welcome upward swing affect your plant? Does it bring into use electrical equipment that has remained idle during the past few years? If so, this message is of vital importance to you.

Inactive electrical apparatus has three deadly enemies—moisture, dirt and fumes. These attack even the best insulation, so that machinery, on which you rely for greater production, may fail at a critical time. You can prevent this by calling in the Westinghouse Service Department now to check over your plant. Their recommendations have the stamp of authority, for all the engineers of Westinghouse Service Shops are experienced men, whose judgment is backed by a nation-wide organization.

Perhaps the power factor of your plant can be improved. In a textile mill, for example, without advising any additional equipment, the Westinghouse Service Department was able to raise the power factor from 50 to 65 per cent. simply by rearranging the motors.

It is surely in your best interests to guard against expensive shutdowns or excessive power costs. Engineers from any one of the six Westinghouse Service Shops listed below will gladly call at your bidding.

# Town Planning Aspects of Vancouver and Fraser River Harbours

*W. G. Swan, M.E.I.C.,*
*Consulting Engineer, Vancouver, B.C.*

**Paper to be presented at the Western Professional Meeting of The Engineering Institute of Canada, to be held in Vancouver, B.C. on July 11th to 14th, 1934.**

**SUMMARY.—The present developments in the three divisions of Vancouver Harbour and in the Fraser River are described with reference to such matters as administration, zoning, railway and road transportation, industrial and residental areas and harbour facilities. The problems involved in possible future developments are indicated.**

While we are inclined to view town planning as of greatest importance in zoning, in streets and transit problems, and in parks, civic art and other recreational problems, its application to harbour development is somewhat less definite. In the major seaports of the world, of which Vancouver is one, the harbour is in most cases the greatest single asset of the community. It is usually of much greater than local importance and in many cases is of outstanding national importance. The latter is especially true of Vancouver and the Fraser river harbours, which with Prince Rupert constitute the only outlets for Canada on the Pacific ocean. The actual movement of goods and commodities which pass through these ports comprises over 70 per cent of the total movement, the balance being of local origin or for local consignment. As a part of the town plan for a seaport, there is a rightful demand that future development of the waterfront facilities should recognize proper access for the free movement of freight and passengers to and from the harbour by highway and railway with a minimum of impediment on such movements. The plan should further recognize the need for adequate railway facilities, which include berthside and depressed tracks on pier or wharf, adjacent storage and switching trackage and car storage yards of ample holding capacity within economical proximity to the points of transfer from rail to water, and vice versa. There should be suitable interchange arrangements where two or more railways operate within the terminal area, and if possible a unified control for the operation of the waterfront or terminal railway. The plan should provide for the systematic development of the waterfront with proper lines of demarcation between deep sea, coastwise, industrial, and recreational waterfront facilities. Waterfront roadways should be provided which allow direct connection between various portions of the harbour front and which enable city fire, police, ambulance, and other services to operate with greatest despatch.

To properly understand the town plan as applicable to Vancouver and Fraser river harbours, it is necessary to have a brief description of the natural characteristics of those ports and their method of government and public control.

### Vancouver Harbour

Vancouver harbour comprises all tidal waters east of the line joining Point Grey and Point Atkinson. It is divided into three parts, the outer harbour and False creek, the central harbour lying between First and Second Narrows, and the inner harbour, lying above the Second Narrows. (See Fig. 1.) The total area of the harbour is 48 square miles, and the shoreline has a length of 98 miles. In general, the outer harbour with its beaches and homesite properties along the waterfront has been set aside as a recreational area, and confined to bathing, boating and sea-planing. False creek has been reserved for waterfront development to accompany heavy industrial operations. The central harbour water frontage with the exception of Coal harbour, has all been zoned for heavy industrial development, and there are located thereon, deep sea piers and wharves, coastwise piers and wharves, grain jetties, lumber assembly wharves, oil wharves, ferry terminals and ship repair plants in the form of drydock and marine ways. Coal harbour accommodates light industries in its outer reach, while at the Stanley Park end are located the Vancouver Rowing Club and the winter quarters of the Royal Vancouver Yacht Club. The inner and upper harbour is set aside in part to industrial development, principally on Port Moody Arm, while the North Arm is largely recreational, being used to a large extent for summer homes.

Let us now examine in some detail the regulations which are already in effect and the programme of future use and development of the various areas.

### Outer Harbour

The outer harbour which includes the mouth of False creek contemplates ultimately no industrial development west of Burrard street bridge. There are to-day some nonconforming uses on the north side of the mouth of the creek, but these will eventually be eliminated. Picture then Greater Vancouver's Marine Drive and beaches. Commencing at the westerly point of Point Grey, or even at South Granville street, and the north arm of the Fraser river, one may travel overlooking the ocean, and for the greater part almost along its shore, for a distance of thirty miles past Spanish Banks, Jericho and Kitsilano beaches, across Burrard bridge, westerly along First, Second and Third beaches, around Stanley Park, across the proposed First Narrows bridge at Prospect Point, thence along the north shore to Horseshoe bay and beyond. Further, it is likely that in a few years a marine driveway will extend northward along the east side of Howe Sound to Squamish and Garibaldi Park. Plans have already been completed and estimates compiled, and a public sentiment created to a considerable degree for this project. The beaches of the outer harbour are one of the community's greatest assets for the health and contentment of its citizens.

### False Creek

False creek as noted is zoned for heavy industrial development, and has already progressed to a considerable degree in this direction. Its industries include sawmills and other woodworking plants, bridge and structural steel assembly plants, manufactories heavy and light, fueling terminals, gas plants, marine ways and many smaller concerns. This waterway is the back door to the central business district and to the adjoining residential areas south and east of its shores. Once a shallow arm of the sea extending almost three miles easterly from English bay and connected at high tide with the central harbour, it is now a waterway carrying a dredged depth of twenty feet at low water for a distance of two miles or more. The malodorous tide flats have disappeared, wharves have appeared on the north and south shores, and extensive railway yards have been built at the easterly end of this waterway to accommodate the Canadian National and Great Northern Railways, occupying over five hundred acres and having an ultimate capacity of over twelve thousand cars. From time to time a suggestion has been put forward that False creek be reclaimed and filled with suitable material as far west as Granville street, the principal argument put forward being, that this would solve the transportation problem across False creek. Such a scheme would eliminate bridges, but not viaducts and grade separations, and it would destroy the enormously valuable water transport connection to the so called "back door" of the city.

The final development of False creek is not yet at hand but the accompanying plan (Fig. 2) prepared by the Town Planning Commission indicates what is anticipated as its ultimate development.

### Central Harbour

The central harbour of Burrard Inlet is the most important of the various subdivisions of Vancouver harbour. Here deep sea ships load and discharge cargoes of many varieties. Deep sea and coastwise passengers arrive and depart at and from its piers and wharves; it holds the romance of this ocean port. The south shore is already developed to about seventy per cent of its available shoreline. The nature of this development has already been

Fig. 1—General Plan of Greater Vancouver.

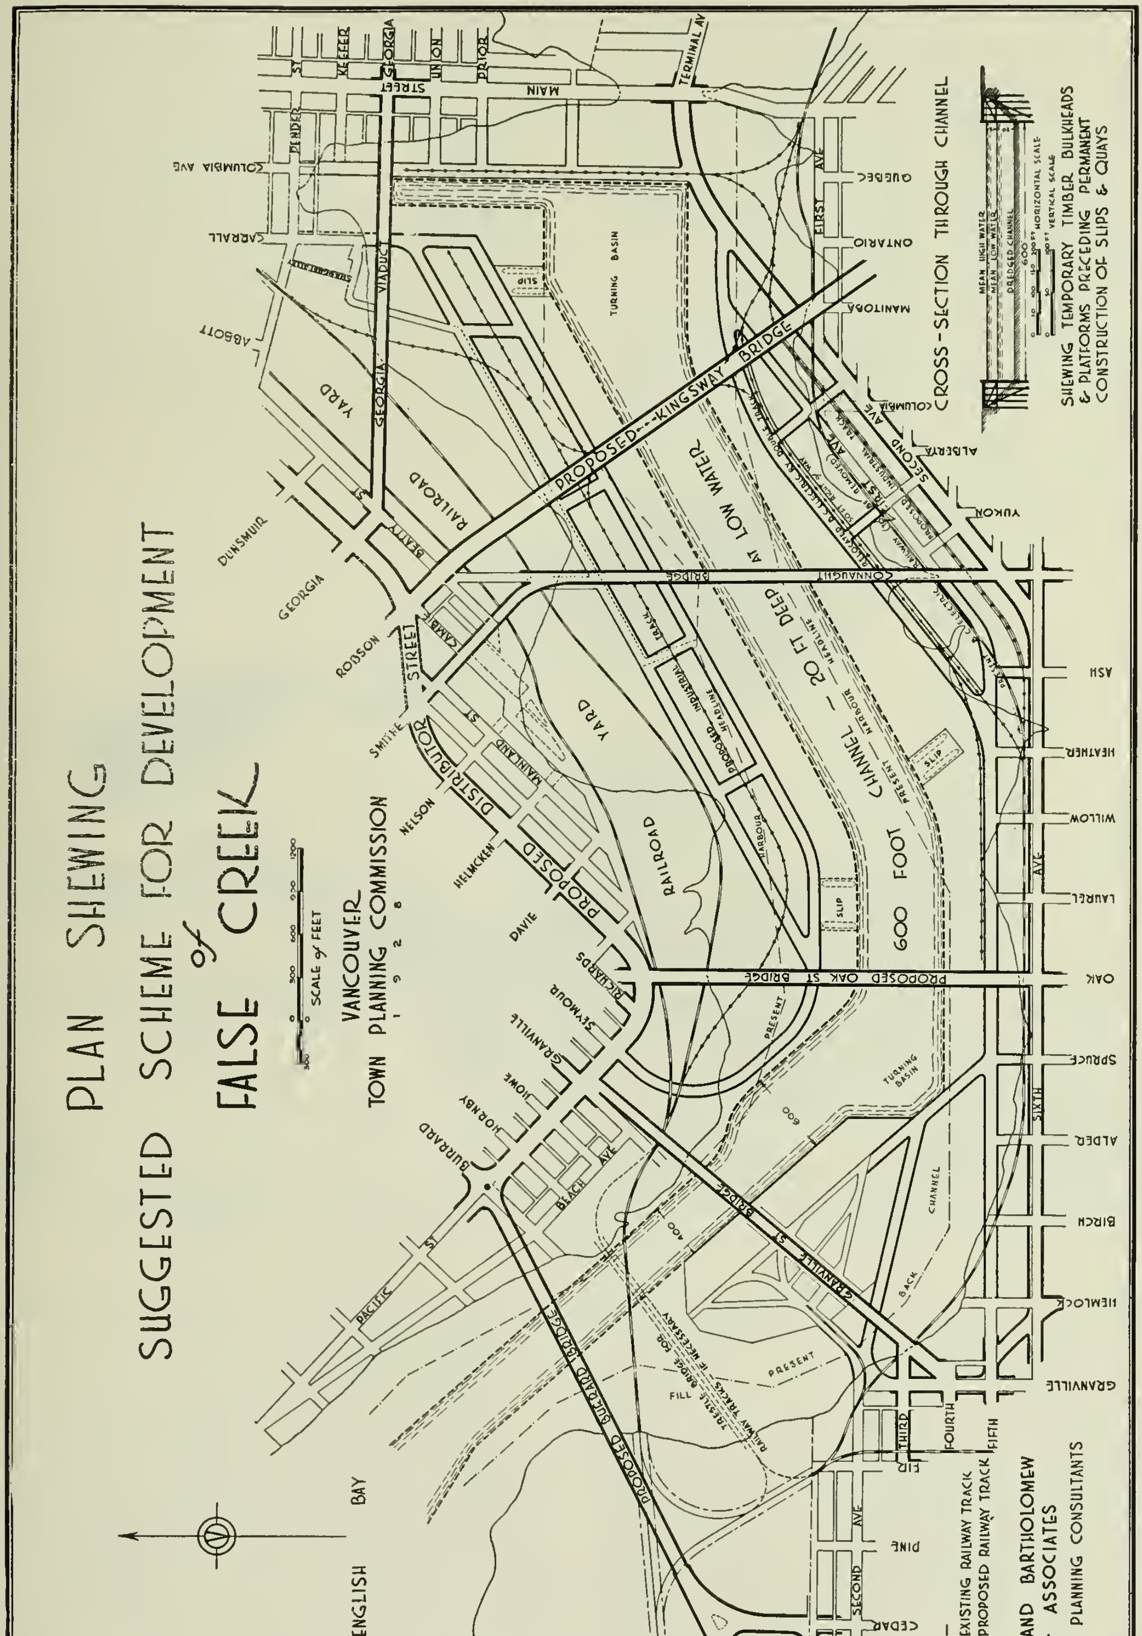

Fig. 2—False Creek Development.

referred to. Much of the development work is of a permanent nature, and several of the deep sea piers are of the finest in existence. The future planning of the south shore calls for an increase in capacity of railway trackage, particularly holding or storage yards, improved access to False creek railway yards (the C.P.R. tunnel being one of the recommendations already put into effect), extension of the waterfront roadway system, and a much improved system of fire mains, fire hydrants, and fire station as a headquarters for fire boats. Railway operating problems on the south shore are as yet quite complex and the maximum efficiency at the minimum of cost will be accomplished only when placed under one control for all local services in the form of a terminal or belt line railway.

The north shore of the central harbour is as yet almost virgin territory so far as any permanent development is concerned. It has in many respects far greater possibilities for development than has the south shore. These possibilities are shown by the plan. (Fig. 3.) Permanent construction has a wider field at lessened cost as compared with the south shore. Foundation and dredging problems are simpler. Railway connections are less difficult. Storage space for trackage is more commodious and adjoining industrial property is of much greater area. While the centre of population is now and will always be on the south shore, there can be no doubt that the north shore will in due time carry on at least half of the port's deep sea business. For this reason it is quite important to the citizens of Greater Vancouver that the town plan of the north shore of the harbour shall provide for the best possible use of its entire shore line when developed to ultimate capacity. Better transportation connections will then be required between north and south shores, for the north shore municipalities will in the course of time develop greatly, and many of their people will reside on the southern slopes of the mountains.

### Inner Harbour

The inner harbour of Vancouver comprises two distinct bodies of water, the Port Moody arm, seven miles in length, being a direct extension of the central harbour, while from this body of water the north arm of Burrard Inlet extends in a north westerly direction about twelve miles. The Port Moody arm is all zoned for heavy industrial development, but with the exception of the extreme upper end which has a shore line of two miles or more, the shores are fairly precipitous and the waterfront development is expensive. The principal expense involved in the development of this waterfront lies not so much in the construction of wharfage as in the excessive cost of reclaiming the shore by virtue of the heavy filling required. For the foregoing reason it is unlikely that the inner harbour industrial section will be extensively developed for a great many years. The Fraser river offers equally accessible waterfrontage with a much lower cost of construction, and of a type which would serve a similar class of business. The north arm of Burrard Inlet, while not definitely zoned as to use, possesses a shoreline which is of little or no industrial value. Its use is almost entirely given up to summer homes of people living in the Greater Vancouver area. The only exceptions to this use are two rock quarries and the Buntzen Lake power plant of the British Columbia Electric Railway Company.

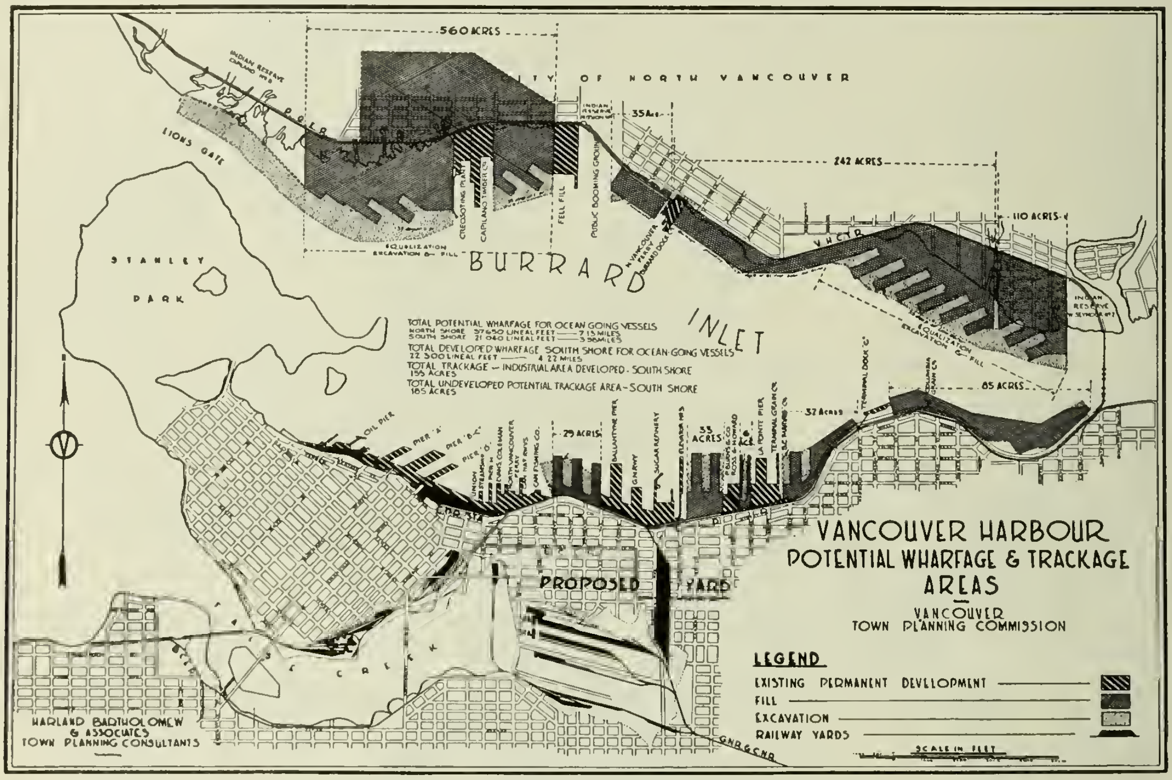

Fig. 3—Central Harbour, Vancouver.

### Improvements Projected and in Hand

While no general plan has been developed to cover the final picture of harbour development, there have been prepared detailed plans covering certain sections of the waterfront and of additional transportation facilities. (Fig. 4.) Many improvements have already been effected, the principal of which has been the betterments to navigation, which, due to heavy tidal currents, have constituted a serious problem. The First Narrows entrance to the inner harbour has over a period of years been widened from 700 to 1,200 feet and the tidal current reduced from six to four knots. Further widening to 1,500 feet is now planned, although it will undoubtedly require a great many years to effect, since coupled with this widening is the demand for increased depth. Some improvement has been effected at the Second Narrows but much remains to be done in

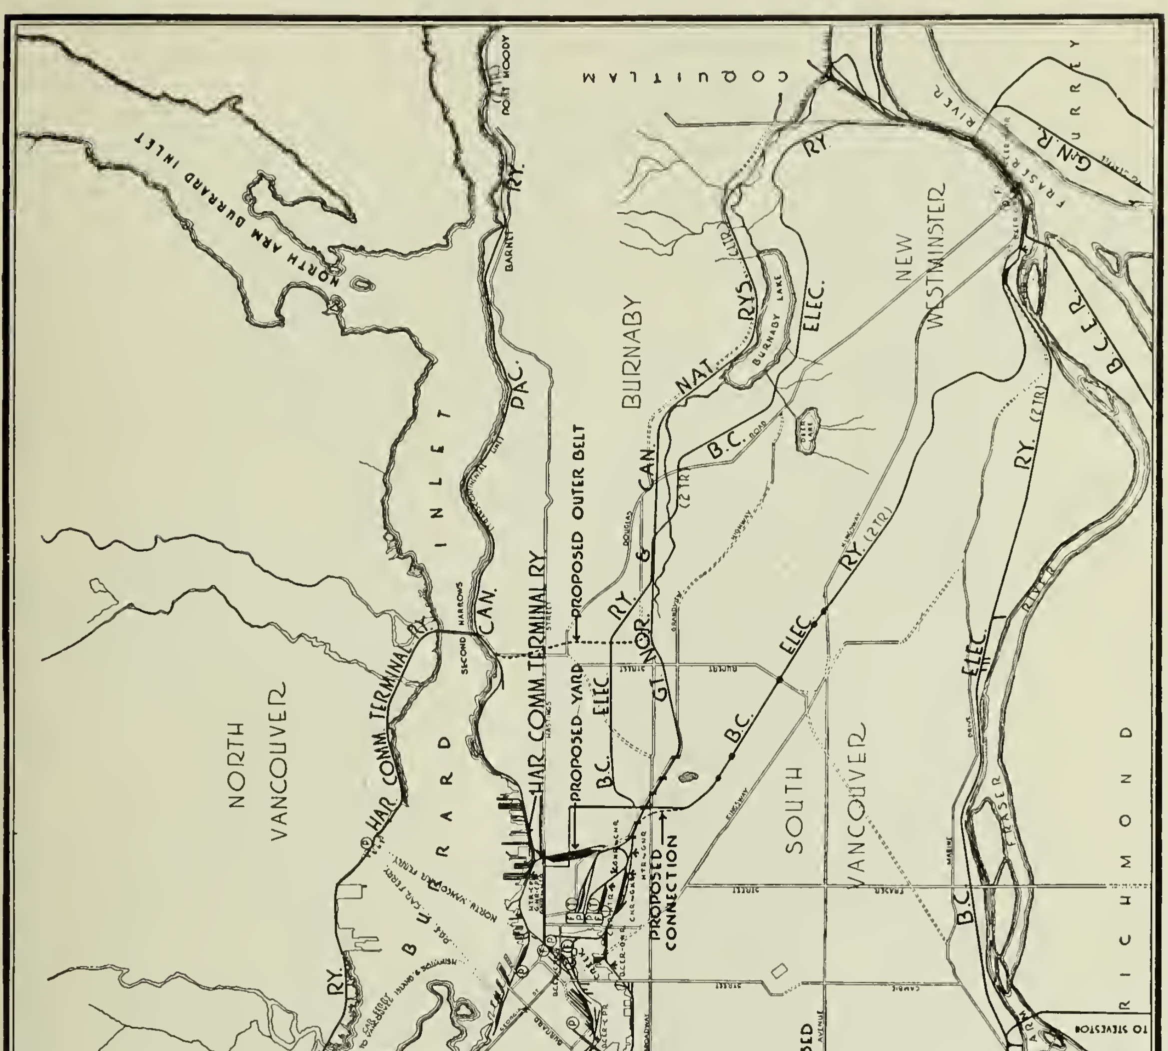

Fig. 4—Railroads and Harbour Plan.

widening and reducing the very heavy tidal current at this point. The Second Narrows bridge has been recently reconstructed, and for a period of at least twenty years, will have to answer the demand of rail transportation to the north shore. It is contemplated that eventually permanent improvement at the Second Narrows will be effected in the form of a lock or locks, possibly, but not definitely accompanied by a dam which would make the inner harbour a fresh water one. This subject has so many angles that it could only be dealt with in a separate paper. The False creek channel has been deepened to 20 feet at low water and has now a minimum width of 300 feet. Further improvements already referred to are contemplated in the extension of the shore line and further widening of the dredged channel.

Due to growth of population on the north shore, further transportation facilities will be required in the near future, and the project is well advanced for a high level bridge crossing at Prospect Point, the entrance to the inner harbour.

Plans for increased railway facilities within the Vancouver terminal and for additional waterfront roads are well advanced and some of the work which this scheme embraces has been placed under way. A waterfront roadway outside the railway tracks is planned extending from Lapointe pier to Port Moody. This embraces a very large programme of reclamation and filling; approximately 15 per cent of this work has been completed in the inner harbour and more is in progress. Provision is now made in all waterfront leases for the setting aside of a 90-foot strip to permit the continuation of this work in the future. The scheme also includes a belt line or terminal railway for the entire waterfront with the exception of the heavily developed portion of the inner harbour from Lapointe pier westerly to Coal harbour. Additional railway facilities have been planned and recently two new storage yards have been constructed, one known as the Glen Drive yard at the head of False creek, and the second the Harbour Commissioners' Hastings mill yard. The construction of these yards has considerably simplified the movement of traffic from Canadian National and Great Northern Railways to the waterfront of the central harbour. A large section of terminal railway, about four miles in length, including a 2,000-foot subway under the Esplanade and a very heavy grading operation at Moodyville, has in recent years been constructed on the north shore of the central harbour. The terminal railway, it should be explained, is owned and operated by the Vancouver Harbour Commissioners, a body appointed by, and representing the Federal government interest in the port. This body has full control and administration of all port business and is represented on the Vancouver Town Planning Commission.

Many minor and some quite interesting development projects of Vancouver harbour have been planned, but space does not permit a description of their details.

### Fraser River Harbours

The control and administration of the development of the Lower Fraser river is at the present time vested in two Harbour Commissions representing the Federal interests therein. The New Westminster Harbour Commissioners control and govern the main river from its mouth to Douglas island at present head of deep sea navigation, a distance of 25 miles. The north arm of the Fraser is controlled and governed by the North Fraser Harbour Commissioners. For the purposes of this paper, however, it is proposed to disregard the artificial division which has been set up in the control of these waters and to deal with them jointly in the matter of their use and service to the Dominion and more particularly to those areas which they serve. The main channel of the Fraser river is available for deep sea shipping, and now permits the operation of ships which draw not more than 26 feet of water when loaded. There is considerable difficulty in maintaining an adequate depth of water at the mouth of the main river, due to the silting often found in the deltas of such streams. This difficulty, however, is gradually being overcome by the construction of training walls and jetties to confine the water to a definite channel. Approximately 40 per cent. of the programme of work contemplated has been carried out at an expense of three million dollars. The principal development of the river to date has taken place in the vicinity of New Westminster, where ocean wharves have been constructed, providing berthage for fourteen deep sea ships at one time. No passenger business is at present transacted in the harbour of New Westminster but a growing freight traffic is well established. The Fraser river harbours do a very large part of the lumbering business of the province, and in the year 1929 reached a peak of five hundred and twenty million feet, of which approximately two hundred and fifty million was exported by water. The total cut represented approximately 30 per cent of the lumber manufactured by the entire province.

### New Westminster Harbour

The main channel of the Fraser river from Douglas island to the sea provides for almost continuous industrial development on both banks, although in most cases a certain amount of dredging is required, which fortunately can be utilized in the preparation of the site on the inshore side. The saw mill industry is particularly well accommodated on the main channel of the river, its only drawback being the movement of logs to the mill site during the freshet season, when the current is so heavy as to make towing upstream almost impracticable. The policy of the Dominion government with respect to industrial development has been generous, and in almost all cases, the dredged material is made available for the on-shore site at a nominal cost to the new industry. Dredging improvements are carried out entirely by the hydraulic method, two large dredges being used for this purpose, one of the usual hydraulic type pumping continuously through a pipe line to the shore or the land, the other the carrier type which picks up its own load of dredged material in the stream and pumps it out either on the shore or in deep water outside the mouth of the river.

The problem of road and rail access to various water frontages of the Lower Fraser is simple compared with Vancouver harbour. Railway service is already available to the entire frontage on both banks of the Fraser river with the exception of a ten-mile strip on the south shore from a point opposite Annacis island to the sea. With the exception of the city of New Westminster, no definite plan has as yet been adopted with respect to waterfront roads, but it is anticipated that these will follow and parallel the existing railway lines. In the city of New Westminster itself a waterfront road known as Front street has been developed in rear of the waterfront wharves and adjoining railway trackage. This is a wide thoroughfare, and will adequately care for future requirements. Railway trackage adjoining the river is ample and convenient and the cost comparatively light. As yet no definite step has been taken towards serving the waterfront by a terminal railway system, although it has been before the Harbour Commissioners for their consideration, and inter-switching arrangements between the various operating railways have been modified and improved from time to time at a gradual decrease in cost. Four railways at the present time serve various sections of the waterfront of the harbour of New Westminster, namely the Canadian National Railways, Great Northern Railway Company, Canadian Pacific Railway and the British Columbia Electric Railway Company.

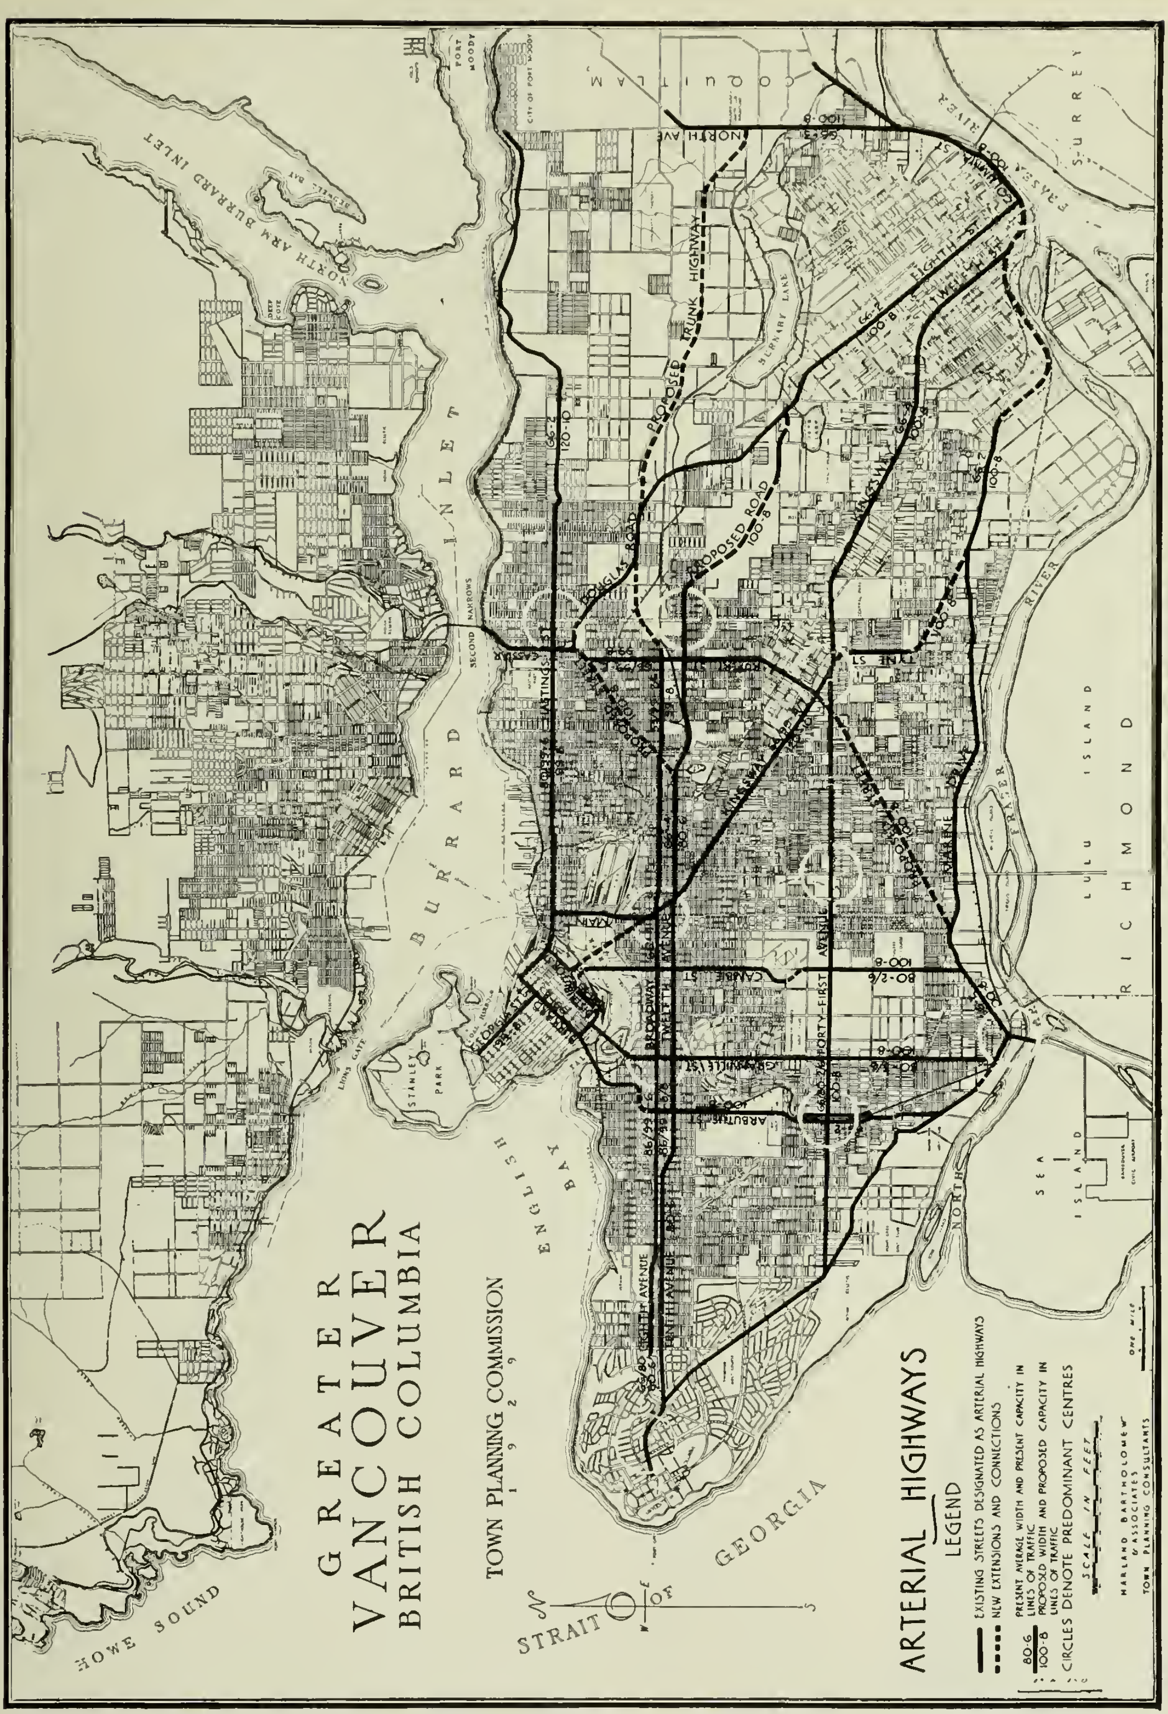

Fig. 5—Arterial Highways.

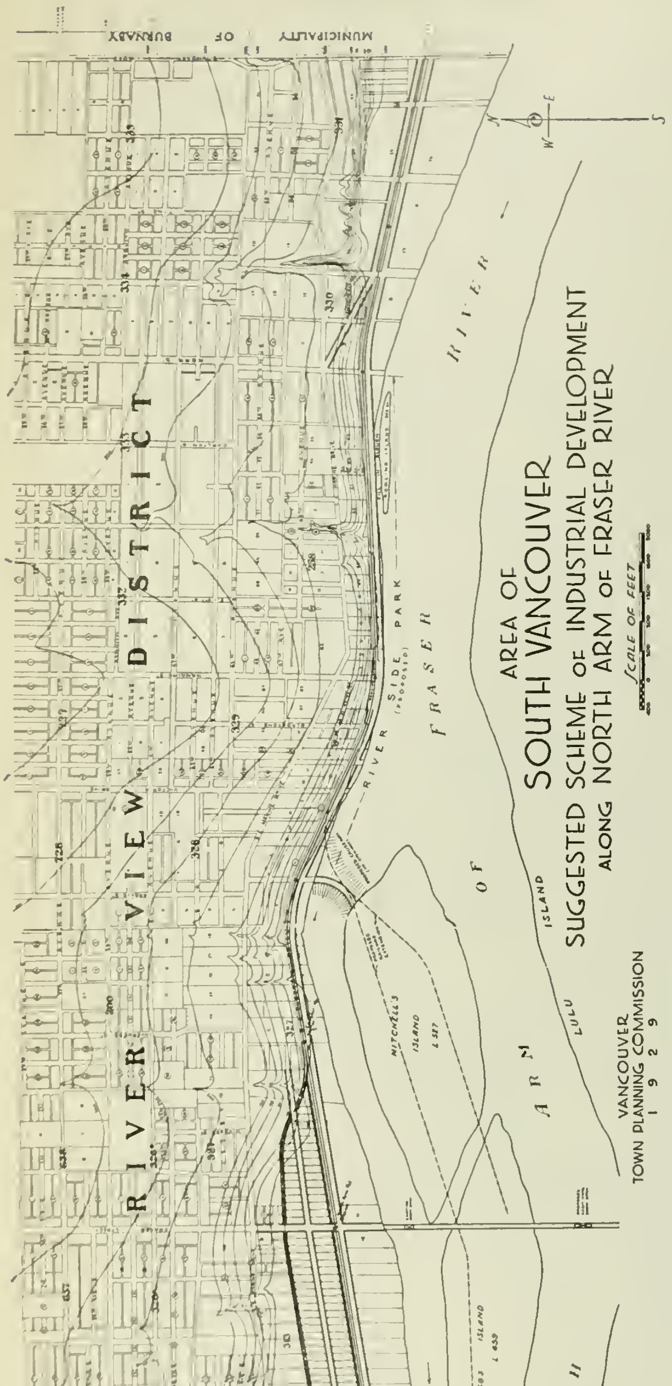

Fig. 6—South Vancouver Shore Development.

The largest single development on the river operating an export business is the Pacific Coast Terminals. This company operates four terminals in the city limits of New Westminster and provides for seven deep sea berths. The railway handling at its main No. 1 terminal is carried out by its own motive power, the company operating two locomotives for its own use.

A recent development of the port has been the construction of a grain elevator on the south shore opposite New Westminster by the New Westminster Harbour Commissioners. This elevator is leased to one of the larger private companies, and for the first time during the past season an appreciable amount of grain has been handled. The total shipment this year will amount to approximately three million bushels.

Transportation across New Westminster harbour is at the present time adequate so far as railway service is concerned, but quite inadequate for vehicular traffic. A large ferry is operated on the lower river between Ladner and Woodward's Landing, accommodating motor vehicular traffic and passengers. The New Westminster bridge is a combined railway and highway bridge, but the highway portion is unsuitable for present day traffic, due both to the narrowness of the thoroughfare and the fact that it was originally designed for much lighter motor truck loading than now exists. Two proposals are before the Harbour Commissioners for improvements, namely highway bridges at Ladner and at New Westminster. Charters have been granted by the province to private bridge companies for these two sites and there is every reason to believe that one, if not both of these structures will be built in the near future. The improvement which would follow would undoubtedly stimulate industrial development in the port of New Westminster.

Actual and proposed arterial highways are shown in Fig. 5.

The government of the harbour of New Westminster is similar to that of the port of Vancouver with the exception that the city of New Westminster nominates one of the three commissioners and in addition the Act provides that the net revenue of the port shall become the property of the city of New Westminster from time to time when such revenue is not needed for development plans of the immediate future.

In general it may be assumed, and the policy of the commissioners is directed accordingly, that the port of New Westminster will secure the bulk of those industries requiring substantial amounts of waterfrontage with considerable rear area for their operations and extension. Cheapness in the question of sites, in their development cost and in maintenance indicate strongly that this type of development will ensue. There is no teredo or other marine borer action on the Lower Fraser river, and in consequence it is unnecessary to use treated material for the foundation of waterfront structures there.

### Future Development

To date there is only one large project and definitely planned development which has been stated and planned by the Port Authority. This is the construction of a land locked deep sea harbour in the Annacis channel. It is proposed to close the upper end of that channel by means of a dam and causeway, and deepen and widen the channel for its entire length. This development will provide approximately three and one half miles of deep sea waterfrontage on the two banks of the deep sea channel so formed. Ample room exists in rear of the channel on both banks for a very valuable development of this section of the harbour.

### North Fraser Harbour

The North Fraser harbour limits extend from the Lulu island bridge at the upper end of Lulu island to the straits of Georgia. The actual shore line of this body of water lies in four separate municipalities, namely New Westminster, Burnaby, Vancouver and Richmond. It accordingly becomes difficult to deal with this development in the same comprehensive way as in Vancouver. So far, the on-shore planning has been confined almost entirely to the area bounded by the city of Vancouver. Of this area the westerly portion from the foot of Angus drive to the sea has been zoned as residential and recreational, while the balance, easterly to the city boundary with Burnaby, has been zoned for industrial use. There is one exception to the above, namely, a park area has been set out for approximately 6,000 feet of frontage immediately east of Mitchell island, which it is proposed to denote as "Riverside Park." (See Fig. 6.)

The general use of the north arm so far as the city of Vancouver and Burnaby are concerned, is not dissimilar to that of False creek. It now serves and will in future serve to a greater extent the local needs of the community living on the south slope of Vancouver and Burnaby. There is considerable sawmill development and in the neighbourhood of Eburne there is an industrial section which embraces several types of industry. The channel is used entirely for shallow draught shipping, its depth at the present time being maintained as 15 feet at low water. The final plan proposes 20 feet at low water, which will then accommodate coastwise shipping. The movement of logs to lumber mills on the main river from points on Vancouver island and the northern coast is confined almost entirely to this channel and the Harbour Commissioners have provided certain booming and mooring grounds to assist in the log movement.

As on the main channel of the river, a training wall has been constructed at the mouth of this channel, which, when completed, will confine the flow of the water to a comparatively narrow area between this training wall and the shore line of the Point Grey section of the city of Vancouver. Approximately $900,000 has been spent on this improvement work to date, and its completion will involve an additional expenditure of approximately the same amount. It will have to be accompanied by a considerable programme of dredging in the same area. The general problem of dredging, however, is less onerous than in the main river, due to the fact that a comparatively small amount of silt laden water passes through this channel during freshets. Consideration has been given to the construction of a lock at the point where the north arm leaves the main river. Such an arrangement would entirely eliminate silting and would assist in the maintenance of depth in the main river by virtue of the fact that a greater amount of water would then pass through the main channel. While it is quite possible that this scheme may eventually materialize, the expense is considerable and certainly is not warranted at the present time.

The government of North Fraser harbour is by Commission, organized similarly to that of Vancouver, but due to the fact that very little revenue is received in its operation, no general plan of development has so far been prepared. Pier headlines have been established throughout its length on both sides of the river and as development gradually takes place, the channel becomes better defined and consequently maintains its dredged depth more satisfactorily.

Railway connections to the north arm are fairly complete, there being in existence continuous service to both sides of the channel from New Westminster to Eburne. It is probable that in due course additional railway service may be extended to Sea island, but this appears to be well in the future. Roadway access to the waterfront is well developed on Lulu island and in the Vancouver area but considerable remains to be done in the area covered by the municipality of Burnaby.

A modern airport known as the Vancouver Airport and Seaplane Harbour has been established and at a cost of $300,000, partially constructed, on the south arm of the North Fraser harbour. The site when completely developed will comprise six hundred acres of flying field and five thousand feet of seaplane waterfrontage, the width of the seaplane harbour being sixteen hundred feet. The site in question was recommended by the Vancouver Town Planning Commission.

In the matter of government, it seems to be generally conceded that with the three distinct corporations administering the port business of the harbours of Vancouver, New Westminster, and the North Fraser, control is excessive. Undoubtedly two corporations would be sufficient for all purposes and in the course of time it is probable that the joint interests of all three bodies will become so intermingled as to make advisable the setting up of one port authority in the entire area. Due to differences in the form of administration and to local prejudices, the time is not yet opportune for such a proposal but a better understanding of these differences is gradually ironing out much of the prejudice. It is but one more example in Canada of the high cost of too much government.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, March 29th, 1934.

SUMMARY.—The paper outlines the early development of the Diesel engine and discusses its characteristics as regards the methods of injecting the fuel into the cylinder and the process of combustion as influenced by the type of injection and the design of the cylinder head. A number of points in design and construction require attention when applying the Diesel engine to automotive work. These are mentioned and data given as to the performance and economy which may be expected.

### Historical

While Dr. Rudolf Diesel, the inventor of the engine so universally named after him, undoubtedly had in mind the possibility of his engine being used in road vehicles, he unfortunately did not live to see the real fulfilment of this objective. For many years after its conception the development of the Diesel engine was slow, but finally the transition from the heavy slow moving type of engine to the high speed automotive engine came about very quickly when the magnitude of the development is taken into consideration.

Although the original patent specification was published in the year 1892 it was not until five years later that the first Diesel engine was put into commercial operation. This was at the works of the M.A.N. company at Augsburg in Germany. Great interest was taken in this engine and it was generally acclaimed as being the most efficient form of heat engine known; a condition which still holds good.

During the next fourteen or fifteen years the development of the use of the Diesel engine was naturally slow,—there were many obstacles to be overcome, not only with regard to the design and manufacture of the engine itself but also with regard to its public acceptance. Fear of the shortage or high price of suitable fuels was raised, possibly by competitors, and the inventor was himself largely responsible for proving the tremendous variety of fuels which could be successfully employed in this type of engine. However, at this time land installations were becoming quite common in all countries of the world and in the year 1911 there were probably as many as three hundred vessels in service with Diesel motors for propulsion purposes, the largest of which, however, would not exceed 1,000 h.p. in output.

During the next fifteen years or so, up to, say 1926 and 1927, the development was more rapid, not only with regard to its use but also with regard to size. Land installations had multiplied all the world over, numbers of manufacturers were building the engine, and in many countries the Diesel engine had become as familiar as the older reciprocating steam engine. At sea, however, a very striking advance had been made; not only were there as many motorships being built as steam ships, but the available horse power per engine had been increased to 15,000 in actual service and 20,000 designed.

Throughout this period, however, the heavy weight, large bulk and slow speed of the Diesel engine made its use in the automotive field out of the question. Up to the year 1925 weights were at least 200 pounds per horse power, while many types of engine exceeded this figure. Nevertheless attention was being paid to the possibility of the engine being built in a much lighter form and with higher speeds suitable for use in vehicles. In the year 1909 Dr. Diesel built a 30-h.p. four cylinder reversible engine, which ran at the very high speed (for that time) of 600 r.p.m., to which he referred as being "for an automobile engine for heavy loads or marine work."

By 1927, however, considerable advance had been made, especially in Germany, and engines of 50 brake horse power, weighing about 1,500 pounds and turning at speeds up to 1,000 r.p.m. were in actual use. At the same time the development of the high speed Diesel particularly for marine service was also taking place, and in 1929 and 1930 engines with specific weights reduced to 30 pounds per horse power were quite common.

It might be said that in 1927, commercially the automotive Diesel was almost unknown, by 1930 it was recognized as a real possibility and by 1933 there were at least thirty manufacturers producing automotive Diesels with weights as low as 10 pounds per horse power, speeds as high as 4,000 r.p.m. (more generally, of course, at much lower speeds) and in sizes from about 40 h.p. up to say 150 h.p.

The history of the development would be incomplete without at least a reference to the fact that some few years ago the Diesel also became available for use in the aeroplane, having its weight reduced to as low as 2¼ pounds per horse power, a truly remarkable achievement.

### Stages of Mechanical Development

There has been a certain amount of controversy regarding the real origin of the type of engine which has become universally known as "Diesel," owing to differences of opinion regarding the responsibility for the invention of some of the finer points. However, as far as the "man on the street" is concerned he has been satisfied to apply the name to almost every type of internal combustion engine using oils heavier than gasoline provided compression ignition either wholly or in part, was used.

Diesel's patent specification is a lengthy one covering every feature of a "process for producing motive work from the combustion of fuel." After drawing attention to the faulty process in previous use and describing in detail the working of his engine, either with a pulverized solid fuel or with a liquid fuel, he claimed as his invention an engine in which high compression created a sufficiently high temperature to ignite the fuel without other means, and in which combustion took place on a constant pressure cycle.

During the course of the years both these features have gone through many changes and variations. For example, for a long period, and indeed up until quite recently, many engines were built which did not have a sufficiently high compression to give compression ignition in its entirety but relied on some form of additional heat being supplied to aid ignition. The term "Semi-Diesel" was applied to these engines. The extra heat required was obtained in many ways, such as hot tubes, hot bulbs, uncooled portions of the cylinder heads, electric igniters and so forth, the chief advantage of this form of engine being the use of lower compression ratios which facilitated manufacturing and at the same time gave a somewhat more silent running engine. However, it had the disadvantage of not obtaining the highest possible efficiency. In recent years the Semi-Diesel has been almost entirely eliminated and practically all forms of the modern engine are "Full Diesel."

Similarly the constant pressure cycle has not been adhered to. Many engines have used a constant volume cycle, and many are designed to operate on a combination of constant pressure and constant volume cycles. However, the actual internal cycle has not been considered of sufficient importance to warrant special reference in the designation of the engine. The automotive Diesel of today almost entirely operates on a combined cycle and indeed may change its cycle during its operation to meet different conditions.

While the question of whether an engine operates on a two-cycle or four-cycle principle has nothing to do with the Diesel principle, which is equally applicable to either type of engine, nevertheless there developed in the world of Diesel engine users and builders a "battle of the cycles." In the automotive field, however, the two-cycle engine is almost non-existent (with the exception of the Junkers opposed piston type engine which is two-cycle in principle) so it is unnecessary to enter into this controversy in discussing the automotive engine.

Another phase of the mechanical development has been the use of compressed air in conjunction with fuel injection giving rise to the terms "blast air" and "air injection." Dr. Diesel makes reference in his specification to the use of air at a higher pressure than the compression pressure but apparently it is not cited as one of the essential features of his invention. Nevertheless for many years air injection came to be looked upon as one of the essential features of the engine, and as very high pressures, up to 3,000 pounds per square inch and more, were required, this was a feature which led to a great deal of mechanical trouble. Diesel engines thus came to be divided into two classifications, "air-injection" and "solid injection." The latter has been steadily gaining ground and in the case of the automotive engine is universal.

Up to the time of the introduction of the automotive Diesel, therefore, there were alternative combustion systems available described as Diesel and Semi-Diesel, and at the same time there were available two- and four-cycle engines and also air injection and solid injection engines. In the case of the automotive engine it is fortunate that these controversial features have all been settled, as the Diesel, four-cycle, solid injection engine is the only type being used. However, there must be controversy, and at the present time it is broadly over the general merits of the two main types of combustion systems used, namely direct injection versus pre-chamber, the latter system having in turn a number of variations.

During the various stages of mechanical development considerable departure was made from the ideas originally contained in the Diesel patent, and many arguments were raised against the continued use of the name Diesel as applied to engines which were characteristically different and in the marine world the name has been more or less dropped and the term "motorship" generally adopted. Similarly in the automotive field in Great Britain the term "oil engine" has been universally adopted. In the United States the name Diesel has been retained and in Canada both forms of nomenclature are used. The use of the name Diesel leads to a certain amount of confusion especially to the lay mind, nevertheless the term "oil engine" is far from being a correct description of the characteristics of the engine.

### Characteristics of the Diesel Engine

In their mechanical construction the majority of automotive Diesels follow conventional designs, quite similar to gasoline engine practice. This is a very fortunate circumstance for the development of the engine because only a few of the larger users could possibly develop especially trained personnel. In the great majority of cases the automotive Diesel has to be operated and maintained by a personnel which has been brought up on gasoline engines. The inherent parts of the engine such as the crankshaft, connecting rod, pistons, valve gear and valves are essentially the same as in gasoline engine practice but are designed to take care of higher working stresses and higher compressions. It is of interest to note, however, that the automotive Diesel has not come into existence as a development of the gasoline engine but rather as a development of the heavier types of Diesel, which accounts for the fact that very few gasoline engine manufacturers had very much success in their first attempts to produce a Diesel. The Diesel engine, and especially the automotive type, is far from being an easy engine to build, a fact which was fully appreciated by the inventor, as in a preface to "Diesel Engines" by Chalkley, written in 1911, he states "The Diesel motor must be constructed with extreme care and the best materials employed in order that it may properly fulfil all its capabilities; only the best and most completely equipped works can build it . . . The Diesel motor is therefore not a cheap engine, and I would add a warning that the attempt should never be made to try to build it cheaply, by unfinished workmanship, particularly for export."

The fundamental difference between the Diesel and gasoline motor comes about entirely through the fact that compression ignition is utilized in the former, and all other differences are subsidiary to, and resultant from this particular feature. The use of compression ignition leads to the impossibility of compressing, on the up stroke of the piston, a combustible mixture, otherwise pre-ignition would take place. In the gasoline engine a charge of air and fuel, well mixed by the carburation process, is drawn into each cylinder and compressed to a point where the resultant temperature is not high enough to cause ignition of the mixture, and then ignited at the required instant by means of an electric spark. This necessity of avoiding pre-ignition places a definite limit on the highest useful compression ratio which varies with the type of engine and particularly with the type of fuel. For example, with low grade gasolines, the ratio will be as low as 4½ to 1, while with high grade ethyl and aviation gasolines it may be as high as 7 to 1. In the case of the Diesel engine compression ratios of at least 13 to 1 and as high as 19 to 1 are in use, with the consequent necessity of only admitting fuel at the instant when it is proper for combustion to take place, namely near the top dead centre.

The problem which therefore had to be solved, was that of measuring out very accurately minute quantities of fuel oil, forcing it into the combustion chamber against a fairly high pressure and at the correct instant and for the correct length of time, disintegrating it into still smaller droplets and finally distributing these droplets uniformly throughout the combustion chamber. Furthermore the whole performance must be repeated with great regularity and frequency. Actually in an average size Diesel engine the amount of fuel to be injected for each combustion stroke may be as little as a cubic millimeter, the length of the injection period may only be 1/150 or 1/200 of a second and occurring perhaps twenty times every second.

The actual process of fuel combustion is different in the two types of engine. In the case of the gasoline engine the combustion chamber is to all intents and purposes completely filled with a combustible mixture of air and gasoline vapour at a pressure of about 100 pounds per square inch, when a spark is applied creating a flame which gradually spreads throughout the chamber burning up all the oil. The term "gradually" is of course relative, but is very important. It is only by insuring the gradual propagation of the flame throughout the chamber that a smooth running engine will be obtained. From the instant when the spark is applied there is a definite delay period before the flame spreads and causes an increase in pressure. This delay period varies with different fuels but in any one engine is fairly constant in point of time regardless of the speed of the engine, which leads to the necessity of varying the time of ignition with the speed of the engine in order that the end of the delay period may approximately coincide with top dead centre, otherwise there will be a knock if ignition is too early or a loss of efficiency if it is too late. Care has to be taken, however, that the rate of pressure rise in the combustion chamber after the delay period is kept below a critical figure otherwise detonation will take place giving rise to a knock. In other words if the rate of propagation of the flame is too great, the pressure on the unburned portion of the fuel mixture rises so rapidly that the resulting heat cannot be dissipated fast enough with the result that this unburned portion of the fuel ignites spontaneously, that is to say, explodes or detonates, causing an objectionable knock.

Briefly, therefore, combustion in the gasoline engine may be described as taking place in two distinct periods, first the delay period during which the nucleus of a flame is being formed without any particularly noticeable pressure rise, and secondly, the period when the flame spreads throughout the combustion space causing a definite rise in pressure.

In the case of the Diesel engine, however, the process is essentially different owing to the fact that the fuel itself is only gradually admitted during the combustion period. What actually occurs is that at the correct instant, which in practice is from 10 to 20 degrees before top dead centre, fuel injection commences, but as in the case of the gasoline engine there is a certain delay period before the commencement of the real pressure rise. This period is also fairly constant in time for a given fuel, leading to the necessity of varying with the speed of the engine the time at which ignition commences. During this period some of the very finest particles of the injected oil are ignited by the hot air, forming the nucleus of the flame in very much the same way as in the gasoline engine, but from this point on the flame has to be fed with additional fuel instead of being allowed to spread through the fuel that is already present. It naturally follows that since the fuel is being injected at one point, either the products of combustion must be removed from the vicinity of the injector and replaced by fresh air supplies, or else the fuel itself must be injected through the burning area to the fresh air beyond, which leads to the necessity of providing a very definite turbulence or commingling of the air and fuel if complete combustion of the maximum amount of fuel is to take place. In a gasoline engine turbulence is necessary but a sufficient amount is created by the compression normally provided; in the case of the Diesel, however, this is not nearly sufficient and a much greater stirring up of the air and fuel and indeed a controlled stirring up is absolutely necessary. There are many methods of obtaining this turbulence, and what happens during the combustion period in any particular engine depends entirely on the method adopted. For example, the oil injected during the latter part of the injection period may be shot right past the flame, ignited as it passes, and completing its burning in the more distant parts of the chamber, thus giving rise to a condition somewhat similar to the spreading of the flame in the gasoline engine. On the other hand the flame may be kept more or less stationary and adjacent to the injection nozzle with provision for bringing up fresh supplies of air continually displacing the products of combustion.

At this point reference might be made to the difference in pressure conditions. In the gasoline engine, the pressure at the end of the compression stroke may be about 100 pounds per square inch and the pressure rises to say 250 pounds per square inch. Maximum pressure naturally has to be obtained within a few degrees of top dead centre but it is at least possible to spread this rise over 8 or 10 degrees of crank angle hence avoiding too rapid a pressure rise which would cause a knock. In the case of the Diesel, however, much higher pressures are involved, and within a comparatively small crank angle it is now necessary to reach a maximum pressure of six or seven hundred pounds per square inch making it very difficult to avoid some knock, which has been one of the characteristics of the Diesel engine. It has been possible, however, to build automotive Diesel engines in which the transition from one stage to another is so smoothly made that the characteristic knock largely disappears especially at high speeds.

The use of heavier oils than gasoline comes about as the result of the compression ignition system, because far more efficient combustion takes place at the higher pressures. It is a characteristic therefore of the Diesel engine, that not only does it burn its fuel far more efficiently than a gasoline engine, but at the same time it has the capability of burning low grade fuels which naturally cost very much less than the highly refined gasolines. It is quite possible to burn some of the heavier oils in a low compression engine with the carburation system, but the efficiency is low, added to which is the difficulty of obtaining reliable ignition under all circumstances. Conversely gasoline can be burned in a compression ignition engine with high efficiency, but the engine would have to be designed for use with gasoline for which commercially of course, there is no justification. If gasoline is burned in a Diesel engine designed to operate on a heavier oil, the combustion characteristics will be different with the result that a smooth running engine would no longer be the case and it would only be a matter of time before mechanical troubles might ensue.

Another characteristic of the Diesel which is essentially different from the gasoline engine is the lower mean working temperature, which also comes about as the result of the compression ignition system. While the temperature at the end of the compression stroke is very much higher in the

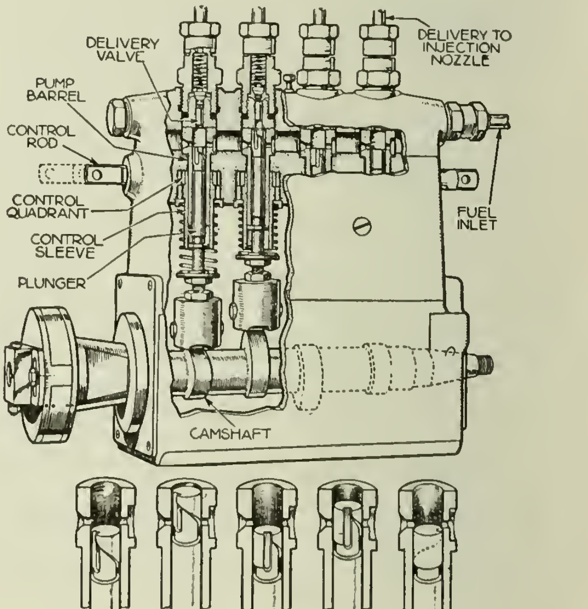

Fig. 1—The Bosch Pump.

Diesel, the temperature at the end of the pressure period or at the beginning of the working stroke is very much lower owing to the smaller quantity of fuel more efficiently burned. The exhaust gases are also discharged at a very much lower temperature, and losses to cooling water and by radiation are lowered, all contributing to the higher overall efficiency of the engine.

It will be clear that the designer and builder of an automotive Diesel engine had a number of problems to solve, which may be broadly summed up as follows:—First of all he had to devise a method of measuring and pumping at high pressure very small quantities of fuel with very accurate timing and with great frequency, and at the same time to provide for considerable flexibility owing to the necessary speed and load variations. Secondly, he had to provide a means of injecting the fuel into the cylinder head. Thirdly, he had to provide for the dissemination of the fuel throughout the combustion chamber, under widely varying conditions of load and speed in the same engine. While solving his problems he had also to take care that his final product had all the good points of the gasoline engine such as flexibility, speed range, smoothness, clean exhaust and silence. Needless to say success did not always crown his efforts, nevertheless taking into consideration the nature of the problems to be solved, he has been remarkably successful.

## Mechanical Features

*Fuel Pumps.*

There are naturally a large variety of fuel pumps in service today and indeed a variety of systems. The system which is almost universally used, however, is that in which there is an individual fuel pump for each cylinder of the engine. In this system the fuel pump itself performs the functions of timing, measuring and delivering thus avoiding the necessity of timing valves at the injectors themselves, which are used in some of the other systems. Pressure has to be provided to at least 1,000 pounds per square inch in many engines, to 2,000 pounds in most direct injection engines, and in some rare cases to 10,000 pounds per square inch. Furthermore the amount of fuel to be measured out must be variable under the control of the governor or accelerator pedal, and the timing of the commencement of injection must also be varied in accordance with the speed of the engine.

Obviously the manufacture of such a pump is a highly specialized proceeding and it is not surprising that many Diesel engine manufacturers have found it preferable to purchase this part of the equipment from the Bosch company, who originally became famous as manufacturers of magnetos for gasoline engines. While the Bosch pump is in more extensive use than any other type, a study of all the various means of obtaining the same end is of interest to the mechanically minded. There are constant stroke and variable stroke pumps, there are single plunger and double plunger pumps and many other combinations.

The Bosch pump, which is illustrated in Fig. 1, has all the simplicity of the constant stroke single plunger type, with an ingenious arrangement whereby the effect of a variable stroke is obtained. A special camshaft is usually provided driven at one-half engine speed, and a cam is set for each cylinder. A series of plungers are mounted over the cams in units of one, two, three or four to a set. Every plunger has a roller at the lower end which is kept in contact with the cam by means of a heavy spring, so that as long as the engine is turning the plunger is moving up and down with a constant stroke. The plunger, however, is free to turn on its vertical axis under the control of a geared quadrant which meshes with a horizontally sliding rack which in turn is under the control of the governor or accelerator pedal. The upper end of the plunger, which is a close sliding fit in its barrel, is cut away helically for a portion of its periphery below the top, leaving an irregular annular passage of varying depth. By turning the plunger by the above mentioned quadrant, the period for which the inlet ports are closed can be varied, being proportional to the depth of the annular passage below the top of the plunger; thus the discharge of the pump can be controlled by the pedal or by the governor from nothing to the maximum.

The necessary variation of the time of injection is obtained by rotating the camshaft in relationship to the crankshaft—a simple mechanical problem carried out in various ways.

*Injectors or Sprayers.*

As in the case of the fuel pump there are many types of injector in use, but in the main they may be divided into two classes, namely high and low pressure. The former are essential for use in direct injection engines and the latter may be used in conjunction with other forms of combustion system, such as the pre-chamber design, to which reference will be made in due course.

The purpose of the sprayer is to break up the fuel stream into fine particles and to distribute the particles throughout the combustion chamber. It is necessary that this should be done without any "dribble" and with a clean cut-off at the end of the injection period. The majority of sprayers have some form of spring loaded valve which is raised as soon as the pressure developed in the feed line by the pump reaches a pre-determined amount. The oil is then forced through the nozzle by the pump. The nozzle itself varies in different designs. For example in the case of a direct injection engine, it usually contains a number of very small orifices set radially. For engines where a high degree of turbulence is provided, it is not necessary to break up the fuel so minutely and so nozzles of the Pintle type or with a single jet are utilized. It will readily be seen, however, that any study of sprayers is contingent upon the design of combustion chamber with which it is to be used.

*Combustion Chambers.*

As previously explained the combined design of combustion chamber and sprayer must be such as to permit the complete burning of the maximum amount of fuel if the highest efficiency is to be obtained. The large variety of designs in general use can be broken down into four groups, each of which has its own characteristics, its own advantages and disadvantages, and its own adherents.

There are probably more engines in use with direct injection systems than with any of the other types, so this system will be described first. A general type is illustrated in Fig. 2A. In a direct injection engine, the combustion chamber is simply the space between the top of the piston, which may be slightly dished, and the flat under side of the cylinder head. As only a limited degree of turbulence is possible with this design, it becomes necessary that high injection pressures and very fine sprayer nozzle orifices must be used, in order to atomize the oil into the smallest possible particles and at the same time project these particles to the farthest limits of the combustion chamber. One manufacturer very simply solves the problem of creating such turbulence as is necessary with this system by shielding one side of the inlet valve, with the result that the incoming air on the suction stroke, enters the cylinder tangentially setting up a swirl which is maintained during the compression stroke, with the final result that the oil is injected into a revolving mass of air.

In another design the sprayer is set tangentially so that the action of the spray is to set up a swirl within the combustion chamber.

A second system, illustrated in Fig. 2B, is a modification of direct injection utilizing a separate chamber formed in the cylinder head, into which the oil is injected. This chamber is usually in the form of a sphere directly open to the main body of the cylinder. The effect during operation is that on the compression stroke air is forced into the sphere with a definite rotary motion and fuel is then injected into this highly turbulent mass. In this way the necessity of fine atomization is avoided, and as the maximum travel required within the combustion chamber is very much less than in the case of the direct injection engine a very much lower pressure of injection can be used. The process of combustion is started with the finer particles of oil, and the expansion resulting therefrom working its way out into the main cylinder space results in so much turbulence that the larger particles of oil are burned up in due course.

The third system, illustrated in Fig. 2C, is the pre-chamber proper, which is not very extensively used in

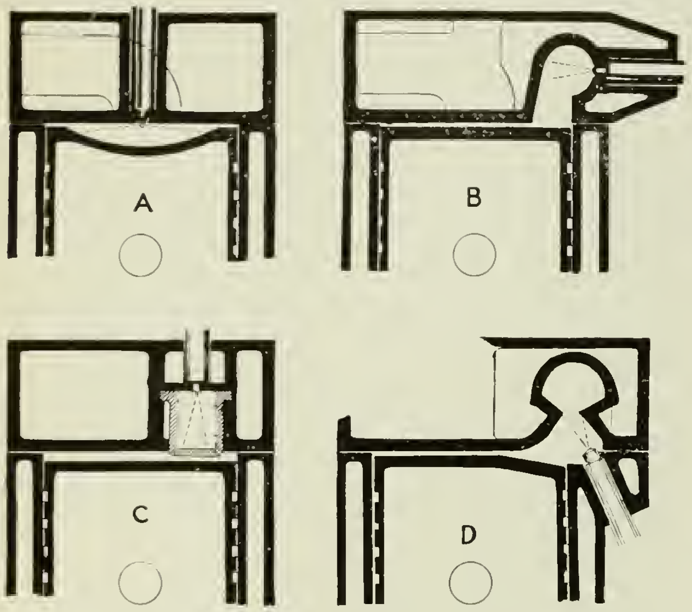

Fig. 2—Types of Combustion Chambers.

automotive engines, but nevertheless has its adherents in some of its forms. In this design the fuel is injected into a chamber formed in the cylinder head, which is only connected with the cylinder proper by comparatively small orifices. The action is somewhat as follows:—During the latter part of the compression stroke air rushes through the small orifices at considerable pressure and velocity, thereby setting up a high degree of turbulence in the chamber. Oil is then injected, and again it is not necessary to have fine atomization or high spray velocity hence a low pressure single spray orifice can be used. As the finer particles of oil burn in the chamber a considerable pressure is built up therein, finally rushing through the small orifices, carrying the heavier particles along with it into the cylinder proper where combustion is finally completed. The high velocity obtained through the orifices sets up a high turbulence in the cylinder thereby enabling combustion of the larger particles of oil to take place.

In the fourth system, illustrated in Fig. 2D, an expansion chamber is provided either in the cylinder head or in the top of the piston, with a somewhat constricted entrance. The amount of the constriction varies in different designs. The sprayer is so located that oil is injected against the narrow part of the opening into the chamber and not directly into the chamber. During the compression stroke considerable turbulence is set up owing to the passage of air into the chamber. When injection commences, combustion starts around the mouth of the chamber and partly within as well, with the result that the air in the chamber expands, rushes out against the oncoming stream of oil, carrying it into the body of the cylinder, in this way setting up high turbulence.

In giving consideration to the relative merits of the different systems, the problem has to be viewed from two different angles, namely manufacturing and operating. From the manufacturing point of view the direct injection system has the disadvantage of requiring high pressure injection, and very efficient sprayers, but also has the advantage of a very simple design of cylinder head and piston. The various chamber designs have the disadvantage of requiring complicated cylinder heads, but the advantage of lower injection pressures and less efficient sprayers. There would also appear to be some substantiation of the suggestion that the chamber systems are to a large extent the outcome of the air-injection school of thought and the direct injection follows the line of solid-injection practice. Adherents of air-injection were of the opinion that complete combustion could only be obtained with the aid of air-injection, which not only helped in the atomization of the fuel but also created added turbulence. Adherents of solid injection systems have always maintained that complete combustion could be obtained without the added complication of air-injection.

From the operating point of view, the advantage is entirely with the direct injection engine, because it has a materially lower fuel consumption, lower compression ratio, and readily starts from "all cold" without the aid of electric igniters, which are necessary adjuncts to the starting up of most types of pre-chamber engine. The running is smoother and absolutely clear exhaust is obtained with direct injection engines.

In the final analysis therefore, it would appear that the advantages are very much in favour of the direct injection engine, once the manufacturing difficulties have been solved. As far as the operator is concerned high injection pressures are no objection.

*Starting Methods.*

One other feature in which the Diesel is characteristically different from the gasoline engine is in the starting process. When electric starting is used, as it generally is, the only difference is that a starting motor and battery of much larger capacity must be used in order to overcome the high compression. It is necessary, however, to provide for hand starting, because batteries and electric starters have been known to fail. With the high compression pertaining to the Diesel engine it is obviously out of the question to expect any average individual to pull the engine over the compression stroke. Means are therefore usually provided whereby compression may be entirely relieved by holding either the exhaust or the inlet valves off their seats under the control of the operator. Under this condition he is then able to spin the engine by means of a crank handle to a reasonable speed in say three or four revolutions, he then releases the compression relief control and there will be sufficient energy in the flywheel to carry the engine over a compression stroke with the result that firing is commenced and the engine is running. In effect this is easier than cranking a gasoline engine and furthermore has the advantage that the danger of a back-fire is eliminated. It is also noteworthy, that from the moment of the first firing stroke the engine is ready to take up full load without the necessity of warming up or adjustments of fuel-air ratios so commonly necessary with the gasoline engine when it is cold.

*Auxiliary Equipment.*

There is only one item of auxiliary equipment which has to be treated differently in a Diesel engine and that arises owing to the fact that there is no appreciable drop in pressure in the inlet manifold, in other words there is no vacuum system available for operating the fuel system, windshield wiper, booster brakes or other auxiliaries. This feature is readily taken care of, however, by driving a small exhauster from a suitable part of the engine.

Water circulating pumps, fans, charging dynamos, fuel supply and so forth all follow gasoline practice with small variations. Somewhat less radiation is needed, less water circulation and very frequently a fan can be entirely dispensed with. Other variations from gasoline engine practice are more or less straightforward ones created by heavier stresses and so forth to which further reference will not be made.

### Application of the Automotive Diesel

As far as the general principles of the Diesel engine are concerned there is no reason why it should not be used in every type of road vehicle, whether it be a pleasure car, bus, truck or "steam roller." At the present time, however, it is not being produced in small enough sizes to make its use possible in smaller passenger cars, nor even in the small trucks. It has on the other hand been used quite successfully in larger types of pleasure car, in racing cars, and literally in thousands of buses and trucks in all parts of the world, operating under all kinds of conditions. Its use is really determined by economic conditions rather than by mechanical considerations.

In comparing Diesel engines and gasoline engines as prime movers, it will be found that they have somewhat different characteristics as far as their application is concerned, but comparatively little difference when it comes to operating characteristics. In general the Diesel engine is liable to be longer, wider, higher and heavier than its gasoline counterpart. These features are generally taken care of quite easily, especially in designing a new vehicle, and the fact that in the early days of the development practically every Diesel vehicle put into operation was converted from a gasoline driven vehicle is an indication that there are no insuperable obstacles to be overcome.

The point of real divergence comes about through the Diesel being run at maximum speeds considerably less

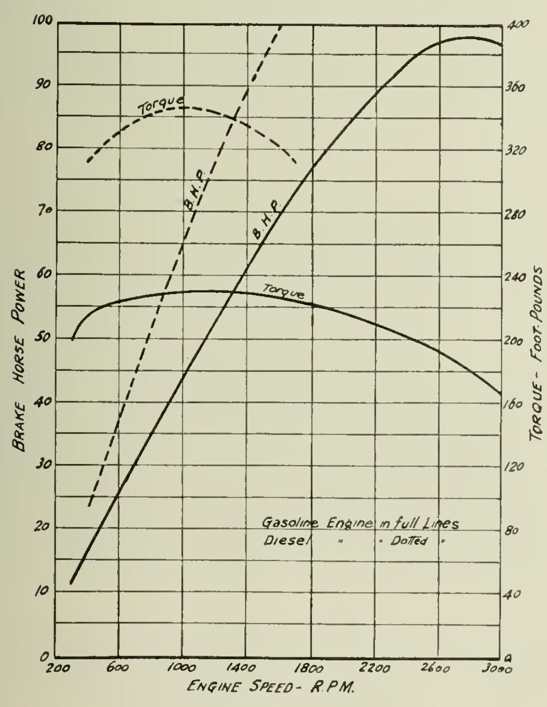

**Fig. 3.**

than the maximum speed of the gasoline engine. Commercially Diesels are usually limited to about 2,000 r.p.m., while gasoline engines are run at speeds of 3,000 r.p.m. and over. The reasons for this speed difference have nothing to do with the compression ignition system as Diesel engines are actually run at speeds of 4,000 r.p.m., but the lower speed ordinarily obtaining is probably the result of mechanical considerations combined with manufacturer's policy. Mechanically the difficulty of running at high speed comes about through the high stresses set up in rapidly moving and fairly heavy parts. It would also seem probable that the Diesel engine manufacturer has been in a position to dictate to the user to a greater extent than in the case of the gasoline engine manufacturers. The life of an engine is to a great extent proportional to its speed, and therefore the high speeds of the gasoline engines reduce their effective life, on the other hand being a cheap engine this is not a serious matter and indeed the

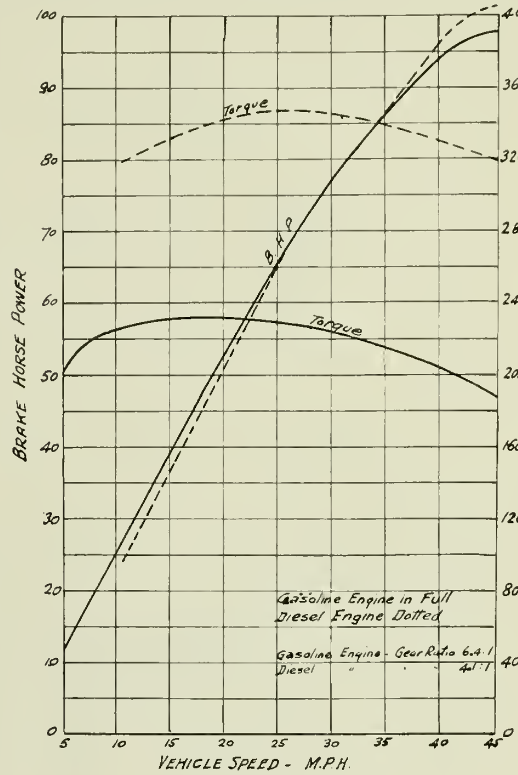

**Fig. 4.**

demand of the market has generally been for higher speeds even at the expense of more frequent replacements. On the other hand the Diesel is an expensive engine and it must have a long life if it is to be economically worth while.

In any event the user of the engine is not so much interested in the rotative speed of the engine as he is in the speed of the vehicle and he demands just as much speed with the Diesel as with the gasoline engine and he can get it, but different mechanical arrangement especially with regard to gear ratios becomes involved. The rear axles must both turn at the same speed and therefore a very much lower rear axle ratio is required in the case of the Diesel engine. If a high road speed is required such as 60 miles per hour, this ratio may become lower than commercially practicable or than commercially available and in that event a gear box with an "overdrive" or an auxiliary gear box may be employed, in either case the effect is to step up the speed of the propellor shaft as compared with the engine speed. On the other hand if low speeds especially for heavy trucking are satisfactory a standard rear axle ratio can be made use of.

If a vehicle is to be driven with a certain load, at a certain speed with certain road conditions, it will take so much horse power (data are sadly missing as to how much) and the amount will be just the same whether a high speed gasoline engine or a low speed Diesel engine is to be used. (See Figs. 3 and 4.) The Diesel engine with its low speed develops a higher torque than the gasoline engine, but as tractive effort is a function of torque multiplied by the overall gear ratio the final result in terms of tractive effort is the same in either case for a given horse power. Figure 5 indicates the tractive effort obtainable at various gear ratios with a typical gasoline and Diesel engine. There is however a feature which is quite different and that is in regard to the stresses which will be set up in the transmission. For example, a 100 b.h.p. Diesel engine will develop a torque of 350 foot-pounds as compared with 250 foot-pounds for the corresponding higher speed gasoline engine, with the result that the Diesel must have a gear box

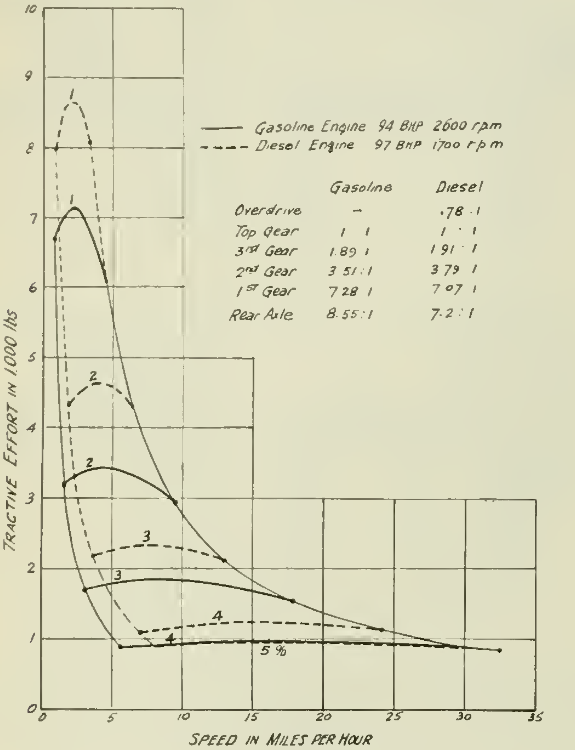

**Fig. 5.**

capable of withstanding the higher torque. Similarly the propellor shaft must also be stronger unless an overdrive gear box is used, in which case there may be little difference in the torque.

As far as operating results are concerned there is no very marked difference (except of course in cost) between the Diesel and the gasoline engine, but nevertheless the driver of the Diesel vehicle will notice some features which are not quite the same. First of all, when he goes to start up, even if the engine is quite cold, he gets the benefit of full power immediately, he does not have to nurse the engine until warm, or make carburetor adjustments. Secondly, the accelerator pedal usually operates through a governor, so that while the gasoline accelerator has the function of controlling the amount of fuel supplied to the engine, the pedal on the Diesel actually controls the speed of the engine, with the result that generally there is considerably less foot work—not a very important feature, but nevertheless of interest as being characteristically different. Thirdly, gear ratios are different on account of the slow engine speed of the Diesel and generally the effect is such that the Diesel appears to pull very much better at slow speeds than the gasoline engine, actually resulting in less gear changing.

With regard to the question of reliability this naturally varies with different makes of engine in both fields. But broadly speaking everything is in favour of the Diesel. Troubles in the gasoline engine frequently develop in some part of the ignition system or in the carburetor. These features are eliminated in the Diesel and their part taken by the fuel pumps and sprayers. There has now been sufficient experience gained to warrant the statement that these elements give less trouble than the corresponding elements in the gasoline engine. A little dirt in gasoline seriously interferes with the operation of the carburetor and reacts on the operation of every cylinder in the engine. Dirt in fuel oil is likely to choke a sprayer, wholly or in part, but this will cause a loss of power in one cylinder only. The probability of impairing the efficiency of all the sprayers is very remote unless there has been the grossest of carelessness in handling the fuel. Furthermore with the high pressures involved there is always the possibility that a choked sprayer will clear itself before very long. However, if this does not happen the changing of a sprayer takes very little longer than changing a spark plug.

There is nothing in the Diesel to cause mechanical breakdowns to be any more frequent than with gasoline engines, and indeed the lower mean temperatures should have the result of eliminating some of the causes of such troubles. When Diesels first appeared in the automotive field it was only natural that they should not be quite as reliable as the gasoline engine with its years of development and experience back of it, but today there is no question but that it is mechanically as reliable as the gasoline engine and even more so when all factors are taken into consideration.

A discussion of the characteristics of fuel and of lubricating oils is a subject unto itself, and as there are commercially available any number of oils for both purposes which are quite satisfactory, there is no necessity of entering into such a discussion. Different fuels naturally have quite a different reaction in the combustion process, and hence the actual running of the engine. Generally speaking however, the distillates of petroleum are the most satisfactory; care has to be taken however, that a clean oil is obtained. Similarly, with regard to lubricating oil, the automotive Diesel requires a high quality oil of the correct viscosity for the type of lubrication involved.

### Economics

The comparative economics of Diesel and gasoline engines only will be dealt with, and not the broader subject of the economics of motor vehicle operation, except in so far as the use of Diesel engines has effect thereon.

The fundamental reason for the existence of the automotive engine of the Diesel type is that of its inherent economical operation, and its natural field is therefore almost entirely limited to vehicles which are directly used for money making purposes or where the cost of operation, such as in municipal services, is a serious item. While the day may come when the oil engine is extensively, if not entirely, used in all vehicles the possibility is not in sight at the present time and therefore discussion may be limited to operations such as heavy duty or long distance trucking, bus and coach services, or municipal services of various kinds.

The first reason for the economy obtainable is the low fuel consumption of the Diesel owing to the high efficiency obtained with compression ignition. Test bed consumptions of gasoline engines give about 0.75 pounds per b.h.p. hour, while the corresponding figure for the Diesel is only about 0.40 pounds per b.h.p. hour. In actual road service, however, experience shows that under parallel conditions the fuel consumption of the Diesel may safely be taken as being one-half that of the gasoline engine, while if a comparison is made between the best of Diesels and an inefficient gasoline engine the ratio will become as low as one-third.

The second reason for economy is the lower cost of the fuel used, and in the case the actual amount is liable to be somewhat problematical owing to the influence of outside factors. The cost of gasoline varies considerably with different grades, and with different marketing conditions, fuel oil of a suitable nature, however, usually varies between a minimum of 8 cents per gallon and a maximum of 12 cents. There are of course exceptional cases, but a figure of 10 cents per gallon is reasonable for most economic studies. There is however, the possibility of a "gasoline" tax being applied to fuel oil when it is used for motor vehicles. However, under present day conditions, the differential between gasoline and oil could hardly be less than 8 cents per gallon and might be as much as 20 cents. In other words fuel oil may cost from ⅔ to ⅓ of the cost of gasoline. Hence the fuel expense ratio, combining the lower consumption with the lower cost may vary from at least ⅓ to a possible $^1/_9$. In a number of instances in actual service a saving of 80 per cent in the fuel cost has been reported.

It is interesting to note that the same question is raised today, as when the Diesel first made its appearance—"What about the supplies and price of suitable oils?"—coupled with the suggestion that when Diesels become universal the demand for oil will cause the price differential to be reduced or eliminated. However, certain common sense features cannot be overlooked, namely: (*a*) suitable Diesel fuel oil is cheaper to produce than gasoline, especially the high grade gasoline required for modern engines; (*b*) a wide range of oils can be utilized; (*c*)the same oil as is used in domestic oil burners is suitable so the price may well have to be kept low in order to compete in this field with coal; (*d*) suitable oils are being distilled from coal giving a new and independent source of supply; (*e*) the use of Diesel engines in vehicles cannot possibly approach the universal within a great many years, and the proportion of oil required for Diesel vehicles will be small in relation to total gasoline consumption. It would therefore appear that within the normal life of any engine which is being put into service today there is no reason to assume that there will not be a substantial differential in favour of Diesel oil.

While the principal economy obtained from the Diesel is from the low fuel consumption as outlined above, experience shows that there are other economies. Consumption of lubricating oil is an item of some importance. During the early days of the automotive Diesel it was apt to consume more lubricating oil than the comparable gasoline engine in similar service. Experience, however, has enabled this condition to be rectified and there are Diesel engines in operation today consistently giving lubricating oil consumptions of 1,500 miles to the gallon even under such difficult conditions as city bus service. Under similar conditions the gasoline engine consumes at least five times as much oil. This is the result of the lower mean working temperatures of the Diesel, its lower speed, and the reduction of dilution effects.

Maintenance costs are definitely less with the Diesel. This can be traced to the high quality of materials which have of necessity to be used, low working temperatures, and low speed. One operator of a large fleet has stated that he only finds it necessary to dock his Diesel vehicles every 10,000 miles for valve grinding, carbon removal and so forth, as against 5,000 miles for similar operations with gasoline vehicles in similar service.

In order to indicate what may be expected from the operation of a Diesel vehicle, the following table gives some general figures, based on the use of a heavy duty vehicle with an engine of about 100 brake horse power capacity, either gasoline or Diesel. Two different values are given for the cost of fuel oil due to the possibility of considerable variation existing in practice.

| | Gasoline | Diesel | |
|---|---|---|---|
| Price of fuel.................cents per gallon | 25 | 10 | 16 |
| Fuel consumption............miles per gallon | 5 | 12 | 12 |
| Lubricating oil consumption...miles per gallon | 250 | 1,500 | 1,500 |
| Cost of fuel per mile..................cents | 5.0 | 0.83 | 1.33 |
| Cost per mile, fuel and lubricating oil....cents | 5.3 | 0.88 | 1.38 |
| Cost of running 10,000 miles..............$ | 530 | 88 | 138 |
| Cost of running 50,000 miles..............$ | 2,650 | 440 | 690 |
| Cost of running 200,000 miles..............$ | 10,600 | 1,760 | 2,760 |
| Total saving on basis of 200,000 miles representing the approximate life of either engine..............................$ | — | 8,840 | 7,840 |

The question may naturally be raised as to whether there are some compensating items of increased cost, or serious mechanical or operating disadvantages to offset the tremendous advantage of economy of operation. Outside of the possibility of higher taxation the answer is definitely in the negative.

There is, however, one offsetting feature and that is the higher initial cost of the Diesel. Diesel engines have been produced cheaply, and a Diesel engine might be obtained at a price that would compare favourably with the cost of a gasoline engine of the best quality, but with the cheap Diesel the full advantages of economy of operation and maintenance are not obtained. The advantages of economy which have been referred to above are such as will be obtained with the use of a high class carefully built Diesel engine, which naturally costs more to produce than a gasoline engine. Before the final economic answer can be obtained provision has to made for the writing off of this additional cost; however, the foregoing table of savings indicates that at the end of what may be looked upon as the ordinary economic life of an engine the savings are sufficient to offset any possible excess cost of the Diesel. In fact the operator of a heavy duty vehicle, or coach, where a Diesel engine of 100-h.p. is customarily used will be from four to five thousand dollars in pocket when the time comes to discard his engine.

# The Tidal Phenomenon

*H. F. Bennett, A.M.E.I.C.,*
*District Engineer, Department of Public Works, Canada,*
*Sault Ste. Marie, Ontario.*

**Paper presented before the Sault Ste. Marie Branch of The Engineering Institute of Canada, April 27th, 1934.**

SUMMARY.—Describing briefly the various factors which influence the rise and fall of the ocean tides, the author gives examples of the complicated tidal phenomena occurring on the Atlantic coast of Canada. He also indicates some of the ways in which tidal currents affect the work of the harbour engineer in providing safe conditions for navigation.

Rise and fall of tide are recorded on the Great Lakes, but for the unbroken and easily distinguishable evidence of this phenomenon we must turn to the great oceans of the world.

Two theories are advanced to account for tidal action:—

(*a*) the Newtonian, or statical theory, and

(*b*) the Laplace, or dynamical theory.

Newton explained the phenomenon by reason of the differential attraction exerted by the moon and the sun on the earth's centre and on the water at its surface, the moon's influence predominating in the ratio of 5 to 2 on account of its greater proximity to the earth. Laplace considered the fact of the earth's rotation, and made the movement of the water a resultant of this and lunar attraction.

The fact that the higher tides are an invariable accompaniment of times of new and full moon shows that lunar influence is concerned in their production. This deduction is confirmed by the further fact that the times of high and low water occur about fifty minutes later every day, which coincides with the average period taken by the moon to pass the same meridian on succeeding days.

Generally, two high and two low tides occur in each period of twenty-four hours and fifty minutes, that is, high water to low water is about six hours and twelve minutes, and so on.

The tidal range in mid-ocean is estimated by various authorities at from 2 feet to 4 feet, increasing as it approaches the coasts, where local influences act on the progress of the wave so that the tidal conditions, both as to time and height, vary in relatively short distances.

This variation is especially evident along the coast of the British Isles. The single tidal wave from the Atlantic is divided off the southwest coast of Ireland and at Land's End into three portions: the main wave continues its course along the west coast of Ireland, while two branches diverge into the Irish Sea and into the English Channel respectively.

After performing their several circuits of Great Britain and Ireland, the waves meet at the north producing great variations in the rise of tide, from a range of almost zero at a point on the east coast of Ireland to about 30 feet on the Lancashire coast. The ocean wave passing west of Ireland and being least obstructed passes south into the Irish Sea and also into the North Sea, meeting the two north-bound waves with a variety of conditions.

It is presumed that each tidal wave originates in the southern oceans and proceeds northward. The wave appears to travel upwards of 500 miles per hour in ocean depths of 4,000 fathoms or over; at about 400 miles per hour in the north Atlantic Ocean where depths are generally less than 2,500 fathoms; at about 60 miles per hour in depths of 50 fathoms, and only 15 miles per hour in depths of 5 fathoms. Thus the tide which originates in the southern ocean does not reach the eastern coast of Canada the same day, but actually takes thirty-six hours or three complete tidal periods. It is for this reason, therefore, that the highest spring tides do not occur on the east coast of Canada, at the time of new or full moon, but actually thirty-six hours later.

We are, of course, more concerned with the tidal movement in its relation to the shore line and it is here that the tidal phenomenon develops its most interesting features. On the shore of the ocean the water level does not remain stationary, as it appears to on the shores of lakes. It gradually rises till it reaches its highest point, termed high water, and then it falls till it reaches its lowest point, which is termed low water. The difference in level is called the range of tide, and this movement goes on continually. As the tide moves vertically on the shore, the water flows into the bays, river estuaries, etc. on the rising tide and outwards on the falling tide. The inflow is called the flood and the outflow the ebb.

The higher tides with the greater range are termed spring tides and those with the lower range, neap tides. Not that the high tides occur in the spring, but rather that they spring upwards to a greater height.

Every movement of the sun and moon has an influence on the tide. The period from new moon to new moon is the synodic month and is about twenty-nine and a half days. The point on the moon's orbit which is nearest the earth is perigee and the point where it is farthest is apogee. The period of rotation from perigee to perigee is called the anomalistic month. Its length is slightly over twenty-seven and a half days.

While every movement of the sun and moon has its effect on the tide, in different parts of the world some one movement of the moon has a dominating effect, and the others become secondary. These variations in cause and effect have evolved three distinct types of tides:—

(*a*) The synodic, in which the leading variation in the range of the tide takes place twice a month, the range being greater at new and full moon, and less at the moon's quarters.

(*b*) The anomalistic, in which the greatest variation in the range accords with the moon's distance, and takes place once a month.

(*c*) The declinational, in which the changes due to the moon's declination (which makes the two tides of the day unequal in range) are so large and obvious that all other features of the tide are obscured.

While one of these variations is dominant in the several types of tides, the others are not entirely absent.

The synodic has fifty-seven tide intervals from new moon to new moon; the anomalistic fifty-three from perigee to perigee, and the declinational fifty-three from the moon's crossing of the equator to the next crossing in the same direction.

The synodic type of tide is predominant in the North Atlantic, on most of the coasts of Europe and North America. The anomalistic type is that found in the Bay of Fundy and Hudson Strait. The declinational type is found in the Pacific Ocean and to a marked degree in portions of the Gulf of St. Lawrence around the coast of Prince Edward Island and the north shore of New Brunswick.

When the moon is full or new, the line of its attraction coincides with the sun's attraction and the lunar and solar tides are added to one another by being super-imposed. It is then that we get spring tides. At the moon's quarters the tides are opposed and we get the neap tides.

It is known that the position of the sun in the heavens is north of the equator between March 21st and September 21st each year and south of the equator from September 21st to March 21st. The moon moves exactly in the same way except the period of time is less than a month instead of a year. The moon, therefore, has a north or south declination according to its position north or south of the celestial equator.

When the normal phases of the moon have the greatest influence on the tidal conditions, that tide is of the synodic type; when the moon's distance has the greatest influence the tides are of the anomalistic type, and when the moon's declination has the greatest influence the tides are of the declinational type.

There is a degree of uniformity in the tides of the synodic and anomalistic types, with two high and two low waters each twenty-five hours, but tides of the declinational type, while they do not entirely lose the effect of springs and neaps, show considerable inequality in the height of the two tides of the day when the moon is at a high angle of declination. This change in the height of the tide is termed "diurnal inequality," and when it does occur, there is also a pronounced inequality in the time interval between successive high waters. At this time there is usually only one high water each day, the second high water only approaching half tide level. Such a tide occurs at Victoria, B.C., and on the north shore of Prince Edward Island. When the moon is over the equator, however, the tidal action returns to normal and the two high and two low water periods occur as elsewhere.

The Dominion of Canada was very fortunate in having a scientist of the standing of Dr. W. Bell Dawson, M.E.I.C., F.R.S.C., as Superintendent of Tidal Surveys during the years of investigation and development. Primary tidal stations were established beginning in 1894 and secondary stations were established for short periods, so that today it is possible to predict the time and height of high and low water for almost any harbour on the Canadian seaboard, a condition which is absolutely necessary for the safe navigation of tidal harbours and their approaches.

It has been found that it takes eighteen years and eleven days for the sun, the moon, and the earth to occupy the same relative positions in the heavens. Consequently, tidal phenomena are reproduced under similar conditions at the end of successive periods of this duration, and the observation of the series of tides during one complete period will suffice to establish an accurate prediction for any future date of the interval studied.

Lord Kelvin invented an apparatus, which is now in the South Kensington Museum, for the mechanical prediction of tides. The National Physical Laboratory has since designed the "India Office Tide Predicting Machine," which can be used for predicting the tides, and preparing tide tables for any year, for any port for which the constants requisite for setting the machine have been determined by observation. The Dominion of Canada prepares tables of these predicted tides which are extremely accurate.

We may digress for a moment to get a picture of the approach of a tidal wave to the Atlantic coast of Canada. Figure 1 shows a portion of the coast at morning high water on October 23rd, 1934. The tide tables state that this tide arrives at Halifax at 7.58 a.m. Atlantic Standard time, at Saint John, N.B., at 11.45 a.m. and so on. If you study a chart of the Atlantic coast, you will find that the edge of the continent is really about 40 miles east of Sable island or 140 miles east of the main shore of Nova Scotia. Along this line we find that the ocean depth decreases rapidly from 1,000 fathoms to about 50 fathoms and, no doubt, the progress of the tidal wave is much impeded at this point and its velocity reduced considerably.

Co-tidal lines have been plotted on this map (Fig. 1) showing approximately the advance of high water level towards the coast at time intervals. You will note that the high water which reaches the continental bank east of Sable island at 6.00 a.m. requires two hours to reach Halifax; five hours and forty-five minutes to reach Saint John; twelve hours to reach the north shore of Prince Edward Island, and thirteen hours to reach Quebec. It must not be imagined that the water actually moves these distances, as the tidal wave is due to external forces, and

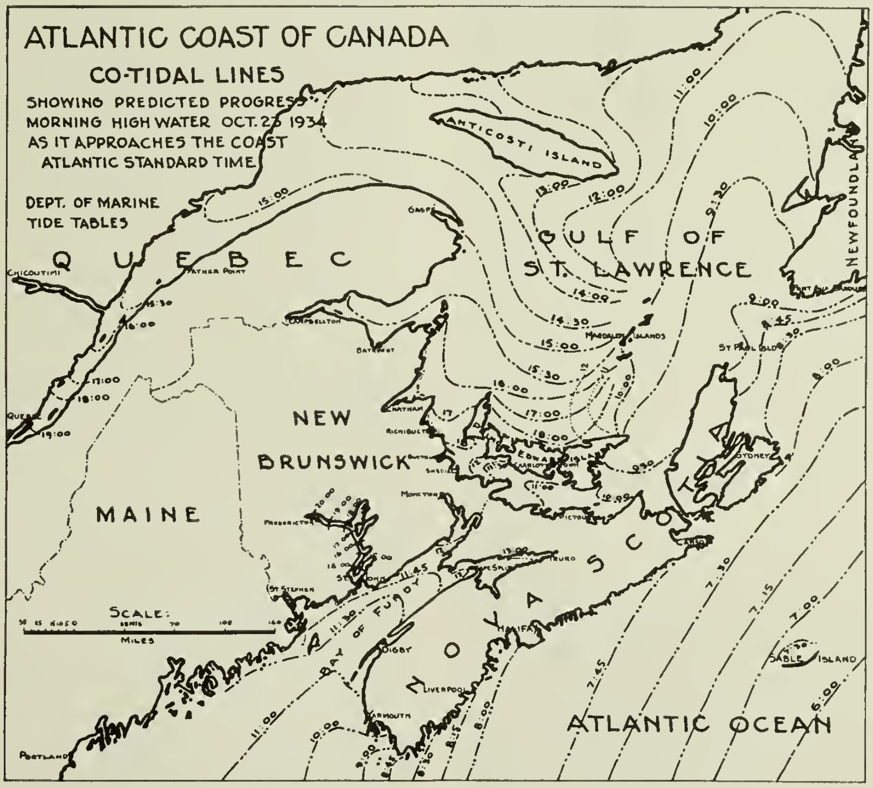

Fig. 1—Co-Tidal Lines, Atlantic Coast of Canada.

the water does not move horizontally except at a very slow rate and not always in the direction normal to the progressive time intervals.

There are three points on the map where the tidal waves, progressing from opposite directions, meet with varying effects. The first is at the northeast corner, where the tidal wave through the Strait of Belle Isle meets the wave progressing northward along the west coast of Newfoundland. The high waters of these two waves meet between Port Saunders, Newfoundland, and Bonne Esperance, P.Q., with no appreciable effect other than the normal high water condition.

The second is the wave from the Atlantic progressing north through the Strait of Canso, between Cape Breton Island and the mainland of Nova Scotia, meeting the wave which has passed around the north end of Cape Breton and southerly towards the east end of Prince Edward Island. In this case the times of high water are not simultaneous, the two tides are of different types, and the normal range is 4½ feet and 6 feet. The result is that a considerable tidal stream with a maximum velocity of 4 knots per hour flows through the strait. It has been possible to predict the change in direction of this current, which information materially assists navigation.

The third point of interest is the meeting of the two tidal waves in the Northumberland Strait west of Cape Tormentine. There appears to be a difference in time of about six hours with the result that the tide tables make the following explanation:—

"In the region at the western end of Northumberland Strait, when the declination of the moon is at all high, the tide shows a pronounced range once only in the day; but with a singular reversal of its features in a short distance.

"At Richibucto, it is the rise which is pronounced, and the other tides remain near the low-water level; while in Shediac Bay the fall is pronounced, with little variation from the high-water level on the other tides, whose range is not over 1½ feet. At Buctouche, which is midway between these localities, the limiting type of tide is reached. The tide remains for nearly half the day within about a foot of the same level, and drops once in the day to lower low water. It is only when the moon is quite near the equator that this is not the case. Thus at high water there is almost always a long stand, which continues from two hours to as much as eight hours. It is only at perigean springs, when the rise is greatest, that the high water is sharp and definite in time. The middle point of this long stand is within an hour or two at the same time of day, without the usual progression, for six to nine days altogether. The actual time falls between midnight and 7 a.m. in early summer (June and July) but towards the autumnal equinox, the mid-time of the long stand retrogrades into the previous day; and then remains during the autumn, between 4 and 9 p.m. as a rule. Because of the length of the stand at high water these hours may be depended on for practical purposes; except when its duration is shortened at perigean springs."

Attention may be drawn to two nationally known tidal features which are of particular interest:—The Reversing Falls at Saint John, and the Tidal Bore at Moncton, N.B.

Saint John Harbour is a river estuary. The St. John river, with its many branches, empties into the harbour through a narrow rocky gorge. Obstructions in the water area of the gorge form a dam which keeps the water level of the river above elevation 16.0 feet above low water or 2.0 feet above mean sea level, so that at low water spring tides there is a fall from the river level above the falls to harbour level below the falls of about sixteen feet.

When the tide rises to elevation 16.0 or about 16.5 above low water spring tide, a period of slack water occurs at the falls and for the following hour it is possible to navigate the passage with safety. The tide in the harbour continues to rise until a maximum height of 28.0 feet above low water spring tide, or 14.0 feet above mean sea level, is reached, during which time the harbour waters flow upriver through the gorge, giving a maximum fall towards the river of about nine feet.

The effect of the tidal flow into the river is to cause a tidal range of about 2¼ feet just above the falls and this tide continues up the river for about ninety miles until the next rapids section is reached.

This process continues with another slack water period on the falling tide and so on. During the freshet season in the river the slack water period occurs nearer the time of high water.

The city of Moncton is located on a bend in the Petitcodiac river which empties into the Bay of Fundy at its northeast end. The spring tide rise at the mouth of the river is about 44 feet. For some miles below Moncton the river is practically dry at low water so that the tidal wave travelling up the river is obstructed by the friction of the bottom and the wave changes to one of translation with the top of the wave travelling faster than the bottom. The bore is first noticeable about eight miles below Moncton and travelling at a speed of about 8 miles per hour passes Moncton with a height of about 3 to 4 feet. The bore arrives at Moncton about three hours and forty-five minutes after high water at Saint John. A bore is also noticeable in the Salmon river at Truro, N.S. and in the Shubenacadie river, N.S. as well as in the Amazon, Hooghly, Severn, Tigris and Euphrates, Seine and the Dordogne.

It has been a common question to ask "Why is it not possible to harness some of this tidal power and generate electric power?" It has been done, but not in Canada. However, extensive investigations have been made, especially on the shores of the Bay of Fundy. The most noteworthy, of course, is the Passamaquoddy Bay project which has been proposed by United States interests, as the waters are on the International boundary. This scheme involves interference with navigation and fishing rights of both countries and no development has yet taken place, pending legislative enactments.

Prior to this, proposals were made to develop tidal power at the mouth of the Petitcodiac river. Schemes have also been suggested to make some use of the Reversing Falls, and also the swift tidal stream which passes Cape Split at the entrance to the Minas Basin in Nova Scotia.

Tidal action plays a part in the design, construction, equipment, maintenance and operation of any harbour on the Atlantic coast.

It is natural that we should be more conversant with the details of piers, sheds, loading and unloading equipment of our harbours than of any other feature. It is not the design, construction and operation of these which give the harbour engineer his greatest engineering worries, but rather the maintenance of channel depths in the approaches and the protection of such approaches so that shipping may come and go without hindrance.

Years ago it was a common statement of those not directly connected with shipping to state that the approaches to the tidal harbours in the Bay of Fundy were navigated with danger, due to the considerable rise of tide and the prevalence of fogs. It is true that there are certain tidal streams in the Bay of Fundy as well as fog, which must be considered by all navigators, but it is also true that the investigations carried out by the Canadian government have been so thorough that today the navigator is provided with definite information as to the nature, extent and time of these currents, so that he meets them where they are expected and proceeds to his port of destination without

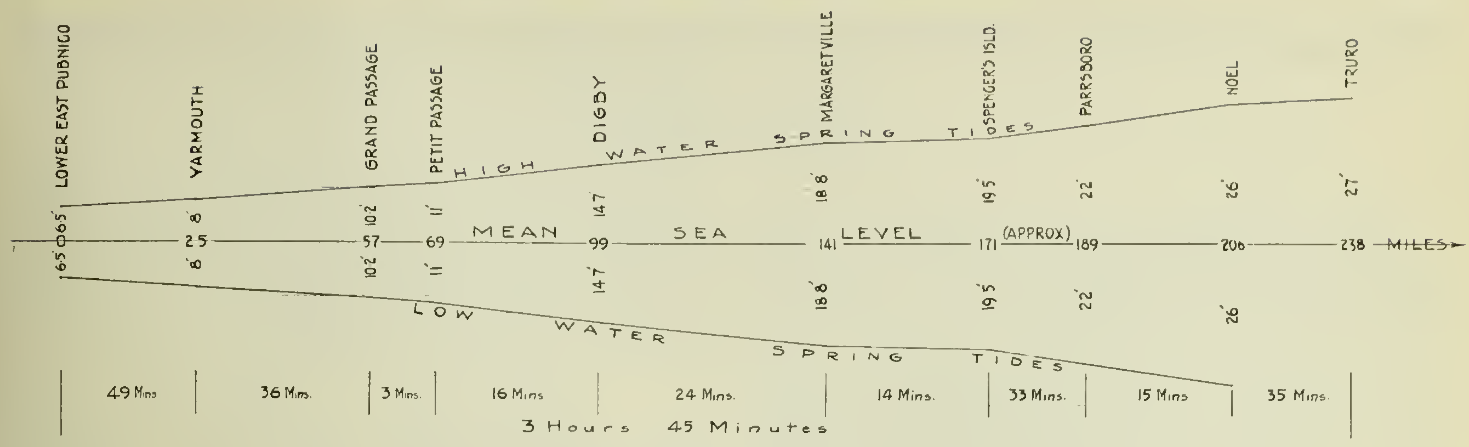

**Fig. 2—High and Low Water Along Nova Scotia Shore of the Bay of Fundy.**

delay. Radio equipment, of course, has largely removed the fog menace.

While the need for the construction of works to protect the harbour approaches from storm waves is not due to the rise and fall of the tide, the location and extent of these works in relation to the deep channel portion of the approach must be considered in their influence on the horizontal movement of the tidal currents.

The restriction of harbour entrances, either by parallel jetties or by converging breakwaters, naturally changes the normal movement of the waters in and out of those harbours. The flow of the water, either tide water alone or augmented by effluent river waters, has produced a balance in the formation of the underwater surface, and permanent change in that surface will not usually occur unless some artificial element is introduced.

All tidal harbours experience an inflow and outflow of water. Usually the inflow occurs during the rising or flood tide and the outflow during the falling or ebb tide. Where the harbour is a river estuary, as is often the case, the ebbing tidal waters are augmented by the fresh water from the river, usually giving a longer period of outflow than of inflow.

If the traffic of a natural harbour increases sufficiently to warrant improvements in landing facilities, depths at the piers, increased channel depths, and protection works, the experienced harbour engineer must closely examine the present conditions and study carefully the changed conditions which will exist if channels are deepened, entrances are narrowed, or the tidal capacity of the harbour is increased or decreased by the removal of old structures, by the deepening of berths and inner areas, or by the construction of additional piers, quay walls, etc.

It has been an axiom that, as far as possible, the tidal capacity of a harbour should not be decreased. If extra tidal capacity is provided, the incoming tide will attempt to fill up the added space and in doing so, the velocity of the flood stream is increased. The increase of the velocity naturally increases its carrying capacity for sand, gravel, etc., which covers the bottom.

The same is true of the ebb stream flowing outwards, with the result that a new balance is ultimately found and the depth of water in the entrance becomes stable after meeting the requirements of the increased tidal flow.

It can be readily seen that a change in the conditions of the tidal flow will occur if the entrance channel is enlarged or reduced, by the deepening of the channel, the increasing of its width, or the reduction of the width by the construction of works such as parallel piers or jetties, or converging breakwaters.

When such a channel is deepened, it must be realized that if the new depth cannot be maintained by the natural flow of the inward and outward tidal currents, expensive artificial means will have to be employed. If the entrance channel is restricted, the velocity of the current is increased, scour of the bottom occurs, with a natural increase in the depth of water. But as soon as the restrictions are passed the current is suddenly reduced and a bar is formed outside the piers with the material carried by the tidal stream, unless this reduced velocity occurs in an area where the coastal or littoral current is sufficiently strong to carry the transported materials beyond the areas required for safe navigation.

There is a fascination about tidal studies and a satisfaction in controlling the tide to provide improved conditions for the benefit of trade and navigation. The construction of piers, quay walls, wet docks, etc. in tidal harbours has been and is an expensive undertaking. It was the English practice, as seen at Liverpool and London, to accommodate ocean vessels in wet docks which are entered at high water through gates just as a vessel enters a lock in our Great Lakes canals. The loading and unloading proceeded at the walls of these wet docks with the vessels afloat.

The Canadian practice in the harbours of great tidal range, such as Saint John and Quebec, is to build quay walls and piers at which the vessel moves up and down with the tide with, usually, sufficient water at the pier at low water to float any ship which may call. This, of course, necessitated a great height of pier wall—in the case of Saint John about 70 feet—to provide 36 foot depth at low water spring tides.

The British practice required a less height of wall; it gave a stable height of vessel with relation to sheds, loading equipment, etc. as against the continual up or down movement of the vessel at the Canadian piers. It is significant, however, that in France there is a movement towards the increase of "tidal accommodation" as opposed to the use of wet docks. Major DuPlat Taylor recently stated that "twenty-five years ago it was thought that tidal berths were unsafe for ships and practically all the berthage was provided in impounding docks. In 1912 the river jetty at Tilbury was the first structure of any size on the Thames to provide tidal accommodation. It was 1,000 feet long of reinforced concrete on precast cylinders. All the new docks at Le Havre are tidal and the new deep water berths at Southampton are of this nature."

It is possible, therefore, that we have not lagged behind in the type of harbour facilities best suited for tidal harbours.

The author is indebted to the Department of Marine of Canada for the use of works on this subject by Dr. W. Bell Dawson, for the free use of their annual tide tables, and to Mr. H. W. Jones, M.E.I.C., of the Tidal Survey Branch, for advice on the movement of the tides in the Gulf of St. Lawrence.

*Raymond D. Johnson*[1]

## DISCUSSION

H. C. Boardman[2]

The author has reached his conclusion in a manner savoring of legerdemain. Only by wizardry could he have made the mental journey from $\Delta$ to $\delta$ to $\delta'$ to $f'$ and $a$ by the path which he travelled. The writer confesses his inability to follow the trail exactly. In places he found the signs illusory if not false. The promise that "It will be shown that where the tube is not precisely round before external pressure is applied, the bending stresses are *directly* proportional to the initial amount of deviation from a true circle" is not and, of course, cannot be fulfilled since the bending moment obviously increases with the distortion, just as it does in the case of an initially curved column.

Equation (5) is a close approximation based on the assumption, contrary to fact, that the moments at the points of maximum deflection are equal. This case is covered in Section 59, pages 242, 243, and 244 of the first edition of "Applied Elasticity" by Timoshenko and Lessells. Equation (5) may be instructively written in the form, $M = pr\ (\Delta + \delta)/2$, where $\Delta/2$ is the initial, and $(\Delta + \delta)/2$ the final maximum radial departure from a truly circular form.

Equation (6) also appears to be an approximation derivable for the special cases of a variable external loading on a cross-section initially perfectly round, a quadrant of which is illustrated by Fig. 4. $P$ is any point on the quadrant arc, and $M_p$ the moment at $P$. Because of symmetry it is evident that the tangent lines at $A$ and $B$ do not rotate when the load is applied. This is expressed mathematically by the equation

$$\int_o^{\frac{\pi}{2}} M_p r\, d\theta = 0$$

$$\text{or } \int_o^{\frac{\pi}{2}} \left[ -M_A + wr^2\,(1 - \cos\theta) - \frac{1}{2}\, wr^2 (1 - \cos\theta)^2 \right] r\, d\theta = 0$$

$$\text{or } \int_o^{\frac{\pi}{2}} \left[ -M_A + \frac{1}{2}\, wr^2 \sin^2\theta \right] r\, d\theta = 0$$

whence $M_A = M_B = wr^2/4$ numerically. The shortening $\delta$ of the vertical diameter is

$$\frac{2}{EI_o} \int_o^{\frac{\pi}{2}} M_p r^2 \cos\theta\, d\theta,$$

whence $\delta = wr^4/6\, EI_o$. The ratio of $\delta$ to $M_A$ is $2\, r^2/3\, EI_o$. Therefore $\delta = 2\, r^2 M_A/3\, EI_o$ which is the author's equation (8). Obviously, the same moment and deflection would be obtained by assuming a uniform external pressure and, in addition, the vertical loading of Fig. 4. The moments are assumed to be unaffected by the deflection.

It, therefore, appears that the ratio of moment to deflection resulting from the special loading of Fig. 4 on an initially round ring with the effect of the deflection on the moment ignored, is assumed to be the same as the corresponding ratio for an initially deformed ring subjected to a uniform external pressure with the effect of the deflection on the moment included. Considering that $\Delta$ is small as compared to $r$, this assumption seems reasonably accurate but a rigorous proof is elusive, and desirable.

The point $C$ of Fig. 4 represents one corner of an inscribed square. Under the special loading there shown the change in length, $Z$, of one side of the square is

$$\frac{2}{EI_o} \int_o^{\frac{\pi}{4}} M_p \left( r \cos\theta - r \cos\frac{\pi}{4} \right) r\, d\theta,$$

whence $Z = 0.0589\ wr^4/EI_o = 0.3536\ \delta$, which agrees with equation (10).

Equations (5), (8) and (10), and the beam formulae, are the tools which the author ingeniously and almost mystically uses to evaluate $\delta$ and $\delta'$. He first assumes a ribbed tube out-of-round by an amount $\Delta$ for its entire length, then imagines a uniform external pressure $p$ applied, which lengthens the longest and shortens the shortest rib diameter an amount $\delta$, and causes the shell between adjacent ribs to act as four extraordinary beams, having neutral axes along the node lines where they join, and subjected to a complicated and intangible loading made up of four components, one of which is uniform and positive, one uniform and negative, one variable according to the deflection curve and positive, and one similarly variable and negative. These components are obtained from the expression

$$\int_o^l p'\,(\Delta' + y)\, dx,$$

using $8\ \delta'/15$ as the mean value of $y$. The justification for using $p'\,(\Delta' + y)$ as a beam load perpendicular to the plane of the nodes eludes the mind of the writer. To accept it requires an act of faith. Is $p\Delta'/2$ of equation (5) a *load* on the ring perpendicular to the node lines?

The peculiarly elusive nature of the author's analysis, which appears to be mathematically accurate, is due to the following facts:

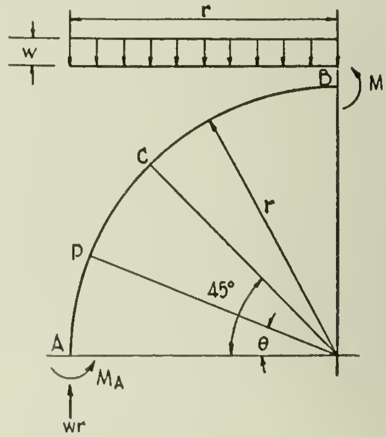

**Fig. 4.**

(*a*) The analysis assumes a constant ratio of maximum moment and maximum deformation in a ring, whether the peripheral edges be free from shearing stresses as in the case of equation (5), or subjected to shearing stresses as in the case of rings cut out by transverse planes between ribs.

(*b*) The beams are treated without reference to the *actual* loads upon them, which loads are the uniform external pressure, the end reactions at the junctions with the

[1] Paper presented at the General Professional Meeting of The Engineering Institute of Canada, Montreal, 1934, and published in the January, 1934, issue of The Journal.

[2] Chicago Bridge and Iron Works, Chicago, Ill.

ribs, and the forces on the node lines. The reader tries in vain to picture how $p'(\Delta' + y)$ is a beam load and, if so, in what direction it acts, and where it is applied. He can see that the summation of the $p'r(\Delta' + y)\,dx$ values over the length $l$ results in $M'$, or in other words, that the moments of which the plates are relieved because the rib is present are carried by the rib, but he cannot see $p'(\Delta' + y)$ as an actual physical load on the beam.

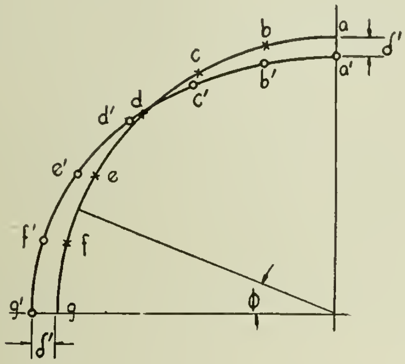

Fig. 5.

(*c*) The assumed beam action seems bizarre. The node lines of each beam are taken as the double neutral axis, requiring that the longitudinal stresses in the beam be either all compression or all tension; the node lines move farther apart or nearer together under the load, and deflect perpendicular to the node plane only 0.3536 as much as the corresponding point on the outermost fibre; yet the usual deflection formulae for beams are used and assumed to apply to the node lines.

The writer suggests the following method of approach to the general problem:

Figure 5 represents a quadrant of a circle with equally spaced points $a$, $b$, $c$, $d$, $e$, $f$ and $g$ marked thereon, and a quadrant of an ellipse having the same circumference as the circle, with equally spaced points $a'$, $b'$, $c'$, $d'$, $e'$, $f'$ and $g'$ marked thereon. By inspection, it is apparent that, if the circle quadrant deforms into the ellipse quadrant, it can do so only by a practically tangential movement of the node point $d$ and by entirely radial movements of the points $a$ and $g$. Point $d$ moves to $d'$, and points $a$ and $g$ move to $a'$ and $g'$, respectively.

These observations lead to the conclusion that, if the circle represents a rib and the ellipse represents the outline of the deformed tube midway between ribs, there must be shearing stresses, varying in intensity as a function of $\phi$, on every transverse section between the mid-section represented by the ellipse and the rib represented by the circle. In each quadrant of each transverse section the shear intensity must be a maximum near the point for which $\phi = 45°$, where the shear is nearly all tangential, and at points for which $\phi = 0°$ and $\phi = 90°$, the tangential shear must be zero, and the radial shear intensity small because $\delta'$ is small as compared to $\Delta$, and because the plates have slight bending strength in radial directions. It, therefore, seems reasonable to neglect the radial shears and assume that the tangential shear intensity varies as $\sin 2\phi$.

This reasoning applies also if the rib outline is an ellipse and the tube outlines on transverse sections between ribs are ellipses having eccentricities greater than the eccentricity of the rib ellipse. To facilitate the computations a circular initial shape for the ring and rib is assumed. Figure 6 represents a quadrant of a ring cut out by two transverse planes one inch apart; $P$ is any point on the arc; $s$ is the tangential shear per inch of arc, and $k$ is a constant to be evaluated so that $s = k \sin 2\phi$ and so that $M_A = M_B = pr(\Delta + \delta + y)/2$. The end axial force

$$V = H = kr\int_0^{\frac{\pi}{2}} \sin 2\phi \cos\theta \, d\theta = 2\,kr/3.$$

The moment at the point $P$ is

$$M_p = M_A - \frac{2}{3}kr(r - r\cos\theta) + kr\int_\phi^\theta \sin 2\phi\,[r - r\cos(\theta - \phi)]\,d\phi$$

$$= M_A - \frac{1}{3}kr^2\sin^2\theta.$$

Because of symmetry the tangents to the arc at $A$ and $B$ do not rotate when external pressure is applied to the ring.

Therefore $\int_0^{\frac{\pi}{2}} M_p\,ds = M_A\,r\int_0^{\frac{\pi}{2}} d\theta - \frac{1}{3}kr^3\int_0^{\frac{\pi}{2}} \sin^2\theta\,d\theta = 0$

whence $M_A = kr^2/6 = pr(\Delta + \delta + y)/2$, from which $k = 3p(\Delta + \delta + y)/r$ and $s = (3p/r)(\Delta + \delta + y)\sin^2\phi$.

Tangential shearing stresses distributed according to this equation, on an initially circular ring, would result in moments practically equal, at corresponding points, to those due to the uniform pressure $p$ on a ring initially out-of-round by the amount $\Delta + \delta + y$.

This demonstration makes it appear highly probable that there exist on transverse sections of a properly ribbed tube initially out of round substantially tangential shearing forces which relieve the tube plates of practically all girth moments, and transfer them to the ribs. Obviously this can be true only if the ribs are designed to resist these bending moments without undue distortion.

Since $M' = (f - pr/t)\,I/e$, equation (8) can be written in the form $\delta = \frac{2r^2}{3EI}\left[\frac{I}{e}(f - pr/t)\right]$ from which an approximate value of $\delta$ can be calculated. If $pr/t$ be omitted for safety and simplicity, the formula becomes $\delta = 2r^2f/3Ee$, and therefore $\Delta + \delta = \Delta' = \Delta + 2r^2f/3Ee$. The term $y$ is small compared with $\Delta$ and $\delta$; by neglecting it, and assuming that all bending moments are carried by the rib, $M' = prl\Delta/2 = [\Delta + 2r^2f/3Ee]\,prl/2$, which is suggested for use in place of equation (25).

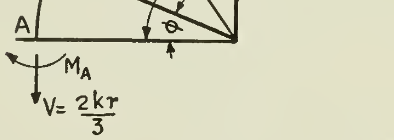

Fig. 6.

The corresponding maximum shear intensity between rib and shell is $3pl\Delta'/r = [\Delta + 2r^2f/3Ee]\,3pl/r$ per inch of arc.

The author condemns designs based on studies of "the elastic instability of perfectly circular tubes,"—perhaps rightly. Nevertheless Euler's column formula, though based on a study of the elastic instability of perfectly straight and homogeneous columns, has for years been very successfully used in designing columns which admittedly were not originally straight or homogeneous. Euler's formula gives the load under which a perfectly straight and homogeneous column may be expected to suddenly buckle. The factor of safety used with it allows for the unknown initial departures from perfection. The writer believes that the results of studies of "the elastic instability of perfectly circular tubes" can with equal success be applied to the design of tubes initially slightly out-of-round if the factor of safety be judiciously chosen. He has found the following line of reasoning very helpful, although not rigorously accurate.

Euler's formula for pin ends is:

$P = \frac{\pi^2 EI}{L^2}$, in which

$P$ = Total critical load on the column.
$E$ = Modulus of elasticity of steel.
$I$ = Least moment of inertia of column cross-section.
$L$ = Length of column.

A ring cut out of a tube by two transverse planes one inch apart may be considered to act under uniform external pressure, as four Euler columns, each a quadrant long.

Let:

$t$ = Tube plate thickness.
$p_o$ = Critical external pressure; that is, the pressure at which a tube initially perfectly round will probably buckle.
$r$ = Radius of tube.

Then, referring to Euler's formula above,

$$P = p_o r,\ L = \frac{\pi r}{2},\ L^2 = \frac{\pi^2 r^2}{4},\ \text{and}\ I = \frac{t^3}{12},$$

whence,

$$p_o r = \frac{\pi^2 E\left(\frac{t^3}{12}\right)}{\left(\frac{\pi^2 r^2}{4}\right)} = \frac{Et^3}{3R^2},\quad \text{or}\quad p_o = \frac{Et^3}{3\,r^3}$$

Let $p$ = The allowable working pressure, using a factor of safety of 4 with respect to the pressure. Then:

$$p = Et^3/12\,r^3 \ \text{or}\ t^3 = 12\,pr^3/E,\ \text{or}\ t^3 = pr^3/2{,}500{,}000$$

$$\text{or}\quad t = (r\sqrt{p})/136 \ \text{or}\ p = 2{,}500{,}000\ (t/r)^3,$$

which are convenient forms for practical use in designing long cylinders.

The result of this admittedly loose way of reasoning agrees exactly with the formula derived in Slocum and Hancock's "Text-Book on the Strength of Materials." Practically the same result is also obtained on pages 245, 246, 247, 248 and 249 of Timoshenko and Lessel's "Applied Elasticity," if the factor of safety be 3 instead of 4.

In the case of a ribbed tube, such as the internal riser of a surge tank, the formula corresponding to $t^3 = pr^3/2{,}500{,}000$ becomes $I = pr^3l/E$, in which $I$ and $l$ are the same as in the author's paper. This formula applied to the design problem chosen by the author gives:

$$I = \frac{(15)\ (60)^3\ (210)}{30{,}000{,}000} = 23.$$

If a factor of safety of 5, instead of 4, with reference to pressure were used, $I$ would come out about 30, which corresponds closely with the author's chosen value of 31.53.

Formulae based on elasticity stability hold only when the stresses do not exceed the elastic limit.

The author's practice of designing on the basis of stresses, rather than on the basis of elastic instability, deserves commendation, and his methods have proved their practical worth. Nevertheless, a reader of his paper wishes that his results could have been reached in a less devious and elusive manner, and harbours a suspicion that their successful use is due not so much to their exactness as to the remarkable strengthening effect of stiffening rings on thin walled steel tubes. Just as there are many structurally successful combinations of sizes, shapes and spacings for the supports of pipe lines and horizontal tanks, and for the stiffeners of web girders, so there are probably many structurally successful combinations of rib sizes, shapes, and spacings for thin walled tubes subjected to uniform external pressure. Wind girders for standpipes are astonishingly effective in preventing the collapse of the shells under irregular and fluctuating wind pressures.

If the author would present a rigorous stress analysis for an elliptical ribbed tube of considerable eccentricity and apply it to a slightly out-of-round tube as a limiting case, and if he would also present critical test data to support his design methods, he would be rendering an unquestioned great service to the engineering profession.

Professor Gilbert Cook[3]

An important subject has been dealt with, and one which has never yet been successfully treated by analytical methods. Indeed, the problem of stability of a perfectly cylindrical tube with end constraints has not been completely solved; and the added complication of irregularities in shape and thickness makes it still more intractable to mathematical analysis. The employment of coefficients in order to allow for imperfections of form is rational when such coefficients bear a definite relation to the type and magnitude of the imperfections; but, as a rule, they perform the functions of a factor of safety rather than as a reliable measure of the deficiency of strength.

The author is therefore to be congratulated on the courage he has displayed in his attempt to put the design of stiffened tubes, with known imperfections, upon a rational basis. He would have earned the gratitude of all who have worked on this subject if he had made his treatment more intelligible. An unnecessarily complicated notation has interfered considerably with the process of logical argument, and certain symbols have been employed for quantities whose existence is based upon assumptions which are not sufficiently justified or even clearly stated.

It is well known that a long tube would deform, by the application of external pressure, into the shape shown by Fig. 2. It will not be disputed that a stiffened tube, in which the ribs are comparatively weak will deform similarly, the rib partaking of the same type of deformation as the shell. The author gives the impression (in the paragraph in the middle of the second column, page 2), though it could not of course be his intention, that the tube is actually weakened when the rib is made so strong that deformation into an elliptical shape is prevented.

The essential feature of the author's method is the conception of a tube made up of four longitudinal beams, the stiffness of which resisted the deformation. The action of a stiffening rib on the stresses in the shell is, however, as the author recognized, much more complicated than this; and it requires more detailed consideration as to how far the assumption is permissible. The reactions at the rib will consist of shearing forces having components radially and tangentially, and of couples having components both in the radial and transverse planes, all these components varying from point to point round the rib. Which of these components will be predominant at any given point is not at once obvious, but it might safely be presumed that the actions in the shell will not be any simpler in character than the reactions at the rib. The author might elucidate a part of his argument which is particularly obscure, and which appears to be fundamental to his treatment. This refers to the matter between equa-

(3) King's College, London, England.

tions (19) and (22) including Fig. 3, and especially the paragraph beginning with the statement "Inasmuch as these opposing forces do not support each other with the girth stiffness neglected, they must somehow be entirely counteracted by the beam loads." What does the author really mean by a "beam load"? The only load on an element of the shell is the external pressure; all the other actions on it are due to internal stresses. A little elaboration of Fig. 3, explaining the exact significance of the various arrows, would help towards making its meaning clear. As it stands, Fig. 3 would appear to suggest that the girth stress in the shell is compression at one point and tension at another.

While, therefore, the assiduity with which the author has pursued his investigation is greatly to be admired, it is a matter for regret that he has not made his argument sufficiently clear to call forth effective criticism. In view of the numerous assumptions made, the validity of his equations will in any case ultimately depend upon the extent to which they are found to agree with the results of actual tests.

S. Clifford Doughty[4]

The author's paper should be regarded more as a guide to design of large steel tubes than as a solution of a problem in stress mechanics; in the former respect it is eminently successful. It has, too, the backing of the author's long practical experience in construction of large tubes.

Technically, the treatment of the shell stresses as simulating those in conventional beams may be open to further development in the way of precise stress analysis, such as the statement of the shear deformations, and an adjustment of the moment of inertia of a beam to provide for fibre stresses not proportional to ordinates from the chord through the nodes, the effect of all of which, however, on the deflection of the beam is apparently well represented by the author's conception of the beam deflection as that of the node line. For though the stresses have not at present been solved by rigorous analysis, a small amount of calculation will serve to convince technicians that a different treatment of the longitudinal behaviour of the shell will have almost no effect on the moments and stresses in the ribs, none at all on the recommended spacing of ribs in equation (40) and only such effect on the shell stresses as to increase, rather than decrease, the small disparity between the calculated and experimental rupture pressures given in the tabulation by Mr. Laber, which has been brought to the writer's notice. Such larger disparity, of course, may be accounted for by slight imperfections in the single spans used in the experiments, where continuity of the beams is interrupted and the slope of the ends may not remain exactly zero, thus inducing a lower rupture pressure.

The remaining uncertainty of the exact value of $d$, although possibly trifling, is nevertheless likely to be of far more consequence than any further refinement of the stated shell behaviour. However, from the point of view of the science of elastic structures, known and unknown, it will be desirable to have in the future an exact analysis of the shell stresses, which may be of considerable importance in types of structures yet to be invented.

In any discussion of the validity of the present argument, it should be borne in mind that the prime consideration for engineers in designing tubes with angles, or other yielding rings, as stiffeners, is the exact evaluation of the rib stresses, along with a rule for rib spacing which will insure these always being greater than the shell stresses. This has been accomplished, to a degree of precision within known limits, where the recommended spacing of ribs is used and criticism of the shell stresses themselves is in this respect immaterial.

N. R. Gibson, M.E.I.C.[5]

The author's paper is the only complete analysis of the stresses in stiffened circular tubes under external pressure that has come to the attention of the writer, and he is to be complimented on having derived precise working equations covering this important and complex problem.

Upon receiving this paper, the writer, with the assistance of Mr. L. S. Bernstein and Mr. E. B. Strowger, undertook the task of checking the equations and reporting upon their usefulness in the field of practical designing. All the equations have been substantiated. This discussion would, therefore, be confined to comparing the results of using the author's exact method with the results of an approximate method as used by an experienced designing engineer.

For this comparison, three pipes have been selected having diameters of 8, 10 and 12 feet subjected to an

Average 4.4 per cent.

external pressure of 15 pounds per square inch. The results using the two methods are shown in Table II. The saving in weight is about 5 per cent when the author's method is used. In addition to this saving in weight, there would be an additional saving in shop and field work due to the great stiffener spacing allowed, which might result in a total saving of as much as 10 per cent in the total cost of the pipe.

Based upon this investigation, it is evident that the use of the author's method results in a substantial gain in economy.

For the approximate design the following assumptions have been made:

(1) The pipe between the stiffeners was assumed to be divided into four beams, each of one-quarter circumference, and all of which carry the load to the stiffener section. The entire load was assumed to be carried to the stiffeners, i.e., the pipe walls carried no girth stresses.

(2) These beams were designed as continuous beams, taking a load equal to the resultant total pressure on the quarter circumference.

(3) The stiffener section was designed as a closed ring, taking direct and bending stresses due to the beam loads. A width of plate, equal to one-sixth the span, was assumed acting with the stiffener angle to make up the stiffener section.

(4) No allowance has been made for the strengthening effect of the adjacent quadrants upon each of the four beams. The allowable unit stress in bending of 15,000 pounds per square inch had been used, and the plane of bending has been taken through the centre of gravity rather than through the nodes.

As to assumption No. 1 where the entire load is considered as carried to the stiffeners, it has been shown in several works on elasticity* that a circular unstiffened tube with a small ratio of thickness to diameter tends to buckle under uniform external loads, the circumference breaking up into a varying number of even division, prior to failure, beginning with 4 where it is comparatively stable. The critical value of the pressure beyond which more than four divisions occur and where the tube becomes highly unstable is $p = \frac{3\,EI}{r^3} = \frac{Et^3}{4\,r^3}$. Using this formula it can be readily shown that the load carrying capacity of the plate as a tube is very nominal without stiffeners. Taking the author's example for a true circular section, the critical value of $p$ for a thickness of 7/16 of an inch and a radius of 60 inches is 2.93 pounds per square inch. This is less than 20 per cent of the load of 15 pounds per square inch which must be carried. Moreover, for an elliptical section with $\frac{\Delta}{r} = 0.01$ as the true original shape of pipe, the eccentricity sets up girth bending moments which cause further deflections, which would further limit the critical value of $p$.

As to the assumption No. 4 it is probable that an experienced designer in making a solution in the absence of Mr. Johnson's exact method would allow for the stiffening effect of the adjacent sections of the pipe by using a higher unit stress in the plate rather than shift the axis of the plate from its centre of gravity to a chord through the nodes. Even with this assumption and a unit stress as high as 20,000 pounds per square inch in the steel plate, there would still be a saving of approximately 4 per cent in weight and 7 per cent in cost, if the pipe were designed in accordance with the author's formulae.

*See "Applied Elasticity," by Timoshenko and Lessels.

Eugene E. Halmos[6]

This paper, while seemingly a formidable mathematical treatise, is of the greatest practical value to the profession. It places at the disposal of engineers formulae, sadly lacking heretofore, with the help of which they will be able rationally to solve problems now necessarily handled by the "common sense" or "rule of thumb" method.

The problems to which the subject matter of the paper is applicable are numerous and are frequently encountered in almost every field of engineering activity. It appears that there should have been a long standing and widespread demand for thorough knowledge of the stress conditions existing in circular pipes with both rigid and yielding stiffeners supporting external fluid pressure and it is truly remarkable that something new could be produced in this field of structural mechanics. Nevertheless, the writer believes that the formulae developed and published by Mr. Johnson are the first which make it possible to design such pipes, like any other structure, for definite stresses and with a known factor of safety.

The writer knows of three previous formulae dealing with the strength of pipes subjected to external fluid pressure:

(1) The Boussinesq* formula

$p = 3\,IE/r^3$ or, in the author's notation $p_o = Et^3/4r^3$. . .(a) giving the unit exterior fluid pressure, under which an unstiffened circular pipe of given material, radius and shell thickness will just fail.

(2) An equivalent formula, which includes the effect of Poisson's ratio, was derived by Bresse in 1829,

$$p_2 = \frac{Et^3}{r^3}\left(0.25 + 2.706\,\frac{r^4}{l^4}\right) \qquad \text{(b)}$$

This formula, derived by Forcheimer, was published by the writer himself.† It proposes to give the unit exterior fluid pressure, under which a pipe of given material, radius and shell thickness, of a length $l$ between, and simply supported by, rigid stiffeners, would just fail.

This formula was reached incidentally in a study of the strength against buckling of a pipe loaded in an axial direction. In its derivation no account was taken of the beam-strength of the shell quadrants and, therefore, the rupture pressure given by the formula is too low, or, conversely, the thickness of the shell for a given rupture pressure is too great, or the distance between stiffeners too small.

(3) A third formula,

$$p_k = \frac{2\,E}{(n^2-1)\left[1+\left(\frac{nl}{\pi a}\right)^2\right]^2}\cdot\frac{h}{a} + \frac{2\,Em^2}{3\,(m^2-1)}\left[n^2 - 1 + \frac{2\,n^2 - \frac{m+1}{m}}{1+\left(\frac{nl}{\pi a}\right)^2}\right]\cdot\frac{h^3}{a^3} \qquad \text{(c)}$$

where

$p_k$ = critical unit radial pressure on pipe shell
$l$ = length of pipe between bulkheads
$a$ = radius of pipe
$2\,h$ = thickness of pipe
$\frac{1}{m}$ = Poisson's ratio
$n$ = a positive whole number $\geq 2$, which makes $p_k$ a minimum. It should not be confused with the symbol $n$ in the author's notation.

[6] Chief Engineer, Parklap Construction Corporation, New York, N.Y.

*Comptes Rendus 97 (1883), pages 844, 1131.

†Trans. A.S.C.E., Vol. 85, page 668. According to Engesser, "Centralbaatt der Bauverwaltung," Vol. 8, the coefficient of the second member in the bracket would become 13.5 for a shell fixed to the rigid stiffeners.

Values of $n$ for different ratios of radius to length and of shell thickness to radius, are given in the table below:—

| $\frac{100\,h}{a}$ | .2 | .4 | .6 | .8 | 1.0 | 1.2 | 1.4 | 1.6 |
|---|---|---|---|---|---|---|---|---|
| $\frac{a}{l} = 0$ | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 |

| $\frac{a}{l} = 0.3$ | 6 | 5 | 5 | 4 | 4 | 4 | 4 | 4 |
| $\frac{a}{l} = 0.4$ | 7 | 6 | 5 | 5 | 5 | 4 | 4 | 4 |
| $\frac{a}{l} = 0.5$ | 8 | 6 | 6 | 5 | 5 | 5 | 5 | 4 |

Now $n$ represents the number of waves into which the pipe shell divides itself at the point of failure; and $2\,n$, therefore, is the number of nodes. The formula is not applicable for the cases when the computed critical load, $p_k$, would result in a direct compressive stress in the pipe shell, $p^k a/2\,h \geqq$ the elastic limit of the material. For steel, with $E = 30 \times 10^6$ pounds per square inch, and an elastic limit of 27,000 pounds per square inch, the values corresponding to this condition are those below and to the right of the heavy line in the table.

This formula was derived by R. von Mises* for the case of a pipe fixed at its ends to rigid bulkheads. The formula correctly expresses the amount of the external pressure under which such a pipe, of given material, radius, shell thickness and length will be at the point of failure. The results of a number of tests, made by loading pipes of various sizes to destruction, demonstrated a satisfactory agreement between the calculated and observed rupture pressures.

It will be noted that (leaving lateral deformation out of consideration) formulae (b) and (c) revert to formula (a) for $l = \infty$, which is the case of an unstiffened pipe. This same result is obtained from the author's formula (30).

As already pointed out, formulae (a), (b) and (c) are intended to give the unit radial, exterior pressures, under the action of which a perfectly circular pipe will fail. They do not give the critical pressure for tubes which are "out of round" nor any information on the unit stresses in the pipe shell and stiffeners when loads are applied which fall below the rupture loads or when stiffeners are used which are not perfectly rigid. Nevertheless, it is customary to use the formulae for design by arbitrarily choosing 1/3, 1/4 or 1/5 of the critical load as the permissible loading of the pipe, on the assumption that the factor of safety will increase in the inverse proportion. Such a procedure, of course, is not founded on facts and may lead to faulty or uneconomical design, or both. This uncertainty is eliminated by the use of the author's formulae which give practically correct results as to the magnitude of the actual stresses in the pipe shell and stiffeners for any assumed loading and deviation from the true circle in all cases when the design is such that these stresses are well within the elastic limit of the structural material as is usually required by the specifications.

*Zeitschrift des Vereines Deutscher Ingenieure, 1914.

The method followed by the author in deriving his formulae is original and nothing short of ingenious. He first describes the observed behaviour of a pipe under external load and states that, for proper design, the formation of only 2 complete waves (4 beams) in the shell should be considered.

A study of the table just given reveals the interesting fact that as the product of the shell thickness and length increases, the number of nodes decreases and approaches 4 so that $n = 2$. The decrease in the rigidity of the stiffeners evidently has the same effect as the increase in length. Also, the author's working formulae are predicated on a reasonable proportional rigidity of pipe shell and stiffeners which tends to increase the product $hl$ (or $tl$) and enhances the formation of a minimum number of nodes. If we now consider that, by hypothesis, the pipe is already slightly out of round, it becomes obvious that the assumption of 4 nodes by the author is warranted by theory as well as by practical experience, so long as the shell thickness is sufficient to permit the shell quadrants to maintain their integrity as beams acting between stiffeners.

The author takes no account of the effect of axial and shearing forces, and of Poisson's ratio on the deformation of the shell and rib and assumes that all deformation is due to bending moments only. The writer believes that these omissions are fully justified within the limits claimed for the application of the author's formulae. The studies made by Becker,* Matsumura and Mahabe† and Haigh‡ give sufficient evidence to show that, for practical purposes, the author's assumptions are permissible.

The author did not follow the method of analysis according to Love, Timoshenko and von Mises, nor that more recently developed by Bauersfeld and Dischinger; von Mises found the rigorous solution of the critical external pressure of a pipe with rigid ribs and Dischinger that of the stresses in a thin vault acting as a beam with rigid diaphragms at the point of support. The solution of these problems by means of the "membrane theory" led to extremely involved mathematics and the writer ventures the opinion that the attempt to solve the problem on hand in the same rigorous manner would meet with insurmountable analytical difficulties.

The author approaches his task by first evaluating the co-efficients which permit the expression of bending moments in terms of deflections and vice versa. Next, based on sound reasoning and by remarkable skill in mathematical treatment, he determines the portion of bending moment supported by the girth strength of the shell and that supported by the rib to which it is transmitted through beam action. Eliminating successively the unknown terms, he finally expresses these moments in known quantities, and, dividing by the proper section modulus, he arrived at the stresses sought.

In the course of the operations just described, the author makes two approximations, both of which are believed to be permissible.

The first, and more important, is that the author treats the beams as if they were able to deflect independently of each other. This, of course, cannot be so, because one beam deflects inward, the other outward, and they are joined at the nodes which are contained in the plane of the neutral axes of both beams. Therefore, in the vicinity of the nodal lines, there must be a region in the shell where an adjustment of these two tendencies must take place. The writer believes that this region is too narrow to affect materially the value of the moment of inertia of the beam

*University of Illinois Eng. Expt. Sta. Bull. 85.
†Memoirs Coll. of Eng. Kyoto Univ., 1915.
‡Proc. British Assn. 1919 and 1921.

cross-section. He bases his opinion, first, on the fact that the deflections should be very small with the working stresses assumed and the large section moduli of the shell quadrants and, therefore, the adjustment can take place in a short distance from the node especially when it is considered that the formulae are recommended only for thin shells having a thickness of 0.006 to 0.02 of the radius. Second, the author's formulae revert to the classical formula (a) for $l = \infty$; and, finally, a comparison of results obtained from formula (36) shows a reasonable agreement with those of formula (c) and with values furnished by tests.

The second approximation is, that the author used, for $I'$, the moment of inertia of a circular quadrant instead of the deformed one. The permissibility of this procedure seems obvious.

The consideration of imperfect construction is extremely important from a practical point of view. It is obvious that, even should the use of any of the formulae (a), (b) or (c), if the safety factor is selected high enough, result in a safe theoretical pipe, a comparatively small deviation from the circular shape in the actual pipe may reduce the margin of safety to zero. The great value of the author's paper is believed by the writer to lie in that it gives to the designer the means of fitting his design to practical tolerances.

Dr. T. H. Hogg, M.E.I.C.[7]

The author is to be complimented in having derived a workable formula, which is particularly useful in the determination of the maximum stress in the stiffening rib angles of a circular tube subject to uniform external pressure. He states that the same principles are also applicable to penstocks under partial vacuum, but presumably this would not apply to horizontal pipe lines or tunnels under external water pressure, except where the external pressure is of large magnitude compared with the diameter of the pipe.

Empirical formulae have been derived from tests to determine the allowable plate thickness for cylindrical furnaces. One of these is the Board of Trade formula

$$WP = \frac{99{,}000 \times t^2}{(L + 1)\, d}$$

where

$WP$ = working pressure in pounds per square inch,
$t$ = allowable thickness of plate in inches,
$L$ is the unsupported length of the tube in feet, and
$d$ is the diameter of the tube in inches.

In these tests, made on tubes up to 3 feet in diameter, the tube is probably completely restrained from distortion at the ends.

Mr. Johnson's study, however, covers the condition where the stiffening ribs are of less than infinite rigidity. Since the bending in circular pipes subject to external pressure is due to deformation in manufacture, the author's basis of assuming a reasonable limit of deformation to be specified and the design of the various members to meet this requirement, appears a most logical procedure. The tolerance recommended by the author appears a reasonable one, viz., a difference of one per cent between diameters in the same transverse plane.

The practical application of formula No. 40, as worked out in the numerical example given, is of great interest. The law of similitude mentioned is particularly useful, and should enable the preparation of tables or curves for given working pressures and plate thickness. A tabulation which has been worked out from Mr. Johnson's formula and the law of similitude is given below. The figures given are for a head of water of 40 feet on the rib, and a maximum stress in the rib of 15,000 pounds per square inch.

| Plate Thickness | Rib Angle | Rib Spacing | Diameter |
|---|---|---|---|
| inches | inches | inches | inches |
| ¼ | 3½ × 3½ × ¼ | 100 | 69 |
| 5/16 | 4 × 4 × 5/16 | 126 | 86 |
| ⅜ | 5 × 5 × ⅜ | 151 | 103 |
| 7/16 | 6 × 6 × 7/16 | 176 | 120 |

The rib angles have been assumed to have equal legs, and to be of the same thickness as the plate, which simplifies the determination of the maximum stress, and at the same time provides good structural design. Similar tables could be calculated for other heads.

The profession is indebted to Mr. Johnson for his many contributions on hydraulic subjects, particularly in connection with the design of Johnson valves, surge tanks (both simple and differential), and intakes. The writer was fortunate in having been associated with him in the early days at Niagara Falls on differential surge tank studies, on which subject he has given much extremely interesting and useful data. This work has now been supplemented by this present paper on the determination of stresses in the internal riser, which offers a rational solution to a heretofore uncertain feature of design.

Herbert J. Laber[8]

The author is to be complimented for his valuable contribution to a definite phase of engineering. Designers who have been confronted with the problem of properly stiffening a tube under external pressure will fully appreciate its merit.

When the engineer considers the great amount of uncertainty involved in using stability equations based on infinite stiffeners in such designs he comes to the conclusion that he never knew how much of a factor of safety there actually was, either on the load or stress. This paper, which is an expression in stress, now made it possible for the designer to compute with fair accuracy his margins of safety on stress and load.

The author's conception of a figure slightly out of round initially in the development of his theory deserves praise. Here, for the first time, is a stress equation based on a practical shape with which engineers have to deal. Theories based on perfectly circular tubes with infinite stiffeners are subject to criticism in that they involve theoretical rather than practical structures. The writer does not discredit earlier theories involving collapsing pressures but merely endeavours to point out the practicability of the author's paper.

Although the author professes little credence in his values of $p_c$ it is interesting to see just how these compare with some experiments, and those as computed from the collapsing pressure equation of R. von Mises*. The experiments listed are those of Fairbairn† and Bach‡, with all the values tabulated to conform to the author's nomenclature.

A résumé of the Fairbairn experiments indicates four of the author's values for critical pressure practically agreeing with the experiments, one value less, and the remaining three greater. A similar comparison of the Bach experiments shows two values less than the experimental and the remaining value greater by 6.5 per cent. It should be noted, however, that the collapsing pressure in each

case of the Bach experiments, according to Mises equation is greater than either the experimental or the author's value of $p_c$. In the Fairbairn experiments, however, the collapsing pressures according to Mises equation agree more closely at times with the tests than do those determined by the author's equation. Fairbairn covered no great range in his experiments but merely confined them to tests on tubes of small diameters. Because of this limitation it is possible that his specimens conformed more nearly with the rigid requirements demanded by the Mises equation and consequently the loads computed with the latter are more nearly an indicator of the collapsing pressures.

When the experiments of Bach are considered the results agree more with the author's theory. This probably can be partly accounted for by the larger diameter of tubes. Here a true circular form is more difficult to obtain and hence the premises are not strictly adaptable to the stability theory. When it is realized that the author's equation is an expression at the limit of a theory involving stress on a shape slightly out of round initially his value of $p_c$ is a better indicator of collapse when any eccentricity in shape is likely to be present. Fairbairn attributed some of the discrepancies in his experiments to the fact that some of his specimens were possibly out of round to a slight degree. Although the author's theory differs entirely with the thought involved in Mises derivation it is interesting to note that the same number of nodes are developed using the two equations for collapse.

The purpose of the foregoing comparison is not to prove the accuracy of the author's equation over others but merely to illustrate the possibilities of its usage.

Professor G. H. MacCullough[9]

The difficulty of the problem which Mr. Johnson has had the courage to attack in his paper is appreciated. Therefore it is not surprising that during a casual reading of this paper several queries arose in the mind of the present discussor. Perhaps a more detailed explanation of some of the assumptions would have cleared up some of the apparent difficulties. The following comments may be pertinent:—

1. Has the elastic stability of the pipe wall been considered?

2. The author assumes four kinds of loads. It is not clear how each arises. Are these loads forces or are some of them moments at various sections? Are they real or artificial loads?

3. If there are axial forces present as well as forces at right angles to the deflection curve, the statement of the first paragraph, page 3, concerning the sum of the individual deflections equaling the resultant deflection is questionable. For under these conditions, there is no linear proportionality between the magnitude of the compressive force and the deflection which it produces.

4. When dealing with plates, such as the wall of the pipe should not $\frac{E}{1-\mu^2}$ be used instead of $E$? $E$ is correct only for bending of ordinary beams. $\mu$ is Poisson's ratio.

Julian C. Smith, M.E.I.C.[10]

This paper seems to the writer to be an original and valuable contribution to the mathematical treatment of a difficult subject. The engineer who gets the usual amount of mathematics finds in books on mathematics or hydraulics a treatment of circular tubes, under external pressure, which shows only compressive stresses up to the point of failure. The tube, however, does not ordinarily fail in this way. Usually it begins to collapse from instability, and by the time the full strength of the material is reached the tube will have deformed to such an extent that it is useless for the purpose which it was to fulfil.

The introduction of stiffening rings changes this elementary conception of stress, by introducing longitudinal stresses arising from beam action. With truly circular tubes having truly circular stiffeners of infinite rigidity, the strength of the tubes is indeterminate, and is subject to slight variations in material, in thickness and in the method of attachment to the rings.

If the rings are not infinitely stiff, they will distort, and stresses will arise which, as the author points out, are complicated. His assumption of an initial departure from circular form is ingenious and original, and the concept of beam action is a reasonable simplification. On this basis, the argument proceeds mathematically until it is summarized in two equations with which a safe design can be made.

The author does not go into details as to many applications of his mathematical treatment of this problem. He has used it, as he states, in the design of the risers in the surge tanks, these risers under certain conditions being under external pressure. There are many other instances which would occur to an engineer in which this problem is of importance. Pipes laid under water, or under ground sufficiently soft to permit an assumption of uniform pressure: submarines and other structures of this shape are all problems of importance to engineers.

The mathematical development appears difficult because it is necessarily much condensed. Once the fundamentals are clearly seen, the rest of the subject follows from some very complicated substitutions which do not require any advanced mathematical theory, though one may admire the ingenuity exhibited in their treatment. The physical meaning of these substitutions, however, will probably be apparent only to a few.

The Institute is fortunate in the presentation of such a paper: one which will stimulate interest and thought on the part of our members in this method which gives a direct solution to a problem of frequent occurrence.

R. D. Johnson[11]

An insignificant error in the "Percentage Increases" listed in the table should be noted. These may be refined with sufficient accuracy by multiplying each of them by

(9) Professor of Engineering Mechanics, Worcester Polytechnic Institute, Worcester, Mass.

(10) President, Shawinigan Water and Power Company, Montreal.

(11) Hydraulic engineer, 67 Wall Street, New York, N.Y.

the quantity (1.21 — .01 $n$). This error is the result of a trifling misstatement of the general expression* for the moment of inertia of a segment of tube about its chord as an axis. If the discrepancy had remained undiscovered, no harm would have been done.

The author wishes to take this opportunity to express his appreciation of the interest shown in his monograph and to thank those who have participated in the discussion.

He expected his analysis would receive the benefit of criticism by two distinct classes of commentators, namely, expert technicians who would be inclined to discredit it and competent engineers who would be likely to endorse it. The prevalence of the former class on committees of the two great American engineering societies drove him abroad for enough understanding to gain acceptance of his paper for publication. The latter class have been able to follow his reasoning without assistance from him and he could but conclude that further elaboration is unnecessary. The approval of such men as Messrs. Smith, Gibson, Hogg and Halmos constitutes adequate confirmation. Mr. Macphail's effort at elucidation was effective enough to bring forth Dr. Gibson's concise statement that "All the equations have been substantiated" not only by himself but evidently also by Messrs. Strowger and Bernstein.

A careful reader will discover that the author accomplished, at any rate, what he set out to do when he arrived at the closely approximate equation (40) having shown that the value of $K$ is usually so small as to be negligible. Therefore, no matter how many technical faults may be found in the behaviour of shell stresses as set forth, the fact remains that engineers have received substantially if not precisely what they have long been seeking. That is all he tried to do and he is little interested in controversies over fine points which would doubtless ensue. The paper is more practical than academic.

Mr. Doughty's comments are clearly the result of much sound and careful thought. The precise extent to which the stated shell stresses and deflections depart from the truth must apparently remain in doubt pending further refinement. Meantime, the author retains his own faith in their reliability, sufficient at least for an accurate outcome of his purpose.

Mr. Boardman opened his discussion vigorously by repudiating the whole analysis, denying the basic consideration that bending stresses are directly proportional to $\Delta$. Defence against this and his other imputations, seem impossible without repetition of arguments.

Professor Cook might find Mr. Laber's comparisons satisfactory. They were largely new to the author and most gratifying. Necessity for improvement in the proposed method of design was not here indicated.

It was suspected that Professor MacCullough's casual reading accounted for the questions, which would doubtless later resolve themselves. It may be remarked, however, that "elastic stability" has been so well considered as to have been almost entirely discarded; that "four kinds of loads" have not been assumed but proved to be acting; that extraneous axial forces have been neglected as unimportant especially when shortening of the tube under load is permitted; that the use of Poisson's Ratio has not been considered necessary in the type of analysis submitted.

The author begs to be excused from trying further to justify his conclusions to experts whose methods, however laudable and generally superior to his own, have nevertheless been incompetent, thus far, to produce a design both economical and trustworthy for the particular case under consideration. It is assuming too much to suppose that he could be more convincing by striving to emulate them. He wishes to reiterate that no claim is made to a rigorous analytical perfection and some minor errors may be expected to become evident, as many discarded odds and ends, thought to be unimportant, may be woven into the theory by those who are clever enough. Engineers, however, are interested only in such criticism as would improve the practical formulae offered and the experts are invited to furnish something better than mere doubt.

* $I' = r^3 t\,(\theta - 3\sin\theta\cos\theta + 2\,\theta\cos^2\theta) + rt^3\,(\theta - (1/3)\sin\theta\cos\theta)/4$
where $\theta = \pi/n$

## The Toronto Centenary

Canada is commemorating this year two events which stand out in the country's romantic history, and which are separated by an interval of three hundred years. In 1534 Jacques Cartier made his first voyage in search for a north-west passage to the east, landed at Gaspé, and sailed up the Gulf of St. Lawrence. In 1834 the City of Toronto was incorporated and the little settlement of York came into its own.

The French adventurers of the sixteenth and seventeenth centuries were well endowed with that spirit of enterprise which has resulted in the building of Canada as we know it today. Cartier himself ascended the St. Lawrence as far as the Lachine Rapids, and his voyages led the way for his successors, Champlain and his followers, whose work, more than seventy years later, ultimately resulted in the establishment of the French regime in Lower Canada. Some of the early French explorers were traders; some were churchmen; others, like LaSalle, were in the King's service. Many of our principal cities now stand on sites marked out by these men, and one of them is Toronto.

In 1720 a French trading post was established at a harbour on Lake Ontario, named by the Indians "Place of Meeting," and later a fort was built there to check the enterprise of the English, who were then active at Oswego across the lake. This fort, known as Fort Rouille, was abandoned after the termination of the French regime, but in 1794 its site was selected by Governor Simcoe as the seat of government of the new province of Upper Canada. It is interesting to note that one of the first ceremonies of the Toronto Centenary this year, held on May 24th, was an official reception of descendants of the Marquis de la Jonquière, who was Governor of New France at the time of the building of this fort, and the descendants of Major-General Simcoe. The town was named York, and the first Provincial Parliament met there in 1797.

At that time the backbone of the population of Ontario was composed of the Loyalists from the newly formed United States, who sought homes under the British flag, and who gave to Upper Canada its desire for tolerance and responsible government. The town saw something of the war of 1812, suffering severely at the hands of the American Generals Pike and Dearborn. At that time the population numbered only 456. When peace was restored the work of creating a capital for Upper Canada was resumed, and in 1834, by which time the population numbered 9,256, the Provincial Legislature incorporated the city under the original Indian name of its site, Toronto. The inhabitants lived mainly between York street and the Don, and several public buildings, such as the Parliament Buildings and Osgoode Hall, had already been erected, together with a residence for the Lieutenant-Governor. The principal power plant of the city at that time was a windmill near the mouth of the Don.

Following incorporation, the first years of the city's existence were somewhat troubled by political unrest, but after the union of Upper and Lower Canada in 1840 this condition terminated when much needed reforms were obtained during Lord Elgin's Governorship.

The railway era of the 50's gave great impetus to the growth of Toronto and it became a terminal and distributing point for the railways which began to cover the more thickly settled portions of the province. The first locomotive built in Canada was constructed in Toronto in 1853, and the first through train between Toronto and Montreal ran over the Grand Trunk Railway in October 1856. Since that time the growth of population has been rapid, being over 40,000 in 1864, passing the 100,000 mark in 1884, and reaching 600,000 in 1928.

With citizens mainly of British stock, Toronto has also become the home of many new Canadians from continental nationalities, a fact which gives a cosmopolitan tinge to its crowded streets. The striking view of Toronto's towering buildings, as seen from the harbour, is a visible sign of the city's importance as a commercial, industrial and financial centre, a status exemplified by banking statistics which showed bank clearings of over four billion dollars in 1932. Lying in the most highly industrialized area of Canada, the gross value of its manufactured products was over five hundred million dollars in 1930. Ever since the development of the Cobalt camp in 1907, Toronto has held a leading position in connection with the mining industry, and Ontario, with a mineral production of a hundred million dollars a year, looks to the city as the headquarters of that industry.

The city is justly proud of its harbour, that natural feature which adds so much to its amenities, and is of such importance as the only harbour of refuge on the north shore of Lake Ontario. Harbour development, particularly during the last decade, has been remarkable, and the Harbour Commissioners, while reclaiming nearly two thousand acres of land suitable for industrial areas, have provided wharfage and harbour terminals for the use of large steamers up to 25 feet draught, and have taken the opportunity of constructing a new thoroughfare along the entire waterfront of the city from east to west, leading from the industrial centres in the east to the Exhibition Grounds and the recreational and park areas at the west end. There are few cities whose waterfront development has been so well balanced, or where the various agencies of modern transportation have been so well co-ordinated in the interests of both commercial activity and the public welfare. The city administration in Toronto has always been progressive as regards public health and sanitation, and the cheap and plentiful supply of electrical power developed in Ontario by the Hydro-Electric Power Commission has enabled its citizens to take full advantage of the most modern aids to domestic life. In all of these projects the engineer has had a leading part, whether in construction, highway development, transportation, or in the civic services.

Today Toronto is an outstanding Canadian example of a great city which is not only a busy centre of commercial, industrial and educational activity, but is pre-eminently a city of homes. Its Centenary is being marked by a series of ceremonies which began on March 5th, the actual anniversary of the city's Charter, were followed on May 24th by a characteristic historic pageant, and which will be continued during the summer and fall. In carrying out all these events, and in reviving the memory of their historic past, Toronto citizens have the hearty goodwill of their fellow Canadians, from their own province, from the Maritimes, the Province of Quebec, the Prairies, and the Pacific Coast.

## Meeting of Council

A meeting of Council was held at Headquarters on Friday, June 15th, 1934, at eight o'clock p.m., with President F. P. Shearwood, M.E.I.C., in the chair, and ten other members of Council present. Mr. D. C. Tennant, M.E.I.C., chairman of The Institute's Committees on Membership and Unemployment, was also present by request.

Replies were received from several of the Ontario branches in regard to the point raised by Mr. H. D. Anger, Barrister, of Toronto, regarding the difficulty in cases where engineers perform work for municipalities in Ontario without engagement in the form prescribed by law. As a result, it was decided that the corporate members of The Institute in Ontario should be informed regarding the situation, and that a communication should also be addressed drawing the matter to the attention of the Association of Professional Engineers of Ontario.

A memorandum presented by Councillor C. M. Pitts, dated May 30th, 1934, with reference to the co-ordination of the engineering profession in Canada, received further consideration, and expressions of opinion were read from a number of members of Council regarding Mr. Pitts' plan. Past-President Lefebvre outlined the activities of The Institute in this direction, which had been commenced in 1925, explaining the reasons for the slow progress that had been made. He pointed out that the co-ordination of the Professional Associations themselves was now in the hands of a Committee of Eight, composed of representatives of the eight organizations concerned, and he believed that it would be undesirable at this time to complicate matters by the formation of an Institute committee. After further discussion it was resolved to give the matter further consideration in the fall.

Discussion took place regarding the subject for the Past-Presidents' Prize for the year 1934-1935, and it was unanimously decided to approve the subject recommended by the Lethbridge Branch, namely, "The Co-ordination of the Activities of the Various Engineering Organizations in Canada."

Mr. Tennant, chairman of The Institute's Membership and Unemployment Committees, attended by request, and reported regarding the recent activities of these committees. It was noted that the applications for admission showed some increase as compared with last year, but Mr. Tennant felt that there should be no relaxation of the efforts made by the various branches to induce qualified engineers to join The Institute. This could only be done if members in each branch took an active interest in the problem.

As regards unemployment, the committee's report indicated a distinct improvement as compared with last year, but it was realized that there was still much work to be done by the branch unemployment committees.

Following a letter from Mr. J. J. Traill, M.E.I.C., chairman of the Toronto Branch Annual Meeting Committee for 1935, it was decided that the Forty-Ninth Annual General and General Professional Meeting of The Institute should be held on Thursday and Friday, February 7th and 8th, 1935, at the Royal York Hotel, Toronto.

Nine resignations were accepted, a number of reinstatements were effected, one special case was dealt with, and one Life Membership was granted.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

| *Elections* | | *Transfers* | |
|---|---|---|---|
| Member | 1 | Member to Assoc. Member | 2 |
| Assoc. Members | 4 | Junior to Assoc. Member | 3 |
| Juniors | 4 | Student to Assoc. Member | 2 |
| Students admitted | 14 | | |

The Council rose at eleven forty p.m.

## Annual Meeting 1935

At the meeting of Council held on June 15th, 1934, the invitation of the Toronto Branch to hold the Forty- Ninth Annual General and General Professional Meeting of The Institute at Toronto on February 7th and 8th, 1935, was accepted with appreciation.

## The Past-Presidents' Prize 1934-35

Council has selected as the subject of the essays to be submitted for the competition for the prize year July 1st, 1934 to June 30th, 1935:—

### The Co-ordination of the Activities of the Various Engineering Organizations in Canada

The rules governing the award of this prize are as follows:—

The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved, as the case may be.

The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July first to June thirtieth.

The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local branch.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on June 15th, 1934, the following elections and transfers were effected:

*Member*

STIRLING, John Bertram, B.Sc., (Queen's Univ.), partner in firm, E. G. M. Cape and Company, Montreal, Que.

*Associate Members*

BECK, Humphrey Campbell, (Fed. Polytechnic Inst., Zurich), engr. for Brown-Boveri & Company, (Home) Sandringham, Norfolk, England.

CORNER, Edward Ponsonby, (Glasgow Tech. Coll.), representative, Prov. of Quebec, Hamilton Gear and Machine Co., 1120 Castle Building, Montreal, Que.

GILBERT, Gordon Macdonald, B.Sc., (Univ. of Man.), acting engr. and supt., Vancouver and District Joint Sewerage and Drainage Board, Vancouver, B.C.

HANSEN, Darrel Adrian, B.Sc., (Univ. of Alta.), asst. to divn. engr., Northern Division, Calgary Power Company, Edmonton, Alta.

*Juniors*

GAUDEFROY, Henri, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), 4590 Hutchison St., Montreal, Que.

GILCHRIST, John, B.Sc., (Univ. of N.B.), designer and dftsman., General Steel Wares, Montreal, Que.

STEPHENS, Donald McGregor, B.Sc., (Univ. of Man.), technical dftsman., surveys br., Dept. of Mines and Natural Resources, Winnipeg, Man.

TAYLOR, Andrew, B.Sc., (Univ. of Man.), technical dftsman., surveys br., Dept. of Mines and Natural Resources, Winnipeg, Man.

*Transferred from the Class of Associate Member to that of Member*

EVANS, Edwin Ronald, (Mt. Allison Univ.), civil and struct'l. engr., Lewisville, N.B.

GAHERTY, Geoffrey Abbott, B.E., (Dalhousie Univ.), President, Montreal Engineering Company, Ltd., and Calgary Power Company Ltd., 244 St. James St., Montreal, Que.

*Transferred from the class of Junior to that of Associate Member*

O'HALLORAN, James, B.Sc., (McGill Univ.), plant engr., Anglo-Canadian Pulp and Paper Mills, Ltd., Quebec, Que.

SEXTON, Jack Kenneth, B.Sc., (Univ. of Sask.), Calgary Power Company, Ltd., Seebe, Alta.

WAY, William Russell, B.Sc., (McGill Univ.), asst. supt. of operation, Shawinigan Water and Power Company, Montreal, Que.

*Transferred from the class of Student to that of Associate Member*

COWAN, Elijah, B.A.Sc., (Univ. of Toronto), control man, Lake St. John Paper and Power Company, Dolbeau, Que.

LORD, George Ross, B.A.Sc., (Univ. of Toronto), M.Sc., (Mass. Inst. Tech.), lecturer in mech'l. engrg., Univ. of Toronto, Toronto, Ont.

*Students Admitted*

AMAN, Thomas Freeman Stewart, (Queen's Univ.), 77 Highland Ave., Belleville, Ont.

BELLAMY, Keith Lacy, (Queen's Univ.), 2548 Taylor St., Niagara Falls, Ont.

BENTLEY, Kenneth Earl, B.Sc., (N.S. Tech. Coll.), Billtown, Kings Co., N.S.

DAVIS, Ralph Cargill, B.Sc., (Univ. of Alta), Etzikom, Alta.

DEMOCKO, Gerald George, (Queen's Univ.), Fort William, Ont.

ELLIOTT, John Courtenay, B.Sc., (Queen's Univ.), 335 James St., Ottawa, Ont.

ELLSWORTH, Arthur Crayton, (Queen's Univ.), R.R. No. 1, Ridgeway, Ont.

GAYFER, Edwin Ralph, B.Sc., (Univ. of Man.), 9917-108th St., Edmonton, Alta.

HAZELTON, William Beverley, B.Sc., (Univ. of N.B.), Beebe, Que.

McCANN, William Neil, B.Sc., (Univ. of Man.), 2517 Wallace St., Regina, Sask.

MONTGOMERY, James William, B.Sc., (Univ. of Alta.), Wetaskiwin, Alta.

TAPLEY, Donald Gordon, B.Sc., (N.S. Tech. Coll.), 65 Walnut St., Halifax, N.S.

WALLMAN, Clifford George, B.Sc., (Univ. of Man.), 322 Home St., Winnipeg, Man.

WILLIAMS, Leslie Chevers, B.Sc., (Queen's Univ.), 23 Ossington Ave., Ottawa, Ont.

## Result of May Examinations of The Institute

The report of the Board of Examiners presented at the meeting of Council held on May 18th, 1934, certified that S. G. Johre, London, Ont., having passed the examination of The Institute under Schedule C for admission to Associate Membership, has satisfied the examiners as regards his educational qualifications for that class of membership.

# OBITUARY

## William Gore, M.E.I.C.

Widespread regret will be felt at the death at Long Branch, Ontario, on June 7th, 1934, of William Gore, M.E.I.C.

Born at King's Lynn, England, on April 13th, 1871, Mr. Gore was apprenticed to Alfred Dodman, M.Inst.M.E., at Kings Lynn from 1888 to 1892, and in 1892-1893 he was assistant engineer on the design, construction and erection of steam engines, boilers, pumps and general mechanical constructional work. From 1893 until 1896 Mr. Gore attended the Central Technical College of the City and Guilds of London, receiving the diploma of Associateship (A.C.G.I.), the Whitworth Exhibition in 1894, and the Siemens Memorial Medal in 1895.

WILLIAM GORE, M.E.I.C.

From 1896 until 1897 he was chief draughtsman to the Fowler Waring Gables Company at North Woolwich, England, and later, until 1899, was assistant to George F. Deacon, consulting engineer, London, on design, construction, arbitration and parliamentary work in relation to engineering works of highest magnitude. From 1899 to 1912 Mr. Gore was chief assistant to Mr. Deacon and to Sir Alex. Binnie, Son and Deacon, his successors, being connected with, among others, the following works: London Water Supply, Welsh scheme; Liverpool Water Supply, Vyrnwy scheme; Ebbw Vale Water Supply; London Underground Railways; Petrograd Water and Sewerage; Athens water supply; Malta and Gozo sewerage; Sydney sewage outfall; Ravi crossing Bari Doab canal irrigation project. In 1912 Mr. Gore became consulting engineer to Ransome verMehr Machinery Company of London, England, to John verMehr Engineering Company, of Toronto, and was located at Toronto, Ontario. In 1919 Mr. Gore became a partner in the firm of Gore, Nasmith and Storrie, consulting engineers, Toronto, retaining the association until the time of his death. During his association with that firm his wide experience in water works and sewerage problems caused Mr. Gore to be regarded as an authority on sanitary engineering and questions of public health. He was engaged on the water supply projects for Toronto, Ottawa, Belleville, Windsor, St. Thomas, Hamilton and Calgary. Among the principal sewerage and sewage disposal plants on which he advised may be named those for North Toronto, Toronto, York Township and Kitchener.

Mr. Gore was a member of the Institution of Civil Engineers, and the Institution awarded the George Stephenson gold medal to him in 1907.

He joined The Institute as a Member on January 29th, 1918.

# PERSONALS

Chas. W. West, A.M.E.I.C., formerly division engineer, Welland Ship Canal, Department of Railways and Canals, at Thorold, Ont., has been appointed superintendent engineer.

B. W. Pitfield, S.E.I.C., graduate in civil engineering from the University of Alberta this year, has secured a position with Canadian Industries Limited, Montreal.

Charles E. Garnett, A.M.E.I.C., vice-president and chief engineer of Gorman's Limited, Edmonton, Alta., was recently elected vice-president of the Canadian Institute of Mining and Metallurgy.

H. B. Price, S.E.I.C., has joined the staff of the Canadian Fire Underwriters' Association, Montreal. He graduated from McGill University with the degree of B.Eng., in 1932.

Donald Rhodes, S.E.I.C., is now district engineer in the Sherbrooke district of the Bell Telephone Company of Canada. Mr. Rhodes graduated from McGill University in 1928.

L. E. Ennis, A.M.E.I.C., has been appointed district engineer in the Quebec district of the Bell Telephone Company of Canada, and is now located in Quebec, Que. Mr. Ennis was formerly toll pole and wire engineer, at Montreal.

Eric L. Hartley, S.E.I.C., is now civil engineer in the Farm Lands and Properties Department of James Richardson and Sons Limited, Winnipeg, Man. Mr. Hartley graduated from Queen's University in 1933 with the degree of B.Sc.

W. J. S. Dormer, A.M.E.I.C., formerly division toll plant engineer, Quebec district, Bell Telephone Company of Canada, Montreal, has been appointed district engineer in the Three Rivers and Montreal suburban districts, with headquarters in Montreal.

R. L. Strong, S.E.I.C., is in the Ballistics Department of Canadian Industries Limited, at Brownsburg, Que. Mr. Strong, who graduated from the University of Toronto in 1931 with the degree of B.A.Sc., was in 1932 research assistant at McGill University, Montreal.

W. D. Black, M.E.I.C., president of the Industrial Relations Committee of the Canadian Manufacturers Association, and vice-president of the Otis-Fensom Elevator Company Limited, Hamilton, has been appointed employers' delegate to the International Labour Conference in Geneva.

Graham Kearney, M.E.I.C., is with the firm of Sawford and Kearney, electrical and mechanical engineers, Vancouver, B.C. Mr. Kearney had been engaged in private practice in Montreal since 1932. He was at one time sales engineer with the Canadian General Electric Company, Limited, Montreal.

E. D. Gray-Donald, A.M.E.I.C., superintendent of the power division of the Quebec Power Company, has been awarded the degree of M.Sc. from Laval University, Quebec. Mr. Gray-Donald graduated from McGill University in electrical engineering in 1926, and has since been with the Shawinigan Water and Power Company and the Quebec Power Company.

J. R. Donald, M.E.I.C., is president, and H. W. B. Swabey, M.E.I.C., is secretary, of the newly-formed firm of Donald-Hunt Limited, inspecting engineers and metallurgists, Montreal.

Mr. Donald, who was managing-director of J. T. Donald and Company, Limited, Montreal, graduated from McGill University in 1913, following which he joined the Nichols Chemical Company, Limited, at Sulphide, Ontario. The next year he was engaged in general consulting with J. T. Donald and Company Limited. From 1916-1918 he was chief inspector of explosives, chemicals, for the Ministry of Munitions, Canada, and in 1919 he was appointed chemical engineer and chief chemist of the Canadian Packing Company Limited, Toronto, later rejoining J. T. Donald and Company Limited.

Mr. Swabey has been associated with J. T. Donald and Company Limited since 1926. He was supervising engineer on the construction of the Atlantic, Quebec and Western Railway; resident engineer, for a time, on the construction of the Quebec and Saguenay Railway, and served the Canadian Pacific Railway Company as resident engineer on the construction of the Campbellford-Lake Ontario and Western Railway. During the war, as chief inspector of steel, Mr. Swabey had charge of the inspection of all steel and forgings for shells manufactured in Canada for the British government.

E. M. VanKoughnut, Jr.E.I.C., is now connected with Messrs. Crane and Company, a firm of stockbrokers, Montreal. Mr. VanKoughnut, who graduated from the Royal Military College, Kingston, in 1922, was in 1923-1924 with the Steel Company of Canada. In 1926-1928 he was on the staff of the Shawinigan Engineering Company, and in 1928 he was with the Brazilian Traction Company at Toronto. In 1929 Mr. VanKoughnut was in Sao Paulo, Brazil, with the Sao Paulo Tramway, Light and Power Company Limited. Mr. VanKoughnut was subsequently with the late Frederick B. Brown, M.E.I.C., Montreal.

A. W. Sinnamon, M.E.I.C., formerly works manager of the Van Dorn Iron Works Company of Cleveland, Ohio, is now factory manager of The Geometric Stamping Company of the same city. Mr. Sinnamon was born in Ireland, and upon coming to Canada in 1901, was first employed in the mechanical department of the Dominion Iron and Steel Company Limited, at Sydney, N.S., following which he was appointed chief engineer of the Canada Foundry Company Limited at Toronto, Ont. In 1913 he was engaged in private practice in Ottawa, and was later, for six months, chief engineer of the Anniston Ordinance Company, Alabama, returning to Montreal to accept the position of mechanical superintendent of Armstrong-Whitworth and Company of Canada, Limited. From 1917 to 1918 Mr. Sinnamon was manager of the Joliette Steel Company, Joliette, Que., and subsequently was engaged in organizing the Terrebonne Electric Power and Steel Company to develop hydro-electric power at Terrebonne, Que. In 1919 he was appointed assistant chief engineer of the Algoma Steel Corporation Limited, at Sault Ste. Marie, Ont. In 1921 he was engaged in private practice, and in 1924 he became mechanical engineer of The Hubbell and Benes Company, Cleveland, Ohio. In 1927 Mr. Sinnamon took over the position from which he has recently resigned.

## Recent Graduates in Engineering

Congratulations are in order to the following Students of The Institute who have recently completed their course at the various universities:—

### McGill University

#### Honours, Medals and Prizes

Daignault, Lawrence George, Verdun, Que.—B.Eng., (Ci.); Honours in Civil Engineering; British Association Medal.

Mellor, Alfred Geoffrey, Westmount, Que.—B.Eng., (El.); Honours in Electrical Engineering; The Engineering Institute of Canada Prize.

Sarault, Gilles Edouard, Outremont, Que.—B.Eng., (El.); Honours in Electrical Engineering; Montreal Light, Heat & Power Consolidated Second Prize.

Swartz, Joseph Norman, Fort William, Ont.—B.Eng., (Chem.); Honours in Chemical Engineering; British Association Medal.

Young, Gilbert Maxwell, Montreal, Que.—B.Eng., (Mech.); Honours in Mechanical Engineering; British Association Medal; The Jenkins Brothers Limited Scholarship.

### Degree of Bachelor of Engineering

Bellew, Leo Thomas Frederick, B.Eng., (El.), Montreal, Que.
Benoit, André Persillier, B.Eng., (Ci.), Montreal, Que.
Brumell, Orby Richard, B.Eng., (Mech.), Buckingham, Que.
Butler, John Arthur Tweed, B.Eng., (Mech.), Montreal, Que.
Clarke, Bruce Porteous, B.Eng., (Mech.), Lennoxville, Que.
Cross, Douglas Henry, B.Eng., (Mech.), Sherbrooke, Que.
Fraser, Allan Donald William, B.Eng., (El.), Outremont, Que.
French, Philip Bemis, B.Eng., (Mech.), Montreal, Que.
Graham, Charles Allison, B.Eng., (Mech.), Chesterville, Ont.
Gregory, Jack Henry, B.Eng., (Mech.), Winnipeg, Man.
Hankin, Edmund Alfred, B.Eng., (Mech.), Westmount, Que.
Harrison, Ronald Dex, B.Eng., (Mech.), Montreal, Que.
Johnson, James Richard, B.Eng., (Mech.), Revelstoke, B.C.
Kerr, Robert Allen, B.Eng., (El.), Montreal, Que.
McCann, Edward Howard, B.Eng., (Mech.), Regina, Sask.
McMath, Andrew Allan Brown, B.Eng., (Mech.), St. Lambert, Que.
Mullen, Thomas James, B.Eng., (Mech.), Montreal, Que.
Nichols, Judson Timmis, B.Eng., (Mech.), Westmount, Que.
Phillips, Robert Weston, B.Eng., (Mech.), Chambly Canton, Que.
Pistreich, Archie Loebel, B.Eng., (El.), Montreal, Que.
Rogers, Carl Lemual, B.Eng., (El.), Moncton, N.B.
Ross, Oakland Kenneth, B.Eng., (Mech.), Montreal, Que.
Sturdee, Charles Parker, B.Eng., (Mech.), Vancouver, B.C.
Tannenbaum, Joseph, B.Eng., (Mech.), Montreal, Que.

### Master of Engineering

Jehu, Llewellyn, B.Sc., (McGill Univ. '30); M.Eng., (Ci.), Lachine, Que.
Richards, Victor Lloyd, B.Sc., (Queen's Univ. '32); M.Eng., (Mech.), St. Thomas, Ont.
Savage, Palmer Ernest, B.Sc., (McGill Univ. '31); M.Eng., (Ci.), Montreal West, Que.

## Queen's University

### Degree of Bachelor of Science (with honours)

Campbell, Fraser, B.Sc., (Ci.), Richmond, Que.
Hillier, Cecil Henry, B.Sc., (Mech.), Sarnia, Ont.
Sawle, Ross Tregerthen, B.Sc., (El.), Welland, Ont.

### Degree of Bachelor of Science

Arthey, George Clayton, B.Sc., (Mech.), Tweed, Ont.
Blaine, Donald Smith, B.Sc., (Ci.), Trenton, Ont.
Buell, Milton Allan, B.Sc., (Ci.), Kingston, Ont.
Elliott, John Courtney Lang, B.Sc., (Ci.), Ottawa, Ont.
Ingles, Charles Leycester, B.Sc., (Ci.), Toronto, Ont.
Kauth, Carl Gladstone, B.Sc., (El.), Gowanston, Ont.
Klotz, Carl Otto Paul, B.Sc., (Ci.), Westboro, Ont.

## Nova Scotia Technical College

### Honours, Medal and Prize

Woods, William Daniel, Halifax, N.S.—B.Sc., (Mech.); Honours in Mechanical Engineering; the Governor-General's Medal; Association of Professional Engineers of Nova Scotia Prize.

### Degree of Bachelor of Science (with honours)

Bentley, Kenneth Earle, B.Sc., (Ci.), Billtown, Kings Co., N.S.
Holder, Allan Scott, B.Sc., (Mech.), Truro, N.S.
Reinhardt, Gerard Victor, B.Sc., (Mech.), La Have, N.S.

### Degree of Bachelor of Science

Bacon, Charles Ives, B.Sc., (El.), North Tryon, P.E.I.
Colgan, Patrick Joseph, B.Sc., (El.), Halifax, N.S.
Corkum, Philip Byron, B.Sc., (El.), Halifax, N.S.
Granville, Francis Xavier, B.Sc., (Ci.), Halifax, N.S.
Hamilton, Cecil Roy, B.Sc., (El.), Weymouth, N.S.
McLeod, Wilson Churchilll, B.Sc., (Mech.), Caledonia, Queen's Co., N.S.
Matheson, Joseph Silver, B.Sc., (Mech.), Halifax, N.S.
Powell, Clarence Wilhelm, B.Sc., (El.), Halifax, N.S.
Tapley, Donald Gordon, B.Sc., (El.), Halifax, N.S.

## University of New Brunswick

### Honours and Medal

Crowe, Frederick Ernest, Jeffrey, Kings Co., N.B.—B.Sc., (El.); Honours in Electrical Engineering; Lieutenant-Governor's Bronze Medal

### Degree of Bachelor of Science

Gorman, David Donald, B.Sc., (Ci.), Fredericton, N.B.
Hazelton, William Beverley, B.Sc., (Ci.), Beebe, Que.
Manzer, Ronald Wendell Mowatt, B.Sc., (Ci.), South Devon, N.B.
Stevenson, Charles Lester, B.Sc., (Ci.), Saint John, N.B.
Walker, Alexander Harold, B.Sc., (Ci.), Montreal, Que.

## University of Manitoba

### Honours and Medal

Love, Edwin Reginald, Winnipeg, Man.—B.Sc., (El.); Honours in Electrical Engineering; The University Gold Medal.

### Degree of Bachelor of Science

Brown, Alan Coatsworth, B.Sc., (Ci.), Winnipeg, Man.
Bubbis, Nathan Simon, B.Sc., (Ci.), Winnipeg, Man.
Dunlop, Duthie MacIntosh, B.Sc., (Ci.), Winnipeg, Man.
Lupton, Mac Joseph, B.Sc., (Ci.), Winnipeg, Man.
McCann, William Neil, B.Sc., (Ci.), Regina, Sask.
Mitchell, William Reginald, B.Sc., (Ci.), Winnipeg, Man.
Moore, Robert Hugh, B.Sc., (El.), Winnipeg, Man.
Sandilands, Adam, B.Sc., (El.), Winnipeg, Man.
Wallman, Clifford George, B.Sc., (El.), Winnipeg, Man.

### Degree of Master of Science

Woodhall, Thomas Latimer, B.Sc., (Univ. of Manitoba '30); M.Sc., (El.), Winnipeg, Man.

## University of Alberta

### Honours

Hayes, Herman R., Edmonton, Alta.—B.Sc., (Ci.); Honours in Civil Engineering with First Class General Standing.

### Degree of Bachelor of Science

Barnhouse, Frank William, B.Sc., (El.), Edmonton, Alta.
Burke, John Abel, B.Sc., (El.), Lethbridge, Alta.
Brownie, Frank Austin, B.Sc., (Ci.), Calgary, Alta.
Davis, Ralph Cargill, B.Sc., Etzikom, Alta.
Mair, Robert Comrie Mair, B.Sc., (Ci.), Edmonton, Alta.
Mason, George Anthony, B.Sc., (El.), Calgary, Alta.
Montgomery, James William, B.Sc., (Ci.), Wetaskiwin, Alta.
Pidoux, John Leslie, B.Sc., (Ci.), Edmonton, Alta.
Pitfield, Barclay Wallace, B.Sc., (Ci.), Edmonton, Alta.

### Degree of Master of Science

Jackson, Kenneth Arthur, B.Sc., (Univ. of Alberta '32); M.Sc., (El.), Pincher Creek, Alta.

## University of British Columbia

### Degree of Bachelor of Applied Science

Stirling, Andrew Grote, B.A.Sc., (Min.), Kelowna, B.C.
Thorne, Henry Leonard, B.A.Sc., (Geol.), Vancouver, B.C.

## University of Toronto

### Degree of Bachelor of Applied Science (with honours)

Girdwood, Arthur James, B.A.Sc., (El.), Barrie, Ont.
Lyman, Stuart Lauchland, B.A.Sc., (El.), Dundas, Ont.

### Degree of Bachelor of Science

Green, John Scott, B.A.Sc., (Mech.), Hagersville, Ont.

### Degree of Master of Applied Science

Bridgland, Charles James, B.A.Sc., (Univ. of Toronto '33); M.A.Sc., Toronto, Ont.
Hammond, Rowland Ernest, B.A.Sc., (Univ. of Toronto '33); M.A.Sc., Angus, Ont.

## Ecole Polytechnique

### Honours, Medals and Prizes

Faure, Marcel A., Outremont, Que.—B.A.Sc., (Ci.); The Ernest Cormier's Prize.
Fleury, Maurice, Outremont, Que.—B.A.Sc., (Ci.); Bronze Medal offered by Association des Anciens Elèves de l'Ecole Polytechnique.
Paquet, Jean M., Quebec, Que.—B.A.Sc., (Ci.); Honours in Civil Engineering; Silver Medal offered by Association des Anciens Elèves de l'Ecole Polytechnique.
Vincent, Paul, Outremont, Que.—B.A.Sc., (Ci.); Honours in Civil Engineering; Bronze Medal offered by Association des Anciens Elèves de l'Ecole Polytechnique.

### Degree of Bachelor of Applied Science

Lefebvre, Jean, B.A.Sc., (Ci.), Outremont, Que.
Descoteaux, Paul R., B.A.Sc., (Ci.), Montreal, Que.

# RECENT ADDITIONS TO THE LIBRARY

### Proceedings, Transactions, etc.

Institution of Mechanical Engineers: Proceedings Vol. 125, 1933.
Institution of Civil Engineers: Proceedings, Vol. 235, 1932-1933.

### Reports, etc.

*Ontario, Department of Mines:*
Bulletin 91, Report on the Mining Accidents in Ontario in 1933.
Bulletin 94, Mines and Metallurgical Works in Ontario in 1933.
*Canada, Department of Mines, Mines Branch:*
Investigations in Ore Dressing and Metallurgy, 1932.
Investigations of Fuels and Fuel Testing 1932.
*Quebec, Department of Municipal Affairs:*
Statistical Year Book 1933.
*Canada, National Research Council:*
Research Activities 1933-1934.
*Lethbridge Northern Irrigation District:*
Annual Report 1933.
*British Engineers Association:*
Classified Handbook of Members and Their Manufactures, 1934.
*Canada, Department of Mines, Geological Survey:*
Memoir 171, Geology and Ore Deposits of Copper Mountain, B.C.
*Canadian Electrical Association:*
Advance Reports for the 44th Annual Convention, June 1934.
*American Public Health Association:*
Chlorination in Sewage Treatment.
*Corporation of Professional Engineers of Quebec:*
List of Members 1934.
*Association of Professional Engineers of Ontario:*
By-laws, List of Members, etc., 1934.

### Technical Books, etc., Received

A History of the Growth of the Steam Engine, by R. H. Thurston (*Kegan Paul, Trench and Co., London*). (Presented by Mr. R. J. Durley, M.E.I.C.)
The Case for Railway Unification, an Address by E. W. Beatty.
Applied Hydro and Aero Mechanics, by Prandtl and Tietjens (*McGraw-Hill Book Company*). (Engineering Societies Monographs.)
Fundamentals of Hydro and Aero Mechanics, by Prandtl and Tietjens (*McGraw-Hill Book Company*). (Engineering Societies Monographs.)
Theory of Elasticity, by Timoshenko (*McGraw-Hill Book Company*). (Engineering Societies Monographs.)

# BULLETINS

*Pumps*—A 4-page folder received from Worthington Pump and Machinery Corporation, Harrison, N.J., gives particulars of Worthington single-stage volute Type R centrifugal pumps.

*Pulverized Fuel Equipment*—Foster Wheeler Corporation, New York, have issued a 24-page bulletin containing information regarding their aero type impact mill and Hardinge type tricone ball mill pulverizers. General information on auxiliary equipment used in pulverized fuel systems such as intervane and cross jet burners, level controllers for ball mills, dividers for unit systems, switching valves, etc. is given.

*Waste Heat Boilers*—A 12-page booklet received from Foster Wheeler Corporation, New York, describes the various applications of waste heat muffler boilers as applied to Diesel engines, natural gas engines, and blast furnace gas engines ranging from 90 to 7,000 h.p. It also describes waste heat water heaters used for heating process or service water with the heat in the exhaust gases of internal combustion engines.

*Steel Sheet Piling*—A 4-page circular received from Canadian Sheet Piling Company Limited, Montreal, gives particulars of steel sheet piling used in the extension of the Ouseburn quay, Newcastle-on-Tyne.

*Centrifugal Blowers*—The Roots-Connersville Blower Corporation, Connersville, Ind., have issued a 4-page folder containing particulars of type OI single-stage blower for handling air or gas under pressure or vacuum. These are made in capacities up to 8,000 cubic feet per minute at pressures up to 3 pounds.

*Speed Reducers*—A 12-page booklet received from the Hamilton Gear and Machine Company, Toronto, Ont., describes small size worm gear speed reducers and gives information on how to select the correct size of reducers which are made in a varied number of sizes and types.

*Radiators*—The Dominion Automatic Water Heater Company Limited, Toronto, have issued a 12-page bulletin giving particulars and dimension of types of Richvar convector type cast iron radiators, for steam, hot water, vapour or vacuum.

*Portable Instruments*—A 4-page folder received from the Roller-Smith Company, New York, N.Y. describes a line of portable measuring instruments known as Types NPD and NPA which includes direct current ammeters, voltmeters, milli-voltmeters and milli-ammeters of all ranges.

*Control Switches*—The Roller-Smith Company, New York, have issued Catalogue No. 9, an 8-page booklet describing Type R rotary instrument and control switches for switch-boards and control panels.

*Signaling Systems and Devices*—A 56-page catalogue published by Edwards and Company of Canada, Limited, Montreal, contains particulars regarding the various types of equipment manufactured by the company which includes a large range of signaling systems and devices.

## The Institute's Committee on Unemployment

At a meeting of The Institute's Unemployment Committee of which Mr. D. C. Tennant, M.E.I.C., is chairman, held on June 6th, 1934, progress made during the past year was reviewed and particulars submitted to Council. The following summary of this report is published for the information of the membership.

To check employment conditions since January 1st, 1934, when the last report of the Committee was submitted, a letter was sent to all Branches in April, requesting particulars of conditions in their districts. The replies received indicate that considerable improvement has taken place in conditions generally. This is mostly apparent in mechanical, chemical, mining and metallurgical lines, with some slight improvement in civil engineering in some parts of the country.

The Committee estimates that there has been a reduction of 25 per cent in the unemployment of members since January 1st. Actually, however, this does not reduce the number of members registered in the Employment Service Bureau, as a number of 1934 graduates have recently been listed. Placements by The Institute's Employment Service Bureau during the last few months show an improvement over 1933 of approximately 150 per cent. Positions vacant and listed with the Bureau also show an increase over a year ago, although these are still very few in numbers, and in most cases special qualifications are demanded. Due to the confidential nature of the enquiries or to the large number of members already registered and available, it has been found unnecessary to advertise most of these positions.

All members should be urged to register with the Bureau and thus have up-to-date records of their experience available on file.

Recent reports also indicate that there is a decrease in the number of members at present in need of relief.

Few placements on the supervisory staffs of the Department of National Defence Camps have been recorded during the past six months, and any further supervisory appointments will depend on the total strength of the personnel in the camps. During the spring months this dropped considerably, and as the supervisory staffs have not been decreased in proportion it is doubtful whether the Department will engage many engineers in the near future.

The Committee, in closing its report, observes that although there has been some improvement in employment conditions, it is still necessary to take the situation seriously and maintain efforts to find employment for members and other engineers. The Institute Committee can only make suggestions and depends on the Branch Employment Committees to obtain the necessary information as to local conditions, urge unemployed members to file their records, and inform local unemployed members and Headquarters of any local activities which seem likely to result in the employment of engineers.

Branch Employment Committees are asked to continue to investigate conditions in their districts, as a report on the unemployment situation will be requested during the early fall in order that some forecast may be made as to the measures which will be necessary to assist unemployed members during the coming winter.

## The Institute's Membership Committee

The activities of The Institute's Membership Committee in the past year have recently been reviewed, and particulars presented to Council, and it is believed that the following information will be of interest.

It will be remembered that this Committee of which Mr. D. C. Tennant, M.E.I.C., is chairman, after its appointment in February, 1933, sent out a circular letter to all Branches drawing attention to the need for activity as regards membership, and outlining a proposed course of procedure. This was followed in June, 1933, with a circular to all corporate members, enclosing a form on which each member was invited to fill in the names of prospective members.

As a result, a number of the Branches appointed special Membership Committees; in other cases the Branch Executive Committees undertook to act, and the names of over two hundred engineers who were considered eligible for membership were received at Headquarters. These names after classification were sent to the Branches concerned for action. The results to October, 1933, were contained in a report presented to the Plenary Meeting of Council, and this, with a further note by the chairman of the Committee, was presented at the Annual Meeting of The Institute in February, 1934, and printed in the February, 1934, issue of The Journal.

The number of new members obtained from among the names submitted as mentioned above was disappointing, but the Committee takes an optimistic view of the situation, as during the past twelve months the number of new members obtained shows a marked increase in comparison to the previous twelve months. It is believed that the membership campaign last spring was indirectly responsible for this, together with the reduction of entrance fees, and the assistance given many members by the Employment Service Bureau. The Committee believes that this improvement will continue, and will extend, provided that Branch efforts are not relaxed. It is hoped to obtain at least three hundred applications per annum, the approximate number required each year to fill the vacancies caused by deaths, resignations, etc. The Committee also urges that an increased effort should be made to interest students in the activities of The Institute through the formation of Junior Sections and other means. It has been noted that where attention has been given to this in the past, a notable increase in the admission of Students has been apparent.

# BRANCH NEWS

## Calgary Branch

*J. Dow, M.E.I.C., Secretary-Treasurer.*
*H. W. Tooker, A.M.E.I.C., Branch News Editor.*

On the evening of May 3rd, 1934, the members of the Calgary Branch and their friends witnessed two interesting reels of motion pictures depicting the construction and operation of the British Grid system, on which work was started in 1926.

Prior to the pictures being shown, G. H. Thompson, A.M.E.I.C., gave a short introductory address explaining the films and their object.

The first film presented a comprehensive survey of the activities in the important industries which went to the creation of the grid, the making of basic materials, like iron and steel, aluminum, etc., for the fabrication of the conductors and cables, switching apparatus and other equipment, and finally the erection of the towers and the completion of the transmission system. The grid was shown in operation and the movement of the electricity traced from the great modern generating stations to points where it is tapped off for distribution to the consumer. The picture then went on to show the enormous quantities of materials used and the sequence of casting 90,000 tons of steel required for the transmission towers, also the factory which provided upwards of 12,000 tons of aluminum for overhead lines.

The production of copper wire for the manufacture of cables was shown in detail and the sequence of smelting, refining, drawing and annealing emphasized the many processes involved in the manufacture of the product.

The final section of the picture was devoted to the actual construction of the grid, the preparation of the foundations, the erection of the towers and the stringing of the conductors. It also showed the erection of the 487-foot Thames towers at Dagenham, the tallest of the grid. The film concluded by showing in succession the main features of the grid.

The grid was shown in operation, tracing the movement of electricity from its production in a selected power station to its use by the consumer. Glimpses into the interior of one of the new generating stations were shown, also the switching station which furnished very effective pictures of load dispatching.

The films, which occupied some two and a half hours, gave an excellent idea of the enormous amount of time and work spent in the construction of such a complete and efficient service as the British Grid system.

## Hamilton Branch

*A. Love, A.M.E.I.C., Secretary-Treasurer.*
*V. S. Thompson, A.M.E.I.C., Branch News Editor.*

The May meeting of the Branch was held in the Science hall of McMaster University, and in spite of the call of spring there was an attendance of about seventy members and friends. H. B. Stuart, A.M.E.I.C., occupied the chair, and there were also present E. G. Cameron, A.M.E.I.C., of St. Catharines, vice-president of the zone; also C. G. Moon, A.M.E.I.C., a member of the executive of the Niagara Peninsula Branch.

The speakers at this meeting were both Hamilton men, A. B. Dove, S.E.I.C., assistant to the superintendent of the Canada Works, Steel Company of Canada, and Mr. C. D. Meals, wire rope engineer of the B. Greening Wire Company.

### Corrosion, Wire-Drawing and Galvanizing

Mr. Dove's subject was "Corrosion, Wire-Drawing, and Galvanizing." Using black-board illustrations, he outlined the simpler manufacturing of wire from the rod through pickling, baking and drawing, touching on the changes produced in the physical properties of the steel by the cold drawing process. The changes and pressures produced upon the rod, he stated, were dependent upon the yield point of the steel, while this, in turn depended upon the analysis of the steel under fabrication.

Corrosion was the next subject reviewed and the history of corrosion theories was covered in part.

The process of hot galvanizing of wire was covered, the speaker explaining in the course of his talk why each portion of the equipment was used. The wire was heat treated before processing to permit control of the physical properties; the pickling tanks removed scale; the water tanks removed the products of the pickling reactions; the flux deoxidized the wire and actual galvanizing took place in the spelter pan.

The spelter coating, he stated, was not merely zinc but a series of combinations varying from almost pure zinc at the surface to almost pure iron at the base, but consisting mainly in three layers—a bonding layer, one of brittle zinc-iron alloy, and finally a soft, easily formed layer of spelter.

In conclusion, Mr. Dove spoke of testing methods, showing by actual experimental results that the Preece test was not a true test of quantity of zinc present, and demonstrating how this may be shown by coating methods using the A.S.T.M. formula where $C$ (weight of coating) = $163\,dr$.

$$r = \frac{\text{Weight after coating} - \text{weight before}}{\text{Weight before}}$$

$d$ = diameter of wire in inches
$C$ = ounces zinc per square foot

The talk concluded with a discussion of various points brought up in the course of the lecture and was heartily entered into by those present.

### Wire Rope Manufacture and its Applications

Mr. Meals spoke on "Wire Rope Manufacture and its Applications." He opened his address with the statement that 1934 is the centennial year of wire rope as it was in 1834 that Albert of Clausthal in Germany first made rope of soft iron wire. In 1836 Smith and Hood made wire rope in England and Roebling in 1841 in America. All these ropes were made by hand in the same manner in which hemp ropes were made.

In 1840, Newall in England was granted a patent for a machine for making wire rope but it was not until 1875 that the development of the various constructions of rope was started. Lang of England, patented Lang lay rope in 1879 and Batchelor patented the 18 by 7 non-rotating rope in 1884. Latch and Batchelor patented locked wire cable in 1884 and flattened strand ropes in 1888, while Conners of Bridgeport, Conn., patented tru-lay preformed wire rope in 1923.

Transportation was the prime-mover in the development of wire rope, chiefly the removal of coal from mines. Later they were used for canal transportation and suspension bridges. Modern high buildings and deep mines as well as many engineering and construction feats of to-day would hardly be practicable without wire rope.

Although wire drawing has been practised since the earliest times the first tempered steel wire was made in England in 1854. This opened up the field of development of the high strength steel wire of today. Prior to this the tensile strength was about 90,000 pounds per square inch while modern improved plough steel wire will develop 280,000 pounds per square inch. Recent wire rope research has indicated that the lower strength wire will better withstand bending stresses than the higher strength wire under certain conditions of operation.

The grade of steel has little influence on the flexibility of the rope, which is a function of the construction and the lay of the rope. Regular lay ropes are those having the exterior wires of the rope running parallel to the longitudinal axis of the rope. Lang lay ropes have the exterior wires running diagonally across the longitudinal axis of the rope.

The reserve strength of a wire rope is the strength of the inner wires, granting that corrosion has not affected them. The outer wires are subjected to deterioration from breakage and abrasion. The reserve strengths vary from 18 per cent for a 6 by 7 rope to 58 per cent for a 6 by 37 rope.

The speaker stressed the importance of proper lubrication for wire rope and gave some valuable tables on the efficiency of different kinds of fittings.

H. A. Lumsden, M.E.I.C., in moving a vote of thanks to the two speakers, voiced the feelings of all present.

Mr. E. G. Cameron addressed the meeting briefly and expressed his gratification at being elected vice-president and promised all assistance to the Branch which it was in his power to give.

This meeting closed the Branch activities for the spring, and we are looking forward to another interesting series of meetings in the fall.

## Moncton Branch

*V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.*

On April 10th, 1934, a combined meeting of Moncton Branch and the Engineering Society of Mount Allison was held at Mount Allison University, Sackville. T. H. Dickson, B.Sc., A.M.E.I.C., delivered a very interesting illustrated address on "Streamlined Vehicles." C. Baggs, President of the Engineering Society, was in the chair and introduced the speaker.

### Streamlined Vehicles

The word "streamlined" is used frequently and in a somewhat loose way. One hears of streamlined cars, trains, planes and boats, and in many cases there is little actual streamlining; possibly in a car it consists of the removal of the exterior sun-visor and a slight increase in the angle of slope of the wind-shield.

Although the word "streamlined" is modern, the principle is not, Nature knew about it thousands of years ago. Consider the swallow. the eagles and hawks among the birds; the whippet and greyhound among the animals and the sword-fish, shark and tarpon among fish. All these creatures are examples of nature's streamlining; the swallow might have been a model for the Schneider Cup winning seaplane; the retractile landing gear used on some high speed planes is just a logical result of the study of a bird, for almost every bird tucks his feet up under his body when flying.

The rounded nose and tapering tail of the fish mentioned are merely to cut down resistance when swimming.

The slim body, pointed nose, graceful head and slim legs of the greyhound all indicate ability to travel fast and the cross-section of the greyhound's leg is similar to a section of a plane's strut.

One may wonder why this streamlining is necessary, and as it has always existed why more has not been heard about it in the past. However the principal reason is that it is not of much importance at vehicle speeds under 30 miles per hour, and does not increase appreciably until 50 miles per hour.

Actually air resistance increases as the square of the speed, so that, if the speed is doubled, the air resistance becomes four times as great.

If all other factors were equal, four times as much horse-power would be required, actually with an automobile eight times is about the figure, as wheel friction, bearing friction, in fact, all mechanical friction increases also in proportion to the speed, and the total friction varies as the cube of the speed. This is one of the main reasons for the continually increasing horse-power of automobiles.

Wind resistance losses are divided into the following: 1, head-on resistance; 2, skin or side resistance; 3, eddy currents caused by suction at the rear of the car or train.

These three components depend on cross-sectional area, direction of the wind and general type of construction, with head-on resistance usually the largest of the three, and that depends on the shape, a semi-circular shape being the most satisfactory.

The skin or side resistance depends on the general surface, a smooth unbroken surface being that which offers the lowest resistance; for this reason, all windows should be glazed as nearly flush with the surface as possible; hinges, door handles, rivets, etc. should be either eliminated or set in as much as possible. Any part which has to project should not do so abruptly, but should be built with a streamlined housing.

The eddy currents caused by suction at the rear have a powerful retarding effect on the car. A bicycle, ridden behind a sedan or bus, is pulled along with little effort, in fact a record of 72 miles per hour was made in this way. This same effect can be noted by rowing a boat in the wake of a large steamer. A perfect rear end for a car would be approximately wedge shaped.

In conclusion, the speaker described in detail the new high speed streamlined trains that are being given so much publicity. The description was illustrated by photographs kindly supplied by the Union Pacific Railway.

A vote of thanks was tendered Mr. Dickson on motion of Allan Millar, seconded by James English.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

The last regular noon luncheon of the spring season was held at the Chateau Laurier on May 3rd, 1934, at which J. Clark Reilly, of Ottawa, manager of the Canadian Construction Association, and a member of the National Construction Council, was the guest speaker. His subject was "What the Construction Industry Means to Canada."

What the Construction Industry Means to Canada

Mr. Reilly reviewed the construction industry in Canada for the past few decades, quoting figures to indicate the present status of the industry. Thus, for sixty-one cities in Canada the aggregate amount of building permits issued for March, 1934, was $1,089,481 as compared with $10,634,491 for March, 1926, and $24,068,018 for March, 1929. The last mentioned was the peak point of construction in recent years.

Labour costs, assuming those for 1913 as 100, were represented by the figure 158.0 in 1933 and by a maximum figure of 203.2 in 1930. The wholesale prices of building materials, with reference to 1926 as 100, were 78.3 in 1933 or 24 per cent lower than the average from 1920 to 1933.

Mr. Reilly stressed the importance of the construction industry in its relationship to the unemployment situation. He claimed that no one actually knows how many persons are now unemployed in Canada, although in March of the present year some 1,436,000 persons were receiving relief, as compared with 1,569,000 persons a year previously. To offset this, however, relief costs are rising as the individual resources of those on relief are diminishing.

Control of governmental and municipal construction would go a long way toward offsetting periodic unemployment, stated Mr. Reilly. If large items of such construction could be held over and undertaken during those periods when private building enterprise is inactive, it would tend to take up the slack in employment that would otherwise result. He quoted W. D. Black, M.E.I.C., of Hamilton, in this connection, who presented a paper on this subject at the last annual meeting of The Engineering Institute at Montreal.

Mr. Reilly's address was accompanied by lantern slides illustrative of modern trends in the construction industry.

Alan K. Hay, A.M.E.I.C., chairman of the local Branch of The Institute presided, and in addition head table guests included: Major-General A. G. L. McNaughton, M.E.I.C., Dr. H. M. Tory, R. J. Durley, M.E.I.C., General Secretary of The Engineering Institute of Canada, A. J. Hazelgrove, Group Captain E. W. Stedman, M.E.I.C., Wing Commander W. R. Kenny, A.M.E.I.C., J. Albert Ewart, A.M.E.I.C., T. W. Fuller, Hugh J. Graham, J. E. N. Cauchon, A.M.E.I.C., T. A. McElhanney, A.M.E.I.C., and Dr. R. W. Boyle, M.E.I.C.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

The Branch held the annual meeting at the Fox-Head inn at Niagara Falls on May 17th, 1934, with W. R. Manock, A.M.E.I.C,. in the chair, and Colonel Morrow of old Fort Niagara as the principal speaker.

President F. P. Shearwood, M.E.I.C., honoured the Branch by coming up from Montreal, and among other visitors were H. B. Stuart, A.M.E.I.C., and Messrs. E. P. Muntz, M.E.I.C., F. W. Paulin, M.E.I.C., and Alex. Love, A.M.E.I.C., from Hamilton; Messrs. J. D. Burbank, A.M.E.I.C., and R. Dunstan from Buffalo, and Mr. A. E. H. Fair, President of the Chemical Society of St. Catharines, and Colonel C. H. Vandersluys of Niagara Falls.

Following the dinner, Walter Jackson, M.E.I.C., introduced the President, who spoke briefly upon the affairs of The Institute. They were not in good shape just at the present time, but with careful economy being practised, the prospects appeared to be brightening, and he hoped that it would not be long before the printing of Transactions could be resumed. His thought was that it might be advisable to modify The Journal somewhat and carry therein general items of news and papers which were of a descriptive nature, while the more technical subjects and discussions could be carried in The Transactions in a form which would be suitable for permanent filing. There was not enough discussion at the present time and it is possible that more value would be derived if the original papers and the discussions were brought together in one volume. The vote on the By-laws was very small, about 30 per cent, but to his mind this did not convey indifference but rather it was a sign of indecision as to whether the time was yet ripe for a change and whether some further discussion was not advisable.

The Russian-Japanese Campaign in Manchuria

Mr. John Jackson, M.E.I.C., then introduced Colonel Morrow, who described "The Russian-Japanese Campaign in Manchuria." The treaty of Portsmouth had granted to Japan "paramount rights" in Manchuria and she has never failed to realize that this region forms her natural outlet for expansion as she is barred from the United States, Canada, Australia and New Zealand. Every such expansive movement, however, carried within it the seeds of a possible war unless the greatest tact and diplomacy are used. The Chinese Eastern Railway and the northern border along the Amoor river, are the danger points. China is quiescent and torn by internecine warfare and banditry, but Russia is uneasy fearing a clash between her armed railway guards and the Japs and fearing to remove them and leave her half interest in the Chinese Eastern Railway unprotected. The Japs have made Russia a fair offer of some thirty million dollars for her interest and, if this offer is not accepted, it is possible that Japan will not only take over the railway but, as a protective measure, take such military steps along the eastern end of the Trans-Siberian Railway as to effectually prevent retaliation by Russian troops. Trade makes and unmakes empires, and despite Japanese industrialism there still remains great possibilities for trade between the western world and China, Japan and Manchuria. Japan will not interfere seriously with the Chinese trade, said Colonel Morrow, and with the opening up of Manchuria, a still greater market may be foreseen.

## Peterborough Branch

*H. R. Sills, Jr.E.I.C., Secretary.*
*E. J Davies, Jr.E.I.C., Branch News Editor.*

Annual Inspection Trip

The annual inspection trip of the Branch was held on Saturday, June 1st, 1934, when sixty-five members and guests motored to Oshawa, Ontario, for a visit to the plant of the General Motors of Canada Ltd. The tour was under the capable supervision of Lieut.-Colonel F. Chappell, A.M.E.I.C., who explained each feature and operation in a most interesting manner.

The first point of interest was the modern and well equipped hospital, and particularly the optical department. A recent visitor from Mexico was so impressed with the completeness of this department that he obtained a complete specification for a similar installation in his own plant. It was explained that all new employees were given a thorough medical examination, particularly those who had been unemployed for some time, as this enabled the company to check on features which otherwise might constitute an accident hazard.

A photographic bird's-eye view of the complete plant at Oshawa as well as affiliated plants in other cities, and a photographic production chart was explained, then the various departments were visited as follows: wood storage and drying, wood and metal body parts, body assembly, body painting, cloth and leather cutting, metal trim, upholstery, wiring and hardware assembly, chassis assembly and final assembly of complete car, radiator and fender department, test and check up department and shipping department.

One was impressed with the production system which enabled so many departments to operate with such smooth co-ordination, and turn out the product at so great a speed. Another feature was the realization of the great number of outside companies, mostly Canadian, which contributed their products towards the building of a car.

J. W. Pierce, M.E.I.C., Branch chairman, expressed to Colonel Chappell and the General Motors Co. Ltd. the thanks and appreciation of the Branch for a very interesting and profitable afternoon.

## Quebec Branch

*Jules Joyal, A.M.E.I.C., Secretary-Treasurer.*

Mardi soir, le 17 avril 1934, la Section de Québec avait le plaisir et l'honneur d'entendre Monsieur J. A. Lalonde, A.M.E.I.C., Ingénieur en Chef de A. Janin & Compagnie Limitée de Montréal, dans une conférence illustrée intitulée

La Sous-Structure et les Approches du Pont du Lac St-Louis

La base de la causerie de Monsieur Lalonde fut le texte publié sous le titre susmentionné dans le numéro de mars 1934 du Journal de l'Institut, et les nombreuses projections illustrant les diverses phases de l'exécution des travaux, commentées et expliquées par le conférencier, rendirent cette conférence très instructive; tous ceux qui étaient présents furent des plus satisfaits de leur soirée.

Le conférencier fut présenté par Monsieur Hector Cimon, M.E.I.C., Président de notre section et Monsieur Ivan E. Vallée, A.M.E.I.C., Sous-Ministre et Ingénieur en Chef au Ministère des Travaux Publics de Québec fut chargé de le remercier.

Il est à noter que Monsieur Vallée est bien au courant de ce projet puisqu'il a agi comme ingénieur-conseil dans l'étude et l'exécution de ce projet de pont.

L'Honorable Honoré Mercier, Ministre des Terres et Forêts dans le gouvernement de Québec, que l'on pourrait à juste titre appeler le papa de ce projet, nous fit l'honneur d'assister à cette réunion et de nous adresser quelques mots.

Nous croyons intéresser nos lecteurs en donnant ici un bref historique de ce pont:

Les origines de ce projet de liaison des deux rives du St-Laurent, près de Lachine, remontent à 1910. C'est alors qu'une requête demandant l'établissement d'une voie carrossable sur le pont du chemin de fer Pacifique Canadien, qui traverse la rivière à cet endroit, fut présentée au Département des Travaux Publics de la Province de Québec, par les municipalités de plusieurs comtés avoisinant l'Ile de Montréal. Mais la "grande guerre" qui survint quelques années après, captant toutes les attentions ainsi que toutes les ressources, fit nécessairement reléguer le projet dans l'ombre et, ce ne fut que douze ans plus tard que la question fut ramenée au jour. On revint alors à la charge pour solliciter de nouveau cette amélioration dont le coût devait s'élever à quelques $2,300,000.00.

Toutefois, en présence de l'importance que prenait le développement du réseau routier du district environnant et l'augmentation de la circulation, on abandonna, en 1927, cette idée de l'addition d'une voie carrossable sur le pont du chemin de fer pour proposer la construction d'un pont-route indépendant à quelques cent vingt pieds en aval.

Des plans préliminaires furent alors dressés pour ce nouveau projet par les ingénieurs du Département des Travaux Publics et la législature provinciale élabora une loi, pourvoyant à la construction et à l'entretien du pont projeté ainsi qu'à la formation d'une commission dite "Corporation du Pont du Lac St-Louis" qui devait s'occuper de son exécution. Deux ans plus tard un amendement fut ajouté à cette législation par lequel le Gouvernement de la Province se portait garant des déficits qui pourraient résulter de cette entreprise jusqu'à concurrence des deux-tiers. La même année, une autre loi, émanant du pouvoir fédéral celle-ci fut également sanctionnée pour autoriser la construction du projet et c'est alors que le gouvernement provincial assuma cette nouvelle obligation de garantir 100% du déficit.

Lorsque l'on en vint à l'étude approfondie des perspectives de développement futur de la circulation, on se rendit compte des difficultés que présenterait l'accès au pont ainsi que du danger de congestion possible du trafic sur les approches si le site primitivement projeté, à proximité du pont du chemin de fer, était adopté; et, après examen de quelques autres endroits, le choix d'un nouveau site fut définitivement fixé en un point situé à quelque distance en aval.

A la suite de ces travaux préliminaires et de l'adoption définitive du site choisi par le Département des Travaux Publics, la Corporation du Pont du Lac St-Louis, dont l'Honorable Grothé est président, nomma Monsieur O. Lefebvre, M.E.I.C., ingénieur en chef de la Commission et Monsieur Ivan E. Vallée comme ingénieur-conseil. Les plans définitifs furent alors préparés en vue de la demande des soumissions et les travaux de construction commencèrent à l'automne 1932.

## Saguenay Branch

*J. W. Ward, A.M.E.I.C., Secretary-Treasurer.*

On Wednesday evening, May 9th, 1934, at the offices of the Aluminum Company of Canada Limited, Arvida, Que., a meeting of the Saguenay Branch was held, at which thirty-five members and guests were present. F. Newell, M.E.I.C., of the Dominion Bridge Company, and Mr. E. Normand of the A. Janin Company, who with P. L. Pratley, M.E.I.C., the speaker of the evening, had come to Chicoutimi from Montreal to make a final inspection of the recently completed Chicoutimi-St. Anne bridge, were also present.

Due to the unavoidable absence of the chairman, A. W. Whitaker, Jr., A.M.E.I.C., also the vice-chairman, G. E. Lamothe, A.M.E.I.C., the chair was taken by N. F. McCaghey, A.M.E.I.C., our chairman of last year. In his introductory remarks Mr. McCaghey mentioned that the branch executive had tried for a long time to get Mr. Pratley to address the Branch, but something had always turned up to prevent it. The opportunity finally presented itself during his trip of inspection of the Chicoutimi-St. Anne bridge.

Recent Bridge Construction in the Province of Quebec

The subject of the address was "Recent Bridge Construction in the Province of Quebec."

Mr. Pratley first described the Montreal Harbour bridge, showing by means of a map the various proposed sites, pointing out some of the difficulties in connection with each scheme. This was followed by a description—well illustrated with slides—of the nature of the river bed, types of foundations for piers, and methods of construction of these foundations and piers. Particularly interesting was the description of the caisson work.

The steel work, which was designed, constructed and erected by the Dominion Bridge Company, was next described and illustrated. Many of the beams and trusses were of massive proportions, and great skill was shown in the way in which they were erected and temporarily supported until the spans were completed. The finished bridge presents a very pleasing appearance and it must be with a feeling of pride that Mr. Pratley and all of his associates look upon this great engineering work.

A number of other bridges in the province in which the speaker as consulting engineer was interested, were also described. These included, among others, the Chicoutimi-St. Anne bridge, which spans the Saguenay river at Chicoutimi, the Chibougamo railway bridge at Isle-Maligne, and the bascule bridge at Sorel. This last bridge is of particular interest as it is the first bascule bridge, erected in Canada, to have been designed solely by Canadian engineers. While on this point the speaker mentioned the difficulty our engineers had in the past to convince our own government that they were capable of designing and building these special moving span bridges. It had taken years of effort on the part of Canadian designers to make the government see the light, and this bridge at Sorel is ample proof that it can be done, for not only does this bridge present a very pleasing appearance but it works perfectly.

In moving a vote of thanks, Mr. P. E. Radley mentioned our good fortune in having this opportunity to hear this talk by Mr. Pratley. During the last few years the number of prominent engineers visiting this district who were willing to speak were very few indeed.

## Winnipeg Branch

*E. W. M. James, A.M.E.I.C., Secretary-Treasurer.*
*E. V. Caton, M.E.I.C., Branch News Editor.*

New Fertilizer Plant at Trail

On Thursday, April 12th, 1934, a joint luncheon meeting was held with the local branch of the Mining Institute, at which Mr. R. W. Diamond, of the Consolidated Mining and Smelting Company, presented a very interesting paper on the new fertilizer plant at Trail, B.C.

Mr. Diamond pointed out that this fertilizer development is a result of the 26 per cent sulphur content of the ore from the Sullivan Mine at Kimberley. This sulphur is combined with lead and zinc in the form of sulphides and during smelting operations large quantities of sulphur dioxide are produced. Previous to 1931 this gas was allowed to escape into the atmosphere, as there was no economical use for it. However, it appeared that during certain wind conditions this gas would be blown over the United States border and damages to vegetation were claimed by nearby residents of the state of Washington.

Therefore it was decided that in order to overcome the smoke nuisance it would be necessary to fix this sulphur dioxide in the form of sulphuric acid, which would in turn be used to make various fertilizers.

For the production of the acid three contact process plants were constructed for a capacity of 375 tons of 100 per cent sulphuric acid per day.

Since ammonium sulphate is a valuable fertilizer, ammonia is first produced from its elements nitrogen and hydrogen. Hydrogen is obtained by means of electrolysis of water, and the plant produces on the average of 9 tons of hydrogen and 72 tons of oxygen per day. For the production of nitrogen two standard Claude liquid air units are used in which air is first liquefied and the nitrogen obtained by fractional distillation, the capacity being 44 tons of nitrogen per day.

In producing ammonia, these two gases are mixed in the proportion by volume of 3 of hydrogen to 1 of nitrogen, and after compression of about 250 atmospheres is passed into a synthesis column where under the influence of heat and a catalytic agent the gases combine to form ammonia $NH_3$. This ammonia is then combined with sulphuric acid to make ammonium sulphate, the capacity at the present time being 200 tons of sulphate per day.

Another branch of the fertilizer department is the phosphoric acid plant. Here phosphate rock, which is imported from the state of Montana, is ground and treated with sulphuric acid, the reaction resulting in the production of phosphoric acid and ordinary gypsum.

With the four raw materials, sulphuric acid, ammonium sulphate, phosphate rock and phosphoric acid, it is possible to obtain the following fertilizers:

1. Ammonia + Sulphuric Acid = Ammonium Sulphate.
2. Ammonia + Phosphoric Acid + Sulphuric Acid = a wide range of Ammonium Phosphate-Sulphate products.
3. Ammonia + Phosphoric Acid = Ammonium Phosphate.
4. Phosphate Rock + Sulphuric Acid = Superphosphate.
5. Phosphate Rock + Phosphoric Acid = Triple Superphosphate.

The great number of chemical fertilizers on the market is always confusing to the layman, but it is apparent that a large variety is required because of varying soil, moisture, temperature, and crop conditions. In these days of over-production and of low prices for agricultural products, the wisdom of fertilization is often questioned. The answer is evident and convincing—if farmers are to prosper, they must farm a smaller acreage of better lands more intensively, and secure lower unit production costs.

Mr. Diamond illustrated his talk with slides and motion pictures.

At the conclusion of the address a vote of thanks was tendered to the speaker by F. V. Seibert, M.E.I.C.

# EMPLOYMENT SERVICE BUREAU

**The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.**

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Wanted

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, French, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

INDUSTRIAL ENGINEER, B.SC., McGill Univ. Age 29. Married. Mechanical and electrical engineering experience with four large Canadian companies; including supervision of manufacture of various products, reduction of manufacturing costs, factory planning and investigation of piece work systems. Available on short notice. Apply to Box No. 132-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian, married, 34 years of age, with 13 years' experience in the industrial field, including design, construction and operation, 8 years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details upon request. Apply to Box No. 161-W.

CIVIL ENGINEER, age 44, open for employment anywhere, experience covers about 20 years' active work, including 7 years on municipal engineering, 2 years as Town Manager, 3 years on railway construction, 3 years on the staff of a provincial highway department, 2 years as contractor's superintendent on pavement construction. Apply to Box No. 216 W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257 W.

MECHANICAL ENGINEER, age 28, nine years all round experience, Grad. Inst. of Mech. Engs. England, S.E.I.C. Technical and practical training with first class English firm of general engineers; shop, foundry and drawing office experience in steam and Diesel engines, asphalt, concrete machinery, boilers, power plants, road rollers, etc. Experience in heating and ventilation design and equipment; 18 months designing draughtsman with Montreal consulting engineers. 2½ years sales experience, steam and hot water heating systems, power plant equipment, machinery, oil-burning apparatus. Canadian 4th class Marine Engineers Certificate; C.N.S. experience. Available at short notice. Apply to Box No. 270-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

PLANE-TABLE TOPOGRAPHER, B.SC., in C.E. Thoroughly experienced in modern field mapping methods including ground control for aerial surveys. Fast and efficient in surveys for construction, hydro-electric and geological investigations. Apply to Box No. 431-W.

ELECTRICAL ENGINEER, B.SC., A.M.E.I.C., AM.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.SC., and C.E., A.M.E.I.C., age 30, married. Experience over the last ten years covers construction on hydro-electric and railway work as instrumentman and resident engineer. Also office work on teaching and design, investigations and hydraulic works, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M A.SC. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

## Situations Wanted

CIVIL ENGINEER, B.SC., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

MECHANICAL ENGINEER, B.SC. Age 28, married. Four and a half years on industrial plant maintenance and construction, including shop production work and pulp and paper mill control. Also two and a half years on structural steel and reinforced concrete design. Available at once. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years' technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

### Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters or Branch secretaries.

ELECTRICAL AND MECHANICAL ENGINEER, B.SC., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment.Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

CIVIL ENGINEER, age 25, single, graduate. Creditable record on responsible hydro and railroad work in both Eastern and Western Canada. Apply to Box No. 567-W.

MECHANICAL ENGINEER, A.M.E.I.C., with twenty years experience on mechanical and structural design, desires connection. Available at once. Apply to Box No. 571-W.

MECHANICAL ENGINEER, B.A.SC., '30, desires position to gain experience, and which offers opportunity for advancement. Experience in pulp and paper mill and one year in mechanical department of large electrical company. Location immaterial. Available immediately. Apply to Box No. 577-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.SC., University of Alberta, '30. Age 31. Single. Six seasons' practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years' experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box No. 609-W.

## Situations Wanted

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.SC. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box No. 651-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing office. Office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., 29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.SC., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

## Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, graduate '29. Married. One year building construction, one year hydro-electric construction in South America, fourteen months resident engineer on road construction. Working knowledge of Spanish. Apply to Box No. 744-W.

SALES ENGINEER, B.sc., McGill, 1923. A.M.E.I.C. Age 33. Married. Extensive experience in building construction. Thoroughly familiar with steel building products; last five years in charge of structural and reinforcing steel sales for company in New York state. Available at once. Located in Canada. Apply to Box No 749-W.

CIVIL ENGINEER, S.E.I.C., B.sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.sc., '25, JR.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten year diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

MECHANICAL AND INDUSTRIAL ENGINEER, S.E.I.C., B.sc. in Mech., (Queen's, '32) and M.Eng. in Indust., (McGill, '34). Age 25. Single. Forty months as moulder's helper, machinist, etc. in foundries, machine shops, and on hydro-electric construction. Now completing two-year Rockefeller Foundation Fellowship at McGill. Good references. Available on short notice. Apply to Box No. 797-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Exrerience includes surveying, draughting concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.sc., A.M.E.I.C., with fifteen years experience mostly in pulp and paper mill work, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

ELECTRICAL ENGINEER, S.E.I.C., grad. '29, age 24, married; experience includes one year Students Test Course, sixteen months in distribution transformer design and eight months as assistant foreman in charge of industrial control and switchgear tests. Location immaterial. Available at once. Apply to Box No. 828-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years exporience in charge of legal field surveys. Owns own surveying equipment. Eight years on technioal, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in chargo of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.O., B.sc. '32 (Univ. of N.B.). Age 25 married Two years experience in power line construction and maintenance; ono year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial Apply to Box No. 840-W.

CIVIL ENGINEER, B sc. '15, A.M.E.I.O., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once Apply to Box No 841-W

## Situations Wanted

CIVIL ENGINEER, B.sc. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years' experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

CIVIL ENGINEER, B.sc., Montreal 1930, age 26, single, French and English, desires position technical or non-technical in engineering, industrial or commercial fields, sales or promotion work. Experience includes three years in municipal engineering on paving, sewage, waterworks, filter plant equipment, layout of buildings, etc. Available immediately. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., JR.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.sc., '25, McGill Univ., JR.E.I.C., P.E.Q., age 32, married. Experience as rodman and instrumentman on track maintenance. Seven and one-half years with Canadian paper company, as assistant office engineer handling all classes of engineering problems in connection with woods operations, i.e., road buildings, piers, booms, timber bridges, depots, dams, etc. Apply to Box No. 933-W.

ELECTRICAL ENGINEER, Dipl. of Eng., B.sc. (Dalhousie Univ.), S.B. and S.M. in E.E. (Mass. Inst. of Tech.), Canadian. Married. Seven and a half years' experience in design, construction and operation of hydro, steam and industrial plants. For past sixteen months field office electrical engineer on 510,000 h.p. hydro-electric project. Available at once. Apply to Box No. 936-W.

CIVIL ENGINEER, B.sc., O.P.E. Exporience includes several yoars on municipal work-dosign and construction of sewers, steel and concrete bridgos, watermains and pavoments. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.sc. (Univ. of Sask. '33), S.E.I.C., ago 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street, improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

## Situations Wanted

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.sc. (Queen's 14), A.M.E.I.C., Dominion Land Surveyor, 5 months' special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographio surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, age 27, graduate 1930, single. Experience includes detailing, designing and estimating structural steel, plate work and pressure vessels; also hydrographio surveying. Available at once. Apply to Box No. 1111-W.

ELECTRICAL ENGINEER, B.sc., in E E. (Univ. of N.B. '34), S.E.I.C. Experience in bridge and road construction and auto repairing, desires position in industrial or power plant. Any locality. References on request. Apply to Box No. 1114-W.

CIVIL ENGINEER, B.sc. Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and roinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C.), M.S. (Univ. of Pittsburgh). Canadian. Age 26. Single. One year graduate student course, W.E. and M. Co., East Pittsburgh. Three and a half years engineering research in mechanics with the same company. Location immaterial. Available at once. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box No. 1127-W.

PETROLEUM CHEMIST, B.sc. in Chem. Eng. Age 25, Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

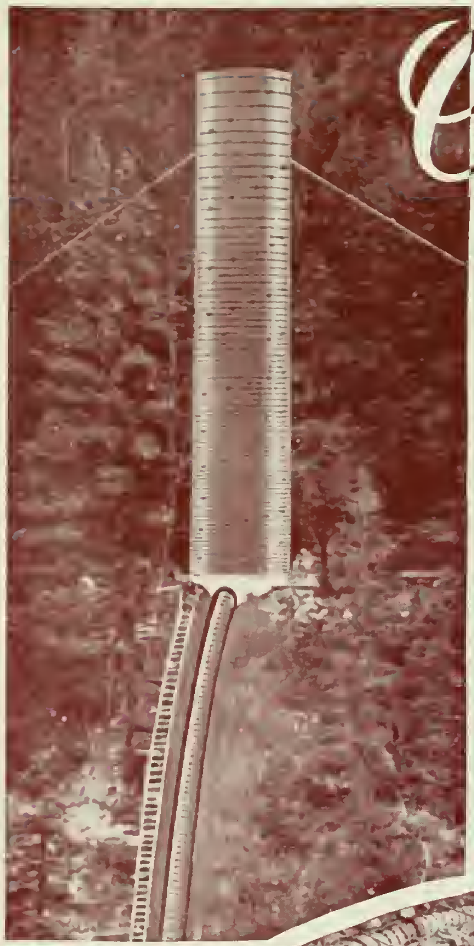
## Wood Pipe & Tanks
### SELECTED BY PIONEER MINE



THE NEW CANADIAN BUTT JOINT illustrated at left below, was used for the first time at the Pioneer Gold Mines, largest producer in Bridge River. After a year's service in blistering heat and sub-zero cold, this new joint is absolutely rigid and tight.

David Sloan, Managing Director of Pioneer Mine, stated on June 15th: "We can thoroughly recommend the new end joint made on continuous wood stave pipe which we bought from Canadian Wood Pipe & Tanks Ltd. last summer. The head on the lower end of the pipe is 300 feet. The weather did not go below 15 degrees below zero this winter. There were no leaks in the end joints. We think it okay."

The Canadian Butt Joint, obtainable only with Canadian Continuous Stave Wood Pipe, is supplied at no extra cost. Specify Canadian Continuous Stave or Wire Wound Wood Pipe and Canadian Wood Tanks.

*Pioneer Mine hydro-electric pipe line is 30 to 42 inches diameter and more than a mile and a half long. Surge tank is 12 feet diameter and 70 feet high.*

30 YEARS IN BUSINESS

The Romance of Road Building in Canada
SINCE earliest times roads and highways have been undertaken in response to demands for improved means of communication between different localities. The development of road making has, as a rule, kept step with the material development of the human race.
In Canada footpaths and roads were laid out by the aboriginal inhabitants, whose ability in location, combining ease of grade and directness of route appears to have been instinctive. Their locations are in many cases followed by existing roads today.
From Manitoba to the Pacific we have in Canada over 245,725.5 miles of all types of road in use.
Explosives played a large part in this construction work and NOW a new, economical and efficient method of building highways across swamps and marshy ground can be carried out by the use of C-I-L Explosives.

# Guard–

*The power industry recognizes that a thousand or more "black eyes" to customer relations and economical operation, lie in the manifold service hazards of an antiquated distribution system. Engineers and management, alike, are now giving their best thought and consideration to this important area where investment, service, and operating values are concentrated.*

# THE AREA of CONCENTRATION

## These O-B Distribution Products Give Added Assurance to the Success of Your Plans « « «

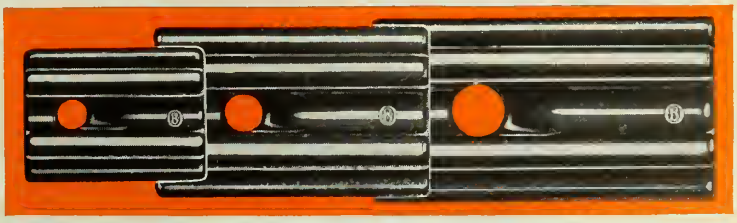
A REVERSION to the simple truth that the millions of dollars invested in power plant equipment, transmission systems, and in sub-stations is spent only for the purpose of delivering energy to customers' meters, has cast the spot-light of attention upon the distribution system—the area of concentration.

On many properties, active work is under way to guard this area. Old and uneconomical distribution transformers are being replaced. Distribution systems are undergoing rehabilitation. Slip-shod or any-old-way construction in alleys and streets is giving way to well-laid construction—planned with thoroughness and foresight. In this planning, it seems apparent that what is good practice and what are good materials for the highest-voltage lines, are likewise good for the distribution system. For years, the O-B trade mark has been synonymous with utmost dependability in high-voltage transmission. O-B has many distribution necessities, all branded with this same mark of dependability. In guarding the distribution area, where investment, operating, and service values are concentrated, why not turn to O-B products for the added assurance they can give to the success of your plans for the distribution system. They cost no more, and they cost less when viewed from the standpoint of long life and freedom from trouble.

*Sisters Under the Skin to O-B High-Voltage Insulators. Made of Same Porcelain with Same Technical and Manufacturing Control.*

*High Mechanical and Electrical Ultimates. Available with either Hook, Eye, Clevis, or Ball-Socket Attachments.*

*A Wide Variety of Easily-Put-Up Strain and Suspension Clamps to Delight the Men on the Pole.*



*Made in Accord with N. E. L. A. Standards. Will Reduce Former Stocking, Purchasing, and Installation Troubles.*

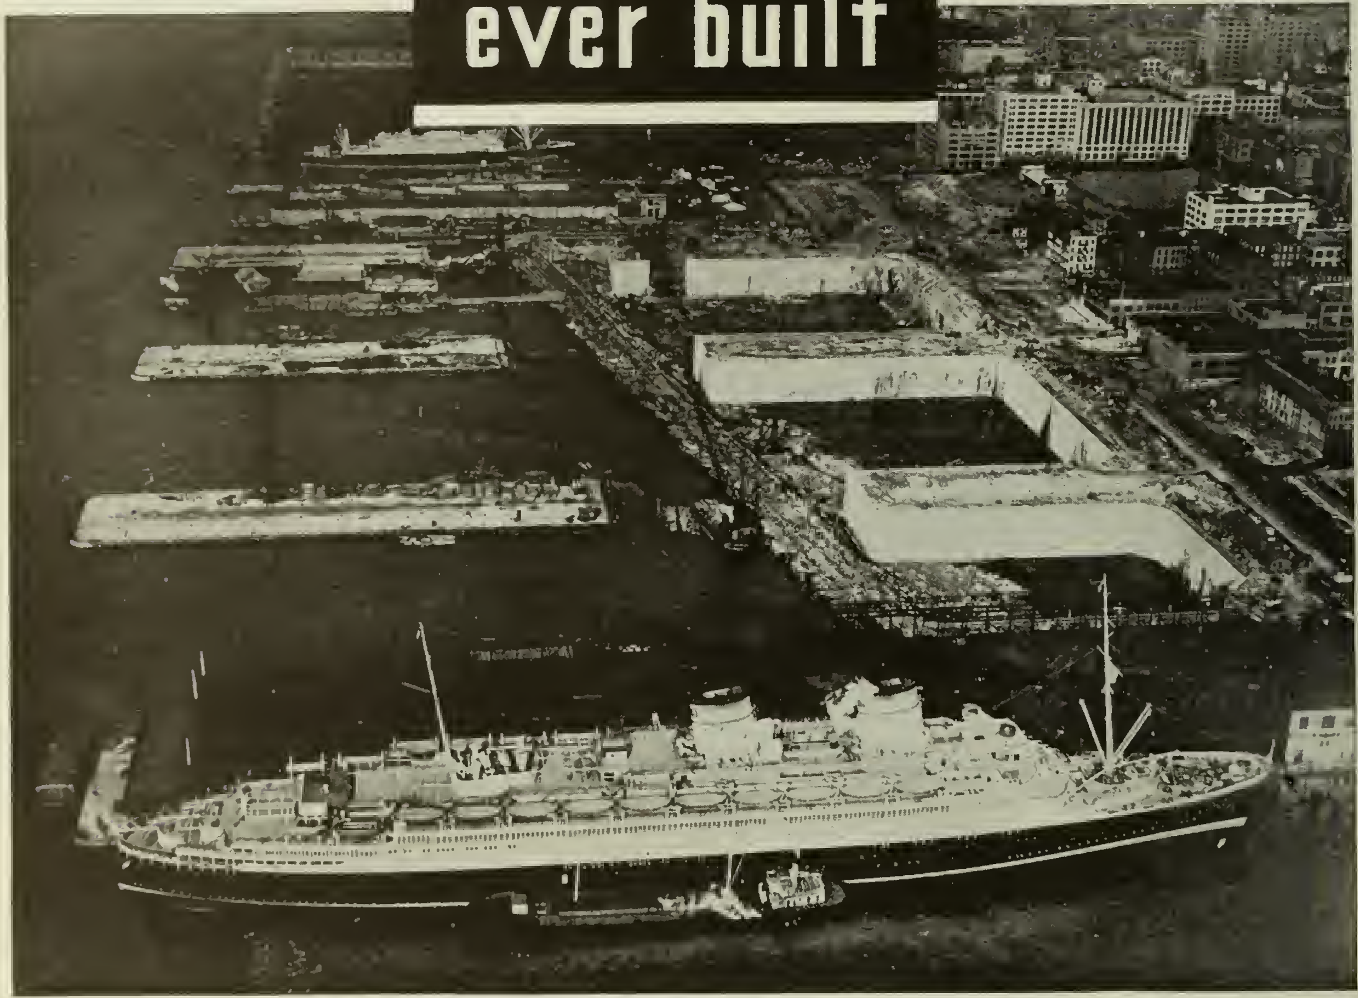
# The Largest Cellular Cofferdam ever built



*Contractor: Allen N. Spooner and Son, Inc.; Consulting Engineer: H. A. Sloane.* Photograph from Wide World

This 1500 ft. x 300 ft. cellular cofferdam, the largest ever built, was used in the construction of three piers in the Hudson River at New York City. It consisted of 43 pockets, filled with earth material, and extended from between 46th and 47th Streets to 52nd Street.

The cofferdam was built of 15-in. x $\frac{3}{8}$-in. straight-web Bethlehem Steel Sheet Piling. About 7500 tons were required, in lengths ranging from 46 ft. to 96 ft.—the latter the longest unspliced length of sheet piling ever used.

As the cofferdam was unwatered, the rock in the basins between the piers was excavated in the dry to a depth of 46 ft. below mean low tide, or 54 ft. below maximum high tide. The concrete portions of the piers were constructed, resting on solid rock, and the timber foundations were built for the outer portions of the piers.

Following removal of the steel piling, the outer, timber piers were extended shoreward to meet the concrete portions. The finished piers are 1100 ft. x 125 ft.

Any job, large or small, that involves the retaining of earth or water is a job for Bethlehem Piling. Our engineers, experienced in the application of this piling to a wide range of problems, will gladly confer with you regarding any project you may be planning.

# The Substructure of the Reconstructed Second Narrows Bridge

*P. L. Pratley, M.Eng., M.E.I.C.,*

*Monsarrat and Pratley, Consulting Engineers, Montreal, Que.*

**Paper presented at the Western Professional Meeting of The Engineering Institute of Canada, held in Vancouver on July 11th to 14th, 1934.**

SUMMARY.—The steel bridge carrying highway and railway traffic over the Second Narrows of Vancouver Harbour four and a half miles above the city, has been reconstructed after its wreck in 1930. The paper traces the events leading to the selection of the new design and discusses the difficulties which had to be overcome in building the substructure for the new lift span. Two new piers were put in by caisson work carried out in strong tidal currents and one existing pier was demolished.

The Second Narrows bridge crosses the Burrard Inlet at a point approximately in the middle of the Vancouver Harbour Commissioners' territory and at the eastern boundary of the city of Vancouver, 4½ miles from the business centre. It was originally constructed in 1924 and 1925 after many years of consideration and several interruptions. The work executed at that date is described in the Minutes of Proceedings of the Institution of Civil Engineers, Vol. 225, pp. 321-352, where an illustrated paper by Mr. A. D. Swan, M.E.I.C., and some discussion will be found. Since that date, however, the bridge has suffered from numerous accidents of major or minor importance, most of which have been of the nature of collisions between vessels and the structure due to tidal conditions and to the location of the piers and the opening span relative to the waterway. Figure 1 gives a line diagram of the layout as referred to in the above mentioned paper, and Fig. 2 is a photograph of the bridge as then completed.

The following list of accidents, Table I, is taken from technical and daily press reports and serves to indicate that the passage of vessels and log-booms has been hazardous at times, although undoubtedly an examination of some of the instances would disclose insufficient care on the part of the navigators.

TABLE I

ACCIDENTS AT SECOND NARROWS BRIDGE

| | | |
|---|---|---|
| Sept. 8, 1924 | Logs in tow of tug *Shamrock* fouled pier | $16,000 |
| Nov. 3, 1924 | Log-boom broken up in collision with pier, Cliff Towing Co. | 400 |
| Sept. 30, 1925 | Tug *MT No. 1* sunk in collision with bridge | 3,000 |
| Sept. 30, 1925 | Vancouver Lumber Co. scow damaged | 700 |
| Nov. 26, 1925 | SS. *Canadian Ranger* drifted into bridge, saved by tug | unstated |
| Dec. 1, 1925 | Tug *Lorgnette* collided with pier | unstated |
| Jan. 5, 1926 | SS. *Canadian Ranger* hit north pier | 1,070 |
| Jan. 9, 1926 | Oil tanker *Mina Brea* hit pier | 8,000 |
| Feb. 25, 1926 | Oil tanker *Mina Brea* collided with pier again | 1,200 |
| Feb. 27, 1926 | Oil tanker *Vancolite* hit pier | 1,000 |
| April 11, 1926 | Boom of logs broken up, lost | 600 |
| April 14, 1926 | Cliff Towing Co. scow damaged | 3,000 |
| April 14, 1926 | Gas boat *Chummy 2* struck pier, crushed by scow, sank | unstated |
| May 5, 1926 | Scow in tow of *Seal Swell* collided with pier | 1,040 |
| May 25, 1926 | Tug *Pacific Monarch* hit pier | unstated |
| July 26, 1926 | Boom in tow of *B.C. Boy* hit pier No. 2 | unstated |
| Mar. 10, 1927 | S.S. *Eurana* struck fixed span | $30,000 |
| | Tug *Shamrock* fouled pier | 9,694 |
| April 24, 1928 | S.S. *Norwich City* struck fixed span | 50,000 |
| April , 1930 | S.S. *Losmar* collided with pier 4A (Fig. 3) | 75,000 |
| Sept. 19, 1930 | Hulk *Pacific Gatherer* towed by Tug *Lorne* struck 300-foot span becoming wedged beneath it. Incoming tide caused hulk to lift span from bearings throwing it into Inlet | 140,000 |

NOTE—Minor accidents not included.

The adoption by the Vancouver Harbour Commissioners of a new by-law, in 1931, rendering it obligatory for vessels over a certain size to pass the bridge only against the tide, has minimized the chance of collision and strict enforcement of this by-law should be demanded by all interested parties.

The bridge was built privately by the Burrard Inlet Tunnel and Bridge Company under certain agreements with the local municipalities as to a guarantee of bond interest, and the contracting company (The Northern Construction Company) accepted part of its compensation in securities. In addition, as Mr. Swan's paper points out, they undertook certain heavy responsibilities in respect of the unknown foundation conditions. Figure 1, which is taken from plate 5 of Mr. Swan's paper, shows that the superstructure between the timber trestle approaches consisted of four fixed spans and one bascule span of the Strauss overhead type, the latter furnishing a 175-foot opening toward the south side of the navigable water. The substructure supporting these spans included concrete piers numbered from the north 00, 0, 1, 2, 3, 4, 4A, 5, of which No. 2 is the most interesting both in the original construction and for present considerations. Piers numbers 00, 0, 1, 5 and 4A, as rebuilt after one of the accidents, consist of reinforced concrete cylinders sunk into gravel or into the sandstone rock, but pier 2 was of pneumatic construction and presented exceptional difficulties on account of the nature of the bottom encountered during sinking. As to capacity, the bridge carries a single line of railway between its trusses and a 10-foot highway on either side with a narrow footwalk outside the eastern highway only.

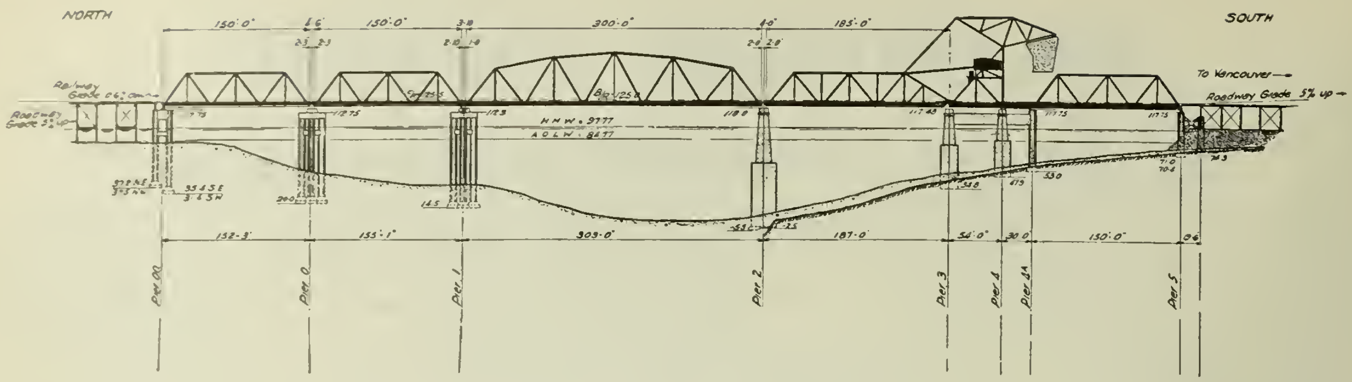

Fig. 1—Elevation of Original Bridge.

The reconstruction work of which this paper treats was occasioned by the catastrophe of September 19th, 1930, when the 300-foot fixed span between piers 1 and 2 was lifted off its supports and pushed into the water as a result of the rising tide acting on a vessel, the *Pacific Gatherer*, which had become jammed under the span (see Fig. 4). The span was salvaged, more or less, and examined as to condition but in spite of many rumours and press notices as to the possibility of restoring it to service, it was ultimately cut up and shipped as scrap to Japan. Nothing was done toward replacing it and the bridge was simply left in an incomplete and useless condition for three and three-quarter years.

The Second Narrows bridge had been a paying venture during its active but checkered life, forming as it did a very useful and popular link between the city of Vancouver and the north shore municipalities. In 1928 and 1929, for example, the traffic figures were reported as follows:—

| | 1928 | 1929 |
|---|---|---|
| Persons | 2,349,400 | 2,693,694 |
| Vehicles (autos and cycles) | 850,824 | 979,465 |
| Trucks, etc. | 140,741 | 164,510 |

and it can readily be understood that the interruption of such a facility for a period of years constituted a severe inconvenience to the population immediately affected, which had probably been built up as a result of the original construction of the bridge.

The sequence of accidents and the cessation of revenue naturally ate into the financial resources of the owning company and a receiver was appointed on February 23rd, 1932, on request of the bondholders. In spite of continuous pressure from public opinion and the press, satisfactory means could not be found to finance the rehabilitation until December, 1932, when the Federal government finally came to the rescue and an Order-in-Council was passed authorizing the Vancouver Harbour Commissioners to acquire the bridge and its appurtenances in order to undertake reconstruction. The intention was that by this means money could be obtained through the Department of Marine to effect the necessary work and that ownership would remain with the department until the expenses involved in such reconstruction had been recovered from revenue, after which the bridge would revert to the receiver.

The author's firm had been asked to advise the Vancouver Harbour Commissioners on the technical features of a scheme proposed by contracting companies to the Receiver previous to this Order-in-Council, and continued in this capacity when the Commissioners took over these new responsibilities. Under the new conditions, however, the methods of awarding a contract which had previously been under discussion, were abandoned in favour of open bids on prepared plans and the engineers' suggestion to make adequate borings in the neighbourhood of the existing pier 2 was immediately put into effect by the Commissioners under Colonel Monsarrat's personal direction. These borings were made in January, 1933, and are illustrated in Fig. 5. Meanwhile, office studies were being made by the author's firm of the schemes already proposed by the local contractors, and all variations therefrom, with a view to finding means of removing the causes for criticism which had gained for the bridge the epithet "A menace to navigation."* The foundation conditions were of extreme importance in all these studies. The earlier experiences at the site of pier 2 were, therefore, carefully investigated and all pertinent information assiduously canvassed. As several of the suggested schemes involved further foundations alongside the existing piers 1 and 2, and as some of these schemes would have involved also the distribution of heavy loads between new and old piers, the best obtainable knowledge regarding the foundation material was felt to be absolutely essential.

A general principle had by this time seemingly established itself in the minds of all those interested in the reconstruction, that the navigating channel should be moved from the present location between piers 2 and 3 to a new location between piers 1 and 2 and that a vertical lift span over this navigable channel should replace the existing bascule. The immediate problem was thus the precise method of supporting the towers for this vertical lift span and confining the total cost of reconstruction within

Fig. 2—Original Second Narrows Bridge.

the sum authorized by the Order-in-Council. Working from the information in the Institution of Civil Engineers' paper, several plans had been made by the author's firm, who had tentatively been appointed by the receiver under the earlier conditions of reconstruction, and other schemes had been advanced by the local contracting companies who

*From judgment of Privy Council re appeal of owners of steamship *Eurana* which collided with the bridge on the 10th of March, 1927—see Engineering News Record, December 2nd, 1931.

had been negotiating with the receiver for the work. Borings had been looked upon as almost impracticable during these earlier considerations by many parties, as the current and tidal conditions rendered such an undertaking very difficult; but in the engineers' opinion the difficulties that existed during the initial construction were to some extent diminished by the fact that the bridge itself formed a working platform for drilling apparatus and, as a matter of fact, after adequate consideration had been given

**Fig. 3—Accident in April 1930, 150-foot span being cut up.**

to the problem, borings were carried out successfully without undue trouble. When, in March, 1933, the author's firm were appointed engineers by the Vancouver Harbour Commissioners acting for the Department of Marine, the borings had been completed, and the opinion definitely arrived at, that any attempt to found a new pier or piers in front of or alongside pier 2 would be fraught with grave uncertainties and would, therefore, be unsound practice. Figure 6 is being included to show several of the proposed ideas which at this point had to be abandoned but some of which are of sufficient interest to be mentioned, at least descriptively. Technical reasons against their adoption may perhaps be of interest and will be briefly stated before proceeding to the scheme actually carried out.

The schemes considered and abandoned fall into various categories distinguished by the treatment accorded two

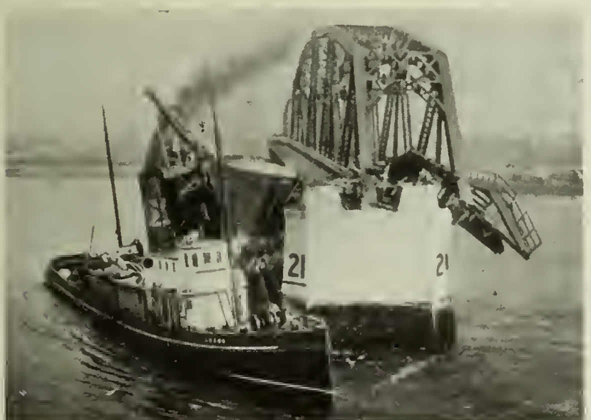

**Fig. 4—The *Pacific Gatherer* under Span, September 1930.**

or three principal features. There are those schemes which involved the old 300-foot span contemplated at the time as being still serviceable and capable of being refitted for use as a lift span. Alternatively, there were those schemes which anticipated the construction of an entirely new span, either of 300 feet or some slightly shorter length. The retention or abandonment of the existing bascule span was also a feature by which the schemes can be classified. Again, there were certain schemes which included new pier sites as distinct from the enlargement of old pier sites. Many types of piers were considered; the principal methods of construction being: sheet steel piling, generally by the cage method, Fig. 6a; reinforced concrete cylinders somewhat similar to those used in the existing piers 1 and 0, these being for additions to the piers 1 and 2; and pneumatic or open caissons, for entirely new piers.

Major events occurred during the discussion of the project which ruled out some of the proposed schemes and which controlled in various ways the features to which allusion has been made. For instance, in the first place a decision was arrived at by the government departments concerned that they did not want to retain the present bascule opening and would not be party to the spending of any sum for the mere purpose of such retention. This attitude, based on the known unwillingness of navigators to use the bascule opening if some more desirable opening to the north were provided, was stiffened by the prospect of dismantling and re-using most of the existing machinery for the new span and so reducing the new capital cost. Secondly, the borings which were taken in January, 1933, showed the impracticability of sinking auxiliary piers adjacent to pier 2 with sufficient certainty and satisfaction. The lack of overburden in certain areas militated against all piling schemes, some of which, particularly the cage scheme illustrated in Fig. 6a, were otherwise very favourably

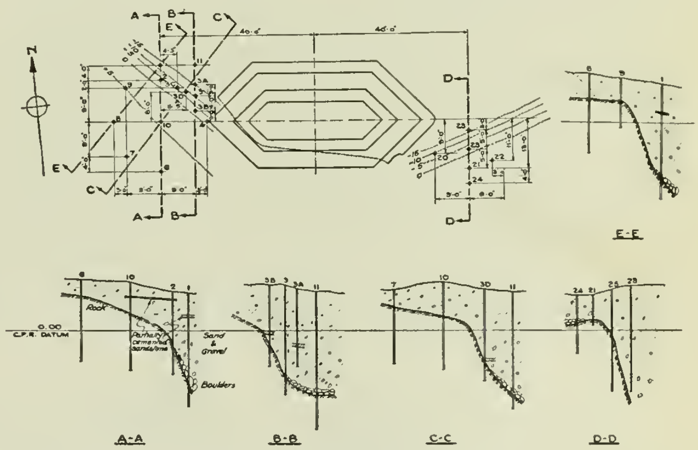

**Fig. 5—Plan and Sections Showing Borings Adjacent to Pier 2.**

regarded. The prospect of having to found some cylinders on rock, others on gravel, and even in some cases the same cylinder partly on rock and partly on gravel, did not appeal to the engineers. Caisson construction so close to the old pier was not looked on with favour and thus, gradually but definitely, all schemes for the enlargement of pier 2 were discarded in favour of an entirely new pier. Thirdly, the assumption that the old 300-foot fixed span could be rehabilitated was finally abandoned, although the present author cannot state exactly when and by whom the decision to scrap it was actually made. However, advantage was taken thereafter of the economy to be obtained by the adoption of a somewhat shorter span of higher strength steel which would thus impose much lighter loads on the towers and substructure.

The preference for placing the new pier 2 to the south instead of to the north of the old pier 2 was dictated by considerations arising from both the first and the second of the above mentioned events. A site to the south would obviously be on rock and within reach of reasonable working pressures for pneumatic construction. To the north, on the other hand, the depth of water increased and the bottom became gravel and, although an open caisson could undoubtedly have been sunk with or without the use of an artificial sand island, as indicated on Fig. 6f, the fear of creating a serious raceway for the tidal currents between the old and new piers and the resulting tendency to excessive scour around the bases of these piers was felt to be a powerful argument against placing a new pier in this locality. Furthermore, the position of the corresponding new pier 1 would also have been awkward with a lift span of 282 feet or thereabouts. A similar tidal raceway would have been created and the prospect of demolishing the old pier 1 was not viewed with much assurance.

Referring to the figures of the abandoned schemes, these will indicate without further explanation whether or no the bascule span was to be retained, whether or no the old 300-foot span or a new lift span was to be used, and whether the substructure was designed as an enlargement of existing piers or as a pair of new piers.

Figure 6b, scheme 1, which in regard to its superstructure closely follows that submitted by the Dominion Bridge Company in March, 1932, involved a pair of towers each consisting of eight vertical posts and connected at their tops by horizontal bracing trusses. The counterweights were on the outsides and called for four sheaves per tower while both the lift span and the bascule were housed between the inside legs of each pair of towers. The substructure to support these rectangular towers was, of course, distinctly long in the east and west direction and involved the sinking of eight cylinders for the north pier and four for the south.

Figure 6c, scheme 2, also evolved by the Dominion Bridge Company as far as the superstructure is concerned, counted upon a new lift span, some small modification at the nose of the bascule and north flanking spans, and rectangular towers seated upon transverse loading girders. In this case the bascule trusses and the lift span trusses were housed between the inside legs of the tower posts, but the cantilevered roadways were cut off short of the tower construction and a suitable portion built over the pier. The substructure for this case was alternatively designed as being of reinforced concrete cylinders or of steel sheet piling prisms, the shape of these prisms being such as to present cut-waters up- and down-stream and provide bearings for the transverse loading girders. Two sheaves per tower were required and counterweights were placed on the longitudinal centreline of the bridge as is the normal practice.

Figure 6d, scheme 3, was a later development resulting out of consultations between the Dominion Bridge Company and the author's firm during the period when the receiver was considering the reconstruction of the bridge. The scheme, as illustrated, involved towers of the more

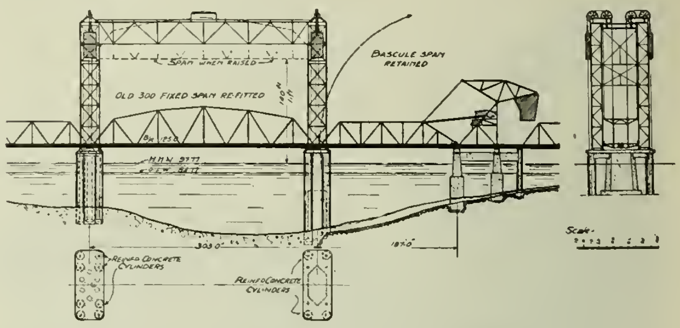

Fig. 6b—Abandoned Scheme No. 1, March 1932.

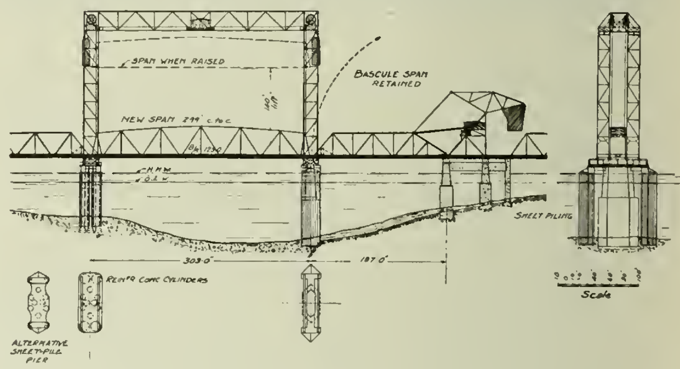

Fig. 6c—Abandoned Scheme No. 2, June 1932.

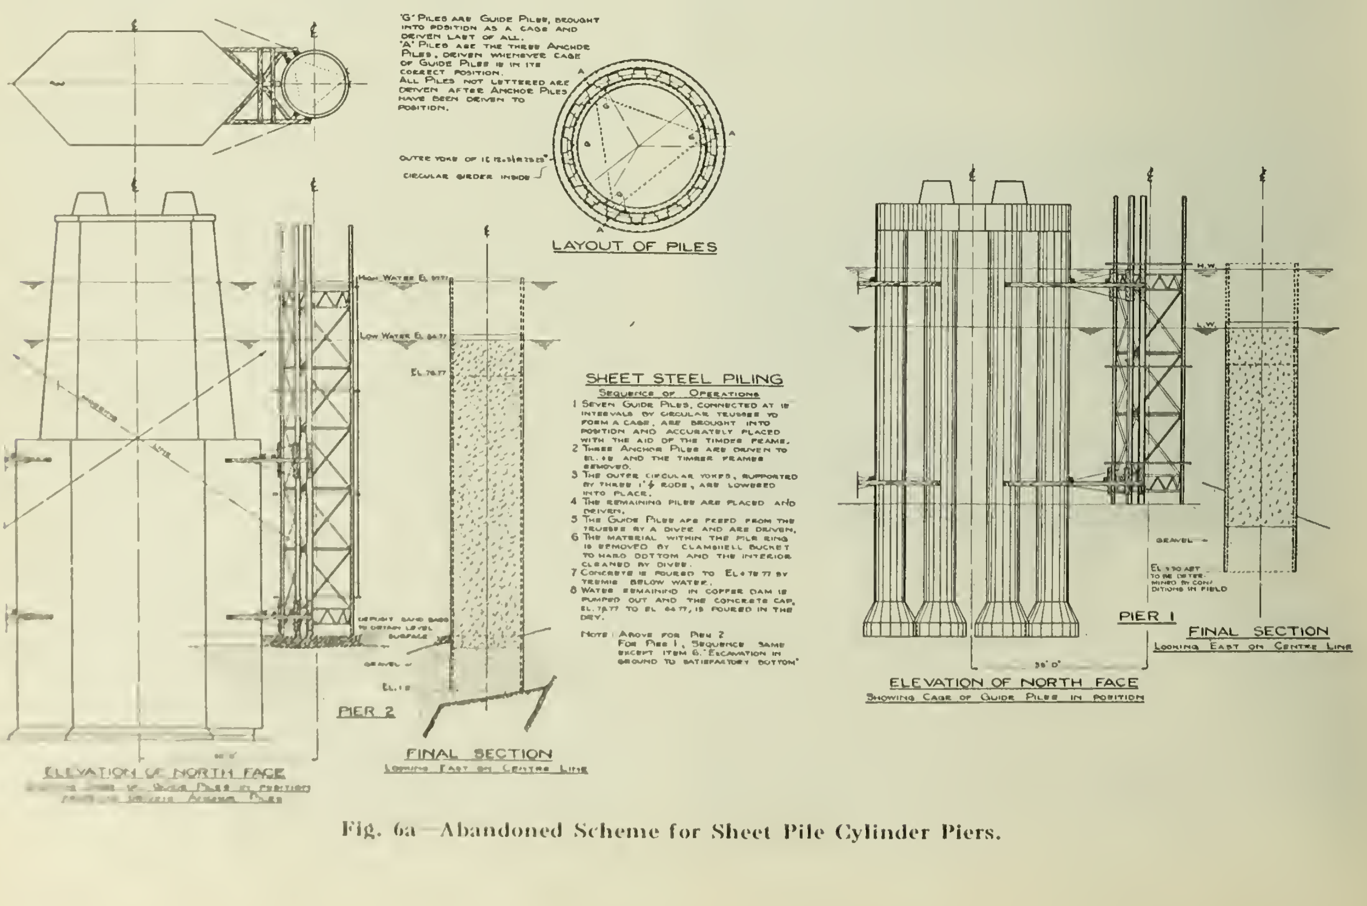

Fig. 6a—Abandoned Scheme for Sheet Pile Cylinder Piers.

usual type carried on two legs 78 feet apart, which legs were seated entirely on new cylindrical steel sheet piling piers. The interior posts shown on the side elevation were merely guides for the span movements and not intended to take any vertical load. In view of the prospective uneven settlement of the two piling cylinders, they were not rigidly connected across the top but jacking arrangements were provided whereby the superstructure could be maintained on an even keel. Each of the two cylinders at each

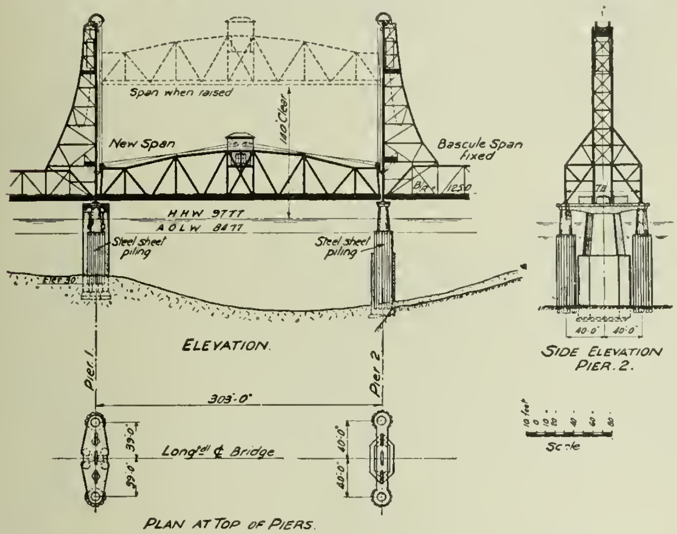

**Fig. 6d—Abandoned Scheme No. 3, December 1932.**

pier was narrowed down at its top to pass through a circular hole in the horizontal beam. This horizontal beam was designed to carry its own weight as a cantilever on the old pier and to absorb any lateral forces which might be delivered at the feet of the tower legs on the new piers. Alternative designs for the substructure were made in which lozenge shaped steel piling piers were used instead of cylinders and various devices were studied for taking care of uneven settlement.

Figure 6e, scheme 4, was an early scheme suggested largely by the Hamilton Bridge Company for using the old span, retaining the bascule, and moving the navigating channel further to the north.

Figure 6f, scheme 5, was an adaptation of scheme 4 using a new and shorter lift span.

The layout finally recommended to the Department of Marine, and approved by the Department of Public Works in Order-in-Council P.C. 651, is indicated in Fig. 7, which is the engineers' drawing No. 4 and which forms part of the subsequent contract. This layout calls for two piers numbered 1B and 2B south of the old piers 1 and 2 respectively, but south by different distances. The old pier 1 remains in the structure; the old pier 2 is demolished, thus providing a clear channel at low water level of 272 feet with a span of 286 feet between centres of the new main piers. This compares with the old channel of 175 feet and the span of 187 feet between piers. The new layout thus provides almost 100 feet wider fairway for navigation.

The new vertical lift span is designed to rise 117 feet 3 inches and to give, when raised, 140 feet clearance above high water level which is 97.77 to the harbour or C.P.R. datum. As is usual in such bridges an emergency lift of 3 feet extra is rendered possible by the structural and mechanical provisions. The towers are supported on flanking spans, that to the north being a new span, that to the south being the shortened moving leaf of the existing bascule. This bascule is cut to 129 feet in length by the removal of two panels and a large portion of the dismantled steel was used to make up the 70-foot flanking span to the north. The counterweight mass and the counterweight truss and tower of the bascule bridge were not removed, and must not be removed in the future without definite study of the resulting stress conditions in the remaining portion of the bascule span. Some of the balancing blocks have been removed and will be re-used, and much of the machinery including the main motors, the standby gas engine, gears, and bearings, are also reinstalled in the new machinery house at the centre of the lift span. Figure 7 shows that by spacing the new pier 2B, 53 feet south of the old, a solid rock foundation was obtained and all uncertainty removed. The new pier could thus be dimensioned to suit requirements and all superimposed loads would be borne on one shaft. Similarly, pier 1B being sunk in gravel of fairly well established properties, would be designed to meet loading requirements without any trouble from uneven settlement. In the engineers' specifications, pier 2B was stipulated to be pneumatic in order that the rock might be bared for visual inspection. For pier 1B the choice between pneumatic and open sinking was left with the bidders in the instructions issued with the call for substructure tenders; but the engineers showed, on their construction drawings, an open-dredging caisson. They felt that with the necessity of providing air plant for one caisson, the extra cost of pneumatic as against open sinking of the second caisson would not be serious and that the experience of the different contractors might lead them to differing preferences. Bidders were required to state their choice in their tender so that the engineers would be the better guided in comparing prices. Bidders were also warned of the difficulty of controlling floating caissons in the currents, eddies, and tide conditions bound to be encountered at this site and were required to visit the site as well as to submit their experience in similar work together with evidence as to their qualifications in resources and personnel.

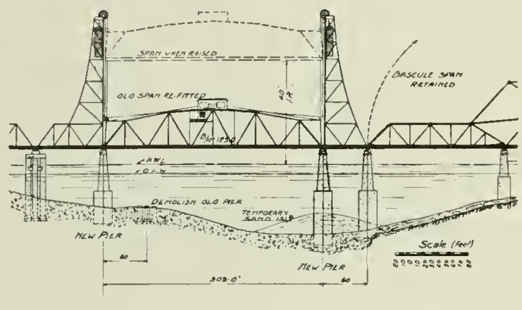

**Fig. 6e—Abandoned Scheme No. 4, March 1932.**

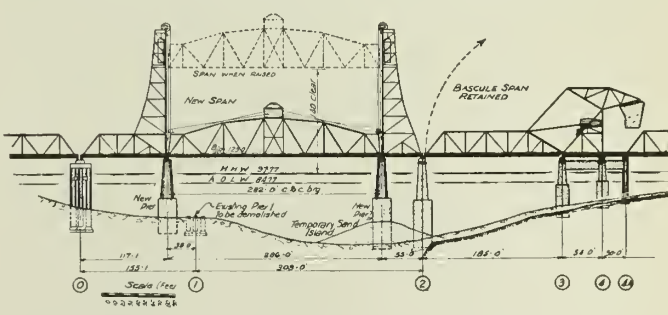

**Fig. 6f—Abandoned Scheme No. 5, February 1933.**

A glance at the map (Fig. 8) will serve to indicate that two fresh water rivers, known as Lynn creek and Seymour creek, flow into the inlet immediately west and east of the bridge approach. At different stages of the tide and at different seasons of the year the effect of these creeks on the direction of the flow in the channel at the bridge site varies widely. Moreover, the difference in specific gravity between the fresh and salt water tends to complicate the situation with respect to the intensity of current at various

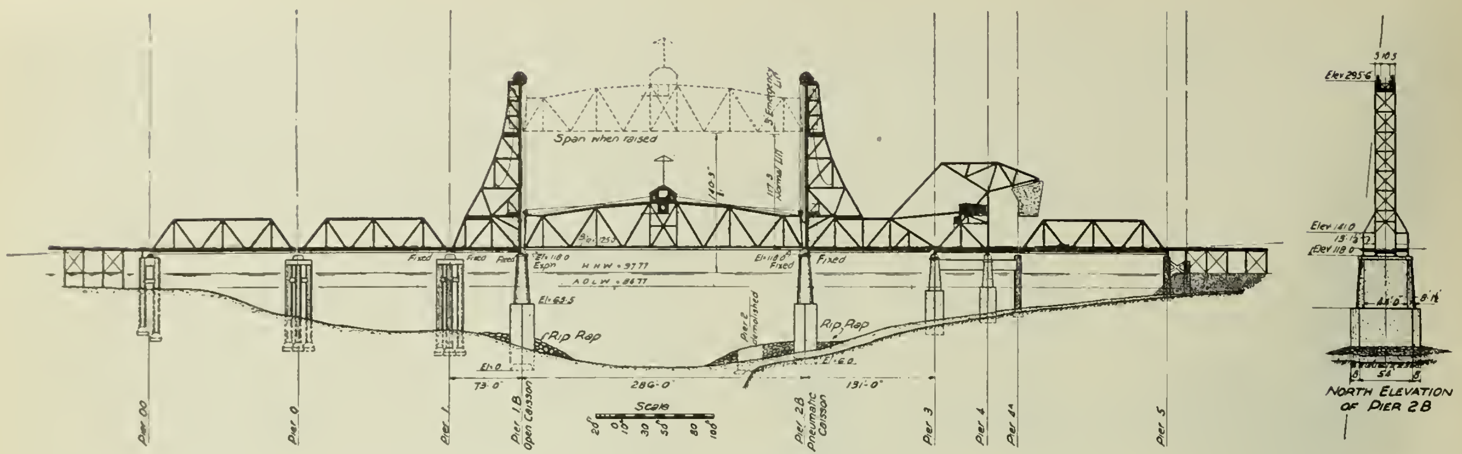

Fig. 7—Elevation of Reconstructed Bridge.

depths. All of this makes it evident that not only special vessels, such as the floating caissons, but also the ordinary type of steamer or even barges and log tows, must be very carefully handled and need to be provided with plenty of operating room even when the tides appear to be slack on the surface. The tidal phenomena are, in addition, unusual in respect of the sequence of high and low tides, in so much as the difference between the low and two neighbouring highs is sometimes extremely small and other times as much as 15 feet as will be seen from typical diagrams Fig. 9. Another complication is the fact that the new tides seem to flood in on the south side of the inlet west of the Second Narrows bridge and then to shoot across to the north on the surface adjacent to, practically parallel to, but in the opposite direction from, the flow of Seymour creek. This of course causes unusual eddies, particularly evident at the bridge site and around the piers as constructed. It was the knowledge that these extraordinary conditions exist and are undoubtedly responsible for many of the major and minor accidents to navigation in this vicinity, that led the engineers to emphasize the necessity of a close acquaintance with the actual conditions and with the hazardous type of work resulting therefrom.

As is usual in these cases, the need of a tremendous hurry was discovered as soon as the engineers had been appointed and every effort had to be made to expedite the preparation of plans and specifications sufficient for tendering purposes. Fortunately, the studies and inquiries which had been made previous to actual appointment enabled the engineers to reach their conclusions, make their recommendations to the departments of government concerned, secure tentative approvals and issue the call for tenders within a few days, so that invitations to bid were advertised on March 17th, 1933, and tenders were received in Montreal on April 18th. All bidders chose to sink pier 1B by an open-dredging caisson and the Foundation Company of Canada, Limited, were recommended to the Department of Marine for the award of the contract. The tender form required a lump sum bid for the work shown on the drawings and described in the specifications, and also unit prices for additions or deductions and for variations in depth. The successful bidder quoted $333,733 as the lump sum, which was between 91 and 92 per cent of the engineers' estimate, and even with the payment for extra depth in 2B and other small additions consequent upon the completion of the superstructure drawings the cost to the Vancouver Harbour Commissioners does not exceed 96 per cent of the engineers' estimate.

The general design of these two new piers is indicated in the various figures and is dimensioned on Fig. 10 which is taken from engineers' drawing No. 5. The shafts above elevation 65.5 are identical, are 10 feet wide by 54 feet long under the coping, and batter at the rate of 1 in 16 to 16 feet 3 inches by 60 feet 3 inches at the point where they sit on the base. The shafts are semi-circular at their east and west ends but the base caissons are pointed, the included angle at the noses being 108 degrees. The bases are slightly different in dimension due to loads and foundation material, pier 1B being 24 feet wide inside the sheathing and pier 2B being 22 feet. The corresponding overall lengths are respectively 71 feet 5½ inches and 69 feet 11¾ inches nose to nose. These dimensions ensured that for all the specified loads, tension in the concrete was avoided and toe pressures on the river bed were within the working values of the materials encountered. For pier 2B, which was sunk into the sandstone rock, the units at the bottom of the shaft, elevation 65.5, are shown on Fig. 11. For determining maximum and minimum pressures the water level was considered as either low or high tide; concrete was taken as weighing 150 or 147 pounds per cubic foot; wind was considered as being from the north, south, east, or west and acting on towers, spans, train, and pier, or any combination of these; current pressure was considered as from ebb or flood tide; the span was considered as up or down; live load was considered as off or on, accompanied by impact or not, and producing traction or not; eccentricity of superimposed loading was allowed for; the presence of timber was considered in estimating the weight of the pier; temperature was taken as ranging between 0 degrees and 120 degrees and skin friction was admitted or neglected. The most adverse possible combinations were determined by numerous separate calculations and the units indicated in the figures are, therefore, such as are hardly likely to occur in fact. In figuring the current a surface velocity of 11 feet per second was used and it was assumed that this velocity would also persist down to elevation 75, from which point

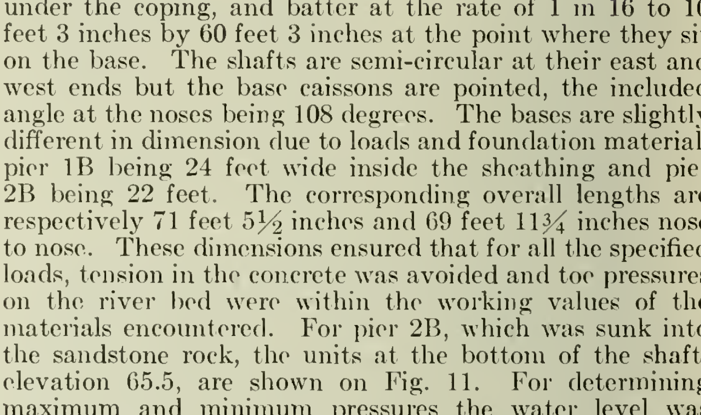

Fig. 8—Location Map.

down the velocity would reduce parabolically to zero at the top of the riprap, which is about elevation 37 for pier 1B and about elevation 30 for pier 2B. Coefficient $k$ in the formula for pressure $P = W . k . \frac{v^2}{2g}$ was taken at ¾ for the semicircular ended shaft and 4/3 for the pointed caisson. To allow for cross currents 20 per cent of the pressure, as figured for the east and west direction acting on the ends of the piers, was assumed as acting in a north or south direction on the sides of the piers. As will be mentioned later, the caisson for 2B was not quite accurately placed and the resulting eccentricity of the upper shaft weight and the superimposed loading altered the base pressures from those shown in Fig. 12 to those shown in Fig. 13. Table II, showing conditions of loading, will assist the reader in understanding the references to case numbers on the figures.

In view of the fact that pier 2B sits on what appears to be solid rock, the relieving effect of buoyancy or flotation may be absent and alternative calculations were made on this basis. Figure 14 shows that for the pier as built the maximum unit pressure, under the most adverse combinations imaginable, comes on the south west shoulder and reaches 12 tons per square foot under the assumptions

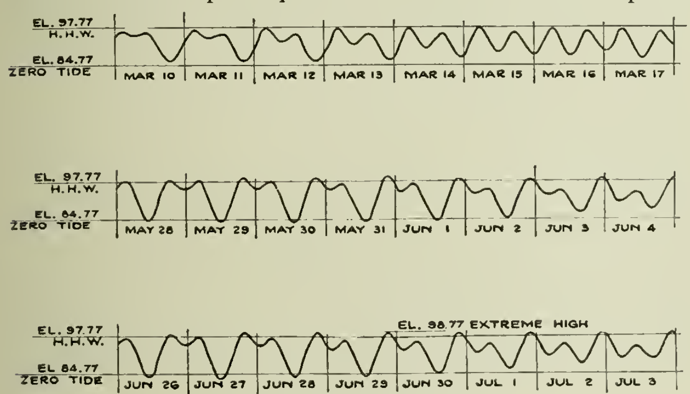

**Fig. 9—Types of Tides.**

adopted. Recapitulating these assumptions for this figured condition, they include no buoyancy; concrete at 150 pounds; high water; full live load, impact and traction; coldest temperature; actual eccentricity of shaft and superimposed loads; east wind on tower, span, train and pier; flood current at 7½ miles per hour (case $3_d$).

For pier 1B in gravel the corresponding values are given on Fig. 15.

A fair idea of the general stability of the structure may be obtained from the end elevation on Fig. 7, showing pier 2B and the superimposed tower, where a battered line is drawn from the centre of one sheave to the pier nose at the base elevation. This line batters 27 feet 6 inches in

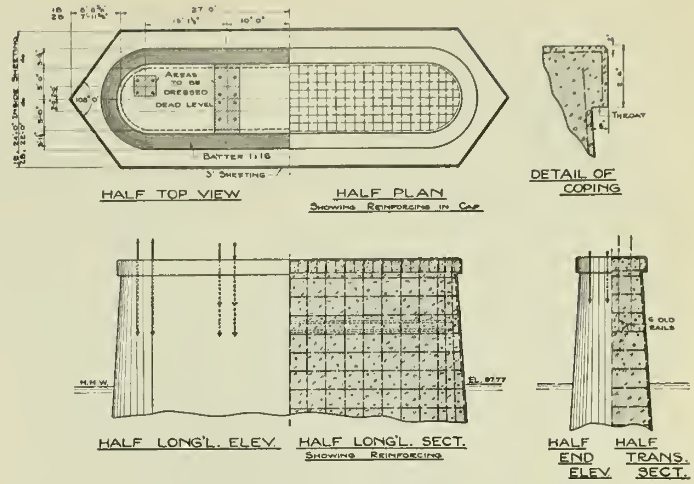

**Fig. 10—Detail of Tops of Piers 1B and 2B.**

the vertical height of 289 feet 6 inches and lies entirely within the pier.

Immediately upon the award of the contract, detailed drawings of the cutting edges and of the timber caissons, following in general the sketches prepared by the engineers, were put in hand by the contractor and agreement was arrived at sufficiently quickly to permit steelwork to be ordered in Vancouver during July. The Foundation Company had arranged an association with the Pacific Salvage Company of Vancouver by virtue of which the personnel and equipment of the latter company were to be available for caisson construction and water-transport. This association proved very satisfactory, as ample marine plant was thus provided for all contingencies, superintendents and foremen familiar with the local conditions were secured for responsible direction of this portion of the work, and space properly fitted for timber-ship-building was provided for the construction, launching, and floating of the caissons.

By the middle of August the author was able to inspect the cutting edge and working chamber of the pneumatic caisson of pier 2B, in the shops of the Western Bridge Company, and by August 21st this framework was set on the specially built ways at the Pacific Salvage Company's dock in North Vancouver. (Fig. 19.) Figure 16 shows the transverse and longitudinal sections of the working chamber. The latter is of ¼-inch plate suitably stiffened and all-welded, while the cutting edge is partly riveted and is of heavier material. Three shafts penetrate the ceiling of the working chamber and the usual supply of pipes for high and low pressure air, water, light, whistles, and telephones, grouting, etc., was installed.

On September 5th the caisson was timbered to 16 feet above the cutting edge and launched. The concreting plant

had been completed by this date and was mounted on a scow alongside, so that on September 9th 117 cubic yards were poured into the cutting edge, increasing the draught to 12 feet 6 inches from 6 feet 9 inches. On the mixer scow (Fig. 17), beside the steam raising plant and driving engine, were a timber tower, with the necessary chutes, and an inundator with batch measuring apparatus and hoppers for the storage of aggregates.

From this point on the caisson was constructed by raising the timber work, consisting of waling, strutting, and sheathing, in stages and concreting the walls to preserve stability. A plan of the caisson for pier 2B is also shown in Fig. 16 and indicates the wells which were watered, de-watered, and concreted to suit flotation requirements during towing and sinking operations as illustrated in Fig. 18. A fairly elaborate system of anchorage had been prepared in advance for holding the caisson and the various craft in their proper places and Fig. 20 indicates the general arrangement, while the photograph Fig. 21 shows one of the 30-ton concrete anchor blocks being tipped overboard. The basic idea was to moor two large scows 30 feet by 90 feet, one on either side of a space to be occupied by the caisson, and to tow the caisson upstream on the flood tide, pushing and hauling it into place by means of a big derrick boat and hoisting engines mounted on the scows.

The caisson weighed 2,600 tons, including 1,045 yards of concrete, when ready for towing, and drew 62 feet with 32 feet 6 inches of freeboard. It was towed up the inlet to its final site on October 12th, the river bottom having been previously levelled-off by dredging and the deposition of gravel in bags. On arrival at the site a smaller sized tug boat picked up the chain from the 30-ton west main anchor and also took hold of the 1¾-inch cable attached to the western towing bridle on the caisson. The eastern towing bridle was hooked onto the cable and tackle extending from the east main anchor, so that by operating the hoists on the scows the whole line from anchor to anchor could be tautened and the caisson itself moved up- and down-stream in this line. Struts of logs, 3 feet or 4 feet in diameter, were later placed between the scows, fore and aft of the caisson, to keep them apart and 1¼-inch cables run off another drum on the hoists served to keep the scows from separating. After checking for position east and west, water was admitted into the caisson and the latter was sunk, to ground on the bottom at about half ebb tide. The west side anchor lines were then interchanged and crossed, similar to those on the east side, so that they would have more purchase in keeping the scows in position. The cutting edge settled down at about elevation 20, the south west corner being on the exposed rock. During the night, and probably due to several causes such as cross currents, eddies and tides, uneven bottom, non-uniform pull on the anchor lines, etc., the caisson walked and settled to a different position, which is indicated on Fig. 22.

The contractors were prepared to pump out the caisson and lift it in the hope of securing a more accurate placement, but Colonel Monsarrat, who was present during these operations, was of the opinion that the error was not of serious consequence and that the difficult conditions of handling were such that improvement could not be guaranteed even if attempted. He, therefore, accepted the first placement as being within the margin of play allowed for. The caisson moved somewhat more during sinking, and this subsequent movement increased the deviation from exact placement, so that finally the situation at elevation 65.5 was that shown as final on Fig. 22. For purposes of calculation this situation was also assumed to obtain at elevation 6, the assumption being more or less justified by

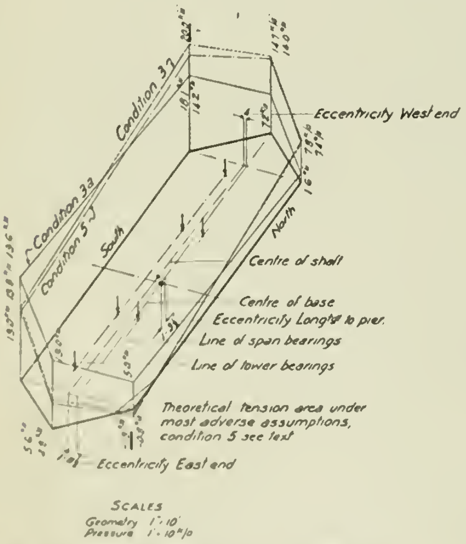

Fig. 13—Pier 2B Governing Pressures as Sunk assuming Buoyancy.

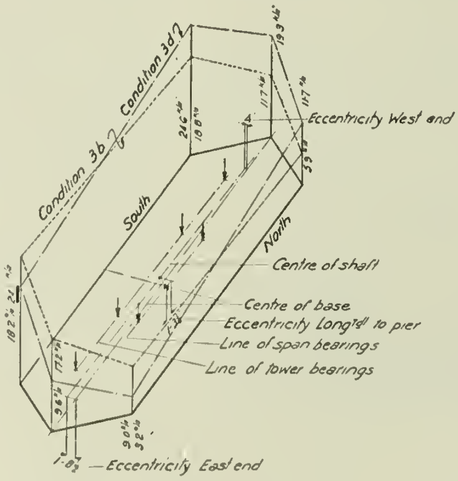

Fig. 14—Pier 2B Governing Pressures as Sunk but without Buoyancy.

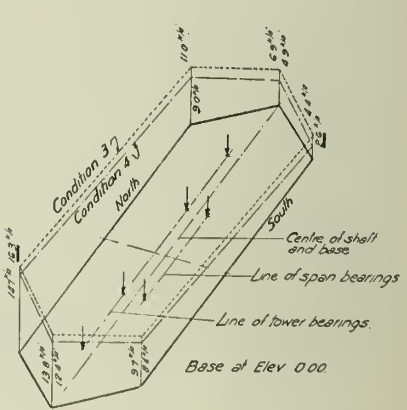

Fig. 15—Pier 1B Governing Pressures.

the continuous care given during excavation to keeping the caisson plumb.

The photographs, Fig. 23, were taken on October 12th, during the towing operations.

During the early part of October the pneumatic plant with its motors, air compressors, hospital lock, change houses, etc., had been installed at the south end of the bridge, on the shore alongside and under the timber trestle, and piping laid along the bascule span ready to connect up to the locks and the working chamber. The locks were assembled on shore and then fitted in place on the caisson about October 17th and on the 19th the men were entered into the chamber with air pressures up to about 33 pounds per square inch. Two Sullivan angle compound, electrically-driven compressors furnished the air, one single-stage producing 1,565 cubic feet at low pressure for the men, the other 2-stage producing 750 cubic feet per minute at high pressures for tools. Three portable Ingersoll-Rand gas-driven compressors, having a total rated capacity of 860 cubic feet per minute, were provided as a standby for emergency use.

The west end was excavated first, after the fitting of all conveniences and devices to the caisson and the preliminary cleaning had been carried out, and the cutting edge was taken down to elevation 14 before rock was available at the north east corner to support the caisson for its entire periphery. Some attempts were made to "throw" the caisson back toward the true position but without avail, and concreting by tremie in the interior pockets was carried out vigorously from the time when the cutting edge was finally completely landed on rock. The rock was not of uniform character, some of it being a greyish green sandstone and some a type of limestone shale or indurated clay. This latter was soft enough on exposure to the atmosphere to be cut with a knife and was not felt to be sufficiently solid for bearing purposes. Even the sandstone seemed to be only in process of formation, particularly in parts. It was not at all difficult to break up and seemed to occur in layers or lenses. At the south west corner the first rock encountered was harder than the average but at the north east corner the soft shaley material was met and this only

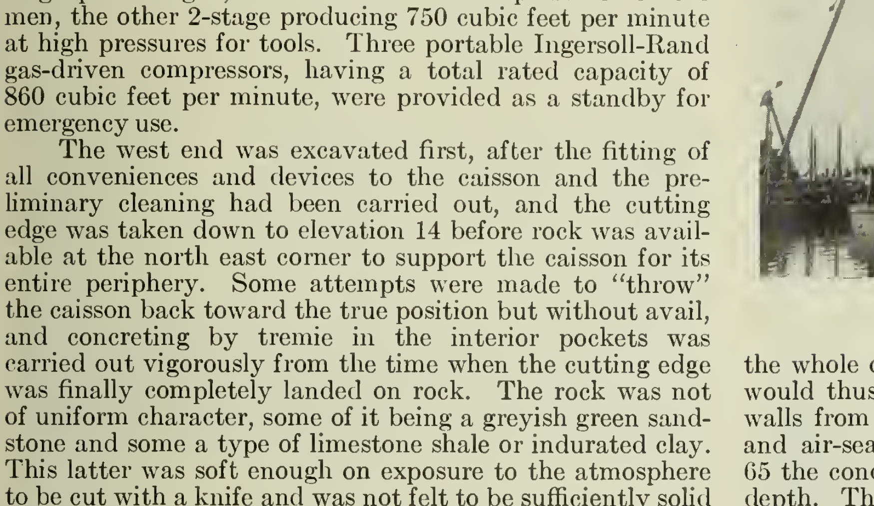

**Fig. 16—Pneumatic Caisson for Pier 2B.**

became distinctly harder after considerable excavation. At the expected final elevation (elevation + 8) the rock at the west end was again hard and was much more closely grained but at the east end was far from uniform and still of a shaley nature. The cutting edge was, therefore, sunk to about elevation 6, when the rock under the east nose became harder and better. At this point all rock seemed to be sound and solid and there was no indication that greater uniformity could be found at lower elevations, so that this condition was accepted and the cutting edge founded at elevation about 5.6 referred to in the figures as elevation 6.0. Instructions were given on November 28th to concrete the working chamber, and this was completed the next day. Grouting followed, after which the air equipment was dismantled, and the concrete in pockets carried up to elevation approximately 51.3. It had originally been expected to pump out at this stage completely and pour all the remaining concrete entirely in the dry. Had this been possible

**Fig. 17—Mixer Scow.**

the whole of the concrete surface exposed to the sea water would thus have been poured in the dry. As it was, the walls from elevation 20 to elevation 53 were actually dry and air-seasoned but between elevation 53 and elevation 65 the concrete was poured into still water of a few inches depth. The mix was, therefore, temporarily enriched to the 8 sacks per yard specified for concrete in or under water and was gradually reduced to the regular dry mix requirement of 5.6 sacks to the yard as the top of the caisson, elevation 65.5, was reached. A continuous pour of 540 yards brought the base to this level on December 14th.

A point of interest which arose during the final sinking operations was the need of kentledge. This need arose from the extra buoyancy which occurred, due both to sinking two feet deeper, and to extra high tides reaching as high as elevation 100. The caisson was weighted down with heavy metal rings and was also strutted from the bascule span, which was itself loaded.

The ready-mix concrete used for filling the pockets and completing the base of pier 2B was delivered by Diethers Limited from the yards of Champion and White, on Main street, about four miles away from the site. A fleet of ten trucks, of the revolving drum type, each of 3 yards capacity, operated at the rate of 15 trucks per hour during the day. The 540-yard batch began to be poured at 1.40 p.m. on the 13th and was finished at 4.10 a.m. on the 14th, elapsed time being about fourteen and a half hours, making an average of 32½ yards per hour. Naturally the rate of supply slackened at times, particularly around 5 to 6 p.m., but later reached 50 yards per hour during the night when the roads were all clear and the round trip of a truck could be speeded up from the normal forty minutes occupied during day-time hours.

The upper shaft of the pier was then carefully laid out for the setting of forms so that on the 18th a pour of concrete to elevation 82 was made followed on the 22nd by one to elevation 90 and on the 23rd by one to elevation 99. The

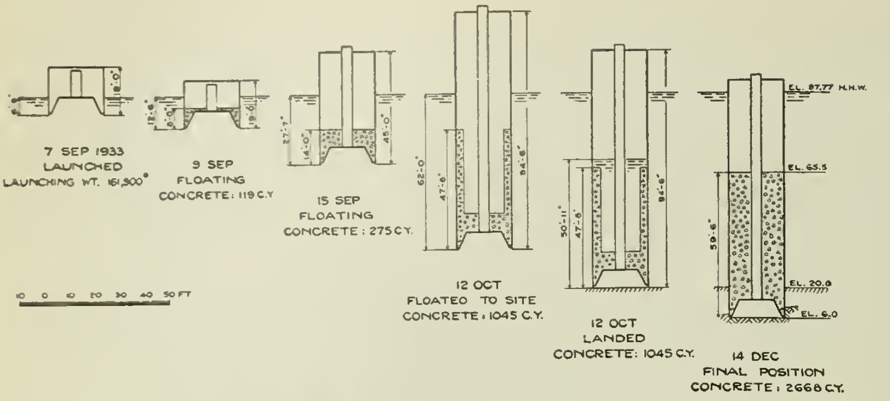

Fig. 18—Pier 2B—Floating and Sinking Diagrams.

creek. In grading these aggregates the same procedure was followed as for pier 2B. In the case of materials from Seymour creek only screened aggregates were permitted, because the plant was equipped with a disc crusher, which produced a very large proportion of flats.

The inspection of the materials and the design of the mix were carried out for the engineers by Macdonald and Macdonald, inspection engineers of Vancouver, B.C., these inspectors being under the control of the resident engineer on the work. A typical design sheet for dry concrete gives the following information:—

heavy anchor bolts, 3½ inches diameter, 15 feet and 15 feet 6 inches long, and about 12 feet 6 inches in the pier, belonging to the superimposed tower bases, were finally set on December 28th and the concreting completed to elevation 118 on the 30th, this being exactly the schedule requirement. Dressing the seats for these tower bases began early in the new year when the concrete had had the

Fig. 19—Cutting Edge of Caisson for Pier 2B.

opportunity to set, and on January 15th the superstructure contractors set the base slabs in place.

The total net yardage of concrete placed in the pier was 4,039 to make which 25,536 sacks of cement were used. The specification called for a strength-designed concrete exhibiting a minimum of 2,500 pounds per square inch after twenty-eight days, with a further provision, as already stated, that concrete poured into sea-water or under sea-water in the pockets should contain eight sacks per yard.

The sand and gravel used in the construction of both caissons and for the shaft and base of pier 2B were brought by scow from a pit on the Fraser river. After screening, the various sizes were recombined to give aggregates conforming to the requirements of the specifications. Oversizes were crushed and used in the coarse aggregate.

For the shaft and base of pier 1B, aggregates were brought to the mixing plant by truck from nearby pits. About half of the aggregates came from a dry pit and half from the bed of Seymour

and the resulting strength tests showed 1,608 at seven days and 2,830 at twenty-eight days. The general run of tests

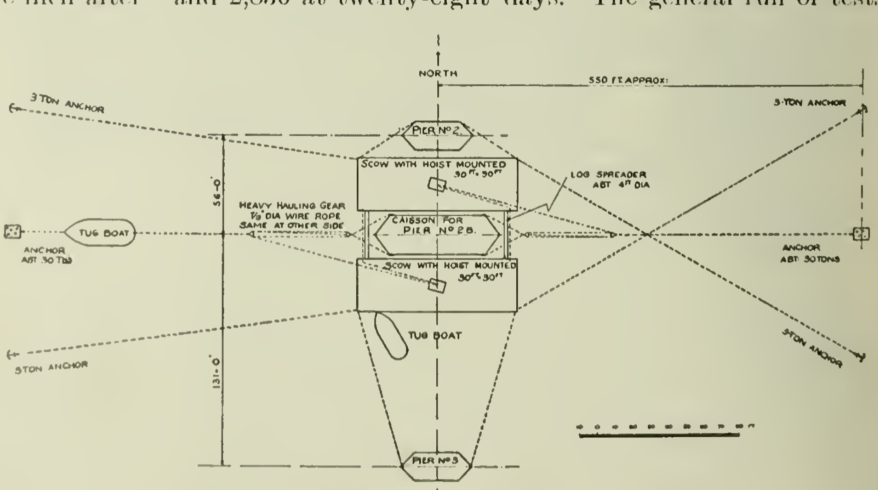

Fig. 20—Pier 2B—Anchoring System for Caisson.

of the eight-sack concrete poured under water showed from 3,350 to 3,500 pounds per square inch at twenty-eight days, the specimens in each case being actually taken from below water level as poured.

The programme for the construction of pier 1B was so laid out that the work would follow at a convenient interval behind that of 2B for all the stages where the same personnel and equipment could be used for both. The steel cutting edge was also built by the Western Bridge Company as subcontractors, was received on the building ways of the Pacific Salvage Company on September 12th, and timbering was commenced at once. Figure 24 shows the steel assembly being landed from scows on which it had been towed from False creek to North Vancouver and Fig. 25 is made to illustrate the construction of this cutting edge. The differences between it and that for pier 2B will be apparent. In addition to the slightly larger overall dimensions, caisson 1B has three cross-walls for the support of

Fig. 21—Placing 30-ton Anchor for 2B, October 11th, 1933.

which steel cutting edges are also provided. These are about 2 feet 6 inches higher than the circumferential edge. The latter consists of a 10-inch at 20-pound channel section backed downwards, acting as the main bearing member, but the cross-walls are provided with bent nose plates designed to be filled with reinforced concrete. Being an open-dredging caisson there is no ceiling as in the case of the pneumatic caisson, but the skin plate on all the cutting edges is of $\frac{1}{4}$-inch thickness stiffened by welded channel sections. The vertical outside sheathing plate is $\frac{3}{8}$ths thick and extends 32 inches upwards from the cutting edge to which it is connected by countersunk stitch rivets and a $\frac{3}{8}$ths continuous weld.

Above the steel frame the caisson is of timber construction, as illustrated in the figure, covered outside the wales with vertical T and G sheathing dressed to $2\frac{3}{4}$ inches. The circumferential concrete walls are 40 inches in thickness and the cross-walls are 48 inches. All these walls were poured in stages after launching, and the timber strutting, except that which was actually bedded in the walls, was all designed to be removable and to leave four large dredging-wells. Above elevation 60 the design included timber struts directly above the concrete cross-walls and a closely spaced system of timber wales above and replacing the side walls. The resulting four dredging-wells were open-sheeted with vertical planking 3-inch by 8-inch at 16-inch centres, so that the essential members of the framework would be protected against damage from buckets during excavation. All timber above elevation 65.5 was subsequently removed; the interior struts during the building of the shaft, and the exterior walls after completion.

To permit the caisson to float after launching, a false or temporary floor of timber was constructed before launching just above the cutting edge. Dynamite charges were placed by divers in holes prepared to receive them.

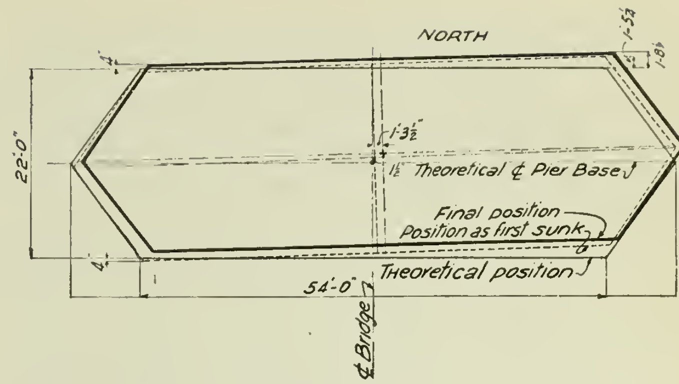

Fig. 22—Pier 2B—Plan showing Deviation from Theoretical Position.

When the caisson had been centred on its final site and sunk by water ballast, the floor was blown out and the flotation destroyed. Figure 26, taken from the contractor's drawing No. 18, shows a few of the stages of construction between launching and sinking. The caisson was launched at 4 p.m. on September 29th when the timbering had been completed up to 20 feet above the cutting edge. During the operation of launching, the caisson skewed slightly (Fig. 27) and one corner overhung the skidways. A floating crane pulled the caisson down into the water but some warp was left in the framework as a result of this experience. The caisson was, therefore, put into dry-dock the next day and overhauled. The caulking of the sides was found to have held up very well, but that around the false bottom had loosened when the corner of the caisson skewed on the ways, and had to be tightened. On refloating on October 2nd no evidence of damage remained and the warp had seemingly disappeared. On October 5th, when the

Fig. 23—Caisson 2B—October 12th, 1933. Taken from Roadway.

Fig. 24—Steel Assembly being Landed from Scows.

timbering had been carried up 32 feet above the cutting edge, the latter was filled with concrete to a height of 15 feet after which the caisson drew 19 feet 6 inches of water. From this point on a regular succession of building up, sheeting, forming, placing reinforcing, and concreting was pursued until the timber framing had reached a point 89 feet above the cutting edge, and the concrete in the walls had been poured up to a height of 52 feet 8 inches.

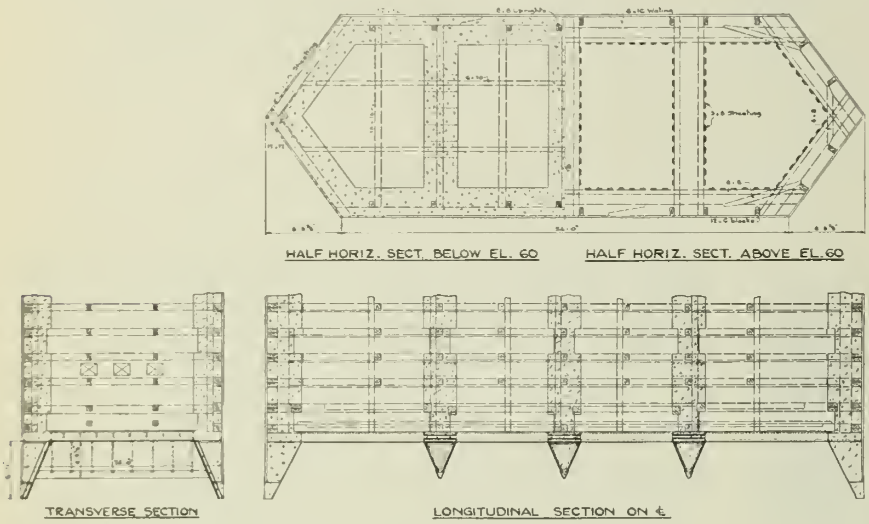

Fig. 25—Open Caisson for Pier 1B.

Preparations were then made for floating the caisson up the inlet and setting it in its proper place. The anchorage system used for mooring scows alongside the caisson of pier 2B was lifted and transferred to the site of 1B where it was finally reassembled as shown on Fig. 31. The bottom was levelled off, at about elevation 24, by a clamshell excavator, the caisson was pumped out and cleaned, and on November 9th, when tide and weather conditions were favourable, the vessel was towed into position, filled with water by opening the valves provided and thus sunk. It reached its place at 11.40 a.m., just previous to high tide and grounded as the tide fell, hitting bottom just before 2 p.m. at about half tide.

The concreting plant used for pouring pier 1B consisted of a one cubic yard Ransom mixer equipped with a scale for weighing the cement and aggregates. The stone and sand bins were erected above the floor of the roadway. The mixer itself was carried on a platform suspended under the railroad track, immediately adjacent to and north of pier 1, and discharged into a hopper from which the concrete was transported to the pier by means of a belt conveyor. A stiff-leg derrick with a long guyed wooden boom was also set up on pier 1 to aid the floating derricks in moving the caisson and also to handle the excavating buckets. On Fig. 31, already referred to, it will be noticed that for this pier the scows were respectively east and west, or ahead and astern, of the caisson instead of alongside, the floating derricks being brought up to the south while the fixed derrick above described operated from the north.

Concreting was resumed on November 14th, the circumferential and cross-walls being poured up to 60 feet above the cutting edge on this day. The extra weight seemed to be sufficient to disturb the foundation material to some extent and initiate scour on the south side. The caisson began to settle unevenly and scow loads of rock being excavated from pier 2B were immediately dumped along the south edge in order to arrest this tendency. This was recognized as a temporary provision only and proved quite inadequate in itself, but was immediately followed by the depositing of heavy quarry riprap along the short side of the caisson between the south east shoulder and the east nose. Simultaneously, jetting along the northern edge was arranged for in order to permit the sinking of this edge if the south side continued to settle from natural causes. Considerable movement and tilting actually took place about this time, the difference in elevation on the top wale, which was 89 feet above the cutting edge, becoming as much as 4 feet 2 inches. The caisson originally grounded with its cutting edge at elevation 23.3 on the average and fairly level, but on November 16th the south east corner was down to 18.3 feet while the north west corner was at about 22.5 feet. The current and tide conditions were quite unfavourable on the evening of this day so that the caisson was attached by cable to pier 0. The photograph Fig. 29 was taken on November 17th and indicates the condition of affairs substantially as it is described, which was practically the worst situation encountered. On the 18th the continuous placing of heavy riprap began to have the desired effect. Some of the water ballast was pumped out and the caisson gradually righted itself. A check for position indicated that the translational and rotational movements had been rather too much to leave uncorrected, so that on the 20th, at 4 p.m., the caisson was dewatered and refloated. No difficulty whatever was experienced in this operation or in handling it and resinking it; so that finally it was successfully located with a degree of accuracy which was definitely satisfactory.

Riprap continued to be supplied in large sizes and ample quantities. Two panels of the railway floor steel of the old 300-foot span were found to be available and these were dropped to the bottom south east of the south east shoulder and acted as grids holding the granite riprap in

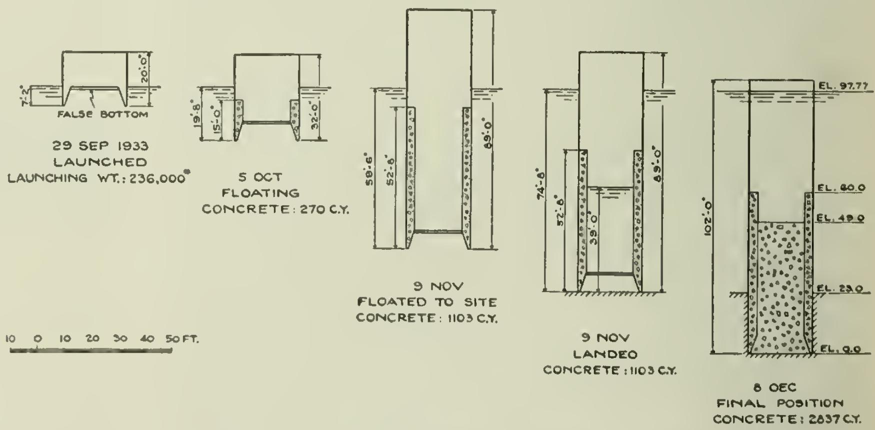

Fig. 26—Pier 1B—Floating and Sinking Diagrams.

place and helping to reduce the scour to negligible proportions.

On November 23rd the caisson was completely filled with water and the temporary timber floor was shot out, pocket by pocket. After the material floated up by this process had been cleared away, dredging in the wells was undertaken. Both the derrick on pier 1 and one of the floating derricks were used for this purpose and the work was continued all night. By 7 p.m. the next day the cutting edge was very nearly level at an average elevation of 13.72 and excavation work was delayed at this point while the remaining 13-foot strake of caisson wall was added. Every opportunity offered by slack tides was taken to increase the riprap toward the south-west, south, south-east, and east borders of the caisson where the divers reported that the scour had been most apparent. The material excavated from caisson 1B was very constant in character and a scow-load of it is photographed in Fig. 28 where the presence of an ordinary envelope 7½ inches by 4 inches will assist in estimating the size. This gravel was quite clean and of mixed grades up to 6 inches or 8 inches diameter and was judged to form excellent bearing material at the specified depths. A 2-yard clamshell bucket and a one-yard orange peel grab were used by the contractors for the excavation and were very effective in lowering the caisson. On November 30th the cutting edge was down to elevation 1.0 and the interior portions were below the final specified elevation of 0. Operations were, therefore, stopped so that any natural settlement might take place during the night. Very little actually occurred so that two small dynamite charges were inserted, one toward each nose, to gently jar the caisson down to a final position where stability could be assumed. Elevations taken on December 2nd showed the cutting edge to have come to rest on a very even and level periphery, on an average elevation of −0.36. Riprap was still being placed at all slack tides and ultimately some 3,800 to 4,000 tons were used at this pier, very closely in accord with the original intentions and estimates, this quantity being placed as carefully as possible following check soundings which were made every few days as the slack tides permitted. Simultaneously, scow loads of granite riprap were also dumped around the upstream end of pier 2B to fulfil the requirements of the specifications, until the south side and the east end were satisfactorily protected. In view of the prospective demolition of old pier 2, the final placing of riprap on the north side of pier 2B was delayed insofar as the debris from demolition would undoubtedly act to a certain extent as protective riprap and surveys would need to be made after the demolition.

**Fig. 27—Caisson 1B stuck on Ways at Launching, at Point of Sliding Off.**

Concreting in the pockets of caisson 1B was commenced during the evening of December 4th.

The mixer discharged onto a belt conveyor which in turn fed the hopper, from which chutes or tubes depended leading to the bellmouth of the 10-inch tremie pipes. The centre pockets, numbers 2 and 3, were first filled by continuous pouring up to elevation 49 by which time large deposits of laitance had gathered in the bottom of the two end pockets, 1 and 4. This laitance was quite soft and could be readily removed by suction pumps guided by divers. Great care was demanded in completely evacuating this laitance and when pocket 4 at the east end had also been concreted to elevation 49, pouring had to cease while pocket 1 at the west end was thoroughly cleared. On December 8th this last pocket was then filled to the same elevation and all concrete was given several days to set. An additional 6 feet of timber sheeting was added to the top of the caisson to prevent waves from breaking over, and pumping out was then attempted on the 14th. It was soon noticed that the pumps could not unwater the caisson and an exhaustive examination failed to disclose any major defect to which this fact could be attributed. Extra pumps were added and canvas was placed outside the sheeting. Divers who had been sent inside to examine the caulking in the seams began to locate numerous small leaks as soon as any headway was made with the dewatering process, and it now became apparent that the straining of the caisson walls during the periods of uneven settlement was responsible for this temporary trouble. On December 19th, by dint of much effort, the water was successfully lowered to elevation 60. The side walls were thus revealed and further pumping bared the top of the concrete in the pockets. Again laitance had to be dealt with and considerable quantities were loosened and cleaned off until the concrete surfaces were acceptable for further pouring. Leaks were caulked, pumping being maintained, and on the 23rd all the pockets were filled to elevation 58.5 with dry concrete. The weather had meantime become somewhat wintry and heat was applied to the mixing water for the succeeding lift of 293 yards which finished the base of the pier at elevation 65.5.

**Fig. 28—Gravel from Bottom of Open Caisson 1B. White Patch is envelope about 4 by 7½ inches. November 30th, 1933.**

**Fig. 29—Caisson 1B from northwest, November 17th, 1933.**

The shaft above this level was merely a repetition of that for pier 2B and needs no further comment beyond noting the need of altering the chuting system as the height of the shaft grew. The coping was reached on January

11th, the daily reports showing that the outside temperature at this time was approximately 43 degrees. The total net yardage in this pier was 4,804 cubic yards to the making of which 30,959 sacks of cement contributed.

Dismantling of plant on caisson walls followed during the middle of the month and upon the concrete becoming sufficiently well set the bearing areas were dressed to receive the steel bedplates. On both piers the outside surface of the shaft was rubbed and finished with a coat of

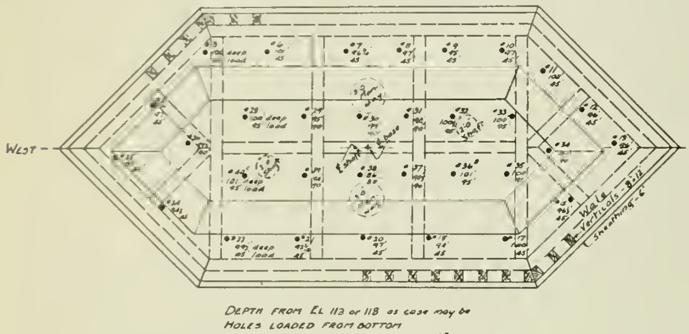

**Fig. 30—Layout of Blasting Holes, Pier 2.**

cement-wash to improve the general appearance, but the submerged portions, particularly between tides, quickly acquired a coating of marine slime to which doubtless molluscs will cling in the near future. Experience with teredo and other local marine life ensures that the exposed untreated timber will be eaten away within a few years. Examination of the existing structural steelwork shows that even on the painted surfaces above the roadway level a type of green moss flourishes comfortably.

The remaining work of the substructure contract was the demolition of the old pier 2. The specification called for this old pier to be taken down to an elevation determined by the riprap requirements. Manifestly, the debris would need to be distributed by drags up- and down-stream so that no obstruction would be caused to the normal flow of water. A tentative line shown on the drawings as the line of riprapping to the north of the new pier served to give the bidders an indication of the amount of demolition involved. The clause inserted into the instructions-to-bidders in this connection reads as follows:—

> "Clause 45: In demolishing the existing pier No. 2, as indicated on the drawings, numerous light shots should be used. No heavy blasting will be permitted, and the greatest care must be exercised to avoid any damage being done to any other parts of the work. The Contractor must submit his proposed method for handling this work, for the approval of the Engineer."

Furthermore, each superstructure bidder was asked to state in his tender:—

> "Clause 4 (a): Whether or not he will require the old pier No. 2 to be retained intact for his use during the work of dismantling the end of the existing bascule span."

All bidders replied negatively to this question, so that the substructure contractors were given full liberty as to where in their programme the demolition should occur. They, very naturally, found the old pier useful during all mooring operations and early decided to leave its destruction until completion of the new piers.

The method adopted for demolition was to drill numerous holes from the top to about elevation 18, the central ones vertically and the side ones slightly inclined so as to approach the surface of the base at the lower levels. It was then intended to charge these holes with dynamite and to detonate the charges according to some preconceived plan. The precise plan was modified from time to time as further opinion was brought to bear on the scheme and ultimately the engineer's approval was asked for an arrangement by which thirty-two holes were to be shot in groups of three at intervals ranging from 0.8 to 2.2 seconds covering a total period of 12.8 seconds. In December, 1933, the idea had been to blow off the north side in layers at intervals wide enough apart to permit examination of the effect of the first blast before shooting the second. By this means it was hoped that the concussive effect transmitted through the water would be directed generally northward and that the standing portion of the old pier would serve to protect the new pier 2B.

Subsequent expert advice to the Foundation Company led them to doubt the efficacy of this method, particularly in respect of the uncertainty as to what might happen to the unshot holes, whether loaded or unloaded, during the shooting of the first layer or series. The revised scheme was, therefore, to shoot in layers to the east but with all holes loaded and wired for delayed firing as above indicated. The presence of steel tie-rods, timber framing, three or four man- and material-shafts, none of which could be very

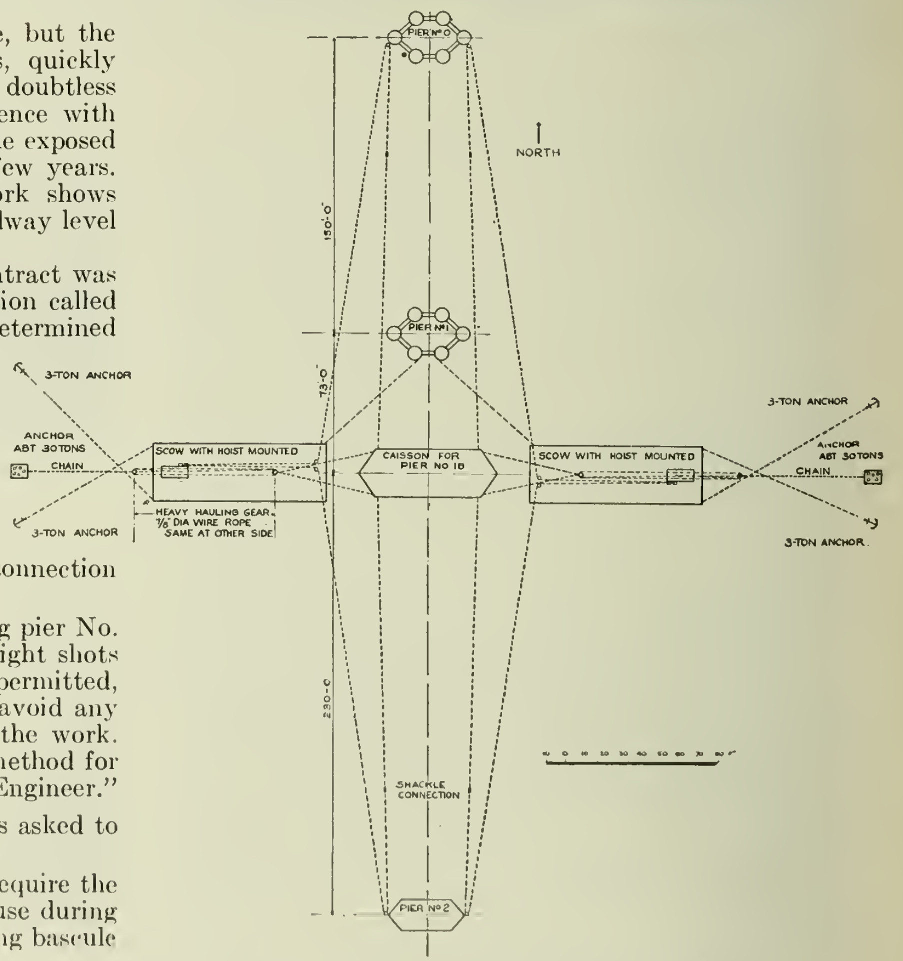

**Fig. 31—Pier 1B—Anchoring System for Caisson.**

definitely located from the incomplete plans available, not only interfered with drilling progress, but raised some doubts as to the degree of break-up and shattering which might finally be achieved. The drill holes, roughly located on Fig. 30, were mostly of 3-inch diameter although five holes, numbers 8, 9, 10, 11, 12, were only of 2-inch diameter. The charges were from 45 feet to 100 feet in depth per hole, were of 2½-inch or 1½-inch diameter, 60 per cent dynamite and, in the case of the outer holes, the 45 feet of charge extended from the bottom up to approximately elevation 65, the joint between base and upper shaft. In all, nearly 5,000 pounds of dynamite was used.

The blast was fired on the night of March 1st but listening witnesses all agree that, instead of 11 distinct shots separated by intervals averaging 1.2 seconds, there were firstly 2 or 3, or possibly 4, such distinct shots, after which came one huge blast wherein all the remaining charges detonated together, which of course was directly contrary to what had been required and planned for.

The pier was well demolished although a considerable amount of dredging and dragging had to be done to satisfactorily spread the debris, and several lengths of old steel manshaft had to be pulled off and taken away.

Unfortunately, the concentrated blast vibrated the neighbouring new pier 2B and caused some spalling at the construction joint at elevation 99, as well as some local distortion in the steelwork immediately connected to the anchor bolts which had been built into the concrete. The two outer panels of the bascule span had been removed sometime previously, by the superstructure contractors, and the remaining portion, partly disconnected, had been tied down by new material to these embedded anchors, as the removal of dead weight had interfered with the condition of balance previously existing between the bascule span and its counterweight. There were probably some 50 or 60 tons of uplift per truss actually being transmitted through the anchorage system to the new pier at the time of the blast, and the initial lateral amplitude of the vibration although immediately dampened by inertia, by stress in the steel span, and by water pressures, was sufficient to bend certain of the steel parts beyond the elastic limit.

A very thorough survey of the pier and the span was initiated on the morning of March 2nd, by the resident engineer and responsible representatives of both the contracting companies. The author, who arrived at the site a few days later, completed this survey and issued all the necessary instructions for repairs, and saw all of these repairs commenced and most of them carried out. The spalled parts were removed and a complete band around the pier at elevation 99 was cut out by air tools so as to bare the temperature steel for 2 feet below and above the construction joint. This band was cut about 6 inches deep at the joint itself and uniformly feathered off up and down. All steel was reinforced by the addition of spliced material thoroughly wrapped with steel wire. Furthermore, a continuous mesh was built up around the whole band behind the steel rods and gun-driven concrete (Gunite) applied under air-pressure. The band was thus refilled and, after completion, was found to ring hard and true under severe inspection. As a further precaution, a number of grout holes were drilled from the top downwards to approximately elevation 93 and, after heavy dowels had been inserted in the circumferential holes, these latter were grouted up and then the interior holes grouted under pressure in order to ensure that no voids had been left in any portion of the joint at elevation 99.

The repairs to the steelwork were promptly and simply carried out under the author's personal supervision, and superstructure erection then proceeded in the normal manner.

Dragging the debris, placing riprap, and the necessary sounding operations continued during favourable tide conditions throughout the month of April, at the end of which month the substructure contract was considered complete.

Incidentally, it might here be noted that the reduction in low-tide waterway, as between the reconstructed bridge and the original bridge, is just under 3,000 square feet or about 7½ per cent.

A twelve-day strike of compressed air workers, during November, almost as soon as they had started work after long periods of unemployment, hindered operations to some extent and aroused some concern for the safety of the caisson. The fair wage schedule drawn up by the Federal Department of Labour had been incorporated into the tender form and subsequently into the contract, but the settlement of the strike, which was accomplished by conferences between the interested parties, the Federal fair-wage officer, and the Provincial Deputy Minister of Labour, resulted in an increase of wages to sandhogs, lock tenders, and allied classes of labour.

For the Foundation Company of Canada, Mr. A. G. Mackay was superintendent in charge of the work at the site, and Mr. J. W. Roland, M.E.I.C., was resident engineer for the author's firm. Acknowledgment is gladly made to the Foundation Company (Mr. R. R. Holland, vice-president) for permission to use some of their sketches, and to the resident-engineer for illustrative progress photographs.

# Main Cables and Suspenders for Suspension Bridges

*C. D. Meals,*
*Wire Rope Engineer, The B. Greening Wire Company Limited, Hamilton, Ontario.*

**Presented before the Montreal Branch of The Engineering Institute of Canada, April 5th, 1934.**

SUMMARY.—The paper contains useful data, specifications and information based on recent practice as to the physical properties of steel wire for bridges, the various types of main cable and their characteristics, and the results of tests. Particulars regarding suspender ropes and end fastenings for wire ropes are also given.

Steel wire is the strongest material available to the bridge engineer and offers unsurpassed advantages for the main tension members of suspension bridges, the main cables and suspender ropes.

Bridge wire is, preferably, made from acid open hearth steel, as experience has shown that a "pure process product," such as acid steel, is more consistent in quality than a "purified product," like basic open hearth steel.

This wire is a cold-drawn product, in which cold-working greatly increases the elastic limit and tensile strength of the steel, and the only cases where cold-drawn bridge wire has not been used were for the Mount Hope and Ambassador bridges. On these bridges, a heat-treated wire was used, and the high strength was secured, not so much from the wire drawing as from the heat-treatment which formed a continuous process with the cleaning and galvanizing of the wire.

While heat-treated bridge wire was a costly and an unsuccessful experiment, as the cables had to be dismantled, it resulted in further improvements in the standard cold-drawn wire. Since the building of the Brooklyn bridge fifty years ago there has been a steady improvement in the physical properties of steel bridge wire, which is shown in Table I.

Table I
Bridge Wire Strengths

| Bridge | Date Finished | Span Feet | Diameter Wire Inches | Finish | Tensile Properties Breaking (Pounds per square inch) | Yield point (Pounds per square inch) |
|---|---|---|---|---|---|---|
| Brooklyn | 1883 | 1,595 | .187 | galvanized | 160,000 | ....... |
| Williamsburg | 1903 | 1,600 | .192 | bright | 200,000 | ....... |
| Manhattan | 1909 | 1,470 | .195 | galvanized | 212,000 | 134,000 |
| Bear Mountain | 1924 | 1,632 | .195 | galvanized | 218,000 | 149,000 |
| Philadelphia | 1926 | 1,750 | .196 | galvanized | 223,000 | 150,000 |
| Ambassador | 1930 | 1,850 | .195 | galvanized | 225,000 | 170,000 |
| George Washington | 1932 | 3,500 | .196 | galvanized | 234,000 | 184,000 |

In the case of the heat-treated wire, first used on the Ambassador bridge, the yield point was 190,000 pounds per square inch on wire of 225,000 pounds per square inch breaking strength.

On bridges prior to the Brooklyn bridge, the main cable wires were usually .148 inch in diameter and 90,000 pounds per square inch strength. High-strength "patented" steel wire was first introduced to the trade in 1854 by a British wire mill in Birmingham, England.

With the data pertaining to recent developments in bridge wire available, a specification may be compiled as follows:

Specifications for Galvanized Steel Bridge Wire

For the main cables, suspenders and hand ropes, the wire shall be of acid open hearth steel and be cold-drawn.

Physical Properties

| | |
|---|---|
| Tensile strength, pounds per square inch* | 220,000 minimum; 225,000 average |
| Yield point, pounds per square inch* | 165,000 minimum |
| Elongation in 10 inches while under tension | 4 per cent minimum |
| Reduction in area | 30 per cent minimum |
| Modulus of elasticity, pounds per square inch | 27,500,000 minimum |
| Diameter tolerance (on No. 6 wire) | + .003 inch |

*On gross cross-section, including galvanizing.

The yield point is the unit stress that will produce an elongation of 0.75 per cent in 10 inches.

Chemical Properties

| | | |
|---|---|---|
| Carbon | 0.85 maximum | (+10 per cent on check analyses) |
| Manganese | 0.70 maximum | (+10 per cent on check analyses) |
| Phosphor | 0.04 maximum | (+25 per cent on check analyses) |
| Sulphur | 0.04 maximum | (+25 per cent on check analyses) |
| Silicon | 0.30 maximum | (+10 per cent on check analyses) |

The galvanizing bath shall consist of 99.75 per cent pure zinc, containing not more than 0.03 per cent of iron and it shall be applied in the molten state on the wire, so that the wire shall have an average gauge of not more than 0.005 inch larger than the bright wire.

The galvanized wire shall be capable of coiling around a mandrel 1.5 times its own diameter without signs of fracture and shall bend continuously around a 1-inch diameter mandrel, for a No. 6 bridge wire, without developing cracks in the galvanizing that are visible to the naked eye.

All galvanized wire shall be capable of withstanding the Preece test; immersions in a standard solution of copper sulphate, without showing a bright metallic copper deposit on the samples, to the following requirements:—

Wires .064 to .079 inches diameter —3 one-minute immersions.
Wires .080 to .092 inches diameter —3 one-minute and 1 one-half-minute immersions.
Wires .093 inches diameter and larger—4 one-minute immersions.

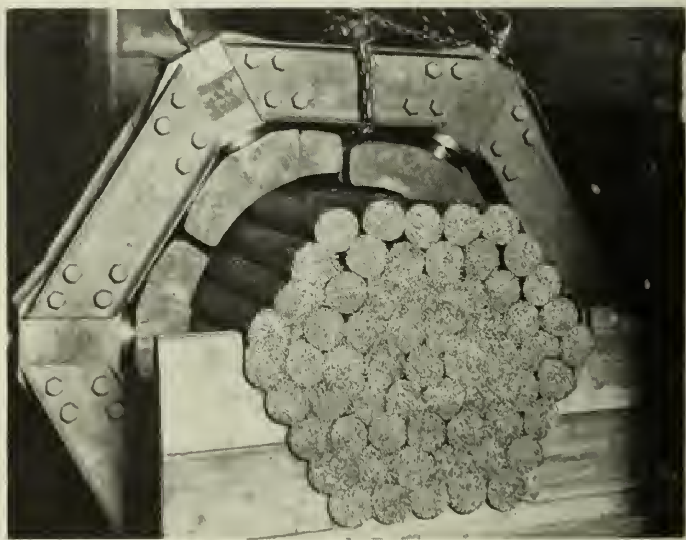

**Fig. 1 Type (a) Main Cable as Initially Fabricated—Philadelphia Bridge.**

## MAIN CABLES

Main cables of suspension bridges are of four types in their structural details and methods of fabrication, and these may be arbitrarily classified as:—

(*a*) Cables of parallel wires, spun in the air.
(*b*) Cables of parallel wires, laid up on the ground at the bridge site.
(*c*) Cables of a multiple of rope strands, as fabricated in the shop and laid parallel in the cable.
(*d*) Cables of one or a multiple of wire ropes, as fabricated in the shop and laid parallel in the cable.

Too many factors are involved to give any definite rules regarding the range of application of these types of main cables, but considering the recent trend in cable design, the following are given, again arbitrarily:—

Type (*a*) main cables for heavy and long span bridges, 1,400 feet and longer.

Type (*c*) main cables on moderate and heavy bridges of spans 300 to 1,500 feet.

Type (*d*) main cables on light and moderately heavy bridges of spans up to 500 feet long.

Type (*b*) main cables were used extensively by the early French and American bridge builders and recently on three bridges: the 700- and 689-foot span bridges over the Ohio river at Portsmouth and Steubenville, Ohio, respectively and the 802-foot span bridge over the Gila river at Dome, Arizona; all built in 1927 and 1928. It is doubtful if this type of main cable will be used again, as the type (*c*) main cables offer many advantages.

Type (*a*) main cables have been used on spans shorter than 1,400 feet but there is a limit, as was found on the 705-foot span Kingston, N.Y., bridge, built in 1922. This span was too short to attain the desired uniformity in tension in the No. 6 bridge wire used, although a smaller diameter wire would have eliminated this trouble.

### Main Cables—Type (*a*)

The No. 6 bridge wire is generally utilized for type (*a*) main cables and is the largest size used to date; however, wires of other diameters may be used and their properties are noted in Table II.

Table II

Properties of Galvanized Steel Bridge Wire

| Size No. | Diameter of wire-Inches Bright | Galvanized | —Galvanized wires— Area Square inches | Weight per 100 feet pounds | Breaking strength at 225,000 pounds per square inch |
|---|---|---|---|---|---|
| 6 | .192 | .196 | .03017 | 10 | 6,780 |
| 7 | .177 | .180 | .02545 | 8.5 | 5,730 |
| 8 | .162 | .165 | .02138 | 7.2 | 4,810 |
| 9 | .148 | .151 | .01791 | 6.0 | 4,030 |

Modulus of elasticity—28,000,000 to 29,500,000 pounds per square inch. For the main cable itself, the modulus may be taken as 27,500,000 pounds per square inch.

Type (*a*) main cables are usually considered as 100 per cent efficient; in the main span, equal tensions in the wires are undoubtedly attained but at the anchorages, the placing of the wire around the 20-inch strand shoe involves the human element and equal wire tensions are problematical.

Tests have been reported* of parallel wire strands which were laid up as carefully as possible, with either sockets or the wires laid around 20-inch strand shoes, at the ends and these are noted in Table III.

Table III

Tests of Parallel Wire Strands

| Wires Diameter Inches | Number | End fittings | Length feet | Aggregate Strength Pounds | Actual Strength Pounds | Efficiency Per cent |
|---|---|---|---|---|---|---|
| .194 | 306 | strand shoes | 28 | 1,974,206 | 1,880,000 | 95.2 |
| | | | | 2,002,688 | 1,883,000 | 94 |
| .197 | 37 | sockets | .. | 242,470 | 234,300 | 96 6 |
| .192 | 80 | sockets | 5 | 484,000 | 460,000 | 95 |
| | | | | 487,780 | 464,000 | 95.1 |

The modulus of elasticity of the 306 wire strands was 27,400,000 pounds per square inch.

As initially made the main cables are hexagonal, they are then compacted into a cylindrical shape, except over the saddles. The diameter $D$ of the finished cylindrical cable, in terms of $\delta$, the diameter of the individual wires, and $n$, the number of wires, is given quite accurately by equation (1) as

$$D = 1.12\,\delta\,\sqrt{n} \quad \ldots\ldots\ldots\ldots\ldots\ldots(1)$$

The largest cables are those of the George Washington bridge; each of the four cables is 35⅞ inches in diameter and consists of 61 strands of 434 wires .196 inch in diameter, or a total of 26,474 wires per cable.

The finished cylindrical cables are closely wound, wrapped with an annealed galvanized iron wire of .151 inches diameter, having a strength of approximately 65,000 pounds per square inch though in some cases a .135 inch wrapping wire has been used. This wrapping helps to exclude moisture and holds the mass of wires tightly together, preventing chafing and ensuring united stress action.

Fig. 2—Type (a) Main Cable as Compacted into Cylindrical Shape—Philadelphia Bridge.

The hexagonal shape of a cable as initially fabricated is shown in Fig. 1, this being one of the main cables of the Philadelphia bridge; the 61 strands, each of 306 wires .196 inch in diameter (18,666 wires total) are easily identified. The cable is 35½ inches across the corners.

The same main cable is shown in Fig. 2, after being compacted into the cylindrical shape and before being wound with the .151 inch diameter galvanized iron wrapping wire; the diameter of the cable as shown is 29-15/16 inches.

### Main Cables—Type (*c*)

Main cables of rope strands are not a recent idea, as George Morison proposed† in 1896, in the design of a 3,200-foot span railway suspension bridge over the Hudson river, to use 253-2⅛-inch diameter rope-strands in each of the four main cables. His proposal created considerable discussion at the time and this showed one unfavourable feature. Tests of the rope-strands with sockets on the ends showed some were only 80 per cent efficient. However, the method of fastening the sockets with split and solid wedges was crude and the sockets as attached to-day will develop 91 to 94 per cent of the aggregate strength of the wires, which represents the full efficiency of the rope-strands.

Prestressed rope-strands are not an innovation either, as Morison noted that "by adjusting the rope-strands

* Final Report of the Board of Engineers to the Delaware River Bridge Joint Commission, 1927.

†"Suspension Bridges—A Study," by G. S. Morison, Transactions Am. Soc. Civil Engineers, 1896.

under stress at the factory, it is believed that the length can be so accurately fixed that no further adjustment will be required on the bridge."

An eminent bridge engineer* stated recently that "the rope-strand cable offered an economy in cost and erection time, yielding greater strength with equal rigidity and that the shorter the span, below the equal-cost limit of 1,500 feet, the greater will be the economic advantage of this type of cable"; and their high breaking strength efficiency and high modulus of elasticity substantiate this statement.

One of the earliest, if not the first long span bridge having rope-strand main cables, is the 949-foot span bridge over the St. Maurice river at Grand'Mere, Que. erected in 1929. Since then quite a few highway bridges of this type have been built and these are listed in Table IV.

Table IV

"Rope-Strand" Main Cable Bridges

| Bridge | River | Date | Span Feet | Main Cables Rope-strands Inches |
|---|---|---|---|---|
| Grand'Mere, Que | St. Maurice | 1929 | 949 | 37-1¼ |

*Under construction—1933-35.

The breaking strength $T$ of a rope-strand in terms of the individual wire strengths $S$ and the angle of lay $\alpha$ of the wires in the strand, is given quite accurately by equation (2).

$$T = \sum_{1}^{n} S \cos^3 \alpha \quad \ldots\ldots (2)$$

The efficiency of the "rope-strand" may be determined from this equation and will vary from 91 to 94 per cent, depending upon the construction and the length of lay of the rope-strand. The construction is fixed largely by the prevailing practice of limiting the outer wire diameters to a No. 6 bridge wire (.196 inch galvanized diameter) and the core wires to .208 inch in diameter.

The various constructions of rope-strands are shown in Fig. 3 and their properties are noted in Table V, the breaking strengths being based upon wire of 225,000 pounds per square inch strength.

Table V

Galvanized Steel Rope-Strands

| Diameter Inches | Construction | Area Square inches | Weight Per 100 feet pounds | Breaking Strengths Tons of 2,000 pounds |
|---|---|---|---|---|
| ¾ | 1×19 | .3330 | 116 | 35 |
| 13/16 | 1×19 | .3889 | 136 | 41 |
| ⅞ | 1×19 | .4540 | 158 | 48 |
| 15/16 | 1×19 | .5190 | 181 | 54 |
| 1 | 1×19 | .5882 | 205 | 62 |

*D. B. Steinman in Engineering News-Record of March 17, 1932, page 387

Yield point load at 70 per cent of breaking strengths.

Modulus of elasticity up to 50 per cent of breaking strengths as a minimum, may be taken as:

1⅝ inch diameter and smaller ........ 24,000,000 pounds per square inch
1-11/16 inch to 2⅛ inches diameter .. 23,000,000 pounds per square inch
2¼ inches to 2½ inches diameter .... 21,000,000 pounds per square inch

Brazing or welding of the outer wires of rope-strands should not be allowed; this, however, does not apply to the inner wires.

Both right and left lay rope-strands are used in the same main cable in adjacent layers as shown in Fig. 4; as strands in adjacent layers, when of opposite lay, afford a better bearing surface and when the rope-strand stretches under stress, it rotates or untwists and the right and left lay strands neutralize this rolling effect in the cable.

Prestressing to 50 per cent of the breaking strength eliminates the constructional stretch and increases the elastic modulus. The strands are then measured to length under a tension equal to the calculated average dead-load stress and at the same time the saddle, centre of span, and cable-band points are marked on the strands from the calculated values. In addition the strands are marked with a continuous longitudinal stripe, so that any untwisting, which will increase the length, may be controlled in subsequent handling at the bridge site; this latter is an important consideration.

Variations in measured lengths can be kept within the limits of ± ½ inch per 1,000 feet of length. For the 2,722-foot length strands for the St. Johns, Oregon, bridge, the variation in measured lengths was ± 1 inch.

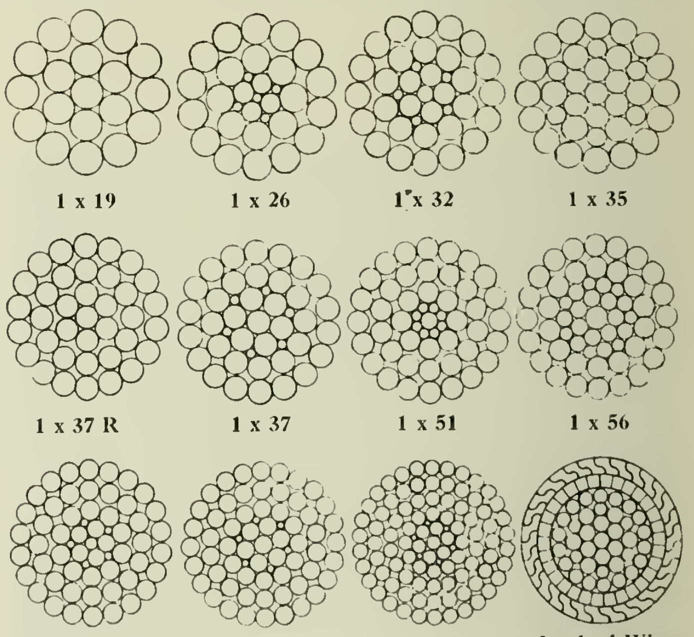

Fig. 3—Main Cable Rope-Strands.

Data covering rope-strands of various bridges are given in Table VI.

Table VI

Rope-Strands of Various Bridges

| Bridge | Strands Diameter Inches | Strands Type | Area Square inches | Breaking Strength Tons | Modulus of Elasticity Pounds per square inch |
|---|---|---|---|---|---|
| Grand'Mere | 1¼ | 1×35 | .9558 | 99.5 | 25,000,000 |
| Bucksport | 1⅜ | 1×37 | 1.1361 | 108 | 26,600,000 |
| St. Johns | 1½ | 1×51 | 1.3492 | 150 | 25,000,000 |
| Maysville | 1 9/16 | 1×59 | 1.4702 | 167 | 24,700,000 |

Rope-strand main cables are hexagonal in shape and wood and aluminum fillers have been used to make the finished cables cylindrical in shape, after which the cable is wrapped with a .151 inch galvanized annealed iron wire. The wrapping of the finished cylindrical cable is shown in Fig. 5. On the Maysville bridge the six-corner rope-strands were made smaller in diameter, which made the cable more cylindrical in shape, and effected a saving in the weight of the fillers.

With a more careful planning of the main cable cross-section the fillers could be eliminated entirely, or if wrapped in its hexagonal shape, the cable would hardly be objection-

**Fig. 4—Right and Left Lay Rope Strands in Adjacent Layers—Maysville Bridge.**

able æsthetically and certainly a cable so wrapped would be as effective and more economical. The main cables of the Cologne-Mulheim bridge over the Rhine river in Germany were left hexagonal in shape and were not wrapped.

Tightly grouped rope-strand main cables are not a requisite, as main cables with the rope-strands arranged in tiers, with an open space between each rope-strand, have been utilized for some time past by the continental European bridge engineers.

In some respects this open grouping of the rope-strands has merit, in that each rope-strand is susceptible to inspection and maintenance; the heavy compression of strand on strand over the tower saddles is eliminated; the cable-band design is simplified and the bridge, with the seemingly heavier main cables, is aesthetically improved. One of the main cables of the Ozark Mountain bridge as noted in Table IV, is shown in Fig. 6.

Continental European engineers favour the locked wire strand (see Fig. 3), not galvanized and claim the following advantages: (1) compactness, (2) smooth outer surface and (3) sealing against moisture by the locked outer wires; (1) and (2) are admissible and desirable; (3) is questionable, as it is extremely doubtful if the locked wires fit so snugly that moisture is excluded.

Furthermore, locked wire strands are objectionable in that (*a*) the interior bright wires cannot be examined for their condition regarding corrosion; (*b*) the "strength/weight" factor is approximately 20 per cent higher than that of the rope-strands and (*c*) the modulus values are somewhat lower.

The data in Table VII on a few sizes of locked wire strands may be of interest for comparison with the rope-strands:—

Table VII

Locked Wire Strands—Not Galvanized

| | | | | | | |
|---|---|---|---|---|---|---|
| Diameter—Inches..... | ¾ | 1 | 1¼ | 1½ | 1¾ | 2 |
| Area, square inches.... | .3710 | .6711 | 1.0141 | 1.4386 | 1.9031 | 2.5498 |
| Wgt. per 100 feet lbs.. | 133 | 239 | 373 | 558 | 750 | 967 |
| Strength—tons........ | 33 | 60 | 93 | 136 | 182 | 240 |

Modulus of elasticity 20,000,000 to 23,000,000 pounds per square inch.

The two main cables of the Cologne-Mulheim highway suspension bridge of 1,033.45-foot main span, each consisted of 37 locked wire strands, not galvanized, 3.15 inches in diameter, and each of these strands possessed the following physical properties:

Metallic area..........6.595 square inches
Breaking strength......652.5 tons
Weight per linear foot..24.66 pounds
Unit wire strengths.....192,000 to 213,500 pounds per square inch
Modulus of elasticity...22,800,000 pounds per square inch of strands prestressed to 265 tons for two hours' duration.

Main Cables—Type (*d*)

Wire ropes for main cables are not as economical in price or strength as rope-strands but offer an advantage in ease of handling and less likelihood of being damaged by the erectors.

These ropes are made up with 6 strands covering either a strand centre or an independent wire rope centre; the former is preferable as the rope is more compact and results in a higher modulus of elasticity value. The strength of these wire ropes may be calculated from equation (3), the

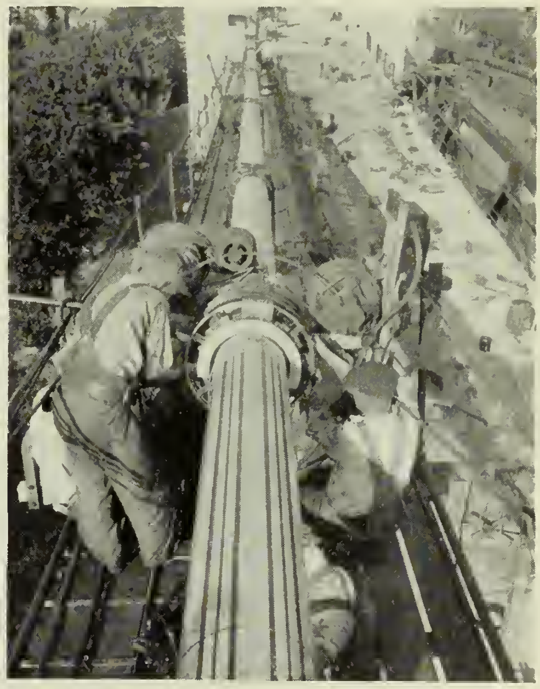

**Fig. 5—Wrapping the Maysville Strand Cable which was made Cylindrical in Shape by the use of Aluminum Fillers.**

first term being for the 6 outer strands and the second term that of the strand centre:

$$T = N \cos \beta \sum_{1}^{n} S \cos^3 \alpha + \kappa \sum_{1}^{n} S \cos^3 \alpha \quad \ldots\ldots\ldots (3)$$

in which,

$N$ = number of outer strands in rope.
$S$ = strength of the individual wires.
$\kappa$ = construction factor, having a value of 0.80 to 0.85.
$\beta$ = angle of lay of the outer strands in the rope.
$\alpha$ = angle of lay of the wires in the strand.

Three constructions of main cable wire ropes are shown in Fig. 7 and the properties are listed in Table VIII, the breaking strengths being based upon commercial steel wire of 215,000 pounds per square inch.

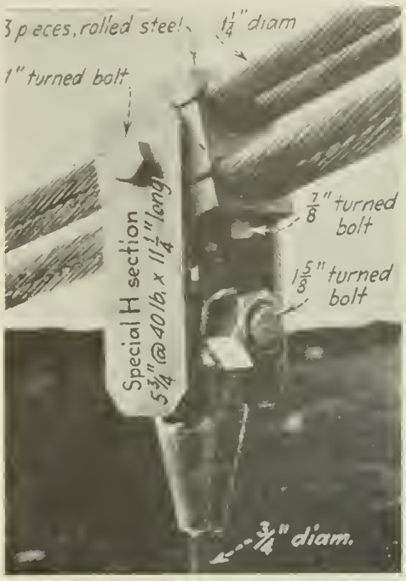

**Fig. 6—Main Cable with Cable-Band and Suspender Strand Connection—Ozark Mountain Bridge.**

Table VIII

Galvanized Steel Wire Ropes for Main Cables

| Diameter Inches | Construction | Area Square inches | Weight Per 100 feet pounds | Breaking Strength Tons |
|---|---|---|---|---|
| ¾ | 6×7/1×19 | .2596 | 95 | 25 |
| ⅞ | 6×7/1×19 | .3566 | 134 | 35 |
| 1 | 6×7/1×19 | .4628 | 170 | 45 |
| 1⅛ | 6×7/1×19 | .5841 | 214 | 56 |
| 1¼ | 6×7/1×19 | .7257 | 267 | 70 |
| 1⅜ | 6×7/1×19 | .8742 | 321 | 84 |
| 1½ | 6×7/1×19 | 1.0367 | 381 | 100 |
| 1⅝ | 6×19/1×37 | 1.3211 | 485 | 126 |
| 1¾ | 6×19/1×37 | 1.5298 | 562 | 146 |
| 1⅞ | 6×19/1×37 | 1.7610 | 646 | 168 |
| 2 | 6×19/1×37 | 1.9916 | 732 | 190 |
| 2⅛ | 6×19/1×37 | 2.2474 | 825 | 215 |
| 2¼ | 6×19/1×37 | 2.5393 | 935 | 242 |
| 2⅜ | 6×19/1×37 | 2.8171 | 1,035 | 269 |
| 2½ | 6×19/1×37 | 3.1243 | 1,147 | 298 |
| 2⅝ | 6×19/1×37 | 3.4320 | 1,260 | 328 |
| 2¾ | 6×19/1×37 | 3.7623 | 1,380 | 355 |
| 2⅞ | 6×37/1×61 | 3.9301 | 1,445 | 371 |
| 3 | 6×37/1×61 | 4.2827 | 1,575 | 405 |
| 3¼ | 6×37/1×61 | 4.9958 | 1,835 | 472 |
| 3½ | 6×37/1×61 | 5.8081 | 2,135 | 549 |
| 3¾ | 6×37/1×61 | 6.6834 | 2,460 | 631 |

The moduli of elasticity, which are approximate as the manufacturing facilities of the rope maker will be a factor, are as follows:

| Construction | As manufactured Pounds per square inch | Prestressed at 30 per cent of strength Pounds per square inch |
|---|---|---|
| 6×7/1×19 | 18,000,000 | 20,000,000 |
| 6×19/1×37 | 16,000,000 | 18,000,000 |
| 6×37/1×61 | 14,000,000 | 17,000,000 |

The 460-foot span highway bridge over the Bulkley River canyon in British Columbia, erected in 1931, has main cables of 19-1½ inches diameter wire ropes and wood fillers were used to make the finished cable cylindrical in shape and the cables were wrapped with canvas and galvanized wire to exclude moisture. These ropes were prestressed at the bridge site.

### Suspender Ropes

Suspender ropes are made with an independent wire rope centre and the constructions are as shown in Fig. 8. The strength of these ropes may be calculated from equation (4):

$$T = N \cos \beta \sum_{1}^{n} S \cos^3 \alpha + \kappa N_1 \cos \beta_1 \sum_{1}^{n} S \cos^3 \alpha \quad (4)$$

in which the nomenclature is the same as given for equation (3); the value of $\kappa$ being taken as 0.80 and of $N_1$ in the second term for the independent wire rope centre, as 7 instead of 6.

The properties of these ropes are noted in Table IX, the breaking strengths being based upon wire of 225,000 pounds per square inch strength.

Table IX

Galvanized Steel Suspender Ropes

| Diameter Inches | Construction | Area Square inches | Weight Per 100 feet pounds | Breaking Strength Tons |
|---|---|---|---|---|
| ⅝ | 6×7/7×7 | .1780 | 66 | 17 |
| ¾ | 6×7/7×7 | .2526 | 94 | 24 |
| ⅞ | 6×7/7×7 | .3447 | 129 | 33 |
| 1 | 6×7/7×7 | .4494 | 168 | 43 |
| 1⅛ | 6×7/7×7 | .5676 | 212 | 54 |
| 1¼ | 6×7/7×7 | .7057 | 264 | 68 |
| 1⅜ | 6×7/7×7 | .8466 | 316 | 81 |
| 1½ | 6×19/7×7 | 1.0682 | 400 | 103 |
| 1⅝ | 6×19/7×7 | 1.2604 | 470 | 121 |
| 1¾ | 6×19/7×7 | 1.4493 | 580 | 139 |
| 1⅞ | 6×19/7×7 | 1.6674 | 623 | 160 |
| 2 | 6×19/7×7 | 1.8950 | 710 | 182 |
| 2⅛ | 6×37/7×7 | 2.0850 | 780 | 200 |
| 2¼ | 6×37/7×7 | 2.3470 | 880 | 225 |
| 2⅜ | 6×37/7×7 | 2.6186 | 980 | 252 |
| 2½ | 6×37/7×7 | 2.8744 | 1,075 | 276 |
| 2⅝ | 6×37/7×7 | 3.1803 | 1,190 | 306 |
| 2¾ | 6×37/7×7 | 3.4928 | 1,305 | 336 |
| 2⅞ | 6×37/7×7 | 3.8262 | 1,430 | 368 |
| 3 | 6×37/7×7 | 4.1727 | 1,560 | 402 |

The moduli of elasticity will be approximately as follows:

| Construction | As manufactured Pounds per square inch | Prestressed at 25 per cent of strength Pounds per square inch |
|---|---|---|
| 6×7/7×7 | 15,000,000 | 18,000,000 |
| 6×19/7×7 | 12,000,000 | 16,000,000 |
| 6×37/7×7 | 11,000,000 | 15,000,000 |

The diameter tolerances are generally as given in Table X.

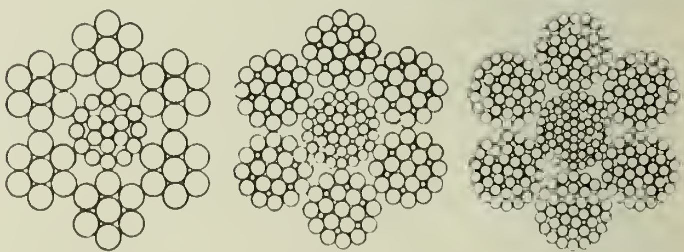
Table X

Diameter Tolerances of Suspender Ropes

| Nominal Diameter | Oversize | Undersize |
|---|---|---|
| ¾ inch and smaller | 1/32 inch | 0 |
| ⅞ inch to 1½ inch | 1/16 inch | 0 |
| 1⅝ inch to 2¼ inch | 3/32 inch | 0 |
| 2⅜ inches and larger | ⅛ inch | 0 |

On moderate and long span bridges, the suspender ropes are looped over the cable-bands on the main cables, as shown in Fig. 2; there will be a loss of strength due to this bending, and the strength of the rope so bent may be calculated from equation (5).

$$T_1 = \kappa_1 e A \left( t - \frac{E_r \delta}{D_1 + d} \right) \quad (5)$$



**6 x 7/1 x 19 6 x 19/1 x 37 6 x 37/1 x 61**

**Fig. 7—Main Cable Wire Ropes.**

in which,

$T_1$ = breaking strength of rope bent over cable-band.

$A$ = metallic area of rope, square inches.

$t$ = unit tensile strength of wire, pounds per square inch.

$E_r$ = modulus of elasticity of rope as manufactured.
$d$ = diameter of suspender rope in inches.
$\delta$ = diameter of outer wires of rope, which are as follows:
$6 \times 7$ rope $.107\, d$.
$6 \times 19$ rope $.065\, d$.
$6 \times 37$ rope $.046\, d$.
$D_1$ = tread diameter of groove of cable-band.
$e$ = efficiency of rope construction as determined from equation (4) or from strengths given in Table X.
$k_1$ = correction factor, of the following values,

| $D_1/d$ | 8 | 10 | 12 | 14 and larger |
|---|---|---|---|---|
| $k_1$ | 1.08 | 1.055 | 1.03 | 1.00 |

Suspender ropes have always been made regular lay but recent tests as made by A. S. Rairden* show that a Lang lay rope bent over a cable-band is more efficient. However a Lang lay rope is inherently cranky and the advantages gained will be offset by the chances of damaging the rope in handling at the bridge site, unless a preformed Tru-lay Lang lay rope is used, but the increased price of the Tru-lay rope excludes its usage.

Data pertaining to the suspender ropes as used on various bridges are listed in Table XI:

Table XI
Suspender Ropes of Various Bridges

| Bridge | Diameter Inches | Type | Area Square Inches | Strength—Tons Single Part | Strength—Tons Double Part | Modulus of Elasticity as manfd Pounds per square inch | Modulus of Elasticity Pre-stressed Pounds per square inch |
|---|---|---|---|---|---|---|---|
| Portsmouth..... | 1¼ | 6×7/7×7 | .7352 | ..... | ..... | 12,000,000 | 16,300,000 |
| Mount Hope.... | 1⅜ | 6×7/7×7 | .8611 | 80 | ..... | 16,000,000 | 20,500,000 |
| Ambassador..... | 1⅞ | 6×19*W*/7×7 | 1.6678 | 151.5 | ..... | 12,000,000 | 16,000,000 |
| Philadelphia.... | 2¼ | 6×37*R*/7×7 | 2.2262 | 218.3 | 194.2 | 8,000,000 | 12,000,000 |
| Geo. Washington | 2⅞ | 6×37*W*/6 ×7/1×19 | 4.0474 | 389.3 | 333.8 | 13,500,000 | 18,000,000 |

The values of $D_1/d$ for the Philadelphia and the George Washington bridges were 14.2 and 13.6 respectively and the corresponding loss in rope strengths, as bent over the cable-bands, were 11 and 14.3 per cent.

Galvanized steel rope-strands, as listed in Table V and shown in Fig. 3, may be used for the suspenders as they offer maximum strength with minimum stretch but under no consideration should they be used in double part by looping or bending over the cable-bands.

## END FASTENINGS

The terminal or end fittings on the rope-strands, the wire ropes for the main cables and also the suspender ropes, are sockets. These are attached in the usual manner by brooming out the cleaned wires and pouring molten zinc over them into the basket of the socket; under no consideration should the wires be bent back hook shape.

In order to keep the compression of the zinc cone within allowable limits the proportions of the socket baskets are as follows:—

| | Length of taper | Included taper |
|---|---|---|
| Rope strands for main cables..... | $5\, d$ | .320 inches per inch |
| Wire ropes for main cables....... | $4.25\, d$ | .320 inches per inch |
| Suspender ropes................ | $4\, d$ | .300 inches per inch |

*Discussion in Carstarphen's "Effects of Bending Wire Rope" in Transactions Am. Soc. Civil Engineers, 1933.

To prevent movement between the socket and the zinc cone, either by rotating of the socket or "backing-out" of the cone, an annular ring is machined or cast in the socket basket and a hole drilled or two steel pins are set into the side of the socket projecting into the basket and the zinc poured over them.

For the designer, the following maximum unit working stresses are suggested:

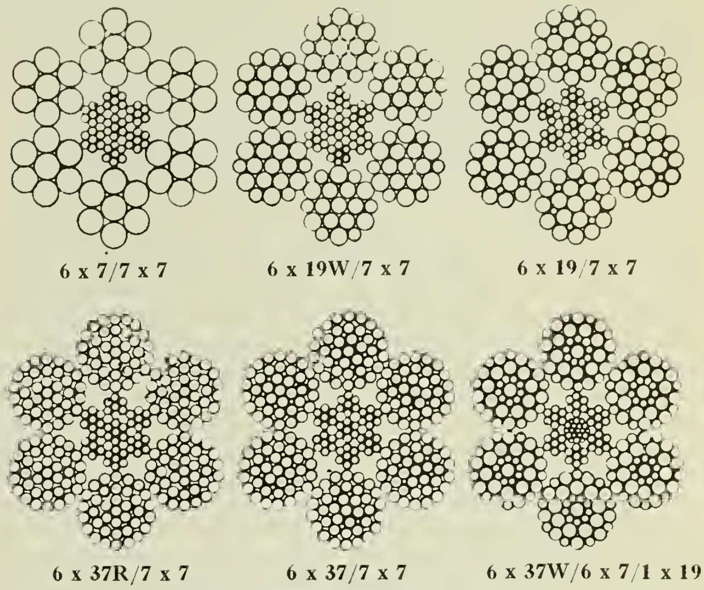


Fig. 8—Suspender Ropes.

Allowable Working Stresses

| | |
|---|---|
| *Main Cables* | |
| Parallel wire cables—type (*a*) | 80,000 pounds per square inch |
| Rope-strand cables—type (*c*) | 75,000 pounds per square inch |
| Wire rope cables —type (*d*) | 65,000 pounds per square inch |
| *Suspender Ropes* | 48,000 pounds per square inch |

D. B. Steinman in his excellent book "Suspension Bridges" states that "bridge engineers have been too conservative in the past in fixing wire cable working stresses, in comparison with stresses permitted for other materials, and that stresses as high as 100,000 pounds per square inch or even higher may safely be used for this unexcelled bridge material for the main cables."

Considering the advances that have been made in the analyses of stresses in suspension bridges and in the quality of steel bridge wire in recent years, the higher working stresses suggested by Dr. Steinman are quite in order. In the past, ever increasing values have been used, as indicated from the following maximum stresses allowed on various bridges:—

| Bridge | Date | Max. Stresses—Pounds per square inch Main Cables | Suspenders |
|---|---|---|---|
| Brooklyn | 1883 | 47,500 | .... |
| Williamsburg | 1903 | 50,300 | .... |
| Manhattan | 1909 | 73,000 | .... |
| Philadelphia | 1926 | 72,000 | 45,000 |
| Cologne-Mulheim | 1929 | 81,000 | .... |
| Ambassador | 1930 | 76,000 | 30,000 |
| George Washington | 1932 | 82,000 | 35,000 |

# Residential Heating as a Public Utility

## With Particular Reference to Residential District Service as Practised in Winnipeg, Manitoba

*W. G. Chace, M.E.I.C.,*
*Consulting Engineer, Toronto, Ont.*

SUMMARY—The author discusses the application of district heating in three areas in Winnipeg, chiefly residential in character. The largest system distributes steam to some twelve-hundred customers. The others supply steam to apartment blocks, schools, etc., and hot water to residences. Notes are given on the boiler equipment required to use Saskatchewan lignite, the methods of measuring the heat supplied to customers and on construction methods and difficulties.

In the following will be included consideration of the applications, principles and advantages inherent in the utility along with particulars of the author's experiences in the design, construction and operation of two systems of heat distribution throughout the residential areas in Winnipeg, Manitoba. Whereas a long drawn out house heating season combined with high costs of fuel warrant this type of public utility as a sound investment in Winnipeg and in other north western cities, there exist in a number of metropolitan districts in eastern Canada certain conditions favourable to the practice, and to an even greater degree than in the west. A few such may be noted: the considerable areas in several cities in which high class houses are densely built; the urgent need for a cleaner atmosphere as well as the cleaner home conditions which attend the distribution of heat from a single fuel burning station; the not inconsiderable lessening of street traffic which results from cessation of the retail distribution of huge quantities of coal, and the collection of ashes, a feature of no little importance in consideration of the existence generally of narrow thoroughfares already overcrowded with traffic of all sorts; and the fact that members of these communities can well afford the cost of the higher standard of home conditions which attend the entry of this clean, convenient and not unreasonably expensive domestic service. If there is, as seems to be recognized in many quarters, a real prospect of growth of the business of supplying equipment for "conditioning" the air of the home, there should be anticipated with equal degree of probability, the development of the business of heat distribution, an enterprise which offers no small field for qualified engineers, and a fresh field for sound investment.

The subject discussed covers several phases of heat supply:

(*a*) A single source of heat for duplex homes.

(*b*) A central source of heat for groups of buildings under single management; as exemplified by:
- McGill University buildings, Montreal,
- Parliament and other government buildings, Ottawa,
- University of Toronto and other buildings, Toronto,
- Toronto Terminal Railway Company including the Royal York hotel, Union station, Custom House and railway yards.

(*c*) Distribution throughout the business district of heat from electric power stations, as in North Battleford, Sask., Brandon, Man., London, Ont. and in Winnipeg, Man.

(*d*) Heat distributed through business districts by private corporations as in Lockport, N.Y.; by New York Steam Company in New York city; by Detroit Edison subsidiary in Detroit, Mich., and in many other cities of the United States.

(*e*) Heat distributed throughout closely built higher class residential areas of certain cities, instances of which form the main subject of this discussion.

Two papers—"Central Heating System of the City of Winnipeg" by G. W. Oliver, and "The Central Heating Plant of the Toronto Terminal Railway Company, Toronto" by J. A. Shaw—were presented before The Engineering Institute of Canada in February 1932 on the occasion of its General Professional Meeting. The former described the public utility originally erected as a long term outlet for a steam electric standby to the municipal electric utility of the western city; the latter paper describes a privately owned service. Both papers describe systems designed essentially to serve commercial buildings and entities and both cover engineering details of the investment quite fully, along with load and certain operating data.

Central heating—as a public utility—began in America at Lockport, N.Y., in 1877 and there were developed several of the items of equipment required by this type of service. Many corporations in cities of the United States and a few in cities of western Canada are now engaged in the distribution and sale of heat. Most of these sell steam, and base their measurements and their sales accounts on the quantity of condensate derived from its use. A few efforts to provide heating service through the medium of hot water have met but moderate success and because of the difficulty of measurement of heat as delivered, the practice of flat rate charges has been general. This opens the door to widespread waste by the customer, with consequent unreasonable demand upon the system, not only for fuel consumed in heating the water, but also in excess boiler plant and distribution pipe line investment.

Steam heat has been distributed by public service bodies in Brandon, Man., and in Battleford, Sask., for some years, and with commercial success, although necessarily on a moderate scale.

Mr. Shaw gave five reasons for the use of central heat at the Toronto terminals:

1. The elimination of boilers, with attendant noise and dust, from the various buildings, together with the trucking of coal and ashes, one plant replacing eight.

2. The saving of space in expensive locations for more remunerative undertakings, by eliminating boiler rooms and stacks.

3. The removal of smoke and gases from public areas.

4. A decrease of at least 25 per cent in the total fuel required, and a further reduction in cost by the use of a lower quality of coal.

5. Greater safety from fire.

All five apply as excellent reasons for central heating service throughout any compact business district.

With respect to central heating service for residential areas of cities there are certain other advantages:

6. Elimination of the house to house distribution of coal, and avoidance of the concomitant dust from coal and ashes in the house greatly lessens the housewifely duties and reduces the frequency and expense of house decoration. This dust free benefit accrues to the community through clearer atmosphere and cleaner exterior conditions.

7. Freedom from these dusts, and the maintenance of more uniform temperature within the home improves family health.

8. Reduction of fire hazard is recognized by the fire insurance companies through reduction in their premium rates.

9. Basements, hitherto dusty and devoted to the heating boiler and its fuel become real increments to the living rooms; afford playrooms for children, clubrooms for adults, or may otherwise add about ten per cent or more to the utilizable value of the home.

10. Hire of help for furnace attention is avoided, and this item affects partially the possible increment of the cost of central heat over the cost of fuels otherwise purchased.

11. Central heat may be at first classed as a luxury. It really is a domestic service greater than its name implies. As such it should cost the user more than his fuel, and as experience of its advantages is had, the customer forgets its "luxury" feature, and soon considers it a necessity.

12. Reduction of street traffic follows elimination of the use of trucks for distributing coal and collecting ashes.

Further remarks will be confined to central heating services in Winnipeg and the experiences gained through over three years association with their design, construction and operation.

### Central Heating in Winnipeg

There are four separate corporations distributing heat in Winnipeg:

Winnipeg Service Company generating steam from coal and from electricity serves the principal buildings within the most centrally located city block, whose south east corner is at Portage avenue and Main street. Not crossing any public thoroughfare it possesses no city franchise.

**Fig. 1—Wall Street Steam Station.**

The City of Winnipeg Hydro-Electric System distributes steam throughout almost one square mile of the business district, and its system surrounds the area served by the Winnipeg Service Company.

Winnipeg Heating Company, Limited, having obtained a city franchise in 1928, distributes steam throughout Crescentwood, a high class residential district occupying over one-half square mile south of the Assiniboine river.

Northern Public Service Corporation, Limited obtained a franchise in 1930 covering River Heights adjoining Crescentwood on the west and also the area north of the Assiniboine river and chiefly lying south of Portage avenue and west of Sherbrooke street, each district about one-half square mile in extent. This company distributes steam as demanded by apartment blocks, schools, churches and hospitals, and distributes hot water to residences, with but few exceptions.

The author was associated with the Winnipeg Heating Company chiefly in design and supervision of the steam generating plant, but also assisted in obtaining the franchise. During 1930 and 1931 he was in direct charge of designs, purchases and construction for the Northern Public Service Corporation, also assisting in matters of operation in association with Messrs. B. W. Parker and C. A. Clendenning, A.M.E.I.C.

### Winnipeg Heating Company, Limited

In 1931-32 there were about twelve hundred customers, representing nearly eighty per cent saturation along the frontage of distribution. Saturated steam is distributed through wrought steel pipe laid upon cast iron rollers and frames within concrete conduits located generally in lanes. Generated steam pressure, usually in the neighbourhood of 125 pounds per square inch gauge, is reduced at station exit to pressures proportionate to the load and varying from 75 down to 35 pounds per square inch, the object being to maintain at least 15 pounds pressure at the extreme of the longest lateral. The largest street main is 12 inches in diameter, and the smallest lateral is 2 inches. Service pipes to residences are 1 inch in diameter. Mains are insulated with 1-inch asbestos sponge felt and laterals with 1-inch asbestocel. A greater thickness of felt and use of that material throughout would result in economy through reduced transmission losses, which now average over 25 per cent during the season.

Slip type expansion joints anchored to the floor were placed in manholes located at approximately 300-foot intervals. Pipe lines are anchored to conduit walls midway between manholes, using angle iron welded to the pipe. All pipe joints are welded, excepting at service connections and on service pipes.

In most residences heat from the steam purchased is transferred to the hot water system through a condenser (or "pig") set in the basement. The steam fills the cast iron chamber while the water is circulated through the copper tubing, usually through the house furnace jacket, and through the radiation system by thermal head. The condensed steam is passed through a radiator located usually in the first floor hallway, through a screen and a trap and a bucket type meter to the sewer. The supply of heat is intermittently controlled by means of a thermostat, and an electric motor operated globe valve.

A few residences equipped with steam radiation are served through a reducing valve, and the condensate is measured and wasted to sewer in the manner described above.

Residences equipped for air heating are served in the following manner: The furnace is removed from the shell and in its place is set a bank of radiators of area sufficient for the demand. Steam, through a reducing valve, is fed, condensed, measured and condensate wasted in the usual manner. It will be noted that on account of the steam temperature lying between 215 and 250 degrees giving the radiation surfaces a heat release capacity of 250 British thermal units per square foot per hour, the space within the shell of the displaced furnace is generally ample for the house requirements.

The steam generating plant of the Winnipeg Heating Company is located about one-half mile south of the Assiniboine river, and on the south margin of the occupied portion of the franchise area. Fuel is hauled to the station by truck and is dumped into a storage bin of moderate dimensions which occupies the south section of the section. Fuel haulage charges require the use of coals of high heat value at this station. The original plant consists of three 500-h.p. watertube boilers equipped with unit pulverizers; one boiler only is provided with air preheater. Furnaces are roomy and complete combustion is attained before the gases enter the tube banks, which have three passes. At

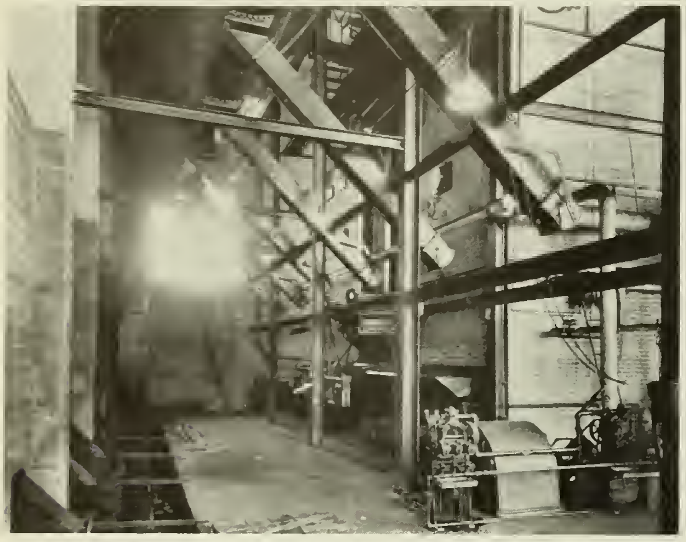

Fig. 2—Boilers 1 and 2, Wall Street Steam Station.

first it was attempted to collect dust from waste gases by means of cyclones and exhaust fans, in the effort to avoid the construction of an unsightly tall chimney; the results were not entirely satisfactory, and, partly for this reason and partly because of additional release capacity required by increase of sales, a neat Custodis chimney was erected during the second year of operation. The station is an attractive building of red brick panelled, and the entire assembly in its present and ultimate form is quite in keeping with the high class of residences thereabout.

Increase of demand required the addition of two larger boilers of 870-h.p. rating; these are equipped with underfeed stokers of the Jones type. All boilers are of the Kidwell design, furnished by Canadian Vickers, Limited.

On account of the very moderate plant load factor in central heating service it is essential that capital charges be kept to a minimum; other than feedwater heaters there are therefore no auxiliaries provided for purposes of steam generating economy.

This type of boiler delivers steam with a superheat of from 20 to 40 degrees; a slight additional superheat succeeds passage through the outlet reducing valve, and this characteristic assists in minimizing condensation in the distribution lines.

Ashes are removed by hand and are disposed of by truck to selected waste areas in the neighbourhood, or are removed by municipal users for lane paving purposes.

In 1932 earnings were sufficient to carry all operating and fixed charges.

Northern Public Service Corporation, Limited

After considerable laboratory study and also a field test by the promoters, this company was organized and in 1930 was granted the municipal franchise heretofore mentioned. The plans were based on the distribution of heated water to all customer homes equipped with hot water radiation or with hot air systems. It was at once recognized that *(a)* control of the rate and quantity of water supply must be had, and *(b)* that the heat extracted from this circulated water must be measured as the basis of charge for service. Both objectives have been accomplished.

*District No. 1—Sherbrooke Franchise*

Designs were begun in May and field construction was begun in July 1930, and service was first rendered in December of that year. The system includes a steam station; a steam main with return line for condensate passing through the middle of the franchise area; heat exchanger pumping stations at approximately 1,000-foot intervals along the steam main; hot water circulating flow and return systems of distribution lines from each exchange-station; and sundry steam line branches to apartments, churches, schools, a large hospital and a municipal library.

In general the steam main lies along Westminster avenue, and the distribution lines lie along lanes which are available throughout the franchise area.

Wall street steam station, an attractive brick and concrete building with chimney, is located just north of Portage avenue alongside the southerly end of a terminal yard of the Canadian Pacific Railway Company. The first installation of two 790-h.p. Kidwell boilers, equipped with Jones underfeed stokers, has been increased by the addition of a third boiler of 870 h.p.; space is available in the station for a fourth boiler when required. The only important auxiliary is a feed water heater which receives the condensate returned from the heat exchanger stations and the makeup required to replace that lost through steam sales. Feed water pumps are in duplicate, one motor driven, the other steam turbine driven, both furnished by Mather and Platt.

Coal, dumped from railway cars into a track hopper enclosed along the west side of the station, is elevated by means of an endless bucket conveyor into an overhead bunker of 300 tons capacity. It is fed by gated chutes through portable weigh lorries into the stoker hoppers. Ashes, raked from below the rear dump plates of the stokers, are carried by chain conveyors to the main bucket elevator and disposed of outside the end of the station, where they are removed by purchaser users.

After a long series of tests of various Canadian coals, the principal supply meantime coming from Pennsylvania coals from lakehead docks, a mixture of coking coal from western Alberta and lignite from southern Saskatchewan has been adopted as standard. The use of lignite prevents solid coking and also reduces wall clinkering to almost zero, and the use of the coking coal prevents the air casting of the friable lignite to the dump plates. A minimum cost of fuel per thousand pounds of steam is also attained.

It must be remembered that Manitoba is the neutral ground west of which coal of high value from the United States fields cannot be sold, even with the advantage which it possesses as a return cargo for the ore boats from Duluth; and east of which the coals from Alberta of values increasing as their source moves westward, cannot be delivered without large transport bonuses. The western coal used costs less than $8 per ton and the Saskatchewan lignite costs less than $3 per ton delivered at the steam station. Resultant steam costs for fuel are in the neighbourhood of 34 cents per thousand pounds. The heat value of this fuel mixture varies between 8,800 and 9,000 B.t.u. per pound.

Before designing the Renfrew steam station for district No. 2, the area covered by the southerly or River Heights franchise, a series of experiments with the use of lignite from the Estevan field were carried on at the Wall street station, on stoker elements modified for the purpose. As a result of these experiments, and following a thorough study by engineers of the company, of equipment used in North Dakota and elsewhere for the burning of similar lignite, it was decided to use lignite alone, as the fuel in the new station. The equipment selected will be described later.

*Heat Exchanger Stations*

These are located under garages on lots located close to the route of the steam main. Their equipment consists of two or more twin units of horizontal condensers; duplicate centrifugal water pumps, one motor, the other turbine driven; on the return side of the circulating system, twin air pressure tanks on the circulating system for the purpose of regulation and of maintaining the house radiation system full of water; and temperature controls on condensate discharge. The condensate passes through Leeds water meters to the steam station via an uninsulated welded wrought steel pipe line located in the conduit which carries the steam main.

The outgoing hot water, at a temperature of 210 to 215 degrees F. and a pressure of about 45 pounds per square inch gauge, is distributed through headers parallel to the steam main conduit to laterals located generally in the three lanes adjacent to the heat exchanger station. A back pressure of 15 pounds per square inch gauge is maintained on the return circulation line, and all overflow pipes and equalizer tanks in the attics of customers are closed off. The distribution layout from each heat exchanger station, for service to a maximum of six hundred average homes, required station outlet pipes of 6 inches diameter, headers across lane ends of 5 inches diameter, and laterals of 3 inches, never larger than 4 inches, the diameter tapering downward by standard differentials through 3, 2½ to 2 inches. All these laterals are valved in manholes on the header line.

These limits for pipe dimensions would not have been sufficient were it not that the company established control of the rate of hot water consumption in combination with a practical and accurate measurement of the quantity of heat shown monthly by each customer. Since hot water radiation can discharge only about 150 B.t.u. per hour per square foot into the room at usual interior temperatures, a needle valve set to permit a draught of not more than one-half gallon of hot water per minute per 100 square feet of house radiation was placed in the ½-inch house delivery line.

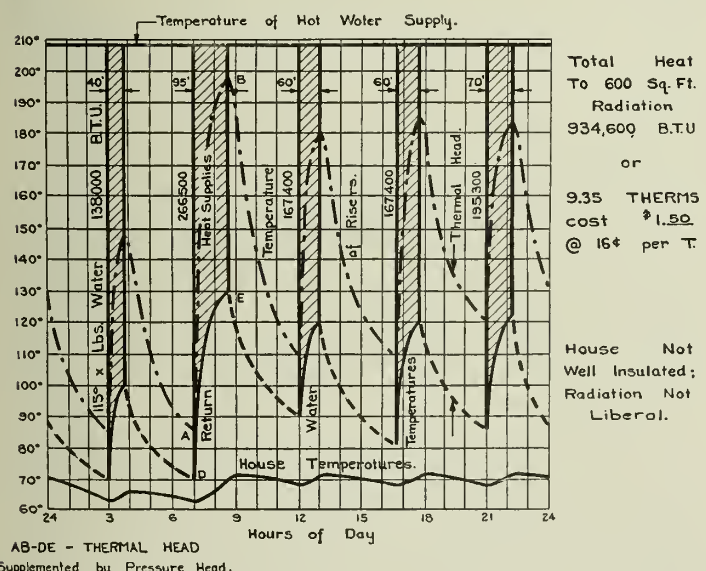

**Fig. 3—Hot Draught from Hot Water Supply System on Cold Day.**

The distribution lines and service pipes are enclosed in conduits of creosoted fir laid with about two feet of earth cover for the lines and one foot for the services. Hot water pipes are insulated with 1 inch of asbestos sponge felt; return lines are bare. The average temperature of water returned to the exchanger station is found to be in the neighbourhood of 140 degrees F.; that from individual services varies as is described later.

*Distribution System*

Under the conditions of practical service a given pipe size will deliver about four times as much heat when carrying water as when carrying steam, e.g. with steam at 20 pounds per square inch gauge pressure and a velocity of 10,000 feet per minute a 6-inch pipe will convey about 210,000 B.t.u. per minute; the same pipe size carrying water at 212 degrees F., from which in practice an average of

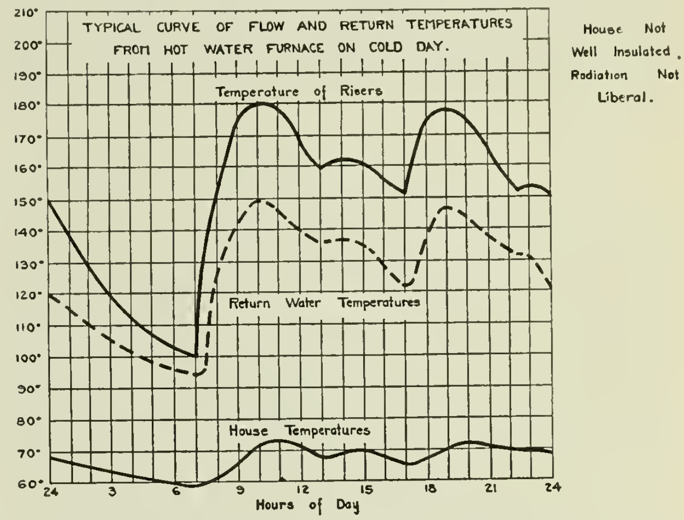

**Fig. 4—Flow and Return Temperatures from Hot Water Furnace on Cold Day.**

about 90 B.t.u. per pound can be usefully delivered, will convey about 850,000 B.t.u. per minute with a water velocity of 10 feet per second.

In Winnipeg practice the maximum distances for conveyance are about one mile and a quarter for steam and one-quarter mile for water. Steam mains vary in size downward from 18 inches, and laterals down to 3 inches; water mains and laterals from 6 to 2 inches, necessarily as duplicate piping. Costs of insulation and of conduits and manholes cause investment for lines of equal diameter to be nearly alike for the two systems of distribution. Because of the fact that the "morning warm up" occurs about the same hour in all homes the diversity factor governing gross peak draught of heat from the exchanger station is large. The duration of this draught, except in the coldest weather, is commonly less than one-half an hour however, and the pressure drop in the lateral is less than 20 pounds per square inch gauge leaving a minimum differential between "flow" and "return" lines of 10 pounds per square inch available for the most distant house served.

In order that water of high temperature may be available at all homes it is the practice to equip each lateral end with a sylphon controlled bypass between the "flow" and the "return" line. There is a temperature drop in laterals of not over 7 degrees F. below the temperature of water sent out from the pumping station. This feature is attained only by excellent insulation of the "flow" line.

In order to minimize the cost for manholes it is the practice to establish U-bends in the lateral at intervals of about 400 feet, the pipes being firmly anchored midway between bends. Services are screwed to nipples welded into lateral pipes, clearances in service box connections to lateral conduit being made sufficient to prevent binding as expansion or contraction alters the length of lateral sections between anchor points.

*House Services*

Wrought steel service pipes one inch in diameter lead from the lateral to within the basement of the house. Gate valves are furnished on both lines inside this entrance. Pipes one-half inch in diameter lead the water to the furnace jacket, the flow line being equipped with a strainer, the needle valve above mentioned, and a motor operated weighted control valve governed by the house thermostat. The heat meter is located on the return line leaving the "return" header on the furnace. Circulation through the house piping is forced by the pressure differential between "flow" and "return" lateral pipes, aided by the natural "thermal" head within the circulation system of the house. When the control valve is closed the circulation of heated water within the system continues under the influence of this head. It is thus important that no air be allowed to pass through the furnace, its draughts being sealed and the smoke pipe damper closed, obviating wasteful cooling of the considerable body of hot water in the furnace jacket.

*Heat Meter*

This unique device was designed and developed by the company's engineers and its function is to determine the quantity of British thermal units extracted by the customers' radiation system from the hot water supplied from without. Its essentials are a control valve with two ports and two pipe connections operating in parallel. On one leg a water meter is located and the other leg a bypass. The quantity of water diverted through the bypass rises as the temperature of the returned water rises, the valve being so adjusted that the proportion of returned water flowing through the water meter corresponds to the heat extracted from the hot water delivered to the house and this water is for all practical purposes at uniform temperature. Tests and practice prove this type of meter to be correct to within 2 per cent for all return temperatures over a 100-degree range above 90 degrees F., which is the limit of the minimum return temperature measured. Whenever, by reason of excess capacity in house radiation, considerable returned water is of a lower temperature than 90 degrees F., the bypass valve can be so adjusted to determine the facts as to heat consumption.

*Temperature of Returned Water*

The determination of these temperatures was early known to be necessary, and a great number of studies of house heat losses were made in various house systems with differing radiation characteristics. Consideration of the sequence of events following the admission of hot water to the relatively cool radiation system shows:

(1) A rise in temperature of water in the furnace jacket, and a coincident discharge of water at low temperature to return laterals.

(2) A rather prompt rise in temperature of the water in radiators and a slower rise in temperature of the return water.

(3) The temperature of water entering each radiator approximates that of hot water supplied to the system; and the rate of rise of the temperature of water discharged by the radiators lessens.

(4) If the flow be continued for a sufficient period, the temperature of the return water reaches a maximum; this temperature is lower from a system of unduly large area of radiation than from a system whose radiation is barely sufficient to maintain proper house temperature.

In practice it is found that the temperature of return water asymptotic to time is seldom reached with any system, because the house temperature reaches the setting of the thermostat and the valve governing admission of hot water is automatically closed before that stage occurs; unless the thermostat setting has been lowered manually or by clock for the sleeping period even the morning warm-up is of less duration than that necessary to reach a maximum return water temperature.

It is also found that only in very cold weather is the control valve opened by the thermostat more than four times during twenty-four hours. In mild weather, it is seldom necessary to draw hot water into the radiation more frequently than two or three times in the same period of time. For individual customers these frequencies vary and are dependent on such factors as the degree of house insulation limiting house heat losses; the relative area of radiation surfaces; the style of house construction affecting air movement within; the domestic habits with regard to ventilation and the admission of cold air from without; and the character of house occupation with respect to the radiation surfaces and the ventilation methods and practices in individual rooms.

*Hot Water Heating and Hot Air House Systems*

Since the discharge of heat from hot-water-filled radiators does not average over 150 B.t.u. per hour, there is not accommodation for a large enough area of radiation within the galvanized iron shell of the original furnace. The practice therefore is to set up in place of the furnace a bank of radiators of suitable gross surface area and to enclose it within a new rectangular sheet steel shell. In order to minimize the expense for radiators it is usual to force the air circulation by aid of a motor operated fan, the air riser and the return pipes being connected in the usual manner.

*District No. 2—River Heights Franchise*

Service to this area was begun in October, 1930, the construction of a second substation and the laying of the distribution lines having been commenced in July of that year. Some three hundred homes were supplied. In 1931 a third heat exchanger station was built, along with additional street and lane construction, and a brick steam generating station was erected alongside the railway tracks near the centre of the area ultimately to be served. During the winter of 1930-31 the required steam supply was purchased from the extended main of the Winnipeg Heating Company, the latter company's affairs having been taken over by the backers of the Northern Public Service Corporation, namely, the Middle West Utilities Company of Canada. During the second season a saturation of about 65 per cent was obtained throughout the area occupied by the hot water laterals. Many homes built here during 1931 were not equipped with a furnace, the owners depending upon central service for their heat supply.

*Steam Station for District No. 2, Northern Public Service Company*

As a result of the studies and tests carried on by its engineers the company decided to design this station to use slack lignite from the Saskatchewan field. This fuel is very friable, even dusty; it contains about 33 per cent of moisture and from 5 to 7 per cent of ash; it has a heat value of not over 7,000 B.t.u. per pound, unless selected or cleaned at the mine, when the content may rise to 7,400 B.t.u. Its cost delivered on cars at the railway siding is less than $3 per ton.

As a result of the intensive efforts made during many years in North Dakota and in Canada, the proper style of grate and design of furnace for its efficient consumption had been determined. A fairly thin fire bed is required, also a non sifting grate arranged either for dumping in sections, or as a chain grate with very small air passages. As mentioned previously it is important that capital expense be minimized in such services, and pyramid grates mounted for sectional dumping were chosen rather than Harrington stokers. The author had observed the latter type of equipment working in Dakota at 300 per cent of boiler rating and with as high as 18 per cent $CO_2$ in the stack gases. The capacities and efficiencies attainable with pyramid grates as furnished by Riley Engineering and Supply Company proved quite as high as desired. The first boiler installed, the only one to date, in this station has a quadruple grate each of two dumping sections. Air for each grate is under separate control and is forced into the respective ash pit by means of a steam turbine blower. Fuel is fed to each grate by an individual "kicker" or overthrow stoker. Fuel from the railway car to the station hoppers is handled as in the Wall street station before described.

The station is built to accommodate a second boiler, and a feed-water heater of sufficient capacity for two 870-h.p. Kidwells is installed.

**Fig. 5—Lateral Expansion Loop on Hot Water Line.**

The outgoing steam main, passing along the main highway traversing the franchise area, is connected to the end of the main of the Winnipeg Heating Company. Interchange or sale of steam in either direction is metered through Bailey meters installed in a manhole located at the east end of the Northern Public Service Corporation main.

### Construction Features

Lanes in general are 16 feet wide, and the conduit location chosen by the city engineer lay 5 feet from one margin. The U-bends taking up pipe length changes due to temperature variations lie between that alignment and the nearby lane limit. Except in rare instances the only manhole in a lane is that at the extreme end of the lateral sheltering the thermally controlled bypass from the flow to the return line.

Trenches were excavated with an Austin excavator having a cross belt for side discharge. In order that conduit lumber, pipe, and insulation might be economically distributed, and to facilitate progress in conduit and pipe laying, most of the excavated earth was removed in trucks loaded from the cross belt. This earth was transported to adjacent lanes for use in backfilling trenches; the remainder was wasted to dumps for lot filling.

Conduits were constructed of creosoted fir lumber which had been sized and rebated to permit firm assembly. All conduit fastenings are exterior to the box, thus avoiding the drilling of creosoted material, and accurate cutting of lumber to lengths.

Steam pipe lines are drained by use of Armstrong inverted bucket traps, discharging to the sewer through the manhole in which they are located, or in some instances, to the return condensate line. The Winnipeg Heating Company use Dunham traps discharging to the sewer.

Condensate lines are kept full of water, preferably condensate, throughout the year for the purpose of minimizing corrosion. They discharge into an open type feedwater heater at the steam station and are equipped with dirt trays.

From July 1st to December 31st, 1930, 19,400 feet of conduit carrying 46,000 feet of main and lateral pipe, and 20,640 feet of service boxes were laid; also one steam station and three heat exchanger stations were built and put into service. In 1931, 25,000 feet of conduit, 46,000 feet of pipe in mains and laterals, 21,500 feet of service boxes were laid. The Renfrew steam station and two other exchanger stations were built. Over twelve hundred customers were connected during these first two seasons.

The speed of construction during the half season of 1930 may be compared with the Indianapolis job of 1932 as described in Adsco Advocate, No. 1, Vol. V—47,247 feet of single pipe main in eighty-one days.

### Building Foundations

The surface soil of Winnipeg and the surrounding areas is a lacustrine clay carrying up to fifty per cent of moisture. Even when underdrained it possesses but a moderate bearing power; subsoils undrained have less; changes in moisture content of surface soils alters their volume—and the elevation of the superficies. As a consequence of these characteristics settlement of buildings erected on spread footings, and on "floating" foundations follows during a considerable period. Limestone rock, in some places covered with boulder clay or hardpan, underlies the area at a depth of about 45 feet below the average surface.

The buildings for these two heating utilities are erected upon spread footings of reinforced concrete, the unit loading being kept at about two tons per square foot, and as uniform as possible for all walls so as to ensure uniformity of settlement and avoid distortion of the structure. Success in this feature has attended the designs in all three steam stations. All chimneys stand upon nests of piles driven to refusal. All foundations are underdrained and gravel backfill was used.

Boilers rest upon reinforced concrete slabs independent of the footings of the station walls. Stokered furnaces have

**Fig. 6—Insulating Laterals for Hot Water Line, Academy Road.**

stood as designed and built. The three furnaces fed by pulverizers have settled irregularly and one has been rebuilt. The cause of settlement was due to the high temperature of the combustion chamber which caused excessive drying out of the clays beneath the foundation slab, and in an uneven degree over the area. The floor of the rebuilt combustion chamber has been heavily insulated to prevent recurrence of this experience.

## Engineering as a Profession

On this side of the Atlantic the term engineer suggests to the ordinary citizen either an experienced railway man who drives a locomotive, or a youth in khaki who peers through a three-legged telescope and whose mysterious activities finally result, somehow, in the construction of an enormous dam or bridge. The public in fact is hardly aware that engineering is a profession. It is therefore reasonable to enquire just what is a professional engineer and what is implied by the word profession as applied to engineering.

There are a multitude of occupations whose practitioners claim the title of engineer; some of these can properly be classed as professional work, while in other cases the claim is put forward by a man who has had no training as an engineer in an endeavour to obtain a status or consideration to which his technical requirements and occupation do not really entitle him.

In discussing this matter, reference is often made to two of the "learned" professions, law and medicine, and engineers sometimes feel a slight tinge of envy when they note the manner in which lawyers and doctors (to say nothing of architects) have been able to regulate their professional activities and their relations with the public. They have undertaken certain duties towards their clients and have justly obtained certain rights and privileges which are duly safeguarded. The engineer asks himself to what extent is it possible or desirable to build up a like system for engineering work, with the two-fold aim of protecting the public against incompetent practitioners and protecting the members of the profession against improper or unfair competition.

Such a system necessarily involves the establishment of an approved standard of general and professional training, and adequate control of the right to practise.

In Canada much has already been done along these lines, but much remains to be accomplished. The Engineering Institute of Canada, like most other societies of similar standing, has insisted upon certain educational and professional qualifications before membership is granted, and has emphasized the value of systematic training and a high standard of professional attainment. The Professional Associations have continued the work by obtaining, in some of the provinces at any rate, adequate powers to give legal authority to requirements of the kind. Progress is being made, but is necessarily slow, by reason of many difficulties, some external to the profession, and others due to the very nature of engineering work.

In framing any scheme for the regulation of our professional work, consideration has to be given to such matters as the great diversity of engineering activities, the various kinds of training required for their successful prosecution, the engineer's relation to the employers or clients for whom he acts, and the extent to which his work is specialized. It must not be forgotten that in order to be successful, his efforts must always meet definite financial requirements. In some cases, for example, his services are performed for the purpose of selling engineering materials or equipment, his training and experience enabling him to advise the purchaser as to the selection he should make to obtain the best and most economical results. It will be seen that in many aspects of the engineer's work, his profession differs essentially from that of the lawyer or medical man, for the engineer is always limited by economic considerations, and he deals with materials and their utilization, rather than with people and their troubles and difficulties.

An admirable survey of the many problems relating to engineering as a profession was given by the President of the American Society of Civil Engineers at the Annual Convention of the Society which has just been held in Vancouver together with The Institute's Western Professional Meeting. President Eddy's address* points out that a profession has been defined as a vocation characterized by specialized educational training, which has for its purpose the supply of disinterested counsel and services in return for a definite compensation, "apart from expectation of other business gain." He enquires as to how far engineering, as practised to-day, complies with these requirements, and comes to the conclusion that engineering is certainly a profession in the sense contemplated by the definition, and further, that in view of the dependence of the engineer's work upon the application of so many sciences, it may fairly be regarded as a learned profession. Taking his own special branch as an example, Mr. Eddy remarks that the sanitary engineer has recourse to hydrology, chemistry and bacteriology for information as to the quantity and quality of a water supply; to hydraulics and applied mechanics for the design of his structures; to metallurgy, soil mechanics and many other branches in connection with others of his problems. The trend to-day is towards an ever-increasing application of scientific knowledge and the utilization of the results of research, and this applies to all branches of engineering.

These increased demands on the engineer's scientific knowledge have involved marked development in engineering education, and post graduate work, either scholastic or extra-mural, is now "a necessity for one who is to secure more than mediocrity in engineering."

Many engineers exercise both technical and business functions, which are not easy to separate. A contractor, for example, may function as an engineer in planning his methods of handling construction, while carrying on the business of managing, organizing and financing his work.

*"Trends in Engineering as a Profession in the United States of America." Address at the Annual Convention, Vancouver, B.C., July 11th, 1934, by Harrison P. Eddy, President American Society of Civil Engineers.

The technically trained sales-engineer in many cases renders strictly professional engineering services on behalf of his employer, and along with this development there has arisen a tendency on the part of large corporations towards commercializing engineering practice, which Mr. Eddy deplores. He has observed the growth of industrial and other companies whose operations in the field of engineering advice and design have encroached greatly upon the independent practice of the individual professional engineer. It is also noteworthy that an increasing proportion of the engineering profession consists of employees instead of independent practitioners, and this change has been accompanied by more detailed specialization, so much so that in many cases an engineer finds himself occupied continuously with problems of substantially the same kind, his work thus giving him no opportunity for broad experience.

As regards engineering societies, Mr. Eddy remarks that these perform an indispensable service, but there is to some extent overlapping and duplication of effort in their work of disseminating professional knowledge. In the United States he notes that greater stress is now being laid on the organization of the profession, as is shown by the fact that twenty-eight states now have registration laws, while the voluntary societies have made great efforts to foster the social branches of their work, particularly in connection with the unemployment of their members. He concludes that "the trend is unmistakeable towards better things for the community, the profession and the individual engineer, to be secured in large measure by the co-operative effort of engineers made effective through engineering societies." The task which he outlines for these bodies is a huge one, and effective advance cannot be made without the individual participation of their members in the societies' work.

If the desired aim is to be reached, organizations like The Institute, whose main object is the acquirement and interchange of professional knowledge, must work in harmony with those other bodies whose duty it is to regulate the practice of professional engineering.

Ultimately the public estimation of the engineer as a professional man depends upon the competence, integrity and personal character of individual members of the profession. Membership in our engineering societies and professional associations must be regarded by the public as a guarantee of these qualities if professional recognition is to be generally accorded to the engineer.

# The Western Professional Meeting 1934

There are few places in Canada which offer greater attractions for a summer meeting than Vancouver. The amenities of the city, ideal weather, scenery of great natural beauty and the hospitality characteristic of the west all combined to ensure an enjoyable gathering. This year's Western Professional Meeting was noteworthy, as being the first of The Institute's meetings to be held at the same time and place as the Annual Convention of our friends the American Society of Civil Engineers.

Seymour Falls Water Intake, Vancouver, B.C.

Arrangements for the joint event were in the hands of a local committee of members of both societies, under the chairmanship of E. A. Cleveland, M.E.I.C., M.Am.Soc.C.E.,* on which both the Vancouver and the Victoria Branches of The Institute were represented and the committee gave ample proof of its organizing and executive ability, for the programme went without a hitch. Just before the opening day when the secretaries of the two societies met the secretary of the committee there was little to be done except to express appreciation of the completeness with which all details had been cared for.

An advance party of society members from the east reached Vancouver on July 9th, and a number of them proceeded to Victoria, where they were met by President Shearwood and the Chairman of the Victoria Branch of The Institute, H. L. Swan, M.E.I.C. The party made a tour of the city, visited Butchart's gardens and next morning motored to Nanaimo, reaching Vancouver in the afternoon. The main body of American and Canadian visitors also arrived in Vancouver on the 10th.

After registration at the Hotel Vancouver on the morning of Wednesday, July 11th, the members of both organizations gathered for a joint meeting at which they were welcomed by his Worship the Mayor of Vancouver. Following this, President Shearwood expressed the pleasure of The Institute members in meeting those of the American Society and President Eddy, after replying, delivered his

presidential address to which reference is made elsewhere in this issue of The Journal. Passing from society business for a time, the large audience listened with interest to a breezy talk by Commander B. L. Johnson, D.S.O., R.N.R., on the varied problems and prospects which confront the navigator of a steamship while proceeding through the inside passage from Vancouver to Alaska ports.

**Vancouver by night**

At luncheon, in the unavoidable absence of A. S. Gentles, M.E.I.C., President of the Association of Professional Engineers of British Columbia, who was to have spoken, Dr. E. E. Brydone-Jack, M.E.I.C., gave an illuminating account of the growth and work of that Association. This was much appreciated, particularly by listeners from the United States, where the problem of registration has been treated in a manner somewhat different from that adopted in Canada. The speaker outlined the provisions of the legislation effective in British Columbia and referred in some detail to the working of the system adopted there for enrolling aspirants to the profession, first as pupils admitted to study and then as engineers-in-training in preparation for their formal registration as professional engineers in the province.

In the afternoon a joint technical session was held, at which papers were given on the development of the Columbia River Drainage Area, a subject of international interest, specially in view of the very large scale of the development contemplated on the United States portion of the river. Major J. C. MacDonald, M.E.I.C., sketched the situation on the Canadian side, and was followed by C. W. Webb, M.E.I.C., and J. P. Forde, M.E.I.C., so that both provincial and Dominion officers contributed to the discussion. American engineers then presented papers dealing with the large projects on which the United States government is embarking lower down the river at Bonneville and elsewhere, for developing power, improving navigation, and providing for irrigation and reclamation.

The President of the American Society of Civil Engineers took the chair at the joint dinner in the evening, at which Judge F. W. Howay, a notable authority on the early history of British Columbia, delighted his hearers with the story of the adventures and achievements of the party of Royal Engineers sent to the colony in 1858, who carried on their work of exploration and development till 1865. Many of them remained as settlers, and their descendants are now esteemed citizens of the province. The Judge's address included many characteristic touches illustrating the difficulties of official administration in dealing with the small but active and unruly population which inhabited the Cariboo district in those early days. A programme of song, dance, recitation and dialogue, directed by W. H. Powell, M.E.I.C., formed an enjoyable conclusion to a dinner which all agreed was one of the best ever held.

The serious work of both societies was resumed on the morning of Thursday, July 12th, when separate professional sessions were held, and the committee was able to report a total registration of more than four hundred and fifty.

The various technical divisions of the American Society of Civil Engineers dealt with and discussed no less than twelve papers, one of which, on the projected British Columbia-Yukon-Alaska highway, was of particular interest to Canadians. It was comforting to hear that of the 2,204 miles between Vancouver and Fairbanks, more than 1,000 miles have already been built, and that the cost of the remainder, from Hazelton through northern British Columbia into the Yukon and then on into Alaska, will only be $14,000,000, provided the cheapest type of construction is employed.

The four papers presented at the technical sessions of The Institute were well attended and gave rise to active discussion. The first paper, on the Highway System of British Columbia, by Patrick Philip, M.E.I.C., chief engineer of the Department of Public Works of the Province, dealt with questions of administration, organization and operation, as well as construction, and great interest was shown in the standard type of timber bridges which the department has developed. Mr. Philip was followed by J. M. Wardle, M.E.I.C., chief engineer, National Parks of Canada, who described the work carried on by his department on their portion of the highway around the Big Bend of the

**Dinner of The Engineering Institute of Canada and the American Society of Civil Engineers, Hotel Vancouver.**

Columbia from Golden to Revelstoke. His remarks were illustrated by an admirable film showing construction work in progress on that section.

The Town Planning Aspects of Vancouver and Fraser River Harbours were treated by W. G. Swan, M.E.I.C., who outlined the problems of administration, zoning, transportation and industrial development. The discussion was opened by J. A. Walker, the resident engineer of the Vancouver Town Planning Commission.

S.S. *Princess Louise* at Powell River, July 13th, 1934.

In the afternoon G. M. Gilbert, A.M.E.I.C., described the construction of the new intercepting sewer in English Bay. The information given respecting the somewhat difficult work on the submerged outfall was greatly appreciated, and C. Brakenridge, M.E.I.C., the city engineer of Vancouver, led the interesting discussion which followed.

The final paper of the series, on the substructure of the reconstructed Second Narrows Bridge, Vancouver, by P. L. Pratley, M.E.I.C., was presented, in the absence of the author, by J. P. MacKenzie, A.M.E.I.C. It described the events leading to the reconstruction of the bridge, and treated of the methods adopted and difficulties encountered, in building the substructure for the new lift span. Additional light on the subject was thrown by W. Smaill, M.E.I.C., in opening the discussion on this important paper.

After these technical exercises, the members were glad to take part in the first social event of the meeting in the evening, and the resources of the transportation committee were taxed to provide enough cars for the two hundred members and ladies who took the climb of 4,000 feet to Grouse Mountain Chalet, where a delightful dinner-dance was held. On this occasion Mr. Wardle kindly brought and exhibited films of wild life in the Canadian National Parks,—bear, buffalo and beaver. The pictures showing the beaver living and working under natural conditions were of special interest to engineers. Early in the evening atmospheric conditions were not all that could be desired, but later on the clouds parted, and gave a striking glimpse of the lights of the city far below.

The whole of Friday the 13th was devoted to a steamer trip to Powell River in the C.P.S.S. *Princess Louise.* Any fears which the superstitious might have had were proved groundless by the complete success of the outing. Reaching Powell River at one o'clock, parties were formed and conducted round the mill by well-informed guides under the instructions of Mr. D. H. Parker, the resident manager, and Mr. R. Bell-Irving, A.M.E.I.C., one of the directors. Members from the east, accustomed to six-inch sticks of pulpwood, were naturally interested in the operations of a mill whose pulpwood comes in logs more nearly six feet than six inches in diameter.

Leaving about five o'clock, the return voyage was cheered by a good dinner, followed by dancing and bridge, and the expedition disembarked at ten p.m. with a keen appreciation of the kindness of the Powell River Company and their officials, and the excellence of the arrangements for everyone's comfort on board the boat.

Some of the delegates had to leave Vancouver on Friday evening, but those who were able to remain and take part in Saturday's excursions were amply repaid. A large party motored to the Ruskin Hydro-Electric plant of the British Columbia Electric Railway Company, and after inspecting the plant, which has an ultimate capacity of 188,000 h.p., were hospitably entertained at luncheon by the company. They later drove to Seymour Falls, some eleven miles from the mouth of Seymour Creek. Here they met the party coming direct from Vancouver, and visited both the upper and lower intakes of the Greater Vancouver Water District. Not many cities on this continent are favoured with a natural water supply so abundant and so pure as Vancouver, where the city's very productive watershed, of some 13,000 acres, is owned and rigidly protected by the District.

Special arrangements for the visit were made through the kindness of the Chief Commissioner, E. A. Cleveland, M.E.I.C. The excursion was not only of technical interest, but was rendered more enjoyable by the beauty of the surroundings and the hospitality of the officers of the District.

This event brought to a close a gathering on which all who took part in it will look back with pleasure, and which will do much to broaden and maintain the cordial relations between The Engineering Institute of Canada and the American Society of Civil Engineers. Many of our British Columbia members belong to both organizations and were delighted to take part in welcoming their fellow members of the Society.

It is sincerely to be hoped that international meetings of this kind will take place more frequently in the future and that they may assist, as this one certainly has, in making the aims and work of Canadian engineers better known in the United States.

## The Engineering Institute of Canada Prize Awards 1934

Eleven prizes known as "The Engineering Institute of Canada Prizes" are offered annually for competition among the registered students in the year prior to the graduating year in the engineering schools and applied science faculties of universities giving a degree course throughout Canada.

Each prize consists of twenty-five dollars in cash, and having in view that one of the objects of The Institute is to facilitate the acquirement and interchange of professional knowledge among its members, it has been the desire of The Institute that the method of award should be determined by the appropriate authority in each school or university so that the prize may be given to the student who, in the year prior to his graduating year, in any department of engineering has proved himself most deserving as disclosed by the examination results of the year in combination with his activities in the students' engineering organization, or in the local branch of a recognized engineering society.

The following are the prize awards for 1934:

| | |
|---|---|
| Royal Military College—1933 | Howard Crawford DeBlois, S.E.I.C. |
| University of Alberta | Robert Fraser Logie |
| University of British Columbia | Percy R. Sandwell |
| University of Saskatchewan | Lawrence Crawley Sentence |
| Queen's University | Joseph M. Whyte |
| University of Manitoba | James Munroe Dale |
| Nova Scotia Technical College | Charles Abbot Wright, S.E.I.C. |
| The University of New Brunswick | Wilfrid E. Smith |
| University of Toronto | Robert Hewitt, S.E.I.C. |
| Ecole Polytechnique | Yvon-Roma Tasse, S.E.I.C. |
| McGill University | Charles Peter Paton |

## Engagement of Engineers by Ontario Municipalities

In accordance with the directions of Council the following circular letter has been forwarded to the corporate members of The Institute residing in the province of Ontario:

Dear Sir:—

I have been directed by Council to draw the attention of corporate members of The Institute residing in Ontario to a matter dealt with by Mr. H. D. Anger, Barrister, of Toronto, in his recent address before the Toronto Branch of The Institute, which was printed in The Engineering Journal for May, 1934, pages 207-218.

The particular point to which your attention is called is referred to in Section B-6 of Mr. Anger's address, commencing at the foot of page 213, and refers to the case of engineers who are retained or engaged by municipal councils in Ontario. In Ontario, under the Ontario Municipal Act, such engagement, to be effective, must be of a formal nature and by a by-law passed by the municipality under its common seal, failing which such engagement is void.

This has led to cases in which an engineer, having completed or practically completed his work for a municipality, has found himself unable to recover his fees when payment has been refused after a change of administration.

In the opinion of Council it is important that members undertaking work for Ontario municipalities should invariably take steps to protect themselves by requiring compliance with the Ontario Municipal Act on the part of the corporations engaging them.

Yours very truly,
R. J. Durley, *Secretary.*

## OBITUARIES

### George Warren Fuller, M.E.I.C.

Deep regret is expressed in placing on record the death at New York, N.Y., on June 15th, 1934, of George Warren Fuller, M.E.I.C.

Born at Franklin, Mass., on December 21st, 1868, Mr. Fuller graduated from the Massachusetts Institute of Technology in 1890 with the degree of B.Sc., and later studied for about a year at the University of Berlin, and in the private office of Carl Piefke, engineer of the Berlin water works. About nine years were then devoted to research work on methods of purifying water and sewage from the biological, chemical and engineering viewpoints. He was with the Massachusetts State Board of Health for nearly five years, during the latter part of which he was in charge of the Lawrence Experiment Station. In 1895 Mr. Fuller went to Louisville, Ky., and for two years conducted experiments on the suitability of various processes of water filtration available at that time for purification of a turbid water having wide variations in composition such as the Ohio river at Louisville. Following the Louisville studies he was engaged on similar researches at Cincinnati, Ohio. In 1899 Mr. Fuller entered private practice in New York, N.Y., as consulting hydraulic engineer and sanitary expert. From 1901 to 1911 he was in partnership with the late Rudolph Hering under the firm name of Hering and Fuller. He then continued practice under his own name until 1916 when he formed a partnership with the late James R. McClintock, and continued practice under the firm name of Fuller and McClintock.

In 1917 and 1918 during the War, Mr. Fuller was a member of a Central Committee at Washington having to do with the engineering, planning and sanitation of the various army camps. He was consulting engineer to the United States Public Health Service, and also to the construction division of the army. Mr. Fuller was a member of the Franco-American Engineering Congress convened at Paris directly after the Armistice to consider various reconstruction and economic problems in France.

One of the many important works performed by Mr. Fuller in his special field of engineering was accomplished in 1924 and 1925 for the Sanitary District of Chicago, when as chairman of a board of experts he laboured on the problem of the advisability of installing a new system for disposing of the sewage of that city. For many years Mr. Fuller was connected with the improvement of sanitary conditions for New York City, serving as a consultant on sewerage and sewage disposal for the Metropolitan Sewerage Commission of New York. In 1928 and 1929 he reported to the city upon the Wards Island sewage treatment works, and his firm afterwards prepared the plans for this project. From 1906 to date Mr. Fuller has been consultant to the New York Board of Water Supply on various sanitary problems connected with the development of the Catskill reservoirs and supply system. During his professional career Mr. Fuller served as consulting engineer for major water works and sewerage improvements in more than one hundred and fifty large cities in the United States and abroad.

Mr. Fuller was a member and chairman of an Engineering Advisory Committee of the Reconstruction Commission of the State of New York, and adviser to the International Joint Commission on Boundary Waters between the United States and Canada.

He was chairman of the Committee on Promotion and Attendance for the World Engineering Congress at Tokyo, Japan, in 1929; a past-president of the American Water Works Association, and of the American Public Health Association; and past-vice-president and director of the American Society of Civil Engineers. He was also a member of the American Institute of Consulting Engineers, the American Society of Mechanical Engineers, the American Chemical Society, the American Society of Bacteriologists, the Institution of Civil Engineers of Great Britain, the Vereines Deutscher Ingenieure, L'Association Générale des Hygiénistes et Techniciens Municipaux of France, and The Franklin Institute. He was elected chairman of The Engineering Foundation in 1933, and held that office at the time of his death.

Mr. Fuller was the author of many professional papers, and three books: "Water Purification at Louisville," 1898; "Sewage Disposal," 1912; and "Solving Sewage Problems," 1926.

Mr. Fuller became a Member of The Engineering Institute of Canada on May 11th, 1912.

### Archibald Abercromby Bowman, M.E.I.C.

The membership of The Institute will learn with regret of the death at Montreal, on June 26th, 1934, of Archibald Abercromby Bowman, M.E.I.C.

Mr. Bowman was born at Forglen, Scotland, on March 8th, 1875, and received his early education in that town and at the High School in Glasgow, Scotland. He graduated from McGill University in 1899 with the degree of B.Sc., having served his apprenticeship as an engineer in the shops of the Nova Scotia Steel Company, New Glasgow, N.S., in 1891-1895.

Following graduation, Mr. Bowman was until 1900 draughtsman and erecting engineer with the James Cooper Manufacturing Company, Montreal, and in 1900-1901 he was assistant chief engineer with the Canadian Rubber Company, Montreal. In 1901 Mr. Bowman joined the staff of the Canadian Ingersoll-Rand Company, Limited, as salesman and erecting engineer, and remained with that company until the time of his death, occupying at various times the positions of branch manager at Winnipeg, Toronto, and Montreal, district sales manager, assistant to the general manager, and electrical and mechanical engineer. For the past few years Mr. Bowman was directly concerned with the company's export business.

Mr. Bowman joined The Institute (then the Canadian Society of Civil Engineers) as a Student on March 16th, 1899, and became an Associate Member on April 23rd, 1903, and a Member on April 20th, 1915.

### Frank Panneton, A.M.E.I.C.

Regret is expressed on placing on record the death at Three Rivers, Que., on July 14th, 1934, of Frank Panneton, A.M.E.I.C.

Mr. Panneton was born at Three Rivers on December 10th, 1892, and graduated from the Ecole Polytechnique, Montreal, in 1915 with the degree of B.A.Sc.

In 1915-1916 Mr. Panneton was engaged on survey work with the Dominion government, and following that was until 1924 engaged in private practice. In 1924 he became assistant engineer and chief designer for the city of Three Rivers, which position he held until the time of his death. He was known as an authority on municipal engineering and bridge design.

Mr. Panneton became an Associate Member of The Institute on October 18th, 1932.

### Harry Bonfield Pope, A.M.E.I.C.

It is with regret that we place on record the death at Montreal on July 24th, 1934, of Harry Bonfield Pope, A.M.E.I.C.

Mr. Pope was born at Peterborough, Ontario, on November 2nd, 1879, and following a students' course with the Canadian General Electric Company at Peterborough, he was in 1898-1903 engaged on construction work and switchboard operating with the Lachine Rapids Hydraulic and Land Company. In 1903 Mr. Pope joined the staff of the Montreal Light Heat and Power Company and until 1904 was assistant superintendent of the Lachine power house. From 1904 to 1906 he was in charge of three of the company's substations. In 1906 he became superintendent of the Chambly power house, and in 1910 he was appointed superintendent of the company's generating stations. At the time of his death Mr. Pope was general superintendent of the electrical departments of the Montreal Light Heat and Power Consolidated.

Mr. Pope became a Student of The Institute (then the Canadian Society of Civil Engineers) on January 14th, 1904, and transferred to the class of Associate Member on October 8th, 1910.

## PERSONALS

A. A. Ferguson, Jr., S.E.I.C., who was formerly inspection engineer with the Canadian Fire Underwriters' Association, is now associated with Messrs. Reed, Shaw and McNaught, Montreal. Mr. Ferguson graduated from McGill University in 1931 with the degree of B.Sc.

V. L. Richards, S.E.I.C., has joined the staff of the Canadian Hanson and Van Winkle Company, Limited, Toronto. Mr. Richards graduated from Queen's University in 1932 with the degree of B.Sc., and secured the degree of M.Eng. from McGill University in 1934.

John Morse, M.E.I.C., general superintendent, Shawinigan Water and Power Company Limited, Montreal, was elected president of the Canadian Electrical Association at the annual meeting of that organization held recently.

Malcolm D. Barclay, A.M.E.I.C., and C. C. Lindsay, A.M.E.I.C., are members of newly organized firm of M. D. Barclay Incorporated, Montreal, Quebec Land Surveyors and Civil Engineers.

W. H. Stuart, M.E.I.C., who until recently was superintendent of engineering and construction for the Hotel Department of the Canadian National Railways, has, as the result of the abolition of his position due to reorganization in the Canadian National Railways, become associated with the James Morrison Brass Manufacturing Company Limited of Toronto. Mr. Stuart's position is that of special representative, with headquarters at Montreal, handling the company's business with the railways, the larger industrials, engineers and contractors, and certain phases of the business at Ottawa.

C. K. McLeod, A.M.E.I.C., has been appointed exclusive distributor of Permutit water treating equipment of all types for the provinces of Quebec, Ontario, and the Maritimes, with offices in Montreal and Toronto. Mr. McLeod who was formerly a principal in the firm of Busfield, McLeod Limited has devoted a considerable portion of his time to the Permutit Company's products during the past eight years.

Immediately after graduation from McGill University with the degree of B.Sc. in chemical engineering in 1913,

C. K. McLEOD, A.M.E.I.C.

Mr. McLeod became plant chemist with the Canada Cement Company Limited, remaining with that concern for the next three years. In 1916 he was engaged on the inspection of explosives with the Imperial Ministry of Munitions and remained on this work until the end of 1918. In May 1919, he was appointed chief chemist for the Dominion Glass Company, and one year later became superintendent with the Consumers Glass Company. In May 1921 Mr. McLeod was with the Phoenix Bridge and Iron Works on design and sales of structural steel work. When this firm was taken over in October, 1923, by Canadian Vickers Limited, he occupied a similar position with the new organization. In 1925 he became manager of the Chemical Engineering Equipment Company, the name of which was later changed to Busfield, McLeod Limited.

Mr. McLeod is very well known to the membership of The Institute as Secretary-Treasurer of the Montreal Branch, which office he has held for a number of years.

Frederick Palmer, A.M.E.I.C., who has since 1929 been Canadian Government Trade Commissioner at Oslo, Norway, has been transferred to Bristol, England, where he will occupy the same position. Mr. Palmer has also occupied the position as Canadian Trade Commissioner in New York, Rotterdam, Holland, and Milan, Italy. He received his engineering training at the Nova Scotia Technical College. from which he graduated with the degree of S.B. in 1913, Following graduation he was with the Toronto Structural Steel Company Limited, in their shops at Toronto, and later on erection work at Lindsay and Ottawa. During 1915 he was for a short time on building construction in Halifax, after which he was appointed assistant engineer with Foley Brothers, Welch, Stewart and Fauquier on the Halifax Ocean Terminals. He was on active service overseas from 1916 until the end of the war, serving as a lieutenant in the heavy artillery and being awarded the Military Cross. Following the war Mr. Palmer was with the Nova Scotia Highways Commission. In 1927 Mr. Palmer resigned from the Department of Trade and Commerce of Canada, to take a position with the Ford Motor Company at their Antwerp branch in Belgium, but later rejoined the service.

A. G. L. Atwood, S.E.I.C., is now connected with the Iron Fireman Manufacturing Company of Canada, Montreal, as engineer in charge of installations. Mr. Atwood graduated from the Nova Scotia Technical College in 1927 with the degree of B.Sc., and was subsequently, until 1928, with the Northern Electric Company at Montreal. In 1928 he joined the staff of E. A. Ryan, M.E.I.C., consulting engineer, Montreal.

C. E. Webb, M.E.I.C., district chief engineer for British Columbia of the Dominion Water Power and Hydrometric Bureau, Department of the Interior, was the recipient of the degree of Civil Engineering at the recent convocation of the University of Toronto. Mr. Webb graduated from the University of Toronto in 1910 with the degree of B.A.Sc., and since 1913 has been in the service of the Department, from 1913 to 1918 as assistant engineer to the assistant chief engineer, from 1918 to 1925 as assistant chief engineer and from 1925 in his present capacity.

G. H. E. Dennison, A.M.E.I.C., has joined the staff of the Canadian Carborundum Company Limited at Niagara Falls, Ont., as sales and service engineer. Following graduation from the Royal Military College in 1920, Mr. Dennison was with the Algoma Steel Corporation. From 1921 to 1923 he was with the Lake Superior Paper Company, and from that time until 1927 was on the staff of the Spanish River Pulp and Paper Mills Limited, Sault Ste. Marie, Ont., as assistant hydraulic engineer. In 1927-1928 Mr. Dennison was chief draughtsman with the same company. From 1928 until 1930 he was engineer at the Sault Ste. Marie mill of the Abitibi Power and Paper Company, being engaged on electrical and mill design and the supervision of construction. In 1931 Mr. Dennison was again connected with the Algoma Steel Corporation at Sault Ste. Marie. Mr. Dennison takes a keen interest in the affairs of The Institute, and was appointed Secretary-Treasurer of the Sault Ste. Marie Branch in 1933.

This is an excellent book in every way: well planned, well written and well printed. The authors modestly assert that no attempt has been made to produce a scientific treatise; nevertheless the sections on fundamentals, clearly written as they are, are extensive enough to tax the comprehension of those who have not kept up their physics. Other sections are proportionally thorough. Operating details and interpretation, the phases with which most engineers will be chiefly concerned, are very complete and lucid in their treatment. Careful emphasis is placed on the need for thorough protection against the high voltages and dangerous radiations, and on how to attain it. The publication of this book is most timely.

A few years after the War, Dr. St. John gave a public lecture at McGill Physics building on application of X-ray other than medical, a comparatively new subject; since then industrial radiography has become a matter of course, and to some—for example the users of modern high pressure boilers and other "pressure vessels"—a matter of absolute necessity.

Last winter the Montreal Chapter, American Society for Metals, sponsored a very interesting lecture by the Victor X-Ray Corporation (G.E.) and the Metallurgical Department at McGill University is now radiographing welds, castings, etc., for local investigators. A new tool is well established in the hands of engineers.

One minor criticism might be made: regarding the use of the word "exograph." It seems hardly necessary to add a word of so dubious parentage to an already overburdened language.

## Traffic Survey Engineering Manual

*Prepared under the direction of Sidney J. Williams, Director of Safety and Traffic Surveys, and Peter J. Stupka, Assistant Director of Traffic Surveys, Federal Civil Works Administration, by Burton W. Marsh, Director, Safety and Traffic Engineering, American Automobile Association, Earl J. Reader, Traffic Engineer, National Safety Council, and Maxwell N. Halsey, Traffic Engineer, National Bureau of Casualty and Surety Underwriters.*

The library of The Institute is in receipt of a 142-page mimeographed report entitled "Engineering Manual for Traffic Surveys" prepared under the direction of Sidney J. Williams and Peter J. Stupka, Director and Assistant Director of Safety and Traffic Surveys, Federal Civil Works Administration, U.S.A.

It is interesting to note that this manual developed in accordance with a national programme of uniform street traffic surveys throughout the United States, and is in connection with the operation of the Civil Works Administration and thus offers every community a chance to make a reliable traffic survey and further, helps to answer the problem of what kind of work to give the so-called "white collar" class.

Through having uniform studies it will be possible to compare results with data obtained in a similar manner in other cities and, if necessary, advice may be obtained from a Federal Civil Works Associate Director or Traffic Engineer, a number of whom have been appointed in various regions throughout the States. Further, each community making a survey is asked to submit certain summarized data to the Federal C.W.A. in order that national analyses and recommendations can be made.

The manual is divided into fifteen sections covering the method of organizing and conducting fourteen important studies of a traffic survey and includes copies of field and office forms and detailed instructions for their use.

Included are a General Introduction and Recommendations, Accident Analysis, Vehicle Volume Count, Vehicle Speed Study, Observance Studies, Traffic Law Enforcement, School Child Pedestrian Practices, Inquiry among Drivers, Street Parking and Cordon Count.

In the introduction are included particulars on the selection, training and supervision of the personnel who are to make the survey and further, for example, under the heading Accident Analysis provision is made to obtain data for a "Worst Corner" list, Collision and Condition diagrams and under Traffic Law Observance particulars are compiled on Vehicle and Pedestrian Observance of stop and go signals, Vehicles Observance of stop signs and Hand Signalling.

In fact, many advantageous studies are outlined, but as it is pointed out, all studies that might be desirable in some surveys cannot be included, however it makes an excellent guide and should prove of service to many municipal engineers.

---

*The Toronto Industrial Commission* this year completes five years of operation. Since it was established in 1929, 122 industrial concerns, the majority of them either British or United States manufacturers, have made use of the services offered by the Commission and have commenced manufacturing operations in the Toronto area. Of this number, 101 are operating their own factories, occupying more than one million square feet of floor space, with plant investment of over $5,000,000, while the remainder are having their products made by Toronto manufacturers.

## The Multiplex Aero-Projector

*Mr. Heinz Gruner of the United States Corps of Engineers, Experimental Mapping Division, recently gave a most interesting address before the Ottawa Branch of The Institute, his subject being "The Multiplex Aero-Projector." A report of this appears on page 379 of this issue of The Journal. There were, however, many details of the working which time did not permit Mr. Gruner to cover, and Mr. F. H. Peters, M.E.I.C., has been good enough to give a few further details and his impressions of this equipment, which are given below.*

The multiplex aero-projector and accessories constitute a very portable equipment for small scale mapping of topography from the usual type of vertical air photographs—that is air photographs obtained by a single lens camera suspended vertically and photographing from a uniform altitude in parallel flights, making exposures at equal intervals to give an overlap in the line of flight of about sixty per cent. The spacing of the flights must be such as to give some side or lateral overlap in adjacent strips.

After the photography is obtained, the roll of film is developed and is passed uncut between two glass plates contained in a fixed reducing camera, which results in giving a print on glass, the original photograph 8 inches square being reduced in dimensions thereby to 1½-inch size. Provision is made in the reducer for adjusting the original exposed negatives into a fixed position so that the resulting reduced positives on glass will show calibration marks required for their subsequent insertion in the projector, in their correct position. The reduced diapositives are obtained on a very fine grained emulsion and the size of the reducing apparatus would indicate that a wide angled short focus lens is employed, a graded filter being used to obtain uniformity in the density of the reduction on glass, the reduction factor being about five times.

Nine projectors are supported on a horizontal bar which is adjustable in height and can be tipped and tilted within the range required. In these nine projectors are inserted nine diapositives or prints on glass of nine consecutive vertical air photographs taken in a strip. Each projector is equipped with a lens of about 2 inches focal length by which is projected on the tracing screen below an image enlarged about six times from the diapositive. Thus the projected image from which the plotting is done, is slightly larger in scale than the original field negative.

In setting and plotting, one overlap is examined at a time and use is made of complementary colours to produce a stereoscopic effect. The projection to be viewed by the left eye is for instance projected in a light of a colour which the left eye only can see. This is effected by using a red filter in the projector and a similar red filter spectacle glass over the left eye. The overlapping view is projected in a blue green light by similarly inserting a blue screen filter in the projector and a spectacle glass of blue green filter over the right eye. The observer is seated beside the table on which the projection is made, or on which the tracer screen is moved in a position in which his eye base roughly parallels the horizontal rod supporting the projectors, corresponding in direction to the strip of vertical air photographs. For examination of the projected images a small circular white screen is employed. This screen is adjustable in height and can be moved by hand over the paper on which the plot is traced on its horseshoe support. The screen has a small index or floating mark centrally marked on it, or a small centrally illuminated hole vertically under which is the pencil which traces the features to be mapped. The manner of using the tracer and its construction is very similar to that described by the late Dr. E. Deville in a paper on the "Use of Wheatstone Stereoscope in Photographing Surveying," read before the Royal Society of Canada in 1902.

For orientation of a projector so that the diapositive occupies relatively to the plane of the map the same position which the photograph occupied relative to the horizontal plane when the view was taken, control stands somewhat similar to the tracer screen are employed. These are placed over each control point and set at its elevation called for by the scale of the plot. The distance between adjacent projector lenses corresponds to the respective air base expressed to the scale of the plot. It is understood that the mutual orientation of an adjacent pair of projectors can be made by examining and correcting the stereoscopic result in various portions of the projected images and the time consumed in this operation would appear to represent a very important part of the time employed in producing the map. After the first pair of projectors have been set in correct position, the third projector can be adjusted into correct orientation with the first two, and so on until the ninth or last projector on the horizontal bar is reached. If control is available at this point, the adjustment of the nine projectors to it can then be made. The drawing of contours is effected by setting the screen of the tracer at the elevation expressed to the plotting scale, above or below the datum plane, of such contour and guiding the tracer by hand over the paper in a manner to keep the index mark in apparent contact with the ground shown in relief in the plastic image. Plotting of features is effected by raising or lowering the tracer screen and moving it over the table until the index of the tracer just touches the ground at this feature in the plastic image, the pencil then being released to mark the position on the plan beneath it.

Comparing the use of the multiplex aero-projector with methods of plotting vertical air photographs employed by the Topographical Survey as described in the following paragraphs, it might be noted that apart from a reflecting stereoscope of the Wheatstone type, no other instrument is used by the latter organization.

Contact prints from the field negatives are examined in pairs under the stereoscope and the principal point base common to each pair of photographs is marked on the prints by the stereoscopic method, a procedure which involves about two minutes for each pair of photographs. Auxiliary points, one on either side of the principal point base and lying normal to it from the principal point a distance about equal to the principal point base are next selected and marked two for each photograph. These identical points are next identified and marked on adjacent prints, either visually or by using stereoscopic markers. Tie points to adjacent strips separated by four or five or more overlaps are similarly selected and marked. On the assumption that the photographs are angle true at the principal point, a strip structure is drawn to the approximate scale of the photography by the usual radial or intersection method, by which a plot showing the principal points, auxiliary points and tie points on a uniform scale is produced. The overall scale of this strip plot is determined by comparing the distance between ground control points as plotted with their true distance. This plot is made on transparent linen or Lumarith and the detail of topography, culture, and water features is next added. If contours are also to be shown, they are first drawn on the photographs—every second photograph of the strip, and are based on spot heights obtained in the field. These spot heights are supplemented in the office by use of a stereoscope equipped with grid plates and used for parallax measurements. Exposing at equal intervals in the air produces a uniform length of air base, and so the average length of air base can be determined from the principal point plot. Knowing the flying height, the focal length of the lens employed and the air base, parallax differences on the print corresponding to differences in relief of the ground can be obtained and used with the spot heights for fixing other additional heights on which the contouring is based. With the net work of heights the topographer draws the contours on the photographs as viewed in a reflecting stereoscope. The contours are then transferred to the strip plot, giving to each contour a displacement similar to that as shown by the plot of detail in its vicinity, and of about the same height.

When all the information to be included in the map is plotted on the strip, the whole is photographically or otherwise brought to the scale of the assembly and compiled on a projection sheet, from which the final drawing is made.

The photography is usually obtained by photographing with a wide angle single lens camera at or near the service ceiling of the aircraft. This gives a scale of photograph larger than that of the published map, but it is fixed by the equipment available and it would be preferable from an economic standpoint if this range were reduced.

Without having had experience with the multiplex aero-projector it is difficult to estimate its capacity or adaptability or order of accuracy, or to make a comparison with the graphical radial methods in use. It is in reality a camera plastica machine adapted for stereoscopic vision and equipped with a floating mark, and highly useful for instructional purposes.

## Centenary of Gottlieb Daimler

Of the many eminent German engineers of the latter half of the nineteenth century, Gottlieb Daimler, who was born on March 17th, 1834, a century ago, and died on March 7th, 1900, will always be remembered for his work on the internal-combustion engine and the construction of the first light high-speed engine using spirit as fuel. His patent for this type of engine was taken out in Germany on December 16th, 1883, and two years later, in the gardens at Cannstatt, he made his first trial with a vehicle fitted with one of his engines. That same year, Benz also brought out a motor vehicle, but whereas the speed of his engine was only between 200 r.p.m. and 300 r.p.m., the engines of Daimler revolved at 900 r.p.m., and were thus the forerunners of the petrol engines used to-day in motor cars and aircraft.

Daimler was born at Schorndorf, and became a mechanical engineer. From the shops of a machine-tool factory at Grafenstaden, in 1857, he entered Stuttgart polytechnic, and then had a varied experience in England and Germany. At the age of thirty-eight, in 1872, he became technical manager to Langen and Otto, who had founded the famous Gas-motorenfabrik Deutz A.-G., near Cologne. Together the partners had evolved the fairly successful atmospheric gas engine, and Otto was engaged on further experiments, which, as everyone knows, led him in 1876 to the invention of the all-important four-stroke cycle for internal-combustion engines. For many years the Deutz firm was fully occupied with the construction of the new "Otto" gas engines, but Daimler, realizing the possibility of further develpoments, left Langen and Otto, and in 1882 set up an experimental workshop at Cannstatt. He did not have to wait long for success, for in 1883 he was able to patent his high-speed spirit engine, and in the next two or three years built, first a form of motor-bicycle, then a motor car and a motor boat. In 1887 he sold the French rights for the use of his patents to M. Sarazin, who induced the engineering firm of Panhard and Levassor to take up the manufacture of motor cars. Daimler, himself, in 1890, founded at Cannstatt the well-known Daimler Motoren Gesellschaft, and with this he remained connected, mainly in an advisory capacity, until his death.—*Engineering.*

## Valuation of Non-Metallic Mineral Deposits

*by Marc Boyer, S.E.I.C.*

**Abstract of paper presented before the Quebec Branch of The Engineering Institute of Canada, February 12th, 1934.**

Mineral products may be subdivided into two groups: metallic and non-metallic. From an engineering point of view, these two groups parallel each other closely, but, if viewed from an economic standpoint, there is a strong distinction between them.

Any complex metallic ore found can be reduced to a metal of standard purity which can be marketed through some established sales channels, whereas the marketing of a non-metallic mineral involves intricate problems; the market price of the metal is another distinction between the two groups. Non-metallics are generally low-priced and abundant; therefore the geographic situation of the deposit becomes more important than when dealing with deposits of the higher-priced metallic ores.

Non-metallic substances may be divided into three groups:

1. Minerals whose "place value" (geographic situation) is paramount such as cement materials, clays, limestone, marble, salt, slate, etc.
2. Minerals whose physical and chemical characteristics are paramount, these are: graphite, asbestos, bauxite, talc, sulphur, etc.
3. Minerals for which specifications are rigid but where "place value" is also of importance; some of these are: barytes, bentonite, feldspar, magnesite, etc.

The elements of the valuation of non-metallic mineral deposits may be summarized as follows:

(*a*) Available market for the raw and finished product.
(*b*) Quality and extent of the deposit.
(*c*) Geographic situation or place value.
(*d*) Transportation facilities and costs.
(*e*) Mining and milling facilities and costs.
(*f*) Profitable return on investment.

*Available Markets:* In contrast with metallic ore deposits where the marketing problem is relatively simple, the question of securing a market for most non-metallic substances is difficult and often considered as more important than the deposit itself. When attempting a survey of the market with a view to opening up a new deposit, the following factors should be carefully weighed: the total tonnage absorbed within the area that can be served by the new deposit, price, importance of similar deposits in the district, strength of competitors, seasonal fluctuations, etc.

*Quality and Extent of Deposit:* These are important factors and it is paramount that the physical and chemical characteristics of the substance be known before it is offered for use to prospective consumers; should the quality respond to the accepted standard, one should then ascertain the extent of the deposit in view of estimating its total approximate value.

*Geographic Situation—Transportation:* As non-metallic mineral substances command a low price as compared to metals, their marketing radius is limited by prohibitive freight charges and by competition from similar deposits in adjoining districts. The distance from principal marketing centres and freight rates should be studied and compared with those of already established enterprises in the area.

*Mining and Milling:* A study of mining and milling costs should reveal whether these compare favourably with the costs of producers already established and if the expected margin of profit is sufficient to withstand a possible cut in price due to competition or to a possible momentary demoralized condition of the market.

*Profitable Return on Investment:* What is considered a profitable return on investment? This return is generally viewed in connection with the element of risk inherent to the enterprise; favourable conditions may not last long, new products may come in, tariffs and market centres may change, etc. An annual return of 25 to 40 per cent or 50 per cent on a highly speculative venture is not considered out of proportion by many experienced operators; however, on a ten year investment, 15 per cent would still be conservative.

The above information may appear elemental but many failures in the non-metallic mineral field are the direct result of one or more of these major points.

## Exposition of Power and Mechanical Engineering

The Eleventh National Exposition of Power and Mechanical Engineering will be held this year at the Grand Central Palace, New York, from December 3rd to 8th, 1934. Coming in December of the present year, the power show is an important point in a four-year period, including two years since the last one, and with two years before the 1936 power show. The outstanding success indicated for the exposition is coupled with increased purchasing power and renewed industrial modernization in all of the fields which it serves. The value of this year's event should be outstanding both to the exhibitors and to the men from engineering and industry who attend. As in the case of previous expositions, the International Exposition Company are managers, with Charles F. Roth personally in charge.

# BRANCH NEWS

## Hamilton Branch

*A. Love, A.M.E.I.C., Secretary-Treasurer.*
*Reported by T. S. Glover, A.M.E.I.C.*

Visit to Soaking Pit Building, Dominion Foundries and Steel Limited

Hamilton has many claims to distinction in addition to a rugby team and a mountain. The latest is the erection of the first "100 per cent Canadian" steel building.

Two parties of the Hamilton Branch members of The Institute visited the plant of the Dominion Foundries and Steel Limited on Saturday, June 9th, 1934. The new building contains a soaking pit and heating furnace, and embodies some very heavy steelwork. The main structure of the mill building was fabricated and erected by the Hamilton Bridge Company. Their part of the contract included columns of the conventional I section, but made of plates rolled by the Dominion Foundries and Steel in this plant and welded together. Another interesting feature was the crane runway which had beams made up of locally rolled plates welded together.

Original designs called for imported rolled sections for these parts but the structural sections were redesigned by the Dominion Foundries and Steel engineering staff so that Canadian steel could be used entirely. Angle sections were rolled either in Hamilton or at the Soo, while for purlins, locally rolled plates were pressed into channel shapes.

One particular advantage of using welded columns was clearly demonstrated on the columns which carried the crane runway, the flange carrying the crane load was made of thicker plate than the other. By this means of construction additional metal could be concentrated at the point where it was needed most.

Over four hundred thousand bricks were used in the furnace and pit construction. One particular brick could not be obtained in Canada but was imported from South Africa. The heavy beams and columns in this particular part, also of the welded type, were fabricated and erected by the Dominion Foundries and Steel.

The furnace equipment is of the very latest type on the North American continent and was all made locally.

About twenty-five members in the forenoon and forty in the afternoon took this opportunity of seeing the latest addition to Hamilton's industrial buildings, and they were received with the customary hospitality of the Dominion Foundries and Steel Limited.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*
*Wm. Meldrum, A.M.E.I.C., Branch News Editor.*

On Monday evening, June 4th, 1934, a motion picture of the British Electrical Grid was shown at a special meeting of the Lethbridge Branch of The Engineering Institute of Canada, attended by about sixty, with C. S. Donaldson, A.M.E.I.C., presiding. These films, eight in number, were a presentation of the British Electrical Board which loaned them to The Engineering Institute of Canada to be shown at their different Branches throughout the Dominion. Six reels were on power, showing the manufacture of copper and aluminum conductors, high voltage cables, erection of steel towers and other equipment. The other two reels showed the operation of the generating and transmission system from the plants to the consumers.

Small individual electric power stations have been amalgamated into a single network which is called the British Electrical Grid.

In the head power station the electricity is generated by steam and transmitted to a transforming station where it is raised to 132,000 volts. At all receiving stations the incoming current is measured and half hourly records are made. Current is supplied in bulk for electric railways, being converted for use by the trains.

Receiving stations reduce the voltage from 132,000 to 33,000 and main grid distributing stations to 11,000 volts.

Following the projection of the films, J. T. Watson, A.M.E.I.C., gave a few explanatory remarks and answered several questions. A motion was passed tendering the thanks of the Branch to Mr. Cyril Watson who operated the projector and to G. H. Thompson, A.M.E.I.C., of the Calgary Power Company, and Mr. Forbes Roberts of the Montreal Engineering Works of Regina, through whose kindness the attainment of the films was made possible.

## London Branch

*H. A. McKay, A.M.E.I.C., Secretary-Treasurer.*
*J. R. Rostron, A.M.E.I.C., Branch News Editor.*

By kind invitation of our former Secretary, W. R. Smith, A.M.E.I.C., the annual outing of the Branch was held on June 23rd, 1934, at his residential farm west of Byron.

Mr. Smith boasts of a fair-sized swimming pool on his estate and several of the party took full advantage of it. Canoeing was also indulged in with a mimic towel battle between two of the canoeists.

The rifle shooting at targets proved very popular, the prizes going to Majors Ross and Dickinson and J. Young.

An "al fresco" supper was provided and much enjoyed.

Our host gave us an example of bare-back riding on a somewhat restive pony and while seated on its back was the recipient of a hearty vote of thanks for his hospitality, proposed by J. R. Rostron, A.M.E.I.C., which was unanimously carried.

## Moncton Branch

*V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.*

ANNUAL MEETING

The annual meeting of the Branch was held on May 31st. Professor H. W. McKiel, M.E.I.C., chairman of the Branch, presided. The annual report and financial statement was presented and on motion adopted. The chairman read a letter which he had addressed to Rt. Hon. R. B. Bennett, Premier of Canada, supporting the action taken by Council in urging the Federal government to employ engineers to make detailed engineering studies of contemplated government works, before construction was commenced or tenders called for. A resolution was passed approving the chairman's letter. On motion of F. O. Condon, M.E.I.C., seconded by G. E. Smith, A.M.E.I.C., a vote of thanks was tendered the retiring officers, and also the members of the teaching staff of Mount Allison University for their generosity in furnishing speakers for Branch meetings during the year. The report of the scrutineers was received and the officers for 1934-35 announced.

Brief remarks were then made by the outgoing and incoming chairmen.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

INSPECTION OF C.R.C.O. BROADCASTING PLANT

On Saturday afternoon, May 26th, 1934, members of the Ottawa Branch and their friends made a tour of inspection of the recently completed modern equipment of the Ottawa station of the Canadian Radio Broadcasting Commission.

The party met at the studios of the Commission on the eighth floor of the Chateau Laurier, where they were shown the control equipment for the studios and were given a demonstration of a new and novel method of continuous recording. In this method, magnetic recording takes place on a long narrow steel tape, the modulation of speech or music being converted into variable density magnetism. The process is quite analagous to variable density movie sound-track systems.

When the tape bears a record, it may be filed away for future use or it may at any time be cleared of the record and used again for another one.

In the apparatus as at present designed, facilities for clearing the tape of a previous record, for recording a new one, and for sending out a record to be broadcast, are all included in the one instrument. It is a simple matter to record any broadcast on the tape at the same time as it is being sent out.

After their inspection of the studios the party motored to the transmitting station and antenna system, located at Hawthorne about five miles out of the city. Here the two 200-foot towers were inspected, as well as the transmitting station itself, which is housed in a neat newly-erected bungalow-type of building.

Guides to explain the various features of both studios and transmitter were made available by the Broadcasting Commission, through the courtesy of Lieutenant-Colonel W. A. Steel, A.M.E.I.C., Commissioner.

A NEW INSTRUMENT FOR PLOTTING FROM AERIAL PHOTOGRAPHS

A large number of the members of the Ottawa Branch availed themselves of an invitation to attend an evening meeting on June 15th, 1934, at the lecture hall of the National Research Laboratories, held under the auspices of the Associate Committee for Survey Research of that institution. At this meeting a demonstration lecture on photogrammetric apparatus was given by Mr. Heinz Gruner, of the United States Corps of Engineers, Experimental Mapping Division.

Mr. Gruner traced the history of the aerial camera and the development of methods of plotting from aerial photographs, paying particular attention first of all to such instruments as the aerocartograph and the stereoplanigraph. He then took up a considerable part of his time with an explanation of the multiplex aero-projector, a newly-designed instrument for the preparation of small-scale maps from aerial photographs. His address was illustrated by lantern slides and was followed by a demonstration with a multiplex aero-projector instrument, the latter having been set up for demonstration purposes by Mr. Gruner and by Mr. E. O. Messter, general manager of Zeiss-Aerotopograph, of Jena, Germany.

The multiplex aero-projector is a stereoscopic plotting instrument for producing maps by way of the simultaneous spatial projection of several overlapping vertical aerial photographs of a strip, or series obtained when the plane taking the photograph flies in a straight line. It is intended to have a place between primitive methods of plotting and the large and costly universal plotting machines which for many classes of work are unnecessarily precise. Whereas, for instance, the accuracy of contouring by the use of a stereoplanigraph may be about 1 to 1,500, in the multiplex aero-projector instrument it is only about 1 to 500.

Reduced negatives (1½ inches square) of two successive overlapping vertical aerial photographs are placed in two adjacent projectors, provision being allowed for the adjustment of these projectors in three dimensions to correspond in scale with the actual positions of the original photographs in space when taken. By transmitted light the photographs are projected downward, one through a blue filter and the other through a red filter. The combined images when intercepted at the proper place, and viewed through a pair of two-coloured spectacles (one lens blue and the other red) will give a clear and striking stereoscopic impression of the configuration of the ground. Methods are provided whereby the topographic data so viewed may be traced by the operator on to the plane surface of a drawing board beneath.

Any reasonable number of projectors may be employed in the instrument, consequently the strip of overlapping vertical aerial photographs may cover a corresponding distance in nature between points of control. In practice, as many as nine projectors have been regularly provided for the instrument. As may be expected, at least three points of control are required. The instrument gives best results when the plotting scale is five or six times that of the finished map.

Major E. L. M. Burns, A.M.E.I.C., of the Surveys Section of the Department of National Defence, acted as chairman of the meeting.

*Further details furnished by F. H. Peters, M.E.I.C., appear on page 377 of this issue.*

## Quebec Branch

*Jules Joyal, A.M.E.I.C., Secretary-Treasurer.*

Le 12 février 1934, au cours d'une soirée organisée par notre Section en vue de mettre en vedette nos jeunes ingénieurs de Québec, nous avons eu le plaisir d'entendre, en outre de MM. Marc Boyer, S.E.I.C., et E. D. Gray-Donald, A.M.E.I.C., Monsieur Maurice Royer, I.C., du bureau Ricard et Royer de Québec et directeur de l'Observatoire de la vieille capitale.

Les quelques notes qui vont suivre ne donnent qu'une pâle idée de l'intérêt soulevé par la causerie de M. Royer sur un sujet qui intéresse tout le monde: "La Météorologie Moderne."

LA METEOROLOGIE MODERNE

Les phénomènes météorologiques ont un rôle si important qu'ils ont été étudiés de tout temps, d'abord par de simples constatations, basées sur la seule appréciation et dont la nation du beau ou du mauvais temps est la note dominante, en correspondance avec certains faits particuliers ou signes précurseurs dont on s'est efforcé de reconnaître les conséquences; de ces remarques beaucoup ont donné naissance à des proverbes bien connus mais nous verrons par la suite que nous sommes loin de l'époque où l'on disait: "La lune a les cornes en l'air, on va avoir du *frette*."

Cependant, ces données transmises par les générations ne sont pas sans valeur et de nos jours encore, marins et paysans en tirent parfois des pronostics d'une grande justesse.

Toutefois, la science est plus exigeante et l'on s'est efforcé d'étudier rationnellement les lois de ces phénomènes fort complexes; les progrès de la Météorologie furent lents et les observations vraiment importantes ne datent que de l'invention du baromètre et du thermomètre dont les indications constituent la base fondamentale.

Le but de cette science doit tendre surtout à formuler des indications de plus en plus précises relativement à la prévision des temps, surtout à propos de la formation des orages, tempêtes, cyclones, ce qui est d'une importance capitale pour la sauvegarde de la récolte ou de la navigation; cette prévision s'affirme d'une nécessité impérieuse pour l'aviation dont le rôle, dans notre vie économique, devient chaque jour plus grand.

L'on sait que le baromètre indique la pression atmosphérique et qu'au baromètre bas correspondent les tempêtes et la pluie, tandis que le baromètre haut annonce habituellement du beau temps.

Depuis le milieu du siècle dernier, l'application du télégraphe à cette science a permis de suivre en quelque sortes les mouvements atmosphériques sur des cartes sur lesquelles on trace les lignes d'égale pression (isobars).

Le Service Météorologique du Canada fut organisé en 1872 et les résultats des observations quotidiennes de ce Service sont compilés sur des cartes qui révèlent le fait qu'il existe des centres de basse pression, d'autre de haute pression, et montrent qu'autour de ces centres les vents prennent des directions bien déterminées.

La comparaison de ces cartes qui se succèdent de jour en jour fait voir que ces centres eux-mêmes se déplacent ordinairement (au Canada) de l'ouest à l'est; ces cartes permettent aussi de constater qu'entre deux centres de pressions voisins il existe une zone de grands vents et de mauvais temps, zone qui se déplace en même temps que les centres de pression.

Le conférencier nous a aussi expliqué comment les vents de l'est marchent, en quelque sorte, de reculons; la zone de mauvais temps se déplace vers l'est tandis que le vent qui l'accompagne se dirige vers l'ouest.

## Sault Ste. Marie Branch

*H. O. Brown, A.M.E.I.C., Secretary-Treasurer.*

The regular monthly meeting of the Sault Ste. Marie Branch was held on Friday evening, May 25th, 1934, following the regular dinner at the Windsor hotel, with an attendance of thirty-two.

E. M. MacQuarrie, A.M.E.I.C., chairman of the Branch, was in the chair. The letter of resignation of G. H. E. Dennison, A.M.E.I.C., as secretary-treasurer was read and the appointment of H. O. Brown, A.M.E.I.C., as secretary-treasurer for the balance of the 1934 term by the executive was approved by the meeting. Mr. Dennison has taken a position with the Carborundum Company of Canada and the members of the Branch wish him every success in his new work.

After the business of the evening, the chairman introduced the speaker, D. S. Lloyd, A.M.E.I.C., chief engineer of the Dominion Oxygen Company Limited, Toronto, who addressed the meeting on "The Value of Engineering Supervision of Oxy-Acetylene Welding and Cutting."

Mr. Lloyd's address was well illustrated with lantern slides and the most up-to-date technique was explained by the speaker. The various machines now used for cutting, shaping and welding in the larger shops doing this work was a revelation to many present.

The Branch was pleased to have as visitors a number of engineers from the Carbide Company, Sault Ste. Marie, Michigan. The visitors expressed their thanks for the privilege of attending the dinner and the address, both of which they enjoyed very much. They also expressed a desire to have the opportunity to attend similar future meetings and it is trusted that such visits can be arranged.

There were also present for the address a number of welding operators from the local manufacturing plants who were given an opportunity to attend. These men asked several practical questions on operation after the address and these questions and answers added greatly to the information obtained on the subject.

The meeting closed with an expression of thanks from the Branch to Mr. Lloyd for his very interesting paper.

## An "All-Service" Vehicle for Passenger Transportation

**Abstract of a paper by Martin Schreiber, appearing in the June, 1934, issue of the S.A.E. Journal.**

Street car operation has demonstrated the efficiency and low cost of central-station power supply in the operation of local transportation vehicles. No other form of power has the same degree of efficiency as electricity in delivering the energy needed to perform varying quantities of work.

The trolley-bus on the other hand has many advantages; it is quieter and can accelerate faster than any other highway vehicle of equal seating capacity, moreover, its operation is not limited to trolley rails even if it does require overhead wires.

The gas motor bus for real flexibility in highway transportation has no equal. It is able to manœuvre freely in the flow of traffic and can run on and off to a garage by whatever route is most desirable. It can also detour on other highways than its usual route if necessary.

Is it possible to unite into one vehicle at a reasonable cost all the desirable qualities of street cars, trolley-buses and gas motor buses? The answer is yes, through the use of the gas-electric bus as now developed having a gas engine and an electric generator with two propulsion motors. By the addition of trolley poles and control mechanism to the gas electric bus one has a vehicle that may be used either as a trolley-bus when the engine and generator are omitted or as a motor bus by the simple operation of pulling down the trolley poles. Here is a vehicle that meets the requirements of the trolley bus or of the ordinary street motor bus, and at the same time, the generating and distribution portion of the plant of the street railway can be preserved.

At a recent experimental trial of the first all-service vehicle at Weehawken, N.J. in January, 1934, tests showed that this vehicle negotiated a 6 per cent grade operating as a trolley-bus at a maximum speed of 30 m.p.h. with a full load of 30 passengers. This compares with a normal maximum speed on the whole of ordinary gas-electric buses of 10 to 13 m.p.h.; street cars, 12 to 15 m.p.h.; gas mechanical buses, 15 to 18 m.p.h.; and private cars, 20 to 40 m.p.h.

The all-service vehicle was equipped with a 400 cubic inch poppet-valve engine which develops 105 h.p. at 2,000 r.p.m., a generator, and two propulsion motors. Seating capacity was 29 passengers.

Inasmuch as the gas-electric motor bus is the basis of the all-service vehicle, a few particulars may be of interest. These gas-electric units are simply standard buses manufactured by various companies with capacities ranging from 25 to 73 passengers. Generally the clutches, transmission and differentials were omitted and electric generating and propulsion motors added. The weight of the bus is approximately 1,400 pounds more for the two-motor and 1,100 pounds more for the single-motor equipment than comparable gas mechanical buses.

One of the principal points about the gas-electric bus is its ability to give an efficient account of itself as to upkeep. Things which have militated against the wider use of the gas-electric bus in the past are engineering performance, weight and fuel. These conditions have been largely rectified and higher speeds, compression and improved bearings with more positive lubrication are now available, and since 1925, the the weight per horse power for electric drives has been reduced about 10 per cent. It is true that the fuel cost is 15 per cent more to operate a gas-electric than a straight gas bus, but this additional cost requires only 4 per cent faster schedule to offset it and this is easily obtainable.

In conclusion, the all-service vehicle if compared with the gas motor bus will be found to be considerably more efficient for the same performance, inasmuch as the electric motors may be wound to take care of overloads without interfering with the efficiency of the average operation. The gas-electric features of the all-service vehicle not only eliminate clutch and transmission, but also the differential where there are two electric motors, so that on the whole it affords a smoother and quieter ride. The electric drive does not limit the position of the power plant which may even be placed cross-wise in the rear and under the body of the bus, where it can readily be accessible for repairs. Such an arrangement also lends itself to any replacement with improved power plants.

## List of New and Revised British Standard Specifications

(Issued during May, 1934)

B.S.S. No.

161—1934. Tungsten Filament General Service Electric Lamps. (Revision)
Covers general service lamps only. The remaining schedules for lamps other than general service remain in force and are renumbered B.S.S. No. 555—1934.

334—1934. Chemical Lead (Types A & B). (Revision.)
Provides for two qualities of chemical lead, "pure lead" and lead to which alloying elements have been added. Includes revision and amplification of all the methods of test.

541—1934. Determining the Rideal-Walker Coefficient of Disinfectants, Technique for.
Outline in close detail the method to be used for determining the Rideal-Walker Coefficient of Disinfectants.

548—1934. High Tensile Structural Steel for Bridges, etc., and General Building Construction.
Provides for steel of 37-43 tons per square inch. In other respects the form of the specification and requirements covered, follow closely the existing specification for ordinary mild steel for structural purposes (B.S.S. No. 15).

549—1934. Diacetone Alcohol.

551—1934. Normal Butyl Acetate.

552—1934. Amyl Acetate.

553—1934. Ethyl Acetate.
In these four specifications, limits for the physical and chemical characteristics of the material are laid down with the standard methods of test for determining these properties.

554—1934. Standard Temperature of Volumetric Glassware, Report on.
Standard reference temperature for British Standard volumetric glassware.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28 Victoria Street, London, S.W.1, or, in Canada, from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa, Ont.

## Specifications for Classification of Coal According to Rank and Grade

Tentative specifications for the classification of coal according to rank and grade have recently been approved by a Sectional Committee on Classification of Coal which was organized in 1927 under the sponsorship of the American Society for Testing Materials and the rules of the American Standards Association, and draws its membership from various trade, technical and Governmental organizations interested in the composition, production, and utilization of coal.

The problem facing the committee was a difficult one. The composition and properties of coal vary over an extraordinarily wide range. Not only did the original plants from which the coal was formed vary in nature and kind, but the conditions surrounding the accumulation of the vegetable material differ greatly, as does the subsequent effect of pressure, temperature, and time in the geological ages that have followed the deposition of the original material.

An extended experimental study of the various kinds of coal found in the United States and Canada has been made. On this basis the committee has developed a system of classifying coal according to rank, ranging from lignite on the one hand to anthracite on the other.

The classification of coal according to *rank* is based on the composition and properties of the coal and essentially on those properties which are a result of the degree of metamorphism of the coal in its progressive alteration in the natural series from lignite to anthracite. This classification virtually is determined by nature and cannot be changed by preparing or washing the coal.

The classification of coal according to *grade* depends primarily upon the amount and nature of the impurities present, such as ash-forming constituents, sulphur, fusibility of ash, etc. The grade of a coal can be modified to some extent by methods of cleaning and preparation, and is expressed by its actual heating value as delivered and the percentage of fixed carbon, ash, sulphur, and fusibility of ash.

# Preliminary Notice

## of Applications for Admission and for Transfer

July 13th, 1934

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in September, 1934.

R. J. Durley, Secretary.

* The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

ASSELIN—JEAN CHARLES LEANDRE, of La Tuque, Que., Born at Montreal, Jan. 24th, 1905; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1929; 1922, Quebec Streams Commission (survey); 1924 (summer), Dom. Water Power and Reclamation Service; 1925-26 (summers), Quebec Streams Commission; 1927, prospecting in Abitibi; 1928, Montreal Harbour Commissioners; 1929-32, field and office work with the late Fred. B. Brown, M.E.I.C.; 1932-34, field and office work, Quebec Streams Commission; at present, city engineer and manager, La Tuque, Que.

References: O. O. Lefebvre, P. E. Bourbonnière, J. P. Leclaire, H. Massue, H. A. Terreault.

BAIN—WILLIAM ALEXANDER, of Woodfibre, B.C., Born at Raphoe, Co. Donegal, Ireland, Sept. 25th, 1901; Educ., B.A.Sc. (Mech.), Univ. of B.C., 1926. R.P.E. of B.C.; Summer work—1921-22, mechanic, Britannia Mines. Instr'man., Geol. Survey. Mechanic, B.C. Silver Mines; 1926, safety engr., Brookes, Scanlon, O'Brien, Stillwater, B.C.; 1926-27, asst. elec'l. engr., Munic. of Point Grey; 1927-28, elect'l. contracting (ornamental street lighting); 1928-30, sales engr., power plant equipment; 1930, inspr., Vancouver Water Board and B.C. Electric Rly. (Penstocks, etc.); 1930 to date, constrn. engr., B.C. Pulp & Paper Co., special engrg. work and later res. engr., Woodfibre plant, B.C.

References: A. S. Gentles, W. H. Powell, W. O. C. Scott, P. H. Buchan, E. A. Wheatley.

BROWN—WILLIAM EDWARD, of Hamilton, Ont., Born at Bristol, England, June 12th, 1909; Educ., B.A.Sc., Univ. of Toronto, 1932; 1928 (summer), clerical work, Welland Ship Canal; 1929-30, preparation of monthly estimates on above; 1932-33, asst. engr., highway constrn., Rutherford and Ure, Engrs. and Surveyors, St. Catharines; 1933 to date, asst. foreman, rope dept., B. Greening Wire Co., Hamilton, Ont.

References: E. G. Cameron, G. F. Vollmer, C. R. Young, R. E. Smythe, C. G. Moon.

CAPE—JOHN MEREDITH, of Montreal, Que., Born at Montreal, April 29th, 1910; Educ., Two years Arts, McGill Univ. Grad., R.M.C., 1932; 1928 (summer), survey with Candn. International Paper; 1931 (summer), estimating dept., E. G. M. Cape & Co.; 1932-33, bldg. constrn., Enterprises Centrales-Françaises, Paris, France; 1933 to date, estimating, E. G. M. Cape & Co., Montreal, Que.

References: E. G. M. Cape, L. H. D. Sutherland, H. M. Jaquays, P. F. Sise, D. A. White.

CLARK—GEORGE, of 137 Eugenie St., Norwood Grove P.O., Man., Born at Baildon, Yorks., England, Nov. 14th, 1893; Educ., evening classes, electricity, maths., physics, St. Johns Technical School, Winnipeg. 1930, short course in geology, Univ. of Man.; 1910-11, chainman on constrn., C.P.R.; 1911-12, rodman on location, Medicine Hat-Calgary; 1912-13, rodman on constrn., Suffield S.W. br. and bridge over Bow River; 1916-19, dftsman. in field and office, Can. Nor. Rly.; 1919 to date, with C.N.R., as follows: 1919-20, transitman on location, various lines; 1920-25, dftsman. in office on land survey and gen. engrg. work; 1925 to date, res. engr. and dftsman. on water supply design and constrn., since 1930 on design and constrn. of modern electric drive automatic pumping installns.

## FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

KINGSTON—LAURENCE BRADLEY, of 300 Laurier Ave., Quebec, Que., Born at Ottawa, Ont., Aug. 3rd, 1886; Educ., B.Sc. (Civil), McGill Univ., 1908; 1905-06, dftsman. and topog'r., 1907 (4 mos.), transitman, Nat. Transcon. Rly.; 1908, transitman on land surveys; 1909-10, transitman for Smith, Kerry & Chace, on Metabetchouan Power Co. plant; 1910-13, res. engr. for same company on various plants, also on investigations and reports; 1913-15, engr. with Morrow & Beatty Ltd., on Abitibi Power & Paper Co. hydraulic development and paper mill; 1915-19, overseas, Capt., C.F.A.; 1919-21, mgr. for Morrow & Beatty Ltd., on Bathurst Lumber Co. hydro-electric development; 1921-22, engr. for same firm at head office; 1922-23, engr. with Walter J. Francis & Company, in charge of Paugan Falls investigation and report; 1923-24, engr. with G. L. Campbell, on Welland Canal sub-contract; 1925-26, works mgr., Dominion Safety Lockhert Co. Ltd.; 1926-27, res. engr. for George F. Hardy, M.E.I.C., on Ste. Anne Paper Co. Ltd. mill; 1927-29, constrn. engr., Anglo Canadian Pulp & Paper Mills Ltd.; 1929-32, chief engr., Quebec Logging Corpn. (subsidiary company of Anglo Canadian Pulp & Paper Mills and Ontario Paper Co.); 1932-33, res. engr. for George F. Hardy, M.E.I.C., consltg. engr., and for Anglo Canadian Pulp & Paper Mills management on the extension of the mill of its affiliated company, Anglo Newfoundland Development Co.; at present, engr., Gulf Pulp & Paper Co., Quebec Que. (*St. 1905, A.M. 1912.*)

## FOR TRANSFER FROM THE CLASS OF JUNIOR

BELL—HARRY HEARTZ, of Calgary, Alta., Born at Halifax, N.S., Nov. 9th, 1906; Educ., B.Sc. (E.E.), Nova Scotia Tech. Coll., 1929. S.M. (Master of Science) in business and engrg. administration, Mass. Inst. Tech., 1933; 1924-25 (summers), surveyor, warm water survey, Canadian Atlantic Coast; 1927 (Aug.-Sept.), leveller, bldg. constrn., Anglin-Norcross; 1928 (June-Aug.), student ap'tice, shops of Can. Gen. Elec. Co., Peterborough, industrial control divn.; 1929-32, load and voltage survey of Calgary Power Company system; elect'l. and mech'l. design on 175 mile, 132,000 volt Ghost Edmonton transmission line; misc. operating, production and commercial work. May 1932-Nov. 1933, leave of absence for post-graduate work at Mass. Inst. Tech., at present with above company on special work on financial statements, budgeting, marketing of power and depreciation, with a continuance of transmission line calculations and design, also misc. operating work. (*St. 1928, Jr. 1931.*)

References: W. P. Copp, K. I. Dawson, F. R. Faulkner, H. J. McLean, H. B. [illegible], G. H. Thompson.

GOODMAN—JAMES EDWARD, of Kingston, Ont., Born at Perth, Ont., March 19th, 1901; Educ., B.Sc., Queen's Univ., 1931; 1917-25, working at the machy., elect'l. and constrn. trades as well as assisting engrs. in the field; 1926-27, instr'man., H.E.P.C. of Ontario; 1928-29, instr'man., Geodetic Survey; 1930-31, engr. on grading, paving and reinforced concrete bridges, Dept. of Public Highways; 1931 to date, County and Suburban Roads Engineer for Frontenac County, Kingston, Ont. (*Jr. 1931.*)

References: W. P. Wilgar, W. Casey, W. L. Malcolm, D. S. Ellis, R. A. Low.

GUTHRIE—KENNETH MACGREGOR, of Winnipeg, Man., Born at Guelph, Ont., August 9th, 1900; Educ., 1913-17, Ottawa Collegiate Institute; Professional study while serving with Air Force; 1917-18, cadet, R.F.C. and R.A.F.; 1918-19, pilot, R.A.F.; 1920-23, pilot and administrative duties, Air Board; 1923-34, pilot and administrative duties with the R.C.A.F., and at present Air Staff Officer, Mil. Dist. No. 10, Winnipeg. Administrative duties and flying, R.C.A.F. Station. Chief instructor to No. 12 (A.C.) Squadron, Winnipeg. (*Jr. 1926.*)

References: E. W. Stedman, A. Ferrier, J. A. Wilson, G. O. Johnson, J. L. Gordon.

HINCHCLIFFE—JOSEPH EDWARD, of Mono Road, Ont., Born at Macleod, Alta., Apr. 8th, 1897; Educ., B.Sc. (Civil), McGill Univ., 1926; 1925 (Summer), topog'l. dftsman., Southern Canada Power Co.; 1926-29, detailer, and 1929-33, checker, Canadian Bridge Co. Ltd., (Apr. 1933 laid off with all other dftsman., temporarily. Not engaged in professional work since). (*St. 1924, Jr. 1928.*)

References: C. M. Goodrich, A. E. West, R. C. Leslie, D. T. Alexander, F. J. Bridges, H. J. A. Chambers.

JACKSON—CARL HENRY, of 2317 Wilson Ave., Montreal, Que., Born at Montreal, Mar. 10th, 1900; Educ., B.Sc., McGill Univ., 1921; 1920-21 (summers), floorman and system operator, Southern Canada Power Co., Drummondville, Que.; 1921-22, instructor in elec'l. engrg., Univ. of Sask.; 1922-23, Can. Gen. Elec. Co. Ltd., Peterborough, Ont.; 1924 to date, gen. industrial engrg., including design, layout, inspection, supervision of installn. of equipment, Canadian Industries Ltd., Montreal, Que. (*St. 1921, Jr. 1923.*)

References: L. deB. McCrady, I. R. Tait, A. B. McEwen, C. K. McLeod, A. T. E. Smith, H. G. Thompson.

LAURENCE—EMILE, of Quebec, Que., Born at Montreal, Que., Feb. 28th, 1903; Educ., B.A.Sc., C.E., Ecole Polytechnique, 1926; 1922-23-24 (summers), land surveying and topog'l. surveying (plane table work); 1926-27, with Dufresne Constrn. Co., on Montreal-South Shore Bridge; 1927 (Feb.-Aug.), reinforced concrete design, Montreal Water Board; 1927-28, survey engr., Canadian Laundry Machinery Co.; 1928-29, steel designing, heating, ventilation, with L. A. St. Pierre, C.E.; 1929-30, steel detailing and designing, Dominion Bridge Company; 1930-31, estimating, Corporate Steel Products; Oct. 1931 to date, survey, design inspection, Dept. of Bridge Constrn., Dept. of Public Works, Quebec, Que. (*Jr. 1930.*)

References: I. E. Vallee, A. B. Normandin, O. Desjardins, C. Milot, R. Sauvage, T. M. Dechene, J. F. Brett, J. G. O'Donnell.

MARTIN—LUCIEN, of Quebec, Que., Born at Montreal, Oct. 8th, 1902; Educ., B.A., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1931; 1928-31 (summers), surveying and geology, Dept. of Mines, Quebec; 1931 to date, bridge constrn., Dept. of Public Works, Prov. of Quebec, Quebec, Que. (*Jr. 1932.*)

References: I. E. Vallee, O. Desjardins, C. Milot, A. B. Normandin, T. M. Dechene, R. Sauvage, P. Marcotte.

## FOR TRANSFER FROM THE CLASS OF STUDENT

ATWOOD—ARTHUR GERALD LYSONS, of Montreal, Que., Born at Bedford, N.S., Sept. 3rd, 1905; Educ., B.Sc. (Mech.), N.S. Tech. Coll., 1927; 1925 (summer), storekpr., Halifax Grain Elevator; 1926 (summer), Maritime Telegraph & Telephone Co.; 1927-28, equipment engrg. dept., Northern Electric Co., Montreal; 1928-33, with E. A. Ryan, M.E.I.C., consltg. engr., heating, ventilation and air con. design; 1934 (Jan.-Apr.), boiler design and layout, Babcock-Wilcox; at present, engr. in charge of installn. and pricing, Iron Fireman Mfg. Co. of Canada, Montreal, Que. (*St. 1927.*)

References: E. A. Ryan, F. A. Combe, A. C. J. Paine, H. J. Leitch, C. K. McLeod.

BOYER—MARC, of Quebec, Que., Born at Labelle, Que., Aug. 9th, 1905; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1928; 1932-33, partial student, 3rd and 4th year mining engrg., McGill Univ.; 1925-26-27 (summers), surveying party, Quebec Streams Commission; 1928-30, assayer, Cons. Mining & Smelting Co., Trail, B.C.; 1930 to date, mining inspector and technologist, Quebec Bureau of Mines, Quebec, Que. (*St. 1927.*)

References: A. Frigon, H. Cimon, A. B. Normandin, A. Lariviere, P. Methe, A. R. Decary, L. Beaudry, A. Boyer.

CROSSLAND—CHARLES WILFRED, of 19 Norbiton Ave., Kingston-on-Thames, England, Born at Barrie, Ont., Jan. 4th, 1906; Educ., B.Sc., McGill Univ., 1931; M.Sc., Mass. Inst. Tech., 1932; 1928-29 (summers), dftng.; 1933 to date, aircraft dftsman and technical asst., Hawker Aircraft Ltd., England. (*St. 1928.*)

References: C. M. McKergow, A. R. Roberts, E. Brown, R. DeL. French, L. R. Thomson, E. W. Stedman, S. J. Hungerford.

ELLIOT—DONALD GEORGE, of Montreal, Que., Born at Darjeeling, India, Oct. 14th, 1909; Educ., B.Sc. (1st Class Hons. in C.E.), Univ. of Edinburgh, 1930; 1930-31, dftsman and rodman, and 1931 to date, asst. engr., Messrs. Monsarrat & Pratley, Montreal, Que. (*S. 1930.*)

References: P. L. Pratley, C. N. Monsarrat, J. M. R. Fairbairn, J. W. Roland, R. F. Legget.

FRECKER—GEORGE ALAIN, of Halifax, N.S., Born at St. Pierre de Miquelon, June 29th, 1905; Educ., B.Sc. (E.E.), Nova Scotia Tech. Coll., 1932; 1929 (summer), asst. to field engr., Nfld. Mining Corpn.; 1932 to date, asst. prof. of engrg., St. Mary's College, Halifax, N.S. (*St. 1930.*)

References: F. R. Faulkner, G. C. Reid, S. C. Mifflen, S. Ball, G. H. Burchill.

## FOR TRANSFER FROM THE CLASS OF AFFILIATE

TOWNSEND—CHARLES ROWLATT, of Port Menier, Anticosti Island, Que., Born at Victoria, B.C., Feb. 9th, 1891; Educ., B.Sc., 1920; M.Sc., 1923, Univ. of N.B.; 1910-12, misc. work in saw mills, river driving, etc.; 1912-20, survey work on vacations, etc., except period spent overseas; 1920-23, air service divn., Laurentide Co. Ltd., aerial sketching, photography, etc.; 1923-30, logging divn., same company, and Canada Power & Paper Corpn., on various woods projects including constrn. of marine railroad, hydrographic surveys, reconnaissance surveys for logging flume, etc., etc.; 1930 (Feb.-Aug.), chief forester, Canada Power & Paper Corporation; Aug. 1930 to date, Anticosti Island manager, Consolidated Paper Corporation, Port Menier, Anticosti Is., Que. (*Affil. 1927.*)

References: W. B. Scott, H. O. Keay, H. E. Bates, T. R. McLagan, E. B. Wardle, H. G. Timmis.

## EMPLOYMENT SERVICE BUREAU

**The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.**

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

### Situation Vacant

SALESMEN. A new company recently organized in Montreal desires men of good education and appearance whom they will train as salesmen for advertising specialties. Liberal commissions paid. Men with artistic tendencies preferred. Phone HA. 3642 for appointment.

### Situations Wanted

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, French, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

INDUSTRIAL ENGINEER, B.Sc., McGill Univ. Age 29. Married. Mechanical and electrical engineering experience with four large Canadian companies; including supervision of manufacture of various products, reduction of manufacturing costs, factory planning and investigation of piece work systems. Available on short notice. Apply to Box No. 132-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian, married, 34 years of age, with 13 years' experience in the industrial field, including design, construction and operation, 8 years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details upon request. Apply to Box No. 161-W.

CIVIL ENGINEER, age 44, open for employment anywhere, experience covers about 20 years' active work, including 7 years on municipal engineering, 2 years as Town Manager, 3 years on railway construction, 3 years on the staff of a provincial highway department, 2 years as contractor's superintendent on pavement construction. Apply to Box No. 216 W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257 W.

MECHANICAL ENGINEER, age 28, nine years all round experience, Grad. Inst. of Mech. Engs. England, S.E.I.C. Technical and practical training with first class English firm of general engineers; shop, foundry and drawing office experience in steam and Diesel engines, asphalt, concrete machinery, boilers, power plants, road rollers, etc. Experience in heating and ventilation design and equipment; 18 months designing draughtsman with Montreal consulting engineers. 2½ years sales experience, steam and hot water heating systems, power plant equipment, machinery, oil-burning apparatus. Canadian 4th class Marine Engineers Certificate; C.N.S. experience. Available at short notice. Apply to Box No. 270-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

PLANE-TABLE TOPOGRAPHER, B.Sc., in C.E. Thoroughly experienced in modern field mapping methods including ground control for aerial surveys. Fast and efficient in surveys for construction, hydro-electric and geological investigations. Apply to Box No. 431-W.

ELECTRICAL ENGINEER, B.Sc., A.M.E.I.C., AM.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.Sc., and C.E., A.M.E.I.C., age 30, married. Experience over the last ten years covers construction on hydro-electric and railway work as instrumentman and resident engineer. Also office work on teaching and design, investigations and hydraulic works, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

### Situations Wanted

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

MECHANICAL ENGINEER, B.Sc. Age 28, married. Four and a half years on industrial plant maintenance and construction, including shop production work and pulp and paper mill control. Also two and a half years on structural steel and reinforced concrete design. Available at once. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years' technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Sc., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

#### Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered. Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters or Branch secretaries.

CIVIL ENGINEER, age 25, single, graduate. Creditable record on responsible hydro and railroad work in both Eastern and Western Canada. Apply to Box No. 567-W.

MECHANICAL ENGINEER, A.M.E.I.C., with twenty years experience on mechanical and structural design, desires connection. Available at once. Apply to Box No. 571-W.

MECHANICAL ENGINEER, B.A.Sc., '30, desires position to gain experience, and which offers opportunity for advancement. Experience in pulp and paper mill and one year in mechanical department of large electrical company. Location immaterial. Available immediately. Apply to Box No. 577-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.Sc., University of Alberta, '30. Age 31. Single. Six seasons' practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years' experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box No. 609-W.

### Situations Wanted

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box No. 651-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing office. Office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., 29, B.Sc., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, JR.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.Sc., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

## Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, graduate '29. Married. One year building construction, one year hydro-electric construction in South America, fourteen months resident engineer on road construction. Working knowledge of Spanish. Apply to Box No. 744-W.

SALES ENGINEER, B.sc., McGill, 1923. A.M.E.I.C. Age 33. Married. Extensive experience in building construction. Thoroughly familiar with steel building products; last five years in charge of structural and reinforcing steel sales for company in New York state. Available at once. Located in Canada. Apply to Box No 749-W.

CIVIL ENGINEER, S.E.I.C., B.sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten year diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.sc., A.M.E.I.C., with fifteen years experience mostly in pulp and paper millwork, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

ELECTRICAL ENGINEER, S.E.I.C., grad. '29, age 24, married; experience includes one year Students Test Course, sixteen months in distribution transformer design and eight months as assistant foreman in charge of industrial control and switchgear tests. Location immaterial. Available at once. Apply to Box No. 828-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.sc. '32 (Univ. of N.B). Age 25. married Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.sc '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W

CIVIL ENGINEER, B.sc. (Alta '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works Available immediately Apply to Box No. 846-W.

## Situations Wanted

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years' experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED, Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, B.sc., '25, McGill Univ., Jr.E.I.C., P.E.Q., age 32, married. Experience as rodman and instrumentman on track maintenance. Seven and one-half years with Canadian paper company, as assistant office engineer handling all classes of engineering problems in connection with woods operations, i.e., road buildings, piers, booms, timber bridges, depots, dams, etc. Apply to Box No. 933-W.

ELECTRICAL ENGINEER, Dipl. of Eng., B.sc. (Dalhousie Univ.), S.B. and S.M. in E.E. (Mass. Inst. of Tech.), Canadian. Married. Seven and a half years' experience in design, construction and operation of hydro, steam and industrial plants. For past sixteen months field office electrical engineer on 510,000 h.p. hydro-electric project. Available at once. Apply to Box No. 936-W.

CIVIL ENGINEER, B.sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street, improvements, technical photography Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.sc. (N.S. Tech. Coll., '33), desires work Experience in transmission line construction Location or class of work immaterial. Apply to Box No. 1010-W.

## Situations Wanted

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.sc. (Queen's 14), A.M.E.I.C., Dominion Land Surveyor, 5 months' special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, age 27, graduate 1930, single. Experience includes detailing, designing and estimating structural steel, plate work and pressure vessels; also hydrographic surveying. Available at once. Apply to Box No. 1111-W.

ELECTRICAL ENGINEER, B.sc., in E E. (Univ. of N.B. '34), S.E.I.C. Experience in bridge and road construction and auto repairing, desires position in industrial or power plant. Any locality. References on request. Apply to Box No. 1114-W.

CIVIL ENGINEER, B.sc. Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C.), M.S. (Univ. of Pittsburgh). Canadian. Age 26. Single. One year graduate student course, W.E. and M. Co., East Pittsburgh. Three and a half years engineering research in mechanics with the same company. Location immaterial. Available at once. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box No. 1127-W.

PETROLEUM CHEMIST, B.sc. in Chem. Eng. Age 25, Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

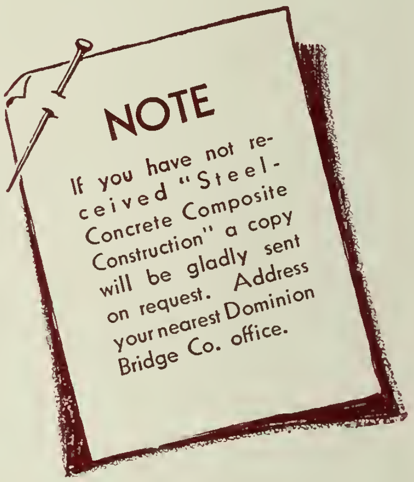
## INDEX TO ADVERTISERS

# STEEL-CONCRETE

## COMPOSITE CONSTRUCTION

## Fully Described and Illustrated in this New Booklet.



Steel-Concrete Composite Construction enables architects, engineers and contractors to build, not only well but with greater speed and economy. It gives the owner a better structure and yet one that can be easily altered at minimum cost. It assures security to the architect and engineer because of its accuracy and reliability.

This booklet is issued in response to the many requests for information regarding this important development in the construction industry.

WATTHOUR METERS

I-16 SINGLE-PHASE
WATTHOUR METERS

## DISTRIBUTION TRANSFORMERS

The "Perfection of Detail" built into G-E transformers pays dividends not only to the consumer, but also to power companies in the form of minimum outages, freedom from maintenance and longer life.

●

## PORCELAIN-HOUSED CUTOUTS

Increased insulation comparable in dielectric strength with that of other parts of modern distribution systems - - Increased current ratings of the smaller cutouts making them suitable for use with larger transformers - - Increased interrupting capacity making possible the use of these cutouts where short-circuit duty is a prime consideration, are three outstanding features of G-E wet process porcelain housed cutouts.

●

## PELLET LIGHTNING ARRESTERS

For best protection every transformer should be protected by a G-E Pellet Lightning Arrester. The reliable performance of these arresters together with advanced methods of installation, provides practical immunity from lightning troubles, justifying individual protection of every distribution transformer - - from the smallest to the largest.

●

## WATTHOUR METERS

More load per residential consumer means more load variation per meter. The "slow" error of the older meters on even present-day peak loads is such that a load-building program can easily build a high percentage of lost revenue. Only modern meters, with their long-range accuracy, will yield all of the revenue from today's and tomorrow's peaks.

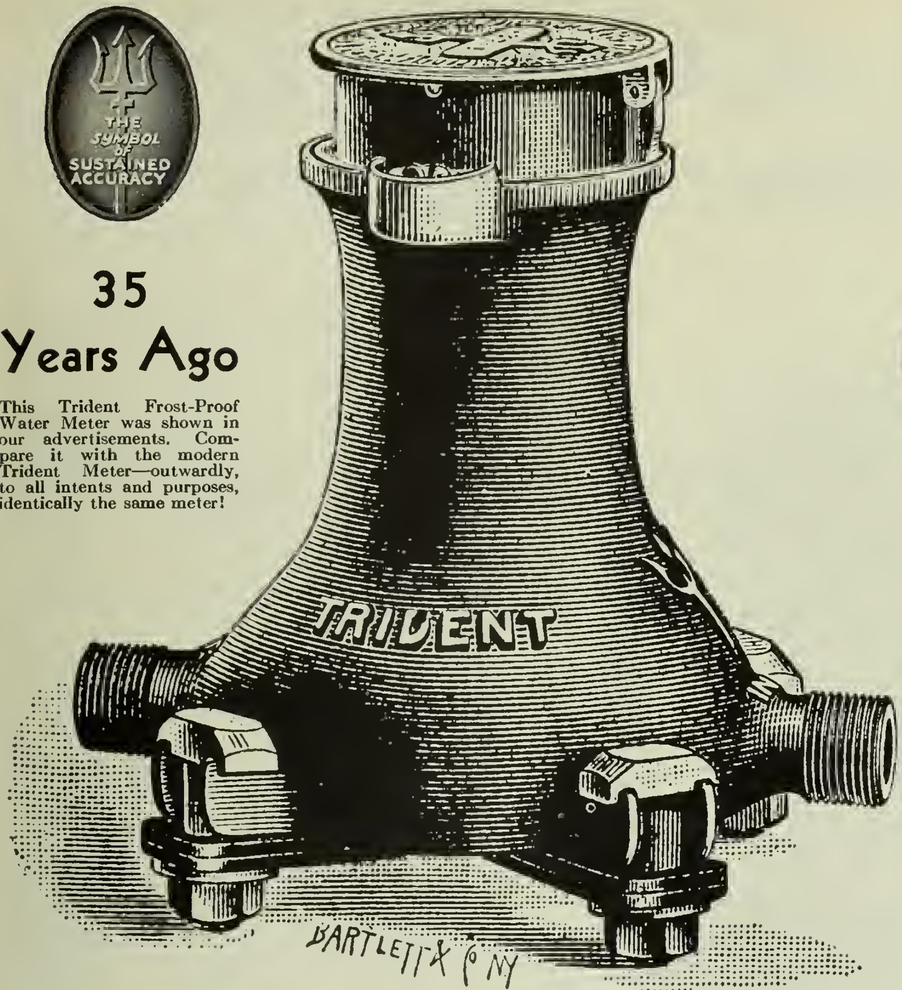
THE SYMBOL OF SUSTAINED ACCURACY

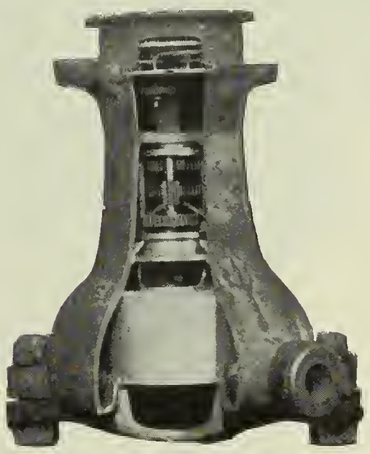


## 35 Years Ago

This Trident Frost-Proof Water Meter was shown in our advertisements. Compare it with the modern Trident Meter—outwardly, to all intents and purposes, identically the same meter!

## TODAY

Compare the modern Trident Frost-proof Meter with that of a generation ago. Practically THE SAME—except for modern, improved interchangeable inner parts.



## OLD CASING... NEW PARTS...

Yes—a Trident casing a generation old MODERNIZED and made good for years more perfect service by the insertion of interchangeable, new, modern parts.

# Buying for the Future

means buying Trident (Made in Canada) Water Meters. The graphic illustration of the great economy of the basic Neptune principle of INTERCHANGEABILITY surely needs no further argument—especially after you've had to scrap water meters that time, use and progress have made obsolete. Remember, we make a type of Water Meter for every requirement. Buy these Water Meters and a small stock of interchangeable parts, and you're fixed for long years of perfect service and minimum maintenance cost. Write for catalogs to the

# TYPE "E" STOKERS
## UP TO 700 NOMINAL H.P.

# 650,000 sq. ft. prove it!

In hundreds of leading industrial plants in Canada under 650,000 sq. ft. heating surface Type "E" stokers have proved their ability to operate with maximum efficiency and low upkeep with all types of coals.

## FEATURES

### Sliding Retort Bottom

Carries main ram and pushers. Feeds and agitates fuel in retort. No pusher rods to warp or buckle.

### Hollow Air-Cooled Firebars

Preheat a portion of the air for combustion. Assure low maintenance. Alternate bars have lateral, adjustable motion. Replacement requires no dismantling of grate surface. Non-sifting.

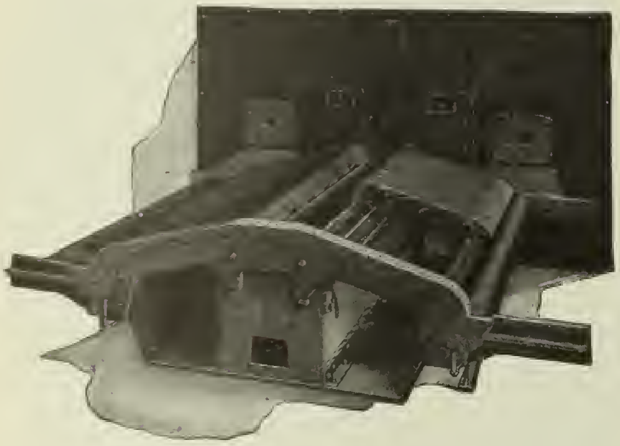
### Proper Coal Distribution

Assured by large throat opening to the retort, full stroke at all ratings and sliding bottom with auxiliary pushers. Lateral motion of firebars gives positive, gradual movement of the coal toward the dump grates.

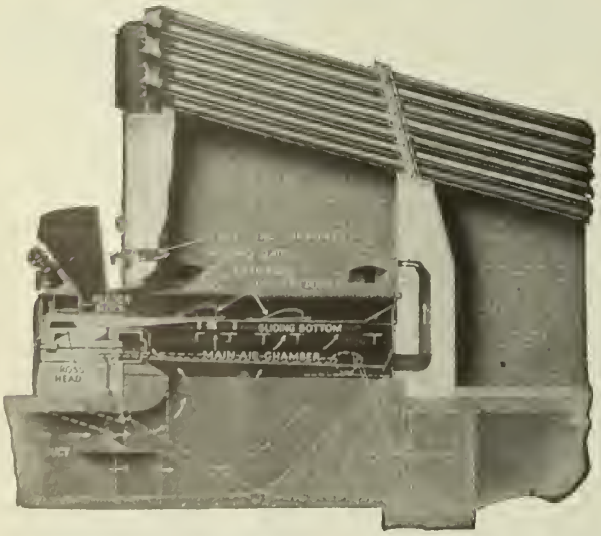
### Complete Air Control

Furnished for entire grate area including dump grates. 100 per cent forced draft surface divided into three pressure zones parallel to the retort. Separate control of air supply to grate surface, dump grates and over the fire. Air pressure is compensated to the thickness of the fuel bed, the greatest pressure being applied to the thickest portion over the retort.

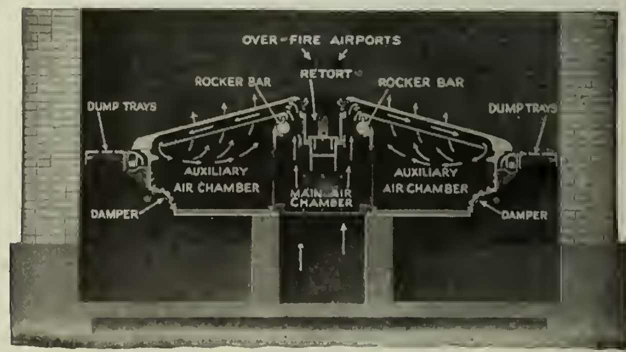
The foregoing, together with its integral steam operating cylinder drive, its smokeless operation, low maintenance cost and easy operation, are fully described in bulletins which will be sent gladly on request.



*Rear view showing retort, grate bars, dump grates and auxiliary windbox.*



*Longitudinal section showing air distribution. Air duct may enter from front or rear.*



*Cross-section showing air distribution. Air may be admitted to dump grates as required.*

# Jenkins announce a superior alloy for valve seats and discs

Jenkins' leadership is again demonstrated by another important contribution to greater valve efficiency.

For some time the efforts of our metallurgical staff have been concentrated on finding a metal of sufficient durability to withstand the severe cutting action borne by the seat and disc of high pressure Globe, Angle and Gate valves. Notable success has been achieved in the development of a metal alloy of extreme toughness, possessing greatly increased resistance to wear.

Exhaustive tests have conclusively proved that the use of this superior alloy for the above-mentioned valve parts improves the operation and greatly prolongs the life of the valve.

So pronounced are the superior qualities of the new Jenkins' alloy that we wish to give it a distinctive name. For the best name conveying some indication of its valuable properties we offer a prize of $100.

The conditions governing this offer are quite simple. Anyone may submit suggestions, except Jenkins' employees and their families. Proper names and names already in use will not be accepted. Choice of the name will be made by the officials of the Company and their decision must be considered final. Any number of names may be sent in. The name selected will become the property of Jenkins Bros. Limited and will be registered by them. In the event of the selected name being submitted by several correspondents, the $100 will be divided equally amongst them.

The name finally selected will be announced subsequently in this publication.

*Address your suggestions to Dept. B-4, Jenkins Bros. Limited, 617 St. Remi Street, Montreal, and mail them to reach us not later than September 30th, 1934.*

# Highways and Highway Transportation in British Columbia

*Patrick Philip, M.E.I.C.,*
*Chief Engineer and Deputy Minister, Provincial Department of Public Works, Victoria, B.C.*

**Paper presented at the Western Professional Meeting of The Engineering Institute of Canada, Vancouver, B.C., July 11th to 14th, 1934.**

**SUMMARY.—Outlining the history and development of the highway system in British Columbia, the author gives particulars as to its administration, organization and operation, with figures as to costs of construction and maintenance. He discusses the experience obtained with various types of road surface and the materials and equipment found suitable for conditions in the province, and describes the practice adopted as regards bridges of various types.**

The administration of highways throughout Canada today is an important function of all the provincial governments and presents many major problems. It is safe to say that there is not one province in Canada in which the programme of highway building and improvement is yet abreast of the needs of modern motor-vehicle transportation. The motor-vehicle industry in Canada, as elsewhere, has become one on which a very great number of persons are directly dependent for a livelihood; the use of motor-vehicles is now general and has revolutionized our social habits, particularly in country districts. This condition has resulted in demands for road extensions and improvements to an extent beyond the resources of the average provincial government.

The general public is financially interested in the efficient administration of each provincial highway system: the costs of highway transportation are governed, to a large extent, by the condition of maintenance and type of construction of the highways and it is the vehicle owners themselves who pay the major portion of the bill and who, therefore, are entitled to the first consideration.

The problems of financing and administration are, broadly speaking, very similar in each province; they differ, however, in detail and, as the title of this paper indicates, it is the intention of the author to present some of the problems and points of interest in the administration of British Columbia's highways.

British Columbia covers a vast territory. In actual land area it is 20 per cent larger than the combined land areas of the provinces of Alberta, New Brunswick, Nova Scotia and Prince Edward Island, but is the least densely populated of all provinces in Canada, having an average density of only 1.92 persons per square mile of land area.

As may be seen from the map (Fig. 1), only approximately one-half of the province is at present served by the existing highway system. The remainder of the province, with the exception of the Peace River district and the settlements at Telegraph Creek, Dease Lake and Atlin, is, to all intents and purposes, uninhabited.

The map only shows the main highways and some of the local roads of the province, representing less than 25 per cent of the entire provincial highway system, a system which has been built entirely within the last seventy-five years and which now consists of 19,522 miles of all classes of highways under provincial jurisdiction.

### EARLY HISTORY

Before dealing with the conditions now existing, it may be of interest briefly to relate the story of the first major highway project in British Columbia.

In the year 1857, except for a few trails, there were no means of land transportation on the mainland of British Columbia and there was practically no settlement. In the year 1858, with dramatic suddenness, following the discovery of rich deposits of gold on the Fraser river, the town of Victoria, on Vancouver Island, became, almost overnight, the jumping-off point for thousands of fortune seekers filled with determination to reach the gold fields by some route or other. The infant Crown Colony was thus faced with a sudden crisis: not only was a road to the interior a necessity for the purpose of transporting supplies and gold, it was also needed for the preservation of law and order in a vast and almost inaccessible region which, until that time, had been practically uninhabited. The building of the famous Cariboo road, nearly 400 miles in length, from Yale to Barkerville within the incredibly short time of four years at a cost of approximately $2,000,000 is a story with which many are familiar; over this road there was transported, mostly in stage coaches, some $30,000,000 worth of gold. Much of the original road is still in use today and, although the building of the two trans-continental railroads later destroyed the sections through the Thompson and Fraser river canyons, the present modern highway through these canyons still follows generally the route first chosen by the pioneers.

*Rapid Development*

The events described in the foregoing paragraph were mainly responsible for the early and rapid development of the province before and after Confederation. It is doubtful whether any factor other than the discovery of gold could have provided the impetus for the phenomenal effort of building a wagon road of such length through mountainous country under the difficult circumstances which existed at that time.

With a road to the interior available, settlement and development were rapid, and the years which followed Confederation were marked with great activity in road building; by the year 1900, when the first measurement of roads was attempted by men with bicycles fitted with cyclometers, 5,615 miles of road had been built, mostly for the purpose of local settlement.

This early road building, necessary as it was for immediate development, was not on scientific lines and it has cost, and will for some time continue to cost, the province large sums to correct the mistakes of those earlier days, for it appears often to have been the custom in laying out the route of a new road to follow the line of least resistance without much consideration for gradient or alignment and without any reference to a general plan for a main highway system, the need for which does not appear to have been fully recognized until about the year 1910, when the automobile was becoming a factor in highway transportation in the western province.

The Highway System

During the past twenty-five years, however, good progress has been made with the development and improvement of the main highway system, although such progress was necessarily somewhat retarded by the war.

As will be seen from the map (Fig. 1), the southerly part of the province is entered from the east by three routes, which pass through the Kicking Horse Pass, Vermilion Pass and Crow's Nest Pass respectively. The first-named pass is the gateway to British Columbia's section of the trans-Canada highway; the last-named connects the southern trans-provincial highway to the Alberta highway system; the two routes are of equal importance and converge at Hope, 99 miles east of Vancouver.

In neither case is the construction of these two routes completed. On the trans-Canada route some 63 miles remain to be constructed at the northerly end of the Big Bend of the Columbia river and, until this work has been completed, vehicles entering the province via Kicking Horse Pass or Vermilion Pass must travel south before they can proceed further in a westerly direction.

On the southern trans-provincial route the new 88-mile link between Princeton and Hope, via Allison Pass (elevation 4,450 feet) is not yet finished, but work on this section is now proceeding as a relief measure under the Department of National Defence; for the time being, it is necessary for vehicles en route from the southern interior to the coast to detour from Princeton to Spence's

Fig. 1—Main Highways, British Columbia.

Bridge, to join the trans-Canada route which, from this point, passes through the canyons of the Thompson and Fraser rivers. The total distance from Crow's Nest to Vancouver via the southern route is 687 miles, including 12 miles by ferry on Kootenay lake. By the trans-Canada route, from the Alberta boundary to Vancouver the distance is 668 miles. These distances include the two uncompleted links referred to.

At some future date a road may be built from Alberta to Prince George and Kamloops via the Yellowhead Pass. A connection with the province of Alberta exists to the north between Grand Prairie, Alberta and Pouce Coupé, B.C., in the famous Peace River district.

A feature of British Columbia's highway system is the number of connections made with the highway system of the United States. As many as 185,418 automobiles have visited the province from the south in one year and the international boundary line is crossed at no less than eighteen places, the more important ones only being shown on the map. The most popular of these routes is the Pacific highway which crosses the boundary at Blaine, 33 miles from Vancouver.

Traffic to and from Vancouver is served by two main highways on the north and south sides of the Fraser river respectively. Both of these well travelled routes have been in use for a long time and 67 miles of these roads have been entirely reconstructed to modern highway standards, with rights-of-way generally 100 feet wide and with easy curvature and gradients. Connection between these two routes across the Fraser river is provided at Agassiz by power-ferry and at Mission by the Canadian Pacific Railway bridge which has been planked for the use of vehicles. The southern route and the Pacific highway cross the Fraser river by a bridge at New Westminster which was built between the years 1902 and 1904 and which, in addition to vehicular traffic, carries the tracks of the Canadian National, Great Northern and British Columbia Electric Railways. As many as 15,016 vehicles have crossed this bridge in one day; two lanes of traffic are available and at times there is a congestion of traffic.

Next in relative importance is the road to Prince George and Hazelton, part of which, from Clinton to Quesnel, follows the old Cariboo road for most of its distance. The total distance from Prince George to Vancouver is 521 miles, but it is not unusual to drive the whole distance in two days, although the road is not paved. Westerly, from Prince George, the road generally parallels the Canadian National Railway to Hazelton, a distance of 823 miles from Vancouver.

A few years ago the road from Quesnel to Barkerville was perhaps considered as one of the least important roads in the province; today the reverse is the case, for the only other means of access to this now thriving town from the Pacific Great Eastern railhead at Quesnel is by aeroplane. The government of British Columbia is fully cognizant of the immense wealth which the present mining activity may be the means of developing in this region, whose resources have remained dormant since the early placer mining days. In order to give every assistance possible to this development, special efforts are being made to keep this road open under all conditions.

An important highway is the road from Kamloops to Penticton in the Okanagan Valley. This route provides a direct connection between the southern trans-provincial highway and the trans-Canada highway and carries a relatively large traffic.

Our description would not be complete without mention of the famous Island highway on Vancouver Island, which road follows the east shore of the island from Victoria to Menzies Bay, a total distance of 185 miles, of which 155 miles are bituminous surfaced or paved. This highway carries a heavy traffic, which has amounted to as many as 3,900 cars in one day and 13,500 cars in a week at some points and it attracts numerous tourists.

In addition to the main highways which have been described, together with the others shown on the map, there is an extensive net-work of local roads, together with many thousands of miles of farm and mining roads, the total being 19,522 miles of highway under provincial control as follows:—

Table I

Mileage of Provincial Highway System and Type of Surface

| *Type of Surface* | *Mileage* |
|---|---|
| Unimproved or cleared only | 2,598 |
| Earth or sand-clay | 10,007 |
| Gravelled | 6,254 |
| Bituminous surfaced | 441 |
| Paved | 165 |
| Other types and mileage under construction | 57 |
| Total | 19,522 miles |

In addition, there are 9,418 miles of trails maintained by the provincial government, of which some 55 per cent are mining trails.

Prior to the year 1919, the cost of all highway work, including new construction, was met from current revenue. Since that time, various loans have been issued for highway purposes, the total amount outstanding for this purpose at March 31st, 1933, being about $40,000,000; the estimated valuation of roads, bridges, wharves and ferries is now placed at $76,430,378.

Throughout the past decade there has been a great deal of activity in highway construction and improvement; during this period the total mileage of highways has increased by 3,377 miles; in addition, a policy of major improvement has been vigorously carried out and, as far as the main highways are concerned, the time is approaching when many of the worst stretches will have been eliminated or greatly improved. Much, however, remains to be done; north of Revelstoke, for instance, on the trans-Canada highway, many miles will require to be widened or reconstructed; portions of the trans-Canada highway between Hope and Chilliwack will also require attention and elsewhere it has been necessary to postpone some much needed diversions and improvements; eventually it is hoped that the trans-provincial highways at least will be hard-surfaced throughout.

### Legislation and Administration

The administration of the Motor Vehicle Act is under the jurisdiction of the Attorney General and the details of administration are carried out by the provincial police, including the licensing of motor vehicles and the enforcement of the various speed and other laws in connection therewith.

The Highway Act is administered by the Minister of Public Works who is the head of the Department of Public Works. Under this Act the Minister has very wide powers in the establishment of highways. The usual method of establishing a highway, other than in closely settled or semi-urban districts, is by the publication of a notice by the Minister in the *British Columbia Gazette* setting out the direction and extent of the lands taken; a description of the centre line and of the initial and terminal points is usually given. Highways are usually established 66 feet in width. In some cases highways are established by depositing a British Columbia Land Surveyor's plan in the Land Registry Office. Compensation is only paid for land when the area taken for highways exceeds one-twentieth of the total area of the parcel; compensation is paid for any improvements acquired in the construction of highways.

The Highway Act also gives the Minister powers to regulate traffic, particularly the gross weights, tire equipment and dimensions of vehicles, for the purpose of protecting the highway from damage; it provides for the control, either in whole or in part, of certain important highways within municipalities. Under the Highway Act, the Minister of Public Works is also responsible for the licensing of public carriers.

In connection with the provincial highway system, a large number of ferries are operated by the government;

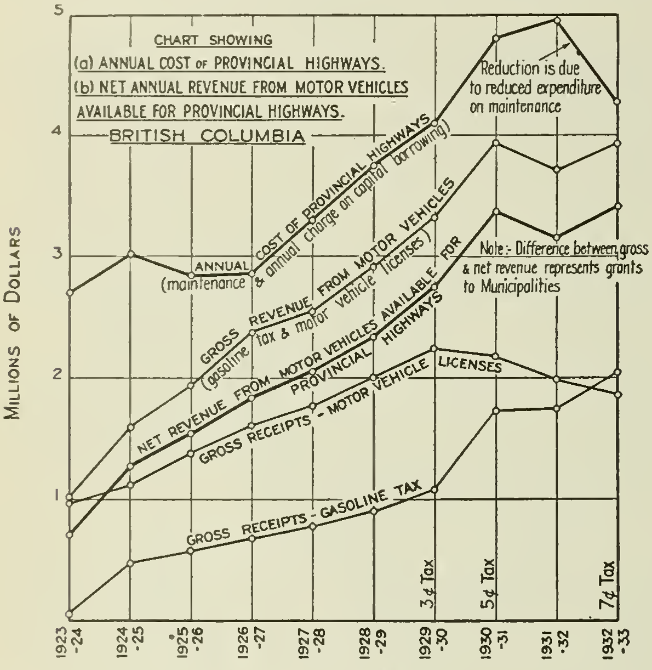

**Fig. 2**

in addition, several ferries are operated by private parties licensed under the Ferries Act, a subsidy being paid by the government in most cases.

### Organization

The province of British Columbia is not divided into counties, townships or other subdivisions for administration purposes and, apart from the municipalities, there is no form of local government. The incorporated municipalities, consisting of thirty-three cities, twenty-eight districts and seventeen villages, although containing about 75 per cent of the provincial population, only contain 0.5 per cent of the entire area of the province, and all highways in the remaining 99.5 per cent of this vast area are under the direct jurisdiction of the Minister of Public Works, in addition to some 520 miles of main municipal highways, most of which lie in the lower valley of the Fraser river. Thus it follows that, in addition to the important work of administering the main highway system of the province, much of the activity of the Department is necessarily devoted to the administration of local highways, requiring careful organization and the division of the entire area of the province, consisting of 359,279 square miles (land area), into districts.

The unit of subdivision for highway administration is the electoral district in charge of an Assistant District Engineer or General Foreman; these officials are either competent engineers or general foremen of long experience in the class of work and have an average of about 670 miles of road under their supervision. Several such districts are formed into an engineering district in charge of a District Engineer, there now being eight such districts and one sub-district.

In addition to the district offices, the Department maintains at Vancouver a small traffic branch for the regulation of Common Carriers, and a Right-of-Way and Claims Agent, while at Victoria there is a clerical staff, accounting staff, bridge department and equipment branch. There is also an architectural branch responsible for the construction and maintenance of all public buildings.

### Highway Transportation

The chief basic industries in British Columbia are mining, lumbering, fishing and agriculture. The topography is generally but by no means entirely of a mountainous nature. The climate varies from moist and equable at the coast, to dry with extremes of temperature in the interior; the average density of population is very low, with 53 per cent of the entire population concentrated in the lower valley and delta of the Fraser river within a distance of about 50 miles from Vancouver.

As a general result of these circumstances, in this province, where automobiles are a necessity rather than a luxury, it is necessary to provide and maintain an extensive mileage of roads for a relatively low volume of traffic of moderate weight. The tourist industry is a valuable one and the maintenance of a reasonably smooth and safe surface on our main highways is a necessity.

Figure 2 illustrates the relation between the annual cost of highways and the net and gross annual revenue received from motor-vehicles, for each year since 1923. By the "annual cost of highways" is meant the maintenance charges plus the interest and sinking fund on capital borrowings. The gross revenue is the amount received from motor-vehicle license fees and registration fees, chauffeurs' and drivers' licenses, and from the gasoline tax; net revenue is the amount available for provincial highways, the difference being the proportion of license fees annually payable by the province to the municipalities, who have no licensing powers. The gasoline tax was first imposed in 1924 and was set at 3 cents per gallon; this was raised to 5 cents per gallon in 1930 and again increased

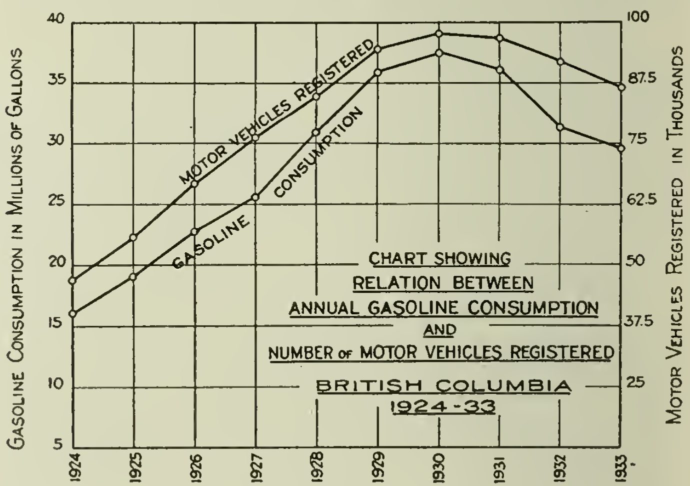

**Fig. 3**

to 7 cents per gallon in 1932. It will be noted that the annual cost of highways is in excess of the total revenue from motor-vehicles.

The growth and recent decline of the use of the motor-vehicle according to annual gasoline consumption is shown by Fig. 3, which also shows the annual motor-vehicle registration; the marked decline for the years 1931 and 1932 is probably in keeping with conditions in other provinces; from the trend of the curves there is justification for expecting a slight improvement in 1934. The gasoline consumption per car in 1933, namely 339 gallons, is very nearly the same as it was in 1924; in 1930 the amount was 388 gallons per car.

Motor-vehicle license fees are now assessed on the basis of net weight of vehicle; the annual fees so payable are shown in the following table; in cases where a license is only taken out for a portion of the year, there is a pro-rata reduction of one-twelfth of the total fees in respect of each month.

Table II
Motor Vehicle License Fees

| Net Weight of Vehicle in Pounds | Annual Fee | Net Weight of Vehicle in Pounds | Annual Fee |
|---|---|---|---|
| 1,500 or less. | $ 12.00 | 16,001 to 17,000 | $250.00 |
| 1,501 to 2,000 | 16.00 | 17,001 to 18,000 | 270.00 |
| 2,001 to 3,000 | 20.00 | 18,001 to 19,000 | 290.00 |
| 3,001 to 4,000 | 25.00 | 19,001 to 20,000 | 310.00 |
| 4,001 to 5,000 | 35.00 | 20,001 to 21,000 | 330.00 |
| 5,001 to 6,000 | 50.00 | 21,001 to 22,000 | 350.00 |
| 6,001 to 7,000 | 65.00 | 22,001 to 23,000 | 370.00 |
| 7,001 to 8,000 | 80.00 | 23,001 to 24,000 | 390.00 |
| 8,001 to 9,000 | 95.00 | 24,001 to 25,000 | 410.00 |
| 9,001 to 10,000 | 110.00 | 25,001 to 26,000 | 430.00 |
| 10,001 to 11,000 | 130.00 | 26,001 to 27,000 | 450.00 |
| 11,001 to 12,000 | 150.00 | 27,001 to 28,000 | 470.00 |
| 12,001 to 13,000 | 170.00 | 28,001 to 29,000 | 490.00 |
| 13,001 to 14,000 | 190.00 | 29,001 to 30,000 | 510.00 |
| 14,001 to 15,000 | 210.00 | 30,001 to 31,000 | 530.00 |
| 15,001 to 16,000 | 230.00 | | |

Owing to the outdoor nature of the industries, the percentage of commercial vehicles is relatively high, averaging 17½ per cent of the total number of vehicles registered. An analysis of these registrations, however, indicates that the proportion of heavy trucks is still comparatively small, it being estimated that not more than 10 per cent of trucks in British Columbia have a potential maximum gross weight of over 6 tons and that it is unlikely that more than 2 per cent exceed 10 tons gross weight.

Permissible gross weights and dimensions of vehicles are set by regulation made by order-in-council. The weights vary with the type or class of construction of the highway and with the season of the year and are as follows:—

Table III
Maximum Gross Weight and Maximum Weight on any One Axle

| Class of Highway | Summer Period | | | Winter Period | | |
|---|---|---|---|---|---|---|
| | Maximum Gross Weight | Maximum Weight on any One Axle | | Maximum Gross Weight | Maximum Weight on any One Axle | |
| | | Vehicles with not more than Two Axles | Vehicles with more than Two Axles | | Vehicles with not more than Two Axles | Vehicles with more than Two Axles |
| | Pounds | Pounds | Pounds | Pounds | Pounds | Pounds |
| I | 24,000 | 14,400 | 12,000 | 24,000 | 14,400 | 12,000 |
| II | 20,000 | 12,000 | 10,000 | 14,000 | 8,400 | 7,000 |
| III | 14,000 | 8,400 | 7,000 | 10,000 | 6,000 | 5,000 |
| IV | 10,000 | 6,000 | 5,000 | 7,000 | 4,200 | 3,500 |

Class I includes all highways constructed entirely of Portland cement or bituminous concrete, or with a granite block, wood block, brick, or bituminous top laid on a Portland cement or bituminous concrete base.

Class II includes all highways constructed of bituminous-bound stone or gravel not laid on a Portland cement or bituminous concrete base.

Class III includes all highways constructed of water-bound macadam or surfaced with gravel, whether surface-treated or not surface-treated with asphalt or with oil.

Class IV includes all highways constructed of earth, without the addition of a gravel or other improved surface.

Permissible dimensions for vehicles are:—

Width.............................. 8 feet
Height.............................. 12 feet 6 inches
Length.............................. 30 feet

Experience has shown that, for all ordinary cases, these weights are generally reasonable and little difficulty

**Fig. 4—Special Permit Plate.**

has been experienced in their enforcement; they are based primarily on the capacity of the bridges, which are the controlling factor as far as gross weight of vehicles is concerned. The distribution of the weights is also set by regulation according to the tire equipment of the vehicle.

Provision is made in the regulations whereby the operation of certain vehicles which exceed the permissible weights is authorized by special permit; the conditions of the permit are such that the operation is entirely under the control of the Department; a cash security deposit is usually required before the permit is issued and the vehicles carry two special permit plates (Fig. 4). The permit system is especially useful as a means of controlling the operations of logging contractors; if such operations were uncontrolled there is probably no reasonable limit to the loads which might be carried on the highways, as is instanced by the following weights of one vehicle found to be operating on a public highway:—

Table IV
Example of Heavy Logging Outfit

| | Gross weight on each wheel Pounds | Tires | Gross weight on each axle Pounds |
|---|---|---|---|
| Right front | 3,000 | 7-inch solid | |
| Left front | 2,300 | 7-inch solid | 5,300 front axle |
| Right rear | 12,800 | 16-inch solid | |
| Left rear | 10,400 | 16-inch solid | 23,200 rear axle |
| Right trailer | 12,800 | 14-inch solid | |
| Left trailer | 14,850 | 14-inch solid | 27,650 trailer axle |
| Total gross weight | 56,150 | | 56,150 |

(Weights as measured by loadometers.)

In general, we find that heavy equipment is improving each year; loads which a few years ago were supported by six solid tires are now carried on ten or fourteen pneumatic tires and the operators have realized that it is against their own interests to damage the highways. Figure 5 is a photograph of a well-equipped vehicle engaged in hauling Douglas fir on Vancouver Island; the gross weight of truck, trailer and load in this case is not less than 14 tons.

In the case of licensed common carriers, special permits for the operation of over-weight vehicles are not necessary; each case is carefully investigated before the license is issued and the license is, *ipso facto*, a special permit for the operation of the vehicle in accordance with the weights stated in the license.

The erection of advertising signs on highways within the right-of-way is not allowed except under permit. The policy of the Department is opposed to the erection of the ordinary advertising sign but signs which may be of use to the motorist indicating the location of beaches, camps, hotels, picnic grounds, etc., are allowed. In the matter of warning signs, the standard yellow and black colour has been adopted and a large number of wooden signs have been erected; wooden signs have not been found sufficiently durable except as a temporary measure.

Fig. 5—Logging Operations on Vancouver Island.

### Construction and Maintenance

For many years it has been the policy of the Department of Public Works to require that all highway improvement or new highway work of any importance be properly surveyed, a policy which results in uniformity and, in the long run, a saving in the cost of the work. While it is true that several major road construction projects remain to be completed, the present need in British Columbia is not so much the construction of new roads as the improvement of the existing roads; such improvement, which has been going forward steadily for years, includes the construction of major diversions, widening, grade revision, improved vision, drainage, replacement of the smaller bridges with culverts and fills, super-elevation of curves, elimination of railway crossings and the like. Work of this nature is usually carried out by "day labour" and, during the last few years, as a relief measure.

The general policy of the provincial government with regard to highway construction in the past has been to carry out such work by contract; during recent years it has been necessary to modify this policy, due, in part, to the change in the economic situation and the resulting need for classing nearly all highway work as "relief undertakings." When contracts are let, they are almost invariably let on a unit price basis with the usual four classifications of solid and loose rock, hardpan and earth. The statute requires that all tenders advertised in the press for public works be opened in public.

The most important highway construction project undertaken in British Columbia in recent years was the reconstruction of the Cariboo road through the Fraser river and Thompson river canyons from Hope to Spence's Bridge, a total distance of 96 miles, at a cost of approximately $2,600,000, during the years 1925 to 1928. Figure 6 shows the Fraser Canyon section of the Cariboo highway with the Canadian Pacific Railway retaining wall on the right and drystone masonry retaining wall 18 feet high on the left.

Space does not permit of describing this project in detail but it was fully dealt with in the author's paper* presented at the Western General Professional Meeting of The Engineering Institute of Canada at Vancouver, B.C., in June, 1928.

With the exception of the portions 22 miles in length between Boothroyd and Lytton and 15 miles between Hope and Yale, the work was carried out by contract in three sections which involved a total of 1,265,000 cubic yards of excavation, of which 28 per cent was in solid rock. This highway forms the main artery from the coast to the interior, and follows, generally, the original route of its predecessor built in the years 1862-65 and later destroyed by the construction of the two trans-continental railways. Prior to the opening of this highway, through travel from the coast to the interior was not possible except by a detour of considerable length through the state of Washington, U.S.A., and the opening of the new highway entirely altered highway transportation conditions in British Columbia. A toll gate is maintained on this highway at Spuzzum, between Yale and Lytton, during the period from April to November, the charges for an ordinary passenger vehicle being $1.00, although local residents are exempted from paying this toll. In the year 1927, the first year of opening of the toll section, 7,659 vehicles passed through the toll gate. This number has gradually increased and, in the year 1931, the number of vehicles was 20,495.

In British Columbia a specialty has been made of low-cost surfaces such as bituminous spray coat and bituminous mulch and it is the practice to carry out part of the work by contract and part by the Department's forces, or the work is occasionally done by the combination of both, the contractor doing the spraying, the Department attending to the gravel aggregate.

Fig. 6—Cariboo Highway, Fraser River Section.

Owing to the topography and geological features of British Columbia, the cost of main road construction per mile is, no doubt, high as compared with many other parts of Canada. It recently became necessary to know the average cost of highway construction in this province and representative contracts for a total of 115 miles of main

*See The Engineering Journal, July 1928, pp. 399-409.

road constructed during the past ten years were analyzed; this gave the following figures which may be of interest for the purpose of comparison:—

Table V

Analysis of 13 Road Construction Contracts Covering Construction of 115 Miles of Main Highway

| Average Cost per Mile (excluding large bridges and gravelling) | | Average Quantities per Mile | |
|---|---|---|---|
| Excavation | $16,640 | *Excavation*, 16,900 cubic yards. | |
| Clearing | 630 | Solid rock | 32.5 per cent |
| Grubbing | 378 | Loose rock and hardpan | 45.5 per cent |
| Culverts | 700 | Earth | 22.0 per cent |
| Trestle bridges | 816 | | |
| Cribs, etc | 2,722 | | |
| Miscellaneous | 1,142 | | 100.0 per cent |
| Total | $23,028 | *Clearing* | 5.75 acres |
| | | *Grubbing* | 1.88 acres |
| | | *Average Cost of Excavation.* $0.98 per cubic yard. | |

Some by no means exhaustive inquiries have also been made into the distribution of the highway dollar, a subject which may be of interest, if it only serves to promote a discussion on a matter which is of vital importance.

Table VI

Estimated Distribution of $100.00 Expended on Highway Construction—Day Labour Work

*Distribution*

| Class of Work | Wages | Materials | Plant rentals | Tools | Gasoline, oil and repairs | Total |
|---|---|---|---|---|---|---|
| Highway construction involving heavy excavation, including clearing and grubbing | $66 | $15 | $ 8 | $6 | $ 5 | $100 |
| Highway construction involving only light excavation, including clearing and grubbing | 76 | 6 | 7 | 6 | 5 | 100 |
| Gravelling | 70 | 2 | 15 | 3 | 10 | 100 |

### Mining Roads

One of the most important activities in British Columbia is mining, and a large proportion of the roads and trails in the interior of the province were originally constructed for the purpose of obtaining access to mineral areas. Nature has so ordered that, just as the finest fruit is often at the top of the tree, the most valuable ore deposits are frequently located in inaccessible regions.

While it is not the policy of the government to construct roads or trails for the benefit of privately owned mining corporations, legislation exists under the Mines Development Act providing for government assistance to be given for the purpose of encouraging bona-fide prospects and, on the recommendation and authority of the Mines Department, the Public Works Department carries out or supervises the construction of a certain mileage of roads and trails annually; the amount so expended during the last ten years has been approximately $100,000 per annum.

### Maintenance of Highways

The average annual cost of maintenance of highways in British Columbia, including maintenance of bridges, is $117 per mile of road. This expenditure is inclusive of snow removal and all incidental expenditures and includes the cost of supervision but not of administration. On main highways the average expenditure for maintenance is about $250 per mile and, where traffic is heavy, reaches as high as $600 per mile.

Although the maintenance of highways may be considered to be a simple matter, past experience teaches that the cost of maintenance can only be kept within reasonable bounds by the adoption of the most modern methods under the direction of experienced officials. A good gravelled or well-kept earth road makes an excellent highway for motor traffic at ordinary speeds, but such surfaces, far from being attained by haphazard methods, are the result of long experience, careful planning and team work on the part of the engineer, foreman and operators.

**Fig. 7—Diversion of New Denver-Rosebery Road.**

Owing to the varied climatic conditions, maintenance problems differ greatly throughout the province. In the interior, generally, there is sufficient moisture and winter frost to cause heaving in the spring while the summer rainfall is usually light; the limited funds available for maintenance do not permit of continuous grading, except on main highways; therefore, to insure that the maximum benefit shall result from the expenditure made, it is usual to concentrate on spring and fall grading.

The best time for spring-time grading is the period between the last severe frost and the time when the road begins to set under the influence of sun and wind, a period which is often a matter of only a few days; grading carried out too soon will have to be done again and, if the critical period is missed and if the grading is done when the road is set, an unstable surface will result.

The majority of the roads in the interior of the province are of earth or gravel; in every district where gravel surfaced roads are maintained, power graders are used. Wherever possible, crushed rock or crushed gravel is used for surfacing. The natural deposits of suitable gravel are widely separated and in many parts of the province the only gravel available is too coarse to make suitable surfacing material and, when crushed or screened down to ¾ inches at the pit, a large volume of over-size material has to be hauled away, an expense which cannot well be avoided.

In filling large holes or depressions the old-time practice of placing coarse material at the bottom with a covering of finer material at the top has been changed, as from experience it has been found that such coarse material, even if deeply buried invariably comes to the surface, necessitating the extraction of any large stones before the road can be successfully graded. Heavy material close to the surface also impedes the light scarifying which is so beneficial in the spring or when the road is damp.

Much of the success or otherwise of grading operations is dependent on the skill of the operator who can improve the vertical alignment of the road by scarifying humps or by filling depressions each time the road is graded. A skilful operator can also gradually improve the shoulders by preventing the encroachment of vegetation and also by mixing in the gravel which has been thrown to the sides of the road with the soil on the shoulders.

HIGHWAY BRIDGES

The economic, physical and climatic features of British Columbia have an important bearing on bridge problems. In order to provide the necessary highway facilities to serve the immense though sparsely populated area, many bridges are required; the streams for the most

Fig. 8—Bridge over Slocan River at Vallican.

part are swift running and some are mountain torrents which periodically get out of control, with devastating consequences.

For the size of the areas they drain, the streams have a very high discharge at high-water periods, a condition which is due, in many districts, to the coincidence of the rainy season with the period of warm winds from the Pacific, which melt the snow in the mountains, a fact which explains why the late autumn is often the period of the most damaging floods. Not only are great quantities of timber drift carried down, but, both in midwinter and in the spring, ice jams are formed which, at times, almost completely dam some of the rivers.

Apart from the natural difficulties which affect it, a bridge policy is necessarily influenced by economic considerations. In British Columbia there are large reserves of fine structural timber suitable for building spans up to 180 feet in length with 16-foot wide roadways sufficient for the needs of moderate traffic; within fairly wide limits, it is therefore possible to build such bridges and renew them every fifteen years at less than the cost of financing permanent structures, if interest, sinking fund and maintenance costs are all taken into consideration. In building bridges of timber, use is being made of the natural resources of the province, as there are no iron mines, blast furnaces or rolling mills; furthermore, the province is only in the course of its development, and therefore the probability of structures becoming obsolete has to be considered.

These and other considerations have resulted in the adoption of the following general policy with regard to highway bridges: firstly, to substitute culverts and fills for minor bridges as far as that is practicable; second, to build in concrete and steel all the major bridges over the main rivers and on main highways where substructures are costly and span lengths are necessarily long; and third, to build of timber the bridges intermediate between these two extremes. Adherence to this policy meets all the real needs of traffic without overstraining our financial resources. It is a "wait and see" policy, it is true; but since it is impossible to foresee the trend of development in many districts, it would be unwise to adopt standards of construction beyond the real needs of the traffic that are reasonably certain to develop in the near future. In other words when the ultimate economy of alternative proposals is being considered, initial cost and probable obsolescence are more important factors than they would appear to be in older, more settled and wealthier communities.

Of the many interesting and historical bridges of British Columbia's earliest days, three may be named: the Hagwilget bridge over the Bulkley river at Hazelton, built by the Indians in the year 1856, has the distinction of having received honourable mention in Mr. Waddell's monumental work; the Alexandra suspension bridge over the Fraser river at Spuzzum, built in the year 1863, was a worthy forerunner to the modern bridge on the same site and an important link in the famous Cariboo highway already referred to; the old bridge at Lytton, which was destroyed by flood in the year 1894, is worthy of mention as one of the few good examples of Burr trusses in existence at that time.

*Types of Bridges*

There are now in British Columbia over four thousand highway bridges, both large and small, the total length of which is about 60 miles. Included in this number are trestles, trusses of all kinds, suspension spans, arches, swing bridges, vertical lift spans, bascules and, in fact, every type of bridge with the exception of the cantilever. Substructures vary from the simplest pile piers to massive concrete piers sunk to a great depth below the stream-beds. The designs as to loadings and widths also vary considerably; the latter range from 10 feet 6 inches to 22 feet and these bridges have been designed for uniform loads ranging from 40 pounds to 100 pounds per square foot and from 8 tons to 20 tons gross per vehicle.

Such is the variety of conditions throughout the province that it would, from an economical standpoint, be unwise to adopt standard specifications with respect to loadings and widths; each bridge is considered with respect to the traffic existing or likely to be developed in the near future and also with respect to such features as alignment, gradient and visibility; if no standard plan is available to suit any particular site, special designs are prepared, bearing in mind that bridges are the most expensive single item in highway costs and that savings may often be made by a careful study in particular cases.

The trend of designs is, of necessity, towards heavier structures of a more permanent nature: this is due not only to the increasing volume and weight of traffic but, as far as

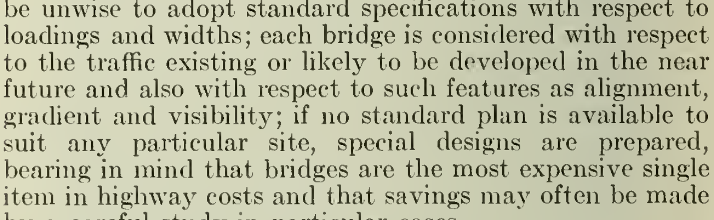

Fig. 9—Fraser Avenue Bridge over North Arm of Fraser River.

substructures are concerned, to the gradual denuding of the forests by logging and fire which results in a more rapid run-off, higher flood levels and large accumulations of timber drift.

In designing, standard practice is generally followed; Canadian Engineering Standards Association specifications are applied consistently to all work; on the whole the Department's practice is perhaps even more conservative than the strict letter of those specifications would demand, especially in steel construction.

*Untreated Timber Bridges*

While great improvements have been made in the design of timber bridges, and in construction methods, the greatest saving has been in the increased life of such structures; it is estimated that $145,000 per year would be saved by extending the average life of timber bridges in the province by only five years. This thought raises the question as to why timber bridges, generally, last so short a time. To this there is practically only one answer: failure of timber bridges is almost entirely due to ordinary "rot."

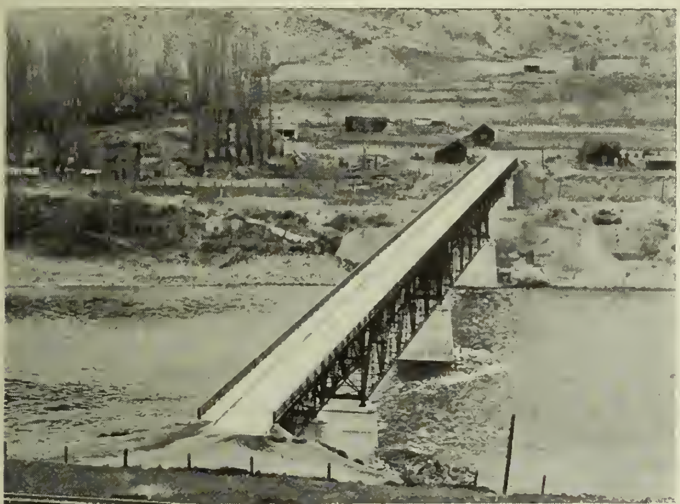

**Fig. 10—Spences Bridge over Thompson River.**

Among timber species in British Columbia available for structural purposes there are only three which are considered satisfactory, namely cedar, tamarac and fir. Cedar is very durable but is low in strength, particularly in impact bending. Tamarac is quite durable and is high in strength. Fir is also quite durable and is the finest structural timber with respect to strength, size, workability and freedom from defects. All of the species named are inherently durable as opposed to decay and will give good service if reasonably protected.

In combating "rot" and in thus lengthening the life of timber structures, the pre-seasoning of the timber is considered important and it is not expensive. Moisture collects and remains wherever timber in a structure is in contact, wherever there are dead air-pockets and at all connections and bearings, and, in so doing, it establishes favourable conditions for decay; connections have accordingly been designed to allow of free circulation of air, while areas in contact are covered with sheet metal, the purpose being, primarily, to permit the timber to dry off quickly and to keep the moisture content down to low limits.

Surfaces in contact are treated before erection with brush coats of hot creosote. It is not advisable to use paint, tar or pitch unless the timber is thoroughly seasoned. It is better practice to permit the timber to "breathe."

Other important points are to avoid bruised and punctured areas in the timber, bad checks on upper faces, closed pockets, collections of dirt and all other conditions which tend to collect and hold moisture. Figure 8 illustrates a typical untreated timber structure consisting of two 130-foot span Howe trusses.

*Treated Timber Structures.*

Prior to 1930 the costs of construction tended steadily upwards, hence the urge to still greater economy by prolonging the life of timber structures. However, with all the improvements made, it did not seem possible to get more than twenty years average life out of exposed untreated timber. Attention was therefore turned to preservative treatments. Encouragement was received in this first by the profound improvement in the art of treatment; second by the tendency towards lower prices for treatment; and third by the well-directed interest in and effort towards the expansion of the use of timber on the part of the timber preserving industry in general and of our own operating companies in British Columbia in particular.

Figure 9 shows an example of an all-creosoted timber structure, that is, with the exception of two concrete piers. The span consists of a 150-foot Howe truss. The roadway width is 20 feet clear and one 5-foot sidewalk.

It was at first assumed that the standard designs, in which the open chord assembly is used, would be satisfactory for treated timber structures, but it was soon realized that, when using properly treated timber, this standard design could be changed to advantage. In proper pressure treatment the timber is seasoned and sterilized prior to its penetration with preservative; during this process, the moisture content is reduced to a relatively low percentage, the timber is rendered free from incipient rot and the outer fibres are rendered immune. Under these conditions it was no longer necessary to provide free circulation of air around the leaves of built-up chords or around connections in contact and thus the expense of machined blocks and keys could be eliminated.

In place of the open chord assembly laminated chords were substituted. Instead of using chord leaves made up of large-sized, long sticks, relatively small sizes and short lengths were used, packed and bolted solidly together. To transfer direct stresses across splices, it was at first thought that it would be necessary to introduce packing keys, dowels or connector rings between the laminations. Such arrangements are quite practicable, but involve the use of both vertical keys and horizontal bolts, the framing for both of which reduces the sectional areas. By a series of tests and calculations it was determined that, provided the bolts were large and numerous enough, keys would be unnecessary. Pipe-bolts were accordingly adopted. This arrangement reduces framing to a minimum, eliminates all clamps and keys and gives a solid compact member with full bearing for angle blocks and with other desirable features.

By this means the construction of such a truss span has been greatly simplified; the framing has been reduced to a minimum and the only machining necessary on the ironwork is the threading of tension rods and bolts and a little finishing on the ribs of the angle blocks.

In constructing bridges of this type the timber is entirely framed prior to treatment, this being a very important feature. To get a deep, uniform penetration, all timber is incised; power-driven machines are used in all these operations. Chord members are completely assembled, clamped and bored for pipe-bolts. Each stick is match-marked in accordance with diagrams. No difficulty has been encountered in erection, mainly on account of the fact that the longitudinal shrinkage of timber in seasoning is practically nil.

On the average, the treatment increases the cost of spans erected by about 12 to 15 per cent. This percentage varies a little depending largely upon transportation charges. The farther the bridge is from the treating plant the less the percentage increase will be. The cost of maintenance is a little less on treated than on untreated spans for the reason that a larger part of the shrinkage takes place in the treating process and hence the adjustment of tension rods and tightening of bolts is much reduced.

It is believed that structures of this type will last over thirty years and probably thirty-five to forty years. That being the case, substructures must of necessity last as long or longer. For this reason concrete substructures for such spans have been generally adopted.

*Steel and Concrete Bridges.*

With respect to steel and concrete structures, Figs. 10, 11 and 12 will give an idea of the characteristics of some of the more modern bridges.

Figure 10 illustrates a modern steel and concrete structure consisting of two 215-foot spans, two 90-foot spans, one 67-foot span and two 40-foot spans. The bridge has a concrete roadway and sidewalk.

The bridge shown in Fig. 11 consists of three 164-foot steel spans on concrete piers and abutments with concrete roadway. An old timber structure, replaced by the steel bridge, is also shown.

The reinforced concrete bridge shown in Fig. 12 has a total length of 280 feet with a main span of 68.5 feet and is built on a 10-degree curve.

**Fig. 11—New Steel and Old Timber Bridges over Kootenay River at Wardner.**

**Fig. 12—Parsons Bridge on Island Highway, Victoria, B.C.**

It is perhaps surprising that, even in this mountainous country, very few bridge substructures are founded on solid rock. This is explained by the fact that the creeks and rivers lie in eroded faults and shear zones where the rock formations dip sharply to great depths. Borings have been taken at major bridge sites where rock outcropped on both banks but was not encountered in the stream-bed anywhere within 150 feet of low water level. Pile foundations, therefore, assume an important place in the substructure work.

The stability of piers naturally has to be given special consideration. Broad based piers with low centre of gravity and batters 1 in 12 and side batters 1 in 18 or 24 are considered the most satisfactory. Reinforcing (bonding) rods extend from bottom to top. The semi-circular cutwaters have also proved the most satisfactory as far as scour is concerned and are found the best for deflecting drift and anchor ice.

Owing to the fact that piers are subjected to very severe conditions, the durability of the concrete is a prime requisite and it is necessary to ensure that great density is secured; a quality of concrete indicated by a twenty-eight-day strength of less than 3,000 pounds per square inch is not sufficiently durable for requirements.

*Paints.*

The best success has been obtained with standard paints which are as follows: one priming coat of red lead, one undercoat of red oxide of iron, and one or two finishing coats of black graphite. These are all linseed oil paints of first class quality. In recent years aluminum paints have been substituted for graphite where it was desired to obtain a light colour, but in no case is the red lead priming coat omitted. Experience in this matter confirms the opinion that the best results are obtained only by adopting a priming coat with inhibitive qualities.

### Ferries

A description of British Columbia's highways would be incomplete without mention of the fifty-five ferries which are operated as part of the system and which carried, in the year 1932-33, 370,000 vehicles and over 1,000,000 passengers, as well as freight and cattle.

Eight of these ferries are privately owned and are operated under license and, in most cases, under a subsidy from the government; three of these boats on which tolls are charged give connection between Vancouver Island and adjacent islands.

With the exception of the S.S. *Nasookin* on Kootenay lake and the M.S. *Kelowna-Westbank* on Okanagan lake (see Fig. 13), the provincially-owned boats are operated free of charge to the travelling public except after normal hours; included in this fleet of ferries are six steam, Diesel or gasoline powered boats, thirty-one ferries operated by current, four ferries operated by engine and cable and two scows with gas boats attached.

Although ferries are a poor substitute for a bridge, they are greatly appreciated by the settlers in districts where the traffic needs would not warrant the cost of a bridge. Under certain conditions, particularly when ice is running or the river is frozen over, they cannot be operated, but at all other times they furnish a more or less satisfactory means of crossing.

The large number of ferries operated by the river current will be noted. In the early days, current-reaction ferries were considered to be simple, primitive craft, but if attention is given to refinements in construction and operation they operate safely and efficiently. The old flat-bottom scows have, in most cases, been superseded by the twin-pontoon type which have a greater capacity, are more easily controlled and are lighter, safer and faster. The real test of whether a reaction-ferry is properly designed and equipped is its performance during high water and it is found that the twin-pontoon type actually performs better at high water than at any other period.

Each ferry requires at least two landings or wharves and the installation and maintenance of these facilities, together with the operation and maintenance of the boats, is a relatively expensive item in the annual highway bill, amounting to an average annual expenditure of $155,000 during the past five years.

### Surfacing

Although there are now a total of 606 miles of surfaced highways in the province, it has not been possible to keep abreast of the progress made in the United States; the main highways on Vancouver Island and in the vicinity of Greater Vancouver and easterly along the Fraser valley are now either paved with concrete or bitumen; with a few isolated exceptions, however, none of the highways in the interior of the province have been paved.

Although it would naturally have been preferred to lay the higher types of pavement, finances have only permitted and traffic justified the construction of 112.46 miles of Portland cement or asphaltic concrete, and 53.23 miles of bituminous macadam pavement, inclusive of municipal highways in the provincial system. These pavements are entirely satisfactory, the maintenance being very reasonable. So many thousands of miles of such pavements have been constructed within recent years on this continent that it is not necessary to enter into any discussion with regard to this class of work.

With a large mileage of roads waiting to be surfaced and with a relatively small population, the chief objective has, of necessity, been the extension of the surfaced mileage, and, having regard to funds available, the choice has been mainly restricted to the less expensive or "low cost" types, of which there are now 441 miles, including 111 miles of bituminous mulch and 330 miles bituminous carpet coat. The field of such low cost surfacing has not yet been fully explored or developed and so many questions remain to be decided that perhaps a few notes on methods and experiences in British Columbia during the past twelve years may be of interest.

The low cost surfacing work ranges from oil or tar spray-coats costing a few hundred dollars a mile to premix mulch 2½ inches thick, costing around $5,000 a mile. This type of work is considered as essentially "stage construction," the idea being that, by subsequent retreatments, a stable asphaltic surface is finally built up of sufficient thickness to withstand all traffic. It is therefore the aim to obtain the best results possible at each stage of construction, with a view to economical maintenance and a saving in the cost of subsequent treatments.

It has been found that, for this class of work, the most important and primary requirement is that the road shall be in proper condition to take the surface; that is to say, the grading of the existing gravel or stone top and the drainage must be the best that can be obtained. A flush or carpet coat will not iron out any surface irregularities due to poor construction, nor will it bridge over any soft spots, neither is it possible satisfactorily to lay a road-mix or premix mulch on an irregular grade, and it follows that, no matter how good the spray or mix may be, if the road is in poor condition prior to treatment, the ultimate repair and maintenance costs are liable to be excessive.

Given a good surface as a base for a bituminous carpet coat treatment, a priming coat is considered to be essential and the best results are obtained with the use of coal tar. In new work, this is followed by an application at the rate of one-third gallon per square yard of either a heavy liquid asphalt or tar product, on which is placed a blinding of ½ inch or ¾ inch clean stone or gravel. By this method satisfactory non-skid surfaces 16 feet wide are obtained at a cost of from $1,000 to $1,600 per mile. Maintenance costs of such surfaces vary from $20 to $250 per mile per year, depending on the volume and weight of traffic, climatic conditions and other circumstances, but on no occasion is the maintenance found to be more than the cost of maintaining a gravel road in the same situation, and of course a dustless surface is provided which is greatly appreciated by the travelling public.

It was previously the practice to lay mulch by the road-mix method, but latterly the premix method has been adopted and this is found to be more economical and satisfactory in every way, although the road-mix method has its value under certain conditions. The cost of 9.31 miles of road-mix, 20 feet wide, averaged $5,536.54 per mile in 1930 as compared with $4,706.67 per mile for 22.85 miles of premix mulch laid in 1931. On the total mileage of the foregoing the maintenance charges have averaged $57.42 per annum per mile.

For many years the renewal and repair work on all types of low-cost surfacing was by means of hot flush coating at the rate of ⅙ to ¼ gallon of bitumen per square yard, followed by the application of a suitable aggregate covering; for filling pot holes, materials were hand-mixed. Such has been the advance made in recent years, that, for similar work and for new mulch work, a premix bitumen combined cold with suitable aggregates in an ordinary cement mixer is being used, and by this method a mixture is produced suitable for almost all repair and resurfacing requirements. It is now no longer necessary, in preparing patching mixtures, to heat the aggregates, which do not even have to be completely dry; pot holes can be repaired with this material, even in wet weather, and it is possible to blade a thin "cap" over an old surface at no greater cost than the cost of respraying by the old method and the resulting surface is superior and is "non-skid" and without "fatty spots."

The cost of all premix material used in 1931 for new surfacing was $3.27 per cubic yard in place, and each cubic yard contained an average of 9.3 gallons of asphalt. For resurfacing by this method about 11 gallons of asphalt per cubic yard of material is used, as it is found advantageous to have an excess of asphalt to assist in adherence to the old surface and for other reasons; the cost per cubic yard of material for the latter averages $3.52 exclusive of placing, the cost of which varies with the nature of the repair or resurfacing work to be done.

For many years it was the practice of the Department to let contracts for supplying, handling, and spraying bitumens at a cost of around 22 cents per gallon. In the year 1930 equipment was purchased to handle this work in Engineering District No. 1 and, apart from the considerable saving in cost, the arrangement is far more satisfactory and has resulted in improvement in all stages of the work, as the contractor's convenience and anxiety to get on with the work of spraying is no longer a factor.

Departmentally-owned equipment for bituminous work now includes the following:—

1 — 680 Imperial gallon distributor.
1 — Tandem (gas) roller.
1 — Power grader, 12-25 dual drive.
1 — Vertical boiler, mounted on a 2½-ton trailer.
1 — Trailer sweeper with 9-foot broom, and tractor connection.
Several portable hand spray tanks.
1 — 500 gallon transport tank.

**Fig. 13—Provincial Government Ferry on Okanagan Lake.**

There are also, at two places, seven and eight thousand gallon storage tanks from which the local repair crews can obtain their supplies instead of purchasing bitumen by the barrel. It is thus possible to avoid the demurrage charges on railway tank cars, which in the past have amounted to quite an item, and also in this way 5 cents per gallon can be saved by buying in bulk.

### Municipal Roads

In addition to the streets in city or urban areas, there are some 2,790 miles of rural municipal roads open to traffic, the control of which is a responsibility of the municipalities and, in addition, there are 520 miles of main municipal highways, the control of which is either partly or wholly a government responsibility.

Prior to the year 1920, the municipalities were entirely responsible for all highways within their areas. In the earlier days of horse-drawn traffic, this arrangement was equitable, as traffic was then of a purely local nature; with the increasing use of the motor vehicle, however, the average distance of normal travel has been greatly extended, and today the major portion of the traffic using main municipal highways is through traffic and is provincial in character; naturally the cost of maintaining these through or arterial highways gradually increased to a point where the municipalities found themselves unable to maintain or improve these roads to the requisite standard.

To correct this situation, special legislation was enacted under the Highway Act, authorizing the classification of important municipal highways affording main channels of communication connecting important centres of population or important terminal points, as deemed necessary from time to time, and providing for the payment by the government of the entire cost or a proportion of the cost of the maintenance and construction of such highways; the control of those highways classified as arterial or primary is in the hands of the Department of Public Works, such highways becoming to all intents and purposes provincial highways. No highways may be classified in cities having a population of over two thousand; thus it is the district municipalities and the smaller cities which benefit from this legislation.

The following tabulation shows the three classifications permitted, the proportion of cost paid in each case by the government, the controlling agency and the present mileage of such municipal highways now classified. The cost to the provincial government in the year 1932-33 for the maintenance for these highways was $150,219; the average cost for maintenance of arterial highways was $398 per mile.

Table VII

Classification of Municipal Highways

| How Classified | Proportion of Cost paid by Government | | Highway Controlled by | Miles so Classified |
|---|---|---|---|---|
| | Construction | Maintenance | | |
| Arterial | 100 per cent | 100 per cent | Government | 311.61 |
| Primary | 75 per cent | 75 per cent | Government | 60.87 |
| Secondary | 50 per cent | 40 per cent | Municipality | 148.50 |
| | | | Total, miles | 520.98 |

Common Carriers

In recent years the question of regulating and licensing motor buses and trucks using the highways as common carriers has become one of relative importance; it is now admitted on all sides that some measure of control of such vehicles is absolutely necessary, not only for the protection of the general public but also for the protection of the carriers from unfair competition by "wildcat" operators who are a menace to the travelling public.

In British Columbia the control of such carriers within incorporated areas is in the hands of the municipalities, except where such carriers operate on a municipal highway classified as arterial or primary; in other words, only those common carriers operating on provincial highways are under provincial control as regards special licensing, and the provincial government has no control over such vehicles when they are operated exclusively within the cities of Vancouver, Victoria or any other city of over two thousand population.

The main highway routes of the province are now well covered by common-carrier passenger and freight services; it is not the policy of the department to issue licenses to all applicants, and the number of licenses granted on any route is generally restricted, as it is considered against the public interest to allow the intensive competition which would result from the opposite policy. Naturally, the restriction of licensing causes some contention, but the public now appears to realize the importance and responsibility which attaches to a common carrier's license and, year by year, there is less difficulty in administering the act and regulations.

Numerically, the whole problem of licensing common carriers in British Columbia is a minor one; the number of common carrier vehicles only represents less than one-half of one per cent of the total number of vehicles registered. Licenses issued during the calendar year 1933 were as follows:—

Table VIII

Number of Common Carriers Licensed, 1933

| *Carrying Capacity* | *No. of vehicles licensed* |
|---|---|
| *Passenger Vehicles* | |
| 1 to 5 passengers | 33 |
| 6 to 10 passengers | 78 |
| 11 to 20 passengers | 37 |
| 21 to 30 passengers | 68 |
| over 30 passengers | 12 |
| Total | 228* |
| *Freight Vehicles* | |
| Up to 1½ tons | 75 |
| Over 1½ tons and up to 2½ tons | 94 |
| Over 2½ tons | 32 |
| Motor cycles | 1 |
| Total | 202* |

*42 of the above passenger licenses and 36 of the above freight licenses were cancelled during the year.

With the exception of a few large firms, the operation of the common carrier vehicle in British Columbia is still very much of an individual or local matter. Out of one hundred and seventy-eight operators, about 65 per cent are the holders of a license to operate one vehicle only and 20 per cent are the holders of licenses to operate two vehicles only.

Additional fees payable by common carriers are based on the carrying capacity of the vehicle and may not exceed one per cent of the licensee's gross receipts.

**Fig. 14—V-Type Plough propelled by Two-Ton Truck.**

At the present time there is no legislation in British Columbia requiring special licensing of the so-called "contract carrier"; it is admitted that in some cases it is very difficult to differentiate between this class of vehicle and the common carrier, and there is no doubt that much of the business done by contract carriers is of a nature that that should be under some control. It is reasonable to expect that, within the next few years, an agreement will be reached by the various provinces with a view to uniformity in dealing with this difficult and contentious problem.

USE OF MACHINERY AND PLANT

It was not until the year 1910 that the provincial government purchased the first mechanical power-operated road machinery. In that year four steam-driven traction engines were acquired, together with four 4-yard hopper-bottom trailers, three steam-rollers and two crushing outfits. About this time two steam-wagons with steam-operated dump boxes of 3-yard capacity were also purchased, having a speed of about 10 miles per hour and capable of carrying water and coal sufficient for a 12-mile run. The first internal-combustion engined vehicles purchased were two 3-yard chain-driven hand-dump trucks capable of a speed of from 15 to 20 miles per hour.

Today the department has equipment in use for construction and maintenance work valued at nearly $2,000,000 including the following major units:—

45 power shovels
366 trucks
170 tractors
84 power graders
77 snow ploughs
45 road drags
13 power road rollers
281 pull graders
24 rock crushers
14 mechanical loaders
30 air compressors
11 concrete mixers
22 stationary engines, gas and Diesel.

It is outside the scope of this paper to discuss the relative merits of any particular make of road machinery. Generally speaking, it may be said a 35-h.p. tractor has been found a very suitable unit for construction work, while the heavy duty leaning-wheel grader, the 40 cubic foot capacity rotary scraper and the 5 point road ripper are the most popular types of machinery in the field for this type of work. For gravelling or general haulage purposes, the 1½-cubic yard capacity steel dump truck is found to be the most satisfactory unit.

For ordinary construction work of a class undertaken by the department's forces, the ½-yard gasoline driven shovel has proved to be very economical in operation and maintenance and most suitable for road construction, while the lighter and more mobile type of ⅜-yard capacity is very popular for clearing small slides, loading gravel, widening and other light operations.

Due to its better traction and lack of vibration and ability to negotiate soft stretches of road, the pneumatic-tire-equipped grader with dual or tandem rear wheel drive has been found most satisfactory; the ability of such machines to travel long distances at a fairly high rate of speed is in their favour. Multi-blade maintainers have proved highly efficient and satisfactory on long stretches of gravel highway but are found to be of little use on a narrow, rocky or uneven road. A 20-h.p. tractor or a heavy-type truck has been found a satisfactory power unit for these maintainers.

With one or two exceptions, all rock or gravel crushers in use by the department are designed for a semi-permanent set-up; the problems in rock crushing are varied and numerous owing to the diversified nature of the rock and gravel encountered, its location and its suitability or otherwise for road material.

In one district there is a double-reduction Diesel-operated plant capable of producing 125 cubic yards of ¾-inch material per day. This type of plant is not economical unless it is possible to keep it in more or less constant operation. The most satisfactory and economical machinery is the type which is mounted on a steel truck with folding elevator and which can be backed into a small pit and be put into operation within two or three hours; such an outfit operated by a tractor is capable of producing 50 or 60 yards of ¾-inch material per day, the material being delivered by chute to truck or stock pile.

With regard to the financing of equipment, the larger units are purchased from a special equipment fund and are rented by the department to the various jobs, the rentals charged being fixed at a rate sufficient to pay for all maintenance costs, repairs and depreciation. By this means it is possible to move units from one part of the province to another as may be required, an arrangement far more satisfactory than the previous one under which units were bought from the district road appropriation and were therefore apt to be looked upon as the property of the district. A very careful record of the exact cost of operating and maintaining each unit is kept and it is thus possible for the department to check any cases of rough usage or uneconomical operation and, in particular, to judge as to the relative merits or demerits of the various makes of equipment. Equipment is subject to constant and careful inspection and proper care and maintenance of all machinery is insisted on.

SNOW PLOUGHING

It is only during recent years that snow-ploughing service, which was begun in a small way, has become a regular feature of winter maintenance work on main and other important roads. During the year of 1932-33, snow removal was carried out on 4,236 miles of highway at an average cost of $13.37 per mile. During the previous year 5,547 miles were kept clear at an average cost of $15.25 per mile. Snowfall in British Columbia varies from light at the coast to exceptionally heavy in the interior, particularly west of Revelstoke and in the south-eastern part of the province. In some cases ploughing has been necessary almost continuously in order to keep the roads clear.

For light snowfalls and on narrow sidehill roads, of which there is a large mileage in this province, the flat blade reversible type of plough has given satisfaction, although lack of sufficient speed is its drawback. The most efficient type of equipment now in use in British Columbia by the Department of Public Works is the "V" type plough with hydraulic operated side wings and propelled by a tractor; this machine is capable of negotiating heavy grades and can deal with snowfalls from three to four feet in depth with ease and can successfully clear all types of road. The cost of operation, however, is somewhat high and the maximum speed obtainable is not over 3½ miles per hour.

CONCLUSION

It is hoped that the foregoing gives a clear outline of the highway system without unnecessary detail.

Queen Victoria was in the twenty-first year of her reign when her Colonial Secretary despatched a company of Royal Engineers to British Columbia for the purpose of laying out townsites, planning and constructing roads and the like. Since that time there has been a continued demand for road building; hardly a year passes when the government is not inundated with requests for public works to an extent far in excess of available resources. Who can foresee what developments will occur within the next decade? The great mining regions of Bridge River, Cariboo, Omineca and the Kootenays are all dependent on adequate highways and no one but the engineer can successfully meet the problems that will arise in the development of our natural resources. In a comparatively young province there must, of necessity, be great tasks ahead.

It will be the part of wisdom to plan carefully, and build wisely and well, so that highway development will take its due part in the march of progress.

# The English Bay Interceptor, Vancouver, B.C.

*G. M. Gilbert, A.M.E.I.C.,*
*Engineer, The Vancouver and District Sewerage Board, Vancouver, B.C.*

**Paper presented before the Western Professional Meeting of The Engineering Institute of Canada, held at Vancouver, B.C., on July 11th to 14th, 1934.**

**SUMMARY.—This intercepting sewer was designed to deal with the sanitary sewage from four outfalls serving some 7,500 acres having an ultimate population of 270,000 Extensive experiments were made to determine the best location of the interceptor outfall, having regard to tidal currents and the proximity of bathing beaches. The methods of construction and equipment used are described, also the arrangements for diverting storm water and avoiding the deposition of grit. The paper also deals with the construction of the submerged outfall, of concrete pipe supported by pile bents; information is given as to progress and costs.**

---

Twenty-three years ago the city of Vancouver and the surrounding municipalities were faced with a serious drainage problem. It was the period of expansion just before the war. Population was increasing rapidly, lands were being cleared for settlement and building activity was general. In the midst of all this development, sewerage and drainage facilities lagged. So far, in fact, that by 1911 it was realized some form of united action was necessary to remedy the situation. In order to obtain this action, the several municipalities joined together to form the Burrard Peninsula Joint Sewerage Committee.

The committee met and decided to secure expert advice. An eminent consulting engineer was retained and under his direction extensive surveys and investigations were carried out over the whole peninsula. His report submitted in 1912 outlined a plan for sewerage and drainage to take care of the estimated population and development for the year 1950. The object of the plan was to give the most efficient service to the whole district, unhampered by municipal boundaries and to insure that each construction unit as undertaken would fit into the general scheme.

The provincial government gave effect to these recommendations by passing the Sewerage Board Act, which set up an administrative body, the Vancouver and Districts Joint Sewerage and Drainage Board, whose duty it is to administer the Act in the Sewerage District.

The Board as now constituted has jurisdiction over an area of 90 square miles, on which the average annual rainfall is 56 inches. It differs from most metropolitan sewerage boards in that it is responsible for surface drainage, as well as the disposal of sanitary sewage. The present municipal members of the board are: the city of Vancouver, the city of New Westminster, the municipality of Burnaby, and the University Endowment Lands.

About half of the whole district has now been divided into separate drainage areas, in each of which the Board maintains a trunk sewer or drainage channel, or both, up to the 400-acre point, and an outfall discharging into one of the tidal waters on the north, west and south.

Some years ago four of these outfalls on the south shore of English bay were discharging an ever-increasing volume of sewage into waters adjacent to bathing beaches. The growing nuisance of the sewage and the rapid development of these beaches led to the demand for the construction of the English bay interceptor, the largest single piece of construction work which the Board had undertaken up to that time.

It should be noted that the original scheme called for the construction of this interceptor before any outfalls were laid into the bay. However, the cost of the work prohibited the undertaking in the early days of the Board.

The function of the interceptor is to pick up the sanitary sewage from each of these four trunk sewers and discharge it into the sea at some point where it will either be carried out into the Gulf of Georgia or be so broken up that it will never reach the foreshore. The first important consideration, then, was the location of the outlet.

Two years were spent in a search for the best position. A careful study was made of the currents existing in English bay at all stages of the tide and during periods of both high and low water on the Fraser river. The water from the north arm of this river, sweeping around the Spanish Banks, exerts a powerful influence on the currents in the bay, especially during flood periods. It was desirable to locate the outfall somewhere in English bay, if possible, so that the length of the interceptor could be kept at a minimum. However, observations were also made at the mouth of the Fraser river and in the gulf, in case it was necessary to extend the interceptor beyond the Spanish Banks.

Several methods were employed to trace the varying current courses. The most successful was the employment of different types of floats.

The surface floats were simply weighted blocks of wood designed to expose as little surface as possible to the wind. The sub-surface floats could be adjusted to test the current at any depth. Their four large fins made them responsive to the slightest movement in any direction. A relatively light surface attachment floating flush with the water offered little resistance. Both types carried a light flag for spotting. (Fig. 3.)

These floats were released in groups from different selected points in the bay and gulf. A group would consist of two surface and five or six sub-surface floats at different depths. They were allowed to drift for eight or ten hours, during which time they went through a complete tide cycle. At regular time intervals, usually every hour, the position of each float was located by sextant angles to prominent points tied in to a shore traverse. The paths followed by the floats were later plotted in the office on a plan which also showed the velocity and direction of the wind, the flow in the Fraser river, and the tide curve for the day.

A study of these results revealed some very interesting facts. For instance, not only did the surface floats follow quite different courses from their under-water fellows, but sub-surface floats of different depths released from the same point frequently drifted in different directions. This made the work of the observer very difficult, as the diverging flags were often several miles apart at the end of the day. Some floats were lost at first and it seemed hopeless to look after eight floats with one boat. Gradually, however, as the currents were understood, it was possible to anticipate the action of the floats under different conditions. Floats of the same depth, released from the same point and under similar tide conditions, would follow the same course time after time.

In general, floats released anywhere in the gulf within half a mile off shore, swept around Point Grey to the Spanish Banks on a rising tide and up the north arm of the Fraser river on a falling tide. Those released anywhere off Spanish Banks swept in towards Kitsilano beach on a flood tide. If the run-in were long enough or strong enough they either went ashore there or crossed the mouth of False creek and went ashore below English bay beach. No matter what their position a turn from flood to ebb would start them drifting out to the open gulf.

This was the general condition and it did not look too promising. A strong flood tide threatened to carry the sewage en masse to the beaches. There were, however, points where the movement inward was not so pronounced and where cross currents were especially active. One such point was located five thousand feet off shore on the line of Imperial street. This was a likely place and many groups of floats were released here and their actions closely studied.

Another type of experiment was also tried at this point to verify the presence of cross currents. Uranine dye was mixed with a light fish oil and the mixture placed in glass containers. These containers were exploded at different depths below the water surface and under different tide conditions. The oil held the dye well together and even from a depth of 80 feet there was no mistaking the appearance of the mixture on the surface of the sea. The various positions at which it appeared promised excellent diffusion conditions at this 5,000-foot point.

While the float observations were in progress, and before an outlet position had been definitely selected, test piles were driven at different points in the bay. On the Spanish Banks hard packed sand was encountered at any depth. Further east the bottom was very soft—so soft that a pile driven 30 feet could be pulled out again with ease. From Point Grey south to the north arm of the Fraser river the material on the sea bed was much the same as that on the Banks, although the actual foreshore was quite rocky.

Temperature tests showed a variation of only 4 degrees F. between winter and summer at a depth of 80 feet, although at the same time the surface water varied from 64 degrees F. to 42 degrees F., and the atmospheres from 72 degrees F. to 44 degrees F. The temperature of the sewage carried in trunk sewers varies somewhat at different times during the day but at periods of maximum flow it is approximately 65 degrees F.

On testing for salinity it was found that during flood periods in the Fraser river as much as 25 per cent of the water over the surface of English bay was fresh. This fresh water layer extended about 10 feet below the surface. For both the salinity and temperature tests, which were taken together, a large round flask with a very narrow neck was used. The cork was suspended on a separate line from the flask. Both lines were lowered to the depth at which it was desired to sample the water, the cork was pulled and after sufficient time had elapsed to fill the flask, it was drawn swiftly to the surface. The sample of water was then transferred to a jar in which a thermometer and a salinometer were inserted.

In analyzing the data obtained, it was apparent that the best location for an outfall was along the line of Imperial street. It was not an ideal location because of the soft bottom, but it had certain definite advantages, viz. there was deep water quite close to shore; active cross currents were in evidence at the 5,000-foot point; an outfall located here gave the shortest possible land line. A much better foundation could be obtained by laying the outfall across the hard packed Spanish Banks. However, this would mean a much longer interceptor, and a longer outfall too, since it would be necessary to traverse about half a mile of sand bar before reaching deep water. The same conditions applied to any location at the mouth of the Fraser river.

Further tests along the Imperial street line gave more encouraging results. A trial trench was excavated and its length, depth, and general shape noted by divers. Three weeks later when the trench was examined it was found that although some silting had occurred, the general shape and dimensions were as before. Twelve piles were driven in four three-pile dolphins forming a square, penetration being about 30 feet. The piles went down with the usual ease and without much driving with the three-ton hammer. In fact, the weight of the hammer itself was sufficient. Twenty-four hours later it was found the piles had stiffened

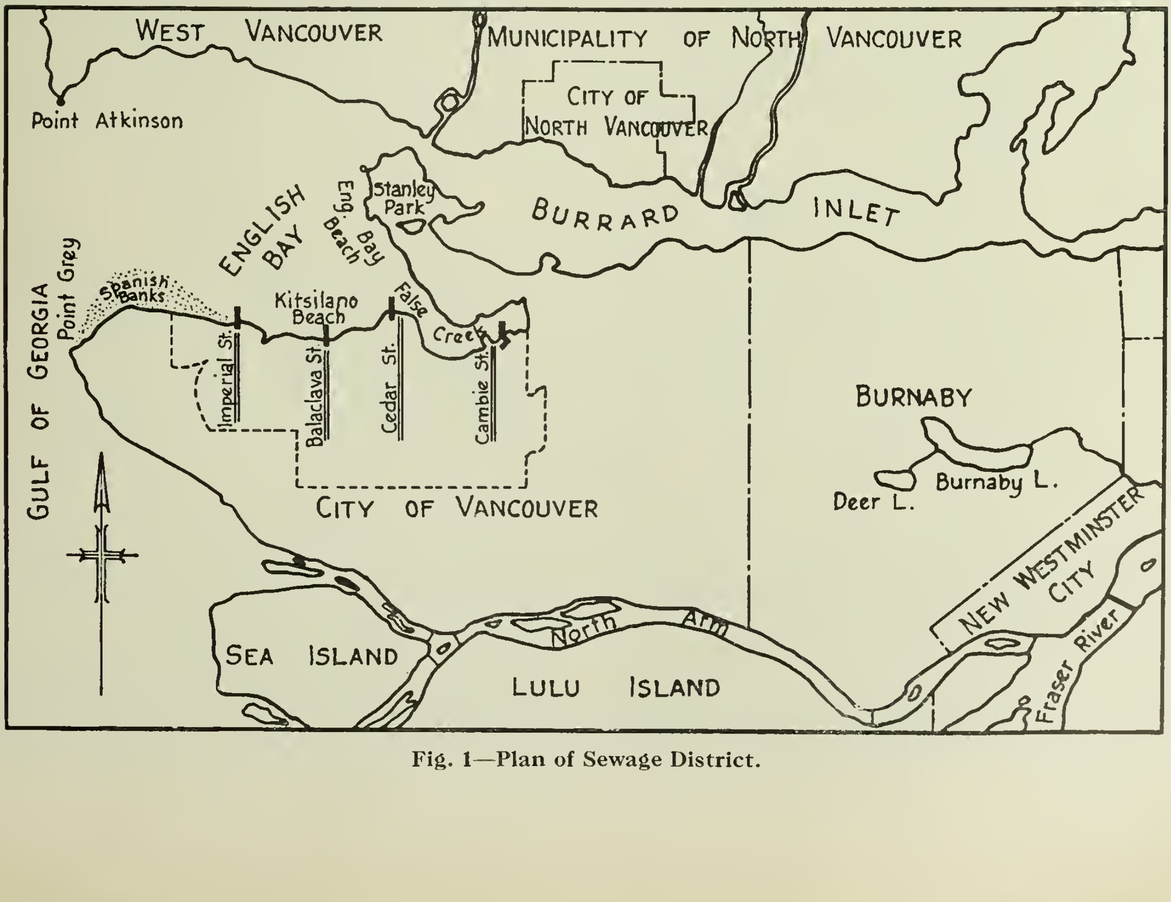

Fig. 1—Plan of Sewage District.

considerably. No longer was it possible to pull them out and it required real driving to get them down further. A platform was laid between the dolphins, and after the exact elevation was recorded it was loaded with 40 tons of short rails and scrap iron. Under this weight the platform sank approximately three inches (the four corners sank different amounts). Next day the rails were taken off and the elevation again observed. No change had taken place. These experiments showed that it was possible to drive a

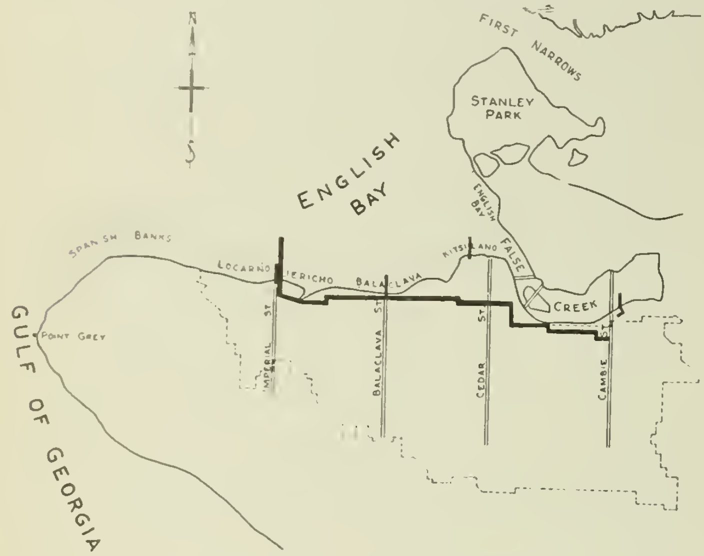

Fig. 2—General Location of Interceptor.

pile foundation in an excavated trench in the kind of material which would be encountered during construction. During these preliminary submarine investigations one fact was noted whose full significance was not realized until construction had begun—it was always pitch dark at the bottom of English bay.

Having selected the position of the outfall, the next consideration was the location of the line of the interceptor. Cambie street was its eastern terminus and its western limit was now fixed at Imperial street. Between these two points several routes were examined. It was thought that a sewer along the foreshore might be built as part of a sea wall. Such a line had the advantage of being at the lowest possible elevation and consequently all territory could be drained by gravity. For economic reasons, however, this proposed location had to be abandoned.

Two other possible lines known as tunnel line No. 1 and tunnel line No. 2 were also investigated. Borings were taken at frequent intervals and showed without exception excellent material for tunnelling. Sandstone and shale alternated with thin seams of coal, a narrow dyke of basalt at one place being the only exception to the regular sandstone-shale strata. The line finally selected began at high water level on Imperial street, and, after traversing the grounds of Jericho Golf Club at shallow depths, entered the Kitsilano hillside at Alma road and from there to Oak street was mostly in tunnel. The total length of the line was 5 miles. (Fig. 2.)

The English bay interceptor was designed to serve an area of 7,500 acres, estimated to contain by 1950 a population of two hundred and seventy thousand. The basis of design was ninety imperial gallons of water per person per day reaching the sewers; plus infiltration of two thousand gallons per acre per day; plus an allowance for light summer rains of 0.03 inches per hour.

There were four main concentration points, one of which was at the foot of Balaclava street. The area contributing here was roughly 2,500 acres, and the town planning map gave the ultimate population density as forty persons per acre, corresponding to an estimated population of one hundred thousand.

To determine the size of pipe required it was necessary first to translate the estimated flow into cubic feet per second. On an average day it would be necessary to provide for 100,000 by 90 or 9,000,000 imperial gallons. But the maximum day was taken as being 150 per cent of the average day, and the maximum hour of the maximum day 175 per cent of that, so at that point provision was made for $1.5 \times 1.75 \times 9,000,000$, or

| | | |
|---|---|---|
| 24,625,000 imperial gallons per 24 hours | =45 | cubic feet per second |
| plus infiltration at 2,000 gallons per acre | = 9 | cubic feet per second |
| plus 0.03 inches per hour of rainfall | =18.75 | cubic feet per second |

(0.25 was selected as the run-off factor suitable for the Balaclava area.) Thus there was a total of 72.75 cubic feet per second tributary at Balaclava street.

Treating the other concentration points in a similar way, it was found that the total estimated flow arriving at the outfall would be 200 cubic feet per second.

Having determined the quantity of flow, it was then necessary to fix the grades. One chief factor governed the grades on which the sewer was laid. This was the desire to include as much territory as possible within the area draining naturally to the interceptor. All lower ground would be pumping areas entailing perpetual expense. In other words, the grades were kept as low as possible consistent with a minimum velocity of three feet per second when the sewer was running half full.

For the interceptor proper and for all its sizes, it was decided to use the "Boston Horse Shoe Section," which is the standard section used on all the Board's trunk sewers. The diameter of pipe required at different stages along the line was estimated by applying a recognized formula to the conditions of flow and velocity which controlled the design at each stage. The result was then checked by the application of other formulae. The coefficient of roughness for the proposed concrete sewer was taken as 0.013, recom-

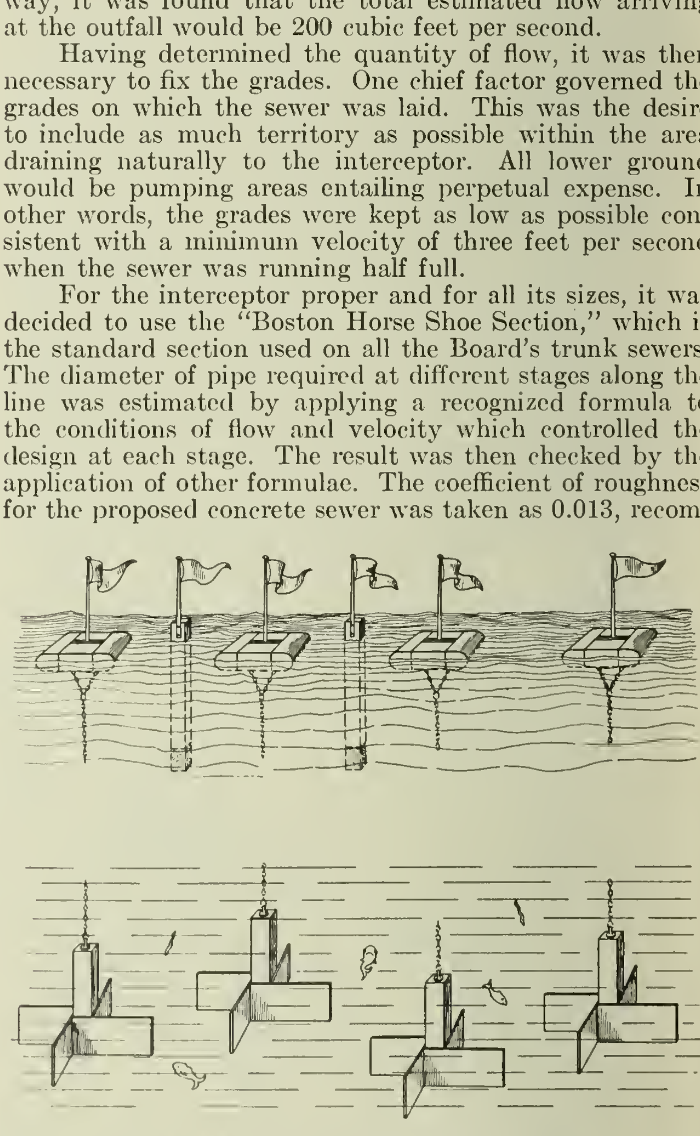

Fig. 3—Surface and Sub-surface Floats.

mended by Metcalf and Eddy. The value of the coefficient $C$ in general was taken as 120, a value which was slightly low by most formulae and consequently gave a conservative estimate of velocity and capacity.

From the foreshore to the first concentration point it was proposed to use a sewer 8 feet in diameter with a fall of 6 inches per thousand feet and under pressure throughout its entire length. The hydraulic radius of such a sewer is 2, and the velocity 3.70 feet per second when passing approximately the required 200 cubic feet per second. (Fig. 4.) Actually an increase in the hydraulic gradient was obtained by a change in design at the lower end of the 8-foot section.

The interceptor had been located down the west side of Imperial street and on the north side of the existing trunk sewer through the grounds of the Jericho Country Club. This necessitated a crossing at the entrance to these grounds and for this purpose a syphon was designed at First avenue, with twin channels each of which would take half of the estimated flow. Each channel was 8 feet wide at the top, 3 feet 6 inches deep at the centre, and 3 feet deep at the sides, the hydraulic radius being 1.2 and the estimated velocity 4.0 feet per second.

This scheme was rejected and it was decided to use the existing trunk sewer already constructed down the east side of Imperial street, which was also 8 feet in diameter with a fall of 1.8 feet per thousand. Although this steeper slope used up more than one foot of elevation, it was considered preferable to use that part of the Alma-Imperial trunk sewer for the interceptor rather than install a syphon at First avenue as mentioned. A new storm sewer was designed, and later built, along the west side of Imperial street to take the place of the section thus appropriated for the interceptor.

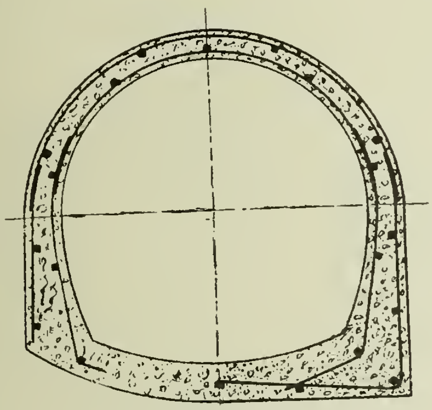

**Fig. 4—Pressure Section, 8-foot Diameter Pipe.**

The interceptor as finally designed and built varied in diameter from 8 feet at the foreshore to 4 feet 6 inches at the upper end. The changes in diameter take place at the various concentration points where the sanitary sewage is diverted into the interceptor.

At these places it was decided to construct in each trunk sewer a curving weir, whose height was just sufficient, under normal conditions, to divert the desired quantity. Using Balaclava again as an example, the height of the weir was calculated as follows:—The trunk sewer down Balaclava street was 8 feet in diameter on a grade of 0.0072 and had a capacity of approximately 800 cubic feet per second; but as only 72 cubic feet per second or 9 per cent of this was to be carried to the interceptor, the height of the flow in the Balaclava sewer under these conditions would be 0.022 of the diameter, or 21 inches. Thus the height of the weir required was estimated as 21 inches.

During heavy rains, however, when a considerable head may be built up, more sewage would be forced into the interceptor from the trunks than the permissible amounts and so a regulating device was designed whose function was to control the flow under those conditions. The regulating machinery, installed in a chamber adjoining the intercepted trunk, consists of a movable gate suspended from a lever arm which is balanced on the other end by a hollow casting or float set in a small separate chamber. The float chamber receives the first water over the weir through a pipe connected to the trunk sewer. The consequent loss in weight of the float upsets the balance and starts the gate closing. A slight grade in the entering pipe drains the float chamber as the flow subsides. (Fig. 5.) It was necessary to design everything in such balance that the operation of closing the gate would be slow and regular.

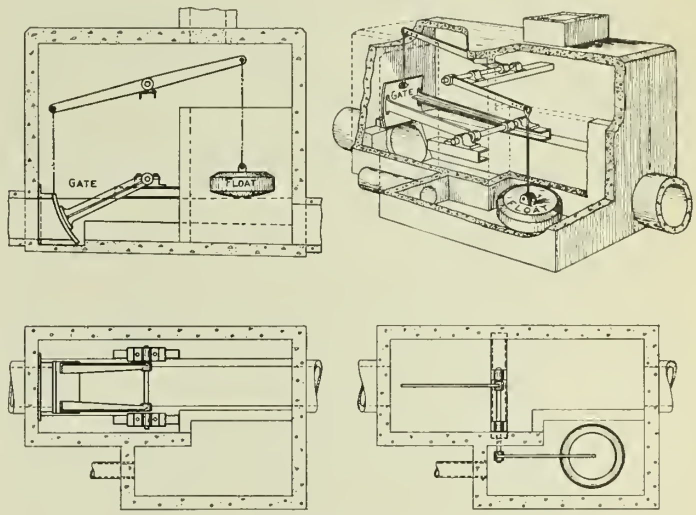

**Fig. 5—Regulating Chamber.**

In addition to controlling the flow it was deemed necessary to control the sand and grit which would be swept into the interceptor. In general the problem of grit in the storm sewers is a very serious one in Vancouver, especially where long flat stretches succeed steep grades, as they do in many cases. It was regarded as essential that no grit should get into the submarine outfall, for once in it would be extremely difficult to remove.

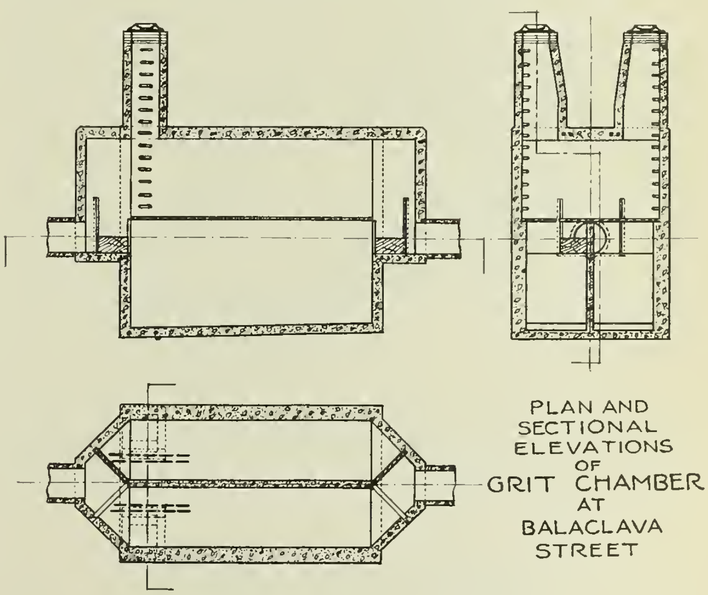

**Fig. 6.**

Two methods of grit control were considered. The first, a large settling chamber on the foreshore just in front of the outfall, or alternatively a series of smaller chambers at each of the intercepted trunks. There were several definite objections to the use of one large chamber. The interceptor was laid on minimum grades and consequently there would be danger of it silting up along the whole length if grit were allowed in. The danger of erosion was an added reason for keeping it out altogether.

The problem of grit interception, while simple in theory, is quite difficult in practice because of the fluctuating flow. If the chamber is narrow, the stream velocity is high during a storm and grit is swept through. If the channel is kept wide, during periods of minimum flow the velocity drops to a point where sewage is deposited along with the grit, causing offensive odours. The only way to meet the situation is by a series of channels, each taking a limited amount of the flow, the more channels the greater control of fluctuation. In this case lack of space limited the design to two.

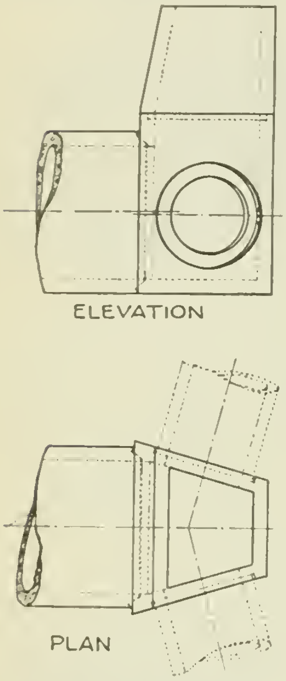

Fig. 7—Outlet at End of Outfall Showing Branch Pipes.

One foot per second is recognized as the velocity at which grit will be deposited without letting down too much sewage. In this case 1.2 feet per second was selected, and at Balaclava with 36 cubic feet per second passing through each channel, the velocity was calculated on a stream area somewhat less than that of the channel to allow for silting up. (Fig. 6.) In each case the grit chamber was designed to lie just below the regulating chamber and connected to it by a pipe of sufficient diameter and grade to take the flow. From the grit chamber another pipe carried the flow to the connecting chamber where it entered the interceptor.

Elevation 105.7 on Vancouver City Datum was chosen as the maximum elevation at which the hydraulic gradient could be fixed at the foreshore, while still keeping the interceptor working properly, and the diameters down to a reasonable limit. The possible extension of the interceptor westward to Point Grey had to be considered. This extra length is about 15,000 feet, most of which would be in deep tunnel. It is altogether likely that the Imperial street outfall will be permanently in operation, but as the University Endowment Lands develop, part of the flow from the interceptor may be diverted westward to join the flow from this area, with an outfall into the gulf south of Point Grey.

In the design of the outfall off Imperial street the problem was to carry a flow of 200 cubic feet per second through a 5,000-foot outfall during a high tide. Zero tide equals elevation 83.5 Vancouver City Datum. Designing to meet the conditions created by a 14-foot tide when the water over the outlet would be 85 feet deep we have:

$$105.7 - 97.5 = 8.2 \text{ feet}$$

but

$$\frac{\text{weight of sea water}}{\text{weight of sewage}} = \frac{64.14}{62.45} = 1.027$$

hence a column of sewage to balance a column of sea water needs 0.32 inches extra for every foot of depth over the outlet.

$$85 \times 0.32 \text{ inches} = 27 \text{ inches.}$$

Now in summer or during periods of flood in the Fraser river there is approximately 25 per cent fresh water over the outlet, and the allowance for the difference in specific gravity then becomes 1.7 feet. There was thus available 8.2 feet − 1.7 feet = 6.5 feet to drive the sewage through a 5,000-foot outfall at high tide. To give a velocity of 5 feet per second this would require a pipe nearly 7 feet in diameter. But this was making provision for the maximum hour's demand, the maximum rainfall and a high tide all occurring simultaneously, a combination whose probability was figured as once in two thousand times. (Using a probable concurrence of the maximum hour's flow with a rainfall of 0.03 inches as three times in a year, together with twenty tides of 14 feet or over.)

Under more usual conditions, to keep the velocity up and to keep the cost of construction down, it seemed desirable to limit the diameter by providing for the maximum amount of sanitary sewage only. This amounted to 140 cubic feet per second. About this time it was also decided to provide a temporary outlet 3,000 feet offshore and to extend the outfall to the 5,000-foot point when the area was more densely settled. Calculating on this newly accepted basis, it was found that using a 5-foot 6-inch diameter pipe on a grade of 1.6 per 1,000 feet for 3,000 feet required 4.8 feet. Branching at the 3,000-foot point into two 4-foot 6-inch diameter pipes on a grade of 1.1 per 1,000 feet for 2,000 feet required 2.2 feet, a total of 7.0 feet.

This was rather more than the available 6.5 feet but was considered close enough. To take any flow in excess of 140 cubic feet per second during the short period that a 14-foot tide would control, there was designed an overflow pipe 3 feet in diameter discharging a little beyond low water mark.

It is to be noted that this overflow would come into action only when rain coincided with exceptional high tides and any sewage thus dealt with would go out on a falling tide. Except in a very wet summer it will seldom operate during the bathing season.

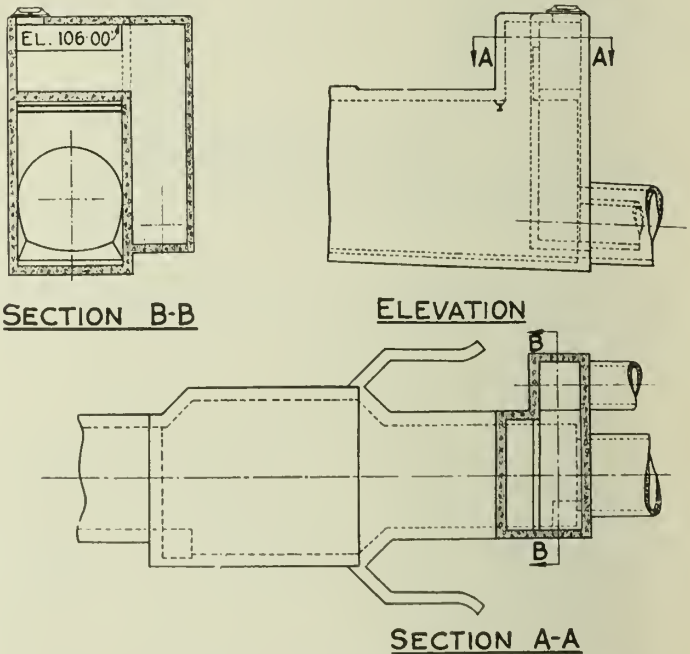

Fig. 8—Overflow Chamber at Foreshore, Imperial Street.

The soft nature of the sea bed off Imperial street precluded any idea of laying the sewer along the bottom and it was decided to use a pile foundation set in an excavated trench and using two steel rails as a cradle for the pipe. Experiments had shown that a ditch would probably stay open long enough to permit piles to be driven.

Reinforced concrete was the material selected for the outfall pipe. The pipes were pre-cast and had two layers of wire mesh reinforcing as well as longitudinal rods. The walls were 7½ inches thick, making a weight of 1,755 pounds per lineal foot. The joint as designed was a combination of the tongue and groove and butt joints. It was open enough to permit caulking as an added safeguard against leakage, although if properly laid the butt joint itself made it watertight. It was decided that 8 feet was the economical length of pipe to use.

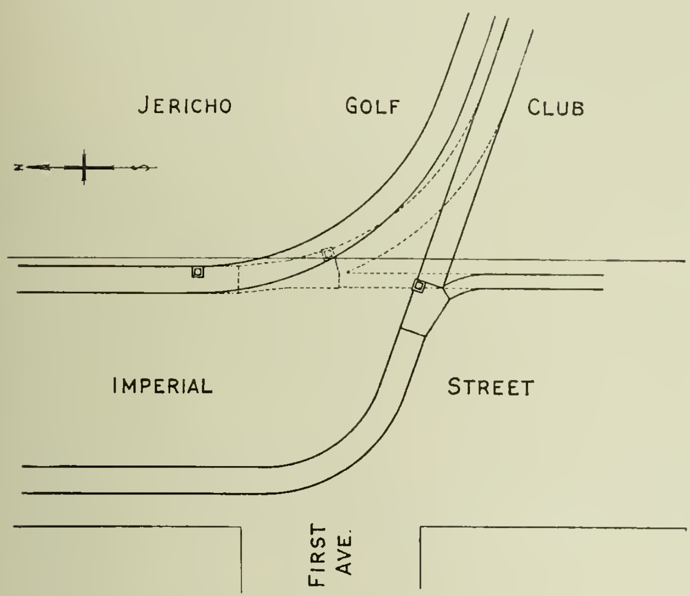

**Fig. 9—Imperial Street Connection After Construction of Interceptor.**

In designing the substructure it was decided to use two-pile bents at 6-foot centres. Numerous experiments had indicated the depth to which the piles should be driven. Applying the "Engineering News" formula $P = \frac{2\,wh}{S+1}$ to the observations recorded during the tests it was found:—

Total weight of pipe and cradle per lineal foot = 1,855 pounds. Assuming two piles every 6 feet and neglecting buoyancy, load on each pile is 5,565 pounds. Using a 5,800 pound hammer, a fall of 7 feet, and penetration per blow of 12 inches the result was:—

$$\frac{2 \times 5{,}800 \times 7}{12 + 1} = 6{,}246 \text{ pounds}$$

Hence piles should be driven until the penetration was about 12 inches under 5,800 pounds falling 7 feet.

Skin friction in silt, according to Fowler's "Practical Treatise on Subaqueous Foundations," may be taken as 120 pounds per square feet of pile surface as safe. Figuring on 9 inches diameter piles with a circumference of 28.27 inches and where $L$ is the required penetration:

$$L \times \frac{28.27}{12} \times 120 = 5{,}565 \text{ or } L = 20 \text{ feet}$$

The bent intervals were increased to 8-foot centres as the ground became firmer farther out. Even at that spacing there was a large factor of safety.

Total weight of pipe and cradle 1,855 pounds per lineal foot. Assuming 2 piles every 8 feet, weight on cap = 1,855 × 8 = 14,840 pounds. Allowing for buoyancy this becomes

$$14{,}840 \times \frac{150 - 62.5}{150} = 8{,}607 \text{ pounds.}$$

The safe concentrated load on a 10 by 12-inch cap with a 9-foot span would be 8,900 pounds; in this case the load was not concentrated and clear span is nearer 8 feet.

The last stages of design were carried on in the midst of an insistent public demand that the interceptor should be built without delay. The local press led a campaign to clean up the bathing beaches and keep them free from pollution.

The spring of 1929 saw the final preparation for construction, including the approval of the plans by the Dominion government and by the engineer originally retained by the Board, whose services as a consultant were fortunately still available. It was decided that the Board would undertake the entire construction itself, rather than let contracts for all or any part of the work.

Ground was broken on May 27th at the foreshore on the west side of Imperial street. Work was commenced with a small crew which was increased as the open trench lengthened. All the way up Imperial street fine running sand was encountered, making it necessary to close-lag the sides of the ditch.

Since the bottom of the excavation was 10 or 12 feet below high tide, water was present at all times, and to keep the trench dry a 5-inch centrifugal pump was installed at the foreshore. This pump, belt-driven by a 20-h.p. gas engine, ran day and night. A subdrain of agricultural tile was laid in gravel below the invert and carried the water to a sump at the lower end of the ditch just beside the pump. The concrete was run in place, in three operations, using movable wooden forms which were greased with a light fish oil for easy and clean removal.

This Imperial street section, 8 feet in diameter, was designed as a storm sewer to take the place of the Alma-Imperial trunk converted into the interceptor. (Fig. 9.)

At the turn into the Jericho Club grounds the storm sewer joined the old combined trunk, and new construction from there was part of the interceptor proper. All parts of the old structure not needed as part of the new scheme were broken up and removed. Through the golf links the

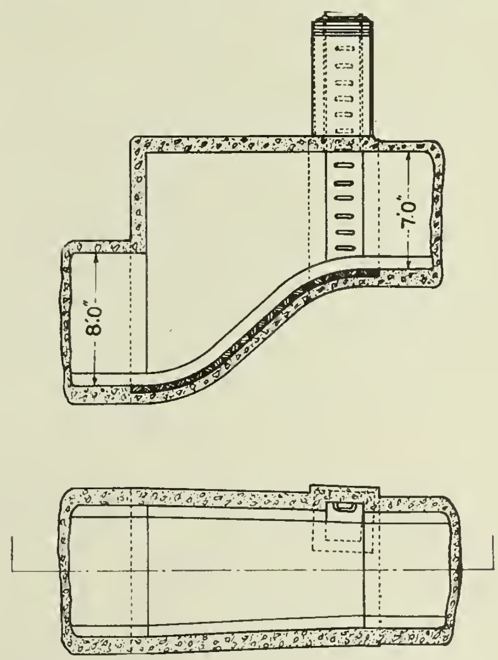

**Fig. 10—Combined Ramp and Transformer.**

material encountered was much the same as below but with less water, although close sheathing was still necessary.

On the Imperial street storm sewer the rough concrete invert was 8 inches thick, on which a thin cushion of sand made a bed for fire-clay brick laid on edge. Reinforcing steel consisted of ½-inch square deformed bars. In the interceptor proper the construction was similar except that instead of the brick invert, a paving finish two inches thick, half pump-sand and half cement, was laid on in sections before the rough concrete had set.

Open cut was the method of construction through the golf links and on to the point where the sewer turned north. The ground was rising rapidly here and the depth of the trench increased, until at 24 feet tunnel construction became more economical and the first portal was established. Very little blasting was necessary to open the ground up to the first portal, but in the subsequent stretches of open cut, sandstone and shale were encountered and constant blasting was required.

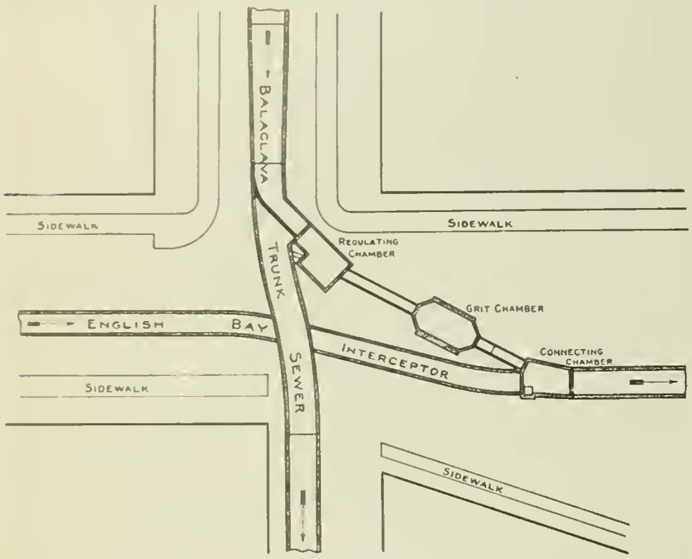

Fig. 11—Balaclava Street Layout.

A combined ramp and transformer just west of portal No. 1 reduced the diameter of the sewer to 7 feet and raised the invert about 6 feet. (Fig. 10.) From this point the sewer was no longer under pressure and consequently less reinforcing steel had to be installed.

The series of connecting structures at each of the intercepting trunks were installed as the open cut reached the different points. No particular difficulty was encountered at any place except at Balaclava street, where the top of the interceptor was designed to cut through the bottom of the existing trunk sewer. To take care of the flow during construction a false bottom was laid at the springing line in the old sewer, and the water was flumed across the point where the work was in progress. The interceptor here took the shape of a flat deformed section so as to cut a minimum of space out of the Balaclava trunk, whose invert was then built up to the top of the interceptor crown. The structures were built practically as designed, only minor changes in dimensions being made to meet underground conditions. (Fig. 11.)

Costs on the open trench sections varied greatly between the large section laid in shallow depths, and the smaller section further up the line which were much deeper and in harder material. For the lower part the average cost of excavation was $2.40 per cubic yard, which included laying of the subdrain, and half the cost of pumping, as well as labour and materials used in digging the ditch. Rock excavation in the upper stretches cost about $6 per cubic yard. Concrete costs over the whole open cut varied from $12 to $15 per cubic yard. This concrete was poured by hand and the price included setting up and removing the forms as well as placing the reinforcing steel. Backfilling costs throughout were fairly constant at 55 cents per cubic yard. Invert bricks cost 10 cents each in place, a price which makes the use of a substitute material very desirable.

The part of the interceptor constructed in tunnel amounted in length to 12,500 feet, and the tunnel was driven throughout grey sandstones and shale. Numerous seams of coal were observed varying in depth from an inch or two to a seam of 2 feet under Granville street. During the winter months some of this coal was used to heat the workmen's shacks, burning freely to a fine ash although rather hard to ignite. A narrow dyke of basalt was encountered under Balaclava street; otherwise the strata were very uniform, dipping about 15 degrees to the south.

Twelve shafts were sunk at various places along the line. The openings were 10 feet by 16 feet giving a 10-foot by 10-foot square shaft and a 6-foot staircase. Elevated bunkers received the dirt from a bucket running on an Alaska trolley. An A-frame on one side of the bunker supported by two deadmen in line on either side provided a cable way for the trolley. The hoist house beside the shaft contained a compact single drum hoist complete with 15-h.p. motor, and having a line speed of 150 feet per minute. An automatic trip discharged the dirt from the bucket into the bunkers. (Fig. 12.)

Headings were driven both ways and a sump at the bottom of the shaft was set low enough to drain both ends. An electric pumping unit installed part way down the shaft kept the sump clear.

To fix the centre line two reels of fine wire were mounted on either side of the shaft on planks. Weights with fins were suspended from the end of the wires and lowered into two buckets of water. When all movement had stopped the wires were centred on top and line was produced below. The transfer of the line from the surface above to the tunnel was repeated many times to obviate error.

The ground varied in hardness but throughout the entire job the drilling was good. However, owing to the tendency of the rock to air-slack, timber sets were placed at 6-foot intervals and a large portion of the roof of the tunnel was close-lagged. The sets were put in square and the sills centred with a transit, the object being to reduce the amount of overbreak to a minimum. Before placing the timber a light pneumatic pick and spader was used to good advantage in trimming the rock.

Not more than two shafts were opened at one time. The headings were advanced with Leyner type drills mounted on horizontal bars, and supplied with air by large compressors centrally located. Thirty per cent polar-

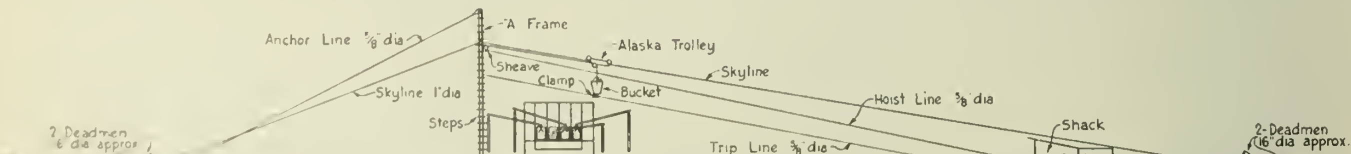

Fig. 12 Diagram of Equipment on Top of Shaft.

forcite was used to dislodge the rock, and charges were exploded by battery from the top of the shaft.

It was necessary to limit the amount of powder used in each round on account of the thickly populated residential district under which the tunnel was driven. For this reason also no blasting was done on the night shift, although mucking and loading went on twenty-four hours a day, six days a week.

The usual powder load was three sticks of 1⅛-inch by 8-inch polar-forcite in the cut holes and lifters, and from 2 to 2½ sticks per hole in the balance of the round. Both forty per cent and thirty per cent polar-forcite were used, but thirty per cent seemed to give better results in this type of ground. Powder consumption worked out at two pounds per cubic yard of rock removed. All holes were tamped with sand in 1¼-inch by 8-inch shells. The shells were empty powder cartridges crimped on one end only and made especially for stemming purposes.

Delay action caps Nos. 0 to 8-inch were used throughout. The use of so many different delays in a round which averaged only twelve holes, arose from the necessity of shooting not more than two holes on one delay to reduce vibration. (Strict control over the blasting materially reduced complaints from residents in the neighbourhood.) The caps were wired up in parallel and fired from a 220-volt power line. Shift bosses were in charge of the loading and firing and the wiring was supervised by the electrician. About 3 feet of rock was pulled in each round from a 5-foot hole, and the average daily advance per tunnel heading was 6 feet.

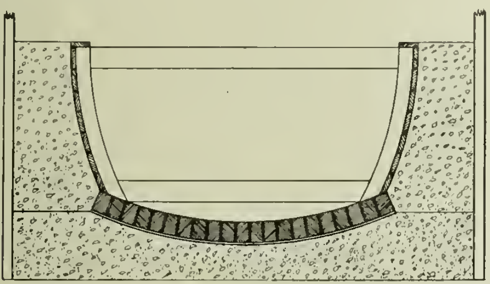

Fig. 13—Formwork for Concrete Invert and Sidewalls.

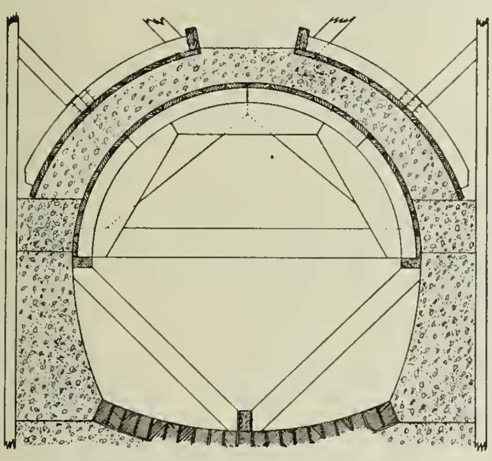

Fig. 14—Formwork for Pouring Crowns.

The tunnel was electrically lighted and a narrow gauge railway, single track with a siding half way to the heading, provided trackage for the small dirt trucks. Mucking was done by hand, 60,000 cubic yards of rock being removed in all. After a few hours in the open, the rock disintegrated into fine sand which was easily handled. Motor trucks removed the material from the bunkers, and disposed of it in nearby fills.

Ventilation was obtained by fans mounted at the top of each shaft. The fans were powered with a 7½-h.p. motor and supplied air through a 10-inch metal pipe which was carried down the shaft and along the tunnel to a point near the heading. The air current could be reversed by an arrangement of slide valves.

The first bore was 10 feet square to give a 7-foot diameter finished sewer inside, and the smallest bore was 7 feet square for the 4-foot 6-inch sewer. Ninety-degree

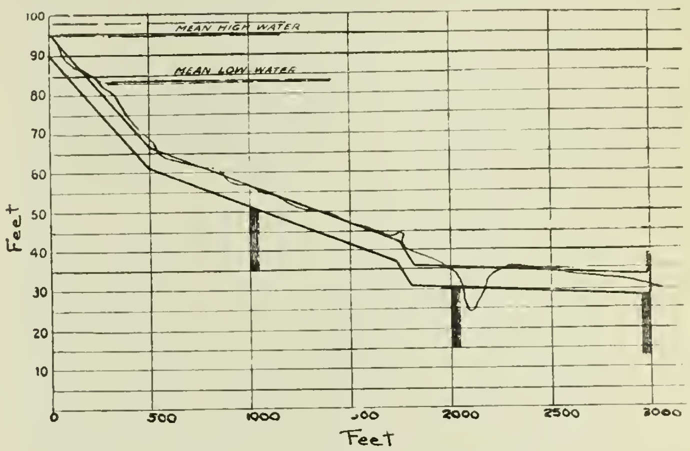

Fig. 15—Profile of Sea Bottom off Imperial Street.

curves were encountered in three of the tunnel lengths, but by using short chords carefully set no difficulty was experienced in getting a good break through when the headings met.

After two headings had been pushed to a junction, the tunnel was trimmed and cleared ready to receive the concrete lining. Concrete was mixed at the top of the shaft and sent to the bottom in chutes. For the invert it was loaded into buggies and sent along the tunnel to be spread. The invert was started midway between two headings and worked back towards the shafts; grout for the paving finish being sent down the other shaft so as not to interfere with the invert concrete, and yet be laid on while it was still soft.

On completion of the invert wooden forms were set up in sections to shape the top part of the sewer. (Fig. 14.) The concrete was placed behind the forms by a Ransome concrete placer, horizontal type, set up at the bottom of the shaft. A 6-inch steel pipe line laid along the top of the drift carried the concrete under pressure of one hundred pounds per square inch to the face. Air was supplied by a five hundred and seventy cubic foot compressor with two storage tanks in line, to keep the pressure up during a blow. The longest placement was 2,040 feet from the source of supply.

Lean concrete was poured in the shafts to bring them down to standard manhole dimensions, and the tunnel was complete. In all, the underground work consisted of two hundred and fifty thousand man shifts, and only one accident resulting in loss of working time occurred. One crew had a narrow escape when a heading broke into an accumulation of water from a leaking main. The water rushed into the tunnel with such force that men were thrown to the ground, but fortunately all were able to make the shaft in safety.

Using the 5-foot 6-inch diameter sewer as an example to illustrate the tunnel costs, it is found that the cost of driving (exclusive of shafts) was $8.50 per cubic yard, the cost of timbering (including lumber) was $2.15 per lineal foot, the cost of concrete invert varied from $12.50 to $13.50 per cubic yard, and that of concrete sidewalls and crown varied from $9 to $10.50 per cubic yard.

Work on the outfall began August 1st, 1929, with the construction of two wharves, each 350 feet long by 20 feet wide. These wharves were adjacent to the line of the interceptor outfall and the line of the storm sewer outfall respectively. They were of standard construction: three-pile bents at 6-foot intervals with diagonal bracing and designed to carry a moving load of 25 tons. These structures were to serve a double purpose. Materials and supplies for the floating equipment could be loaded at any stage of the tide and in addition all of the storm outfall, and the first section of the interceptor outfall, could be laid by a steam crane working off the wharves.

After the completion of these structures about 200 piles were driven in line to form a breakwater. This gave a mooring ground for the scows at night, sheltered from the prevailing west winds. The floating equipment consisted of a pile driver, derrick, dredge, tugboat, two diving scows, and two pipe barges.

Two rows of five-pile dolphins were driven at 100-foot intervals and 40 feet on either side of the proposed centre line. These piles were all driven to a penetration of 50 feet below the sea bed and provided secure mooring for the working scows. Light cable was strung taut along both lines of dolphins (which were in exact line) and painted marks on the cable gave the spacing for the pile bents.

It had been decided to excavate a trench deep enough to keep the top of the pipe below sea bottom. Fortunately the profile of the bottom was fairly regular and only four changes in grade were necessary throughout the whole length to keep the depth of trench within the limits, 10 to 15 feet. The bottom width was 15 feet to give sufficient working space. (Fig. 15.)

The dredge started working about 350 feet from shore, just off the end of the east wharf, using a one and one-half yard bucket, easily filled at every dip in the soft bottom. Large sights with painted cross arms were erected on shore, marking the limits of the ditch, and the depth at first was checked by soundings. A man would ride the bucket, sounding line in hand, testing the bottom every couple of feet. This proved too slow, however, and an automatic depth check was evolved. This consisted of a weight moving in a slot up or down the "A" of the derrick. A light cable ran from the end of the weight over the headblock, out to the end of the boom and down to the bucket. The A-frame was marked off in equal spaces each of which corresponded to a vertical drop of one foot of the bucket. A tide gauge, marked with actual elevations, was nailed to each dolphin. In this way the dredge foreman was able to keep a close check on his depths, and a remarkably smooth ditch was the result.

When the dredge had completed a length of trench sufficient to permit the pile driver to operate, the next stage in the construction was begun. The driver was equipped with extension leads which let down 30 feet below the surface and the same 5,800-pound hammer which had been used on the test piles. Each pile was carefully lined in with the transit, operated first from shore, and later from central platforms erected as the work was carried seaward. Bents were spaced by numbered clamps set on the two taut cables, along the line of the mooring dolphins. A light rope was suspended between corresponding clamps and the piles were brought up against the rope before being centred with the transit.

Piles were let down gently until they just felt the bottom, and then driven carefully to the water surface. A follower pile completed the driving to the required depth. This was several feet above the cut-off level, as no chances were taken in driving too deep. Eight piles, or four bents, completed a set, and the pile driver then moved out of the way while readings were taken.

It was during these first readings that the total darkness on the sea bottom was recognized as a permanent condition. Submarine lights were tried but the slightest movement of the water gave such distorted vision that it was considered more dangerous than no light at all. However, it was a distinct handicap to work without being able to see anything and for that reason no pains were spared to make sure by mechanical checks that the work was correctly carried on below.

A long maple rod 2 inches by 3 inches, spliced and reinforced with metal straps, was let down to a diver who waited on top of the pile. The amount of cut-off having been figured, a metal rod with movable shoe was used. The cut-off length was set as the distance between the shoe and the end of the rod. It was then lowered to the diver who placed the shoe on top of the pile and drove a nail, lightly, opposite the bottom. When all the piles had been read and marked in regular order on both sides, shiplap was lowered and nailed along the piles to form a bearing surface for the saw.

The first cut-offs were made by two divers working with an ordinary cross cut saw, but this proved very slow and also very exhausting to the men. A chain saw driven with compressed air was then tried and proved very successful, although it had never before been used at such depths. The operation of the machine was improved by piping the exhaust air to the surface, and thus reducing the back pressure. With this saw, piles which required twenty minutes to cut by hand, now were off in less than five, and the divers were able to cut eight without a rest.

Considerable care was taken in using the power saw in the darkness at the sea bottom, especially when the cut was nearly through. Once free the piles shot upward with great force, a 20-foot piece frequently leaping clear of the surface as it came to the top. The two-way telephone used on all divers' equipment was a big factor in preventing accidents. As soon as a cut had been made air was shut off from the saw, and not turned on again until the divers had moved to their next position and were ready to start a new cut.

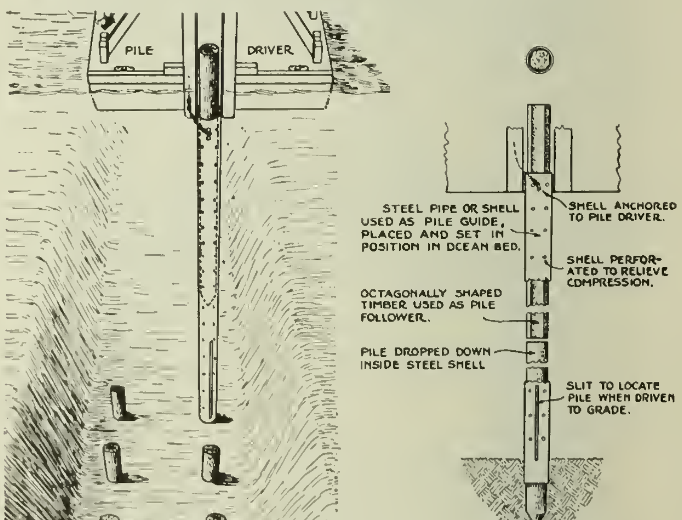

**Fig. 16—Steel Shell used in Driving Short Piles on Outfall.**

When a set of piles had been cut, the elevation of their new tops was checked again with the transit and rod. The sea was seldom perfectly calm and the instrument platforms, although well braced, were always subject to a certain amount of heaving and swaying. Final readings, as often as possible, were taken during periods of slack tide and little wind.

To cap the pile bents straight grained fir was used, each piece 10 inches by 14 inches by 12 feet long. The design had called for 10 inches by 12 inches but because it was impossible to secure exact readings at all times, it was sometimes necessary to notch the ends of the cap where they fitted over the pile.

A problem was to lower the caps so that they would arrive on the bents in a horizontal position and require a minimum of handling by the divers. For this purpose a pair of weighted tongs were devised and used. The caps were set centrally in the tongs on the deck of the pile driver and then lowered with the pile line. The divers manœuvred the timber into position by directions given to the pile driver foreman through the telephone. When in position drift bolts were driven through the cap and into the pile below.

**Fig. 17—Pile Driver ready to lower Bent Cap.**

Instrument readings were again taken to check the final elevation of the top of the caps. In all, four different sets of readings were taken from the time the piles were driven until the bents were capped.

When a pile foundation was completed the next operation was to lay the cradle on which the pipe itself would be placed. 85-pound rails formed the cradle and the gauge was fixed so that there would be a clearance of one inch between the bottom of the pipe and the top of any cap. The rails were assembled in pairs on the deck of the derrick scow and were spiked to light ties. These ties kept the rails at a uniform gauge and were spaced so that they would not coincide with any cap. Measurements obtained by divers before each pair of rails was slung indicated the correct allowance to make. It was essential that the underwater track should be laid in as perfect a line as possible so as to get good joints in the pipe.

A long wooden rod stiffened with metal plates was first used to line in the track but did not prove satisfactory. A heavy all-metal rod was no better. In both cases the movement of the water bellied the rod to such an extent that no true plumb line could be obtained. After pulling up and relaying several sets of rails due to the poor results obtained with the rods, it was found necessary to design something so thin that the movement of the water would have no effect.

To obtain this result a heavy plumb bob (50 pounds) was hung from the end of a very fine wire. The wire hung from a carriage which moved in and out along a swinging arm. This arm was three feet long and swung about a standard which was bolted to the deck of the derrick scow. The wire was reeled at the standard on a ratchet which controlled the drop.

To set the track in position, the derrick scow was brought to the scene of operations, the arm swung over the side and the plumb bob lowered to the diver waiting beside a cap. The diver directed the movement of this scow until the plumb bob was a foot above the cap. The instrument man on top, sighting on the wire then moved the carriage into position. The moment it was directly on line (line being the west flange of the west rail) the bob was released, dropping on to the timber. The diver felt for the resulting dent and marked the place with a nail. Three readings were taken, and if they coincided, the nail was driven in and the same operation repeated on the next cap.

The track was slung from the derrick scow with four chains, spaced so as to give a horizontal set, and lowered on to the caps where the divers placed the flange of the west rail along the series of nails. When it was in place the sling was released, track plates were bolted on at the joints and the rails were spiked to the timber caps.

The pile foundation and cradle were now ready to receive the pipe. This pipe, delivered to the job on scows, was in 8-foot lengths, each length weighing about 7½ tons out of the water. The pipes were lowered into place on a "banjo": a casting weighing 1,200 pounds and having a long lower arm. It was set into the pipe on the deck of the derrick scow and suspended from the boom by a cable which was shackled to one of the holes in the short upper arm of the "banjo." From the deck of the scow the pipe was lowered slowly to the sea bottom. Two divers, waiting on either side of the track below, received it and guided it into place between the rails, giving direction by telephone to the foreman on the scow above. When it was pressed home against the preceding pipe, the cable was slacked off and the "banjo" itself dropped loose and was withdrawn by a rope fastened to its heel and passing to a scow moored north of the scene of operations. Due to the care taken with the pile foundation and the cradle, no trouble was experienced in laying the pipe sections. Each one slipped home and gave a good tight joint. (Fig. 18.)

These joints were specially designed and gave a butt joint effect, yet were accessible for caulking. (Fig. 19.) Several materials were considered for this, lead wool being the material commonly used on work of this type. At the start of construction no caulking material had been selected, but it was decided to try Sika, a British preparation with great powers of adhesion and a very quick set.

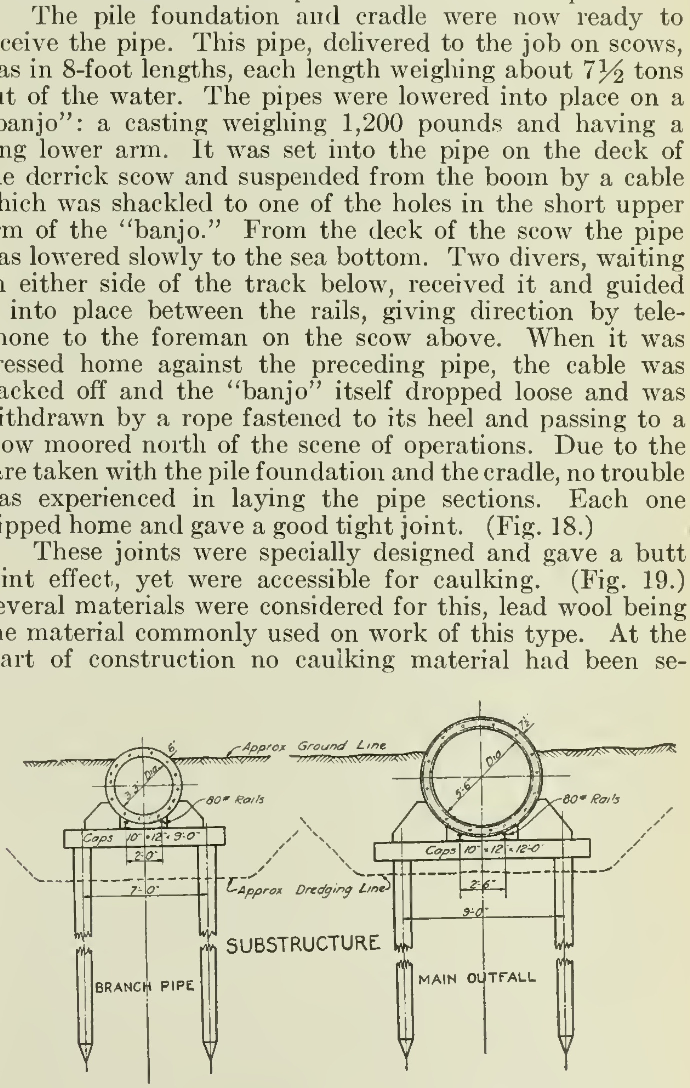

**Fig. 18—Cross Section of Submarine Structure.**

Sika and water were mixed together in the ratio of one to three, and cement was added to the mixture until it had a consistency like putty. This putty was placed in tin pails, covered and lowered to the diver on the pipe below. He removed the lid and quickly inserted the paste into the joint. The first set was almost instantaneous, that is, there was no tendency to dissolve in the water, and the final set took place within fifteen minutes, leaving a material harder than concrete. The pipes were caulked on the inside around the bottom and half way up, and on the outside from one rail over the top to the other, thus assuring a safe overlap in the joint.

This caulking material proved very satisfactory on this submarine work. It was pliable and easy to handle and could be packed into the joint without using tools. It was much cheaper than lead wool, which seems to have a tendency to rot and disintegrate after a short time in salt water. Examination of the first Sika joints made two years after they were put in showed them to be in good condition with no sign of cracking or breaking. However, lead wool would be preferable in any structure that was not absolutely rigid.

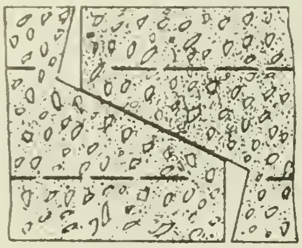

Fig. 19—Special Joint of Outfall Pipe.

Timber chocks cut to the shape of the pipe were placed on either side, and drift bolted through to the cap. Each joint was thoroughly inspected and final rod readings were taken on top of the pipe as a final check. When everything was in order the whole structure was covered over with fill to the level of the original sea bed.

At the 1,500-foot point there was a change in grade as the profile of the sea bed flattened out. Although no submarine manholes had been designed, it was decided to install one here to permit access at a point where grit might settle. The manhole was made on the job by breaking a hole in the 5-foot 6-inch diameter pipe big enough to take a 30-inch diameter pipe with 4-inch walls. Reinforcing wire from both pipes was twisted together and the saddle was filled inside and out with a thick layer of Sika, the inside layer being flush with the surface of the pipe. This T-pipe was lowered on a piece of 12-inch by 12-inch timber set along the arms of the T; no cover was put on at that time. Manholes were installed at 500-foot intervals from the half-way point to the end of the outfall as well as at the 350-foot point where work started and where the first change in grade occurred. (Fig. 20.)

From the 1,500 to the 2,000-foot point the sea bed seemed to be a little firmer and aided by summer weather good progress was made. At the 2,000-foot point, the sea bed, which had been flat and regular, was broken by a channel some 200 feet wide and 14 feet deep at the centre. This channel lay at an angle across the line of the outfall and was thought to be the scene of former dredging operations. Sand has frequently been dredged from the vicinity of the Spanish Banks and taken in scows to fill at some other place.

The outfall was laid across this channel in the usual way and a manhole was put in near the south side. Fill was placed right across and to a point about half-way up the pipe. Back-filling had always followed the pipe laying as soon as possible to prevent teredos getting into the timber substructure. Replacement of piles in the breakwater and to a lesser extent in the wharves had indicated what rapid destruction these teredos could cause. Sewage discharging on the foreshore gave protection to the wharf piles; but the breakwater, close to shore yet out of the sewage field, was vulnerable to attacks of these white worms. Authorities seemed to agree that the teredo did not operate in deep water. They were wrong.

Stormy winter weather forced the floating equipment to leave the outer end at the 2,200-foot point, and it was decided to take advantage of the high winter tides to complete the inshore portion of the outfall and also the storm sewer outfall.

The old outfall pipe had been lifted by the steam crane working off the wharf. Although carrying a hardened mixture of grit and sewage about one-third up the diameter, the pipes when cleaned were found to be in sufficiently good shape to relay on the west side for the new storm sewer outfall. These pipe sections were 5 feet inside diameter in about 5-foot lengths and weighed 4 tons per section. The interceptor outfall proper was completed from the starting point back to the outfall chamber, the joint being made a few feet out from the chamber at low tide.

Some months had elapsed in finishing this inshore work and it was the spring of 1931 when equipment was moved out to complete the last 800 feet of the interceptor outfall. A diver was sent down to mark the end of the completed ditch. He came up with startling news. A strong tide was running and for once the bottom was fairly clear. The old channel was washed clear of the fill, exposing the piles and caps, teredos had been at work, the substructure had collapsed in places and the pipe, vaguely visible, had sunk or was suspended on rails which had no support.

A more detailed examination with instrument readings revealed the extent of the damage. Nineteen lengths or 152 feet of pipe were off the correct grade, varying from half an inch to 3 feet. The pipe was wedged tight even in its deformed position and no large opening was found. Pieces of timber cut off and brought to the surface showed the caps and piles in the exposed channel to be riddled with teredos. The channel was explored and found to run on line with the edge of Spanish Banks and to have a distinct and active current. This current did not seem to follow any regular tidal condition but there was no doubt it was sometimes very strong. In fact since then, this same current closer to Spanish Banks is reported to have been the cause of several drowning accidents.

Fig. 20 T-Pipe with Manhole.

To repair the damage two lengths of pipe were blasted out to form an opening; sixty sticks of dynamite laid around the circumference were used to shatter each pipe.

The other seventeen lengths were then removed as well as the rails and the remainder of the caps, the piles were left in. It was decided to leave the channel open and use creosoted lumber and piling where there was no fill.

It was essential that no crack or split should occur in the creosoted material to allow the teredos to enter. Also it was desirable to limit the length of piles, a difficult problem in 75 feet of water. Various ways of splicing two piles were considered, and were discarded as impractical. Finally a scheme which gave good results was devised. Three steel pipes 18 inches in diameter of ⅜-inch plate were welded together to form a straight steel shell 75 feet long, perforated in several places and with a long slit near the bottom. This pipe was suspended in the leads and dropped slowly to sea bed, keeping a constant strain to prevent it sinking into the soft mud. Then a short straight creosoted pile, 16 inches in diameter or less, was dropped into the pipe and as it floated the follower was placed and driven down. This follower was a straight piece of square timber 16 inches by 16 inches and 70 feet long, with the corners adzed off smooth and with a thick rubber mat nailed to the bottom.

No cut-offs were made on the creosoted piles. As the top approached the required grade a diver kept inserting a rod with a long shoe into the slot near the bottom of the pipe. The height of the hammer drop was shortened and the pile was just tapped into place. Any slight variation was made up on the caps before they were creosoted. All creosoting was done under pressure sufficient to give a penetration of one inch.

After the channel section was restored, no further delays occurred. The long steel shell was retained and short straight piles were used to the end of the job. Although slower, this method paid by its economical use of timber. The sea bed to the outlet was very flat and level and somewhat firmer than close to shore.

For better diffusion it was decided to branch into three outlets at the end of the outfall. Two 36-inch steel pipes were laid north-east and north-west from the main outfall chamber for a distance of 50 feet. Two smaller chambers formed the terminus of the steel pipes. All the outlets turned upward and were provided with manhole covers big enough for a diver to enter. These chambers were cast on the wharf, taken out on a scow and lowered on to prepared pile platforms.

The last work done on the interceptor on land or sea was placing the manhole covers on the T-pipes. These covers were specially designed and had bronze fittings. The last cover set was at the 1,500-foot point. After a struggle it was forced into place and the information was telephoned to the tug. Three minutes later the smooth surface over the outlet was broken by three churning circles as the English bay interceptor went into operation.

The total cost of laying the outfall figured out at \$80 per lineal foot; of which the pipe cost about \$15 per foot, the lumber and piling \$12, and other material, rails, cement, Sika, etc., about \$3 per foot; so that the actual laying cost was about \$50 per foot for the 3,040 feet laid.

Regular inspection of the outfall has been made every spring and fall since the construction was completed. A fill of coarse gravel now extends almost the whole length on both sides of the pipe. It was found that submarine currents tended to shift the light fill and expose the timber. Last year even the channel was filled with gravel as a precaution against dragging anchors. No other improvements or adjustments have been made in any part of the interceptor. It has continued to work in a satisfactory manner and to fulfil the object for which it was constructed —freedom of the foreshore from pollution, and clean and sanitary bathing beaches.

The entire project was carried out by the Vancouver and Districts Joint Sewerage and Drainage Board. Mr. E. A. Cleveland, M.E.I.C., was chairman of the Board, Mr. J. M. Begg, M.E.I.C., was chief engineer of the Board, and Mr. R. S. Lea, M.E.I.C., acted as consultant. The total construction cost was \$1,575,000.

# Electric Soil Heating

*J. W. Tomlinson,*
*Junior Engineer, Winnipeg Electric Company, Winnipeg, Man.*

**Paper presented before the Winnipeg Branch of The Engineering Institute of Canada, March 1st, 1934**

SUMMARY.—The paper discusses the utility of soil heating, describes the equipment needed, gives figures as to the cost of installation and operation, and states some actual results, both in hotbeds and greenhouses.

Everyone is familiar with the comforts and conveniences afforded by electricity in the home. The economies and higher efficiency made possible by the application of electricity to our industries are also generally known. The extension of electric service into rural districts has made possible the application of electricity to yet another field, namely horticulture. All market gardeners, florists and similar growers find that for early plant growth, extra heat other than that provided by nature is a necessity. In the past this has been supplied in the form of steam heated greenhouses and manure heated hotbeds. During the last few years it has been proved that electricity can replace these as a source of heat for growing more than fifty kinds of crops. Electric hotbeds are gradually replacing manure hotbeds. Directly heating the soil on propagating benches for the starting of all kinds of cuttings and for forcing various greenhouse crops can be more than paid for by the saving in fuel, to say nothing of improved growing conditions. Also, heating the soil for outdoor crops has proved very satisfactory in growing intensive high priced crops.

It is of interest to know that the feasibility of supplying heat directly to the soil by electricity was first realized by a Norwegian engineer, more or less by accident. While examining a network of overloaded underground cables he noticed that the vegetation over them was greener and more advanced than elsewhere. From this he conceived that the deliberate conversion of electricity into heat by means of a buried resistance would result in an efficient and easily controllable means of promoting plant growth. During 1922 his experiments were successful, in fact so successful that inside of five years over 12 per cent of all the hotbed sash in Norway was electrically heated. This development was almost paralleled in Sweden, where we find 5,900 square yards of electric hotbeds by 1927 and 24,000 square yards in use by 1929. Denmark, Holland, France, Germany and England have adopted the idea more or less in inverse proportion to the cost of electric power in the different countries. About 1926 saw the introduction of electric soil heating in the United States. By 1929 the power companies became interested in its possibilities with the result that by 1932 over one million kilowatt hours were known to have been used in this way, and in spite of low price levels and other disturbing features the consumption for 1933 is already four times that for 1932. The records show that 2,000 thermostats and 330,000 feet of cable were sold between May 1932 and May 1933. This increasing use everywhere must mean that the heating of soil electrically is economical as well as more efficient.

It was not long before the Canadian power companies undertook to introduce electric soil heating to the Canadian grower. In doing this they have a fortunate advantage in the fact that power rates are on the average much lower than in other countries where electric soil heating has already proved a commercial success.

In 1932 numerous installations were put in in the market gardening districts around Montreal where the Shawinigan Power Company has been the chief sponsor. In Ontario the Hydro-Electric Power Commission has taken an active interest in several installations. In Manitoba the Winnipeg Electric Company is sponsoring experimental installations, and in British Columbia the B.C. Electric Company has already proved its practical value.

### Advantages

The fact that the power companies have been behind most of the experimental installations would indicate that electric soil heating must constitute a desirable load. It is true that the transforming of kilowatt hours into vegetables and flowers can be made profitable both to the producer of kilowatt hours and to the producer of vegetables and flowers. From the power companies' standpoint:—

(*a*) The electric hotbed or propagating bench consumes annually an average of 1,000 kilowatt hours per kilowatt of connected load, which compares favourably with most other electric appliances.

(*b*) The greatest consumption is during the early spring months when water power is most plentiful.

(*c*) Experiments show that it is at least 70 per cent night load and therefore to a large extent an off peak load.

(*d*) For the most part it is connected to underloaded rural distribution feeders, helping them to stand on their own feet with little or no new capital expenditure for extra line equipment.

From the grower's standpoint there are many proved advantages, such as:—

(*a*) The soil temperature best suited to any particular crop can be maintained by thermostatic control, thereby improving growing conditions as well as insuring against sudden change or extreme weather conditions.

(*b*) Crops may be advanced or retarded at will. Often bringing a crop on the market on a certain fixed date, such as flowers at Easter or Christmas, means a great deal to the grower. With other crops, being able to place them on the market ahead of their competitors means much higher prices.

(*c*) The electric hotbed can be used in the fall of the year as well as the spring, since constant temperatures can be maintained as the weather grows colder, whereas this is impossible with manure heat since it loses its heat when most needed.

(*d*) Several successive crops can be raised in the hotbed in one season without removing the soil. With manure heat the bed has to be emptied every six weeks or so and left a considerable time to allow the new manure to start heating.

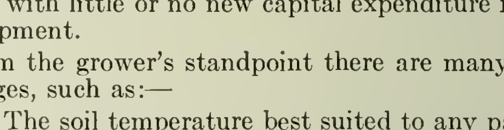

**Fig. 1—Cross Section of Typical Electric Hotbed.**

(*e*) The electric hotbed is clean and free from ammonia fumes. This eliminates many forms of insect life and plant rot.

(*f*) A uniform temperature is maintained throughout the entire bed, a big improvement over the concentrated heat of a manure hotbed.

(*g*) The hotbed temperature can be readily lowered as desired and finally made into a virtual cold frame by merely adjusting the thermostat, yet the heat is always available and will automatically look after unexpected cold weather.

### General Layout

In its experimental stages the use of electricity to heat propagating benches and hotbeds was accompanied by a vast amount of detail regarding special construction features, mostly aiming to eliminate heat losses and thereby conserve electric power. For example, early experimenters claimed that in dull wet seasons as much as 22 per cent could be saved in kilowatt hours by totally insulating the hotbed from the ground by means of air spaces or cinders. This of course involved digging a pit to allow 6 to 8 inches of cinders under the entire bed and a one-foot embank-

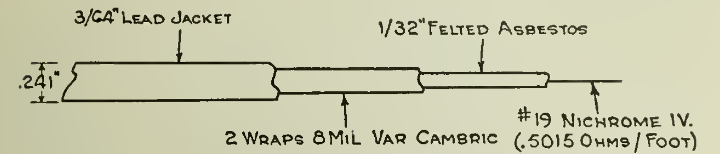

**Fig. 2—Lead Covered Cable used in Soil Heating.**

ment on all sides. While this no doubt prevented considerable heat losses it made construction more difficult and expensive and tended to make the job too complicated to appeal to the average grower. Also this bottom insulation was found to have a detrimental effect on the growth in the bed; this was especially noticeable in longer season crops such as cucumbers, celery, etc. However, 22 per cent power saving could not be overlooked and therefore total insulation was recommended by early authorities.

More recent development indicates that these heat losses can be eliminated by changing the location of the cables instead of bottom insulation. Numerous other examples could be cited showing where construction has been simplified without sacrificing efficiency. However, consideration as to layout is still very important for hotbeds, such as southern exposure to get the maximum benefit of the sun, shelter from prevailing winds and good natural under-drainage. Having chosen a site with these things in mind the usual construction that applies to manure hotbeds has proved quite satisfactory.

### Heating Elements—Types Available

The most important feature of electric soil heating is, of course, the heating elements. There are two main types

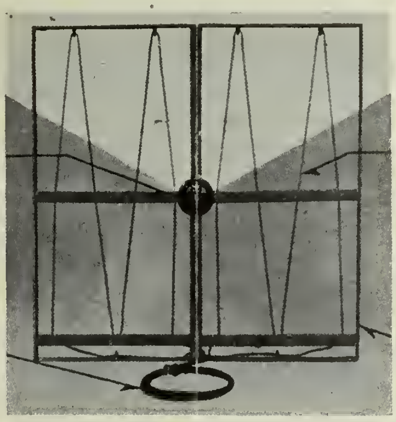

**Fig. 3—Plug-in Unit Open Element Type with Built-in Thermostat.**

of elements offered at present and both have their good points. The most popular type consists of a single nichrome wire, insulated and lead covered, which is designed to be buried in the soil 4 to 6 inches below the surface. The conductor used has a resistance of 0.5 ohms per foot and when 60 feet is connected across 110 volts it gives a 400-watt element. This amounts to 6.7 watts per foot which is not a hot wire element and when buried in moist soil the heat is gradually dissipated throughout the soil. The 60 feet of lead-covered cable gives a very flexible element, which can be laid out with any desired spacing without causing "hot spots" in the soil.

The other type of element consists of an open, low temperature resistance coil, strung on a light frame. The whole unit is slid into a special air compartment immediately below the growing soil. This type of heater has the advantage of supplying the heat directly to the air, not being hindered by the lead covering; also the whole element can readily be removed and used elsewhere. However, the necessity for special air space under the bed tends towards higher heat losses and has the aforementioned bad effects of bottom insulation.

### Capacity Required

The size of heating elements required of course varies according to the size of the hotbed and can best be dealt with in terms of heating capacity or heat flux required per square yard of bed. The installed capacity generally recom-

**Fig. 4—Fitting Element into Air Compartment.**

mended to safely cover Canadian weather conditions is 100 watts per square yard. The capacity actually necessary depends upon the average difference in temperature inside and outside the frame and a factor of safety to allow for weather conditions such as high winds or sudden frosts. Data obtained from experiments using 100 watts per square yard shows that in the greenhouse the heaters were only in use 30 per cent of the time. From this it is obvious the same heating elements could have been spread over double the area and still leave an ample factor of safety for greenhouse work.

Similarly for a fairly well constructed hotbed, while the factor of safety has to be larger because the bed is exposed to outdoor temperature, the whole unit is more enclosed and therefore holds its heat longer. In one test it was found that with an outdoor temperature ranging from 26 to 32 degrees F. during the night with a fairly strong wind, 100 watts per square yard maintained a temperature of 70 degrees in the hotbed without any difficulty, the heat being on only 60 per cent of the time, leaving 40 per cent unused capacity. Opinions would no doubt differ as to whether to leave this unused capacity as a factor of safety for temperatures below 28 degrees F. or to cut down the capacity and allow the temperature in the frame to fall below the thermostat setting if the outside temperature falls below 26 degrees. From the author's experience it is preferable to spread the element over more area and use more nearly its full capacity. The larger crop raised would more than offset any setback there might be on account of temperature dropping say from 70 to as low as 40 degrees for a few hours during an exceptionally cold night. This method is sure to meet with the approval of the grower because he will not require as much equipment to heat his frames, the power company will be benefited by less peak load but the same or more kilowatt hours, and the manufacturers of the equipment will also benefit in the long run, if not at first, because the biggest obstacle in selling electric soil heating is the initial outlay for equipment.

An argument against reducing the capacity per square yard of bed would be that the season when the bed can be used safely is immediately shortened. In Manitoba, at

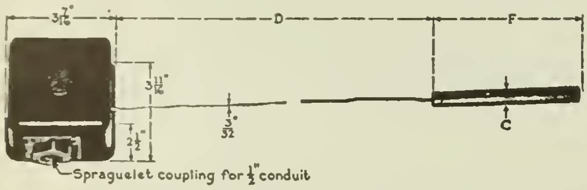

Fig. 5—Soil Heating Thermostat.

least, the electric hotbed is not practical during the period when below zero weather may be expected. The variety of crops which can be grown do not command high enough prices to warrant heating frames if the average night temperature is below 20 degrees F. With the manure hotbed the season does not start until the average temperature is above freezing so that the use of the electric hotbed lengthens the season considerably if it is started when the temperature averages 20 degrees F. The mean temperature curve for Winnipeg for the last four years crosses the 20 degree F. line about March 15th, which gives two and a half to three months during which extra heat is required for spring crops. A similar period in the fall of the year makes a total of five months during which low priced crops can be grown profitably in Manitoba. In the Maritime provinces hotbeds can be used all winter. Soil heating in the greenhouse can be used all year and is most useful during severe weather.

The general opinion of a meeting of representatives of several power companies and government engineers recently held in Hamilton was that the recommended heat flux could safely be reduced to 60 to 75 watts per square yard for spring and fall use, rather than 100 watts as was originally recommended.

### Thermostatic Control

Large variations in temperature from day to day and between night and day necessitate regulation of the amount of heat supplied at different times. This checking and regulating can be done manually by means of a four-way switch, and the electric heat will still be ahead of the manure heat, but the fact that it can readily be done automatically by means of a thermostat is where electric heating shows its real superiority. The electric thermostat is on the job twenty-four hours a day to give the soil just as much heat as it requires and no more.

Thermostats especially designed for soil heating are equipped with a soil bulb which is connected to the thermostat by means of a capillary tube. This bulb is quite sensitive and will actuate the thermostat when the temperature varies about 3 degrees above or below the thermostat setting, making an operating range of 6 degrees at the soil bulb which is hardly noticeable at the surface of the soil.

These thermostats are reliable and at their present price are not too expensive if their full capacity, 2,800 watts, can be utilized. However, for smaller installations, which must be sold first to introduce the larger ones, a smaller and cheaper thermostat would help. A thermostat large enough to control 1,000 watts would suit small installations or smaller units of a big installation. Even large installations are better controlled in smaller units as this gives a factor of safety to allow for failure of any one thermostat. Also different temperatures in different parts of the same bed may be desired to force or retard that portion of the crop.

### Initial Cost

It would be difficult to compare the initial cost of the two types of elements and also rather unnecessary, since more recent improvements have caused the lead-covered cable to be almost universally adopted as the most efficient and adaptable means of supplying the heat to the soil.

The cost of equipment in this district, including thermostatic control, ranges from \$2.60 per square yard in small beds to as low as \$1 per square yard in larger installations. For example, a hotbed of 10 square yards area at the new rating of 75 watts per square yard would require two 400-watt elements costing \$5 each, a joint box and thermostat, making a total of say \$26, depending on the type of thermostat used. This amounts to \$2.60 per square yard of bed. A larger bed, say 80 square yards, would require eight times as much heating cable costing \$80 but only one thermostat, making a total cost of say \$96, or \$1.20 per square yard of bed.

This equipment should give service for several years without further cost.

### Results

In all types of crops, both vegetable and flower, faster growth without sacrificing sturdiness of plant or strength of roots is the aim of electric soil heating. By maintaining the soil temperature higher than the air temperature the effect is first shown in more vigorous root growth which soon results in stronger foliage and finally choicer fruit. Some types of crops will not stand quick forcing to full maturity but can be given a flying start and then encouraged at a slower rate to allow proper maturity. As much as 50 per cent of the time can be saved in germinating practically all seed, but after germination the temperature must be lowered somewhat to conform with the former habits of the plant. When this is done as high as 33 per cent saving in time between germinating and transplanting into the field or garden is effected. Short season crops such as radish, lettuce, cucumbers, etc., which can normally be matured in six to twelve weeks, can be forced to maturity with soil heat in from four to nine weeks. As an example, in Vancouver cucumbers were matured one month earlier, thereby collecting \$1 per dozen more by being on the market before the normal crop. In California 1/10 acre of cucumbers in the field were heated electrically and maintained 25 degrees higher than a similar unheated plot. The heated plot matured in forty-one days, a month earlier than the check plot, and yielded twice as many cucumbers with an additional \$150 revenue from the plot, against which was charged 2,400 kw.h. at 1 cent per kilowatt hour or \$24.

In the propagation of cuttings, much time can be saved because here the primary concern is the forcing root growth. For this reason the heated bench is not boxed in, only the soil being heated, the air temperature being more or less governed by the greenhouse temperature. But more important than the saving in time is that a very much higher percentage of the cuttings will take hold. This is to a large extent due to the fact that the soil, being warmer than the air, evaporates moisture at the surface rather than condenses it, as takes place when the air is losing heat to the soil. This automatically prevents black leg and stem rot, diseases very common to the propagating bench. The lower air temperature also discourages the development of aphis and other forms of insect life which menace the foliage of many plants.

Many of these improvements cannot be evaluated accurately in dollars and cents but will not be ignored by growers who are looking for ways of meeting keen competition and of outwitting backward or unfavourable seasons.

To what extent these results can be applied to local conditions can only be answered by trying them out locally. Sponsored by the Winnipeg Electric Company, first hand experience with electric soil heating was obtained at the Tomlinson greenhouses, Bird's Hill road, where a

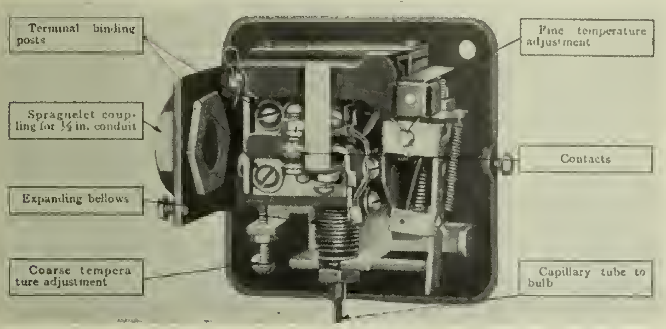

**Fig. 6—Interior of Thermostat.**

400-watt, lead covered heating cable was installed on the greenhouse bench. The temperature was controlled by means of a small water heater type thermostat. At list prices, the total cost of equipment was approximately $13. The bench was used for the germination of expensive varieties of flower seeds, the aim being to improve the percentage germinated. The power was turned on February 18th and was operated along with a check bench exactly similar but without electric soil heat. By March 10th, twenty-two days, several batches of seed were germinated. The bench was kept at a minimum of 70 degrees F. The average temperature of the check bench was 55 degrees F. The power used was 45.3 kw.h. in twenty-one days, or 2.1 kw. per day.

Germination Test Results

| Variety | Time germ. htd. bed | Time germ. chk. bed | Percentages: Germ. htd. bed | Germ. chk. bed | Damp off htd. | Damp off chk. |
|---|---|---|---|---|---|---|
| Lobelia | 4 days | 7 days | 90 | 75 | 0 | 20 |
| Pansies | 6 days | 6 days | 75 | 75 | 0 | 0 |
| Balsam | 4 days | 6 days | 100 | 80 | 0 | 30 |

Electric Soil Heating in the Cold Frame

When the propagating season was over, about March 30th, the same equipment, heating cable and thermostat, was utilized as a prevention against sudden frosts in the cold frame. In this instance the object was to supply just sufficient heat to keep the temperature a few degrees above freezing; thus the 60 feet of cable of 400 watts heating capacity could be spread over a larger area. In this case it was strung around the perimeter of a cold frame 7½ feet wide and 22 feet long. The thermostat was set to go on at 36 degrees and off at approximately 46 degrees F. While no autographic record was kept of the number of times the apparatus was in service, there were at least three nights within two weeks that the electric heat came on and prevented damage by frost; which is proved by the fact that frost was evident in other cold frames even though they were covered with heavy carpeting.

By stringing the heating cable around the sides of the cold frame, close to the glass, heat was supplied close to the source of most of the cold draughts, thereby pre-heating the air entering the frame before it spread or did any damage. At the same time this allows the cable to service more area, keeping down the cost per square yard for equipment.

Electric Soil Heating in the Greenhouse

The soil heating equipment used in the cold frame, and previously on the propagating bench, was now moved back into the greenhouse to be used in the forcing of cucumbers.

The 60 feet of cable was buried along each side of a row of cucumber plants, when they were transplanted from boxes to the greenhouse bench. The cable was laid three inches below the surface of the soil, and approximately five inches from the row on each side. The 60-foot length serviced twelve plants; as a check the row of plants continued further but without any soil heat.

The thermostat was set to turn the heat on when the soil temperature dropped to 56 degrees, turning off again at about 67 degrees, thus maintaining an average of approximately 62 degrees F.

Power Used

| Date | Hours on (Approx.) | Kw.h. Used | Kw. per Day | Remarks |
|---|---|---|---|---|
| May 18th to 25th | 32 | 13 | 1.85 | Heat on 3.5 to 5.0 hours per day. |
| May 25th to June 1st | 28 | 11.2 | 1.60 | Marked difference in size htd. plants in bud. |
| June 1st to 14th | 40 | 16.0 | 1.23 | Small fruit in htd. plants. Chk. plants in bud. |
| June 14th to 24th | 24 | 9.7 | 0.97 | Htd. plants clipped to stop growth, force fruit. |
| Total 37 days | 124 hours (3.4 hr/dy) | 49.9 Kw.h. | 1.35 Kw./day | Weather exceptionally hot for June. |

Although quite warm weather prevailed throughout the test, the heat came on almost every night from May 18th to June 15th and occasionally up to June 24th.

Further tests are needed to see if a higher temperature could safely be used for faster forcing, which would be applied during the day as well. However, it would probably be necessary to supply artificial lighting to lengthen the day, so that the plants would mature earlier, rather than grow too large instead of bearing fruit.

The spring of 1933 will be recorded as an exceptionally good growing season, weather conditions being about a month advanced compared to other years. For this reason the check plants with natural conditions showed quick growth and the artificially heated plants did remarkably

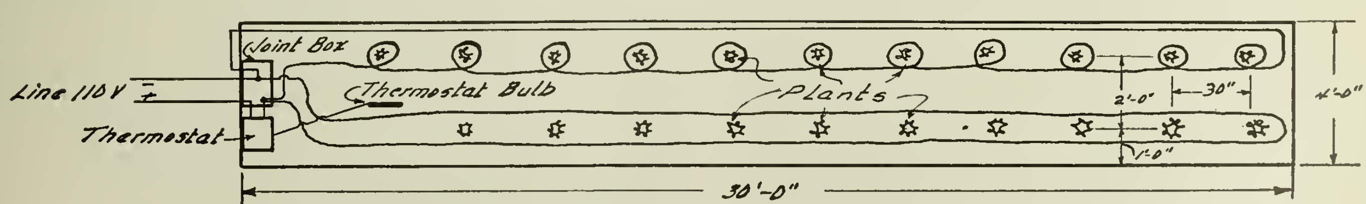

**Fig. 7—Two Methods of Applying Heat to Plants on Greenhouse Bench.**

**By encircling each plant the soil temperature was raised 17 degrees F. near the plant, whereas the lower method raised the soil temperature 10 degrees F. using the same amount of power.**

well to show superiority in size and quality. With average June weather the difference would be more noticeable, and the equipment would have been used for more hours each day.

### Hotbeds

The principal use of soil heating, however, is the electric hotbed. Here electricity replaces manure as a source of heat. In order to give it a fair trial both an experimental installation and a practical farm installation were started last spring. The experimental installation was operated by the Agricultural College, the main object

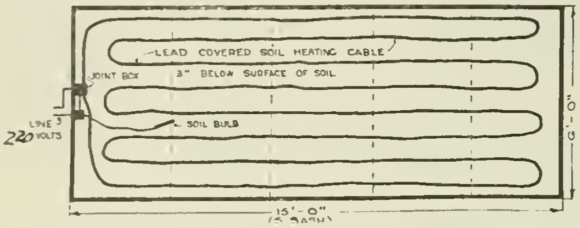

**Fig. 8—Five Sash Hotbed, 120-foot heating cable.**

being to test out a standard electric hotbed under local conditions. The bed was laid out with the recommended heat flux of 100 watts per square yard, which was supplied by 120 feet of lead-covered cable buried 6 inches below the surface of the soil. The temperature was controlled by a soil heating thermostat with the soil bulb also buried in the soil. With the thermostat set at 70 degrees F. no difficulty was experienced in maintaining this temperature in the soil, but it was found that the air temperature fell to as low as 36 degrees even though the lower soil was above 70 degrees. This was mostly due to too heavy a layer of soil above the heating cables, preventing the heat from rising to surface fast enough to replace heat lost through the glass.

Benefiting by this experience an installation of 16 square yards area was installed at the Tomlinson greenhouses. This bed was laid out with a heat flux of 75 watts per square yard supplied by lead-covered cable buried only 3 inches below the surface. In order to further insure against too great variation between soil and air temperatures another 25 watts per square yard heat flux was supplied in the form of 50-watt tungsten lamps suspended from the ribs which supported the sash. It was found that with the heating cables nearer the surface the auxiliary air heating was not necessary, the largest variation between soil and air temperature being 10 degrees. This small difference is not of any consequence and would not warrant

Comparison of Heated Bed and Check Bed Temperatures

| Date | Outside Temp. Degrees Fahr. | Thermostat Setting Degrees Fahr. | Soil Temp. Degrees Fahr. | Air Temp. Degrees Fahr. | Check bed Temp. Degrees Fahr. | Notes |
|---|---|---|---|---|---|---|
| April 12 | | | | | | |
| a.m. | 19 | 70 | 67 | 62 | 24 | Radish showing |
| p.m. | 25 | 70 | 68 | 68 | 37 | (2 days). |
| April 15 | | | | | | |
| a.m. | 27 | 70 | 55 | 62 | 30 | Thermostat not on. |
| p.m. | 45 | 70 | 70 | 72 | 55 | Lights on full time. |
| April 19 | | | | | | |
| a.m. | 30 | 70 | 68 | 67 | 36 | New thermostat put in |
| p.m. | 42 | 70 | 71 | 76 | 50 | service |
| April 23 | | | | | | |
| a.m. | 40 | 65 | 63 | 62 | 46 | Radish showing in check |
| p.m. | 65 | 65 | 70 | 78 | 75 | bed (1½ days). |
| May 1 | | | | | | |
| a.m. | 46 | 65 | 66 | 62 | 60 | Pulled sample of radish, |
| p.m. | 60 | 65 | 75 | 80 | 75 | elec. bed (19 days). |
| May 8 | | | | | | |

Thermostat only on about three hours each night.

special air heating equipment and could be further reduced by placing the heating cables still closer to the surface.

The first crop grown in this bed consisted of radish, spinach and leaf lettuce, which were seeded on April 10th. The radish were fully germinated in three days, thinned out on the seventh day and were harvested between May 9th and May 12th. The manure hotbed, operated as a check bed, took five days to germinate, needed no thinning out, and the first radishes were pulled May 18th.

Between April 15th and April 19th, thermostat trouble caused temperatures in soil to drop too low at night; the lights were switched to a separate circuit so that they could be left on regardless of the thermostat. This supplied sufficient heat to keep out frost while obtaining a new thermostat.

Power Consumption and Cost Data

| | Outside Temp. Degrees Fahr. | Hotbed Temp. Degrees Fahr. | Kw. per day | Kw. per sq. yd. | Hours on (average) |
|---|---|---|---|---|---|
| April 10th to 15th | 27 to 45 | 70 | 20.1 | 1.25 | 12 |
| April 15th to 19th | 26 to 50 | 60 | 5.2 | 0.33 | 24 (lights only) |
| April 19th to 24th | 30 to 60 | 68 | 15.7 | 0.98 | 9.3 |
| April 24th to May 1st | 46 to 65 | 66 | 14.3 | 0.89 | 8.4 |
| May 1st to 8th | 40 to 64 | 64 | 13.1 | 0.85 | 7.7 |
| Average—25 days | 26 to 65 | 66 | 14.85 | 0.93 | 8.7 hours |

In figuring the average, the period from April 15th to 19th was not considered, since the thermostat was out of order.

The total energy used to grow a crop of radish and spinach in twenty-nine days was 392 kw.h. or about 14 kw.h. per day for 16 square yards of bed.

### Improvements from Experience

Every year has seen improvements in the construction of beds, types of elements and their location in the soil, thermostats, and also in the price of power supplied. All have helped to build up an increasing margin of superiority for electric soil heating.

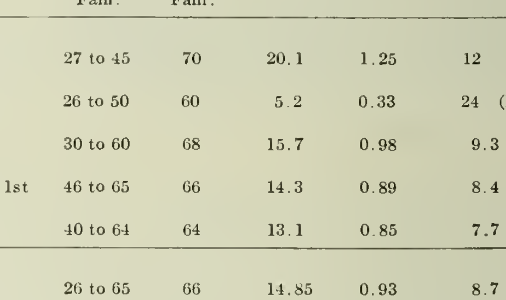

**Fig. 9—Comparison of Temperatures in Unheated Greenhouse Bench, February 10th, 1933.**

There is still considerable argument as to where the element should be placed—deep in the soil, just below the surface, or at the surface.

Repeated tests by the National Project and co-operating growers during the past winter and spring have shown that surface heating is entirely practical in hotbeds and coldframes. By applying the heat directly at the point where it is most needed, power consumption has been reduced and the need for special insulation and laborious or expensive construction obviated. Any hotbed which is well drained, protected from winds, and free from cracks and openings may be made into a satisfactory electric hotbed by laying electric soil heating cable on the soil surface at the time the seeds are planted.

Plants grew in contact with the heating cables without injury. Germination was quicker, plants grew faster, and in the tests reported the plants were sturdy and had larger root systems. Power consumption was considerably reduced during mild weather, and because of the quicker response to falling temperatures there was better protection from frosts and higher night temperatures during periods of cold.

The lead-covered element seems to be reliable, flexible and durable, and its heat flux of 5.7 watts per lineal foot

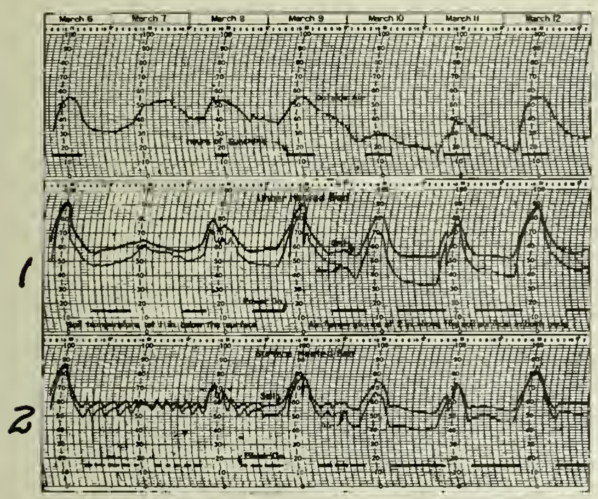

**Fig. 10—Outdoor Soil and Air Temperatures.**
**(1) Underheated Hotbed.**
**(2) Surface Heated Hotbed.**

is ideal where 100 watts per square yard is used. However, with a reduction to 60 to 70 watts per square yard an element of 5 watts per lineal foot would spread the heat better.

One of the methods of saving power in any type of electrically heated hotbed is to cover the beds with mats at night. In an eight day cold weather test burlap bags filled to a thickness of 4 inches with straw resulted in a saving of 33 per cent in the power used in an identical bed without mats. Double glazing of the sash proved to be almost as effective for conserving the heat of the beds. The double glass was effective for twenty-four hours each day whereas the mats could only be used at night.

Persistent inquiry into the matter of thermostats has failed to produce a soil heating thermostat at a price suitable to smaller installations. Capacity and sensitivity could well be sacrificed to keep the thermostat cost down to not more than equal the cost of the equipment it is to control.

Many European installations still use manual control, generally a four-way stove switch giving three different heats on any installation of over 800 watts capacity. While this system has all the inherent disadvantages of manual control, it lends itself admirably to special night rates for power. Power companies in many cases find that they can more profitably supply off peak load at half price rather than install new distribution equipment to supply twenty-four-hour demand. For example, in Norway power can be used between 6 p.m. and 7 a.m. at from 0.4 cents to 0.6 cents per kilowatt hour. A study of our own charts from the newer type of hotbed indicates that 90 per cent of the time the soil heating load automatically confines itself to these hours.

In conclusion it is suggested that the following points require further study, namely:

(1) The proper soil and air temperatures required for various plants and for various stages of plant growth.

(2) The proper electrical capacity to maintain good growing conditions under different weather conditions.

(3) A comparison of manual and thermostatic control under local conditions.

(4) The use of electric light to vary the length of day, in conjunction with electric soil heating.

(5) The best method of selling electric soil heating to the grower.

The electric hotbed is not a luxury—it is an agricultural tool designed to make the work of the grower more pleasant, more efficient and more profitable.

Generally speaking a large installation can be made at a lower cost per bed than a small one, and if one bed can justify itself economically it follows that several should be even more profitable.

There is undoubtedly a splendid field for electric soil heating in Canada. This is evidenced by a summary of operation of electric hotbeds by the Shawinigan Power Company for 1933, which shows twenty-two installations totalling over 2,000 square yards of beds which used 50,000 kw.h. during the early spring season. It is to be hoped that there will be a continuation of the splendid co-operation and interchange of experience amongst all who are engaged in its development.

## Engineers in the Public Service

Ever since Confederation, Canadians have justly taken pride in the quality of the engineering work carried out by their government departments, and in the professional competence and personal character of the members of the departmental engineering staffs.

Engineering work in the public service, whether Federal or provincial, is necessarily performed under conditions differing materially from those obtaining in the case of private enterprises. The government service presents (or used to present) a greater degree of security of tenure, and there was the prospect of a modest pension or retiring allowance at the end of one's active career. Accordingly, the majority of engineers in government employ have in the past been content with salaries somewhat less than they could have obtained from private employment, and have regarded the stability of their employment as some compensation for their lower pay.

Conditions such as these appeal particularly to the type of man who appreciates freedom from financial uncertainty as enabling him to centre his entire interest on the technical or administrative problems of his special line of engineering work. The government services have, in fact, secured on this basis men of outstanding merit, who have rendered disinterested service to the country, and whose work has won general approval from their professional brethren outside the service.

When a change of government occurs, retrenchment in the civil service is always one of the war cries, and the newly elected legislators are apt to hasten to apply the pruning knife. On these occasions the statement is often made that the civil servant is overpaid and underworked. This is certainly not correct in regard to those holding responsible engineering positions in the professional branches. Persons who have had the most intimate contact with the officials of the engineering branches of government departments and are best able to judge, will be the first to admit this. On the other hand, the layman, who has only the vaguest idea of an engineer's actual duties and responsibilities, is apt to take such a statement as gospel without troubling to make enquiries as to its truth or falsehood, and does not realize the necessity of effective engineering work if public funds are to be used economically.

The engineering departments of our public services are responsible for the economical and efficient expenditures of very large sums of money, and deal with new construction as well as the maintenance of our public works. It is regrettable that their advice as to the economic feasibility of these various projects is seldom asked, and if asked, is even more rarely heeded. The government engineer is too often required merely to carry out instructions from his executive chiefs and proceed with the design and supervision of a given piece of work without being asked to make the necessary preliminary studies as to whether it is economically justifiable. Should the project prove unremunerative or ineffective after completion, the engineer is sometimes blamed for this fact, even although he has had no voice whatever in the decision as to the advisability of the work. In any case, when instructed to proceed with an undertaking, its design and construction receives the same careful and competent attention, whether it involves a hundred millions for a Welland canal, or more modest sums for topographical mapping, or the construction of roads in our national parks. The high reputation borne by Canadian engineers in countries outside Canada is in no small degree due to the achievements of the engineers in the Dominion and provincial government services.

In any organization which carries out engineering work the best results can only be obtained if the staff operates on a basis of harmonious co-operation between the different departments, if its members feel that their positions are reasonably secure, if they are adequately paid, and if their work is appreciated by those to whom they are responsible. Events which tend to break down the morale of the staff and cause apprehension on such points as the above, cannot fail to affect the quality of the work performed.

To deal effectively with his technical problems, which are sufficiently worrying in themselves, the engineer, whether in private work or in government employ, must be able to give his mind entirely to the engineering questions involved, so that he may decide correctly as to the best and most economical methods of doing the work which has been placed in his charge.

Even in times of stress, when the necessity for retrenchment makes changes in staff or reduction in pay unavoidable, he should feel that such measures will not be taken arbitrarily, or without due consideration of his interests. The nature of engineering work is such that in many instances the money saved by dispensing with the services of the more experienced men, is only a fraction of the amount which may be wasted by a single major error in judgment, or wrong decision on a question of construction or maintenance.

The recent course of events in Ontario affecting engineers in the employ of the provincial government, has led to some doubt as to whether such points as those just discussed have received due consideration from the authorities concerned. Recognizing this possibility, the Council of The Institute proposes to bring it to the attention of the Premier of the province, in the hope that such measures will be taken as will reassure the engineers concerned, ensure the continuance of efficiency in the engineering work of the province and promote real economy in the provincial technical departments.

# The President's Visits in the West

It would be ungracious to allow this issue of The Journal to be published without an expression of my appreciation of the hospitality extended to me during my visit to the Western Branches of The Institute.

It is not only the entertainment which these Branches gave to me as your President, that I wish to acknowledge gratefully, but what is even more significant, the sympathetic hearing accorded to my remarks and addresses on the affairs of The Institute.

In Victoria and Vancouver local committees had arranged beforehand for the meetings and the entertainment of those attending the joint convention of the American Society of Civil Engineers and The Engineering Institute of Canada. The successful issue of these arrangements has been recorded elsewhere, but it was gratifying to find that in a crowded programme, these Branches, at informal lunches and in personal conversations, made time for, and gave close attention to, the discussion of the problems facing The Institute.

Reluctantly leaving Vancouver, where Mr. Cleveland and his able committees, both social and technical, had made the meetings so enjoyable, I proceeded to Lethbridge, where the members of that Branch listened to my address at a dinner meeting held at the Marquis hotel on July 20th. The following day the Branch, under the chairmanship of Mr. C. S. Donaldson, invited me to join the members on a motor trip through the Glacier National Park and the Waterton Park. This afforded a unique opportunity of seeing a very beautiful part of the Rocky Mountains of which I find it difficult to adequately express my appreciation and admiration.

Arriving at Calgary on the 22nd, the secretary of that Branch met me, and early next morning the chairman, Mr. G. P. F. Boese, drove me through the principal parts of Calgary. A luncheon meeting was held at which our General Secretary, Mr. Durley, gave an account of The Institute's business affairs. That evening a banquet took place at which I was invited to give an address on Institute problems. The members gave me close and courteous attention and discussed these questions in a way that evidenced the active interest of the Branch in the future wellbeing of The Institute and of the engineering profession. The next day Mr. Patrick took me to see the C.P.R. irrigation works, and other members kindly assisted me in obtaining a view of structural works which were of particular interest.

The next stop was at Regina, where again the Branch officers met my train, drove me around the city, and met me at lunch with several other members, at Colonel Linton's charming home. This afforded a welcome opportunity of discussing Institute affairs and of learning the views of the members of the Branch. After a drive to the Qu'Appelle Valley, a dinner was held in the Saskatchewan hotel, where my address concerning The Institute was most satisfactorily discussed. The next morning I was joined by Mrs. Shearwood who arrived from Vancouver, and the cordial hospitality of Regina was doubled by Mr. L. A. Thornton, who drove us across the prairie to his summer home on Lost Mountain lake. The main points of my address were constantly referred to before I left Regina, and in spite of the intense heat, Colonel Linton and his wife were good enough to take us to our train for Winnipeg, in this way giving me another opportunity of explaining the affairs of The Institute in which he was deeply concerned.

Branch officials also met me on arrival in Winnipeg, where a luncheon meeting of the Branch members had been arranged, and again I sensed the warmth of western hospitality together with keen interest in the progress of The Engineering Institute. A private dinner and informal meeting at the home of the Branch chairman, Major A. J. S. Taunton, also helped to bring about a genial discussion of methods of meeting problems before The Institute, and the result was eminently satisfactory. These affairs were again the topic of conversation when the vice-chairman, Mr. H. M. White, and his wife entertained us on Sunday evening.

On Monday, July 29th, the members of the Winnipeg Executive Committee were good enough to lunch with me at the Hudson Bay Rooms when there was a very evident desire on the part of all members to assure me of their loyalty and of their willingness to further the best interests of the engineering profession. All this seemed a vast amount of time and trouble for our Winnipeg Branch to have given, but their hospitality reached its climax that evening when they entertained Mrs. Shearwood and myself at "The Lower Fort," where the picturesque buildings of the old Hudson Bay Fur Trading Post, surrounded by charming gardens, made a fitting setting for the dinner and entertainment given to us by the friendly members of The Engineering Institute and of the Winnipeg Motor Club.

Reaching Port Arthur at a very early hour on the first of August, I was met and entertained by Mr. J. Antonisen, city engineer. After showing us features of engineering interest in Port Arthur, he took Mrs. Shearwood and myself to view the famous Kakabeka Falls thirty miles away. In the evening I gave the story of The Institute affairs at the Armoury, and also spoke on "Bridge Erection." The problems of The Institute evoked an interesting discussion which lasted until after midnight, and some pointed questions were put to me as to our future policies and ways and means of furthering the interests of The Institute.

Arriving at Sault Ste. Marie by steamer, we were met by several members and their wives, who took charge of Mrs. Shearwood and gave her much enjoyment in a drive along the shores of the lake where dinner was served at sunset. Meantime, I was able to visit the Algoma Steel plant, speaking afterwards at a banquet which the Branch had arranged and at which the members gave me the same close attention which it was my privilege to experience in all the Branches visited. On the next day, the last of my western visits was brought to a close by a long country drive with Mr. and Mrs. J. W. LeB. Ross, and lunch at their home on the Sault canal point, followed by a visit to the hospitable camp of the vice-chairman, Mr. and Mrs. F. Smallwood.

As we waved good-bye to the members of the Sault Ste. Marie Branch who came to the boat to see the last of us, I could not help reflecting that The Engineering Institute has a host of friends in the west who are working actively for its welfare. Each Branch has asked for a copy of my address and suggestions on the present state of Institute affairs, which is a gratifying sign of their interest, since they wish to consider my remarks in detail and send in the result of such consideration to the Council meeting in October. In all the meetings I was impressed with the ready response and the many helpful suggestions made for our future progress.

Every opportunity was given me to appreciate western methods of dealing with important problems, and I feel confident that when these views are placed before Council they will be found of great assistance in framing a procedure which will benefit not only the engineering profession, but all its allied undertakings throughout Canada. Experience leads me to feel that Canada is fortunate in the soundness of its Engineering Institute, and especially in the loyalty, friendship and wish for co-operation of its western members.

F. P. SHEARWOOD,
President.

## OBITUARIES

### James Milne, M.E.I.C.

We regret to record the death at Toronto, Ont., on May 21st, 1934, of James Milne, M.E.I.C., chief mechanical and electrical engineer, Works Department, City of Toronto.

Mr. Milne was born at Aberdeen, Scotland, on January 29th, 1864, and received his early education in that city, serving his apprenticeship in mechanical engineering for five years.

Coming to Canada in 1886, Mr. Milne was for a year draughtsman with R. Gardner and Sons, Montreal, and in 1887-1888 he was with M. D. Barr and Company, the general agents in Canada for the Edison Electric Company, as construction engineer. In 1888-1890 he was a member of the Keegans-Milne Company, electrical engineers and contractors, and was later for a time manager of the Windsor Salt Company. From 1892-1895 Mr. Milne was general superintendent of the Incandescent Light Company at Toronto. He later entered the service of the Department of Works of the City of Toronto, and was associated with several important waterworks extension projects, the latest being the duplicate waterworks system.

Mr. Milne joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on December 19th, 1895, and transferred to the class of Member on December 9th, 1897.

### Alexander Milne, A.M.E.I.C.

The membership of The Institute will learn with regret of the death at St. Catharines, Ontario, on August 10th, 1934, of Alexander Milne, A.M.E.I.C.

Mr. Milne was born at Aberdeen, Scotland, on February 19th, 1859, and came to Canada at an early age. For a time he was on the staff of the railway under construction from Toronto to St. Thomas, and later in 1884-1886 was assistant to Mr. J. D. Blaikie, C.E., of St. Thomas, being engaged on surveys and general municipal work. In 1886-1887 Mr. Milne was engaged on the construction of the Aylmer waterworks, and in 1887 was appointed engineer for the town of Aylmer and adjoining townships. In 1900 Mr. Milne became engineer and superintendent of the St. Catharines Waterworks, and in addition to this in 1903-1905 he was engineer to the Waterworks Commission on matters affecting the interests of the city of St. Catharines in relation to the hydraulic works of the Hamilton Cataract Power Light and Traction Company.

During his tenure of office Mr. Milne was responsible for many marked improvements in the waterworks system of St. Catharines, and the betterment of the supply, which is now conceded to be among the best in Canada. Among these improvements was the design, location and construction of a 24-inch main from the reservoir in 1911-1912, the installation of the automatic liquid-chlorine control plant in 1914, and in 1925-1926, the design and construction of the modern filtration plant.

Mr. Milne was a member of the American Waterworks Association, of which he was elected president in 1911, being the first Canadian to hold that office.

Mr. Milne joined The Institute as an Associate Member on October 11th, 1906, and took an active interest in its affairs, being chairman of the Niagara Peninsula Branch in 1927.

## PERSONALS

J. E. Craster, S.E.I.C., is now connected with the Consolidated Mining and Smelting Company in the Warfield plant at Trail, B.C. Mr. Craster graduated from the University of British Columbia in 1930 with the degree of B.A.Sc., and was later for a time on the staff of the Canadian General Electric Company Limited at Peterborough, Ont.

G. E. Humphries, Jr.E.I.C., who was formerly with the Edwards Mine at Lochalsh, Ontario, is now in charge of the Milmac Mines Limited property at Michipicoten River, Ontario.

L. K. Sillcox, M.E.I.C., vice-president of the New York Air Brake Company, New York, N.Y., is chairman of a Mechanical Advisory Committee recently appointed by the Federal Co-ordinator of Transportation, to co-operate with the Section of Transportation Service, Washington, D.C.

Dr. A. Frigon, M.E.I.C., Director General of Technical Education for the Province of Quebec, and Dean of the Ecole Polytechnique, Montreal, is a member of a commission appointed by the Quebec government to enquire into the electricity situation from every angle.

W. M. Murray, S.E.I.C., who graduated from McGill University in 1932 with the degree of B.Eng., has been awarded a scholarship at the Massachusetts Institute of Technology entitling him to a further year's postgraduate study at that institution. Mr. Murray is specializing in mechanical engineering.

J. C. H. Jette, A.M.E.I.C., has joined the staff of the Consolidated Paper Corporation Limited, at Port Alfred, Que. Mr. Jette was at one time field engineer for the Canada Power and Paper Company at Cap de la Madeleine, Que., and was latterly with the Page Equipment and Construction Company at Three Rivers, Que.

A. U. Sanderson, A.M.E.I.C., has been appointed engineer of the Water Supply Section, Department of Works of the City of Toronto. Mr. Sanderson graduated from the University of Toronto in 1909 with the degree of B.A.Sc. and following this he became assistant engineer with the Canadian Pacific Railway Company. In 1910 he joined the staff of the Toronto slow sand filtration plant as assistant engineer, and from 1911 to 1913 Mr. Sanderson was assistant and resident engineer on design and construction for the Department of Works, Toronto. From 1914 to 1917 he was resident engineer on the construction of a drifting sand filtration plant for the Department of Works, Toronto, and in 1918 he became superintendent of the filtration plant. In 1929 Mr. Sanderson was appointed assistant mechanical and electrical engineer with the Water Supply Section, Department of Works, Toronto.

H. E. Mott, A.M.E.I.C., is president and general manager of the newly-formed company of H. E. Mott Company Limited, of Brantford, Ontario, which has purchased the assets of the Goold, Shapley and Muir Company Limited pertaining to the tower, wood tank and textile machinery part of their business.

Mr. Mott graduated from McGill University in 1922, with the degree of B.Sc., and following graduation joined the staff of the Canadian Marconi Company as test engineer. Later, he became engineer in charge of the test room and in May, 1923, he was appointed superintendent of works. In October, 1923, Mr. Mott became works engineer which position he retained until 1927, when he joined the De-Forest Radio Corporation Limited at Toronto as chief engineer. In 1928 Mr. Mott was chief engineer of the Standard Radio Manufacturing Corporation Limited, and in 1929 he became manager, engineering and production, and chief engineer of the Rogers Majestic Corporation, Toronto, successors to Standard Radio Manufacturing Corporation. More recently Mr. Mott has been engaged on consulting work in England and the United States for an American group.

During the War, Mr. Mott served in the Royal Air Force from 1916 until 1919, being retired with the rank of Captain.

# BOOK REVIEW

## Tables of Integrals and Other Mathematical Data

*By Herbert Bristol Dwight, The MacMillan Company, New York, 1934. 5¾ by 8¾ inches, 220 pages, $1.65, cloth.*

Reviewed by PROFESSOR N. B. MACLEAN*

The author has presented herein a very complete collection of mathematical formulae supplemented by the addition of sets of tables of numerical values and of useful references. As a result, the book should be of great service as a ready reference, not only to the practical engineer, but also to the mathematician.

The major portion of the book (pages 1 to 182 inclusive) is devoted to the presentation of the main formulae connected with series, integrals and trigonometric, exponential, logarithmic, hyperbolic, elliptic and Bessel functions and surface zonal harmonics. This section concludes with a brief summary of the more simple standard forms of ordinary differential equations. The few diagrams, tables, and explanatory notes are well-chosen, and, while not extensive, add to the value of the whole.

The Appendix contains tables of numerical values and references. The tables include numerical values of $\sqrt{(a^2+b^2)}/a$, trigonometric data, brief sets of common and natural logarithms, exponential and hyperbolic functions, elliptic integrals of the first and second kind, and Bessel functions, and concludes with a brief set of the more common mathematical constants and the Greek alphabet. In many respects this section comprises a great portion of the value of the whole book.

The references are sufficiently extensive to satisfy at least the practical engineer.

The author and publishers are to be congratulated upon the form and convenience of the book, and upon the clarity of the type.

* *Professor of Applied Mathematics, McGill University.*

# BULLETINS

*Diesel Engines*—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued an 8-page bulletin containing particulars regarding their vertical four-cycle, direct injection Diesel engines, describing types B, C, D and E. The full line covers power requirements from 25 to 600 h.p. The field for these engines includes those of the prime mover, stationary, marine, semi-portable or portable types.

*Stainless Clad Steel*—A 20-page booklet received from the Ingersoll Steel and Disc Company, Chicago, Ill., contains particulars of the fabrication of stainless clad steel. It is entitled "Manual of Welding and Fabricating Procedures for IngAclad Stainless Clad Steel" and contains diagrams to guide the fabricator in working with the material.

*Centrifugal Pumps*—A 6-page bulletin issued by the Worthington Pump and Machinery Corporation, Harrison, N.J., contains particulars of Types C, CA and CB centrifugal pumps. The bulletin contains tables of capacities, speeds and horsepower motor driven and belt driven types of pumps with heads varying from 10 to 80 feet.

# The Value of Engineering Supervision of Oxy-Acetylene Welding and Cutting

*D. S. Lloyd, A.M.E.I.C.,*
*Service Engineer, Dominion Oxygen Company Limited, Toronto, Ont.*

**Paper presented before the Sault Ste. Marie Branch of The Engineering Institute of Canada, May 25th, 1834.**

Engineers who have anything to do with metals know that the oxy-acetylene flame can be used for joining metals and for severing most of the ferrous alloys. The principles involved are fairly simple and have been generally quite well understood by technically trained men. The actual practice of doing the work, however, was looked on by the engineer as a craft somewhat similar to blacksmithing, and he took it for granted that a good workman could be relied upon to indicate the practicability of doing any particular job where these processes might be employed. There are several major factors which make it desirable for the modern engineer to inquire more particularly into his responsibility on work of this kind.

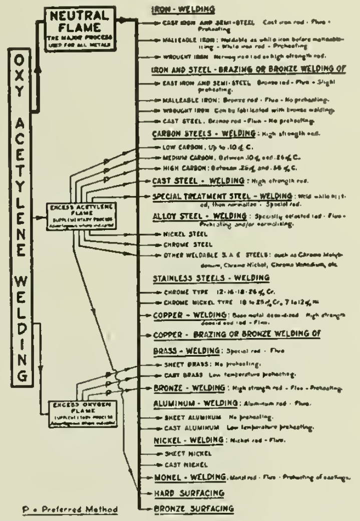

**Fig. 1 Chart of Weldability of Metals by Oxy-Acetylene Process.**

(*a*) The almost innumerable metals and alloys which can be satisfactorily joined by welding—an understanding of the characteristics of all of these being entirely beyond the average workman.

(*b*) The increasing use of corrosion and wear-resisting metals and alloys and the obvious impracticability of expecting the welder to have any accurate knowledge of corrosion problems.

(*c*) The influence of welding and cutting practices on the limits in design.

(*d*) The possibilities of effecting economies in labour and materials through the use of equipment and procedures which will speed up the work.

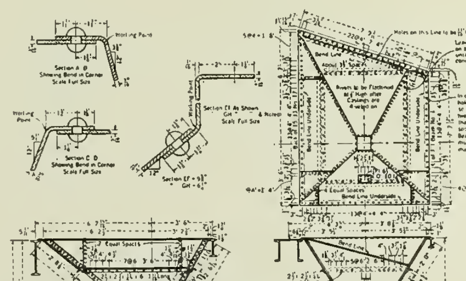

**Fig. 2—Drawing for Riveted Skew Hopper.**

### AVAILABILITY OF TECHNICAL DATA

Ten or fifteen years ago little published data on welding and cutting was available except instruction manuals and sales literature of companies selling the materials. The work of technical societies and the very widespread adoption of these processes for fabricating metals in many industries, has considerably changed this picture.

References are given in this paper to some of the more recent publications which are available to the engineer for detailed study of the various applications of the process.

### Weldability of Various Metals by the Oxy-acetylene Process

The 1933 report of the Oxy-Acetylene Committee(1) of the International Acetylene Association contains a chart of welding applications which should be very interesting to the engineer. It will be noted that a list of metals and alloys is given together with reference to basic information about the procedures for welding, such as the type of flame, whether or not preheating is necessary, the type of welding rod to be used, and whether flux should be used. (Fig. 1.)

The study of such data by the engineer is essential for the most efficient use of the process in any plant, to supplement the knowledge of the practical man. For example, consider the welding of copper. Welds made in good commercial copper using an ordinary copper welding rod of the same composition have low tensile strength and poor ductility due to the impairment of strength in the base metal by the separation of cuprous oxide. Bronze welding may be used and is the most practical way to make a satisfactory joint in commercial copper where good strength and ductility are desired. However, deoxidized copper is available and it is possible by its use to secure strength in the joint of 30,000 to 35,000 pounds per square inch.

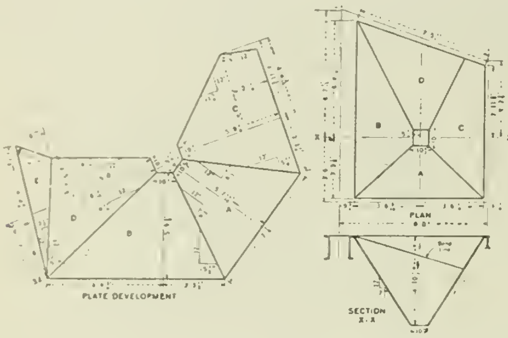

Fig. 3—Drawing for Riveted Skew Hopper Welded.

The average welder is totally incapable of working out the economies of using the more expensive material or judging the practicability of designing so that bronze welding can be used. A study of such factors by the engineer on either repair or production work will in almost every instance result in satisfactory procedures for welding this metal on the particular work at hand.

To ask a welder to work on stainless steel without the engineer having made a study of the weldability of the material is inviting trouble.(2) The chromium steels may be divided generally into several classes from a weldability standpoint. Some are easy to weld, others more difficult. Some need heat treatment after welding, while in other cases this is not required. Not only does the composition have an effect on the weldability but the procedure will affect the qualities of the finished joint. The place of the engineer in analyzing the use of such materials and methods of fabrication is obvious, if, as is usually the case, the most highly efficient joint is required. A careful study of the new nickel alloys and other corrosion resisting metals is required if satisfactory joints are to be obtained. Welding is accepted as the preferred method for jointing these materials but again the engineer must assist the practical man if the finished work is to give satisfactory service under unusual conditions.

Fig. 4—Fuel Regulator Header and Assembly of Separator and Drip.

### Influence of Welding on Design

Designing is naturally the field of the engineer. Whether it be the designing of a complicated chassis for a radio set—where space is at a premium and electrical conductivity problems are all important—or the laying out of a stand for a steel rolling mill—where strength and durability are important—a knowledge of welding is essential today if the lowest production costs and best products are to be obtained. Such design problems are of a specialized nature and do not come within the province of the plant engineer of the average industrial organization.

However, every engineer, whether he be in a textile or paper mill, oil refinery or box factory, has occasion from time to time to lay out rough designs for auxiliary equipment for special work in his particular plant. Perhaps it may be a special pedestal for a motor, or a short pipe line. Again it may be a hopper similar to the one illustrated. Such a piece of equipment is almost always special both in shape and dimensions. The economies in using welded construction start at the draughting board and the finished cost is almost invariably lower if the engineer who plans the use of this equipment has a good general knowledge of the use of welding and cutting.

Layouts for special headers in piping systems(3) as in Fig. 4 again show the simplicity of welded construction. It might be said that the use of welding in design leads invariably towards simplicity. Imagine how much more complicated this construction would be if cast fittings and flanges were used.

The assistance of the engineer is also demanded in the making of templates for pipe cutting preparatory to welding. Although tables(4) for marking out the pattern for making the most common joints are usually available to the pipe welder, complicated specials require engineering assistance in the laying out. Figure 5 shows(5) the template for cutting pipe to make a swage and is a simple piece of descriptive geometry to the engineer. A workman can spend much valuable time trying to lay out such work alone by his own methods where the help and guidance of the engineer in providing proper patterns will greatly speed up the work to say nothing of making the finished job more accurate.

### New Equipment and Procedures

The continuous advances which are being made in the procedures for using the oxy-acetylene flame for both welding and cutting, make it difficult for the practical man to keep up with progress in these processes. A welder who received his preliminary training a dozen years ago, for instance, was probably told that the way to repair a crack in the back of a large cast iron press frame as shown in the illustration, would be by welding with a cast iron filler rod after preheating very carefully. It is doubtful if such a method of repair would be practical on this frame due to the difficulties in maintaining alignment, cost of keeping the whole joint at a red heat during welding and the extra labour required because of the tremendous heat given off. The bronze welding of cast iron has changed the economics of such a repair considerably.(6) Many old time welders do not realize the progress which has been made in the development of new alloy rods for bronze welding. These are also satisfactory for making joints in steel with strengths as high as 55,000 pounds per square inch. Welders not familiar with the progress in this field do not realize that the use of oxidizing flames in this type of work gives greater strength in the bond between the bronze and base metal. It is the place of the engineer to see that the practical man is aware of these changes and that he knows about these new materials and procedures, if the best work is to be done and greatest economies effected.

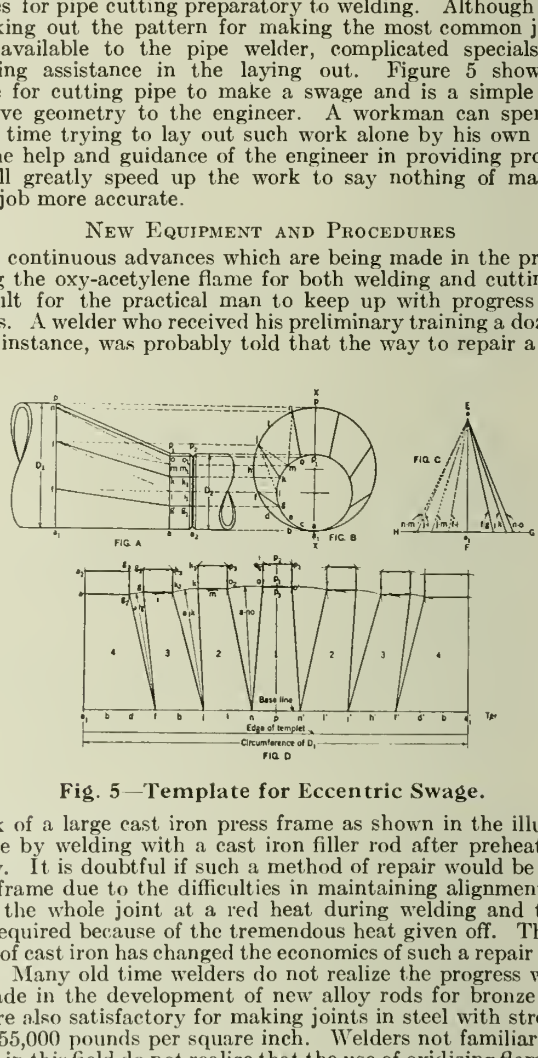

Fig. 5—Template for Eccentric Swage.

Again, the development of a new and faster method of welding steel and the use of semi-automatic blowpipes is of great interest to the engineer. The use of a special technique and new type of welding rod must be explained to the welder if the greatest economy is to be obtained.

The interest and attention of the engineer as well as the practical man is also desirable and necessary in the application of the process to the hard-surfacing of metal parts.(7) Non-ferrous metal coatings may be applied as welding rods for wear resistance but these require in many instances special methods of application if the most satisfactory results are to be obtained.

The development of machines for guiding and controlling blowpipes for oxy-acetylene cutting has progressed rapidly in the past few years and warrants the careful study of engineers in any plant where steel plate or structural steel work is done. Some of these machines are capable of making flame cuts with a flexibility equivalent to woodworking with a jig-saw and of such high quality and accuracy that for many purposes no finishing is required.

The cutability of various steels is another subject of interest to the engineer. Modified procedures(1) have been developed for the severing of cast iron and most alloy steels which in some cases differ radically

(1) etc.—See references page 423

from the technique usually used by an operator. To secure proper results the workmen must be trained in these new methods and it devolves upon the engineer to interpret this information for them.

Until the past few years, the oxy-acetylene cutting process has been used primarily as a severing tool. Ordinary cutting is done with the blowpipe, usually in a plane at 90 degrees to the surface of the part cut. If the blowpipe is held almost tangential to the surface of the metal, and special nozzles are used, grooves up to 2 inches in width and ⅜ inch or more in depth can be cut from the surface at speeds from 15 to 30 feet per minute. The rate of tangential cutting varies but in some cases can be as high as 1,000 pounds per hour with a single jet.

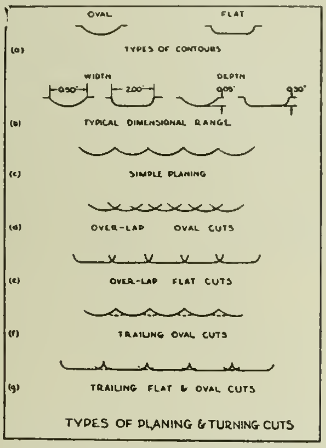

**Fig. 6—Types of Planing and Turning Cuts Produced by Flame Machining.**

This is usually called flame machining and the possibilities of this process for the preparation and shaping of carbon steels in place of using tools seems to be limited only by the degree of precision obtainable commercially by the flame machining nozzle. Figure 6 shows some of the types of planing and turning cuts which can be made by flame machining.

This principle has been in use for deseaming steel billets and cleaning up cracks and sand holes in castings for some time, and is now being used for veeing thick plates preparatory to welding.

This new process naturally interests the engineer in view of the considerable economies which may be possible in the shaping of metal parts.

### Testing Welds and Welders

No paper on this subject would be complete without reference to the place of the engineer in the testing and qualification of welders. The experience of the users of welding has indicated that by proper procedure control, the human element can be readily controlled in welding practice and at the same time economies in the use of the process can be effected.

### TYPES OF TEST FOR WELDS

Qualification—
*Quantitative:* Tensile test.
Reduced-section weld metal test.
All-weld metal tensile test.
Specific gravity test.
Free bend test.
*Qualitative:* Forward bend test.
Reverse bend and fracture test.
Nick-break test.
Leak-proof (bomb) test.
Observation test.
Non-Destructive—Hydrostatic pressure tests.
Air pressure tests.
Reheating welds.
Stethoscope tests.
X-ray test.
Gamma ray test.
Magnetic test.
Electrical resistance.
Special— Fatigue test.
Izod test.
Hardness tests—
Brinnell.
Soleroscope.
Rockwell.
Lay-out test.
Compression and drift tests.

Fusion welding has now reached such a stage of development that the most complicated and important vessels may be fabricated by this process when proper methods of qualification and testing are employed. The American Society of Mechanical Engineers Code(8) allows the welding of practically any type of pressure vessel and specifies the procedures by which the quality of the work will be definitely assured. The accompanying chart shows some of the various tests which are used to insure the highest quality of joints and the greatest economy in the use of welding. The application of such tests is necessarily an engineering function in the production of metal parts and equipment.

The modern engineer, whether he be a designer, fabricator or user of metal products, will do well to study the wide applications of welding and cutting processes and to know, by testing the ability of his workmen, their qualifications for applying the process, so that he can render the proper engineering assistance in the using of these processes most effectively.

## The Electrochemical Behaviour of Tinplate and the Corrosion of Tin and its Alloys

With the aim of overcoming the corrosion of tinplate the importance of investigating the electrochemical relations of tin and iron in different liquid media has long been recognized, but interpretation of the work done in the past has been rendered difficult by the peculiar reversal of potential which occurs under certain conditions. Thus, tin is sometimes anodic and sometimes cathodic to iron.

The mechanism of these changes is more clearly understood as a result of recently published research carried out on behalf of the International Tin Research and Development Council by Dr. T. P. Hoar at Cambridge University. The work described has a direct bearing on the corrosion of tinplate cans by fruit juices, etc., and indicates promising lines for future work aiming at reducing the corrosion of tinplate.

The corrosion of tin and pewter has also been studied by the same investigator and his results are described in a paper recently presented to the Institute of Metals.

Samples of tin and of various pewter alloys have been tested by two different methods. The ability of the materials to produce a protective surface film, and thus to resist the commencement of attack has been determined by means of time-potential measurements. The loss of weight of specimens immersed in various tap waters and dilute acids has also been determined.

The results of these tests give useful information regarding the effect of the composition of the alloy on resistance to corrosion, and also illustrate the different types of attack produced by the several liquids investigated.

Copies of the above papers may be obtained from the International Tin Research and Development Council, 378 Strand, London, W.C. 2, England, or from L. J. Tavener, United States representative, 149 Broadway, New York, N.Y.

## Analysis of Continuous Frames

A revised edition of a 73-page booklet entitled "Analysis of Continuous Frames," by Earle B. Russell, has been published at a price of $1.25 by Ellison and Russell, consulting structural engineers, Pacific Building, San Francisco, Calif. The method employed is stated to be original with the author and to be a practical method which can be used in an engineering office.

The book treats frames for both vertical and transverse loads, and for members with uniform or variable moments of inertia. Tables are presented for members with variable moments of inertia which appear quite complete. These tables may be used directly in the Hardy Cross method. Various types of problems are worked out in detail.

There is also included a well prepared set of tables for continuous beams of variable spans with different combinations of loaded spans.

## Canadian Institute of Mining and Metallurgy

The Annual Western Meeting of the Canadian Institute of Mining and Metallurgy will be held in Calgary, Alta., on September 13th, 14th and 15th, 1934, with headquarters at the Paliser Hotel.

# BRANCH NEWS

## Calgary Branch

*J. Dow, M.E.I.C., Secretary-Treasurer.*
*H. W. Tooker, A.M.E.I.C., Branch News Editor.*

Forty-five members of the Calgary Branch of The Institute met at dinner at the Renfrew Club on July 22nd, 1934, to honour President F. P. Shearwood, M.E.I.C.

In introducing Mr. Shearwood, G. P. F. Boese, A.M.E.I.C., the Branch chairman, referred to the President's achievements as a bridge engineer in Canada, mentioning that he had been actively engaged in bridge construction with the Dominion Bridge Company, of which he is now chief engineer, for many years. During this period he had designed and supervised the building of bridges from coast to coast. In addition to his bridge building activities, Mr. Shearwood is an enthusiastic yachtsman and yacht designer.

### Institute Affairs

In addressing the Branch on the affairs of The Institute, Mr. Shearwood discussed many topics of interest to the engineers, touching on the subjects of membership, finance, unemployment and other problems which face the organization at this time.

### Bridge Building

Later in the evening Mr. Shearwood gave an illustrated lecture on bridge building which was followed with deep interest by those present. He pointed out through the medium of lantern slides the difficulties under which bridge construction is done, emphasizing the need of care in the erection of steelwork.

R. S. Trowsdale, A.M.E.I.C., expressed the appreciation of the Branch at having had the privilege of meeting the President and of hearing him, and went on to ask that men who had firms of their own give due consideration to the graduate just out of university, stating that he thought it was the responsibility of every company to take an interest in the young men who would soon guide the engineering destinies of the country.

## Halifax Branch

*R. R. Murray, A.M.E.I.C., Secretary-Treasurer.*
*C. Scrymgeour, A.M.E.I.C., Branch News Editor.*

The August meeting of the Halifax Branch took the form of a picnic, which was held at "Green Acres," Waverley, some sixty couples attending.

Unfortunately weather conditions were not favourable for the carrying out of a complete programme, which had been arranged by R. L. Dunsmore, A.M.E.I.C., chairman, and R. R. Murray, A.M.E.I.C., secretary. However, in spite of the weather the attendance was very gratifying to the sponsors and showed keen interest in the affairs of the local Branch, particularly when an effort had been made to provide a meeting in which the ladies could take part.

After dinner the evening was spent in the playing of cards and dancing.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*
*A. Meldrum, A.M.E.I.C., Branch News Editor.*

F. P. Shearwood, M.E.I.C., President, The Engineering Institute of Canada, and chief engineer, Dominion Bridge Company, Ltd., Montreal, was the speaker at a special meeting of the Lethbridge Branch of the Institute on Friday evening held in the Marquis hotel, with C. S. Donaldson, A.M.E.I.C., in the chair.

### Bridge Erection

The speaker was introduced by the local councillor, C. S. Clendening, A.M.E.I.C. Mr. Shearwood spoke first on "Bridge Erection," which subject was illustrated with lantern slides, the projector being operated through the courtesy of C. M. Watson. Following this address, he enlightened the members present on matters which were being discussed at Headquarters and invited suggestions for discussion by the Council.

Bridge designing, said Mr. Shearwood, is a most interesting occupation, the most fascinating part of bridge work being the erection and structures. It is fascinating on account of the dangers and unforeseen conditions which may arise. The meeting of these conditions and their surmounting is what requires the long experience of the bridge builders. In the early days of bridge engineering, erection of bridges was what one might call more of a skilled art and science on the part of an old erection foreman.

In present day bridge building, complete plans are made showing the method of erection, and strains and stresses are worked out in minute detail. Forty years ago, practically all steel bridge erection was done on falsework. Nowadays, spans are frequently run out on top of previous spans and lowered into position by derricks.

Slides of more recent bridges, such as the new bridge over the St. Lawrence river, showed that engineers were combining æsthetics with utility, thus beautifying the country.

Following the slides, several questions on bridge construction were ably answered by Mr. Shearwood, after which he proceeded with his address on "Institute Affairs."

### Institute Affairs

Mr. Shearwood pointed out in his talk on this subject that he was trying to discover the views of the members rather than impress his ideas upon them. In regard to work at Headquarters, the speaker said it was hard to realize what has to be done until one comes in contact with it. The preparation of The Journal and other publications, keeping track of technical conditions, as well as ordinary business, takes up the full time of a steady staff. Mr. Shearwood made the suggestion that the numerous branches in The Institute might be provided with provincial headquarters with competent office staffs in charge so that these could work in closer contact with the branches and relay any suggestions and desires on to Headquarters.

In connection with The Engineering Journal, the speaker thought that discussions would add to the interest of any engineering subjects. The qualifications for membership was another point brought up and in connection with this the speaker remarked that the objective of The Institute should not be forgotten. The first objective is to protect the public from incompetent services, the second, the advancement of the profession by the interchange of knowledge and experience.

This outlines some of the questions that are being discussed, and others, no doubt, will come up as time goes on. Local members gave Mr. Shearwood some suggestions which they considered would be to the betterment of The Institute, particularly those relating to Institute membership and an improved basis of financing The Institute branches.

At the close of the evening, G. N. Houston, M.E.I.C., moved a vote of thanks to the speaker, and arrangements were made by a party of the local members to take Mr. Shearwood on a tour through Glacier and Waterton National Parks on Saturday and Sunday.

## Quebec Branch

*Jules Joyal, A.M.E.I.C., Secretary-Treasurer.*

### Assemblee Annuelle

L'Assemblée Annuelle de la Section de Québec fut tenue au Palais Montcalm le 14 mai dernier, à 8 heures du soir.

Le fauteuil présidentiel était occupé par M. Alex. Larivière, M.E.I.C., vice-président de la Section, qui s'est acquitté de cette fonction avec toute la dignité et la maîtrise d'un Commissaire.

Dès l'ouverture de la séance, MM. W. R. Caron, A.M.E.I.C., et P. W. Doddridge, S.E.I.C., furent choisis comme scrutateurs et se mirent immédiatement à dépouiller les bulletins de votation: les minutes de l'assemblée annuelle précédente furent lues puis les rapports du Conseil et du Trésorier pour l'année 1933-34 furent présentés à l'auditoire. Le tout fut approuvé sur motion.

M. Larivière, président du Comité local de Chômage, donne ensuite un rapport verbal des activités de ce comité et communique à l'assemblée une résolution de la Section de Winnipeg et deux lettres adressées à l'Honorable Premier Ministre du Canada, l'une pour la Section de Winnipeg, l'autre par le président de l'Institut, le tout demandant au Gouvernement Fédéral d'employer immédiatement des ingénieurs pour étudier les aspects techniques des projets de travaux publics que l'on propose d'entreprendre pour remédier au chômage; l'Assemblée approuve l'action prise par le Président de l'Institut en l'occurrence.

Les scrutateurs soumettent leur rapport et le président proclame les officiers élus pour 1934-35.

L'on procéda ensuite au choix des membres des divers comités: Législation, Nomination, Excursions, Chômage et Bibliothèque; puis M. Ivan Vallée, A.M.E.I.C., propose un vote de remerciements aux officiers sortant de charge et un vote de félicitations aux nouveaux élus; M. W. S. Buchanan, A.M.E.I.C., seconde cette proposition qui est adoptée.

Comme le président sortant de charge, M. Hector Cimon, avait été forcé de s'absenter pour des motifs urgents, il avait prévu le cas d'une réélection possible et dans une lettre qu'il avait adressée à M. Larivière il disait que si le résultat du scrutin confirmait la décision du Comité de Nomination et qu'il était de nouveau élu président, il remerciait bien sincèrement tous les membres de la section pour la confiance qu'ils mettent en lui, il remerciait aussi ses collaborateurs de l'année écoulée et assurait tous les membres de son entier dévouement pour le plus grand bien de chacun de nos membres, de notre section et de l'Institut en général.

## U.S. Consulting Engineers Oppose Code

In a resolution transmitted to Hugh S. Johnson, Administrator, National Recovery Administration, The Institute of Consulting Engineers has gone on record as being opposed to a code for the proposed engineers' division of the construction industry and as favouring amending Chapter I of the Code of Fair Competition for the Construction Industry, so as to exclude designing from the work covered by the code's definition of the construction industry.

A large majority of the members of the Institute of Consulting Engineers are also members of the American Society of Civil Engineers, the organization submitting the code for the professional engineers' division of the construction industry now before the NRA, and The Institute has been represented on the A.S.C.E. code work and approved the draft of a code submitted in revised form. Its present change of view is the result of a questionnaire recently submitted to its members.

The council believes that the American Institute of Consulting Engineers is more fairly representative of the engineers who are intended to be bound by the code under consideration than is the American Society of Civil Engineers, and feels that the purposes of the NRA would not be furthered in any way by the coding of engineers but that this coding might on the contrary have an adverse effect on general recovery.

# Preliminary Notice

## of Applications for Admission and for Transfer

August 28th, 1934

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in October, 1934.

R. J. Durley, Secretary.

* The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shal be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

BLAIR—DONALD, of 173 Daly Ave., Ottawa, Ont., Born at Fredericton, N.B., Oct. 14th, 1887; Educ., 1908-10, McGill Univ.; 1910-11, asst. engr., city engrg. dept., Moose Jaw, Sask.; 1912, dftsman and transitman, land survey, Peace River District, B.C.; 1917-18, field engr., smokeless powder plant, Trenton, Ont., for Fraser Brace Co.; 1918-22, sanitary engr., Dept. of Public Works, Ottawa; 1923-25, office engr. and clerk, constrn. dept., Temiskaming & Northern Ont. Rly.; 1926, res. engr., Rouyn Branch Lines Co., C.N.R.; 1927-32, engr., Federal District Commission, Ottawa; 1933 to date, struct'l. designing engr., Dept. National Defence, Ottawa. (Structural steel, concrete and heating.)

References: E. J. C. Schmidlin, A. K. Hay, G. G. Gale, W. F. M. Bryce, C. M. Pitts, A. E. Dubuc, W. L. L. Cassels.

CASTLEDEN—GEOFFREY PERCY, of Duparquet, Que., Born at Gosport, Portsmouth, England, April 1st, 1893; Educ., B.Sc. (Mech.), Univ. of Sask., 1927. One year's study toward Civil Engrg. degree, 1932-33; Summer work: 1910-13, survey parties; 1922, Geodetic Survey; 1923-25, instr'man., secondary observations, Geodetic Survey; 1926, dftsman in architect's office; 1917-19, instr'man., Can. Rly Troops; 1927, dftsman., Manitoba Bridge and Iron Works; 1928 (Jan.-June), instr'man., Underwood & McLellan, Saskatoon; 1928-30, asst. engr., 1930-32, asst. mechanic, Sherritt Gordon Mines; Nov. 1933 to date, asst. mechanic, Beattie Gold Mines, Duparquet, Que.

References: J. J. White, R. A. Spencer, H. B. Brehaut, A. R Greig, Y. R. Anderson.

DICKSON—ARCHIBALD, of Calgary, Alta., Born at Motherwell, Scotland, Mar. 21st, 1886; Educ., Public and High School, Motherwell; 1903-08, ap'ticeship, and 1908-11, junior dftsman, Lanarkshire Steel Co., Motherwell; 1911-13, dftsman., Manitoba Bridge and Iron Works, Winnipeg; 1913 to date, with Dominion Bridge Co. as follows: (Winnipeg) 1913-20, dftsman., 1920-26, checker, 1926-30, squad leader, and 1930 to date, chief dftsman. at Calgary, Alta.

References: H. M. White, A. Campbell, C. T. Barnes, R. Barnecut, J. R. Wood, H. B. LeBourveau.

STEWART—FREDERICK CHOATE, of 2748 Dundas St., Vancouver, B.C., Born at Mission, B.C., March 2nd, 1898; Educ., B.A.Sc., C.E., Univ. of B.C., 1923; Member, Assn. Prof. Engrs. B.C.; 1916, chainman, Great Northern Rly.; 1917-19, overseas, Can. Engrs.; 1919-21, instr'man., City of Vancouver; 1922-23-24 (summers) with C.P.R., asst. to divn. engr. at Cranbrook and Vancouver; 1924-26, with City of Vancouver, design and layout of pipe lines, also res. engr. in charge of pipe line constrn.; 1926 to date, asst. engr. with Greater Vancouver Water District. Design and layout of pipe lines; res. engr. in charge of constrn. of pipe lines (riveted and welded); concrete dam and intake, Seymour Falls; concrete reservoir at Vancouver Heights; pressure tunnel under the First Narrows; Surveys and investigations (hydraulic and geological) of Capilana Canyon, also prelim. design and estimate for a 300 ft. dam; field engr. in charge of surveys and gen. investigation for hydro-electric development on Cheakamus River, also prelim. designs and estimate of power cost for report on same.

### FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

LOVE—ALEXANDER, of 40 Paisley Ave. So., Hamilton, Ont., Born at Saltcoats, Ayrshire, Scotland, Dec. 6th, 1890; Educ., B.Sc. (Engrg.), Glasgow Univ., 1912; Summer work: 1909-10, mech. dftsman., W. Young & Sons, Ardrossan; 1911, mech. fitter, Ardeer Iron Works; 1912, tracer, Hamilton Bridge Co.; 1912-13, dftsman., C.P.R., divn. engr's. office, Toronto; 1913-14, instr'man., Ont. Divn., C.P.R.; 1917-19, Lieut., Can. Engrs., C.E.F.; 1919 to date, with the Hamilton Bridge Company as follows: 1919-23, detailer, checker; 1923-27, designer; 1927 to date, plant engr. (*A.M. 1920.*)

References: R. K. Palmer, J. A. McFarlane, H. B. Stuart, F. W. Paulin, W. F. McLaren, H. A. Lumsden.

### FOR TRANSFER FROM THE CLASS OF JUNIOR

FRY—JOHN DAWSON, of Westmount, Que., Born at Montreal, March 17th, 1901; Educ., B.Sc., McGill Univ., 1923; (Summers) 1919, mach. shop, Thos. Davidson & Co.; 1920, Price Bros. & Co., Kenogami; 1921, with McDougall & Friedman; Aug. 1923 to date, with McDougall & Friedman, Consltg. Engrs., as assistant, work consisting principally of the preparation of plans and specifications, together with supervision in connection with the mech'l. equipment of bldgs. (*St. 1919, Jr. 1924.*)

References: G. K. McDougall, F. J. Friedman, C. P. Creighton, J. H. Larmonth, M. V. Ross.

GOODALL—ERNEST LORNE, of 18 Winnipeg Ave., Port Arthur, Ont., Born at Ottawa, Ont., Apr. 10th, 1901; Educ.: B.Sc., McGill Univ., 1924; 1921-24, road survey, Ottawa Suburban Roads Commn.; 1924-27, paper mill engrg., Abitibi Power and Paper Co., Iroquois Falls, Ont.; 1927-28, field engr. for same company at Smooth Rock Falls, Ont., and 1929-30, central engrg. office of same company in Toronto; 1930 to date, res. engr. in charge of constrn., mtce., repairs and engrg., Provincial Paper Ltd., Port Arthur, Ont. (*St. 1924, Jr. 1929.*)

References: G. H. Burbidge, R. B. Chandler, J. Antonisen, J. A. Dickinson, H. J. Buncke, G. R. Duncan.

LAZENBY—THOMAS WILLIAM, of 17 Colborne St., Kingston, Ont., Born at York, England, Feb. 13th, 1900; Educ., 1915-22, York Technical School (evenings), Cert. of Merit, 1922; One year, Leeds Univ. (evenings); 1915-21, 7 years ap'ticeship as mech. dftsman., with H. Leetham & Sons, York, England. 3 years, drawing office on design and detail of flour milling machy., and 4 years engrg. shops, building and testing machines; 1923-31, chief dftsman., E. Leonard & Sons, London, Ont., in charge of all designs, details, bill of materials, etc., on steam boilers, boiler settings, pressure vessels of all kinds, sheet iron work and struct'l. steel; 1931-32, shop supt., in charge of tank shop, for McKelvey & Birch, Kingston. Pressure vessels, storage tanks, sheet iron and light steel work. Riveted and welded constrn. Preparation of shop drawings and misc. details; at present, sub-foreman on constrn., Relief Project 37, Kingston, Ont. (*Jr. 1928.*)

### FOR TRANSFER FROM THE CLASS OF STUDENT

ACHESON—HARRY ROSS MACDOUGALL, of Edmonton, Alta., Born at Toronto, Ont., June 26th, 1907; Educ., B.Sc. (E.E.), Univ. of Alta., 1929; R.P.E. Alta.; Summer work: 1926, rodman, and 1927-28-29, instr'man., C.P.R.; 1930 (Nov.-Dec.), transitman, C.P.R., Kamloops, B.C.; 1931 to date, dftsman., tech. divn., Dept. Lands and Mines, Prov. of Alberta, Edmonton. Responsible for charge of records and preparation of legal descriptions in connection with grazing leases. Also math. computations and misc. dfting., corres., statistics, etc. (*St. 1926.*)

References: F. K. Beach, D. A. Hansen, H. J. MacLeod, R. S. L. Wilson, H. R. Webb, J. A. McCoubrey, G. H. N. Monkman, J. A. Henderson.

ADAMS—ERIC G., of Montreal, Que., Born at Hull, Que., May 3rd, 1907; Educ., B.Sc. (E.E.), McGill Univ., 1929. 1929-31, at Harvard Graduate School of Business Administration. M.B.A. degree. (Specialized in transportation); 1928 summer), insulation dept., Can. Gen. Elec. Co.; 1930 (summer), business research dept., Westinghouse Elec. and Mfg. Co.; 1931-33, engr. and economist, Cockfield Brown & Company, Montreal, research divn. (preparing reports on various business problems for clients); 1933 to date, account executive for same firm, planning and preparing advertising for clients such as Northern Electric Co., etc.) (*St. 1928.*)

References: G. D. MacKinnon, C. V. Christie, G. A. Wallace, L. R. Thomson, R. E. Jamieson, J. G. Notman, R. J. Durley.

BLACK—JOHN ALFRED, of Amos, Que., Born at Chicago, Ill., Aug. 6th, 1905; Educ., B.Sc. (Civil), N.S. Tech. Coll., 1930; 1927 (2 mos.), tester in carbon lab., Aluminum Co. of Canada; 1928-29 and 1931 (12 mos.), recorder and plane table topog'r., Geol. Survey of Canada; 1930 (4 mos.), locating and field engr., power line constrn., International Power & Paper Co., of Nfld.; 1931 (3 mos.), instr'man., Beauharnois Constrn. Co. Ltd.; 1932 (5 mos), field engr. on hydro-plant constrn., Treadwell Yukon Constrn. Co. Ltd.; 1932-33, amalgamator, 1933-34, surveyor and dftsman., 1934, mill supt., with Bussieres Mining Co. Ltd.; at present, mill supt., Perron Gold Mines Ltd., Amos, Que. (*St. 1929.*)

References: F. R. Faulkner, P. G. Gauthier, D. Hutchison, M. G. Saunders, E. V. Gilbert, S. Ball.

DOULL—ROBERT MORSE, of Montreal, Que., Born at Halifax, N.S., June 11th, 1907; Educ., B.Sc. (Mech.), McGill Univ., 1929; 1926-27, timekpr., highway constrn., Dept. Highways Nova Scotia; 1928-29, junior estimator, and 1929-31, estimator, Dominion Engineering Works; 1931-34, purchasing agent, Construction Equipment Co. Ltd., in complete charge of all engrg. purchases and misc. special work, and at present asst. manager of company. Also purchasing, estimating and engrg. for associated company, Gunite and Waterproofing Ltd., and from 1933 to date, manager of company. (*St 1927.*)

# The Growth and Work of the Association of Professional Engineers of the Province of British Columbia

*Dr. E. E. Brydone-Jack, M.E.I.C.*

**Abstract of an address given at a luncheon of the American Society of Civil Engineers and The Engineering Institute of Canada at the Hotel Vancouver, July 11th, 1934.**

In Canada the first real step toward Dominion-wide legislation in regard to the registration of professional engineers was made by The Engineering Institute of Canada in February 1919, when a committee was appointed to draft a model act as a basis for procuring such legislation in the different provinces of the Dominion. Under the British North America Act such enactments are a provincial, not a Federal, responsibility.

Engineering acts had been in existence in Quebec and Manitoba previously, these were revised, and in 1920 acts were passed in Nova Scotia, New Brunswick, Alberta and British Columbia. Later, in 1924, Ontario, and in 1930, Saskatchewan, also obtained acts.

In the British Columbia Act, all registered professional engineers constitute the Association of Professional Engineers of British Columbia, and a professional engineer is defined as any person engaged in the practice of professional engineering. Further, professional engineering is defined as the carrying on for hire, gain or hope of reward of any branch of civil, mining, mechanical, electrical, chemical or structural engineering, including report on, designing, or directing the construction of any works which require for their design or the supervision of their construction, or the supervision of their maintenance, such experience and technical knowledge as are required by or under the act for the admission by examination to membership in the Association.

This definition of the professional engineer was further amplified by an amending act of 1930.

The act is administered by the executive council of the Association, consisting of eleven members, the president, vice-president and four councillors, being elected annually by the Association, the past-president is a councillor *ex officio*, and four councillors, who must be registered professional engineers, including one from the faculty of the University of British Columbia are appointed by the Lieutenant-Governor-in-council. Thus the control of the profession rests in the hands of the profession itself, and only those registered in the Association or licensed by the council of the Association are allowed to engage in the practice of professional engineering. Temporary licenses are available to non-residents on providing satisfactory proof of their qualifications.

Registration is granted largely by examination, which may be an oral thesis or a written examination, as the council may require. A board of examiners for each branch of engineering is appointed by the council.

An important feature of the Association's work is the system which has been devised to care for the growth and development of the student whether he is of the university or non-university class. In the case of the university student, registration as an engineering pupil is granted under the authority of an applied science course, as an engineer-in-training on graduation, and as a professional engineer when he has completed four years of practical experience after graduation and upon presentation of a satisfactory thesis or engineering report.

In the case of a non-university student, junior or high school matriculation or the equivalent is required before formal listing as a prospective student. After this a preliminary examination will admit him as an engineering pupil, an intermediate examination as an engineer-in-training, and later a final examination admits to registration as a professional engineer.

The proper administration of any registration act makes it necessary to prescribe a definite system of training for all who would become members of the profession and to let established engineers know exactly the qualifications required. Further, the public must be advised of the wide difference which exists between the skilled mechanic or the stationary engineer and the scientifically trained professional engineer.

Such a student system replaces the earlier haphazard methods of entering the profession and gives an orderly approach to registration. The university student is taught to think professionally and among other things this creates a higher regard for the profession he is about to enter. Ninety-five per cent of the undergraduates in engineering in the University of British Columbia are enrolled as engineering pupils to-day and the Association keeps in constant touch with these younger men.

The engineering profession should have just as high standards as any other profession. This is due to the profession and to the general public.

There is a certain amount of educational work to be done constantly with the public and with the engineers. Public bodies such as cities must be made aware that registered engineers must be employed in their engineering work, and senior engineers must be urged to give recognition to the enrolled or registered engineer for positions under their control.

The Association to-day has an enrollment of about eight hundred registered engineers, two hundred and fifty engineers-in-training and two hundred and fifty engineering pupils.

This progress has been made by steady striving for the ideal year by year, and there is still much to be done. In this connection, the highest tribute should be paid to the registrar and secretary of the Association, Mr. E. A. Wheatley, A.M.E.I.C., for his efforts and unflagging zeal.

## EMPLOYMENT SERVICE BUREAU

**The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.**

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Vacant

SALES ENGINEER wanted by a large pulp and paper machinery manufacturer. Applicants should be young men and experienced in modern pulp and paper mill practise. Apply to Box No. 1056-V.

METALLURGIST. Recent graduate wanted for junior position in manufacturing plant near Montreal. Please reply giving particulars of education, experience, and salary expected to Box No. 1062-V.

SALES ENGINEER. A company established fifteen years specializing in the heating, ventilating, air conditioning and power plant field is seeking the services of an engineer familiar with such equipment, preferably one with sales experience. To the right individual this position holds out excellent prospects. Send complete experience record to Box No. 1064-V.

INDUSTRIAL SALESMAN. A natural gas company in the Canadian West desires to receive applications for the position of industrial engineering salesman. Applicants must have received engineering training specializing in heating and combustion problems, and must have had wide experience in the practical application of this specialized training. Apply to Box No. 1066-V.

## Situations Wanted

ESTABLISHED SALES ENGINEER. Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, French, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

INDUSTRIAL ENGINEER, B.Sc., McGill Univ. Age 29. Married. Mechanical and electrical engineering experience with four large Canadian companies; including supervision of manufacture of various products, reduction of manufacturing costs, factory planning and investigation of piece work systems. Available on short notice. Apply to Box No. 132-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian, married, 34 years of age, with 13 years' experience in the industrial field, including design, construction and operation, 8 years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details upon request. Apply to Box No. 161-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257 W.

MECHANICAL ENGINEER, age 28, nine years all round experience, Grad. Inst. of Mech. Engs. England, S.E.I.C. Technical and practical training with first class English firm of general engineers; shop, foundry and drawing office experience in steam and Diesel engines, asphalt, concrete machinery, boilers, power plants, road rollers, etc. Experience in heating and ventilation design and equipment; 18 months designing draughtsman with Montreal consulting engineers. 2½ years sales experience, steam and hot water heating systems, power plant equipment, machinery, oil-burning apparatus. Canadian 4th class Marine Engineers Certificate; C.N.S. experience. Available at short notice. Apply to Box No. 270-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.Sc., A.M.E.I.C., Am.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

## Situations Wanted

CIVIL ENGINEER, B.A.Sc., and C.E., A.M.E.I.C., age 30, married. Experience over the last ten years covers construction on hydro-electric and railway work as instrumentman and resident engineer. Also office work on teaching and design, investigations and hydraulic works, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No 467-W.

MECHANICAL ENGINEER, B.Sc. Age 28, married. Four and a half years on industrial plant maintenance and construction, including shop production work and pulp and paper mill control. Also two and a half years on structural steel and reinforced concrete design. Available at once. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years' technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Sc., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

### Employment Service Bureau

This bureau is maintained by The Engineering Institute of Canada for the benefit of members and organizations employing technically trained men.

An enquiry addressed to 2050 Mansfield Street, Montreal, will bring full information concerning the services offered Details can also be obtained from Branch secretaries who are located in the larger centres throughout Canada.

Brief announcements of men available and positions vacant will be published without charge in The Engineering Journal and the Bulletin. Replies addressed in care of the required box number will be forwarded to the advertiser without delay.

An additional service also offered those who are unemployed or wish to change their positions, is the opportunity of placing their names and records on file at 2050 Mansfield Street for consideration by employers wishing to employ engineers. This is of great assistance as many employers will not advertise or wish to locate a suitable man on short notice. If desired the information contained in these records can be kept confidential.

Forms for registration purposes may be obtained from The Institute Headquarters or Branch secretaries.

MECHANICAL ENGINEER, A.M.E.I.C., with twenty years experience on mechanical and structural design, desires connection. Available at once. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.Sc., University of Alberta, '30. Age 31. Single. Six seasons' practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years' experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

## Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentics Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box No. 651-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing offices. Office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., 29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.Sc., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

## Situations Wanted

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operstor in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Locstion immsterial. Apply to Box No. 740-W.

CIVIL ENGINEER, graduate '29. Married. One year building construction, one year hydro-electric construction in South America, fourteen months resident engineer on road construction. Working knowledge of Spanish. Apply to Box No. 744-W.

SALES ENGINEER, B.Sc., McGill, 1923, A.M.E.I.C. Age 33. Married. Extensive experience in building construction. Thoroughly familisr with steel building products; last five years in charge of structural and reinforcing steel sales for company in New York state. Available st once. Located in Canada. Apply to Box No. 749-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimstor for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good rsferences. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes ons year test course, one year switchboard design and two yesrs switchboard and switching squipment sales with large electrical manufacturing company. Thres summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, singls. Experience includes mining surveys, assistant on highwsy location and construction, and assistant on large construction work. Steel and concrete lsyout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, singls. Exoerience includes surveying, draughting concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experiencs in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with fifteen ysara experience mostly in pulp and paper millwork, reinforced concrete and atructurs1 steel design, field surveys, layout of mechanicsl equipment, piping. Availsbls at oncs. Apply to Box No. 825-W.

ELECTRICAL ENGINEER, S.E.I.C., grad. '29, age 24, married; experiencs includes cne year Students Test Course, sixteen months in distribution transformer design and eight months as assistant foreman in chargs of industrisl control and switchgear tests. Location immaterial. Availabls at once. Apply to Box No. 828-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experisnce in charge of legal field surveys. Owns own surveying squipmsnt. Eight years on technical, administrative, and editorial office work. Expsrienced in writing. Desires position on survey work, assisting in or in charge of prsparation of house organ, on staff of technical or ssmi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B). Age 25. married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W.

## Situations Wanted

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years' experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one yesr draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experisnce in steam power plants or heating and vsntilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduats Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of sams. Marine experience B.O.T. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; sight years in shops, estimating and sales divisions of wsll-known gas engineering and construction companies in the United States. Excellent referencss. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experiencs includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduats 1929, S.E.I.C. Single. Experience includes two years with slectrical manufacturing concern and ons on highway construction work. Available at oncs. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED, Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, rsquires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half ysars in the Toronto Buildings Department checking steel, reinforced concrete, and architsctural plans. Available at oncs. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position prefsrred but not essantial. Fiftesn ysars expsriencs in designing power plants, engins and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pnsumatic tubes, and refrigeration, alao heating, elsctrical work, and specifications. Apply to Box No. 913-W.

ELECTRICAL ENGINEER, Dipl. of Eng., B.Sc. (Dalhousie Univ.), S.B. and S.M. in E.E. (Mass. Inst. of Tech.), Canadian. Married. Seven and a half years' experience in design, construction and operation of hydro, steam and industrial plants. For past sixteen months field office electrical enginser on 510,000 h.p. hydro-electric project. Available at oncs. Apply to Box No. 936-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes ssveral years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Expsrience in testing hydro-electric equipment, draughting, surveying, city street, improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

## Situations Wanted

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's 14), A.M.E.I.C., Dominion Land Surveyor, 5 months' special courss at ths University of London, England, in municipal hygiens and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at oncs. Apply Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two ysars experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical msasurements, resistance dsterminations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Expsriencs includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, sxpsrienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, age 27, graduate 1930, single. Experience includes detailing, designing and estimating structural stesl, plate work and pressure vessels; also hydrographic surveying. Available at once. Apply to Box No. 1111-W.

ELECTRICAL ENGINEER, B.Sc., in E.E. (Univ. of N.B. '34), S.E.I.C. Experience in bridge and road construction and auto repairing, desires position in industrial or power plant. Any locality. References on request. Apply to Box No. 1114-W.

CIVIL ENGINEER, B.Sc. Sask. '30. S.E.I.C. Age 24 years. Experiencs in municipal engineering, including sewer and watsr construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhers. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Availabls at oncs. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C.), M.S. (Univ. of Pittsburgh). Canadian. Age 26. Single. One year graduate student course, W.E. and M. Co., East Pittsburgh. Three and a half years engineering research in mechanics with the same company. Location immaterial. Available at oncs. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodstic and topographical survsys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent mathod of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

# The Romance of the Construction Industry in Canada

Toronto skyline from the waterfront

Sept. 17, 1930—East Heading Shaft No. 6

## FILTERED WATER TUNNEL *for the* City *of* Toronto

FROM early times, water has been conveyed in aqueducts formed by tunnelling. These tunnels were of small cross-sections, and many of them were of great length. They generally followed the grade of the flowing water and where valleys were encountered they were crossed by aqueducts of stone arches, many of which still exist.

The new filtered water tunnel completed last year by the Water Works Department of the City provides for the future water supply of Toronto. The tunnel extends from Keele Street on the West to the city limits on the East, covering a distance of some 9½ miles, at a depth varying from 100 to nearly 200 feet below the water level. The construction of the tunnel was carried on through shale rock formation. The diameter of the tunnel varies from six to ten feet and has a capacity of 140,000,000 gallons per day.

In projects such as this, explosives played a large part, doing the work quickly and economically; in fact, without the use of explosives, the completion of the Toronto filtered water tunnel would be far off.

Dec. 21, 1931—Intake from Shaft South

# New Leakproof Butt Joint for

THE new CANADIAN BUTT JOINT for continuous-stave wood pipe has proven absolutely leak-proof under severe tests of blistering heat, sub-zero frosts and pressures, after a year's service at the famous Pioneer Mine, Bridge River District, B. C. The International Paper Co. Ltd., Timiskaming, Que., also selected the Canadian Butt Joint for its new 5-foot mill-supply line, 6,250 feet long.

An integral part of the pipe, this new joint withstands more pressure than the pipe itself. There are no extra fittings to become lost, no metal to rust or corrode, and no delays in setting up. The Canadian Butt Joint surpasses all types of metal tongues or fittings and is, in our opinion, the greatest single improvement in wood-pipe history.

It can be obtained only with Canadian Continuous-Stave Wood Pipe and is supplied at no extra cost. To get the many advantages of the new CANADIAN BUTT JOINT, make certain you order Canadian Wood Pipe.

## Canadian Wood Pipe & Tanks
Limited

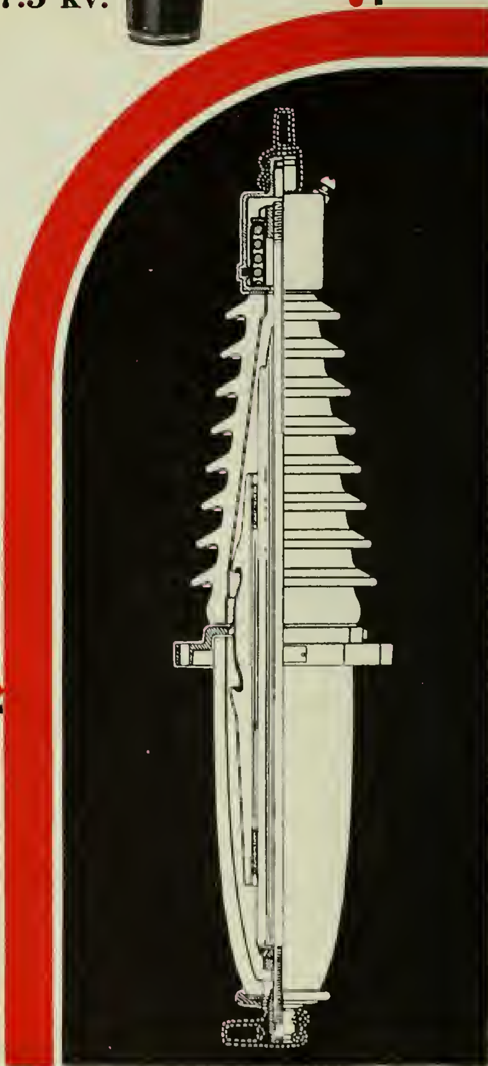
**550 Pacific Street** **Vancouver, B.C.**

30 YEARS IN BUSINESS

69 kv.

34.5 kv.

7.5 kv.



*Line drawing showing the compression-assembly used in O-B Class L Bushings. Note the absence of cemented joints. All external porcelain parts are under compression, insuring great mechanical strength and making the bushing absolutely leak-proof.*

# NOW-Ⓑ OIL-FILLED BUSHINGS *for Voltages as Low as 7.5 kv.*

For years, oil-filled bushings have played an important part in the proper functioning of transformers and circuit-breakers in high-voltage service. Now, the same desirable characteristics of these higher-voltage, oil-filled bushings are incorporated in a new line of O-B bushings for voltages ranging from 69 kv. to 7.5 kv.

The new lower-voltage, oil-filled bushings, known as the O-B Class L, have internal porcelain baffle systems and internal grading shields. Many features, unusual to lower-voltage bushings, are found in this new O-B design.

1. Porcelain is used to maximum extent for internal insulating core.
2. Bushings are free from radio interference.
3. Internal electrical grading is used.
4. The bushings will flashover without puncture.
5. Provision is made for installing co-ordinating gap at any time.
6. All external joints are self-tightening.
7. There are no external cement joints.
8. The bushings are oil-and-weather tight.
9. Ample room is provided for oil expansion.
10. The bushings have convenient means for sampling oil.
11. The bushings can be repaired readily in the field.

If sub-station design and maintenance is your interest, we believe you will find much of value in these new bushings that warrants giving them full consideration, perhaps with the view toward incorporating their advantages in your scheme of operation.

These new bushings are completely described on pages 118 to 150 of your New C-O-B Catalog No. 21.

# ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

ENTERED AT THE POST OFFICE, MONTREAL, AS SECOND CLASS MATTER.

THE INSTITUTE as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

VOLUME XVII — MONTREAL, OCTOBER, 1934 — NUMBER 10

# Geology and Civil Engineering

## Their Relationship, with reference to Canada

*R. F. Legget, A.M.E.I.C.**

Paper presented before the Montreal Branch of The Engineering Institute of Canada, January 18th, 1934.

SUMMARY.—The paper surveys the applications of geological principles and methods to the practice of civil engineering. Although the "Father of British Geology," William Smith, was a civil engineer, the importance of geology to civil engineers was for long neglected: probable causes of this neglect are indicated. A broad outline of the science of geology is presented to provide a background for a discussion of the application of the science to a number of general divisions of civil engineering work, illustrated by examples taken from actual practice. In conclusion, a summary of the principal means of contact of the science and the art are suggested. An appendix provides a guide to references to civil engineering geology in the records of The Institute, and in general literature.

William Smith, world renowned as the "Father of British Geology," was a civil engineer. Born in 1769 of humble origin, he spent an appreciable part of his life of fifty years as a canal engineer in Somerset, England, becoming later a land agent near Scarborough. He was one of the first to introduce into what was then a purely descriptive science the concept of quantitative study and regular stratigraphical succession, and so helped to establish the science on the basis on which it is founded today. The work for which he will ever be remembered was the preparation of the first real geological map of England and Wales. He practised extensively as a consultant on geological matters, often with special reference to their application to engineering work.[1]

Other early engineers were vitally interested in geology and applied its principles to their work, their direct approach to the many problems encountered naturally leading them to considerations of the structure and constituents of the earth's crust. Robert Stephenson stands out from amongst them: to him must be accredited the first scientific investigation of the movement of water in sand, his observations on the underground water encountered during the construction of the Kilsby tunnel completed in 1838 being classical, although contained only in reports to directors.[2]

These early days offer a strange contrast to the divorce of the science from engineering which has persisted through many of the intervening years. The divergence is the more strange when it is considered that in every branch of civil engineering some contact with geological conditions is inevitable. For geology is essentially the study of the nature of the earth's crust, whilst the civil engineer, in seeking to control the forces of nature for the use and convenience of man, constructs something on, in, or through the earth's crust, using a variety of materials, amongst which some natural product of the earth is almost always included. The contact is so intimate that to stress it unduly would be out of place, and yet it may be that its very intimacy has been a potent cause for its neglect.

Brief consideration of some of the more indirect causes is instructive. It is suggested that one such reason has been the prevalent misconception as to what the science of geology actually is, its scope, what it can do, and on the other hand the limits of present day geological knowledge. A further cause has been undoubtedly the natural antipathy of the practically minded engineer to the popular idea of a geologist as one whose preoccupation was an unceasing hunt for fossils.

In recent years there may have been a reaction on the part of engineers who have had unfortunate contacts with pseudo-geologists, of whom there have been some in the mining field. Others may have found it difficult to envisage applied geology in any other field but that of mining. The most potent factor of all, perhaps, is the question of expense. To employ a geologist in consultation means the expenditure of additional money; civil engineering works have been carried out in the past without the aid of geologists; so why employ one now? So runs a familiar argument which, superficially, is difficult to refute. Fundamentally, however, the argument is fallacious, as it is the intent of this paper to show. Finally, amongst younger men there is often an unfortunate distaste for geology, due to injudicious choice of textbooks and to the method of presentation of the subject to them, as students.

The state of affairs indicated by the foregoing is unfortunate, and demands attention. It is not common practice to publish details of, and to discuss failures of civil engineering works, and even public discussion of difficulties encountered during construction is infrequent. This tendency is to be regretted since it is only by the analytical consideration of failures that some discoveries are made. If failures of civil engineering works could be analysed, there can be no doubt but that the majority would be found to be due to defective foundation conditions or to defects in geological structure.

In the course of the discussion of a paper[3] giving details of remarkable difficulties encountered in founding piers for a bridge in New South Wales, presented before the Institution of Civil Engineers, Dr. W. L. Lowe Brown, M.Inst.C.E., stated:—

"If a small fraction of the time spent on refined calculations and very accurate designing were spent on watch-

*Canadian Sheet Piling Company Limited, Montreal.

ing the preliminary boring operations and in examining the foundations when work was in progress, the benefit would probably be many times greater than any advantage from the greatest attention to refinement of calculation of design."

The adequate performance of the duties just mentioned necessitates some geological knowledge. Similar statements can be made with respect to tunnel work and open excavation and prove to be even more applicable.

The experience obtained in a tunnel but a few feet from The Institute headquarters need be no more than mentioned as a case in which the neglect of geology prior

Fig. 1—Gaillard Cut, Culebra, Panama Canal.

to construction is said to have led to difficulties and extra expense, all of which might have been avoided.* In any publication on geology and civil engineering, mention of the troubles encountered in the excavation of the Panama canal has become almost proverbial. Yet the "classical" nature of the upheavals caused by the failure of argillaceous sandstone renders an apology for mention of the case scarcely necessary.

The accompanying illustration, Fig. 1, shows the Gaillard Cut, Culebra, after the disastrous slide of September 1915, when the island seen in the centre came up overnight out of 30 feet of water. One third of the material excavated from this cut has been due solely to slides.[4, 5, 6]

The "preventative" work, indicated in the foregoing paragraphs, which geology can effect when applied to civil engineering, is but one phase of their relationship. Definitely, constructive information is equally as important an outcome of contacts of the science and the art. Excavation and tunnelling methods may often be aided materially both as regards cost and speed by adequate study of geological conditions. New building stones can only be fully investigated if subjected to microscopical examination and tested in relation to their position in the geological structure. Underground water supply is a matter founded almost solely on geological investigations. Other examples will be cited in the course of this paper.

The selection of the data to be submitted in order to bear out what has already been indicated in general terms has been difficult owing to the wide scope of the subject and to the mass of information available. In this paper a brief review of the science, its methods of investigation, etc., is first given in order to provide a background for the adequate appreciation of its application to civil engineering. Points of contact of the two are then considered, illustrated by examples from practice.

*In this connection see reference by Dr. Ries on page 6 of The Engineering Journal for January 1929.

### *Geology*

#### An Outline of the Science

Geology is perhaps best defined as the branch of natural science devoted to the study of the physical features of the earth, the composition and structure of the rocks composing it, and the evolution of animals and plants from their unknown beginnings. Intimately associated with it is the twin science of mineralogy which describes and classifies the various kinds of minerals constituting the earth's crust, and meteoric bodies which reach the surface of the earth.

The pioneers of geological investigation are all men of the last two centuries, and of many nationalities, from amongst whom Sir William Logan (1798-1875) will long be remembered for his pioneer work in Canada.

The science may to-day be conveniently divided into five main sections:—

(*a*) *Cosmogony:*
The study of the relation of the earth to the solar system, and to the universe, and of the origin and early stages of the terrestrial sphere.

(*b*) *Physical Geology:*
The study of the form of the earth's surface, its structure, manner of origin, and the nature of the modifying processes at work upon it.

(*c*) *Petrology:*
The comparative study of rocks and the constituent minerals, found in the accessible crust of the earth (part of this field being covered jointly with mineralogy).

(*d*) *Palaeontology:*
The study of the biology of fossil life.

(*e*) *Stratigraphical Geology* (or Stratigraphy):
The study of the history of the earth and its geography in past ages by means of present structural relationships of the component materials in the earth's crust and of their fossil contents.

Field geology covers part of the work of all sections, as the science has been built up by patient observation of, and consequent speculation upon, the nature and details of the earth's crust. Results of investigations in stratigraphy are recorded by means of geological maps, sections and tables of succession, the other divisions utilizing standard methods of record. Detailed study of specimens by means of chemical tests, the microscope, the use of polarized light, the comparative study of fossil forms, and more recently the adoption of mechanical methods of analysis have enabled many aspects of the science to be studied in the laboratory as well as in the field. Within recent years, the development of geophysical methods of prospecting have put into the hands of the geologist a new and invaluable tool, the full significance of which is not yet generally realized.

Economic geology is the general term that has been given to the applications of the findings and methods of the pure science to utilitarian purposes. It may be divided conveniently into four main groups:—

(*a*) Mining geology concerned with the discovery and working of metallic ores;
(*b*) Mining geology concerned with the discovery and working of useful "earths";
(*c*) Mining geology concerned with the discovery and working of natural fuels;
(*d*) Civil engineering geology.

With the first three sections this paper is not directly concerned, but the work achieved in each case by the application of geology has been of inestimable benefit to mankind.

It is hoped that the above outline is reasonably clear, since although each individual contact of the science and civil engineering may be limited to one branch of geology, the proper application of that branch can only be made if the particular problem can be considered in relation to the science as a whole. Before passing on, some further notes on those divisions of the science directly concerned with such contacts may well be made. These are physical geology, petrology and stratigraphy. Between them, they cover the investigation of the form and structure of the earth's crust at the present time, and its general composition, a field which can be seen to be exactly that which the civil engineer must enter in order to conduct his operations.

Physical geology is based on direct and indirect field observations of what may perhaps be termed the "mechanical" aspects of the earth's surface, considered in relation to the well known geological cycle of denudation, deposition and earth uplift. The analytical study of topographical maps is one basis for such work. Coupled with the study of surface waters goes the investigation of underground water, as revealed in wells, by springs and general indications of water tables. Erosion and silting form important lines of study. Finally, the study of volcanic action, seismology and all associated work on active earth movement occupies an important part of the field of physical geology.

Stratigraphy, and associated with it, structural geology, may justly be regarded as the logical development of physical geology, field observations again forming a foundation on which the whole fabric of stratigraphical knowledge has been built. The study finds its main expression in geological maps and sections, as distinct from topographic maps. The nature of these maps will be generally known —how that by means of colouring or shading the varying nature of the rock outcropping over the mapped area is indicated. Notations of dip and strike (i.e. of the angle made by the beds of rock with the horizontal, and the direction of a line running horizontally along the beds) result in the map being more than a record of surface conditions, and geological sections frequently accompany each map sheet in order to show the structural relation of the various types of rock encountered. Folding, faulting, unconformities and erosion of rock strata can readily be discerned from such maps. After a careful examination of an area in which a sufficient number of rock outcrops occur an accurate prediction of conditions far below the surface becomes possible. The presence of superficial, drift or glacial deposits often complicates the preparation of such "solid" maps and leads (in some districts) to the necessity for two sets of geological maps. The other directions of stratigraphical enquiry do not affect directly the civil engineer or his work.

Petrology, the study of rocks, is more the field of the expert than either of the divisions previously considered, being based on observations of hand specimens and microscopic sections which often require mature experience for their interpretation. The elements of the study can however easily be mastered and on these experience is built up. The appearance, weight, texture, structure, hardness and feel of hand specimens enables the investigator to classify them broadly. Simple chemical tests and examination of thin sections through a microscope will enable a more detailed classification to be made, and this is generally sufficient for all engineering purposes.

### *Geology: Applications in Civil Engineering*

#### General Preliminary Work

The first essentials in any civil engineering project are a reasonably definite idea of the work to be built and knowledge of the topography of the location selected. Requisite foundation depths and rock levels underground are usually assumed. If the project proves to be a favourable one, the next steps taken will be the collection of such physical data as need to be utilized, the preparation of a detailed plan of the site and in some cases the drilling of test holes and the digging of test pits in locations dictated by considerations of topography. Utilizing information so obtained, final designs are prepared, arrangements for construction made (when finance permits) and active building starts.

Such is the general case and no alternative is suggested to this logical procedure but in almost every case it should be extended to include geological investigation. When the preliminary surveying is carried out, geological survey work of a corresponding degree should also be done. The two branches of work can be carried out at the same time and possibly by the same engineers. Such geological survey work would include the recording of all solid rock outcrops in the area to be mapped, details of their dip and strike, the nature of the rocks exposed, signs of earth movement, nature of overburden, etc. This last item is of special significance in Canada in view of the wide distribution of glacial drift and similar surface deposits. Field observations of such strata may seem trivial, but they can often be of great value. From this information a general idea of conditions obtaining below ground level can be derived. If the area in question has been mapped by the Geological Survey, the published map will often suffice for this part of the work.

It is, however, in the final planning of projects that geology should be of most avail. Concurrently with the preparation of the final topographic maps, geological surveys should be carried out of such a nature as is called for by the type of work in hand. In the case of a tunnel, an accurate geological survey along all possible routes of the tunnel is the main requirement; for a reservoir, a map and section showing the relation of the strata in the adjoining valleys; for a bridge, a section along the centre line of the pier foundations. To be fully effective, the two surveys should be carried out either simultaneously or in the closest co-operation. Another section of geological field work of general application to civil engineering work is a reconnaissance of the district around the site, chosen with a view to the location of suitable sand and gravel for concrete work, and possibly of building stones or road metal. In the case of surveys of small areas in populated parts, the work will often involve an examination of available geological records of adjacent properties. At the same time a diligent search through all available geological literature which may have any bearing on the area under consideration should be made—a task that can only properly be done by a geologist.

Finally, drill holes and test pits call for special mention. These exploratory aids are widely employed. The observation cannot be withheld, however, that if the money that has been wasted in the past by the injudicious location of drill holes and test pits—even in Canada—could be calculated, the total would be surprising. For to put down test pits and borings without relation to the geological structure of the ground, as is generally the case, is surely the most illogical of all practices in civil engineering. Figure 2 illustrates how deceptive drill holes can be. It is based on an actual section and is but one of many ways in which a trial boring can lead to incorrect conceptions of the underlying strata. The incorrect nature of the deductions as to foundation conditions which would be drawn (normally) from the drill holes marked is clear. The only comment to be made is that the presence of the fault and the porous sandstone would be undetected unless the structure of the surrounding ground had been carefully studied and especially in relation to the results obtained from the borings.

Test borings are however an essential in all but exceptional cases: the foregoing remarks point only to the fact that to be effective the location of such holes must be carefully selected with reference to the geological information available. All such exploratory work must be carried out with the greatest care, constantly under the supervision of an engineer and/or geologist who can record accurately the results obtained and interpret them correctly. The information revealed by cores should always be plotted on the geological sections available while work proceeds. Trial pits may be necessary in certain isolated cases and when the depth to be explored is small. A careful boring will, however, generally give the same information at a fraction of the cost of such a shaft. Test pits involve some

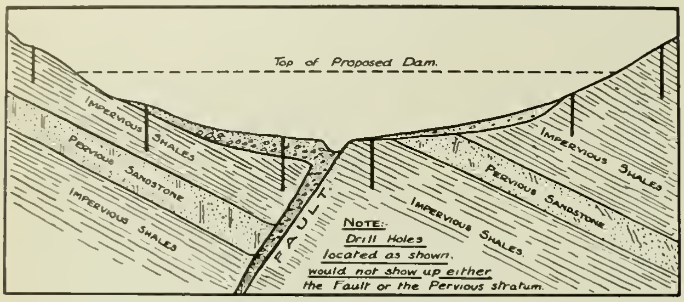

Fig. 2—Sketch of Section of River Valley.

hazard in construction, can only be constructed slowly, and if boulders are encountered either drilling will have to be resorted to, or else a definite result can not be obtained. Details of drilling work need not be given here but it is suggested that work of this nature should be paid for on a day-labour basis in order to obviate the slightest possibility of the work being improperly executed. Drilling should not be stopped until it can be stated with certainty that the result obtained is definite, i.e. that rock has been reached and not merely a boulder.

The almost insuperable difficulties met with during the construction of the Silent Valley dam for the Belfast City and District Water Commissioners were due, very probably, to the assumption that granite boulders encountered by the original test boreholes were solid rock. Actually, instead of a rock foundation being found at a depth of about 50 feet below ground level, the cut off trench had to be carried to a depth of 180 feet, through running sand of such a nature that the use of the maximum working pressure of compressed air only served to reduce the water level a few feet. The final solution of the problems thus encountered provides a fascinating study.[7]

There are available to-day alternatives to the exploratory methods just considered in cases where the surface of rock is concealed by overburden. These can be classed generally as geophysical methods and include gravitational, electrical and seismic prospecting. Methods of this kind depend on theoretical considerations which permit of no succinct explanation and so no more than this passing reference can be made to them here. Informative literature on these prospecting methods is generally available.[8, 9] Again, however, records of depth to rock so obtained can only be of real avail if considered in conjunction with the results of general geological investigations, and when confirmed by drilling.

The information obtained by methods outlined above will often influence design to some degree, as will presently be explained: facts will also be available which may influence construction methods. These data, although reasonably accurate, lack the precision attainable only by actual measurement. They must therefore be constantly checked as construction proceeds and actual sections are revealed. Work of this nature is just as important as the initial investigation and should be as carefully attended to, for if troubles unforeseen at the start of construction are to be encountered, some indication will be given, almost invariably, which will act as a warning if interpreted aright. The nature of such "check" geological work will vary according to the nature of the civil engineering project, but the importance of careful observation and recording of all new sections opened up on every undertaking cannot be over-emphasized.

A paper by Dr. J. A. Allan published in The Engineering Journal[10] in 1927 is an admirable example of such preliminary geological studies as have been described. Numerous references to preliminary geological investigations carried out for the Shawinigan Water and Power Company in the Upper St. Maurice Valley have appeared in the press and were mentioned in a paper describing the survey work in this area recently printed in The Journal of The Institute.[11] The publications of the United States Geological Survey include several papers devoted to investigations of this kind.[12, 13] As further examples of such exploratory work, two notable civil engineering works in Great Britain will be cited, as each was in its way unique at the time the work was undertaken. Both are instances of useful co-operation between geology and civil engineering in preliminary investigations.

The Vyrnwy dam, impounding water for the supply of the City of Liverpool, was the first "great" dam to be built in Great Britain, construction occupying the years 1880 to 1890.[14] Mr. Thomas Hawksley and Dr. G. F. Deacon, MM.Inst.C.E., were the engineers responsible for this project. In the preliminary surveys of the Vyrnwy valley, the engineers deduced from surface indication that the valley was the site of an old glacial lake, held up at one time by a rock bar. They placed the centre line of the dam, for the Parliamentary plans, along the deduced position of this rock bar. Subsequent detailed investigation by trial drill holes and shafts proved the inference to be practically correct, and the dam was built as originally located. Dr. Deacon afterwards estimated that between $1,500,000 and $2,000,000 were saved on what the dam would have cost had it been located only 220 yards either upstream or downstream of the location selected.

The River Mersey provides a natural barrier between the City of Liverpool and the Wirral Peninsula. Two tunnels now penetrate the bed of the river, at Liverpool,

Fig. 3—Vyrnwy Dam showing Exposed Foundation Bed of Glaciated Rock.

and the construction of each one was materially assisted by the application of geology. The first, that in which runs the Mersey Railway, was constructed between 1881 and 1886.[15] The tunnel was driven through the local Bunter sandstone, and its level was modified in view of the prediction by a local amateur geologist, Mr. T. Mellard Reade, some years previously[16] of a buried channel in the present bed of the river. This prediction and also that of a sub-Mersey fault by another geologist, Mr. G. H. Morton, were verified during the tunnel construction.

The Mersey vehicular tunnel, which has just been opened, is the greatest subaqueous tunnel in existence. The experience mentioned above and subsequent records compiled by other local geologists have been utilized by Professor P. G. H. Boswell, F.R.S., in connection with his notable work as geological advisor on this project and a full description of this application of geology is shortly to be published.

TUNNELS

The examples just given might well be regarded as an introduction to the consideration of geology as applied to tunnelling, than which there is no more vital application of the science. The best route to be followed, the minimum allowance of rock cover (in the case of pressure tunnels), the necessity for and design of reinforced linings, construction methods to be adopted, and the possibility of encountering underground water during construction—all these major issues in tunnel work depend essentially, and in some cases wholly on the geological features to be encountered.

Preliminary work having been discussed, it will suffice to state here that there are few tunnel locations which cannot be mapped geologically prior to construction, with a fair degree of accuracy. The rocks liable to be met with will generally outcrop locally and so can often be examined and compared with similar rock encountered on other tunnel work. These comparisons will, in certain cases, lead to useful information. With such data available before construction starts, the civil engineer is enabled to base his designs on a rational basis rather than on empirical assumptions. He will also be able to draw up specifications which will apply fitly to the work to be done, thereby aiding the contractor and leaving few if any loopholes for dispute due to constructional difficulties. The question of overbreak is probably that which causes more trouble and litigation after tunnel driving than any other. Although no final statements can be made about it until construction is under way, yet adequate preliminary geological investigation will permit of the inclusion of clauses in the specification and terms of contract which will admit of little questioning when construction is over.

Throughout the construction of a tunnel it is essential to keep a continuous and accurate geological record of the section of the earth's crust that is pierced. This should be regularly checked with that prepared beforehand and with general surface details both topographical and geological. In this way it is probable that any unusual difficulties will be foreseen. The actual work of excavation depends primarily on the nature of the rocks encountered, but also on the dip and strike of their strata. While the latter can be foretold with some degree of accuracy, structural displacements may cause unexpected changes. Again close observation and a carefully compiled record of the dip and strike encountered as driving proceeds will aid in forecasting such changes thus enabling the requisite adjustments in drilling and blasting arrangements to be made. Should there be serious trouble with overbreak, a geological section obtained during construction will always be the determining factor in deciding any case that may come into a court of law.

The preceding remarks apply generally to tunnels through solid rock, but some apply also to excavation work through clay and other softer material. In such cases, and in certain cases of tunnels in rock, underground water will often prove to be one of the main difficulties encountered. Geology can here be of avail in providing the means for a study of underground water table conditions, the methods of grouting which can be most advantageously adopted, and in indicating what means of drainage exist. As an interesting example, the drainage of one of the "tube" railways in London, England, may be mentioned. Driven through the well known London clay, all drainage water leaves it *down* a drain pipe leading to the underlying chalk. This unusual expedient was adopted on geological advice and has proved entirely satisfactory. The Kilsby tunnel has already been mentioned[2]: probably no better example could be given of a tunnel, the construction of which was so hindered by water troubles that work on occasion had to stop.

As an example of tunnel work illustrating close co-operation between geology and civil engineering, the Lochaber water power tunnel will be cited. Located in the north of Scotland, this work is described because of its size and of the fact that the author had the privilege of being intimately associated with the work, on the staff of the consulting engineers, Messrs. C. S. Meik and Halcrow. The Lochaber development will generate ultimately 120,000 h.p. under a head of 800 feet, at a power house adjacent to Fort William, Inverness-shire. All this power will be utilized for the manufacture of aluminium by the British Aluminium Company for whom the project is being carried out. References are given to complete descriptions of the works.[17, 18]

**Fig. 4—Tunnel Running at Right Angles to Strike.**

Loch Treig is the main reservoir for the scheme, located more than 15 miles from the power house site, and joined to it by means of a pressure conduit consisting of a pressure tunnel and a steel pipe line. The tunnel is just over 15 miles long and has an average effective diameter of about 15 feet so that it constituted, when constructed, the largest of its kind in the world. Prior to construction a geological survey of the route selected for topographical reasons was made by Professor E. B. Bailey, as a result of which this route was confirmed. The tunnel passes under Ben Nevis and through rock strata constituting one of the most geologically complicated parts of Great Britain, the rocks encountered varying from shattered mica schist to granite and baked schist so hard that three sets of drill steel were required for each hole in each round.

Most of the staff of the resident engineer had a working knowledge of geology and so a close check was kept on all rock features encountered during construction. Professor Bailey made a complete geological survey of the tunnel during construction and in this way the public records were enriched. Few unusual features were encountered, deductions from surface exposures being generally confirmed. Figures 4 and 5 show clearly the effect of drilling into and at right angles to the strike and along it, in the mica schist, features which affected the excavation programme of the contractors. At the Loch Treig end of the tunnel some bad slips in soft mica schist occurred, but caused no serious trouble as all but two were located accurately from surface indications. The excavation of the tunnel was completed in 1929, its successful completion and the absence of serious troubles being undoubtedly due, in great part, to the constant assistance rendered by geology.

### Earthworks

This division is intended to cover excavation in open ground for purposes other than confined foundations. Again, the success and stability of such works is dependent

Fig. 5—Tunnel Running along Strike.

ultimately on geological features. A study of these conditions can often avail much in aiding and expediting excavation work in ways already indicated.

A special feature of all earthwork problems is the general question of the angle of slope or repose to be adopted for the material excavated or embanked. Too often this important factor is chosen either arbitrarily or by the use of empirical rules. Yet the change in volume of material effected by even a small change in the angle of repose assumed is large and is generally realized. The fact that almost an infinite variation of the type of material forming either the sides of excavation or an embankment is possible, explains the initial adoption of empirical rules for slope angles, and is at the same time the strongest of reasons for the individual consideration of each case of such work. For this reason alone, in practically all major work involving earth slopes, the angle of internal friction of the materials being worked should be determined as carefully as possible before work commences and checked periodically as work proceeds. Experimental methods are available for giving the information desired and experimental results can be utilized with confidence so long as the drainage of the slopes is watched and due consideration given to the possibilities of the slopes becoming waterlogged, as in the case of the banks of a reservoir.

Mention of drainage suggests the general matter of landslides. So many factors enter into these oft-time disastrous earth movements that to generalize about them in such a paper as this is difficult. It can be stated definitely, however, that whenever remedial works have to be carried out after either indications of an impending slip or an initial earth movement, the principles of geology should always be utilized by the civil engineer responsible. In all cases they can be of some avail; in some they will suggest remedial measures; in others they will prevent further damage being done by injudicious operations. Failure or erosion of the weakest bed in certain strata is one potent natural cause of slips, particularly of rock slips and rock falls (utilizing Professor Heim's classification). Interference with natural drainage conditions is probably the most general cause of soil slips and earth slides, the interference being either natural or caused by adjacent works. There are on record several notable instances of the stopping of earth movement by suitable drainage, including the saving of a pier of a large steel bridge of the Chicago and North Western Railway in the Des Moines river, but space does not permit of detailed reference to them. It is, however, instructive to note that William Smith employed this same method in order to prevent serious damage due to a possible land slide at Coombegrove, near Bath, in the year 1800. For a similar reason the composition and construction of earth dams, now an extensive and involved subject, can be but noted. The effect of earth movements, generally known as faulting, must however be mentioned, for as much trouble is caused in earthwork due to this as occurs in rock excavation. Major faults can generally be mapped from surface indications, but minor faults are often obscured by vegetation and so are difficult to ascertain until excavation is in progress. Careful observation is the first essential in all localities, and, coupled with some knowledge of the local geology, will often be the means of preventing serious trouble.

Some open excavation work of especial significance will be quoted to illustrate this division; it has been described in a paper presented to the Institution of Civil Engineers.[19] This was the opening out of the Cofton tunnel on the Birmingham to Gloucester section of the London Midland and Scottish Railway in England. The tunnel was constructed in 1838-1841 and forms a part of the route taken by this line of railway in crossing a fairly high ridge of land immediately south of Birmingham. Modern traffic requirements had made necessary its opening up and reconstruction as a cutting. The strata shown up in the cuttings on either side of the tunnel were soft false bedded sandstones with thin beds of marl (north) and thick beds of hard sandstone and beds of tough marl (south) so that to the civil engineer they can be classified generally as neither rock nor earth. No records of the construction of the tunnel and the strata passed through were available, but the Geological Survey map of the district showed a major fault traversing the tunnel. Troubles due to earth movements were therefore anticipated and some of a serious nature were encountered very early in the work. Before the final eighty yards of tunnel were demolished a careful geological survey of the surrounding country was made in order to attempt a deduction of the hidden structure yet to be encountered. The survey was considered in conjunction with the records of dip and details of faults recorded from the start of the work. This investigation, carried out in the midst of construction, although incomplete was yet of sufficient value to be of great service.

The work was finally completed satisfactorily, but only after surmounting great difficulties. The evidence tended to show that the tunnel had originally been built instead of an open cutting because of a realization of the troubles to be encountered. Examination of the Geological Survey map showed that if the original line had been located either 200 yards west or 300 yards east of its actual position, little or no trouble due to the Longbridge Fault would have been experienced. The paper describing the work is one of those rare civil engineering publications dealing with unusual difficulties in construction and their surmounting and as such is worthy of special study. It is interesting also to note that at least one member of the staff of the Geological Survey of Great Britain was in constant attendance on the work.

### Foundation Work—General

The main criterion in all foundation work is the maximum bearing pressure which can be utilized without there being fear of settlement of the structure to be erected or the setting up of undue stresses in adjacent strata. This necessitates a knowledge of the strata and structure beneath the surface on and near the site, in addition to the usual "local" knowledge of the final surface to be built on and the loads it will carry. The Trenton limestone underlying the city of Montreal provides a good example of the need for such additional information, the thin beds of clay to be found beneath the surface having already caused trouble in certain foundation work.

The procuration of these data comes generally under the preliminary work already described. In built up industrial areas direct investigation of this kind is usually an impossibility unless time can be spent by putting down test borings. Records of adjacent excavations therefore provide the only means of obtaining the desired information accurately. Unfortunately the publication of such records is not a common occurrence and particularly is this true in Canada. Could they be regarded as the equivalent of design or the result of costly and special research by the parties concerned, publication could only be suggested as desirable. But the structure and composition of the earth's crust is part of the fixed order of nature and is not the prerogative of any one man or industrial group. It is therefore almost a duty to make available, for legitimate purposes, records obtained in excavation for foundations, the drilling of wells, etc., not only of rock formations encountered but also of underground water levels. The most careful records of all geological features met with in such foundation excavation work should therefore be kept, not only for the benefit of the particular job, but for the use and convenience of adjacent works and the enrichment of the public records.

Fig. 6—L.M. and S. Railway, England. Combination of Trough Slips as under X and Hanging Wall Slips.

The geological departments of the universities can and do act as repositories and clearing houses for such geological data. The compilation and co-ordination of these are part of the normal activities of the Dominion Geological Survey. When these records are known to be available, specifications can be drawn up by the engineer which cover fully the work to be done, and leave open no possibility for unreasonable claims for extra payments due to foundation-bed conditions.

These observations on foundation-bed records apply to work in all classes of earth and rock. The study of rock foundation beds can be regarded as reasonably complete after bearing tests have been made and all relevant data examined. Foundations which are to rest on clay and sand, however, introduce further complications, so much so that there may be said to be arising to-day a new branch of study, belonging solely to the field of civil engineering geology, namely, that which has been termed soil mechanics.

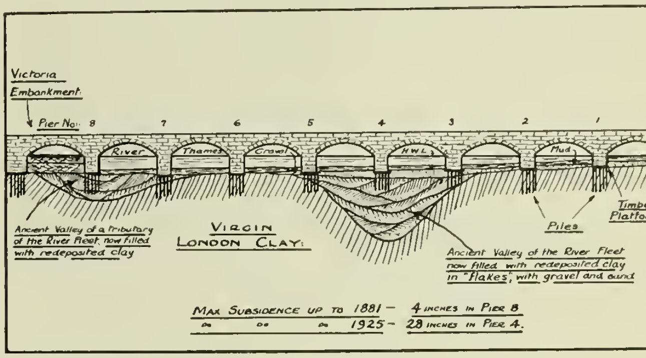

Fig. 7—Waterloo Bridge, London, England.

Great strides have been made in the study of the mechanism of the soil in the last decade, both in Europe and on this continent, and many ingenious lines of research have been opened up. The subject has already attained considerable proportions and so this reference to it can only be brief. Investigation has proceeded, and still does, by experiment and analytical study of the composition of sands and clays. Because of its complexities, the art of erecting structures on "unstable" foundation beds is fascinating and has provided in the past some most ingenious solutions through the co-operation of geologist and engineer. On the other hand, recent researches have detected signs of movement in most unusual locations, the Tower of London for instance having been found to be moving towards the River Thames. Another unusual result of recent research work has been the demonstration that in certain cases the driving of piles through clay foundation beds decreases instead of increases the bearing capacity of the foundations.

The founding of bridge piers requires special mention. The actual location of a bridge will be fixed in the first instance by economic considerations and in many cases the position of the centre line cannot be changed by more than a few yards. A geological section along such centre lines is imperative if the bridge piers are to be located economically. Due to the submersion of most of the solid surfaces along the centre lines of all waterway bridges, the preparation of sections is often fraught with unusual difficulties. Yet with the aid of a few carefully located under-water borings, a section can often be built up with some reasonable degree of accuracy when the local geological conditions have been correlated with drilling results. The drilling of such test holes must be conducted with the utmost care and the records obtained must be without blemish since no change of location can generally be made when once construction of a bridge pier has been started. A paper to which reference has already been made[3] describes some unusual difficulties in founding bridge piers in New South Wales, Australia, and repays careful study.

An interesting theory has been advanced by Mr. F. H. Macintosh, who states that the failure of the central piers of the world famous Waterloo bridge spanning the River Thames at London, England, is due to the underlying geological structure.[20] He suggests that the existence of an old river valley in the blue clay of the present river bed since filled up with redeposited clay is the direct cause of the subsidence of the piers at fault as shown in Fig. 7. It is urged, by the same writer, that no scheme for the reconstruction of the bridge should be considered until the geological strata beneath the piers have been adequately examined.

Finally the question of vibration must at least be mentioned, for each year the problem becomes more intense due to the loading, frequency, and speed of road traffic adjacent to engineering structures and tall buildings. The noticeable vibration at the top of comparatively old buildings is a telling reminder of the existence of a real problem. As yet it is comparatively unexplored, but the research that has been done into the natural period of vibration of buildings, etc., in areas subjected to earthquakes may prove to be the start of a branch of study of great significance in the future.

This extended reference to foundation problems is pardonable, since it covers so wide a field, and is certainly suggestive of a great deal of co-operative work in the future between the geologist, civil engineer and architect.

### The Foundation of Dams

It is perhaps not generally appreciated that the erection of a dam to retain water causes more interference with natural conditions than does any other civil engineering operation. The most general effect of the engineers' activities is to put unusual loads on to certain parts of the earth's surface or to cause undue stresses by interference with the natural structure of the earth's surface. The construction of a dam will often have both of these effects, but in addition hydrological conditions are changed, often to a remarkable degree. Above the dam, the levels of the underground water tables at each end of a dam are raised correspondingly to the level of the impounded water; below the dam, the water table level is unchanged or possibly lowered and so steep underground hydraulic gradients may be set up. Further, increased hydrostatic pressure is exerted on all rock in the bed of the reservoir formed by the dam, as well as below the foundation of the dam itself, and in the case of a porous foundation bed, this may often lead to surprising results. Underground water tables are also affected throughout the entire valley above the artificial reservoir formed by the dam.

If broad consideration be given to the question as to why dams stand up, it can clearly be seen that no matter how safe may be the structural design of the dam itself, it cannot be expected to stand up if the foundation beds are not adequate. From a selection of engineering papers descriptive of dam design and construction, one would probably obtain very little, if any, insight into the subject other than the mathematical proportioning of the dam section and the means adopted for constructing the work to these lines. Foundations, on the other hand, always obtain full publicity whenever any dam failure occurs, and defective foundations are generally, and often rightly, blamed for such disasters. In view of this wide publicity, dam failures will not be referred to again, the constructive aspect of the subject rather receiving attention.

There are three geological problems to be investigated in connection with the design of all dams, namely, the ability of the foundation bed to support the superimposed load proposed, the resistance that the foundation bed will offer to the increased hydrostatic pressure, and the possible effects of the creation of underground hydraulic gradients at the ends of the dam. A fourth problem has to be faced in all cases where earth movement has occurred at any section of the area to be covered by the dam, in determining how far the effects of this extend in the adjacent rock and in assisting in the selection of the necessary protective features in the design.

A detailed geological survey of the dam site is the prime necessity, to be obtained as outlined in the earlier part of this paper. In practically every case of the investigation of a dam site, diamond drilling (or geophysical prospecting) will be a necessary resort at key locations, to complete and/or confirm the results of surface investigations. The survey will include full details of overburden on the banks and will extend upstream and downstream for some appreciable distance. Detailed investigation of the rocks to be encountered will be a vital part of such work, including an investigation of the effect of prolonged contact with water.

One result of the survey will be the preparation of a geological section along the base line of the dam and one down stream crossing the centre line of the dam approximately at right angles. From these sections the practicability of the construction of a dam can be determined and the especial difficulties to be expected anticipated. Some idea of the depth to which excavation will have to be taken can also be obtained. From a consideration of all data available, it should be possible to draft specification clauses that will result in the foundation beds being prepared in a satisfactory manner, leaving no doubt as to what will be required of the contractor. The general occurrence of faulting in the rocks under dam foundations is of especial significance in eastern Canada due to prevalence of faults running up existing river valleys, and to the frequent traces of earth movement so widely distributed in many sections of the Pre-Cambrian rocks.

In cold weather exposed rock foundations will become so chilled that it is extremely difficult to determine their physical properties under normal temperature ranges. The author has seen some diabase which, when frozen, appeared to be absolutely solid, but which was actually thoroughly disintegrated. So well had the frost cemented the fragments together that even steam jets made no impression on it, but its location adjacent to a fault was evidence enough for its removal before concreting operations started.

From the many examples of dam foundations presenting special geological features two only can be mentioned. The Hales Bar dam on the Tennessee river, U.S.A., has

Fig. 8—Foundation Beds, Prettyboy Dam.

been described as "the greatest object lesson that the history of engineering foundations has to offer" by reason of the disastrous results of ignorance of geological conditions at the dam site. Leakage occurred under the dam to an alarming degree, and although the dam stands to-day it has cost about $10,000,000 and taken over ten years to conquer this condition. Amongst the unsuccessful means used in an attempt to stop the leakage were train loads of cement, bales of hay, wrecked bedsprings and corsets. Finally, liquid asphalt was pumped into the cracks under pressure, and this proved effective.[21]

There has recently been completed on the Gunpowder river, the Prettyboy dam which is to impound water to improve the supply of the City of Baltimore, Maryland, U.S.A.[22, 23] Work on the dam was started in 1930, the site being 25 miles to the north of the city. The site is physically a good one, the valley being quite deep, but geological conditions have required unusual precautions in the excavation of the cut off trench below the base of the main structure. This has called for the placing of about 190,000 cubic yards of concrete. The rock formation

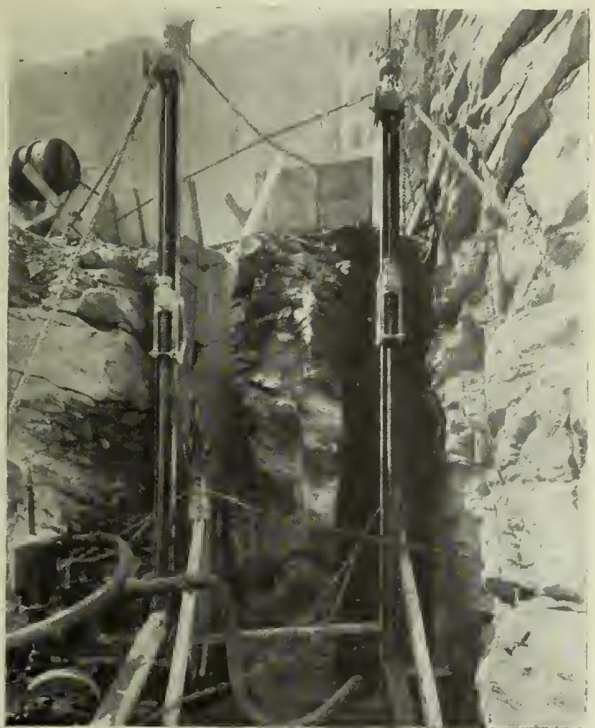

Fig. 9—Wire Saw Rigs Set up in Calyx Drill Holes.

beneath the dam is mainly mica schist with some limestone, gneiss and intruded quartz, and it has been twice subjected to earth movement. Faulting was therefore to be expected. The exposed rock had undergone weathering to a considerable degree. It was realized that extreme care would have to be taken in blasting for the excavation of the foundation bed. As a preliminary operation, it was decided to drill several deep shafts, 36 inches in diameter, excavated with Calyx core drills, which permitted the consulting geologists of the Johns Hopkins University, under Dr. J. T. Singewald Jr., to be lowered into them so as to study the formation of the schist in place. By this means, the geologists were enabled to prepare accurate sections showing the position of all faults and large seams as well as the direction of their strike and dip.

Disintegration of the schist on the hanging-wall side of a major fault, traced in this way, caused a considerable increase in the volume of excavation. Further, it was in this way possible to obtain truly representative samples of the schist wherever desired, and the study of these samples constituted an interesting investigation in pure geology.[24] The highly foliated nature of the rock, together with the extensive faulting, resulted in such overbreak and general rock movement in blasting operations that other methods had to be adopted for the excavation of the cut off trench. After repeated trials, a novel expedient was adopted. Wire rope saws were rigged up between pairs of the Calyx drill holes and with these the necessary trenching work has been successfully carried out, this being probably the first occasion on which wire saws have been used on a highly quartzose rock. Two wire saw rigs can be seen in Fig. 9.

### Reservoirs and Catchment Areas

Geological examination of reservoir sites and catchment areas introduces some special problems. The sides of a valley are generally assumed to be natural watertight dams withholding the water impounded in a reservoir in a manner similar to that of the man-made dam across the valley, and causing all rainfall to drain towards the watercourse running out of the valley. But they may not be, and for two general reasons.

These two broad types of escape are best demonstrated in diagrammatic form; Figs. 10 and 11 illustrate them. The first shows a valley underlain by porous and impervious strata. It will be seen that rain water falling on to the upper part of the left hand side of valley "A" and soaking into the ground will not drain into that valley, but will eventually reach the stream in valley "B." Similarly if the water level of a reservoir in the former valley is raised above point "X" water will escape by leakage through the pervious strata.

Figure 11 illustrates a not uncommon structure which in certain special cases may cause loss of water from a reservoir. The section is taken across the side of a valley at some depression in the ridge. The saddle effect given by anticlinal structure is frequent and erosion will occasionally lead to such a case as that illustrated. Should there be constructed a dam across the valley which will bring the water level opposite this saddle up to such a point that the gradient of the water table between valleys "A" and "B" is large enough for flow to ensue, leakage will result. This leakage may often have disastrous effects in

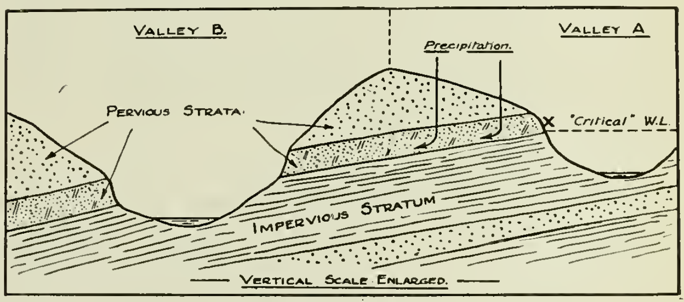

Fig. 10

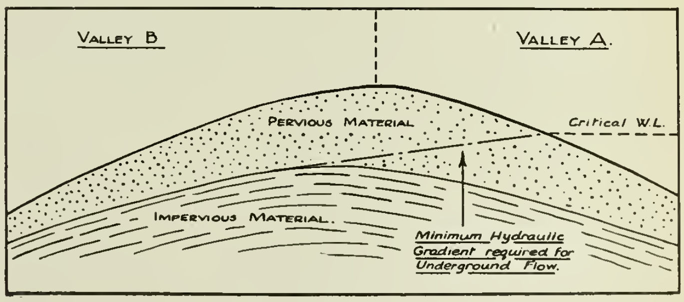

Fig. 11

the adjoining valley and in at least one such case, resulting landslides necessitated a considerable lowering of the water level in the reservoir. Although neither of these cases is common, both are always a possibility and so steps must be taken to ensure that no such leakage can occur.

On the other hand, pervious strata following the topography of the valley can have the opposite effect and provide more run-off than the area of the valley warrants (as in valley "B" supra) and also a vast underground reservoir. This underground water storage may be of special value since it will drain more slowly than an open body of water. The capacity of such a reservoir can sometimes be calculated, at any rate roughly, when sufficient geological information has been acquired, and this may have an appreciable effect on the height of the dam to be built. A minor investigation often necessary in the design of reservoirs is a study of the earth movements possible when once the water level has been raised and natural underground water conditions have been interfered with. If serious damage will result from such movement, an investigation along these lines is imperative.

### Underground Water Problems

This section of applied geology is perhaps the most difficult of all to discuss adequately in this paper. The diversity of the problems involved makes it of supreme importance, whether the water be utilized for supply, or removed as drainage, for in each case a vast number of people depend on the success attained in handling the water underground. It is a fascinating study because of the many structural geological problems involved and also of the debatable question of the origin of plutonic waters, the existence of which cannot be doubted. And it is essentially a matter for study by a geologist since the existence of water underground depends solely on certain features of geological structure. At this statement, the supporter of the "divining rod" will demur. While admitting the successes of water diviners in many instances, the author has yet to be convinced that such success was not a combination of luck and shrewd superficial knowledge of surface geology in so far as it affects water supply.[25, 26] Whether a divining rod is used to discover underground water or not, the fact that its existence is due to certain geological structure remains unchanged. And so, as an essential preliminary to all well drilling, except in localities where proved wells exist, a geological study should be made if waste of time and money is to be avoided. Artesian conditions are generally recognizable after a broad study of local geology, whilst waterless substrata can also be detected readily. Underground drainage has been mentioned previously.

### Construction Materials

The study of the properties of rock used in construction, such as building stone, road stone, or concrete aggregate, to be effective should be a co-operative effort on the part of the geologist and civil engineer. To test for compressive strength alone is not enough.

Stone, using the generic term to cover all types of rock used for construction, unlike artificial structural materials, is not a uniform material with predeterminate qualities. It is, generally, a mass of granular particles cemented together, not always of stable chemical composition and not always as strong structurally as may at first appear. Knowledge of the type of rock from which a specimen is taken is a first essential to a proper study of its qualities. Further it is desirable generally to know the relation of the specimen to the bedding planes of the stratum from which it has been taken. Microscopical examination of thin sections of rock specimens under investigation is generally an essential part of such work, as being the most convenient means of examining the texture of the rock. This feature is of the utmost importance in rock selected as road material, as is also the mineral composition of the rock. Detailed explanation of the significance of these features will be found in references noted, the Geological Survey of Canada having paid special attention to the selection of good road material in the course of its work.[27]

Building stones have been the subject of much research work, particularly in Great Britain in recent years, and there are available many excellent publications dealing with the selection, testing, weathering and preservation of stones used for building purposes.[28, 29] Tests which may be suggested as imperative for all stones are for weight, porosity, effect of repeated wetting and drying, effect of alternate freezing and thawing, mineral composition in relation to local atmospheric conditions and texture as revealed by the microscope. All these tests are additional to the usual tests of compressive strength.

### General

In conclusion, certain specialized branches of civil engineering work may be mentioned, in which geological principles can often be of real avail but which do not belong to the field of Canadian practice to the same extent as the divisions already considered.

(*a*) *Silting up of Reservoirs.* Reference to the serious silting up effect caused by impeding the flow of silt laden streams receives mention by as early a writer as Herodotus. It affects dam design considerably, but the probable rate of silting can only be calculated by empirical rules based on observations of the silt carrying capacity of the stream considered in conjunction with the geological aspects of the river bed from its source to the dam. Based on such calculations it is estimated that the reservoir to be formed by the Boulder dam will take at least one hundred and ninety years to silt up to a serious degree.[30]

(*b*) *Irrigation.* Irrigation engineering in arid lands introduces some problems akin to those caused by silting, and others on the borderline of soil mechanics. Such problems are, however, in the main localized and so do not call for more than this recognition of their existence.

(*c*) *River Training Works.* The erosion of river banks is a problem often encountered in civil engineering: in some cases the solution is not by any means an obvious one. In this, as in associated river training work, the science can often prove of avail, physical geology including the special study of river flow and river movement.

(*d*) *Coastal Works.* On certain coasts, notably the east and south coasts of England, trouble is continually being experienced due to littoral drift and other movements of shore material. Remedial works for such movements can only be effective if based on a careful study of the causes of movement. Study of this kind definitely constitutes a section of physical geology—the science thus again being an essential aid to the engineer.

(*e*) *Earthquake Construction.* Seismology forms a distinct and highly specialized branch of physical geology. Despite a certain well remembered shock in the Lower St. Lawrence valley some years ago, Canada can be regarded as generally free from the possibility of seismic disturbances. Interest in all engineering work in areas not so fortunate has, however, a universal appeal, and so the work that is being done in the direction of adjustment of design to cover the possibility of earth movement is fairly generally known. Vibration is again an aspect of the subject which must at least be mentioned.

### *Conclusion*

Some indication has now been given of the very definite and widely distributed relationship of the science of geology and the art of civil engineering. The practical examples quoted have generally been typical, although some were unique at the time of their original presentation, being selected from an ever widening field of such useful contacts.

This brings the line of thought suggested back to the widely current argument stated in the introduction, which was therein pronounced as fallacious. No direct reference has been made to it in the main body of the paper, but it is hoped that indirectly its falsity has been proved. If a summary answer may be attempted, it is this. Geology can be to civil engineering the broadest type of insurance. While in many cases the geologist will be able only to confirm what surface indications suggest, in others he will be able to warn the civil engineer of unseen dangers and difficulties. In all cases he will be able to eliminate very largely the general element of risk in civil engineering undertakings, due to their nature. When difficulties do occur due to troublesome geological conditions, the civil engineer may be able to surmount them unaided, but a geologist will in most cases be able materially to assist with advice based on his special experience. Further, in detailed work involved in the correct application of construction methods the geologist will often be able to proffer advice of material value. In all such cases, it must be observed, the geologist is but the adviser of the civil engineer; it is the latter who must act on the advice so received, and make all decisions. Finally, the existence of so many "border line" subjects between geology and civil engineering should do much in the future towards bridging whatever gaps remain between the two.

The relation of the two has been likened also to that of faith to works, the "works" of the engineer being based on the "faith" of the geologist.[31] As faith has been defined as confidence in things unseen, the metaphor is by no means far fetched. And this faith will be needed more and more in the future, as the best sites for dams are used up, as foundation loads increase, and as more attention is paid to the economic aspect of engineering work.

Throughout this paper, for the sake of clarity, geology and civil engineering have had to be considered as separate, whereas in actual practice many civil engineers by training and through experience are acquainted with methods of investigation herein classed strictly as geological, and these they apply in the ordinary course of their work. It is thought that they are, however, a small minority, and it is certain that a notable change must be effected in the general reaction towards geology in relation to civil engineering if full avail is to be taken of all the benefits that may accrue from their co-operation. It is for this reason that the last of the "indirect causes" for the past neglect of geology in civil engineering is so singularly unfortunate, since it is by the general training of all undergraduate civil engineers in geology as applied to their professional work that the desired change can best be attained. The general field of engineering education cannot, however, be encroached upon here, and so beyond emphasizing the vital importance of such training, nothing further can be said. Table I has been prepared to show the present status of geological studies as an integral part of the civil engineering courses of Canadian universities.

It may be convenient to summarize, in conclusion, the principal ways in which the essential contacts of the science and the art may be maintained and strengthened to their mutual benefit. No mention will be made of the obvious recourse to a specialist in civil engineering geology for consultation on all unusual and special problems.

(*a*) Preliminary studies of all civil engineering projects, apart from certain isolated small cases, should include as a leading part of the work a geological examination of the ground under consideration, and an investigation of all publications, records, etc., dealing in any way with the geological structure of the area concerned and/or the materials there to be encountered.

(*b*) If trial drill holes are found necessary or even advisable, as will be practically always the case, such holes should only be put down under the guidance of someone trained in geology, so that by the economic location of holes, waste may be prevented and full benefit obtained. Drilling work should always be done on a day-labour basis; it should be constantly under competent supervision; and the records of the work should be kept with extreme accuracy.

(*c*) In the preparation of specifications due regard should be had for all special geological aspects of the work to be undertaken, and suitable safeguarding clauses inserted. The dip and strike of rock in tunnel work, and the possible effect of

Compiled from Official Calendars for 1932–1933 Session.

overbreak; the levels of underground water, and rock, in foundation work; the strength of local stones; adequate examination and preparation of foundations; facilities for the taking of ample records; all are matters which should receive definite and unequivocal mention in all general specifications for work to which they apply.

(*d*) All qualified civil engineers engaged on construction projects should have had training in geology. They should be entrusted with the inspection of all foundations and the study of adjoining formations. They will be able to recommend consultation with a specialist if any unusual or doubtful features are revealed in the course of construction.

(*e*) On the record drawings of every civil engineering work the fullest possible details of geological structure should be given, this being an essential part of the work of the qualified engineers mentioned above.

(*f*) All publications dealing with civil engineering works should contain some reference, if not a whole section, devoted to the geological aspects of the foundation beds, etc. This is necessary in order to bring to light the only unknown elements in design and construction. As each project will differ in this respect to some extent, publication of such details will never be a routine matter, proving rather to be the source of valuable information.

(*g*) The attention of the Director of the Geological Survey of Canada should be drawn to any excavation work of unusual size, or of an unusual nature, so that if necessary he may arrange for a member of the Survey staff to visit and examine the sections uncovered. This applies particularly to all excavation which is to be covered permanently. The courtesy, where possible, should be extended to the head of the Geological Department of the nearest university for a similar reason. Likewise if any records of strata, as in boring of trial holes, or data of underground water levels, as in wells, are obtained, copies of these should be forwarded to the two geologists suggested, together with the record drawings of foundations mentioned in (*e*) supra.

This last suggestion can be classed definitely as a courtesy, since it involves the expenditure of but little time, money, or trouble on the part of those in charge of works. And as illustrating how such co-operation is appreciated by geologists, the following extract from the report of a speech by Dr. T. Robinson of the Geological Survey of Great Britain, at the Institution of Civil Engineers, forming part of the discussion of the paper referred to under reference[19] can hardly be bettered.

"The records of the Geological Survey showed conclusively that closer co-operation between the geologist and the engineer would be greatly to the advantage of both, and it was a pity that there was no direct way in which geologists could be kept informed of the progress of important excavations. Such information would teach them more about the rocks themselves, and so enable them to anticipate their behaviour more precisely; it would also assist in engineering operations."

Science is generally regarded as a great disciplinarian, the scientist being well versed in all the implications of the doctrine of acceptance. The civil engineer can be regarded as even in advance of this position. For not only does he accept the unalterable facts of Nature but he advances, armed with all the technique of his art, and adapts them for the use and convenience of his fellow men. With how much more confidence can he thus carry on the work of his profession if he is armed also with reasonably accurate information about that part of the earth's crust in which his operations are to be conducted?

## APPENDIX

*A list of the publications, papers, etc., referred to in the foregoing text.*

## ACKNOWLEDGMENTS

This paper could not have been prepared without the advice and encouragement of many friends and associates whose long experience in geological work, and in civil engineering, is equalled only by the interest of the author in co-ordination of the two, a field of work in which he is still but an amateur. Especially does he desire to record his indebtedness to Professor P. G. H. Boswell, F.R.S., Professor J. J. O'Neill, and Mr. F. J. Fraser. To the following, his thanks are due for permission readily granted to reproduce information and/or photographs kindly supplied:—Mr. W. T. Halcrow, M.Inst.C.E., of Messrs. C. S. Meik and Halcrow of Westminster, London, England; Mr. F. H. Macintosh of London, England; Mr. Bernard I. Crozier, chief engineer of the Department of Public Works, Baltimore, Maryland, U.S.A., and Mr. C. B. Cornell of this department; Dr. Joseph T. Singewald of Johns Hopkins University, Baltimore, U.S.A.; the Washington Office of the Panama Canal; Col. J. R. Davidson, M.Inst.C.E., water engineer of Liverpool, England; and Mr. A. Newlands, M.Inst.C.E., chief civil engineer, and Mr. R. T. McCallum, M.Inst.C.E., of the London, Midland and Scottish Railway Co., England.

# The Elements of Hydrodynamic Analysis

*T. R. Loudon, M.E.I.C.,*
*Professor of Applied Mechanics, University of Toronto, Toronto, Ontario.*

**SUMMARY.**—A presentation in condensed form of the mathematical analysis necessary as a preparation for the study of the stream line motion of a fluid. The fundamental equations are derived which relate to such quantities as stream functions. velocity potential, sources and sinks, and combined stream lines, and which are needed in understanding many papers on hydrodynamic and aeronautical topics.

---

The following paper is placed before the readers of engineering literature in the hope that it may serve as a guide to further study by those interested in hydrodynamic problems. The writer feels that the reader who tries to look all this up for himself may become discouraged by the maze in which he finds himself involved, and consequently has attempted to put together into one paper the various steps which are to be found in many texts and which go to make up a certain type of interesting analysis of stream line flow.

## Partial Differentiation

Throughout the following presentation, it will be necessary to consider functions of two or more variables; and in order to save time should the reader not have been following mathematical work continuously, some of the basic principles of partial differentiation are given concisely without going into proofs which can be verified easily if any one wishes to do so.

A function $z$ of two variables $x$ and $y$ may be indicated as follows:

$$z = f(x, y)$$

The partial derivative (as it is called) of $z$ with respect to $x$ is written: $\frac{\partial z}{\partial x}$ and is found by assuming that $y$ is constant. The partial derivative of $z$ with respect to $y$ is found by assuming $x$ constant and is written: $\frac{\partial z}{\partial y}$.

For instance, if $z = x^2 + y^2$, $\frac{\partial z}{\partial x} = 2x$; and $\frac{\partial z}{\partial y} = 2y$.

Partial derivatives of higher orders are found by differentiating again with respect to the desired variable and keeping the other variable constant. For instance, using the same given function:

$$\frac{\partial^2 z}{\partial x^2} = 2; \text{ and } \frac{\partial^2 z}{\partial y^2} = 2.$$

It is possible, however, with a function of two or more variables to get a form of derivative, which when indicated, might lead to confusion if the simple process were not understood.

Taking $z = x^2y + y^2x$, we get $\frac{\partial z}{\partial x} = 2xy + y^2$.

Now, it may be desirable to find the next higher derivative with respect to $y$ which is indicated as follows:

$$\frac{\partial^2 z}{\partial y\, \partial x} = 2x + 2y,$$

which was found by keeping $x$ constant since the derivative was with respect to the other variable $y$.

The same result may be obtained by another path:

$$\frac{\partial z}{\partial y} = x^2 + 2xy; \text{ and } \frac{\partial^2 z}{\partial y\, \partial x} = 2x + 2y.$$

The partial differential of a function of two or more variables is found by differentiating with respect to the desired variable and keeping the other variables constant. Thus, if $z = x^2y + y^2x$, $d_xz = 2xy\,dx + y^2dx$

and $d_yz = x^2dy + 2xy\,dy.$

Now it will be noticed that if we write

$$d_xz = (2xy + y^2)\,dx,$$

the quantity in the brackets is $\frac{\partial z}{\partial x}$: so that symbolically we may write $d_xz = \frac{\partial z}{\partial x} . dx.$ In the same way,

$$d_yz = \frac{\partial z}{\partial y} . dy.$$

The total differential of a function of two or more variables is expressed as the sum of the partial differentials. Thus, using the last function $z = x^2y + y^2x$, by ordinary differentiation we get:

$$dz = (2xy + y^2)\,dx + (x^2 + 2xy)\,dy$$

which may be expressed:

$$dz = \frac{\partial z}{\partial x} . dx + \frac{\partial z}{\partial y} . dy \quad \text{(A)}$$

This is the sum of the partial differentials.

This last symbolic expression of a total differential will be most useful later on and should be kept in mind.

## Exact Differentials

The following proposition is generally presented to students of the calculus as one of many others without sufficient emphasis being placed upon its value in mathematical analysis, especially in the realm of physics.

Let $P\,dx + Q\,dy$ be a given relation where $P$ and $Q$ are functions of $x$ and $y$. It is desirable to know under what conditions this quantity is what is called an "exact differential." In other words, what are the relations between $P$, $Q$, $x$ and $y$ which make the given quantity the differential of some function which we may designate as $\psi$? If the given quantity is an exact differential of $\psi$, then:

$$d\psi = P\,dx + Q\,dy \quad (1)$$

But $P$ and $Q$ are functions of $x$ and $y$, therefore the differential may be written in general terms as indicated by equation (A) in the former section on partial differentiation:

$$d\psi = \frac{\partial \psi}{\partial x} . dx + \frac{\partial \psi}{\partial y} . dy \quad (2)$$

And since (1) and (2) are expressions of the same operation, it follows that

$$P = \frac{\partial \psi}{\partial x} \quad (3)$$

$$Q = \frac{\partial \psi}{\partial y} \quad (4)$$

Differentiating $P$ with respect to $y$ and $Q$ with respect to $x$, we get:

$$\frac{\partial P}{\partial y} = \frac{\partial^2 \psi}{\partial y . \partial x}$$

$$\frac{\partial Q}{\partial x} = \frac{\partial^2 \psi}{\partial y . \partial x}$$

From which it follows that:

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x} \quad \ldots\ldots\ldots\ldots\ldots\ldots(5)$$

Now this result was derived on the assumption that the given relation $P\,dx + Q\,dy$ was an exact differential. So that (5) is a relation which must follow if we have an exact differential; and is therefore called *the test for an exact differential.*

It also follows that if $P\,dx + Q\,dy$ is an exact differential, there exists a function $\psi$ related to $P$ and $Q$ by the partial derivatives with respect to $x$ and $y$, as shown in (3) and (4).

The following simple examples illustrate the use of the above propositions.

Determine whether or not the following are exact differentials.

(*a*) $2\,x\,dx + 2\,y\,dy$

In this case $P = 2\,x$ and $Q = 2\,y$

$$\frac{\partial P}{\partial y} = 0 \qquad \frac{\partial Q}{\partial x} = 0$$

therefore $$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$$

and (*a*) is an exact differential.

(*b*) $2\,(x + y)\,dx + 2\,(x + y)\,dy$

$$P = 2\,(x + y) \text{ and } Q = 2\,(x + y)$$

$$\frac{\partial P}{\partial y} = 2 \qquad \frac{\partial Q}{\partial x} = 2$$

therefore $$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$$

and (*b*) is an exact differential.

### Complex Numbers and Variables

In the general discussion of the theory of functions it is found necessary to introduce the idea of what is called a complex number. The reader if he so desires can find the full explanation of the necessity of this step in any good treatise on the theory of functions. This necessity will be accepted here without further explanation.

The relation $(a + ib)$ where $a$ and $b$ are real values and $i = \sqrt{-1}$, is called a "complex number." It is seen that this number is made up of a real and an imaginary part: $a$ and $ib$ respectively.

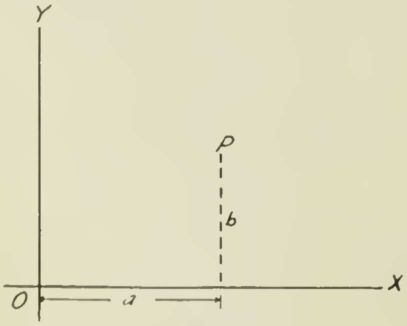

Fig. 1

This idea can be extended to form "complex variables" such as $(x + iy)$; where values of the real variables $x$ and $y$ determine the values of the whole "complex variable."

These complex numbers and variables may be represented graphically by certain conventional agreements which if understood are easily followed.

The complex number $z = (a + ib)$ may be represented on the $X$, $Y$ plane by laying off the real values $a$ and $b$ in the usual manner of co-ordinate geometry as indicated in Fig. 1. It is agreed, then, that the point $P$ found by this process represents the complex number $z$. A particular value of the complex variable $z = (x + iy)$ may be represented by the same conventional process as indicated in Fig. 2; where the point $P$ is said to represent $z$. These diagrams such as Figs. 1 and 2 are called Argand Diagrams.

In the representation of these variables, it is seen that if $y = 0$, the values of $z$ will all be real and will be represented by points on the axis of $X$ which consequently is

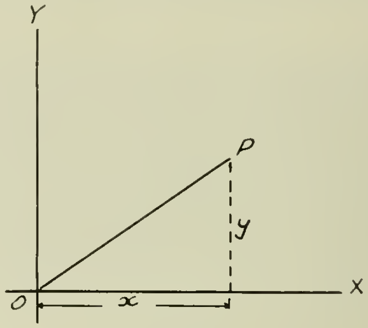

Fig. 2

referred to as *the axis of reals.* On the other hand, if $x = 0$, $z$ will have purely imaginary values all represented on the axis of $Y$ which is called *the axis of imaginaries.*

In Fig. 2, let $OP = r$. Then this distance $OP = r$ is called the *modulus of z* and is conventionally written $|z| = r$. The angle which the modulus of $z$ makes with the axis of $x$ is called either the *argument of z* or the *amplitude of z*, abbreviated to arg. $z$ or amp. $z$. In this case, arg. $z = \theta$ the angle $XOP$ in Fig. 2.

If polar co-ordinates are used, the complex variable $z = (x + iy)$ may be written:

$$z = (r\cos\theta + ir\sin\theta) = r\,(\cos\theta + i\sin\theta)$$

Another useful form of expressing the complex variable may be obtained as follows:

$$d\,(\cos\theta + i\sin\theta) = (-\sin\theta + i\cos\theta)\,d\theta$$
$$= i\,(\cos\theta + i\sin\theta)\,d\theta$$

Then: $$\frac{d\,(\cos\theta + i\sin\theta)}{(\cos\theta + i\sin\theta)} = i\,.\,d\theta$$

Integrating:

$$\log\,(\cos\theta + i\sin\theta) = i\,.\,\theta$$

or $$(\cos\theta + i\sin\theta) = e^{i.\theta} \quad \ldots\ldots\ldots\ldots\ldots(B)$$

And since $$z = r\,(\cos\theta + i\sin\theta),$$

we get $$z = r\,.\,e^{i.\theta}$$

This gives three methods of expressing the complex variable:

$$z = (x + iy) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots(6)$$
$$z = r\,(\cos\theta + i\sin\theta) \quad \ldots\ldots\ldots\ldots(7)$$
$$z = r\,.\,e^{i.\theta} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots(8)$$

These complex numbers may be added, subtracted, multiplied and divided. The results are easily obtained if certain simple rules are remembered; otherwise the actual operations are tedious and wasteful of time.

In Fig. 3, let $P_1 = z_1;\; P_2 = z_2.$

Then, $OP_1 = |z_1|;\; O\,P_2 = |z_2|.$

Let $z_1$ be added to $z_2$, then:

$$z_1 + z_2 = (x_1 + iy_1) + (x_2 + iy_2)$$
$$= (x_1 + x_2) + i\,(y_1 + y_2)$$
$$= z_3$$

It is easily seen that this result is obtained by constructing $P_2P_3$ equal and parallel to $OP_1$. Obviously,

$$(x_1 + x_2) + i\,(y_1 + y_2) = z_3$$

is represented by $P_3$. $OP_3$, then, is the modulus of $z_3$. The value of $z_3$ which is represented by $P_3$ may be found by treating $|z_1|$ and $|z_2|$ in the same way as ordinary vectors. The $|z_3|$ is the resultant vector of $|z_1|$ and $|z_2|$. The operation of subtraction may be treated in the same vectorial manner.

If several complex numbers $z_1$, $z_2$, $z_3$ etc., are multiplied together, it is easily shown that:

$$z_1.z_2.z_3.\dots = r_1.r_2.r_3\dots\dots [\cos(\theta_1 + \theta_2 + \theta_3\dots) + i\sin(\theta_1 + \theta_2 + \theta_3\dots)]$$

From this result, it follows that the modulus of the product of several given complex numbers is the product of the given moduli; and the argument of the same result is found from the sum of the given arguments.

It may also be easily shewn by the actual but tedious operation that when two complex numbers such as $z_1$ and $z_2$ are divided, we get:

$$\frac{z_1}{z_2} = \frac{r_1}{r_2}[\cos(\theta_1 - \theta_2) + i\sin(\theta_1 - \theta_2)]$$

That is: the modulus of the result is found by dividing the given moduli and the argument is obtained by subtracting the original arguments.

### Functions of a Complex Variable

It is possible to establish functions of these complex variables, which have just been discussed, in very much the same manner as with ordinary functions.

Let us suppose that $w$ is a function of the complex variable $z$. This may be expressed in the ordinary manner.

$$w = f(z)$$

Then, $w$ being a function of a complex variable, is itself a complex quantity which may be written $w = (\phi + i\psi)$. It follows from this that:

$$w = (\phi + i\psi) = z = (x + iy)$$

or

$$(\phi + i\psi) = (x + iy)$$

It is seen that since a real value cannot have any imaginary portion to it, we get the following identities:

$$\phi = x$$
$$i\psi = iy$$

or

$$\psi = y$$

Another easy example of this operation is seen when we consider $w = z^2$, where $w = (\phi + i\psi)$ and $z = (x + iy)$. Expanding these results, we get:

$$(\phi + i\psi) = (x + iy)^2 = (x^2 + 2\,ixy - y^2)$$

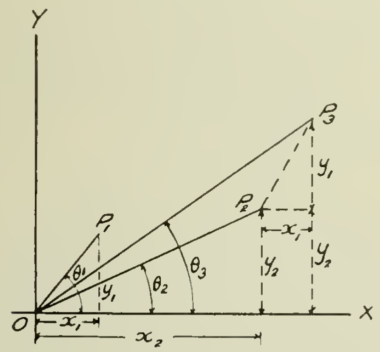

Fig. 3

Then equating real and imaginary parts of both sides, we get:

$$\phi = x^2 - y^2$$
$$\psi = 2\,xy.$$

This operation, illustrated with the simplest possible cases, is known as equating real and imaginary values; and it is from this process that very valuable results will be obtained with more complicated cases.

### Holomorphic Functions

When certain relations exist between a function and the variable, the function is said to be *holomorphic.* The terms monogenic and analytic functions are sometimes used to express variations of the same idea but space does not permit of a discussion of these points. For the present purpose, it is merely necessary to define a holomorphic function as one which is single valued, continuous and has a continuous derivative. Such a function may be differentiated without reference to the path by means of which successive values of the variable are arrived at. If $w = (\phi + i\psi)$ is a holomorphic function of $z = (x + i.y)$ then:

$$\frac{\partial\phi}{\partial x} = \frac{\partial\psi}{\partial y} \text{ and } \frac{\partial\phi}{\partial y} = -\frac{\partial\psi}{\partial x}\dots\dots\dots\dots(9)$$

For instance, if $w = z^2$; we get by equating real and imaginary parts:

$$\phi = x^2 - y^2$$
$$\psi = 2\,xy$$

Then,

$$\frac{\partial\phi}{\partial x} = 2\,x = \frac{\partial\psi}{y}$$
$$\frac{\partial\phi}{\partial y} = -\,2\,y = -\frac{\partial\psi}{\partial x}$$

so that $w$ is a holomorphic function of $z$.

The proof of (9) is tedious but simple and can be followed in any of the texts on Functions of a Complex Variable if the reader so desires.

### Laplace's Equations

Differentiating $\frac{\partial\phi}{\partial x} = \frac{\partial\psi}{\partial y}$ with respect to $x$, we get

$$\frac{\partial^2\phi}{\partial x^2} = \frac{\partial^2\psi}{\partial y\,\partial x}\dots\dots\dots\dots\dots\dots(B)$$

Differentiating $\frac{\partial\phi}{\partial y} = -\frac{\partial\psi}{\partial x}$ with respect to $y$, we get

$$\frac{\partial^2\phi}{\partial y^2} = -\frac{\partial^2\psi}{\partial y\,\partial x}\dots\dots\dots\dots\dots\dots(C)$$

Equating (B) and (C):

$$\frac{\partial^2\phi}{\partial x^2} = -\frac{\partial^2\phi}{\partial y^2} \text{ or } \frac{\partial^2\phi}{\partial x^2} + \frac{\partial^2\phi}{\partial y^2} = 0\dots\dots\dots(10)$$

In the same way, we obtain by differentiating $\frac{\partial\phi}{\partial x} = \frac{\partial\psi}{\partial y}$ with respect to $y$ and $\frac{\partial\phi}{\partial y} = -\frac{\partial\psi}{\partial x}$ with respect to $x$ a similar result for the function $\psi$, that is:

$$\frac{\partial^2\psi}{\partial x^2} + \frac{\partial^2\psi}{\partial y^2} = 0\dots\dots\dots\dots\dots\dots(11)$$

These two results (10) and (11) are known as Laplace's equations, solutions of which are referred to as *plane harmonic functions.*

It is understood of course, that the symbols $\phi$ and $\psi$ used above may be replaced by any other symbols or quantities suitable. $\phi$ and $\psi$ are solutions of Laplace's equations and are sometimes referred to as *conjugate functions.* If one of these functions is known, it is often possible to determine the other which may furnish a means of determining useful data when only part of it is fully known.

For instance, let $\phi$ be given as a function of $x$ and $y$ satisfying the required conditions of holomorphism. If $\phi$ is a solution of Laplace's equations, it is required to determine the conjugate function $\psi$ which must also be a function of $x$ and $y$.

From this we see that since $\psi$ is a function of $x$ and $y$,

$$d\psi = \frac{\partial\psi}{\partial x}dx + \frac{\partial\psi}{\partial y}.dy.$$

But since the conditions of holomorphism are satisfied,

$$\frac{\partial\phi}{\partial x} = \frac{\partial\psi}{\partial y} \text{ and } \frac{\partial\phi}{\partial y} = -\frac{\partial\psi}{\partial x}.$$

By substitution from these conditions, we get:

$$d\psi = -\frac{\partial\phi}{\partial y} \cdot dx + \frac{\partial\phi}{\partial x} \cdot dy.$$

So that by integrating:

$$\psi = \int\left(-\frac{\partial\phi}{\partial y} \cdot dx + \frac{\partial\phi}{\partial x} \cdot dy\right) \quad \ldots\ldots\ldots (12)$$

As an example, suppose $\phi = x^2 - y^2$ be given and it is required to determine the conjugate function $\psi$ and to form the function $w = (\phi + i\psi)$.

First determine the partial derivatives required in (12).

$$\frac{\partial\phi}{\partial y} = -2y; \frac{\partial\phi}{\partial x} = 2x.$$

Substituting these values in (12) we get:

$$\psi = \int(2y \cdot dx + 2x \cdot dy) = 2xy + C.$$

From these results the function $w = (\phi + i\psi)$ may be formed by putting in the above values of $\phi$ and $\psi$:

$$\begin{aligned} w &= (\phi + i\psi) \\ &= (x^2 - y^2) + i(2xy + C) \\ &= x^2 + 2ixy - y^2 + iC \\ &= (x + iy)^2 + iC \\ &= z^2 + \text{const.} \end{aligned}$$

If $\psi$ be given and it is required to determine the value of the conjugate function $\phi$, it is easily verified by the same process as that used in forming (12) that:

$$\phi = \int\left(\frac{\partial\psi}{\partial y} \cdot dx - \frac{\partial\psi}{\partial x} \cdot dy\right)$$

These conjugate functions have an interesting and very important property when they are placed equal to constant values. For instance, if:

$$(\phi + i\psi) = (x + iy)^2,$$

then $\phi = x^2 - y^2$ and $\psi = 2xy$

If $\phi$ and $\psi$ be placed equal to constant values, we get equations of a series of curves $(x^2 - y^2) = C$ and $2xy = C$ which are orthogonal; a property which will be shown later on to be of practical importance.

### Hydrodynamics

In the following discussion, the fluid flow will be considered as parallel to the $X$, $Y$ plane and of uniform thickness equal to unity, the fluid being perfect.

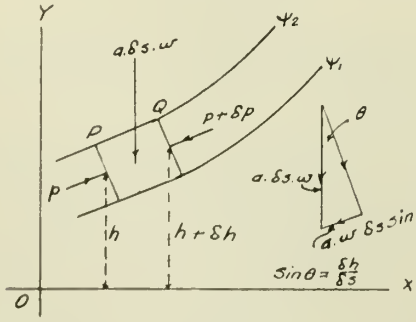

Fig. 4

A *stream line* will be considered as a curve across which there is no flow, the direction of the velocity of flow being tangential to this curve at all points.

### Bernoulli's Equation

In Fig. 4, let $\psi_1$ and $\psi_2$ be two stream lines. Take two right cross sections at $P$ and $Q$ very close to one another such that $PQ = \delta s$. The right cross section areas at $P$ and $Q$ being so close together may be considered equal with a value, $a$.

Consider the forces acting on the small mass of fluid $\delta m$ between $P$ and $Q$. The total pressure on the right cross section at $P = p \cdot a$ and at $Q$ is $(p + \delta p)\, a$. The weight of the fluid between $P$ and $Q = a \cdot \delta s \cdot w$ where $w$ is the weight of fluid per cubic foot. The resolved part of the weight of this

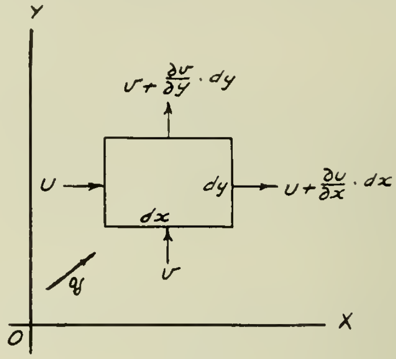

Fig. 5

small mass of fluid in the direction of the unit pressure $p$ is $a \cdot w \cdot \delta h$. This follows from the fact that if the inclination of the tangent to $\psi_1$ at the section through $P$ is $\theta$, then $\sin\theta = \frac{\partial h}{\delta s}$ and the required resolved part is

$$a \cdot \delta s \cdot w \cdot \sin\theta = a \cdot w \cdot \delta h.$$

This resolved part is opposed to the total pressure $(p \cdot a)$ on the section through $P$.

The effective force acting on $\delta m$ is

$$p \cdot a - (p + \delta p)\, a - a \cdot w \cdot \delta h = -\delta p \cdot a - a \cdot w \cdot \delta h$$

Then if the acceleration produced by this effective force is $\frac{\delta v}{\delta t}$, we may write the equation:

$$-\delta p \cdot a - a \cdot w \cdot \delta h = \delta m \cdot \frac{\delta v}{\delta t}$$

In the limit, this may be written:

$$\begin{aligned} -dp \cdot a - a \cdot w \cdot dh &= dm\frac{dv}{dt} \\ &= \frac{a \cdot ds \cdot w}{g} \cdot \frac{dv}{dt} \end{aligned}$$

But $$\frac{ds \cdot dv}{dt} = v \cdot dv;$$

so that $$-dp \cdot a - a \cdot w \cdot dh = \frac{a \cdot w \cdot v \cdot dv}{g};$$

or $$\frac{dp}{w} + \frac{v \cdot dv}{g} + dh = 0$$

Integrating this last result, we get:

$$\frac{p}{w} + \frac{v^2}{2g} + h = \text{const.} \quad \ldots\ldots\ldots\ldots\ldots (13)$$

This result is Bernoulli's equation from which it is possible to determine pressures and velocities at various sections provided these quantities are known at some starting point on a stream line. The equation forms the basis of a large part of hydraulic analysis when another factor is added to account for the various friction losses.

### Equation of Continuity

Let the small rectangular mass in Fig. 5 of dimensions $dx$, $dy$ and unit thickness be located at some point at which the velocity of the fluid is $q$. This velocity has resolved parts $u$ and $v$ in the directions of $X$ and $Y$ respectively. The magnitudes of the resolved parts are supposed to vary so as to give values at the opposite sides of the rectangle as indicated.

The condition of continuity of fluid mass requires that there shall be the same quantity of fluid flowing out as that which flows into the rectangular figure.

The quantity of fluid flowing into the rectangle is,

$$(u \,.\, dy + v \,.\, dx);$$

and the amount of fluid flowing out is:

$$\left(u + \frac{\partial u}{\partial x} \,.\, dx\right) dy + \left(v + \frac{\partial v}{\partial y} \,.\, dy\right) dx$$

Equating these two values, we get:

$$\left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y}\right) dy \,.\, dx = 0$$

or

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \qquad (14)$$

This last result is the analytical condition governing the continuity of fluid flow and is called the Equation of Continuity of Flow.

Now if (14) be written:

$$\frac{\partial u}{\partial x} = -\frac{\partial v}{\partial y},$$

we recognize this from (5) as the condition whereby an expression $(u \,.\, dy - v\, dx)$ is an exact differential of some function which we may designate $\psi$. In other words,

$$d\psi = (u \,.\, dy - v \,.\, dx).$$

If this is so, it follows from propositions (3) and (4) that:

$$u = \frac{\partial \psi}{\partial y} \quad \text{and} \quad v = -\frac{\partial \psi}{\partial x} \qquad (15)$$

So that if we can discover this function $\psi$, it will be possible to determine the resolved parts of the velocity $q$ in terms of the partial derivatives with respect to $x$ and $y$ as indicated by (15).

In order to determine the meaning of the function $\psi$, let it be assumed that it is related to another function $\phi$ such that $(\phi + i\psi)$ is a holomorphic function of $(x + iy)$.

If this is so, we know from (9) that:

$$\frac{\partial \phi}{\partial x} = \frac{\partial \psi}{\partial y} \quad \text{and} \quad \frac{\partial \phi}{\partial y} = -\frac{\partial \psi}{\partial x}.$$

Consequently, by substitution in (15), it follows that:

$$u = \frac{\partial \psi}{\partial y} = \frac{\partial \phi}{\partial x}$$

$$v = -\frac{\partial \psi}{\partial x} = \frac{\partial \phi}{\partial y} \qquad (16)$$

Now since $(\phi + i\psi)$ is a holomorphic function of $(x + iy)$, both $\phi$ and $\psi$ must be functions of $x$ and $y$. So that if we write the equations of a series of curves given by:

$$\psi = f\,(x \,.\, y) = \text{constant},$$

it follows that:

$$d\psi = \frac{\partial \psi}{\partial x} \,.\, dx + \frac{\partial \psi}{\partial y} \,.\, dy = 0;$$

and

$$\frac{dy}{dx} = -\frac{\partial \psi}{\partial x} \Big/ \frac{\partial \psi}{\partial y} \qquad (17)$$

This result (17) is the slope of the curves given by the equations $\psi$ = const.

But the slope of the velocity of $q$ in Fig. 5 is given by $\frac{v}{u}$

and this value is seen from (16) to be:

$$\frac{v}{u} = -\frac{\partial \psi}{\partial x} \Big/ \frac{\partial \psi}{\partial y},$$

which is identical with (17).

We see, therefore, that these curves, formed by putting the function $\psi$ = constant, have the same directions as the flow of the fluid. These curves, then, must be stream lines; and the function $\psi$ is consequently referred to as the *stream function.*

Another series of curves formed by putting $\phi$ = constant are orthogonal to the stream lines which follows from the fact that $\psi$ and $\phi$ are conjugate functions. This other series of curves has a meaning which will be referred to later on in the discussion.

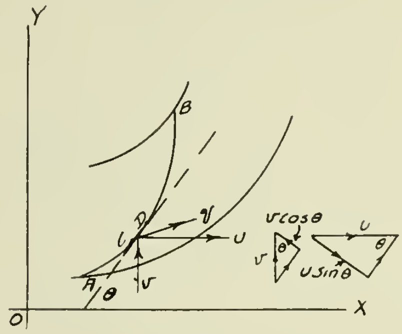

**Fig. 6**

From equations (16) it is also possible to write the value of the velocity $q$ in terms of these conjugate functions $\phi$ and $\psi$ as follows:

$$q^2 = u^2 + v^2$$

$$= \left(\frac{\partial \psi}{\partial y}\right)^2 + \left(-\frac{\partial \psi}{\partial x}\right)^2$$

$$= \left(\frac{\partial \phi}{\partial x}\right)^2 + \left(\frac{\partial \phi}{\partial y}\right)^2 \qquad (18)$$

Let $A$ and $B$ (Fig. 6) be any two points on the stream lines indicated, and let $ACDB$ be any curve connecting these two points. Let $CD$ be a distance $ds$ on this curve and let the slope of $ds$ with reference to the axis of $X$ be $\theta$ as indicated. Resolve $u$ and $v$ perpendicular to $ds$ as shown in the diagram.

Then the flow across $ds = (u \sin\theta \,.\, ds - v \cos\theta \,.\, ds)$

If we integrate along the curve $AB$, the total flow across this curve, which is really the flow between the stream lines is given by:

$$\int (u \sin\theta - v \cos\theta)\, ds.$$

Substituting in this the values of $u$ and $v$ from (16), we get for the flow between $A$ and $B$:

$$\int \left(\frac{\partial \psi}{\partial y} \sin\theta\, ds + \frac{\partial \psi}{\partial x} \cos\theta\right) ds.$$

But $\sin\theta\, ds = dy$ and $\cos\theta\, ds = dx$; so that the value of this flow becomes:

$$\int \left(\frac{\partial \psi}{\partial y} \,.\, dy + \frac{\partial \psi}{dx} \,.\, \partial x\right) = \int d\psi = \psi + C.$$

We see then that $\psi$ is in reality a function which may represent the actual flow of fluid between stream lines.

The usual procedure is to take one stream line as a base line and calculate the flow between this and any other stream line. It is also generally convenient to lay out stream lines so that the flow between any adjacent two is of equal amount.

### Velocity Potential

The function $\phi$ conjugate to $\psi$ is also capable of interpretation in hydrodynamic analysis.

It has been shown that if $w = (\phi + i\psi)$ is a holomorphic function of $z = (x + iy)$, we may write:

$$u = \frac{\partial \phi}{\partial x} \quad \text{and} \quad v = \frac{\partial \phi}{\partial y} \qquad \text{(See (16))}$$

But this last statement is merely the condition whereby there exists a function $\phi$ such that the following expression is its exact differential:

$$d\phi = u\,dx + v\,dy.$$

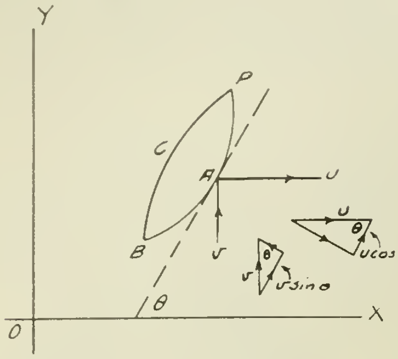

**Fig. 7**

From which, we get:

$$\phi = \int (u\,dx + v\,dy)$$
$$= \int \left( u \frac{dx}{ds} + v \frac{dy}{ds} \right) ds$$
$$= \int (u \cos\theta + v \sin\theta)\, ds \ldots\ldots\ldots (19)$$

From Fig. 7 we see that if the angle $\theta$ in (19) is the angle of inclination of the tangent at a point $A$ on any curve taken in the flow, then $u \cos\theta$ and $v \sin\theta$ are merely the resolved parts of the velocities $u$ and $v$ taken along this tangent. So that (19) is the integral of the tangential flow along any curve in the area being considered. This integral, in general, has not the same value for different paths from $B$ to $P$ along $BAP$ and $BCP$ for example. However, when the motion is irrotational, this integral has the same value for all paths from $B$ to $P$. In such cases the function $\phi$ is called the *velocity potential*.

If the integral is found along a closed curve such as $BAPCB$ the value is called the *circulation* along the curve. The circulation along a closed curve is zero for irrotational flow.*

Curves of equi-velocity potential are formed by putting $\phi$ = constant. These curves are orthogonal to the stream lines which follows from the fact that $\phi$ and $\psi$ are conjugate functions.

### Velocity of Flow

Now that we have established the relations of the functions $\phi$ and $\psi$ to stream line flow, it is possible to derive certain other practical results.

The velocity of flow at any point on a stream line may be found from the modulus of the derivative of

$w = (\phi + i\,.\,\psi)$ with respect to $z = (x + i\,.\,y)$.

Let $A$ and $B$ (Fig. 8) be two values of $z$ separated by infinitesimal amounts. The plane on which these values of $z$ are represented is called the $z$ plane. Similarly in Fig. 9 let $C$ and $D$ be two values of $w$ infinitesimally close together on the $w$ plane. Let $AB = ds$ and $CD = d\rho$, then:

$$\left(\frac{d\rho}{ds}\right)^2 = \frac{d\phi^2 + d\psi^2}{dx^2 + dy^2} \ldots\ldots\ldots\ldots\ldots (20)$$

But since $w$ is assumed to be a holomorphic function of $z$:

$$d\phi = \frac{\partial\phi}{\partial x}\,.\,dx + \frac{\partial\phi}{\partial y}\,.\,dy;$$

and
$$d\psi = \frac{\partial\psi}{\partial x}\,.\,dx + \frac{\partial\psi}{\partial y}\,.\,dy\ldots\ \ldots\ldots\ldots (21)$$

*This statement is true for paths which enclose fluid only. If the circulation is taken around a body it has a constant value.

Substituting values from (21) into (20), we get

$$\left(\frac{d\rho}{ds}\right)^2 = \left(\frac{\partial\phi}{\partial x}\right)^2 . dx^2 + \left(\frac{\partial\phi}{\partial y}\right)^2 . dy^2 + \frac{2\,\partial\phi^2}{\partial y\,\partial x} . dy\,.\,dx +$$
$$\left(\frac{\partial\psi}{\partial x}\right)^2 . dx^2 + \left(\frac{\partial\psi}{\partial y}\right)^2 . dy^2 + 2\,\frac{\partial\psi^2}{\partial y\,\partial x} . dy\,.\,dx/dx^2 + dy^2 \,.\,.\,(22)$$

But
$$2\frac{\partial\phi^2}{\partial y\,\partial x} = 2\frac{\partial\phi}{\partial y}\cdot\frac{\partial\phi}{\partial x}\ldots\ldots\ldots\ldots\ldots (23)$$

Substituting from (9) values for $\frac{\partial\phi}{\partial y}$ and $\frac{\partial\phi}{\partial x}$ into (23), we get:

$$2\frac{\partial\phi^2}{\partial y\,\partial x} = -\,2\frac{\partial\psi}{\partial y}\cdot\frac{\partial\psi}{\partial x} = -\,2\,\frac{\partial\psi^2}{\partial y\,.\,\partial x}\ldots\ldots (24)$$

If we substitute from (24) into (22), it is seen that the third and sixth terms of the right hand side of equation (22) cancel out and (22) becomes:

$$\left(\frac{d\rho}{ds}\right)^2 = \frac{\left[\left(\frac{\partial\phi}{\partial x}\right)^2 + \left(\frac{\partial\psi}{\partial x}\right)^2\right] dx^2 + \left[\left(\frac{\partial\phi}{\partial y}\right)^2 + \left(\frac{\partial\psi}{\partial y}\right)^2\right] dy^2}{dx^2 + dy^2}$$

This expression becomes by substitution from (9):

$$\left(\frac{d\rho}{ds}\right)^2 = \frac{\left[\left(\frac{\partial\phi}{\partial x}\right)^2 + \left(\frac{\partial\psi}{\partial x}\right)^2\right] dx^2 + \left[\left(-\frac{\partial\psi}{\partial x}\right)^2 + \left(\frac{\partial\phi}{\partial x}\right)^2\right] dy^2}{dx^2 + dy^2}$$
$$= \frac{\left[\left(\frac{\partial\phi}{\partial x}\right)^2 + \left(\frac{\partial\psi}{\partial x}\right)^2\right](dx^2 + dy^2)}{dx^2 + dy^2}$$
$$= \left(\frac{\partial\phi}{\partial x}\right)^2 + \left(\frac{\partial\psi}{\partial x}\right)^2 = \left(\frac{\partial\phi}{\partial x}\right)^2 + \left(-\frac{\partial\psi}{\partial x}\right)^2$$

Substituting values from (9) again this becomes:

$$\left(\frac{d\rho}{ds}\right)^2 = \left(\frac{\partial\phi}{\partial x}\right)^2 + \left(\frac{\partial\phi}{\partial y}\right)^2$$

This expression is the same as (18) which is the value of

$$q^2 = u^2 + v^2$$

So that we find:
$$q^2 = \left(\frac{d\rho}{ds}\right)^2 \ldots\ldots\ldots\ldots\ldots\ldots (25)$$

In Fig. 8, $A$ and $B$ are two values of $z$ differing by an infinitesmal amount. $OA$ is the modulus of one value and $OB$ the modulus of the other value. The difference between the values of $z$ will give $dz$; and from former discussions, it

**Fig. 8**

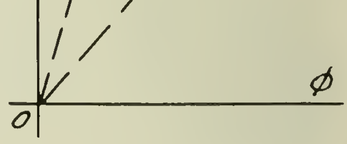

**Fig. 9**

is seen that, subtracting the moduli vectorially, $AB = ds$ has the same value as the modulus of $dz$. In the same way, it is seen that $CD = d\rho$ (Fig. 9) has the same value as the modulus of $dw$.

Result (25) may then be written:

$$q = \left|\frac{dw}{dz}\right| \ldots\ldots\ldots\ldots\ldots\ldots\ldots (26)$$

### Combined Stream Lines

It will be seen further on that certain types of stream lines are arrived at most conveniently by combining two or more well known and easily derivable flows. It is necessary, therefore, to derive the method by means of which these stream lines can be combined.

Consider two forms of stream lines given by $\psi_1 = C_1$ and $\psi_2 = C_2$.

The $x$ and $y$ resolved parts of the velocity of flow are related to the stream function as follows: (See 15)

$$u_1 = \frac{\partial \psi_1}{\partial y}; \quad v_1 = -\frac{\partial \psi_1}{\partial x}; \quad u_2 = \frac{\partial \psi_2}{\partial y}; \quad v_2 = -\frac{\partial \psi_2}{\partial x}.$$

Let the desired resultant stream function of $\psi_1$ and $\psi_2 = \psi$. Let $u = \frac{\partial \psi}{\partial y}$ and $v = -\frac{\partial \psi}{\partial x}$ be the $x$ and $y$ resolved parts of the velocity of flow related to $\psi$. Then combining resolved parts in the same direction, we get:

$$u = u_1 + u_2 = \frac{\partial \psi_1}{\partial y} + \frac{\partial \psi_2}{\partial y} = \frac{\partial (\psi_1 + \psi_2)}{\partial y} = \frac{\partial \psi}{\partial y}$$

$$v = v_1 + v_2 = -\left(\frac{\partial \psi_1}{\partial x} + \frac{\partial \psi_2}{\partial x}\right) = -\frac{\partial (\psi_1 + \psi_2)}{\partial x} = -\frac{\partial \psi}{\partial x}$$

From which it is evident that $\psi = (\psi_1 + \psi_2)$. That is: the resultant stream lines $\psi =$ const. are formed by adding together the superimposed stream functions.

### Types of Stream Lines

One of the most useful theoretical conceptions of stream flow is a point from which fluid issues at a uniform rate in all directions. Such a point is known as a *source*. The volume of fluid which appears from a source in unit time is known as its *strength*.

Let $O$ (Fig. 10) be a source of unit strength $m$. Take $OX$ as the base line from which to calculate stream flow, i.e. $OX$ is the stream line $\psi = 0$.

Then if a uniform depth is maintained at all points, the flow between $OX$ and any other stream line $OA$ will be

$$\psi = \frac{m}{2\pi} . \theta = \frac{m}{2\pi} \tan^{-1} \frac{y}{x}.$$

On the other hand, the conception of a point at which fluid disappears at a uniform rate is called a *sink* which may be regarded as a negative source.

Mathematically, the idea of a source can be arrived at by considering the function of a complex variable given by the expression:

$$w = \log z,$$

where $w = (\phi + i . \psi)$ and $z = (x + i . y) = r(\cos\theta + i \sin\theta)$ $w = \log z$ may be written $e^w = z$; and if the values of $w$ and $z$ be substituted, we get:

$$e^{(\phi + i\psi)} = e . ^\phi e^{i . \psi} = r(\cos\theta + i\sin\theta)$$

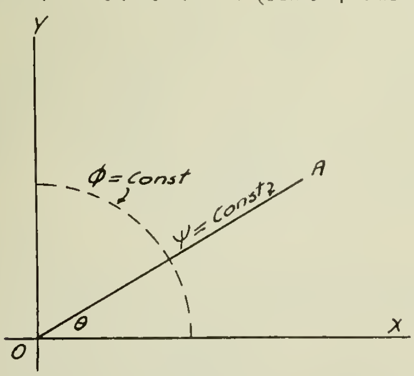

Fig. 10

But since $\quad e^{i\theta} = (\cos\theta + i\sin\theta)$ ............(See B)

it follows that: $\quad e^{i\psi} = (\cos\psi + i\sin\psi)$.

Then by substitution:

$$e^{(\phi + i\psi)} = e^\phi . e^{i\psi} = e^\phi(\cos\psi + i\sin\psi) = r(\cos\theta + i\sin\theta)$$

from which: $\quad e^\phi . \cos\psi + ie^\phi \sin\psi = r\cos\theta + i . r . \sin\theta$

Equating real and imaginary parts:

$$\begin{aligned} e^\phi \cos\psi &= r\cos\theta \\ e^\phi \sin\psi &= r\sin\theta \end{aligned} \quad \text{.............. (27)}$$

Squaring and adding these results:

$$(e^\phi)^2 (\sin^2\psi + \cos^2\psi) = r^2(\sin^2\theta + \cos^2\theta)$$

$$e^\phi = r \text{.................. (28)}$$

or

$$\phi = \log r = \log |z| \text{ ............. (29)}$$

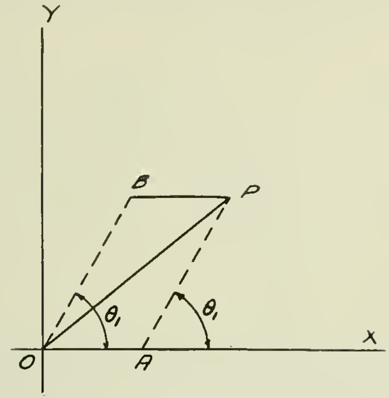

Fig. 11

Then by substituting the value of $r$ from (28) into (27), we get

$$e^\phi \cos\psi = e^\phi \cos\theta$$

$$\cos\psi = \cos\theta$$

$$\psi = \theta = \text{arg. } z \text{........... (30)}$$

So that it is seen that the original expression $w = \log z$ gives stream functions and velocity potential values which may be determined from (29) and (30).

The stream lines given by placing $\psi =$ const. are evidently straight lines. For $\psi = \theta =$ const. expresses the fact that these are straight lines radiating from a point which we recognize as a source.

The velocity potential curves are given by

$$\phi = \log r = \text{const.}$$

and are evidently a series of circles with the source as centre.

The velocity at any point (see 26) is given by:

$$q = \left|\frac{dw}{dz}\right| = \left|\frac{d \log z}{dz}\right| = \left|\frac{1}{z}\right| = \frac{1}{r}.$$

From which it is seen that the velocity varies inversely as the radius from the source.

It is easily seen from the above that a sink being a negative source, either of the following forms will give expressions from which sink results may be obtained:

$$w = -\log z = \log \frac{1}{z}.$$

The addition of a numerical constant to the variable in the above logarithmic functions gives a method by means of which any number of sources and sinks may be combined. For instance: $w = \log(z - 1)$ is a function from which source stream lines may be obtained; but the source has been shifted from the origin to a point $+1$ along the axis of $X$. This may be seen from Fig. 11.

Let $P$ and $A$ in Fig. 11 represent the points $z$ and $+1$ respectively with $O$ as origin. Then if $PB$ be constructed equal to $-(+1)$, the point $B$ represents $(z - 1)$ with $O$ as origin. But it can be seen from the construction that since $AP = OB = |z - 1|$, the point $P$ may represent $(z - 1)$ with $A$ as origin.

Let $|z - 1| = AP = r_1$ and arg. $(z - 1) = \theta_1$.

Then since

$$w = \log(z - 1)$$

$$(z - 1) = e^w = e^{\phi + i\psi} = e^\phi . e^{i\psi}$$

$$= e^\phi(\cos\psi + i\sin\psi) = r_1(\cos\theta_1 + i\sin\theta_1)$$

From which by the same process as for the derivation of (29) and (30). we get:

$$\phi = \log r_1 = \log |z - 1|$$
$$\psi = \theta_1 = \text{arg.}\ (z - 1)$$

It is seen that if $\phi$ and $\psi$ be placed equal to constant values, we have a source at $A$ (Fig. 11).

As an illustration of the usefulness of the last proposition, consider the case where

$$w = \log \frac{(z-1)}{(z+1)} = \log (z - 1) - \log (z + 1)$$

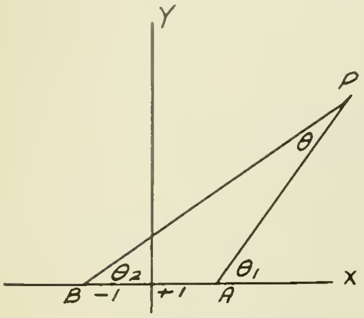

Fig. 12

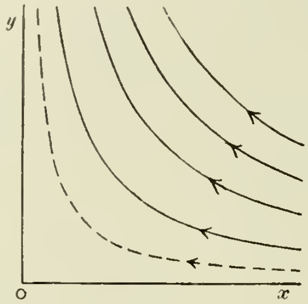

Fig. 13

Here we have the case of a source located at + 1 from the origin and a sink at a point − 1 from the origin.

The stream lines are given by the stream function:

$$\psi = \text{arg.}\ (z - 1) - \text{arg.}\ (z + 1) = \text{const.}$$

or $$\theta_1 - \theta_2 = \text{const.}$$

In Fig. 12, the source is located at $A$ and the sink at $B$. Then the point $P$ is located upon a stream line given by $\theta_1 - \theta_2 = \text{const.}$

But evidently $\theta_1 - \theta_2 = \theta$; and if $\theta$ is a constant value, then the point $P$ must be located on a circle passing through $A$ and $B$.

The combined stream lines of a source and sink may therefore give a series of circles passing through the source and sink. These stream lines have an analogy in the well known electromagnetic lines from a north to a south pole.

The theory of sources and sinks may be made use of to give a variety of stream lines especially when combined with uniform parallel flow. The reader will find numerous examples of these stream lines described in aeronautic and hydrodynamic literature.

The determination of stream line forms from other functions of complex variables gives a field of speculation which is very interesting. It is not easy to determine the equations for given forms as will be seen if the reader tries to find stream lines to fit a given predetermined outline.

Some of the simpler equations will give an idea of what can be done. Hard work and research must be depended upon to yield further results.

Throughout this discussion one simple form $w = z^2$ has been used for the purpose of illustration. This is one of the series: $w = z^n$. If $n = 2$, $w = z^2$ and

$$\phi = x^2 - y^2$$
$$\psi = 2\,xy$$

The stream lines for this take the form $\psi = 2\,xy =$ const. which if plotted give rectangular hyperbolae as shown in Fig. 13. The stream line $2\,xy = 0$ is formed by the axes of $x$ and $y$. So that in effect we get the theoretical flow between two planes perpendicular to one another.

If we put $n > 2$, we get a flow of the type indicated in Fig. 14. On the other hand by putting $n < 1$, we get the flow shown in Fig. 15.

The equation $w = z + \frac{1}{z}$ gives an interesting form from which further valuable results may be obtained. Expanding this equation, we get:

$$w = (x + iy) + \frac{1}{(x + iy)}$$
$$= (x + iy) + \frac{(x - iy)}{(x^2 + y^2)}$$
$$= \frac{x^3 + ix^2y + xy^2 + iy^3 + x - iy}{x^2 + y^2}$$
$$(\phi + i\psi) = \frac{(x^3 + xy^2 + x)}{x^2 + y^2} + \frac{i\,.\,y\,(x^2 + y^2 - 1)}{x^2 + y^2}$$

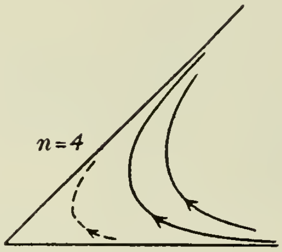

Fig. 14

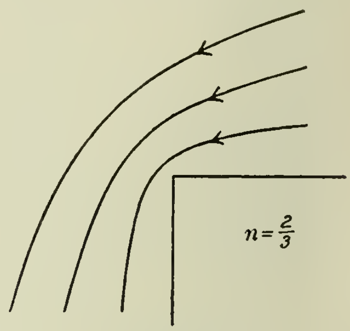

Fig. 15

Equating imaginary parts, it is seen that

$$\psi = \frac{y\,(x^2 + y^2 - 1)}{x^2 + y^2}$$

If this result be placed equal to constant values, the stream line resulting from $\psi = 0$ gives us:

$$\frac{y\,(x^2 + y^2 - 1)}{x^2 + y^2} = 0$$

So that either: $x^2 + y^2 - 1 = 0$ or $y = 0$.

The first result is the equation of a circle of radius unity, the other being the equation of the axis of reals.

We see then that the boundary of this stream line flow is the axis of $x$ and the circumference of a circle, the remaining stream lines giving a flow as indicated in Fig. 16.

### Conclusion

These fundamental ideas should enable the reader to continue his studies on the subject. It can be shown, for instance, that the flow around a circle placed in a uniform parallel flow may be transformed, as it is called, to flow around airfoil sections. Other combinations of sources and sinks will give outlines approximating air ship and boat sections. Of course, a great amount of design is dependent

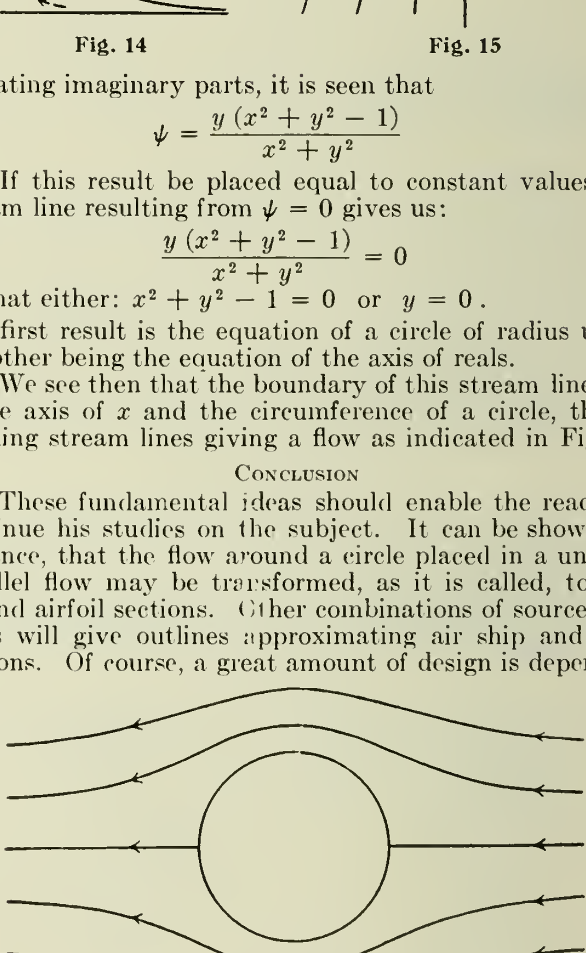

Fig. 16

upon experimental data; but a true comprehension of what is going on can never be had if the theoretical basis of hydrodynamics is not understood.

# The National Parks of Canada and The Trans-Canada Highway

*J. M. Wardle, M.E.I.C.,*
*Chief Engineer, National Parks of Canada, Ottawa, Ontario.*

**Presented together with Mr. Patrick Philip's paper on Highways and Highway Transportation in British Columbia, at the Western Professional Meeting of The Engineering Institute of Canada, Vancouver, B.C., July 11th to 14th, 1934**

There is a very close association between the National Parks of Canada and the Trans-Canada highway since, west of the Great Lakes, eight great parks are within an easy day's motoring, or less, of the highway, and the latter actually goes through two of them.

Banff National Park, with an area of 2,585 square miles, and Yoho National Park adjoining it to the west, with an area of 507 square miles, are practically bisected by the road. This geographical fact is of tremendous mutual advantage; on the one hand the two National parks mentioned have Canada's main highway as their main tourist artery, and on the other hand trans-Canada motorists will have the advantage of traversing some of the most scenic mountain areas of the Dominion.

After traversing the prairie sections of the highway, motorists, west bound, will see from Calgary the snow covered peaks of the Rocky Mountain range through which the route will lead them. Along it they will enjoy world famous views of mountain peaks, valleys, snowfields and lakes, and glaciers and alplands.

Seventy-three miles west of Calgary the highway enters Banff National Park—and for 89 miles traverses National park areas. Of this distance 57 miles is in Banff Park and 32 miles in Yoho Park. This section of the highway was constructed some years ago by the National Parks Branch of the Department of the Interior, and is maintained by that Branch to the degree necessary for the safety and comfort of the motoring public.

In addition to the splendid mountain scenery visible from the Trans-Canada highway itself, there are 96 miles of first class roads tributary to it in Yoho and Banff Parks,

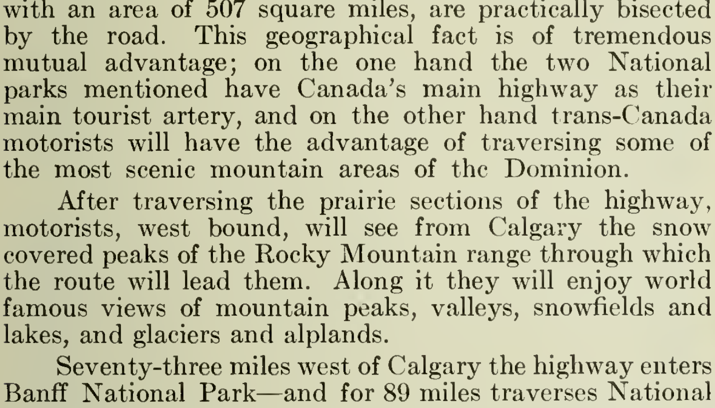

**Fig. 1**

that make accessible to the motorist many well known scenic points. Among them are

Moraine Lake and the Valley of the Ten Peaks,
Marble Canyon,
Lake Louise, Hector Lake,
The Yoho Valley and Takakkaw Falls, and
The Emerald Lake District.

Then 20 miles west of Banff, the Banff-Windermere road branches off to the south to go through Kootenay Park, crossing the Continental Divide by the Vermilion Pass at an elevation of 5,660 feet. After 73 miles it connects with a provincial road at Parkgate, B.C. By motoring north from this point some 67 miles, connection is made with the main highway again at Golden, B.C., thus providing an alternative route through the Rocky Mountain range.

While the National Park section of the highway is in the Rocky Mountain range, grades and alignment are

**Fig. 2—Trans-Canada Highway in Banff National Park. Massive Range in Background.**

remarkably good. The ruling grade is 6 per cent with a maximum of 8 per cent—the latter being found in only two short stretches totalling 2,500 feet.

Curvature is continually being reduced and particular attention is paid to superelevation.

The average width of actual road way is twenty feet —and all major revisions and improvements are now being constructed to a standard that provides a 22-foot wheelway exclusive of side ditches. Extra width is given on all curves in proportion to the degree of curvature. The road is well surfaced with screened gravel, and the entire 89-mile section through Banff and Yoho National Parks is treated with dust-laying oil each season. Motorists can consequently enjoy the mountain driving in comparative safety and comfort.

The elevation of the highway through Yoho and Banff Parks varies from 3,700 feet to 5,450 feet, the latter elevation being near the Continental Divide in the Kicking Horse Pass. Timber line is consequently not far away and the spring run-off from the bare rock exposures above it is usually short and intense.

These natural conditions result in a tremendous variation in stream flow. For forty-six weeks of the year half of the culverts may carry no water whatever. For the remainder of the year they must have sufficient capacity to carry flood run-offs. An interesting example of flow variation is that of the Bow river—which rises in the Bow

Lakes area on the continental divide—62 miles northwest of Banff.

The minimum flow of the Bow at Banff is some 350 second feet—while in the spring floods in June its flow reaches 9,300 second feet.

A much wider flow variation in proportion is shown by Corral Creek in the Lake Louise district. A short maximum flood run-off of 300 second feet is reduced in the low water period to 3 second feet. In the first instance

Fig. 3—Trans-Canada Highway in Yoho National Park. President Group of Mountains in Background.

the drainage structure required is a 70-foot bridge costing $4,500. In the second instance a 2-foot by 3-foot culvert at a cost of $80 would be sufficient.

The fan shaped gravel and loose rock ridges built up by the mountain streams when they reach the main valleys complicate the location of bridge sites and make the choice of the latter a matter of careful adjustment between alignment and length of span.

So far in maintaining the Parks section of the Trans-Canada highway as much trouble has been experienced in the winter months withice conditions, as in the spring run-off. Alternative flooding and freezing of streams at bridge sites—coupled with the formation of anchor ice—frequently raises the water surface above flood levels. Ice forming under bridges will reach a thickness of from 8 to 12 feet and on occasions has reached the lower chords. In such cases explosives are used to relieve the situation.

Culverts occasionally fill with ice during the winter months and are practically ice blocked when the spring run-off occurs. More than normal capacity is consequently provided in the case of all drainage structures where ice troubles are anticipated.

The comparatively high elevation of the Trans-Canada highway through the National Park section results in winter conditions prevailing for from six to six and one-half months of the year. Such conditions are however by no means extreme. The entire route is naturally open from about May 20th to November 1st, which gives an ample margin of time over and above the length of the average tourist season.

By the use of snow ploughing equipment the open season for the Parks section of the road can be indefinitely extended.

The 16½ miles of road west from Lake Louise—and crossing the Great Divide—is the only section where serious drifts occur and these offer no great obstacles to a rotary plough. The maximum depth of snow on the level ranges from four to six feet.

The Trans-Canada route through the Rockies is remarkably free of snow-slide areas and is perfectly safe in this respect.

At Leanchoil, B.C., the west boundary of Yoho Park is reached and the Trans-Canada highway there becomes the responsibility of the province of British Columbia. After 17 spectacular miles through the lower Kicking Horse Canyon, the road passes through the town of Golden on the way to Donald, B.C.—15½ miles further west.

The Golden-Donald section is still under construction. At Donald, the highway returns to the temporary jurisdiction of the National Parks Branch which is constructing the 78-mile section from Donald to Canoe river as a Federal Government project. This section is part of the uncompleted link of the highway in British Columbia between Golden and Revelstoke, B.C.

A short route between these two points could be found over Rogers Pass parallel to the main line of the Canadian Pacific Railway, and would pass through Glacier National Park. However, owing to the shorter summer season on this route, the prevalence of snow-slides, the heavier gradients encountered, and general construction difficulties, it was mutually agreed by the Federal and Provincial Governments that the longer but easier route following the Columbia river—and called the "Big Bend Road"—would be adopted.

The National Parks Branch is building the east leg of the Big Bend section in lieu of spending an equal amount in the construction of the 36-mile section through Glacier Park, which would have been necessary if the Rogers Pass route had been chosen.

The location of this section of the Trans-Canada highway, together with that of the section through the National parks, is shown on the maps accompanying this article. These show the close relation between Canada's parks and her trans-continental highway, each being a distinct asset to the other.

VOLUME XVII OCTOBER 1934 No. 10

## Young Engineers and The Institute

The young man who desires to enter upon an engineering career to-day finds himself greatly handicapped by existing economic conditions. His experience during the early years of his professional life should enable him to realize that his academic training is only the first stage in his engineering education, and this experience can only be obtained through actual contact with industry and with other members of his profession. Active membership in an engineering society is of particular value to him at this time, since it gives opportunities for personal contacts of the most valuable kind, and can exert a powerful influence on his professional development. Unfortunately, as things now are, he finds it difficult, if not impossible, to secure employment involving any professional responsibility or practical experience in industry or construction, and he may even feel that he cannot well afford the modest sum needed for the junior classes of membership in such a body as The Engineering Institute. These conditions, which are, of course, not peculiar to Canada, present a very definite problem, which demands and is receiving attention from practically all leading engineering societies. The graduating classes of our engineering schools are yearly turning out fresh additions to the ranks of these "engineers-in-training," if one may use the apt expression employed in British Columbia, and the graduates from these schools form the principal source from which our members of the future must be drawn. Actually, our Student and Junior members make up about a quarter of the total membership of The Institute.

Recently, the General Secretary, during his visits to the western branches, had the interesting experience of meeting and hearing the views of a considerable number of members of these younger groups from the western universities. They are keenly interested in the profession they have chosen. They are seeking, but not always finding, further training through professional employment, and need all the help that older members can give them. It must be remembered that many of these young graduates will eventually become corporate members of The Institute. It is therefore of primary importance to The Institute, as well as to the young men themselves, that membership should be available to them, and that they should be induced to take an active part in The Institute's affairs. This can be done if our branches, wherever the need exists, will take such measures as will bring these younger men within the influence of The Institute, assure them of the sympathy and help of the older members, and make definite arrangements for their participation in branch and Institute activities, both in regard to meetings and committee work. The actual course to be taken to secure this desirable result depends on local conditions. In some of our larger centres active and enthusiastic Junior Sections of the branch are already at work, the members of which organize and hold their own meetings for the presentation and discussion of papers arranged for by themselves. In other cases the sympathy and assistance of The Institute branch has been given to a junior engineering society formed within the local engineering school. In most of the smaller branches such arrangements as these are not possible, but much can be done by encouraging the participation of the younger men in meetings specially held for them, which may well be of a somewhat less formal nature than the regular meetings of the branch.

The Institute itself, and several of our branches, encourage the work of the Students and Juniors of The Institute in competing for special prizes awarded for meritorious papers, and in one of the western branches the younger members are invited to prepare short talks to be delivered before small groups at several of the meetings of the branch during the coming season. Many of the younger men, while anxious to work for and with The Institute, feel a natural diffidence in expressing their views in the presence of a large number of their older confrères. An article discussing the relations of Juniors and Students to The Institute will be found on another page, suggested by a thoughtful report recently presented to the American Society of Mechanical Engineers and prepared by a group of junior members of that body.

The report tells what an engineering society "can do for the junior member, and suggests activities for him that will strengthen his interest and increase his value and loyalty."

An enquiry of this kind is only one indication, among many others, of the sincere desire of the younger groups for constructive action leading to improvement and wider opportunities for self-development. Youth to-day is not content to accept as unchangeable existing conditions which are due to mere inertia, or which press hardly, and for which the rising generation does not feel itself responsible. The younger men are seriously concerning themselves with questions of the day, seeking solutions for them, and are anxious to help in bringing about the developments which are needed to make the world a better place to live in. The seniors have their part also, that of giving tactful guidance to these efforts, such help as is possible in securing professional experience and information, and encouragement in any movement showing constructive thought and activity on the part of their younger confrères. Such activities, if based on the enthusiasm and co-operative effort of youth, and rightly directed, will naturally bring out new points of view and throw unexpected light on time-worn problems. They can set in motion constructive agencies which are capable of great results when backed by the sympathy and tempered by the experience of the older men.

These considerations apply not only to our economic and industrial difficulties—they are equally applicable to the problems of professional education and training and to the questions of organization and administration which confront professional engineering societies.

## Meeting of Council

A meeting of Council was held at Headquarters on Friday, September 21st, 1934, at eight o'clock p.m., with President F. P. Shearwood, M.E.I.C., in the chair, and eleven other members of Council present.

A statement from the chairman of the Finance Committee indicated that to date the total revenue and expenditure were very close to the amounts anticipated in the budget.

The President and Secretary reported that during their visits to the western branches a number of questions had been raised and some suggestions made regarding Institute organization and policy, and these were presented for Council's consideration. It was decided that before taking any action, a memorandum covering the suggestions made should be forwarded to all members of Council with a request for written comments to be considered at the October meeting of Council.

It was felt that the Council should put on record its appreciation of the excellent work done by those responsible for the organization of the recent Vancouver meeting of The Institute and the American Society of Civil Engineers, which had been such an outstanding success. Accordingly the Secretary was directed to express Council's thanks and appreciation to the chairman of the local joint committee, Mr. E. A. Cleveland, M.E.I.C., M.Am.Soc.C.E., and to the committee members.

The report of the Nominating Committee was received and held over pending the receipt of all necessary letters of acceptance from nominees.

The tentative programme for the Annual General and General Professional Meeting of The Institute in February 1935, as submitted by the Toronto Annual Meeting Committee, was noted and approved.

Attention was drawn to the fact that following the change of government in Ontario a number of engineers employed by the government had been dismissed, the majority of whom, however, had been given the option of remaining at their tasks at salaries to be decided upon later.

The President reported the action so far taken, including the despatch of telegrams to the Premier of Ontario and to the Chairman of the Hydro-Electric Power Commission of Ontario, suggesting that action be delayed pending the receipt of representations from The Institute. After prolonged discussion, it was decided that a memorandum along the lines of a draft already submitted to the Ontario branches should be prepared and forwarded from the Council of The Institute to the Premier of Ontario.

Two resignations were accepted, a number of reinstatements were effected, and several special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

| *Elections* | | *Transfers* | |
|---|---|---|---|
| Assoc. Members | 8 | Assoc. Member to Member | 1 |
| Juniors | 3 | Junior to Assoc. Member | 6 |
| Affiliates | 2 | Student to Assoc. Member | 3 |
| Students admitted | 5 | Affiliate to Assoc. Member | 1 |
| | | Student to Junior | 5 |

The Council rose at eleven fifty p.m.

## Annual Meeting 1935

The Forty-Ninth Annual General and General Professional Meeting of The Institute is to be held at Toronto, Ont., on Thursday and Friday, February 7th and 8th, 1935. On Saturday, February 9th, a number of plants will be visited.

## OBITUARIES

### Sven Svenningson, M.E.I.C.

Widespread regret will be felt at the death of Sven Svenningson, M.E.I.C., which occurred suddenly at Bailey Island, Maine, on August 16th, 1934.

Mr. Svenningson was born at Oslo, Norway, March 19th, 1884, and graduated from the Polytechnic Institute of Christiania in 1907 with the degree of M.E. Upon his graduation he entered the turbine department of Kvaerner Brug, Christiania, where he was employed as a designer for a little over a year. In 1908 and 1909 he was in charge of the design and construction of a rubber factory for the Svenska Gummivarefabrik, Christiania.

SVEN SVENNINGSON, M.E.I.C.

In 1909 he left Norway for the United States and joined the engineering staff of the Pennsylvania Water and Power Company on the construction of their hydro-electric plant at Holtwood.

From that time Mr. Svenningson was engaged on hydro-electric work almost continuously until the time of his death, and gained recognition as a leader in this field.

After five years in the United States, during which time, in addition to his work at Holtwood he was engaged with the Fargo Engineering Company at Jackson, Mich., and on the Mississippi River development at Keokuk, Iowa, for Stone and Webster, he came to Canada in 1913 as assistant engineer in charge of structural and mechanical design on the Cedars' development of the Cedars Rapids Manufacturing and Power Company.

Upon the completion of this work in 1915, he became designing engineer of The Shawinigan Water and Power Company. In 1918, when The Shawinigan Engineering Company was formed to handle the major designing and construction activities of the parent company, he was appointed its chief engineer and in 1921 was made vice-president and chief engineer of Power Engineering Company, formed to supervise similar work for all the subsidiaries as well as for the allied interests of the parent company. These positions he held at the time of his death

These were busy years, marked by rapid growth in the Shawinigan Company's system and the engineering organization was called upon to investigate and design a large number of power developments for the Shawinigan Company and others. Upon Mr. Svenningson's advice, and in most cases under his direction, such outstanding developments as La Gabelle and Rapide Blanc on the St. Maurice river; Great Falls on the Winnipeg river; Chelsea, Farmers and Paugan on the Gatineau river; and others totalling more than a million horse-power were brought into successful operation. His contribution to the industrial upbuilding of his chosen country was outstanding. Of him, as of few members of his profession in Canada, can it be said in the beautiful words of Mr. Justice Holmes: "To gather the streams from waste and to draw from them energy, labour without brains, and so to save mankind from toil that it can be spared, is to supply what next to intellect is the very foundation of all our achievement and all our welfare."

Mr. Svenningson always took an interest in engineering society work. He was a Member of The Engineering Institute of Canada since 1919; a Charter Member of the Corporation of Professional Engineers of Quebec; an honoured Member of the National Electric Light Association on the Hydraulic Power Committee of which he was active for several years; a Member of the American Society for Testing Materials and of the Canadian Engineering Standards Association, serving on the Heavy Forgings Committee.

Keen of mind, sound in judgment and possessing engineering ability of a high order, Mr. Svenningson impressed his personality on all those with whom he came in contact and at the same time endeared himself to his associates by his kindliness, sympathy and good-fellowship.

On Sunday, the 19th of August, Mr. Svenningson's friends and colleagues laid him to rest in a little cemetery on the crest of Bailey Island, Maine. Not far away are the homes and wharves of the fisherfolk, whose company, year after year, he and his growing family sought, because the life along the rock-bound coast of Maine corresponded so closely to that of his boyhood in far off Norway.

The simplicity, dignity and peacefulness of his funeral were in perfect accord with the philosophy of his living, for in the midst of the crises that accompany the progress of the many large hydro-electric enterprises for which he was primarily responsible, he was invariably calm, confident and courageous. Notwithstanding his widespread professional responsibilities, his private life was extraordinarily simple and happy. Those of his colleagues in the public utility business in Canada and the United States, and those members of the engineering profession who were in attendance at his funeral, were all comforted with the knowledge that his long, useful and notable engineering career should be so fittingly concluded.

### John Herbert Munro, A.M.E.I.C.

Regret is expressed in placing on record the death at London, Ontario, of John Herbert Munro, A.M.E.I.C.

Mr. Munro was born at Inverness, Scotland, on September 5th, 1881, and received his education at the Inverness Royal Academy, the Merchiston Castle School, Edinburgh, and the Inverness Technical School. From 1899 to 1904 Mr. Munro was an apprentice with Mr. James Fraser, of Inverness, and in 1904-1905 he was assistant engineer with Mr. Fraser. In 1905-1907 he was assistant engineer with the Bombay Burmah Corporation of Burmah and Siam, and in 1907-1908 was again with Mr. Fraser as assistant engineer. In 1908-1909 he was resident engineer on Inverness harbour works, and in 1909-1910 was engaged in the same capacity on harbour works at Portgordon. Coming to Canada, Mr. Munro joined the staff of the Public Works Department at Ottawa as assistant engineer, and remained with the Department until 1915, when he went overseas with the Canadian Engineers. He was promoted to the rank of Captain early in 1918, and returned to Canada in 1919 when he was in the assistant chief engineer's office of the Department of Public Works, Ottawa. He was later attached to the Department at Antigonish, N.S., and Halifax, N.S., and in 1924 was transferred to London, Ont. where he remained until the time of his death.

Mr. Munro joined The Institute as an Associate Member on April 13th, 1912.

## PERSONALS

A. W. Crawford, A.M.E.I.C., Deputy Minister, Department of Labour, Ontario, of Toronto, Ont., has been appointed chairman of the Minimum Wage Board of the same Department.

G. Morrison, M.E.I.C., has become connected with the Commonwealth Electric Corporation Limited, and is located at Welland, Ontario. Mr. Morrison was at one time district manager in the maritime provinces for the English Electric Company of Canada Ltd., at Sydney, N.S., and was later with the same company at Toronto and St. Catharines, Ontario.

Brigadier J. L. Gordon, A.M.E.I.C., formerly O.C. of military district No. 12 at Regina, Sask., is now at Military district No. 10, Winnipeg, Man. Brigadier Gordon was at one time director of Civil Government Air Operations, with the Department of National Defence, Ottawa, Ont.

Gordon W. Hatfield, Jr.E.I.C., is now sugar chemist with Crosse and Blackwell (Canada) Limited, at Toronto, Ont. Mr. Hatfield, who graduated from McGill University in 1931 with the degree of B.Sc., was formerly assistant chemist with the Atlantic Sugar Refineries Limited, at Saint John, N.B.

A. T. Cairncross, S.E.I.C., who graduated from Queen's University in 1931 with the degree of B.Sc., has left Canada for Chungking, China, 2,000 miles in the interior up the Yangtze river, where he will be employed on railway construction and operation by the government of Chungking province.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on September 21st, 1934, the following elections and transfers were effected:

*Associate Members*

ASSELIN, Jean Charles Leandre, B.A.Sc., C.E., (Ecole Polytechnique), town engineer and manager, La Tuque, Que.

BAIN, William Alexander, B.A.Sc., (Univ. of B.C.), res. engr., B.C. Pulp & Paper Co. Ltd., Woodfibre, B.C.

DUPUIS, René, E.E., (Univ. of Nancy), asst. supt., Quebec Power Company, Quebec, Que.

LIGERTWOOD, Henry Cormack Grant, B.Sc., (Univ. of Man.), Relief Project 103-2, Ethelbert, Man.

MacGREGOR, Kenneth Roy, B.Sc., (Queen's Univ.), foreman-in-charge, Race Horse Camp, Petewawa, Ont.

OLSEN, Aleksander, (Horten Navy College), estimator and engr., Atlas Construction Company, Montreal, Que.

WALKER, John Marshall, engr. and chief dftsman, water supply section, Dept. of Works, Toronto, Ont.

YAPP, Spencer Raymond Anthony, B.Sc. (Eng.), (Univ. of London), manager, Bepco Canada Limited, 1050 Mountain St., Montreal, Que.

*Juniors*

BROWN, William Edward, B.A.Sc., (Univ. of Toronto), asst. foreman, rope dept., The B. Greening Wire Company, Hamilton, Ont.

CAPE, John Meredith, (Grad., R.M.C.), estimator, E. G. M. Cape & Co., Montreal, Que.

COLPITTS, Gordon Lloyd, B.Sc., (N.S. Tech. Coll.), junior engr., Imperial Oil Refineries Limited, Dartmouth, N.S.

*Affiliates*

OLSON, Haldor Theodore, (Prov. Inst. of Tech., Calgary), switchboard operator, Island Falls, Sask.

VERRIER, Edward John, (Rugby Tech. Coll.), 2171 Dorchester St. West, Montreal, Que.

*Transferred from the class of Associate Member to that of Member*

KINGSTON, Laurence Bradley, B.Sc., (McGill Univ.), engr., Gulf Pulp & Paper Co., Quebec, Que.

*Transferred from the class of Junior to that of Associate Member*

BELL, Harry Heartz, B.Sc., (N.S. Tech. Coll.), M.Sc., (Mass. Inst. Tech.), engr., Calgary Power Company, Calgary, Alta.

GOODMAN, James Edward, B.Sc., (Queen's Univ.), county road engr. of Frontenac, Court House, Kingston, Ont.
HINCHCLIFFE, Joseph Edward, B.Sc., (McGill Univ.), R.R. No. 2, Mono Road, Ont.
JACKSON, Carl Henry, B.Sc., (McGill Univ.), engr., Canadian Industries Ltd., Montreal, Que.
LAURENCE, Emile, B.A.Sc., C.E., (Ecole Polytechnique), bridge engr., Dept. of Public Works, Quebec, Que.
MARTIN, Lucien, B.A.Sc., C.E., (Ecole Polytechnique), engr. on bridge constrn., Dept. Public Works, Quebec, Que.

*Transferred from the class of Student to that of Associate Member*

ATWOOD, Arthur Gerald Lysons, B.Sc., (N.S. Tech. Coll.), i/c engrg. dept., The Iron Fireman Mfg. Co. of Canada, Montreal, Que.
BOYER, Marc., B.A.Sc., C.E., (Ecole Polytechnique), mining inspr. and technologist, Quebec Bureau of Mines, Quebec, Que.
HALTALIN, B.Sc., (Univ. of Man.), asst. engr, Winnipeg Electric Company, Winnipeg, Man.

*Transferred from the class of Affiliate to that of Associate Member*

TOWNSEND, Charles Rowlatt, B.Sc., M.Sc., (Univ. of N.B.), Anticosti Island Manager, Port Menier, Anticosti Is., Que.

*Transferred from the class of Student to that of Junior*

CROSSLAND, Charles Wilfred, B.Sc., (McGill Univ.), M.Sc., (Mass. Inst. Tech.), technical asst., Hawker Aircraft Limited, Surbiton, Surrey, England.
ELLIOT, Donald George, B.Sc., (Univ. of Edinburgh), asst. engr., Monsarrat and Pratley, consltg. engrs., Montreal, Que.
FRECKER, George Alain, B.Sc., (N.S. Tech. Coll.), asst. professor of engrg., St. Mary's College, Halifax, N.S.
LEVERIN, Harald Leicester, Capt., R.C.E., (Grad., R.M.C.), B.Sc., (McGill Univ.), Works Officer, M.D. No. 11, Work Point Barracks, Esquimalt, B.C.
SPARKS, Wilbur Hamilton, (Univ. of B.C.), 829-14th Ave. East, Vancouver, B.C.

*Transferred from the class of Junior to that of Affiliate*

GUTHRIE, Kenneth MacGregor, Flt.-Lt., R.C.A.F., (Ottawa Collegiate Inst.), Air Staff Officer, M.D. No. 10, Winnipeg, Man.

*Students Admitted*

JONES, Allison Maurice Steeves, B.Sc. (Civil), (Univ. of N.B.), engr., Anglo-Canadian Pulp & Paper Co., Quebec, Que.
JORDAN, Jack McLean, B.A.Sc., (Univ. of Toronto), Dept. of Highways, Port Hope, Ont.
ESDAILE, Hector Milton, (McGill Univ.), 3450 Melrose Ave., Montreal, Que.

# RECENT ADDITIONS TO THE LIBRARY

### Proceedings, Transactions, etc.

Highway Research Board, U.S. Proceedings of 13th annual meeting held at Washington, D.C., December, 1933.

### Reports, etc.

*Southern Rhodesia Geological Survey:*
The Mining Industry of Southern Rhodesia.
*International Boundary Commission:*
Establishment of the Boundary between the United States and Canada from the source of the St. Croix river to the Atlantic Ocean.
*Canada, Department of Labour:*
23rd annual report of Labour Organization in Canada, year 1933.
*International Tin Research and Development Council:*
First General Report, 1934.
*Canada, Bureau of Statistics, Transportation Branch*
Preliminary Report on Statistics of Steam Railways in Canada, 1933.

### Technical Books, etc., Received

Practical Everyday Chemistry, by H. Bennett. (*Chemical Publishing Company.*)
Use of Steelwork in Buildings, by D. H. Lee. (*E. and F. N. Spon Ltd., London.*)
The Elements of Reinforced Concrete Design, by H. C. Adams. (*Concrete Publications Limited.*)
Mechanical Vibrations, by J. P. DenHartog. (*McGraw-Hill Book Co.*)

# BOOK REVIEWS

## Planning, Estimating and Rate-fixing

*By A. C. Whitehead, Sir Isaac Pitman and Sons, London, 1933. 5½ by 8¾ inches, 293 pages. Figs., tables. 10/6. Cloth.*

Reviewed by Professor E. A. Allcut, m.e.i.c.*

During the past few years, considerable attention has been paid to the allied subjects of engineering economics, organization and management. These are cognate subjects because the object of all of them is to obtain economical production for the purpose of reducing selling prices or increasing profits. Such books may be divided into two classes viz.:—

(*a*) Those in which the primary object is to enunciate the *principles* of organization and management.
(*b*) Those that deal mainly with the *application* of those principles to practical problems.

The book under review must be placed in the second category as Chapters III to IX, comprising 162 pages, are devoted entirely to details of the principal workshop processes such as drilling and tapping, planing and shaping, milling, turning, grinding and sheet metal work. These, and other allied processes, are discussed exhaustively and are illustrated by many quantitative examples. If, for instance, it is desired to find the time to be taken by a new turning operation, the average times required for chucking various sizes of work in either self centring or independent jaw chucks is given in Table XXI. Following this are tables and formulae for cutting times and speeds, gauging times, handling times and costs. This brief analysis will give some idea of the information contained in the other chapters in which different processes are similarly analysed.

The introductory Chapters I and II are devoted respectively to a general consideration of planning and time study. The former indicates that "there is no appreciable difference in the speed of working in different parts of the country as regards the constituents, when the conditions are similar," and that "although exceptional operators vary by at least 20 per cent above or below the average in manipulative speed, the great majority are not far from the mean rating." Consequently, the time required to perform a given series of operations can be predicted with reasonable accuracy. The readings necessary and the precautions to be observed are described in Chapter II and are illustrated by examples of time study.

Three of the author's *obiter dicta* are noteworthy:

(1) That planning is one of the arts and requires imagination as well as opportunity and perseverance (page 6).
(2) That unfair contracts must be avoided (page 10).
(3) That the rate-fixer's idea of a fair bargain with the operator is usually correct and that the bargaining process is therefore short and relatively simple (page 17).

The reviewer is in general agreement with (1) and (2) but has very considerable doubts about (3).

Chapter XI is entitled "Works Economics" and deals largely with process costs. The book ends with a chapter on "Plant Capacity and Arrangement," describing the method of calculating the number and sizes of machines required for a given production programme with some observations on "loading charts."

This book is generally suitable for assistant foremen, time study men or senior apprentices who wish to become familiar with the details of time study and rate fixing methods. From a Canadian standpoint, however, it suffers from the disadvantages that examples and rates are given in sterling units and the larger weights in cwts. (112 pounds). The rates of pay quoted are different from those customary in the Dominion and consequently the examples given are not necessarily applicable in this country.

Also, in the chapter dealing with "Tapping," the threads referred to are Whitworth standard, which are not used in America.

Apart from, and in spite of, these minor defects, the book should be useful to those engaged in workshop practice.

---

**Professor of Mechanical Engineering, University of Toronto, Toronto.*

## Railways and Roads in Pioneer Development Overseas

*By J. Edwin Holmstrom, P. S. King and Son Ltd., London, 1934. 5¾ by 8¾ inches, 304 pages, 15s. Cloth.*

Reviewed by S. W. Fairweather*

One of the most difficult and controversial problems of present day transportation policy is that of assessing the relative merits of railway and highway for purposes under various conditions. In attacking this problem, the author has spared no pains in assembling a comprehensive array of data, covering all phases of the subject. Unfortunately there are some phases which do not lend themselves to statistical analysis, and "logical guesswork" must be substituted. The necessity for interjecting justification or apology for so many weak links in the chain of argument detracts somewhat from the clarity and conciseness so desirable in any text-book or work of reference. This defect is no fault of Mr. Holmstrom, but merely an unavoidable stumbling block which must be faced by every writer venturing into the practically uncharted field of fixed and variable costs. That he is under no delusions as to the practical value of his work is shown by his modest conclusion:—

"Conditions change too rapidly, and too many factors are involved to allow of transport policy being dogmatically formulated for many years in advance. The problem demands unremitting study from every aspect, and if this work has suggested useful viewpoints its purpose will have been served."

To anyone not already thoroughly familiar with the pitfalls of the subject, but under the necessity of making a practical decision involving any phase of it, this book should be helpful. The author has kept his feet on the ground, and while his thesis is naturally linked with his own experience in eastern Asia, the main outlines of the problem and general nature of its solution are bound to be the same where any undeveloped territory is under consideration. To the student desiring a preliminary academic acquaintance with the "truck versus train" controversy in all its ramifications, the book should be not only enlightening, but, as obviously intended, provocative of original research and analysis.

* *Director, Bureau of Economics, Canadian National Railways, Montreal.*

## Practical Everyday Chemistry

*By H. Bennett, The Chemical Publishing Company, New York, 1934. 305 pages. 5¾ by 8½ inches. $2.00. Cloth.*

How is enameling put on steel saucepans? What is the difference in composition between Old Tom Gin and Gordon Gin (both presumably synthetic)? How does Roquefort cheese differ from Gorgonzola? How do you poison earthworms? What proportion of rubber is there in the material of a tire tread?

These are some of the thousands of questions which may be answered by referring to this book. The compiler has assembled a mass of information on the compositions or methods of making a multitude of things used in daily life. The work is not a chemistry book in the ordinary sense, but rather a collection of recipes and descriptions of manufacturing methods. There is a good index and a very necessary directory of trade names and suppliers.

The names of many of the substances mentioned will be unfamiliar to the layman, even if he has a smattering of chemistry: information as to some of these might have been included with advantage.

The book is interesting to anyone with an enquiring mind.

## BULLETINS

*Inert Gas Producers*—Roots-Connersville Blower Corporation, Connersville, Ind., have issued a 4-page folder describing the Harrison inert gas producer. These units are built to produce inert gas containing less than one per cent oxygen and zero per cent carbon monoxide when operating on manufactured or natural gas, or fuel oil. Built in sizes ranging from 7,500 to 40,000 cubic feet of inerts per hour, measured at 60 degrees F. against a pressure of 2 pounds, and the drive unit can be either a gasoline engine or an electric motor.

*Pumps*—An 8-page booklet issued by the Economy Machinery Company, Chicago, Ill., describes that company's non-clogging centrifugal pump and contains selection table for capacities ranging from 50 to 10,000 gallons per minute, heads up to 120 feet.

*Steel Sheet Piling*—An 8-page leaflet received from the Canadian Sheet Piling Company Ltd., Montreal, gives particulars of sheet piling used in the highway bridge across the Saguenay river at Chicoutimi, Que.

*Cement Bound Macadam*—The Portland Cement Association, Chicago, Ill., have issued a 24-page booklet containing particulars of design, the selection of aggregates, the latitude in the use of available materials, grout and methods of grouting, with a table for estimating material quantities, together with construction procedure and specifications.

*Vibrated Concrete*—A 32-page booklet issued by the Portland Cement Association, Chicago, Ill., contains details regarding the placing of concrete by the vibrating method describing the equipment used, and giving test data, information on the proportioning of concrete, recommended practice, and bibliography of recently published articles.

*Steam Operated Piston Pumps*—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued two 4-page folders describing their horizontal duplex piston pumps for general services. Type VA is for handling liquids at pressures up to 125 pounds per square inch, with capacities of 30 to 400 gallons per minute, and Type VC for handling liquids at pressures up to 250 pounds per square inch with capacities of 6 to 250 gallons per minute. The company has also issued two 4-page folders describing a similar line for the petroleum industry, type VB and VD, for handling oils at temperatures up to 350 degrees F. Type VB has capacities of 60 to 400 gallons per minute, and Type VD 30 to 280 gallons per minute.

*Centrifugal Pumps*—A series of four 4-page bulletins have been issued by the Worthington Pump and Machinery Corporation, Harrison, N.J., describing the company's centrifugal pumps for refineries, covering Type UV, four-stage, Type UT, two-stage, and Types LT, UW, UX, and UY.

*Compressors*—A 4-page folder issued by the Worthington Pump and Machinery Corporation, Harrison, N.J., gives particulars concerning steam booster compressors which can be furnished for either team or motor drive.

## Juniors and Students

The coming of the fall and winter, when Branch activities are once more in full swing, suggests the desirability of finding ways in which membership in The Institute could be made more beneficial to the younger engineers and also to The Institute. An opportune report* prepared by a group of junior members of the American Society of Mechanical Engineers makes some excellent suggestions in this connection.

This report observes that the principal objectives of a young engineer in joining a society may be stated as follows:

1. "Professional contact and acquaintance with other engineers.
2. Technical news and data supplied through meetings, society publications and the Engineering Societies Library.
3. Professional training and development.
4. Prestige gained from membership in a professional society of recognized high position."

"The act of joining a society signifies that the new member is in a receptive mood, and he should be met by something more than a membership certificate and a statement of dues payable. This is the opportunity to see that he retains his favourable attitude and to give some guidance to his contacts with the society."

In some of our branches the new member is welcomed by the branch officers, but in many cases a more systematic effort to establish friendly contact is needed, and would be well worth while. For instance a statement concerning the scope of the branch activities, the names of the officers, a summary of the work of their committees and a request that the new member introduce himself to the secretary or chairman, at the next meeting, would secure his interest and active support immediately.

While it may seem unnecessary to give detailed information regarding The Institute's activities to new members on what is apparently so obvious, yet it should be borne in mind that the young engineer may have only the vaguest conception of The Institute's activities, and further, may have little chance of learning about them if he does not subscribe to The Engineering Journal. Under a change in the by-laws introduced a few years ago, Students need not subscribe to The Journal unless they so desire, and this is taken advantage of to a considerable extent. The result is that to many young engineers, the Branch and its activities represent The Institute, and too much trouble cannot be taken by branch officers in informing them of branch and Institute affairs.

The junior (using this term to include all the younger members of a branch) is in real need of guidance and instruction during the first critical years of his professional life. It is suggested that great help could be furnished if each branch appointed a small group of tactful men who would act as advisers to the younger men, suggesting studies and reading, and keeping them informed of Institute affairs. The effort would be well worth while, as it would react to the good of the branch, and the capable man would soon be of assistance to his fellow members.

Possibly older members will say that the engineer's reticence will not allow him to welcome this assistance. It should be remembered, however, that this so-called reticence is usually only prevalent in the older engineer—the junior has not yet acquired the feeling. As evidence of this it may be noted that in several branches the younger men have already endeavoured to meet and discuss their problems, and organize activities of their own at which matters of general interest are discussed and technical papers on minor subjects are presented.

It would appear that it would be to the advantage of The Institute as a whole if each branch would start and guide efforts of this nature, as a result of which the more capable juniors would soon be prepared to be absorbed into the senior section. Further, until an engineer has learned to work for his professional society he has not any real appreciation of the worth of that society, nor does he obtain the full benefit of his membership. Perhaps the first efforts of the junior are not considered to be of much value to the society, however, they are an effort, and it is hoped a commencement to other activities.

The Institute has at the present time several awards† obtainable by juniors that are not sought after as they should be, or would be if the branches stressed them and pointed out the advantages to be gained in competing with other equally keen young men.

Senior awards and various branch awards are also open to the Juniors, and only last year the Past-Presidents' Prize was won by a Student.

Further, though the important technical and committee work of the society must be guided by experienced men, there is always a place for the capable junior, particularly in branch committee work.

It must be remembered also that work originated and carried on by these younger men will benefit those who initiated it.

*Mechanical Engineering, April, 1934.

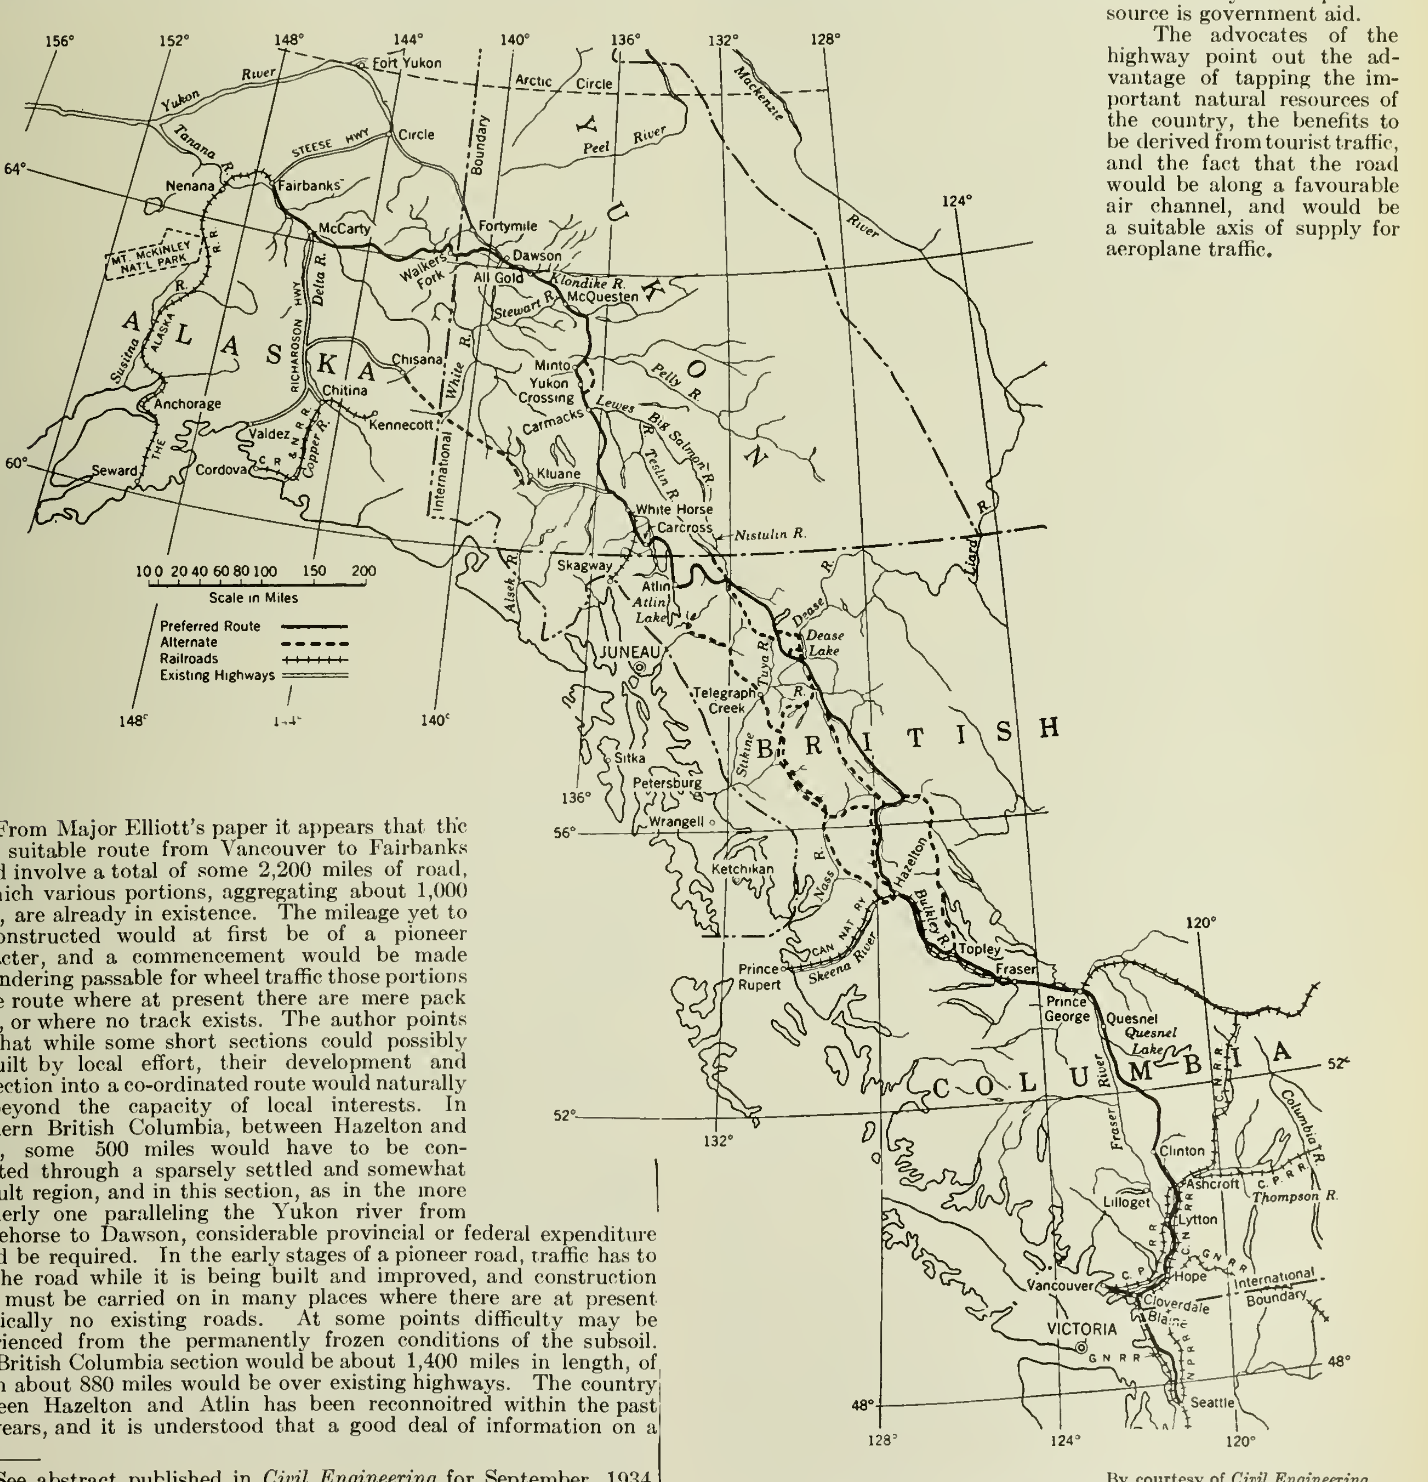
†Five prizes each of the value of twenty-five dollars may be awarded to Students and Juniors of The Institute each year as follows:

The H. N. Ruttan Prize in the four western provinces.
The John Galbraith Prize in the Province of Ontario.
The Phelps Johnson Prize for an English Student or Junior in the Province of Quebec.
The Ernest Marceau Prize for a French Student or Junior in the Province of Quebec.
The Martin Murphy Prize in the Maritime Provinces.

## The Alaska-United States Highway Project

One of the papers presented at the Vancouver convention of the American Society of Civil Engineers* was of special interest to Canadians, as it dealt with a project which has been under consideration for some time in the United States, that of building a through highway to connect the United States with Alaska by a road through British Columbia and the Yukon. The author, Major Malcolm Elliott, of the United States Corps of Engineers, was a member of a special commission appointed by the President of the United States to study the subject with the co-operation of Canadian representatives.

Another paper, by E. W. James, gave particulars as to the preliminary survey which has been made for a continuous motor route from Panama to the Rio Grande. Both schemes are stated to be practicable, and, if and when completed, would realize the hopes of the enthusiasts who visualize a Pan-American highway from South America to Alaska.



By courtesy of *Civil Engineering*

**Proposed Route of Alaska-United States Highway.**

From Major Elliott's paper it appears that the most suitable route from Vancouver to Fairbanks would involve a total of some 2,200 miles of road, of which various portions, aggregating about 1,000 miles, are already in existence. The mileage yet to be constructed would at first be of a pioneer character, and a commencement would be made by rendering passable for wheel traffic those portions of the route where at present there are mere pack trails, or where no track exists. The author points out that while some short sections could possibly be built by local effort, their development and connection into a co-ordinated route would naturally be beyond the capacity of local interests. In northern British Columbia, between Hazelton and Atlin, some 500 miles would have to be constructed through a sparsely settled and somewhat difficult region, and in this section, as in the more northerly one paralleling the Yukon river from Whitehorse to Dawson, considerable provincial or federal expenditure would be required. In the early stages of a pioneer road, traffic has to use the road while it is being built and improved, and construction work must be carried on in many places where there are at present practically no existing roads. At some points difficulty may be experienced from the permanently frozen conditions of the subsoil. The British Columbia section would be about 1,400 miles in length, of which about 880 miles would be over existing highways. The country between Hazelton and Atlin has been reconnoitred within the past few years, and it is understood that a good deal of information on a suitable general location for that portion of the road is in the hands of the British Columbia government. The highest summit on the route is not expected to be at an elevation of more than 4,500 feet.

The general topography of the proposed highway in the Yukon is much better known than in the northern part of British Columbia, for it parallels the now-travelled river route to Dawson. Major bridge work would be needed in crossing the Yukon and Stewart rivers. Passing through Dawson, connection would be made with the existing Richardson highway in Alaska, the distance from Dawson to Fairbanks being about 339 miles, of which 155 miles would be over existing roads in Alaska and the Yukon.

As regards cost, present estimates can only be of a tentative kind, but Major Elliott considers that for a gravelled surface 16 feet wide, the total cost of the construction necessary in Canada would be approximately twelve million dollars; and that in Alaska two million dollars. It seems unlikely that any large proportion of this sum would be covered by local contributions, and, as the author points out the only other possible source is government aid.

The advocates of the highway point out the advantage of tapping the important natural resources of the country, the benefits to be derived from tourist traffic, and the fact that the road would be along a favourable air channel, and would be a suitable axis of supply for aeroplane traffic.

*See abstract published in *Civil Engineering* for September, 1934, pages 461-465.

# Recovery By Construction

*Gilbert E. Jackson, B.A. (Cantab.),*
*Professor of Economics and Supervisor of Studies for the Course in Commerce and Finance, University of Toronto, Toronto, Ontario.*

**Address given before the Toronto Branch of The Engineering Institute of Canada, January 18th, 1934**

*(Abridged)*

There is no doubt that your group of industries has been the heaviest hit by the depression. It is your function to produce goods of a lasting character. Your contracts are financed by the savings of the community. The structures you build are additions to capital equipment.

It is characteristic of periods of prosperity that in them great additions to capital equipment can be made, and your industries are kept active.

But demands for capital equipment are of a postponable character. During a depression they are postponed; and this intensifies the depression. We live in a vicious circle; and your industries are at the centre of it.

By contrast, those industries which produce consumable goods, food and clothing, footwear and fuel and so forth, have suffered, and are suffering, very little. It is in proportion as the product is durable, that employers and workers engaged in making it have been compelled to suffer.

So when it is proposed that $50,000,000 or $100,000,000 should be spent by the government on construction, that is not only news of great moment to yourselves—it is also news of moment to the country—for such expenditures, setting to work the most seriously depressed industries, strike right at the heart of things.

May I begin by saying that I am not very much impressed by the proposal to spend in such a manner, and on such a scale: not if such a proposal is put forward as a recovery programme.

The proposal to revive industry by spending public funds is not in itself foolish. It is not original, either. In this, as in so many other things, we are copying our American cousins, whose lead we naturally follow because we are a politically timid people. President Roosevelt has shown us the way, spending dollars by the billion on construction. We propose now to follow his example, but spending a dime only, where he spends a five dollar bill.

My criticism of what we propose to do relates largely to the size of the sum that we propose to spend. We seem to be trying to make the best of both worlds; to be spending money for the revival of the most depressed industries (which is calculated to please them), and to be spending on a very modest scale (which is calculated to give the minimum of pain to the taxpayer).

If this expenditure is intended to revive construction, it is likely to be not enough; but if it is intended merely to substitute it for direct relief, then we are making a reversion from a cheap method of relieving unemployment, to one that is much more expensive—in short, I suggest that we must make a choice, which should, indeed, have been made some time ago; and that the projected expenditure of $50,000,000 is really nothing but a postponement of the necessary choice.

I do not want to make the choice for you. In fact, neither you nor I, but the country will make the choice. All that I hope for is that you will make a clear decision in your own minds, before proceeding to influence public opinion in its choice, as you may well do.

I said a moment ago, that the proposal to revive industry by spending public funds is not in itself foolish. In spending public funds on a colossal scale for this purpose, President Roosevelt can point to precedents in plenty in which this has been done, and in which industry, previously depressed, has again become active. We have only to study the great wars of modern times, to know that this is so.

For example, in August, 1914, industry was severely depressed in this Dominion, and conditions were daily getting worse. Hundreds of thousands of workers were unemployed. Actual starvation was not unknown.

Without warning, we were plunged into war on a world-wide scale. What happened? In the first few months, while our war expenditures were light, there was a further slump in business, and an increase in unemployment. The suffering of the people, in the winter of 1914-15, was as tragic as it has been in recent winters. Our war expenditures, in that winter, were quite modest.

But in the spring of 1915 we really began to spend. With the British Empire's existence at stake, we spent without counting the cost; and as we spent, we made industry once more active, so that our unemployed workers were absorbed, we lifted the country's business out of the trough of the depression. In 1916, 1917 and 1918; even in 1919 and the beginning of 1920, the wheels of industry were going at full speed. So long as we continued to spend, they kept on turning.

That is a triumphant instance of government expenditure on a large scale, and what it can do. What we did in the first years of the War, anybody can do. President Roosevelt can do it. We can do it. But on one condition. We must spend on a large enough scale. The force must be suited to the mass which needs moving. To spend on a small scale is worse than useless.

And so today—with the national income has been reduced by 40 per cent—when hundreds of thousands of our workers are still unemployed—I do not grow really enthusiastic over a relatively small expenditure. My own belief is that we should either spend with both hands, or else not spend at all for this purpose.

Does that mean that we should go further — should imitate President Roosevelt in the scale of his expenditures, as well as in their nature?

He proposes, apparently, that the United States government shall incur deliberately, during the next eighteen months, a deficit of about $10,000,000,000. Does that mean (allowing for the relative size of our countries) that the federal government in Canada should incur deliberately, within the same period a deficit of about $800,000,000?

Not necessarily; in fact, I think we should pause very carefully before considering such a possibility. Let me ask you to go back again to the tale of our war expenditures.

Everything went well until 1920. So long as we continued to spend money like water, this Niagara of public money continued to turn the wheels of industry.

But what happened in 1920? We ceased to spend public money thus freely. Governments began once more to practise economy. Private spending was needed, to take the place of public spending. But there was no private spending on the same, or even on a comparable, scale. The result was a great industrial crash, which is still fresh in all our memories, and all the familiar 1914 phenomena were back again.

While I have no fear but that Mr. Roosevelt, if he spends enough, can bring about in his own land an industrial recovery, I do rather fear for what may follow.

More particularly, I anticipate this: that recovery, and the devaluation of the dollar that accompanies it, may bring in their train an ungoverned rise of prices; and that then, when the rise of prices has occurred, the capitalists of the United States may realize that this spending orgy was really just our old friend the capital levy in disguise; and that a large proportion of their capital has been taken away from them; just as a large proportion of the French capitalists' possessions was taken from them, in the devaluation of the franc, five years ago.

While I feel frankly nervous about the results, nevertheless, I have attempted to present to you the case for public spending on a large scale, in a not unsympathetic manner. For it does deserve serious consideration. Among the members of my own profession, it has the support of lots of economists in the United States. Mr. Keynes in England has recently been preaching a sermon in behalf of deliberate public spending for recovery. Many Canadian economists could be found, who would endorse Mr. Keynes and (on this point at least, if not on some others) the Brain Trust of President Roosevelt. To yourselves, the notion of such spending has an obvious appeal of self-interest; and it would be strange indeed if it did not strike a responsive chord in your hearts.

But before we answer the question—whether a programme of this kind should be supported or not—let us remember that Britain has had a recovery programme of a very different kind: that she launched it long before President Roosevelt came into power: that it is based upon a quite different conception from that of President Roosevelt: and that subsequent events have done much to validate the British programme also.

The Mother Country does not advertise: or at least, when she does advertise, it is her mistakes and their consequences to which she generally calls attention. Her great strokes of policy she launches without advertisement.

The British act first, and talk about their actions afterwards. They launched their recovery programme in the fall of 1931; they have talked very little of it since then. But in the meanwhile, events have talked louder than words.

Whereas the recovery process in the United States is now more than twelve months old, there have been in Britain nearly three years of continuous recovery. We shall do well to ask, what were the policies preceding the British recovery, and on what conceptions do they seem to have been based?

Britain's recovery was certainly facilitated by two factors which do not directly concern us in this discussion—her abandonment of the gold standard, and the clearance of her glutted markets by the new tariff on imports. Without dwelling on these, let me proceed to the third aspect of British policy, the ruthless balancing of all budgets, governmental and municipal.

We all know that Britain was the first country, during the depression, to bring her budget into balance. I wonder, however, whether we have appreciated either the sacrifices that she made to do this, or the significance of her achievement.

She did it by ruthlessly cutting down all payments. She did it at the cost of her civil servants, at the cost of her teachers, at the cost of her (then nearly three million) unemployed, and at the cost of a lot of others. It is literally true that the great majority of her people were made temporarily the poorer by this effort. But they have a wonderful readiness to follow strong leadership. They gave their support, and without bitter feeling, to the proposals of the National Government.

What Britain did was to clear the government and the municipalities right out of her money market—which should properly be the meeting place of private investment and private enterprise, anyway. By this means, and only by this means, she was enabled to get down her dangerously high long term rate of interest; to bring about the lowest long term rate of interest to be found in the great money markets of the world; to put at the disposal of business cheap supplies of long term capital (so bringing down drastically her domestic costs of production); and to refund billions of dollars of her public debt at the new low rates.

As a result of all this the British Chancellor of the Exchequer has actually had a surplus to play with.

Britain has cleared government and municipalities alike out of her money market, and private business is borrowing both for purposes of expansion, and for the refunding, at low rates, of old obligations bearing high rates of interest. We, too, have experienced a drop in the long term rate of interest, but it is still, as you know, high—high, that is, in relation to present prices, or to past rates of interest in periods of low prices.

Not unconnected with our own relatively high rate of interest is the fact that in the past three years our governments and our municipalities, between them, have borrowed, either by guaranteed loans or directly, something like $1,200,000,000—by far the greater part of the savings made available to borrowers in this country. No wonder the rate of interest has been comparatively slow to fall!

Now what difference do high rates of interest make to business? In the price of a shirt the rate of interest, whether high or low, makes little difference. It does not take long to make a shirt. It is quickly paid for—even in this credit-ridden generation, we do not yet purchase our shirts with instalment payments. It is almost equally quickly worn out.

But what of more durable goods—goods which take time to construct, which last over a long period, and which involve heavy carrying charges over that period? What of the structures that you gentlemen build? What difference does a high rate of interest mean to the cost of these structures, and so to you who build them?

It is scarcely necessary to ask this question. In the case of durable goods the price depends, in a very large measure, on the rate of interest that has to be paid during the life of such goods. A high rate of interest may make the cost of them prohibitive. A low rate of interest may make them easy to carry. Whether the rate of interest is high or low, may decide the question whether they shall be constructed at all, or not.

During a depression such as this, there is a danger that we may forget the close connection between the rate of interest and the cost of construction. That is because we depend so much, just at present, upon public bodies for contracts. But you will agree that this is a most abnormal and unusual condition.

In these days of reduced construction activity, it is true that public contracts bulk relatively large. By my reckoning, in 1932, for instance, more than 40 per cent of all the construction contracts let in Canada were on account of public bodies. But in 1932 the total value of all construction contracts, public and private, was less than $140,000,000.

In ordinary times, on the other hand, public contracts bulk relatively small: in the period of eight years, from 1925 to 1932, they seem to have been little more than 25 per cent of all contracts. The bulk of the business was private business, brought, not by public bodies, but by corporations and individuals.

This means that, taking the long view, your business activity will depend upon the business brought to you, not by governments and municipalities, but, as in the past, by corporations and private persons. The business that they will bring you must obviously depend in a large measure on the cost to them of undertaking new construction; and in that cost the single element of interest bulks very large. It is imperative, for your sakes, that we get down the rate of interest.

That is what has been done in Britain. As we have seen, it was done, first of all, by clearing public borrowers out of the money market. That has not been done here: because every Canadian public body that we know has a deficit to meet. So long as the savings of our people are being absorbed by public bodies to meet their deficits, just so long will the fall of interest rates be delayed in Canada.

I should like now to lay down this proposition, which logically follows from what I have just said—that our own construction industry cannot function actively, during any long period of years together, unless the funds by means of which its activities are financed are obtainable at moderate rates. To men in other lines of business, low rates of interest are a convenience. To you, low rates are an absolutely vital necessity.

With this thought in mind, I ask you to look once more at the topic of my remarks this evening—Recovery by Construction. Your industry badly needs revival, but we shall not revive it effectively by spending public funds, only to the tune of a few scores of millions of dollars, upon new construction. On the other hand, we might produce a real revival by public spending on a scale much larger: by following the Roosevelt plan in Canada. But such expenditures, if we do make them on a sufficient scale, can keep construction active only for a limited time. Then the demand of private bodies for construction must replace the demand of public bodies—unless we are to have another slump: and the demand of private bodies will be conditional upon low carrying charges for construction.

Which should we do? Should we take as our slogan, "Bigger and better deficits," and act accordingly? Should we launch upon a programme of public spending on a large scale, as in the United States? Or should we launch upon a programme of the severest public economy, following the lead of Britain?

To do the former, to follow Mr. Roosevelt on a scale sufficiently large, would certainly revive business: how permanently, how safely, we do not know. On the other hand, to do the latter, to follow the lead of Britain, would be to provoke at first a deflationary movement, with a view to restoring more permanently the health of our money market and your industry.

As I see the problem, that is the choice before us. It is a choice which, so far, we have hesitated to make. We have lacked the nerve to declare in favour of inflation. We have lacked the nerve to declare in favour of deflation. Here is yet another instance of our political timidity.

Let me put one plea, in closing these remarks. It is that you will consider this problem impersonally, just as a physician considers the problems of disease: and not in relation to your immediate, personal self-interest.

If we look first to the forwarding of our own special interests, we make it impossible for this Dominion to have an efficient democracy. Self must be second in our politics to the general welfare, if we wish democracy to function as it should.

Our admiration goes out in full measure to Britain, because in a time of crisis, the British people will follow brave leadership; because the man in the street gladly makes great sacrifices to restore the general equilibrium. At the present stage in our affairs, we have the strongest reasons for following this good example.

And if we will not? Then I suppose we shall continue drifting, as we have drifted for the past four years. In a haphazard way, we shall pile up more debts for posterity, because we have not the courage rigidly to retrench.

Ultimately, no doubt, if we cannot make the choice, if we cannot choose a course to steer by, we shall drift into some sort of harbour. But the way will be long, and the passage tedious.

## Highway Lighting with the Sodium Vapour Lamp

**(As installed near Three Rivers, Que.)**

*A. C. Abbott, A.M.E.I.C.,*
*Distribution Engineer, Shawinigan Water and Power Company, Three Rivers, Que.*

The hope held by many that some day main highways between important centres will be brightly illuminated either over their entire length or at least throughout their most hazardous sections, may have been brought a step nearer realization by the development of the sodium vapour and high pressure mercury lamps. Both these units have high efficiencies of between 40 and 50 lumens per watt and the belief is held that 70 lumens per watt is a distinct probability.

It is only within recent years that this type of lighting has been applied to street and highway illumination and to date, the development has been largely European. Carbon dioxide, mercury and sodium have been the gases in most general use, and each appears to have its advantages and disadvantages.

Carbon dioxide, while it gives a fine white light, does so at an efficiency comparable to that of the incandescent lamp and it is for that reason that the larger number of known existing installations make use of either mercury or sodium. Germany and Holland have a number of installations of sodium lighting, while English engineers seem to have pinned their faith to the high pressure mercury lamp, as evidenced by the original installation in June 1932 at Wembley of the 'Osira' lamp followed by many additional installations, including those at Croydon, Lewisham and Manchester.

While the development has been more recent on this continent, the sodium lamp is attracting particular attention and there are now five known installations of highway lighting using the sodium unit.

The first of these installations was made near Schenectady, N.Y., in 1933 on a section of the Balston road, while the others are at Revere Beach and Newton, Mass., Wallingford, Conn., and in Canada the installation put into service by the Shawinigan Water and Power Company in June 1934, on a half-mile stretch of the Montreal-Quebec highway just west of the city of Three Rivers.

The Shawinigan Water and Power Company has for some time been actively interested in the possibilities of highway lighting, and some years ago made a trial installation with 1,000 candle power incandescent lamps. At that time, however, interest in the question did not run to the same pitch as to-day. This was possibly due in part to the lack of appreciation of the extent to which accidents could be reduced by good highway illumination and, in part, to the fact that the volume of traffic has increased tremendously during even the past few years. As a result, nothing came of the original trial, but interest in the possibilities of this form of lighting was still maintained and close touch kept with following developments in lighting technique, with the result that the experimental installation mentioned above was decided upon.

### Description of Sodium Lamp

The present form of 10,000 lumen A.C. sodium lamp in use in the five installations on this continent (see Fig. 1) consists of a long bulb of special glass enclosing at each end a coiled filament, which serves as a cathode, and an open-ended box of molybdenum, which serves as an anode; the lamp then has two anodes and two cathodes. Each anode is connected electrically to one side of the filament coil so that only two conductors lead from each assembly. The leads pass through a seal at one end of the bulb and are fastened to the tubes of a pin base cemented to it. A sodium resistant washer is cemented in the neck of the bulb to prevent the sodium vapour from attacking the seal. A small quantity of metallic sodium and a small amount of neon gas are included in the bulb, the neon being used for starting. The lamp is about 16 inches long from tip to base, excluding the pins on the base, and about 3 inches maximum diameter.

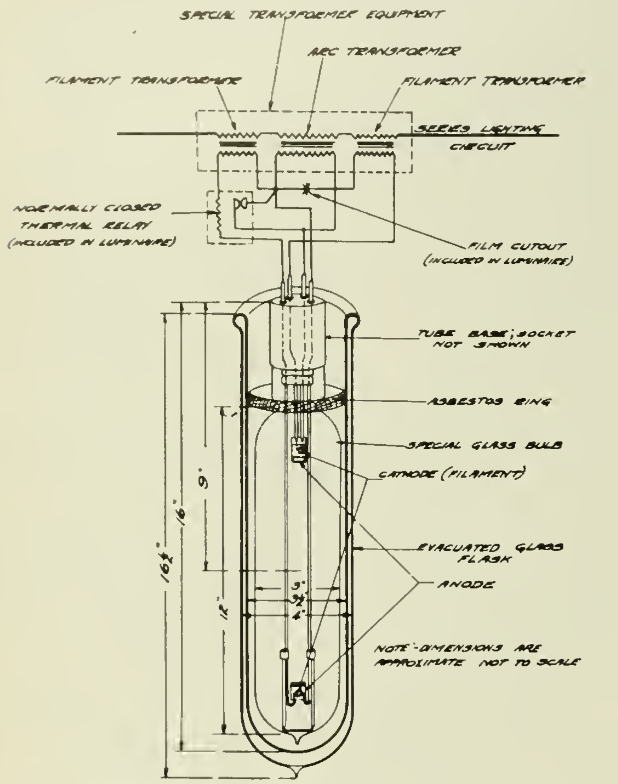


**Fig. 1—10,000 Lumen A.C. Sodium Lamp with Series Transformer.**

A double-walled evacuated glass flask having an outside diameter of about 4 inches and an overall length of some 16½ inches is used with this lamp. Asbestos washers around the neck of the bulb fill the open end of the vacuum flask to prevent heat loss.*

The lamps recently installed near Three Rivers, P.Q., are operated on a 6.6 amp. series circuit, the ten 10,000 lumen units being supplied from one 3 kw. type "RO" constant current pole type transformer having a 2,300-volt primary. Mounted on the pole with each unit is an "IL" transformer 6.6 to 6.6 amperes which is required largely as a result of insulation limitations in the luminaire of the unit. Each luminaire, which is the complete lighting unit with reflector as mounted on the end of the channel cross arm, contains auto transformers for reducing the voltage to the cathode to between 2 to 3 volts, the cathode heating current being approximately 10 amperes at that voltage. In addition, a choke and capacitor are supplied as a guard against possible radio interference.

The arc current is 6.6 amperes and is maintained by a voltage of about 27 volts. A higher voltage is required to strike the arc and this is obtained from the open circuit voltage of the "IL" transformer which exists for a very short interval prior to the arc being struck. This starting voltage is said by manufacturers of the lamp to be in the neighbourhood of 185 volts.

*Taken from a description of the lamp furnished by the General Electric Company.

Briefly, the operation of the lamp is as follows: With the energizing of the main 6.6 ampere series circuit, the cathodes of each lamp become energized while the anodes are short-circuited by a timing device contained in each luminaire. The anodes are held short-circuited for a period of about one minute, known as the heating period. The timing device then operates momentarily open-circuiting the "IL" transformer and the arc is struck from the open circuit voltage of the transformer as already described. The lamp first glows with red from the neon gas which is used for starting but soon sufficient heat is generated to vapourize the sodium and the colour changes from red to red-orange, and finally, to the characteristic orange-yellow of sodium, this change taking in all some thirty minutes during which time the lamp does not develop its full output of 10,000 lumens. For this reason, an installation of sodium lamps should be energized some time before any incandescent lighting in the same neighbourhood.

**Fig. 2—Installation at Three Rivers, Que.**

It is interesting here to note that the lamp now in use differs quite radically in some respects from the original units installed by the General Electric Company at Schenectady about a year ago. These were 4,000 lumen units requiring both alternating and direct current for their operation. The cathode circuit was much the same as that of the new lamp requiring 10 amperes at approximately 2 volts, but the arc circuit was direct current. To obtain direct current the original installation called for rectifier equipment and constant current regula-

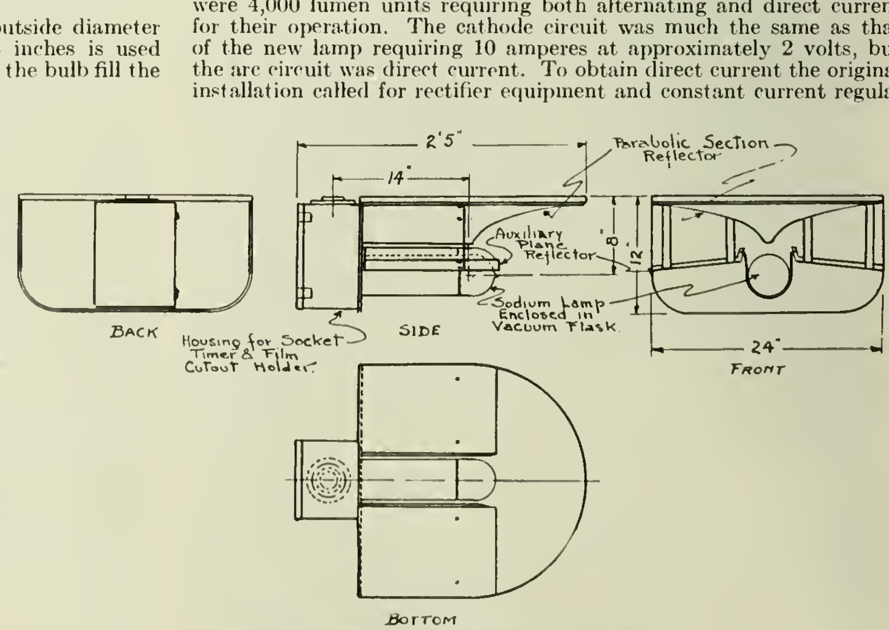

**Fig. 3—Assembly of Sodium Luminaire.**

tion for the arc circuit. These facts are mentioned with the idea of illustrating how rapidly improvements and simplification have already been made.

Description of Installation

The ten units on the Montreal-Quebec highway are installed over a two strip concrete section of the roadway with a spacing between the units of 250 feet. The lamps are staggered and so installed as to have a distance of 25 feet from the roadway surface to the light centre. As the Bell Telephone Company have a pole line along the opposite side of the highway from the Shawinigan Company's distribution line, permission was obtained to overbuild the telephone company in order to provide for the staggering of the units. Figure 2 shows a daytime view of a section of the installation and brings out clearly the typical difficulties to be encountered in work of this kind along Quebec highways, namely trees and foreign plant usually in the form of telephone circuits.

The "IL" transformer can be seen on the pole above the level of the mast arm. Twin conductor rubber insulated cable with a single braid of weatherproofing was used to run from the transformer to each luminaire.

Figure 3 illustrates the general appearance of the lamp when assembled with the aluminum reflector.

As has already been mentioned, the ten lamps are supplied by a 3-kw. "RO" transformer. This transformer is energized through a Novalux controller which in turn is controlled by a Weston photronic relay.

Figure 4 shows the transformer and controller on the upper level and the Weston photronic control made up of the light collector seen on the left hand side of the picture and its related relays contained in the left hand weatherproof wooden box.

The control is set for a light intensity of about 12 foot-candles, and it is interesting to note that during one severe storm the lamps actually came on as a result of a dropping in the light intensity to a figure below that of the relay setting. This condition must have existed for an appreciable time as the control is equipped with a small time delay to guard against any pumping through occurrences of a similar nature.

Figure 5 illustrates a wiring diagram of the 609 model photronic relay which device functions as follows: When the light intensity has reached the level for which the sensitive relay is set, the low contact is made. This completes the circuit to the time delay relay. After approximately one minute its low contacts make which causes the

Fig. 4—RO Transformer, Novalux and Photronic Controls and Metering.

power relay contacts to close. The power relay contacts will stay closed even after the low contacts on both the sensitive and time delay relays have opened. When the light intensity in the morning has come up to the upper value for which the sensitive relay has been adjusted the high contacts close. This completes the local circuit to the high contacts on the time delay relay causing them to close after approximately one minute. This releases the contacts on the power relay and opens the circuit to the artificial illumination.

The lead resistance between the cell box and the relay cabinet does not affect the correct operation of the equipment and permits the cell box to be located at a distance from the circuits that are to be controlled.

In order to obtain operating data on the sodium lamp, it was decided to install a simple form of metering equipment and to meter the installation from the 6.6 amp. side of the constant current transformer. This was done in order to meter only the input to the lamps and the losses of the circuit and equipment, and was considered quite

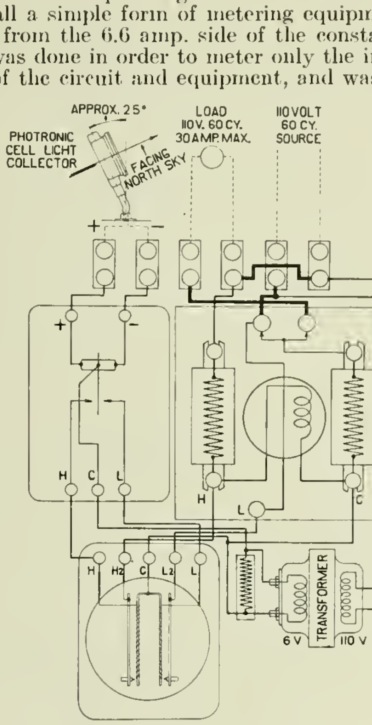

Fig. 5—Wiring Diagram of Photronic Relay.

safe practice as the open circuit voltage of a transformer with that rating is not high, being approximately 650 volts. The metering consists of a Lincoln type ED demand meter from which the input to the ten lamps and their kilowatt hour consumption can be obtained and this meter, together with current and potential transformers and the usual test links, is contained in the weatherproof box shown in Fig. 4 on the right hand side of the pole opposite the Weston control.

The meter is read at regular intervals and the input measured corresponds to the information given by the manufacturers, being in the neighbourhood of 2.5 kw. for 10 lamps or 250 watts per lamp. From the kilowatt hour registration, it is expected to obtain a fairly close approximation of the burning hours.

From June 9th to September 8th, comprising a total of ninety-one nights, the kilowatt hour consumption of the ten lamps was 2,149 or an average nightly consumption per lamp of 2.36 kw.hrs. Of course, due to the fact that the nights are now getting longer, the consumption has increased, as during the early part of the summer there was an average consumption per lamp per night of 2.2 kw.hrs. The average kilowatt peak as measured by the demand meter which includes the input and losses to the ten lamps and the half mile of circuit is 2.7 kw. over the period considered.

At present the lamps are guaranteed for thirteen hundred and fifty burning hours, but it is understood that a considerably longer life is hoped for.

Future Possibilities of Highway Lighting

There would appear to be two requisites necessary for the development of this form of lighting, namely the interest of those making use of the highways and of the local or provincial road departments, as the case may be, and the first cost of an installation or installations.

Already, considerable interest has been shown both by automobile owners and automobile clubs. Those who have travelled through the section at night have generally commented on the definition of detail made possible by the monochromatic light from the units and on the complete absence of glare. The only adverse criticism heard has been that the light intensity appears to be too high in contrast to the unlighted highway at both ends of the experimental section.

As to costs, it is obvious that before power companies can hope to develop this additional outlet equipment, costs must of necessity be low. While it is admitted that with a light output from the sodium lamp of between two and a half and three times that of an incandescent lamp with the same power input, it is now possible to cut down the number of units per mile over what would be necessary in a corresponding section lighted by incandescent lamps and still give the same intensity of illumination on the roadway, yet when the great stretches of highway which might be illuminated are considered, it can easily be seen that power companies will have difficulty in selling this possible service if their yearly charge per unit is high due to high installation costs. At the present time, however, it is hardly fair to talk of installation costs—the units now in use are made to order and, in the opinion of the manufacturers, costs would be very much reduced with an appreciable increase in demand.

# BRANCH NEWS

## Montreal Branch

*C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.*

Some two hundred members of the Montreal Branch of The Institute were the guests of the Dominion Bridge Company Limited on the evening of September 6th, 1934, when they had an opportunity of inspecting the plant of the Chas. Walmsley Company of Canada Limited at Longueuil, and witnessed the actual prestressing and measuring of one of the 2,500-foot cable strands for the Isle d'Orleans suspension bridge.

Each strand is 1⅜ inch in diameter and is composed of 37 main wires (.201 and .193 inches diameter) and 8 filler wires .080 inch diameter. The outer layer of 18 wires is laid opposite hand to the inside wires to counteract any uncoiling tendency. The strand has a cross sectional area of 1.12994 square inch, a specified minimum ultimate strength of 217,000 pounds, a specified minimum yield point (.70 per cent elongation in 100 inches) of 167,000 pounds, a minimum modulus of elasticity (up to 50 per cent of ultimate strength) of 24,000,000 pounds per square inch, and is manufactured by the Dominion Wire Rope Company Limited of Montreal and Toronto.

### Prestressing Operations for Main Cable Strands

After being unreeled in the trough, one end of the strand is connected to a dead anchorage and the other end connected, through a series of adjustable links, to the hydraulic prestressing machine.

The applied loads are measured on two special extensometers which are located in the line of pull, one at each end of the strand. During prestressing and marking operations the strand is wholly supported on ball bearing rollers to minimize friction.

Sensitive thermometers are clamped on the strand near each end and temperatures are carefully recorded.

Marking stations are located in the trough at points corresponding to the intersection of the strand on the cable bents, towers, centreline of span, and the faces of the sockets. Their locations have been carefully chained and adjusted for the difference between average and actual marking stress and an allowance for subsequent shortening due to reeling.

The sequence of prestressing operations is as follows:—

1. Apply sufficient load to take up slack. Check the manufactured length.
2. Raise load to 10,000 pounds. Paint reference mark on strand at end station.
3. Raise load to 120,000 pounds and lock for thirty minutes. Measure elongation at end station to check uniformity of manufacture.
4. Unlock strand and lower load to 10,000 pounds by decrements of 10,000 pounds. Note shortening at each stage and calculate modulus of elasticity.
5. Increase load until close to marking load (59,000 pounds). Calculate pull and temperature corrections and apply to strand at end marking station.
6. Bring mark to alignment at end station and lock. Apply intermediate reference marks to strand.
7. Unlock strand, raise load to about 65,000 pounds, slack off to about marking load thus reversing friction and repeat as in No. 5. Apply permanent paint marks, the mean of Nos. 5 and 7, and re-reel strand.

Specimens for the specified tests are cut after prestressing and marking. A tolerance of one inch, plus or minus, is allowed in the geometric length of 2468.392 feet, face to face of sockets.

Each main cable is composed of 37 prestressed strands, banded together in hexagonal form, rounded out by wooden fillers, and wrapped with soft galvanized wire. The strands of each horizontal layer are of opposite lay to those of the adjacent layers, there being 17 right hand and 20 left hand laid strands in each cable.

At the close of the meeting refreshments were served through the courtesy of the Dominion Bridge Company Limited.

## Quebec Branch

*Jules Joyal, A.M.E.I.C., Secretary-Treasurer.*

### Visite au Pont de l'Ile d'Orleans

Le 15 juillet dernier, les membres de la Section de Québec et quelques-uns de leurs amis, soit une cinquantaine en tout, avaient le privilège d'aller visiter les travaux du pont de l'Ile d'Orléans.

Cette visite, organisée par M. Théo. M. Déchêne, A.M.E.I.C., ingénieur au Ministère des Travaux Publics de la Province de Québec et membre du Comité d'Excursions de notre section, fut un véritable succès; la température était idéale et le départ s'est effectué du Palais Montcalm à 4 heures 30 pour arriver sur les lieux vers cinq heures p.m.

Le groupe des visiteurs fut accueilli avec la plus grande cordialité par MM. J. W. Roland, M.E.I.C., et W. H. Smick respectivement ingénieur résident pour Monsarrat et Pratley, ingénieurs-conseils qui ont préparé les plans et devis de la partie centrale du pont, et surintendant des travaux pour la compagnie "Foundation of Canada"; ces messieurs se prêtèrent volontiers à fournir aux visiteurs toutes les informations de nature à les intéresser.

Tous ont pu examiner à loisir les travaux en voie d'exécution et l'outillage parfait que possède la Cie "Foundation" pour des travaux de cette nature; cette visite des lieux a duré environ deux heures et tous ceux qui y ont pris part étaient enchantés de cette petite excursion récréative en même temps qu'instructive.

Ce pont est construit sur le St-Laurent entre le village de Montmorency et l'Ile d'Orléans pour le compte du département des Travaux Publics qui est représenté par MM. Ivan E. Vallée, A.M.E.I.C., Sous-Ministre et Ingénieur-en-chef et O. Desjardins, A.M.E.I.C., Ingénieur-en chef adjoint.

La longueur totale du pont, y compris les approches est de 14,600 pieds répartis comme suit: Approches du côté de Montmorency village: 2,145; du côté de l'Ile d'Orléans: 6,755; longueur entre culées: 5,700.

La longueur de 5,700 entre les culées se répartit comme suit: 2,128 pieds de viaduc du côté de Montmorency, 1,678 pieds du côté de l'Ile et 1,894 pieds de tablier en suspension répartis en trois travées dont l'une, la centrale, a une longueur de 1,059 pieds et laisse un dégagement de 106 pieds au-dessus des eaux hautes.

La voie charretière a 20 pieds de largeur et est bordée de chaque côté par des trottoirs ayant cinq pieds de largeur. Les culées et les piliers sont en béton mais ces derniers sont recouverts d'un revêtement en granit jusqu'au dessus des hautes eaux.

Les tours supportant les cables auront une hauteur de 227 pieds au-dessus des piliers et les cables seront constitués de 37 torons de un pouce et trois huitièmes chacun pour donner avec l'enveloppe un cable d'environ 10 pouces de diamètre.

La culée et les piliers du côté nord, sauf le pilier de support principal reposent sur pilotis, du côté de l'Ile, de même que le pilier de support du côté nord, toutes les unités de support reposent sur le roc.

Ce pont sera terminé au cours de l'été 1935.

## Saguenay Branch

*J. W. Ward, A.M.E.I.C., Secretary-Treasurer.*

On Thursday evening, August 2nd, 1934, a meeting of the Saguenay Branch was held in the main office of the Aluminum Company of Canada Ltd. at which thirty-five members and friends were present.

The speaker of the evening was F. L. Lawton, A.M.E.I.C., who read a paper on "Heat Economy and Comfort in the Home, as Influenced by Heating Methods and Building Construction."

Mr. Lawton has spent considerable time in the study of this subject, in connection with the house-heating experiment being carried on in this district by the Saguenay Electric Company. The tremendous waste, through faulty building construction, is estimated by the Dominion Fuel Board at thirty million dollars annually. The effect of insulation, weather-stripping, storm doors and windows, as well as exposure to wind and sunshine were mentioned.

He went into the heat requirements, heating methods and costs very thoroughly. For day-time comfort a temperature range of 68 to 72 degrees F. with a relative humidity of 40 to 50 per cent was required. In the coldest weather, that is from 20 degrees to 40 degrees below zero, a relative humidity exceeding 40 per cent will cause frosting on the windows, and the formation of ice around doors which are not well weather-stripped. The cost of heat insulation for a new house will average 5 per cent of the cost of the house, and should result in a reduction in the heating cost over that of an uninsulated house of 30 to 50 per cent.

The Saguenay Electric Company have fifty or more houses in the Saguenay district equipped for electric heating. Where the house was heated by a hot air furnace, heating elements were installed inside the casing of the furnace, and operated automatically through a contactor and thermostat which is located usually in the dining or living room. Where hot water was used as a heating medium, a water heater of the electrode type was used, connected in parallel with the furnace. The control is through a contactor and thermostat located in one of the central rooms.

One of the slides shown was that comparing the cost of a given amount of heat (B.t.u.'s) delivered to a house, using different heat producers. The point on this diagram of particular interest to the members present was that showing the cost of electricity at one-third of a cent per kilowatt-hour. This compares with anthracite coal at $13.00 per ton, fuel oil at $0.105 per imperial gallon and wood at $3.75 per short cord. In this comparison the coal contains 13.500 B.t.u.'s per pound, and burned at 50 per cent seasonal efficiency. The fuel oil contains 168.600 B.t.u.'s per gallon, and burned with a seasonal efficiency of 65 per cent. The wood is assumed to be air dry white birch, cut 16 inches long and contains 23.400.000 B.t.u's per standard cord, and is burned with a seasonal efficiency of 50 per cent. Electricity is consumed at 100 per cent seasonal efficiency.

Heating by reversed refrigeration is one of the latest developments in the house heating field, and one which holds promise for the near future.

Radiation or panel heating is increasing in popularity.

District heating is a development which has met with considerable success also.

At the close of the address an active discussion took place, and many questions were asked concerning some of the features of electric heating. A vote of thanks was tendered to Mr. Lawton for this very interesting paper.

Following the address, a business meeting was held. A Nominating Committee was first appointed to make nominations for the annual elections. N. F. McCaghey, A.M.E.I.C., and S. J. Fisher, M.E.I.C., were appointed by the executive, and M. G. Saunders, A.M.E.I.C., G. H. Kirby, A.M.E.I.C., and F. L. Lawton, A.M.E.I.C., were appointed by the other members attending the meeting.

Following the closing of the nominations a discussion took place concerning the programme in connection with the annual meeting. The date was set for August 30th, 1934.

### Annual Meeting

The annual meeting of the Saguenay Branch was held on the evening of August 30th, 1934, at the Arvida Staff Club.

During the afternoon several of the members enjoyed a round of golf at the Saguenay Country Club. At 5.30 in the afternoon members were taken through the plant of The Aluminum Company of Canada.

At 7.00 p.m. seventeen members met at the Arvida Staff Club where dinner was served. Following the dinner the meeting was called to order by the chairman, A. W. Whitaker, Jr., A.M.E.I.C., who asked the Secretary-Treasurer to read the minutes of the last annual meeting, also the report of the secretary for the year. The motion for the adoption of the minutes and the secretary's report as read was made by B. Pelletier, A.M.E.I.C., and seconded by H. R. Wake, A.M.E.I.C.

The chairman then read the report of the scrutineers for the ballots of the annual election, the results of which were as follows:

For Chairman: G. E. LaMothe, A.M.E.I.C.

For Vice-Chairman: J. Shanly, A.M.E.I.C.

For the two vacancies in the Executive committee made through the retirement of S. J. Fisher, M.E.I.C., and A. Cunningham, A.M.E.I.C., the following two were elected: M. G. Saunders, A.M.E.I.C., and E. Lavoie, M.E.I.C.

Before turning the meeting over to the new chairman, Mr. Whitaker expressed his appreciation for the assistance he had received from the members of the Executive and extended his good wishes to the new chairman.

Mr. LaMothe now took the chair, and expressed his appreciation of the honour given him in electing him to the chairmanship of the branch. He hoped to be able to procure speakers for the coming year who would maintain interest in the meetings. He also thought the members should be more active in their attempts to obtain more members. There are a number of engineers in this district who are qualified for membership, and could be persuaded to join if a more determined effort was made to induce them to do so.

### The Production and Explosibility of Gases Generated in Electric Steam Generators

The chairman then introduced M. G. Saunders, A.M.E.I.C., who read a paper on "The Production and Explosibility of Gases Generated in Electric Steam Generators." Mr. Saunders commenced by giving a résumé of all the published data on this subject he had been able to collect. One of the first research results published was that of Messrs. Shipley and Blackie, who collected samples of gases from electrode type water heaters using alternating current, and found them to be explosive when mixed with air. Messrs. Kaelin and Matheson, who have done a great deal of research in connection with electric steam generators, brought out the information that the formation of gases in such generators is mainly a function of current density, and that electrodes should be designed to distribute the current evenly over the whole surface of the electrodes. Most commercial boilers are designed so as not to exceed one ampere per square inch of electrode surface, which is well below the point at which any gas will be generated, provided of course the electrodes are clean.

A further contribution to the published work on this subject was made by Messrs. Campbell and Rogers, who summarize their results as follows:

1. Under certain operating conditions, steam coming from an electric boiler may be contaminated by electrolytic gases, produced by the decomposition of the water or the steam in the boiler, although the gas is not known to be explosive when diluted with steam under ordinary operating conditions. It has been known however to corrode iron surfaces. When the steam condenses and the gas becomes concentrated it is very explosive.
2. When the electrodes are free from scale and condensate is used for feed water, no electrolytic gas could be detected.
3. Gradual scaling of the electrodes due to the use of impure feed water causes a gradual increase in gas formation. Under these conditions more gas is produced with 25-cycle than with 60-cycle current.

In studying these results and their application to the electric steam generating system at Arvida, tests were made to find out whether gases in explosive proportions were generated, and if so, if there was any tendency to accumulate in any part of the system. Also whether an explosion hazard existed as long as these gases were combined with steam.

The results of these tests may be summarized as follows:

1. Gases are generated by an electric boiler in explosive proportions.
2. These gases have not been found in any quantity in any part of the system.
3. Where steam is exhausted from radiators by a vacuum pump, the gases are diluted with so much air as to render them non-explosive.
4. At temperatures and pressures met with in ordinary boiler operation a very small quantity of steam is sufficient to prevent any gas explosion, and any smaller quantities of steam tends to dampen the effect of the explosion appreciably.
5. In some cases segregation of gases may permit an explosion, but only when one part of the container is cooler than 100 degrees C.

After the reading of the paper, which was illustrated with slides, an active discussion took place. The meeting closed with a vote of thanks for the paper so interestingly presented by Mr. Saunders.

## Sault St. Marie Branch

*H. O. Brown, A.M.E.I.C., Secretary-Treasurer.*

The Sault Ste. Marie Branch of The Institute discontinued the regular monthly dinner meetings for the summer after the meeting of May 25th, 1934, which was addressed by D. S. Lloyd, A.M.E.I.C.

The Executive committee met from time to time as items of business required attention. The chairman, E. M. MacQuarrie, A.M.E.I.C., was out of town on survey work most of the summer and F. Smallwood, M.E.I.C., vice-chairman, acted in his place.

Two special meetings were held during the summer when the General Secretary, R. J. Durley, M.E.I.C., and the president, F. P. Shearwood, M.E.I.C., visited the Branch. These were in the form of dinner meetings at the Sault Country Club, and gave the visitors an opportunity to become acquainted with the members of the Branch. The attendance was very good.

Mr. Durley was entertained on July 26th, and after dinner gave a very interesting talk to the members of the Branch on his visit to the western Canada branches and the Western Professional Meeting of The Institute at Vancouver. A general review of the work of The Institute was also given and various points brought up for discussion with members of the Branch.

The President, Mr. Shearwood, was a guest on August 3rd, and after dinner addressed the Branch on the general affairs of The Institute. Mr. Shearwood also gave a talk on "Bridge Erection," which was illustrated with excellent slides. This meeting was well attended as almost all of the resident members of the Branch took advantage of this opportunity to meet Mr. Shearwood.

## Short Count Traffic Surveys and their Application to Highway Design

A 40-page booklet by Dr. Miller McClintock of Harvard University, which has been received outlines a practical, simple and low-cost way to make traffic studies. The "short count" method makes it possible for road officials with limited funds to give the same study to their problems as is given the larger problems of state and Federal systems.

This method is based on the fact that the percentage of total daily traffic occurring in any given hour is approximately constant at different points along the same route, or on routes of the same character in the same district or region.

As few stations are counted as is necessary to provide a control, or hourly relation, for each type of route and neighbourhood in the area to be studied. With twenty-four-hour counts of traffic at these stations, two-hour counts may be made at base stations, and a twenty-four-hour total can be computed. The base stations may be located wherever the highway engineer feels a need for traffic data.

Factors for both passenger cars and trucks are derived from the control station count.

This information gives a sound and logical basis for planning road improvements.

The booklet is No. 3 of a Highway Planning and Design series and is available without cost on request to the Portland Cement Association, 33 West Grand Avenue, Chicago, Ill.

## Rapid Acceleration

The London, Midland and Scottish Railway have introduced a new passenger service in East Lancashire, operated by a Lancashire-made 40-seater Diesel-hydraulic light rail car. This service is additional to the ordinary passenger service.

The rail car is specially designed with a view to rapid acceleration, being able to attain a speed of 50 miles an hour in 49 seconds from a dead stand. It weighs ten and a half tons, and is powered by a 130-h.p. Diesel engine with hydraulic transmission.—*Industrial Britain.*

---

*The H. E. Mott Company Limited*, of Brantford, Ontario, has purchased the assets of the Goold, Shapley and Muir Company Limited of Brantford, pertaining to the tower, tank and textile part of their business, including all business and engineering records, patterns, drawings, machinery and equipment, and will continue the manufacture of these lines. The president and general manager of the new company is H. E. Mott, A.M.E.I.C. It is the intention of the H. E. Mott Company Limited to extend the engineering control and development of the business, with a view to keeping in the van of new developments and assuring the maintenance of the very highest quality in their products.

# Preliminary Notice

## of Applications for Admission and for Transfer

September 27th, 1934

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in November, 1934.

R. J. Durley, Secretary.

* The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

FARNHAM—ANSELL CASS, of 151 London St., Sherbrooke, Que., Born at Martinville, Que., Aug. 17th, 1905; Educ., Junior Matric. (Science), McGill Univ., 1923; 1923-25, dfting., and 1925-31, gen. engrg., designing, and supervision of steel erection, MacKinnon Steel Corporation, Sherbrooke, Que.; 1931 to date, chief designer, Stewart Construction Co. Ltd., Sherbrooke, Que.

References: G. D. MacKinnon, G. M. Dick, J. T. Morkill, F. H. Hibbard, W. L. R. Stewart.

### FOR TRANSFER FROM THE CLASS OF JUNIOR

BANKS—SHEWELL REGINALD, of Lachine, Que., Born at Liverpool, England, Jan. 11th, 1904; Educ., B.Eng., 1924, M.Eng., 1926, Univ. of Liverpool. A.M.Inst.C.E. (Great Britain); 1922-23, marine experience during vacations; 1924-27, junior engr., Dept. of Scientific and Industrial Research, England. Investigation of impact stresses in rly bridges. In charge of various recording instruments; 1927-29, asst. with Messrs. Rendel, Palmer & Tritton, consltg. engrs., Westminster. Design and drawing of long-span rly. bridges and locomotive shops for rlys. in India; 1929-32, with Dominion Bridge Company, Lachine, Que. Design, estimating, and detailing of various types of structures including movable bridges. Also field engr. on foundation and erection of steelwork (pulpwood equipment and hydro sluice gates); 1932 to date, asst. engr., with Messrs. Monsarrat & Pratley, consltg. engrs., Montreal. Design, inspection, etc., sub-aqueous foundations and suspension bridge superstructures. (*Jr. 1930.*)

References: C. N. Monsarrat, P. L. Pratley, F. Newell, D. C. Tennant, D. B. Armstrong, F. A. Bowman.

CORNISH—WILFRED ERNEST, of Edmonton, Alta., Born at Broadview, Sask., Feb. 22nd, 1901; Educ., B.Sc. (E.E.), Univ. of Man., 1925; M.Sc., Univ. of Alta., 1933; 1926-27, testing, Can. Gen. Elec. Co.; 1927-33, lecturer, and 1933 to date, asst. professor, dept. of elec. engrg., University of Alberta, Edmonton, Alta. (*St. 1926, Jr. 1930.*)

References: R. S. L. Wilson, E. P. Fetherstonhaugh, F. K. Beach, W. M. Cruthers, H. J. MacLeod.

### FOR TRANSFER FROM THE CLASS OF STUDENT

DOVE—ALLAN BURGESS, of Hamilton, Ont., Born at Ayr, Scotland, April 9th, 1909; Educ., B.Sc., Queen's Univ., 1932; 1925-26, Can. Westinghouse Co.; With the Steel Company of Canada, Hamilton, Ont., as follows: 1928-32 (summers), gen. control, costs, plant operation, etc.; 1932 to date with same company, and at present chem. engr. and asst. to West Mill supt., in charge of chemical operation and gen. plant operation and control of West Mill, galvanizing and wire depts., etc., including operation throughout mill, electroplating, equipment design and plant layout. (*St. 1932.*)

References: A. Love, V. S. Thompson, L. F. Goodwin, D. S. Ellis, A. Macphail.

PORTEOUS—JOHN WARDLAW, of Edmonton, Alta., Born at Galt, Ont., Jan. 12th, 1907; Educ., B.Sc. (E.E.), Univ. of Alta., 1928; 1925 and 1927 (summers), Dominion Forestry Survey; 1926, C.P.R. constrn. survey; 1930 to date, lecturer, Univ. of Alta., Edmonton, Alta. (*St. 1929.*)

References: H. J. MacLeod, R. S. L. Wilson, H. R. Webb, F. K. Beach, J. R. Dunbar.

## List of New and Revised British Standard Specifications

(Issued during June, 1934)

B.S.S. No.

485—1934. Tests on Thin Metal Sheet and Strip (not exceeding 0.128 in. (10 S.W.G.) in Thickness).

This specification—which supersedes B.S.S. No. 485-Part 1 issued last year—has now been amplified by the addition of two further sections dealing with bend and hardness testing respectively. An interesting note on the usefulness of cupping tests is also included. The scope of the specification has been extended so that it now covers the testing generally of thin sheet and strip material up to 10 S.W.G. (0.128 in.) thick.

556—1934. Cement Concrete Cylindrical Pipes and Tubes (not Reinforced).

Provides for nominal sizes from 6 inch upwards and includes requirements as to quality and hydraulic pressure, crushing, and absorption tests. The thicknesses are not standardized and only such dimensions for the sockets are laid down as will ensure interchangeability of pipes.

557—1934. Alternating-Current Line Relays (single-element, 2-position) for Railway Signalling Purposes.

An addition to the series of specifications for railway signalling relays. This issue covers relays of the induction type, intended for use on railway signalling circuits not exceeding 250 volts.

558—1934. Nickel Anodes (for Electroplating).

This specification has been compiled to ensure the purity of nickel anodes. The maximum amount of each purity is given; also the methods for their determination.

559—1934. Electric Signs.

Covers construction, electrical apparatus and wiring of electric signs of box, or other forms using filament lamps and/or discharge tubes operating in conjunction with double-wound transformers, and auxiliary apparatus.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28 Victoria Street, London, S.W.1, and from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa, Ont.

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Wanted

ESTABLISHED SALES ENGINEER. Univ of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENCINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, French, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian, married, 34 years of age, with 13 years' experience in the industrial field, including design, construction and operation, 8 years of which had to do with the development of specifications and ordering of equipment and materials for plant extensions and maintenance; one year engaged on sale of surplus construction equipment. Full details upon request. Apply to Box No. 161-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257 W.

MECHANICAL ENGINEER, age 28, nine years allround experience, Grad. Inst. of Mech. Engs. England, S.E.I.C. Technical and practical training with first class English firm of general engineers; shop, foundry and drawing office experience in steam and Diesel engines, asphalt, concrete machinery, boilers, power plants, road rollers, etc. Experience in heating and ventilation design and equipment; 18 months designing draughtsman with Montreal consulting engineers. 2½ years sales experience, steam and hot water heating systems, power plant equipment, machinery, oil-burning apparatus. Canadian 4th class Marine Engineers Certificate; C.N.S. experience. Available at short notice. Apply to Box No. 270-W.

DESIGNING DRAUCHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.SC., A.M.E.I.C., AM.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENCINEER, B.A.SC., and C.E., A.M.E.I.C., age 30, married. Experience over the last ten years covers construction on hydro-electric and railway work as instrumentman and resident engineer. Also office work on teaching and design, investigations and hydraulic works, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENCINEER, B.SC. Age 28, married. Four and a half years on industrial plant maintenance and construction, including shop production work and pulp and paper mill control. Also two and a half years on structural steel and reinforced concrete design. Available at once. Apply to Box No. 521-W.

## Situations Wanted

CIVIL ENGINEER, Canadian, married, twenty-five years' technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.SC., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment.Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

### Up-to-date Information

Members registered with the Employment Service Bureau are requested to keep the Bureau advised of any change of address or of any temporary employment they may secure.

Considerable difficulty has arisen during the past few months through employers not being able to secure the services of men recommended due to these men being already employed.

Are you interested in selling?

Have you registered?

CHEMICAL ENGINEER, S.E.I.C., B.SC., University of Alberta, '30. Age 31. Single. Six seasons' practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years' experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.SC. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box No. 651-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

## Situations Wanted

MECHANICAL AND STRUCTURAL ENCINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Cood education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., 29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENCINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNC CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENCINEER, S.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER. M.SC., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering Read, write and talk French. Married. Served in France. Will go anywhere at any time Experienced journalist. Apply to Box No 737-W.

RADIO AND ELECTRICAL ENGINEER, B.SC. '31, S.E.I.C. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.SC. '29, A.M.E.I.C. Married. One year building construction, one year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

## Situations Wanted

SALES ENGINEER, B.Sc., McGill, 1923, A.M.E.I.C. Age 33. Married. Extensive experience in building construction. Thoroughly familiar with steel building products; last five years in charge of structural and reinforcing steel sales for company in New York state. Available at once. Located in Canada. Apply to Box No 749-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with fifteen years experience mostly in pulp and paper mill work, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

CIVIL ENGINEER, B.A.Sc., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. '32 (Univ. of N.B.). Age 25. married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works Available immediately. Apply to Box No. 846-W.

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years' experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.Sc. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.Sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED, Young engineer, B.A.Sc. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

ELECTRICAL ENGINEER, Dipl. of Eng., B.Sc. (Dalhousie Univ.), S.B. and S.M. in E.E. (Mass. Inst. of Tech.), Canadian. Married. Seven and a half years' experience in design, construction and operation of hydro, steam and industrial plants. For past sixteen months field office electrical engineer on 510,000 h.p. hydro-electric project. Available at once. Apply to Box No. 936-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.Sc. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street, improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.Sc. (Queen's 14), A.M.E.I.C., Dominion Land Surveyor, 5 months' special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.Sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.Sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, age 27, graduate 1930, single. Experience includes detailing, designing and estimating structural steel, plate work and pressure vessels; also hydrographic surveying. Available at once. Apply to Box No. 1111-W.

ELECTRICAL ENGINEER, B.Sc., in E.E. (Univ. of N.B. '34), S.E.I.C. Experience in bridge and road construction and auto repairing, desires position in industrial or power plant. Any locality. References on request. Apply to Box No. 1114-W.

CIVIL ENGINEER, B.Sc. Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.Sc.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

MECHANICAL ENGINEER, B.A.Sc. (Univ. of B.C.), M.S. (Univ. of Pittsburgh). Canadian. Age 26. Single. One year graduate student course, W.E. and M. Co., East Pittsburgh. Three and a half years engineering research in mechanics with the same company. Location immaterial. Available at once. Apply to Box No. 1123-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box No. 1127-W.

PETROLEUM CHEMIST, B.Sc. in Chem. Eng. Age 25, Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.Sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.Sc., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married Apply to Box No 1207-W.

## For Sale

ONE ZEISS 11 level with telescopic tripod. Compact, three screw, internal focussing, with gradienter-controlled buddle viewed from eyepiece end. Offered at $100.00, (roughly half present market price new). Apply to Box No. 20-S.

## Wanted to Purchase

COMPASS. Good second hand surveyors compass required. Suitable for use on surveys in connection with timber leases. One with four inch needle preferred. Apply to Box P-23.

# for transmission equipment

FAIRBANKS-MORSE men are trained to analyse transmission problems and to recommend the most suitable belt, pulley, shafting, bearing or hanger for any drive. And they will accept undivided responsibility for every installation. At our Branches you will find large stocks of all necessary equipment including such proven leaders as Flex-Mor V-Belt Drives, Graton & Knight Leather Belting, Dick's Balata Belting, Hyatt Roller Bearings, Barry Steel Pulleys, Fairbanks Wood Pulleys, Shafting, Hangers, Pillow Blocks and general supplies.

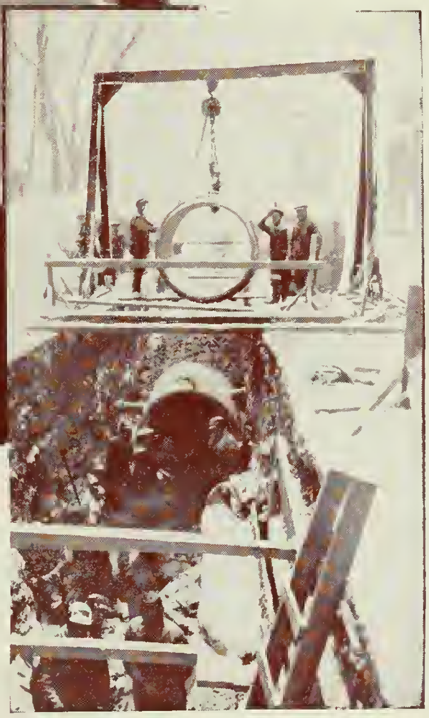
### ALL-CANADIAN RELIEF-WORK



Winter, the season when relief work is needed most, presents no serious handicap to carefully planned concrete sewer construction.

Whether the pipe is secured from established products plants or, as was the case in Longueuil, it is manufactured by the municipality itself, a maximum of local labor is used for the money spent. Write our Service Department for any information pertaining to concrete.

Alexander Thurber, Mayor.
Hillaire Dubuc, Chairman Public Works Commission.
A. Vincent, City Engineer.
A. Plamondon, Consulting Engineer.
H. Leclerc, Asst. Engineer.

# The Romance of Road Building in Canada

DURING the year 1934 some 338.3 miles of new road and repairing work was carried on in the Province of Ontario. This work included the laying of various types of pavement and a considerable amount of grading work.

Some nineteen bridges were built during this period. The two photographs shown above are taken near Stoney Creek, on King's Highway No. 20. The centre picture shows the blasting of a cut through a hill, the other photograph the almost completed road.

Explosives played their part in this construction activity, and NOW a new, economical and efficient method of building highways across swampy and marshy ground can be carried out by the use of C-I-L Explosives.

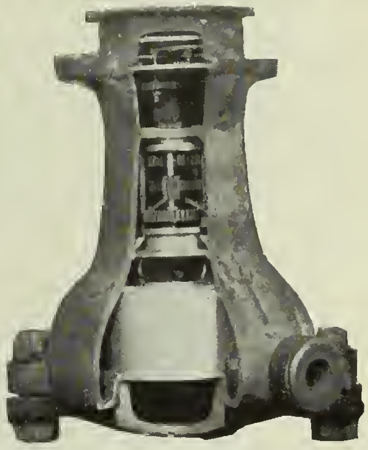
## CANADA WATER METERS
### with modern interchangeable parts

New models and improvements make the best water works equipment obsolete in a few years—all equipment except Trident Water Meters! You couldn't modernize the pumping-engine above with new parts,—but, new, improved, interchangeable parts fit perfectly into the Tridents of that day—and make them more efficient than ever—good for years more trouble-free, low cost, accurate service. Buy your water meters once and for all . . . we make a type for every problem and every condition of service. Write for catalogues to



*Here are modern new interchangeable parts in a Trident Meter casing installed in 1899. Forty years from now the parts may look different (improved); but the principle of INTERCHANGEABILITY will be the same; and as long as the meter casing lasts—they'll fit!*

THE MINING INDUSTRY
marches on!
. . . toward new highs in production
. . . toward new lows in mining costs
. . . toward new efficiency in plant design and equipment
Ferranti is proud to have a prominent part in the progress of the mining industry in Canada. For mine milling, dependable uninterrupted power is a necessity. The power transformer is a vital link in the power supply system and none but the most reliable transformers should be installed.
Over forty years ago Ferranti in England built the first high-voltage power transformers in the world. Since that time, years of continuous specialized experience have built up an unequalled reputation for reliability.
Most of the prominent mines, public utilities, and industrial plants in Canada are using Ferranti equipment; repeat orders evidence satisfaction. The illustration shows a Ferranti installation at McMillan Gold Mines Limited sold through the Northern Electric Co. Ltd. Recent orders include Ventures Limited, Canadian Malartic Gold Mines Limited, McKenzie Red Lake Gold Mines Limited, Lamaque Gold Mines Limited, and Wingold Mines Limited.
Let us quote you on your transformer requirements.

## You're off our minds for a good many years"

O-B insulators are like that! For downright satisfaction, they can't be beat. Once on the pin, they are off your mind for a good many years. O-B pintype insulators, installed on lines built in the early years of the century, are still giving satisfactory service. What could be a better basis upon which to buy insulators for new construction or line re-insulation?

# GARLOCK'S LATEST DEVELOPMENT

## A NEW OIL SEAL

*This Booklet Tells the Story —Write for Your Copy.*

ORIGINAL in design — new in principle — simple in construction — dependable in operation — the Garlock Klozure has established remarkable performance records on many types of equipment.

Its mechanical precision, its resistance to oils at high or low temperatures and the semi-automatic action of its resilient sealing element are all features which combine to make the Garlock Klozure an outstanding device for any oil seal application.

A Garlock representative will gladly furnish you with literature and samples.

The illustration above shows the simple and effective design of the Garlock Klozure. Consisting of four parts only, this sturdy oil seal gives leak proof performance under the most severe conditions. Klozures are available in a wide range of sizes.

# The Columbia River in Canada

*J. C. MacDonald, M.E.I.C.,*

*Comptroller of Water Rights, Department of Lands, Province of British Columbia, Victoria, B.C.*

**Paper presented before the Western Professional Meeting of The Engineering Institute of Canada, July 11th to 14th, 1934, at Vancouver, B.C.**

SUMMARY.—Beginning with a summary of the early history of the Pacific coast, the author describes the Columbia river and its drainage area north of the international boundary. He describes the facilities for navigation, the irrigation problems, questions of dyking and drainage, power development and water storage possibilities on the Canadian side of the border.

As a supplement to the paper, abstracts are given of three papers by American engineers dealing with the projects in the United States for power, navigation and reclamation at Grand Coulee and the Columbia Basin north of the Snake river and those for power and navigation below its mouth.

The portions of the Columbia river and its tributaries that lie north of the international boundary are relatively of much less importance than those to the south. It may be as well, therefore, to devote some considerable part of this paper to the historical and international viewpoints.

With the exception of the Skagit river and one or two negligible streams near the coast, the Columbia and its tributaries are the only streams which cross the international boundary west of the continental divide. The Flathead, the Kootenay, the Pend d'Oreille or Clark's Fork, the Kettle, the Okanagan, the Similkameen, are all parts of the great Columbia system. (See Fig. 1.)

The uses and development of the river constitute the main international water problem on the west coast. Fortunately, there are few phases of the question which are likely to be contentious, but if the early history of the Pacific coast had been different, the situation might have been quite otherwise.

Perhaps the most magnificent gift in recorded history was that of Pope Alexander VI to the Court of Spain, when he gave to His Catholic Majesty the Pacific Ocean and lands bordering thereon. This was in 1493. The title so acquired by Spain was strengthened by a vigorous policy of exploration, settlement and spoliation. Although Queen Elizabeth of England had expressed her disregard of the exclusive Spanish right, the first serious challenge came from the Russians, who, attracted by the fur trade, had come down from the north and set up several establishments in the Aleutian Islands. The Spaniards investigated the Russian activities and remonstrated with the Russian government, but apparently decided to limit their claims to the coast south of latitude 54–40.

In 1776 Captain Cook set out from England by way of the Cape of Good Hope to locate the western end of the long-sought Northwest Passage. At Plymouth he anchored beside three ships of the Royal Navy which were awaiting favourable weather to set out with the last division of Hessian troops which took part in the war of the American Revolution. Cook was strictly enjoined not to interfere with Spanish ships or settlements on the Pacific coast. Cook's ships returned to England with stories of the great wealth of furs on the coast and of the possibilities of trade in these commodities with China. Within a few years adventurers from England and the eastern coast of the newly-formed United States of America were actively engaged in the new trade and were having their troubles with the Spaniards. The difficulties became so serious that England and Spain began to mass their fleets and to rally their allies in preparation for war. An open breach was avoided by the Nootka Sound Convention by which in 1792 Spain recognized the British right to trade and settle on those parts of the coast not already occupied. This convention recognized the parallel of 54–40 as the southern limit of Russian territory.

The Americans began to move westward and in 1811 Astor's company, the Pacific Fur Company, established a post at Astoria at the mouth of the Columbia. Spain's hold was weakening. She was having her troubles in Europe and was no longer in a position to force her claim so far west. The more bleak and sparsely populated shores of the North Pacific did not furnish the rich harvest of loot she had gathered in the south, and in 1819 by the Florida Treaty she relinquished her claims to territory north of the 42nd parallel. This left the United States and Great Britain as the only claimants on the coast between latitudes 42 and 54–40.

Great Britain had never occupied or been interested in the sections south of the Columbia river and the dispute narrowed down to the ownership of the coast from the mouth of that river to the Russian boundary. In 1818 the 49th parallel had been adopted as the boundary from the Lake of the Woods to the Stoney mountains, but there the agreement stopped. Clauses of old treaties, discoveries, occupation and settlement were all drawn into the argument, which was settled for the time being by a convention like that of Nootka Sound to the effect that the country with its harbours, bays and creeks and the navigation of the rivers should be free and open to the subjects of both powers for a term of ten years. In 1827 this was extended indefinitely, being terminable on twelve months' notice by either party.

The dispute continued until 1846, at times being forgotten and at times forming the main topic of discussion in the American Congress and to a lesser extent in the British House of Commons. The British proposed an extension of the 49th parallel to the Columbia and the

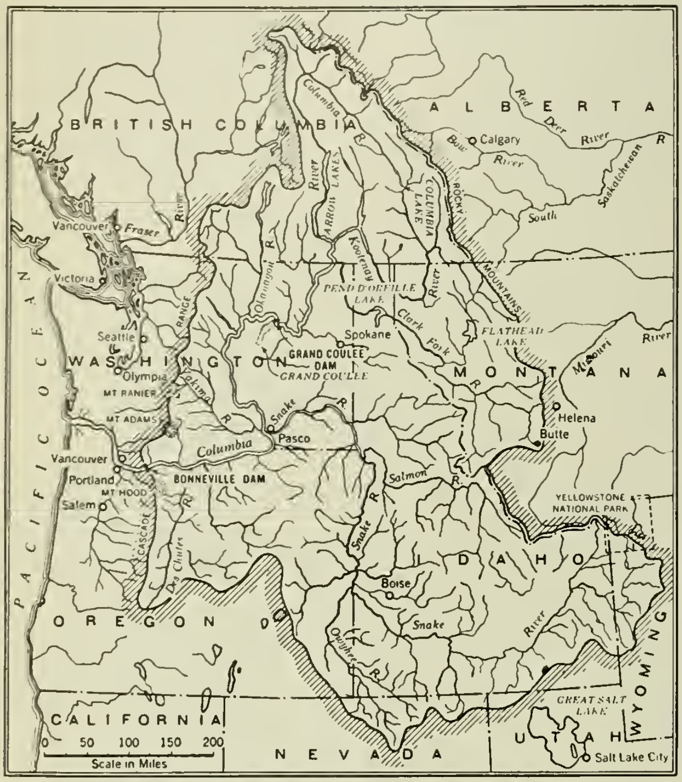

**Fig. 1—Columbia River Basin.**

centre of that river to the coast as the dividing line. The Americans stood out for the whole country to 54–40.

As time went on American settlement increased in what is now the State of Washington, and British settlement on the south end of Vancouver Island grew in size and importance. Public feeling in the United States, excited by the slogan of the politicians "54–40 or Fight!" became more intense. The British ships on the coast offered to settle the question in their way. But for some years the saner heads on both sides had been tending toward the extension of the 49th parallel with a deviation around the southern end of Vancouver Island. In 1846 one proposed it, the other at once accepted it, and the question was settled.

It must be remembered that during all this discussion California was in the hands of the Spaniards. There was not one good harbour between Spanish territory and Puget Sound. The British never seriously viewed the country as a settlement project—it was too remote, and the part of it they knew too rugged to interest them. They wanted an outlet on the Pacific and the nearer to China the better.

Had the Americans had access to the port of San Francisco and the British a true appreciation of the great wealth of the land, the Columbia river might have been the boundary between the two nations, and a real problem would have resulted—another St. Lawrence river problem. But fortunately negotiation and its attendant ill-feeling are past, and the present problem is one of co-operation to secure the maximum benefits to the people of both countries.

Description of the River System

The watershed of the Columbia and its tributaries in British Columbia comprises just over 40,000 square miles and lies entirely within the North American cordillera between the 49th and 53rd parallels of latitude. A cross section of the country gives one an appreciation of its general character. (Fig. 2.)

Only about 15 square miles in the entire area lie under the 1,000-foot contour. Narrow valleys among the mountain peaks contain the only land suitable for human habitation. Roughly 8,000 square miles lie between 1,000-foot and 4,000-foot contours, and only about 310 square miles or 200,000 acres are suitable for cultivation. The population of the watershed is seventy-eight thousand, of whom approximately half are engaged in agriculture and half in mining with some few in lumbering. The precipitation varies from 65 inches in the summits of the Selkirks to under 20 inches in the valleys. The valleys and adjacent benches are fertile, and, where irrigation water is available, very productive.

The climate is temperate, except for short distances up the Okanagan and Similkameen rivers, where subtropical flora and fauna are found.

The area is estimated to have thirteen billion, eight hundred million feet of accessible merchantable timber. Of this from 250 to 300 million feet are cut in a normal year, giving employment to about two thousand men. Up to the present transportation difficulties have prevented the manufacture of pulp and paper.

Mining has been the main industry in the area. Many of the tributary streams carry placer gold and have been worked spasmodically since 1863. Large deposits of high-grade coal occur in the Crow's Nest Pass and at Princeton and Coalmont, and have been mined continuously for many years. The recent general slump in the coal mining industry has had its effect in these localities. Lode gold mining began seriously in the late 80's and has been stimulated recently by the increased price of that metal. The whole area is highly mineralized and large deposits of copper, lead and zinc which carry good value in silver and gold occur in many places.

The main stream of the Columbia has its source in Columbia lake, which lies at an elevation of 2,650 feet in the great trough between the Rocky and Selkirk mountains just north of the 50th degree of latitude. The mountains on either side of the narrow valley rise to a height of 11,000 feet. At its source the river drains the east slope of the Selkirks, the drainage from the Rockies being cut off by its tributary, the Kootenay. The river flows in a north-westerly direction on an easy grade through the beautiful Windermere lake to Golden just north of the

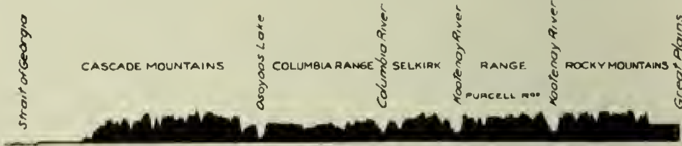

**Fig. 2—Cross Section of the Cordillera at the 49th Parallel.**

51st degree. Here its moderate flow is increased by that of the Spillimacheen river from the Selkirks and the Kicking Horse, which brings in the first of the Rocky Mountain drainage. The character of the stream changes. It flows through a series of canyons and rapids unbroken save for a short stretch through Kinbasket lake. At Boat Encampment just north of the 52nd parallel, it is joined by the Canoe river from the north and turns abruptly south between the Selkirks and the Monashee ranges. It continues its turbulent course through a narrow valley with mountain rising over the 10,000-foot level on each side.

to Revelstoke. Between Golden and Revelstoke the river drops 1,130 feet in 180 miles. Here the profile flattens out. It falls only 40 feet in the next 30 miles, and in flood spreads itself over what might otherwise be a fertile valley. At Arrowhead it widens and deepens into the Arrow lakes, which extend with a minor restriction to Castlegar, about 25 miles north of the boundary. Here it is joined by the Kootenay. It picks up speed and drops 70 feet in 28 miles, being joined almost at the boundary by the Pend d'Oreille or Clark's Fork.

As would be expected from the character of the country drained, the Columbia is a very flashy stream, having its major discharge when the hot suns of the summer solstice attack the everlasting snow and ice of the glaciers, and its minimum flow during the late winter when the mountain tops are frozen and the effect of the stored ground water generally exhausted. The lakes of the main system have very little regulatory effect. Columbia and Windermere lakes are too small and too near the source to be of any value. Arrow lake is 110 miles long, but very narrow, being not much more than a widening and deepening of the river. The natural storage is almost negligible. The river at Golden has a maximum recorded flow of 23,700 cubic feet a second (June 25, 1916) and a minimum of 502 cubic feet a second (January 2, 1926). At the international boundary the maximum recorded flow is 451,000 cubic feet a second and the lowest since records have been kept was approximately 17,500 cubic feet a second. The phenomenal run-off of 1894, before any records were established, greatly exceeded the maximum given above, probably to the extent of fifty per cent.

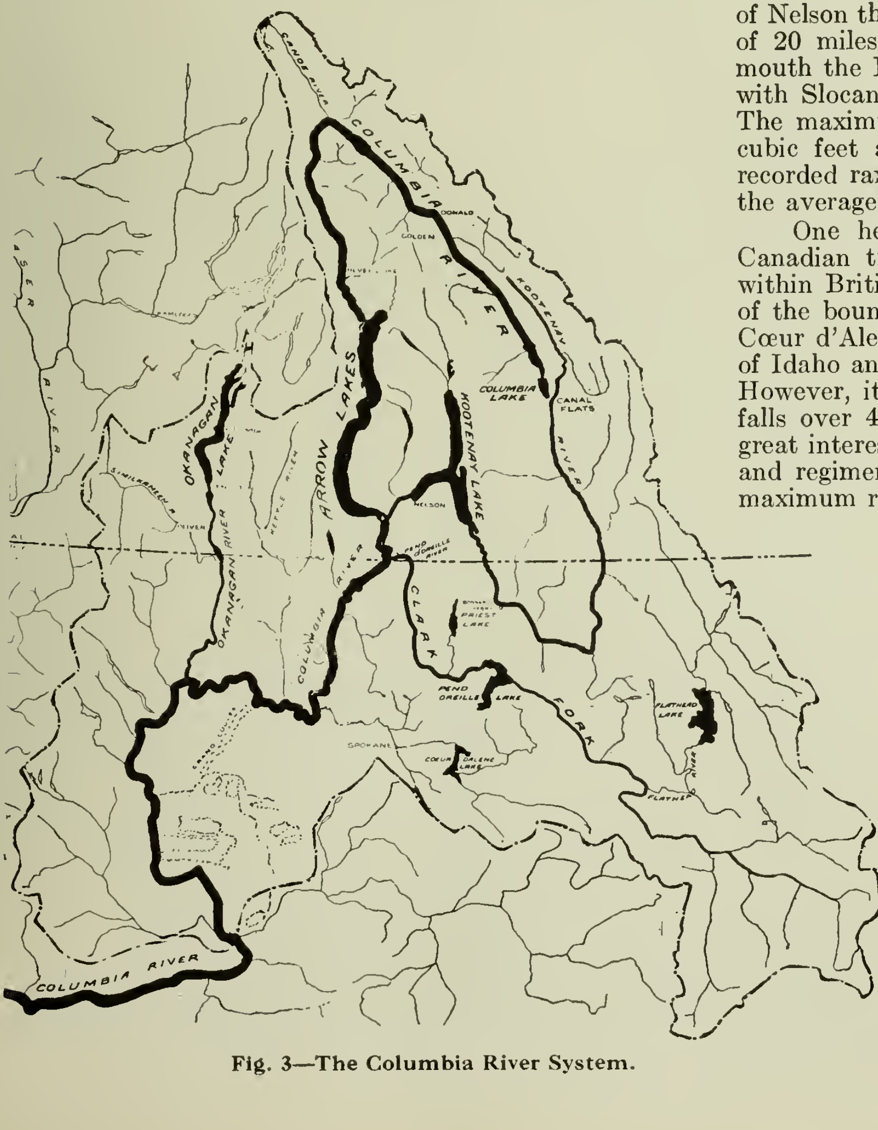

Fig. 3—The Columbia River System.

The main Canadian tributary of the Columbia, the Kootenay, has its source in a small lake on the west slope of the Rockies about the 51st parallel of latitude. This lake is only 8 miles from the main Columbia at Castledale. A considerable tributary, the Vermilion, heads some 15 miles further north. The Kootenay flows parallel to but in a reverse direction to the Columbia for some 60 miles and approaches within 2 miles of Columbia lake at Canal Flats. At this point it is about 11 feet in elevation above Columbia lake and could be easily diverted into the main river. The Kootenay flows in a southerly direction with a fairly constant grade of 3½ feet to the mile. It picks up St. Mary's river from the west and the Bull and Elk rivers from the east, and enters the state of Montana at Gateway. It continues south to Jennings, then turns northwest to Bonners Ferry in Idaho. Here the river flattens out and at low water flows in a tortuous and sluggish channel which twists back and forth across a fertile alluvial valley about 4 miles wide. At high water it overflows its banks and, except where confined by dykes, floods the entire valley. Then it re-crosses the international boundary at Porthill and enters Kootenay lake. This last stretch of the river offers an extremely interesting reclamation problem, which will be referred to later.

Kootenay lake is 65 miles long and varies from 4 miles in width at the south end to 2 miles at the north and occupies a deep trench in the heart of the Selkirk mountains. The lake is fed at the north end by Lardeau and Duncan rivers, which with their lakes, collect the drainage of the interior of the Selkirks.

Midway on the west side Kootenay lake thrusts a narrow arm into the mountains and just below the city of Nelson the river begins a drop of 360 feet in the distance of 20 miles to the Columbia. About 10 miles from its mouth the Kootenay is joined by the Slocan river, which, with Slocan lake, drains another section of the Selkirks. The maximum recorded flow of the Kootenay is 146,000 cubic feet a second; the minimum 2,400. The extreme recorded range in level of Kootenay lake is 24.8 feet and the average annual fluctuation is about 17 feet.

One hesitates to describe the Pend d'Oreille as a Canadian tributary, for though it enters the Columbia within British Columbia about a quarter of a mile north of the boundary it collects its water in the Flathead and Cœur d'Alene mountains of Montana and the Bitterroots of Idaho and its flow is regulated by lakes in those states. However, it flows for 14 miles in Canadian territory and falls over 400 feet in that length. It is consequently of great interest because of its power potentialities. Its flow and regimen are similar to those of the Kootenay. The maximum recorded is 139,000 cubic feet a second and the minimum 2,500 cubic feet a second.

The tributaries to the west of the Columbia are all of minor importance. The Kettle rises in the Columbia range and flows south to the international boundary at Midway. At Midway it turns east and crosses and recrosses the boundary to Cascade, where it turns south and joins the main river at Marcus. One of the early power developments in the boundary country was situated on this river at Cascade. In recent years, due perhaps to extensive logging in the watershed, the flow of the Kettle has become very flashy and the power plant has been abandoned.

Okanagan river rises in Okanagan lake and its course in Canada is about 35 miles long with very little fall. It joins the Columbia at Brewster.

The Similkameen rises on the north slope of the Cascades and is a flashy stream with a maximum flow of 23,700 cubic feet a second and a minimum of 760 cubic feet a second. It joins the Okanagan at Oroville, where it is used for irrigation on the American side of the line.

### Navigation

The Columbia river with its tributaries and lakes formed an important transportation system in the early development of the Kootenay country. Prior to 1885 placer miners and occasional prospectors found their way into the district from the coast over the Dewdney trail or along the lakes and rivers from the south. In 1885 the main line of the Canadian Pacific Railway was finished, touching the navigable parts of the Columbia system at Golden and Revelstoke. The possibility of transporting machinery, and ore and concentrates of the base metals brought into life the lode mining which has been the main activity of the district.

Palatial steamers of the type so well-known on the Mississippi plied the waters of Kootenay, Arrow, Slocan and Okanagan lakes. Small shallow-draught boats worked their arduous passages up and down the river stretches carrying machinery and supplies to the mines, and high-grade ore and concentrates to the smelters. The Kootenay river was navigable by such small craft from Jennings, Montana, to Canal Flats, British Columbia, the Columbia from Canal Flats to Golden, from Downie creek to Northport.

During the 90's short lines of railway were built along the shores of the faster waters from Nelson to Robson, from Revelstoke to Arrowhead, from Kuskanook to Porthill, and the smaller craft disappeared.

The larger boats continued to do business until in 1916 the Kettle Valley Railway was carried over the mountain tops to the coast, cutting the time from Vancouver to Nelson by ten hours. The Crow's Nest Pass branch of the Canadian Pacific Railway had been built to Kootenay Landing at the south end of the Kootenay lake in 1900, and after 1915 a stern-wheeler maintained a daily service for passengers and express between Nelson and Kootenay Landing on this branch transcontinental line. Freight was carried across the gap on car barges. In January, 1931, railway construction along the shore of the lake was completed, and the steamer service ceased.

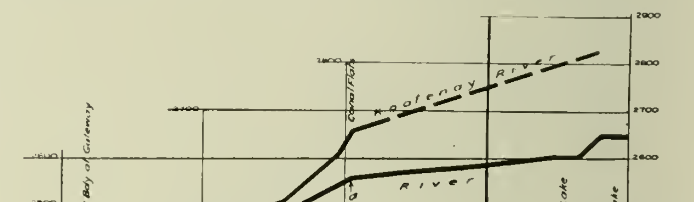
On Okanagan lake, before the completion of the Kettle Valley, a branch line from Sicamous to Okanagan Landing and the boats on the lake served the whole valley and the adjacent country. The Kettle Valley cut heavily into the traffic, but in the fruit season the boats still carried capacity loads. In 1925 the Canadian National Railway built through to Kelowna, and since then the improvement in the roads and the ferry service crossing the lake have induced a heavy motor and truck traffic. The boat still runs, but more as a concession to local public sentiment than as a utility.

Automobile ferries operate across Okanagan lake at Kelowna, across the Columbia at Sidmouth, Castlegar and Edgewater and across the Kootenay at Nelson, Harrop and Balfour, and car barges on the lakes still serve isolated local points, but navigation on the Columbia system in Canada is done, unless some major economic change revives it. The remaining steamer services are temporary links in the railway and highway systems.

This history further demonstrates the axiom that water transportation on a small scale cannot compete with railways and has even less chance against the new agencies that are now threatening the reign of the locomotive.

### Irrigation

The irrigation problem in the Columbia unfortunately cannot be as easily dismissed as the navigation. A large percentage of the land irrigated in British Columbia lies in the Columbia basin and although the acreage is small relative to the states to the south, the problems are just as acute.



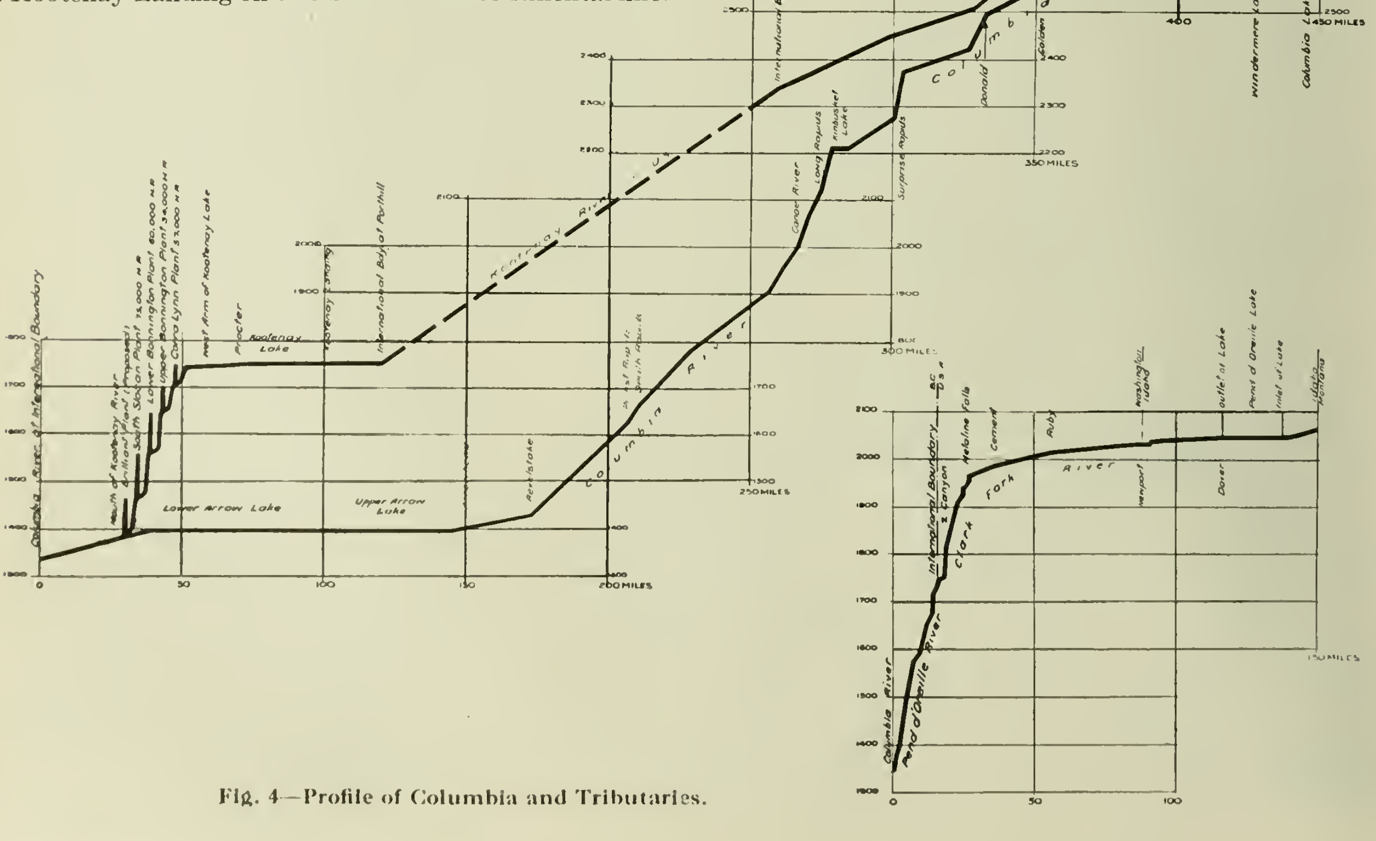


Fig. 4—Profile of Columbia and Tributaries.

Organized irrigation as a means of stimulating land sales began in the interior of British Columbia about 1900. Some of the early promoters received prompt and handsome dividends, and as a consequence by 1910 some fifteen to twenty companies were selling irrigated land in the dry belt. Although attempts were made to induce colonization, the number of incoming settlers was entirely inadequate, and the companies found themselves in difficulties.

About 1914 the water-users began to realize that the companies could not be relied on for the replacement of the perishable portions of the works and that there was grave danger that the supply to their lands and orchards, which were then becoming valuable, would cease. They approached the government for some assurance of protection or assistance. In 1918 the situation became so acute that the government created a special conservation fund to finance necessary repairs and reconstruction. In 1920 legislative provisions were made for the organization of irrigation districts and thereafter the necessary funds were loaned to these districts. The districts took over the systems formerly operated by the companies, compensation, if any, being arranged for by negotiation.

The funds necessary for the acquisition and reconstruction of the systems were advanced by the provincial government. No bonds or other form of security were demanded, but the moneys loaned were made a direct charge against the lands within the district. Six per cent interest was charged and repayment was required on terms depending on the probable life of the irrigation structures built by the district. The regulations required that all moneys needed for interest and repayment of borrowings for capital expenditure should be collected as a special district tax on the land and provided that any portion of the remaining requirements of the district, such as for operation and maintenance, might at the option of the local authorities be collected as a tax or as a toll or charge on the water delivered.

Considerable latitude was allowed to the district authorities, but in general taxes were levied only on the land that could be benefited by the use of irrigation water, and were applied irrespective of whether or not the land was actually cultivated. The method of collecting tolls varied, but they generally applied only on the land actually cultivated and producing. In some cases, a higher toll was charged for water delivered after the natural run-off had passed and the storage reservoirs were opened.

The relative functions of the district and the individual users were quite definitely laid down, and generally, the districts carried water to the boundary of each individually-owned parcel. In larger holdings water was delivered to several points within their boundaries.

The first payments from the districts were demanded in 1921 and were promptly met. The payments due in 1922 were met before it was recognized that there was a serious collapse in the market for agricultural produce. As a result of the importunities of the growers, the government declared a two-year moratorium on irrigation loans and thus the problem definitely entered the political field. This moratorium was continued for a further two years and since that time the problem has never left the doorstep of the parliament buildings.

It is now quite evident that the estimates of assessable land made at the time of organization of the districts were too optimistic and that a considerable portion of the land included can not survive if required to pay its portion of the total indebtedness. The land lies above the natural storage basins and the water is taken from mountain tributaries and carried relatively long distances along the mountain sides to reach the arable benches. The natural flow of these tributary streams fades out early in the season necessitating the creation of storage at high elevations. The capital cost of the developments is consequently high, in some cases approaching $150.00 per acre. Only intensive cultivation and high-priced crops, such as fruit and truck, can pay the resultant costs, and unfortunately only a part of the land is suitable for such produce. The seasons are relatively late and the various varieties of fruit reach the market too late to bring the best prices. The marketing problem is even bigger than the irrigation and is apparently far from a successful solution.

There is only one government owned and operated irrigation project in the province. This is in the Okanagan valley just north of the international boundary and was started in 1919 in response to a post-war demand for employment and for land for soldier settlers. To date only about 30 per cent of the land has been taken up and there have been several adjustments of prices and terms of payment with the settlers demanding further concessions.

### Dyking and Drainage

British Columbia has a dyking problem as well, but so far it is associated with the Columbia river in only a small way. The main dyking areas in the province lie in the lower valley of the Fraser. As mentioned earlier, the Kootenay river, before it enters the main lake, flows for some 45 miles through an alluvial valley which is annually flooded at high water. This land on the Idaho side of the boundary has nearly all been successfully reclaimed.

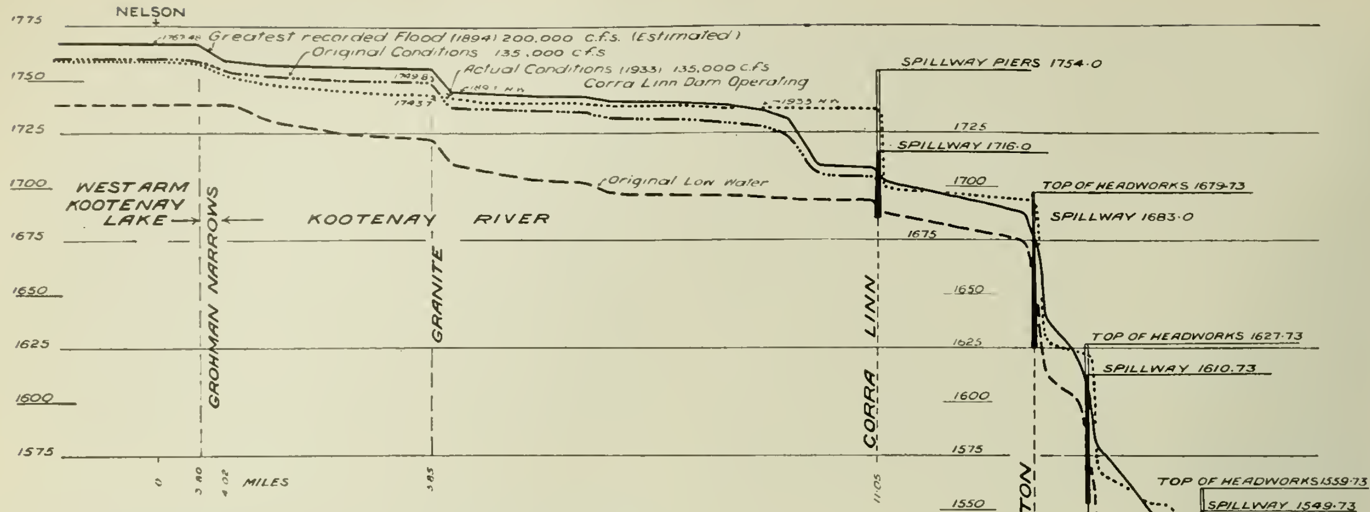
About 1890, a promoter proposed to reclaim the whole Kootenay flat by diverting the upper reaches of the Kootenay river into Columbia lake. He even secured approval and a concession from the provincial government. Luckily the scheme was blocked and the proposed diversion channel converted into a navigation canal. This work was completed about the time navigation on the upper reaches of the Kootenay ceased and one boat was passed through the locks and the canal was permanently closed.

An attempt was made to dyke some 7,000 acres adjacent to the international boundary, but the 1894 floods wiped out most of the work almost before it was completed and attempts to restore these dykes since have met with indifferent success.

About eight years ago a group of residents of Creston secured a provisional grant of 10,000 acres of the flats to be reclaimed near that town. This brought forward an interesting international angle. Under the "Boundary Waters' Treaty" of 1912 between the United States and Canada, it was agreed that except in cases provided for in special agreement, they would not permit the construction or maintenance on their respective sides of the boundary of any remedial or protective works or dams or other obstructions... in waters at a lower level than the boundary in rivers flowing across the boundary, the effect of which was to raise the natural level of the waters on the other side of the boundary, unless the construction or maintenance thereof was approved by the International Joint Commission. This provision applied to the proposed reclamation on the Canadian side but not to that on the American side, therefore the Canadians had to secure permission from the Commission before such work could be undertaken. The Commission has quite naturally recognized that what has already been done on one side should be permitted on the other, and has given unconditional approval to the two applications which have been made.

### Power

On the Canadian side the main interest in the Columbia river lies in its power potentialities. Plants with an installed capacity of 259,000 h.p. are at present in operation on the river and its tributaries. According to our present information, the system is capable of providing a total of 803,400 continuous and 1,348,000 seasonal horsepower.



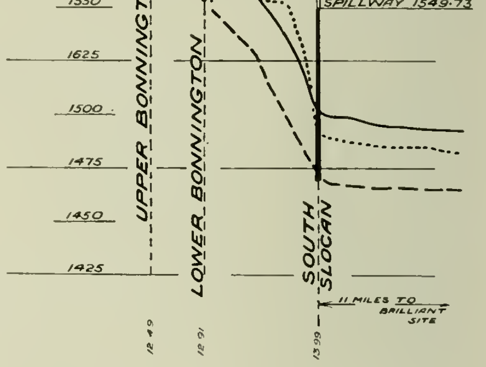


**Fig. 5—Profile showing Location of Power Plants on the Kootenay River.**

The tributaries west of the main river are all of minor importance and their uniform gradients and flashy flows make development of appreciable size very improbable. A plant of 1,600 h.p. on the Similkameen supplies the mines at Hedley, one of 660 h.p. on Granby creek supplies the city of Grand Forks, and one of 100 h.p. on Trepanier creek supplies the town of Peachland. As this tributary area is within reach of the transmission lines of the West Kootenay Power and Light Company, it is unlikely that any further development will take place.

Along the Columbia proper a plant of 1,400 h.p. on the Illecillewaet river supplies the city of Revelstoke and one of 150 h.p. on Nakusp creek supplies the town of Nakusp. Throughout the length of the river similar small plants could be installed on the tributaries to serve any local needs. The main river between Golden and Revelstoke drops over 1,100 feet in 180 miles. This stretch is estimated to be capable of producing 104,000 continuous and 246,000 seasonal horsepower, but nothing has been attempted.

The Kootenay, like the parent stream, has on its tributaries many possible small developments to supply local needs. The larger possibilities of the river have been quite intensively developed. The East Kootenay Power and Light Company has a 15,000-h.p. plant on the Elk river and one of 7,200 h.p. on the Bull. These developments in conjunction with a steam plant at Coleman just across the provincial boundary in Alberta, supply the mines in the Crow's Nest Pass and at Kimberley, the cities of Cranbrook and Fernie and the adjacent territory. The West Kootenay Power and Light Company has a development of 1,050 h.p. on the Goat river to supply the town of Creston.

The main Kootenay above the lake has easy gradients and no power possibilities, but between the lake and the Columbia the river has a drop of 360 feet concentrated in a distance of 20 miles, on which there are completed developments of 232,000 h.p. and a projected further development of 90,000. With the exception of a 6,500-h.p. plant owned and operated by the city of Nelson, this stretch of the river is held under licence by the West Kootenay Power and Light Company, a public utility company which serves the entire boundary country to the west as far as Princeton and up the Okanagan valley to Kelowna. This company has four power plants in this stretch of the river:

| | | |
|---|---|---|
| No. 1 | at Lower Bonnington with an installed capacity of | 60,000 h.p. |
| 2 | Upper Bonnington " " " | 34,000 " |
| 3 | South Slocan " " " | 75,000 " |
| 4 | Corra Linn " " " | 57,000 " |

Each plant consists of three vertical units and there are four interchangeable transmission lines operating at 60,000 volts to Trail.

The development of the river offers an interesting example of careful conservation of head. The tailrace of each plant is practically the forebay of the next below. Obstructions to flow in the intervening stretches have been cleared away to the economic limit. In the three lower plants long spillways have been developed to hold down the levels of the tailraces above. Above the upper plant at Corra Linn some 900,000 yards of material were taken out of the river, giving a minimum cross section of 24,000 square feet, and completely removing all restrictions below Grohman rapids. The dam at this plant is a sluice-gate structure, having fourteen openings 34 feet wide, and is capable of passing the maximum flood in the river without affecting the levels above. With the exception of Upper Bonnington, which shares the stream-flow with the Nelson city installation, the plants are designed to use 10,000 cubic feet a second. The flow available on the average over twenty years of record may be observed in Table I.

Table I

| | | |
|---|---|---|
| Over 10,000 c.f.s. | for 250 | days in the year |
| " 9,000 " | " 267 | " " " |
| " 8,000 " | " 290 | " " " |
| " 7,000 " | " 311 | " " " |
| " 6,000 " | " 330 | " " " |
| " 5,000 " | " 360 | " " " |

The company has the right to install another plant at Brilliant near the mouth of the river and when this is built every available foot of head on the Canadian section of the main Kootenay will be developed.

As previously mentioned, the Pend d'Oreille has a fall of over 400 feet in 14 miles in Canadian territory. Over twenty-two years of record the river flowed on the average as noted in Table II.

TABLE II

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| 11,000 | c.f.s. | for | 240 | days | of | the | year |
| 10,000 | " | " | 261 | " | " | " | " |
| 9,000 | " | " | 301 | " | " | " | " |
| 8,000 | " | " | 431 | " | " | " | " |
| 7,000 | " | " | 347 | " | " | " | " |
| 6,000 | " | " | 359 | " | " | " | " |
| 5,000 | " | " | 363 | " | " | " | " |

It is considered to be good for 210,000 continuous and 350,000 seasonal horsepower.

STORAGE

On a stream with as wide a fluctuation of flow as the Columbia river, the storage of flood water for the purpose of increasing the low-water flow is all important from the power standpoint. The maximum economic development of the stream is governed by a number of factors, the basic one of which is the minimum flow. Navigation as well is usually benefited by regulation.

The flow of the Columbia river, including the Kootenay river, at Trail, available on the average over eighteen years of record, may be observed from the following Table III.

TABLE III

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Over | 40,000 | c.f.s. | for | 186 | days | in | the | year |
| " | 40,000 | " | " | 217 | " | " | " | " |
| " | 30,000 | " | " | 240 | " | " | " | " |
| " | 25,000 | " | " | 274 | " | " | " | " |
| " | 20,000 | " | " | 298 | " | " | " | " |
| " | 17,500 | " | " | 324 | " | " | " | " |
| " | 15,000 | " | " | 351 | " | " | " | " |
| " | 12,500 | " | " | 364 | " | " | " | " |
| " | 10,000 | " | " | 365 | " | " | " | " |

The area of the lakes on the Columbia system in Canada is small compared to the total drainage area, and consequently complete regulation of flow is quite impossible, but sufficient storage can be economically developed to materially increase the power capacity of the river. It is in this connection that the greatest opportunity for international co-operation lies. It must be remembered that every cubic foot per second added to the dependable flow of the Columbia at the boundary means a cubic foot per second added to the dependable flow of each of the plants now operating, or that may be constructed, on the river south of the line, and each cubic foot per second added to the dependable flow of Clark's Fork at Metaline Falls means an additional cubic foot per second at the plant it is hoped to construct on the Pend d'Oreille, as well as at those on the lower Columbia.

The Arrow lakes on the main Columbia have an area of 155 square miles and a normal rise and fall of 20 feet. This gives a storage capacity of nearly 2,000,000 acre-feet between high and low water, which would have no very serious effect upon any adjacent property. On the basis of the lowest year of record, this would increase the minimum flow at the international boundary by 6,460 cubic feet a second. Unfortunately from the international aspect this storage is of no value on the Canadian side of the line and our legislation makes no provision for storage by other than our own nationals.

The regulating dam would be an interesting structure. It would of necessity be capable of passing the extreme flood in the river without any appreciable increase in the natural water level.

Kootenay lake has an area of 170 square miles and a normal rise and fall of about 18 feet, which would produce a storage of about 1,950,000 acre-feet. Unfortunately this range of elevation is not available as some 60,000 acres of arable land are below the high-water line.

The West Kootenay Company's power dam at Corra Linn could be operated to hold up the lake level to 6 feet above extreme low water. The company has applied to the International Joint Commission for permission to operate the dam for storage to that extent and estimates that the dependable flow of the river will be increased from under 5,000 to over 10,000 cubic feet a second. There would be as well an arithmetically similar increase in the flow of the Columbia.

The briefs presented to the Commission by and on behalf of the company and the objectors in Idaho constitute a very interesting and instructive engineering discussion.

Duncan and Trout lakes at the north end of Kootenay lake have an area of 10.5 and 11 square miles respectively. The normal range of elevation is not great and the storage compared with that of the larger lakes is of minor importance.

By an arrangement which has been in force since 1913, all hydrometric work in British Columbia is done by the Dominion Water Power and Hydrometric Bureau.

The government of British Columbia is initiating a series of snow surveys, on the Nevada system, and is establishing ranges at the headwaters of the Columbia and Kootenay. The area is not one that lends itself to accuracy of prediction from snow data, but it is hoped that within a few years seasonal records will be available which will be of material assistance in estimating total run-off.

The various parties interested in the river on the two sides of the line should make the most of every opportunity to become better acquainted, and it might be of advantage to get together in a semi-formal way for the specific purpose of promoting a co-operation that will be of advantage to both countries.

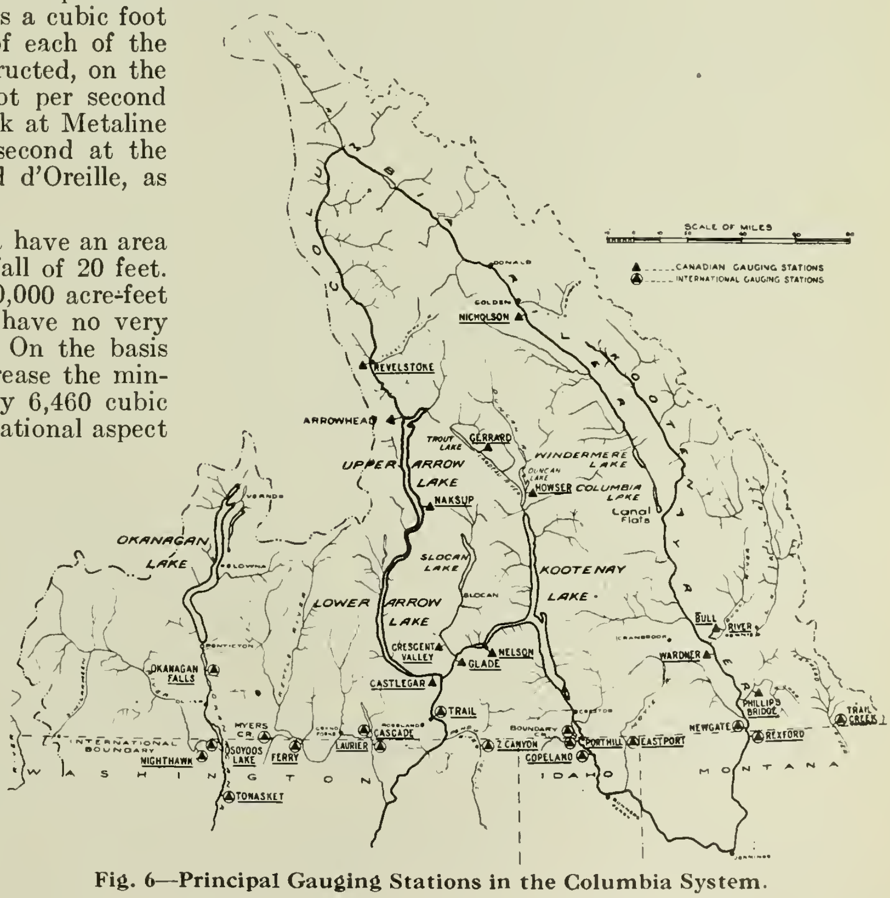

Fig. 6—Principal Gauging Stations in the Columbia System.

# DISCUSSION

C. E. Webb, M.E.I.C.[1]

All water problems concerning navigation, development of water power, irrigation possibilities and control of floods are dependent on basic stream flow data.

The Dominion Water Power and Hydrometric Bureau of the Department of the Interior maintains gauging stations on the principal lakes and rivers throughout Canada in co-operation with the different provinces, and under an agreement of 1930 between Canada and the United States, international gauging stations have been established to obtain basic data in connection with the utilization of waters flowing across the boundary line west of the Great Lakes.

By maintaining these international stations under the joint supervision of the United States Geological Survey and the Dominion Water Power and Hydrometric Bureau, the basic stream flow data developed therefrom are immediately acceptable to interests in either country.

As mentioned by the author, the Columbia drainage basin includes the majority of the international streams west of the Rocky Mountains, and gauging stations are maintained on them as indicated on Fig. 6. From east to west they may be noted as follows: Flathead river on Canadian side near Trail Creek, Montana; Kootenay river at Newgate, B.C., and Rexford, Montana, where the Kootenay flows south into the United States; Moyie river at Eastport; Kootenay river at Copeland and Porthill, Idaho, where the Kootenay flows north into British Columbia; Boundary creek near Porthill; Pend d'Oreille river at "Z" Canyon below Metaline Falls; Columbia river at Trail; Kettle river at Ferry, Washington, at Cascade, B.C., and at Lautier, Washington; Myers creek near Myncaster, B.C., Okanagan river at Okanagan Falls, B.C., at Osoyoos lake near Oroville and at Tonasket, Washington. A station is also maintained on the Similkameen river at Nighthawk. Aside from these seventeen international gauging stations, continuous records are being obtained on thirteen other stations in the Columbia basin, in co-operation with the province of British Columbia, the more important of which are the following:

In the upper reach Columbia river at Nicholson, 361 miles above the international boundary, at an elevation at low water of 2,560 feet; at Revelstoke above the Arrow lakes, 176 miles above the boundary, low water elevation 1,428 feet; at Arrowhead and Nakusp in the Arrow lakes, 145 and 115 miles respectively above the international boundary, low water elevation 1,380 feet, and at Castlegar below the Arrow lakes, 30 miles above the boundary, low water elevation 1,372 feet. On the Kootenay river stations are maintained at Wardner (elevation 2,600 feet), Nelson (elevation 1,740 feet) and Glade (elevation 1,455 feet), along with gauging stations as previously intimated on all minor tributary streams. Hydrometric records of these stations constitute the basis of hydraulic studies of the Columbia river in Canada.

It should be noted that discharge records in this area are available since 1913.

Extensive hydraulic studies have been carried out, both above and below Kootenay lake, in connection with the application now before the International Joint Commission, of the West Kootenay Power and Light Company, for permission to utilize their recently constructed dam at Corra Linn for storage of six feet on low water in Kootenay lake.

Some interesting international slope observations have recently been developed, in co-operation with the United States Geological Survey, on the Columbia river between Birchbank, B.C., and the Little Dalles, Washington, a distance of 37 miles, throughout two years range of stage. Additional slope studies have this year been extended to Revelstoke above the Arrow lakes. From a study of these records it would appear that backwater from the Little Dalles is reflected during high water for some distance above the international boundary line.

For several years bulletins have been issued each spring giving a rough synopsis of existing snow cover and anticipated runoff resulting therefrom, on the Columbia and Fraser river drainages, being the two major streams in the province. It is interesting to note the author's statement that the government of British Columbia is initiating a series of snow surveys at the headwaters of the Columbia and Kootenay rivers. These data will presently be of very material assistance in predicting runoff in that area.

With the close co-operation of the two railways and the provincial government, a very satisfactory flood warning service has been maintained on the Fraser river for a number of years past. This has developed to such an extent that it is now possible to predict closely the water elevations on the lower Fraser three to four days in advance. This same service could be developed on the Columbia river whereby the anticipated flow at the international boundary might be similarly predicted.

Every country where water power studies are being carried on has, up to the present time, used its own particular method for calculating potential water powers. In Canada all estimates by the Dominion Water Power and Hydrometric Bureau represent continuous twenty-four-hour power at 80 per cent efficiency and have been based on calculations for "Ordinary Minimum Flow" which is the average over all years for which records are available of the mean flow for the two lowest consecutive seven-day periods in each year, and "Ordinary Six-Month Flow" which is the average over all years for which records are available of the mean flow for the lowest seven consecutive days in the lowest of the six high months in each year.

The United States Geological Survey base their power computations on 70 per cent efficiency and results have been computed in horse power available 90 and 50 per cent of the time respectively.

These two methods, although different, give results that are quite comparable.

The World Power Conference in preparing statistics on power resources has decided to follow the same method for computations in every country. These statistics will include a write-up on water power sites, potential power resources, gross capacity of power sites computed for three different rates of flow, defined as follows by the International Electro-Technical Commission, 95 per cent of the time, 50 per cent of the time and arithmetical mean flow.

# Abstract of Symposium on United States Aspect of the Columbia River Drainage Basin Project

**Taken from Papers read at the Annual Convention of the American Society of Civil Engineers at Vancouver, July 11th, 1934**

(See *Civil Engineering*, September, 1934.)

## POWER AND NAVIGATION BELOW THE SNAKE RIVER

*C. F. Williams,*

*Corps of Engineers, District Engineer, Portland, Ore.*

The distance from the Snake river to the mouth of the Columbia river is about 325 miles; the tidal section has a length of 145 miles and extends upstream to approximately the Bonneville dam site: the non-tidal portion, 180 miles in length, rises some 305 feet. (See Fig. 7.)

The combined watershed area at the mouth of the Snake river is 212,000 square miles. Below the mouth of the Snake, the combined additional tributary watershed is 47,000 square miles. The mean annual flow at Bonneville for the period 1878-1933 was 210,000 cubic feet per second. The lowest year produced about 60 per cent of the mean, and the highest 155 per cent. The maximum flood flow recorded at this point is 1,170,000 cubic feet per second, and the minimum 40,000 cubic feet per second.

At the mouth of the Columbia the tidal heights vary from a maximum of about 12 feet above to a minimum of about 2.5 feet below mean lower low water and the range averages about 8 feet. At Portland, Ore., little or no tidal range is noticeable when the river stage is about 10 feet. At low stages in the river the average range is about 2½ feet.

Two rubble mound jetties have been constructed at the mouth of the river. The south jetty, about 7 miles long, and the north jetty, about 2½ miles long, have their ends 2 miles apart and were completed in 1918 at a cost of about $14,000,000. These jetties have succeeded in providing and maintaining a depth of 45 feet over the ocean bar without the aid of dredging.

The present project provides for an inner channel 35 feet deep and 500 feet wide from the mouth of the Columbia to the mouth of the Willamette river, a distance of 99 miles and thence up the Willamette to Portland, about 14 miles; a channel 28 feet deep and 300 feet wide in the Columbia from the mouth of the Willamette to Vancouver, Wash., 4½ miles; and other auxiliary channels.

All initial dredging and dyke construction under the project were completed in 1933 at a total cost of about $4,900,000.

This artery of commerce averages 6,600,000 tons per annum in inter-coastal and foreign trade, and an equal tonnage, although of less value, moves between ports on the river.

The non-tidal section of the river is a series of pools and rapids. There are two principal rapids, the first extending from the Bonneville dam site to the head of the Cascade locks, where there is a fall of 35 feet in a distance of 4 miles, and the second extending from The Dalles to the head of Celilo Falls, where there is a fall of 82 feet in 11 miles.

Above The Dalles, where in many places the river is flowing on basalt, the selection of good foundations has not been particularly difficult. On the other hand, the location of a suitable foundation for a dam at or near tidewater has been a very difficult problem. Extensive borings have failed to locate bedrock at depths permissible for a dam foundation anywhere below Bonneville.

At The Dalles site, at the upper end of the Bonneville pool, foundation conditions would permit the construction of a dam of sufficient height to back the water up to the mouth of the Snake. However, considerations of economics, influenced greatly by flowage costs and carrying charges on one high dam, led to the selection of three dams for the complete canalization of this section of the river.

In its present state the non-tidal section of the Columbia is navigable at low water for boats of 5-foot draught to the mouth of the Snake river, although navigation

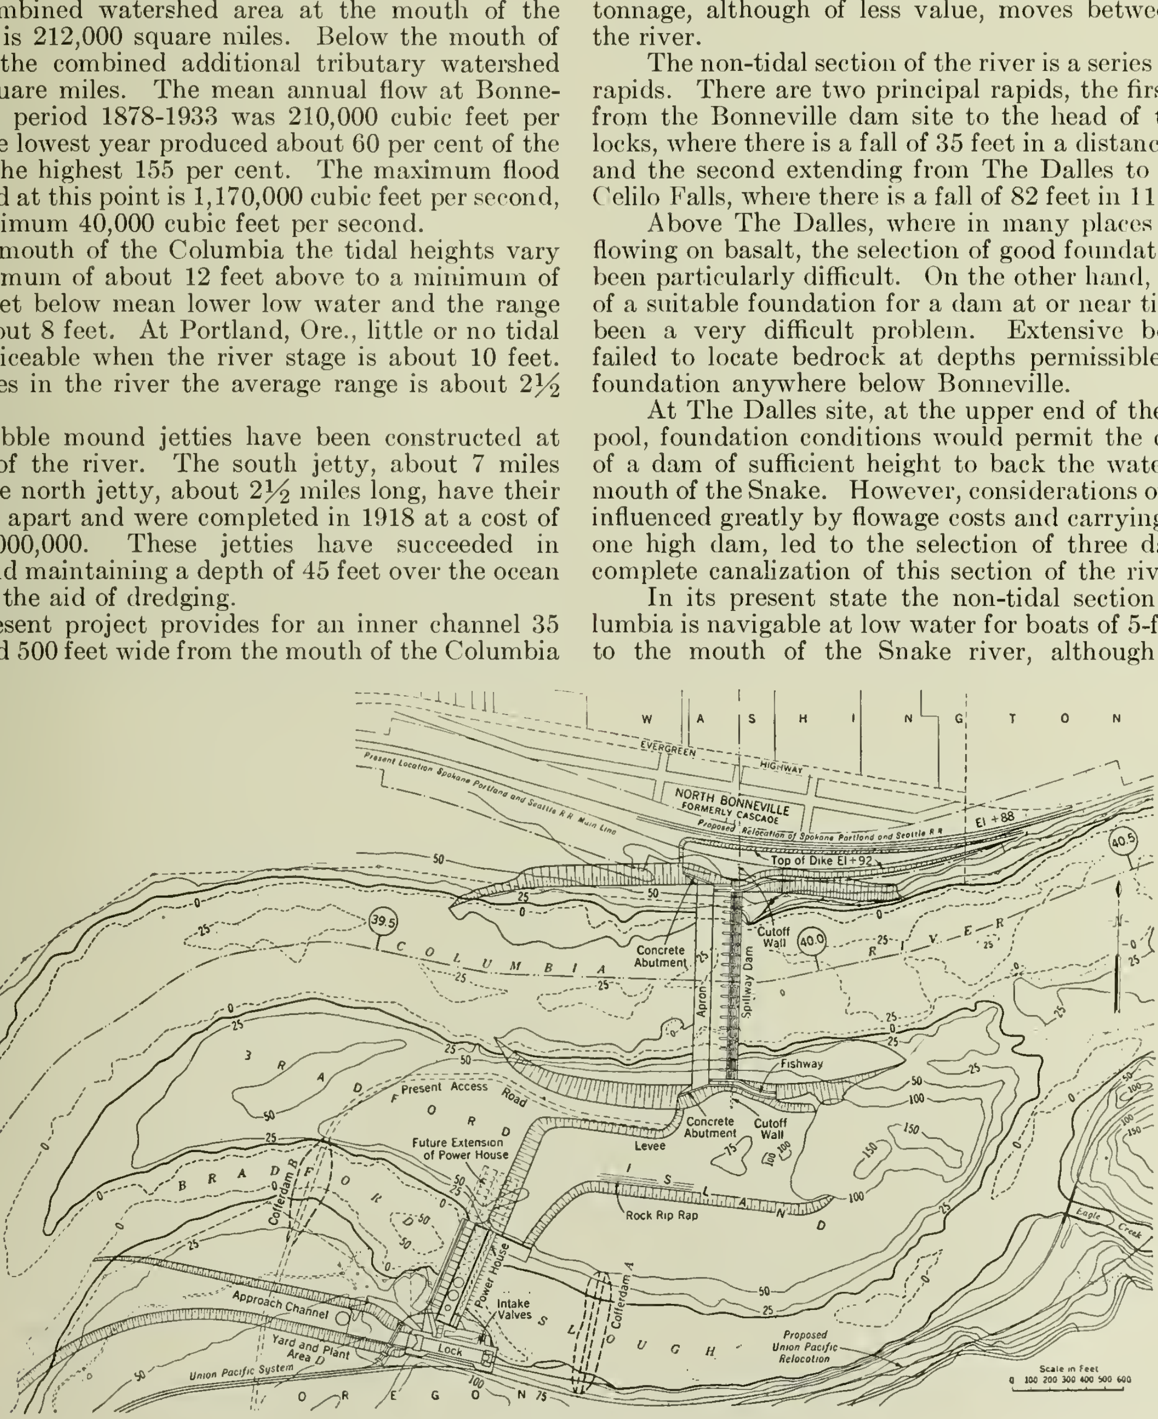

**Fig. 7—Site of Bonneville Dam.**

above The Dalles is difficult because of swift currents. The Cascades and Celilo rapids are passed by lateral canals with locks.

TABLE I

PROPOSED DAMS ON THE COLUMBIA RIVER BELOW THE SNAKE

| Site | Distance above Mouth in miles | Maximum height in feet | Useful storage thousands of acre-ft. | Flow 90% of time thousands of cu. ft. per sec. | Corresponding head in feet | Power* capacity 90% of time thousands of kw. |
|---|---|---|---|---|---|---|
| Umatilla Rapids..... | 292 | 104 | 135 | 66.0 | 71 | 318 |
| John Day Rapids..... | 216 | 159 | 245 | 66.0 | 108 | 485 |
| The Dalles... | 192 | 260 | 80 | 70.7 | 75 | 360 |
| Bonneville.... | 143 | 130 | 100 | 74.0 | 60 | 300 |

*(Flow 90 per cent of time) × (corresponding head) × 8.600.

As now authorized at an estimated cost of $31,000,000 the Bonneville project provides for a gate-controlled spillway dam across the main river channel, creating a head of 67 feet at low water; a power plant with two complete units with a partially completed or skeleton structure for four additional units; a barge lock having a width of 76 feet, a clear length of 360 feet, and a minimum depth of 10 feet on the sills; and fishways in both the dam and power house channels. (Fig. 7.) The power house is being constructed across Bradford Slough so that it can be extended in the future to permit a total installation of ten or even twelve units of 43,000-kw. capacity each. The lock, also in Bradford Slough, is so designed that it may in the future be used as an integral part of a tandem-lift ship lock.

The pool formed by the dam will have a length of 48 miles, a minimum depth of over 30 feet, and an area of 30 square miles.

In the main channel, the spillway dam is to be an overflow, gravity-type structure, consisting essentially of a base block of mass concrete, approximately 75 feet high, 180 feet wide and 1,000 feet long across the river, with eighteen steel gates of the vertical-lift type each 50 feet wide by 50 feet high.

At the dam the principal engineering problems are the unusual volume of flood water to be passed, the soft rock available for the foundation, the large scale river diversion, and the construction and unwatering of the cofferdams.

Precedent in the design of a navigation structure with a maximum lift of 67 feet would dictate a double lift or tandem lock, but foundation conditions at Bonneville would require expensive construction for such a lock and as core borings showed definitely that a single-lift chamber could be founded entirely on rock, designs were made accordingly.

Studies of models in operation form an important part of the design programme for the Bonneville dam. Model studies for the dam centre around the choice of a spillway-deck and baffle-sill combination best suited to the maintenance of a stable hydraulic jump over the range of flows and combinations of gate operation required. The problem is complicated by a possible range of 60 feet in tailwater elevation and by the desire to operate a central group of gates to care for all minor fluctuations in flow in order to maintain near the abutments the most desirable flow conditions for trapping fish and transporting them safely over the dam.

As at July 1st, 1934, the cost of work done or under construction amounted to $16,000,000 and it is contemplated that the power plant will be ready for operation by December 31st, 1937.

## BONNEVILLE POWER HOUSE AND EQUIPMENT

*B. E. Torpen,*
*Member, American Society of Civil Engineers,*
*Senior Engineer, Corps of Engineers, U.S. Army, Portland, Ore.*

Full regulation of the Columbia during the past fifty-five years would have required a storage of 450 million acre-feet; for regulation during the past twenty-nine years 200 million would have been necessary. Obviously long-time regulation cannot be obtained. The ultimate storage of 12 million acre-feet useful for power would provide a minimum continuous flow of 100,000 cubic feet per second at Bonneville, but this development lies so far in the future that it has not been considered an important factor in the present design.

As authorized, the Bonneville project consists of ten 43,000-kw. generating units, of which only two are to be completed now.

TABLE I

POWER OUTPUT OF THE BONNEVILLE PROJECT AT VARIOUS HEADS

| Gross head in feet | Corresponding flow in Columbia river cu. ft. per sec. | Percentage of time this flow is exceeded | Turbine horse-power | Generator kilowatts | Cubic feet per second required per unit |
|---|---|---|---|---|---|
| 35 | 950,000 | 0.1 | 38,250 | 28,100 | 11,470 |
| 45 | 550,000 | 5.6 | 53,000 | 38,700 | 12,330 |
| 50 | 286,000 | 22.5 | 60,000 | 43,860 | 12,420 |
| 55 | 150,000 | 47.5 | 60,000 | 43,860 | 10,600 |
| 65 | 40,000 | 100 | 60,000 | 43,860 | 9,000 |

Since the width of the south channel is about 500 feet and the power units are spaced 82 feet apart on centres, only six are required to make the closure. The power house superstructure for the present will consist of a control room, an assembly bay, one 2,500-kw. house unit, and two 43,200-kw. main units. The intakes and skeleton substructures for four more main units will be constructed at this time to complete the dam across the south channel. The ultimate extension of the power house beyond this point is provided for by the present construction of a reinforced concrete cantilever wing wall about 120 feet high to retain the backfill and to act as a future cofferdam for unwatering footings for the ultimate installation of four or six more units.

Three gates 21.33 by 43 feet are required for each unit. On the downstream side of the power house a single intermediate 6-foot pier divides the draught tubes into two 34-foot spans for closure by stoplogs during unwatering. (Fig. 8.)

In the intake the openings will be closed by gates of conventional structural steel design. The gate wheels will run on hardened nickel-steel tracks attached to heavy structural guide members which will distribute the loads over the concrete bearing area. The gate and stop-log grooves were placed as far downstream as practicable to ensure a large water load on the intake slab during unwatering operations. The value of the water load may be realized from the fact that about $20,000 worth of concrete per unit would be required to give equal stability.

The power house turbines will be of the Kaplan type with blades automatically adjustable. Extreme variations in head may be from 20 to 70 feet but a characteristic of this type of turbine is its high efficiency over a wide range of head and load.

The turbines will be designed for 60,000 h.p. at a 50-foot head for 75 r.p.m. and for 85 per cent of efficiency. Under these conditions each unit will require only 12,200 cubic feet per second. As the flow at Bonneville corresponding to this head is 286,000 cubic feet per second, which is exceeded for 22.5 per cent of the time, more than half the available water must be wasted.

When the flow falls to 75,000 cubic feet per second of water or less, which happens only 7.5 per cent of the time, the gross head increases to 60 feet or more because of lowered tailwater elevation. The efficiency at 60,000 h.p.

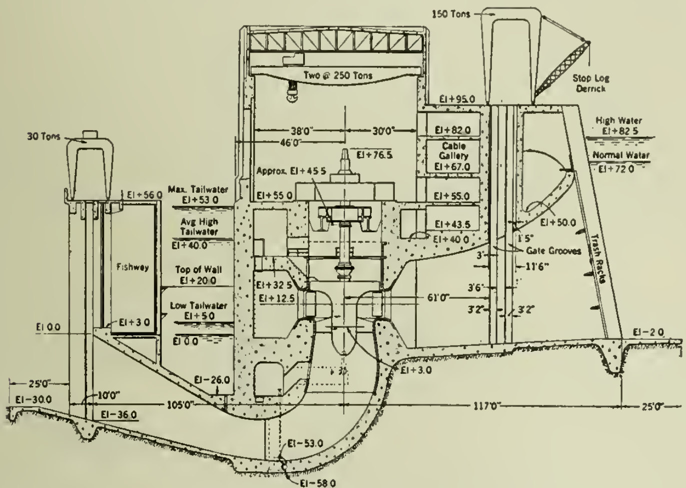

**Fig. 8—Section through Power House at Bonneville.**

at a 60-foot head is 90 per cent, and a flow of only 9,650 cubic feet per second is required. The efficiency at a 60-foot head is maintained at about 90 per cent for outputs varying from 60,000 h.p. down to about 35,000 h.p. by the automatically adjustable blades and gates of the turbine. For other heads similar characteristics prevail.

Tests on small models of scroll cases and draught tubes are being conducted to determine the most efficient types.

The rating of the 3-phase, 60-cycle generators will probably be about 43,200 kw. at 13,800 v. Because of the physical location of the power house, the surrounding topography and uncertainty as to ultimate uses, the selection of electrical equipment is particularly difficult.

## COLUMBIA BASIN AND GRAND COULEE PROJECTS

*F. A. Banks,*
*Associate Member American Society of Civil Engineers, Construction Engineer, U.S. Bureau of Reclamation, Almira, Wash.*

Millions of years ago, after the Columbia river had laboriously cut its way through 1,500 feet of solid basalt and granite, a glacier advancing southward from Canada crossed the canyon of the Columbia east of the Okanagan river and became the original Grand Coulee dam. It raised the water surface of the river 1,500 feet and caused it to cut a new channel, now designated as the Grand Coulee—50 miles long, up to 900 feet deep, and 5 miles wide—and constituted the first step in the construction of the Columbia Basin project. Receding later, the glacier permitted the river to return to its former channel and left the Grand Coulee a monument to its efforts.

During the process of erosion, a cataract was formed in the lower part of the coulee, the crest of which is 400 feet high and 6 miles long, now known as Dry Falls.

Present plans for the construction of the Columbia Basin project involve the utilization of that part of the Grand Coulee above the Dry Falls for the storage of Columbia river water. This would be conveyed to the lands of the project by building dikes at each end of the Upper Coulee and by lifting the water up to the reservoir thus formed by means of the Grand Coulee High Dam, power plant and pumping plant. The Grand Coulee Low Dam which constitutes about a third of the work involved in the High Dam is now being constructed exclusively for power purposes as a part of the national programme for industrial recovery and should be completed in the early part of 1939.

The irrigable lands of the Columbia Basin project lie in the northeastern part of the state of Washington, east of the Columbia river, south of Quincy, Ephrata and Soap Lake and north of Snake river. (Fig. 1.)

Present plans for the pumping project involve the irrigation of about 1,200,000 acres of land and include the following major features, here listed in the order in which they will probably be constructed: (1) The Grand Coulee High Dam and power plant; (2) the Grand Coulee pumping plant and pipe line; (3) the Grand Coulee north and south dikes, forming the Grand Coulee reservoir; and (4) the main canals and distribution system.

The site chosen for the High Dam and power plant is on the Columbia river just below the head of Grand Coulee. The dam will be of the straight gravity type 4,000 feet long and 500 feet high above the lowest foundation. Its purpose is to raise the water surface of the river 350 feet above low water, regulate the flow of the river, and provide a pressure head for the generation of power. Its spillway controlled by drum gates, will have a length of 1,800 feet and a capacity of 1,000,000 cubic feet per second. In addition there will be in the east end of the spillway section at least twenty sluice gates, 5 feet 8 inches by 10 feet in size. Since 1913 the discharge of the Columbia river at this point has varied from 17,000 to 492,000 cubic feet per second, and the annual run-off has varied from 56,830,000 acre-feet in 1929 to 98,800,000 acre-feet in 1927, the mean being 79,000,000 acre-feet for the calendar year, corresponding to an average discharge of 109,000 cubic feet per second.

Extending upstream, 151 miles to the Canadian boundary, the reservoir created by this dam will have a capacity of 5,000,000 acre-feet in the top 80 feet of its depth. It is of prime importance in the development of the river as a whole, since the regulation effected by it will increase the firm power output at all sites between the Grand Coulee and the mouth of the Snake river by 100 per cent and at all sites below that point by 50 per cent. It is for this reason that the Grand Coulee High Dam holds the key position in the development.

The power plant will have an installed capacity of 1,890,000 kw. and will consist of eighteen units of 105,000 kw. capacity, nine on each side of the river. There will also be two service units of 6,000 kw. each. This power plant will furnish power for the operation of the pumping plants and for commercial purposes. It is estimated that 2,400 million kw. hours will be required annually for irrigation pumping and that 7,500 million kw. hours of energy will be available for sale.

Just upstream of the west abutment of the dam will be a pumping plant containing twenty units each consisting of a pump having a capacity of 800 cubic feet per second when operating under a total head of 370 feet. Each pump will be direct connected to a 33,000 h.p. motor.

The Grand Coulee reservoir, formed by the north and south dykes at each end of the upper Grand Coulee, will have a length of 23 miles, an area of 2,100 acres and a capacity of 1,050,000 acre-feet. Its function will be to convey irrigation water through the coulee, regulate the supply to meet the demand, and permit the use of off-peak and secondary power for pumping purposes. The north and south dykes will be respectively 92 and 97 feet in height above the original ground.

The main canal will extend southward from the south dike about ten miles and then divide into an east and a west canal which will serve 1,000,000 acres directly and 200,000 acres indirectly by re-pumping to a height not to exceed 100 feet.

It is estimated that the cost of the dam and power plant will be $168,366,000, and that of the irrigation features $208,265,000, exclusive of interest during construction.

In the construction of the Grand Coulee Low Dam and power plant, which has been under way since the first of this year, about a third of the work involved in the High Dam is required. This dam will be of the straight gravity type, 3,500 feet long and 300 feet high above the lowest foundation.

The spillway, which is uncontrolled, is 1,800 feet long and 150 feet above low water. With an overflow depth of 26 feet, leaving a freeboard of 5 feet, it will discharge 1,000,000 cubic feet per second. Into the east end of the spillway twenty sluice gates, 5 feet 8 inches by 10 feet, will be built.

A section of the west side power house of the High Dam is to be constructed to house three main units, two service units, and the repair shop. Consideration is being given at this time to the installation of High Dam units with a capacity of 105,000 kw. each but with runners adapted to the head at Low Dam which will produce 34,300 kw. each.

The building of the High Dam would probably take five or six years after authorization, and the time required for the construction of the irrigation features would depend on the rate of possible settlement. At the rate of 20,000 acres per year, as has been estimated, it would take sixty years to complete the work.

---

# Heat Economy and Comfort in the Home

## As Influenced by Heating Methods and Building Construction

*F. L. Lawton, A.M.E.I.C.,*
*Electrical Engineer, Duke-Price Power Company Limited, Arvida, Que.*

**Paper presented before the Saguenay Branch of The Engineering Institute of Canada, August 2nd, 1934:**

The demand on the part of the public for greater economy in home heating has been accentuated by the present economic depression. The possible savings are indicated by the estimate of the Dominion Fuel Board that some 30,000,000 dollars or more are wasted annually in the heating of Canadian homes, which losses could be saved by the application of sound methods in house building construction.

People are today desirous of more comfort in the home, particularly insofar as heating is concerned. They are demanding convenience, cleanliness, an even temperature, with properly-conditioned air, the heating being as nearly automatic as possible. Moreover, they are beginning to appreciate the very definite relationship of heat comfort to health.

This paper accordingly deals with the two major aspects of home heating: (*a*) economy and (*b*) comfort, as influenced by heating methods or systems and house construction. Of the two aspects, that of comfort is undoubtedly the more important with the majority of people.

For illustration, studies made during the last three years in connection with a large-scale experimental application of electric heating to homes in the Saguenay district,* made possible by the pioneering enterprise of the Saguenay Electric Company, have been largely drawn upon.

### *HEAT ECONOMY*

Heat economy in the home is influenced by a number of variable factors which may be most readily discussed under the following major headings: (i) heat requirements, (ii) heating methods, (iii) heating costs.

#### *Heat Requirements*

The heat requirements of a house depend on the three principal factors of: (i) weather conditions, (ii) building construction, (iii) inside conditions.

There is little that can be done about weather conditions, except in the matter of exposure and orientation for sunlight. The builder has entire control of the construction of a house. The inside conditions are subject to the builder to some extent, but largely to the householder.

#### Weather Conditions

Weather conditions influencing the heat necessary for a house are:—

(i) Temperature.
(ii) Wind velocity.
(iii) Sunshine.

*Temperature.*—It is common knowledge that the heat losses from a building vary directly with the outside temperature under still-air conditions. A glance at the curve of daily maximum and minimum temperatures for any Canadian town illustrates the variable nature of heat requirements for a house. The variation in heating demand is exemplified by the spread between curves *A* and *C* of Fig. 1, showing monthly mean, maximum and minimum temperatures observed at Chicoutimi in the eight years 1926-33, inclusive. During the nine-month heating season from September 1st to May 31st, Chicoutimi averages 9.6 degrees F. below Toronto and 5.8 degrees F. below Montreal.

As expressed by electrical men, the load factor (based on maximum daily heat requirement and average seasonal requirement) inherent in the temperature curves shown for Chicoutimi is approximately 50 per cent for the 1932-3 and 49 per cent for the 1933-4 heating season of eight months (September 15th to May 15th).

*Wind Velocity.*—Wind movement affects the heating of a house in three ways:—

By increasing the heat transmission of exposed walls, glass and roof surface.

By increasing the infiltration of cold air through the walls.

By increasing the infiltration of cold air through the cracks at window sash and frames, etc.

Wind movement wipes heat off the exposed wall, glass and roof surface of a house in the same manner as air currents from a fan increase the heat output of a radiator. Computations based on the latest surface coefficients indicate that a 15 m.p.h. wind increases the heat loss from a

*"Practical Aspects of Heating Residences by Electricity," by F. L. Lawton and P. Tellier in advance Reports and Proceedings of the Canadian Electrical Association for 1934.

standard frame wall consisting of clapboards, sheathing, studding, lath and lime plaster by 11.6 per cent.

Published data indicate that the leakage of cold air through well-built 13-inch brick walls ranges from 0.5 cubic foot per square foot per hour at a wind velocity of 5 m.p.h. to 2.5 cubic feet per square foot per hour at 15 m.p.h., a ratio of 5. Good plastering cuts the infiltration to approximately 1 per cent of the above values. Generally speaking,

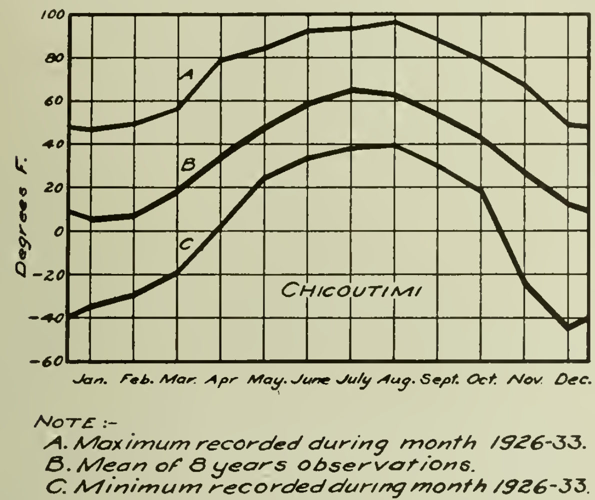

**Fig. 1—Climatic Temperature, Chicoutimi, Que.**

plaster with proper sealing at base-boards cuts the infiltration through ordinary walls (brick, frame, etc.) to a negligible quantity.

The infiltration of cold air around the uncaulked frame of a double-hung wood-sash window increases sixteen times for an increase in wind velocity from 5 to 15 m.p.h., reaching approximately 23 cubic feet per hour per lineal foot of crack. A non-weather-stripped double-hung wood-sash window has about thirteen times the infiltration obtaining after the application of weather-stripping, at 5 m.p.h. wind velocity, and about 5.5 times the infiltration at 15 m.p.h.

The range of wind movements encountered in the Saguenay district is shown in Fig. 2. It will be noted that the monthly mean wind velocity is roughly 8 to 10 m.p.h., although the maximum velocity runs as high as 40 m.p.h. The prevailing direction is west during most months.

While it is common knowledge that a house located on a hill top and exposed to every breeze is harder to heat than a similar house in a hollow or sheltered from the full force of the wind by trees, the extent of the increased heating demand may not be fully appreciated. Figure 3 depicts the effect of wind velocity on the heating requirements of a typical wood-frame house. The curves are based on daily observations of the electrical energy required for heating, the mean temperature and the mean wind velocity. The use of the factor kilowatt hours per 1,000 cubic feet gross volume per degree-day below 65 degrees F. automatically takes care of daily temperature variations and shows the true effect of increased wind velocities.

It may be noted that a 15 m.p.h. wind from the west increased the heat consumption some 32.5 per cent; from the east 26.8 per cent; from the northwest 34.0 per cent. These percentages indicate the gains to be anticipated from building on a sheltered site.

Computed heat losses, for the house on which Fig. 3 is based, gave a value of 0.234 kilowatt hour per 1,000 cubic feet gross volume per degree-day as compared with the experimental value of 0.191, for still-air conditions. With a 15 m.p.h. west wind, the computed value was 0.271 and the experimental 0.253 kilowatt hour per 1,000 cubic feet gross volume per degree-day. That is, the computations show an increase of 15.8 per cent whereas actual observations indicate an increase of 32.5 per cent.

It will be interesting to see how wind velocity affects the heating requirements of a group of residences. Figure 4 is based on observations made on a total of twenty-seven electrically-heated homes in one town. It shows the total house-heating load, wind velocity and temperature over a full day. The load curve fluctuates somewhat from hour to hour due to factors other than wind velocity and outdoor temperature. This chart covers a day with very low wind velocities, but a large temperature change. Observe the decrease in load with rising temperature.

*Sunshine.*—The relative value of various window exposures has been compared by Atkinson* on the basis of the quantity of sunlight passing through an opening one foot square, in a plane normal to the sun's rays, in one hour, which quantity is termed a "sun-hour." Table I gives data on the relative value of various window exposures for a room 24 feet square with a window 3.5 feet wide by 8 feet high, wall thickness 1 foot, sill of window 2 feet above floor, in latitude 40 degrees north.

The heating effect of the sun's rays admitted through the windows of a house is difficult to compute. However, experiments made by Mr. Atkinson with sun boxes show definitely the heating value of windows having a southern exposure. Table II illustrates the relative value of south

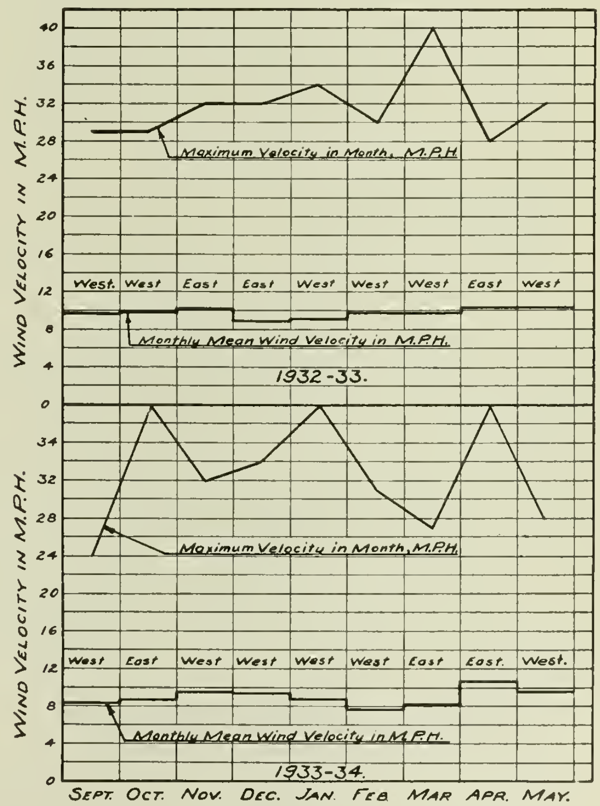

**Fig. 2—Wind Movement, Arvida, Que.**

and east exposures as determined from tests with sun boxes constructed of ordinary ⅞-inch pine boards nailed together without grooving or dovetailing, containing an inner box of similar construction (one foot square inside) covered with one layer of lino-felt, made of flax fibre quilted between two thicknesses of building paper. Sash glazed with ¼-inch plate glass was screwed into place and fitted

*"The Orientation of Buildings or Planning for Sunlight."

tightly against a felt weather strip all around the edges. The boxes were protected from the direct rays of the sun by wooden hoods or covers, except on the window side. The thermometer used for measuring the inside temperature was screened from the sun's rays. The observations were taken with the boxes exposed on a platform three feet above the ground in an open field with free access of sunlight from every quarter.

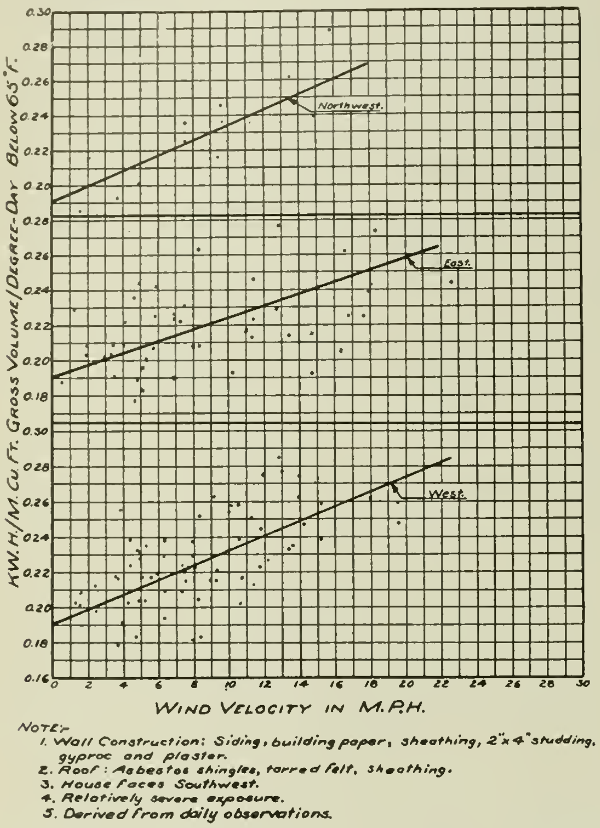

**Fig. 3—Effect of Wind Velocity on Heating Requirements of Typical Wood-Frame House.**

Other experiments of similar nature show that a temperature of 100 degrees F. and over is frequently attained in well insulated sun boxes with the outside air at zero F. or lower.

Lewis* draws attention to the fact that ordinary window glass only retards the entrance of sunlight and sun heat approximately 10 per cent.

While the capacity of the heating system in a house has to be sufficient to take care of the coldest weather conditions which may be experienced and hence cannot be reduced by taking advantage of sunlight, nevertheless the fuel consumption during the heating season may be considerably decreased.

Table I
Relative Value of Window Exposures, in Terms of Sun Hours

| Location of Window | Winter Solstice | Equinoxes | Summer Solstice |
|---|---|---|---|
| North | | | 6.8 |
| Northeast and northwest | | 18.6 | 73.2 |
| East and west | 32.9 | 82.7 | 110.7 |
| Southeast and southwest | 108.5 | 105.5 | 53.4 |
| South | 152.9 | 81.1 | 16.2 |

Note:—For latitude 40° N.

*"Air Conditioning for Comfort."

Table II
Relative Values of Window Exposures, Based on Sun Box Tests

| Date | South Exposure | | | East Exposure | | |
|---|---|---|---|---|---|---|
| | Outside air temperature at time of sun box maximum | Maximum temperature reached in sun box | Temperature rise in sun box | Outside air temperature at time of sun box maximum | Maximum temperature reached in sun box | Temperature rise in sun box |
| October 24 | 59° F. | 125° F. | 66° F. | 45° F. | 93° F. | 48° F. |
| December 22 | 25° F. | 115° F. | 90° F. | 20° F. | 46° F. | 26° F. |

*Estimation of Heat Requirements*

The part played by outdoor temperature, wind velocity and sunshine relative to the heat requirements of a house have been discussed already. The question arises "What is the over-all yardstick of measurement for determining heat requirements?"

Such a yardstick is the degree-day, defined as the equivalent of one degree Fahrenheit difference in temperature between the temperature of reference and the outside temperature over a period of twenty-four hours. The temperature of reference may be 65 or 70 degrees F. It is commonly taken as 65 degrees F. where the house temperature is maintained at 70 degrees for sixteen hours and 55 degrees for eight hours. If the temperature in the house over the day is about 70 degrees, the temperature of reference is taken as 70 degrees F.

If the mean temperature over a period, say thirty days, is 25 degrees and the base is 70 degrees F. the degree-days below 70 in the period equal $(70 - 25) \times 30$ or 1,350.

American and Canadian heating practice makes no allowance in the computation of degree-days for the effect of wind movement and sunshine. However, the two factors partially cancel out. It will be shown in what follows that the heating requirements of a house or group of houses are essentially proportional to the degree-days.

**Fig. 4—Typical Residence Heating Load as Affected by Wind Velocity and Atmospheric Temperatures.**

The relation between degree-days and the fuel requirement for heating residences is clearly shown by Fig. 5, which is based on data for a group of fifteen electrically-heated houses in the Saguenay district. Inspection of the graph reveals that the energy consumption corresponds more closely to the degree-days below 70 degrees than 65 degrees F. This would be expected as the heating was on a flat-rate basis, and a temperature of 70 degrees or higher was maintained twenty-four hours a day. The relationship is quite close, the maximum error due to departure from strict proportionality being about 4 per cent, except in the month of September. The much higher error in September is attributable to the relatively high daytime temperatures and lack of demand for heat by occupants. It should be remembered, of course, that a variable component of the energy consumption is actually accounted for by wind movement.

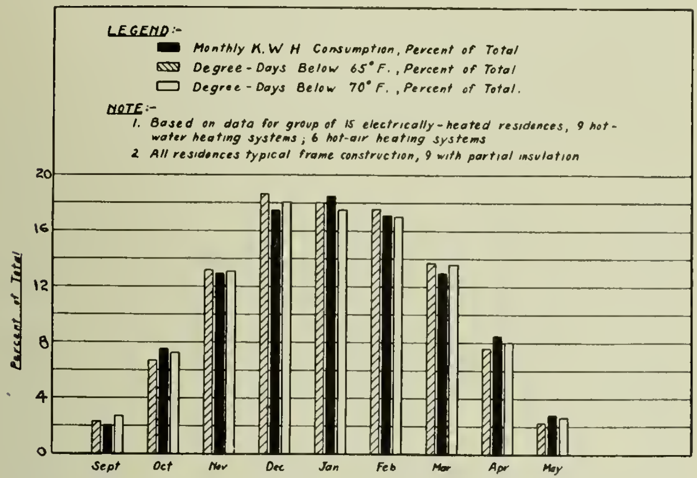

**Fig. 5—Relation Between Degree Days and Consumption of Electrical Energy for Heating Residences.**

There is also a great similarity in the relation between degree-days and heating requirements as derived from data on a large district heating system, supplying steam heat to residences, etc., from a central station.*

One would expect a similar relationship between degree-days and energy consumption used for heating an individual residence, with possibly slightly greater departure from true proportionality, and such has been found to be the case.

### Building Construction

The physical construction of a house has a very important bearing on the heat requirements, being the principal factor which is definitely subject to control.

When stable temperature conditions exist, the heat requirements must equal the heat losses. These result from the flow of heat from the warm interior of the house to the cold exterior atmosphere. Such flow takes place along two channels, and the mechanism of flow may be briefly described as follows. Firstly, heat is received by the inside surface of the exposed walls by radiation from the warm interior walls, radiators, etc., and convection currents, then passes to the exterior surface by conduction and thence to the outside air by radiation and convection. Secondly, difference of air pressure between the interior and exterior of the house due to wind movement and temperature difference results in warm air leaking out and cold air leaking in at cracks and joints and through porous wall materials.

The percentage heat losses from a typical small-to-medium-size residence, based on a relatively large-scale analysis by the American Gas Association, show that transmission through doors and the glass of windows accounted for 29.4 per cent of the total heat losses, infiltration or air leakage 21.0 per cent, and transmission through walls, roof and floor the other 49.6 per cent. An analysis of a limited number of typical residences in the Saguenay district indicates fairly close agreement, the glass and door loss, however, being lower at 15 to 20 per cent, and the roof and wall loss somewhat higher. Mallory† states that under Canadian conditions the loss through doors and windows probably averages about 20 per cent, with a similar figure for air infiltration.

The effect of the installation of storm sash and storm doors is to decrease the heat loss by transmission through windows and doors in the order of 50 per cent. Published test data indicates the application of storm sash to a poorly-fitted window may reduce the infiltration 50 per cent, but has little effect on a properly-fitted window.

In Fig. 6 note the extreme fluctuation in energy consumption with rather moderate changes in wind movement during the period when no storm sash was installed as compared with a similar period afterwards. Allowing for the somewhat higher mean wind velocity existing after the installation of storm sash, the saving due to the addition of storm sash figured out at 5 per cent of the total energy consumption. Values approaching this saving have been noted in other houses studied.

Everyone has recollections of the uncomfortable effect of cold walls when seated nearby. Windows have a similar effect, which may be largely mitigated by the application of storm sash, as depicted by Fig. 7. Note the drop in temperature of the film of air adjacent to the sash from 42 to 16 degrees F. when the inside sash was open. A similar range is encountered when the storm sash is open, leaving only the inside sash closed.

The use of weather-stripping to eliminate leakage around window sash and doors will return large dividends on the small necessary investment, if properly applied. Table III illustrates the very substantial savings arising from the use of weather-stripping on double-hung wood-sash windows and doors. The tabulation is based on published test data for air leakage at windows and doors with average fit, with heat derived from anthracite coal

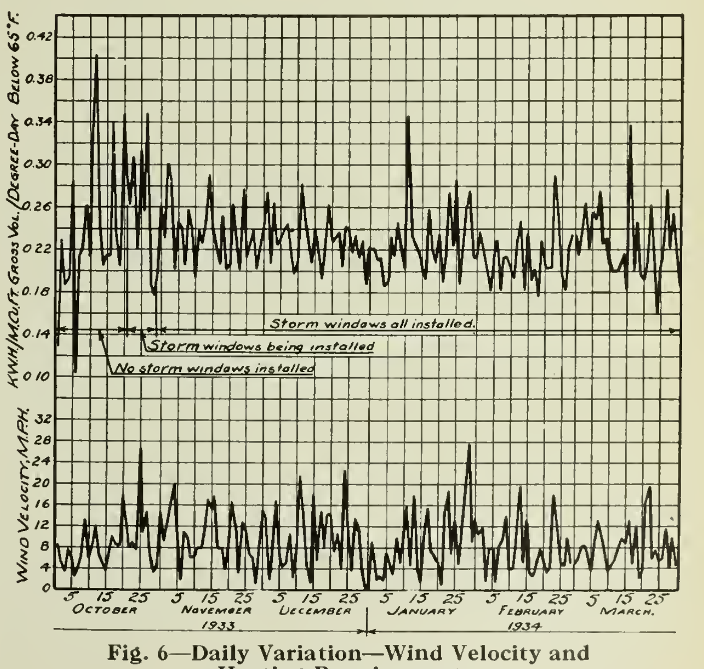

**Fig. 6—Daily Variation—Wind Velocity and Heating Requirements.**

containing 13,500 B.t.u. per pound, costing $15 a ton, and burnt at 50 per cent seasonal efficiency. It is assumed that the outside air is at 0 degrees F. The values stated would be proportionately greater for lower temperatures.

While the tabulation shows the daily cost in cents of infiltration at doors and windows per 100 linear feet of

*"Central Heating System of City of Winnipeg," by G. W. Oliver, Engineering Journal, January, 1932.

†"The Insulation of New and Old Houses," publication of the Dominion Fuel Board.

crack, it will be of interest to look into the probable daily cost of infiltration in a typical small-to-medium-size residence. Such a house may average twelve windows at 4 feet by 2 feet 6 inches each and three at 3 feet by 2 feet 6 inches each. There would be two doors at 6 feet 10 inches by 2 feet 10 inches each. Take one-half of the total crack length as effective for air infiltration, say 124 linear feet for windows and 19 feet for doors, and assume a 15-

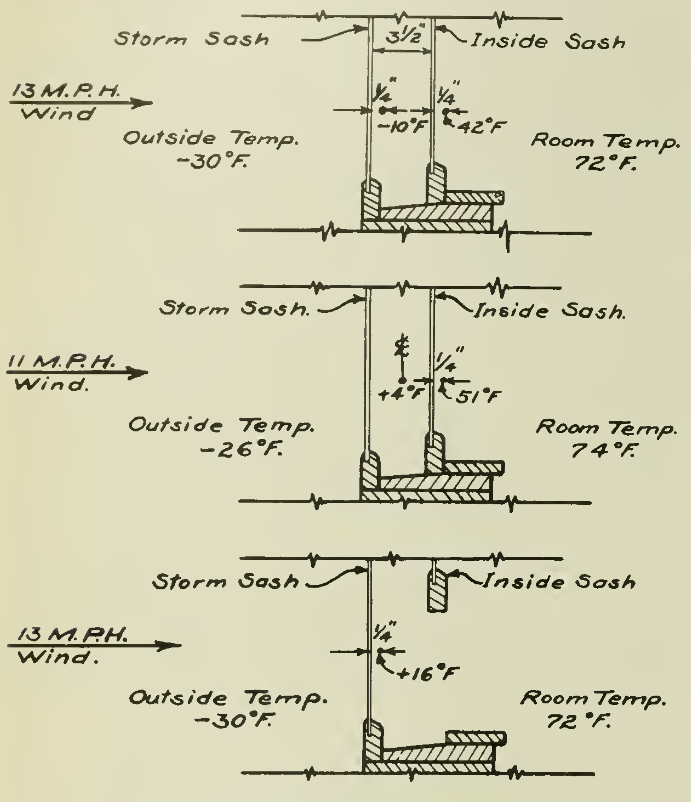

Fig. 7—Effect of Storm Sash on Temperature Gradient at Windows.

m.p.h. wind velocity and 0 degrees F. air temperature outside. The daily cost of infiltration without weather-strip will be 61.2 cents and with weather-strip 9.6 cents. That is, the saving due to weather-strip is 51.6 cents or 84 per cent. It is, of course, assumed ventilation requirements are obtained otherwise than through infiltration.

Heat losses from a house naturally fall into two classifications—unavoidable and avoidable. The unavoidable losses include the window and door loss together with infiltration losses. As indicated previously, the former may be taken at 20 per cent in round figures. The latter ranges around 20 per cent but with proper precautions may be reduced to 10 per cent which is ample for all ventilation requirements. The total unavoidable losses are then 30 per cent, leaving 70 per cent avoidable losses, which take place through the walls, roof and floor. That is to say, 70 per cent of the total heat losses from a house will be affected by improved wall and roof construction and the addition of heat insulation.

McMillan* summarizes the essential requirements for heat insulation as follows:—"Next to perfect vacuum, the most effective insulation against the flow of heat is the minute confined air space. To be most effective the air space must be absolutely enclosed and so small that circulation cannot take place within it nor heat radiate across it to any appreciable extent. Even perfect vacuum would be ineffective for anything except very low temperatures unless it were broken up into very small units or unless the surface were mirrored to prevent radiation."

* In a paper on "Heat Insulation Facts" before the American Society of Heating and Ventilating Engineers.

Table III

Daily Cost in Cents of Infiltration at Doors and Windows per 100 Lineal Feet of Crack

| Infiltration | 5 m.p.h. Wind | 15 m.p.h. Wind |
|---|---|---|
| Around uncaulked frame of a double-hung wood sash window | 0.47 | 7.60 |
| Around sash of a double-hung wood sash window, no weather stripping | 13.21 | 41.66 |
| Around sash of a double-hung wood sash window, with weather stripping | 1.01 | 7.69 |
| Around door, not weather-stripped | .... | 50.40 |
| Around door, with weather-stripping | .... | 0.17 |

*Heat Insulation.*—The various forms of heat insulation in use today are: Air spaces, fillers, rigid boards, flexible boards, slabs, blankets, foil.

It is commonly known that the use of air spaces in wall construction is helpful in cutting down heat losses. However, it is the exception to find maximum advantage taken of the notable savings possible. An illustration of what can be done is indicated by the work of a German investigator who found that a well designed, hollow brick wall with air spaces properly sealed would transmit from 20 to 25 per cent less heat than a solid brick wall of the same thickness.

While the experimental data are such as to lead to some divergence of opinion on the optimum size of air space, it appears that a width of ¾ to 1 inch is as efficient as a greater width. If the air space is wider, the height of the space should not be over 2 feet in most cases, greater heights leading to undue losses from convection currents, amounting to 15 per cent in a two-storey wall without stops.

Appreciable savings at little cost are secured with hollow tile and block walls by placing the tile or block with air spaces horizontal. If placed vertically, the air spaces should be confined in each course.

Heat insulation of the filler, rigid wallboard, flexible board, slab and blanket types is made from a variety of materials, organic and mineral, but in general conforms to the previously-given definition of good heat insulation, containing a multitude of small confined air spaces per volume.

Most heat insulation serves a dual purpose. Fillers act as fire-stops, preventing the spread of flames through air spaces. Rigid wallboard may be used for structural sheathing, plasterboard, exterior or interior finish, etc. Fillers, boards, slabs and blankets possess considerable sound-deadening properties. Rigid wallboards and slabs are also used for acoustical treatment in homes.

Mineral fillers are fire and vermin proof. Other types of heat insulation may usually be chemically treated to render them fire and vermin resistant.

A foil type of insulation, which offers considerable promise, has recently been devised. The low conductivity of air has been combined with the low radiating power of bright aluminum foil in a foil-air cell structure designed to minimize convection currents.

If approximately 70 per cent of the total heat losses are subject to reduction by improved wall and roof construction and the addition of a suitable heat insulator, what over-all saving in heat losses can be secured?

Two small 1½-storey-and-basement frame houses, in the Saguenay district, of identical size and construction, except for heat insulation, have been heated electrically, enabling a direct comparison of heat losses. Exposure was the same for both houses. Heating systems were both similar, of the hot-air type.

The walls of house *A* were constructed of siding, building paper, sheathing, 2-inch by 4-inch studding, plasterboard and plaster. Those of house *B* were identical except for a filler of wood shavings and sawdust. The second-floor ceiling of house *A* consisted of plaster, plasterboard, joists and ⅜-inch rigid insulating board. The second-floor ceiling of house *B* consisted of plaster, plasterboard, joists and 6 to 7 inches of sawdust and shavings. The roofs were of asbestos shingles, paper and sheathing in both cases. Both houses were fitted with storm sash carefully caulked.

House *A* was occupied by two adults, house *B* by two adults and two children. The occupants of house *A* tried to conserve heat by closing an unused room but nevertheless had a slightly lower mean temperature and used 30 per cent more energy over the six-month period of comparison.

That is to say, the complete insulation with sawdust and shavings resulted in a saving of somewhat more than 30 per cent although house *A* was partially insulated.

A similar comparison between houses *C* and *D*, of the same general type of frame construction, indicated a saving of over 35 per cent during an eight-month heating season. In this case, the partially insulated house had 2 to 3 inches of sawdust on the second-floor ceiling instead of the ⅜-inch rigid board.

An analysis of the heat losses for a typical frame-construction 2-storey-and-basement house revealed that filling the 3⅝-inch air space in the walls with 12-pound dry insulex and the space between the second-floor ceiling joists with 6 inches of the same material would reduce the heat losses to 50 per cent of the original total.

Insulating a large fifty-year old, light frame-construction residence with 3⅝ inches granulated cork in the walls and 4 inches between joists in the attic resulted in a saving of 47.5 per cent in heat losses secured for a total expenditure of $175.00 for labour and material. Part of the saving, however, is attributable to metal weather-stripping placed at the time of insulating the house.

The cost of heat insulation for a new house varies from 3 to 7 per cent of the total cost, 5 per cent being about the average. That is, an average outlay of 5 per cent of the total cost will secure a saving of 30 to 50 per cent of the total annual heating cost. It must not be forgotten, also, that the lower heat requirements mean a proportionately lower investment in heating plant. In fact, the difference in heating equipment cost may offset entirely the cost of the insulation.

The cost of heat insulation for existing houses runs higher than for new houses but nevertheless constitutes a very attractive investment. Mr. C. N. Shanly in an informative paper* has fully discussed the cost of insulating seventeen frame houses in River Bend, Que. The material used was a dry gypsum filler made in Canada. Cost of complete insulation for houses with 2-inch by 4-inch studding varied from $9.50 to $15.00 per 1,000 cubic feet gross volume, the average being $11.50.

Not only does heat insulation cut down heat requirements in the winter but it improves acoustical properties of the house, deadens noise, decreases the fire hazard by preventing spread of flames through air spaces or by reason of less forcing of the furnace during extreme weather, decreases the possibilities of an over-heated chimney, improves winter comfort with warm walls and roof, and summer comfort by a cool interior. In some cases, heat insulation is found desirable to prevent wall condensation in extreme weather, with resultant high maintenance costs for wall finish.

*"An Experiment in House Insulation," The Engineering Journal, November, 1929.

The heat-insulation properties of lumber due to its low density and multitude of entrained air cells are often neglected by the average house-builder, who buys solely on a price basis. The heat-insulation value is a function of the density. Accordingly, the lumber used in a house should be cut from low-density wood, durable, properly seasoned, free from cracks, warping, knot holes, etc.

The lumber used in wall construction should be protected against the losses from air leakage through cracks which may develop by one or more layers of tough waterproof building paper. If more than one layer is used it will be found desirable to apply each layer separately, with nailing strips between the layers.

Window and door frames should be properly fitted. The lumber should be carefully fitted and laid on so that no cracks exist in walls and roof. Carpentry work at the gable joins should be of the best, because warm air rising to the top of the house escapes through any available crevice; also at floor junctions and floors over open verandahs to avoid infiltration of cold air.

Good results are secured by using a plastic caulk driven into cracks around door and window frames, etc., with a compressed air gun. Cost of such work is quite moderate.

*Waste Space*.—It is really astonishing how little advance has been made during the last few decades in types of houses and house construction designed to secure maximum advantage from the material used in respect of useful space, minimum heat loss in winter, minimum heat gain in summer, and cost.

Anyone who stops to consider for a moment the average residence of 2-storey-and-basement type will see that 30 to 40 per cent of the total gross volume is given over to unused attic space and inefficiently-used basement space. Probably the most economical house to build and maintain is the 1½-storey type, without dormers or breaks in the roof.

However, this type of construction still includes a basement. Messrs. Clement and Govan have recently stated†:—"The largest item of saving in construction cost is the omission of the usual cellars and concrete foundations. The building can be carried on concrete piers with their bases below frost level, or on creosoted cedar posts; and the floor should be well above the ground, to give good ventilation and to provide access to piping. Sewer and water pipes can be carried below frost level in a protected wooden box. If an insulated floor is used, a plain lattice or slat-work may inclose the under space. If a cellar is desired it should not be large. If a furnace is required where the rocky or swampy nature of the ground would make a cellar too costly, it can be placed in a small insulated addition at the ground level, but under these conditions a hot-air furnace is not satisfactory without fan circulation."

Additional benefits are secured by going to a flat-topped type of construction for two reasons. First, the enclosed space may be utilized to the limit. Second, full advantage can be taken of the natural heat insulation provided by nature in the form of snow which cuts down appreciably the heat losses through a roof on which it is permitted to remain.

### Inside Conditions

Under this heading are grouped those factors largely dependent on the occupants, such as temperature maintained, humidity, ventilation, etc.

Mankind is so constituted physically that it is necessary to maintain in the home a relatively narrow range

†"Planning and Design of Housing and Community Buildings," by Messrs. H. E. Clement and Jas. Govan, Engineering and Mining Journal, March 2, 1929.

of temperature for maximum comfort. This optimum temperature is approximately 68 degrees F. at 45 per cent relative humidity.

Assume the temperature is maintained at 69 degrees F. Then, for Chicoutimi, the seasonal heat requirements will be 2.5 per cent higher, as the requirement is directly proportional to the difference between the average temperature maintained inside and the mean outdoor temperature.

If the householder operates the heating system to maintain an average inside temperature of 70 degrees F. for twenty-four hours a day, it may cost 13.5 per cent more, in this district, than if 70 degrees F. were held for the sixteen daytime hours only and 55 degrees F. for the eight night hours, giving a daily average of 65 degrees F. While the value given is computed, considerable evidence has been accumulated during two years experience with some fifty electric house-heating installations showing it to be approximately correct. Moreover, there is no doubt that the mean daily temperature of 65 degrees F. meets all requirements as to comfort more satisfactorily than the higher temperature.

Numerous observations indicate that the occupants of an artificially-heated house are entirely comfortable with somewhat lower temperature during the daytime than at evening when seated at rest, when the temperature should be about 68 degrees F. at 45 per cent relative humidity. The daytime temperature may be possibly as much as 5 degrees F. lower but should approach the optimum comfort temperature gradually, reaching it at approximately 6 p.m. Such a temperature cycle results in a slight additional heat saving.

Maximum comfort and most healthful living conditions are secured by keeping the air at the right relative humidity or moisture content. Medical authorities agree that the relative humidity should be 40 per cent at least under the usual winter heating conditions. When the relative humidity is above 50 per cent. it will be found that condensation takes place on windows with storm sash in severe winter weather. That is, 40 to 50 per cent relative humidity is about the required range.

Numerous investigators have determined experimentally the relation between air temperature and relative humidity for maximum comfort. (See Fig. 8.) It will be noted that, with about 45 per cent relative humidity, a temperature of 68 degrees F. is comfortable, whereas at 30 per cent humidity 71.5 degrees F. is required. The apparent saving in heat requirement due to the lower temperature has been already indicated. The actual overall saving is much smaller, however, as a large proportion of the apparent saving is consumed in the evaporation of the necessary moisture. The real saving is the intangible one arising from better health and decreased deterioration of fabrics, furniture, etc.

Investigation has shown relative humidities as low as 15 per cent in better-class homes of the Saguenay district, and on the other hand, humidities of 50 to 75 per cent have been observed in some instances where occupants have closed every chink and cut down ventilation to a minimum. Such high humidities have been accompanied by condensation of moisture on the walls during severe weather with resultant damage to interior finish, etc.

It is unnecessary to add that great improvement in humidity can be cheaply secured in the average home by any one of numerous methods. This is particularly true with hot-air heating as the furnace can usually be designed with ample provision for humidification, or readily altered to secure it.

As indicated previously, infiltration of air into the average house is responsible for 20 per cent or more of the total heat requirements. It is also customarily considered that there should be one complete air change per hour in the occupied space. However, there is considerable evidence that all requirements of ventilation are satisfactorily met with about one-half or even one-third of the fresh air now admitted, provided there is good circulation of air within the room. That is, a saving of at least 10 per cent of the total heat requirements for the house can be secured.

One of the serious defects of most present-day house-heating systems is that no attempt is made to overcome the natural tendency of warm air to rise. It is the temperature of the strata in which the human body is immersed under normal conditions of rest and work that must be maintained at a suitable value. The higher temperatures occurring near the ceiling result in increased heat losses through the walls and ceiling or roof.

Observations in moderately well-constructed houses and buildings in this district, with hot-water and steam heating, has revealed at times temperature differences of 18.5 degrees F. between floor and ceiling, the ceiling being about 9 feet 6 inches high. With substantial construction, about 10 degrees F. represents the maximum difference ordinarily observed in −30 degrees F. weather. The highest differences, of course, occur when warming up in the morning.

It is generally considered desirable to hold room temperature constant at what is termed the "breathing line," a horizontal plane 5 feet above the floor. Observation indicates, however, that people at rest breathe in air at a level about 4 feet above the floor. Moreover, even in well-constructed houses, a temperature difference of 4.5 degrees F. between floor and breathing line has been noted. In view of the above, and considerable evidence in favour of warmer floors, it is probable that the optimum level for temperature maintenance is 2.5 feet above the floor.

The personal element has an extremely large influence on heating requirements and from the preceding, it is obvious that the temperature cycle followed, the humidity, and amount of ventilation maintained, affect the heat losses very appreciably and are subject to the control of the occupants.

In the case of fuel heating, there is considerable variation among householders in their ability to secure best results from a given quantity of fuel.

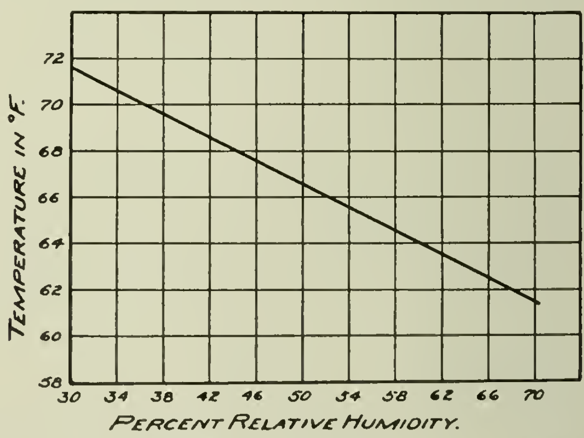

**Fig. 8—Relation Between Humidity and Air Temperature for Maximum Comfort.**

An illustration of the influence of the personal element on heat requirements is furnished by Fig. 9 which depicts the variation of monthly electrical energy consumption required for heating two identical houses due to occupancy changes and type of control over a period of four and a half years. These houses are adjacent and have about the same exposure. Note the extreme increase in consumption of house *A* in the early part of 1932 due to occupancy by three bachelors who regulated temperature by leaving the heater on and opening windows. In spite of a much more severe heating season for 1933-4 than for the 1932-3 season, house *A* had a lower consumption due to using automatic temperature control.

### *Heating Methods*

The heat transfer medium, type of heating equipment and control play an important part in the heat economy of a house. It is therefore proposed to briefly review the more important features, with additional detail on the recent developments in the Saguenay district.

#### Heat Transfer Medium

Heat may be transferred from the heating plant to the occupied space by four mediums: (*a*) hot air, (*b*) hot water, (*c*) steam, (*d*) radiation.

In general, heating systems in use in Canada are designed to maintain the required air temperature in the room. The air temperature then slowly warms the wall, floor and ceiling surfaces. The net result is a high air temperature and cool enclosing surface temperatures. A recent development in England, known as panel or radiant heating, is based on maintaining the proper amount of radiation to the body. The result is that the air temperature slowly increases. With radiant heating the mean air temperature is less so that there is a saving in heat loss through ventilation.

Hot-air heating is cheap, moderately flexible, moderately satisfactory in regard to circulation of air and probably ideal insofar as humidification is concerned. However, it possesses a disadvantage in that it is rather difficult to prevent dust getting into the air stream. Moreover, unless the warm-air distribution system is carefully designed, it is impossible to prevent serious air stratification and dead-air pockets. As the hot-air system has no inherent heat storage any undue diminution of the fire results in a decided degree of discomfort.

Hot-water heating is moderate in cost, simple, and has a considerable range in heating effect due to temperature. It has, however, a rather high temperature inertia and the heat supply lags behind demand. The inertia, nevertheless, tends to smooth out variations in heat supply from the fuel.

A modern development has increased the relative desirability of hot-water heating for houses enormously. It consists in the combination of a small noiseless fan with the radiator in a suitable cabinet. The use of a fan permits a smaller radiator surface for the same heat output, in fact about one-third of that which would be required without a fan. The total installation cost, including the fan, motor and wiring, works out at about the same as for the older system. Much better circulation of the air within a room is obtained. In addition, the fan-equipped radiator makes possible the use of the heating system for summer cooling by forcing room air over the radiator coils containing circulating cold water.

Figure 10 compares test and computed values for a radiator based on a temperature difference of 30 degrees F. between water and room temperatures. It emphasizes the effect of increased air velocities over the radiator surface.

Steam heating with the best modern control permits satisfactory maintenance of room temperature by varying either the quantity or temperature of the heating medium. While flexible as far as heat supply is concerned, steam heating does not appear suitable for home heating, being too complex and too difficult to operate and maintain.

Radiation or panel heating may be accomplished in several ways, such as coils of small pipe embedded in the walls or ceiling and furnished with hot-water or steam from the heating plant; similar coils located in the floor may be used; low-temperature electric heating elements embedded in walls, ceiling or floor surfaces. Developments in radiation heating utilizing low-temperature electrically-heated screens are under observation and offer promise.

#### Fuel-Burning Heating Equipment

Generally speaking, moderately comfortable conditions can be maintained reasonably economically with fuel-burning heaters in one or two rooms, but it is difficult to secure uniformly satisfactory temperatures throughout a house. However, research and inventive ability have resulted in the modern heating system, supplied from a central furnace, which is capable of meeting most requirements in respect of comfort, if properly designed for the particular application.

The fuel-consuming unit or furnace is the most important element in the heating system. Today, there are numerous well-designed furnaces for firing with various types of coal, coke, oil or gas. Some furnaces, such as the

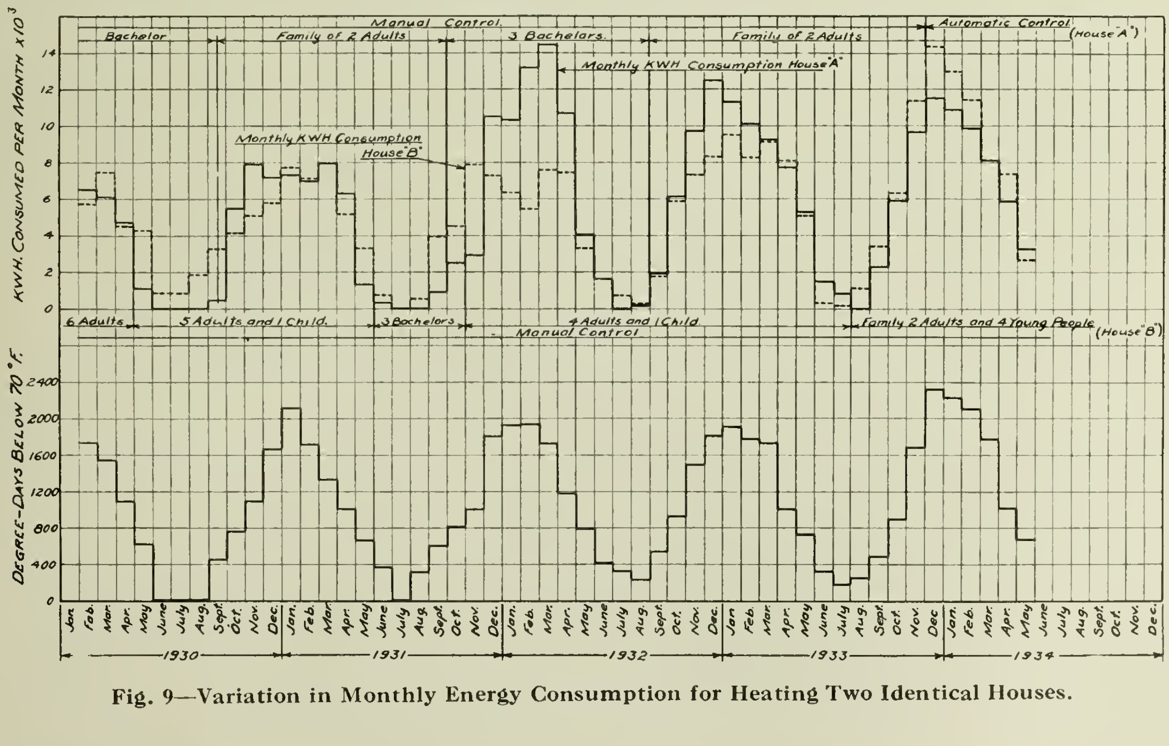

Fig. 9—Variation in Monthly Energy Consumption for Heating Two Identical Houses.

magazine type with blower, oil-burning and gas-fired, are designed for automatic operation with thermostatic control. Others are intended for manual firing only.

Automatic operation generally results in desirable savings, as there is not the tendency to overheat so evident with manual operation during periods of mild weather. Savings of 25 per cent have been secured with conversion

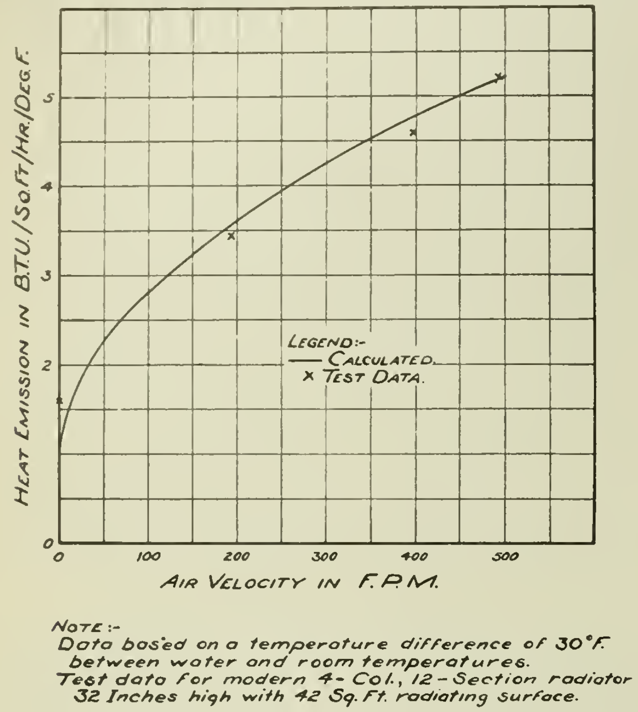

**Fig. 10—Heat Emission in B.t.u. per sq. ft. per hour per degree F. vs. Air Velocity; for Cast Iron Radiators.**

of ordinary steam heating systems circulating steam at pressures above atmospheric to sub-atmospheric systems due to the more perfect control. Also, the conversion of manually-controlled electric heating systems to fully automatic operation have resulted in savings of close to 30 per cent over a relatively long period of time.

To those interested in securing optimum economy from the fuel burnt, a perusal of report No. 10, a publication of the National Research Council, entitled "Fuel Saving Possibilities in House Heating," is recommended.

Table IV presents data derived from various sources relative to the efficiency of coal-fired domestic-type furnaces. The higher values, such as those from the Dominion Fuel Board's Second Progress Report, and tests by the United States Bureau of Mines, were secured during test runs under controlled conditions. Careful observations on furnace performance derived from comparisons between houses heated electrically and similar houses heated by fuel have shown an average efficiency of 50 per cent for the eight months heating season September 15th to May 15th, in the Saguenay district. The best seasonal efficiency appears to be approximately 55 per cent from the above set of comparisons.

While efficiencies approaching 60 per cent have been secured on test runs with the best Canadian air-dry wood fuel burnt in a hot-water boiler of the domestic type, it appears that not over 50 per cent seasonal efficiency, and probably less, would be secured with the air-dry wood fuel obtainable in this territory.

Oil-fired furnaces of the more modern type will probably give test efficiencies of about 75 per cent maximum. Average efficiency over the heating season would be about 65 per cent.

In connection with furnace efficiencies, it is well to remember that it is sometimes stated the hot-water needs of a household can be secured for practically nothing through the medium of a furnace coil. Far from it. Such a coil has been shown by test to require 16 to 20 per cent of the total fuel consumption.

Not all of the heat delivered to the heat transfer medium by combustion of the fuel in the furnace reaches the occupied space. A considerable amount is sometimes dissipated from uninsulated pipes and mains. For instance, in a typical house with hot-water heating some 15 to 20 per cent of the total radiating surface is possessed by the mains and risers in the basement and walls. Not all of this radiation constitutes a loss but a large part is used most inefficiently in heating a large basement space.

District heating is a further development of the idea of supplying heat from a central furnace to radiators or outlets throughout the house. Heat is produced by the consumption of fuel or excess hydro electric power in an

efficient central plant and distributed, throughout the area or community served by the district-heating utility, by means of well-insulated mains to the radiation in customers' homes and buildings. The heat transfer medium is commonly steam but hot water is used in some instances. Mr. F. A. Combe* has summarized the substantial advantages accruing from district heating.

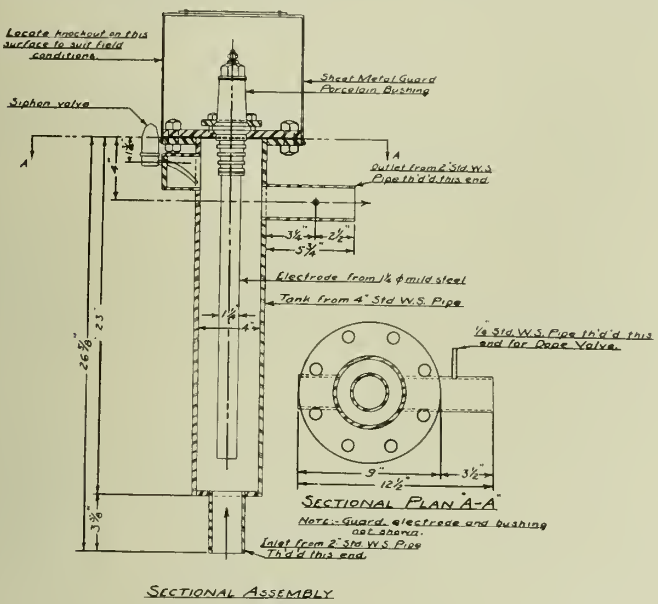

**Fig. 11—Electric Hot Water Heater for Residences.**

### Electric House Heating

House heating electrically is accomplished in a number of ways. Various forms of small radiant-type heaters may be located in rooms. Radiators with electric immersion heaters may be utilized. Low-temperature tubular heaters located around the baseboard are used to an increasing extent. Other systems utilize off-peak power at moderate cost by means of thermal storage in well-insulated hot-water tanks. If the heat transfer medium is hot-water, the hot-water may be circulated to the radiation by a small pump; if hot-air, air is drawn over heated surfaces and discharged through ducts by fans. Such systems are completely automatic.

A large-scale experimental application of electric heating to homes has been in progress in the Saguenay district for the last two years.

The heater used is a small electrode-type hot-water heater, as illustrated by Fig. 11. Power is supplied to the heater at 440 to 550 volts and is dissipated in the water between the electrode and tank. The hot water then carries heat to the radiation by natural or forced circulation.

The system is fully automatic. A thermostat responsive to air temperature controls the heater or heaters, where more than one is used, through a small magnetic switch, as illustrated by Fig. 12. When the air temperature rises slightly above the thermostat setting, power is cut off the heater by the opening of the magnetic switch. Likewise when the temperature drops below the thermostat setting, the magnetic switch is closed, throwing power on the heater.

The heater in this system is capable of meeting a wide range of heating demands as provision is made for changing the conductivity of the water in the heating system through the admission of a weak solution of soda ash or other suitable salt.

The system functions very well, and appears to meet all requirements. No particular difficulties have been encountered with approximately fifty installations.

Figure 13 depicts twenty-four hours of operation with such a heating system, the data being obtained from

*"Central and District Heating," by Mr. F. A. Combe, Report No. 3 of the Dominion Fuel Board.

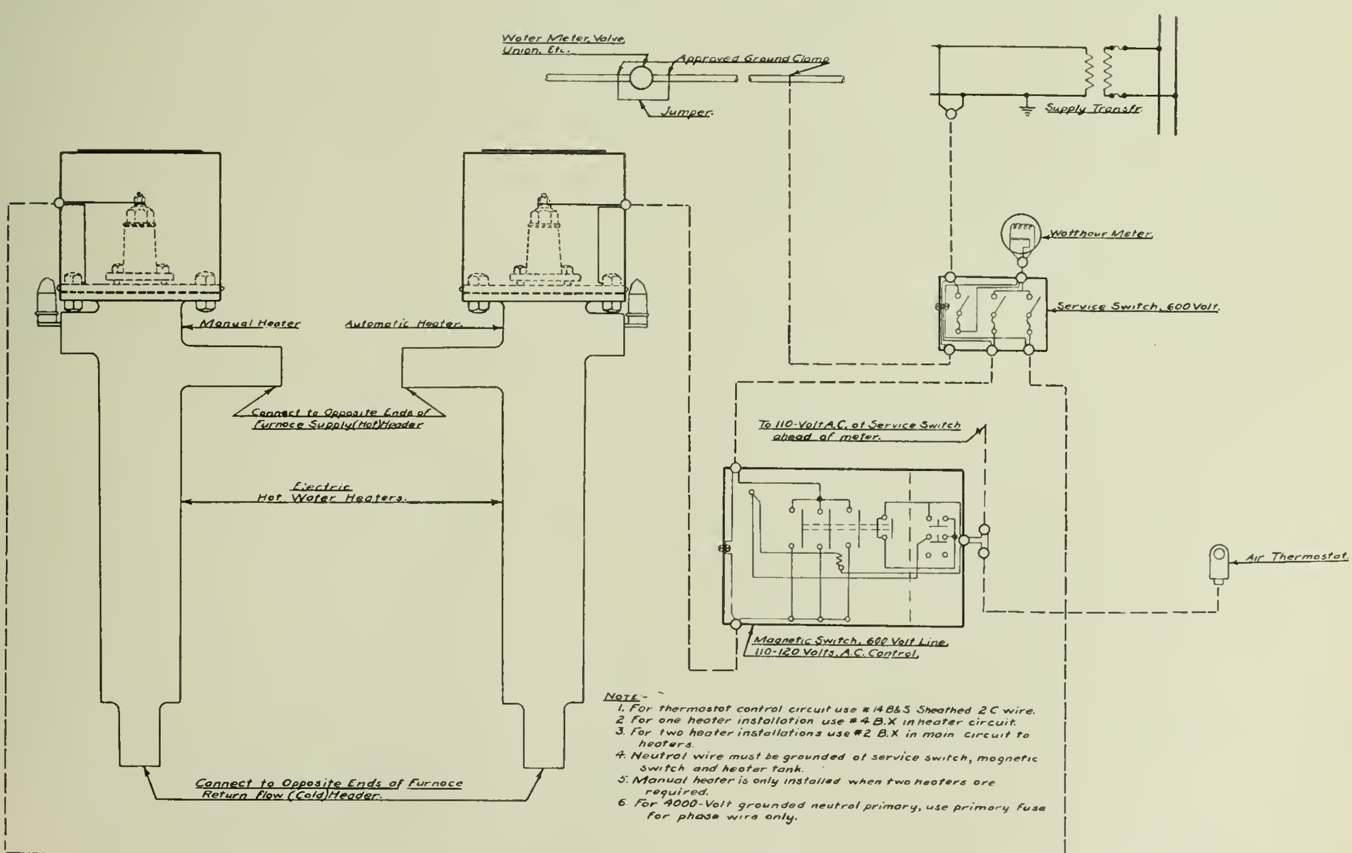

**Fig. 12—Wiring Diagram for Electric Hot Water Heaters.**

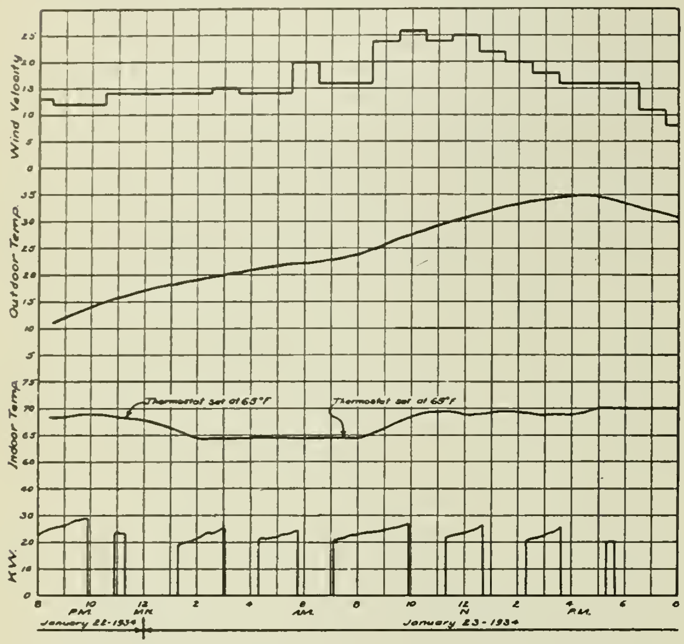
various graphic recorders. It shows the variation in power input with inside temperature, outdoor temperature and wind velocity.

Among the advantages of electric heating are the following:—

No smoke, smudge, ashes, dust or dirt, hence absolute cleanliness.

No gases or odours due to combustion of fuel.



NOTE :-
1. One and one-half story and basement. Substantial wood construction of 1" sheathing, 6" x 6" squared timbers, lath and plaster. Very substantial roof.
2. Moderate exposure.
3. Gross volume 34,270 cu.ft., Net volume 20,740 cu.ft.
4. KW.H/M.Cu.Ft. gross volume/degree-day below average inside temperature. = 0.1796

**Fig. 13—Power Input to Electric Hot Water System.**

Elimination of combustion, fire and flame from house, with increased fire-safety.

Constant temperature regulated as desired.

Automatic control so that house heating can be easily regulated to suit, or even left untouched for weeks at a time with the house vacant.

Heat available when and as required.

No coal and ash handling.

Maximum possible cleanliness of draperies, curtains, wall finish, etc.

No chimneys required.

Decreased ventilation requirements due to no air being required for combustion, and absence of chimneys.

Finally, one of the latest developments in the house-heating field, and the one which holds promise for the near future, is heating by reversed refrigeration.

While the cost of equipment is prohibitive at present, there is every prospect that the relatively near future will see it reduced to a point where the process is economically feasible for the home. Moreover, it offers manifest advantages in air conditioning the year round.

### *Heating Costs*

The final and all-inclusive consideration in a discussion of the heat economy of a house is the net over-all heating cost. This cost comprises two major factors which are: (*a*) Fuel costs, (*b*) intangible costs.

#### Fuel Costs

Everyone is fairly conversant with fuel costs. Probably not everyone, however, realizes, as shown in the preceding discussion, that every time he throws coal on the furnace fire not much over one-half of the heat units inherent in it reach the heating system, or that if he stopped the sources of loss in the house construction the shovelful would last much longer.

Fuel costs obviously vary with requirements, the skill with which the householder fires the furnace, etc. Naturally, best results are secured with a fuel such as electricity capable of 100 per cent efficiency in use and most suitable for automatic control.

To illustrate the relative fuel costs over the heating season, Fig. 14 has been prepared. It shows the cost relationship between the various sources of heat available in the district, based on the probable average seasonal efficiency of conversion, as stated.

#### Intangible Costs

The intangible costs of heating are much harder to ascertain than the fuel cost; however, they are quite real.

The United States Health Service has shown that all respiratory diseases increase from a minimum in summer to a maximum in February, the curve being roughly an inverse of the mean outdoor temperature curve, with a slight time lag.

Medical and associated services affect all so vitally that it is indeed strange more attention is not given to the maintenance of the most healthful conditions in the home.

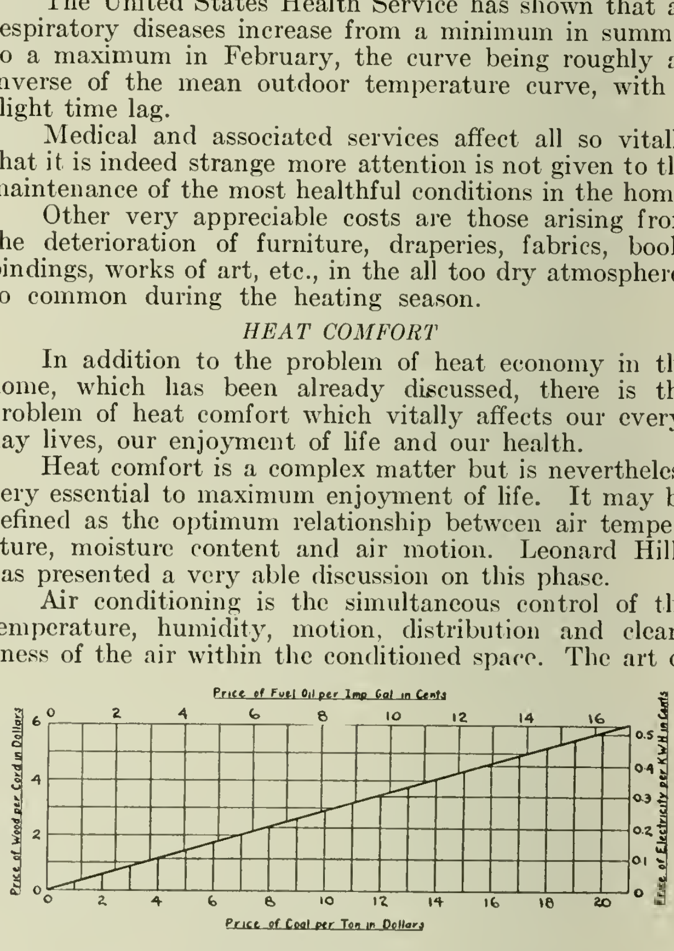
Other very appreciable costs are those arising from the deterioration of furniture, draperies, fabrics, bookbindings, works of art, etc., in the all too dry atmospheres so common during the heating season.

### *HEAT COMFORT*

In addition to the problem of heat economy in the home, which has been already discussed, there is the problem of heat comfort which vitally affects our everyday lives, our enjoyment of life and our health.

Heat comfort is a complex matter but is nevertheless very essential to maximum enjoyment of life. It may be defined as the optimum relationship between air temperature, moisture content and air motion. Leonard Hill* has presented a very able discussion on this phase.

Air conditioning is the simultaneous control of the temperature, humidity, motion, distribution and cleanliness of the air within the conditioned space. The art of



NOTE -
1 Wood assumed air-dry white birch, cut 16 ins long, containing 25,400,000 B T U per standard cord, burnt at 50% seasonal efficiency (From "Heating Value of Wood Fuels" by J D Hale, Forest Products Laboratories of Canada)
2 Coal assumed to be anthracite containing 13,500 B T U per pound as fired, burnt at 50% seasonal efficiency
3 Electricity consumed at 100% seasonal efficiency
4 Fuel oil assumed to contain 168,600 B T U per Imp. gal burnt at 65% seasonal efficiency

**Fig. 14—Comparative Seasonal Fuel Costs.**

air conditioning is really an enlargement of the art of heating, inclusive of those factors necessary to the maintenance of heat comfort the year round.

Under the head of "Inside Conditions" it was pointed out that a relative humidity of 40 to 50 per cent was required for most satisfactory comfort conditions in this climate. Considering Fig. 8, it will be noted that there

*"The Science of Ventilation and Open Air Treatment," His Majesty's Stationery Office, London.

is a definite relationship between temperature and relative humidity or moisture content.

Let us examine the moisture requirement for a home in the Saguenay district. Table V presents in tabular form the mean outdoor temperature and relative humidity at Arvida, Que., during 1933. While the relative humidity of the air during the heating season was high, the temperature was low, and hence the absolute humidity was low. The amount of water which must be evaporated daily to secure 45 per cent relative humidity at 68 degrees F. air temperature in 1,000 cubic feet of occupied space with one air change per hour was worked out and the daily requirement and its variation from month to month is given in Table VI.

Table V

Mean Outdoor Temperature and Relative Humidity at Arvida, Que., During 1933

| Month | Temperature Deg. F. | Per cent Relative Humidity |
|---|---|---|
| January | 11.4 | 93.97 |
| February | 9.5 | 93.14 |
| March | 16.9 | 88.50 |
| April | 36.3 | 80.15 |
| May | 48.3 | 66.95 |
| June | 59.2 | 71.50 |
| July | 63.9 | 75.85 |
| August | 61.4 | 79.63 |
| September | 54.6 | 87.13 |
| October | 40.8 | 82.60 |
| November | 15.4 | 89.90 |
| December | − 2.8 | 98.51 |

It is then evident that the maintenance of maximum comfort in a home in this district during January, 1933, required an average daily evaporation of 7.2 imperial pints per 1,000 cubic feet of occupied space assuming normal ventilation of one air change per hour, or a daily total of 9 gallons for an occupied space of 10,000 cubic feet.

The element of heat comfort which probably has the largest effect on our health is humidity. When the relative humidity is low in the home, the hot, dry air breathed into the lungs absorbs moisture from the mucous membranes and decreases their ability to filter out, as it were, the various disease germs.

Table VI

Amount of Water Which Must Be Evaporated per 1,000 Cubic Feet of Occupied Space, for Maximum Comfort, Assuming One Air Change per Hour

| Month | Amount of Water which must be Evaporated to Secure 45% R.H. at 68° F. Inside Temperature* |
|---|---|
| January | 7.2 Imp. pints daily |
| February | 7.4 |
| March | 6.8 |
| April | 3.9 |
| May | 2.3 |
| June | 0 |
| July | 0 |
| August | 0 |
| September | 0 |
| October | 3.2 |
| November | 6.9 |
| December | 8.1 |

*For Arvida, Que., based on 1933 data.

Temperature plays an important part also, as evidenced by the incidence of accidents in industry. The minimum occurs at about 68 degrees F. On either side, the accident rate is higher.

Properly-designed heating systems are necessary to maintain the correct balance between air temperature, humidity, and air movement which is so necessary to the proper functioning of the bodily temperature regulating mechanism.

It is probable that the apparent greater comfort experienced with radiation heating is due to a better balance between the bodily heat losses through convection and radiation than is secured with most present-day heating systems.

No matter how satisfactory a heating system may be installed in a house, it is impossible to secure real heat comfort unless the wall, floor and ceiling or roof construction is suitable.

It may be concluded that in the average home there are many ways in which better over-all results can be secured from the money spent for heating.

Another conclusion which may be drawn is that the average householder should give more consideration to his house heating from the angle of its effect on the enjoyment of health and comfort by his family and himself.

# THE SUBSTRUCTURE OF THE RECONSTRUCTED SECOND NARROWS BRIDGE

*P. L. Pratley, M.E.I.C.*[1]

## DISCUSSION

Major J. R. Grant, m.e.i.c.[2]

Since making a report for Messrs. Cleveland and Cameron, engineers for the Bridge Company, on the designs submitted for the Second Narrows bridge in 1914, the writer has followed with interest the different chapters in the eventful history of the project.

It was unfortunate that the high standards that governed the design in 1914 had to be so completely sacrificed in 1923. Mr. A. D. Swan in his paper on the Second Narrow bridge in the October, 1928, Proceedings of the Institution of Civil Engineers, stated:

> "Before the scheme was proceeded with, he informed the Bridge Committee and the people of Vancouver that it appeared to be possible to built a bridge which would be good enough for the purpose intended until such time as more money was available to provide a better structure."

The costs have increased until now the capital charge is a heavy burden while the poor facilities for highway traffic have not been improved.

In 1927, after many serious accidents to shipping, a Joint Committee of the Vancouver Merchants Exchange, Board of Trade and Shipping Federation of British Columbia requested a committee of local engineers to report as to the feasibility and cost of making such alterations to the bridge as would materially improve conditions. The writer as one of this committee recommended the conversion of the 300-foot fixed span into a lift span if the piers at either end proved to be satisfactory. The publication of Mr. Swan's paper in 1928, with details of the foundation of pier 2, appeared to eliminate this pier or any extension of it, as one of the supports for a long lift span with high towers and heavy counterweights. With the wreck of the 300-foot span in 1930 conditions appeared to be in favour of a swing span for the suggested reconstruction.

Mr. Pratley in his discussion of Mr. Swan's paper stated:

> "The reasons leading to the selection of a bascule of that type and at that point in the stream would, if available, be of considerable interest. Economy in first cost and in operation would appear to lie with the horizontal swinging type."

Or as stated by a well known authority on movable bridges:

> "When the conditions at the site are favourable and there are no restricting circumstances, a swing bridge is the simplest, best and most economical type in first cost and maintenance."

In the study of the different schemes for the reconstruction of the bridge was a swing span considered? A span north of pier 2, slightly longer than, but not as heavy as the 581-foot 6-inch swing span proposed by Sir John Wolfe Barry, Lyster and Partners for the structure in 1914, would have provided two openings each practically equal to the one provided by the present lift span. The vertical clearance would not have been restricted to 140 feet above high water, the load on pier 2 would have been less than what it originally carried and the obstruction in the waterway would have been considerably less than with the present structure. The trusses are only 20 feet centre to centre but the full width of the deck would have been available for lateral stability over pier 1, which could have been strengthened at a reasonable cost, to provide adequately for the loads it would have had to carry as a pivot pier. The two north 150-foot spans would have been strengthened to serve as the ends of the swing span. The saving in the cost of reconstruction and maintenance would have meant earlier relief of the north shore municipalities from the carrying charges on the bridge bonds they guaranteed.

Footwalks could have been provided on both sides to permit the span to swing through 180 degrees. Over the Harlem river, New York City, where heavy traffic and navigation require quick operation, swing spans have turned through 180 degrees without a stop, the one arm of the span following the boat as it passed through the channel.

Some engineers have a prejudice against the swing bridge and favour the bascule or lift span even for locations where the horizontal swinging type is the logical structure. This prejudice is sometimes due to a comparison of a modern bascule or lift span with an ancient swing bridge. Good salesmanship frequently sold a bascule bridge for a site where the needs of traffic and navigation, cost and æsthetics would have favoured the swing span.

Bascule and lift spans have an advantage when passing small craft as they have only to be lifted a short distance but the time required for the actual movement of the span is usually a small proportion of the total time traffic is delayed for the passage of a boat.

Timber fender piers would have been required for a swing span but should not all piers in channels used for navigation be provided with timber fenders for the protection of shipping? The Towboat Section of the Vancouver Merchants Exchange, in 1927 stressed the need of such protection to obviate the frequent breaking of log booms. The piers of the San Francisco-Oakland Bay bridge are to be provided with timber fenders although the two main spans are 2,310 feet. The long fender piers required for swing spans are frequently an aid to navigation.

It is unfortunate that the unsightly counterweight and counterweight trusses of the old bascule span have not been removed and that the original construction included the rock fill, extending from the south shore to pier 5, which undoubtedly increased the cross-current from the south shore to the north-east mentioned by the author.

P. B. Motley, m.e.i.c.[3]

There are a few remarks which occur to the writer in regard to the æsthetic side of bridge designing, which have been suggested by the details of the bridge.

A good appearance is an asset in connection with any structure, especially those which occupy such prominent places as bridges. Too many public works are not beautiful, and the engineer is usually looked upon as one who has not that quality which goes by the general term of "Art."

The designing engineer, on account of his desire to arrive at the stresses that will occur in a structure, often overlooks the æsthetic side. However, beautiful outlines can be obtained even in a steel framed structure just as in

[1] Paper presented at the Western Professional Meeting of The Engineering Institute of Canada, Vancouver, July 11th to 14th, 1934, and published in the August, 1934, issue of The Journal.

[2] Consulting engineer, Vancouver, B.C.

[3] Engineer of bridges, Canadian Pacific Railway Company, Montreal.

any other material, if the engineer combines in himself sufficient artistic instinct to correctly proportion his work. It is not sufficient for a mathematician to do his best—or worst—and hand the design over to an architect for beautification. What is required is the combination of the artist with the engineer in the same person, and while it may be a rare combination, it is not unreasonable that there should be some authority at Ottawa who shall have the power to veto designs which are likely to shock the artistic sense of the beholder.

In the case of the important work under discussion, the engineer for the construction company has admitted that the bridge was designed to suit a certain sum of money which was available. It seems that this, as a basis of bridge designing, is very undesirable, though far too common. A bridge should be built to suit the requirements of the case, and while true economy should always be kept in mind the cheapest design should not necessarily be approved.

In rebuilding this bridge, again cheapness has doubtless caused the engineers to leave in the old bascule and its counterweights. Would any architect have remodelled a building and left in so much of its original unused details for all to behold besides perpetuating the hazard to the structure should the span in question be struck by another ship, to say nothing of the cost of maintenance of the counterweight which is likely to be considerable. The cost of removing or redesigning the bascule bridge and the removal of the counterweight trusses would have been money well spent.

Mention has been made of the proposed glance booms to steer ships through the right span, and while no details of these are provided, they should be of such rugged construction that they can at all times be depended upon.

It is to be hoped that some day there will be an authority at Ottawa, who first of all shall have an æsthetic sense and then the power to say "No" to all cheap bridge designs, and thus avoid defacing the natural beauty of this country.

Otis E. Hovey[4]

The writer would refer to the wisdom of using fenders adjacent to the piers which support the lift span.

Near New York there was a Scherzer bascule span which was built over tide water. The rolling segment was supported on heavy plate girders between which was a double track open railway floor and heavy lateral bracing. A 10,000-ton steamer, out of control, struck the plate girder supporting span opposite the middle floor beam, and although the boat was moving very slowly, the force of the collision wrecked the floor system and laterals, and twisted the entire bascule span and its supporting girders on the piers so that the movement at one corner was nearly two feet. However, if each supporting pier had been provided with fenders of proper shape the steamer probably would have collided with one of them, and expended its energy in destroying the fender rather than in damaging the bridge. This bridge was out of service until extensive repairs could be made, while damaged fenders usually would not obstruct traffic.

Inadequate fenders may fail to protect a bridge superstructure as in the case where a steamer collided with the end of a centre pier fender of a swing bridge. The swing span was open and it struck the fender in the centre of its end. The fender was a little longer than the span and of light construction and the steamer cut through the fender, struck the end of the open span, also of light construction, and followed it endwise, causing a complete wreck of both the fender and the span. The damage to the boat was well above the water line and amounted to only a small fraction of that to the bridge.

When money is available for building a movable bridge, the additional amount required to protect the piers and the bridge by adequate fenders should prove to be a wise investment. If a vessel collided with a fender it would destroy a relatively cheap structure but probably would not damage the piers, or the bridge.

(4) Consulting engineer, 71 Broadway, New York, N.Y.

Wm. Smaill, m.e.i.c.[5]

There were originally proposals for a high level bridge, but only for highway traffic. Later a railway connection to the north shore was desired to develop the manufacturing sites there and it was also considered as an ideal place for a free port. An American firm of bridge builders stated they would build a bridge at this place for the amount of money and bonds which the bridge company had at that time, but after investigating, said that it could not be done for the amount available. The writer's company had just completed the Ballantyne pier and had equipment on the north shore for cylinder piers, and it was believed that a bridge might be built with these piers. The firm spent some $25,000 on soundings and meter readings, with the result that it was necessary to change the layout and use caissons.

Estimates were made for a swing span and finally a design was completed which it was felt could be built for the money and bonds available. It was decided to use air caissons on pier No. 2 and the bascule support. The writer was not proud of the layout, but it was the best that could be done with the funds available.

Seven different designs had been prepared, lift spans, 200-foot spans, 300-foot spans and a lift span with railway above it, and attempts were made to see if the Federal government would accept one of these. Any of these schemes would have cost less than the repairs cost on the bridge later. The government did promise to dredge the last span on the north, which would stop the cross-currents; however, they only dredged a short hole on the south side of the bridge. A bad cross-current comes down there, and would interfere with the up-traffic coming in at about high tide.

After the bridge was wrecked and six years after it was built, the Harbour Board brought in a regulation that boats were not to go through unless going against the tide. It is absolutely impossible for any boat going against the tide to hit a pier because the sheer of the water coming down would throw the vessel back away from the pier and keep it in the centre of the draw. There has not been a single accident at that bridge which has happened with a boat going against the tide.

R. K. Palmer, m.e.i.c.[6]

No accident has happened to the bascule span or in the operating channel but accidents have happened to the spans on both sides of the operating channel. It will certainly be unfortunate if a boat collides with the bascule under the new construction because the bascule is now supporting the back legs of one of the towers and as no boat would attempt passage unless the lift span were up, a wreck of the bascule span would crash the structure.

It is a curious thing that the old counterweight is left in place and is depended on to so modify the stresses in the bascule leaf as to partially take care of the new load coming in from the back legs of the lift bridge tower. Of course, with the bascule span not operating there are no reversals of stress in the counterweight framework and,

(5) Chief engineer, Northern Construction Company and J. W. Stewart Limited, Vancouver, B.C.

(6) Chief engineer and vice-president i/c operations, Hamilton Bridge Company, Hamilton, Ont.

therefore, little chance of trouble arising from the counterweight, although counterweights have given trouble in the past on operating spans.

JOHN PORTAS, M.E.I.C.[7]

The imposing list of accidents from which the Second Narrows bridge has suffered, draws attention to the grave responsibilities of the engineer in matters concerning choice of location and major features of design.

In the absence of any evidence justifying the original layout, the writer can only suppose that it was adopted in the interests of economy. Actually it has proved to be anything but economical, for the misplaced, undersized, movable span and the main pier situated in the middle of the shipping channel have occasioned heavy financial loss, caused serious inconvenience and damage to river traffic, and resulted in complete cessation of land traffic for a period of years. Because of its critical position at the intersection of land and water traffic, the case of the movable span calls for special attention. When, as in this case, the problem is complicated by extraordinary conditions of tide and current, the importance of preliminary studies cannot be magnified. The author's firm is to be congratulated on the care with which the preliminary work for the rehabilitation of the bridge was carried out and on the close estimate of cost which resulted.

The layout finally adopted, a lift span of 286 feet in the centre of the channel, should remove from the bridge, its well earned epithet, "a menace to navigation." Æsthetically also the structure must be considered satisfactory, in view of the limitations imposed by the original layout.

The writer has had occasion recently to make a preliminary design and estimate for a 300-foot double-deck lift span for combined highway and railway loading and is impressed by the economy of this type, in construction and operation. At the Second Narrows the choice of a vertical lift for this loading and span is obvious, but it would be interesting to hear if comparative estimates were made for other types.

The writer questions the desirability of making use of the old bascule leaf in the new structure. Was the saving effected by this means sufficient to justify such unconventional treatment of the problem? Has any thought been given to the possibility of strengthening this span by welding, and cutting away counterweights and supporting frame?

Of the many alternatives examined by the author's firm the one adopted—which involved the demolishing of the badly located pier No. 2—is the one which appeals to the cursory reader. If, as is suggested, the old 300-foot span was still serviceable it seems regrettable that it was mislaid. At very little cost it could have been converted into a lift span and the additional 14-foot span would have been by no means out of place on this difficult passage.

The account of the conditions of loading resulting in the maximum possible pressure at the base of the pier and of the effect of eccentricity of the shaft of pier No. 2 B, is most interesting. In view of the many accidents which have occurred in the past and the possibility of future collisions which may occur in spite of greatly improved conditions, it would be interesting to know if there are figures available showing the effect on a pier of a possible head-on collision by a ship of the maximum tonnage using this channel? Has any consideration been given to the necessity of providing fenders for pier protection?

[7] Chief engineer, J. W. Cumming Manufacturing Company, Ltd., New Glasgow, N.S.

P. L. PRATLEY, M.E.I.C.[8]

The author in replying to the discussion, wishes again to express his regret that he was unable to attend the meeting and to present in person his response to the observations offered and the questions raised. He is more than grateful to Colonel J. P. Mackenzie for reading the paper and is pleased that so many members found it interesting enough to comment upon.

Mr. Grant quotes from the author's own discussion on Mr. A. D. Swan's paper before The Institution regarding the need for remembering that the horizontally swinging span still has its place in the active service list of efficient movable bridges, and then adds a note to which the author heartily subscribes. The reference is to the fear that supersalesmanship has quite often been the controlling influence in displacing the non-patented swing span by the patented bascule.

Several gentlemen mentioned the retention of the old bascule in the completed work and enquired the reasons therefor. As pointed out, the removal of the bascule was found to be quite an expensive undertaking, the estimates made and received varying up to $60,000. Those responsible for financing the project could see no advantage in such an expenditure at this time, and under the governing circumstances no engineer could justifiably recommend it. Investigations were carried out regarding methods to be adopted if and when such a procedure could be undertaken, and as Mr. Portas surmises, the necessary strengthening of the flanking span was definitely considered as a welding job. The support and demolition of the concrete counterweight and its enclosed steel framework was naturally the most troublesome item in any removal scheme.

Whether the present ignominious position of the bascule is such as to evoke sympathy, commiseration or compassion, is a matter of opinion but there can be little doubt as to the negative value of the advertisement.

The author admits of no keener enthusiast for æsthetics in bridgework than himself, but, as Mr. Motley readily gathered, he was compelled to shut his eye to the old bascule and do the best he could with the new construction. As a matter of fact, viewed from the ferry boats or from Brockton Point, the new work has quite appropriate lines, and a satisfying appearance.

Mr. Grant also refers to the possibility of a 600-foot equal-arm span, using the old 150-foot spans as parts of its arms, resting on a huge pivot-pier, which would replace or absorb the existing pier No. 1, and using piers Nos. 2 and 00 as end rests. The swing-span possibility was not envisaged quite in this way by the author's firm, for reasons which seem sufficient to determine it as uneconomic. For instance, the pivot-pier would without doubt have to be entirely new, to avoid unequal settlements. The loads on its base would be enormous from consideration of its own weight and the weight of the totally supported swing-span above, even if cellular construction were adopted. The wind and current effects would probably prove quite important, quantitatively. To use the old 150-foot spans would remove the opportunity of lightening the swinging weight at essential points by adopting high-strength alloy steel. Pier No. 0 would have to be demolished and probably pier No. 00 would need extensions. Neither can it be agreed that pier No. 2 would necessarily be relieved of load, having regard to the specified conditions of swing-span loading and the resulting weight of materials. The bascule could have been retained in such a scheme as in several others illustrated in the paper, but no one wanted to retain it, and the re-use of its machinery was a desirable economic feature. Furthermore, it is at least questionable whether any saving in operation or maintenance could have been

[8] Monsarrat and Pratley, Montreal.

made, under the climatic and navigational conditions obtaining at the site. Finally, the matter of fenders arose as a serious additional cost, as fenders of some type would be absolutely necessary for a span extending 300 feet up and down the waterway. This question was also raised in the author's discussion of Mr. Swan's paper to which Mr. Grant made reference. Timber construction may be cheap in this neighbourhood, as Mr. Hovey suggests, but the amount of such timber work and the means for supporting it, without anchors in the waterway, would have added considerably to the cost of rehabilitation. Mr. Smaill points out the extreme improbability of a vessel striking a pier under present harbour regulations, and although it is recognized that rafts of logs may and do wrap themselves round the noses (of pier No. 1 especially), yet this type of occurrence involves no real danger to the superstructure, or even damage to the piers. Cutting such rafts loose is not a long or a hazardous job, and moreover the occurrence should become increasingly rare as the by-laws become better known and more strenuously enforced.

Mr. Palmer raises the question of collision between vessels and the old bascule span, now acting as south flanking span. Obviously such a collision cannot be dismissed as impossible, but the conditions of navigation are vastly improved, and no longer is a vessel asked to make for an unnatural 175-foot channel. Such conditions as may be imposed by regulation really constitute an engineering feature entering definitely into the design of the structure.

Answering Mr. Portas, it can be stated that various arrangements of bascule spans, single and double lift, were sketched and studied. Few of these advanced to the stage of being actually estimated because of physical or constructional problems which rendered them unsound or undesirable. No bascule arrangement giving equal lateral clearance seemed available without much greater cost, due largely of course to piers having to be placed in the deep channel without rock foundation. Mr. Portas raises a further point in attempting to appraise the effect of a possible head-on collision between a heavy ship and one of the piers. Mr. Smaill, as above mentioned, dealt with the general question, but the direct answer to Mr. Portas depends entirely upon the assumptions made regarding the rate of destruction of the ship's energy. The figures appearing in the calculation brief can be summarized as follows:—

If 1,000 tons dead weight moving at 10 feet per second strikes the east or west nose directly, head-on, and the energy is used up in one second, the equivalent blow is 313,000 pounds, and the lever arm from elevation 90 to the riprap level being 53 feet, the moment of this blow divided by the section modulus gives 1,200 pounds per square foot as the resulting extreme fibre stress. This unit obviously varies directly with the mass of the vessel and inversely with the time or space element allowed for the destruction of momentum or energy. Expressed in pounds per square inch the figure is apparently not excessive for ships of moderate tonnage, and no additional quantitative provision was made for such an eventuality.

## Progress Towards Sound Public Finance

An encouraging sign of the times is to be found in the increased extent to which professional men, business men, and those occupying responsible positions in our main industries are concerning themselves with public affairs and taking a national rather than a local point of view in discussing public problems. This tendency is no less marked in the west than in the east; the employee as well as the employer is seeking for information on problems of the day. The public is at last beginning to realize that even though conditions are improving, the outlook in Canada is serious so long as there are no definite prospects of relief from the burden of taxation, or assurance that our present burden of debt will be dealt with on sound business principles, and that our national budget will be balanced.

The only way in which the community can control taxation and enforce economy in public expenditure is through the vote, and the building up of an informed public opinion regarding these matters is therefore an essential preliminary to any constructive action. Among the organizations whose efforts are contributing to this very desirable end, the Canadian Chamber of Commerce stands high. Its campaign for sound public finance, directed by a committee of sixty business leaders under the chairmanship of Sir Henry Drayton, is now in its second year of activity. That committee is making studies of provincial as well as federal finance and taxation, and results beneficial to national economy have already been secured. Other activities of the Chamber include the consideration of such questions as immigration, extra-provincial taxation, fire-prevention in its national aspect, the encouragement of the younger men in studying public questions, the trade relations of Canada with Great Britain and the United States, and many other important topics.

The influence of the Chamber is further extended through articles on public questions contributed to the press and published in the Chamber's monthly magazine. An outstanding example of these is a recent discussion* of the debt situation in Canada, which may well be read in conjunction with the address on "Recovery by Construction,"† published in the last number of The Engineering Journal. Like Professor Jackson, Mr. McDonald points out that the Dominion has not yet faced the situation in the decisive manner adopted in Great Britain by clearing up government debts, by cutting down expenditure on all social services which are not indispensable, and by generally setting its financial house in order.

War debts, private speculative debts incurred during the boom, and governmental debts, are our chief obstacles to progress. The first two classes are no longer represented by any assets capable of providing means of repayment and are gradually being wiped out by the ordinary business processes of voluntary or forced concession. Debts of the third class, however, are due to the capitalization of federal, provincial and municipal government deficits, and to the failure to pay off debts incurred by our numerous governments for capital expenditure. Little, if any, progress is being made in regard to them.

In examining the way in which these government debts have grown in Canada, Mr. McDonald observes that most of our federal debt, and a large part of the debt of some of the provinces, has been the result of the conduct of business enterprises (including railway transportation) by governments. As regards governmental expenditure on social and educational work, he thinks the function of government should have been rather to see that such work is properly provided for, than to furnish the funds for it. A tendency is now becoming manifest for municipalities to lean on provincial governments, and for these in turn to rely on the Dominion government for support. "Looking at this situation," Mr. McDonald continues, "it must be obvious to everyone that Canadians must take a more intelligent and active interest in their governments and in the people chosen as their representatives. The functions of the different governments should be re-defined so that a situation where everybody seemed to be leaning on the central government might never occur again. In the definition of these functions the federal government should keep out of purely provincial and municipal affairs, retire entirely from the field of business and restrict its functions to those of a regulatory nature . . . It should be remembered that when a private business fails, the shareholders and creditors bear the loss, but when a government enterprise gets into difficulties the taxpayers must assume the burden of debt."

As regards the amount and incidence of taxation, we are in a very difficult position in this country. One fundamental difficulty in our present system of taxation is that it does not "bring home to every citizen of the community his responsibility to contribute to the cost of government." How can governments be expected to function efficiently while the general public displays little or no active interest as to what is really going on?

It happens that the burden of present financial conditions presses severely on the professional and salaried classes, to which The Institute's members belong. They have, therefore, a special interest in trying to bring about sounder conditions in government finance. The widespread organization of our branches, and the representative character of their membership in each locality, would seem to afford a special opportunity for constructive work on their part. Would it not be helpful if our members would occasionally turn from the consideration of engineering topics and technical papers to direct their individual and collective thought and effort towards arousing a local

*"The Challenge of Debts," Geo. C. McDonald, Canadian Business, April 1934, p. 18.

†"Recovery by Construction," Gilbert E. Jackson, Engineering Journal, October 1934, p. 460.

public opinion which will demand constructive progress in public finance, whether federal, provincial or municipal?

As one of the organizations affiliated with the Chamber, The Engineering Institute of Canada was recently asked to aid in the work of the Chamber's National Committee on Sound Public Finance, by submitting recommendations as to the conditions which it is desirable to observe in obtaining tenders and letting contracts for public works, this with a view of insuring efficiency and economy in carrying out these expensive undertakings. Gladly complying with the request, Council at once appointed a committee of prominent members, including two contractors, two government engineers, and a consulting engineer, and the committee's report, embodying the results of the wide experience of its members, will shortly be presented to Council for approval and transmission to the Chamber. It is a duty as well as a privilege for The Institute to assist in this way in the work of a body one of whose main purposes is to bring about much-needed improvement in our financial situation.

## Meeting of Council

A meeting of the Council of The Institute was held at the Royal York Hotel, Toronto, on Friday, October 19th, 1934, at seven thirty p.m., with President F. P. Shearwood, M.E.I.C., in the chair, and fourteen other members of Council present.

The membership of the Plummer Medal Committee for the year 1934 was approved as follows:

L. F. Goodwin, M.E.I.C., *Chairman.*
L. M. Arkley, M.E.I.C.
A. G. Fleming, M.E.I.C.
H. J. Roast, M.E.I.C.
N. C. Sherman, M.E.I.C.

Communications from the Winnipeg Branch were considered suggesting certain changes in the organization of the Branch Executive committee which it is hoped will facilitate the Branch's co-operation with the Association of Professional Engineers of Manitoba. The proposals were received with marked interest, and Council expressed its approval of the experiment, the results of which it will watch with great interest.

During the western journey of the President this year a number of questions regarding organization and policy were raised by the various branches. These having been placed before councillors by correspondence, the Secretary presented written opinions received in reply. It was found that some of the suggestions made had already been put in practice; one or two were not considered advisable, and in the case of the remainder it was decided to take no action at the present time.

The Council learned with sincere regret of the death of Calvin W. Rice, Secretary of the American Society of Mechanical Engineers, and a resolution of condolence was unanimously passed, the Secretary being directed to send a copy to the Society and to Mr. Rice's family.

One resignation was accepted, one member was placed on the Non-Active List, and two special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

| *Elections* | | *Transfers* | |
|---|---|---|---|
| Member | 1 | Assoc. Member to Member | 1 |
| Assoc. Members | 4 | Junior to Assoc. Member | 3 |
| Students admitted | 7 | Student to Assoc. Member | 1 |
| | | Student to Junior | 5 |
| | | Junior to Affiliate | 1 |

The Council rose at 12.03 a.m.

# OBITUARIES

## Calvin Winsor Rice

The death on October 2nd, 1934, of Calvin Winsor Rice, for nearly twenty-eight years Secretary of the American Society of Mechanical Engineers, ended the career of a man who has rendered distinguished services to the engineering profession.

He was remarkable for leadership, vision, enthusiasm and organizing ability, and for a genius for co-operation, gifts which enabled him to take a leading part in the movement which resulted in housing the activities of the great American engineering organizations in their monumental Engineering Societies Building in New York.

During his Secretaryship the Society developed greatly in prestige as well as membership, which grew from some three thousand in 1906 to over nineteen thousand in 1930 when the Society celebrated its fiftieth anniversary. His work in connection with professional-society organization and policies brought him into contact with a host of engineers of all nations; his many active international relationships were largely the result of his magnetic personality, his thoughtfulness, and his unfailing kindness and consideration. His activities in connection with the Kelvin memorial form an illustration of the spirit in which Dr. Rice seized every opportunity of promoting international comity. It is not generally realized that following the visit of the American Society of Mechanical Engineers to England in 1910, it was at his suggestion that through the efforts of British and American engineering societies a window in Westminster Abbey was provided, and the well-known Kelvin medal was established, as a memorial to his friend Lord Kelvin.

Dr. Rice was born at Winchester, Massachusetts, on November 4th 1868, and after attending school in his native town and at Boston and New Haven, was for four years at the Massachusetts Institute of Technology, graduating from that institution in 1890 with the degree of B.Sc. in electrical engineering.

Soon after graduation he became assistant engineer with the Thomson-Houston Company at Lynn, and later entered the service of the General Electric Company, and was stationed at Schenectady and Cincinnati. Subsequently he turned his attention to mining and obtained a position with the Silver Lake Mines in Colorado and the Anaconda Copper Mining Company of Montana. Later appointments were with the King's County Electric Light and Power Company, the New York Edison Company, the Consolidated Subway Company, the Nernst Lamp Company, and the General Electric Company in New York. In 1906 he became Secretary of the American Society of Mechanical Engineers.

Dr. Rice became a member of the American Institute of Electrical Engineers in 1897 and in 1900 joined the American Society of Mechanical Engineers. In addition he was a member of many other engineering and professional societies including the association of members in Argentina of the National Engineering Societies, the Koninklijk Instituut van Ingenieurs of Holland, the Club de Engenharia, of Rio de Janeiro, the Masaryk Academy, Czechoslovakia, the Deutsches Museum, Munich, Germany, the Instituto de Engenieros de Chile, the Technisches Museum, Vienna, and the Institution of Electrical Engineers of London.

Among other honours in Germany he received the honorary degree of Doctor of Engineering (Dr.-Ing.E.h.) from the Technische Hochschule of Darmstadt, in 1926.

The many courtesies shown by Dr. Rice to officers and members of The Institute will long be remembered. He was a welcome visitor to Canada on many occasions and his friends here will join in the regrets which the Council of The Institute has conveyed to the American Society of Mechanical Engineers and to Dr. Rice's family.

### Walter Charles Treanor, A.M.E.I.C.

Deep regret is expressed in placing on record the death at Ottawa, Ont., on September 11th, 1934, of Walter Charles Treanor, A.M.E.I.C.

Mr. Treanor was born at Roscrea, county Tipperary, Ireland, on September 12th, 1879, and received his technical education at the Great Southern and Western Railway Technical Institute and the City of Dublin Technical College, graduating from the latter institution in 1900. Mr. Treanor served an apprenticeship at the Great Southern and Western Railway works from 1895 to 1900. From 1900 to 1901 he was in the drawing office of the North Wall Marine and Engine Works, Dublin, and in 1901-1903 was junior engineer on the construction of the Fastnet Rock lighthouse, south of Ireland, in the Commissioners of Irish Lights' service. From 1903 until 1905 he was with the White Star Line as marine engineer, and coming to Canada in 1905 occupied the same position with the Canada Steamship Company on the Great Lakes. In 1906-1907 Mr. Treanor was engaged on the installation of the power plant and the erection of mechanical equipment of the Royal Mint at Ottawa, and in 1908, on the opening of the Mint, he was placed in charge of all the coining presses and remained in that position until the end of July 1913, when he was appointed by the Civil Service Commission, Canada, to the position of mechanical engineer in the Commissioner of Lights' Branch of the Department of Marine, Ottawa. Mr. Treanor was attached to the same Branch until the time of his death.

Mr. Treanor joined The Institute as an Associate Member on November 23rd, 1920.

### J. Emile Vanier, A.M.E.I.C.

With the death of J. Emile Vanier, A.M.E.I.C., at his home in Montreal on October 11th, 1934, The Institute loses one of its oldest members.

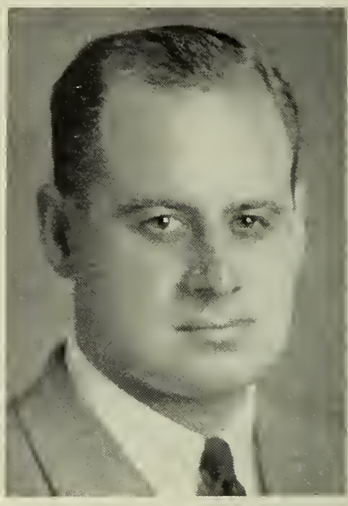
Mr. Vanier was born at Terrebonne, Que., on January 20th, 1858, and graduated from the Ecole Polytechnique, Montreal, in 1877. Following graduation he was assistant engineer on the Hochelaga sewers, and in 1878-1879 held a similar position on the irrigation works of the Lake Vineyard Land and Water Company, and the San Raphael Rancho tunnel at Los Angeles, California. In 1880-1881 and 1882 he was engaged on the preparation of plans, and superintending construction for various works, and in 1884 had charge of several hydrographic works, amongst these being one on the Riviere des Mille Isles in Terrebonne county. In 1885-1886 Mr. Vanier was chief engineer of the Valleyfield Water Works and of the Montreal and Western Railway, and in 1887 he held the same office with the Valleyfield Electric Light Company, later being chief engineer on the construction of a large highway bridge over the Yamaska river at St. Hyacinthe, Que. Later in the same year Mr. Vanier became chief engineer of the Cote St. Louis sewerage work, and in 1888 and 1889 was chief engineer of the St. Henry sewers also the Beauharnois and Lachine Water Works. Mr. Vanier later entered private practice as a consulting engineer and architect in the city of Montreal and at the time of his death was president of the Laurin and Leitch Engineering Company Ltd., and director of the Montreal Crushed Stone Company Limited.

Mr. Vanier was a prominent member of the profession and in 1927 was awarded the degree of D.A.Sc. by the University of Montreal. He was a member of the Royal Architectural Institute of Canada, and was a Past-President, and for many years Honorary Secretary, of the Architects Association of the Province of Quebec.

Mr. Vanier was a charter member of The Institute, joining on January 20th, 1887. He was made a life member on April 28th, 1933.

## PERSONALS

H. M. Black, A.M.E.I.C., has been appointed Ontario sales manager of the English Electric Company of Canada Limited, with headquarters in Toronto. Mr. Black graduated from McGill University in 1923 with the degree of B.Sc., and subsequently joined the staff of the Allis Chalmers Manufacturing Company, being engaged until 1924 on general design and checking, in 1924-1925 on engineering design and estimating, and in 1925-1927 as assistant to the engineer in charge of the steel mill division of the electrical department. In June 1927 Mr. Black became associated with the English Electric Company of Canada as representative in the Northern Ontario mining districts, which position he retained until 1931 when he became power apparatus salesman for the Northern Electric Company Limited at Toronto, Ont.



H. M. BLACK, A.M.E.I.C.

Richard Thorn, S.E.I.C., has joined the staff of Imperial Oil Refineries at Dartmouth, N.S.

W. M. Reynolds, A.M.E.I.C., has accepted the position of engineer with the God's Lake Gold Mines Company and is located at God's Lake, Man.

J. Y. Stanfield, S.E.I.C., who graduated from the Nova Scotia Technical College in 1933 with the degree of B.Sc., has joined the staff of the Consolidated Paper Corporation at Shawinigan Falls, Que.

G. A. Frecker, Jr.E.I.C., has been appointed lecturer in engineering at Memorial University College, St. John's, Newfoundland. Mr. Frecker graduated from the Nova Scotia Technical College in 1932 with the degree of B.Sc.

J. C. Kemp, A.M.E.I.C., has been appointed assistant to the president of Dominion Stores Limited, with headquarters at Montreal. Major Kemp, who was for some time in private practice as a consulting engineer, had been examining engineer with the National City Company at Montreal since 1926.

F. E. Palmer, Jr.E.I.C. is now designing engineer with Sherbrooke Machineries Limited, Sherbrooke, Que. From 1926 until 1931 Mr. Palmer was on the staff of Price Brothers and Company at Quebec and Riverbend, Que., and in 1932-1933 he was designing engineer with the Plessisville Foundry Company, Plessisville, Que. From that time until May of the current year Mr. Palmer was connected with Canadian Copper Refiners Limited at Montreal East, Que.

E. V. Moore, M.E.I.C., formerly district manager of coal sales for the Dominion Steel and Coal Corporation, Ltd., for New Brunswick and Prince Edward Island, with headquarters at Moncton, N.B., has been transferred to Toronto, where he is sales manager for the Ontario Dock and Forwarding Company. Mr. Moore was for many years closely associated with research work in connection with the manufacture of peat fuel, having been attached to the Division of Fuels and Fuel Testing, Department of Mines, Canada, and was responsible for the design and installation of the government peat plant at Port Alfred, Ontario.

Donald A. Gray, S.E.I.C., has joined the staff of the English Electric Company of Canada, Limited, Montreal, as sales engineer in the industrial field. Mr. Gray graduated from McGill University in 1925 with the degree of B.Sc., and was subsequently for two years with the Westinghouse Electric and Manufacturing Company at East Pittsburgh and Grand Rapids, Mich. He was later for a year and a half in the plant engineering department of the Bell Telephone Company of Canada Limited, following which Mr. Gray was for four years sales engineer in the compression department of the Canadian Ingersoll-Rand Company Limited, Montreal. He was more recently with Messrs. Laurie and Lamb, of Montreal, specializing in the sale of Diesel engines.

W. A. Mather, M.E.I.C., has been appointed general manager of Western Lines of the Canadian Pacific Railway Company, at Winnipeg, Man. Prior to graduation from McGill University in 1908 with the degree of B.Sc., Mr. Mather served with the Canadian Pacific Railway Company during the summer months as axeman, tapeman, rodman and instrumentman at Rush Lake and Deception, Ontario. In 1909 he was instrumentman at Kenora, Ont., and transitman at Laggan, B.C. In 1910-1912 Mr. Mather was resident engineer at Winnipeg and Portage La Prairie, Man., and in 1912 became acting superintendent at Kenora, Ont. From January 1913 until December 1914 he was superintendent at Kenora. For the first six months of 1915 Mr. Mather was superintendent of district 1, Alberta Division, at Medicine Hat, Alta., and from June 1915 until October 1918 he was assistant general superintendent of the British Columbia District, being located at Vancouver, B.C. From then until November 1922 he was general superintendent of the Saskatchewan district at Saskatoon, and in December 1932 Mr. Mather was appointed general superintendent of the Alberta district at Calgary. In May 1933 he was brought to Montreal as assistant to the vice-president of the company.

Graham Kearney, M.E.I.C., has been appointed district manager of the English Electric Company of Canada, Limited, and its subsidiary, the Canadian Crocker-Wheeler Company Limited, at Montreal, Que. Mr. Kearney graduated from McGill University in 1911 with the degree of B.Sc., and was subsequently, until 1917, connected with the Canadian General Electric Company successively as apparatus salesman, agent at Prince Rupert and Victoria, and district sales engineer at Vancouver. Mr. Kearney then went to China as professor of electrical engineering at the Tangshan College of the Chiao Tung University, which position he held until 1919, when he joined the staff of Andersen Meyer and Company Limited, remaining with them until 1926 and holding the following appointments: 1919-1921, engineering sales work; 1921-1923, in charge of engineering sales Tientsin Branch office; 1923-1925, manager of Canton branch office, and 1925-1926, manager of Hongkong and Canton branch offices. Returning to Canada, Mr. Kearney joined the staff of the Canadian General Electric Company Limited, Montreal, being engaged on engineering sales. In 1932 Mr. Kearney was engaged in private practice in Montreal, and in April of the present year he went to Vancouver, B.C., as a member of the firm of Sawford and Kearney, electrical and mechanical engineers.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on October 19th, 1934, the following elections and transfers were effected:

*Member*

STEWART, Frederick Choate, B.A.Sc., C.E., (Univ. of B.C.), asst. engr., Greater Vancouver Water District, Vancouver, B.C.

*Associate Members*

BLAIR, Donald, (McGill Univ.), struct'l. designing engr., Department of National Defence, Ottawa, Ont.

CASTLEDEN, Geoffrey Percy, B.Sc., (Univ. of Sask.), asst. mechanic, Beattie Gold Mines, Duparquet, Que.

CLARK, George, dftsman., C.N.R. Winnipeg, Man.

DICKSON, Archibald, chief dftsman., Dominion Bridge Company, Calgary, Alta.

*Transferred from the class of Associate Member to that of Member*

LOVE, Alexander, B.Sc. (Eng.), (Glasgow Univ.), plant engr., Hamilton Bridge Company, Hamilton, Ont.

*Transferred from the class of Junior to that of Associate Member*

FRY, John Dawson, B.Sc., (McGill Univ.), engr., McDougall and Friedman, consltg. engrs., Montreal, Que.

GOODALL, Ernest Lorne, B.Sc., (McGill Univ.), res. engr., Provincial Paper Ltd., Port Arthur, Ont.

LAZENBY, Thomas William, sub-foreman, Project 37, Dept. National Defence, Kingston, Ont.

*Transferred from the class of Student to that of Associate Member*

BLACK, John Alfred, B.Sc., (N.S. Tech. Coll.), mill supt., Perron Gold Mines, Ltd., Amos, Que.

*Transferred from the class of Student to that of Junior*

ACHESON, Harry Ross Macdougall, B.Sc., (Univ. of Alta.), dftsman., Dept. Lands and Mines, Prov. of Alberta, Edmonton, Alta.

ADAMS, Eric G., B.Sc., (McGill Univ.), M.B.A., (Harvard Univ.), account executive, Cockfield Brown & Co., Montreal, Que.

BOWEN, John Alfred Clarke, (Univ. of Toronto), P.O. Box 294, Long Branch, Ont.

DOULL, Robert Morse, B.Sc., (McGill Univ.), asst. mgr., Construction Equipment Co. Ltd., and mgr., Gunite and Waterproofing Ltd., Montreal, Que.

SVARICH, John Paul, B.Sc., (Univ. of Alta.), 10564-98th St., Edmonton, Alta.

*Transferred from the class of Junior to that of Affiliate*

CHAUSSEE, Pierre Maurice, engr., elect'l. dept., Montreal Water Board, Montreal, Que.

*Students Admitted*

BLAIR-McGUFFIE, Malcolm Hugh, (McGill Univ.), 517 Pine Ave., Montreal, Que.

LOCHHEAD, John Starley, (McGill Univ.), 345 Ballantyne Ave. North, Montreal West, Que.

ROSE, Alexander, (McGill Univ.), 3806 Wilson Ave., Montreal, Que.

RULE, Albert Edward, B.A.Sc., (Univ. of Toronto), 100 Humbercrest Blvd., Toronto, Ont.

SMITH, Wilfrid Ewart, (Univ. of N.B.), 852 George St., Fredericton, N.B.

WIGDOR, Edward Irving, (McGill Univ.), 510 Wiseman Ave., Outremont, Que.

WONG, Henry G., (McGill Univ.), 1090 Chenneville St., Montreal, Que.

---

### Exposition of Power and Mechanical Engineering

The eleventh National Exposition of Power and Mechanical Engineering is to be held at Grand Central Palace, New York, on December 3rd to 8th, 1934, occurring simultaneously with the Fifty-Fifth Annual Meeting of the American Society of Mechanical Engineers. It is stated that the latest developments in power economy and machine efficiency will be revealed. From the generation of power, through its transmission, up to the final machines which manufacture the products, literally in every phase of mechanical industry, the pageant of mechanical engineering progress will be complete.

## Nominations

The report of the Nominating Committee was presented to and accepted by Council at the meeting held on September 21st, 1934. The following is the list of nominees for officers as prepared by the Nominating Committee and published for the information of all corporate members as provided by Sections 68 and 74 of the By-laws.

List of Nominees for Officers for 1935 as Proposed by the Nominating Committee

| | | |
|---|---|---|
| President: | Frederick A. Gaby, M.E.I.C. | Toronto. |
| Vice-Presidents: | | |
| *Zone "A" | E. V. Caton, M.E.I.C. | Winnipeg. |
| *Zone "C" | P. L. Pratley, M.E.I.C. | Montreal. |
| Councillors: | | |
| ‡Halifax Branch | H. S. Johnston, M.E.I.C. | Halifax. |
| ‡Saint John Branch | G. A. Vandervoort, A.M.E.I.C. | Saint John. |
| ‡Saguenay Branch | G. H. Kirby, A.M.E.I.C. | Riverbend. |
| ‡St. Maurice Valley Branch | B. Grandmont, A.M.E.I.C. | Three Rivers. |
| ††Montreal Branch | A. Frigon, M.E.I.C. | Montreal. |
| | E. A. Ryan, M.E.I.C. | Montreal. |
| ‡Ottawa Branch | A. K. Hay, A.M.E.I.C. | Ottawa. |
| | E. W. Stedman, M.E.I.C. | Ottawa. |
| ‡Kingston Branch | L. F. Goodwin, M.E.I.C. | Kingston. |
| †Toronto Branch | A. B. Crealock, A.M.E.I.C. | Toronto. |
| ‡London Branch | J. A. Vance, A.M.E.I.C. | Woodstock, Ont. |
| ‡Border Cities Branch | C. G. R. Armstrong, A.M.E.I.C. | Windsor. |
| | R. C. Leslie, A.M.E.I.C. | Windsor. |
| ‡Lakehead Branch | G. H. Burbidge, M.E.I.C. | Port Arthur. |
| ‡Saskatchewan Branch | R. A. Spencer, A.M.E.I.C. | Saskatoon. |
| | S. Young, A.M.E.I.C. | Regina |
| ‡Edmonton Branch | R. M. Dingwall, A.M.E.I.C. | Edmonton. |
| | H. R. Webb, A.M.E.I.C. | Edmonton. |
| ‡Vancouver Branch | A. S. Wootton, M.E.I.C. | Vancouver. |

*One Vice-President to be elected for two years.
‡One Councillor to be elected for two years.
†One Councillor to be elected for three years.
††Two Councillors to be elected for three years each.

*Additional Nominations*

Section 68 provides also that "Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot."

---

### Activities for Younger Members

The following notice received recently from the Calgary Branch of The Institute serves as an example of the manner in which many of the branches of The Institute are striving to interest the younger members. It is also in line with the thought expressed in the Editorial appearing in the October, 1934, issue of The Journal.

NOTICE

Calgary Branch

Younger members are invited to prepare short talks to be delivered in small groups at several of the General Meetings of the Branch during the coming season.

These talks will be in competition for a small prize or prizes, donated by a Member whose desire is to encourage contributions by the younger members.

The following rules govern:

1. Open to Corporate, Junior and Student members under the age of 30 years.
2. Competitors may choose any subject—preferably concerning work, research or hobby on which they have been personally engaged—not essentially technical, but desirably of an engineering nature.
3. Time of delivery not to exceed 10 minutes.
4. Notes permitted, but papers must not be read.
5. Notice of intention to compete to be in the hands of the Secretary not later than September 30th.

Analysis of Continuous Frames, by E. B. Russell. (*Ellison and Russell.*)
Principles of Mechanism, by C. E. Pearce. (*John Wiley and Sons, New York.*)
Die Castings, by H. L. Chase. (*John Wiley and Sons, New York.*)
Lighting Calculations, by H. H. Higbie. (*John Wiley and Sons, New York.*)
Design and Construction of Concrete Roads, by R. A. B. Smith. (*Concrete Publications Limited.*)

## BULLETINS

*Cut Gears*—A 12-page booklet received from the Hamilton Gear and Machine Company, Toronto, Ont., contains gear data required on enquiries or orders for cut gears and includes the recommended practice of the American Gear Manufacturers' Association.

*Packings*—The Canadian Johns-Manville Co., Limited, Toronto, have issued a 48-page booklet containing particulars regarding the various packings made by that company, and including a detailed list of packing recommendations for various services.

*Water Meters*—A series of five eight-page folders received from the Worthington-Gamon Meter Company, Harrison, N.J., gives information regarding their "watch dog" disc meters of the following types: Frost-proof model with open gear train and enclosed gear train; split case model with open gear train and enclosed gear train, and Model R disc meter. These water meters are made in ⅝, ¾ and 1 inch sizes.

*Gas Engines.*—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued a 6-page folder outlining the features, specifications and arrangement of type CG vertical gas engine.

*Packing.*—A 16-page booklet received from The Garlock Packing Company, Palmyra, N.Y., contains particulars of the Garlock Klozure used to retain oil and grease within a bearing and to exclude dust and dirt. A list of standard sizes is included.

*Concrete.*—The Portland Cement Association, Chicago, Ill., have issued a 48-page bulletin which contains a discussion of concrete bridge details, some of the subjects dealt with being abutment movements; wingwalls; bridge seats; bearings; expansion joints; prevention of seepage; wearing surfaces, etc.

*Gauging.*—A 28-page booklet received from Adam Hilger Limited, London, England, gives particulars and application of the Angle Dekkor and other optical tools for mechanical and engineering gauging and inspection.

*High Intensity Mercury Lamps*—A 4-page bulletin received from the Canadian Westinghouse Company contains particulars regarding the company's high intensity mercury lamp. The lamp is 12¾ inches long, 2 inches in diameter, consumes 400 watts, has an efficiency of approximately 35 to 40 lumens per watt, and is designed for an average of fifteen hundred hours. 240 volts are required in starting and 155 in operating.

## New Books of Interest to the Engineer

Building an Engineering Career, by C. C. Williams. McGraw-Hill, New York, 247 pp., $2.00. Primarily for college students. Describes what engineering is; the education necessary for and objective of engineering. The historical background and achievements in engineering.

The Design and Use of Instruments and Accurate Mechanism, by T. N. Whitehead. MacMillan Company, New York, 285 pp., $3.50. For those who use or design instruments such as clocks, precision lathes, carburetors and magnetos. Components of machinery for many industries. Treats with the theory of errors and general principles of design.

Engineers Sketch Book of Mechanical Movements, by T. W. Barber. E. and F. N. Spon Ltd., London, 6th edition, 355 pp., $4.50. Contains almost three thousand sketches of machines and machine elements of all kinds classified and indexed.

The Design and Construction of High Pressure Chemical Plant, by Harold Tongue. Chapman, Hall Ltd., London, 420 pp., 30s. Present status of high pressure commercial processes with details of the design and construction of major pieces of apparatus such as compressors, pipes, valves and fittings, etc.

Applied Acoustics, by H. F. Olson and Frank Wassa. Blakeston's Son and Co., Philadelphia, 430 pp., $4.50. Current practice in the field of electro-acoustics with the fundamental equations of sound developed and a description of microphones, telephone receivers and loud speakers, also a discussion of methods of calibration and fields of use.

Short Wave Wireless Communication, by A. W. Ladner and C. R. Stoner. Wiley and Sons Inc., New York, 384 pp., $3.75. Development of short waves, propagation, modulation and details of practical equipment used in modern practice. A final chapter on the ultra short wave field.

The Kinetic Theory of Gases, by L. B. Lock. McGraw-Hill, New York, 2nd edition, 687 pp., $6.00. Provides students and investigators with the classical and more modern aspects of the Kinetic theory. Suitable for text book or reference work.

Manufacture of Seamless Tubes, Ferrous and Non-Ferrous, by G. Evans. H. F. and G. Witherby, London, 187 pp., 40s. Concise description of the methods for making seamless tubing by rolling, drawing, extending and casting. Various processes and equipment also described.

Mathematical Treatise on Vibrations in Railway Bridges, by C. E. Inglis. MacMillan Company, New York, 203 pp., $7.50. Simple yet scientific formulae whereby the dynamic effects on bridges may be predicted with sufficient accuracy for practical requirements.

Heat, by J. M. Cork. Wiley and Sons Inc., New York, 279 pp., $3.00. Provides the advanced student with a survey of recent developments. Brief but complete with references to original papers.

Industrial Furnaces, vol. I, by W. Trinks. Wiley and Sons Inc., New York, 3rd edition, 456 pp., $6.00. Comprehensive exposition of the principles which underlie the design and operation of furnaces for heating and annealing metals. Discussed theoretically and practically.

Principles and Practice of Surveying, vol. II. Higher Surveying, by C. B. Breed and G. L. Hosmer. Wiley and Sons, New York, 4th edition, 603 pp., $3.50. Chiefly the conducting of topographic and hydrographic surveys, their control and details of methods used.

Cost Accounting and Control, by T. H. Sanders. McGraw-Hill, New York, 2nd edition, 517 pp., $4.00. Revised edition of "Industrial Accounting" brought up to date and including new problems introduced by government control of industry.

Loud Speakers (Theory, Performance, Testing and Design), by N. W. McLachlan. Oxford University Press, New York, 399 pp., $13.50. An aid to development and research in improving loud speaker design.

Mechanical Engineering Practice, by C. F. Shoop and G. L. Tuve. McGraw-Hill, New York, 2nd edition, 477 pp., $4.00. Reference text on experimental engineering. Discusses methods of mechanical measurement and the instruments used.

Power Plant Testing, by J. A. Moyer. McGraw-Hill, New York, 4th edition, 614 pp., $5.00. Details of approved methods of testing engines, turbines, boilers and power plant auxiliary machinery with descriptions of the apparatus used.

Design, Construction and Maintenance of Docks, Wharves and Piers, by F. M. DuPlat-Taylor. Ernest Benn, London, 2nd edition, 521 pp., 45s. The engineering commercial and managerial aspects of port works considered in a practical way.

Civil Engineering Handbook, by L. C. Urquhart. McGraw-Hill, New York, 885 pp., $5.00. Provides practising engineer with comprehensive book for reference. Divided into ten sections and pays particular attention to fundamental theory.

---

*Canadian Johns-Manville Co. Ltd.*, Toronto, have announced in a new 16-page booklet a new type of electrical conduit "Transite Conduit" which is made of asbestos fibre and Portland cement combined under high pressure. Particulars and dimensions of various sizes are listed, ranging from 2 inches to 6 inches in diameter and 5 and 10 foot lengths.

## A Statistical Study of the Power Equipment in Canada

*H. E. M. Kensit, M.E.I.C.,*
*Ottawa, Ontario*

Estimates of the total amount of power installed in Canada usually contain only certain standard items for manufactures, mines, public utilities and sometimes steam railroads. These practically covered the field up to say twenty-five years ago—they have covered it less completely every year since and they no longer cover more than a fraction of it. A statement of the total power installed in Canada should include the total equipment necessary to the nation for at least all major uses and if it does not it is incomplete. Let us consider the case for making such a statement inclusive of all uses.

First take motor traction, by far the largest use of all. The first impulse is to think that this should not be included in such a list, but since we include steam and electric railroads without question and motor traction has now gained so large a part of the freight and passenger traffic of both classes of railroads that these are severely affected, it is surely illogical to exclude a use that has now become an essential in modern business and conditions of life.

Next consider agriculture. Few people realize the immense amount of power required for this and no previous estimate appears to have been made. The greatest demand for power in agriculture is for tractors for drawing harvesters, combines, binders, threshing machines, etc., and for motor trucks and automobiles for transport, all of which are just as necessary to the farmer as stationary power is to the manufacturer.

Then there is the power equipment of the army, navy and air force —a small matter in Canada but a large one in many countries and in view of the growing mechanization of military and naval forces, an essential part of the national existence.

Similar remarks apply to the smaller but growing field of commercial aircraft. This has been providing regular passenger and mail services for some years and giving immeasurable assistance in the development of our northern areas by both these and freight service. As Lord Londonderry, Secretary of State in Great Britain, recently put it: "Flying, which so short a time ago seemed almost miraculous, has become a common and necessary part of the equipment of civilization." In Canada, in spite of our very high railroad mileage, it is claimed that seventy-five per cent of the area of the Dominion is not yet served by either rail or road.

Lastly we may speak of shipping—that is the equipment of power-operated ships and boats; shipping creates large land industries and is an essential part of the national life—much of it is occupied in internal and coast-wise traffic and in Canada in particular there is the large and entirely internal traffic on the Great Lakes, and on the principal rivers, where water routes frequently form an alternative to the more expensive railroad haul; the power of the ocean-going ships of 1,000 h.p. or more constitutes only about 16 per cent of the total Canadian registration.

These last four important uses of power, in addition to what has been termed above the standard items or uses, are all essential to our business and prosperity—they furnish extensive employment and make large demands on our fuel resources, and it is submitted that there is no logical reason to exclude them from any statement of the national power equipment.

There are also several other minor uses that are not included in any census but reach a considerable aggregate, such as building and construction; municipal power for pumping, road machinery, etc.; hand industries and repair shops; dredging; drilling for oil and water; plants in railway stations and yards; private plants in office and apartment buildings, institutions, colleges, hospitals, etc., which may be termed non-industrial power. Buildings and construction and municipal power are considerable items that should be stated separately; the remainder of the above items may be put together under the heading of "miscellaneous."

The only country that appears to have so far attempted any complete estimates on the above lines is the United States, where several have been published. The most complete are two papers by C. R. Daugherty* that may well be referred to by those interested in the subject. It is now desired to form, as nearly as possible, a complete or "all-in" estimate of the total power required for all applications in Canada.

On the above defined bases an estimate, prepared from official sources on all main items and agreed therewith as to minor items, of the total power installed for all purposes in Canada is shown in Table I below. This table is divided into two sections, the first including all the subjects or uses covered by census and the allied applications not included in any census, and the second showing the additional national uses, which constitute a much larger aggregate.

Throughout the following matter we are speaking entirely of installed horsepower, that is of the primary horsepower as rated by

---

*"Power Capacity and Production in the United States." Water Supply Paper 579, U.S. Geological Survey, 1928.

"Horsepower Equipment in the U.S." American Economic Review. September, 1933.

the manufacturer, not of actual use. The official censuses of manufactures, mineral industries and public utilities show the rated horsepower installed, that is the necessary equipment irrespective of the amount actually in use at any particular time, and it has been endeavoured to put all the other items on as nearly as possible the same basis.

Table I
Total Power Installed in Canada, 1932
(An "All-In" Table)

| | Census and allied uses | Primary horsepower | Per cent | |
|---|---|---|---|---|
| 1. | Manufactures | 1,463,000 | 8.0 | |
| 2. | Mineral industries | 195,000 | 1.1 | |
| 3. | Central electric stations | 6,529,000 | 36.1 | |
| 4. | Steam and electric railroads | 5,750,000 | 31.8 | |
| 5. | Agriculture | 3,453,000 | 19.1 | |
| 6. | Building and construction | 500,000 | 2.8 | |
| 7. | Municipal | 73,000 | .4 | |
| 8. | Miscellaneous | 125,000 | .7 | |
| | Sub-total | 18,088,000 | 100.0 | 21.8 |
| | Other Uses | | | |
| 9. | Army, navy and air force | 193,000 | | .2 |
| 10. | Commercial aircraft | 58,000 | | .1 |
| 11. | Ships and boats | 715,000 | | .9 |
| 12. | Motor traction | 64,000,000 | | 77.0 |
| | Grand-total | 83,054,000 | | 100.0 |

In the above table the items commonly included in statements of the "total power installation," viz. manufactures, mines and central stations, constitute only 10 per cent, or with the addition of railroads only 17 per cent, of the inclusive total, that is of the entire equipment required by the Dominion.

To make Table I of value, to make it satisfying, it is desirable to set forth the basis of each item therein, some because they seem so small and some because they seem so large, as follows:—

(1) *Manufactures.* The census of 1932 shows that excluding central stations, the total amount installed was 4,157,000 h.p. Of this electric motors operated by central station energy totalled 2,694,000 h.p. and this is included under central stations, so that the net primary power was 1,463,000 h.p.

(2) *Mineral industries.* The census of 1932 shows that the total amount was 924,000 h.p. Of this 637,000 h.p. was purchased from central stations, leaving 287,000 primary horsepower; 92,000 h.p. of this, used in manufacturing processes, was included in "Manufactures." The net primary horsepower was therefore 195,000.

(3) *Central electric power stations.* This is the total shown by the census for 1932.

(4) *Steam and electric railroads.* The annual reports of the Bureau of Statistics show the number of steam locomotives and the average tractive force in pounds, but do not give the horsepower. The formula used by the United States Bureau of Locomotive Inspection has been used for this purpose. To this there has been added 10,000 h.p. for electric railroads not included in the census of electric power stations. There is also a small amount for oil-electric locomotives.

(5) *Agriculture.* This item is so large that it will be well to describe the method of estimating it somewhat fully. The Census of Farm Facilities, 1931, lists the number of power producing units of each kind (including farmers' automobiles and trucks) but not the power rating thereof. The numbers of portable units as given by the census and the average horsepower as estimated by leading manufacturers are thus:—

| | Number | Average horsepower | Total horsepower |
|---|---|---|---|
| Automobiles | 321,276 | 58.4 | 18,750,000 |
| Motor trucks | 48,402 | 47.8 | 2,315,000 |
| Tractors | 105,269 | 27.0 | 2,840,000 |
| | | | 23,905,000 |

In addition to this there is estimated to be 24,000 h.p. in automotive combines and power equipment on harvesters and 682,000 h.p. in gasoline engines and electric motors, giving a grand total of 24,611,000 h.p. Some farmers have also developed small water powers but the amount of this is not known. This figure of nearly 25,000,000 h.p. for agriculture seems surprisingly high but except possibly to a small extent in the average horsepower per unit there appears no room for error. As regards the entry in Table I, to avoid duplication there has been deducted from this total the amount for automobiles and motor trucks, as these are included in registration returns and are therefore in the item for "Motor Traction," but not farm tractors which are not included in the registration, and there has also been deducted the amount for farmers' electric motors operated on purchased power and therefore included in the item for "Central Stations." The net amount shown in Table I is, therefore, made up of farm tractors, of automotive combines and harvesters and of gasoline engines, and totals 3,453,000 h.p., but the complete total is restated under the later heading for: "The Total Power in Separate Industries."

(6) *Building and Construction.* In Canada the Census collects no statistics of this and not even an estimate of the horsepower of plant employed therein is available. The Monthly Letter of the Canadian Bank of Commerce in June 1927 said:

> "In recent years building operations, the construction of roads and of power transmission lines and other work of similar character, have rightly been regarded as comprising a distinct industry, the importance of which cannot be over-emphasized. In 1926 construction of all classes exceeded in value of production every other industry except agriculture; it afforded employment for a great number of men—it provided for extensive use of mechanical equipment and it created a wide market for materials."

Many items might be added to the above extract; the construction of railroads and hydro-electric works with their power shovels, construction locomotives, cranes, stonebreakers, cement mixers, pile drivers, etc.—for example the vast equipment for the Queenston-Chippawa and Beauharnois Canals did not find its way into any census; construction of harbours, docks and wharves; contractors' woodworking and other shops, etc., etc. It is certainly too large and important an item to be omitted. The United States does not take a census of this either, but weighty estimates were from 6 to 10 million horsepower in 1929—say 8 million. Estimating for Canada pro-rata to population gives 660,000 h.p.—pro-rata to manufactures 585,000 h.p., and it appears that the figure may reasonably be taken at 500,000 h.p. Only a small part of this could be in use at the present time but it represents the equipment that is available for such work and that will be made use of as the business recovery gains momentum. It may be added that this figure represents only two per cent on the total of the first section of Table I.

(7) *Municipal.* Here again is a considerable amount of power that is not included in any census and for which there are no definite data—waterworks and sewage pumping (over 150 cities and towns use steam plants for this), road machinery, stone crushers, street sweepers and sprinklers, snow-plows, etc. It has been estimated at 5 per cent of the primary power for manufactures.

(8) *Miscellaneous.* A list of the principal items included under this heading was given in the introduction and it has been estimated at 110,000 horsepower.

Summing up regarding the first section of Table I, the only doubtful items, Building and Construction, Municipal, and Miscellaneous taken together amount to only 3.8 per cent of the total, and to only 0.8 per cent of the grand total—a trifling matter, but it is the aim to make this statement as nearly inclusive and correct as possible.

(9) *Army, Navy and Air Force.* The particulars for this item were obtained from the Department of National Defence. They include motor traction used by the defensive forces as this is not covered in the provincial registration of motor vehicles, but do not include purchased power as this is covered by the figure for central electric stations.

(10) *Commercial Aircraft.* This figure covers commercial and private aircraft and those lent by the Royal Canadian Air Force for commercial purposes. The record thereof is kept by the Department of National Defence.

(11) *Shipping.* This figure is obtained by summarizing the data in the Registry of Shipping of the Marine Department. About 94 per cent of the ships and boats registered therein were built in Canada and the great majority are clearly for local traffic.

(12) *Motor Traction.* The summary of registration figures issued by the Bureau of Statistics is the basis for number of vehicles, but this source does not give the horsepower. An approximate figure was obtained from manufacturers for the average horsepower of each class of vehicle such as passenger and taxi cars, trucks, motor-cycles, etc., and the total horsepower was obtained by the weighted average. It is thought that this must give quite a close approximation to the actual total.

### The Total Power Equipment in Separate Industries

As set forth in the foregoing explanatory notes to Table I, since that table shows the total installation in electric power stations and the total amount for motor traction in accordance with the registration records, to avoid duplication the figures for the leading industries do not show the total power equipment of each industry. To clarify this point as far as possible the total equipment for the three leading productive industries may be restated as follows. The first column includes purchased power in each case and for agriculture it includes power driven field machinery, which is equivalent to the stationary power for manufactures. The second column shows for agriculture the total power equipment including automobiles and trucks for transport, but no similar particulars are available for manufactures or mineral industries.

Total Equipment in Horsepower

| | Excluding Automobiles and trucks | Including Automobiles and trucks |
|---|---|---|
| Agriculture | 3,453,000 | 24,611,000 |
| Manufactures | 4,157,000 | ......... |
| Mineral industries | 924,000 | ......... |

Horsepower Per Capita

The population of the Dominion in 1932 was 10,506,000. Referring to Table I, items 1 to 4, which may be termed the regular or standard items, show an installation equivalent to 1.32 horsepower per capita—adding items 5 to 8, which are allied to and should be included with the regular items, the horsepower per capita rises to 1.72.

On the grand total for all items, including defensive forces, commercial aircraft, ships and motor traction, the figure becomes 7.9 h.p. per capita.

*The conclusion as to total power equipment is, therefore, that a modern nation such as Canada requires an installation of 8 h.p. per head of population to meet its normal requirements.* This, be it noted, is per head of population, not per "wage earner," these being less than 25 per cent of the total.

The foregoing has dealt entirely with the installed horsepower as classified by nature of use, and we may now consider the proportions of the various types of prime movers as set forth in the following Table II:

Table II
Types of Prime Movers, 1932

| | Installed horsepower in 1000's | | | |
|---|---|---|---|---|
| | Steam | Water power | Internal combustion | Total |
| 1. Manufacturing | 741 | 653 | 69 | 1,463 |
| 2. Mineral industries | 103 | 70 | 22 | 195 |
| 3. Central stations | 457 | 6,036 | 36 | 6,529 |
| 4. Steam and electric railroads | 5,740 | 10 | Small | 5,750 |
| 5. Agriculture | 57 | | 3,396 | 3,453 |
| 6, 7 and 8. (See Table I) | 413 | 147 | 138 | 698 |
| Sub-total | 7,511 | 6,916 | 3,661 | 18,088 |
| 9. Army, navy and air force | 129 | | 64 | 193 |
| 10. Commercial aircraft | | | 58 | 58 |
| 11. Shipping | 692 | | 23 | 715 |
| 12. Motor traction | | | 64,000 | 64,000 |
| Grand Total | 8,332 | 6,916 | 67,806 | 83,054 |

In the foregoing Table II, the sum of the water power used in the separate industries comes out a little less than the official figure at that date, so the latter will be substituted in the following summary for obtaining the percentages:

Summary of Table II

| Type of prime mover | Horsepower | Per cent |
|---|---|---|
| Steam | 8,332,000 | 10.0 |
| Water power | 7,045,000 | 8.5 |
| Internal combustion | 67,806,000 | 81.5 |
| | 83,183,000 | 100.0 |

In surveying the results shown in Table II, we should remember that they are for a country that is possessed of abundant water power and that has made exceptionally good use thereof—yet the water power plant is only 8½ per cent of the total for all purposes, and steam power, including railroads, accounts for only 10 per cent. It is the internal combustion engine, so little referred to in general discussions on the use of power, that supplies the vast majority of the indispensable power requirements of the nation—adding together all uses of these engines the total is nearly 68,000,000 installed horsepower or over 82 per cent of the grand total of power in Canada.

*The conclusion as to types of prime movers is therefore that in 1932 fuel plant (steam and internal combustion) constituted 92 per cent of the total installed in the Dominion.*

It is of course the case that if we consider the actual production and use of energy the situation is largely altered. If however we assume an average load factor of 70 per cent for water power (and with pulp and paper, electrochemical, electric steam boilers and other long hour uses it is about that), and an average load factor of only 15 per cent for fuel (including steam railways, motor traction, etc.), the energy produced by fuel plant in Canada would still be nearly two and a half times that produced by water power. It may be added that the assumed load factor of 15 per cent for fuel power covers all such plant in manufactures, mineral industries and central stations and that the "productive" or long hour portion of the traction load, such as taxis, buses, trucks and tractors, must possess quite a good load factor.

# BRANCH NEWS

## Border Cities Branch

*C. F. Davidson, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, S.E.I.C., Branch News Editor.*

The regular monthly meeting of the Border Cities Branch was held the evening of May 18th, 1934, in the Prince Edward hotel.

Mr. Sheppard, of the firm of Sheppard & Masson, architects for Windsor's new Federal building, was the guest speaker.

He gave a very interesting picture of the points that were given special consideration in the construction of the new Post Office, a part of the government's employment programme.

Prior to the letting of the contract, test borings were taken to a depth of 40 feet and concrete piles were chosen for the foundation. However, the contractor after driving a test pile with considerable difficulty took further borings to an approximate depth of 127 feet. This uncovered subsoil conditions that were not expected and after consultation it was decided to put in a concrete mat foundation. Another point that had to be taken into consideration was the difference in bearing values of the soil at one end of the building to that at the other.

Mr. Sheppard then went into details regarding the sources of the Canadian materials and how well they compare with imported material.

Heating, ventilation, lighting and power were all considered. Special mention of the network system (3-4 wire) being made, as this is the first use of this type of wiring in the Border Cities.

The structure is built with the idea of future floors being added. In this connection, the elevator penthouse is designed of steel so that it may be knocked down and reassembled at the new elevation.

Mr. Sheppard extended an invitation to visit the building in a body, which was heartily accepted.

The following Friday evening the group reassembled at the new Post Office, where they became acquainted with the mechanical brains in the penthouse which controls the elevator, the up-to-date details in the boiler room, and the modern heating and ventilating devices.

## Calgary Branch

*J. Dow, M.E.I.C., Secretary-Treasurer.*
*H. W. Tooker, A.M.E.I.C., Branch News Editor.*

Through the courtesy of the management of the Earl Grey Golf Club, the members of the Calgary Branch of The Institute were on Saturday afternoon, September 15th, 1934, privileged to hold their annual golf tournament, which consisted of a nine hole competition and putting contest for both ladies and gentlemen.

The day was fine and quite a good number of the members turned out to enjoy this ancient out-of-door sport.

The prizes, presented by Mrs. G. P. F. Boese, were won by the following members and ladies:

| | | |
|---|---|---|
| Best Gross Score (Nine Holes) | 1st | F. Hughes. |
| | 2nd | R. L. Bonham, A.M.E.I.C. |
| Best Net Score Men (Nine Holes) | 1st | R. S. Stockton, M.E.I.C. |
| | 2nd | B. Fessenden |
| Ladies | 1st | Mrs. F. Peel. |
| | 2nd | Mrs. R. L. Bonham. |
| Hidden Hole (Handicap) | | B. P. Townsend. |
| Putting (Men) | 1st | G. P. F. Boese, A.M.E.I.C. |
| | 2nd | G. H. Patrick, A.M.E.I.C. |
| (Ladies) | 1st | Mrs. H. B. Sherman. |
| | 2nd | Mrs. T. Lees. |

Following the completion of the contests, tea, provided by the kindness of the ladies, was enjoyed by all, and presided over by Mrs. G. P. F. Boese, assisted by Mrs. J. Hadden.

## Halifax Branch

*R. R. Murray, A.M.E.I.C., Secretary-Treasurer.*
*C. Scrymgeour, A.M.E.I.C., Branch News Editor.*

The first meeting of the 1934-1935 winter season activities of the Halifax Branch of The Institute was held on Friday evening, October 12th, 1934, at the Nova Scotia Technical College, when the members of that Branch had as their guests the engineering students who had graduated from Dalhousie and St. Mary's College, and were commencing their training at the Technical College.

The chairman, R. L. Dunsmore, A.M.E.I.C., addressed the meeting and outlined the proposals for the season's activities, and also expressed pleasure at the large attendance of the members of the local Branch at the first meeting of the season.

Included in the regular business which was brought up for the attention of the members, was a resolution which was passed, and which endorsed the amalgamation of the Association of Professional Engineers and the Branches of The Institute in each province. This was as follows:

> "That whereas the members of the Halifax Branch of The Engineering Institute of Canada consider it to be in the interest of all members of The Institute that renewed steps should be taken to effect the amalgamation of the associations of Professional Engineers in the various provinces, with the Branches of The Institute

in each province, linking these organizations into one provincial body in each case, with the ultimate object of the formation of a Dominion-wide body formed from the provincial units.

Be it therefore resolved that the Halifax Branch of The Engineering Institute of Canada go on record as supporting any movement toward uniting the engineering organizations in each province and ultimately throughout the Dominion of Canada, and that the Secretary of the Halifax Branch be instructed to convey by letter to the General Secretary an expression of support of the Halifax Branch to any movement with these objectives and further that the General Secretary be requested to present this letter to Council at their next meeting."

At the conclusion of the regular business, Professor F. R. Faulkner, M.E.I.C., welcomed the students of the Technical College as guests of The Engineering Institute of Canada at this meeting, and expressed the hope that the students in their progress through college and into the engineering world, would become members of The Institute and thereby gain much benefit to themselves and also strengthen the membership of The Institute.

At the conclusion of these addresses, motion pictures were shown relative to the manufacture of aeroplanes, shipbuilding and the manufacture of steel, all of which were both highly instructive and interesting, and were appreciated by both the members of The Institute and their guests.

An informal social gathering concluded what was unanimously voted a very successful meeting.

## Hamilton Branch

*Alex. Love, A.M.E.I.C., Secretary-Treasurer.*
*Reported by A. B. Dove, S.E.I.C.*

A meeting of the Hamilton Branch was held at McMaster University on the evening of September 18th, 1934. The speaker of the evening, Dr. L. R. Hess, M.B., F.C.A.P., is one of Canada's foremost X-ray practitioners, and has gained an international reputation in the science. The meeting was the first of the fall series and members of the Hamilton Chemical Association were the guests of the Branch. The lecture room was admirably suited for this lecture and demonstration and the seating accommodation was taxed to its limit, about one hundred and fifty being present.

Dr. Hess was introduced by Professor C. E. Burke, Dean of the Faculty of Science at McMaster.

Dr. Hess stated that in the early days of X-ray, due in the most part to the frailty of the equipment, the science was adaptable only to medicine. Moreover the possibility of exposure of the operator's person to the rays, and the attendant dangers, made the equipment most unsatisfactory for use in other than medical lines. The science has so advanced, however, that apart from its great use in medicine, the X-ray may be applied to spectoscopy, examinations of welds, castings, determination of plate thickness, and even in the examination of sealed boxes with the use of the photographic film or the fluoroscopic screen.

Using the projector, Dr. Hess explained by sketches and pictures the construction of the main types of X-ray tubes and the method of the generation of the rays. From a frail, high vacuum glass tube, dangerous to handle, and uncertain in its work and constancy, there had been evolved a perfectly shielded air or water cooled tube, practically leak proof, and comparatively easy to handle, operating at 200,000 volts. These tubes have a life up to one thousand hours under normal conditions.

Dr. Hess confined the lecture principally to industrial applications of X-rays. Defects which do not appear on the surface are readily visible on the X-ray photograph, and in welded pressure vessels, when the weld is under examination, it is quite often possible to determine the cause of the defect as well as the defect itself. Dr. Hess showed a number of slides illustrating many of the industrial applications of X-rays. In the field of archeology it was also playing an important part, for the Egyptologist had found that the precious mummies which fall apart on exposure to the atmosphere, could be safely studied by the assistance of X-rays without any damage to the ancient corpse.

The speaker demonstrated the use of the fluoroscopic screen for the examination of a great variety of objects such as steel, rubber, wood, glass, leather, soap, and even sealed packages.

He also explained the action of a very interesting machine called the "dosimeter" which measures the quantity or "dosage" of X-rays being given to a patient, and has means of giving warning to the operator when a certain quantity has been given. This machine, of course, is not an X-ray machine but it is the meter used in this particular science.

Professor Walker, of the Chemistry Department at McMaster University, and this year president of the Hamilton Chemical Association, thanked The Engineering Institute of Canada for the opportunity of hearing Dr. Hess speak and proposed a vote of thanks to the speaker. This was enthusiastically endorsed by those present.

H. B. Stuart, A.M.E.I.C., chairman of the Branch, who presided at the meeting, expressed his gratification at the large attendance. He invited all to partake of coffee and sandwiches served in an adjoining room

*V. S. Thompson, A.M.E.I.C., Branch News Editor.*

The Hamilton Branch met in the Science Hall, McMaster University, on Tuesday evening, October 9th, 1934, about seventy-five members and friends being present. H. B. Stuart, A.M.E.I.C., chairman of the Branch, opened the proceedings with a message of welcome to visitors, pointing out that the Branch at all times gladly shared its privileges with any who were interested in its work.

Professor W. H. McNairn, Professor of Geology at McMaster, introduced the speaker of the evening, Rev. Dr. E. M. Burwash, geologist of the Provincial Department of Mines. Dr. E. M. Burwash is a man of great versatility, holding degrees in Arts, Divinity and Philosophy. He is a distinguished geologist, and has published many articles on that subject; he has also written a book on theology. Under the Department of Mines he made surveys during the summer and in the winter conducted courses of lectures for prospectors.

In introducing the subject, "The Geology of the Gold Fields of Ontario," Dr. Burwash showed on a slide the extent of the Pre-Cambrian rocks in North America, and detailed the strata that go to make up this system. He explained the sequence of events that left the rocks as we find them to-day, describing the sedimentary, intrusive, metamorphic, granitic and other rocks. It was in the quartz dykes of the Pre-Cambrian system that gold was found. Early prospecting, and in fact that done to-day for the most part, was on the outcrops. Where mining had been successful on the surface, dykes were sometimes followed down to great depths, the well known Hollinger being sometimes described as five hundred mines in one, as that number of veins were worked from the one shaft.

Dr. Burwash showed many slides prepared from recent geological maps, showing the geological structure at the most important mining areas. He also pointed out that some areas were not producing gold in spite of the fact that their geology would indicate that they should. Unfortunately the dykes did not always bear gold or they had it in such small quantity that it did not pay to work. Much of the north land was overlain with boulder clay which prevented examination for gold bearing quartz, and a great amount of the precious metal was thus possibly hidden from us.

E. G. MacKay, A.M.E.I.C., moved a vote of thanks to the speaker for his address, the audience warmly endorsing this, and the meeting adjourned to a neighbouring room, where refreshments were served.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*
*J. E. Hawkins, S.E.I.C., Branch News Editor.*

The first meeting of the 1934-35 season of the Lethbridge Branch was held in the Marquis hotel on October 13th, 1934. This meeting, which took the form of a ladies night, was preceded by a dinner. During the dinner Mr. and Mrs. George Brown and their orchestra rendered several delightful musical numbers, while Messrs. R. S. Lawrence and Tom Smith rendered excellent solos.

At the conclusion of the musical numbers, chairman C. S. Donaldson, A.M.E.I.C., called upon Wm. Meldrum, A.M.E.I.C., chairman of the programme committee, to outline the programme that had been arranged for the season, which met with the hearty approval of the members.

The chairman having introduced the guests and visitors, who included Dr. Wyatt of the University of Alberta, then introduced the guest speaker of the evening, J. M. Wardle, M.E.I.C., Superintendent of the National Parks. As his lecture, Mr. Wardle gave a very interesting talk on the "Big Bend Highway" in British Columbia. The lecture was illustrated throughout with lantern slides and motion pictures, made by the National Parks Branch. The speaker stated that only about seven miles of the Big Bend highway remained to be constructed to complete the British Columbia portion of the Trans-Canada highway. The illustrations showed the difficulties under which construction is being carried out, and the manner in which these are being overcome.

At the conclusion of the lecture, and after questions had been asked and answered, N. H. Bradley, A.M.E.I.C., voiced the sentiments of the members as well as the ladies when he moved a hearty vote of thanks to Mr. Wardle.

After a short business meeting, all adjourned to the mezzanine floor where Mr. and Mrs. Donaldson were host and hostess for bridge for the remainder of the evening. While refreshments were being served the winners were announced, prizes being awarded to Mrs. C. Watson and Mr. H. W. Meech.

## Montreal Branch

*C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.*

The first meeting of the season was held at Headquarters on Thursday evening, October 4th, 1934, when through the kindness of Vickers Limited, the members of the Branch were privileged to witness a series of six films.

Two showed operations at the steel making works of the English Steel Corporation, two the trials of the Vickers supermarine "Sea Gull V" and the "Scapa" twin engine flying boat and the "Vildebeest" torpedo-carrying plane. Another two showed the construction and trials of the P. and O. steamer "Strathaird" and "Strathnaver" at the works of Vickers-Armstrong Limited at Barrow-in-Furness.

Problems Facing The Institute

On Thursday, October 11th, F. P. Shearwood, M.E.I.C., the President of The Institute, was the principal speaker, the subject of his address being "Some Problems Facing The Institute," in which he discussed various subjects of interest to the members such as administration, employment, membership and technical activities.

He also referred to his attendance at the Western Professional Meeting of The Institute and the Annual Convention of the American Society of Civil Engineers held in Vancouver this year, and his visit to the western Branches of The Institute.

The meeting closed with a short talk on "Important Details of Machinery and Structures Fabricated by Welding" by R. H. Findlay, A.M.E.I.C., mechanical engineer for the Dominion Bridge Company Limited., Lachine, after which refreshments were served.

Meeting of the Junior Section

The first autumn meeting of the Junior Section of the Montreal Branch was held on Monday evening, October 15th, at which the programme for the Fall session was outlined, after which Mr. C. E. Frost, assistant engineer with the Montreal Harbour Commissioners, gave a short talk on his impressions of Mr. Hurst's book "The Technical Man Sells His Services." This proved to be most interesting and provoked a lengthy discussion. Light refreshments were served at the close of the meeting.

Construction Equipment of the Hoist Operated Type

On Thursday evening, October 18th, C. C. Langstroth, A.M.E.I.C., of the Dominion Hoist and Shovel Company Limited, gave a paper on "Construction Equipment of the Hoist Operated Type," which dealt with features of design and their effect on the operation of full revolving cranes, locomotive cranes and continuous chain crawler shovel cranes.

Electrical Section Meeting

Wednesday evening, October 24th, saw the first meeting of the Electrical Section of the Montreal Branch under the new arrangement whereby this section would hold separate meetings of a highly technical nature on nights other than the regular Thursday meeting night.

The paper prsented on this occasion was "Grounds and Grounding," by S. H. Cunha, A.M.E.I.C., which proved to be very interesting and led to considerable discussion.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

Some fifty members of the Branch with their wives, friends and guests from the St. Catharine's Chemical Society visited Old Fort Niagara on September 28th, 1934, to view the restoration work which has been in progress for the last few years.

The "Old Fort" stands on the United States side at the mouth of the Niagara river, directly across from the little town of Niagara-on-the-Lake on the Canadian side, and undoubtedly many shots were exchanged between it and Fort George, which was General Brock's stronghold during the war of 1812.

Built in 1678 by LaSalle, under the name of "Fort Conti," it was the scene of alternate trading and fighting with the Indians and became important as the northerly end of the portage leading around the falls to the upper lakes. This portage route is now paved with concrete and may be followed by automobile to the southerly end at the town of LaSalle on the upper Niagara river.

The fort went through many vicissitudes under the French regime, being destroyed and re-built several times until, in 1759, the British captured it after the battle of LaForella. At that time, new stone block-houses and a central tower were constructed. The Treaty of Paris, in 1783, gave title to the United Colonies but it was not until thirteen years later that the British troops were finally withdrawn.

Since the battles of 1812, the old fort has been of little consequence and gradually fell into disuse and decay, with erosion from the river and lake Ontario threatening to destroy a major part of the property.

In the year 1924, the Men's Club of Youngstown with the assistance of William Wallace Kincaid obtained a grant of $22,000 from the War Department for restoration work. By 1927, twenty different local societies had banded together under the name of "The Old Fort Niagara Association" and since then, more than $500,000 has been expended in sea-walls and repairs to the buildings as well as replicas of many of the old-fashioned fittings.

Mr. Claude Hultzen, who has been in charge of the restoration, gave a most interesting address after dinner in which he told of the difficulties encountered in getting accurate information and in raising the necessary funds.

In the unavoidable absence of chairman W. R. Manock, A.M.E.I.C., the meeting was conducted by Paul Buss, A.M.E.I.C., our vice-president and councillor. E. G. Cameron, A.M.E.I.C., conveyed the thanks of the meeting to the speaker.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

The first noon luncheon of the Ottawa Branch was held at the Chateau Laurier on October 4th, 1934, with J. Grove Smith, Dominion Fire Commissioner, as the speaker. Alan K. Hay, A.M.E.I.C., chairman, presided, and in addition head table guests included His Worship the Mayor of Ottawa, P. J. Nolan, Tom Moore, R. E. Wodehouse, William Dickson, C. A. Bowman, A.M.E.I.C., T. J. Clark Reilly, Group Captain E. W. Stedman, M.E.I.C., J. Albert Ewart, A.M.E.I.C., J. E. N. Cauchon, A.M.E.I.C., and C. McL. Pitts, A.M.E.I.C.

Re-Housing a Nation

Mr. Smith spoke upon the subject "Re-Housing a Nation," and told the story of England's national housing policy. His address was illustrated with lantern slides.

Mr. Smith traced the history of national housing from the time of Charles the Second down to the present day. In 1858 the first Act was passed as a government measure dealing with the housing of the labouring classes.

The change in living conditions in Great Britain was exemplified by the statement that whereas in 1846 about 45 per cent of the population were urban in 1890 the proportion had increased to 80 per cent. As a result overcrowding had become a serious problem in all the larger industrial centres.

From the years 1900 to 1912 there were successive parliamentary inquiries into the housing problem. The Housing and Town Planning Act was enacted in 1909 and immediately twenty-three counties took steps to inaugurate town planning schemes. In 1912 a voluminous report was issued which has formed the basis of later action looking toward the betterment of conditions.

The Great War intervened but subsequently in 1919 the Housing Act was passed and further acts and amendments were passed later. A large number of houses were built under various schemes doing a great deal to alleviate slum conditions.

However, the very poor man has not been entirely provided for up to the present, as the type of houses generally built ranged in cost from about £286 to £350, with a rental value of from 9s to 13s per week. These houses were therefore available to the higher paid clerical and workingmen but not to those who were lower in the financial scale or who were on the "dole." It is estimated that about 6s 6d per week rental would be the limit for over a million people in Great Britain. It was hoped that these people would occupy the quarters vacated by those who would move into the new houses, but this has not developed.

In 1933 an Act was passed permitting local authorities to undertake a census of dilapidated slum districts in order to either effect repairs when such were advisable or to tear them down if it were not. The British people are, therefore, hopeful that within the next five years at least five millions of those people will be re-housed.

The problem was one which existed elsewhere than in England and the case of Poland was cited where there were probably more houses erected per capita in recent years than in any other country of the world. It was a problem that might have more adequately been dealt with in Canada, was the opinion of Mr. Smith.

## Peterborough Branch

*H. R. Sills, Jr.E.I.C., Secretary.*
*E. J. Davies, Jr.E.I.C., Branch News Editor.*

Annual Fall Outing

On Saturday, September 8th, 1934, about thirty brave and hardy members and friends of the Peterborough Branch ploughed through the mud and rain to the Rotary Boys' Camp on Clear Lake for the annual fall outing.

The rain spoiled the outdoor sports, so the afternoon was spent on indoor games and bridge. To compensate for the rain, poor partners and weak opponents, a very splendid dinner was prepared under the supervision of the camp director, Rotarian Doug. Loomis, to which all did ample justice.

After several speeches, and would-be speeches, we again attacked the mud and rain, and on arriving home decided that we had had a real jolly time.

## Sault Ste. Marie Branch

*H. O. Brown, A.M.E.I.C., Secretary-Treasurer.*

On Friday evening, September 28th, 1934. the fall opening meeting of the Sault Ste. Marie Branch of The Institute was held at the Windsor hotel. It was in the form of a dinner meeting with the chairman, E. M. MacQuarrie, A.M.E.I.C., in the chair.

Following the dinner and the usual general business, the evening was devoted to a discussion of some of The Institute problems as outlined in the President's address before the Branch on August 3rd.

A special committee with H. F. Bennett, A.M.E.I.C., as chairman lead the discussion. Three particular subjects were selected and each subject was introduced by a chosen member. These subjects were:

1. Relation of The Institute with Provincial Associations.
2. Administration.
3. Membership.

After a period of discussion on each subject a motion was presented and voted on by the members. From these motions the recommendations of the Sault Ste. Marie Branch was drafted and submitted to Headquarters in accordance with the wishes of the President.

# Preliminary Notice

## of Applications for Admission and for Transfer

October 24th, 1934

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

---

The Council will consider the applications herein described in December, 1934.

R. J. Durley, Secretary.

---

* The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

> The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

BERRY—THEODORE VICTOR, of 3007 West 36th Ave., Vancouver, B.C., Born at Clacton-on-Sea, England, Feb. 12th, 1897; Educ., B.A.Sc., Univ. of B.C., 1923. R.P.E. (Civil) of B.C.; Summers 1920 and 1922, asst. to supt., Dominion Construction Co.; Summer 1921, asst. on topographic survey, City of Vancouver; 1923-24, calculator and dftsman. on hydro-electric surveys and investigations made by J. G. G. Kerry, M.E.I.C., for the City of Vancouver; 1924-26, asst. in municipal engrg. dept., City of Vancouver. Varied experience in design and constrn. of various projects; 1926-30, asst. to W. H. Powell, M.E.I.C., engr., Greater Vancouver Water District. On location, design and constrn. of various projects, including Burwell, Palisade and Loch Lomond storage projects, Seymour Falls Dam, Vancouver Heights Reservoir, Boundary Road Supply Main, Vancouver to Westminster Supply Main, etc., and Aug. to Nov. 1930, asst. to G. M. Gilbert, A.M.E.I.C., on constrn. of English Bay Interceptor; Jan. 1931 to date, secretary-treasurer, Vancouver and Districts Joint Sewerage and Drainage Board, Vancouver, B.C.

References: E. A. Cleveland, W. H. Powell, J. R. Grant, G. M. Gilbert, F. V. P. Cowley, W. O. Scott.

NORTON—JOHN ARTHUR, of 21 Harvie Ave., Toronto, Ont., Born at Toronto, March 16th, 1909; Educ., Evening classes, Advanced Maths., Toronto Technical School. I.C.S. Mech. Engrg. Course; 1926 to date, with H. Griffiths & Company, Toronto—1926-1928 as estimator and designer, from 1928 in charge of all designing and engrg. on work undertaken by the company, including power house and steam distributor at the Can. Gen. Elec. plant at Peterborough. From June 1934 mech'l. supt. or supervising engr. at the North Toronto Sewage Treatment plant, in sole charge of this contract.

References: W. Storrie, J. F. MacLaren, I. H. Nevitt, F. M. Byam, D. Shepherd, D. Cameron.

TREMBLAY—SOLYME NEREE, of Montreal, Que. Born at Les Eboulements, Que., May 11th, 1889; Educ., 2 years, Laval University (surveying); Member by examination of the Corpn. of Prof. Engrs. of Quebec, May 1934; 1911-13, chainman, 1913-14, instr'man., twp. subdivision in Alta.; 1914-19, war service; 1919-21, asst., twp. subdivision in Abitibi, Que.;1 924-26, field engr. on constrn., Port Alfred Pulp and Paper Mill, Mercier Dam, for the Foundation Company; 1926-30, field engr., topographical surveys, location of transmission lines, expropriations, estimates, costs, etc., Gatineau Power Co.; 1930 to date, engr. for the Quebec Streams Commission, topog'l. surveys, ice studies, precise levelling, investigation on property damaged by flooding, etc.

References: O. O. Lefebvre, W. E. Blue, P. E. Bourbonnais, G. J. Dodd, G. G. Gale, S. F. Rutherford.

WINDER—JOHN, of 5400 Waverley St., Montreal, Que., Born at Roanoke, Va., U.S.A., June 27th, 1889; Educ., Evening classes, and Amer. Corres. Schools; 1905-15, with the C.P.R., 1909-15, elect'l. constrn. and mtce., testing and inspection, and 1910-13, telephone equipment mtce. and inspection; 1915 to date, with Molson's Brewery Ltd., 1916-20, elect'l. constrn. and buying of materials, 1920-34, elect'l. constrn. and laying out of new work, mtce. of elect'l. equipment, at present chief electrician and elect'l. engr.

References: J. A. Shaw, J. W. Hughes, G. S. Clark, W. R. Bunting, S. G. Macdermott, C. P. Creighton, G. K. McDougall.

### FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

BERRY—ALBERT EDWARD, of 235 Gainsborough Road, Toronto, Ont., Born at St. Mary's, Ont., Oct. 6th, 1894; Educ., B.A.Sc. 1917, M.A.Sc., 1921, C.E. 1923, Ph.D. 1926, Univ. of Toronto; 1915-16 (summers), gen. engrg. and contracting; 1917 (6 mos.), Ontario Department of Health; 2 years, overseas. Lieut., R.E.; 1919-26, sanitary engrg. asst., and 1926 to date, director, sanitary engrg. divn., Ontario Department ofHealth. (*A.M. 1921.*)

References: C. R. Young, R. E. Smythe, W. B. Redfern, R. O. Wynne-Roberts, G. G. Powell, W. Storrie.

COLHOUN—GEORGE A., of 84 Dalewood Crescent, Hamilton, Ont., Born at Sparta, Elgin Co., Ont., Dec. 23rd, 1881; Educ., Grad., S.P.S., Univ. of Toronto, 1906; 1906 to date, with the Hamilton Bridge Company as follows: 1906-10, dftsman., 1910-14, checker, 1914-21, designer, 1921-29, asst. to designing engr., and 1929 to date, designing engr., in charge of designing and estimating department. (*A.M. 1919.*)

References: R. K. Palmer, E. H. Darling, H. B. Stuart, A. Love, F. W. Paulin, W. G. Milne.

MOUNT—WILFRED ROWLAND, of 11408-100th Ave., Edmonton, Alta., Born at Reading, England, Dec. 5th, 1888; Educ., 1905-08, Camborne School of Metalliferous Mining, Cornwall, England (Certs. in all subjects); 1908-10, practical experience in several mines in Cornwall in the various branches of mining, metallurgy, surveying, assaying, etc ; 1910-11, surveyor and assayor, Broomassie Mines Ltd., Gold Coast Colony, West Africa; 1911-13, office and Instruments, etc., Can. Nor. Rly. (Alberta), Dom. Land Survey, Alberta Land Survey; 1913-14, instruments, engrg. dept., City of Edmonton; 1914-19, overseas, Royal Engrs. Major, M.C.; 1919 to date, general asst. and res. engr., City of Edmonton, Alberta. (*A.M. 1921.*)

References: D. Lyell, R. J. Gibb, E. Stansfield, C. A. Robb, A. W. Haddow.

### FOR TRANSFER FROM THE CLASS OF JUNIOR

HALL—STEWART WILLIAM SHERIDAN, of 393 Montrose Ave., Toronto, Ont., Born at Toronto, Nov. 10th, 1900; Educ., B.A.Sc., Univ. of Toronto, 1928; Summer work, carpenter foreman and transitman; 1927 (summer), engr's inspr., C. D. Howe & Co. Ltd., Port Arthur, Ont.; 1928 to date, plan examiner, city bldg. dept., Toronto, Ont., checking the design of various bldgs., architecturally and structurally. (*Jr. 1929.*)

References: L. A. Badgley, L. A. C. Lee, A. H. Harkness, G. L. Wallace, W. S. Wilson, R. E. Smythe.

### FOR TRANSFER FROM THE CLASS OF STUDENT

CARVER—STANLEY COX, of Victoria, B.C., Born at Leeds, England, Jan. 25th, 1907; Educ., B.A.Sc. (C.E.), Univ. of B.C., 1929; 1927, asst. instr'man., 1928, chief asst. instr'man., Topog'l. Dept., Ottawa; 1929-32, designing dftsman and checker, Western Bridge Co. Ltd., Vancouver, B.C., detailing, checking, designing and estimating, rly. and highway bridges, steel framed bldgs., hydro-electric equipment, piers, warehouses and gen. struct'l. work; 1933 to date, asst. designing engr., Fleming Bros., Struct'l. Engrs., Glasgow, Scotland, and London, England. (*St. 1927.*)

References: J. A. McFarlane, W. H. Powell, F. S. Gumley, R. W. Brock, A. E. Foreman, A. S. Gentles.

WISHART—WILLIAM DONALD, of Camp Borden, Ont., Born at Portage la Prairie, Man., Jan. 19th, 1907; Educ., B.Sc. (E.E.), Univ. of Manitoba, 1931; 1931 to date, Lieut., Royal Canadian Corps of Signals. (*St. 1932.*)

## EMPLOYMENT SERVICE BUREAU

**The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.**

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**

**2050 Mansfield Street, Montreal**

## Situations Wanted

ESTABLISHED SALES ENGINEER. Univ of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections witb automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, Canadian, witb technical training and executive experience in hoth Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for husiness expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, Frencb, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on tbe sale of beavy machinery. Apply to Box No. 142-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial huildings, office huildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257 W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power bouse equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

ELECTRICAL ENGINEER, B.Sc., A.M.E.I.C., Am.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.Sc. and C.E.; A.M.E.I.C., Jun. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of bydro-electric, railway, and aerodrome works. Also office and teaching work on bydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.Sc. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.Sc. Age 28, married. Four and a half years on industrial plant maintenance and construction, including shop production work and pulp and paper mill control. Also two and a balf years on structural steel and reinforced concrete design. Available at once. Apply to Box No. 521-W.

CIVIL ENGINEER, Canadian, married, twenty-five years' tecbnical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.Sc., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and bighway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern wbere the combination of tecbnical and business experience will he of value. Apply to Box No. 564-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

## Situations Wanted

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.Sc., University of Alberta, '30. Age 31. Single. Six seasons' practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical cbemistry; three years' experience teaching. Desires position in any industry witb chemical control. Available immediately. Apply to Box No. 609-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of bydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

### Time Study Work

Enquiries are received from time to time for engineers, particularly young men with mechanical training, experienced in, or having a knowledge of, time study methods and procedure.

If you have qualifications of this nature you should not neglect to forward details to The Institute Employment Service Bureau.

ELECTRICAL ENGINEER, B.Sc. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box No. 651-W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave heam transmission engineering. For further information apply to Box No. 680-V.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power bouse and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, beating and power boilers, hoiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

## Situations Wanted

ELECTRICAL AND CIVIL ENGINEER, B.Sc., Elec., 29, B.Sc., Civil '33. Age 27. Jr.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Availahle immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoha, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or tbe west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.Sc., University of N.B., '31. Experience includes three months field work with Saint John Harhour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Higbest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), witb experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.Sc. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of hridges and huildings. Available at once. Apply to Box No. 729-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turhines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.Sc., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc. '31, S.E.I.C. Age 27. Experience in installation of power and ligbting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.Sc. '29, A.M.E.I.C. Married. One year huilding construction, one year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on barbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

SALES ENGINEER, B.Sc., McGill, 1923, A.M.E.I.C. Age 33. Married. Extensive experience in building construction. Thoroughly familiar with steel building products; last five years in cbarge of structural and reinforcing steel sales for company in New York state. Available at once. Located in Canada. Apply to Box No 749-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general huilding, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, B.Sc., '25, Jr.E.I.C., P.E.Q., married. Desires position, preferably witb construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

## Situations Wanted

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, S.E.I.C., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No 795-W.

CIVIL ENGINEER, S.E.I.C., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, B.E. (Sask. Univ. '32), S.E.I.C. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, B.SC., A.M.E.I.C., with fifteen years experience mostly in pulp and paper mill work, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

CIVIL ENGINEER, B.A.SC., D.L.S., O.L.S., A.M.E.I.C., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, S.E.I.C., B.SC. '32 (Univ. of N.B.). Age 25. married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, B.SC. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W

MECHANICAL ENGINEER, JR E.I.C., Technical graduate, bilingual, age 32. Eight years experience in design of boiler plants; steam, water and gas piping; heating, ventilating, air conditioning and plumbing systems; writing of specifications and technical translation. Experience includes: two years in engineering department of large company, five years with consulting engineers and one year on large piping and construction projects Available at once. Apply to Box No. 850-W.

BRIDGE AND STRUCTURAL ENGINEER, A.M.E.I.C., McGill. Twenty-five years' experience on bridge and structural staffs Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, B.A.SC., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, B.SC. '32, S.E.I.C. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere Apply to Box No 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience B.O.T certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, B.SC. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED, Young engineer, B.A.SC. in C.E., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, A.M.E.I.C. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

ELECTRICAL ENGINEER, Dipl. of Eng., B.SC. (Dalhousie Univ.), S.B. and S.M. in E.E. (Mass. Inst. of Tech.), Canadian. Married. Seven and a half years' experience in design, construction and operation of hydro, steam and industrial plants. For past sixteen months field office electrical engineer on 510,000 h.p. hydro-electric project. Available at once. Apply to Box No. 936-W.

CIVIL ENGINEER, B.SC., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, B.SC. (Univ. of Sask. '33), S.E.I.C., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street, improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, S.E.I.C., B.SC., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

CIVIL ENGINEER, B.SC. (Queen's 14), A.M.E.I.C., Dominion Land Surveyor, 5 months' special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.A.SC. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, B.SC. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, age 27, graduate 1930, single. Experience includes detailing, designing and estimating structural steel, plate work and pressure vessels; also hydrographic surveying. Available at once. Apply to Box No. 1111-W.

ELECTRICAL ENGINEER, B.SC., in E.E. (Univ. of N.B. '34), S.E.I.C. Experience in bridge and road construction and auto repairing, desires position in industrial or power plant. Any locality. References on request. Apply to Box No. 1114-W.

CIVIL ENGINEER, B.SC., Sask. '30. S.E.I.C. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, B.SC.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, D.L.S., M.E.I.C. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box No. 1127-W.

PETROLEUM CHEMIST, B.SC. in Chem. Eng. Age 25, Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. B.SC., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal. but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, B.A.SC., S.E.I.C., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No 1207-W.

MECHANICAL ENGINEER, B.SC. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

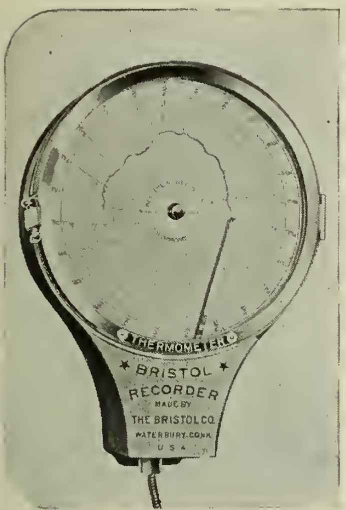
# Ship your Old Recorders
## *to our Service Laboratory*



*Original Form Recording Thermometer, Model 210*

Old Bristols' Recorders are still good as gold—worth real money to you. Ship them to our Service Laboratory. Let us recondition them—and give them a new lease of life so they will be good for many more years of service.

Be sure to pack carefully. Also mail shipping notice and order authorizing work.

## THE ENGINEERING INSTITUTE LIBRARY

An excellent collection of engineering literature is to be found in the library of The Engineering Institute, 2050 Mansfield Street, Montreal, Que.

This comprises some five thousand volumes, and nearly two hundred technical journals and magazines are received regularly.

A list of information readily available on any desired subject can be furnished on request. Technical books are loaned for a period of two weeks or longer if required, on deposit of $5.00 per volume. This deposit is refunded on return of the book to the library.

The library is open from 9 o'clock a.m. to 5 o'clock p.m. and the reading room from 9 o'clock a.m. to 9 o'clock p.m. On Saturday the hours are 9 a.m. to 1 p.m. and 9 a.m. to 6 p.m.

## INDEX TO ADVERTISERS

# THE EMPLOYMENT SERVICE
## OF THE
# ENGINEERING INSTITUTE OF CANADA

**You can assist us . . .**

Do you know of any firm or individual who requires the services of an engineer or has an opening in his organization that can be filled by an engineer?

If so, remind him of, or advise the Employment Service of the Engineering Institute of Canada. This service is maintained to assist, without cost, members and employers to locate experienced engineers in all branches of the profession.

**Now** is the time to solve personnel problems. Engineers are available in all parts of Canada.

**Address communications to:**

**2050 Mansfield Street, Montreal**

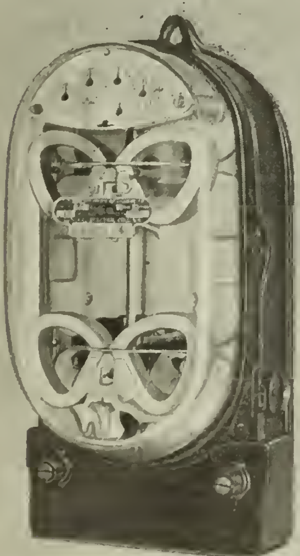
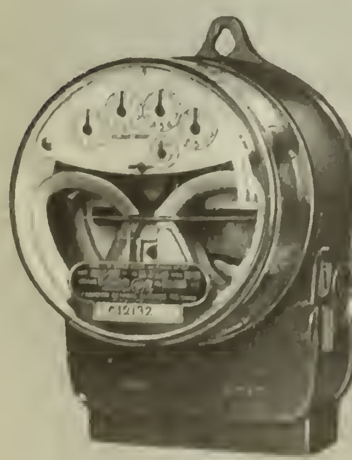
DISTRIBUTION TRANSFORMERS
PORCELAIN-HOUSED CUTOUTS
PELLET LIGHTNING ARRESTERS



D-14 POLYPHASE
WATTHOUR METERS



I-16 SINGL. HASE
WATTHOUR METERS

## DISTRIBUTION TRANSFORMERS

The "Perfection of Detail" built into G-E transformers pays dividends not only to the consumer, but also to power companies in the form of minimum outages, freedom from maintenance and longer life.

●

## PORCELAIN-HOUSED CUTOUTS

Increased insulation comparable in dielectric strength with that of other parts of modern distribution systems - - Increased current ratings of the smaller cutouts making them suitable for use with larger transformers - - Increased interrupting capacity making possible the use of these cutouts where short-circuit duty is a prime consideration, are three outstanding features of G-E wet process porcelain housed cutouts.

●

## PELLET LIGHTNING ARRESTERS

For best protection every transformer should be protected by a G-E Pellet Lightning Arrester. The reliable performance of these arresters together with advanced methods of installation, provides practical immunity from lightning troubles, justifying individual protection of every distribution transformer - - from the smallest to the largest.

●

## WATTHOUR METERS

More load per residential consumer means more load variation per meter. The "slow" error of the older meters on even present-day peak loads is such that a load-building program can easily build a high percentage of lost revenue. Only modern meters, with their long-range accuracy, will yield all of the revenue from today's and tomorrow's peaks.

# THE ENGINEERING JOURNAL

VOL. XVII No. 12

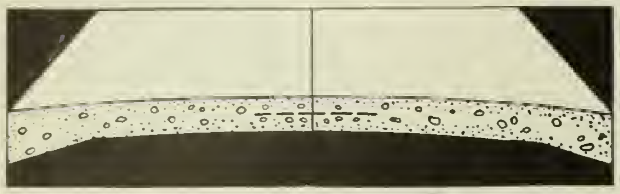
DECEMBER 1934

## *In this issue*

PUBLISHED MONTHLY BY

THE ENGINEERING INSTITUTE *of* CANADA

# Accurate design of highways —pays!



$$\delta = \frac{1.92\,w}{d^2}$$

$$d^2 = \frac{1.92\,w}{\delta}$$

$$= \frac{1.92 \times 8000}{350}$$

$$d = 6.7$$

OVER-DESIGNED pavements are wasteful of highway funds because the extra strength is not used.

Under-designed pavements require excessive maintenance. Excessive maintenance may accumulate until it consumes the entire highway fund, leaving nothing for new construction.

What traffic will Route 4 have to carry if a new concrete pavement is laid?

Should Route 4 have a 10—6.7—10 section . . . or will a 7.5—5—7.5 section last indefinitely under anticipated traffic?

Questions such as these may be answered simply and definitely by means of these two books.

*"Short Count Traffic Surveys"* by Dr. Miller McClintock, Director of the Erskine Traffic Bureau of Harvard, tells how to make traffic surveys by a new low cost method and how to present and interpret them.

*"Concrete Road Design Simplified and Correlated with Traffic"* by Frank T. Sheets, offers short-cut methods for computing pavement stresses.

From the standpoint of the public, concrete is the standard by which all roads are judged. From the standpoint of the engineer, concrete is the one material which permits pavements to be designed —as are bridges, buildings and other engineering structures—to carry anticipated loads.

Either or both of the above books will be sent to you free of charge on request.

# Photoelastic Determination of Temperature Stresses in an Arch Bridge Model

*Z. Levinton, S.E.I.C.,*

*University of Saskatchewan, Saskatoon, Sask.*

SUMMARY.—After a brief account of the photoelastic method of determining stress by polarized light, the paper describes a series of tests on a bakelite model of an arch of the Broadway bridge at Saskatoon, made to ascertain the stresses in the arch ribs and columns due to change of temperature. The experimental results are compared with those obtained by calculation.

During the past few years experimental methods of stress analysis have become prominent in the solution of many engineering problems. Among these methods photoelasticity has been developed as a powerful tool in determining stress concentration in structural members and machine parts of a complicated character which cannot be readily treated theoretically, such as plates with holes, notches and other discontinuities, hooks, chain links, gears and screw threads.

In the field of concrete construction many indeterminate structural forms are being introduced which present difficulties in stress analysis, and in important structures it is highly desirable that theoretical stress analysis be supplemented by some experimental method for determining the validity of the theoretical assumptions involved, as well as for a check on the accuracy of the voluminous computations.

It was with this view in mind that the author undertook the solution of temperature stresses in the new Broadway bridge at Saskatoon, when the problem was suggested to him by the designer, Dean C. J. MacKenzie, M.E.I.C., of the University of Saskatchewan. The characteristics of the design and construction of the bridge are described in an article published in the January 1934 issue of The Engineering Journal.

Among the peculiar features in the design was the consideration of the effect of temperature changes on the structure. To relieve the excessive temperature stresses the deck of the structure was cut over each pier, and each arch with its superstructure of columns and deck considered separately and analysed by means of the elastic theory. The temperature stresses in the arch rib were calculated by first considering the rib alone, then allowing for the effect of the superstructure. The latter effect was estimated with the aid of the experimental results obtained by Professor W. Wilson of the University of Illinois from a series of experiments on models of arch bridges with various degrees of rigidity and of various geometrical proportions.

The temperature stresses in the end columns directly supported by the piers were readily calculated by assuming that the expansion of the deck deflected the tops of the end columns horizontally, the stresses in which were obtained by then treating the columns as deflected cantilevers with both ends restrained from rotation. In the case of the spandrel columns, however, the conditions are too complex for satisfactory theoretical treatment. The top of a spandrel column is deflected and rotated due to the expansion and warping of the deck and its base is rotated due to the rise and rotation of the arch rib. Certain assumptions could be made as to the combined effect of the deck and the arch rib upon the spandrel columns, but the validity of those assumptions could not be well proved.

To solve the problem the author proposed to make a bakelite model of one span, to subject it to temperature stresses by heating it in a chamber with heating elements and to determine the stresses by the photoelastic method. The largest arch, of 186-foot span and 47-foot rise, was selected for this purpose.

### THE PHOTOELASTIC METHOD

Photoelasticity, as the name implies, is the correlation of the laws of optics and elasticity and their application to problems of stress analysis. The basic phenomenon of photoelasticity is that of double refraction produced by stress. It was discovered by Brewster, in 1816, that when a ray of polarized light passes through a glass plate under stress, the ray breaks up into two rays vibrating in the directions of the principal stresses in the plate. The two rays propagate in the plate with different velocities and emerge as an elliptically polarized ray with a phase difference proportional to the difference between the two principal stresses at the point of passage of the ray and to the thickness of the plate. The law is expressed by the equation $R = C\,(p - q)\,t$, where $R$ = phase difference, or relative retardation of the rays, $p$ and $q$ = principal stresses, $t$ = thickness of the plate, and $C$ = constant depending on the material of the plate and the wave length of the light. When the elliptical light issuing from the stressed specimen is passed through an analysing Nicol prism, which transmits vibrations in one plane, the emerging light is made up of two coplanar waves which interfere. The effect of interference is that of colours when white light is used and dark bands when monochromatic light is used. With increasing stress the colours change, following approximately Newton's scale of colours, and repeat themselves in higher orders. Thus there are yellow, red and green of the first order; yellow, red and green of the second order, etc. Points in the stressed plate where the stress difference $(p - q)$ is the same will form a band of colour, or "isochromatic," corresponding to that stress difference. Both tension and compression give the same colours for equal numerical values of stress.

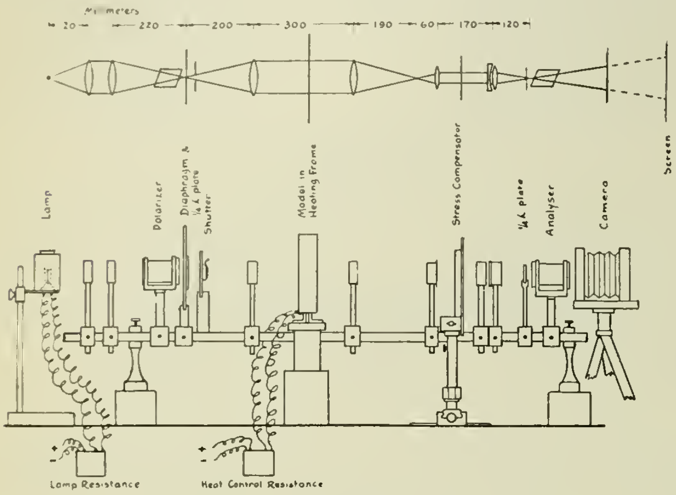

**Fig. 1—The Optical Set.**

The stress values of the isochromatics can be determined by comparison with the isochromatics of a simple specimen, such as a beam, where the stress distribution is thoroughly understood.

The stress difference at a point in the plate can be also determined by the "method of compensation" which consists in introducing the comparison beam or tension piece in series with the stressed plate and applying stresses until the total effect is zero and a dark spot occurs at the point. This is the "point of compensation" and the value of $p - q$ in the plate is equal to the known stress in the compensating piece. By proper orientation of the latter with respect to the directions of the principal stresses in the plate, it is possible to determine the sign of $(p - q)$, i.e. to distinguish between tension and compression.

To find the directions of the principal stresses in a plate, a "method of isoclinics" has been proposed by Clerk Maxwell and later developed by Filon, Coker and others. To obtain the separate values of $p$ and $q$, Coker (1)* devised a lateral extensometer and Filon (3) developed a mathematical method of graphical integration.

In many instances, such as in the present problem, it is obvious that the maximum stresses are at the extreme fibres, or boundaries. In such cases there is no necessity for stress separation, since at a free boundary there can be only one stress tangential to it, i.e. either $p$ or $q$ is zero.

From the discovery of the photoelastic law by Brewster until the beginning of the present century, glass was the only material available for the study of photoelasticity. The discovery of celluloid, bakelite and phenolite gave a new impetus to research. The ease of shaping into models and the higher stress-optical sensitivity of the new materials made possible the application of the method to many problems and greatly increased its accuracy. Ziro Tuzi (5) used phenolite in his photographic and kinematographic "fringe method." Frocht (11) further developed kinematography with monochromatic light and bakelite models. Solakian (7) successfully used the photographic method with white light. A commercial method is described by Baud (8). A new optical method of stress separation is due to Favre (6). The petrological microscope has been adapted to photoelastic work by Hall (12).

*Numbers refer to bibliography at end of paper.

### The Optical Apparatus

The optical set shown in Fig. 1 was assembled by the author from Nicol prisms, lenses and quarter wave plates supplied by the Physics Department of the University of Saskatchewan. Two ¾-inch steel shafts for the optical bench. The lenses, diaphragms, Nicols, etc., are attached to iron bars riding on the shafts. The various parts can be moved along the bench and clamped in positions determined by the focal lengths and diameters of the lenses and by the apertures of the Nicol prisms.

In the arrangement in Fig. 1 the Nicols are set with their axes crossed and the axes of the quarter wave plates are at right angles to each other and at 45 degrees to the axes of the Nicols. The light from a tungsten ribbon projection lamp is converged through the polarizer, the plane polarized beam passes through a diaphragm with a ⅛-inch hole and through a quarter wave plate. The emerging light is circularly polarized. The stressed model is placed in the path of parallel beam of circular light. The circular light becomes elliptically polarized due to the stresses in the model. The light further passes through the second quarter wave plate which cancels the effect of the first plate and the phase difference of the light passing through the analyser is entirely due to the stress difference in the model. The interference colours are projected on the glass screen where the isochromatics can be observed and traced on paper. For photographic work a camera with its lenses removed is placed close to the analyser. The shutter of the camera is placed in a convenient place in the system as shown in the figure.

The stress compensator shown in Fig. 2 is a dynamometer by means of which a known stress can be applied to a beam made of the same material as the model. This compensator is capable of horizontal and vertical motion and rotation about a vertical and horizontal axis, which enables one to place the compensating beam in various positions corresponding to the stress directions at the points of the model studied.

### The Model

The material used for the model was bakelite C-25 in sheets 7 by 12 by ¼ inches. The sheet was ground on both sides with emery powders and polished with white rouge. This treatment gave a sheet of good transparency and quite uniform thickness.

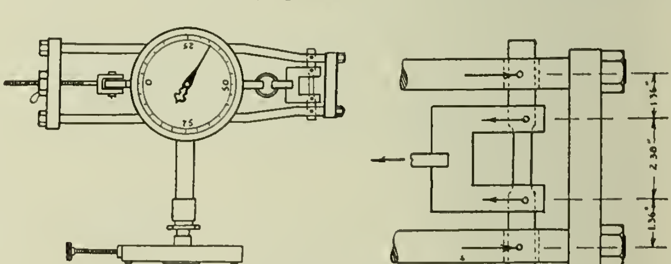

**Fig. 2—The Stress Compensator.**

In calculating the dimensions of the model the following principle of similarity had to be considered. The distortion of the model under stress must be similar to that of the structure. To obtain the above condition it is necessary (1) to have the centre lines of the model form a figure geometrically similar to that of the gravity axes of the members of the structure, and (2) the relative stiffness of the members of the model must be proportional to the relative stiffness of the members of the structure. The stiffness of a member is measured by the ratio $I/l$ where $I$ = moment of inertia of its cross section and $l$ = its length. With the thickness of the model of 0.240 inch throughout, it was necessary to adjust the widths of the arch ring, the columns and the deck to give moments of inertia in accordance with the requirements of similarity. The dimensions of the model, shown in Fig. 3, are 6 by 12 inches including the piers.

**Fig. 3—The Model.**

The centre lines and boundaries of the model were scratched on the bakelite sheet by means of a scriber attached to a micrometer vernier reading to 1/1000 of an inch. The model was first cut roughly to shape leaving about 3/32 of an inch of material around the boundaries. From the same sheet as the model, tension pieces and a beam were cut and filed roughly to shape.

The model and the accessory pieces, when examined in the polariscope, exhibited considerable initial stresses and annealing was necessary. Accordingly, they were placed between two glass plates with sheets of paper between the glass and bakelite. The glass plates with the model between were buried in fine silica sand in a pan, with about 2 inches of sand on all sides of the plates. The pan was placed in a hot air constant temperature oven. The temperature was raised to 175 degrees F. and kept constant for one and a half hours to ensure penetration of the heat through the sand and glass. The oven was then allowed to cool to room temperature for a period of sixteen hours. After the annealing, the examination in polarized light revealed very slight initial stresses left in the material. After annealing the model was finished with fine files to the boundaries and carefully measured with micrometer calipers. The variation in width of the members when finished was about 2/1000 inch.

The model was placed in the heating frame and the piers protruding below the frame were firmly bolted to two iron bars with serrated surfaces, as shown in Fig. 4. While the iron bars were at constant room temperature and held the piers in place, the superstructure could expand and undergo distortion due to the rise of temperature in the frame. The latter was heated by three heating elements in which the current was controlled by means of a resistance. Direct radiation from the elements was prevented by tin baffles and the temperature inside the frame was equalized by convection currents induced by stirring the air in the frame. A thermometer inserted at various depths into the frame gave a fairly uniform reading of the temperature.

### The Procedure of the Tests

The stresses corresponding to the various colours were determined by applying a load to the bakelite beam in the compensator and projecting the isochromatics on the screen. The neutral axis, the zone of zero stress, of the beam is shown as a dark band. In Fig. 5 the boundaries

Table I
Temperature Stresses in the Arch Rib

| Section | | Model | Conversion Factor | Structure | |
|---|---|---|---|---|---|
| | | Temp. Stress | | Temperature Stress | |
| | | 45° F. Rise | | 45° F. Rise | 90° F. Fall |
| 1 | Extrados...... | −550 | .322 | −177 | +350 |
| | Intrados...... | +350 | " | +112 | −220 |

| Crown | Extrados...... | + 50 | .360 | + 18 | − 40 |
| | Intrados...... | −300 | " | −108 | +220 |

Tension = +.

of the colour bands are shown, the lengths of the lines being proportional to the stresses.

The initial stresses left in the edges of the model after annealing were determined by compensation with the beam compensator. These stresses were recorded and used for correcting the values of the temperature stresses.

To study the temperature stresses the air in the frame was heated from room temperature of 75 to 120 degrees F., a rise of 45 degrees F. It took about an hour for the heat to penetrate the model and give a condition of equilibrium.

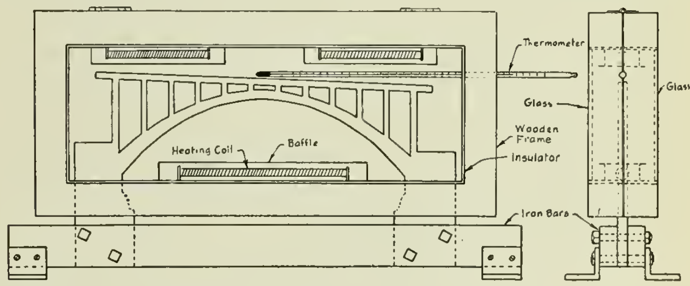

**Fig. 4—Model in Heating Frame.**

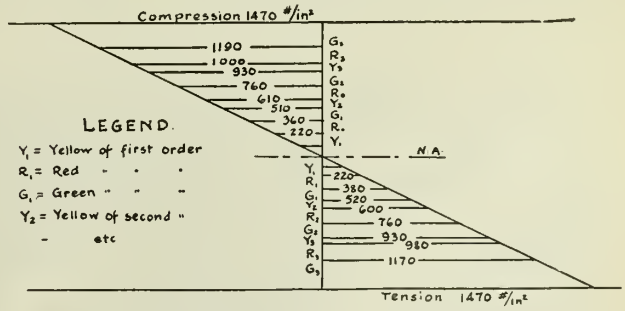

**Fig. 5—Bakelite Beam Calibration.**

At the end of the hour the isochromatics became stable and could be traced and photographed. The heating was repeated several times with different parts of the model in the path of the polarized light. The magnitudes of the stresses at the edges (extreme fibres) were determined by comparison with the colours of the calibrating beam pro-

Table II
Columns
Maximum Stress at Extreme Fibres

| Column | Model | Conversion Factor | Structure | |
|---|---|---|---|---|
| | Temperature Stress | | Temperature Stress | |
| | 45° F. Rise | | 45° F. Rise | 90° F. Fall |
| $C_1$ | −300 | .833 | −250 | +500 |
| $C_3$ | −300 | .925 | −280 | +560 |
| $C_4$ | −400 | " | −370 | +740 |
| $C_5$ | −400 | " | −370 | +740 |
| $C_8$ | −400 | " | −370 | +740 |
| $C_9$ | −400 | " | −370 | +740 |
| $C_{12}$ | −250 | .908 | −230 | +460 |

jected on the screen side by side with the portion of the model under examination, and the signs of the stresses (tension or compression) were determined by compensating or overlapping the model with the compressive or tensile side of the beam.

The stresses due to 45 degrees rise in temperature were small and only colours of the first order were observed. The author considered it unsafe to raise the temperature higher for fear of approaching the annealing or plastic state of bakelite.

### Results of Tests

In the second column of Tables I and II the observed temperature stresses, corrected for initial stresses, are given. In case of the columns the maximum stress due to a rise in temperature is compression. Columns 4, 5, 8 and 9 are under the highest stress, with 400 pounds per square inch compression at the extreme fibres at their bases. The section of highest stress in the arch rib is at the springing line, with 550 pounds per square inch compression on the extrados side and 350 pounds per square inch tension on the intrados side.

To convert the stresses in the model to those in the prototype structure, conversion factors had to be calculated for each section, taking into account the scale of the model, the coefficients of expansion of bakelite and concrete and their respective elastic moduli.

The stresses observed for a 45 degree F. rise in temperature will be doubled for a 90 degree rise and their signs reversed for a 90 degree drop. In the last columns of Tables I and II the stresses are converted for a 90 degree drop for purposes of comparison with the designers' theoretical computations in which such range of temperature had been assumed.

The thermal coefficient of bakelite for the range of temperature used in the experiments was determined to be .000026 inch per inch per degree F.

The elastic modulus was taken as 600,000 pounds per square inch.

### Comparison of Experimental Results with Theoretical Calculations

With the elastic modulus of concrete taken as 2,500,000 pounds per square inch and a coefficient of thermal expansion = .0000065, the theoretical temperature stress at the crown of the arch due to a 90 degree drop is 240 pounds per square inch. This compares well with 220 pounds per square inch as derived from the tests. (See Table I.)

While the thrust at the crown was not considered to be affected by the superstructure, the theoretical thrust and moment at the springing were corrected for the effect of the deck by empirical factors 2.5 and 1.75 respectively. These factors are based on those derived by W. Wilson of the University of Illinois from tests on a span of similar proportions. The theoretical stress at the springing, thus corrected, is 403 pounds per square inch, as compared with the photoelastic value of 350 pounds per square inch.

Table III
Comparison of Experiments with Theory

| Member | Maximum Stress | |
|---|---|---|
| | Theoretical | Experimental |
| Arch Crown | 240 lbs./in.² | 220 lbs./in.² |
| Arch Springing | 403 " | 350 " |
| Base of Column 1 | 480 " | 500 " |
| Base of Column 12 | 370 " | 460 " |

At the base of column 1 the theoretical stress of 480 pounds per square inch is closely checked by the experimental value of 500 pounds per square inch, while for column 12 the theoretical and photoelastic stresses are 370 and 460 pounds per square inch respectively. This latter discrepancy is indicative of the probable degree of accuracy to be expected from the experimental method. Table III summarizes the comparison of theory with the experiments.

### The Rise of the Arch Crown Due to Temperature

A novel use of the polariscope was made in measuring the rise of the crown of the model due to temperature. The quarter wave plates were removed and the Nicols were set parallel, the screen was moved back to give a large image of the model. The magnification thus obtained

Fig. 6 Photograph of Arch Springing and Base of Column 1.

Fig. 7 Detail of Isochromatics of Base of Column 1.

Fig. 8. Arch Rib at Column 9. Photograph of Isochromatics.

was 29. A cross engraved on the crown of the arch axis gave a dark image on the screen and its positions before and after heating were marked. The observed magnified movement of the arch was 0.33 inch corresponding to a true rise of the model arch of 0.0114 inch for a 45 degree rise in temperature. This corresponds to a 1.37-inch rise for the prototype structure with a 90 degree rise in temperature, which compares well with the theoretical value of 1.31 inches. Levels taken in the field gave a movement

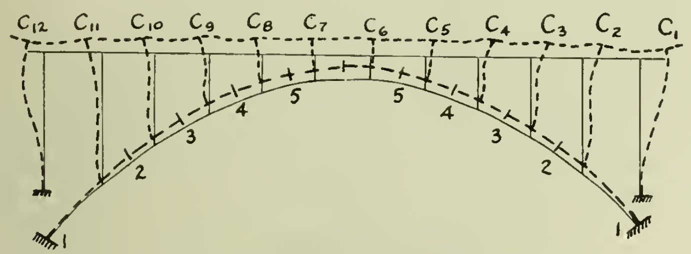

Fig. 9—Distortion with Rise of Temperature.

of crown of 1.47 inches for a temperature range of 92 degrees. (See Engineering Journal, January, 1934.) The agreement of the three values is a good check on the model showing that it is proportioned correctly and is representative of the actual structure.

### Conclusions

A question will undoubtedly arise in the mind of the critical reader as to the degree of accuracy obtained in the results of the experiment on the model, and as to the reliability of the conclusions with regard to the stresses in the structure itself.

The inherent error of the photoelastic method is the inaccuracy in determining the stress values of the isochromatics. This error may easily reach 5 per cent and where initial stresses are present the error is obviously doubled. In the present case a second annealing might have eliminated all initial stress in the material and increased the accuracy.

As to the error of "optical creep," or variation of optical effect with time after application of the load, this is quite negligible at low stresses.

An interesting problem is the possibility of variation of the stress-optical constant ($C$) with temperature. It is cited by Filon who found that glass changes slightly its optical coefficient when heated from 18 to 90 degrees C. With the small range of temperature used in his work the author considers it unlikely that the optical characteristics of the bakelite model were changed appreciably, but definite proof must be obtained experimentally. Another determination is necessary as to the possibility of variation of the elastic modulus for the same range of temperature. The uncertainty of the modulus of the material in the model, however, is not greater than the uncertainty of the modulus of concrete in the structure itself.

The author considered that the method of heating the model in a chamber more nearly approximates the conditions in the actual structure than the method of horizontal displacement of a pier, such as is used in the mechanical stress analysis. In the latter method a horizontal thrust is produced by displacing one pier horizontally, the arch is shortened and rises, transmitting the pressure to the deck through the spandrel columns and the deck acts as a beam tied to the piers by the end columns. With heating, however, an expansion of the deck takes place as well as a rise of the arch, and it is the combined effect of the two movements on the stresses in the spandrel columns that is of special interest in the present case.

The method of pier movement may have its advantage in enabling the formation of higher stresses with colours of higher order and consequently, greater accuracy. The author intends to try this method on the same model.

On the whole, the total error in determining the temperature stresses in the short columns is probably less than 20 per cent, which is quite satisfactory in a problem of this nature. In converting the model stresses into the structure more errors are introduced due to the fact that the reinforced concrete is not homogeneous. It was assumed in the calculation of the conversion factors that the stress distribution across a section in the structure is similar to that in the model. Since the columns are under dead load in compression, it was further assumed that the concrete may take temperature tension to the full amount of this initial compression. Where the temperature tension exceeds the dead load compression, cracks will form and the concrete will open up, changing the character of the section and the stress distribution.

With all the above mentioned uncertainties and difficulties, it is felt that the problem of temperature stress has been clarified to a great extent by the photoelastic method. The compressive and tensile stresses at the extreme fibres give a general idea of the dangerous sections and permit one to visualize the shape of the distorted frame. Figure 9 gives such a qualitative picture of the distortion of the span under a rise in temperature. The quantitative results, though by no means exact, give sufficient indication that the temperature stresses in the spandrel columns are serious and are to be considered in the design and construction of structures of this nature.

# Notes on the Operation of a Lobnitz Rockbreaker

*C. S. MacLean, A.M.E.I.C.,*
*Inspector, Department of Public Works, Saint John, N.B.*

Paper presented before the Saint John Branch of The Engineering Institute of Canada, March 27th, 1934.

SUMMARY.—Effective work has been done in the harbour of Saint John N.B., by a rockbreaker dropping a 15-ton chisel thus shattering the rock at the bottom of the channel. The advantages and limitations of the method are described together with the procedure for fixing the position of the cut and allowing for variations of tidal level during operation.

The Lobnitz rockbreaker *Glenbuckie* operated by the Saint John Dry Dock and Shipbuilding Company Limited, on the contract with the Department of Public Works of Canada for the main channel improvements in Saint John harbour is a device which possesses some interesting features. Its outstanding characteristics are ruggedness and simplicity and within its limits it does effective work very cheaply. Figure 1 is a plan of part of the harbour at Saint John, N.B., and the hatched areas indicate where the Lobnitz rockbreaker worked.

The apparatus was developed by Lobnitz and Company Limited, of Renfrew, Scotland, and consists essentially of a heavy chisel that is lifted and dropped on the rock, chopping pieces off the face of the cut. The chisel of the *Glenbuckie* consists of a steel cylinder 27 feet long by 22½ inches diameter and weighing 15 long tons, with an alloy

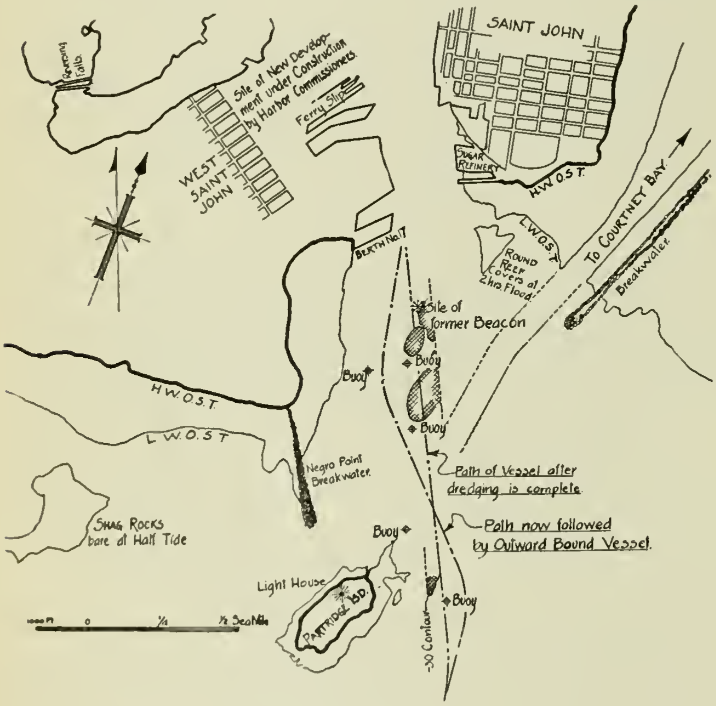

Fig. 1—Portion of Harbour Saint John, N.B.

steel point with a shank fitting into a hole in the end of the body. This point is renewable when worn; the body being heated in a portable oil furnace until it expands enough to allow the shank to enter, and a number of setscrews are set up after it is cooled and shrunk onto the shank. The chisel works in a tube of heavy plate, lined with a wooden bushing that serves to guide and restrain it, and through which the descending chisel expels the water with a force sufficient to wash away the broken rock at the spot being worked. The apparatus is mounted on a steel hull 160 feet long by 45 feet beam and steam is furnished by a Scotch marine boiler to the main winch, the manœuvering winch, a winch to handle the tube, and to the auxiliary apparatus. (See Figs. 2 and 3.)

The main winch, which operates the chisel, has a rather unusual clutch. This clutch consists of a helical spring of tapering rectangular section, attached to the hoisting drum, free to rotate with it when not engaged. (See Fig. 4.) The spring is coiled about another drum driven through double reduction gears by the engine. To engage the clutch, a collar, sliding on a feather on the shaft of the driven drum, is made to push against a bell-crank (moving it to a position as shown by the dotted line) which in turn communicates its motion to the free end of the spring at *A*, tightening it around the driven drum. This locks the

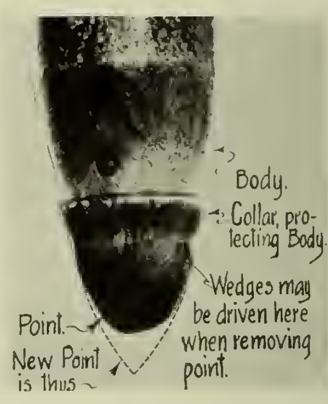

Fig. 2—Worn Chisel Point.

driven drum, spring, and hoisting drum together. When the collar is withdrawn the spring immediately lets go allowing the cable to run out and the chisel drops. The crank has a set screw at *A* for adjustment as the length of the spring varies with temperature changes. The clutch is all metal, there is no appreciable wear; clearances are small and only a small motion of the collar is needed. Except for occasional adjustment and lubrication it has worked without attention since August 1st, 1931. The collar is worked by a hand lever whose effect is reinforced by a steam ram with whose valve gear the hand lever is interconnected.

In operation three blows per minute may be struck, the chisel being hoisted and dropped 15 feet each time.

The vessel is manœuvred from six anchors, one ahead, one astern, and two on each side. The cables are brought through fairleads to a winch amidships. The six drums of this winch, each holding 1,000 feet of seven-eighths wire cable, are fitted with jaw clutches and brakes, three on each of two parallel shafts driven through worm gearing by an engine. The vessel swings to the bow anchor upstream, which is heavier than the others; and is moved across the cut by slacking the brakes and paying out the required amount of cable on one side, while the same amount is taken in on the two drums on the opposite side that are in gear. A swing of over two hundred feet can be made if the anchors are placed correctly.

To break rock, the face of the cut is pounded with the chisel until the chisel descends to the elevation to which it is desired to dredge, at points spaced three to five feet apart. In shaley rock, which shatters easily, four-foot spacing breaks it into pieces the size of a finger. In rock of a denser structure, four-foot spacing is apt to leave the fragments too big for convenient dredging, especially if the rock has well-defined bedding planes that are horizontal, and in that case it breaks off in four-foot square blocks. Three and a half foot spacing breaks it into pieces, the largest of which would go into a barrel, and that is generally used.

The rate of penetration depends upon the hardness of the rock, and upon the depth to be broken down—as dredgemen say "on the amount to come off." Under the same conditions the time required for one hole, so-called, increases about as the square of the amount to come off. When this becomes considerable, it is economical to do the work in two or more lifts, breaking first to a depth such that the rate of penetration begins to be slow in proportion to the amount of rock broken; then dredging the broken rock and repeating the process until the desired grade is attained. (See Fig. 5.)

Fig. 3—Replacing Chisel Point.

In some kinds of rock, the dredge *Leconfield* could dig to an elevation one or two feet below that to which the chisel was worked; elsewhere this has not been found possible.

Presumably the process is similar to cutting off the end of a wide board with a narrow carpenter's chisel. "Presumably"—because attempts by a diver to find out what had gone on below gave no results. He could only work at high water when the current was slack; and since the depth of water was then about 55 feet it was too dark to see and he could not tell by feeling. But if the analogy of the carpenter's chisel holds true, it is evident that the chisel must be spotted very exactly along the face of the cut. If the chisel is too far ahead of the face it only punches a dent in the solid rock; if behind, it only mashes up rock already broken. If correctly spaced at the face of the cut pieces are split off; and the chisel penetrates with each blow. Material already broken cushions the blow completely and penetration through it is slower than into solid rock. When the chisel hits on clean solid rock, the first few blows make a characteristic noise heard below decks, and causes a distinct quiver in the hull. But some arrangement must be provided whereby the vessel can be lined in and swung squarely across the cut precisely on that line. Attempts to operate by estimating the spacing of the holes either along or across the channel by mooring cables only ended in confusion. With six or eight hundred feet of cable to each anchor, rising and falling tides, swift currents, and occasional dragging anchors, the face of the cut could not be maintained.

### Range Guides

The shores are too far away in most cases to admit of satisfactory ranges being placed there, and they are often hidden by weather or smoke for long periods. Sometimes for weeks Fort Howe and its elaborate targets could not be seen and this difficulty, which at one time seemed serious, was overcome by erecting working ranges of weir-poles such as fishermen use. The forest of sticks that appeared between the main channel and Courtenay bay was composed of the dolphins used in this connection. One big dolphin was of large piles driven by a pile-driver, the many others were weir-pole dolphins. They are comparatively cheap and easily erected; and can in most cases be located close enough to be seen in any but the thickest weather. (See Fig. 6.)

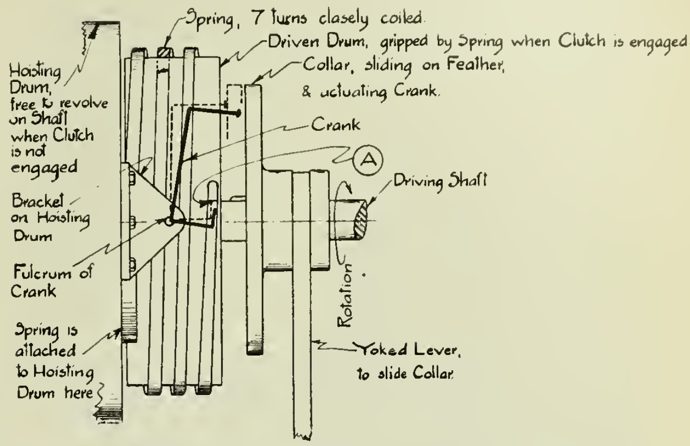

Fig. 4—Diagram showing action of Clutch on Main Winch.

These ranges guide the vessel across the cut but it is also necessary to be able to locate the distance from the side-line of the channel. After considerable experiment with a three-point fix by double angles with station-pointers, stadia, angles to a known point from a base-line on the deck, and a measuring line or tag line, the range-and-angle method was found most satisfactory. At first sight a tag line run out to a mooring would seem the simplest and most positive; but it is carried off by the current, requires shifting often as the vessel moves, is always in the way, and gets foul of drifting trash.

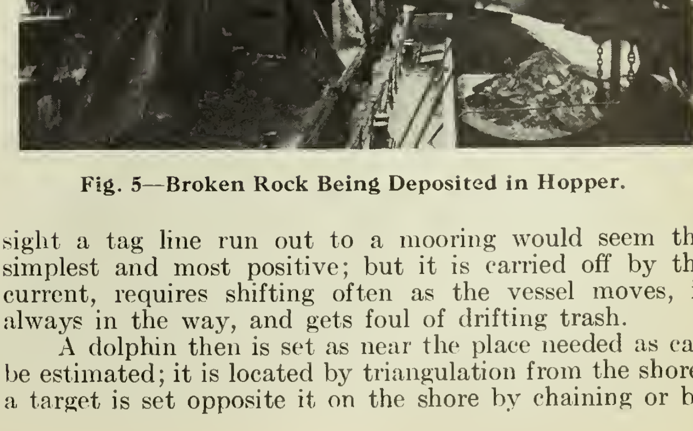

Fig. 5—Broken Rock Being Deposited in Hopper.

A dolphin then is set as near the place needed as can be estimated; it is located by triangulation from the shore; a target is set opposite it on the shore by chaining or by transits so that the range formed is at right angles to the channel; another dolphin can now be set on that line near enough to be seen from the channel. Sometimes the pile-driver can be lined in from the shore by a transit or by cross-bearings but often it is difficult to signal from the distant shore with vessels coming between. When one good range is obtained, others can be located from the deck of the rockbreaker. Three stakes, about eight inches

Fig. 6—Pile Dolphin—Weir Pole Dolphin in Background.

diameter at the butt, and long enough to bare at half tide, are driven, braced and tied together with smaller stock nailed to them. A top-stake of smaller diameter is fixed to the top of this structure and reaches to about 32 feet above low water. A fisherman's weir-pole driver having a hammer made from a large block of birch is used. (Fig. 6.)

A measuring frame of angle iron is placed along each side of the rockbreaker and marked in feet scaled off from the chisel. Plumb-bobs are hung from corresponding points on these frames and the range poles are lined in with them across the deck. A third dolphin is set ahead, or behind this range by an amount that may be determined by any convenient method. Then taking the angle between the range and the third dolphin with a sextant, a right angled triangle is obtained whose solution gives the distance to this third dolphin, and so the distance from the side line of the channel. If the dolphins are not too far away, say within 700 feet, and with a convenient range of values for the angle, results to the nearest 6 inches may be obtained with one setting of a 10-inch slide-rule. The whole operation of obtaining the chainage along the channel and the offset from the side line can be done with a sextant and slide-rule in one minute.

The greatest difficulty was encountered near the site of the old beacon because the rocky bottom did not allow driving poles near the channel and also here the most difficult rock was found. At Partridge island there is a glassy volcanic formation, very hard but brittle and further up the channel, about half way to No. 17 berth, red sandstone, laid down in carboniferous times, occurs. This gives place to slatey shales in which the fossil remains of cordaites, a carboniferous era tree, are found. Then there is a hard but brittle quartzite that breaks along the joint and bedding planes and is intersected by veins of white quartz crystals as much as one inch wide. However the rock near the old beacon site is a homogeneous quartzite apparently without any definite cleavage planes. It is very hard, and exceedingly tough and abrasive. The point of the chisel, that would last for a month elsewhere, was worn so as to require replacement in three days. It has been suggested that this rock, rising from deeper water and with different formations all around, may have been a sandy beach in pre-Cambrian times, and was formed from the disintegration of still older quartz rock. It has become solid through the infiltration of silicon dioxide in solution in hot waters acting as a cementing agent. Its great hardness has preserved it while later rocks have been formed on and about it, and have since disappeared. (Fig. 1.)

### Ideal Conditions for Short Periods Only

Delays in the work were caused by tide, storms, fog, and undertow. Of these the undertow is the most serious obstacle in the outer harbour and is the local name for the swell that runs in from the southwest and is due to causes at work beyond the harbour and beyond the Bay of Fundy itself. During September 1933 the local weather was not severe, but there was a succession of hurricanes in the West Indies. Many of these did not reach beyond the Caribbean, and no storm nor even strong wind blew in Saint John; yet the undertow ran all month. It would be interesting to know its origin and propagation.

An easterly storm in the Bay of Fundy raises a short sharp sea that soon dies away if the wind falls or shifts to the north. If however the wind hangs in the southwest or west, the waves lengthen from about 30 feet to 70 or 125 feet, and persist for perhaps a week. Days of fine clear weather, with only the gentlest southwest airs, pass; still the long smooth waves come rolling in in endless succession. They may die out at low water, but as the flood makes they are there again. The fog seems to encourage it, as do spring tides. North-north-west to east-south-east winds, or a heavy rain, and the ebb tide, run it down. The actual amplitude of the wave is small, only a few inches, except that every now and then three big waves in succession occur; they cause no inconvenience to shipping, but if breaking rock is attempted the chisel is set swinging like a pendulum and severe strains are imposed on the gear. Even when it is not bad enough to stop work this swing causes the chisel to hit incorrectly, dissipating its energy; thus progress is slow while the undertow lasts.

As a sample of favourable winter conditions, between December 9th, 1931, and January 16th, 1932, the rock-breaker was delayed 15 percent of the total possible working hours by a number of storms, 17 percent by tidal currents, and 28 percent by undertow; and this at a comparatively sheltered spot inside the Negro Point breakwater. During the winter it is seldom altogether absent outside of No. 17 berth.

When the velocity of the current exceeds two and a half knots it affects the chisel and tube so much that work must be stopped. August and September of 1933 were the first times in two years that the river was so low the *Glenbuckie* could be operated during low water. Schemes have been suggested for holding the tube against the current to permit working while the current was swift, but the writer doubts the efficacy of any of them.

### Tide Gauges

It was often difficult to set a tide gauge where it could be seen from the vessel. Sometimes the nearest pier or dolphin that could be used was 1,000 feet away and the divisions of a gauge could hardly be distinguished at night in the beam of a searchlight, and of course not at all in fog. It is necessary to know the height of the tide at all times when working, for the elevation to which the rock is broken is found by measuring from the point of the chisel, by means of marks on the cable, to the surface of the water. As it is the last few inches of penetration that take the most time, it is considered necessary to know the height of the tide to the nearest quarter of a foot.

The analysis of the rise and fall of the tide is exceedingly complex. It was thought it might be possible to predict the height of the tide at any time between high and low water by having the tide tables of the Hydrographic Service of the Department of Marine to go by; but this has not proved easy. The reason is discussed at length in various references and in particular by Dr. W. Bell Dawson, M.E.I.C., who was formerly Superintendent

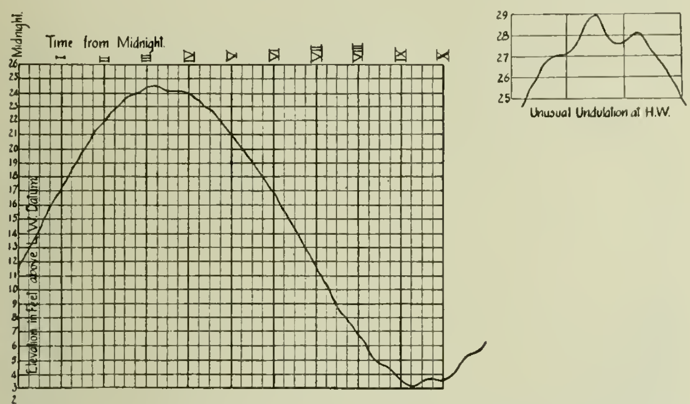

**Fig. 7—Typical Secondary Undulation at High and Low Water.**

of Tidal Surveys at Ottawa. Dr. Dawson contributed many papers to the Royal Society of Canada, containing the results of his researches; as well as his publications issued by the Tidal Survey, of which H. W. Jones, M.E.I.C., is now in charge.

THE TIDES AT SAINT JOHN

Where the tide is greatest in the Bay of Fundy, it rises and falls as a symmetrical curve when the height is plotted against time. This seems to be very nearly a sine (or cosine) curve; on the assumption that the rise or fall varies as the cosine of that angle which is that proportion of 180 degrees that the elapsed time since high or low water bears to the duration of the flood or ebb, an estimate can be made with the help of the tide tables. Sometimes this is satisfactory, agreeing with observed values for several days. But a difference may enter which can hardly be predicted. This is the "Secondary Undulation," due probably to barometric differences over wide areas of the open sea. This is said to be greatest where the range of the tide is least* and it is very pronounced at the Mag-

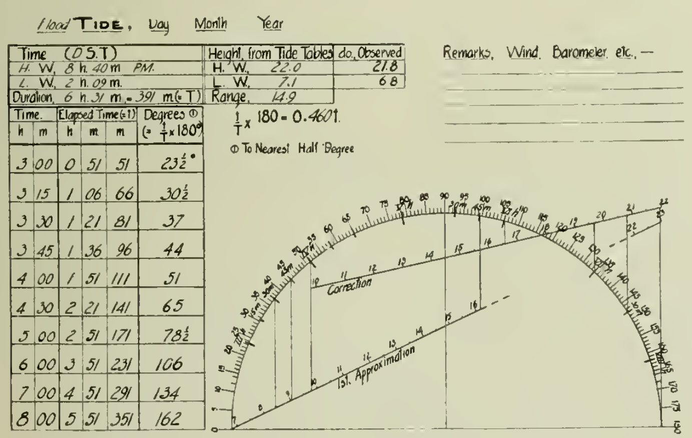

**Fig. 8—Chart for Estimating Elevation of Tide.**

dalens, in the Gulf of St. Lawrence, and at Halifax, N.S., where it is almost continuously present. At Yarmouth, N.S., there was a secondary undulation amounting to 45 percent of the range of 10.4 feet on a certain date; on the same date it amounted to 11 percent of the range of 18.0 feet at Saint John. It disappears as the tide progresses up the bay †and is present in about half of the tides at Saint John. Its period at Saint John is in the neighbourhood of forty minutes; the mean period of the true tidal undulation is twelve hours and twenty-five minutes. (See Fig. 7.)

So although this irregularity seldom amounts to 10 percent of the range of the tide at Saint John, 10 percent of a 20-foot tide may make a great difference when trying to break down 8 feet of rock with a Lobnitz apparatus.

Since the tide enters so largely into the life of the harbour it is essential that pilots and mariners, as well as engineering enterprise, should know in advance when high and low water occur, and what the depth will be at these times. This information is supplied in the daily Tide Tables issued annually for a year in advance by the Hydrographic Service of Canada.

Low Water Datum or Chart Datum is a local plane of reference established by the Tidal Surveys and from this the height of the tide is measured upward and the depth of water downward. It is an arbitrary plane and is chosen so as to be most convenient for tide calculations and to best represent the depth of water when the tide is out. It is different in different places, as the range of the tides differs. The elevation of a point half way between high and low water differs a little from tide to tide, but the mean from year to year is constant except in estuaries

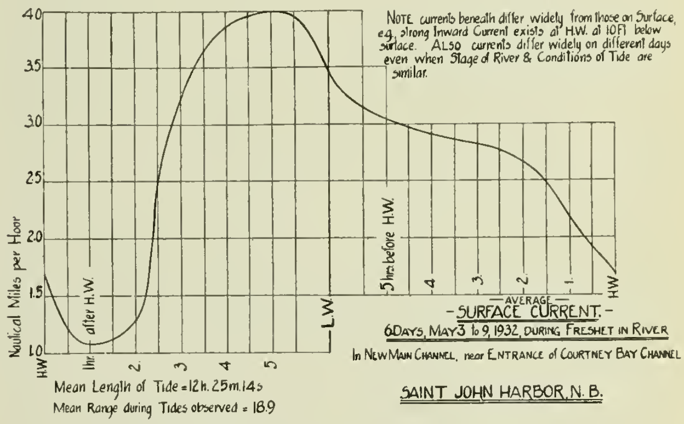

**Fig. 9—Chart of Surface Current.**

and rivers where the slope does not allow the water to fall to a true low water. This mean is Mean Sea Level and the Canadian and United States systems of precise levels show it to be the same for the whole Atlantic coast. Except for a possible secular change it is the most stable datum there is.

High or "spring" tides occur twice a month, at the full and change of the moon, but the elevations between which they rise and fall depend on the distance of the moon and the extreme range is seldom attained. At these times the tide is high between eleven o'clock in the morning and noon. Then a week later the tide is not high until evening and the range is very much less. For a precise discussion of these features the reader is referred to the pamphlets listed in the catalogue of publications of the Department of Marine, which not only contain exact information but present it in a most interesting form; and a recent paper by H. F. Bennett, A.M.E.I.C.‡

The tidal undulation is transmitted up river to Fredericton, about eighty-four miles, where it is high water some eight hours after Saint John. A few miles above Fredericton the effect of the tide disappears in the swifter water there. It is stated on the river chart that low water datum there is two and a half feet above Mean Sea Level. The tide there may rise about three quarters of a foot above

*Dr. Bell Dawson, Trans. Royal Soc. of Can.

†"Tides at the Head of the Bay of Fundy," Tidal Service of Canada.
‡The Engineering Journal, July 1934.

this datum. The surface of the water in the harbour at high tide may thus be considerably above the water level at Fredericton since at Saint John the tide may rise 14 feet above Mean Sea Level.

There are tables and charts for estimating the height of the tide during ebb or flood, based on the assumption that the fall or rise is harmonic. This arrangement has been used by the author; for it is often necessary to make (Fig. 8) a guess at the tide over an hour or so while a gauge is temporarily hidden. The form with the protractor on it is printed from a tracing on a blue line or ozalid print and the data, which are obtained from the tide tables, can be arrived at and filled in in a few minutes. Then if the gauge can be seen occasionally and if the tide is not rising or falling as expected, the curve of rise or fall will at least be nearly parallel to a sine curve, and a correction can be made on the form. In the example shown the times were calculated and spaced off on the protractor, any intervening time to the nearest five minutes being readily interpolated mentally or with a pair of dividers. Low water was observed to be 6.8 feet, and the height at four o'clock, p.m., d.s.t., twelve hour notation, was 9.8 feet. Choosing a suitable scale, it was placed on the diagrams so that 6.8 fell on the low water and 9.8 on a perpendicular through four o'clock. This line is the "first approximation" and the tide was read from this by dropping a perpendicular upon it from the time, until at half tide a chance to see the gauge seemed to show the tide was not rising as fast as this line would indicate. The fact that it showed that high water would be nearly 23, instead of 22 as predicted in the tables, would lead one to expect that the rate of rise had become less. Accordingly steps were taken to obtain a good reading of the tide gauge and at five hours and forty-five minutes it was found to be 15.7, instead of 16.2 as the curve showed. A new line, the "correction" was drawn, having 9.8 at four o'clock as before and 15.7 at five forty-five. This was found to agree with the gauge as closely as it could be read when visible, for the remainder of the flood; and showed high water 21.9 whereas 21.8 was observed (the average of several readings obtained during the high water stand) and 22.0 was predicted. But this or any other device may fall one and a half feet in error within twenty minutes of having verified a value by gauge when the secondary undulation is well developed.

Contrary to the firm convictions of many, the wind does not seem to affect the tides greatly, or at any rate regularly. It hardly seems possible but that a strong south-west wind should cause the tide to rise higher than it otherwise would for it can be seen to affect the surface filaments of current; and probably anyone can recall a high south-west wind accompanied by a high tide. But a high wind accompanied by a tide lower than would be expected from astronomical arguments does not attract much attention; nor does a tide higher than would be expected, with no wind at all, especially at neaps, and these often occur. Dr. Dawson has stated that the more he investigated currents, the less he found to attribute to wind. Perhaps the same applies to the elevation that the tide attains in Saint John harbour.

The currents vary greatly from day to day in both direction and velocity. The maximum outward current runs during the latter part of the ebb, and appears uniform from surface to bottom until a short time before low water, when it slackens. Its direction is nearly straight outward along the line of the new channel; but at other stages of the tide it takes different directions at different distances beneath the surface. Seldom if ever does it run inward on the surface, but at high water a strong inward current may occur below the surface, swinging a 45-pound sounding lead out of plumb. A study of the currents over a time long enough to show their different phases would be interesting. The curve (Fig. 9) is an attempt to show what might be expected at a depth of about five feet below the surface during the height of the freshet of 1932, at a point half way between No. 17 berth and Partridge island. A surface velocity of five and a half knots was noted for a short while each day during the height of the freshet of 1933. During September 1933 the surface velocity did not rise above 2.3 knots.

During the first part of the ebb the surface velocity is small, until a streak of broken water appears, drifting out of the harbour. As soon as this passes the surface velocity increases to a maximum and becomes strong and uniform as noted above. It is to be regretted that men and equipment were not available for a precise and detailed study of the current while the rockbreaker was moored in the harbour during 1932 and 1933, as apart from the interest in a research of this nature the results should be of value to the port.

Figure 10 shows a series of curves plotted from actual records obtained from an automatic tide gauge at Saint John.

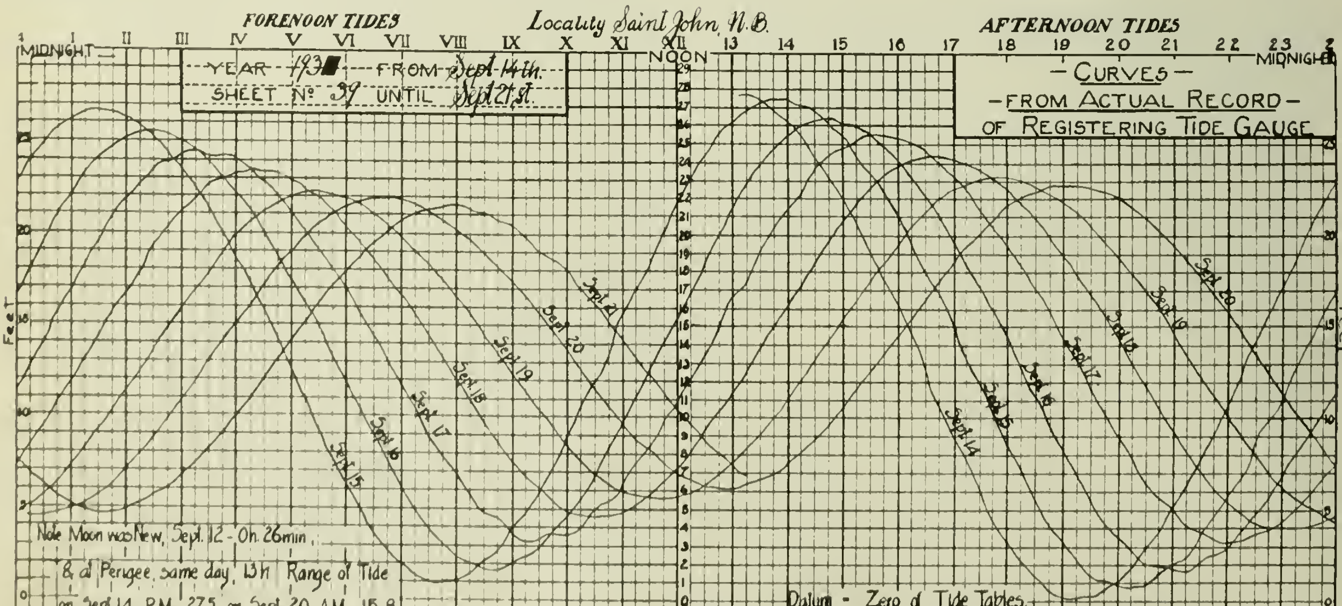

Fig. 10 Actual Record of Registering Tide Gauge.

# Maintenance of Substructure of the Lethbridge Viaduct

*F. W. Alexander, M.E.I.C.,*
*Engineer, Maintenance of Way, Western Lines, Canadian Pacific Railway, Winnipeg, Man.*

**SUMMARY.—The author describes the difficulties experienced in maintaining the foundations of the western end of the Lethbridge viaduct, and the remedial measures employed in carrying foundations down to rock and in providing for drainage.**

The purpose of this paper is to describe the unusual maintenance work that has been carried out on the railway viaduct crossing the Belly river at Lethbridge, Alberta. The maintenance period covers an elapsed time of some twenty-two years. Ordinary operations, such as tie renewals, painting, etc., will not be described as they are common to all bridges irrespective of size. In the case referred to the unusual maintenance work is due to the immense size of the structure, coupled with adverse natural conditions at the bridge site.

**Fig. 1—St. Mary's River Crossing.**

Before taking up the subject of the paper, it will be of interest to outline the events leading to the construction of this bridge. Subsequent to the completion of the main line of the Canadian Pacific Railway the Alberta Coal and Navigation Company secured a charter and in 1885 built a narrow gauge line from Dunmore, on the Canadian Pacific main line, to Lethbridge. This narrow gauge line was primarily built to haul coal from mines located at Lethbridge to eastern markets. The track was widened to standard gauge in 1893 and later a charter was secured and during 1897 and 1898 a railway was built from Lethbridge to the west, through the Crow's Nest Pass. The west end of the Alberta Coal and Navigation Company's railway was on top of the east bank of the Belly river and immediately west of this was a valley over 300 feet in depth and 1¼ miles wide. A high level bridge at this point was too expensive to be undertaken at that date and the alternative was to develop a longer line and work down to a low level crossing. A junction was made about one mile east of Lethbridge and a line turning to the southwest was located on a 1.2 grade, working down the banks of the Belly and St. Mary's rivers to a low level crossing. This line along the river banks crossed numerous deep coulees, necessitating an aggregate length of 2.8 miles of bridge in a distance of 37 miles. All of these bridges were built of timber.

As the large timber bridges are getting to be a thing of the past two views are shown of these interesting old structures. The St. Mary's river crossing (Fig. 1) was 2,933 feet long and 65 feet in height and was built entirely of piles except for the two Howe truss spans over the river. Figure 2 shows another typical structure over a creek adjoining the St. Mary's river.

In addition to fire hazard and the usual maintenance of timber bridges there was very heavy maintenance at practically all of these structures due to sliding banks. In Fig. 2 the ground bracing between the towers should be noted. The pressure on the end of these 12 by 12 braces was so great that in many instances the timbers bearing on the end of the braces were completely crushed or sheared off.

Prior to the time it became necessary to replace or abandon these bridges, a study was made of a scheme to build directly west from Lethbridge. Information showed this line would be about six miles shorter, the grade would be .4 instead of 1.2, and only two bridges would be necessary —one over the Old Man river, 1,892 feet in length and 145 feet high, and the other over the Belly river, 5,327 feet long and 312 feet above the bed of the river.

Figure 3 shows a map of the territory giving the location of the new and the abandoned lines. The bridge over the Belly river is the subject of this paper and here the slope on the east bank was clay, reasonably flat and offering no serious handicap or apprehension as to stability. There were, however, a number of old mine workings in the bank directly under the bridge site. Plans and other records were available for some of these and the old workings were, as far as possible, located and filled in. One pedestal, which came directly over an old tunnel, was carried down to the solid ground below. The west bank, however, was a different proposition as it was of clay, very steep, being almost perpendicular in places. The formation showed that an old land slip occupied at least a part of the site selected for the bridge location. Before construction

**Fig. 2—Structure over Creek Adjoining the St. Mary's River.**

started the bank was sloped as well as possible and, in order to keep the foundations off the steepest part of the slope, one special length deck truss span was introduced. The foundations were concrete pedestals constructed on short concrete piles, the only exception being the pedestals in the river which were on shale, making piles unnecessary. This bridge was completed and turned over for operation during the fall of 1909 and Fig. 4 is a general view of the completed structure looking east along the north side.

A short time after the bridge was placed in operation it was noticed that the deck was going out of line and surface and a complete line of check levels was run in July 1913. At that time it was found that pedestal No. 53 South was down 2½ inches, 53 North 1⅜ inches, 54 South down 1⅜ inches, and 59 South 1⅜ inches. There were other differences but 53 South was the cause of immediate concern. Figure 5, on which is shown a general elevation, gives the location of these pedestals and it will be noted that bent 53 is the first bent west of the river and under one of the highest towers.

A study of conditions on the ground, and records of this foundation, led to the conclusion that the water saturated ground from below the pedestal was being squeezed out towards the river. In order to counteract this and retain ground in position, it was decided to build a row of heavy concrete buttresses along the river bank. These were tied into the light reinforced wall that was built during the construction of the bridge, and riprap was also added to prevent erosion below and above the bridge site. There were many gopher holes in this bank and some of these showed up as the usual small round burrows, others showed as cracks. This latter peculiarity led to an investigation of the whole bank. Men with pointed steel rods sounded the entire area searching for cavities and those found were usually cracks covered on the top with loose soil or sage brush. Some of the cracks could be traced for a length of 6 feet to 8 feet, and when uncovered showed widths up to 8 inches. The usual width was 3 to 5 inches but the depths were not determinable as the sides were irregular. Some holes of considerable size were found; one of them was 7 feet deep and opened into a large crack. All cavities were carefully uncovered and then filled with clay, which was tightly rammed into place. After this filling was completed shallow concrete lined ditches were constructed. These followed small natural depressions along the hillside and were designed to quickly collect and carry away all surface water. Observations had disclosed that during rain storms large quantities of water

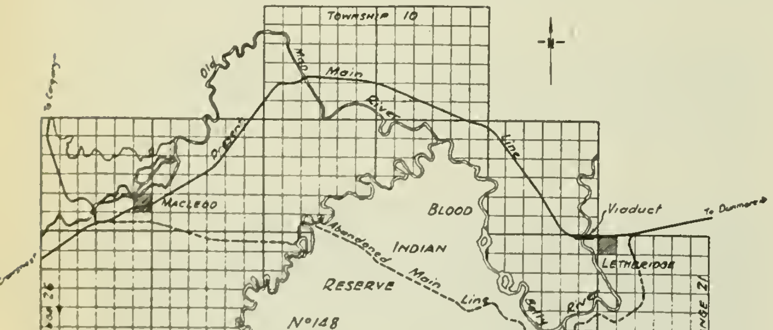

Fig. 3—Present and Abandoned Main Lines Between Lethbridge and MacLeod.

were collected by the exposed area of the long tower legs. This water ran down the leg and off the top of the pedestal, softening the ground in the immediate vicinity. Galvanized iron pans were fitted around the bottom of the long legs to collect this water and spouts were arranged to carry it to the above-mentioned concrete lined ditches. This completed every possible scheme that could be thought of to quickly dispose of surface water.

Levels on the foundations continued to be run at different periods, and it was noted with considerable satisfaction that pedestals 53 and 54 South had come to rest with a maximum settlement of about 4 inches and 2½ inches respectively. Pedestal 59 South, which is one of the pedestals supporting the tower at the east end of the long span, continued to give trouble. Records of this foundation showed a concrete pedestal 25 feet high on fourteen concrete piles approximately 10 feet long. The material below the foundation was yellow clay. During an inspection in February 1922, both anchor bolts of this pedestal were found in place in the steelwork but broken off close to the top of the concrete and from their appearance

Fig. 4—Lethbridge Viaduct from North West.

they had been broken for some time. Levels at this time showed this pedestal had settled about 2½ inches and that it had also moved towards the river. An examination of the steel superstructure did not show any damage either to rivets or bracing, although the track on the top of this tower was low and out of line.

For the following four or five years the movement was very slow and it was hoped that it would come to rest before it was necessary to undertake major repairs. This turned out to be a vain hope, however, as during an inspection in March 1930, it was noticed that a passing train caused an up and down movement of the leg at the top of the pedestal. Examination showed that when the bridge was unloaded there was a space of approximately ⅜ of an inch between bearings. Steel shims, in the form of wedges, were immediately driven (to a height of 1⅛ inches) under the shoe. These wedges not only took up the visible slack but also raised the steelwork stopping all movement due to loading. By jacking up steel depth of shims were increased to 1⅞ inches. Levels disclosed a total settlement of 4¾ inches, an increase of 1⅝ inches since the last levels were taken and probably within a short period immediately preceding discovery of the slackness at this foundation.

Steps were immediately taken to get information as to conditions below the old pedestal and the chance, if any, for a solid foundation. A drilling rig, equipped to drill 6-inch holes and extract cores, was put to work and six holes were put down at different points surrounding the pedestal. The material encountered was principally a wet clay, one seam of gravel and a general mixture of various kinds. Shale was struck at a depth of approximately 50 feet below the ground surface and 33 feet below the bottom of the pedestal. The only way to secure a solid foundation was to go down to this shale and the problem was how to support the steel while foundations were being carried down to this depth below the pedestal without starting a disturbance that would accelerate movement and perhaps cause trouble to the foundation next on the bank above. One scheme considered was to drive piles on each side of 53 South, cross cap these pile towers and support the steelwork on this cross capping. The old pedestal would then be removed and excavation carried down inside sheet piling to shale. Another was to drive sheet piling on either side of pedestal, excavate inside this piling down to shale and fill with concrete, cut away the top of the old pedestal and support the leg on I beams resting on the two new supports. These schemes presented objections, the principal one being the chance of disturbing the ground and aggravating existing conditions.

The procedure finally adopted was to sink two round reinforced concrete caissons, one on the upper and one on the lower side, fill these with concrete, cross cap with steel beams after cutting away the old pedestal and take the weight of the tower leg on the top of the new construction. In deciding the size for the caissons, consideration was given to working space for men and room for a bucket for hoisting material. The height of the form was governed by what was considered a maximum day's work in sinking the excavation. The clear inside dimension was set at 6 feet with an 8-inch reinforced wall. The height of the form was set as 5 feet and above this angle irons were left projecting for the purpose of suspending the inside form and for general handling.

In starting the work a shallow pit was made; in this was cast, in a wood form, a reinforced concrete cutting edge or shoe. This shoe was very carefully made. On the east cylinder, which was the first one put down, the diameter of shoe was 1¼ inches in excess of the diameter of the main caisson. The shoe on the second cylinder was reduced in size to ½ inch in excess of the main cylinder. Above this shoe the outer steel form was placed on cross timbers very carefully levelled and firmly braced to prevent movement. This was very important as it was the only means to insure the caisson being sunk plumb. The inside form was suspended from an overhead framework and this framework also carried a sheave for a line used in hoisting material. The programme called for the excavation, the building and the sinking of the form to proceed simultaneously. Ciment Fondu was used in the caisson in order to insure against delays while waiting for concrete to set. The caisson form, as first designed and used, had channel iron fillers as connections in the inside form and it was necessary to slack off the inside form to allow the concrete to settle. Later a slightly tapered hardwood filler was used and this tapered filler eased off the friction on the sides of the form, and as soon as the concrete caisson was well started its own weight pulled it down (without any slacking off of form) as fast as the material was excavated below the cutting edge.

Figure 6 gives a general plan of an elevation of the form, together with a section of the concrete caisson, also the new and old foundation. The excavation inside the open caisson was carried down to shale by ordinary pick and shovel methods. The excavated material was loaded in a cylindrical bucket 18 inches in diameter which had a capacity of 3½ cubic feet. A single line was run from this bucket to the sheave attached to the overhead frame and a horse on the other end of the line provided the power for hoisting. A 3-inch plank platform, leaving room for the hoisting bucket, was securely suspended for protection above the workmen inside the caisson. A storage battery with a single light for illuminating the work was attached to this platform.

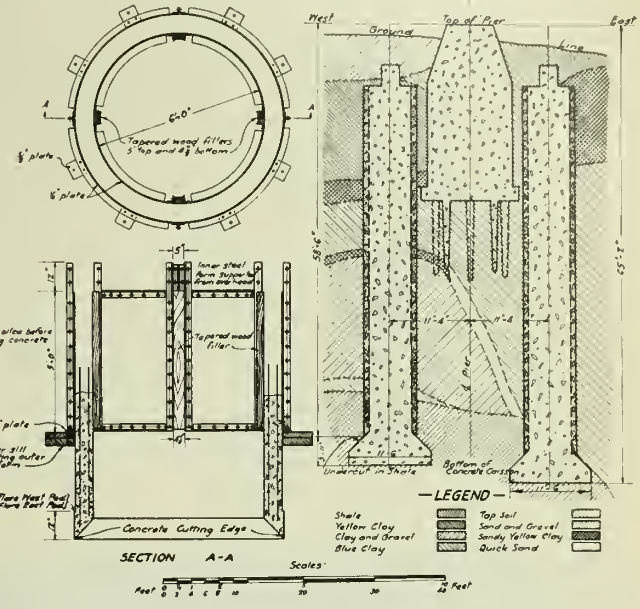

**Fig. 6—Steel Form for Concrete Caissons and New and Old Foundation for Pier 59 South.**

A gang of nine men sunk these caissons at an average of 3 feet 10 inches in an eight-hour day and the maximum day's work was 4 feet 6 inches. The downhill or east caisson was first put down and shale was encountered at an average depth of 58 feet below the top of the old pedestal. The excavation was carried to a total depth of 65½ feet and while the top of the shale was on a considerable slope towards the east, the shale bedding was practically level. The material through which the excavation passed above the shale was principally a wet clay, some gravel and a little sand. There was sufficient water to collect in small pools in the bottom of this excavation. After the caisson was well landed in the shale, the excavation was carried below the cutting edge and enlarged for extra bearing. The size of the enlarged footing was 11 feet 6 inches in diameter.

The steel form was now moved to the upper side, where a site had already been prepared, and the cutting shoe cast. After the experience gained with the first caisson, this shoe was only given a clearance of one quarter

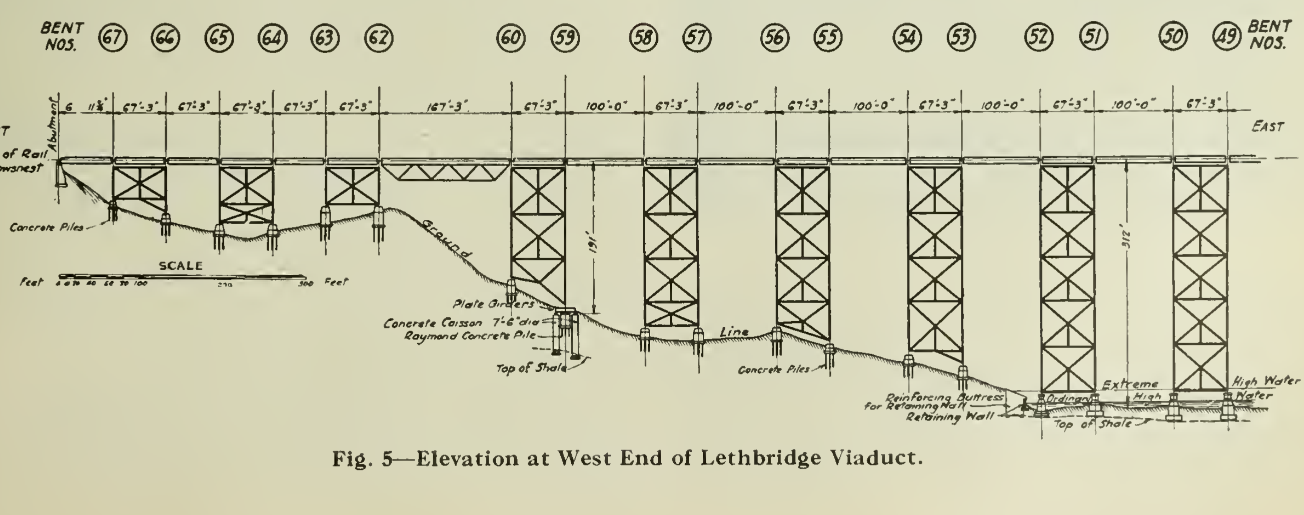

**Fig. 5—Elevation at West End of Lethbridge Viaduct.**

of an inch. While the second excavation was underway the inside of the first caisson was filled and capped with a concrete block. The material encountered in the second excavation was much the same as the first, with the exception of a seam of water-bearing gravel just above the shale and there was sufficient water at this point to collect to a depth of 4 or 5 feet during the night. This caisson was landed in the shale at a depth of 52 feet and the excavation was carried below this and undercut to give the extra bearing. The next procedure was to cut away the top of the old pedestal. In order to do this the two outside girders were placed first and the inside was then worked out by alternate cutting and blocking, after which the blocking was removed between trains and the two inside girders placed. Figure 7 shows the pedestal being cut away and Fig. 8 illustrates the completed job.

It will be recalled that the cutting edges were slightly larger than the barrel of the caisson. Dry sand, to the amount of forty cubic feet, was poured into the visible space between the outside of the barrel and the ground and this sand was firmly rodded into place. The top of the sand was kept about 5 feet below ground level and above this the space was filled with thin concrete. The idea was to leave no space to start a re-adjustment of the ground in this vicinity. The amount of dry sand and concrete introduced outside the caisson almost exactly made up for the difference in area between the cutting edge and the barrel, which was a very satisfactory condition. Levels

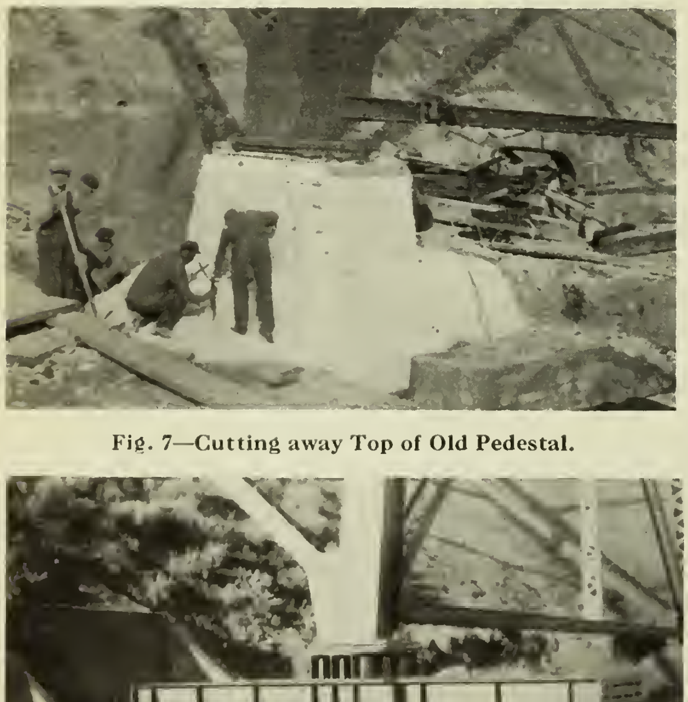

Fig. 7—Cutting away Top of Old Pedestal.

Fig. 8—Completed Job with Girders in Position.

had been taken on the old pedestal every few days while the work was going on and due to precautions taken there was no extra settlement during the time caissons were being placed and filled. This made pedestal 59 South safe from settlement though there was still the uncertainty of the bank sliding and overturning the new foundations. The total cost of the work, as outlined above, was $10,502.00, which included $2,146.00 for the steel beams used in cross capping.

As previously mentioned, water in considerable quantities had been found in the excavation for No. 2 caisson. This water-bearing stratum was about 50 feet below ground level and too deep to drain by ordinary methods. It was thought that local relief could be secured by jacking a drain pipe into the bank and a location was selected north of the bridge and below the level of the area which it was proposed to drain. A 6-inch wrought iron pipe was lined up and jacked into the bank, however to be of use this had to land on, or very close, to the top of the shale. Jacking was rather slow but not expensive as only a few men were engaged. The necessary distance was about 154 feet and as pipe was pushed into the bank the inside was cleaned out with a water jet. After reaching the objective it was found that there was no flow of water so the pipe was withdrawn a few feet and after working with it for some time it started to discharge at the rate of twenty-two gallons per hour and continued at this rate for a long period, when the flow gradually dropped to fifteen gallons per hour. The relief offered by this drain was very material but limited in area so consideration was then given as to what other remedies might be applied and it was decided to drill the river bank to see if the flow of water could be found and cut off before it reached the bridge site. The bank south of the bridge seemed to offer greater possibilities for water than the north side so it was selected for prospecting with the same drill as used around pedestal 59 South. Seven holes in all were put down, as shown in Fig. 9, which also shows the location of the drain pipe described above and the location of the tunnel which will be described later.

The hole marked No. 2 showed a heavy flow at a point about 204 feet below the ground surface and just on top of the shale. Other holes showed water at various levels but no large quantities at any point. It will be noted from the profile on Fig. 10 that hole No. 2 indicates a depression or valley in the shale surface which appears to offer a reasonable explanation for encountering the most water at this location.

After studying the information obtained by this drilling it was decided to drive a tunnel from a point in the bank about 450 feet south of the bridge in a line through holes 7, 1, 2 and 3. The tunnel was to be located in the shale (except for a distance of approximately 120 feet at the entrance) the top being kept just even with the top of the shale at its lowest point as located at hole No. 2. There was considerable discussion as to size and method of lining and it was decided that there should be a clear inside height of 4 feet 10 inches and a width of 4 feet with a lining of cedar. Cedar lining gave promise of a life of twenty-five years or more, and the size gave room for men to work comfortably and to use a good sized mucking car. The tunnel was started in January 1932 and the first 120 feet was driven through clay. At this point shale was encountered in the bottom of the excavation and also a flow of water which was estimated to be at a rate of 35 gallons per hour. The shale now started to raise and at a point 175 feet from the portal, the excavation was entirely in shale and here an additional flow of 25 gallons of water per hour was encountered.

The tunneling through the shale went forward in a routine manner at a rate of about eight feet a day. Air drills of various types were tried but in the end an auger similar to the ordinary bridge auger was used as it was found that this gave the best results.

On May 17th, 1932, the tunnel had reached drill hole No. 2 and when the heading was shot, the shale over the roof caved in. Water and gravel poured into the tunnel, filling about fifty feet with debris and the water ran from

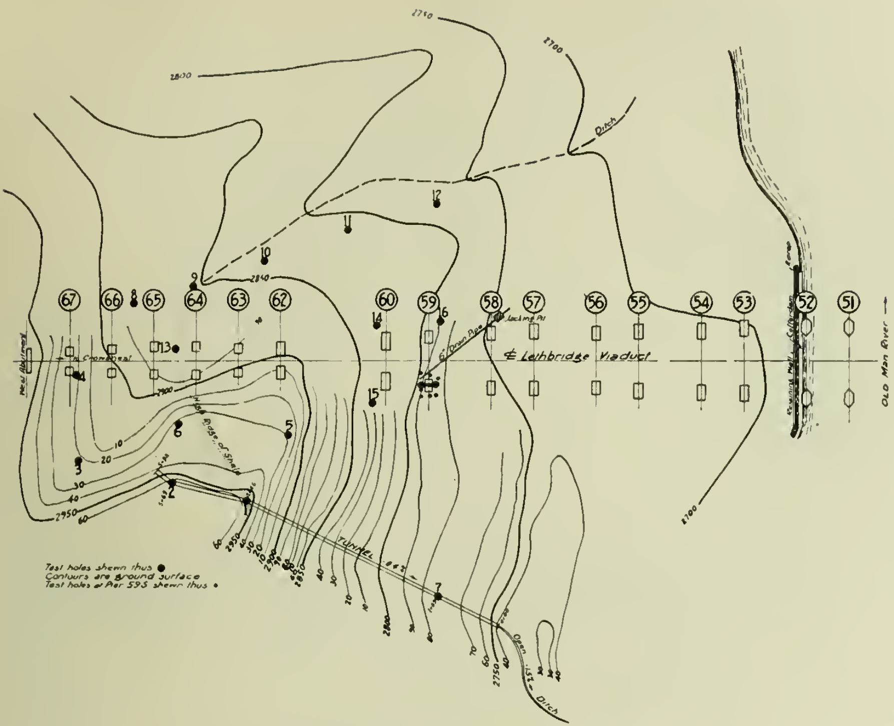

Fig. 9—Plan of Drainage Tunnel.

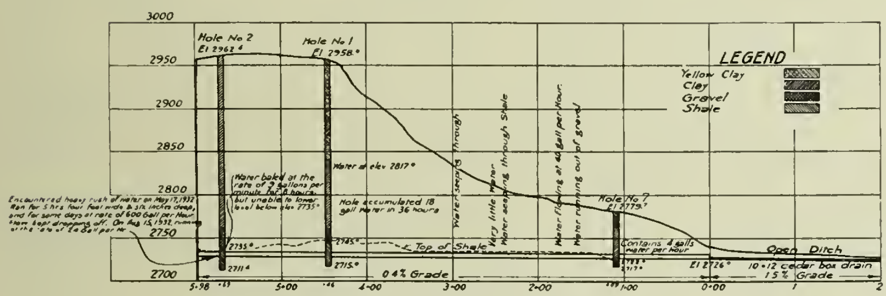

Fig. 10—Section of Drainage Tunnel.

the tunnel for five hours in a stream five inches deep and four feet wide on a four-tenths grade. After this first rush, the water eased off but still continued to flow in a large volume. On the morning of May 28th the flow was at the rate of 480 gallons per hour and an attempt was made to continue the tunneling; however there was so much trouble with water that as soon as the heading was made safe, work was temporarily abandoned. In August the flow of water had dropped to 20 gallons per hour and the tunnel was advanced to station 5 plus 94, where it was all in dry shale and the work was then closed down for an indefinite period. The flow from the drain pipe and tunnel was measured from time to time and although there was a continued reduction at each point, it was thought best to continue investigations by drilling on the north side of bridge with the idea of driving a second tunnel in that location if investigations disclosed any water pockets.

Drilling was started on this investigation on May 1st, 1933, and holes 8 to 16 inclusive were put down in selected locations. The material in all the holes was quite similar, consisting of a surface layer of yellow clay fairly dry varying from 20 to 40 feet thick; then 40 to 70 feet of blue clay mixed with sand and gravel; and below this about 25 feet of gravel overlying shale. In holes 8, 9 and 13 the blue clay carried water; in the others it was only moist. The shale at hole 8 was encountered at elevation 2735.8, practically the same as at hole 2, where the large body of water was encountered in the tunnel on the south side. At hole 9, the surface of shale was 2742.7 or about 7 feet higher and hole 13 was drilled with the idea of proving whether or not the ridge in the shale was continuous. If this was the case water could not flow out the valley as located by holes 2 and 8; except by way of the drainage tunnel. Hole 13 showed shale at an elevation of 2744 and definitely established a dyke or ridge in the shale cutting off the flow of water to the east. Holes 14, 15 and 16 were put down to secure additional information as to the elevation of the shale in the vicinity of pedestals 59 and 60. The results obtained were all similar: 5 to 10 feet of fairly dry yellow clay on top, then about 50 feet of moist blue clay with about 20 feet of gravel overlying the shale.

The information as disclosed by this drilling showed no accumulation of water and due to the slope of the shale no chance for an accumulation such as had been tapped by the tunnel already driven on the south side. The question of driving another tunnel was therefore abandoned. However a perforated casing filled with gravel was installed in holes 8, 9 and 13 to drain as much water as possible from the wet blue clay to the gravel overlying the shale where it would eventually make its way to the drainage tunnel already built.

A measurement of the flow of water in August 1933 showed 9.2 gallons per hour from the tunnel and 4.3 gallons per hour from the drain pipe. In October 1933 the flow was 4.0 gallons from the tunnel and 2.9 in the drain pipe and on January 20th, 1934, following a long mild spell after a fall of snow, the tunnel flow was 7 gallons per hour and the pipe flow 3.46 gallons. By May 9th the tunnel flow fell off to 4.0 gallons and the pipe flow was 3.4 gallons per hour. On October 19th, 1934, the tunnel gave 4.6 gallons per hour; the pipe 3.5 gallons per hour.

Therefore from present indications it would appear as if the drainage problem has been solved. If so, the trouble with settlement of foundations should also be about ended, much to the relief of all those responsible for the maintenance of this structure.

# The Hydrostatic Cord

*J. B. Macphail, A.M.E.I.C.,*
*The Power Engineering Company, Montreal.*

The problem of the hydrostatic cord is an interesting mathematical byway leading to the determination of the shape of a flexible weightless cord, hung from two supports in the same horizontal plane, when subjected to a loading similar to hydrostatic pressure. It is briefly mentioned in some of the older English text-books on elasticity but never to the extent of a complete treatment of the many possible cases which can occur.

The curve which the cord takes is a portion of a more general curve representing the several shapes into which a thin springy metallic spline can be bent, including a variety of loops and bends shown in Love's "Mathematical Theory of Elasticity." Another portion of the curve was used by R. D. Johnson in designing a large conduit with the wall in tension only, and later by H. H. Burness in England with a much fuller mathematical development.* Yet another portion of the curve was used by Rankine in his treatment of the hydrostatic arch.†

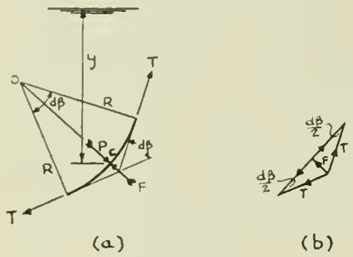

Fig. 1

The hydrostatic cord is not exactly the mathematical equivalent of a cross-word puzzle, as some might suspect. The present writer became interested in the matter in the course of a routine investigation of shapes and stresses in a certain steel plating problem. The equations which were found or which were developed in the course of the work suggested that they might be particular forms of a more general case, and their extension seemed to be of sufficient interest to justify this presentation. They appear also to have a real application to the design of bunker bottoms, troughs and flumes.

Consider in Fig. 1 (*a*) a flexible weightless cord of unit width, hung from two supports in the same horizontal plane, and subjected to a fluid loading which produces a tension $T$. Since there are no tangential forces, this tension is constant over the length of the cord. Take an element of length $ds$ about a point at depth $y$, and let $R$ be the radius of curvature and $d\beta$ the included angle. Since the element is in equilibrium, the resultant of the tensions on it must equal the normal force of the fluid pressure and be collinear therewith. Resolving the tensions along and perpendicular to the radius $OC$ as shown in Fig. 1 (*b*), the perpendicular components cancel and the unbalanced elements are $F = 2\,T \sin (d\beta/2) = T\,d\beta$. The internal force $P = wyds$ where $w$ is the unit weight of the fluid. Equating these and putting $ds = R\,d\beta$ we have $T = wy\,R$ or $R = a^2/y$ where $T/w = a^2$, the parameter $a$ having the dimensions of a length.

The complete curve has several possible shapes, shown in Fig. 2, but to assist in the subsequent analysis the one shown in Fig. 3 will be taken to illustrate the most general case.

*"Engineering," Vol. 124, page 632, 11th November 1927.
†"Applied Mechanics," 10th Edition, page 190.

We have then, taking $y$ positive downwards,

$$ds = R\,d\beta = a^2 d\beta/y \quad\text{and}\quad ds = -\,dy/\sin\beta.$$

Hence $\quad \sin\beta\,d\beta = -\,(y/a^2)\,dy$

which on integration becomes

$$y^2 = 2\,a^2\cos\beta + c^2 \quad\ldots\ldots\ldots\ldots(1)$$

where $c^2$ is the constant of integration having dimensions of $(\text{length})^2$.

At $\quad y = h \quad \beta = 0 \quad \therefore h^2 = 2\,a^2 + c^2$

At $\quad y = eh \quad \beta = \alpha \quad \therefore e^2h^2 = 2\,a^2\cos\alpha + c^2$

Then $\quad h^2 = (1 - \cos\alpha)\,2\,a^2/1 - e^2$

$$c^2 = h^2 - 2\,a^2 = (e^2 - \cos\alpha)\,2\,a^2/(1 - e^2)\ldots(2)$$

$$\cos\alpha = 1 - (1 - e^2)\,h^2/2\,a^2\ldots\ldots\ldots\ldots(3)$$

This equation contains four quantities, and when any three are known from the physical circumstances of the case, the fourth can be found. If any of the known characteristics happen to be the length of the curve or the dimension $x_o$ the subsequent equations for their values must be solved by successive approximations to give the quantities in equation (3).

Values of $x$ are obtained by integrating the equation

$$dx = ds\cos\beta = (a^2/y)\cos\beta\,d\beta\ldots\ldots\ldots(4)$$

Substitute (2) in (3) and get after a little reduction

$$y^2 = 4\,a^2\left[-\sin^2\frac{\beta}{2} + \frac{1}{1 - e^2}\sin^2\frac{\alpha}{2}\right]\ldots\ldots\ldots(5)$$

The subsequent development proceeds by two paths, according as the second term in the bracket is greater or less than unity. First, putting $\left(\sin^2\frac{\alpha}{2}\right)\Big/(1 - e^2) = k^2$ where

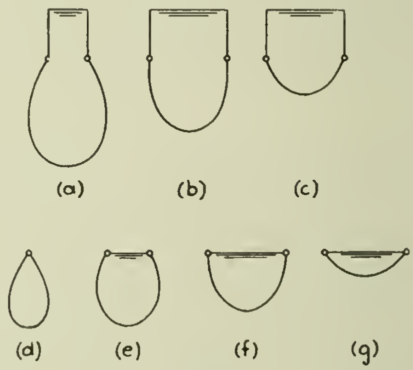

Fig. 2

$k \overline{\gtrless} 1$ and putting $\sin(\beta/2) = k\sin\phi$ we get $y = 2\,ak\cos\phi$ and (4) becomes

$$x = \int_o^\phi \frac{a\,(1 - 2\,k^2\sin^2\phi)}{\sqrt{(1 - k^2\sin^2\phi)}}\,d\phi$$

which gives on integration a result in terms of elliptic integrals

$$x = a\,[\,2\,E\,(k, \phi) - F\,(k, \phi)\,]\ldots\ldots\ldots\ldots(6)$$

Tables of elliptic integrals are readily available, and numerical results can be calculated with ease.

If $k > 1$ this procedure is not applicable, and we must put $k^2 = 1/f^2$ where $f < 1$ and put $\phi = \beta/2$. Then $y = (1 - f^2\sin^2\phi)^{\frac{1}{2}}\,2\,a/f$ and equation (4) becomes

$$x = af\int_o^\phi \frac{1 - 2\sin^2\phi}{\sqrt{(1 - f^2\sin^2\phi)}}\,d\phi$$

which on integration gives

$$x = af\left[F(f, \phi) - \frac{2}{f^2}\{F(f, \phi) - E(f, \phi)\}\right] \ldots\ldots (7)$$

The length of any arc, measured from the bottom point, is given by integration of the equation $ds = R\, d\beta$

$$s = afF(f, \phi) \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

$$s = aF(k, \phi) \ldots\ldots\ldots\ldots\ldots\ldots (9)$$

according as $k$ is greater or less than unity.

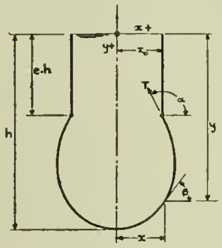

Fig. 3

The area bounded by the curve, the vertical boundaries and the water surface comes directly from consideration of the tension at the supports, since $wA/2 = T \sin \alpha$ and hence, if $A$ is this area,

$$A = 2a^2 \sin \alpha \ldots\ldots\ldots\ldots\ldots\ldots (10)$$

The general type of curve is shown by the following relations for the cases in Fig. 2:

$h^2(1 - e^2) > 2a^2$ Fig. 2 (*a*)
$= 2a^2$ Fig. 2 (*b*)
$< 2a^2$ Fig. 2 (*c*)

and when $e = 0$ the same relations apply respectively to Figs. 2 (*e*), 2 (*f*) and 2 (*g*). In Fig. 2 (*d*) there is the condition that $x_o = 0$.

The case of the fluid level below the points of support does not require consideration in detail because dimensions must then be referred to the plane of the water surface, and the cord will follow its tangents at the water surface to the points of support.

The curve can also be constructed graphically from the equation $R = a^2/y$.

In the particular case of Fig. 2 (*f*) when the tangents at the supports are vertical and $e = 0$ there are the simple relations $h^2 = 2a^2 = A$; $x_o = 0.847\, a$ and the length of the curve between supports is $3.708\, a$.

# Forty-Ninth Annual General Meeting

## Toronto, Ont.

OUTLINE OF PROGRAMME

(*Subject to Minor Change*)

Thursday, February 7th:—

*Morning*..... Registration and Business Session. Induction of incoming President and Council.

*Noon*......... Formal Luncheon.

*Afternoon*..... Discussion on the Status of the Engineer. Reception and Tea for Ladies.

*Evening*...... Annual Dinner of The Institute followed by a Dance.

Friday, February 8th:—

*Morning*...... Technical Sessions.

*Noon*......... Luncheon.

*Afternoon*..... Discussion on the Water Supply of the Prairie Provinces.

*Evening*...... Smoking Concert. Entertainment for Ladies.

Saturday, February 9th:—

*Morning*...... Visits to Engineering Works of Interest.

Toronto from the Harbour. (*By courtesy of Canadian Pacific Railway Co.*)

# The Rationalization of Load Factors for Aeroplane Wings

*Charles Wilfred Crossland, S.E.I.C.,*
*Technical Assistant, Hawker Aircraft Limited, Kingston-on-Thames, England.*

**From a thesis submitted to the Massachusetts Institute of Technology and reprinted by permission.**

SUMMARY.—In the past load factors for aeroplane wings have been decided on an empirical rather than on a rational basis. The author refers to previous investigations bearing on this subject and describes briefly the various methods for the determination of principal wing load factor for which data are available He discusses the results obtained by rational methods and suggests a new expression, based on the equations of motion and assuming an instantaneous pull up from horizontal flight at maximum velocity. Recommmendations are given with regard to the load factor to be assigned to aeroplanes both of the restricted and unrestricted classes.

When the art of flying was in its early stages of development, scientific investigation was largely directed toward the aerodynamic aspects of the problem of flight; when it had been demonstrated that mechanical flight was possible and feasible, the attention of experimenters was concentrated on the problem of building structures sufficiently light and strong to fly. Theory and experimental research produced satisfactory aerofoils, and for a number of years aeronautical engineering was chiefly concerned with aeroplane structures. During and since the World War, research and experience have solved the most pressing problems in structural design, and in the past few years more and more attention has been paid to aerodynamics, and there has been a decided tendency toward replacing empirical methods and formulae by more rational means. At the present time, the rationalization of load factors is occupying a prominent place in such discussions; a number of attempts have been made to put the specification of load factors on a rational basis: some of these have mingled a slight amount of theory with a large amount of empiricism; others have been based on pure theory, simplified as necessary by reasonable assumptions. In this work an attempt will be made to present a number of proposed solutions of the load factor problem, to correlate their results and to select what is thought to be the best method.

Before proceeding further it would be well to state clearly what is meant by the term "load factor." In general, in aeroplane structures, the stress is not proportional to the load, and it has long been the rule to design members to their ultimate strength, multiplying the normal load by a load factor. Throughout this work, we shall be concerned solely with wing load factors, and accordingly,

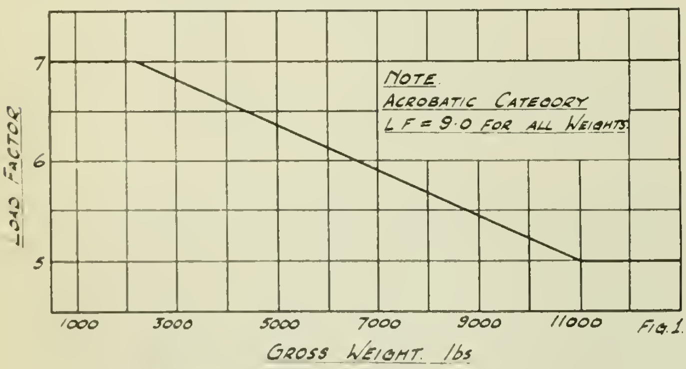

**Fig. 1—Current British Load Factors.**
**Factors for Centre of Pressure Forward Case**
**(High Angle of Incidence).**
**From Air Publication 1208—Airworthiness Handbook for Civil Aircraft.**

may define load factor as the ratio of the maximum load likely to be sustained by the wings of an aeroplane in flight, to the normal load. Further, we shall confine ourselves to wing load factors caused by curvature of the flight path, and not by changes in angle of attack due to atmospheric disturbances, which is an entirely separate field of study.

It goes without saying that an accurate knowledge of the maximum load occurring on the wings is of first importance; for if the aircraft is designed to too low a factor, the wing structure will fail when the machine is put through a violent manœuvre, or encounters a strong gust in "bumpy" air; while if the specified load factor is too high, a needless sacrifice of useful load is made, and the aircraft is thereby penalized. It is well known that it is impracticable to build an aeroplane of such strength that it cannot be broken in the air by a reckless and violent pilot, and there is no reason why this should be the aim, since skilful and careful handling, with due regard to the limitations of the aeroplane, is to be fairly expected of the pilot.

When governmental authority turned its attention to the need for uniformity and control in the specification of load factors, rules for future designs were based on existing aeroplanes which had shown evidence of satisfactory strength. the gross weight being the criterion. The British system of assigning load factors is still based on gross weight, while that employed in the United States is based on gross weight and power loading. This method is purely empirical, and while it is thought that the load factors given are high enough, due to the rarity of structural failures now occurring, it is not known whether they are too high, or higher for some aircraft than others, in respect to the actual load factors which may be experienced in flight. It is therefore considered that the method of assigning load factors should be put on a more rational basis, which would more closely approximate the factor actually sustained by the aircraft, and which would be less likely to be out-moded by changes in design.

The aim of the semi-rational methods has been to evolve a formula which would give results closely approximating those of the present method, for the majority of machines, but which would define the required load factor in terms of more rational variables than at present employed, take care of the increasing spread in the range of speeds, and make some allowance for manœuvrability. As shown in a "Preliminary Study of Load Factor Determination,"[1] the theoretical load factor is a function of the square of the speed range. The first attempts at rationalization were based on this factor. More rational methods attempted to set up the equations of motion in a specified manœuvre, and found the load factor by mathematical means. In some of these, sufficient assumptions were made that the equations could be solved; in others, step-by-step integrations were carried through. These methods will be considered in some detail in the following sections.

## Objections and Preliminary Suggestions

The principal objection to the present system of assigning load factors, is simply that it is too empirical, and therefore not as trustworthy as desired. It has proved reliable enough in the past, but with improvements in design and increase of power and speed, it could not be applied with full confidence. Any empirical method requires constant revision, and in the nature of things, such revision is bound to have a considerable time lag. It is well known that there are other factors besides the gross

[1] Air Commerce Bulletin, Nov. 2, 1931.

weight and power loading, which affect the load factor attainable in flight, but the system now in use completely ignores them, and therefore must be adjusted to suit designs which are the worst in this respect, thereby penalizing improved designs. The type of aircraft, the service for which it is intended, the degree of manœuvrability, the speeds at which the aeroplane will be manœuvred, and the manner in which it is handled, are major considerations which are not taken into account.

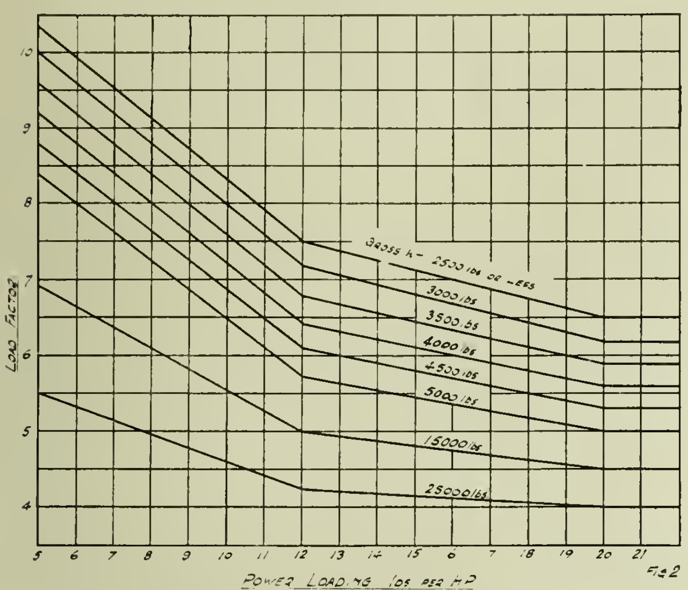

**Fig. 2—American Load Factors.**
**Factors for High Angle of Incidence (Recently Amended).**
**From Aeronautics Bulletin No. 7-A of the U.S. Dept. of Commerce—Airworthiness Requirements.**

One of the first remedies for this state of affairs, is the division of aeroplanes into classes, according to the type of service. The British Load Factors Sub-committee suggests division into two classes, viz.: General and Commercial (see R. & M. 673, 776); aeroplanes falling into the general class to be strong enough to allow stunting (acrobatic); and stunting to be prohibited in the commercial class. This is a step in the right direction, and could be carried further. For example, a private owner is likely to want an aeroplane in which a moderate amount of stunting would be permissible, but his machine need not be capable of the violent acrobatics which are demanded of fast military pursuit ships and diving bombers. Some limitation would have to be placed, and the best way would be to post a notice in the aeroplane, stating the maximum safe speed for manœuvring; this speed being that used in determining the design load factor. The pilot would thereby be warned to handle the machine with more than ordinary care at higher speeds. The pilot's skill is another variable, which could also be taken care of in fixing the maximum safe speed to be used in design.

The type of service for which an aeroplane is intended limits the manœuvres it should be able to withstand with safety. It is therefore necessary to discover, first, what type of manœuvre results in the greatest wing loads; second, whether the class of machine under consideration is to be handled in this manner; and third, which is the worst condition to be designed for in this class.

It is generally agreed that the worst condition is that of a sharp pull-out from a dive at terminal velocity; and it is also generally agreed that it is safe to assume that a commercial aeroplane will never be dived at its terminal speed. The opinion is held that the design condition should be, instead, a sharp pull-up from level flight at maximum speed. It is quite possible that a commercial machine would be subjected to this manœuvre, but it is only likely to occur in an emergency. Experiment shows that, excepting the pull-up from a dive, the pull-up from horizontal flight at maximum speed gives the greatest loads; and for machines of moderate size, it is also reasonable to assume that this condition is a fair representation of loads imposed by bumpy air. In the case of a large machine, such loads may be much greater than loads due to manœuvring, and will probably be the design condition.

The limitations upon attainable load factor are given by Edward P. Warner as follows[2]:

1. Physiological limitation of the maximum load factor that the pilot can sustain without losing consciousness.
2. Limits imposed by the manœuvrability characteristics of the airplane and the time taken for its attitude to change from that of diving to that corresponding to a high-lift coefficient.
3. Limit of rapidity with which the pilot can pull back the stick.
4. Limit upon the force that the pilot is physically able to exert on the stick.

The first, third and fourth limits are known with reasonable accuracy: it is, in part, the purpose of this study to shed some light on the second.

It has been recommended (R. & M. 706, see page 533) that the terminal velocity should be used as a basis for all design, and the load factor modified by a design factor of one-half, for all classes. The argument for this is, that the terminal speed depends on the design, whereas any other value depends on the engine installed. The objection that engine power might be increased without making allowance for the increased load factor, may be forestalled

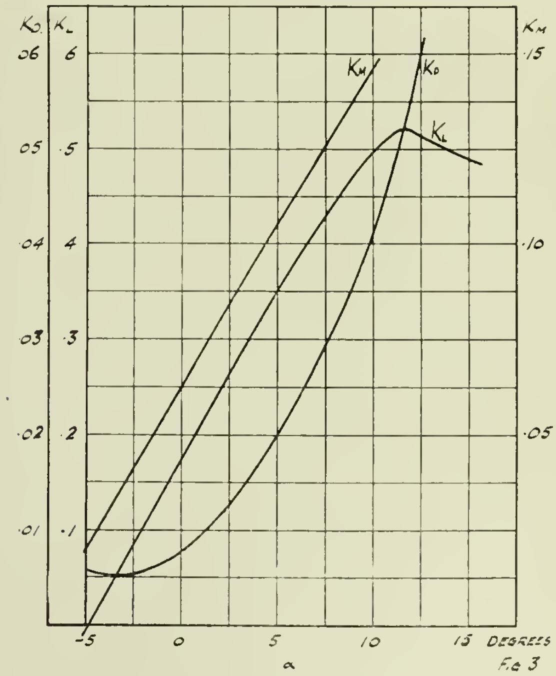

**Fig. 3—Curve of Lift ($K_L$), Drag ($K_D$), and Moment ($K_M$) coefficients vs. Angle of Incidence for R.A.F. 28 Aerofoil. (The Moment Coefficient is referred to the Leading Edge.)**

by governmental regulation. (See U.S. Department of Commerce regulations.) Approximate formulae exist for estimation of maximum level speed and minimum speed; these should be refined by further comparison with actual aeroplanes.

[2]"The Rationalization of Airplane Load Factors"—paper read at the Aeronautic meeting of the Society of Automotive Engineers, April 1932.

Summing up, it is recommended that:—

(*a*) Aeroplanes be classed as "restricted" or "unrestricted."

(*b*) Unrestricted aeroplanes to be designed to withstand manœuvres which they are specifically intended to carry out.

(*c*) Restricted aeroplanes to be designed to withstand a sharp pull-up from level flight at a speed to be decided on by the manufacturer, and posted in the cockpit, but not less than the maximum speed in level flight.

### General Experimental Conclusions

A report by J. H. Doolittle on "Accelerations in Flight"[3] was one of the earliest experimental investigations of load factors experienced in flight. The aeroplane used in these tests was a Fokker PW-7, with balanced control surfaces, and powered by a Curtiss D-12 engine. The results of this investigation were:—

1. The worst condition is in pulling out of a dive; in which case the accelerations go to within 3 or 4 per cent of the theoretically possible.

2. Accelerations due to rough air do not amount to more than 2.5 *g*.

3. The pilot can stand instantaneous accelerations of 7.8 *g*, but not more than 4.5 *g* if continued for several seconds.

4. The load depends on:

   (*a*) The ratio: $(V/V_{\min})^2$. (The speed of the manœuvre divided by the stalling speed.)

   (*b*) The longitudinal stability of the aeroplane.

   (*c*) The damping due to pitching.

   (*d*) The time required to pull back the stick.

In the case of a highly manœuvrable aeroplane of this type, especially one with balanced elevators, the results (1) and (4) above, are to be expected, since the damping is quite small. The accelerations due to rough air are questionable, since air conditions much worse than those experienced are sometimes encountered. In the discussion of Professor Newell's paper,[10] Lieutenant R. D. MacCart, U.S.N., is quoted as saying, "The maximum acceleration that can safely be sustained by what might be called the high-acceleration pilot may be nine, although the average pilot will not voluntarily accept, even momentarily, as high an acceleration..." It would appear from this that the maximum load factor to which any aeroplane need be designed would be about 15, leaving a substantial margin of safety.

In more recent experiments,[4] measurements were made of air speed, angular velocity, linear acceleration and position of the control surfaces, by instruments in the aeroplane, during loops, push-downs, pull-outs from dives, pull-ups from level flight, barrel rolls and spins. A camera obscura was used in obtaining flight path co-ordinates.

For the F6C-3, the maximum normal accelerations were obtained in a pull-up from a dive and a pull-up from horizontal flight, both with abrupt control; the accelerations in both cases being 6.65 *g*. The same manœuvres gave maximum accelerations for the F6C-4, the accelerations being, for the pull-up from a dive, 9.3 *g*; and for the pull-up from horizontal flight, 7.8 *g*. These tests showed that the reduction in velocity, and time taken to reach the maximum load, are negligibly small.

In a report by E. Finn and A. E. Woodward Nutt[5] a total of 340 manœuvres on 14 different types of aircraft were analyzed. Free flight tests showed that for manœuvres correctly performed by skilled pilots, the average maximum acceleration was of the order of 2 *g*.

These results do not seem to be significant. Evidently "correct" performance is taken to mean handling the aeroplane in such a manner as not to impose a high acceleration. However, it does show that manœuvres *can* be performed without imposing great loads.

The results of a number of accelerometer tests which were made by the U.S. Air Corps at McCook Field are tabulated in "Airplane Structures" by Niles and Newell, page 22. Tests were made on training, observation, pursuit, bombing and cargo aeroplanes. The last two classes gave quite low load factors, while the highest, 7.8, was reached by a PW-7 pursuit aeroplane, in a sharp pull-out at high speed.

The results of these tests are valuable for comparison, but suffer from lack of accurate knowledge of the speed during manœuvres; and it is probable also that higher load factors than those recorded could have been developed by these aeroplanes.

A report by Heinrich Hertel[6] covers a very complete series of tests. The maximum values are:—for two-hand pull—275 pounds belted in, 187 pounds free; for one-hand pull or push—143 pounds with belt, 187 pounds free. The maximum quickness of operation was found to be 6.56 feet per second, and was independent of the load; the stick movement being 7.87 inches.

Another report[7] covers similar tests to the above. The bulk of the motion was found to occur in 0.2 seconds, independently of resistance. The maximum speed was found to be 5.25 feet per second; the motion of the control stick being nearly twice as great as in the above tests. The usual maximum stick force was about 165 pounds, but one experimenter reached 200 pounds and another about 230 pounds; these were with the initial position of the stick 30 degrees forward. A ten-pound lead weight was placed on the stick to represent the inertia of the controls.

All these considerations lead to the following recommendations:—

(*a*) The maximum load factor for any aeroplane to be taken as 15 or thereabouts.

(*b*) The reduction in velocity during a sharp pull-up to be neglected.

(*c*) The maximum control column force to be taken as 200 pounds, applied instantaneously.

### Empirical and Semi-rational Methods

One of the first attempts to put the determination of load factors on a rational basis was that of Major F. H. Bramwell[8] in 1920. Working from certain theoretical considerations and considering a vertical bank, he obtains equations for the minimum radius of turn, the acceleration, and the load factor.

This determination is too familiar to require much discussion. It is invalidated by completely neglecting the damping due to pitching. The equations apply to the wing alone, and would represent approximately the case of a tailless aeroplane. This treatment represents the first elementary stage in the rationalization of load factors.

In another early and well-known attempt at rationalization,[9] manœuvrability is assumed to be a function of

[9] N.A.C.A. T.N. 263—"A Load Factor Formula," by Roy G. Miller, 1927.

gross weight and the speed range squared. Certain arbitrary constants are assumed, and the formula given as:

$$\text{Load factor, } N = 1.75 + (V_{\max}/V_{\min})^2 \frac{112}{\sqrt{5000 + W}}$$

where $W$ = weight of aeroplane, pounds
$V$ = speed, feet per second.

The formula is checked by comparison with aeroplanes which have experienced structural failure, and those which have not. The only points in favour of the formula are that it includes the speed range squared, and that it corresponds to experience up to that time, but this point is a very dubious one, as mentioned previously.

The treatment in a paper by Joseph S. Newell[10] is based on the fact that the load factor depends on the speed range of the aeroplane and its ability to manœuvre. It is further pointed out[11] that the increase in normal force coefficient, due to pitching, more than offsets the decrease in velocity during a pull-up. It is shown that the maximum loads will occur when the aeroplane is flown in the high angle of attack condition and at terminal velocity. It is proposed to base load factors on the speed range, i.e. the maximum level flight speed divided by the stalling speed, and a control surface constant that is the horizontal tail surface area divided by the wing area, times the length of the tail divided by the mean aerodynamic chord. An empirical constant of 3.5 is introduced, apparently in order to make the results agree as closely as possible with existing load factors.

In summing up, it is recommend that aeroplanes be divided into acrobatic and non-acrobatic classes (see page 531); the factors for the first class, in the high angle attitude, to be based on the maximum possible or endurable accelerations, and for the second class, in terms of the speed range and a manœuvrability factor. The tail loads would be determined in each case, from the maximum velocity for an abrupt pull-up, and the factors for the low angle attitude to be based on the loads possible in mild pull-outs at terminal speeds, and would be determined from the ratio of terminal velocity to the level flight velocity at the same angle of attack.

A number of bulletins,[12] published by the U.S. Department of Commerce, Aeronautics Branch, contain a series of articles dealing with load factors.

In the first of the series, a formula is presented which is based on the square of the speed range, and a constant which depends on gross weight, and is so chosen that the results will be the same as at present in use. The procedure is very similar to that of Roy G. Miller, reviewed above, and is subject to the same criticism. Coefficients are given which are to be used to modify the high speed formula suggested for different types of aeroplanes. Minimum values are proposed for the constant and speed range squared.

In the January 15th bulletin, the article, "A General System of Load Determination for Aircraft," presents a more rational method of attack, and, without developing a formula for load factor, indicates the salient points to be dealt with and their manner of treatment. It is continued in the last bulletin of the series, in which a formula is given, without derivation, for the design lift coefficient.

Examination of the formula shows that the damping of the tail due to pitching was neglected in the derivation, and it is accordingly "damned with faint praise," for if control is sufficient to get the tail down to make a three-point landing, as it should be, and there is no damping, there is nothing to prevent the aeroplane from reaching the maximum-lift attitude. Accordingly, if damping is to be neglected, the load factor is simply:

$$N = \left(\frac{V_{\max}}{V_{\min}}\right)^2$$

The damping of the tail is obviously an important factor, which cannot be neglected in a rational treatment of the load factor problem.

### Load Factor Determination by Rational Methods

The equations of motion following were step-integrated by Bryant[13] to find the flight paths during loops and pull-outs from loops and dives.

$$k_B^2\,\ddot{\theta} = M/m + M_q\dot{\theta} \qquad (1)$$
$$\dot{w} = u\dot{\theta} + Z - g\sin\theta + Z_q\dot{\theta} \qquad (2)$$
$$\dot{u} = -w\dot{\theta} + X - T/M - g\cos\theta \qquad (3)$$

where $k_B$ = longitudinal radius of gyration of aeroplane
$M$ = pitching moment
$M_q$ = pitching moment due to pitch
$m$ = mass of machine in slugs (32.2 lb. mass)
$\theta$ = angle between longitudinal axis and the vertical
whence $\dot{\theta}$ and $\ddot{\theta}$ = angular velocity and acceleration in pitch
$w$ = velocity along vertical axis
$u$ = velocity along longitudinal axis
$Z$ = force along vertical axis
$X$ = force along longitudinal axis
$T$ = airscrew thrust.

Curves showing the variation of $M$, $M_q$, $Z$ and $X$ with elevator setting and angle of incidence, were plotted from model test data. The flight paths are plotted; load factor, load on tail, angle of incidence and forward speed being indicated at points along the path.

Conclusions are drawn as follows:—"It appears that the maximum wing loading will occur at the critical angle of incidence and at a speed not more than 150 to 160 m.p.h.; and that for most modern machines with unbalanced elevators and the usual control leverages it is then probably about twelve to thirteen times normal load... The greatest load, therefore, will not in general occur after diving at the limiting speed, but when the pilot exerts his hardest pull for a second or two while the speed is considerably less than the limiting speed. In the course of a loop after a steep and prolonged nose dive the loading of the wings of a very fast machine should not exceed 5 times normal, even if the pilot initially exerts a pull approaching his greatest, provided that he slackens his pull again immediately. There is greater risk in pulling hard at lesser speeds, particularly when flattening out after looping. The maximum loading will usually occur in the second quadrant of a loop, but may occur near the top of a loop if the machine is looping at a very high forward speed."

A load factor of 8 to 10 is recommended for fast military machines. This report appears to be an excellent treatment of the load factor problem, but unfortunately, no general conclusions can be drawn from it, except possibly, for highly manœuvrable aeroplanes.

The method followed in an investigation by Professor Pippard[14] was as follows:—An aeroplane of the B. E. class was taken to be flying on a path inclined at 20 degrees downward to the horizon. The elevators were then con-

sidered to be raised, the engine cut out, and the subsequent motion investigated. The equations of motion (given in "Applied Aerodynamics" by Bairstow) were step-integrated, varying the terms one at a time in order to determine to what extent each influenced the value of load factors. The terms varied were, velocity, mass of the aeroplane, longitudinal moment of inertia, pitching moment due to the inclination of the aeroplane to the relative wind, pitching moment due to pitching, and distance between the C.G. and the C.P. of the tail. It was found that the only terms which affect the loading in a pull-up are: velocity, mass, pitching moment due to inclination and pitching moment due to pitching. The formula for load factor is deduced from the results as:

$$N = 0.208\,(V/V_o)^{1.7}\,[1 - 3.32\,(M_1/M_q{}^1)^{7/15}]$$

where $V_o$ = stalling speed, feet per second

$M_1$ = pitching moment due to the inclination of the aeroplane to the relative wind.

$M_q{}^1$ = value of pitching moment due to pitching at a rate of one radian per second.

This formula is plotted as a family of curves and as a nomograph. The author points out that this result is obtained for one type of aeroplane only, and that further work is required to determine the effect of the wing section and the degree of longitudinal stability. $V$ is the terminal speed, a design factor of 1/2 being introduced.

The chief value of this report, or any similar treatment, is that it indicates the factors which are most important and must be included in any rational determination, and those for which approximations can be made, or which can be neglected. The most important terms are the speed range, the pitching moment, and the pitching moment due to pitching, i.e., the damping. The gross weight is implicitly included in the speed range, and the tail length in the moment terms.

In a report by H. Bolas and G. A. Allward,[15] step-by-step calculations were made of wing and tail loads for a machine of specified characteristics, in pulling out of a dive. Variations in gear ratio between elevator and control stick were assumed, as well as variations in the total time required to pull the stick back, and in the initial diving speed.

Conclusions were drawn as follows:—

(1) A variable gear ratio is of no great value in reducing the maximum loads.

(2) Increasing the time does not greatly reduce the wing loading, but the tail loading is considerably reduced. A device to prevent the stick from being pulled back too quickly would not reduce the loading appreciably.

(3) For a safe manœuvre low hand loads must be employed. "In the case considered, a maximum hand load of about 33 pounds produces a wing loading of 4 *g*."

"The incorporation of a means whereby only a limited load could be applied to the elevator, would produce the desired effect. This might for instance take the form of a control stick provided with a hinge at some convenient point—a strong spring being introduced which would insure a virtually rigid stick for all normal work, but which would allow the stick to 'break' when the pull back exceeded a certain predetermined load, say for instance, 50 pounds in the present case."

(4) The pull-out from a terminal velocity dive represents the worst possible case, and shows that increase of load factor as a means of overcoming the difficulty is out of the question.

This report does not produce a general formula for load factor, but like the previous one, it indicates the factors affecting the maximum loading. The recommendation of a spring device in the control column, to limit the hand load, seems impractical. Pilots would be likely to remove the device and replace it with the ordinary stick. Further, having the stick "break" when pulled up sharply in an emergency, would be most disconcerting. The conclusion to be drawn from the report is therefore that the maximum wing loading cannot be limited by mechanical appliances, and it is very doubtful if such a solution of the problem would even be considered, at least on this continent.

The static stability of the aeroplane is considered to have a predominating effect on the motion of recovery which follows a given change in the force exerted on the stick.[16] From calculation made during the war on the motion of S.E. 5 in pulling out from steep dives, by step integration, it was established that the variation in forward speed remains small until after the maximum aerodynamic load occurs. The forward speed was therefore assumed constant, and the equations of lift and pitching moment were integrated in terms of inclination of the flight path to the vertical and the angle of incidence, measured from zero lift.

An equation is set up which expresses a relation between the pilot's pull on the column and the lift coefficient at maximum load, and connects stick force with load factor.

The following points are noted:—

(1) Load factor ($N$) is independent of the longitudinal moment of inertia.

(2) For an aeroplane of given weight, tail volume, and C.G. position, $N$ is independent of the cleanness of design, i.e. of the speed in the dive, for a given pull.

(3) For a given pull, $N$ decreases as the weight increases, but this variation is a function of stability. In a neutrally stable aeroplane, $N$ is independent of the wing loading.

(4) $N$ increases with the height of the manœuvre.

(5) For geometrically similar aeroplanes of given normal loading, in which the gearing of the control is constant, $N$ for a given pull goes down rather faster than the inverse cube of the linear dimension.

The results show that load factor varies greatly with the type of aeroplane. The results on the whole are somewhat unconvincing. The conclusion that the load factor is independent of the speed in the dive is contradictory to the last report, and in fact, to the results of most, if not all investigations. In the writer's opinion it is preferable to base the load factor on elevator deflection instead of stick force, because the poor data available for hinge moments limits the practicability of the method, and hinge moments are very difficult to measure, especially with balanced control surfaces. A separate calculation can be made to take the stick force into account.

A good part of the work, and the last formula given, are of little use since they apply only to aeroplanes of neutral stability, whereas it is stated in the beginning that the static stability has a predominating effect on the motion of recovery, and therefore, it is to be inferred, on the load factor.

### A Proposed Rational Method of Load Factor Determination

This method is here presented for the first time. The method of treatment of the moment equations was suggested by Professor Otto Koppen of the Massachusetts Institute of Technology.

As the equations of motion cannot be integrated directly, during the recovery from a dive, it is necessary to make some simplifying assumptions, based on results found from experiment and step-by-step integration. The case considered is that of an instantaneous pull-up from

[15] R. & M. 1229—"Loads on the Main Planes and Tail of an Aeroplane when Recovering from a Dive," by H. Bolas and G. A. Allward, 1928.

[16] R. & M. 1232—"On the Maximum Loads in Pulling Out from Vertical Dives," by S. B. Gates and H. B. Howard, 1928.

horizontal flight at maximum velocity, with the following assumptions:—

1. The lift coefficient is a linear function of angle of incidence, the maximum point being neglected in the equations.
2. The aeroplane is trimmed at maximum level speed, with zero elevator deflection.
3. The reduction in forward speed during the pull-up is negligible. This is verified by experiment (page 532) and is also on the conservative side.
4. The control column is pulled back to the maximum elevator deflection, and the maximum load comes on the wings, all in a negligibly short time. The equations apply when equilibrium conditions have been attained.

The symbols used and their meanings, are as follows (see Handbook of Aeronautics R.Ae.S., and R. & M.):

$W$ = gross weight, pounds
$k_L$ = absolute lift coefficient = $L/S\rho V^2$
$a$ = distance of the C.G. behind the leading edge of the mean aerodynamic chord
$c$ = mean aerodynamic chord
$L$ = length from C.G. to C.P. of tailplane
$S_w$ = wing area, ft²
$S_t$ = horizontal tail area
$S_\eta$ = elevator area
$\alpha_w$ = angle of incidence of wing, degrees, measured from zero lift
$\alpha_t$ = angle of incidence of tail to relative wind, degrees
$\varepsilon$ = angle of downwash
$\alpha_{T_o}$ = angle between wing and tailplane = $(\alpha_T - \tau\eta)$
$\alpha_T$ = stabilizer setting
$\eta$ = angle of deflection of elevator
$A$ = equivalent monoplane aspect ratio
$M_{cg}$ = moment about centre of gravity
$\rho$ = air density
$s$ = wing area
$k_{mcg}$ = moment coefficient about centre of gravity
$q$ = angular velocity in pitch, radians per second
$K$ = $k_L/k_{L_{\max}} = (V_{\min}/V_{\max})^2$
$N$ = load factor
$k_m$ = pitching moment coefficient = $M/cS\rho V^2$

The equation of static equilibrium is:

$$M_{cg} = k_{m_o} c S_w \rho V^2 + k_L (a - .25\,c) S\rho V^2 - L S_t \rho V^2 (dk_L/d\alpha)_t \alpha_t$$

$$\alpha_t = \alpha_w - \varepsilon + \alpha_{T_o}$$

$$k_{m_{cg}} = k_{m_o} + k_L (a/c - .25) - \frac{L}{c}\frac{S_t}{S_w}\left(\frac{dk_L}{d\alpha}\right)_t (\alpha_w - \varepsilon + \alpha_{T_o})$$

$$= k_{m_o} + Bk_L - F(\alpha_w - \varepsilon + \alpha_{T_o}) \quad \ldots\ldots\ldots\ldots (1)$$

where $k_{m_o}$ = moment coefficient of the wing about the quarter-chord.

$$B = (a/c - .25)$$

$$F = \frac{L}{c}\frac{S_t}{S_w}\left(\frac{dk_L}{d\alpha}\right)_t$$

Differentiating (1):

$$\frac{dk_{m_{cg}}}{d\alpha_w} = \frac{dk_{m_o}}{d\alpha} + B\left(\frac{dk_L}{d\alpha}\right)_w - F(1 - d\varepsilon/d\alpha) = k \text{ (say)} \ldots\ldots (2)$$

$k$ may be called a "stability constant." Its value should be between $-0.0025$ and $-0.005$ for satisfactory stability. (See Göttingen tests.)

Now, $dk_{m_o}/d\alpha = 0$ (approximately, for all aerofoils)

$\varepsilon = k_1 k_L / A$ (Warner's "Aerodynamics" p. 342)

therefore $$\frac{d\varepsilon}{d\alpha} = \frac{k_1}{A}\left(\frac{dk_L}{d\alpha}\right)$$

Hence $$\frac{B}{F} = \frac{k}{F\left(\frac{dk_L}{d\alpha}\right)} + \frac{1}{\left(\frac{dk_L}{d\alpha}\right)} - \frac{k_1}{A} \ldots\ldots\ldots (3)$$

In curvilinear flight, the force on the wings,

$$L = \frac{WV^2}{gR} + W\cos\theta = k_L \rho S V^2$$

where $R$ = radius of curvature of flight path and $\theta$ = angle to the horizon.

Taking $\cos\theta = 1$, corresponding to the case of a sharp pull-up from level flight,

$$1/R = gk_L\rho\, S/W - g/V^2$$

In curvilinear flight, $V = qR$

therefore $$1/R = q/V = gk_L\rho\, S/W - g/V^2 \ldots\ldots (4)$$

The equation of equilibrium in curvilinear flight is:

$$k_{m_{cg}} = k_{m_o} + Bk_L - F(\alpha_w - \varepsilon + \alpha_{T_o}) - 57.3\, FLq/V = 0$$

$$k_{m_o} + Bk_L - F(\alpha_w - \varepsilon + \alpha_T - \tau\eta) - 57.3\, FLq/V = 0 \ldots\ldots\ldots (5)$$

where $\alpha_{T_o} = (\alpha_T - \tau\eta)$

Dividing through by $F$ and making the substitutions for

$$\alpha = \frac{k_L}{(dk_L/d\alpha)}$$

$$\varepsilon = k_1 k_L / A$$

$$q/V = gk_L\rho S/W - g/V^2$$

$$\frac{k_{m_o}}{F} + \frac{B}{F}k_L - \frac{k_L}{\frac{dk_L}{d\alpha}} + \frac{k_1 k_L}{A} - \alpha_T + \tau\eta - 57.3\, g\, k_L\rho LS/W + 57.3\, g\, L/V^2 = 0$$

Collecting $k_L$ terms,

$$\frac{k_{m_o}}{F} + k_L\left(\frac{B}{F} - \frac{1}{\left(\frac{dk_L}{d\alpha}\right)_w} + \frac{k_1}{A} - 57.3\, g\,\rho LS/W\right) - \alpha_T + \tau\eta + 57.3\, Lg/V^2 = 0$$

Substituting for $B/F$ from (3):

$$\frac{k_{m_o}}{F} + k_L\left(\frac{k}{F\left(\frac{dk_L}{d\alpha}\right)} + \frac{1}{\frac{dk_L}{d\alpha}} - \frac{k_1}{A} - \frac{1}{\frac{dk_L}{d\alpha}} + \frac{k_1}{A} - 57.3\, g\,\rho\frac{LS}{W}\right) - \alpha_T + \tau\eta + 57.3\, L\, g/V^2 = 0$$

$$k_L = \frac{-\frac{k_{m_o}}{F} + \alpha_T - \tau\eta - 57.3\, Lg/V^2}{\frac{k}{F\left(\frac{dk_L}{d\alpha}\right)} - 57.3\, g\,\rho\frac{LS}{W}}$$

Differentiating with respect to elevator angle:

$$\frac{dk_L}{d\eta} = \frac{-\tau}{\frac{k}{F\left(\frac{dk_L}{d\alpha}\right)} - 57.3\, g\,\rho\frac{LS}{W}} \ldots\ldots\ldots\ldots (6)$$

From equation (4):

$$V^2/R = g\, k_L\, \rho\, S\, V^2/W - g$$

$$\frac{d(V^2/R)}{dk_L} = g\,\rho S V^2/W \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (7)$$

In level flight $W = K\, k_{L_{\max}}\, \rho\, S\, V^2$

or $V^2 = W/K\, k_{L_{\max}}\, \rho\, S$

where $K = (k_L/k_{L_{\max}}) = (V_{\min}/V_{\max})^2$

Substituting for $V^2$ in (7) and assuming speed remains constant,

$$\frac{d(V^2/R)}{dk_L} = g\,\rho\frac{S}{W} \times \frac{W}{K\, k_{L_{\max}}\, \rho S} = \frac{g}{K\, k_{L_{\max}}} \ldots\ldots (8)$$

From equations (6) and (8):

$$\frac{d(V^2/R)}{d\eta} = \frac{d(V^2/R)}{d\,k_L} \times \frac{d\,k_L}{d\eta}$$

$$= \frac{g}{K\,k_{L_{max}}} \times \frac{-\tau}{\dfrac{k}{F\left(\dfrac{d\,k_L}{d\alpha}\right)} - 57.3\,g\rho\dfrac{LS}{W}}$$

where $\frac{d(V^2/R)}{d\eta}$ is the rate of change of acceleration normal to the flight path, with elevator deflection.

Therefore, load factor,

$$N = \frac{-\tau\eta_{max}}{K\,k_{L_{max}}\left[\dfrac{k}{F\left(\dfrac{d\,k_L}{d\alpha}\right)} - 57.3\,g\rho\dfrac{LS}{W}\right]}$$

*Determination of the Elevator constant*

$\tau$ may be defined as the rate of change of effective tail angle of attack with elevator angle, which is seen from differentiating the expression for angle of attack of the tail:

$$\alpha_t = \alpha_w - \varepsilon + \alpha_{T_o} = \alpha_w - \varepsilon + \alpha_T - \tau\eta$$

$$d\alpha_t/d\eta = \tau$$

$\tau$ is a function of the ratio of elevator area to total tail area, and of elevator angle. Various expressions for $\tau$ are given by Diehl, Glauert, Bréguet and Toussaint. Curves were plotted from these formulae, as well as from tests made by the U.S. Army Air Corps and by the Göttingen Research Institute, and from comparison of the curves, it was decided to use the expression given by Diehl, for the purposes of this work. This is (see "Engineering Aerodynamics"):

$$\tau = (1.90 - 0.57\,t/c - 0.014\,\eta_o)\,t/c$$

where $t$ = mean chord of elevator
$c$ = mean chord of tail plane
$\eta$ = elevator angle.

*Simplification of the Load Factor Formula*

The following simplifying assumptions represent average values of the constants of the aeroplane, and are, in general, on the conservative side.

1. Wing aspect ratio, $A = 6$
whence[17] $(dk_L/d\alpha)_w = .037$
$(d\varepsilon/d\alpha) = 0.3$ (approx.)
2. Tail aspect ratio, $A = 3.5$
whence $(dk_L/d\alpha)_t = .0323$ (theoretical)
$= .0323 \times .87 = .0281$ (actual)[18]
3. Maximum elevator angle, $\eta = 30°$ (up)
4. $S\eta/S_t = t/c = 0.45$
whence $\tau = 0.545$
$\tau\eta = 16.35$
5. $k_{L_{max}} = 0.7$

From these it follows that:

$$k = .037\,B - .7\,F$$

$$N = \frac{-16.35}{.7\,K\left(\dfrac{.37B - .7F}{.37F} - 4.38\dfrac{LS}{W}\right)}$$

$$= \frac{-16.35}{.7\,K\,(B/F - 19.7 - 4.38\,LS/W)}$$

*or*

$$N = \frac{(V_{max}/V_{min})^2}{k_{L_{max}}} \times \frac{-16.35}{(B/F - 19.7 - 4.38\,LS/W)}$$

[17] See Warner—"Aerodynamics" p. 362, and $kL$ curves.

[18] See "Determination of the Slope of the Lift Curve of Horizontal Tail Surfaces," by Benjamin F. Ruffner, Jr., "Aviation Engineering," Vol. III, No. 10, Oct. 1930.

A simple nomograph may be constructed which will give a graphical solution of this equation, giving values of $N$ for known values of $B/F$, $LS/W$ and $K$, or speed range.

*Hinge Moments*

A relation between the pilot's pull on the control column and the elevator deflection, is as follows:

Hinge moment, $M_H = k_H S_\eta c_\eta \rho V^2$

where $k_H = b_1\alpha_T + b_2\eta$

therefore $M_H = (b_1\alpha_T + b_2\eta)\,S_\eta c_\eta \rho V^2$

$$\eta = \frac{M_H - b_1\alpha_T S_\eta c_\eta \rho V^2}{b_2 S_\eta c_\eta \rho V^2}$$

$\alpha_T$ is the angle between the stabilizer and the relative wind at the time the stick force is being applied and $= (\alpha_w - \varepsilon + \alpha_{T_o}) = \alpha_t$.

The hinge moment applied by the pilot,

$$M_H = kP$$

where $k$ = leverage ratio, given as 1.8 in R. & M. 1232
$P$ = pilot's pull on stick, maximum 165 to 200 pounds

therefore $M_{H_{max}} = 360$ ft-lbs., approximately.

Average values of $b_1$ and $b_2$ are:

$b_1 = .0082$; $b_2 = .014$.

See R. & M. 1095 and Göttingen Research Institute reports.

*Example*

Load factor calculations for a hypothetical aeroplane; and the effect upon load factor of changing the various physical constants of the aeroplane. Values of the various terms are assumed, and the load factor calculated.

Assumptions:

| | |
|---|---|
| $W/S = 12$ | $a/c = .35$ |
| $S_t/S_w = .12$ | $L = 16$ ft. |
| $S_\eta/S_t = .45$ | $c = 5$ ft. |
| $k_{L_{max}} = 0.7$ | $L/c = 3.2$ |
| $K = .25$ | $LS/W = 1.33$ |
| $\eta = 30°$ | |

Wing aspect ratio = 6, whence $(dk_L/d\alpha)_w = .037$

Tail aspect ratio = 3.5 " $(dk_L/d\alpha)_t = .0323 \times .87 = .0281$

$(d\varepsilon/d\alpha) = .3$

$B = .35 - .25 = .10$

$F = 3.2 \times .12 \times .0281 = .0108$

$k = .10 \times .037 - .0108\,(1 - .3)$

$= -.0039$ (retained constant)

$\tau = .545$

$$N = \frac{-16.35}{.25 \times .7\left(\dfrac{-.0039}{.0108 \times .037} - 4.38 \times 1.33\right)}$$

$$= \frac{-16.35}{.175\,(-9.76 - 5.83)}$$

$$= 6.00$$

Note that this result is greater than the speed range squared $(1/K)$, and therefore the correct load factor for this case is $1/K$, i.e. 4.

Effect of changing the constants. Variation in the constants of the aeroplane, one at a time, keeping the same degree of static stability ($k$), affect load factor as follows:

Load factor increases with increasing values of:

Centre of gravity location (moving backwards)
Wing aspect ratio
Wing loading
Ratio of elevator area to total tail area

Maximum elevator displacement
Speed range and
Tail constant ($F$),

and decreases with increasing values of:

Tail length and
Maximum lift coefficient.

These are for constant static stability. Load factor also decreases with increased static stability.

Effect of thrust of propellor. The equilibrium equations were modified to include the effects of thrust due to the propeller, slip-stream, and propellor downwash, and a sample calculation gone through, as above. These effects are somewhat doubtful, but do not appear to have much effect upon load factor. It was thought advisable to neglect them, as their inclusion makes the work too complicated to be practicable.

For highly manœuvrable aeroplanes the formula for load factor may be expected to give results which are too high; firstly, because the lift coefficient has been assumed to continue indefinitely as a linear function of angle of incidence, and secondly, because the load factor in such cases may be limited by the pilot's ability to pull the control stick full back and to withstand the resulting acceleration. The load factor given by the formula should be checked against the square of the speed range, the smaller value being the correct load factor. The maximum attainable elevator deflection may be found from the formula given under hinge moments.

In an unrestricted machine which is to be sufficiently strong to withstand a sudden pull-out from a dive at terminal velocity, a correction may be made by putting $K$ equal to the square of the ratio of stalling speed to terminal speed, instead of maximum horizontal speed. This is not exact but would probably be a sufficiently close approximation.

## Conclusion

In the preceding sections an attempt has been made to present in brief form, all the methods of determination of principal wing load factor for which data are available, except purely arbitrary rulings. We may now set down some general conclusions.

The exigencies of every-day use in designing aeroplanes require that any method of ascertaining load factors should be as simple and easy to apply as possible. From this point of view alone, the present British system of assigning load factors on a basis of gross weight alone, is ideal; but a certain minimum number of calculations are necessary in the design of an aeroplane: a balance diagram must be drawn, and a calculation for static stability, at least, should be made. It is therefore imposing no hardship on the designer to require him to perform these operations in order to determine the load factor, but a step-by-step integration for each design would not be a practical possibility.

We may now sum up the conclusions and recommendations made in previous sections, as follows:—

1. In general, it may be assumed that the pilot is capable of pulling back the control column instantaneously.

2. The load factor cannot be made sufficiently large to cover the worst condition of loading possible.

3. Any rational method of determination of load factor must include the damping moment caused by the tail plane in pitching.

4. The most important factors to be included in the determination are:

(*a*) Minimum speed, which is a function of gross weight and wing area,
(*b*) Maximum speed, which implicitly includes engine horsepower and the over-all cleanness of design,
(*c*) Pitching moment, or static stability,
(*d*) Damping moment, or dynamic stability.

5. General conclusions cannot be drawn from step-by-step calculations, at least until a very large number of such calculations have been made for widely varying types of aeroplanes.

6. Incorporation of any device to place a limitation on the maximum wing loads attainable, is not a practical solution of the problem.

7. The longitudinal moment of inertia is, at least, not an important factor.

## Recommendations

1. All aeroplanes to be divided into restricted and unrestricted classes.

(*a*) Restricted aeroplanes to be designed to withstand a sharp pull-up from level flight at a speed to be decided on by the manufacturer, and posted in the cockpit, but not less than the maximum speed attainable in level flight.
(*b*) Unrestricted aeroplanes to be designed to withstand manœuvres which they are specifically intended to carry out.

2. The maximum load factor in any case to be taken as 15.

3. The reduction in velocity during a pull-up to be neglected.

4. The maximum force which the pilot can exert on the control stick to be taken as 200 pounds.

In view of all these considerations, it is believed that the method presented on pages 535 and 536 is a satisfactory solution of the problem of principal wing load factors in the high angle of attack condition.

THE
# ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XVII DECEMBER 1934 No. 12

## The Forty-ninth Annual General Meeting

The formal Annual General Meeting for 1935 will be convened at Headquarters on Thursday, January 24th, 1935, at eight o'clock p.m. for the transaction of the prescribed routine business, and will be adjourned to reconvene at the Royal York Hotel, Toronto, at ten o'clock a.m. on Thursday, February 7th, 1935.

## Water for the Western Farmer

Those who have not seen for themselves the conditions existing in the so-called drought areas of the prairie provinces will find it difficult to realize the serious situation which exists in South-Eastern Alberta, Southern Saskatchewan, and South-Western Manitoba. Fortunately the districts at present affected are only a portion of Canada's grain producing territory; the stricken areas, moreover, have been productive in the past, and are favourably situated as regards transportation. The discouragement due to successive crop failures has nevertheless resulted in proposals for the wide-spread shifting of population from these areas to regions where conditions during the past five years have been more favourable.

It is reassuring to learn that the area is small over which conditions are such as to make abandonment actually necessary. There is, of course, land which never should have been cultivated, but should have retained its original prairie vegetation, but this condition only applies to restricted districts, and over the greater part of the region affected there is good reason to believe that remedial measures will prove effective.

It is important, therefore, that efforts should be directed towards discovering how to provide water for the dry areas rather than towards their abandonment.

The existing difficulty is not a new one; serious drought conditions existed in 1917 and 1921. They were succeeded by years of more normal precipitation, and long term records give no reason to suppose that a period of adequate rainfall will not follow the present dry cycle. In the past we have been in error in not realizing fully the possibility of so serious a condition as now exists. Too little attention has been given to the conservation of moisture and its utilization, and the farmer's efforts have rather been in the direction of drainage of his land in order to commence work earlier in the season, and draining the sloughs in order to get additional area under cultivation. The shortage of ground water is now such that in some districts, although the farmer has been able to grow wheat, he has not been self-supporting as regards stock and vegetables. An adequate water supply for each farmer's home, enabling him to raise practically all the food he requires, is a pressing need, and is just as important to the welfare of the west as an adequate supply for its cities and towns.

The problem is vital to the prosperity of Canada as a whole, as well as to the prairie provinces, and has naturally been a matter of particular anxiety to the western provincial governments. Speaking recently in Winnipeg, Premier Bracken laid stress on the fact that the question is truly a national one. He is familiar with conditions in Saskatchewan as well as in Manitoba, and has a thorough knowledge of western farming. He believes that the governments of the prairie provinces should co-operate in a complete study of the situation, for which the aid of the Dominion government should be secured, with the object of deciding upon a co-ordinated policy. Such a policy should not only provide for the fuller utilization of the scanty supplies of water now available, but should also be such as to insure the conservation and better use of the rainfall which will come when the present drought is broken.

Our drought problem in Canada is on a small scale as compared with that existing in the United States, where a stricken area extends over a wide belt of the mid-west from Texas in the south to North Dakota and Montana on the Canadian border. The Federal government has for some time been giving attention to the difficulties of this mid-western region, and it is therefore particularly desirable that there should be full consultation between the Canadian and American governmental authorities concerned before we adopt any definite policy involving the expenditure of a large sum of money. The government departments at Washington have always been generous in making their technical information available for the benefit of other nations, and the results of their experience in conservation and reclamation in the dry belt cannot fail to be of great benefit to us in Canada in considering what has to be done in this country.

Suggestions of all kinds have been made as to the course to be pursued. It seems now to be agreed, in Saskatchewan at least, that measures of reclamation and agricultural readjustment depending upon local soil and climatic conditions are the most promising. Farmers may have to co-operate by changing their methods of cultivation, planting drought resisting grasses, establishing hedges and other means to lessen soil drifting, and so on. But these efforts will have to be supplemented by a policy of water conservation on a wide scale, based on the co-ordination of all the reliable information that is available. Among the factors which must be considered are precipitation, run-off, the underground water supply as affected by geological structure, the effect of surface water areas, trees, and vegetation, the possibilities of further utilizing existing streams and rivers, and the conservation of run-off water by the construction of local ponds and reservoirs.

It is in connection with these portions of the programme that technical advice is necessary. Recognizing this fact, the Council of The Institute has approved a suggestion coming from our western members that one entire session at the forthcoming Annual Meeting of The Institute should be devoted to a discussion on "The

Water Supply of the Prairie Provinces and its Bearing on their Economic Development." Arrangements are being made accordingly, and it is intended to base the discussion on a series of papers dealing with separate aspects of the problem. It is expected that these will be supplemented by contributions from officers of the Dominion Meteorological Service, the Dominion Water Power and Hydrometric Bureau, the Geological Survey, and the provincial technical officers concerned.

The subject is not an entirely new one to members of The Institute, papers dealing with it having already been presented at western branch meetings. This will be the first time, however, that an attempt has been made to render available to all our members and to the public the collected views of engineers and technical officers who have made a study of this important question.

The ultimate solution of the many problems involved will no doubt require federal as well as provincial expenditure, a circumstance which gives all good Canadians a very personal interest in the methods to be adopted.

## Meeting of Council

A meeting of the Council of The Institute was held at Headquarters on Friday, November 16th, 1934, at eight o'clock p.m., with President F. P. Shearwood, M.E.I.C., in the chair, and eleven other members of Council present.

The Council gave further consideration to the communication from the Vancouver Branch, dated October 3rd, 1934, dealing with the future policy and lines of development of The Institute. This was one of the communications received from various branches in response to the President's request for an expression of branch opinions on problems now before The Institute, and will be available for consideration when the problem of re-organization comes up for consideration in detail.

It was noted that the revenue and expenditure of The Institute up to the end of October had been kept well within the budget estimates.

Letters were received from the Hamilton Branch pointing out that the work of The Institute Nominating Committee this year had not been carried out in exact accordance with the by-laws. The Secretary submitted explanatory statements received from the chairman of the Nominating Committee and was directed to transmit these to the branch.

Discussion took place with regard to the possible nomination of engineers on the directorate of the Bank of Canada, and Council received with appreciation and approval a report prepared by a committee of the Ottawa Branch with regard to the nomination of a suitable candidate in each of the three categories.

The Secretary submitted certain amendments to the Winnipeg Branch by-laws, which have been proposed by the Branch Executive Committee with a view of facilitating the co-operation of that Branch with the Association of Professional Engineers of Manitoba. These amendments were approved, and the Secretary was directed to publish in The Journal for the information of the membership of The Institute an account of the effort which is being made by the engineers in Manitoba to promote that object.

It was decided that the formal Annual General Meeting for 1935 should be convened at Headquarters on Thursday, January 24th, 1935, at eight o'clock p.m., for the transaction of the prescribed routine business, to be adjourned to reconvene at the Royal York Hotel, Toronto, at ten o'clock a.m. on Thursday, February, 7th, 1935.

It was noted that three candidates had sat for The Institute's examinations on November 6th, 1934, and that all had failed to satisfy the examiners.

Discussion took place on a suggestion received from the President of the Association of Professional Engineers of Alberta that The Institute general office might act as a clearing house in communications between the Associations of Professional Engineers and the Department of Immigration with regard to applications for the admission of foreign engineers to Canada. The suggestion was approved, provided the consent of all the Professional Associations to the arrangement could be secured.

Four members were replaced on the active list, and two Life Memberships were granted.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

| *Elections* | | *Transfers* | |
|---|---|---|---|
| Assoc. Member | 1 | Junior to Assoc. Member | 4 |
| Students admitted | 6 | Student to Assoc. Member | 2 |
| | | Student to Junior | 2 |

The Council rose at ten thirty-five p.m.

## OBITUARIES

### Paul Albert Nicolas Seurot, M.E.I.C.

Widespread regret will be felt at the death in Montreal on November 18th, 1934, of Paul Albert Nicolas Seurot, M.E.I.C.

Mr. Seurot was born in Paris, France, on August 26th, 1869, and was educated at the Ecole Turgot in that city, graduating as Ingénieur diplômé with the "certificat d'Etudes supérieures" and in 1887-1890 was engaged on post graduate work, and as tutor at the Ecole Fénelon.

In 1890 Mr. Seurot came to the United States, and until September of that year was employed by C. M. Jacobs, consulting engineer, as a rodman on triangulation on the New York harbour, and on various surveys for railway work. From that time until 1892 he was on the Long Island Railroad as rodman, instrumentman and chief of surveying corps and in 1892-1894 was assistant engineer in charge of the reconstruction of and double tracking of roadway and reconstruction of bridges on some of the Long Island Railway lines, and was also in charge of parties for preliminary and relocation surveys. From 1894 until

P. A. N. Seurot, M.E.I.C.

1898 he was with Jacobs and Davies, consulting engineers, and was associated with some important engineering achievements in and about New York, particularly on the construction of the East River gas tunnel and on the designs and reports of the proposed Brooklyn Rapid Transit system. During the years 1895-1901 he was also retained by the Panama Canal Company in their dealings with the Interstate Commerce committee at Washington. From 1901 to 1906 Mr. Seurot was engineer on the Atlantic Avenue improvement (Brooklyn Rapid Transit Company), engineer on the Pennsylvania tunnels under the North River (New York), on the Hudson tunnels and McAdoo underground and rapid transit systems in New York and New Jersey. In 1905 he was sent by Jacobs and Davies to Norfolk, Va., to make a study, report and estimate on a tunnel under the Elizabeth river, and during the summer of 1906 the same firm sent him to France to make on their behalf a complete study, estimate and report to the French Minister of Public Works on the construction of a tunnel under the estuary of the Seine. In 1906-1907 Mr. Seurot was office engineer on the Hudson Tunnels, and in 1907-1911 he was in Paris as representative of Jacobs and Davies, in charge of the work of construction of the Paris Metropolitan tunnel under the Seine, known as the Concord tunnel.

Coming to Canada in 1911, Mr. Seurot established his own practice, and was retained on many important projects in Montreal and Toronto and was in addition chief engineer to the Montreal Tunnel Company. The city of Montreal also retained his services to report on and design the proposed tunnels under the Lachine canal. He was also attached to the Canadian delegation sent to France by the Minister of Trade and Commerce. In 1918 he was appointed chief engineer of the Montreal Tramways Commission, and from 1927 until his death he was engineer of rapid transit of the Montreal Tramways Company.

During his active life Mr. Seurot wrote a number of important papers dealing with engineering problems and in 1914 was the recipient of the Gzowski medal awarded by The Institute (then the Canadian Society of Civil Engineers) for his paper on "Subaqueous Tunnelling." His services were recognized by France, which made him a Chevalier de la Légion d'Honneur, and Officier d'Académie, while he was also the holder of the Gold Medal of Honour of the French Humane Society.

Mr. Seurot was a member of the Institution of Civil Engineers (Great Britain), the American Society of Civil Engineers, and the Corporation of Professional Engineers of the Province of Quebec.

He became a Member of The Institute on May 11th, 1912.

### Kenneth Murray Chadwick, M.E.I.C.

It is with deep regret that we record the death of Kenneth Murray Chadwick, M.E.I.C., which occurred at Victoria, B.C., on October 21st, 1934.

Mr. Chadwick was born at Leeds, England, on August 11th, 1878, and in 1895-1899 served articles of apprenticeship with the city engineer of Leeds.

From that time until 1902 he was resident engineer for the city on the construction of bacteriological sewage filters and contact beds, and on the construction of a large water-main system. In 1903-1905 Mr. Chadwick was engaged on the design and construction of an addition to the main sewerage system of the city, and in 1906 he was assistant engineer of design on the city's sewage disposal scheme. In 1907, having come to this country, his work was at first in connection with building construction in Ontario and later in British Columbia. In 1916-1917, Mr. Chadwick was in the inspection service of the Imperial Munitions Board, and following this, in 1918, he became engineer of construction for the Victoria Gas Company, Victoria. At the time of his death Mr. Chadwick was not engaged in practice.

Mr. Chadwick joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on March 12th, 1908, and on October 27th, 1925, became a full Member. For many years he took an active interest in Institute affairs, having served as secretary-treasurer of the Victoria Branch from 1927 until 1931, as vice-chairman of the Branch in 1932 and 1933, and as member of Council in 1931. He was elected an Associate Member of the Institution of Civil Engineers in 1904.

## PERSONALS

A. D. W. Fraser, S.E.I.C., who graduated from McGill University this year with the degree of B.Eng., has joined the staff of Siscoe Gold Mines, Limited, at Siscoe, Que.

Pierre Warren, S.E.I.C., a graduate of the Ecole Polytechnique of the year 1932, is now assistant engineer with the Department of Publics Works, Canada, at Rimouski, Que.

Gordon M. McLean, S.E.I.C., is now with the Perron Gold Mines Limited, at Pascalis, Que. Mr. McLean graduated from the Nova Scotia Technical College in 1932.

J. B. DeHart, M.E.I.C., District Inspector of Mines, Province of Alberta, Lethbridge, Alta., has been elected president of the Association of Professional Engineers of the Province of Alberta.

A. LeB. Ross, S.E.I.C., is now connected with the Railway and Power Engineer Corp., at Toronto, Ontario. Mr. Ross, who graduated from McGill University with the degree of B.Eng. in 1932, was formerly with Noranda Mines Limited, at Noranda, Que.

A. L. Graham, S.E.I.C., has become connected with Eastern Power Devices Limited, Toronto. Mr. Graham graduated from the University of Toronto in 1931 with the degree of B.A.Sc., and in 1932 he was with the Canadian General Electric Company at Peterborough, Ontario.

Wm. H. Hunt, S.E.I.C., who graduated from the Nova Scotia Technical College in 1933 with the degree of B.Sc., has joined the staff of the Maritime Telegraph and Telephone Company, at Halifax, as junior maintenance assistant in the general plant department.

O. Desjardins, A.M.E.I.C., formerly joint chief engineer of the Department of Public Works of the Province of Quebec, has been appointed chief engineer of the Department. Mr. Desjardins, who has been with the Department for many years, is a graduate of the Ecole Polytechnique, Montreal, having graduated from that institution in 1919 with the degree of B.A.Sc.

J. M. Breen, A.M.E.I.C., of the Canada Cement Company Limited, has been transferred from the Toronto office of the company to Montreal, where he has assumed the position of chief of the technical staff. Following graduation from the University of Toronto in 1921 with the degree of B.A.Sc., Mr. Breen was employed for a time with the Toronto Harbour Commission, and later with the Roads Department of the city of Toronto. In 1922 he entered the employ of the Canada Cement Company Limited as engineer in the Toronto office, and has been connected with that office up to the present time.

Eric G. Adams, Jr.E.I.C., has been appointed secretary of the Newsprint Export Manufacturers Association of Canada, at Montreal. Mr. Adams is a graduate of McGill University, having obtained the degree of B.Sc. in 1929, and was formerly with Messrs. Cockfield Brown and Company, Montreal. Mr. Adams will be remembered by the membership of The Institute as the winner of the Past-Presidents' Prize for the year 1932-1933 for his paper on "The Relations of Economics to Engineering." He also received the Phelps Johnson Prize for Students and Juniors in the province of Quebec for the year 1930-1931, for his paper entitled "Some Economic Problems Confronting the Wider Application of Railroad Electrification in America."

E. S. Mattice, M.E.I.C., has severed his connection with the National Bridge Company of Canada, of which he has been vice-president and manager since 1929, and has become vice-president and general manager of Farand and Delorme, structural miscellaneous steel work, Montreal. From 1923 until 1925 Mr. Mattice was chief engineer of Canadian Vickers Limited, at Montreal, and was later, for four years, manager and chief engineer of Steel Gates Company Limited, St. Catharines, Ontario, being in charge of the construction and erection of the steel gates of the Welland Ship canal. Following that he accepted the appointment from which he has recently resigned.

### T. C. MacNabb, M.E.I.C., Receives Appointment

T. C. MacNabb, M.E.I.C., has been appointed general superintendent for the New Brunswick district of the Canadian Pacific Railway Company.

Mr. MacNabb is a graduate of the University of Manitoba, having graduated with the degree of B.A. with honours, in 1902. Immediately following this he joined the staff of the Canadian Pacific Railway Company, and has been engaged on various works with that company throughout Canada ever since. He was first with the construction department, and in succession occupied various positions commencing as chainman and rodman in 1902, being promoted to topographer in 1903, and later draughtsman in the field office at Winnipeg; in the following year he was instrumentman, and in 1905 became resident engineer. In this capacity his work took him to Saskatoon, Lethbridge and Battle River. In 1908 Mr. MacNabb was made assistant engineer on construction, the following year, division engineer on maintenance, and in 1916, assistant engineer for Saskatchewan. In 1917 he became superintendent at Revelstoke. In 1926 Mr. MacNabb was appointed engineer of construction of the company's western lines with office at Winnipeg, Man., and has held that position up to the present time.

### Beaudry Leman, A.M.E.I.C., President of Banque Canadienne Nationale

Beaudry Leman, A.M.E.I.C., has been elected president and managing director of the Banque Canadienne Nationale. Mr. Leman, who was formerly vice-president and general manager of that institution, is a graduate of the University of Lille and of McGill University. He commenced his engineering career in the employ of the Shawinigan Water and Power Company, devoting six years to the development of hydro-electric enterprise. In 1906 he took an active part in the establishment and construction of the railway which connects the city of Three Rivers with the towns of Shawinigan Falls and Grand'Mere. For some years he represented a group of Belgian and French banks interested in Canadian enterprises, and in 1912 entered the service of the Banque d'Hochelaga, rising rapidly to the important position which he now holds with the Banque Canadienne Nationale. Mr. Leman who has served a term as President of the Canadian Bankers' Association, has also acted as a member of the Electric Service Commission of Montreal, and of the National Advisory Committee on the St. Lawrence Waterways project. He was a member of the Royal Commission appointed in 1931 to enquire into the Canadian Railway situation.

Mr. Leman became an Associate Member of The Institute (then the Canadian Society of Civil Engineers) on April 10th, 1902.

---

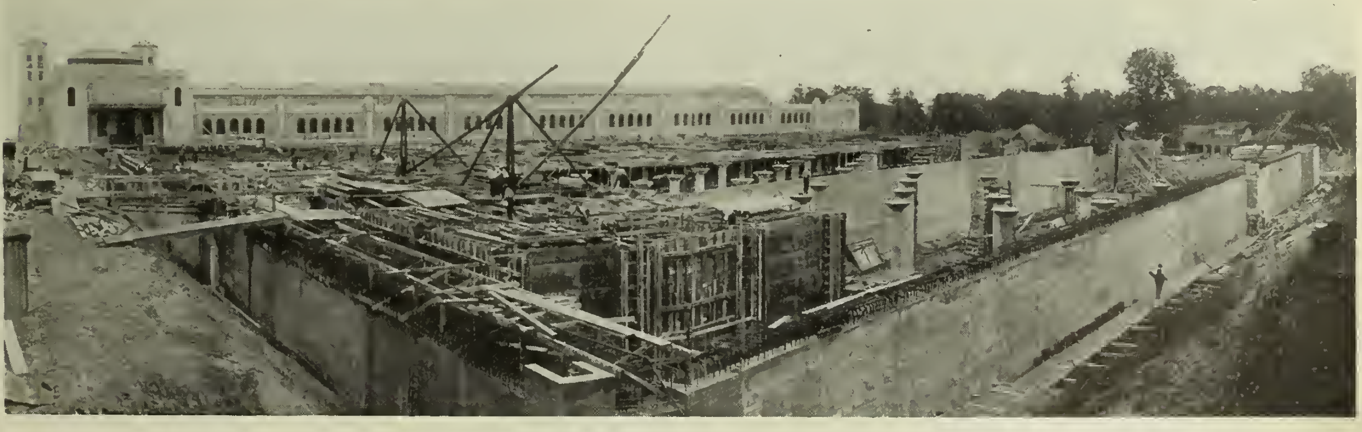
# Annual General and General Professional Meeting, Toronto,

## FEBRUARY 7TH AND 8TH, 1935

At the professional sessions on February 7th and 8th papers will be presented for discussion dealing with many topics of interest and of national importance, such as:

- The Status of the Engineer—(three papers).
- Electrical Inspection and Testing at the Laboratories of the Hydro-Electric Power Commission of Ontario.
- Gaseous Conductor Lamps and their Applications.
- Graphical Solutions for Pressure Rise in Pipe Lines.
- The Montreal Neurological Institute and its Service Equipment.
- The Toronto Waterworks Extensions.
- Bascule Bridges.
- The Water Supply of the Prairie Provinces and its Bearing on their Economic Development (eight papers).

The presentation of the papers on "The Status of the Engineer" and the "Water Supply of the Prairie Provinces" will be followed by discussions, which will occupy an entire afternoon session in each case.



Victoria Park Filtration Plant, Toronto.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on November 16th, 1934, the following elections and transfers were effected:

*Associate Member*

DEMPSEY, Wesley Thomas, B.Sc. (Civil), (Univ. of Sask.), Dundurn Camp, Dundurn, Sask.

*Transferred from the class of Junior to that of Associate Member*

BANKS, Shewell Reginald, B.Eng., M.Eng., (Univ. of Liverpool), asst. engr., Monsarrat & Pratley, Montreal, Que.

CORNISH, Wilfred Ernest, B.Sc. (E.E.), (Univ. of Man.), M.Sc., (Univ. of Alta.), asst. professor, Dept. of Elect. Engrg., University of Alberta, Edmonton, Alta.

DOULL, Robert Morse, B.Sc. (Mech.), (McGill Univ.), asst. mgr., Construction Equipment Company, mgr., Gunite and Waterproofing Ltd., Montreal, Que.

TAYLOR, Andrew, B.Sc. (C.E.), (Univ. of Man.), technical dftsman., Surveys Branch, Dept. of Mines and Natural Resources, Winnipeg, Man.

*Transferred from the class of Student to that of Associate Member*

ORANGE, Frank A., B.Sc., (Queen's Univ.), designer, mech'l. engrg. office, International Nickel Co., Copper Cliff, Ont.

SAUER, George Douglas, B.Sc., (McGill Univ.), designer, Beauharnois Light Heat and Power Co., Beauharnois, Que.

*Transferred from the class of Student to that of Junior*

DOVE, Allan Burgess, B.Sc., (Queen's Univ.), chem. engr. and asst. to West Mill supt., Canada Works, Steel Company of Canada, Hamilton, Ont.

PORTEOUS, John Wardlaw, B.Sc., (Univ. of Alta.), lecturer, University of Alberta, Edmonton, Alta.

*Students Admitted*

DOW, Gordon Young, B.Sc. (E.E.), (Univ. of N.B.), Pacific Dairies Ltd., Saint John, N.B.

KIMPTON, Geoffrey H., (McGill Univ.), 71 Birch Ave., St. Lambert, Que.

L'ALLIER, Lucien, (McGill Univ.), 5022 de la Roche St., Montreal, Que.

REDMOND, William Lawson, (Univ. of Alta.), 9818-108th St., Edmonton, Alta.

SCHUYDER, Max, (McGill Univ.), 1477 Fort St., Montreal, Que.

WATTERS, Edgar Steen, B.Sc. (E.E.), (Univ. of N.B.), 83 Prince St., West Saint John, N.B.

## RECENT ADDITIONS TO THE LIBRARY

### Proceedings, Transactions, etc.

*Punjab Engineering Congress:*
Proceedings, 1934.

*American Railway Engineering Association:*
Proceedings 1930, 1931, 1932, 1933 and 1934. (*Presented by J. E. Armstrong, A.M.E.I.C.*)

*Society for the Promotion of Engineering Education:*
Proceedings of 40th Anniversary and 41st Annual Meeting, 1934.

### Reports, etc.

*Financial Post:*
Survey of Corporate Securities, 1934.

*Quebec Bureau of Mines:*
Annual Report, 1932, part E.

*Province of Alberta, Geological Survey Division:*
Geology of Central Alberta, by J. A. Allan and R. L. Rutherford.

*American Institute of Steel Construction:*
Annual Report, 1934.

*Electrochemical Society Inc.:*
Joseph W. Rickards Memorial Lecture.

*International Tin Research and Development Council:*
A Rapid Test of Thickness of Tin Coatings on Steel, by G. G. Clarke.

*Canada, Department of Marine:*
67th Annual Report, 1933-1934

*University of London:*
Calendar, 1934-1935.

*New Orleans Sewerage and Water Board:*
68th Semi-annual Report, December 31st, 1933.

*American Waterworks Association:*
Membership List, Constitution and By-laws, etc., 1934.

*City of New York, Board of Water Supply:*
Annual Report, 1933.

*Canada, Hydrographic Service, Tidal and Current Survey:*
Tide Tables for the Pacific Coast of Canada, 1935.

*American Society for Testing Materials:*
Symposium on the Outdoor Weathering of Metals and Metallic Coatings.

### Technical Books, etc., Received

Industrial Standardization, its Principles and Application, by John Gaillard. (*The H. W. Wilson Company.*)

History of Rensselaer Polytechnic Institute 1824–1934, by P. C. Ricketts. (*John Wiley and Sons.*)

Structural Design in Steel, by T. C. Shedd. (*John Wiley and Sons.*)

Handbook of Aeronautics, 2nd edition, Volumes I and II, by A. Swan. (Published under the authority of the Council of the Royal Aeronautical Society, by Sir Isaac Pitman and Sons.)

The Stone Industries, by O. Bowles. (*McGraw-Hill Book Company.*)

An Introduction to Practical Organic Chemistry, by W. A. Waters. (*Longmans Green and Company.*)

Explosives, by A. Marshall. (*Presented by Mr. R. J. Durley.*)

Handbook of Chemistry, by N. A. Lange. (*Handbook Publishers Inc.*)

## BOOK REVIEWS

### Design and Construction of Concrete Roads

*By R. A. B. Smith, Concrete Publications Limited, London, 1934. 5½ by 8¾ inches, 264 pp. 8s. 6d. Cloth.*

Reviewed by Professor R. de L. French, M.E.I.C.*

Although those on this side of the water interested in concrete highway design, construction and maintenance, will not agree entirely with the views expressed by the author of this book, they will do well to read it attentively. It leaves one with the impression that the British engineer is either not very favourably impressed by the results of American experience and research, or that he finds these results of little use under British conditions.

For example, Mr. Smith feels that there are other and better methods of securing the necessary strength at the edges of a road slab than that which has become practically standard practice here, the thickening of those edges. He also has some pretty definite views on joints, well worth study, as well as on finishing, curing and other matters.

The differences between American and British construction practices are brought out, incidentally. Much is still done by hand in Britain that we do by machine. Nowhere is there any mention of machine subgrade finishing, nor even of machine surface finishing, both common practices with us. The typical—and excellent—British attention to details is apparent throughout the text, and in the illustrations, which seem to this reviewer to be above the average both in selection and quality.

Some useful material with respect to colouring concrete, to the layout of junctions with curves, to "footpaths" (sidewalks) and to accessories, such as drainage inlets, traffic markings, fences, sign and lamp posts, and kiosks—the latter practically unknown here—with a good index, complete the body of a book of distinct usefulness.

One appendix deals with Professor H. M. Westergaard's development of the theory of the stresses in road slabs, the second contains suggested clauses for specifications, and a third outlines the British Standard tests for concrete and concrete materials. There is also a short bibliography of reports of the Ministry of Transport regarding concrete roads.

*Professor of Highway and Municipal Engineering, McGill University, Montreal.

### Principles of Mechanism

*By C. E. Pearce, John Wiley and Sons Inc., New York, 1934. 6 by 9¼ inches, 283 pages. $3.50. Cloth.*

Reviewed by Professor L. M. Arkley, M.E.I.C.*

As stated in the preface this book is designed especially as a text book for sophomore classes in college, and as such it should be satisfactory.

Chapter one treats of machines in general and touches on the different kinds of motion found in them.

Chapter two is on transmission by direct friction, and illustrations are given of such examples of this as grooved friction wheels, rolling cones with external and internal contact and speed variators.

There are three chapters devoted to transmission by toothed wheels and screw gears, chapters three and four are more or less decriptive with illustrations of the different types while in chapter fourteen methods of finding the true shape of involute and cyclodial curves for gear teeth are given.

The chapter on power transmission by flexible connectors which include belts, wire rope drives and chains is fairly comprehensive.

One of the best chapters in the book is number ten, dealing with vector representation of motion and in it is shown clearly the use of the instantaneous centre method of analysing the velocities of the links of different chains. Linear and angular velocity ratios are discussed and at the end of the chapter are many excellent illustrative mechanisms and problems.

The next chapter treats of the transmission of power by means of linkages and gives analyses of such well known mechanisms as the slider crank chain with its different inversions including quick return motions, the oscillating engine mechanism and universal couplings. In fact these two chapters contain so much that is necessary to the study of the fundamentals of mechanism that it seems they might have been placed nearer the beginning of the book.

There is little new in the treatment of the subject of cams, but an interesting chapter follows on the subject of mechanisms with some special geometrical properties, such as straight line motions.

In several of the chapters there does not appear to be a sufficient analysis of the principles treated to enable students to apply these to the solution of the problems given at the end of the chapter; and the reviewer believes the arrangement of the material in the book might be improved by placing some of the fundamental principles in the first chapters.

The book is well illustrated by excellent cuts and at the end of each chapter is an unusually long list of problems to be solved.

*Professor of Mechanical Engineering, Queen's University, Kingston, Ont.*

## Handbook of Aeronautics

*Published under the authority of the Council of the Royal Aeronautical Society by Sir Isaac Pitman and Sons Inc., London, 1934. 5¾ by 9 inches. 2nd edition. 2 volumes. 40s. Cloth.*

This handbook has been published under the authority of the Council of the Royal Aeronautical Society of Great Britain for the purpose of collecting in as accurate and authoritative a form as possible, information which will be of every day use to the designer and constructor of aircraft and the aeronautical engineer. It has been prepared by engineers of recognized standing in the various branches of the profession.

During the past twenty-five years a mass of scientific data dealing with aeronautics has been published, mainly in official reports, and a difficulty is experienced by young engineers not only in obtaining access to these reports, but also in sorting out the information which they contain.

The Handbook of Aeronautics has, therefore, a definite value, because not only does it give an indication of the problems which have to be faced and the method of attacking them, but also it gives a very valuable series of references to other published material. More experienced engineers will perhaps find that some sections are inadequately dealt with, particularly those dealing with aerodynamics, design data and formulae, but these engineers will already possess information with which to fill up the gaps.

In the section dealing with aerodynamics much recently published work done at high Reynolds numbers has been omitted, as also has reference to modern devices such as split flaps and servo gears.

The chapter on performance is well written and contains useful information.

Construction is perhaps an incorrect name for chapter III, because this chapter deals mainly with material specifications, dimensions of standard parts, tables of constants for various sections and similar data of assistance to the designer, without dealing in any way with the methods of construction, which one would expect to find under this heading.

The properties of materials have been successfully summarized in the fourth chapter.

Chapter V deals with meteorology in a very brief manner, but sufficiently for the purpose of this book.

Aircraft instruments, wireless and air survey are each dealt with rather briefly.

The chapter on design data and formulae cannot replace a text-book on aircraft design without becoming unduly long, and for this reason this section of the book seems to be incomplete, in that it does not give a beginner a good introduction to this important part of the work of an aircraft designer.

The second volume is devoted to aero engines and airscrews. It outlines the problem of aero engine design in a satisfactory manner, and gives data which should be of value not only to the aero engine designer, but also to other designers of internal combustion engines.

After dealing a little critically perhaps with the individual chapters, one is left with the impression that the authors have undertaken a very heavy task in attempting to combine in one book the many branches of a subject so wide in its scope as aeronautics, and that the result obtained is upon the whole very satisfactory. The book is one which should be possessed by every aircraft and aero engine designer and by students of aeronautics. E.W.S.

## Structural Design in Steel

*By Thomas Clark Shedd, John Wiley and Sons, New York, 1934. 6 by 9¼ inches, 560 pages. $5.00. Cloth.*

Reviewed by W. Chase Thomson, M.E.I.C.*

This work deals primarily with the details of design for steel structures, a subject which had not previously been adequately covered by available text-books. In it the student is assumed to be familiar with the principles involved in the strength of materials, and to have considerable skill in the calculation of the principal stresses in simple structures. The author has made a special feature of the numerous design sheets for actual structures, with calculations arranged in accordance with usual practice in the office of a designing engineer; and he is to be commended for this method of teaching by example as well as by precept.

Chapter I is introductory, and refers briefly to some of the problems treated in work. Chapter II discusses types of structure and of structural framing; it is illustrated by many photographic views of existing structures, also by line drawings.

The most important part of the book is contained in chapters III, IV and V. In chapter III, rolled beams and built-up girders are treated in great detail, giving particular attention to maximum shears, to splices and to riveting. Chapter IV treats of tension and compression members, including those which are also subject to bending moments, stresses in columns due to flexure, latticing and other details. Chapter V deals with connections of all kinds, including those for tension and compression, for shear only and for shear and bending moments combined. It also gives careful consideration to the stresses in and to the proportioning of gusset plates.

In chapter VI, treating with the design of structural steel for buildings, and in chapter VII, with that for bridges, the principles set forth in chapters III, IV and V are further illustrated by practical examples. Chapter VIII deals satisfactorily with the principles and present practice of structural welding.

The volume closes with three appendices, A, B and C.

Appendix A is a specification for the design of steel railway bridges, in general agreement with that prepared by the committees of the American Society of Civil Engineers and the American Railway Engineering Association, published in the Proceedings of the American Society of Civil Engineers, December 1929, but slightly modified by the author to suit his own views with respect to allowable intensities of stress, loading, provision for net section and in some other matters of minor importance.

Appendix B is a general specification for the design of steel highway bridges, generally in accordance with that prepared by representatives of the American Association of State Highway Officials, and the American Railway Engineering Association, printed in Bulletin 314, Vol. 30, of the latter organization, February 1927.

Appendix C is a specification for the design, fabrication and erection of structural steel for buildings, adopted by the American Institute of Steel Construction in 1923 and revised to January 1934.

The book is well written and the numerous illustrations distributed through the text, including the design sheets, are neat and clear. In addition to these illustrations there are nine folding plates which, for greater convenience are loose and are placed in a pocket provided in the back cover.

As a text-book this work should be valuable for use in colleges and of great assistance to the young structural engineer. As a book of reference it should also be found of much value to structural engineers of greater experience.

*Consulting engineer, Montreal.*

## Symposium on the Outdoor Weathering of Metals and Metallic Coatings

### American Society for Testing Materials

The above symposium which has been received in the library of The Institute evaluates the performance data obtained from extensive outdoor weathering tests carried out by two committees of the American Society for Testing Materials and is intended to illustrate applications of corrosion test data in solving materials problems.

The five papers included discuss outdoor test results on bare and metal-coated ferrous specimens; the harmony of outdoor weathering tests; influence of rainfall and smoke on the corrosion of iron and steel; early interpretation of test results in the atmospheric corrosion of non-ferrous metals and alloys, and galvanic corrosion by contact of dissimilar metals.

An interpretation of corrosion test results necessarily introduces various viewpoints and a portion of the publication is devoted to discussion. Extensive contributions from technologists in England indicate results of widespread test programmes conducted there and comparisons with conclusions reached in the United States.

Copies of this 113-page book can be obtained from the American Society for Testing Materials at 260 S. Broad Street, Philadelphia, Pa., at $1.25 a copy.

## Civil Aviation Map

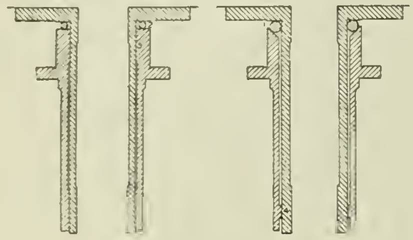
The Department of National Defence in co-operation with the Department of the Interior has issued a map of Canada showing the airports, intermediate aerodromes, and seaplane ports and anchorages. The various types of landing stations are designated by separate symbols.

Copies of the map may be obtained from the Topographical and Air Survey Bureau, Department of the Interior, Ottawa, at ten cents per copy.

# Testing and Improving the Performance of the Wild Precision Theodolite

*Professor James Weir, A.M.E.I.C.,*
*Assistant Professor of Geodesy, McGill University, Montreal.*

In the March 1934 number of the Canadian Journal of Research, National Research Council, Ottawa, there appear three papers by officers of the Geodetic Survey of Canada, Department of the Interior, and entitled: "Variable Personal Equation of Bisection in Primary Triangulation," by J. L. Rannie, M.E.I.C., and W. M. Dennis, M.E.I.C., 5 pages; "Improving the Performance of Primary Triangulation Theodolites as a Result of Laboratory Tests," by J. L. Rannie, M.E.I.C., and W. M. Dennis, M.E.I.C., 15 pages; "A Field Test of Primary Triangulation Theodolites," by J. L. Rannie, M.E.I.C., 11 pages.*



(a) (b)
**Fig. 1—(a) Original and (b) Modified Alidade Axis.**

These papers embody the results of an investigation—the first of its kind, so far as is known—into the causes and remedies for certain puzzling errors which were suspected to exist in the Wild precision theodolite designed for precise angle measurements. The results of the investigation apply also to smaller models of several makes which are in general use by engineers.

The investigation was carried on both outdoors and, mainly, in the collimator laboratories of the National Research Council by officers of the Geodetic Survey of Canada.

The Wild precision theodolite (a 5½-inch instrument slightly larger than the small 3¾-inch type used by a considerable number of Canadian engineers) was the instrument under investigation. Ten of these theodolites have been in use by the Geodetic Survey for primary triangulation, and, as one of the criteria of accuracy of this class of work is that the sum of the three measured angles of a triangle shall, on the average, be within one second of the true amount, it is seen that angles must be correctly measured within a fraction of a second. In many cases this precision was obtained without trouble with this new

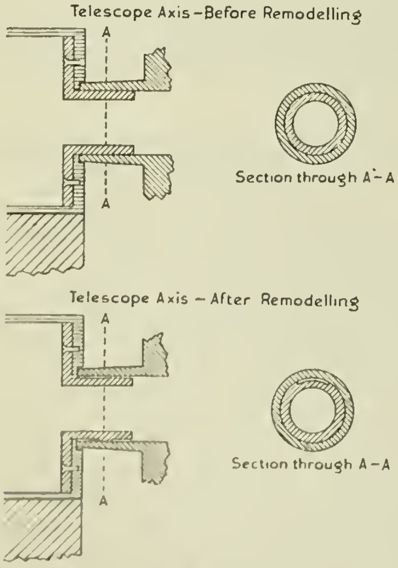


**Fig. 2—Original and Modified Telescope Axis.**

type of theodolite, but in a number of other cases errors as high as two to four seconds were indicated.

While angular errors of these magnitudes are occasionally caused by atmospheric disturbances, their occurrence with this instrument was rather too frequent to be attributable to this phenomenon, and it was decided to subject the instruments to a very comprehensive test to determine if any errors, hitherto undiscovered, really did exist in this type of theodolite.

*Reprints of these papers may be obtained from the Director of the Geodetic Survey of Canada, Ottawa.

One cause of trouble which had been noticed in some of the instruments (and this has also been found in a number of cases with the small model) was that the alidade axis, as well as the telescope axis, developed stiffness in service. Noticeable stiffness in the alidade or vertical axis can be removed by lapping, while that in the telescope axis is generally cured by adjustments to the bearing blocks at the ends of the telescope axis. This stiffness was later found to be an exaggeration of the trouble found with the Geodetic Survey theodolites.

These theodolites are constructed with the cylindrical alidade and telescope axes of hardened steel which are fitted with very small tolerances; it is well known that many metals are subject to dimensional changes for some years after machining and heating processes; due to these circumstances it was found that minute lacks of fit developed in the alidade and telescope axes, and these produced minute strains in the metal which changed as the telescope was swung in azimuth and changed in elevation. These strains were found to be transmitted through the instrument to the telescope and caused changing deflections of the line of collimation, thus producing errors in angular measurements varying from zero to about four seconds. A dangerous feature of these strains is that, unless excessive, they do not result in definite stiffness of motion of the axes. The method employed to measure these errors was to change the position of the footscrews between groups of measurements of the same angles, in this way changing the relation between the

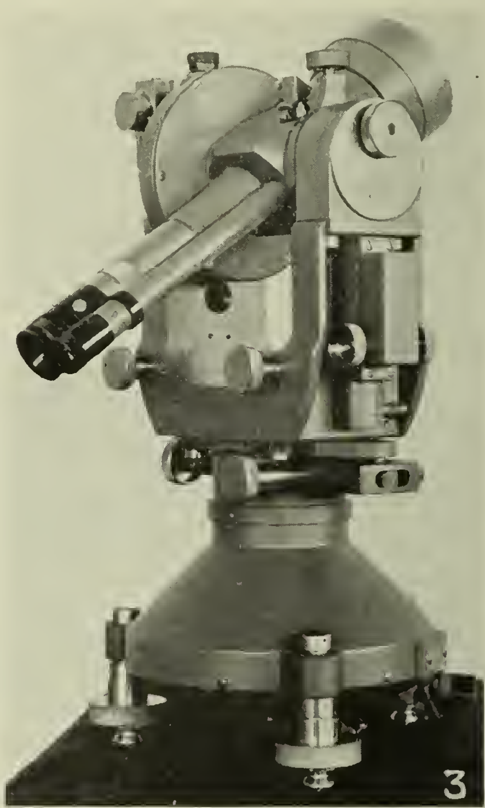

**Fig. 3—Wild Precision Theodolite 5½-inch Horizontal Circle.**

alidade axis and its socket and changing the strains which produced these errors.

Nine of the ten Wild precision theodolites examined were found to be affected by axis strain in varying degree.

The errors discovered in the alidade and telescope axes were eliminated by employing the principles of kinematical design so far as was found possible. The full application of these principles removes the necessity of precision fits, such as cylinders, which are expensive to manufacture and are seldom permanent; these advantages are bringing these principles into increasing use in the design of engineering mechanisms. The original and re-modelled alidade and telescope axes used on the Wild theodolites are illustrated in Figs. 1 and 2 respectively.

The remodeled instruments were subjected to the same extensive series of tests as before and gave very much improved results, as good as or better than those with older and larger theodolites which had given years of satisfactory service. The improved instruments were also used in the field with entirely satisfactory results.

Two other important results of the investigation were, the development of a method of testing geodetic theodolites out of doors, and the rediscovery that some observers consistently make very different pointings on bright and dim lights, resulting in angular errors which with certain observers may be as large as two or three seconds.

The results of this investigation are of real importance to the average engineer, since a considerable number of the small model of

Wild, Zeiss and Cooke (Tavistock) instruments are in use. These may not be kept in as perfect condition as those used by a geodetic survey so that, while errors of three or four seconds may appear trivial to the average engineer. it is evident that errors of several times this amount may be produced if there is any noticeable stiffness of movement of the alidade or telescope axes.

Several precautions and observational procedure suggested by this investigation are equally applicable to smaller types of theodolites, either those with cylindrical or conical axes:

1. The footscrews must be kept much tighter during observations than is necessary with heavier theodolites.
2. If there is any suggestion of stiffness in the action of the alidade axis it should be lapped to a loose fit. A slack centre is preferable to a tight one.
3. Meticulous care should be taken to avoid any stiffness in the telescope axis, by adjustments of the blocks at the tops of the standards (Wild type).
4. To minimize the effect of changing axis strain the levelling screws should be moved 120 degrees between each third of a programme of observation.

## Branch Unemployment Relief Activities

The activities of the various branch unemployment committees during the past two years, and the assistance given these committees by many members of The Institute, have not received the attention that they might have.

The following letter to corporate members and juniors of the Montreal Branch should, therefore, be of interest. Similar requests on the part of several of the other branches (notably Toronto and the Border Cities), have also received excellent support, which is the more appreciated as in many cases the donors are themselves in reduced circumstances.

October 29th, 1934.

Gentlemen:—

After due consideration your Executive deem it necessary to again ask for subscriptions to the Unemployment Relief Fund. Even if you subscribed previously it is trusted that you will send in your contribution with the enclosed card.

As a result of a survey on unemployment made two years ago the Unemployment Relief Fund was started to help members of the Branch who were in extreme need of assistance.

The first appeal went out in December 1932, when 240 members subscribed. The second appeal was made in December 1933 when 190 subscriptions were received and the situation now is as follows:

| | | |
|---|---|---|
| *Receipts* | | |
| 1932-3 Subscriptions | $1,577.88 | |
| 1933-4 Subscriptions | 872.50 | |
| Interest | 19.34 | |
| Amount repaid by 2 members | 43.83 | |
| | | $2,513.55 |
| *Disbursements* | | |
| 1932-3 Assistance | $1,625.93 | |
| 1933-4 Assistance | 1,079.24 | |
| Printing and postage | 28.85 | |
| | | $2,734.02 |

It is estimated $1,000 will be required to make up the deficit and enable the Committee to carry on during the coming winter.

Yours very truly,

(Sgd.) C. K. McLeod, A.M.E.I.C.,
*Secretary-Treasurer.*

*Note:*—It may be of interest to know that on November 30th the amount of the subscriptions received as a result of this letter amounted to $553.00.

## Salary Standardization and Administration

This report is the result of a survey that was made by the Policyholders Service Bureau of the Metropolitan Life Insurance Company to determine the details of such scientific methods as now are in effective use.

Although progress has been made in developing scientific control of the pay of wage earners, few organizations have attempted to evolve similar procedures with reference to salaried positions. The outstanding reasons for such control vary from that of obtaining a complete accurate and impersonal description of the work done by each employee, to the determination of fair minimum and maximum salaries for each position or kind of work done throughout the organization.

Positions up to the rank of department heads have been included but most of the companies co-operating in this study limit standardization to those positions paying up to a maximum of about $300 a month.

The report states that the success of salary standardization depends upon the intelligence with which jobs are evaluated and classified. The list of grades used by a number of organizations are given in detail in the report and the methods of making evaluations are discussed, also the determination of salary limits for each group.

Copies of the report may be obtained from the Policyholders Service Bureau, Metropolitan Life Insurance Company, 180 Wellington Street, Ottawa, Ont.

# BRANCH NEWS

## Border Cities

*C. E. Davison, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, S.E.I.C., Branch News Editor.*

The Electronic Valve

At the regular meeting held October 11th, 1934, Mr. G. Chute, of the General Electric Company, Detroit, former industrial power engineer and now in charge of research work on the electronic valve, presented the members with a very interesting talk on the latter subject.

The electronic valve is evolved from the common electric light which is composed of a metal filament enclosed in a glass bulb. When the filament is heated by an electric current, electrons are given off in innumerable quantities. Remembering that all electrons are negative in character, the next step was to insert a metal plate into the bulb making it positive in character.

Now the electrons instead of just being thrown off and wandering around willy-nilly, as in the light bulb, are attracted to the positive plate. By varying the voltage on this plate the quantity and speed of the electrons is varied. Evacuation of the tube aids the travel of the electrons as there is nothing left to hinder their progress. This set-up corresponds to our first radio tube.

This was not satisfactory as it did not reproduce or amplify the impulses clearly, but left the tones hazy. This was due to the filament not cooling quickly enough after the original impulse had stopped. To offset this, a grid or screen was placed between the plate and the filament and charged negatively. By varying the charge on the grid, the electrons passing through it to the plate could be controlled. Further refinements were made by introducing a metal that was known to be a good electron producer into the valve and using the filament as a source of heat. Now the valve contains all the principles in our present day radio tubes.

There are two types of electronic valves; one like the radio tube which given a small impulse may be controlled or amplified gradually, the other called the thyratron tube in which an atmosphere of some gas is introduced.

Knowing that heat and light are the same thing acting at different frequencies produced the electric eye. Instead of electrical impulses being transformed into heat as in the radio tube, we have light impulses which have the same effect as heat on the electron producing plate within the tube.

The latter portion of the talk was on the use of the thyraton tube in the development of the thyratron motor. This will be of great advantage to power transmission for it would then be possible to transform alternating current to direct current and vice-versa. This would do away with the third wire in present day transmission lines and more than likely would save many of the other transmission line losses.

At the conclusion, Mr. Chute was heartily applauded by all, his home-made demonstrators and practical appliances creating much humour and adding a good deal of spice to an already interesting lecture.

## Calgary Branch

*J. Dow, M.E.I.C., Secretary-Treasurer.*
*H. W. Tooker, A.M.E.I.C., Branch News Editor.*

Thursday evening, October 18th, 1934, was the opening night for the Calgary Branch of The Institute. On this occasion over sixty-five members, their wives and friends, were present to witness five reels of motion pictures entitled "From the Ground Up," procured from Ottawa through the Director of Publicity, by the efforts of the chairman, G. P. F. Boese, A.M.E.I.C., and vice-chairman, J. Hadden, M.E.I.C.

The pictures illustrated the manufacture of the motor car in Canada from the raw materials to the finished article, and showed the many different types of machines employed to produce the various moving parts, and also the moving assembly table.

This proved to be most interesting and gave a very clear conception of the enormous amount of machinery required to construct a car in the short space of time that they are manufactured in to-day.

Following the pictures, through the kindness of the ladies, refreshments were served and they thus did their share in making the opening night a success.

Thursday evening, November 1st, 1934, was the occasion of an address given to forty members of the Calgary Branch and their friends by W. H. Greene, M.E.I.C., whose subject was "Timber for Structural Use, its Design, Working Stresses and Preservative Treatment." It was also the first evening for a series of ten-minute addresses, being a competition open to the younger members, for which a small cash prize is offered.

Following the announcement of the rules governing the competition, which are as follows:

1. Open to Students, Juniors and Corporate Members.
2. Subject to be chosen by themselves.
3. Subject to be preferably of a technical nature, but may relate to a hobby or research work.
4. The address must be delivered extemporaneously and not read. Notes permitted.

The chairman, G. P. F. Boese, A.M.E.I.C., called upon the first competitor, D. C. Fleming, S.E.I.C., whose subject was "Photo-electric Cells and some of their Applications." He explained that a photo-electric cell is one which changes light pulsations into electrical pulsations of which there were three types. He then went on to give particulars of these types and their applications.

The second competitor, James Blair, S.E.I.C., chose as his subject "Pressure Vessels for Oil Cracking," and went on to explain that the use of the cracking process is growing at an ever-increasing rate. Increasing operating temperatures and pressures for gasoline making has brought about an increase in manufacturing difficulties to produce large vessels to withstand the conditions desired.

The process of manufacture was described, stress relieving and the use of the X-ray in testing welds being also discussed.

The chairman then called upon the speaker of the evening, Mr. Greene, to deliver his address:

TIMBER FOR STRUCTURAL USE, ITS DESIGN, WORKING STRESSES AND PRESERVATIVE TREATMENT

Wood preservatives can be defined as the art of protecting structural timber from destructive agents, the most common of which are decay, insects, marine borers, mechanical abrasion and fire.

In the prairie provinces the greatest enemy in timber structures is a low form of plant life known as fungi. The spores are blown about by the wind and lodge on the surface or in cracks of the timber and can remain dormant for long periods. By injecting or impregnating wood with poisonous chemicals these enemies are deprived of nutrition and decay is prevented. Many chemicals have been advocated but only a few possess the necessary qualifications.

To date there are only two chemicals that have proved themselves in accordance with specifications, namely creosote oil and zinc chloride. Creosote is the best preservative discovered to date, and is injected into the wood by pressure and heat.

Modern timber technology considers it good practice to take the fibre stress at the elastic limit and not more than 56 per cent of the modulus of rupture and the working stress at 60 per cent of the fibre stress at the elastic limit, or in other words the working stress is 39 per cent of the modulus of rupture.

Consider a structure of untreated timber; the recommended working stresses are based on "green conditions" and these will also be reduced to provide for considerable loss of strength due to decay. The initial strength of the wood would be greater than that used in arriving at the working stresses and this is necessary for immediately after being built into the structure, or even before it, the timber will absorb moisture from the air, rain or melting snow and return to the green unseasoned condition. This is not the case with creosoted timber, and for structures not continuously immersed in water, will keep the moisture content at, or below, the fibre saturation point.

Mr. Greene illustrated his lecture with many interesting slides and graphs and by motion pictures graphically depicted the various methods of treating timber in a modern creosoting plant.

At the close of the lecture the following took part in the discussion: W. S. Fetherstonhaugh, M.E.I.C., A. Griffin, M.E.I.C., J. Dow, M.E.I.C., J. Blair, S.E.I.C., G. P. F. Boese, A.M.E.I.C., F. N. Rhodes, A.M.E.I.C., and R. S. Stockton, M.E.I.C.

A hearty vote of thanks was given the speaker.

## Hamilton Branch

*A. Love, A.M.E.I.C., Secretary-Treasurer.*
*V. S. Thompson, A.M.E.I.C., Branch News Editor.*

On the evening of October 26th, 1934, the Hamilton Branch of The Institute held a joint meeting with the Babcock-Wilcox and Goldie-McCulloch Engineering Society of Galt. The meeting was held in the Science Building of McMaster University, Hamilton, and the accommodation was taxed to the limit, two hundred and fifty being present, including more than one hundred from Galt.

Mr. H. B. Stuart, A.M.E.I.C., chairman of the Hamilton Branch, welcomed the audience and expressed his pleasure at seeing such an enthusiastic gathering. Mr. P. L. Evans, President of the Babcock-Wilcox and Goldie-McCulloch Engineering Society, then took charge of the proceedings. He referred to the past joint meetings which had been most enjoyable and was delighted to see that this one had proved such a drawing card. Mr. McCulloch, president of the Babcock-Wilcox and Goldie-McCulloch Company of Galt, brought felicitations from the company and hoped that the meetings would continue. The Galt Society acted as hosts and provided an illustrated description of the work being done at the Boulder dam on the Colorado river.

R. M. Dilly read a descriptive article concerning this great construction project which was illustrated by numerous lantern slides.

The Boulder dam construction was authorized by Act of Congress in 1928, is part of the scheme for control of the Colorado river, to provide flood storage, store water for irrigation and domestic use, and provide a settling basin for mud and silt. The project also includes the construction of a power plant to generate nearly two million horse power. The total estimated cost of the project is 165 million dollars. The reservoir created by the dam will have an area of 227 square miles and will take nearly two years to fill. The dam is 730 feet high, 650 feet thick at the base and 45 feet at the top, 4,400,000 cubic yards of concrete are being used in its construction. The river is temporarily diverted through four tunnels, cofferdams being constructed above and below the dam site to allow work to proceed.

The construction of the diversion tunnels, 50 feet in diameter and about 4,000 feet long, was the first part of the undertaking. According to the original plans, the tunnels were to be used directly as power tunnels, but it was later thought that there might be risk of trouble from rock slips, so it was decided to build a steel pipe, 30 feet in diameter, within the tunnel—this pipe being capable of withstanding the full head of water or a pressure of 300 pounds per square inch. These pipes are fabricated in a plant which has been erected at the dam site. Three plates 2¾ inches thick and weighing 23 tons each are rolled to diameter and welded together to form a 12-foot section of the 30-foot pipe. The welds are examined by an X-ray machine and the pipes are stress relieved in a specially designed oil-fired furnace.

The lecture illustrated the extent and equipment of the shop, the method of transporting the heavy section of the pipe from the shop to the site, and also the tests that were carried out to determine pipe sag, stress and reinforcing.

At the conclusion of the lecture films were shown, descriptive of of the work at Boulder dam, and it was learned that the successful bidders—six companies incorporated—had to build a fair sized city in the desert, to house their huge army of workers and their families.

F. W. Paulin, M.E.I.C., moved a hearty vote of thanks to the Babcock-Wilcox and Goldie-McCulloch Engineering Society for their enterprise in securing these pictures and bringing them to Hamilton, and also to Mr. Dilly for his reading of the descriptive article. At the conclusion of the meeting refreshments were served.

## London Branch

*H. A. McKay, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting of the Branch was held on October 31st, 1934, in the City Hall auditorium, the speaker being Mr. William Duffield, president of the City Gas Company.

The chairman of the Branch, Frank C. Ball, A.M.E.I.C., presided. The speaker was introduced by D. M. Bright, A.M.E.I.C., a member of the Papers committee, and in the course of his remarks he mentioned the fact that the City Gas Company were applying to the city council for permission to bring natural gas to the city of London and that it was proposed to submit the proposition to the electors for approval or otherwise at the municipal election in December next.

The speaker first pointed out that the City Gas Company had been producing and distributing artificial gas to the city of London since 1864 and that in 1914 a proposition to introduce natural gas from the Tilbury field was defeated by the electorate owing to the disagreeable and sulphur-laden gas then produced in that area. Since that time the Tilbury gas had been greatly purified by filtration and the sulphur content rendered almost negligible.

However the present proposition was to draw gas from the "Dawn Field" about 55 miles south west of London. This is a new field and the gas from it is absolutely odourless and gives about twice the heat value of artificial gas.

Mr. Duffield went on to show that the new gas would be supplied at a much cheaper rate than the present manufactured gas, effecting a saving of from 37 to 48 per cent (according to quantity used) and owing to greater heat content (1,050 B.t.u. compared to 520 B.t.u. per cubic foot of the present artificial gas) only about half the quantity would be required to obtain the same heat value.

Re-arrangement of the pipe lines in the city would be undertaken so as to ensure an even pressure to all consumers. This together with the pipe line from Dawn would involve an outlay of $1,000,000 which would provide employment for a large number of local men. All gas appliances would be adjusted free of cost to the consumer and all present employees of the Gas Company would be retained.

From careful investigations made by expert engineers and geologists over a long period the supply was found to be practically inexhaustible.

Mr. Duffield also gave a history of natural gas supplies and touched on the necessary legislation. Size of pipe lines and pressures were given. A map was also exhibited showing the proposed high pressure and feeder lines in the city.

Many questions were asked and satisfactorily answered by the speaker.

A vote of thanks was proposed by Colonel I. Leonard, M.E.I.C., and seconded by E. V. Buchanan, M.E.I.C., and unanimously carried.

## Montreal Branch

*C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.*

CITY NOISES AND THEIR CONTROL

On October 25th, 1934, Professor H. E. Reilly of McGill University delivered an address on the above subject. He observed that noise regulation was an essential part of "air conditioning" which term should include "the provision of an adequate acoustic atmosphere." In this Professor Reilly also included smoke elimination. The speaker advanced several constructive suggestions as to the means of eliminating excessive noise which was a danger to health. H. J. Vennes, A.M.E.I.C., acted as chairman.

MODERN SEWAGE TREATMENT PRACTICE

On November 1st, Mr. E. B. Besselievre, sanitary engineer with the Dorr Company Inc., of New York, presented a paper dealing with the most modern methods of sewage treatment as distinct from sewage disposal. The speaker stressed the advantages of proper treatment and the revenue which might be obtained from the high calorific gas emanating from the decomposition of sewage which was suitable for power production and could also be sold to local gas companies or exchanged for electric power. Professor R. de L. French, M.E.I.C., presided.

JUNIOR SECTION MEETING

A meeting of the Junior Section was held at the Engineering Building, McGill University, on October 29th, at which two interesting papers were given, one on "Recent Trends in Small Heating Plants" by A. G. L. Atwood, A.M.E.I.C., engineer with the Iron Fireman Manufacturing Company, Montreal, and the other on "Disc Tumbler Locks and Key Fitting Devices" by Mr. A. Zion, a student in fourth year mechanical engineering at McGill University.

PLANT VISIT

On the evening of November 5th, through the courtesy of the Bell Telephone Company of Canada, one hundred members of the Junior Section paid a visit to the Toll Building of the company on Belmont street. Guides were provided and the visitors were given an opportunity to examine the power equipment and witness the arrangements for long distance operating, radio hook-ups, trans-Atlantic telephony, teletype and telegraph operations, etc.

STUDENT NIGHT

The semi-annual students night of the Branch was held on November 8th and two papers were presented: "Un nouveau gazogène pour l'industrie Canadienne" by Paul Vincent, S.E.I.C., who is a graduate of 1934 of the Ecole Polytechnique, and who is now undertaking post graduate studies at that university, and "A Small Power Plant for a Game Lodge" by Mr. E. S. Cooper, a fourth year student in electrical engineering at McGill University.

The President of The Institute, F. P. Shearwood, M.E.I.C., took this occasion to present the E.I.C. Student's Prize which was awarded to Yvon R. Tasse, S.E.I.C., by the Ecole Polytechnique.

ECONOMICS OF THE DURABLE GOODS INDUSTRY

On November 15th Dr. D. M. Marvin, economist of the Royal Bank of Canada, gave an exceptionally interesting talk in which he developed the argument that durable goods industries—notably construction—were greatly affected by the recent depression. He discussed unemployment in various groups of industries, the N.R.A., and contrasted the methods used by the United States and Great Britain to restore prosperity. The speaker prophesied that with the return of active business there will be a building boom in Canada on a much larger scale than most people realize. The future was bright and a real recovery had been achieved.

Professor R. E. Jamieson, M.E.I.C., acted as chairman.

## Niagara Peninsula

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

Through the kindness of Mr. Ellis Jones, manager of the Yale and Towne Manufacturing Company, the Branch was invited to visit the factory at St. Catharines on October 24th, 1934.

Meeting at 3 p.m., the members were guided through the extensive plant and explained the complicated process by which the materials pass from the raw state to the finished product.

Steel, iron, tin, copper and nickel are the principal metals used in the delicate castings and forgings which go into the modern locks, door closers and chain hoists. Lacquering, bronzing and the Bower-Barff process are also used as protective coverings.

At six o'clock the party adjourned to the Lincoln hotel for dinner and, afterwards, Mr. Jones gave a brief history of lockmaking with some examples of the modern lock to illustrate the strides which have been made in the last eighty years.

Locks are by no means a modern method of fastening, said Mr. Jones. A wooden lock with a key six feet long has been found in the ruins of Nineveh and the pin-tumbler principle was known to the early Egyptians in a crude form. Some of the hand-wrought iron locks of the middle ages are fine pieces of workmanship.

Locks may be classified roughly under three types: (1) the warded lock, 4 to 12 key changes, wherein the key is shaped to fit over fixed wards either at the ends or sides; (2) the lever-tumbler lock, 12 to 144 changes, where the obstacle is one or more pivoted flat tumblers which the key has to move into certain positions before it can be turned; (3) the cylinder pin-tumbler lock which is undoubtedly the safest and is capable of unlimited combinations. The series used in commercial practice consists of 30,000 changes and the probability of duplicates is therefore in that order.

Master key systems have many variations and Mr. Jones described one for a modern hotel installation, as follows:

1. Guest key—Good for only one room in the hotel.
2. Floormaid's key—Good for one floor only, except when locked from inside or when locked by keys No. 5 or No. 6.
3. Housekeeper's or Manager's key—Good for any lock in the hotel with the same exceptions as No. 2.
4. Emergency key—Good for any lock, with no exceptions.
5. Shut-out key—Used only to prevent keys No. 1, No. 2 or No. 3 from operating the lock.
6. Display key—An individual "shut-out" key for salesmen who wish to leave valuable property in certain rooms and will prevent keys No. 1, No. 2 and No. 3 from operating.

The safe deposit box is now protected by a recently developed lock which has 4,000 combinations and therefore each new customer may select an entirely new key to which, by an ingenious arrangement, the combination is adjusted to fit.

At the close of the meeting Mr. Jones presented to each member a souvenir in the form of a small "personal lock" which can be attached to the inside of any door for extra security. E. P. Johnson, A.M.E.I.C., and A. W. F. McQueen, A.M.E.I.C., proposed a vote of thanks to the speaker. Paul Buss, A.M.E.I.C., acted as chairman.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

STREAMLINING

At the second noon luncheon of the Ottawa Branch, held at the Chateau Laurier on October 18th, 1934, Dr. J. J. Green, of the National Research Laboratories, spoke upon the subject of "Streamlining." Head table guests, in addition to the speaker and the chairman, included: V. I. Smart, Deputy Minister of the Department of Railways and Canals; Major J. G. Parmelee, Deputy Minister of the Department of Trade and Commerce; J. Patterson, Director of the Meteorological Services of Canada; Dr. S. J. McLean, Acting Chief Commissioner of the Board of Railway Commissioners; G. J. Desbarats, M.E.I.C.; Squadron Leader A. T. Cowley, A.M.E.I.C.; A. E. MacRae, A.M.E.I.C.; Squadron Leader A. Ferrier, A.M.E.I.C., and C. McL. Pitts, A.M.E.I.C.

Dr. Green for the past four years has been engaged in aeronautical research and testing and gave a brief outline of the phenomena accompanying the passage of a body through a fluid, with particular reference to the types of resistance encountered and to the possibilities of minimizing it by attention to exterior design.

When a body is moving through a fluid, he stated, two types of resistance are encountered. One, due to the inertia of the fluid is called the "form drag." The other, due to its viscosity is known as the "skin friction."

Two distinct types of flow have been observed. At very low speed, the flow follows closely the contour of the body, the form drag is negligible, and the resistance is almost entirely made up of skin friction. As the velocity is increased, this ideal type of flow gives way to the second type. The flow now breaks away from the body at some point on the surface aft of the nose and a "wake or vorticity" is generated toward the rear of the body. This vortex wake is associated with a large form drag and, by comparison, a small skin friction. The breakaway of the flow in this type is explained by a failure of the viscous forces to restrain the fluid particles, and by the adverse pressure gradient around the body which opposes the motion of the fluid in the thin layer close to the surface of the body. This latter is known as the "boundary layer."

The principle involved in streamlining consists in so shaping the body on the downstream side that the sharpness of the angle through which the flow must turn in order to adhere to the surface is reduced.

The speaker then referred to the two types of flow possible in the boundary layer. These are, respectively, a "laminar" flow or one following closely and evenly along the exterior surface of the body, and a "turbulent" flow or one in agitation or commotion as it follows along the body surface.

The address was illustrated by lantern slides showing attempts at reducing air resistance in the design of airships, aeroplanes, automobiles, steam railway and electric trains, and even motorcycles. Much further investigation remains to be done in the way of streamlining for most efficient results, stated the speaker.

STEEL-MAKING, AEROPLANE AND MARINE CONSTRUCTION IN ENGLAND

A series of six films relating the steel-making, aviation, and steamship construction in England were shown at an evening meeting on October 25th, 1934, at the R.C.A.F. rooms of the Jackson Building. It was one of the most largely attended evening meetings in the history of the Branch, the projection room of the Photographic Section of the R.C.A.F. being taxed to its capacity. The chairman, A. K. Hay, A.M.E.I.C., presided. The films were supplied by the Vickers-Armstrong Company.

The first film depicted steel-making operations at the works of the English Steel Corporation, Sheffield, including electric furnace charging, pouring, stripping and forging. The full extent of these operations however could hardly be adequately shown by the limited medium of the film.

The next three films showed the naval construction works of the company at Barrow-in-Furness and followed the construction at that place of the P. and O. steamers *Strathaird* and *Strathnaver*.

The two remaining films presented respectively the launching and trial flights of the Vickers Supermarine *Seagull V.* with tests of a launching catapult; and the trials of the *Scapa* twin engine flying boat, erection and tests of *Vildebeest*, torpedo carrier, with torpedo dropping trials, and other types of aircraft.

At the conclusion of the showing, which took about an hour, a vote of thanks was passed to the Vickers-Armstrong Company for the use of the films, and to Group Captain G. M. Croil, A.M.E.I.C., the Senior Air Officer of the Photographic Section of the R.C.A.F., for the use of the projection room.

## Peterborough Branch

*H. R. Sills, Jr.E.I.C., Secretary.*
*E. J. Davies, Jr.E.I.C., Branch News Editor.*

Impressions of Soviet Russia

The first fall meeting of this Branch was held on October 11th, 1934, at which Mr. T. Fechney, of the Pratt and Whitney Company of Canada Limited, gave a most interesting address on his recent visit to Russia.

Mr. Fechney was one of a party of twenty-one engineers who went to Russia in 1930, under a three-year contract with the Soviet government to install steel mills. He gave many interesting anecdotes of their travelling, bringing out the wholly inadequate transportation system; the utter disregard of schedule or time tables; the importance of freight over passenger trains, as a result of which the latter were frequently side tracked for the former; and the difficulty of getting meals or hotel accommodation en route.

The Russians seemed to have had a penchant for doing things on a lavish scale and then overlooked or skimped on small but important items. They provided a splendid modern staff house for the visiting engineers, equipped with modern appliances and hot and cold plumbing, but overlooked a water heater. One hundred heavy duty machine tools, such as planers, boring mills, etc., which cost from $15,000 to $100,000 each, were bought for one plant and then the government would not provide proper cutting tools.

The Russians seemed determined to carry out the production as called for by the Five Year Plan, whether the product was satisfactorily produced or not, as frequently happened through stubbornness on the part of the officials, who did not always agree with the foreign engineers. Another reason for loss or damage was their desire to train their own young engineers and allow them to try their ideas. If these ideas proved wrong, it was considered part of the plan. The officials and particularly the foremen did not always have their own way with the men: for, since they were elected by the men, if their orders or methods did not please, the foremen were promptly removed by election.

Mr. Fechney explained that although most plants ran continuously in eight-hour shifts, each man worked four days and rested the fifth. There was no such thing as Sunday, Christmas, etc. The original idea of the same wage for all has been abandoned for a sliding scale, but the worker, i.e. factory producer, still was better off than the professional man who was not a producer.

He felt that some progress has been made, but a little more open-mindedness and co-operation would greatly assist the progress. Although many churches have been converted to clubs, museums and theatres, there were still some churches being used as such, and if fifty percent of the people in any community applied for a church, it would be established. The tendency in this direction seems to be becoming stronger.

The lengthy and animated discussion which followed the address indicated the interest with which the large audience had followed the address. The thanks of the branch was tendered, through the chairman, J. W. Pierce, M.E.I.C., by W. T. Fanjoy, Jr.E.I.C.

## Quebec Branch

*Jules Joyal, A.M.E.I.C., Secretary-Treasurer.*

Le 20 octobre dernier, les membres de la Section de Québec visitaient pour la seconde fois les travaux du Pont de l'Ile d'Orléans; tous ont pu constater les changements opérés durant les deux mois écoulés depuis la première visite et ceux qui ont pris part à cette réunion ont été vivement intéressés. Cette fois encore, M. Théo. M. Déchène, A.M.E.I.C., Ingénieur au Ministère des Travaux Publics de Québec, fut l'organisateur de cette excursion et sur les lieux les visiteurs furent cordialement accueillis par MM. J. W. Roland, M.E.I.C., et W. H. Smick, qui se prêtèrent volontiers à donner toutes les explications demandées.

Deux jours plus tard nos membres se réunissaient de nouveau au Palais Montcalm pour voir se dérouler des films très instructifs mis à la disposition des diverses sections de l'Institut par la compagnie Vickers-Armstrong Ltd.

## Saskatchewan Branch

*S. Young, A.M.E.I.C., Secretary-Treasurer.*

City Manager Form of Local Government

The regular monthly meeting of the Saskatchewan Branch, The Engineering Institute of Canada was held in the Parliament Buildings, Regina, at 7.45 p.m. October 19th, 1934, the attendance being twenty. H. C. Ritchie, A.M.E.I.C., occupied the chair.

S. R. Muirhead, A.M.E.I.C., reported for the Papers committee, stating that the next meeting of the Branch would be held in Regina on Friday evening, November 16th, 1934. The speaker of the evening would be Mr. Fawkes, his subject being "The City Manager Form of Local Government." Mr. Fawkes is a member of the Association of Professional Engineers, British Columbia, and formerly held the position of City Commissioner, Moose Jaw.

Mr. Muirhead also gave a brief resumé of the contents of the October number of The Journal, urging the members to read The Journal.

Moving pictures of the construction of that portion of the Big Bend highway in the National Park, British Columbia, were then shown, the films having been loaned by J. M. Wardle, M.E.I.C., chief engineer, National Parks of Canada, Banff, Alberta. The films indicated the various stages in the construction of the highway from its location and survey of right-of-way to the finally constructed highway.

The meeting concluded with a brief outline of Institute affairs, especially in the matter of Institute development, by P. C. Perry, A.M.E.I.C., and general discussion by those present. Mr. Perry, after pointing out the difficulties in the way of Dominion-wide amalgamation of The Institute with the several associations of professional engineers, suggested the desirability of local co-ordination of the activities of this Branch of The Institute with the Saskatchewan Association of Professional Engineers. The general conclusion was that in order to have an organization of engineers similar to the Royal Architectural Institute of Canada it would be necessary to build from the Provincial Associations.

The first of a series of meetings being sponsored by the Saskatoon Section, Saskatchewan Branch, Engineering Institute of Canada, was held in the Engineering Building, University of Saskatchewan, Saskatoon, on October 22nd, 1934.

Dr. J. B. Mawdsley, head of the University of Saskatchewan geology department, delivered a very able address upon "The Modern Prospector," in which he gave those present an insight into the work of these forerunners of mining operations as only one of his vast experience in this field is capable.

The address of the evening was preceded by the showing of "The Big Bend Highway" films, loaned by J. M. Wardle, M.E.I.C., chief engineer, National Parks Branch, Banff, Alberta, and shown through the kindness of Mr. Kerr, advertising manager of the International Harvester Company, Saskatoon.

Both features of the programme were highly enjoyed by over one hundred members of The Institute, the Graduate Engineers Club, practising engineers of the city and engineering and geology students of the university.

Chairman R. A. Spencer, A.M.E.I.C., presided.

## Winnipeg Branch

*E. W. M. James, A.M.E.I.C., Secretary-Treasurer.*
*E. V. Caton, M.E.I.C., Branch News Editor.*

The winter session of the Manitoba Branch of The Engineering Institute of Canada was opened on October 4th, 1934, with A. J. Taunton, A.M.E.I.C., in the chair. After the general business was completed the chairman gave a brief resume of the activities of the Branch during the summer and of the visit of the General Secretary and later on the President.

In discussing the summer activities the chairman mentioned that during the visit of the General Secretary the opportunity was taken to discuss many of the business affairs and the relation of the Branches to The Institute, and considerable benefit was derived by both parties due to the candid expression of opinion and the realization of the problems of Headquarters. At the meeting of the Branch called during Mr. Durley's visit, he gave an address on the responsibility of the engineer to his National Technical Association, which was greatly appreciated by the members.

During the time the Branch was honoured by the visit of the President, in addition to addressing the Branch on Institute affairs he also gave a most interesting paper on "Bridge Construction." Special meetings were arranged at which the Executive and other members of the Branch were able to discuss the many problems of the Branches and Headquarters. The President and Mrs. Shearwood were entertained at a dinner at the Lower Fort Garry Country Club. The general opinion of the Branch was expressed that visits of this sort should be more frequent, as they tend to much closer co-operation between the Branches and Headquarters.

Science in Naval Warfare

The speaker for the evening of October 4th was Professor J. F. T. Young, Professor of Physics, University of Manitoba, who gave an address on "Science in Naval Warfare."

The speaker indulged in some reminiscences of developments in the theory and practice of naval warfare which came to his notice during service in the Great War. Attention was given chiefly to the submarine campaign of the Germans which by its intensity and ruthlessness proved to be an almost decisive factor in 1917. The general method of protection of merchant ships by dazzle-painting and by the convoy system, a revival of Napoleonic times, proved efficient so far as they went but were purely defensive measures. More aggressive action followed from the development of new scientific devices based upon hitherto unused properties of ships. In addition to the improvements in contract mines, special mines based on the acoustic and magnetic properties of ships were proposed and those of the latter type proved very successful indeed. Incidental to these investigations with new mining methods, extensive researches on pressure waves in underwater explosions were carried out to determine the kind and amount of explosive most suitable for the destruction of ships, submarines in particular. Very interesting and important data resulted which added to the effectiveness of the later phases of the naval campaign. Blockade methods, such as used at Zeebrugge and as proposed for the English Channel with the famous "Mystery Towers," were discussed.

The lecture closed with a brief mention of the application of these new inventions to naval tactics and as aids to peace time navigation, in position plotting and depth sounding. Many lantern slides throughout the lecture illustrated the various phases treated.

# Preliminary Notice

## of Applications for Admission and for Transfer

November 26th, 1934

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in January, 1935.

R. J. Durley, Secretary.

* The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

AVERY—ERIC, of 733 Alexander Crescent, Calgary, Alta., Born at London, England, Sept. 16th, 1902; Educ., Public Schools and St. Johns Technical School, Winnipeg, 1908-19; Private tuition over five years; 1919 to date, with the Dominion Bridge Company as follows: 1919-24, dftsman., 1924-25, field erection, 1925-29, designing and estimating, Winnipeg, and from 1929 to date, chief engr. at Calgary. Work includes designing, estimating, sales, shop production, drawing office production, supervn. of field erection.

References: F. P. Shearwood, H. M. White, A. Campbell, J. R. Wood, T. Lees, J. C. Trueman, R. Barnecut, R. C. Harris.

BAILEY—CHARLES DAVID, of 544 Notre Dame St., Lachine, Que., Born at Glasgow, Scotland, July 2nd, 1903; 1917-22, cert. for five year course in engrg., Clydebank Technical School (in affiliation with Royal Technical College, Glasgow); 1918-23, articled ap'ticeship with Beardmore Company, Engrs. and Shipbldrs., Dalmuir, Scotland; 1923-25, junior engr. with same firm, design of ship forms, powering of ships, and design of screw propellors. Experimental work on resistance of ship forms, on seaplane floats and on flying boat hulls. General estimator and stress engr.; 1925-29, with H.M. Air Ministry, Design and Research Dept., Cardington, England. Design of form of rigid airships. Analysis of model results. Assessment of loading systems from static and aerodynamic distributions. Strength of aircraft structures. Reduction and analysis of full scale experiments on aerodynamic pressure distribution on aircraft and on struct'l. strength of airship hulls. Stress checking of design and detail mech'l. drawings. Test trials on engines and experiments on water recovery from exhaust gases of internal combustion engines; 1929 to date, engr. and estimator with Dominion Bridge Company, Ltd., Montreal. Design of cranes and electric hoists, hydraulic regulating gates and hydro-electric auxiliary machinery. Design and experimental work on gearing and rollers. Stress analysis on braced structures.

BEATON—NEVILLE, of Powell River, B.C., Born at London, England, May 22nd, 1894; Educ., Guildford Technical School, England, 1909-14. Private study; Member, Assn. Prof. Engrs. B.C.; 1909-14, student ap'tice, Royal Aircraft Factory, Farnborough, England. Complete course in all depts. of shops, labs. and drawing office; 1915-18, mgr. of airship and kite balloon factory, of J. Mandleberg & Co. Ltd., Manchester, England; Charge of entire plant and all incidental depts., including dfting., planning, purchasing, and clerical; 1919, in business for self; 1920-24, asst. equipment engr., Dept. of Highways, Ontario; 1924, chief inspr., Brooks Steam Motors, Stratford, Ont.; 1925, plant engr., Gregory Tire Co., Coquitlam, B.C., charge of design, production and plant operation; 1925 to date, with Powell River Co. Ltd., Powell River, B.C., as dftsman., checker, chief dftsman., plant engr., and at present res. engr. In charge of all operations, plant equipment, hydraulic development and records; plant extensions, engrg. contracts, designs and records; field engrg. dept., etc.; reports and recommendations on development work.

JOHNSTON—ALEXANDER CHARLES, of Arvida, Que., Born at Dundee, Scotland, Feb. 7th, 1886; Educ., Public and Private Schools, Toronto. Private study and corres. course; 1904-09, asst. electr'n. and mechanic, Smart-Woods Ltd., Montreal; 1909-10, master mechanic and electr'n. with E. A. Wallberg, contractor, Matabitchewan power house; With Canadian Westinghouse Company as follows: 1910-11, constrn. electr'n., 1911-12, erecting engr., 1913-18, district engr., Toronto, 1918-19, sales engr., Toronto; 1919-22, technical asst., and 1922-27, asst. supt., Northern Aluminum Co.; 1927 to date, elect'l. supt., Aluminum Company of Canada, Arvida, Que.

References: N. D. Paine, A. W. Whitaker, Jr., J. Palmer, J. W. Ward, H. U. Hart.

PERRY—AUBREY HUFFMAN, of St. Catharines, Ont., Born at Port Hope, Ont., Oct. 7th, 1906; Educ., B.A.Sc., Univ. of Toronto, 1930; June 1930 to date, asst. sanitary engr., Public Health Engrg. Divn., Great Lakes District, Dept. of Pensions and National Health, St. Catharines, Ont. Supervision of drinking water supplies on all classes of common carriers engaged in interprovincial and international traffic; problems connected with the pollution of boundary waters; design of small structures connected with water supply; sewage disposal, garbage incineration, etc.; preparation of reports on various sanitary problems.

References: G. H. Ferguson, A. E. Berry, C. R. Young, W. S. Wilson, F. M. Brickenden.

RIGGS—HENRY EARLE, of 527 East Liberty St., Ann Arbor, Mich., U.S.A.; Born at Lawrence, Kansas, May 8th, 1865; Educ., B.A., Kansas Univ., 1886; Degree of Civil Engr. granted by Univ. of Mich., 1910; Member, A.S.C.E. (Director 1932 to date); 1890-96, chief engr., Toledo, Ann Arbor and North Mich. Rly.; 1896-1912, member of firm, The Riggs and Sherman Co., Toledo, Ohio, designed and built electric rlys., industrial lines for steam rlys., docks and wharves, waterworks, etc.; 1912-30, professor of civil engrg., and head of Dept. of Civil Engrg., Univ. of Michigan. Retired in 1930 with title of Honorary Professor of Civil Engrg.; From 1908 to date, engaged principally in valuation work, also as arbitrator and consltg. engr.

References: C. H. Mitchell, J. A. Heaman, F. C. McMath, J. M. R. Fairbairn, F. H. Kester, H. P. Eddy, J. L. Harrington.

SMITH—GEORGE HILLIER, of 3472 Van Horne Ave., Montreal, Que., Born at Hull, England, July 7th, 1887; Educ., 1901-07, Hull Technical School. 21 years private study, materials handling machinery (all branches). Assoc. Member, Amer. Soc. Mech. Engrs.; 1901-07, dftsman., Earles Shiphuilding Co., Hull, England; 1907-11, asst. to chief engr., Rohilkhand & Oudh Ry., Lucknow, U.P., India; 1915-25, conveyor divn., Dunlop Tire and Rubber Co.; 1911-15, sales engr., Federal Engrg. Co., Toronto; 1925-28, conveyor and transmission engr. (sales), Dodge Mfg. Co., Toronto; 1928-29, manager, Montreal Office, Stephens-Adamson Mfg. Co.; 1929 to date, engr. for design and layout, Materials-Handling Divn., Plessisville Foundry Ltd., Montreal, Que.

References: M. V. Sauer, R. W. Angus, A. P. Theuerkauf, M. Eaton, E. B. Wardle, H. L. Johnston.

STOBBART—WILLIAM MORLEY, of 4835 Patricia Ave., Montreal, Que., Born in Cumberland, England, June 22nd, 1896; Educ., High School, Carlisle, England, 1905-12; 3 years engrg. course, Carlisle Technical School; Advanced engrg. course, Northampton Polytechnic, London, England; 1912-20 (interrupted by war service), ap'ticed as mech'l. engr., passing through shops and drawing office, Cowans Sheldon & Co. Ltd., Carlyle, England; 1920-22, mech'l. designer, steel works, cranes, chargers and gen. steel works equipment, Wellman, Smith Owen Engrg. Corpn., London, England; 1922-24, asst. engr., design and production of cranes, hoists and materials handling equipment, Sociedad Espanola de Construc., Bilbao, Spain; 1924-26, designing engr., cranes, hoists and coal and ore bridges, Stohort & Pitt Ltd., Bath, England; 1926-29, designing engr., cranes, hoists, hydraulic regulating gates and equipment. Launching machines for seaplanes designed in collaboration with Admiralty. Ransome & Rapier Ltd., Ipswich, England; 1929-31, mech'l. designer, cranes, hoists, hydraulic regulating gates and equipment, and at present asst. engr., Dominion Bridge Company, Ltd., Montreal, Que.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

ADDIE—GEORGE KYLE, of 148 St. Cyrille St., Quebec, Que., Born at Sherbrooke, Que., June 16th, 1868; Educ., B.Sc., McGill Univ., 1889; Q.L.S., 1889; 1886-89, articled ap'tice. to A. W. Elkins, C.E., Q.L.S.; 1889 to date, private practice as consltg. engr., employed by many railway, mining and lumber companies, municipalities and private individuals. Engaged as expert on many lawsuits. From 1906-12, Divisional Intell. Officer, M.D. No. 5, retiring in 1912 with rank of Lt.-Col., and long service decoration. (*St. 1887, A.M. 1898.*)

References: H. Cimon, A. Lariviere, A. B. Normandin, J. T. F. King, J. G. O'Donnell, R. B. McDunnough, P. Methe, L. Beaudry.

FOR TRANSFER FROM THE CLASS OF JUNIOR

KILLAM—DONALD ALEXANDER, of Montreal, Que., Born at Weymouth, N.S., June 16th, 1901; Educ., B.Sc., McGill Univ., 1927; 1925 (summer), instr'man., hydrographic survey; 1926 (summer), instr'man. and checker on constrn., Ste. Anne paper mill; 1927-28, dftsman., paper mill design; 1928-29, Canada Power & Paper Co., designing for Windsor Mills and Anticosti paper mill and wood handling equipment; 1929-30, International Power & Paper Co., chief dtfsman. in charge of design for mill extensions; 1930 to date, designing engr. for various plants, bldgs. or equipment. Involving investigation of processes, complete plant layout and details of same. Also requisitioning materials and equipment, and, on occasions, supervising erection and installn. of same. (*St. 1925, Jr. 1928.*)

References: C. C. Langstroth, G. R. Stephen, I. R. Tait, J. B. D'Aeth, A. B. McEwen.

FOR TRANSFER FROM THE CLASS OF STUDENT

ADDISON—JOHN HILLCOCK, of Noranda, Que., Born at Toronto, Ont., Feb. 25th, 1912; Educ., B.A.Sc. (Civil), Univ. of Toronto, 1933; 1928-29 (summers) on constrn. for Dominion Bridge Company; 1930 (summer), paving on Ferguson highway, Bituminous Spraying Co.; Sept. 1933 to date, civil engr. in charge of surveying with Minefinders Ltd., Toronto, Ont. (*St. 1932.*)

References: D. C. Tennant, C. R. Young, T. R. Loudon, C. H. Mitchell, W. J. Smither.

MILLER—CHARLES, of Arvida, Que., Born at Watford, Ont., July 16th, 1907; Educ., B.Sc. (Civil), Queen's Univ., 1930; 1928 (summer), dftsman., Aerial Survey Dept., and 1929 (summer), instr'man. on survey party in Manitoba, for Topog'l. Surveys, Ottawa; 1930 to date, on engrg. staff of Duke-Price Power Co. Ltd., Arvida, Que. Experience includes: layout of sewers, waterlines, streets, sidewalks, etc. for Town of Isle Maligne; design, layout and inspection for reinforced concrete bases for towers and transformers for 140 KV substation for electrical boiler installn. at Dolbeau, and concrete transformer fire cells in Isle Maligne power house; misc. topog'l. surveys for flooded lots, etc.; hydraulic studies of Lake St. John watershed; in charge of hydrographic survey at entrance of Grand Discharge from Lake St. John. (*St. 1928.*)

References: F. L. Lawton, G. H. Kirby, N. F. McCaghey, D. A. Evans, A. Macphail, W. P. Wilgar.

## List of New and Revised British Standard Specifications

(issued during July and August, 1934)

B.S.S. No.

110–1934. Air-Break Circuit-Breakers for Voltages not exceeding 660 Volts. (Revision.)

130–1934. Totally-Enclosed Air-Break Circuit-Breakers for Voltages not exceeding 660 Volts. (Revision.)
These two specifications cover circuit-breakers for use on both A.C. and D.C. circuits. The standard sizes have been reduced and the temperature limits revised.

560–1934. Engineering Symbols and Abbreviations.
A list of British Standard symbols and abbreviations recommended for the most commonly used terms in all branches of engineering. For authors of text books and technical papers.

561–1934. Alternating-Current Line Relays (2-Element, 3-Position) for Railway Signalling Purposes.
An addition to the series of specifications for railway signalling relays. This issue deals with A.C. line relays of the 2-element, 3-position, induction type, intended for use on railway signalling circuits, not exceeding 250 volts.

563–1934. Land Aerodrome and Airway Lighting.
The specification is based on the decisions of the International Commission on Illumination and deals with the characteristics of aerodrome and airway beacons, boundary lights, aerodrome, airway and air navigation obstruction lights, landing area obstruction lights, landing area floodlights and illuminated wind indicators.

564–1934. Nickel Ammonium Sulphate and Nickel Sulphate for Electroplating.
The use of material to this specification will obviate the danger of the solution being contaminated by impure salts in electroplating baths.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28 Victoria Street, London, S.W.1, and from the Canadian Engineering Standards Association, 79, Sussex Street, Ottawa, Ont.

## Canadian Chemical Industries

The chemical industry of Canada ranks well among the chemical industries of the world. Canadian Industries Limited, developed from Canadian Explosives Limited, have expanded and diversified production until to-day they are the largest Canadian manufacturers of acids, alkalis, chlorines and fertilizers, and have also become an important factor in the paint industry. In addition, they are the principal manufacturers of artificial leathers and the only manufacturers of cellophane in Canada. Among their most interesting products are those derived from cellulose. Cellulose was first used chemically as a base for gun cotton. At the present time the chemist transforms it into cellophane, fabrikoid, or lacquers such as Duco, and in combination with resins, it is used in the manufacture of many other products.

In practice, chemical companies tend to produce a continually increasing variety of products from the same set of raw materials with which they have manufactured their first or primary product. In an exceptionally interesting article entitled "The Invisible Science" in a recent issue of Maclean's Magazine, there appeared a chart showing the use made of seven basic materials in the ten major divisions of Canadian Industries Limited. In six of the ten divisions, four or more of these seven basic materials are used and sulphuric acid in nine of them.

When one considers the widely varying forms into which cellulose may be transformed, it is not surprising that a chemical company usually makes use of comparatively few raw materials. Many chemical products are used almost entirely in the manufacture of more complex chemicals. Thus, from an industrial point of view, there are few chemicals of greater importance than sulphuric acid. At Coppercliff, Ont., the smoke from the smelter of the International Nickel Company contains a large proportion of sulphur. This smoke is now used by Canadian Industries for the manufacture of sulphuric acid at the rate of about one hundred and fifty tons per day.

At Shawinigan Falls, Que., a chemical industry is established which is essentially Canadian in character. It was developed by Canadian chemists and has utilized Canadian resources. It has found a world-wide market for its products and Shawinigan Chemicals Limited is one of the largest power consumers in the country. Even before the War this plant produced calcium carbide on a large scale; the calcium carbide in turn is used to produce acetylene gas which is of importance in modern welding. In 1915 these processes became of great importance in the production of acetone for cordite and acetic acid. To-day the plant has been much enlarged and its production greatly diversified. By the application of hydro-electric energy to lime and coke, carbide is made and from carbide a series of synthetic organic compounds. It is a peculiar fact that the physical properties of the different members of this group of organic chemicals, some of which are used in explosives, may be controlled in such a manner as to produce the resilient resins necessary for a chewing gum (now on the market) or transformed into a hard transparent resin which may eventually prove satisfactory as a substitute for shatter-proof glass. In the meantime, other forms and colourings of this same group are being used for new and attractive sets of brushes and combs, cups and various decorative containers. It has the advantage over the celluloid group of products in that it is relatively non-inflammable.

Perhaps the largest source of sulphuric acid in Canada is the plant of the Consolidated Mining and Smelting Company at Trail, B.C. The great stacks of this plant emitting huge volumes of sulphur smoke were considered a menace to vegetation in the surrounding country. When the wind carried this smoke over the international boundary, famous lawsuits ensued. Now that Smelters make use of this smoke for the production of sulphuric acid and then use the sulphuric acid for fertilizers, trouble from this source is a thing of the past.—*Royal Bank of Canada Letter.*

---

The first figures published in connection with the Mersey tunnel, which connects the ports of Liverpool and Birkenhead, England, show that between July 18th when the tunnel was opened, and August 31st, no fewer than 527,347 vehicles and 819,585 paying passengers had passed through, paying £42,021 in tolls.

These figures greatly exceed the estimates of the traffic experts. It was estimated that 1,590,000 vehicles of all kinds would use the tunnel annually, or just over 209,000 for the period under review. The actual returns are more than two-and-a-half times this number.

—*Industrial Britain*

## EMPLOYMENT SERVICE BUREAU

**The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.**

***All correspondence should be addressed to***

**The Employment Service Bureau, The Engineering Institute of Canada**

**2050 Mansfield Street, Montreal**

## Situations Vacant

MECHANICAL OR CHEMICAL ENGINEER, with experience in pulp and paper mill, preferably in the control dept. Must be unmarried. Apply giving full particulars of experience to Box No. 1086-V.

YOUNG ENGINEER WITH CAPITAL

Contracting engineer will sell part holdings in active company to young engineering graduate desirous of learning contracting business. Salary $65 to $75 per month. Capital needed $7,000 minimum to $10,000 maximum. Location eastern Canada. Apply to Box No. 1090-V.

CIVIL SERVICE OF CANADA
*List No. 608*

The Civil Service Commission announces an open competitive examination for the following position:

An Instructor (in Chemistry and Physics), Male, for the Royal Military College, Kingston, Ontario, Department of National Defence, at a salary of $2,460 per annum, less a deduction of 10 per cent, authorized by legislation for the fiscal year beginning April 1st, 1934.

*Duties.*—Under direction, to give instruction in Chemistry and Physics at the Royal Military College; on occasion, to give individual instruction to cadets; to correct and criticize exercises; to prepare, examine and rate examination papers; to give lectures; and to perform other related work as required.

*Qualifications required.*—Graduation from a University of recognized standing with specialization in Chemistry and in Physics; at least three years of experience in the teaching of Chemistry, Physics, or related subjects, in an institution of higher education, or two years of such experience together with professional training in pedagogy at a College of Education; thorough teaching ability, and ability to deal tactfully and firmly with cadets; good personality. As no definite age limit has been set for this competition, age may be a determining factor in the making of a selection.

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, NOT LATER THAN DECEMBER 13, 1934. Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at Prince Rupert, Vancouver, Victoria, Edmonton, Calgary, Regina, Saskatoon, Winnipeg, Quebec, Fredericton, St. John, Charlottetown, and Halifax, or from the Secretary of the Civil Service Commission or The Engineering Institute of Canada.

Candidates must be British subjects, and have resided in Canada for at least five years.

## Situations Wanted

ESTABLISHED SALES ENGINEER. Univ. of Toronto '24, with plant and manufacturing experience, wishes to represent manufacturers of technical equipment. Connections with automobile and electrical equipment dealers, throughout Canada. Will make small investment if necessary. Apply to Box No. 1-W.

MECHANICAL ENGINEER, Canadian, with technical training and executive experience in both Canadian and American industries, particularly plant layout, equipment, planning and production control methods, is open for employment with company desirous of improving manufacturing methods, lowering costs and preparing for business expansion. Apply to Box No. 35-W.

MECHANICAL ENGINEER, A.M.E.I.C. Married. Experience in machine shops, erection and maintenance of industrial plant mechanical and structural design. Reads German, French, Dutch and Spanish. Seeks any suitable position. Apply to Box No. 84-W.

MECHANICAL ENGINEER, graduate McGill Univ. Experience on hydro-electric power construction and design and installation of equipment of pulp and paper mills. Desires position as mechanical engineer in an industrial plant or pulp and paper mill, or as representative on the sale of heavy machinery. Apply to Box No. 142-W.

REINFORCED CONCRETE ENGINEER, B.SC., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

## Situations Wanted

ELECTRICAL ENGINEER, B.SC., A.M.E.I.C., AM.A.I.E.E., age 30, single. Eight years experience H.E. and steam power plants, substations, etc., shop layouts, steel and concrete design. Location immaterial. Available immediately. Apply to Box No. 435-W.

CIVIL ENGINEER, B.A.SC. and C.E.; A.M.E.I.C., JUN. A.S.C.E., age 32, married. Experience over twelve years as assistant and resident engineer on the construction of hydro-electric, railway, and aerodrome works. Also office and teaching work on hydraulic designs and investigations, reinforced concrete, bridge foundations and caissons. Location immaterial. Available at once. Apply to Box No. 447-W.

SALES ENGINEER, M.A.SC. Univ. of Toronto, wishes to represent firm selling building products or other engineering commodities, as their representative in Western Canada. Located in Winnipeg. Apply to Box No. 467-W.

MECHANICAL ENGINEER, B.SC. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

### Finding Work

This is the title of a pamphlet just received from the American Society of Mechanical Engineers. It was prepared at the request of their Council by Mr. Samuel S. Board, placement specialist of New York, and deals in a practical way with the important problem of finding work.

The author outlines "a standard technique applied to the needs of engineers" and comments on such subjects as the types of work open to engineers, sales engineering, about which he disclaims many of the older ideas concerning this branch of engineering. Among other phases covered are engineers in business, where to look for a job, looking ahead while working, and professional advancement.

Copies of this booklet are available on request from the Employment Service Bureau of The Engineering Institute of Canada, 2050 Mansfield Street, Montreal.

CIVIL ENGINEER, Canadian, married, twenty-five years technical and executive experience, specialized knowledge of industrial housing problems and the administration of industrial towns, also town planning and municipal engineering, desires new connection. Available on reasonable notice. Personal interview sought. Apply to Box No. 544-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.SC., A.M.E.I.C. Experience includes C.G.E. Students' Test Course and six years in engineering dept. of same company on design of electrical equipment. Four summers as instrumentman on surveying and highway construction. Several years experience in accounting previous to attending university. Desires position with industrial concern where the combination of technical and business experience will be of value. Apply to Box No. 564-W.

MECHANICAL ENGINEER, A.M.E.I.C. Experienced on plant maintenance, steel plant, cement plant and mining plants. Available on short notice. Apply to Box No. 571-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

CHEMICAL ENGINEER, S.E.I.C., B.SC., University of Alberta, '30. Age 31. Single. Six seasons practical laboratory experience, three as chief chemist and three as assistant chemist in cement plant; one year's p.g. work in physical chemistry; three years experience teaching. Desires position in any industry with chemical control. Available immediately. Apply to Box. No. 609-W.

## Situations Wanted

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E., Ontario; three years construction engineer on industrial plants; fourteen years in charge of construction of hydraulic power developments, tower lines, sub-stations, etc.; four years as executive in charge of construction and development of harbours, including railways, docks, warehouses, hydraulic dredging, land reclamation, etc. Apply to Box No. 647-W.

ELECTRICAL ENGINEER, B.SC. in E.E. (Univ. of Man., '30). Age 25. Two year Can. Westinghouse Apprentice Course. Depts.—Switchboard assembly, general draughting office, switchboard engineering, test office. One year's experience since then designing and rewinding small motors and transformers. Location immaterial. Apply to Box. No. 651-W.

ELECTRICAL AND RADIO ENGINEER, B.SC. '30. Variously engaged on receiver development work, testing, and transformer development, under direction. More recent experience includes transmitter test room procedure and short wave beam transmission engineering. For further information apply to Box No. 680-W.

DIESEL ENGINEER. Erection and industrial engineer, A.M.E.I.C., technically trained mechanical engineer with English and Canadian experience in erection and operation of steam and Diesel equipment in power house and mines, pumping, rock drilling, air compressors. Experienced in industrial and steel works operations including rolling mills, quarries, sales. Open for position on maintenance, operation or sales engineer. Location immaterial. Apply to Box No. 682-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC., Elec., '29, B.SC., Civil '33. Age 27. JR.E.I.C. Undergraduate experience in surveying and concrete foundations; also four months with Canadian General Electric Co. Thirty-three months in engineering office of a large electrical manufacturing company since graduation. Good experience in layouts, switching diagrams, specifications and pricing. Best of references. Available immediately. Apply to Box No. 693-W.

MECHANICAL ENGINEER, B.SC., '27, JR.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in western or eastern Canada immaterial. Apply to Box No. 703-W.

COMBUSTION ENGINEER, R.P.E., Manitoba, A.M.E.I.C. Wide experience with all classes of fuels. Expert designer and draughtsman on modern steam power plants. Experienced in publicity work. Well known throughout the west. Location, Winnipeg or the west. Available at once. Apply to Box No. 713-W.

ELECTRICAL ENGINEER, B.SC., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

MECHANICAL ENGINEER, age 41, married. Eleven years designing experience with project of outstanding magnitude. Machinery layouts, checking, estimating and inspecting. Twelve years previous engineering, including draughting, machine shop and two years chemical laboratory. Highest references. Apply to Box No. 723-W.

CIVIL ENGINEER, B.SC. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

DESIGNING ENGINEER, M.SC. (McGill Univ.), D.L.S., A.M.E.I.C., P.E.Q. Experience in design and construction of water power plants, transmission lines, field investigations of storage, hydraulic calculations and reports. Also paper mill construction, railways, highways, and in design and construction of bridges and buildings. Available at once. Apply to Box. No. 729-W.

## Situations Wanted

MECHANICAL ENGINEER, s.e.i.c., b.a.sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, b.sc. '31, s.e.i.c. Age 27. Experience in installation of power and lighting equipment. Temporary operator in radio station; studio experience with part time announcing. Two summers in switchboard and installation department of telephone company, eight months on extensive survey layouts. Interested in sales work of electrical or radio equipment. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, b.sc. '29, a.m.e.i.c. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanish. Apply to Box No. 744-W.

CIVIL ENGINEER, s.e.i.c., b.sc. Queen's Univ. '29. Age 25. Married. Three years experience as construction supt. and estimator for contracting firm. Experience includes general building, bridges, sewer work, concrete, boiler settings, sand blasting of bridges and spray painting. Available at once. Apply to Box No. 776-W.

CIVIL ENGINEER, b.sc., '25, jr.e.i.c., p.e.q., married. Desires position, preferably with construction firm. Experience includes railway, monument and mill building construction. Available immediately. Apply to Box No. 780-W.

DRAUGHTSMAN, experience in civil engineering, forestry engineering, land surveying and house construction. Good references. Apply to Box No. 781-W.

ELECTRICAL AND SALES ENGINEER, s.e.i.c., grad. '28. Experience includes one year test course, one year switchboard design and two years switchboard and switching equipment sales with large electrical manufacturing company. Three summers Pilot Officer with R.C.A.F. Available at once. Apply to Box No. 788-W.

ELECTRICAL ENGINEER desires position as engineer or manager for industrial plant or factory. Over ten years diversified electrical and mechanical experience in the industrial field. Apply to Box No. 795-W.

CIVIL ENGINEER, s.e.i.c., graduate '30, age 23, single. Experience includes mining surveys, assistant on highway location and construction, and assistant on large construction work. Steel and concrete layout and design. Apply to Box No. 809-W.

CIVIL ENGINEER, college graduate, age 27, single. Experience includes surveying, draughting, concrete construction and design, street paving both asphalt and concrete. Available at once; will consider anything and go anywhere. Apply to Box No. 816-W.

CIVIL ENGINEER, b.e. (Sask. Univ. '32), s.e.i.c. Single. Experience in city street improvement; sewer and water extensions. Good draughtsman. References. Available at once. Location immaterial. Apply to Box No. 818-W.

CIVIL ENGINEER, b.sc., a.m.e.i.c., with fifteen years experience mostly in pulp and paper mill work, reinforced concrete and structural steel design, field surveys, layout of mechanical equipment, piping. Available at once. Apply to Box No. 825-W.

CIVIL ENGINEER, b.a.sc., d.l.s., o.l.s., a.m.e.i.c., age 46, married. Twelve years experience in charge of legal field surveys. Owns own surveying equipment. Eight years on technical, administrative, and editorial office work. Experienced in writing. Desires position on survey work, assisting in or in charge of preparation of house organ, on staff of technical or semi-technical magazine, or on publicity, editorial or administrative office work. Available at once. Will consider any salary, and any location. Apply to Box No. 831-W.

CIVIL ENGINEER, s.e.i.c., b.sc. '32 (Univ. of N.B.). Age 25. Married. Two years experience in power line construction and maintenance; one year of highway construction; one summer surveying for power plant site, location and spur railway line construction. Available at once. Location immaterial. Apply to Box No. 840-W.

CIVIL ENGINEER, b.sc. '15, a.m.e.i.c., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

CIVIL ENGINEER, b.sc. (Alta. '31), s.e.i.c., age 24. Experience, three summers on railroad maintenance, and seven months on highway location as instrumentman. Willing to do anything, anywhere, but would prefer connection with designing or construction firm on structural works. Available immediately. Apply to Box No. 846-W.

## Situations Wanted

MECHANICAL ENGINEER, jr.e.i.c., Technical graduate, bilingual, age 32. Eight years experience in design of boiler plants; steam, water and gas piping; heating, ventilating, air conditioning and plumbing systems; writing of specifications and technical translation. Experience includes: two years in engineering department of large company, five years with consulting engineers and one year on large piping and construction projects. Available at once. Apply to Box No. 850-W.

BRIDGE AND STRUCTURAL ENGINEER, a.m.e.i.c., McGill. Twenty-five years experience on bridge and structural staffs. Until recently employed. Familiar with all late designs, construction, and practices in all Canadian fabricating plants. Desirous of employment in any responsible position, sales, fabrication or construction. Apply to Box No. 851-W.

STRUCTURAL ENGINEER, b.a.sc., a.m.e.i.c. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

MECHANICAL ENGINEER, b.sc. '32, s.e.i.c. Good draughtsman. Undergraduate experience:—One year moulding shop practice; two years pipe fitting and sheet metal work; one year draughting and tracing on paper mill layout; six months machine shop practice; and eight months fuel investigation and power heating plant testing. Desires position offering experience in steam power plants or heating and ventilating design. Will go anywhere. Apply to Box No. 858-W.

MECHANICAL ENGINEER, age 31, graduate Sheffield (England) 1921; apprenticeship with firm manufacturing steam turbine generators and auxiliaries and subsequent experience in design, erection, operation and inspection of same. Marine experience b.o.t. certificate thoroughly conversant with Canadian plants and equipment. Available on short notice. Any location. Box No. 860-W.

CHEMICAL ENGINEER, b.sc. (McGill '21), a.m.e.i.c., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

CONSTRUCTION ENGINEER (Toronto Univ. of '07). Experience includes hydro-electric, municipal and railroad work. Available immediately. Location immaterial. Apply to Box. No. 886-W.

ELECTRICAL ENGINEER, graduate 1929, s.e.i.c. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

AGENCIES WANTED. Young engineer, b.a.sc. in c.e., with business and sales experience, speaking fluent French, would consider representing a firm as agent for Montreal or the province of Quebec. Apply to Box No. 891-W.

ELECTRICAL ENGINEER, grad. Univ. of N.B. '31. Experienced in surveying and draughting, requires position. Available at once. Will go anywhere. Apply to Box No. 893-W.

CIVIL ENGINEER, b.a.sc., jr.e.i.c., age 29, single. Experience includes two years in pulp mill as draughtsman and designer on additions, maintenance and plant layout. Three and a half years in the Toronto Buildings Department checking steel, reinforced concrete, and architectural plans. Available at once. Location immaterial. At present in Toronto. Apply to Box No. 899-W.

DESIGNING ENGINEER, a.m.e.i.c. Permanent and executive position preferred but not essential. Fifteen years experience in designing power plants, engine and fan rooms, kitchens and laundries. Thoroughly familiar with plumbing and ventilating work, pneumatic tubes, and refrigeration, also heating, electrical work, and specifications. Apply to Box No. 913-W.

CIVIL ENGINEER, b.sc., o.p.e. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

CIVIL ENGINEER, b.sc. (Univ. of Sask. '33), s.e.i.c., age 28, single. Experience in testing hydro-electric equipment, draughting, surveying, city street improvements, technical photography. Available at once. Location immaterial. Apply to Box No. 986-W.

ELECTRICAL ENGINEER, s.e.i.c., b.sc., (N.S. Tech. Coll., '33), desires work. Experience in transmission line construction. Location or class of work immaterial. Apply to Box No. 1010-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

## Situations Wanted

CIVIL ENGINEER, b.sc. (Queen's, '14), a.m.e.i.c., Dominion Land Surveyor, 5 months special course at the University of London, England, in municipal hygiene and reinforced concrete construction. Experience covers legal and topographic surveys, plane tabling and stadia surveying, railway and highway construction, drainage and excavation work. Available at once. Apply to Box No. 1035-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. Age 36. Married. Seven years experience in geophysical exploration using seismic, magnetic and electrical methods. Two years experience with the Western Electric Company of Chicago, working on equipment and magnetic materials research. Experienced in radio and telephone work, also specializing in precise electrical measurements, resistance determinations, ground potentials and similar problems of ground current distribution. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, b.a.sc. Univ. Toronto '28. Experience includes Can. Gen. Elec. Co. Test Course. Also more than two years in the engineering dept. of the same company. Available on short notice. Preferred location central or eastern Canada. Apply to Box No. 1075-W.

ELECTRICAL ENGINEER, b.sc. Married. Eight years electrical experience, including operation, maintenance and construction work, electrical design work on large power development, mechanical ability, experienced photographer, employed in electrical capacity at present. Available on reasonable notice. Apply to Box No. 1076-W.

GRADUATE IN MECHANICAL ENGINEERING, 1927, desires opportunity in Diesel engine field, preferably in design and development work. Skilled draughtsman and clever in design. Familiar with basic theories of the Diesel engine and in touch with recent developments and applications. Anxious to obtain a foothold with up-to-date company. No objection to shopwork or other duties as a start but would prefer shopwork and assembly if possible. Apply to Box No. 1081-W.

CIVIL ENGINEER, b.sc., Sask. '30. s.e.i.c. Age 24 years. Experience in municipal engineering, including sewer and water construction, sidewalk construction, paving, storm sewer design, draughting, precise levelling, and reinforced concrete bridge construction. Unmarried. Available at once. Will go anywhere. Apply to Box No. 1115-W.

ELECTRICAL ENGINEER, b.sc.e.e. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

GEODETIC AND TOPOGRAPHICAL ENGINEER, d.l.s., m.e.i.c. Experience in all kinds of geodetic and topographical surveys, especially photo-topography, well versed in all kinds of air photo surveys; Canadian and U.S. patent method of determining position and elevations of points from air photographs. Available at once anywhere in Canada or the United States. Apply to Box. No. 1127-W.

PETROLEUM CHEMIST, b.sc. in Chem. Eng. Age 25. Single. One and a half years experience as assistant chemist. Capable of taking charge in small refinery. Wishes position anywhere in Canada. Apply to Box No. 1130-W.

ELECTRICAL ENGINEER. b.sc., Queen's '33. Single, age 23. Anxious to gain experience. Present experience installing small private hydro-electric plant. Location immaterial. Available at once. Apply to Box No. 1137-W.

CIVIL ENGINEER, a.m.e.i.c., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

CIVIL ENGINEER, b.a.sc., s.e.i.c., age 26, single. Experience includes one year in bridge construction, plain and reinforced concrete, pneumatic caissons and surveying. Available at once. Any location. Apply to Box No. 1204-W.

PHYSICIST ENGINEER, B.Sc.Mech. (Queen's 1913), M.Sc., Ph.D.Physics (McGill 1929, '30). Experience in municipal engineering, producer gas installation and operation, university plant maintenance. Experienced teacher of college physics. Industrial and pure physical research experience. Age 42. Married. Apply to Box No. 1207-W.

MECHANICAL ENGINEER, b.sc. (Queen's Univ. '28), age 36, married, desires position of trust and responsibility. Experience includes fitting and assembly of machine tools, production, draughting, and maintenance. Five years teaching draughting and mathematics. Available on reasonable notice. Location immaterial. Apply to Box No. 1210-W.

COMBUSTION ENGINEER, a.m.e.i.c., with extensive experience in all phases of combustion engineering, including plant layout, piping, etc. Lately connected with prominent firm of automatic oil burner manufacturers. Apply to Box No. 1224-W.

# Something's gone wrong in Vancouver!

WHEN temperatures, pressures or levels rise or fall in Vancouver, or at any other place a few feet or a thousand or more miles from headquarters, Bristol's Metameter records it instantly. A 12-inch chart right before your eyes keeps a continuous record of every fluctuation at the distant point. Any change from normal, whether alarmingly abrupt and large or minute and gradual, is immediately recorded.

The latest development by the pioneers in telemetering, Bristol's Metameter enables you to control process conditions or operations no matter how distantly conducted. It consists of a transmitter at the location where the temperature or pressure is being measured, an electrical circuit for conveying the impulses automatically sent out by this transmitter, and a recording instrument at headquarters for mechanically translating the impulses received into the continuous charted record.

The *durations* and not the *intensities* of the transmitted impulses are proportional to the values measured. Only a simple two wire circuit is needed. Where available any existing telephone line may be employed without danger of interference with or from conversation carried, or line capacity.

In addition to the large easy-to-read chart, notable features are the use of any kind and frequency of line current, small line current and voltage, freedom from interference by changes in voltage or other line conditions, no exposed contacts, small power consumption, synchronous power sources unnecessary, Bristol's standard measuring elements, self-checking accuracy, self-restoring, use with remote control.

Interesting details are given in a bulletin now on the press. Write for your copy.

# THE EMPLOYMENT SERVICE
OF THE
# ENGINEERING INSTITUTE OF CANADA

**You can assist us...**

Do you know of any firm or individual who requires the services of an engineer or has an opening in his organization that can be filled by an engineer ?

If so, remind him of, or advise the Employment Service of the Engineering Institute of Canada. This service is maintained to assist, without cost, members and employers to locate experienced engineers in all branches of the profession.

**Now** is the time to solve personnel problems. Engineers are available in all parts of Canada.

**Address communications to:**

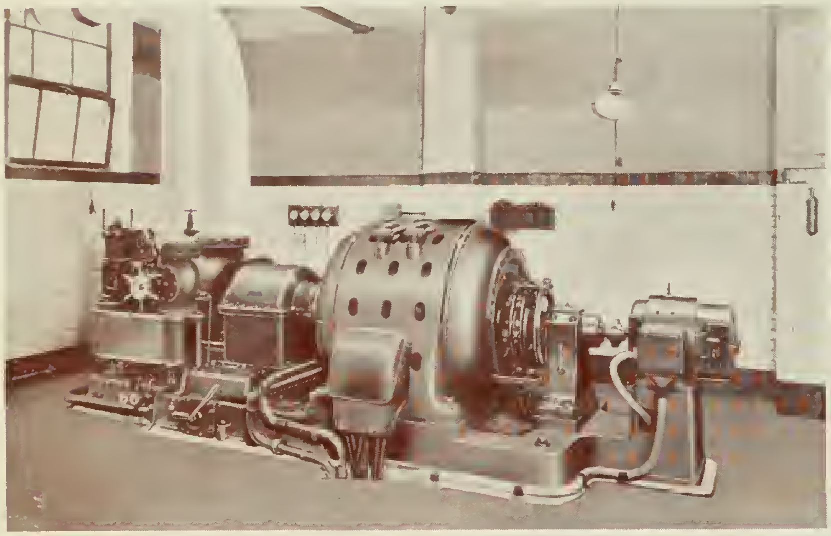
**2050 Mansfield Street, Montreal**

## INDEX TO ADVERTISERS

# PROFESSIONAL CARDS

# ANNOUNCEMENT

Messrs. W. H. Allen Son & Co., Limited, Bedford, England, announce the appointment of Babcock-Wilcox & Goldie-McCulloch Ltd. as sole Canadian agents for Allen Diesel Oil Engines and Allen Steam Turbines. In Allen equipment is embodied the highest quality of the world famous British engineering design and workmanship, and the new connection here announced is the Canadian purchaser's assurance of prompt, efficient and intelligent service.



*400 K.W. Back Pressure Allen Turbine connected through reducing Gear to Generator.*

## TURBINES

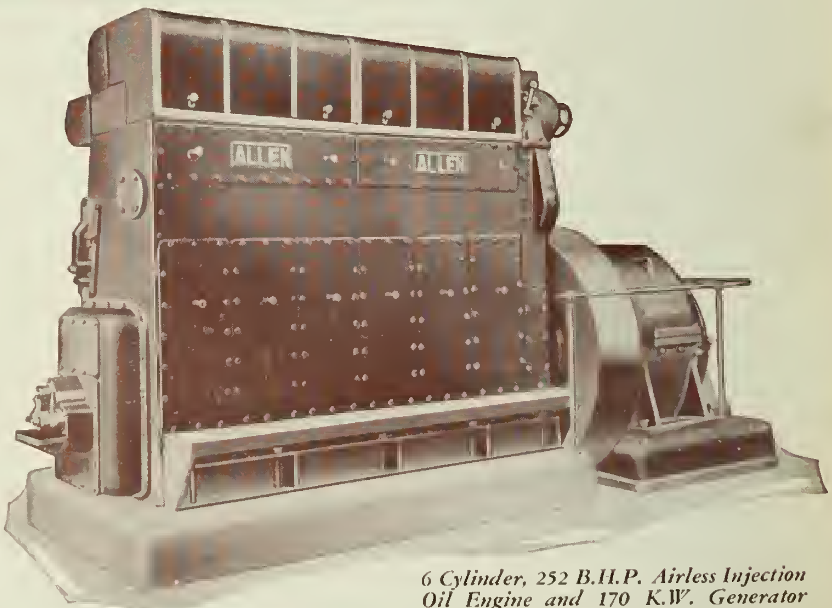
The economy of producing Power as a By-Product with an Allen Steam Turbine should be investigated where the need for Electric Power exists side by side with a process or heating Steam Load.

Allen Turbines have an established reputation for economy and reliability in operation.

## OIL ENGINES

For Power Generation, Driving Centrifugal Pumps and Air Compressors, as well as for Railway and Marine Propulsion.

Characterized by Easy Starting... Smooth and Silent Running... Absence of Vibration... Long Working Life... Economical running and upkeep costs with absolute dependability.



*6 Cylinder, 252 B.H.P. Airless Injection Oil Engine and 170 K.W. Generator for land installation.*

# Babcock-Wilcox & Goldie-McCulloch, Ltd.

*Head Office and Works:* GALT, CANADA

*Branches at:* MONTREAL TORONTO WINNIPEG VANCOUVER

**Manufacturers of Power Plant, Pumping and Air Compressor Equipment**
