Apart from the use already referred to, there are now many more applications, both static and dynamic. One such has been the "G" Restrictor made by British Messier Ltd. This was a unit which warned the pilot when a critical vertical acceleration on the aircraft was reached by imposing a resisting load on the control column. Should the pilot ignore the initial resistance and impose a greater vertical acceleration on the aircraft, the "G" Restrictor developed sufficient force to move the control against the pilot's force and thus reduce the vertical acceleration.

It employed a heavy alloy weight, which would not have been possible to make from lead because of the electrolytic action between the hydraulic fluid used and the component. Nor was steel a practicable alternative, since it would occupy twice the space, increasing the size of the chamber where this was very limited.

An even greater test of the material's strength is that to which it is subjected in aircraft gyroscopic instruments. The stability of gyroscopic movement depends on angular momentum and a maximum mass density at as large a radius as possible within the allowable limitations on physical dimensions and overall weight must be provided.

### ARE CONFERENCES WORTH WHILE?

*The Times Review of Industry,* v. 8, n. 88 (New Series) May 1954, p. 15.

One of the difficulties about the conference as it is today offered to industry is that it is not really a conference at all; it stands somewhere — not necessarily midway — between the conference and the lecture or course of lectures. At the lecture a man who is presumed to have some special knowledge stands on a platform to impart his learning to an audience for the purpose of acquiring it. At the conference, properly so called, an assembly of delegates discuss matters of common interest under the guidance — and, only in so far as the delegates accept their own standing orders, under the direction — of a chairman.

That a conference session may consist of anything from a free-for-all discussion to a completely formal lecture certainly affords a considerable flexibility in theory; in practice it often discourages the conference organizer from thinking carefully about what his conference is really for and treacherously leads him on to the conclusion that "anything does providing there is not too much of it". It appears to be the search for variety for its own sake — in the belief that variety will ward off boredom — rather than the selection of the most appropriate medium for stimulating learning that often governs the form of particular sessions. Thus a conference may consist of a lecture, a lecture plus discussion, and a lecture followed by discussion syndicates followed by reporting back sessions and further, discussions; to all these may be added discussion on films and filmstrips, role-playing, questionnaire filling-in (a source of some most improbable generalizations), unashamed entertainment and, as the background to this hotchpotch, the licensed bar where the organizer fervently hopes personal contacts will be made which will justify his conference however badly he has arranged it.

It would be unfair not to appreciate the difficulties of organizers. For the most part — the adult education institutions which offer conferences for industry are the chief exceptions — organizers must find suitable accommodation. Stretch the meaning of "suitable" as far as you can, that accommodation is limited. Thus the nature of available accommodation has exercised an undue influence on the nature of conferences. More particularly, the break-even point of any particular accommodation has dictated the size of the conference to be held in it, if 150 delegates were required to make a conference pay at the Hotel Splendido-Magnifico, then 150 delegates there would have to be in spite of the fact that the theme and personnel of the conference suggested an optimum size of 80.

Nothing would ease the accommodation problem so much as a severe cut in the number of conferences offered, and more cooperation between organizers would give some relief. Why is it that the organizers seem to have shunned moderation and cooperation? One is forced to the regrettable conclusion that it is because, at least until recently, the running of conferences has been fairly profitable business.

If it is true there are too many (and too many bad) conferences, what can be done about it? First, there should be fewer of them. Only heartsearching of an intensity which is scarcely anywhere apparent is likely to effect a voluntary reduction in the numbers offered. The threat of bankruptcy is a much stronger inducement. If conference-running is coming up against the law of diminishing financial returns that is not surely a matter of regret, though one hopes that organizers will recognize the threat before it becomes a fact. Secondly, organizers should constantly try to improve their conferences should be much more discriminating in patronizing what is offered to it.

The organizers must consider the form that the conference will take and the procedure at sessions that is most appropriate to the subject matter. Correct procedure is important and the value of variety should not be overrated. Speakers, especially, those not in the direct employ of the organizers, should be carefully and forcefully briefed. If a subject is best treated by formal lecture, then a formal lecture there must be. It simply will not do for a speaker to lecture without notes, (not because he is a gifted and orderly impromptu talker, but because he has not bothered to prepare them); nor has a speaker the right, if he has been asked to lecture, to get up and say "I shall talk only for a few minutes and then I thought we would have a good discussion on your questions"; nor should a speaker be invited twice if, with an air of omniscience often belied by his performance, he ends his rambling talk with "well my time is up, although I haven't said half of what I intended".

Organizers should certainly demand from their speakers some concrete evidence that their promised talks will be worth listening to, and they should not shrink from cancelling an advertised lecture if the speaker replies "of course, I am never quite sure what I shall say, until I get up". If there are to be discussion groups, they should be in the charge of people with at least a rudimentary knowledge of controlling and directing a discussion. The selection of a discussion group leader should not be regarded by the organizer as a means of paying a compliment or of inflicting a fatigue nor should it be presented to the group as an exercise in democratic election.

Finally, the organizers should depend more on their own personal efforts and less on badges and the accumulated effect of attendance at the bar for ensuring that the delegates become personally acquainted. The more naturally reserved delegates may, in fact, be precisely the people who never enter the bar.

A firm's first step, on deciding that an offered conference is worth patronage is to determine who shall attend. This task is only slightly simplified when the conference is intended for a closely defined group of people, sanitary engineers, canteen managers or directors. It may be that there is only one canteen manager in the firm, but if he is incapable of benefiting from conference experience (and this may be no reflection on his professional competence) there is no point in sending him. When there is a choice, a firm should select the man most capable of absorbing conference discussion and instruction. It should be made perfectly clear that the firm regards conferences (or at least those which it intends to support) as having an educational value and that selection for attendance does not imply approval of hard work, a better prospect for promotion, that "his turn has come round again" or "he is a single man and won't mind". The prospective delegate should certainly discuss the programme with his superiors before leaving and be given some plain indication of the firm's concern and interest. In certain firms, it is understood, there is a practice where a considerable choice is offered — for a conference of, say, foremen — of allowing the foremen's association to make its own choice. It seems a practice quite without merit.

On returning from a conference a delegate should certainly be expected to report both on the way the conference was run and on the value that he personally found in it. These reports are much the best way of assessing the organization's competence for running conferences and of ensuring that the delegate applied himself to the conference with some diligence.

No doubt there will be many who will object that all this is to be much too severe on the conference delegates, and there are certainly some conference organizers who argue that since delegates will arrive straight from one week's work and return straight to another they ought to limit strictly the conference's intellectual demands. This attitude seems to be wholly mistaken. A conference that does not require a marked intellectual effort is not worth attending, and the relaxations should be provided not by the organizer during the conference but by the firm after it. Furthermore, a casual attitude to conferences on the part of a firm which nevertheless insists on supporting them may have an unfortunate effect on its delegate. The delegate may well resent the money lavished on his attendance at a worthless conference in a relatively luxurious hotel (i.e. one to which he could not afford to take his family), and can scarcely be blamed for regarding cynically future injunctions to raise efficiency and avoid waste.

None of the forgeoing should be taken as decrying the value to industry of educational conferences. But those who, in the recent past, have attended them frequently, must have been impressed by the unevenness of their standards and the low level to which they could fall.

## VACUUM FORMING OF PLASTICS GAINS FAVOR

C. H. Vivian, *Compressed Air Magazine*, v. 59, n. 4, April 1954, pp. 108-110.

Articles composed of thermoplastic materials have commonly been manufactured by melting a powder and injecting the resulting liquid into molds. By a newer method called vacuum forming, which is fast gaining favor, a heat-softened sheet is drawn into a mold by means of suction. In the older equipment designed to do this the sheet is transferred to the mold after being softened, but the Auto-Vac Company, of Fairfield, Conn., has developed a machine in which the sheet is heated while it rests in position on the mold. This has shortened the operating cycle and consequently reduced the production cost.

Vacuum forming has its limitations, of course. The process is not suitable for making all thick or deep articles, or those with complicated interiors or that require molded-in inserts, but it will turn out many items at a lower unit cost than injection molders can meet. Where it is applicable, the newer method has definite advantages. For one thing, it will produce larger pieces than even the biggest injection equipment. Some of the vacuum machines now in service have platens 30 square feet and are capable of forming an object weighing 25 pounds.

The leading products of the Auto-Vac process are advertising and Christmas displays and deep-embossed component parts for industrial and household machines and appliances. Among the many other things being manufactured are toys, air mattresses, suitcases, typewriter and cosmetic cases, rigid handbags, tops for office furniture, aprons, TV masks, shower curtains and bath mats, tablecloths and place mats, as well as doors, ducts, etc., for air-conditioning installations, and reflectors, ceiling panels, decorations, illuminated and unilluminated signs, butter trays, etc. The most important items now under development are packaging materials, visual and profile containers, snap-on-lids, inflatable novelties and lighting fixtures.

As to raw materials, various sheet plastics are suitable, but the rigid vinyl copolymers are most used, especially for making relief maps, store displays, containers, toy parts and lighting fixtures.

Flexible vinyl is utilized for deep embossed products such as bath mats, wallets and ladies' pocketbooks. Components of refrigerators, shower baths, washing machines, radio cabinets and many other household articles are molded from styrene copolymers, while cellulose acetate, straight styrene sheet material and polyethylene and Teflon also are used in varying quantities.

The method is especially advantageous where products are to be decorated with colors because the latter can be applied to the flat sheet before it is formed. In doing this, the design is purposely distorted in such a manner that the different colors will be in their desired places when the sheet is drawn into shape. They are put on either by silk screening or by one of the available printing processes, with lithographing in most common use. As many as may be required can be applied at one time to an area 8 to 10 square feet in size.

An important contribution towards the economy of vacuum forming is the low cost of the molds. Those for relatively small runs are generally made of a hard plaster such as Hydrocal (U.S. Gypsum) or Densite (Certainteed Products) often reinforced with screenings.

After it is cast, the plaster mold is impregnated with a resin such as Bakelite's C8 epoxy, which gives it a hard, durable surface. Molds of this type have remained in good condition after producing 50,000 pieces.

Molds for longer runs are made by spraying metal on a master cast until a shell from ⅛ to 5/16 inch has been built up. This is removed and backed up with a plaster or a mixture of resin and fibrous glass, the latter being sometimes preferred because of its lighter weight.

No matter which of the two molds is utilized, it must have numerous tiny holes through which the air can be exhausted to draw a suction of the softened plastic sheet. They may be drilled in both the plaster of the metal type or, in the case of the latter, protruding pins may be inserted in the master cast and then pulled out after the work of spraying and backing up the shell has been completed.

In preparation for the forming operation the sheet of plastic, cut to proper size, is placed over the mold and a clamping ring is lowered and secured to prevent any leakage of air into the space between the sheet and the mold. An electric element, capable of supplying uniform heat up to 700° F. throughout a large area, is next pulled into position over the sheet, usually within 1½ or 2 inches of it. When the plastic has softened sufficiently (it takes from seven to thirteen seconds per 1/100 inch of thickness, depending upon the kind of material used), vacuum is applied and the sheet is forced into the mold depressions by atmospheric pressure acting on it. After a short period to allow for cooling, the clamping ring is removed and the formed plastic stripped from the mold.

## BIG SNOW MELTING SYSTEM

Edson E. deCastro, *Heating, Piping and Air Conditioning*, v. 26, n. 5, May 1954, pp. 130-132.

A number of articles have been written about the Boston Central Artery, and some of them have given brief descriptions of the snow melting system now being installed in the ramps of that elevated highway.

The superstructure of the elevated portion of the artery is a steel framed viaduct with reinforced concrete deck — except for the lower ends of the ramps, which are on earth fill between retaining walls. It is these earth filled lower ends of the ramps in the downtown area, where central steam service is available, that are to be heated for snow removal in order to provide sure acceleration areas on "up" ramps and safe braking areas on "down" ramps.

Snow melting is being installed only in the earth filled portions of the ramps.

The system is conventional in that a warm anti-freeze solution is circulated through pipe grids in the ramp pavement. It was designed to melt approximately 1 in. per hr. of snow. However, the solution heaters have twice this capacity in order to reduce the time for warming up the roadway slabs and to provide sufficient overload capacity.

A greater rate of snow melting was considered but the larger quantity of steam required was not available. The ability of the utility company to supply steam had to be considered, particularly because the use factor of snow melting systems is quite low and the demand rate quite high. Large snow melting loads only become practical when the utility company has a large connected heating load. Most snowfalls occur in the 20 to 30 deg. temperature range, whereas the greatest space heating load is at zero or lower. A surplus of steam for snow melting is therefore usually available at the time when most needed.

Pipe design for snow melting on the ramps presented several problems. The two most pressing were the necessity for balancing the solution flow through the piping, and the problem of air removal. A ramp must slope and it may be curved entirely or only in part. This curvature results in the highway being banked and complicates the problem of air removal. The above-mentioned design problems limit the possible configuration of the snow melting piping considerably.

Sinuous coils cannot be easily used because of the problem of venting the air from each separate hairpin loop when one side of the roadway is higher than the other. A further limiting consideration is added when access boxes for balancing valves cannot be placed in the roadway due to high roadway loading, continuous traffic and a covering of blacktop over the concrete.

Due to the limitation on access boxes, the piping systems in the ramps must be self-balancing. Pipe grids with opposite inlets and outlets meet this requirement, and, therefore, the piping in the ramps consist of a series of grids. Since the grids are at right angles to the roadway, the grid headers butt each other, forming continuous headers running the length of the slab. Baffles are placed in the headers at regular intervals to direct the flow across the ramps and form a series of grids.

Entrapped air is vented up each ramp to a point of elimination through a ⅜ in. vent hole drilled through the top of each baffle. Air passes readily through the holes, and only about 4 per cent of solution bypasses the grids since the pressure head between any two adjacent grids is small. Another advantage of the series of grids arrangement of the piping is that it facilitates construction. The grids—consisting of ten 1 in. pipes on 12 in. centers, welded into 2 in. headers—can be shop fabricated and joined together in the field. Field welding is thus greatly reduced and construction made easier.

The wrought iron pipe grids rest on four parallel rows of supporting bars. These supporting bars are fastened to steel uprights. The supporting uprights are set to proper level before the pads are poured. The 1 in. pipes of the grids are then securely wired to the supporting bars.

The normal maximum length of concrete roadway slab is about 105 ft. The ramp slabs in the snow melting system vary from 60 to 110 ft. Each slab, therefore consists of from six to 11 grids in series, each ramp comprising one or two slabs as required. Loops are placed between the slabs to provide for expansion. Catch basins are located as close as possible to the lower end of the heated portion of each ramp in order to remove all water from melted snow and prevent puddles that might later freeze on the unheated part of the roadway.

All of the piping connecting the ramps with their respective pump houses runs underground, with the exception of the return lines to the pump house near the North Station. These returns are overhead, concealed in the highway structural steel as much as possible. All of the steel solution piping slopes back to the pump houses for drainage. Pipes are run parallel, are grouped together, and are encased in vermiculite water resistant insulating concrete, which in turn is wrapped in a waterproof envelope.

There are five pump houses. Each takes care of from two to four ramps, there being a total of 14 heated ramps. The return pipe from each slab has a separate regulating cock and thermometer in the pump house, making it possible to properly proportion the quantity of solution being pumped to each slab.

Steam is supplied to the snow melting system at three locations by the Boston Edison Co. Service manholes are located near North Station, Fort Hill Square, and on Minot St. just off Nashua St. The North Station manhole furnishes steam to two pump houses, as does the manhole at Fort Hill Square.

Each pump house contains pumps, heat exchangers, an expansion tank and control equipment. The pumps are sized to circulate the required quantity of ethylene-glycol antifreeze solution through the grids. The solution heater is designed for twice the normal capacity calculated to raise the temperature of the antifreeze solution 30° F. The economizer is sized to extract the maximum possible heat from the condensate before discharging it to the sewer.

Snow melting equipment in the pump house can be automatically controlled after starting, but requires manual starting. Consideration was given to various schemes for starting snow melting equipment at the beginning of a snowfall, but it was decided that starting the system at the beginning of a snowfall was too late and, therefore, any such system would be inadequate. It takes 4 to 8 hours or more to warm up the slabs to snow melting temperatures. Therefore, either the system must be maintained during the winter months at the snow melting temperature (35° F.) or it must be started several hours before a predicted snowfall.

Two control systems are provided. One maintaining the slabs at 35° F. during periods of threatened snowfall. The other maintains the antifreeze solution leaving the heater at a set snow melting temperature as long as desired. Either system must be manually started by pushbutton control and the change from one control system to the other is also manual. An automatic bypass control is provided in order to prevent the returning solution from ever reaching the pumps at a temperature lower than 35 deg. which would possibly freeze the economizer. The solution from the heater tempers the solution returning from the ramps so that the temperature of the mixed solution entering the pumps will never be lower than 35 deg.

Initially, the temperature of the solution leaving the pump houses will be limited to 160° F. to eliminate any possibility of softening the blacktop where it rests on the concrete. Although there is no danger of reaching temperatures high enough to soften the blacktop while actual snow melting is in progress, there is a possibility that the temperature of the blacktop may become too high when drying off the roadway to prevent later freezing of the wet surface. Such freezing would be as great a skidding hazard as the original snowfall, and therefore, the ramps must be free from water before heating is discontinued.

## WE WANT TO BE OURSELVES

*The Financial Post*, v. XLVIII, n. 25, June 19, 1954, p. 6.

Canadians may have their faults but no observer who pretends to know anything of this country has ever accused them of narrow nationalism. We simply want to be Canadian.

Long ago we decided that we wished to develop an independent nation, to create within our own political framework, a Canadian social and cultural life and our own industrial and economic structure.

At the annual meeting of the Maclean-Hunter Publishing Co. last week, President Floyd S. Chalmers summed it up this way:

> "We want to know how other people live, we want to sing some of their songs, see some of their films, read some of their books and magazines, and buy some of their products. We want to be independent but not isolated; we want to form ideas from the world just as we share ideas with the world. But at the same time we do not want to live someone else's way of life; we want to be Canadians, living the Canadian way of life".

How can we accomplish that reasonable aim?

Mr. Chalmers stressed one major contribution, the development of a national periodical literature, literature that keeps Canadians informed of the achievements of their own people, "that inspires, informs and entertains in Canadian terms" and that does this in a national setting that "breaks down the excessive sectionalism that has been the bugbear of Canada's historical development".

Outsiders cannot build a strong and independent Canada. They can help and their help is welcome. But the major responsibility for building Canada must always rest on Canadians themselves.

## THE PUBLIC HEALTH SIGNIFICANCE OF ENVIRONMENTAL CONTROL BY ENGINEERING MEANS

John A. Logan, D.Sc., and Robert P. Burden, d.sc. *Bulletin of Hygiene*, v. 29, n. 3, March, 1954, pp. 221-229. Chadwick Public Lecture Presented on November 17, 1953, at the Royal Sanitary Institute, London, S.W. 1, England.

More than one hundred years have passed since Sir Edwin Chadwick presented his revolutionary Sanitary Report (The Sanitary Condition of the Labouring Classes) in 1842, and during this period there have been remarkable improvements, throughout the world, not only in sanitation and in public health but in the attitude of peoples and of governments to the necessity for these amenities. Owing in great part to Chadwick's stimulus and enthusiasm it is now possible to say that, throughout a considerable part of the world, the first objectives of public health have been attained.

It is suggested that, by employing the same basic principles evolved in developing the science of public health engineering, it should be possible for engineers to consider in a rational way the more fundamental problem of environmental control. This would involve a broad engineering analysis of environmental conditions, followed by measures designed not only to eliminate those factors which are harmful but to produce the conditions most favourable for health.

### The Population Problem

The present population of the world is estimated at more than 2,500,000,000 (UNO, 1952) and by the year 2031 it will probably reach 4,000,000,000. The population pattern is changing as a result of the increasing adoption of modern public health and medical practices. Infant and child mortality are decreasing, people are living longer, and the world's population, on the average, is becoming middle-aged. The increasing number of people and their increasing age (which means more adults and more family units) will require more food, more energy, more housing, more medical services, more educational facilities and more communications. All of this will place greater and greater demands on the world's physical resources which, in turn, means that these limited resources will have to be utilized more rationally in the best interests of mankind as a whole.

### Health and Housing

Although, in terms of both morbidity and mortality, the health of the world is improving, it is generally agreed that two-thirds of the people lack elementary medical and nursing facilities, basic sanitation, insect control and adequate maternal and child health programmes. This means that for approximately 1,500,000,000 people now living the need for such essentials as water distribution systems must be measured in millions of miles, for insecticide in millions of pounds, for doctors and nurses in millions, and for hospitals in tens of thousands.

Liberia, for example, has an average of one physician for every 63,000 inhabitants, one nurse for every 61,000 and one hospital bed to each 4,000 (Winslow, 1952). In Ethiopia (UNO 1952a) there is one trained physician for each 150,000 people and only 3,200 hospital beds to serve the country's 15,000,000 people. In Switzerland, on the other hand, there is a trained physician for every 700 inhabitants and there are 71,763 hospital beds for the population of 4,694,000. In Ethiopia alone, in order to bring the country up to Swiss standards, it would require more than 21,000 additional trained doctors and the construction of hospital facilities to house more than 225,000 hospital beds.

In the field of housing an even more unsatisfactory situation exists. The United Nations Tropical Housing Mission has estimated that more than 100,000,000 Asian families (and perhaps as many as 150,000,000) at present live in crowded, insanitary sub-standard quarters (ILO, 1953). The Department of Social Affairs of the United Nations has estimated (1952) that the total need for the world may mount to 180,000,000 family dwelling units.

### Water

It is apparent that the presence or absence of water, in many parts of the world, constitutes the difference between a thriving, prosperous community and an empty, barren desert. Irrigation in such countries as Egypt and India and specific projects such as the Gezira project in the Sudan are brilliant examples of the benefits of water use. But the potential advantages of adequate water supplies have barely been tapped, and even in such countries as England, which is normally assumed to have adequate rainfall, it has been estimated (Pirie, 1953) that large areas could benefit substantially by irrigation, with crop production of certain types increased by as much as 100 per cent.

From the point of view of hydro-electric power, it has been estimated by Simon (1951) that there is sufficient potentially available to take care of about one-third of the world's present consumption. So far, however, only about 10 per cent of this is being utilized. The remaining 90 per cent, will be more difficult and therefore more expensive to develop.

Water is considered by many scientists as the key to development. Economic supply in adequate quantities and of a satisfactory quality is undoubtedly one of the major problems facing mankind, and the development of the world's water economy will rapidly assume a greater and greater significance.

### Food and Energy

Although there has been a certain amount of guarded optimism regarding our ability to maintain world food production and the Food and Agricultural Organization has recently been quoted in The Times (September 14, 1953) as stating that: "World Food production has caught up with the growth in world population for the first time since before the war", it is evident that a great imbalance remains between supply and demand in most parts of the world. Most of the recent increases have taken place in a few countries such as Argentina, the United States, Canada and Australia, while many other areas such as the West Indies and India are still very short of their requirements. In

1950, for example, while the Canadian diet was estimated to consist of approximately 3,147 calories per caput per day, that of India was barely 1,600 (FAO, 1952). And, although the population of India increased by more than 60,000,000 from 1940 to 1952, grain production actually decreased (Forbes, 1952; see Figure III).

But the food problem is, in the final analysis, only a part of the larger problem of the world supply of energy, and from this angle the outlook is more hopeful provided that a rational approach is adopted. Energy, in the broad sense, is obtained from "recurring" sources such as plants ,animals, water power, fuel and wood, and from "irreplaceable" sources such as natural gas, petroleum and coal. It is evident that all energy, recurring and irreplaceable, is derived, or has been derived, from the sun.

An examination of the magnitude of the potential sources of energy available shows that solar energy (only a very small amount of which is used) is incomparably greater than all of the other sources of energy combined. For example it is estimated that in the United States, the energy striking the roof of an average house in one-half hour on a sunny summer day is enough to supply that house with heat, light and utilities for a whole year (MacNevin, 1953. An area of the size of Venezuela could, at present rates of consumption, supply the power requirements of the entire world. Atomic power, as yet impracticable but rapidly being developed, will greatly increase the potential of our irreplaceable resources, while the use of wind-power, tides, atmospheric electricity, the heat of the earth's interior and of tropical waters would also increase the amount of energy available.

### The Engineering Contribution

The rapid increase in world population and the universal demand for higher standards of living have been shown to be matters of urgent importance. With population increasing at a rate approaching 30,000,000 per year, the magnitude of this problem is apparent. While the problems created by the attempt to raise living standards are not so apparent, they are of the same magnitude.

Faced with this situation, more and more people are convinced that the fundamental solution is population control. Although this approach is a difficult one owing to the mass of religious, moral and social scruples which are associated with it, progress is being made, and it may not be too long before it will be possible to consider population control calmly, dispassionately and rationally.

But while population control becomes increasingly necessary in order to maintain the total number of people within the limits imposed by the capacity of the world to support them, there must, simultaneously, be a determined effort to increase the world's 'population capacity'.

Environmental and population control are, therefore, of equal importance. Population control, however, presents a great many social and cultural difficulties; the control and development of the environment, on the other hand, is already a soundly established practice.

In the actual application of engineering techniques, it is becoming axiomatic that they can be successful only if due consideration is given to all the agricultural, educational, social, economic and health aspects which are involved; unilateral development, based on any one of these disciplines, is doomed to failure from the beginning.

### Environmental Control by Engineering Means

Engineering, like medicine, is an applied science that has grown to include a wide range of specialties, all based on the correlation and adaptation of science to human needs. One of these special fields, sanitary or public health engineering, has been concerned with a particular human need, the control of disease.

A natural evolution in the development of sanitary engineering has been from a concentration on these aspects of environmental control which have a direct bearing on disease to a broader consideration of environmental control as it affects health, health being understood in its positive sense. This new concept may best be described as "environmental engineering". Although the basic principles of environmental sanitation remain, the restrictions imposed by the original limited concept of health have been broadened by the acceptance of the modern concept of health as including general, as well as physical, well-being.

The engineering problems involved in environmental control are universal in character, whether in highly developed areas such as the United Kingdom or the United States, or in such relatively underdeveloped areas as Nigeria or Nepal. While in the less developed areas the problems to be faced are of a more fundamental character and the environment is Nature herself, as economic development proceeds the problems encountered are more likely to involve those arising from by-products of man's misuse of Nature.

### Environmental Control Practice

#### *Water*

In considering the environment as a whole, water stands out as the major constituent which enters into almost every phase of man's life and activity. In particular, the shortage of water for domestic, agricultural and industrial use is one of the most serious technical problems of the present-day world, not only in the tropics and subtropics but in many parts of the temperate zones. The availability of adequate supplies of water would change the entire status of the Mediterranean area, of the arid zone of Australia, the South-western United States, Mexico and North Africa, and would raise living standards throughout the world. It has been said that the provision of water is the basic need which, if satisfied, would go a long way to assuring the acceptance and the maintenance of sanitation in those areas where it is now lacking.

#### *Climate*

Climatic factors include those such as wind, humidity, changes in temperature and the air itself. Our primary interest in these fields is concerned with providing man with protection from adverse climatic factors through housing and shelter, certain special problems in connection with clothing, the prevention of atmospheric pollution and, in some special cases, problems such as the fixation of atmospheric nitrogen.

In the field of housing, for example, it has proved difficult to obtain a direct correlation between the standard of housing and disease. This has limited the interest of public health personnel in the housing field. Considered from the broader point of view of comfort and convenience, however, there is a much greater scope for effectiveness, and there is every reason to believe that the health team could make a much greater contribution to housing standards than has heretofore been possible.

#### *Sunlight*

Sunlight, as has previously been pointed out, is the ultimate source of the world's power, both recurring and irreplaceable. The earth daily receives from the sun a potential quantity of power far in excess of all other forms of power, and this offers possibly the greatest single challenge to mankind in the rational utilization of the world's resources. Here again, from an engineering point of view, it would be valuable to examine this environmental factor from the health concept. Cheap sources of power are fundamental to the utilization of sea water for irrigation purposes through either distillation or dialysis; economic power sources in the tropics might prove to be the major technological advantage needed by these areas to put them on a competitive basis with the rest of the world as far as economic development is concerned.

#### *Biological Factors*

The living environment (excluding man) has been of concern essentially because of weeds, rodents, disease-carrying insects, and the cultivation of domestic crops and animals. Here again a variety of professional groups have of necessity developed to handle the many problems involved in this complicated field; again, however, the virtues of examining this problem from the environmental point of view are obvious. This would involve such problems as insect and rodent control, diseases of plants and animals, and the destruction of extraneous vegetation. The production of food in sea water, possibly in combination with waste disposal, is another major problem.

### Conclusion

The events of recent years give promise that man has within his grasp the scientific technique necessary to revolutionize the scientific control of the environment throughout the world. The work of medical pioneers such as Manson, Ross, Smith, and Gorgas has laid the groundwork for the present status of insect control; the brilliant work of British engineers on the Nile and in India complemented by the success in the United States of the Bureau of Reclamation, provides an inspiring example of man's ability to control floods and to turn destructive flood water to the useful purpose of irrigation. The outstanding work of the Colonial Service in such widespread areas as Mayala, Uganda and the Gold Coast is an impressive example of achievement in such fields as reforestation, education, agriculture and health; the more recent examples of planning and development in the Americas by the Tennessee Valley Authority and the Office of Inter-American Affairs are also noteworthy. Modern developments—combine to provide us with a previously undreamed of wealth of knowledge to tackle the problems with which we are faced.

# FROM MONTH TO MONTH

**Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers**

## Overseas Reception

It has become a custom over the last eight years for the Institute to hold a reception for its members in the United Kingdom whenever the president or a senior officer is in London on Institute business.

It began in 1946 when the then president, J. B. Hayes of Halifax, was attending the Conference of Commonwealth Institutions. In 1950 James A. Vance of Woodstock was there on his return from the next conference held in Johannesburg. He was then vice-president and president elect. The reception was held at the Institution of Civil Engineers. In 1952 L. F. Grant of Kingston, a past president and field secretary of the Institute, was there in his capacity as chairman of the Engineers Council for Professional Development. This time the reception was at the premises of the Institution of Electrical Engineers.

In 1954 the Commonwealth Conference was back in London, and D. M. Stephens of Winnipeg, president of the Institute, held the reception at the headquarters of the Civils. In all, about one hundred and forty guests attended. In the receiving line with the president were Mrs. Stephens, Past-President and Honorary Member, Dr. C. J. MacKenzie, the general secretary and Mrs. Wright.

As well as members of the Institute, there were many officers of British engineering organizations. Also several Athlone fellows turned out to meet their president.

The buildings of the British engineering institutions are suited excellently to social events of this kind. They have several halls and auditoriums from which to choose, and catering facilities are readily made available either by the institution's staff or by outside caterers. The Engineering Institute is fortunate indeed to have such excellent facilities available to it.

The record of attendance is not complete, but here is the list of those who accepted the president's invitation:

Dr. P. Dunsheath, Prof. Fred Webster, C. A. Abbott, E. H. Allen, R. E. Burridge, Capt. Jack Adams, R. B. Grimsdick, Brig. Bonn, S. R. Banks, A. O. Barrie, G. L. Bodwell, C. R. Boehm, F. W. Bruce, Sheldon Cherry, W. B. Dodd, John Duby, W. E. Erlebach, D. C. Floyer, D. H. Franklin, Peter Currie, M. G. Ionides, B. H. Colquhoun, C. R. Cruttwell; E. H. Harrison; G. F. Lloyd, A. S. Lowe, Capt. Guy Lefebvre, C. B. R. McDonald, Hugh MacKenzie, J. F. MacLean, J. E. D. McCord, Dr. F. G. Malloch, R. W. Marsh, G. A. Williams, T. R. Wingate, R. H. Hales, Col. A. J. Kerry, Capt. H. L. King, R. W. Foxlee, C. H. Oakes, H. H. Poulton, A. U. Schiach, P. Simpson, F. W. Slingerland, F. G. Tanton, Colin McCallum, Major W. A. McDill, G. Monkman, H. C.

## Cover Picture

The cover picture shows eight of the twelve penstocks for the Sir Adam Beck-Niagara Generating Station No. 2, at Niagara. Each penstock will be 19 feet in diameter, 492 feet long and will weigh some 500 tons. They descend the cliff on a 60 degree angle. There are two papers on the Niagara hydro-electric developments in this issue.

**Receiving overseas guests, (left to right) President D. M. Stephens and Mrs. Stephens; General Secretary L. Austin Wright and Mrs. Wright; Honorary Member C. J. Mackenzie and Mrs. Mackenzie.**

Morris, R. N. Morrison, Robert Mortimer, G. L. Phillips, W. J. De Coursey, Miss A. M. Vidal-Hall; D. H. Waller, D. T. Wright, David Watson; Dr. C. J. Mackenzie.

Commonwealth Conference delegates: W. P. Shepherd-Barron, A. S. Quartermaine, V. A. M. Robertson, Alexander McDonald, A. Bannister, Dr. R. W. Bailey, A. C. Hartley, Brian Robbins, Mr. Platt, Mr. Bispham, H. Bishop, J. Eccles, Col. B. H. Leeson, W. K. Brasher, and F. Jervis Smith, of Britain; C. W. Candy, C. H. D. Harper, of Australia; Major-General H. Williams, Prof. M. S. Thacker, India; R. S. Maunder, P. R. Angus, New Zealand; T. W. Longridge, Rhodesia; C. W. J. A. Sandrock, L. T. Campbell Pitt, Prof. G. R. Bozzoli, A. J. Adams, of South Africa.

## Engineers International Conference

A conference unique in engineering history took place in Brussels on June 11 and 12.

It brought together delegates from three international conferences who between them represented 75 per cent of all engineers in the world outside of the iron curtain.

The three conferences cover most of the engineering world outside the communist circle. They are the Europe and United States Engineers Conference known as "Eusec". The Conference of Engineering Institutions of the British Commonwealth, and the Pan American Engineers Conference known as "Upadi."

The object of this special conference was to consider the objectives of the three conferences in order to determine how they might be worked out together to better advantage, and to develop joint policies and activities by which the three organizations might become of increasing value in the national and the international fields.

The host for the occasion was the Royal Belgian Society of Engineers and Industrialists, and excellent hosts they proved to be. The business conferences were held in the society's offices, the Hotel Ravenstein — one of Belgium's most ancient palaces. This building is famous for many things, but from the British point of view, one of the most interesting is that Anne of Cleaves, one of Henry VIII's wives, was born there.

The social program included a visit to Brussels University, a reception by the Bourgomaster and Aldermen of Brussels in the world famous Brussels Town Hall. A tour of the Congo Museum at Tervueren, terminating with a formal dinner at the Galerie Louise.

The business accomplished by the conference will be reported on later, after approval of the Council of the Institute.

**Brussels Conference. Around this table sit delegates from engineering organizations in Great Britain, Canada, South Africa, Australia, New Zealand, India, United States, South America, Belgium, Denmark, Sweden, Austria, Finland, Italy, The Netherlands, France and Switzerland. The photo was taken in the Board Room of the Royal Belgian Society of Engineers and Industrialists. They represent three international engineering organizations, i.e. the Commonwealth Conference of Engineering Institutions, The European and United States Council (EUSEC), and The Pan American Conference of Engineering Organizations (UPADI).**

## The "Abstracts" Return

In the November, 1938 issue of *The Engineering Journal* a new feature was introduced under the heading of "Abstracts of Current Literature".

Articles in the leading technical journals of various countries were abstracted and published continuously until the end of 1943. At that time the restrictions on the use of paper by the War Time Prices and Trade Board necessitated a reduction in the size of the publication. As a result, the Publication Committee were obliged to reduce or delete certain features and the "Abstracts" section has been absent since that time.

For the past year or more it has been recognized that the publication of abstracts should again serve a useful purpose in providing the member-readers with a broader and more diverse range of technical literature. To this end, the Publication Committee authorized early this year, the preparation of a selected list of abstract material in order that publication of this feature could be resumed as soon as considerations of time and space would permit.

This time has now arrived and once again with this issue, "Abstracts of Current Literature" will be found regularly immediately following the technical papers section.

## National Industrial Design Competition

The National Industrial Design Council will again give awards to designs of merit in Canadian manufactured products in 1955. The judges for the awards, which will be presented next February have been selected and preliminary judging of entries will take place each month by a reviewing committee at the Design Centre, Ottawa. Serving on the main jury will be: Jean M. Raymond, vice-chairman National Industrial Design Council, Montreal; J. D. Ferguson, president, Canadian Manufacturers' Association, Rock Island, Que.; John Bland, director, School of Architecture, McGill University, Montreal; Mark Ely, president, Canadian Retail Federation, Toronto; Mrs. John Butterfield, chairman of the Consumer Research Section, Canadian Association of Consumers, Toronto.

Regulations remain unchanged and emphasis continues to be placed on pleasing appearance, functional efficiency, good value and suitability to Canadian needs. Only those designs which have been produced and marketed since July 1, 1953, may be entered. Further information can be obtained from the N.I.D.C. Office, 80 Elgin Street, Ottawa.

Last year 95 awards in as many different categories of production ranging from lighting fixtures and furniture to kitchen stoves and toys were given to 72 Canadian manufacturers. An illustrated booklet describing all the Design Awards has recently been published and is available to interested consumers and retailers on application to the Design Centre, Ottawa.

Many of the products selected in 1954 will be included in the official Canadian display participating in the Triennale exhibition in Milan this early autumn. This will be the first time Canada has entered this great international exhibition devoted exclusively to good design in industrial products. Canada's display has been prepared by the Canadian Government Exhibition Commission in co-operation with the National Industrial Design Council.

## "Clarkson College Convocation"

The American Society of Mechanical Engineers and The Engineering Institute of Canada have accepted an invitation of the Clarkson College of Technology to hold a convocation on "Trends in Mechanical Engineering Education." The program for this event is given on the opposite page.

We in Canada are indeed fortunate to have this opportunity of participating in such a gathering and it exemplifies once again the benefits arising from the close cooperation between the American Society of Mechanical Engineers and the Engineering Institute of Canada.

Because of the limited accommodation, attendance must be by invitation only and it is sincerely regretted that a meeting of such widespread interest must be restricted in this way. However every effort will be made to report fully on the findings and recommendations of the convocation in *The Engineering Journal* for the benefit of our members who are unable to take part.

PLUMMER MEDAL PRESENTATION

The recent annual dinner dance of the Sarnia Branch provided the opportunity to present to J. S. Moloney the Plummer Medal of the Institute. E.I.C. vice-president G. R. Henderson (left) made the presentation. The meeting is reported in "Branch News".

# ASME-EIC INVITATION CONVOCATION

## TRENDS IN MECHANICAL ENGINEERING EDUCATION

## CLARKSON COLLEGE OF TECHNOLOGY, POTSDAM, N.Y.

*October 6-7-8, 1954*

**FIRST SESSION—Can Present Mechanical Engineering Curricula be Improved?**

*Moderator:* Thomas D. Jolly, Vice-President, Aluminum Company of America, Pittsburgh

*Speakers:*

R. J. Askin, Vice President, Abitibi Power & Paper Co. Ltd., Toronto
E. G. Bailey, Chairman of the Board, Bailey Meter Company
E. A. Allcut, Professor of Mechanical Engineering, Faculty of Applied Science and Engineering, University of Toronto
C. Richard Soderberg, Dean of Engineering, Massachusetts Institute of Technology

**SECOND SESSION—Panel Discussion**—Messrs. Askin, Bailey, Allcut, and Soderberg

*Discussion Leaders:*

Henri Gaudefroy, Dean of Engineering, Ecole Polytechnique, Montreal.
George B. Thom, Chairman, Department of Mechanical Engineering, Newark College of Engineering, Newark, N.J.
H. N. Meixner, Engineering Dept., E. I. du Pont de Nemours & Co., Inc.
D. C. R. Miller, Director and General Manager, Dow Corning Silicones, Ltd., Toronto

**BANQUET**

*Presiding:* William G. Van Note, President, Clarkson College of Technology

*Addresses:*

Donald M. Stephens, President, EIC; President, Winnipeg Electric Company, Winnipeg; Chairman, Manitoba Hydro-electric Power Board
Lewis K. Sillcox, President, ASME; Honorary Vice-Chairman of the Board, New York Air Brake Company.

**THIRD SESSION—Dangers of Overspecialization in the Curriculum**

*Moderator:* A. G. Christie, Professor Emeritus of Mechanical Engineering, Johns Hopkins University, Baltimore

*Speakers:*

D. L. Mordell, Professor and Chairman, Department of Mechanical Engineering, McGill University, Montreal.
R. S. Sproule, Manager, Hydraulic Dept., Dominion Engineering Works Ltd., Montreal
Jess H. Davis, President, Stevens Institute of Technology, Hoboken, N.J.
Karl B. McEachron, Jr., General Electric Company, Erie, Pa.

**ACADEMIC CONVOCATION**

*Presiding:* William G. Van Note, President, Clarkson College of Technology

*Address:*

Ralph S. Damon, Chairman of the Board of Trustees, Clarkson College of Technology; President, Trans-World Airlines, Inc.

**DINNER**

*Presiding:* W. A. MacIntosh, Principal and Vice-Chancellor, Queen's University, Kingston
*Address:* "Post-Graduate Education in Engineering"
D. L. Thompson, Dean, Faculty of Graduate Study and Research, McGill University, Montreal

# First a Subway, Now an Expressway

The Municipality of Metropolitan Toronto, which came into existence only this year, has wasted no time in tackling its pressing problems. One of the more important of these is the relief of traffic congestion in the central part of the city. While Toronto's new subway, opened last March, will no doubt improve conditions a good deal, it will not affect some sources of congestion. More relief is needed, which it is proposed to afford by building an expressway along the lake front from the Queen Elizabeth Way in the west to Coxwell Avenue at the Woodbine Racetrack in the east, a distance of about nine and a half miles.

A report on this project was submitted to the Municipality's Co-ordinating Committee on April 26 last by Margison, Babcock & Co., consulting engineers, of Toronto; Associated with them were DeLeuw, Cather & Co., consulting engineers, of Chicago, and Norman D. Wilson, M.E.I.C., consulting engineer, also of Toronto. From this report we have prepared the summary which follows.

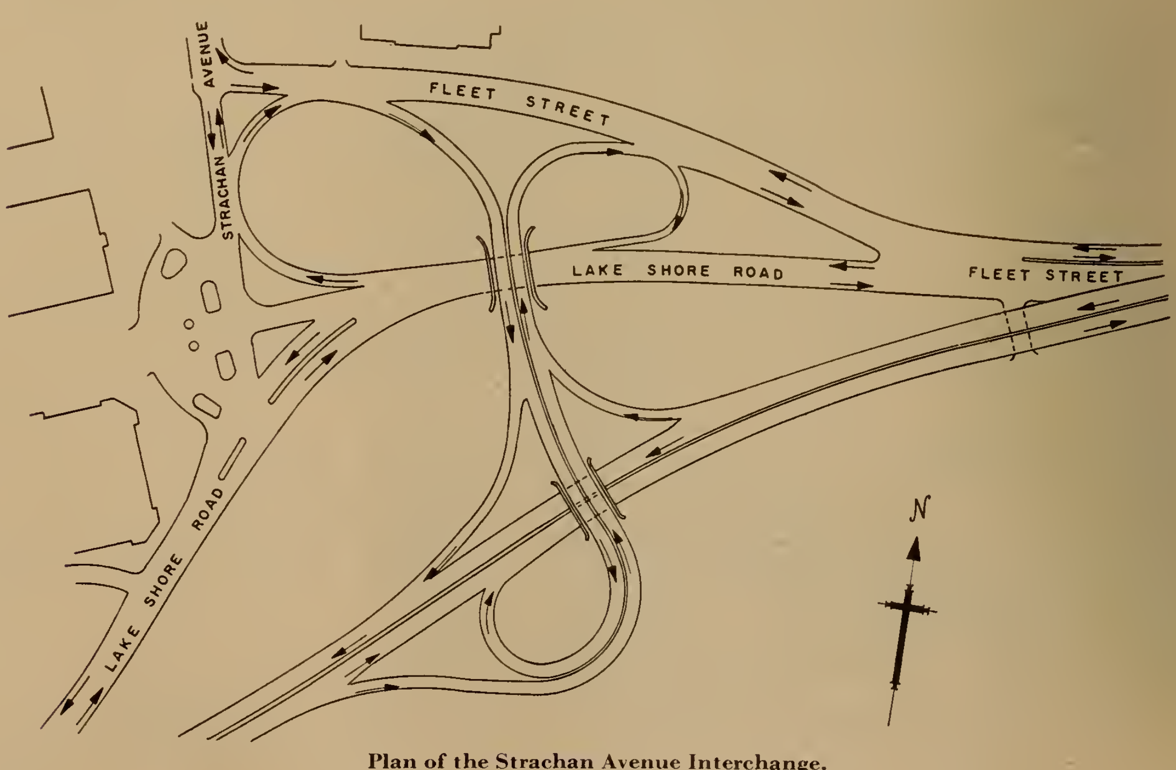
The idea of a throughway along the lakeshore is not new. As long ago as 1841 the Esplanade Plan provided for something of the sort as part of a lakeside park, but this scheme was upset by the appropriation of half the area concerned for a railway right of way. Following its creation in 1912, the Harbour Commission has tried to carry out its improvements with a throughway in mind. Actually, there is a major road development along the lake, which was planned with all the foresight possible at the time it was built and as far as available funds permitted, but it is woefully inadequate.

Predicted future traffic requirements, based on today's conditions, indicate that a total ultimate daily flow of 100,000 vehicles should be provided for and that this will require six traffic lanes, three in each direction with a separation strip between them. Attention was given to a non-separated, five-lane artery, which would be lower in cost, using the center lane for traffic one way in the morning and the other way at night. However, because of increased accident hazard, complications at inter-connections and for other good reasons, this scheme was abandoned.

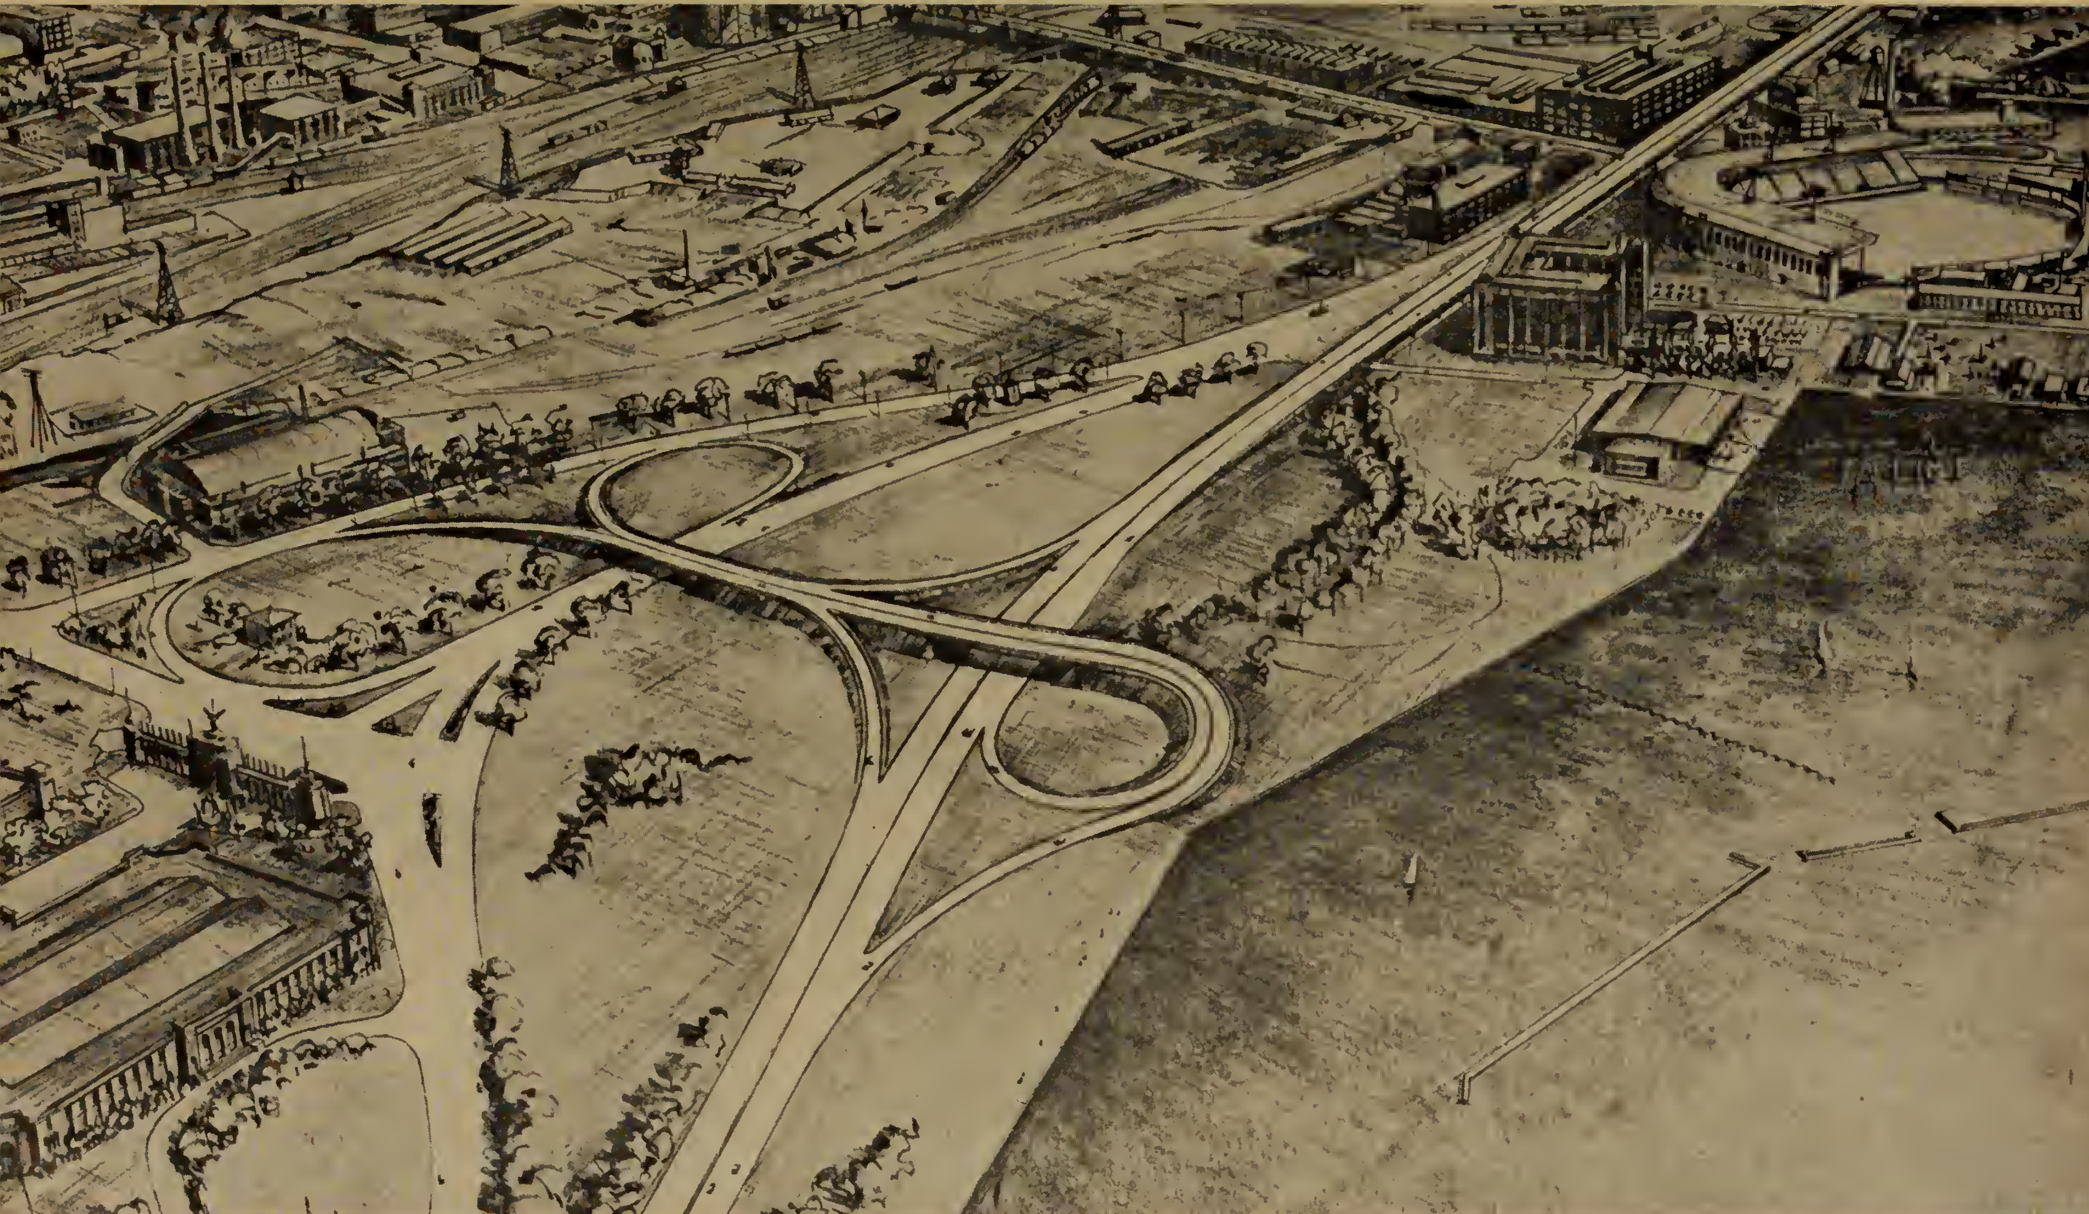
The expressway will be at grade where conditions allow, but from Bathurst Street to the Don River crossing it will be on a viaduct. Through the Sunnyside area and through Exhibition Park, it will closely follow the present Lake Shore Boulevard at grade, but elevated on fill at the Humber River, at Riverside Drive and at Jameson Avenue to accommodate interchange underpasses; there will be another interchange at Strachan Avenue. For further relief in this area, Queen Street will be extended from Roncesvalles Avenue westward across the Humber to the Queensway; the cost of this extension is included in the estimates for the expressway. Pedestrian overpasses for access to Sunnyside and Exhibition Parks will be provided. Through the latter the expressway will be located on fill between the existing seawall and breakwater and a new breakwater will be built.

The viaduct section will be over Fleet Street from Bathurst Street to Yonge Street and again from Parliament Street to Cherry Street; in the intervening section Fleet Street will be split into eastbound and westbound strips with the expressway between them, with parking facilities under the viaduct. From Cherry Street to the Don River the viaduct will be over private property. Thirteen ramp connections will be provided to the viaduct.

After crossing the Don, the expressway will continue on fill to



Plan of the Strachan Avenue Interchange.



The Strachan Avenue Interchange — from the air.

Logan Avenue and Morse Street, where there will be ramps. There will also be an interchange at the Don Roadway. Underpasses will be provided in this section for through streets.

East of Morse Street the route willl be at grade, with underpasses for Leslie Street and for the Keating Street extension. Like Fleet Street, Keating Street will be split into eastbound and westbound strips and the expressway located between them. At Coxwell Avenue a turn to the north will be made and the expressway will end. A diagonal connection across the Woodbine racetrack property to the Kingston Road is also planned, but this will interfere with the track itself and will probably not be built for some years to come.

Only enough detailed designing was done to afford a basis for reasonably accurate estimating, but the standards chosen are high and in line with those which have proved satisfactory for expressways already built elsewhere.

Eastbound and westbound lanes will be separated by a ten-foot median strip where the expressway is at grade, on fill or in cut and by a four-foot strip on the viaduct and on bridges. Traffic lanes will be twelve feet wide and there will be ten-foot surfaced shoulders, except on structures, where three-foot six-inch walks and railings will replace them. Guard rails will be used on all fills over six feet high. All curbs of the median strips and the outside curbs on structures will be non-mountable; at grade, on fills or in cuts outside curbs at the shoulders will be mountable.

Ramps are designed for single-lane passing or two-lane passing as estimated traffic volume may dictate, and have acceleration and deceleration lanes long and wide enough to allow safe entry and exit. Design speeds are 50 m.p.h. for the expressway and 30 m.p.h. for interchange ramps. There will be no traffic lights on the expressway.

Other details of design are:

| | |
|---|---|
| Maximum grades: | |
| On expressway . . . | 3 per cent |
| On ramps, . . . . . | 6 per cent |
| Minimum grades: | |
| At grade, on fill or in cut . . . . . . | 0.50 per cent |
| On structures, . . . | 0.35 per cent |
| Maximum curvature . | 6°30′ |
| Minimum radius of curvature without superelevation, . . . . . . . . | 4,000 ft. (1°26′) |
| Minimum length of horizontal curves . . . . | 500 ft. |
| Minimum sight distance, | 500 ft. |
| Maximum superelevation . . . . . . . | 1 in. per ft. |
| Minimum clearances: | |
| Over roadways . . | 15 ft. 0 in. |
| Over railways . . . | 22 ft. 6 in. |

At today's prices it is estimated that the cost of the expressway will be:

| | |
|---|---|
| Construction, . . . . . . | $32,758,000 |
| Right of way, . . . . . . | 6,852,000 |
| Relocation of roads, . . . | 1,796,000 |
| Alteration of utilities, . . . | 857,000 |
| Maintenance of traffic; engineering, park rehabilitation; central area parking; contingencies . . . . . | 7,541,000 |
| | $49,804,000 |

This report is a printed volume of letter size and 24 pages and includes 21 plates, most of them folding. We reproduce a plan of the Strachan Avenue interchange and the artist's conception of what it will look like when completed.

And the report is a credit to its authors. If and when its recommendations are implemented the east- or west-bound traveller by automobile, and commercial vehicles, will be able to pass through Toronto without interference from or interference with local traffic, and, of course, the expressway will bring many parts of metropolitan Toronto closer together in point of time.

# Columbia River Power

For forty-three years the International Joint Commission has been dealing with problems arising along the boundary between Canada and the United States. Most of them have had to do with boundary waters—the Chicago Sanitary District diversion from Lake Michigan, the use of water at Niagara Falls and the levels of Lake Ontario and of the Lake of the Woods—but there have been other problems, too, such as atmospheric pollution in Washington from the smelters at Trail, B.C.

The Commission's record is outstanding. Questions referred to it have at first sight often seemed almost insoluble, but thanks to the good sense and skill of the two sections of the Commission, Canadian and United States, and to the spirit of give and take shown by the disputants in the cases, solutions have been arrived at, which, if not entirely satisfactory to everybody, were at least the best under the circumstances and were accepted as such.

One of the most important matters now before the Commission has to do with power development on the Columbia river, much of the watershed of which is in Canada. Present developments on the river in the United States use flow originating in Canada under the hitherto accepted concept that the origin of flow is of little consequence; the concentration of head at any point confers the right to develop power at that point without upstream interference as regards flow.

The Columbia river watershed has a total power potential of about 34 million kilowatts. Some 60 per cent can be derived from heads and flows, including flows from storage, in the United States, about 20 per cent from heads and flows entirely in Canada and the other 20 per cent represents extra energy which can be developed in the United States from regulated flows from storage in Canada. The crux of the problem lies in this last one-fifth.

United States interests propose to build a power dam at Libby, Mont., which would raise the level of the river at the boundary by 150 feet and would flood it back into Canada for 42 miles. There would be about a million horse-power available at this site and the storage would add about 6 billion kilowatt-hours to the annual output of plants below it, some on the West Kootenay in Canada, but most on the Columbia in the United States.

This storage scheme involves international co-operation for its functioning and there are questions of compensation for flooding agricultural, forest and mineral lands and for the relocation of railways, roads and telegraph and telephone lines. Many buildings would have to be removed or replaced and cemeteries perhaps re-established. All these damages can be assessed and can be paid for in money.

The more difficult question is compensation for heads at downstream sites created by this storage in Canada and the regulated flow made possible by this same storage. The downstream interests wish to settle only in money; the upstream interests will not permit flooding and storage except for a proper share of the power produced by them. And here the matter stands.

To Canadians the position of the upstream interests seems just and equitable. Our Pacific coast area could, no doubt, use any money compensation to good advantage, but it needs, or will shortly need, additional power and money payments would not be too useful in that respect. We should not sell out for a mess of pottage.

In a speech delivered in New York on October 16, 1953, before the Engineers' Council for Professional Development, General A. G. L. McNaughton, chairman of the Canadian section of the International Joint Commission, said:

"I must forecast that this problem will not only trouble the International Joint Commission, but that it will also trouble many other people, until the situation clears and the lines of equity appear and are accepted. Meanwhile, it will be well to remember the vastness of the issues which are being determined in the Columbia basin and the vital consequences which the decisions will have on the future of industrial development and its placement, whether in Canada or in the United States. It will be well also not to forget Article II of the Treaty of 1909 and the physical fact that natural topographical advantages for the storage of water are assets just as real as are minerals from the mines and the products of the fields and forests. Actually, storage for water is far more precious than the most precious of mines, for the reason that the flow of water will go on forever, whereas minerals are a wasting asset, used up in being put to use.

It is most important that those concerned with power development on the Columbia, both in Canada and in the United States, should fully understand the conditions and the facts which I have mentioned, because the Treaty of 1909 is a binding agreement between our two countries and it is not to be expected that either country will give up its rights thereunder. I hope that the public of both countries may be fully informed, because public misinformation is the fundamental cause of misconception, and this breeds misunderstanding."

# C.E.A. Meets at Murray Bay

The Canadian Electrical Association's sixty-fourth annual convention was held at the Manoir Richelieu, Murray Bay, Quebec, on June 24, 25, and 26, 1954. More than 500 delegates from utilities, and manufacturing and engineering organizations from all parts of Canada were in attendance. A. M. Howard of Calgary Power was elected president for the ensuing year, with J. G. Dale of Canadian Utilities as vice-president for the Western Zone. V. A. Ainsworth of the Newfoundland Light and Power Co., and J. A. Page of Southern Canada Power were chosen as vice-presidents for the Eastern Zone.

### President's Address

President C. I. Bacon, in his welcoming address to delegates, pointed out that with requirements doubling every twelve years Canada will in another quarter century have used up all her natural hydraulic resources. This meant power must be secured from other sources, steam, diesel or atomic reactors.

Conventional fuel costs, he observed, will rise considerably over the next few decades. Without some competitive fuel coming in there will be no brake on the rise in fuel prices. Atomic energy supplies such a brake.

It was going to take courage, enthusiasm and some cold, hard cash to see this problem through, he said. Within five and ten years considerable power would be produced from atomic reactors. Just as coal consumption per produced kilowatt had been lowered from fifty pounds at first, to the present 7/10 of a pound, similar progress would be made in developing power from atomic reactors.

Calling attention to the growing foreign competition threatening to undersell Canadian products today, and undermining our high plateau of prices, Mr. Bacon warned that we must somehow get down from this high plateau, to face realities and still maintain as high a living standard as possible. More hours must be worked for the same or less money if our industries are not to be priced out of the market. Little had been done since the end of the war, he said, in reducing the cost of government. Some reduction could be made which would start a reaction towards achieving a stable economy.

### Power Costs to Rise Appreciably

"Canada's competitive position in the supply of electric power in industries will remain strong, though power costs are sure to rise appreciably in coming years." This was the opinion expressed by J. A. Fuller, president of the Shawinigan Water and Power Company. The cost of electric power was a basic element, whether small or great, he said, in the cost of all industrial production today.

Where power cost is a vital consideration, such as in the production of aluminum, Canada's position will remain excellent because of the undeveloped hydro-electric potential which, though remote, is often close to ore deposits or located at tidewater with easy access to raw materials and ocean transport.

In Pacific northwest states needs of secondary industries and domestic consumers would put prices out of reach of industries to which power costs are all-important, he explained. Vast resources of power for such industries exist in Quebec, the Yukon, British Columbia and Labrador. In time these would be developed, since at the moment there was no other source of electric energy at comparable cost.

In a second type of industry, that in which power cost is significant but may be outweighed by other items such as transportation cost, Canada's position is not so strong, Mr. Fuller continued. "I therefore believe we are less likely than in the past to see new plants in this type of industry locate in Canada, at least where they look elsewhere for markets for their products," he said.

In a third class of industry, where power is a relatively minor element of cost, such as in automotive, implements, electrical apparatus, textiles, clothing and petroleum products, Canada's position will remain good because our power prices will long remain lower on the average than those, for instance, in the United States.

Annual cost of hydro power in an investor-owned plant was 65 per cent for carrying charges and only 35 per cent for operating expenses and depreciation, he stated. Carrying charges had increased rapidly in recent years. With thermal plants 35 per cent of the cost was for carrying charges and the balance, half of which was fuel cost, went for operation and depreciation. The cost of energy from the modern thermal plant close to its source of fuel approached closely the cost of energy from a hydro plant more than 100 miles from load centres.

"Thermal plants will undoubtedly occupy an increasingly important position in Canada," Mr. Fuller predicted, "because of the lessened advantage of hydro production, but also because of new sources of energy in Canada, particularly oil and gas, with the possibility that atomic fuel will someday become competitive."

### The Demand for Power

The vigorous programs being carried out to meet Canada's power demands over the next decade were outlined in a symposium on "The Demand for Power", by leading utility engineers and executives. Speaking for British Columbia, T. Ingledow, vice-president of British Columbia Electric, cited several good hydro sites still undeveloped close to population centres, such as the Cheakamus river with 200,000 horsepower within 50 miles of Vancouver, and the Fraser with 3 million horsepower of potential power within 250 miles. In the Pacific northwest the U.S. was looking to Canada for help with water storage. Such storage rights could be traded for power in perpetuity. British Columbia's total potential capable of development was 10 million horsepower, he said, to which could be added another 5 million horsepower from the Yukon river by diversion through British Columbia.

### Prairie Provinces

The situation in the Prairie Provinces was described by W. D. Fallis, general manager, Manitoba Power Commission. Power requirements for Alberta to 1964 indicated a steady increase to an anticipated installation of 840,000 kilowatts. This would mean an increase of 528,000 kilowatts or 169 per cent over installed capacity in 1953.

Saskatchewan, he said, lacked economical water power resources. Its main resource of thermal fuel, low grade lignite coal, was located in the extreme southeast corner of the province. But the current search for oil and gas may change the picture quite rapidly. Demand, he predicted, would increase nearly threefold in the next ten years to approach a total of 440,000 kilowatts, up 300,000 kilowatts from today.

Rapid growth of demand in Manitoba would soon have used up all the resources of the Winnipeg river, said Mr. Fallis. The province is now planning a considerable increase in steam generated power as the next most economical step prior to developing northern rivers which are at a disadvantage due to their distance from load centres. From a 1943 peak demand of 435,000 kilowatts, a 109 per cent increase to 910,000 kilowatts is expected by 1964.

### Central Provinces

"In Ontario, St. Lawrence power is the last remaining major hydro site in Southern Ontario, and power from it would be required by December 1958," stated Dr. R. L. Hearn, general manager and chief engineer of Ontario Hydro. With this development completed, additional power will be needed by 1961 if a reasonable reserve is to be kept. Under study are additional sites in Northern Ontario and additional fuel electric plants using coal, oil or gas, and nuclear power plants, he said.

"Quebec will require 8,750,000 horsepower by 1960. Completion of the Bersimis project will just about meet this demand," stated Dr. Huet Massue, of Shawinigan Power Company. Per capita production of energy in Quebec is already 50 per cent higher than in any nation in the world, due mainly to particular requirements of the pulp and paper industry and the smelting and refining of aluminum.

### Maritime Provinces

J. L. Feeney, chief engineer, New Brunswick Electric Power Commission, referred to the widely held impression that his province lacked power resources. "Certainly we have no Shipshaws or Niagaras," he declared, "but we have substantial amounts of potential hydro energy and coal fields which jointly provide reliable power at a reasonable price."

He referred to a recently competed study of the Saint John River which showed a grand total of potential from six sites of 536,000 kilowatts. The Commission's present installed capacity is 107,500 kilowatts, while for 1960 the estimated peak will be 140,000 kilowatts. To meet this demand the partial development of a 68,000-kilowatt site at Beechwood is contemplated.

W. G. Macdonald, chief engineer of Nova Scotia Light and Power Company, said his province would depend on steam, gas turbine or diesel for new electric resources. Atomic power may be expected to follow. Some 117,000 kilowatts additional capacity would be required over the next ten years.

Listing presently developed power resources in Newfoundland and Labrador, both public and privately operated, totalling some 285,000 horsepower, Eric Hinton, of Bowaters Newfoundland Pulp and Paper Mills Ltd., estimated a load growth of 15 million kilowatt hours per year in the Avalon peninsula. Paper mills and surrounding areas would require an additional 30,000 kilowatts in the next decade. Rural electrification would be an important factor in the future power requirements, he stated.

### Light's Diamond Jubilee

"This year the electrical industry, through Light's Diamond Jubilee, are honouring the memory of a man whose achievements made the industry possible," said Walter H. Sammis, president of Ohio Edison Company and immediate past-president of the Edison Electric Institute. "Thomas Alva Edison's invention of the light bulb started a chain reaction that has had a profound impact on the social and economic life of the world."

"Electricity is truly the servant of the people," said Mr. Sammis; "it is a bright, cheerful and instantly responsive servant, tireless, able, multi-skilled, does not watch the clock, asks no time off, never complains about too many little monotonous jobs, nor balks at herculean tasks. Unlike other servants, it asks for very little pay."

Production of electricity in Canada, he stated, had multiplied 3.6 times in the last 25 years and installed capacity of central electric stations about three times. The residential use of electricity is still the largest component of the power load and is growing rapidly.

As an example he pointed out that 25 years ago there were nineteen types of home appliances on the market; today the list adds up to 54 and is still on the increase. "I venture to predict," he added, "that achievements which today appear to us very advanced, may seem quite archaic to our successors, and perhaps in a shorter time."

Recalling some of the developments of the early "nineties" in the electrical industry in Montreal, C. A. Morrison, vice-president of Canadian General Electric, told delegates that 'Edison's key invention broadened the horizons of the industrial revolution almost infinitely. It was the 'time fuse' that released new industries, basic changes in the ways of getting the world's work done, and fundamental adjustments in our lives and human comforts."

**The Investor and the Utility Industry**

E. R. Alexander, vice-president and treasurer, Sun Life Assurance Co. of Canada, told members that the institutional investor, who today provides the bulk of the capital for public utility financing, assessed the value of utility securities under six headings: economic conception, technical requirements, engineering soundness, public relations, financial structure and quality of management. "A good mark in five out of six," he said, "is not enough to pass."

The electric business was one of what economists call "increasing returns." Increasing use cuts unit cost. Since the war, however, inflation with its rising prices and costs had outrun the effects of increasing volume and technological progress. "There is no defence against a rubber dollar except a rate structure with some elastic in it," he warned.

In Canada there is no solid basis for rate regulation. There is considerable legislation and a long background of regulating activity. However, both these can be changed, and the fundamental constitutional guarantee of property rights that in the U.S. limits an intransigent regulatory commission is completely lacking. Thus the investor can rely only on the record in assessing the likelihood that a utility will be forced to exist on a starvation diet.

Disappearance of the gold standard had obliterated the old automatic restraint on excessive expansion, continued Mr. Alexander. Politicians have not been slow to realize how powerful a weapon is placed in their hands. Everyone likes full employment, production and purchasing power. To the party interested in continuing in office this means we should have perpetual over employment and boom conditions. "This," he pointed out, "is why we have had, until recently no perceptible business let-down for fifteen years, but the cost includes a 54 cent dollar in terms of 1939. Responsibility for this disturbing situation lies largely in the principal national capitals."

There are two things we can do about it. We can arrange our investment portfolios to provide an incomplete measure of protection against a depreciating dollar. Secondly, we can preach, and within limits, practice sound finance.

"I am convinced," he concluded, "that we would be better off with an economic structure into which a $4\frac{1}{2}\%$ interest rate for high grade corporation bonds fitted better than a $3\frac{1}{2}$ per cent rate. The effect of this slightly higher rate of return on the customer's bill is a negligible contribution for him to make in return for a monetary policy conducive to stability in the value of the currency."

**Rate Policies for the Future**

"Today in Canada and the United States certain provincial and most State governments have commissions with the right to regulate utility rates within their boundaries. In the States where operations cross State lines rates, financing and accounting also fall under the jurisdiction of the Federal Power Commission", stated Robert S. Quig of Ebasco Services Inc., in an address on "Rate Policies for Adequate Public Service."

In 1922, in its famous Bluefield opinion, the U.S. Supreme Court said: "A public utility is entitled to such rates as will permit it to earn a return on the value of the property . . . equal to that generally being made in the same general part of the country in other business undertakings . . . but it has no constitutional right to profits such as are realized . . . in highly profitable enterprises or speculative ventures. The return should be reasonably sufficient to assure confidence in the utility's financial soundness, and . . . adequate . . . to maintain and support its credit . ."

"Under existing regulatory standards," said Mr. Quig, "you may have a legal right to a fair return. No method of regulation, however, guarantees that fair return, and it is up to your operators to earn that return. Thus no rate or price can be set and left alone."

Rates require careful planning and watchful administration to see that they are reasonable and adequate. The whole industry and our customers are today beneficiaries of what yesterday was classed as a revolutionary or untried venture. This kind of risk taking in rate making must continue, he said, if we are to develop to the utmost our abilities and our markets.

The customer expecting adequate service must be informed regarding the importance of adequate rates, and rate policies must be geared to future system planning and revenue requirements, continued Mr. Quig. Regulation must recognize that the best service is not necessarily the cheapest service. Adequate pricing of utility service requires more than the cost accounting approach.

The customer's interest is closely tied to the investor's interest. An adequate return must recognize more than the mere cost of capital. Regulatory commissions must be informed of changing economic facts. In the words of Mr. Justice Frankfurter: " . . . the process of rate making is essentially empiric. The stuff of the process is fluid and changing . . . the resultant of factors which must be valued as well as weighted."

Looking ahead, there is a big job to be done, the speaker concluded. Future rate policies must consider that peak load requirements will double in ten years; that management, materials and money will be needed in ever increasing amounts; that maximum responsibility will be placed on management to provide the service so necessary to our way of life; employees will have to be better educated, and customers better informed as to the value of the service; and regulators will have to review and revise those regulatory standards and interpretations that will be detrimental to a broader concept of adequate public service.

# *Thirty-five Years Ago*

## Comment on the *JOURNAL* of August 1919

Every editor wishes he had that kind of foresight which would permit him to select for publication not only those articles which are of current interest, but also those which will be of more or less permanent value. The former is easy, the latter more difficult, for editors are no better prophets than the rest of us. In 1919, however, the editor of the *Journal* had two topics which forced themselves upon him; one was the effort of engineers to improve their professional status through legislation, a matter which presumably could be settled sometime fairly definitely, and the other was engineers' salaries, which bade fair to be a subject for continuing discussion.

That part of the August, 1919, *Journal* which was given over to the discussion of Institute affairs shows just how important these two matters were then. First, let us see how the struggle for better working conditions for engineers in the Civil Service was progressing. It was disappointing to learn that the Civil Service bill, to the drafting of which the Institute has contributed so much, failed to get to the floor of the House and so would be held over until its following session. But at least the bill was introduced.

This bill was noteworthy for the wide powers it gave the Civil Service Commission. Among other things, under it the Commission would be able to reclassify federal employees from time to time without special legislation in each case. Thus it would in future be much easier than formerly to adjust duties and salaries in keeping with the changes which were sure to take place as Canada grew.

The classification itself was prepared by Arthur Young & Co., of Chicago. We wonder if the retention of this firm caused as much unfavourable comment then as it probably would now. It is quite possible that there was not then any Canadian firm competent to make such a classification, in which case the Government could be excused for going abroad for help.

"Information as to the duties of an office was obtained by means of questionnaires . . . (Then) a tentative classification was adopted for each position . . . ; departmental lines were eliminated . . . (and) the first schedule was drawn . . ." The principles underlying the schedule of salaries were that:

1. Rates of pay should be the same for the same work;
2. They should be relatively right for different classes;
3. They should be fair to the employee and also to the taxpayer;
4. Each salary should provide a minimum and a maximum;
5. Salaries should not be based on the depreciated dollar of 1919;
6. In many cases, a war bonus should be paid in addition to salary.

There was a good deal of criticism of individual items of the schedule, though it was hailed as a great improvement over existing conditions. "Technologists . . . (will) begin their careers at widely differing rates of pay, according to the subjects in which they have graduated . . . There are undoubtedly many changes which should be made . . . (but this is) a great step in advance, and if carefully revised in the light of more detailed information and intelligently applied to the personnel; it should greatly improve the status of engineers . . ."

The *Journal* offered a quasi-apology for not reporting the results of the letter ballot of members on the proposed model licensing act; the scrutineers had not been able to complete their work in time for publication. In the meantime, individual members and the branches were giving the act a good going over. In a long letter, C. C. Kirby defended and explained the act; it will be remembered that he wrote in July along the same lines. Another correspondent objected principally to the use of the term "professional"; he preferred "registered." "Professional engineer is undignified and foolish, for all persons who earn a livelihood by any particular vocation or trade are professionals, such as professional hair-cutters, professional prize-fighters, professional golfers, etc." Among the branches, Sault Ste. Marie added its support to the model act by passing an appropriate resolution.

But at this time most of the branches seemed to have other things on their minds; many of them, of course, had already endorsed the model act. Saint John and Montreal heartily supported the Government's proposal to set up a National Research Institute. Saint John's committee on the remuneration of engineers was circulating questionnaires among the branch members, asking for salary data. A special committee of the Ottawa Branch, which had been "lobbying" for the Civil Service bill — in a perfectly legitimate way, of course — was preparing to become even more active when the bill should reach the debate stage in the House.

The account of Council's July meeting showed nothing but the routine admission and promotion of members.

Not the longest, but perhaps the most interesting, paper in this *Journal* was F. A. Bowman's "Effects of the Halifax Explosion on the Telephone Plant and Service." The explosion occurred at 9.05 a.m., December 6, 1917, when the S.S. *Mont Blanc*, laden with 5,000 tons of explosives, blew up in Halifax harbour. The results to the city were disastrous, as everyone whose memory goes back that far will recall. Telephone service at that time was already disorganized, because of a blizzard of wet snow and rain which had hit the province four days earlier; the explosion put the finishing touch to an unhappy situation, not made any happier by another blizzard on December 7.

At first, telephone service was completely crippled, but the Lorne exchange got back into partial operation four hours after the disaster, though one of its walls had to be shored up and falling plaster and trim were still menaces. Windows and doors were blown out in the St. Paul exchange, but the equipment was not seriously damaged. Pretty much the same things happened to the Harbour exchange. Outside plant was thoroughly wrecked; one and a half miles of aerial cable, 19 miles of twin rubber-covered wire, 16 miles of bare wire and both submarine cables across the harbour to Dartmouth were destroyed. Most long-distance service was cut off.

The first job was to get the operators back to work. Many lived or had relatives in the devastated area, so had to leave for a time at least. ". . . To their eternal credit be it said, the great majority came back as soon as they could, many of them with very sad hearts . . . Everyone . . . who knew anything about operating was called to the boards . . . Two operators were killed . . ."

In addition to restoring regular service, extra service had to be given to the railways, to the Red Cross and to various relief agencies, 135 of them in the end. By the end of the next day, a toll line to Saint John was set up by a roundabout route and a little later on, one to Boston, over which the Associated Press sent out the first complete story of the disaster. One good cable was made out of the undamaged parts of the two to Dartmouth, and another, fortunately on hand, was laid, too. Material was rushed to Halifax from the stores of suppliers and from other telephone companies and outside line was restored as soon as possible.

"Then came the reaction. Nobly as the (operators) had stuck to work in the crisis, they sooner or later had to think of themselves . . . Some broke down and resigned . . . Some . . . came from the country . . . and went . . . home . . . The same difficulty was met among the men . . . Military service took away a large percentage, whose places had to be filled by . . . inexperienced boys."

It is hard to imagine what conditions must have been like. Mr. Bowman did not soft pedal the company's troubles, neither did he exaggerate them, but one may read between the lines of his paper and infer that he put his best foot forward. It is doubtful if the *Journal* has ever published anything of more human interest.

Mr. V. I. Smart in "The Operation of Railways as an Engineering Problem" takes 12 pages, with numerous illustrations and numerical examples to prove his thesis, that more engineers in railway operating departments were needed. He seems to make a pretty good case and ends his paper by saying, "Is it not fair to conclude that the services of (the) engineer in the transportation department would be a decided advantage to all concerned, and that methods of increasing the loading of cars and engines, the saving of lost time on the road, the prevention of capital expenditures before they are strictly necessary, and the general increase in efficiency in means and methods, would result?"

We have heard a good deal about our natural resources lately, but the subject is not a new one. "The Resources of Western Canada", by Dr. R. C. Wallis, Commissioner for Northern Manitoba, was as optimistic as anything written in this year of grace of 1954 by Canada's biggest booster, who, by the way, was probably someone from south of the border; Americans seem to be more lyrical about our resources than we are ourselves. "Much of the reward that Ontario already enjoys will be the portion of (Manitoba) . . . Saskatchewan is *par excellence* the agricultural province . . . In Alberta there is a greater variety of wealth; . . . notwithstanding the comparative non-success of the . . . search for oil . . . there is yet a future for Alberta as an oil country . . . British Columbia came into being as a mineral country . . . but (it) does not now depend on its mineral wealth alone . . ." Who could have done better than Dr. Wallis?

## News of Other Societies

The 1954 triennial reunion of the **Engineering Alumni of the University of Toronto** is to be held in Toronto on October 29, 30, and 31, at the Royal York Hotel.

The 1954 gathering will be the largest ever and arrangements have been going on for some time so that the 3-day event will be an outstanding success. The program will include an industrial tour, class luncheons, business meetings, stag dinner and evening, dinner party and dance. Saturday afternoon football game (Varsity and McGill), and special entertainment for the ladies.

Every University of Toronto Engineering Alumni member will receive complete details with an advance registration card, toward the end of the summer.

---

A recent review of the history of the **Institute of Administration** (1549 Burnside Place, Montreal) reported its progress and its activities since the work of a small group of Montrealers interested in management and administration brought about the first general meeting of the Institute in January 1939. Prof. J. A. Coote was the first chairman; T. M. Moran, vice-chairman; C. H. Fraser, secretary-treasurer. The group was limited to 30.

Members took their duties seriously and many worthwhile papers resulted; four volumes of papers were published, beginning in 1947. The Institute was instrumental in the establishment of an extension course in management and administration at McGill University. This course was carried on for five years, with a total registration of several hundred, and with Professor Coote teaching. Some of its graduates are active in the work of the Institute.

Those who have served as chairman of the Institute are: C. A. Peachey, J. H. R. Robertson, H. A. Wilson, S. W. Fairweather, George Henderson, J. A. Calder, Huet Massue, D. L. Adams, J. E. Dion, J. G. Campbell.

---

In recent months, members of the **Institute of Marine Engineers** have been meeting in Toronto with a view to forming a Great Lakes Section.

The Institute is a world-wide organization, originating in England in 1889. Membership is comprised of all those who are connected with marine engineering in any way, and the aim of the Institute is to advance the profession of marine engineering in all its fields and phases.

Information about the new Section can be obtained from T. M. Pallas, 165 Lakeshore Blvd., Toronto, Ont.

A series of major events developing the theme of the "The Engineer's Place in Our World" will be conducted in 1955 to mark the 75th anniversary of the **American Society of Mechanical Engineers** (29 West 39th Street, New York 18, N.Y.).

Dr. Jess H. Davis, president, Stevens Institute of Technology, who is chairman of ASME's 75th Anniversary Committee, has announced that the areas of inquiry will concern "the engineer and his relationship with the world in which he lives and works: not just the mechanical engineer—and not just his contributions to his fellow man—but all engineers, and the entire pattern of relationships between engineers and the rest of the world."

The anniversary date of the founding of ASME will be observed on February 16, with a commemorative ceremony in the offices of the McGraw Hill Publishing Company, a panel discussion at the Engineering Societies Building, on the theme, "The Engineer and His Communications", and a banquet featuring a major address on communications.

The second special meeting on April 7 on the campus of Stevens Tech., Hoboken, N.J., will consider "The Engineer and the World of Education". This gathering will commemorate the first organization meeting of ASME, also held at Stevens, at which Professor Thurston was elected first president of the Society.

A meeting in Baltimore, Md., April 18-21, will centre around a discussion of "The Engineer and the World of Government". Another in Boston, Mass., June 20-23, will have two panels treating of "The Engineer and the World of Science". The fifth national anniversary meeting will take place in Chicago, Ill., November 13-18, and will be devoted to discussion of "The Engineer and the World of Commerce and Industry".

---

There will be a Summer Institute of Nuclear Physics in Engineering Education at Northwestern University, Evanston, Ill., September 7-11, 1954. Open to physics and engineering educators, and with attendance limited to 150 persons, the conference is sponsored by the American Society for Engineering Education, the American Institute of Physics, the National Science Foundation, and Columbia and Northwestern Universities. For information write to Professor Robert L. Young, Technological Institute, Northwestern University, Evanston, Illinois.

The eighth National Chemical Exposition to be held in the Chicago Coliseum, October 12 to 15, 1954, will be sponsored by the Chicago Section of the **American Chemical Society** (86 East Randolph Street, Chicago 1, Ill.).

---

The Corrosion Congress of 1954 will be carried out by the Working Party on Corrosion, in Frankfurt (Main) on November 11 and 12, 1954. This congress will also form the annual general meeting of DECHEMA (**German Chemical Apparatus and Equipment Association**, Frankfurt (Main) W.13, Postfach, Rheingauualle 25). The Working Party on Corrosion which held its last meeting as an international body in 1943, and is resuming activity for this congress, is formed of representatives of the leading German scientific and technical societies.

---

The third Salon de la Chimie et des Matières Plastiques will be held at the Parc des Expositions, Porte de Versailles, Paris, from December 3 to 12, 1954. Four complementary exhibitions, will be devoted to laboratory equipment, chemical products, chemical engineering, plastics industry.

# Elections and Transfers

At the meeting of Council held in Montreal, on Friday, July 30, 1954, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

*Members.*

R. C. Adams, *Cornwall*
W. S. Allen, *Montreal*
L. P. Blaser, *Toronto*
C. P. Bradley, *Sarnia*
H. W. H. Casperd, *Toronto*
B. Cooper, *Vancouver*
A. B. Danard, *Montreal*
P. C. Garsonnin, *Montreal*
G. Glinski, *Ottawa*
J. Gyulveszi, *Tillsonburg*
B. C. Halley, *London, Eng.*
H. C. Hood, *Montreal*
G. L. Houghton, *Montreal*
C. M. J. W. Kohler, *Toronto*
M. J. Kruzynski, *Montreal*
F. J. Langer, *Montreal*
J. C. E. Lowcock, *Toronto*
R. Macrae, *Toronto*
R. J. Marriott, *Ottawa*
R. D. Mawhood, *Sherbrooke*
I. W. McCaig, *Niagara Falls*
J. P. McLaughlan, *Corner Brook*
W. E. Mercer, *Fort William*
S. J. Menich, *Kitchener*
D. G. Miller, *Ottawa*
J. S. Moloney, *Sarnia*
F. Petricek, *Clarke City*
E. I. Rubinsky, *Ottawa*
P. D. Smith, *Toronto*
R. C. Smythe, *Montreal*
R. L. Snitch, *Coniston*
E. G. Taylor, *Toronto*
J. A. Whelihan, *Lethbridge*
F. G. York, *Ottawa*

*Juniors.*

R. J. Arnold, *Calgary*
D. S. Bate, *Sarnia*
P. Beyeler, *Grand'Mere*
J. F. G. Bockstael, *St. Boniface*
R. Burns, *Toronto*
W. D. Croft, *Shawinigan Falls*
R. P. Crawford, *Sudbury*
A. Darragh, *London*
M. J. J. Dembinski, *Montreal*
H. J. Edens, *Toronto*
M. C. Edwards, *Toronto*
L. J. O. Holmes, *Sheffield, Eng.*
J. L. Hope, *Niagara*
F. E. Jones, *Sarnia*
J. A. Kane, *Montreal*
G. T. Keys, *Kingston*
R. W. Luchtenstein, *Goose Bay*
H. D. McPhee, *Glace Bay*
G. E. McIntyre, *Pickering*
W. G. Miller, *Amherst*
E. W. Petzold, *Toronto*
G. F. Pharo, *Kenogami*
D. R. Rae, *Montreal*
R. C. Roll, *Montreal*
J. N. Schilizzi, *Shawinigan Falls*
H. W. R. Smith, *Labrador*
O. Spijkerman, *Amherst*
W. Taciuk, *Brandon*
C. J. T. Van Leeuwen, *Montreal*

*Affiliates.*

L. A. Cox, *Montreal*
L. G. Ogilvie, *Montreal*
T. M. Parr, *Toronto*

*Transferred from the class of Junior to that of Member.*

A. E. Beazely, *Calgary*
H. B. Brock, *Montreal*
E. O. Butts, *Port Hope*
K. L. F. Coupland, *Ottawa*
H. K. Craibbe, *Hamilton*
M. M. Davis, *Toronto*
M. J. J. Dayton, *Vancouver*
H. Dederer, *Winnipeg*
C. M. Douglas, *Vancouver*
H. G. Dutz, *Edmonton*
J. R. Gregory, *St. Catharines*
G. Grenier, *Montreal*
F. C. Hamata, *Calgary*
J. R. Hazle, *Shawinigan Falls*
R. L. Hicks, *Toronto*
H. J. Hoseason, *Toronto*
Y. Kato, *Montreal*
C. H. Killoran, *Niagara Falls*
Y. H. O. Lee, *Niagara Falls*
J. A. Legris, *Toronto*
R. J. Leigh, *Toronto*
J. A. McKinnon, *Vancouver*
M. J. Nimmo, *Vancouver*
I. Orloff, *Kingston*
A. V. Overend, *Toronto*
H. H. L. Pratley, *Montreal*
R. G. Ryan, *Montreal*
A. W. Skene, *Sarnia*
S. Stoller, *Los Angeles*
P. J. L. Troalen, *Montreal*
E. C. M. Tuff, *Toronto*
D. L. Turner, *Malton*

The following Students were admitted:

*University of British Columbia*

T. R. Bagot, G. E. B. Nixon
L. M. Harper, W. D. Rion
J. Huva, E. W. Scratchley
R. J. Kania, W. H. Taylor

*University of Alberta*

H. T. Andersen, R. M. Morison
S. G. Howard

*University of Toronto*

R. G. Aishford, H. W. Cunningham
W. G. Banner, C. C. Henderson
P. B. Buchan, K. L. Murphy
D. A. Buchanan, D. C. Patel

*McGill University*

P. E. Bieler, N. Dodis
P. H. Butler, E. L. C. Miller
J. Dlouhy, D. C. Patel

*Queen's University*

R. F. Doughty, S. M. Jones
J. H. Ferguson, G. H. Walker

*Nova Scotia Technical College*

D. P. Andrews, L. D. Martell

*Mount Allison University*

J. L. Cutcliffe, W. R. Lowther
D. F. L. Hamilton, H. C. J. Webb

*University of Manitoba*

L. D. Arthurs

*University of New Brunswick*

J. H. White

*University of Detroit*

E. Halas

**Applications through Associations:**

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

*Members.*

L. G. Alexander, E. L. M. Ryll
M. L. Coulson, H. S. Sparrow
G. Ross, P. D. J. Vinkenborg

*Junior.*

D. Bing-Wo, W. C. Sellehs

*Junior to Member.*

R. B. Butler, B. C. Van Hees
K. S. Smith

*Student to Junior.*

A. R. Towell

SASKATCHEWAN

*Members.*

A. C. Anderson, F. G. McBean
F. W. Bigsby, D. W. Organ
P. S. Friesen, D. C. Rotherham
W. H. Griffin, C. R. Usher
E. D. Johnson, Z. Wolski

*Junior.*

D. W. van Es

*Student.*

C. L. Slegel

*Junior to Member.*

E. W. G. Bodrug, J. T. J. Raleigh
J. A. Bryan, J. S. Sugiyama
J. M. Crook, B. L. Walsh

NOVA SCOTIA

*Members.*

R. L. Alexander, R. E. Wallar
W. L. Griffin

*Junior to Member.*

R. C. Bezanson, G. H. Love
A. A. Bruce, W. T. Windeler

NEW BRUNSWICK

*Member.*

W. E. Jarratt

*Junior to Member.*

A. L. Bond, A. E. McDevitt
F. V. Maddox

# The ASME Boiler Code

## Interpretations

The Boiler Code Committee meets monthly to consider "Cases" where users have found difficulty in interpreting the Code. These pass through the following procedure (1) Inquiries are submitted by letter to the Secretary of the Boiler Code Committee, ASME, 29 West 39th Street, New York 18, N.Y.; (2) Copies are distributed to Committee members for study; (3) At the next Committee meeting interpretations are formulated to be submitted to the ASME Board on Codes and Standards, authorized by the Council of the Society to pass upon them; (4) They are submitted to the Board for action; (5) Those which are approved are sent to the inquirers and are published in Mechanical Engineering.

The following Case Interpretations were formulated at the Committee meeting June 11, 1954.

### Case No. 1119-2
(Reopened)
Special Ruling

***Inquiry:*** May austenitic chromium-nickel alloy steels which are stabilized with columbium plus tantalum be used under Code rules which are applicable to the use of stainless steel Types 309Cb, 316Cb and 347?

***Reply:*** It is the opinion of the Committee that austenitic chromium-nickel alloy steels which are stabilized with columbium plus tantalum instead of columbium only may be used under the Code rules which are applicable to the use of Types 309 Cb, 316Cb and 347, with the following restrictions.

(1) Material — The material shall conform to an approved specification and grade covering Types 309, 316 or 347 modified by additions of columbium, except that the requirements for columbium contents shall be modified as follows:

Columbium — determination not required.

Columbium plus tantalum — 1.25 per cent max., 8 x the carbon content min.

(2) These steels, stabilized with columbium alone, may be used with a minimum columbium content of 8 x the carbon content.

(3) Working stresses shall be the same as those listed for the standard grades stabilized with columbium alone.

### Case No. 1122-3
(Reopened)
Special Ruling

***Inquiry:*** May the extra low carbon grades of the austenitic stainless steels Types 304, 316, and 317 be used under the applicable Code rules pertaining to the regular grades of austenitic stainless steels?

***Reply:*** It is the opinion of the Committee that the extra low carbon grades of Types 304, 316, and 317 may be used for construction under the Code rules applying to the regular grades of Types 304, 316, and 317 with the following modifications:

(1) The material shall conform to the requirements of an approved specification which covers the same grade with regular carbon content, except that:

(a) The carbon content shall be limited to 0.03 per cent max.

(b) The mechanical properties shall be as follows:

Tensile strength......70,000 psi min
Yield strength........25,000 psi min
Elongation in 2 in. — as required by specification.

(c) The stress values in tension (see table below) are to be used for vessels under internal pressure.

(2) The extra low carbon grades of austennitic steels Types 304, 316, and 317 may be used for the construction of vessels under external pressure under the Code rules applying to the regular grades of Types 304, 316, and 317.

(a) The material shall conform to paragraphs (1)(a) and (b) above.

(b) The required thickness of shells and heads, and the required moment of inertia for stiffening rings, shall be determined from the chart in Fig. UHA-28.3 for Type 304L, and from the chart in Fig. UHA-28.4 for Types 316L and 317L.

### Case No. 1134-1
(Reopened)
Special Ruling

***Inquiry:*** May seamless steel pipe or tubing conforming to the following chemical analysis (including check analysis) and having minimum specified tensile strength, yield strength and elongation shown below be used in the construction of special integrally forged unfired pressure vessels?

| | Per cent |
|---|---|
| Carbon.............. | 0.25–0.50 |
| Manganese.......... | 0.35–0.90 |
| Phosphorus.......... | 0.05 max. |
| Sulphur.............. | 0.05 max. |
| Silicon.............. | 0.15–0.40 |
| Chromium........... | 0.74–1.16 |
| Molybdenum........ | 0.12–0.25 |

| | | |
|---|---|---|
| Minimum Specified Tensil-Strength..... | 120,000 psi. | 100,000 psi. |
| Minimum Specified Elongation in 2″..... | 18% | 22% |
| Minimum Specified Yield Strength...... | 74,000 psi. | 70,000 psi. |

***Reply:*** It is the opinion of the committee that these materials may be used for the construction of seamless vessels to operate at temperatures between minus 20°F and 150°F and at a maximum stress value of one fourth of the minimum specified tensile strength and that the vessels may be stamped with the code symbol provided the following requirements are complied with:

(1) The material is made by the open hearth or electric furnace process.

(2) There are no stress raisers such as openings, welded attachments, or stampings on the shell portion.

(3) The maximum inside diameter of the shell is 24 in. and the maximum volume of the vessel is 5 cu. ft.

(4) The integral heads are hot formed, concave to the pressure, and so shaped and thickened as to provide details of design and construction of the center opening which will be as safe as those provided by the rules of the Code. The center openings shall not exceed 50% of the outside diameter of the vessel or 3 inch pipe size. Other openings in the head shall not exceed ¾″ pipe size and shall be placed at a point where the calculated stress, without holes, is not more than one-half the maximum allowable stress value.

(5) No welding is utilized.

(6) After all forming operations, vessels are heated to a temperature above the upper critical temperature, but in no case exceeding 1700°F., quenched in oil and then tempered at not less than 1100°F. for one hour per inch of thickness but in no case less than one hour.

(7) (a) For batch furnace treatment, one tensile specimen is tested from a ring of material heat treated with each furnace batch or from one of the vessels constituting the batch. If the batch exceeds 200, one tensile specimen shall be tested from each lot of 200 or less.

(b) For continuous furnace treatment, one tensile specimen is tested from a ring of the material heat treated with each lot of 200 or less. In no case may one tensile specimen represent more than four hours furnace production.

(c) Rings for tensile specimens or vessels from which tensile specimens are cut are from one of the melting furnace heats of steel in the vessel being treated and each melting furnace heat of steel is represented by at least one test.

(d) Recording temperature devices are used and records are made available to the inspector.

(8) The material of the vessel is not subject to corrosion on the interior or exterior.

(9) The vessels comply with all other requirements of Section VIII, 1950 Edition, including requirements for pressure relief devices.

**Item 1(c) Case No. 1122-3**

| Alloy Material (L) | Spec. Min. Tensile | −20 to 100 | 200 | 300 | 400 | 500 | 600 | 650 | 700 | 750 | 800 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Type 304 (T.S.)*........... | 70,000 | 17,500 | 17,000 | 16,000 | 15,000 | 14,000 | 13,000 | 12,500 | 12,000 | 11,500 | 11,000 |
| Type 304 (Y.S.)............ | 70,000 | 17,500 | 17,000 | 13,400 | 11,000 | 9,700 | 9,000 | 8,750 | 8,500 | 8,300 | 8,100 |
| Type 316 (T.S.)*........... | 70,000 | 17,500 | 17,500 | 15,800 | 14,750 | 14,000 | 13,600 | 13,450 | 13,250 | 13,000 | 12,700 |
| Type 316 (Y.S.)............ | 70,000 | 17,500 | 17,500 | 14,500 | 12,000 | 11,000 | 10,150 | 9,800 | 9,450 | 9,100 | 8,800 |
| Type 317 (T.S.)*........... | 70,000 | 17,500 | 17,500 | 15,800 | 14,750 | 14,000 | 13,600 | 13,450 | 13,250 | 13,000 | 12,700 |
| Type 317 (Y.S.)............ | 70,000 | 17,500 | 17,500 | 14,500 | 12,000 | 11,000 | 10,150 | 9,800 | 9,450 | 9,100 | 8,800 |

*At temperatures from 200°F. through 800°F. these stress values meet all of the criteria specified for establishing stress values except that they exceed 62½ per cent but do not exceed 90 per cent of the yield strength at temperature. They may be used where slightly greater deformation is permissible.

Typical sections of special seamless vessels are shown on a sketch available from the Committee.

### Case No. 1167-1
(Reopened)
Special Ruling

Add the following paragraph as a last paragraph to the Reply.

A further consideration of available data indicates that a stress value of 11,700 psi. is satisfactory for operation at temperatures up to and including 250°F.

### Case No. 1174-1
(Reopened)
Special Ruling

*Inquiry:* Will unfired pressure vessels fabricated by fusion welding under the applicable rules of Section VIII, 1952 Edition, meet the intent of the Code if the base material is an aluminum-magnesium-chromium alloy having the following composition (Alloy GR40A Specification SB-178):

| | |
|---|---|
| Magnesium, per cent | 3.1 to 3.9 |
| Chromium, per cent | 0.15 to 0.35 |
| Copper, max., per cent | 0.10 |
| Manganese, max., per cent | 0.10 |
| Zinc, max., per cent | 0.20 |
| Iron plus silicon, max., per cent | 0.45 |
| Other, each, max., per cent | 0.05 |
| Other, total, max., per cent | 0.15 |
| Aluminum | remainder |

*Reply:* It is the opinion of the Committee that the aluminum-magnesium-chromium alloy described in the Inquiry may be used for the construction of unfired pressure vessels according to the applicable rules of Section VIII, 1952 Edition, subject to the following conditions:

(1) The mechanical properties of the material are not less than the following:

| Condition | Tensile Strength psi. | Yield Strength psi. (0.2 per cent off-set) | Elongation in 2 in., per cent |
|---|---|---|---|
| Annealed | 30,000 | 11,000 | 18 |
| H112 | 30,000 | 11,000 | 8 |
| H32 | 36,000 | 26,000 | 8 |
| H34 | 39,000 | 29,000 | 6 |

(2) Sheet and plate further meet the applicable requirements of Specification SB-178.

(3) Rod, bar, and shapes further meet the applicable requirements of Specification SB-273.

(4) Pipe and tube further meet the applicable requirements of Specification SB-274.

(5) Fabrication is by fusion welding using filler metal complying in composition with the base material.

(6) The welding requirements and applicable paragraphs of Section IX, 1953 Edition, apply except that the tensile strength of the reduced-section tensile specimens shall be not less than 30,000 psi.

(7) The following maximum allowable stress values are used in applying the design rules where reference is made to Table UNF-23:

**Item 7. Case No. 1174-1**

| Condition | Metal Temperature not Exceeding, Deg. F. 100 | 150 | 200 | 250 | 300 | 350 | 400 |
|---|---|---|---|---|---|---|---|
| Annealed and H112 | 7,350 | 7,350 | 7,350 | 7,000 | 6,400 | 5,650 | 4,900 |
| H32 | 9,000 | 8,950 | 8,850 | 8,250 | 7,400 | 6,500 | 5,600 |
| H34 | 9,750 | 9,700 | 9,500 | 8,800 | 7,900 | 6,900 | 5,900 |

(8) For welded joints, the allowable stress values for annealed material are used.

(9) In view of the fact that this alloy does not undergo a marked drop in impact resistance at low temperatures, no additional requirements are specified for temperatures down to −325°F. (See Par. UNF-65).

(10) The joint efficiency factors, inspection, and testing comply with the applicable paragraphs of Section VIII, 1952 Edition.

(11) Thermal stress-relieving is not mandatory.

(12) Bolting materials conform to an aluminum alloy listed in Table UNF-23 or of one of the grades of austenitic steel of Specification SA-193. These bolting materials shall not be welded. The allowable stress values in Table UNF-23 or UHA-23 shall apply.

(13) In addition to the material described herein, any of the aluminum alloy materials for which allowable stress values for welded construction are given in Table UNF-23 may be used for appurtenances and other attachments. These parts and their connections shall be designed in accordance with the lower of the stress values in Par. (7) above and the applicable values in Table UNF-23. The welding process for these connections shall be qualified in accordance with the applicable rules of Section IX, 1953 Edition, except that the strength of the reduced-section tensile specimen shall be not less than the lower of the specified tensile strength of the two materials in the annealed temper.

(14) Cylindrical and spherical shells for external pressure and formed heads convex to pressure shall be designed by the rules of Pars. UG-28 and UG-33, respectively using Fig. UNF-28.13.

### Case No. 1188
Special Ruling

*Inquiry:* Is it permissible in welded construction conforming to the requirements of Section VIII to use plates, pipe, tubes, and forgings which meet the following chemical and physical requirements:

| | |
|---|---|
| Carbon, max., per cent | 0.07 |
| Manganese, per cent | 2.00 |
| Phosphorus, max., per cent | 0.035 |
| Sulphur, max., per cent | 0.035 |
| Silicon, max., per cent | 1.00 |
| Chromium, per cent | 19.00 - 21.00 |
| Nickel, per cent | 24.00 - 30.00 |
| Molybdenum, per cent | 2.00 - 3.00 |
| Copper, per cent | 3.00 - 4.00 |
| Columbium plus Tantalum, min., per cent | 8 x C |
| max., per cent | 1.00 |
| Tensile Strength, min. psi. | 75,000 |
| Yield Strength, min. psi. | 30,000 |
| Elongation, min. in 2″ per cent | 30 |

*Reply:* It is the opinion of the Committee that the materials specified in the inquiry may be used in the construction of welded pressure vessels under the rules of Section VIII provided the following additional requirements are complied with:

(1) The various product-forms shall meet all the requirements of the following specifications except that the chemical and physical requirements shall be those specified in the inquiry.

*SA-240*—Corrosion-Resisting Chromium and Chromium-Nickel Steel Plate, Sheet, and Strip for Fusion-Welded Unfired Pressure Vessels.

*SA-312*—Seamless and Welded Austenitic Stainless Steel Pipe.

*SA-249*—Welded Austenitic Stainless Steel Boiler, Super-Heater, Heat Exchanger and Condenser Tubes.

*SA-182*—Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service.

(2) The maximum allowable stress-values shall be those given in Table I.

**Table I: Case No. 1188 Maximum Allowable Stress Values in Pounds per Square Inch**

| For Metal Temperatures not Exceeding, Degrees F. 100 | 200 | 300 | 400 | 500 | 600 | 650 | 700 | 750 | 800 |
|---|---|---|---|---|---|---|---|---|---|
| 18,750 | 18,750 | 17,900 | 17,500 | 17,200 | 17,100 | 17,050 | 17,000 | 16,900 | 16,750 |

(3) The special design, fabrication and inspection requirements given in Part UHA for Type 304 austenitic stainless steel shall apply to this material.

(4) The material shall be subject to the same requirements in Section IX as for Type 304 austenitic stainless steel.

(5) The thickness of material used shall not exceed 1½″. A separate welding procedure qualification shall be made for each thickness from each heat of material that exceeds ¾″ in thickness.

(6) All longitudinal and circumferential joints shall be of the double-welded butt type or its equivalent.

(7) All butt-welded main joints shall be fully radiographed when the thickness at the welded joint exceeds ⅜″.

(8) All welds used throughout the vessel shall be examined by the fluid-penetrant method.

(9) For qualifying the welding procedure the material shall be included under P-number 8 of Table Q-11.1 and A-Number 8 of Table Q-11.3 of Section IX.

*Cautionary Note:* By publishing these specifications, the American Society of Mechanical Engineers disclaims responsibility for infringement of any letters patent by the user of such specifications; and such publication is not to be construed as a representation that the specifications may be used or applied without the permission of the owner of any patent involved therein or as a recommendation of any patented material which may be covered by the specifications.

### Case No. 1189
Special Ruling

*Inquiry:* Will flanged connections be considered to comply with Pars. H-31 and H-88 if they are designed with diameter and bolting according to Tables A-5 to A-8* and with other dimensions calculated according to the rules in Appendix II of Section VIII?

*Reply:* It is the opinion of the Committee that steel flanged connections designed with diameter and bolting according to Tables A-5 to A-8 and with other dimensions calculated according to the rules of Appendix II, Section VIII will comply with the intent of the Heating Boiler Code.

*Appendix to Section I.

# NEWS OF THE ASSOCIATIONS & CORPORATION

**Information received through co-operation with the provincial organizations**

## Nova Scotia

### Thanks

The privilege of having this means of conveying news to the membership is very much appreciated. Sincere thanks is hereby extended to the E.I.C. officials and editorial staff of the Journal.

The Nova Scotia representatives to the Dominion Council would like to take this opportunity of expressing thanks for the many courtesies received during the sessions of the Council. It also seems fitting at this time to acknowledge the fact that the Ontario Association of Professional Engineers made many valuable contributions to the success of the Council sessions, and after working hours they were perfect hosts.

### Salary Schedules

Those who have a keen interest in salary schedules must have been pleased to read the Ontario and Quebec news items in the June issue of the Journal. It is difficult to explain in a few words the tremendous amount of work accomplished by the Ontario Association and the Corporation of Quebec. The Nova Scotia Association is grateful to both engineering groups for making the results of their efforts available. The members will soon receive the new salary schedule.

### New Members

The following, having complied with all necessary requirements, were approved for registration as Professional Engineers of Nova Scotia at a recent meeting of the Council of the Association.

Robert Lewis Alexander, Assistant Chief Engineer, Canada Electric Co., Ltd., Amherst, N.S.

Robert Charles Bezanson, Construction Engineer, Seaboard Power Corporation, Sydney, N.S.

Wilfred Lester Giffin, Civil Engineer, Fundy Construction Co., Ltd., Halifax, N.S.

John James Kinley, Jr., Vice-President and Managing Director, Lunenburg Foundry & Engineering Limited, Lunenburg, N.S.

George Harry Love, Sales Engineer, Construction Equipment Co., Ltd., Halifax, N.S.

Francis Patrick Martin, Engineering Assistant, Maritime Telegraph and Telephone Co., Ltd., Halifax, N.S.

Walter O. Sorby, District Sales Manager, Canadian Westinghouse Co., Ltd., Halifax, N.S.

Robert Edwin Wallar, Chemical Engineer, Imperial Oil Refinery, Dartmouth, N.S.

## Quebec

### Saguenay Region

### Annual Report of Activities

The past year has seen the organization and subsequent existence of the Saguenay Region of the Corporation of Professional Engineers of Quebec. Commencing last fall as Region 6 of the C.P.E.Q. with 147 members, the Saguenay Region is ending its first season with 164 members who have had the opportunity of participating much more actively than formerly in engineering and Corporation affairs. Regional policy and aims as set forth in a circular letter to all members some months ago have come a substantial way along the road to realization, as is apparent from the description of the season's activities. The cornerstone of both our policy and our activities has been close co-operation with the Saguenay Branch of the Engineering Institute of Canada. It must be pointed out that the large measure of liaison and co-operation which was freely given by the Saguenay Branch E.I.C. and its executive have been fundamental to the success of the past season of the Region.

After some months of exploration and planning of local C.P.E.Q. activity and E.I.C.-C.P.E.Q. relations, the Saguenay Region was formally initiated. Its first

**The General Committee; Maritime Professional Meeting. Left to right: Front Row: O. K. Smith, secretary; J. E. Clarke, president, Association of Professional Engineers of N.S.; R. N. Fournier, general chairman; M. L. Baker, general vice-chairman; back row: G. W. Frey, chairman, publicity committee; J. D. Kline, representative of the Association; A. E. Flynn, chairman, speakers committee; J. R. Kaye, chairman, finance committee; Missing from the photo: W. V. Lodge, chairman, registration committee; A. J. E. Smith, chairman, entertainment committee; G. F. Bennett, O. N. Mann, representatives of the Halifax Branch, E.I.C., G. J. Currie, representative of the Association; Mrs. J. R. Kaye, Ladies Committee.**

and presently retiring executive was elected at a general meeting held at Arvida last October 8th. This meeting was attended by the president, vice-president, general secretary, and two councillors of the Corporation. There followed a period of active organizational activity in which the executive explored, defined and finally circulated branch policies and intentions, selected and set up committees, gathered records, set up its communications, and generally got its bearings. A great deal of assistance was given by the headquarters of the Corporation, an example of which is the fact that both the vice-president and general secretary paid the Region a second visit during the season in March and May respectively. Three meetings of the executive were held and a number of Saguenay Branch E.I.C. executive meetings were attended. The specific activities of the Region during the past season may best be described by considering those of the various committees.

The regional representative, Laurent Simard, has been exceedingly active, having attended a number of meetings of the Council of the Corporation, and the Annual General Meeting, and having in addition served as an active member of the Corporation's sub-committee on the question of Regional Branches, and he will report shortly on the activities of Council during the past season.

### *E.I.C.-C.P.E.Q. Relations*

The standing committee on E.I.C.-C.P.E.Q. relations was composed of the full executives of the Saguenay Branch E.I.C. and the Saguenay Region C.P.E.Q. Their object was to study and promote the eventual integration of the various Canadian engineering bodies, and for a short range objective to effectively accomplish such unity locally. They authorized the joint endorsement and circulation of the Smith "Plan for Unity" which was published in Ontario last December. Accordingly, this was jointly sent all across Canada to all councillors and officials of the E.I.C. and to all the provincial professional engineering groups. A large number of replies were received and all indicated support of this movement. It is hoped that our support gave additional impetus to it; certainly interest in it has been widespread. At the present time this plan is being widely studied.

### *Papers and Meetings*

The papers and meetings, and entertainment committees under J. E. Dyck and J. G. Jefferies collaborated with the local branches of the E.I.C. and C.I.C. in arranging the following activities in which the Region participated: two general meetings, five technical meetings, four open meetings, four student guidance meetings, one debate and study groups.

Publicity in both French and English was given in various newspapers to these activities.

### *Regional Constitution*

The committee on a regional constitution under the chairmanship of J. A. Pollock has spent considerable effort in the preparation of a framework of policies and by-laws under which branches could operate within the Corporation. This framework was recently submitted to the Corporation sub-committee on Regional Branches upon whose request it was prepared.

### *Membership*

The membership committee consisting of H. H. Lockwood, chairman, Lloyd Laventure and J. H. McCulloch conducted an active membership campaign in which about 75 non-member engineers were written and interviewed. A file on prospective members was established. Through their efforts, the Region gained 16 new members during the season. In connection with membership, it is of interest to note that the Region has established a policy of inviting to its meetings, those engineers who would like to join the Corporation but are barred from so doing by the citizenship clause in the Quebec Engineers' Act. Locally, these number seven at present.

In conclusion, it is hoped that the foundations of successful future regional activity has been laid, and that participation in the affairs of the Corporation through regional branches will continue to increase.

The retiring executive wish to thank the Region members for their confidence and help, the executive and members of the Saguenay Branch E.I.C. for their help and confidence, and headquarters of the Corporation for their support.

Submitted on behalf of the executive of the Saguenay Region of the Corporation of Professional Engineers of Quebec.

P. SCHOPFLOCHER,
*Secretary-Treasurer.*

### Young Engineers' Committees

For the last year and a half the younger members of the Corporation living in Montreal have been given an opportunity to meet periodically to discuss freely among themselves professional problems of particular interest to them.

An average of three general meetings a year have been held during which many topics have been aired: should there be a class of engineers in training within the Corporation; should young engineers sign plans and specifications they prepare; relations with architects, etc.

The formation of this group came about in 1952 when an important number of members voiced strong opposition against the opinion that a serious shortage of engineers existed.

Following his election to council, Dr. T. A. Monti organized a provisional committee to investigate the conditions under which a young engineers' group could exist. A constitution was drafted and a permanent Committee of the Young Engineer was elected and subsequently appointed by council. This committee directs the operations of the young engineers' group and acts as its mouthpiece.

At the general meetings called by the committee young members are forthright in expressing their ideas as to how the profession should be governed. Most of the time the president and some members of council attend. They gather the feeling of the group and quite often give in return illuminating comments on the policies of the Corporation.

Recently council suggested that a young engineers' committee should also be instituted in Quebec City. A very enthusiastic preliminary meeting has been held and the decision was taken by the young members present to establish such a committee on perhaps a different basis from that of Montreal. An investigating committee is now at work.

Each generation of young engineers has exhibited the same impetus and imaginative power. Athwart such a torrent the committee should prove to be a valuable water-wheel.

## Manitoba

### Golf Tournament

The first half of the Association of Professional Engineers annual Golf Tournament was held at the Pine Ridge Golf course. The weather and the attendance were excellent. At the dinner afterwards the presentation of the awards was made by J. Sill, chairman of the golf committee. The prize winners were as follows: low net, H. Burns; high net, George Tough; low gross, T. Gauvin; hidden hole prizes, J. Sill, H. Willms, and H. Yeomens. The remaining half of the golf tournament will be held in September with the Sullivan Cup as the coveted prize. A larger attendance is anticipated.

### A Plan for Unity

J. H. Smith, past president of the Ontario Association of Professional Engineers was guest speaker at a meeting arranged by the management committee of the Engineering Institute of Canada, Winnipeg Branch, and held at the Canadian General Electric Company plant in Winnipeg. Mr. Smith who is vice president and general manager, wholesale division, for C.G.E. discussed his plan for a unified engineering body in Canada under one leadership. A lively discussion on the pros and cons of his plan was then held and some of the members taking part in this discussion were: D. M. Stephens, president of the E.I.C., N. Bubbis, and C. V. Antenbring.

C. D. Osterland, district manager of the Canadian General Electric Company in Winnipeg was a genial host and on behalf of the C.G.E. provided the guests with an interesting tour of the plant as well as a very fine dinner.

### Official Plant Opening

The Pioneer Electric Company, manufacturers of transformers, held the official opening ceremonies for its new plant in Fort Garry, Manitoba, on June 17, 1954. The opening address and laying of the corner stone was done by the Premier of Manitoba, the Honorable D. L. Campbell. Following his address the Premier was presented with a miniature trowel by the president of the board of directors of the company, A. K. McKenzie. The Honorable R. D. Turner, Minister of Industry and Commerce, after a short address, pulled the switch which officially set the plant in operation. An interesting speech was made by E. V. Caton, retired chief engineer of the Winnipeg Electric Company, after which a plaque was unveiled, commemorating the delivery to the Pioneer Electric Plant of the equipment originally used at Pinawa, the first hydro-electric power development on the Winnipeg River.

### Appointments and Transfers

**V. S. Buckler** has recently accepted the post of chief electrical engineer with the firm of Green Blankstein Russell and Associates, architects and engineers. Mr. Buckler was formerly chief electrical inspector for the city of Winnipeg. He is succeeded in that position by Mr. J. S. Hicks, P. Eng., formerly with the Manitoba Telephone System.

**C. S. Landon,** secretary of the Association of Professional Engineers of Manitoba was named a commissioner of the Greater Winnipeg Sanitary District.

**W. I. Shuttleworth** has joined the firm of Green Blankstein Russell and Associates, architects and engineers. His duties involve the field inspection of all company building projects. He formerly served in the same capacity for the firm of Moody and Moore, architects.

# Ontario

### Engineering Science at Western Ontario

The Board of Governors of the University of Western Ontario, London, has announced the establishment of a department of engineering science on 1st July, 1954, and the appointment of L. Stuart Lauchland, as professor and head of the department.

A two-year course in engineering will be offered, with first-year instruction only in the 1954-1955 session and both first-year and second-year instruction in the 1955-56 and succeeding sessions. The course will be designed so that students who complete the program successfully may continue their engineering studies at other Canadian universities.

Professor Lauchland has been a member of the staff of the University of Toronto since 1937 and has been an associate professor of electrical engineering since 1951.

With overseas service during World War II, Lieut. Col. Lauchland has been in command of the University of Toronto C.O.T.C. for the past few years.

### Heads Division

H. S. Scott has resigned from the staff of McMaster University, Hamilton, and is Director of the Resources Survey Division of The Photographic Survey Corp. Ltd., Toronto.

His responsibilities, as head of this division, entails the direction of geological, forestry, soils and land use surveys in many parts of the world.

### Deputy Commissioner

Frank E. Wellwood, has recently been appointed deputy commissioner of buildings for the City of Toronto.

A graduate in civil engineering from the University of Toronto, Mr. Wellwood has been with the Engineering Department of the City of Toronto for a number of years. Latterly he has held the position of chief engineer, Department of Buildings.

### Contract Manager

Russell E. Upper has been named to the position of contract manager of the Standard Iron and Steel Works Ltd., of Toronto. Graduating in civil engineering from the University of Toronto in 1945. Mr. Upper has followed his profession in the structural field. Laterly he was associated with Wallace Carruthers & Associates Ltd., of Toronto.

# Saskatchewan

### E. D. Wilson Is Promoted

E. D. Wilson has been appointed management assistant in Imperial Oil's western producing division and a member of the division management committee, it was announced recently in Regina.

Formerly assistant manager of Imperial's Regina exploration district, Mr. Wilson graduated from the University of Alberta in 1939 with a degree in mining engineering. On graduation he joined the Royalite Oil Company.

In 1946 he joined Imperial's producing department in a production and petroleum engineering capacity. In 1948 he became division petroleum engineer, and in 1950 he was transferred to the producing department in Toronto.

Mr. Wilson joined the Saskatchewan Association in January of 1953 by transfer from the Ontario Association.

### Halifax Command for Col. C. G. Kirby

Lt.-Col. C. G. Kirby, M.B.E., assistant director of electrical and mechanical engineering (vehicle section) at army headquarters, Ottawa, will command the Royal Canadian Electrical and Mechanical Engineers at headquarters, eastern command, Halifax, army headquarters announced recently.

Col. Kirby was born at Fertile, Sask., and educated at the University of Saskatchewan, where he received his mechanical engineering degree. He enlisted in the Royal Canadian Engineers in 1939 and proceeded overseas in June, 1940 as a Lieutenant. He served in the United Kingdom, Italy and Northwest Europe and returned to Canada in June, 1945. Since the war he has served in various RCEME appointments before going to army headquarters in 1950.

Col. Kirby joined the Saskatchewan Association in June, 1949.

### E. C. B. Macnabb Appointed

E. C. B. Macnabb, formerly C.P.R. district engineer at Moose Jaw has been appointed superintendent at Saskatoon. He succeeds A. E. Hartley who retired July 1.

Mr. Macnabb served the railroad at Revelstoke, has been a road master at Yorkton and for 7 years was division engineer at Moose Jaw. He worked as a chainman and labourer at Nipawin, Debden, Meadow Lake and Shellbrook.

Mr. Macnabb is a 1937 graduate of McGill University in civil engineering. He joined the Saskatchewan Association in October, 1950 and was elected a member of the Council in February, 1954.

# British Columbia

### Engineers in the News

**A. R. D. Robertson** and **R. H. Forsberg** have accepted positions with the engineering services division of the B.C. Forest Service. They were formerly with the B.C. International Engineering Company.

**C. W. Leek** and **R. W. Hole** have recently been elected vice-president and director, respectively, of the National Association of Master Plumbers and Heating Contractors of Canada.

**F. R. Jones** has accepted the position of mine superintendent for the MacIntyre Development of National Lead Company in Tahawus, New York. Mr. Jones was formerly chief engineer with the Canadian Exploration Co. Limited at Salmo, B.C.

**D. A. Saunders** has recently been transferred to the position of manager of the Cowichan Sawmill Division of the B.C. Forest Products at Youbou. He was formerly situated in Vancouver.

**F. D. Bolton** is now president of Electric Panel Manufacturing Limited, and **W. A. Williamson** is vice-president and general manager.

**W. Bruce Scott** has recently been appointed as construction superintendent for McCarter, Nairne and Partners, architects and engineers. Mr. Scott will be in charge of construction work on the new $10,000,000 post office in Vancouver.

---

The following appointments in the Consolidated Mining and Smelting Company of Canada Limited have recently been announced by R. D. Perry, general manager:

**S. M. Rothman,** ore buyer and assistant superintendent, Smelting Department

**J. F. Douglas,** supervisor of Budgetary Control.

**J. H. D. Hargrave,** Superintendent of Development, Metallurgical Division.

**J. D. Hartley,** Assistant Superintendent of Zinc Department.

**Lloyd Williams,** Superintendent of Development, Engineering Division.

**L. S. Piper,** Superintendent of Engineering Services.

---

***The Maritime Professional Meeting***

of The Engineering Institute and the Associations of Professional Engineers of Nova Scotia, New Brunswick and Newfoundland.

## News of the Personal Activities of Members of the Institute

**Air Vice Marshal A. L. James, C.B.E., C.D.,** M.E.I.C., will join on September 1 the board of the Bristol Aeroplane Company of Canada and that of its subsidiary. Bristol Aero Engines Limited. He will also become vice-president (engineering) of the latter company.

A.V.M. James joined the R.C.A.F. in 1924 and has held many senior appointments in the Air Force, including that of Air Officer Commanding Air Defence Command in which he was responsible for the past two years for the Canadian side of the planning and implementation of an arrangement by which the air defence systems of Canada and the United States will operate as a team in the event of an emergency.

He has been well known in aviation circles in England for many years, having flown at the Royal Aircraft Establishment at Farnborough in 1929. As the Air Member for the Technical Services at R.C.A.F. headquarters between 1946 and 1951, he became well acquainted with the British aircraft industry.

He is a graduate of McGill University and he also undertook post-graduate study in aeronautics at the Imperial College of Sciences and Technology in London.

**H. William Tate,** M.E.I.C., formerly assistant general manager of the Toronto Transit Commission, has been appointed executive vice-president of De Leuw, Cather & Company of Canada, Limited, which has been newly organized by De Leuw, Cather & Company of Chicago.

H. W. Tate, M.E.I.C.

After graduation in civil engineering from the University of Toronto, Mr. Tate spent some years in mining, railway and municipal engineering. He served overseas with the rank of major during the First World War, and joined the Toronto Transportation Commission in 1920.

He is a past-president of the Canadian Transit Association.

**Professor C. F. Morrison,** M.E.I.C., has been appointed head of the department of civil engineering at the University of Toronto.

Professor Morrison, who has served as professor of civil engineering and as a consulting engineer, graduated from the University of Saskatchewan and received his M.Sc. degree from McGill University. He taught in the departments of mathematics and civil engineering at the University of Alberta before coming to Toronto in 1928 as a lecturer.

Prof. C. F. Morrison, M.E.I.C.

Professor Morrison is co-author with dean emeritus C. R. Young of the textbook, "Structural Problems". He was chairman of the organizing committee of the first Canadian Conference on Prestressed Concrete held at the University of Toronto last January, and he is active in the Canadian Standards Association, having served on several of its committees. He is a past-chairman of the Toronto Branch of the Engineering Institute, and a past-councillor of the Institute representing the Toronto Branch.

Professor Morrison has been consultant to the Canadian Broadcasting Corporation on antenna structures, namely TV towers across Canada and the CBC International Service shortwave towers in Sackville, N.B. He has also been employed with the Dominion Bridge Company in Winnipeg and Toronto.

**Dr. Gordon Patterson,** M.E.I.C., has been appointed head of the department of aeronautical engineering at the University of Toronto. He is director of the university's Institute of Aerophysics at Downsview airport, and is a member of the aerodynamics panel at the United States Naval Ordnance Laboratory at White Oak, Mississippi.

Dr. Gordon Patterson, M.E.I.C.

A native of Edmonton, Dr. Patterson graduated from the University of Alberta in 1931, and undertook post-graduate work in the department of physics at the University of Toronto.

He spent four years as scientific officer in the aerodynamics department of the Royal Aircraft Establishment at Farnborough, England, and in 1939 was appointed by the Australian Government to set up an aerodynamics research laboratory at Melbourne. In 1945 he began a two-year period of post-doctoral study and research at the California Institute of Technology and at the Institute for Advanced Study at Princeton.

Dr. Patterson will continue to direct the Institute of Aerophysics.

**H. Little,** AFFIL.E.I.C., has been appointed president of R & M Bearings Canada Limited in Montreal. He was previously sales manager and vice-president of the company.

**F. A. Orange,** M.E.I.C., mechanical design engineer with the International Nickel Company, has been elected chairman of the Sudbury Branch of the Engineering Institute for the term 1954-55.

Mr. Orange was born in Salt Lake City, Utah. He received his early education in Sudbury and afterwards attended Queen's University, graduating with a B.Sc. degree in mechanical engineering in 1927.

After graduation he joined the engineering staff of the Carborundum Company in Niagara Falls, N.Y.

He entered the employ of the International Nickel Company in 1931 and has been associated with the mechanical and construction department since that time.

F. A. Orange, M.E.I.C.

Mr. Orange served from 1942 until 1947 as captain with the Royal Canadian Engineers, and latterly was occupied with research and development of engineering equipment at National Defence Headquarters in Ottawa.

Mr. Orange has been a member of the Engineering Institute since 1927, and became a charter member of the Sudbury Branch upon its formation in 1950. He is also a member of the Association of Professional Engineers of Ontario.

**Lt-Col. F. W. W. Doane,** HON.M.E.I.C., celebrated his ninety-first birthday this year, and a photograph taken on that occasion has been obtained for publication.

A Student Member at the time the Institute was founded in 1887, he was later a councillor and was awarded Honorary Membership in 1952. At that time his impressive engineering career in the Maritimes was reviewed in the *Journal*. He retired in 1924 after forty years' service as city engineer of Halifax, after which he entered into private practice. In 1931 he became associated as a consulting engineer with the firm Standard Paving Maritime Limited, of which his son, H. W. L. Doane, M.E.I.C., is now the manager.

It is of interest to note that another Honorary Member in the person of past-president A. J. Grant, also celebrated his ninety-first birthday this year by attending the recent annual meeting in Quebec, as noted in the meeting reports.

Lt-Col. F. W. W. Doane, M.E.I.C.

**E. A. Lawrence,** M.E.I.C., assistant city engineer for the City of Lethbridge, has been elected chairman of the Lethbridge Branch of the Institute for 1954-55.

Mr. Lawrence was born in Sydenham, London, England, and received his education in Alberta.

He joined the engineering staff of the irrigation branch of the Department of National Resources of the Canadian Pacific Railway in Lethbridge, Alta., in 1927 and became assistant engineer in 1945.

During World War II he served with the Royal Canadian Artillery from 1941 until 1945 when he was discharged with the rank of major.

He returned after the war to the Canadian Pacific Railway in Lethbridge, serving there as assistant engineer until October, 1945 when he joined the staff of the City of Lethbridge as assistant city engineer.

E. A. Lawrence, M.E.I.C.

Mr. Lawrence was secretary-treasurer of the Lethbridge Branch of the Institute from 1933 until 1941. He is a member of the Association of Professional Engineers of Alberta.

**W. E. Wakefield,** M.E.I.C., recently retired from the Forest Products Laboratories of the Department of Northern Affairs and National Resources after 28 years of service. He was head of the timber mechanics section.

Mr. Wakefield was born in England. He was trained as a mechanical engineer and materials inspector with the Midland Railway and at the Derby Technical College.

During the first war he served with the Royal Engineers in Palestine, after which he came to Canada where he was employed as a mechanical engineer with the City of Prince Albert.

He joined the Forest Products Laboratories as a test engineer in the timber mechanics section in 1926.

During the second war he was a member of the Subcommittee on Wooden Aircraft of the National Re-

W. E. Wakefield, M.E.I.C.

search Council. He was also a member of the associate Committee on Aeronautical Research, and the Joint Canadian-U.S. Mission to the United Kingdom to study wooden aircraft production methods.

In 1951 he represented Canada at the second meeting of the Food and Agricultural Organization mechanical wood technology panel, and at the third meeting of the F.A.O. mechanical wood technology panel in Paris.

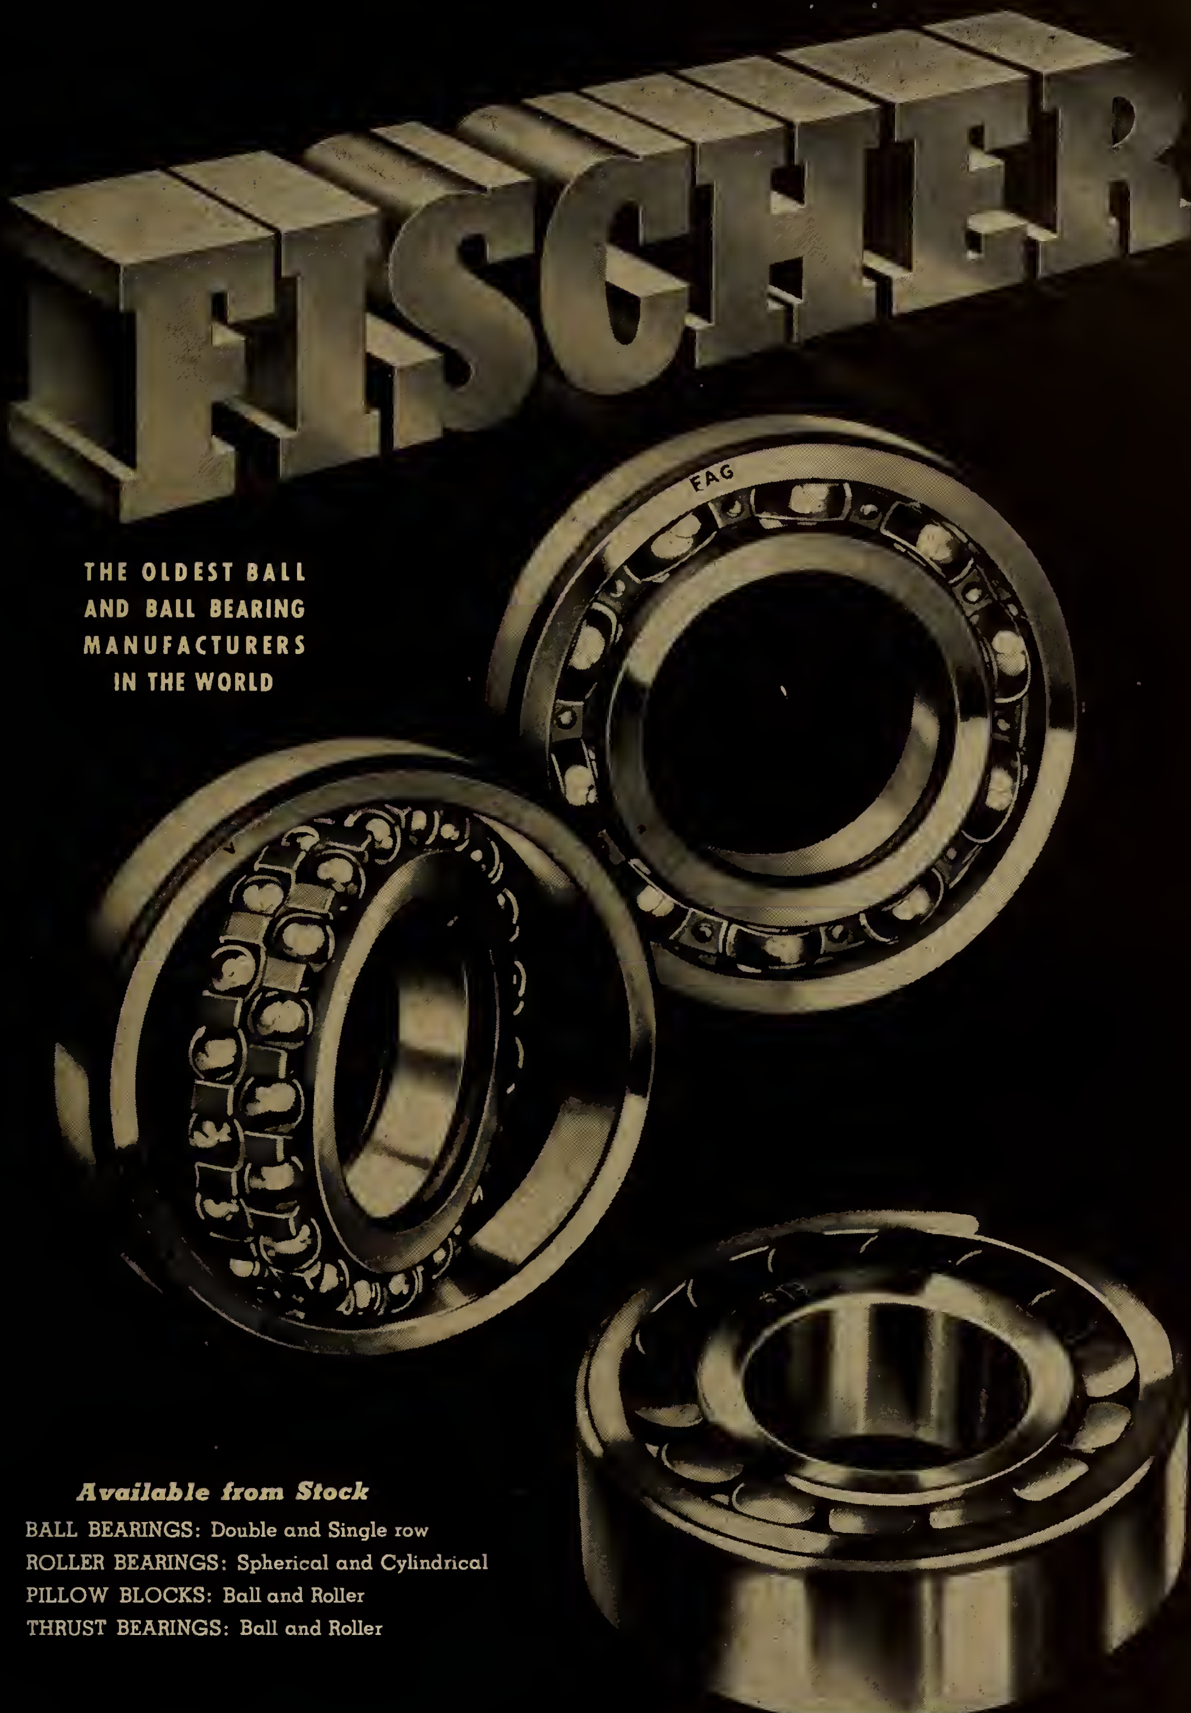
Mr. Wakefield was for a number of years a director of the Professional Institute of the Public Service of Canada. He made a noteworthy contribution as chairman of the technical committees which have prepared Canadian standards specifications for structural timbers, "Glue-Lam" construction, and cedar poles. He has also been active on a number of technical committees of the American Society for Testing Materials.

He is the author of a number of papers on subjects pertaining to the mechanical properties of wood and plywood.

Mr. Wakefield has been for the past two years a member of the Management Committee of the Ottawa Branch of the Engineering Institute.

**T. M. Moran,** M.E.I.C., is now a partner in the industrial and management engineering firm of Chas. W. Murray & Associates Ltd., He was vice-president of Stevenson & Kellogg Ltd., management engineers, for a number of years prior to which he had been associated with Dominion Rubber Co. Ltd. and Aluminum Co. of Canada Ltd.

Mr. Moran is a graduate of McGill University, class of 1923.



FISCHER
FAG

**John Stanley Waddington,** M.E.I.C., chief engineer of Phillips Electrical Company (1953) Ltd., has been elected chairman of the Brockville Branch of the Engineering Institute.

Mr. Waddington was born in Winnipeg. He received his B.Sc. degree in electrical engineering from the University of Manitoba in 1934, and the following year joined the Canadian Marconi Company in Montreal.

He entered the Phillips Electrical Works Ltd. in 1936 and was associated with the company's manufacturing department in Brockville and Montreal until 1938 when he was appointed technical secretary to the president in Montreal. In 1944 he entered the engineering department and three years later was named chief engineer. He received his present appointment of chief engineer of Phillips Electrical Company (1953) Ltd. in 1953.

Mr. Waddington is a member of the American Institute of Electrical Engineers, the Canadian Standards Association, the Canadian Electrical Manufacturers Association and the Association of Professional Engineers of Ontario. He has served on several technical committees of CSA and CEMA, and is at present acting chairman of the CSA Committee on Insulated Power Cable. He also served as a member of the Committee on the Canadian Electrical Code, Part I. Mr. Waddington is secretary-treasurer of the Brockville Public Library Board.

John S. Waddington, M.E.I.C.

**D. S. Simmons,** M.E.I.C., has been appointed general manager of the manufacturing department of Imperial Oil Ltd., succeeding G. L. Macpherson who was elected a director of the company at the annual meeting.

Mr. Simmons, a native of Sarnia and an engineering graduate of Queen's University, was assistant general manager of the department before his recent appointment.

**C. E. Hawke,** M.E.I.C., has been appointed general manager of Charles Warnock & Co. Ltd. of Montreal.

Prior to his new appointment, Mr. Hawke was chief engineer of the Warnock organization. He will carry on in the same capacity in addition to his new duties.

He is a graduate civil engineer of the University of Toronto, class of 1934.

**R. E. Tweeddale,** M.E.I.C., chief of the development division of the New Brunswick Electric Power Commission, has been elected chairman of the Fredericton Branch of the Engineering Institute.

Mr. Tweeddale was born in Arthurette, N.B. He received his early education at Plaster Rock High School and was granted his B.Sc. degree in electrical engineering by the University of New Brunswick in 1935.

After graduation he was employed as district highway engineer with the New Brunswick government. He joined the Royal Canadian Air Force in 1940 and served overseas as radar officer until his

R. E. Tweeddale, M.E.I.C.

discharge as a flight lieutenant at the end of the war.

He then joined the engineering department of the New Brunswick Electric Power Commission and was subsequently named manager of operations.

When the International Joint Commission was authorized to study the power potential of the Saint John River Basin in 1950, the development division was set up with Mr. Tweeddale as chief. The division is responsible for the Commission's system planning and the investigation of new power developments in New Brunswick. During the study of the Saint John River by the International Joint Commission, Mr. Tweeddale served on a number of committees of the engineering group and is now acting as liaison engineer for the New Brunswick Electric Power Commission and the Shawinigan Engineering Company which recently has been engaged to design the 135,000 hp. Beechwood hydro-electric development.

**Dr. J. J. Green,** M.E.I.C., of Ottawa, has been elected the first president of the Canadian Aeronautical Institute, a newly organized association of Canadian aeronautical engineers.

Dr. Green is scientific advisor to the chief of air staff and chief of Division B., of the Defence Research Board, Ottawa. He is a councillor of the Engineering Institute, a former chairman of the Ottawa Branch.

**C. M. Smyth,** M.E.I.C., has been appointed consulting engineer for Eastern Light and Power Company Limited in Sydney, N.S. Previous to his present appointment he was general superintendent of the company.

Mr. Smyth is a 1909 graduate of the London Polytechnic.

**G. A. Robb,** JR.E.I.C., of the New Brunswick International Paper Company, has been elected chairman of the Northern New Brunswick Branch of the Engineering Institute.

Mr. Robb was born in Edmonton, Alta. He received his early education there and afterwards attended McGill University where he graduated with a B.Eng. degree in mechanical engineering in 1948. As a student he spent three summers in the employ of The Shawinigan Water and Power Company.

After graduation he undertook the Canadian General Electric test course, and then served for a time with the Canadian Blower and Forge Company and its associate company, Canada Pumps Ltd.

**M. D. MacKenzie,** M.E.I.C., is now manager of the Regina Branch of the Associated Engineering Services Ltd.

He was previously city engineer in North Battleford, Sask.

Mr. MacKenzie graduated from the University of Saskatchewan in civil engineering in 1948.

**J. L. F. Gaboury,** M.E.I.C., is now in private practice as consulting engineer in Montreal, Que. He was previously associated as designing engineer with Lord and Company Limited in Montreal and with the St. Maurice River Valley Company in Three Rivers, Que.

Mr. Gaboury is a 1923 civil engineering graduate of the University of Toronto.

**Col. C. W. Jones,** M.E.I.C., who was appointed commanding officer of R.C.E. M.E. School at Barriefield Camp, Kingston, Ont., in June 1953, has been promoted recently to the rank of colonel and made commandant of the school. He served in the Canadian Army throughout the 1939-45 war in various capacities, both in Canada and overseas and was on the headquarters staff of the R.C.E. M.E. Corps at Ottawa before taking over command of the school.

**Raphael Belanger,** M.E.I.C., has been appointed vice-president of Deschamps & Belanger Ltd. in Valleyfield, Que. He was previously in private practice as construction engineer in Valleyfield, Que.

Mr. Belanger graduated in civil engineering from Ecole Polytechnique in 1923.

**G. R Minty,** M.E.I.C., has been appointed manager of the marketing research department of the major appliances division of Canadian General Electric Co. Ltd. in Montreal.

Mr. Minty was formerly product planner with Canadian General Electric Co. Ltd. in Montreal.

He is a graduate in mechanical engineering of the University of Saskatchewan, class of 1941.

**L. Williams,** M.E.I.C., has been named to the post of superintendent of development in the engineering division of The Consolidated Mining and Smelting Company.

Mr. Williams was born in Asbestos, Que. In 1932 he obtained his B.A.Sc. degree in electrical engineering from the University of British Columbia.

He made his start with the company in 1934 as a smoke tester. Between 1935 and 1940 he did research work in the instrument department and was then transferred to Calgary. He completed his service with the company's Alberta nitrogen department in Calgary as assistant general superintendent in 1947, when he was appointed superintendent of engineering trades at Trail.

He is president of the Trail branch of the Association of Professional Engineers of British Columbia and an active member of the Trail Chamber of Commerce.

**J. E. Cranswick,** M.E.I.C., has been appointed sales manager of the apparatus and supply division of the Canadian Westinghouse Supply Company with headquarters in Toronto. He was formerly sales manager of the Canadian Westinghouse Company's industrial products division.

Mr. Cranswick joined the Westinghouse organization in 1929 after graduating in electrical engineering from the University of Manitoba. After completing the company's apprentice course he was assigned to sales work in the Alberta district. In 1944, after considerable experience with both apparatus and consumer products, he was appointed branch manager in Edmonton. In 1951 he was named central region manager of apparatus sales, and the following year was appointed sales manager for the industrial products division.

J. E. Cranswick, M.E.I.C.

Mr. Cranswick is a past-chairman of the Edmonton Branch of the Institute, and served as councillor representing that Branch in 1949.

**R. L. Morrison,** M.E.I.C., is now chief engineer of maintenance and operation of the United Electric Coal Companies in Chicago, Ill.

He was previously manager of Blairmore Iron Works in Blairmore, Alta.

Mr. Morrison is a graduate of the University of British Columbia, class of 1929.

**D. E. Ellis,** M.E.I.C., has been appointed personnel manager of The Shawinigan Water and Power Company in Montreal. He has been assistant manager of the personnel department since 1949.

Mr. Ellis was born in Ottawa. He received his B.Sc. degree in electrical engineering from McGill University in 1931, and joined The Shawinigan Water and Power Company the same year. After spending three years in training at Victoriaville, Quebec City, Shawinigan Falls and Montreal, he was assigned to the company's commercial and distribution department at Three Rivers. He subsequently became assistant distribution engineer there, and in 1945 was transferred to the personnel department in Montreal as safety engineer.

David E. Ellis, M.E.I.C.

**Leon A. Duchastel,** M.E.I.C., has long appointed assistant manager of the personnel department of The Shawinigan Water and Power Company in Montreal. He has been general personnel supervisor for the past five years.

Mr. Duchastel is a native of Montreal. He received his engineering degree from Ecole Polytechnique and is now the president of that university's alumni society. He has been with the Shawinigan organization since 1927 and has been employed on some of the first plans for hydro-electric generating stations on the upper St. Maurice River. In 1935 he was transferred to the parent power company's commercial and distribution department in the power sales division, and in 1943 was made manager of that division. He moved to the personnel department as employment supervisor in 1946.

L. A. Duchastel, M.E.I.C.

Mr. Duchastel is a past-councillor of the Engineering Institute representing the Montreal Branch.

**D. B. Leightner,** M.E.I.C., has been appointed director of manufacturing and engineering of Reliance Electric & Engineering (Canada) Ltd. in Welland, Ont. He formerly held the position of chief engineer.

Mr. Leightner is a native of Jansen, Sask. Since his graduation from the University of Manitoba in electrical engineering, he has had twenty years of experience in the engineering field, the last eight of which have been with Reliance. He was appointed chief engineer of the company in 1950.

D. B. Leightner, M.E.I.C.

He is a member of the American Institute of Electrical Engineers and the Association of Professional Engineers of Ontario.

**W. B. White,** M.E.I.C., has been transferred by Canadian National Railways from Winnipeg, Man., to the research branch of the department of research and development in Montreal, Que.

Previous to his transfer, Mr. White was assistant engineer in Winnipeg.

He is a graduate in civil engineering from the University of Manitoba, class of 1937.

**C. P. Flemming,** M.E.I.C., has been appointed director of sales for Pre-Engineered Supplies Ltd. in Halifax, N.S.

He was formerly field engineer with McDonald Construction Co. Ltd. and Nova Scotia Construction Co. Ltd. in Halifax.

Mr. Flemming graduated in civil engineering from the Nova Scotia Technical College in 1937.

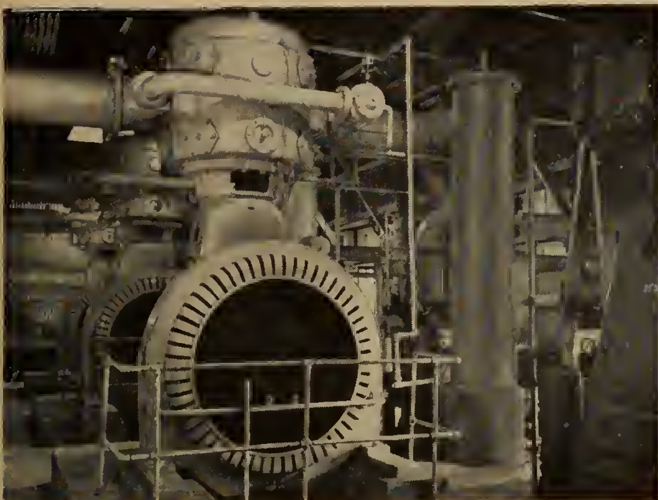
**C. W. Coote,** M.E.I.C., has been appointed assistant manager of British American Oil Co. Ltd. in Montreal.

Prior to this appointment Mr. Coote was refinery manager with The British American Oil Co. Ltd. in Calgary, Alta.

He is a graduate in chemical engineering of the University of Alberta, class of 1939.

**J. W. Morgan,** M.E.I.C., has been transferred as assistant manager of manufacturing with the British American Oil Co. Ltd. in Toronto, Ont. from Montreal, Que., where he was refinery manager.

Mr. Morgan is a graduate in chemical engineering of the University of Alberta, class of 1939.



Over 30,000 cubic feet of air per minute for drilling, and countless other jobs, was supplied by Ingersoll-Rand Compressors in batteries like this. Many of the twenty I-R XVH compressors were veterans of other Hydro projects, moved easily and economically to this location, and moved on the job to wherever required. Access shafts sunk along the tunnel line were serviced by four Canadian Ingersoll-Rand Mine Hoists. The muck hoists each handled loads of about 6,800 tons of broken rock per 24-hour day.

Wagon-mounted Drifter-drills on the canal section of the project. Similar drills cut an access road down the steep side of the Niagara Gorge to facilitate construction of the Generating Station.

*The photos on this page provide an indication of how some of the work was accomplished. The complete story of the project has been reprinted and copies can be obtained from*

**Canadian Ingersoll-Rand Company Limited**

620 CATHCART STREET, MONTREAL, QUEBEC

Ask for Form 174, "More Canadian Kilowatts at Niagara."

Huge Quarrymasters were used in drilling the 70 foot deep canal. This picture shows a drill at each side of the canal putting down line holes to obtain a solid vertical face.

Rail-mounted Jumbo, used for benching, carries 17 power-feed drifter type drills. The Jumbo is moved by air-powered "Tugger" hoists.

**G. R. Goring,** M.E.I.C., has joined the staff of the Steel Company of Canada Ltd. in Montreal.

He was formerly assistant division engineer with Consolidated Paper Corporation in Grand'Mere, Que.

Mr. Goring is a graduate in mechanical engineering of McGill University, class of 1939.

**J. D. McPherson,** M.E.I.C., has been appointed manager of the new Regina branch of Construction Equipment Co. Ltd. He was previously located in the company's Toronto office.

Mr. McPherson is a graduate in civil engineering of the University of Alberta, class of 1943.

**A. T. Girard,** M.E.I.C., is now assistant manager of the Carthage Machine Company in Carthage, N.Y.

He was formerly maintenance engineer with Brown Corporation in La Tuque, Que.

Mr. Girard is a graduate in mechanical engineering of the University of Toronto, class of 1943.

**G. A. Thompson,** M.E.I.C., has been appointed manager of Mattagami Construction Co. Ltd. in Kapuskasing, Ont.

He was formerly construction engineer with Spruce Falls Power & Paper Co. Ltd. in Kapuskasing, Ont.

Mr. Thompson received his B.A.Sc. degree from the University of Toronto in 1934.

**R. B. Wotherspoon,** M.E.I.C., formerly of the Aerocrete Construction Company Limited, has joined Imperial Chemical Industries of Canada Ltd. as senior engineer.

He is a 1935 graduate of the Royal Military College.

R. B. Wotherspoon, M.E.I.C.

**A. Nechi,** M.E.I.C., is on the engineering staff of Surveyor, Nenniger & Chenevert in Montreal, Que.

He was formerly design engineer of Cowans Engineering Co. Ltd. in Montreal, Que.

Mr. Nechi is a graduate in mechanical engineering of the University of Vienna, class of 1944.

**Dr. J. T. Hugill,** M.E.I.C., has joined the staff of Spaco Incorporated in New York.

Dr. Hugill received his B.Sc. and M.Sc. degrees from the University of Alberta in 1939 and 1940, respectively, and his Ph.D. in physical chemistry from McGill University in 1946.

He was formerly associated with the Liquid Air Company, in Paris, France.

**J. Boles,** M.E.I.C., is now manufacturing engineer in Plant No. 2 of Canadian Westinghouse Ltd. in Hamilton, Ont.

He was previously general manager of Johnson Turner Electric Repair and Engineering Company in Windsor, Ont.

Mr. Boles graduated in electrical engineering from Queen's University in 1940.

**J. G. Fitzpatrick,** M.E.I.C., is assistant general superintendent with Richard and B. A. Ryan Ltd. in Montreal.

Previous to this appointment he was Maritime manager with the company in Lancaster, N.B.

Mr. Fitzpatrick is a graduate of McGill University, class of 1944.

**H. M. Edwards,** M.E.I.C., is now on sabbatical leave from Queen's University where he has been a lecturer. During his leave of absence he will undertake postgraduate work in highway and traffic engineering at Purdue University. He will return to Queen's upon completion of this work.

Mr. Edwards is a civil engineering graduate of Queen's University, class of 1944.

**N. J. Weedmark,** M.E.I.C., is now associated with the Iindustrial Development Bank in Toronto, Ont.

He was previously assistant to the electrical superintendent of the International Nickel Company of Canada in Copper Cliff, Ont.

Mr. Weedmark graduated in electrical engineering from the University of Toronto in 1944.

**H. G. Farish,** M.E.I.C., is a project engineer with Bristol Aeroplane Engines (E) Ltd. in Montreal.

He was formerly mechanical engineer with the National Harbours Board in Montreal, Que.

Mr. Farish is a graduate in mechanical engineering of the University of London, class of 1947.

**R. F. Brooks,** M.E.I.C., has been appointed assistant superintendent of the system operating division of the Shawinigan Water and Power Company in Montreal.

He was previously assistant superintendent of Shawinigan Falls Power Developments in Shawinigan Falls, Que.

Mr. Brooks is an electrical engineering graduate of the University of New Brunswick, and joined the company as a graduate in training in 1949.

**A. I. Wotherspoon,** M.E.I.C., has been transferred from Sault Structural Steel Co. Ltd. in Sault Ste. Marie, Ont., to the Dominion Bridge Company Ltd. in Montreal.

Mr. Wotherspoon graduated in civil engineering from Glasgow University in 1949.

**M. A. Nelson,** M.E.I.C., has joined the Simpson Elevation Company in Calgary, Alta.

He was previously employed by Stock, Ramsay & Associates in Regina, Sask.

Mr. Nelson is a 1947 mechanical engineering graduate of the University of Saskatchewan.

**Ernest C. Brisco,** M.E.I.C., and **Herbert H. Todgham,** M.E.I.C., of Chatham, Ont, have changed the name of their firm from McCubbin, Brisco and Todgham to Brisco and Todgham, civil engineers and surveyors.

**M. D. Puziak,** M.E.I.C., has been appointed an associate of P. Winkiski & Associates, consulting engineers and land surveyors in Toronto, Ont.

He was previously employed by Catalytic Construction of Canada Ltd. in Sarnia, Ont.

Mr. Puziak graduated in civil engineering from the University of Lwow, Poland.

**D. Drake Oldreive,** M.E.I.C., is now design engineer with the works department of the Township of York in Toronto, Ont.

He was formerly field engineer with M. M. Dillon and Company in London, Ont.

Mr. Oldreive is a civil engineering graduate of the University of Toronto, class of 1943.

**M. F. Rodman,** M.E.I.C., who is associated with Canadian Overseas Projects Limited of Montreal, will serve for the next year with the Pakistan Industrial Development Corporation at Daud Khel, Mianwali District, in West Pakistan.

Mr. Rodman is a graduate in civil engineering of the University of Toronto, class of 1944.

**D. M. Venton,** M.E.I.C., formerly engineer of streets and sanitation for the City of Ottawa, has joined Nordic Truck and Equipment Ltd. of Weston, Ont., as sales representative in the municipal equipment division.

Mr. Venton is a graduate of civil engineering of the University of Toronto, class of 1945.

**D. K. Plummer,** M.E.I.C., former professor of electrical engineering at the University of New Brunswick, is now senior engineer with Sylvania Electric Products Inc. in Buffalo, N.Y.

Mr. Plummer is a graduate in electrical engineering of the University of New Brunswick, class of 1945.

**R. S. Lockeberg,** M.E.I.C., is now associated with B. W. Deane & Company of Montreal.

He was formerly with Canadian Ingersoll-Rand Co. Ltd. in Montreal.

Mr. Lockeberg is a graduate in mechanical engineering of Queen's University, class of 1947.

**J. E. Mallabone,** M.E.I.C., is employed as geologist with Anerada Petroleum Corporation in Calgary, Alta.

He was formerly field geologist with Imperial Oil Ltd. in Edmonton, Alta.

Mr. Mallabone graduated in geological engineering from the University of Alberta in 1948.

**Robert C. T. Stewart,** M.E.I.C., has joined Cameron Contracting Ltd. in Halifax, N.S.

He was previously associated with the Rankin Company Maritime Ltd. in Halifax, N.S.

Mr. Stewart is a graduate in civil engineering of McGill University, class of 1949.

**Frank C. O'Neill,** M.E.I.C., has entered partnership in the firm of Connor & O'Neill, engineering consultants in Halifax, N.S.

He was formerly associated with Industrial Engineering Co. Ltd. in Halifax, N.S.

Mr. O'Neill graduated in electrical engineering from the Nova Scotia Technical College in 1949.

**K. M. Mote,** M.E.I.C., of the British Cellophane Limited, Bridgewater, Somerset, England, is now in Mexico where he will be associated for the next year with Celorey, S.A., in Monterrey, Nuevo Leon.

Mr. Mote is a graduate of the Birmingham Central Technical College, class of 1949.

**J. L. Aikman,** M.E.I.C., formerly power engineer with Canadian Celanese Ltd. in Drummondville, Que., has joined Cyprus Mines Corporation in Skouriotissa, Nicosia, Cyprus, as assistant chief engineer.

Mr. Aikman received his B.Eng. degree from McGill University in 1950.

**J. H. MacDonald,** M.E.I.C., is structural engineer with Supercrete Ltd. in St. Boniface, Man.

He was formerly associated with Underwood, McLellan & Associates in Saskatoon, Sask.

Mr. MacDonald graduated in civil engineering from the University of Saskatchewan in 1950.

**Steve Hegion,** M.E.I.C., is now a consulting petroleum geologist in Regina, Sask.

He was previously associated with Well Analysis Ltd.

Mr. Hegion graduated in mining and geology from the University of Toronto in 1950.

**J. W. Davies,** M.E.I.C., formerly intermediate design engineer on the staff of the city engineer of Hamilton, Ont., is now associated with the Orillia Water, Light and Power Commission.

Mr. Davies is a 1950 graduate in civil engineering of Cardiff University.

**S. N. Bugaresti,** M.E.I.C., has joined the staff of the construction and maintenance department of the marketing division of Imperial Oil Limited in Regina, Sask.

He was previously associated with Western Dominion Coal Mines Ltd. in Taylorton, Sask.

Mr. Bugaresti graduated in mechanical engineering from the University of Saskatchewan in 1950.

**P. C. Kempe,** M.E.I.C., has been appointed plant engineer with Canadian Iron Foundries Ltd. in Hamilton, Ont.

Mr. Kempe graduated in mechanical engineering from Ballarat School of Mines in 1950.

**Aime Loranger,** AFFIL.E.I.C., is now associated with Defence Construction (1951) Ltd. on engineering inspection in Montreal.

He was previously service engineer with Accessories Machinery Ltd. in Montreal.

**S. E. Rutledge,** JR.E.I.C., formerly with Calgary Power Ltd. in Canmore, Alta., is now employed by Montreal Engineering Co. Ltd. in Montreal, Que.

Mr. Rutledge is a civil engineering graduate of the University of Alberta, class of 1946.

**Mario Tammaro,** JR.E.I.C., is now office supervisor of the engineering department of the Bell Telephone Company of Canada in Montreal, Que.

Mr. Tammaro graduated from McGill University in electrical engineering in 1947.

**B. T. Kerr,** JR.E.I.C., has been appointed president of Charles Warnock and Company, Limited in Montreal, Que.

He was formerly vice-president of Purdy & Henderson Co. Ltd. in Montreal.

Mr. Kerr is a graduate in civil engineering of Nova Scotia Technical College, class of 1947.

**Jean J. Lafleche,** JR.E.I.C., is now on the engineering staff of the City of Montreal.

He was previously associated with the Brossoit Refrigeration Co. Ltd. in Montreal, Que.

Mr. Lafleche is a civil engineering graduate of Ecole Polytechnique, class of 1947.

**R. G. Johnson,** JR.E.I.C., is president of Defence Construction (1951) Ltd. in Ottawa, Ont.

He was formerly associated with the Ford Motor Co. of Canada.

Mr. Johnson graduated in mechanical engineering from the University of Saskatchewan in 1948.

**C. W. Higgins,** JR.E.I.C., is now associated with Western Electric Co. Inc. as product engineer in Jersey City, N.J.

He was formerly sales service engineer with the Bailey Motor Company in Halifax, N.S.

Mr. Higgins graduated from the Nova Scotia Technical College in mechanical engineering in 1948.

**W. A. Thompson,** JR.E.I.C., is methods engineer with Northern Electric Co. Ltd. in Montreal.

He was previously with the Bell Telephone Co. of Canada in Montreal.

Mr. Thompson graduated from Queen's University in mechanical engineering in 1949.

**M. B. Paterson,** JR.E.I.C., has opened a private practice as a B.C. land surveyor in Vancouver, B.C.

He was previously associated with Underhill & Underhill, B.C. land surveyors in Vancouver.

Mr. Paterson graduated from the University of British Columbia in civil engineering in 1949.

**W. G. Greene,** JR.E.I.C., has been appointed supervisor of automotive equipment with the Bell Telephone Company in Montreal, Que.

Mr. Greene has been associated with the Bell Telephone Company since his graduation in electrical engineering from Queen's University in 1949.

**R. A. W. Bond,** JR.E.I.C., has joined the Canadian International Paper Company in Hawkesbury, Ont.

He was formerly associated with the Montreal Engineering Company at Chute des Georges, Que.

Mr. Bond is a graduate of London University, class of 1949.

**P. J. Newsom,** JR.E.I.C., is now design engineer with Abitibi Power & Paper Co. in Toronto, Ont.

He was formerly junior engineer with the St. Anne Paper Co. Ltd., an Abitibi subsidiary in Beaupre, Que.

Mr. Newsom is a 1949 mechanical engineering graduate of the University of Manitoba.

**J. S. Swietanski,** JR.E.I.C., has been transferred from McColl-Frontenac Oil Company Ltd. to the staff of the Trans-Northern Pipe Line Company in Toronto.

Mr. Swietanski is a graduate in mechanical engineering of McGill University, class of 1949.

**John C. Gilmore,** JR.E.I.C., formerly associated with the Gatineau Power Company in Ottawa, is now employed by the Public Utilities Commission in Port Arthur, Ont.

Mr. Gilmore graduated in electrical engineering from the University of Manitoba in 1949.

**Hedley G. Saville,** JR.E.I.C., is an electronic engineer with Radio Valve Co. of Canada Ltd.

He was formerly associated with Ferranti Electric Limited in Toronto.

Mr. Saville graduated in engineering physics from the University of Alberta in 1949.

**E. J. Penrose,** JR.E.I.C., has been appointed a management consultant with Bois, McCay and Associates in Montreal, Que.

He was previously warehouse supervisor with Dominion Tar & Chemical Co. in Montreal, Que.

Mr. Penrose graduated from McGill University in chemical engineering in 1949.

**G. L. Laycock,** JR.E.I.C., is now superintendent of the Okanagan and Similkameen division of West Kootenay Power and Light Company, Limited in Penticton, B.C.

He was previously associated with Consolidated Mining & Smelting Co. of Canada Ltd. in Trail, B.C.

Mr. Laycock is a graduate in electrical engineering of the University of Alberta, class of 1950.

**K. Colin Kent,** Jr.E.I.C., is a sales engineer with Bristol Company of Canada Limited in Montreal, Que.

Before joining the company he was associated with Johnson, Matthew & Mallory Ltd. in Montreal.

Mr. Kent graduated in electrical engineering from McGill University in 1950.

**Richard B. Parker,** Jr.E.I.C., is a research and development engineer with Canadian Celanese Ltd. in Drummondville, Que.

Mr. Parker is a graduate of the Nova Scotia Technical College in chemical engineering, class of 1950.

**F. C. Brown,** Jr.E.I.C., is assistant district municipal engineer with the Ontario Department of Highways in Kingston, Ont.

Mr. Brown is a civil engineering graduate of Queen's University, class of 1950.

**J. J. Leydon,** Jr.E.I.C., has been appointed superintendent of the Dominion Salt Company Ltd. plant at Unity, Sask.

Mr. Leydon was born in Cambridge, Mass., and received his early education in Halifax, after which he obtained his engineering diploma and B.Sc. degree from St. Mary's University in 1945. He received his B.E. degree in mechanical engineering from the Nova Scotia Technical College in 1950.

After graduating he was employed by Dominion Salt Company Ltd. at Amherst, N.S. as assistant plant superintendent, which position he held until his recent appointment.

For the past year Mr. Leydon has served as secretary-treasurer of the Amherst Branch of the Institute.

**J. J. Leydon, Jr.E.I.C.**

**P. A. Hardwick,** Jr.E.I.C., is now employed as Winnipeg branch manager by Taylor Instrument Companies of Canada Ltd.

Mr. Hardwick graduated in mechanical engineering from Nova Scotia Technical College in 1950.

**J. W. Drover,** Jr.E.I.C., has returned from Jamaica and is now associated with Saguenay Power Co. Ltd. in Isle Maligne, Que.

Mr. Drover graduated from McGill University in civil engineering in 1950.

**D. H. Rutherford,** Jr.E.I.C., has been transferred from Stone & Webster Canada Ltd. in Trail, B.C., to Stone & Webster Engineering Corporation in Roanoke Rapids, North Carolina.

Mr. Rutherford is a graduate in civil engineering of the University of Manitoba, class of 1950, and was employed for a time with the division of building research of the National Research Council in Ottawa.

**David B. Harper,** Jr.E.I.C., has been appointed senior assistant engineer with the Aluminum Company of Canada in Montreal.

He was formerly on the research staff of the mechanical engineering department of the Massachusetts Institute of Technology.

Mr. Harper is a mechanical engineering graduate of the University of British Columbia, class of 1950.

**Herman Erkku,** Jr.E.I.C., has returned to the Aluminum Company of Canada Ltd. in Arvida, Que., after post graduate study at Ecole Polytechnique.

Mr. Erkku graduated in civil engineering from Laval University in 1950.

**Raymond V. Quintal,** Jr.E.I.C., has joined the firm of Surveyer, Nenniger & Chenevert in Montreal.

Mr. Quintal graduated in civil engineering from Ecole Polytechnique in 1950.

---

**E. L. Mercer,** Jr.E.I.C., is now employed by Laminated Structures Limited in Montreal.

He was formerly associated with Timber Structures of Canada Ltd. in Peterborough, Ont.

Mr. Mercer is a 1950 civil engineering graduate of the University of Toronto.

**M. A. Jackson,** Jr.E.I.C., has joined Maloney-Crawford Tank & Service Co. Ltd. in Edmonton, Alta.

Mr. Jackson is a 1950 graduate of the University of Alberta in petroleum engineering.

**G. E. Reid,** Jr.E.I.C., is control engineer with Canadian International Paper Co. Ltd. in Three Rivers, Que.

He was formerly control engineer with Anglo Newfoundland Development Co. Ltd., in Grandfalls, Nfld.

Mr. Reid is a 1950 graduate of the University of Toronto.

**K. S. Smith,** Jr.E.I.C., is associated with Poole Construction Ltd. in Edmonton, Alta.

Mr. Smith is a 1950 civil engineering graduate of the University of Manitoba.

**Ross Taylor,** Jr.E.I.C., is now a transformer design engineer with English Electric Co. of Canada Ltd. in St. Catharines, Ont.

Mr. Ross graduated in electrical engineering from McGill University in 1950.

**H. L. Snyder,** Jr.E.I.C., is assistant engineer with the City of Kingston, Ont.

He was formerly with the C. D Howe Co. in Chalk River, Ont.

Mr. Snyder graduated in civil engineering from McGill University in 1950.

**F. G. Holyroyd,** Jr.E.I.C., is design engineer with Foundation of Canada Engineering Corporation in Montreal.

He was previously field engineer with C. D. Howe Company in Montreal.

Mr. Holyroyd is a graduate of the University of Manchester, class of 1950.

**Martin McGregor,** Jr.E.I.C., is engaged in concrete design and detailing with Cowin & Company in Winnipeg, Man.

Mr. McGregor graduated in civil engineering from the University of Manitoba in 1951.

**J. B. Motta,** Jr.E.I.C., is now sales engineer with Canadian General Electric Co. Ltd. in Toronto, Ont.

Mr. Motta graduated in mechanical engineering from the University of Saskatchewan in 1951.

**W. R. Coles,** Jr.E.I.C., has transferred from the Aluminum Company of Canada Ltd. in Vancouver, to Demerara Bauxite Co. Ltd. in MacKenzie, British Guiana.

Mr. Coles graduated in civil engineering from McGill University in 1951.

**S. Olenik,** Jr.E.I.C., is now on the power plant engineering staff of Trans-Canada Air Lines in Winnipeg, Man.

He was formerly design engineer with A. V. Roe (Canada) Ltd. in Malton, Ont.

Mr. Olenik is a 1951 mechanical engineering graduate of the University of Manitoba.

**J. H. A. Lavallee,** Jr.E.I.C., is associated as plant engineer with the Bell Telephone Company of Canada in Montreal.

Mr. Lavallee is a 1951 civil engineering graduate of Ecole Polytechnique.

**R. D. Mignault,** Jr.E.I.C., is now employed by C. D. Howe Co. Ltd. in Montreal.

Mr. Mignault graduated in electrical engineering from McGill University in 1951.

**D. E. Quail,** Jr.E.I.C., has been transferred by Shell Oil Company of Canada, Ltd. from Vancouver, B.C., to Toronto, Ont.

Mr. Quail is a 1951 mechanical engineering graduate of the University of British Columbia.

**W. G. Gerry,** Jr.E.I.C., has joined Haddin, Davis and Brown in Calgary, Alta.

Having completed his studies toward his M.Sc. degree in civil engineering from the Colorado A. & M. College, he was employed for a time with Burn & McDonnell, consulting engineers.

Mr. Gerry graduated in mechanical engineering from the University of Toronto in 1951.

**John K. Cavers,** Jr.E.I.C., has recently joined F. D. Bolton Ltd. as sales engineer in Vancouver, B.C.

A mechanical engineering graduate of the University of British Columbia, class of 1951, Mr. Cavers was previously associated with Canadian General Electric and Bepco Canada Ltd. He will now be responsible for the sale of electrical apparatus including transformers, circuit breakers, and motors in the British Columbia area.

**John K. Cavers, Jr.E.I.C.**

**Robert Hunter Dunn,** Jr.E.I.C., is now associated with Dominion Tar & Chemical Ltd. in Toronto.

He was previously with the Fraser-Brace Engineering Company in Montreal.

Mr. Dunn is a graduate in civil engineering of McGill University, class of 1951.

**R. S. Taylor,** Jr.E.I.C., is employed as field engineer with Central Mortgage and Housing Corporation at the Comox airport in Cumberland, B.C.

Mr. Taylor is a graduate in civil engineering of the University of British Columbia, class of 1951.

**C. T. Taylor,** Jr.E.I.C., is special projects engineer for the City of Edmonton, Alta.

Mr. Taylor graduated from the University of Alberta in civil engineering in 1951.

**A. G. Westaway,** Jr.E.I.C., has been promoted to the position of plant engineer for Clayburn Co. Ltd. in Abbotsford, B.C.

Before his promotion he was assistant plant engineer.

Mr. Westaway is a 1951 mechanical engineering graduate of the University of British Columbia.

**W. T. Haggert,** Jr.E.I.C., has been named president of Engineering Associates (Western) Ltd. in Vancouver, B.C.

Prior to joining the company, Mr. Haggert was associated with International Engineering Co. Ltd. in Vancouver.

He is a graduate of the University of British Columbia in electrical engineering, class of 1951.

**Howard A. Bradley,** S.E.I.C., has joined Cartier Construction Ltd. at Labrieville, Que.

He was formerly junior office engineer with Stone & Webster Engineering in Toronto, Ont.

Mr. Bradley is a 1949 graduate in civil engineering of the University of Toronto.

**James F. Longley,** S.E.I.C., has joined the staff of the department of civil engineering of Queen's University as a lecturer.

He was previously associated with Canadian International Paper Company in Temiskaming, Que.

Mr. Longley is a 1953 graduate in civil engineering of Queen's University.

**John R. Jenkins,** S.E.I.C., has been transferred by the Petroleum and Natural Gas Conservation Board to Calgary, Alta., as assistant gas engineer.

He was previously located in Lloydminster, B.C.

Mr. Jenkins is a 1953 chemical engineering graduate of the University of Alberta.

**Douglas Walker,** S.E.I.C., has joined the staff of the structural steel department of Dominion Structural Steel Ltd. in Toronto, Ont.

Mr. Walker graduated in 1953 from McGill University in civil engineering.

**James C. Gilley,** S.E.I.C., is now with Northern Construction Ltd. at Goldbridge, B.C.

He was previously with the Canadian Bechtel Company in Vancouver, B.C.

Mr. Gilley graduated from the University of British Columbia in civil engineering in 1953.

**Murray E. McRae,** S.E.I.C., is construction superintendent with Storm Construction Co. Ltd. in Toronto, Ont.

Mr. McRae graduated in civil engineering from McGill University in 1953.

## Win Overseas Fellowships

**Jean Paul Dick,** S.E.I.C., Laval University, **D. D. Jack,** S.E.I.C., University of British Columbia, and **P. K. Lauren,** S.E.I.C., and **J. B. Haworth,** S.E.I.C., of McGill University, sailed to England during August to start training under English Electric fellowships.

Graduates of this year's engineering classes, they are in a group of six students, who will train for two years in the various works of the Company in England, with the object of obtaining a knowledge of British engineering skills and equipment. They will return to Canada for employment in the Scarborough, Toronto and St. Catharines plants of John Inglis Co. Limited and English Electric Company of Canada Limited.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Charles Michael Morssen,** M.E.I.C., founder and former president of the Atlas Construction Company in Montreal, Que., died on May 13, 1954, at the Hotel Dieu Hospital after a brief illness.

Mr. Morssen was born in Jankowse, Austria, on January 6, 1872. He obtained his B.Sc. degree with honours from the government college at Lemberg, Austria in 1892 and four years later received his diploma in civil engineering from Ecole Nationale des Ponts and Chaussees in Paris.

Upon graduation he served as a lieutenant in the technical regiment of railroads and telegraphs of the Austrian Army, and a year later joined the government railroad as assistant engineer in Lemberg, during which time he was engaged in the construction of a line between Teresin and Skala. The following year he was appointed engineer in charge of construction of a 16-mile line between Kolomyjer and Hefanowka. He joined the Hennebique Construction Company as engineer and designer in Paris in 1900 and a year later he became engineer and general manager of the company's branch office in Lemberg. During this period he designed and built 50 bridges for the Austrian Government, as well as many water tanks, heavy foundations and factories.

Mr. Morssen came to the United States in 1906 and was employed for six months with the Underwriters Engineering Company in New York, during which time he designed a powerhouse for Seattle, a factory for Troy, N.Y., and a retaining wall for Hamilton, Ohio.

He then came to Canada to join the Hennebique Company in Montreal where he was engaged in the construction of the Southam Building.

In 1908 he opened his own contracting and engineering offices in Montreal under the firm name of Morssen & Company.

He subsequently founded the Atlas Construction Company in Montreal and served as the company's consulting engineer and president for more than 20 years. Mr. Morssen retired a few years ago.

Mr. Morssen was closely associated with the late Dean Ernest Brown of McGill University. Together they built the *Concretia,* the first self-propelled concrete ship launched on the American continent in November, 1917.

He was an Associate Member of the American Society of Civil Engineers and a governor of the Montreal General and Queen Elizabeth Hospitals.

A winner of the Gzowski Medal of the Engineering Institute, Mr. Morssen joined the Institute as an Associate Member in 1909 and transferred to Member in 1914. On January 1, 1947 he was granted Life Membership in the Institute.

**James Macgregor Forbes,** M.E.I.C., chairman of the Alberta Assessment Commission, died in hospital on May 21, 1954, after a lengthy illness.

Mr. Forbes was born in Callander, Scotland, on January 21, 1891. He attended the McLaren High School there and completed the Stirling High School technical course during which time he also served as apprentice for five years with Messrs. R. W. Christie & Davidson, civil engineers in Dunblane, Scotland.

He came to Canada in 1912 and joined the engineering staff of the Canadian Northern Railway as assistant to the division engineer. Two years later he was engaged on railway location work as leveller and draughtsman.

In 1917 he joined the provincial civil service as engineer in charge of drainage work at Holden, Daysland, Bawif and Hay Lake. He transferred to the Department of Highways in 1924 as a resident engineer on construction work and later became district engineer.

In 1946 Mr. Forbes became director of assessments, administrator of the Communal Property Act and chairman of the Alberta Assessment Commission. He held the two latter offices at the time of his death.

Mr. Forbes was a member of the Association of Professional Engineers of Alberta. He joined the Engineering Institute of Canada as an Associate Member in 1920, transferring to Member in 1940.

**Ronald Morrison McKinnon,** M.E.I.C., former commissioner of works for the City of Halifax, N.S., died on April 23, 1954.

Mr. McKinnon was born at Sydney River, Cape Breton, N.S. on May 22, 1885. He received his B.Sc. degree from Dalhousie University and the Nova Scotia Technical College in 1912.

After graduation he was appointed assistant city engineer for the City of Sydney, and four years later became acting city engineer, and subsequently, city engineer.

After serving with the City of Sydney for nearly 20 years, Mr. McKinnon went to Halifax, N.S. in 1930 to join the city works department. In 1940 he was appointed deputy commissioner of works, succeeding W. J. DeWolfe, and a year later, he was named commissioner of works, succeeding H. W. Johnston. It was under Mr. McKinnon's direction that the City took steps to assure itself of adequate reserve water supplies. The booster pump at Dutch Village Road was installed to increase water pressure from Chain, Long and Spruce Lakes, and Big Indian Lake was hooked up for reserve supply. In addition to holding the position of commissioner of works, Mr. McKinnon also served the City as building inspector for many years. He retired from the works department in 1951.

Mr. McKinnon joined the Engineering Institute of Canada as an Associate Member in 1921 and transfered to Member in 1940.

**Clifford Rutherford Kinnear,** M.E.I.C., former assistant engineer of way with the Toronto Transportation Commission, died on February 15, 1954.

Mr. Kinnear was born in Halifax, N.S., on January 26, 1882. He received his education at Kings Collegiate School in Windsor, N.S., and through the International Correspondence Schools.

Between 1902 and 1921 Mr. Kinnear was associated with the engineering departments of the Halifax Electric Tramways Company, the Pittsburgh Railways Company and the Montreal Tramways Company.

He joined the Toronto Street Railway Company as office engineer in 1921. In 1930 he was appointed assistant engineer of way, the position he held at the time of his retirement in 1949.

Mr. Kinnear joined the Engineering Institute of Canada as an Associate Member in 1921 and transferred to Member in 1936. He attained Life Membership in the Institute in January of this year.

**Casper Dull Meals,** M.E.I.C., chief engineer of the wire rope division of the Bethlehem Steel Company, died at his home in Williamsport, Pa., on April 27, 1954.

Mr. Meals was born in Harrisburg, Pa., on April 15, 1891. He received his technical high school education there and at the Drexel Institute in Philadelphia. He also had private tutoring in mathematics, mechanics, strength of materials, machine design and structural engineering for seven years.

In 1911 he joined John A. Roeblings & Sons as draughtsman in Trenton, N.J. Eight years later he was appointed assistant engineer.

In 1922 he became associated with Wilcox, Crittenden & Company in Middleton, Conn., and in 1923 entered the Bethlehem Steel Company as structural draughtsman in Bethlehem, Pa. He spent the following year as sales engineer with the American Cable Company, and in 1926 he was named assistant chief engineer of the company, becoming chief engineer in 1927.

Mr. Meals joined the New York Cordage & Cable Company as chief engineer and general manager in 1930, and within the same year became president and general manager of the Wire Rope Corporation of America in New Haven, Conn.

He came to Canada in 1931 as wire rope engineer with B. Greening Wire Company Limited in Hamilton, Ont. He remained in Hamilton for six years before returning to the United States as chief engineer of the wire rope division of the Bethlehem Steel Company in Williamsport. He continued in this position until the time of his death.

Mr. Meals joined the Engineering Institute as a Member in 1935.

**Henry Lewis Schermerhorn,** M.E.I.C., county engineer for Lennox and Addington, Ont., died on March 19, 1954.

Mr. Schermerhorn was born in Selby, Richmond Township, on May 2, 1895. He attended the Napanee Public School and the Napanee Collegiate. He served with the Royal Air Force during World War I and afterwards attended Queen's University.

Having worked during the summers as rodman with the Ontario Department of Highways, he joined the department on a permanent basis in 1921. He remained with the department for 16 years, becoming district engineer for municipal roads.

In 1937 he became roads engineer for the County of Lennox and Addington.

He enlisted in 1941 in the Canadian Army and was in the first class to graduate from the officers' training course at Brockville, Ont. He served with the Royal Canadian Engineers for three and a half years, and upon his discharge, returned to his duties as county engineer.

Mr. Schermerhorn was chairman of the building committee of the Napanee and District Community Centre. He was a member of the Association of Professional Engineers of Ontario.

He joined the Engineering Institute as an Associate Member in 1937 and transferred to Member in 1940.

**Francis W. Clark,** M.E.I.C., who retired recently from the generation department of the Hydro-Electric Power Commission of Ontario in Toronto, died in the Toronto Western Hospital on June 7, 1954.

Mr. Clark was born in St. Paul, Minn., on January 23, 1887. He received his early education at the Harbord Collegiate in Toronto, and graduated from the School of Practical Science (University of Toronto) in 1911.

Before entering the School of Practical Science, Mr. Clark served for a year as chainman and rodman on construction with the Canadian Pacific Railway. In 1909 and 1910 he was employed as chainman and instrumentman on the first transmission lines and substations of the Hydro-Electric Power Commission of Ontario.

In 1911 Mr. Clark served as assistant engineer with the International Waterways Commission.

He returned to the Hydro-Electric Power Commission in 1913 and was placed in charge of surveys of the Lake of the Woods and the Grand River for regulation and flood control purposes, respectively. In 1914 and during the ten ensuing years he was engaged on preliminary surveys and the construction of the Queenston development, and served as division engineer on construction for the river and canal sections. In 1924 he was employed on surveys and preliminary studies on the Ottawa River from Mattawa to Carrillon for power development purposes, and in 1927 he made reconnaissance surveys of the Mississagi and Montreal (Algoma) Rivers.

Mr. Clark was appointed resident engineer on the construction of Lac Seul conservation dam and first powerhouse at Ear Falls in 1928. This was the most northerly work undertaken by the Commission up to that time.

From 1930 until 1939 he was engaged in surveys of the Nipigon River from Pine Portage to Lake Nipigon, on general hydraulic work in the Toronto office, including small surveys on the Wahnapitae and English Rivers, on surveys of Madawaska River, particularly at Stewartville, Barrett Chute and Bark Lake, and on field investigations and the preparation of a report on the control of the Thames River.

In 1939 he undertook at the Toronto office general administrative work dealing mainly with negotiations and the preparation of agreements and leases with outside concerns. He continued with this work until his retirement in March, 1954, at which time he had completed more than 42 years of service in the Commission's hydraulic and development department.

Mr. Clark joined the Engineering Institute as a Member in 1940.

**Charles Gordon Hutton,** M.E.I.C., vice-president and general manager of Heaps Waterous Limited in New Westminster, B.C., was killed instantly as the result of the Trans-Canada Air Lines and Harvard trainer collision over Moose Jaw, Sask., on April 8, 1954.

Mr. Hutton was born in Burnaby, B.C., on December 24, 1910. He received his education at the Kingsway West Public School and the T. J. Trapp Technical School in New Westminster, and in 1928 became an apprentice machinist with Heaps Engineering Company Limited. He was promoted to the position of general machinist in 1932.

Mr. Hutton became draughtsman and estimator in 1934 and was named chief draughtsman of the company the following year. In 1940 he was appointed designer and chief engineer of the succeeding company, Heaps Engineering (1940) Limited.

In the years that followed, Mr. Hutton occupied the positions of production and sales engineer, executive assistant to the president, sales manager and chief engineer, and chief engineer and technical sales supervisor, vice-president and general manager of the firm.

**C. G. Hutton,** M.E.I.C.

Mr. Hutton was a member of the Association of Professional Engineers of British Columbia.

He joined the Engineering Institute of Canada as a Member in 1948.

**David Franklin Bond,** M.E.I.C., died as the result of an automobile accident near Chester, England, on May 11, 1954.

Mr. Bond was born in Regina, Sask., on November 3, 1923. He received his high school education in Calgary, Alta.

After serving with the Royal Canadian Air Force as a flying officer during the Second World War, he attended the University of Alberta where he graduated with a B.Sc. degree in electrical engineering in 1950.

He was employed by the Saskatchewan Power Corporation in Regina and last July obtained a bursary from English Electric Company Limited and proceeded overseas for special field work.

He was a member of the Association of Professional Engineers of Saskatchewan.

Mr. Bond joined the Engineering Institute of Canada as a Junior in 1952 and transferred to Member in 1953.

**Michael George Duval Hawkes,** S.E.I.C., sales and service engineer with Picker X-Ray of Canada Limited in Edmonton, Alta., died on February 16, 1954.

Mr. Hawkes was born at Greencourt, Alta., on November 11, 1918. He received his early education there and in 1939 joined the Canadian Army. He served overseas with the Second Division of the Canadian Corps of Signals and was awarded the Certificate of Merit by General Montgomery for outstanding service.

At the close of the war, Mr. Hawkes attended the University of Alberta. During the summer of 1948 he worked for the City of Edmonton in the engineering department, and during the summer of 1949 he was employed by the Department of Communications in Ottawa.

During the summer of 1950 he joined Picker X-Ray of Canada Limited as a sales and service engineer working out of Edmonton. While working for this company he contracted polio, and was an iron lung patient for many months.

The University of Alberta at its 1954 spring convocation honoured Mr. Hawkes posthumously with the B.Sc. degree in electrical engineering.

Mr. Hawkes joined the Engineering Institute of Canada as a Student Member in 1950.

# Employment Service

**THIS SERVICE is operated for the benefit of members of The Engineering Institute of Canada and for industrial and other organizations employing technically trained men—without charge to either party. It would be appreciated if employers would make the fullest use of these facilities to list their requirements—existing or estimated.**

**NOTICES appearing in the SITUATIONS WANTED column will be discontinued after three insertions. They will be reinstated, on request, after a lapse of one month.**

**REPLIES to advertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Canada, 2050 Mansfield Street.**

**INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLateau 5078—may be arranged by appointment.**

## SITUATIONS VACANT

### CHEMICAL

CHEMICAL ENGINEER required 1954 graduate with pulp and paper experience. Investigation of paper quality or production problems on both laboratory and mill scale, analysis of test data, development of test methods, etc. Working under the divisional chemist. File No. 4864-V.

GRADUATE CHEMICAL ENGINEER from Canadian University required by manufacturer of organic chemical products. Attractive opening in new project located in Ontario. Several years of practical experience in production and process development is required. File No. 4900-V.

CHEMICAL ENGINEER required to work in control department of paper mill located in Province of Quebec. Graduate from a Canadian or British University. Pulp and Paper experience desirable but other chemical engineering experience would be acceptable. File No. 4915-V.

### CIVIL

ASSISTANT CHIEF ENGINEER wanted for large construction company. Applicant must have thorough knowledge and experience in reinforced concrete design capable of estimating buildings, road construction and all branches of general construction work. Excellent salary to the right man. Good prospects for the future. Do not apply unless you are thoroughly experienced. File No. 4853-V.

CIVIL ENGINEER REQUIRED by the technical co-operation service department of Trade and Commerce, Ottawa, Canada, to serve in Burma. The union of Burma has plans for an expansive scheme in Hydro Electric development. The engineer should be Canadian and will act as special advisor to the chairman of the Burmese electricity supply board to review the designs and specifications and supervise general construction. Salary would be in the range of $14,000 to $17,000 per annum. Free furnished accommodations, cost of internal travel, free hospital and medical treatment. File No. 4857-V.

ENGINEER CIVIL PREFERABLY, wanted for young progressive construction company. Preferably one with experience in sewage and water supply as well as cement work as we are specializing more in this line of work. When replying, please state age, graduation and experience. File No. 4865-V.

QUALIFIED ENGINEER required as principal Ahsanullah Engineering College, Dacca, Pakistan. Candidate should possess a good honours degree in civil engineering from a recognized University. He must have enough of practical experience of actual execution of large projects, and their organization, and teaching and administrative experience in a recognized engineering institution. Candidate should preferably be 45 years of age or thereabouts. Further information apply file number 4878-V.

THE CITY OF MONCTON N.B. invites applications from engineers preferably with municipal experience, for service in the city engineers office. In reply please give details of experience, including any service with H.M. Forces and indicate salary required. File No. 4887-V.

GRADUATE CIVIL ENGINEER for company in Brazil as technical assistant for chief planning. Age around 40, with 5 years experience in: 1) preparing and completing preliminary and basic studies and layouts of hydro electric developments for consideration as to technical and economic feasibility; 2) analyzing and evaluating hydrological topographical and geological data with relation to power development studies; 3) determining survey work required. Position requires engineer of maturity and judgment with teaching experience and leadership ability. File No. 4888-V.

CONSTRUCTION DEPARTMENT OF prominent oil company with headquarters in Maritimes requires experienced man to supervise construction of bulk plant facilities and pipelines. Position has an excellent potential. Please write details. and if possible enclose photo. File No. 4889-V.

CIVIL ENGINEER required with experience in municipal engineering including the design and supervision of water supply and sewage road construction, subdivision design and related work. Permanent position and the salary would be commensurate to the qualifications and experience. Location Toronto. File No. 4909-V.

THE TOWN OF BRIDGEWATER, Nova Scotia, requires the services of an experienced civil engineer for regular municipal services. Reply stating age, municipal experience, and when available to File No. 4921-V.

SALES ENGINEER for promotion and sales in professional field. Background in structures and/or construction. Preferred age early thirties. Location Ontario. File No. 4922-V.

GRADUATE CIVIL ENGINEER with about 2 years experience required by major oil company. Duties include job inspection; service stations, bulk storage depots and marine terminals. Preferably bilingual but not necessary. Territory Quebec and Eastern Ontario. File No. 4932-V.

CIVIL GRADUATES. Recent graduates in Civil Engineering required by structural steel firm, Montreal. Men to be employed in Engineering Department. Experience in structural steel design of advantage but not necessary. Chances of advancement excellent. File No. 4938-V.

### ELECTRICAL

ELECTRICAL ENGINEER with several years experience required mainly with experience on production engineering of electronic equipment. Salary would be commensurate with the applicant's experience and qualifications. File No. 4862-V.

ELECTRONIC ENGINEERS required for attractive positions. Degree in electrical engineering or equivalent, 5 to 10 years general experience with 1 to 5 years specific radar experience. Supervisory ability, able to maintain liaison and work efficiently under pressure. Canadian citizenship or British nationality a requisite. Attractive employee benefits. File No. 4874-V.

SENIOR ELECTRONIC ENGINEER with degree in physics or electronics from a recognized university with at least five years experience in electronic circuit design. British subject preferred. Salary commensurate with ability. Send resume to File No. 4877-V.

ELECTRICAL ENGINEER (Electronics) required by major worldwide electronics organization. Present opening for a fully experienced electrical engineer to do project development work on monochrome T.V. The successful candidate must have a minimum of 3 years in T.V. receiver design and 10 years in electronics in general. Salary will be commensurate with ability. Reply in writing, stating details of age, experience, education and salary desired. All applications will be held in strictest confidence. File No. 4892-V.

JUNIOR ELECTRICAL ENGINEER — single, 25 to 30 years of age with 1-5 years experience in metering department of a large public utility or manufacturer. Location Rio de Janeiro, Brazil. File No. 4898-V.

GRADUATE ELECTRICAL ENGINEER wanted as demonstrator in the electrical engineering department, University of Toronto for the session 1954-55. Session commences on September 20, 1954 and extends seven months. File No. 4911-V.

ELECTRICAL SALES ENGINEER required by manufacturer of switchboards high and low tension, panelboards, busways and switches to cover

territory East of Province of Quebec and Maritimes. Bilingual preferred. Opportunity for the right man to become district sales manager. File No. 4918-V.

ELECTRICAL ENGINEER required to take charge of draughting and inspection of switchboards, panelboards, busways, switches, etc. Location Province of Quebec. Bilingual preferred. Opportunity for right man to become plant superintendent. Previous practical experience preferred. Permanent position, salary depending upon qualifications. File No. 4918-V.

ELECTRICAL ENGINEER required by paper mill located in the Province of Quebec. Well qualified engineer to act as assistant electrical superintendent. File No. 4925-V.

PROJECT ENGINEER to join a rapidly expanding company which is a leader in the electronics field and offers scope for advancement. Applicant should be graduate in Electrical Engineering with a minimum of 2 years experience in Television designing, and the development of television and radio receivers, a knowledge of production manufacturing and production processing desirable. Excellent working conditions and a complete programme of employee benefits. Salary is open for discussion. File No. 4927-V.

LARGE ALBERTA ELECTRICAL wholesale firm will, due to retirement, require an executive, qualified as an electrical engineer about 45 years of age. Must be a first rate administrator, now holding a very responsible position and able to manage a large portion of the company. A substantial investment in this company, will be made available to a top man with proper qualifications, personally and technically. File No. 4930-V.

# National Research Council Canada

requires at Ottawa

a

# Health and Safety Engineer

Under direction, to develop a program of safety consciousness throughout the laboratories of the Council.

The duties will include the investigation of potential accident and health hazards, accidents and fires, and the recommendation of safety measures.

Graduation in Engineering, Chemistry or Physics, from a university of recognized standing is required; must be physically fit, and have several years' experience in technical work; safety engineering experience desirable but not essential.

Initial salary will depend on qualifications.

Apply to the Employment Officer, National Research Council, Sussex Street, Ottawa 2, Ontario, giving full details of qualifications and experience.

PROCESS ENGINEER with about ten years manufacturing experience preferably in the electrical industry. He would report to the works manager and would be responsible for methods and cost reduction studies, plant layout work and the supervision of time study, tool room and maintenance departments. A knowledge of sheet metal work, plastic moulding, metal finishing, assembly operations, material handling, etc., is desirable. The salary would depend upon the applicant's qualifications. File No. 4931-V.

### MECHANICAL

CHIEF MECHANICAL ENGINEER, salary up to $7,200., required by Department of National Defence, Ottawa. Details and application forms at your nearest Civil Service Commission Office, National Employment Office and University Placement Office. Quote Competition No. 54-1204. File No. 4855-V.

MECHANICAL ENGINEER required as product designer. Recent graduate with Canadian background for training in spring and hydraulic components design, one year experience in production and general machine shop practices desirable. Location in Montreal. Write giving full particulars of training and experience. File No. 4884-V.

TOOL DESIGNER REQUIRED, mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools, light, sheet dies, forging dies, fixtures, jigs and gauges. Canadian background required. Location in Montreal. Write giving full details of training experience and state salary desired. File No. 4884-V.

cation surveys and selling same. Position has an excellent potential. Please write details and if possible enclose photo. File No. 4889-V.

MECHANICAL ENGINEER required in Edmonton Alberta who has graduated from a recognized Canadian University, and who has about five (5) years experience in a chemical plant or refinery. He will deal mostly in equipment used in the manufacture of petrochemicals and synthetic fibres. Duties will consist of general engineering, which will include design, layout, estimating and some administration. Must be able to handle project work and general plant engineering problems. File No. 4891-V.

MECHANICAL ENGINEER required who has had practical experience in structural design. He will be required for commercial vehicle designing particularly. This is a good opportunity with a sound future. Location Ontario. File No 4893-V.

GRADUATE MECHANICAL ENGINEER required as assistant to engineering superintendent of large manufacturing company. Administrative qualities and thorough knowledge of modern maintenance control methods are required together with practical experience in the maintenance and installation of pumps, ventilation and steam and refrigeration systems. Age 30-35. File No. 4912-V.

MECHANICAL ENGINEER, $4,100.00-$5,820.00 for Post Office Department, Montreal, P.Q. Details and application forms at your nearest Civil Service Commission Office, Post Office or National Employment Office. File No. 4916-V.

PRODUCTION MINDED ENGINEER required as assistant production manager after suitable training period in paper converting firm about 60 miles from Montreal. A recent graduate, preferably but not necessarily, mechanical who is bilingual would best meet our requirements. Adequate recreational and housing facilities available. An outstanding opportunity for an engineer to acquire experience in production and apply his training to methods and management problems with excellent future prospects. File No. 4923-V.

MECHANICAL ENGINEER to act as Assistant to plant superintendent required by large bottling plant in Montreal. Recent graduate preferred with some plant experience. File No. 4929-V.

WANTED GRADUATE MECHANICAL ENGINEER with several years experience for work on design of steam power plants and industrial steam plants. South Eastern Ontario location. State full details, your letter will be treated in strictest confidence. Our Staff knows of this ad. File No. 4933-V.

### MISCELLANEOUS

YOUNG CIVIL OR MECHANICAL engineer required by a pulp and paper company in Quebec. Applicant should have a minimum of three years experience in engineering and maintenance preferably in the pulp and paper industry. Applicant should be fluent in either French or English and should be able to get along in both. Replies should outline qualifications, experience age and salary expected. File No. 4768-V.

THREE SALES ENGINEERS required by manufacturer of multiwall Kraft bags and related paper products. 1954 graduates to 3 years of experience. Training period in Montreal. Subsequent work in variety of locations. File No. 4777-V.

CIVIL AND/OR MECHANICAL engineer required by a firm of consulting engineers in Western Ontario. Preference given those with experience in municipal engineering and sewage treatment plant design, or commercial and industrial building design. This position can lead to an interest in the firm if qualifications are sufficient. All replies treated with strict confidence. Please provide complete outline of experience and background with first letter. File No. 4854-V.

RESEARCH PHYSICIST or engineer required by the Pulp and Paper Research Institute of Canada to take charge of a long-range project now being initiated on the fundamentals of mechanical pulping, i.e. the factors governing the mechanical separation of paper making fibres from wood. Necessary qualifications will include a post-graduate physics or engineering degree with emphasis on mechanics and mathematics; experience in planning, executing, and reporting research projects, and the ability to confer with mill staffs on the practical data pertinent to the problem. Salary will be commensurate with training and experience. File No. 4856-V.

ENGINEER REQUIRED by paper board converter organization manufacturing a wide variety of cardboard containers and special packaging. Duties include a considerable amount of machine design and in addition to investigate a preventative maintenance program to cover all production equipment. Applicant should be prepared to continue on as assistant engineer in the engineering department. Salary would be based on qualifications. The location will be London, Ontario. File No. 4858-V.

SENIOR TIME STUDY engineer required by a progressive plant in south Western Ontario. A production engineer 28 to 35 years of age to head their time study department. Applicants should state experience, age and salary expected. File No. 4871-V.

SALES ENGINEER wanted by established transformer manufacturer, for Montreal district. Bilingual preferred. State age, education, experience and salary required. File No. 4873-V.

FOUNDRY METALLURGIST required by large manufacturing concern in Montreal, operating steel cast iron and bronze foundries. Experience desirable but not essential. File No. 4876-V.

LECTURER REQUIRED in an expanding department. Subjects economic geology, geomorphology, stratigraphy, M.A. desirable. University year September 15 to May 15. Salary range $2500 to $3,000. File No. 4880-V.

ENGINEER REQUIRED by consulting firm located in Calgary, Alberta. Minimum 5 years experience in sales and foundations with some post graduate training. Applicant should state age, summary of experience and salary expected. File No. 4883-V.

GRADUATE CHEMICAL or mechanical engineer required with two to five years experience on industrial maintenance work. As project engineer duties include the maintenance of the buildings and equipment of the plant, including some design work in the nature of alterations and improvements. Location Province of Quebec. File No. 4885-V.

YOUNG ENGINEER either mechanical or electrical to assist in the design and manufacture of blueprinting and white printing. Location Ontario. File No. 4894-V.

TWO INSTRUCTORS required to divide the following subjects: tool design, manufacturing analysis, metrology, engineer drawing and strength of materials; applicants should have a genuine interest in teaching at the junior college level and have had some industrial experience. They should be Professional Engineers with either a degree or the Higher National Certificate. These positions lead to a permanent appointment in the Ontario Civil Service providing a three week annual vacation, adequate superannuation and sick leave benefits. File No. 4895-V.

CANADIAN SALES REPRESENTATIVE, preferably a professional engineer required with successful sales record to industrial organizations. Must have knowledge of materials handling, dust collection and fume disposal equipment. Work can be undertaken in conjunction with other activities if desired. Exclusive territory. File No. 4896-V.

STRESS ENGINEER graduate in mechanical or civil engineering, with two or three years experience in stress analysis of steel structures and machinery. Required by manufacturer in the Montreal area, opportunity for varied experience in the stress analysis of heavy machinery and structures. Salary commensurate with experience. File No. 4897-V.

A CIVIL OR MECHANICAL engineer preferably with knowledge of soil mechanics and some practical experience to work on the engineering aspects of snow and ice research, especially on field studies of ice and snow. A Physicist or Engineering Physicist with M.Sc. or Ph.D. degree to assist with the research programme. Positions are in connection with the completion of special laboratory facilities for snow and ice research in the new building, Research Centre, Ottawa. Salaries will depend on training and experience. The opening provides challenging opportunities in a new field of work. File No. 4899-V.

YOUNG ENGINEERS for industrial engineering training in the textile industry in Ontario. Besides technical ability work will require ability to sell ideas and to deal successfully with mill personnel. Replies should outline experience, age and salary expected. File No. 4901-V.

ELECTRICAL UTILITY has opening for two junior electrical engineers or engineering graduates in Halifax, N.S. The work will provide opportunities for advancement along both technical and administrative line. Applicants should have a university degree and not over three years post graduate experience. File No. 4904-V.

HEATING VENTILATION AND air conditioning specialists. Salaries up to $7,200 per annum. Department of Public Works. Transport and National Defence at Ottawa. Details and application forms at your nearest Civil Service Commission Office and National Employment Office. No. 54-1209. File No. 4905-V.

ELECTRICAL ENGINEERS (electronics and radar), salaries up to $6,840. per annum. Department of National Defence and Post Office Department, Ottawa. Details and application forms at your nearest Civil Service Commission Office. and National Employment Office. No. 54-1150. File No. 4906-V.

PROJECT ENGINEER, process-instrument engineer, and piping layout draughtsmen required by consulting firm located in Niagara Peninsula. Applicants must have considerable experience in refinery and chemical plant design and construction. Please write stating qualifications and full details to File No. 4910-V.

MECHANICAL OR ELECTRICAL ENGINEER with education equivalent to graduation in engineering and at least four and preferably six years of engineering experience. Must be registered professional engineer. Experience in plant maintenance and plant engineering is desirable, as well as experience in job installation supervision and in layout and design. Duties will consist of preparation of equipment layout for supermarkets and supermarket renovation and warehouse; plans for refrigeration, air conditioning, ventilation, plumbing, electrical, etc. for supermarkets, supervision of mechanical plans prepared by consultants and correlation of these plans with architectural plans; calling of tenders for mechanical trades; the preparation of maintenance work orders for field forces and minor amount of field supervision. File No. 4914-V.

PATENT OFFICER REQUIRED at Ottawa. The successful applicant will be required to undertake various duties dealing with patent applications in the electronic field. University graduation in engineering physics, electrical engineering or physics, with specialization in electronics is required. Pertinent experience desirable but not essential. Initial salary up to $4620.00 per annum depending on qualifications.

Apply by letter giving full details of education and experience. File No. 4917-V.

FIRE PROTECTION ENGINEER required for employment on a national basis in Canada preferably with headquarters at Ottawa, under direction of a group of regional and national forest industry associations to design and carry out fire research on all phases of the fire protection problem in Canada, to coordinate educational activities in fire protection and fire prevention, to generally conduct a public relations program on fire protection for the improvement of the standards of fire protection in all classes of properties and occupancies. Should have qualifications for membership in the Society of Fire Protection engineers. Should have experience in modern fire prevention theory and practice with some knowledge of the principle of fire insurance underwriting and fire loss adjustments; and should have ability to meet and address the public with authority on the above subjects. Salary commensurate with qualifications. Duties to commence as soon as satisfactory arrangements can be made. File No. 4919-V.

TECHNICAL MINING EDITOR required by Canadian Mining Journal Established 1879. Must hold mining engineering degree from recognized university and have had some practical operating experience in industry. Position offers excellent salary, prestige, and opportunities for travel. Please state qualifications, experience, references, earliest possible starting date. File No. 4920-V.

OPERATIONS MANAGER required by long established and progressive premixed concrete company in major Canadian City. Man who is capable of taking complete charge of operating its 5 modern concrete plants and 100 plus truck mixer fleet. Applicants must have had previous experience and successful record in a similar capacity. Give age, particulars of experience, references, state when available and salary requirements. All replies will be treated strictly confidential. File No. 4924-V.

THE SASKATCHEWAN RESEARCH COUNCIL requires an industrial engineer preferably with mechanical or chemical experience to assist in making industrial surveys, to prepare reports on process and developments, and to provide liaison between science and industry. Position available immediately. Salary will depend on academic attainments and experience. Apply with all particulars, recent photo and addresses of reference, to File No. 4926-V.

GRADUATE ENGINEER required to act under the supervision of the plant engineer by manufacturer of telephone dial switching equipment and associated apparatus such as telephone relays etc. The incumbent will be connected closely with the maintenance of equipment and the provision of general plant building service. One or two years general experience in this field would be of considerable assistance to the person selected. File No 4928-V.

## SITUATIONS WANTED

ELECTRICAL ENGINEER, B.Sc. (E.E.), Manitoba 1943, P.Eng. (Ont.), M.E.I.C., age 34, married, requires immediate employment. Six years with industrial motor control manufacturer, mainly application engineering including circuit design, plus general supervisory and manufacturing experience and liaison with sales, purchasing, production and inspection department. Eighteen months with National Research Council, Ottawa. Three years Cdn. Army (R.C. Signals) immediately after graduation. Desires responsible position with consultant or manufacturer. Will locate anywhere. File No. 1408-W.

MECHANICAL ENGINEER, M.E.I.C., with apprenticeship and university background available for responsible position, on reasonable notice, interested in representing manufacturers wishing to develop and service markets in Canada or abroad. Experience includes design, construction and maintenance in the pulp and paper industry, several years handling sales of power plant equipment Working knowledge of French and German. Free to travel. File No. 2642-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng., interested in design or development work in I.C. engine, automotive or similar field or in instrumentation and control. Available on one month notice to present employer. File No. 3460-W.

MECHANICAL ENGINEER Jr.E.I.C., single, age 26, N.S.T.C., 1951. Seeking position with insurance underwriters or in some branch of sales. Experienced in building construction, design of manufactured gas installation and presently employed as fire survey engineer. File No. 3903-W.

CIVIL ENGINEER B.A. (Honours) maths. B.Sc. (Civil Eng.) M.Eng. (McGill University). About two years experience in field and design work (structural and hydraulic work) in Canada. Age 26. Married, one child. Citizen of India. Available from October 1954 for teaching engineering design work in India or Colombo Plan countries, or Indonesia. Keen, hard working, good references. File No. 4108-W.

MECHANICAL ENGINEER M.E.I.C., graduated, married, sound Canadian practice, twenty years experience includes: design, estimating in piping, heating, ventilation, air conditioning, refrigeration, plumbing, steam and power plant installations. Experience in manufacturing industry, foundry, boilers, pressure vessels, pumps, compressors, valves, shopwork, paper and pulp industry construction. Capable for administrations, organizing, supervision, sales. Desire a position of responsibility suitable to past experience with possibilities for advancement. Location in Montreal. Available on one month's notice. File No. 4211-W.

MECHANICAL ENGINEER, Jr.E.I.C., '51 McGill graduate, 29 years of age, single. Completed 2 years graduate student training course with Canadian Electrical manufacturer. Presently engaged as manufacturing engineer. Desires a position with opportunity to demonstrate his ability. Location—anywhere. File No. 4217-W.

MANAGEMENT ENGINEER, M.E.I.C., age 39, family. Queen's 1936, B.Sc. (Hon.) mechanical, P.Eng. (Ont.). Seventeen years industrial experience; eight years in aircraft, three years in bus and five years in miscellaneous sheet-metal manufacture; last year spent in light construction industry operating own business. Experience includes all phases of factory operation as well as top level general management assignments. Good record in organization work, labor relations and product development through all phases of design, tooling, material and production control, sales cost accounting and management control. Seeking management career opportunity, any location domestic or foreign with Southern Ontario preferred. Available on short notice. File No. 4219-W.

CONSTRUCTION ENGINEER, Jr.E.I.C., B.Eng. (Civil) McGill 1951, married. Considerable experience in design and field supervision of industrial and commercial projects, including steel, concrete and timber structures. Thoroughly familiar with office routine, estimating, writing specifications and preparing plans for tendering. Interested in position with progressive, growing firm of consultants or contractors. File No. 4273-W.

CIVIL ENGINEER, graduate Delft Technological University, Holland (specialization: hydraulics, dike building), age 28, 1½ years experience in reinforced concrete structure and surveying; interested in prestressed concrete. Presently employed as instrument man in Western Canada. Desires position with possibilities for advancement. Available on about one week notice anywhere in Canada. File No. 4318-W.

CHEMICAL ENGINEER with several years experience in control, operation and development in the field of metal finishing and protective coatings for appliances, chemical and food industry. Has had varied experience in finishing, design and maintenance of large factory equipment as well as small serial articles in aluminium, magnesium, steel and brass. Multicolor finishing on anodized aluminium. Formulation of cleaning, etching and phosphating solutions etc. Desires permanent position with opportunity for advancement. Will locate anywhere. File No. 4359-W.

CHEMICAL ENGINEER, 32, B.A.Sc. (Hon.), P.Eng., Jr.E.I.C., veteran, 1½ years process and quality control supervision. 2½ years process development in cellulose products, lacquers and solvent recovery, 3 years business experience, desires responsible position preferably in Southern Ontario, supervisory and/or technical. File No. 4391-W.

GRADUATE MECHANICAL ENGINEER, McGill 1950, with master of business administration degree, University of Michigan 1954, looking for a career with a progressive company. Three and a half years experience in industrial engineering and also summer work in several industries. Would want to start in production or industrial engineering work. File No. 4444-W.

GRADUATE MECHANICAL ENGINEER 1952, Jr.E.I.C., married, age 30, with varied maintenance experience on high pressure equipment in the chemical industry, electrical repair for a mining company and some industrial engineering experience. Desires employment on plant maintenance or field supervision of industrial equipment installation and alteration. Location preferably in Ontario. File No. 4453-W.

ELECTRICAL ENGINEER, Graduate 1949, power and machinery, Edinburgh, Scotland, M.E.I.C., Grad.I.E.E., Whitworth Prizeman, age 29, married, two children. 5 years electrical engineering apprenticeship, 3 years electrical draughting, 3 years electrical engineer. Experience on rural and urban distribution; construction, maintenance and operation; H.V. and M.V. lines, cables, substations and associated gear; estimating, profile surveying, pressure testing, fault location, etc. Also inspection, testing and maintenance of all types industrial electrical machinery and cabling in paper mills, quarries and other industry; i.e. generators, motors, switchgear, transformers, elevators, etc. Desires employment on either distribution work, plant maintenance or with consulting engineer, commencing beginning of September. File No. 4475-W.

SENIOR MECHANICAL ENGINEER B.Sc., P.Eng., M.E.I.C., age 41 years. Member A.S.M.E., A.S.H.V.E., A.S.R.E., over twenty years experience in air conditioning, heating and ventilating, piping, plumbing, refrigeration design and installation, waterworks and sewerage plant, workshops and plant layout, buildings, roads, and utilities and fully experienced in all mechanical and steam power plant boilers, pumps hot water systems, design, specifications installation, maintenance and planned maintenance desires an engineering appointment anywhere in Canada, U.S.A., or on overseas projects. Previous experience as resident engineer on very large projects overseas, on construction of varied type jobs on contract basis for government departments. Further particulars will gladly be forwarded to interested employers. File No. 4481-W.

ADMINISTRATOR, Professional Engineer in early forties, extensive manufacturing experience, large corporations; well qualified industrial relations including contract negotiations, arbitrations, proven record in safety, supervisory training, policy formation, cost budgetting, maintenance and stores control; sales and warehousing experience; seeks challenging position in small or medium company. File No. 4496-W.

CHEMICAL ENGINEER, Jr.E.I.C., 27, graduated from University of Toronto 1950. Four years experience in the protective coatings industry dealing with plastics, paints, varnishes, and waxes. Engaged in sales, supervisory and research capacities. Presently employed but seeking a more challenging position. Would consider other fields than protective coatings if sufficiently interesting. File No. 4505-W.

ELECTRICAL ENGINEER, Australian citizen, age 39, single. Associate Member of Institution of Engineers Australia and Member of Association of Professional Engineers Australia. Desires position with a supply authority whilst establishing professional status in Canada. Twenty years experience in Electrical industry, 14½ with supply authorities in Australia and 1¼ with consultants and construction engineers Great Britain. Experienced in design, construction, maintenance and operation of distribution works, substations and thermal station electrical installations. Experience up to 66KV. Field experience on 275 KV general line construction British Electrical Authority. File No. 4506-W.

CIVIL ENGINEER S.E.I.C., P.Engineer, located in Montreal desires evening work in draughting, design, etc. File No. 4507-W.

ELECTRICAL ENGINEER, Jr.E.I.C., B.Sc., Manitoba 1950, married, 2 children. Age 30. Seeks position in electrical ultility or plant maintenance in industrial concern. 4 years in transformer design, production and test. Some sales. Western Canada preferred. File No. 4508-W.

ELECTRICAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.) B.A.Sc. 1948, M.A.Sc. 1951, U.B.C., age 28, married, one year on design of substation layout and control with a large public utility prior to receiving M.A.Sc. Completed industrial training and sales course with a large electrical manufacturing company. Experience in application and manufacture of low voltage air circuit breakers, power fuses and grounding resistors. Design of metal clad switchgear control circuits and layout of wiring diagrams. Also teaching experience. Desires position requiring initiative, organizing and supervisory ability with opportunity for advancement. File No. 4509-W.

ELECTRICAL ENGINEER, B.Sc. Queens 1951; power option; Jr.E.I.C., P.Eng., aged 26, married, one son, and am a veteran. Employed since graduation by large chemical company. Have had varied experience in mechanical design, plant start-up trouble shooting and in electrical maintenance. Some experience with pneumatic instrumentation. Good knowledge of electronics through signal corps and amateur radio. Have done electrical estimating on minor plant projects. Would like to further electrical training through position with construction company installing generation equipment, or with constructing engineer on design and layout of plant power distribution systems. Location no object. Will send transcript of education, details of work background and references on request. File No. 4510-W.

CIVIL ENGINEER, honours graduate, of Glasgow University, with two years of construction experience, desires position in design office or on construction. Single, willing to work anywhere in Canada. File No. 4514-W.

CIVIL ENGINEER, Manitoba 1952, Jr.E.I.C., age thirty, married, one child. Presently employed by oil company on work becoming more the province of petroleum engineer desires employment with consultant or contractor on heavy construction or municipal projects. Five summers experience in highway and drainage construction, bituminous and concrete paving as instrument man and resident engineer. Location immaterial. File No. 4518-W.

MECHANICAL ENGINEER seeks senior executive position in chemical or allied industry, or firm of consulting engineers. 12 years experience in the financial and engineering side of large scale plant expansions in the chemical industry. Excellent knowledge of the following processes; ammonia, methanol, urea, formaldehyde, chlorine, wood saccharification, alcohol distillations. 5 years experience in dyestuffs including complete design and erection of services and maintenance workshop. Superintendent planning engineer in charge of drawing office of 40 men, re-organization of engineering department of large concern. Excellent references, bilingual, graduate 1942, M.E.I.C. File No. 4519-W.

ELECTRICAL ENGINEER, M.E.I.C., P.Eng., with 3 years urban distribution experience and CGE test course in switch gear, motor generator, installation and transformers seeks post with utility, involving generation, transmission and distribution. Present salary in power transformer engineering sales $350 per month. File No. 4525-W.

EUROPEAN CIVIL ENGINEER would accept some part time work in structural designing. File No. 4526-W.

AGRICULTURAL ENGINEER, M.E.I.C., U. of S. 19[illegible] available December 1, 1954. 4 years teaching experience, 3 years research engineer for Sask. Research Council. Thoroughly acquainted with automotive and internal combustion equipment. Age 38, married. File No. 4527-W.

ELECTRO - MECHANICAL ENGINEER, P.Eng. (Ont.), membership several English Professional Institutions. 2 years post graduate course in servo-mechanisms and control equipment. Practical experience of electro-hydraulic mechanisms. Desides position in administrative capacity. Minimum salary $7,000 per year. File No. 4528-W.

STRUCTURAL ENGINEER, A.M.I., Struct. E., P.Eng., desires responsible position in the Hamilton area. Experienced in the competitive design of light and heavy industrial and commercial structures and road and rail bridges. Eight years and three years English and Canadian experience respectively. At present employed in Hamilton. File No. 4529-W.

CIVIL ENGINEER, graduate of U. of Latvia in Riga 1926. 18 years experience in railroad, road, reinforced concrete and structural steel constructions. Seeking position in any part of Canada. File No. 4530-W.

ELECTRICAL ENGINEER, graduated Norwegian University 1950, age 30, married. Experience: 2 years design and development of hydro-power station and lighting engineering, 1 year as a sales engineer. Available immediately, location anywhere. File No. 4531-W.

CIVIL ENGINEER (European), graduate Polish University College, London, Jr.E.I.C., age 41. Married. Seven years experience (including two years in Canada) in design, draughting and supervision of all sorts of engineering structures, buildings, industrial plants, bridges and earthworks. Will accept position in line with his experience. Location preferred Montreal or Southern Ontario. Available on reasonable notice. File No. 4532-W.

CIVIL ENGINEER, member E.I.C., A.C.I., graduate University of Pennsylvania, U.S.A., bilingual, married, 2 children, 18 years varied experience abroad and in Canada. Last 9 years specialized in design and supervision of reinforced concrete and steel structures of all types. Seeking permanent position where technical skill and experience would be of value. Available on reasonable notice. File No. 4533-W.

CIVIL ENGINEER, graduate of technical university of Norway, 1949, age 30, married, no children, 3 years experience in structural engineering and two in construction. Desires position in construction engineering. Free to travel, but would prefer to be in eastern provinces. File No. 4534-W.

CIVIL ENGINEER, B.Sc., U.B.C., 1951, Jr.B.C.P.E., Jr.E.I.C., age 25, 3 years heavy construction experience having responsible work in layout and construction supervision during the excavation and construction of an underground power house and power tunnels. Seeks position in design office or responsible field position where experience will be of value. Preferably in Montreal or vicinity. File No. 4539-W.

MECHANICAL AND INDUSTRIAL ENGINEER, graduate, 1937; M.E.I.C., P.Eng., A.S.M.E., age 45, married, now employed as plant manager, wishes to locate outside Quebec. Reason, plant closing. Seasoned senior engineer with vast mechanical experience in paper making, construction and the steel industries. Well qualified for the positions of plant manager, chief engineer, plant engineer, mechanical superintendent, etc. Seeks a position in a reliable company where application and effort will be rewarded with advancement, peace of mind, and permanency in order to establish a home. File No. 4540-W.

ELECTRICAL ENGINEER, B.E., M.E.I.C., 12 years of experience in responsible positions including operation and testing of AC and DC machinery, design and supervision of construction of transmission lines, overhead and underground distribution systems, and substations, also system planning, report writing, economic studies, budgeting, staff supervision, etc. Desires position with increasing responsibility. Excellent references. Available on suitable notice to present employer. File No. 4541-W.

CHEMICAL ENGINEER, 33, veteran, graduate with five years wide experience in mechanical, chemical and electrical engineering, presently employed by plant manufacturers in Scotland, available for employment in Canada in August, 1954. Desires responsible position in planning, plant or production engineering, or industrial research and development work. Resume and references on request, languages. locality no barrier. File No. 4542-W.

CIVIL ENGINEER, P.Eng., M.E.I.C., with extensive experience in design and detailing of R.C. structures. Seeks part time employment in Toronto area. File No. 4544-W.

MECHANICAL ENGINEER, Jr.E.I.C., Polytechnique, 1953, P.Eng., equivalent of 4 years in plumbing and heating business as an apprentice, service man, design, estimate, sales and surveillance of complete plumbing and heating system for a contractor in Eastern Townships. Seeks employment in similar work preferably in Eastern Townships or Montreal but would locate anywhere. Married, one child, 2½ years old, bilingual. File No. 4548-W.

CHEMICAL ENGINEER, M.A. (Hons. Engineering), Cambridge University, England; A. F. Inst. of Petroleum, 28, married, recently arrived from England. Four years service wtih Royal Engineers as survey officer in the Middle East. Three and a half years supervisory experience in control, development, and maintenance of various types of petroleum refinery plants. Desire responsible position any where in Canada. File No. 4551-W.

CHEMICAL ENGINEER M.E.I.C., P.Eng., Toronto 1942, married, 12 years industrial experience in chemical plant project supervision, process equipment and piping design and fabrication. Seeks position with chemical company on new projects supervision or with process plant design engineering and construction company. File No. 4552-W.

ELECTRICAL ENGINEER, McGill 1953, S.E.I.C., presently employed, seeks position which calls for judgment, initiative and willingness to accept responsibility. Over two years varied experience (including summer work) in switchgear, rotating equipment, household appliances, sales, and drafting. Location Montreal. File No. 4553-W.

PROFESSIONAL ENGINEER, Jr.E.I.C., B.A., B.A.Sc., Athlone Fellow '52, age 27, bilingual. Post graduate studies in engineering production and management principles, Birmingham University, England. One year experience in construction, Canada; and one year experience with manufacturing concern. Seeks employment in the Montreal area preferably. Available for work at the beginning of September. File No. 4554-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.A. (Eng.), A.M.I.E.E., British, aged 44, family; seeks administrative, sales or consulting engineering post, any location not involving prolonged separation from family. Twenty-two years technical sales of heavy electrical plant, generation with all types of prime mover, distribution, application. Newly arrived from five years in Brazil as technical chief, selling and supervising diesel and diesel alternator installations. File No. 4555-W.

GEOLOGIST, SOILS ENGINEER and Surveyor, M.E.I.C., P.Eng., age 41, 18 years experience in geological and geophysical exploration (oil, coal, chromum, tin, iron), glacier research, soil mechanics (foundations, airports, hydrology, laboratory), diamond drilling, terrestrial and aerial photogrammetry, photogeological interpretation. 8 years consultant in Europe. Very experienced alpinist. Seeking responsible position with occasional field work in Western Canada, preferably Calgary. Permanently employed. File No. 4556-W.

MECHANICAL ENGINEER, Jr. E.I.C., 1949 N.S.T.C., age 28, married with children, desires a responsible position with an energetic company. Experience in general mechanical design, standardization, cost reduction, shop supervision, personnel administration and manufacturing methods. Interested in manufacturing, sales or design. File No. 4557-W.

ELECTRICAL ENGINEER, Jr.E.I.C., N.S.T.C., 1952, age 23, single. Interested in all fields of electrical engineering activity and willing to take responsibility and apply himself. Presently in second year of graduate student training course with large and reliable Canadian manufacturer of electrical equipment. Experience includes one year in transmission and distribution departments of hydro-electric utility. Some accounting experience. Desires position in Canada and would give special consideration to Newfoundland as a location. File No. 4558-W.

MECHANICAL ENGINEER Jr.E.I.C., graduate N.S.T. College 1951. Experience includes 1 year research work and 2 years mechanical design. Interested in position in plant engineering maintenance or design. Preferably located in Montreal area. File No. 4559-W.

ELECTRICAL ENGINEER Jr.E.I.C., B.Sc. (Maths. and Chem.) Acadia University 1949, B.E. Nova Scotia Technical College 1952. Age 27, married. Experience: One year as engineer in distribution department of small electrical utility; presently taking Westinghouse Graduate Training Course. Desires position offering scope for learning and advancement with smaller company or utility. File No. 4560-W.

CONSTRUCTION ENGINEER B.Sc. (1943) M.E.I.C., A.M.I.C.E., A.M.I. Struct. E., 11 years experience. Seeks responsible position. Has held the following positions: General superintendent, assistant project engineer, estimator. Experienced on light and heavy construction excavation water mains, sewers, concrete, etc. Married, 33 years old, bilingual. File No. 4561-W.

MECHANICAL ENGINEER, M.Sc. Delft Institute of Technology (Netherlands) 1953, married, age 26. Experience: one year pre-graduate training with various industries, including pulp — and paper-mill, one year Canadian Westinghouse graduate training course. Desires position in mechanical field; manufacturing, development, plant engineering. References include present employer. Location preferably Ontario or Western Canada. Available on short notice. File No. 4562-W.

CIVIL ENGINEER, B.E. 1953 U. of S., Jr.E.I.C., seeks position in design and construction. Working at present with prominent Government engineering department. Interested in position with good possibilities for advancement. Willing to work hard. Single with car. Experience in surveys (all types), supervision of survey crews and construction crews, design in water and sewer lines, some concrete design. Was completely in charge of installation of many hydraulic structures. highway-type bridges, large culvert installations and a gravel contract. Has also had experience photo-elastic analysis, soils studies and river studies. Has taken night classes in photography, welding and carpentry. Interview can possibly be arranged. File No. 4563-W.

GRADUATE CIVIL ENGINEER, D.R.T.C. (Glasgow), A.R.T.C. (Glasgow), San. Eng. (Glasgow), age 31 years, single, bilingual, willing to travel, desires senior position with responsibility in municipal engineering, contracting, concrete or structural steel installations. Experience: one year research work, 3 years general municipal engineering, 4 years drainage and irrigation experience in Malaya including supervision of earth moving plant, reinforced concrete design, estimating, surveying, office routines design of irrigation schemes and structures, chief assistant on a $5,000,000 (Canadian) irrigation scheme. Experienced in jungle clearing and swamp drainage. Available September 1st. File No. 4565-W.

MECHANICAL AND INDUSTRIAL ENGINEER, P.Eng., M.E.I.C., A.M.I.Mech.E., Junior executive, 10 years experience of industrial plant specifications, layout, design and erection, also specialized machine design and plant maintenance. Interested in entering consulting field in Southern Ontario. File No. 4568-W.

ELECTRICAL ENGINEER, B.A.Sc., M.E.I.C., P.Eng., age 40, married, three children, requires immediate employment preferably in consulting industrial or utiity. C.G.E. test course, four years production engineering, eight years apparatus sales engineering. File No. 4576-W.

**A well-engineered** blasting operation shattered this 34,500 cubic ard rock plug, allowing the new canal to cross over the existing ne. Eighteen tons of "Nitrone", a new C-I-L blasting agent, were sed in this successful operation.

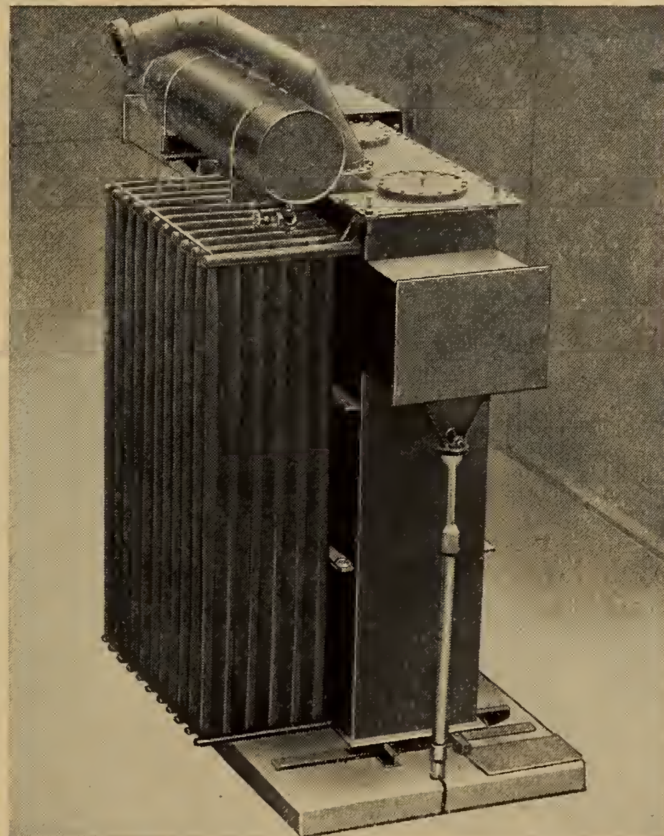
In B-A Oil Company's Refinery at Clarkson, Ont. — G-E 7500 KVA Power Transformer



Also in B-A Oil Company's Refinery at Clarkson, Ont. — G-E 750 KVA Power Transformer

# Now . . . delivery of G-E RM Power Transformers

# in only 8 weeks

Owing to greatly expanded plant facilities, you can now get speedier deliveries on G-E Standard Repetitive Manufacture Power Transformers – as follows:

> Transformers with standard RM Ratings of 250 to 2500 KVA can be shipped in 8 weeks . . . standard RM Ratings of over 2500 up to 10,000 KVA can be shipped in 16 weeks.

Speed of delivery is not the only advantage G-E RM Power Transformers offer. They embody all the refinements of design, high quality of materials and precise manufacturing methods which have made G-E Power Transformers outstanding. Their flexibility makes them widely adaptable to many situations where custom-built installations may at first seem inevitable.

G-E's Repetitive Manufacture of Power Transformers is based on standardized pre-engineered design. It permits quantity production and stock of parts common to several ratings. This improves the product and lowers the price—as much as 7½ percent. For further information, write Apparatus Division, Canadian General Electric Company Limited, 212 King Street West, Toronto, Ontario.

## British Columbia

H. D. De Beck, Jr.E.I.C.,
*Secretary-Treasurer*

***Joint Meeting***

A general meeting was held at the Golf Club in Kamloops on April 9, 1954, with 29 members and guests present.

Refreshments were available and dinner was served. Following dinner, the business of the evening was introduced by Chairman M. L. Zirul.

It was announced that before dinner a group of members had made an inspection tour of the new Royalite Oil Refinery adjoining the Golf Club. Following a discussion, it was proposed to try to arrange a tour of the Okanagan Flood Control Project to precede the next meeting at Penticton.

After the business meetings, John Wach, superintendent of the Royalite Refinery at Kamloops, was guest speaker. He was introduced by Dan Campbell, construction superintendent for the refinery.

## Halifax

K. F. Marginson, M.E.I.C.,
*Secretary-Treasurer*

F. H. Tremain, M.E.I.C.,
*Branch News Editor*

***Joint Meeting***

The Halifax Branch of the Engineering Institute of Canada held a joint meeting with the Military Engineers Association of Canada, on Tuesday evening, April 6, 1954, in the Officers' Mess (R.C.E.) Halifax Armouries. Major H. L. Mitcheltree, R.C.E. was the guest speaker and gave an illustrated address on "Engineering Problems in the Arctic".

A regular monthly supper meeting was held at the Nova Scotian Hotel on Thursday, April 22, 1954. The guest speaker was E. D. Brown, vice-president and general manager, National Gypsum (Canada) Limited, Halifax, Nova Scotia.

Mr. Brown gave a very interesting talk on the "National Gypsum's New Development at Milford, N.S." The speaker outlined the development at the quarry or mine, the quantity of the mineral being very extensive in this area as proven by diamond drilling. Shipment is by rail from Milford to Bedford Basin where it is loaded on ships and taken to the foreign market.

Approximately sixty members attended each of these meetings.

***Supper Meeting***

A buffet supper meeting was held in the Wright Auditorium, Y.M.C.A. Building, Halifax, N.S., on Tuesday, May 11, 1954. The special speaker was J. Herbert Smith, vice-president and general manager, wholesale division, Canadian General Electric Company, Limited, Toronto. His subject was "A Plan for Unity".

His talk covered a plan to unite the Engineering Institute of Canada and Dominion Council of Professional Engineers into one body. This body would be able to speak more effectively as one national organization for all engineers in Canada.

A discussion period followed the talk in which several of the members participated.

This was the last general meeting of the Halifax Branch until the fall.

## Lakehead

G. E. Cook, M.E.I.C.,
*Secretary-Treasurer*

H. Penner, Jr.E.I.C.,
*Branch News Editor*

***Annual Meeting***

The annual meeting of the Lakehead Branch of the Engineering Institute of Canada was held Tuesday evening, June 22, 1954, at the Port Arthur Country Club. Sister professions, represented by Dr. C. A. Shaffer of the dental association, John Carrel of the law society, Dr. R. J. G. Park of the medical society and Mr. Walker Love of the pharmaceutical association, brought greetings to the engineers. The various committee chairmen of the Lakehead Branch then read the reports of their activities for the past year. All indications were that the Engineering Institute had a banner year. The nominating committee under the chairmanship of W. H. Small, presented the slate of officers for the coming year. These were as follows:

Chairman, F. E. Ayers; Vice-chair-

**W. H. Moore, chairman of the Student Guidance Committee, Montreal Branch, shakes hands with high school student, Denis Gravel, on the occasion of another of a series of forums organized by the committee. Left to right: Henri Gaudefroy, dean of Ecole Polytechnique; Jacques Laurence; J. A. Lalonde, past chairman Montreal Branch, guest speaker; A. Dupré, director of French high schools; W. H. Moore; Henri Audet, vice-chairman of the committee, chairman of the forum; Denis Gravel. Each year the committee holds two forums for students of English high schools and two for French high school students.**

*14" Blow Valve, electrically operated, for digester in sulphite pulp mill. Made of CF-12M cast stainless steel by Welland Electric Steel Foundry Ltd., Welland, Ont.*

The high nickel-chromium-iron alloys are essential to provide long uninterrupted service life in cast parts of equipment exposed to corrosion and high temperature effects. These materials, as a class, are characterized by (1) resistance to many corrosive liquids and gases at ordinary and elevated temperatures; and (2) unusual strength at very high temperatures, frequently up to 2000°F.

Consult us on the use of alloys containing nickel in your equipment. Send the coupon for your copy of "Heat and Corrosion Resistant Alloy Castings in Industry"

Professional Engineers of the
Province of Ontario.

**Friday, October 15, 1954.**
**Hotel Sheraton-Brock,**
**Niagara Falls, Ont.**

Dinner: 7:00 p.m.
Dance: 9:00 p.m. to 1:00 a.m.
Dress Optional

Advance tickets available: $9.00 per couple.

man, E. T. Charnock; Secretary-treasurer, G. E. Cook; Directors: Fort William, W. D. Beckett, G. B. Anderson, D. B. McKillop; Port Arthur, G. Eriksen, L. B. Walker, W. D. McKinnon; Past chairman, G. S. Halter; Councillor, H. M. Olson; Eastern district representative, J. H. Hargrave; Western district representative, M. S. Fotheringham.

G. S. Halter thanked the branch for the privilege of serving them as chairman before handing over the gavel to F. E. Ayers, the incoming chairman. Mr. Ayers thanked the branch for the honour which it had bestowed on him and expressed his desire to do a good job in the coming year.

## Northern New Brunswick

G. Melanson, jr.e.i.c.,
*Secretary-Treasurer*

R. W. Rankine, jr.e.i.c.,
*Branch News Editor*

### Annual Meeting

At the first annual meeting at Kent Lodge on June 12, G. A. Robb, of Dalhousie, was elected chairman of the Northern New Brunswick Branch of the Engineering Institute of Canada for 1954.

Other officers are:

Vice-Chairman: W. S. Hosking, Bathurst. Secretary-Treasurer: Gerard J. Melanson, Bathurst and Dalhousie.

Executive members for the three counties covered by the branch were chosen as follows:

Gloucester: G. P. Milton, G. E. McLellan, both of Bathurst.

Restigouche: D. C. MacCallum, Dalhousie; T. Turgeon, Campbellton.

Northumberland: A. V. Tracy-Gould, M. E. Cyr, both of Newcastle.

Retiring Chairman Robert C. Eddy presided at the banquet held in the evening. After introductory remarks and a short history of the young branch, he called for financial and auditors' reports, which were adopted as read.

### Emphosis on Profession

The evening's guest speaker, R. J. Love, head of the Department of Education of the University of New Brunswick, was introduced by J. G. Chalmers.

"Engineering is becoming more important as our society becomes more complete. It has great appeal for youth, and hereby poses a problem," said Mr. Love, who was speaking from an educator's point of view. "While the adoption of the profession comes from three motives, to improve man's welfare, to meet an interest, and for money," the speaker continued, "there is the danger of the subject not being properly adapted."

Mr. Love cited the qualifications of a good engineer as skill in problem analysis, adeptness at mathematics and physics—so he could think in the abstract. "The engineer must be thorough," he went on, "be able to accept responsibilities, have a sense of accuracy and order and be able to get things done."

"Engineering trains one to be a potential manager and is a foundation also for a varied career." The speaker demonstrated this point by mentioning such outstanding personalities as C. D. Howe, Rube Goldberg, Hon. R. W. Winters and Arthur Murray. "It requires a co-ordination of the natural laws, personal and professional knowledge and intellectual techniques acquired in college, as well as specialized skills learned in practice. But a college certificate does not make an engineer. Originality and creative spirit is necessary."

Referring to the financing of education, Mr. Love mentioned that since the province paid 50 per cent of the overall cost, the municipalities should not complain too much. University professors are paid lower salaries than most high school teachers, he noted, so it was difficult getting competent people, because most are not interested unless they have a sideline to augment meager salaries.

Criticising the plight of students with great ability but no money, Mr. Love said that unlike Canada, students in the United States are well aided with scholarships. There are 30 per cent between the ages of 18 and 24 studying under scholarships, compared with 6 per cent in Canada.

The scholarships, he went on to say, are often underwritten by large corporations to train men who will later become competent members of their staffs. The speaker paid tribute to a Canadian firm, Canadian Union Carbide, which has recently decided to spend half a million dollars in scholarships at the rate of two hundred $500 bursaries a year.

"Professional improvement must be constant," concluded Mr. Love, in emphasizing the importance of organizations such as the Engineering Institute, whose suggestions to universities in improving their courses will be greatly welcomed.

G. A. Robb thanked the speaker.

After the meeting members and guests attended an enjoyable dance at the Lodge.

## Peterborough

R. A. Blount, jr.e.i.c.,
*Secretary-Treasurer*

G. T. Davis, jr.e.i.c.,
*Branch News Editor*

### Public Relotions

The speaker at the May 6 meeting of the Peterborough Branch of the Engineering Institute of Canada was C. S. Watson, vice-president, public relations, O'Keefe's Brewing Company. Mr. Watson, speaking on "Public Relations" emphasized that in both private and business activities, public relations should be given serious consideration by everyone. As an example of this, a public opinion survey taken in 1943 revealed that 54 per cent of the Canadian population were antagonistic towards the brewing industry. The industry set out to develop its public relations policies and in 1953, when a similar survey was taken, public opinion was only 24 per cent adverse.

A concerted effort towards the improvement of public relations is also desirable in certain of the professions in Canada. The speaker described how a public opinion survey can, with honest interpretation, be a very useful tool in determining along which avenues of approach public relations efforts may be directed.

### From the President Down

In an industry, public relations must be foremost in the minds of all employees, from the president down, if the best results are to be obtained. For this reason, his company had decided that public relations was a matter of executive importance and had included a public relations officer at the executive level. In this way decisions by company management are not made without approval of someone well qualified to consider the problem from the point of view of public relations. At the same time, however, it is equally important that persons having contact with the public be carefully chosen so that they will have the most desirable effect on all the people they meet. It is also important that people who do not normally meet customers during their normal duties be public relations minded so that they will not adversely affect the people they meet during their off-duty hours.

### And in Community Life

Public relations is not a subject to be considered only by large companies or by commercial groups but has an equally important place in community life. Without good public relations, the success of neighborhood enterprises cannot be guaranteed.

After the formal part of his presentation, Mr. Watson ably replied to the questions of his audience.

### Engineering in Peterborough

The regular monthly meeting of the Peterborough Branch of the Engineering Institute of Canada was held at the Kawartha Club on Thursday, June 3, 1954.

The Branch chairman, J. C. Watts, presided over a gathering to which students and others new to the community were particularly invited. The program was devised to make more widely known the scope of engineering activities in the city and was presented by a group of local members representing various prominent industries.

### Oats

The first speaker of the evening was A. J. Bonney, chief engineer of Quaker Oats, who outlined briefly the methods of handling and processing the various products of the mill.

The plant is capable of receiving twenty carloads of grain in eight hours which after weighing and sampling is transferred by automatic handling equipment to thirty-six grain storage tanks having a capacity of one and one-half million bushels.

The output of the mill in flour, feeds, "ready to eat" products and rolled oats amounts to some forty carloads per day.

Mr. Bonney described in some detail the process of puffing wheat and made brief reference to services provided by the control laboratory.

***Dairies***

The next speaker was O. J. Frisken, chief engineer of the DeLaval Company, who briefly outlined the past history and associations of the company and referred to its contribution to the mechanization and development of the dairy industry. The Canadian plant is chiefly concerned with the design and production of milking machines, pasteurization equipment and storage facilities for farms and dairies. Such equipment has contributed very largely to the high standards of hygiene now prevailing throughout the dairy industry.

***Clocks***

The third speaker was F. R. Pope, superintendent of Western Clock company's plant, manufacturers of Westclox watches and clocks. Mr. Pope said that the science of chronology is not one appearing in the engineering curricula of the engineering schools and colleges and in point of fact there is only one such school on the continent. There have been few changes in the basic design of clock mechanisms for some two hundred years and progress has been largely along the lines of refinement and development to permit the use of mass production techniques. Manufacture involves the maintenance of very close tolerances, high finishes and close control of assembly methods. It is a highly competitive business in which the material content of the product is low and costs can be brought down only by mechanization and reduction of labour.

***Paper and Tape***

The fourth speaker was Garth Wade, plant engineer of the Nashua Paper Company, manufacturers of gummed papers and tapes, and of specialty waxed papers for containers and wrappers. In general Kraft papers are used in the gumming division and sulphite papers used in the waxed paper division.

Mr. Wade dealt at some lengths with the problems associated with the wax treatment of papers and described in detail a method developed for handling the wax in a liquid state from the original vendor and throughout the process, in place of the original method of purchasing in solid form.

***Friction Materials***

The final speaker of the evening, J. S. Munro of Canadian Raybestos, discussed in some detail the properties and application of the various friction materials produced by his company. Coefficient of friction, wear resistance, absence of noise, freedom from moisture absorption and absence of brake fade are the principal factors involved in the selection of material and process. Asbestos base materials may be woven and pressed, or may be moulded using a resin or rubber base binding agent. The engineering application of these materials in the automotive and other industries is largely based on experience rather than theoretical considerations and any completely new application may be the subject of trial and error until a satisfactory solution is reached.

At the conclusion of each paper there was a short, lively discussion.

The vote of thanks extended to the speakers by E. Cotton was heartily endorsed by the meeting, which was one of the most heavily attended of the season.

A buffet supper concluded the meeting with a period of social conversation.

## Sarnia

R. A. McGeachy, M.E.I.C.,
*Secretary-Treasurer*

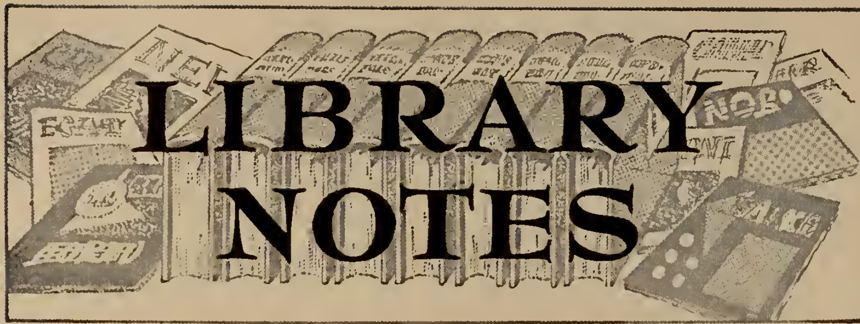
C. N. Lund, Jr.E.I.C.,
*Branch News Editor*

***Annual Dance***

The annual dinner-dance of the Sarnia Branch was held on June 18 at the Harrington Hotel, Port Huron, Michigan. This is the third year that this purely social event has been held, and it is hoped that it will develop into a regular annual attraction.

The members and their ladies enjoyed a steak dinner, after which Bob Meade's orchestra provided music for dancing in the ballroom. A feature of the evening was the presentation of the Plummer Medal, awarded by the Institute for the best paper on a chemical or on a metallurgical subject, to Mr. J. S. Moloney. The presentation was made by G. R. Henderson, regional vice-president. (See Month to Month Section.)

Preparations for the affair were under the chairmanship of Frank Belshaw. The Branch chairman, S. V. Antenbring, presided at the dinner.



## Additions to the Institute Library

### BOOK REVIEW

**Climate and architecture.** J. E. Aronin. New York, Reinhold, 1953. 304 pp., illus., $12.50 (U.S.).

In the many books being published on architecture now considerable emphasis is being placed on the adaptation of design to climatic surroundings.

This volume, however, goes even farther, and the aim of the writer is "To acquaint architects, architectural students, engineers, city planners, builders, present and prospective home owners and others, expecially those in North America, with the demands and phenomena of the large and small scale climate, known respectively as the macroclimate and microclimate; and to inform them how to apply this knowledge to the design and orientation of buildings and towns."

All types of climates are included, along with the appropriate building materials.

Chapter headings include Sun, Temperature, Wind, Precipitation, and other climatic factors, including lightning and humidity. Copious photographs and illustrative diagrams demonstrate or enlarge on each topic as it is considered, and fourteen pages of pertinent bibliography are included.

The author should be of particular interest to our Canadian members, as he graduated from the University of Manitoba, and took his master's degree at McGill.

In nineteen forty-six, while still a student, he went as a correspondent on Exercise Muskox, representing Canadian University students, and the seed of this book was probably sown at that time.

It will be of technical interest and value to the engineer and architect, but the amateur interested in building design and preservation will also find his fancy taken. E.K.

### BOOK NOTES

**Prepared by the Library**
**The Engineering Institute of Canada**

*Review provided through the courtesy of the Engineering Societies Library in New York.

**Abaques ou nomogrammes.** A. Giet. Paris, Dunod; Montreal, Fomac, 1954. 224 pp., figs., $7.50.

Regardless of the academic level of the student or engineer using this book, it will be of value, in that it instructs the user in how to prepare or construct tables and nomogrammes for his own use.

It is a theoretical study and a practical presentation which should be of great value in the mechanical, electrical and physical fields.

***Air conditioning, refrigerating data book, 1953-54.** New York, American Society of Refrigerating Engineers, 1953. irreg. paging, diagrs., $7.50 (U.S.).

A comprehensive coverage of refrigeration design, theory, thermodynamics, refrigerant properties, and related topics written by authorities in the various fields. There are new chapters on the heat pump, absorption and steam jet units, and abbreviations and symbols, and many chapters have been considerably revised. A buyer's guide is included.

**Atomic power symposium held at Chalk River, September 1953. Report.** Chalk River, Atomic energy of Canada, 1953. 202 pp., figs., $2.00. (CRR-548-A. AECL-82).

This report contains the unclassified papers presented at the Atomic power symposium held last September at Chalk River. The idea of the symposium was to permit personnel of various companies manufacturing power and power equipment to exchange ideas on atomic power with the staff at Chalk River, and with each other.

The papers included cover the present methods of producing power, and give the most comprehensive view of research at Chalk River ever presented to private industry. Topics discussed include the design and control of reactors, the disposal of fission products, radiation hazards, etc. In contrast, there are papers on steam electric generating systems, and another on Canadian power resources, excluding atomic energy.

**Calcul et exécution des ouvrages en béton armé. v. 2. Fondations et superstructures des bâtiments. Silos, canalisations, réservoirs,** 3rd ed. V. Forestier. Paris, Dunod; Montreal, Fomac, 1954. 232 pp., figs., $5.00.

This second volume of the third edition of this work, besides being brought up to date on all points as indicated in the subtitle, includes also special chapters on mushroom beam, coated beam and prestress concrete decking, and should be a valuable addition to the field.

***Chambers's shorter six-figure mathematical tables.** L. J. Comrie. New York, Chemical Publishing Company, 1954. 387 pp., $6.50 (U.S.).

Tables essential for purposes requiring more than four-figure accuracy are presented in this volume. Many are reprinted from the two-volume edition, although some have been reset with a wider interval of argument. Among the tables included are logarithms of trigonometrical functions of angles in degrees, minutes and seconds; trigonometrical functions of angles in degrees, minutes and seconds; circular functions, or trigonometrical functions with the argument in radians; exponential and hyperbolic functions; and many others.

**Conquest of the moon.** Cornelius Ryan, ed. Toronto, Macmillan, 1953. 126 pp., illus., $5.25.

The first collection of scientific factual information regarding potential travel to the moon, this book is the result of a scientific symposium which appeared in Collier's magazine under the title "Man on the Moon".

The Space station, Building the moonships, the journal itself, and the possibilities afforded after landing, are all presented, based on accepted scientific facts.

Watch the teen-age members of your family on this one, our future space engineers.

**Dictionnaire technique anglais-français chauffage industriel.** I. Dusnickis. Paris, Dunod; Montreal, Fomac, 1954. 144 pp., $3.55.

Although not indicated by the title, this dictionary is both English-French and French-English, and will fill a great need in the industrial heating field, covering as it does, five thousand words.

It is divided into five separate parts, Abbreviations and Conversions of Meas-

## LIBRARY REGULATIONS

### Summer Hours

Mon.–Fri. . . . . . . . . 9 a.m. - 5 p.m.
Closed all day Saturday

### Bibliography and Reference Service

Short subject bibliographies are compiled on request. When placing these requests, please give as much detail and background information as possible.

### Borrowing

Books, periodicals, pamphlets and films may be borrowed for two weeks at a time. All books included in the Library Notes Section of *The Engineering Journal* are available for loan. **A fine of 25c per day is charged for each day borrowed items are retained beyond the two-week period.**

A library deposit of $5.00 at par in Montreal is required, for which two items may be borrowed at a time. Temporary deposits (30 days or less) $10.00. Books are sent anywhere in Canada, and carrying charges are payable by the member concerned.

### Ordering

Any book or pamphlet may be ordered through the library. All publications of affiliated societies, whether books, pamphlets, or periodicals, should be ordered through the library, as reduced rates are applicable on these to all members. Except in the case of library deposits **please make no payments in advance.** Non-members may consult the library, but may not borrow material. Please address all requests to **The Library.**

FIRST COST
QUALITY
CRANE
150

ures, General and Technico-Commercial terms, Steam generators and auxiliaries, Furnaces and Metallurgy, and Control and regulation.

**Effects of taxation: depreciation adjustments for price changes.** E. C. Brown. Boston, Harvard graduate school of business administration, 1952. 161 pp., $3.25 (U.S.).

This study is a comprehensive attack on the problem of depreciation allowances for tax purposes brought on by changing price levels.

Section One treats of the effect on national income and federal income taxes if replacement costs depreciation were applied for tax determination; and an analysis of the efforts made by companies and individuals to meet the price changes problem.

The second section deals with the possible effect of this on the national economy, and all is then summarized in the author's conclusions.

***Electronics.** G. F. Corcoran and H. W. Price. New York, Wiley, 1954. 459 pp., $7.00.

Designed for a first course for junior students, this text emphasizes circuitry aspects of the subject but does not neglect basic principles. It includes chapters on vacuum-diode operations and mobile charges, conventional material on linear and non-linear operations, and chapters on feedback circuits, germanium diodes, transistors, and oscillators.

***Elementary fluid mechanics,** 3rd ed. K. Vennard. New York, Wiley, 1954. 401 pp., diagrs., $5.50.

Fundamentals, physical properties, and fluid statics are discussed first, and then follows a chapter on one-dimensional flow presented as background for general treatment of fluid flow problems. Incompressible ideal fluid flow and the impulse-momentum principle are similarly considered, as important tools for future use. The discussion of basic facts of flow of a real fluid leads to flow in open pipes and channels, and fluid measurements are dealt with. A chapter on flow about immersed objects concludes this edition which has been critically reviewed and revised.

***Elements of mechanism.** V. L. Doughtie and W. H. James. New York, Wiley, 1954. 494 pp., diagrs., $6.00.

Completely rewritten, this edition of a standard textbook gives the fundamentals of kinematics in the field of mechanical movements. Early chapters cover motion in general, velocity and acceleration analysis, and linkages. Cams, gears, belts and trains are considered in detail in the later chapters. The last chapter discusses miscellaneous mechanisms.

***Engineering contracts and specifications.** R. W. Abbett. New York, Wiley, 1954. 429 pp., $6.00.

Legal and business aspects of the engineering profession are presented in this book which has been revised and expanded throughout. Material on contracts, specifications and the presentation of legal rights and obligations in construction work has been considerably amplified, and other sections have been rewritten in the light of current professional practice.

***Engineering mechanics,** 2nd ed. F. L. Singer. New York, Harper, 1954. 525 pp., diagrs., $6.00 (U.S.).

Fundamentals are presented in a manner that shows how they may be applied to practical engineering problems. As in the previous edition, both analytic and graphic methods are used, and equations have been interpreted in terms of their geometrical equivalents. The complete text has been rewritten, with some discussions expanded and others simplified. Summaries at the end of each chapter aim to make the text useful for a review of the subject in post-college work.

***Flow and fan.** C. H. Berry. New York, Industrial Press, 1954. 226 pp., $4.00 (U.S.).

The data needed and methods used for finding the aggregate resistance of ventilating systems, and for selecting a fan for particular purpose are presented in simple terms for the student and practicing engineer. Flow measurements, losses, fan performance, and fan operation and control are among the subjects covered. The material appeared previously in "Heating and Ventilating".

**French-English dictionary for chemists,** 2nd ed. A. M. Patterson. New York, Wiley, 1954. 476 pp., $6.50.

Although intended primarily for chemists, this dictionary includes non-technical words and terms taken from related sciences and industry which are likely to be encountered in a technical book.

Various technical vocabularies were consulted in order to make this new edition as complete as possible, chemical nomenclature has been revised in accordance with the latest practices, and there are in all about forty-two thousand entries included.

Where words have different meanings in different connections, this is indicated. Formulae are given for many substances, and the English meaning of many French abbreviations is also included.

This new edition of this French-English dictionary will be a useful addition to the reference shelf.

**Graphic problems in petroleum geology.** L. W. LeRoy and J. W. Low. New York, Harper, 1954. 238 pp., spiral binding, figs., $4.50 (U.S.).

Intended basically as a textbook and manual for petroleum geology, the topics covered in this volume include lithofacies mapping, geologic cross-sections, contour maps, oil field development, stereographic projection and interpretation of air photographs. There is, in addition, a list of suggested readings. The book has a spiral binding for convenience in use, and has been prepared primarily "to teach the student how to apply what he knows".

***Graphics in engineering and science.** A. S. Levens. New York, Wiley, 1954. 696 pp., illus., $7.00.

Graphics is treated as a means of communication for the engineer and scientist. The first part emphasizes fundamental principles, primarily of orthogonal projection, and applies these to a variety of space problems in engineering. The second part covers standards; representation of threads and fasteners, cams, and gears; dimensioning practices; and the preparation of working drawings. Part three deals with graphical analysis and graphic methods of computation. Appendices give symbols, standards, and other data, and there is a selected bibliography.

**High altitude rocket research.** H. E. Newell. New York, Academic press, 1953. 298 pp., illus., $7.50 (U.S.).

Written to be easily read by the general scientific public, this is the first book to be written on the use of rockets for studying ionosphere, earth's magnetic field, solar radiation, and cosmic rays, atmosphere. The WAC corporal, V-2 Aerobee, and Viking rockets are all described, and all the upper-air research firings conducted by United States agencies from nineteen forty-six through nineteen fifty-two are listed.

The book is both illustrated, and indexed and the chapters include bibliographical references.

**Introduction à l'électronique.** P. Grau. Paris, Dunod; Montreal, Fomac, 1954. 212 pp., figs., $7.75.

Serving as a general introduction to the vast field of electronics, this volume touches on electronic measuring, telecommunication, electronic acoustical devices, pilotless planes, servo-mechanisms, etc.

It carries a detailed table of contents, and has over two hundred illustrations.

***Liants hydrocarbonés; mortiers et bétons bitumineux.** M. Duries and J. Arrambide, Paris, Dunod; Montreal, Fomac, 1954. 728 pp., figs., $25.20.

A comprehensive treatise on hydrocarbon-base binders. The introductory chapter reviews such topics as viscosity, plasticity, surface phenomena, and the nature of colloids. Succeeding chapters deal with the preparation, composition, and properties of coal and petroleum tars and their derived products; with the influence of time, temperature, and environment on their rheological characteristics; and with their use in highway and airport runway construction and as sealing materials for buildings and for dams, embankments, and other hydraulic structures. Tests, analyses, and specifications are given.

**Métallurgie. v. 2 Elaboration des métaux,** 2nd ed. C. Chaussin and G. Hilly. Paris, Dunod; Montreal, Fomac, 1954. 202 pp., figs., $4.15.

Brought up-to-date in this second edition with new statistical information and exercises, volume two of Métallurgie deals with the newest developments in the elaboration, finishing and improving of metals and alloys, and will be of particular value to technical students.

**The new architecture in Great Britain, 1946-1953.** E. D. Mills. London, Standard Catalogue Company, 1953. 209 pp., illus., 40/.

Being volume one of a planned larger work, this book is composed of articles contributed to Architectural Design from nineteen-fifty-one to nineteen fifty-three.

Opening with a historical chapter to present-day architecture, and a list of important modern buildings in Great Britain up to nineteen forty-five, fifteen different examples of buildings are then discussed in detail from the technical, engineering, and aesthetic viewpoint.

Photographs and plans are on every page, making of the whole production a fascinating overall picture of the modern trend in general.

**Specialized home and portable radio manual,** v. 8. New York, Rider, 1954. 96 pp., diagrs., $1.65 (U.S.).

The specialized series of Rider radio manuals of which this is volume eight has been prepared to provide service technicians with factory prepared dependable service information on particular makes of radio receivers.

This volume deals with home and portable radio receivers produced by the Radio Corporation of America during the period June 1951-December 1953.

**Specification writing for architects and surveyors.** A. J. Willis. London,

# How to get 3 years' lighting from a Fluorescent Lamp

*Specify G-E Fluorescent Lamps. Operating at 48 hours a week, they provide an average of three years of lighting. (Based on a spectacular rated life of 7500 hrs.)*

**G-E Fluorescent Lamps** not only provide an *average* of 3 years' lighting, but they are so uniform in quality that even after the first two years, nearly every lamp is still in operation. Apply the benefits of the consistent long-life performance to your lighting problems . . . see how you can reduce replacement and maintenance costs to the very minimum.

Rigid manufacturing standards give G-E Fluorescent Lamps their outstanding superiority. By specifying 'G-E' you assure low overall lighting costs . . . combine good lighting with good business. Investigate all the advantages of G-E Fluorescent Lamps by contacting your G-E Lamp Distributor or mail the coupon below.

EJA LAD 40303

Crosby Lockwood, 1953. 88 pp., spiral binding, 7/6.

Intended both for students and those in active practice, the aim of this book is to provide a list of the main points which should be covered in each of the sections of a specification. The author's intention in doing this is to provide some means of ensuring that there will be no gaps left in the specification when completed.

The author has referred throughout to British standards, and Codes of practice published by the British Standards institution, and in listing the points to be included has followed the British standards sequence of trades and items.

This should prove a useful book for all of our members who have at any time to prepare a building specification, and the handy spiral binding makes for ease of use.

**The superhet manual**, 5th ed. F. J. Camm. Toronto, British Book Service, 1954. 143 pp., diagrs., $1.30.

The majority of modern radio receivers work on the super-heterodyne, or superhet, principle. This manual is concerned with different aspects of superhet design, operation and servicing. The first chapter covers the fundamental principles of radio, leading up to the problems of selectivity which it is the special function of the superhet to solve. There are many wiring diagrams included in the text, and the manual should prove useful to all those interested in this aspect of radio design.

**TV manufacturers' receiver trouble cures**, v. 5. M. S. Snitzer. New York, Rider, 1954. 120 pp., diagrs., $1.80 (U.S.).

The fifth volume in this series, this book deals with television receivers manufactured by firms whose names begin with the letters S to Z. The trouble cures given are those suggested by the manufacturers themselves, and this book, taken together with the other four volumes in the series covers practically the whole field of sets manufactured in the United States.

**Tables of barometric pressures at varying temperatures.** J. D. W. Ball. Toronto, Longmans, Green, 1953. 23 pp., $1.25.

The five sets of tables in this book record:

1. The equivalents of millimetres of mercury in kilogrammes per square centimetre.
2. The equivalents of inches of mercury in pounds per square inch.
3. The equivalents of inches of mercury in pounds per square foot.

(All the above at temperatures varying from 0°C. to 40°C.)

The other two tables are provided to convert:

1. Kilogrammes per square centimetre to bars at standard gravity, and
2. Kilogrammes per square centimetre to bars at Greenwich.

These tables should prove useful to those engaged in making calculations based on atmospheric pressure when it is desirable to use one of the above basic units of pressure rather than pressure recorded in terms of inches or millimetres of mercury.

**Who's who in engineering**, 7th ed. W. S. Downs and E. N. Dodge, eds. New York, Lewis, 1954. 2861 pp., $17.50 (U.S.).

The seventh edition of Who's who in engineering, this is the second to be published under the auspices of the Advisory Committee of the Engineers Joint Council. The editors emphasize that now, more than ever, inclusion of an engineer is in no way influenced by purchase of the book.

The principle qualification for inclusion is at least ten years' active practice, a minimum of five of which shall have been spent in charge of an important engineering work. Teachers of engineering subjects at an accepted college or university are included if they have been in charge of a major engineering course for at least five years.

Engineers in the volume include all those in the 1948 edition who signified their wish to be included again. In addition, members of the various American national and state societies qualified for admission were invited to submit information for inclusion, so that coverage of the profession could be as complete as possible.

The great majority of engineers listed, however, are from the United States. The geographical listing shows only a handful of Canadians, and a few engineers from other parts of the world.

With the limitations as cited above, this new edition will be a useful volume for the library reference shelf, both for the biographical data included, and for the list of nation- and state-wide engineering and allied societies included.

## BOOKS RECEIVED

**Achieving your career; a vocational guidance manual.** J. S. Kopas and

W. Garrett. Youngstown, Industrial Information institute, 1953. 138 pp., figs., $1.50 (U.S.).

**Airplane structures,** v. 1, 4th ed. A. S. Niles and J. S. Newell. New York, Wiley, 1954. 607 pp., figs., $7.75.

**Bibliography of interlingual scientific and technical dictionaries,** 3rd ed. United Nations educational, scientific and cultural organization. Toronto, University press, 1953. 178 pp., $1.75.

**Canada's tomorrow; papers and discussions. Canada's tomorrow conference, Quebec City, November 1953.** G. P. Gilmour, ed. Toronto, Macmillan, 1954. 324 pp., $3.50.

**Classified directory and buyers' guide, 1954.** Engineering industries association. London, Standard Catalogue, 1954. 474 pp., 32/6.

**Design and operation of septic tanks: third European seminar for sanitary engineers.** World Health Organization. New York, Columbia University press, 1953. 124 pp., $1.50 (U.S.). (WHO Monograph series, No. 18).

**Electrical ignition equipment.** F. G. Spreadbury. Toronto, Longmans, Green, 1954. 227 pp., illus., $4.50.

**Engineering analysis.** D. W. Ver Planck and B. R. Teare. New York, Wiley, 1954. 344 pp., figs., $6.00.

**Ferrous process metallurgy.** J. L. Bray. New York, Wiley, 1954. 414 pp., figs., $6.50.

**Flow properties of disperse systems.** J. J. Hermans, ed. New York, Interscience Publishers, 1953. 445 pp., illus., $9.90 (U.S.).

**The molecular theory of gases and liquids.** J. O. Hirschfelder, C. F. Curtiss and R. B. Bird. New York, Wiley, 1954. 1219 pp., $20.00.

**New Brunswick almanac, 1954.** Fredericton, Brunswick Press, 1954. 224 pp., pa. $1.00.

**Plastics progress, 1953.** Phillip Morgan, ed. London, Iliffe, 1953. 439 pp., illus., 50/-.

**Principles of geomorphology.** W. D. Thornbury. New York. Wiley, 1954. 618 pp., illus., $8.00.

**Slide rule: the autobiography of an engineer.** Nevil Shute. Toronto, McLeod, 1954. 240 pp., illus., $4.00.

**Statistical methods in electrical engineering.** D. A. Bell. Toronto, British Book Service, 1953. 175 pp., $4.25.

**The steel skeleton. v. 1. Elastic behaviour and design.** J. F. Baker. Toronto, Macmillan, 1954. 206 pp., illus., $7.15.

**The structure of metals and alloys,** 3rd ed. W. Hume-Rothery and G. V. Raynor. London, Institute of metals, 1954. 363 pp., figs., $5.50.

**A textbook of metallurgy.** A. R. Bailey. Toronto, Macmillan, 1954. 560 pp., illus., $5.00.

## TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

**Agricultural institute review.** Reprint: The use and conservation of Canada's farm lands. March-April 1954.

**British institute of management:** Construction of Esso refinery, Fawley; a study in organization, by A. P. Gray and Mark Abrams. 3/6.

**Canada. Dominion coal board:** Canadian energy sources, by C. L. O'Brian. Reprinted from the Canadian institute of mining and metallurgy. Bulletin, June 1953.

**Central mortgage and housing corporation:** Normes de construction (maison d'appartements non comprises). Ottawa, 1954. 104 pp.

Small house design: bungalows and split-level houses. 1954. 87 pp.

**Dominion fire prevention association:** Proceedings of the thirty-second annual conference of the Association of Canadian fire marshals and the thirty-fifth annual meeting of the Dominion fire prevention association, Winnipeg, May 1953.

**Engineering foundation. Council on wave research:** Gravity waves; tables of functions, by R. L. Wiegel. 30 pp. $1.00.

**Institution of metallurgists:** The microscopy of metals. 132 pp. 15/6.

**Purdue University. Engineering experiment station:** Research activities, 1952-1953.

**Purdue University. Engineering extension dept. Engineering bulletin:** No. 82—Excessive moisture in homes, by W. T. Miller and F. B. Morse. No. 83—Proceedings of the eighth industrial waste conference, May 1953.

**Royal society of arts:** Bicentenary issues of the Journal, April 1954.

**Winnipeg water district:** Annual report of the Greater Winnipeg water district for the year ended December 31st, 1953.

# STANDARDS REVIEWED

**American society for testing materials, 1916 Race Street, Philadelphia 3, Pa.**

**Report on the principles involved in the determination of absolute viscosity.** 1953. pa. $1.00

The purpose of this report was to encourage the recognition and use of instruments yielding results in standardized units having true physical dimensions that will convey the same meaning in all laboratories.

Prepared by Subcommittee 9 on rheological properties of ASTM committee E-1, this report was published originally in the 1951 ASTM Proceedings. While not to be considered a laboratory manual, but rather an introduction to rheology from a practical point of view resting on a sound theoretical base, this book will prove a valuable asset to those concerned with viscosity determination. It is well illustrated with drawings, and includes a bibliography. An appendix lists the names of fourteen American suppliers of viscometers.

**Standards on engine antifreezes.** 48 pp., pa. $1.25.

This publication includes all ASTM methods of test pertaining to engine antifreeze in one convenient book, and is sponsored by ASTM committee D-15 on engine antifreezes. Of eight methods, five included in the previous edition have been revised and one is new; also both specifications have been revised. Methods cover sampling and preparing aqueous solutions for testing purposes; freezing point of aqueous solution; physical tests for boiling point of engine antifreezes, and specific gravity of concentrated engine antifreezes by the hydrometer; chemical tests for ash content; reserve alkalinity; pH of concentrated engine antifreezes; and water in concentrated engine antifreezes by the iodine reagent method.

The book should prove of value to both producers and consumers interested in this field.

**Selection and use of engine antifreezes.** 16 pp., pa. 40 cents. (Special technical publication No. 120).

An excellent companion book to the above, providing information and advice on engine cooling system antifreezes and corrosion inhibitors. The detrimental effects which can occur when improper antifreezes are used are discussed and there are a number of illustrations showing the results of the use of faulty antifreezes on engine parts.

**British standards. British standards institution, 2 Park Street, London, W.1. British standards are available from the Canadian standards association, National research building, Ottawa, Canada.**

**B.S. 2064: 1953 — Dimensions of diamond abrasive wheels and tools.** 4/-.

This Standard specifies dimensions and tolerances for diamond abrasive wheels and tools of the following types in resinoid, vitrified and metallic bonds: peripheral wheels, straight cup wheels, double cup wheels, taper cup wheels, bull-nosed cup wheels, dish wheels, cut-off wheels, chip-breaker wheels, milling tools, hollow drills, stone saws and hones. The information is given in tabular form, and some is also shown diagrammatically.

**B.S. 2082: 1954 — Code on disappearing-filament optical pyrometers.** 6/-.

The disappearing-filament optical pyrometer occupies an important position in the field of high temperature measurement. In the metallurgical, heavy chemical and coking industries it is used either directly as the temperature-control instrument or as the reference standard for other instruments. It is thus important that these pyrometers should be capable of giving high accuracy and reliability. In order to make known the possibilities of improved design the British standards institution has published this standard.

The Code should prove useful to both manufacturers and users of optical pyrometers, for a wider field is covered than simple recommendations on design. The reasons for certain features of design are fully discussed and this has led to the inclusion of a summary of the basic principles of optical pyrometry; in order, however, to avoid digression from the main arguments, certain aspects of the subject are separated into appendices of which there are seven. The main text is divided into five parts under the headings:—1. General (including definitions and a description of a typical optical system): 2. Principles of optical pyrometry: 3. Design requirements: 4. Calibration procedure: 5. Selection and training of operators.

In part three no rigid specifications are given but only an indication of the design requirements so that originality of design may not be prevented. Among the appendices there is for example a discussion on the precautions necessary in the use of optical pyrometers, including emissivity data and emissivity corrections to be applied to pyrometer readings; another of the appendices considers a scheme for the statistical assessment of observers, while a third sets out the method of calculation of the effective wavelength of the red glass of an optical pyrometer in some special cases in continuation of the discussion on this subject in the main text of the Code.

**B.S. 2084: 1954 — Cotton covered round copper wires (metric units).** 2/6.

This is a metric edition of B.S. 1791, which has the same title. It has been prepared primarily from the point of view of exports and differs from the 1951 edition of B.S. 1791 only in that all qualities are expressed in metric units, and the range of diameters covered is 0.150mm. to 5.00mm.

For normal purposes in the United Kingdom B.S. 1791 is still the appropriate standard to be used. The technical details contained in the new specification are taken entirely from B.S. 1791 with the addition of an Appendix giving constants and reciprocals of constants for coverting resistances at various temperatures to those at the standard temperature of 20°C. It gives details of diameters, resistances and thickness of covering, together with tests relating to bending and elongation of the covered wire. It includes an Appendix on measurement of conductor diameter and overall diameter.

**B.S. 24 Part 5: 1954—Railway rolling stock material—copper.** 4/-.

This revised edition of the standard specifies requirements for copper in the following forms:

Specification No. 11—Copper plate for locomotive fireboxes.

Specification No. 12—Copper rod for locomotive stay bolts, rivets, etc.

Specification No. 13—Copper tubes for locomotives.

Specification No. 14—Brass tubes for locomotive boilers, which was included in the earlier edition of the standard has been omitted, as the small demand for brass tubes for locomotive boilers is met by the existing British standard 885—Brass tubes for general purposes.

Details of chemical composition have not been included. In some cases tolerances and mechanical properties have been modified and a gassing or hydrogen embrittlement test has been added for deoxidized material in the form of plate and rod. Wherever possible the individual specifications have been modelled on the corresponding general purpose standard, but the main requirements are substantially unaltered from the earlier edition.

**B.S. 327 Part 2: 1954—Derrick cranes (hand-operated)** 6/-.

This is the third revision of this standard, and follows similar lines to the previous editions in that it indicates the minimum requirements for hand-operated derrick cranes of the normal type and is intended to secure the general observance of such fundamental principles as appear desirable to secure reliability and safety without hampering the freedom of the crane maker in his selection of the most appropriate design for the purpose in view.

The standard deals with hand-operated cranes of the Scotch derrick and guy derrick types and specifies requirements for the design of the crane structure and moving parts. Hoisting equipment and brakes are dealt with, and an Appendix gives the requirements to be observed when a hand-operated crane is converted to power operation.

The clauses on electrical wiring and cables have been brought into accord with the twelfth edition of the Regulation for the electrical equipment of buildings published by the Institution of electrical engineers, and the Appendix on the design of struts has been revised so as to follow the general method of application of the Perry-Robertson formula for struts adopted in other British standards.

**B.S. 336: 1954—Fire hose and suction hose couplings, branch pipe and nozzle connections.** 4/-.

This revised British standard applies to the following:

Delivery hose couplings and connectors of the instantaneous pattern, hose couplings with ribbed and multi-serrated tails and single lug twist release connector.

Suction hose couplings.

Branch pipe and nozzle connections.

The revisions in this standard include the introduction of an instantaneous connector with twist release, and a material clause which provides for the use of both copper alloys and aluminium alloys.

This standard also provides for both ribbed type tail pieces and multi-serrated type tail pieces.

The standard size of coupling adopted is that known hitherto as the '2½ in. gauge'.

The design of the suction hose couplings has been modified and now provides for an external locking ring instead of an internally screwed sleeve. For suction couplings, a two-ribbed type of tail end has been introduced in place of the serrated type. A slight modification has also been made to the branch pipe in that a shroud has been provided to ensure that the washer is adequately retained in position.

**B.S. 1991 Part 1: 1954—Letter symbols, signs and abbreviations. Part 1. General.** 6/-.

When it was decided to revise two well established and partly overlapping British standards, B.S. 560—Engineering symbols and abbreviations, and B.S. 813—Chemi-

cal symbols and abbreviations, it was thought desirable to take this opportunity of combining them so as to remove unnecessary conflict and pave the way to the development of a consistent system for the whole field.

The committee entrusted with this work decided that, in the first instance, attention should be focused on the more fundamental quantities of common concern to all branches of pure and applied science, on conventions relating to their use, and on abbreviations for relevant words, especially the names of unit. This standard is the outcome of this decision, and it will be left to groups of experts in specialized fields to build in various directions on the foundations thus laid.

It is recognized that the attainment of a reasonable measure of agreement will entail the abandonment of a few practices that are well established in certain fields of work. Departures from well-established usages are recommended, however, only where they are considered to be of serious importance.

The standard is intended to give guidance towards the development of a general system. It urges that the general principles put forward should be accepted and followed rather than that there should be rigid adherence in all instances to recommendations on the use of individual symbols or abbreviations.

**B.S. 2051 Part 2: 1954—Olive, soldered nipple and flared types of copper and alloy tube fittings for engineering purposes.** 12/6.

This new standard provides for the complete dimensional standardization of the copper tube fittings known as olive, soldered nipple, flared and inverted flared fittings for use with copper and copper alloy and other suitable tube designated by its fractional o.d. size for a wide range of engineering purposes and covers the following classes and ranges of fittings:

a. Olive fittings of sizes ranging from 1/8 in. to ¾ in. inclusive.
b. Soldered nipple fittings of sizes ranging from 1/8 in. to ¾ in. inclusive.
c. Flared fittings of sizes ranging from 1/8 in. to 1 in. inclusive.
d. Inverted flared fittings of sizes ranging from 1/8 in. to ¾ in. inclusive.

These fittings are provided with 'B.S.P. Whitworth' threads to B.S. 84 or Unified threads to B.S. 1580. Material requirements and tests for porosity are specified, and also details of the maximum working pressures for these fittings.

Illustrations of the fittings together with tables of dimensions of each type of fitting are included in this standard.

**B.S. 2079: 1954—Steam receivers and separators.** 12/6.

This new British standard forms one of a series for land boilers and unfired pressure vessels. It applies solely to steam receivers and separators used for piping installations for and in connection with land boilers. It is not intended to cover process vessels or steam receivers and separators, the design temperature of which exceeds 900°F.

The standard applies to welded and riveted receivers and is divided into four parts: general, materials, construction and workmanship, and scantlings.

Two appendices illustrate typical methods of attachment for branches, pads and bosses secured by welding alone, and also typical acceptable methods of attachment of receiver ends.

**B.S. 2451: 1954—Chilled iron shot and grit.** 2/-.

The primary purpose of this standard is to assist in overcoming the difficulties which have been experienced by users in obtaining uniform grades and sizes of chilled iron shot and grit for use in shot blasting and kindred applications.

The main object in preparing the standard has, therefore, been concerned with the separation and sizing of the chilled shot and grit and designating grade and size numbers. It has also been considered desirable to include requirements for hardness.

The grades and sizes of chilled iron shot and grit covered by this standard have been designated 7, 8, 9, 10, 12, 15, 18, 22, 30 and 40.

Screen sizes and tolerances are given to determine the particle size.

**Canadian standards, Canadian standards association, National research building, Ottawa.**

**C.S.A. B89-1954—1½ inch fire hose couplings screw thread and tail piece internal diameters, 2nd ed.** 50 cents.

The first edition of this standard was issued in 1948, and this second edition has been revised to cover the internal lip diameter and core diameter of the tail piece on both male and female couplings. The specification covers standard 1½ inch fire hose coupling screw thread for general use in fire protection equipment. The details are based on the latest edition of American standard B33.1, Hose coupling screw threads.

**C.S.A. B89.2-1954—2½ inch fire hose couplings and fittings,** 2nd ed. 50 cents.

This specification covers a standard 2½ inch screw thread for general use in fire protection equipment. The specification has been revised from the first edition issued in 1949 to include the internal lip diameter and core diameter of the tail piece on both male and female couplings. Included in the specification is an appendix giving calculations for arriving at thread form American national standard thread.

**C.S.A. Z102.10-1954—Skidding of machinery for shipment.** $2.00.

Prepared by the Committee on wooden containers this specification is one of a projected series covering nailed wooden boxes and crates, cleated plywood boxes and wirebound boxes, etc. The specification covers the design and construction of skids for machinery but does not provide for the design and construction of acrate superstructure, either open or sheathed. For machinery requiring these, the other appropriate specifications must also be used. There are many diagrams showing details of construction.

**C.S.A. A82.57—1954—Inorganic aggregates for use in interior plaster,** 2nd ed. 50 cents.

This specification covers the aggregates which are most commonly used in interior plaster. These include perlite, sand (natural and manufactured), and vermiculite, although others may be used if tests have proved them to yield plaster of satisfactory quality.

Information is given on the sizes and weights of aggregates, and methods of sampling are included.

**C.S.A. C22.2 No. 16-1954—Construction and test of insulated conductors for power-operated radio devices,** 4th ed. $1.50.

Providing minimum requirements, this specification applies to insulated conductors intended for use in power-operated radio devices, but does not apply to the supply cords.

Details are given of general requirements, conductors, insulation and braids to be used, and of tests for different types of conductors.

**C.S.A. C22.2 No. 103—1954—Construction and test of electric fence controllers.** $1.00.

This standard applies to indoor and outdoor types of stationary electric fence controllers for primary potentials up to and including 125 volts between conductors. It does not apply to electric fence controllers of a continuous (uninterrupted) current type, or equipment intended for indoor use, such as electric fly screens, etc.

Details are given for all phases of construction, including frames and enclosures, mounting, wiring, insulating, motors, grounding, etc. Tests are given for output requirements, temperature, dielectric strength, weatherproofness and endurance.

**C.S.A. C22.3 No. 3—1954—Inductive co-ordination; definitions, principles and practices,** 2nd ed. $1.00.

Another in a series of standards covering outside wiring rules, this revised edition of a standard originally published in 1936 covers the principles and general practices applicable to supply or communication systems, or both, for the purpose of effecting inductive co-ordination in cases where inductive interference exists, or is expected to occur.

Definitions are given of all the terms used in the standard, the principles which should be followed by parties owning oroperating communication systems are outlined, as are the practices which will promote the inductive co-ordination of supply and communication systems.

An appendix considers separately noise induction from two classes of harmonic current or voltage components on the supply line, that is, balanced components and residual components.

**C.S.A. S16—1954—Steel structures for buildings,** 4th ed. $1.00.

This fourth edition of the specification for steel structures for buildings differs in both content and form from the three previous editions. The changes have been made as it was desired to cast it in a manner acceptable to the National Building Code, and also in one suitable for adoption by municipalities. The numbering system has been completely revised, and the appendices deal with different subjects to those in earlier editions.

Among the subjects covered in the standard are types of design, materials, plans, loads and forces, stresses, beams, rivets and bolts, girders, lacing systems, steel joists, workmanship, shop painting, erection and inspection. The appendices cover the weighing and shipping of structural steel, the assembly of structural joints using high-tensile steel bolts, and specifications for cold riveted construction.

## Appointments and Transfers

**New Jobs at Bird-Archer.** — Roy H. Standen has been appointed service engineer in the Toronto office of the Bird-Archer Co. Ltd., water treatment engineers.

Ronald S. Trump is the new Bird-Archer district representative in Quebec, with headquarters in Quebec City.

●

**Peacock Brothers.**—Following the annual meeting of Peacock Brothers Limited, the following executive changes were recently announced: W. P. Ferguson, M.E.I.C., president and general manager; F. A. Lucas, vice-president and director of sales; A. E. Patterson, secretary treasurer.

Elected to the Board of Directors were L. N. Harlock and F. H. Hunt Re-elected to the Board were J. D. Collier, W. P. Ferguson, W. D. Howitt, F. A. Lucas, A. E. Patterson and Hon. J. Kenneth Weir, C.B.E.

After 50 years with the company, John Bryson, former president and secretary treasurer, has announced his retirement.

●

**Inglis Expands.** — The Ontario Branch office of the John Inglis Co. Limited's refrigeration and air conditioning division has moved from the company's main plant on Strachan Avenue, Toronto, to new offices at 49 Niagara Street, Toronto.

Headquarters staff, under manager W. S. McLeese, has been increased.

R. R. Cox, Ontario branch manager, has a full staff of salesmen, engineers and mechanics to provide complete service and installation facilities for all customers in Ontario.

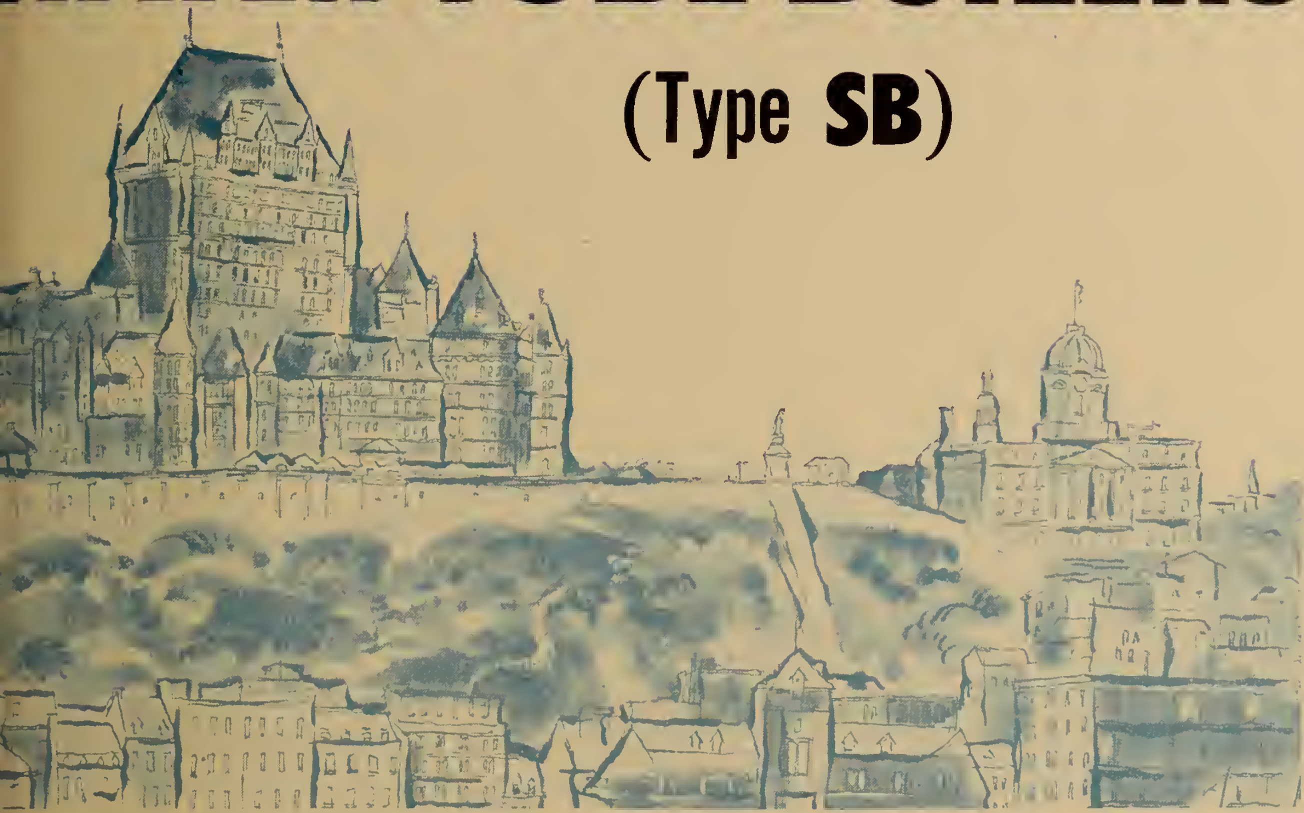
# WATER TUBE BOILERS

## (Type SB)



In the ancient city of Quebec — modern equipment and machinery is used to provide the vital public utilities.

For example: the two Dominion Bridge SB Water Tube ilers which produce steam for gas manufacture and heating purposes at the Quebec Power Company (Gas Division).

These boilers are of the latest type and designed for quick conversion from bunker "C" fuel oil and tar -product firing to coal firing by stokers.

The nature of the service causes rapid load fluctuations, which are easily accommodated by the boilers.

***Other SB features:***

- HIGH EFFICIENCY
- LARGE DRUMS
- EASE OF CONVERTIBILITY
- POSITIVE CIRCULATION
- WATER COOLED FURNACES
- ACCESSIBILITY

J. H. Buttery

**Robbins and Myers.**—K. C. Berney has announced his retirement as executive vice-president, managing director and treasurer of The Robbins and Myers Company of Canada Limited. He will continue to act as a director and will be employed by the company in an advisory capacity. C. Allen Mills has been appointed as vice-president and general manager. He will also act as a director and as treasurer of the company.

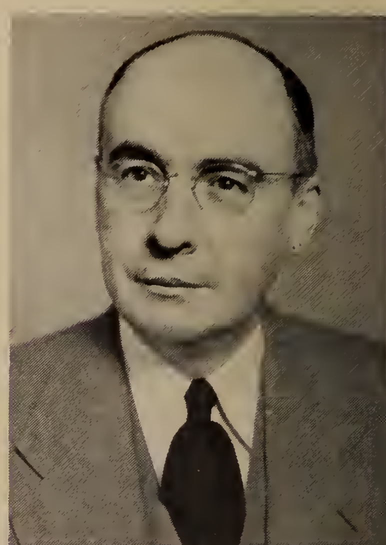
•

**Otis Appointments.**—W. J. W. Reid, president, recently announced the election of William Gordon Robson as vice-president of Otis Elevator Company Limited, effective July 15, 1954.

Mr. Robson after extensive service in the International Division of the Otis organization, returns to the Canadian company, in which he will have general responsibilities having special regard to sales, service and construction operations.

•

*(Continued on page 1040)*



C. Allen Mills

*(Continued from page 1035)*

**Trane Works Manager.**—Grant E. Cole, executive vice-president and general manager, Trane Company of Canada, Limited, has announced the appointment of J. H. Buttery as works manager responsible for all matters of the production division.

Mr. Buttery recently returned from Lille, France, where he was works manager for an international concern with extensive manufacturing operations abroad.

•

**Canadian Arsenals.**—Air Vice Marshal John L. Plant, CBE, AFC, CD, has been appointed a director of Canadian Arsenals Limited.

Recently Air Vice Marshal Plant was appointed Air Member for Technical Services at R.C.A.F. Headquarters in Ottawa. Prior to this appointment he had been Chief of Staff to the Commander in Chief of Allied Air Forces, Central Europe. In Canadian Arsenals he will replace Air Vice Marshal D. M. Smith, who was recently appointed chairman of the Canadian Joint Staff in London, England.

•

# New Equipment and Developments

**Electrothermal Armoured Heater.**—The electrothermal armoured heater is a flexible heating cable constructed of a mineral core and insulated according to temperature range. A suitable resistance alloy is moulded in wire form beneath the insulation covering and the whole assembly is then enclosed in a braided nickel alloy sheath. The nickel alloy input terminals insulated with ceramic have been designed for trouble-free operation at maximum temperature.

The heater is produced for a wide range of heating applications for industry. It is ideal in circumstances where a high rate of heat transfer is required. The heater may be applied directly to metal vessels or pipes and may be lagged or close-coiled. When close-coiled on a metal vessel a loading of 20 watts per square inch (3.1 watts/sq. cm.) of surface area is attained with the 450° C. type heater and 30 watts per square inch (4.65 watts/sq. cm.) with the 800° C. type heater.

It has been successfully applied to metal reaction vessels, catalyst tubes, pipes, etc.

The electrothermal armoured heater is supplied in standard dimensions. In addition, any reasonable length can be made to suit individual requirements. It is suitable for operation on supply mains from 12 to 250 volts A.C. or D.C. with wattage ratings up to 60 watts per linear foot (200 watts per metre) in the 450° C. range and 100 watts per linear foot (330 watts per metre) in the 800° C. range. Manufacturer of the cable is Electrothermal Engineering Ltd., London, England.

●

**Research Laboratory.** — $1,500,000 research laboratory—first building of a five-unit research center—will be built at Kingston, Ontario, by Du Pont Company Limited, it was announced.

The laboratory, to provide facilities for about 80 technical and supporting personnel and to be completed in the fall of 1955 will have a three-fold purpose:

To give basic support to the highly technical sales and production programs of Du Pont of Canada in the chemicals, packaging films and textile fibre fields;

To investigate new processes and products directed toward diversification of the company's operations;

To advance scientific knowledge in fields of present and potential interest to the company without specific commercial objectives.

The project represents the beginning of what will be a sustained, independent program of basic industrial research pertaining particularly to Canadian needs in fields of present and potential interest to the company.

●

**Photosensitive, Anodized Aluminum Sheets.**—Photosensitive, anodized aluminum sheets, designed for photographic reproduction by standard darkroom methods, has been announced by the Metalphoto Corporation, 2903 East 79th Street, Cleveland 3, Ohio. Known as Metalphoto, the aluminum sheets, which measure 0.020 inches in thickness, and which are available in sizes 4" x 5", 8" x 10", and 10" x 12", may be used to produce such products as name plates, dial and watch faces, wiring diagrams, instructions, instrument and slide rule scales, and other products where resistance to abrasives is vital.

Photographs and drawings are processed from ordinary photographic negatives using simple darkroom techniques and standard solutions. The non-facing image is permanently sealed within the sapphire-hard anodized layer. This layer protects the dimensionally stable image from abrasion, temperatures up to 1000° F., and acids, salts and organic solvents.

Additional information may be obtained from the company at the above address.

●

**Voltage Regulator.** — Ferranti Electric announces the development of a new single-phase step-voltage regulator designated RS-32. The new product employs 32 steps to provide 10% or 15% voltage regulation in a wide range of standard voltage and current ratings.

The new regulator has been designed much smaller and lighter than the company's previous products of similar ratings. The control compartment of the new RS-32 contains the well known Astatic Voltage Relay as the main relay. There is also a line-drop compensator and operation counter in the control compartment.

The control compartment can be unbolted from the main tank and installed at the foot of the pole when the regulators are cross-arm or platform mounted. This provides access to the controls without pole climbing.

A position indicator is mounted on the side of the main tank and tilted to be easily read from ground level.

For further details, write to the company requesting Ferranti Flashes, Volume 19, Number 2.

●

**Portable Testing Machine.**—A portable testing machine announced by Soiltest, Inc., 4520 West North Avenue, Chicago 39, makes possible rapid on-the-job testing of concrete and similar materials with laboratory accuracy.

The 200,000 pound capacity Portable Testing Machine can be used in field and laboratory testing of concrete cylinders and beams and other construction materials. The tester is entirely self-contained and no electrical or pressure connectors are required.

The machine is simple to operate. Loads are developed by means of a hand operated, two speed concentric pump which actuates the piston of the main hydraulic system. The unit meets ASTM and AASHO specifications for design and accuracy of hydraulic concrete testing machines.

Use of the portable testing machine is not confined to concrete testing. It can be used as a high capacity shop or laboratory press; compression testing machine for castings or small vessels; experimental press for powdered metals work; and as a laboratory testing machine, for all types of routine work on small sized specimens such as ceramic pieces, rock cores, timber and welded sections.

●

(*Continued on page 1042*)

(*Contined from page 1040*)

**Water Chillers.**—Three larger size CenTraVac water chillers for comfort or process air conditioning have been introduced by Trane Company of Canada Limited. With the additional units the line now includes 8 sizes from 45 to 400 tons capacity.

Trane CenTraVac incorporate a hermetic centrifugal compressor that automatically matches power consumption to load variations from 100 per cent to 10 per cent of compressor capacity. Power input is limited to actual cooling requirements, reducing power costs.

The CenTraVac starts, stops and runs automatically with the controls interlocked for added safety.

The compressor motor is hermetically sealed inside the casing, eliminating need for shaft seals and consequent shaft seal maintenance and possible loss of refrigerant through the seal. The compressor is direct drive type.

For complete information write for Bulletin DS399 to Trane Company of Canada Limited, 4 Mowat Avenue, Toronto 3, Ont.

●

**Insulation Testing Set.** — A 2,500 volt portable insulation testing set, developed to meet the demand for a safe and economical device for making insulation tests required by the Canadian Standards Association on domestic and industrial appliances that are operated on 110, 220 and 500 volt circuits, is available from Canadian General Electric Company.

The range of secondary voltages will allow the testing of fractional horsepower motors, switches, wiring devices, hair waving equipment and small capacitors.

This easily portable set weighs only 42 pounds and is equipped with a convenient handle and a set of hangers for wall or post mounting.

The insulation testing set consists of a 0.240 k.v.a. air-cooled transformer contained within a metal case. The different high voltages are obtained by changing taps on the primary winding or supply side of the transformer by means of a plainly marked dial switch. The high voltage winding is connected directly to the testing leads.

For further information write to Specialty Transformer Sales, Canadian General Electric Company, Ltd., 830 Lansdowne Ave., Toronto, Ont.

●

**Hydraulic Overhead Loader.** — A new overhead loader and angledozer, known as the McEwen Hydraulic Overhead Loader, puts on the market for the first time a machine that automatically gives free and complete track oscillation while dozing and oscillation restriction while loading. This gives maximum efficiency in both operations. Instantaneous finger tip control and low hydraulic pressure are features. Simplicity in changeover from loader to dozer allows the operator to complete the job alone in less than 15 minutes. Designed for mounting on a D2 Caterpillar Tractor, it has a nominal bucket capacity of 1 cu. yd. Loading from a bank its 16 second load cycle allows a 5 cu. yd. body to be filled in from 1 to 2 minutes. In snow it has easily handled 4 cu. yds. per scoop. The manufacturers are receiving enquiries from as far away as Africa. Selling is through the Caterpillar dealers. Further information may be had from the manufacturers — The Atlantic Bridge Company, Limited, Lunenburg, N.S.

●

**New Company.**—H. K. Ferguson Company of Canada, Ltd., engineers and builders, with headquarters in Montreal recently announced the formation of a new British company known as H. K. Ferguson Company of Great Britain, Limited, with headquarters at 19 Berkeley Street, London, England.

The offices will be equipped to offer engineering and building services and will have accounting, estimating and purchasing departments.

Charles P. Stolberg, assistant chief of operation, will direct engineering and construction, and Raymond B. Aufmuth is chief engineer.

●

**New Steel.**—Coated with ice at 45 degrees below zero, four large closed pressure tanks of a new kind of steel were recently put through burst and impact test paces at Birmingham, Ala.

The vessels were made of a new quenched and tempered steel known as "Carilloy T-1". This new material is

(*Continued on page 1044*)

(*Contined from page 1042*)

the product of United States Steel Corporation's Research Laboratory.

Two separate test methods — burst tests and drop impact tests—were used to demonstrate the strength and toughness of the steel. Two burst tests were made on alternate days to determine how much internal pressure the tanks could withstand before they burst. In the drop tests a new method of testing full-scale vessels was used. A 26,700 pound steel weight was let fall upon the tanks from heights of 52, 73 and 101 feet to show the toughness of the steel at low temperatures. Internal pressure in the drop tests was 1,875 pounds per square inch.

Results of the tests performed on the four tanks were as follows: (1) June 29 burst test non-stress relieved vessel at 45 degrees below zero 2,850 pounds per square inch internal pressure at moment of burst. (2) June 29 drop test non-stress relieved vessel at 45 degrees below zero 26,700 pound weight dropped from 101 feet caused break. (3) June 30 first test on stress relieved vessel at 45 degrees below zero 2,850 pounds per square inch internal pressure at moment of burst. (4) June 30 drop test on stress relieved vessel at 45 degrees below zero, 26,700 pound weight dropped from 101 feet caused break.

•

**Heating Division, Marine Industries Limited.**—Establishment of a new sales and executive office in Montreal of the heating division, Marine Industries Limited, is announced by Omer E. Guevremont, manager of the division. The new office will head up the distribution of Dravo Counterflo and Paraflo space heaters which are manufactured in Sorel by Marine Industries.

Mr. Guevremont announced the introduction of a new type of space heater, the Paraflo, which has been designed to meet specific heating problems. It has an output capacity of 200,000 to 250,000 btu's per hour, suitable for machine shops, auditoriums and similar buildings. The larger Counterflo space heater output ranges from 400,000 to 2,000,000 btu's per hour.

•

**Static Frequency Converter.** — A 5-kw static frequency converter that provides 360-cycle square-wave current at 600 volts for high-frequency operation of fluorescent lamps has been announced as available from Canadian General Electric Co. Ltd.

Designed particularly for such applications as experimental and commercial plant growth rooms, television and radio studios, luminous ceilings and libraries, the G-E frequency converter increases light output and assists in the lowering of heat loss. Noise is reduced because the converter can be located remotely. Fixtures in the system are lighter and smaller since they do not require the familiar transformer-type ballast.

The completely packaged unit combines the functions of frequency converter, step-up transformer, current regulator, and square-current generator.

Further information may be obtained by writing to Specialty Transformer Sales, Canadian General Electric Co. Ltd., 940 Lansdowne Ave., Toronto.

•

**Titanium Electrolytically Produced.**—The Shawinigan Water and Power Co., has been successful in making high-grade titanium metal by an electrolytic process, and is planning to expand this work to the scale of a larger pilot plant as a step toward commercial production.

The company has applied for patents in many countries, and the experience derived from operation of the semi-commercial pilot-plant will be a guide in subsequent installation of units of full commercial size.

Comparable to steel in strength, and with a weight about halfway between steel and aluminum, non-corrosive and highly heat resistant, titanium meets many special requirements of modern design for defence and civilian purposes.

Work on the development of titanium has been underway since 1945, and Shawinigan believes that the electrolytic method is capable of being developed into a continuous process.

•

**The "Gammagage" Density Gauge.**—Designed as a versatile instrument that will meet a number of industrial uses, Isotope Products' new density gauge is currently on tour of a diversified group of industries to explore its range, accuracy, stability and value.

Just as the betameter can measure paper, sheet metal, rubber, plastics, asbestos and a wide range of other materials, the density gauge is designed to measure such diverse products as oil, liquid foodstuffs, chemicals, mine and mill concentrates, other industrial fluids and powdered solids.

It has been successfully tested and proven in many industrial applications and at the moment the instrument is at Isotope Products' Oakville laboratory where it is being tested for its use in controlling concentration of uranium from pitchblende ores. Thus, the latest device of atomic research may assist in production of atomic energy's basic raw material, as it may help in production of basic materials for many other industries.

The density gauge is one of that group of gammagage instruments which are harnessing gamma radiation to a range of applications. For example one type of gammagage is used to detect and plot corrosion patterns, another type measures liquid level in vessels.

•

**Soil Testing Equipment.**—A new line of soil testing equipment designed by Karol and Warner has been announced by the Tinius Olsen Testing Machine Company. Included in this line are unconfined compression machines, triaxial testers, consolidation load frames, direct shear machines, consolidometers, compaction molds and other related soil testing equipment. Information about the entire line is available upon request to Tinius Olsen Testing Machine Company, 3053 Easton Road, Willow Grove, Pa.

•

**Conversion Slide Rule.**—A conversion slide rule is available bearing 64 linear, liquid, energy and miscellaneous factors on one side plus a complete trig scale arrangement on the reverse side consisting of A, K, DF-CF, T, S, CI, C-D and L scales. By "positioning" a conversion mark opposite an index mark, any conversion is automatically set and read on the C, D, CF or DF scales without moving the slider or further computation. The same automatic conversion principle is adaptable to any set of specialized conversion factors on either pocket-size or 10-inch rules for any line of work. The new model 903-T single-setting conversion rules is made of light weatherproof metal alloy, is 12⅛ x 1¼ x 3/32 inches in size with white facing, and weights 2¾ ounces. Manufactured by Pickett & Eckel, Inc., 1109 S. Fremont Street, Alhambra, California.

•

**Dawe Instruments Ltd.**—Dawe Instrument Limited have announced the formation of a Canadian division located at 59 Crown Crescent, Ottawa, Ontario. They have announced that plans have now been finalized for the sales and service of Dawe Precision Electronic Instruments to be handled by MJS Electronic Sales Limited, 2028 Avenue Road, Toronto.

•

**Radioactive Tracer Techniques.**—Radioactive tracer techniques have been successfully applied to the plastics industry to measure defects smaller in size than the proverbial needle in a haystack.

Believed to be the first peacetime application of atomic energy to plastics molding, the new techniques can detect and measure one tiny bit of metal in twenty million plastic parts, according to a General Electric Company executive.

The technique involves irradiation of a plastics mold part in an atomic pile at Brookhaven National Laboratory at Upton, N.Y.

Further information may be obtained from the Molded Plastics Section, Canadian General Electric Company Limited, Cobourg, Ontario.

# Publications

**For copies of the publications mentioned below please apply to the publishers at the addresses given in the items.**

**Please mention *The Engineering Journal* when writing.**

**Steam Generators.** — The publication "Power" is Canadian Vickers' latest release on Vickers Keeler steam generators. This booklet is divided into two sections; the first deals with boiler descriptive matter, while the second part carries a number of ready reference tables valuable to engineers.

A copy will be sent upon request. Write to Canadian Vickers Limited, P.O. Box 550, Place D'Armes Station, Montreal.

●

**Betratron Industrial Radiography Laboratory.**—Factors to be taken into consideration in planning and constructing a betratron industrial radiography laboratory are discussed in a new eight-page bulletin released by Canadian Allis-Chalmers Limited.

The bulletin describes and portrays features of Allis-Chalmers' betratron laboratory which was placed in operation at its West Allis Works in 1952. Its cost was completely amortized in less than a year by savings resulting directly from its use.

Several pages in the bulletin are devoted to a description of the construction of the laboratory. The bulletin also weighs the advisability of altering existing radiography facilities for betratron use and sets forth such general requirements as location, construction, work handling equipment, heating and ventilating, location of electrical gear, etc., to be considered in arranging for a betratron laboratory.

Copies of the bulletin, "Laboratory Planning and Construction - Industrial 22-MV Betratron Radiography, "31B8121, are available on request from Canadian Allis-Chalmers Limited, Box 37, Montreal, Quebec.

●

**Telemetering Bulletin.**—A new expanded edition of Bulletin M1710 telemeters and accessories has just been published by The Bristol Company of Canada Limited.

In addition to telemetering over telephone circuits, carrier current and private wires, the bulletin features microwave telemetering, telemetering with selective calling and time multiplexing telemetering.

Specific information and application illustrations are given on how Metameter telemetering may be applied to the measurement and transmission of pressure, flow, liquid and water level, mechanical motion, electrical units and totalized power load. Each category is treated separately.

Copies of the bulletin, may be obtained by writing The Bristol Company of Canada Limited, 71-79 Duchess Street, Toronto, Ontario.

●

**Gages and Valves.** — New Catalog No. 236 covers practicaly the complete Jerguson line of liquid level gages and valves with a condensed presentation of the most pertinent data and specifications. Included are illustrations of the various standard and special function Jerguson gages and valves, description of features and uses, materials used, steam ratings of gauges, dimensional drawings, and a full page table giving standard and optional construction features and specifications of Jerguson valves.

Write Peacock Brothers Limited, P.O. Box 1040, Montreal, Quebec.

●

**Maintenance and Construction.** — The Tremco "Quick Reference Guide" released by The Tremco Manufacturing Co. (Canada) Limited, Toronto, is a compact, illustrated 24 page booklet of special interest to all concerned with problems of building maintenance and construction. A number of Tremco products are described and various maintenance problems of roofs, floors, sash, masonry preservation, etc., are discussed.

Copies of the "Quick Reference Guide" may be obtained from your local Tremco representative, or by writing The Tremco Manufacturing Co. (Canada) Limited, 220 Wicksteed Ave., Leaside, Toronto 17, Ontario.

●

**Shipping and Packing Equipment.** — Canadian Steel Strapping Company Limited new catalogue (154) is a guide to shipping and packing equipment.

The first part of it is about the "Signode" system of tensional steel strapping. The second part covers miscellaneous packing and shipping room equipment. Shipping problems from light parcel post to heavy carload shipments are dealt with. Anchoring of loads in truck or freight cars is mentioned. Particulars are given of stencil equipment, gum tape machines, carton stitchers, tacking machines, nailers and other equipment.

A copy of this catalogue will be sent to those inquiring for it on their company's letterhead.

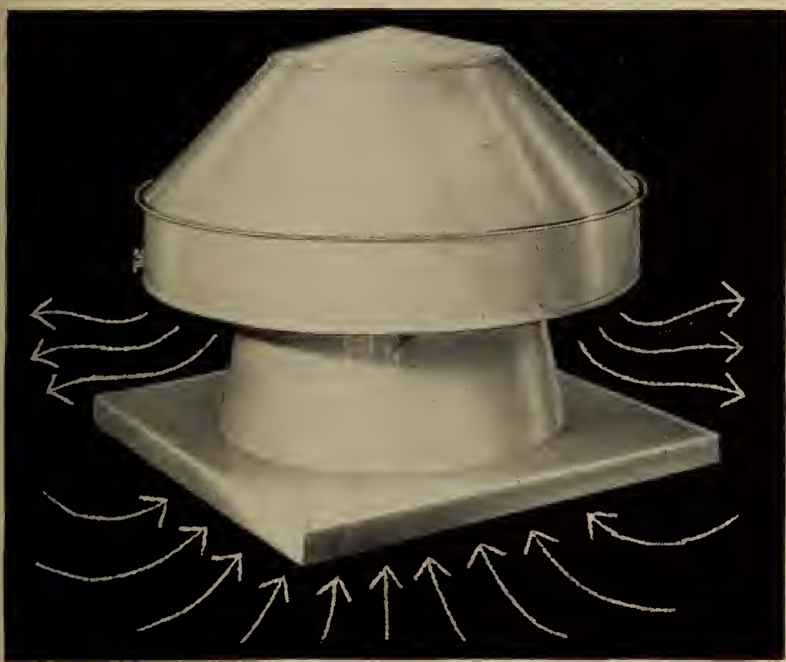
●

**Lighting.**—A Curtis-Miller 28-page catalogue recently announced features the complete Miller line of industrial and commercial lighting available in Canada through Curtis Lighting of Canada Limited, 195 Wicksteed Avenue, Toronto 17, Ont. Copies of this catalogue are available upon request from Curtis Lighting.

●

**Water, Sewage and Trade Waste Equipment.**—Hardinge Company, Incorporated, York, Pennsylvania, has released a 6-page, colour brochure describing its line of water, sewage and trade waste treating equipment. Included are several typical flow sheets

# DIRTY AIR?



## GET RID OF IT... with SHELDON ROOF VENTILATORS

Dust, Fumes, Heat and Injurious Gases are eliminated from working areas — in a hurry.

To give best results in the different situations that arise we have engineered three designs to fit most common applications.

The Sheldon FR is illustrated directly above with action of air as indicated. Use it to exhaust impure air from large areas.

If plant air is perhaps dangerously contaminated in certain departments — use the Sheldon VR Unit. It discharges vertically at high velocity. This unit and its action is illustrated at top right. Sheldon Roof Ventilators are shipped to you as complete packaged units — ready to install.

NEW CATALOGUE No. 6001 on SHELDON ROOF VENTILATORS. Write today for your copy.

For use with ductwork system and where quiet operation is required — use Sheldon Unit H2.

## NEW PLYMOUTH HARBOUR BOARD NEW ZEALAND CONSTRUCTION OF WHARF

**Tenders will be received until 5 p.m. on 26th October, 1954, for the construction of Moturoa Jetty in reinforced concrete approximately 1,100 feet by 90 feet. Drawings and contract documents may be inspected at the New Zealand Trade Commissioner's Office, 609 Sun Life Building, Montreal, P.Q., and may be obtained from the Consulting Engineer, Mr. W. G. Morrison, 28 Buller Street, Wellington, New Zealand.**

and a brief description of auxiliary apparatus such as digestors and flocculating equipment. Ask for bulletin AH-442.

●

**Foundry Mechanization.** — Link-Belt Limited's complete line of equipment for mechanization of ferrous and non-ferrous foundries and its use in increasing production and producing better castings are covered in a new 40-page book No. 2423.

This comprehensive book will be helpful in selecting a specific piece of materials handling equipment to improve a particular phase of production or as an aid in planning a completely mechanized foundry operation. Descriptions of sand preparation and mold, core, casting and sand handling equipment are supplemented by over 70 pictures of actual installations.

A copy of the book will be sent on request from Link-Belt Limited, Box 173, Station "H", Toronto 13, Ont.

●

**Educational Aids.** — How industry furthers education programs in secondary schools is emphasized by an Educational Aids catalogue just released by Canadian Westinghouse Company Limited. Produced by the firm's public relations department, the publication describes a wide variety of free or low cost booklets, charts, posters, and other aids available to high school and vocational school teachers.

Educational topics include science, rural electrification, home economics, industrial arts and photography. The catalogue also has sections on lighting, technical publications and project aids for students and teachers.

Copies of the catalogue may be obtained from the public relations department, Canadian Westinghouse Company, Limited, Hamilton, Ont.

●

**Heating Control Bulletin.**—A new 12-page bulletin on simplified heating controls for all oil burners has been announced as available from appliance control sales, component product department, Canadian General Electric Company Limited, 212 King Street West, Toronto.

Especially written for oil burners dealers and servicemen, the two-colour publication includes step by step installation photographs on the complete line of G-E oil burner controls. It also provides information on the company's heating control exchange plan and free promotional aids available to all C.G.E. servicing distributors and dealers.

Designated GEA-6118, this new bulletin is available on request to appliance control sales, Canadian General Electric Company, 212 King Street West, Toronto.

●

**Developing Canada.**—"Ingersoll-Rand's role in developing Canada" is the title of an interesting booklet recently distributed by that company. Together with a brief history of the company's formation there are interesting notes about Canada's growth in plant construction, hydro-electric projects, etc. For emphasis two specific "miracles" are referred to in this article, the Kitimat project in B.C. and the Bersimis project in Quebec.

Montreal address of Canadian Ingersoll-Rand Co. Ltd. is 620 Cathcart St.

●

giving substance to dreams
Installation of this English Electric 106,000 KVA generator at Kemano marks another step in translating the vision of the planners into reality. English Electric is proud to have shared in equipping another of the world's great projects.
For hydro-electric stations the world over English Electric produces complete turbine generator units and associated equipment for any head and output. The quality of their design and workmanship has been proved under all conditions. There is an English Electric office near you, equipped to provide all necessary information on your electrical requirements.
*English Electric generator stator in transit from the service bay to its permanent location in unit No. 3 in the background. (Alcan B.C. project—photo courtesy Aluminum Co. of Canada Ltd.)*

**Corrosion.**—A 346-page book containing 3512 abstracts of articles and books on corrosion has been published and is now available from the National Association of Corrosion Engineers, 1061 M & M Building, Houston 2, Texas. The articles are from more than 500 periodicals published all over the world and are abstracted by some 30 agencies that authorize NACE to use their abstracts.

This third volume of abstracts published by NACE contains summaries of articles and books published in 1948-49, topically indexed and cross-indexed and with both alphabetical subject and author indexes. The two previous volumes covered articles published in 1945, and 1946-47. Copies of all are available from the association, a non-profit organization concerned with corrosion control.

●

**Safety Devices.**—The National Safety Council's new book, "Safety Devices and Ideas," describes more than 90 safety devices which have been tried and found effective in plant use.

The devices were originally part of a safety gadget show presented during the chemical sessions of the 1953 National Safety Congress. Although designed for use in chemical plants, the devices have application in other industries as well.

Most of the devices are not commercially available, having been thought up and constructed by plant personnel to meet some particular hazard.

Each idea is illustrated with a large photograph which shows clearly the details of construction. The text accompanying the pictures gives other pertinent data.

"Safety Devices and Ideas" is available for $1.25 to Council members and $2.50 to others. For further information write the National Safety Council, 425 N. Michigan Ave., Chicago 11, Ill.

●

**Gas Regulators.**—Air Reduction's complete line of gas regulators is fully described in the new 36-page catalogue now being offered. Cylinder, manifold and pipeline regulators are illustrated with complete descriptions covering specifications and operating data.

Each regulator has a chart showing types of gauges used with it, inlet and outlet connections, maximum flow cfh and maximum working pressure psi.

Also included are flow and pressure charts indicating at what point the regulators can be used to perform a particular job.

For complete information, request a copy of this catalogue by writing to Air Reduction Canada Limited, 905 Hodge Street, St. Laurent, Montreal 9, Quebec.

●

**Sewer Structures.**—The four important requirements for sewers are discussed in a new Armco bulletin—easy handling, fast assembly, long life, and installed economy. The theme of the piece is that all sewer problems are different. They may involve as many as eleven considerations. How, where and when to choose the right type of sewer structure for the right purpose frequently puzzles city officials, engineers and contractors. This bulletin should help. Write to Armco Drainage & Metal Products, Inc., Middletown, Ohio, for a free copy.

●

**Magnetic-Particle Tester.**—A new illustrated bulletin that explains the operation of a magnetic-particle test unit called Portaflux is available gratis from the research and control instruments division, North American Philips Company, Inc., 750 South Fulton Avenue, Mount Vernon, N.Y.

Data covers method used in quickly and economically checking steel and iron objects for surface cracks or discontinuities. Objects under study are magnetized either by passing a current through the metal or through a surrounding cable in the form of a coil.

Magnetic iron oxide or precipitated iron powder distributed over the surface aligns itself in such a way that surface defects may be clearly located. Powders are usually black, gray or red to make the pattern readily visible to the naked eye.

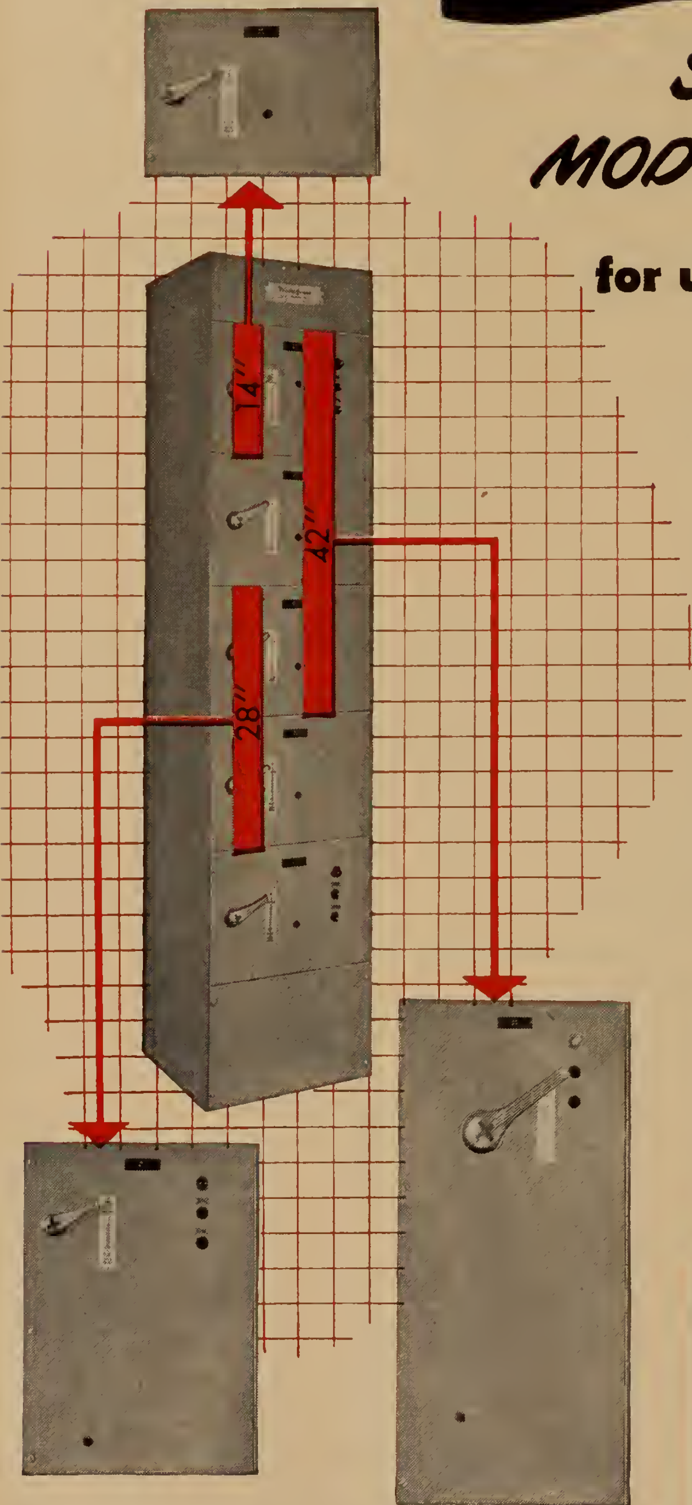
# Westinghouse

... the greatest advancement in "PLUG IN" control center design

## STANDARDIZED MODULAR DIMENSIONS

### for unmatched flexibility



No other control center gives you so much flexibility as the new Westinghouse design. Standardized, modular dimensions are the source of this important advantage.

Vertical structures of standard width and depth are 76″ or 90″ in height. Starter units are 14″ high or in multiples of 14″. This modular design permits many combinations of starter units in single vertical structures. It provides for simple interchangeability between large and small units to meet changing requirements.

The new Westinghouse design also provides for back-to-back mounting without increasing depth. This permits a greater number of starter units to be installed in each vertical structure. To meet growing control requirements, additional vertical structures may be added to the group already in service.

**Consider all the advantages of this new control center!**

New Magna-Grip "plug-in" connectors for greater operating simplicity; a large vertical wiring trough for greater wiring convenience; interlocking handles and "tilt position" disconnect for extra safety. These are random examples. The complete story is in Booklet B-5621. For your copy, write to

*Montreal, Que.*

*A paper presented before the 68th Annual Meeting of the Engineering Institute of Canada at Quebec, May, 1954.*

Built during years of material shortages due to the Korean War, both plants here described delivered power within 21 months of the time construction commenced. This speedy progress was partly due to replacing the conventional power house superstructure by a semi open-type design, with gantry crane to remove equipment to a closed repair bay at one end of the substructures.

As seen from Fig. 1, the Peribonka River empties into Lake St. John, Quebec, on the north side, by way of a narrow inlet some twelve miles long extending in an easterly direction. At its base is the village of Ste. Monique de Honfleur, and a mile up the river, at Chute à la Savane, the Peribonka No. 2 plant is located. Here, the river swings northward. The Chute du Diable site of the Peribonka No. 1 plant is located some 12 miles upstream, skirting the junction of the Precambrian Uplands and the pleistocene deposits of the Lake St. John Basin.

The earlier construction of the Isle Maligne and Chute à Caron plants on the Saguenay River first utilized the great storage capacity of Lake St. John. When Shipshaw No. 2 was commenced in 1941, the capacity of 1,200,000 h.p. pointed the way to storage development on the Grand Peribonka River, to increase the minimum regulated flow out of Lake St. John.

Accordingly, Lake Manouan and Passe Dangereuse storages, of 78.5 b.c.f. and 183 b.c.f. respectively, were built and placed in service in 1941 and 1943.

With the greatly increased demands for power following the Second World War, attention was turned to the two sites on the Peribonka River.

At Chute du Diable, the river dropped some 26 feet. There were three natural channels, separated by high, rocky outcrops. At the east was a narrow, deep gorge, and in the centre a shallow, boulder-filled passage, which, before development, was dry for flows below 14,000 c.f.s. The channel on the west side carried water only during freshet periods. With the exception of the gorge, the site was characterized by massive boulders and outcroppings of rock. A mile downstream, the river again divides into three channels with rock ledge bottoms which form a control to river flow.

At Chute à la Savane, the natural drop in the river was approximately sixteen feet. As compared to Chute du Diable, the terrain is more open, necessitating a long crest length of dam, and there is a comparative absence of rock outcrops. Half a mile downstream a narrow gorge forms a partial control for certain elevations of Lake St. John. However, when the Lake is full, it floods back to the foot of Chute à la Savane.

Surveys showed that gross heads of 113 and 115 feet could be developed at the upper and lower sites respectively, with forebays at elevations 488 and 375, and allowing for improvements in the tailwater elevations of both. The drainage area above Chute du Diable is 10,260 square miles, of which 6,420 is controlled by the Manouan and Passe Dangereuse storages, leaving 3,840 square miles to be controlled at the headpond.

Between elevations 488 and 463 of the headpond there is an estimated pondage of 13 billion cubic feet flooding back to Grande Rapide, some thirty miles upstream. Between the two sites the Alex River joins the Peribonka, providing an additional drainage area of 500 square miles.

The average monthly run-off from the watershed, based on thirty-six years of record, varies from a low of 0.50 c.f.s. per square mile in February to a high of 5.56 c.f.s. in May, with a yearly average of 2.0 c.f.s. per square mile. The regulated flow of the river for both plants is estimated at 19,800 c.f.s. Before construction it had been the practice of the Aluminum Company of Canada to draw heavily on the Peribonka storages to hold the level of Lake St. John.

Thus, commencing in December and extending through in most years until March, a flow of 40,000 c.f.s. was maintained. In March, the storages were greatly reduced, and the flow dropped off to 10,000 c.f.s. or less until spring floods replenished the reservoirs. This method of operation was maintained during construction, and had

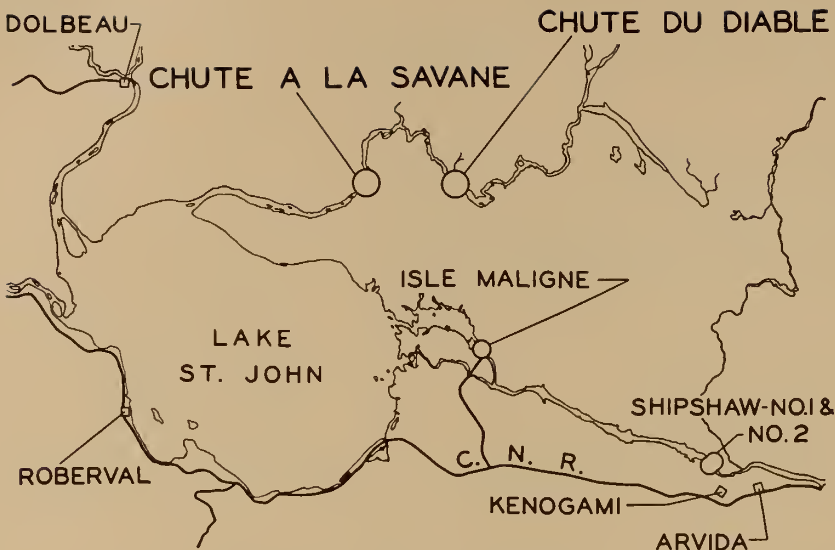

Fig. 1. Peribonka developments.

a very important bearing on the unwatering scheme, as well as the scheduling of the work.

The maximum spring flood on record occurred in 1928, and was estimated 225,000 c.f.s. from Quebec Streams Commission records. In the years following construction of the Passe Dangereuse and Manouan storages, it has not exceeded 90,000 c.f.s. Based on the regulated flow and a capacity factor of approximately 80 per cent, it was decided to install capacities of 275,000 h.p. and 285,000 h.p. at Peribonka No. 1 and No. 2 respectively.

In all, nine schemes were studied for the upper development and eleven for the lower, before selection of the final arrangements described hereafter as the most suitable from an operating and economic point of view.

#### General Description of Developments

Fig. 2 shows a general plan of the Peribonka No. 1 Development. Assuming the river to flow in a northerly direction, the regulating gate section is located on the east end of the dam, in the gorge previously mentioned. This section, in the initial stages of the development, formed the by-pass at which final closure was made. The base line of the structure is roughly at right angles to the direction of flow, and, to the eastward beyond a knob of rock, a cut-off 140 feet long was required to close the contours. The log chute is located to the west, followed by the power house and intake structures. On the west side of the power house a deep cut was made into the rock, and a drainage ditch provided. The lining of the ditch was carried up the rock face and topped by a low retaining wall.

At the top of the knob, the base line of the dam turns through 47°, stations east and west being dimensioned from this turning point. Between stations 2+95W and 6+90W, the spillway section is located, with a retaining wall on the east side of the flood channel downstream. At station 10+00W, the base line turns through an angle of 77°-15′ and the concrete bulkhead terminates some 30′ beyond. Along this base line, bed rock is below forebay level, as low as elevation 460. Due to the great length of seepage path and the relatively impervious nature of the overburden, it was decided not to pour concrete to close the contours against the bed rock. In the event of any tendency for the bank extending along the flood channel to slide, plans were prepared to provide a concrete retaining wall on rock. A roadway 16 feet wide is provided on top of the dam from the west abutment to the intake section, with provision to complete it to the east bank at a later date.

Fig. 3 shows the general arrangement at Peribonka No. 2. Here, the river flows southward. The regulating gate section, comprising the by-pass in the initial stage as in the upper plant, is located in the cascade, with the log chute and power house on the same base line to the east. Proceeding westward from the regulating section along this base line, the spillways are located on top of the west bank, with excavated approach and flood channels. A retaining wall some 215 feet long carries the flood discharge well below the dam before allowing it to fall over the bank into the river.

On the east and west ends, wingwalls turn back upstream. The west wingwall terminates on a rock knob, virtually at forebay level, and beyond it bed rock dips down below. The overburden in this area is relatively impervious, and forms an embankment to effectively impound the headwater. Beyond the east wingwall, however, the overburden is deep, and the ground drops off downstream to an elevation some 40 ft. below forebay level. There, special treatment was required, as described later.

#### Dewatering

The by-pass section at Chute du Diable was located in the gorge. It was designed to pass 70,000 c.f.s. with upstream water level at elevation 430. The design called for cofferdams Nos. 1 and 2, above and below the by-pass structure, to be constructed before the winter regulated flow of 40,000 c.f.s. commenced. While the by-pass concrete was being poured, the river flow, which in this period rose to 40,000 c.f.s., was to be passed through the centre

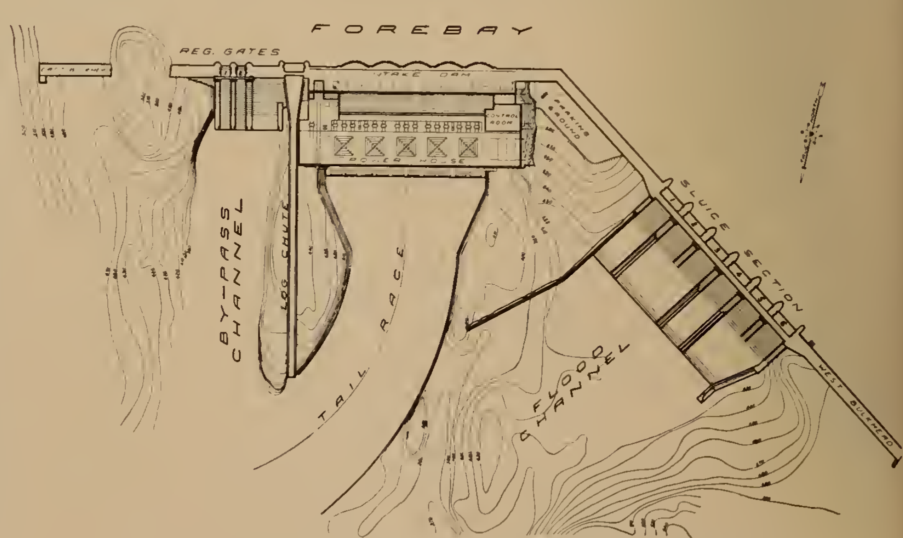

Fig. 2. General plan of the Peribonka No. 1 development.

channel (where the power house is located).

Following the completion of the by-pass structure, and before the following spring flood, the river was to be turned through the by-pass, and cofferdams Nos. 4 and 5 built to unwater the centre channel, No. 4 cofferdam being sealed against the bulkhead adjoining the by-pass. Since No. 6 cofferdam to unwater the tailrace could not be completed until after the spring flood, the auxiliary cofferdam No. 5 was provided below the power house to enable work to commence in this area, with excavation of the tailrace to proceed on completion of No. 6. Cofferdam No. 3 closed off the spillway area and was to be built with cofferdams Nos. 1 and 2.

As matters turned out, construction was commenced later than anticipated, and the heavy draft from storage was required earlier. It proved impossible to cofferdam the gorge with the higher flow, and an auxiliary by-pass channel was put through at the location of Nos. 4 and 5 spillways. The story of how the gorge was finally cofferdammed will, it is hoped, be told at another time. This constituted one of the highest crib dams built in this country, being over 65 feet high.

At Chute à la Savane, the unwatering required the improvement of the secondary channel against the east bank to a width of 120 feet, to pass 40,000 c.f.s., while the closure section was unwatered and its concrete poured. An identical design of closure section with Peribonka No. 1 was used. Cofferdams here had a total crest length of some 1,300 feet.

**General Geology**

The Precambrian rock at both sites belongs to the Anorthosite Series, and is cut by acidic and structurally weak mica-rich dykes. Where unaffected by faulting, the anorthosite is a strong, dense rock, grey to black in colour. In some sections, jointing is well developed, and excavation had to be carried below the zone of weathering along these joints. Grouting was required to seal the joint cracks.

The pleistocene deposits consist of boulder till, laid down by the glaciers, and silty clay and sand laid down by a subsequent marine inundation. The boulder till is not everywhere present, and the silty clay is frequently found in contact with the bed rock. This Lake St. John clay frequently has a high water content; is thinly bedded or varved; is relatively impervious although it may contain sand lenses or zones. It is very sensitive to vibration. The sand deposits, usually found at higher elevations, are of variable thickness, and sometimes are water-logged and contain perched ponds.

At Chute du Diable, the main channel of the river was located by faulting in the bed rock. A multitude of parallel or intersecting faults were uncovered. Movement along the individual faults was of a minor nature, but the total residual horizontal movement was in the order of 30 feet.

It was necessary to carry out deep excavation, and while the rock finally uncovered was structurally sound, it was badly shattered and some of the faults were open. Extensive diamond drilling and pressure grouting was required to seal this section. In the log chute and intake section, further shattered rock was uncovered, and deeper than normal excavation was required to secure adequate foundations. Curtain grouting effectively sealed this area.

At Chute à la Savane, the main channel was located by faulting along a granitic dyke. It was found that this granite was so badly shattered by faulting that the upper material could be shovelled away. Clay gouge was developed along many of the faults. Here, again, movement along individual faults was minor, but the aggregate movement was in the order of tens of feet. Deep excavation was necessary to secure good foundations, and the subsurface rock was sealed with closely spaced grouting.

On the east side of the river, mica-rich, structurally weak dykes that crossed the east bulkhead area offered a serious foundation problem. Weathering was deeply effective along these dykes, and clayey gouge was developed at the contacts with the wall rock and along shear planes in the dykes. Deeper than normal excavation, and a tight grout seal to depth, were required.

As excavation progressed, deep troughs were found in the bed rock surface. Faulting exposed in the bottom of the troughs necessitated additional rock excavation and closely spaced diamond drilling and grouting to secure tight foundations.

At both sites the drilling for foundation investigation and for grouting was by diamond drills. The hole size used was AXT, which gave a hole 1-7/8 inches in diameter, and the core recovered was 1-5/16 inches in diameter. The depth of the holes varied from 50 to over 200 feet. This hole size allowed entrance of an injection and sealing assembly which made sectional water-testing and step-grouting possible.

All holes were washed after drilling; water-tested to determine the location of cracks and openings in the bed rock, then the holes were grouted to refusal in steps from the bottom up. After the grout had taken its initial set, the holes were washed and re-grouted to refusal.

Pressures used for testing and grouting varied from 10 to 20 psi. at the surface to over 200 psi. at depths over 100 feet. Grout used consisted of Portland cement and water; the water cement ratio varied

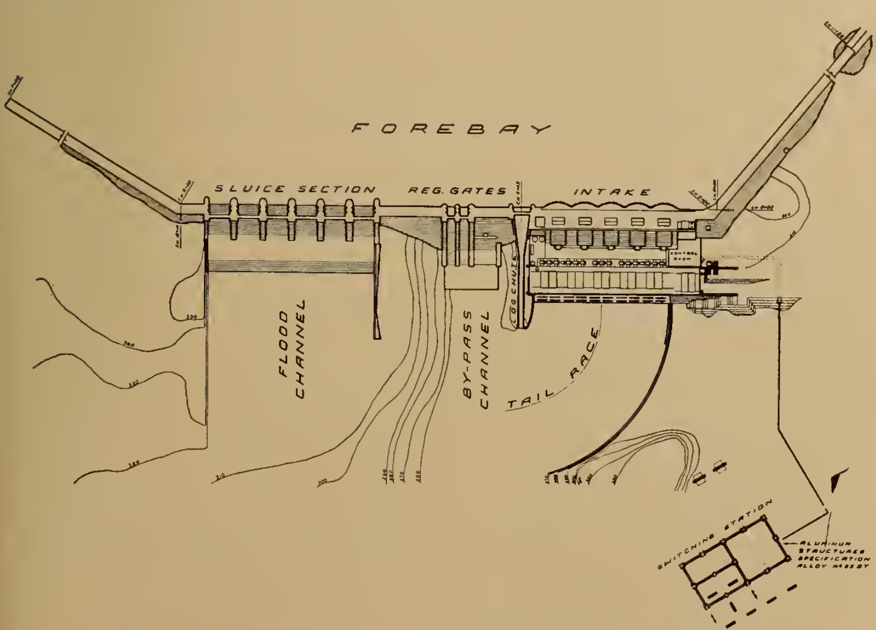

Fig. 3. General plan of the Peribonka No. 2 development.

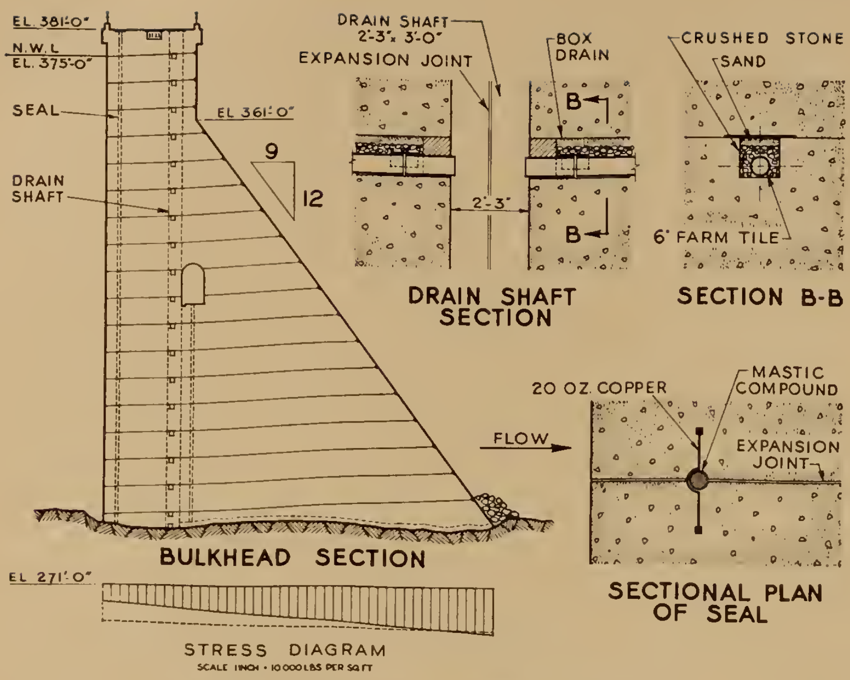

**Fig. 4. Typical bulkhead section, Peribonka No. 2.**

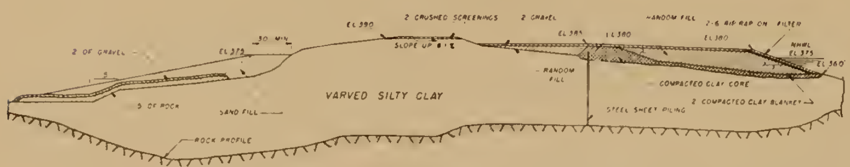

**Fig. 5. Developed section through earth dam. Peribonka No. 2 development.**

from 5.0 to 0.5; pumps were used to inject the grout.

The sealing program consisted essentially of the establishment of a grout curtain to depth, at or near the upstream face of the structures. In sections where foundation conditions were good, a single row of vertical holes was sufficient to seal all cracks and openings. In other sections, where the bed rock was badly shattered and faulted, it was necessary to drill and grout three or more rows of closely spaced vertical and inclined holes to depths of over 150 feet, to secure a tight cut-off.

### Bulkhead Section

The bulkhead section, which was the same in both developments, is shown in Fig. 4. It was designed as a solid gravity dam for a height above rock of 120 feet, this maximum height being required at the closure section. Design conditions were as follows:—

Horizontal Forces:

(a) Ice at 10,000 pounds per lineal foot acting one foot below normal forebay level.

(b) Water load for normal headpond level.

(c) Silt assumed as a hydrostatic load at 20 pounds per cubic foot in excess of water load for a height of 36 feet above the foundation.

or, alternatively:

(a) Water load for extreme flood within one foot of the top of the dam.

(b) No ice.

(c) Silt as above.

Vertical Forces:

Weight of concrete at 150 pounds per cubic foot.

Uplift:

(a) A rectangular upward loading diagram equal to tailwater elevation above foundation acting over 100 per cent of the area of the base.

(b) A triangular upward loading diagram equal to headwater minus tailwater at the heel, decreasing to zero at the toe, the pressure being assumed to act on 2/3 of the area of the base.

The dam was built with a top width of 20 feet, to accommodate the roadway clear across at the upper development and to the intake section at the lower. Vertical contraction joints are placed at fifty foot intervals, and sealed for protection against spalling by a sealing compound around the perimeter. At the upstream face of each contraction joint, a water seal is provided, consisting of a 20 oz. copper sheet extending into the pour on each side. The seal bounds the upstream semi-circle of a 6 in. hole, which is filled with a specially selected mastic compound, which retains its resiliency at low temperatures. Keys are provided at roughly ten-foot centres, and the face is coated with two coats of emulsified asphalt, to break the bond.

The drainage system consists of a French tile drain at each horizontal pour, located 14 ft. 6 in. in from the upstream face. These drains open into vertical chimney drains at each expansion joint, with embedded ladder rungs to permit inspection. A box drain on rock also runs into these vertical drains and then to

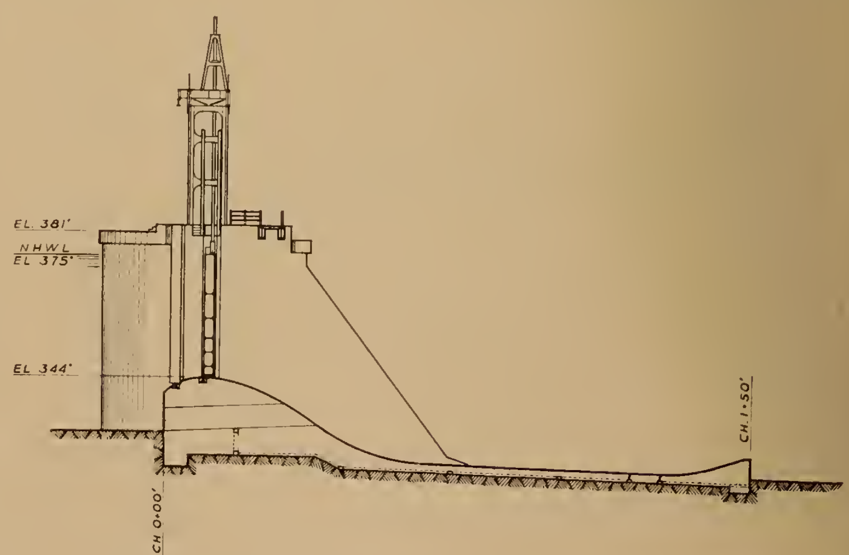

**Fig. 6. Typical section through spillway, Peribonka No. 2.**

the downstream face of the dam, where loose backfill is placed to prevent freezing during the winter.

At Peribonka No. 2, inspection tunnels were placed in the east bulkhead and in the gravity section which fills the 50 ft. opening of the by-pass. Six-inch pipes, on 5 ft. centres, extending down to rock, were embedded in the floor of these tunnels, and, through these, holes were drilled approximately 20 feet into rock. Thus, they form a relief against uplift at subfoundation levels, and indicate leakage. Additional grouting into rock can be performed at a later date from the inspection tunnel if necessary.

### East Bulkhead Extension

During the winter of 1951-52, a very extensive detailed geophysical and diamond drill survey was undertaken to determine the bed rock contour in the general area. This indicated that the bed rock topography was very irregular, and that excavation to depths of over 120 feet through the silty clay overburden, and consequent large volumes of concrete, would be required to found a concrete closure on rock.

The varved silty clay overburden was carefully investigated, and it was decided to form the closure with an earth dam that would utilize this inplace silty clay of the ridge as a core. Extensive strengthening was required to ensure the stability and water-tightness of this ridge.

In Fig. 5, a developed section through this earthdam, the final design is shown in detail. On the downstream side of the ridge, coarse rock topped with a free-draining gravel layer and a heavy sand fill to El .375 was placed. This not only added mass to the dam, but also would act as a filter should any seepage occur. On the forebay side, sand was stripped from the underlying clay; the surface was compacted, and a compacted clay blanket was carried up from elevation 360 and topped with a compacted clay core to elevation 383.

This whole area, and the section above the core, were protected by random fill. The top of the ridge and the fill were protected against erosion with a 2 ft. blanket of gravel or crusher screenings. The portion exposed to the forebay was protected with a gravel filter and rip-rap. The junction with the concrete of the bulkhead and the clay of the ridge was made with compacted clay. A section of sheet piling was embedded in the end of the concrete, and a row of sheet piling was to be driven to rock throughout the length of the dam.

### Spillways

The spillway capacity is the same for each development. (Fig. 6) It consists of six 50 foot openings, with sills 31 feet below normal forebay level, and two regulating gates each 21 feet wide, with sills 21 feet below normal forebay level. A 6 foot freeboard is provided on the dam, and the design is made so that, during extreme floods, the forebay can be allowed to rise within one foot of the top.

These openings are ample to pass the combined maximum discharge capacities of the storages above, with a conservative allowance for the uncontrolled run-off below them. Each regulating gate has a capacity approximately 40 per cent in excess of the rated discharge of one unit.

The sill shape of the spillway at Peribonka No. 2 is a parabola, with vertex 10 ft. from the upstream face, and having an equation: $X = 7.4y^{5/6}$, $y$ being measured as positive downward. Upstream of the vertex, the profile is a circle of 14 ft. radius, with centre 9 ft. 6 in. from the upstream face. This latter profile is somewhat fuller than the theoretical true profile, and is provided to allow for stop-log gains and sill beams, with sufficient clearance for working space in front of the gate. The complete profile was checked by model test to ensure that there is a positive pressure at all points on its surface.

A circle of 50 foot radius joins the sills and aprons tangentially. The apron consists of a reinforced concrete slab of 18 inch nominal thickness, extending below the base line. At its lower end, it sweeps up to a lip which serves to prevent erosion of the rock at the toe. It is particularly effective, and there is a marked dissipation of energy here. The drainage system is designed to prevent uplift on the slab due to high tailwater levels, and also to carry away gate leakage.

Expansion joints are provided on each side of the piers, which are

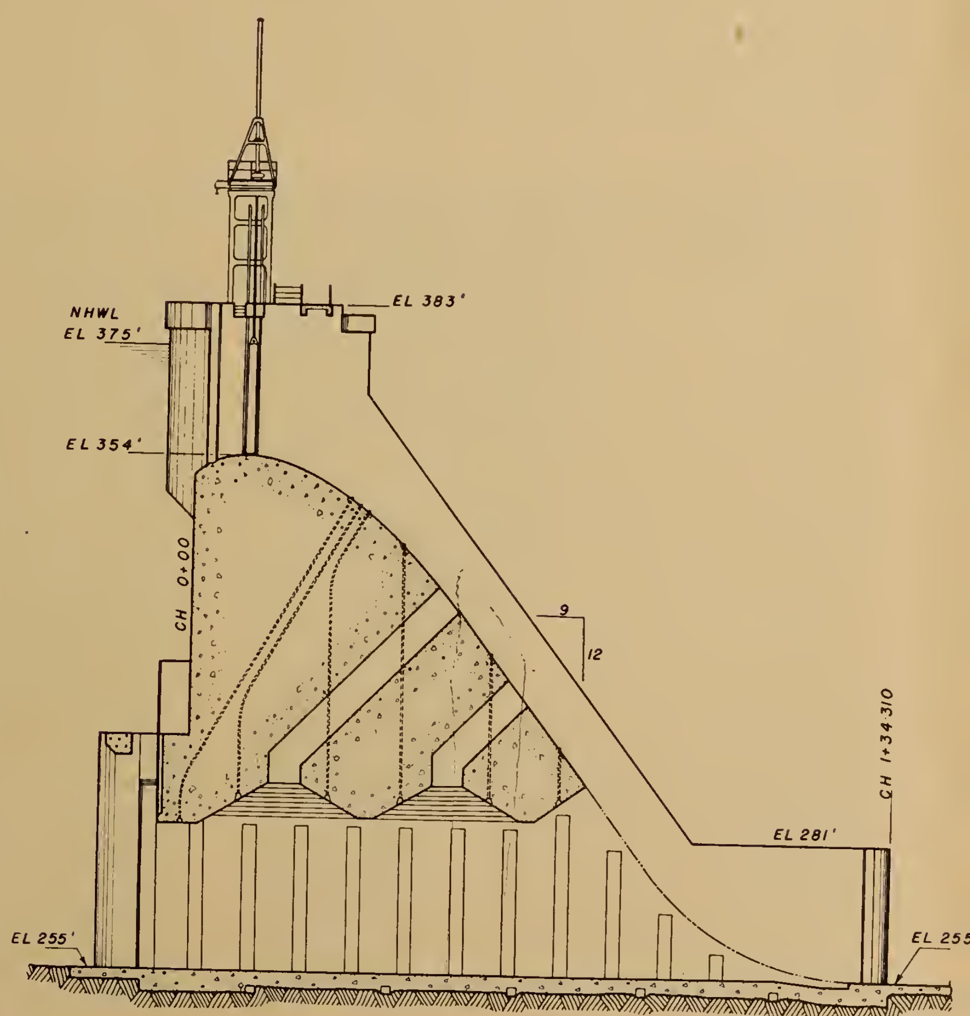

Fig. 7. Typical section through No. 2 regulating spillway showing by-pass opening.

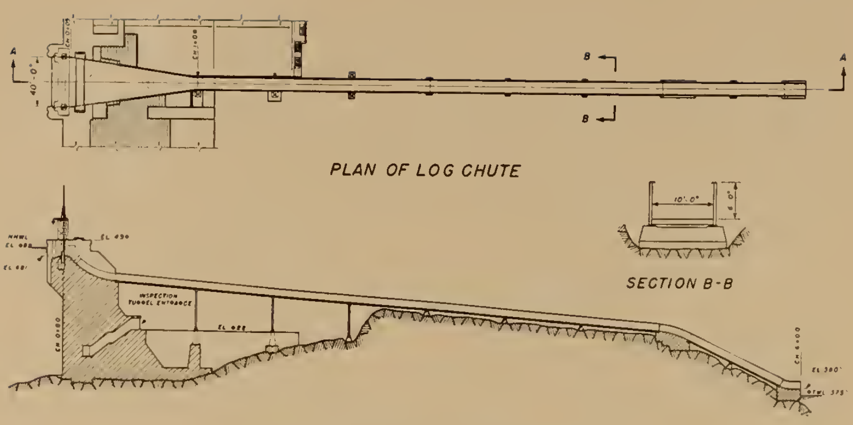

Fig. 8. Log chute, Peribonka No. 1.

fifteen feet thick. Sills and piers are therefore designed to be separately stable, and reinforcing steel is placed through the pour joints in the sills, to ensure safety against sliding.

The gates are 50 feet wide by 31 ft. 6 in. high, of the fixed wheel type, and operated by screw hoists carried on steel towers and bridges. In order to accommodate the maximum head over the crest of 36 feet, the piers were raised to El .383, two feet above the elevation of the top of the bulkhead, so that the tower height above concrete did not have to be increased over that of an existing design.

The towers are designed to withstand the loading due to a 30-mile wind acting at right angles to the gate in the fully raised position. Special anchorage steel is provided in the top of the pier to secure the tower bases. A monorail hoist, mounted on the towers, handles the stop-logs, only one set of which is provided for all gates.

The spillways at Peribonka No. 1 are similar, with the exception that the apron levels were varied to suit rock levels. Retaining walls are provided where the apron levels change. These are necessary to avoid cross-flow, which would decrease the effectiveness of the upturned buckets, and also to prevent undue scouring downstream of the deepest apron. On the west side, the retaining wall turns in on the No. 6 apron, to deflect the flow from a protruding rock face below. Bridges are provided to span the piers downstream from the gates.

The by-pass consisted of three openings: one, 50 feet wide and open to the top; the other two, 21 feet wide and roofed over for a height at the inlet end of 28 feet. Taking Peribonka No. 1 for descriptive purposes, the floor level of all openings was at El. 385. Maximum design capacity was 70,000 c.f.s. for a still water level upstream of El. 430.

An approach channel was excavated, with invert at such a grade that flow was at sub-critical velocities, both upstream and through the passages over practically all ranges of flow. At the downstream end the grade was increased, so that flow reached critical depth at this point, and proceeded onward at supercritical velocities. This was done to eliminate the difficulties of shooting or rapids flow at the gate and stop-log gains.

The scheme of closure called for the 50 foot opening to be closed first, when the river flow had drop-

Fig. 9. Log chute model test in the hydraulic laboratory of the National Research Council.

Fig. 10. Prototype flow in Peribonka No. 1 log chute.

ped after the spring flood to 10,000 c.f.s. Stop-logs were placed in gains, formed in the piers at both upstream and downstream ends, the 50 foot steel stop-logs from the spillways being used in the upstream gains. Hence, while the reduced flow was being passed through the remaining two 21 ft. openings, the bulkhead closing off the opening was to be poured to El. 470, or to the top, as time permitted.

Following this, the two 21 foot openings were closed simultaneously by dropping closure gates, using hoists temporarily installed on the piers above. At this stage, the sills of the regulating gates were poured, and stop-logs were in place. The spillway sills were scheduled to be completed by this time, so that, as the forebay level rose, discharge commenced over these, reaching a capacity of 40,000 c.f.s. at El. 468, a figure which was considered conservative for the season of the year.

With timber stop-logs in place at the downstream end, placing of concrete could be carried out to fill the openings. The roofs of the openings were shaped somewhat like inverted bins, (Fig. 7), to which openings 6 ft. square were led from the sill faces. These were designed so that concrete could be chuted in to completely fill the openings, and, at the same time, provide massive keys against punching shear due to hydrostatic pressure. Grout pipes were led to annular grooves around these openings, and the grouting program was arranged for final grouting one month after pouring the plugs.

These high roofed openings served another interesting purpose. Calculations showed that, for the maximum by-pass flow, the entrances would be submerged so that they would act as orifices under low heads. The openings thus permitted ample aeration of the opening downstream from the entrance, so that the flow here would retain the characteristics of open channel flow. In this way it was estimated that the openings could pass the flow without dangerous vibration for a head of some 40 ft. above the centre-line. Actual flows of this order were never reached during construction, thus, there is no confirmation of this point. The regulating gates are of similar construction to the sluice gates, and are 22 feet high by 21 feet wide.

**Log Chutes**

The log chutes at both developments are designed on the same basic principles, although their profiles differ. Each has a depressed type gate 40 feet wide, and a rectangular flume 10 feet wide by 6 feet deep. The gates are operated by screw hoists, and provision is made for lifting the gate clear of its well for servicing and winter storage.

Stop-logs are set in grooves upstream from the gate. These are put down in winter, and, with the gate lifted clear, any leakage is interrupted by the gate-well and drained off clear of the flume. The well is heated to prevent accumulation of ice, reducing the otherwise heavy ice load on the spans of the flume.

Each chute has a capacity at 50 per cent efficiency of 1,980 cords of pulpwood per hour, with a head of 3 feet over the crest. The discharge is 640 c.f.s., corresponding closely to 3 cords of wood per c.f.s. Provision is made for a variation of forebay level of 4 ft. during the log-passing season.

Fig. 8 shows the log chute at Peribonka No. 1. The concrete crest is at El. 481, and immediately downstream the profile drops off on a curve such that the nappe will strike it tangentially for all positions of the gate. Aeration, to prevent depression of the nappe for raised position of the gate, is provided by a slot in each side pier just below the gains. A circle of 52 ft. radius is run in, tangent to this curve and the 8 per cent grade of the flume. At the lower end, the flume drops off on a circle of 65 ft. radius and proceeds on a 1:2 slope to a horizontal lip at El. 380, which delivers the logs to the tailrace.

The flume is steel-lined throughout its entire length, and designed as continuous beams in three sections, to allow for thermal expansion. Where the rock is low, it is supported by three pin-connected bents, and, at other places, on concrete piers. The bents allow for the lateral movement due to the expansion, with a negligible effect on the alignment of the flume. At the lower end, concrete walls and a massive concrete base are provided against ice action.

These chutes are designed for super-critical velocities of flow at all points from the gate downward. The calculated velocity in the flume is 44.5 ft./sec. for a depth of 1.43 feet. Actual depths and velocities are affected by aeration, which has the effect of reducing the velocity and increasing the depth.

It is probable that the logs actually skid on the steel plate liner, but this in no way detracts from its operation. Similar chutes have been designed where the depth of unaerated water was six inches. In these cases, the logs definitely skid on the bottom, and yet there has never been a jam in the flume.

In order to direct the flow from the wide gate section to the relatively narrow flume, at these high velocities, the transition must be carefully designed. Here a shock type of transition was used in which negative shock waves are super-imposed on positive waves so that, below the transition, the wave effect is zero.

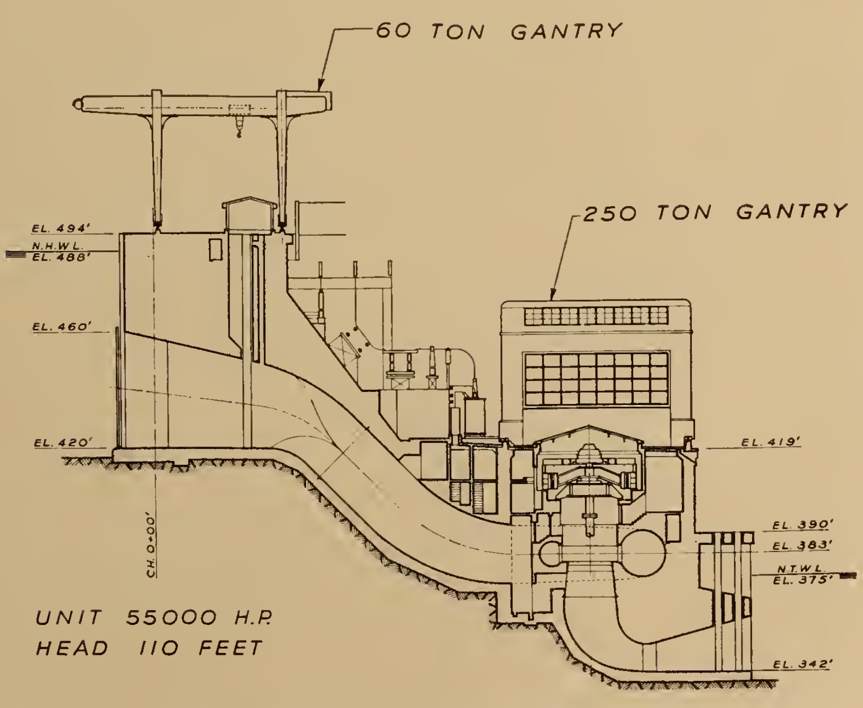

**Fig. 11. Section through intake and powerhouse, Peribonka No. 1.**

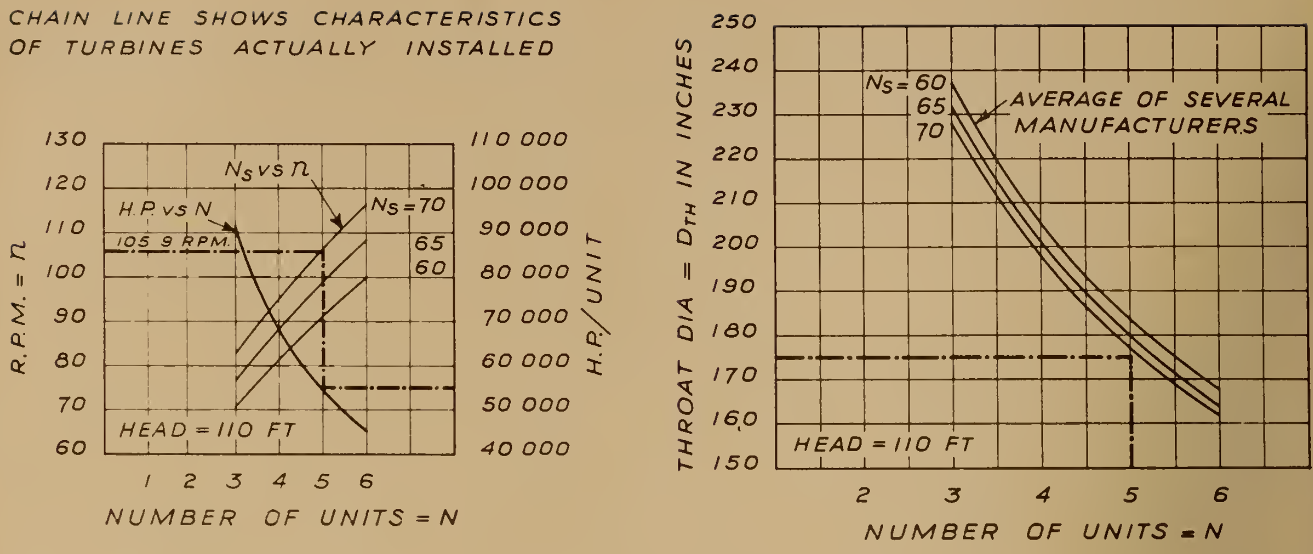

In practice, this is not perfectly achieved, but the waves, which would otherwise overtop the sides and kick the logs clear of the flume, are reduced to a negligible value. The transition was perfected by model tests in the hydraulic laboratories of the National Research Council. Figs. 9 and 10 show model and prototype. Close agreement is evident.

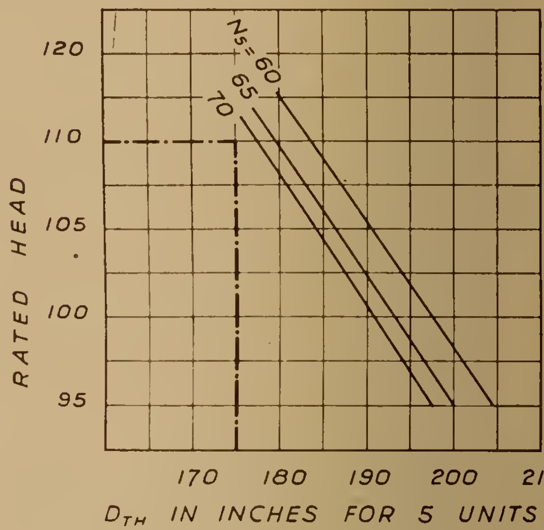

**Fig. 12. Peribonka No. 1 turbine selection chart. Based on plant flow of 25,000 cfm.**

### Intakes

The intakes of each plant are the same except for minor adjustments due to difference of drawdown. While the general design is that of an integral power house and intake, the latter is made separately stable, since it has contraction joints between units while the power house has not, thus necessitating a sliding joint between the two structures, and also because the shear could not be developed at the up-stream wall of the power house.

As can be seen from Figs. Nos. 2 and 11, each of the five intakes has four sets of racks, each 14 feet wide by 40 feet high, but only one head gate, 22 feet by 30 feet. Intakes are 60 feet on centres, with contraction joints between. The transition from rectangular to round occurs on the arc of a 45 degree bend commencing just below the gate. A steel penstock 23 feet in diameter provides the water passage from the transition to the scroll case inlet, being entirely embedded in concrete.

At Peribonka No. 1, the floor of the intake is at El. 420, and the roof is at El. 460 at its entrance, thus providing for a drawdown of 25 feet from a normal forebay level of 488. At Peribonka No. 2, the corresponding permissible drawdown is 18 feet. The depth of the opening is partly fixed in the latter case, to ensure proper submergence of the gate during normal operation, and it is doubtful if the full drawdown will ever be used.

Upstream from the gate, the water passages have the appearance of a wedge-shaped fan which is opened out to the contour of the side-walls. Three steel piers, filled with concrete, support the roof and the gains for the racks. They are shaped to offer a minimum obstruction to the flow. With this arrangement it is possible to obtain a gradual acceleration of the flow from 2.5 feet per second at the racks to 8 feet per second at the gate.

Motor-driven drum gate hoists are provided for each head gate, arranged for remote tripping from the control room in the event of a penstock failure or runaway of a unit with wicket gates inoperative. A 60-ton gantry is provided on the intake for installing and removing head gates, and, in the case of Peribonka No. 1, to service the transfer bay. This gantry has a cantilever extension of its bridge, to handle trash racks and emergency gates.

The covers for the gates are removable as a unit. To provide a light-weight structure, yet resistant to corrosion, these are clad entirely in aluminum. Since the gate vents open inside the structure, large grilles are built in under the eaves. These grilles allow entrance of air above a false ceiling.

In this ceiling, weight-controlled dampers are provided so that, if a gate tripped, they allow a large inflow of air with small reduction in pressure inside the cover. Under normal conditions, they are closed, and thus the heating load is reduced. Additional dampers, by the same method, allow outward flow of air.

This design of intake permits large rack areas per foot height of opening, thus saving excavation. At the same time, the steel reinforcing design is simple, and contraction joints are easily provided. Hydraulic losses are low, and the number of gates, with their sets of embedded parts and hoists, is reduced to one.

At Peribonka No. 1, an elevator is provided at the west end of the intake. Here, also, a washroom, gauging pit, and the headworks 575 volt power distribution centre are located. A tunnel runs from an intermediate landing the full length of the intakes, with adits to the inside of each hoist cover, thus permitting inspection without going outside.

Since all equipment must be handled via the roadway on top of the intakes, a transfer bay is located at the east end, by means of which equipment is lowered to a truck running on tracks at the power house roof level. At Peribonka No. 2, there is no transfer bay, since equipment is brought in under the crane on a roadway coming in to the east end of the power house.

### Power House

Fig. No. 11 shows a cross-section through the power house at Peribonka No. 1, and applies, also, except for different elevations, to the lower development. It is designed as a semi-open type; that is, a roof is brought over at the level of the aluminum generator covers, and a gantry crane is provided in place of the more conventional overhead travelling crane used in power houses with superstructures.

The covers over the generator can be removed, and the units thus dismantled. These are the first of their kind to be built in Canada. In addition to being the most economical type where a sufficient number of units are installed, it has the great advantage of speeding up the construction schedule, and, consequently, the on-power delivery date.

There are five units at 60 foot centres in each power house. They number from right to left looking upstream. To the right of Unit No. 1, a service bay is provided consisting of five levels. The sump is at El. 338.5 (for Peribonka No. 1), and, above it, an intermediate deck at El. 359. The sump pumps are set on the 373 floor. On the 387 and 397 floors, the latter being the generator floor level, the station auxiliaries are located.

Still further to the right, a space 38 ft. x 59 ft., extending from the 387 level to the roof at El. 420, forms the repair bay. There is sufficient room for two rotors at one time here, or one rotor and the principal turbine parts. The cover of the repair bay is built of aluminum, in halves, which rest on rubber seals in the closed position, and are raised, then rolled back to provide the opening through which the equipment is lowered by means of the gantry. A 15-ton travelling crane is provided inside the repair bay.

The transformers and switching structures are located between the power house and intake, with transformer pipe tunnel, conduit tunnels, etc. below. The transformer oil filtering room opens off the pipe tunnel to the left of intake No. 5. Downstream of the units, a governor pipe tunnel at El. 387 runs the full length of the power house.

The office section comprises three levels, and extends from the elevator shaft down to the upstream wall of the repair bay. On the397 floor, there is the conduit chamber directly under the control room, and a corridor running back to the elevator. Power supply and control cables to the top of the dam run back from the conduit chamber to the cable shaft rising beside the elevator.

On the 423 floor are located the control room, offices, battery room, small stores, first-aid room, telephone, and air-conditioning rooms. These are arranged around a corridor giving exit on the transformer deck and running back to the elevator. On the 440 floor above, a mess room and a lavatory are provided for the operating staff.

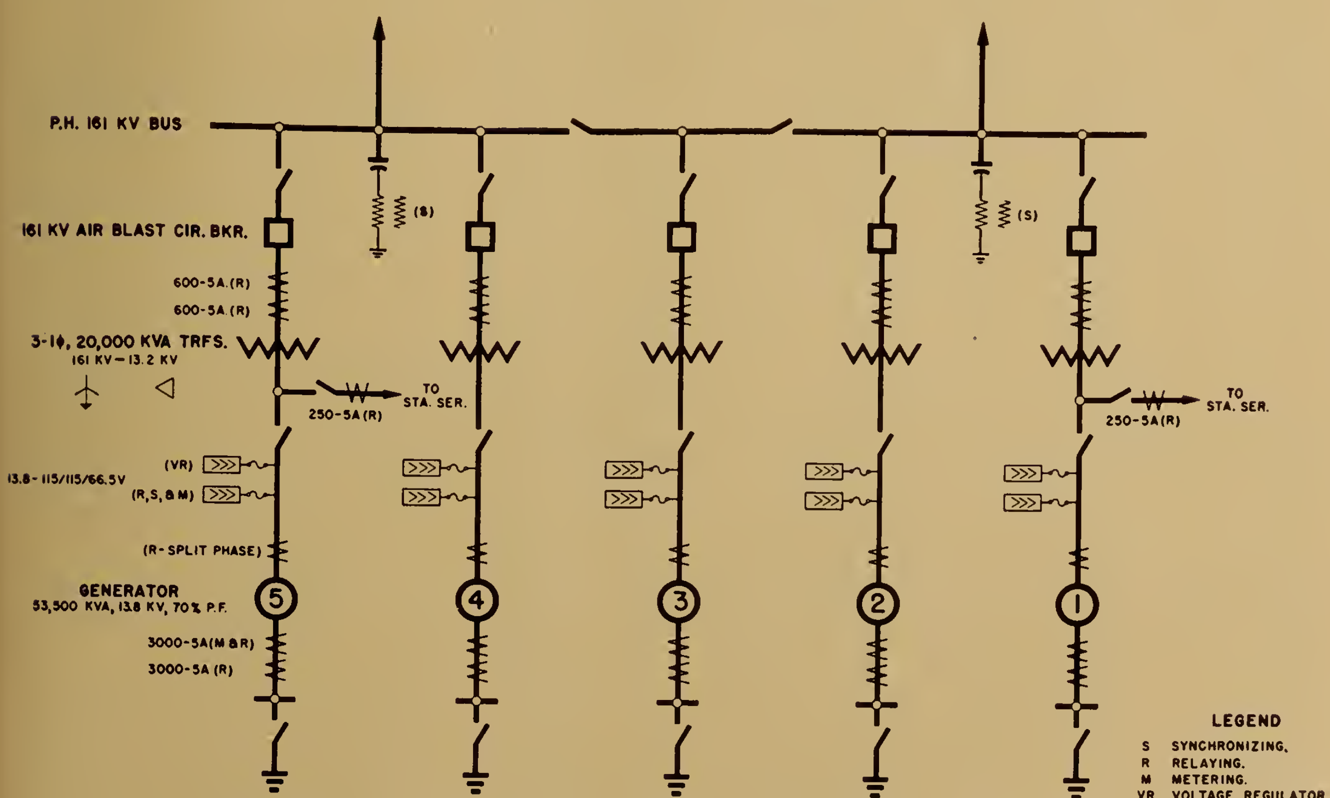

Fig. 13. Peribonka developments power house. Single line diagram.

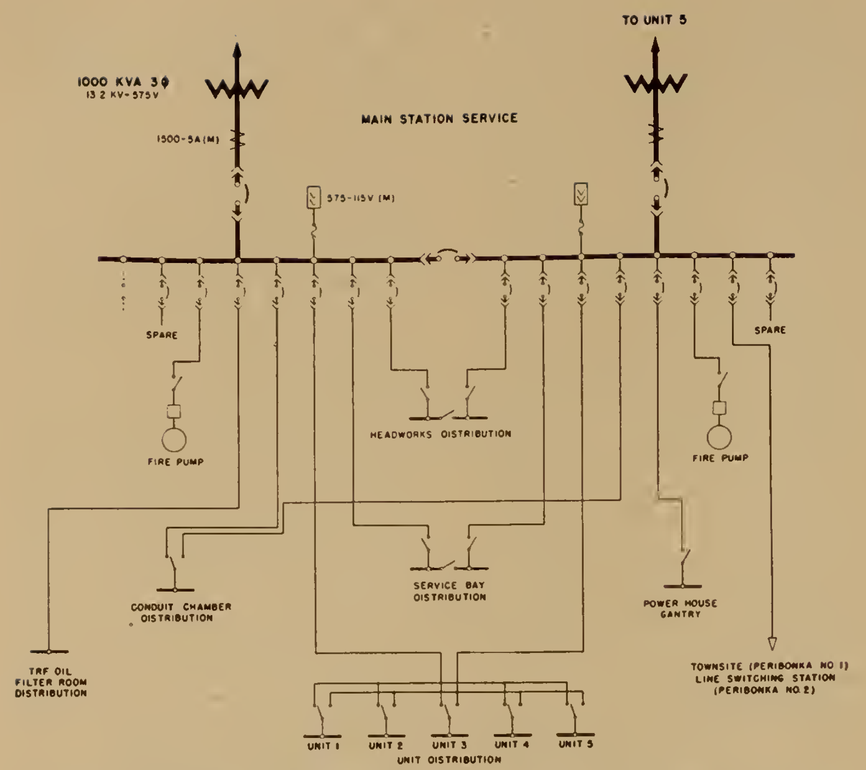

Fig. 14. Peribonka developments station service. Single line diagram.

### Turbines

Preliminary studies at Peribonka No. 1 contemplated the installation of four adjustable blade units of 71,250 hp. capacity, at a net effective head of 110 feet. Further investigation showed, however, that delivery could not be arranged to meet the on-power date, and a final decision was made to install five vertical-shaft Francis turbines. The rating of these units was fixed at 55,000 hp. at 110 feet effective head for a speed of 105.9 r.p.m. Maximum efficiency is guaranteed at 90 per cent for an expected output of 49,000 hp. Maximum horse power is at least 56,500. The expected variation in peak efficiency for the variation in head of 25 feet is approximately 2.5 per cent.

When the decision was made to install these units, it was urgent to determine the best rating and the approximate physical dimensions, in order to proceed with power house layouts. Accordingly, the preliminary selection curves shown in Fig. No. 12 were prepared. With the aid of these, it was possible to select the units and to proceed with the power house design while the final design of the turbine was proceeding. Physical dimensions are a function of the throat diameter of the units, so the latter is the key dimension.

The Peribonka No. 1 units have plate steel scroll cases of all-welded construction. Centre-line of distributor is at El. 383, and normal tailwater level is at El. 375. The units at Peribonka No. 2 are rated at 57,000 hp. under 110 ft. effective head for a speed of 105.9 r.p.m. Centre-line of distributor is at El. 266 for a designed tailwater level of 260. Plate steel scroll cases here are welded, except for the connection to the stay ring, which is rivetted.

### Power House Auxiliaries

A gantry consisting of a steel frame 48 ft. high, 63 ft. wide, and 42 ft. long, clad with .04 in. thick corrugated aluminum mill sheets, operates on the open deck of the power house. The trolley is equipped with a main hook of 250-ton capacity and an auxiliary hook capable of handling 25 tons. The function of this gantry is to transport any transformer or generator to the repair bay, should the need arise.

Retractable doors permit it to pass over the generator housings and to admit the transformers. The gantry is propelled by four 30 hp. motors, and is designed to resist a 30 lb. wind. For safety reasons, the usual practice with outdoor cranes of limiting the travel to a 5-lb. wind (35 m.p.h.) is stipulated.

The strained water supply and governing system of both plants are arranged on the unit system. Strained water of sufficient capacity to supply cooling water to the generator air coolers, thrust bearing, and turbine and generator guide bearings, is drawn off each penstock and passed through an automatic strainer. These are interconnected by a 10 inch header, and water to fire systems is taken off this header. Provision is made at each unit to connect in a dual strainer, should the motorized strainer be inoperative, and two dual strainers are installed, thus providing spare capacity for fire in addition to the above-mentioned service.

In the same manner, each unit has its own governor oil pressure pump, sump, and accumulator tanks. Pressure and return lines to the governor actuators of each system are interconnected by headers, and each oil pump has sufficient capacity for normal regulation of two units. The pump is controlled by an unloader, and each accumulator tank can be interconnected with others to make the pump control effective for more than one unit. Two 25 cfm. compressors, operating at 225 psi., are provided at the service bay to charge these accumulator tanks.

Additional auxiliaries include lubricating oil filtering system, transformor oil filtering system, purified water supply, and 210 cfm. general service air compressor. Two sump pumps—one of 4,000 gpm. capacity and the other 1,000 gpm. capacity—are located over the sump.

### Single Line Station Diagrams

Fig. 13 "Power House Single Line Diagram" may be considered as applying to both developments. Power is generated at 13.8 kv.; the H.V. busses and lines operate at 161 kv. High voltage switching only is employed; there are no low voltage circuit-breakers between the generators and transformers. Each generator, transformer bank, and high voltage circuit breaker is connected as a unit; there is no low voltage bus. The 161 kv. power house bus is sectionalized by two disconnecting switches, permitting Unit No. 3 to be connected to either bus section when the station is being operated with sectionalized busses.

A manually operated disconnect switch is provided in the low voltage bus between each generator and transformer bank to permit isolation for testing and maintenance. Power for station service is taken from Units 1 and 5 to separate station service transformers. The generators are connected for solidly grounded neutral operation; a manually operated single pole disconnecting switch permits isolation of the generator neutral for testing purposes. At Peribonka No. 1 the two 161 kv. transmission lines feed out directly from the power house busses to the Isle Maligne Switching Station.

At Peribonka No. 2 the two 161 kv. power house bus sections are connected to a 161 kv. transmission line switching station adjacent to the power house. Two lines connect to Isle Maligne and two lines feed a large paper mill load at Dolbeau. For both developments, all 161 kv. disconnecting switches are motor-operated and remotely controlled, and control circuit interlocks are provided to prevent incorrect operation.

### Main Power Apparatus

The generators at each development are rated 53,500 kva., 70 per cent power factor, 13.8 kv., 60 cycles, 105.9 rpm. The stator coil insulation is continuous mica tape. Generators are all totally enclosed and water cooled. The field poles are provided with non-continuous amortisseur windings. The generators at Peribonka No. 1 are of the umbrella type, having a thrust bearing and single guide bearing mounted below the rotor.

The generators at Peribonka No. 2 are a modification of normal design, and have the thrust bearing and an upper guide bearing installed above the rotor, with provision only for the lower guide bearing in the future if necessary. Special consideration was given in the designs of these generators so that stator coils may be replaced in the minimum possible time without removing the rotor.

Each generator is connected to three single phase transformers, connected low voltage delta—high voltage grounded wye. Each transformer is rated 20,000 kva., 55°C. rise, type ONW, 13.2 kv.-172 kv. with full capacity off-load reduced voltage taps on the high voltage winding. One spare single phase transformer is provided at each power house.

It is of interest to note that one bank of three transformers at Peribonka No. 1 is constructed with aluminum windings. These three transformers are the same physical size as the other transformers and weigh approximately 1.5 per cent less. While the transformers for the two developments are not identical in physical size or arrangement, the power house and transformer designs are arranged so that the transformers are interchangeable to meet emergency conditions.

The 13.8 kv. low voltage connections between the generators and transformers are designed as open buswork fabricated on the job, with aluminum ducts or sheet metal screens for protection. The main three-phase busses consist of two 4 in. aluminum channels, alloy No. 50S-A33, in a square configuration, and are rated 2,500 amps. The delta connections to the single phase transformers are 2-1/2 in. I.P.S. aluminum tubes, also alloy No. 50S-A33.

Flexible connectors and slip-fit bus clamps are used to provide for the thermal expansion of the aluminum conductors. The insulators are

Fig. 15. Peribonka No. 1 and 2 developments. Tabulation of protective and alarm functions-generating units.

**Fig. 16. Chute du Diable—looking south. From left to right the dam sections are—regulating gates, log chute, head block and powerhouse, bulkhead over the island, sluice gates.**

CEMA strength Class 40, and have an impulse withstand of 150 kv. To minimize the quantity of spare insulators required in power house stores, the same porcelain insulators are used throughout the 13.8 kv. system for bus supports, disconnecting switches, and fuse supports.

The 161 kv. circuit breakers for the generating units in both power houses are 3 pole, high speed, air-blast circuit breakers rated 800 amps. and have a symmetrical interrupting capacity of 2,500,000 kva. Separately mounted 161 kv. oil-filled current transformers are installed on the transformer side of these air blast circuit breakers. All 161 kv. disconnecting switches are motor-operated, 3 pole, rated 800 amps., and are of the centre-break two-rotating insulator stack type. The one circuit breaker installed at the present time in the line switching station at Peribonka No. 2 is a conventional 3-tank motor-operated oil circuit breaker.

The insulators used for all 161 kv. buswork have the standard impulse withstand of 750 kv. In general, all buswork is constructed of 795 MCM A.C.S.R. conductor, 54/7 stranding. Compression type connectors are used exclusively, including special spring-loaded T-connectors for the bus taps. Extra-flexible braid connections are used at the air blast circuit breakers and current transformers to reduce the stresses on the porcelain insulator columns due to vibration. Self-supporting aluminum tubes alloy No. 1-S are used for the 161 kv. connections from the transformers.

The 161 kv. air blast circuit breakers, current transformers, and disconnecting switches in the power house switching stations are mounted on platforms above the level of the transformer deck. These platforms and connecting walkways consist of galvanized open-type gratings carried on galvanized steel structural members.

All towers, trusses, and switch structures in the line switching station at Peribonka No. 2 are fabricated of aluminum alloy No. 65ST, with galvanized steel bolts, as are the two intermediate towers carrying the two lines from the power house. The design of these structures conforms to Alcan specification No. 136 "Specification for Design of Outdoor Station Aluminum Structures".

#### Station Service Power Distribution

The major components of the station service power distribution system is typical for both developments. (Fig. 14). The utilization voltage for station service is 575 volts. Each of the two station service transformers is rated 1,000 kva., 55 C. rise, type ONS, 3 phase, 13.2 kv.—575 volts, connected delta-delta, with off-load ratio taps only. These transformers are installed outdoors with the main power transformers, and are connected to the 13.8 kv. busses without circuit breakers.

The 575 volt main station service switchboard is of self-supporting, totally-enclosed, dead-front construction, and is installed in the low voltage bus tunnel. Air circuit breakers are used throughout. At Peribonka No. 2 all breakers are of the draw-out type; at Peribonka No. 1, only the main transformer feeders and bus tie breakers are draw-out.

Each sub-distribution switchboard is of dead-front, totally-enclosed construction, and air circuit breakers are utilized throughout for the branch circuits. Duplicate radial feeders are provided from the main station service switchboard to each sub-distribution switchboard, except for the transformer oil filter room where only a single feeder is provided. Interlocks are provided throughout, to prevent paralleling the two main power sources.

The subdistribution switchboard in the service bay is actually a motor control centre, and contains all branch circuit breakers, motor starters, and the motor control-circuit equipment. Echelon control is provided for the governor and circuit breaker air compressors.

A separate sub-distribution panel is provided at each generating unit, and each 60 ft. generator bay in the power house is supplied with auxiliary power for motors, lighting, and heating on a unit basis.

Single phase, dry-type distribution transformers rated 575—115/230 volts are located indoors, and generally adjacent to the sub-distribution switchboards for the lighting, heating, and power supply to fractional horse-power motors in each of the sub-distribution areas.

#### Control, Metering, and Relay Equipment

The control room equipment at each power house consists of four major items—benchboard, duplex board, voltage regulator board, and operator's desk. All of this equipment was factory assembled and wired, ready for installation and connection at the site.

The benchboard is of conventional design, having a sloping top for the mimic bus, control switches, and indicating lamps. The station annunciator, and remote control and position indication for the headgates and regulating gates are included on the benchboard. The duplex board is a tunnel-type switchboard with the indicating instruments on the front panels and protective relays on the rear panels. The front panels also contain the main 125 volt d-c. distribution panel, water level indicators, and temperature recorder. The rear panels also contain the relays for the unit remote-automatic "start-stop" control.

The regulator board is a self-supporting enclosed switchboard having one panel per unit containing the voltage regulator, main exciter and pilot exciter overvoltage relays, and one panel for the clock, frequency recorder and station total load recorder. The operator's desk is a standard steel office desk with a special console added for the operator's communication circuits, signalling equipment, and the governor synchronizing motor controls.

The panels of all of the foregoing equipment are of steel, and are painted "eye-rest" green. The control room itself is finished with an acoustic tile ceiling, plaster walls, and a rubber tile floor. The size of the control room is approximately 37 ft. x 30 ft.

A generator field cubicle is located on the generator room floor adjacent to each unit. This cubicle contains the main exciter field circuit breaker and motor-operated rheostat, the 125 volt d-c. sub-distribution panel for the unit, and the turbine and generator bearing thermometers.

These cubicles are totally enclosed self-supporting steel structures, and are set flush in the upstream partition wall between the generators. The generator field circuit breaker, discharge resistor, and shunt are mounted in a separate cubicle located on the frame of the generator inside the generator housing. These field cubicles were all factory assembled and wired.

Fig. 15 is a tabulation of the protection and alarm features for a typical generating unit. The annunciator plate containing the alarm lamps is located in the centre section of the benchboard. The lamps are coded and mounted in symbols representing the station single line diagram. Similarly coded lamps are mounted in legend plates to identify the annunciator points. The alarm circuit utilizes one alarm relay per point. A bell and repeating single stroke gong are used to give audible distinction between the alarm points which annunciate only and the protection points which actually trip the unit off the bus.

Fig. 15 includes a list of the types of relay protections utilized for the generator and transformer. Draw-out type relays are utilized extensively, but rear mounted blocking switches are provided to isolate the relays for testing wherever non-draw-out relays are used. Neon supervisory lamps are installed to indicate the presence of d-c. voltage on the trip relays. The protective relays are grouped on two hand-reset trip relays which trip the various circuit breakers.

A feature of the voltage regulating equipment is the inclusion of an a-c. overvoltage relay, which, on the presence of overvoltage, inserts a block of resistance in the field of the main exciter and at the same time operates the main exciter motor operated field rheostat in the "lower" direction. This feature gives a degree of back-up voltage regulation, both with and without the actual voltage regulator in service.

An interesting feature employed to assist the operating staff in their duties is the facility for remote starting and shutting down of the generators from the control room. The unit can be started only after a chain of supervisory switches is closed signifying the presence of proper governor oil pressure, cooling water on the bearings, brakes are released, etc. By pressing the "Start" control button, the unit will automatically come up to speed-no-load and normal voltage ready for synchronizing. Automatic tripping of the various circuit breakers in the correct sequence and automatic braking are used to bring the machine to standstill when shutting down.

The usual metering arrangements have been provided, but are not listed in detail herein. A remote speed indicator for each unit is provided on the duplex board, calibrated both in rpm. and cycles per second. The station total load recorder is operated from thermal converters, and is equipped for future telemetering. Manual synchronizing only is provided, utilizing capacitor potential devices on the 161 kv. bus sections and potential transformers on the generator busses.

All control circuits operate at 125 volts d-c., from a 60 cell, 17 plate battery having a capacity of 40 amps. for 8 hours to 1.75 volts per cell. One such battery is installed in each power house, and space provision has been made for a duplicate battery to be installed in the future. Two fully automatic battery charging selenium rectifiers, each having a maximum charging rate of 17.5 amps., are provided, with switching facilities so that either or both batteries may be charged.

**Fig. 17. Chute-à-la-Savane, looking north. Left to right: west wingwall, sluice gates, regulating gates, log chute, headblock and powerhouse, east wingwall. The aluminum switching station is in the foreground.**

#### Fire Protective Equipment for Transformers

All main power and station service transformers are protected in case of fire by fixed nozzle water spray systems. The nozzles for each bank of three main power transformers are controlled by an electrically operated, remotely controlled, manually reset deluge valve. The push button control station for these deluge valves is in the vestibule leading to the transformer deck, within sight of the transformers.

A hose station is located adjacent to each transformer bank; one deluge valve is used to control all hose stations. The nozzles on the station service transformers operate whenever the nozzles on the adjacent power transformers operate. Water is supplied to the system by two 1,000 U.S. gal. per min. booster pumps, which operate automatically upon the opening of any of the deluge valves. Provision has been made for automatic thermostatic operation of the deluge valves in the future if required.

#### Cables, Trays, and Ducts

In general, all cables for control, metering, and relaying are multi-conductor with 600 volt thermoplastic insulation and thermoplastic outer covering. A lead, rather than thermoplastic, outer covering is used for all cables installed in the line switching station at Peribonka No. 2. All 575 volt single and three conductor power cables for station service distribution are either varnished cambric or heat resistant rubber insulated with a neoprene jacket. Mineral insulated cables are used extensively for connections to outdoor apparatus and outdoor lighting.

All cables in the power house and intake section are run on open sheet steel cable trays. Perforated sheet steel trays in 3 in. to 12 in. widths are used extensively for branch cable runs. The cables in the bulkhead sections of the dam are run in fibre conduit duct banks, with a manhole at each expansion joint.

The cables for the line switching station at Peribonka No. 2 are installed in precast haydite surface trenches. These trenches were cast in 8 ft. sections, having inside dimensions of approximately 12 in. wide x 7 in. deep, and are provided with removable checkered steel cover plates. This trench also serves as a walkway between the power house and the line switching station.

#### Heating—Power House

One large central ventilating fan having a capacity of 36,000 cfm. is provided for air circulation in the general areas and tunnels in the power house. For winter heating, heat is extracted from the hot air chambers of the generators and circulated throughout the power house. For summer ventilation, outside air is drawn in and the heated air from the power house is discharged to atmosphere. Certain specific areas in the power house and intake section are provided with thermostatically controlled electric blower heaters.

Offices and individual rooms are heated by wall mounted electric heaters controlled by 3-heat switches. The control room and telephone room are provided with a central air conditioning system containing air filters, thermostatically controlled electric heaters, and automatic humidification, with provision for the future installation of cooling equipment if required.

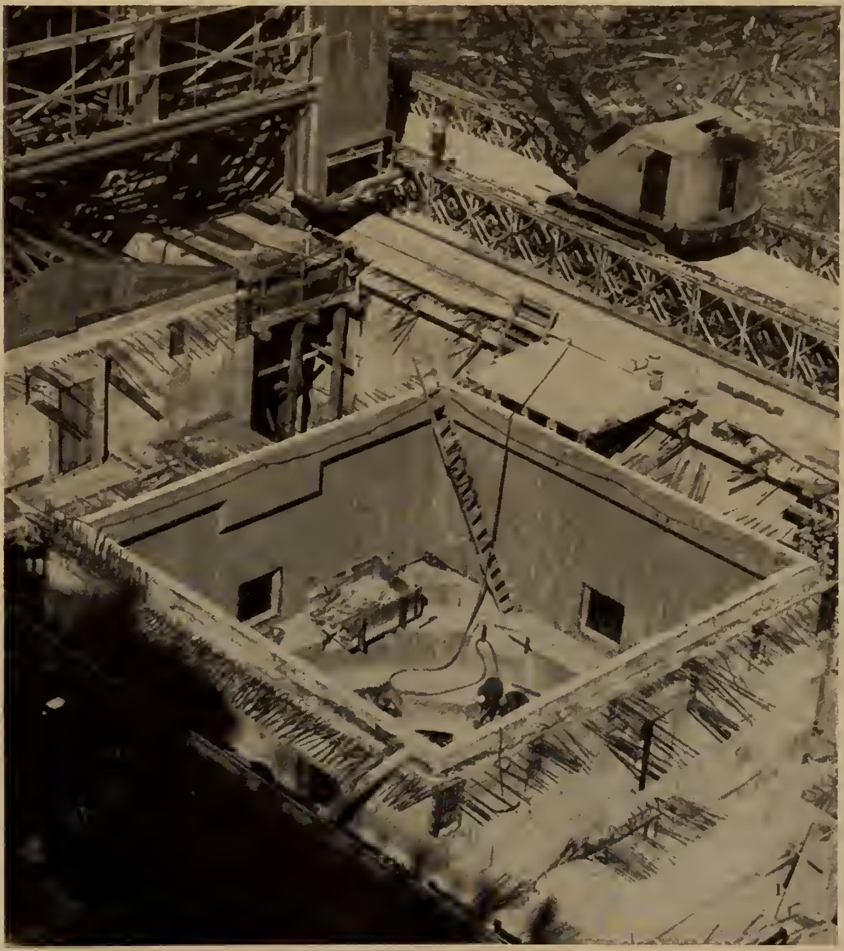

Fig. 18. Concrete pit for generator at Peribonka No. 1.

#### Heating—Regulating and Sluice Gates

Two regulating and two sluice gates are heated at each power house, to permit winter operation of these gates should this ever be necessary. The gains are heated by long tabular heaters installed in ducts extending the full height of the gate and located close to the upstream and downstream guides. These heaters are 550 volts, single phase, of 4 kv. and 6 kv. capacity for each of the regulating and sluice gate guides respectively.

The gates proper are heated by enclosing the downstream side with insulating sheeting, and circulating warm air inside the gate chambers. For each regulating gate, a fan having a capacity of 1,250 cfm. at 1.25 in. s.w.g. and a 15 kw., 550 volt, 3 phase heater is used. For each sluice gate, two fans, each with a capacity of 3,500 cfm. at 2.0 in. s.w.g., and two 15 kw. heaters are used.

Sheet metal supply and return ducts with adjustable registers are installed within the gate for the warm air distribution to each chamber. These gate heating systems are designed to prevent ice formation on the skin plate down to a minimum ambient air temperature of −40°. The heaters are thermostatically controlled to give intermittent

operation at higher ambient winter air temperatures.

### Lighting

Incandescent lighting is used throughout the general areas in the power houses, using prismatic refractor-type glass luminaires. The average values of illumination designed and achieved in these areas are in the range of 15—25 foot candles. Fluorescent lighting is used in the control room and office sections; the fixtures in the control room are set flush in the acoustic tile ceiling, and are provided with ribbed glass covers. The measured values of illumination in the control room vary between 35 and 50 foot candles.

Some of the incandescent units used for normal lighting are arranged to provide emergency lighting from the station battery through an automatic a-c./d-c. transfer switch. These units are located at the major equipment, stairs, and passages throughout the power house. Separate small incandescent units are installed in the control room for this emergency lighting.

Power for lighting is taken from dry type transformers for each of the sub-distribution areas in the power house. Each 60 ft. generating unit bay is thus provided with a separate transformer, panel and branch circuits for the lighting in that bay.

### Communication Systems

Each power house is provided with a PAX (private automatic exchange), having 30 lines with provision for 20 additional lines. This exchange is fully automatic for local calls within the power house area, but employs magneto ringing for outside trunk calls. Three outgoing trunk circuits are provided via microwave equipment to the Shipshaw generating station. A feature of interest which is provided by the PAX equipment is the automatic code call service via signal bells throughout the power house area to contact a person who cannot be reached at his regular telephone.

Communication between the various generating stations of the Saguenay system is achieved by a microwave network. There are five microwave stations in all—one each at Shipshaw, Isle Maligne, Chute du Diable, and Chute à la Savane, and an unattended repeater station at St. Charles, between Shipshaw and Isle Maligne. The outgoing trunk calls from each power house thus connect directly to the operator at Shipshaw via this microwave network.

### Grounding System

In both power houses, reasonable locations for low resistance earth connections were found for driven ground rods in the flooded areas in the forebays; 50 and 82 copper clad ground rods were driven at Peribonka Nos. 1 and 2, respectively. It was impossible to drive ground rods in the area of the line switching station of Peribonka No. 2, but the grid of ground conductors buried just below the surface assists in lowering the ground resistance through capacity coupling to earth.

The counter-poise and overhead ground wire connections from the transmission lines are connected to the station grounding systems. It was calculated that the ground resistances of these installations would not be greater than one ohm at each power house. Ground busses were installed in the power houses in the conventional manner for the grounding of power apparatus and equipment.

Pertinent data on the schedule of the developments is briefly summarized in Table 1. A list of the manufacturers of the major apparatus in these two power houses is also included.

The general contractors were Fraser-Brace Engineering Co. Ltd., for Peribonka No. 1, represented by G. R. Stephen, vice-president, and F. J. Palmer, project manager; and the Pentagon Construction Company, Limited for Peribonka No. 2, represented by H. R. Montgomery, vice-president, and D. G. Ross, project manager. Excavation was carried out by C. A. Pitts Construction (Quebec) Limited and Peacock & McQuigge Limited respectively, with grouting on both projects by Concrete Repairs & Waterproofing Co., Ltd. Canadian Comstock Limited carried out the electrical installation.

### Acknowledgment

The Peribonka Power Developments were built by the Aluminum Company of Canada, Ltd., the Canadian production subsidiary of Aluminium Limited. R. E. Powell is president; A. W. Whitaker, Jr., vice-president and general manager; McNeely Dubose, vice-president; and W. L. Pugh, chief engineer.

The Shawinigan Engineering Company is indebted to the executive, the management, and the engineering division of the Aluminum Company of Canada for their great assistance and prompt action on all questions referred to them. Closely associated with this work were:— W. L. Pugh, chief engineer; R. F. Ogilvy, co-ordinating engineer; A. O. Hawes, construction manager; G. T. Malby and F. A. Dagg, resident engineers, responsible for the supervision of construction at Peribonka Nos. 1 and 2 respectively. Dr. W. K. Gummer, geologist, supplied all geological data for both projects. Professor Hurtubise was retained by Alcan for soil problems.

Associated with the engineering company was Dr. A. Casagrande, consultant on soil mechanics. W. P. Harland and J. H. Scovil were resident engineers for the Shawinigan Engineering Company on the work.

# Discussion

### H. R. Montgomery[1]

We have listened, I am sure, with a great deal of interest to the paper so ably presented describing the work recently carried out along the Peribonka River. As our company was one of the two contractors engaged in this work, the paper was of especial interest to me.

Both the Peribonka developments were carried out as rush programs, dependent not only upon a very tight construction schedule, but also upon the delivery of vital manufactured components according to a predetermined pattern. All efforts in the field to achieve the target dates would have been pointless without the efforts put forward by the manufacturers of hydraulic parts and electrical equipment to meet their scheduled dates of delivery. Consistent consultation with these manufacturers on the part of the Engineering Department of the Aluminum Company and regularly held job meetings were successful in bringing all parties together and achieving deliveries on time and completion of various parts of the work according to the requirements of the schedule. In these arrangements recognition had to be made of the fact that road conditions between the railhead and the site would not permit heavy loads to be transported during the spring breakup.

Joint railhead facilities were set up at the terminus of the A. & J. Railway at Isle Maligne. Through this yard passed practically all the materials and components for the two jobs, including many thousands of tons of timber, cement, structural steel, turbine parts, generators, transformers and so on. Cement was brought in bulk by rail, stored in large tanks at the railhead and transported by a fleet of special tank trucks over the 25 miles of road to the two sites.

Due to the extreme turbulence of the river at both sites, it was impossible to predetermine exactly the shape or nature of the foundations for the rock filled coffer dams. Actual conditions found were, for the most part, less favourable than anticipated and necessitated considerably more work to be carried out than the allotted time. In the same fashion as disclosed in Mr. Heartz' paper, it was found that rock excavation had to be carried deeper for sound foundations and hence more concrete had to be placed than was anticipated but all within the allotted time, since the owner's requirements for hydraulic head to be maintained at Lake St. John was of paramount consideration and the timber blocking of part of the channel by coffer dams had to be integrated with these flows from upstream storage.

Both sites were distant from a large center of population and it was therefore necessary, immediately upon receiving orders to proceed, for the contractors to rush the construction of camp sites and facilities while at the same time commencing the work of clearing and coffer dam construction. Modern camp sites capable of housing and feeding several thousand men were erected at both jobs, including not only the usual bunk houses, mess halls, staff houses and so on, but upwards of twenty houses for married personnel. These houses were moved to other locations at the termination of the work and now house the operating personnel and their families.

One unusual feature of these projects not met in Canada heretofore is the semi open type of power house which was called for. As far as the work of construction is concerned, this design requires a different treatment, specially in the stages nearest completion, for there is no generator floor at a convenient level for use in transporting materials and components along the axis of the power house to the various units. Some other method of handling materials and heavy parts must be adopted which will be independent of the power house itself. At Peribonka No. 1 this was accomplished by a "sky hook" consisting of a 25-ton cableway so located as to cover the whole power house area.

At Peribonka No. 2 we used a travelling revolver crane of large capacity which could move along a temporary steel trestle erected parallel to the axis of the power house between the power house and the head works and able to span from the upstream side of the head works to the tailrace side of the power house. Other construction equipment was free to use the same trestle and to move through the space occupied by the revolver since it was mounted on a gantry with standard railway clearance. This afforded plenty of elasticity for different operations and the possibility of carrying out concreting operations or other work at several points along the power house or head work simultaneously. The steel legs of the trestle were buried in the concrete as it rose and were later burned off.

As stated earlier, the successful completion of these two projects within the short space of time allotted to them was due to the collaboration of many firms and individuals. Mention also should be made of the assistance of the provincial, municipal and church authorities in helping to avoid troubles which might, without their assistance, have arisen through the major dislocation of road traffic and the segregation of large bodies of men remote from their homes.

### F. L. Lawton, M.E.I.C.[2]

The authors are to be congratulated on the manner in which the paper has been presented, as dealing with two different developments in one paper, in a co-ordinated fashion, is not too easy.

The Chute du Diable and Chute-à-la-Savane hydro-electric developments afforded an unusual opportunity to use the same basic design for the several elements, this arising from the relative similarity of physiographic features, flow and head. This tends to reduce costs of development.

An interesting opportunity is also afforded in the two developments for comparison of performance, in the years to come of the main generating units. One feature of this opportunity grows out of the use of the umbrella-type design at the Chute du Diable or No. 1 development, with a thrust bearing and single generator guide bearing mounted below the generator rotor, as contrasted with that at the No. 2 development where the thrust bearing and upper guide bearing are installed above the rotor, with provision only for the lower guide bearing to be installed in the future if necessary. Performance to date shows that the lower guide bearing is not necessary. The omission of the lower guide bearing at the No. 2 plant arises from the close coupling of generator and waterwheel.

It would be helpful if the author would indicate the factors, engineering and cost, influencing the selection of the screw-hoist-operated spillway gates.

It is noted the author indicates no provision was made for earthquake stresses in the design of the bulkhead section. Presumably this is

[2]Chief engineer, Power Department, Aluminium Laboratories, Limited, Montreal.

due to the relative freedom of the area from other than infrequent and minor earth tremors.

In connection with the semi-outdoor design of the power plants, it should be noted that the No. 1 and No. 2 developments are, so far as known, the farthest north in the world; at least, climatic conditions are the most severe.

**Robert F. Ogilvy**[3]

It has been a pleasure indeed to follow the excellent presentation of Mr. R. E. Heartz and his two associates in describing design standards and details for the two Peribonka power developments. This very thorough review has recalled the many months of intensive work on the part of the consulting engineers, and the discussions with Alcan's management and engineering staff as the initial decisions were made which permitted the job to take shape gradually, and then the later discussions with the contractors as details were modified or confirmed as the result of field conditions which developed or were disclosed as construction progressed.

Design may be divided into three sections,—the very rough outlines of possible arrangements, the preparation of complete drawings for the scheme selected, and then the modification of such designs as may be required by field conditions. These three phases are decidedly different in character.

(a) The first must progress to a rapid conclusion reached by the owners after discussion with the consulting engineers. Preparation of nine layouts for Diable and eleven for Savane indicates only partially the volume of work to be done in the office before actual working drawings can be started and certainly long before actual construction can start in the field.

(b) The second phase consists of a great volume of steady work to produce perhaps 1,000 drawings detailed for field construction. There were about 1,000 drawings for each of the two Peribonka jobs.

(c) The third phase involves modification or amplification of design, and may be emergency effort under great pressure. The field requires immediate instruction because of some unexpected development. Construction of the 65′ deep cofferdam was in this category. The entire scheme was examined and planned for months, but when the cofferdam actually was being built, water in the river was higher than expected. Then Alcan introduced the desire to bring down the Peribonka River from headwater storage just about double the already high flow! That was an emergency which had to be examined in great haste, and thoughts had to be clear—and complete!

Our consulting engineers carried out all phases of this work expeditiously and capably, and co-operated fully in maintaining very pleasant relations with the owners' and contractors' staff organizations. This paper has described the technical aspects of a job which involved personnel contacts also, all of which were completed most satisfactorily.

[3]Aluminum Company of Canada, Limited, Montreal,

**The Authors**

The authors are very grateful to those who have given their time to comment and enlarge upon various phases of these projects.

We assume that Mr. Lawton's query regarding the engineering and cost factors influencing the selection of the individual screw hoists for the spillway gates is made with the alternative of a gantry crane or cranes in mind.

The screw hoists were selected as providing the most economical and dependable method of raising and lowering the gates. With a continuing trend towards automatic operation of hydro-electric plants, the screw hoist is the most readily adaptable from the point of view of remote operation, although for lowering, special precautions must be taken to ensure that the screw will not be buckled.

With respect to the Peribonka developments, where six sluice gates are installed, and two regulating gates not immediately adjacent to the sluice gates, two gantries would be required for the sluice gates only, in order to ensure positive operation of the gates. The cost of these two gantries would be greater than the total cost of the individual screw hoists. At the same time, if one gantry, located near mid-position of the sluice section should have its travel mechanism inoperative, only the gates which could be reached by the other gantry would be available for operation. In addition, while we do not recommend that these large gates be used in a partly open position, this condition very often occurs in practice, and with gantries it would be necessary to provide a dogging device.

A project requiring a great number of gates presents a different economic picture. A point is reached where the cost of the gantries is less and the factors favouring individual screw hoists become relatively less important. Stop-log gains can be designed to accommodate the gate, and the use of gantries makes it a simple matter to transfer the gate to the upstream position if necessary.

However, gantry ropes must be periodically renewed, thus imposing a not inconsiderable increase in operating cost which is not present with screw-operated hoists. In our experience, the latter have given dependable service, with little or no maintenance cost, over a period of years. √

# Death by Automobile

A tabulation showing deaths from automobile accidents was published recently in the Monthly Bulletin of the Royal Automobile Club of Canada.

The average number of deaths resulting from automobile accidents per 10,000 registered motor vehicles indicates how small has been the progress made in accident prevention in the past 20 years in Canada, and particularly in the province of Quebec, as compared with the United States. These statistics are compiled from reports of the Dominion Bureau of Statistics insofar as Canada is concerned and of the Highway Research Board, Washington, D.C. for the United States. It should be remembered that even though there is a decline in the average, actually the number of fatalities and accidents are increasing each year, and it is because of the great increase in the number of motor vehicles registered that the average decreases. As no figures for 1952 or 1953 from the Province of Quebec have been made available to the Dominion Bureau of Statistics, the comparative averages for those years cannot be given.

| | Average for Canada | Province of Quebec |
|---|---|---|
| 1931....... | 10.96 | 19.77 |
| 1936....... | 10.61 | 20.43 |
| 1941....... | 11.78 | 20.89 |
| 1946....... | 10.98 | 18.89 |
| 1951....... | 9.36 | 16.34 |

| | Province of Ontario | Average for United States |
|---|---|---|
| 1931....... | 10.21 | 13.0 |
| 1936....... | 9.56 | 13.5 |
| 1941....... | 11.30 | 11.6 |
| 1946....... | 10.25 | 9.8 |
| 1951....... | 8.22 | 7.1 |

*A paper presented before the 68th Annual Meeting of the Engineering Institute of Canada, at Quebec, May, 1954*

# The Application of Computors to Industry

*by*

W. J. M. Moore, M.E.I.C.

*Assistant Research Officer,*
*Radio and Electrical Engineering Division,*
*National Research Council*
*Ottawa*

Two types of computors are available today, the analog and the digital. The former are inexpensive and easy to understand but limited in accuracy. the latter are required for such uses as accounting and inventory control where greater accuracy is desired.

These electronic brains control airport traffic, keep track of airline reservations, take inventories and make stock reports, calculate load distribution on power networks, predict election results and even translate Russian speeches.

The future role of computers for supervision and control in the automatic factory is only beginning to be realized, when fully exploited its impact on industry will really be felt.

Many of the popular magazines, such as *Time, Fortune* and *Scientific American*, have told us of the various computing machines. These are the so-called "Electronic Brains" which are coming to the aid of engineers and scientists everywhere, in the solution of problems which would otherwise take a lifetime to solve. Perhaps the reader has wondered whether these machines, which apparently give the answers to some fabulous equations in atomic physics and relativity, can also be applied to some of the more down-to-earth problems which arise every day in industry.

The answer is, of course, that they certainly can. A great deal of effort is now being directed toward finding ways in which they may be used in such fields as inventory control, census and insurance calculations, and engineering design. Before delving into some of the specific instances in which computors have been used, however, let us take a look at what sort of thing a computor is, how they work, and what they can do.

The various computing machines available today can, in general, be divided into two distinct classes—analog and digital. Their basic difference lies in the fact that the analog depends on the measured value of various physical quantities and the relationship between them, while the digital relies on the spacing and logical use of pulsed or on-off data with time. Analog computors use the technique of models, or more specifically, mathematically equivalent models. Digital computors, on the other hand, use a language, the language of counting.

### Analog Computors

The analog computor operates by setting up either the physical analog of the system or device being studied, or by representing the various mathematical equations involved with analogs of mathematical operations. The analog is then either displaced from its balanced state by the insertion of an initial condition, or excited by the use of some arbitrary disturbance or forcing function. The manner in which each variable in the analog subsequently behaves provides the information leading to the solution of the problem.

Analogs have been achieved by mechanical means, by electric circuitry or, as is most common nowadays, by the use of electronic operational amplifiers with feedback. This latter type of analog is probably one of the most widely used general-purpose computors today, being relatively inexpensive and easy to understand. It is capable of operating on a 1 : 1 time scale, that is, in real time, and may be used either to solve a complete equation or to simulate certain functions in connection with actual equipment.

Since analog computors rely on the measurement of physical quantities for determining the value of various parameters, however, their accuracy is usually limited to one part in 1,000, or at most, one in 10,000. This accuracy is, in many cases, sufficient, especially in development work where one is usually satisfied with trends, and absolute accuracy is unnecessary. If, however, greater accuracy is desired, as in accounting and inventory control one must turn to a digital machine.

### Digital Computors

Digital machines, since they work with discrete quantities, can be made as accurate as desired, since it is only necessary to provide a sufficient number of significant figures. One digital computor, the Harvard Mark I for example, is capable of handling up to 23 significant figures in the decimal system. This is an early computor, using relays, which was built by I.B.M. and given to Harvard in 1944.

The operation of the digital computor may be compared to that of using a modern desk calculator for solving a problem. The exception is that every operation is automatic from the time the machine reads from the input device the operation required, and the numbers to be operated on, until the answer is displayed by the output device. In the interests of reliability, however, the machine uses devices in which only two stable states exist, such as a relay or its electronic equivalent, and this predicates that all information concerned with the problem be reduced to the point where the solution can be determined by a sequence of yes or no decisions.

It is like using a desk calculator with a human operator of no intelligence, capable of following instructions and of exerting no judgement. The setting down of these minute instructions, or programming as it is called, is what consumes time in digital computor operation. While carrying out a solution with the machine is probably a matter of minutes, the programming may take a couple of weeks. Fortunately, however, a program, once written, may be stored on tape for future use and a library of programs or routines built up. The usefulness and flexibility of a computor is thus enhanced by a large library of these routines.

As in a desk calculator (where slips of paper are used), only one set of numbers can be operated on at one time. Some device must be provided for the storage of numbers and instructions while they are not being used. The memory units determine the capacity of the computor. Devices used for this purpose include magnetic drums, tapes, magnetic flip-flops, punched cards, cathode-ray tubes, and delay lines. They are characterized by their "access" time, the time required to find and extract a given bit of data.

The fact that the digital computor is calculating one mathematical operation at any instant, rather than the complete problem, prevents its use as a simulator in the usual sense. However, where the physical variation is slow compared to the time required by the computor to make the desired calculation, the digital machine may have some application in the simulator field.

### Use in Power Networks

Turning now to applications, let us take a look at how computors are being used today. Computing machines are of most value where the calculations involved, though simple, are long and tedious. One activity where such problems arise is in the calculation of load distribution and stability in large electrical power transmission networks. A form of analog computor, the network analyzer, has been in use now for over 30 years and it is estimated that there are more than 25 of these instruments in existence today.

An indication as to their usefulness is given by the fact that seven private utilities in the United States have decided to build a new $400,000 analyzer at the Franklin Institute in Philadelphia, using private capital. This analyzer is to have the equivalent of 28 generating stations, 270 transmission lines and 90 loads.

### For Aircraft and Guided Missile Development

Another industry which has made considerable use of computors is that concerned with the design and development of aircraft and guided missiles. This group alone, in connection with defence contracts, has probably been responsible for most of the post-war computor (especially analog) development to date. At least three companies have been actively engaged in computor development which has resulted in actual general purpose computor design.

An indication of the importance of computors in aircraft development may be obtained by considering the following statistics relating to the computing section of one of the large aircraft companies:

Equipment available or on order:
- 2 I.B.M. Defence Calculators
- 5 I.B.M. Card Programmed Calculators
- 1 Electric Analog Computor
- 1 Electronic Operational Analog Computor.

At the end of 1952, it was estimated that this equipment would require a staff of about 73 persons, occupy approximately 11,000 square feet of floor space and would use about 425 kva. of electric power. Costs directly chargeable to the operation of the equipment, including salaries, was estimated to be in the neighbourhood of $75,000 per month.

### For Pilot Training

In addition to development work, computors are also being used by the aircraft people for training pilots, in the form of flight simulators. Some attention has recently been given in the press to one such simulator under development in Canada. These simulators compute for a given flight condition realistic instrument readings, which are displayed in a simulated cockpit where the trainee sits. Whatever action he takes to correct the situation is fed back to the computing section which calculates the new instrument readings.

Apart from the obvious advantage of preventing loss due to improper response, these simulators present a real saving in costs of training personnel. The cost per hour for operating a flight simulator is in the neighbourhood of $10.00, whereas the cost of flying an F-86 is about $150, a B-50 $400, and a B-36 bomber $1,000.

### For Airport Traffic Control

Another problem, to which computors have recently been applied is airport traffic control. This system, known as Volscan, or Volume scanner, determines by radar the position of each aircraft approaching the airport at ranges up to 60 miles. It automatically calculates the optimum time of arrival of each aircraft and the flight path it must follow, at constant speed, to arrive at the prescribed time. Instructions are then transmitted to the aircraft.

Arrangements are provided to ensure that two aircraft do not arrive at the same time, and to recalculate the flight path and arrival time if an error is made in following the instructions or an emergency develops. With this system, it is possible to land up to 120 jet aircraft per hour, where formerly only 40 per hour could be landed, and that only in good weather.

### The "Reservisor"

Airline reservations data handling is another phase of the aircraft business which has received some assistance from computing machines. Normally, this information was handled by placing a large blackboard indicating open flight space within sight of a number of sales agents with telephones. Under the best conditions, this board was several minutes behind schedule and could only handle data for a three- to five-day period.

A recent development, the "Reservisor", which uses a magnetic-drum memory, is capable of checking seat availability, and selling or cancelling from one to four seats of any eight flights at one time, on a total of 1,000 flights per day for a ten-day advance period. Requests for information may be entered from remote stations by telephone link, and during a normal ten-hour day, 22,000 calls are handled. The machine was developed by the Teleregister Corporation, in co-operation with American Airlines, at a cost of $500,000. It was placed in operation in New York in July 1952.

#### Used by Mail Order Houses, Restaurants, Groceries

Another application, also using magnetic-drum memory, is the "Distributon", which keeps track of inventories for a mail-order house in Chicago. The machine takes account of 13,000 items, and prepares totals as to number of orders, number of cancellations and current inventory balance. The first real trial of the device occurred last Christmas, when it replaced 60 part time clerks with ten operators with input devices. The machine can not only take care of 90,000 tallies per day, but it can also be set to type out a daily stock report at night. The time required to complete one operation is about 0.4 seconds.

Over in England, the firm of J. Lyons & Co. Ltd. have sponsored the construction of a digital computor for use in their large restaurant and grocery business. This machine, which they have named "Leo", the "Lyons Electronic Office", is not only to be used for office accounting, but also for controlling stocks of foodstuffs. The programming of a machine to handle such problems is of course a formidable one, and this phase is still being worked out.

At present, the machine only works about five hours per week for the company, but the remainder of the time it is profitably contracted out to defence industries. All told, the computor occupies about 1,100 square feet, weighs 15 tons and requires six operating and maintenance personnel. It can carry out, in one second, calculations requiring eight minutes by existing office machinery.

#### UNIVAC Predicts Election Results

Quite a lot of work is also being done with computors in the field of statistics. It is here probably that the digital computor finds its most important use, since statistics after all is mostly counting.

Most of you are probably aware of the use made of computors in the last U.S. election to predict the outcome, and perhaps some of the details concerning the use of UNIVAC would be of interest. A study of how UNIVAC might be used for this purpose was initiated some six months in advance of election night.

The whole country was sub-divided into a number of sections as indicated by their past voting habits, and a mathematical system set up whereby the machine could predict:

— the probable outcome of each state, and the majority.

— the number of states for each candidate.

— both the electoral and popular vote for each candidate.

— the relative chances of each candidate.

Three to one, and ten to one odds were worked out in each case. Three complete machines were used, two acting as a check on one another, and the third standing by. A time of 6 minutes was required to make a prediction on a given group of data.

How well it worked is illustrated by what actually happened. At 8.30 p.m. on election night, when only 3,400,000 votes were in, and 21 states were unheard of, the machine predicted 100 to one in favour of Eisenhower. This produced some consternation on the part of the operators, since a close election was expected, and it was not understood how the machine could be so sure of itself when so many states had not reported in.

A quick check of the programming was made, but no error was found. It was then decided to make a slight change in the factor representing the unheard-of states, to show a closer election for this set of returns. Ten minutes later, however, when more complete results were in UNIVAC repeated its prediction of 100 to one, and it was realized that no mistake was made.

#### From War Priorities to Translation

Another tremendous problem being investigated by digital machinery is one of inter-industry economics, where the inter-dependence of one industry on others is studied and their effect on the output of each is determined. Such an undertaking is of great importance in time of war; for example, where production must be speeded up and priorities laid down. The old time requirement that military commitments be met at all costs is now giving way to a planned program, which can be achieved within the existing industrial structure.

Computors have also been applied to many other problems. They have been used to study the behaviour of underground oil pools, the United States census, beam vibrations, automatic control problems, and, most recently, language translation.

The successful demonstration of this last capability was given early this year, when the International Business Machines 701 computing installation in New York city was programmed to translate Russian sentences into English. More than 60 sentences, involving 250 different words were translated, the time for each sentence being about 8 seconds. The process was achieved by setting in the machine all English words which are required to describe the various meanings which the Russian word may denote, and a set of six rules for determining which English word is the proper one to use.

#### Many New Applications to Come

The use of computors in industry is not an entirely new development, of course. Card-programmed calculators have been used in accounting for many years. The idea of using punched cards was in fact first conceived over 100 years ago by Jacquard in France, for the control of patterns in weaving, and this technique is still being used today in that industry. The "Analytical Engine" which Babbage designed in 1833, contained many of the principles used in modern computors.

But it has really been only in the past 15 years or so that scientific know-how and manufacturing technique have advanced to the point where general purpose computors become a feasible proposition. Every day, new applications are being found for these machines, and office procedures and manufacturing processes are being converted to a form where they can be accurately and speedily handled by machine computation.

The future role of the computor, that of supervision and control in the automatic factory, is only beginning to be realized in such developments as the punched tape controlled automatic milling machine at M.I.T. When this capability of the computor is fully exploited, the impact of the computor on industry will really be felt.

# Discussion

## G. Glinski[1]

Mr. Moore should be highly complimented for such a lucid presentation on the subject of the application of computors to industry.

In my short discussion of his paper, I would like to elaborate on one aspect of the problem which I feel should be of particular interest to the members of this Institute: How much Canadian engineers and scientists contributed to the developments in the computor field.

My own activity in this field goes back to 1946 when I prepared, as a consultant, a proposal for a large scale audio frequency network analyzer for a firm in Toronto.

The interest of our Armed Services goes back to 1948. The names of Lt. Cmdr. J. Belyea of R.C.N. and W/C J. G. Wright of R.C.A.F., should be particularly emphasized.

The National Research Council and Defence Research Board sponsored, since 1948, the activities of the Computation Center of the Toronto University. At the University, such people as Professor V. G. Smith, Dr. C. C. Gotleib, Dr. J. Kates and Dr. A. G. Ratz made many contributions to the techniques and art of computation.

In 1948, also, a first Canadian company specializing in electronic computation, was organized: Computing Devices of Canada, Limited, in Ottawa. I have been associated with this Company from its inception.

In 1949, Ferranti established a separate department, specializing in computing problems.

In 1951, Professor F. S. Howes of McGill University, decided to organize the postgraduate courses on digital and analog computation and I was asked to lecture at both McGill University in Montreal, and Carleton College in Ottawa. Since then, these courses became well established and, I think, we have now more than 100 people who have been initiated into the mysteries of computation.

I like to stress this problem of manpower particularly, since, on having a sufficient number of people who can build the computors, operate them and see their potentialities for particular applications, lies the future of computing in Canada.

A few years ago, even in my own Company, many colleagues considered me as an impractical fellow, whose computing obsession will ruin the business. These fears, of course, are things of the past.

Whereas in 1948, I could count on the fingers of my right hand the number of people in Ottawa who knew something about computors, now in 1954, even Deputy Postmaster General invents "built-in brains".

I have no time to dwell upon particular technical contributions to the art of computation which originated here in Canada, but I would like to mention a few. We developed many specialized computors for military applications. We built prototypes of a few general purpose computors. We invented several new computor components such as: matrix tubes, magnetic pulse elements, electro-mechanical devices, magneto-striction delay line memories, etc. We introduced first unitized construction of digital computing equipment.

In my short discussion of computing in Canada, I probably omitted some important names, dates or accomplishments. Of course, this is not intentional but simply because of the impromptu character of these remarks.

## Dr. J. Kates[2]

Much of the literature about computors, especially popular and semi-popular, places heavy emphasis on the large size of computors and large size of the problems computors can handle. In the very excellent paper we have just heard, large figures also played a prominent part. I recall statements as to: 23 significant figures—

$400,000
500,000
22,000 calls per day
13,000 items
1,000 square feet
15 tons

Now it is true that machines, particularly earlier models, are fairly large and costly and require staff possessing considerable qualifications. But in emphasizing these points, we tend to scare smaller

[1]Consulting Engineer, Director, Computing Devices of Canada Limited, Ottawa.

[2]Adalia Limited, Consulting Engineers, Toronto.

industry away from the very considerable and worthy applications for computors of a smaller and more limited scope, applications which exist at present. Let me here just give two examples:—

At Toronto about a year ago, we used our computor for calculations connected with the St. Lawrence Seaway. These calculations required 400 hours machine time and cost $60,000.

Now we are programming a design procedure for a company. One set of calculations will take only a few minutes and will cost between $10 and $20.

By a calculation such as the $60,000 Seaway calculation, millions of dollars can be saved by minimizing earth moving operations. By the $10 design calculations, a few thousands of dollars will be saved every year in engineering time. Also it will be possible to obtain immediate estimates instead of waiting a few weeks. The important point is that the digital computor is an economic tool for small jobs as well as for big ones. Too few people realize that short or lengthy sequences of operations and manipulations can be recorded on an ordinary teletype tape. This means that into this tape, or cards or other devices, an engineering or an accounting or a planning department may record those of their operating sequences which occur repetitively. Once such a master tape is entered into a general purpose computor, this computor assumes the characteristics of a machine specially built for the particular task. And yet this transformation is accomplished without changing one item of hardware on the machine. This master program which is on the large tape sets up the process. A separate tape, the data tape, is used so that the master program can deal with a great variety of problems of a similar nature.

I should like to underline Mr. Moore's point that it is not necessary to construct a new program every time a problem is handled. Rather, the same program can be used for a great number of applications.

Engineers, scientists, accountants and businessmen can now (and this is not five years from now, but at any time they choose), have a particular repetitive type of design operation, estimating procedure or other calculation, programmed, i.e. put on a tape. This tape represents an investment which does not deteriorate with time for there is no depreciation involved. Moreover, it is fairly easy to broaden such programmes later on.

By running such a tape together with the data of particular interest into a computor, you can then have the computor go through the sequence of steps far more cheaply, quickly and reliably than a human chain of either girl operators or highly skilled engineers could do. In order to avail yourself of such computors in a very large number of cases, you do not necessarily require to either own or build a computor nor do you require staff who are experienced with computors. Experienced programmers are available at a number of centres who can work with your company's own staff in order to adapt computors to your company's operations.

Computors are not expensive; they are really cheap. You can now buy computor time by the minute, i.e. by the dollar. And in one dollar's worth of time, a computor can do considerable work.

This means that industry can now relieve its staff, particularly highly trained engineers who are in short supply, from tedious and costly calculations and operations. It means that industry can make savings by reducing the cost of operations and at the same time increase revenue by employing their highly skilled staff more efficiently and more intensively. This is particularly important for Canada because here engineering departments tend to be small. In order to utilize our engineering manpower most effectively, we must relieve them of lengthy repetitive design routines.

Every executive knows that he should not do something that he can delegate to someone else; and that a human being should not be wasted on tasks which a machine can do so much better. And so it is important for Canadian industry to get acquainted—to "get its hands wet", so to speak, with the newest and most flexible tool that has been developed so far. This tool will become as important to technology as the assembly line, much sooner than you think. Industry should scan its operations everywhere—first, for smaller tasks, and then for the larger tasks which might be done by automatic machines.

Thus:

1. Industry can economize on these tasks;

and

2. Industry can better realize the potentialities of these new techniques. √

---

## Future Power Developments, Northern B.C.

The future power developments and metallurgical projects planned for Northern British Columbia and the Yukon will rank among the major engineering developments of the world today. T. Lindsley, president of the Frobisher and Ventures group of companies recently met with Premier W. A. C. Bennett and Honorable Robert E. Sommers, B.C. Minister of Lands and Forests and Minister of Mines, to discuss the project.

The total watersheds to be developed extend 200 miles north-south from the south end of Atlin Lake to the mouth of Big Salmon River, and an east-west distance of 300 miles from Rancheria to Burwash.

The industrial phase of the project calls for the construction of smelters and refineries to treat ores and concentrates which will be shipped in from distant parts of the world as well as those from the Pacific area of Canada.

The hydro-electric project, officially known as the Yukon River-Atlin Lake-Taku River Power Project, plans to utilize the run-off from the upper drainage system of the Yukon Territory. Northern B.C. Water from other watersheds west and east of the Upper Yukon Valley will also be diverted. A group of large lakes forming the headwaters of the Yukon River will be used as storage reservoirs. The project will divert the flow of the Upper Yukon River and adjacent rivers and streams, to the valleys south of Atlin lake. Ultimately this will generate some 4,300,000 horsepower. The first stage of the project calls for the development of 880,000 horsepower by 1962.

The development is being undertaken by Northwest Power Industries Limited, a subsidiary of Quebec Metallurgical Industries Limited, and Frobisher Limited, a subsidiary of Ventures Limited.

Work will begin next year, assuming the necessary licences are obtained from the governments of Canada and British Columbia before the end of this year. √

# Electronics in The Pulp and Paper Industry

*by*

W. A. Messervey

*Pulp and Paper Mill Application Engineer, Canadian General Electric Co., Ltd., Peterborough, Ont.*

Like many another process industry, paper making is becoming more and more automatic. Production and quality may now be kept up to standard, or improved, by means unkown only a few years ago. Much of this advance in technique is attributable to electronic instruments and devices, like those described in this paper. All such advances should be good news to Canadians, each of whom is to some extent, directly or indirectly, dependent on pulp and paper for a part of his daily bread.

The pulp and paper industry in Canada leads all others in value of production, in exports, in wages paid and in capital invested. It is the largest consumer of electric energy, purchasing some 17 per cent of all central station power developed, and also generates more water power than all other industries combined. It is the largest industrial buyer of goods, services and transportation. Canada's newsprint output is five times that of any other country and supplies one-half of the world's needs. Canada also is the world's greatest exporter of wood pulp and the world's second largest producer of pulp.*

This paper describes briefly electronic equipment applications which have assisted the industry to keep pace with our heavy industrial expansion, and also describes more recent applications which will further assist the industry.

### Paper Making Process

A brief description of the paper making process will be of assistance to those not too familiar with the industry. Figure 1 is a simplified flow sheet of a newsprint paper mill.

Pulpwood is brought in from the woodpile or log pond and the bark is removed by a barker. In eastern mills this is usually a cylindrical drum in which the logs are tumbled and the bark removed by friction. The hydraulic debarker is more common on the west coast where logs are much larger. In this type the bark is removed by high pressure water jets.

Some of the cleaned wood goes to the chippers where it is reduced to chips about ¾ inch thick. These chips are then cooked in an acid bath which produces almost pure cellulose. The resulting pulp is washed, screened and refined and goes to the sulphite stock chest.

The remainder of the debarked wood goes to the grinders where it is reduced to pulp. This groundwood pulp in turn is screened and refined and goes to the groundwood stock chest. The groundwood and chemical pulp are then mixed in the proper proportion, for newsprint roughly 80/20, and pumped into the head box. There it is mixed with more

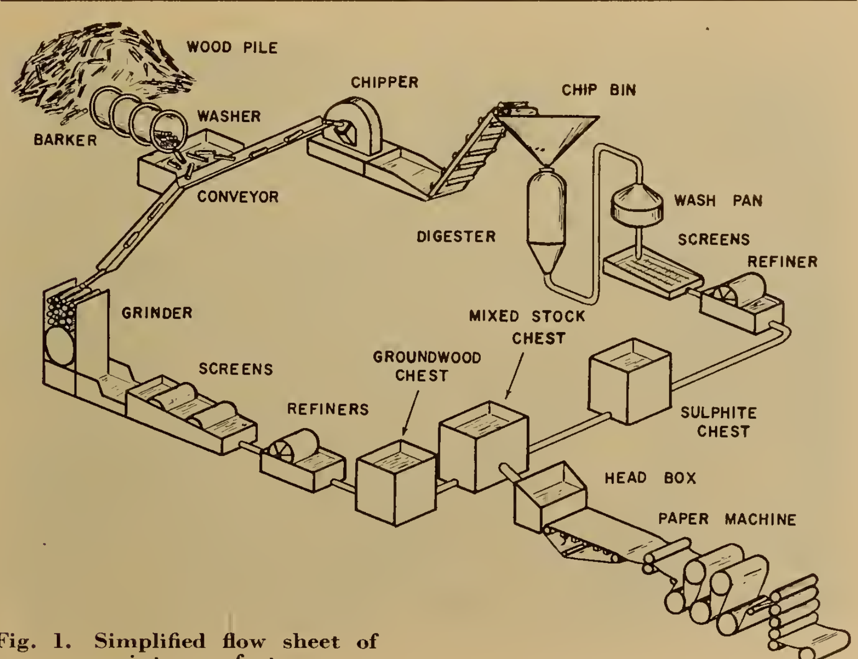

Fig. 1. Simplified flow sheet of newsprint manufacture.

* Based on data from Canada Year Book, 1952-53.

water and flows out on the paper machine, where it is formed into a continuous sheet of paper.

### Theory of Electronics

This paper is much too general to cover in detail the theory of electronics and of electronic tubes. A brief description of what electronics can do, however, is worthwhile, because making use of one or several of these abilities constitutes in part the art of application engineering for electronic equipment.

#### *Rectifying*

Electronic tubes can pass current in only one direction; thus they serve as a means of converting alternating current to direct current for generator and motor excitation. By using grid-controlled rectifiers the amount of current flow can be adjusted, permitting variable excitation.

#### *Amplifying*

Signals applied between the grid and the cathode of a tube produce corresponding changes in the current that it will conduct. By proper selection of the plate resistor, the change in plate current can be converted into a change in voltage many times greater than the original signal. The power requirements of the grid circuit are extremely small, so a very minute signal may be detected and, by placing several tubes in cascade, may be amplified as many times as desired to give a working signal to control a machine or process.

#### *Light Sensitive*

Light shining on the cathode of a phototube causes an increase in current flow and this may be amplified to provide enough power to operate the desired mechanism.

#### *Voltage Regulating*

In cold-cathode gas-filled tubes, commonly known as "glow tubes", the voltage drop across the tube remains practically constant regardless of changes in the amount of current flowing through it, within the rating of the tube. This constant voltage is used to provide for stable power supplies to electronic circuits and to act as a reference voltage in regulating circuits.

A combination of the above properties, together with proper circuit design, is usually necessary to meet the desired application requirements. For example, a voltage amplifier would require a power supply and one or more amplifying stages. The power supply would involve rectification and perhaps voltage regulation in order to supply a stable d-c. voltage to the amplifier from the a-c. lines.

### General Electronics Applications

#### *Metal Detector*

The application of electronics in the paper industry can be found at the very beginning of the process.

Spikes, pieces of wire rope and other metal can become embedded in logs during cutting and transporting, particularly if the logs are floated or towed in rafts. Stray metal can cause damage to chipper knives and grinder stones. Figure 2 shows a metal detecting installation in which the detecting coil is partly submerged and logs are floated through it. The detecting circuit employs an inductance bridge of which this coil forms a part. Metal introduced through the coil causes the bridge to become unbalanced electrically. This unbalance is amplified electronically and the output operates an alarm or can be arranged to operate a reject device.

**Fig. 2. A log passing through coil of metal detector.**

**Fig. 3. Adjustable speed control panel: "brain" unit at top; motor armature rectifier testers at bottom left; motor field rectifiers at bottom right.**

The coils are rugged, single-turn devices; the four-foot coil can detect magnetic materials equivalent in volume to a ½-inch sphere at the centre of the coil opening. This is a conservative figure; the sensitivity increases several-fold as the metal approaches the coil. This equipment will detect non-ferrous metal of about twice the diameter of magnetic material.

#### *Adjustable Speed Drives*

There is a growing need for inexpensive, yet high quality, adjustable speed drives in the smaller horsepower ranges for new processes and machines, or to provide adequate control to an older process made more critical by increased production.

The direct current motor and electronic control combination has proved well suited to meet these requirements, particularly where speed ranges are wide, load changes are frequent and large, and where automatic control, speed regulation, tension regulation, timed acceleration or current limit acceleration are indicated. These electronic d-c. drives are classed according to the nature of their power supply:

a. Figure 3 shows the panel for an adjustable speed drive with an all-electronic power supply. This drive is most economical in the smaller sizes and is accurate, versatile and fast acting. Because few paper mill applications require all its features, its cost in the larger sizes is sometimes not justifiable.

Both the field and the armature of the direct current motor are supplied with power from grid-controlled rectifiers connected to the a-c. lines. The rectifier grids are controlled in turn by an amplifying unit which is responsive to speed, voltage or current signals. A glow tube is sometimes used to act as a reference for the signal to be controlled. The amplifying part is often referred to as the "brain" unit.

b. Figure 4 illustrates another type of adjustable speed drive. It can be used with or without electronics. The unit consists of an induction motor driven d-c. generator which supplies armature power to the d-c. machine motor; a d-c. exciter for control power and motor field excitation; induction motor starting equipment; and the necessary d-c. magnetic control. The whole is housed in a sheet steel enclosure, complete with air filtering and ventilating equipment. With electronics, this drive is controlled by a unit similar to the brain already mentioned, which regulates small grid-controlled rectifiers. The latter supply excitation to the d-c. generator field in proportion to the control signal. These drives are available in package form up to 200 hp. and are used in such paper mill applications as for stock washers, for rewinders, for windups and unwinds of supercalenders, for small paper machines and for pulp drying machines. Their use is also indicated where only small control signals are available.

### *Grinder Load Regulators*

Newsprint consists of over 80 per cent groundwood. The grinding process uses more than 50 per cent of the total power requirements of a newsprint paper mill and it is desirable to keep the mill power load approximately constant. There is also a definite relation between grinder power and pulp quality and quantity, so it is common practice to regulate grinder motor input kilowatts. This is accomplished by changing the feed rate of the wood onto the stone, but is not by any means an easy regulating task. The sharpness of the stone, the species of wood, the quality of a given species, voids in the wood supply and power system changes all contribute to the wide variation in the feed rate required.

In continuous types of wood grinders, feed mechanisms are driven by d-c. motors through gears with ratios in the order of 30,000 to 1. Thus, while grinder loads may change suddenly, the time of response of the electrical system is partly nullified by this high ratio and by backlash. Rapid, jerky correction is not permissible because of its detrimental effect on groundwood quality. What is required is a sensitive high-gain regulator, having a minimum time lag consistent with smooth wood feed.

Numerous types of regulators have been installed in the past thirty years, the majority of them using some form of contact-making wattmeter as the sensing means. These usually perform adequately, but require considerable maintenance of contacts and relays. In addition, it is now difficult and expensive to obtain replacement parts. The operating range of these regulators is also somewhat limited and the on-off system tends to give choppy woodpulp. An attempt has been made in the past few years, therefore, to build some static form of regulator and, while some success has been attained, it is only recently that a static circuit has been developed which is truly responsive to watts, even under conditions of varying power factor, line voltage and frequency.

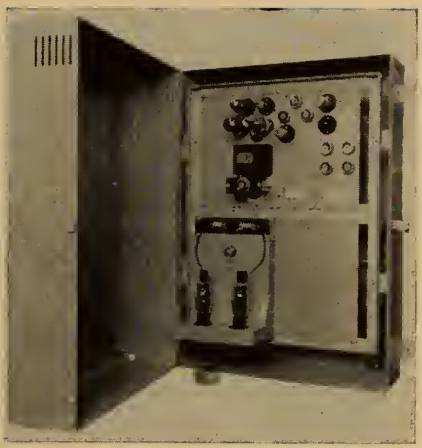

**Fig. 5. Electronic grinder load regulating panel; electronic watt meter at upper right.**

After several years of research and testing, regulating equipment as shown in Figure 5 has been built and installed; this appears to have all the requirements of a successful grinder load regulator. The circuit is shown in simplified form in Figure 6. The equipment is inexpensive, accurate, reliable, completely static and can be adapted to existing regulating systems if the rotating equipment is adequate.

The heart of the regulator is the electronic wattmeter which delivers a d-c. voltage directly proportional to watts over a wide range of time, voltage, power factor, frequency and ambient temperature. This voltage is compared to a precise glow tube reference, which is adjustable to set the kilowatt load. If any difference exists between the reference and the wattmeter signal, it is amplified in the next stage and this in turn controls the grids of the output rectifier tubes, thus controlling the excitation of the field of the feed-motor generator. This changes the

**Fig. 4. 40 hp. electronic speed control power unit; motor generator set at bottom; magnetic control at upper right; electronic control at upper left.**

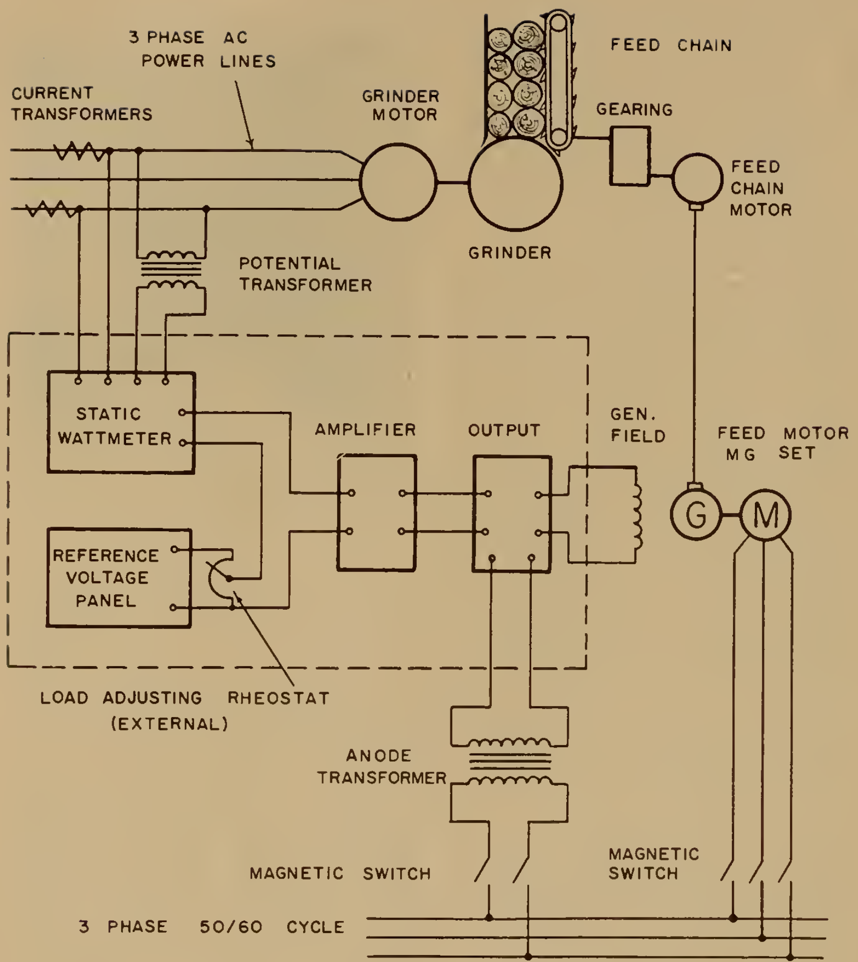

**Fig. 6. Simplified diagram of electronic grinder load regulator.**

voltage of the generator, which changes the speed of the feed chain motor, changing the rate at which the wood is fed onto the stone. This in turn restores the load on the grinder motor to the desired value. A drop in load would occasion an increase in feed motor speed and vice versa.

Operating experience with this equipment shows an accuracy well beyond that of any existing static device and superior to the contact-making wattmeter in all but exceptional cases.

### The Paper Machine

The whole output of a paper mill has to pass through its paper machines to obtain the required product. It will be realized, then, that utmost reliability is a criterion for any equipment associated with the machine, otherwise production will be lost or product quality will suffer.

A brief look at the paper making process will reveal some of the problems that can be met only by reliable and accurate control. Figure 7 shows in elevation a typical newsprint machine. Stock flows onto an endless wire screen belt from the head box in the proportion of 199 parts of water to 1 part of pulp. As the stock moves along with the travelling wire much of the water is removed by passing through the openings in the screen. The wet sheet then passes over a number of suction boxes and around a suction roll, called the "couch roll", where more water is removed. At this point the sheet looks much like waterlogged newspaper, having little mechanical strength and still containing a great deal of water. Then it passes through two or more press sections, which wring out more of the water. The sheet then passes into the dryer section which consists of a multiplicity of steam heated rolls. By the time the paper has reached the end of the dryer section it is completely dry. A controlled amount of moisture is then put back into the sheet by passing it over a sweat roll. From there it passes to a calender section, which polishes the paper to make it suitable for printing. The final product is wound into rolls on the reel section. Machines for other types of paper vary in makeup according to requirements, but in general the objective is the same.

These rolls of paper are then rewound and slit on a winder with the proper tension and desired width. Paper breaks are spliced on the winder and poor quality paper, if present, is removed.

#### *Sectional Drives*

Paper machines may be driven either by a mechanical lineshaft or by a sectional electric drive. In the former, a lineshaft extends the length of the machine. Each section of the machine is mechanically coupled to the shaft through a clutch and cone pulley drive.

In the sectional drive each section is driven by a direct current motor;

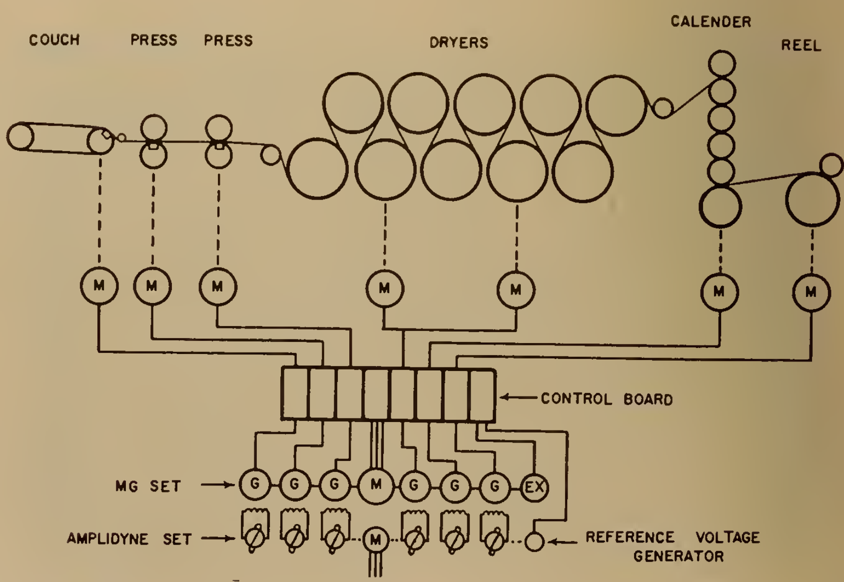

**Fig. 7. Diagram of paper machine showing section drive equipment and control.**

the majority of larger, higher-speed machines use this type of drive. Such a drive is called upon to perform satisfactorily under unusually stringent conditions with the utmost reliability and with extreme accuracy. The sections vary widely in horsepower and inertia; the speed of each section must be independently variable and, once set, must hold the difference in speed, commonly known as "draw", extremely closely. In addition, overall machine speed must also be held closely in order to produce a uniform product. Fig. 8 shows a sectional drive set-up.

As paper machine speeds have increased, the electronic-amplidyne drive has proved itself adequate to meet these stringent requirements. Some tissue machines are now in operation at speeds in excess of 2,500 f.p.m.; kraft and newsprint machines are consistently running above 1,600 f.p.m. and in some cases approaching 2,000 f.p.m. In Canada, almost 200 section-years of operation have proved this type of regulator to give quite satisfactory performance. It is interesting to note that the majority of these drives has been installed on old machines, many of which are now running at double their original designed speeds.

Usually each section of the machine is driven by an individual motor, except in the case of the dryer section, where two or more motors are used for mechanical reasons. As shown in Figure 9, each motor is supplied with armature voltage by its own generator. The motor field excitation is constant. Speed control is obtained by varying the armature voltage. Each generator is excited by its individual amplidyne generator, the latter being a very high-gain, high-speed d-c. exciter. The amplidyne requires only a few watts of excitation and this can be supplied quite adequately by the electronic amplifier.

Each section motor has a pilot generator connected to it. This pilot is a heavy duty, non-aging, temperature-compensated, alnico-magnet-field tachometer generator, which delivers a voltage directly proportional to motor speed. This voltage is compared in the electronic amplifier to a very precise d-c. voltage, called the "reference voltage", which is the master voltage for each paper machine; every section pilot generator voltage is compared to it and this master voltage therefore sets the overall speed of the drive. If any difference exists between the pilot generator voltage and the master voltage, it is amplified in the amplifier.

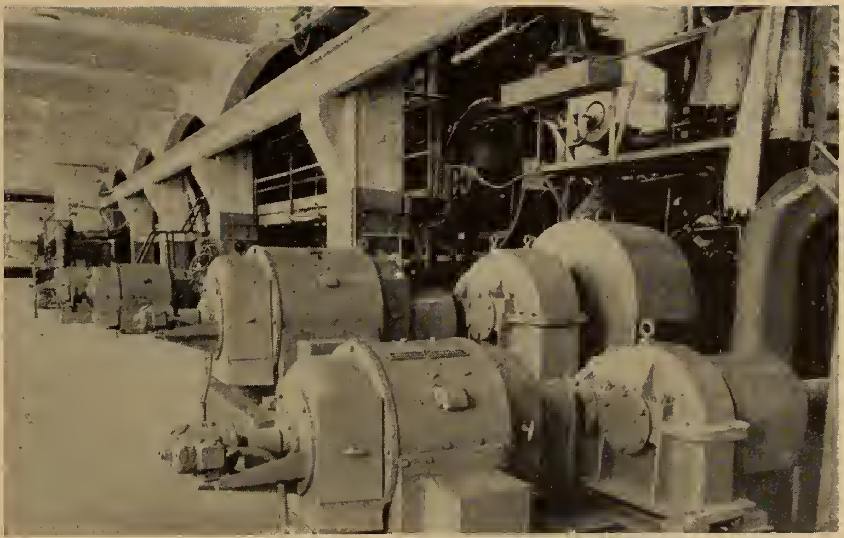

Fig. 8. Paper machine drive units each consisting of a d-c. motor, a gear unit, and speed regulating tachometer generator. Motors range from 40 to 500 horsepower.

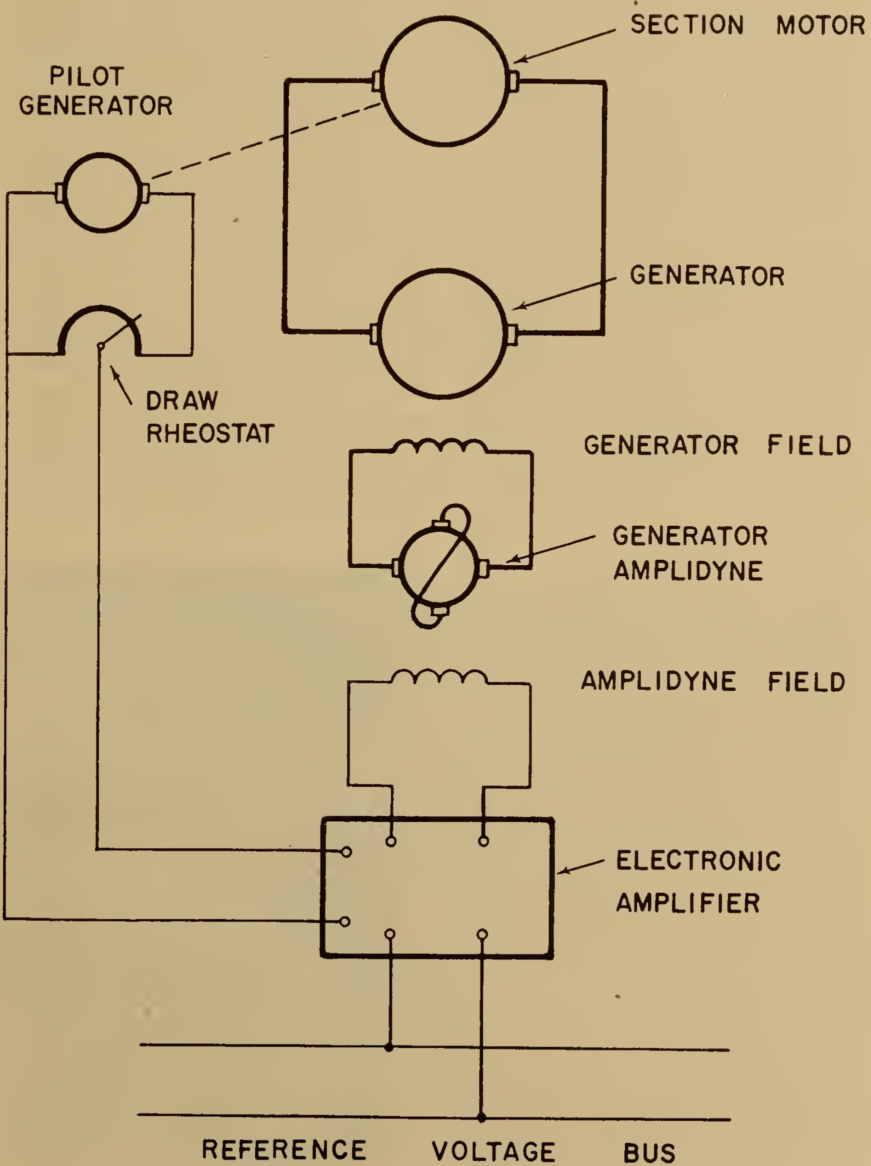

Fig. 9. Simplified diagram of one section of a multiple-generator electronic amplidyne sectional paper machine drive.

Suppose a sudden load were applied to a section. Its speed would temporarily drop and the pilot generator voltage would decrease slightly. This change in voltage would be amplified. The output of the amplifier would increase the excitation of the amplidyne generator, which would in turn increase the excitation of the section generator. This would increase the armature voltage of the section motor to speed it up and restore it to the original speed.

This system has phenomenally high gain and rapid speed of response, because of the electronic amplifier-amplidyne generator combination. Stabilizing and accelerating circuits are a part of the electronic equipment and adjustments are now refined to the point where a field engineer can set up a section in half a day and know the drive will "make paper" with little or no further adjustment. The control and the system are flexible and can meet future machine changes and additions, as well as being adaptable to instrumentation and automatic control.

Performance investigations of the electronic amplidyne speed regulator have established that it will operate for long periods with an error of less than 0.1 per cent. From a maintenance standpoint these drives compare favourably with any. Extreme care in selection of components, in manufacture and in assembly go into all sectional drives. Gone are the days of the breadboard electronic amplifier. Instead, heavy duty industrial equipment, made with conservatively selected components is used, wired and cabled in industrial fashion with wire and device numbers marked. Actual downtime due to vacuum tube failure is considerably less than ½ minute per section per month.

### Paper Machine Instrumentation

Electronics has made it possible to measure with high accuracy and low first cost, functions or quantities heretofore impossible of measurement. Four of these electronic instruments are the basis weight gauge, the draw speed indicator, the tensiometer and the moisture monitor. All are of assistance in maintaining the production and the quality of paper.

#### *Basis Weight Gauge*

The paper sheet passes through the gauging head without touching it. (Figure 10). One jaw of the gauging head contains a radio-active source sending a beam of beta rays across the gap into the other jaw, which has an ionization chamber. If material is in the gap, some of the beta rays will be absorbed by that material. The unabsorbed rays which reach the chamber ionize the air within it and the ions and electrons so formed are collected by charged electrodes. The flow of charged particles to the electrodes constitutes a minute current, the strength of which is dependent on the amount of unabsorbed beta rays reaching the chamber. This current is bucked against a reference and any difference is amplified electronically to show up as a deviation from a set weight per unit area of absorbing material. Thus this device provides for continuous measurement of paper weight, without marking the sheet or interfering with production.

There are pioneer installations utilizing this type of gauge to control the stock flow or the paper machine speed so that basis weight will be maintained automatically. Installations to date have been on slow machines, but the future looks promising for use on higher speed installations.

#### *Differential Speed Indicator*

Paper machine section speeds progressively increase as the sheet proceeds from the wet end toward the dry end. The difference in speed between the couch and the first press might be as high as 5 per cent in a newsprint machine. This difference in speed, or "draw", is an important physical concept in paper making, and many mills are finding it to their advantage, both from a production and quality control viewpoint, to know what this draw is at all times. The draw meter can be inexpensively applied to any machine. This is all the more true when applied to a machine equipped with electronic amplidyne drive, because the draw meter can operate from the same tachometer generators as used for speed regulation.

Figure 11 indicates the simplicity of the circuit. A portion of the signal from say the couch tachometer generator ($V_1$) and a portion of the signal from that of the first press ($V_2$) are compared by an electronic self-balancing potentiometer. In essence this is a sensitive galvanometer with an extremely stable electronic amplifier follow-up, yet relatively simple in form and circuitry. The output of this potentiometer operates an indicating or recording instrument, or both. These can be calibrated in feet per minute if desired. The only adjustments are as shown. These are necessary to set up the equipment to account for differences in tachometer gearing, roll diameter changes, etc.

#### *Tensiometer*

While this is not an electronic device, its use as a tension regulator depends largely on its association with electronic equipment.

At the dry end of the paper machine, the sheet is relatively strong and small speed changes can cause large tension changes. The heavier the paper, the truer this is. Moisture or stock changes can also affect the tension, causing paper breaks from excess tension, or calender cuts and poor reeling from too slack a sheet.

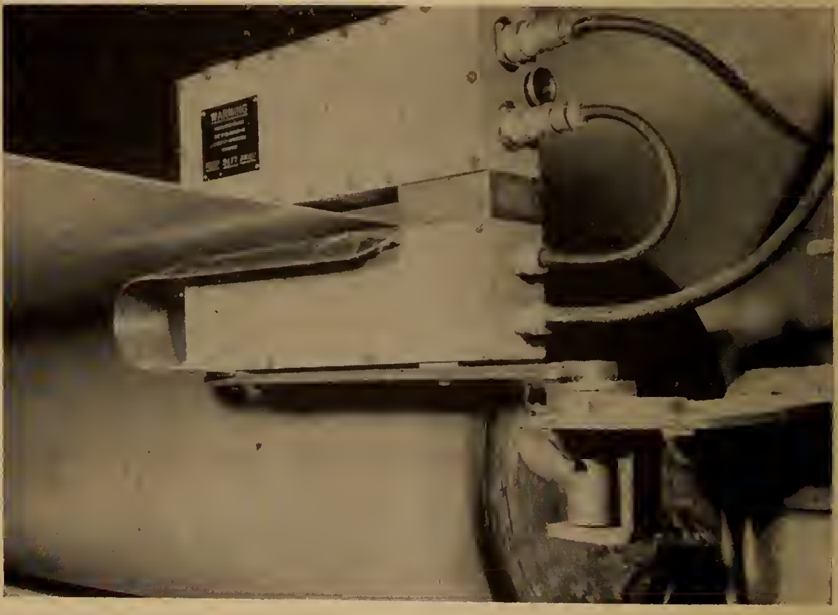

Fig. 10. Beta-ray basis weight head used to measure sheet thickness on a board machine.

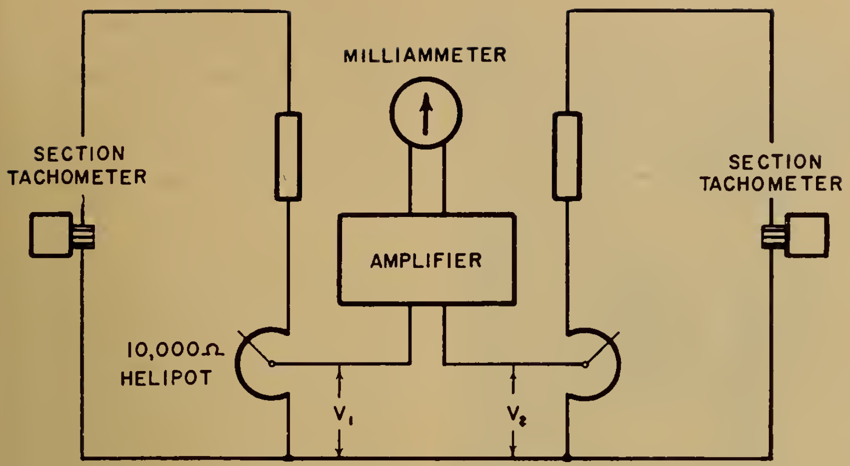

**Fig. 11. Line diagram of differential speed indicator circuit.**

Paper machines which operate over a range of speeds and paper weights can be particularly troublesome. During changeovers the drying function is temporarily upset and the moisture content will change. Relatively large tension changes will occur and, because of the inertia of the drying system, several minutes may be required before the system will settle down. During this time the operator must be continuously on the alert otherwise production will suffer.

The tensiometer head has a four-inch roller connected by a leaf spring to a variable gap magnetic structure. The tensiometer rides on top of the moving paper sheet so that the roller makes a slight dimple in the sheet (Figure 12). Variations in sheet tension change the spring deflection, which alters the air gap, thus changing the output voltage of the device. This voltage is compared to a reference voltage and the difference is fed into the input of the section amplifier, over-riding the speed signal. Thus paper tension can be maintained accurately under all conditions. The instrument eliminates inconsistencies of human judgement and frees the operator for other duties. It can also be used to indicate or record tension by means of a voltmeter and so can be applied to any machine.

*Moisture Monitor*

This device must be considered still in the development stage, although work has been in progress for several years and test data are promising.

The sheet of paper is passed over a capacitor made up of a number of interlaced metal plates. This capacitor forms part of a sensitive electronic measuring bridge. The moisture content in the sheet of paper is part of the dielectric in the capacitor. Any change in moisture content, therefore, represents a change in capacitance and this upsets the measuring bridge. This deviation is indicated or recorded on an appropriate measuring device.

**Light-Sensitive Electronics**

Numerous applications of the photoelectric electronic principle can be found throughout the industry; because they are similar in function they have been grouped under this one heading for easier comprehension.

Photoelectric installations require a light source, one or more photoelectric tubes, an electronic amplifier and the indicating or actuating device. The simplest applications employ the on-off principle in which the light beam is interrupted. One such application is log-counting, where the log passing the counting stand interrupts the light beam. The change in current in the phototube is amplified and the output actuates a counter.

Another on-off application is the detection of paper breaks on the paper machine. Here the light beam is normally interrupted by the paper travelling through the machine. If a paper break occurs, light will shine on the phototube and the output of the tube can be made to sound an alarm, or the system can be arranged to break down the paper sheet at the couch section by shutting down the first press.

*Pinhole Detector*

Certain of the finer papers for precise printing or blueprinting must be relatively free of small holes or slits. A photoelectric hole detector has been perfected for the quality inspection of these papers during production. If a hole is detected the equipment can be arranged to operate a counter, actuate a reject mechanism, shut down the drive or energize a marking device.

The device consists of a wide light source installed on one side of the paper sheet and a similar width photoelectric pickup, consisting of a multiplicity of phototubes, on the other side. Considering the speed of travel of the paper sheet the equipment is remarkably sensitive. Holes as small as 1/25 inch in diameter can be detected at speeds up to 1,000 f.p.m. and as small as 1/12 inch in diameter at 2,000 f.p.m. Intermediate speeds will permit detection of holes of proportionate size.

It is interesting to note that this equipment has been in use in the

**Fig. 12. Tensiometer installed between two calender sections and mounted on screw to adjust for different pass line to second calender.**

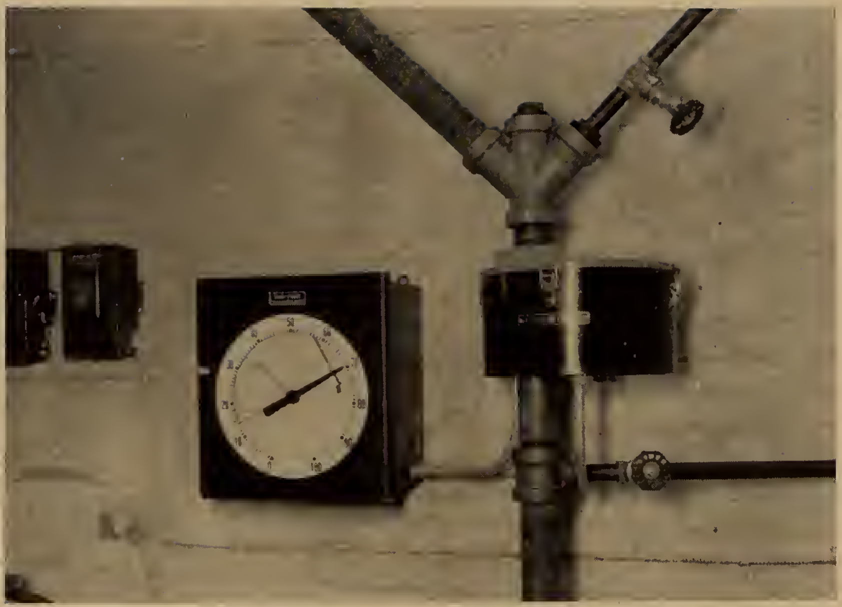

Fig. 13. Recording turbidimeter; sampling head on right, connected in pipe line.

steel industry for many years but has only recently been applied to the inspection of paper.

*Recording Turbidimeter*

While this equipment can be considered as just past the final development stage so far as its application in the pulp and paper industry is concerned, it has been used for a number of years in water and sewage plants and in the food, beverage and chemical industries.

The instrument is designed to measure and to record continuously the amount of material suspended in a liquid. Its use, therefore, is indicated in measuring pulp stock consistency, particularly just before it goes to the paper machine, and in monitoring the "white water", tailings or rejects that have drained out with the water on the paper machine. The present device can measure stock having a consistency of up to ½ per cent and a number of runs in an actual installation show good accuracy when checked with gravimetric measurements.

The liquid to be measured passes through a sampling head connected into the piping which carries the liquid (Figure 13). A glass chamber in the sampling head has a photocell on one side. A mirror and shutter arrangement pulses light through the liquid, first directly through the liquid onto the cell and then at right angles to the cell. In the latter case the light that reaches the cell is that reflected from the particles in suspension. Turbidity in equation form is a function of the ratio of the amount of scattered light to the amount of transmitted light. Thus the greater the turbidity the more the scattered light and the less the transmitted light.

The two signals thus obtained are "remembered" and compared in the recording device. The ratio is then indicated by the recording meter and is permanently marked on the chart.

This system is stable and inherently compensates for variations in sensitivity, line voltage, ambient temperature and color of the liquids.

**Conclusion**

This paper has by no means covered every present and possible application of electronics. Rather, specifically interesting applications have been selected to show the wide variety of uses. For instance, communication by radio between the mill, the woodland operations and the purchasing office have made the operation of remote mills both close-knit and economical. Instrumentation throughout the mill in the chemical, the steam and the hydraulic processes utilizes much electronic equipment. In laboratory operations there are also precise applications. The whole trend in paper making is toward a more scientific approach, with processes automatically controlled. Undoubtedly electronics will be one of the major contributors in this endeavor.

# Discussion

**J. G. Langley**[1]

The use of electronic equipment for industrial purposes has increased steadily since the last war and the pulp and paper industry is by no means unique in this regard. It is interesting to note that all the applications of electronics mentioned by Mr. Messervey, with the possible exception of the use of photo-electric cells, are postwar developments which have been introduced in the pulp and paper industry.

It has been said that the time will come when the paper making process will become a continuous process, controlled and operated by means of instrumentation. Electronics will undoubtedly perform the major role in any such form of automatic control. However, one of the few things which electronics cannot do is service itself. Some manufacturers have built duplicate apparatus which automatically monitors itself so that failure of one piece automatically cuts in the standby with no loss of operating time. Needless to say the part which failed must still be located and corrected by a service-man or maintenance electrician.

Speaking from the point of view of the user of electronic equipment in a paper mill, one of the chief requirements is that any such electronic equipment shall operate with a minimum of servicing and in the event of a breakdown, can be serviced and put back into operation in a matter of minutes.

Due to the absence of moving parts, electronic equipment generally speaking, requires very little attention. In the design of electronic equipment for industrial use, much can be done to facilitate servicing. Unitized construction and accessibility are most important in order that critical units may be speedily replaced by a spare unit in the event of failure. The use of more rugged and dependable components than are normally used in the average radio (or TV set if you like) are gradually coming on the market and being utilized by the makers of industrial electronic equipment.

One manufacturer of electronic tubes has brought out a few types

[1]Plant Engineer, Donnacona Paper Company, Donnacona, Que.

of tubes especially designed for industrial use. These tubes are more uniform and especially designed for industrial use. They have a minimum life expectancy of 10,000 hours or 16 months of operation on the basis of a 24-hour day, 6-day week. This is just an example of the sort of thing we are looking for in the pulp and paper industry where electronics are being applied to the manufacturing process.

The suppliers of electrical apparatus have, generally speaking, made remarkable improvements during the past few years with regards to providing a more reliable and serviceable type of electronic equipment to the pulp and paper industry. However, on the other hand we have the makers of instruments for stock preparation and control purposes still supplying a laboratory type of electronic instrument. Such equipment has yet to be widely accepted due to their unreliability and difficulty of servicing. The use of non-preferred tube types, closely rated components and needlessly compact construction are but a few of the troublesome features we find in electronic control instruments today.

It would appear that little or no thought has been given to the fact that such instruments in most cases will be subjected to corrosive fumes, high humidity, dirt, moisture and the day to day hard knocks of operating personnel and machinery.

Since the average paper mill of today may have only one or two service men qualified in electronics on its electrical staff, it is essential that first line servicing of electronic equipment be simple enough for the average shift electrician to deal with where production is on a 24-hour basis.

I was impressed by Mr. Messervey's figure of ½ minute lost time per section per month due to tube failure on an electronic paper machine drive. For a standard six section paper machine this would represent a total of 36 minutes per year lost time attributable to tube failures. Personally I feel that this is an optimum figure or something for the electrical servicemen to aim at. Careful pre-selection and periodic testing of tubes will certainly reduce lost time due to electronic tube failure but much depends on just when, where and how the failure occurs.

In closing I would like to compliment Mr. Messervey on his presentation of a most interesting, informative and timely paper.

**T. Foulkes, M.E.I.C.**[2]

Mr. Messervey is to be congratulated for having brought together for our edification a large number of electronic applications which have already been proved or may prove to be useful in the pulp and paper industry.

The first reaction to the use of vacuum tube devices on paper machines was one of extreme caution, but over the past few years especially with the introduction of the industrial or heavy duty tubes they have been used more extensively.

The electronic type speed regulator with its associated rotating equipment has given the paper maker greater precision in speed regulation which is essential to the good operation of the paper machine.

In the paper making process a machine twenty feet in width operating at a speed of 1400 f.p.m. is reducing a mixture of one half of one per cent fibre and 99.5 per cent of water to a sheet of the consistency of a rain soaked newspaper in 12 seconds. In transferring the sheet in this condition from one section of the machine to the following section the paper is stretched at the rate of sixty feet per minute. It must be recognized that speed variations even of a very small order create a real problem for the person responsible for the operation of the machine.

The Draw Speed Indicator which Mr. Messervey has described has proved to be a very useful tool in determining the sources of difficulties encountered at the aforementioned transfer point. It has also assisted materially in checking on changes in operation conditions caused not only by the drive equipment, but also due to variations in stock conditions, vacuums, etc.

The pinhole detector seems to offer possibilities for the inspection of high-grade papers during the winding or finishing process.

Such devices as the Tensiometer, Basis Weight Gauge, Moisture Meter and the Turbidimeter are interesting electronic applications which would appear to warrant, and are receiving study in our industry.

The Grinder Load Regulator has been applied to a continuous type of grinder and we understand it is operating successfully at a Canadian mill. Have you developed an application which can be used with the hydraulic type of grinder ?

[2]Chief Plant Engineer, E. B. Eddy Co., Hull, Que.

**W. A. Messervey**

Development work is now being carried out to adapt the Electronic Grinder Load Regulator for use with hydraulic type grinders. Basically this does not present any great technical problems.

In the hydraulic type of grinder the pulp wood is pressed on to the stone by pistons, usually under hydraulic pressure although any other means such as steam or air pressure could be used. The greater the pressure the faster the wood is ground. The pressure, therefore, is analagous to the speed of the feed chain motors in the continuous type of grinders.

Thus the problem is one of converting the signal from the electronic wattmeter into a means of varying the pressure rather than varying the voltage applied to the feed chain motors.

In keeping with our policy, however, a pioneer installation will be made to prove the theory and to obtain best possible results. √

---

# The Development

of

# The Axial Flow

Although of particular interest for the aeronautical engineer, this paper also shows the reader some of the reasons why it takes so long to get a new type of aircraft into mass production. The author also calls attention to the fact that fans designed according to the methods used in the aircraft industry would show great advantages in industry.

The multi-stage axial flow compressor is now about as old as powered flight, but it was not until the last war and the advent of the jet engine that really intensive development for aircraft propulsion began.

Although the centrifugal compressor has made a very useful contribution to the progress of the aircraft gas-turbine engine, the axial compressor forms the basis for almost all new military aircraft engines today. It has won this position because of its high mass flow per unit frontal area, its high efficiency and the possibility of acceptable characteristics up to pressure ratios of 6 or 7.

As an example of the characteristics of such a compressor, Fig. 1 shows those of the original design of compressor of the Orenda engine. At design speed more than 13,000 hp. is required to drive the compressor under standard inlet conditions. Since the rig has only 6,000 hp. available it is necessary to test with throttled inlet, and for this purpose a drilled plate is inserted in the inlet duct.

The characteristics shown were measured at an equivalent pressure altitude of about 30,000 ft. at design speed, and have not been corrected for the effect of Reynold's number. A normal engine working line is shown across the characteristic. The distance between the working line and the compressor surge line has a very important effect on the acceleration time of the engine, as is illustrated by the broken line which represents a possible acceleration.

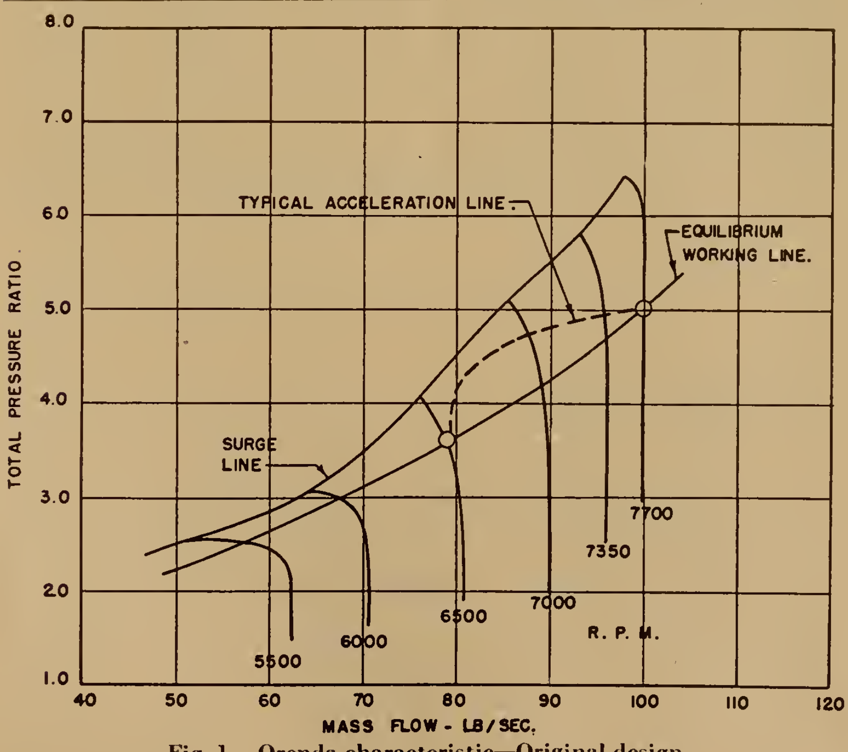

Fig. 1. Orenda characteristic—Original design.

In order to accelerate the engine, the fuel flow to the combustion chambers is increased. This forces the working point closer to the surge line. Considering acceleration, the desirable surge line should be so far from the equilibrium working line that the limit on fuel addition should be established by turbine inlet temperature before compressor surge occurs. The shapes of the characteristic and the equilibrium working line are usually such that this is true in the high speed range of operation; at lower speeds the surge line often approaches the equilibrium working line over a certain speed range, thereby imposing a limit on acceleration.

It is interesting to note here that all the centrifugal compressor engines of which the author has experience had an opposite tendency. Surge was always a high speed trouble, with the equilibrium working line sometimes meeting the surge line at high engine speed. Although the first build of an aircraft compressor may do all that

*A paper presented before the 68th Annual Meeting of The Engineering Institute of Canada at Quebec, May, 1954.*

# Compressor for The Orenda Engine

*by* F. H. Keast

*Assistant Chief Engineer, Gas Turbine Division, A. V. Roe Canada Limited, Toronto, Ont.*

the design called for, the aircraft industry can never remain static. Development aimed towards higher mass flow, pressure ratio, efficiency and improvement of surge characteristics is an essential part of the business of building better engines.

Although in no way complete, this paper attempts to indicate some of the methods of attack in the development problem. The scope of the paper has been largely restricted to aerodynamic development and such important considerations as blade vibration, a subject in itself, have of necessity been mentioned only where they affect the aerodynamic performance.

The compressor development can be divided into three groups of tests, (a) stationary blade or cascade tests (b) single stage tests and (c) full compressor tests. This paper concentrates on (b) and (c) since much has already been published on (a).

### Cascade Testing

Much has already been published on cascade testing, and the author has described the methods used by him (1). Compressor cascades of thirty different types have been tested in 173 configurations over a complete range of incidence and Mach number. Since this paper is largely concerned with stage matching, it is important from cascade tests to determine the air angles for optimum operation of the blades. Howell recommends designing compressor blading to operate at a nominal deflection defined as 0.8 of the stall deflection measured from cascade tests (2).

For this condition it is important to know the air angles associated with any given cascade for this nominal condition. He suggested a value of nominal deviation for blades of circular arc camber, i.e. the difference between the air and blade outlet angles, given by the equation.

$$\delta^* = 0.26\,\theta\sqrt{s/c}$$

In a later report, (3), this equation was modified to

$$\delta^* = m\theta\sqrt{s/c}$$

where, for C4 base aerofoils

$$m = 0.23\left(\frac{2a}{c}\right)^2 + 0.002\,a_2^*$$

Our tests to date on C7 base aerofoil sections (5) on circular arc camber lines (i.e. $2a=c$) have confirmed that this equation is valid within $\pm\,0.04\,\theta\sqrt{s/c}$. The equation for the C7 section is given in the appendix. Associated with this nominal deviation is the nominal incidence, for which our tests have indicated the value given below.

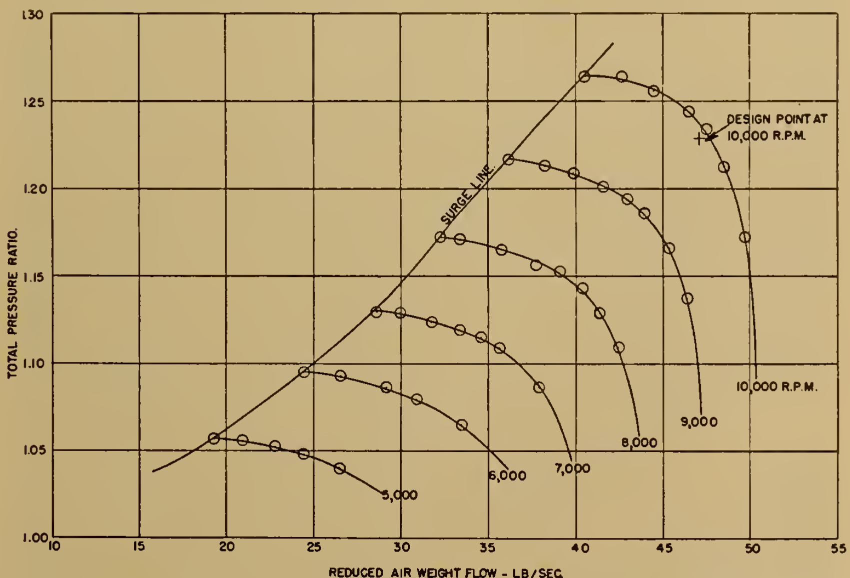

**Fig. 2. Single stage characteristic measured by instrumentation at mean blade height.**

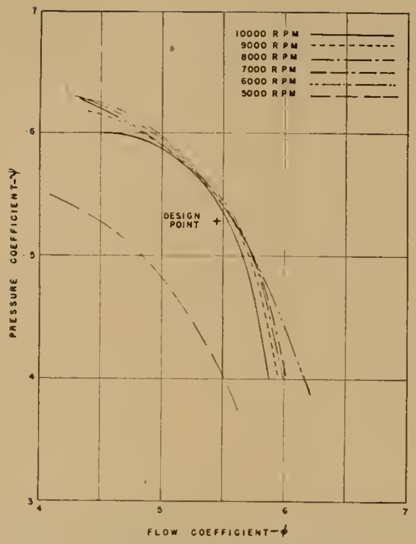

**Fig. 3.** Single stage characteristic of fig. 2 in dimensionless form.

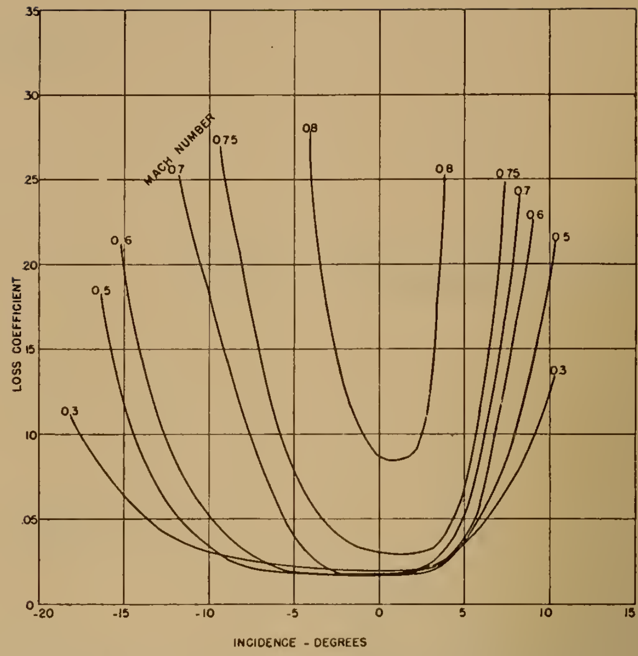

**Fig. 4.** Typical cascade performance 10C730C50.

$$i^* = \frac{11.7}{(s/c)^{0.75}} - 0.4\theta - 1.2$$

This equation has proved reasonably accurate over a range of inlet angle ($\alpha_1$) from 30° to 60° for ten percent thick aerofoils. The value is about one degree lower for five percent thickness.

### Characteristics of a Single Stage

Figure 2 shows a typical set of characteristics of a single stage, measured at mid-blade height behind the outlet stator using a manifolded pitot rake. It is interesting to plot these characteristics in the form shown in Fig. 3. The abcissa $\phi$ is the flow function defined as the ratio of axial velocity to blade speed. In the absence of secondary effects a given value of $\phi$ defines the shape of the velocity triangles and, for a given velocity triangle the work done as well as the losses should be proportional to the square of the blade speed.

The ordinate, the pressure coefficient, is a function of pressure ratio and blade speed. It is actually the ratio of isentropic temperature rise to the temperature equivalent of the mean blade speed.

$$\phi = Va/u$$

$$\psi = \eta \Delta T/\theta_u$$

where $\theta_u = \frac{u_m^2}{2gJC_p}$ (°C.)

$$\eta \Delta T = T_1 \left[R^{(\gamma/\gamma-1)} - 1\right] (°C)$$

Figure 3 shows that the five higher speeds fall closely together, but that the low speed curve is quite different. It is clear that as the speed increases from 6,000 r.p.m. to 10,000 r.p.m. the stall values of $\phi$ increases and of $\psi$ decreases. At the other end of the characteristic the value of $\phi$ is gradually reduced as the speed increases. Both of these effects are due to the increase of blade Mach number. This effect is qualitatively shown in Fig. 4, which shows the variation of loss coefficient in a two-dimensional cascade at different inlet Mach numbers.

The reduction of incidence range is clearly shown in this figure, which represents a cascade section very similar to that at the mid blade height of the rotor of the test compressor. Quantitative correlation of the cascade performance to the single stage performance is difficult because of three-dimensional effects. With the single stage the effects of high Mach number will, for this particular stage, occur first at the rotor tip.

Figure 5 shows the variation of the values of $\phi$ and $\psi$ at stall, plotted against r.p.m. The very marked drop in both functions between 6,000 and 5,000 r.p.m. is due to the effects of Reynold's number. Figure 6 plots the values of the rotor mid-blade height Reynold's number and relative Mach number at stall versus compressor speed, and also includes the estimated stall incidence. Critical Reynold's number effects appear to occur at a value of about 220,000.

Figure 7 shows the characteristics of the same stage, estimated from measurements of wall static pressure at inlet and outlet, and the measured total temperature at inlet and outlet. It will be seen that, although as one might expect, the actual values of the ratios are different, the general shape is very similar. Thus it might be expected that in a multi-stage machine, where it is difficult to make mid-blade height measurements, useful information on matching might be obtained from the provision of wall statics.

As pointed out later, this can be misleading if strong three-dimensional effects are present but, on the whole, considerable success has been achieved in studying matching by this method and benefits have been realized, particularly in the control of the surge line. Methods of deriving the characteristic curves

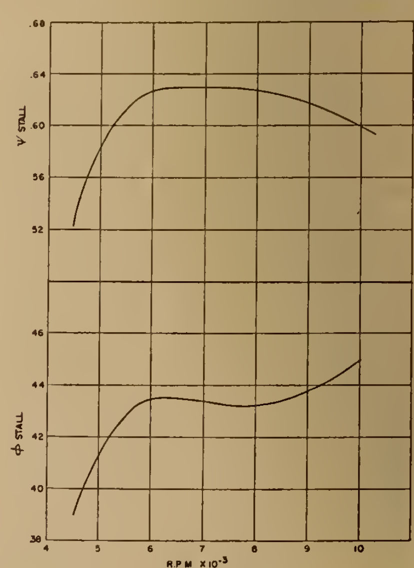

**Fig. 5.** Pressure and flow coefficients at stall.

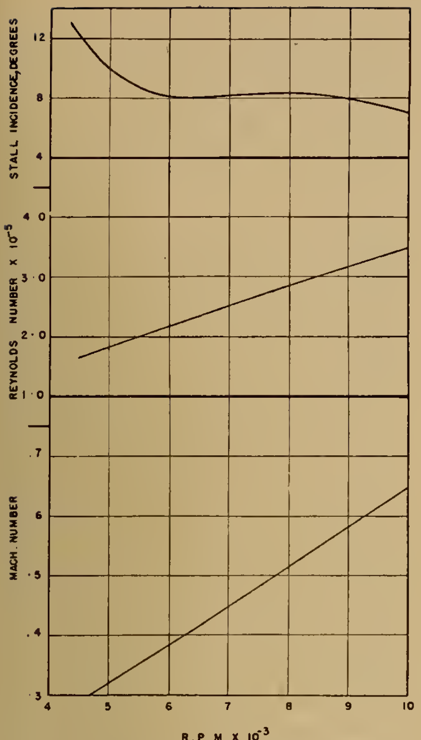

Fig. 6. **Incidence, Reynold's No. and Mach. No. at stall.**

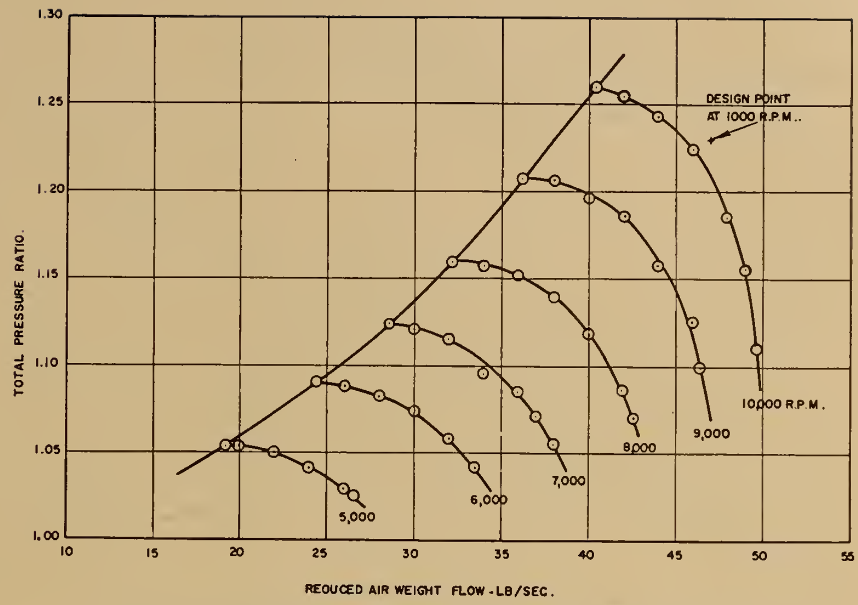

Fig. 7. **Characteristics estimated from wall static pressure.**

from wall statics can be used varying in complexity.

For instance, attempts can be made to allow for the radial static pressure variation in order to estimate the mid-blade height value. In practice it is found that, as long as the pressures are measured at equivalent points, e.g. at outlet from the stator preceding and the stator following, it is reasonably accurate to assume that the ratio of wall static pressures is equal to the ratio of mid-blade height static pressures.

In order to estimate the flow coefficient $\phi = Va/u$, it is found reasonably accurate to assume the design stator outlet air angle and use the mass flow measured at inlet to the compressor, wall static pressures and a total temperature estimated by taking a fixed ratio of the measured overall temperature rise to the inlet of the stage in question. If there are no indications to the contrary this is normally assumed to be the design ratio.

The effect of error in the temperature assumption is not too great but, in order to check this, tests on a full compressor were made with stagnation type thermocouples buried in the leading edge of a few stator blades in each row, as shown in Fig. 8. For the long blades at the front of the compressor some blades had three thermocouples as shown; others had two, placed at stations between those shown, so that temperature was measured at five radii. The shorter blades at the rear had only three measuring points.

Some of the results are shown in Fig. 9. These were found to confirm that, for practical purposes, the assumption of a fixed ratio gave results which were accurate enough for stage matching analysis.

Figure 10 is an illustration of the value of casing static pressure measurements for the analysis of matching. This is the first stage characteristic converted to non-dimensional form, points denoted by any given symbol being measured by holding the compressor speed constant and varying the outlet throttle setting.

This figure illustrates the way in which the working range on the first stage narrows as the speed increases, until at the high speed the working range degenerates into a single point except for a small range close to the overall compressor surge. This indicates that some stage further back, or possibly

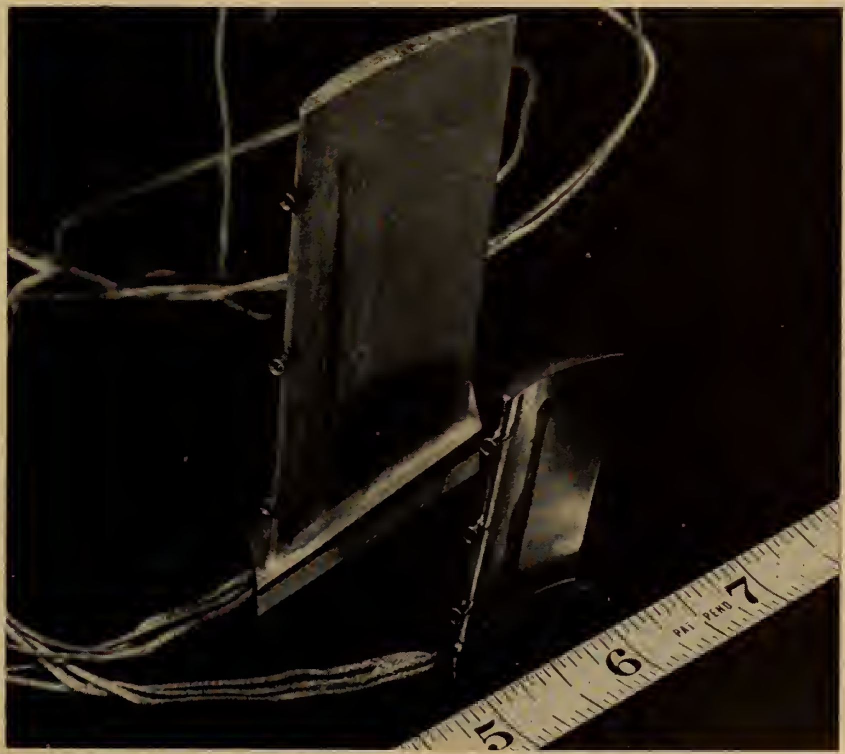

Fig. 8. **Temperature instrumented stators.**

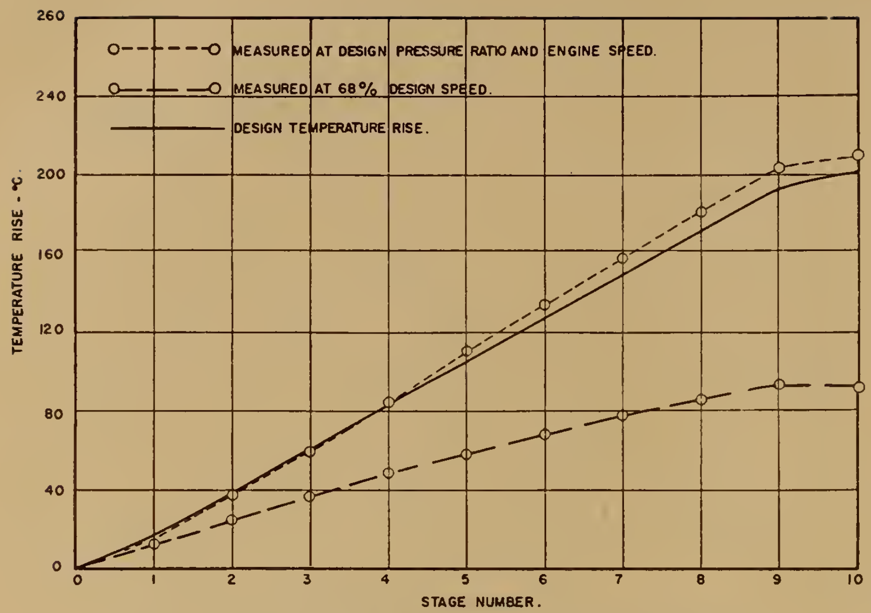

**Fig. 9. Orenda interstage temperatures—Original design.**

the outlet diffuser, has choked, so that adjustment of the outlet throttle cannot possibly affect the first stage except at high pressure ratios close to surge.

#### Finding Stage that Fixes Mass Flow

This is a very useful indication of which stage is responsible for fixing the high speed mass flow of the compressor. If we plot the characteristics of each stage, all of those ahead of the offending stage will have single working points. As soon as the choking stage is reached the working points will again expand to cover a range of the stage characteristic.

If the choking stage is early enough in the compressor, it is sometimes possible to increase the flow by opening up the critical area. It is usually possible, by examining the design of the blading, to deduce whether the rotor or the stator is applying the control. If wall statics are available at stator inlet as well as outlet, these can help in the evaluation. Area increase may be effected by reducing the number of blades, decreasing the blade camber, (by a change of curvature over the front sections of the blade) or by reducing the stagger angle of the blade.

The first and last of these methods are simpler to perform, as they merely entail different broaching of the disc and possibly a minor reworking of the blade platform. This means that they are easily introduced into production engines. These measures are not without their dangers, as they may substitute for the choke some other undesirable factor, such as stall. In certain cases the desired improvement is achieved at high speed, but an unacceptable kink may be introduced in the surge line at lower speeds.

Another approach to the problem is to leave the restricting area unchanged, and attempt to increase the pressure ratio of the stages ahead of it so that the increased pressure at the restriction allows a greater mass flow. In all such attempts to increase mass flow and pressure ratio a careful check must of course be made to ensure that all blades have enough strength margin to take the increased loading.

As an example, let us consider reduction of stagger of the first stage rotor. This will in general displace its characteristic towards high flow coefficients, and may or may not increase the peak pressure coefficient depending on the changed stalling incidence. The rest of the compressor in practice operates with the same non-dimensional characteristic, based on values at inlet to the second stage.

It has been seen that at high speed in the normal operating range there is only one working point on the first stage. Reducing stagger of the first stage gives a small increase in temperature to the second stage, reduces the value of non-dimensional speed of this stage and therefore reduces its non-dimensional mass flow.

The increase in temperature also results in a slight further decrease of the value of $W/P$ but the increase in $P$ overrides these reductions, so that a net increase in mass flow results roughly proportional

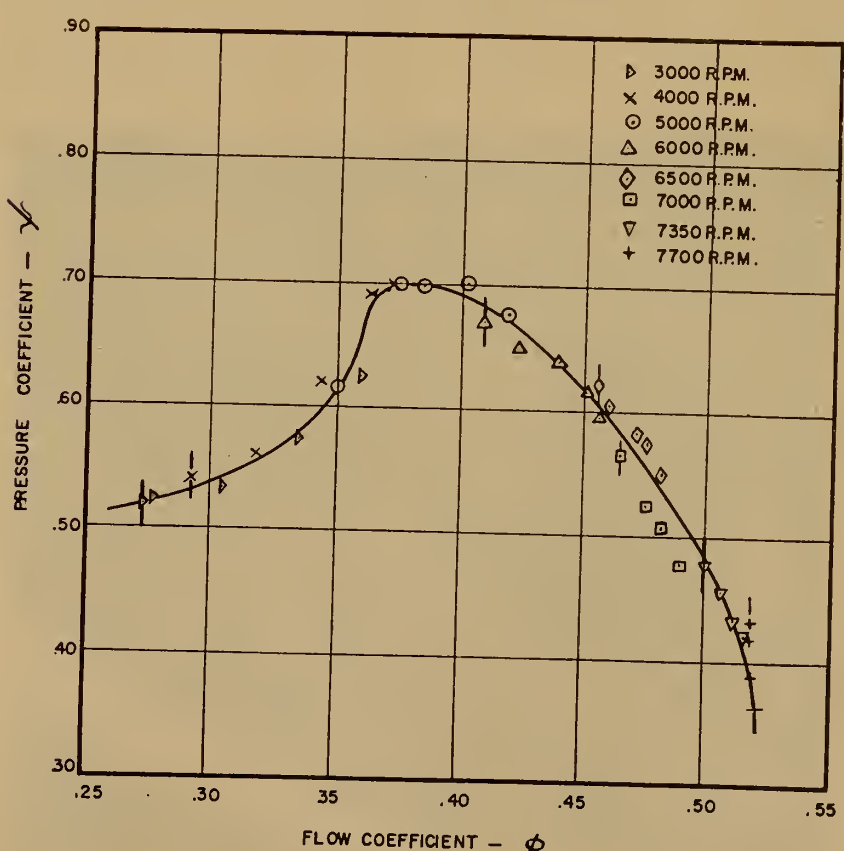

**Fig. 10. Orenda first stage characteristic from wall static pressures.**

to about the 2/3 power of the increase of pressure at the second stage inlet, so that a curve of $\frac{W}{P^{2/3}}$ drawn from the operating point on the old characteristic cuts the new characteristic near the new operating point.

The two-thirds power rule assumes that the changes are small, the polytropic efficiency of the first stage remains unchanged at a value of 6/7, and that the non-dimensional mass flow for the rest of the compressor is proportional to its non-dimensional speed, i.e.

$$Q_2 \propto N/\sqrt{T_2}$$

All of these assumptions are accurate enough to be useful as a rough check on the effects of possible changes. Figure 10 shows that the first stage is never stalled even at surge at high speed. At 5,000 r.p.m. stall is first encountered near surge and at lower speeds (below 4,000 r.p.m.) the stage is fully stalled over the complete range measured.

It is interesting to observe that the Orenda compressor in its original form exhibited a rasping or buzzing noise at low speeds, which changed abruptly to a high pitched scream above about 5,400 r.p.m. This coincided with the unstalling point for the first stage blades. At exactly the same speed the first stator vibration amplitude, as measured by strain gauges, dropped sharply to about one third of the value it had below the "change speed".

### Discussion of Single Stage Characteristic

If we take a characteristic measured by the wall static method as in Fig. 10, it is of interest to plot this on a base of non-dimensional mass flow at outlet, as in Figs. 11 and 12. If the stage is now removed from the multi-stage compressor, from which the complete characteristic has been derived, we may see how it might be expected to operate if tested on a single stage test rig with a simple outlet throttle.

The non-dimensional outlet flow from the stage is the same as the non-dimensional inlet flow to the throttle. Thus, if the rig discharges back to ambient pressure we may draw the throttle characteristic on the same diagram, one line for each throttle setting. Two stage characteristics are shown, a low speed and high speed one. Both demonstrate that, if the compressor is maintained at constant speed and the throttle closed, a value is reached where there is a sudden drop in mass flow and pressure ratio, the

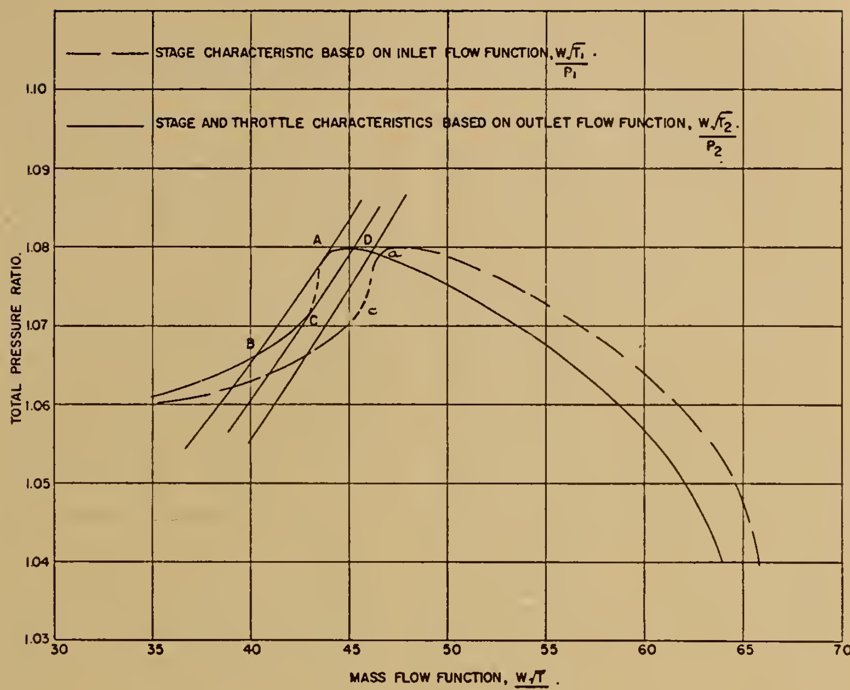

Fig. 11. Derived characteristics at low speed.

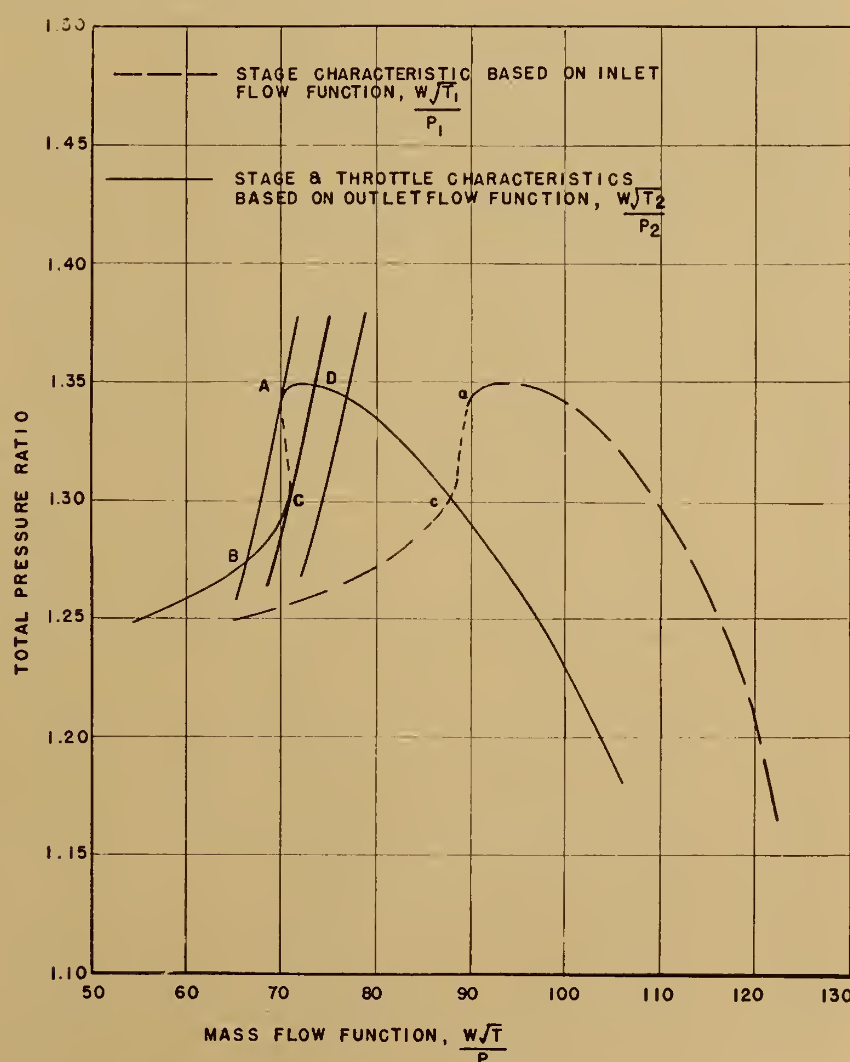

Fig. 12. Derived characteristics at high speed.

corresponding points being labelled A and B. This indicates stalling of the stage.

On opening the throttle again, the stage will remain stalled until point C is reached, when a sudden jump to the unstalled state at point D occurs. Thus there is a marked hysteresis in the stalling and unstalling. The dotted part of the characteristic cannot be measured on such a test rig. It is interesting to note, however, that if the outlet throttle discharged constantly into a receiver maintained at a sufficiently low pressure to ensure choking of the throttle, the throttle characteristics for each value of throttle area would be vertical. Under these conditions the whole characteristic at low speed could be measured whereas at high speed a sudden stall would still be encountered with a drop in pressure ratio.

Tests show on a low speed compressor that this transition characteristic between unstalled and fully stalled operation can be a region where local stalling of some of the blades can occur over part of the blade height (8). This gives rise to the so-called rotating stall where a usually symmetrical pattern of perhaps two, three or four stalled areas rotates with the rotor blades, but at a smaller rate than the blades. This can give rise to severe vibrations and possibly blade failure.

Huppert and Benser (8) distinguish between a progressive stall, which they have found to be a stall occurring in discrete areas progressing inward from the tip, and a so-called "root-to-tip" stall which might, with less ambiguity, be called a full span stall. The progressive stall is more likely to occur with low hub-tip ratio, i.e. at the front, where blade section characteristics can vary widely from root to tip. The full-span stall is likely to be found at the rear where hub-tip ratios are high and section characteristics are very similar over the full blade height.

The authors indicate that the latter type of stall may exhibit a hysteresis of a different character from that mentioned earlier. They give examples that indicate a stall which, on opening the throttle, persists beyond the point designated C in Fig. 11, so that even the characteristic based on inlet conditions can give a pressure ratio which is a two-valued function of mass flow.

As with the fully choked throttle, it is possible in a multi-stage compressor for a stage to operate in the partially stalled condition. This occurs at lower speeds, where the stage characteristic plotted on outlet flow has not yet exhibited a vertical transition curve. Referring to Fig. 12, it is evident that no matter what the characteristic of the back of the compressor, the stage illustrated will exhibit a sharp stall at high speed.

For the low speed characteristic, however, if the matching is such that the steep positive slope of the first stage during the partial stall combines with a high negative slope of the following stages, the overall characteristic can exhibit a quite favorable slope. The combination of characteristics of individual stages does not always give a complete description of a multistage compressor performance.

If the stage characteristics derived by the method described are compounded analytically, an extension of the characteristic well beyond the practical surge point can be estimated. The stalling of one stage often gives what would appear to be completely insignificant local kink in the characteristic.

### Stage Stall Can Cause Surge

The drop in mass flow and overall pressure ratio and efficiency may appear incapable of causing more than a minor embarrassment to the engine, yet a violent surge may be initiated with severe drop in flow and disastrous rise in jet pipe temperature. It seems, then, that the apparently insignificant nature of a stage stall can nevertheless act as a trigger for the surge, although in a different area of operation the same stage may stall with no trouble.

Two possible explanations can be considered. Firstly, a stage stall may, under certain conditions, so change the flow at inlet to following stages that their characteristics are materially changed, and combine to cause a complete disruption of flow. When two or more stages stall simultaneously, surge can usually be expected. Secondly, the cause may be a dynamic instability, depending on whether pulsations in flow caused by a stage entering stall experience positive or negative damping from the rest of the compressor.

Various analyses have been made on the latter possibility (7) (8). Some have indicated that the dimensions of the inlet and outlet ducting to the compressor can have an appreciable effect on the phenomena. This, however, can offer little hope towards solution of troublesome surge conditions, since the outlet volume, i.e. the combustion and exhaust system, is fixed for reasons beyond the control of the compressor designer.

Moreover, the inlet is either a ram type with an effective volume of infinity, or is a duct which is inevitably one of the most unchangeable and inflexible parts of the aircraft. Space in an aircraft is always at a premium, and the engine inlet ducts are so determined by the requirements of external aerodynamics, aircraft structure, fuel tanks, wheel bays, cockpit and all the equipment that must be packed in somewhere, that any changes to the shape or size of the ducts leads to a major redesign of the aircraft.

We must therefore concentrate on the compressor itself for the answer. The approaches available are:

1. Soften the stall by redesign of blading,
2. Change the blade angles of the stalling stage to move the stall in relation to the other stages, so that it occurs at a lower mass flow,
3. Change some other blade row in the compressor to steepen the stable slope of the rest of the compressor at the stall of the offending stage.

Method (3) was used on the Orenda when surge due to first stage stall was greatly improved by redesign of the last stage, some tests of which will be described later.

### Description of Orenda Compressor

The original design of the Orenda compressor was completed in 1946. It was a ten stage half vortex design, to give a mass flow of 100 lb./sec. at a pressure ratio of 5:1 at 7,350 r.p.m., to give 5,500 lb. thrust with the possibility of developing the engine by overspeeding to 7,800 r.p.m. up to a rating of 6,500 lb. thrust.

The choice of half vortex whirl distribution was made with the following thoughts in mind. Free vortex theoretically satisfies radial equilibrium with a constant axial velocity from root to tip. It has the disadvantage of leading to high Mach numbers at rotor and stator tips. (Here the stator tip refers to the section at the inside diameter.) Constant reaction blading gives lower Mach numbers at these stations but, if constant axial velocity is used, departs from radial equilibrium. Also the Mach number distribution is such that all sections of the blade tend to reach critical almost simultaneously.

Considering overspeed combined with the high effective speeds encountered at altitude, it was feared that a rapid fall in efficiency might result under these conditions. Half vortex whirl distribution is the average of that of free vortex and constant reaction, and so avoids the extremes of each. Use of constant $V_a$ made possible the use of various factors empirically determined to allow for 3 dimensional effects, e.g. work-done factor. Use of radial equilibrium design would at that time have been a departure which would possibly invalidate past experience available.

In addition to these thoughts it is rather amusing to reflect, almost eight years after the event, that, with the limited computing facilities available at that time, the incorporation of radial equilibrium would have added a couple of weeks to the time required to design the blading. This would have caused the drawing release of blade co-ordinates to have fallen behind schedule.

The second to ninth stages were made aerodynamically identical, in that they were designed so that at any given radius the design air angles were identical, so each would give the same stage temperature rise, as long as velocity profile deterioration was not too serious. This had the mechanical advantage of reducing the number of blade masters required, but, more important, was chosen to give the greatest possibility of achieving proper stage matching.

Bad matching is the most powerful means of reducing efficiency. By having eight out of ten stages identical gives the best chance of matching, since if mass flow is under- or over-estimated for one stage, this will apply to all as long as the stage pressure ratios are achieved, so that they will still be matched at the new flow.

The last stage design was different from the rest, in that the work was substantially reduced to limit the absolute exit angle from the stage to a value that was felt could be handled by a single stator row with axial exit into the diffuser. The last stage also was used to give a moderate amount of diffusion from 480 fps to 450 fps before entering the exit diffuser.

As is usual on such a project, the engine parts received priority over test rigs, so the engine was on the bed and considerable running had been accomplished before a test compressor was available. From engine running it was determined that the compressor more than met its design performance, but left something to be desired in acceleration characteristics, acceleration time from idling being of the order of 15 to 18 seconds.

Blow off valves had been incorporated in the original design at the eighth stage as a possible aid to acceleration. It was found that, when they were opened, the jet pipe temperature increased considerably. Although they might possibly have helped the surge line, the acceleration was then limited by the amount of overfuelling which could be used without exceeding the jet pipe temperature limit which, was arbitrarily fixed at a value which, in review, would now be regarded as very safe indeed. Following the first runs therefore, these valves were locked and later omitted completely. The collector manifold which had fed them became useful as a source of air, for aircraft uses such as cabin pressurisation.

### Stage Matching

In order to study the stage matching, casing static pressure orifices were installed wherever possible. Some stations had to be omitted, as the casing was provided with air take-off passages at the second and fifth stage outlets, and also the blow-off valves at the eighth stage.

It is impossible to completely define the compressor characteristic from engine test. Changing the final propelling nozzle of the engine only moves the compressor working line slightly before jet pipe temperature limits are reached, so that only a thin band on either side of normal working line is possible. From the limited information available it was evident that the first stage was improperly matched to the rest of the compressor, since at high r.p.m. the first stage pressure rise was much lower than design.

With the limited information available from these tests, it was decided to be necessary to move the first stage characteristic towards higher mass flow to bring it into match and, in an attempt to do this, disc slots which held the first stage rotor blades were rebroached to reduce stagger, i.e. to turn the blade chord closer to the axial direction.

On engine test, the engine performance was worse and high jet pipe temperatures were encountered. No accelerations were attempted during these tests, which were terminated when the first stage rotor blades broke off close to the root and removed the rest of the blading. This, then, was not the answer.

The next step was to rebuild an engine with the original disc broaching, and to introduce probes between the first stage stator blades to find what the first rotor blades were doing. This had not been done earlier because of the danger of introducing a heavy wake from the probe, with the attendant risk of exciting excessive vibration into the rotor blades behind it, or of an upstream pressure field doing the same thing to the rotor blades ahead of the probe.

Fortunately it was decided to use a temperature probe as well as a pressure probe, as the results of the pressure probe alone would have been very misleading. They showed a remarkably constant total head pressure behind the rotor. The temperature probe, however, explained the trouble by showing that the temperature rise at the tip was very high, falling rapidly to a value slightly below design at the mid-blade height, and indicated heavy stalling over the outer 20 percent of the blade.

### Redesign Necessary

It was therefore evident that the centrifugal pressure gradients could not be ignored, and that there existed a radial flow through the inlet guide vanes, such that the axial flow velocity was considerably reduced at the outer sections and increased near the hub. This caused high positive incidence at the tip and reduced the incidence, and therefore the temperature rise, at the inner sections. On the strength of this the first stage was redesigned, retaining the original whirl velocity distribution, but calculating an axial velocity profile to satisfy the simplified radial equilibrium equation.

$$\frac{144}{\rho}\frac{dp}{dr} - \frac{Vw^2}{rg} = 0$$

Redesign of the second stage was necessary to blend the new design into the remainder of the compressor. The effect of the new blades was to take out the kink in the surge line, so that engine accelerations of 12 seconds could be guaranteed. In flight tests at altitude the effect of the new blading was even more marked. Acceleration time at 20,000 ft. was of the order of 40 seconds, if surge was to be avoided. With the new blades acceleration times of less than 12 seconds were measured at 30,000 ft.

There was a slight drop in mass flow at high speed with these new blades of the order of one to two per cent. This was restored by reducing the inlet guide vane stagger by five degrees. Blading manufacture at the time was a very critical supply problem and, unfortunately, after over 2,000 total hours of engine running, the seventh stage rotor blades began to exhibit a vibration problem.

This and the subsequent vibration troubles pushed acceleration into the position of a second priority problem. This was especially so since the manufacture of new blades to cure the vibration problem conflicted strongly with the supply of the revised front stages. At the same time, there was a strong desire not to change the blades that were free from vibration troubles.

The accumulated running time on the new front stages was not judged adequate to justify release for initial production so that the first production engines were delivered with the original compressor design only modified by the various schemes introduced to cure the vibration problem on the later stages. These included thicker rotor blades on the seventh, eighth and ninth stages to raise the natural frequency of the blades and an increase in the number of blades per row in the sixth, seventh, eighth and ninth stator rows, to raise the exciting frequencies out of the engine speed range.

The result of these changes made little difference to the compressor mass flow, but reduced the compressor efficiency by 2 to 3 per cent at take-off rating, which was accompanied by a drop in pressure ratio (Fig. 1). The new front stages were found to be the limiting ones for mass flow at high speeds, so a compressor test rig program was begun to increase mass flow, by reducing stagger on both the inlet guide vanes and on the first rotor blades.

It was demonstrated that the mass flow and pressure ratio could be substantially increased by this means, but that a deterioration in the low-speed surge line accompanied the change. This was diagnosed from wall static pressures as first stage stall. Analysis of the rear stages indicated that there was a possibility of increasing the work on the last stage, at the same time steepening the stable slope of rear stages.

A new tenth stage was therefore designed, and when tested proved that all the benefits of increased mass flow and pressure ratio could be achieved with a surge line that was even better than that with the radial equilibrium stage at its design stagger. The resultant characteristics with the engine equilibrium working line is shown in Fig. 13. It can be seen that mass flow and pressure ratio have been increased appreciably, and that the relative positions of the surge and working lines are greatly improved from those shown in Fig. 1.

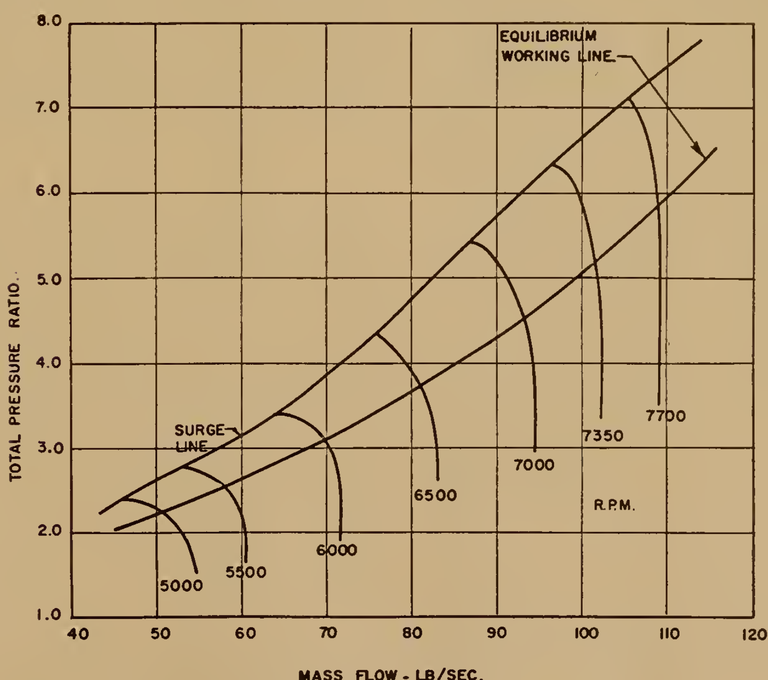

Fig. 13. Improved Orenda characteristics.

### Conclusions

In conclusion attention should be drawn to the implications which this work of the aircraft industry can have upon other industry. A recent article describes a mine ventilation scheme which pumped 300,000 cubic feet per minute, employing a fan with variable-pitch rotor weighing 20 tons. Presumably this must have included the driving motor and all of the external structure, which stood 42 ft. high.

The drawing of the installation was an artist's impression and only an outside view, but scaling what appeared to be the fan section gave a diameter of about eighteen feet. The Orenda first stage passes 90,000 cu. ft. per minute, so that an increase in diameter to about 58 in. would handle this air requirement, and result in a compact high-efficiency unit.

One factor which has probably hampered the design of ventilating equipment is that of noise level. It cannot be denied that with blades operating at tip speeds of the order of 1,000 fps the decibel level is almost painful. It seems however that improved technique in silencing has been neglected. A few feet of accoustic material arranged in the inlet and outlet ducts would cure this problem, as the sound is of very high frequency and readily absorbed.

The fan efficiency for the relatively low pressure-ratio required would be of the order of 90 per cent. The use of variable pitch inlet guide vanes can give a substantial working range, without the complication of variable pitch rotors. It is felt that the great disparity in size which this example shows cannot be justified on the grounds of economy, reliability or durability.

### Appendix

Coordinates of the base aerofoil C7 section are given in Ref. (5). Equations of a type which are useful for fitting aerofoil sections are described in Ref. (6). Using these basic equations the constants were determined to fit the C7 section as closely as possible. The resulting equations are as follows:

For $o < x \leqslant 0.4$

$$y = \sqrt{x}\,(0.13368 - 0.25545x + 0.50014x^2 - 0.50726x^3)$$

For $0.4 \leqslant x < 1$

$$y = 0.018842 + 0.16707x - 0.2511x^2 + 0.070459x^3$$

At $x=1$ this gives a finite thickness which is in practice replaced by the trailing edge radius.

**Symbols**

$a$ Position of maximum camber from leading edge. (inches)
$c$ Chord (inches)
$c_p$ Specific heat at constant pressure.
$g$ Acceleration of gravity (ft./sec.$^2$).
$i$ Incidence = $\alpha_1 - \beta_1 (°)$
$J$ Mechanical equivalent of heat (ft.lb./C.H.U.)
$m$ Deviation coefficient.
$N$ Rotational speed (r.p.m.)
$p$ Static pressure (psi).
$P$ Total pressure (psi).
$Q$ Mass flow function $= \frac{W\sqrt{T}}{P}$
$r$ Radius (ft.)
$R$ Pressure ratio.
$s$ Blade Pitch (inches).
$T$ Total temperature (°K).
$\Delta T$ Temperature rise (°C).
$u$ Blade speed (fps).
$V$ Air Velocity (fps).
$W$ Mass flow (lb.sec.).
$\alpha$ = Air angle from axial direction (°).
$\beta$ = Blade angle from axial direction (°).
$\gamma$ = Ratio of specific heats.
$\delta$ = Deviation $= \alpha_2 - \beta_2$ (°).
$\eta$ = Adiabatic efficiency.
$\theta$ = Blade camber $= \beta_1 - \beta_2$ (°).
$\theta_u = u^2/2gJc_p$ (°C).
$\rho$ = Air density (lb./ft.$^3$).
$\phi$ = Flow coefficient $= Va/u_m$
$\psi$ = Pressure coefficient $= \frac{\eta \Delta T}{\theta_u}$

***Subscripts***

$m$ = mean.
$1$ = inlet.
$2$ = outlet.
$a$ = axial.
$w$ = whirl.

# "Here is How to Reduce Costs"

**Reprinted from "Business Newsletter" of George H. Elliott & Company, December 8, 1953.**

About a year ago, a small company in New York (sales of approximately $1,000,000) figured that business wasn't always going to be so easy to get . . . that things might get a little rough in '53. So they decided to try reducing costs through a wage incentive plan based on time study. Like many other companies, they weren't certain that this might be the way to achieve their objective. Their union was "officially" opposed to such plans, too. But they decided to experiment anyway. They called in outside help. Here's what happened:

After a work simplification program, foreman training in how to make methods improvements —standards were set and the wage incentive plan went into effect. *Production increased by 50%. Labor's take-home pay increased by 20%.* Management said, "Let's reduce our selling prices, really get competitive!" They did . . . and something else happened. *Sales increased 50%. (Incidentally, we are using round figures to disguise the company itself . . . but the figures are correct within one to three percent.)*

The most important point of all. Because of the wage incentive plan—and its total effect—*profits increased 380%!*

The "before and after" balance sheets of the company, again using only round figures, are shown at the bottom of this page.

*This is no isolated case.* In our files we have such records from a significant number of companies in a wide variety of industries. Of course . . . sometimes incentive programs backfire, won't work out as planned . . . but the ONLY reasons for this are: (1) the wrong initial approach by either management or the consultant, (2) improper administration of the plan once it has been installed . . . and to be brutal about it, (3) foolish mistakes, and (4) prejudices.

This is putting it pretty strongly . . . but it is fact nonetheless. And don't blame wage incentive plan failures on labor unions! If the plan is fair and sound, and the unions are allowed to participate in the planning, they will almost invariably go along, even though "officially" the national headquarters of many unions frown on the principles of incentives. And, frankly, you can't blame them. They have been used all too often for "speed-up" purposes by unwise managements. And if this is the objective of management, then wage incentives are wrong. But the objective is to *increase production, reduce costs, increase labor take-home pay* —AND *increase profits* so that *selling prices can be reduced* . . . then there can be no failure . . . anywhere . . . if the people who set up the program know their business. And there are a goodly number of consulting firms who do.

*Final word.* To deny the great benefits of wage incentives is to deny Frederick W. Taylor, the first man to try to put "science" into management, to make it the *profession* that it is . . . just as surely as are the professions of law and medicine. And it is to deny Frank Gilbreth, and so many other pioneers in management research, whose work has made the middle of 20th Century U.S., the mass-production miracle . . . the undisputed leader of Western civilization.

Somebody should say some of these things more often. We've said it. We will stand on it. And we will say it again and again. Our advice: *if you don't have a wage incentive payment plan in effect, then get one (or stop complaining about narrowing profit margins.) And if you have one, then check it immediately for looseness.* You will find it is one *sure* way to reduce costs. There are others, but here you can't miss!

| | SALES (Before Incentives) $1,000,000 | SALES (After Incentives) $1,500,000 | DIFFERENCE 50% |
|---|---|---|---|
| Labor | $260,000 | $312,000 | +20% |

# Safe Conduct for Salmon

by

H. L. Mahaffy, M.E.I.C.

*General Superintendent of Construction, Power Corporation of Canada Limited Montreal, Que.*

One of the most successful examples of fishway construction to date in Canada is the one recently completed at the Tobique Narrows hydro electric development for the New Brunswick Electric Power Commission. During its first operating season in 1953, it has passed just short of 4,700 salmon during their migration upstream.

The Tobique River, though small compared with many other salmon rivers entering the Atlantic, has long been a favourite stream for anglers. It passes through unsettled woodlands, contains many rapids, falls and pools, yet is readily accessible by excellent logging roads. A number of fishing clubs maintain lodges on its upper reaches and tributaries.

### Many Interested in Salmon Preservation

Many groups of Canadians are interested in the preservation of salmon. On the Pacific Coast, salmon canning is a major industry of British Columbia, and both the canneries and their employees are directly affected by any event or action which improves or lessens the yearly migration of salmon up the rivers to the spawning grounds in fresh water on their upper reaches.

On the Atlantic Coast, salmon fishing is a sport as well as an industry, but none the less a matter of wide interest. The Maritime Provinces derive handsome revenue from fishing licences and from leases to fishing clubs, many of them supported by wealthy American sportsmen. Many Maritimers find employment as guides.

On both coasts, power companies or commissions, and logging and pulp and paper interests are also much concerned with the problem of fish preservation, because the Federal Department of Fisheries is charged with assuring that for any structure built on a Canadian river, or changes in the natural flow of the river, adequate provision is made for unimpeded passage of fish both up and down stream.

### Life History of the Salmon

Salmon are found in both the North Atlantic and North Pacific, and differ from one another in these areas in at least one important respect. Although both fish migrate to their birthplace in fresh water to spawn, the Pacific salmon die after the breeding season and "never return to the sea". (Encyc. Brit.). The Atlantic salmon returns to the sea after spawning and may return to spawn again. They grow to 4 or 5 feet in length.

Beginning with their birth the life cycle of the salmon is briefly as follows:— The young fish are hatched in the spring and remain in the river two or three years, growing to "Fry" then to "Parr", then to "Smolt". These Smolt, averaging about 8 inches long, generally descend to the sea the third year in the late summer. If they remain in the sea for only one year and then return to spawn at a weight of 3 to 7 or 8 pounds, they are known as "Grilse". If they remain at sea for a year or more they return as full grown salmon weighing up to 40 pounds.

Spawning takes place during October. The female salmon scoops out a hollow in the riverbed on which her eggs are laid. After fertilization the eggs are covered by the male, and hatch out the following spring. The parents return to the sea in the fall or spring as "Slinks" or "Black salmon" after spawning. Opinion is that few salmon return a second time, though this belief has not been completely accepted by anglers. On this basis, if the Smolt get down to the sea safely without injury, little concern need be felt for the larger downbound fish or "Slinks", since these will not likely spawn again.

### Fishways on the Pacific Coast

The past history of fishways is somewhat disappointing. Perhaps many of these were built merely to fulfill the legal requirements. It has been only in this century that better results have been obtained. During this era fish facilities have increased in size and consequently in cost, with most recent designs indicating good efficiency.

The largest fishways system in operation in the Pacific Coast region is at Bonneville Dam on the Columbia River, at which fish ladders and fish locks were installed. The fish ladders are working satisfactorily and the locks on an experimental basis. Collection systems, downstream migrant passes and auxiliary water supplies have been considered as a part of the dam.

This system based upon 1930 prices cost seven and one-half million dollars. At McNary Dam on the Columbia River the same basic facilities, with modifications based upon Bonneville operations, will cost some seventeen and one-half million dollars. This means that the fishways represent an estimated 8 to 12 per cent of the total cost of the projects, with of course an annual cost for operations. The use of

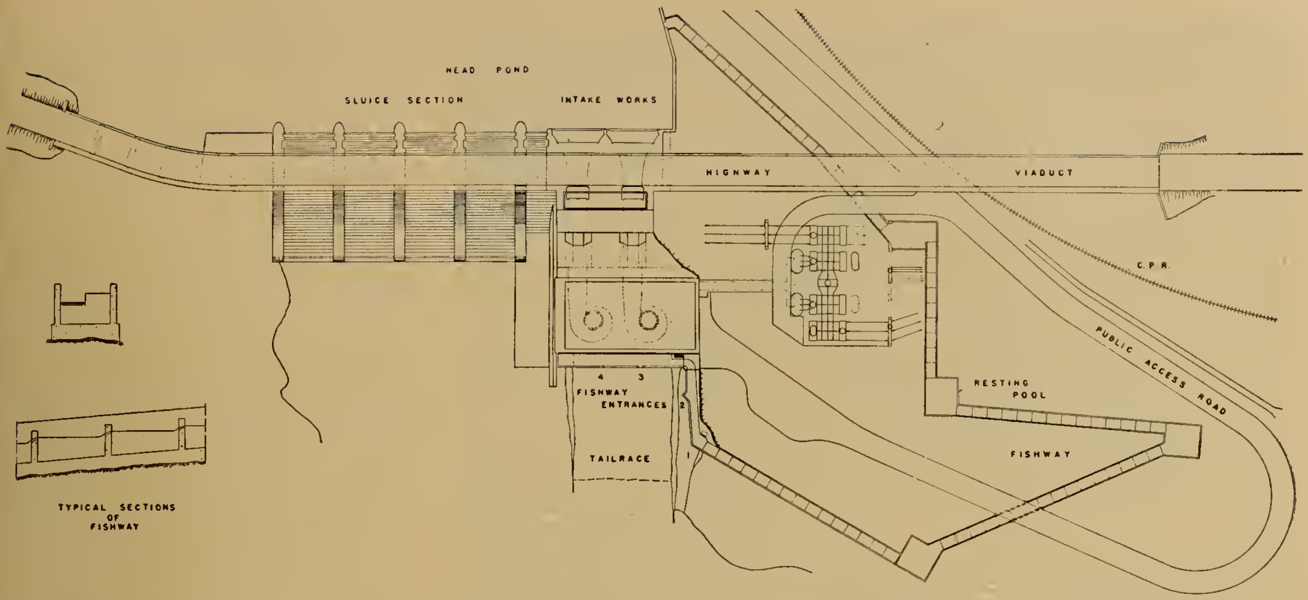

**Fig. 1. Outline plan of Tobique Narrows power development showing general layout of fishway.**

temporary facilities during construction has cost hundreds of thousands of dollars because it is equally essential to maintain fish runs during the construction period, which incidentally presents many difficult problems.

A further complication in fisheries stream management has arisen in the Pacific Coast regions where there is a growing tendency to use water instead of steam for standby or peaking power. It can readily be appreciated what it means to the stability of stream flow and fisheries, when such plants are sharply cut off during periods of minimum power loads. This is mentioned to indicate that operational changes can upset existing stream balances, and interfere with salmon runs.

### Atlantic Coast Fishways

A considerable number of fishways or fish ladders have been built at power sites in Canada's Maritime Provinces and in Quebec. In most cases they have been small, inexpensive and of cheap temporary construction. Some were built on the Mersey River by the Nova Scotia Power Commission. Though records are lacking on the number of fish migrating upstream in the Mersey, if the smolts were coming down presumably the adult fish were also passing upstream for spawning.

### Requirements for Fishways

In designing a power development on a river used by salmon and other fish that spawn in fresh water, efficient fishways must be provided to permit migration up and downstream. The essentials for a fishway are:—

(a) The entrances, especially downstream, must be attractive and easily located by the fish.

(b) The flow through the fishway must be such that passage upstream does not overtax any but the weakest fish.

(c) Fish should be able to swim through without risk of injury, and unhampered in their swimming movements.

(d) There should be sufficient resting pools.

(e) There should be no sharp projections.

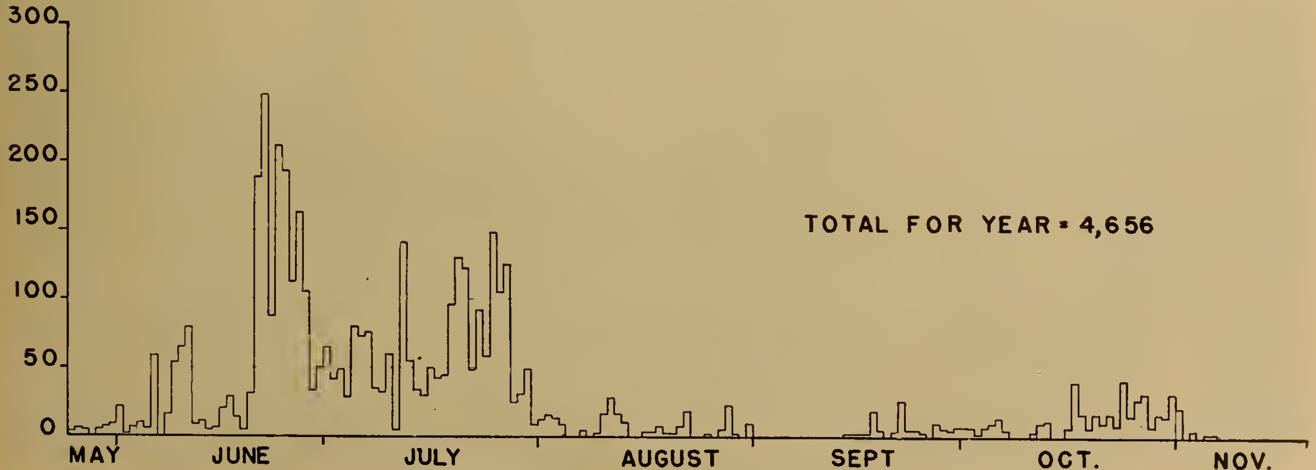

**Fig. 2. Daily count of salmon migration up Tobique Fishway during the year 1953.**

Salmon can, as a last resort, surmount some obstacles by leaping, if they have sufficient length of take-off in deep water. It is recorded that salmon can surmount a rise of over 11 feet, but this may be regarded as quite exceptional. Six feet is generally accepted as a maximum.

There are two kinds of fishways, the channel or "Denil" type and the jet type. The former consists of a sloped box-like flume with baffles; the latter may take the form of a series of weirs or overfalls, or with a submerged opening, or a combination of the two. In the latter case the difference in level between the pools should not exceed 18 inches.

### Location and Dimensions

The New Brunswick Electric Power Commission decided in 1950 to develop 27,000 hp., by building a 75-foot dam and powerhouse at Tobique Narrows, a mile above where the Tobique Flows into the Saint John River. Advice was sought from the Federal Department of Fisheries at Ottawa, regarding the type of fish ladder required. A small scale model of the dam was built in the N.R.C. Laboratory at Ottawa, on which the behaviour of the discharge was observed with turbines operating and closed, and with various combinations of sluice gates opened.

It was decided the most favorable location would be on the left bank of the river (Fig. 1), with an entrance gallery containing two entrances built along the downstream face of the power house. Later, it was considered advisable to provide two additional entrances along the first or lower leg of the fishway which runs roughly parallel to the tailrace, which might be preferred by the fish during times when the river was in flood and the tailrace level was higher.

The design provides for an operating flow of 9½ c.f.s. which can be varied by manipulating the orifices on the upstream exit. An auxiliary pipeline from the intake to the gallery entrances, with valve control, provides an additional flow of some 5 to 10 additional c.f.s. for flushing at high velocity. This creates additional current to attract the fish.

The Department of Fisheries was principally concerned with location of the entrances, the upstream exit, the inside dimensions of the channel, height and spacing of the lifts or jumps, and the provision of resting pools at suitable intervals along its length. The decision to build it of concrete, rather than of timbers, was made by the commission.

Owing to the rugged topography at the site, and the limited amount of room for access roads to the plant and for a switching structure with its banks of circuit breakers and transformers, the location of the ladder presented a difficult problem.

As built, the ladder has 78 steps or jumps a foot each in height. Between the steps are pools 8 feet wide, 11 feet long and 3 feet six inches in depth. Four resting pools, each with a surface area of 700 sq. feet, and with minimum depth of 5 feet, are placed at intervals along its total length of close to 1,000 feet.

### Migration Upstream

From the commencement of the summer upstream migration which generally occurs between mid-May to mid-October, Department of Fisheries game wardens directed the operation of the fishway. Figure 2 shows the daily count of the number of fish ascending, from late in May to the middle of November 1953.

It was found that early in the season the salmon preferred the two entrances provided along the lower leg of the fishway, probably because of the higher tailrace levels. Later in the season when the flow decreased, they favored the entrances built into the gallery along the downstream face of the powerhouse. With sudden changes in tailrace levels, mostly on weekends when the wheels were shut down, it was usually necessary to change from one entrance to another to find which ones the fish preferred.

In May a large number of eels and suckers entered the openings and crowded some of the resting pools. Many of these were killed. The jump immediately above the fourth resting pool was 18 inches in place of the 12 inches for the others, and appeared to be too high for the eels and suckers to negotiate, otherwise they would have continued on up into the headpond.

A total of 4,656 salmon passed up the fishway between May 24 and November 8. The largest monthly total was 1,979 during July, while the largest daily run was on June 22 when 248 passed through the trap. Early in the season all salmon passed up during the daylight hours. Later they started to run at night and at the end of the season runs were about equally divided between daylight and darkness.

From records of weather conditions and temperatures it appeared

Fig. 3. Tobique Narrows power house, showing four entrances to fishway from the tailrace.

that sunny or dull cloudy days made little difference in the number of fish entering. Nor did it appear that the presence of many anglers and spectators during weekends had the effect of frightening the fish so that they did not enter.

#### Migration Downstream

No accurate count could be made of the smolts migrating downstream, since these do not use the fishway but come down when the sluice gates are opened, or at other times through the turbines. The turbines are equipped with Kaplan type runners of five blades, similar to the ordinary ship's propeller, rather than with the Francis type runner, commonly used with medium-and-low-heads. The minimum clearance between blades is nine inches.

This is doubtless the reason that a constant watch did not verify that any downbound fish had been cut or killed by the blades, though dead eels floating in the tailrace attracted gulls and fish hawks in October. These evidently had entered the turbines while they were shut down.

In November large numbers of salmon were seen in the head pond, but after the gates were opened on November 15 they disappeared. No dead smolt were found below the dam and powerhouse at the time the smolt run left the river.

Fig. 4. Tobique Fishway. Lower leg from No. 1 entrance looking upstream.

#### Operation Satisfactory

The results of the first year's operation of the fishway is proof that it is adequate. Fishing clubs and sportsmen, who had been skeptical regarding the results, are now satisfied that salmon fishing on the Tobique is as good as ever. A number of fish and game associations, power producers and government wildlife services have addressed inquiries as to its design and operation.

One possible improvement might be to diminish the width of the openings at the baffles and so reduce the turbulence in the small pools. Whether the width of the channel could have been reduced below 8 feet, and so reduce the cost of construction, is open to conjecture. If the presence of suckers is a menace to the salmon eggs during the spawning and hatching period, one or more 18 inch jumps just above the entrances would appear to be useful in preventing these fish from entering the fishway.

Fig. 5. Tobique Fishway. Looking downstream to first resting pool.

#### Acknowledgement

The fishway was designed and built by Power Corporation of Canada, Limited, as part of the Tobique Narrows Power Development. Advice on fisheries requirements was obtained from officials of the conservation and development service, Department of Fisheries, at Ottawa. √

### Marginal Cost in Engineering Design

By D. F. Coates, M.E.I.C., Department of Civil Engineering, McGill University, Montreal.
*The Engineering Journal*, March 1954 issue, Page 246.

**J. W. Forster, M.E.I.C.** [1]

Mr. Coates has developed mathematically the economic principle that net revenue from an engineering project reaches a maximum at that stage of development where marginal cost equals marginal benefit. As an example, the principle has been applied to determine what is termed the economic or optimum height of a simple hydro electric storage dam.

The writer wishes to discuss two aspects of the subject: first, by illustrating how the method may be applied to a project having several inter-related features; and second, by demonstrating that the marginal cost criterion defines the "optimum" height only under certain conditions or assumptions, and that under other conditions a lesser extent of development may be economically preferable.

#### Pumped Water for Hydroelectric Plant

As an example of a project with several inter-related features, consider a system studied by the writer in Brazil and shown schematically in Fig. 1. Water is diverted from an existing reservoir to a high head plant. To increase the water supply, a dam is proposed further downstream to back water up to the existing dam where it will be pumped into the existing reservoir. A waterway from the upper end of the new reservoir to the pumping plant intake can be provided by rock excavation. The problem is to determine the upper and lower pool levels yielding maximum net revenue; i.e. the economic amount of storage, and the water levels between which it is to be provided. Total cost and gross revenue will be considered in turn.

[1]Civil Engineer, Aluminum Company of Canada Limited, Kemano, B.C.

#### *Total Costs*

In this case, for any given storage within the range considered, the combination of the several inter-related features which results in the minimum combined or overall cost must be determined before marginal cost analysis can proceed.

It will be seen that as the upper pool level or dam height increases, costs of dam and reservoir, including land, buildings, and relocation of highways, railroads, transmission lines etc., increase, as indicated by the Curve *A* in Fig. 2. On the other hand, for any given amount of storage, as the upper pool level increases, costs of canal excavation, pumping plant and pumping decrease, as shown by the *B*-curves. Addition of curves *A* and *B* results in total cost curves *C*, which indicate the upper pool level resulting in minimum total cost for storage capacities from 10,000 to 100,000 ac. ft. Minimum points on the *C* curves are connected by a dotted line.

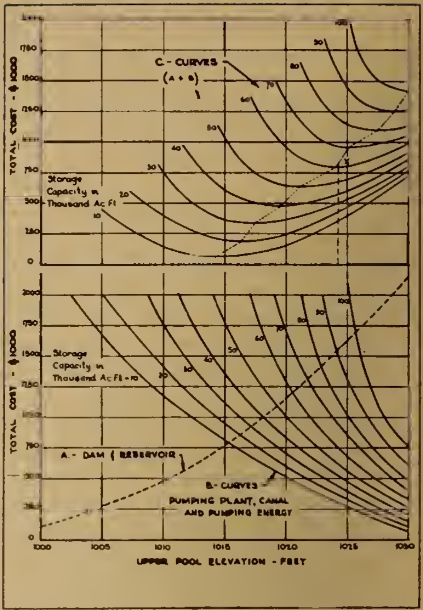

Fig. 2. Costs of dam and reservoir.

It is this minimum cost value for each given amount of storage that enters into the marginal cost analysis. Using these minimum values, the marginal or incremental cost of each increment of storage can then be plotted as Curve *D* in Fig. 3.

As the author showed, in the first step of the marginal cost analysis, it is unnecessary to determine actual *total* project costs; it is necessary to determine only increments in total costs corresponding to increments in project size, in this case measured by storage volume.

#### *Gross Revenue*

Provision of storage capacity permits holding and later use of

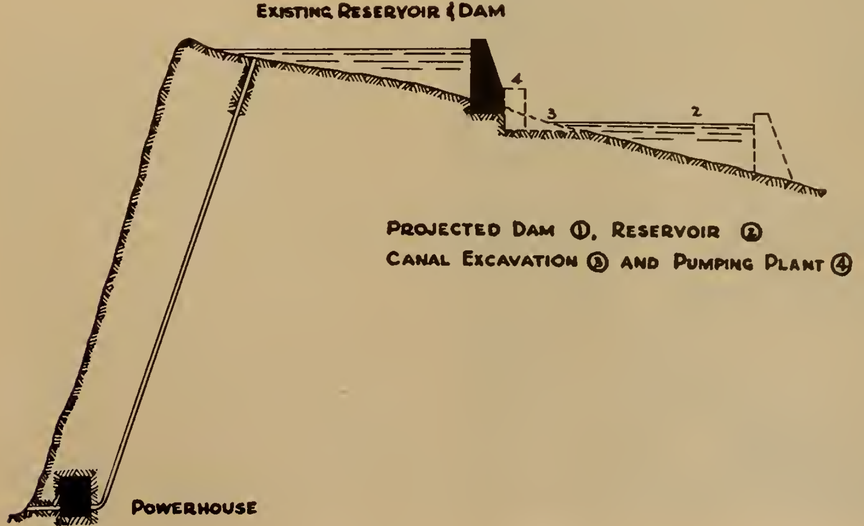

Fig. 1. System studied in Brazil.

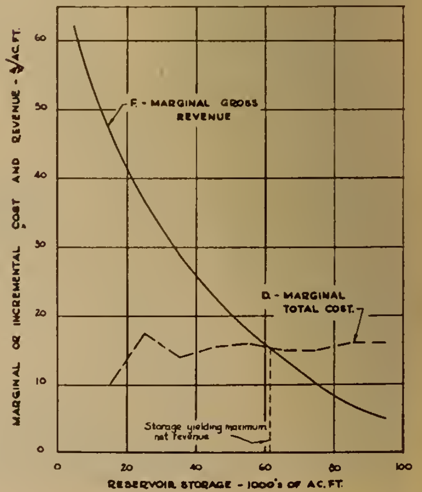

Fig. 3. Marginal cost and revenue.

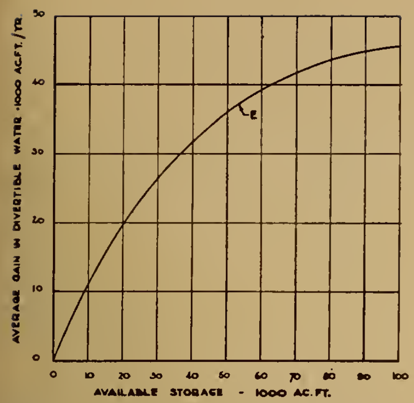

Fig. 4. Increase in divertable water.

freshet and flood flows which exceed diversion capacity and would otherwise be lost downstream. By analysis of flow records, the increase in divertable water resulting from any given storage capacity can be determined, as plotted as curve *E* of Fig. 4, and the corresponding increase in revenue computed over a range of storage. This yields the marginal gross revenue curve *F* of Fig. 3.

### *Results*

Storage capacity resulting in maximum net revenue is indicated in Fig. 3 as 61,000 ac. ft. by the intersection of marginal total cost and marginal gross revenue curve *D* and *F*. Then, by referring back to curve *C* in Fig. 2, upper pool elevation giving minimum cost for this storage is determined at point *X* as 1,024 ft., the corresponding lower level subsequently being obtained from the reservoir water level vs. storage curve.

### *Economic Analysis of Projects*

Considering a hydroelectric storage development as the author did, fixed or investment costs normally comprise by far the major portion of total costs, which increase rapidly as the structure outgrows the natural limitations of the site. On the other hand, gross revenue resulting from provision of each additional unit of storage diminishes after the capacity exceeds the volume of the minimum annual flood. Typical total cost and gross revenue curves for this type of development can be represented by curves 1 and 2 in Fig. 5.[2]

Whenever development is economically feasible, the total cost and gross revenue curves will intersect at two dam heights, *a* and *d*. Between these limits, net revenue, or gross revenue less total cost, is represented by curve 3, which reaches a maximum at dam height *c*. This height affording maximum net revenue is that at which the marginal gross revenue and marginal total cost curves, 5 and 6 respectively, intersect, as the author showed mathematically. Marginal curves 5 and 6 also illustrate that any increase in dam height beyond *c* is made at a net loss, and hence is not economically justified.

However, decision as to the desirable or optimum extent of development may well be governed not so much by the absolute amount of net revenue as by the per cent return on invested capital. The latter is indicated by curve 4, representing the ratio of gross revenue to total costs, and reaching a maximum at dam height *b*. (It will be found that as long as gross revenue exceeds total cost over some range of dam height, then point *b* lies to the left of *c*. If, however, total cost exceeds gross revenue for all dam heights, that is, if curves 1 and 2 have no points of intersection, then point *b* moves to the right of *c*. For the borderline case where curves 1 and 2 touch only at one point, then *a*, *b*, *c* and *d* are coincident).

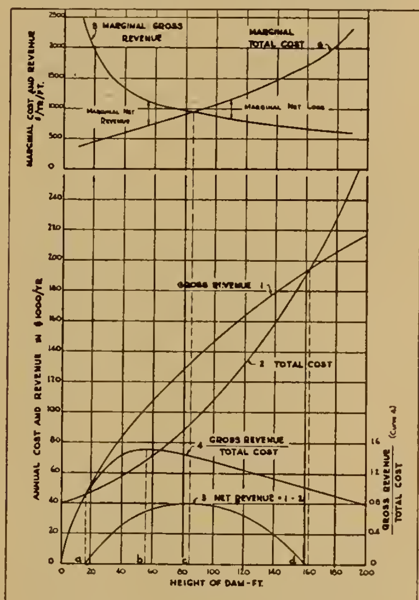

Fig. 5. Cost and revenue.

The basic limitation of the marginal cost criterion is that the extent of development which it indicates is independent of the net return on the investment. To illustrate, consider the cost curve 1 being simply shifted upwards (due for example to increased cost of access roads or foundation treatment) until it lies entirely above the gross revenue curve 2, so that any dam height would entail a net loss. Marginal cost and revenue curves would be unchanged, still indicating the optimum height at *c*, which would then represent the, height of minimum loss. In this case however, the truly optimum development, economically speaking, would be no dam at all.

### Optimum Height Definition Reconsidered

A logical economic criterion to govern the extent of development is that the rate of return on the investment should be not less than that considered commensurate with the risk involved. Of course, this rate is somewhat arbitrary and subject to experienced judgement in any particular case. However, once it has been decided, curves 3 and 4 then indicate the optimum extent of development. Three cases are possible, as reference to Fig. 6 will show.

First, if the minimum desired rate of return (indicated by ratio of gross revenue to total cost) is above the maximum value on curve 4, then at no point will the project yield an attractive return, so that no development is economically justified.

Second, if the required rate of return is lower, the length of dam must lie between *e* and *f* which are both less than *c*. In this case the height selected would be at *f*, since curve 3 indicates this point to yield the maximum net revenue within this range.

Third, if the required minimum rate of return is still lower, the height of dam must lie between *e'* and *f'*. In this case, the height selected would be at *c*, which yields the maximum net revenue within these limits.

In the first two of these three ranges the height indicated by the marginal cost analysis cannot be considered the optimum.

### Advantages and Limitations of Marginal Cost of Analysis

In any proposed hydroelectric project, regardless of the size of the structure within a reasonable range, cost of certain items such as pro-

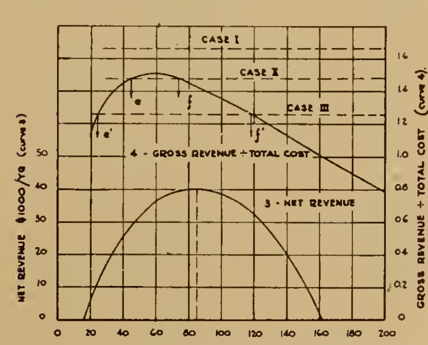

Fig. 6. Rate of return possibilities.

[2]See "Symposium on Multiple-Purpose Reservoirs", A.S.C.E. Transactions, Vol. 115, p. 789.

viding access to site, preparation of site and establishment of construction plant are more or less fixed. It is usually more difficult to make accurate estimates of these fixed costs than of incremental costs resulting from increasing size of structures within the feasible range considered. Since marginal cost analysis is independent of the less easily predictable fixed construction costs and is governed only by incremental costs, it lends itself to a quick determination of the maximum net revenue point without having to make detailed estimates of total project costs.

Also, since the optimum extent of development is never more than this maximum net revenue point, marginal cost analysis serves in preliminary studies to indicate the approximate upper limit of the range to be investigated in detail.

However, marginal cost analysis does not indicate whether or not the project is economically feasible on the basis of net return on investment, nor does the maximum revenue point which it indicates necessarily comprise the optimum extent of development, as shown above. To determine this it is still necessary to compute total costs.

There may be a tendency to carry economic studies to a degree of refinement not warranted by the accuracy of cost and revenue data on which they depend. Probably few hydroelectric projects construct- in the last 15 years have come within ten or even twenty per cent of their estimated costs. Until more accurate cost estimates are possible, refinements in the economic analysis appear to be of more academic than practical interest.

**D. F. Coates, M.E.I.C.**

Mr. Forster has presented a very good example of the application of the marginal cost analysis in engineering design. I should think that it would be interesting to most engineers to see a series of articles showing how this technique can be applied in different fields, e.g., in determining the optimum height of a hotel or office building, the optimum diameter of a pipe, the optimum depth for an open pit mining operation, the optimum chemical concentration in an industrial process involving a mass action reaction, etc.

At the same time, Mr. Forster's discussion contains some misconceptions that should be understood.

1. Mr. Forster has not shown the conditions under which "a lesser extent of development may be economically preferable." He has suggested that another criterion other than making net revenue a maximum might be used, but has not shown how or when this would be preferable to equating marginal cost and revenue. This is a large subject.
2. The alternate criterion suggested for designing an engineering project is to make the rate of return a maximum. As a theoretical point, this is certainly possible. But, first of all, it is not represented by the $R_g/C_t$ ratio. Secondly, to determine the point at which the maximum rate of return is obtained is quite difficult. This can be readily seen by examining the equation incorporating the rate of return:

$$R_n' = I_c \frac{i}{1-(1+i)^{-n}}$$

where $R_n'$ is the revenue net of operating costs (all costs except depreciation and interest on capital) in \$/yr;
$I$ is the capital invested in the project in \$;
$i$ is the rate of return represented by $R_n'$ on $I_c$ in % or \$/\$/yr.;
$n$ is the economic life of the project in years.

Thus no simple expression can be obtained for the rate of return. Moreover, the theoretical solution to the problem of obtaining the size for the maximum rate of return would require the differentiating of $i$ with respect to size and equating to zero. This would be difficult to do even by a trial and error procedure.

3. The "Symposium on Multiple-Purpose Reservoirs", that Mr. Forster refers to, suggests that the maximum Benefit/Cost ratio (Mr. Forster described this correctly as the $R_g/C_t$ ratio) may be an alternate criterion for design purposes. There are thus three alternate objectives that may be achieved by an engineering project:
   i) the maximization of net revenue,
   ii) the maximization of the Benefit/Cost ratio,
   iii) the maximization of the rate of return.

The correct criterion to use is actually a question of the intention of businessmen or government officials when investing in industrial plant. Recent surveys[3] have shown that not only are executives seldom explicit to the degree of following one of these three objectives, but that they are often irrationally influenced by non-economic factors in making investment decisions. At the same time it seems likely that of the three, businessmen, in increasing numbers, are most likely to base these decisions on the objective of maximizing net revenue.[4] In this case, it would behoove the engineer to direct his efforts to the ends of the executive, i.e., use the marginal cost analysis.

On the other hand government agencies seem to favour the use of the Benefit/Cost ratio. Engineers working for these bodies should thus use this alternate criterion. It is to be emphasized that the objectives of government bodies or businesses is sufficiently controversial that the superior officers must make the decisions on these questions; the engineers' role is to assist in obtaining it.

4. It is not correct to say that the marginal cost method of design "is independent of the net return on the investment." To determine the annual cost of amortization of plant, which is one component of the total annual cost, some rate of return or interest rate must be used. The appropriate figure may be close to the rate of interest on the borrowed capital for a non-profit making government organization incurring little risk. For a business organization, it may be what is judged to be the minimum attractive rate of return, or it may be some higher rate, which would be in the nature of a cut-off. rate for the purpose of budgeting capital. In any event, the higher the rate selected the higher would be the amortization cost with its influence on the design study.
5. In Mr. Forster's second to last paragraph it is not correct to say "marginal cost analysis does not indicate whether or not the project is economically feasible." In step 5 of the example in my paper, I pointed out that an essential step in the design study is to determine the actual rate of return at the point where the marginal cost equals the marginal revenue, for this point with an uneconomic project would be "Simply where losses are the least."

## CPR RECEIVES FIRST OF 173 NEW PASSENGER CARS

*Railway Age*, v. 137, n. 1, July 5, 1954, p. 10.

The first unit of its 1953 order for 173 streamline, all-stainless-steel passenger cars for transcontinental service was delivered to the Canadian Pacific by the Budd Company on June 29. The rest of the cars, which will go into service as delivered, will be completed at the rate of about three a week over approximately the next year.

The full order, which includes Canada's first dome cars, will be distributed in 15 train sets for service between Montreal-Toronto and Vancouver.

The first car, which was personally inspected and received from Budd by N. R. Crump, executive vice-president of the CPR, was a sleeper, containing eight roomettes, one drawing room, two double bedrooms and four sections.

Representing an investment by the CPR of some $40 million, the order includes regular and dome-lounge sleepers, standard and dome coaches, diners and baggage-dormitory cars.

## USE DOCK-BARGE IN GULF DRILLING

*The Iron Age*, v. 174, n. 1, July 1, 1954, p. 65.

Mobility plus stability in offshore drilling are the major advantages claimed for a new unit which recently went into service for a major oil company in the Gulf of Mexico. Unit is a DeLong dock-barge specially rigged for oil drilling.

Basically, it's a 203 x 70 ft. steel barge 8½ ft. deep mounting a series of special jacks on the deck. By means of the jacks, the 2500-ton barge pulls itself up 40-ft. out of the water on ten 160-ft, long steel caissons, converting itself into a stable drilling platform.

Fabricated by Consolidated Western Steel Division of United States Steel Corp., unit is leased by DeLong-McDermott Co. to the oil firm.

Forward deck provides a helicopter landing space as well as crew quarters. Drilling equipment is aft on the port side and functions through a 12-ft. slot in the unit's side. Slot permits the barge to be swung away from the drilling well when it has been completed. Internally, the hull is honeycombed with steel ribs for strength. Storage space is provided in the interior for fuel, oil and water.

Each half of the unusual air jacks is lined with rubber tubes. Similar tire-like tubes circle the caisson between sections. Tubes 6 in. above the deck are inflated, gripping the caisson. Air is pumped into the tubes between the sections which forces the caisson downward. Inflating the top tubes then clamps the caisson with the barge at its higher level and the bottom grip is released. Retraction here climbs the barge still higher. Centre tubes are next deflated and the operation starts anew. Reversing this cycle lowers the dock.

## DIRECTIONALITY OF MECHANICAL PROPERTIES IN HOT WORKED STEELS

A. R. Troiano and L. J. Klingler,
*Welding Journal* — v. 33, n. 5, May, 1954, pp. 209.

Steel that has been rolled or forged does not have the same mechanical properties in all directions. This directionality is called anisotropy and occurs in both cold-worked and hot-worked steel. In pressure vessel steels the greatest interest is in the properties parallel to and transverse to the rolling or forging direction.

In rolled, forged or otherwise hot-worked steel, the tensile and yield strength exhibit little or no directional properties over a wide range of testing temperatures including subzero temperatures. However, other related tensile properties usually show anisotropy. Both elongation and reduction of areas, for instance, decrease markedly as the angle between the test specimen axis and the rolling direction increases and approaches 90 degrees.

All notch properties exhibit directionality and invariably are inferior in the transverse direction, although the magnitude of the difference will, in some cases, depend upon the test employed and the criteria selected for comparison. This applies to the transition temperature, which may be considerably higher for specimens in which the notch is parallel to the direction of rolling than for specimens notched transverse or perpendicular to the direction of rolling. There is some indication that fatigue properties also are effected.

The extent to which hot-worked steels exhibit anisotropy depends upon many variables. One of these is the amount of reduction in working. It has been demonstrated repeatedly that reductions by forging up to 3:1 or 4:1 improves both longitudinal and transverse properties (tensile and yield strength excepted.) With continued reduction beyond this ratio the longitudinal properties improve only slightly but the transverse properties deteriorate markedly. Cross rolling tends to reduce the amount of directionality in plates.

Steel quality, as evidenced by non-metallic inclusions, banding, segregates, porosity and voids, is probably the single most important variable which influences the amount of directionality found in hot-worked material. Evidence indicates that the number of discontinuous stringers of oxides and other brittle inclusions fragmented in rolling, as well as continuous stringers such as silicates and sulfides; correlates quite well with transverse ductility. As the inclusion count increases, transverse ductility decreases while the longitudinal ductibility is not affected appreciably. There is agreement that nonmetallic inclusions account for only a part of the anisotropy, and that segregation, such as carbide stringers, as well as heterogeneous distribution of elements in solid solution accounts for most of the remainder.

Heat treatment *per se* appears to have little effect in reducing anisotropy. Homogenizing treatments have, in some instances, improved transverse properties by eliminating, banding and segregation but, as the nonmetallics are unaffected, such treatments cannot be relied upon to reduce directionality to any important degree. However, the amount of anisotropy may vary appreciably with changes in strength level produced by heat treatment and, in general, anisotropy increases as the strength level of the steel is increased by heat treatment.

Some forms of heat treatment may embrittle steel even at low-strength levels. An example of this is temper embrittlement, a phenomenon which occurs more or less in all steels if treated at appropriate subcritical temperatures for sufficient time, such as may be encountered in postweld stress-relief treatments. There is a greater susceptibility to temper embrittlement in the transverse than in the longitudinal direction.

Rolled plate used in construction of pressure vessels usually will exhibit lower ductility in the transverse direction than in the longitudinal direction. This difference, which is a function largely of steelmaking and rolling practice, tends to be relatively low in cross-rolled plate. Since this directionality in properties is most recognized by any of the applicable Codes except in limiting the maximum thickness of structural quality plate, and since no failures of pressure vessels have been attributed to it, it is not always rated as a significant factor in pressure vessel design or fabrication. However, in view of the fact that directionality in mechanical properties is known to exist in hot-rolled steel plate, additional work seems warranted to determine the magnitude of this effect in typical commercial plate of different thicknesses and under various conditions of manufacture and treatment.

## SALARIES AND ENGINEERS

*Chemical Engineering Progress*, v. 50, n. 5, May, 1954, p. 215.

Nothing interests us like ourselves, especially a comparison of our salary to the salaries of other engineers. Salary surveys continue to appear, ranging from the personal search of the want-ad columns and rough comparisons of the amounts offered clerks, deep sea divers, barbers and laborers with the current salaries offered engineers, to the complicated investigations of the professional engineering organizations. The newspaper search often causes deep concern. Engineers seem to be in no more favourable position than drivers of garbage trucks, and based on such quick surveys, premonitions of disaster for the whole profession are easy to come by.

For chemical engineers the A.I.Ch.E has, in the past, relied on its own studies. The most recent survey of the whole membership was published last July, and, in summary, in January of this year. The results were not at all discouraging. As a matter of fact the curves showed on the whole steady increases, and the picture for A.I.Ch.E members was promising.

But now the Engineers Joint Council has published a study of engineers' salaries which requires explanation to Institute members, and caution must be used if the figures are to mean anything. Titled "Professional Income of Engineers", it is the work of a Special Surveys Committee and is an adjunct to a survey on demand of engineers in industry. Data were collected from companies employing engineers, not from individual engineers, and in the report no differentiation is made in the kind of engineers on whom the company supplied data.

Direct comparison of the A.I.Ch.E. and E.J.C. data is difficult; nevertheless in the early professional period, up to ten years out of school, the E.J.C. study follows closely the experience of A.I Ch.E. members. But after the ten years are up, a peculiar thing happens. The salaries of the engineers in the E.J.C. survey, reported by the companies, begin to level off and soon hit a plateau, and in comparison with those of Institute members sink lower and lower, ending up below the A.I.Ch.E. third quartile. The E.J.C. survey shows that an engineer out of school since 1930 is earning $8,780. The A.I.Ch.E. shows him earning close to $14,000. The break seems to come at the ten-year experience level—graduates of 1942. Both surveys show them earning (in late 1952 and early 1953) a medium $7,200. From there on, however, Institute figures show a steadily increasing advantage. There are several explanations for this difference.

First and important is the fact that E.J.C. obtained data on all engineers employed by the chemical companies reporting. The companies were asked for information on any, many having an engineering degree. There was confusion as to the meaning of this requirement. Some companies interpreted the request to be for data on those still doing engineering work. Others gave the data on everyone (including executives) having an engineering degree. Second, the survey tapped only a limited sample. Out of the seventeen companies only one could be considered a major, in that it reported on 1,000 engineers. Finally the reporting sample of companies from the chemical field was not particularly representative.

Those who made the study for E.J.C. admit these short-comings and claim only that this survey is valuable in that it reports salaries of *ALL* engineers, and is not "limited by being restricted, for the most part, to members of professional societies". Therein is probably the answer for the vast difference in salary experience after the ten-year level.

Other surveys have revealed this same fact—members of a professional society command higher salaries. Many assumptions can be made as to why, but perhaps it is all summed up by saying that the man who joins a professional society is the man who looks upon engineering as a profession. The man who does not join his professional society looks upon engineering as a job, as a way of earning a living. As so often in life, devotion to a principle brings added things.

Professional membership must have its influence on the work, the mental attitude, the information quotient, the conversational interests, and the pride of everyone who joins. And over the years, this might just make the difference.

## THIN-SKINNED HOTEL

*Engineering News-Record*, v. 152, n. 23, June 10, 1954, pp. 31-33.

Exterior walls of the 16-story, $5.5 million Statler Hotel (approaching completion in Hartford, Conn.), are only 1¼ in. thick. This is only a small fraction of the thickness that would have been required if conventional masonry construction had been adopted.

The thin, lightweight walls, (they weigh only 4½ psf.) were made possible by treating the building exterior, from floor to ceiling in each story, as if made of glass. To eliminate a fire-resistant backup that the local building code otherwise would have required, the enclosure where not actually of glass had to have the same fire resistance as wire glass, sufficient strength to carry wind loads, excellent durability, good insulation qualities and ability to keep out rain. Metal-faced sandwich panels were devised to meet these requirements and then installed in aluminum sash, in the same manner as glass.

Development of these panels was not without problems, many of which had to be solved before erection started. Their successful solution made possible another step forward in the development of metal walls for tall buildings.

The trend toward metal exteriors for skyscrapers in this decade can be traced easily—beginning with the four renowned office buildings in Pittsburgh built in 1951 and 1952. The 525 Wm. Penn Place Building has a stainless steel facade backed up with 8 in. of brick. The two buildings in Gateway Center are enclosed with stainless steel panels into which a 4 in. lightweight concrete backup had been cast prior to erection. And the Aloca Building is faced with aluminum panels, which are backed up with 4-in. thick pneumatically placed, insulating concrete (ENR. April 3, 1952).

At the present time, several buildings under construction will have exterior curtain walls comparable in thickness with that of the Hartford Statler. One of the most noteworthy is the Republic National Bank Building in Dallas, with 1½ in. wall thickness—⅛ in. aluminum sheet plus vapor seal and insulation.

Wall panels for the Pittsburgh buildings were one story high. However, aluminum panels two stories high were adopted for the 99 Park Ave. Building in New York City last year, to speed construction. Following the pattern of the Pittsburgh buildings, though, these panels also have a backup—4 in. of brick. Local building codes require the backup for fire resistance, though none would be required if the whole space between floor and ceiling were enclosed with glass.

Designers of the Hartford Statler, taking cognizance of this, decided to treat the exterior wall as if made of glass. An exception was the spandrel facing, where the concrete spandrel beam itself provides ample fire resistance.

The designers called for large picture windows, which can be opened for cleaning from the inside by a key and hinge arrangement. Areas between and below the windows are occupied by wall panels that the city building department accepted as a substitute for glass. Aluminum sash for these panels and the windows were set as a single unit and the frame bolted to the building's concrete frame.

At first, an attempt was made to hold the 1¼ in. thick panels in place with the ordinary spring action of a glazing bead. However, this was found to be difficult in practice, because the bead tended to rotate. This troublesome movement was eliminated by anchoring the bead with screws.

Striated aluminum panels cover the reinforced concrete spandrel beams and columns. These panels also are clipped into the aluminum frame.

The wall panels are of sandwich construction, with a 1-in. thick glass-fiber insulation core and aluminum-foil vapor seal glued to two facing materials. The interior facing is a flat, ⅛ in. thick asbestos-cement board. The exterior is a laminate of ⅛ in. asbestos-cement board and a 20-ga. steel sheet with a blue-green porcelain-enameled outer surface. Purpose of this laminate is to eliminate "oil canning" or warping, of the facing.

In addition, the porcelainized metal was given a mottled, crinkly finish in an irregular texture, with some gloss. This color variation and texture are expected to make unnoticeable any minute irregularities in the shape of the surface, which the designers wished to appear as flat as window glass.

Edges of the panels are sealed with tape. However, small holes were punched in the tape to prevent building of pressure in the interior of the panels. Heat of the sun, the designers estimated, could set up a vapor pressure of 200 psi., if no relief were provided.

The panels vary in size, some of the largest being about 2½ x 7 ft. They have a heat-transmission coefficient of 0.20, compared with 0.16 for the walls of the Alcoa Building in Pittsburgh and 0.23 for the Gateway Center buildings. Cost in place is estimated to be $5 per sq. ft. A total of 1,640 panels (18,000 sq. ft.) was required to enclose the building.

## THE RAILROAD'S INHERENT ADVANTAGES

William J. Rae, *Railway Age*, v. 137, n. 1, July 5, 1954, pp. 22-26.

What are the inherent advantages of the railway? What are the characteristics of the railway structure and method of operation that give it advantages over its competitors? These must in some sense first be physical, but their final and most important manifestation may well be in pricing, or more simply in the setting of rates.

Although completely fundamental to the idea of a railroad, it is frequently overlooked that on a properly constructed railway the amount of power required per unit of transportation is small. It is only necessary to compare the horsepower of even the largest locomotive, designed to handle 5,000 or more trailing tons, with the horsepower of the large transport and passenger plane, or the combined horsepower of the trucks required to handle a like tonnage. Furthermore, it is relatively cheap power to build and maintain, in terms of the units of transportation provided.

Akin to this power advantage is the relatively small amount of labor required. One has only to visualize the five-or six-man crew of a railway train and compare it with the number of truck drivers and airplane crews required to move a like tonnage, to recognize the nature of the advantages inherent in the railway operation. Not so evident but just as real are the few men required to maintain equipment as compared to road and air competitors, relative to the tonnage handled.

Interchangeability of equipment is another advantage inherent in the modern railway, which frequently escapes comment and appreciation only because it is so commonplace.

Transportation is material handling, and the railway should, by background and interest, be the foremost exponent of its techniques, on the broadest scale. Few unit loads are as large as the normal freight carload, or travel so far without additional "handling".

There are a number of subsidiary physical advantages—such as freedom from weather interference, comparative freedom from extreme traffic conditions, and control of right of way—all quite inherent in the techniques of railroading.

These operating advantages are real, clearly witnessed by the fact that American railways can and do produce a ton-mile of freight transportation at a cost so much below the cost of the same unit by air or truck transport that the comparison is startling!

The inherent advantages so far are not fundamentally threatened or denied by anyone. Full crew and train-limit laws and other kindred restrictions may limit their ultimate development, but nothing more. The fact is that the advantages so far mentioned except the mechanical advantages of wheel on rail are all manifestations of the general principle that a railway of any size requires heavy capital investment, and a substantial supply of labor, including all management, sales, control and procurement groups as well as operating and maintenance personnel, whether a small tonnage or a large one is contemplated or immediately available. The railway is therefore most responsive to the economic pressures of overhead costs, and reaps the reward of decreasing unit costs in such dramatic fashion that it is a more imposing example of this characteristic type of American industry than the motor car or the packaged food industries.

The unit cost of railway transportation decreases as the number of units of transportation provided increases. Additional staff and facilities may be required as tonnage increases, and momentarily the cost per unit may increase until tonnage catches up with the capacity of the added units. The important fact is that, as the units of transportation provided increase, they do not call for like increases in total cost of the operation, and therefore the unit cost decreases.

Granted, this same influence is at work in other transportation agencies, but to a much restricted degree. A comparatively small increase in tonnage forces a transport operator to buy another truck, and take on another driver, but it takes a relatively large increase in traffic to require additional facilities on the railway. Relatively speaking, this is an advantage so inherent in the technique of railroad operation that it cannot be duplicated in all its manifestations by any other type of carrier.

It must be quickly recognized that unless the railway is permitted to obtain traffic in large volume, it will not produce transportation at low unit costs, but on the contrary, the so-called inherent advantage will become an inherent disadvantage and result in not low cost, but high cost transportation. This is the real "inherent advantage" that must be protected and which the railway must be free to exploit.

And how does the railway set about obtaining this large volume of traffic? Fundamentally by pricing its product in such a way as to attract the greatest tonnage. How to keep the price of the product as low as possible, while making an adequate, or more realistically the highest, profit concomitant with the fulfilment of service obligations to the public, is a proper statement of the problem.

Naturally the first reaction to this requirement is to decide that each transportation movement must be priced at least high enough to pay all the costs of producing it and as much more as can be obtained. But this is impossible, unless the railway chooses to give up that major inherent advantage of high overheads and decreasing unit costs, which it could not do even if it would remain in any modern sense a railway. Fortunately the real solution is even better, incorporating as it does another major "inherent advantage."

This second major inherent advantage is the fact that railway transportation is a classic example (in the terminology of the economist) of "joint product." The full cost of any particular movement of goods by railway is indeterminate. Not only is the total cost of any particular movement indeterminate, but only a small part of the known elements of cost can be directly attributed to the movement in question. Furthermore, most of the costs go on whether the individual movement takes place or not. The result is that the lowest price at which the railway can offer any particular service — and remain solvent — is one which just recovers the directly attributable "out-of-pocket" costs. The most important fact about this price is that it is usually very low. That is a real advantage and "inherent" in the fullest sense. Any price lower than the sum of the out-of-pocket costs would attract freight which it would be better to do without. Freight which pays more is advantageous for the railway to obtain —except to the extent that it may prevent the handling of some other freight which would pay an even higher rate relative to out-of-pocket costs.

That is not to say that this low "out-of-pocket cost" rate is that which should be charged. Very seldom would this be the case. The correct rate, once the out-of-pocket cost point has been surpassed, is that which results in the largest gross revenue, i.e., tonnage times the price or rate. The importance of this proposition is most clearly seen when considered along with another elementary economic observation: that generally, but with many modifications, the lower the price, the more goods will be purchased. The railway's inherent advantage is that it can, in pragmatic search for this price at which the maximum return will be obtained, lower rates further than most of its competitors.

It will have occurred to anyone familiar with the subject that all that has so far been written is no more than has been said in one form or another in even the most elementary texts on transportation economics. Nothing new has been said, nor was it intended to be otherwise. The basic facts have been known for many years, but has become obscured both by their simplicity and by the welter of social, as contrasted with economic objectives being sought by the many regional and political interests that combine to constitute the nation. They have diverted our attention from a purely economic phenomenon of great importance to our material welfare. Our purpose is to redirect attention to it, for even some railway managements seem to have overlooked the fundamental importance of this advantage.

What action then is indicated? First, would seem to be the direction of railway accounting talents to closer and more illuminating studies of out-of-pocket costs in connection with all important sources and types of traffic. Furthermore, it is not enough to make the studies—they must be presented to the sales management, or traffic departments in transportation parlance, in forms that will make the information informative. The fact that railway costing is perhaps the most difficult of all industrial costing is no reason for abandoning it. Rather it is an incentive to develop it in spite of its problems. Without appropriate cost information railway rates cannot be properly determined, in the sense that the resultant rate will supply service to the nation at the lowest possible cost per unit of transportation and at the same time provide a maximum of service, and as large a profit as possible. That is what railway management is supposed to be doing.

Detailed studies of the major sources of traffic should also be made to determine as closely as possible the rates that will bring about the greatest gross revenue. Skilful use of pricing is needed to capitalize on the railway's inherent advantages.

Secondly, the railways should work unremittingly to regain the right to price their own product. Restrictions, based primarily on monopoly conditions or the threat of such conditions, on the right of the railway to set its own prices, should be removed except where such conditions actually continue to exist.

The railways should therefore object most strenuously to the use of freight rates as a means of subsidizing geographic areas, political entities, industries or products. Railroading is a business, and tampering with prices always produces side effects and distortions of economic use, which finally increase the total cost of the national product and benefits other than those for whom the subsidy was originally conceived. Railway or other transportation rates should not be used as instruments of national policy, and the railway should reject all such proposals no matter what carrier is involved, and no matter how enticing the bait that is offered.

In this connection, the railways should strive to have removed the highly legalistic limitations on rate-making. In this day and age an "unreasonable" rate should be one that is clearly below out-of-pocket costs, or so high as to be extortionate in the absence of competition, and proof of absence of competition should be a required condition to support the charge. "Unjust discrimination" likewise should apply only where conditions are very similar, and where lack of competition suggests the possibility of quasi-monopolistic action on the part of the railway. The railways must keep in mind, however, that shippers will never let them attain the removal of these limitations until they are satisfied as to the railways' ability and intention to price their services efficiently and fairly.

The railways' inherent pricing advantage is only fully applicable when all competing carriers have charged against them the full cost of their operations. Therefore the railways should continue their fight to put their competition on a full-cost basis.

In implementing this program the railways should be careful to avoid vindicativeness and super-showmanship, not underestimating the essential intelligence and good taste of their public. Since much of what is proposed implies the need for a different social and political outlook on the part of the citizens of the country, the railways must engage in a broad program of economic education for the voting public, not the selling of a small number of "ideas" or slogans chosen for their ease of "recall" rather than factual context.

Many of the railway's problems are political in its most inclusive sense. It has been demonstrated many times that what the voter knows and understands the politician will soon learn and apply. The greater appreciation the public attains of the economic facts of life, the more certain that public policy will reflect that understanding.

Governments of course should review their approach to control of competitive business enterprises, and direct their attention to the maintenance of unsubsidized competition.

However, we must not expect governments to act with any strength unless the voting public understands and approves of such proposals, as there are too many short-term advantages to be gained from the present practices. The railways will have to create circumstances in which changes are possible, and they can do this only by taking their story to the people intelligently, moderately and persistently, and by practicing what they preach. They would do well to remember that their own employees as well as those of competing carriers are part of that public.

In summary it is held that the primary inherent advantages of the railway is its ability:

(1) To handle large volumes of heterogeneous traffic at low costs;
(2 To accept added volume at small additional cost of operation; and
(3) To price its service in such a way as to attract the larger volume required to reduce costs. The railway must exploit these advantages fully, and campaign intelligently and unremittingly to maintain conditions under which such exploitation is possible.

## THE ENGINEER'S TASK IN FUTURE WARS

Major-General G. N. Tuck, C.B., O.B.E.

*Chartered Civil Engineer,* November 1953, pp. 17-18.

The shape of any future war will be profoundly influenced by the advance of science and the engineer applications of new discoveries. If there is another major war it is likely to be very different from the last, and successful military planning will depend upon skill in adopting novel methods to fit the new conditions. New conceptions, those of "Mulberry" flavour stemming from an engineering approach to a strategic or tactical aim, may well govern the military solution. Two conclusions are drawn. Firstly, the importance of the close collaboration between the Royal Engineers and the civil engineers in engineer planning and engineer organization for a major war. Secondly, the Author suggests that civil engineers should contribute to military study with the aim of suggesting new solutions to strategic and tactical problems which become possible through technical progress; they will not be taking a full share in defence if they hesitate to express their views until a firm engineer requirement is specified by the Services.

In the land and tactical air force battle, greater effort may well be required on defensive and protective works. Machinery and prefabrication may help to solve defence problems. New types of obstacles to land forces which are cheaper, lighter and easier to handle, are required.

Equipment and assault bridging is of military rather than civil interest because the problems are special ones. The army's new designs to handle greater loads with simplicity of construction, light and handy components and ease of transportation, represent a great advance on last-war bridges. Modern military loads entail classification and strengthening of civilian bridges; many main road bridges even in the United Kingdom are not strong enough.

Airfields, and in particular hastily made airfields for the deployment of tactical air forces, present new problems due to wheel loading and jet resistance. Soil stabilization and new types of airfield surfacing are two lines of approach, but as yet no solution has been found to satisfy both the time factor and the operating requirements.

Among a long list of other tasks are fuel supply pipelines, "across the beach" delivery of commodities, rapid repair and construction of roads and railways, accommodation, field workshops, field tools, power supply, lighting and illumination including project illumination, and stores handling.

Military plant and equipment must be, where possible, the standard British made civilian product. Often the incorporation of some feature essential to military use can enhance the commercial value of a civilian machine, certainly for those designed for use in undeveloped countries. Collaboration between the Army and civilian makers is an important feature in defence preparations, and civil engineers are playing an active part in collaboration with the Royal Engineers, in the study of engineer tasks in war.

## TITANIUM:
### Tests on New Alloy Continue

*The Iron Age,* v. 174, n. 1, July 1, 1954, p. 72.

A titanium alloy that after proper heat treatment, has given tensile strength up to 192,000 psi in limited testing has been reported by Col. B. S. Mesick, commanding officer of Watertown Arsenal, Watertown, Mass. The alloy, a titanium-aluminum combination with beta stabilizing elements, was developed by Armour Research Foundation.

The material marks a major accomplishment in a 3 year titanium research program and the present announcement follows about 7 months of testing on alloys of this particular type. At least one 1000-lb. commercially produced ingot of the alloy has been shipped for further testing and other large ingots have been ordered. If test results confirm expectations, it is probable that general specifications for the material will be ready in 4 months.

# From Month To Month

**Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers**

## "Hands Across the Sea"

As a further development in the close and friendly relationship which has long subsisted between the two societies, the Council of The Institution of Electrical Engineers and the Council of the Engineering Institute of Canada recently have entered into arrangements whereby, in certain cases, no entrance fee will be payable when an applicant who is already a member of one is elected to membership of the other.

The following are the conditions under which the entrance fee will be waived:

1. On election to the Engineering Institute of Canada, if the applicant

> Is a Corporate Member or Graduate of The Institution in good standing, permanently resident in Canada, and
>
> Makes application within twelve months of his taking up residence in Canada or, if already resident there, within twelve months of the appearance of this notice.

2. On election to The Institution of Electrical Engineers if the applicant

> Is a Member or Junior Member of The Engineering Institute of Canada in good standing, permanently resident in Great Britain, including Northern Ireland, the Isle of Man and the Channel Islands, and
>
> Makes application within twelve months of his taking up residence in Great Britain or, if already resident there, within twelve months of the appearance of this notice.

The Councils of the two societies hope that the introduction of these arrangements will lead to a still further strengthening of the links which bind them.

## Institution of Electrical Engineers and Engineering Institute of Canada Reach New Agreement

The Institution of Electrical Engineers and the Engineering Institute of Canada have concluded negotiations whereby a member of one organization may become a member of the other, without payment of the entrance fee. (See official notice in this issue of the *Journal*).

These negotiations go back to 1952 when the president and secretary of the Institution were in Canada and visited with some of the members in cities such as Toronto, Ottawa and Montreal. At that time it became apparent that many members of The Institution of Electrical Engineers had come to Canada and that it was possible the Engineering Institute could be of service to them.

In accordance with the policy of the Conference of Commonwealth Engineering Institutions, all members of the affiliated institutions of the Commonwealth were given 12 months "guest" privileges when visiting or moving to another country represented on the membership of the Conference. Thus it is that the members of the Institution of Electrical Engineers in Canada have been welcomed by the Engineering Institute of Canada branches and invited to their technical meetings and the social events as well. The new agreement now provides membership beyond the 12 months period, on a preferred basis.

This agreement will be a matter of satisfaction to Institute members, and in particular to branch officers. It should result in many new members and increased activity in the field of technical meetings. Perhaps new members from the electrical branch of the profession will encourage more branches of the Institute to establish technical sections, and in particular electrical sections. The Institute and the branches are set up in such a way that any branch can have all the specialized technical meetings they wish. A transfusion of electricals from the British Institution should go a long way in extending the technical program of several branches.

## Cover Picture

The cover picture relates to the paper "Engineering Aspects of the Peribonka Developments" which starts on page 1051 of this issue. It is a view looking west along the downstream side of the intake at the Chute-à-la-Savane power house of the Aluminum Company of Canada Limited, showing 161-kv. transformers and buswork.

### Wide Co-operation

The Institute now has agreements for co-operation extending special privileges to the members of many organizations. Perhaps it will be interesting to list them here. First there are the agreements with the provincial professional organizations. With the exception of Quebec where it does not apply, the arrangement includes a joint fee and joint meetings. The organizations with whom such agreements apply are the provincial professional associations in Nova Scotia, New Brunswick, Manitoba, Saskatchewan, Alberta and the Corporation of Professional Engineers in Quebec.

The first written agreement made with an organization outside of Canada was with the American Society of Mechanical Engineers. This has been operative for 11 years. Right now the International Joint Council is considering an extension of this agreement whereby additional benefits may be available to members of both organizations.

Through the joint undertaking of the Conference of Commonwealth Engineering Institutions, the Institute has agreements with the national institutions in New Zealand, Australia, India, South Africa, Rhodesia and the United Kingdom. In the latter case, there are three institutions included, the institutions of civil, of electrical, and of mechanical engineers.

Another agreement is referred to elsewhere in this *Journal*. It relates to the recently formed Canadian Aeronautical Institute. The Council of the Institute has officially approved arrangements whereby the Engineering Institute of Canada members on joining the new organization are given certain special benefits, including a reduction in their fee.

Counting up all the organizations concerned, the Institute now has agreements with nineteen engineering societies.

## Ceremony at Government House

An occasion of unusual importance and interest to all engineers in Canada, was the presentation to His Royal Highness the Duke of Edinburgh, of a certificate of Honorary Membership in the Institute. This took place in Government House, Ottawa on Thursday, July 29.

It is not likely that any one of the seven members in the delegation, will ever forget the occasion. To have almost an hour of Prince Philip's undivided attention, in a delightfully informal atmosphere was an experience to remember.

The Institute is indebted deeply to His Excellency the Governor General Vincent Massey, for arranging the presentation at Government House and for being present with his aides throughout the ceremony.

**Presentation of a certificate of honorary membership to His Royal Highness the Duke of Edinburgh, Rideau Hall, Ottawa, July 29, 1954. Left to right: L. Austin Wright, general secretary, E.I.C.; B. G. Ballard, Ottawa, vice-president; G. R. Henderson, Sarnia, vice-president; C. J. Mackenzie, Ottawa, past-president and honorary member; His Royal Highness the Duke of Edinburgh; His Excellency the Governor General The Right Honorable Vincent Massey; Irving R. Tait, Montreal, vice-president; Donald M. Stephens, Winnipeg, president; J. O. Martineau, Quebec, vice-president.**

His Excellency's secretary, Mr. Lionel Massey, had much to do with the details that made the event so pleasant. The Institute's thanks are due also in great measure to Lieut. Commander Michael Parker, R.N., the Duke's private secretary. He was very helpful in the negotiations which led up to the acceptance of Honorary Membership by His Royal Highness, and that culminated in the certificate presentation.

The Institute party present for the presentation was made up of the president D. M. Stephens of Winnipeg, two vice-presidents from Ontario, Guy Ballard of Ottawa and Gordon Henderson from Sarnia, two vice-presidents from Quebec, J. O. Martineau from the City of Quebec and Irving Tait of Montreal, past-president and Honorary Member C. J. Mackenzie of Ottawa and the general secretary.

In making the presentation the president pointed out that in the Duke's tour of the northland, he would see for himself the work the engineers were doing in the gigantic task of nation building and that the engineers were proud that he had consented to be associated with them. (The full address follows).

The program and itinerary for the tour were in the hands of an engineer, a graduate of Saskatchewan in civil engineering, Group Capt. E. A. McNab, R.C.A.F. The Institute is indebted to him for the interest he took in making possible this presentation under such ideal conditions. Another interesting and interested member of the group of aides was Captain Adam Butler whose father is the Chancellor of the Exchequer of Great Britain.

Of all the brilliant events that make up the history of the Institute, it is doubtful if any exceed this, in significance, importance and in genuine satisfaction.

### The President's Address

Your Royal Highness, Your Excellency, Gentlemen,

To His Royal Highness I should like to say, on behalf of the Council and membership of The Engineering Institute of Canada, that we appreciate very much indeed, Sir, the fact that you have graciously consented to become associated with us through accepting Honorary Membership in our Institute.

To His Excellency the Governor General I should like to express my own appreciation and that of my colleagues for your kindness, Sir, in permitting us to meet for a few moments with your eminent guest, His Royal Highness the Duke of Edinburgh. We appreciate very deeply your further kindness, Sir, in having graced this occasion with your own distinguished presence.

Perhaps before presenting our Certificate of Honorary Membership I might be permitted to say to him that The Engineering Institute of Canada is an organization which embraces within its membership professional engineers from every one of the many specialties which are practised in the engineering fields today. In the Engineering Institute of Canada we are joined together not only by our common professional ties but through our Institute we seek to enhance the effectiveness of engineers and engineering in the development and strengthening of our country.

We know something of the interest which His Royal Highness is taking in the industrial and economic health of the United Kingdom; and we know something of the enthusiasm with which his interest and his leadership are being accepted by the engineers and industrialists of Great Britain. The members of our Institute, like all citizens of the Commonwealth, are proud of the great work which His Royal Highness is doing for the Commonwealth and the increasing strength and vigour and effectiveness which his influence and leadership are already gaining for our family of free nations.

As engineers of Canada we are gratified to know that in the course of the next few days His Royal Highness will visit so many of Canada's newest developments and that he will witness at first hand something of the tremendous strides that are being taken in our subarctic region.

How to give to Canada an economic breadth more nearly to conform with its geographic breadth —that has been the primary challenge to our generation of Canadians! As he visits our northland in the next few days His Royal Highness will see, and we know he will appreciate, how vital is the role of the engineer in establishing these new industrial frontiers well into the higher latitudes of Canada. At each and every point on your itinerary, Sir, you will find fellow members of our Institute and you will, I am sure, share our pride in the work that our engineers are doing in this gigantic task of nation building.

I am now going to ask you, Sir, to accept this Certificate of Honorary Membership in The Engineering Institute of Canada. The engineers of Canada are proud that you have consented to associate with us. We hope that you will find in this membership another instrument to your hand, and in our Institute yet another vehicle to aid you, Sir, in the work which you are doing for our family of nations and through them for all free men everywhere.

I am sure that my colleagues in the Council and all members of The Engineering Institute of Canada would feel particularly happy if you would be so kind as to convey to Her Most Gracious Majesty Queen Elizabeth a message of the warmest affection and loyalty from the entire membership of our Institute.

## It Took 250 Million Dollars

At 10 million tons a year it will take over 40 years to exhaust the supply of iron ore, already blocked out at Knob Lake. The attack on this huge mass of potential wealth was started officially on July 31st, through the medium of a ceremony held at the new town of Seven Islands in Quebec.

The *Engineering Journal* has published three papers on this project* so there is little technical material to repeat now. However, the president and general secretary of the Institute were guests of the company at the inaugural ceremony and an occasion of this kind is too significant to Canada, to be passed over without comment.

Preparations for the inauguration were very elaborate and far reaching. A cruise ship was chartered to transport the bulk of the guests from Montreal, but many came by air as well. A press party of over fifty were sent down by rail to Mont Joli, and then flown over to Seven Islands. Several C.P.R. passenger cars were shipped from Montreal so the guests could make a trip of 20 miles on the new railway to see the largest tunnel and the longest bridge on the line.

There was to be a great assembly outdoors to hear speeches and to see the Premier of Newfoundland and the Premier of Quebec push

*The Location and Construction of the Quebec North Shore and Labrador Railway, B. M. Monaghan, M.E.I.C., *Engineering Journal*, July, 1954.

Menihek Power Development, L. A. Carey, Jr.E.I.C., *Engineering Journal*, May, 1954.

Reconnaissance of the Labrador Railway, 1945, D. A. Livingston, M.E.I.C., *Engineering Journal*, April, 1954.

The first steamship taking iron ore from Seven Islands to Philadelphia.

two buttons that tipped two cars and started the ore towards the ore carrying steamer standing at the nearby pier. Unfortunately, the weatherman was not in the mood, and the assembly had to be transferred hastily to a large freight shed.

To one who had flown up to the ore field at Knob Lake previously, it seemed clear that no one who had gone only as far as Seven Islands, could ever get any conception of the gigantic work which had been accomplished. Of course, it was impossible to fly that huge crowd to the end of the line, but it did seem too bad that they would see only Seven Islands and go away with the idea that that was all.

This project of the Iron Ore Company of Canada staggers the imagination, not only because of the difficulties overcome in building the railway, but even more because of the economic impact it will have on Canada's economy. Think of what 10 million tons of ore a year can mean eventually to Canadian industry. Think of what it means to our national defence. Think of the colossal treasure house that is now open to man—and all under the control of this great country.

Great credit is due the hardy people who persisted in promoting and building this enterprise. The story of discovery, financing, design and construction is one of the thrilling tales of this country. This member of the Seven Islands audience was disappointed that none of the several speakers took much (or any) time to give credit to the people who had made it all possible. Here was a time for acknowledgement and tribute, but the opportunity was lost.

This little railway, 358 miles long will be a busy one for several months of the year. Although only single track, it has 22 passing tracks, and a theoretical capacity of 42 trains a day, each of over 100 cars. It will be able to handle easily 20,000,000 tons in a season, when the yard facilities are enlarged.

It is strange to contemplate that the port of Seven Islands may well become the busiest port in Canada. Montreal now handles about 15,000,000 tons of shipping a year. Seven Islands is certain to go beyond that figure with iron ore alone. When you consider the proposals there are for hauling grain to elevators to be built at Seven Islands, and of railway connection to Montreal, it becomes a bit staggering.

Coming back to the ceremony—the chairman for the day was Mr. Jules R. Timmins of Montreal, who certainly seems to be the one who most merited that honour. Hon. George M. Humphrey, secretary of the Treasury of the United States, and a former president of the Iron Ore Company, made an excellent speech as did also Mr. Joseph H. Thompson, president of the Company. The meeting finished up with two talks from the two premiers, and of course the pressing of the two buttons referred to earlier. Unfortunately, the altered location of the meeting, made it impossible to see the two cars that were supposed to tip at the press of the fingers, but it is assumed that everything went off as arranged.

The inaugural ceremony was a tremendous undertaking, as it should have been, to mark the start of another colossus in the business affairs of Canada.

## A New Institute Makes Its Bow

For some years there has been an interest, manifested through much correspondence and several meetings, in setting up in Canada, an organization devoted wholly to the technical matters associated with aeronautics and aircraft.

The Engineering Institute has been a party to the discussions and to the negotiations. The final proposal was approved by the Council of the Institute, and their support was demonstrated by a modest financial contribution to the funds of the new society.

The first president of the Canadian Aeronautical Institute is Dr. J. J. Green, immediate past chairman of the Ottawa Branch of the Engineering Institute. This is an early and splendid indication of the close collaboration of the two institutes. The inaugural meeting of the Aeronautical Institute and Dr. Green's induction took place at the Chateau Laurier in Ottawa on May 25. The Engineering Institute was represented officially by Guy Ballard, a vice-president of E.I.C.

The Canadian Aeronautical Institute starts out with the good wishes and the support of other organizations as well as the Engineering Institute. For instance the Royal Aeronautical Society is another of the sponsors. They were represented at the inauguration by Dr. Ballantyne, secretary of the society. Similarly the Institute of the Aeronautical Sciences (Headquarters in New York) is a backer of the Canadian Institute. They too were represented at the inauguration by their secretary, Robert Dexter. The I.A.S. have had branches in Canada but these have now been merged with the C.A.I.

For many years the Engineering Institute endeavoured to meet the needs of its members—and others—in the aeronautical field by the operation of an aeronautical section at Ottawa. A partner to the activity was the Royal Aeronautical Society. The Ottawa group functioned excellently but when war broke out, all activities ceased, for obvious reasons.

After the war, the Ottawa members of the Engineering Institute who were interested in the subject, started a study of the post-war position to see if a new co-operative agreement could be devised and made operative. The situation had changed considerably. The chief factor was that Canada was now in the aircraft business in a big way. It was no longer a matter of research, development and design. This meant that many people other than engineers were interested in a society.

As an indication of the change it should be noted that the Institute of the Aeronautical Science had come into Canada, with a strong branch at Toronto, and Montreal. This organization had grown to great strength in a remarkably few years, and was doing a fine work in the United States. They had definite advantages to the aeronautical people, as compared to the Ottawa activity. One of these of prime importance in these considerations was that their membership is not restricted to engineers. There are many people in the industry who are not engineers and therefore the Engineering Institute could not serve them.

A further factor that was influential in the creation of an all Canadian aeronautic institute, was that the situation was confused by the presence and activities of so many societies endeavouring to cater to the same people. Besides the I.A.S., the R.Ae.S. and the E.I.C., there was the Institute of Aircraft Technicians. In the midst of this overlapping it seemed only logical that a new, all-embracing organization should emerge. The Canadian Aeronautical Institute is the outcome.

By a feat of imagination, daring, and intelligence the organizers of the new group brought about a miracle . . . or at least a near miracle. They have obtained—in writing—the full support of all the organizations that previously competed within the Canadian field. This support is not just theoretical. It is real, as is shown very substantially by financial contribution from all organizations. In return the C.A.I. gives the members of these organizations special reductions in their fees. It looks like a fine arrangement, though a novel one.

The officers and the members of the Engineering Institute wish the best of everything for the new society and assures them that they are proud to be associated with them and at all times are willing and ready to co-operate, to collaborate and to help.

# A Qualifying Condition

For many years prior to the late war, the Civil Service Commission of Canada and the Department of National Defence used "qualifications for membership in the Engineering Institute of Canada" as a criterion of qualifications for employment by the government or for a commission in certain branches of the armed services. During the war the demand for technically qualified persons became so great that these standards had to be abandoned. There just were not enough with E.I.C. qualifications to fill the vacancies.

During the war and subsequent to it, the provincial professional associations suggested to the Civil Service Commission that qualifications for registration should be used as a standard. For several years no decision was made by the Commission, but recently a suggestion has been made that seems wise and statesmanlike. It should solve the problem to everyone's satisfaction.

The Engineering Institute has been asked to sanction the following wording for use by the Civil Service Commission in seeking engineers. One of the qualifications shall be "graduation from an accredited course in engineering and qualifications that would permit of membership in a provincial association or the Corporation of Professional Engineers and/or the Engineering Institute of Canada."

Recent advertisements for engineers, published by the Commission have been using this wording.

# Recognition

If we recall correctly, the Canadian Fairbanks-Morse Co., Ltd., were one of the advertisers in the very first issue of the *Journal* and have been with us ever since, so we regard them as quite of our family. Our latent feelings of kinship with them have been brought to the surface by the recent receipt of a collection of half a dozen proofs of advertisements they propose to run in various periodicals in the near future.

To receive advance copy of this kind is not unusual, but at the moment we cannot recall ever having seen any advertising just like this, built up as it is around the theme of paying tribute to the engineer. Perhaps its purpose can be best explained by quoting, though not verbatim, from the announcement accompanying the proofs:

> The skill and ability of the professional engineer are the cornerstones on which Canada was built. The roads and railways that brought settlers, the development of natural resources, the creation of modern cities and industrial plants, have been in the capable hands of the engineer. How well these tasks were accomplished is reflected today by our industrial and commercial might. The engineer's contribution to our way of life is found everywhere.
>
> To assist the engineering profession to obtain the recognition it so richly deserves, the Canadian Fairbanks-Morse Co. is pleased to present the series of advertisements you will find on the pages of this booklet. These will appear in magazines and newspapers in all major cities from coast to coast, so that millions of Canadians may see and more fully appreciate the meaning of the words "professional engineer".

No doubt many other firms feel as the Canadian Fairbanks-Morse Co. do toward the engineer, but so far, to the best of our knowledge, this is the first of our advertisers paying so great a tribute to him.

Our own readers do not need to be reminded of the importance of the engineer in modern life, so perhaps one might feel that the publication in the *Journal* of advertisements such as these would produce little impact. But note that these will appear "in magazines and newspapers . . . from coast to coast", which means that some, at least, will be read by those who are not engineers and so have a hazy conception, if any, of what engineering is all about.

These advertisements are an indication that hard-headed business believes the engineer is entitled to more recognition than he gets. These advertisements are a graceful gesture, a tribute, which will be appreciated by all engineers and we hope, by the public as well.

# Engineering Education

Education is not static; it changes with the needs and ideals of the times. Perhaps its process of continuous evolution is most evident in education for the medical and engineering professions, which must keep pace with new discoveries and changed concepts. Certain it is that today's engineering curriculum is far different from the one to which the writer was exposed fifty years ago. The emphasis is now on the fundamentals, where it belongs, and little attention is paid to turning out graduates who have acquired some little skill as draughtsmen, surveyors, pattern makers or machinists.

But most engineering educators are still not satisfied with things as they stand. They think that teachers, teaching and curricula can be improved and no doubt they are right. So in May, 1952, the American Society for Engineering Education appointed a Committee on Evaluation of Engineering Education, whose interim report of June 15, 1954 has just reached our desk. Too long to reprint or even to abstract satisfactorily here, it is certainly comprehensive, running, as it does to some 11,000 words, plus two short appendices, and based on opinions expressed by 122 engineering schools in the United States and in Canada. One suspects that most of the conclusions and recommendations represent the reactions of the United States schools; this writer does not believe that all of them reflect current Canadian opinion.

The objectives of engineering education are set forth at considerable length; a "set of specifications" for the ideal engineering faculty is proposed; the qualities desirable in an engineering curriculum are explored and a more or less "perfect" curriculum is outlined.

The ideal engineering teacher is pictured as such a paragon of perfection that it is hard to imagine that more than, say, 30 per cent of us—the writer has been *trying* to teach engineering subjects for most of his professional life—could even begin to qualify under the usual university pass mark. To our mind, too little emphasis is laid in this report on the personality of the teacher and too much on his professional attainments.

We think the discussion on curricula will be generally approved in Canada, and is less upsetting to us than it probably will be to some schools in the United States. Canadian schools have never been fond of bits-and-pieces curricula; they have managed to stick pretty well to the fundamentals and the changes in curricula they have made have been mainly in the direction of more training in the basic sciences.

Notwithstanding that, practically every reader of this report will disagree with parts of it, he will also agree with it in general. It is really remarkable that the 52 members of the Committee could produce a report which reflects so little difference in opinion.

A minor criticism, but a criticism from this writer's point of view, is that the report is hard to read. Though in impeccable English, it would be improved by the occasional use of a monosyllabic word with an Anglo-Saxon root, *vide* the Duncan report on coal mining in Nova Scotia.

For copies of the report write to the general secretary E.I.C. 2050 Mansfield St., Montreal 2.

---

# C.T.A. Golden Jubilee Meeting

The Canadian Transit Association's 50th annual meeting was held at the Algonquin Hotel, St. Andrews, N.B., June 14—16, 1954, with some 200 delegates in attendance. They were welcomed to the Province by the Hon. D. L. MacLaren, P.C., the lieutenant governor of New Brunswick. M. T. Bancroft of Quebec City was elected president of the Association for the ensuing year.

President S. Sigmundson of Vancouver, in his presidential address, told the representatives of transit companies from coast to coast that their industry had failed to come to grips with its mammoth competitor, the private automobile. While the auto industry has glamorized its products and sold them at higher and higher prices, transit had not emphasized the services it sells and what these services mean to the public.

"The business which should be channelled to surface transit services", he said, "is going to the private automobile because the transit industry has been too poverty-conscious in its thinking and too unimaginative about what people are willing to pay for a product they want".

### Annual Report

In his annual report, the general secretary, H. E. King drew attention to the growth of the Association since receiving its charter fifty years ago. Membership had grown from 12 in 1904 to a total of 110 in 1954,

**Officers and guests of the Canadian Transit Association, at the recent annual meeting. Left to right: D. E. Blair, Montreal, a charter member; M. T. Bancroft, Quebec, president; and S. Sigmundson, past-president; back row, Stuart E. Preston, Kitchener, vice-president; and H. E. King, general secretary.**

made up of 35 active member companies, 71 associate member companies and 4 associate members.

Revenue passengers carried had risen from 18,200 in 1904 to 830 million in 1929 and to 1,223 million in 1953, while passenger revenue showed a rise from $8.93 million in 1904 to $126.6 million last year. "Over this fifty year period average wage rates had roughly tripled in each 25 year period", he stated, "though fares had by no means followed this trend".

Comparing operating expenses for 1953 with those of the previous year for 29 companies reporting, 15 of them had reported increases in revenue and 14 a reduction; 18 companies had shown increased operating expenses while 11 had reduced their cost of operation.

The basic adult fare structure for 35 comparable properties ranges from a high of 15c cash or 4 tickets for 50c, to a low of 10c cash or 3 tickets for 25c, he reported. The predominant fare combination which prevails in 17 of the 35 properties is 10c cash or 3 tickets for 25c.

#### Better Leadership Needed

Mayor D. H. MacKay of Calgary, in an address on "What is Required of Public Transit ?", declared the answer could be summed up in the words, "Wanted, Better Leadership". Speaking as a public official, he said, he was impressed with the need for the transit problem to be fully understood by the public at large.

Everything was being done today to encourage more and more vehicles to come into the downtown area, while nothing was being done to alleviate traffic congestion. Emphasis had been placed by those who hadn't the interest of the transit vehicle at heart, on the need for accelerating the movement of vehicles. We had listened to that voice too long and it had been too effective, he stated. Off street parking facilities, one way streets, traffic control, all these were designed to bring more vehicles downtown. Caught right in the middle of them was the transit vehicle.

Yet today at least 70 per cent of the purchasing public were travelling downtown by transit. This must be told more emphatically and effectively, and the time to tell it was now, before it was too late. "We need more leadership in the selling department of our transit industry to convince people that we must work in terms of the best interests of the majority. We must give the green light to the transit efforts of every community", he warned.

Transit officials, continued Mayor Mackay, had an important story to tell. No one else would do the sales job for them. A sound educational and promotional approach to the transit industry could accomplish the ideal of changing the whole plan of public thinking on the problem.

#### Strikes Reveal Importance of Transit

George Anderson, executive vice-president, American Transit Association, speaking of transits' achievements during the past year, told the meeting that in large American cities provision of express bus service and the adoption of zone price rates were devices now being used to attract fares. Many cities were currently installing "premier parking lots", where the car owner may park his automobile at the outskirts of the business area and ride on a bus to work. Greater amounts of transit revenue have melted into the air in the U.S.A. than in Canada, he said, because the Canadian organization had exerted more rigid control over its affiliates.

"Strike action by transit employes can be beneficial to the transportation industry as well as harmful", continued Mr. Anderson. "A mass-scale walkout has the tendency to reveal to the public the vital importance to a city of its transit service. While such strikes will have only a temporary effect on the industry, public apathy can often ruin a transportation concern".

#### Trolley Buses Losing Popularity

A symposium on the question: "Has the trolley coach lived up to expectations ?" was conducted on the final day of the meeting with five speakers, under the chairmanship of H. W. Tate of the Toronto Transportation Commission. George Anderson stated that trolley buses were backsliding in the United States and losing their appeal. Many American cities are finding installation of the overhead electric wiring systems used for trolley buses too inconvenient, he stated, due to continual changes in city planning.

Other speakers included L. Wingerter, president of ATA whose subject was "Signposts on the Road to Better Earnings"; Dennis O'Harrow, executive director, American Society of Planning Officials, who spoke on "Town Planning and Public Transit"; and C. E. DeLeuw of Chicago, who discussed "Transit Planning for the Future".

#### Charter Member Recalls Early Days

D. E. Blair of Montreal, only surviving charter member of the CTA was presented with a sterling silver cigar box in recognition of "his magnificent contribution to the transit industry in Canada". In his reply, he recalled some of the changes that had occurred over the fifty-year period. In the early days, he said, cars were equipped with hand brakes only. Contrary to some government regulations, he had proved by demonstration that cars could be stopped quicker with hand brakes.

Mr. Blair told of the early battles to maintain transit service during the winter months. In March 1901, Maple Avenue in Quebec City was blocked two weeks by snowdrifts, with no organization for snow removal as exists today. Drifts were so high that men had to be stationed to warn people not to touch the trolley wires. One year in Cartierville a rotary snow plow was kept in use 24 hours a day for a whole month without entering the shops for inspection.

---

## ECPD Survey on Awarding Professional Degrees

The Recognition Committee of the Engineers' Council for Professional Development, under the chairmanship of R. H. Barclay, has completed a survey of the awarding of the professional degree by various engineering institutions. The survey, with its excellent response—of the 146 institutions sent questionnaires 142 responded—will serve as a basis for formulating recommendations concerning the practice of awarding the professional degree as a means of professional recognition.

Of the engineering schools surveyed, 86 award the professional degree while 62 do not. Of the 86 awarding the degree, 74 use professional experience as a basis for awarding the degree, 8 require resident graduate study and 4 include both professional experience and resident graduate study as prerequisites for awarding the professional degree.

In regard to their future plans concerning the professional degree, 69 colleges will continue awarding the degree, 2 will institute the professional degree, 13 will abandon it, 49 will continue not to award it, and 17 are uncertain as far as future plans are concerned. The survey shows that approximately 1/5 of the schools offering the professional degree have either dropped it or are making plans to do so.

The Committee also reported an increase of approximately 80 per cent in the awarding of professional degrees in the last five years as compared with the previous five-year period. In the last 10 years, 1387 to 1398 professional degrees have been awarded, and of these, 917 to 922 have been awarded during the last five years.

The Committee believes this survey to be the most comprehensive of its type ever undertaken and will use it in formulating recommendations on the practice which they believe should be followed in respect to awarding the professional degree as a means of professional recognition.

---

# Chemical Institute Conference

The Chemical Institute of Canada held its 37th annual conference and exhibition at the Royal York Hotel, Toronto, June 21-23, 1954. E. R. Rowzee, F.C.I.C., vice-president and manager, Polymer Corporation, Ltd. of Sarnia, was elected president for 1954-55, with Dr. Roger Gaudry of Montreal as vice-president. Dr. Garnet T. Page, 18 Rideau St., Ottawa 2, continues as general manager and secretary. Forty prominent Canadian chemists and chemical engineers were elected as Fellows of the C.I.C. Dr. R. K. Stratford of Imperial Oil Ltd. was presented with the C.I.C. Medal for his outstanding contributions to Canadian chemistry and chemical engineering.

**L. E. Westman Memorial Address**

Dr. Linus Pauling, outstanding American research chemist of the California Institute of Technology, presented the annual L. E. Westman Memorial Lecture at the opening session, entitled "The Significance of Molecular Structure in Biology". Stating that recent research had shown some diseases are the result of the genetically-controlled manufacture of protein molecules with abnormal structure, he pointed out that four kinds of abnormal adult hemoglobin have been discovered so far.

In the case of sickle-cell anemia, discovered in 1945, the red blood cells are normal in the arteries but shaped like the blade of a sickle in the veins. Patients have a form of hemoglobin in their red blood cells that has different properties from normal hemoglobin. "These diseases", he stated, "are clearly molecular diseases, and while other diseases are likely caused by molecular structures, these anemias are the only ones that clearly show this factor".

**E. Ralph Rowzee, President, Chemical Institute.**

**Sound Principles of Past Must be Followed**

"It is much more difficult today for the research chemist to make a substantial contribution to scientific progress, than it was 30 years ago", observed Dr. R. K. Stratford in his C.I.C. Medal address. Noting a tendency on the part of the scientist in many fields today to neglect, under pressure of competition in manufacturing, the careful systematic work that had been the classical approach to all scientific progress, he emphasized that "little will be accomplished unless they continue to follow the sound principles of the past".

Industrial research groups must have sympathetic support and freedom of action, he added. The industrial scientist must collaborate widely with scientists in other fields so new ideas and discoveries, no matter where they originate, can be put into commercial practice. In particular, industry should be prepared to give unrestricted support to fundamental research at universities.

**Symposium on Management**

A symposium was conducted during the first day's afternoon session under the title "Molecules to Management". J. T. McCay of Montreal, speaking on "Communications and Human Relations", advised delegates to . . . "look to your words, learn what you can do with them and what they can do to you. By so doing you can develop ability to listen and observe, and these are important factors in obtaining co-operation from fellow workers."

"The success you have in getting people to work wholeheartedly with you towards a common goal" he continued, "depends on how much you know about them. The more you know, the better you can predict how they will react to what you do and say, and most of your information about them comes by listening and observing."

J. B. White, vice-president, Aluminum Co. of Canada, speaking of the training of personnel, stressed that "management, as distinct from technical work, is the job of enlisting, directing and co-ordinating human effort". There are two sides to management, he added, the technical and the administrative. Technical ability, knowing the techniques and knowledge that underlie processing, engineering, accounting, marketing, finance and sales, is a requirement for managerial work.

Besides this it is necessary to have administrative ability, which involves, among other things, the ability to get work done through and with others, to delegate, plan and organize the work of others, to be skilled in the art of conference and discussion and to develop and further the growth of subordinates. The ability to do all these things effectively is good management", he said.

Francis J. Curtis, vice-president of Monsanto Chemical Company, St. Louis, discussing "Developing Managerial Abilities of Employes", warned that "companies can no longer depend on haphazard methods of obtaining executives. It is now necessary to develop all possible candidates for executive positions. Only thus can the rapidly expanding chemical industry keep a supply of its scarcest component, top grade managers", he said.

The core of his company's system of management development was on-the-job coaching, Mr. Curtis pointed out. In his opinion this was the best way to teach a man to handle himself, to make his own judgments and to stand or fall on his actions. This plan calls for a limited amount of job rotation.

### Symposium on "The Chemical Engineer in Canada"

"The future of the Canadian chemical engineer is dependent on Canada's development in the future, and both look promising", stated Dr. J. R. Donald, president of J. T. Donald & Co., Montreal. He estimated that 9,000/10,000 engineers would be required in Canadian chemical industry by 1975, though at the present rate of graduation only 5,000 would be available by then. Thus, he urged, more students should be encouraged to study chemical engineering. Most of these graduates will be employed by the chemical industry, though a good number would go to other industries, as all industry, he noted, is becoming more and more chemical.

The greatest number will be required in plant operation and production, thus the greatest demand will be for those trained in these fields, he observed, adding that since the only answer to increased competition is lower production costs and refinement of operations, the demand for competent operators will always exceed supply.

While all Canadian manufacturing had doubled in size since 1939, the production of basic chemicals had tripled, the speaker stated. Chemical consumption in Canada would be doubled by 1975, he predicted, but the industry would only double in size if it was able to supply this increasing demand. Tariff policies would play an important role in helping the industry to meet these requirements, he said. Since prohibitive tariffs prevent the export of all important chemicals except fertilizer materials, the industry must look to Canadian markets for its future growth.

"The present trend in business is taking more engineers out of the plant and is placing them in managerial, executive, presidential and public positions of responsibility where technical competence alone is not sufficient and additional qualities are required." This was pointed out by R. R. McLaughlin, head of the Department of Chemical Engineering, University of Toronto, in discussing "Non-technical Aspects of the Training of Chemical Engineering Students".

"The rigorous student engineer is apt to regard time spent on non-technical subjects as wasted, in view of the vast amount of scientific knowledge that he should encompass," he observed. "On the other hand, the successful mature engineer is inclined to over-emphasize the importance of non-technical subjects. He realizes their importance in the later stages of his career, but forgets he has acquired them by his own efforts, and that actually his success is based primarily on his technical competence. "Technical competence", he concluded, "is paramount, although paradoxically, not at the expense of general knowledge and interests."

"The primary qualification of a chemical engineer should be a good basic understanding of the fundamentals of his branch of engineering", stated D. S. Simmons, assistant general manager, manufacturing, Imperial Oil Ltd., Toronto. "Without technical competence in your own chosen field", he continued, "you may never have the opportunity to demonstrate your other sterling qualities."

But while he must have a good grounding in basic fundamentals, his employer does not expect him to know the applications of this knowledge to industrial problems. This is something the employer expects to teach him. The value of post graduate training is that it certifies the man's intelligence, his knowledge, and his skill and imagination in applying these fundamentals. "Industry is beginning to appreciate this fact more and more", he said. "This is illustrated by the trend to an increased spread between starting salaries of those with bachelors, masters and doctors degrees."

Mr. Simmons expressed the view that it was better for the student to be put to work immediately, rather than to first have a training course. This gave the company a chance to spot the people not suited to the industry before they were there too long. Training courses, he said, seemed more profitable for men who had already proved they can handle a specific job.

### Symposium on Chemical Education

"The ultimate aim of the average scientific curriculum in high schools should be attainment of skills and logical processes of thought, with gaining of empirical knowledge only secondary". This was the view of Dr. M. R. Foran, professor of chemical engineering, Nova Scotia Technical College, Halifax.

Present day criticisms of the modern curriculum arise from too much emphasis on trying to meet the public's demands and from today's materialistic trend of thinking. This resulted in too much money being spent on modern schools and too little on teachers, he observed.

Differentiation should be made between students with greater and less ability, he believed, and while this might seem undemocratic it would lead to greater efficiency in teaching. There would be more time for thought and learning in the school if duplication of learning between the school, the home, and the community could be eliminated.

Speaking on "Occupational Guidance", H. R. Beattie of the Ontario Dept. of Education, outlined the three stages of vocational interest; romanticism, enlightenment and decision. These stages, he pointed out, lead to a period of decision when a choice must be made. These decisions are greatly influenced by the previous stages, and co-operation of the school and organizations of all kinds is necessary to ensure that romanticism is coupled with enlightenment so that the inevitable result is sound decisions. Our way of life depends on it.

Dr. W. Charles Cooper, chief chemist, Canadian Copper Refiners Ltd., advocated adequate instruction on instrumental methods of analysis in chemistry and allied sciences. Particularly important, he felt, was the need for short term courses in instrumentation for industrial chemists.

Dr. J. A. McCoubrey, of the Department of Research and Development, Canadian National Railways, outlined the problems associated with chemical plant location and the bearing some of these factors have on the final decision for a specific site. How some of these topics may be of interest to the chemical educator were outlined, with particular reference to Canada's chemical industry.

•

### Technical Papers

Other technical papers were presented relating to chemical engineering, including those on the subjects of packed tower design; distillation columns; the heat pump; bubble cap tray design; cracking of ethane, cracking of hydrocarbons and pyrolysis of waste sulphite powder.

A wide range of technical papers was also presented relating to analytical, organic and physical chemistry, biochemistry, agricultural chemistry, and rubber chemistry. Many of them dealt with metallurgical subjects of specific interest to mining engineers and metallurgists. Others, such as those on biochemistry, were of particular interest to the medical profession or to pharmacists.

**Conservation**

The guest speaker addressing the luncheon meeting on the final day of the convention was F. H. Kortright, president, the Conservation Council of Ontario, Toronto, who told delegates that — "Here in North America we have broken all records in the rate of destruction of natural resources. Over one hundred million acres of fertile soil have already been rendered useless.

"Conservation is the concern of everyone", he pointed out; "there is no business that does not owe its prosperity, if not its very existence, to our natural resources. It is our responsibility to protect these renewable resources such as forests, soil, water and wildlife, for future generations, but so far we have largely ignored this obligation."

The destruction of our forest has proved most serious for it affects the rest of our resources, continued Mr. Kortright. Income loss from unwise deforestation is tremendous, and the folly of this practice is obvious when we realize that forestry products represent 30 per cent of the wealth created by our basic sources of production. Lumbering operations are conducted with little or no thought for the future.

In Ontario alone 85 per cent of once permanently flowing streams have become totally or temporarily dried up in part of the summer, thus lowering the ground water so vital to crops. Early farming methods resulted in wasteful exploitation of the soil. "We have been tragically slow to realize the vital importance of protecting our farmlands from erosion and loss of fertility", he added.

Plant tours were conducted to Victory Mills Limited; Canadian Breweries Limited; Canada Wire and Cable Company; Ford Motor Company of Canada Limited, Oakville; Canadian Industries Limited Works and Development Laboratories, and the British American Oil Company Limited refinery at Clarkson. Forty-five exhibits of chemicals and equipment were on display in the banquet hall during the convention.

# *Thirty-five Years Ago*

Comment on the *JOURNAL* of September 1919

The *Journal* for September, 1919, strikes this writer as rather dull. Excitement over the proposed model engineers' licensing act and over the bill to improve conditions in the Civil Service had receded from its peak. The two papers published were not outstanding. Council had little to report other than its routine activities. The personals referred mostly to members who were gradually returning to Canada after military service overseas. All in all, there seemed little to get excited about.

Returns from the letter ballot of June showed 475 votes in favour of the proposed model act, 138 against it and 3 spoiled ballots, a total of 616. As nearly as we can ascertain, there were then about 2,500 members entitled to vote, so those who exercised their franchise amounted to only about 25 per cent. This suggests that perhaps the issue had been receiving at least its full share of publicity. Quite apparently there were a good many members who weren't much interested, one way or the other, in trying to improve their status through legislation.

Council laid these returns on the table for future action "in view of the lengthy agenda." It also voted to buy 50 Institute badges in gold, 200 in silver and 250 in bronze and to sell them at $3.75, $2.25 and $1.50 each, respectively, "all complete and engraved with the member's name and badge number." It instructed the secretary to carry members' names on the rolls with their military titles. Council also ventured into the social field by "noting" a report on improving the education of Canadian children and by asking the Winnipeg Branch to appoint representatives to the "National Conference on Moral Education in the Schools in Relation to Canadian Citizenship". On the other hand, it refused to nominate a representative to the American Welding Society as "it was not feasible." Some load may have been lifted from Council's collective mind by the refusal of the American Association of Engineers to charter chapters in Canada.

The Civil Service bill was still somewhat in the limelight. The Toronto Branch thought the schedule of salaries suggested "not . . . adequate or reasonable" and urged "that . . . Council . . . take as energetic action as possible . . . to induce the Government to make such changes in this . . . reclassification as are necessary to provide a fair and proper remuneration to all engineers." But the Border Cities Branch wanted Council to support the proposed salary schedule as it stood.

On August 21, 1919, Montreal staged an uproarious welcome home to Gen. Sir Arthur Currie. In the course of an impromptu speech, Sir Arthur said, "I have always called a spade a spade. When a man was good, I promoted him if I could, and if he was not good, I fired him." Later in Sir Arthur's career, when he became principal of McGill University, he followed pretty much the same philosophy.

Lt. Col. Blair Ripley wrote on "Bomb-Proofing the Wimereux Viaduct." This three-span masonry bridge lay near Boulogne on the railway to Calais. Over it passed most of the supplies for the Allied front in Belgium, so its destruction would have been a calamity. More and more successful bombings by the Germans made it imperative to assure the safety of the viaduct so far as possible. This was accomplished by building timber arch centers for each of the three spans, similar to those used during construction, and by providing a "bomb bursting floor" on the deck. This floor was made of steel rails, laid parallel and alternately head up and base up. The efficacy of the scheme was never tested; the work was done in June, 1918, and the war ended the next November. In the intervening five months the Germans were too busy elsewhere to bother with the Wimereux viaduct.

The other paper in this *Journal* was "The Design and Construction of Reinforced Concrete Covered Reservoirs," by R. DeL. French. Filling 16 pages and with a number of charts and tables, it should have been of some help to the engineer of 1919 who was faced with the job of designing and building one of these structures. Changes in the basis of reinforced concrete design have made this paper obsolete, but it must have been some good, for it received a Gzowski medal.

Andrew Carnegie died on August 11, 1919, at Lenox, Massachusetts. The *Journal* devoted half a column to an appreciation of his interest in engineering; it will be remembered that he provided the funds for the United Engineering Societies building in New York, the home of the great engineering societies of the United States.

Woodstock, N.B., adopted the city-manager form of town government and made a contract with R. Fraser Armstrong, A.M.E.I.C., to act as its first manager. The *Journal* published the contract in full. It certainly gave Mr. Armstrong all the powers he could reasonably ask for.

A summary of questions asked by Civil Service employees and answered by the Commission in regard to classification was also given in this *Journal*. Some of them were from engineers; for example, one A.M.E.I.C. with six years of experience was told that his salary would be between $1,680 and $2,040. Most of the questions, however, came from clerks, accountants, etc.

# Correspondence

### More about Engineers in Government

In the June issue of the *Journal* I read in the Correspondence column the most thought-provoking letter I have read in years in our conservative organ. I am referring to the correspondent who asked for anonymity and who obtained it under the initials F.D.R., probably borrowed from one of the two great men known locally.

So "How would I like to be an M.P. ?" As you invited comments, either for or against, I shall supply you with both and leave to your discretion the question of anonymity. I share most of F.D.R.'s opinions, but I think some points might have been treated too superficially, which is quite understandable when one has to stay within the limits of a letter.

Let's pick some of these points. I quote: "It has been said many times that the qualities instilled into one by engineering training and experience are those that are needed badly by our legislators . . .".

### A Touch of Psychology

True, some legislators may learn from engineers to be more objective in their thinking. But, on the other hand, it cannot be generalized that the engineer's habit of thought can be applied directly to public problems. There are factors in life which cannot be put into equations. One can still be very objective in public affairs and add to the technical, the financial and the legislative, a touch of psychology. He must also take into account the past and the present and in doing so, he is so much more objective in his thinking. On this point, engineers can learn from other professions.

I quote again: "For example, engineers are impatient with delay . . . still less patient with cranks . . . their interest is generally limited to certain classes of people . . . co-workers . . . clients . . . Not many have great interest in the fisherman and the farmer . . . and the princes of the church . . ."

### Know Your Neighbour

F.D.R. must admit that a consulting engineer wanting to build up a clientele, does already practise those disagreeable tasks and for mercenary reasons. Why could this not be done for a much higher ideal ? I must concede that some politicians do it for mercenary reasons also, and very often far beyond the needs of their family. By the way, who invented baby kissing ? Certainly not the engineers.

Aside from the idea of meeting people only to get something out of, or from them, I think it is essential for any man in any profession to have a sincere interest in all classes of people . . . from the Prince of the Church to the fisherman. Wasn't He a fisherman ? And are we not supposed to practise what He preached ? At least, if we do not love our neighbour, we might try to know him.

I quote again: "In spite of valiant attempts on the part of the universities and on his own, to overcome the handicap, the engineer is still a rather dumb individual. He will talk to another engineer freely enough, or perhaps turn out a top-hole report . . ."

Some of our universities, according to engineers who made a success of their profession, have made valiant attempts to make engineers dumb and some have succeeded. In trying to cram very little of many subjects, the results may not be as good as the digesting of fewer subjects. As for the top-hole reports, maybe F.D.R. refers to top pigeon-hole reports. God knows how much effort some engineers will spend to undress their reports of any original idea or positive conclusion, thus following the training given by some of those valiant educators who have in mind success by the shortest and softest road.

### Praise of Being Dumb

By all means, being dumb may, in certain circumstances turn out to be an asset. Some statesmen have succeeded in staying in office for a whole generation without emitting any ideas lest they might have endangered their personal security or that of the party. I admit such a policy, if it is one, may have been preferable for the good of the country. Professional writers have been digging into the lives of some public men only to come out with the praise of being dumb when circumstances require such a course. Different times require different sorts of men. After all, F.D.R. should not despise the valiant attempts of some of our universities, whether those attempts are successful or not, insofar as engineers contemplate going into public life.

Here, I must introduce a rather incongruous parenthesis. At first sight, mathematics, or logics, seem universal; at least, we suppose they are in the physical world. But in the realm of human affairs, one should not contend too harshly that 2 and 2 make 4. That is all right between engineers, but in politics, it is preferable not to insist too much on such trivial conventions.

I quote again: "He seldom feels strongly enough on any non-technical matter to produce an article about it worth reading . . ."

I agree with F.D.R. that we should not boast about being ignorant of things not pertaining directly to our every-day technique. If that is the case for one of us, then it is a sign that he should take off his blinkers.

F.D.R. says: "Engineers are not familiar enough with what, for lack of a better term, are often called 'cultural subjects' . . ."

### Culture Is Universal

F.D.R. could have found the right term if only he had used the world "culture" instead of the periphrase "cultural subjects". Culture, by definition, is universal. It is not a matter of subjects. It is an atmosphere, a climate. It is something one breathes. It is a world to live in. It has quite remote relations with politics as understood today. Or, why such a fuss over Sir Winston who paints, writes and talks and puffs.

Though politics do not require a degree of any kind, it is commonly conceded that lawyers have been the most successful in the game, their training making them able to talk about anything at any time.

F.D.R. admits there are exceptions and he gives two names, Howe and Winters, to whom I bow, but not for the same reasons in each case. It is of public knowledge that even spelling is no obstacle in solving international affairs. Basic

English can save the world or blast it. As for one of the two ministers mentioned by F.D.R., I have read, written by him, one of the most enlightened papers on the national scale which no lawyer, nor doctor, nor financier could have brought forth. I take off my hat to that engineer-statesman, and I take off my hat twice to his ghost writer, if he has one. The world is full of ghosts anyhow.

#### Legislative and Executive

F.D.R. seems to confuse the legislative with the executive. The two engineers he mentions as having made a success in politics, are really serving the state in an administrative capacity, professional politicians putting up smoke screens to protect them from politicians of the other parties.

Ministers do not legislate, or at least they should not. Their job is to administer which, of course, implies much more direct responsibility than legislating. The members are only responsible towards the voters of their own constituencies. They usually judge of national affairs from a personal and local point of view. Very few up to now have been jailed for their mistakes. Ministers, on the contrary, are the responsible heads of workers in more or less specialized fields of state activity. They are responsible to the body of legislators for the way they handle the business entrusted to them, and they are also responsible to the nation at large, though they are shielded from the nation, more or less, by the M.P.'s who see that the decisions taken do not affect the rights of the majority, viz: the interests of the party.

#### Statesmen Are Scarce

To summarize, the qualities which make great statesmen are the same as those you will find in any great man in any field. As most discoveries, even in the technical field, have been made by men without training, or at least without degrees, statesmen have come from every walk of life, some with little learning, some with more, though learning certainly helps to compensate the other handicaps. Politicians are plentiful, statesmen are scarce. Politicians are the oysters, statesmen are the pearls.

Politics has been described as the art of looking for trouble, finding it everywhere, diagnosing it wrongly, and applying unsuitable remedies. And he who gets the votes is right.

An engineer would be quite naive if he should expect to apply to politics what he has been taught for years not to do. I guess this is the general idea of F.D.R.'s approach to the problem.

I trust, Mr. Editor, that I did not go beyond the physical limits of a letter, nor beyond the ethical limits of your *Journal*, but I think a good laugh once in a while cannot hurt. Politicians are the first to laugh even when the joke is on themselves. That is at least one lesson they can teach engineers.

Yours Politically,

JEAN ASSELIN, P. Eng., M.E.I.C.,
Montreal,
July 9, 1954

---

## News of Other Societies

The annual meeting of the **Canadian Chamber of Commerce** for 1954, is scheduled for October 4, 5, 6, 7 at the Nova Scotian, The Lord Nelson and the Carlton Hotels in Halifax.

Information is available from General Manager D. L. Morell, Board of Trade Building, Montreal 1, Que.

---

The newly formed **Canadian Institute of Timber Construction** reports activity in the preparation of design data and industry standards on timber construction, and work on building codes and standard specifications. Membership falls into three general divisions—timber fabricating companies, pressure treating companies, and trade extension organizations—with associate membership available to companies and individuals interested in structural timber. At the first annual meeting in March 1954, a broad plan of organization was made. The second annual meeting will take place in Montreal early in 1955.

R. F. DeGrace, of Ottawa, is executive vice-president and general manager of the Institute.

---

Towards the end of September every member of the **Toronto Engineering Alumni** will personally receive news of the 1954 Triennial Re-Union, October 29, 30, 31, in Toronto.

The executive of the Triennial Re-Union reports that plans are progressing, and that they expect one of the most popular events will be the dinner and dance on Friday night, October 29. The Engineering Alumni medals will be presented after the dinner.

First awarded in 1939, and regarded as one of the highest honors attainable by S.P.S. graduates, the Alumni Medal has become a symbol of engineering achievement.

---

The twenty-second annual meeting of the **Engineers' Council for Professional Development** (29-33 West 39th Street, New York 18) will be held on October 28-29, 1954, at the Hotel Alms, Cincinnati, Ohio.

---

The **American Concrete Institute** (18263 West McNichols Road, Detroit 19, Mich.) lists: the seventh regional meeting, October 28-29, 1954, Statler Hotel, Los Angeles, Calif.; the 51st annual convention, February 21-24, 1955, Hotel Schroeder, Milwaukee, Wis.

---

The **National Safety Council** (425 North Michigan Ave., Chicago 11, Ill.), will hold the National Safety Congress and Exposition in Chicago, October 18-22.

The Council, preparing the meeting for safety personnel in all fields —industrial, traffic, farm, school and home—expects an attendance of 12,000.

---

The 61st annual meeting of the **American Society of Heating and Ventilating Engineers** (62 Worth St., New York 13, N.Y.) will be held in Philadelphia, Pa., January 24-27, 1955.

---

A conference on "Plastics in Building", at the National Academy of Sciences in Washington, D.C., October 27 and 28, 1954, will be the seventh major conference to be conducted by the **Building Research Institute.**

Co-sponsors are the Society of the Plastics Industry (67 West 44th Street, New York 36); the Manufacturing Chemists Association, Washington, D.C.; and the Building Research Advisory Board.

---

Dr. R. Harding Bliss will be the editor of a new publication to be issued by the **American Institute of Chemical Engineers** (120 East 41st St., New York 17, N.Y.) starting in January 1955.

Dr. Bliss will continue his teaching program at Yale University, where he is professor of chemical engineering and fellow of Jonathan Edwards College.

---

The **Society of Automotive Engineers** (29 West 39th St., New York 18, N.Y.) announces meetings as follows: October 5-9, 1954, Hotel Statler, Los Angeles, Calif., national aeronautical meeting, aircraft production forum and aircraft engineering display; October 18-20, The Sheraton-Plaza, Boston, Mass., national transportation meeting and truck and bus engineering display; October 26-28, Hotel Statler, Cleveland, Ohio, national diesel engine meeting; November 4-5, The Mayo, Tulsa, Oklahoma, national fuels and lubricants meeting; January 10-14, 1955, golden anniversary annual meeting and engineering display, Sheraton-Cadillac Hotel and Hotel Statler, Detroit, Mich.

---

The **American Society of Mechanical Engineers** (29 West 39th Street, New York 18) lists the following meetings for the fall session: October 28-29, 1954, ASME-AIME joint fuels conference, William Penn Hotel, Pittsburgh, Pa.; and the ASME annual meeting, Statler Hotel, New York, November 28 to December 3.

---

The following conventions are scheduled by the **American Society of Civil Engineers** (33 West 39th St., New York 18): New York Convention, Hotel Statler, October 18-22, 1954; San Diego Convention, Hotel U.S. Grant, February 6-11, 1955; St. Louis Convention, Jefferson Hotel, June 13-17, 1955.

---

# The ASME Boiler Code

### Interpretations

The Boiler Code Committee meets monthly to consider "Cases" where users have found difficulty in interpreting the Code. These pass through the following procedure (1) Inquiries are submitted by letter to the Secretary of the Boiler Code Committee, ASME, 29 West 39th Street, New York 18, N.Y.; (2) Copies are distributed to Committee members for study; (3) At the next Committee meeting interpretations are formulated to be submitted to the ASME Board on Codes and Standards, authorized by the Council of the Society to pass upon them; (4) They are submitted to the Board for action; (5) Those which are approved are sent to the inquirers and are published in Mechanical Engineering.

The following Case Interpretations were formulated at the Committee meeting June 11, 1954.

#### Case No. 1190
Special Ruling

***Inquiry:*** Will the use in pressure vessels of bronze castings conforming to ASTM Specification B-143-52 meet the intent of Section VIII of the Codes. ?

***Reply:*** It is the opinion of the Committee that the use of castings conforming to ASTM Specification B-143-52 will meet the intent of Section VIII of the Code, provided no welding of this material is involved.

The maximum allowable design stresses given in Table UNF-23 for SB-61 will apply.

#### Case No. 1191
Special Ruling

***Inquiry:*** When alpha aluminum bronze alloy plates, sheets, pipes, tubes and shapes conforming to an approved specification are used for the construction of vessels to be used for external pressure, under what rules shall they be designed and fabricated. ?

***Reply:*** It is the opinion of the Committee that alpha aluminum bronze alloy plates, sheets, pipes, tubes and shapes that conform to an approved specification may be used for the construction of external pressure vessels and the vessels may be stamped with the Code symbol providing the following requirements are complied with:

(1) The applicable rules in the 1952 edition of Section VIII of the Code covering vessels under external pressure when constructed of nonferrous materials shall be adhered to.

(2) The thickness of shells and heads and the required moment of inertia for stiffening rings shall be determined from the charts in Fig. UNF-28.14 for alpha aluminum bronze and in Par. UNF-30.

The chart is available from the Committee.

#### Annulment of Cases

| *Case No.* | *Reason for Annulment* |
|---|---|
| 1053 | Seamless tubing is readily available. |
| 1074 | External pressure vessel charts are now available. |
| 879<br>1022<br>1165<br>1176 | The provisions of these Cases are now included in the 1953 edition of Section IX, Welding Qualifications. |
| 1146<br>1150 | These two Cases are no longer emergency alternate provisions. |
| 1136 | Government restriction on molybdenum has now been cancelled. |
| 1158 | The provisions of this Case are included in Section II, 1952 Edition. |

### Proposed Revisions and Addenda to Boiler and Pressure Vessel Code

As need arises, the Boiler Code Committee entertains suggestions for revising its Codes. Revisions approved by the Committee are published here as proposed addenda to the Code to invite criticism.

In the following the paragraph numbers indicate where the proposed revisions would apply in the various sections of the Code.

Comments should be addressed to the Secretary of the Boiler Code Committee, ASME, 29 West 39th Street, New York 18, N.Y.

#### Power Boilers, 1952

***Par. P-111.*** Add the following as a third sentence —

Furnaces shall be rolled to practically a true circle with a maximum permissible deviation from the true circle of not more than ¼".

***Par. P-11.*** Add the following specification reference to the end of paragraph SA-369, Ferritic Alloy Steel Forged and Bored Pipe for High Temperature Service.

#### Ring Reinforced Furnaces

The original inquiry regarding Ring Reinforced Furnaces came from the Dominion Bridge Company, Ltd. of Canada on April 8, 1947. From that date on there were a number of inquiries involving similar construction. Although not providing for the construction proposed, these inquiries did result in Case No. 1101, (June 1949) which subsequently became a revision in Paragraph 242 (4) permitting the assembly of an Adamson Furnace by welding.

On November 10, 1950 we again received an inquiry on this same subject. Following this inquiry it was suggested that such a furnace be built and tested in service. After reporting the plan to the Boiler Code Committee on May 1, 1951 (Item 51-065), a number of interested manufacturers co-operated in raising funds for that purpose and the program was carried out. After careful consideration of the various design problems, the test furnace of the design shown on sketch No. A10-196-1 (available from the Committee) was built and installed in a boiler that was placed in operation at the Adelman Laundry in Milwaukee. The test in service began on May 6, 1953.

The boiler was operated 5½ full days per week during the test period, the total number of days the boiler was actually fired was 130. The burner was equipped with high-low controls, and in operation the burner was permitted to swing between the high and low fire in accordance with steam demand. The average number of reversals in a working day was about 125.

An inspection by the Fire Tube Sub-Group, and guests, was made after the boiler was shutdown on October 1, 1953. This inspection showed that there were no signs of overheating in any section of the furnace and no other signs of distress of any nature. The original roundness tolerance after construction of the furnace was ⅛". This was gauged and found to have remained unchanged.

The Sub-Group on Fire Tube Boilers then began the development of proposed rules for the construction of Ring Reinforced Furnaces. Steam from the boiler was not needed until approximately February 1, 1954. On that day the boiler was again put into operation with the same burner adjustments that were observed by the Sub-Group. On February 15 the boiler operator observed distortion in the front end of the furnace between the front head and the first and second supporting rings. The boiler was immediately taken out of service, drained and opened for inspection.

The distortions appeared between the head and the 1st ring and between the 1st and 2nd rings. Between the head and the 1st ring there was ¼" distortion at 1 o'clock, a ¼" distortion at 5:30 o'clock. It might be noted that the long seam of the furnace was located at 6 o'clock. In the section between the 1st and 2nd rings the distortions were as follows: two ¾" at 1 o'clock, one 9/16" at 3 o'clock with a continuous ⅝" distortion between them. There were two ¾" distortions located on either side of the long seam at 6 o'clock. The areas at the reinforcing rings were carefully checked with a templet accurately formed to the inside diameter of the furnace. At the rings and the furnace plate immediately adjacent to the rings there was no more deviation from a tube than when the furnace was originally formed.

An examination of the tubes showed that the first tubes in the 2nd, 3rd, 4th, 7th and 8th rows from the bottom on both sides of the furnace had been bowed outwardly toward the shell. Two tubes above the furnace at approximately 12 o'clock were bowed upward. The maximum distortion was in the tubes in the 2nd and 3rd rows from the bottom. This maximum distortion was estimated by sight to be approximately 2″. The other tubes in the rows mentioned were bowed to a lesser extent.

Hand hole plates were removed and a coating of oil was observed on all of the tubes accessible through the openings, being heaviest on the upper rows. Subsequently investigation showed that a serious deposit of oil covered the internal surfaces of the boiler. The oil entered the boiler from a reciprocating engine.

The fact that the damage was in the zone forward of the 2nd supporting ring may have been due to the location of a refractory collar just to the rear of the 2nd supporting ring. The collar extends into the furnace 7½″, is 9″ wide and is provided to improve combustion of the fuel.

While the accidental introduction of oil into the boiler with the results described above is regretted, this occurrence gave the ring reinforced furnace a more severe and conclusive test than any that could be devised by the Sub-Group, short of lowering the water level until the furnace was damaged.

The Cleaver-Brooks staff in its original calculations had shown that the heat transfer through a furnace wall supported by rings was greater underneath the rings. The inspection made on October 1st by the Committee revealed that, to all appearances, the furnace plate had remained cooler under the rings than between them. As a matter of fact the location of the rings could be determined from the inside of the furnace from the color of the plate. The inspection made on February 17, 1954 further substantiates these calculations in that all distortions occurred between the rings and feathered out to zero adjacent to the rings themselves. The additional heat transfer from the furnace wall to the surface of the reinforcing rings kept the furnace tube itself cooler in the areas adjacent to the rings. This prevented the serious deformation of the furnace tube.

This proposed construction is not new and untried. Ring reinforced furnaces have been built in this country and used in non-code jurisdictions. As far as is known, no unsatisfactory experience developed. Investigation developed furnaces of this type are also quite common in Great Britain. The British rules follow their formula for Adamson Ring Furnaces and place restrictions on the ring width and depth.

The Sub-Group on Fire Tube Boilers recommends the following revisions for the construction of Ring Reinforced Furnace be incorporated in Par. P-242 and in order to give members a chance to study this report that action on the proposal for adoption and publication be held over until its June Meeting.

***Par. P-242, Adamson Type.*** Revise present Par. P-242 to Par. P-242(a) and add the following as (b):

(b) ***Ring Reinforced Type.*** Horizontal circular flues or furnaces (Fig. P available from the Committee) may be constructed with completely circular reinforcing rings provided:

1. The reinforcing ring is rectangular in cross section and is fabricated from one piece of plate, or from plate sections or bars provided full penetration welds are used in assembling.

2. The reinforcing ring after fabrication has a thickness of not less than 5/16″ and not more than 13/16″ and in no case thicker than 1¼ times the furnace wall.

3. The ratio of the height of the reinforcing ring to its thickness ($H_r/T_r$) is not over 8 or less than 3.

4. The reinforcing ring is attached to the furnace by a full penetration weld on each side.

5. The thickness of the furnace wall or flue is a minimum of 5/16″ and a maximum of 13/16″.

6. The spacing of the rings on the furnace, $L$, is no greater than $60t$ or 36″ whichever is smaller.

7. In the use of chart, (Fig. P-), the temperature of the metal is taken as 100°F higher than the water temperature.

8. The furnace design permits replacement. A flared or welded OG ring would be an acceptable assembly.

9. The completed furnace assembly is stress relieved but radiographic examination is not required.

10. The thickness of the furnace wall and design of stiffening rings are determined by the use of Fig. P-. The notations defined below, and shown in Figs. P- and P- are used in the formulas of this paragraph:

= minimum required wall thickness of furnaces or flues, inches.

$L$ = design length of a furnace section, taken as the greatest center to center distance between any two adjacent stiffening rings; or the distance from the center of the first stiffening ring to the center of the furnace weld attachment, inches. In case a flared end assembly is used the distance shall be measured to the point of tangency between the flare and the furnace and the adjcent stiffening ring.

$D_o$ = outside diameter of furnace or flue, inches.

$P$ = design pressure, pounds per sq. inch.

The required wall thickness of a ring reinforced furnace or flue shall not be less than that determined by the following procedure:

1: Assume a value for $t$ and $L$. Determine the ratios $L/D_o$ and $D_o/t$.

2: Enter left-hand side of Fig. P- –. (This figure will be the same as Fig. UCS-28.2 in Section VIII) at value of $L/D_o$ determined in step 1.

3: Move horizontally to the line representing $D_o/t$ determined in step 1.

4: From this intersection move vertically to the material line of the proper temperature.

5: From this intersection move horizontally to the right and read the value of $B$.

6: Compute the allowable working pressure $P_a$ by the following formula:

$$P_a = \frac{B}{D_o/t}$$

7: Compare $P_a$ with $P$. If $P_a$ is less than $P$, a greater value of $t$ must be selected or a smaller value of $L$ or some combination of both to increase $P_a$ so that it is equal to or greater than $P$. (An example is shown in Appendix A-200).

The required moment of inertia of a circumferential stiffening ring shall not be less than that determined by the formula:

$$I_s = \frac{D_o 2\, L\, (t + \frac{A_s}{L})\, A}{14}$$

where: $I_s$ = required moment of inertia of the stiffening ring about its neutral axis parallel to the
4.
axis of the furnace, inches

$A_s$ = cross-sectional area of the stiffening ring, square inches.

$A$ = factor determined from Fig. P- –.

$P$, $D_o$, $L$, and $t$ are as defined above.

The moment of inertia for a stiffening ring shall be determined by the following procedure:

1: Assuming that the furnace has been designed and $D_o$, $L$, and $t$ are known, select a rectangular member to be used for a stiffening ring and determine its area, $A_s$, and its moment of inertia, I. Then calculate $B$ by the formula:

$$B = \frac{P D_o}{t + \frac{A_s}{L}}, \text{ where;}$$

$B$ = factor on the right-hand side of Fig. P- –.

$P$, $D_o$, $t$, $A_s$ and $L$ as defined above.

2: Enter the right-hand side of Fig. P- – at the value of $B$ determined in step 1.

3: Follow horizontally to the material line for the correct temperature.

4: Move down vertically to the bottom of the chart and read the value of $A$.

5: Compute the value of the required moment of inertia $I_s$, from the formula given above.

6: If the required $I_s$ is greater than the moment of inertia, $I$, for the section selected in step 1, a new section with a larger moment of inertia must be selected and a new $I_s$ determined. If the required $I_s$ is smaller than $I$ for the section selected in step 1, that section should be satisfactory. (An example is shown in Appendix A-201.)

The longitudinal and circumferential joints may be fusion welded of the double-welded butt type, the only requirements being that the welds are stress-relieved in accordance with Par. P-108 and a bend test of a sample of the welding for each furnace meets the requirements of Par. P-102, no radiographic examination being required.

### Heating Boilers, 1952

***Pars. H-31 and H-88.*** Revise to read:

It is recommended that dimensional requirements of bolted flange connections to external piping conform to:

Steel Pipe Flanges and Flanged Fittings ASA B16e 1953.

Such flanges may be used for pressure-temperature ratings in accordance with the Standard.

Steel flanges may also be designed in accordance with the rules in Appendix II of Section VIII for the design pressure and temperature conditions. The outside diameter and bolting shall conform to a recognized ASA Standard.

### Unfired Pressure Vessels, 1952

***Appendix Q, Pars. UA-601 (b) and UA-602 (b).*** Revised to read:

(1) 1/5 of the tensile strength as adjusted to minimum; and

(2) ¼ of the yield strength (as defined in the material specifications) as adjusted to minimum.

# NEWS OF THE ASSOCIATIONS & CORPORATION

**Information received through co-operation with the provincial organizations**

## Quebec

### Tournoi Provincial de Golf

Un tournoi de golf provincial pour les ingénieurs a été organisé pour la première fois cette année au Manoir Richelieu à La Malbaie.

Au delà de 100 joueurs ont participé au tournoi qui a été favorisé d'une température idéale.

Le champion golfeur de 1954 pour la province de Québec est M. Charles E. Rochette, qui a réussi un pointage brut de 88 dont 39 pour le premier neuf et 49 pour le second. Il a détaillé pour la première position avec MM. Guy Sicotte et René Dansereau qui avaient également enregistré un pointage de 88.

Chez les dames, Mme J. P. Drolet s'est classée première. M. Henri Savoie a mérité la première place parmi les invités.

### C.P.E.Q.'s 5,000th Member

The number of professional engineers registered in the Province of Quebec passed the 5,000th mark last spring. The 5,000th member was a lady, Mrs. Per Hall, wife of a vice-president of the Foundation of Canada Engineering Corporation Limited (FENCO).

At a brief ceremony during the annual meeting, president R. F. Shaw noted this as follows:

"I would now ask Mr. Per Hall, Professional Engineer, if he would be good enough to escort Mrs. Hall to the head table.

On any winter week-end this vigorous "Great Dane" can be seen skiing too fast down too big hills followed by this brave lady.

On any summer week-end they can be found sailing a too little boat over a too big wave.

At almost any time you will find engineering principles being applied by this charming hostess to the entertainment of what most of us would consider too many guests. But on week days, Nina Hall will be found in the home draughting room (for which it is rumoured she pays rent) designing and detailing structures.

Ask Per Hall to solve a knotty engineering problem and he will ask for time to "think it over". I hope he pays a fee.

Nina Hall—athlete, hostess, housewife, professional engineer — and the mother of three delightful children.

Mrs. Hall—Canada is most fortunate that you and your fine husband chose to become her citizens. Your profession is proud to welcome you as the five thousandth member of the Corporation."

### Third Permanent Officer At Headquarters

A larger membership plus overworked staff equals a requirement for additional help. The president and Council of the Corporation are pleased to announce the recent appointment of Mr. J. H. Legere, to the permanent office staff. This appointment will allow the Corporation to continue and to extend the many activities now being carried out for the protection of the public and the betterment of the engineering profession, and should do much to "balance" the above equation.

Mr. Legere began his career when he graduated from St. John Vocational School in 1940 with a certificate in Wireless Telegraphy and Radio Maintenance. During the following five years, until May, 1946, he was engaged in the maintenance and operation of heavy wireless stations in Canada and overseas, for the Canadian Army Signal Corps, first as a signalman, and later as an administrative officer.

Following demobilization, he registered in the Faculty of Engineering at McGill University, and graduated in 1950 with the degree of Bachelor of Engineering Physics. He became a member of the Corporation in the same year.

Mr. Legere's experience since graduation has been divided between the Bell Telephone Company of Canada, where he spent 2½ years on transmission engineering and traffic administration, and Canadian Aviation Electronics Ltd., where he acted as assistant to the chief

**C. E. Rochette, at right, receives from President G. Demers, the Corporation's trophy awarded to the best golfer in the provincial golf tournament for professional engineers.**

J. H. Legere.

Five Cavanagh brothers got together at the Engineer's Club in Toronto recently to fete brother J. Richard who has just gone into private practice. Left to right are: Daniel, Patrick, of Toronto; Robert, of New Jersey; Raymond and J. Richard. All are members of The Association of Professional Engineers of Ontario.

engineer for approximately one year, and assistant to the vice-president, Engineering and Manufacturing for a period of approximately 6 months.

Mr. Legere brings with him a wealth of engineering administrative experience, gained in his work and by participation in business administration and management courses through the Extension Department of McGill University.

## Ontario

### Changes in Highways

A reorganization of the Highways Department of the Province of Ontario has affected a considerable number of members of the Association.

Among the changes is the appointment of M. A. Elson, as deputy minister.

Heading the administration is the deputy minister and the chief engineer, W. A. Clarke. This in turn is broken down into five sections as follows: director of planning, W. J. Fulton; services manager, C. A. Robbins; financial comptroller; directors of personnel, to be appointed; and the registrar of motor vehicles.

P. M. Higgins, is named as consultant to the chief engineer, W. A. Clarke; W. Q. MacNee, traffic study section; and K. H. Siddall, location surveys section.

Other branches of the Department are: construction engineer John Walter; bridge engineer H. N. Lamont; maintenance engineer, C. Tackaberry, and municipal engineer, J. V. Ludgate. Consultants to the foregoing are: T. F. Francis (construction); A. Sedgwick (bridges); J. M. MacInnes (municipal).

Other appointments in the head office group include: J. P. Howard, and H. Irwin, municipal regional engineers; H L. Main, special projects engineer; H A. Tregaskes, contract control engineer; F. C. Brownridge, materials and research engineer; D. G. Ramsay, R. E Clarke, and H. W. Adcock, inspecting engineers.

New appointments affecting division engineers include: B. R. Heavysege, Stratford; H. C. Dernier, Huntsville; R. A. Panter, North Bay; J. B. Wilkes, Cochrane; E. A. Cash, Fort William; E. H Jones, Kenora; G. F. Wetherall, New Liskeard.

## British Columbia

### Public Relations Officer

R. M. Williams, M.B.E., of Vancouver, has been appointed Public Relations Director of the B.C. Engineering Society, effective July 15.

He will work from the offices of the Society at 1166 West Pender Street, as an integral member of the staff, to develop further the program which was approved by letter ballot of the membership and effectively initiated last year through the Public Relations Committee with the assistance of Mrs. Margaret Ecker Francis.

A review of this program is now being undertaken by the Committee, and a report on future plans and procedure will be published in the *B.C. Professional Engineer*.

Mr. Williams was born in Vancouver 46 years ago, and was active in local advertising and publicity until the last war, in which he served overseas as Public Relations Officer with the R.C A.F. Since then, as Chief of the Advertising and Publicity section of the Information Division of the Department of Trade and Commerce, in Ottawa, he was responsible for setting up the publicity organization for Canada's biggest international public relations effort, the Canadian International Trade Fairs. Among his other responsibilities was the public relations organization for the decennial census of Canada. He returned to Vancouver two years ago as Western Canada representative for the Financial Times.

This concrete slab, for the grandstand at Portage la Prairie, Manitoba, was precast and raised according to the patented Youtz-Slick system of lifting slabs. Structural design was done by Cowin and Company Limited, structural engineers; the lifting contractor was F. R. Lount and Sons; the general contractor was James F. Hamilton.

# Personals

## News of the Personal Activities of Members of the Institute

**T. R. Loudon,** M.E.I.C., has retired as head of the University of Toronto's civil engineering and aeronautical engineering departments. He will be associated with the design office of DeHavilland Aircraft Company.

Prof. Loudon has been actively interested in aeronautics for many years. At the University of Toronto, he was the classmate and associate of two pioneers in aviation: J. A. D. McCurdy, later the lieutenant governor of Nova Scotia, who in 1909 was the first man to fly a plane in Canada, and Casey Baldwin, first Canadian to pilot an aircraft—this was in 1908.

Prof. Loudon graduated in civil engineering from the University of Toronto in 1906. He went on the staff of the University in 1907 as a lecturer in the applied science and engineering faculty. Thus he joined his father, W. J. Loudon on the university staff, the elder Loudon having been professor of mathematics and physics for some years.

During World War I he served with the Royal Engineers overseas, and was mentioned in despatches. At the end of the war, holding the rank of major, he returned to the University as an associate professor. He commanded the University C.O.T.C. contingent, with the rank of lieutenant-colonel. Prof. Loudon's interest in aviation had been maintained since those early days of flying, and after the war he pursued the study of aerodynamics and other related subjects, which he subsequently taught when these were introduced in the engineering curriculum. He was later appointed professor of applied mechanics, and in 1943 he succeeded Dean C. R. Young as head of the Department of Civil Engineering, with the title of professor of civil engineering and aeronautics. It was in 1945 that the department of aeronautical engineering was created, and Professor Loudon was appointed to head it as well.

During his many years of academic work he was also active in the practice of civil engineering, first with the firm of Harkness, Loudon and Hertzberg. After 1929 he maintained his own practice as a consultant in civil engineering and in later years transferred his interest to aeronautical engineering.

Because of Prof. Loudon's advance knowledge and prominence in Canadian aviation he was selected to command the first school of aeronautical engineering organized in Montreal in 1940 under the British Commonwealth Air Training Plan. He was promoted to the rank of Wing Commander in the R.C.A.F. in 1940, and was appointed chief technical officer of the R.C.A.F. Test and Development Establishment in Ottawa. He became commanding officer in May 1941. On his return two years later to Toronto he retained his liaison with the armed forces, commanding the R.C.A.F. Air Training Corps at the University of Toronto.

Prof. Loudon joined the Institute as an Associate Member in 1910, transferring to Member in 1919. He was chairman of the Toronto Branch, served on the Council, and he was a vice-president in 1930-31. He acted on many of the committees of Council, notably as chairman of the Service Bureau Committee, under the direction of which the system of the Employment Service Bureau was extended in 1928 and the "E.I.C. News" was established as a weekly news and employment bulletin. He is also a member of the recently formed Canadian Aeronautic Institute, in which he is an honorary fellow. He is a past president of the Toronto Flying Club, and holds a private pilot's licence.

Prof. Loudon has been a lifelong devotee of athletics, and for many years coached the University of Toronto rowing teams, not to mention his interest in other sports. He was elected president of the Amateur Athletic Union of Canada in 1929. He still maintains his interest in sailing as an active member of the Royal Canadian Yacht Club.

**Sir Godfrey Rhodes,** M.E.I.C., consultant to the firm Peter M. Amcotts & Partners, Nairobi, Kenya Colony, visited in Canada recently. He accompanied a team of athletes from Kenya to the Empire Games in Vancouver.

C. K. Lockwood, M.E.I.C.

**C. K. Lockwood,** M.E.I.C., vice-president of the stainless steel and alloys division of Shawinigan Chemicals Limited in Montreal, was elected president of the Alloy Casting Institute at the Institute's annual meeting in New York in June.

Originally from Brighton, Ont., Mr. Lockwood graduated from McGill University with a chemical engineering degree in 1934 and with a metallurgical engineering degree in 1935.

He joined Shawinigan Chemicals in 1937 and was appointed sales manager of the stainless steels and alloys division in 1945. In January of 1953 he became vice-president, and this year was elected to the board of directors of the company.

Mr. Lockwood has been active in the American Society for Metals, serving as chairman of the Montreal chapter, as well as in the National Research Council in Ottawa. He was on loan from Shawinigan in 1951 and 1952, serving as chief of the stainless steels section, steel division of the Canadian Department of Defence Production.

**Dr. Albert R. Decary,** M.E.I.C., superintending engineer for the Province of Quebec, has retired after 54 years in the Department of Public Works, of Canada. He is a past-president of the Engineering Institute.

Dr. Decary was born in Montreal. After having completed an arts course at College Ste. Marie, Montreal, he later attended Ecole Polytechnique. Upon graduation he engaged in private practice in Montreal. In 1900 he entered

***The 69th Annual Meeting***

*of*

THE ENGINEERING INSTITUTE OF CANADA, TORONTO, ONT.

ROYAL YORK HOTEL, MAY 11, 12, 13, 1955

the public service as an engineer on the hydrographic survey of the St. Lawrence River, and five years later he was promoted to the position of district engineer at Quebec. In 1913 he was named superintending engineer for the Province.

Dr. Decary represented the Government of Canada at the World Conference of the Permanent Association of Navigation Congresses held in Philadelphia in 1912.

He was intimately connected with all important river and harbour works of the Dominion Government, including the Champlain drydock at Quebec and the Esquimalt drydock in British Columbia. In connection with this latter undertaking he was chairman of the board of engineers specially entrusted with the designing and preparation of all plans.

Dr. Decary joined the Engineering Institute in 1900 as an Associate Member and in 1907 transferred to Member. He was elected a councillor in 1914 and continued as such until 1924 when he became a vice-president. He was named president of the Institute in 1927.

When the Quebec Branch was formed in 1907 he was one of the charter members and a member of the first executive committee. He was chairman of the Branch for eight years and upon his retirement from active chairmanship, the Branch elected him honorary chairman for life.

Dr. Decary was a charter member of the Corporation of Professional Engineers of the Province of Quebec and served as its president from 1919 until 1938. He is a charter fellow of the Royal Architectural Institute of Canada and a member of the Province of Quebec Association of Architects, the Permanent Association of Navigation Congresses and l'Institut Canadien de Quebec. He is also president of the Town Planning Commission of Quebec.

He was honoured by the University of Montreal and Laval University with the degree of doctor of science.

**H. Lloyd Johnston,** M.C., M.E.I.C., has been appointed chief engineer of Du Pont Company of Canada Limited.

A native of Vancouver, B.C., Mr. Johnston was educated at the University of British Columbia and at McGill University where he received his degree in civil engineering in 1927. That same year he joined the Canada Power and Paper Corporation and served with that company until 1936 when he became associated with Canadian Industries Limited at Windsor, Ont., where he rose to the position of works manager. After 12 years in Windsor, he returned to Montreal as assistant chief engineer in 1950.

Mr. Johnston is a veteran of both wars, having served overseas with the Canadian Expeditionary Force in World War I, and with the 30th Reconnaissance Regiment Reserve during World War II. He was awarded the Military Cross for his services in the first war.

Mr. Johnston is a past chairman of the Border Cities Branch of the Engineering Institute.

**Howard W. Umphrey,** M.E.I.C., has been appointed chief engineer of Canadian Industries (1954) Limited.

A native of Miami, Man., Mr. Umphrey received his early education there. He then obtained his B.A. degree

H. Lloyd Johnston, M.E.I.C.

H. W. Umphrey, M.E.I.C.

from McMaster University and his S.M. degree in mechanical engineering from Harvard University.

Mr. Umphrey joined the company in 1934 as a construction engineer. He became works engineer of the alkali plant at Cornwall and two years later was transferred to the engineering department in Montreal as a design engineer.

In 1939 he was appointed works manager of the alkali plant at Shawinigan Falls, Que., and in 1943 was named acting production manager of the chemicals department in Montreal.

During World War II he was on loan to Defence Industries Limited as resident engineer of construction at the de Salaberry, Que. plant. He became production manager of the chemicals department of Canadian Industries Limited in 1948 and was employed in that capacity until his recent appointment.

**H. D. Davison,** M.E.I.C., chairman of the board of Welland Electric Steel Foundry Limited in Welland, Ont., has been elected chairman of the Niagara Peninsula Branch of the Engineering Institute. *(Continued on page 1126)*

(*Continued from page 1120*)

**H. D. Davison,** M.E.I.C.

Mr. Davison was born in Bridgewater, N.S. He received his early education at St. Andrews College, then in Toronto, and graduated with the degree of B.Sc. in mechanical engineering from the University of Toronto in 1913.

Upon graduation he was employed by the Welland Ship Canal until 1916. The following year he joined the British American Shipbuilding Company at Welland.

In 1924 Mr. Davison founded his own business, Welland Electric Steel Foundry Limited. The company at present operates a foundry and pattern shop, machine and fabricating shops engaged in the manufacture of articles in carbon, alloy and manganese steels, and specializing in stainless steel which the company first made in 1928.

**A. Gordon Murphy,** M.E.I.C., port manager of Montreal for the past seven years, has been appointed to the post of chief engineer of the St. Lawrence Seaway Authority.

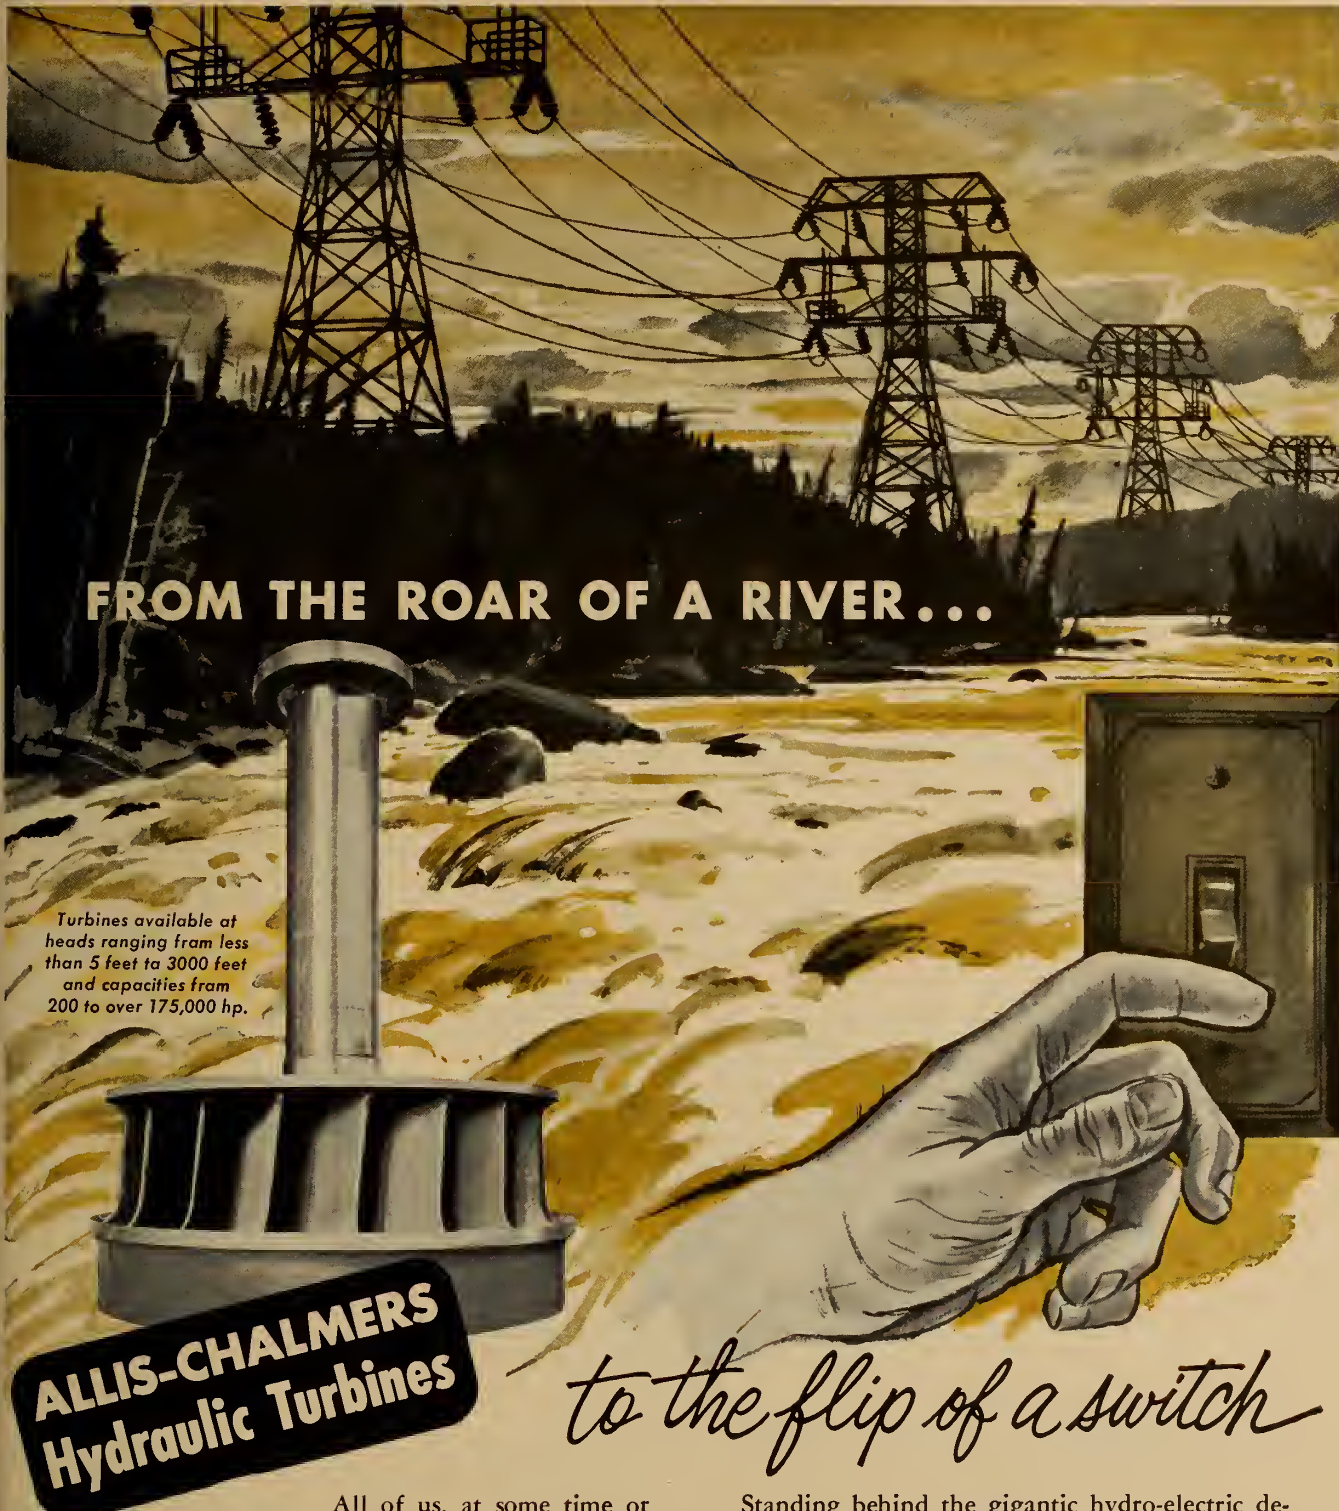
Mr. Murphy began his engineering career in 1917 when he served as inspector on the Quebec Bridge construction. After graduation from McGill University in 1922, he joined the Department of Railways and Canals as bridge and structural engineer on the Welland Canal until 1931, and for the next five years, was employed on the Hudson Bay terminal and elevator construction at Prescott.

He joined the National Harbours Board in 1936 as an assistant engineer and in April, 1947, was appointed to the position of port manager in Montreal.

**T. R. McLagan,** O.B.E., M.E.I.C., president and general manager of Canada Steamship Lines Ltd., has been appointed a member of the board of directors of Canadian Liquid Air Company Limited. Mr. McLagan is a director also of Canadair Ltd., Abitibi Power and Paper Co. Ltd., the Electric Boat Corporation.

A graduate of Lower Canada College and McGill University in mechanical engineering, Mr. McLagan began his engineering career with the Laurentide Company in Grand'mere, Que., in 1924, and has been successively a partner in Dufresne, McLagan & Associates, Montreal industrial consultants, and president and general manager of Canadian Vickers Limited in Montreal. He was appointed to his present position with Canada Steamship Lines in 1951.

**T. R. McLagan,** M.E.I.C.



All of us, at some time or another, have stared into a turbulent river and marvelled at its power. Rushing, tumbling, stumbling along its bed, it suddenly falls into man-made traps.

Little do we realize the important part great rivers with hydro-electric power stations play in our every-day lives. With the flick of a finger whole cities come ablaze, our homes are taken from darkness, and the wheels of industry begin to roll.

Standing behind the gigantic hydro-electric developments in Canada is Allis-Chalmers. They make the turbines, valves, pumps, electric motors and a host of other high quality products vital to our great power networks.

There's hardly an industry contributing to your better living today that isn't serviced at some point by Allis-Chalmers. For further details contact Canadian Allis-Chalmers Ltd., P.O. Box 37, Montreal, Quebec.

# CANADIAN ALLIS-CHALMERS

54-CAC-2

Lt. Col. C. G. Kirby, M.E.I.C.

**Lt. Col. C. Gordon Kirby,** M.B.E., M.E.I.C., has relinquished his position as assistant director of electrical and mechanical engineering at Army headquarters in Ottawa, to take up the new appointment of command electrical and mechanical engineer at Halifax, N.S.

Lt. Col. Kirby received his B.Sc. degree in mechanical engineering from the University of Saskatchewan in 1936. Previous to the war he was employed with the Vulcan Iron Works in Winnipeg, Man.

Lt. Col. Kirby was first commissioned in the Royal Canadian Engineers and in 1942 was appointed to the Royal Canadian Ordnance Corps and later to the Royal Canadian Electrical and Mechanical Engineers. He served with the R.C.E.M.E. in the United Kingdom, Italy and northwest Europe. Since the war he has held various R.C.E.M.E. appointments in Petawawa, Regina, Montreal and Ottawa.

He is a member of the Association of Professional Engineers of Saskatchewan.

**F. A. Dagg,** M.E.I.C., assistant to the general manager of Saguenay Terminals Limited and Roberval and Saguenay Railway in Arvida, has been elected chairman of the Saguenay Branch of the Engineering Institute.

Mr. Dagg was born at Holland, Man. He received his general education at the high school there and proceeded to the University of Manitoba where he gained his B.Sc. degree in civil engineering in 1929.

F. A. Dagg, M.E.I.C.

Upon graduation he joined the Winnipeg Hydro Commission to work on concrete design. In 1930 and 1931 he was employed as steel foreman for Stuart & Grant Ltd., and on bridge design for Manitoba roads. After three years in non-engineering work he became a construction engineer with the Kanuchuan Power Company.

In 1936 he was appointed district engineer with the Prairie Farm Rehabilitation and continued as such until 1940 when he joined Ducks Unlimited in Winnipeg, Man. as construction engineer.

Mr. Dagg entered the Aluminum Co. of Canada Ltd. in 1942 as a concrete design and detail engineer, working later as a construction engineer. In 1944 he was appointed superintendent of the atomizing plant at Isle Maligne, and the following year, superintendent of industrial engineering in Arvida. He was later named resident engineer in charge of construction on the Chute-à-la-Savane power house, and in 1953 he was appointed engineering assistant to the general manager of Saguenay Terminals Limited. Mr. Dagg came into his present position this year.

**W. O. Richmond,** M.E.I.C., head of the department of mechanical engineering of the University of British Columbia, has been elected chairman of the Vancouver Branch of the Engineering Institute.

W. O. Richmond, M.E.I.C.

Professor Richmond was born in Rouleau, Sask. He obtained his B.A.Sc. degree in mechanical engineering from the University of British Columbia in 1929, and in 1933 his M.Sc. degree in mechanical engineering from the University of Pittsburgh.

Upon graduation from the University of British Columbia he joined the Westinghouse Electric and Manufacturing Company in East Pittsburgh as research engineer in the mechanics division. He remained there until 1934. During 1935-36 he was research assistant in the testing materials laboratory of the Massachusetts Institute of Technology, and the following year became instructor in mechanics and materials at the Case School of Applied Science in Cleveland, Ohio.

He joined the mechanical engineering staff of the University of British Columbia in 1937 as assistant professor of mechanical engineering. He was named associate professor in 1943, and four years later, professor of mechanical engineering. He has been head of the mechanical engineering department since 1950.

The summer months from 1941 to 1946 were used for engineering work with the Powell River Co. Ltd., in Powell River, B.C., United Shipyards Ltd., in Montreal, Boeing Aircraft Company of Canada Ltd. in Vancouver, the B.C. War Metals Research Board, the B.C. Research Council, and Consolidated Mining and Smelting Co. Ltd. in Trail, B.C.

Professor Richmond is a member of the American Society of Mechanical Engineers and the Association of Professional Engineers of British Columbia.

**Dr. E. G. Faludi,** M.E.I.C., has been elected president of the Town Planning Institute.

Dr. Faludi is president and managing director of Town Planning Consultants Ltd. in Toronto, Ont. He received his doctorate in architecture from the Royal School of Engineering in Milan in 1927.

**Walter Murray,** M.E.I.C., is now president of Consolidated Insulation Limited in City View, Ont.

He was formerly associated with The Rankin Co. Ltd. as chief engineer of project construction and as assistant to the director of the Montreal division.

Mr. Murray is a graduate in civil engineering of the University of Edinburgh, class of 1926.

# Marconi

*always a leader in electronics*

*- now a leader in* **RADIO RELAY SYSTEMS**

*Terminal microwave Relay building on Alcan's Peribonka project showing tower at left. (Courtesy Aluminum Company of Canada Limited).*

Canadian Marconi Company now offers a complete radio relay systems "package" to customers.

This includes systems engineering and selection of suitable station sites, provision of access roads, fences, buildings and towers. Power (including stand-by), installation of electronic equipment, and training of customer personnel and maintenance are also part of Marconi engineering services.

Marconi radio relay systems are simpler in design, give better, more reliable technical performance, and are easier to maintain.

You've looked to Marconi with confidence for your electronic needs in the past. Again you can turn to Marconi with confidence when it comes to radio relay systems.

*For further information consult the Commercial Products Division, Canadian Marconi Company.*

CMC
CANADIAN MARCONI COMPANY

CANADA'S LARGEST ELECTRONIC SPECIALISTS

J. R. Mills, M.E.I.C.

J. W. Eakins, M.E.I.C.

**J. R. Mills,** M.E.I.C., president and director, has announced the formation of Geocon Limited, formerly Gunite and Waterproofing Limited.

Other officers of the new company include **N. D. Lea,** M.E.I.C., vice-president; **J. W. Eakins,** M.E.I.C., general manager; and **A. G. Hyde,** Jr.E.I.C., assistant general manager.

**David McMillan,** M.E.I.C., is chairman of the Ottawa Transportation Commission.

He was formerly associated for many years with the Department of Mines and Technical Surveys, Geodetic Survey of Canada, in Ottawa.

**G. P. Wilbur,** M.E.I.C., has retired from his position as vice-president and manager of the Ontario division of Dominion Bridge Co. Ltd., but will continue to serve the company in a consulting capacity.

G. P. Wilbur, M.E.I.C.

Mr. Wilbur was born in Victoria Harbour, Ont., and was educated in Toronto, starting his engineering career with Polson Iron Works. He then joined Canada Foundry Co. Ltd. after which he began his long association with the Toronto branch of Dominion Bridge Co. Ltd. in 1913.

He was appointed chief draughtsman of this division in 1922 and subsequently, contracting engineer and sales manager. In 1942 he was named manager of the Ontario division, and in 1952, a vice-president of the company.

Mr. Wilbur is vice-president of the Sault Structural Steel Co. Ltd. and a director of Dominion Engineering Works Ltd.

He is a past-president of the Canadian Institute of Steel Construction and of the Toronto Builders Exchange, and a past-chairman of the Toronto branch of the Canadian Manufacturers Association. He is now a director of the Toronto Industrial Commission and of the Canadian Welding Bureau, and a member of the Association of Professional Engineers of Ontario.

**R. H. Findlay,** M.E.I.C., has retired from his position of mechanical engineer of the Eastern division of Dominion Bridge Co. Ltd. His services as consulting mechanical engineer will be retained by the company.

Mr. Findlay was born in Scotland where he studied at the Royal Technical College and Glasgow University and served his engineering apprenticeship

R. H. Findlay, M.E.I.C.

He joined the Dominion Bridge Company as a draughtsman in the structural department in 1911, and later became a designer in the mechanical department, chief mechanical draughtsman and production engineer. In 1928 he was made assistant mechanical engineer at Riverside Iron Works, but returned to Lachine in 1931 when he was appointed mechanical engineer.

Mr. Findlay has served as a councillor representing the Montreal Branch of the Engineering Institute. He is a member of the Corporation of Professional Engineers of Quebec, and of the Association of Iron and Steel Engineers.

**W. G. H. Holt,** M.E.I.C., has been appointed mechanical engineer of the Eastern division of Dominion Bridge Co. Ltd., succeeding R. H. Findlay, M.E.I.C.

Mr. Holt was born and educated in

W. G. H. Holt, M.E.I.C.

Toronto. He graduated in mechanical engineering from the University of Toronto in 1936. He joined the Dominion Bridge Company that year and has since worked in the mechanical design department, production department and in mechanical sales work. At the time of his recent promotion he held the position of assistant mechanical engineer.

Mr. Holt is a member of the Corporation of Professional Engineers of the Province of Quebec and of the Montreal Board of Trade.

**P. Millar,** M.E.I.C., has been appointed works manager of Dominion Bridge Co. Ltd. at Lachine, Que.

Mr. Millar was born in Lochwinnoch, Scotland, and received his education at the Royal Technical College in Glasgow.

He served his draughting apprenticeship with Mechans Ltd. in Glasgow, and came to the Dominion Bridge Company in 1923 as a draughtsman. Before his recent appointment as works manager, Mr. Millar was successively assistant plate and boiler engineer, structural superintendent, operating superintendent and general superintendent.

Mr. Millar is chairman of the Montreal West School Board and a member of the Protestant School Board of Greater Montreal.

**William Herbison,** M.E.I.C., has been appointed general superintendent of Dominion Bridge Co. Ltd. in Lachine, Que.

Mr. Herbison was born in Clydebank, Scotland, and received his education at the Clydebank Technical School and the Royal Technical College in Glasgow. He served his shop and draughting apprenticeship at John Brown & Co. Ltd., Clydebank engineers and shipbuilders.

He joined the Dominion Bridge Company in 1926 as a draughtsman in the structural and mechanical department and later was employed as a designer in the plate and boiler department.

In 1946 he was appointed superintendent of the structural and boiler division, and six years later became assistant general superintendent.

Mr. Herbison is a governor of the Lachine General Hospital.

**J. P. Borbey,** M.E.I.C., has been appointed assistant sales manager of the Eastern division of the Dominion Bridge Co. Ltd. in Lachine.

Mr. Borbey was born in New York, U.S.A., and was educated in Toronto where he attended the University of Toronto, graduating in civil engineering in 1934.

He joined the Dominion Bridge Company in Lachine in 1936 and was employed in the plate and boiler drawing office and design department. In 1942 he entered the plate and boiler sales department.

Mr. Borbey is a member of the Corporation of Professional Engineers of the Province of Quebec and of the Montreal Board of Trade.

**H. I. King,** M.E.I.C., has been appointed manager of the precast division of the Cooksville Company Limited in Toronto.

He received his B.Sc. degree in civil engineering from the University of New Brunswick in 1937 and since 1941 has been associated with the construction industry in Montreal and Toronto.

Mr. King served with the Royal Canadian Engineers during World War II. He is a member of the Association of Professional Engineers of Ontario.

**H. G. Ambrose,** M.E.I.C., has been appointed sales manager of the precast division of the Cooksville Company Limited in Toronto.

Mr. Ambrose received his B.A.Sc. degree from the University of Toronto in 1942. In 1946, after serving overseas with the Royal Canadian Electrical and Mechanical Engineers, he entered the construction field and has been associated with civil and municipal engineering works since that time.

He is a member of the Association of Professional Engineers of Ontario.

H. I. King, M.E.I.C.

**W. T. Bothwell,** M.E.I.C., has been appointed technical superintendent of the Regina refinery of Imperial Oil Limited. He was previously assistant co-ordinator of manufacturing operations in Toronto.

Mr. Bothwell is a graduate in chemical engineering of the University of Alberta, class of 1944.

George O. Saunders, M.E.I.C.

**George O. Saunders,** M.E.I.C., has been appointed works manager of the Canadian Locomotive Company's plant in Kingston, Ont.

A graduate of Queen's University in mechanical engineering, Mr. Saunders has served with the company for 12 years. He began as an assistant in the plant engineering department, moving to diesel engineering and subsequently becoming manager of locomotive sales. He was recently appointed assistant to the works manager in charge of steam locomotive production.

Mr. Saunders is a member of the Association of Professional Engineers of Ontario.

H. G. Ambrose, M.E.I.C.

**Arnold Thomas Girard,** M.E.I.C., is now assistant manager of the Carthage Machine Company in Carthage, New York.

Mr. Girard had been employed with the Brown Corporation in La Tuque, Que., since 1946. His earlier experience included service as an instructor in hydraulics at the University of Toronto, as a lieutenant in the R.C.E.M.E. Canadian Workshops, and as design engineer on air compressors with John Inglis Co. Ltd. in Toronto.

Mr. Girard received his B.A.Sc. degree in mechanical engineering from the University of Toronto in 1943.

**J. F. McGuire,** M.E.I.C., has been appointed welding engineer with Racey, MacCallum & Associates Ltd. in Montreal.

He was formerly with Canadian Chemical & Cellulose Co. Ltd. in Montreal.

Mr. McGuire graduated in electrical engineering from McGill University in 1934.

**C. W. Currie,** M.E.I.C., has been appointed assistant district engineer with the Department of Public Works of Canada in Charlottetown, P.E.I. He joined the Department in Charlottetown in 1934 after working for six years on design with the Nova Scotia Power Commission.

Mr. Currie graduated in electrical engineering from the Nova Scotia Technical College in 1928.

**S. I. Stothers,** M.E.I.C., is a production engineer with Canadian Locomotive Co. Ltd. in Kingston, Ont. He was previously associated with J. R. Leach & Son Ltd. in Prince Albert, Sask.

Mr. Stothers graduated in mechanical engineering from the University of Saskatchewan in 1950.

**Sydney Sheinberg,** M.E.I.C., has been appointed general manager of Hollinger Machine Co. Ltd. in Montreal, Que. He was formerly with the Canadian International Paper Company in Hawkesbury, Ont.

Mr. Sheinberg is a graduate in mechanical engineering of McGill University, class of 1943.

**Helmut Wittnick,** M.E.I.C., has been appointed assistant to the industrial engineer of Alnce Wood Products Inc. in Montreal, Que., and has been placed in charge of production control.

He was previously associated with the R.C.A. Victor Company in Montreal.

Mr. Wittnick graduated in mechanical engineering from the Hamburg Technical University in 1948.

**D. R. Webster,** M.E.I.C., has joined H. J. G. MacLean Ltd. in Montreal, Que., as sales engineer. He was formerly a sales engineer with Scottish Machine Industries (Canada) Ltd. in Montreal.

Mr. Webster graduated in civil engineering from McGill University in 1944.

**Jack Langford Tremaine,** M.E.I.C., has joined the engineering staff of Canadian National Railways in Montreal, Que. He was formerly associated with the heating and air conditioning department of Canadian Industries Ltd. in Montreal.

Mr. Tremaine graduated in mechanical engineering from the Nova Scotia Technical College in 1946.

**Major M. O. Rollefson,** R.C.E., M.E.I.C., is serving in Korea as commanding officer of the Third Field Squadron of the

Owner: The Aluminum Company of Canada, Ltd., Montreal, Quebec;
Consltg. & Des. Engrs.: Shawinigan Engineering Co., Ltd.;
Contr.: Fraser-Brace Engineering Co., Ltd., Montreal.

# engineers of Peribonka Power Plants employed POZZOLITH* to help meet requirements

Specifications for these important projects were rigid and exacting. Several types and classes of concrete were involved. Engineers insisted on adequate flow and workability without excessive bleeding or segregation.

Field tests showed that despite problems introduced by air-entrapping sands, Pozzolith with its adaptations facilitated production of concrete of the specified qualities, and at a cost far less than by other known methods.

Pozzolith has proved to be an effective aid in producing excellent results and important savings on major jobs from Labrador to Kitimat.

We would welcome an opportunity to work with you to help obtain similar results on your jobs. More details on these and other hydraulic structures in Master Builders Reporter No. 3 —48 pages, illustrated. Copy on request.

***POZZOLITH**... reduces unit water content up to 15% for a given placeability, and fully complies with the water-cement ratio law. Adaptations of Pozzolith permit rigid control of entrained air. Produced in three standard formulations—High Early Pozzolith, Normal Pozzolith and Low Heat Pozzolith—to give the results required under varying job conditions.

## Correction

In the August Personals, page 993, an item about R. G. Johnson, JR.E.I.C., was incorrect.

Information about R. G. Johnson, president of Defence Construction (1951) Limited in Ottawa, was mistakenly entered in the membership record of R. G. Johnson, JR.E.I.C., of Windsor, Ont.

Ronald Garth Johnson, JR.E.I.C. (B.Sc., mechanical engineering, University of Saskatchewan, 1948), according to our last information was associated with the Ford Motor Company of Canada in Windsor.

---

(*Continued from page 1132*)

Royal Canadian Engineers, and has been promoted from the rank of captain. He was previously stationed at Army headquarters in Ottawa in the Directorate of Works and Accommodation.

Major Rollefson graduated in civil engineering from the University of Alberta in 1941.

**R. E. Williams,** M.E.I.C., is now project engineer with the Canada Paper Company in Windsor Mills, Que. He was formerly on the staff of Canadian Comstock Co. Ltd. in Montreal.

Mr. Williams is a 1924 B.A.Sc. graduate of the University of Toronto.

**K. C. Williams,** M.E.I.C., has been appointed electrical sales engineer with Railway and Power Engineering Corporation in New Glasgow, N.S.

Mr. Williams received the higher national certificate in electrical engineering from Rugby College of Technology in 1939.

**Thomas E. Molyneux,** M.E.I.C., is now assistant project engineer with Abitibi Power and Paper Company Ltd. in Toronto, Ont.

He was previously assistant to the vice-president of Defence Construction (1951) Ltd. in Ottawa.

Mr. Molyneux graduated in civil engineering from the University of Saskatchewan in 1942.

**Dr. Alan W. Trorey,** JR.E.I.C., of Vancouver has been appointed research engineer on the staff of the California Research Corporation at La Habre.

Dr. Trorey is an engineering physics graduate of the University of British Columbia. Until recently he has been engaged in post graduate work at Stanford University where he obtained his M.S. and Ph.D. degrees.

**D. Hussman,** JR.E.I.C., has joined the Kilborn Engineering Company in Toronto, Ont. He was formerly associated with R. M. Way & Co. Ltd. in Toronto, Ont.

Mr. Hussman graduated in mechanical engineering from the University of Saskatchewan in 1947.

**E. H. P. Palmer,** JR.E.I.C., is owner and president of E. H. Palmer & Co. Ltd. of Montreal. He was previously a sales engineer with Control Equipment Co. Ltd. in Montreal.

Mr. Palmer graduated in mechanical engineering from McGill University in 1948.

**Capt. J. J. Eatock, R.C.E.,** JR.E.I.C., is the officer commanding the Northwest Territories and Yukon Works Detachment of the Royal Canadian Engineers.

This detachment provides engineer services to buildings and property of the Northwest Territories and Yukon Signals System which has radio stations as far north as Aklavik and has its headquarters in Edmonton, Alta. Approximately 20 isolated and semi-isolated stations are involved which extend west to the Yukon and east to within approximately 200 miles from Hudson Bay. This area presents many interesting problems involving construction and maintenance of buildings and utilities where perma-frost and extreme climatic conditions are involved.

Capt. Eatock graduated in chemical engineering from the University of Alberta in 1949.

**W. B. McCoy,** JR.E.I.C., has joined the Shell Oil Company in Calgary, Alta. He was previously on the staff of McGill University.

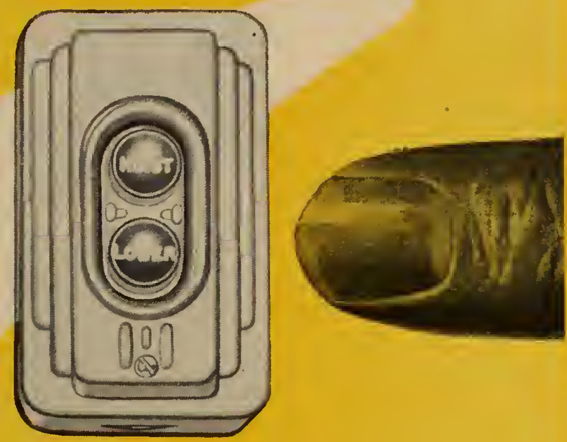
Mr. McCoy is a 1949 graduate in civil engineering of McGill University.

**S. Oancia,** JR.E.I.C., formerly with the Quebec North Shore Paper Company in Baie Comeau, Que., has joined George Mills & Sons Ltd., general contractors in Sydney, N.S. In his new position Mr. Oancia will be a project engineer and assistant superintendent on wharf and breakwater construction.

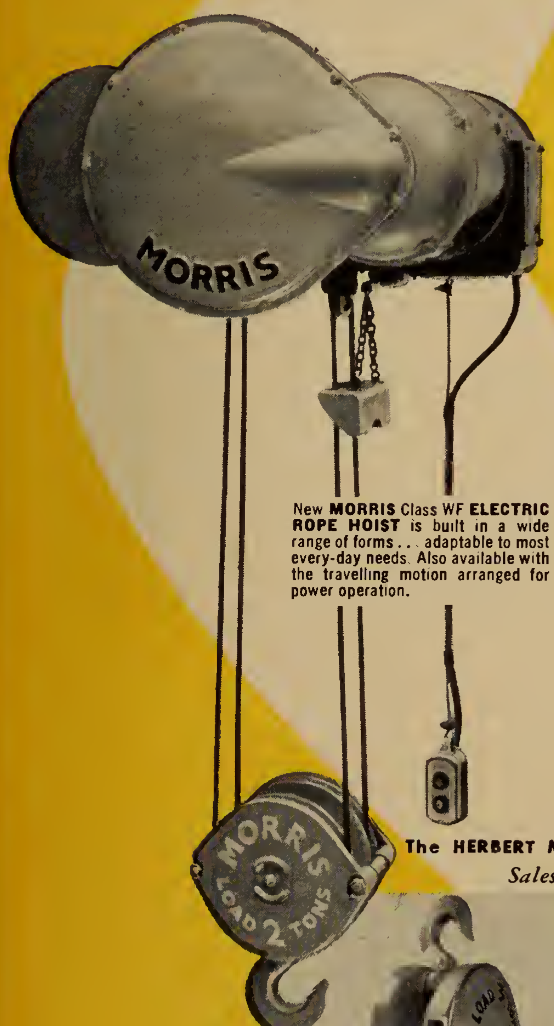
He is a civil engineering graduate of the University of Alberta, class of 1950.

**Aime Blais,** JR.E.I.C., is now process development and quality control engineer with the Panelyte division of St.

# here's dependable mobility



## AT YOUR FINGERTIPS . . .



New **MORRIS** Class WF **ELECTRIC ROPE HOIST** is built in a wide range of forms . . . adaptable to most every-day needs. Also available with the travelling motion arranged for power operation.

If you're constantly confronted with lifting, shifting or stacking problems which call for greater speed in handling and accuracy of placement, the most economical and efficient answer may be found in the new MORRIS Electric Rope Hoist.

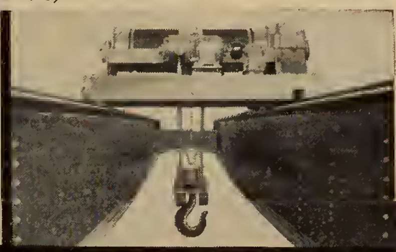
Combining modern design and engineering quality, the MORRIS Rope Hoist is built to give years of low-cost, dependable service under almost all conditions of use. The helical motor pinion and the fine, machine-cut gears make for quiet operation backed by complete safety . . . all the way from long stroke, electro-mechanical braking to well-guarded rope sheaves.

Every consideration has been given to time-saving with the new MORRIS Rope Hoist. Lubrication methods, push-button control, accessibility for maintenance have all been streamlined to help you speed up movement and servicing. You'll find all the details and specifications in the MORRIS folder No. 300. Write for your copy to Dept. B, at MORRIS.

**The HERBERT MORRIS CRANE & HOIST COMPANY LIMITED, Niagara Falls, Ontario.**
*Sales and Service Branches in Montreal, Toronto, and Hamilton.*

**MORRIS CHAIN HOIST** now streamlined for ease of handling, but rugged as ever! Although practically 40% lighter still unsurpassed for hard work and economy of operation.

**MORRIS ELECTRIC CHAIN HOIST** does away with manual lifting wherever there's electricity. Combines speed and strength with ease of handling. No special wiring required. Just plug in and start hoisting.



**MORRIS INDUSTRIAL CRANES** are "custom-made" for your heavy industrial needs. Variously produced in a wide range of lifting-capacity combinations with full selection of speeds for each separate motion.

DEPT. H

Regis Paper Co. (Canada) Ltd. in St. John, Que.
Mr. Blais is a 1950 graduate in chemical engineering of Laval University.

**Donald W. Gordon,** Jr.E.I.C., is now associated with Bridge & Tank Co. Ltd. in Winnipeg, Man.
He was previously on the staff of the Toronto Iron Works in Toronto, Ont.
Mr. Gordon graduated in mechanical engineering from the University of British Columbia in 1950.

**Paul J. Delicaet,** Jr.E.I.C., has joined the staff of J. E. and D. P. Connolly, Bathurst, N.B. contractors. He was previously employed with New Brunswick International Paper Co. Ltd. in Dalhousie, N.B.
Mr. Delicaet is a 1951 mechanical engineering graduate of McGill University.

**S. D. Stabler,** Jr.E.I.C., has joined Canadian Petrofina Ltd. as construction engineer in Montreal, Que.
He was formerly associated with Morrison-Knudsen Company of Canada Limited and McColl-Frontenac Oil Co. Ltd. in Montreal.
Mr. Stabler graduated in civil engineering from Queen's University in 1951.

**Louis D. Roberts,** Jr.E.I.C., is the branch manager in Prince Rupert, B.C., for the Central Mortgage & Housing Corporation. He worked for the Corporation in Vancouver previously.
Mr. Roberts is a graduate in civil engineering of the University of B.C., class of 1951.

**Emeric Leonard,** Jr.E.I.C., is a field engineer on the deep waterway project with the Department of Transport in Beauharnois, Que.

**J. N. Frenette,** Jr.E.I.C., is chief design engineer with F. I. Raskin Inc., in Montreal, Que.
He was formerly resident engineer with the Provincial Road Department in Ste. Hyacinthe, Que.
Mr. Frenette is a 1952 graduate in mechanical engineering of McGill University.

**Armand Richard,** Jr.E.I.C., is associated with Canadian Johns-Manville Ltd. in Asbestos, Que.
Mr. Richard graduated in mining engineering from Laval University in 1952.

**Grant M. Locke,** Jr.E.I.C., is an engineer for Pittsburgh Des Moines Steel Company in Pittsburgh, Penn.
Mr. Locke graduated in civil engineering from the University of New Brunswick in 1952.

**C. E. Laverty,** Jr.E.I.C., is a student engineer in the switchgear sales department of Canadian Westinghouse Co., Ltd. in Hamilton, Ont.
Mr. Laverty graduated in electrical engineering from the University of Alberta in 1952.

**Jean Marc Mayrand,** Jr.E.I.C., is working for the special projects branch of the Dominion Department of Transport in Montreal, Que.
Mr. Mayrand graduated in civil engineering from Ecole Polytechnique in 1952.

**Robert Marcotte,** Jr.E.I.C., is an engineer on the staff of the Consolidated Paper Corporation in Port Alfred, Que.
Mr. Marcotte graduated in civil engineering from Laval University in 1952.

**A. D. Scharf,** Jr.E.I.C., is a sales application engineer with Ainsworth Electric Co. Ltd.
He was formerly with the Canadian National Telegraphs in Toronto, Ont.
Mr. Scharf graduated in electrical engineering from the Univesity of Saskatchewan in 1952.

**C. R. Whalen,** Jr.E.I.C., is a design engineer with the New Brunswick International Paper Company in Dalhousie, N.B.
Mr. Whalen graduated in civil engineering from the University of New Brunswick in 1952.

**Carol Wagner,** Jr.E.I.C., formerly of Truscon Steel Co. of Canada has joined Defence Construction (1951) Ltd. in Montreal.
Mr. Wagner graduated with a B.A.Sc degree in civil engineering from Ecole Polytechnique in 1952.

**Charles L. Dodge,** Jr.E.I.C., is an assistant engineer with T. C. Gorman (Nova Scotia) Ltd., in Halifax, N.S.
Mr. Dodge graduated in civil engineering from the Nova Scotia Technical College in 1952.

**Vincent M. Jolivet,** Jr.E.I.C., received his master's degree with distinction from the Harvard Graduate School of Business Administration in June, and has accepted an appointment to the faculty of the school as a research assistant in financial management. At the same time he will work toward his doctorate.
Mr. Jolivet graduated in civil engineering from McGill University in 1952.

**G. W. Spratt,** Jr.E.I.C., is a field engineer in the waterworks department of the City of Regina.
Mr. Spratt is a 1953 graduate in civil engineering of McGill University.

**Dick Jamieson,** Jr.E.I.C., is a research fellow at the Ontario Research Foundation in Toronto.

**Milton E. Reid,** S.E.I.C., is associated with Canadian Westinghouse Ltd. in Montreal, Que.
Mr. Reid graduated from Laval University in electrical engineering in 1953.

**D. R. Gilley,** S.E.I.C., is a sales engineer with Canadian Bitumuls Co. Ltd. in Toronto, Ont.
He was formerly resident engineer with the Toronto Water Works.
Mr. Gilley graduated in 1953 from the University of Toronto in civil engineering.

**Robert McWhinnie,** S.E.I.C., is on the engineering staff of Canadian Bridge Co. Ltd. in Walkerville, Ont.
Mr. McWhinnie graduated from the University of Toronto in civil engineering in 1953.

**John D. M. MacDonald,** S.E.I.C., is a bridge engineer with the Prince Edward Island Department of Public Works & Highways in Charlottetown.
Mr. MacDonald is a graduate in civil engineering of Nova Scotia Technical College, class of 1953.

**R. H. Walkey,** S.E.I.C., is working in Louiseville, Que., as a plant engineer with Laminated Structures Ltd.
Mr. Walkley graduated from the University of Toronto in civil engineering in 1953.

**F/O J. P. Pagnutti, R.C.A.F.,** S.E.I.C., has been posted to the technical training unit of the R.C.A.F. in Vancouver, B.C.
He was previously stationed in Aylmer, Ont.
Mr. Pagnutti graduated in mechanical engineering from Queen's University in 1953.

**Robert Newey,** S.E.I.C., is an engineering student apprentice with C. A. Parsons & Co. Ltd., in Newcastle on Tyne, England.
Mr. Newey graduated in mechanical engineering from the University of Manitoba in 1953.

**H. G. Cox,** S.E.I.C., is at the Guelph, Ont., works of Canadian General Electric Co. Ltd. He joined C.G.E. as an engineer in training after graduating in electrical engineering from the University of Manitoba in 1953.

**D. A. Wiegand,** S.E.I.C., joined Packard Electric Co. Ltd. in Toronto, Ont., after graduating in electrical engineering from the University of Toronto this year.

**O. N. Smith,** S.E.I.C., is on the engineering sales staff of the Minneapolis Honeywell Regulator Company in Montreal, Que.
Mr. Smith is a 1954 graduate of McGill University in mechanical engineering.

**Kingsley G. Drake,** S.E.I.C., is a sales engineer with the Minneapolis Honeywell Regulator Company in Montreal, Que.
Mr. Drake graduated this year in mechanical engineering from McGill University.

**G. S. Roy,** S.E.I.C., graduated in electrical engineering from Nova Scotia Technical College this year, and is associated with the engineering staff of the Shawinigan Water & Power Company in Three Rivers, Que.

**J. Vilagos,** S.E.I.C., an engineer trainee in the research and development department of Canadian National Railways in Montreal, is a 1954 graduate in mechanical engineering of McGill University.

**R. G. Legare,** S.E.I.C., is a sales engineer with Minneapolis-Honeywell Regulator Co. Ltd. in Montreal, Que.
Mr. Legare graduated from McGill University in mechanical engineering this year.

**E. P. Rimmer,** S.E.I.C., graduated this year and is employed as junior engineer with the Winnipeg and Central Gas Company in Winnipeg, Man.

**Quentin W. James,** S.E.I.C., is with the engineering department of Super Motor & Lighting Limited in Kitchener, Ont.
He was previously associated with Fleet Manufacturing Ltd. (Canadair) in Fort Erie, Ont.

**H. Fedorak,** S.E.I.C., B.Sc., electrical engineering, University of Alberta, 1954, has joined the staff of the Hydro-Electric Power Commission of Ontario.

**Martial Quesnel,** S.E.I.C., of Montreal, has joined the engineering department of the Iron Ore Company of Canada at Knob Lake, Que.

**L. V. Woytiuk,** S.E.I.C., is an engineering laboratory chemist in the wire and cable division of the Northern Electric Company in Lachine, Que.
He worked as an industrial sales representative with Armstrong Cork Canada Ltd. in Montreal, after graduating from McGill University in 1953.

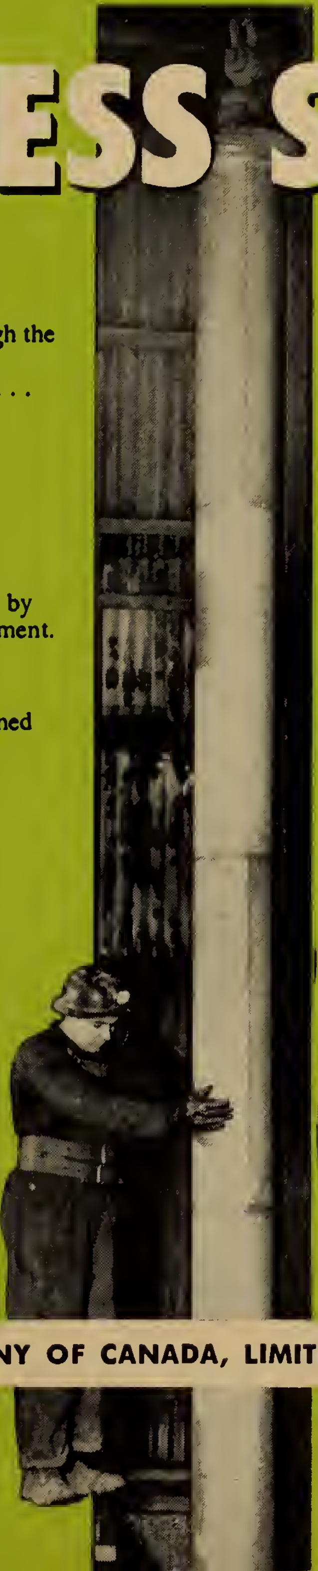
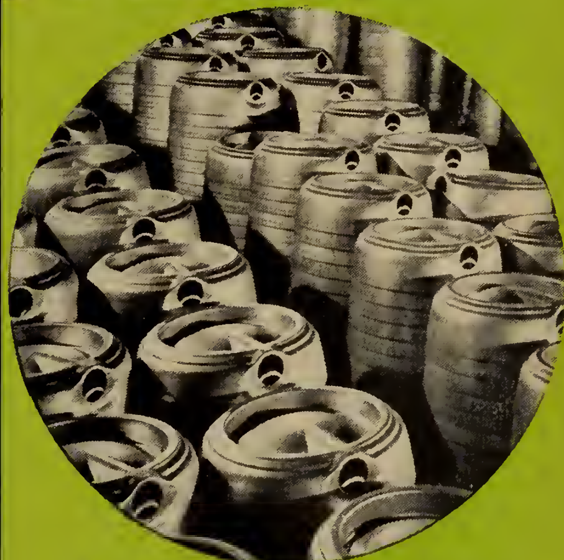
# Chromium Nickel STAINLESS STEEL

Chromium-nickel stainless steel head box on a Fourdrinier machine in the plant of Provincial Paper Limited, Thorold, Ont.



Hundreds of companies are today setting new standards of low-cost performance through the use of chromium-nickel stainless steels. Not only can you trim bulk and deadweight . . . you can assure longer service life because these alloys are resistant to attack by nearly all oxidizing acid conditions. In elevated temperature service they resist creep, scaling or oxidation, and at low temperatures they remain tough and offer exceptional resistance to impact. Investigate all the economies you may obtain by using chromium-nickel stainless steel equipment.



Firestone chromium-nickel stainless steel beer barrels, manufactured in Canada by The London & Petrolia Barrel Company Limited, London, Ont.

## SOURCES OF SUPPLY

Nickel-containing stainless steel can be obtained either direct from the mill or from warehouse stocks located in the principal cities of Canada.

## INCO *proven* SERVICE

Over the years, a fund of useful information on the properties, treatment, fabrication and performance of chromium-nickel stainless steels has been accumulated. This information is yours for the asking.

Mine water pipe lines made of Type 316 stainless steel are providing excellent service in Canada's major metal mines. Fabricated by Welland Electric Steel Foundry Limited, Welland, Ont.

EMBLEM OF INCO SERVICE
TRADE MARK

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Charles Ross Lindsey,** M.E.I.C., retired vice-president of The Shawinigan Engineering Company Limited, died at his home in the Town of Mount Royal, Que., July 12, 1954, following a lengthy illness. Mr. Lindsey was the engineer who did most of the investigative work on the hydro-electric potential of Quebec's St. Maurice River.

Mr. Lindsey was born in Congress, Ohio, on May 21, 1879. He took his engineering degree at Ohio Northern University and spent several years on geological survey work for the United States government. In 1906 he joined the Shawinigan Water and Power Company to work on the installation of a turbine at Shawinigan Falls, remaining there until 1925 as a leading figure in the growth of the St. Maurice Valley centre. He planned and laid out much of the present city, serving frequently as town engineer, and was the architect and builder of the first Protestant church there.

One of his last duties before retiring from the Shawinigan Engineering Company early in 1951, was the final inspection of the Trenche hydro-electric development which he had first envisioned 35 years earlier on the Upper St. Maurice. He had been appointed vice-president of the Company in 1947.

During his career he investigated power potentialities of 36 sites on the St. Maurice River and also carried out power surveys of other rivers in Quebec, Ontario, British Columbia and New Brunswick. Between 1946 and 1949, he supervised the design and construction of the Bridge River development in British Columbia.

Mr. Lindsey joined the Engineering Institute as an Associate Member in 1916, transferring to Member in 1940 and becoming a Life Member in 1951

**Edward Horace Phillips,** M.E.I.C., died on June 15, 1954, at his home in Saskatoon, Sask., after a long illness.

One of Saskatchewan's pioneer civil engineers, Mr. Phillips was born in Whitby, Ontario, on December 19, 1878. He graduated from the School of Practical Science at the University of Toronto in 1900. His early topographical work in 1900 and 1901 took him to the Crow's Nest Pass area, to Rogers Pass in the Selkirk Mountains and to Northern Alberta. He became a Dominion Land Surveyor about this time and worked for the Department of the Interior. In 1904 he went to Saskatoon as inspector of surveys for the Department, and returned to Ottawa to work in the Surveyor General's office. In 1907 he settled in Saskatchewan, taking the position of district surveyor and engineer for the provincial government.

Mr. Phillips worked for the provincial government until 1909, when he entered private practice with W. M. Stewart, now deputy-minister of highways, and Roger M. Lee, now retired, under the firm name of Phillips, Stewart and Lee. He remained active in this business until 1951 when it was taken over by his son, E. K. Phillips, M.E.I.C.

In the earlier days, Mr. Phillips and his associates surveyed many subdivisions in the city of Saskatoon, as well as many town and village sites and branch lines for the two railways. In his latter years in practice, he concentrated on the survey of Saskatoon lots.

Mr. Phillips joined the Engineering Institute as an Associate Member in 1917, transferring to Member in 1940 and became a Life Member on January 1, 1953. A charter and life member of the Saskatchewan Land Surveyors Association, he was its president at one time, chairman of the Association's first board of examiners, and its representative on the University of Saskatchewan senate for several years. He was an honorary member of the Canadian Institute of Surveying and Photogrammetry, and an original member of the Saskatchewan town planning committee, under the chairmanship of Dr. C. J. Mackenzie.

**Leopold Laferme,** M.E.I.C., died suddenly on June 20, 1954, at his home in Montreal. Mr. Laferme was for many years superintendent of Public Works for Montreal's Western Division.

Mr. Laferme was born in Paris, France, on March 6, 1891. He matriculated from New College, England, and from 1908 to 1911 he was a pupil with Melleish & Harding, Land Surveyors, in London.

When first employed in Canada by the Canadian Pacific Railway from 1911 to 1914 he was rodman and instrumentman on location and construction.

He served from 1915 to 1917 as an inspector for the Imperial Ministry of Munitions, after which he was overseas for two years with the Canadian Railway Troops.

He returned to railway work with the Canadian Pacific Railway, and in 1920 became an assistant engineer for the Grand Trunk Railway. He was on the staff of the City of Montreal Technical Services from 1922 to 1941, being appointed superintendent of Public Works for the Western Division in 1941, and retiring in 1953. He has since been associated with the Sicily Asphalt Co. Ltd. in Montreal.

He joined the Engineering Institute as a Junior in 1920 transferring to Associate Member in August of 1921.

**Harold Sawbridge Clark,** M.E.I.C., passed away on March 31, 1954, at his home in Windsor, Ont. He was a field engineer for the Ford Motor Company of Canada at Windsor, Ont.

Mr. Clark was born at Port Dalhousie, Ontario, on August 10, 1889. He received his B.A.Sc. degree from the University of Toronto in 1911.

His early engineering experience was gained in railroading, when he served for the Canadian Pacific Railway's Ontario Division. He worked before the First World War on the location and construction of the Welland Ship Canal. He was in the Canadian Army from 1914 to 1919, serving in England. He was adjutant of the Canadian Base Depot from 1917 to 1910, and was mentioned in despatches.

Mr. Clark returned to the Department of Railways and Canals to work on harbour construction in connection with the Welland Ship Canal. About 1938 he joined the Ford Motor Company in Windsor, Ont., as a construction and maintenance engineer.

In 1921 he joined the Engineering Institute as an Associate Member, and transferred to Member in 1940.

**Walter Raymer McCaffrey,** M.E.I.C., general manager of Canadian Standards Association, died suddenly at his home in Ottawa on July 11, 1954.

Col. McCaffrey was born at Markham, Ontario, on June 23, 1894. He attended Riverdale Collegiate and studied civil engineering at the School of Practical Science, University of Toronto, graduating in 1915. During the First World War, he enlisted in the Canadian Cyclist Corps, transferring overseas to the Royal Field Artillery. After the war he commanded the Seventh (Toronto) Regiment, Royal Canadian Artillery, comprising the 3rd Field Brigade and 4th Medium Brigade, and transferred to Reserve of Officers in 1937.

His earliest work was in hydrometric engineering for the Irrigation Branch of the Dominion Government in Alberta. After World War I he was associated with the National Fireproofing Company of Canada in Toronto for eight years, and later with the brick manufacturing industry for nine years.

He was appointed secretary of the Canadian Engineering Standards Association, Ottawa, in 1937, and when the name of the Association was changed to the Canadian Standards Association he was its general manager. His work for the association has been of great importance to the engineering profession in Canada. He was to have attended the International Standards Association meeting in September in Geneva, Switzerland.

Col. McCaffrey joined the Engineering Institute as a Member in 1939. He was also a member of the Association of Professional Engineers of Ontario. He was a speaker for the British Israel World Federation and president of the Ottawa Branch.

# Employment Service

**THIS SERVICE is operated for the benefit of members of The Engineering Institute of Canada and for industrial and other organizations employing technically trained men—without charge to either party. It would be appreciated if employers would make the fullest use of these facilities to list their requirements—existing or estimated.**

**NOTICES appearing in the SITUATIONS WANTED column will be discontinued after three insertions. They will be reinstated, on request, after a lapse of one month.**

**REPLIES to advertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Canada, 2050 Mansfield Street.**

**INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLateau 5078—may be arranged by appointment.**

## SITUATIONS VACANT

### CHEMICAL

GRADUATE CHEMIST, required to be trained as assistant to chief chemist. Plant located at Cardinal in Ontario in one of Canada's oldest food industries. Forward all details of experience, education, with pictures, and anticipated salary to File No. 4837-V.

GRADUATE CHEMICAL ENGINEER from Canadian University required by manufacturer of organic chemical products. Attractive opening in new project located in Ontario. Several years of practical experience in production and process development is required. File No. 4900-V.

CHEMICAL ENGINEER required to work in control department of paper mill located in Province of Quebec. Graduate from a Canadian or British University. Pulp and Paper experience desirable but other chemical engineering experience would be acceptable. File No. 4915-V.

CHEMICAL ENGINEER or chemist, preferably with experience in paint, printing inks, rubber or plastic industries. To sell chemicals in Toronto district. Apply fully in writing to File No. 4960-V.

### CIVIL

QUALIFIED ENGINEER required as principal Ahsanullah Engineering College, Dacca, Pakistan. Candidate should possess a good honours degree in civil engineering from a recognized University. He must have enough of practical experience of actual execution of large projects, and their organization, and teaching and administrative experience in a recognized engineering institution. Candidate should preferably be 45 years of age or thereabouts. Further information apply File No. 4878-V.

THE CITY OF MONCTON, N.B., invites applications from engineers preferably with municipal experience, for service in the city engineers office. In reply please give details of experience, including any service with H.M. Forces and indicate salary required. File No. 4887-V.

GRADUATE CIVIL ENGINEER for company in Brazil as technical assistant for chief planning. Age around 40, with 5 years experience in: 1) preparing and completing preliminary and basic studies and layouts of hydro electric developments for consideration as to technical and economic feasibility, 2) analysing and evaluating hydrological topographical and geological data with relation to power development studies, 3) determining survey work required. Position requires engineer of maturity and judgment with teaching experience and leadership ability. File No. 4888-V.

CONSTRUCTION DEPARTMENT of prominent oil company with headquarters in Maritimes requires experienced man to supervise construction of bulk plant facilities and pipelines. Position has an excellent potential. Please write details, and if possible enclose photo. File No. 4889-V.

THE TOWN OF BRIDGEWATER, Nova Scotia, requires the services of an experienced civil engineer for regular municipal services. Reply stating age, municipal experience, and when available to File No. 4921-V.

SALES ENGINEER for promotion and sales in professional field. Background in structures and/or construction. Preferred age early thirties. Location Ontario. File No. 4922-V.

GRADUATE CIVIL ENGINEER with about 2 years experience required by major oil company. Duties include job inspection; service stations, bulk storage depots and marine terminals. Preferably bilingual but not necessary. Territory Quebec and Eastern Ontario. File No. 4932-V.

CIVIL GRADUATES. Recent graduates in Civil Engineering required by structural steel firm, Montreal. Men to be employed in Engineering Department. Experience in structural steel design of advantage but not necessary. Chances of advancement excellent. File No. 4938-V.

CIVIL ENGINEER required by established construction firm operating in the west suburbs of Toronto. Duties entail sewer, water and road layouts planning and general construction problems. Opportunity for a young man wanting to advance. Please reply stating age, education and experience. File No. 4939-V.

CIVIL ENGINEER required in a city in Western Canada to assist in the planning and designing and supervising of construction in extensions of sewers and also sewage treatment plant. File No. 4940-V.

OFFICE ENGINEER AND ESTIMATOR REQUIRED BY LARGE CONSTRUCTION organization opening new office in Montreal. Services of bilingual graduate engineer experienced in heavy construction. Duties involve quantity takeoffs, estimating and design. Good opportunity with permanent position for right party. File No. 4945-V.

CIVIL ENGINEER or architect engineer to act as assistant to chief engineer with large organization in the flour, feed and associated industries. Ten years in civil engineering required. 5 years of design, foundations, superstructures, steel and reinforced concrete, 3 years in construction, 2 years in project co-ordination and administration. $12,000. starting with annual improvements, benefits include health insurance, retirement plan etc. File No. 4946-V.

GRADUATE CIVIL ENGINEERS required for specialized work in soil mechanics and foundation engineering. Post graduate study essential. Locations Montreal and Toronto with some travelling. File No. 4968-V.

### ELECTRICAL

ELECTRICAL ENGINEER (Electronics) required by major world-wide electronics organization. Present opening for a fully experienced electrical engineer to do project development work on monochrome T.V. The successful candidate must have a minimum of 3 years in T.V. receiver design and 10 years in electronics in general. Salary will be commensurate with ability. Reply in writing, stating details of age, experience education and salary desired. All applications will be held in strictest confidence. File No. 4892-V.

JUNIOR ELECTRICAL ENGINEER—single, 25 to 30 years of age with 1-5 years experience in metering department of a large public utility or manufacturer. Location Rio de Janeiro, Brazil. File No. 4898-V.

GRADUATE ELECTRICAL ENGINEER wanted as demonstrator in the electrical engineering department, University of Toronto for the session 1954-55. Session commences on September 20, 1954, and extends seven months. File No. 4911-V.

ELECTRICAL SALES ENGINEER required by manufacturer of switchboards high and low tension, panelboards, busways and switches to cover territory East of Province of Quebec and Maritimes. Bilingual preferred. Opportunity for the right man to become district sales manager. File No. 4918-V.

ELECTRICAL ENGINEER required to take charge of draughting and inspection of switchboards, panelboards, busways, switches, etc. Location Province of Quebec. Bilingual preferred. Opportunity for right man to become plant superintendent. Previous practical experience preferred. Permanent position, salary depending upon qualifications. File No. 4918-V.

ELECTRICAL ENGINEER required by paper mill located in the Province of Quebec. Well qualified engineer to act as assistant electrical superintendent. File No. 4925-V.

PROJECT ENGINEER to join a rapidly expanding company which is a leader in the electronics field and offers scope for advancement. Applicant should be graduate in Electrical Engineering with a minimum of 2 years experience in Television designing, and the development of television and radio receivers, a knowledge of production manufacturing and production processing desirable. Excellent working conditions and a complete program of employee benefits. Salary is open for discussion. File No. 4927-V.

LARGE ALBERTA ELECTRICAL wholesale firm will, due to retirement, require an executive, qualified as an electrical engineer about 45 years of age. Must be a first rate administrator, now holding a very responsible position and able to manage a large portion of the company. A substantial investment in this company, will be made available to a top man with proper qualifications, personally and technically. File No. 4930-V.

PROCESS ENGINEER with about ten years manufacturing experience preferably in the electrical industry. He would report to the works manager and would be responsible for methods and cost reduction studies, plant layout work and the supervision of time study, tool room and maintenance departments. A knowledge of sheet metal work, plastic moulding, metal finishing, assembly operations, material handling, etc., is desirable. The salary would depend upon the applicant's qualifications. File No. 4931-V.

A LARGE MANITOBA UTILITY requires a graduate electrical engineer to fill the position of assistant to the distribution engineer. Applicant should have at least three years experience in distribution practices, including layouts of large distribution areas; estimating of costs of distribution changes and extensions; improvement of voltage conditions and expansion of existing systems, basic economic studies and design of transformer and other special distribution system structure. Ability to write clear and concise reports to supervise one or more junior engineers and a group of draughtsmen and to deal with field staff is essential. A limited amount of travel within the province will be required. Location is in Winnipeg. Applicants should submit details of family status, age, educational background and experience. Applications will be treated confidentially. File No. 4948-V.

ELECTRICAL ENGINEER with at least five years experience on electrical maintenance and operating problems of generating stations and substations, of public utility companies. Permanent positions with long established consulting organization New York. Some travel in Latin America. Spanish or Portuguese useful. Salary commensurate with experience. Reply stating age, education, experience and personal particulars. File No. 4950-V.

ELECTRICAL ENGINEER required as junior or assistant distribution engineer. Graduate with at least 3 years field experience operating utility company. Permanent position with long established consulting organization New York. Some travel Latin America necessary in future. Knowledge of Spanish or Portuguese useful. Salary commensurate with experience. Reply giving age, education, experience and personal particulars. File No. 4950-V.

TWO COMPETENT EXPERIENCED graduate electrical engineers, with approximately 10 years experience in design, operation and maintenance of distribution facilities in established rapidly growing utility located South America. Reply giving resume education, experience and personal data to File No. 4950-V.

GRADUATE ELECTRICAL ENGINEER interested in a career in Latin America with a Canadian owned electric light and power utility located Maracaibo, Venezuela. Age limited 30 years and should have 4 to 5 years' experience in electrical distribution. Immediate prospects for promotion to assistant distribution superintendent and ultimately to executive position if qualified. File No. 4953-V.

ELECTRICAL ENGINEER required by oil refinery in Montreal to act as instrument engineer. Duties include the design and maintenance of flow instruments. File No. 4958-V.

### MECHANICAL

MECHANICAL ENGINEER required as product designer. Recent graduate with Canadian background for training in spring and hydraulic components design, one year experience in production and general machine shop practices desirable. Location in Montreal. Write giving full particulars of training and experience. File No. 4884-V.

TOOL DESIGNER REQUIRED, mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools, light, sheet dies, forging dies, fixtures, jigs and gauges. Canadian background required. Location in Montreal. Write giving full details of training experience and state salary desired. File No. 4884-V.

MECHANICAL ENGINEER required in the lubrication department of prominent oil company with headquarters in Maritimes to be trained in doing lubrication surveys and selling same. Position has an excellent potential. Please write details and if possiblo enclose photo. File No. 4889-V.

MECHANICAL ENGINEER required in Edmonton, Alberta, who has graduated from a recognized Canadian University, and who has about five (5) years experience in a chemical plant or refinery. He will deal mostly in equipment used in the manufacture of petro-chemicals and synthetic fibres. Duties will consist of general engineering, which will include design, layout, estimating and some administration. Must be able to handle project work and general plant engineering problems. File No. 4891-V.

MECHANICAL ENGINEER required who has had practical experience in structural design. He will be required for commercial vehicle designing particularly. This is a good opportunity with a sound future. Location Ontario. File 4893-V.

MECHANICAL ENGINEER $4,100.00-$5,820.00 for Post Office Department Montreal, P.Q. Details and application forms at your nearest Civil Service Commission Office, Post Office or National Employment Office. File No. 4916-V.

WANTED GRADUATE MECHANICAL ENGINEER with several years experience for work on design of steam power plants and industrial steam plants. South Eastern Ontario location. State full details, your letter will be treated in strictest confidence. Our staff knows of this ad. File No. 4933-V.

GRADUATE MECHANICAL ENGINEER required by Quebec (Eastern Townships) paper mill to act as assistant to mechanical superintendent. Some experience preferred but not essential. File No. 4944-V.

MECHANICAL ENGINEER with approximately ten years experience in production and administration for small metal plant located in Toronto vicinity. Excellent opportunity for future. File No. 4949-V.

MECHANICAL PLANT ENGINEER required by operating division of service organization. University graduate preferred having 5 to 10 years experience in operation and betterment of steam plants operated by public utilities. Location New York, some travel. Spanish desirable, but not necessary. Reply by letter giving age, education, experience, personal data, and minimum salary acceptable. File No. 4950.

SENIOR TOOL DESIGNER required by high class tool and gauge manufacturer in Southern Ontario. Must be mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools screw thread systems, fixtures, jigs and fixed and indicating types of gauges. Position provides good prospects for the future. Salary will be commensurate with ability. Reply in writing, stating details of of age, experience, education and salary desired. Applications will be kept confidential. File No. 4951-V.

YOUNG MECHANICAL ENGINEER required for sales work. Must be energetic, have a good personality and the ability or a real desire to sell. Some knowledge of heating and ventilating equipment and their applications is desirable. Good opportunity for ambitious man, with right future in a growing business. Location Montreal. Write giving full particulars including training, experience, age and marital status. File No. 4954-V.

GRADUATE MECHANICAL DESIGN ENGINEER experienced in heavy industry machine design. He should have three or more years of applicable experience. His general duties would include, supervision of work of several draughtsmen, stress analysis of structural steel machine frames and machine parts. Evaluation of new designs and improvements to existing designs. Good salary and opportunity for the right man with a well established medium sized manufacturer of pulp and paper-mill equipment. Location, northern New York State. Enclose full details as to qualifications, experience, salary expected, and recent photograph. File No. 4955-V.

MECHANICAL ENGINEER required in Regina, Sask., who is a graduate mechanical engineer and has at least five years practical experience in the design of heating, ventilating, air conditioning and refrigeration systems for buildings. Applicants reply giving full details and expected salary in first letter. File No. 4963-V.

MAINTENANCE ENGINEER required for the works engineering department of a chemical process industry. Preferably mechanical engineering graduate with three to five five years of applicable plant engineering or maintenance experience. Must have ability to supervise craft foremen. Works is located in a P.Q. town, twenty miles from Ottawa. File No. 4967-V.

### MISCELLANEOUS

LECTURER REQUIRED in an expanding department. Subjects economic geology, geomorphology, stratigraphy, M.A. desirable. University year September 15 to May 15. Salary range $2,500 to $3,000. File No. 4880-V.

YOUNG ENGINEER either mechanical or electrical to assist in the design and manufacture of blueprinting and white printing. Location Ontario. File No. 4894-V.

CANADIAN SALES REPRESENTATIVE, preferably a professional engineer required with successful sales record to industrial organizations. Must have knowledge of materials handling, dust collection and fume disposal equipment. Work can be undertaken in conjunction with other activities if desired. Exclusive territory. File No. 4896-V.

STRESS ENGINEER, graduate in mechanical or civil engineering, with two or three years experience in stress analysis of steel structures and machinery. Required by manufacturer in the Montreal area. opportunity for varied experience in the stress analysis of heavy machinery and structures Salary commensurate with experience. File No. 4897-V.

A CIVIL OR MECHANICAL engineer preferably with knowledge of soil mechanics and some practical experience to work on the engineering aspects of snow and ice research, especially on field studies of ice and snow. A physicist on engineering physicist with M.Sc. or Ph.D. degree to assist with the research program. Positions are in connection with the completion of special laboratory facilities for snow and ice research in the new building, Research Centre, Ottawa. Salaries will depend on training and experience. The opening provides challenging opportunities in a new field of work. File No. 4899-V.

ELECTRICAL UTILITY has opening for two junior electrical engineers or engineering graduates in Halifax, N.S. The work will provide opportunities for advancement along both technical and administrative line. Applicants should have a university degree and have not over three years post graduate experience. File No. 4904-V.

HEATING VENTILATION AND air conditioning specialists. Salaries up to $7,200 per annum. Department of Public Works, Transport and National Defence at Ottawa. Details and application forms at your nearest Civil Service Commission Office and National Employment Office. No. 54-1209. File No. 4905-V.

ELECTRICAL ENGINEERS (electronics and radar), salaries up to $6,840. per annum. Department of National Defence and Post Office Department, Ottawa. Details and application forms at your nearest Civil Service Commission Office, and National Employment Office. No. 54-1150. File No. 4906-V.

PROJECT ENGINEER, Process-Instrument Engineer, and Piping Layout Draughtsmen required by consulting firm located in Niagara Peninsula. Applicants must have considerable experience in refinery and chemical plant design and construction. Please write stating qualifications and full details to File No. 4910-V.

MECHANICAL OR ELECTRICAL ENGINEER with education equivalent to graduation in engineering and at least four and preferably six years of engineering experience. Must be registered professional engineer. Experience in plant maintenance and plant engineering is desirable, as well as experience in job installation supervision and in layout and design. Duties will consist of preparation of equipment layout for supermarkets and supermarket renovation and warehouse; plans for refrigeration, air conditioning, ventilation, plumbing, electrical, etc., for supermarkets, supervision of mechanical plans prepared by consultants and correlation of these plans with architectural plans; calling of tenders for mechanical trades; the preparation of maintenance work orders for field forces and minor amount of field supervision. File No. 4914-V.

PATENT OFFICER REQUIRED at Ottawa. The successful applicant will be required to undertake various duties dealing with patent applications in the electronic field. University graduation in engineering physics, electrical engineering or physics, with specialization in electronics is required. Pertinent experience desirable but not essential. Initial salary up to $4,620.00 per annum depending on qualifications. Apply by letter giving full details of education and experience. File No. 4917-V.

FIRE PROTECTION ENGINEER required for employment on a National basis in Canada preferably with headquarters at Ottawa, under direction of a group of regional and national forest industry associations to design and carry out fire research on all phases of the fire protection problem in Canada, to co-ordinate educational activities in fire protection and fire prevention, to generally conduct a public relations program on fire protection for the improvement of the standards of fire protection in all classes of properties and occupancies. Should have qualifications for membership in the Society of Fire Protection Engineers. Should have experience in modern fire prevention theory and practice with some knowledge of the principle of fire insurance underwriting and fire loss adjustments; and should have ability to meet and address the public with authority on the above subjects. Salary commensurate with qualifications. Duties to commence as soon as satisfactory arrangements can be made. File No. 4919-V.

TECHNICAL MINING EDITOR required by Canadian Mining Journal established 1879. Must hold mining engineering degree from recognized university and have had some practical operating experience in industry. Position offers excellent salary, prestige, and opportunities for travel. Please state qualifications, experience, references, earliest possible starting date. File No. 4920-V.

OPERATIONS MANAGER required by long established and progressive premixed concrete company in major Canadian City. Man who is capable of taking complete charge of operating its 5 modern concrete plants and 100 plus truck mixer fleet. Applicants must have had previous experience and successful record in a similar capacity. Give age, particulars of experience, references, state when available and salary requirements. All replies will be treated strictly confidential. File No. 4924-V.

THE SASKATCHEWAN RESEARCH COUNCIL requires an industrial engineer preferably with mechanical or chemical experience to assist in making industrial surveys, to prepare reports on process and developments, and to provide liaison between science and industry. Position available immediately. Salary will depend on academic attainments and experience. Apply with all particulars, recent photo and addresses of reference, to File No. 4926-V.

GRADUATE ENGINEER required to act under the supervision of the plant engineer by manufacturer of telephone dial switching equipment and associated apparatus such as telephone relays, etc. The incumbent will be connected closely with the maintenance of equipment and the provision of general plant building service. One or two years general experience in this field would be of considerable assistance to the person selected. File No. 4928-V.

NATIONAL PARKS ADMINISTRATIVE OFFICERS, $4,260.00-$4,860.00. National Parks and Historic Sites, Department of Northern Affairs and National Resources, Ottawa. Details and application forms at your nearest Civil Service Commission Office, Post Office or National Employment Office. Quote No. 5:-652. File No. 4934-V.

SPECIALIST ON WEAPON Analysis. Salary up to $7,900.00 depending upon qualifications. Department of National Defence, Ottawa. Preferably graduation in mechanical or electrical engineering. Details and application forms at your nearest Civil Service Commission Office and National Employment Office. Quote No. 54-1205. File No. 4935-V.

TECHNICAL ASSISTANT to the Chief Cartographer. Department of Mines and Technical Surveys, Ottawa. Salary $5,760.00 to $6,480.00. Address all enquiries to the Civil Service Commission of Canada, Ottawa, and quote competition No. 54-1707. File No. 4936-V.

ASSISTANT CHIEF ENGINEER. Salary $10,000.00 per annum. Harbours and Rivers Branch Department of Public Works, Ottawa. Details and application forms at your nearest office of the Civil Service Commission, Post Office and National Employment Office. Competition No. 54-1258. File No. 4937-V.

ENGINEERING FIRM, Toronto, requires the services of a graduate engineer with high academic standards and particular interest and qualifications in applied gas dynamics and fluid mechanics with special reference to flow machines. Applicant must also be willing to work on a broad range of investigation, design and development assignments including both mechanical and electro mechanical problems. File No. 4941-V.

DESIGN ENGINEER REQUIRED to undertake, under general supervision, the design and development of a wide range of mechanical products and devices. Preference given to applicants having Higher N.C. and with design experience on aero engines or their accessories, alteratively to University graduates with post graduate experience in design of highly stressed light weight mechanical devices. Small engineering company located in Toronto Suburb. File No. 4941-V.

TWO MARINE ENGINEERS draughtsmen required preferably with experience in pipe arrangements for engine room work. Preferably those with U.K. training to engage in work on Marine installations in the engine drawing office. Location Victoria, B.C. File No. 4942-V.

APPLICATIONS ARE INVITED for positions requiring engineers and technicians with adequate technical qualifications and practical in board and paper industry. Locations in West Pakistan. Free furnished married accommodation will be provided. Appointment on contract for 3 years including six months probation and provision for passage and leave. Successful applicants required at site early October, 1954. Applications stating full qualifications, experience, position held, age and accompanied by copies of reference and passport size protographs should be sent in duplicate. For further information apply to File No. 4947-V.

YOUNG GAS ENGINEER wanted in connection with operation of two manufactured gas plants and distribution systems. Excellent opportunity for future. Desire mechanical chemical graduate with few years experience manufactured gas. Reply stating age, experience, education and personal particulars. Location Panama, R. de P. File No 4950-V.

METER SUPERINTENDENT required by established rapidly growing utility in Brazil with 10 years experience in meter department of Canadian or large Latin American public utility to supervise meter departments in several operating companies. Single man preferred as considerable travelling involved. Reply giving resume education, experience and personal data. File No. 4950-V.

FIRE PROTECTION ENGINEERS required by well known insurance brokers office. After a period of training, duties would consist mainly in inspection work and sprinkler equipments and eventually general work usual to an insurance brokerage business. Position offers excellent prospects to right party. File No. 4952-V.

SALES ENGINEER required by manufacturers of centrifugal pumps offer opportunity to young college graduate age 22-28, in sales engineering career. Edmonton area. Salary and commission. Reply in writing giving full particulars of age, education and background, including photograph. File No. 4956-V.

MECHANICAL OR ELECTRICAL ENGINEER for the position of instrumentation engineer to be responsible under the chief design engineer, for the application, design and selection of instrumentation and control equipment in connection with all operational phases of a self contained pulp and paper mill. File No. 4957-V.

ENGINEER FOR PATENT ATTORNEY'S office. Ambitious recent graduate with flair for writing and willing to learn, wanted as technical assistant in large Toronto patent law firm. This man will qualify to try registered patent agent examinations in three years. Apply by writing giving full details of education and experience. File No. 4959-V.

SALES ENGINEER required by progressive Vancouver company specializing in process equipment in Western Canada. Canadian graduate preferred with experience in chemical or petroleum industries. Excellent opportunity for man with initiative and personality. File No. 4961-V.

INDUSTRIAL ENGINEER required to head department of plant manufacturing diversified machinery and structural steel. Location Province of Quebec. Prefer bilingual French Canadian. Good opportunity for advancement. Applicant should have good basic training, qualifications and technical references. Applications should be written in French and will be held in strict confidence. File No. 4966-V.

---

**SENIOR DESIGN ENGINEER**

A professional engineer with a degree in electrical engineering is required for our rotating machines, direct current design section.

Applicants should be between 30-45 years of age, with at least six years experience on design of rotating electrical direct current machines in all sizes, including motors, generators, converters and rotating regulators. He must possess ability to organize, plan, schedule, promote cost reduction and product improvement in Engineering. In addition, he must have a thorough knowledge of direct current machine application, and the ability to promote teamwork.

This is a senior appointment with excellent opportunity for promotion.

Reply in confidence, giving full personal resume, experience, salary expected and occupational goal to

Manager, Graduate Placement,

**CANADIAN WESTINGHOUSE COMPANY LIMITED**
**Hamilton, Ontario**

CITY OF CALGARY
ELECTRICAL DISTRIBUTION SYSTEM
requires

## ELECTRICAL ENGINEER

DUTIES: To prepare reports on problems of electrical distribution and utilization; to consult with large wholesale power customers concerning their electrical supply; to maintain technical records and perform related engineering tasks as required.

SALARY: $335 to $408 per month (graduated scale).

QUALIFICATIONS: Graduation in electrical engineering from a recognized university with some experience, preferably in electrical distribution system work.

APPLICATION forms are to be obtained from and returned to the Personnel Director, City Hall, Calgary, Alberta, not later than Oct. 15, 1954.

---

**SENIOR DESIGN ENGINEER**

A professional engineer with a degree in electrical engineering is required for our rotating machines, small motor design section.

Applicants should be between 30-45 years of age, with at least four years experience on design of all types of fractional horsepower motors. He must possess ability to organize, plan, schedule, promote cost reduction and product improvement in engineering. In addition, he must have a thorough knowledge of small motor application and the ability to promote teamwork.

This is a senior appointment with excellent opportunity for promotion.

Reply in confidence, giving full personal resume, experience, salary expected and occupational goal to

Manager, Graduate Placement,

**CANADIAN WESTINGHOUSE COMPANY LIMITED**
**Hamilton, Ontario**

---

**SENIOR ESTIMATOR WANTED**

An outstanding opportunity for a qualified graduate engineer.

Applicants must have had extensive supervisory experience in the construction of highways, dams, tunnels, bridges and like projects, together with a thorough knowledge of estimating and the preparation of tenders.

This is a permanent position with an established firm. Write giving full particulars.

**PERINI QUEBEC INC.**
**1510 Drummond Street,**
**Suite 850**
Montreal, Quebec

## SITUATIONS WANTED

ELECTRICAL ENGINEER, B.Sc., (E.E.) Manitoba, 1943, P.Eng. (Ont.). M.E.I.C., age 34, married, requires immediate employment. Six years with industrial motor control manufacturer, mainly application engineering including circuit design, plus general supervisory and manufacturing experience and liaison with sales, purchasing, production and inspection department. Eighteen months with National Research Council, Ottawa. Three years Cdn. Army (R.C. Signals) immediately after graduation. Desires responsible position with consultant or manufacturer. Will locate anywhere. File No. 1408-W.

MECHANICAL ENGINEER M.E.I.C., with apprenticeship and university background available for responsible position, on reasonable notice. Interested in representing manufacturers wishing to develop and service markets in Canada or abroad. Experience includes design, construction and maintenance in the pulp and paper industry, several years handling sales of power plant equipment. Working knowledge of French and German. Free to travel. File No. 2642-W.

MECHANICAL ENGINEER, M.E.I.C., P. Eng. (Ont.), B.Sc., (Queens) 1941, age 38, 13 years experience in manufacturing methods, process engineering, production engineering of high precision components, plant layout and engineering desires position as plant engineer or mechanical superintendent; available immediately. File No. 3272-W.

MECHANICAL ENGINEER. Jr.E.I.C., P.Eng., interested in design or development work in I.C. engine, automotive or similar field or in instrumentation and control. Available on one months notice to present employer. File No. 3460-W.

CIVIL ENGINEER, Jr.E.I.C., Alberta 1951, Veteran, age 38, single. 3½ years experience in hydro-electric field, both in design and field work. Also experience in municipal engineering. Two years experience in airport construction with the Department of Transport. Location preference, Alberta or British Columbia. Desires position in hydro electric field, but will welcome offers from other civil engineering fields. Available on month's notice. File No. 3489-W.

MECHANICAL ENGINEER, Jr.E.I.C., single, age 26, N.S.T.C., 1951. Seeking position with insurance underwriters or in some branch of sales. Experienced in building construction, design of manufactured gas installation and presently employed as fire survey engineer. File No. 3903-W.

GRADUATE ENGINEER, 1951 (Mining), age 30, is interested in position offering scope and responsibility where an engineering background is helpful (not necessarily in the mining field). Other training includes military engineering, R.C.A.F. service and business management course. Mining experience as miner, surveyor, layout engineer and mine engineer in base metal and industrial mineral operations. More recent duties have included engineering reports and studies and supervision of construction. Married, one child, available on reasonable notice. File No. 4000-W.

GRADUATE MECHANICAL ENGINEER, Jr.E.I.C., age 28, with four years experience in design and research in the hydraulic field is seeking position with a progressive company as designer and/or sales engineer. File No. 4102-W.

CIVIL ENGINEER, B.A. (Honours) maths, B.Sc. (Civil Eng.) M.Eng. (McGill University). About two years experience in field and design work (structural and hydraulic work) in Canada. Age 26. Married, one child. Citizen of India. Available from October, 1954, for teaching engineering design work in India or Colombo Plant countries, or Indonesia. Keen, hard working good references. File No. 4108-W.

GRADUATE ENGINEER, B.Sc., 1951, Jr.E.I.C., P.Eng., married, 3 years varied experience in mechanical handling and municipal engineering desires position in plant, mechanical handling or industrial engineering. File No. 4207-W.

MECHANICAL ENGINEER, Jr.E.I.C., '51 McGill graduate, 29 years of age, single. Completed 2 years graduate student training course with Canadian Electrical manufacturer. Presently engaged as manufacturing engineer. Desires a position with opportunity to demonstrate his ability. Location—anywhere. File No. 4217-W.

1943 GRADUATE IN civil engineering, University Berlin, age 3?, married, 2 children, specialist in hydraulics, 7 years experience in design of navigable waterway, dams, locks and hydro power station. Hydraulic research and hydraulic laboratory work and also river regulations and water supply. File No. 4244-W.

CONSTRUCTION ENGINEER, Jr.E.I.C., B.Eng. (Civil), McGill 1951, married. Considerable experience in design and field supervision of industrial and commercial projects, including steel, concrete and timber structures. Thoroughly familiar with office routine, estimating, writing specifications and preparing plans for tendering. Interested in position with progressive, growing firm of consultants or contractors. File No. 4273-W.

CHEMICAL ENGINEER with several years' experience in control, operation and development in the field of metal finishing and protective coatings for appliances, chemical and food industry. Has had varied experience in finishing, design and maintenance of large factory equipment as well as small serial articles in aluminium, magnesium, steel and brass. Multicolor finishing on anodized aluminium. Formulation of cleaning, etching and phosphating solutions, etc. Desires permanent position with opportunity for advancement. Will locate anywhere. File No. 4359-W.

MECHANICAL ENGINEER, Jr.E.I.C., 1950 graduate, Toronto, veteran, 32, single; some research experience, over three years in chemical industry on project and design work, involving process and services equipment and piping, instrumentation and building construction, including some estimating, purchasing, expediting and inspection. Desires position of greater responsibility in similar work or in maintenance work of a general nature. File No. 4418-W.

GRADUATE MECHANICAL ENGINEER, 1952, Jr.E.I.C., married, age 30, with varied maintenance experience on high pressure equipment in the chemical industry, electrical repair for a mining company and some industrial engineering experience. Desires employment on plant maintenance or field supervision of industrial equipment installation and alteration. Location preferably in Ontario. File No. 4453-W.

CIVIL AND STRUCTURAL ENGINEER, Jr.E.I.C., P.Ont. Cambridge University, 1947. 6½ years experience, civil and structural engineering in industry, consulting engineering and research. Expert knowledge in structural analysis, specialising in prestressed concrete. Presently employed in Toronto. Desire change of employment where experience could be best utilized. File No. 4467-W.

ADMINISTRATOR, professional engineer in early forties, extensive manufacturing experience large corporations; well qualified industrial relations including contract negotiations, arbitrations, proven record in safety, supervisory training, policy formation, cost budgetting, maintenance and stores control; sales and warehousing experience; seeks challenging position in small or medium company. File No. 4496-W.

CIVIL ENGINEER, member E.I.C., A.C.I. graduate University of Pennsylvania, U.S.A., bilingual, married, 2 children, 18 years varied experience abroad and in Canada. Last 9 years specialized in design and supervision of reinforced concrete and steel structures of all types. Seeking permanent position where technical skill and experience would be of value. Available on reasonable notice. File No. 4533-W.

CIVIL ENGINEER, graduate of technical university of Norway, 1949, age 30, married, no children. 3 years experience in structural engineering and two in construction. Desires position in construction engineering. Free to travel, but would prefer to be in eastern provinces. File No. 4534-W.

CIVIL ENGINEER B.Sc., Jr.E.I.C., 1950 grad., R.C.A.F. veteran, age 34, married with 2 children. Have had extensive experience in plant maintenance, administration and design. Now wishes to broaden experience and would be interested in a responsible position in the field surveying or general field engineering. Will be available July 15th. File No. 4538W.

CIVIL ENGINEER, B.Sc., U.B.C., 1951, Jr.B.C.P.E., Jr.E.I.C., age 25. 3 years heavy construction experience having responsible work in layout and construction supervision during the excavation and construction of an underground power house and power tunnels. Seeks position in design office or responsible field position where experience will be of value. Preferably in Montreal or vicinity. File No. 4539-W.

MECHANICAL & INDUSTRIAL ENGINEER, graduate, 1937; M.E.I.C., P.Eng., A.S.M.E., age 45, married, now employed as plant manager, wishes to locate outside Quebec. Reason, Plant closing. Seasoned senior engineer with vast mechanical experience in paper making, construction and the steel industries. Well qualified for the positions of plant manager, chief engineer, plant engineer, mechanical superintendent, etc. Seeks a position in a reliable company where application and effort will be rewarded with advancement, peace of mind, and permanency in order to establish a home. File No. 4540-W.

ELECTRICAL ENGINEER, B.E., M.E.I.C., 12 years of experience in responsible positions including operation and testing of AC and DC machinery, design and supervision of construction of transmission lines, overhead and underground distribution systems, and substations, also system planning, report writing, economic studies, budgeting, staff supervision etc. Desires position with increasing responsibility. Excellent references. Available on suitable notice to present employer. File No. 4541-W.

CHEMICAL ENGINEER 33, veteran, graduate with five years wide experience in mechanical, chemical and electrical engineering, presently employed by plant manufacturers in Scotland, available for employment in Canada in August, 1954. Desires responsible position in planning, plant or production engineering, or industrial research and development work. Resume and references on request, languages, locality no barrier. File No. 4542-W.

CIVIL ENGINEER P.Eng., M.E.I.C., with extensive experience in design and detailing of R.C. structures. Seeks part time employment in Toronto area. File No. 4544-W.

MECHANICAL ENGINEER, Jr.E.I.C., Polytechnique, 1953, P.Eng., equivalent of 4 years in plumbing and heating business as an apprentice, service man, design, estimate, sales and surveillance of complete plumbing and heating system for a contractor in Eastern Townships. Seeks employment in similar work preferably in Eastern Townships or Montreal but would locate anywhere. Married, one child, 26 years old, bilingual. File No. 4548-W.

CHEMICAL ENGINEER, M.A. (Hons. Engineering), Cambridge University, England; A.F. Inst. of Petroleum, 28, married, recently arrived from England. Four years service with Royal Engineers as survey officer in the Middle East. Three and a half years supervisory experience in control, development, and maintenance of various types of petroleum refinery plants. Desire responsible position any where in Canada. File No. 4551-W.

CHEMICAL ENGINEER, M.E.I.C., P.Eng., Toronto, 1942, married, 12 years industrial experience in chemical plant project supervision, process equipment and piping design and fabrication. Seeks position with chemical company on new projects supervision or with process plant design engineering and construction company. File No. 4552-W.

ELECTRICAL ENGINEER, McGill, 1953, S.E.I.C., presently employed, seeks position which calls for judgment, initiative and willingness to accept responsibility. Over two years varied experience (including summer work) in switchgear, rotating equipment, household appliances, sales, and drafting. Location Montreal. File No. 4553-W.

PROFESSIONAL ENGINEER, Jr.E.I.C., B.A., B.A.Sc., Athlone Fellow '52, age 27, bilingual. Post graduate studies in engineering production and management principles, Birmingham University, England. One year experience in

*The practical design of the new Chute-a-la-Savane powerhouse is photographically illustrated above. Hatch covers of crimped, batten-seamed aluminum, form the roof over the G-E Generators. The aluminum housed, rail-mounted 250-ton gantry crane, can be spotted over each generator for servicing. The covers roll back and aluminum sides can be lowered on the crane to make a weather-proof work area above each unit. If rotors must be removed for repair or inspection, they can be moved to a large repair bay at one end of the powerhouse.*

# on the Peribonka . . .

FIVE giant G-E Generators, installed in one of Canada's first "outdoor powerhouses" at Alcan's Chute-a-la-Savane project on the Peribonka River, add another quarter million horsepower to Northern Quebec's electrified industries in the Saguenay - Lake St. John area.

The new Savane powerhouse, one of two built on the Peribonka by the Aluminum Company of Canada, is unique in that the conventional walled-superstructure to house the generating equipment, has been eliminated. Instead, the reinforced roof of the permanent structure is approximately level with the tops of the generators. Access to the equipment is gained through galleries at various levels around the generators. From these galleries maintenance work, including coil replacement, is carried out.

This practical powerhouse design involved no change in the concrete work on the machine areas. It cut down on the amount of material shipped into this remote location, saved on building costs and added flexibility and safety to the structure. The skilled technicians who build and install giant G-E Equipment for such remote regions, know from extensive experience the magnitude of the engineering, construction and transportation difficulties involved. They consider the Chute-a-la-Savane project a credit to all those who contributed to its successful completion.

To the C-G-E engineers it represents another big job satisfactorily completed in the service of our many customers. They're ready to provide the same kind of service for you through nation-wide sales and engineering offices. For help on any job, big or small, contact the nearest C-G-E office, or write to: Apparatus Division, Canadian General Electric Company Limited, 212 King Street West, Toronto.

***The Engineers' Ball***

The 1954 Engineers' Ball Committee of the Hamilton Branch is busy with preparations and arrangements for a function designed to duplicate, or if possible improve upon, the successes of past years. The Ball has been announced for Friday, October 15, and will occupy the combined Century and Burgundy Rooms of Fischer's Hotel in downtown Hamilton. Featuring music from 9.00 to 1.30 by Chris Lovett's orchestra, favours and prizes which proved so popular last year, and a buffet lunch at 11.30, the Ball promises to be one of the events of the year for Hamilton engineers. Tickets are in circulation at $5.00 each.

***Annual Outing***

The annual outing of the Peterborough Branch of the Engineering Institute of Canada took place on June 26. Approximately 60 members attended a tour of the operations of the Nepheline Mines which are located approximately 40 miles north of Peterborough.

Company officials acted as guides for the event and the visitors were able to examine the operation of the open pit mine, the underground workings, and the mill. The hill on which the workings are located is practically pure nepheline and the actual tonnage available is not known. However, the hill is approximately 3 square miles in area and 300 to 400 ft. high. Drillings have been taken and they reveal that the mineral is still to be found well below the base of the hill.

The material taken from the open pit mine is trucked to the top of several shafts that have been cut vertically down through the hill. The bottom of the shafts is approximately at the level of the mill and the material that is dropped down the shafts is taken by rail cars to the mill where it is crushed and ground to various grades.

During the milling operation magnetic impurities are extracted by magnetic separators. There is an extremely small percentage of waste in the mined material.

The mill product is used widely in the manufacture of glass and also used to a considerable extent in the manufacture of pottery.

After the tour the visitors enjoyed themselves in a game of baseball and following this they cooled themselves off in a nearby lake. After the sporting event was over a very fine camp cookhouse dinner was enjoyed.

***Annual General Meeting***

The Annual General Meeting of the Kingston Branch was held on May 18, at the Cataraqui Golf and Country Club. Dinner and refreshments were served to members and guests.

Following the dinner two films were shown. These were provided through the courtesy of the Aluminum Company of Canada, Limited. The films, entitled "Prelude to Kitimat" and "Platform Pilots" are in colour. The first deals with the construction of the Kenney Dam and progress made at Kemano and Kitimat. The second, produced by Bell Aircraft Corporation, deals with the use of helicopters in connection with the work at Kemano.

***Metalclad Switchgear***

The final meeting of the season for the electrical section was held on March 29th. A large group of section members heard D. A. Drynan, supervisor of engineering in power switching equipment of the Canadian General Electric Company speak on "What's New in Switchgear".

Mr. Drynan explained the features of modern metalclad switchgear emphasizing its versatility, ease of maintenance, low installation costs, greater service continuity and greater safety.

Modern metalclad switchgear comes from the factory as a packaged unit, and requires the minimum of installation time and equipment. A completely enclosed structure, it provides positive safety for substation employees. Mr. Drynan showed with the aid of a working scale model how safety features are present throughout the design of the cubicle, particularly in the circuit breaker and the potential transformer sections. Bus bars, potheads and other components are contained in isolated sections to reduce hazards to a minimum, but are still accessible through bolted panels that makeup the unit.

***Scale Model***

Using his scale model, Mr. Drynan showed how the circuit breaker is positioned in the cubicle. The model is made of steel and brass, and can be stripped and reassembled exactly as the equipment itself could be. It is scaled 1" to 1' and was constructed by Mr. Collet of the apparatus division who spent some 300 hours perfecting it.

The gears in the circuit breaker rating mechanism were obtained from a watch. These were pinned to their shafts by a drill whose diameter was less than three times the thickness of a human hair.

After an interesting discussion period members were invited to inspect the model.

Mr. Drynan was heartily congratulated for providing a very interesting evening. The meeting was then adjourned for refreshments.

## BOOK REVIEW

**The international year book and statesmen's who's who: with supplement** London, Burke's peerage, 1954. 1125p., £8.8.0.

The first edition of this publication appeared in nineteen fifty-three, and in less than a year has proved itself an invaluable reference tool and mine of world information.

This nineteen fifty-four second edition, contains two hundred more pages than its predecessor, besides a supplement of information received too late for press.

The so called introductory section gives accounts of the various International Organizations of the world, including scientific and cultural organizations and large quasi-political bodies.

Following this comes the Diplomatic List, which groups, under each of the world capitals, the ambassadors and ministers accredited to each state. The Reigning Royal Families of the world, and a map section, complete this first portion.

Entitled the States of the World, the first main section includes the form of government of each country, constitution, population and area, financial and banking system, exports and imports, production, legal and educational systems, and religions. Brief information regarding origins of new states is included.

About ten thousand biographies comprise the second half of the main section, the entries being limited by the canons of selection. But what the policy of these same canons of selection can be remains an enigma, no matter how long we study the section. Apart from the apparent inconsistency of representation with a preponderance of "business executives", and "company directors" from one country, the inestimable value, otherwise, of this section lies in its variety.

Well known figures in very small states and countries throughout the world are included, people whose biographies would otherwise be very difficult to find.

Readers who are familiar with the Almanach de Gotha, which ceased publication in nineteen forty-four, will be pleased to read that this volume is a potential successor to that almost two hundred year old publication, and it will be published ultimately, it is hoped in more than one language.

Packed with world wide information, this International Yearbook is a must for most libraries, and an invaluable asset to both individuals and business offices who have any dealings in international affairs, in any country. E. K.

## BOOK NOTES*

**Prepared by the Library**
**The Engineering Institute of Canada**

* Review provided through the courtesy of the Engineering Societies Library in New York.

***Airplane structures,** volume I. A. S. Niles and J. S. Newell. New York, Wiley, 4th ed. 1954. 607p., $7.75.

This is essentially an elementary text on the general theory of structures, with emphasis on methods for the analysis of structures in which high strength/weight ratios are required, and with examples drawn mainly from the aeronautical engineering field. While all chapters have been revised to incorporate new methods and applications to new types of structures, the most important change is the increased emphasis on thin metal construction. There are lists of reference after most chapters.

**Analyse matricielle des réseaux électriques.** P. Le Corbeiller; tr. G. Lehr. Paris, Dunod; Montreal, Fomac, 1954. 124p., $4.50

Originally published in the United States under the title Matrix analysis of electric networks, the object of this volume is to present an elementary introduction to calculation methods of fixed electrical networks.

Bibliographic footnotes and illustrative problems and diagrams are liberally included, and the book will be a welcome addition to the French technical field.

**Beton-Kalender, 1954.** Berlin, Ernst, 1954. 2v., figs, together DM. 16.

In spite of the growing knowledge of concrete here, up to date information from the European continent is both welcome and informative.

This handbook of concrete and reinforced concrete is in its forty-third year of publication, and comes in two volumes, in cloth and paper.

The first volume is divided into fourteen chapters, and the second into ten, each chapter prepared by a specialist in the particular field.

All types and conglomerates of cement and concrete are considered, and their building potentialities in the various fields.

Graphs, diagrams, illustrative drawings, and tables are copious. References are to German standards, and in many cases these are included.

This will be an invaluable contribution to its field.

**Britain: an official handbook.** Ottawa, United Kingdom Information Office, 1953. 334p., maps, $1.40 pa., $2.00 cloth.

Presenting a factual background of Great Britain to-day, this *handy* little volume will both serve as a *vade mecum* to the traveller, and an information booklet for thousands of potentially interested readers.

Historical background, government and administration, defence, finance, trade, industry and labour, social welfare, religion, the arts, and radio broadcasting, are all covered, and included at the back is an excellent bibliography arranged by chapter and subject.

**Cathode-ray tubes,** M.G. Say, ed. Toronto, British Book Service, 1954. 216p., figs., $4.25.

This is an authoritative and up-to-date account of cathode-ray tube theory and practice. The first sections deal with the operation, design, construction and

## LIBRARY REGULATIONS

### Hours

| | |
|---|---|
| Mon.–Fri. | 9 a.m. - 5 p.m. |
| Saturdays | 9 a.m. - 12 noon |

### Bibliography and Reference Service

Short subject bibliographies are compiled on request. When placing these requests, please give as much detail and background information as possible.

### Borrowing

Books, periodicals, pamphlets and films may be borrowed for two weeks at a time. All books included in the Library Notes Section of *The Engineering Journal* are available for loan. **A fine of 25c per day is charged for each day borrowed items are retained beyond the two-week period.**

A library deposit of $5.00 at par in Montreal is required, for which two items may be borrowed at a time. Temporary deposits (30 days or less) $10.00. Books are sent anywhere in Canada, and carrying charges are payable by the member concerned.

### Ordering

Any book or pamphlet may be ordered through the library. All publications of affiliated societies, whether books, pamphlets, or periodicals, should be ordered through the library, as reduced rates are applicable on these to all members. Except in the case of library deposits **please make no payments in advance.** Non-members may consult the library, but may not borrow material. Please address all requests to **The Library.**

performance of the tubes, while later sections cover television, radar, instrument and modern camera tubes, as well as oscilloscope technique. A final section deals with switch, storage and other special tubes.

**Chauffage et rafraichissement combinés des habitations,** 2e ed. C. Boileau. Paris, Dunod; Montreal, Fomac, 1954. 313p., Complete vol. v. 1, $6.80; v. 2, $3.30.

Largely the result of discussions and findings at the International Convention of heating ventilating and air conditioning, held in Paris in May nineteen fifty-two, the idea of the author, in writing this double volume was to provide a handbook for interested engineers.

Panel heating, heat exchangers, and thermodynamics, and refrigerating machines, are particularly treated in this edition, from the domestic point of view. The book carries a few bibliographical footnotes.

*__Design and operation of septic tanks.__ Third European seminar for Sanitary Engineers, 1952. World Health Organization (Monograph Series, no. 18) Geneva (available in U.S. and Canada from Columbia University Press) 1953. 122p., paper. $1.50 (U.S.).

A collection of papers on the treatment and disposal of domestic sewage in unsewered areas, with special reference to Europe. The papers cover health considerations, design of small sewage plants, a study of the effectiveness of treatment in small plants, a review of septic tanks and small plants in Switzerland, and a comparative study of septic tanks. There is also a selective bibliography.

**Dry rot and other timber troubles.** W. P. K. Findlay. Toronto, McGraw-Hill, 1953. 267pp., illus., $5.50.

Written in non-technical language this volume explains why timber decays, its nature, causes of deterioration, discolouration, stains and blemishes, and its destruction by insects and disease.

The importance of prompt action in dealing with the first signs of dry rot and other deterioration is stressed, and wood preservatives and their uses are discussed and explained. The book has a short bibliography and a detailed index.

**Electrical earthing and accident prevention,** M. G. Say, ed. Toronto, British Book Service, 1954. 248p., illus., $4.25.

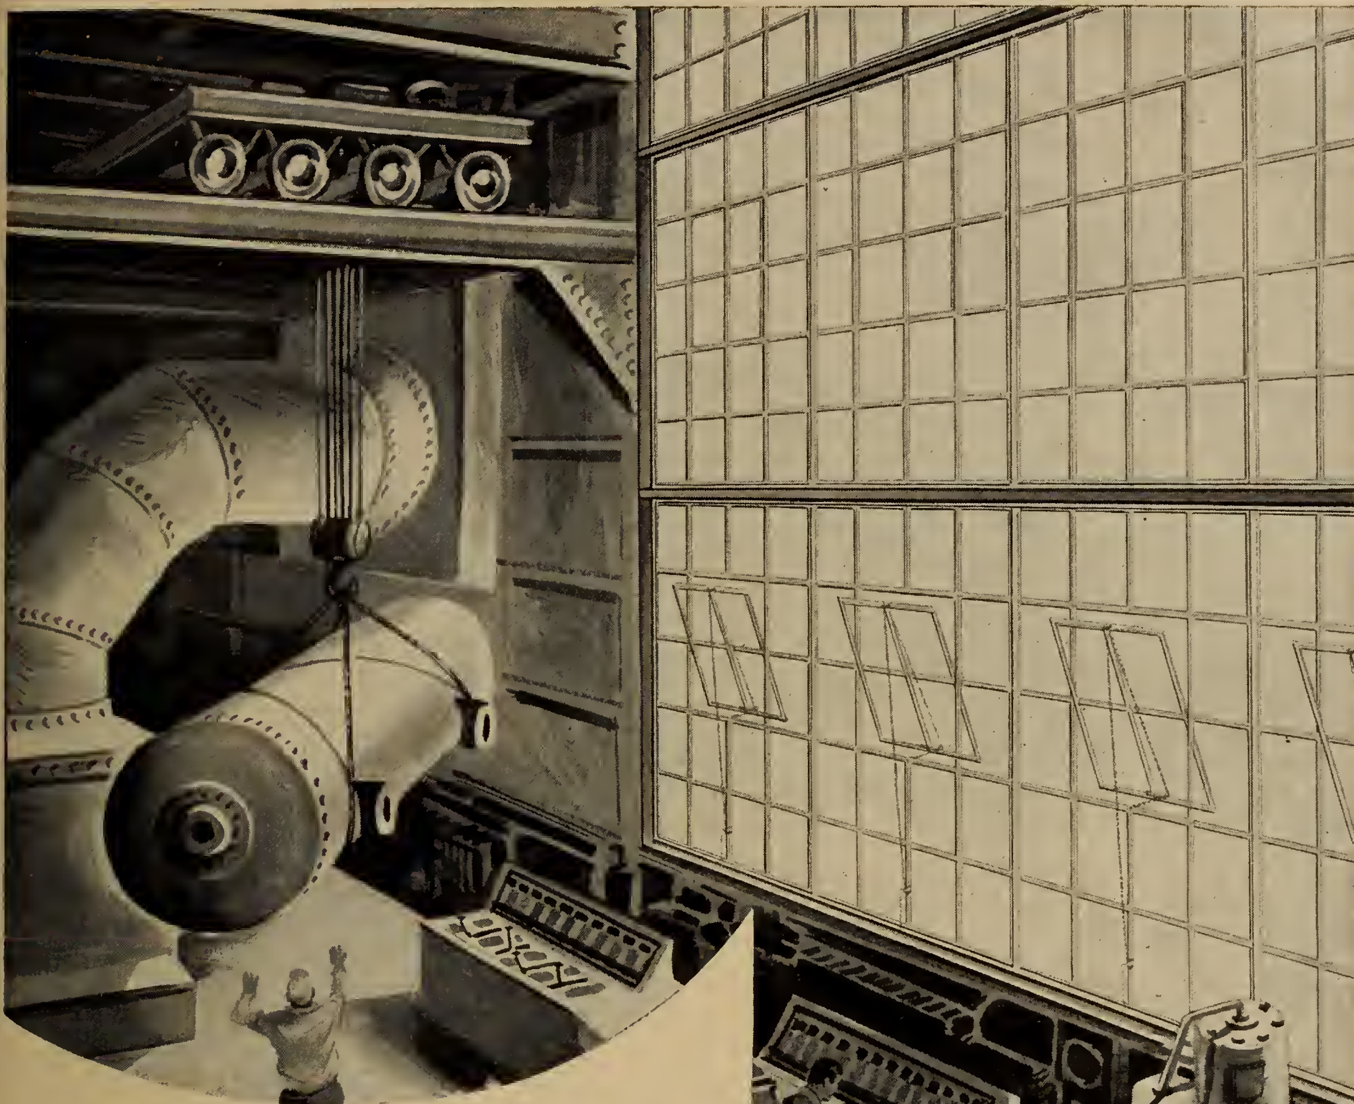
Written by nineteen specialists in the field, this book covers current practice and recent developments in the earthing of power systems, installations and communication systems. Domestic and industrial installations, telecommunication systems, ship, mining and aircraft installations and electric traction systems have all been covered, as has been the earthing of portable tools, etc.

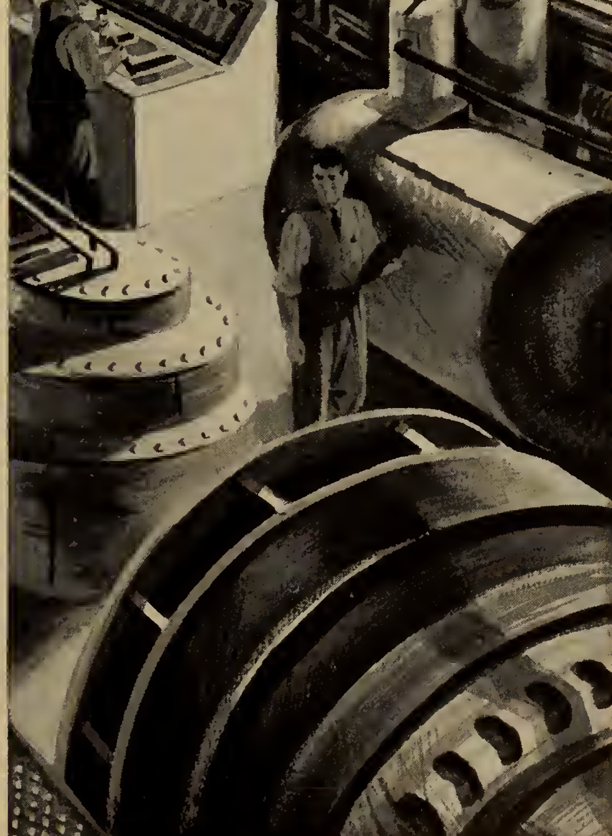
*__Electronics.__ T. B. Brown. New York, Wiley, 1954. 545p., $7.50.

This textbook for a basic course covers thermionic tubes, electron emission, gas in electron tubes, radio frequency circuits, and instruments. Descriptions of laboratory and demonstration experiments are integrated with the text in order to emphasize practical applications.

*__Elements of structural engineering.__ E. C. Harris. New York, Ronald press, 1954. 505p., $7.00 (U.S.)

A textbook on analysis and detail de-





## daylight costs nothing...

# WESTEEL WINDOWS

**steel or aluminum . . modular or standard sizes**

Westeel Windows help to bring the "outside" in ... help to create an atmosphere of airy spaciousness that pays off in higher employee morale and efficiency. Westeel Windows actually cost less than most solid walls. Types and sizes for all installations. Your enquiry is invited.

Complete details of all Westeel Windows are yours on request.

Write today for Westeel Windows Information Book No. 24.

## WESTEEL PRODUCTS LIMITED

MONTREAL TORONTO WINNIPEG REGINA SASKATOON CALGARY
EDMONTON VANCOUVER - Sales Offices also at: HALIFAX QUEBEC OTTAWA

sign, written for non-civil engineering students. The first six chapters discuss basic principles of analysis; equilibrium reactions, shear, thrust, and bending moment, trusses and braces, moving loads, and deflections in beams. The last four chapters deal with the design of steel members and connections, and design in concrete and wood. Examples and problems are from mechanical, electrical and other non-civil engineering fields.

*__Enginering analysis.__ D. W. Ver Planck and B. R. Teare, Jr. New York, Wiley, 1954. 344p., $6.00.

An exposition for graduate and undergraduate students of professional methods for the solution of engineering problems. Most of the book is made up of cases, drawn from electrical mechanical, and industrial engineering fields, which illustrate how to define a problem, plan an approach, check results, and draw conclusions useful in dealing with future problems.

*__Ferrous process metallurgy.__ John L. Bray. New York, Wiley, 1954. 414p., $6.50.

A junior or senior text covering raw materials, blast and electric furnaces, the Bessemer and open hearth processes, and ingots and ingot molds. It differs from the author's earlier Ferrous Production Metallurgy in the use of physical chemistry as a tool for explaining processes, and in the omission of historical, price, statistical, and other data.

**How to use meters.** J. F. Rider. New York, Rider, 1954. 156p., pa. $2.40 (U.S.)

The aim of this book is to provide information for all those interested in the practical application of a-c and d-c voltage and current measuring devices. Very little theory is included, and most of the book is concerned with the application of meters to home electronic devices, radio and television receivers, radio amateurs transmitters, etc.

**Introduction to color TV.** M. Kaufman and H. Thomas, New York, Rider, 1954. 140p., illus., pa. $2.10 (U.S.)

The purpose of this book is to present the fundamentals of the system proposed by the National television system committee for the transmission and reception of colour television. Emphasis is placed on the receiver, and both the three-gun and single-gun tube is described, although the former is treated in greater detail as it was more easily available at the time receiver production was started.

**Introducton to the theory of plasticity for engineers.** Oscar Hoffman and George Sachs. Toronto, McGraw-Hill, 1953. 276p., figs., $7.80.

Intended both as a text for advanced engineering students, and as a reference book for practicing engineers, this volume presents the fundamentals of the theory of plasticity, and its more important applications.

Part I deals with the mechanics of continua and the basic theories of postelastic behaviour. The second and third parts present problems in plastic flow, the majority being those involving small plastic strains. However, the last chapter of Part III, and all of Part IV are devoted to problems characterized by large plastic strains. The fourth part is also specifically concerned with metal-forming processes.

It is assumed throughout the text that

# Cork particles add high compressibility to new fiber gasketing

Accopac, Armstrong's new gasket material, has many features unusual in a cellulose fiber sheet material.

An important example is the addition of finely ground cork particles. They give Accopac high, uniform compressibility as shown by the graphs at right. This compressibility makes Accopac equally effective on light or heavy flanges.

With a stamped metal flange, for example, Accopac conforms to normal irregularities without distorting the flange between bolts. With a heavy casting, Accopac fills ordinary surface imperfections to produce a tight, dependable seal.

**Won't shrink, won't grow.** Accopac has unusual dimensional stability. Its saturants are non-volatile and non-extractable and cannot be leached out by fluid action. An Accopac gasket won't shrink, dry out and leak in any recommended application.

In addition, Accopac suffers no permanent or progressive dimensional change through variations in humidity. Even after months of storage, Accopac gaskets still fit and seal perfectly.

**High crush resistance.** Accopac's crush resistance is amazingly high. It withstands 100,000 psi without damage (conventional fiber sheets often rupture under 25,000 psi).

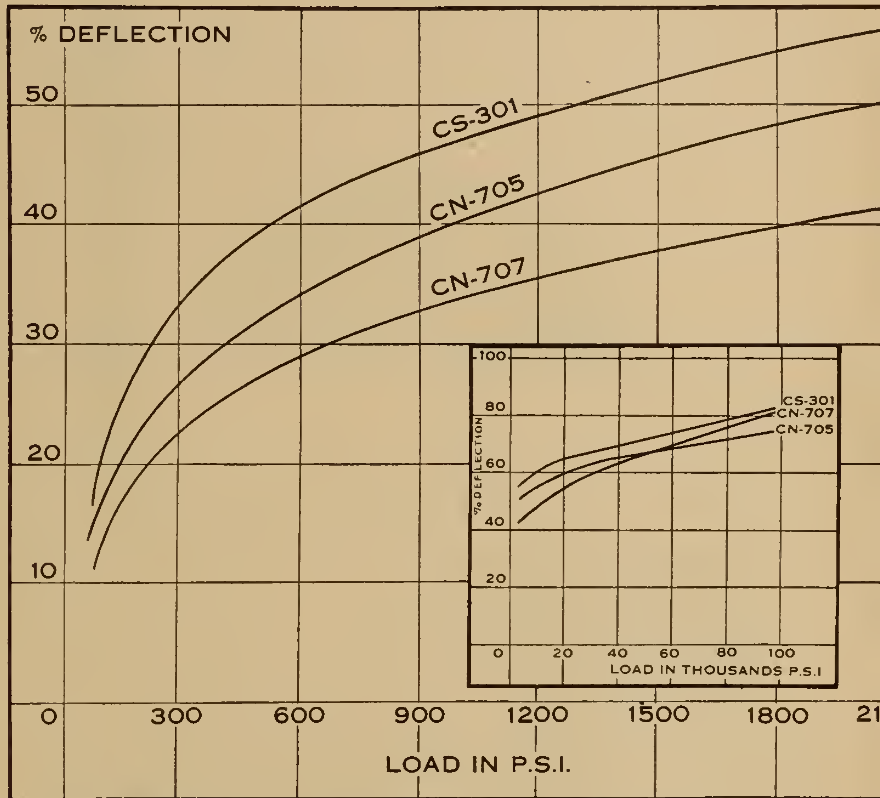
Crushing is often possible under the extreme high pressures found at local high spots along a flange. Accopac gives you unequaled protection against leaks caused by crushing.

**Fibers locked in rubber.** Accopac is made by a new beater saturation technique. Each fiber and cork particle is completely and evenly covered with rubber saturant — literally "locked in rubber." This new process makes Accopac unusually impervious and allows much larger amounts of rubber to be deposited than is possible with other known saturation methods.

Accopac is available in sheets, rolls, ribbons, or die-cut shapes.

**Write today for samples.** If you cut or use gaskets, make your own tests with Accopac. For samples, call your Armstrong representative or write to Armstrong Cork Canada Limited, Industrial Division, 6911 Decarie Boulevard, Montreal, P.Q. Dept. J-13

Arcana



**LOAD-COMPRESSION CURVES.** Main graph shows that Accopac compresses under very light pressures. Inset reveals that Accopac retains its compressibility without rupture up to 100,000 psi. Together, these smooth, unbroken curves prove Accopac will seal equally well on light and heavy flanges.

**NEVER DRIES OUT.** These two fiber sheet gaskets were used for 6 months in a gear pump circulating hot hydraulic oil. The conventional gasket lost its glycerine plasticizer, dried out, shrunk, hardened — and leaked badly. The Accopac gasket remained virtually unaffected as shown in the above photo.

# ARMSTRONG'S ACCOPAC

the reader has a knowledge of calculus, and the authors have tried to present the material in a way best adapted to the needs of engineers.

**Kempe's engineer's yearbook, 1954,** 59th ed. London, Morgan brothers, 1954. vol. 1, 1345p.; vol. 2, 1413p., $15.00.

The normal procedure in reviewing these handbooks which are published year after year, is simply to inform the members of slight additions and changes, and when new developments have been included.

This fifty-ninth edition of Kempe, however, is the one that must be bought, regardless of which other ones you may have purchased in the past.

From the physical point of view, it has been completely reset in Times Roman 6-point. With the resetting, copious revisions were inevitable, as well as numerous additions, which latter include chapters on Atomic power, Explosives, Fundamentals of Electrical Engineering, Industrial Safety, Mechanical handling, Plastics, Powder metallurgy, and Theory of structures. Headings and technical terms have been revised and brought up to date, and new developments added.

It is also a pleasure to have many of the advertising pages omitted.

All in all, the new Kempe well merits your considered attention.

***Lubrication of industrial and marine machinery.** W. G. Forbes. Rev. by C. L. Pope and W .T. Everitt. New York, Wiley, 2nd ed. 1954. 351p., $6.50.

This is a practical manual integrating discussion of fundamental principles of lubricants with explanation of common mechanisms and their lubrication requirements. It causes the chemistry refining, compounding and specifications of lubricants; lubrication of such mechanisms as bearings, gears, pumps, etc; and practical examples of the lubrication of equipment.

**Magnetic amplifiers and saturable reactors,** M. G. Say, ed. Toronto, British Book Service, 1954. 198p., figs., $3.60.

Another in the Electrical engineering progress series edited by M. G. Say, this volume deals with the magnetic amplifier in which interest has recently been revived. The aim of this book is to provide an account of how saturable reactors, magnetic amplifiers and magnetic modulators function, and how they may be applied to particular problems. An Appendix gives an account of the M.K.S. system of units.

**The mathematical solution of engineering problems.** M. G. Salvadori. Toronto; Oxford, 1953. 245p., $4.50.

Originally prepared as a set of mimeographed lecture notes for engineering mathematics at Columbia University School of Engineering, the object of this volume is to bridge the gap between a knowledge of theoretical mathematics and the technique of solving physical problems by mathematical methods.

A certain knowledge of undergraduate mathematics and calculus is assumed. Each mathematical technique is introduced by a simple physical problem. The solution of the problem is then carried to its numerical conclusion, with special emphasis on accuracy of computation and practical numerical schemes. The book has a good detailed index.

**Mathematics for students of engineering and applied science.** L. B. Benny. Toronto, Oxford, 1954. 783p., $5.25.

Prepared for students reading for general science and engineering degrees, the bulk of this volume treats of differential equations, partial differential equations, harmonic analysis, and vector analysis. The author also considers Bessel and Legendre functions, theory of errors, spherical trigonometry, and astronomy. Numerous exercises are included as well as many illustrative examples, and the volume is briefly indexed.

**Mechanics of materials:** 3rd ed. P. G. Laurson and W. J. Cox. New York, Wiley, 1954. 414p., $5.75.

Originally written in nineteen thirty-seven, the volume is now in its third edition sixteen years later.

Some of the most noteworthy changes since the last edition include an increased emphasis on stresses by statics and free-body diagrams; increased emphasis has been placed upon Mohr's Circle in the section on combined stress; information on mechanical properties of materials has been almost completely rewritten, and tables of structural shapes have been revised to conform to present standards.

Fourteen pages of tables follow the text, and the book is indexed.

**Modern developments in fluid dynamics: high speed flow.** Comp. Fluid motion sub-committee of the aeronautical research council, ed. L. Howarth. Toronto, Oxford, 1953. 2 vols. $12.50 per set.

Issued as a part of the Oxford Engineering Science series, this is a companion volume to Goldstein's Modern developments in fluid dynamics.

The findings contained are largely the result of developments during the last war, and deal with compressible flow at subsonic and supersonic speeds, both theoretical and experimental.

Each section is written by a specialist in the field. Bibliographic references are included; figures and diagrams are numerous throughout the text, and illustrative plates are grouped towards the back of the first volume.

There are detailed author and subject indices.

**Modern wiring practice,** 2nd ed. W. E. Steward. Toronto, British Book Service, 1954. 228p., illus., $3.00.

The aim of this book is to provide a guide to the most up-to-date methods of wiring domestic and industrial premises for lighting and power. The latest British wiring rules and regulations are explained, and other topics covered include installation methods, various wiring systems, lighting fittings, switches, etc., earthing and testing.

***Molecular theory of gases and liquids.** J. O. Hirschfelder, C. F. Curtiss and R. B. Bird. New York, Wiley, 1954. 1219p., $20.00.

Part one surveys equilibrim statistical mechanics as the basis for theoretical development of the equation of state and discusses main applications of the theory. Part two covers non-equilibrium statistical mechanisms, transport phenomena, and hydro-dynamic applications. Part three deals with the electro-magnetic and quantum mechanical theory of forces between molecules, atoms, ions, and free radicals. The book is intended for students in chemical physics and as a reference work for industrial engineers and others.

**Out of the earth: the mineral industry of Canada.** Toronto, University Press, 1954. 126pp., illus., $3.50.

It would be a fairly safe assumption that, apart from specialists in the field, the majority of Canadian people would like to know more about mines and minerals in this country.

For these thousands of people, this book is the answer. Related in non-technical language, it briefly explains how mineral deposits came to be, how they are located and taken from the earth. The processing of the ores is also described, and the transforming of crude oil into high grade gasoline.

How a mine is financed is described with the explanations of the prospector —engineer—government—mine operator —financier and investor combination. The resulting jobs, professional and otherwise, are then discussed.

In short, the whole thing is interesting, fascinating and challenging — a really Canadian book.

**Power and process-steam plant,** E. Molloy, ed. Toronto, British Book Service, 1954. 184p., figs., $3.00.

The aim of this book is to provide the latest information on the use of combined power and process-steam plants. It covers the principles of power and process-steam schemes, the choice of prime movers, turbines, steam engines, boilers, and thermal storage. It is intended both for the engineer who has to decide what type of plant to use, and for the works engineer who is responsible for the installation and maintenance of steam-driven prime movers.

*__Relays for electronic and industrial control,__ R. C. Walker. Toronto, British Book Service, 1953. 303p., figs., $7.25.

This is a descriptive survey of the features and uses of relays as switching devices, intended to make some of the less known controls more familiar to engineers. Opening chapters deal with functions and classification of relays, fundamentals of electromagnetics, relay coils, and contacts. Then follow chapters on direct and alternating current relays, high speed relays, and time elements in relays. The last two chapters cover methods of control, and miscellaneous applications. A list of references follows most chapters.

**Rotating amplifiers: the amplidyne, metadyne, magnicon and magnavolt and their use in control systems,** M. G. Say, ed. Toronto, British Book Service, 1954. 152p., figs., $3.00.

Many industrial processes now call for a precision of performance which is obtained by the use of an automatic control or a servo mechanism. An amplifier, through which a very small error can develop large compensating power, is an essential feature of this type of control. This book covers the operating principles, construction, testing and maintenance of the four commercial amplifying machines, and the principles of control systems and their various applications

**Statistical yearbook, 1953.** United Nations. Toronto, Ryerson, 1953. 582p., $7.50 cloth, $6.00 paper.

Compiled by the Statistical office of the United Nations, this fifth edition of the Statistical yearbook contains all the information in the 1952 edition, with the addition of statistics for 1952.

A great variety of topics is covered, ranging from statistics on population and manpower, to those on industry, trade and finance, and education. The information is arranged geographically, and explanations of the tables are given in both French and English. There are two indices, one arranged alphabetically by subject, and the second by country; these indices are also given in both languages.

*__The steel skeleton. Volume I: Elastic behaviour and design.__ J. F. Baker. Toronto, Macmillan, 1954. 206p., $8.50.

Largely a report of investigations made for the Steel Structures Research Committee (Great Britain) from 1929 to 1939, with some references to later work bearing directly on the subject. There are chapters on tests made of experimental frames, hotel, office, and residential buildings; on stresses and loadings of beams and columns; and on a design method developed by the Committee. An appendix discusses design of bomb-resistant frame structures.

**Who's who in British science.** London, Hill, 1953. 292p., 42/-.

There are over 3,000 entries in this directory of workers in British science, both pure and applied. The fields covered include chemistry, physics, engineering, agriculture, microbiology, mathematics, social sciences, etc. The information for each entry was obtained from questionnaires sent to those whom the editors wished to include.

# *at last!* A CONDENSATE TRANSFER UNIT THAT FITS *BOTH* HORIZONTAL AND VERTICAL PUMP INSTALLATIONS

## ...and it is competitively priced!

Here at last is a condensate pump that incorporates more customer suggestions than any other on the market! Designed for use with all types of heating and process equipment, the universal Darling UNICON transfer unit features a completely enclosed impellor, hydraulically balanced; a stainless steel shaft with a submerged permanent graphite bearing that *requires no lubrication* and is not subjected to pump pressure. The pump has been designed without close clearances: efficiency is thus maintained and there is no wear on moving parts. Another vital feature, from the user's standpoint: the Darling UNICON Condensate Pump is fitted with a motor that is readily interchangeable with *any* other Canadian make. Motor requires no lubrication—it is sealed for life. Finally, the pump has been fitted into a **cast iron** receiver of novel design.

***Write, wire or phone for Bulletin No. 49 giving complete information on the new universal Darling UNICON Condensate Pump.***

This Who's Who will be a useful volume for all those interested in any way in British science.

**Winter concreting: abbreviated translation into English of Direction no. 17, Betonstobning om Vinteren.** P. Nerenst, et. al. Copenhagen, Danish Institute of Building Research, 1953. 61p., $1.25.

Dealing with all aspects of cold weather concreting, this volume considers also soil engineering, and the effect of cold and intense cold on its structural properties, and these same aspects of cement and concrete mixtures.

The English edition is an abbreviated translation of the more detailed Danish, and must be used along with the original, as this latter contains all the original diagrams.

This merits the attention of all our members interested either in concrete, or in cold weather construction.

## STANDARDS REVIEWED

**ASTM standards, American society for testing materials, 1916 Race Street, Philadelphia.**
**1953 supplement to book of ASTM standards, including tentatives, 7 parts, 1954.**

**American welding society specifications, American welding society, 33 West 39th Street, New York 18, N.Y.**

**A5.9-53T—Tentative specifications for corrosion-resisting chromium and chromium-nickel steel welding rods and bare electrodes.** (ASTM No. A371-53T).

These specifications cover stainless steel filler metals for use with the inert-gas metal-arc process, and are issued jointly by the ASTM and the AWS. They include corrosion-resisting chromium and chromium-nickel steel welding rods and bare electrodes. The rods are for use with the atomic hydrogen and inert-gas metal-arc (nonconsumable electrode) welding processes. The bare electrodes are used with the submerged arc and inert-gas metal-arc (consumable electrodes) welding processes.

Thirteen classifications of filler metal are established by these specifications. A table gives the chemical analysis of the different classifications. An Appendix is included as an aid to users in selecting the most suitable filler metal for their needs.

**British standards, British standards institution, 2 Park Street, London, W.1. British standards are available from the Canadian standards association, National research building, Ottawa, Ont.**

**B.S. 115:1954 — Metallic resistance materials for electrical purposes.** 3/-.

This revision of the 1938 edition classifies the various forms of resistance material, i.e. wire, strip, tape and sheet as follows:

Class A. Applications where low temperature coefficient of resistance is of primary importance.

Class B. Applications where the temperature coefficient of resistance is important but may be larger than that permitted for Class A.

Class C. Applications where the working temperature is above 250°C. or where the temperature coefficient of resistance may be larger than that permitted for Class B.

The electrical requirements dealing with resistivity and resistance and appropriate tolerances are unchanged as are the tolerances on dimensions of metallic resistance materials in their various forms.

All references to resistance castings have been omitted from this edition. A table of standard wire sizes is included for reference purposes.

**B.S. 1498:1954 — Gear hobbing machines for turbines and similar drives.** 4/-.

This specification was drafted for the purpose of establishing standards of accuracy for gear hobbing machines intended for the production of high grade gears for turbines and similar drives.

This revision introduces a number of amendments in detail which have been found desirable as the result of experience in use. The two grades of accuracy originally specified are maintained: Grade A for machines capable of producing gears for relatively heavy loads with high pitch line velocity, and Grade B for machines suitable for producing high quality gears for normal loads and pitch line velocities.

The text has been revised and the sections re-arranged in a more logical sequence, and a chart showing maximum permissible transverse pitch errors, based on the formulae given in the text, has been added.

**B.S. 1523: 1954 — Glossary of terms used in automatic controlling and regulating systems.**
**Section 3: Kinetic control. 4/-.**
**Section 5: Components of servo-mechanisms. 5/-.**

Section three covers the terms used in kinetic control systems, i.e. systems for controlling the displacement, velocity or acceleration of a mechanical load, such as a crane, a die-sinking machine, or a gun; it therefore includes terms associated with servo-mechanisms.

This section includes terms covering basic principles, feedforward and feedback, types of control systems, parts of a servo system, types of servo-mechanisms, types of continuous control action, and the performance of control systems. In defining a monitored control system, notes are given setting out the difference between a closed loop system and a system with a closed sequence of dependence.

An appendix is included giving the effects of derivative and integral controls in a displacement-displacement kinetic control system for a load possessing inertia and viscous friction.

Section five defines many of the terms which relate to the mechanical and electrical devices used in the building up of servo-systems — particularly those dealt with in Section three—and

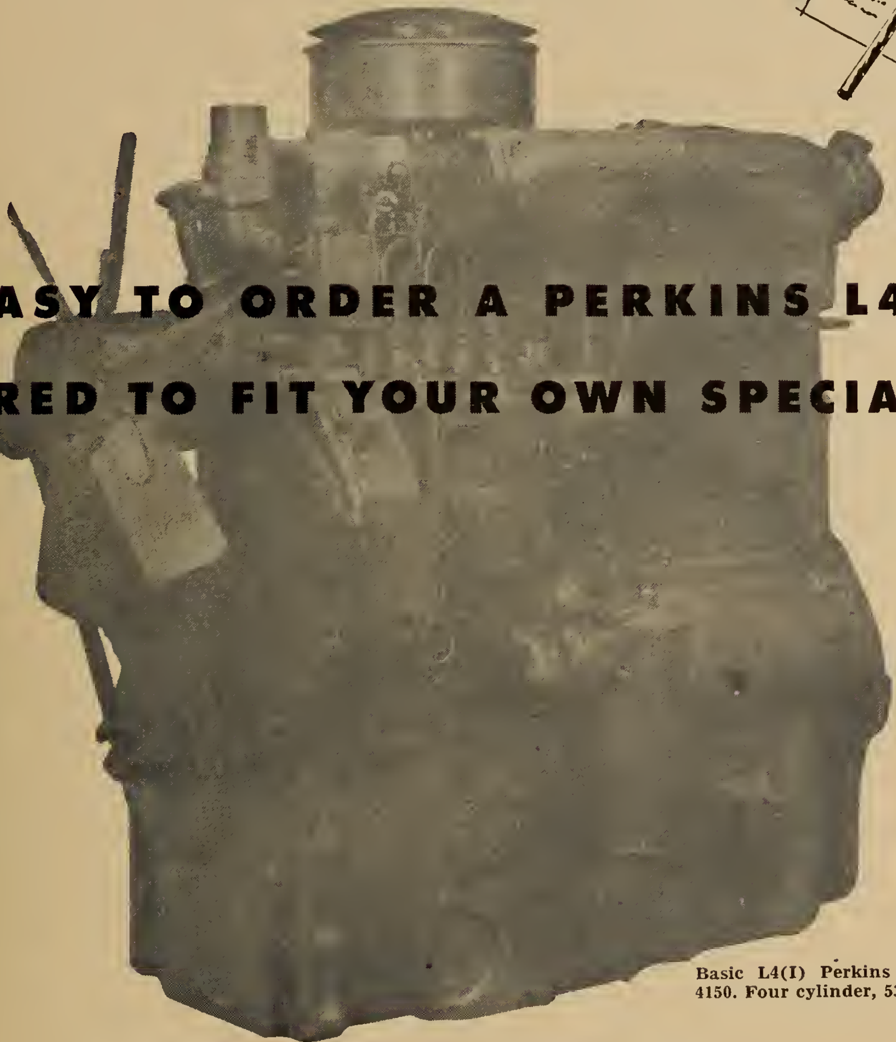
## IT'S EASY TO ORDER A PERKINS L4 DIESEL TAILORED TO FIT YOUR OWN SPECIAL NEEDS



Basic L4(I) Perkins diesel to parts list 4150. Four cylinder, 53 b.h.p. at 1800 r.p.m.

The wide range of optional accessories now available with the Perkins L4 diesel makes possible an astonishing variety of engine specifications from **one set of basic components.** You get famous Perkins diesel reliability and economy to begin with. You have the alternative of a governor for variable speed or for constant speed operation. But you don't need to buy a new transmission if you already have a good one—or a radiator or fuel tank if those you now have are in good shape. With the Perkins L4 you have a choice of 22 different flywheel and housing assemblies—and a vast assortment of engine support brackets, mounting feet, radiators, oil coolers. You can specify the simplest fan-to-flywheel engine—or a complete self-contained power unit. You can repower existing equipment—or power a new generating set with close limit frequency control and automatic emergency shut-off gear. Light-weight, high-speed Perkins L4 industrial diesels are now at work in more than 300 different power applications. For full details about the low-cost, versatile L4, write us to-day. Or call in your nearby Perkins dealer . . . he'll help you write your own ticket!

**Perkins**

5406

covers devices used for deviation measurement, amplifiers and their components, computing devices, stabilizing and response-modifying devices, servomotors and tachometers.

Transductors, which are important components of magnetic amplifiers, have been fully dealt with; their definitions have been made clearer by the inclusion of diagrams showing the various arrangements of windings.

Important components of servo-mechanisms are synchros and their various modifications, which are known by a variety of existing proprietary and descriptive names. The difficulty of dealing with these has been solved by the inclusion of an appendix which compares the 'Standard' terms with names of existing variations and gives some details of the latter in respect of the number of their winding paths and their energy transfer systems.

In each section a distinction is drawn between preferred and deprecated terms.

**B.S. 2094:1954—Glossary of terms relating to iron and steel. 6 parts.** Part 1, 6/-; Parts 2-6, 2/6 each.

Part 1—General metallurgical, heat treatment and testing terms.

Part 2—Steel making.

Part 3—Hot rolled steel products (excluding sheet, strip and tubes).

Part 4—Steel sheet and strip.

Part 5—Bright steel bar and steel wire.

Part 6—Forgings and drop forgings.

The Glossary has been prepared to establish as far as possible uniformity in the interpretation of the numerous terms in current use.

The scope has been limited to those terms in general use in the different producing sections of the iron and steel industry. Terms dealing with the various applications of iron and steel products, e.g. in welding and electrical engineering are covered in other British standard glossaries.

Part 1, covering general metallurgical heat treatment and testing terms, is complementary to the other parts of the glossary which deals with particular sections of the industry.

**B.S. 2457:1954—Protractors for drawing office use. 2/-.**

**B.S. 2458:1954—French curves for drawing office use. 2/-.**

**B.S. 2459:1954—Set squares for drawing office use. 2/-.**

**B.S. 2460:1954—Drawing instruments for drawing office use. 2/-.**

These standards are part of a series perpared to cover the range of standard drawing office equipment and materials.

Preferred sizes are listed, based on current practice; and recommendations are made for other dimensional factors—thickness, graduations, tolerances—with the object of establishing standard ranges of articles of sound quality.

Full, medium and small sets are recommended, to meet the requirements of the expert draughtsman as well as the apprentice and student.

The properties of suitable metals for the manufacture of drawing instruments are set out, but no definite material is specified. Guidance is, however, provided on this subject.

Manufacturing requirements are given in some detail in order to ensure uniformity of quality in instruments supplied by various makers. The dimensions and

material of needles are, in particular, clearly specified.

The meaning of the B.S.I. Certification marks scheme is explained.

**B.S. 2464:1954—Hose couplings for petrol, oil and lubricants (¾ in. to 4 in. nominal size). 7/6.**

This Standard applies to the reduced bore type of couplings and adaptors for hose of size ¾ in. to 4 in., for use at pressures not exceeding 100 lb. per sq. in.

Two forms of screw threads have been specified for the couplings: Whitworth (B.S.P.) threads in accordance with B.S. 84 and American threads in accordance with ASA specification B33.1 and with Federal Standard Stock Catalogue ZZ-H-466b. Details of these American hose coupling threads are given in the appendices.

These couplings may be secured to the hose by clamps, by clips, or by other suitable means.

**B.S. 2469: 1954 — Tins for lubricating greases. 2/-.**

This standard for round tins for lubricating greases standardizes the nominal diameters and gross lidded volumes based on nominal net weights with the requisite ullage. Heights of tins are not defined as their standardization would result in differences in volumes of the tins owing to the fundamental differences in the designs of lever rings and caps.

**B.S. 2475: 1954 — The performance of octave-band-pass filters. 2/-.**

This standard deals with a set of band-pass filters intended primarily for the analysis of noise into a series of consecutive frequency bands each one octave wide. The minimum performance characteristics specified have been chosen so that they can be met without too great difficulty by filters of simple design.

The purpose of the standard is to ensure:

a. Uniformity in the choice of frequency ranges.
b. Consistency between results obtained with different filter sets.
c. That the filter shall have an equivalent bandwidth equal to one octave within the tolerances given for a distributed spectrum in which the rate of variation with frequency of the sound pressure level is not too great.

It is not intended to imply that filters with the frequency ranges and the minimum characteristics specified in this standard are suitable for all purposes.

**B.S. 2478: 1954 — Tapes and spools for commercial and domestic magnetic tape sound-recording and reproduction. 2/-.**

The standard specifies the dimensions and certain features concerning the use of magnetic tape and spools in magnetic sound-recording and reproduction apparatus for normal commercial and domestic purposes.

Information on tape dimensions and tape speeds is given, together with certain requirements concerning recording and reproducing from dual track tape.

Dimensions for spools are specified, and a table sets out the nominal length of tape that may be accommodated on standard size spools.

**B.S. 2499: 1954—Tests to assess the properties of hot applied joint sealing compounds for concrete pavements. 4/-.**

This standard is intended to define the necessary properties of joint sealing compounds of the hot applied type for use on roads and airfields. Special requirements outside the scope of this standard may, however, be necessary for the application of this material to airfields used by jet aircraft.

The important properties required are that the compounds can be applied without difficulty, that that they adhere strongly to concrete, are sufficiently extensible to accommodate joint movements at low temperatures with cracking, and that they do not become so soft in hot weather that they flow or permit ingress of excessive quantities of grit into the joint.

It is extremely difficult to combine all the desirable properties to a satisfactory degree in one compound. The standard lays down a series of testing procedures for each of the above aspects of the behaviour of sealing compounds, and limits are prescribed appropriate to Great Britain.

**SP. 107 to SP. 112: 1954 — Tab washers for unified hexagons for aircraft. 2/6.**

These standards specify the materials, dimensions and finish of mild steel and corrosion-resisting steel straight, right angle and left angle tab washers suitable for use with the aircraft series of unified hexagons. A recommended method of application when washers are fitted into drill holes is shown in an appendix.

**S.P. 113: 1954 — Cadmium plated close tolerance shear pins for aircraft. 3/-.**

This standard specifies the materials, dimensions, finish and part numbers of the shear pins, which are cadmium plated to be suitable for insertion in aluminum alloy material. The standard is divided into three sections, the first specifying the requirements applicable to all pins, and the others dealing with the particular requirements for pins machined from bar and those produced by a cold heading process.

**British standard codes of practice. CP 304 (1953) — Soil and waste pipes above ground. 6/-.**

This code is concerned with the design and installation of sanitary plumbing systems. Included are soil, waste and ventilating pipes where they occur above ground, both inside and outside a building. Topics covered are materials, design considerations, work both off and on site, inspection and testing, and maintenance.

**British standard code of practice. Draft code 352—Mechanical ventilation.** 12/6.

This code, with its associated subcodes, deals with the work involved in the general designing, planning, installation and testing of ventilating systems, whereby air is forced into, or extracted from, buildings.

When all comments received on the draft have been considered, the code will be published as part of the series of Codes of practice for buildings.

**Canadian standards, Canadian standards association, National research building, Ottawa, Ontario.**
**A82 Series—Brick and hollow tile.** $3.75 a set.

The seven specifications in this series are:

A82.1—Building brick (made from clay or shale).

A82.2—Standard methods of sampling and testing brick.

A82.3—Sand-lime building brick.

A82.4—Structural clay load-bearing —wall tile.

A82.5—Structural clay non-load-bearing tile.

A82.6—Standard methods for sampling and testing structural clay tile.

A82.7—Facing brick (made from clay or shale).

The first editions of these specifications were issued in 1944, and numbers one to five have now been revised and are based on the standards of the American society for testing materials, slightly modified to bring them into conformity with Canadian practice. The sixth specification in the series is a re-affirmation of the 1944 edition, whilst the seventh is completely new, although based on an ASTM standard.

**A82.31-1954—Gypsum wallboard application.** 50 cents.

This specification is designed to provide minimum requirements for gypsum wallboard application. In addition to details on the actual methods of application, information is also given on delivery, handling and storage, as well as definitions of the material used. An appendix gives recommendations for decorating gypsum wallboard.

**A82.32-1954—Design requirements for reinforced gypsum concrete.** 50 cents.

Included in the scope of this specification are units precast at manufacturing mills, as well as those poured-in-place. Details covered are materials, strength of gypsum concrete, allowable stresses, and design.

**A82.33-1954—Poured-in-place reinforced gypsum concrete roof decks using permanent formboards.** 50 cents.

This specification covers the installation of "Poured-in-place" reinforced gypsum concrete roof decks erected over permanent formboards. It does not cover the structural design of reinforced gypsum concrete which is covered in A82.32 listed above.

Details covered include forms and reinforcing, mixing and pouring, and cold weather operations.

**A82.34-1954—Gypsum formboard.** 50 cents.

This specification covers requirements for gypsum formboard for poured-in-place reinforced gypsum concrete roof decks. Details are given on composition, sampling and testing, flexural strength, dimensions, weights, and permissible variations, finish, shipment, inspection, rejection and rehearing.

**C22.2, No. 15-1954—Construction and test of electrically-heated warming pads,** 2nd ed. 75 cents.

Applying to electrically-heated warming pads for connection either in single-phase a-c. or d-c. circuits of 125 volts or less between conductors, this specification covers both general-use and waterproof pads for both hospital and domestic purposes. Details are given for the construction and marking of pads, and the tests to which both pads and thermostats should be subjected.

**C22.2 No. 21-1954—Construction and test of cord sets and power-supply cords,** 3rd ed. 75 cents.

Another in the series of Part Two of the Canadian electrical code, this specification applies to cord sets and power-supply cords designed to be employed on circuits operating at not more than 125 volts, and for use in making electrical connection between outlets and portable lamps, appliances, etc. In common with other specifications in this series, details are given for construction, marking and tests to be applied.

**G30 Series-1954—Reinforcing materials for concrete.** $1.00.

The six specifications contained in this series cover the various materials used in concrete reinforcing. These are: billet-steel bars, rail-steel bars, cold-drawn steel wire, fabricated steel bar or rod mats and welded steel wire fabric. The specifications are all revised editions and have been altered to bring them into line with change in similar standards issued by the ASTM.

The sixth specification giving the minimum requirements for the deformation of deformed steel bars for concrete reinforcement is a new Canadian specification, but is also similar to one issued by the ASTM.

**O121-1954—Douglas fir plywood and western softwood construction plywood,** 2nd ed. 50 cents.

Prepared at the request of the Plywood manufacturers association of British Columbia, this specification lists the requirements for plywood manufactured from Douglas Fir and Western softwood. In addition to these, the various tests are also listed, as are many definitions connected with this material.

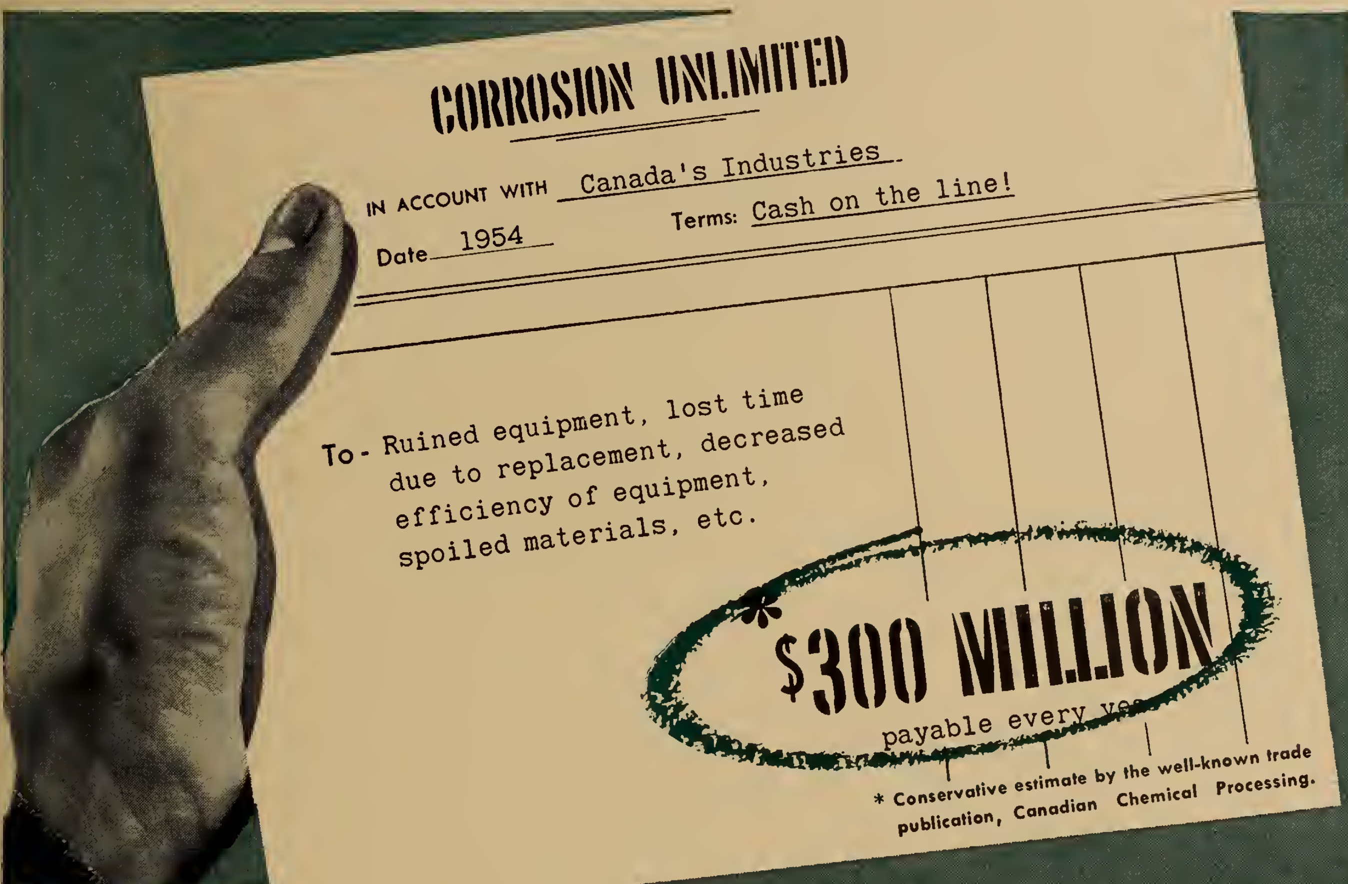
**Z7.1.7.17-1954—Tentative specification covering 16-millimeter optical sound film projector class B (for industrial and educational use).** $1.25.

This specification has been prepared to define the minimum performance standards of 16-millimeter sound projectors for industrial and educational use only. Both minimum performance requirements and operating requirements are given, as are methods of test for cooling systems, film driving mechanism, frequency response, etc.

**Z129-1954—Insecticide vapourizers (continuous type).** 75 cents.

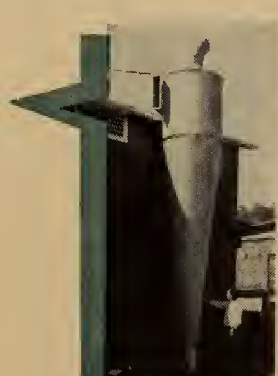
Since the application of the principle of continuous vapourization of chemicals for insect control was first made on this continent in 1947, one of the main problems has been to reach an air concentration of chemical which will be effective and yet not dangerous from a health point of view. This standard provides for the design, construction and installation of thermal devices adjustable in output to the volume of air to be treated, or fixed to suit specific spaces. It also covers markings and tests and testing methods.

# How much of this annual bill are YOU paying?



## STAINLESS STEEL IS INDUSTRY'S NUMBER ONE WEAPON IN THE FIGHT AGAINST COSTLY CORROSION!

Here's Just One Example of How Stainless Can Slash Corrosion Costs....



This cyclone-type dust collector made from Atlas stainless steel, has replaced a galvanized unit which failed due to the corrosive action of hot, moisture-laden air and fine dust. The galvanized unit had to be replaced about every 18 months. The service life of the stainless steel unit is conservatively estimated at 10 years. While the Stainless equipment costs approximately twice as much as the galvanized, its greatly increased life expectancy (up to 10 to 1) means very obvious overall savings.

## Appointments and Transfers

**Frank W. Shaw.**—United Steel Corporation Limited announce the appointment of Frank W. Shaw as general manager, Standard Steel Construction Company, Port Robinson, Ont. Mr. Shaw joined the Company in 1950 as chief engineer.

Frank W. Shaw

Previous to that time, he was associated with Dominion Bridge Company, Limited, Toronto and Canadian Bridge Company, Walkerville.

●

**Dominion Bridge Co.**—Following the retirement of G. P. Wilbur, W. Taylor-Bailey, president, announces the appointment of R. C. Pearse to the position of vice-president and manager of the Ontario division. Mr. Wilbur's services are being retained in a consulting capacity.

Mr. Pearse was born in the town of Ipswich, near London, Eng., and received his formal and technical education there. He left England in 1929 to join the Montreal staff of Dominion Bridge as a mechanical designer. During the next 10 years Mr. Pearse filled various positions with the company. During most of World War II, he was manager of the Vancouver Ordnance plant. In 1944 he returned to the east as assistant works manager of the Lachine plant and a year later he was appointed works manager. In 1953, he went to Toronto as assistant manager of the Ontario Division. (For other officers of the company see Personals.)

●

**H. R. Stenson and No-Co-Rode.**—No-Co-Rode Company Limited is the new name of the fibre conduit division of Dominion Tar & Chemical Company Limited. This announcement of the change in name comes simultaneously with the appointment of H. R. Stenson as vice-president and general manager of the company.

Head office of the newly named company has been moved to Cornwall, On-

Mr. R. C. Pearse

MECHANICAL DIVISION*
DOMINION BRIDGE
COMPANY LIMITED

tario, from the Sun Life Building, Montreal.

Mr. Stenson, prior to this appointment was associated with Canada Creosoting Company as Eastern regional manager, in Toronto. His appointment to the No-Co-Rode Company Limited almost coincides with completion of that company's plant expansion in Cornwall, Ontario.

●

**C.I.L. (1954) Limited.**—The following company officers and department managers are announced by Canadian Industries (1954) Limited:

*Officers:* H. Greville Smith, president; *Leonard Hynes and W. T. D. Ross, vice-presidents; *D. W. Shales, secretary; *E. L. Hamilton, treasurer; *W. H. Flynn, assistant treasurer.

*Department Managers:* J. F. Armitage, real estate; J. C. Asselin, Q.C., legal; *Monty Berger, public relations, *A. F. M. Biggs, advertising; J. D. Converse, chemicals; D. S. Hart, traffic and customs; L. W. Haslett, explosives and ammunition; Leonard Hynes, paints and coated fabrics; **S. C. Jones, employee relations; *D. S. Kirkbride, development; V. B. Lillie, agricultural chemicals; H. G. Littler, plastics; I. R. McHaffie, research; *H. W. Umphrey, engineering; E. J. Wain, purchasing.

*—Occupy posts not held previously.
**—New department combining industrial relations and staff unit.

●

Gordon C. Campbell

**Bird-Archer.**—With headquarters in Calgary, the new sales and service representative for Alberta of the Bird-Archer Co., Ltd., water treatment engineers, is Gordon C. Campbell.

●

**Geocon Limited.**—The formation of Geocon Ltd., formerly Gunite and Waterproofing Ltd., was recently announced by J. R. Mills, president and director. The original name of the company was not suitable for the broadened scope of work it engaged in. Under the new set-up, which retains the original Charter, there will be three divisions known as: Gunite and Waterproofing, Geotechnical Services and Pre-Engineered Steel Buildings. The division managers are: A. G. Hyde, J. Morgan and M. F. Rodger, respectively. Secretary-treasurer of the company is S. A. MacLeod and F. R. J. Traynor is the ass't. secretary-treasurer.

●

**G. L. Read for Bucyrus-Erie.**—George L. Read has been appointed Canadian Sales Manager for Bucyrus-Erie Co., according to an announcement from the company's main office in South Milwaukee, Wis. He takes over responsibility for the sales of all Bucyrus-Erie products except water and oil well drills in all provinces of Canada east of and including Saskatchewan. His new office and residence is located at 1 Swindon Road, Toronto 18, Ontario, Canada.

●

**Rybka's Regina Office.**—William N. Stowe will be in charge of the Regina office recently opened by Karel R. Rybka, M.E.I.C., consulting engineer. The new office will be located in the Black Block.

●

**Bulldog Electric's New Sales Offices.**—Opening of new district sales and service offices at Montreal and Vancouver has been announced by J. H. Wilson, general sales manager of Bulldog Electric Products Company (Canada) Limited.

Appointed district sales managers are: Clifford C. Barrett of Montreal and Warren G. Sutton of Vancouver.

Announcement of the new branches coincided with announcement of a change in company from Dominion Bulldog Limited, to Bulldog Electric Products Company (Canada) Limited.

●

**C.I.L. Explosives Division.**—M. J. Watson, assistant manager of the explosives division of Canadian Industries (1954) Limited, has been appointed manager, succeeding C. A. Kirkegaard who retired on pension on August 1. Mr. Watson joined the company in 1928 and has held various positions at C.I.L. commercial explosives plants at James Island, B.C., Nobel, Ont., and Beloeil, Que.

●

# New Equipment and Developments

**Indoor Potential Transformers.**—A new indoor potential transformer completely enclosed in a tough, shatterproof plastic casing and costing 10 per cent less than previous models, has been announced by Canadian General Electric Company's Apparatus Division.

Representing the first major change in indoor potential transformer design in 24 years, the new unit is easier to install, offers longer life, eliminates maintenance and exceeds the requirements of the highest metering accuracy, according to development engineers at the company's Davenport (Toronto) Works.

Approved by the Department of Trade and Commerce, the new transformer—designated type PV-3—is rated up to 15 kv. class of insulation—200 volt amps—and is obtainable in voltage from 6900 volts to 13,800 volts high voltage —115 volts low voltage. It is designed to replace the old steel-encased compound-filled types currently used by utilities, industries and switchboard manufacturers for operating meters, instruments, relays and control devices.

Completely Canadian-designed, the new transformer can be installed in any position and offers adjustable feet for surface mounting. It has a higher impulse level than previous models—110 kv. compared to 70 kv. and weighs only 65 pounds. It has a thermal rating of 1.75 kva. and its metering accuracy rating of .3WXYZ exceeds the highest requirements. Flash-over arc distances have been doubled.

The epoxy resin plastic envelopes enclosing the element ensures shatterproof construction and requires no painting.

●

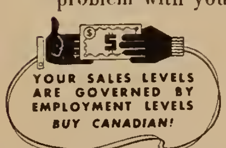
**Mathematical Services Mathematical Computing Service.** 67-24 211th St., Bayside 64, N.Y., specializes in performing services for industries desiring engineering calculation, charts and nomographs of a high degree of complexity and the treatment of related mathematical problems in the various fields of engineering. An important function of the group is the mathematical formulation and complete solution of a problem from given physical data. The staff consists of consultants holding doctorate degrees who are qualified to treat problems in applied mathematics related to the physical sciences.

●

**Electrical Demonstrating Equipment.**—The Canadian Westinghouse Company has adopted unique demonstrating equipment to keep sales and service personnel well informed of new developments in the supervisory field. The demonstrator is a completely-portable, working model of the Westinghouse visicode supervisory control and will be scheduled for demonstration at major centers from coast to coast.

The demonstrating model consists of two major parts—the dispatcher's panel and the substation panel—joined by a 2-wire channel. Operation is similar in all respects to an actual installation, except that the substation panel contains latching relays to simulate circuit breakers. Control relays, escutcheons and pushbuttons are the same as those used in commercial equipment.

Practically every feature of an actual



YOUR SALES LEVELS ARE GOVERNED BY EMPLOYMENT LEVELS
BUY CANADIAN!

No!
Don't kid me!

visicode installation may be demonstrated. The operator may select a point, note the check-back signal and perform a control operation such as closing a breaker. The equipment will close the breaker, change the lamp indication and check the operation. The model shows how this same point may provide a synchronizing indication when delayed operations, such as the closing of a motor-operated disconnect switch, may be shown. Quantities at the substation may be telemetered. Battery and channel failure are brought to the operator's attention by bell and lamp alarms. An automatic operation at the substation is seen reporting an alarm to the dispatcher's panel and if more than one such operation occurs simultaneously, the reports reach the dispatcher individually.

●

**Workshop Ohmmeters.** — Evershed workshop ohmmeters are intended for quick, easy and accurate measurements of insulation or conductor resistance, and are particularly suitable for large quantity production testing. They are similar in principle to the well-known "Megger" insulation tester, except that the hand generator is replaced by an external d.-c. supply. The d.-c. source may be a battery, a generator, or rectifier, depending on the application, and whether low or high voltage is required.

The moving element consists of two coils, (the control coil and the deflecting coil) fixed at an angle to one another, swinging in the field of a permanent magnet, and arranged so that the torques developed by the coils are in opposition to each other. When a current of any value flows through the control coil, but no current is flowing in the deflecting coil, the control coil, (influenced by the magnetic field) brings the pointer to rest at the infinity end of the scale. If the movement is displaced from this position (by current flowing through the deflecting coil) the control coil develops a restoring torque which increases with the displacement. This coil, therefore, is effectively similar to a spring.

The coils are so connected that one is influenced by the current flowing in the resistance under test, and the other by the applied voltage. The ratio between the two values indicates the resistance under test. The design of the ohmmeter circuit depends on the range of the instrument. The instruments are highly accurate, individually calibrated. Insulation testers have a "guard" system which prevents error due to leakage on or in the instrument.

Two types are available: (a) Switchboard type, with 6½ inch scale, for vertical mounting. (b) Bench type in teakwood case, with 4½ in. scale arranged horizontally.

Detailed specifications may be had in List 414/2a, available from R. H. Nichols Ltd., 2781 Dufferin St., Toronto 10.

●

**Cominco Gives $325,000.** — Gifts of recreational facilities totalling about $325,000 to Trail, Rossland and Fruitvale were recently announced, by R. W. Diamond, executive vice-president, western region, on behalf of The Consolidated Mining and Smelting Company of Canada Limited.

For Trail, the company will provide a large modern gymnasium with seating for 900 spectators and all other necessary facilities at a cost in the order of $275,000. The building will form a planned extension of the Trail Memorial Centre which already houses a number of community facilities, including the ice arena presented by Cominco in 1949.

Forty thousand dollars will be given to Rossland for the completion of the ice arena.

●

**System Logs 48 to 144 Points.**—A recording system capable of continuously logging conditions found in multiples of 48 to 144 points, at the rate of a point every one to five seconds, has been developed by the industrial division of Minneapolis-Honeywell Regulator Company.

The new multipoint logging system was especially designed for testing and research applications where a record of all measurements is required. It has a single set point as contrasted to the firm's more expensive elaborate electronic scanning system which has one set point for each group of nine points and which scans and logs up to 270 points.

The new system includes a strip chart recording instrument, a junction box (functioning as the control center for the system) and up to three switch units. Each switch assembly controls two banks of thermocouple points—24 points to a bank. Also incorporated in the system is an alarm signal unit. This provides a signal light when an abnormal condition exists and remains on until reset manually.

The multipoint logger may be stopped on any one point and utilized as an indicator recording that point continuously.

There are two types of the new system—a 24 volt d.-c. system and a 115 volt, 60 cycle a.-c. system. Special arrangements are available to modify the new system for some double range calibration.

●

**House of Weather Magic.** — A "House of Weather Magic" has gone into operation at Trane, creating samples of "terrible weather" from almost anywhere in the world, and then helping develop the machines to overcome it.

It's all the work of the new research and testing laboratory of The Trane Company, La Crosse, Wis., constructed for research and product development in the company's fields of air conditioning, heating, ventilating and heat transfer.

The laboratory is one of the few on the continent devoted exclusively to the science of heat transfer, contributing to solution of problems affecting the public in many ways.

Heat transfer problems range from heating a home to cooling a guided missile, from air conditioning a factory to figuring in the purification of nitrogen or performing a vast number of varying duties in the process industries.

Heat exchange is vital in a host of processes in industries including foods, drugs, chemicals, petroleum and metals such as steel and aluminum. While in some industries, the need is for handling higher temperatures, some processes in other industries now demand 300 to 350 F. below zero.

Unusual features of the laboratory include a "room-within-a-room" where the outside of the inner chamber is refrigerated to simulate outdoor winter conditions and enable testing and rating

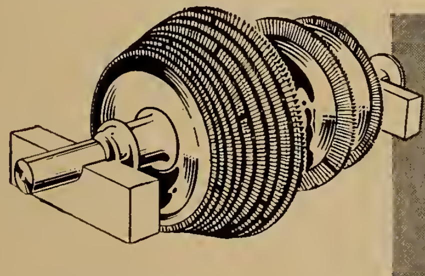
# Inglis turbines

## POWER "CANADA AFLOAT"

Around the Horn or through the Soo, for peaceful trade or vigilant defence, Inglis turbines power "Canada afloat."

There are two good reasons for the supremacy of Inglis turbines. One is Inglis itself, one of Canada's great engineering manufacturers, with every technical resource, and with the highest standards of workmanship and quality. The second reason is Inglis' association with Parsons and Pametrada, the world's most famous builders and engineers of turbines. Through this association, Inglis has access to the most advanced developments in turbine engineering as soon as they are produced.

To Canadians afloat or ashore, the Inglis plant has much to offer, whether it be turbines, pumps, compressors, boilers or special equipment for every basic industry.



Inglis
CANADA

**JOHN INGLIS CO. LIMITED · TORONTO · CANADA**

GENERAL ENGINEERING DIVISION

6-900-54

MONTREAL WINNIPEG CALGARY EDMONTON VANCOUVER of heating equipment in the inner room.

In normal operation, the inside wall of the inner chamber is maintained at about 55 degrees F. by this refrigerating system to simulate wall temperatures in an average home on a winter day. It could, however, be made much colder because temperatures in the shell around it could be driven down to 10 or 20 degrees below zero if desired for any special test project.

The shell surrounding walls, floors and ceiling of the inner chamber can also be equipped for heating so as to test air conditioning equipment in the inside room.

A network of sensitive recording instruments make it possible to take all necessary temperatures and other measurements from outside the exterior chamber. This is done because body heat from a technician in the test chamber would upset results of such tests.

The scope of the work to which the laboratory may eventually contribute includes atomic energy, jet aircraft, guided missiles, electronics.

●

**International Electro-Technical Commission.**—E. W. Henderson, manager of rotating equipment engineering of the English Electric Company of Canada, Limited is chairman of T.C. 2 of the Canadian National Committee of International Electro-Technical Commission, as well as being second vice-president of the Canadian National Committee. Due to the present activity in new insulating materials, and in the standardization of motor dimensions, this Committee is particularly active. Mr. Henderson expects to be one of the Canadian representatives to attend the Jubilee Convention this fall.

The celebration of the Golden Jubilee of the International Electro-Technical Commission is to be held in Philadelphia in September of this year. The aim of this Commission is the recommendation of international standards in the very wide field of electrical apparatus and electricity in general. Its membership includes all countries the world over.

Canada is represented in this work through the Canadian National Committee of I.E.C., the Committee being sponsored by and responsible to the Canadian Standards Association as a special committee interested in standardization.

●

**X-Ray Microscope.**—The General Electric Co. has disclosed development of an X-ray microscope that "looks inside" magnified specimens and is capable of wide use in medical science, biology and industry.

The disclosure, at an international scientific meeting in London, climaxes many years of effort in the laboratories of the U.S. and European countries to develop a practical device of this kind that can be produced in quantity.

The instrument, which magnifies up to 1,500 diameters, is expected to:

Aid in the development of new alloys and in studies of such things as corrosion and welding of metals; help researchers learn more about tooth decay, diseases of the bones and such other human ailments as mineral deficiencies and hardening of the arteries; assist in the study of such things as the covering or bonding quality of paints, adhesives and finishes, and in some cases provide a speedy substitute for chemical analysis.

In the study of alloys, plastics and composition rubber, the X-ray microscope shows the mixture of the materials and can identify them by their relative X-ray absorbing power.

To understand the principle of the X-ray microscope, think how you can cast a shadow on a wall by placing your hand near a lighted candle. The image of your hand is magnified in ratio to the distance of the candle from the wall and from the candle to your hand. But how sharp the shadow is depends upon how small the flame is.

By replacing the candle flame with an X-ray source, an enlarged X-ray image is obtained, and can be made visible by a fluoroscopic screen or an X-ray negative. But, as in the case of the candle, the sharpness of the X-ray image depends upon how small the X-ray source can be made. A conventional X-ray source cannot be made less than about one-eighth inch in diameter, and even a source as

This is one of the rotary kilns in which "HAYDITE"* aggregate is being produced from pure iron-bearing high silica-alumina lorain shale at temperatures exceeding 2000° Fahrenheit. This intense heat burns out all foreign matter and causes an explosive expansion of the shale creating myriads of microscopic, totally-enclosed non-interconnecting air bubbles, each in its own vitreous shell. This is "HAYDITE" aggregate, which is chemically inert, highly resistant to fire and humidity and light in weight—concrete made with "HAYDITE" aggregate weighs 33% less than sand and gravel concrete. In "HAYDITE" kilns some of the largest buildings on this continent have been born!

**Let us tell you about "HAYDITE" for poured-in-place structural reinforced concrete; for precast roof and floor slabs; for roof and floor fill; for refractory concrete; for guniting applications, and for building blocks.**

**Registered trade mark*

THE **Cooksville Company** LIMITED

*general sales offices:* 1055 Yonge Street, Toronto

*montreal:* Aerocrete Construction Co. Ltd., Lakefield Ave., Montreal East small as one 1,000th of an inch gives magnification no greater than an ordinary reading glass.

In the G-E X-ray microscope, the X-ray source is only one 100,000ths of an inch—300 times smaller than the diameter of a human hair.

This is achieved by focussing the electrons—tiny electrically-charged particles from which x-rays are made—through two electro-static lenses, which are essentially doughnut-shaped metal rings to which voltage is applied. The magnified x-ray image thus obtained can be seen by the eye or photographed for permanent record.

The instrument also provides great stability for the longer exposures needed for high quality pictures, and is the first to employ a built-in camera that provides developed photographs immediately after a subject is exposed.

It is not affected by magnetic materials and therefore can be used in the study of steel and alloys.

The wave length of x-rays can be changed without changing focus, making it possible to vary the contrast of pictures. The instrument also has built-in safety controls to protect the operator from accidental exposure to x-rays.

•

**B.t.u. Recorder.**—Fast, continuous measurement and control of rate-of-heat input or output is now possible through the use of the new Dynamaster B.t.u. recorder-controller systems just announced by The Bristol Company of Canada Limited, 71-79 Duchess St., Toronto, Ontario. These can be used to measure and record the quantity of heat supplied to or drawn from process vessels, refrigerating plants, air conditioners, and a wide variety of other heat-exchanging devices. Control apparatus is available for regulating the temperature or flow-rate of the heat-transfer medium.

In the basic Bristol B.t.u. recording system, one Dynamaster measures the temperature difference with two resistance thermometer bulbs and receives the flow-rate from a flow transmitter. From the two variables, it then continuously computes and records the B.t.u. product.

Other systems are offered that provide for recording temperature difference along with B.t.u. on a single round or strip chart by a single two-pen Dynamaster, recording of B.t.u. and either flow-rate or temperature difference by two separate instruments. In most instances, totalizers can also be furnished with the B.t.u. recorder to integrate the energy or heat-transfer.

Matched resistance bulbs are not required. An optional bulb trimming adjustment can be supplied, enabling the user to install a replacement bulb, and match it to the system by trimming the bulb and lead wires with the bulb trimming adjustment.

Other systems, to meet specific needs, can be provided.

•

# Publications

**For copies of the publications mentioned below please apply to the publishers at the addresses given in the items.**

**Please mention *The Engineering Journal* when writing.**

**Safety Standards.**—A completely revised edition of the "Handbook of Industrial Safety Standards", a recognized classic in its field for more than 30 years, is now available, the Association of Casualty and Surety Companies announced recently. The handbook has been developed by Accident Prevention Department of the Association, with the assistance of outstanding engineering specialists of the Association's member insurance companies.

The new ninth edition, which is 50 per cent larger than the previous edition, includes several new chapters, illustrations and tables in its 315 pages. The subject matter runs the gamut of industrial safety topics.

Copies may be obtained from any of the Association's member companies or directly from the Association at 60 John Street, New York 38, N.Y. The price is $1.40 per copy.

•

**Training Brochure.**—Persons faced with business or industrial training problems will be glad to learn of a free booklet

"The Training Job and How to Meet It", offered by the Cooperative Training Division of the International Correspondence Schools, Scranton 9, Penna.

The 24-page illustrated booklet traces the correspondence approach to industrial training pioneered by ICS for more than half a century. The sudden and urgent industrial expansion during World War II underscored the value of this type of industrial training.

"The Training Job and How to Meet It" appraises the various ways that correspondence education can be adapted to meeting training problems on either an individual or group basis.

Outlines of typical courses now being used by more than 4,500 companies in the U.S. and Canada are included in the brochure.

•

**Conveyors.** — Stephens-Adamson Mfg. Co. of Canada Limited, Belleville, Ontario. announce the availability of a new engineering catalogue No. 66 which will be of interest to companies having conveyor problems. The 655-page book contains all the latest technical information regarding bulk material handling and the use of conveyors and elevators in industry. Copies are available by request on company stationery.

•

**Tips for Steel Valve Users.**—A "Technical Tips" booklet describing and illustrating data gathered by the Edward laboratories on valve material, installation and usage has just been published by Edward Valves, Inc., subsidiary of Rockwell Manufacturing Company, East Chicago, Indiana.

Subjects discussed include "what heat does to valve trim hardness", "what thermal expansion does to valve materials", "use of globe valves for throttling service", "high temperature lubricants for valve studs and bushings", and "creep robs metal strength at high temperatures".

Copies of the "Technical Tips" bulletin 542 are free and may be obtained from Edward representatives or directly from Edward Valves, Inc., 1201 W. 145th Street, East Chicago, Indiana.

•

**Lighting Equipment.**—A new Curtis condensed catalogue was recently issued. This catalogue is designed for the convenience of the user. It covers the complete Curtis line with full illustrations and simplified index. Copies are available on request from Curtis Lighting of Canada Limited, 195 Wichsteed Ave., Toronto 17, Ontario.

•

**Mapping and Reports.**—The Charpeney-Coopman area ,which covers over 200 square miles of Saguenay County, is described in a preliminary geological report P.R. No. 296. just released by the Department of Mines of the Province of Quebec. It gives the results of an investigation made for the Geological Surveys Branch of the Department. The map-area is 40 miles east of Seven Islands and extends inland from the Gulf of St. Lawrence for 15 miles.

The area is underlain by Precambrian gneisses and intrusive rocks. Concentrations of titaniferous magnetite are found in gabbroic rocks.

The Ste. Justine area, in Montmagny, Bellechasse and Dorchester counties about 50 miles southeast of Quebec City, is also described, in a preliminary geological report. P.R. No. 297.

The rock of the area range in age from Cambrian (or Precambrian) to possibly Devonian and are folded into northeasterly-trending belts. They are, for the most part, sandstones, slates and quartzites, with some volcanic rocks and gabbroic instrusives.

The area has recently been the scene of considerable prospecting, following the discovery in 1951 and 1952 of nickel, copper and zinc deposits, and of gold, in areas not far to the north.

The reports and geological maps may be obtained from the Department of Mines, Parliament Buildings, Quebec, Que., or from offices of the Department situated elsewhere in the Province.

•

**Heat Drying of Coal.**—"New Development in the Heat Drying of Coal", a paper describing research in the use of multi-louvre dryers for drying and pelletizing fine coal, has been published in Link-Belt book No. 2507. The paper was prepared by W. W. Coffin, engineer in charge of dryer equipment for Link-Belt.

An extensive experiment was conducted to determine the drying characteristics of fine coal with a 20 per cent moisture content and the amount of pelletization possible. The findings, supplemented by pictures, tables and a flow diagram, are covered in this book.

In addition, a plant designed to reclaim commercially suitable product from a 35 acre bituminous coal slurry is pictured and described.

Copies of this paper are available from Link-Belt Ltd., P.O. Box 173, Station "H", Toronto 13, Ont.

●

**Humidity Engineering.**—A new issue of the humidity Engineer, devoted to industrial humidity conditioning problems has just been released by the Kathabar division of Surface Combustion Corporation.

One article describe the air conditioning and mechanical system installed in the southwestern home office of the Prudential Insurance Company of America, Houston, Texas.

A second article discusses the air conditioning needs of the photographic film industry. Typical installations for solvent evaporation, emulsion chilling and raw film strip drying are described.

This issue also describe the latest application of humidity conditioning. One is the drying of caves and mines, so they can be used for underground storage areas. Another is the conditioning of pilot plant operations for the making of germanium transitors. The third discloses the availability of facilities to test glue and gelatin. The object is to develop a time-temperature cycle for low temperature drying, peculiar to individual products and processes.

A new 18-page brochure on "humidity conditioning" is also offered. It contains case histories, a section on humidity problems and their solution.

Copies of this issue may be obtained by writing the Editor, The Humidity Engineer, Surface Combustion Corporation, Toledo 1, Ohio.

●

**Preventive Maintenance.**—"Preventive Maintenance for Industrial Trucks", an article written by John A. Draxler of the Elwell-Parker Electric Company, and presently available in reprint form, details the many requirements of a proper preventive maintenance program for industrial vehicles.

Explaining the importance of good lubricants and correct lubrication, and enumerating the principal causes of equipment failure and breakdown, the booklet also contains several maintenance forms used by Elwell-Parker which may be copied for a company's own use.

Additional sections of this article emphasize the vital importance of accurate record-keeping and development of the proper attitude by employees toward maintenance regulations.

A preventive maintenance check list which is included provides a valuable aid to all users of industrial trucks, whether their schedule necessitates weekly, monthly or quarterly check-ups.

Copies of this report may be obtained without cost from the Elwell-Parker Electric Co., 4205 St. Clair Ave., Cleveland, Ohio.

●

**Air Conditioning and Hot Water Storage Heaters.**—Two new publications are now available from Sarco Canada Limited. One is a catalog issued by the Patterson-Kelley Co., Inc. on hot water storage heaters. This catalog gives complete engineering data on the company's type B (horizontal) and type L (vertical) units designed for service where hot water requirements are not constant or where a large volume of heated water must be held in storage.

The second publication is a bulletin on the Modine Air-conditioner, a new heating and cooling unit designed for year 'round air conditioning of individual rooms. Both are available from Sarco Canada Limited, 611 Gerrard St. E., Toronto 8, Ont.

●

**Mechanical Power Transmission.** — A newly revised 8-page, two-colour catalogue (B20-53) describing the complete line of Morse mechanical power transmission products is now available from United Steel Corporation Limited, 58 Pelham Avenue, Toronto 9.

The new catalogue describes and illustrates silent chain, roller chain and Hy-Vo drives; sprockets, cable chains, drive shafts, couplings and clutches.

New information is included in the catalogue on taper-lock sprockets, cam clutches and torque limiting clutches. Brief specifications, stock sizes, applications and descriptions are included for each product.

●

**New Quarrymaster Bulletin.**—Ingersoll-Rand has announced the availability of a new and colourful bulletin describing the New QM-2 Quarrymaster, which the manufacturer claims is the only machine of its kind developed as a dual purpose

blast hole drill for either rotary or percussion drilling.

Th new bulletin tells the story of the QM-2 as a percussion drill pointing-up its features and its uses. Two additional pages do the same thing for the unit as a rotary drill. The center spread, by means of a large illustration and easily read captions, depicts the individual features that make up the Quarrymaster.

Other pages of the bulletins show "in-use" pictures, give dimensions and specifications and list accessories that are available.

For your copy of the bulletin write Canadian Ingersoll-Rand Company, Limited, 620 Cathcart Street, Montreal, Quebec, or contact your nearest Canadian Ingersoll-Rand branch office and ask for Form 4153.

●

**Brown Boveri Publications.** — Brown Boveri recently issued two publications, No. 2346E — Large Condensing Steam Turbines, and No. 2323E — Gas Turbines. They deal with subjects of timely importance to Canadian engineers, since today the trend is toward prime movers, other than water power, to drive the generators producing Canada's electric power.

Within the next two months, a 25,000 Brown Boveri steam turbo-alternator will be started up at Winnipeg, Manitoba, and Canada's first gas turbine generating station, a complete Brown Boveri plant, will begin feeding power into Alberta's power system at Vermillion. Copies of the publications are available from the company at 1015 Beaver Hall Hill, Montreal.

●

**Steam-Water Cycle Deposits.**—The application of analytical techniques which assure positive identification of deposits found in steam-water cycles has reached the point where constituents are normally reported in terms of mineral names rather than chemical formulae.

As a means of helping operators obtain a better understanding of such analyses, Allis-Chalmers water conditioning section has prepared a tabulation giving the mineral name, chemical formula, usual areas in which the deposits are found, the normal causes, and some suggested preventive measures.

Copies of this general information, Bulletin 28X8155, are available on request from Allis-Chalmers Manufacturing Company, 1270 S. 70th Street, Milwaukee, Wisconsin.

●

helicopters designed for future airline services operating to city centres. The 173 carries 16 passengers at a cruising speed of about 135 m.p.h.

Two companies are working on turbine-powered helicopters. Fairey Aviation Co. Ltd. are building the Rotodyne which will be powered by two Napier Eland turboprops, mounted on stub wings, with rotors driven by jets mounted at the tips. The Rotodyne is designed to hold 40 passengers and baggage, with a cruising speed of 150 m.p.h. Percival Aircraft Ltd is developing an 8-seat machine, the Percival P74. This has a Napier low-pressure system claimed to make mechanical coupling between the source of power and the rotor blades unnecessary.

●

**Dial Square for Engineers.** — A new precision engineers' square, incorporating a highly sensitive dial gauge, has been patented by The Acru Electric Tool Mfg. Co. Ltd., Chapel St. Levenshulme, Manchester 19, England. Used for testing the angles between finished plane surfaces, the square enables angular error to be read directly from the gauge.

The glass-hard blade of the square is pivotally mounted into the stock, so that the included angle may be varied. The true right-angle and the extent of departure from it is indicated. The dial can be rotated to zero, and each division represents 0.001" error per foot. Errors up to 0.030" per foot plus and minus can be read. Any variation caused by a knock or jar is automatically recorded on the dial and can be eliminated before any harm is done.

Other advantages over the rigid square are that no feeler gauges have to be used, angles of both 90° and 270° plus-or-minus 0.030" per foot can be measured instantaneously, and if required the centre screws can be tightened making it as rigid as an ordinary square.

Patents for the square have been taken out in Switzerland, the U.S.A. and Western Germany and agents have been appointed in Canada and the U.S.A

●

**Overhead Travelling Crane.**—An overhead travelling crane, believed by its makers to be the first of its kind, has been produced by J. H. Carruthers and Company, Ltd., of Glasgow, Scotland. For some years the firm has been investigating the ratio between lifting capacity and the deadweight of overhead cranes for different spans. The object has been to evolve a design which would give a considerably lower deadweight for a given span than would be possible for conventionally designed cranes fabricated from rolled-steel sections. The outcome is a crane entirely fabricated from tubular steel, excepting for the end plates, traveller rails and wheel-carriages.

The weight of the main girder is stated to be approximately half of that of a similar girder fabricated from structural steel. In the case of a crane spanning 55 feet (16.76 metres) there is a saving in weight of approximately ten tons. This saving in weight leads to several advantages, in that the load on the columns supporting the running rails is reduced by a like amount which, in the case of a building proposed for erec-

## Notes From Britain

**Accurate Measurement of Shaft Speed.** — The latest techometer, which has an accuracy of better than 0.1% at all speeds, is an electronic precision engine speed indicator made by The Plessey Company Limited, Ilford, Essex, England. The tachometer, which gives an accurate direct reading, is portable and extremely versatile. It will find applications in many fields of engineering and is ideal for use as a standard when calibrating other instruments

To operate the indicator, the rotary motion of the shaft is converted into electrical pulses. This may be done in a number of ways: aero engines are usually equipped with a small electric generator used in conjunction with the normal magnetic-drag tachometer, and the output from the generator can be used to control a frequency multiplier unit. For engines not fitted with such a generator, a photo-electric device, which imposes no load on the shaft to which it is attached, has been specially developed. It consists of a photo-cell amplifier with an associated opaque disk having 60, 30 and 10 equally spaced slots. The disk is attached to a synchronous motor driven by the aircraft tacho-generator, and when the 60 slot spacing is selected the instrument reading is direct in r.p.m.

The instrument counts the number of pulses generated during a period of one, two or four seconds and gives the result in terms of revolutions per minute on a dekatron display unit. Normally, the pulses are counted for one second, the result is displayed for 0.8 second and the apparatus then returns to its original state, when the cycle is recommenced. A switch enables any result to be retained for as long as desired, after which continuous counting may be resumed. The result is given in terms of r.p.m. by a display unit consisting of four dekatrons to record thousands, hundreds, tens and units. The one-second period is controlled by a 4 kc/s. crystal oscillator, accurate to 0.005%, the output of which is divided to produce a 1 c/s. pulse. In addition, a 2 kc/s. signal may be switched and fed to the input terminal to check the operation of the display unit.

The magnetic-drag tachometer seldom had an accuracy of greater than 0.5% at full scale deflection and is subject to ageing, whereas with the electronic precision engine speed indicator an accuracy of 0.1% is easily obtained. At high rates of counting the accuracy becomes even greater, reaching a limit of 0.03% at 3,000 pulses/second, with a one-second count and results better than 0.01% are available when a longer count can be used.

**Future of Helicopters.** — With the opening of the new British European Airways passenger service with helicopters, the Society of British Aircraft Constructors has been reviewing the present experimental services. It is hoped that a larger and faster twin-engined helicopter will follow the present experimental type and that later on the turbine-powered helicopter will come into its own.

Experimental work on "rotor-bus" helicopters includes three twin-engined Bristol 173's being built for service with the B.E.A. These are powered by two Alvis Leonides Major piston engines at each end of a 28' fuselage. A synchronizing shaft runs along the roof of the fuselage, ensuring that both rotors turn at the same speed, and that one engine can drive both rotors if the other engine should fail. British authorities insist on this twin-engined safety factor in all tion, permits the use of lighter columns and foundations for any given lifting capacity. Conversely, by replacing a crane of conventional design with one of tubular construction, a greater lifting capacity can be obtained for the same total weight and load on the columns.

The makers point out that, whereas a 15-ton crane of 100 foot (30.48 metres) span and of conventional design can lift only 15 tons, a similar crane of tubular construction and with the same structural weight, can lift 20 tons; an increase of 33 per cent in lifting capacity without requiring any structural alterations to the biulding in which the crane is located.

Travelling, traversing and hoisting speeds are suited to users' requirements. One crane was recently supplied with a travelling speed of 420 feet (128 metres) per minute. The speed of the 15-ton crane is 300 feet (91.44 metres) per minute, the traversing and hoisting speeds being respectively 100 feet (30.48 metres) and 20 feet (six metres) a minute. This particular crane is also fitted with a two-speed gearbox giving a two to one speed reduction and permitting a load of seven and a half tons to be hoisted at 40 feet (12.19 metres) a minute.

Control of the three motions is from a driver's cabin suspended below the main framework at one end and may be obtained in the form of what is termed "Microsen" creeping-speed crane control. This system enables such small movements to be made under power that they are scarcely noticeable, and it gives an extremely high degree of gentle and sensitive control. "Microsen" control may be fitted to any or all of the three motions, depending on the user's requirements.

•

**Four Plastics In Welding Torch.**—An argon arc welding torch, in the construction of which four plastics have been used, has recently been developed for a wide range of welding operations It is the "Actarc" made by the Arc Manufacturing Company, Ltd., of Actarc Works, Glasgow, Scotland, and of 50, Oxgate Lane, Cricklewood, London, N.W.2., England. It is intended for use in welding applications ranging from 16-gauge aluminium sheet to heavy plate requiring welding currents in the order of 300 amperes. Polyvinyl chloride, polythene, nylon and phenolic laminates have all been employed for varying purposes in order to reach the exact aim of the design.

The torch consists essentially of a detachable water-cooled nozzle, screwing into a single-piece head and body, the base of the body being attached to a long, hollow handle, through which the current lead, water and gas supplies run. The body and head are of high-conductivity copper alloy covered with black polythene to provide insulation and prevent corrosion, the hot components being simply dipped in polythene powder to obtain this coating. The water-cooled nozzle, which again consists of high-conductivity copper, is held on to the head by a ring of paper-based phenolic laminates; the cover which is mounted at the back of the head and which protects the tungsten electrode is also machined from similar phenolic laminate. These laminates provide good insulation and are readily machined to the required shape.

To carry cooling water from the body of the torch to the nozzle, there are two outside pipes for which polyvinyl chloride has been used to give the necessary electric insulation. These tubes are tightened to the body by knurled nylon nuts, employed because of the high mechanical and electrical strength of nylon and its low friction preventing twisting of the tubes when the nuts are tightened. The long hollow handle of the torch is machined from paper-based phenolic-bonded laminated rod and screws into the body of the torch by a brass ring pressed into the handle tube. The shield which fits over the handle is machined from similar laminated sheet. The use of laminate for the handle means that good insulation is provided for the welder, the handle also being shatter-proof.

RED FEATHER SERVICE

# EMPLOYMENT SERVICE

(*Continued from page 1147*)

construction, Canada; and one year experience with manufacturing concern. Seeks employment in the Montreal area preferably. Available for work at the beginning of September. File No. 4554-W.

ELECTRICAL AND MECHANICAL ENGINEER, B.A. (Eng.), A.M.I.E.E., British, aged 4?, family; seeks administrative, sales or consulting engineering post, any location not involving prolonged separation from family. Twenty-two years technical sales of heavy electrical plant, generation with all types of prime mover, distribution, application. Newly arrived from five years in Brazil as technical chief, selling and supervising diesel and diesel alternator installations. File No. 4555-W.

GEOLOGIST, SOILS ENGINEER and Surveyor, M.E.I.C., P.Eng., age 41, 18 years experience in geological and geophysical exploration (oil, coal, chromium, tin, iron), glacier research, soil mechanics (foundations, airports, hydrology, laboratory), diamond drilling, terrestrial and aerial photogrammetry, photogeological interpretation. 8 years consultant in Europe. Very experienced alpinist. Seeking responsible position with occasional field work in Western Canada, preferably Calgary. Permanently employed. File No. 4556-W.

MECHANICAL ENGINEER, Jr.E.I.C., 1949, N.S.T.C., age 28, married with children, desires a responsible position with an energetic company. Experience in general mechanical design, standardization, cost reduction, shop supervision, personnel administration and manufacturing methods. Interested in manufacturing, sales or design. File No. 4557-W.

ELECTRICAL ENGINEER, Jr.E.I.C., N.S.T.C., 1952, age 23, single. Interested in all fields of electrical engineering activity and wiling to take responsibility and apply himself. Presently in second year of graduate student training course with large and reliable Canadian manufacturer of electrical equipment. Experience includes one year in transmisison and distribution departments of hydro-electric utility. Some accounting experience. Desires position in Canada and would give special consideration to Newfoundland as a location. File No. 4558-W.

MECHANICAL ENGINEER, Jr.E.I.C., graduate N.S.T. College 1951. Experience includes 1 year research work and 2 years mechanical design. Interested in position in plant engineering maintenance or design. Preferably located in Montreal area. File No. 4559-W.

ELECTRICAL ENGINEER, Jr.E.I.C., B.Sc. (Maths. and Chem.), Acadia University, 1949, B.E. Nova Scotia Technical College 1952. Age 27, married. Experience: One year as engineer in distribution department of small electrical utility; presently taking Westinghouse Graduate Training Course. Desires position offering scope for learning and advancement with small company or utility. File No. 4560-W.

CONSTRUCTION ENGINEER, B.Sc. (1943), M.E.I.C., A.M.I.C.E., A.M.I. Struct. E., 11 years experience. Seeks responsible position. Has held the following positions: General superintendent, assistant project engineer, estimator. Experienced on light and heavy construction excavation, water mains, sewers, concrete, etc. Married, 33 years old, bilingual. File No. 4561-W.

CIVIL ENGINEER, B.E., 1953, U. of S., Jr E.I.C., seeks position in design and construction. Working at present with prominent Government engineering department. Interested in position with good possibilities for advancement. Willing to work hard. Single with car. Experience in surveys (all types), supervision of survey crews and construction crews, design in water and sewer lines, some concrete design. Was completely in charge of installation of many hydraulic structures, highway-type bridges, large culvert installations and a gravel contract. Has also had experience photoelastic analysis, soils studies and river studies. Has taken night classes in photography, welding and carpentry. Interview can possibly be arranged. File No. 4563-W.

GRADUATE CIVIL ENGINEER, D.R.T.C. (Glasgow), A.R.T.C. (Glasgow), San. Eng. (Glasgow), age 31 years, single, bilingual, willing to travel, desires senior position with responsibility in municipal engineering, contracting, concrete or structural steel installations. Experience: one year research work, 3 years general municipal engineering, 4 years drainage and irrigation experience in Malaya including supervision of earth moving plant, reinforced concrete design, estimating, surveying, office routines, design of irrigation schemes and structures, chief assistant on a $5,000,000 (Canadian) irrigation scheme. Experienced in Jungle clearing and swamp drainage. Available September 1st. File No. 4565-W.

MECHANICAL AND INDUSTRIAL ENGINEER, P.Eng., M.E.I.C., A.M.I.Mech.E., Junior executive, 10 years experience of industrial plant specifications, layout, design and erection, also specialized machine design and plant maintenance. Interested in entering consulting field in Southern Ontario. File No. 4568-W.

ELECTRICAL ENGINEER, B.A.Sc., M.E.I.C., P.Eng., age 40, married, three children, requires immediate employment preferably in consulting industrial or utility. C.G.E. test course, four years production engineering, eight years apparatus sales engineering. File No. 4576-W.

CIVIL ENGINEER, McGill, 1951, Jr.E.I.C., P.E.Q., married. Presently employed as area field engineer, on large project. Experience: 6 months drafting, 2½ years office engineer (quantities, costs, progress reports, etc.) and 1½ years varied field engineering in heavy construction. Seeks responsible and permanent position in Montreal with firm requiring above experience, or in design office. File No. 4579-W.

CHEMICAL ENGINEER, M.E.I.C., 1937 graduate, married, Canadian, would like to locate in the Toronto area. Experienced in pilot plant design, production and management phases of organic chemical plants both in Canada and the U.S. Interested in production and in sales in the field of chemical plant equipment or engineering services. File No. 4580-W.

ENGINEERING AND BUSINESS graduate, Jr.E.I.C., P.Eng. Ontario, B.A.Sc. Toronto (honours) 1953, age 24, single, C.G.E. test course graduate, tool design and sales experience. Desires position with small or medium sized company in Toronto or South Central Ontario area. Prefers manufacturing or industrial engineering position leading to supervision and management. File No. 4581-W.

A YOUNG CIVIL ENGINEER, 27, married, with Master's degree in hydro-electric structures from Columbia University, New York, and with 4½ years' practical experience in design and construction of hydro-electric projects and reinforced and steel structures in U.S.A., India, and Canada. Knows Eastern and Indian languages. Desires a suitable job with any concern working overseas in any part of the world, preferably in Eastern or Middle Eastern countries. Presently employed. File No. 4582-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng. (Que.), B.Eng. McGill 1951, single, age 26 1½ years experience technical assistant sales in rubber industry, assistant construction engineer for new pulp and paper mill in New Zealand, assistant power engineer pulp and paper mill in Australia. Desires position with small manufacturing company in Montreal. File No. 4584-W.

CIVIL ENGINEER, university graduate, P.Eng., age 38, married, one child, with practical experience in road construction, surveying, steel structures and reinforced concrete (industrial structures and heavy foundations for power stations, steel mills, etc.), both with contractors and with consulting engineers, used to work on own initiative and responsibility, attending to correspondence, site meetings and negotiations with clients, some knowledge of accounting and financial matters, at present with consulting firm. Desires responsible position with construction company, consulting engineers or investment organization requiring the services of a competent engineer, preferably but not exclusively in Toronto. Apply File No. 4586-W.

MECHANICAL ENGINEER (Polish University College, London. 1951), specializing in aero and thermodynamics. Three years' experience as designer and draftsman in pneumatic and electric equipment. One year in Canada. Interested in position in research or development. Age 35. Will go anywhere. File No. 4587-W.

CIVIL ENGINEER, McGill 1950, with five years excellent construction experience (design, supervision of construction, costing). Two and a half years on construction with Canada's largest textile company. Recent overseas experience in pulp and paper mill construction, oil refinery construction, building design. Desires position with company allied with the construction industry where there is a chance for responsibility and advancement. Willing to work anywhere but preferably in the Toronto-Montreal area. File No. 4588-W.

DIPLOMA ENGINEER — CIVIL, age 41, with 10 years of varied continental and British experience on the design of concrete buttress, gravity and arch dams, weirs, sluices, tanks, fishpasses, large steel welded pipe lines, and structural steelwork, reinforced concrete and prestressed concrete bridges and industrial structures with shell roofs. Seeks responsible position in British Columbia, Ontario or Quebec. File No. 4590-W.

## Attention, Members

Please telephone in advance and make an appointment if you propose using the Institute's Employment Department.

This will result in a better service to everyone concerned.

**TELEPHONE PLATEAU 5078**

**Except in special cases all interviews will be arranged between the hours of 9 and 12.**

# THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME 37 — MONTREAL, OCTOBER 1954 — NUMBER 10

Price $6.00 a year in Canada. British Possessions. United States and Mexico, $7.50 a year in Foreign Countries. Current issues, 75 cents a copy, back issues from $1.00 per copy up. To members and affiliates, 50 cents a copy, $4.00 a year.—Authorized as second class mail. Post Office Department. Ottawa.

# New Starter Scores on Toughest Job!

**EXOLON COMPANY DELIGHTED WITH AMAZING SERVICE OF NEW**

## Westinghouse *Life-Linestarter* MOTOR CONTROL

The Exolon Company of Thorold, Ontario, had a tough motor starter problem. A conveyor between primary and secondary crushers had to be stopped at least 20 times a minute for the hand selection of abrasive aggregate. Intense atmosphere of rock dust, plus excessive motor starter operations required new contacts once a month for ordinary starters. These production shut-downs were a costly nuisance!

On September 17th, 1952, Exolon installed a Westinghouse Life-Linestarter!

Since then, the Westinghouse Starter has operated continuously without attention — original contacts are as good as new! Maintenance costs in well over a year are zero!

There's good reason for this outstanding performance. Westinghouse Life-Linestarters are an entirely new motor control development. Patented De-ion Arc Quenchers do away with contact pitting, spring loaded, clapper-type breaker mechanism cannot foul. Straight-through wiring and pressure-type connectors make installation easy. Maintenance is simplified with all five sizes of Life-Linestarter of the exact same design—all parts are front removable with a screwdriver.

For a new concept of motor control service, for elimination of breakdowns, reduction in maintenance, install Westinghouse Life-Linestarters. Full details are yours by writing to Industrial Division, Canadian Westinghouse Company Limited, Hamilton.

# Instrumenting A Nylon Intermediates Plant

by
F. G. Carson
*Chief Supervisor, Maintenance-Instrumentation,*
*Canadian Industries Limited,*
*Maitland, Ontario*

The day of the automatic factory has not yet arrived, but it is on its way and nowhere more rapidly than in the chemical industry, where control of quantity, pressure and temperature, rather than of mechanical operations, is paramount.
Mr. Carson's paper describes the instrumentation and control installation in a very new plant, from its conception to its completion.
This paper was presented at the annual meeting of The Engineering Institute of Canada, at Quebec City, May, 1954.
On July 1, 1954, the Maitland Plant of Canadian Industries Limited came under the ownership and operation of Du Pont Company of Canada Limited. Mr. Carson now occupies the same position with Du Pont of Canada's Textile Fibres Division as he formerly held with Canadian Industries Limited.

With its many advantages in quality improvement and cost reduction, instrument control is becoming an increasingly important function in every industrial plant. As production throughputs have increased and the price of labour has risen, batch processes have become uneconomical and have been gradually replaced by continuous systems.

With new techniques, particularly in the field of centralized control, rapid progress has been made towards the concept of the automatic factory. One of the most modern of Canadian chemical plants is Canadian Industries Ltd.'s (C-I-L) Maitland Works, wherein are manufactured two complex chemicals, the raw materials required for the spinning of nylon staple and yarn. The plant is built on a 1,700 acre plot on the shores of the St. Lawrence River.

This paper outlines a number of the instrument problems and programs encountered in the design construction and operation of a complex plant of this type. The stages leading to the completion of this plant covered approximately a three-year period starting with design in October, 1950; construction in October, 1951; and final plant startup in August, 1953.

The solutions developed should not be considered the only, nor necessarily the best ones, but in each instance they suited the particular needs of the particular problem.

Before the reader can visualize the many difficulties encountered in a project of this type, he must have in mind a picture of the basic measuring instruments, centralized control, graphic panels and the many facilities required to link the components.

Fig. 1. Aerial view of the plant.

Fig. 2. Interior of a control room.

#### Centralized Control

Operations at Maitland are distributed through several separate buildings. The process variables, such as flow, temperature, pressure and liquid level, are measured by instruments and are transmitted to one of two control buildings where they are suitably and compactly displayed for observation by the few operators. For each controlled area one operator is located in the control room and up to two in the operating buildings. The control room operator observes process conditions, makes panel settings and advises the outside operator if field adjustments are required. Fig. 1 shows the plant area with the two control centres in the brick buildings at left center and right center of the process block.

Transmission of most messages concerning the operating process is done pneumatically by instruments. These measure the process variables and transmit air pressure signals which actuate pressure gauges on the control panel. These gauges are marked directly in terms of the process conditions being measured. Quarter-inch copper tubing acts as the nerve system linking a transmitter to a panel gauge.

To assist in communicating with the area, public address and telephone systems are provided for each process building. Automatic alarms are used to direct the operators' attention to critical conditions. Certain variables are recorded to indicate trends and to provide operational histories.

Each of these control centres contains approximately 80 feet of graphic panel and 30 feet of recorder panel. A typical graphic panel is laid out like a process flow diagram with symbols depicting process equipment, colour coded lines depicting process piping and miniature instruments indicating a process variable at the point in the process where that variable is measured. For example, the symbol which represents a hold-up tank may be surmounted by a dial. This dial indicates the level in the vessel. The operator, therefore, has a direct reading of the current liquid level in the hold-up tank.

Fig. 2 illustrates the graphic method of instrument presentation. Recorder panels are located to the right and left of the main panels. Fig. 3 shows the tubing runs used for transmitting the signals and located behind the panels.

Recent developments in miniature instruments for graphic presentation have made present day centralized control both feasible and practical. Miniature instruments have reduced what might have been 200 to 300 feet of panel to a more reasonable figure of 80 feet for this plant. One of the major advantages of this compact panel is that it assists the operator to observe and to interpret the many process variables under his jurisdiction. It leads to an easily and safely operated plant. The operator is required to adjust controls and to perform remote manual operations to maintain the process variables at those rates and values required for optimum quality and economy.

So far, panel gauges have been considered merely as indicators. Many of the instruments will automatically maintain the process at some preset value. The miniature panel control station, occupying approximately 5 x 5 in. of panel, is the main instrument in these control loops.

This versatile instrument, shown in Fig. 4, provides an indication of the process variable, an indication of the set point, a means of adjusting the set point, a means of taking over direct manual control of the automatic valve and a means of spot checking the valve position when on automatic control. The controllers themselves are separate from the transmitters and may be mounted at the panel, or near the transmitter and control valve in the process area.

Fig. 3. Backs of two instrument panels.

#### Statistics

There are approximately 2,000 instruments at Maitland including 350 control valves, 150 temperature transmitters, 100 pressure transmitters, 125 flow transmitters and 80 level transmitters. The control rooms house 160 feet of graphic panels, 60 feet of recorder panel and 125 feet of alarm and special interlock equipment. These numerous components are linked by some 100 miles of copper tubing.

When one considers, in addition to so many instruments, the feet of pipe and numerous hand valves for process connection, the plugging problems introduced by handling materials that solidify up to temperatures of 130°C., the corrosion problems resulting from the handling of strong acids, the high pressure problems resulting from operating pressures up to 7,000 p.s.i. and the general freezing problems encountered as a result of open operating areas, an overall picture of the instrumentation may be appreciated.

#### Design

After preliminary planning it was concluded that the design of the intermediates plant would be made by C-I-L engineers. Fully aware of the potential of modern instrumentation, they determined to take full advantage of continuous flow design and automatic operation.

Instrument application and project design techniques have been the subject of much study. In spite of this, the information needed to purchase suitable instruments and to lay out installation detail is not readily available in present day texts. The techniques of structural, electrical and piping design are only beginning to be paralleled in instrumentation. In addition, choice of control equipment has become more difficult as the numbers of available types have increased.

What is the significance of this condition when the design of a new automatic plant is being considered? It means, first, that the correct type of individual must be developed, one with the special skills required to cope with a new science. Little provision has been made for education in instrument matters in engineering schools.

The instrument application engineer is concerned with the size of vessels, pressure drop in lines and equipment, types of heat exchangers, location of valves, process reaction times and many other problems usually considered the exclusive domain of the process engineer. In addition, he must have the operating engineer's understanding of procedures and safety and, further, an intimate knowledge of instruments, maintenance problems and control techniques.

It means, second, that as each new program is launched, known techniques must be reviewed, their application to the problems at hand studied and revised where necessary to obtain the most up to date design.

To obtain a clearer picture of the specific phases through which any instrument process design will pass, the fundamental stages followed at Maitland are listed and outlined below. It will be recognized that the basic approach is similar to that used in attacking most design problems.

##### *a. Scheduling, organization and man-power predictions*

As in planning any program it is important to develop from the beginning a logical and systematic attack. Specific questions must be asked and answered. Although these questions may be many when detailed, they can be simply grouped as follows:

What is the problem? How much will it cost to solve it? How should it be solved? Who is going to supply and install the equipment? When should installation be finished?

Realizing the importance of co-ordinating instrument and process design, both programs were developed simultaneously starting in September, 1950.

After the major task of designing, constructing and operating a nylon intermediates plant, and program scheduling had been carefully defined, it was necessary to develop engineers to attack the instrument assignment. Since in most instances qualified persons were not available, engineers were put through a training program, including a chemistry review, a process study and visits to similar plants.

The training of engineers was sufficiently broad to cover the design, construction and operating programs. Since the process at Maitland is very similar to that used at E. I. du Pont de Nemours' Sabine River Works in Orange, Texas, engineers visited that plant for periods ranging from two to twelve months starting in January, 1951. The guidance and information obtained from instrument engineers at Sabine and from the E. I. du Pont de Nemours' engineering department in Wilmington, Delaware, were of particular value in preparing the C-I-L engineers for conducting their program.

Each instrument engineer was assigned to work with a project engineer on a specific area of the plant. Their responsibility included the selection and purchase of instruments and the preparation of sufficient drawings to enable the construction program to be completed. Instrument engineers reported to a central instrument authority, which assisted in maintaining uniform methods and choice of instruments.

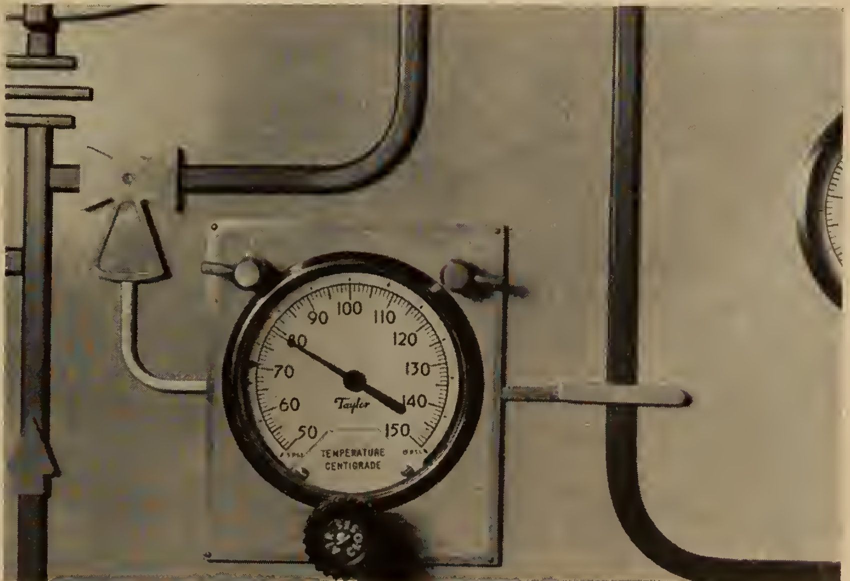

Fig. 4. Miniature panel control station.

*b. Preparation of control diagrams, estimates and techniques*

For a number of months the control of the process was studied in detail to determine what type of measurement and control was necessary. For reasons of safety and simplicity graphic type panels were chosen.

These studies led to the preparation of instrument control diagrams and panel layouts and finally to cost estimates. On the subject of costs it is interesting to note that, in a project of this type, the cost of installing an instrument is approximately the same as the purchase price.

To provide a uniformity of approach, the instrument engineers agreed on standard procedures for listing, specifying and recording basic data. Design techniques for control valve sizing, averaging liquid level control and orifice sizing were discussed and finalized. Space requirements, ease of maintenance and methods for connecting into vessels and process lines were carefully studied to provide the project engineer with information for building layouts and piping arrangements. To assist in instrument selection, required accuracies were discussed from both a process and an accounting point of view.

*c. Instrument study and specification*

Once the type of instrument was chosen and process conditions established, the actual make of instrument to perform the function with satisfaction was selected.

Instrument specifications must deal with accuracy, stability, operating range, type and size of connection, mounting arrangement and materials of construction. In specifying, an effort was made to purchase instruments constructed of materials as suitable as the materials of which the process equipment was to be fabricated. No one seems to question the detailed specification required for the construction and purchase of a process vessel. The same attention to instrument specification pays dividends by providing better and safer instruments. The specifications become more complicated to prepare when stainless steel instruments are required; the problems of low carbon and stabilized stainless steels are not generally appreciated by all instrument suppliers.

*d. Procurement*

The next stage covers the placing of orders and the finalizing of delivery dates. Most jobs will proceed towards completion at a rate in direct proportion to the amount of follow-up. The value of a fast moving expediting group to keep in touch with and assist the supplier cannot be over emphasized.

*e. Preparation of Drawings*

In preparation for a smooth running construction program, clear and accurate drawings must be made available at an early date. It is desirable to answer at the design stage every possible question that may arise during construction. The construction engineer is particularly grateful for this approach since it relieves him of the pressure of making many small decisions, when he is, at the best, operating under pressure.

Drawings must show what instruments are required; where they are to be located; how they are to be mounted; and how they are to be connected. In addition, numerous detail drawings are required to permit accurate shop fabrication of the many components required to fit the puzzle together. A draughting squad leader, supervising a group of between five and eighteen draughtsmen, over a fourteen-month period produced approximately 490 drawings to provide the necessary field detail.

*f. Procurement of miscellaneous parts*

In any construction program a small bolt may be as important as a major instrument; in fact, the instrument often cannot function until every last nut, bolt and valve is in place. The detail drawings were made to show all the small parts needed and therefore to facilitate accurate quantity take-offs. The procurement of

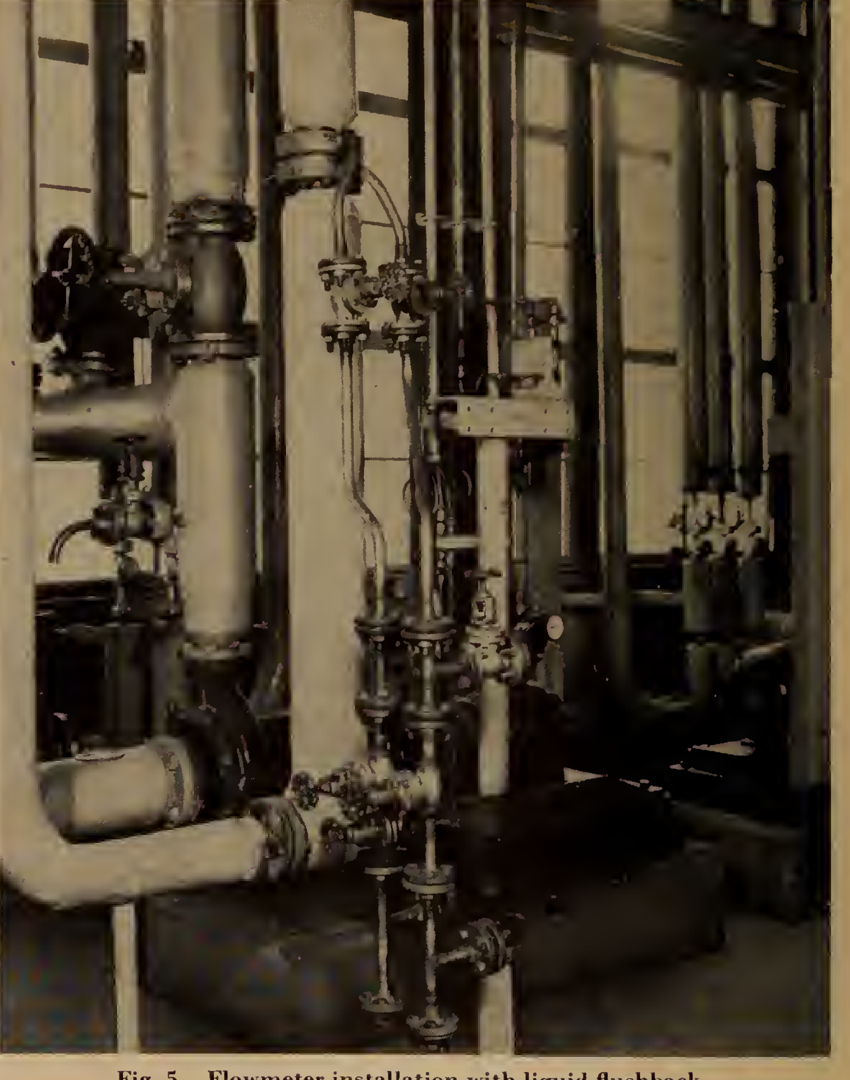

Fig. 5. Flowmeter installation with liquid flushback.

these many thousands of parts is a vital program not to be left until the last moment.

The design continued through to May, 1953, with a considerable portion of the later months devoted to answering field problems, expediting previously ordered items and ordering parts missed during the initial take-offs.

### Design Techniques

A few of the techniques used during the design of the plant may be of interest and are outlined below.

***a. Lane system***

To assist in sorting out and routing the maze of piping, tubing and conduit, an allocated lane system was used wherever possible. Instrumentation and electrical services were assigned an area extending down to approximately nine inches below the bottom of the ceiling beams. Instrument tubing, conduit, junction boxes and air and purge supply lines were all run in this well defined space and thus interference with other piping was considerably reduced.

***b. Instrument maintenance***

Each instrument installation was arranged to provide adequate space for maintenance purposes. Although control room space in the centralized system is reduced, additional room for mounting transmitters is required in the process buildings. The process engineer must consider these needs from the day he starts to lay out the building.

Control valves were in most instances lowered to a distance of approximately two feet from the floor. Instruments were mounted not higher than five feet. The general working area was made sufficiently clear to provide safe access to each unit.

***c. Instrument air***

Many of the small passages in instruments are of the order of a few thousandths of an inch in diameter. Even minute traces of oil or dirt will interfere with the operation of the pneumatic systems to a point where maintenance problems may be greatly increased. In addition, if freezing conditions are to be encountered, the air must be dried to a dew point below the lowest expected temperature. At Maitland this critical temperature was found to be −30°F.

To provide a satisfactory air supply two electrically driven Nash compressors, with chemical driers, were installed. Should the electric power fail, a stand-by steam-driven Nash compressor, with an automatic starting system, guarantees a continuous air supply.

***d. Prefabrication***

To provide positive, leak-proof process connections flanged joints were used throughout. Instruments were therefore purchased with flanges and linked to the process by special adapter and manifold assemblies. Every effort was made to design each of the assemblies to permit its fabrication in a pipe and welding shop.

Fig. 5 shows a typical flowmeter installation with liquid flushback. All assemblies, except the two between the valve at the orifice flange and the tee piece above the three-valve manifold, were prefabricated. Since slight strains on the instrument bodies will introduce appreciable error, it is important to construct these assemblies with sufficient accuracy to avoid stresses.

***e. Instrument mounting***

Mounting instruments on pipe lines and on process equipment was avoided by the use of the pipe stands shown in Fig. 5. This practice permitted instrument installation to parallel that of the piping and equipment.

Instruments were mounted on their stands in the central shops and connected with tubing to a pneumatic manifold which served in much the same way as a terminal strip in an electrical circuit. By transporting the entire assembly to the field, extensive tubing work in the construction area was avoided.

***f. Tubing installation***

Two widely differing methods of installing tubing are in use at present. One system involves the laying of tubes in a channel, so that each tube is exposed throughout its entire length and easily accessible for maintenance purposes. The other involves the installation of tubing in a completely enclosed pipe conduit. This latter scheme eliminates the accessibility feature, but provides protection for the tubes. This system was chosen at Maitland.

Tubing was bundled and pulled into electrical conduit as is done with cable, conduits being filled to a maximum of 75 per cent of their capacity.

One of the largest distributing boxes installed at Maitland is shown in Fig. 6. The tubing enters the box and forms a complete loop before leaving on its final conduit run to an instrument stand. For reasons of accessibility the tubing unions were installed at the bottom of the loop in the junction box.

Fig. 7 shows the tubing enclosed in conduit and carried to the instrument stands where it loops into the manifold. The largest installation consisted of pulling approximately 140 tubes into a 75-foot run of four-inch conduit containing two right-angled bends and a double offset. A three-ton pull was required.

***g. Steam tracing and lagging***

As a result of both the freezing characteristics of the process liquids and the outside winter temperature conditions, many of the instruments required special steam tracing.

Tracers of ⅜-in. tubing were installed parallel to the impulse lines and around the instruments. Fiberglas pipe insulation covered with roofing felt for outdoor installations or canvas for indoor installations was used to encircle the tracer and pipe. Irregular shapes were insulated with fiberglas and finished with an asphalt emulsion.

The two systems used for housing the instruments are illustrated in Fig. 8. One system involved the fabrication of compact metal boxes, insulated on the inside and

**Fig. 6. One of the largest distributing boxes at Maitland.**

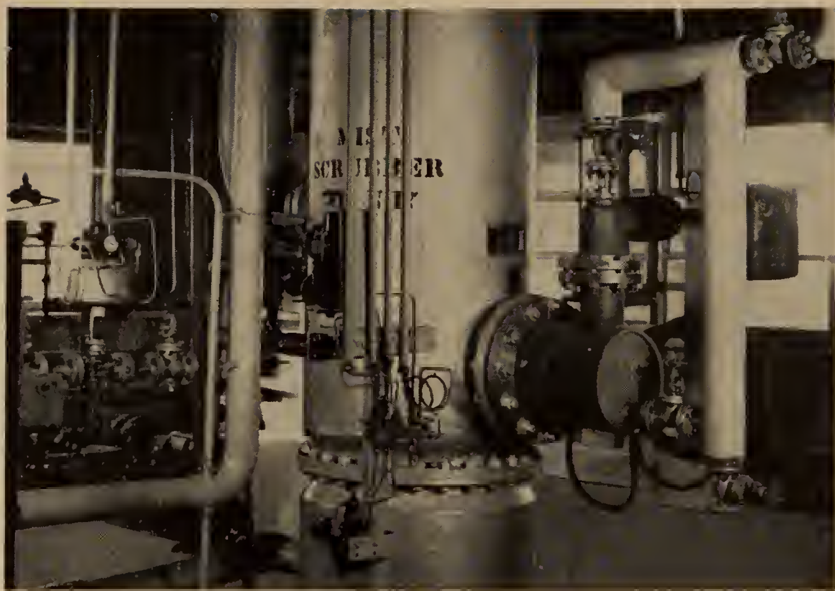

Fig. 7. Tubing enclosed in conduit.

completely enclosing the unit. The second scheme involved the use of asbestos canvas and Fiberglas to fabricate special blankets to be wrapped around the equipment. The blankets themselves are held in place with metal straps. Considering both cost and accessibility, the second method has proven superior.

*h. Spare parts*

One of the most important phases of instrumentation and one which is vital to plant start-up and operation, is the procurement and storing of spare parts. The need for these parts is usually accentuated during the startup period while many "bugs" are being gradually eliminated from the units. This in itself is a task involving several man months and requires the securing of accurate drawings and parts lists from each supplier, preferably including such requests as part of the order procedure.

### Mechanic Training

By March, 1951, difficulties in obtaining trained mechanics for the construction and maintenance programs had become apparent and it was concluded that a special training effort would be required.

One of the early ideas was to train mechanics by sending them to various instrument suppliers for short courses on specific instruments. In the light of scheduling and transportation problems this program was set aside in favour of a course to be conducted by C-I-L engineers and foremen and streamlined to cover those instruments to be used at Maitland. A six-month training program was subsequently launched.

The basic educational requirement for instrument mechanics at Maitland is junior matriculation or its equivalent. Each man must have an aptitude for working on precision equipment. He must be resourceful and be able to get along with people. Eventually, he is required to develop an understanding of the process and operating procedures so that he can work with operators and with other trades in trouble shooting. Since much of his work is done without direct supervision, he must be conscientious and reliable.

Applicants were carefully screened by the use of mathematical, mechanical comprehension and general knowledge tests and were interviewed by both personnel and technical representatives. The course curriculum included mathematics, physics, the chemistry of the process itself and the principles of measurement and control. Shop training on the major instruments to be used was provided, each unit being repeatedly torn down, assembled and calibrated. The class assisted in developing techniques that were later used during construction. At this stage, emphasis was placed on training all-around mechanics rather than specialists.

An incentive pay schedule was used to raise the mechanics from trainees' to mechanics' rates over an eighteen-month period, with increases every three or four months.

Since present demands for experienced mechanics far exceed the supply, every expanding chemical plant should be prepared to conduct its own mechanic training program.

### Construction

For approximately twelve months after the school training was completed, the mechanics assisted in the installation of instruments. This period provided each with a good grasp of the plant layout and of the mechanical problems of handling the equipment.

The construction period may be divided into the following phases:

*a. Receiving, shop calibration and storage*

On receipt, each unit was checked to make certain there was no mechanical damage. After

Fig. 8. Housing of instruments.

shop calibration to establish that instruments would function correctly and accurately, they were tagged and binned to make them readily accessible for scheduling into the field. A well organized and clean storage area is vital at this stage.

***b. Roughing-in***

The roughing-in stage included the installation of tubing, electrical runs, panels, instruments and instrument stands; prefabrication of the many piping assemblies, etc. Instrument stands were laid out and assembled by mechanics in the shop and transported complete to the field.

***c. Connecting***

This phase covered the connecting of the instruments on both the process and their pneumatic sides. The entire piping and tubing installation was then tested for leakage.

***d. Prestartup calibration***

No matter how careful the preinstallation shop check may be, it is vitally important to calibrate each instrument in the field, immediately prior to the plant startup. The bumping and thumping of a construction program can introduce intolerable errors. This includes not only a calibration, but a check to make certain that connections are correct, that controllers are acting properly, that valves are functioning and that air is turned on; the more checking there is at this stage, the smoother will be the startup period.

By July and August, 1953, the initial effort had reached its climax and the startup period had arrived. Operators had been given specific operational training on the instruments with which they were concerned. Instrument engineers and mechanics provided an around-the-clock coverage, working closely with operating personnel. A startup is, under the best of circumstances, a hectic period. It presents a real challenge to engineers and mechanics and each person's experience and initiative are utilized to the limit.

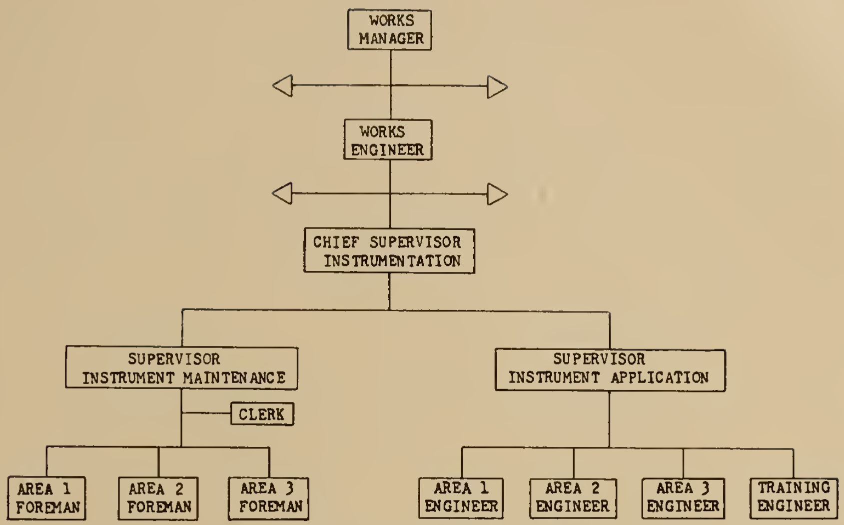

**Fig. 9.** Maitland Works instrument group organization.

### Operating Organization

Separate instrument organizations are relatively new in operating plants. Before establishing a group of this type, the scope of its work and its areas of responsibility must be carefully defined. At Maitland, the instrument group has a dual design and maintenance function. Not only must it be prepared to maintain and repair instruments, but it must select new equipment and design and develop new installations. In addition, the group must work closely with the operating and technical departments in assisting them in trouble shooting process systems and in developing process alterations.

Fig. 9 shows the Maitland Works instrument group organization. The chief supervisor (instrumentation) reports directly to the works engineer. The engineers, reporting to the supervisor (instrument application), are responsible for the selection and application of new instruments. They are located where they can assist operating personnel and instrument foremen on special problems arising out of day-to-day effort. These engineers have no direct responsibility for personnel administration. One engineer has been assigned to group training duties. In addition to keeping the present mechanics up-to-date on the process and instrumentation, he develops training programs for new mechanics. The maintenance organization is headed by a supervisor under whom are three foremen. Reporting to each foreman are between six and ten mechanics.

A decentralized maintenance system is used, with three shops—one in each of two operating areas and one in a central building. Most maintenance is carried out in the areas, with the central shops responsible for work requiring extensive space, specialized facilities or major expense for test equipment.

Mechanics rotate from shift work to various assignments throughout the plant, in an effort to broaden their experience with all instruments and with all phases of the process.

To assist in a preventive maintenance program, equipment record cards are being set up to provide a repair and cost history on each major unit. Preventive maintenance falls into bi-weekly visual checks, quarterly calibrations and yearly overhauls.

The foreman is responsible for scheduling his day-to-day work with the operating staff. Weekly and shutdown planning conferences are held each Thursday to plan the program for the following week. A maintenance control engineer assists in scheduling weekly and shutdown programs. Patrol, standing and work orders are used to control maintenance and alteration work and costs.

### Summary

In the last twenty years tremendous progress has been made in the application of automatic control. Viewing the process industries today, many new trends in instrumentation are noted. The popularity of electronic equipment in coping with difficult control problems is increasing. Continuous process analysis is becoming more and more a reality, as new types of instruments are developed and tested. Servo-mechanism techniques and analogue computors are every day providing more detailed and exacting knowledge that will eventually assist in removing a part of the guess work from instrument application and process control. Developments of even greater significance are being evolved in the minds of their creators and these will assist in extending the field of process control.

# Discussion

**J. J. Hillen**[1]

I would like to make a few remarks on F. G. Carson's paper which from the standpoint of The Engineering Institute and your general interest in this subject would seem to be timely.

The process at Maitland is without doubt a complex one. It is made so because continuous processing systems must be used in the chemical industry if products are to be manufactured which will sell in a competitive market. Because of such high speed processes, detection of off-quality products must be made quickly and accurately, if lost product or lost intermediates are to be minimized. In this industry particularly high quality is a "must", and off-quality a loss of accountable dollars.

In the days of low speed batch processes, an operator could take samples of the constituents at many separate stages. The operator was an artisan trained to thus control the process. His was the brain directing product quality from the first stage along to the final result.

The more complex the process the more equipment that was needed —and the more operators in attendance.

As through-puts came to be increased and cost of good labour rose so high, the continuous process was developed. In charge of the various steps along the way—instruments for measurement and control.

No matter how we centralize—no matter the number of instruments that are used—the brain is not there. The instruments can be the eyes, ears, arms and heart of the system but no inanimate control instrument can think. Only the human brain has this capacity.

It is necessary that we properly design processes to make the most effective use of the instruments or tools that are available to us. To properly apply automatic control, knowledge is a must. Chemical and process engineers and others must be trained in the fundamentals of measurement and control. Instrument people are needed who can specialize in this new branch of engineering: men who will keep abreast of developments, and co-operate with the process designer in applying new instruments to industry.

It is time for us to decide that the instrument engineer is an important person in the design group. Because of his importance, top management should be aware of his place in the business society and he should be given the stature and backing that his position deserves.

Groups such as the Instrument Society of America—of which there are four Canadian sections—are actively engaged in instrumentation as such. They have educational programs underway. Their influence has already been felt in the questions of standardization of instrument components.

A number of colleges and universities now have courses in industrial instrumentation and control as part of their curricula.

Mr. Carson has mentioned that the new concepts of automatic control augur well toward the completely automatic factory.

Let me say—as an instrument supplier—that many new developments are even now in the research laboratories of the leading instrument companies. They will be released as the market demands, but the time is not yet here. Altogether too few companies in the process industries are in a position to profit from advances in the science—for it is a science—as only these few have the qualified personnel available to absorb and apply the new techniques. A large number of concerns are not so fortunate, for they have so far not become aware of what instruments can do for them—have not yet become adept at using the tools which are now available.

I would commend your continued attentions to the science of instrumentation for measurement and control so that the automatic factory may become a reality.

[1]Peacock Brothers Limited, Montreal.

**H. L. Johnston, Jr. E.I.C.**[2]

Mr. Carson has spoken to you objectively about the instrumentation of a project that he was very close to for three or more years. As he was responsible for the design and installation of all of the instrumentation, and subsequently for its maintenance, his was truly an undivided responsibility, and just as truly goes to him the credit for a job well done.

Of particular interest is the use that was made of electrical conduit and junction boxes for supporting copper tubing. It was the first time that C-I-L had used large electrical conduit for this purpose and it was due to the unswerving conviction of Mr. Carson and his associates that large numbers of copper tubes could be pulled through a single conduit that this effective means of installing tubing was adopted. Most engineers would agree that one or two copper tubes could be pulled through a small conduit having one or possibly two very long radius bends but I for one was doubtful of the practicability of pulling 140 tubes through a four-inch conduit 75 feet long and containing two or more bends. This amounts to two miles of tubing in a four-inch pipe 75 feet in length. Needless to say, the use of the conduit and junction boxes contributed greatly to the unusually neat appearance of the tubing installation.

Another matter of interest referred to briefly by Mr. Carson was the mounting of instruments in the shops on prefabricated and standardized instrument stands and connecting them to standardized pneumatic manifolds. This procedure permitted instrumentation installation to proceed independently and at times in advance of the installation of the equipment to be controlled. Mounting the stands on the floor permitted great flexibility of location and the appearance of the instrumentation was enhanced in many areas by installing the instrument stands in line with one another and well away from any wall or other structural support. √

The entire technical content of the November issue will be devoted to papers about the Kemano-Kitimat project. See page 1266 of this issue for details.

# Rational Design for Building Frames with Semirigid Connections

by

J. L. de Stein, M.E.I.C.

*Associate Professor,*
*Department of Civil Engineering,*
*McGill University,*
*Montreal*

In this Quebec annual meeting paper, Professor de Stein shows that there are methods for dealing with the design of framed structures with semirigid joints, the common type, which will lead to good balance and hence to economical use of materials. He deals only with structural steel, because the experimental data for it are available, but his methods are just as applicable to other materials, given the necessary data.

In the design of steel building frames a common method of analysis is to assume that, for vertical loads on the horizontal members of the frame, the joints or connections at the ends of the members are flexible and allow the members to rotate freely at their ends. For lateral loads on the frame the same connections are often expected to be relatively rigid, with a capacity to resist sizeable bending moments. In some frames the assumed flexible connection is counted upon to supply adequate stiffness to the building.

Connections can be classified as rigid, semi-rigid, or flexible, according to their behaviour in the frame. A rigid connection is one in which the angle between tangents to the elastic curves of a beam and a column remains virtually unchanged on loading the frame. A flexible connection is one which will allow free rotation between the two members, and semirigid is a condition intermediate between rigid and flexible. The differences in these three categories are indicated in Fig. 1. Common connections, such as web connections and top and bottom flange connections, may be classified as semirigid.

By ignoring the connection characteristics in the analysis of frames the final design often becomes unbalanced. The various components of the frame would fail under different loadings. The bending moment, due to vertical loads, acting on the column, the connection, and the end of the beam, and induced into the frame by the rigidity of the connection, is disregarded. If the column is to be properly designed, then the bending moment should be taken into account. If the connection and the column will supply some definite and reliable restraint to the end of the beam, then advantage might be taken of this restraint in the design of the beam. If the connection is to be counted on to supply lateral rigidity, or to carry an additional moment induced by lateral forces, the moment on the connection due to vertical loads should be known, in order to judge the adequacy of that particular connection for the lateral loading. It appears that for many building frames a design method, to be rational, should include the effect of the connection in the analysis of the frame and the

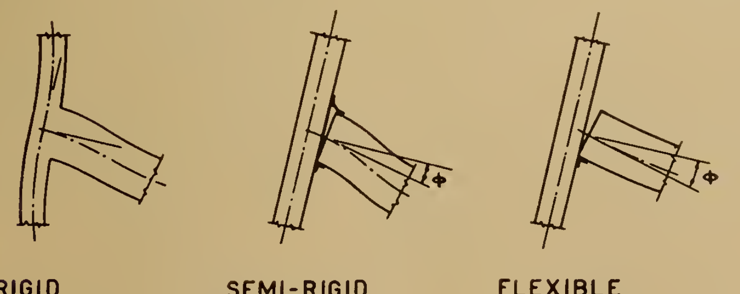

**Fig. 1. The three categories of connections.**

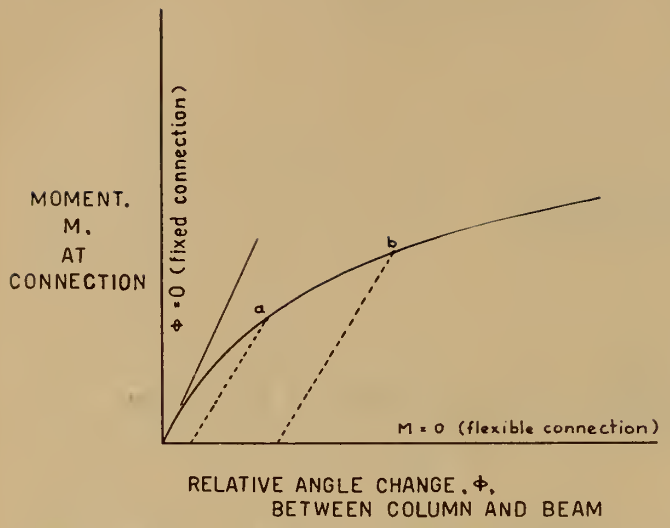

**Fig. 2.** $M{:}\phi$ **test results for a semi-rigid connection.**

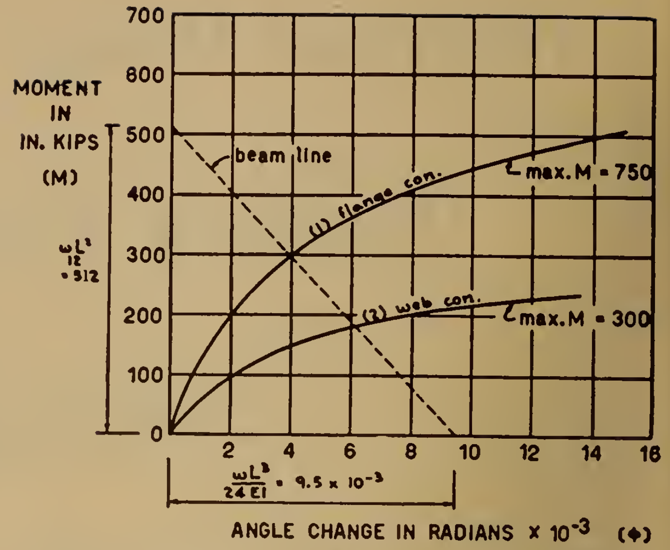

**Fig. 3. Experimental values of the** $M{:}\phi$ **relationship for two particular connections on a 12-in. I-beam.**

proportioning of the various components.

For some buildings the concrete encasement of beams, and columns; the diaphragm action of roofs and floors; the stiffness contributed by interior walls and partitions; and the restraint of exterior walls are indeterminate quantities which affect the building frame to a greater degree than the behaviour of connections. However, with modern architectural design demanding large and continuous areas of fenestration; exterior wall constructions of prefabricated, non-masonry and light materials; and open planning of floor areas, it appears that in many of to-day's buildings, the frame, wholly or in part, is resisting the applied loads.

In recent years several papers, notably those by Johnston and Hechtman (1), Lash (2), Johnston and Deits (3) and Hechtman and Johnston (4) have indicated how an economical advantage may be taken of connection restraint in the design of steel beams. In Great Britain a *Joint Committee of the Institution of Civil Engineers and the Institution of Structural Engineers* has recently recommended the reduction of simple span moment when using top and bottom flange angles. In Canada the C.S.A. *Committee on Steel Structures for Buildings,* in its recent specification (1954) allows a reduction in beam bending moments when the degree of restraint of the end connection is definitely known.

The amount of restraint offered by a connection at the end of a beam is related to the moment-rotation, $M{:}\phi$ characteristics of the connection. The relative rotation at a beam-to-column connection, between the end of the beam and the column, is a function of beam depth, of type of connection, of width, thickness and length of connection angles, of thickness of column web or flange, of size and extent of rivets or welds, of location of rivets or welds and of initial rivet tension. This $M{:}\phi$ relationship is highly indeterminate and accordingly is best obtained from actual tests. Considerable data are now available for a variety of beam-to-beam and beam-to-column connections, through experimental work reported by Wilson and Moore (5), Young and Jackson (6), Steel Structures Research Committee of Great Britain (7), Rathbun (8), Pippard and Baker (9), Hechtman and Johnston (4), and Lyse and Gibson (10). Most of the data are for beam depths of 12 to 18 inches. The test results for a certain semirigid connection might be as shown by the curved line in Fig. 2. This line indicates the relationship of the moment at the connection to the relative angle change between column and end of beam. The ratio of moment to angle change is not linear, indicating that the connection does not behave as an elastic member. This is characteristic of semirigid connections. If the connection is unloaded when it reaches the point *a*, the unloading would follow along the dotted line. The reloading curve would be approximately on the same dotted line to the point *a*, and then along the curve. The behaviour would be similar if it were unloaded at *b* and reloaded.

A graphical method, credited to Batho (7), can be used for determining the end moment which a given connection will develop for a given beam with definite span and load. The method can be readily used for those cases where there is little or no rotation of the column at the beam connection; that is, where the rotation of the end of the beam is due to the flexibility of the connection. This condition would exist for interior beams of a frame where spans are equal in length and have identical symmetrical loading. The condition could also be approached in the lower floors of a building when the column stiffness is considerably greater than the beam stiffness.

Batho's method can be appreciated best by the use of an example. Consider a 12-in. beam, with a moment of inertia of 216 in.$^4$, carrying a uniform load of 1,280 lb. per ft. on a span of 20 ft. and connected to rigid columns. For joining the beam to the columns either a standard web connection, or top and bottom flange connections might be used. Predetermined experimental values of the $M{:}\phi$ relations for these two particular connections on a 12-in. I-beam are shown in Fig. 3. Curve 1 is for the flange connections and Curve 2 is for the web connection. For a beam, which rotates an amount $\theta$ at each end, it can be shown that the moment at the end of the beam in terms of the rotation of the beam, for a uniformly distributed load $w$, is given by

$$M = \frac{2EI\,\theta}{L} - \frac{wL^2}{12}$$

The dotted line of Fig. 3 expresses

this equation for the given beam. When $\theta = 0$, a fixed beam condition, then $M = wL^2/12$, a fixed end moment. When $M = 0$, then $\theta = wL^3/24EI$, a simple beam rotation at the end. When the beam is joined to a column which does not rotate at the connection the relative angle change, $\phi$, between column and beam, is also the absolute rotation, $\theta$, of the end of the beam. Therefore, the actual rotation and the end moment on the beam, for any particular connection, is given by the intersection of the beam line with the $M{:}\phi$ curve for that particular connection. From Fig. 3 it can be seen that when the web connection is used the end moment on the beam is 180 in.-kips and the end rotation relative to the column is 0.006 radians. When the top and bottom flange connection is used the end moment is 300 in.-kips and the rotation is 0.004 radians. In designing the beam, the simple span moment of $wL^2/8$, or 768 in.-kips, might be reduced by the value of the end moment, either 180 or 300 in.-kips, depending on the connection being used. The magnitude of the true moment acting on the connection, relative to the ultimate strength of the connection, should also be considered in the overall design or analysis.

The moment-rotation characteristics of connections can be used to study the behaviour of beams, connections and frames, under the action of vertical and horizontal forces. These $M{:}\phi$ curves mightalso be used to determine the adequacy of a connection for a certain required rigidity. For example, assume that the connections for the previously analysed beam have to carry an additional moment, due to wind, of 120 in.-kips. If web connections were used, the moment on the connection would be 180 in.-kips from the vertical load, together with the additional 120 in.-kips, or a total of 300 in.-kips. It is obvious that this web connection should not be employed in this case, as the ultimate strength of the connection is only 300 in.-kips. If the top and bottom flange connections were used, then the moment on the connection would be 300 in.-kips from the vertical load, plus the 120 in.-kips ,or a total of 420 in.-kips. This latter condition is shown in Fig. 4. For this example, is has been assumed that the vertical load of 1,280 lb. per ft. is made up of a dead load of 640 lb. per ft. and a live load of 640 lb. per ft. The beam lines for dead load and dead and live load are marked on Fig. 4. The total moment of 420 in.-kips, acting on the connection, is noted on the curve by point *c*. The corresponding angle change between beam and column may be taken directly from the figure. From the relative angle change approximations might be made as to the movement of the frame. This would have to be compared to some permissible value, which would depend in part on the wall material and would probably bear some relation to column height. If a connection appeared inadequate for the required stiffness then a more rigid one might be tried, using the same procedure. The dotted lines in the figure indicate unloading and reloading, *b* to *d* and *d* to *b* being unloading and reloading of live load. Unloading of wind and live load would take place along line *ce;* any future loading on the connection would be along this line. If the action of the wind causes a change in the dead and live load moment on the connection, and thus a change in the restraining moment on the beam, then this should be allowed for in the design of the beam.

For many building frames an accurate analysis for moments need be made only for vertical loads, as the moments due to wind loads can be approximated without complex calculations. The wind moment on any connection is influenced considerably by the column size, but in many cases, is not significantly affected by the type of connection.

The analysis of a semirigid frame for vertical loading is not much more difficult than that for an equivalent rigid frame. Baker (7) and Johnston and Mount (11) have indicated how slope-deflection and moment-distribution methods can be used for the analysis of such frames. Moment-distribution is probably the simpler method for frames with more than three or four unknown moments. It should be noted that, before beginning an analysis, the connections have to be assumed for each joint, as well as beam and column sizes. The actual moment at each joint is related to the $M{:}\phi$ characteristics of connections as well as to beam and column stiffness. Batho's graphical procedure may be used to establish end moments for the vertical loads, considering the columns as initially held against rotation. The stiffness factors and carry-overs for each member can be found from fundamental principles. The mechanical procedure of releasing each joint,

distributing the unbalanced moment and inducing moments at opposite ends of members, is carried out in the same manner as for rigid frames.

Some single and double frames, with member sizes and load as indicated on Fig. 5, were analysed to observe the influence of connections on the moments induced in the frames. The beam taken for this study is the same as that previously analysed for end moments when connected to rigid columns (see Fig. 3). Calculations were made for frames with rigid connections, with top and bottom flange connections, and with standard web connections. The semirigid connections used for the examples were those with the $M{:}\phi$ relations indicated in Fig. 3. The calculated moments at the junctions of beam and column, for various proportions of frame, are shown in Tables I and II. In order to simplify the moment calculations, the $M{:}\phi$ curves were replaced with straight lines. As the straight lines were chosen to follow the curves closely, the calculated moments are reasonably correct. It is not suggested that the members for the various frames are well or properly designed. However, for the assumed components, a reasonably correct analysis has been made.

From Table I, for the single-span frames, it may be noted that when a standard web connection is used on frame heights of 10, 15 and 20 feet, the corner moments are 67, 74 and 80 per cent, respectively, of the rigid-frame moments. That is, a so-called flexible connection in some places has a performance approaching that of a rigid connection. Some of the data indicated in Table II, for double-span frames, are equally surprising, when considered in relation to conventional design methods. When a standard web connection is used on frame heights of 10 feet or more, the moment at the exterior column is greater than the equivalent rigid frame moment. It appears to be somewhat of a paradox that, when using web connections the moment is ignored, and when using rigid connections the moment is considered. For the 10-ft. single-span frame with standard web connections, the corner moment would cause a bending stress in excess of 9,000 lb. per sq. in. in the column. If moments are ignored, might not the resultant design be unbalanced ?

The procedure for analyzing and studying semirigid frames has been discussed only in reference to structural steel members, because steel connection characteristics are available. A similar procedure might be used for timber, precast concrete or composite frames, timber and steel, concrete and steel or timber and concrete. It is essential only that the moment-rotation relation of the proposed connection be known. In some cases where straps and brackets are used, it should be possible to establish an approximate behaviour from a theoretical study.

A rational analysis of frames with semirigid connections, taking into account connection behaviour, has certain advantages. The calculated behaviour parallels the actual behaviour; accordingly it should be possible to approach a balanced design where the various components reach their ultimate strength at the same time. A more nearly balanced design should result in a better use of material.

# Telecommunications

# in

# Canada

*by*

A. G. Lester

*Assistant General Manager—Toll Area,*
*The Bell Telephone Company of Canada,*
*Montreal*

It is good occasionally to stop long enough to survey the past, examine the present and dream about the future, as Mr. Lester has done in this paper. Although it contains some technical data, it is not beyond the comprehension of any engineer and it ought to be required reading for all, for it concerns everybody. The paper gives an account of the steady and at times almost miraculous, but little publicized, progress being made in our communications, especially in telephone service and in the newer forms—facsimile, teletype and TV. The paper was presented to the 68th Annual Meeting of The Engineering Institute of Canada, May, 1954, Quebec City.

**Definition and Scope**

"Telecommunications" is really a coined word. The Greek prefix "tele"—"far off"—is used in designating instruments or practices, usually electrical, which control or accomplish action at a distance. Thus telecommunications can be defined as "far off communications". A more precise definition, contained in the Radio Regulations of the International Telecommunications Union (1) is

> "any transmission, emission, or reception of signs, signals, writing, images and sounds or intelligence of any nature by wire, radio, visual, or other electro-magnetic means".

This definition is complete and all-embracing. However, in this paper certain types of telecommunications, such as radar, sonar, asdic, and individual broadcasting or telecasting stations are excluded. Consideration is given only to telecommunication systems, which, in general, are common carriers for public use in transmitting written, oral, or visual intelligence.

All telecommunication systems contain two broad categories of plant:—

(a) Instruments permitting the customer to originate or receive the transmitted intelligence.

(b) Network facilities to transmit intelligence between instruments. These facilities may be entirely within a building or a city, or they may be country-wide in scope, connecting cities and towns by wire line, carrier, or radio.

This paper deals particularly with long distance networks, although local instrumentalities will be brought into the picture where required for clarification. Developments described are those which have taken place in Canada, with those elsewhere covered only as they appear on the Canadian scene.

There are a number of major telecommunication agencies in Canada. First, there are the railway telegraph agencies, the communications department of the Canadian Pacific Railway Company and the Canadian National Telegraph Company. In each case the telegraph agency is a separate organization within the parent railway system.

The two telegraph systems unite in furnishing certain long haul teletype networks. These systems, and a number of smaller agencies, such as the Ontario Northland Railway and the Dominion Government Telegraph Service, furnish commercial telegraph service throughout Canada and also provide a number of privately-leased circuits, both telegraph and telephone.

On the telephone side there is the Trans-Canada Telephone System, furnishing long distance telephone service to the public across Canada and also providing privately-leased telephone and telegraph circuits. This is an association of the seven principal telephone systems in Canada:

| *System* | *Area of Operation* |
|---|---|
| Maritime Telegraph & Telephone Co. Ltd. | Nova Scotia |
| Island Telephone Co. | Prince Edward Isl'd |
| The New Brunswick Telephone Co. Ltd. | New Brunswick |
| The Bell Telephone Co. of Canada | Quebec and Ontario |
| Manitoba Telephone System | Manitoba |
| Saskatchewan Government Telephones | Saskatchewan |
| Alberta Government Telephones | Alberta |
| British Columbia Telephone Co. | British Columbia |

Each of these companies operates an extensive telephone network within its own territory and together they span the mainland of Canada. In Newfoundland, the Avalon Telephone Company and the Canadian National Telegraphs collaborate in furnishing telephone service, while in the Yukon and Northwest Territories, the Northern Communication System and the Army Northwest Territory and Yukon systems provide some facilities. In both cases circuits are connected to the main trunk lines of the Trans-Canada System.

In addition to these major systems there are hundreds of small, and some not so small, independent companies, from groups with about 25,000 telephones each to small farmers' lines of a dozen telephones. In practically all cases these small units connect with the major systems, making them part of the country-wide network. The Canadian telephone calling rate per telephone is the highest in the world, about 1,700 conversations per telephone per year.

Network facilities for radio and television purposes are furnished by both the telephone and telegraph companies.

How did these organizations and networks come about? What is their present scope? What kind of services and instrumentalities do they now provide and what of the future? This paper will try to answer these questions in broad outline.

### The Past

The telegraph came first. In Canada, the first telegraph line was built in 1846 from Toronto through Hamilton to Niagara Falls, followed shortly by a line from Montreal to Troy, N.Y. The Montreal Telegraph Co. formed in 1847, bought out the two earlier ventures in 1852, and proceeded to establish a network of lines and offices in central Canada. A number of competing companies grew up, the most important being the Dominion Telegraph Co., formed in 1868. By 1878 this company had extended its lines to the Maritime Provinces, where the New Brunswick Electric Telegraph Co. and the Nova Scotia Electric Telegraph Co. had been established in 1848 and 1851, respectively.

By 1880 the Montreal Telegraph Co. had over 20,000 miles of wire, connecting 1,200 offices, and the Dominion Telegraph was not far behind. Access to these lines became a problem, to which the first solution was telegraph call boxes, permitting a subscriber, by means of a code, to call for a messenger, the police, firemen, a doctor, etc. The telephone was obviously a better solution, but after a brief period when the telegraph companies operated telephone exchanges as parts of their networks, the telephone business was taken over by others. In 1881, the Great Northwestern Telegraph Co. leased the lines of both the Montreal and the Dominion companies, and embarked on extended expansion both in Eastern Canada and on the prairies, in "friendly alliance with the Western Union Telegraph Company". (2)

The Great Northwestern served the Canadian commercial telegraph field until 1915, although the Western Union had its own lines connecting the Maritime Provinces with the eastern United States. Great attention was paid to press service; the Great Northwestern for thirty years, until the formation of the Canadian Press in 1912 (3), was a news gathering agency for Canadian newspapers.

The Canadian Pacific transcontinental railway line was completed in 1885, the Canadian Northern was expanding, the Grand Trunk, the Intercolonial, and a number of other railways were operating. The railway telegraph poles marched beside the tracks. Telegraph circuits were required for train dispatch and control, still a vital role of railway communicationsal, though telephones are now used extensively. To meet public demand for telegraph service in new settlements, the railway companies expanded their facilities.

The C.P.R. formed a separate communications department initially to look after this telegraph and its associated leased-line business. In 1915, control of the Great Northwestern Telegraph Co. was acquired by the Canadian Northern Railway, which thus developed practically a Dominion-wide network. With the subsequent amalgamation of railways into the Canadian National system, what is now known as the Canadian National Telegraph Co. emerged. Since the early 1920's the railway telegraph agencies have been the principal telegraph common carriers in Canada.

### Technical Development

Technical development kept pace with the demand for more and better telegraph service. To the simple grounded telegraph circuit, limited in distance and quality, were added half- and full-duplex operation, full-metallic circuits, faster keys and faster operators. Then came carrier telegraph of various types, handling a number of telegraph channels on one pair of wires or radio circuit. Now there is voice-frequency carrier telegraph, permitting twelve and eighteen telegraph channels where there was only one channel before.

### International Scope

Transoceanic telegraphy became an accomplished fact in 1866, with the successful laying of the first trans-Atlantic cable. This brought to a halt the scheme of a land line telegraph connection to Europe by way of Alaska and Russia. Telegraph connection to Australia and New Zealand via the Pacific was set up in 1902. Canada's telegraph development was international in scope from its early days.

### The Teletypewriter

One of the most far-reaching developments in telegraphy has been the teletypewriter. Machines for transmitting telegraph signals began to appear early in the history of telegraphy. In fact, Morse himself experimented with apparatus for sending signals automatically. Two systems which became firmly established were the Crede system in Great Britain and Europe, and the Teletype Corporation system on this continent. Producing a written record at each end of a circuit, reliable, easy to operate and fast, this new medium caught on rapidly. Today practically all commercial telegraph business is on a teletype basis. Use of the teletype in private business has also grown.

Growth in telegraph business and facilities in Canada to 1939 is shown in Fig. 1. At the left is shown total telegraph messages per year at 10-year intervals from 1899 to 1939. The right side of the chart shows the number of wire miles in service through the same period. The climb in telegraph business was rapid and steady from its thriving state in 1899 to the boom days of 1929. The depression struck hard; even by 1939 message telegraph business had only partially recovered from the low 1933. However, leased private lines, particularly teletype, were increasing and this trend has continued.

### Telephony

Telephony is a direct descendant of telegraphy. Bell's original patent of March, 1876, described his invention as "an improvement in telegraphy". Telegraph lines were used to demonstrate the telephone's capacity to transmit and receive sound. In fact, the telegraph companies organized and operated most of the telephone exchanges in this country before 1880.

The telephone business was started in Canada in 1877, when Bell assigned 75 per cent of his Canadian patent rights to his father.

As already mentioned, the telegraph companies needed some means of local access to their intercity network, and had introduced the telegraph call box to this end. The telephone was obviously a better answer, so the call box system was changed to a telephone exchange in Hamilton in July, 1878, and in Toronto in April, 1879. The telegraph companies proceeded with this program in the ensuing few years. In May, 1878, the Montreal Telegraph Co. became agents for the Edison and Phelps telephone and in February, 1879, the Dominion Telegraph Co. contracted with Professor Bell to promote his telephone.

By 1880, there were two telephone exchanges in each of Montreal, Ottawa, Quebec and Halifax, operated by the rival telegraph companies, with no interconnection between the systems. In August, 1879, Bell's father had tried to sell his Canadian patent rights to the Dominion Telegraph Co. without success. Bell then sold the Canadian, as well as the American, rights to the American Bell Telephone Co.

This company sent Charles F. Sise to Montreal to try to bring together the conflicting telephone interests into one company, to be owned and operated entirely by Canadians. The result was The Bell Telephone Co. of Canada, established in April, 1880, by Dominion charter. It took over the telephone plant of the Montreal and Dominion companies, as well as local companies in Hamilton, Toronto, London and Windsor. Mr. Sise and his associates then actively pursued the organization of telephone branches right across Canada.

The company early disposed of its interests in the Maritime Provinces to local companies. The Prince Edward Island system was sold in 1885, that in Nova Scotia in 1888, and in New Brunswick in 1889. The New Brunswick Telephone Co. took over there. In Nova Scotia several smaller campanies had grown up, but the Maritime Telegraph & Telephone Co. was finally established as the province-wide agency, with the Island Telephone Co. as a subsidiary in Prince Edward Island.

In 1908 and 1909 The Bell Telephone Company disposed of its plant in the three prairie provinces to their provincial governments. Telephone service in British Columbia had begun with a number of companies, the principal one being the British Columbia Telegraph Co. Following growth and the absorption of small companies, the B.C. Telephone Co. was finally incorporated in 1916.

Growth in extent and in quality of service was steady. Automatic telephone operation for local calls, after a disappointing start in eastern Canada in 1893, was established in Whitehorse, Yukon territory, in 1901. Substantial increase in dial service followed in the western provinces in the 1905-1909 period, and small installations were made in the Maritimes and in Ontario in 1903-1905. Major dial installations did not start in eastern Canada until 1924.

### Long-Distance Service

Long-distance service lagged behind local service in quality during the early period. By 1881, long distance lines had been set up from Toronto to Hamilton, and for short distances at other points. Montreal-Toronto lines were established in 1885 and small networks within the three groups of cities in the Maritimes, the central provinces, and the prairies were established gradually. Progress was slow, however. The Pupin coil, antecedent to present day loading coils, had been invented in 1900 and De Forest's vacuum tube appeared in 1907. Mechanical repeaters were designed in the 1904-1912 period, but it was not until the development of the vacuum tube repeater in 1915 that long-distance had the technical tools to progress rapidly. The first transcontinental telephone line in the United States was established in 1915, and by February, 1916, Montreal could reach Vancouver over these lines.

In British Columbia, demands for service from the lumbering and the fishing industries, coupled with the difficult terrain, lent impetus to radio telephone development, and gradually an extensive network of radio communications, centred on Vancouver, was established up the west coast.

### Canadian Jubilee Broadcast

By 1927, developments had reached the point where the Canadian jubilee broadcast could be undertaken. Using all kinds of lines and equipment, an all-Canadian network was set up for that event on July 1, 1927. The telephone companies then decided that transcontinental service should also be developed on an all-Canadian basis, and planned accordingly. The Trans-Canada Telephone System was opened for service in January, 1932. Regular trans-Atlantic radio telephone service was inaugurated in 1927 via New York, and direct service was opened from Montreal to London in 1932.

### Telephone Development

Fig. 2 shows telephone development from 1899 to 1939 in terms of number of telephones. From a total of 50,000 at the turn of the century, telephones in service rose to 785,000 in 1919. By 1929, this had jumped to about 1.4 million. The depression struck hard—a net loss of 190,000 between 1929 and 1933—but by

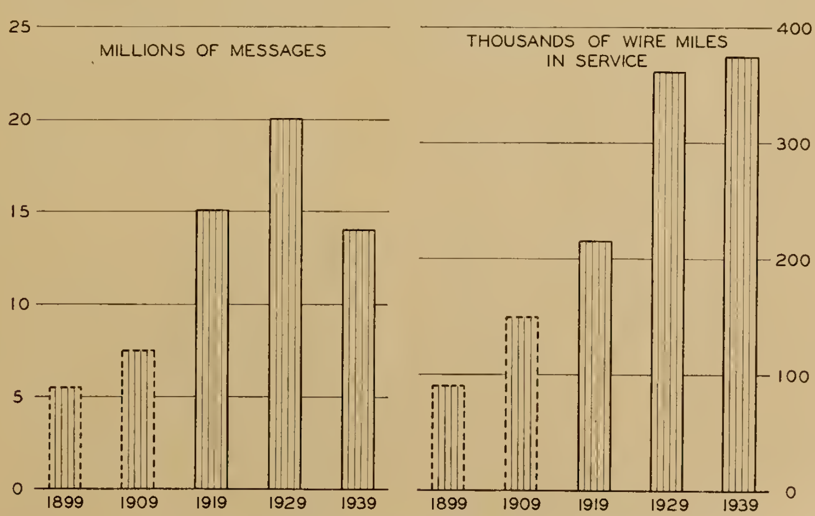

**Fig. 1. Telegraph Development — Canada 1899-1939.**

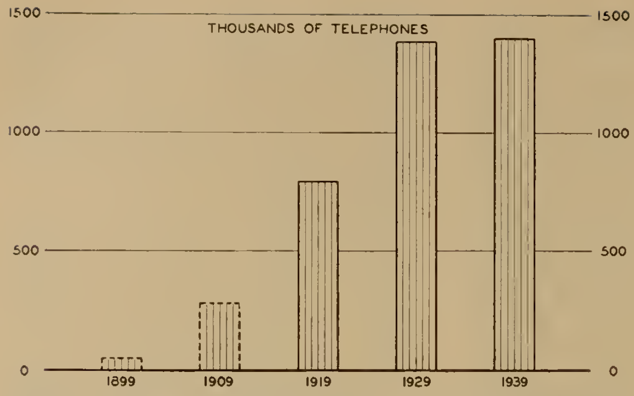

Fig. 2. **Telephone Development — Canada 1899-1939 (Telephones).**

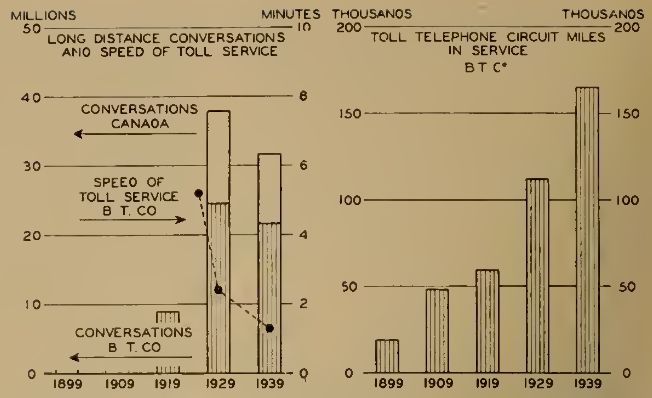

Fig. 3. **Telephone Development — Canada 1899-1939 (Toll).**

1939 development was slightly above the 1929 level.

Fig. 3 shows, at the left side, the number of long-distance conversations per year through this period, with the corresponding improvement in speed of service which took place. From a few thousand calls in 1899, which, of course, were for short distances only, total calls reached 9 million in 1919 and about 38 million in 1929. Long-distance calls follow the business cycles pretty closely. Consequently, the volume dropped to 24 million in 1933, but by 1939 was back to nearly 32 million calls.

Speed of service,—i.e., the interval from the time the customer originates the call until the first report of the called party—improved steadily from nearly 6 minutes in 1923 to less than two minutes in 1939. Circuit miles in service rose steadily until 1929, and in the late '30's, to reach an approximate total of 165,000 miles for the Bell Telephone Co. of Canada alone.

By 1939, both telephone and telegraph business appeared to have reached an even keel after the depression. World War II provided a tremendous impetus to long-distance traffic of all sorts. The phenomenal expansion in Canada's production, troop movements, continental defence,—all the myriad activities of war—strained the communications network to its limit. Materials, and therefore means for expansion, were restricted, service was slow, but the telegrams and telephone calls were handled.

Defence communication activities during World War II were extensive in terms of construction and maintenance, particularly on the east and west coasts, to the point where it was possible, using both defence and common carrier networks, to set up a telephone call from Alaska to St. John's, Nfld.

**Post-War Development**

With peace, some recession in business was expected, but, on the contrary, the growth in telephone business hit a pace which had never been equalled. Substantial increases also took place in telegraph business, particularly in leased-line business. A few figures will be useful. The data are shown in Table 1.

In the eight years since the war, then, the number of telephones in Canada has about doubled, long-distance telephone calls, having doubled during the war years, have doubled again since then, and toll telephone circuit mileage has doubled. Speed of service, having slipped due to overloaded facilities, has improved greatly during the past few years. Telegraph messages are up 19 per cent and telegraph channel mileage is also up substantially, reflecting the heavy growth in leased circuits. It might be interesting to note that the Trans-Canada part of this toll telephone business was over five times greater in 1945 than it was in 1939 and by 1953 was over double the 1945 figure.

There is, then, an impressive telecommunications network in Canada. In Fig. 4 are shown geographically the major routes now existing across the country. In the heavy industrial complex of Quebec and Ontario, twin telephone cables run from Quebec City to Windsor, from Toronto to Buffalo, and from Montreal to the United States border. These are now reinforced by radio relay facilities joining Buffalo, Toronto and Montreal, and Toronto and London, carrying telephone facilities in the Toronto-Montreal, and shortly in the Montreal-Quebec, sections, and the television network from Buffalo to Montreal and from Toronto to London.

Extending east and west from the central provinces to both coasts are extensive broadband carrier telephone and telegraph facilities, the former on the lines of the Trans-Canada System and the latter chiefly on the railway telegraph lines. There are now approximately 425 telephone circuits in the Montreal-Toronto section, roughly 95 west from Toronto to Winnipeg and Calgary, 70 east from Montreal to Saint John, N.B., 65 from Calgary to Vancouver and 100 from Saint John to Halifax. In 1939 there were nine circuits in the Toronto-Winni-

peg cross section. So much for the past.

### The Present

Under the heading of "The Present" the kinds of service now provided by the telecommunication networks, and the structures and intrumentalities used to provide that service will be described.

### Principal Services

The principal services furnished over telegraph facilities are listed in Table 2. Message telegraph service is available at public offices in nearly every town and village in Canada. Generally messages can be telephoned to the telegraph office. Full-rate, delayed, and night letter service is provided.

Leased wire services present considerable variety and complexity. These are all private circuits, provided for the exclusive use of a customer, usually a business firm. Practically all are operated by teletype. The simplest form is a point to point circuit with teletype machine at either end. The addition of other offices by bridging onto the circuit is comparatively simple, with all data passed to all machines on the network. As the length of circuit and number of machines increase, regenerative repeaters are necessary. Many of the leased networks, employ selective mechanisms usually actuated by dial or teletype pulses, by means of which a particular station or stations can be connected into the circuit automatically. Teletype systems such as this serve the major department stores across Canada, the press, the air lines and a number of large industrial firms.

Defence networks, although reaching into more remote parts of Canada than do the normal business leased lines, provide essentially the same kind of service, and are generally actuated by teletype.

Weather reporting can be linked with wire photo and facsimile transmission. An optical unit scans the picture to be transmitted, passing a frequency modulated signal over the circuit to the distant point. There the signal is received, amplified, and applied to sensitized paper. In some techniques, the paper is then developed to give the finished product; in others, the sensitized paper is moist when the signals are applied and dries as the finished picture.

1. Normal commercial.
2. Right of way companies.
3. Defence networks.

(c) Leased Wire Service — Short Period.

---

Then there is the growing variety of control circuits, that is becoming more important as time goes on. Control of oil or gas flow through pipe lines, remote control of power stations, fault-alarm circuits from unattended telephone or telegraph repeater stations—all of these use a basic telegraph circuit to carry pulsing codes which convey the necessary information.

In Table 3 are listed the principal varieties of long-distance telephone service. First and foremost, of course, there is message toll service available from virtually every telephone, including mobile telephones, and providing connection throughout Canada, the United States, and

**Fig. 4. Canada — Main Telecommunication Routes.**

to 101 other foreign countries, representing over 90 per cent of the world's telephones. In general, both person-to-person and the cheaper station-to-station service are available. Reduced rates are in effect at night and on Sundays. Canadians ran up a total of about 150 million toll telephone calls last year.

Telephone service is also available on a leased-circuit basis, either for short periods at stated intervals, i.e., short-period talking circuits, or on a full-time basis. Most of such circuit leases are from point to point. However, a number of more comprehensive telephone network leases are in existence, such as the air traffic control circuits and certain defence circuits.

Service to right-of-way companies covers telephone circuits associated with pipe lines, power company distribution systems, etc. Generally, the companies find they are better off from both service and economic standpoints if they lease facilities from the common carriers rather than "going it alone".

As in the case of telegraph service, comprehensive telephone networks for defence purposes have become decidedly necessary. The telephone and telegraph companies are collaborating in the furnishing of both types of facilities to meet the requirements of the armed forces.

#### Television

Television is comparatively new in Canada, but it is a voracious user of telecommunication facilities. Local pickup of a television program, where it is a "one shot" affair, is often carried from a mobile field radio terminal at the camera to the broadcasting studio over a direct radio channel. In other cases, usually at locations where TV programs originate regularly, e.g., major hockey rinks, special cable pairs, shielded by P.S.V. (polyethylene string video) are leased from the common carriers.

Long-distance network transmission of television programs is also provided by the telecommunications companies. In the United States by the end of 1953, some 50,000 channel miles of television circuit were available to the telecasters, an increase of 50 per cent in the year 1953 alone. In Canada at present, a television channel is provided by The Bell Telephone Co. from Buffalo through Toronto to Ottawa and Montreal, with a channel in the reverse direction available as required. From Toronto to London the railway telegraph systems are providing TV network services. The network service available is generally capable of carrying colour, as well as monochrome, television signals.

#### Basic Performance

The basic performance which must be provided by network facilities if these services are to be satisfactory are:

1. *Frequency space.* A 100-speed teletype circuit requires 170 cycles in which to operate. This allowance will take care of other telegraph uses except facsimile, which requires full-voice facility. An ordinary commercial-grade telephone circuit requires 3,400 cycles although somewhat narrower bands are reasonably satisfactory. A radio broadcasting circuit should pass 5,000 cycles and in some cases 8,000 cycles. High-fidelity transmission of music requires about 15,000 cycles. The nominal overall frequency bandwidth for a television signal, either black-and-white or coloured, is 4.2 megacycles, although reasonably satisfactory black-and-white signals can be transmitted over 2.8 megacycles.

2. *Strength and Quality of Signal.* Telegraph signals must be capable of actuating teletype machines or other devices at the distant end of the circuit without failure or distortion. This requires that overall loss shall not exceed 30 per cent. Telephone circuits must transmit intelligible speech with minimum distortion. Overall transmission loss to which the telephone network is now designed, including loss in instruments, switching systems, and circuits, is 20 decibels. Television transmission presents a number of additional problems. Almost uniform amplitude and delay response is required over the full frequency range. Amplitude distortion requirements are about ten times, and interference requirements three times, as severe as in telephone transmission, and delay distortion requirements are much more rigid. Requirements for colour transmission are more severe than for monochrome, particularly in the frequencies below 300 kilocycles, and in the colour subcarrier region (3.58 mc.)

3. *The telecommunications network must work as a system.* It is not enough that a piece of equipment work by itself, or a circuit provide reasonable transmission between two isolated points. The equipment and the circuits must be so designed and integrated within the whole network that they are completely balanced and compatible, and will continue to function as part of the system, ready to provide service to and from any part of the network, for many years. This means making haste slowly. It means continuous and thorough research on all parts of the network facilities, careful design of new equipment and extensive trials before any new item is made a permanent part of the system.

4. *Continuity of service is all important.* Circuits are no use to the public or to the owner when out of service. Thus every major telecommunications agency devotes great attention to maintenance operations, training and methods; to maintenance materials; and to design problems which may spell future maintenance difficulties. A new piece of equipment is good only if it can be maintained in service satisfactorily.

#### Network Facilities

Present day telecommunication network facilities can be considered under the three headings of basic structures, multiplex systems and switching arrangements. This assumes as common the requirement of instruments and local distribution facilities at either end of any long distance network.

##### *Basic Structures*

First in point of time, and still providing a substantial part of long-haul circuit facilities in Canada, is the open wire pole line, equipped with copper wire and, for many years now, with superimposed carrier systems. Modern open-wire carrier systems demand great precision of wire spacing and transposition. A line fully transposed for a 12-channel carrier should have wire spaced at 8 inches between wires of the same pair, with 24 inches between pairs on a crossarm. Wire must be uniformly sagged, and precise adherence to a laid down pattern of point transpositions is required to secure inductive balance. This involves an average of about 18 transpositions per pair mile.

Toll cable, originally used only for entrance facilities to the large towns and cities, now forms the backbone of storm-proof plant in the heavy traffic areas of the country. Most circuits over inter-city cables are now on cable carrier. The basic structure may be twin cables, usually buried, or it may be a single cable, with, in both cases, superimposed broadband cable carrier systems of various types. Cables are brought to repeater points at intervals dictated by the requirement of their carrier systems, where the pairs are balanced out to ensure minimum noise and cross-talk.

Coaxial cable has not been used as yet in Canada for intercity purposes, although it is used extensively in both the United States and in Europe. The basic unit is a copper tube, in the two U.S. designs 3/8 in. or 1/4 in. in diameter, with a centrally positioned copper wire. The tube is suitable for telephone, telegraph, and television network circuits. The whole assembly is shielded and a number of the tubes are incorporated in a cable.

The proposed Trans-Atlantic telephone cable, on which planning and engineering are now actively under way, will be of the coaxial type with polyethylene insulation. In the main trans-oceanic section between Newfoundland and Scotland, it will consist of twin coaxial cables of American design, with repeaters enclosed within the cable sheath at 40-mile intervals. In the shorter Newfoundland-Nova Scotia section, a single coaxial cable of British design will be used. Power will be fed to the repeaters from the shore terminals through the central conductor.

The most recent addition to basic structures is the radio-relay system. Although some few systems in the very high frequency (V.H.F.) range have been used, most systems are in the ultra high frequency (U.H.F.) band. A number of systems with limited numbers of channels operate in the neighbourhood of 400, 500, and 900 megacycles. Generally speaking, such systems have been used, in this country, on branch routes for purposes of voice and telegraph channels only. For major routes with television and/or multiple telephone and telegraph requirements, the Bell Telephone TD2 system and the Standard Telephones & Cables system are being used.

The S.T. & C. system has been used extensively in the United Kingdom and an installation has recently been made by the railway telegraph companies between Toronto and London. The system operates in the 4,000 megacycle band and is capable of accommodating 14 one-way radio frequency (RF) channels. Each of these RF channels will provide a one-way television channel, and a pair, with present techniques, will take care of a maximum of 600 voice telephone channels. Operation of television and voice over separate RF channels of the same system is feasible, but has not been used extensively to date. Table 4 and Fig. 5 will give some idea of the physical appearance of this system.

The TD2 system was designed by the Bell Telephone Laboratories and is used throughout the United States, along with coaxial cables, to carry the trunk television network and the large cross sections of telephone circuits. The system is designed to give balanced performance over a 4,000-mile route, and operation on a transcontinental basis has proven the design to be satisfactory. Over 10,000 route miles of the system are now in use.

This system also operates in the 4,000 megacycle band. Twelve one-way RF channels may be developed. RF channels are 40 megacycles apart, with an effective channel band width in the order of 8 megacycles. Each is capable of handling a TV channel, either black and white or colour. Each pair of RF channels when equipped with L-I carrier, will accommodate 480 voice channels at present, and plans are established to increase this to 600 voice channels. Thus a fully equipped TD2 system can now handle two one-way TV channels, a guard channel in either direction, and 1,920 telephone channels (2,400 channels on the 600 cct. per RF channel basis). Alternatively, and still assuming the guard channel reserved, the remaining ten one-way or five two-way RF paths could carry ten TV programs simultaneously or 2,900 telephone circuits. The new L-3 carrier system will permit further expansion of capacity in the TD2 system.

Repeaters are located on a line-of-sight basis, average spacing

between relay points being about 30 miles. Between Buffalo and Montreal, a route distance of 410 miles, there are 14 relay points or 15 sections, an average spacing of 27 miles. A few figures will serve to indicate some of the features of the system, and of the Buffalo-Montreal TD2 route. Fig. 6 shows channel frequency assignments, in pairs of one transmitting and one receiving frequency 40 mc. apart. Frequencies are transposed between channels at each repeater station. Fig. 7 gives some idea of the type of equipment mounting, in this case the transmitter-receiver bay. Fig. 8 shows the route of Montreal-Toronto-Buffalo.

The company is now extending the TD2 network to Quebec, and engineering is actively underway on a Toronto-Winnipeg TD2 system.

Developments now underway will permit the addition of RF channels above the frequency range of the TD2 system, but using the same physical route and basic structures, thus providing for further expansion of television and telephone facilities on main trunk routes.

At the other end of the scale, a number of systems are under development in Canada, in the United States and in Europe, to cover requirements for 12, 24 and 36 voice channels, or equivalent telegraph capacity on "thin" routes. These systems should prove useful in the less populated areas of Canada.

Although not strictly a toll telephone network facility, mobile telephone facilities should be included here. Using VHF. frequencies in the 150-160 and 35-45 megacycle bands, the company now has a network of fixed transmitters and receivers to serve mobile telephones in the cities of Toronto and Montreal, and over the main highway system from Windsor to Montreal and from Toronto to Huntsville.

*Multiplex Systems*

Physical circuits can, of course, be derived from pairs of wires by using proper terminating networks, composite sets, phantom coils and voice repeaters. However, the majority of circuits are now derived by means of multiplex, or carrier systems of various types. Except for open wire, and in some cases even there, the physical pair or radio channel is used as a vehicle only, all voice or telegraph channels being on a superimposed multiplex system.

Starting with the four-channel "Type A" carrier system in 1918, the Bell Telephone Laboratories have designed others running from A to O. Other designers have also established many different multiplex systems. A look at the frequency spectrum occupancy of these various systems will be useful. Fig. 9 shows this for most of the carrier systems now in use in Canada.

Of the narrow band equipment, the "Type C" three-channel system, with pilot wire regulation, has for many years been widely used for long circuits. Its range of operation is well over 1,000 miles for one system, and several systems can be operated in tandem. The other narrow band systems, H, G, M, Lenkurt 33, etc., are used for shorter distances. Lenkurt and some other recently designed systems in this bracket have a built-in signalling channel, which is useful for toll dialing.

Of the Bell-designed broad-band systems, the "J" and "K" are 12-channel, basically alike, for use on open wire and twin non-loaded cable pairs respectively. Systems may be connected in tandem through a 4,000 mile network. The "N" 12-channel system is used on non-loaded pairs of single cables, and is generally confined to systems under 300 miles in length. Repeaters are spaced a maximum of 8 miles apart, compared with 16 miles for "K" carrier. Repeaters may be pole-mounted except at power supply points, which generally are at every third repeater location.

The "O" and "ON" are recent developments. The "O" design includes a basic 4-circuit unit, with 4 such units stacked (OA, OB, OC, and OD) covering the overall frequency range of 2 to 156 kc. In the cable "ON" version, 20 channels may be derived on two cable pairs, or one quad, with repeater spacing the same as for "N" systems. Single-side band operation is used for both "O" and "ON" systems.

Lenkurt broad-band carrier in the "45" series is now available, again using the 4-channel basic unit arrangement, with application to open wire, cable and radio. Lynch, Federal, C.G.E. and others are in the field as well, with systems which are being used at suitable locations in the Canadian networks.

The L-1 carrier system is used on both coaxial cable and TD2 radio relay in the United States. In Canada, it is in use on the Toronto-

Ottawa-Montreal TD2 route of the Bell Telephone Co. Total capacity of this system is 600 telephone channels. Circuit provision is made in units of 12 channels, which are stacked in groups of five to form supergroups of 60.

One of the most recent additions to the series of broad band systems is the L-3 carrier system. This system is applicable to coaxial cable and is also expected to be used on radio relay facilities. The L-3 system will provide 1,800 telephone channels over a pair of coaxial conductors, or it may be used to provide up to 600 telephone circuits and a 4.2 megacycle television channel simultaneously.

On the telegraph side, there are a number of carrier systems. Probably the most extensively used now is the 40-C-1 system, providing up to 18 telegraph channels of 170 cycle width, over a voice channel. The 43A-1 system, a newcomer, is considerably less expensive and more flexible than the older systems. A number of frequency modulated systems are also in use. Frequency shift telegraph, using different frequencies for marks and spaces, has been used chiefly over radio facilities where its characteristic of transmitting a readable signal with low power is advantageous.

***Switching Arrangements***

Some of the most spectacular advances in telecommunications in recent years have been in switching. For many years, while local calls advanced from operator handling to automatic switching of various types—step-by-step, rotary switch, panel, and crossbar—long-distance calls continued to be operated on a manual basis. The extensive information required for call completion and the personalized nature of a considerable portion of the traffic tended to delay mechanization.

Manual switching systems developed steadily in quality and speed. Today, toll telephone switchboards in most of the major cities are of the Bell System No. 3 type. Circuits terminate in switching pads, which are kept in the circuit on a terminal call, but cut out automatically on through switches, to ensure satisfactory transmission. The boards can be equipped for dialing, either with a position dial or a keyset.

There are, of course, a number of other types of switchboards providing similar features.

Operator dialing of calls over short distances has been done in various parts of Canada since the early thirties, using, in general, step by step switches of the same type as is used for local dial switching. By 1950, substantial short-haul networks had been established around a number of the principal cities. In the last few years, there has been extensive use of step equipment for toll purposes in Bell of Canada territory, to handle terminal traffic to and between Montreal, Toronto and Ottawa.

Elsewhere in Canada, Siemens-type auto-toll boards and associated automatic switching equipment have been installed in Halifax, Winnipeg, Edmonton and Brandon, permitting operator dialing of a substantial proportion of both terminal and switched traffic at these points. As opposed to the Bell cord-type boards, the Siemens board is key operated, with rotary type switches. Two-tone signalling is employed on long-distance circuits. This system is used extensively in the United Kingdom and in Australia. It requires certain modifications, however, to permit full integration in a network as extensive as that in North America. Approximately 35 per cent of Canadian toll telephone traffic is now operator dialed, and plans are underway for a substantial increase.

Extensive private teletype switching systems are in operation by the armed forces, and, on a leased basis, for department store chains, manufacturing companies, news agencies, etc. For a number of these, switching is on a selector code basis. For the largest systems, however, there are switching centres where reperforator transmitters, multiple routing of tape, etc., greatly facilitate the handling of heavy traffic.

The telegraph companies operate similar switching centres for commercial telegrams, for minimum of handling and maximum speed. The so-called "T.W.X." service has not yet been introduced in Canada. Under this arrangement, teletype subscribers may have their machines connected to any other on the network in the same general manner as for a telephone long-distance call.

**The Future**

Anyone who would make categorical statements about the future of either telegraphy or telephony must have a much clearer crystal ball than this writer.

**Telegraphy**

In telegraphy, a fuller development of the special uses of telegraph circuits appears to be indicated. Telemetering and control circuits will grow in number and complexity with the expansion of power, pipe line and railway activities. There is a growing demand for this type of facility and the telecommunication companies are preparing to meet it.

**Facsimile Transmission**

The use of facsimile transmission is also increasing. New and im-

**Fig. 8. Montreal-Toronto-Buffalo radio relay route.**

Fig. 10. Numbering plan areas with codes — U.S. and Canada.

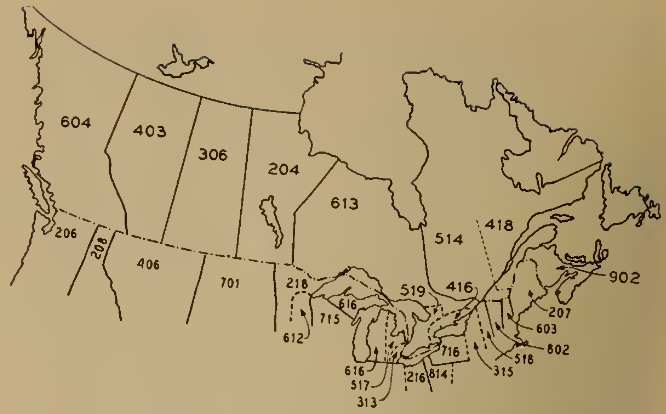

Fig. 11. Numbering plan areas with codes — Canada.

proved apparatus, both of European and American design, is coming into the market, bringing with it better performance and wider use. Facsimile transmission of printed matter is now possible in some degree and such transmission of commercial telegrams may prove economically attractive.

### Teletype

Teletype switching systems for private networks will undoubtedly grow in number and complexity. It also seems likely that some random switching system will come into use in this country, to fill the need of business houses which deal with a number of other companies, but do not have sufficient traffic with them to warrant full-time connections.

As to volume of business, growth will probably be chiefly in leased line business, following the trend of the past few years.

### Television

Coming to television networks, the future appears easier to forecast. Television transmitting stations are now operating in Montreal, Toronto, Ottawa, London, Kitchener and Hamilton and plans are underway for stations at most of the other major cities in Canada. Our growing sense of national consciousness, the need of cultural bonds urged in the Massey Report, and the announced plans of the Canadian Broadcasting Corporation, point to the early completion of a nationwide television network.

The next three to six years will probably see the establishment of a trunk television network on radio relay facilities from Vancouver to Halifax and Sydney, and ultimately to St. John's, Newfoundland. Key cities located away from this trunk line will be fed by branch routes, also on a radio relay basis. Colour television, when it comes, will use the same type network facilities as black-and-white transmission.

### Telephone Network

As to the future of the telephone network, the figures show the tremendous growth which has taken place in toll calling over the past 15 years. The pace has slackened somewhat during the last year in the Maritime provinces, but traffic in central and western Canada is continuing to grow rapidly. Trans-Canada calls today are 10 per cent higher than a year ago. Lack of adequate local facilities still prevents realization of the full potential of toll calling in places such as the Alberta oil fields and Newfoundland. The improvement in service inherent in dialing should help to sustain growth over the next few years, given reasonably stable business conditions. The telephone companies are forecasting a continuation of the present trend through 1954, with some tapering in the rate of growth through 1955 and 1956. A further increase in traffic at a somewhat slower pace beyond that date also seems to be indicated.

The concept of the kind of toll telephone service available in the future is a broad one. Ten years into the future, it is expected that:

1. About 60 per cent of all calls will be dialed direct by the subscriber without the aid of operators. The remaining 40 per cent, representing person-to-person traffic, calls where the called telephone number is not known, etc., may continue to be dialed by the operator.

2. The circuit and switching network will be arranged in such a way as to provide virtually no delay service on all calls.

3. Transmission quality for most calls will be within the present overall limit of 20 db, and a considerable proportion will be well within this limit.

The goal is really a continent-wide exchange, with faster, better service, largely under control of the subscriber himself. Plans have been laid to obtain this goal and the techniques to accomplish it are known. The whole plan centres around a continent-wide numbering and switching scheme.

In order to permit continent-wide dialing, every subscriber must have a telephone number which does not conflict with that of any other subscriber. To provide enough numbers within the local calling area of a large city, it has been found necessary to adopt a numbering plan consisting of the first two letters of the office name, followed by five numbers. The two letters and the first number designate the central office unit and the last four digits the subscriber's number in that unit. A maximum of about 500 central office codes are thus available.

In planning continent-wide dialing, this scheme of local numbering was adopted and the continent was divided into numbering plan areas, each estimated to contain no more than 500 central office units at the ultimate date. There are some 93 of these numbering plan areas, and each area has been assigned a three-figure code of its own. Fig. 10 shows the numbering plan areas for the United States and Canada, and Fig. 11 gives a little fuller picture of the Canadian areas. Within each area, each telephone central office will have its own code, for example UN6 (for UNiversity 6) in Montreal or JA8 (for JAckson 8) in Hamilton in the "416" area. Thus a man with the number "JA8-1234" will be reached by dialing that number from any office in the 416 area.

From offices outside that area, he would be reached by dialing "416-JA8-1234.

With the numbering plan fully established each subscriber will have a 10-digit number (in a few cases 11 digit) which is not repeated anywhere on the continent. The total capacity of the system is about 500 million telephone numbers, which leaves room to grow.

The next, and perhaps the most important, feature of the scheme, is the toll switching plan. The continental toll switching plan follows a tree-like pattern. There are, in the United States and Canada, some 2,600 offices at which the handling of long-distance telephone traffic is concentrated. These are called "toll centres" and each one is surrounded by a cluster of tributary offices which feed calls into it. These satellites may be local offices in a large city or they may be small towns surrounding the larger centre.

Under the general toll switching plan, these 2,600 toll centres are divided into five categories, depending on their size and strategic location with respect to cross-roads in the continental circuit network.

Fig. 12. Switching regions — U.S. and Canada.

### National Centre

This will be St. Louis, Missouri, which should more truly be called a "continental centre." It will be the final clearing house, from a traffic routing standpoint, for calls between any two points on the continent.

### Regional Centres

These will be nine major switching centres in the United States; St. Louis, White Plains, Pittsburgh, Chicago, Denver, Sacramento, Atlanta, Dallas and Los Angeles. In Canada present plans indicate that Montreal and Regina will also be regional centres.

These regional centres will be interconnected by circuit groups which are engineered on a so-called "high-usage" basis. They will also connect with the continental centre.

Each regional centre will be the focal point for traffic within its own region. Fig 12 shows the switching regions and the corresponding regional centres as contemplated. It will be noted that Regina, based on present plans, will serve a region extending from the head of the Lakes to the Pacific coast, with Montreal serving the eastern half of Canada.

### Sectional Centres

These will number approximately 35 and in turn will be the centres of groups of offices within the regional area. They will be connected by liberally engineered final groups to their regional centre. Figs. 13 and 14 show for Canada the present view of sectional centres. Calgary, Winnipeg, Toronto and Saint John, as well as Regina and Montreal, are included in present plans.

Fig. 13. Western Canada switching region.

Fig. 14. Eastern Canada switching region.

### Primary Centres

There will be approximately 125 of these, each forming the focal point for traffic from a cluster of toll centres within a sectional area. Each primary centre will be connected by a liberally engineered or "final" circuit group to its sectional or regional centre.

### Ordinary Toll Centres

These are the remaining 2,400 toll centres on the continent. In each case they will be connected by liberally engineered equipment to a nearby switching centre of greater magnitude. Each toll centre will handle the traffic for its own cluster of tributary points, called "end offices".

Offices coming under categories 1 to 3, inclusive, are classified as "control switching points". The equipment functions of these offices are vital to the whole switching system.

1. The equipment must have the ability to test alternate routes automatically and to select an available circuit.

2. It must be able to recognize and analyse the area and office code on any telephone call, i.e., the first six digits, to determine the proper routing for the call, to pass on the necessary code information to the next office in the chain—which may involve a change in code from what is received—and finally to determine the type of pulsing required.

3. Because of the number of possible links in the total connection, switching at the control switching points is on a four-wire basis, to avoid unbalance and to keep transmission loss in the switching process to a minimum.

4. In the interests of speed and accuracy, multi-frequency signalling will be used, employing five tones, two of which are used to represent each digit.

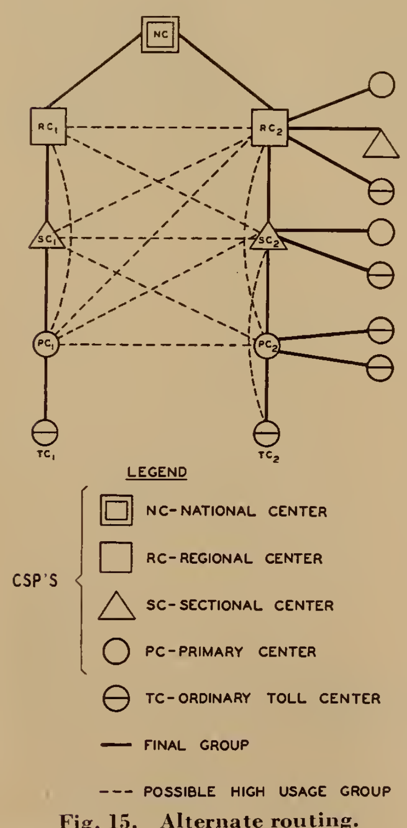

**Fig. 15. Alternate routing.**

Throughout the Bell System crossbar toll switching equipment is being used for this purpose. However, other equipments such as Siemens and Automatic Electric step equipment can be adapted to provide at least some of these functions.

So far as circuit provision is concerned, so-called "high usage" groups of circuits are established on the basis of need between any pair of offices. In these groups, the number of circuits provided is less than the total number required to handle all the traffic offered in the busy hour. Thus these circuits carry all the traffic for most of the day, but during the busy periods, using automatic alternate routing, they overflow into "final" groups. This arrangement, in addition to ensuring no-delay service, is important from the economic standpoint, because it results in a lower overall investment in circuit plant than would be the case if each circuit group were made to carry full-peak load traffic.

Fig. 15 illustrates the alternate routing principle on which the whole circuit arrangement is based. The crossbar toll switching equipment has the facility of testing a first route and up to five alternate routes in a very short time. Therefore, on traffic originating at a toll centre the operator can first test a high-usage group and, if this is busy, will dial the call into the machine at the adjacent control switching point. From here on the process is entirely automatic. The machine will test high-usage groups in a predetermined order, and if all are busy will unload the call over the final group to the next higher switching office. This process of search takes place at all offices along the route until the connection is finally established. The overall time required to establish a connection through the eight links shown on the diagram, from the start of dialing to ringing on the final connection, would be about 35 seconds. Most calls would have fewer links and therefore be set up even more rapidly.

The general pattern of final routes can be observed in Fig. 16. This indicates in diagramatic form the series of office clusters already described, with final liberally engineered groups established throughout the network.

Customer toll dialing has been in operation in parts of Europe for some years. In Belgium and Switzerland, for example, this type of dialing has been available for at least 15 years, and extends over distances of 150 miles or so. However, on this continent, customer dialing had, up to recently, been confined to local or very short haul toll traffic.

On November 10, 1951, nationwide or "foreign area customer dialing" was introduced in the United States when the Mayor of Englewood, N.J., dialed a ten-digit number and reached the Mayor of Alameda, California. At the present time, three offices in the United States—Englewood, N.J., Birmingham, Minn. and East Pittsburgh, Pa., are equipped for customer dialing. Subscribers at these points have direct access to 13 million telephones in the United States—and they like it.

The essential additional requirement for customer toll dialing is a recording mechanism to provide details of the call for charging purposes. For short-haul calls, generally between distant parts of large cities, a system of unit charges has been used, following the pattern of ordinary message rate service. For the longer haul traffic, a number of systems are available, but the principal one which will be followed in the continental plan is "centralized automatic message accounting". Under this system details of the calling and called number, the time of the call and the charges, will be recorded on a punched tape at the central operating point. These tapes will later be processed through a mechanism from which individual statements for each call, and finally for all calls, from the one telephone number will be provided. Initially, the calling number will be punched into the tape record by an operator, but plans are underway to eliminate this feature later.

Fig. 17 gives a picture of a fully manual connection followed by the gradual mechanization of the call, first in the local office, then at the distant end and intermediate switching offices and finally, with the adoption of customer dialing, at the originating toll office.

A "toll fundamental plan" for Canada incorporating a long-range program of establishing major switching centres and routes across the country was adopted by the Trans-Canada Telephone System in March, 1953. This plan will be closely integrated with the American plan. Under it, Regina and Montreal will probably be regional centres, and will probably have final connection with the continental centre of St. Louis. They will also have a liberally engineered circuit group between these two points so that all Canadian traffic may be routed completely through Canada. Calgary, Winnipeg, Toronto and Saint John will be sectional centres. Vancouver, Lethbridge, and Edmonton will be primary centres out of Calgary, Saskatoon out of Regina, Brandon out of Winnipeg, North Bay and London will be primary centres out of Toronto, Ottawa and Quebec out of Montreal, Halifax and ultimately St. John's, Nfld., out of Saint John, N.B. Behind each of these major cities, of course, will be the cluster of toll centres and tributaries which have already been mentioned.

Implementation of this plan, so far as operator dialing is concerned, has been under way in Winnipeg, Brandon, Edmonton and Halifax, using Siemens equipment, for several years. A considerable amount of direct circuit dialing has been done in Bell of Canada territory for some years. Crossbar toll dialing equipment will be placed in service in Toronto in 1955 and in Montreal in 1956, thus permitting the dialing of approximately 85 per cent of Bell of Canada traffic, as compared with the present 40 per cent. Plans are going ahead for equipment installation through the 1955 to 1958 period in Regina, Calgary, Vancouver and Saint John. It would therefore appear that the nation-wide network on an operator-dialing basis should be well established within the next four or five years.

Customer dialing may overlap this somewhat, and will probably appear first on the shorter haul traffic surrounding the large cities. Its progress will, of course, be dependent both on technical and economic factors, but it does not seem too unrealistic to say that within the next ten years a very substantial portion of all toll telephone traffic in Canada will be dialed by customers.

The future of telecommunications in Canada is one of growth, of constant change and of modification to incorporate new techniques and to improve equipment. Most important is the need for continued planning for an integrated system, so that all the new things may fit into the network and thus meet the requirements of the public in the most satisfactory manner.

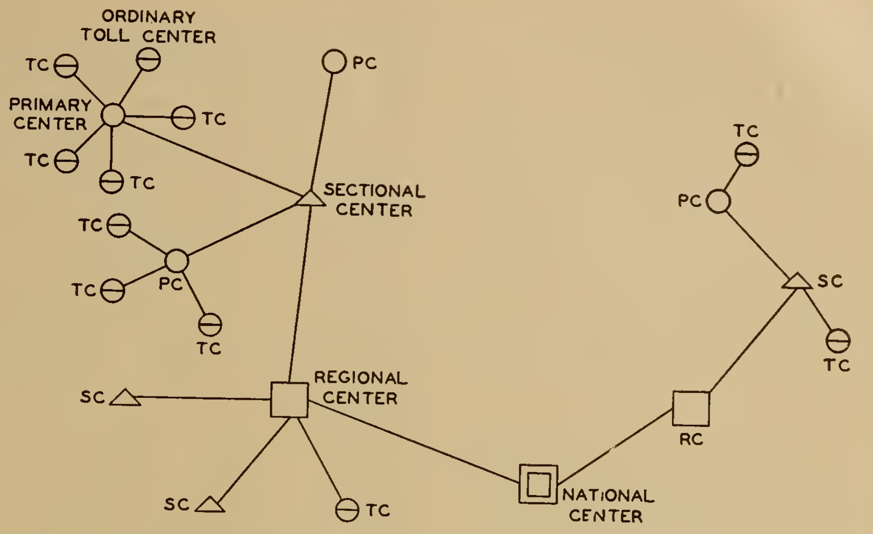

Fig. 16. Prepared general toll switching plan (basic principle).

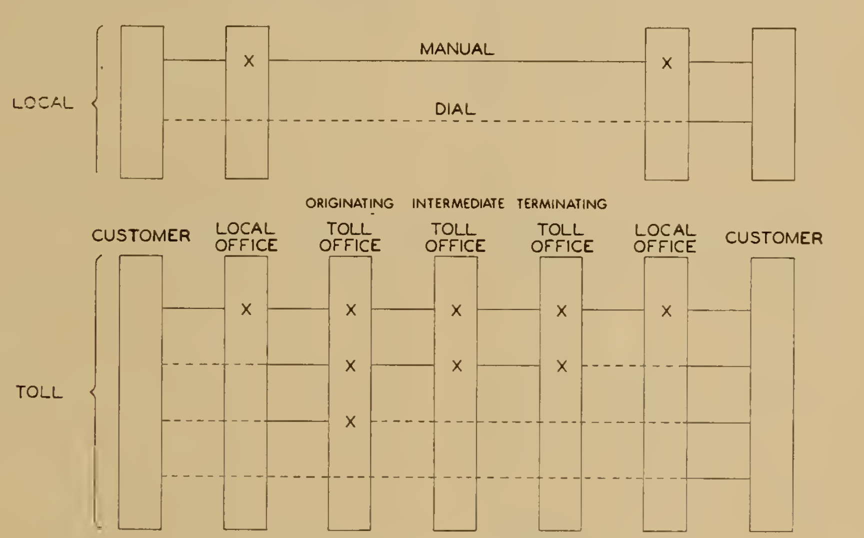

Fig. 17. Progress in mechanization.

# Discussion

**R. B. Steele**[1]

Mr. Lester has presented to you today a very fine paper on his chosen subject. He is to be commended for preparing a paper which reviews in considerable detail, and with great accuracy, not only the history of the inception and growth of communication facilities, but also the scope of communication facilities and services available to Canadians today. He goes still further and discusses probable developments for the future.

The discussion of a technical paper usually deals with some portion of the paper with respect to which the author of the discussion and the author of the paper disagree. I am in agreement with the things that the author of the paper has said, and, therefore, find myself restricted to a discussion on a number of things he did not say,

[1]Chief Engineer, Canadian National Telegraphs, Toronto.

but which are pertinent to the sketching of a picture of communications in Canada.

In introducing the historical portion of his paper the author points out that the telegraph came first with a telegraph line which was built in 1846 from Toronto to Hamilton and Niagara Falls. This was a single wire line on poles cut from the nearby bush, but you may be interested to know that the company which built it operated under the grand name of Toronto, Hamilton, Niagara and St. Catharines Electro-Magnetic Telegraph Company. This communication route, but obviously not the original line, is today a part of the communications plant of Canadian National Telegraphs. The author traces the development of the telegraph business from this humble beginning to the present time, where the villages and settlements without telegraph service (and this applies even to Newfoundland) are very few in number.

In the slide presented as Table 2 of the paper, the author lists the principal services furnished over telegraph facilities, and, similarly, in Table 3 the principal varieties of long distance telephone service. The classifications as listed are acceptable for descriptive purposes, but the titles should not be taken to imply that all the telegraph facilities are furnished by the telegraph companies, or that all the telephone facilities are furnished by the telephone companies. The author subscribes to this at a number of points in his paper but the inclusion of these tables gives me the opportunity to point out that the Canadian Pacific Communications and the Canadian National Telegraphs are designated as "communications departments" in their company families, and this designation recognizes the fact that they are both engaged in all kinds and types of overland communications with open wire, cable, and radio facilities, and providing telegraph, ticker, telephone, facsimile, sound broadcasting, video broadcasting, and other similar services.

As I have already had the privilege of pointing out in a paper given before another professional society, network sound broadcasting in Canada dates from Christmas Day 1923, when experimental radio stations "OA" in Ottawa was connected to station "CHYC" in Montreal by means of a pair of railway telephone wires. The network broadcast was sponsored by the then recently organized, Canadian National Railways, and the principal speaker was its president, Sir Henry Thornton. This successful venture into network broadcasting encouraged the Canadian National to organize a radio department as a part of its public relations activities, and to sponsor network broadcasting from a number of stations across Canada, including a station at Moncton and one at Vancouver. These broadcasts were handled through modified telephone facilities comprising a part of the railways' communications plant. Some experience in this type of communications service had already been acquired when the Jubilee Broadcast mentioned in the paper was organized. The communications departments of the railways collaborated with the other major communication companies of Canada in providing this network, and contributed approximately 4,000 miles of program channel to it.

On May 26, 1932, the Canadian Radio Broadcasting Commission was created by parliament for the purpose of improving program service to the Canadian public. Each of the railway companies was by then operating trans-Canada program distribution service, and they were selected by the commission to provide with co-ordinated facilities the national program transmission service. Except for limited sections they have continued to provide this service to the C.B.C. and with continually increasing volume of plant assigned to serve a continually increasing number of radio broadcasting stations. The program transmission network used in this service today comprises more than 20,000 miles of program circuit and over 78 repeaters.

In his paper the author makes a number of references to the use of radio beams for telecommunications, including the transmission of TV programs between cities. As noted, the railway communications systems are presently providing the TV network service between Toronto and London. This service includes connections to intermediate stations at Hamilton and Kitchener and is being extended from London to Windsor and from Montreal to Quebec.

For general communications purposes, the railways have used radio facilities to extend or supplement their communications networks as circumstances warranted. Perhaps the first instance of such a radio facility was the establishment in 1936 of a radio telegraph channel between Amos and Val d'Or in Northern Quebec to extend telegraphic communications into Val d'Or, prior to the construction of the railway line. Since World War II, and with the availability of V.H.F. radio equipment suitable for multiplexing, other radio facilities have been added to the plants of both the railways, including a number in Ontario and Quebec, one between Vancouver and Vancouver Island, and two wide band beams from Nova Scotia to Newfoundland. These V.H.F. beams are channelized to meet local needs and contribute to the communication plants additional telegraph, telephone, and program transmission channels.

The author mentions in his paper the communications operations carried out by the communications department of Canadian National along the Alaska Highway and in Newfoundland. In both these areas communications are provided by conventional methods, but the character of the country, the weather conditions met with, and the requirements for further and rapid expansion to meet national needs have given them unusual prominence amongst our activities. The Newfoundland operation is unique in that in addition to wire lines, and to a substantial use of V.H.F. radio beams, single channel radio telephone and telegraph facilities are operated to give residents of coastal villages, accessible only by boat, contact with centres of population.

In his discussion of future developments, the author of the paper presents a fascinating picture of the volume and character of communication facilities which will be necessary to meet the demands of our increasing population and our rapidly expanding business activity. It may well be that the facilities in use some years hence will outstrip his prophecies, but in any event they are valuable to us today for an appreciation of an activity essential to our everyday life but not too well known by most of us.

**L. A. W. East, M.E.I.C.**[2]

I think Mr. Lester is to be congratulated for an excellent paper which gives so comprehensive an outline of telecommunications development in Canada. In addition to engaging your immediate interest, his paper is a valuable contribution to the records of this development. Certainly this must have been

[2]Chief Engineer, Communication Department, Canadian Pacific Railway Company, Montreal.

prepared with great care and I find no reason to differ with the facts he has presented. My remarks will, therefore, be limited to some additional information bearing on the subject which I think may be of general interest.

Under historical events, reference is made to the handling of press by the Great Northwestern Telegraph Company prior to 1912. In this connection, it may be mentioned that the Canadian Pacific Telegraphs also handled press wire service during the period 1907 to 1912 and since the latter date has provided all communications facilities for the Canadian Press Association to date. For the benefit of those who may be unaware of the fact, it may be mentioned that the two major railway systems in Canada as distinct from other countries, occupy a unique position in furnishing a variety of leased wire services in addition to the handling of railway and commercial telegraph messages. For example, they have provided coast to coast broadcast service for the Canadian Broadcasting Corporation since its formation in May 1932. At present, this involves over 20,000 channel miles of network operating 16 hrs. per day.

Other services include Meteorological teletype and Airways Traffic Control telephone facilities linking all of the principal airports throughout the country. During the past year a Weatherfax network linking the various meteorological offices has been added for the facsimile transmission of 24″ by 18″ weather-maps, involving some 3,500 miles of voice circuit and approximately 30 offices. At this writing, Canadian National and Canadian Pacific are together making initial installations of Deskfax Facsimile equipment at Montreal for local service to industrial and business offices. In the field of special leased wire teletype services, one of the largest networks furnished to a single industrial user connects offices in all principal cities from coast to coast and handles approximately 50,000 messages per month.

In the rapidly growing field of television network transmission, the two major railway systems have a contract with the Canadian Broadcasting Corporation for provision of regular network service between Toronto-London-Windsor and Montreal-Quebec. These installations are now in the course of construction with temporary service having been established since the first of the year between Toronto and London, with subsequent extensions to Kitchener and Hamilton. The permanent installations will, of course, be suitable for both television and general communications. At the present rate at which television stations are coming into existence, it may well be that Mr. Lester's prediction of 3 to 6 years will see the establishment of an all-Canadian coast to coast television network.

The spectacular growth in long distance telephone service in Canada during the past 8 to 10 years as indicated in Mr. Lester's Table I, seems to indicate the excellent organization and working relations of the various independent systems through the Trans-Canada Telephone Association. This, I think, is further exemplified by the long range plans of the association for national and continental operator toll dialing and eventually customer toll dialing.

Certainly it seems that development of telecommunications in Canada is keeping pace with its growth as a great nation of which all of us may well be proud. √

---

# Filing for Engineering Departments

The classic department problem of unravelling its filing systems of reference data is solved in many cases by adopting a basic classification system and applying its classification and indexing methods to the file drawer or bookshelf.

The manufacturers' catalogs in a Plant Engineering and Product Design File can be divided into seven and four major product classifications, respectively. The sub-classifications in the plant engineering file total 36; those in the product design file total 23. Yet these simplified ramifications of product data embrace nearly every area of engineering interest.

The detail for general plant engineering departments is as follows:

1. Mechanical Equipment
   a. material handling
   b. vertical transportation
   c. power transmission
   d. pumps and compressors
   e. plate construction, tanks
   f. pipe, fittings, strainers
   g. valves and traps.
   h. instruments and controls
   i. lubrication
   j. finishing
   k. production equipment
   l. miscellaneous equipment and supplies
2. Electrical Equipment
   a. distribution
   b. panelboards, motors, controls
   c. power tubes
3. Materials
   a. metals
   b. glass, plastics
   c. masonry
   d. wood and wood preservatives
   e. roofing and siding
   f. gratings, grids, floor plates
   g. flooring, wall covering
   h. masonry, treatments, waterproofing
   i. paints, finishes, protective coatings
4. Thermal Insulation, Sound Control
   a. thermal insulation, refractories
   b. sound control, vibration isolation
5. Structural Equipment.
   a. structural system
   b. doors and hardware
   c. skylights, ventilators
   d. partitions, fences, guards
6. Plant Utilities
   a. power generation
   b. water conditioning
   c. air conditioning, heating, refrigeration.
   d. lighting
   e. protection
7. Service Equipment, Services
   a. service equipment
   b. services

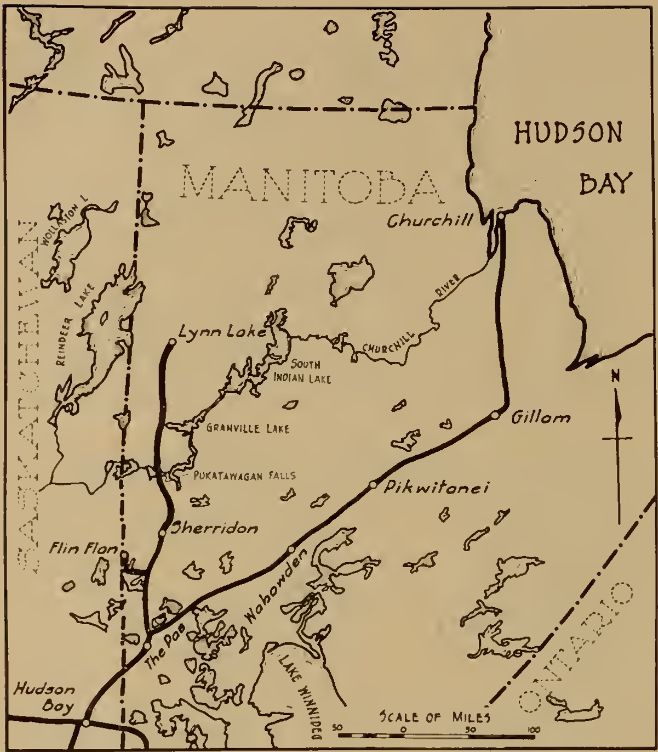
This is the classification for literature of interest to product designers:

1. Materials
   a. metals
   b. metal fabricators
   c. plastics
   d. plastic processors and fabricators
   e. rubber
   f. wood
   g. glass
   h. other materials
2. Electrical Parts
   a. motors and generators
   b. controls
   c. other electrical parts
3. Mechanical Parts
   a. transmission
   b. flexible shafts
   c. bearings
   d. hydraulic and pneumatic equipment
   e. pumps and compressors
   f. fittings and valves
   g. flexible tubing and hose
   h. gaskets, packing and oil seals
   i. instruments and controls
   j. lubricating systems
   k. fastening devices
   l. other mechanical parts
4. Techniques and Services

These classifications are not static and may be easily adjusted to information requirements.

Under each subsection, arrange the literature in alphabetical sequence by manufacturers' names. A convenient fractional indicator to identify each piece of literature consists of three parts: in the numerator, the major section number followed by the subsection letter; in the denominator the first two letters of the manufacturer's name in upper and lower case. This allows discarding of obsolete data without having to revamp the indicators.

Information supplied by Harry W. Smith Incorporated, New York.



# Location and Construction of C.N.R.'s Extension

**Fig. 1. C.N.R. lines in Northern Manitoba.**

The development of Canada has been influenced to a great extent by the engineers who located our railways. They were men having a strong pioneer spirit, who desired to see "what is on the other side of the mountain"; they had the vision and appreciation to open and build up our vast new territories. It was their privilege to work to a great extent on their own personal initiatives.

Location was, and is yet, interesting work. After hard periods of pushing through undeveloped country on foot, there is considerable satisfaction and reward in viewing, from the comfort of a passenger train, the farms and industries which have grown up to make Canada.

### Mining Activities

The depression of 1930 brought railway location to a halt and it became almost a lost art, until renewed mining activities again drew attention to the vast fields of the North.

During 1941, Sherritt-Gordon Mines, Limited, discovered nickel-copper ore at Lynn Lake, but they did not commence active development until 1945. By the fall of 1946 results indicated an ore body of such potential value that it was expected a mine would be brought into production within a few years. For this to be practical, heavy transportation facilities would be necessary and the Canadian National Railways were informed that before long they would probably be requested to construct a railway to the new mine.

Drilling and development works were prosecuted with energy by the Sherritt-Gordon Mine officials, and they established a definite program to bring the new mine into production during October, 1953. As a result of negotiations between the mine and the railway, reconnaissance to select a general route from existing Canadian National Railways was commenced in February, 1951.

Examination of available maps showed the position of Lynn Lake to be Latitude 56° 50′ North, and Longitude 101° 03′ West, 500 miles northwesterly from Winnipeg and 260 miles southwesterly from Port Churchill. (Fig. 1). The nearest existing railhead was at Sherridon.

During summer the only practical means of transportation to Lynn Lake was by aircraft, a distance of 120 miles due north from Sherridon; therefore all heavy materials, equipment and supplies had to be hauled in over a winter tractor trail, 167 miles long, via Pukatawagan and Granville Lake. This winter road also served for the haul of all materials and equipment for construction of the power plant at Laurie River and for erection of the transmission line, approximately 44 miles, to Lynn Lake.

Alternative turnoffs for the proposed railway from existing rail lines were considered—from Flin Flon and from two points on the Hudson Bay Railway, one just north of Wekusko and one south of Thicket Portage.

### The Route

The principal obstacle to be overcome was the crossing of the Churchill River. The Churchill is a typical northern river, having long comparatively level and wide reaches, which are virtually lakes, with narrows and rapids between them; therefore there are few practical bridging sites. Two promising ones were:

(a) Bloodstone Falls and Pukatawagan Falls on an extension from either Flin Flon or Sherridon.

(b) Twin Falls and Granville Falls on a turnoff from the Hudson Bay Railway.

After reconnaissance from aircraft, landing to examine some of the principal features on the ground and study of comparative factors—distance, topography, formation, ruling gradients, rise and fall, curvature, construction costs, maintenance costs and operating features—it was decided to extend the Sherridon Subdivision northerly, crossing the Churchill River at Pukatawagan Falls.

Except for the Indian settlement at Pukatawagan, the territory between Sherridon and Lynn Lake is entirely without habitation. In the summer, ground transportation is confined to canoe routes; unfortunately these were not convenient to the proposed railway route.

Starting from scratch, the time

The Sherridon-Lynn Lake extension of the Canadian National Railways is another example of the railway man following the miner. This 144-mile line was built in about 25 months through rock and muskeg and where surface transportation was impossible except in the winter. This paper, which has been presented before the Lakehead and Winnipeg Branches, gives a brief description of the work, featured by the use of an efficient track laying machine.

# from Sherridon to Lynn Lake

by

J. L. Charles, M.E.I.C.

*Regional Chief Engineer, Canadian National Railways, Western Region, Winnipeg*

available was only 32 months to locate and construct approximately 150 miles of railway from a single base railhead, through virgin country of rock, clay, sand, muskeg and lakes; the percentage of water area is remarkably high. Time was the essence of the project.

### Location Survey

The first step was to carry out a survey to establish a location for the line. As aerial methods, especially photogrammetry, are developed to such a high degree, and as two companies, one Canadian and one American, engaged in aerial surveys, were keen to make a survey, consideration was given to working from the air. However, after consulting the Department of Mines and Technical Surveys and after careful study, it was decided to employ ground survey parties to be aided by observation from aircraft and by examination of aerial photographs in stereoscopic pairs, and also to move camps and to transport supplies by aircraft.

The reasons for this decision were that a ground survey would be necessary to establish both lateral and vertical controls on which to base the photogrammetric contour maps, and then, after projecting the line on these maps it would be necessary to run it on the ground. The only saving in ground work with an aerial survey would be the cost of one topographer and helpers —three men in a party of twenty— and further, it was necessary to commence the work during the winter season. Two parties were employed. All mapping and estimating of quantities and costs were carried out in the field, as the surveys proceeded.

After deciding upon the route by observation from aircraft and by study of aerial photographs, preliminary lines were run and maps plotted (scale 200 ft. to 1 in., with contours at 5-foot intervals)—of the country from 500 to 1,000 feet each side of the line; through the more difficult areas one or more alternative lines were run and compared.

The location was then projected on these maps and run in on the ground. After further study revisions were run where improvements in alignment or reduction in construction costs or both could be effected.

In relation to initial traffic expected, the ruling gradient was established in both directions at 1.75 per cent, compensated for curvature by a reduction of 0.04 per cent per degree. Lighter grades would necessitate either increased distance or heavier grading, either of which would require additional capital investment.

Although there are no great differences in elevation on the line, there are many intermediate valleys and ridges, up to say 200 feet high, mostly solid rock, running in an east-west direction, which cause considerable rise and fall. However, the 1.75 per cent maximum gradient permitted surmounting these obstacles without too much increase in distance.

Comparatively heavy curvature, up to a rate of 15 degrees, was introduced to keep capital cost to a minimum in relation to traffic, maintenance, operating costs and prospective revenues.

In addition to the principal commodities, 90,000 tons of nickel and 15,000 tons of copper concentrates, to be hauled out annually, fish is handled from Reindeer and other large northern lakes and perhaps pulpwood will be cut in this area for outward shipment. Inbound traffic will be all supplies, fuels and equipment required to serve the mine and the town of Lynn Lake and the trading posts in the territory.

However, the location is based upon the principle that, if other new mines are developed as a result of more intensive prospecting further into the North, which will now be possible from the new railhead, and heavier tonnage is to be transported, then betterments—reduction of gradients and curvature —will be practicable.

The length of the line as finally located is 144 miles, which, considering the obstacles of large areas of water, muskeg and rock, is not greatly in excess of the air line distance of 120 miles.

### Muskeg, Permafrost and Solid Rock

By careful location, the percentage of the line on muskeg was kept comparatively low, and, of the total quantities excavated, not more than ten per cent were solid rock. This was favourable both in relation to cost and to time required for completion of the job. It is much better than would be expected from a general reconnaissance of this territory, the formation of which is largely solid rock ridges with muskegs between, excepting northerly from the Chruchill River, where there are some low ridges of sand and fine gravel. The balance of the material is clay, some of which, as is typical of these latitudes, is fine grained and grey in colour and very difficult to handle when wet.

Permafrost occurs at some locations on the line where there is a heavy insulating layer of moss and muskeg, but the percentage of permafrost in the total excavation was not large. However, owing to the short summer season, some of the clay areas are not free of frost until July, and commence to freeze again early in October; to complete the job within the limited time available it was necessary to concentrate more equipment on the job and to excavate more frozen material than would be necessary under normal conditions.

Tenders were advertised for in July, 1951, on a unit price basis for clearing, grading, installation of culverts and timber bridges, also for the concrete substructures for steel bridges, and a contract was awarded in August. Actual grading was commenced September 29, 1951.

### Materials and Supplies

It was then necessary to make preparations to haul from Sherridon by winter tractor road all camps, materials, supplies, fuels and equipment required for 1952 operations, into positions ahead prior to the spring break-up. No omissions could be permitted as, during the summer, there would be no means of correcting mistakes or supplementing supplies except by aircraft.

For clearing the right of way—2,100 acres—power machines were tried out, but owing to the difficulty of piling the debris so that it could be burned, the use of machines was abandoned and this work was let to subcontractors who carried it out by hand.

There are 55 timber bridges on the line. These were all constructed ahead of grading, during winter seasons when materials and pile driving equipment could be moved over frozen ground and swamps from site to site.

Rock drilling was done with drilling machines, wagon drills and jack hammers. Power shovels and draglines ¾ to 1½ cubic yard capacity, carryall scrapers and bulldozers were the principal grading machines used.

Grading quantities of all classifications—solid rock, loose rock, hard pan, permafrost and all other materials—totalled 3,381,000 cu. yd.

### Crossing the Churchill

The crossing of the Churchill River required spanning three channels. There was no delay in obtaining the steel required, through truss spans 201 ft. 4 in.; 155 ft. 10 in. and 201 ft. 4 in. respectively—as a number of such spans had been fabricated in Canada for shipment to the Chinese National Government, but delivery was cancelled and consequently these bridges were available for purchase. (Fig. 2).

Aggregate required for the 964 cu. yd. of concrete in the six abutments was obtained from an island about 10 miles upstream from the crossing and hauled to the sites with trucks over the ice early in 1952; the abutments were built during the following summer.

Normally, steel bridges are hauled by rail to the site after track has been laid to the near bank of the river, but to reduce overall construction time to the minimum, the steel members were hauled from Sherridon to the Churchill River over the winter trail, approximately 70 miles, during the tractor freighting season of 1951-52. This permitted erection of the three spans, during the summer and fall of 1952. Thus when the track was laid to the Churchill River there was no delay in crossing it and in establishing a material yard on the north bank for transfer of bridge and culvert materials, fuels and supplies, etc., from railway cars to sleighs for further haul ahead by tractors during the winter season of 1952-53, as required to complete the grading and bridging between the Churchill River and Lynn Lake by October, 1953.

### "Pioneer" and "Bull Moose"

Track was laid by the railway's own forces, using a self-propelled machine termed the "Pioneer" (Fig. 3). This is a standard flat car, on which two gasoline engines are mounted and geared to the axles. There are also air compressors to operate an overhead crane used to handle rails into place and to operate brakes and a spike hammer. This machine hauls sufficient materials—ties, rails and fastenings—for half a day's work.

The centres of the Pioneer car and of the cars immediately behind it are left clear to allow passage of a forked lift truck, termed the "Bull

Fig. 2. 201 ft. 4 in. through truss crossing north channel of Churchill River.

Fig. 3. Front view of "Pioneer" showing ties rolling forward and rail being lowered into position.

Moose", which is used to haul ties over the decks of the flat cars to the Pioneer, where the ties are placed on a conveyor to roll down to the front and then into position on the roadbed.

The rails are also hauled up by the Bull Moose and then handled by the overhead crane to the front and lowered into position on the ties. Splice bars are half bolted on and rails quarter spiked and the Pioneer moves slowly ahead as the track is laid. One man operates the controls to propel the machine and for the overhead crane to place the rails. Men operating power machines follow the Pioneer to complete spiking and bolting.

The total tracklaying gang did not exceed fifty men; an average of 3,600 feet of track was laid in 10 hours, including travelling to and from the camp cars, etc. If it had been necessary to do so, by working two shifts 1.4 miles of track could have been laid daily. The only work train attendance required was to switch up material at the commencement of the working day and at noon.

#### Trainfilling, Ballasting and a Good Eye

Trainfilling and ballasting, a total of 950,000 cubic yards, were carried out by railway forces. Power shovels of 2 cu. yd. capacity were used for excavation and loading into cars; length of haul was up to 30 miles; unloading was done by use of specially equipped bulldozers, which are run over aprons from car to car as they are unloaded. Power jacks and power tamping machines were operated to place the ballast and surface the track to stakes set to the correct top-of-rail elevation.

The final operation, to line the track to the centre stakes was the only phase of the operation which was done entirely by men, who worked with steel lining bars, and were directed by a foreman with an exceptionally good eye.

Track was laid to the mine plant on October 23, and the first revenue carload of freight—building materials for Sherritt-Gordon Mines, Limited—was delivered to Lynn Lake October 26, 1953, one week ahead of schedule.

Terminal and plant tracks were then laid and the last spike, solid nickel from the mine, was presented by Mr. Eldon Brown, President, Sherritt-Gordon Mines, Limited, to Mr. Donald Gordon, C.M.G., President, Canadian National Railways, and was driven by Mr. Gordon at Lynn Lake on November 9, 1953. This ceremony was followed by the Sherritt-Gordon Mines loading the first car of nickel concentrates for shipment to their refinery at Fort Saskatchewan, near Edmonton, Alberta.

Special covered hopper cars have been provided for the transportation of the nickel concentrates, a very fine powder which must be well protected against the weather. The line is being operated with 1,200 hp. diesel electric locomotives, double-headed; they haul up to 1,600 gross tons per train on the maximum gradients. Three to four round trips weekly are required to handle the present production from the mine, other freight, express and passengers.

#### Acknowledgments

The contract for clearing, grading, installation of culverts and timber bridges, also for the concrete substructures for steel bridges was awarded to C. A. Pitts General Contractor Ltd. and Associates, Toronto; winter hauling from Sherridon to the Churchill River was done by the Patricia Transportation Co., Ltd., and the three spans across the Churchill River were erected by the Dominion Bridge Co., Ltd.

The writer wishes to express his appreciation of the hard work carried out by the men actually on the job, particularly those on the location surveys, under all conditions, summer and winter. √

# The Resistance of Aluminum

to

# Some Alkaline Building Materials

*by*

T. E. Wright, H. P. Godard
*Chemical Division*
and
I. H. Jenks
*Publications Division*
*Aluminium Laboratories Limited*
*Kingston, Ont.*

EDITOR'S NOTE

The increasing use of aluminum in building construction and the prospect that this will expand in future, raises the question of the action on it of other building materials, especially of those of an alkaline nature. The authors have been experimenting along these lines for the past ten years. This paper presents a description of their work and a summary of their results, which should go far to allay the fears of those who have perhaps had some doubts as to the durability of aluminum.

Aluminum in many forms is being used in increasingly large quantities as an architectural and structural metal. It is used in both urban and rural settings for such building applications as roofing and siding, flashings, window frames and sash, doors, door sills and mouldings, trim of all kinds, store fronts, marquees, copings and parapets, foil vapour barriers and reflective insulation, industrial and domestic duct work, electrical conduit, cables and wiring, nails, rivets and screws and many others. As a structural material, it is used for roof trusses and joists, purlins, girts, transmission towers, substation parts, for many applications in shipbuilding and for bridges of all types.

Many of these uses involve contact of the metal with alkaline building materials such as concrete, brick mortar, stucco and plaster. The literature contains numerous references on this subject (1-6). However, the behaviour of materials is often affected by their origin and it was therefore desirable to test aluminum in contact with building materials available on the Canadian market. A program to acquire this information was initiated at Aluminium Laboratories Limited, Kingston, in 1945, and is still continuing.

### Aluminum in Concrete

***Test Plan***

In the initial project, a number of uncoated tubes of 57S alloy[1] were embedded in small blocks of concrete and exposed to the atmosphere on the roof of the laboratory. Specimen tubes were broken out of the blocks at yearly intervals up to five years. The tubes were cleaned and the amount of corrosion estimated visually and by measurement of the tube diameter with a micrometer.

In the second phase of the experiment, sets of unweighed specimens of 3S sheet and tubing, 50S extruded bar and 65S extruded bar in both the unprotected condition and with three types of coating — clear lacquer, zinc chromate primer and bituminous paint — were partially embedded in blocks of concrete dummy brick walls, stucco and hardwall plaster. These were stored under three conditions: (1) in the atmosphere on the laboratory roof, (2) dry, indoors, (3) immersed in a tank of water within the building (some mortars and plasters excepted). Sets of specimens were removed and cleaned after periods of eight days, six months and eighteen months and examined visually. One group remains for inspection after ten years. (See Figs. 1A, B and C).

In the third section of the experiment, duplicate weighed specimens of 3S sheet were partially embedded in blocks of concrete prepared from portland cement obtained from nine major Canadian cement plants, to check the influence of the source of supply. At the same time, several blocks were made varying the concrete mix, using two brands of cement. In both series duplicate blocks were made and exposed to the weather. After one year the specimens were removed from one set, cleaned and reweighed, while the other set remains on exposure.

***Description of materials***

The nominal composition of the aluminum alloys used, is given in Table 1. The description and source of the ingredients used for the "aluminum in concrete" program is given in Table II.

***57S Tubing in concrete exposed to weather***

6″ lengths of 2″ diameter 57S tubing (wall thickness ⅛″) were embedded to a depth of 4″ in 6″ x 6″ x 5″ blocks of concrete (1:2:4 mix). A number of variables were studied: (a) concrete inside the tube up to the block level, (b) no concrete inside the tube, (c) concrete-tube (outside) interface concave to collect rain, (d) interface convex to shed rain, (e) tubes stoppered, (f) tubes open.

After varying time periods up to five years, specimens were broken out, cleaned, as will be described later, and examined visually. The diameter and wall thicknesses were then checked.

Tubes removed after one, two and

[1]All alloys mentioned in this paper are Alcan alloys produced by the Aluminum Company of Canada, Limited.

**Fig. 1. Alcan 3S, 50S and 65S specimens exposed on the roof of the laboratory embedded in (a) concrete blocks (b) two types of mortar in "dummy brick walls" (c) plaster on "mocked-up" wall sections.**

five years had the same appearance and showed a mild surface etch. There was no measurable loss in thickness of the tube walls. The variables in block type and stoppering had no measurable effect on the results, although, of course, some specimens were etched only on the outside. Figure 2 shows two specimens which were embedded for two and five years respectively.

***3S, 50S, 65S alloys in dry, wet and weathered concrete***

***Preparation of test blocks***

The 3S sheet specimens were 2″ x 6″ x 0.064″. The 3S conduit specimens were 6″ lengths, of 1¼″ I.P.S. The extruded bars of 50S and 65S were 6″ lengths, 1⅛″ by ⅜″ in cross section.

The coatings were applied by dipping. The clear lacquer (Roxalin No. 3455, believed to be a methacrylate type) dried in about an hour and gave an average film thickness of 1.0 mils[2] (range 0.6 — 1.5 mils). The zinc chromate primer dried rapidly with a film thickness of about 2.3 mils (range 1.8 — 2.6 mils). The bituminous coatings dried to the touch in about an hour, but remained soft for as long as a week. The film thickness was approximately 5 mils.

Batches of concrete (1:3:3 mix) were prepared in a small 4 cu. ft. power-driven mixer, holding the water-cement ratio to a maximum of 0.60. The concrete was poured into 9″ x 9″ x 6″ forms and the specimens inserted to a depth of 4″, separated from each other and from the edges of the block by about 2″. Four specimens, one of each alloy type, were embedded in each block, all either unprotected or with a given coating.

A set of blocks for one time period was prepared with concrete containing calcium chloride[3] to the amount of 2 per cent of the cement content or 125 grams per block.

After pouring, the blocks were kept moist for a week; some were then placed in the weather, some in a dry location in the basement while another group was immersed in a tank of water which was changed at monthly intervals.

At the end of the test period the blocks were broken up with hammer and cold chisel and the specimens removed. The coatings were removed by suspending the specimens in trichlorethylene vapor. The specimens were then treated in an inhibited acid bath (A.S.T.M. B137-45) to remove residual concrete film. Light scrubbing with soap-impregnated steel wool pads (S.O.S.) completed the cleaning treatment.

**Observations**

***General***

For the first thirty minutes, until

[2] 1 mil = 0.001 in.

[3] The chloride was added as it is sometimes used in cold weather to accelerate setting and to depress the freezing point of the concrete slightly. Its advantages are doubtful, but it was tried because it represents a condition sometimes found in practice.

**Table I—Nominal Composition of Aluminum Alloys Tested**

| Alcan Alloy | Form | Per cent | | | | | |
|---|---|---|---|---|---|---|---|
| | | Cu | Fe | Mg | Mn | Si | Cr |
| 57S-H | Tubing, 2-1/8″ x 1/8″ | — | 0.20 | 0.25 | — | 0.10 | 0.25 |
| 3S-1/2H | Sheet, thickness 0.064″ | — | 0.40 | — | 1.20 | 0.25 | — |
| 3S-F | Conduit 1¼″ I.P.S. | — | 0.40 | — | 1.20 | 0.25 | — |
| 50S-A33 | Extruded bar 1-1/8″ x 3/8″ | — | 0.30 | 0.65 | — | 0.40 | |
| 65S-T | Extruded bar 1-1/8″ x 3/8″ | 0.30 | 0.35 | 0.95 | — | 0.60 | 0.25 |

The description and source of the ingredients used for the "aluminum in concrete" program is given in Table II.

**Table II—Materials for Concrete Mixes and Their Origin**

| Material | Origin; Company and Specific Plant |
|---|---|
| Standard portland cement | Canada Cement Co., Montreal, Quebec. |
| High early strength cement | Canada Cement Co., Montreal, Quebec. |
| Standard portland cement | Canada Cement Co., Hull, Quebec. |
| Standard portland cement | Canada Cement Co., Belleville, Ontario. |
| Kali-crete cement | Canada Cement Co., Port Colborne, Ontario. |
| Standard portland cement | Canada Cement Co., Port Colborne, Ontario. |
| Kali-crete cement | Canada Cement Co., Fort Whyte, Manitoba. |
| Standard portland cement | Canada Cement Co., Fort Whyte, Manitoba. |
| Standard portland cement | Canada Cement Co., Exshaw, Alberta. |
| Medusa white portland cement | Medusa Products Company, Paris, Ontario. |
| Portland cement | British Columbia Cement Co., Victoria, B.C. |
| Portland cement | St. Mary's Cement Co., St. Mary's, Ontario. |
| Dry sand (—8 mesh) | Kingston Sand & Gravel Co., Kingston, Ontario. |
| Crushed limestone (1″ size) | Frontenac Quarries, Ltd., Kingston, Ontario. |

the concrete began to solidify, bubbles of hydrogen gas were noticed emerging from the concrete around the bare aluminum specimens; this was taken as evidence of attack. No gas was evolved from the coated specimens.

*After eight days*

This set included only four blocks which were exposed outdoors. None of these blocks cracked. The lacquered specimens removed from the blocks were practically unaffected, as was also the case with the bituminous coated specimens. Some of the zinc chromate primed specimens showed patches of superficial etching, while the bare samples showed general etching.

*After six months*

This set included twelve blocks. Before the six months were up, the blocks on the roof showed a tendency to crack, with the cracks radiating from the specimens. The cracking was not influenced by the coatings. However, the blocks stored in the basement, both dry and under water, did not develop cracks in the same period. This strongly suggests that cracking in the atmosphere was due to temperature changes and the difference in coefficients of expansion of aluminum and concrete.

The specimens from blocks stored indoors were almost completely unaffected and the amount of superficial corrosion was no more than those examined after eight days. The specimens from blocks exposed outdoors showed slightly more corrosion, but it was still of a superficial nature. On all specimens, except those with the bituminous coating, which were unaffected, there was a thin adherent coating of hard scale. In the case of the sheet specimens, the coating spalled off when they were flexed and, in all cases, the scale was readily removed by abrasion with wire brush and steel wool. After separation of the scale from the specimens, it was found to be relatively insoluble in warm concentrated nitric acid and in sodium hydroxide. The cleaned specimens showed no loss of thickness.

The appearance of specimens taken from blocks stored in water were similar to that of the preceding group, although there was more of the adherent scale. The bare samples showed the most corrosion, but even these had received only a superficial etching and, again, there was no measurable thinning. Among the coatings, the zinc chromate primer had given the least protection and had led to a patchy distribution of superficial etching. The lacquer had not given full protection, but the bituminous coatings gave almost complete protection. There was no difference in behaviour among the three alloys and no measurable loss of thickness in any of the specimens.

*After eighteen months*

This set included 16 blocks, four of which had added calcium chloride. In general, these specimens were similar to those exposed for six months, and there was little evidence of continued corrosion. There was still no measurable loss of thickness in any of the specimens.

Again, there was no difference in behaviour among the alloys. The bituminous coatings gave almost

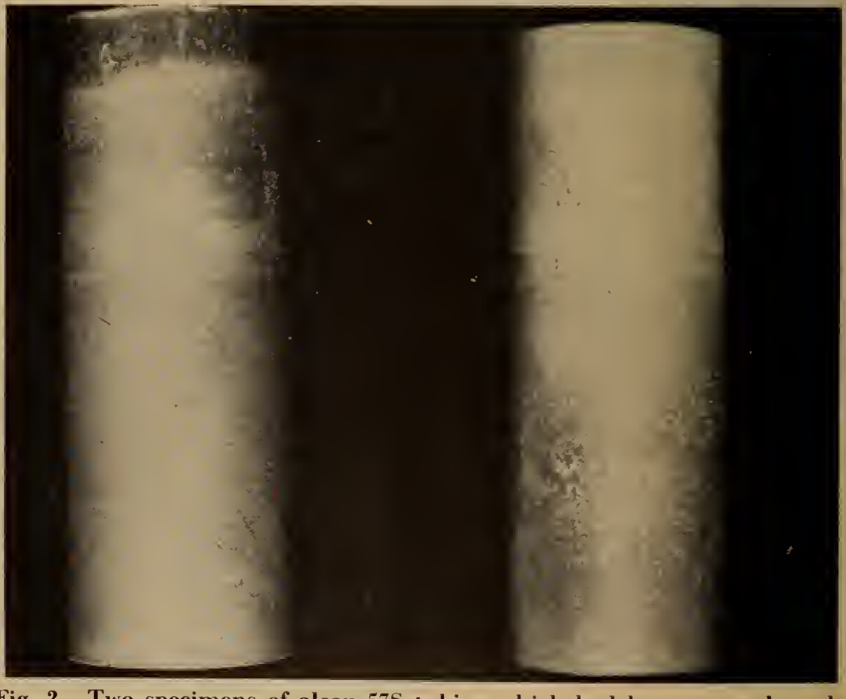


Fig. 2. Two specimens of alcan 57S tubing which had been exposed to the atmosphere while embedded in concrete for (a) 2 years (b) 5 years. Note only light superficial etching.

complete protection, even under water, and the metal surface beneath was smooth and shiny. The lacquer gave less protection under wet conditions, but was fairly satisfactory on the dry and atmospheric specimens. As before, the zinc chromate primed specimens were etched in patches, to a depth greater than with the bare specimens.

The atmospheric specimens from concrete with added calcium chloride were not corroded any more severely than those from the standard mix.

Figure 3 shows the most corroded 3S sheet specimens removed from the submerged blocks. These are typical of the group and show only mild attack.

***Weighed 3S Sheet in different concretes in weather***

***Preparation of test blocks***

For the experiments to determine the effect of the source of cement and variation of cement mixes, two blocks measuring 6″ x 6″ x 6″ were made up with each of twelve bags of cement, the sources of which are listed in Table II. The mix used was 1:3:3, with the water-cement ratio 0.60. The concrete was mixed by hand. Duplicate 2″ x 6″ degreased and weighed aluminum specimens were embedded in each block and the blocks were exposed to the atmosphere on the roof of the laboratory. Also, using standard portland cement from two sources, that from two blocks were made up as above, using each of the following mixes: 1:3:3, 1:3:5, 1:2:4, 1:1:2 and 1:3:0. Sheet specimens measuring 2″ x 6″ which had been degreased and weighed, were embedded in each block and the blocks were then exposed on the laboratory roof.

**Observations**

***General***

Cracks were noticed in some of the blocks within a week of pouring and even before they had been placed on the roof for atmospheric exposure. Duplicate blocks in each set behaved the same way so far as this tendency to cracking is concerned. A typical cracked block is shown in Figure 4. At the end of a year, those blocks which had cracked within a week were much more severely cracked; those which had not cracked on exposure, after a week indoors while kept wet, were either unaffected or showed only hairline cracks.

Table III shows the weight losses of the 3S specimens after one year in 1:3:3 concrete.

In all cases corrosion took the form of a uniform surface etch.

**Table III—Weight Losses After One Year of Aluminum in 1:3:3 Mixes Using Cement from Main Sources in Canada**

| Source | Type | Condition of block | | Weight losses (gm) | | | Calculated loss of thickness (mils per side) |

**Table V—Description of Building Materials Used**

| Material | Origin; Company and specific plant | Remarks |
|---|---|---|
| Lime | Gypsum Lime & Alabastine Company of Canada, Ltd., Paris, Ont. | Green Stripe finishing lime |
| Plaster | Gpsum Lime & Alabastine Company of Canada, Ltd., Paris, Ont | Paristone hardwall plaster |
| Gyproc lath | Gypsum Lime & Alabastine Company of Canada, Ltd., Paris, Ont. | Standard building lath |
| Metal lath | ——— | 24-gauge, diamond mesh, galvanized steel. |

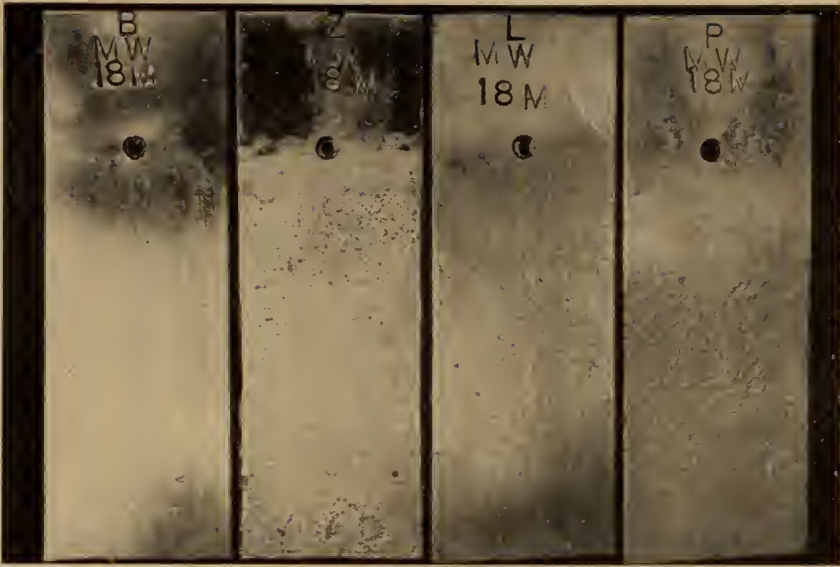

**Fig. 3. Alcan 3S sheet specimens removed from concrete blocks submerged 18 months. These are typical of the group. Note B=Bare; Z=zinc chromate; L=lacquer; P=bituminous paint.**

There was good agreement between the duplicate specimens. A relationship was apparent between the tendency to crack and the amount of corrosion.

Table IV shows the weight losses for the different concrete mixes with two brands of cement.

It is apparent that the amount of corrosion increases with the richness of the mix, but even the maximum loss (4.2 grams for 1:3:0 mix) is equivalent to a thickness loss per side of only 4.4 mils. If the metal cross section is adequate, this can be tolerated since attack occurs mainly during setting and further corrosion is slow, as shown in the preceding sections.

### Aluminum in Brick Mortars, Stucco and Plasters

***Test plan***

This work was done at the same time as the second concrete series and involved the same alloys (3S sheet and conduit and 50S and 65S extruded rod), and the same coatings (clear lacquer, zinc chromate primer and bituminous paint).

Bare and coated specimens were embedded in standard portland cement brick mortar and in lime brick mortar in small dummy sections of brick walls. Wall sections were exposed on the roof and in the basement, some dry and some immersed in water. At intervals of eight days, six months and eighteen months, sets of specimens were broken out, cleaned and examined visually for corrosion. Thickness measurements were also made.

Similar specimens were embedded in a wall section of portland cement stucco, built upon metal lath, both exposed on the roof and stored dry in the basement. Sets were examined at the same time intervals as above.

Other bare and coated specimens were embedded in a wall section of hardwall plaster built upon Gyproc lath. These were stored dry in the basement and sets examined after the same time intervals.

***Description of materials***

The aluminum alloys and specimens have already been described in the section describing the experiments with concrete.

The additional building materials are described in Table V.

Brick mortars:

Two types of brick mortar were investigated:

(a) Lime brick mortar, made as follows:
  - Lime putty, 1 part by volume.
  - Sand, dry, passing No. 8 mesh, 3 parts by volume.
  - Water, to suit.

(b) Standard brick mortar, made as follows:
  - Standard portland cement, 1 part by volume.
  - Hydrated lime putty, 1 part by volume.
  - Sand, dry, passing No. 8 mesh, 6 parts by volume.
  - Water, to suit.

The lime putty was made up one or more days in advance. Lime brick mortar contains no cement and is used less frequently than in the past. It is said that the setting time is a matter of months for midsections of masonry using this mortar.

Standard brick mortar is used extensively for present day construction and as the recipe indicates, contains cement. The setting time is

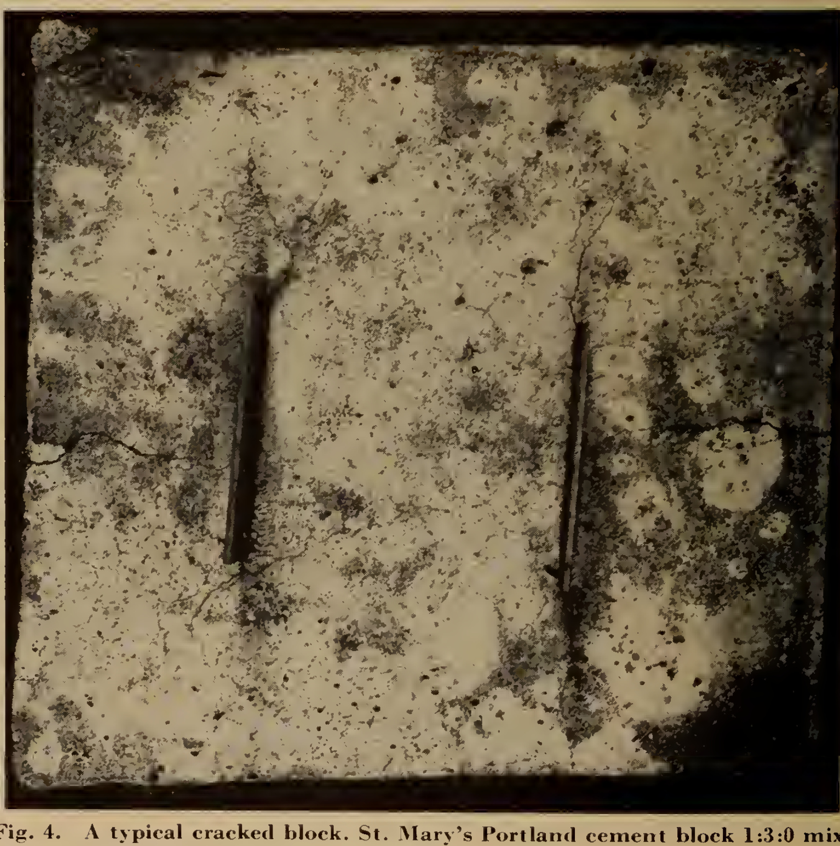

**Fig. 4. A typical cracked block. St. Mary's Portland cement block 1:3:0 mix.**

shorter and the compressive strength is greater than for lime mortar. The quick setting time makes it necessary to add the cement to the lime putty just before use.

Brick piers were made four bricks high, four bricks long and two bricks thick, as shown in Figure 1B. The piers were covered by forming a sheet of aluminum into a suitable flashing. Each pier contained 16 specimens consisting of a bare, a lacquered, a zinc chromate and a bitumen coated specimen of each of the four test materials — 3S sheet, 3S conduit, 50S bar and 65S bar. It was necessary to chip the brick to set the conduit in the mortar in the pier. All specimens passed through the pier.

One pier was made of standard brick mortar with 250 grams of calcium chloride, approximately 2 per cent of the cement content by weight, added and exposed on the roof. It was broken open after six months to determine whether the calcium chloride had had any harmful effect. This was also done with a similar pier for an eighteen-month period.

#### Observations

After eight days, a standard mortar brick pier was broken open. The bare specimens had suffered slight uniform corrosion, but the coated specimens were practically unaffected.

After six months, three more piers were broken up, one of which had been exposed on the roof, one in water and one in a dry indoor location. No cracks were noticed in the mortar prior to breaking the piers. The specimens from the pier on the roof and in the dry location were much like the eight-day specimens already described. The bare specimens were slightly more corroded, while the coated specimens were in excellent condition.

The specimens from the pier stored in water were much like the specimens from concrete stored under water. The marked superiority of the bituminous coating could be seen. The 3S sheet specimens looked slightly worse than the other alloy specimens, but once again the attack was considered superficial.

The various specimens removed from the standard brick mortar after eighteen months were remarkably similar to those removed after six months, for locations in the dry, in atmospheric exposure and under water. Standard brick mortar showed approximately the same degree of corrosive action as concrete; however, no serious corrosion occurred, as will be seen from Figure 5, which shows the 3S conduit specimens removed from the pier which had been immersed for the 18-month period in water. It will be noticed that the bituminous coatings offered effective protection, and also that the zinc chromate coated specimen was pitted, rather than uniformly corroded, as was the bare specimen. At 18 months, the lacquer on the various lacquered specimens was flaking seriously, and this coating is not considered effective protection after 18 months.

Specimens from piers containing calcium chloride, showed no more corrosive effect than was apparent at the same time period without this additive.

When the specimens were removed from the lime brick mortar pier after eight days, it was found that the coated specimens were unaffected and that the bare specimens were slightly etched in places. The general appearance was better than that of specimens from the standard mortar piers.

After six months, similar piers from the roof and the basement (dry) were broken open. The roof pier was already badly cracked in many places, but the pier from the basement was in good condition. All specimens were in good condition; the lacquered and bituminous coated specimens were unaffected.

The 18-month lime mortar specimens, removed from piers stored in the basement and under atmospheric conditions, were similar to the standard mortar specimens exposed under the same conditions, although on the whole, the attack was somewhat less. Figure 6 shows the 50S-A33 specimen from the dry block and demonstrates the effectiveness of bituminous paint in preventing corrosion. Note that the bare specimen was uniformly corroded, whereas the lacquered and zinc chromate coated specimens were protected over some areas by the coatings.

#### Wall plaster and stucco:

Two types of plaster were investigated:

(1) Hardwall plaster such as is used on walls and ceilings of rooms in houses where conditions are not damp, made up as follows:
    Hardwall plaster, 1 part by weight.
    Plastering sand, dry, screened through fly screen (16 mesh) — 1st coat, 2 parts by weight. 2nd coat, 3 parts by weight.
    Water, as required.

(2) Portland cement plaster such as that used for exterior stucco and for damp locations, as in basements, made up as follows:
    Standard portland cement, 1 part by volume.
    Plastering sand, 3 parts by volume.
    Hydrated lime putty, 10

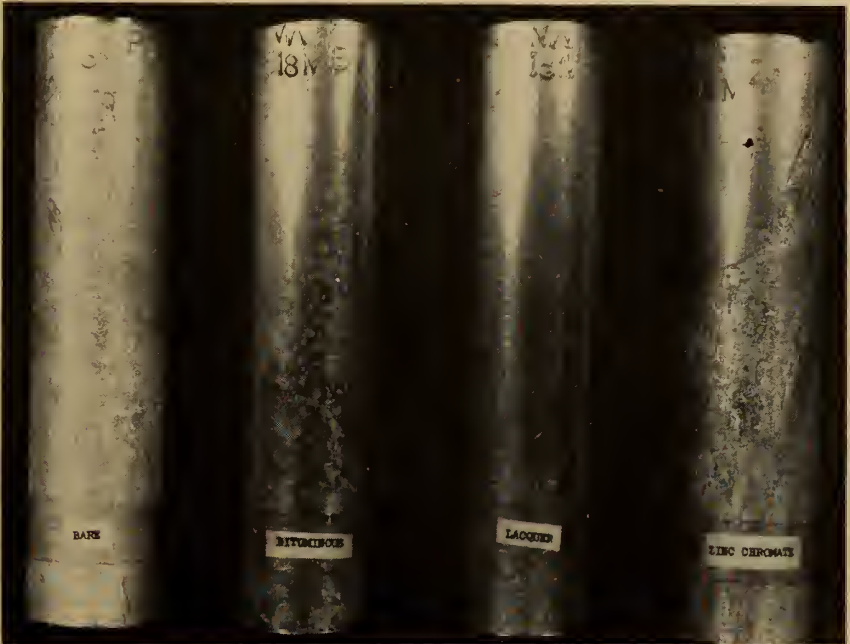

**Fig. 5. Alcan 3S conduit specimens removed from standard brick mortar pier submerged 18 months.**

per cent by weight of cement.

Water, as required.

For the hardwall plaster tests, frames about 36″ wide x 48″ high were made up of 2″ x 4″ scantlings placed at 16″ centres. Both sides of this frame were covered with Gyproc lath and the frames were edged with a ¾″ beading strip to provide a stop for the plaster around the perimeter. The specimens were embedded in such a way that they ran through the plaster on the frame, with approximately ¾″ in contact with the plaster.

The portland cement plaster (stucco) wall sections were made up in a similar way to the hardwall plaster frames, except that they were 48″ x 48″, with 16″ between centres of the uprights, and that these frames were covered with 24-gauge diamond mesh galvanized steel lath. (See Figure 1C.)

**Observations**

At the end of eight days, this group of specimens was removed from the hardwall and portland plaster frames on the roof and from the hardwall plaster frame stored in the basement. The eight-day specimens showed no corrosion whatever, except on the bare specimens which had been embedded in the portland cement plaster and left outdoors. With the 18-month specimens, both for hardwall and portland plaster, no corrosion was apparent except in the case of portland plaster specimens exposed to the atmosphere. These showed some slight superficial corrosion over the ¾″ band which had been in direct contact with the plaster. (See Figure 7.)

Notice the mild etch attack on the bare specimen. The bituminous coating offered good protection to this specimen, but the lacquered coating offered only partial protection. The zinc chromate coating offered little protection and thus some pitting occurred in the affected area.

**Fig. 7. Alcan 3S sheet specimens removed from a portland plaster (stucco) wall section exposed outdoors for 18 months. Notice only slight superficial attack confined to the ¾″ band of contact with the stucco.**

Aluminum nails were used in one frame to fasten the metal lath to the frame work. Part of the shank was bent over with the result that approximately ½″ of the shank and the head were embedded in Portland plaster. Upon removal of these nails, it was observed that although some slight superficial attack had taken place, the nails were essentially in good condition.

Keene's cement — Since Keene's cement is a frequently used building product, a brief test with this product was carried out, even though it is acid in reaction. A complete set of specimens was placed in neat Keene's cement in an 8″ x 10″ porcelain tray. The fast-drying cement set in a few minutes and the tray was stored in a dry location for six months. At the end of this period, the specimens were in absolutely perfect condition in every case.

**Fig. 6. 50S-A33 specimens from the dry lime brick mortar pier after 18 months. Note the effectiveness of the bituminous paint coating.**

**Discussion**

The results of these experiments indicate that:

(1) Aluminum alloys are not seriously corroded by contact with concrete, standard brick-mortar, lime brick-mortar, hardwall plaster and stucco over extended periods. Slight, superficial etching takes place during the period when concretes, mortars, plasters or stucco are setting; unless there is frequent intermittent wetting and drying, no appreciable corrosion takes place. The amount of attack is not sufficiently great to cause deterioration in the properties of the aluminum in other than thin sections.

(2) Even under continuously wet conditions, aluminum alloys embedded in concrete are only slightly attacked.

(3) Increasing the cement content of concretes (enriching the mix), increases the amount of attack[4]. The relative corrosive action of common Canadian alkaline building materials to aluminum, in decreasing order, is as follows: concrete, standard brick-mortar[5], lime brick-mortar, stucco, hardwall plasters.

(4) All the aluminum alloys tested (Alcan 3S, 50S, 65S, 57S) perform similarly.

(5) The effectiveness of a single coat of bituminous paint in preventing corrosion of aluminum embedded in various building materials has been well demonstrated by its consistently good performance over the various time periods tested in this program. Clear lacquer is less protective. Thus, where aluminum may be in contact with damp concrete or mortar, or with intermittently wet and dry alkaline materials of this type, it is recommended practice to paint the contact surfaces with bituminous paints.

(6) Calcium chloride additions to concrete mixes do not cause an increase in the corrosion rate. However, some work recently completed, indicates that if stray electric currents are present, corrosion may be greatly increased. Also, where aluminum is embedded in concrete containing calcium chloride and is in contact with steel similarly embedded in concrete, appreciable

[4]Also, depending on the origin of the cement, the free alkali content may vary slightly; the amount of attack would then vary in direct proportion.

[5]Actually, concrete and standard brick-mortar show approximately the same degree of corrosivity toward aluminum.

# The National Significance of Two Decades of Engineering Research in Canada

*by*

Dr. C. J. Mackenzie, Hon.M.E.I.C.
*President*
*Atomic Energy Control Board*

**The following address was delivered at a meeting held at the Institution of Mechanical Engineers, London, on Wednesday, June 2, 1954 by Dr. Mackenzie who had the same day been presented with the Kelvin Medal by Field Marshal the Right Honourable Earl Alexander of Tunis, K.G., G.C.B., G.C.M.G., G.S.I., D.S.O., M.C., on behalf of the Councils of the institutions participating in the award. Dr. R. W. Bailey, president of the Institution of Mechanical Engineers, was in the chair.**

**Dr. Mackenzie was the banquet speaker at the annual meeting of the Engineering Institute in Quebec in May 1954. His subject at that time was the same as that used in his London address. It was agreed between the two organizations that the same manuscript would be used in both publications.**

In Canada, as elsewhere, there has been notable progress in recent years in the art of engineering in all its many phases, but it is of the science and not of the art that I wish to speak this evening. Further, I shall not talk of scientific matters in detail, but of what the intensification of the scientific base of Canadian engineering has meant to our national industrial economy and outlook.

Since the end of the 1939-45 war we in Canada have been almost embarrassed by the many favourable comments which have come from Britain and elsewhere about our progress, our resources and our prospects. Certain present and indisputable facts can be marshalled, but what these facts really mean for the future is, of course, the important question. Does the present undoubted prosperity of Canada rest on the shifting sands of an ephemeral post-war boom, or does it represent real progress of a permanent character based on a firm foundation? These are the questions which we in Canada have been asking ourselves very seriously.

My thesis this evening is that great and fundamental changes have taken place over twenty-five years quietly and without the sounding of trumpets, and that they have changed the basic industrial and economic structure of our country and laid a sound basis for steady and permanent growth, and that, as a consequence, Canada is now entering a period of normal and healthy expansion and not facing collapse due to an unstable post-war boom.

Before outlining in detail some of the things which have been happening I should like to tell you a true story, which I think dramatizes in a general way what has occurred. I shall go back to one of the real crises of the 1914-18 war. It had to do with one of the many critical shortages which occurred, the munitions shortage in France in 1914-15. The demands for cordite could not be met, and the situation was desperate. One of the most urgently needed chemicals was acetone. In the search for new sources, Lloyd George heard of the work of a quiet, modest research professor of chemistry at Manchester, who in an attempt to make butadiene had found a fermentation method by which, unfortunately, (as he saw it) there was also produced acetone in quantity. The professor's failure was great news for Lloyd George, who wanted

Dr. C. J. Mackenzie, Hon.M.E.I.C.

acetone above all things. He immediately got in touch with the professor, pilot plants were initiated, and before long plants were being built in the United Kingdom, in Canada, and, later in the war, in the United States; but it is not unfair to say that the most successful plant was that in Toronto, Canada. It was successful because it was well operated and because the plants in Britain could not afford to bring grain across the ocean to make acetone, whereas we had the grain for making it to hand in Canada. The fact that the professor, Chaim Weizmann, 30 years later, became the first President of Israel may not be purely coincidental, but neither has it anything to do with my central theme this afternoon.

What I wish to point out is what happened at the end of World War I. In Canada, the operations ceased immediately. We dismantled our plant and the doors were closed; but in the United States the similar plants were not dismantled but became the nucleus of a great industrial development on the American continent. The 'surplus' butyl alcohol became the raw material of the nitro-cellulose industry, which grew very rapidly and parallel with the growth of the motor industry.

What happened in the case of the acetone factory in Canada happened also with our aircraft, chemical and the other war industries. We just stopped. My point is that the opportunities were there and the United States seized them; but Canada, the country to whom this twentieth century was to belong (in the words of a famous politician), was not scientifically ready in 1918.

Now to 1940, another world war and again shortages of which rubber was one of the most critical. Incidentally, one of the key components of artificial rubber was the same butadiene that Weizmann had been looking for in 1914 when he discovered a new method of making acetone. It is interesting to speculate that Weizmann in England might have developed artificial rubber twenty years before the Germans did, had he not been deflected from his research. That is a not uncommon experience in Britain, where great fundamental researches have paid handsome dividends in other countries.

But what did Canada do about this shortage in 1940? Again in cooperation with her allies, she built and put into operation with speed and efficiency a most intricate artificial rubber plant, based on scientific technique which we formerly thought was practicable only in research laboratories. The significant difference, however, is that at the end of the 1939-45 war this factory was not dismantled as was the acetone plant in 1918 but was kept going, and today is one of the essential components of a young, rapidly growing and vital chemical industry, which is so essential to any country.

Again I have used this story of our artificial rubber factory not because of its special importance, though it is important, but to illustrate what happened to most of our war and other plants and to indicate the significant changes which have taken place, in the scientific approach and outlook of our engineers and industrialists.

The question is, how did this change come about? What was the fundamental difference between Canada in 1918 and Canada in 1945 which accounted for this change in procedure and outlook? In 1918 we did have enterprising industrialists and reasonable skills, judged not on a 1945 basis but on a 1918 basis. We had no dearth of industrial resources. We had a few research scientists in the universities, and ten years before 1918 had one of the first aeronautical research associations in the world operating in Nova Scotia, where the first aeroplane flight in the British Empire was made. We had plenty of competent and resourceful design and construction and operating engineers, but we had very few real applied scientists and development engineers. There was no definite public recognition of the vital national need for co-ordinated and vigorous research. In 1918 we were still 'Colonial minded' in the realm of applied science.

In 1945 the situation was very different. By 1939 we had created a sizable corps of highly qualified and experienced research scientists and scientific engineers. We had strengthened immeasurably all our Government establishments and our universities and our industries everywhere had become interested in the application of science. We had resources of men of experience and competence to organize quickly extensive research and scientific services for our industries, without which no such operations can remain permanently successful. In addition, however, there had developed by 1945 a strong public conviction that Canada's economic future must rest on a strong and progressive Canadian applied science and technology. These changes in outlook and potential may seem to have appeared suddenly, but in fact the results apparent today are based on the unspectacular work of twenty years, during which our fundamental scientific forces and facilities have been slowly but soundly built up.

Before outlining how that scientific build-up developed, I should like to give you a more general picture by mentioning a few facts which will help to illustrate broadly the recent economic and industrial growth of Canada. Since 1939 our population has increased from 11 million to 15 million, or by about 35 per cent in 15 years, which is well above the average but not really spectacular. During the same period, however, our national income and output have increased, in terms of constant 1939 dollars (I am not using inflated figures), by over 150 per cent. To put that in another way, our national income per head of population is about twice as great today as it was before the war, which means that our 1954 population, man for man, is producing in goods and services approximately twice as much as in 1939. That, I think, is very significant in terms of effective productivity and on the standard of living. Our Government revenues and expenditures have also doubled, as measured in constant dollars, but our scientific research expenditures—and I want to emphasize this point—have increased fourfold. The value of our foreign trade in 1953 was also four times what it was in 1939, and today Canada, with her relatively small population of 15 million, less than 0.5 per cent of the world population, has a volume of import and export trade exceeded only by that of Britain and of the United States.

Since the 1939-45 war Canada has been able to operate on a balanced budget. Our national debt has been decreased by over 15 per cent, and when all the controls on our currency were removed the Canadian dollar rose *vis-a-vis* the United States dollar and now stands at a premium of two or three per cent. All these things are indisputable and, I think, significant facts. It is also true that since the 1939-45 war a great deal of capital from Britain and from the United States has sought profitable investment in Canadian enterprizes which is the surest indication that many people of experience throughout the world believe that Canada has a sound and attractive future. That Canadians share this confidence is evidenced by the fact that the extraordinarily large capital investments made in Canada during the past decade have come in the main from Canadian and not from foreign sources; 86 per cent of all the capital investment in Canada in the last few years has come from Canadian sources, and only 14 per cent has come from the outside world. At the same time, the Canadian people have invested more than 14 per cent in other countries.

All this makes for confidence in the soundness of our economic position, but it does not explain what has happened to bring about this situation. I do not, of course, suggest that there is any one answer or reason to account for what has happened; national development is far more complex than that, and there are many factors. Current events and a measure of good luck have all played a part. We hear a great deal about Canada's recently discovered and abundant natural resources, and that picture is impressive. It seems reasonably clear that in Western Canada there will be found oil reserves comparable with those of Texas, and in the vast pre-Cambrian Shield there are indications of great reserves of nickel, copper, zinc, titanium, and asbestos, to say nothing of uranium, and that is very important in a world where the reserves are dwindling very rapidly in relation to the demand.

The point is, however, that Canada has always had rich resources, and has known of them for a long time. While the oil and iron deposits have only recently been proved we always believed that they would be found. Great as these resources are, they do not dwarf or equal our great agricultural resources, our existing mining industries, our hydro-electric power or our forest industry of lumber, pulp and paper. We have had all these things for many years, so that our natural resources, while they are a major asset, have not just been discovered, and the reason for Canadian prosperity is not primarily the recent discovery of oil and iron. Many other factors, national and international, have played major roles, only a few of which I can mention.

Canada's history has been greatly influenced by world events and the actions of other people. The 1914-18 war made Canada conscious nationally in the military, diplomatic and international sense and had a profound effect on our industrial and financial economy. It contributed little, however, towards the development of an indigenous, scientifically-based secondary industry. In Canada the years between 1919 and 1939 saw the growth of a quite considerable amount of secondary industry, but, with the significantly important exceptions based on exploitation of our hydro-electric resources and forestry, it was largely a growth of branch factories. The basic activities of research, development, design and direction were done elsewhere, outside our borders, in the United States or the United Kingdom.

Between 1919 and 1939, however, a very important thing happened which had a far-reaching effect: the slow, gradual but sure building up across Canada of research facilities and the training of scientists and scientific engineers. We are all familiar with the developments in low-cost hydro-electric power which made possible the great pulp and paper industry, and also the building of electro-chemical and metallurgical enterprises such as the Aluminium Company. Cheap power also stimulated the growth of many smaller industries and assisted in opening up remote areas which in turn provided new resources and market demand. But significant as such developments were, I am convinced, as I have already said, that the creation of the Canadian scientific and industrial research potential during that period has been the major factor in shaping the real character of our economic expansion since 1939.

From 1918 to 1939, owing largely to the branch factory type of development which I have mentioned, the great expansion in industrial research laboratories which occurred in the United States and in Britain simply did not take place. Fortunately, however, Canadian Governments did recognize that a country must have adequate industrial research facilities within its borders if its industries are to meet successfully all challenges. This was proven very well in Canada during the 1939-45 war, when most of Canada's branch industries were completely cut off from the military research of their parent companies in the United States on account of security and other reasons, and Canada in her military and atomic energy activities received no assistance whatever from these large American research laboratories. Research laboratories beyond your borders can be of some assistance in peace-time, but when an emergency occurs they are of no value at all. That is our experience.

Now for a little history. In 1916, as a result of a suggestion from the Government of the United Kingdom, the Canadian Government, as did those of other countries, formally established a National Research Council, which did not, however, really start operation until 1918. This Research Council was set up, like your Department of Scientific and Industrial Research, to promote, stimulate and co-ordinate industrial research, but, contrary to your experience, our Research Council discovered that there were no industrial research activities to co-ordinate; found that universities' research facilities were sadly limited, and that there were only a few well-trained research scientists in the whole country. I do not talk of quality but quantity. This was only 21 years before the outbreak of the 1939-45 war.

The governing body of the National Research Council of that date was a very wise body, made up of university people who understood the fundamentals of science and technology, and they in their wisdom set about training a body of research scientists by providing scholarships and creating the necessary facilities for such training by making grants in aid of research to universities. Both these programs have continued and grown greatly since 1919.

The result was that when war broke out the wisdom of these programs became apparent, and the consequences have been profound. Even in 1939 there were few private industrial research laboratories where development contracts could be placed, and our Government laboratories were sparsely staffed. When I took over the Presidency of the Research Council in 1939 the total staff was 300 and the budget 750,000 dollars; but we had just completed large and well-equipped laboratories and there was, for the first time in our history, a sizable reservoir of young, well-trained research scientists and engineers who were not in profitable employment at that time. This reservoir made it possible for the Council to recruit and to put to work about 2,000 within a relatively short time.

Since 1946, separate agencies have been organized to take over defence research and atomic energy responsibilities and today the combined establishments which grew out of the Research Council now employ 6,000 people. The 300 staff of 1934 have increased to 6,000. The money expenditure is, in proportion even greater.

With the National Research Council as the nucleus, Canada in 1939, for the first time was able to enter the field of development engineering and scientific industry. The result was revolutionary. In an amazingly short time we built, equipped and were able to operate a line of specialized industries. From secret information supplied by British establishments before the war broke out we built and installed radar equipment in Halifax in 1940. Subsequently, we built large radar laboratories and factories which immediately after the attack on Pearl Harbour supplied radar equipment to help protect the Panama Canal and other parts of the United States. We built factories to make aircraft, tanks, ships, optical glass, artificial rubber, electronic equipment and metallurgical and chemical plant of various kinds. In the field of atomic energy, in joint partnership with you in Britain, we built the first reactors to operate outside the United States and our contributions and activities in this field have been and are acknowledged everywhere.

In brief, then, Canada came out of the 1939-45 war a very different country, technologically and industrially and, since 1946, further advances, not retreats, have been the order of the day. Therefore, when thinking of the present status of Canada and her future role, it is necessary to realize that the 1939-45 war not only strengthened Canada in her political, diplomatic and autonomous position but changed her economic and industrial framework from the 1939 model, based largely on the production of primary products and branch factory manufacture, to a 1950 model, based on science, advanced technology and industrial know-how. This is of primary importance in appraising the future of Canada as an industrial and trading nation of the first rank.

To summarize, then, the Canadian economy has, during the past few years, expanded rapidly. The reasons are many and complex, and no one factor is solely responsible. I do claim, however, that, because the scientific base of our engineering and industry has been strengthened and broadened, we are justified in concluding that our economy has been and is going through a period of rapid but well-balanced and soundly-based development rather than through a violent and narrowly-based boom.

I would also emphasize the fact that it is a transition which is still taking place. Our scientific facilities are by no means adequate as yet and, particularly in the fields of pure research and development engineering, we are very far behind Britain. The significant fact is not, however, where we are today but where we are going. I submit very seriously that during the past two decades a real revolution has taken place not only in our outlook towards industrial research but in the magnitude and quality of our scientific activities, and this change means that the current expansion of our national economy rests on the only firm foundation which can support such an economy.

I do not want, however, to give you the idea that we in Canada either desire or expect to become a completely integrated, self-sufficient isolated industrial State. That is certainly not so. We are a country blessed with an abundance of raw materials, but we have no wish to hoard these selfishly, because it would be a false selfishness anyway. We are and must remain a trading nation of the first rank. I do not know whether or not you realize it, but 25 per cent of Canada's national production goes into export trade. That is a very large percentage, and compares with 5 per cent in the case of the United States. This means that we, like you, must exchange with other countries reasonable quantities of raw materials as well as finished manufactured products. We are, by virtue of these factors, internationally minded, and we believe that the hope of the free world depends in a very great measure on international trade and co-operation. As an engineer, I feel that these desirable ends can best be achieved if we all build and expand our economies, whatever they may be, on a sound foundation of science and its applications, and this we in Canada are attempting to do. √

## THE RESISTANCE OF ALUMINUM TO SOME ALKALINE BUILDING MATERIALS

(*Continued from page 1256*)

galvanic corrosion of the aluminum may occur, especially under damp conditions.

(7) There are occasions in construction work where it may be necessary to place aluminum conduit or structural sections in contact with concrete or mortar surfaces. To avoid a line of contact which may trap and hold water and eventually lead to corrosion, clearance should be arranged between the aluminum member and the structure proper or, if this is not possible, the aluminum should receive an adequate coating of bituminous paint.

### CARGO HANDLING AT PORTS
#### The Benefits of Mechanization

James Steel, *The Duck and Harbour Authority*, v. 35, n. 403, May 1954, pp. 15-17.

James Steel, *The Dock and Harbour Authority*, v. 35, n. 403, May 1954, pp. 15-17.

The chief aim of every port is to load and discharge ships with maximum speed and economy. Outdated methods of cargo clearance means longer delays and increasing costs. Mechanization is the key to this problem. In many ports the speed of turn-round is governed by the handling on board ship and not by the shore operation, but in others the flow of cargo through the port is not sufficiently smooth and exports are not brought forward or imports cleared fast enough to keep pace with work at the ship's side.

To obtain the full benefits of mechanising general cargo handling it is necessary:

(1) To provide ships with ideal facilities for cargo to come inboard and ashore and to permit the best use of mechanical handling aids.

(2) To improve road conditions in the port area for mobile plant; to plan the layout to prevent congestion of increasing road traffic; to provide modern sheds with easy access for cranes, lift trucks and tractor trailers. To improve the road approaches to the port area, which are often much inferior to the rail approaches.

(3) To have a full knowledge of all the many available mechanical aids to cargo handling; to understand the advantages and limitations of each; and to know how to integrate selected plant into a general scheme of cargo handling.

If the flow of cargo through the port is interrupted from any cause, there will be a delay in clearing ships. Therefore the movement of traffic through the port area and in its immediate vicinity is of vital importance. The approach to these problems should be one of progress rather than tradition, and the correct selection and use of mobile mechanical aids is not the least of these three essentials.

A wider adoption of unit loads designed for modern handling methods would be a great advance. A sack of cement or a bag of nails is certainly a unit load, but the size and weight were fixed long ago to suit the strength of a man. New units should be adopted to suit the power of the crane or truck, which has relieved the human muscle of its load. The palletised load and the container are excellent examples of this progressive outlook, but they cannot bring their full benefits until modern handling methods are used at every stage of the journey of the merchandise. In handling general cargo it is desirable to use different plant for the most efficient handling of different kinds of cargo—fast light lifts, slow heavy lifts, and grabs for loose materials—and it is a great advantage to have the shore based plant mobile.

It is a useful exercise to analyse the handling operation into its component parts as, for example, in loading a ship:

A. Horizontal movement in the port area which may consist of:

(1) Cargo called forward by rail direct to the ship's side.
(2) Cargo called forward by road direct to the ship's side.
(3) Cargo accepted into transit sheds to await shipping.
(4) Cargo taken from transit sheds to ship's side.

Of these, all except (4) are transport problems and outside the present scope. The fourth merits careful study of average distance run, terminal waiting time, and empty journeys.

B. Vertical movement at the ship's side which may be:

(1) From road or rail truck into hold.
(2) From dock trucks into hold.
(3) From lighter into hold.

C. Stacking and unstacking in transit sheds and re-handling areas.

D. Stowing in the hold.

For the horizontal movement we may choose between plant which picks up its own loads, such as mobile cranes, squeeze trucks, fork lift trucks, stillage trucks, and straddle trucks, and those which must have the load put on them and taken off again, such as the load carrier and the tractor/trailer system. The choice will be governed by the length of the run. If the transit shed or rehandling area is within 100 yards of the berth it will probably pay to let the lifting machine also transport. If the average distance is greater, the more expensive machine would be spending too much time transporting, and it is more economical to have a lifting machine at each end of the run and to use cheaper trucks for the transport.

The choice between loadcarriers and tractor/trailer system is governed by the bulk and weight characteristics of the cargoes and the ratio of terminal waiting time to travelling time. If the cargo is so bulky that the platform of a loadcarrier about 8-ft. x 3-ft.—cannot accommodate enough to utilize its full tractive effort, it is economical to use a tractor to pull 2 or 3 trailers. If loadcarriers with their drivers are kept waiting whilst sets are being landed from the ship, it pays to let the unattended trailers wait and the tractor draw them away when loaded. Thus the expensive plant and the driver are always doing profitable work.

The choice of mobile lifting-and-carrying plant depends largely upon how the cargo is packed. The fork lift truck, for example, can only handle loads that are palletised. The ownership of pallets presents a great problem at the present time, and the failure to agree any international standard of size bids fair to neutralize the advantages of this excellent pack. The pallets must go all the way from consignor to consignee and there is little advantage in palletising for one stage of the journey only or merely to facilitate storage. The straddle truck is excellent for sawn timber and steel bar stock. The stillage truck is good for small heavy units, such as castings, which cannot easily be made up into larger unit loads without a container. The bale clamp or squeeze truck is the fastest and best means of handling bales which are not damaged by side pressure.

The mobile crane is the most generally useful machine. It is the only one able to handle both heavy and bulky loads. Equipped with automatic tongs, it can pick up and put down cases, drums, bales, sacks, coils, etc., without the help of a slinger. By means of a magnet it can pick up and release all ferrous goods, and with a grab it can handle most loose materials.

For vertical movement at the ship's side we have the electric quay cranes—portal, semi-portal, and tower, the new mobile cargo cranes, ship's gear, and strut or cantilever jib cranes for loading and discharge of small coasting vessels, barges and lighters.

Until there are deep water berths for every ship in every harbour of the world, cargoes must sometimes be loaded or discharged overside when berthed at buoys. Only the ship's gear, or a floating crane for the heaviest lifts, is then available to handle general cargoes from or into lighters. For certain ports, therefore, the ship's derrick and winch is an essential. When ships are trading between ports without deep water berths, a more efficient ship's gear for loading or discharge overside will so speed up the turn-round that the extra cost of modern gear may quickly be recovered. Some shipowners and builders are therefore replacing derricks and samson posts with modern diesel/electric cranes having luffing jibs and 360° slewing, located fore and aft of the hatchway. These can plumb any part of the hatch square, reach over to lighters on port or starboard, and operate independently of ship's main or auxiliary engines, whilst using fewer men than the conventional type of gear.

The shore based crane is, however, always preferable when the quay width and structure permit its use; its operators are more skilled in its use; they have a better view of their work; the cranes are independent of the movement of the ship; and they are usually kept in better order than ship's gear exposed to seas and weather.

For transferring from lighter to quay, or vice versa, pneumatic-tyred mobile cranes are being increasingly used. Those with cantilever jibs are ideal for loads up to 10 tons, and larger cranes are available with strut jibs for heavier lifts up to 20 tons. Full circle slewing is regarded as an essential to obviate the need to manoeuvre into position on the road wheels, and diesel/electric cranes give the best results due to the absence of clutches and gears.

Stacking and unstacking in transit sheds and rehandling areas is one of the costliest items of cargo handling if not fully mechanized. The principal objectives are to stack to maximum height to obtain full revenue from the shed, to avoid damage to cargo, to reduce handling costs, and to provide easy access for customs check and selective unstacking.

All plant working inside the transit shed should certainly be electrically operated. In addition to the obvious advantages of low fuel costs and low maintenance costs, long life, and ease of driving, the cleanliness, silence, absence of fire risk and absence of contaminating fumes are of vital importance in transit sheds where all kinds of cargo are stored.

What is perhaps the last phase of cargo handling to receive the attention of the mechanical handling expert is the stowing and unstowing of cargo. Much can be done to reduce manhandling in holds by using power shovels, small mobile cranes, lift trucks, rotary slingers, and portable elevators in the hold itself. To make the best use of these aids, the structure of coamings and holds should be designed to hinder their movements as little as possible. Small mobile cranes, fork trucks, angle dozers, front-end loaders and portable conveyors can trim the wings of the hold and 'tween decks; this eliminates much manual work and avoids the "dragging" which so often causes damage to cargo.

General cargo has been well described as "heterogeneous assortment of miscellaneous commodities inadequately packed in an endless variety of containers". In many commodities the individual pieces can be made up into a unit load suitable for mechanized handling of, say, 1 or 2 tons. The shape of this may be suitable for entry of forks and slings without being either palletised or cased. Preferential freight rates should be given to those shippers who consign their merchandise so packed, which would penalize the few who stand in the way of progress by clinging to outdated methods.

## SOME PROPERTIES AND APPLICATIONS OF INDIUM

*Machinery*, v. 84,n. 2160, April 9, 1954, pp. 751-752.

Although indium was first discovered in 1863, it has only been made available on a commercial scale for a period of less than 15 years. One of the principal sources of supply of the metal is in British Columbia, where the Consolidated Mining & Smelting Company of Canada, Ltd., are extracting it from the by-products of lead and zinc smelting operations. By electrothermic and electrolytic processes, indium, having a purity exceeding 99.95 per cent, is obtained in commercial quantities.

Indium is a silvery-white metal similar in appearance to platinum, and is one of the softest of the solid metals that are stable in air. It can be readily scraped with the fingernail, and can be made to adhere to the surfaces of other metals merely by rubbing.

Tests performed on the metal after annealing for one week at 110 to 130 deg. C., reveal that it has a Brinell hardness of 0.9, a tensile strength of 380 lb. per sq. in., an elongation of 22 per cent on 1 in., a reduction in area of 87 per cent, and a modulus of elasticity of 1.57 x $10^{-6}$ lb. per sq. in. The true compressive strength (at 10 per cent true strain) is 310 lb. per sq. in. The relatively low elongation, and the high reduction of area, are due to the fact that almost all the deformation in the tensile tests is localized, since indium does not work-harden. The values quoted were obtained in tests on sheet-material, and tests using conventional round-section specimens yield much higher results, a reduction of area of 99 per cent having been then recorded. This value indicates more truly the capacity of indium for undergoing local deformation during tensile tests.

Among the physical properties of the metal may be noted a density of 7.31 gm. per c.c. and a co-efficient of expansion of 33 x $10^{-6}$ per deg. C., both values being obtained at a test-temperature of 20 deg. C. The thermal conductivity of indium is 0.057 calories/sq. cm./cm./deg. C./sec., and its melting point is 156.4 deg. C. Indium dissolves slowly in dilute, cold mineral acids, more readily in hot, dilute acids, and rapidly in concentrated acids. It is not attacked by strong alkalis or by acetic acid, but is susceptible to attack by oxalic acid. Although indium has no toxic effects on operators handling or working it, and does not act as an irritant on the human skin, it is unsuitable for use with food products since it readily dissolves in food acids.

The principal application of indium has been in aircraft sleeve bearings. In one type of bearing, indium is plated and diffused into a steel backing-shell which has been previously coated with silver and lead. After diffusion, the concentration of indium, at the surface of the bearing, is about 16 per cent, this value corresponding to the proportion of indium in a solid-solution with lead. It has been found that the hardness and strength of the bearing are improved, and that, generally, indium increases the resistance of the metal surface to corrosion by the acids in lubricating oils. When indium is diffused into a steel-backed, cadmium-alloy bearing, the corrosion resistance is improved without adverse effect upon the fatigue resistance of the alloy.

Indium-coated bearings are employed, in the B.R.M. racing car, for the crankshaft, which runs at 12,000 r.p.m. The bearings, supplied by Vandervel Products, Ltd., Western Avenue, London, W.3, consist of mild-steel shells with a copper-lead alloy coating. This coating has a very high fatigue resistance and withstands the high working stresses imposed. An indium coating is applied to the copper-lead shell to provide a low coefficient of friction, a good resistance to corrosion, and a marked resistance to seizure.

Various low-melting point alloys have been prepared with indium content, and the addition of this element to Woods'-metal alloy lowers the melting points of these materials by 1.45 deg. C. for every 1 per cent added.

The alloy of this type having the lowest melting point (47 deg. C.) contains 19.1 per cent of indium. An alloy comprising 24 per cent indium and 76 per cent gallium, melts at 16 deg. C., and is liquid at room temperature.

An alloy containing equal amounts of indium and tin is capable of "wetting" glass and can be employed for making glass-to-glass or glass-to-metal seals. The alloy is applied to the pre-heated glass component by swabbing, and the joint is then made in the conventional manner. Vacuum-tight joints can be obtained with a high degree of consistency, and tin-indium alloys are particularly useful for making joints in glass components where the application of high temperatures is not permissible.

Investigations are proceeding to determine the value of indium as an additive to lubricants in the form of a fine suspension, or as a soluble chemical compound. It is also reported that, when the element is added to chromium-plating baths, the brittleness of the plated coating is reduced, and further experimental work is being carried out in this connection.

## NONE SO BLIND

Editorial, *Aeronautics*, v. 30, n. 5, June 1954, p. 25.

It is inconceivable that, in this year of 1954, anyone who has learnt the elements of metrology could be in any doubt about the status of British Imperial weights and measures, or about the status of the metric system of weights and measures. British Imperial weights and measures and the bastardized versions of them used in the United States of America and elsewhere are derived from untrustworthy and unstable prototypes, they are not decimalized; they are not coherent; they are not international; they are not systematic. They are confused, muddled and misleading measures. The metric system of weights and measures, however, is decimalized, coherent, systematic and international. It is simple to use. The prototype units are stable and trustworthy. These facts are known to most educated people. British Imperial measures are an antiquarian curiosity at best; a hindrance to engineering and commercial progress, a source of error, a cause of waste and a headache to the logically minded at worst.

## VIEWS ON WATERSHED CONTROL

*Journal American Waterworks Association,* v. 46, n. 5, May, 1954, pp. 403-405.

The ideal source for a public water supply is an isolated, forested watershed without habitation and with all recreational use prohibited. It is obvious that, with automobile transportation available to everyone, this situation is impossible to attain. It should be recognized that there are several types of watersheds, although the particular water utility is interested only in the one under its control. Up to the present, no concerted effort has been made to develop the watershed picture in its entirety.

Small cities and towns rely mainly on well supplies. Of all American cities with more than 100,000 population, approximately 20 per cent also depend upon these sources, while the remaining 80 per cent are about equally divided between those cities utilizing impounding reservoirs and those taking water from the Great Lakes or from large rivers.

Cities located on large rivers that serve as their source of supply do not have direct control over their watersheds and must rely on the various state health departments to abate nuisances and eliminate industrial wastes. These conditions apply to such typical rivers as the Potomac, Susquehanna, Ohio, Missouri, and Mississippi.

The Great Lakes cities are in a different category. There is a large volume of water in the lakes, and pollution from domestic sewers and industrial wastes enters at the shoreline. To overcome these hazards, intakes or cribs have been extended several miles offshore. Control over the wastes discharged at the shoreline is vested in the health departments of the states bordering on the lakes. In these instances, the water utilities and health departments maintain close co-operation in pollution control.

Impounded small rivers flowing through sparsely inhabited woodland or farming country with small villages are found in many sections of the United States. The responsibility for the sanitation of such watersheds, although vested in the various state health departments, is usually delegated to local health agencies, with which the water departments must co-operate.

It is apparent that watershed sanitation will differ for various types of supply sources. It has been pointed out that the Great Lakes cities and those on large rivers cannot directly control pollution on their watersheds. Water from large rivers is grossly contaminated, but, with modern purification processes and constant vigilance, these cities produce drinking water that conforms to modern standards of safety and palatability and they have extremely low waterborne-disease death rates. It must not be inferred, however, that stream pollution control should be neglected: on the contrary, it should be enforced as well as local conditions permit.

The primary use of a river is for water supply, and the object of stream pollution control is to minimize the density of pathogenic organisms and industrial wastes in the stream, so that the purification facilities will not be overburdened. Stream pollution control is of vital importance as it is the only watershed sanitation measure available for large rivers.

No hard and fast rule determine what is and what is not pollution. In many instances, the criteria have the protection of aquatic life and the provision of a water supply as free from contamination as possible. It is now known that "much of stream life, (degradation) formerly attributed to pollutants, is really occurring because our streams and lakes are growing old, and are changing in nature and aquatic population with changes in their environment."

Many years ago the Pennsylvania Sanitary Water Board proposed that stream pollution control should be governed by the classification of the stream according to its use. It is now recognized that this fundamental concept is correct, and that fixed standards, as determined by chemical and biological constants, cannot be established or enforced for an entire river. Usage in relation to pollution factors of separate sections or zones must be the basis for pollution control, and procedures that best fit local needs should be instituted. In the last analysis, the object of stream pollution control is to protect the existing clean waters and to improve the unclean and contaminated waters, so that they may be utilized by the most people for the greatest number of purposes. It is believed, however, that water of a purity eoual to that of an impounding reservoir should be the goal where potable supplies are involved.

With modern purification, it becomes evident that for an impounded river supply, a virgin woodland watershed is archaic. Unless storage and chlorination are the only purification processes used, this type of watershed may be considered a relic of the past. Raw water with as little pollution as practicable should, however, be obtained. The courts have usually recognized the need for a utility to protect its watershed even though a limitation of private property rights results. On this type of watershed, protective practices are limited to the control of the area surrounding the reservoir and to periodic inspection of properties upstream. Authority to enter private property in order to abate a nuisance and enforce regulations is usually vested in the water supply agency.

There should be some economic balance between expenditures for purification and those for watershed sanitation, when both are practiced. If a modern treatment plant is part of the system, less money should be spent on watershed sanitation than if reliance is placed upon reservoir storage and subsequent chlorination of the effluent. It must not be forgotten, however, that the most efficient watershed control measures cannot replace purification.

## TEAPOT TEMPESTS COME OF AGE

Homer J. Wood, *SAE Journal*, v. 62, n. 6, June 1954, pp. 21-23.

Small gas turbines (50 to 500 hp.) still can't push piston engines out of many of their jobs, but they've got what it takes to cop some of them. Turbines have, for example, won many posts as aircraft auxiliary powerplants. And they're a serious contender for any other powerplant "positions" where weight reduction is important.

Put another way, if it takes more than a 4-cylinder engine to do the job, the turbine may be competitive; if four cylinders or less are good enough, the turbine can't compete. What's more, it won't be able to for a long time.

The past seven or eight years have seen a great deal of activity in the field of small gas turbines (below 500 hp.). And, from time to time, the proponents thereof have proclaimed the forthcoming obsolescence of piston engines in this size class.

Yet some difference of opinion must be involved, since major automotive companies continue to invest many millions of dollars in tooling for new engines which they say will be in use for 10 years.

This would indicate that the men who control these companies are not convinced that the "teapot tempest" has come of age in the automotive field. In fact, there are people in the gas turbine business who argue that souud and practical applications of small gas turbines are still several years away and, indeed, may never come to pass.

Those who would condemn small gas turbines have some valid arguments.

In the first place, the best fuel consumptions achieved by small turbines today are about 50% higher than would be considered high for reciprocating engines. And this is only part of the story. Most piston engines are capable of maintaining reasonably good fuel economy down to and below 25% load. A gas turbine, on the other hand, tends to consume three to four times as much fuel as a reciprocating engine at similar loads.

Furthermore, gas-turbine engines tend to lose their much-vaunted simplicity or to operate at unfavorable stresses or temperatures when they seek to better their fuel economy. Thus, unless some revolution occurs, the temperature and stress limitations of known materials will leave the small gas turbine in an unfavorable fuel-consumption position for quite some time to come.

Perhaps the answers to a few other questions about small gas turbines as they exist today would be revealing:

*Question:* Are the turbines cheaper in initial cost than present-day piston engines of equal power?

*Answer*—No!

*Question:* Have gas turbines been proved to be more reliable under field conditions than piston engines?

*Answer*—No!

*Question:* Have gas-turbine maintenance costs been proved to be lower under field conditions?

*Answer*—No!

*Question:* Is there any category of gas-turbine superiority that has been demonstrated by practical application?

*Answer:* Yes, low specific weight. This favors transportability.

*Question:* Are there any operating conditions which clearly favor gas turbines?

*Answer:* Yes, low temperature operation, particularly with respect to starting without preliminary heating.

*Question:* Do gas turbines have installation advantages?

*Answer:* Yes, in so far as space required per horsepower is concerned. This is particularly true when postin-engine cooling requirements are included in the comparison.

In view of the number of unfavorable characteristics admitted above, it would seem that the writer exercises considerable temerity in stating that small gas turbines have proved themselves to be useful members of the prime mover society.

This position is taken because of the overwhelming importance of low weight for certain applications. To be more specific, the small gas turbine has come of age as an aircraft auxiliary powerplant where the auxiliary service is primarily for (1) making the airplane self-contained by providing power on the ground when the main engines are inoperative, or (2) for relatively short portions of the flight plan which render fuel consumption of secondary importance.

In such applications, no other form of prime mover can reasonably be substituted—even though life and reliability of small turbines needs to be improved.

The same bold statement is not necessarily as secure with respect to air-transportable ground equipment. For such applications as external-store streamlined pods, there can be no doubt that piston engines are quite undesirable.

However, for equipment that is designed to be transported in cargo aircraft, it can be argued that the weight penalties of piston engines may be accepted.

It is the writer's firm opinion that this is a transitory matter. Why? Because of rapid developments that are coming as a result of field experience. These will soon put gas turbines into a class of life and reliability that will make them unquestionably superior to piston engines for ground equipment that must be air transported.

Laboratory endurance tests have demonstrated, for example, that overhaul life between 500 and 1000 hr. is well within grasp, provided the machines are not subject to misuse or abuse.

It may be argued that a 500 to 1,000-hr. period is not enough (to which we reply that this is not an upper limit). But, somewhere between 1,000 and 2,000 hr. of overhaul life, we would have to start thinking in terms of increasing specific weight substantially.

Actually, when it comes right down to it, there are relatively few lightweight piston engines whose overhaul life exceeds 1,000 hr.

What's more, it is felt that within three years, small gas turbines will have the same service life and reliability as piston engines weighing two to three times as much.

The matter of cost must, of course, enter the picture.

Here again, we believe that in three years the turbine will be able to compete costwise with piston engine in equal production quantities. However, turbines will be unable to compete in first cost with piston engines that represent conversions from fields of large production where, for various reasons, the gas turbine is not suitable.

In discussing this question of cost, it should be noted that the number of cylinders in the competing piston engine plays a major role.

In the aircraft propulsion field, piston engines equivalent to gas turbines must have upwards of 24 cylinders, and the resulting engine are complex and costly. On the other hand, in the 500 h.p. and below market we find anywhere from 1 to 12 cylinders.

And while small gas turbines tend to be simpler than their large relatives (jet engines), the degree of simplification is nowhere near as great as it is between large and small piston engines.

Thus, this generalization seems reasonable. Wherever four cylinders or fewer are good enough to do the job, it will be a long time before a gas turbine can compete. From four cylinders up, increasing piston-engine complication gives the gas turbine a chance to offer competition in the not-too distant future.

Noise level frequently has been cited as a disadvantage of the of the gas turbine. Actually, however, a completely unmuffled piston engine of the same rating as a gas turbine would have approximately the same total noise level, though in different frequency ranges.

The problem with a gas turbine is to provide muffling without excessive intake and exhaust pressure losses. The feasibility of providing such muffling has been demonstrated, but the sacrifices in weight and bulk are noticeable. Even so, a substantial weight advantage exists in favor of the turbine.

Now, what about the future?

It is felt that the first three questions raised earlier in this article aren't always going to be answered in the negative. With time, these answers are going to pass through a "maybe" stage . . . and finally into affirmative answers through normal operation of the "learning curve."

As for the evolutionary trend of small gas turbines, it is toward simplicity, reliability, and adaptability—with fuel consumption and frontal area being of secondary importance. It is not felt that the possible improvements in fuel consumption that could be achieved with more complexity would offset the increased cost and reduced reliability necessarily implied.

This does not mean that fuel consumption reduction is being ignored. The distinction is that we do not believe that the complications necessary in large gas turbines to achieve this end can be justified in small machines.

In summary, the writer believes the small gas turbine is here to stay as a prime mover. It has already demonstrated its basic suitability for aircraft auxiliary power. And it will shortly prove a serious contender in all fields where weight reduction of the prime mover is important (the extent of such fields is not yet fully explored). However, it is likely to be many years before the small gas turbine seriously invades those markets where low weight is not an important consideration.

To venture a prediction, propulsion of small helicopters looks like the next field where the "teapot tempest" will come of age.

## LATEST IDEAS ON RUBBER BELT USE IN PULP MILLS

Donald R. Scheu, *Paper Trade Journal*, v. 138, n. 24, June 11, 1954, pp. 24-28.

Many new, improved types of belting, designed specifically for use in the pulp industry are proving the economy of the belt method of mass materials transportation. Outstanding example in the industry, however, is the economy and efficiency demonstrated by rubber belting in the log-handling operations.

Where a new cord conveyor belt has gone to work in log-handling service, replacement and maintenance problems traditionally associated with conventional systems have been virtually eliminated.

A study of pulp mill conveyor belt operations recently conducted reveals the versatility of belts designed for handling pulp wood logs. Such belts may be used as yard belts for general outdoor transportation of the logs, as recovery belts for bringing the logs in from the storage piles, as debarking drum feeder belts, as sorting belts after the debarking process and as chipper feed belts.

The study showed that for most economical service each application must be individually engineered to meet specific service conditions. In every case, however, the major problem is that of providing a loading method which will induce least injury to the belt. For this reason, the study indicates, the successful use of conveyor belts depends directly on the coordination of thinking between conveyor designers and belt designers.

Yard belts generally receive logs from trucks, railroad cars and barges. Loading is generally from along the sides of the belt. It is nearly impossible to establish impact-absorbing equipment under the entire belt. The belt itself must incorporate the impact resisting features through the use of heavy top covers, cushioned cord tensile members, and synthetic filled fabrics. Rubber covered idlers are of some assistance in protecting the yard belts as it is virtually impossible to prevent the logs from being thrown on the belt directly over the idlers.

Recovery belts are used to bring the logs into the processing plant from the storage piles. Recovery from storage may be accomplished by the use of an orange peel grapple, by hand or by the use of a bulldozer or similar pusher. When a grapple is used, the logs are dropped into a movable hopper which travels along the belt conveyor. Feed from the hopper to the recovery belt is indirect. The hopper construction which is considered best is one having a feeder belt bottom.

The belt for this application is generally short and massive especially designed to withstand the impact and gouging of the logs dropping from the grapple. This service is extremely severe. The use of a short bottom provides an easily replaceable item and prevents undue damage to the longer main conveyor belt. Combination cord and fabric belts have been found to withstand the impact of the logs better than the conventional fabric constructions. A measure of relief for the hopper bottom belt can be developed by supporting the belt on pneumatic impact idlers or solid rubber impact idlers.

The main conveyor belt is loaded by direct discharge over the head pulley of the hopper bottom feeder belt. The direct fall is represented only by the height of the hopper bottom head pulley above the main conveyor belt. A chute on the hopper frame can be of considerable value if it is designed to direct the logs properly onto the main conveyor belt.

Belt speed generally considered suitable for yard belts and recovery belts are from 250 to 350 f.p.m. For debarking drum feeder belts, speeds are reduced to 125 f.p.m. or less.

Perhaps the belts which receive the most severe service are those which receive the logs from debarking drums and are used for sorting of debarking logs. For a newly designed installation it is recommended that an impact plate be built in front of the debarking drum so that the logs tumbling from the drums will land on the plate and thence bounce to the conveyor belt. Unfortunately, in a good many of the older installations there is insufficient room in front of the drums for such a plate.

Where no means can be provided for absorbing the impact, the belt must be designed to withstand the entire forces created by the falling logs. There are several designs of loading points for sorting belts. One of the most popular consists of loading on an open belt span. This consists of removing the idlers under the impact area and replacing idlers at each end of the impact area with rubber covered pulleys 12" or larger in diameter. When the logs hit the open span of belting the belt itself acts as a hammock and through its longitudinal and transverse resiliency absorbs the forces of impact.

Another design involves the use of a pad belt which is merely a short heavy belt running under the sorting belt over its own pulleys. The principle of loading will be the same as that described above as open span loading, or impact idlers can be used to support the pad belt.

A third design consists of supporting the belt on pneumatic tires. The pneumatic tire idlers consist of smaller tires toward the center of the belt and larger tires toward the edges all on the same shaft. The inflation in the tires provides a resilient cushion against which the belt is forced by the impact of the logs. It is necessary that the tires be supported on very heavy shafts.

The use of spring supported impact beds or belt take-ups using dashpots ot springs is not recommended. All of these have the disadvantage of high inertia due to the weight. With the spring loaded mechanisms the periodicity of the springs may easily cause higher impact on the belt than normally would be encountered.

Chipper feed belts present a few problems of their own depending upon the manner in which the chipper is fed. If the belt is started and stopped frequently to supply the logs to the chipper, sufficient strength must be incorporated in the belt to offset the starting stresses. If the chipper is fed by means of a gate and the belt is permitted to run and slide under the logs, there is a problem of providing adequate cover thickness and abrasion resistance.

Although each belt must be specifically designed for its application there are certain general features which can be covered. Balanced cord construction belt, using a relatively heavy top cover with bias laid transcord breakers, has been successful. This construction would incorporate two or more fabric plies having nylon filling to provide transverse strength. Two bias laid transcord breakers will provide superior gouging resistance in the cover and greater adhesion between cover and carcass.

The cord construction is more resistant to the loading shocks by virtue of the fact that the cords are floated in rubber and are displaceable without rupture. The cord construction can readily be designed to give the required operating longitudinal strength. Placement of cords above and below the fabric protect the fabric from shock impact transmitted downward from logs and upward from idlers.

Another important general application of belts in a pulp mill is for handling chips. Choice of belt for handling is dependent on the type of wood chips handled. Hard wood chips do not present unusual problems. The southern soft-wood or pine chips can be very detrimental to improperly chosen belts. Heat created in the chips tends to vaporize turpentines and resins in the wood and then causes these vapors to affect the rubber in the belts.

In order to obtain increased volumetric capacity on chip belts, concentrating idlers are frequently set at 45° This increased angle is not detrimental to a properly designed belt. With the advent of rayon fabrics, thin belts can be built with sufficient strength for handling the load.

As a word of caution, the usual maximum incline angle of 27° for chip-handling belts is applicable only when there is no possibility of frost forming on the belt. Occasions have occurred where the warm, damp chips have been taken from storage silos and loaded on a belt run through an unheated gallery. There seems to be no successful way to prevent cascading of the chips when the moisture forms frost on the belt surface. An angle of perhaps 15° should be the maximum considered where low gallery temperatures are likely to exist.

Handling pulp does not present any major problems unless there is contained in the pulp acids or alkalies of high concentration which could affect the belt. If pulp is at a high temperature, consideration should be given to selection of belting to resist that temperature. Take-ups on pulp belts should allow adequate movement for accommodation of the shrinking or stretching of the belt as caused by the action of the moisture and temperature on the belts.

Ordinary strip bark can be handled on low priced belting without difficulty. If the bark is shredded, consideration should be given as to whether or not deleterious resins or oils may be liberated. If so, an oil resistant type belt should be used.

## ULTRASONICS FOR EMULSIFYING, HOMOGENIZING AND BLENDING

F. Rose, *Canadian Chemical Processing*, v. 38, n. 6, June, 1954, pp. 36-38.

The past few years have seen great strides in the ultrasonics field and the long period of careful research has finally paid off with the perfection of a method to produce effective ultrasonic waves by purely mechanical means. This method has proved the most economical one so far developed to generate low frequency ultrasonics for emulsification, homogenization and blending, and the simplest one perfected for general industrial use. The economics of the ultra-vibration technique of producing emulsions or dispersions lie in the speed and the efficiency of this method, which has been shown to surpass anything achieved previously.

This ultrasonic method can produce particle sizes as small as one micron (one twenty-five thousandths inch), and emulsions made by this process will, therefore, be more stable than those produced by conventional means. It follows that stable emulsions or suspensions can be produced with less and, in some cases, without any emulsifying or stabilizing agents whatever, which is particularly useful where these agents are undesirable in the finished product.

In the latest type of mechanical frequency generator, the sound waves are produced purely mechanically by a blade which vibrates at its own frequency in the liquid stream of the medium passing over it after emerging out of a high velocity jet nozzle. The frequency in liquid is approximately 22 kilocycles per second. At these ultrasonic frequencies particles of the liquid medium are subjected to alternating compression causing pressure spots, a phenomenon known as cavitation. Collapsing of the cavities causes minor local explosions and violent molecular acceleration in the medium as it rushes over the blade maintaining it in continuous ultrasonic vibration.

Resultant pressures of high intensity up to 30,000 lbs. per square inch are released locally and complete the process of breaking down the particle size.

The production unit comprises a low hp. electric motor (as small as 2 hp. for up to 420 gallons per hour), a gear pump driven by the motor, suction and delivery pipes and, at the end of the delivery pipe, the cylindrical shaped ultrasonic head which contains the vibrating element.

The longer inlet pipe takes the liquid under suction up to the pump, which, in turn, forces it at high velocity and pressure through the outlet pipe into the ultrasonic head where the vibrations are generated.

The vibrating element, i.e. the ground edge blade and the jet nozzle are enclosed in a cylindrical housing, or resonant bell, especially shaped to concentrate and disperse the vibrations equally through the medium, and to ensure that the velocity of the jet across the blade is maintained regardless of whether the vibrating element is submerged, or above the level of the liquid in the vessel. The blade position is adjustable in relation to the jet, i.e. fine variations in the vibration frequency can be made according to the desired end product. A filter is used to prevent solid particles from entering the vibrating element and to ensure maximum efficiency of both jet and blade.

The ultrasonic equipment is suitable for use either in open vessels, or closed circuit systems under pressure. A typical example of the latter is the continuous emulsification of margarine. In this application the oil, water and stabilizing agents are mixed in the churns from where they are passed to the gear pump of the ultrasonic unit and then delivered at high pressure and velocity through two or more ultrasonic heads in parallel; depending on the output required. No recirculation is necessary, and in passing through the ultrasonic heads the mixture is emulsified and ready for straight continued passage into the cooling drums or votator. This set-up includes a trough in which the emulsion is kept at a constant level.

One of the first and most successful applications was the processing of salad dressing and mayonnaises. This led to other food products involving butterfat or dried milks dispersion such as cream soups, sauces, ice-cream mix, sugar syrups, soft drink essences, flavors and processed dairy products. Whole milk has not yet been perfectly homogenized by ultrasonics, but research continued and good progress is being made in the right direction.

Among many other successful applications are wax emulsions, spray insecticides, dyes, photographic emulsions, resin preparations, paper coatings, detergents and adhesives, showing the extreme versatility of the ultrasonic method of producing fine dispersions with the minimum of effort.

## To the Students from the President

It is my privilege, on behalf of the Council and membership of the Engineering Institute of Canada, to extend greetings to the undergraduates of the engineering faculties and colleges in Canada as they commence another term of studies and as they thus mark another year in their advance toward entrance into a great profession and a great fellowship.

No country in the world today is at quite such a dynamic and exciting stage in national building as is ours; and at no time in our history have we had so many interesting and constructive jobs for engineers to do. Older practising engineers will find themselves just a little envious when they consider the conditions under which you are likely to take on your first full-time engineering jobs.

Without exception the standards of instruction in the universities and degree granting colleges of Canada are exceedingly high and every engineering undergraduate will have the great good fortune of getting to know at least some of the outstanding engineers who comprise the teaching staff.

I know you would not expect an older person to miss such an opportunity as this to offer some advice and I shall not disappoint you on this score. But just two things: First, do not be too prone to treat some of the broader general subjects as unsuited to the needs of an engineer. Remember that more and more engineers are being drafted into managerial posts and the universities, being cognizant of this, have arranged their curricula accordingly. My second bit of advice would be that you do not delay too long in identifying yourself with The Engineering Institute of Canada. The closest possible affiliation with our fellow engineers from one end of this great country to the other will help us all immeasurably and the sooner we become a part of this association the greater the benefit not only to ourselves and our profession but to our country also. One final word, and though some of us may have peculiar ways of showing it, we recognize that the undergraduates in engineering are by much the most important group of young men in the country today.

Good luck to you, in all your endeavours.

D. M. Stephens, *President.*

## Something Different for November

The entire technical section of *The Engineering Journal* for November will be devoted to a series of papers—11 in all—dealing with the gigantic Kitimat, Kemano Nechako project of the Aluminum Company of Canada in British Columbia.

This has been made possible by the co-operation of the company. The selection of subjects and authors has been determined solely by the officers of the company, and the papers will be checked, approved and co-ordinated by the company. Thus it is that the November issue will contain in effect the full and official story of the project

It is only when specially significant projects, of importance to the economy of Canada and to engineers, are available, that an issue of the *Journal* is devoted exclusively to them. The Publications Committee believe that these developments which are really important segments of the story of Canada's growth, deserve such special attention from the profession. Not only is it important that the whole story be told at one time, but it is equally important that such documents be available to record for future technical reference and for posterity, the achievements of industry and the profession today.

Following is a list of the subjects which will be dealt with, and the authors. This shows how complete is the coverage and how wide the interest will be for all engineers, regardless of the branch in which they may have specialized. The papers will require from 90 to 100 pages.

Already it is apparent that some

## Cover Picture

The cover picture is a closeup of the "crossbar" telephone switching equipment being installed in the Toronto long distance centre of The Bell Telephone Company of Canada. These "crossbar" switches, vastly different from the "step-by-step" dial switches currently in use throughout most of Canada, are scheduled to go into service in Toronto in 1955.

They will bring one step closer the day when operators and eventually telephone callers themselves will be able to dial numbers in cities throughout North America on their own telephone dials. This dramatic photograph shows the vertical and horizontal bars which give the equipment its "crossbar" name.

The technical paper on page 1231 of this issue is a review of "Telecommunications in Canada".

members will want extra copies. A greatly increased number will be printed but to be sure that every member has a chance to get extra copies it is important that Headquarters be advised as soon as possible. Please keep this in mind and write immediately if you need more.

# Addition to Staff

Group Captain E. C. Luke, O.B.E., C.D., M.E.I.C., joined the staff of the Institute on September 1 in the post of assistant general secretary. This position was advertised in *The Engineering Journal* of January

**Group Captain E. C. Luke, O.B.E., C.D., M.E.I.C.**

this year, and he was one of the applicants.

Group Captain Luke was brought up in Montreal, and attended Westmount High School. He graduated from Royal Military College in 1924. From 1925 to 1928 he was a pilot in the R.C.A.F., but left the service to go into civilian engineering, first with the Northern Construction Company at Vancouver, and then over a period of nine years with B.C. Electric, P. G. E. Railway and Western Bridge Company. During this period he became a member of the Association of Professional Engineers of B.C.

In 1938 he returned to the Air Force as chief works officer in Vancouver. A year later he was moved to Headquarters at Ottawa as deputy director of works and buildings. In 1941 he was transferred again to the Western Air Command on a variety of duties including operations, personnel, organization, construction and administration.

1945 saw him at Central Air Command, Trenton, Ontario, with duties somewhat similar to those he performed at Western Air Command. In 1949 he was back again at R.C.A.F. Headquarters in Ottawa as chief logistics planner with a portion of his work being related to NATO. Later he became a member of the R.C.A.F. working party on the planning of the NATO air forces, which took him to both Washington and Paris.

From the latter part of 1951 to September 1954 he was director of construction, Allied Air Forces Central Europe with Headquarters at Fontainebleau, France. This work included military responsibility for the control and supervision of a program embracing 105 NATO airfields, costing about 700 million dollars. He retired from the Air Force and joined the staff of the Institute in September.

Mr. Luke is well known across Canada, and has had a variety of experience that should fit him excellently for his new post. Incidentally, he is bilingual, which also should be helpful to him in his new work.

With Mr. Luke becoming assistant general secretary, Colonel H. G. Thompson's title has become executive assistant general secretary.

# Digby Does It Again

Over the years, the bi-annual professional meeting held in the Maritimes by the Institute branches and the provincial associations has built up a fine reputation for itself. This time it was Nova Scotia's turn and of course the locale was the Digby Pines Hotel. As has been almost a standard custom for these meetings at Digby, everything went off without a hitch, to everyone's satisfaction, with even the weather on its best behavior. From the middle of a long period of bad weather, the committee plucked out three days that could not be beaten.

Two things are vital to the success of such a gathering, first the weather, and that has been dealt with, and then the attendance. The most important single element affecting the success of any meeting is the people who attend. They must be the right people and there must be enough of them. Both these requirements were met fully, to put it mildly. The hotel and cottages could not contain the 285 persons who registered. Fortunately not all registrants attended for all three days. Thus it was that over the period more people were accommodated in the hotel than would seem possible, although some had to register at other hostels in the town. The youngest registrant

beyond a doubt was Master Michael Bromley, 3 month old son of Mr. and Mrs. George Bromley of Wolfville. He was accompanied by his parents.

It is always a source of surprise to persons attending a maritime meeting for the first time to discover that it is not just a local meeting. This year again there were engineers in goodly numbers from Manitoba, Ontario, Quebec and the United States. To the newcomer it is surprising also to discover how many of the visitors from distant places are regular attendants. However once he has experienced a meeting himself he understands the great pulling power developed by this event. It was a very pleasant experience this year to greet again the many people who have become great friends through the medium of this meeting.

#### Edna Arrives Late

The much touted gale known technically as Edna hit the area, but not until Saturday. By then the festivities were over and most people were on their way home. Those who came across the Bay of Fundy in the afternoon, arrived at Saint John in much better condition than they had expected. Edna did not really get under way until Saturday night, but by Sunday morning she had made quite a showing. Delegates from "Upper Canada" were more than slightly inconvenienced by Edna on their way home. The Montreal train carrying several of them sat out the storm for six hours, and those who motored had a variety of experiences, but everyone reached their destinations eventually and in good order. Even Edna could not down the lustre of the occasion for anyone, but it is just as well she arrived late.

#### Council Meets

Wednesday afternoon was the occasion for a regional meeting of the Council of the Institute, with the president in the chair. While there is no official record to prove it, the attendance appeared to be a record with 41 present, representing 14 branches. Special guests were the president and director of the Ontario Association, Professor W. L. Sagar and T. M. Medland from Toronto.

#### New Publication

A feature not presented previously was *The Eager Beaver*, a newspaper which appeared under everyone's door early Thursday morning, printed on a grade of coated paper that made *The Engineering Journal* stock look like newsprint. Its masthead bore the motto "The facts if necessary but not necessarily the facts"—a basis of operation much envied by other editors.

The paper contained a lot of well written articles, all spoofing the profession in one way or another. One in particular was presented as an account of the council meeting. One subject reported to have been considered was a salary scale for wives, but this "was thrown out after heated debate."

The real feature of *The Eager Beaver* was "Where to Find Them," a list of persons attending the conference, with their local addresses. This took up two of the four sheets. At the top of the list there was this helpful note *The Eager Beaver* will be happy to rectify any errors or omissions in this list, and the editors should be advised at once so that suitable corrections can be made in our next issue—about September 1958."

Congratulations to *The Beaver*. It certainly fills a long felt want—too bad its publishing dates are so far apart.

#### Technical Program

The technical program was excellent, and if critical comment is permitted, this writer would like to say it was the best overall program ever presented for these meetings. Naturally under such circumstances, the attendance also was a new record. Every session had people standing at the side and at the back of the room.

On Thursday morning there were two papers—(1) Some Industrial Applications of Fluid Drive, by Antony Vickers, executive director of Fluid Drive Engineering Company Limited of Middlesex, England, and (2) Gas Turbine Power Plants by C. J. Burke of the Westinghouse Electric Corporation, Philadelphia. These authors knew their subjects well, and in addition knew how to present them. In both instances the subject was presented in such a way that everyone, regardless of his branch of engineering, could understand and enjoy them. This, it must be admitted, is not too easy to do.

On Friday morning the sessions were (1) St. Lawrence Waterways by L. E. Mitchell, special projects engineer, Canadian National Railways, Montreal, and (2) Atomic Power by Dr. John Convey, director Mines Branch, Department of Mines and Technical Surveys, Ottawa. It was Mr. Mitchell who had the difficult assignment. Anyone, even faintly familiar with the St. Lawrence situation will realize how many things there are about the project which have not been settled and of some that have been settled but in such a way as to puzzle even the casual observer. With all these pitfalls around, Mr. Mitchell did a job that landed him in no trouble at all.

Some persons stated that Dr. Convey's paper was the best of all, in that it made the subject seem reasonably simple, and gave information that satisfied, at least partially, the desire to know something about when such power will be available.

#### Lunches and Dinners

Thursday's luncheon was presided over by C. A. Knight, vice-president of the Newfoundland Association. There were three speakers —the Mayor of Digby who very nicely extended the proverbial freedom of the city, W. L. Sagar, president of the Ontario Association and of Dominion Council, followed by D. M. Stephens, president of the Engineering Institute. Frightening and all as a program of three speeches might be, it all worked out extremely well, and possibly proved that short speeches not only take less time, but contain in concentrated form as much good material as the standard length (if there is a standard length).

Thursday's dinner saw John E. Clarke, president of the Nova Scotia Association, in the chair, with Allan J. MacEachren, M.P. for Richmond-Inverness, as speaker. His subject was "The Pattern of Maritime Development."

After dinner terpsichore took over in the lounge, much to everyone's delight. The program suggested that the dance would discontinue at 11.30 p.m., but who cares about time at a maritime meeting! Certainly not the group assembled at Digby.

Friday's "eating-talking" events included a luncheon and a dinner (this time called a banquet). Luncheon was under the direction of J. K. Godfrey, manager, Truro Electric Commission, and the speaker was Leslie Roberts, the Canadian author. Mr. Roberts gave no title to his talk, but it might well have been called "the anecdotage."

The banquet was chaired by R. N. Fournier, general chairman of the committee responsible for the whole meeting. The speaker was O. L. Vardy, Director of Tourist Development in the province of Newfoundland.

#### Swing Your Partner

Again the evening was devoted to dancing, but this time the program said "square dance." Added colour in noticeable variety and strength suddenly burst on the scene as couple after couple returned from their rooms bedizened in allegedly western or rural garb. The wild nature of the colours and styles doubtless had its influence on the character of the party. There is no doubt but that a good time was had by all, even the spectators.

Here again the passing of time and the fading out of the orchestra had no effect on the party. Volunteers—and with considerable skill—laid the music on the line for what was really hours but seemed like minutes. The square dance was forgotten and in its place they substituted oval, elliptical, hexagonal, triangular and straight line patterns. It was a good party.

#### To the Committee

It is hardly necessary to say that the numerous committees were worthy of the thanks and con-

gratulations which they received. Everything was planned carefully and carried out expertly. The Maritimes have proven again that the greatest natural resource of the area is people who know how to do things and who are not afraid to do them.

## "More Power to You"

When over 2,000 people stand for almost an hour and a half in the pouring rain, without shelter of any kind, to participate in an official opening of any kind, it is indeed a tribute. That is precisely what happened at Niagara Falls on August 30, when the Ontario Hydro's Sir Adam Beck Generating Station No. 2 was officially and formally "put on the line".

Ordinarily a heavy rain lasting all day is regarded by hydro power men as perfect weather, but on August 30, that kind of weather was just what was not wanted. An open air ceremony under such conditions has to be experienced to be appreciated.

However, in spite of the downpour, the ceremony was carried out as planned. Following the speech of chairman Robert H. Saunders, which opened the program, the Duchess of Kent, after delivering an excellent address, pushed the button, and wheels began to turn. True, the wheels were only mounted on the backdrop of the platform setting, but they did revolve. Accompanied by the roar from the P.A. system of a 100,000 horsepower generator getting under way, the whole effect was excellent, and impressive. It was well staged.

**R. L. Hearn, M.E.I.C., is general manager and chief engineer of Ontario Hydro. Sir Adam Beck No. 2 has been his principal interest for several years.**

The Sir Adam Beck No. 2 Station is really something of note. Its usefulness to Ontario will be tremendous. The addition of 1,828,000 horsepower to the province's resources, will have a most stimulating effect on industry. The total horsepower now developed by Ontario Hydro amounts to the staggering figure of 4,800,000.

This particular power development has in it much of special interest to an engineer and in particular a Canadian engineer, for this was an all-Canadian project. The plant was designed by Canadians, built by Canadians (mostly), financed by Canadians, and the power is for Canadians. It is a great tribute to Canadians, and is further proof of the oft expressed thought that Canadians can do practically everything there is to be done in Canada. It should do something to shake the beliefs of those who seem to think that a thing or an idea to be good, must be imported.

Already *The Engineering Journal* has published articles on this notable project* and arrangements have been made for publishing shortly the final and complete story, but it may be of interest to note here and now some of the general facts associated with this gigantic undertaking.

Cost figures are considered as one of several means by which to gauge the importance of a project. Sir Adam No. 2 cost $343,742,000. This

*Canadian Hydro Electric Developments on the Niagara River, Dr. R. L. Hearn, M.E.I.C., *Engineering Journal*, August, 1954.

*One vice-president to be elected for two years.
†One councillor to be elected for two years.
‡One councillor to be elected for three years.
§Two councillors to be elected for three years each.

**Gordon Mitchell, M.E.I.C., was project manager on the Sir Adam Beck Generating Station No. 2. Its successful completion left him free to go into the St. Lawrence Power Project as director for Ontario Hydro.**

places it alongside or just ahead of some other great industrial undertakings recently completed in Canada.

Ontario Hydro history shows that this is the fourteenth development to go into service since 1945. During the past eight years the Commission has raised its dependable peak capacity by 84 per cent. All these developments have brought the assets of the Commission up to $1,491,000,000, a really impressive figure.

A special word of appreciation and congratulation must go to Hydro's engineers. According to chairman Saunders the Hydro now has an engineering department of over 900. This would seem to make it the largest in Canada. In addition there are many engineers not in the engineering department, but employed in administrative work, from the general manager down.

To each and everyone of these, *The Engineering Journal* offers its congratulations on this, their greatest achievement. Individually and as a team they are outstanding. The profession is justly proud of them, and with them looks ahead to more and more achievements in the future.

# St. Lawrence Power and Seaway Project

## Inaugural Ceremonies

The official commencement of the long-awaited St. Lawrence River Power and Seaway Project marked the initiation of an undertaking which is likely to have far-reaching effects on the economy of both Canada and the United States for many decades to come.

Appropriately, the occasion took the form of "ground-breaking" ceremonies in the international section on both sides of the river near Cornwall, Ontario, and Massena, New York. On August 10, 1954, Governor Thomas E. Dewey of the State of New York pressed a button shortly after 11.00 a.m. to set off a charge of dynamite at the edge of Barnhart Island. He was assisted by Chairman Robert Moses of the New York State Power Authority and a large delegation from Canada was present along with many others from United States points.

Approximately one and one half hours later, the official party had moved to the Ontario Hydro Transformer Station some three miles west of Cornwall on Highway No. 2 for the Canadian ceremony. This is to be the location of the Ontario Hydro's new power plant and three sods of earth were turned to mark the occasion. Prime Minister Louis St. Laurent, Premier Leslie M. Frost of Ontario and Governor Dewey each participated in turn. Assisting at the ceremony were the Right Honourable C. D. Howe, Hon. M.E.I.C., Minister of Trade and Commerce and Minister of Defence Production; the Honourable Lionel Chevrier, president of the St. Lawrence Seaway Authority; General the Honourable A. G. L. McNaughton, M.E.I.C., chairman of the Canadian Section of the International Joint Commission; Mr. Moses; Lloyd Davis, chairman of the St. Lawrence Committee; Robert H. Saunders, chairman of the Hydro-Electric Power Commission of Ontario; the Honourable George H. Challies and W. Ross Strike, first and second vice-chairman respectively of the H.E.P.C.

During the course of the ceremonies, various speakers spoke at length in emphasizing the persistent efforts and close co-operation on the part of those individuals and governments in both the United States and Canada which had been necessary to bring about the actual commencement of this great international development.

Repeated mention was made of the long years which had passed since the project was first conceived. Some made reference to the forty years gone by since Ontario Hydro first began to study and survey the hydro-electric power potential of the St. Lawrence River between Prescott and Cornwall in 1913. Others spoke in terms of the thirty year period since the first report was submitted by Ontario Hydro to the International Joint Commission. Members of the Engineering Institute will be sorry to know that at no time was any reference made to the preachings and prophecies of that great engineer and philosopher, Thomas Coltrin Keefer, first president of The Engineering Institute of Canada who more than a hundred years ago visualized the St. Lawrence River as the highway which would carry the commerce of the world to the farthest ports of the Great Lakes, a thousand miles and more from the sea.

# The President Visits the Branches

For the first time in over twenty years, it is not planned this year that the president shall visit all the branches. With the number of branches now reaching forty-seven and with seven branch sections as well, the task has become practically impossible. For some time Council has recognized this situation, but it is only this year that the revised program has been agreed upon.

The idea is that the branches not visited one year will be included in the itinerary of the president for the following year. The pattern cannot be fixed too rigidly but it is evident to everyone that a scheme of this kind is necessary if the Institute is to continue to have at its head, leading representatives of industry, education and the profession.

President Stephens will do all his visiting over four short periods, none of them requiring him to be away from Winnipeg for more than two weeks at a time. Already one of the jaunts is over. Accompanied by Mrs. Stephens he attended the Maritime meeting at Digby. On the way there he visited Fredericton and on the way back he stopped at Moncton and Sherbrooke.

His next journey will be to the ASME-EIC conference at Potsdam, N.Y. on October 6, 7 and 8. He visits the Ottawa Branch on the

4th and the Brockville Branch on the 5th. The latter meeting will be a regional function shared in by the Kingston and Cornwall Branches. All these events are ahead as this is being written but they will be over before it is read.

In November he does the western areas. The branches visited will be at Winnipeg, Saskatoon, Edmonton, Lethbridge, Trail and Vancouver.

In February he does the balance of Ontario. The branches included in his itinerary are Belleville (including Port Hope and Peterborough), Toronto (including Huronia), Hamilton (including Niagara Falls and Kitchener). A meeting for members in Sarnia, Windsor, London and surrounding areas will be held in Chatham. This centre has been agreed upon because it is within reasonable distance of each branch.

To make this new plan effective it is necessary to have the support of the members. It is important that members of nearby branches attend the meeting when the president is in their neighbourhood. Only in this way can the new arrangement be satisfactory, both to the president and the Institute.

A feature of the president's visit this year will be a discussion with branch executives on the important subject of confederation. Council has asked the president to talk this over with the branches, and to gather together the opinions and the ideas of the members as he visits with them. Only in this way can Council and the committee be kept informed of the members' wishes.

---

# Minutes of The E.I.C. Student Conference

## Chateau Frontenac, Quebec, May 11th, 1954

### Part 1 — General

Chairman: Mr. D. C. MacCallum, the chairman, opened the meeting at 9.30 a.m.

### 1. Roll Call

The following members of the Institute, delegates and observers were present:

Carl R. Johnson, University of British Columbia; James Tod, University of Alberta; Baine A. Holmlund, University of Saskatchewan; M. P. Schioler, University of Manitoba; Grant E. Sims, University of Manitoba; J. N. Rossall, University of Toronto; W. C. Moffatt, Royal Military College; J. D. Fowler, Queen's University; R. L. Wright, McGill University; Pierre DeGuise, Ecole Polytechnique; Claude Pouliot, Laval University; Eric C. MacNearney, Nova Scotia Technical College; C. C. Atkinson, University of New Brunswick; D. C. MacCallum, chairman; Col. T. F. Grant, field secretary; R. F. Shaw, J. B. Stirling, D. M. Stephens and R. L. Dobbin, senior counsellors.

### 2. Welcome from Institute Officers

The delegates were warmly welcomed by the new chairman of the Student Conference, D. C. MacCallum, and the outgoing chairman, R. F. Shaw.

### 3. Appointment of Secretary of Conference

The delegate from the University of B.C., C. R. Johnson, was appointed secretary for the Conference.

### 4. Appointment of Resolutions Committee

Resolutions Committee members appointed were: Claude Pouliot, Grant E. Sims, Eric C. MacNearney, J. N. Rossall.

### 5. Report on 1953 Resolutions

(a) 1953 resolution of one conference delegate acting as liaison officer for one year, for the E.I.C student section and the various engineering undergraduate societies, with regard to student news in the *Journal*—it had failed.

(b) 1953 resolution of desire to have exchange of information between universities (e.g. financial structures, activities, etc). It was done, but not too well supported.

#### Discussion on (a) and (b)

(i) C. Pouliot suggested that all information be sent to the General Secretary for publication in the *Journal*.

(ii) Colonel Grant agreed; and suggested cutting out articles and editing bits for the *Journal*.

(iii) A discussion followed.

(iv) Result: made same resolution.

(v) Delegates E. C. MacNearney and J. N. Rossall arrived.

(vi) Further discussion arose regarding the type of information to be sent out to each university by each of the other universities. Manitoba stressed their need for information on social functions. Jim Tod, Alberta, suggested that each delegate appoint a man in his respective organization to be responsible for sending any information.

Result was to form the same resolution.

(c) 1953 resolution regarding Unemployment Insurance.

(i) R. Wright reported that they could collect if the Unemployment Insurance Commission could not find work of an engineering nature after 5.00 p.m.

Regarding 1953 tax exemption resolution:

(ii) Pierre DeGuise suggested a $1,500 exemption.

(iii) Colonel Grant suggested it be an exemption on fees.

(iv) J. Rossall further suggested that the student be classed as a dependent regardless of age.

(v) Colonel Grant: exemption to include fees, instruments, books for all faculties.

(vi) Various methods of advertising the proposal followed, such as: students writing to their respective Members of Parliament, getting E.I.C. to write respective administrations of universities.

A new resolution was to be sought.

(vii) Arrival of Mr. Demers and Mr. Stirling.

(viii) Discussion with Mr. Demers regarding employment:

1. A decision between doing post-grad work vs. going into business was a personal one he stated.
2. Similarly with regard to consulting vs. research.
3. He stated: experience is best gained when you work a while outside your field.
4. How to become a consultant (personal decision). Few years in—
   (a) Public affairs,
   (b) Research,
   (c) Design.
5. Parting words for the new consultant: work without a final contract but be sure of your job.

(ix) Discussion with Mr. Stirling:

1. Canada — a good place to work.
2. Do all types of jobs in a plant (usually decided by the boss and is a rotation scheme).

**Part 2 — Employment Conditions**

1. Colonel Grant:
   (a) Employment good for grads; high starting salary but not a great increase in salary.
   (b) He emphasized the fault of students not punctually or even ever acknowledging an offer from a company. (It reflects poorly on all students as well as on the university.)
2. J. Rossall quoted similar breach of contracts by the employers. This astonished the senior members. Similar situations were voiced by Queen's and Manitoba.
3. Western universities voiced the poor job possibilities in their provinces (in certain fields).
4. Mr. R. Griffith (Federal Civil Service) gave a talk.
   (a) They cannot find enough engineers.
   (b) They are the biggest employer of engineers.
   (c) He commented on positions in the Patent Office.
   (d) Salaries were $300 a month for grads.
   (e) Conditions with them are to improve.

**Part 3 — The Institute and the University**

1. Note to the Resolutions Committee to publish our minutes.
2. Purpose of the Institute.
   (a) Exchange of engineering knowledge and the advantages of personal contacts.
3. Mr. Shaw spoke on relation between the E.I.C. and the Association.
   (a) E.I.C.: promotion of education, prestige in community.
   (b) Association: professional; it overlaps in the field of welfare with E.I.C.
   (c) The two are not competitive.
4. Colonel Grant:
   (a) E.I.C. is to fill in the gaps in education which are left in college, i.e., the social, philosophic, humanitarian, etc. "Make an engineer a man of parts."
5. Mr. Shaw — on counselling:
   (a) Concentrate on High Schools.
   (b) E.I.C. has had a committee working for two years on this problem.
   (c) Pamphlet "After High School Now What" distributed to American and Canadian Universities.
   (d) National Film Board has a film available — "Careers in Engineering Professions."
6. G. Sims — desired to have a published list of industrial men willing to give counsel.
7. General feeling among the seniors was to use the graduates more with regard to counselling.
8. G. Sims — expressed poor publicity of E.I.C. scholarships.
9. Colonel Grant: "Engineering is a creative profession and is not just Canadian."
10. C. Pouliot: desired French articles in the *Journal* as a worthy gesture. Everyone agreed and sincerely applauded his speech about the French in Quebec being as much Canadian as the people of other provinces.
11. Note to resolutions committee regarding French articles came from Colonel Grant.
12. Mr. MacCallum interrupted to ask that our enthusiasm be retained until fall and that we publish a personal report in our faculty paper.
13. Mr. Buchanan was introduced and he reminded us of the existence of the Harry Bennet Educational Fund.
14. Nominations for student chairman were called for. C. Pouliot and G. Sims were nominated — C. Pouliot won — applause.
15. R. Wright moved that the Resolutions Committee be responsible for further resolutions, seconded by M. Schioler.
16. Resolutions Committee to meet at 9.30 a.m. Wednesday, May 12th, Salon 2.
17. R. Wright moved a vote of thanks to C. Pouliot, all seconded it with applause.
18. A vote of sincere thanks and deep appreciation was made by E. MacNearney to the E.I.C., which was seconded by J. Rossall — the ensuing applause adjourned the meeting.

C. R. Johnson,
Secretary 1954.

**Resolutions made and passed by the Student Delegates to the 1954 Conference in Quebec, Que.**

1. RESOLVED that this Conference request E.I.C. headquarters to appoint a co-ordinator who will contact local branches to make available to the Undergraduate Engineering Students a suitable counsellor through a local liaison.
2. RESOLVED that each delegate of this Conference be responsible for the mailing of any student publications (such as: handbooks, newspapers, financial statements, constitutions, etc.) to each undergraduate society. n.b. a report on social activities.
3. RESOLVED that immediate steps be taken to have university student fees made deductible from taxable income and that the following actions be taken:
   (a) The E.I.C. be requested to approach the proper authorities to endeavour to carry out the foregoing aims.
   (b) The E.I.C. be requested to obtain the support and assistance of the university administrative bodies.
   (c) The delegates of the Conference approach the student government at their respective universities for support.
   (d) The delegates of this Conference initiate a letter writing campaign on their campus to their Members of Parliament.
4. RESOLVED that the E.I.C. be requested to continue distributing one free copy of the *Journal* to all students in one undergraduate year; and in order to stimulate interest in the Institute, the Conference recommends that this issue:
   (a) Contain a summary of the minutes and resolutions of this Student Conference, and any other material of student interest such as the counselling service and loan fund and scholarships.
   (b) Contain a letter from the President of the E.I.C. to the students.
   (c) Be distributed by the first of November so that the membership campaign can be conducted before the pressure of studies becomes too great.
5. RESOLVED that in order to create a better understanding between Canadian cultures, the Conference recommends to the E.I.C. that more French language papers be published in the *Journal.*

# Recognition from the Press

The following quotation is from the lead editorial in the *Globe and Mail* of August 31. Not often have Canadian newspapers so clearly and emphatically patted Canadian engineers on the back. The paper's recognition of the achievements of Canadians is very gratifying, and engineers across the Dominion will be grateful for it.

**Engineering Triumph**

The formal opening by the Duchess of Kent of the giant Sir

Adam Beck Generating Station heralds the approaching completion of one of the greatest engineering works ever constructed in Canada. Superlatives are themselves inadequate to describe the scale of the project. Although the actual amount of electricity to be generated has been matched elsewhere, nothing so large has been built by the Hydro-Electric Power Commission of Ontario. In many respects, as an engineering feat, the project outstrips even the St. Lawrence power development.

The most gratifying aspect of this great achievement is that the planning has been the work of Canadian engineers. Beyond question, from now on Canadian professional competence in this field will be recognized as equal to the best anywhere and henceforth any similar work through the world will pay its tribute through the flattery of imitation. Some astonishingly ingenious inventions and discoveries have been worked out by these engineers in mastering the problems which the project presented. The nation is proud to commend them.

# Correspondence

**Report from Pakistan**

Dear Mr. Editor:

I am sorry that I have not written to the Institute Headquarters before this date to send along my annual subscription.

Since mid-December I have been back to London, England, from a Food and Agricultural Organization assignment in Ceylon; now I have taken on a two year contract with the Department of Trade and Commerce under Colombo Plan to act as field service engineer with the Department of Agriculture of the Government of Sind. My location will be in the Hyderabad, Sind, area where summer temperatures go as high as 120 degrees.

**British Machinery**

While I was in Britain waiting for the Department to produce the contract I managed to spend some time at my own expense visiting factories, agricultural machinery testing stations, and meetings of the Institutions of British Agricultural Engineers. The day's visit to the Ford Co. plant at Dagenham to see the New Fordson Major tractors and Consul and Zephyr cars being built was an eye-opener. I had a quick look through the Oshawa G.M. plant in 1936, so it was not my first visit to an automobile plant. I was very interested in the "runing-in" process for the Diesel, petrol and vaporizing oil engines before they are installed in the frames, as we had had trouble in Ceylon with a large batch of another make of tractor which had developed cylinder head gasket trouble at about 190 hours on about every third machine.

Then there was the visit to the Harry Ferguson organization at Coventry (which is now part of the Massey-Harris-Ferguson Co.); I saw the famous Stoneleigh Abbey Training School for tractor operators and instructors, and the Banner Lane factory of Standard Motor Co., which can turn out up to 350 tractors a day. Though British factory management has been criticized in the past for having less installed horsepower per worker as compared to Canadian and American factories, I think that that discrepancy is being overcome.

I went on up to see the Massey-Harris factory which is being enlarged on a trading estate site outside of Kilmarnock. The tractor production there consists of less direct manufacturing and more assembling of purchased parts.

Another up-and-coming company is the Rotary Hoe organization of Horndon, Essex. They are selling their products very admirably in the American market. Their new and extra factory at Basildon, nearby, will be as modern as any I have seen in Canada. Though there is less mass-production than in Canadian or American factories, it must be realized that for every article or farm machine that can be produced in the 1,000s, there are many very essential machines that are only needed in the 100s or 50s each year. That is where such small companies like Rotary Hoes take over where the mighty Ford organization fears to tread. It is better to market a semicustom-built machine that a few farmers need and will willingly pay for than a multipurpose machine that gets cluttered up with gadgets and extras for every particular job.

**Government Research**

The most intriguing place to visit was the National Institute of Agricultural Engineering, Silsoe, Beds., between Luton and Bedford; it is the government sponsored testing and research station, and it has an excellent library, tractor-testing facilities and laboratories. The hydraulic-propulsion agricultural tractor, was being readied for its field trials when the cold weather abated. This machine, with its simple single control, which controls the travel forward and reverse direction, may be the most significant advance in tractor design since an internal combustion engine was coupled to a standard gear transmission and differential many years ago.

Though mechanization of agriculture started in Britain after it started in America and Canada, it has made great strides since the war, and the future looks good with such an institute as this to lead in fundamental and even practical research. I visited its sister institution in Scotland, the Scottish Machinery Testing Station, at Mid Calder, near Edinburgh. There is nothing to compare with Silsoe in Canada or the U.S.A., for the American visitors who have seen the Beltsville, Md., installations of the U.S.D.A. have made that comment. It is even proposed to branch out to study the machinery and equipment requirements in tropical and arid areas, so that British manufacturers can use the information and expand their sales into colonial and foreign markets. Small manufacturers use the Institute for secret tests if they cannot employ their own staff.

**How Canada is Affected**

As I had to make up tool and equipment purchasing lists on two occasions in Ceylon, and am assisting American advisers to compile a tool and equipment list for a workshop here, I have studied the problem of marketing and selling machinery in this country, and especially how Canada is affected.

First of all, more cotton, jute, hides, and furs (karakul and "persian lamb" types) will have to be purchased by Canadian manufacturers before other companies can export back here. In my line of work there is a large demand for heavy crawler tractors, but only Britain, the U.S.A. and Italy are the manufacturing countries. A really more important item is Diesel engine fuel injection test equipment and electrical automotive testing equipment, but there again Britain and the U.S.A. are the only manufacturers. A great deal of money has been spent on large North American cars but the garages are poorly equipped and managed. Automotive equipment will be the main way of opening up large areas of this country as we all know that railroad costs of construction are very prohibitive. Diesel buses have exhaust fumes like coal burners!

**No Tear Shed on Engineer Shortage**

I have noticed that once again the Institute is making press releases to the extent that Canada is not training enough young engineers. For Canada's future the prospects of a shortage of engineers may be an urgent problem, but I cannot shed a tear for those companies who cannot get enough young men; my problem has been that, even if you have studied at the nation's expense under D.V.A., and have served in the Armed Forces for five years, if you have reached the age of forty you are not wanted. Massey-Harris in 1948 when I was 35 said I was too old, and I.H.C. of Hamilton said the same in 1952. That is why I am overseas trying to get experience which will cause some company to ask me to join them; perhaps that will eliminate the snobbish attitude that I have noticed in most personnel employment offices.

**Specialization a Drawback**

I have often regretted that I took the specialized option of Agricultural Engineering; though the course consists of basic Mechanical and Civil Engineering, many prospective employers seem to swallow hard on the word "agricultural" irrespective of whether I tell them that I attended a College of Engineering or not. Perhaps it would be better to advise all these hordes of young fellows who will flood the engineering colleges that they should take one of the major branches, such as Mechanical, Civil, Electrical or Mining, and forget about such offshoots as Agricultural, Aeronautical, Engineering Physics, or Petroleum Engineering. Then they will be able to change companies in future years without too much trouble. Around the University of Saskatchewan in the 1945-49 period many young fellows direct from country high schools came to Saskatoon and wanted to be chemical engineers, or engineering physicists. They could not keep up the high standard required and eventually ended up as just plain civil or mechanical engineers.

**Needless Export of Experts**

Out here there are about five times as many law college students as engineering students. I met one engineer working for the Sind Public Works Dept. who wanted to travel to Canada to study for his doctorate in engineering. I advised him to travel to Canada, either under government or private sponsorship, and work for a construction company or architect for two or three years, and then return to Pakistan to form his own company, as I know he has money. In that way he could demonstrate new ways of building houses, government buildings or roads and still make a good living. Why should technical experts come to Pakistan to train people, when engineers from here want to settle in Canada!

Hugh A. Templeton, jr.e.i.c.
Karachi, Pakistan

# Utilization of Engineering Manpower

An interesting report recently appeared about a week-long conference on the development and utilization of the services of three types of professional workers in the United States—engineers, medical personnel and the teaching profession. The conference, convened by the National Manpower Council, was held in October of 1953 on the Harriman Campus of Columbia University.

The sessions, held in three panels, were designed to focus attention upon manpower problems and practices in the fields to be covered, specifically with a view to evolving any helpful suggestions for the future. The meeting proceeded from acceptance of the point of view that to some extent there are present shortages of engineering, medical and teaching personnel in the country; but developing shortages, given a continuance of present trends, threaten an eventual problem of considerable magnitude unless timely measures are taken to obviate such a situation.

The stage was set for the engineering working group discussion by posing five questions basic to a fresh study of the future demand for engineers. These were: (1) has the ratio of workers to engineers stopped declining since 1950; (2) has there been a marked increase in trained technicians; (3) will new defence plants need fewer engineers; (4) will declining Federal research costs release more engineers and scientists and (5) what is the outlook for industry?

The report of the engineering working group cited twelve points on utilization to which the engineers agreed. The full Conference reaffirmed the importance of two themes of this report. One is that better utilization requires a consideration of the whole man or woman, off the job as well as on. The second is the need of cooperation between the engineering profession and the education world to provide that exchange of men and knowledge which is needed by both the universities and industry.

The Proceedings, published by the Columbia University Press, report the three phases of the Conference. The discussions centered around conditions in the United States, but are not without significance when applied to conditions in Canada.

# *Thirty-five Years Ago*

Comment on the *JOURNAL* of October 1919

The fifth general professional meeting of the Institute was held in Saint John, N.B., on September 10, 11 and 12, 1919. The *Journal* for the following October is naturally almost entirely devoted to accounts of what went on at this meeting and to the publication of some of the papers presented there.

Registration was 106, all, with few exceptions, from the Maritime Provinces. This figure included members and guests, of whom three or four came from across the line in Maine and one from as far away as Boston. We notice the name of one member from Windsor, Ont.; he seems to have travelled the farthest. The Institute had not as yet developed a thoroughly national character; its members were still inclined to think in terms of their own immediate environments.

Not much Institute business was transacted at this meeting; it was given over to papers and to limited social functions. The Institute's committee to investigate the action of sea water on concrete reported, regretting that it had not been able to accomplish much on account of the short time since its appointment and that "no replies or expressions of opinion" had been received from queries it had addressed "to various engineers stationed in Nova Scotia." It had therefore drawn up a "report based on the experience and opinions of its members." The general conclusion, qualified in some particulars, was "that the chemical action of sea water on mass concrete . . . is not serious in itself . . . (but) the belief that a reinforced concrete marine structure will require little or no maintenance does not . . . appear to be fully warranted . . ."

The social side was not entirely neglected at this meeting in Saint John. "Muriel" and her "room" had not then appeared, of course, so there was little to tempt members to stay away from the presentation of papers. The ladies were completely ignored; for all one can gather to the contrary, the meeting was a congress of bachelors.

The Saint John Board of Trade lent its rooms for the meeting and entertained those present at luncheon one day. Another luncheon was tendered visiting members by the Saint John Branch. A visit was paid to the Courtenay Bay harbour works, then under construction. The contractors, the Bedford Construction Co., Ltd., provided lunch: "In a dining hall especially constructed for the occasion, surrounded by evergreens and having at one end a beautifully arranged design in sweet peas bearing the letters 'E.I.C.', about one hundred men sat down to a well appointed banquet which would have done credit to the chef of a modern hotel."

#### Council Supports Legislation

At its meeting of September 23, 1919, Council resolved "that the Council will further in every way the desire of the members regarding legislation, and inasmuch as the actual application of such legislation is in the hands of the engineers in each province, it is desirable that the branches and provincial divisions in co-operation with other engineering organizations in each province, take the initiative . . . in which they are assured of the moral support of the Institute." The Saint John Branch did not wait for this go-ahead signal. It had sponsored a meeting on September 12 of all engineers in New Brunswick to form an association of professional engineers, to present the model act with slight modification to the provincial legislature and to ask for its enactment, and to locate the headquarters of the organization in Saint John. The Halifax Branch was also becoming active in much the same way. These were the first concrete results of the long period of study and discussion of legislation for engineers initiated and carried out by the Institute.

It was reported that the Civil Service bill, which would improve the working conditions of engineers in the federal government, had been so thoroughly criticised that its classifications were being "fifty per cent" rewritten. Council's advice to some impatient members was "to refrain from expressing any personal dissatisfaction . . . in order that the bill may be passed and that their individual cases can be considered by the machinery provided."

Halifax was the only branch reporting in this issue and most of its report was given over to the remarks of its chairman on the occasion of the then recent visit of H.R.H. the Prince of Wales to the Studley Quoit Club. Who says that engineers are without civic consciousness or social graces?

Seeing that the matter of legislation had been disposed of for the time being by the resolution already quoted, and that progress was being made with the Civil Service reclassification, Council found little of much importance on the agenda of its two meetings in September, 1919. It was noted "with pleasure" that the Canadian National Railways had adopted the Institute's standard specifications for portland cement. It voted to present a gold Institute badge, "engraved for presentation" to each honorary member. It appointed Brig.-Gen. Sir Alexander Bertram as treasurer of the Institute; the October *Journal* carried his portrait and an announcement of his appointment. A rumour that "road work" in British Columbia was to be undertaken by a "prominent politician" without engineering help was also noted, but nothing was done because "no direct word had yet been received from either of the branches in British Columbia" regarding the matter.

#### Technical Papers

The nine papers which appeared in this *Journal* were all presented at the Saint John meeting just past. They dealt with a variety of subjects; the day of the planned program limited to various aspects of one or two topics had not yet arrived. The stabilization of beaches and dunes by planting grass, forestry in New Brunswick, the water powers of the same province, a tidal power development scheme on the Petitcodiac and Memramcook rivers, the new Bear River bridge of the Dominion Atlantic Ry., high-frequency apparatus, telephone cables and the problems of Canadian military engineers in France all came in for attention.

Most of these papers are of little interest today. "Usefulness of Vegetation in Maritime Engineering" was an exception. Though E. T. P. Shewen, its author, was brief, what he said is still useful. "The Water Powers of New Brunswick" was really an informal report of what had been accomplished by the province's power commission in the first year of its life. The author, C. O. Foss, M.E.I.C., was chairman of the commission. R. F. Armstrong's paper on the work of our military engineers in France was most readable, made so by homely touches: "The Germans had large dumps of . . . bridging timbers and with these . . . many bridges were constructed, the Canadian sapper being very much in his element with a cross-cut saw, squared timber and spikes, a welcome change from . . . pick and shovel work."

Looking through the news items and the personals, we note that the Nova Scotia Water Power Commission had just been organized, with K. H. Smith, A.M.E.I.C., as chief engineer and acting secretary, that the Canadian Engineering Standards Association "is beginning to exercise the influence . . . (that it was) hoped it would", by appointing new committees. Mr. C. LeMaistre, secretary of the British Engineering Standards Association, was then on a visit to Canada and asked for the C.E.S.A.'s co-operation in "obtaining some degree of Anglo-American agreement as to screw thread standards." He got the co-operation, but it took another world war to get any agreement on standards.

The war had raised hob with the Institute's membership rolls, so the *Journal* published two pages of names of "lost" members. All of us would recognize among them the names of some who have since become prominent in one way or another; the writer found twenty-odd without half trying.

We also find that Dr. F. D. Adams was acting as principal of McGill University until Sir Eric Geddes could take over the post. Actually, he never did, as he was appointed British Ambassador to Washington and never returned to

Canada. Portraits of R. S. L. Wilson, later dean of the engineering faculty at the University of Alberta, and of S. J. Hungerford, later president of the Canadian National Railways, appeared.

The few employment notices followed the usual line. Quite inadequate salaries by any standard were being offered, e.g., $3,000 for an electrical engineer with long executive experience and $1,040 for a junior mechanical draughtsman.

"And so to bed."

## Elections and Transfers

At the meeting of Council held at The Pines, Digby, N.S., on Wednesday, September 8, 1954, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

*Members*

G. J. W. Baker, *Vancouver*
P. A. Benn, *Montreal*
C. G. Campbell, *Calgary*
J. A. Chalmers, *Ottawa*
G. E. Crippen, *Vancouver*
E. H. Dithridge, *Port Hope*
E. F. Foord, *Montreal*
D. Fulton, *Montreal*
W. G. Huber, *Vancouver*
H. R. Jorgensen, *Winnipeg*
P. Kubilius, *Montreal*
R. R. Lloyd, *Montreal*
A. M. H. Norris, *Windsor, N.S.*
J. H. Redding, *Norfolk, Eng.*
A. B. Whelan, *Montreal*
C. A. Wright, *Montreal*

*Juniors*

J. H. Allen, *Montreal*
V. G. Barnden, *Montreal*
L. C. Cossette, *Montreal*
F. W. Orlando, *Montreal*
S. F. Smith, *Valleyfield*
H. S. Watson, *Montreal*
J. A. Waugh, *Amherst, N.S.*

*Transferred from the class of Junior to that of Member*

K. Barlow, *Vancouver*
A. Blauer, *Montreal*
D. F. Coates, *Montreal*
D. G. Dunbar, *Vancouver*
R. W. McKnight, *Winnipeg*
G. F. McLean, *Montreal*
W. E. Mulholland, *Windsor*

*Transferred from the class of Student to that of Junior*

M. Lacroix, *Quebec*

*The following Students were admitted*

W. W. Brown, *Hamilton, B.Sc., Queen's 1954*
R. M. Francis, *Montreal, Student C.P.E.Q.*
J. D. Koppernoes, *Halifax, N.S.T.C.*
J. L. Lemay, *Three Rivers, B.Eng., N.S.T.C., 1954*
H. O'Beirne, *Toronto, B.A. Cambridge 1953*
B. S. Sheehan, *Halifax, St. Mary's University*
F. B. Stankiewicz, *Sarnia, Student Ontario Assn.*
W. S. Zawadzinski, *Toronto, B.Sc., Eng., Polish Univ. Coll. 1954*

**Applications through Associations:**

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

*Juniors*

B. M. Dafoe
H. M. MacKay
J. M. Willsher

*Junior to Member*

J. C. D. Mallet-Paret

*Student to Junior*

D. A. Carlson

## News of Other Societies

**University of Toronto Engineering Alumni** are meeting on October 29-31, in Toronto for the 1954 triennial reunion.

"Highways for Tomorrow" will be the theme of the 1954 convention of the **Canadian Good Roads Association** (270 Maclaren Street, Ottawa) at the Royal York Hotel, Toronto, November 8-10.

The program will include again the "Roads Round-up", at which federal, provincial and municipal highway ministers and engineers report on the progress of road building and maintenance; and a general session on "Factors in Long-Range Planning".

The annual meeting of the **American Institute of Chemical Engineers** (120 East 41st Street, New York City 17, N.Y.) will be in New York City, at the Statler Hotel, December 12-15, 1954.

The 21st national exposition of power and mechanical engineering will take place at the Commercial Museum in Philadelphia, December 2-7, under the auspices of the **American Society of Mechanical Engineers.**

For this technical and professional show admission is by invitation and registration. The International Exposition Company (480 Lexington Ave., New York, 17, N.Y.) is managing the Power Show.

The 62nd annual meeting of the **Society of Naval Architects and Marine Engineers** (74 Trinity Place, New York 6, N.Y.) will be held at the Waldorf-Astoria Hotel, New York City, on November 12 and 13, 1954.

**The Society of the Plastics Industry Inc.** (67 West 44th Street, New York 36, N.Y.) will hold the thirteenth SPI Canadian conference on February 22-23, at the Hotel London, London, Ontario.

Norman L. Mochel, manager, metallurgical engineering, Westinghouse Electric Corporation, Philadelphia, is the president of the **American Society for Testing Materials** for the year 1954-55.

Duncan M. Jones, Eastern Canada representative of Curtis Lighting of Canada Limited, Montreal, recently was elected president of the **Illuminating Engineering Society.**

At the recent annual meeting of the **Canadian Management Council,** A. M. Mackenzie, M.E.-I.C., vice-president of the Bell Telephone Company, was elected president. The vice-president is C. T. MacKenzie, of the Treasury Department of T. Eaton Company; J. A. Coote, M.E.I.C., chairman of the Institute of Administration is secretary and P. W. Wright, of Shawinigan Chemicals Limited, is treasurer.

Assisting these officers in the work of the Council there will be C. A. Peachey, M.E.I.C., past-president, and the following directors: J. G. Campbell, S. M. Gossage, Bruce A. C. Hills, M.E.I.C., E. B. Jubien, M.E.I.C., F. R. Manuel, M.E.I.C., and John Walters.

# NEWS OF THE ASSOCIATIONS & CORPORATION

Information received through co-operation with the provincial organizations

## Quebec

### Results of Salary Surveys for Graduating Engineers

The annual Salary Survey of the 1954 graduating classes in engineering at McGill and Ecole Polytechnique revealed that initial salaries in the spring of this year were still on the upgrade.

The median salary for 1954 graduates was $310. per month at both universities, and the average salary was $314. per month at McGill and $316. per month at Polytechnique.

The highest average salaries were paid to metallurgical and mining graduates, with chemical, civil, mechanical and electrical following in that order.

The comparable figures from the 1953 survey, which were published in the November 1953 issue of the Bulletin, were $300. per month for the median salary and $301. per month and $307. per month for the average salary.

Of considerable interest is the fact that placement salaries for new engineering graduates released by the National Employment Service, technical division, gave an average of $314. per month.

### Quebec Now Has Five Universities

The Corporation of Professional Engineers of Quebec is very happy to hail the birth of a fifth university in the Province of Quebec. It is particularly pleased to do so since the new institution, Sherbrooke University in the Eastern Townships, has, at its very beginning, established an engineering school within its Faculty of Science.

One hundred and twenty-four students have already registered in engineering for the 1954-1955 session. The three first years of the courses will be offered initially with the more advanced courses being organized later on as laboratories and apparatuses are installed.

The four existing universities of Quebec are: Laval in Quebec City, McGill and Montreal (whose school of engineering is called Ecole Polytechnique) in Montreal and Bishop's in Lennoxville. The first three named offer excellent five year courses in all major branches of engineering.

The provincial government has created this new university in the knowledge that by so doing it will provide the population of the Eastern Townships with a more convenient means of attaining to a higher education.

### Evening Courses for Montreal Engineers

For the past several years McGill University has offered a valuable educational service to graduate engineering students through their post graduate evening extension courses. They have also offered a number of undergraduate courses in engineering subjects, and in many cases these courses could be applied towards the qualifying examinations for membership in the Corporation of Professional Engineers of Quebec.

Through the co-operative efforts of the Corporation and McGill University, there has been a movement towards making the extension courses more directly applicable to the requirements of the C.P.E.Q. examinations. This year some of the elementary mathematics and engineering courses have been especially designed to assist persons who are working towards qualifying themselves as professional engineers through written examinations.

The Corporation has also conferred and co-operated with Ecole Polytechnique who are offering evening courses in engineering subjects for the first time this year. Similar courses have been in operation at Laval University in Quebec for two years.

The Corporation is particularly happy that qualified engineers are thus afforded the opportunity to improve and enlarge their technical knowledge under the guidance of recognized leaders in the various branches of engineering technology. All professional engineers are urged to avail themselves of these opportunities to increase their knowledge and advance the standards of the engineering profession.

The assistance given to members qualifying for the C.P.E.Q. examinations is also commendable. While we believe that there is no substitute for a regular engineering undergraduate education, there are those who find such a course impossible, and for those persons the advantage of skilled guidance through the university extension courses is strongly recommended.

### List of Members

The Corporation has just issued its annual list of members. The names of all professional engineers authorized to practise their profession in the Province of Quebec are recorded therein with an indication of their function, employer, university graduation and addresses. Copies may be had from the Corporation's headquarters, 1290 St. Denis Street, Montreal.

## Ontario

### Sales Manager, Ontario District

G. B. Hunnisett, of Packard Electric Co. Ltd., of St. Catharines, has been recently appointed Ontario district sales manager of the company.

He joined the company upon graduation in electrical engineering from the University of Toronto in 1939 and prior to his recent promotion was Toronto area manager.

### Staff Changes at C.G.E.

Three members are affected by a realignment of responsibilities within the electronic equipment department of the Canadian General Electric Co. Ltd., Toronto. Henry S. Dawson, is named manager—engineering; David H. Johnston, manager — manufacturing; and James R. Warren, manager—marketing.

Prior to joining the company in 1948 H. S. Dawson had a wide experience in research, as chief engineer of CRFB Toronto, assistant chief engineer of Research Enterprises and as general manager of the Canadian Association of Broadcasters. Latterly he has been manager of product planning and defence co-ordination in the electronic equipment department of C.G.E.

Mr. Johnston joined the company in 1947 and for five years was in sales and product planning work on mobile communication, broadcast and television. His recent position was manager of the manufacturing subsection of the electronic equipment department.

Mr. Warren likewise joined the company in 1947 and the following year was made manager of the transmitter division, Royce Works. For the past two years he has been manager of manufacturing and engineering in the electronic equipment department.

### Dr. D. R. Derry

Dr. D. R. Derry, of Toronto, who was formerly the chief geologist of Ventures Ltd., and is a Member of Council of the Association, has been made executive vice-president of Rio Canadian

Exploration Ltd., Toronto. This company succeeds Ownamin Ltd., of London, England, and Segemines Ltd., the Canadian company which is associated with the Belgian group of Societe Generale de Belgique. Dr. E. B. Gillanders, who was manager of Ownamin Ltd., is vice-president of Rio Canadian Exploration Ltd.

### Art Show

An innovation at the Canadian National Exhibition at Toronto this year was an exhibit of paintings by members of the various professions. This "Amateur Art Show" formed a part of the Fine Arts Display and included pictures by professional engineers, architects, lawyers, educators, ministers, doctors and pharmacists. In all over one hundred entries of the foregoing professions were on display. The Associations entries were the result of the fine job done by the Committee comprising R. C. Poulter, P. J. Croft, and J. R. Cavanagh.

The comments of the various art critics of the Toronto press indicate the warm reception accorded this new venture of the Art Committee of C.N.E., whose chairman is Col. Mackenzie Waters, F.R.A.I.C., and the probability of similar exhibits in succeeding years.

In practically all pictures entered adherence to conventionalism was the "school" and people and places the subjects. Those of the Association of Professional Engineers whose work was shown included Gordon Alison; G. E. Booth; W. R. Carruthers; J. R. Cavanagh; P. J. Croft; Dr. D. R. Derry; Dr. O. W. Ellis; P. W. Geldard W. J. Gibson; A. V. Grundmanis; H. H. Leeming; E. C. Little; Prof. J. W. Melson; F. Aimeer; A. L. Ross A. Russell; Dr. K. R. Rybka; H. Teekman; M. B. Watson; Dr. C. R. Young.

### To Indo-China

Lieut. Col. A. L. Maclean has been appointed to the International Supervisory Commission and has left for Indo-China. It is expected that he will be away from Canada for about a year, during which time he will be working as part of the Canadian Military Truce Team. His promotion to the rank of Lieutenant-Colonel coincided with the above appointment.

A graduate in metallurgy of the University of Toronto, he served with R.C.E.M.E. in England and on the Continent during World War 2.

Latterly he was a staff officer with R.C.E.M.E. at Canadian Army Headquarters at Ottawa.

### U. of T. Engineering Alumni Reunion

Final details are rapidly being completed for the October 29, 30, and 31 University of Toronto Engineering Alumni Triennial Reunion and already advance registration indicates a record attendance.

On Friday morning, October 29, delegates to the Reunion will have an opportunity of going behind the scenes at Toronto's Union Station. Included will be a general tour of the Station facilities, visits to the switching control tower, and the steam plant. It is also expected that a new diesel engine will be available for inspection.

All main events of the 15th Triennial Reunion will be held at the Royal York Hotel. Further information can be obtained from the Reunion Office, Suite 301, 73 King Street West, Toronto. The chairman in charge of all events for this 15th Triennial Reunion is J. D. Breithaupt, of Page-Hersey Tubes Ltd., Toronto.

## Manitoba

### Golf Tournament

The final round of the Association of Professional Engineers of Manitoba, annual golf tournament, was held on Thursday afternoon, September 2, at Elmhurst Country Club. The turnout, according to J. Sill, golf chairman, was the largest in many years.

At the dinner afterwards several prizes were distributed and the winner of the coveted Sullivan cup, donated by the late J. G. Sullivan, was R. D. Cahoon, prairie regional engineer for the Canadian Broadcasting Corporation, who turned in the low net score. The cup was presented to Mr. Cahoon by D. M. Stephens, president of the Engineering Institute of Canada. Other prize winners were: low gross—E. H. Chippendale; high hidden hole—R. N. Sharpe; low hidden hole—R. M. Gordon.

The Association is grateful to the following firms for donations of prizes and active participation in the tournament: Armco Drainage and Metal Products of Canada Ltd., Westeel Products Ltd., Harris Construction Co. Ltd., Building Products and Coal Co. Ltd., McCurdy Supply Co. Ltd., Bird Construction Co. Ltd., and Commonwealth Construction Co. Ltd.

## British Columbia

### B.C. Municipal Engineers' Convention

More than 200 delegates attended the B.C. Municipal Engineers' Convention in Kelowna, September 16 to 18, including representatives of cities and municipalities throughout British Columbia.

Highlighting the all round participation of professional engineers in community development was the paper on "The City Engineer's position in Civil Administration" presented by W. C. Miller, city engineer of St. Thomas, Ontario, and first president of the City Engineers' Association.

Technical subjects included papers on "Sewage Treatment" by N. J. Goode, of the B.C. Department of Health and Welfare; "Streets and Sidewalks" by R. M. Martin, Vancouver's assistant city engineer; "Town Plan of Penticton" by J. A. Walker, and "External Corrosion" by H. T. Libby, of the B.C. Electric Co.

The Hon. P. A. Gaglardi, Minister of Public Works for B.C., was guest speaker at the annual banquet in the Royal Anne Hotel. Mayor J. J. Ladd extended to the delegates the official welcome of the City of Kelowna.

The social program specially for the ladies included a morning "Koffee Klatch", an afternoon tea, and a smorgasbord dinner.

### Engineers in the News

The appointment of **J. H. Salter** to the newly created position of general superintendent, Chemicals and Fertilizers Division, was announced recently by R. D. Perry, general manager of The Consolidated Mining and Smelting Company of Canada Limited. In his new position Mr. Salter is directly responsible to the manager of the division, E. A. G. Colls. The appointment became effective September 1.

**G. F. Winterburn,** has just returned from a four months vacation motoring through ten of the European countries. He is now employed by the Canadian Comstock Company as estimator.

**L. W. Wight,** assistant manager, Nanaimo-Duncan Power District, B.C. Power Commission is now a member of the Nanaimo School Board.

**B. Finerty** who has been with B.C. International Engineering at Kemano has accepted a position with B. D. Bohna, J. L. Miller & Company.

**G. Sanders,** has received an appointment with the B.C. Department of Public Works as district engineer at Golden, B.C. He was formerly assistant municipal engineer at Kitimat, B.C.

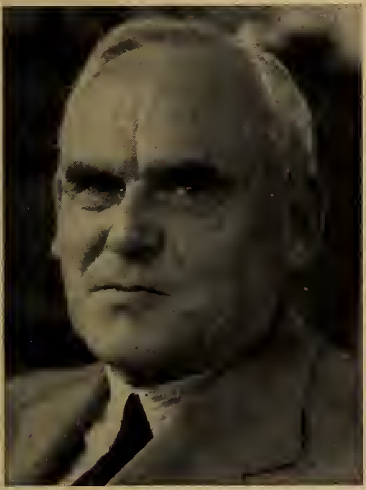
## News of the Personal Activities of Members of the Institute

**Rt. Hon. C. D. Howe,** HON. M.E.I.C., minister of trade and commerce and minister of defence production, was awarded the Daniel Guggenheim Medal on October 8 at the session of the National Aeronautic meeting of the Society of Automotive Engineers which sponsors the award jointly with the American Society of Mechanical Engineers and the Institute of the Aeronautical Sciences.



**The Right Hon. C. D. Howe, Hon.M.E.I.C.**

Mr. Howe has been so honoured for "initiating and organizing commercial air routes and services, promoting aeronautical research, development and production of aircraft and engines, and advancing the art of aeronautics."

A native of Waltham, Mass., and a 1907 civil engineering graduate of the Massachusetts Institute of Technology, Mr. Howe has served as a cabinet minister since 1935 and has been responsible for most of the Canadian developments in aviation. To him goes the credit for organizing the ground and operating services for Canada's first trans-continental air route and for founding the government-owned Trans-Canada Air Lines.

As minister of munitions and supply during World War II, he supervised the growth of Canada's aircraft industry from 200 planes per year to 4,000 planes per year. As postwar minister of reconstruction, he saw to it that government-owned companies were turned over to private industry on terms insuring a continuing aircraft industry.

His position as minister of trade and commerce makes him chairman of the Privy Council on Scientific and Industrial Research, which has responsibility for a number of government aeronautical laboratories.

He has received the Herbert Hoover Medal awarded jointly by four leading American engineering societies, and the Order of Merit of the United States. As a recipient of the Guggenheim Medal, he joins the company of such earlier medalists as Orville Wright, Donald Douglas, James H. Doolittle, **Sir Frank Whittle,** HON. M.E.I.C., Igor Sikorsky, and Charles Lindbergh.

**A. C. Crepeau,** M.E.I.C., who was recently awarded an honorary doctor's degree from Laval University, has been appointed dean of the faculty of science of the new University of Sherbrooke.

Dean Crepeau has had for many years his private practice as consulting engineer in Sherbrooke.

**Gordon Mitchell,** M.C., M.E.I.C., project manager of Ontario Hydro's 1,828,000-horse-power Sir Adam Beck-Niagara Generating Station No. 2, has been recently appointed director of the St. Lawrence Power Project.

Graduating from the University of Toronto in 1915 in civil engineering, he had a distinguished record in the first World War, and was awarded the Military Cross. Upon his return he became assistant superintendent on powerhouse construction at the Sir Adam Beck-Niagara Generating Station No. 1. After a varied and colourful career in power plant construction for Ontario Hydro and other organizations, he was named in 1937 Hydro's construction engineer, generation, culminating in his appointment to the Niagara project in 1951.

**Wm. L. Fraser, M.E.I.C.**

**William L. Fraser,** M.E.I.C., has been appointed project manager of Sir Adam Beck-Niagara Generating Station No. 2 Project to succeed Gordon Mitchell, M.E.I.C., who was recently named project manager of the St. Lawrence Power Project.

A graduate of Dalhousie and McGill Universities, Mr. Fraser first joined Ontario Hydro in 1947 as project manager for the Chenaux development on the Ottawa River, and continued in that position until his appointment to Niagara in January, 1951 as field project engineer.

**William M. Hogg,** M.E.I.C., project field engineer of Ontario Hydro's Sir Adam Beck-Niagara Generating Station No. 2, has been recently appointed to a similar post on the St. Lawrence Power Project.

**Wm. M. Hogg, M.E.I.C.**

Mr. Hogg began his hydro training as a water boy on the original Niagara development, the Sir Adam Beck-Niagara Generating Station No. 1. Later, following graduation in 1939 from the University of Toronto, he held many important engineering posts with the Commission, including those of designing engineer in the generation department and senior resident engineer at the Des Joachims development on the Ottawa River.

J. F. Mills, M.E.I.C.

**J. F. Mills,** M.E.I.C., president of Siemens Brothers (Canada) Limited, has been appointed commissioner and general manager of the Manitoba Telephone System.

Mr. Mills was associated with the Siemens Company from 1926 until 1936 In 1930 he undertook a special telecommunication engineering course in the main factory in London, England.

He joined the Manitoba Telephone System in 1936 and was appointed chief engineer in 1945, and in addition, assistant general manager in 1948.

Mr. Mills became vice-president of Siemens Brothers (Canada) Limited in 1952, and president of the company in January, 1954.

He assumed his new position with the Manitoba Telephone System following the recent retirement of Peter Millar, commissioner and general manager since 1945.

**C. W. West,** M.E.I.C., formerly senior deputy minister of transport, has been appointed a member of the St. Lawrence Seaway Authority.

An honour graduate in engineering of the University of Toronto, Mr. West was employed prior to World War I with Smith, Kerry and Chase, consulting engineers, on hydro-electric power development as a senior assistant engineer on Trent Canal construction, and as assistant engineer on hydraulic reports and investigations with the Ontario Hydro-Electric Power Commission.

During World War I he served with the Canadian Infantry and the Canadian Engineers, and after demobilization, was appointed senior assistant and division engineer in charge of the construction of sections 3, 4 and 4b of the Welland Ship Canal.

In 1933 he organized the operating staff of the Welland Ship Canal and became the first superintending engineer, which position he held until 1947, when he was transferred to Ottawa as director of Canal Services. He was appointed senior deputy minister of the Department of Transport in October, 1953.

**Col. R. D. Harkness,** M.E.I.C., president of Northern Electric Co. Ltd., and **T. W. Eadie,** M.E.I.C., president of the Bell Telephone Company of Canada, were recently promoted to commander brothers of the Most Venerable Order of the Hospital of St. John of Jerusalem.

**R. R. Noyes,** M.E.I.C. general sales manager of Canadian Sirocco Company, Ltd. in Windsor, Ont., has been elected a member of the board.

A mechanical engineering graduate of the University of Toronto, class of 1936, he joined Canadian Sirocco the same year as a sales engineer, working out of the Montreal office. In 1947 he was appointed eastern district manager in Montreal, and in 1952 he was moved to Windsor to occupy his present position.

R. R. Noyes, M.E.I.C.

Mr. Noyes is a member of the Association of Professional Engineers of Ontario, the American Society of Heating and Ventilating Engineers, and a past-president of the Society's Montreal chapter, the American Society of Mechanical Engineers, and the Canadian Pulp and Paper Association.

**Air Vice Marshal C. R. Dunlap,** R.C.A.F, M.E.I.C., has been transferred from the National Defence College in Kingston where he served as commandant, to Air Force headquarters in Ottawa, where he will be vice chief of the Air Staff.

**F. G. East,** M.E.I.C., former development engineer of Hamilton Gear and Machine Co. Ltd. of Toronto, has been appointed general manager. Mr. East joined the company in 1924, and during the past 20 years has been responsible for the development of all new products including new lines of gear reduction units and couplings.

He has been active in the Ontario section of the American Society of Mechanical Engineers, and has served as chairman. He has also been active in the American Gear Manufacturers Association and the Canadian Standards Association.

**Ben Russell,** M.E.I.C., has retired from the services of the Alberta government and has accepted the position of chief engineer with Square M. Construction Ltd. of Edmonton. At the same time he will serve as consulting engineer.

For the past ten years he has been director of water resources for the Alberta government, and prior to that he was chief engineer with the irrigation branch of the Department of the Interior where he pioneered in irrigation and water power development in western Canada.

Mr. Russell, a civil engineering graduate of McGill University, is a Dominion Land Surveyor, and a member of the Prairie Provinces Water Board, secretary of the Irrigation and Drainage Council for Alberta, and a Life Member of the Engineering Institute.

E. R. McMullen, M.E.I.C.

**Elmer Russell McMullen,** M.E.I.C., general superintendent of the Laurentide division of Consolidated Paper Corporation Limited in Grand'mere, Que., has been elected chairman of the St. Maurice Valley Branch of the Engineering Institute.

Mr. McMullen is a native of Middleboro, N.S. He received his B.Sc. degree in pure science from Mount Allison University in 1924, and his B.Sc. degree in mechanical engineering from the Nova Scotia Technical College in 1930. During the intervening years he served as head master of a private school in Calgary.

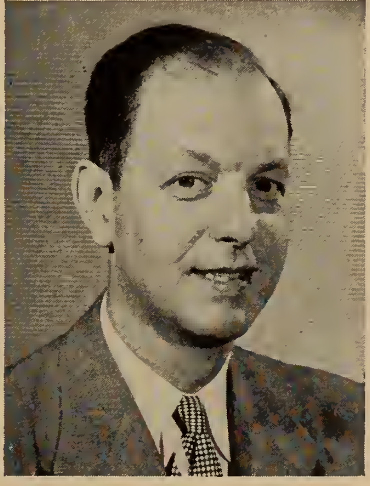
Mr. McMullen joined the Consolidated Paper Corporation in 1930 as assistant superintendent of the control department. In 1933 he was appointed divisional accountant and he was named to his present position in 1946.

Mr. McMullen is a member of the Corporation of Professional Engineers of the Province of Quebec.

**G. E. M. Proctor,** M.E.I.C., has become a partner in Proctor, Redfern & Laughlin, Toronto consulting civil engineers, according to a recent announcement made by **E. M. Proctor,** M.E.I.C., senior partner.

Mr. Proctor, manager of the Scarborough branch of the company, is a civil engineering graduate of McGill University, class of 1946.

**O. Nelson Mann,** M.E.I.C., of the Nova Scotia Department of Trade and Industry,



O. Nelson Mann, M.E.I.C.

has been elected chairman of the Halifax Branch of the Engineering Institute.

He was born in Sydney, N.S., where he received his general schooling. He then obtained his engineering certificate from Acadia University in 1933, and his B.E. degree in mechanical engineering from the Nova Scotia Technical College in 1935.

His early engineering training was in the shops of the steel plant in Sydney and at the Imperial Oil Refinery in Halifax. In 1937 he moved to the Montreal area and during the war was superintendent of process engineering on small arms manufacture with Defence Industries Ltd. After the war he was associated in the consulting engineering field with J. D. Woods & Gordon, Ltd. and Stevenson & Kellogg, Ltd. in Toronto.

At the beginning of 1950 Mr. Mann returned to his native province with the Nova Scotia Research Foundation, later moving to the Department of Trade and Industry.

**J. B. Carswell,** O.B.E., M.E.I.C., consulting engineer and chairman of the board of Kitimat Constructors Ltd. in Vancouver, has announced the opening of his private consulting engineering office in Toronto.

**Eric R. Jacobsen,** M.E.I.C., president of Brazaco S.A., which represents the United States Steel Export Company in Sao Paulo, Brazil, recently paid a visit to Engineering Institute headquarters in Montreal.

Mr. Jacobsen graduated in civil engineering from McGill University in 1929 and received his M.Eng. degree from the same university in 1932. After graduation he was first associated with Dominion Bridge Company Limited. During the war he was on loan to the Australian War Supplies Procurement in Washington, D.C., and in 1945, joined the United States Steel Corporation in New York.

**Wing Commander R. M. Aldwinkle,** R.C.A.F., M.E.I.C., is now R.C.A.F. resident engineering officer at Canadair Limited in Montreal. He was previously stationed at the R.C.A.F. Staff College in Armour Heights in Toronto.

Within the past year he has been elected an associate fellow of the Royal Aeronautical Society and a member of the Society of Automotive Engineers.

**Douglas T. Bayer,** M.E.I.C., has been appointed general superintendent of Eastern Light & Power Co. Ltd. in Sydney, N.S.

A graduate in electrical engineering of the Nova Scotia Technical College, class of 1932, he previously held the position of assistant general superintendent.

**James L. Patterson,** M.E.I.C., who has been factory manager of La France Fire Engine and Fomite Ltd. since 1947, now heads Eade Wood Products at Kleinburg.

A mechanical engineering graduate, Mr. Patterson, has been associated in the past with Aluminum Company of America, Canada Cycle and Motor Co. Ltd. and A. P. Green Fire Brick Co. Ltd.

**Ross Stanley,** AFFIL.E.I.C., is operating his own office as architect in Edmonton. He was formerly a partner in the firm Dewar, Stevenson & Stanley in Edmonton.

Mr. Stanley received his B.Sc. degree in architecture from the University of Alberta in 1938.

**Commander (L) W. E. Smith,** R.C.N., M.E.I.C., has been transferred from H. M. C. Electrical School in Halifax to Sorel, Que. where he will serve as principal naval overseer with Marine Industries Ltd.

Commander Smith received his B.Sc. degree in electrical engineering from the University of New Brunswick in 1935.

**W. A. Williamson,** M.E.I.C., former general sales manager of Reliance Electric & Engineering (Canada) Ltd. in Welland, Ont., is vice-president and managing director of Electric Panel Mfg. Ltd. in Vancouver.

Mr. Williamson is a 1934 graduate in electrical engineering of the University of Toronto.

**O. Margison,** M.E.I.C., will continue as president of A. D. Margison and Associates Limited, the consulting professionnal engineering firm in Toronto whose name was recently changed from Margison Babcock and Associates Limited.

**H. A. Babcock,** M.E.I.C., has withdrawn his directorship in the firm.

**A. D. Margison,** M.E.I.C., will continue to serve as vice-president and general manager, and **V. D. Hunter,** M.E.I.C., as secretary-treasurer and assistant general manager.

Associates in the firm include **J. E. Margison,** M.E.I.C., chief engineer of the process department, **D. L. B. Hamlin,** M.E.I.C., chief engineer of the structural department, **W. A. Stewart,** JR.E.I.C., chief engineer of the municipal department, and **R. A. Cunningham,** M.E.I.C., of the field supervision section.

**George W. Hand,** AFFIL.E.I.C., has been named manager of the real estate department of the Montreal Trust Company in Montreal.

**John L. Darimont**, M.E.I.C., is resident engineer with R. M. Hardy & Associates Ltd. in Whitehorse, Yukon Territories. He was formerly resident engineer with Engineering and Construction Services Ltd. in Whitehorse.

Mr. Darimont received his B.Sc. degree in mining and metallurgy from the University of Alberta in 1934.

**Kenneth R. Shipley**, M.E.I.C., has been transferred by Imperial Oil Limited from Winnipeg to Toronto where he is serving as assistant chief engineer of the pipeline division.

Mr. Shipley is a 1935 B.A.Sc. graduate of the University of Toronto.

**F. Petricek**, M.E.I.C., formerly field engineer with the Gulf Power Company in Clark City, has joined H. G. Acres Co. Ltd. in Niagara Falls.

Mr. Petricek graduated in civil engineering from the Technical University in Prague in 1938.

**E. D. Wilson**, M.E.I.C., has been transferred from Regina to Calgary as management assistant in the producing department for the western division of Imperial Oil Limited.

Mr. Wilson is a 1939 mining engineering graduate of the University of Alberta.

**R. H. Nicolson**, M.E.I.C., a 1939 civil engineering graduate of the University of Alberta, is superintendent of the waterworks distribution system in Edmonton.

Mr. Nicolson has been associated with the engineering staff of the City of Edmonton since his return from overseas service with the Royal Canadian Engineers in 1946.

**C. R. Phillips**, M.E.I.C., formerly associated with Kelvinator Company of Canada Ltd. in London, Ont., has joined Ex-Cell-O Corporation of Canada Ltd. in London.

He is a graduate in mechanical engineering of the University of Toronto, class of 1939.

**E. Kostitch**, M.E.I.C., who graduated in civil engineering from Ecole Speciale des Travaux Publics in 1939, is structural designing engineer with Lord & Company in Montreal. He was formerly with the bridge division of the Department of Public Works for the Province of Quebec in Quebec City.

**Bruce Wm. Hamer**, M.E.I.C., is now district engineer for the Department of Fisheries in Prince Rupert, B.C. Previous to accepting this position, he was resident engineer in the engineering department of the City of Ottawa.

Mr. Hamer graduated in mining engineering from the Nova Scotia Technical College in 1939.

**E. A. Sprenger**, M.E.I.C., former production manager with Sorel Industries Ltd., is now assistant chief inspecting engineer with Dominion Engineering Works in Lachine.

Mr. Sprenger received his B.Eng. degree in mechanical engineering from McGill University in 1940.

**J. C. Finlayson**, M.E.I.C., has been transferred from the air services branch of the Department of Transport, to the aircraft branch of the Department of Defence Production as senior production officer.

Mr. Finlayson received his B.A.Sc. degree in mechanical engineering from the University of Toronto in 1940.

**M. Konforti**, M.E.I.C., has recently entered into partnership in the Tesla Technical Company in Toronto. He was formerly a partner in Dunsan Lazarevic in Toronto.

Mr. Konforti received his mechanical engineering degree in 1937 and his electrical engineering degree in 1941 from the University of Belgrade.

**Major M. O. Rollefson**, R.C.E., M.E.I.C., is commanding officer of the 3rd Field Squadron, R.C.E. in Korea, and has been promoted from the rank of captain.

Previous to this appointment he was stationed at Vedder Crossing, B.C.

Major Rollefson is a 1941 civil engineering graduate of the University of Alberta.

**Major K. F. Collins**, R.C.E.M.E., M.E.I.C., has just returned from a tour of duty in Germany as commanding officer, No. 1 Canadian Base Repair Section, R.C.E.M.E. in the Ruhr. His new appointment is to the staff of the R.C.E.M.E. School at Barriefield, Ont.

Major Collins graduated in 1941 in chemical engineering from Queen's University.

**Paul M. Smith**, M.E.I.C., is now superintendent with William R. Souter & Associates, Hamilton architects, and is employed on the plant extension of the Chrysler Corporation of Canada in Windsor.

A 1942 graduate in civil engineering of Ecole Polytechnique, Mr. Smith was formerly associated with Surveyer, Nenniger & Chennevert in Montreal.

**H. B. White**, M.E.I.C., formerly design engineer with B.C. International Engineering Co. Ltd. in Vancouver, has joined Aluminum Company of Canada Limited in Montreal as development engineer.

Mr. White is a graduate in civil engineering of the University of Toronto, class of 1944.

**J. Blair Scott,** M.E.I.C., has been appointed an associate engineer with Pandia Incorporated of New York City, manufacturers and designers of continuous pulping equipment and other pulp and paper machinery.

Previous to this appointment he was pulp superintendent with the Richmond Pulp & Paper Company in Bromptonville, Que.

Mr. Scott graduated from Queen's University in mechanical engineering in 1945.

**Andrew T. Wilson,** M.E.I.C., formerly supervisor with Foundation Co. of Canada Ltd. in Montreal, is resident engineer with Racey, MacCallum & Associates Ltd. in Sherbrooke.

He received his B.Sc. degree in civil engineering from the University of Belfast in 1946.

**James Ross Dalrymple,** M.E.I.C., formerly with the market research and product planning department of the Canadian General Electric Company in Montreal, has joined Standard Tube and T.I. Ltd. in Woodstock, Ont.

He graduated in 1944 from the University of Toronto in mechanical engineering.

**Thos. P. Hutchinson,** M.E.I.C., has joined H. K. Ferguson Company of Canada, Ltd. of Montreal. Previous to joining the company, Mr. Hutchinson was senior engineer with Aluminum Company of Canada, Ltd. at Chute du Diable, Que. He was also associated with James MacLaren Co. Ltd. in Buckingham, Que., and with Canadian National Railways as resident engineer.

Thos. P. Hutchinson, M.E.I.C.

A graduate civil engineer of McGill University, class of 1944, Mr. Hutchinson served as a lieutenant in the Royal Canadian Engineers during World War II. He is a member of the Association of Professional Engineers of Ontario and the Corporation of Professional Engineers of the Province of Quebec.

**J. S. Sugiyama,** M.E.I.C., formerly associated with Rule, Wynn and Rule in Calgary, has become a partner in the firm named Izumi, Arnott and Sugiyama of

## Correction

In the September *Journal*, page 1132, **C. W. Currie,** M.E.I.C., was said in error to have been appointed district engineer with the Department of Public Works of Canada in Charlottetown, P.E.I.

Mr. Currie's new appointment is that of district engineer. Previous to this he served as assistant district engineer, having joined the Department in Charlottetown in 1934 after working for six years on design with the Nova Scotia Power Commission.

He is an electrical engineering graduate of the Nova Scotia Technical College, class of 1928.

---

Regina which will specialize in architecture, city and rural planning and engineering.

Mr. Sugiyama is a 1947 civil engineering graduate of the University of Manitoba.

**S. G. Jackson,** M.E.I.C., is associated with Charles Warnock & Co. Ltd. in Montreal. Before joining this company, he was highway engineer with Fraser Brace Terminal Constructors in Saint John, N.B.

Mr. Jackson received his engineering degree from Norwich City College of London in 1947.

**J. R. Lewis,** M.E.I.C., is associated with General Steel Wares Limited in Toronto, and is employed as production superintendent of the kitchen equipment department.

A 1948 graduate in mechanical sciences of the University of Cambridge, Mr. Lewis was previously with the Canadian International Paper Company in Temiskaming, Ont.

**W. H. Griffin,** M.E.I.C., is regional engineer with The British American Oil Company Ltd. in Regina.

He is a graduate in civil engineering of Queen's University class of 1948.

**Norman S. Trouth,** M.E.I.C., formerly division superintendent with West Kootenay Power & Light Co. Ltd. in Penticton, B.C., is now manager of Kelwood Corporation Limited, a land development company in Calgary. Previous to joining this company, Mr. Trouth was briefly associated with Messrs Haddin, Davis & Brown, as resident project engineer in Edmonton.

Mr. Trouth graduated in electrical engineering from the University of Alberta in 1949.

**G. MacGregor,** M.E.I.C., former electrical draughtsman with Canadian Vickers Ltd. in Montreal, has joined the Manitoba Power Commission.

He is a 1949 electrical engineering graduate of the University of Edinburgh.

**L. A. W. Davis,** M.E.I.C., formerly electrical testing engineer with Canadian Vickers Ltd. in Montreal, is now defence research technical officer with C.A.R.D.E. in Quebec City.

Mr. Davis, an associate member of the Institute of Electrical Engineers, is a 1950 graduate of Melbourne Technical College in Australia.

**F. T. Peters,** M.E.I.C., former structural design engineer with Anfo Steel Corporation in Toronto, is manager of Ontario Bridge Co. Ltd. in that city.

Mr. Peters received his B.Eng. degree from the Nova Scotia Technical College in 1950.

**S. J. Medwasowski,** M.E.I.C., formerly project engineer on the staff of the

Foundation of Canada Engineering Corporation in Montreal, is now on the staff of the civil engineering department of the University of California where he is also pursuing a course of graduate study leading to the degree of Ph.D. in structural mechanics.

Mr. Medwasowski is a graduate of the Polish University College, London, class of 1950.

**D. E. Doxsee,** M.E.I.C., is field construction engineer with Canadian Kellogg Co. Ltd. in Edmonton. Before joining this company, he was on the staff of Brown & Root Ltd.

He is a mechanical engineering graduate of the University of British Columbia, class of 1951.

**R. L. Donaldson,** M.E.I.C., is plant laboratory supervisor for Sherritt Gordon Mines Ltd. in Fort Saskatchewan, Alta. He was previously associated as sales engineer with Northwest Industries Ltd. in Edmonton.

Mr. Donaldson is a 1951 graduate in chemical engineering of the University of British Columbia.

**W. H. George,** M.E.I.C., former resident engineer with the Department of Northern Affairs and National Resources in Jasper, has joined Hipperson Construction Co. Ltd. in Regina.

He is a 1951 civil engineering graduate of the University of Saskatchewan.

**Lieut. Comm. (L) L. R. Wagener,** R.C.N., JR.E.I.C., is stationed at the Royal Canadian Naval Station at Dartmouth, N.S. He was previously stationed at Naval headquarters in Ottawa.

Lieut. Comm. Wagener received his B.Sc. degree in electrical engineering from Queen's University in 1946.

**H. M. Sullivan,** JR.E.I.C., a 1946 chemical engineering graduate of Queen's University, has joined the staff of McLean Budden Ltd. in Montreal.

**Major R. W. Potts,** D.S.O., R.C.E., JR.E.I.C., has been appointed officer commanding of No. 1 Field Squadron, R.C.E. at Vedder Crossing, B.C., following his return from overseas where he was officer commanding No. 58 Independent Field Squadron, R.C.E.

He is a 1947 civil engineering graduate of the University of Saskatchewan.

**R. N. Flaherty,** JR.E.I.C., is on the staff of the engineering department of the Township of Scarborough in Toronto.

A 1947 graduate in civil engineering of McGill University, Mr. Flaherty was previously design engineer with the Anfo Steel Corporation in Toronto.

**W. H. Potts,** JR.E.I.C., formerly associated with Electric Reduction Co. of Canada Ltd. in Buckingham, Que., is now with Shepherd & Powell, consulting engineers in Toronto.

Mr. Potts graduated in civil engineering from Queen's University in 1948.

**A. F. Inderwick,** JR.E.I.C., has been transferred by Defence Construction (1951) Ltd. from the R.C.A.F. Station in Edgar, Ont. to Chatham, N.B.

He received his B.Sc. degree in civil engineering from London University in 1948.

**K. W. Stairs,** JR.E.I.C., is a consultant engineer with the inspection services of the Department of National Defence in Ottawa. He was formerly with the Directorate of Installations, U.S.A.F., at Pepperrell Air Force Base in St. John's, Nfld.

Mr. Stairs is a civil engineering graduate of the University of New Brunswick, class of 1948.

**Squadron Leader C. E. F. Underwood,** R.C.A.F., Jr.E.I.C., is stationed at Air Force headquarters in Ottawa. Formerly, associate professor in the civil engineering department of the Royal Military College in Kingston, Squadron Leader Underwood is a graduate in civil engineering of the University of British Columbia, class of 1948.

**D. M. Stewart,** Jr.E.I.C., is now employed with the Alberta Government Telephones as an engineer in training in the transmission department. Before accepting this position he was on the staff of the Schlumberger Well Surveying Corporation in Calgary.

Mr. Stewart is a 1949 electrical engineering graduate of the University of Saskatchewan.

**R. L. Wood,** Jr.E.I.C., is associated with Brown Boveri (Canada) Ltd. in St. Johns, Que. He was previously with the Canadian Westinghouse Company in Hamilton.

Mr. Wood is a 1949 graduate in electrical engineering of the University of New Brunswick.

**Gerald Flanagan,** Jr.E.I.C., who has been an engineer in training with the Canadian Johns Manville Company in Toronto, has been transferred to Montreal as sales engineer in the contract sales department.

Before joining the company, Mr. Flanagan was associated with the Reymer Atlas Construction Company in Niagara Falls.

He is a 1949 graduate in civil engineering of McGill University.

**R. M. MacKenzie,** Jr.E.I.C., is sales engineer with the Butler Manufacturing Company, manufacturers of steel products in Minneapolis, Minn.

A graduate in engineering and business of the University of Toronto, class of 1950, Mr. MacKenzie was formerly associated with Federal Mogul Service in Dallas, Texas, Calgary and Toronto.

**Wm. O. Codrington,** Jr.E.I.C., has been transferred by Aluminum Company of Canada Ltd. from Arvida to Kemano.

Mr. Codrington is an electrical engineering graduate of the University of British Columbia, class of 1950.

**Richard I. de St. Croix,** Jr.E.I.C., who received his master's degree in business administration from the University of Michigan this year, has joined the staff of The McKinnon Industries, Limited in St. Catharines.

R. de St. Croix, Jr.E.I.C.

A mechanical engineering graduate of McGill University, class of 1950, Mr. de St. Croix was previously employed by the Ford Motor Company in Windsor.

**Thos. D. Leaver,** Jr.E.I.C., is on the staff of Northern Electric Co. Ltd. in Montreal. He was formerly in the employ of Canadian Vickers Ltd. in Montreal.

Mr. Leaver received the higher national certificate in electrical engineering in 1950. He is a graduate member of the Institution of Electrical Engineers.

**John C. Heath,** Jr.E.I.C., a 1950 graduate in mechanical engineering of the University of Manitoba, is now on the staff of Canadian Aviation Electronics in Winnipeg.

Mr. Heath was previously diesel supervisor with the Algoma Central and Hudson Bay Railway in Sault Ste. Marie.

**W. L. Garvin,** Jr.E.I.C., a 1950 mechanical engineering graduate of the University of Manitoba, is on the staff of Defence Construction (1951) Ltd. in Winnipeg.

**Dale A. Douglas,** Jr.E.I.C., is communication design engineer with Canadian General Electric Co. Ltd. in Toronto. He previously occupied the position of chief engineer with Essex Electronics in Trenton Ont.

Mr. Douglas is a 1950 electrical engineering graduate of the University of British Columbia.

C. E. Petite, Jr.E.I.C.

**Chesley E. Petite,** Jr.E.I.C., formerly associated with the Fisheries Research Board of Canada at the Atlantic biological station in St. Andrews, N.B., has joined Canadian Oil Companies in Montreal.

Mr. Petite received his mechanical engineering degree from the Nova Scotia Technical College in 1950.

**Herman Erkku,** Jr.E.I.C., who has been temporarily employed during the summer with Aluminum Company of Canada, Limited in Arvida, has returned to the Massachusetts Institute of Technology where he is pursuing post-graduate study in chemical engineering.

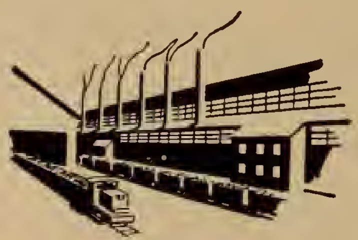
Mr. Erkku graduated in chemical and metallurgical engineering from Ecole Polytechnique in 1950.

**James H. Legere,** Jr.E.I.C., is now on the staff of the Corporation of Professional Engineers of Quebec.

A graduate in engineering physics of McGill University in 1950, Mr. Legere undertook post graduate study from the same university in business administration and management. Upon graduation

# HOW MUCH CAN YOU PROFIT WITH CANADIAN SIROCCO AIR HANDLING PRODUCTS?

**For better ventilation in your plant . . . for low-cost methods to lick chemical processing problems . . . for precise control of temperature and humidity — read how Canadian Sirocco equipment can serve you.**



## BETTER VENTILATING . . .

The process of converting boatloads of iron ore into usable steel involves some mighty extreme temperatures. Proper ventilation to handle the escaping smoke, fumes and gases is vital. Many steel mills rely on Canadian Sirocco HS Fans for this job. Engineers like these fans because of their non-overloading power characteristics and remarkably high efficiency over a wide range of operation. May we help you with a similar problem?

## BETTER PROCESSING

Why not call on Canadian Sirocco to help with the air handling assignments in your chemical process work? We've had plenty of firsthand experience. Major chemical producers use Canadian Sirocco fans and blowers (both standard and special types) in processing chlorine, elemental phosphorus, sulphuric acid, bleach and caustic. Our branch office personnel can often save you time with on-the-spot suggestions.

## ℞ FOR AIR . . .

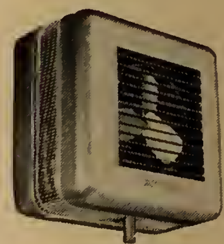
One of the stiffest tests air handling equipment can get is that imposed by manufacturers of pharmaceuticals. Cultures and processes require a sterile atmosphere. Temperature and humidity must often be exact. Recently, an important company in this field selected Canadian Sirocco Fans and Coils for its main air conditioning system . . . a fine tribute not only to the quality of Canadian Sirocco products, but also to the effectiveness of our research and testing methods. Why not put this valuable experience to work for you?

**Whatever your needs,** Canadian Sirocco heating, cooling, drying, air conditioning and air handling equipment contributes toward improving over-all comfort and efficiency. Phone or write for data. Branches in principal cities.

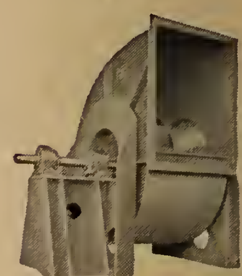
**Power Roof Ventilators**

**Mechanical Draft Fans**

**Dust Collectors**



**Unit Heaters**



**Industrial Fans**

CANADIAN SIROCCO COMPANY, LTD.
310 ELLIS STREET, WINDSOR, ONTARIO

**YOUR BEST BUY CANADIAN SIROCCO AIR HANDLING EQUIPMENT**

*In the United States:* AMERICAN BLOWER CORPORATION • DETROIT 32, MICHIGAN he served as engineering assistant with the Bell Telephone Company of Canada in Montreal.

In November, 1952 he entered Canadian Aviation Electronics Ltd. as assistant to the chief engineer, and in December, 1952 was appointed executive assistant to the vice-president in charge of manufacturing and engineering.

**J. E. Savage,** Jr.E.I.C., formerly inspecting engineer for Manitoba with the Trans-Canada Highway division of the Department of Public Works in Winnipeg, has been appointed supervising engineer for Saskatchewan.

Mr. Savage received his B.Eng. degree in electrical engineering from McGill University in 1950.

**K. R. Simmons,** Jr.E.I.C., has been appointed town engineer for the three towns of Acton, Georgetown and Milton of Ontario. He was previously on the staff of Imperial Tobacco Co. of Canada Ltd. in Montreal.

Mr. Simmons is a 1950 engineering and business graduate of the University of Toronto.

**W. G. Thompson,** Jr.E.I.C., has recently accepted the position of plant manager with Pioneer Electric Alberta Ltd., located in Red Deer, Alta. He was formerly associated with Reliance Electric and Engineering (Canada) Ltd. in Welland, Ont.

Mr. Thompson graduated in electrical engineering from the University of Manitoba in 1950.

**W. E. Trann,** Jr.E.I.C., a 1950 mechanical engineering graduate of the University of Manitoba, is plant engineer with the Anthes Imperial Co. Ltd. in Winnipeg.

**Roy S. Thibodeau,** Jr.E.I.C., formerly associated with Molson's Brewery Ltd., is now industrial sales engineer with Crane Limited in Montreal.

Mr. Thibodeau graduated in 1950 in mechanical engineering from the Nova Scotia Technical College.

**Hugh A. Templeton,** Jr.E.I.C., who has completed a Food and Agricultural Organization assignment in Ceylon, is now under a two-year contract with the Department of Trade and Commerce under the Colombo Plan to act as field service engineer with the Department of Agriculture for the Government of Sind. He is located in the Hyderabad area.

Mr. Templeton, a 1950 agricultural engineering graduate of the University of Saskatchewan, was formerly associated with the engineering department of Cockshutt Farm Equipment Limited at Brantford, Ont., and with W. C. Wood and Company in Guelph, Ont.

**C. J. Deines,** Jr.E.I.C., a 1951 electrical engineering graduate of the University of Alberta, has joined the Texaco Exploration Company in Stettler, Alta. He was formerly associated with Western Geophysical Co. Ltd. in Calgary.

**J. J. Lazurko,** Jr.E.I.C., is electrical-mechanical inspector of mines with the Ontario Department of Mines, covering the Kenora and Thunder Bay districts.

Previous to joining the Department in March, 1954, Mr. Lazurko was associated with Steep Rock Iron Mines Ltd. in Steep Rock Lake.

He is a 1951 electrical engineering graduate of the University of Saskatchewan.

**J. E. Jansen,** Jr.E.I.C., a mechanical engineering graduate of the University of Toronto in 1951, is associated with the Bendix Aviation Corporation in Baltimore, Maryland.

**William J. Howell,** Jr.E.I.C., formerly with the Ford Motor Company in Windsor is now on the staff of Babcock Wilcox and Goldie McCulloch Ltd. in Galt, Ont.

Mr. Howell graduated in mechanical engineering from the University of Toronto in 1951.

**A. T. Nikiforuk,** Jr.E.I.C., is on the staff of Defence Construction (1951) Ltd. in Edmonton. He was previously electrical inspector for the Government of Alberta in Edmonton.

Mr. Nikiforuk is a 1951 electrical engineering graduate of the University of Alberta.

**T. J. Sluymer,** Jr.E.I.C., formerly design engineer with consulting engineer Henry Jasen in Montreal, is now structural engineer with Precompressed Concrete Engineering Co. Ltd. in Montreal.

Mr. Sluymer graduated in 1951 from the University of Delft in civil engineering.

**Constructor Lieutenant H. A. Shenker,** D.F.C., R.C.N., Jr.E.I.C., has completed a three-year course in naval architecture and marine engineering at the Massachusetts Institute of Technology, and has received the advanced degree of naval engineer.

A civil engineering graduate of the University of Toronto, class of 1951, Lieut. Shenker's next appointment will be on the staff of the Naval Constructor-in-chief at National Defence headquarters in Ottawa.

**R. T. Worden,** Jr.E.I.C., a 1951 mechanical engineering graduate of McGill University, is industrial heating sales engineer in the apparatus division of Canadian General Electric Co. Ltd. in Montreal.

**C. R. Wilkins,** Jr.E.I.C., of the Montreal Engineering Co. Ltd. in Montreal, has been transferred to Seebe, Alta. where he is employed as construction engineer on the Pocaterra-Interlakes hydro-electric development.

Mr. Wilkins is a 1951 civil engineering graduate of the University of Saskatchewan.

**Donald T. Vanstone,** Jr.E.I.C., has been transferred by Canadian Industries Ltd. in Maitland, Ont. to Dupont Company of Canada, Ltd. as design engineer in Montreal.

Mr. Vanstone graduated in chemical engineering from Queen's University in 1951.

**John H. Dinsore,** Jr.E.I.C., has been transferred from Peterborough to Toronto by Canadian General Electric Co. Ltd. He is an electrical engineering graduate of McGill University, class of 1952.

**Paul Hamel,** Jr.E.I.C., is on the staff of C. D. Howe Limited in Montreal. He was formerly technical advisor and designer with Peltier Handling Equipment Co. Ltd. in Montreal.

Mr. Hamel received his B.A.Sc. degree in mechanical and electrical engineering from Ecole Polytechnique in 1952.

**R. T. Giovannetti,** Jr.E.I.C., is on the staff of the layout engineering department of the Ford Motor Company in Windsor. He was formerly in the employ of Canadian Industries Ltd. in Windsor.

Mr. Giovannetti is a 1952 mechanical engineering graduate of the Nova Scotia Technical College.

**R. J. D. Gardner,** Jr.E.I.C., formerly on the staff of Lethbridge Iron Works Co. Ltd. in Lethbridge, has joined the staff of the Hudson's Bay Company as research engineer.

Mr. Gardner is a mechanical engineering graduate of the University of British Columbia, class of 1952.

**Urban P. Burke,** Jr.E.I.C., is associated with Giffels & Valet of Canada Ltd. in Windsor, Ont. He was formerly on the staff of the Dominion Coal Company in Glace Bay, N.S.

Mr. Burke is a graduate in mechanical engineering of the Nova Scotia Technical College, class of 1952.

**E. S. Eichmann,** Jr.E.I.C., a 1952 B.Sc. graduate of the University of Alberta, is a research assistant on the staff of the University of Illinois.

**H. P. Gillespie,** Jr.E.I.C., who graduated in 1952 in civil engineering from the Nova Scotia Technical College, is construction engineer with Canadian Petrofina Ltd. in Montreal.

**K. J. Ellis,** Jr.E.I.C., is attached to the U.S. Army Corps of Engineers at Goose Bay, Labrador. He was previously associated with Messrs R. P. Allsop & Associates in Toronto.

Mr. Ellis graduated in civil engineering from the University of Birmingham in 1952.

**David R. Hughson,** Jr.E.I.C., is now on the staff of Turnbull Elevator Co. Ltd in Toronto.

**David R. Hughson, Jr.E.I.C.**

After graduation from the University of Toronto in engineering and business in 1951, he joined Canadian General Electric Co. Ltd. on the Company test course. In 1952 he enrolled in the Harvard Graduate School of Business Administration and completed the two-year course this year, graduating with an M.B.A. degree.

**Eric W. Spurrell,** Jr.E.I.C., is employed by the Department of Transport in Ottawa He was formerly attached to the United States Corps of Engineers at Goose Bay, Labrador.

Mr. Spurrell graduated in electrical engineering from the Nova Scotia Technical College in 1952.

**Rene Bedard,** Jr.E.I.C., is now on the staff of Canadian Industries Ltd. in Montreal. He was previously a patent examiner in the Patent Office in Ottawa.

Mr. Bedard is a 1952 chemical engineering graduate of Laval University.

**A. P. Kilroy,** Jr.E.I.C., is now attached to the Corps of Engineers, U.S. Army, at

Goose Bay, Labrador. He was previously junior works engineer in the City of Toronto Department of Works.

Mr. Kilroy graduated with a B.A.I. degree from Trinity College, Dublin, in 1952.

**L. Gasner,** JR.E.I.C., a 1952 mechanical engineering graduate of the University of Toronto, has set up his own business in Ranee, Ont., under the firm name of Auto Parts Exchange Ltd.

**Alcide J. LeBlanc,** S.E.I.C., is project engineer with Dominion Wabana Ore Ltd. in Wabana, Nfld.

A 1953 civil engineering graduate of McGill University, Mr. LeBlanc was previously assistant to the resident engineer of the Quebec North Shore & Labrador Railway Company.

**Wallace L. Angus,** S.E.I.C., a 1953 graduate of the University of Toronto, is mining exploration engineer with Ventures Limited at Ore Knob Mine in Jefferson, N.C.

He was previously an engineer in training with Wright Hargreaves in Kirkland Lake, Ont.

**Tom McGreer,** S.E.I.C., is associated with the Department of Highways of the Province of Alberta in Two Hills.

Mr. McGreer received his B.Sc. degree in civil engineering from Queen's University in 1953.

**R. W. J. Moore,** S.E.I.C., has accepted the position of assistant city engineer with the City of Woodstock, Ont.

Mr. Moore graduated in civil engineering from the University of Toronto this year.

Johannes Defeyter, S.E.I.C.

**Johannes Defeyter,** S.E.I.C., who has been an engineer in training with the Canadian Westinghouse Company in Hamilton, has joined Canadian Industries Limited.

A native of the Netherlands, Mr. Defeyter received his M.Sc. degree in engineering from the Institute of Technology in Delft in 1953.

He is a member of the Royal Society of Engineers in Holland.

**Robert Brunette,** S.E.I.C., has been transferred from Beauharnois, Que. to the Northwestern Quebec System of the Quebec Hydro-Electric Power Commission in Noranda.

Mr. Brunette is a 1953 electrical engineering graduate of Ecole Polytechnique.

**Ronald T. Haine,** S.E.I.C., is maintenance engineer with Canadian Tube & Steel Products Ltd. in Montreal.

A 1953 graduate in mechanical engineering of Queen's University, Mr. Haine was previously associated with the Consolidated Pulp & Paper Company in Grand'mere, Que.

**Derald A. Harris,** S.E.I.C., formerly with Quebec Metallurgical Industries Ltd. in Whitehorse, Y.T., is now design engineer with the architectural branch of the Province of Alberta.

He is a 1953 graduate in civil engineering of the University of Alberta.

**C. Irwin Cameron,** S.E.I.C., has left the employ of the City of Saint John, N.B., where he served as structural engineer and is now on the staff of the bridge department of the Province of Nova Scotia.

Mr. Cameron is a graduate of the University of New Brunswick in civil engineering, class of 1953.

**W. A. Pangborn,** S.E.I.C., is associated with the John F. Wickenden Construction Company in Three Rivers, Que.

Mr. Pangborn graduated in civil engineering from McGill University in 1953.

**Maurice Steele,** S.E.I.C., a 1953 geology graduate of the University of Manitoba, is on the staff of the Hydro-Electric Power Commission of Ontario.

**D. I. Tilden,** S.E.I.C., a 1953 graduate in civil engineering of the University of Saskatchewan, is in the employ of the Pate Engineering Company of Tulsa, Okla.

**J. Alberto Dada,** S.E.I.C., a graduate this year in electrical engineering of McGill University, is associated with the firm Dada-Dada & Co. in San Salvador, El Salvador.

**Danny T. Nishimura,** S.E.I.C., who graduated this year from the University of Alberta in chemical engineering, is associated with Atomic Energy of Canada Limited in Deep River, Ont.

**Anthony King,** S.E.I.C., is with Canadian Pratt & Whitney Aircraft Co. Ltd. in Longueuil, Que.

Mr. King graduated in mechanical engineering from the University of Manitoba this year.

**Morris Jakowec,** S.E.I.C., is associated with the Dibblee Construction Company in Hawkesbury, Ont.

Mr. Jakowec graduated this year in civil engineering from Queen's University.

**A. E. Houghton,** S.E.I.C., after graduating in mechanical engineering from the Nova Scotia Technical College this year, has accepted employment with Cia Colombiana de Electricidad in Barranquilla, Colombia.

**Andre C. Hebert,** S.E.I.C., a graduate this year in electrical engineering of Laval University, is associated with the Hydro-Electric Commission of Quebec in Montreal.

**D. L. Gingerick,** S.E.I.C., is petroleum engineer with the Tide Water Associated Oil Company in Regina.

He graduated this year in mechanical engineering from the University of Saskatchewan.

**John M. MacLeod,** S.E.I.C., who graduated this year in metallurgical engineering from the Nova Scotia Technical College, is on the staff of the production department of the Shell Oil Company in Calgary.

**Charles E. Brabant,** S.E.I.C., formerly with the Calgary division of the Shell Oil Company, is now with Metropolitan Vickers Electrical Company Limited in Trafford Park, Manchester, England, on an Athlone Fellowship.

Mr. Brabant graduated this year in electrical engineering from McGill University.

**Gilles E. Dorion,** S.E.I.C., who graduated in civil engineering from McGill University this year, has joined the firm of Geo. Demers, consulting engineer in Quebec City. He was previously associated with Canadian National Railways as junior assistant engineer in Quebec City.

**Donald A. Buchanan,** S.E.I.C., is on the staff of the patent section of the research development department of the Hooker Electrochemical Company in Queenston, Ont.

Mr. Buchanan graduated this year in chemical engineering from the University of Toronto.

**Richard P. Stewart,** S.E.I.C., a graduate this year in mechanical engineering of McGill University, is on the staff of Canada Iron Foundries Limited in Three Rivers.

**Henry Strozyk,** S.E.I.C., is associated with Canadian Petrofina Limited in Montreal.

**G. Sernas,** JR.E.I.C., who graduated in civil engineering from the University of Toronto this year, is on the staff of consulting engineer Gordon Urwin of Oakville, Ont.

**Eugene M. Yaremy,** S.E.I.C., a graduate this year in mechanical engineering of Queen's University, is on the staff of the application engineering department of Taylor Instrument Companies of Canada in Toronto.

**Jean Tetreault,** S.E.I.C., has been employed on the Bersimis Quebec transmission line as engineer for technical projects for the Quebec Hydro-Electric Commission since graduation this year in civil engineering from McGill University.

**A. N. Tufts.** S.E.I.C., a graduate of this year of the University of Saskatchewan in mechanical engineering, is on an 11-month training program with the British American Oil Company in Toronto.

**M. Tomlinson,** S.E.I.C., has been employed as field engineer with Shawinigan Engineering Co. Ltd. in Montreal since his graduation in civil engineering from the Nova Scotia Technical College this year.

**Frank W. Taylor,** S.E.I.C., who graduated this year in civil engineering from the Nova Scotia Technical College, is maintenance engineer in the explosives division of Canadian Industries Ltd. in Nobel, Ont.

**Ivar Thomassen,** S.E.I.C., has been employed by the Hydro-Electric Power Commission of Ontario in Toronto since his graduation in civil engineering from the University of Manitoba this year.

**E. C. Barrett,** S.E.I.C., is development engineer in the Welland plant of North American Cyanamid Ltd. in Niagara Falls.

Mr. Barret graduated this year in chemical engineering from the Nova Scotia Technical College.

**S. A. Endersby,** S.E.I.C., is on the staff of the Aluminum Company of Canada Ltd. in Isle Maligne, Que.

**Jose Weiss,** S.E.I.C., a 1953 mechanical engineering graduate of McGill University, is treasurer and technical advisor with Industrias Lanacero, S.A. in Havana, Cuba.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Laurence Bradley Kingston,** M.C., M.E.I.C., formerly of the Gulf Pulp and Paper Company of Quebec City, was killed together with his wife at a level crossing near Kingston, Ontario, on October 1, 1953. This information only recently reached the Institute.

Mr. Kingston was born in Ottawa on August 6, 1883. He received his general education at the Ottawa Collegiate Institute, and in 1908 obtained his B.Sc. degree in civil engineering from McGill University.

Previous to graduation he was employed as a draughtsman, topographer and transitman with the National Transcontinental Railway. Upon graduation he became transitman with Smith, Kerry and Chace Ltd. on the Matabitchouan Power Company plant. During the succeeding five years he was resident engineer for the same firm on the Auburn Power Company plant, the Healey Falls Power Company plant and the Sidney Power Company plant. In 1913 he became engineer with Morrow and Beatty Ltd. on the Abitibi Power and Paper Company's hydraulic development and paper mill at Iroquois Falls.

He joined the Canadian Field Artillery in 1915 and served overseas until 1919, first as a lieutenant and then as a captain. He was awarded the Military Cross for outstanding service.

Upon his return to Morrow and Beatty Ltd. he was appointed manager of the Bathurst Lumber Company's hydro-electric development. Mr. Kingston was associated during 1922-1923 with Walter J. Francis and Company on the Paugan Falls investigation and report. He was employed by Dominion Safety Locknut Co. Ltd. as works manager in 1925-1926, and the following year served as resident engineer with consulting engineer George F. Hardy on the Ste. Anne Paper Co. Ltd. mill.

In 1927 he joined the Anglo Canadian Pulp and Paper Mills Ltd. as construction engineer, and two years afterwards became chief engineer of the Quebec Logging Corporation, a subsidiary of that company and the Ontario Paper Company. In 1932 he was appointed resident engineer with George F. Hardy and the Anglo Canadian Pulp and Paper Mills on the extension of the mill of its affiliated company, the Anglo Newfoundland Development Company.

He became chief engineer in 1934 of the Gulf Pulp and Paper Company which operates a groundwood mill at Clarke City, Que. Nine years later he re'oined the Anglo-Canadian Pulp and Paper Mills Ltd. at Quebec City as works engineer in the shipbuilding division, and in 1944 he was engaged in developing a new town water supply and storage system for the Municipality of Chandler, Que.

He was plant engineer for Gaspesia Sulphite Co. Ltd. at Chandler in 1948 and 1949, and also acted as consulting engineer for the Municipality of Chandler during the year 1951, after his official retirement from the company in 1949.

Mr. Kingston joined The Engineering Institute of Canada as a Student in 1905, transferring to Associate Member in 1912, and to Member in 1934.

**Roderick Bearce Young,** M.E.I.C., associate director of research of the Hydro-Electric Power Commission of Ontario, and one of the world's top authorities on concrete, passed away in the Wellesley Hospital in Toronto on August 24, 1954.

Mr. Young was born in Minneapolis, Minnesota on April 24, 1891. He was educated at schools in both the United States and Canada and matriculated from the Brandon Collegiate Institute. He received his B.Sc. degree in civil engineering in 1913 and his C.E. degree in 1919 from the University of Toronto.

Previous to graduation he was employed during the summers as axeman, tapeman, rodman and instrumentman with the Canadian Pacific Railway, and as an apprentice engineer in the shop, sales and test departments of Canadian Westinghouse Co. Ltd.

After graduation he joined the Hydro-Electric Power Commission of Ontario as assistant engineer in the structural materials department of the laboratories responsible for carrying out all chemical and physical testing and research investigations of engineering materials as well as field and shop inspection work. He was then promoted successively to the positions of engineer in charge of the structural research department and assistant chief testing engineer. In the latter position he was responsible for the shop inspection of all generating equipment, penstocks, castings, tower steel, and similar items used by the Commission. Mr. Young became assistant director of research when the research and testing department obtained division status in the general reorganization of the Commission in 1948. He was appointed associate director of research in 1951 and from that date until the time of his death he served in a consulting and advisory capacity.

Mr. Young was well known for his work in the field of concrete research, particularly through his activities with the American Concrete Institute which he joined in 1917, served as its president in 1940-1941, and which elected him to honorary membership in 1953. He was, either as author or co-author, one of the most frequent contributors of papers in the Institute. In 1937 his paper, "Concrete — Its Maintenance and Repair" was awarded the Wason Medal of the American Concrete Institute for "the most meritorious paper of the year". Earlier, his paper, "Producing Concrete of Uniform Quality" earned him in 1928 the Thomas Fitch Rowland Prize of the American Society of Civil Engineers. This was one of the few instances when the award was made outside the Society.

Mr. Young was a member of the Committee for the Long Time Study of Cement Performance in Concrete, organized by the Portland Cement Association. He was also active in other fields both in this organization and in the American Society of Testing Materials.

He joined The Engineering Institute of Canada as a Student in 1911, transferring to Junior in 1916, to Associate Member in 1918, and to Member in 1923. He was a past chairman of the Toronto Branch and served as a councillor representing that branch. In January of this year he was named a Life Member of the Institute.

**Stuart Southmayd Scovil,** M.E.I.C., Ottawa consulting engineer and authority on river flow, storage and related branches of hydraulic engineering, passed away in hospital on July 17, 1954.

Mr. Scovil was born at Kenora, Ontario, on May 17, 1886. He received his B.Sc. degree in electrical and civil engineering with honours from Queen's University in 1912. While attending university he was employed during the summers of 1908 and 1910 as chainman on Alberta government road surveys and on the assembly department staff of Canadian Westinghouse Co. Ltd. in Hamilton.

In 1912 Mr. Scovil was appointed assistant engineer by the Department of the Interior in Winnipeg, and was engaged on power and hydrometric surveys of Manitoba. The following year he was transferred to Ottawa as assistant chief engineer.

In 1914 he was named chief engineer of the Lake of the Woods Technical Board of the Water Power Branch of the Department of External Affairs. This board was organized at that time to co-ordinate various Canadian interests in making representations to the International Joint Commission. He was later engaged on other investigations in connection with Rainy Lake and other boundary waters. He resigned from the Department (now known as Dominion Water Power and Resources) as assistant director in 1925, but continued to serve the Department in a consulting capacity until 1934. For a year, 1926-1927, he was a partner in the firm of H. G. Acres and Company at Niagara Falls, maintaining an office in Ottawa.

In 1927 he began a consulting practice as a hydraulic engineer in Ottawa. In this capacity he was retained by the Gatineau Power Company, the Hydro-Electric Power Commission of Ontario, the Dominion Government, the Winnipeg Electric Company and the International Paper Company as well as many construction companies. He was long associated as consulting engineer to Montreal Power and later to Quebec Hydro, and for the last several years, was superintending and consulting engineer for the Chaudiere Water Power owners and lessees. One assignment during this period was in connection with the extensive hydraulic investigation related to the Beauharnois hydro-electric development on the St. Lawrence River.

From 1935 until 1940 he was Canadian arbitrator on an international arbitration case on the Saint John River which he won.

In 1951 Mr. Scovil designed the cut at the Seven Sisters power plant in Manitoba.

Mr. Scovil enlisted for overseas duty in 1915, but was recalled by Sir Robert Borden to continue work on the Western Waterways. He was then sent to Washington where he assisted in drafting the Western Waterways treaties. When these were completed he re-enlisted and served overseas from 1917 until 1918.

He was a member of the Association of Professional Engineers of Ontario. He joined The Engineering Institute of Canada as a Member in 1921.

**Harold Stewart Dunn,** M.E.I.C., founder and president of Dunn Construction Company Limited in Truro, Nova Scotia, passed away on June 2, 1954.

He was born in Moncton, New Brunswick, on December 14, 1891, and received his general schooling at the Aberdeen High School there. He graduated in 1926 from the International Correspondence Schools in mining and railroad engineering.

Mr. Dunn began his engineering career as chainman on the Intercolonial Railway, and as rodman and transitman on the National Transcontinental Railway. In 1911 he joined the Grand Trunk Pacific Railway as transitman in Saskatchewan and Alberta, and later in the same year, the Canadian National Railways in Ontario where he remained until 1913. During the next two years he served as transitman for the same railway company in Truro and New Glasgow.

He joined the Canadian Expeditionary Force in 1916 and served as a lieutenant with the Canadian Engineers until May, 1919. Upon his return to civilian life he resumed his position with the Canadian National Railways in New Glasgow.

In 1920 Mr. Dunn joined the Bras d'Or Coal Company in North Sydney, Nova Scotia. He continued there as mining engineer until 1926 when he was appointed chief engineer with the Alton, Quincy and Northern Railway in Quincy, Illinois. Returning to Canada in 1929, he became resident engineer on construction work with Canadian National Railways. In 1932 he was named superintendent of construction for the William Cooke Company in North Sydney.

Mr. Dunn joined the Royal Canadian Engineers during the period of 1940 to 1946 and served as officer commanding of No. 6 Company in Halifax, and as district works officer. He retired from the Army in 1946 with the rank of major, and subsequently founded his own construction company in Truro.

Mr. Dunn was a charter member of the Association of Professional Engineers of Nova Scotia, and a member of the Nova Scotia Roadbuilders Association. He joined The Engineering Institute of Canada as an Associate Member in 1931, transferring to Member in 1940.

**Robert Percy Donkin,** M.E.I.C., professor emeritus of Nova Scotia Technical College, and one of Nova Scotia's best known authorities on technical research, passed away suddenly in Halifax on April 5, 1954.

Professor Donkin was born at Port Mulgrave, Nova Scotia, on July 4, 1888. He attended Horton Collegiate Academy, and Acadia University where he received his engineering certificate in 1912, and the Nova Scotia Technical College from which he graduated with a B.Sc. degree in engineering in 1914.

Professor Donkin began his engineering career in 1915 as a draughtsman with Blair Manufacturing Co. Ltd. in Dartmouth. The following year he became associated with Nova Scotia Tramways and Power Co. Ltd. as chief draughtsman on gas works construction, and was promoted to the position of assistant to the general superintendent in 1917. During the following two years he was associated with the Department of Soldiers' Civil Reestablishment as instructor in machine tool operation, mathematics, gas engines and draughting.

In 1920 he became an instructor in mechanical engineering on the staff of the Nova Scotia Technical College, and subsequently became associate professor of mechanical engineering, a position he held for many years. As such he was well known throughout the province and eastern Canada for his work in connection with fuel research.

Professor Donkin was a director of fuel research for the Nova Scotia Research Foundation, and a member of the Association of Professional Engineers of Nova Scotia. He was also a member of the board of directors of the Halifax Infirmary and the Blue Cross Medical Association.

He joined The Engineering Institute of Canada as a Member in 1940.

**Robert Lee Schleihauf,** JR.E.I.C., sales engineer with Dow Corning Silicones Limited in Toronto, was drowned on July 22, 1954, while swimming in Lake Huron at Sarnia, Ontario.

Mr. Schleihauf was born at West Lorne, Ontario, on January 8, 1929. He received his early education there and at Dutton. In 1946 he entered Queen's University, and in 1950, graduated with a B.Sc. degree in chemical engineering.

During the summer of 1948 he was employed by the Department of Lands and Forests of Ontario, and did survey work on crown lands in eastern Ontario. The following summer he was employed as a pipe cleaning machine operator by Dokken Pipe Line Construction Co. Ltd. in Edmonton, Alberta.

He joined Aluminum Company of Canada Ltd. after graduation and was appointed ore plant supervisor at the Arvida plant. Two years later he left Arvida, and after a brief period of employment with Alsco Products in Toronto, he joined Dow Corning Silicones Limited.

Mr. Schleihauf joined The Engineering Institute of Canada as a Junior Member in 1951.

# Employment Service

THIS SERVICE is operated for the benefit of members of The Engineering Institute of Canada and for industrial and other organizations employing technically trained men—without charge to either party. It would be appreciated if employers would make the fullest use of these facilities to list their requirements—existing or estimated.

NOTICES appearing in the SITUATIONS WANTED column will be discontinued after three insertions. They will be reinstated, on request, after a lapse of one month.

REPLIES to advertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Canada, 2050 Mansfield Street.

INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLateau 5078—may be arranged by appointment.

## SITUATIONS VACANT

### CHEMICAL

GRADUATE CHEMIST, required to be trained as assistant to chief chemist. Plant located at Cardinal in Ontario in one of Canada's oldest food industries. Forward all details of experience, education, with pictures, and anticipated salary to File No. 4837-V.

CHEMICAL ENGINEER required to work in control department of paper mill located in Province of Quebec. Graduate from a Canadian or British University. Pulp and paper experience desirable but other chemical engineering experience would be acceptable. File No. 4915-V.

CHEMICAL ENGINEER or chemist, preferably with experience in paint, printing inks, rubber or plastic industries. To sell chemicals in Toronto district. Apply fully in writing to File No. 4960-V.

SALES ENGINEER required by progressive Vancouver company specializing in process equipment in Western Canada. Canadian graduate preferred with experience in chemical or petroleum industries. Excellent opportunity for man with initiative and personality. File No. 4961-V.

CHEMICAL SALES OPPORTUNITIES for engineering graduates. Young graduates to develop three-on-the-job training within sales organization and graduates with sales experience in chemical or allied field. File No. 4964-V.

CHEMICAL ENGINEERS required for refinery located in South America. Must be experienced in process engineering including design, economic studies, and/or scheduling of operating programs. Write giving age, education, marital status and complete details of experience. File No. 4970-V.

CHEMIST OR CHEMICAL ENGINEER for control department of a newsprint and specialty mill in P.Q. Preferably some experience in pulp and paper. Duties to include development and mill investigations. Give details of experience and references in initial letter. File No. 4982-V.

### CIVIL

THE TOWN OF BRIDGEWATER, Nova Scotia requires the services of an experienced civil engineer for regular municipal services. Reply stating age, municipal experience, and when available to File No. 4921-V.

SALES ENGINEER for promotion and sales in professional field. Background in structures and/or construction. Preferred age early thirties. Location Ontario. File No. 4922-V.

GRADUATE CIVIL ENGINEER with about 2 years experience required by major oil company. Duties include job inspection; service stations, bulk storage depots and marine terminals. Preferably bilingual but not necessary. Territory Quebec and Eastern Ontario. File No. 4932-V.

CIVIL GRADUATES. Recent graduates in Civil Engineering required by structural steel firm, in Montreal. Men to be employed in Engineering Department. Experience in structural steel design of advantage but not necessary. Chances of advancement excellent. File No. 4938-V.

CIVIL ENGINEER required by established construction firm operating in the west suburbs of Toronto. Duties entail sewer, water and road layouts planning and general construction problems. Opportunity for a young man wanting to advance. Please reply stating age, education and experience. File No. 4939-V.

CIVIL ENGINEER required in a city in Western Canada to assist in the planning and designing and supervising of construction in extensions of sewers and also sewage treatment plant. File No. 4940-V.

OFFICE ENGINEER AND ESTIMATOR REQUIRED BY LARGE CONSTRUCTION organization opening new office in Montreal. Services of bilingual graduate engineer experienced in heavy construction. Duties involve quantity takeoffs, estimating and design. Good opportunity with permanent position for right party. File No. 4945-V.

CIVIL ENGINEER or architect engineer to act as assistant to chief engineer with large organization in the flour, feed and associated industries. Ten years in civil engineering required. 5 years of design, foundations, superstructures, steel and reinforced concrete, 3 years in construction, 2 years in project co-ordination and administration. $12,000., starting with annual improvements, benefits include health insurance, retirement plan, etc. File No. 4946-V.

GRADUATE CIVIL ENGINEERS required for specialized work in soil mechanics and foundation engineering. Post graduate study essential. Locations Montreal and Toronto with some travelling. File No. 4968-V.

APPLICATIONS WILL BE received by The Federal District Commission for the position of Junior Engineer on highway work in the Ottawa area. Duties would be to assist in design and supervision of highway location and construction. A recent graduate would be suitable preferably with experience on highway work. Salary will depend on qualifications and experience. Position may lead to permanent employment. File No. 4969-V.

AN OUTSTANDING OPPORTUNITY for a qualified graduate engineer. Applicants must have had extensive supervisory experience in the construction of highways, dams, tunnels, bridges and like projects, together with a thorough knowledge of estimating and the preparation of tenders. This is a permanent position with an established firm. Write giving full particulars. File No. 4975-V.

WORLD RENOWNED INSTITUTE requires immediately a research engineer to work full time in the materials field for a highway research project. Work includes as well as practical testing, emphasis at the present time on bituminous pavement problems. Young civil engineer with at least a bachelor's degree. He should be interested in research and be able to work on his own. Experience in the materials field will be helpful. The opportunity is given to take one course per term. The salary is in the range of about $350 to $450 per month depending upon education and experience. File No. 4984-V.

CIVIL ENGINEER required by a municipal corporation in Western Canada. Recent graduate having some experience in railroad maintenance preferred. Other duties will cover the design and construction of water and sewage works. This job offers a good variety of experience in the municipal engineering field. File No. 4991-V.

### ELECTRICAL

ELECTRICAL UTILITY has opening for two junior electrical engineers or engineering graduates in Halifax, N.S. The work will provide opportunities for advancement along both technical and administrative line. Applicants should have a university degree and have not over three years post graduate experience. File No. 4904-V.

HEATING VENTILATION AND air conditioning specialists. Salaries up to $7,200 per annum. Department of Public Works, Transport and National Defence at Ottawa. Details and application forms at your nearest Civil Service Commission Office and National Employment Office. No. 54-1209. File No. 4905-V.

ELECTRICAL ENGINEERS (electronics and radar) salaries up to $6,840 per annum. Department of National Defence and Post Office Department, Ottawa. Details and application forms at your nearest Civil Service Commission Office, and National Employment Office. No. 54-1150. File No. 4906-V.

ELECTRICAL SALES ENGINEER required by manufacturer of switchboards high and low tension, panelboards, busways and switches to cover territory East of Province of Quebec and Maritimes. Bilingual preferred. Opportunity for the right man to become district sales manager. File No. 4918-V.

ELECTRICAL ENGINEER required to take charge of draughting and inspection of switchboards, panelboards, busways, switches, etc. Location Province of Quebec. Bilingual preferred. Opportunity for right man to become plant superintendent. Previous practical experience preferred. Permanent position, salary depending upon qualifications. File No. 4918-V.

PROJECT ENGINEER to join a rapidly expanding company which is a leader in the electronics field and offers scope for advancement. Applicant should be graduate in Electrical Engineering with a minimum of 2 years experience in Television designing, and the development of television and radio receivers, a knowledge of production manufacturing and production processing desirable. Excellent working conditions and a complete program of employee benefits. Salary is open for discussion. File No. 4927-V.

LARGE ALBERTA ELECTRICAL wholesale firm will, due to retirement, require an executive, qualified as an electrical engineer about 45 years of age. Must be a first rate administrator, now holding a very responsible position and able to manage a large portion of the company. A substantial investment in this company, will be made available to a top man with proper qualifications, personally and technically. File No. 4930-V.

PROCESS ENGINEER with about ten years manufacturing experience preferably in the electrical industry. He would report to the Works manager and would be responsible for methods and cost reduction studies, plant layout work and the supervision of time study, tool room and maintenance departments. A knowledge of sheet metal work, plastic moulding, metal finishing, assembly operations, material handling, etc., is desirable. The salary would depend upon the applicant's qualifications. File No. 4931-V.

A LARGE MANITOBA UTILITY requires a graduate electrical engineer to fill the position of assistant to the distribution engineer. Applicant should have at least three years experience in distribution practices, including layouts of large distribution areas; estimating of costs of distribution changes and extensions: improvement of voltage conditions and expansion of existing systems, basic economic studies and design of transformer and other special distribution system structure. Ability to write clear and concise reports to supervise one or more junior engineers and a group of draughtsmen and to deal with field staff is essential. A limited amount of travel within the province will be required. Location is in Winnipeg. Applicants should submit details of family status, age, educational background and experience. Applications will be treated confidentially. File No. 4948-V.

ELECTRICAL ENGINEER with at least five years experience on electrical maintenance and operating problems of generating stations and substations of public utility companies. Permanent positions with long established consulting organization New York. Some travel in Latin America. Spanish or Portuguese useful. Salary commensurate with experience. Reply stating age, education, experience and personal particulars. File No. 4950-V.

ELECTRICAL ENGINEER required as junior or assistant distribution engineer. Graduate with at least 3 years field experience operating utility company. Permanent position with long established consulting organization New York. Some travel Latin America necessary in future. Knowledge of Spanish or Portuguese useful. Salary commensurate with experience. Reply giving age, education, experience and personal particulars. File No. 4950-V.

TWO COMPETENT EXPERIENCED graduate electrical engineers, with approximately 10 years experience in design, operations and maintenance of distribution facilities in established rapidly growing utility located South America. Reply giving resume education, experience and personal data to File No. 4950-V.

GRADUATE ELECTRICAL ENGINEER interested in a career in Latin America with a Canadian owned electric light and power utility located Maracaibo, Venezuela. Age limit 30 years and should have 4 to 5 years' experience in electrical distribution. Immediate prospects for promotion to assistant distribution superintendent and ultimately to executive position if qualified. File No. 4953-V.

CITY IN WESTERN CANADA requires an electrical engineer. Duties: to prepare reports on problems of electrical distribution and utilization: to consult with large wholesale power customers concerning their electrical supply; to maintain technical records and perform related engineering tasks as required. Salary $335 to $408 per month (graduated scale). Qualifications: graduation in electrical engineering from a recognized university with some experience, preferably in electrical distribtuion system work. File No. 4976-V.

GRADUATE ELECTRICAL ENGINEER required with 1-5 years experience in contracting or consulting work to train as electrical representative in Hamilton office. File No. 4978-V.

SENIOR DESIGN ENGINEER with a degree in electrical engineering is required for our rotating machines. direct current design section. Applicants should be between 30-45 years of age, with at least six years experience on design of rotating electrical direct current machines in all sizes, including motors, generators, convertors and rotating regulators. He must possess ability to organize, plan, schedule, promote cost reduction and product improvement in engineering. In addition, he must have a thorough knowledge of direct current machine application, and the ability to promote teamwork. This is a senior appointment with excellent opportunity for promotion. Reply in confidence, giving full personal resume, experience, salary expected. File No. 4980-V.

SENIOR DESIGN ENGINEER required with a degree in electrical engineering for our rotating machines. Small motor design section. Applicants should be between 30-45 years of age, with at least four years experience on design of all types of fractional horsepower motors. He must possess ability to organize, plan schedule, promote cost reduction and product improvement in engineering. In addition he must have a thorough knowledge of small motor application and the ability to promote teamwork. This is a senior appointment with excellent opportunity for promotion. Reply in confidence, giving full personal resume, experience, salary expected. File No. 4980-V.

### MECHANICAL

TOOL DESIGNER REQUIRED mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools, light, sheet dies, forging dies, fixtures, jigs and gauges. Canadian background required. Location in Montreal. Write giving full details of training experience and state salary desired. File No. 4884-V.

MECHANICAL ENGINEER $4,100.00-$5,820.00 for Post Office Department, Montreal, P.Q. Details and application forms at your nearest Civil Service Commission Office, Post Office or National Employment Office. File No. 4916-V.

WANTED GRADUATE MECHANICAL ENGINEER with several years experience for work on design of steam power plants and industrial steam plants. South Eastern Ontario location. State full details. Your letter will be treated in strictest confidence. Our Staff knows of this ad. File No. 4933-V.

GRADUATE MECHANICAL ENGINEER required by Quebec (Eastern Townships) paper mill to act as assistant to mechanical superintendent. Some experience preferred but not essential. File No. 4944-V.

MECHANICAL ENGINEER with approximately ten years experience in production and administration for small sheet metal plant located in Toronto vicinity. Excellent opportunity for future. File No. 4949-V.

MECHANICAL PLANT ENGINEER required by operating division of service organization. University graduate preferred, having 5 to 10 years experience in operation and betterment of steam plants operated by public utilities. Location New York, some travel. Spanish desirable, but not necessary. Reply by letter giving age, education, experience, personal data, and minimum salary acceptable. File No. 4950-V.

SENIOR TOOL DESIGNER required by high class tool and gauge manufacturer in Southern Ontario. Must be mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools screw thread systems, fixtures, jigs and fixed and indicating types of gauges. Position provides good prospects for the future. Salary will be commensurate with ability. Reply in writing, stating details of age, experience, education and salary desired. Applications will be kept confidential. File No. 4951-V.

YOUNG MECHANICAL ENGINEER required for sales work. Must be energetic. have a good personality and the ability or a real desire to sell. Some knowledge of heating and ventilating equipment and their applications is desirable. Good opportunity for ambitious man, with right future in a growing business. Location Montreal. Write giving full particulars including training, experience, age and marital status. File No. 4954-V.

GRADUATE MECHANICAL DESIGN ENGINEER experienced in heavy industry machine design. He should have three or more years of applicable experience. His general duties would include supervision of work of several draughtsmen, stress analysis of structural steel machine frames and machine parts. Evaluation of new designs and improvements to existing designs. Good salary and opportunity for the right man with a well established medium sized manufacturer of pulp and papermill equipment. Location, northern New York State. Enclose full details as to qualifications, experience, salary expected, and recent photograph. File No. 4955-V.

MECHANICAL ENGINEER required in Regina, Sask., who is a graduate mechanical engineer and has at least five years practical experience in the design of heating, ventilating, air conditioning and refrigeration systems for buildings. Applicants reply giving full details and expected salary in first letter. File No. 4963-V.

PLANT MAINTENANCE ENGINEER, mechanical graduate with three to five years of applicable experience and the ability to supervise personnel for a chemical works engineering department located in the Province of Quebec. Please reply with full particulars to File No. 4967-V.

MECHANICAL ENGINEER required by paper mill located in Province of Quebec with head offices in Montreal. Ap-

## National Research Council Canada

### DIVISION OF BUILDING RESEARCH

## Snow and Ice Research

**With the completion of special laboratory facilities for Snow and Ice Research in the New Building Research Centre, Ottawa, the National Research Council, Division of Building Research invites applications for the following Research Officer positions:—**

**A Civil or Mechanical ENGINEER, preferably with knowledge of Soil Mechanics and some practical experience to work on the engineering aspects of snow and ice research, especially on field studies of ice and snow.**

**A PHYSICIST or Engineering Physicist with M.S.C. or Ph.D. degree to assist with the research programme to be developed in the new laboratory.**

**Salary will depend on training and experience. The opening provides challenging opportunities in a new field of work, vitally important to Canada. Applications with full details of education and experience should be sent to the Employment Officer, National Research Council, Ottawa 2, Ontario.**

---

plicant should have some paper mill experience or interest to be trained for such a position. File No. 4972-V.

MECHANICAL ENGINEERS REQUIRED for refinery located in South America. Must be thoroughly qualified and experienced in design of refinery or chemical plant equipment including piping, pressure vessels, heat exchangers, etc. Write giving age, education, marital status and complete details of experience. File No. 4970-V.

YOUNG MECHANICAL ENGINEER required for sales work. Must be energetic with a good personality and the ability or a real desire to sell. Some knowledge of heating and pumping equipment and their applications desirable. Location Toronto. Good opportunity with long established business concern. Write giving full particulars including training, experience, age and marital status. File No. 4981-V.

MECHANICAL ENGINEERS required for sales positions with prominent Canadian manufacturer. Experience in gear and mechanical power transmisison field would be an asset. Will be located in Ontario or Queoec. Write giving full details of training, experience and salary desired. File No. 4988-V.

JUNIOR DESIGN ENGINEER to be a graduate mechanical engineer, required for designing and making layouts of piping and equipment installations in a chemical engineering plant. Two years experience essential. Location Ontario. File No. 4990-V.

### MISCELLANEOUS

PROJECT ENGINEER, process-instrument engineer, and piping layout draughtsmen required by consulting firm located in Niagara Peninsula. Applicants must have considerable experience in refinery and chemical plant design and construction. Please write stating qualifications and full details to File No. 4910-V.

MECHANICAL OR ELECTRICAL ENGINEER with education equivalent to graduation in engineering and at least four and preferably six years of engineering experience. Must be registered professional engineer. Experience in plant maintenance and plant engineering is desirable, as well as experience in job installation supervision and in layout and design. Duties will consist of preparation of equipment layout for supermarkets and supermarket renovation and warehouse; plans for refrigeration, air conditioning, ventilation, plumbing, electrical etc. for supermarkets, supervision of mechanical plans prepared by consultants and correlation of these plans with architectural plans; calling of tenders for mechanical trades; the preparation of maintenance work orders for field forces and minor amount of field supervision. File No. 4914-V.

PATENT OFFICER REQUIRED at Ottawa. The successful applicant will be required to undertake various duties dealing with patent applications in the electronic field. University graduation in engineering physics, electrical engineering or physics, with specialization in electronics is required. Pertinent experience desirable but not essential. Initial salary up to $4620.00 per annum depending on qualifications. Apply by letter giving full details of education and experience. File No. 4917-V.

FIRE PROTECTION ENGINEER required for employment on a national basis in Canada preferably with headquarters at Ottawa, under direction of a group of regional and national forest industry associations to design and carry out fire research on all phases of the fire protection problem in Canada, to coordinate educational activities in fire protection and fire prevention, to generally conduct a public relations program on fire protection for the improvement of the standards of fire protection in all classes of properties and occupancies. Should have qualifications for membership in the Society of Fire Protection engineers. Should have experience in modern fire prevention theory and practice with some knowledge of the principle of fire insurance underwriting and fire loss adjustments; and should have ability to meet and address the public with authority on the above subjects. Salary commensurate with qualifications. Duties to commence as soon as satisfactory arrangements can be made. File No. 4919-V.

---

## REFINERY ENGINEERS

### SOUTH AMERICA

**Staff positions are available with a large American Company.**

**MECHANICAL ENGINEERS — must be thoroughly qualified and experienced in design of refinery or chemical plant equipment including piping, pressure vessels, heat exchangers, etc.**

**CHEMICAL ENGINEERS—must be experienced in process engineering including design, economic studies, and/or scheduling of operating programs.**

**Can also consider recent graduate Mechanical and Chemical Engineers for training.**

**Attractive salaries, liberal annuity and savings programs offered.**

**Write giving age, education, marital status and complete details of experience.**

**Box 308-Z**
**Radio City Station**
**New York 19, N.Y.**

---

OPERATIONS MANAGER required by long established and progressive pre mixed concrete company in major Canadian city. Man who is capable of taking complete charge of operating its 5 modern concrete plants and 100 plus truck mixer fleet. Applicants must have had previous experience and successful record in a similar capacity. Give age, particulars of experience, references, state when available and salary requirements. All replies will be treated strictly confidential. File No. 4924-V.

THE SASKATCHEWAN RESEARCH COUNCIL requires an industrial engineer preferably with mechanical or chemical experience to assist in making industrial surveys, to prepare reports on process and developments, and to provide liaison between science and industry. Position available immediately. Salary will depend on academic attainments and experience. Apply with all particulars, recent photo and addresses of reference, to File No. 4926-V.

NATIONAL PARKS ADMINISTRATIVE OFFICERS, $4,260.00-$4,860.00. National Parks and Historic Sites, Department of Northern Affairs and National Resources, Ottawa. Details and application forms at your nearest Civil Service Commission Office, Post Office or National Employment Office. Quote No. 54-652. File No. 4934-V.

SPECIALIST ON WEAPON Analysis. Salary up to $7,900.00 depending upon qualications. Department of National Defence, Ottawa. Preferably graduation in mechanical or electrical engineering. Details and application forms at your nearest Civil Service Commission Office and National Employment Office. Quote No. 54-1205. File No. 4935-V.

TECHNICAL ASSISTANT to the Chief Cartographer. Department of Mines and Technical Surveys, Ottawa. Salary $5,760.00 to $6,480.00. Address all enquires to the Civil Service Commission of Canada, Ottawa, and quote competition number 54-1707. File No. 4936-V.

ASSISTANT CHIEF ENGINEER. Salary $10,000.00 per annum. Harbours and Rivers Branch Department of Public Works, Ottawa. Details and application forms at your nearest office of the Civil Service Commission, Post Office and National Employment Office. Competition number 54-1258. File No. 4937-V.

ENGINERING FIRM Toronto requires the services of a graduate engineer with high academic standards and particular interest and qualifications in applied gas dynamics and fluid mechanics with special reference to flow machines. Applicant must also be willing to work on a broad range of investigation, design and development assignments including both mechanical and electro mechanical problems. File No. 4941-V.

DESIGN ENGINEER REQUIRED to undertake, under general supervision, the design and development of a wide range of mechanical products and devices. Preference given to applicants having higher N.C. and with design experience on aero engines or their accessories, alternatively to University graduates with post graduate experience in design of highly stressed light weight mechani-

### FOR 4 AGGRESSIVE YOUNG ENGINEERS

**SALES**

**One young graduate to develop thru on-the-job training within sales organization.**

**One graduate with sales experience in chemical or allied field.**

**PROCESS**

**Two chemicals to progress thru process development department to process supervision.**

**For details write**
**W. M. Kirk, Personnel Manager**

## DOW CHEMICAL OF CANADA, LIMITED

### SARNIA, ONTARIO

**(Inquiries Confidential)**

**CONTROL ENGINEERS FOR PAPER MILL AND PULP MILLS**

**Control engineers for paper mill and pulp mills situated in urban area in the province of Quebec. Applicants must be university graduates with a minimum of 3 to 5 years experience. Opportunity for advancement excellent. Salary commensurate with experience. File No. 4992-V.**

cal devices. Small engineering company located in Toronto Suburb. File No. 4941-V.

APPLICATIONS ARE INVITED for positions requiring engineers and technicians with adequate technical qualifications and practical in board and paper industry. Locations in West Pakistan. Free furnished married accommodation will be provided. Appointment on contract for 3 years including six months probation and provision for passage and leave. Successful applicants required at site early October, 1954. Applications stating full qualifications, experience, position held, age and accompanied by copies of references and passport size photographs should be sent in duplicate. For further information apply to File No. 4947-V.

YOUNG GAS ENGINEER wanted in connection with operation of two manufactured gas plants and distribution systems Excellent opportunity for future. Desire mechanical chemical graduate with few years experience manufactured gas. Reply stating age, experience, education and personal particulars. Location Panama, R de P. File No. 4950-V.

METER SUPERINTENDENT required by established rapidly growing utility in Brazil with 10 years experience in meter department of Canadian or large Latin American public utility to supervise meter departments in several operating companies. Single man preferred as considerable travelling involved. Reply giving resume education, experience and personal data. File No. 4950-V.

FIRE PROTECTION ENGINEER required by well known insurance brokers office. After a period of training, duties would consist mainly in inspection work and sprinkler equipments and eventually general work usual to an insurance brokerage business. Position offers excellent prospects to right party. File No. 4952-V.

SALES ENGINEER required by manufacturers of centrifugal pumps offer opportunity to young college graduate age 22-28, in sales engineering career. Edmonton area. Salary and commission. Reply in writing giving full particulars of age, education and background, including photograph. File No. 4955-V.

MECHANICAL OR ELECTRICAL ENGINEER for the position of instrumentation engineer to be responsible under the chief design engineer, for the application, design and selection of instrumentation and control equipment in connection with all operational phases of a self contained pulp and paper mill. File No. 4957-V.

ENGINEER FOR PATENT ATTORNEY'S office. Ambitious recent graduate with flair for writing and willing to learn, wanted as technical assistant in large Toronto patent law firm. This man will qualify to try registered patent agent examinations in three years. Apply by writing giving full details of education and experience. File No. 4959-V.

INDUSTRIAL ENGINEER required to head department of plant manufacturing diversified machinery and structural steel Location Province of Quebec. Prefer bilingual French Canadian. Good opportunity for advancement. Applicant should have good basic training, qualifications and technical references. Applications should be written in French and will be held in strict confidence. File No. 4966-V.

MECHANICAL, ELECTRICAL AND CIVIL ENGINEER required by organization in Ontario undergoing large development program. Each should have some construction experience. File No. 4962-V.

DIRECTOR ENGINEERING and water resources Branch. Salary up to $11,000., depending upon qualifications. Department of Northern Affairs and National Resources, Ottawa. Details and application forms at Office of the Civil Service Commission, Post Office or National Employment Office. Quote No. 54-685. File No. 4965-V.

**Mechanical or Civil Engineer**

**Mechanical or civil engineer required by large mining and milling firm in Eastern Townships for design of plant mechanical installations under supervision of a senior engineer. Will be responsible for layout, specifications, scheduling and engineering supervision of installations. Blue Cross, group life and pension plans available. Personal interview will be arranged at company expense for suitable applicants. Reply giving full particulars, including salary expected, to:**

**Employment Manager,**
**Canadian Johns-Manville Co. Ltd.,**
**Asbestos, Quebec.**

VEHICLE EXPERIMENTAL and Proving Officer. $5,100 to $5,820. Department of National Defence, Orleans, Ontario. Details and application forms at nearest office of the Civil Service Commission, Post Office or National Employment Office. Quote No. 54-1210. File No. 4971-V.

GRADUATE ENGINEER required for Industrial Work. This is an unusual opportunity in a reputable Montreal organization for a man between 25 and 35 years of age with experience in equipment maintenance and plant engineering. Some planning and development experience would also be advantageous. Please state full details of personal and professional background and salary required in first letter. All applications treated in strictest confidence. File No. 4973-V.

COMMUNICATIONS SYSTEMS PLANNING engineer. A leading Canadian electronics manufacturing and sales organization requires a senior engineer in its sales systems group. This man must be well versed in power utility communications, supervisory control, systems, telemetering, etc. Since this position is in a technical sales group, experience on or an adaptability for sales customer contact, cost estimation and contract bidding is essential. Salary will be commensurate with qualifications and demonstrated ability. File No. 4974-V.

GRADUATE ENGINEER in mechanical, civil or electrical engineering with a maximum of two years experience. General shop experience preferred. The duties of this engineer would be to assist the mechanical superintendent in the specification and procurement of material, as well as to study and follow up maintenance problems. The position leads to that of mechanical superintendent. Salary open. File No. 4977-V.

DESIGN ENGINEER for editorial position required on new technical publication covering the whole field of engineering design. Applicant should be a University Graduate in either mechanical or electrical engineering with practical experience in design engineering work. This is a senior position in a major publishing house and calls for a man who had technical writing experience. A most attractive proposition with good salary and hospitalization, life insurance and pension plans. All applications will be treated in strict confidence and should be as comprehensive as possible, detailing age qualifications and experience. File No. 4983-V.

AN ENGINEER NOT OVER 45 with some experience in estimating. We are a young company specializing in sewer and waterworks. We also do some wharfs and breakwater, etc., apply stating age, salary expected for the first year, graduation, experience and references. If satisfactory, the applicant will be sold an interest in the company. File No. 4987-V.

TIME STUDY ENGINEER preferably with a University Degree and 5 or 6 years experience required by electrical manufacturer in Ontario. Lacking a degree a good technical background might suffice provided the applicant had the necessary practical experience in time study. This position is permanent. File No. 4985-V.

ELECTRO CHEMICAL ENGINEER for plant operating electric arc furnaces. College graduate or equivalent with two years plant experience to carry out technical investigations and process studies. Ability to picture ideas by drawings essential. A working knowledge of French, mechanically inclined, have initiative and able to work with other members of our staff are all necessary qualities. File No. 4989-V.

DESIGN DRAUGHTSMAN required for designing and making layouts of piping and equipment installations in a chemical engineering plant. Five years experience essential. Age 24 to 30. File No. 4990-V.

## SITUATIONS WANTED

ELECTRICAL ENGINEER, B.Sc. (E.E.). Manitoba, 1943, P.Eng. (Ont.), M.E.I.C., age 34, married, requires immediate employment. Six years with Industrial

**Dept. of National Defence Ottawa.**

**To supervise inspection and proof of light and heavy ordnance equipment in Canada.**

**Details and application forms at Post Office, National Employment Office or nearest Civil Service Commission Office.**

**Quote Competition 54-1212.**

**CIVIL SERVICE OF CANADA**

Motor Control manufacturer, mainly application engineering including circuit design, plus general supervisory and manufacturing experience and liaison with sales, purchasing, production and inspection departments. Eighteen months with National Research Council, Ottawa. Three years Cdn. Army (R.C. Signals) immediately after graduation. Desires responsible position with consultant or manufacturer. Will locate anywhere. File No. 1408-W.

MECHANICAL ENGINEER age 32, Polytechnique 1945, bilingual. Employed as combustion engineer with large distribution of coal and fuel oil in Montreal. Extensive field experience on all aspects of fuel utilization, sales and service. Seeks employment with oil company or equipment manufacturers related to power engineering as combustion and/or sales engineer. File No. 2554-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng. (Ont.) B.Sc. (Queens) 1941, age 38, 13 years experience in manufacturing methods, process engineering, production engineering of high precision components, plant layout and engineering desires position as plant engineer or mechanical superintendent; available immediately. File No. 3272-W.

CIVIL ENGINEER, Jr.E.I.C., Alberta 1951, veteran, age 38, single. 3½ years experience in hydro-electric field, both in design and field work. Also experience in municipal engineering. Two years experience in airport construction with the Department of Transport. Location preference, Alberta or British Columbia. Desires position in hydro electric field, but will welcome offers from other civil engineering fields. Available on month's notice. File No. 3489-W

ELECTRICAL ENGINEER B.Sc. (E.E.) 1950 Jr. E.I.C., age 33, married. Presently employed managerial capacity in sales and sales promotion, directing small sales staff. Present earnings in excess $5,000.00. Varied experience in sales, sales promotion, office management and with Public Utilities. Desires responsible position in sales, sales representative or in line with experience. Details of education, experience and reference upon request. File No. 3375-W.

GRADUATE ENGINEER 1951 (Mining), age 30, is interested in position offering scope and responsibility where an engineering background is helpful (not necessarily in the mining field). Other training includes military engineering, RCAF service and business management course. Mining experience as miner, surveyor, layout engineer and mine engineer in base metal and industrial mineral operations. More recent duties have included engineering reports and studies and supervision of construction. Married, one child, available on reasonable notice. File No. 4000-W.

GRADUATE MECHANICAL ENGINEER, Jr.E.I.C., age 28, with four years experience in design and research in the hydraulic field is seeking position with a progressive company as designer and/or sales engineer. File No. 4102-W.

CIVIL ENGINEER B.A. (Honours) maths. B.Sc. (Civil Eng.) M.Eng. (McGill University). About two years experience in field and design work (structural and hydraulic work) in Canada. Age 26. Married, one child. Citizen of India. Available from October 1954 for teaching engineering design work in India or Colombo Plan countries, or Indonesia. Keen, hard working good references. File No. 4108-W.

MECHANICAL ENGINEER, Jr.E.I.C., 51 McGill graduate, 29 years of age, single. Completed 2 years graduate student training course with Canadian Electrical manufacturer. Presently engaged as manufacturing engineer. Desires a position with opportunity to demonstrate his ability. Location—anywhere. File No. 4217-W.

CONSTRUCTION ENGINEER, Jr.E.I.C., B.Eng. (Civil) McGill 1951 married. Considerable experience in design and field supervision of industrial and commercial projects, including steel, concrete and timber structures. Thoroughly familiar with office routine, estimating, writing specifications and preparing plans for tendering. Interested in position with progressive, growing firm of consultants or contractors. File No. 4273-W.

CIVIL ENGINEER, M.Sc., M.E.I.C., P.Eng. (Ont.), graduate 1947 is available. First class designer of all types of modern structures, inventive, enterprising and with flair for structures involving complex statical problems. File No. 4173-W.

GRADUATE ENGINEER, B.Sc., 1951, Jr.E.I.C., P.Eng., married, 3 years varied experience in mechanical handling and municipal engineering desires position in plant, mechanical handling or industrial engineering. File No. 4207-W.

CHEMICAL ENGINEER with several year's experience in control, operation and development in the field of metal finishing and protective coatings for appliances, chemical and food industry. Has had varied experience in finishing, design and maintenance of large factory equipment as well as small serial articles in aluminium, magnesium, steel and brass. Multicolor finishing on anodized aluminium. Formulation of cleaning, etching and phosphating solutions etc. Desires permanent position with opportunity for advancement. Will locate anywhere. File No. 4359-W.

MECHANICAL ENGINEER, Jr.E.I.C., 1950 graduate, Toronto, veteran, 32, single; some research experience, over three years in chemical industry on project and design work, involving process and services equipment and piping, instrumentation and building construction, including some estimating, purchasing, expediting and inspection. Desires position of greater responsibility in similar work or in maintenance work of a general nature. File No. 4418-W.

CIVIL AND STRUCTURAL ENGINEER, Jr.E.I.C., P.Ont. Cambridge University 1947. 6½ years experience, civil and structural engineering in industry, consulting engineering and research. Expert knowledge in structural analysis, specializing in prestressed concrete. Presently employed in Toronto. Desires change of employment where experience could be best utilized. File No. 4467-W.

ADMINISTRATOR, professional engineer in early forties, extensive manufacturing experience large corporations; well qualified industrial relations including contract negotiations, arbitrations, proven record in safety, supervisory training, policy formation, cost budgeting, maintenance and stores control; sales and warehousing experience; seeks challenging position in small or medium company. File No. 4496-W.

ELECTRICAL ENGINEER, B.A.Sc., Toronto, 1950, P.Eng. (Ont.) Jr.E.I.C., age 30, married, experience in industrial construction, field supervision, electrical generation and distribution, paper mill operation and maintenance. Desires position offering opportunity. Will locate anywhere. File No. 4545-W.

CIVIL ENGINEER, B.E. 1953 U. of S., Jr.E.I.C., seeks position in design and construction. Working at present with prominent Government engineering department. Interested in position with good possibilities for advancement. Willing to work hard. Single with car. Experience in surveys (all types), supervision of survey crews and construction crews, design in water and sewer lines, some concrete design. Was completely in charge of installation of many hydraulic structures, highway-type bridges, large culvert installations and a gravel contract. Has also had experience photoelastic analysis, soils studies and river studies. Has taken night classes in photography, welding and carpentry. Interview can possibly be arranged. File No. 4563-W.

GRADUATE CIVIL ENGINEER, D.R.T.C. (Glasgow), A.R.T.C. (Glasgow) San. Eng. (Glasgow), age 31 years, single, bilingual, willing to travel, desires senior position with responsibility in municipal engineering, contracting, concrete or structural steel installations. Experience: one year research work, 3 years general municipal engineer, 4 years drainage and irrigation experience in Malaya, including supervision of earth moving plant, reinforced concrete design, estimating, surveying, office routines, design of irrigation schemes and structures, chief assistant on a $5,000,000 (Canadian) irrigation scheme. Experienced in jungle clearing and swamp drainage. Available September 1st. File No. 4565-W.

MECHANICAL AND INDUSTRIAL ENGINEER, P.Eng., M.E.I.C., A.M.I.Mech.E., junior executive, 10 years experience of industrial plant specifications, layout, design and erection, also specialized machine design and plant maintenance. Interested in entering consulting field in Southern Ontario. File No. 4568-W.

CIVIL ENGINEER, McGill, 1951, Jr.E.I.C., P.E.Q., married. Presently employed as area field engineer, on large project. Experience— 6 months drafting, 2½ years office engineer (quantities, costs, progress reports etc.) and 1½ years varied field engineering in heavy construction. Seeks responsible and permanent position in Montreal with firm requiring above experience, or in design office. File No. 4579-W.

CHEMICAL ENGINEER, M.E.I.C., 1937 graduate, married, Canadian, would like to locate in the Toronto area. Experienced in pilot plant design, production and management phase of organic chemical plants both in Canada and the U.S. Interested in production and in sales in the field of chemical plant equipment or engineering services. File No. 4580-W.

ENGINEERING AND BUSINESS graduate Jr E.I.C., P.Eng. Ontario, B.A.Sc. Toronto (honours) 1953, age 24 single, C.G.E. test course graduate tool design and sales experience. Desires position with small or medium sized company in Toronto or South Central Ontario area. Prefers manufacturing or industrial engineering position leading to supervision and management. File No. 4581-W.

A YOUNG CIVIL ENGINEER, 27, married, with Master's degree in hydro-electric structures from Columbia University, New York, and with 4½ years' practical experience in design and construction of hydro-electric projects and reinforced and steel structures in U.S.A., India and Canada. Knows Eastern and Indian languages. Desires a suitable job with any concern working overseas in any part of the world, preferably in Eastern or Middle Eastern countries. Presently employed. File No. 4582-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng. (Que.), B.Eng. McGill 1951, single age 26, 1½ years' experience technical assistant sales in rubber industry, assistant construction engineer for new pulp and paper mill in New Zealand, assistant power engineer pulp and paper mill in Australia. Desires position with small manufacturing company in Montreal. File No. 4584-W.

CIVIL ENGINEER, university graduate, P.Eng., age 38, married, one child, with practical experience in road construction, surveying, steel structures and reinforced concrete (industrial structures and heavy foundations for power stations, steel mills, etc.) both with contractors and with consulting engineers, used to work on own initiative and responsibiltiy, attending to correspondence, site meetings and negtiations with clients, some knowledge of accounting and financial matters, at present with consulting firm, desires responsible position with construction company, consulting engineers or investment organization requiring the services of a competent engineer, preferably but not exclusively in Toronto. Apply File No. 4536-W.

MECHANICAL ENGINEER (Polish University College, London, 1951) specializing in aero and thermodynamics. Three years' experience as designer and draftsman in pneumatic and electric equipment. One year in Canada. Interested in position in research or development. Age 35. Will go anywhere. File No. 4587-W.

CIVIL ENGINEER, McGill 1950, with five years excellent construction experience (design, supervision of construction, costing). Two and a half years on construction with Canada's largest textile company. Recent overseas experience in pulp and paper mill construction, oil refinery construction, building design. Desires position with company allied with the construction industry where there is a chance for responsibility and advancement. Willing to work anywhere but preferably in the Toronto-Montreal area. File No. 4588-W.

DIPLOMA ENGINEER—CIVIL, age 41, with 10 years of varied continental and British experience on the design of concrete buttress, gravity and arch dams, weirs, sluices, tanks, fishpasses, large steel welded pipe lines, and structural steelwork, reinforced concrete and prestressed concrete bridges and industrial structures with shell roofs. Seeks responsible position in British Columbia, Ontario or Quebec. File No. 4590-W.

MECHANICAL ENGINEER, London University 1948. Experience includes 6 years, project and plant engineering in chemical industry, U.K. and Argentina. Presently employed in Canada in non-technical capacity. Desire position in line with previous experience. Location immaterial. File No. 4596-W.

CIVIL ENGINEER, B.Sc., Manitoba, M.E.I.C., ten years varied experience as designer and field engineer on plant construction and maintenance. Supervised structural and mechanical installations in Canada's largest pulp and paper, foundry, and automotive industries. Seeks position as assistant to resident or plant engineer with progressive company. Highest references and executive evaluation reports. File No. 4597-W.

PROFESSIONAL ENGINEER with master's degree in business administration, bachelor's degree engineering, 3½ years utility, 6 years manufacturing and sales, test course. Author technical papers. Accustomed to responsibility. Age 30. Seeks position with future. File No. 4599-W.

MUNICIPAL ENGINEER, M.E.I.C., age 46, bilingual, seeks managerial or senior engineering position with an expanding municipality. Also would consider work for a consulting firm specializing in town planning, design of subdivisions and municipal services. The advertiser would require some 2 or 3 months notice from his present position of project engineer for a large urban subdivision. File No. 4600-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng., married, 7 years design experience in pulp and paper equipment, heavy industrial and marine equipment, 4 years research and development in combustion engines, mainly diesel. File No. 4601-W.

MECHANICAL ENGINEER, M.E.I.C., P. Eng., grad. U. Riga, Latvia, age 43, family, 8 years preliminary and 14 years responsible practice. Latter includes: heating and plumbing, design and installation; industrial engineering, process, research, production, maintenance, design and supervising of plant expansions; construction engineering; roads — survey, design, construction. Four years of this experience in Canada and five under U.S. army in Germany. Available for an engineering appointment in Montreal area, end of April 1955. Interview—Jan. 1955. File No. 4602-W.

ELECTRICAL ENGINEER, B.Sc.E.E., Man. 1950, Jr.E.I.C., age 26 married, 1 child. Four years with public electric power utility, including supervision of transformer repair dept., supervision of recloser servicing, experience in metering installations and meter testing, and experience in various operational problems of power lines and associated equipment. Seeks position in work related to experience, preferably design, with manufacturer, power utility, or industrial concern where conscientious work and ability result in opportunity for advancement. Available on suitable notice to present employer. File No. 4603-W.

MECHANICAL ENGINEER, age 33, married, no children, university of Toronto 1943, veteran. Ten years industrial experience, four years design, engineering, manufacturing, production and purchasing, six years application, marketing, sales and service. Experience covers power plant equipment, pumps, feed water conditioning apparatus, boiler controls, materials handling equipment, electric, hydraulic and pneumatic control systems, petroleum products, mining machinery and power transmission machinery. Presently employed but desires challenging work for aggressive firm with opportunity for administrative and/or management career in sales, service or manufacturing. Would prefer Ontario, Alberta, or British Columbia. Particulars willingly supplied to interested employers. File No. 4604-W.

MECHANICAL ENGINEER, Australian. Graduated 1943, A.M.I.E. Australia, 32, married. No children. Experience includes field installation of mechanical or electrical plant, army workshop. Supervision large scale refrigeration unit. Design, development and manufacture of welded steel pipe plant. Physical testing, instrument calibration, materials investigation, lecturing in mechanical engineering and laboratory supervision Factory management. Consultant on steel fabrication factory design and layout. Recently arrived Canada. Desires position in or near Montreal. Available immediately. References. File No. 4605-W.

CIVIL ENGINEER, B.Sc., P.Eng., M.E.I.C., age 30, family. Desires to become permanently established in large city, preferably in Western Canada. Three years experience as city engineer in charge of public works and utilities. Experienced in sewer and water main installation, sidewalk and curb construction, drainage, paving. Four years experience as resident engineer on highway construction, four summers on federal government geodetic and irrigation surveys. Further particulars will gladly be forwarded to interested employers. File No. 4606-W.

MECHANICAL ENGINEER, M.E.I.C., P. Eng., age 36, married, wide experience in plant engineering, maintenance, plant layout, design and development in industrial and aeronautical field. Proven executive ability. Presently employed in managerial capacity. Wishes permanent position in progressive organization requiring initiative and ability. Montreal area preferred. Resume on request. File No. 4607-W.

# Attention, Members

Please telephone in advance and make an appointment if you propose using the Institute's Employment Department.

This will result in a better service to everyone concerned.

## Hamilton

N. A. Parry, Jr.E.I.C.,
*Secretary-Treasurer*
F. S. Gue, Jr.E.I.C.,
*Branch News Editor*

On Friday, September 17, Hamilton branch members were guests of the Hydro Electric Power Commission of Ontario during a visit to the St. Lawrence Hydraulic Model at Islington, Ont.

All present were impressed with the detailed information which could be obtained from the elaborately constructed concrete model of "Canada's River." From the model an insight into the proposed Seaway was obtained which would be unavailable in any other way.

A model of the projected bascule dam structure and corrective works to be built in conjunction with the Sir Adam Beck G.S. No. 2 was also inspected.

The Branch is indebted to Mr. Don Harkness, Assistant Hydraulic Engineer, Power Generating Division, H.E.P.C., for supervising the tour.

Louis Bresolin, Jr.E.I.C.,
*Secretary-Treasurer*

***Professional Development Program***

Four years ago the Toronto Branch initiated a Professional Development Program consisting of a series of lectures, with discussions, on a general range of subjects. From its outset the program was an outstanding success, and last year a second group was added to permit a larger participation, and to round out the development of those who had already attended the previous series. The enthusiasm of the graduates of this second series was so great that they have decided to continue their association by meeting in a discussion group this autumn which will be called Professional Development Course III. Registration took place in late September, and regular meetings will be held once a week for each group in the Wallberg Memorial Building at the University of Toronto.

The tentative program received by the *Journal* indicates that this year's activities will hold plenty of interest, and could well fulfil the announcement's promise of the best year yet. It is particularly noteworthy that this whole Professional Development Program is being organized and directed by the younger members of the Toronto Branch, the chairman of the three groups being either Juniors or Students.

***Plant Tour***

On Sept. 9 some 35 members of the Cornwall Branch of the Engineering Institute of Canada toured TCF of Canada Limited, a plant that is producing transparent packaging material. The members were guided on a two-hour tour by works manager A. E. King and departmental heads. The Company's president R. K. Tinkler was also present.

Manufacture of TCF — transparent cellulose film — is largely automatic, and although the company plans to produce some 200 tons of the material a week it employs less than 300 men and women.

***Viscose Extrusion***

Main operation of the process is extrusion of viscose on two identical machines that carry the product through several solutions, rolling the semi-finished film on spindles ready for the coating department.

The liquid viscose, contained in several large tanks, is filtered through screens and by a vacuum process before being pumped to the production machines. It is passed through a long aperture into a bath of sulphuric acid which changes the viscose to a semi-solid state.

From there, the material passes on rollers through baths of weaker solutions, each contributing to its coagulation. At this stage in the manufacture, the film remains semi-opaque and milky-white.

Passing at speed along the complex equipment, it is washed free of acid, bleached for transparency, washed again, softened with a glycerin solution before passing through a drying chamber.

After the drying process, another chamber adds some seven per cent of moisture to the product before it is rolled on spindles for the coating room.

The finished film is considerably narrower than the original viscose extrusion. Officials told the engineers that some 45 per cent is lost in the process.

Temperature control is strictly enforced in the coating department where potentially explosive nitro-cellulose is used for moisture-proofing. Here, the film is again placed on rollers, run through a lacquer bath, then up 90 feet through the drying tower.

***Recovery Plant***

A fully automatic recovery plant makes it possible to use 95 per cent of lacquer solvent released in the atmosphere of the drying tower.

Final stage of the tour took the visitors to the shipping rooms where the clear, crinkly film is cut to sizes specified by customers, packed and sent to manufacturers as far away as South Africa. Four grades of film are produced.

---

### Film Available for Branch Meetings

"Breakthrough" the drama packed motion picture on the driving of Alcan's ten-mile power tunnel at Kemano, B.C., has just been released by Canadian Ingersoll-Rand. Produced in sound and full color the film records in a concise and understandable manner the complete story of modern hardrock tunnelling.

The "breakthrough" of this 10-mile, 25-foot diameter giant tunnel represents a remarkable achievement in organization and team work, and an impressive tribute to the design and construction of the equipment used.

The company has arranged to show the film throughout the country and will give priority to requests received from Branches of the Institute. If your Branch is interested contact the local Ingersoll-Rand branch or write to the Film Department, Canadian Ingersoll-Rand Co. Ltd., 620 Cathcart St., Montreal, Quebec.

# LIBRARY NOTES

## Additions to the Institute Library

**Reviews — Book Notes — Abstracts**

### BOOK REVIEW

**Canada's tomorrow; papers and discussions, Canada's tomorrow conference, Quebec City, November 1953.** G. P. Gilmour, ed. Toronto, Macmillan, 1954. 324 pp., $3.50.

To celebrate its fiftieth anniversary, Canadian Westinghouse sponsored a conference in Quebec City in October 1953, the theme of which was "Canada's tomorrow". Nearly three hundred people attended, to participate in this experiment in national self-examination and prophecy.

The nine papers presented at the Conference, together with a digest of the discussions on them, are reproduced in this book, which is edited by G. P. Gilmour, the President of McMaster University.

The subjects discussed cover many aspects of the Canadian scene; the people, natural resources, the roles of science, industry and government, education, and cultural development. The last two papers deal with Canada's place in world affairs, and an outsider's view of the country.

The papers are both an analysis of past events and developments, and an attempt at objective appraisal of what the next fifty years may bring. The editor says in his introduction: "To many nations, the next fifty years will present problems of survival and of unity, of needed change in institutions or traditions: but to Canada the next half-century presents a happier prospect, of a people greatly blessed with goods and resources . . . with a record of representative government remarkably free from corruption, and with habits of honesty and decency of inestimable value. If it is not given to us to map the future, we can at least get a running start into it by discovering where we are and by what stages we have come thus far, and by gaining a sense of direction and an awareness of possible dangers."

Every Canadian interested in the future of his country should read this serious, stimulating book, written by some of Canada's leading figures. S.C.

### BOOK NOTES*

**Prepared by the Library**

**The Engineering Institute of Canada**

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

**Achieving your career.** J. S. Kopas and Wiley Garrett. Youngstown, Industrial information institute, 1953. 138 pp., $1.50 (U.S.).

Intended primarily for those attending high school in the United States, the aim of this book is to present a review of the various types of occupation existing in that country, and the educational and other requirements needed for each.

The material is presented in a simple form, and the book should be of interest to Canadian high school students, uncertain for which type of job they are best fitted.

**Bibliography of interlingual scientific and technical dictionaries,** 3rd ed. United nations educational, scientific and cultural organization. Toronto University press, 1953. 178 pp., $1.75.

This third edition of the Bibliography lists over fifteen hundred dictionaries in seventy-five languages, under more than two hundred and thirty subject headings.

The dictionaries are arranged by subject according to the Universal Decimal Classification. A key to this is included and there are language, author and subject indices. As it was intended to make the bibliography as complete as possible, listings include dictionaries which are not up-to-date, as well as those known to be out of print. The compilers have indicated those works known to them to be satisfactory and obtainable.

This bibliography will be an invaluable addition to the reference shelf of any library.

**Cabma register of British products and Canadian distributors, 1954-55** London, Kelly's directories and Iliffe 1954. 780 pp., $7.50.

The various sections of this register are: the Buyers' guide, an alphabetical list of products with their British suppliers and names of their Canadian representatives, followed by the French-English glossary giving the French equivalents of these products; an alphabetical directory of British manufacturers and distributors with details of the 4,500 firms concerned; Canadian distributors' announcements; proprietary names and trade marks. This new edition will thus quickly show the nearest, quickest and most convenient source of supply of any British product sold in Canada.

**Climatological atlas of Canada.** Canada, National research council. Ottawa, N.R.C., 1953. 253 pp., spiral binding, maps. $2.00.

Prepared jointly by the Meteorological division of the Department of transport, and the Division of building research of the National research council, this atlas was originally intended to be part of the 1953 revision of the National building code. However, it became evident that the amount of information available warranted the preparation of a separate work.

The eighty-four maps included in the Atlas show temperatures, both average and extreme, humidity, wind, snowfall, rainfall and total hours of sunshine.

A section of the book is devoted to Hythergraphs. These show in diagrammatic form the average annual climate of many Canadian locations, and of severa cities outside Canada for purposes of comparison.

This Atlas provides information on the Canadian climate in a form which will be of use to all those whose work is influenced by the weather: builders, architects, engineers and others, and will be of interest to those who are merely curious about our weather.

**Coastal engineering. Proceedings of the fourth conference on coastal engineering, October 1953. J. W.** Johnson, ed. Berkeley, Council on wave research, 1954. 398 pp., illus., $5.00 (U.S.).

This collection of papers covers a wide variety of problems connected with coastal engineering. The four main sections are titled Basic information for shoreline investigation; Shoreline sediment problems; Shoreline protection problems; .Design of shoreline structures. The

### LIBRARY REGULATIONS

#### Hours

Mon.–Fri. . . . . . . . 9 a.m. - 5 p.m.
Saturdays . . . . . . 9 a.m. - 12 noon

#### Bibliography and Reference Service

Short subject bibliographies are compiled on request. When placing these requests, please give as much detail and background information as possible.

#### Borrowing

Books, periodicals, pamphlets and films may be borrowed for two weeks at a time. All books included in the Library Notes Section of *The Engineering Journal* are available for loan. **A fine of 25c per day is charged for each day borrowed items are retained beyond the two-week period.**

A library deposit of $5.00 at par in Montreal is required, for which two items may be borrowed at a time. Temporary deposits (30 days or less) $10.00. Books are sent anywhere in Canada, and carrying charges are payable by the member concerned.

#### Ordering

Any book or pamphlet may be ordered through the library. All publications of affiliated societies, whether books, pamphlets, or periodicals, should be ordered through the library, as reduced rates are applicable on these to all members. Except in the case of library deposits **please make no payments in advance.** Non-members may consult the library, but may not borrow material. Please address all requests to **The Library.**

individual papers are too numerous to detail but many of them concern the shorelines of the Great Lakes and two deal with the coast of the Netherlands as it was effected by the floods of 1953. Other studies have as their subjects statistical analysis of wave records, characteristics of natural beaches, effect of ice on shore development and the shock pressure of breaking waves.

The papers are not indexed but the table of contents partially fills this need.

*__Diesel engine catalog,__ volume 19, 1954-1955. R. W. Wadman, ed. Los Angeles, Diesel Engines, Inc., 1954. 390 pp., $10.00 (U.S.).

Details on the engines and auxiliary equipment produced by the major manufacturers are given in this book. New designs and developments of the past year have been added to this edition and the accessories section has been expanded.

*__The economic almanac,__ 1953-1954. National Industrial Conference Board. New York, Crowell Company, 12th ed., 1953. 740 pp., $3.95. (U.S.).

Statistical tables on population, income, resources, foreign trade, individual industries and many other topics, selected on the basis of their significance to business and the general public, currency, and reliability. A glossary of terms and detailed index is provided.

**Electrical ignition equipment.** F. G. Spreadbury. Toronto, Longmans, Green, 1954. 227 pp., illus., $4.50.

In this book we find a comprehensive study of electrical ignition equipment within the framework of existing conditions which make new and greater demands upon this type of ignition. The use of ignition equipment ranges from driving the small auxiliary engine to propelling large tanks and aero engines, and the author outlines the principles, design and construction of equipment to meet these applications.

Formulae and tables help to illustrate the text which is divided into chapters on the ignition of explosive mixtures, sparks, ignition coils, magnetos and the testing of ignition equipment. Written at an intermediate level, its scope covers most present day ignition systems as well as some details of those that may have wider future applications e.g. electronic ignition systems.

*__The electromagnetic field in its engineering aspects.__ G. W. Carter. Toronto, Longmans, Green, 1954. 360 pp., $6.30.

A systematic, non-mathematical treatment of the theory of electromagnetism with reference to its engineering applications. Fundamentals of conductors, insulators, electric circuit theory, electromagnetic induction, and related topics are discussed, and are illustrated by appropriate problems. The MKS system of units has been adopted.

**Estimating construction costs.** R. L. Peurifoy. Toronto, McGraw-Hill, 1953. 315 pp., illus., $7.95.

This book, which determines unit costs of materials, equipment, and labor, should be useful to Canadians involved in construction work. These unit costs, which in this volume are related only to the preparation of detailed estimates, can be applied to any locality. The information consists of descriptive material, tables and examples. Tables involving labour give the approximate man-hours required to perform a specified quantity of work.

Separate chapters are devoted to various types of construction: earthwork and excavation; highways and pavements; foundations; concrete structures; floor systems; masonry; timber and steel structures; water and sewerage systems. Appendices include compensation insurance rates, costs of owning and renting equipment and a depreciation schedule.

**Fundamentals of transistors.** L. M. Krugman. New York, Rider, 1954. 140 pp., $2.70 (U.S.).

This is a practical manual of transistor information written for the technician and amateur. The first brief chapter outlines the basic physics of semi-conductors then the construction, operation, gain, and impedance characteristics of typical transistors are considered. In the fifth and sixth chapters transistor amplifiers and oscillators are considered with the text supplemented by many formulae and graphs. The basic circuitry, applications and limitations of the transistor are discussed in all these chapters, and the book closes with miscellaneous considerations, including transistor operation at high frequencies.

**Highlights of colour television.** J. R. Locke. New York, Rider, 1954. 44 pp., .99c. (U.S.).

This timely booklet is concerned with a practical system of colour television receiving. It is a qualitative explanation of this mode of television and is based on the recommendations of the National

Television System Committee. It defines colorimetry and discusses the transmitter and receiver with special attention to the problem of producing a colour television receiver which must perform all the functions of a black and white receiver and also provide the necessary circuitry to reproduce the colour information.

***Industrial fermentations,** volume I. L. A. Underkofler and R. J. Hickey, ed. New York, Chemical Publishing Company, 1954. 565 pp., $12.00 (U.S.).

The chapters in this volume, contributed by experienced industrialists and research workers, discuss in considerable detail specific fermentation processes of present or potential industrial significance. This volume covers alcoholic and butanol-acetone fermentations; the production of yeast; and the fermentative production of organic acids. Data given includes historical background, raw materials, microbial cultures, laboratory and plant practice, uses of products, and so forth. There is a bibliography after each chapter.

**Metals engineering design.** American society of mechanical engineers, edited by O. J. Horger. Toronto, McGraw-Hill, 1953. 405 pp., illus., $4.50.

Sponsored by the Metals engineering handbook board of the A.S.M.E., this volume is the result of a survey in 1941 by the Metal engineering division, which revealed the need of a ready reference to the properties and characteristics of metals.

It treats of modern refinements that affect design practices, analytical methods which replace older empirical formulae, and the economic aspects of the determination of one method of processing over another.

Selective bibliographies are included with each paper for more detailed study.

**The National building code of Canada, 1953.** Canada, National research council. Ottawa, 1953. 15 parts, $3.75.

This revision of the 1941 Building code shows many and drastic changes, especially in the arrangement of the parts. Each of the eight parts is complete in itself, requiring little if any cross-references to other parts. The first part gives administrative requirements and refers to local ordinances in allied fields. The second deals with climate and contains twelve climatic maps. The third part includes all the requirements for a building code which are dependent on the use and occupancy of buildings, irrespective of their type of construction. Part four is concerned with the actual structural design of buildings and part five contains all the specifications which have to be used to detail all ordinary building materials. The last three sections deal with general services, plumbing and safety measures.

This new building code will be a necessary reference work for anyone connected in any way with construction in Canada, and the compilers hope that this new Code will be adopted by all those municipalities which have been using the existing one.

**New Brunswick almanac, 1954.** Fredericton, Brunswick Press, 1954. 224 pp. pa. $1.00.

Described as an "attempt to provide a concise and ready source of information about the province of New Brunswick and its institutions, population, judiciary and government at all levels", this is the first issue of this almanac.

Provincial government and private organizations are listed and also registered barristers, dentists and doctors.

Miscellaneous government information, both provincial, federal and educational, cultural and religious organizations and statistics are included.

This will be a most useful handbook.

**Permafrost at Norman Wells, N.W.T.** R. A. Hemstock. Calgary, Imperial Oil Ltd., 1953. 100 pp., loose leaf binding.

Much attention is presently being paid to the subject of Permafrost, but exactly what constitutes Permafrost is a little difficult to define.

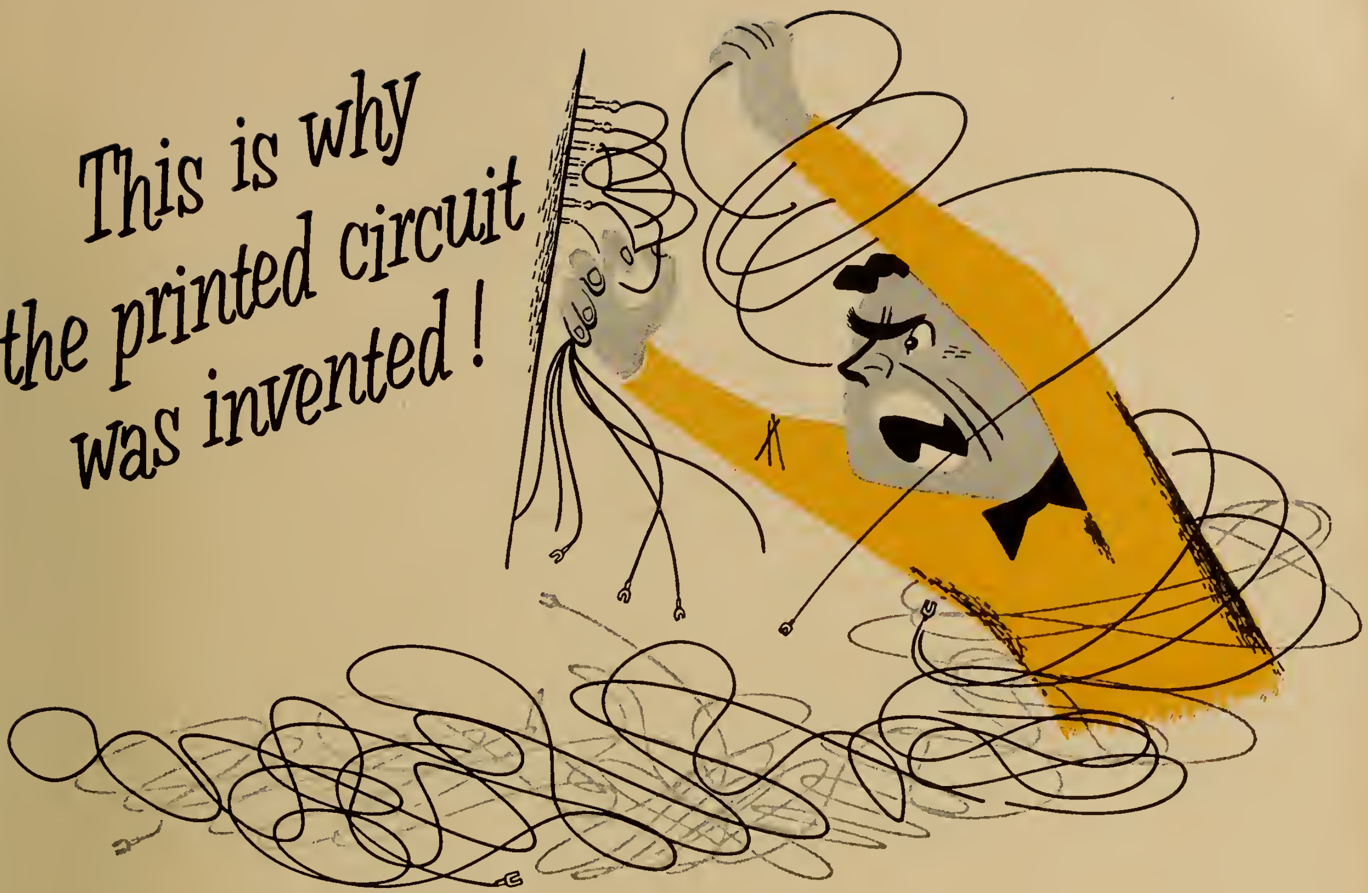
In this booklet, the whole subject of distance of frost beneath the surface, terminology, vegetation, break up, soil mechanics and their properties, and building potentialities and hazards are all considered and discussed from actual findings at Norman Wells. Numerous charts, maps and photographs are included with the text, as well as a number of bibliographical references.

This will be a valuable reference source for all engineers engaged in this field.

**Plastics progress, 1953.** Phillip Morgan, ed. London, Iliffe, 1953. 439 pp., illus., 50/-.

The papers and discussions which form the basis for this book were part of the British Plastics Convention held in June 1953. Plastics materials, methods and uses are covered and special attention is given to glass and asbestos reinforced plastics. Two chapters are devoted to unplasticised

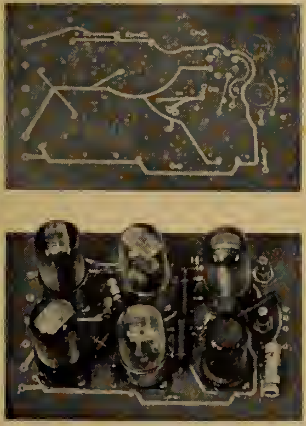
# This is why the printed circuit was invented!



The printed circuit is the inevitable and successful result of inventive man's effort to do old things in new and better ways. The old way of installing an electrical circuit, in such fields as radio, television, hearing aids, automatic signals and other low-power applications, was a slow, expensive hand-process which was susceptible to error. Many a complex system had real nuisance value for the manufacturer. The new way eliminates all this because the circuit itself is etched, or printed, onto a sheet of copper foil bonded to a base material.

Copper-Clad Phenolite—by National—holds the secret of success in printed circuits. The Phenolite core is a scientifically compounded laminate possessing *all* the properties and characteristics demanded for the job. Among these are high dielectric and mechanical strength, resistance to heat, moisture, solvents, oils, acids, alkalies. It is light in weight—can be machined, punched, sawed, drilled. Phenolite is the perfect material for printed circuits . . . and for many other uses in the electrical, electronics, and general industries.

There are 35 standard grades of Phenolite, each with special qualities. May we demonstrate their value to you . . . show you how these remarkably versatile materials can help you?



**PRINTED CIRCUIT . . . THE NEW WAY!**

*(Top) Copper-Clad Phenolite showing the etched conductor pattern for an audio amplifier. (Bottom) Here is the same etched circuit with tubes and other components in place. We have a complete bulletin crammed with ideas and data about our laminated plastics. May we send you a personal copy? Write either address, Dept. AB-10.*

**NATIONAL**

**FIBRE COMPANY OF CANADA, LTD.**

ATLANTIC & HANNA AVES., TORONTO • 1411 CRESCENT ST., MONTREAL

PHENOLITE Laminated PLASTIC

*Also manufacturers of Vulcanized Fibre, Vul-Cot Waste Baskets, Peerless Insulation, Materials Handling Equipment and Textile Bobbins.*

polyvinyl chloride in various forms, describing its composition, properties, fabrication and uses. Large mouldings and high quality injection moulding are discussed and four chapters describe the new uses of plastics in the fields of cables, vacuum coating, conveyor belting and footwear. A series of papers tells of the latest ideas on selling plastics to the public in the form of tableware, toys, etc. Graphs, photographs, bibliographies and a subject index increase the value of this collection.

***Principles of industrial psychology.** T. H. Ryan and P. C. Smith. New York, Ronald Press, 1954. 534 pp., $5.50 (U.S.).

An introductory survey of the entire field presenting a complete summary of the results of research and practical experiments. It covers selection, placement, motivation, fatigue, and other questions of importance to management, labor, industrial engineers, and personnel directors. The authors point out what the industrial psychologist can and cannot do at the present time and suggest directions for future research.

**Radio receiver design,** part 1. K. R. Sturley. Toronto, British Book Service, 1953. 667 pp., figs., $9.75.

Originally published in 1942, this is part one of the second revised edition, dealing with radio frequency amplification and detection.

Chapter 1 has been completely rewritten with increased stress on fundamentals of transmission and reception, and to Chapter 2 is added information on the calculation and measurement of valve noise.

Ensuing sections give additional information on self capacitance and mutual induction of coils and new material on crystal coupled I.F. transformers, and many symbols have been brought into line with accepted practice.

The very detailed index is a great addition to this volume.

**Slide rule; the autobiography of an engineer.** Nevil Shute. Toronto, McLeod, 1954. 240 pp., illus., $4.00.

Here is a fascinating book written by a man who is a success both as a novelist and as an aeronautical engineer. His experiences as a pioneer in aviation are worth telling to the world and his professional manner of presenting them make this autobiography interesting reading for engineers and the general public alike.

Nevil Shute begins his story with a brief account of his life up to the time when he became a summertime employee of the new De Havilland company, including the rather pathetic tale of the young man whose stammer prevented him from obtaining a commission in the R.A.F. Some mention is made of his early attempts at writing fiction and of his time spent at Oxford. But the greater part of his life history is closely linked to the history of aviation in England during the Twenties and early Thirties. The most exciting single event of that period was the building of the rigid airship R-100 which began in 1924 and culminated in a flight from England to Canada in 1930. Shute was at this time an engineer with Vickers but he later launched his own company, Airspeed, Ltd., and the latter part of his book describes the struggles and accomplishments of the growing business.

The few photographs of early aircraft make the reader wish that there were more, but few other criticisms can be made of this personalized chapter in the romance of aviation.

***Statistical analysis in chemistry and the chemical industry.** A. Bennett and N. L. Franklin. New York, Wiley, 1954. 724 pp., $8.00.

This book presents a selection of the statistical techniques most frequently used in the chemical and allied industries and is written on the level of the chemistry or engineering graduate. Basic principles of statistical inference are developed and more specialized methods — analysis of variance, design of experiments, analysis of counted data, and others — are treated in detail. Most of the examples have been taken from real situations in the chemical industry.

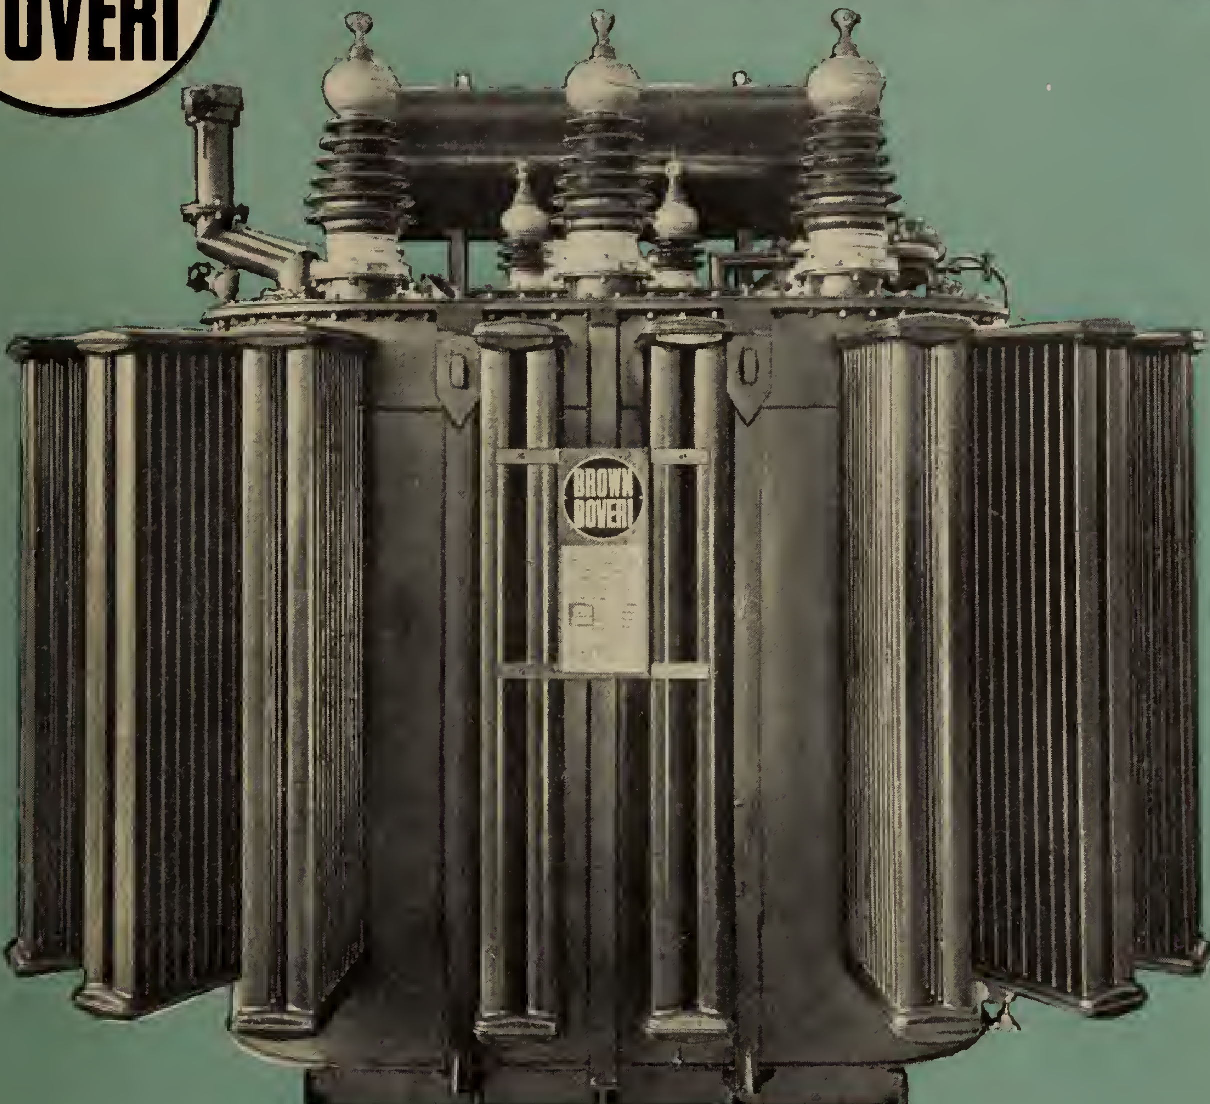
**Statistical methods in electrical engineering.** D. A. Bell. Toronto, British Book Service, 1953. 175 pp., $4.25.

This text is based on a series of lectures given at the University of Birmingham, and is directed to those wanting a work on the theory and applications of statistics of electrical engineering.

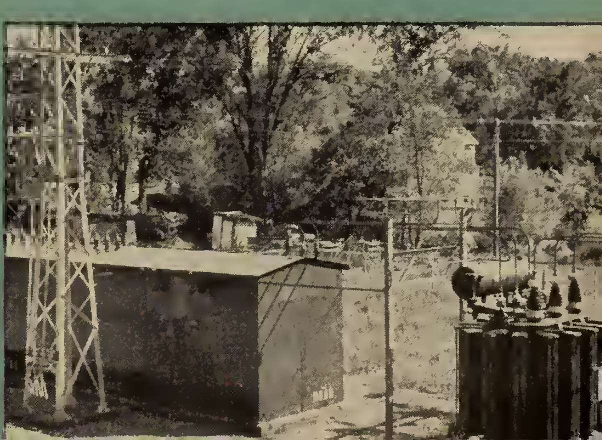
For this reason the bias of the book is towards continuous or quasi-continuous distribution. Some of the topics covered in the text are probability theory, qualitative classification, frequency distributions, curve fitting and the principles of quality control.

***The structure of metals and alloys,** 3rd. ed. W. Hume-Rothery and G. V. Raynor. London, Institute of Metals, 1954. 363 pp., $5.50 (U.S.). (Monograph and Report Series, No. 1).

The present edition, like the first, nineteen thirty-six, is written on an elementary level and deals mainly with the structure and composition limits of single phases. Topics covered include electronic background, crystal structure of elements, atomic radii, primary metallic solid solutions, intermediate phases in alloy systems, and imperfections in



BROWN BOVERI



crystals. A new section on steel and cast irons has been added, and the complete text has been brought up to date.

**The theory and practice of reinforced concrete,** 3rd ed., v. I. C. W. Dunham. Toronto, McGraw-Hill, 1953. 499 pp., illus., $8.50.

A new edition of this important book indicates the widespread interest in the subject of reinforced concrete. Many changes have been made in this edition, the most significant being that it has been divided into two volumes. Volume one, which is presented here, contains only the first nine chapters of the second edition, with six new chapters added, and the similar length of the two editions shows the amount of expansion which has taken place. This volume is directed to the undergraduate, while indeterminate structures and advanced material are to be included in a subsequent volume.

As in the second edition the first seven chapters present fundamental principles and concepts: beams, columns, bond stress, bending and compression. The next part of the book deals with retaining walls, footings, large slabs and forms. Because of the developments in prestressed and precast concrete and ultimate-load design, the author has included an introduction to these subjects. Tables and diagrams are again found in the Appendix and the last chapter is devoted to design problems.

**Vegetation and watershed management.** E. A. Colman. New York, Ronald, 1953. 412 pp., illus., $7.00 (U.S.).

The relationship of vegetation management to water control and supply is the central theme of this book which will be an important asset to the fields of water-supply and civil engineering, agricultural engineering, reclamation work, forestry, hydrology and soil science. For those readers who are not concerned with the technical details there are summaries of the research results in the pertinent chapters, and the liberal use of graphs and maps is an additional aid to full use of the information.

Dr. Colman describes the influence of vegetation on hydrologic processes and shows how proper management can increase ground-water supplies, check soil erosion and siltation, and reduce flood peaks. The present-day situation in the U.S. and abroad is analyzed and future opportunities and methods of managing vegetation in watershed lands are outlined.

An eighteen page bibliography and a subject and name index further increase the value of this book.

**Who's who, 1954.** Toronto, Macmillan, 1954. 3,266 pp., $15.00.

Now in its one hundred and sixth year of issue, Who's Who scarcely needs an introduction to our readers.

The very useful list of abbreviations introduces the text of this volume, and is followed by an obituary list from mid December nineteen fifty-two to mid December nineteen fifty-three.

The Supplement lists brief entries for returns received too late for inclusion in the main body of the book, and Knights Gazetted since January first nineteen fifty-four.

The biographies fill over thirty-two hundred pages, and the volume is, as usual, a necessity for practically every library, and a welcome addition to many private reference shelves.

**Wind-tunnel testing,** 2nd ed. Alan Pope. New York, Wiley, 1954. 511 pp., illus., $8.50.

Recent developments in high speed aerodynamics have produced revisions of data and procedures in this new edition. Material on the design and use of low-speed wind tunnels has been rewritten and simplified, and new information on high-speed wind tunnel practice is included.

New chapters cover testing at near-sonic, transonic, supersonic, and hypersonic velocities. The testing of helicopter rotors is described in detail and non-aeronautical uses of wind tunnels are suggested.

The revised work contains numerous photographs and new problems with answers provided in an appendix. References are given at the end of each chapter.

**Workshop calculations, tables and formulae,** 11th ed. F. J. Camm. Toronto, British Book Service, 1953. 186 pp., figs., tables, $1.30.

While this book does not approach the scope of the author's larger work, Newnes' engineers' reference book, it does provide the tables and formulae used by the mechanic and draughtsman. In this new revision complete tables of unified screw threads are included. Other sections include trigonometrical formulae and logarithmic tables, continued fractions, arithmetrical, geometrical and harmonical progressions, physical and electrical units, gearing, Brinell hardness numbers, drill sizes and wire gauges.

## BOOKS RECEIVED

**Alternating-current machines,** 3rd ed. A. F. Puchstein, T. C. Lloyd and A. G. Conrad. New York, Wiley, 1954. 721 pp., illus., $8.50.

**Bibliography of books and published reports on gas turbines, jet propulsion, and rocket power plants, January 1950-December 1953.** E. F. Fiock and Carl Halpern. Washington, U.S. govt. printing office, 1954. 110 pp., .50c. (Supplement to National bureau of standards circular 509).

**Chimie et structure cristalline.** R. C. Evans. Paris, Dunod, Montreal, Fomac, 1954. 331 pp., figs., $17.50.

**Comparative bridge designs.** J. G. Clark, ed. Cleveland, Lincoln arc welding foundation, 1954. 211 pp., diagrs., $2.50 (U.S.).

**Data book for civil engineers, v. 3. Field practice,** 2nd ed. E. E. Seelye. New York, Wiley, 1954. 394 pp., illus., $7.50.

**Electrical transients.** L. A. Ware and G. R. Town. Toronto, Macmillan, 1954. 222 pp., $4.75.

**Electronics for everyone.** Monroe Upton. New York, Devin-Adair, 1954. 370 pp., illus., $6.00 (U.S.).

**Engineers' dreams, great projects that could come true.** Willy Ley. Toronto, Macmillan, 1954. 239 pp., illus., $4.25.

**Formal job evaluation and some of its economic implications.** L. G. Nicolopoulos. Montreal, McGill University. Industrial relations centre, 1954. 43 pp., $1.00.

**A glossary of terms in nuclear science and technology.** U.S., National research council, Conference on nuclear glossary. New York, American society of mechanical engineers, 1953. 9 sections, $7.00 (U.S.).

**Hydraulic systems and equipment.** R. Hadekel. Toronto, Macmillan, 1954. 224 pp., figs., $3.00.

**Linear transient analysis, v. 1 Lumped-parameter two-terminal networks.** Ernst Weber. New York, Wiley, 1954. 348 pp., figs., $7.50.

**La machine-outil, v. 3. Usinage par outils en rotation. v. 6 Usinage par abrasion.** A. R. Métral, ed. Paris, Dunod, Montreal, Fomac, 1954. v. 3. 432 pp., illus., $23.60; v. 6. 168 pp., illus., $11.25.

**Manual on cutting of metals with single-point tools,** 2nd ed. A.S.M.E. research committee on metal cutting data and bibliography. New York, American society of mechanical engineers, 1952. 546 pp., illus., $10.00 (U.S.).

**Metal industry handbook & directory,** 1954 ed. London, Cassier, 1954. 472 pp., 21/8.

**Model analysis of structures.** T. M. Charlton. Toronto, British Book Service, 1954. 142 pp., figs., $3.80.

## STANDARDS REVIEWED

**ASTM specifications, American society for testing materials, 1916 Race Street, Philadelphia 3, Pa.**

**ASTM specifications for steel piping materials,** pa., $3.75.

The 1954 edition of this compilation sponsored by ASTM Committee A-1 contains in their latest approved form the 53 widely used ASTM specifications for carbon-steel and alloy-steel pipe and tubing, including stainless.

Materials covered include: pipe used to convey liquids, vapors, and gases at normal and elevated temperatures; boiler, superheater, and miscellaneous tubes; still tubes for refinery service; heat-exchanger and condenser tubes. Also included are specifications for the following materials used in pipe and related installations: castings; forgings and welding fittings; bolts and nuts. The ASTM standard classification of austenite grain size in steels (E 19) with two sets of charts; also the American Standards

covering wrought steel and wrought iron pipe (B 36.10) and stainless steel pipe (B 36.19) are a part of the book.

In this special compilation 22 of the specifications included in the previous edition have been revised, of this number 17 are tentatives and 5 are standards. A new specification covers ferritic alloy steel forged and bored pipe for high-temperature service.

These specifications are in widespread use and this book is of distinct service to those concerned with pressure piping, power generating, the petroleum field, distribution of water, gas and oil, and to individuals in every industry where these materials are so important.

**ASTM standards on cement (with related information)**, pa., $2.75.

This 1954 compilation of ASTM standards on cement brings together in compact, readily usable form, the ASTM test methods, specifications, and definitions widely used in this field.

Chemical and physical test methods cover: portland cement — autoclave expansion; calcium sulfate; chemical analysis; fineness; heat of hydration; sodium oxide and potassium oxide. Also included are test methods for: hydraulic cement — air content; chemical resistance; compressive strength; fineness; mechanical mixing; normal consistency; sampling; soundness; specific gravity; tensile strength; time of setting; and flow table.

Specifications cover: cement — portland, natural, and masonry.

Appendices include information on analytical balances and weights, a manual of cement testing, a list of selected references on portland cement, and an article on "The Principle of the Methoxyl Method for Determining Vinsol Resin in Portland Cement."

This new edition embodies numerous revisions of existing tests and specifications and includes a new method of test for mechanical mixing of hydraulic cement mortars of plastic consistency. In this special compilation 19 of the standards included in the previous edition have been revised, of this number 10 are methods of test, 7 are specifications, and 2 are definitions.

An easily usable table of contents is included (by subject and ASTM serial designation) and an extensive index.

**ASTM standards on gaseous fuels**, pa., $2.50.

The 1954 edition of this compilation of ASTM standards on gaseous fuels contains in their latest approved form all of the ASTM test methods used in this field.

Sponsored by ASTM Committee D-3 on Gaseous Fuels the test methods cover: measurement of gaseous fuel samples; sampling (natural gas; manufactured gas; liquefied petroleum gases); analysis of (natural gases by the volumetric-chemical method; natural gases and related types of gaseous mixtures by the mass spectrometer; carbureted water gas by the mass spectrometer); gaseous fuels (water vapor content, by measurement of dew-point temperature; calorific value, by the water-flow calorimeter; specific gravity); sulfur in petroleum products and liquefied petroleum gases by the $CO_2$-$O_2$ lamp method; vapor pressure of liquefied petroleum gases.

Of the 12 ASTM standards in this publication, 5 tentative test methods are new, and 5 of the 7 methods included in the previous edition have been revised.

New methods of test cover: sampling manufactured gas; sampling liquefied petroleum gases; analysis of carbureted water by the mass spectrometer; sulfur in petroleum products and liquefied petroleum gases by the $CO_2$-$O_2$ lamp method; and vapor pressure of liquefied petroleum gases.

**ASTM standards on materials for radio tubes and electronic devices and electrical-heating, resistance, and related alloys**, pa., $2.75.

The 1954 edition of this compilation includes in their latest form 44 widely used ASTM standards, including 30 test methods; 10 specifications; and 4 recommended practices.

Materials and subjects cover: electrical-heating alloys; electrical-resistance alloys; electric-furnace alloys; radio tubes, electronic devices, and lamps; heat-resisting alloys; electrical contact materials; and thermostat metals.

This new edition embodies numerous revisions of existing tests and specifications and much new material prepared since the previous edition.

New material includes specifications for: circular cross-section nickel cathode sleeves for electronic devices; two specifications for chromium-iron alloy for sealing to glass (one for 17 per cent, the other for 28 per cent); high-resistivity, low-temperature-coefficient wire; and round chromium-copper wire for electronic devices — test methods for sag of tungsten wire; relative thermionic emissive properties of materials used in electron tubes; hardness of electrical contact materials; and sublimation characteristics of metallic materials by electrical resistance — recommended practices for cathode melt prove-in testing; and conducting time-for rupture tension tests of metallic materials.

A convenient table of contents is included (by subject and ASTM serial designation).

**British standards. British standards institution, 2 Park Street, London, W.I. British standards are available from the Canadian standards association, National research building, Ottawa, Canada.**

**A. 109 and A. 110-Shear bolts and nuts (unified hexagons and UNF threads) for aircraft. 5/-.**

**A. 112- Cadmium plated shear bolts (unified hexagons and UNF threads) for aircraft. 3/-.**

These standards specify the materials, dimensions, finish and testing of shear bolts and nuts for use on aircraft and contain details of the method of identification. A. 112 provides a range of steel bolts cadminum plated to be suitable for insertion in aluminum alloy materials.

**B.S. 192:1954 — Open-ended spanners. 5/-.**

The attributes of open-ended spanners — the steel from which they should be manufactured (and its treatment), their proportions and dimensions form the basis of this latest revision of B.S.192. Since the standard was last revised in 1943, the range of hexagon sizes has been considerably extended by the addition of the several Unified series, but the spanner specification has not been left behind — its tables have also been extended and cater for all.

This 1954 revision, the third since the British Standard for spanners was first published in 1906, also attempts to solve the difficult question of what special marking should apply to the spanners suitable for the new Unified hexagons. The solution adopted is completely new and almost revolutionary; for this new method actually ventures to drop the historic (and vulgar) fraction and proposes simple figures based on the decimal equivalent of the size across the flats. It will be found, therefore, that the contents of the newly revised Standard are interesting and, as they are coupled with a pleasing and attractive layout, it is well worth getting.

**B.S. 2485: 1954 — Tee slots. 3/6.**

In preparing this specification, the British Standards Institution will have done a great deal toward alleviating the irritation caused by the present somewhat bewildering multiplicity of odd tee slot sizes and pitches.

The unregulated array of different widths has had a very adverse economic impact in that the manufacturers of tee bolts have been called upon to make a large number of different sizes to suit the slots found in machine tables, often in small quantities. The differences in many cases were slight and no valid technical reason could be advanced for them.

This new British Standard is an attempt to control this slightly chaotic situation by specifying the dimensions and tolerances of a range of tee slots and tee bolt heads from ¼ in. to 1in. inclusive, and comparing them with their nearest metric counterparts. During the work of preparation, due note was taken of Continental and American practice and thus this Standard should have a world wide interest. The specification for milling cutters, B.S.122, is being amended to provide suitable tee slot cutters.

**B.S. 2467: 1954—Minimum safety requirements for lighting fittings for use with hot cathode tubular fluorescent lamps. 2/-.**

This standard covers those factors which affect the safety and protection of the user of non-portable lighting fittings for use with hot cathode tubular fluorescent lamps where the nominal maintained voltage at the incoming terminals of the fittings does not exceed 250 volts. Included are clauses devoted to design and construction, materials, mechanical and electrical requirements, together with appropriate tests.

**B.S. 2452: 1954—Electrically driven jib cranes mounted on a high pedestal or portal carriage (high pedestal or portal jib cranes). 7/6.**

This new standard is one of a number relating to jib cranes. It applies to electrically driven jib cranes, mounted on a high pedestal or portal carriage, or the level luffing, derricking or fixed radius types, used with hook or grab. It therefore covers the types of ten referred to as 'wharf' or 'dockside' cranes.

As with other British standards for cranes, the object of this specification is to ensure reliability and safety without placing restrictions on the general design of the cranes or on the methods employed in their construction.

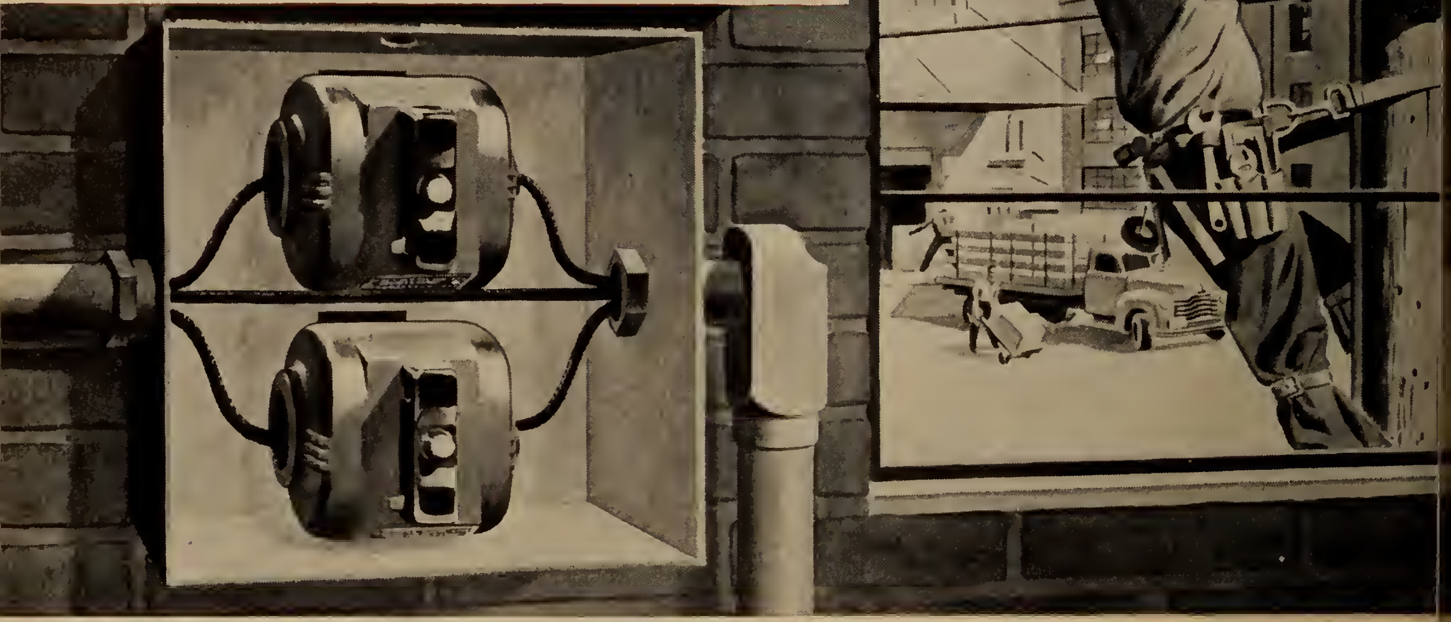
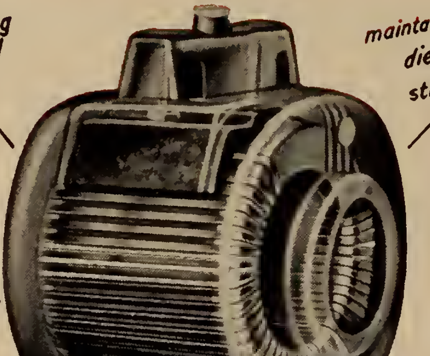
# AVAILABLE IN CANADA FOR THE FIRST TIME



# G-E indoor-outdoor Current Transformer



**INSULATION, SUPPORT, AND CASING** are of molded butyl. Laboratory and service tests proved butyl resists weather — making single indoor-outdoor design practical, assuring dependable service.

**NEW BUTYL-MOLDED LINE REDUCES STOCK REQUIREMENTS — CUTS INVENTORY COSTS**

For the first time in Canada, you can buy a transformer design for *both* indoor *and* outdoor use.

The new G-E butyl-molded Type JKP-O can also be used a three-wire transformer . . . another economy feature.

It can be flat-mounted indoors in any position. Because s-ondary terminals are on top, transformers can be mounted cl e together . . . especially useful in small box mountings. U d outdoors, transformers can be installed on poles without cr s arms or enclosing boxes.

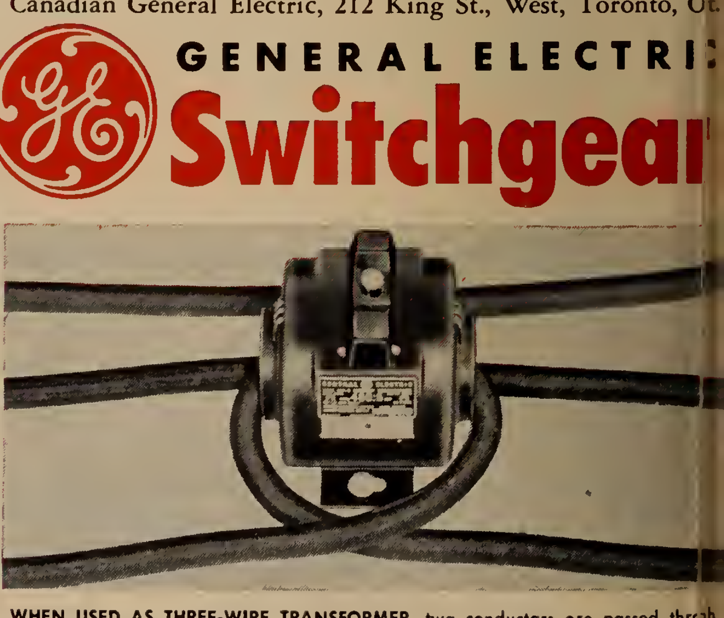
Type JKP-O is a 600 volt window-type transformer wh primary ratings of 200-, 400-, 600-, and 800-amperes.

For further information, write to: Apparatus Divisi , Canadian General Electric, 212 King St., West, Toronto, Ot.

GENERAL ELECTRI

**Switchgear**

**SECONDARY TERMINAL COVER** cannot be put in place unless short-circuit switch is properly positioned — protecting personnel, equipment. The terminal block can be reversed for convenience.



**WHEN USED AS THREE-WIRE TRANSFORMER,** two conductors are passed thr gh the window as shown. The extra-large, two-inch window allows easy insertio of full-sized primary cables for either indoor or outdoor installations.

## Phillips
## ROCKBESTOS
### POWER AND INDUSTRIAL CABLE

**Illustrated Rockbestos A.V.C. Cable.**

- withstands the hazards of extreme heat.
- resists attack by oils, greases and corrosive fumes.
- provides a high safety factor . . . flameproof.
- gives years of trouble-free service.

**CABLE TYPES FOR ALL YOUR NEEDS**

**1. Rockbestos All-Asbestos-Cables.** Designed for 600V use in open wiring at maximum copper temperature 125°C.

**2. Rockbestos A.V.C. Cables and Boiler Room Wire.** Similar to "All-Asbestos" type, but has a varnished cambric insert added for high dielectric strength. Rated for 600V or higher, in exposed or closed installations at maximum copper temperature 110°C. Can be supplied with a lead sheath for excessive moisture or corrosive conditions.

**3. Rockbestos Apparatus Cables.** For generating plants, boiler rooms, mills and other similar locations. Supplied with flexible conductors.

Motor Lead Cables, Switchboard and Rheostat Cables designed specifically for these jobs are also available.

Before installing any power or industrial cable—consult us. There is a Rockbestos Power Cable to suit your specific requirements.

## Appointments and Transfers

**Trans-Canada Pipe Lines.** — Appointment of Charles S. Coates as executive vice-president and general manager of Trans-Canada Pipe Lines Limited is announced by N. E. Tanner, president of the company. In that capacity, Mr. Coates will direct the construction and operation of the 2,200-mile pipeline which will carry Alberta natural gas eastward as far as Montreal.

•

**B.A.-Shawinigan.**—The appointment of Geoffrey K. Wright as sales manager of B.A.-Shawinigan Limited was announced by V. G. Bartram, president.

Mr. Wright, who has his office at the B.A.-Shawinigan plant in Montreal East, also assumes responsibility for traffic, advertising and public relations.

•

**Alaska Pine & Cellulose Limited.** — Additional technical service facilities are being established by Alaska Pine & Cellulose Limited of Vancouver, B.C.

W. C. Koerner, president, announces creation of a new post, that of technical service director in the cellulose division.

Leslie K. Bickell, formerly the company's chief chemist, with headquarters at Woodfibre, B.C., has been appointed to the newly-created post and will move to Vancouver. The appointment was effective July 1st, 1954.

•

**C-I-L.**—R. B. Carpenter, assistant works manager at the C-I-L commercial explosives works, Beloeil, Que., has been appointed works manager at the James Island plant in British Columbia to succeed W. S. Thatcher.

Mr. Carpenter was born in Lachute, Que. He attended public and high school in Calgary and Vancouver respectively, and was graduated from the University of British Columbia with a B.A.Sc. degree in chemical engineering.

•

**Garlock's Sales.**—J. B. Sewell, presently vice-president of The Garlock Packing Company of Canada, Ltd., will become general sales manager of Garlock's sales in Canada and the United States on October 1. Announcement of this promotion was recently made by George L. Abbott, president of The Garlock Packing Company, Palmyra, New York.

•

**Shawinigan Chemicals Limited.**—Four appointments in the sales department of Shawinigan Chemicals Limited, in Montreal, were announced recently.

Terrence A. Gill, domestic sales manager until now, becomes administrative assistant for sales; and Gordon H. MacDougall, export sales manager, has been named assistant general sales manager.

Donald O. Tirrell succeeds Mr. Gill as domestic sales manager and Kenneth C. Clarke has been named to succeed Mr. MacDougall as export sales manager.

•

**C.I.L. Paints and Coated Fabrics.**—R. C. Williamson has been appointed manager of the paints and coated fabrics department of Canadian Industries (1954) Limited. He joined C-I-L in 1936 in the general chemicals division. In 1943 he was appointed manager of Alchem Ltd., a C-I-L subsidiary with headquarters in Burlington, Ont. He has been vice-president of Alchem since 1945 and succeeds Leonard Hynes who has been elected a vice-president of the company.

●

**Monsanto Canada.**—Appointment, effective immediately, of Dr. Arthur F. McKay as director of research and development, Monsanto Canada Limited, was announced today by Leo E. Ryan, executive vice-president and operating head of the company.

An outstanding Canadian chemical research scientist, Dr. McKay will direct Monsanto's extensive program of research and development from the Montreal head office laboratories including among his responsibilities the company's research activities in Vancouver.

●

**Sales Appointments at Packard.**—Packard Electric Company Limited has recently announced the appointments of D. F. Martin as general sales manager, G. B. Hunnisett as Ontario district manager and R. C. Short as Quebec district manager.

C. W. Spratt will continue as vice-president—sales, and will act in an advisory capacity.

●

**Allis-Chalmers.**—The board of directors of the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., have paid their first visit to Canadian Allis-Chalmers Limited, their subsidiary, at Lachine, Que.

Host to the group was M. C. Lowe, president of Canadian Allis-Chalmers, which has general offices and works at Lachine and also operates a plant at St. Thomas, Ont. Several company officers accompanied the board of directors delegation, which was headed by A-C president W. A. Roberts.

A luncheon arranged at the Sheraton Mount Royal Hotel provided an opportunity for board members to meet some of Canada's business, education and civic leaders.

Guest speaker at this event was J. A. Calder, president of the Canadian Manufacturers Association, who told the attendants that those who warn of recession, depression and the like are suffering from super-heated imaginations.

Since it was the heavy demand for certain goods by overseas countries which provided the incentive for a considerable expansion of Canadian capacity, the decline in demand meant adjustment in both production and prices, Mr. Calder stated.

The group of directors which arrived in Montreal on Thursday, September 9, from Boston, Mass., where a monthly meeting had been held, visited various parts of the city and showed special interest in the Montreal harbour and its installation, particularly in relation to their bearing on the St. Lawrence Seaway development.

●

**Proctor, Redfern & Laughlin.**—E. M. Proctor, M.E.I.C., senior partner of Proctor, Redfern & Laughlin, consulting civil engineers, announces the admission of G. E. M. Proctor, M.E.I.C., and D. B. Redfern into the partnership, and John F. Wyllie, Roy G. Tredgett, Gordon U. Proctor as associates.

The firm, which was founded in 1912, has supervised the design and construction of a wide range of major municipal and industrial projects throughout Canada. (See Personals).

# WATER TUBE BOILERS

## AT DU PONT OF CANADA'S NYLON PLANT, MAITLAND, ONT.

*Aerial view of Du Pont Company of Canada Limited Nylon Plant, Maitland, Ontario.*

The new nylon intermediates plant at Maitland, Ontario, brings the control of manufacturing processes by instrumentation to a new high level in Canada. In the manufacture of the two complex chemicals required as raw material for nylon staple and yarn, an efficient and constantly reliable source of steam is essential. Three Dominion Bridge Water Tube boilers were chosen to meet this need. Details and specifications are shown at the left.

***For particulars of Dominion Bridge Water Tube boilers write for catalogue No. BF-103***

*View of power house.*

**Margison, Babcock & Associates.**—O. Margison, M.E.I.C., announces that the name of this firm will change to A. D. Margison and Associates Limited, consulting professional engineers, effective July 1st, 1954.

The following Associates will continue with the firm: G. R. Beavers, chief engineer, building services department; J. J. Stewart, chief engineer, supervision department, A. G. Keith, chief architect, architectural department; J. E. Margison, chief engineer, process department; D. L. B. Hamlin, chief engineer, structural department; W. A. Stewart, chief engineer, municipal department; H. R. Musson, engineer, thermodynamics section; K. N. Craig, engineer, power plant and piping section; F. I. L. Dyke, engineer, electrical section; R. A. Cunningham, engineer, field supervision section.

Withdrawing as directors and shareholders and terminating their association with the firm as of the 1st July are H. A. Babcock and W. G. Cutler. (See Personals).

# New Equipment and Developments

**Rubber Hose Defies Molten Steel and Flame.**—A rubber hose that has defied molten steel and white-hot flame for more than 270 heats of an open hearth steel furnace has been announced by the B. F. Goodrich Company Industrial Products Division. The hose, armored with wire for strength and protected by asbestos for heat, outlasted the life of the furnace.

Attached to the hollow steel doors of open hearth furnaces, the new hose circulates water inside the doors to keep them from melting under the intense heat. Build-up of slag on hose, a factor which shortens the life of other hose in this service, is reduced by a newly developed hose construction.

Despite the cooling effect of the water, heat generated inside the furnace doors often becomes great enough to change the water to scalding steam. The same type of hose is used to draw off steam and hot water emerging from the circulatory system. The hose has a special heat-resistant tube.

Hose is needed for the unusual furnace door application to permit a flexible connection to the water circulation system so that the doors may be opened to charge the furnaces. A new type of flexible construction used in the new hose permits the use of shorter hose lengths to make these connections. Because of its light weight and flexibility, the new hose may be installed by one man.

**Auto-Transformers.**—The most powerful auto-transformers ever built by the Canadian Westinghouse Company have been ordered by the Quebec Hydro Commission for the giant Bersimis system.

The 150,000, 3 phase, 60 cycle units will be installed at the Charlesbourg transformer station where they will step down power from 290,000 volts to 230,000 volts. Distribution will then be made throughout the Shawinigan area. The 300-odd ton transformers are scheduled for delivery in 1956.

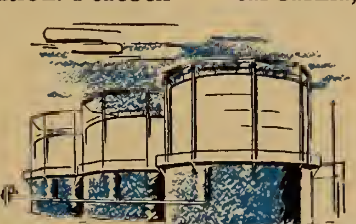
Westinghouse also recently received another transformer order for the Bersimis development. The company will supply 40,000 kva, single phase units in banks of three to step up generator voltage at the northeastern Quebec power site.

**New Locklite High Bay Unit.**—A new ventilated high bay lighting unit, particularly suited to assembly areas, press shops, foundries and other heavy machinery areas where high light output

(*Continued on page 1352*)

# WHERE THERE'S GAS THERE'S PEACOCK

Accurate control of pressures and flow, together with precise measurement, are the most essential requirements for efficient handling of gas at every stage . . . from field to final distribution. Peacock equipment, used throughout the industry, has a proven record for economical, dependable operation in meeting these requirements. Typical installations illustrated above are:



*Top:* Nordstrom lubricated plug valves in metering system at Dawn compressor and storage station of Union Gas Company of Canada Ltd., near Sarnia, Ontario. *Left:* Foxboro Flow Meters and Pressure Recorders in metering house of large Canadian gas distributor. *Right:* Another view of Nordstrom gear operated valves in metering system of Canadian gas company.

PB54-13T

**PEACOCK BROTHERS LIMITED**

MONTREAL

SYDNEY · TORONTO · SUDBURY · WINNIPEG · CALGARY · VANCOUVER per luminaire is required, is now available from the Canadian Westinghouse Company.

The new luminaire—the Locklite—is designed for either mercury or incandescent lamps and numerous construction features make it particularly efficient from both performance and maintenance standpoints.

Ventilation apertures, located between the reflector and the neck extension, enable airborne dust and dirt to escape from the reflecting surface of the unit. The continuous circulation of this dirt-bearing, heated air results in a higher efficiency for longer operation periods and reduces the time required for maintenance.

The Westinghouse Locklite design provides positive action, for the unit will light only when mechanically secure. The reflector assembly is connected mechanically and electrically to the wired hood by a simple clockwise turn. Removal for maintenance is equally easy.

Other features of the new Locklite Unit which Westinghouse cites include a cooler lamp base and holder, complete lamp protection from falling water and dirt through the overhanging design of the ventilation opening and improved light control by the unit's baffle design.

●

**Compact Indicator Speeds Up Measurements.**—A new electronic measuring instrument in many cases 100 times faster and more consistently accurate than conventional galvanometers for making bridge-type measurements has been developed by the Minneapolis-Honeywell Regulator Company's Industrial Division, it was recently announced.

The new instrument, called an ElectroniK Null Indicator, is the first radical departure from the conventionally used galvanometers. Housed in a portable, compact case (which minimizes bench space) the new instrument speeds up resistance and potential measurement by utilizing precision potentiometers and bridges. To operate the Null Indicator it is only necessary to close the switch and balance the bridge. The balance point is indicated by the return of the indicator pointer to zero. By contrast, light-beam galvanometers will lose time while waiting for the pointer to cease oscillating, or come back on scale. In addition, the new instrument is not affected by vibration, one limitation of the conventional galvanometers, nor is it necessary to level the indicator since its operation is unaffected by position. Overloads of several hundred per cent will not affect the new instrument.

The input terminals on the instrument can be used with either pin, spade or banana jacks. The instruments can be used with the case and one side of the input circuit grounded or with the case grounded and the input circuit floating above the ground. An accessible screw driver sensitivity adjustment is provided.

Data Sheet 10.0-12 available from the company gives complete information.

# SYLVANIA
**ELECTRIC (CANADA) LTD.**
Montreal

*Manufacturers of Fluorescent, Incandescent, Photographic Lamps, and Television Receivers* now being erected in San Francisco is the first really tall building to go up under that city's strict 1948 building code. When San Francisco enacted the code in 1948, which specifies shears twice the magnitude of Unified Building Code, it was freely predicted that no more tall buildings would be erected in that city.

According to The Lincoln Electric Company of Cleveland, Ohio, welded design was selected for critical beams and columns, both for economy and architectural reasons.

Limitation to depth of floor beams imposed by embedded duct work made it necessary to carry all lateral loads, including seismic, on the exterior walls. This meant using large columns and spandrel beams. The solution to column and spandrel beam design, complicated by splicing heavy flanges and making beam to column connections, was found in a continuously tapered column and tapered butterfly spandrel beam, both fabricated with the automatic hidden arc welding process. Beam to column connections have full butt welds on the flanges and double fillet welds on the webs. The tapered columns vary from 42 x 1½" webs and 18 x 3" flanges at the base to 12" webs and 16" flanges at the fourteenth story. Welding is being done with Lincoln Fleetweld 5, an E-6010 electrode. If cracking in the root passes of joints in heavy sections is encountered, the root pass is made with LH-70, an E-7016 electrode.

●

**X-Ray Diffraction Unit Accessories.**—A many-fold increase in efficiency, and a drastic reduction of error in the higher frequencies, are two of the many advantages of a new proportional counter tube and proportional counter preamplifier just announced for use with the General Electric x-ray diffraction unit.

Both accessories, acting together, perform linearly over 5 times the range of the argon-filled mutil-chamber Geiger tubes, and about 20 times the range of linearity of typical single-chamber Geiger tubes. The new counter assembly has less than 1 micro-second resolution time.

The new proportional counter preamplifier converts present G.E. Geiger tubes easily to proportional counter operation.

The new krypton-filled proportional counter tube has a much higher absorption efficiency than the argon-filled tube, and has no noticeable thermal sensitivity. Tube failure due to extremely high intensities and voltages has been virtually eliminated.

Because of the high-intensity measurements made possible by the new accessories, the productivity of an x-ray diffraction unit is greatly enhanced, and since the user may choose more efficient technics for greater accuracy at high scanning speed.

The new proportional counter tube is extremely efficient over the wide wavelength range of interest in x-ray diffraction and x-ray spectroscopy. The gain in efficiency of krypton over argon-filled counter tubes is about 4 times for molybdenum K-alpha radiation, 10 times for silver, and a few per cent for copper. For copper, and longer wavelengths, the semimonochromating effect of the argon absorption curve with respect to short wavelengths may be preferred.

Proportional counters are expected to last substantially longer than Geiger tubes, because by omitting the self-quenching gas, the main cause of ultimate failure of Geiger tubes is eliminated.

●

**Silicone Water-Repellent.**—A new silicone water-repellent for masonry—capable of more effective performance on common brick than any previous available material—has been announced by Canadian General Electric Company's chemical materials sales.

Designated Silicone Dri-Film 103 water repellent, the transparent silicone resin is said to prolong the useful life of masonry, reduce maintenance costs, and not only help maintain the masonry's natural beauty but allow it to "breathe" freely after treatment.

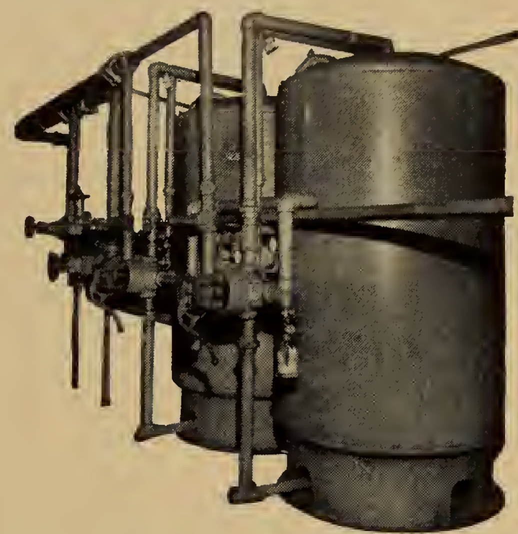
C.G.E. engineers said Dri-Film 103 minimized efflorescence, greatly retards spalling and cracking, and makes possible cleaner exterior surfaces, when properly applied to above-ground brick, concrete, mortar and other masonry materials. The new water-repellent may be applied either by brush or spray; one gallon of diluted material affords a coverage of 90-120 square feet in one coat on most surfaces.

Independent laboratory test results indicate that silicone-treated common

(*Continued on page 1356*)

# Dearborn OFFERS A COMPLETE WATER CONDITIONING AND ENGINEERING SERVICE

Whether you require a manual, semi-automatic or completely automatic system, Dearborn gives you a customized program including (1) the initial plant survey; (2) external and internal treatment recommendations; (3) properly designed feeding equipment; and (4) supervisory service. Here, from a single source, you have all the facilities for maximum efficiency and economical performance in your water conditioning operations.



## ZEOLITE SOFTENERS ▶

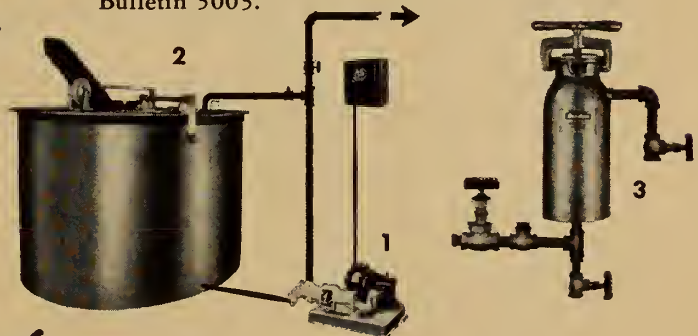
A Dearborn installed 500,000-gallon Zeolite water softener for the treatment of boiler water makeup.

## ◀ DE-IONIZING PLANTS

This Dearborn 2-bed De-Ionizing unit is capable of producing 75,000 gallons of demineralized water per day. Piped throughout with Saran-lined steel. Includes corrosion-resistant ejectors, rubber-lined tanks and valves. On special applications where mineral-free water is required, a Dearborn De-Ionizing plant will reduce the mineral content of water to the equivalent of that produced by evaporation . . . and at a much lower cost. Write for Bulletin 5005.

## INTERNAL TREATMENT ▶

(1) High-pressure pump, (2) hand-agitated chemical tank for delivering treatment directly into the boiler drum, (3) Type H feeder for manual application of either briquette or powdered treatments. Write for Bulletin 5000.



**why you can rely on Dearborn**

Dearborn has specialized in the conditioning of water and the control of corrosion since 1887. This broad experience in water treatment and rust prevention—plus Dearborn's extensive laboratory and research facilities—are at your service . . . at no obligation. You'll find it will pay you to . . .

**know your Dearborn engineer**

DEARBORN CHEMICAL COMPANY, Ltd., 2454 Dundas St. W., Toronto 9
Calgary • London • Edmonton • Saint John • Vancouver

brick will only absorb 0.01 per cent moisture after being immersed in water for a one-week period. Common brick was treated with five per cent silicone solids diluted with commercial solvent. This moisture absorption rate is technically superior to all competitive water repellents for common brick.

Since rain splashes and runs off silicone treated surfaces—carrying away dirt deposits—exterior surfaces are kept clean for a longer period of time.

According to company engineers, peeling and flaking of interior walls is also minimized since the new water repellent reduces the passage of moisture through the masonry. They said that silicones prevent water mingling with salts inhering in brick or mortar, thus minimizing or eliminating unsightly white or yellowish salt deposit marks on outer masonry surfaces.

Dri-Film 103 is an addition to Canadian General Electric's current broad line of silicone water repellents.

Further information may be obtained from Chemical Materials Sales, Canadian General Electric Co. Ltd., 940 Lansdowne Avenue, Toronto.

•

**Shawinigan and Firth-Vickers.**—Two pioneer commercial producers of stainless steels, one British and the other Canadian, have just established a transatlantic liaison for exchange of information which is expected to further development in both countries.

The companies are Firth-Vickers Stainless Steels Limited, of Sheffield, England, which, as Thomas Firth and Sons first commercially developed stainless steel in 1913, and Shawinigan Chemicals Limited, of Montreal, through its stainless steel and alloys division, which is the largest and one of the oldest producers in Canada.

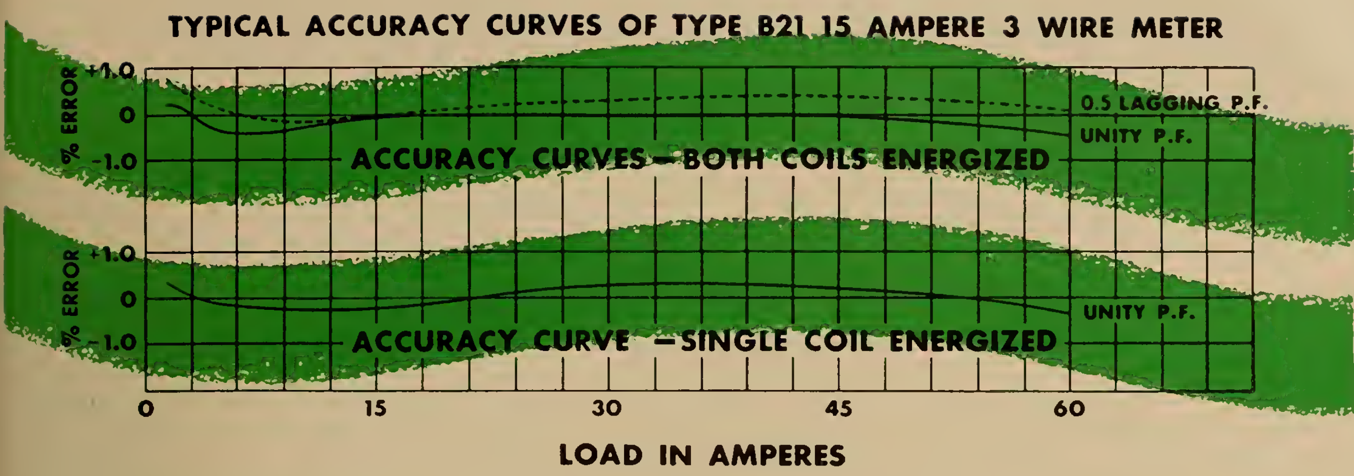
C. K. Lockwood, of Montreal, vice-president of Shawinigan Chemicals in charge of the stainless steel and alloys division, said the agreement covers the exchange of technical information on all phases of foundry practice including melting, moulding, and heat treatment procedures.

•

**Recovering Cast-Iron Swarf.**—To assist in the conservation of ferrous and non-ferrous materials not readily processed by conventional baling equipment, Fielding and Platt, Ltd., of Gloucester, England, has designed and is making a 400-ton automatic hydraulic press which is claimed to be revolutionary in design and to have wide possibilities in the recovery of cast iron. The machine is capable of converting cast iron machinings (swarf) into high-density briquettes, suitable for direct remelting, at a rapid and constant rate of production. It is stated that the machine may also be used for producing briquettes from brass and aluminium turnings and drillings.

In making briquettes from cast-iron swarf, no bending or sintering is required and the press is capable of producing between 300 and 340 briquettes of 85 per cent density an hour, the weight of the briquettes ranging from four to six pounds (1.8 to 2.7 kilogrammes). The length of the stroke of the machine's main ram is 15 inches (38 centimetres) and the specific pressure exerted on the material is 48 tons per square inch (30.4 kilogrammes per square millimetre). The press is of the vertical four-column type, having fabri-

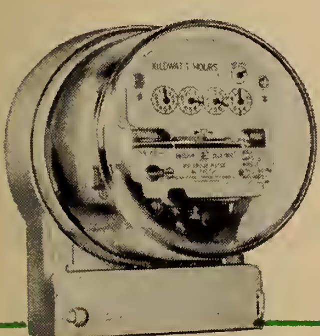
*(Continued on page 1358)*



## GET MORE ACCURATE BILLING OVER A WIDER LOAD RANGE...

The English Electric Type B21 gives greater accuracy over a wider useful load range and a much more consistent performance from meter to meter than has ever been possible before.

The advanced design reduces the damping effect of the current flux and the meter requires less than usual overload compensation.



***These 4 money saving features of the B21 are important to you.***

(1) MORE ACCURATE BILLING
(2) LESS BEARING WEAR
(3) EASIER SERVICING
(4) REDUCED MAINTENANCE

# 'ENGLISH ELECTRIC'

Vancouver, Calgary, Winnipeg, Toronto, Ottawa, Montreal and Halifax
English Electric Company of Canada Limited, St. Catharines, Ont.

PA 5407

cated tables with a mould assembly mounted on the lower table. Oil is supplied by two high-pressure radial pumps, one driven by an 80-horse-power motor and the other by a 50-horse power motor.

Control of the press is effected by push buttons, through direct current solenoid-operated valves of the balanced type for operating with oil. Completely automatic working may be arranged.

Swarf is loaded into a bunker of approximately one ton capacity. From the bunker, the swarf runs by gravity on to a vibrating screen which rejects large pieces of metal or other unsuitable material; these are carried down a small side chute fitted at right angles to the direction of the flow. The screened swarf passes into a receiver at the foot of an elevator which conveys it to a small hopper at the top of the press. A vibrator attached to this hopper ensures that a continuous supply of swarf enters a dispenser which weighs out swarf for one briquette. After filling, the dispenser is tipped by air cylinders for the discharge of its load down a chute and into a mould ready for briquetting.

As soon as the swarf is discharged, the dispenser is returned to its original position, its action being fully automatic and interlocked with the pressing cycle of the machine. There is, however, an overflow pipe for returning surplus material to the lower receiver should the elevator supply swarf faster than the machine can deal with.

When the mould is filled with swarf, the main-ram mandrel of the press enters it and compresses the contents to form a briquette. Pressure is then held in the main cylinder while the mould is raised by four small lifting rams, thus stripping the briquette from the mould. The main ram is then returned to the up, or filling, position, and the briquette is completely released. It is finally ejected from the press and pushed down a small chute by the plunger of a horizontal air cylinder. The mould then returns to the filling position, when the dispenser supplies a new charge of swarf. The total time cycle of the press is approximately 11.5 seconds.

●

**Transformers.** — Together with their monthly Ferranti Distribution Transformer stock list, Ferranti Electric announces that they are now prepared to quote on CSP type transformers.

The Ferranti CSP unit employs "Deion" type lightning arresters at the high tension bushings. A secondary breaker is mounted on top of the core and coils and visible on the outside of the tank is the red warning light and relay reset handle combined in a single unit.

There are internal high voltage protective links in series with the high voltage leads. These protect the transformer feeder against short circuits within the transformer.

When CSP transformers are used, separate lightning arresters and cutouts are no longer required. This provides for an economical and neat appearing installation.

For full information contact your Ferranti salesman or any Northern Electric representative.

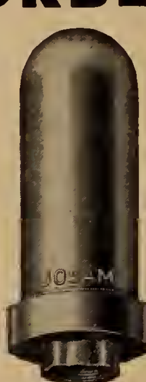
●

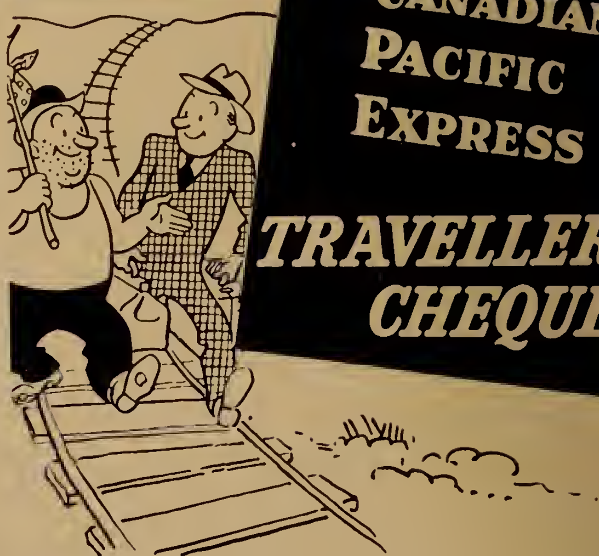
**Industrial Piping.**—A new general-purpose industrial piping, known as "Armourvin", which is manufactured on automatic machinery, can be run off in lengths up to two miles (3.2 kilometres) long, according to thickness. Armoured with steel wire, it is so strong, the makers claim, that a six-ton truck can be run over the diameter without fracturing the pipe.

The hose is made of flexible plastic, reinforced with tempered steel spring. Since the spring is in the well of the pipe, it can be used to carry most acids and alkalis as well as oil, water and grease, to which it is resistant. It is also so flexible that it can be bent double or twisted tightly without reducing the internal bore. The makers state that it is ideal for connectors, using British Standard pipe or special fittings, and can also be supplied in translucent form for use as a sight feeder. Every length is free from laminations and is of one-piece construction. Makers: Creators Ltd., Plansel Works, Sheerwater, Woking, Surrey, England.

●

(*Continued on page 1360*)





**Drafting Unit.**—Dargue Brothers, Ltd., New Simplon Works, South Parade, Halifax, Yorkshire, England, has produced a new dual reference drafting unit for which many advantages are claimed. It is stated to save not only 50 per cent of drafting time but also 50 per cent of space. The drafting board support quadrants are built integrally with the top of the table and give a clear reference area for each draughtsman at the back of the alternate board.

Four personal drawers, one full-size filing drawer and book-case ends are immediately adjacent to each draughtsman. The board can easily be adjusted for both height and angle. The surface can be provided faced with heat and scratch resisting materials.

●

**New Magnetic Meter.**—A new electromagnetic flow meter, designed for 2″ to 8″ flow lines, has been introduced by The Foxboro Company of Foxboro, Mass. Incorporating all the unique advantages of electromagnetic metering, the instrument is additionally rated for unlimited maximum flows, making practical a number of flow measurement applications impossible with ordinary metering equipment.

The magnetic flow meter will measure the volume flow rate of any liquid of sufficient conductance and velocity. Unaffected by the pressure, viscosity, density or changes in conductivity of the flowing liquid, it is recommended for aqueous solutions, slurries, acids and other corrosives, in addition to food and drug products requiring sanitary processing.

The unit consists of a nonmagnetic flow tube with an insulating liner containing flush-mounted metallic electrodes and surrounded by an a.c. electromagnet. When conductive liquid passes through the tube, an alternating voltage is set up between the electrodes which varies linearly in proportion to the rate of the flow. Lead wires from the electrodes transmit this voltage output to an electronic recorder, producing a chart record in appropriate units of flow.

Over-all accuracy is within ±1% of the scale span from maximum flow down to zero flow despite such factors as turbulence, dirty flow, etc. Meter produces no more pressure drop than a length of pipe equivalent to the meter tube.

Complete specifications are available in a technical report, TI 27-A-71a, available on request from Peacock Brothers, sole sales agents in Canada, Ville Lasalle, P.Q.

●

**Flame-Plated Core Rods.**—Core rods, flame-plated with tungsten carbide, last 30 times longer than steel rods according to tests run by a metal products manufacturer. Steel core rods were no longer usable after 10,000 parts had been produced because of a 0.0001 in. wear limit. A core rod that had been coated with tungsten carbide by Linde Air Products Company's flame-plating process, however, produced 291,905 parts at the last count and showed no noticeable wear. When this flame-plated core rod finally does wear undersize, the tungsten carbide coating may be easily removed and reapplied again, and again. Substantial savings in downtime and replacement costs are thus readily achieved.

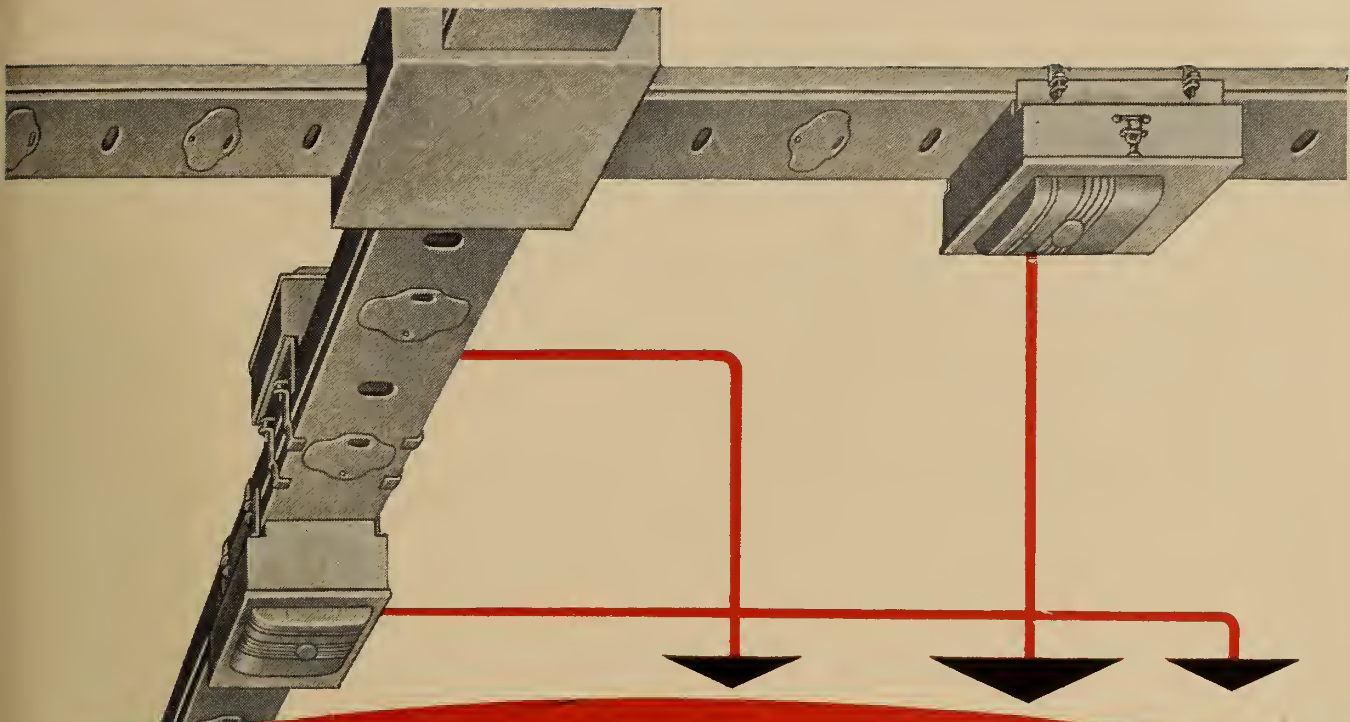
Flame-Plating is a process developed by Linde Air Products Company, a division of Union Carbide and Carbon Corporation, for depositing a thin coating of tungsten carbide on the surfaces of parts and many tools where extra wear-resistance is required. In this manner a tool such as a core rod can be given a highly wear-resistant surface while retaining the toughness of the base metal which minimizes breakage problems. Because the temperature of the part being plated does not exceed 400 deg. F., finished and semi-finished parts can be flame-plated without causing distortion or a change in the physical properties of the base metal. The coating may be left in as-coated condition (similar to fine emery cloth) or finished down to 1-5 microinches rms.

Many parts and tools such as plug and ring gauges, turbine shaft seals, gripping dogs, wire straightening rollers, spindles, and bushings are now being flame-plated with outstanding success. Flame-plating is available in Canada from Dominion Oxygen Company, division of Union Carbide Canada Limited, Toronto.

●

**Canadian Terylene Plant.**—The first Canadian "Terylene" textile fibre plant, is being constructed at Millhaven, Ontario,

(*Continued on page 1362*)



and 1,400 acres of land at that location are being purchased by Canadian Industries (1954) Limited, it was announced today by C-I-L president H. Greville Smith following a meeting of the company's board of directors.

Acquisition of this property and construction of the Millhaven works were undertaken early in 1953 by Imperical Chemical Industries of Canada Limited, which announced at that time that the project would subsequently be offered to Canadian Industries (1954) Limited. Pilot plant production has now begun at Millhaven and it is expected that full operating capacity will be available by next summer.

The $20,000,000 plant, situated on Lake Ontario 11 miles west of Kingston, will be capable of supplying over 11,000,000 pounds of yarn and staple annually to the Canadian textile industry which, until now, has been receiving small quantities of that fibre produced in Great Britain. The large area of the Millhaven site lends itself to the development of other chemical undertakings by the company.

When in full operation the plant will employ about 800 people. Present employees will become part of the C-I-L organization.

The enterprise will be handled within C-I-L by a new department—the Textile Fibres Department—headed by R. B. Winsor, formerly chief engineer of C-I-L and before that assistant manager of the chemicals department. Other senior officials in the department will be D. R. Fraser, sales manager; MacMillan Boyd, assistant sales manager; B. J. Moriarty, technical service manager; Frank Thomson, control manager; Harris Sherwood, works manager at Millhaven with R. M. Beatty production superintendent.

•

**C.G.E's Transformer Plant.**—Whatever the primary source of energy—water-power, coal, oil, natural gas or the atom—its mounting use will entail an increasing use of electrical equipment, Trade and Commerce Minister C. D. Howe said as he officially opened the Canadian General Electric Company's $12 million power transformer plant.

At the opening ceremony, Mr. Howe touched off a 3-million-volt blast of man-made lightning between the plant's impulse generator and one of the first large transformers built there. The blast symbolized the vast voltages controlled by the electrical equipment produced at the plant.

Rated as one of the world's best-equipped engineering and production centres for the design and manufacture of large power transformers, the new plant represents the largest expansion in the 62-year history of the Canadian electrical industry. With 700 workers now on the payroll, it is already Guelph's largest employer, and is ultimately expected to provide work for 1,000 people.

The new facility produces power transformers for the distribution systems of Canada's electrical utilities and industries. These units step up voltages at power sites for transmission to centres of population and again reduce voltages at these points for distribution and utilization.

The plant and its satellite buildings occupy 60 acres of the 207-acre site purchased by the company in 1952, with a large part of the remainder ticketed for future expansion. At peak employment during construction, over 750 workers were employed at the site. The plant's floor space totals 374,963 square feet.

Built as the result of the heavily increased demand for such equipment, the plant represents a significant addition to the nation's capacity to produce capital equipment vital to Canada's expansion and to the nation's defence. It increases the company's power transformer manufacturing capacity by 50 per cent. A. L. Graham is manager of the company's power transformer department.

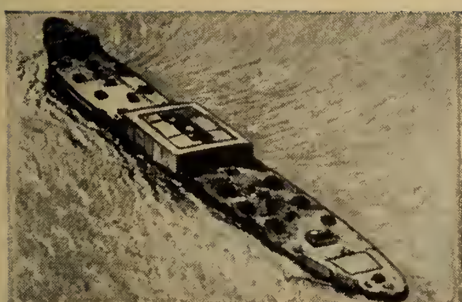
•

**The New Johns-Manville Asbestos Mill.**—The most important single project in Johns-Manville's expansion and replacement program during the past decade is the construction of a new mill at Asbestos, P.Q., Canada, where the company mines more than one-third of the world's supply of asbestos fibre from the largest known asbestos ore deposit in the world, the Jeffrey Mine. This new Mill will replace the present mills, which are becoming obsolete, and which are located in the caving area of the local underground

(*Continued on page 1364*)

**"HAYDITE"***
**THE LIGHTWEIGHT AGGREGATE**
**SO DURABLE . . .**

# 34 years of salt water didn't affect it!



Near Galveston, Texas rests the hull of the "HAYDITE" concrete ship "Selma" launched in 1919 and beached some years later. For 35 years the "HAYDITE" concrete in the hull had endured thousands of cycles of wetting and drying. In 1953, physical examination showed that "... the concrete was in excellent condition and the reinforcing steel showed no deterioration whatsoever even though in most places it had only ⅝ inch cover".

"HAYDITE" aggregate is a pure iron-bearing high silica-alumina lorain shale, produced in rotary kilns at temperatures exceeding 2000° Fahrenheit. This intense heat burns out all foreign matter, and causes an explosive expansion of the shale creating myriads of microscopic, totally-enclosed non-interconnecting air bubbles, each in its own vitreous shell. This is "HAYDITE"—a remarkably durable lightweight aggregate (concrete made with "HAYDITE" aggregate weighs 33% less than sand and gravel concrete) that is chemically inert, has amazing strength, and is highly resistant to both fire and humidity.

**Let us tell you about "HAYDITE" for poured-in-place structural reinforced concrete; for precast roof and floor slabs; for roof and floor fill; for refractory concrete; for guniting applications, and for building blocks.**

*general sales offices:* 1055 Yonge Street, Toronto
*montreal:* Aerocrete Construction Co. Ltd., 2501 Lakefield Ave., Montreal East

mine. It will provide some additional production capacity and will operate at lower costs.

The New Mill is constructed of steel and concrete, fourteen storeys high and covered with "Transite" sheathing — an asbestos-cement product manufactured by Johns-Manville. The first half of the building is now completed and the first quarter of the machinery is installed and ready to go into operation. The entire project should be completed by the spring of 1956. This new plant incorporates the most modern facilities for the milling and production of high quality asbestos fibres — an essential objective in today's competitive asbestos industry.

**Du Pont of Canada.**—A plant for the manufacture of "Freon" fluorinated hydrocarbons, gases which create the cooling action in air-conditioning and refrigeration systems and are the basic propellants in aerosols, will be erected immediately at Maitland, Ont., by Du Pont Company of Canada Limited, it was announced recently. Maitland is on the St. Lawrence River between Brockville and Prescott.

The plant will be of sufficient capacity to fill all Canadian requirements for these chemicals, now largely imported from the United States, and will use Canadian base materials wherever possible. It is being built adjacent to Du Pont of Canada's nylon intermediates plant which went into production a year ago.

The project is the second announced by Du Pont of Canada since July 1. The first building of a research center already is under construction at Kingston, Ont., beside the company's nylon spinning plant there.

"Freon", Du Pont's trade name for fluorinated hydrocarbons, was first produced commercially in the U.S. in 1931, and was developed to meet widespread demand for a nontoxic, nonflammable, odorless refrigerant to replace the hazardous materials then in use. Following the introduction of "Freon", the refrigerant industry expanded 20-fold in the next 20 years. One of the major uses is in the family refrigerator.

Then, during the war, an entirely new use for the compounds was developed. As the answer to the problem of insects in the Pacific and other tropical areas, "Freon" was used as the propellant in the "bug bombs" employed to kill mosquitoes and other disease-carrying insects. This development in turn led to today's rapidly expanding aerosols industry with a wide variety of household and personal products, from room deodorants to shaving cream, packaged in aerosol containers.

# Publications

**For copies of the publications mentioned below please apply to the publishers at the addresses given in the items.**

**Please mention *The Engineering Journal* when writing.**

**Paper on Laticrete.**—A reprint of a paper on the characteristics and performance of Laticrete has been issued by the latex and reclaim division, Dominion Rubber Company, Limited. The paper was originally presented by W. M. MacLean, division sales manager, at the meeting of the chemical and petroleum engineering division of the Chemical Institute of Canada, in Montreal last March.

Laticrete is a unique preparation combining the structural characteristics of concrete with the abrasion and corrosion resistance of rubber, and possessing the ability to bond firmly to concrete, steel, and other materials. It is used for the

*(Continued on page 1366)*

repair of damaged or worn concrete and as a tank lining material. Laticrete also has the properties of being flexible, waterproof, non-skid, and unaffected by oil or by temperature changes.

Installation of Laticrete is said to be easy. The one-quarter inch thickness required for most flooring repairs, resurfacings, or tank linings, makes Laticrete economical in initial cost, and additional savings result from the increased service life in many uses.

Laticrete has also been successfully employed for bedding, acid-proof bricks, or ceramic tile, and as an adhesive for polyester sheets and foamed glass.

Copies of the report are available from company offices in Montreal, Toronto and Winnipeg.

•

**Molecules to Management.**—Reprints of the "Molecules to Management" Symposium which was held during the 37th Annual Conference and Exhibition of The Chemical Institute of Canada in Toronto, June 21-23, 1954, are now available from the Head Office of the Institute, 18 Rideau Street, Ottawa.

Papers included in this eight-page reprint are: "Developing the Managerial Abilities of Employees," by Francis J. Curtis, Monsanto Chemical Company, St. Louis; "Finances and Financial Controls", by C. A Kline, E. I. Du Pont de Nemours, Wilmington; "Training Technical Personnel for Management," by J. B. White, Aluminum Co. fo Canada Limited, Montreal; "Communications and Human Relations," by J. T. McCay, Bois McCay Associates, Montreal; "Recipe for a Good Manager," by O. E. Ault, Civil Service Commission, Ottawa; "Engineers in Management," by K. F. Tupper, University of Toronto.

•

**Cast Stainless Alloys.**—The Alloy Casting Institute, technical association of high alloy foundries, has just published a set of data sheets covering the properties of all the more popular grades of alloys used for corrosion resistant (stainless steel) castings. Consisting of 13 individual data sheets describing each of the cast corrosion resistant alloy grades, the complete set, bound in an attractive file folder, is available from the Alloy Casting Institute, 32 Third Avenue, Mineola, N.Y.

Representing the most complete and up-to-date compilation now available on this subject, publication of these useful data culminates a project begun ten years ago. During this period information has been collected from many sources and in co-operation with other groups, notably the American Society for Testing Materials and the Society of Automotive Engineers.

Each data sheet lists chemical compositions, physical properties, mechanical properties, and includes a discussion of design considerations. The alloys are fully described with respect to metallurgical structure and characteristics, and preferred heat treatments are recommended. The general industrial fields of application are listed together with the various corrosives in which each grade has been successfully employed.

A compilation of data for the heat resistant cast high alloys is nearing completion, and is expected to be published in similar data sheet form some time next year.

•

**Tube Costs and Capacity.**—A publication which has just been released by the Unifin Tube Co. entitled "An Opportunity to Cut Costs and Increase Capacity with Unifin Tubing" is available from the company at P.O. Bcx 7, 1109 York St., London, Ontario. This bulletin gives complete technical and design data on the application of Unifin tube in shell and tube heat exchangers for oil refining, chemical processing and other industries. Equipment economy and operating advantages are clearly demonstrated through case histories. The engineering section gives complete information for design and selection of requirements.

•

**Small Boilers.**—A new bulletin, AD-135, describing the recently announced CB50-80 line of small boilers has been issued by

(*Continued on page 1368*)

the Cleaver-Brooks Company of Milwaukee, Wisconsin.

Bulletin AD-135 completely describes these new CB boilers which are available in 50 to 80 hp. (15 to 150# steam, 30# hot water) for heating and processing. This illustrated bulletin contains complete information of these major advantages—silent operation, fuel flexibility, fast, easy maintenance, automatic safe operation.

Also illustrated and explained are the new hinged front and rear doors, forced draft system, full five square feet of heating surface per boiler horsepower, four pass construction assures a minimum guaranteed efficiency of 80% when operating with oil, and eye level control panel. This four-page, two-color bulletin also includes drawings and specifications on the CB50-60-70-80-hp. models.

Cleaver-Brooks Company, 326 East Keefe Avenue, Milwaukee 12, Wisconsin. Form AD-135.

•

**Booklet on Welding Problems.**—"How to Overcome Your Welding Problems and Improve Your Welding Techniques" is the tile of a new 8-page, fully illustrated booklet, just released by Eutectic Welding Alloys Corp., Flushing, N.Y.

Written for welders by welders it is a practical down-to-earth manual designed for those who wish to increase their welding knowledge and improve their skill. Metallurgists and welding engineers also will find this booklet very useful because they will gain an insight into the many problems facing the maintenance welder.

The many variables the maintenance welder has to face are mentioned and explained; the causes of stress raisers, starter cracks and hard spots are discussed and methods indicated whereby they may be avoided or minimized.

The section on design shows by means of illustrations how weld failures can be avoided if due consideration is given to joint design to allow for multi axial stresses.

Many of these problems are eliminated if the correct welding techniques are used. Drawings indicate how a simple change in joint design will reduce these dangers of weld failure.

The practical welding experience of many years is packed into this 8-page booklet and should be of inestimable value to the welder who takes a pride in his work and wants to know some of the answers to everyday problems.

Copies may be had free of charge by writing to Eutectic Welding Alloys Corp., 40-40 172 Street, Flushing 58, N.Y.

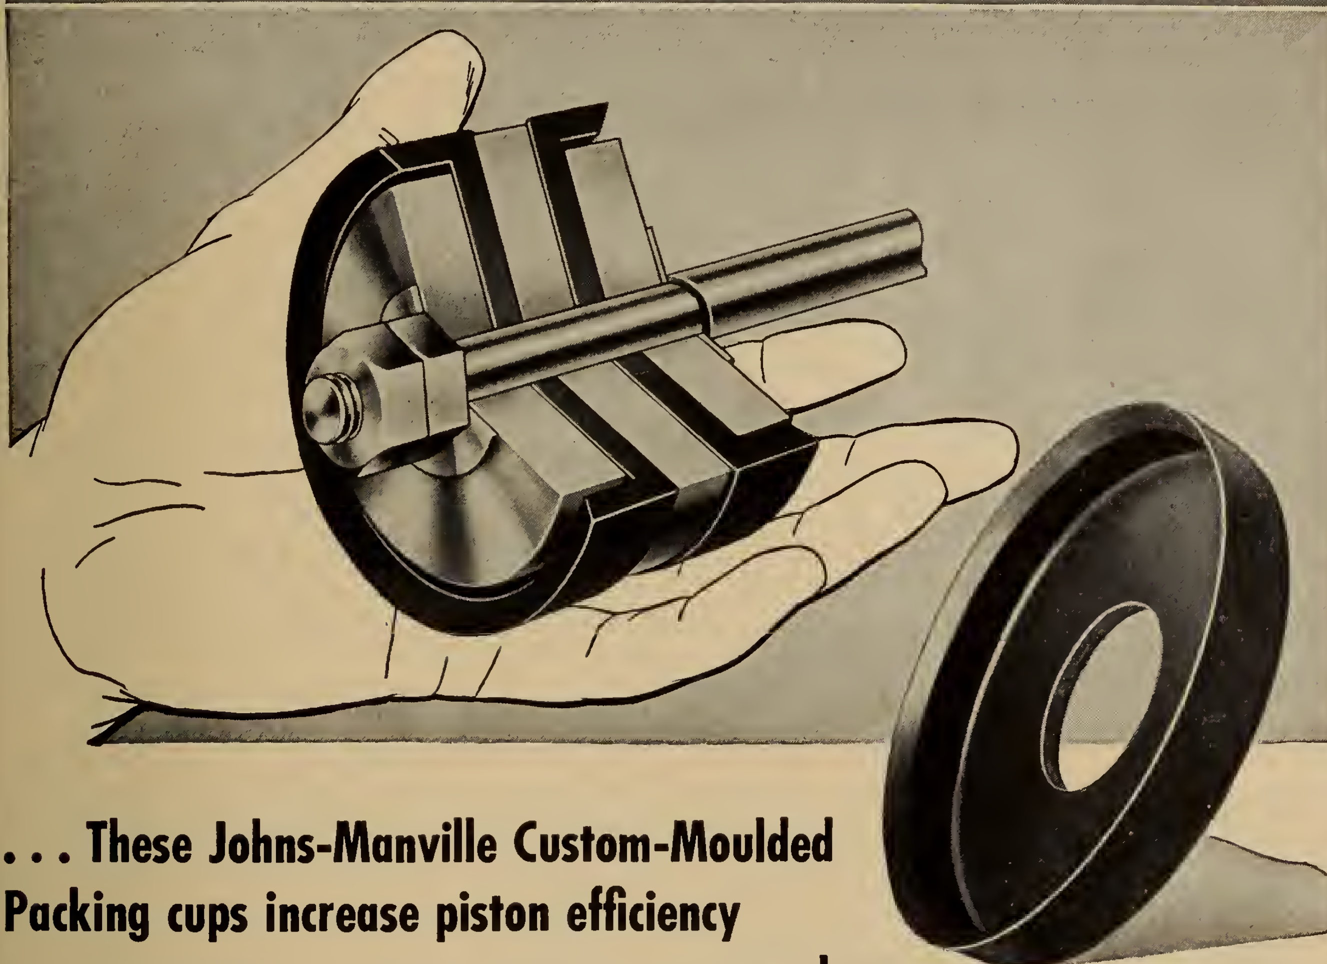
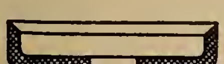
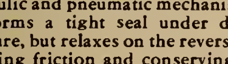
# Looking for a more efficient piston design?



## ... These Johns-Manville Custom-Moulded Packing cups increase piston efficiency ... save space ... save power ... serve longer



**TYPE A** . . . The Type "A" J-M Moulded Packing Cup is the "standard" for use on the pistons of pumps and on various hydraulic and pneumatic mechanisms. The lip forms a tight seal under discharge pressure, but relaxes on the reverse stroke, reducing friction and conserving power.



**TYPE B** . . . This type of cup is essentially the same as Type A, except that the leading edge of the lip is square instead of beveled. This construction provides greater strength where the lip may be exposed to distortion or excessive wear due to openings in cylinder walls.

Johns-Manville Moulded Packing Cups can help you improve piston designs. They provide a highly efficient seal . . . improve equipment performance . . . lower operating and maintenance costs. These custom-made packings are extensively used on all types of slow moving pistons and rams operating under high or low pressures and temperatures.

Johns-Manville Moulded Packing Cups may be used on practically all air or hydraulic-operated cylinders. For instance, those which are in such equipment as reciprocating pumps, hydraulic jacks and presses, pneumatic chucks, governors, lift trucks, grease guns, valves, drilling and boring machinery . . . or on any other equipment where efficient piston design is essential.

You have your choice of a number of styles and compositions of these precision-moulded cups to meet temperatures and pressures encountered in hydraulically operated equipment. Types "A" and "B," shown here, are most widely used on inside-packed pistons with the outside edge or lip contacting the cylinder wall or liner. Other types are available, however, for other services.

If you would like more information on these or other types of Johns-Manville Custom-Made Piston Packings, get in touch with your Johns-Manville Packings Distributor, or write Johns-Manville, 199 Bay St., Toronto.

I-173 JOHNS-MANVILLE JM PRODUCTS

**Johns-Manville PACKINGS & GASKETS**

approximate actual operating conditions and reflect the increased ability of modern belts. The horsepower tables permit the design or re-design of V belt drives at lower cost by reducing the number of belts needed to carry a given load and indicating the potential use of lower cost sheaves. The tables cover speed ratings from 100 to 6,000 feet per minute.

Other subjects covered in the new handbook include: selection of correct multi-V drives, installation and care of V belt drives, principles of V belt design, selection of pre-engineered V-V drives, designing a standard V-V drive not in pre-engineered tables, designing V-flat drives, multi-V quarter turn drives and double-V belt drives. A multi-V belt drive calculation sheet is also included.

A series of 22 simplified, easy-to-read tables cover such aspects of V belt engineering as installation and takeup allowance, belt speeds, length correction factor, calculation of centre distance and a geometry chart for drives. Thirty-one pages of tables are devoted to pre-engineered drives calculated with stock sheaves and stock sizes of V belts. Ninety per cent of two-pulley standard drives can be selected from the pre-engineered drive tables. For further information, please write Public Relations Manager, B. F. Goodrich, Kitchener, Ontario.

**Pipeline Construction Equipment.**—Canadian Ingersoll-Rand has announced availability of a 64-page catalogue of compressed air-operated machinery for pipeline construction. The laying of oil and gas pipe in the ground has created a group of contractor "specialists," and the catalogue has been designed for this group, although it is of general interest to all contractors.

The catalogue is divided into three sections for easy reference; rock drills, air compressors, and air tools. The rock drill sections cover the complete line of Ingersoll-Rand drilling equipment, and includes specifications of all the drills. The new "PLM" pipe line mounting, for side-boom tractor or crane mounting, is fully described.

Construction features, weights, dimensions and capacities of all the Ingersoll-Rand portable air compressors is detailed, including the Gyro-Flo or rotary type of portable.

Air picks, diggers, sump pumps, utility hoists, air wrenches and concrete vibrators are all listed in the Air Tool section of the catalogue, and the wide range of sizes of these tools that is available is readily apparent from the listings of specifications.

Write Canadian Ingersoll-Rand Company Limited at 620 Cathcart St., Montreal, Que., or contact your nearest Canadian Ingersoll-Rand branch office for a copy of this catalogue. Ask for Form CF-552.

●

**Liquid Level Gages.**—Catalog No. 246 covers in detail the three standard types of Jerguson convex scale and flat scale Truscale remote reading gages, showing how these gages bring the liquid level down to where it can easily be seen . . . therefore protecting valuable equipment and preventing expensive shutdowns. Included are features of design and construction; description and schematics showing operation; schematics and charts graphically illustrating the three types of datum columns to meet specific needs; illustrations and descriptions of typical applications; and information on visible and audible alarms and Truscale repeaters. Write Peacock Brothers Limited, P.O. Box 1040, Montreal, Que.

**Power Tunnel at Kemano.**—"Breakthrough," the drama-packed motion picture on the driving of Alcan's ten-mile power tunnel at Kemano, B.C., has just been released. This tunnel carries water to generators which will furnish the power which is indispensable to aluminum production. Produced in sound and full colour for Canadian Ingersoll-Rand, the film catches all the romance and excitement of underground rock-drilling. At the same time, it records in a concise and understandable manner the complete story of modern hardrock tunnelling practice with "Carset" tungsten-carbide-tipped Jackbits.

The "breakthrough" of this 10-mile, 25-foot diameter giant tunnel represents a remarkable achievement in organization and team work among men, and an impressive tribute to the design and construction of the equipment they used. Working in an isolated wilderness, 400 miles north of Vancouver, Canadian hardrock miners worked 24 hours a day for almost two years to drill, blast and muck some 2,300,000 tons of rock from the heart of a mountain — and shattered world records for driving this size of tunnel. (One crew advanced 61 feet in a single day — more than twice their scheduled target of 26 feet).

Lew Parry Film Productions of Vancouver had seven-man crews on location for the formidable task of lighting and filming the motion picture in the tunnel. To light the drill mounting of "jumbo" at the tunnel face and to film mucking operations it was necessary to carry a thousand pound transformer and a ton of cables and lighting equipment two and a half miles into the tunnel. To light the tremendous powerhouse cavern it was necessary not only to draw all available underground power but to light giant flares as well. Canadian Ingersoll-Rand has arranged to show the film throughout the country and interested groups (mining, construction, educational, service clubs, etc.) are invited to arrange showings with their local Ingersoll-Rand Branch, or by writing to the Film Department, Canadian Ingersoll-Rand Co. Ltd., 620 Cathcart Street, Montreal, Quebec.

●

**Air-Powered Vises.**—A new 4-page brochure describing air powered vises, discusses the many timesaving applications of these versatile units in production holding and pressing jobs. It includes many illustrations and describes how the usefullness of these air-powered vises is multiplied, (1) by using special jaw faces; (2) by unusual mounting in other than standard position; and (3) by using two or more air vises operating in unison from a single foot controlled valve. It also discusses safety and the elimination of operator fatigue with increased production. Copies available from: Van Products Company, 3736 West 12th St., Erie, Pa.

## LIBRARY NOTES

(*Continued from page 1323*)

Detailed requirements, including minimum factors of safety, are specified for the design of the crane structure and moving parts, and there is an appendix on the design of struts.

Wire ropes, rope drums and pulleys, lifting hooks and grabbing are dealt with, and an appendix is included on customary types of grab.

There are clauses on electric motors, brakes and electric braking, controllers, protective gear and switches, lighting and heaters, cables and wiring and earthing.

**CP 325 (1953) — Farm and horticultural electrical installations. 15/-.**

This code deals with the provision of electrical installations for farm buildings, nurseries, market gardens and private gardens. It covers such things as consumers' controls and distribution system, lighting of buildings, yards and roadways, heating, motive-power, battery-charging and electric fences.

**Canadian standards, Canadian standards association, National research building, Ottawa, Canada.**

**C.S.A. A82.20: 1954 — Standard methods of testing of gypsum and gypsum products,** 2nd ed., $1.25.

This specification replaces the 1950 edition and in it a number of changes are found which correspond to the latest issue of ASTM standard C26. It now includes an appendix covering the alcohol wash method of sieving gypsum and gypsum products. As in the first edition this standard covers procedures for the chemical analysis and physical testing of the products in question.

**C.S.A. C22.2 No. 1: 1949 — Appendix B — Construction and test of power-operated radio devices,** 3rd ed., .50c.

This appendix supplements the above standard and applies to power-operated television receivers and similar equipment, including remote units, portable units and electronic test equipment designed to be used on supply circuits operating at not more than 150 volts to ground. The tests apply to temperature, dielectric strength, short-circuits and arcing.

**C.S.A. C22.2 No. 13: 1954 — Construction and test of transformers for luminous-tube signs, oil- or gas-burner ignition equipment, cold-cathode interior lighting,** 2nd ed., $2.25.

This specification replaces the first edition issued in 1935 and is divided into three sections. Section A, concerning luminous-tube signs, applies to transformers of portable and stationary types, for potentials up to and including 600 volts low-potential, and 15,000 volts open-circuit high-potential, and includes outdoor and indoor types and reactors, if supplied as part of a transformer. The section on oil- or gas-burner ignition equipment deals with transformers for potentials up to and including 600 volts low-potential and 15,000 volts open-circuit high-potential. Section C applies to transformers for cold-cathode, high-voltage, luminous tubing, for potentials also up to and including 600 volts low-potential and 15,000 volts open-circuit high-potential.

**C.S.A. C22.2 No. 74: 1954 — Construction and test of lampholders and control equipment for use with electric discharge lamps,** $1.25.

Three sections are included in this specification, covering ballasts, automatic and manual starters, and lampholders and starter holders. The first applies to resistor- and reactor-type ballasts for use with electric-discharge lamps of the hot or cold cathode type, involving potentials of 1,000 volts or less and designed to be employed on circuits of not more than 750 volts between conductors. The information contained in the next two sections is to be used in conjunction with these ballasts covered in Section A.

**C.S.A. C22.2 No. 98: 1954 — Construction and test of power-operated radio transmitters,** $1.00.

This is part two of the Canadian electrical code dealing with the essential requirements and minimum standards covering electrical equipment, and includes all types of radio transmitting equipment irrespective of the type of modulation employed. Included in the tests are rating, temperatures, shock hazard and fire test, electrolytic capacitor and dielectric strength test.

## Introduction

*by* McNeely DuBose, M.E.I.C.
*Vice-President*
*Aluminum Company of Canada, Limited.*

On August 3, 1954, H. R. H. the Duke of Edinburgh, Hon.M.E.I.C., watched the pouring of the first aluminum ingot at the Kitimat Works of the Aluminum Company of Canada, Limited. That operation was the realization, after forty years of thought and effort, of the production of useful power and the development of industry by the diversion of water from the north central plateau of British Columbia directly through the coast range mountains to the Pacific Ocean.

#### General Description

The Cascade Mountains form the coast line of northern British Columbia. Behind them lies a plateau from two to four thousand feet above sea level. During glacial times, this plateau was buried under several thousand feet of ice, which spilled through a number of low points in the mountain barrier and gouged deep glacial valleys on the coastal side. Many of these valleys were cut down to a bottom elevation of a thousand feet or more below present sea level and are now fjords that reach as far as a hundred miles inland from the ocean front, their heads lying deep in the mountains.

One of these deep channels, called Gardner Canal, passes only twenty miles from the western end of a lake, called Tahtsa, which lies on the interior plateau at El. 2,800 and drains east and south through the Nechako and Fraser Rivers 700 miles to the Pacific Ocean. The Kemano River enters Gardner Canal through a smaller fjord, the bottom of which has, over the years, been filled with alluvium to above sea level. Ten miles up the Kemano River, and only ten miles from Tahtsa Lake, the river bed is less than 200 feet above sea level, providing a clear difference in elevation of 2,600 feet below Tahtsa Lake in a horizontal distance of only 10 miles.

The potential power resources of this fjord-plateau area remained a challenge for years, partly because the smallest possible development would be gigantic, with unknown engineering problems, and partly for lack of a consumer to use the power output; the initial investment would be enormous and could not be undertaken without a reasonable assurance of a large initial power load. The search for a user of this power eventually turned to aluminum production. Of all Canadian industries, aluminum smelting uses the most electric energy per dollar of product; it is the largest power consumer in the country; and it requires the assembly of large tonnages of raw materials from various parts of the world, making an adjacent seaport, such as could be provided by a fjord, a practical necessity. So aluminum production was a natural, if not the only, prospect as the developer of this area and the efforts of the Government of British Columbia concentrated over the years on attracting an aluminum industry. Today, the Kemano power station and the Kitimat aluminum smelter stand as evidence of the success of those efforts.

#### Surveys and Stream Flow

The site of the Kemano power station and the route of the tunnel from Tahtsa Lake to it were roughly surveyed by British Columbia government engineers nearly 25 years ago and records of stream flow in various rivers on the plateau have been maintained by the Federal Government since that time. By 1939 the Provincial Government had assembled enough information to publish a series of reports outlining various alternative schemes for developing power in that area, and in 1941 the premier of British Columbia asked the president of the Aluminum Company of Canada, Limited, to investigate the power possibilities of his province, with an eye to establishing an aluminum industry on the west coast. The Aluminum Company agreed, but after a year of preliminary investigation, the war discouraged exploratory work, the company concentrated its attention on the construction of its Shipshaw power development in Quebec and the British Columbia project was shelved.

In 1947 the Aluminum Company was again approached by the British Columbia Government and urged to give further consideration to the establishment of an aluminum industry in British Columbia. The company was willing and preliminary engineering on a number of possible sites was carried out by the company in 1948. In 1949 it was

McNeely DuBose, M.E.I.C.

decided that the most interesting possibility was the Tahtsa-Kemano project, expanded by the addition of a dam on the Nechako River high enough to impound the waters of all the principal lakes on its watershed, including Tahtsa Lake, so that the combined waters of the entire Nechako watershed could be diverted by a tunnel from Tahtsa Lake to the Kemano River. Additional water could be obtained by raising the level of nearby Nanika Lake by a dam at its outlet and its inflow could be diverted to the Nechako reservoir by a short tunnel.

### Smelter and Townsite

At Kemano, there was no room for an aluminum smelter and its accompanying townsite, but at the head of an adjacent fjord, called Douglas Channel, lay the Kitimat valley, several miles wide, extending 40 miles over a low divide to the Skeena River, where there were existing rail and highway facilities. Kitimat offered all the essentials and most of the desirable features for a smelter location. There was ample space, a good harbour for ocean shipping and easy road and rail connections. But its use would necessitate a 50-mile transmission line across the mountains from Kemano.

In early 1951, after two years of engineering work, the Alunimum Company decided to proceed with this development and construction of the first stage of the project was started. It took nearly a year to establish the basic system of access roads, wharves, camp and shop facilities and communications. At present, there have been completed and put into operation the Kenney dam across the Nechako River, one tunnel from Tahtsa Lake to Kemano (a second to be built later), one-half of the penstocks and eventual power station, both underground, a transmission line to Kitimat, an aluminum smelter of 90,000 tons annual capacity, harbour works and part of a townsite at Kitimat. A rail connection to the C.N.R. transcontinental line is approaching completion.

Although Kitimat has been in existence as an incorporated municipality since March, 1953, the first permanent houses were not occupied until the spring of 1954 and much remains to be done there. The planning of the town has been described in various architectural and town planning publications and no further description is attempted among these papers.

### The Engineering Story

The full engineering story behind this event is being told for the first time in the accompanying group of articles. There have been so many engineering problems to be solved that an exhaustive report of all of them would fill volumes, so in this series the emphasis has been placed on those parts of the job which have in them something new or different in the engineering field. This emphasis does not mean that the importance of sound, conventional engineering is underrated; it is the starting point for all innovations.

The conception, design and construction of the Kitimat development has required a wide variety of talents and consultants from various parts of Canada and other countries have been retained for specialized advice on different parts of the project. In addition, the technical staffs of the various suppliers and manufacturers of components of the work have provided that consultation which has come to be an indispensable part of modern engineering projects. The design of the power facilities has been the responsibility of the British Columbia International Engineering Company, Limited, and the smelter and harbour facilities were designed by the general engineering department of the Aluminum Company of Canada, Limited. √

# Hydraulics

## of the

# Kemano Development

*by*

W. W. Wolcott

*Senior Engineer,*
*International Engineering Company, Inc.*
*San Francisco*

**In this paper the author gives a brief summary of the hydrology and hydraulics of the power scheme, ultimately to deliver 1,650,000 horsepower at the smelter in Kitimat. Notwithstanding the relative paucity of precipitation, evaporation and streamflow data, the results of his calculations are believed to be close to those which will be attained in operation.**

At the Alcan project in British Columbia is one of the largest water power sites in the world, where the fundamental requirements of a good water supply at a high elevation relatively near a point of low elevation are admirably satisfied. This fortunate combination of natural conditions was recognized in the early 1920's by provincial government engineers and confirmed by surveys and in reports in the late 1930's. Elsewhere in this series is to be found the history of Alcan's interest in this site,* leading to a field reconnaissance in 1948 and to the subsequent rapid construction of the first stage of development.

Except for a small area in the northeast corner, the reservoir catchment lies entirely in Tweedsmuir Park, about 400 miles due north of Vancouver, B.C. The centre of the area is closely at 53° 30′ north latitude and 126° 30′ west longitude.

**W. W. Wolcott**

The height of land on the west consists of mountain peaks and ridges averaging 8,000 feet above sea level. From these heights the general slope of the catchment is downward towards the east, with most of the change in elevation taking place on the east slopes of the Coast Mountains, so that the remaining drop from the west end of the natural lake system to the main storage damsite is on an unusually easy gradient. The natural lakes which are combined and raised to make the reservoir, are long, relatively narrow, and deep, formed by several periods of glaciation in the area, which left the characteristically complex relief of gravel, sand and boulder till remnants on and around the sedimentary and extrusive rocks.

The Coast Mountains are generally the eroded remnants of a large granitic batholith lying in contact with the older formations to the east.

Since glaciation throughout the catchment area occurred relatively recently and, in fact, is still present at the higher elevations, the land is rather new and lean and of little value for cultivation or even for the production of timber. Some cattle and hay are raised commercially along the north shore of Oostsa Lake, but except for this small portion of the catchment, the cover below tree line is poor quality lodge pole pine, spruce or poplar.

The total area tributary to the main reservoir is 5,450 sq. mi., including approximately 350 sq. mi. of natural lake area.

#### Precipitation and Temperature

Precipitation varies greatly in the 130-mile length of the catchment, with probably 100 in. per annum along the westerly limits and less than 20 in. along the east boundary. For example, the precipitation is now known to total about 75 in. annually including 40 feet of snow at the west end of Tahtsa Lake, whereas snowfall rarely exceeds a total of three feet at Kenney dam.

Until the beginning of construction, the only available records of precipitation and temperature were those taken at Wistaria on Ootsa Lake and at towns along the Canadian National Railway about 60 miles north of the catchment. Average annual precipitation over a period of 25 years at Wistaria was 18 in. The high, low and mean annual average temperatures at this station were 48° F, 26° F. and 37° F. respectively. Although snow fall is was given a capacity of 60,000 cfs.

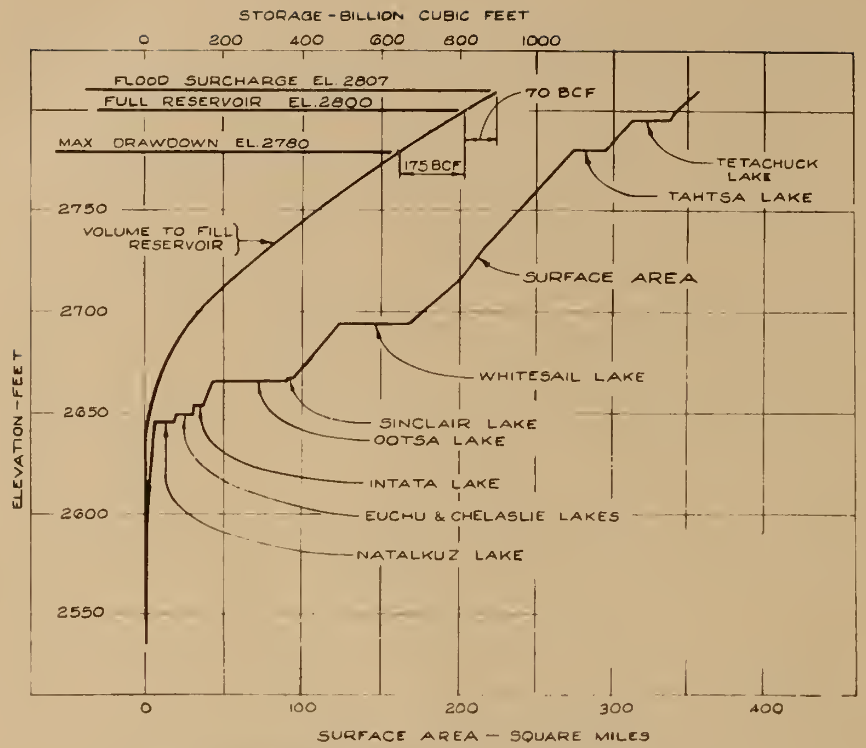

**Fig. 2. Nechako reservoir area and capacity curves.**

very heavy over the coastal end of the catchment, winter temperatures are moderate and ice rarely forms on the lakes until February. At Ootsa Lake and eastward, winter temperatures range much lower and ice does not move out of the lakes until mid-May.

### Runoff

The runoff records for the catchment were obtained by the Dominion Resources Bureau over a period of about 20 years prior to 1948. Gauging stations were maintained, with some lapses during the severe winters, at four key points on the rivers connecting the lakes, with a fifth important station measuring the entire Nechako River discharge about 50 miles downstream from Kenney damsite. The westerly 35 per cent of the catchment supplies about 80 per cent of the total runoff. From these records the following average flows were adopted for use in power project studies:

Minimum water year—4,490 cfs.
Maximum water year—8,510 cfs.
Average water year—6,495 cfs.

The flooded land areas, with reservoir full, will be about 110,000 acres. Net loss by evaporation from this surface area will be about 125 cfs, as calculated from stream discharge and rainfall records.

Firm flow for power generation of 6,080 cfs. from the Nechako catchment was adopted, based on economic considerations of the height of Kenney dam and of the saddle dams, on the size of channel excavation at the outlet of Tahtsa Lake to permit water to flow from the main reservoir into Tahtsa Lake during periods of maximum drawdown, and on considerations regarding the intake structure for power conduits. Three years of stream gauging on the Nanika River indicated a mean flow there of 950 cfs.; thus 920 cfs. from Nanika plus 6,080 cfs. from Nechako give the 7,000 cfs. assumed available for the ultimate project.

Inflow to the Tahtsa Lake basin alone was taken at an average of 930 cfs. for power generation prior to the rise of downstream storage to merge with the Tahtsa Lake natural storage.

The record of maximum floods, as obtained at the several gauging stations mentioned above, was thoroughly analyzed in arriving at a rational estimate of flood flows for the design of control works. The common type of flow probability curve made up from the record of discharges, increased by storage on the natural lakes, gives maximum daily average inflows to the catchment of 60,000 cfs. for the 1,000-year flood and 68,000 cfs. for the 10,000-year flood. Required maximum spillway releases with available storage become respectively 30,000 and 35,000 cfs.; the spillway was given a capacity of 60,000 cfs.

### Reservoir

This large reservoir is created by a major dam on the Nechako River and nine saddle dams along the north rim of the basin. The main spillway is located between two of these saddle dams and about midway between the east and west ends of the reservoir.

When filled to design El. 2,800, the surface area will be approximately 340 sq. mi. and the volume between this level and the surfaces before impoundment will total about 820 billion cu. ft., or 18.8 million acre feet, of which 175 billion cu. ft., or 4 million acre feet, is considered as live storage. These relationships are shown graphically in Figure 2.

This amount of live storage is a maximum requirement from the record to date and may be needed only when the generating plant is developed to its ultimate size, with Nanika Lake water diverted into the main reservoir. Prior to that time, the storage required for reservoir regulation will, of course, be proportional to the number of units operating at the power plant. Draft for Stage I installation with two units operating will be about 1,000 cfs., which is less than the minimum daily flow of record, therefore in an average year, about 3.9 million acre feet will have to be released through the spillway to maintain the reservoir at desirable elevations.

After the reservoir is filled and during Stage I operation, the surface will be maintained at about El. 2,790 minimum and spillage will be confined to the May to November periods when the reservoir is free of ice. Only moderate uniform spillway discharges should be required with this lower reservoir surface elevation.

From the start of plant operation in mid-summer, 1954, until about January, 1956, water for plant operation must come from the Tahtsa Lake basin alone, augmented by an initial surcharge obtained by building a temporary dam at the outlet of Tahtsa Lake to store surplus runoff in 1954.

### Spillway

The spillway consists of two 35 x 35-foot radial gates with sills at El. 2,765 and a 73-foot length of ogee spillway with crest at El. 2,800. With the reservoir surface at El. 2,800, the gated portion of the spillway will discharge about 44,000 cfs. and with 7 feet of surcharge on full reservoir elevation, the computed discharge of the free crest and gated sections together becomes 60,000 cfs.

The location of the spillway at this point will lead to the development of what amounts to a new 45-mile long channel for the Nechako River. In order to direct the releases into the low ground between the spillway and Skins Lake, which is at natural El. 2,731, a starter channel with a bottom width of 50 feet was excavated to El. 2,780 and along one side of this, a pilot ditch was carried 15 feet lower to El. 2,765. Inflow to the main reservoir will be stored, in order to bring the water surface as rapidly as possible to a point where it will feed back into the Tahtsa Lake basin. Beyond this point it is planned to continue storage to El. 2,800, after which spillway discharges will be increased as necessary to hold the reservoir at desired levels. These large and sustained discharges will erode new channels and create delta fans in Skins Lake and in the much larger Cheslatta Lake, 12 miles distant and about 200 feet lower than the present outlet of Skins Lake. The formation of a channel to carry upwards of 20,000 cfs. flows through this route will be one of the several more interesting engineering features of the operating history of the project.

### Hydraulic Conduit

Water supply for power generation is taken from the west end of the reservoir through a conduit system, including an intake structure of conventional type with No. 1 service gate sill at El. 2,725, thence through 10 miles of nominal 25-foot horseshoe tunnel to a connection with a simple surge shaft and with the upper ends of two 11-foot diameter steel penstocks. Each of these penstocks slopes downwards through the end of the mountain a total vertical distance of about 2,386 feet to four turbine manifolds.

The 25-foot modified horseshoe section planned originally for the entire length of the tunnel was used for about three-quarters of the entire length, with the remaining easterly quarter of the bore driven to 22½ x 28-foot and 21-foot modified horseshoe and 20-foot horseshoe shapes. The area of the 25-foot modified horseshoe section with 9 in. of average overbreak would be 563 sq. ft. Actual average overbreak throughout the tunnel was 24 per cent of the cross-sectional area inside neat lines. Calculation of friction losses in this long conduit involved consideration of a tunnel floor which is concrete paved throughout, a total of 15,415 feet of concrete lined sections of waterway area ranging between 490 sq. ft. and 314 sq. ft. and an equivalent gunited length of 21,050 feet. Adopted coefficients of friction for use with Manning's formula are:

For unlined or gunited sections .................. 0.038
For concrete lined sections. 0.014

Normal maximum flow in each tunnel (No. 1 and No. 2) will be 3,500 cfs. or half of the total firm flow of the ultimate development, which includes Nanika water. However, with only one tunnel available for operation, it would be desirable to operate the eight units on the tunnel at full gate, which would draw about 4,800 cfs. through that tunnel. Giving effect to all the variations in flow conditions throughout Tunnel No. 1 as built, the calculated head losses in the tunnel would be as follows:

1. Initial condition—1,000 cfs.................. 7 feet
2. Normal operating maximum—3,500 cfs....... 83 feet
3. Maximum draft—4,800 cfs.................... 157 feet

This leads to a minimum low level of El. 2,642 in the surge shaft under steady flow conditions, or five feet above the roof of the tunnel at that point.

### Surge

The relatively small quantity of water required to damp out surges in the conduit flow resulting from increase or decrease of demand at the power plant, will be provided by a 25-foot diameter shaft on a 48° slope with overflow lip at El. 2,850, or 50 feet above normal full reservoir.

Calculated departures of water surface in the surge shaft from steady flow levels are as follows:

1. Seven units operating, full gate to zero in 60 secs. +200 feet.
2. Five units operating full gate, two units on in 30 secs. −103 feet.
3. Eight units operating full gate, one unit off in 30 secs. +48 feet.

Unit operation at this plant will normally be ideal with respect to fluctuations, since the load is practically constant throughout the year and any routine changes in demand or supply can be planned with ample time for very slow operation of the turbine needles. However, surge calculations are based on 30-second closure of sphere valves or jets and a penstock pressure rise of 10 per cent is assumed for water hammer.

### Penstock

The 11-foot diameter portion of the welded steel penstock is 4,438 feet long from the wye branch at the end of the power tunnel to the first wye branch at El. 210. Using a friction coefficient of 0.012, and making conventional assumptions for losses at bends, changes of section and branches, the total head losses chargeable to the steel lined portion of the conduit are as follows:

Stage I, 1,000 cfs., —21 feet.

Normal full load on four units, 2,000 cfs., —52 feet.

Maximum possible, 2,400 cfs., —75 feet.

For the normal maximum flow of 2,000 cfs. through the penstock system, the following velocities would be obtained:

1. 11-foot diameter section, 21.0 fps.
2. 7-foot 9 in. diameter section, 21.2 fps.
3. 5-foot 6 in. diameter section, 21.1 fps.
4. 5-foot diameter section, 25.5 fps.

### Power Available

Supplied through the tunnel and penstock described above, and giving effect to all losses, the available firm power at the various stages of penstock construction will be as given in Table 1. √

**Table 1: Available firm power at various stages of penstock construction**

| | Discharge, cfs. | Effective head, feet | Horsepower, thousands | |
|---|---|---|---|---|
| | | | At powerhouse low tension bus | At high tension bus at Aluminum plant |
| Penstock No. 1, 4 units, 3 units operating, . . . . . . . . | 1,800 | 2,512 | 438 | 425 |
| Penstock Nos. 1, & 2, 8 units, 7 units operating, . . . . . | 4,200 | 2,402 | 977 | 950 |
| Penstocks Nos. 1, 2 & 3, 12 units, 10 units operating, . . | 6,000 | 2,435 | 1,415 | 1,374 |

# The Kenney Dam

*by*

Harry Jomini, M.E.I.C.

*Resident Engineer,*
*Aluminum Company of Canada, Limited.*

The Kenney dam is the key to Alcan's Kemano power development, turning the waters of the Nechako River from east to west. Largest of its type in the world, its total yardage exceeds four million and its construction involved handling other millions of cubic yards of material not in the dam itself, as well as half a million tons of freight for workers. Its building was not made any easier by its being many miles from any substantial base of supply. The story is well told here by the engineer who was the owner's representative on the dam construction.

The Kenney dam is the largest sloping, rockfilled, clay-core dam in the world. It raises the water some 300 feet at its face and some 17 feet in Tahtsa Lake, the western extremity of the lake-chain system where the intake of the tunnel carrying the reservoir water to the power house at Kemano is located. The dam is situated some 60 miles south of Vanderhoof at the entrance to the Nechako canyon in the Nechako River, one of the larger tributaries of the Fraser River.

### General Topography

From the Coast Range east to the Nechako plateau some 120 miles, there is a gradual sloping off in terrain into what might be classified as a rolling to undulating area, with a number of rugged, but low-range, hills. Elevations range from about 2,300 to over 4,000 feet. The undulating to rolling terrain rises fairly steeply from the lake basin to the hills, reaching 500 to 1,000 feet above the lakes. In places the terrain is precipitous, broken and rugged. The whole district was heavily glaciated; glaciation generally had the effect of deepening and enlarging numerous depressions, which today form the many lake basins. The ice also smoothed and rounded the more rugged relief features. During the recession of the ice, coarse, glacial deposits of an unassorted mixture of sands, clays and stones were laid down over most of the surface. Temporarily blocked drainage created large lakes in many of the present lake basins. Silts, sands and clays were deposited in these large, post-glacial lakes and now form agricultural lands lying along portions of the present lakeshores and rivers.

### Topography of the Job Area

The site of the Kenney dam at the entrance to the Nechako canyon topographically is ideally suited for a dam location. From the top of the gorge, some 80 feet above the river, the rock rises steeply on both flanks to a height of 500 to 600 feet. In proximity to the dam area, on the slope of low-range hills on either side of the Nechako River, there are deposits of clays, sands and gravels. The whole area is heavily covered by pine.

### Project Description

The job necessitated first gaining access into this remote area by building a 60-mile road south from Vanderhoof to the dam site area through bush and muskeg, establishing a camp site and moving in equipment. The dam area, as well as clay, sand and gravel material areas, was cleared. A 32-foot horseshoe tunnel was driven on an arc through 1,540 feet of the canyon wall and the Nechako River diverted through it. Upstream and downstream cofferdams within the dam area were constructed and the canyon dewatered. The next problems were the cleaning of the riverbed and of the canyon sides, on which the dam was to be built, to fresh, clean rock and removing any abrupt changes in contour of the rock foundation, particularly under the clay-core area; the placing of a concrete pad in the canyon bottom and guniting and grouting the area on the walls upon which the clay core was to rest; the developing of a quarry for the rockfill and of clay, sand and gravel pits for the clay core and filters; and, finally, the connecting of all with a maze of haul roads before the actual placing of the fill in the dam commenced.

### Geology

*General Outline*

The Nechako River, on leaving the lowest of the finger lakes, flows northeast across the interior Nechako plateau, following the foot of the south slope of a high ridge of volcanic rock which rises 1,000 feet or more above the plateau. Some 16 miles from the lake, the river makes a sharp bend and flows in a westerly direction for approximately five miles, then makes a right-angle bend to the north, cutting across

H. Jomini, M.E.I.C.

the volcanic ridge and forming what is known as the "Grand Canyon of the Nechako." The canyon forms a deep notch cut directly across the high volcanic ridge.

### *Local Geology*

The rocks exposed in the canyon consist of volcanic flows and tuffs of the tertiary age and it is on these that the dam rests. The volcanic strata are nearly flat, but dip slightly in a westerly direction. The lowest member of the strata series consists of a pile of tuffs and other ash rocks, the upper surface of which is at a depth of about 150 feet below the river at the axis of the dam. The member immediately above this is a coarse, volcanic breccia about 150 feet thick. Over this is a series of highly vesicular, volcanic flows about 200 feet in total thickness and above these are more massive and non-vesicular, volcanic flows of unknown thickness which extend far above the crest line of the dam.

Besides these rocks, there are several large dykes of felsite or feldspar porphyry which strike more or less parallel to the volcanic ridge, or, in other words, cross the Nechako canyon at right angles.

### General Description of Dam

The dam measures 1,500 feet along its longitudinal axis, 1,170 feet along its transverse axis and 317 feet in height, with a thickness on its crest of 40 feet. At full reservoir elevation of 2,800 feet, the water level will be 25 feet below its crest.

It is a rockfilled dam of an earth-diaphragm type in which the load-carrying element is a dumped rock-fill. This fill supports sloping layers of filter material, which enclose the impervious section of the rolled-earth construction. The upstream surface of the upper filters is loaded with gravel and rock to retain the filters and diaphragm in place and to resist erosion by wave action.

The composite structure forms a solid dam with a high factor of safety. The water load on a dam of this type deflects it downstream in plan and causes it to settle vertically. To compensate for this deflection, the entire structure is arched slightly upstream and a camber is provided in the longitudinal profile of the top. The adjustment of the structure to load tends to wedge the main rockfill and impervious diaphragm between the abutments, thus increasing the resistance against further movement of the dam and leakage through the diaphragm.

### Typical Section

The dam consists of a mass of quarry-run rock to El. 2,785, with a slope on the downstream side of 1:1.4 and provided with a series of berms so disposed that a slope line of 1:1.75 will pass through approximately the centre of the width of each berm. On the upstream side there is a slope of 1:1.37.

On the upstream side of the quarry-run rockfill and lying on the 1:1.37 slope, there are three layers of carefully graded filter material. The first layer is a bed of three-to-ten-inch gravel, 13¼ feet thick. Above this there is the second filter bed consisting of three-quarter-to-three-inch gravel, again 13¼ feet thick, measured at right-angles to the slope. On top of this is the third filter layer of zero-to-three-inch sand, which is 15 feet thick.

Overlying these three filter beds is the impervious rolled-fill section, on the same 1:1.37 slope, 50 feet thick at the bottom and 30 feet thick at El. 2,785, thinning down to 24 feet thick at its top elevation, 2,820. The upstream face of the impervious rolled fill is at a slope of 1:1.5.

Placed on the sloping upstream face of the impervious fill there is a sand filter bed five feet thick made up of material passing a ¾-inch screen. This layer of sand, as well as the core, is held in place by a mass of pit-run gravel and quarry-waste rock, with a layer of riprap consisting of quarry-run rock above it.

### Quantities

In the embankment of the dam there is a total quantity of 4,016,893 cu. yd. of materials. Breaking this total into various sections of the dam, the following figures result:

| | Cu. yd. |
|---|---|
| Quarry-run rock | 1,796,512 |
| Gravel, 3-10" | 136,697 |
| Gravel, ¾-3" | 164,680 |
| Sand, 0-¾" | 208,777 |
| Impervious rolled-fill material | 514,671 |
| Upstream sand below El. 2,820 | 74,970 |
| Pit-run gravel | 746,464 |
| Upstream riprap, including cap and downstream slope from top to El. 2,785 | 246,599 |
| Concrete pad under impervious rolled fill | 4,830 |
| Concrete in fault zones under core trench | 1,394 |

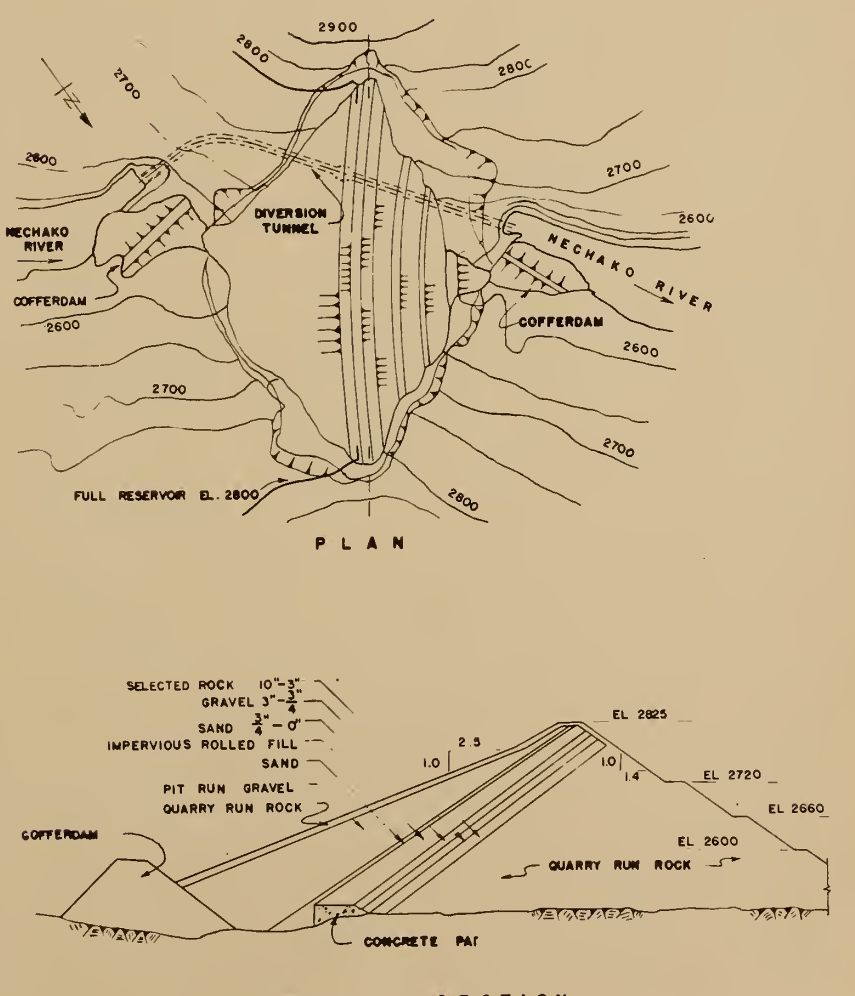

Fig. 3. Plan and typical section.

**Fig. 4. Nechako River before diversion. Stripping in progress and forms for tunnel gate structure in place.**

| | |
|---|---|
| Concrete in fault zones outside core trench | 1,026 |
| Original upstream cofferdam to El. 2,585 | 88,476 |
| Downstream cofferdam | 31,797 |
| Total | 4,016,893 |

### Diversion Tunnel

In order to divert the waters of the river, which normally ran at high velocity through the part of the canyon to be closed, a 32-foot horseshoe tunnel was bored in an arc through 1,538.4 feet of canyon wall, removing some 50,239 cu. yd. of material. Progress on this tunnel averaged 30 feet a day and the rock drillers finished their work in less than two months. Concrete portals were poured on the upstream side and gate guides fitted. The tunnel was lined with concrete 195 feet back from the portal, through what is known as the "transition" stage. This length, as well as that part of the tunnel underneath the core trench was grouted to seal up all possible cracks in the rock and to prevent any seepage or leakage of water.

Considerable attention was given to the sloping of the approach banks of the channel at the entrance to the tunnel portal, and the exposed rock face upstream and adjacent to the portal was gunited to prevent erosion.

### Cofferdams

Cofferdams cutting off the canyon and directing the water flow into and out of the diversion tunnel were built. These consisted of heavy rock placed across the canyon, with sand and silt dumped on their water faces to form impervious seals. A diversion channel to the tunnel portal was cut, a channel blasted in the rock to the river from the downstream portal and the river diverted.

Once this was accomplished, the clay core of the upper cofferdam, with filters back and front, with a mass of quarry rock on the downstream side and with riprap on the upstream face, was finished off and later this cofferdam was churn-drilled and grouted to make it as impervious as possible.

The downstream cofferdam was built on similar lines, but with less care, and without grouting, as, due to the gradient through the canyon, it had only to act as a guide for channelling the water discharging from the tunnel into the river.

### Dewatering Canyon

On the dam site between the two cofferdams, four 6-inch and 12-inch deepwell turbine pumps were installed and the canyon was dewatered. While this was in progress, stripping of the dam site area to a 1:1 slope or flatter was being accomplished by shovels, trucks and bulldozers, removing some 756,791 cu. yd. of earth.

### Trimming Canyon Walls and Dam Site Area

From the area lying beneath the downstream filters to upstream, including the upstream sand filter, all overburden was removed to rock. The canyon slopes were trimmed to approximately a 1½:1 slope and all overhanging cliffs, etc., were reduced to a ½:1 slope. Overhanging cliffs of less than ten feet height were disregarded. The core trench area was excavated to solid rock. This entailed the drilling, blasting and removing of some 104,957 cu. yd. of rock.

### Core Trench Area

The core trench area is the contact area between the impervious clay core within the dam and bedrock.

*Trimming:*

The core trench area was excavated to sound rock from the base to the top of the abutments on each end of the dam. Blasting was permitted, but excavating methods causing excessive overbreak and damage to otherwise acceptable rock was not permitted. This requirement entailed a considerable amount of light shovel work and hand cleaning. In the final stage, the trench was thoroughly hand-cleaned of all loose material. Stresses produced by the fill and water loads on the core foundation area are of small magnitude. Therefore, all excavation and treatment along the core trench were directed toward securing and maintaining imperviousness between the rolled-fill core and the grout curtain in the foundation rock.

Rock excavation was held to a minimum for efficiency in constructing the grout curtain and to provide the specified contact slope surfaces. Blasting was controlled and maintained at a slope no steeper than 1.5 to 1. Further excavation of the rock in the core contact area required after blasting was accomplished by barring only, except for local, narrow trenches, where grout or gunite surface was placed as part of the cutoff in the foundation.

Trenches or large pockets in the vesicular rock strata of the core trench area were filled with grout to the general plane of the adjacent trench area Re-entrant corners and pockets were filled with gunite to a radius of at least 6 inches in plan and profile.

*Core Foundation Pad:*

A core foundation pad in the core trench area was placed across the canyon bottom. This block of concrete in the bottom of the original river channel forms the core foundation in the lowest point in the profile. The pad varies with the contour of the canyon walls from 30 to 60 feet in width, having a vertical upstream face of 35 feet. Lengthwise, the pad is flat on top for 80 feet at El. 2,520. It then slopes at $1\frac{1}{2}$:1 to bedrock on the downstream edge. There are keys at right angles to the length of the 80-foot flat-top surface, trapezoidal in cross-section, with a long base of 14 inches and a short base of 8 inches; the depth is 8 inches and they are spaced at 22-inch centres throughout the upstream and downstream width of the pad.

*Guniting:*

One of the most difficult things to do by usual methods is to get the upper or surface zone of rock adequately sealed off. If the rock is seamy, as is often the case due to blasting or natural causes, but otherwise considered sound, and grouting is used, grout may leak to the surface in the immediate vicinity of the hole, often at lower than desired pressures. This naturally means that more holes are needed nearby to consolidate the surface, so that higher pressures can be used at lower depths. In order to get better results in grouting shallow holes, the surface of the rock at Kenney dam was gunited throughout the whole of the core trench area. Weep or telltale vents were left at frequent intervals along seams or joints. This forced the grout to spread laterally around the hole, particularly near the surface. If and when grout showed at these vents, they were plugged, forcing the grout still farther out in the upper zone of rock. The desired pressure was therefore held with the gunite seal, which meant that the grout spread more thoroughly throughout the depth of the hole.

Gunite need not be thick. It was found that from $\frac{1}{2}$ to 1 inch was satisfactory over fine cracks, the thickness depending on the crack or joint size and shape. As a general rule, gunite need not be applied over solid rock areas, but in this case the foundations did not have large areas of solid rock. There were areas of nearly vertical columnar joints; here the gunite held the grout in the joints.

Gunite served to prevent water from coming up through the rock at unpredictable points under the core and finding a path downstream. In other words, by means of guniting, the full efficiency of the core was maintained in the vicinity of the rock surface.

In order to meet schedules, guniting operations were commenced in midwinter and sections of the core trench area being gunited were totally housed in by canvas. The temperature under cover was kept above freezing by the use of coke salamanders and oil heaters. As one section of the core trench area was gunited and grouted satisfactorily, the cover was moved to an adjacent section.

Before guniting, the rock surface was thoroughly cleaned and all surface water removed. During freezing weather, the temperature of the rock was raised, to thaw ice frozen in the cracks. Gunite was applied as quickly as possible to the thawed and warmed rock, after which the fresh gunite was protected from freezing.

**Fig. 5. Damsite before placing of core material was started, looking upstream.**

It was kept at a temperature of 50°F. for not fewer than two days, then protected with a coverage of insulating material for a period of a week. Water for gunite was heated (during cold weather), to bring the mixture to approximately 50°F. Sand for gunite was free from ice. For best results, it contained only from 3% to 5% moisture. All sand was dried in a sand drier. Bone-dry sand was not acceptable, for it caused considerable static. The gunite mixture used was one part cement to three parts sand.

*Grouting:*

A cutoff curtain was extended down into the foundation rock by pressure grouting from the bottom of the core trench area and under both abutments of the dam. The purpose of the cutoff grouting was to prevent leakage from the reservoir through the foundation of the rolled-fill core. This requirement was satisfied by a continuous, but relatively thin, zone of thoroughly grouted rock.

Grouting was accomplished by a method of sequence drilling and grouting. First, as already explained, the area was gunited. Following this, a series of holes, known as the "first stage", was drilled, 30 feet deep at 20-foot centres, and grouted at from 30 to 50 pounds. The second stage was to drill and grout a series of intermediate holes 30 feet deep, grouting at 50 pounds. The third stage consisted of drilling to 75 feet through the first series of holes and grouting at pressures of from 75 to 100 pounds. The fourth stage consisted of drilling the final deep holes to a depth of 125 feet or greater, between the third stage holes, rather than deepening the latter. Grouting here was done at pressures of from 100 to 150 pounds or better to final refusal.

The principal difference in this program, as compared with usually accepted methods, lies in the location of the final deep holes between the third-stage holes, rather than deepening the latter. This was done to fill any possible sections between the third-stage holes that might not have been thoroughly grouted above the 75-foot depth.

In the grouting operations, 20,198 feet were drilled in rock to a depth of 30 feet and 32,939 feet were drilled to a depth of 30 feet in grout. In opening grout holes from 75 to 150 feet in rock, 21,736 feet were drilled and through grout at the same depth the footage was 2,336.

For pressure grouting of the core trench area, 48,760 sacks of cement were used. There were 684 grout connections or one connection for each hole, and 104 weep pipes were set in the same manner as grout connections, except that the pipe was of smaller diameter.

The total actual area, which was cleaned for the core trench prior to guniting and grouting, including a 3-inch strip on both sides of the trench area, was 24,134 sq. ft., and 18,872 sacks of cement were required in guniting this surface.

### Sources of Fill Material

*Roads:*

To develop sources of fill material and to haul this material to the dam site, some 45 miles of access roads, some of which were constantly changing, were built in and around the job site. These roads had to be of such a nature that, irrespective of prevailing weather conditions, they could carry loads in excess of 25 tons day in and day out, night after night, week after week, month after month, without stoppage of the haul equipment. To prevent congestion of traffic in the dam site area, roads in many cases were one-way, for, with 350 pieces of mobile equipment digging, hauling and delivering fill material to the dam site, traffic at times was as heavy as, if not heavier than, at the corner of Peel and St. Catherine Streets in Montreal. The roar of engines equalled or exceeded that found at any busy city intersection.

*Quarry:*

Adjacent to the left abutment of the dam was a perpendicular face of durable basalt rock, extending in a ridge some 3,000 feet or more, which was considered suitable rockfill material.

*Preparation of Site:*

The quarry site, of almost 200 feet vertical face exposure, was lightly wooded by small pine and other coniferous trees and covered by varying depths of overburden, from a few inches to several feet in the pockets and crevices in the basalt lava flow.

Stripping was commenced in late August and early September, 1951, by bulldozers, draglines, etc., the

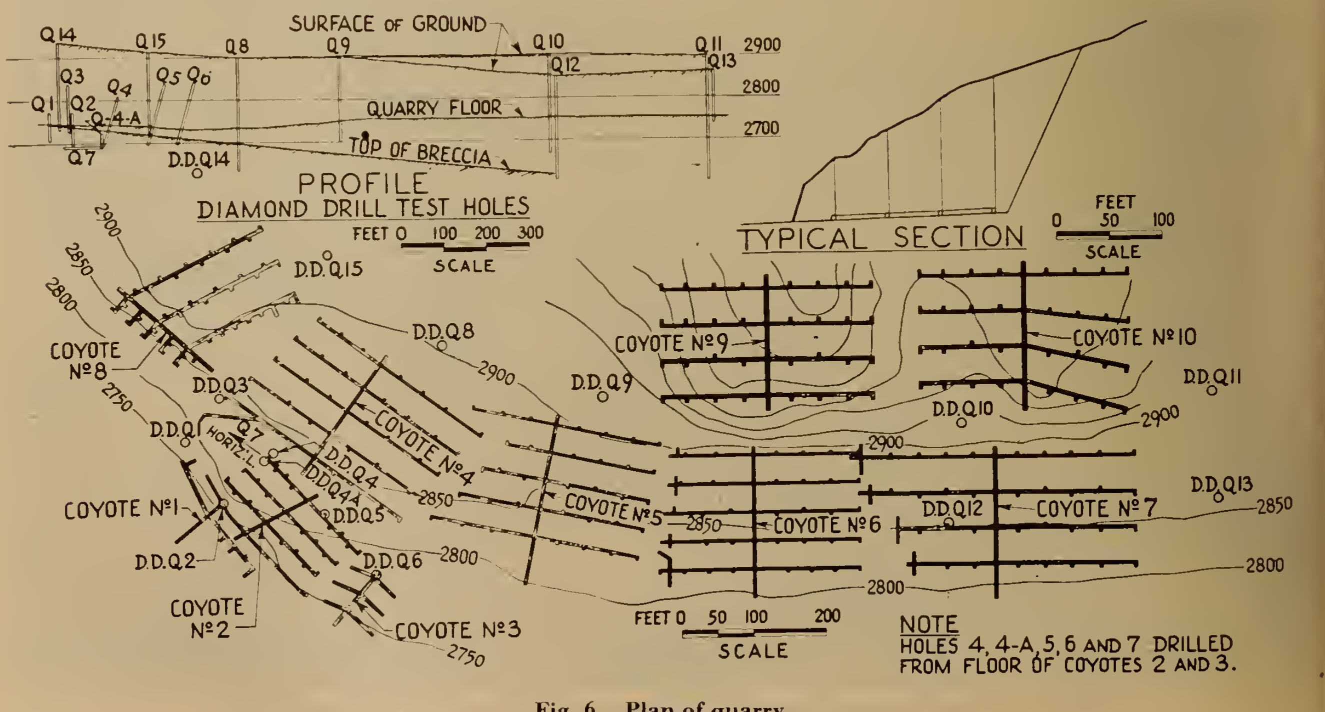

Fig. 6. Plan of quarry.

Fig. 7. Coyote hole blast in quarry.

lighter units crossing the Nechako some six miles upstream from the dam site area by a Klondyke ferry; the shovels and dragline equipment too heavy for the 20-ton maximum load of the ferry were forded across the river under their own power and with the additional aid of two TD-24 caterpillar tractors anchored on the far bank with winch tow lines, which successfully helped pull these heavy units through water up to their running boards.

After the quarry site had been stripped as clean as possible by these heavy units, it was sluiced off by high-pressure water. The first quarry floor was developed at El. 2,692. The face was first prepared by wagon drill equipment and later a 4- x 6-foot coyote tunnel was driven some 150 feet into the rock, loaded and blasted. The broken material was found to contain a large percentage of volcanic ash, breccia and fragments of basalt. The ash was obviously unsuitable and the breccia also appeared to be unsuitable for rockfill. The breccia was composed of fragments of basalt from a few inches to a few feet in diameter, cemented together in the matrix of volcanic glass, chloropal, opal and fine ash or pumice. The basalt fragments were strong and durable, while the cementing materials were not only weak, but some of them, on exposure to the atmosphere, shrank and cracked, thus causing disintegration of the whole rock. So a search was made for other sources of this fill material.

A locality east and north of the first quarry development and about 50 feet higher was examined. Here, high, bare bluffs of basalt extended from about El. 2,750 up to El. 2,950 and along a length of 1,000 to 1,500 feet. It was calculated that this area would yield from one quarry face, upward of 1,000 feet long and 100 to 200 feet high, all the rock required for the entire dam. Diamond drilling upward from the second coyote started at the lower quarry floor level of El. 2,692, as well as surface examination, strongly indicated that the rock in this 200-foot ledge would be entirely of basalt, more or less vesicular. The basalt exposed on surface was fresh, strong and durable, therefore, it was decided to move to this higher level of approximately El. 2,750 in order to establish a working quarry floor as quickly as possible at this new elevation, the second coyote, which had been driven some 918 feet, including main drift and tees, was blasted and any material suitable for rockfill was sorted out and saved, the remainder of the blast being levelled off to form a new quarry floor.

*Method of Quarrying:*

The development of the quarry and the winning of rock was done by a system of coyote hole drifts with a varying number of crosscuts and tees, depending upon the burden. As one coyote was blasted, a second neared completion and a third was already started. This sequence continued along the whole length of the quarry face, starting at the southern extremity and working to the northern end. In all, there was a total of ten coyote drifts with crosscuts and tees driven in the above sequence.

Tunnelling was done by drilling with Swedish-type drill and drill steel rods with tungsten carbide bit inserts. The average life of each steel rod and bit was from 500 to 600 feet. Regrinding of each bit was necessary after from 40 to 60 feet of drilling. The blasted muck was hauled out of the coyote drift by slusher scrapers worked by a double drum, air driven hoist. The blasted material was removed from the coyote portals by bulldozer and spread on the quarry floor.

*Explosive Charges:*

Explosive used in the coyote drifts and crosscutting tees was 40 per cent forcite dynamite. In the coyote blasting, 20 and 65 per cent ammonia dynamite was loaded and detonated by a single primer and primacord, fired through a blasting switch box connected with 220 or 440 volts direct from a heavy motor generator set, or with the camp's main power supply.

Tables 1 and 2 give the comparative quarry loading factors and figures.

*Excavating:*

Rock was excavated from the rock quarry by four shovels with 3½-yd. buckets or 4-yd. rock-type, wide-mouthed buckets. In addition, there were three 2½-yd. shovels. For clean-up work around the shovels there was a fleet of three bulldozers. The shovels loaded the rockfill into a fleet of end-dump trucks of 10- to 17-cu. yd. capacity. On the average,

Fig. 8. Loading trucks in quarry.

this working fleet consisted of between thirty and forty trucks.

A traffic system was set up with a control tower and, as each truck driver approached, a shovel number was flashed from the control tower ordering him to load from the shovel designated. In this way it was possible to obtain maximum loading efficiency from all shovels. The usual procedure was to have one truck loading on one side of the shovel, an empty one ready to load on the other side and a third either moving into position or standing by to move into position. The trucks were spotted under the shovel by the shovel greaser. Bunching or grouping of the trucks around one shovel, causing others to go lean, was overcome by this traffic system. After shovel runners had become used to their machines and to routine loading, all units in the quarry averaged better than a minimum of 150 cu. yd. per hour and as high as a maximum of 300 cu. yd. per hour or better. A four-lane divided highway connected the quarry to the dam site a mile away. This was constantly watered and maintained. Each of the 30 to 40 trucks hauling from the six shovels achieved a 12-minute turn-around from dam site to quarry. One load was dumped every 45 seconds. It was not unusual to see pieces of rock up to 20 tons in weight promptly loaded and placed in the fill as they were.

***Selection of Rock:***

A rigid control was kept of the rock being delivered. Specifications required that the rockfill be composed of strong, durable blocks of basalt. Soft, laminated or weakly-jointed blocks, or rock displaying any tendency to slack in air or water, were not acceptable. No vegetable matter was placed in the rockfill section of the dam. Earth, rocks, spoil and other quarry fines were permitted in the mass in an amount not exceeding that required to fill the voids in the coarser materials, except that quantity in any one truck load was not to exceed 15 per cent by volume of the total load.

A staff of competent inspectors saw that these specifications were maintained. Any unacceptable loads of rock loaded by the shovels were despatched by signal from these inspectors to a waste-rock dump in front of the quarry. Acceptable loads were signalled by inspectors to proceed to the dam site.

***Downstream Filter Material:***

Material for the downstream filters was obtained from gravel pits in the low-lying hills in the immediate vicinity of the dam. While several pits proved to have suitable pervious gravel, most of the material came from one pit only. The gravel was screened into three grades and stockpiled. The grades consisted of sand of 0 to ¾ inches; gravel of ¾ to 3 inches; gravel, 3 to 10 inches; and crushed basalt rock from the quarry of 3 to 10 inches. Due to the shortage of 3- to 10-inch gravel in the gravel pits, it was necessary to crush and screen 115,650 cu. yd. of quarry rock to make up the deficiency.

Besides the rock crushing and screening plant for the production of this graded rock, it was also necessary to set up a second screening plant and screen out gravel for the ¾-3-inch gravel and the 0-¾-inch sand of the downstream filters. Further, the sand filter adjacent to the impervious clay core having to be free of silt, it was necessary to desilt this material. The specifications called for silt content in the finer sands to be not more than 2 per cent.

To obtain clean sand a washing plant of simple hydraulic design was set up, capable of producing 2,400 cu. yd. per hour. The design was adapted from classifier washers used in mineral dressing industry. It comprised a sand tank whose capacity depended upon the quantity of water overflowing at the separating mesh and the dimensions at the overflow level. In theory, for all practical purposes, all water entering can be considered as overflowing vertically, which gives a rising water velocity of $V=Q/A$ where $A$ is the tank cross-section at the overflow level, $Q$ is the volume of water overflowing per unit of time and $V$ is the velocity. The settling velocities of the sands treated were considered as lying in the Newton Range.

Without some means of adjustment of the overflow, the character of the sand from such a tank will vary widely under the fluctuating conditions of the stream flow normally prevailing. This condition was overcome to a certain extent by installing a cross baffle and by adjusting its distance from the overflow lip. Then that part of the tank on the overflow side of the baffle was figured for rising current. The rising velocity for a given water flow increased as the baffle was moved toward the overflow lip. Sensitivity was increased to the point where the fluctuation in the top level of the sand was small. Scour under the baffle entered as an element determining the size of the overflow. The whole became substantially automatic for a given setting of the baffle over a considerable range in feed volume. Adjustment in the depth of the baffle permitted some control of sharpness of separation. The overflow discharge from the tank went to waste and the bottom discharge through air-operated gates was the finished product. The setting of the baffle and the adjustment of the depth of overflow for sharpness of separation was controlled by sampling and screening the product every twenty minutes.

As indicated, the immediate downstream filter beneath the impervious core was made up of natural wash sands and gravels passing a ¾-inch screen and having the below gradation:

| Tyler sieve size | Percentage finer than Upper limit | Lower limit |
|---|---|---|
| ¾″ | 100 | — |
| No. 4 | 83 | 55 |
| No. 8 | 73 | 40 |
| No. 14 | 61 | 27 |
| No. 28 | 48 | 14 |
| No. 48 | 32 | 3 |
| No. 100 | 17 | 0 |
| No. 200 | 0 | — |

The coarse filter supporting the downstream sand filter, as mentioned, was of screened gravel or crushed stone, all graded and within the respective size ranges already specified.

### Impervious Core Material

High grade clay was found in quantity about a mile from the dam site. The whole area was thoroughly drilled, samples taken every 5 feet of depth and tested for standard Proctor density, Atterberg limits, permeability coefficiencies, moisture content and mechanical analyses. Also, a plasticity chart was made of all holes tested. A thorough and complete knowledge of the nature, properties and characteristics of the clay in all sections of the clay pit was therefore established. The material used as the impervious core was maintained by blending and selection within the upper and lower limits by volume given in Table 3.

Prior to the commencement of delivery of the clay core material, two clay test strips were laid down in the clay pit area and varying thicknesses of lift were spread with a varying number of passes by a sheepsfoot roller on these lifts. Field density tests were run on the material, as well as corresponding laboratory density tests. These tests indicated that a 10-inch lift with 16 passes of a sheepsfoot roller at a unit pressure of 1,100 to 1,200 lb. per sq. in. would give satisfactory compaction of the fill.

Areas of the clay pit were then ripped by a caterpillar tractor and rooter to a depth of two and a half feet and water added with a sprinkling truck to the desired amount, so the material was brought very close to the correct moisture content in the pit; any required final adjustment could be made by sprinkling and raking on the main fill itself. A bulldozer-mounted rake with two rows of teeth 18 inches apart and staggered 9 inches apart followed behind the tank truck, raking the clay material. For sprinkling and moisture control in the clay pit, it was divided into four sections of approximately equal area, each section ripped to a depth of two to two and a half feet and then watered by the sprinkling truck. The section was allowed to stand for at least three to four days, after which it was mixed by bulldozers before the material was hauled to the dam site. A close check was kept on the moisture content and the depth of penetration of moisture in each area in order that additional water could be added if necessary. By working areas consecutively, it was always possible to have material available which had been irrigated for the prescribed time. It was found that the material required three to four days for the moisture to penetrate uniformly throughout and thus ensure a satisfactory fill.

All stones in the material large enough to impede the action of sheepsfoot rollers on the fill in the dam were removed by hand. In general, stones left within the impervious section were limited to a maximum dimension of one-half the thickness of the compacted layer, with an absolute maximum of 6 inches in greatest dimension. Moisture content aimed at was 14 per cent. Production from the pit reached a maximum in excess of 6,000 cu. yd. per day.

In order not to interrupt production of the clay pit during freezing weather by the formation of moisture crystals in the clay, the pit was treated and clay was stockpiled with one per cent of salt, in the early fall of 1952. This was estimated to be satisfactory for use down to a temperature of at least 10°F. and perhaps lower.

Investigation, testing, control and inspection of all phases of producing and placing the clay core material was under the direct supervision of Engineering and Construction Services, Ltd., of Edmonton.

#### *Upstream Filter Material*

*Sand Filter:*

As for the downstream filter, the material for the upstream filter was obtained from natural deposits in the vicinity of the dam site. Sand for this filter was produced from the screened material delivered from these deposits to the screening plant. The material passing a ¾-inch screen was used. The silt and clay particles found in the deposits were desirable and therefore no washing of the product from the screening plant was required.

*Pitrun Gravel:*

Pitrun gravel was produced directly from the material found in the natural deposits in the area and loaded and hauled directly to the dam site.

#### *Riprap Upstream Face of Dam*

*Large Run-of-Quarry Rock:*

For the upstream riprap, large boulders produced in the quarry operations were selected and set aside. This large run-of-quarry rock averaged chunks weighing 2,000 lb. or more.

### Placing of Fill Materials

The placing of fill materials commenced May 10, 1952, the first load of rock being dumped in the rockfill section of the dam. The placing of the clay core material and of the downstream filters commenced on June 17 and was completed on October 20. On October 8, the two 110-ton gates in the concrete gate structure at the upstream diversion tunnel portal were dropped and the Nechako River sealed off. On November 28 the placing of a total of

**Table 3: Approximate limits for impervious core**

| | Grain size, mm. | Percentage finer than Upper limit | Lower limit |
|---|---|---|---|
| Clay | 0.005 | 30 | 9 |
| Clay and silt | 0.05 | 54 | 18 |
| Clay, silt and very fine sand | 0.10 | 60 | 21 |
| Clay, silt and fine sand | 0.25 | 70 | 26 |
| Clay, silt and sand | 1.00 | 85 | 35 |
| Sand | 5.00 | 100 | 50 |

4,016,893 cu. yd. of all types of fill material was completed.

***Rockfill Material — Quarry-run rock:***

The placing of quarry-run rock in the dam was accomplished in seven consecutive stages.

This rockfill was placed by dumping from the greatest height practicable. Lifts or stages were advanced in the initial construction of the rockfill from the south abutment to the north and continued thus until El. 2,730 was reached, when filling from both sides toward the centre of the dam was commenced. The top of each lift was maintained approximately level as the lift advanced and was thoroughly roughened to bond with the succeeding lift.

By selection of loads, the massive blocks were placed on the downstream slope of the embankment. As each load was dumped on the fill, its discharge arc was met by the jets of two air-actuated hydraulic giants so that the smaller sizes in the load were thoroughly washed into the interstices of the larger rock, filling voids, crevices, etc. The total quantity of water supplied for this purpose was twice to four times the volume of the rockfill being placed.

It was originally expected that by dumping the fill from the greatest practicable height the best consolidation of the rockfill would occur. At first, heights greater than 40 feet were specified as desirable, but, it was found that compaction and consolidation of the rockfill from a height of over 40 feet was not particularly advantageous, provided ample sluicing water was applied.

Each portion of that lift which lies outside the downstream slope of 1:1.4, beginning at El. 2,785, provides additional weight to resist earthquake shocks and was placed without sluicing water after the completion of the rockfill.

***Downstream Filters:***

The downstream filter zone was placed against the slope of the main rockfill, the material being placed in horizontal layers not more than 12 inches thick and each layer being suitably compacted by crawler tractors before the next was placed. First, the 3 to 10 inch gravel and crushed rockfill was placed. Against this was placed the ¾ to 3 inch gravel, followed by the 0 to ¾ inch washed sand. Each layer was built up and maintained approximately 5 feet above the adjacent upstream layer.

*3-10-inch Filter* — Both screened gravel and crushed stone were used for this layer, gravel below El. 2,650 and crushed rock above this elevation. At El. 2,650 there was a transition zone of approximately 20 feet in height from the gravel to the crushed rock. Thus, they made up separate areas in the filter and were not mixed. The transition between the two materials was made in steps in the 20-foot height.

Fig. 9. Sluicing dumped rock fill.

*¾-3-inch Gravel Filter* — The placing of the ¾-3-inch gravel followed the placing of the 3-10-inch gravel layer. To accomplish thorough compaction within a distance of 100 feet from the ends of this filter layer adjacent to each abutment, a reduction in the thickness of the lifts laid here was made to 10 inches and each lift was thoroughly compacted by caterpillar tractors, or by hand tampers wherever inaccessible to tractors.

*0-¾-inch Washed Sand Filter* — Particular care and attention was given to the placing of this sand filter directly beneath the core, for, should a crack open up in the core in spite of all trimming precautions, the water flowing through the crack would enter the fill. If this filter were absent, or if it were veined by coarse material, the water would gradually erode a tunnel across the earth section. The material of this filter layer had therefore to satisfy the condition that it should be perfectly cohesionless, thus eliminating the possibility of the formation of cracks across the filter layer, and yet be fine enough to retain any solid particles detached from the walls of the cracked core. The material for this filter was closely graded in order to reduce the natural tendency of mixed grain materials to segregate according to grain size during the process of placing and spreading.

Along the contact between this filter and the second filter layer, particles of the filter were washed into the interstices of the second one by jets of water and a transition layer between the two filters was thus formed.

During the process of placing and spreading the sand filter material, definite steps were taken to make sure that no segregation according to particle size took place. The filter was placed in 10-inch lifts and compaction was performed by single caterpillar tractor; the whole filter was adequately moistened, making the resultant sand fill very compressible. Because the high compressibility was associated with excessive strains in the core compaction of the sand filter within a distance of 100 feet from each end, the sand was spread in layers with a thickness of not more than from 4 to 6 inches and compacted as thoroughly as possible. After the fourth layer of sand filter had been placed, a drill rod was driven with a sledge hammer into the fill for a depth of two or three feet and the number of blows per foot of penetration was noted. These represented the yardstick for measuring the degree of compaction; the measurement was repeated for each 4-foot gain in height of the filter bed. Formation of cracks in this sand filter would defeat its purpose. A distinction was therefore made between those parts of the area to be covered by the filter where the filter layer would be only warped and those parts where it would be seriously bent and stretched. The latter were located in the proximity of the contact between the rock and the filter layer, above those lines where the slope angle of the rock surface increased abruptly in a down-hill direction. In these areas, the sand filter zone, whose normal width was 15 feet, was increased to a total of 16 feet and divided into two layers, each 8 feet thick. For the first layer in contact with the impervious clay core, stockpile sand material in its unscreened state was used. The second was composed of that fraction of screened material which was retained on a 4-mesh screen. Along the contact between the rock and the sand filter the material was hand-tamped. These sections were nicknamed "ball-bearing joints".

*Impervious Rolled Clay Fill:*

After the downstream filter zones were placed to approximately the same elevation for the full length of the dam, the construction of the impervious core or rolled clay fill, which acts like a rubber skin, not failing unless excessively stretched, was started, using equipment and methods standard for rolled earth embankments.

Successive loads of clay were deposited in rows adjacent to one another and approximately parallel to the axis of the dam, the material thoroughly blended in the process of spreading by first being worked over by scraper equipment and then further run out by caterpillar tractors and bulldozers. The fill adjacent to the abutments was built up so that it continued to the top simultaneously with the main body of the clay fill.

The material in the main section of the fill was spread over the embankment in layers from 8 to 10 inches thick, that adjacent to the abutment was spread in layers with an average thickness of at least 2 to 3 inches. Heavy loads were not allowed to track each other on top of the embankment, nor was any unnecessary concentration of travel tending to cause deep ruts, laminations or uneven compaction within the fill allowed. Before spreading any layer, all ruts or unevenness in the existing surface were smoothed out. Before placing each lift the surface was scarified and sprinkled, if necessary, before more material was placed. All oversize rocks were removed from the material. These included any rocks too large to go between the teeth of the sheepsfoot roller and any rock which caused the roller to bump in passing.

The moisture content of the material was kept slightly below, or at, optimum moisture content, varying between 12 and 14 per cent. Methods of transportation which permitted excessive evaporation or change in the moisture content of the material being delivered were not permitted. To maintain uniform moisture content and material of the desired quality, hauling equipment was scheduled so that a uniform rate of delivery of material was maintained.

For compaction, rollers of the sheepsfoot type were drawn by tractors; 16 to 20 passes of the roller at a unit pressure of 1,100 to 1,200 pounds per square inch were made. The roller was not allowed to walk out completely. Approximately 3 to 4 inches of loose material was left on the surface when compaction was correct. Each roller had two drums mounted in tandem, permitting turning on a small radius, and was capable of being propelled in either direction. The teeth of the roller were maintained at least 7 inches long over all and were fitted with hard steel diamond points. Any teeth having a penetrating area of less than 5 square inches each were replaced or were built up by welding. Each drum on the rollers was equipped with cleaner bars. The normal rate of travel was approximately two and a half miles an hour.

Rolling was done in a direction parallel to the centre line of the embankment material and no dumping was allowed in areas where rollers and spreaders were operating. All rollers working in any one area followed the same route. Roller paths overlapped approximately the half width of a roller.

Compaction in the areas of the clay fill adjacent to the abutments and extending from the abutments out into the fill a distance of approximately three feet, as well as in areas inaccessible to the sheepsfoot rollers, was performed by pneumatic tampers. Every precaution was taken to ensure a tight contact of the impervious fill material between the rock and the impervious layer.

Clay processed with one per cent of salt was used above El. 2,809 at each abutment and above El. 2,812 in the centre of the core. This processed clay helped protect the top layer of the core from any frost action in its adjustment to conditions immediately after construction and during the first winter season.

The materials furnished for and the work done on the impervious clay core to meet specifications were subject to rigid inspection. Inspectors on each shift saw that the rollers made the required number of passes on each lift, counting the number of passes in each case and seeing that none of the rollers became dirt-clogged.

On each shift density and moisture tests were taken for at least every 2,000 cu. yd. of fill material placed, as well as in areas where the degree of compaction was doubtful, such as at the junction between mechanical tamping and rolled compaction, in areas where the rollers turned, where too thick a lift was being compacted, where it was suspected that less than the specified number

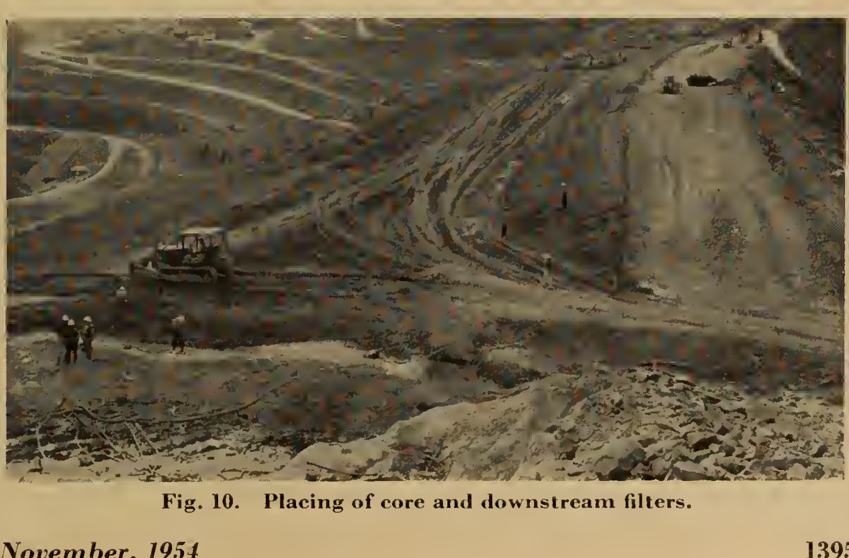

**Fig. 10. Placing of core and downstream filters.**

**Fig. 11. Dam approaching full height.**

of passes were made, where oversize rock which had been overlooked was contained in the fill, where material containing minor amounts of frost had been placed or material placed near freezing temperatures, and in areas containing materials differing substantially from the average or specifications. The inspector in charge of each shift turned in a complete report of activities on that shift, including depth of material placed, the section of the clay pit from which the material was hauled, tests run and the location of the tests. The location of the tests was given on a grid system and the elevation of the tests recorded. Further, the inspectors saw that the material used in the hand tamping operations was free of all rocks down to 2 inches in diameter. Density tests in such areas were performed with a rod having an end area of half a square inch, forced into the soil to get an idea whether it was properly compacted and whether the density was uniform.

The standard Proctor method of soil compaction governed the construction of the core, which included tests for:

- Optimum moisture content.
- Unit dry weight of soil in the embankment.
- Plasticity.
- Permeability coefficient.
- Strength at saturation.

The average dry density of the compacted core was maintained at better than 95 per cent of the standard Proctor density obtained in the laboratory.

In the placing of a total of 514,671 cu. yd. of compacted clay in the impervious core, 541 field density tests, with comparative laboratory tests, were taken as placing progressed. In addition to these tests, 29 test pits were dug between Els. 2,551 and 2,820 and density tests taken in each pit at one-foot intervals to a depth of 8 feet. The test pits served as an additional check on the daily density tests and established if the material had been laid down in too thick layers, if large rocks had been overlooked, if material had been placed at incorrect moisture content or if any stratification was present in the fill. Moisture was checked closely during the entire job and in general was held within two per cent of the desired optimum moisture content.

***Upstream Filters:***

*Sand* — The upstream sand filter was placed in 12 to 24-inch layers, moistened and rolled in the same manner as the downstream filter sand, following the impervious layer as closely as was practical.

*Pitrun Gravel — Quarry-waste Rock* — The upstream random fill, composed of pitrun gravel and quarry waste rock, was placed on top of the upstream sand filter in horizontal layers not greater than 3 feet in thickness and in such a fashion that the upstream sand filter was not disturbed. The permeability of the quarry waste was lower than that of the sand. Therefore, in the event of a drawdown, the descent of the water table in the sand layer or upstream sand filter may lag behind that of the water level in the reservoir. In order to eliminate this possibility by making a permeable fill, the quarry-waste fill located above El. 2,750 was made of material which did not contain more than a trace of particles of sand and silt. As a further precaution, inserted in the quarry-waste fill below El. 2,750, a few layers of pitrun gravel with a thickness of about 3 feet each and spaced approximately 50 feet apart vertically served as weep-holes.

*Riprap* — Quarry run rock was placed on the pitrun gravel and quarry waste fill to riprap all the face of the dam which would be exposed to wave action and erosion from surface drainage during the period of filling to full reservoir and thereafter.

Large, clean chunks of basalt were used for this material, end-dumped from trucks down the face and sloped off to 2.5:1. The top of the dam was capped with this material as well as the upstream face and so was the downstream face to the first berm. To make a 40-foot roadway across the top of the dam, crushed rock was applied over the quarry run material. For fencing the roadway, boulders of the largest size were spaced at intervals of approximately 8 to 10 feet on both sides of it.

#### Settlement and Deflection

For settlement and deflection measurements on the crest of the dam, 13 stations were installed beneath its crest. Settlement and deflection plates were combined and were placed in the top of the clay fill approximately 5 feet below the crest of the dam.

Settlement and deflection plates were also placed in the berm at El. 2,785.0 about three feet below this level in the top of the sluiced rockfill to indicate the rockfill settlement separately.

Tables 4 and 5 record the movement measured from December, 1952, to July, 1954.

#### Tunnel Plug

To seal the diversion tunnel, a 60-foot thick concrete plug was poured into the tunnel, having a 10-foot hexagonal chamber with a 5- x 7-foot connecting passageway for final grouting operations around the plug, 25 feet from its downstream face.

This plug was allowed to set a minimum of 28 days before grouting started. Grouting sequence followed and pressures reached were first, the upstream sealing risers at 30 lb. per sq. in.; second, the downstream sealing risers at the same pressure; and, third, sealing the drain used during construction through the plug at 60 pounds per square inch.

Adequate time was allowed for the grout to set between operations and grout and vent lines not in use were kept open by the circulation of water at low pressure during grouting operations. Finally ring grouting was performed to connect with the main grout curtain of the dam.

A 5- x 7-foot steel door with No. 5 round bars, spaced at 8½-inch centres horizontally and vertically, was placed at the entrance of the connecting passageway to the grout chamber to prevent access from outside. All diamond drill cores obtained during the original investigation of the dam site and during construction were saved for posterity by storing them in the grout chamber. The downstream portal of the tunnel was sealed with earth fill.

### Conclusion

The Kenney dam is unique. With the grout curtain, one might think of it as a rockfill dam above a concrete one. Although no new methods of construction were employed, the speed of its construction might alone be called unique.

Beyond the actual quantities in the dam, millions of yards of material of all types were moved in preparation for construction and in the winning of the materials required. The total yardage moved of all classes, in 12-yard dump trucks, lined up bumper to bumper, would make a line reaching across Canada from Vancouver nearly to Halifax.

To accomplish the moving of this vast quantity of materials, the total bulk of petroleum products used was approximately 4,200,000 gallons.

The job involved flying nearly three-quarters of a million air miles with personnel and stores. Food supplies and other materials brought in by road and rail from all parts of Canada and the United States, added to local purchases, weighed approximately half a million tons.

And, finally, with the rising reservoir, there has been harvested an amount of water equivalent to no less than 359,000,000,000 8-ounce beer glasses! This formerly wasted water is now, thanks to the Kenney dam, available for useful services. √

# Kemano, Underground

*by*
F. T. Matthias
*Assistant Manager, B.C. Project*
*Aluminum Company of Canada, Limited*

The tunnel and powerhouse construction at Kemano was not only a big job in its own right, but was made more difficult by inaccessibility and rugged terrain. Careful planning, however, assured its completion on schedule; not only that, but some progress records were made. This paper describes in considerable detail just how the work was organized and carried out to accomplish these happy results, largely by the free use of the best available equipment. This job will long remain as an example of what can be done when there is sufficient urge.

The Kemano powerhouse is supplied with water through a conduit system completely underground from the reservoir intake at the east end of the project, through the tailrace tunnel which discharges into a short canal to the Kemano River. This article will deal with the underground excavation, the construction of the conduit system and the installation of conduit equipment.

### Intake

A concrete intake is built at the west end of Tahtsa Lake with its sill at El. 2,725, seventy-five feet below the normal reservoir level and controlled by vertical lift roller gates. This structure was built inside a cofferdam unwatered by well points. The downstream side of the structure connects to the main tunnels through cut and cover transition sections. The structure is completed for two tunnels although only one tunnel is included in the initial development.

F. T. Matthias

### Pressure Conduits

The 10-mile main tunnel drops on a uniform grade to El. 2,595 at the west end. Still deep in rock at this end, the tunnel separates through a steel wye embedded in concrete into two main penstock branches. A full description of the penstock system is included in the paper by W. G. Huber in this series.

The penstock system terminates in a valve chamber which houses a valve for each unit. There are now four 54-inch spherical valves in place, one being for a future unit. At the powerhouse each of the three penstock branches that have been installed terminates at the scroll case of an impulse turbine. The fourth branch terminates just below its spherical valve. The total length of pressure conduit from the reservoir to a case is nearly 58,000 feet.

The ultimate installation contemplates a duplicate tunnel with a duplicate system of penstocks and branches to supply an ultimate of 16 units at the powerhouse.

### Access Adits to Pressure Conduits

Three adits, totalling about 3,100 feet in length, gave access to the four headings that were driven in the main tunnel. One was at the intake site, where the access adit sloped down from the natural lake level of about El. 2,787 to the tunnel invert level of about El. 2,723. It intersected the main tunnel at a flat angle about 1,000 feet from the intake. An adit at Horetzky Creek, near the centre of the tunnel, was driven on an almost level grade to develop east and west headings. At the west end of the tunnel, 2,400 feet above the level of the main construction camp at the foot of the mountain, an adit was driven along the main tunnel line to develop the excavation heading towards the east. Branches from this adit diverged to reach the penstock lines and to give access for excavation of the horizontal penstock runs at El. 2,600.

At El. 1,600 another adit 1,343 feet long was driven into the mountain and branched out to reach the two penstock lines. The horizontal runs at that elevation and the inclined sections above were excavated through that adit.

Excavation of the lower penstock branches, of the horizontal runs of the main penstocks and of the inclined sections was done through the powerhouse, where the permanent tailrace and access tunnels were driven early for construction access and transportation.

### Valve Chamber

To house spherical valves, excavation developed a chamber with a

25-foot diameter arch. The section occupied by valves was 37 feet high to arch concrete and 22 feet high in the section opposite the powerhouse service bay. From the north end of the valve chamber a drainage tunnel, 17-foot diameter arch and 22 feet high, was driven around the north end of the powerhouse to connect to the tailrace. This tunnel carries normal drainage from the chamber. It provides a means for carrying away large amounts of water in case of penstock or valve failure, which otherwise might flow into the powerhouse. Unit 5 penstock tunnel was excavated between the valve chamber and the power chamber to a section of 24-foot diameter arch and 25 feet high to provide clearance to move the penstock wyes into position. In addition, a permanent access tunnel was driven between the service bay in the power chamber and the valve chamber, for transportation of valves and heavy parts.

### Power Chamber

The power chamber, 1,400 feet deep inside the mountain, required an excavation 80 feet wide, 120 feet high to the top of the parabolic arch and 700 feet long. This provides space for eight turbine generator units at the north end, an erection and service bay in what will be the centre of the ultimate powerhouse and a clearance space in Unit 9 position at the south end. At the west side of the chamber are galleries for house services, high voltage oil insulated conductors and control conduits and vaults for the 12 high voltage transformers and spares that can step up the generator voltage to 300,000 volts. To carry the high voltage cable runs to the outdoor switch station, a cable tunnel was driven 1,436 feet, with 18-foot diameter arch and 13 feet 6 inches high. The permanent powerhouse access tunnel enters the power chamber at El. 247 at the top floor of the machine room. This will serve the ultimate powerhouse. It also serves as a ventilation tunnel carrying fresh air into the chamber. This tunnel is 1,346 feet long, has an arch diameter of 27 feet and is 27 feet high, to give clearance to carry future units, penstock wyes, transformers and other large pieces into the powerhouse and under powerhouse cranes. From the spring line of the arch, a ventilation exhaust tunnel runs almost horizontally for 1,380 feet to the face of the mountain and is 6 feet wide by 8 feet high.

### Tailrace Tunnels

From the eight turbine pits in the powerhouse, tailrace tunnel branches 16 feet wide by 21 feet high and aggregating 1,250 feet in length, join a common tailrace tunnel, 27 feet wide by 37 feet high, that carries the discharge water 1,400 feet to the face of the mountain, discharging into an open canal to the Kemano River. The upper 27 feet of this tunnel, together with an enlargement of No. 4 tailrace branch, was driven early in the program and formed the major access and transportation route for power chamber, valve chamber and penstock work. The tailrace tunnels now driven will be duplicated when the power chamber is extended to house the future eight units.

### Tunnels

Between Kemano and Tahtsa, the oldest rocks probably belong to the Hazelton group of Jurassic age and are separable into two divisions: a bedded complex of greenstone, schist, quartzite and amphibolite, and an unbedded complex of diorite and greenstone. The latter complex is intruded near Siffleur Lake by a coarse pink granite, which itself is shot through by trap dykes that in some places are quite extensive.

**Fig. 13. General perspective of tunnels and powerhouse.**

Fig. 14. Surface geology.

All the above rocks are intruded by a narrow, easterly-trending tongue of the Coast Range intrusives, consisting of medium- to coarse-grained granodiorite and quartz diorite, with hornblende and biotite as the principal mafic minerals. The granodiorites are faulted in many places and are cut by numerous dykes of pegmatite, aplite, lamprophyre and trap. Along the faults and numerous sets of joints, alteration and oxidation has occurred. At the Kemano end of the tunnel, the Coast Range intrusion is fairly wide, with no signs of major faulting movement inside the tunnel. The easterly-trending intrusive narrows to less than a mile in width at Horetzky. About two miles east of Siffleur Lake and to the north of the tunnel it apparently pinches out altogether.

#### Powerhouse

The rock surrounding the powerhouse is granodiorite containing many small feldspar, aplite, lamprophyre and diorite dikes. The granodiorite body is part of the Coast Range batholith. A shear zone, containing from three to six feet of oxidized gouge, dipping 40°—43° east, running parallel to the powerhouse centre line and roughly 200 feet east of the wall neat line at El. 205, passes over the powerhouse about 50 feet above the arch. A smaller parallel fault on the centre line at El. 290, dipping 75° east, probably intersected the shear zone about 28 feet west of the centre line and 75 feet above the arch. Secondary fracturing ran parallel to these two dominant faults. Two other faults, striking at right angles to the centre line, dipping 80° south, cut the powerhouse on the northern limit and also through the service bay. The faulting and resulting fracture pattern tended to make the east side of the arch and the west vertical walls weak.

#### General Program

Work on the project started in the spring of 1951, with a completion objective of middle 1954. Planning, mobilization of men and equipment and execution of the volume of underground work to be done in that time was a tough and demanding program under good conditions. In the rugged mountain wilds of British Columbia, with no local population from which to draw workers, no roads nor railroads close to any working point, with heavy snows and with a mile-high inaccessible mountain pass separating the work east and west of the Coast Range, the difficulties were multiplied many times. Access and logistics were major problems, expensive and time-consuming, that demanded management attention and organization far in excess of that normally necessary. Limitations of time dictated full-scale attack on the work at all points at the earliest possible dates.

#### Excavation

Table 1 summarizes the quantity of underground excavation work involved and the construction period devoted to each item of permanent work.

#### Concrete

Concrete work required was no less demanding with limited time available. The main tunnel invert was concrete full length and concrete lining was placed in the 15,422 feet that required steel supports during driving, or was unreliable. The equivalent of about 20,000 feet of tunnel received gunite to protect against unravelling of the live, but broken, rock which contained fine seams filled with clay or with decomposed rock. The rest of the 53,040 feet of tunnel was left without lining, but some permanent rock bolting was done to tie exposed blocky, but sound, rock deep into the walls and arch of the tunnel.

In the power chamber, excavation disclosed joint systems that indicated potential weaknesses in the walls and arch. The arch was of reinforced concrete cast against the rock and supported by deep concrete haunches heavily dowelled into the rock walls. Large sections

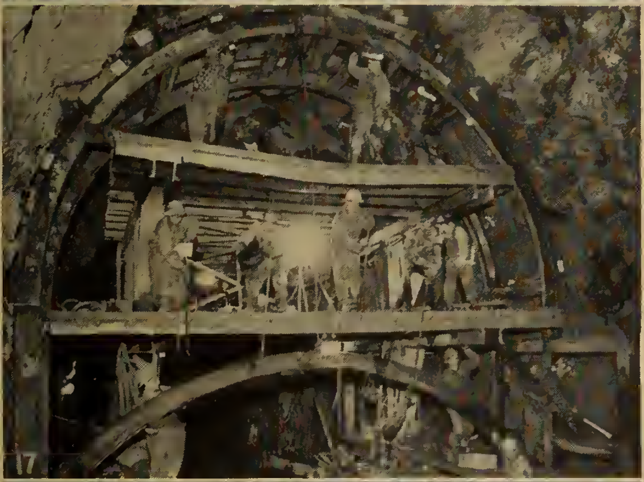

Fig. 15. Three-deck drill jumbo, with platform folded to allow passage of muck cars, doubles as a "cherry picker" car hoist for moving empties over the train to serve the muck loader.

Fig. 16. Drilling at the Tahtsa heading was by Swedish type light drills with "jack leg" pneumatic feeders.

Fig. 17. The Tahtsa heading hit a higher percentage of weak rock than the other three and erection of steel ribs developed into an efficient, systematic operation.

Fig. 18. Electric driven muckers with separate motor drives for belt conveyer and loader did all of the tunnel rock loading.

Fig. 19. Concrete was hauled into the tunnel on railroad cars.

Fig. 20. Dumping of railroad muck cars was done by an elevated outside rail.

Fig. 21. Deep in the tunnel an electric driven booster fan helps keep the air clean.

(1) arch; (2) horseshoe; (3) straight sides.

of the high walls were protected by 45,600 feet of permanent rock bolts, 20 to 40 feet long, anchor wedged deep into the rock. They were designed to hold rock strata in tight contact to prevent movement along shear planes, rather than to resist movement by the shear strength of the bolt. In other sections, concrete was placed to support weak rock. During excavation and concreting 3,763 temporary rock bolts were placed in the powerhouse walls and arch.

Structural concrete in the power chamber carried overhead crane rails on concrete columns from the floor and supported the system of galleries and floors. Prepakt concrete was used for turbine pit-liners and scroll case encasements. Prepakt concrete was also used for nearly all of the embedding and backfill for the penstocks. Table 2 gives the volume of concrete placed underground, including the intake structure.

### Temporary Facilities

The underground work west of the Coast Range had to depend largely on water and plane service for transportation. East of the mountains, air and a combination of truck, rail and barge services handled transportation needs. In both cases roads had to be built to reach into the job areas.

### Access

To serve the east tunnel heading work at the west end of Tahtsa Lake, a road was pushed through in 1951 from Burns Lake on the Canadian National Railways to the east end of Tahtsa Lake, a distance of 105 miles, much of it in difficult

topography. A diesel engine, outboard propeller barge handled the service down the 18-mile lake to the west end.

For the west side, a road from tidewater through heavy timber to the main camp near the powerhouse was built. This 12-mile road was raised from the Kemano River flats, largely muskeg, by gravel fill, some of it on buried log mats. It is a permanent facility serving the powerhouse area, but had to be built to reach the main camp and the site of the first underground work on the west side of the mountains. Construction of a 25-ton tramway was pushed up the mountain slope to serve the penstock heading at the 1,600-foot level and the main tunnel heading at the 2,600-foot level and to supply the camps built at both points. From the main camp near the powerhouse, a 7-mile road was built up the rugged Horetzky valley, rising to about El. 2,675, to serve the two centre headings and the camp at the Horetzky adit.

### Camps

The main camp at Kemano, Camp No. 5, was built near the powerhouse area and housed 2,450 single employees and 44 families. It included a school, a commissary, a theatre, a recreation building, a reconstituted milk plant, a bakery, a laundry, guest houses, a bank and a post office. The mess hall at that camp could seat 800 and fed three shifts per meal at the peak of camp occupancy. Barracks, offices and many of the family houses were Quonset huts at this camp.

A camp at the tidewater dock, consisting of barracks and mess hall, took care of the men who handled the dock work and adjacent open storage area. It could accommodate 60 employees. Between the dock and Camp 5 and about two miles from Camp 5, a trailer camp for privately-owned trailers and a group of 40 small prefabricated plywood houses took care of most of the families. At peak it housed about 250 families. It contained a commissary, a school and recreational facilities. Frequent bus service connected the beach, the family camp and Camp 5.

The 1,600-foot elevation and the 2,600-foot elevation camps were barracks camps, accommodating 120 and 310 employees, respectively. Starting largely as tent camps hugging on the mountainside, they developed into camps of winterized light frame buildings with aluminum roofs, generally about the size of tents.

The Horetzky Creek camp accommodations included 500 single quarters and 9 family houses, most of them Quonset huts. The West Tahtsa camp provided space for 520 single employees and 44 families. East Tahtsa, at the end of the road, housed 24 employees.

### Construction Plant and Equipment

With underground work in progress simultaneously from four locations on the west side and one on the east side of the mountains and with no ground transportation contact across the mountains, extensive construction plant facilities were required. At the main camp at Kemano plant facilities were provided to serve the general area and outlying activities as far as practicable. West Tahtsa on the east side, of necessity provided complete plant facilities, as it was too removed to get help from any other camp. The Horetzky Creek adit operations depended for major repairs and machine shop work on Camp 5, as did the 2,600-foot and 1,600-foot elevation operations.

### Camp Facilities

Camp 5 at Kemano, in the powerhouse area, served the largest concentration of work and had the most complete construction plant facilities.

### Concrete

Concrete aggregates were of natural sand and gravel, obtained from the bed and banks of the Kemano River near the mixing plant and only a few hundred feet from the powerhouse access tunnels. Aggregates were screened through portable plants and stock-piled over a reclaiming belt that delivered sized materials into the elevated mixing plant bins. Automatic batchers delivered to the two two-cubic-yard mixers or dry batches to batch trucks below.

Most of the concrete for the powerhouse level work was hauled into the working area and most of it was placed by Pumpcrete machines. About 75,000 cu. yd. of mixed concrete were produced and handled in this manner. Nearly all penstock concrete and the concrete around the turbine pits and scroll cases was placed by first placing dry aggregates minus sand, then cement grout and fine sand were pumped into the aggregate. Nearly 40,000 cu. yd. of concrete was of this type. Some of the horizontal penstock runs at the 2,600-foot and 1,600-foot levels, as well as the plugs at the adit tunnels and the surge shaft concrete, were batched and mixed by portable units near the point of use. About 119,000 cu. yd. of concrete for the underground work was produced or batched or aggregates supplied from the Camp 5 camp facilities. About 29,000 cu. ft. of permanent gunite was also placed from Camp 5.

At Horetzky Creek, a similar mixing plant produced most of the tunnel concrete. About two miles of the east end of the tunnel was concreted from the West Tahtsa end. Coarse aggregates were produced by crushing tunnel spoil and sand was hauled from Camp 5 up the steep grades that aggregated a 2,400-foot rise in seven miles. About two-thirds of the tunnel gunite work was done from Horetzky; sand for this work was hauled from Kemano. The total concrete mixed and placed from Horetzky was about 90,000 cu. yd. The major part of the tunnel gunite was placed from Horetzky, about 154,000 cu. ft.

West Tahtsa produced concrete aggregates from gravel bars in the deltas of streams discharging to Tahtsa Lake. Part of the aggregate was crushed to balance sizes, but it was mostly natural. Aggregates were hauled by barge (maximum haul 4 miles) and screened through a portable plant. Batching was done by a portable batch plant and concrete mixing by a one-cubic-yard portable mixer. About 29,000 cu. yd. of concrete was produced and about 78,000 cu. ft. of gunite.

No provisions for aggregate production were made in the 1,600- or 2,600-foot areas. Small amounts of concrete were mixed at these points, mostly by truck mounted, dual drum, half-yard paving mixers.

Other plant facilities were provided as shown in Table 3.

### Construction Equipment

Construction equipment was exchanged freely among the four work areas west of the mountains, but no interchange of heavy equipment was practical between West Tahtsa and the other areas. Movements from West Tahtsa would have involved 18 miles by barge, 120 miles by road, about 250 miles by railway to Prince Rupert, 100 miles by salt water and 10 to 17 miles by road to reach Kemano, about 500 miles in all to move equipment from one point to another 10 miles away in a straight line.

Major equipment used at each point is shown in Table 4.

### Main Tunnel Excavation Methods

Even with the main tunnel opened with four headings, the schedule was tight and high-pressure work had to be organized for each heading. The general procedure for tunnel driving was similar at the three west headings. Conway muckers (100 or 75 hp.) were used to load, and combination battery and trolley locomotive-drawn trains of 6 cu. yd. (with built-up sides for 7 cu. yd.) mine cars were used to haul the material out over 36-inch-gauge 60-pound rail track in each heading. Drilling was done from built-up steel jumbos travelling on rails. These jumbos carried a cherry picker car-changer to feed empty cars ahead of the train to the mucking machine.

At all four headings five cars loaded with muck were considered a normal train-load. The work was organized to run on a 6-day week, three 8-hour shifts per day, but in the early days of driving adits and getting the headings under way much of the work was carried out on a 7-day week basis. At the Tahtsa heading a side rolling car changer was used, otherwise the same mucking procedure was followed.

After studies of the relative merits of the Swedish-type light drill, as compared to the normal North American heavy drifter drills, had furnished no conclusive evidence of the superiority of either for this type of tunnel driving, the contractor decided to use the light Swedish-type drill and drill steel rods with tungsten carbide bit inserts at the Tahtsa heading. At the other three headings, 3½-inch-bore drifter drills with 4-wing Type 2 tungsten carbide detachable bits were used. Experience was not conclusive in indicating any clear advantages of one type of drilling equipment over the other, as rock conditions were not sufficiently similar for a valid comparison.

**Table 3—Construction Plant Facilities at Centres Supporting Underground Work**

| Construction plant facility | Kemano Camp 5 | 1,600-foot elevation | 2,600-foot elevation | Horetzky | West Tahtsa |

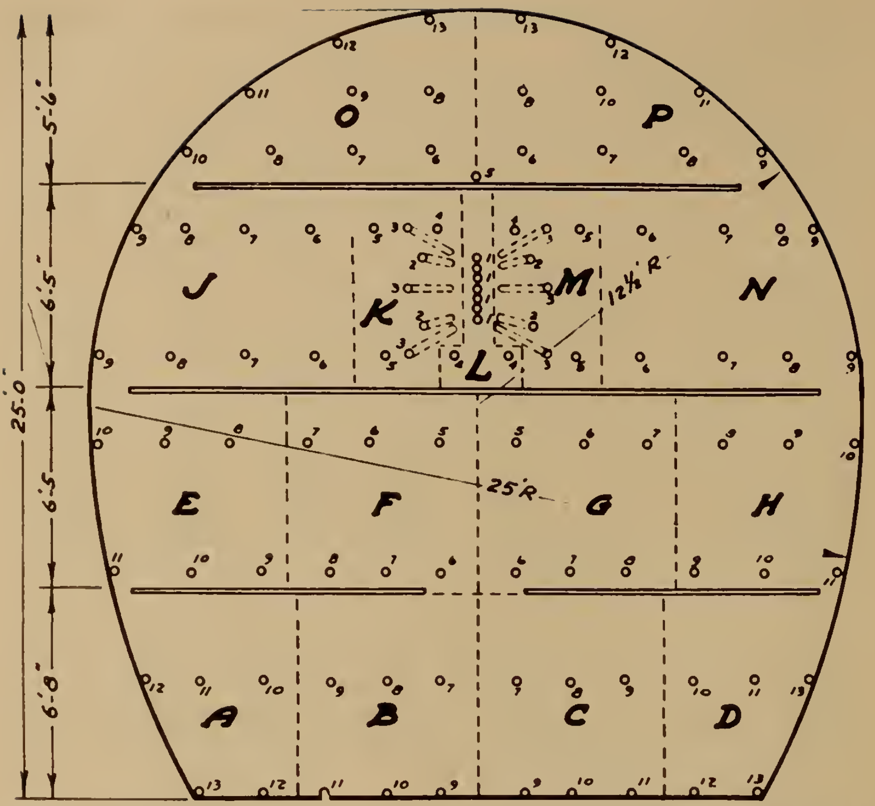

**Fig. 29. 25 foot diameter horseshoe tunnel burn cut, drilling and blasting pattern.**

changes. At each of these headings a steel jumbo, with three working decks, had vertical columns, arms and standard-type dump and swing equipment, on which, usually, twelve drifter drills were mounted. The top deck of each jumbo also carried drifters mounted on jib-type booms. Drilling patterns were varied to fit the character of the rock. For the 25-foot wide arch, horseshoe-shaped tunnel, 102 to 108 holes were normally driven to a distance of 11 to 13 feet past the heading, resulting in an advance of from 10 to 12 feet per round blasted. Where rock was weak, the rounds were shortened and steel supports were erected close to the heading.

The steel used with the drifter was 1¼-inch in diameter, cut into 5 ft. 8 in., 9 ft. 8 in., 11 ft. 8 in., 13 ft. 8 in., and 15 ft. 8 in. lengths, with Type 2 threads and lug shanks. The bits were 4-wing 2-inch detachables with tungsten carbide inserts. A new 2-inch bit was always used on the 5 ft. 8 in. starter steel. Gauge changes reduced by 1/16 inch per change, from 2 in. to 1 15/16 in. and so on to 1 11/16 in. in diameter, before the bits were discarded. Bits were ground normally after 60 feet of drilling, but with the hardest rock encountered had to be ground after 30 feet. The life of a bit varied from 240 feet to 600 feet with 8 to 10 grindings. All drilling was powered by compressed air piped from a central diesel or electric powered plant at each heading, at 100 psi. About 4,000 cfm. were required for drills and accessory equipment for each heading.

For the Tahtsa heading, the Swedish-type drills utilized a chisel-type bit with a tungsten carbide insert permanently set in the ends of 7/8 in. diameter drill rod; the bits were ground as required. Starting holes were 1.34 in. diameter for 2.65-foot-long starting steel and through successive changes available of 4.25 ft., 7.90 ft., 10.50 ft., 13.50 ft., and 15.75 ft. The bit diameter reduced to 1.14 inches for the long steel. Depending on the hardness of the rock drilled, the average life of each steel and bit was from 400 feet to 600 feet. Grinding of the bit was necessary after from 40 feet to 60 feet of drilling. Each bit was ground 8 to 10 times before being discarded. The drill jumbo for these drills had working decks from which the jack-leg drills with pneumatic feeders operated.

The normal shift working crew at each of the three west headings was:

| | |
|---|---|
| Walkers and shifters, | 2 |
| Miners and helpers, | 31 |
| Mucking machine operators, | 1 |
| Motormen, | 2 |
| Electricians and mechanics, | 2 |
| Typical shift crew, | 38 |

At the Tahtsa east heading, the normal crew was:

21 Machines on a Jumbo:

| | |
|---|---|
| Shifters and walkers, | 2 |
| Miners and helpers, | 22 |
| Mucking machine operators, | 1 |
| Motormen, | 4 |
| Electricians and mechanics, | 2 |
| Typical shift crew, | 31 |

16 Machines on a Jumbo:

| | |
|---|---|
| Shifters and walkers, | 2 |
| Miners and helpers, | 18 |
| Mucking machine operators, | 1 |
| Motormen, | 4 |
| Electricians and mechanics, | 2 |
| Typical shift crew, | 27 |

Only one driller was required to operate the light Swedish type drill, whereas it required two men, a driller and a helper, to operate the heavier drill machines.

Blasting was by electric delay detonators exploding 1½-inch by 8-inch 40 per cent giant gelatine dynamite. The time interval of the delay caps used is shown in the following table:

| No. of delay | Explosion time from ignition sec. | Length of cap in. |
|---|---|---|
| Instant | 0.0 | |

| No. 14 | 10.40 | |
| No. 15 | 12.15 | 4¾ |

After blasting, heavy-duty 22 x 60-inch reversible ventilation fans exhausted the fumes through 24-inch diameter vent pipe for a short time, then pumped fresh air into the heading, forcing the fumes back and out of the adit. Within half an hour, the air was generally clear enough for the crew to return to the heading and start loading the rock out. This operation was similar for all four headings.

Each foot of tunnel advance brought out about 21 cu. yd. of rock, solid measure. Thus an average

10-foot round required loading out 210 cu. yd., or 40 to 50 car loads. The 6 cu. yd. side-dump cars used averaged slightly less than 5 cu. yd., solid measure, per load.

The mucking cycle started with an electric battery and trolley locomotive moving up to the heading towing five empties and pushing one. The front car was delivered to and coupled with the mucker. While the mucker loaded the car the locomotive spotted the last car of the train under the car changer which hoisted it high enough to clear the train on the track. The loaded car was picked up by one locomotive and hauled clear of the car changer, then the empty was dropped by the car changer to the track in front of the train and pushed up to the mucker by the train. This was repeated until five cars were loaded and, while one empty car was spotted at the mucker, the loaded train moved out and a train of empties moved in.

Tunnel driving, using the equipment and methods employed at Kemano, demands teamwork, training and careful timing. With inexperienced miners it takes months to train a crew to really good performance; in fact, few tunnel jobs last long enough to reach real teamwork proficiency. After a year of tunnel driving at Kemano, month by month progress showed marked improvements. The previously recognized record for driving a 25-foot tunnel was broken in the summer of 1952 and new records were established three times more before December, 1952. After the annual Christmas exodus, many trained miners did not return to the job and it took about six weeks for the crews to get back to pre-Christmas proficiency. In the week of February 21, 1953, one crew advanced 282 feet in six days, with a record advance in one day of 61 feet. When it is recognized that one 10-foot round advance per shift, or 30 feet per day, is excellent progress, this average of 47 feet per day for a week appears even more spectacular.

Production rates are shown in Table 5.

### Concrete

Except for the two miles at the east end of the tunnel and the adit plug at the west end, all tunnel concrete was placed from Horetzky. Curbs were formed and placed the full length to form a screed guide for invert and a support for wall and arch forms. Mixed concrete was delivered in dump bodies mounted on rail cars for all of the tunnel concrete, the concrete being mixed in a central plant at the adit portal. Paving finishers were used on the invert. The procedure from the east heading was similar, except that concrete came from a portable plant.

Arch and walls were placed in telescoping steel forms. Concrete was delivered from the cars to elevating skips feeding into pneumatic placers and was delivered to the forms through pipe. At the east end of the tunnel, some wooden forms were used and wall and arch concrete placed progressively. Concrete plugs at the adits were heavily grouted.

Gunite, generally about one inch thick after thorough scaling and cleanup, was placed from special jumbos.

### Penstocks Excavation

Drilling and blasting was similar to main tunnel procedure except that, at the powerhouse level, a truck-mounted jumbo was used to carry drilling equipment and loading was by 1½-cubic yard overhead tractor loader into trucks, which hauled out the muck. At the 1,600-foot level, locomotive and car equipment was used, with a 75 hp. mucker loading cars.

### Inclined Sections

The two sections of the two penstocks, one between the powerhouse level and the 1,600-foot level and the other between the latter and the main tunnel grade of El. 2,595, were each driven from the bottom up. A pilot raise, 6 feet wide by 10 feet high, at the bottom centre of the 15-foot diameter section, was raised from each level. A horizontal timber partition followed the driving upward, making the bottom half of the pilot raise a muckway and the top half a manway and service compartment. Steps on the timber and a narrow-gauge track gave access to the heading face. The steps provided access for labour; on the track, a car was pulled up the track by a 50 hp. hoist at the bottom. The timbering and hoist sheave were kept as close to the heading face as possible. The last few feet to the heading face were reached by walkway steps.

Each muck chute was trapped at the bottom and muck was drawn off by air controlled gates discharging into trucks. Most of the time the muck chutes were kept full, but it was found that water and fines accumulated and built up high pressures on the bottom of the timber. This could be cured only by drawing off all of the accumulation.

Originally, it was planned that drilling and timber separator erection go on simultaneously. Supplying materials for both operations was found to be delaying to both and that fact, together with the hazards attending one crew working above the other, led to more of a 'batch' operation. The same crew drilled and blasted a few rounds, then dropped back and erected the timber. Each of these operations consumed about the same time for the crews.

On completion of the pilot shaft the timber was removed. Working downward, railway track was laid and a small jumbo, carrying drill

Fig. 30. Working out from the center the main body of the power chamber excavation was blasted by shooting off slabs 80 ft. high.

mounts at top and sides, drilled the blast holes for the enlargement. The shot rock slid down the shaft and was loaded into trucks through the same gate controlled hopper that was used during the excavation of the pilot raise. Both No. 1 and No. 2 penstocks were completed to this extent. Progress of this slashing operation per heading was about 30 feet per day.

The eight penstock branches, 9 feet in diameter, totalling 816 feet, and the eight tailrace branches, 16 feet wide by 21 feet high, totalling 728 feet, were accessible from both ends. These small, narrow tunnels were drilled from portable platforms. The small penstock branches were excavated largely by slusher scrapers dragging the rock into the powerhouse area, where overhead tractor loaders discharged it into trucks. In the larger tailrace branches, overhead tractor loaders loaded trucks at the heading. A novel adaptation of slusher scraper was employed by mounting the hoist on a truck chassis, which made an easily portable unit.

### Steel Liner

Starting in October, 1953, 4,600 tons of steel liner was then placed in Penstock No. 1 and its branches. The 11-foot diameter steel sections varied from 7/16 to 1 15/16 inches thick. Sections received from the manufacturer were 14 feet long at the bottom; the upper sections were 28 feet long. At the 1,600- and 2,600-foot levels, automatic welding installations combined two sections.

In the tunnel, carefully aligned steel beams were erected on which to skid the sections down the incline. From the welding yard a small railway dolly carried the penstock liner into the head of the incline. As the dolly rolled over the vertical curve, it dropped below the skid beams which then picked up the pipe section on the saddles welded to them. A 200 hp. hoist at each level controlled the slow movement of pipe down the shaft to position.

Welding of the pipe sections was done from platforms erected on the inside of the pipe. All welds, including the preassembly welding, were preheated and low-temperature stress relieved. Penstock branches at the bottom were welded from both inside and outside.

### Concrete

For the backfill concrete between liner and rock, coarse, clean aggregate was hauled up the tramway to the 1,600- and 2,600-foot levels, dropped down the incline in skip cars that dumped to hoppers erected about 100 feet above the top of the liner steel in place. From these hoppers the aggregate was dropped through 10-inch steel pipe that was kept full, and the aggregate was released by burning out openings just above the backfill level. Manual shovelling and high pressure air jets distributed the rock around the pipe and then cement grout and fine sand were pumped in. In the last section to receive backfill, 2,000 feet of incline was filled in one operation. Drains were installed around the pipe discharging into the horizontal run below. Similarly, in the lower horizontal runs of the penstock and around the branches, rock was placed by a specially designed blower.

Cement grout was pumped under

pressure into the dry fill through prepared fittings in the liner shell, working from the bottom upward. Pumping through one set of fittings continued until grout started coming through the next higher fittings. Grouting up each incline was a continuous bottom to top operation. As the head from the bottom increased, additional pumping stages were set up, with each stage below the top stage discharging into a re-mixing tank before being picked up by the next stage.

The final stage of the operation was to diamond drill through the grout fittings into natural rock. The cores indicated good quality backfill and the holes were used for pressure grouting to seal the backfill concrete into the natural rock and to fill up any spaces that might have developed between liner plate and concrete. In the sections of penstock tunnel where poor or broken rock was known to exist, grouting was extended into the rock to add strength to it. The lining, backfill and grouting was completed in early July, 1954.

Table 6 presents performance data on penstock excavation.

### Powerhouse and Valve Chamber Excavation

For the powerhouse and valve chamber excavation, diamond "long-hole" blast-hole drilling was employed. Excavation of the powerhouse, with its 80-foot wide parabolic arch roof 120 feet above the top of the turbine pits, would have presented serious problems of timing if done by the conventional drilling-blasting-mucking cycle. Also, the need for true, trim excavation lines such as have been obtained by the "long-hole" method on other jobs was an important factor in the decision to employ this method at Kemano.

The top two-thirds of the tailrace tunnel was driven into the powerhouse to the centre line of the turbine units and was extended in a 27-foot by 27-foot drift the length of the powerhouse. The small 6 by 8-foot permanent ventilation tunnel was driven into the powerhouse at spring-line level. At right angles, a 10 by 12-foot drift was driven along the 700-foot length of the present powerhouse directly above the tun-

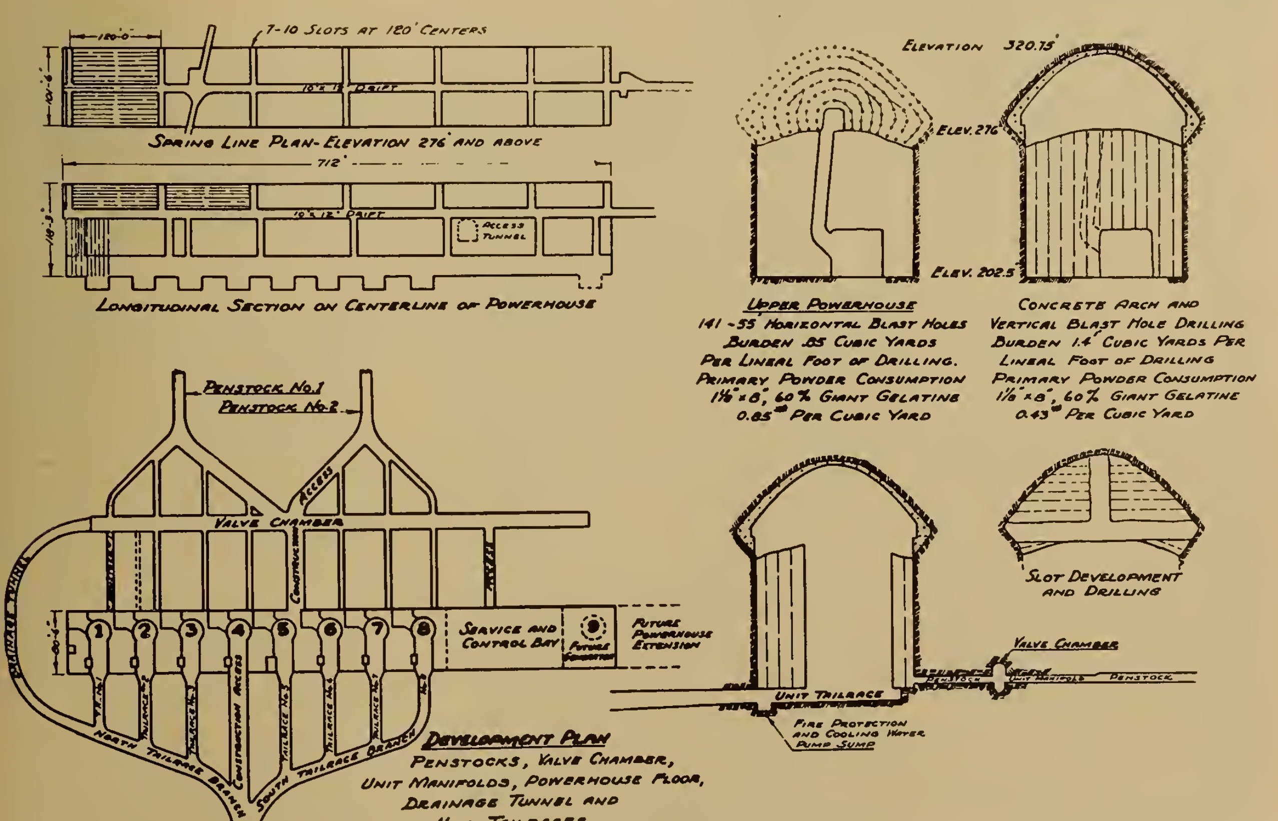

**Fig. 32. Excavation procedure, powerhouse area.**

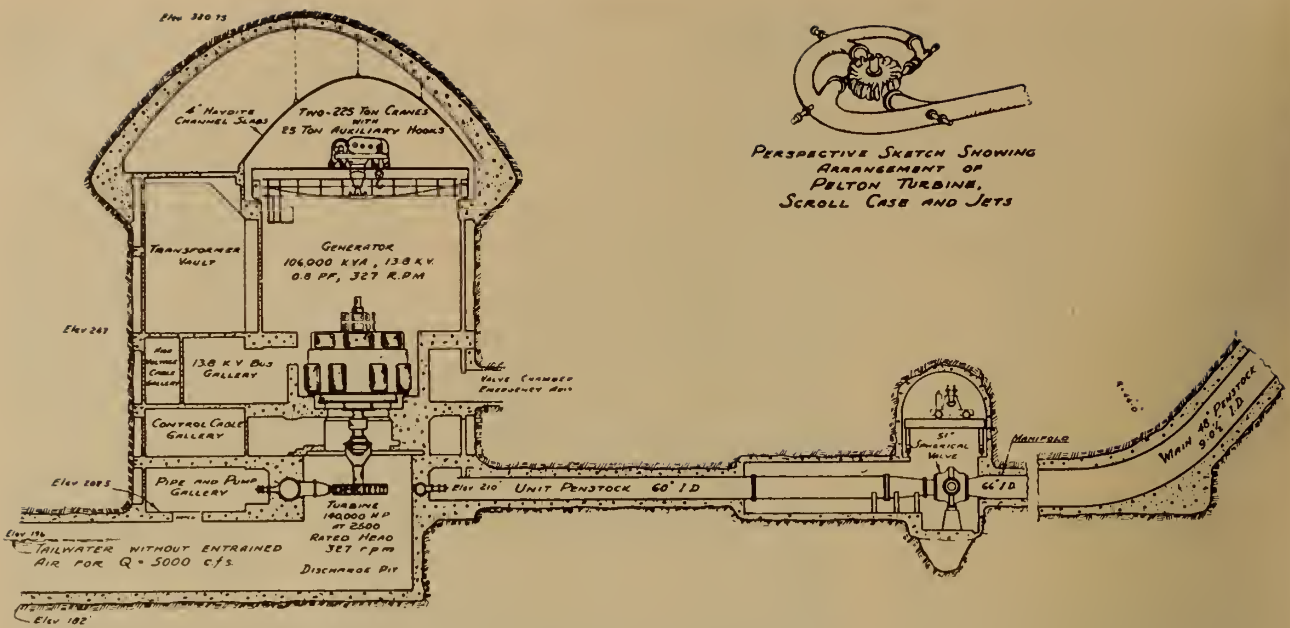

**Fig. 33. Transverse section showing general arrangement of powerhouse, generator, tailrace, penstocks, manifold, and spherical valve chamber.**

nel below, and was continued south to the ultimate end of the powerhouse for a total distance of 1,142 feet.

Seven vertical shafts were raised to connect these two longitudinal tunnels. From the upper powerhouse tunnel, seven 10-foot-wide slots were enlarged above the spring-line at 120 feet centres to two feet outside of the desired trim line of the arch. From these slots, horizontal diamond-drill blast holes were driven 55 feet in each direction.

As soon as the first three slots were drilled, blasting and mucking started. Successive rings were blasted down, expanding from the upper tunnel. The muck was pushed into the vertical shafts by tractors and loaded by power shovels into trucks in the lower powerhouse tunnel. The last shot on each section was in the trim holes along the arch line, resulting in the least possible blasting shock to the remaining rock. In one section of the powerhouse, successive blasts from the tunnel upward disclosed weak, shattered and blocky rock. Here the centre 20 feet was carried up clear to the arch line, and the arch heavily roof-bolted before any further blasting was done at the sides. Progressive widening of the opening with light shots and roof bolting made the arch secure until the arch concrete was in place.

Upon completion of the excavation and of the placing of concrete in the arch, the main body of the powerhouse rock was diamond-drilled with 80-foot long holes. Blasting first caved down the area over the longitudinal tunnel at the bottom and this slot was expanded toward the walls. After a few shots, enough space had been opened to permit muck loading by a standard 1½-cubic-yard shovel fitted with electric drive. Muck was hauled out by diesel trucks to fill an area along the Kemano River for flood and erosion protection. While the cost per foot of hole drilled was higher for diamond drilling than it would have been for normal blast-hole drilling, the method permitted uninterrupted work in one area, while blasting and mucking went on without interruption in other areas. This resulted in much more efficient use of manpower and equipment than for the normal drilling-blasting-mucking-clean-up cycle. Experience in long-hole drilling and blasting in the powerhouse led to the adoption of the same methods in the smaller valve chamber with good results.

#### Access and Tailrace Tunnel

The access tunnel to the powerhouse enters at the generator floor level and the portal is well above the surface of the natural ground. This made it much less desirable as an access route for excavation, but it became increasingly important for moving in and installing powerhouse equipment. The tailrace tunnel invert grade is deep below the general excavation level of the powerhouse and at the portal it is deep below surrounding ground. To improve its value as an access route into the powerhouse and to avoid water problems, the initial excavation was only the top two-thirds, leaving the lower bench to be taken out as the last step in construction. Both the access tunnel and the tailrace tunnel were drilled from truck-mounted jumbos, and standard ¾-cubic-yard crawler shovels loaded the muck into trucks. The access tunnel is 27 feet wide by 31 feet high. The tailrace tunnel is 27 feet wide and 37 feet high.

#### Cable Tunnel

The generators will feed power directly through heavy busses to 300,000 volt transformers inside the powerhouse. Oil-insulated conductors will carry the power through an 18-foot wide by 13½-foot high tunnel, 1,437 feet long, and on through a concrete formed box section to the transmission line terminal. This tunnel was excavated by an overhead tractor loader and the muck hauled out by trucks.

#### Concrete

A variety of concrete handling and placing schemes were employed for powerhouse concrete and for the access cable and tailrace tunnels. The turbine pit liners and scroll cases for the three initial 140,000 hp. units installed were encased in Prepakt concrete. All other concrete was conventional, mixed in the

### Table 7—Power House Excavation

A ACCESS DEVELOPMENT

Ventilation tunnel to power house at El. 277, size 6 x 8 ft. and 1,505 ft. long, completed September 29, 1951.

Upper longitudinal tunnel in power house at El. 277, size 10 x 12 ft., and 1,142 ft. long, started October 20, 1951, completed June 23, 1952.

Upper section tailrace tunnel at El. 203, size 27 x 27 ft., length 1,407 ft., was completed into power house December 22, 1951.

Lower longitudinal tunnel in power house at El. 203 size 27 x 27 ft., and 700 ft. long, driven between December 29, 1951 and March 14, 1952.

Seven 8 x 8 ft. muck raises and two 4 x 6 ft. ventilation raises driven between lower and upper tunnel.

Seven slots, 10 ft. wide and 2 ft. beyond the cross section of the power house arch excavated by expanding on drifts at right angles to long centreline of power house.

B. LONG HOLE DRILLING AND EXCAVATION

| Item | Power house | | Access development & miscel. excavation |
|---|---|---|---|
| | Arch | Bench | |
| Volume | 80,000 cu. yd. | 139,000 cu. yd. | 59,000 cu. yd. |
| Diamond drilling | 89,853 ft. | 90,816 ft. | — |
| Labour: | | | |
| —Drilling and blasting | 48,500 man-hrs. | 49,800 man-hrs. | — |
| —Scaling and temp. bolts | 12,600 man-hrs. | 9,100 man-hrs. | — |
| Dynamite | 56,000 lb. | 62,000 lb. | 242,000 lb. |

**Fig. 39. During the early spring helicopters were the only means of service to West Tahtsa.**

central mixing plant outside and most of it was hauled in by Dumpcrete. Placing in forms was generally by Pumpcrete, although some of the powerhouse concrete was handled in buckets by the temporary and permanent overhead powerhouse cranes.

Concrete for the powerhouse arch was carried into the power chamber through the tailrace tunnel and lifted by a tower skip to Pumpcrete hoppers at the spring-line bench, which delivered it to the full section forms supported on a jumbo frame. The concrete tower was installed in one of the vertical shafts excavated to drop muck from the power chamber bench to the transverse tunnel at El. 202.

#### Logistics

The tunnel and powerhouse construction, involving nearly 1,800,000 cu. yd. of underground rock excavation, the placing of nearly 240,000 cu. yd. of concrete and of over 200,000 cu. ft. of gunite and the installation of 420,000 hp. of turbine generator capacity, was a major job under any conditions. Isolation of the work, difficult communication between different working points, and the need to transport virtually all labour from Vancouver or farther made the supply services and transportation major operations. Nearly 30,000,000 manhours were used for the total hydro-electric development, of which about 70 per cent was for underground work and supporting services. The total cargo moved by barge or ship to Kemano was over 300,000 tons, most of it for underground work. Nearly 40,000 tons were moved 600 miles or more to the east side by train or truck, hauled 105 miles on job-built access road and 18 miles by barge before it reached its point of use.

To maintain supply service, the contractor set up a railway, road and port shipping depot in Vancouver. Purchasing activities were concentrated in Vancouver and bills were paid from Vancouver. Accounting, final receiving, engineering and other administrative service headquarters were located at Kemano. Labour was transported to the job by boat or plane in about equal numbers. Thirty thousand passengers were carried by plane, most of the trips under direct charter contract and most of them for support of underground work. √

**Fig. 40. The 25-ton tramway carried men and cargo from Kemano Camp 5 to the camps at the 1,600 and 2,600 foot elevation.**

# Kemano Penstocks

*by*
W. G. Huber, M.E.I.C.
*General Manager,*
*B.C. Engineering Company, Limited,*
*Vancouver*

The Kemano penstock is one of the largest, if not the largest, to operate under a head as high as it carries. To establish a satisfactory basis of design, a number of tests — of the steel, of welding methods, of the division of load between rock and lining and the like — were carried out. Construction methods were also in some respects unique, and never easy, owing to the rugged character of the terrain. Careful planning, well described in this paper, brought the work to a successful conclusion.

Each of the penstocks, No. 1 and No. 2, to the Kemano powerhouse of Alcan's new British Columbia hydroelectric power and smelting plant, will supply four 140,000-150,000 hp. vertical-shaft impulse turbines under a gross head of 2,600 feet. Normal flow in each penstock will be about 2,000 cfs. with a maximum at full gate on the turbines of about 2,400 cfs. Since the principal load for the power plant will be the smelting of aluminum at Kitimat, and since this process requires the maximum of reliability in the supply of electrical energy, all parts of the hydraulic conduit were designed to minimize outages for inspection or maintenance.

These penstocks connect the west end of Power Tunnel No. 1 to the inlets of the turbine distributor scrolls. In the present Stage I of the development, excavation was completed for both penstocks, but only No. 1 to serve units 1 to 4, inclusive, has been equipped with lining and controls. This penstock consists of about 4,450 feet of 11-foot ID section, made up of a horizontal section at El. 2,596, a sloping run of 1,200 feet, a horizontal run at El. 1,685, then a 2,000-foot sloping run to approximate turbine scroll level at El. 211. Static head at full reservoir varies from 200 feet on the upper end to 2,590 feet at the powerhouse level.

**W. G. Huber**

The sloping sections are at an angle of 48° to the horizontal and the lengths of the horizontal runs are determined by this angle versus the natural profile of the ground and the requirements of rock cover above the conduit, which was fixed for design at 40 per cent of the hydrostatic head at any point.

The penstock is located in a tunnel rather than on the mountain surface in the more conventional manner because of the extreme roughness of that surface; the resultant protection against bombing, or snow or landslides; the economy of plate steel; reduced maintenance; and because the powerhouse itself is placed well under the mountain and at least some large portion of the penstocks would therefore have to be underground in any event.

#### Adopted Diameters

No great refinements were attempted in economic studies leading to the adopted diameters, because reliable cost figures could not be developed for work in this remote region where construction had to be started simultaneously with investigation of the site. Surge effects were investigated for the combination of a ten-mile tunnel and this long penstock for one unit off with eight units operating and for two units on with five units operating. Although the turbine design permits a relatively slow opening and closing of turbine nozzles, water hammer of 10 per cent maximum head was assumed in penstock design, which corresponds roughly to a 12-second closure of the jets. This leads to a maximum dynamic pressure on the line of 2,850 feet head, or 1,235 psi. Turbine governors are set to open in 30 seconds and to close in 60 seconds, and sphere valves are governed to open or close in 30 seconds.

Earlier project estimates were based on one 15-foot diameter, thin walled penstock for each power tunnel and each eight units, but it was felt that this would be too great a departure from any known practice and experience with under-

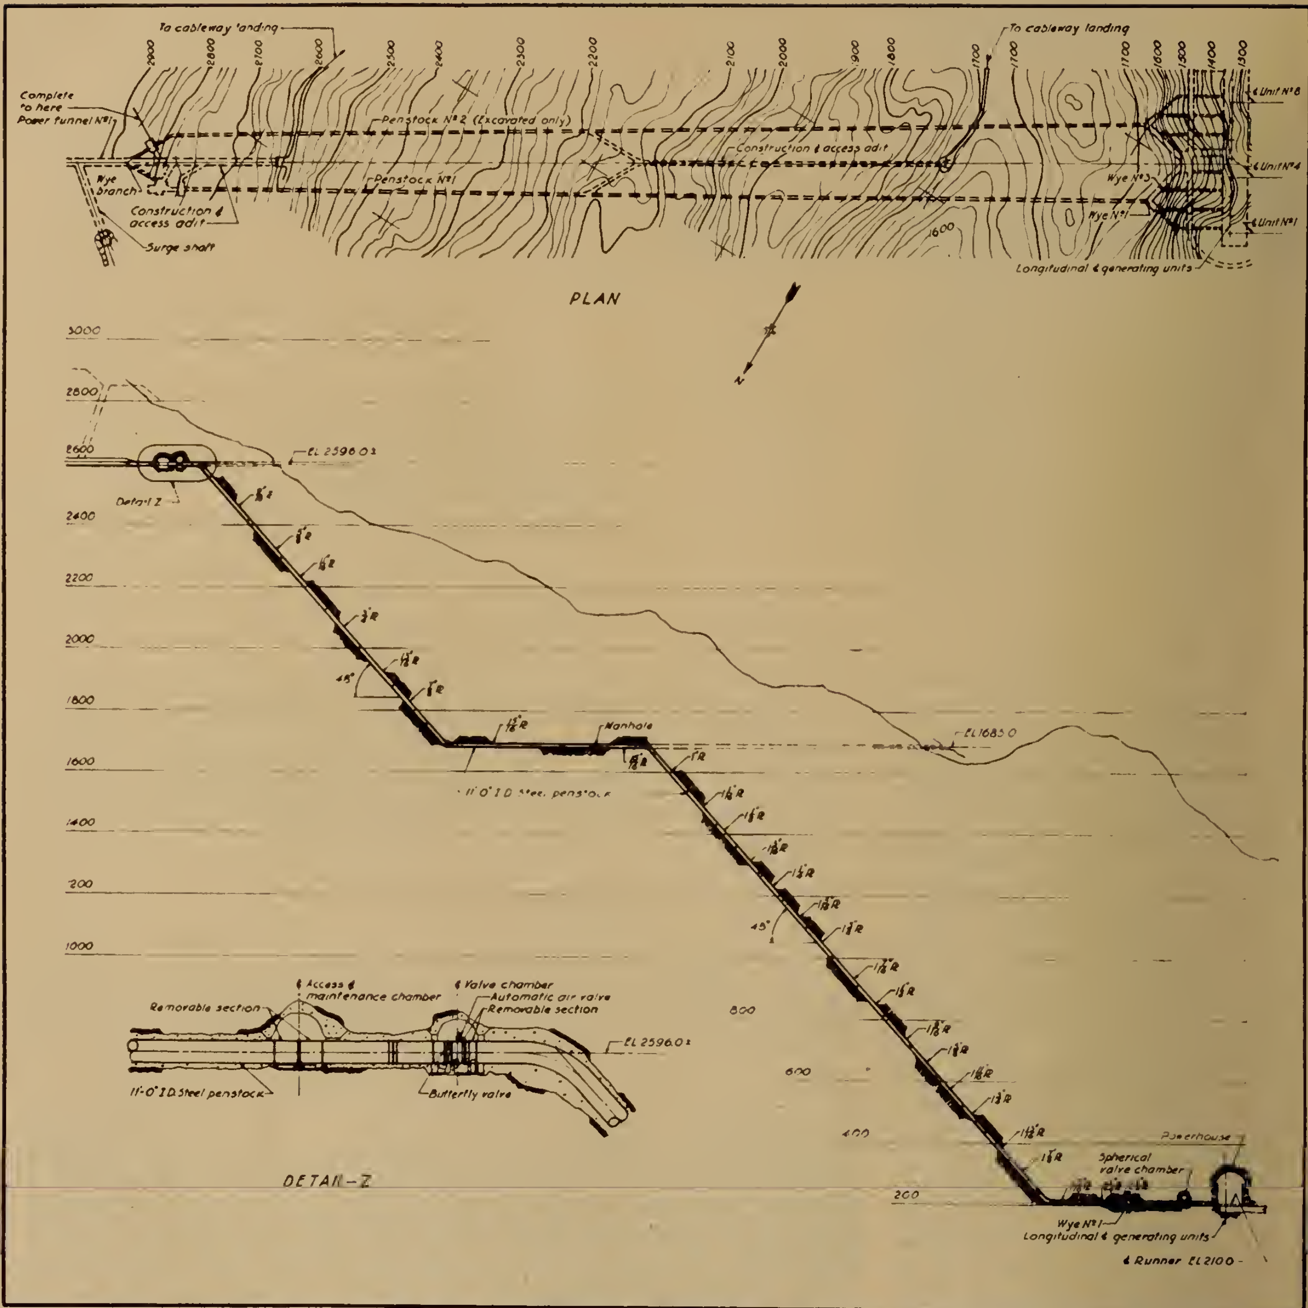

**Fig. 41. Profile on the centerline of Penstock No. 1.**

ground pressure conduits. The approximate hydraulic equivalent of one 15-foot diameter or two 11-foot diameter lines, with thicker plate and valve controls at tunnel level, was adopted although even it is far beyond anything attempted hitherto.

### Plate Thicknesses

Plate thicknesses and other details of the design and construction of this pressure conduit were carefully studied in the light of extensive investigations, particularly in Norway and in Switzerland, on the distribution of load as between steel liner and surrounding rock. Mathematical analyses of such a combination can afford much exercise for those theoretically inclined and will take many forms and produce as many different answers, but any analysis can give little more than a rough approximation of the distribution, because of the many variables introduced by natural site conditions and the practicalities of construction. These include the jointing, stratification, attitude and residual stresses in the surrounding formations, the variation in strength and in modulus of elasticity of the rock, shrinkage and other imperfections of the concrete envelope and variations in the cross-sections and even in the steel quality of the liner itself. Experience elsewhere shows that in such combination the rock takes a permanent set under initial loadings, with corresponding modification of contact conditions under subsequent and long term loading.

### One Theoretical Approach

One reasonable theoretical approach is to consider the surrounding rock as a thick walled cylinder enclosing a "cracked" zone immediately adjacent to the liner, with this cracked zone assumed to act as a series of columns between the exterior of the liner and the uncracked rock cylinder. Another analytical method which indicates that conduit pressures are effective only a very short distance out from the liner, involves application of Poisson's ratio to calculated compressive stresses in the rock along the extension of a horizontal diameter of the penstock. Under this assumption, the concrete encasement serves only as a strut between the active liner and the opposingly active rock, through which a portion of the hydrostatic load is transferred outwards until it is balanced by internal stresses in the rock and strain reduces to zero. For the two points along the conduit where test measurements were made, the distribution computed by this method is approximately 25 per cent on the steel and the remainder on the rock. Initial proof-testing work on Penstock No. 1 included measurements of steel stress in 11-foot diameter sections at Els. 1,685 and 210 by two sets of SR4 strain gages and mechanical extensometers designed to measure diametral change. Load distributions calculated from readings of the SR 4 gages were as follows:

| | | |
|---|---|---|
| El. 1,685 | Steel | 36 per cent |
| | Rock | 64 per cent |
| El. 210 | Steel | 32 per cent |
| | Rock | 68 per cent |

Correlation of electrical and mechanical gages at El. 210 was excellent, but at El. 1,685 observed values were erratic. It is evident that any formula must include a provision for temperature differentials as well as a "shrinkage constant" for the encasement.

### Exploratory Tunnel and a Hollow Sphere

As soon as an exploratory tunnel had been driven into the approximate region of the underground powerhouse in 1951, a hollow sphere of ½-in. plate 10 feet in diameter was concreted into a side adit and tested under pressures up to 3,600 psi. Numerous gages were employed in this experiment to obtain a measure of the modulus of elasticity of rock and of the action of a thin wall closed vessel when backed up by concrete and rock. Despite some unsatisfactory results with the electrical resistance gages, the modulus of elasticity of the rock was determined to be about two million psi. The wall of the vessel did not rupture while carrying a calculated 18 per cent of the total pressure load, a result which supported the basic concept that a thin steel shell, backed up at all points by concrete and sound rock of sufficient thickness, will form a safe watertight conduit under high pressures.

The adopted plate thicknesses actually constitute a compromise of factors including retention of shape during handling, resistance to external hydrostatic pressure when the penstock is empty and limitations for welding round-about joints from one side only. Emptying of the penstock should occur only infrequently and could be done at a very slow rate, also a permanent drain system from the annular space outside the liner is provided. However, the long term reliability of this feature was questioned by some consultants, therefore it was required that at all points the plate thickness should be great enough to withstand external hydrostatic pressure equivalent to the vertical distance from the centerline of the pipe to the surface of the mountain. Minimum thickness of the 11-foot diameter pipe was taken as 9/16 in. for convenience in handling and the maximum thickness, for manual welding from one side only, was taken at 1-15/16 in. Between these limits the thicknesses of plate were increased in increments of 1/16 in. down to a point near the manifold, where provision was made for welding from both sides and thicknesses were increased to 2¼, 2½ and 3-1/8 in. at the field junction with Wye No. 1. From this point downstream, the support assumed to come from the rock was decreased

**Fig. 42. Lifting penstock liner section by cableway from Kemano valley to El. 2600.**

Fig. 43. Lowering liner section down penstock raise.

until the steel liner would take all hydrostatic loads at normal free pipe stresses. This led to plate thicknesses of 2¾ in. for the five-foot diameter turbine branches.

### The Wyes

The wyes, or sections at the branches of the manifold, are proportioned to carry the entire water loads independently of the backfill and were shop tested to 1,435 psi. or 115 per cent of the maximum design pressures. Wye No. 1, 11 feet in diameter, 7 ft. 9 in. diameter and 7 ft. 9 in. diameter at 90° included angle, is a hollow sphere 12 ft. 3 in. ID. of 3-11/16-in. A-212 plate, pierced for stub branches of A-212 and A-201 plate, the latter to assure higher quality of field welds to the connecting straight runs. A special car and railway routing were necessary for transport of this 50-ton weldment, which was 12 ft. 10-3/8 in. wide by 17 ft. 2-3/8 in. high as loaded. The two 45° wyes, 7 ft. 9 in. diameter by 5 ft. 6 in. diameter and 5 ft. 6 in. diameter are of the more conventional "pants" construction, reinforced longitudinally with heavy plate "U" girders and transversely at the crotch. The A-212 plate is 2-5/8 in. thick with stub ends of 2¾ in. and 2¼ in. A-201 plate. Each wye weighed 40 tons.

### Ductility and Weldability

After extensive welding and punch press tests and consultation with experts in the metallurgy of steel, it was decided that ductility and weldability were the most essential properties for the conduit liner. Accordingly, the following qualities of plate were selected:

Less than 1 in. thickness—
ASTM A-285 Grade B Firebox
One in. and greater thickness—
ASTM A-201 Grade A Firebox.

Design of details and plans for installation of the penstock liner were based on the realization that uniformity of support for the liner plate and elimination of stress raisers and embrittlement are of paramount importance. Any voids or other lack of uniformity in the backfill concrete, or physical break in the surface of the liner, or local application of heat to the steel without subsequent stress relieving were considered as potential weaknesses and to be avoided by all possible means.

Although the steel liner is proportioned to carry full external hydrostatic pressures as a cylinder supported at all points of the periphery, a drainage system was added as mentioned above, to tap the annular space between the outside of the liner and the concrete encasement. One system, consisting of two longitudinal headers, each with branches to the liner wall, extends from the butterfly valve chamber to El. 1,685 and the second system extends from this intermediate point to a discharge near the sphere valve chamber at El. 210. Pairs of branches are spaced an average of 41 feet along the pen-

Fig. 44. Welding circumferential joint in liner plate.

stock. This annular space will be extremely small until the penstock is emptied after having been under load for a period sufficient to produce a permanent set in the surrounding rock. Such a drainage system, if free to discharge at all times, will act as a telltale with respect to water tightness of the penstock liner, that is, a sudden change in the amount of discharge might indicate some accession of penstock water. However, continued flow of ground water through the concrete envelope to the drain headers will tend to fill them with carbonates. This and the difficulties of keeping a drain line open during construction are the principal reasons why some engineers will not place dependence on pipes for relief of external hydrostatic pressure on encased steel penstocks.

Rings of grout holes were spaced at about 10 feet centers along the length of the pipe and used first for placing intrusion grout and finally for pressure grouting of the concrete-rock contact and the rock itself. Closure of these grout holes was accomplished by a flush head machine screw plug tightened down against a copper washer and seal-welded with a high ductile rod. Sections of the liner, or "cans", as furnished by the fabricator came equipped with a "half and half" butt strap to act as the backup strip when welding the underground field joints, and with full length shoes or runners to support the pipe on tracks when being lowered in the shafts. These shoes were perforated to admit concrete. Also, at regular intervals along the sloping sections of the liner, lugs are provided to resist any downhill creep of the pipe due to changes of temperature and stress in the metal.

**Fig. 46. Placing coarse aggregate outside liner.**

### Penstock Details

Low-head control of penstock flow is provided by an 11-foot diameter oil-pressure actuated butterfly valve at the tunnel level, El. 2,595, and just upstream from an automatic air valve which will vent the conduit when emptying or filling. Power for oil pumps and lights is supplied through cable from the powerhouse, where the butterfly valve will normally be operated by push button on the main control boards. Between the butterfly valve and the 20 x 11 x 11-foot diameter wye branch at the end of the tunnel proper, a 24-foot section of Penstock No. 1 is provided with flanged ends and an intermediate expansion joint, which make it possible to disconnect and roll back this section to admit personnel and light vehicles. The adits here and at El. 1,685 which are required for the future completion of Penstock No. 2 and for permanent access to penstocks and valves, will be accessible by the 20-ton aerial construction tramway, or by helicopter from the Kemano River level.

At El. 1,685, the plug in the branch gallery is cored out to form a 70-foot long tunnel leading to a 20 in. diameter manhole into the penstock, for inspection and maintenance from this level. Here, as at El. 2,600, lugs are located on the crown of the liner for attachment of skip hoisting tackle.

Control of high pressure flow is afforded by 51 in. diameter double seal sphere valves in a separate chamber at the powerhouse level and by the turbine nozzles with associated jet deflectors. Valve operation is by conventional piston type servomoters using penstock water, and control is local manual, or electrical, or remote from the station switchboard. The Venturi effect created by the increase in conduit size downstream of valves is utilized for an automatic valve control involving a flowmeter. Downstream seal of the sphere valve can be renewed with penstock full

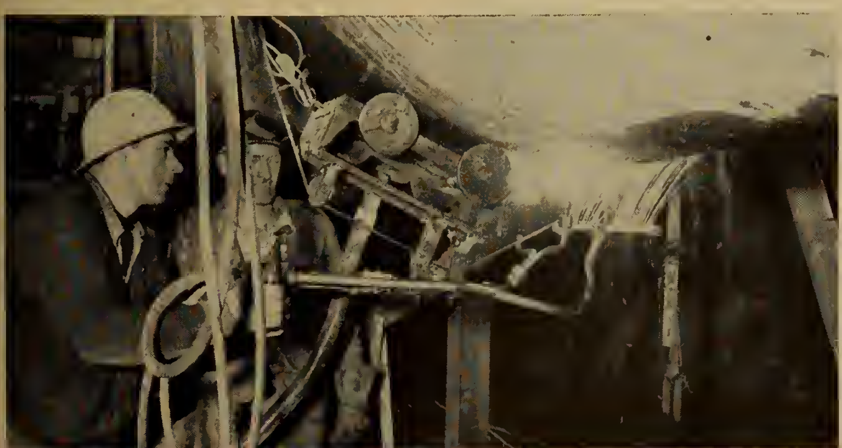

**Fig. 45. Low temperature stress relieving of field weld.**

by removing a 3-foot length of penstock just below the valve. Between this point and the inlet to the turbine distributor scroll, two couplings are employed at penstock joints to simplify closure in construction and to act as contraction joints when the pipe is opened at the sphere valves. It follows that hydrostatic thrust at these valves is taken into the upstream rock by tension in the penstock branches and at the turbines this thrust goes through the encasing concrete to the powerhouse rock.

### Backfill of Pipe

At the upper and lower ends of the penstock, the plate thicknesses are sufficient to carry internal hydrostatic pressures as a free pipe at normal stresses and the concrete encasement serves only to protect the outside of the steel pipe against corrosion and to provide a continuous support. Between the extreme ends of the entire penstock, part of the internal pressure loads must be shared by the rock, in order to keep steel stresses near accepted working values for the material. Consequently, the concrete encasement or backfill between pipe and rock will protect and support the steel and act also as a compression member transferring part of the internal pipe load to the rock. To meet this requirement, the concrete must be durable, of medium but uniform strength and completely free of air voids or segregation, which would lead to concentrations of stress and to excessive strain in the steel. The concrete backfill averaged about 3 feet in thickness. Essential tightness of contact at pipe and rock surfaces called for a minimum of curing shrinkage in the concrete, which was achieved by the use of low heat cement and by intrusion of the mortar fraction of the mix into coarse aggregate previously placed around the pipe. This in effect gave a low pressure grout filling of all voids wherever the technique was used. Observed temperature rise during hydration was about 25°F. from a placing temperature of approximately 50°F.

As a check on the quality of backfill, about 1,000 cores were taken after 21 days age, and normal grouting methods used to fill these core holes and consolidate zones of fractured or water bearing rock. Conventional wet mix concrete was pumped into parts of the horizontal runs where it was difficult to place dry coarse aggregate and where grouting along the crown contact would have been necessary with either method of placement. Hole packers were specified to prevent the grout at pressures of 75 to 300 psi. from entering any space between the liner and the concrete.

Fig. 47. Removable section at head of penstock.

### Construction

Although the adopted plate steels are well known and almost standard throughout North America for unfired pressure vessels with welded joints, an extensive program of testing was carried out to develop welding procedure, and to investigate stress conditions and ductility in and adjacent to heavy welds, the impact resistance of the proposed steels and the efficacy of low temperature stress relieving. Operating temperature of the metal will range between 40°F. and 55°F. The average results obtained in these investigations indicated that the weld metal is somewhat stronger than the plate, but about equal in ductility; that low temperature stress relief of field joints would improve the gradation of locked-up weld stresses; and that a single vee butt joint would be as satisfactory as the three-weld stepped joint used by some European engineers for thick plate welded from one side. The metal as furnished in the completed liner had characteristics as given in Table 1.

Pipe sections were fabricated in the shops complete with skid shoes, grout plugs, handling lugs and edge preparation for field welds, in shipping pieces not more than 28 feet long, or 20 tons in weight. Oven stress relief was the final operation on each can. Total angle of vee for the double-vee submerged arc shop welds was 60° for A-201 and 90° for A-285, 9/16 to 15/16 in. thicknesses which were built in a separate shop of the same firm. Edge preparation for circumferential field joints are given in Table 2.

While part of the field welding was underway in shops at the intermediate and upper portals, excavation of shafts and installation of skid tracks were advanced from two levels. The large notch in the end of Mt. DuBose offered the only practical intermediate access to the penstock site, though at El. 1,685 it is at about the upper third point of the total rise.

Here the 16 x 16-foot adit and branches totalled 1,200 feet in length, with transport service by rail to the cableway landing near El. 1,600. A similar arrangement was made near the west tunnel portal (El. 2,590), and space for construction plant and material storage was developed as muck became available from excavation.

The rock along the penstock site was explored in 1951 by diamond drilling from the mountain surface to obtain some knowledge of conditions to be expected in construction. A few dikes and shear zones were encountered in drill holes, but the most valuable information obtained was confirmation of other evidence that ground water would not be troublesome.

Design size of the full bore was fixed at 15 feet diameter to allow something less than two feet average space outside the steel liner. However, when the shafts were enlarged to full size by slashing down from the upper ends, resulting overbreak gave a shaft of approximately 17 feet equivalent diameter. Size of such an annular space is of course a compromise between construction convenience and cost of backfilling the space. In spite of careful advance planning, it was necessary to do a great deal of work outside the liner and the extra space undoubtedly reduced labor costs by permitting easier access. Generally, rock and ground water conditions were favorable as expected from results of earlier exploratory drilling. In the final cleanup of shaft excavation, all timber supports were removed just ahead of aggregate placement. Steel rock supports were placed when slashing down the raises.

#### The Aerial Tramway

Transport of all materials for penstock construction above the powerhouse elevation was accomplished on an aerial cableway of nominal 20-ton live load capacity, equipped with several skips for different services. Miscellaneous materials, equipment and personnel were carried in a box skip with plate steel floor and sides. A rail mounted frame was substituted for this box skip when transporting liner sections, lashed on two dollies, to the intermediate and upper adits and a hopper was attached to the cableway carriage for transport of concrete or aggregate. As mentioned above, the longest section of 11-foot diameter liner to be handled by skip was 28 feet and the heaviest about 19 tons and 14 feet long.

In order to economize on underground manual welding, each pair of cans as delivered by the aerial tramway was welded by submerged arc process in a shop at the respective portals, so that a double length was transported from these shops to be placed in position in the shaft, with half the required circumferential field joints completed. Shops were complete in all details, with rolls, transfer dollies, preheat, inside and outside welding heads and stress relieving equipment. Welds were examined by centering X-ray apparatus in the pipe with film covering the entire outside circumference of the joint.

#### Installation of Liner Sections

The double length liner sections were moved to the head of the shaft on dollies and when ready to start down the sloping shaft, the load was secured by hoist ropes on the dolly and on the pipe section itself. As it passed through the vertical curve, the leading pipe shoes came to bearing on the skid track in the shaft and the dolly dropped into a recess between these skid rails. When in contact with the adjoining lower section, the specified root opening was maintained by small bars spaced around the periphery. For lowering of pipe sections and handling of numerous welding, radiographing, concreting, and grouting skips, two hoists were required at each adit level, one of 40 tons and the other of 5½ tons capacity.

Installation of the liner sections up the shafts was started soon after the respective lower elbows had been positioned and encased with concrete. With transport established, a pipe section was lowered and tacked into place every 22 hours on the average.

To keep pace with this relatively fast rate of pipe delivery, it was necessary to weld circumferential joints simultaneously from several skips. Calculated volume of welds placed manually with 5/32, 3/16 and 1/8 in. E6016 low hydrogen

Fig. 48. Wye No. 1 eleven foot inlet at upper right.

rods is 20,300 cu. in. for joints at El. 211 between the elbow and turbine scrolls; 40,200 cu. in. from El. 211 to the upstream elbow at El. 1,685; 6,400 cu. in. in the upper raise to the downstream elbow at El. 2,596; and 2,500 cu. in. from that point to the upstream end of the steel liner. Normally the welding crews at a joint consisted of four men and weld deposition averaged 29 cu. in. per man shift.

Plate was preheated to about 400°F. and held at that temperature while welding. Heating was accomplished by a ring of resistance elements jacked against the inside of the pipe on each side of the joint to be welded. Underground field joints were radiographed by centering a cobalt 60 bomb of 1,000 milligram radium equivalent in the pipe cross-section with film tied around the entire outside surface of the joint. The overall average of weld repair in about 5,200 feet of radiographed manual weld was 2.4 per cent and the 2,940 feet of above ground automatic welds required only 0.2 per cent of repair. It is of interest to note that the percentage of weld repair decreased with increase of plate thickness and amounted to only 0.4 per cent for the 913 feet of welds in the heavy plate of the manifold.

The final operation on the underground welded joints was stress relieving by the low heat process, utilizing oxy-acetylene gas in two 6-in. wide heads at 10-in. centers, followed by a water quench.

### Backfill

Backfill concrete for all of the sloping portions and part of the horizontal portions of the 11-foot diameter penstock was produced by the intrusion-prepakt method in which the mortar fraction of the mix is pumped into previously placed coarse aggregate. For this purpose it was necessary to produce an aggregate in sizes between ½ and 3 in. and containing less than 5 per cent of sizes smaller than ½ in. Despite the special screening and washing at the main Kemano River aggregate plant, it was found necessary to rescreen and rewash at the portals, because of the production of fines in the several transport and handling operations and to exercise great care in placing around the pipe to avoid further breakage of particles. Screen analyses of aggregate as placed gave less than 1 per cent sizes smaller than ½ in.

Placing of coarse aggregate in the horizontal runs by combinations of belt conveyers and specially constructed blowers without attrition of the aggregate was particularly difficult, so that the contractor elected to place all concrete backfill at El. 2,600 and portions at El. 1,685 and downstream from Wye No. 1 at El. 210 with pumpcrete equipment. For placing of aggregate on the sloping runs of the penstock a 10-in. pipe was supported on the top centreline of the liner and filled with aggregate from hopper cars at the head of the shaft. With the pipe maintained full of aggregate, gates were burned in the sides of this slickline as filling of the annular space progressed upwards. Aggregate placing averaged 3 feet of penstock length per hour.

The first backfill concrete placed on the slope was in the lower 400 feet of the upper raise. With experience gained there, the upper raise was completed in one lift of 800 feet, then the lower raise backfilled in a single lift of 1,940 feet. The mortar which was pumped into the voids of the coarse aggregate consisted of approximately 7.15 parts by weight of sand screened to a fineness modulus between 1.6 and 2.0; 5.0 parts type II portland cement; 2.16 parts alfasil, plus 0.07 parts intrusion aid and 3.15 parts water. A laboratory investigation, using strain gages on a number of 10 x 20-in. cylinders, obtained approximate values of 0.17 for Poisson's ratio and established the secant modulus of elasticity as $(2.75 + 0.06t)\ 10^6$ psi. where $t$ is age in weeks.

Pumping equipment was located at El. 210 for the lower raise and at El. 1,685 for the upper raise, with booster pumps as necessary intermediate between the grouting skips and the bottom of the raise. Grout was injected into four holes at a time and in a sequence which advanced the grout surface on a slight slope downwards toward the invert of the shaft. 4,700 cu. yd. of grout to make 11,090 cu. yd. of completed backfill concrete was placed in the lower raise in 20 days, making an average progress of 4.0 feet per hour.

Numerous laboratory tests were run to determine a minimum age at which the concrete could safely be loaded. The following age-strength characteristics were obtained:

| *Age days* | *Ultimate strength, psi.* |
|---|---|
| 16 | 2,047 |
| 28 | 2,458 |
| 37 | 2,552 |
| 49 | 3,303 |
| 63 | 3,388 |
| 103 | 3,650 |

Measured temperature rise in the prototype concrete was from 48°F. to 75°F. and back to 50°F. in 14 days.

In order to make certain that the grout had in fact filled the voids and produced a relatively uniform quality and strength of encasement, numerous cores were taken through grout holes to the rock contact, particularly in the lower raise, where the rock must take larger loads. No check hole showed any unfilled voids in the aggregate or other conditions considered detrimental and very little grout was taken by these drill holes when attempting to consolidate the rock or to tighten up the concrete at pressures up to 300 psi.

Since the pH factor, temperature and other qualities of the reservoir water are considered generally favorable as respects corrosion, the penstock was put into service without interior paint, except for short test sections of five coatings in turbine branches No. 1 and No. 2.

**Not the least interesting and spectacular part of the Kemano-Kitimat development was the design and construction of the 51-mile transmission line. The design was required to be unusually heavy to withstand the severe climatic conditions and construction handicaps were as difficult as they could be. All these details are entertainingly discussed in this paper.**

Power for the Aluminum Company of Canada's smelter at Kitimat is transmitted across 51 miles of mountainous topography from the underground powerhouse at Kemano. Characteristics of both route and electrical load make the lines unique in many respects.

### Preliminary Investigations

Initial studies disclosed that a standard approach to transmission line design and construction would be unsuitable. In September, 1949, a helicopter reconnaissance of possible routes disclosed that access and the number of tower lines would be restricted by narrow valleys, steep ridges and alpine passes. Subsequent surveys confirmed that flash flooding and new channel formation by glacier-fed streams, snow movement, ice accumulation and high winds would be significant in structure design and location. The smelter would require an extremely reliable transmission system to maintain the continuous power demand of the aluminum reduction cells, which could be damaged by power outages. These severe mechanical and electrical conditions called for lines of robust design.

The shortest possible route between Kemano and Kitimat crosses an intervening mountain range via Kildala Pass, the only pass which affords suitable tower sites and reasonable access. It could be entered from the Kemano end by a ridge wide enough for two tower lines and crossed at 5,300 feet elevation, with descent on the Kildala side by spans between rock buttes.

As part of the early investigations, costs of the direct overland route were compared with costs of a route down the Kemano River and along tidewater to Kitimat. Because of the generally milder climate near sea level, it was reasoned that a longer 78-mile coastal alternative could be of lighter construction and that the saving in material, plus the longer working seasons, might compensate for increases in other construction costs, as well as for increased power losses. Once in operation, either scheme would need special maintenance equipment, such as helicopters, or work barges and aerial cableways, to repair any major break. There was no reason to assume that one route would be more vulnerable than the other to snow and lanslides, since protected tower sites could be found on both the mountains and on the coastal side-hills. Estimated construction cost of the coastal route exceeded estimates for the overland route, and annual charges against this difference in capital cost were considered more than enough to offset any possible difference in frequency and duration of outages.

Since no weather records were available, meteorological observa-

D. G. Dunbar, M.E.I.C.

Editor's Note: A photograph of Bruce Cooper was not available.

tions were begun at the end of 1949 for use in planning and subsequent operation of the transmission system. First data were obtained at three stations in the period from Autumn, 1949, to the Spring, 1951. The only observation station for the first winter was the base camp at tidewater at the mouth of Kildala River, on the west side of Kildala Pass. For the winter of 1950-51, additional stations were established at El. 3,000 in the upper Kildala River valley and at El. 5,300 on the summit of the pass. At both these points, twenty-foot spans of 795,000 cm. A.C.S.R. conductor were erected for studies of rime and ice formation. The first two years' weather record, though all too brief, helped to establish design criteria and indicated the living, working and flying conditions to be considered in construction and maintenance programs. Spring to fall weather is mild, but snow-melt and heavy rains keep the streams at high stage and both valleys and peaks are often under cloud. The frequency of electrical storms, however, is only about one in two years. To date, the periods from late December to early March have provided the worst weather. Snow depths have varied from 15 feet at the pass to three feet at tidewater, with extensive and rapid shifting of snow by high winds at upper levels. Although snow slides occur on the steep valley walls during winter and spring, there are enough isolated ridges and protected points which will be unaffected by snow movements and which are, therefore, suitable as tower sites.

Ice formation was frequent on the test span at the pass, where a maximum rime load of 2.4 lb. per foot of conductor was measured in February, 1951. Clear ice, which would have produced a conductor load of about 3.5 lb. per foot, formed on ground objects at Kildala Arm once during the two years. Although measured ice loads were light, it was recognized that heavier deposits could occur with a combination of observed wind, temperature and precipitation.

Winter temperatures seldom rose above freezing and dropped to extremes of −24°F. at the pass, and −17°F. on the upper Kildala River. During one storm, wind velocities reached 100 mph. at the pass and 70 mph. on the upper Kildala, but winds generally were gusty as a result of topography. Visibility for flying varied from an estimated 20 days per month in the late fall to five days per month in December and January.

#### Electrical Design

The electrical system was investigated on a network analyzer to determine the most satisfactory voltage and circuit combinations for the proposed generation, transformation, line length and number of lines. The resulting transmission system with very large conductors at high voltage is flexible and efficient.

The analysis brought out that a nominal voltage of 287 kv., phase-to-phase, was by a small margin the best voltage at which to transmit the ultimate load of 1,250,000 kw. In practice, the voltage at the Kitimat end of the line is held at about 275 kv. The voltage at the Kemano end will vary under different conditions, up to a maximum of 301 kv. Any savings in structures, insulation and transformers possible by transmission at the more common 230 kv. would be offset by a large increase in synchronous condenser capacity at Kitimat. Still higher voltages were precluded, primarily, by the limitations of available electrical equipment. 287 kv. was at or above the upper limit of voltage proven in service for oil-filled cable as required between powerhouse and transmission line, and line hardware for voltages above that voltage is special. Some additional assurance was afforded by the fact that transmission of 287 kv. had operated successfully for many years.

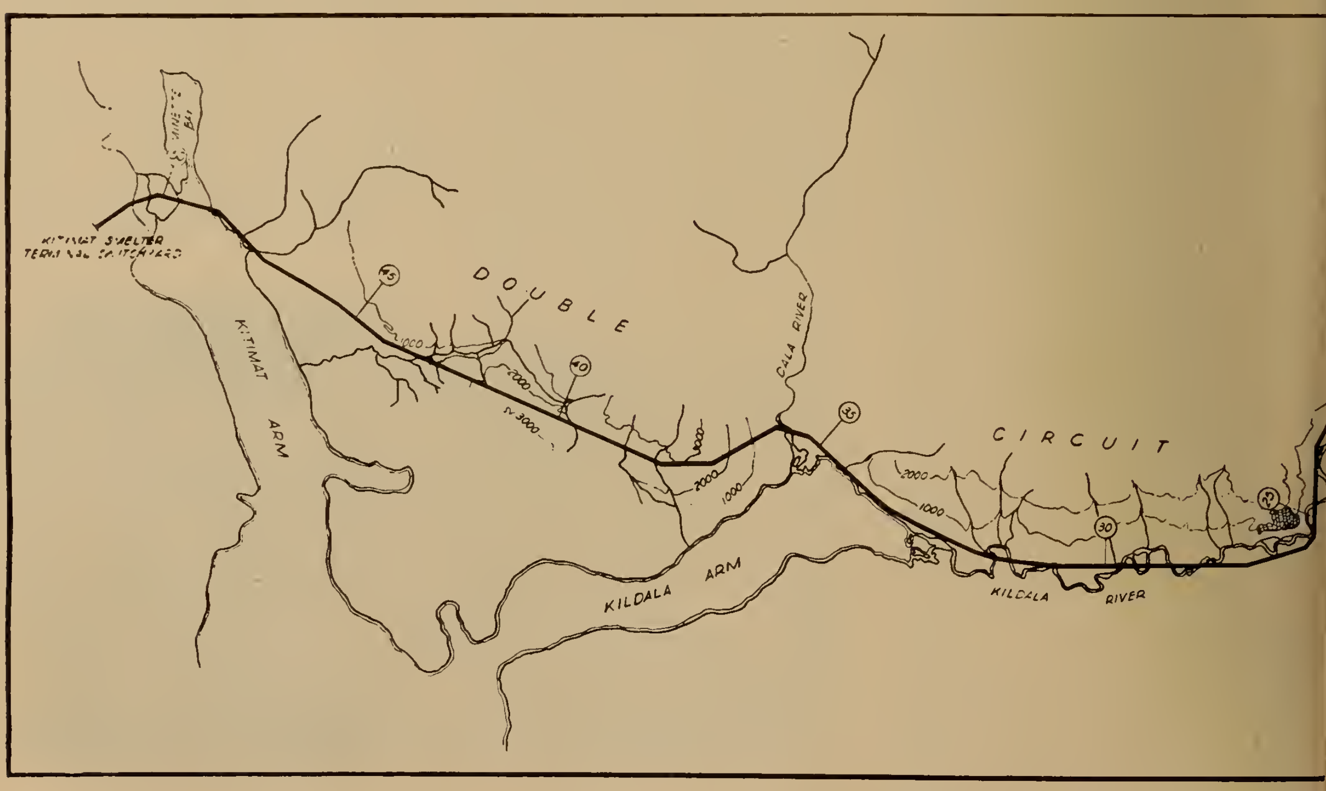

Fig. 50. Route of Kemano-

Circuit types were chosen for maximum of flexibility consistent with mechanical reliability. For the ultimate development, two double circuits with intermediate switching stations would give the best arrangement for isolating faulted sections and would require the least amount of synchronous condenser capacity. Double circuit construction was considered feasible over all sections of the route except through Kildala Pass, where vertical configuration of conductors, with steep spans and heavy loads, could not satisfy the specifications for reliability. Security could be obtained by using two single circuits over the entire route, but this arrangement lacked flexibility and needed the largest amount of reactive correction. The adopted scheme combines both circuit types into one line. Double circuits are used for the relatively accessible, lighter loaded, more regular profile and span sections in the valleys, while single circuits serve for the heavier loaded, irregular profile and span section over Kildala Pass. Switches between the double and single circuits, at both ends of the pass, permit several operating combinations.

Since the initial electrical load can be carried readily by half the transmission system, only one line on both double circuit sections was erected. However, the ultimate development of two single circuits was built to avoid reopening Kildala Pass in future for a second line. Disconnect switches are not installed at the switching stations between the double and single circuit sections; therefore, Kemano and Kitimat are joined by two independent circuits. Switching facilities and the additional double circuit lines will be built in the future.

Large conductors are required for the exceptional electrical and mechanical loads. Under emergency conditions, almost the entire ultimate load of 1,200,000 kv. may have to be carried on half the transmission system. A current of 2,600 amperes per phase on the single circuit calls for a conductor area of 3,300,000 cm., which is about twice the capacity of Falcon, the largest standard A.C.S.R. conductor. Falcon, with an area of 1,590,000 cm., was suitable for the double circuits. Accordingly, conductors were selected with the characteristics given in Table 1.

Insulators for all suspension and strain assemblies are standard 10 by 5¾ in. units. Double circuit suspension assemblies consist of 16 25,000-lb. clevis-type insulators in single or double strings, depending upon span length. Strings in triple or quadruple suspension assemblies, for the single circuit, are increased to 18 units to compensate for the lower insulation provided by each unit at the higher altitudes of Kildala Pass. Strain points on both single and double circuits are reinforced with two extra insulators per string, as future additions at these positions would be difficult. Dead-

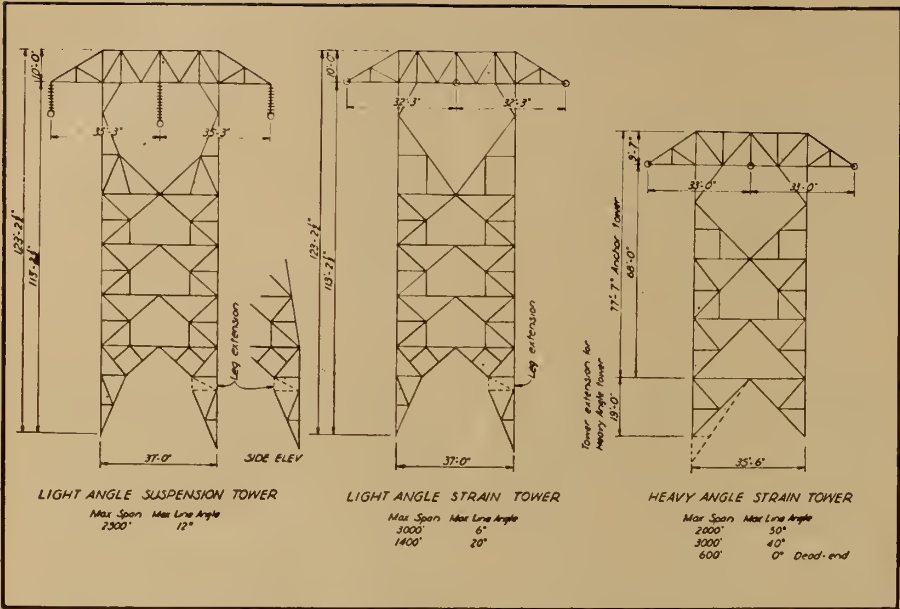

Fig. 51. Single circuit towers.

end assemblies, therefore, consist of three 18-unit strings of 25,000-lb. clevis-type insulators on double circuit, and six 20-unit strings on single circuit. Jumpers at strain positions are supported by 10 by 5¾ in. 15,000-lb. ball-and-socket-type insulators, assembled into 16-unit strings for double circuit and 18-unit strings for single circuit. In case of flashover at strain towers, this insulation unbalance between strain and jumper assemblies could protect the dead-ends from damage that might cause a major outage. Although use of standard insulators led to multiple string assemblies with somewhat complex hardware, this was an overall economy since stronger units were not commercially available.

Conductor clearances to tower members are based upon the impulse flashover characteristics of the suspension insulator strings. A 1,567-kv. design impulse level, for the 16-unit double circuit suspension assembly, fixed clearances at 8 ft. 4 in. for unloaded conductors and 6 feet for a 15-lb. per sq. ft. wind load on the bare conductors. Single circuit design impulse voltage across 18-unit strings was 1,743 kv., which required conductor-tower clearance of 9 ft. 2 in. for unloaded conductors, and 6 ft. 9 in. for conductors loaded only with wind at 15 lb. per sq. ft. Generally, tower framing and hardware provided these clearances, but on steep single circuit spans, it was necessary to check clearances from the center conductors to the members around the throat of the tower.

Ground wires are installed only at the transmitting and the receiving ends of the system. In order to protect switchyard equipment from possible lightning damage, two ¾-in. steel ground wires are placed over the double circuit sections for about one mile from both terminals. Elsewhere, ground-wire protection was considered unwarranted, since lightning storms are infrequent.

A deficiency of overburden along the route ruled against extensive grounding of the lines and counterpoise wire, to lower ground impedance for protection in line surges, would be damaged by water and snow movements. The only feasible grounding method was the removal of static charges by copper-weld ground rods at towers with concrete footings.

Conductors are transposed at the Kemano switching station between double and single circuits and again at the Kildala switching station. Transpositions were accomplished by making only slight modifications of the standard double circuit towers.

Corona was considered in the electrical design of both conductors and hardware. Power dissipated by corona discharge on the line will be negligible, since the diameter of Falcon conductor is greater than necessary for minimum corona loss for 287 kv. at sea level. Even at the pass, (El. 5,300), Emu conductor diameter is larger than required. All conductor-support hardware was designed to keep corona discharge to a minimum, but provision was made for the addition of anti-corona rings if required. Radio interference from corona is important only at the terminals and can be checked during operation.

Conductor de-icing by load transfers among sections of the line was regarded as impractical, because assumptions as to weather would be unreliable and also because there would be periods during construction and early operation when the lines would be carrying no load or too little load for effective ice prevention or removal. Consequently, the lines had to be designed for maximum reliability under full ice-loading.

### Mechanical Design

The selection of basic design loads was made from a study of records on other lines, from weather observed along the route, and from the service requirements of the system. Experiences with heavily loaded transmission lines elsewhere, though not directly applicable, were given close study. In the mountains of south-central France, conductor ice loads were reported at 13 to 27 lb. per foot, while utility companies in the United States Pacific northwest, with 230 kv. lines at 5,000-foot elevation, experience heavy icing, but not of the order of the above. It is their experience that conductor-failure from over-tension occurs only rarely, but unloading of ice accumulations causes structural and hardware damage, as well as short circuits. Their greatest trouble is distortion of members in the lower panels of towers by snow creep loads, or by heavy masses of snow and ice accumulated in the structure during rapid thaws. Vulnerability of structures to snow action in the mountains is confirmed by investigations made in Switzerland by the Avalanche Bureau. All these reports, in combination with the known and suspected weather conditions in the Kemano-Kitimat area and the exceptional degree of reliability demanded of the line, dictated exceptional design loads for all structures.

Accordingly, the following loadings were specified for the conductors:

*Single Circuit*

A: Ice-load of 40 lb. per foot of length at 0°F. to produce yield point stresses in tower members and to stress the conductor to its ultimate strength.

B: Radial ice of 2½ in. at 57 lb. per cu. ft. to produce design stresses in tower members.

C: Radial rime of 2 in. at 19 lb. per cu. ft., combined with wind at 8 lb. per sq. ft. of conductor projection, to produce design stresses in tower members.

D: Radial ice of ¾ in. at 57 lb. per cu. ft., combined with wind at 11 lb. per sq. ft. of conductor projection, to produce design stresses in tower members.

***Double Circuit***

A: Ice-load of 24 lb. per foot of length at 0°F. to produce yield point stresses in tower members and ultimate stresses in the conductors.

B: Radial ice of 2 in. at 57 lb. per cu. ft. to produce design stresses in tower members.

C and D: Same as C and D loads for Single Circuit.

The single circuit towers were all designed to resist the stress induced by the pressure and movement of deep snow, using the following loadings:

For all tower members from ground line to a height of 19 feet:

(a) Load of (3000-100$h$) lb. per lineal ft. of horizontal projection of member length, where $h$ is height in feet above ground line.

(b) Load of 300 lb. per lineal ft. of vertical projection of member length.

Towers for the specified loads and route topography have some special features. Double circuit towers and those of one single circuit line are conventional, four-legged, steel-lattice structures, but many details differ from those of towers designed to standards such as the National Electrical Safety Code. Besides exceptional strength and weight throughout to carry the heavy conductor loads, the single circuit towers have lower panels reinforced by channels and double angles to withstand the above snow-creep loads. Torsional forces transverse to the box crossarms became a factor of importance at strain towers on steep spans and first-panel legs of single circuit towers are vertical to reduce space requirements and simplify footing layout at the restricted sites in the mountains.

It was advantageous to adopt only a few tower types in each general classification. Variations in tower framing to suit the unorthodox loadings were minimized by using one tower type for several applications, leading to economies in fabrication and erection, which more than balanced the value of any excess material. Tower types and their capacities are detailed in Figs. 51 and 52. Tests on prototype single and double circuit towers established their adequacy for field erection and the specified loads.

The second line of the single circuit uses tubular aluminum towers of a unique design developed by Aluminum Laboratories Limited and described in an article which appears elsewhere in this issue of the *Journal.*

Supports on both double and single circuit towers are special to suit the extra-size conductors. Proof tests of suspension clamps designed for the job gave the above average strengths.

Curvature in the suspension clamps for both Falcon and Emu conductors is designed for a maximum vertical angle of 34°.

Tapered armour rods are used at all suspension points, except those of jumpers at strain towers. Armouring reinforces the conductor for vibration loads and protects the conductor from flashover damage. Corona loss at the ends of the armour-rodding is reduced by anti-corona ferrules. At jumper suspension points only flashover-protection, which is afforded by grading rings, is required. Standard design compression assemblies are used for the termination of conductors at strain towers. Special sleeves and compressors were necessary for the large conductors.

A wide variety of footing conditions were encountered along the line. In the valleys, double circuit towers are erected on footings suitable for gravel, talus, rock, muskeg or silt. Double circuit light suspension towers are built on steel grillage footings for sand and gravel, but concrete pad-and-pedestal-type

Fig. 53. Double circuit towers.

Fig. 54. Helicopter landing platform.

footings are needed for the heavier towers. Some structures had to be located in detritus at the bases of valley walls and for these towers, talus-type footings were formed by consolidating a sufficient mass of rock with concrete. Towers based on bedrock use conventional footings of concrete pads and anchor bolts grouted into holes drilled in the rock. Pile-clusters, capped with concrete, hold structures in muskeg in the flat, low-lying, valley bottoms and in the silt of the tidal flats at the entrance to Kitimat. Footings for towers near glacial streams, which are prone to flash-flooding and course-changing, are specially designed to support towers with complete washout of backfill and to protect tower members from floating logs.

Most single circuit towers are founded on the typical granite or diorite of the Coast range mountains. Bases for light angle towers on rock are made up of stub legs set between two 12-in. I-beams, which are keyed by shear lugs to 6-in. concrete pads and held down by two 2¼-in. anchor bolts grouted into the rock. Foundations for towers in one talus area are tied, mass-concrete footings resting just below the surface of the rock rubble, extensive excavation of which might have precipitated slides as the slope recovered stability. Other footing types are special designs for glacial till and soft, biotite-rich diorite and concrete pad-and-pedestal footings in earth for a few towers.

The standard A.C.S.R. graphic method of conductor sag-tension calculations was suitable for design of double circuit spans, but a new method was developed for conductors on irregular single circuit spans. Sags and tensions for double circuit Falcon A.C.S.R. are based on a conductor tension at maximum design load of 27,700 lb. which is 50 per cent of ultimate conductor strength. Maximum accuracy with the graphic method is reached when the spans for ruling-span calculations are flat and of reasonably uniform length. Since sags of some inclined spans, the steepest of which rises 60 feet in 100 feet, deviated too widely from the parabolic assumptions of the graphic method, they were reconciled to equivalent spans for ruling-span computations by increments which were functions of the horizontal spans and the differences in elevation of the supports. The equivalent spans were effectually uniform for design since the length of the longest span in a series between anchors was not more than three times that of the shortest.

The graphic method for conductor sag-tension design was inadequate for the unique situation on the single circuit where towers are restricted to sites on the ridges, rock islands and ledges in the mountains. As a result, spans in a series are irregular and it was discovered that, even with adjustments for slope, the common approach to sagging would result in sag errors as high as 15 per cent. Also, standard A.C.S.R. sag-tension design could not be extended to deal efficiently with variations of required maximum design tensions from one series of spans to the next. A procedure was devised to overcome these difficulties and to enable stringing sags and tensions to be computed for any temperature and from any value of final design conductor tension, which in this case could reach a maximum of 68,000 lb. for Emu conductor.

Other features were considered in the sag and tension design of the conductors for the unorthodox spans. It was appreciated that the conductor, when in the stringing sheaves, would run downhill on the inclined spans, making sags correct only in those spans which were used for sag control. The suspension clamps, when clipped-in, were offset a specified distance from plumb lines at conductor support points to remove or to replace in each span sufficient slack to equalize horizontal tensions and to leave the suspension insulator assemblies hanging vertically. The behaviour of other lines indicates that both double and single circuit conductors should be free from damaging aeolian vibrations, since supports are reinforced with armour-rods and conductor tensions under average unloaded conditions never rise above 14 per cent of the ultimate tensile strengths of the conductors.

Fig. 55. Road from Kemano valley to Kildala Pass.

### Surveys

Ground survey parties pioneered lines in the valleys, along the ridges and over the mountains to obtain topographic data for tower locations and construction access. The surveyors were transported by helicopters and conventional aircraft and assisted by aerial mapping in the areas above tree-line, but in spite of these aids, it was a laborious and often hazardous task obtaining plans and profiles in a region previously traversed by only a few trappers and prospecters. The final surveys established that the nine miles of double circuit lines would leave the powerhouse switchyard at El. 250, follow the Kemano River and terminate at the Kemano switching station at El. 700. The single circuit lines would then rise to the summit of Kildala Pass at El. 5,300 in 3.6 miles and descend to Kildala switching station at El. 500, a total section length of 9.5 miles. The remaining 32.5 miles of double circuits would follow the Kildala River, cross Green mountain at El. 2,900 and traverse Minette Bay and tidal flats to the switchyard at Kitimat.

### Construction

Construction of the transmission lines was a planning and logistics problem of the first magnitude, involving working seasons of uncertain and short duration, particularly on the high ground. Work commenced in the fall of 1951 and was completed in September, 1954.

The first task was to move men and materials to the site of the line. Construction of a road up the Kemano valley from the base camp and supply centre at Kemano powerhouse site to the line switching station was relatively easy. This served the one section of double circuit, while part of the westerly, or Kildala, section was supplied through a dock at Kildala Arm and roads in both directions. This dock is about 70 miles by water from Kemano Bay. In similar fashion, supplies for the double circuit section from Green mountain to Kitimat were landed at Minette Bay and transported along construction roads. Access and supply for single circuit construction were maintained by continuations of the double circuit roads from both Kemano and Kildala switching stations. These roads met at the summit of Kildala Pass, but snows in the upper levels restricted straight-through passage for most of the working period. Roads to the summit of Kildala Pass, negotiable only by four-wheel-drive and track equipment, snaked their way along cliffs and over glaciers in a series of hair-pin curves with grades up to 30 per cent. All roads needed frequent repairs, as heavy rains and snow-melt sluiced the surfacing and created washouts.

Construction could not have proceeded as well without aircraft, which provided almost the only transportation in pioneering stages and were much used for moving men and materials quickly during construction. Single-engine, six-passenger Norseman and Beaver seaplanes supplemented water transportation by hauling personnel and light freight between Kemano Bay, Kildala Arm and Minette Bay. Bell helicopters, with a capacity of one passenger, or 300 pounds, and Sikorsky S-55 helicopters, with a capacity of 10 passengers, or 1,500 pounds, flew many ton-miles, particularly to Kildala Pass for single circuit construction. The Bells were

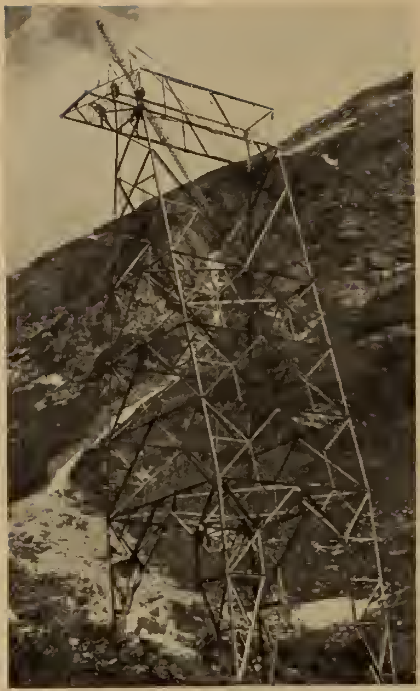

Fig. 57. Top: Compressing joint in "Emu" conductor.

Fig. 56. Left: Erecting single circuit tower with aluminum gin pole.

invaluable for moving men and light loads to any one of the six landing platforms near tower sites inaccessible by road, while the Sikorksy's biggest job was lifting fuel, prefabricated camp buildings and other supplies by cargo slings and dropping the loads where required.

Wherever feasible, roads were built to tower sites, but where the construction cost of a road was prohibitive, highline cableways, powered by gas-driven logging donkeys, moved material from stockpiles beside the main access road. Portable highlines served individual tower sites, but semi-permanent installations were needed for groups of towers.

Steel, cement, lumber and camp supplies were hauled up the steep grades by power wagons, six-by-six army trucks, and special body, short-wheelbase, multiple drive trucks powered by 200-hp. diesels. Four-wheel, dual-transmission drive jeeps were used almost exclusively for transporting personnel. Athey wagons, pulled by tractors, moved much heavy material before roads were built.

A wide variety of construction equipment was required to suit the differing conditions at tower footings. Draglines or backhoes were used for excavations in sand and gravel where ground water proved troublesome, despite heavy pumping with 4- or 6-in. gas-driven pumps. Concrete for double circuit tower footings was trucked to the sites from central mix-plants located at intervals along the right-of-way, while concrete for the small pads of most single circuit tower rock footings was hand-mixed at the sites. For the framed reinforced-concrete, single circuit tower foundations resting on talus, it was necessary to set up crushers, batchers and mixers for the total 2,600 cu. yd. of concrete. Most anchor bolt holes for rock footings were drilled by air hammers, supplied by portable compressors and by air lines up to 1,200

Fig. 58. Stringing operations on single circuit strain tower. Kemano valley in background.

feet long from larger compressors, but at some more inaccessible tower sites holes had to be drilled with portable gasoline-hammers. Special drill supports and tungsten-carbide-tipped bits were utilized to drill 3 in. x 9 ft. holes for double circuit footings and 4 in. x 9 ft. holes for single circuit footings. The anchor bolts were fixed in the holes with grout containing an admixture to prevent shrinkage and to give high early strength. Piles for footings in muskeg in the Kildala valley and in alluvium at Kitimat were driven by a double-acting hammer in leads hung from a dragline or crane and powered by two 500-cfm. portable, diesel air compressors.

Tower erection was carried out by crews in a production-line sequence. After delivery of steel to a tower site, groundmen assembled panels for an erection crew, which raised them into place with 25-ton motor cranes with 105-foot booms and 25-foot jibs. The tower was topped-out beyond reach of the crane by another crew working with a floating aluminum or wood gin pole and 25-hp. hoist. At sites inaccessible to the truck crane, towers were erected entirely with gin poles and member-by-member erection was resorted to at single circuit tower sites where there was no room for ground assembly. After all members were placed, still another crew tightened all bolts and inspected tower details.

Stringing the extra large conductors on both double and single circuits was surprisingly straightforward, although some unconventional procedures and equipment had to be developed. First, insulators and conductor sheaves were hung from the towers. Then stringing sheaves, with one large diameter wheel, or three smaller diameter wheels in line to reduce bending in the large conductors, were suspended by pendants adjacent to insulator strings and threaded with ⅞-in. pulling cables from a tractor-mounted winch to the conductor reels. All six conductors on double circuit towers were pulled at once from the reel carts. Only one single circuit conductor at a time could be strung, as it had to pass through a tension machine to keep the conductor above the rough ground and safe from damage. The stringing length of double circuit conductor between strain towers was from one to two miles. Single circuit strain towers are much closer together, therefore stringing lengths were much shorter. Sizes of reels for transport and handling limited the maximum conductor lengths to 2,360 feet per reel for Falcon and 2,200 feet per reel for Emu, which increased the number of compression joints in the line. A gasoline-powered hydraulic compressor, instead of the conventional manually-operated type, was necessary for the large compression-joint and dead-end assemblies. Required sags were set in one or two spans of the series, being strung by sighting with a transit and controlling the winch operation by radio. Fog, clouds and rough terrain often reduced visibility and blanked out radio signals. The final stringing operation was the application of armour rods and the clipping-in of conductors to suspension insulator assemblies.

The lines have performed satisfactorily since the beginning of plant operations early in July, 1954, but unusual provisions have been made for inspection and maintenance. Since it will not be feasible to keep the access roads in good condition, permanent timber shelters for equipment and personnel have been built along the route. Repair crews, when required, will be flown by helicopter to these shelters, where some supplies and replacement parts will be stored. Observations of weather, snow movement and icing are being continued for a few more years by men housed in the shelter nearest Kildala Pass. √

# Aluminum Towers on the Transmission Line

*by*

Dr. K. Sutter, F. L. Lawton, M.E.I.C.
*and*
A. Soosaar
*Aluminium Laboratories, Limited*

**One of the single-circuit transmission lines from Kemano to Kitimat uses aluminum towers, the other uses the conventional steel towers. These aluminum towers are of novel design and construction, both of which are described in considerable detail in this paper. In their short operating life of less than a year they have completely lived up to expectations. It may well be that such towers will find wide use where their light weight simplifies transportation and their streamlined contour will reduce snow, ice, rime, and wind loads.**

### Introduction

This paper deals with a major innovation in supporting structures for high-voltage transmission lines, as applied to the single-circuit aluminum towers used on the Kildala Pass section of the 300 kv. Kemano-Kitimat system of the Aluminum Company of Canada, Limited, (Alcan) in British Columbia.

After discussing general considerations, the paper deals with investigations made on a tower designed and fabricated for test purposes. After consideration of the findings from this test tower, various aspects of the final design are presented. The paper then discusses fabrication and erection of the towers as finally designed.

The relative economy of aluminum towers as compared with conventional steel towers is dealt with, field investigations and observations on the aluminum towers are discussed and certain findings presented.

### Principal Features of Transmission Line

The left hand line, in the direction of power flow, in the Kildala Pass section utilizes a unique type of transmission tower, fabricated essentially from aluminum, as shown by Fig. 60. The right-hand line uses conventional lattice-type galvanized steel towers. Both lines carry the same 3,364,000 cm. ACSR conductors.

The power line carried by the aluminum towers starts at Tower No. 103L, at El. 1,000 above sea level in the Kemano River Valley, and climbs over a distance of approximately 7,000 feet in a slightly S-shaped route to El. 3,600, at Tower No. 109L, on Twin Peaks. From this point the line descends and attains its longest span of 2,592 feet between Towers Nos. 110L and 111L. Climbing again to the maximum altitude in Kildala Pass, at El. 5,300, at Tower No. 116L, the line is mostly in a narrow gully known as "Glacier Creek draw." Descending, it spans 2,184 feet over the snout of a glacier between Towers Nos. 117L and 118L, and thence drops into the Hanging Valley at the Kildala end of the pass.

Due to the irregular terrain, the line is far from straight. There are only a few towers on the line with tangent spans. The maximum angles in the line are 41°-01′ and 32°-00′. Towers Nos. 132L and 135L are subjected to the heaviest loads due to line deflection. Tower No. 137L, at El. 720, is the last aluminum tower at the Kildala end of the single-circuit transmission line.

Through Kildala Pass both single-circuit lines run side by side, but, due to the rugged topography, they are not parallel. Limited latitude for location of the towers existed in some sections because of the rocky hummocks and the risk of snowslides. As a result, the left-hand and right-hand lines occasionally approach each other, so that only the minimum acceptable centre-to-centre separation exists.

In a total length of 45,320 feet, the transmission circuit with aluminum towers involves 34 spans, distributed as follows:

5 spans of between 2,000 and 2,592 feet.
7 spans of between 1,500 and 2,000 feet.
13 spans of between 1,000 and 1,500 feet.
9 spans of between 634 and 1,000 feet.

There are a total of 19 suspension and 16 strain towers, the height varying from tower to tower.

Heights of these 35 towers are as follows:

8 towers from 128 feet to 139.5 feet high.
13 towers from 113 feet to 125 feet high.
9 towers from 91 feet to 111 feet high.
5 towers from 74 feet to 89 feet high.

The height of tower given here is the average vertical height of all legs from the concrete footing to the bottom of the cross-arm.

**General Considerations**

At the time the decision to build the second of the two single circuits was taken, the Korean war interfered with securing the necessary tonnage of galvanized steel, so those responsible for the design turned to aluminum.

Aluminum as a material for transmission-line towers has many merits. Among these may be noted:

> Its light weight, approximately one-third that of steel.
> Its ease of fabrication.
> Its freedom from corrosion.

Light weight was an important factor in the case of the Kemano-Kitimat transmission line. In the first place, the tower material had to be transported from the fabrication plant which was located in Victoria, B.C., to the end of water transportation at Kemano Bay, Kildala Bay and Kitimat Arm. There it had to be unloaded from barges and reloaded on trucks and hauled and distributed to the tower sites along the transmission-line route. Because of the rugged terrain, actual transporation to the various tower sites involved truck delivery in a few cases, highline (construction cableway)delivery in many cases and anticipated helicopter delivery in others.

It was this helicopter transportation which established limitations on length, size and weight of members. Even in the case of highline delivery, much the same conditions existed. The lower weight of the aluminum towers as contrasted with steel was thus an essential factor.

An additional advantage of aluminum, embodied in its light weight, is ease of erection which carried with it an inherently lower labour requirement for erection.

Another advantage of light weight was the possibility of erecting the towers by means of simple, lightweight, manually-operated equipment, especially applicable in the case of the aluminum towers.

The light weight of aluminum also made for greater ease of fabrication.

Galvanized steel is particularly subject to attack by corrosion during transportation by barge over salt water, even in pure atmospheres such as that of British Columbia. Development of corrosion in such atmospheres is normally slow, but where the galvanizing is damaged, corrosion may develop fairly rapidly. Aluminum tower members are free from such corrosion.

An important factor of the aluminum towers dealt with in this paper is safety of workmen, both during erection and during maintenance. A steel tower, when covered with ice, snow and rime, provides treacherous footing at best and workmen are exposed to the elements. On the other hand, the tubular legs of the aluminum tower, with permanently installed ladders inside, permit safe and sheltered access to its top and through the cross-arm to the conductors.

**Loading Specifications**

Design of the towers is based on an unusually heavy loading. Three factors exercised major influences:

> Climatic conditions, due to the influence of the orographic features on the warm moisture-laden air masses moving inland from the Pacific ocean.
>
> The high capacity conductors necessary with the heavy electrical loading dictated by the limitation in the number of circuits arising from topographic restrictions.
>
> The large deflection angles in the line, the long spans and the sharp breaks in the general slope of the terrain, arising from topographic conditions.

At the time design had to be undertaken, available information as to climatic conditions, was extremely sparse. There were no inhabitants along the route of the line, except for a few Indians near Kitimat. Consequently, in the fall of 1950, an experimental span of 795,000 circular-mil ACSR was erected between two 26-foot high aluminum towers, at El. 5,300 on the summit of Kildala Pass, some 2,000 feet above the timber line. Observers were stationed along the transmission route and the site of the test span was provided with recording instruments. The maximum ice loading observed during the winter of 1950-51 was 2.4 pounds per foot. However, conditions occurring during the one winter are not necessarily the most severe which can arise.

The aluminum towers were designed to the same loading specifications as the steel single-circuit towers*, which are repeated here for convenience:

A: Ice load at 40 pounds per foot of conductor at 0°F. Horizontal component of the conductor tension = 120,000 pounds maximum. This may be described as a yield-point load.

B: 2.5 in. radial ice deposit on the conductor. Horizontal component of the conductor tension = 65,000 pounds. Horizontal pull normal to the cross-arm, $P = 10{,}000$ pounds, at each point of conductor support.

---

**Fig. 60. Erection of aluminum tower.**

$B^1$: 60 percent of B loads, except $P = 45{,}000$ pounds, at each point of conductor support.

C: 2.0 in. radial deposit of rime on the conductor combined with wind of 8 pounds per square foot. Horizontal component of the conductor tension = 35,000 pounds. $P =$ 10,000 pounds, at each point of conductor support.

D: ¾ in. radial deposit of ice combined with wind at 11 pounds per square foot and broken conductor. Horizontal component of conductor tension = 31,000 pounds. At the suspension towers, $P =$ 22,500 pounds at any one point of conductor support. At the strain towers, $P = 25{,}000$ pounds at any one point of conductor support.

The following secondary loads are also used:

Dead weight of tower legs and cross-arm.

Wind load at 20 lb./sq. ft. on circular surfaces and 40 lb./sq. ft. on flat surfaces. Wind loads are supposed to act in the direction of $P$ or $T$ (transverse) loads.

Snow load corresponding to 6 inches of ice on all surfaces, including the legs, and snow-creep pressures on the legs under three categories, varying with the depth of snow and with the slope and roughness of the ground:

Normal load 33,000 pounds in 20-foot depth of snow, with a ground slope of 20°.

Light over-load of 49,500 pounds in 20-foot depth of snow, with a ground slope of 40°.

Heavy over-load of 66,000 pounds in 20-foot depth of snow, with a ground slope over 40°.

The 6 inches of ice is assumed to act simultaneously with snow-creep pressures.

#### General Type of Structure

The aluminum transmission-line towers are braced H-frame structures, which utilize, in general, five thin-walled tubular aluminum legs of 38-inch overall diameter. The legs carry a box-girder aluminum cross-arm, as illustrated by Figs. 60 and 61. The tower legs are arranged as an A-frame and a tripod. The cross-arm rests freely on caps, guided by pins. The caps are bolted to the heads in which the legs of the A-frame and the tripod terminate. There are, however, two towers on the line, where two tripods are used, the A-frame being replaced by another tripod, because of large deflection angles there.

The tubular legs are composed of sections bolted together inside. They are anchored to the rock foundations, or to the concrete foundations by means of four or more 2-inch bolts, grouted into holes drilled to a sufficient depth to transfer the tensile loads in the tower legs to the foundations.

The tubular leg section provides excellent strength and stability under unusually heavy axial loads and the severe moments arising from the snow, rime, ice and wind loading. Heavy icing on the conductors, on insulators and on the tower itself results in loads not usually encountered in power-line design. Snow on sloping terrain, to a depth of 20 feet and more, can occasion heavy creep pressures. The moments on the tower legs from snow-creep pressures must be taken into account. These factors led to developing the tower described, which would perform satisfactorily under the severe climatic conditions to which it would be subjected, without incurring the hazard of being turned into a more or less solid mass of snow, rime and ice, with a large area exposed to wind pressure.

Although the towers are mostly aluminum, welded mild-steel plate was used for the shoes, leg tops and caps, all galvanized after fabrication, largely because time available did not permit the necessary experimentation with these relatively complex members. Galvanized high-tensile steel bolts were also used for the clamp-type inside joints of the legs, shoes and leg tops.

The overall result is a line structure with relatively smooth exterior surfaces and with a minimum tendency to snow and rime accumulation.

#### Design Considerations

The aluminum towers must carry a mechanical loading derived from the principal loads as stipulated, combined with secondary loads, consisting of vertical, longitudinal and transverse components acting on the cross-arm at the three points of conductor attachment I, II, and III, with the cross-arm, a simply-supported beam, resting on the top of the A-frame and the tripod, as in Fig. 62. The geometry of the tower was based on design requirements as follows:—

Minimum distance between conductors, 30 feet.

Maximum insulator swing for strain towers, 30°.

Maximum insulator swing for suspension towers, 36°.

Clearance between conductor and tower at the point of maximum swing, 7.75 feet.

Length of the insulator string:

For strain towers, 11 feet at line angles up to 22°,

For strain towers, 12 feet at line angles up to 45°,

For suspension towers, 13.625 feet.

Angles adopted at the intersection of tower members:

For legs Nos. 1 and 2, 23°
" " " 3 and 4, 23°
" " " 5 and 1, 2, 25°

The angle of intersection is a design consideration, because it involves a relationship between the strength and stability of the legs under severe loading conditions and puts general limitations on the length of the tower legs.

The loads at the points of conductor support were calculated for every individual tower from the loading conditions described, based on the limits of tower application as to span, slope of span and line angle. Individual load components at points of conductor support were figured from the loading specification, in the following manner:

Vertical load, $V$ = dead weight of conductor + ice load on conductor + weight of insulator assembly.

Horizontal load in the direction of the axis of the cross-arm, $T$ = $2 \sin \frac{\phi}{2} \times$ horizontal component of conductor tension where $\phi$ is the line angle.

Controlling cases of the above loading were figured and the $V$, $T$, and $P$ component loads in the cases of $A$ and $B^1$ loads were increased by 5 per cent and for $B$, $C$, and $D$ loads by 50 per cent, in order to obtain loads consistent with the permissible stress in the structure at yield point.

Dead weight, wind loads and snow loads acting on the tower legs produce both bending and normal forces. Bending moments were calculated at three sections—at the top, at the middle and at the bottom of the legs. For design purposes the actual moments were increased by 5 per cent for $A$ and $B^1$ loads, and by 50 per cent for $B$, $C$, and $D$ loads.

The eccentric application of the $P$ load components through the insulator yokes onto the cross-arm results in torque in the cross-arm and bending in the tower legs.

An additional contribution to the moments in the tower legs from

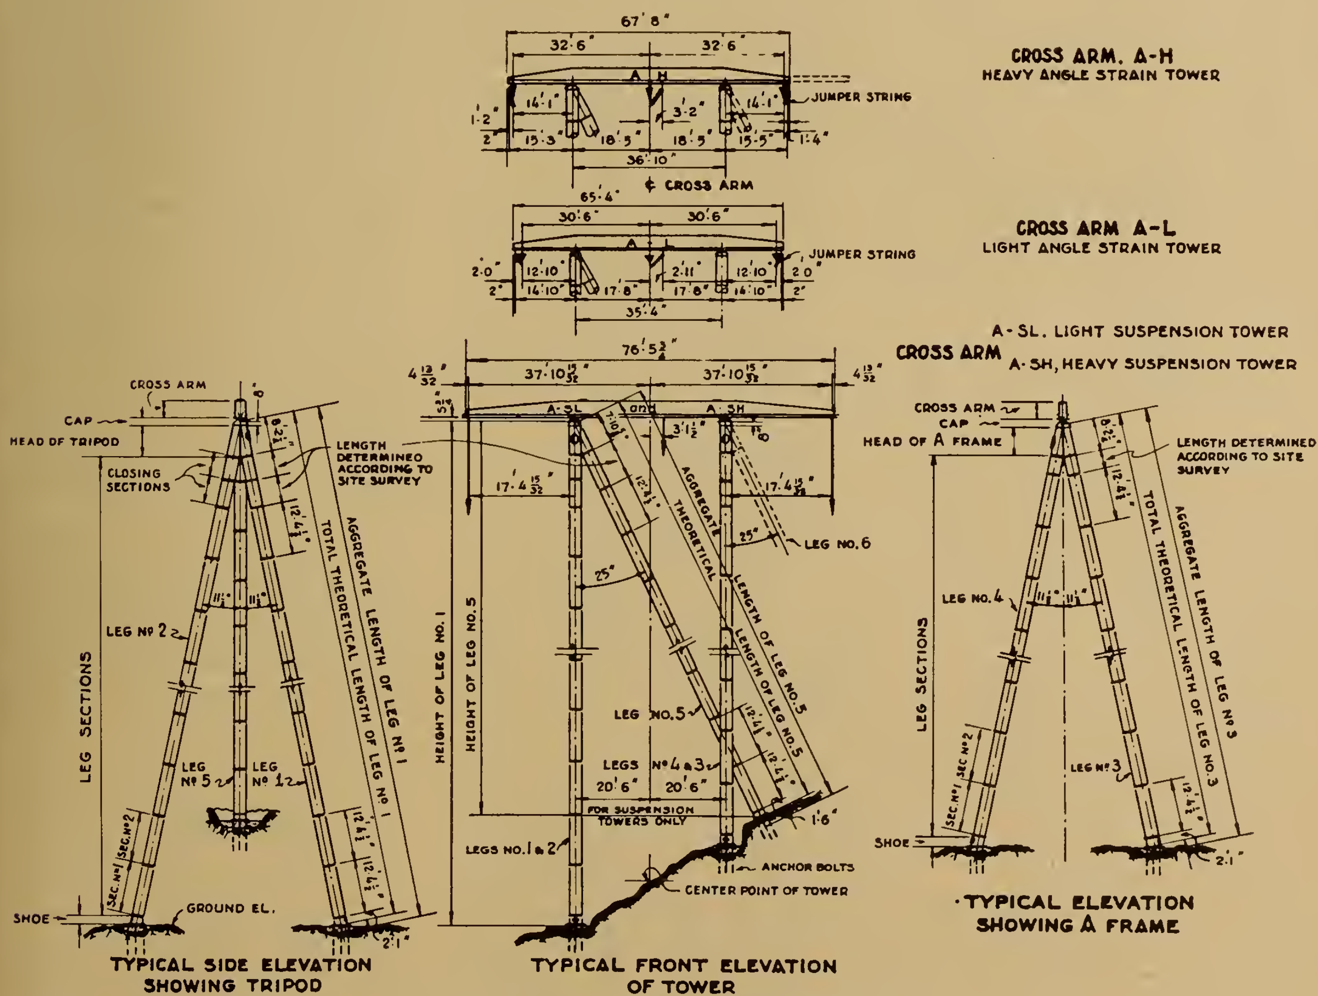

Fig. 61. Typical elevations of aluminum towers.

**Table 1: Maximum Principal Loads on the Cross-arm in Kips**

| Load components | $A$ | $B^1$ | $B$ | $C$ | $D$ |
|---|---|---|---|---|---|
| (1) Light-type cross-arm for the strain towers: | | | | | |
| Vertical load, $V$ | 82.5 | 40.0 | 37.9 | | 17.0 |
| Horizontal load in direction of the cross-arm, $T$ | 29.2 | 41.7 | 15.8 | | 14.9 |
| Horizontal load in direction 90° to the cross-arm, $P$ | 0 | 45.0 | 10.0 | | 25.0 |
| (2) Heavy-type cross-arm for strain towers: | | | | Not significant | |
| $V$ | 100.5 | 39.2 | 45.7 | | 20.0 |
| $T$ | 85.9 | 39.8 | 46.5 | | 29.8 |
| $P$ | 0 | 45.1 | 10.0 | | 25.0 |
| (3) Light-type cross-arm for suspension towers: | | | | | |
| $V$ | 78.7 | Not applicable | 34.7 | | 15.3 |
| $T$ | 25.2 | | 13.6 | | 13.5 |
| $P$ | 0 | | 10.0 | | 22.5 |
| (4) Heavy-type cross-arm for suspension towers: | | | | | |
| $V$ | 115.1 | | 50.5 | | 20.3 |
| $T$ | 20.8 | | 11.3 | | 9.8 |
| $P$ | 0 | | 10.0 | | 22.5 |

temperature gradient was considered, as a result of the difference in temperature on opposite sides of the shell of the leg. One side of the leg, when exposed to the heat of the sun, will expand to a greater degree than the other side, so the leg tends to assume a slight bow. Obersvations made on the test tower indicated that adoption of a temperature difference of 15°F. would be justified for design purposes.

Finally, the compression and extension of long tower legs under the influence of large primary loads is the source of displacements at their tops. The secondary moments due to this tendency to displacement of the top were taken into account.

The load combinations studied were:

1. $A$, $B^1$, $C$, and $D$ loads, combined with dead weight + snow loads.

2. $C$ and $D$ loads, combined with dead weight + wind loads.

In general, the maximum snow loads were not combined with maximum wind loads. From the load combination the limiting conditions were selected.

The following types of towers were designed:—

1. Light-angle strain towers, for line angles up to 23°-49′.
2. Heavy-angle strain towers, for line angles up to 41°-01′.
3. Light suspension towers, for line angles up to 13°-08′.
4. Heavy suspension towers, for line angles up to 8°-28′.

Types 1 and 2 were governed by the line angle, while Types 3 and 4 were governed by the magnitude of the principal loads.

Four different cross-arms were designed, applicable with tower legs designed for the specific loading due to the supported spans and site conditions, loadings being as given in Table 1.

The legs of each tower were designed for the individual principal loads and checked for secondary stresses from the action of principal and secondary loads on the tower.

In order to provide the necessary adjustment in the height of the individual towers, i.e., in the length of the individual tower legs, the following provisions were made:

The height of the tower, the average vertical height of the cross-arm above the ground, could be increased up to 14 feet.

The individual length of each leg could be increased by 5 to 14 feet, with some few exceptions for legs close to 150 feet in length, e.g., the length of the legs for the purpose of stress calculations was rounded out as follows:

Theoretical leg length 86 to 95 feet, taken as 100 feet.

Theoretical leg length 96 to 105 feet, taken as 110 feet.

In addition to these design margins, not expressed in the usual safety factors, the following design assumptions tend to increase the actual safety factors:

1. No deductions for the length of the rigid leg top and the depth of the caps were made; on the other hand, no increase in the length on account of the foundation below the leg shoe was allowed. The effect is that the assumed buckling length of the legs is not 0.7 of the theoretical length (as valid for the fixed footing and articulated top), but the coefficient varies from 0.84 for 50-foot legs to 0.74 for 150-foot legs.

2. No allowance was made for the fact that, in some of the legs, the bottom section and, in some cases, also the second section, were made of aluminum plate with a greater thickness than the rest of the sections. This increase in stiffness of the leg, which would increase still more the above coefficient, was not taken into account.

While there was no special problem in including Items 1 and 2 in the stress calculations, it was felt that the time required to deal with them was out of proportion to possible gains in economy.

For practical reasons, the number of thicknesses of leg sections was kept to a minimum. Design was based on the assumption that the steps in value of sections would be approximately as follows:

Section area ........... 10 per cent
Section modulus ....... 15 "
Moment of inertia ...... 20 "

An overall diameter of 38 inches was selected for all tower legs to achieve minimum weight and requisite strength, and this diameter gave a circumference close to twice the maximum five foot available width of Alcan 65 S-T aluminum plate, which permitted fabricating the leg sections with two longitudinal seams. This diameter also permitted easy access to all parts of the legs; the adoption of leg heads and shoes of corresponding diameter and of identical overall dimensions for all tower legs was convenient.

Limitation of the minimum plate thickness to 3/16 inch and of the maximum to ⅜ inch, with variation of thickness in steps of 1/32 inch, reduced the number of different leg sections to seven.

The procedure employed for stress calculation embodied three general rules:

The principal loads were determined as exactly as possible, based on weight- and wind-spans between towers. The weight-span is the horizontal distance between the apexes of the catenaries of adjacent spans, while the wind-span is the average length of adjacent spans.

The secondary loads, as well as their various combinations, were determined somewhat less exactly, but the error is on the safe side.

The secondary stresses were calculated as exactly as possible, neglecting influences and combinations of influences, which do not contribute in any appreciable extent to the total stress.

Finally, it should be noted that the process of stress calculation for the legs was identical for all towers.

*Normal forces in tower legs*

The load components $V$, $T$, and $P$ produce normal forces in the legs of the tower, which were calculated from the formulas below, with the notation shown by Fig. 62.

For $V$ components, acting at points I, II and III, force in legs is

Legs Nos. 1 and 2,

$$-\frac{1}{2}\left(1+\frac{a_1}{a}\right)\times\frac{V}{\sin 78\frac{1}{2}^\circ}$$

Legs Nos. 3 and 4,

$$-\frac{1}{2}\left(1+\frac{a_2}{a}\right)\times\frac{V}{\sin 78\frac{1}{2}^\circ}$$

Leg No. 5, *0*

For $T$ components, acting at points I, II and III, force in legs is

Legs Nos. 1 and 2,

$$\pm\frac{3}{2}\times\frac{T}{\tan 25^\circ\times\sin 78\frac{1}{2}^\circ}$$

Legs Nos. 3 and 4, *0*

Leg No. 5,

$$\mp\frac{3}{2}\times\frac{T}{\sin 25^\circ}$$

For $P$ components assumed acting at points I and II, or II and III, force in legs is

Nos. 1 and 2,

$$\pm\frac{1}{2}\times\frac{P\,(a+b+a_1)}{a\sin 11\frac{1}{2}^\circ}$$

Nos. 3 and 4,

$$\pm\frac{1}{2}\times\frac{P\,(a+b+a_2)}{a\sin 11\frac{1}{2}^\circ}$$

No. 5, *0*

In the formulas above (−) denotes compression and (+) tension.

*Dimensioning the legs for the normal forces*

The legs were checked first for the centric tensile forces. The stress on the net sectional area of the leg shell was based on the yield point of the aluminum sheet, 35,000 psi.

The subsequent checking of the legs for compression involved both a study of the general buckling strength of the legs and the determination of the maximum stress in bending due to the bending moments and normal forces in the tower legs.

The critical stress in general buckling on the gross sectional area of the sheet was based on the formulas:

$$46{,}000-384\,\frac{l_k}{i},\ \text{when}\ \frac{l_k}{i}<81$$

(elastic range)

$$\text{or}\ \frac{102{,}000{,}000}{\left(\frac{l_k}{i}\right)^2},\ \text{when}\ \frac{l_k}{i}>81$$

(semi-elastic range)

Where $l_k$ = buckling length, $i$ = radius of gyration.

Tests on the test tower proved the applicability of these formulas to the design of the large diameter leg sections.

The deflection at the centre of the leg was computed from the direct acting secondary loads, from the eccentric application of the $P$ loads, from the temperature gradient (15°F.), and from the secondary influence of primary loads.

Graphs for the reduction factors were used for the determination of the permissible buckling stress under eccentric loadings of the legs for the fictitious slenderness ratios $\frac{l_k}{i}$ and eccentricity ratios $m=\frac{er}{i^2}$.

Where $e$ = eccentricity in inches.
$r$ = radius of circular shell section in inches.
$i$ = radius of gyration in inches.

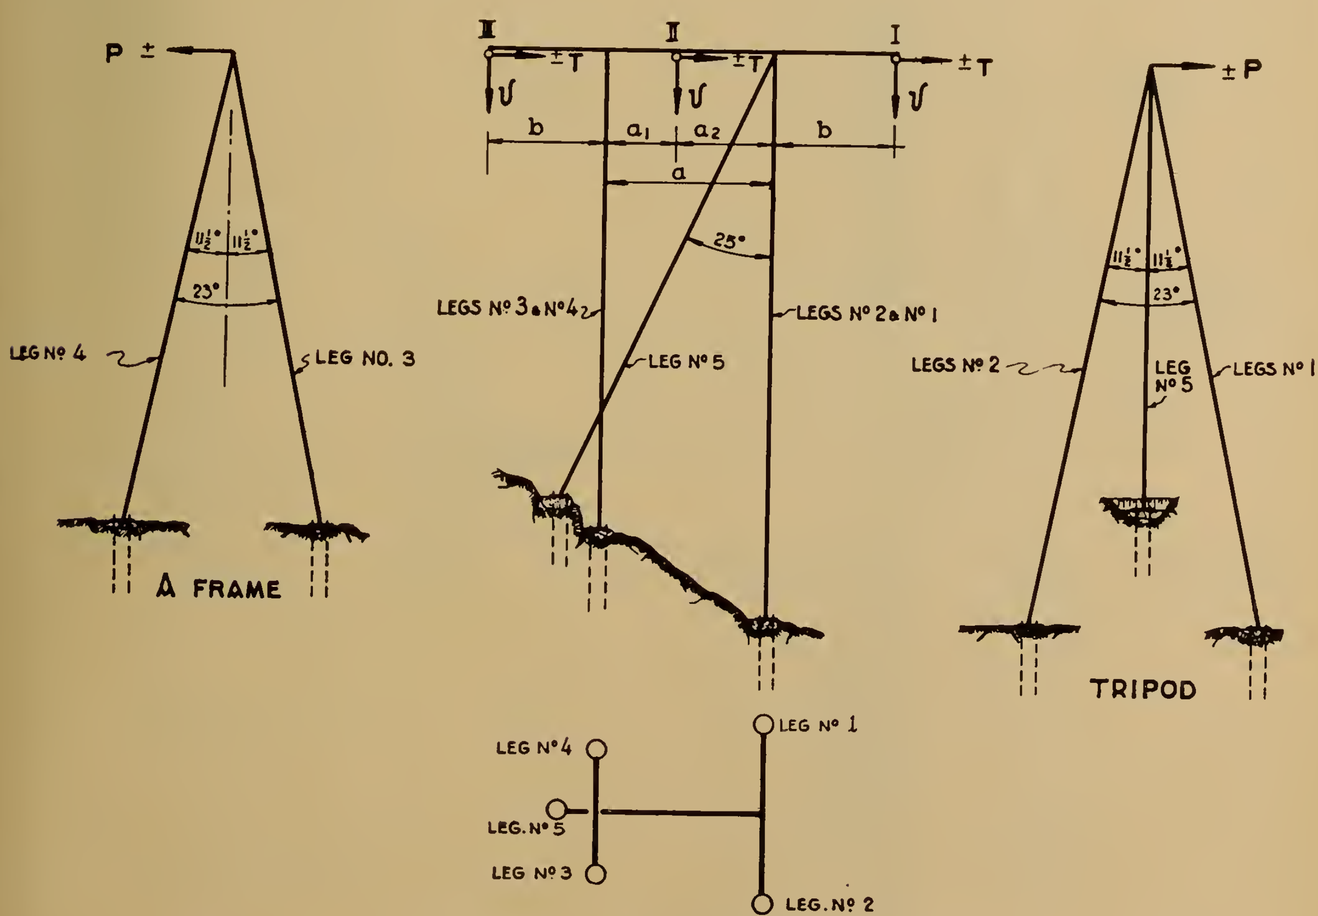

Fig. 62. Basic diagrams for aluminum towers.

**Table 2: Loads in Kips at All Three Points of Conductor Support**

| Type of Load | $A_1$ | $A_2$ | $B_1$ | $B_2$ | $D_2$ |
|---|---|---|---|---|---|
| Vertical load, $V$ | 138.0 | 66.0 | 62.5 | 31.0 | 14.0 |
| Horizontal load in direction of the cross-arm, $T$ | 11.0 | 41.5 | 5.0 | 20.0 | 13.0 |
| Horizontal load in direction 90° to the cross-arm, $P$ | 0 | 0 | 10.0 | 10.0 | 25.0* |

*at any point.

The multiplication of the critical centric buckling stress by the reduction factor gives the critical stress for eccentric buckling. This stress is lower than the yield strength of the material, i.e., less than 35,000 psi on the net area of the leg shell.

***Dimensioning the legs for bending moments***

Dimensioning the legs for bending moments and normal forces involved a stress analysis of the shell of the leg against both the tensile stress and the critical local buckling stress in compression.

Bending moments from secondary loads, i.e., from wind and snow loads on the legs, from the 15°F. temperature difference in the leg shell and from the rigid A-frame top under the action of the normal forces in the legs, were calculated at the top, at the middle and at the bottom sections of the legs. The permissible tensile stress was fixed at less than 35,000 psi, on the net area in these sections of the leg.

Maximum compressive stress was computed at the middle and at the bottom of the leg. The permissible value had to be smaller than the critical local buckling stress and below 30,000 psi.

The critical local buckling stress was figured for the leg sections manufactured from various thicknesses of sheet, based on the formula:

$$46{,}000 - 384\frac{l_k}{i}$$

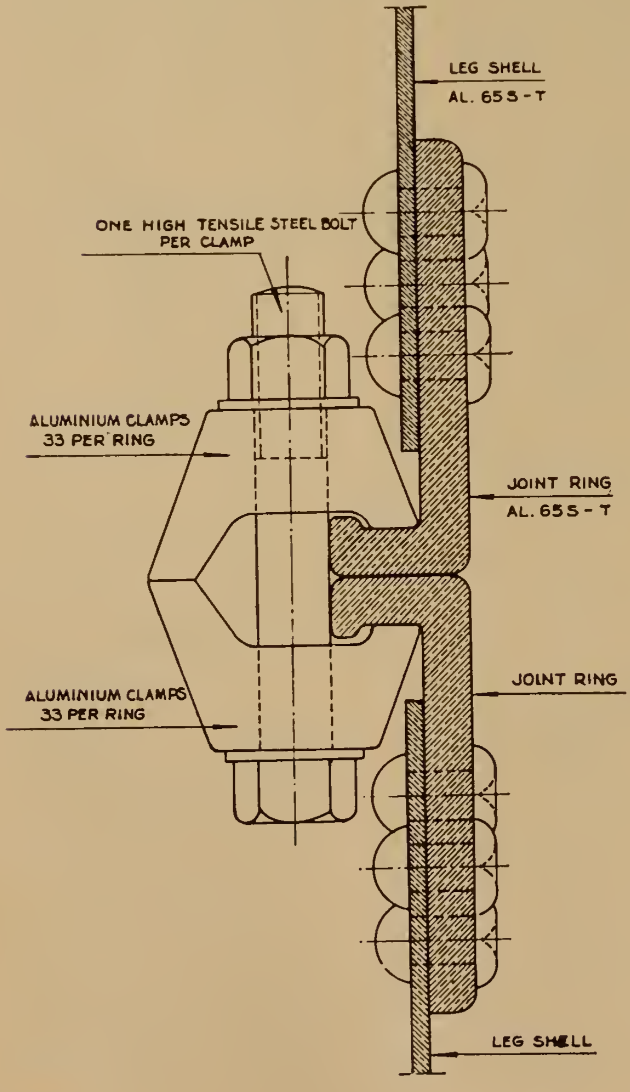
Where

$$\frac{l_k}{i} = 5.7\sqrt{\frac{d}{2t}}$$

$d$ = diameter of leg in inches.
$t$ = thickness of sheet in inches.

Tests on the legs of the test tower indicated that this formula could be used for the fictitious slenderness ratio $\frac{l_k}{i}$ and for the particular size of tubular section, with two longitudinal seams, adopted for the legs, for which information was non-existent.

For a few cases where the maximum compressive stress was in excess of the limit, mainly due to snow-creep pressures, the thickness of the first leg section was increased. All other sections in the leg, up to the top, have the same sheet thickness as adopted on the basis of



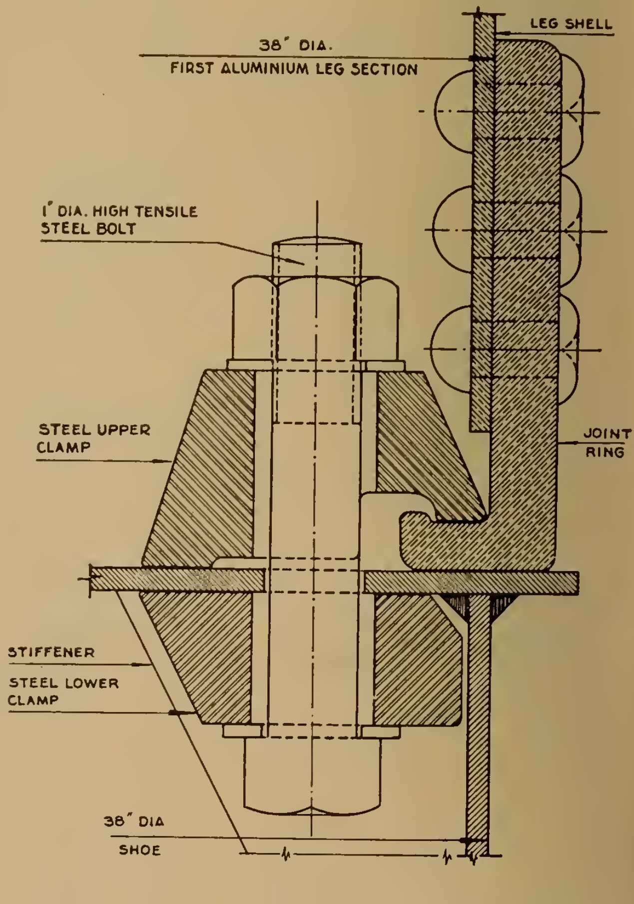


Fig. 64. Above: Detail of leg joint at shoe.

Fig. 63. Left: Detail of leg joint.

stresses computed for the middle section.

### Investigations on Test Tower

Early in 1952 a 100-foot high test tower was fabricated and erected in the Yarrows shipyard in Victoria, B.C., in order to establish the feasibility of the type of transmission tower discussed herein and to investigate both manufacturing and erection problems. It satisfied expectations and contributed valuable data needful in determination of the overall strength of the structure. It also proved the correctness of the formula adopted for general buckling of the compression members of the length and the diameter used for the tower legs.

The geometry of the test tower was similar to that adopted in the final design. However, some of its details were modified in the final designs to cope with conditions brought about by both heavier loads and higher towers on the actual line, as well as to reduce the manufacturing costs.

The legs of the test tower were assembled from 25-foot tubular sections with the following dimensions:

Leg Nos. 1 and 2, Overall diameter, 34 inches, sheet thickness, ⅛ inch.

Leg Nos. 3 and 4, Overall diameter, 30 inches, sheet thickness, ⅛ inch.

Leg No. 5, Overall diameter, 38 inches, sheet thickness, 9/64 inch.

The leg sections and the 65⅓-foot long cross-arms were fabricated from Alcan 65 S-T aluminum sheet. The heads and shoes were made of ¼-inch mild-steel plate.

The design of the test tower provided for rigid bolted connections between the legs and the cross-arm. This arrangement possessed the advantage of permitting a direct passage through the legs to the cross-arm. However, under the loading on the cross-arm due to a broken conductor, the rigid connection distributed sizable moments from the cross-arm into the legs, one result of which was an increased deflection in the middle of the legs, reducing their general buckling strength. Also, from the point of view of the critical local buckling stress, an increase in the moment in the head of the legs produced undesirable effects.

The observations on the test tower and considerations relative to general stability, resulted in the adoption of special supports for the cross-arm caps, which release the legs from moments arising from the cross-arm.

Load specification for the test tower called for the loads, in kips, at all three points of conductor supports, as given in Table 2.

In the cases of the $A_1$ and $A_2$ loads, the maximum permissible stresses were taken 5 per cent lower than the ultimate strength. In the cases of $B_1$, $B_2$, and $D_2$ loads, the maximum permissible stress was taken 50 per cent lower than the yield strength of the materials.

Under certain conditions during the test a slight bowing of the legs in the line direction was noticed. When the A-frames were assembled and were still on the ground, the legs assumed a slight general bend towards the sunny side. It was obvious that the bend was due to the difference in temperature between the sunny and the shady sides of the thin leg shell of relatively large circumference.

Considerable thought was given in testing the tower to the possible occurrence of resonant vibration of the tower legs when exposed to a steady wind strong enough to cause small deflections in a plane at 90° to the wind direction. This vibra-

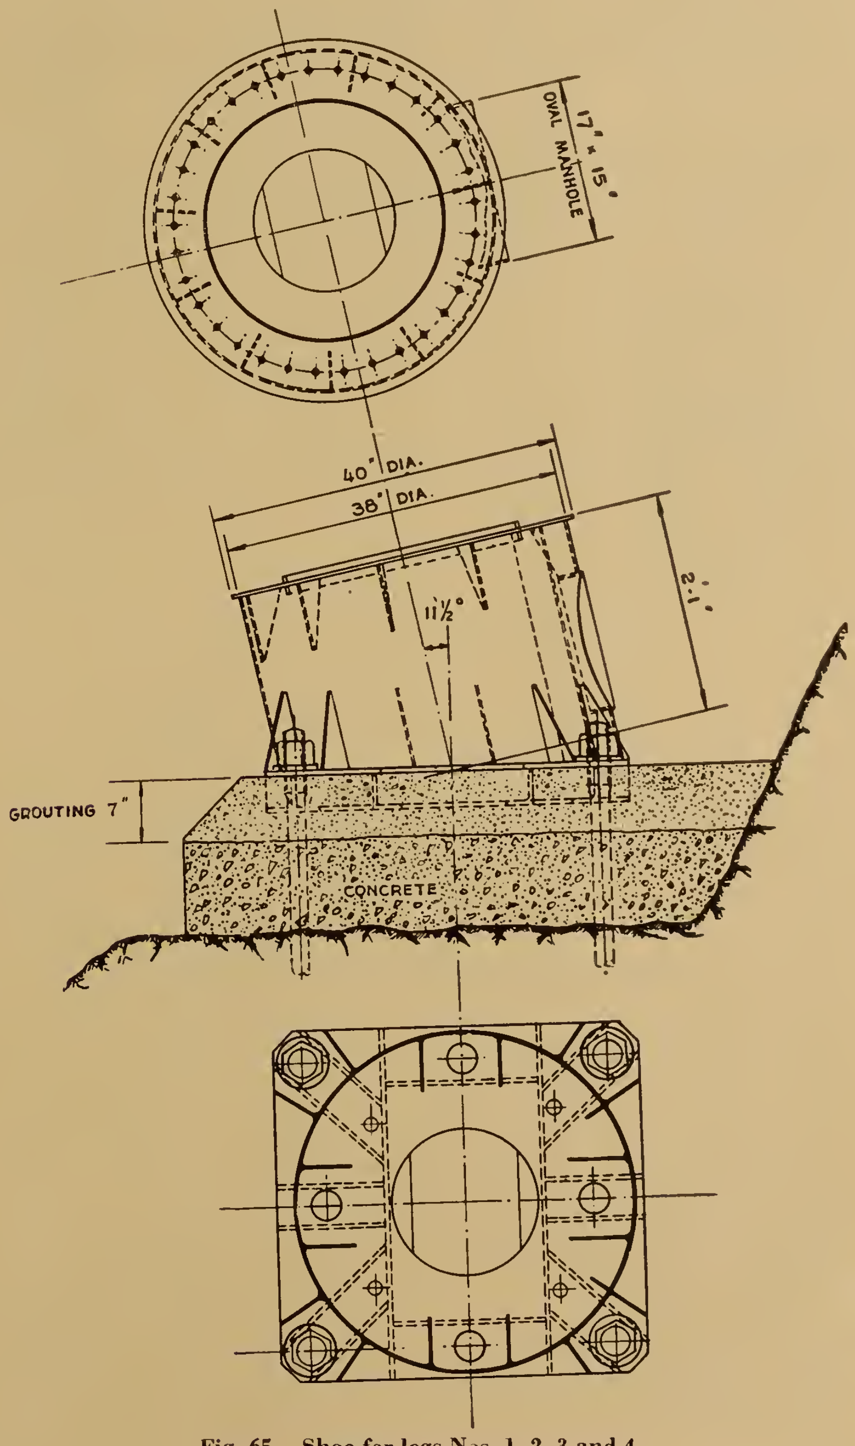

Fig. 65. Shoe for legs Nos. 1, 2, 3 and 4.

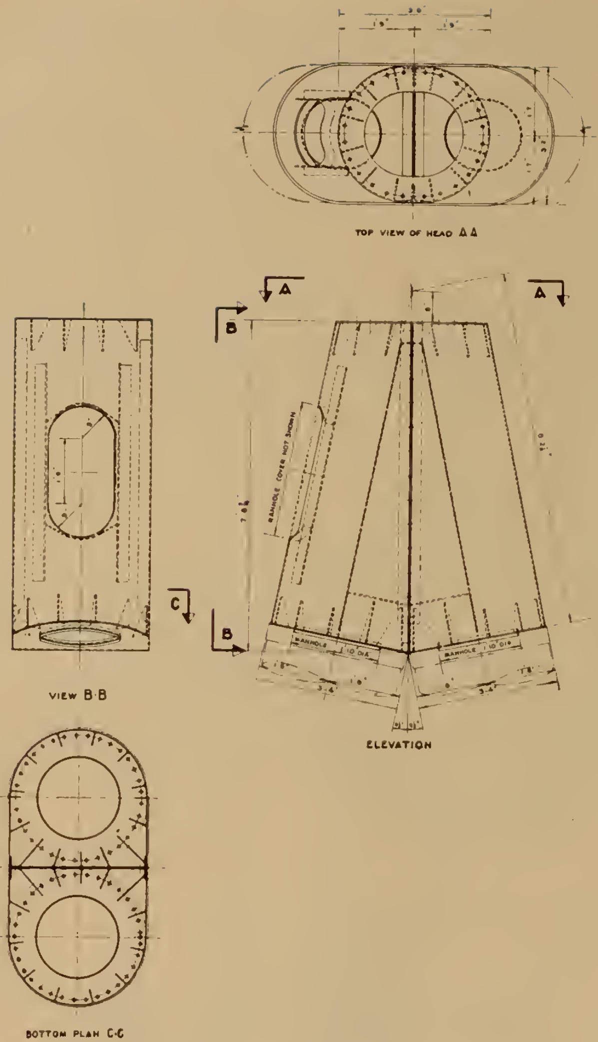

Fig. 66. A-frame head.

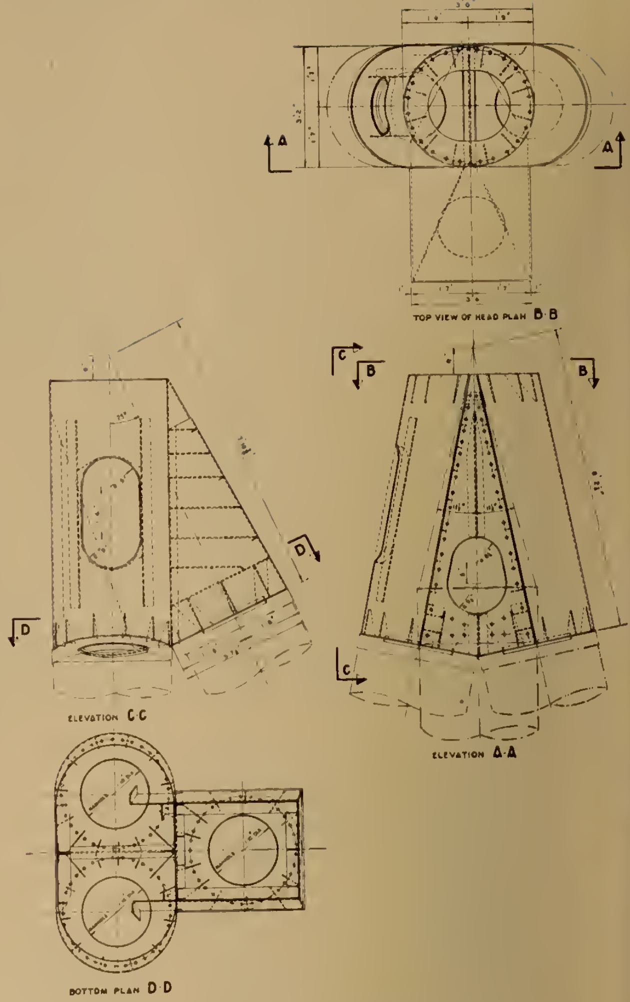

Fig. 67. Tripod head.

tion is due to trains of air vortices, known as "von Karman" vortices, acting on the legs. No such vibration was observed on the test tower under wind conditions.

However, a laboratory test was arranged with a 75-foot tubular section of 30-inch diameter. The section, arranged in a horizontal position between the pin-points of the strong backs of a compression-test arrangement, was forced to vibrate under a small axial load, the impulses of energy being transferred to it through a helical spring attached at its middle. For dampening the vibration, a Stockbridge-type damper was found to be successful and indicated an acceptable method of dampening the vibration in the legs of the actual towers, should it be necessary.

The test tower displayed, in general, the strength expected under the specified loads and demonstrated the feasibility of this type of structure for the transmission towers.

## Final Design

### *Legs*

The tubular tower legs are composed of a number of sections, their strength corresponding to the requirements based on tower height, conductor pull, span and local snow-on-ground conditions. The adopted standard length for sections was 12 feet 4½ inches, and for standard half-sections 6 feet 4½ inches. Half-sections and odd-length top closure sections were used because generally the footings of the tower legs are at different elevations. Half-sections were occasionally utilized to permit using a reasonable length for the top closure sections.

Manholes in the shoes at foundation level provide ingress into the legs, where aluminum ladders afford access to the head of the tower. Access under deep snow conditions is furnished by a manhole in the second section of Leg No. 5. The manhole, 24 x 17½ inches, is reinforced and fitted with a hinged cover.

The thicknesses of aluminum sheet used for fabrication of sections were 3/16, 7/32, ¼, 9/32, 5/16, 11/32 and 3/8 inches. All sections were composed of two semi-circular halves, rolled from 5-foot wide sheet. The halves were joined by shielded argon-arc welding, with a backing strip at each longitudinal seam.

Both ends of the leg section are reinforced with joint rings, aluminum extrusions of Alcan 65 S-T alloy of special shape as shown in Fig. 63. The joint rings are riveted to the leg shell and their flanges serve for joining the leg sections by means of 33 sets of aluminum clamps and high-tensile steel bolts per joint.

Three types of joint rings and clamps were employed; light, medium and heavy. Their strengths correspond to those of the various thicknesses of aluminum sheet:

Light type, for sheet thicknesses of 3/16 and 7/32 inch.

Medium type, for sheet thicknesses of ¼, 9/32 and 5/16 inch.

Heavy type, for sheet thicknesses of 11/32 and 3/8 inch.

Rivets were made of Alcan 16 S-T aluminum, with a typical ultimate shearing strength of 33,000 psi. Rivets of ½-, 5/8- and ¾-inch diameter are used for the light, medium and heavy joint rings, respectively. These rivets have conventional button-type heads for riveting the light and medium joint rings; countersunk heads were used for the heavy joint rings. The set heads are internal.

Bolts used with the clamps are ¾ and 1 inch, high-tensile steel bolts with a yield strength of 106,500 psi. Due to the difference in the thermal expansion coefficients of the aluminum clamps and joint rings as compared with the steel bolts, the bolts tend to slacken at low temperature. Prestress of the order of 30,000 p.s.i. on the net area of the bolts was specified to maintain tightness at an extreme low temperature of −30°F.

***Shoes***

The tower legs are fixed to the foundations with anchor-bolts by means of galvanized steel shoes, illustrated in Fig. 65. These are all-welded tubular elements fabricated from mild-steel plate. These shoes transfer the compressive and tensile forces, as well as the moments from the secondary loads, into the foundations. Each shoe is bolted to its foundation by at least four high-tensile steel anchor bolts, with a net diameter of 2 inches. Provision was made for a total of eight anchor bolts, four in the outer corners of the base plate and four inside the shoe, to secure rational distribution of anchor bolts for different conditions, depending on the magnitude of stresses and on the direction of the snow-creep thrust.

The shoes were fabricated from ¼- and 3/8-inch plate, according to strength requirements, and for leg angles of 11½° from the vertical for Legs Nos. 1, 2, 3 and 4, and 25° from the vertical for Leg No. 5, and for Leg No. 6 where used.

The thickness of the base plates for both types is 9/16 inch; these plates were reinforced by 4- x 3- x ½-inch steel angles. The upper ring of the shoe, joining with the first aluminum section, is stiffened by 11 triangular stiffeners. Interior and exterior triangular stiffeners at the base plate are provided to strengthen the shell against load concentrations at the anchor bolts. The joint between the first leg section and the shoe consists of 11 sets of high-tensile steel clamps, each taking three bolts. Lower and upper steel clamps in sets, with galvanized high-tensile steel bolts, constitute the joint, as shown in Fig. 64. Two types of high-tensile steel clamps sets, light and heavy, were used with the high-tensile steel bolts, with a yield strength 106,500 psi.

***Heads***

Each leg has a top piece, as shown by Figs. 66 and 67, fabricated from mild-steel plate by welding. Plate thicknesses of either 3/16 or ¼ inch were used, depending on circumstances. The top pieces, when bolted together, form rigid heads for the A-frame and for the tripod.

Side plates of the heads are given a contour affording a smooth extension of the leg sections. An exception is the top piece of Leg No. 5, which has flat side plates reinforced with welded stiffeners. This provides a simple plane bolting face for the tops of Legs Nos. 1 and 2. The curved side plates of the heads for the A-frames need minimum reinforcement against general and local buckling. The head of the tripod has been stiffened by two internal bulkheads opposite the side plates of the head of Leg No. 5. Bottom and top rings in the head provide necessary stiffness and the base for bolting adjacent leg sections and cap.

The loads on the head are the reactions of the caps supporting the cross-arm. The compressive and tensile loads in the legs combined with the bending moments require a rigid top.

Bolting of the individual leg tops was done from inside the head. For joining the head to the leg section, standard aluminum clamps were used in the leg, with steel multi-hole washers, between the triangular bottom stiffeners of the top-piece.

***Caps***

Two caps, as illustrated by Fig. 68, support the cross-arm. They are bolted to the heads of the tower by means of eight high-tensile steel bolts, supplemented by a number of subsidiary steel bolts on the perimeter of the bottom. The two caps, both that at the top of the A-frame and that at the top of the tripod, are identical for a given type of tower. These are fabricated from welded 3/8-inch mild-steel plate. The pin in the

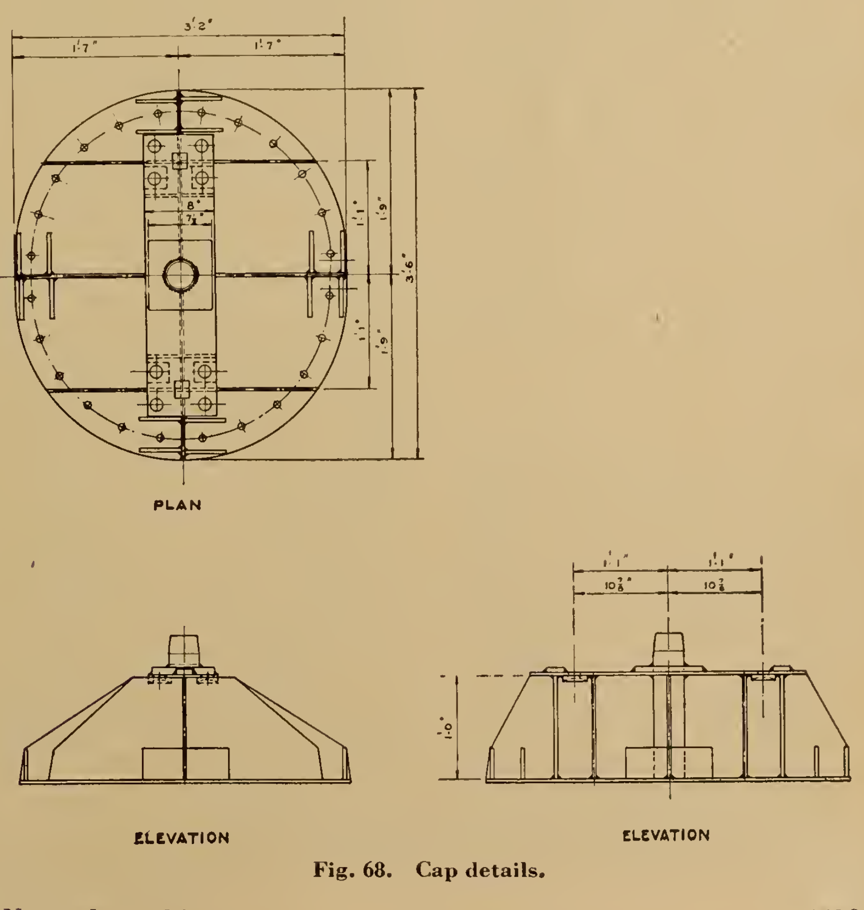

**Fig. 68. Cap details.**

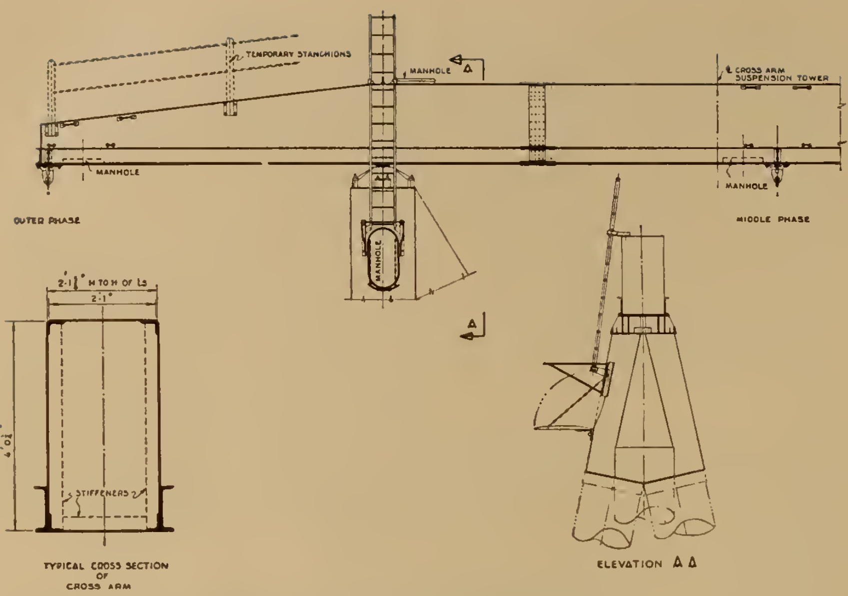

Fig. 69. Cross-arm and accessories.

centre of the cap is a solid steel bar, 3½ or 4½ inches in diameter, for light or heavy caps respectively.

The box-girder cross-arm is supported at two points just below the web plates by the caps. This type of vertical support permits relatively free movement of the cross-arm in any direction and avoids transferring bending moments to the legs. The pins on the centre line of the cross-arm resist the thrust of the unbalanced conductor pull in any horizontal direction. The holes for the pins in the bottom plate of the cross-arm are reinforced by cast aluminum bushings.

There are four silicon steel bolts per cap, with spherical-bearing surfaces fitting in spherical sockets in the cap, which are provided to limit the movement of the cross-arm on the cap, with free centering of the cross-arm on the pins. These bolts are important in view of possible load combinations on the cross-arm resulting in negative reactions.

### *Cross-arms*

Four cross-arms of different lengths and strengths were designed for the aluminum towers, as illustrated by Figs. 61 and 69. These cross-arms provide the requisite clearance between conductors and between conductors and structure under maximum line-angle conditions. Two types of angle-strain tower cross-arms were designed, one for small angles and another longer one for large angles.

The difference in the suspension tower cross-arms is mainly in their structural strength and not in their length. Light suspension tower cross-arms were designed for less severe duty than those for heavy suspension towers, in order to economise on material.

The several types of cross-arms have lengths as follows:

| | |
|---|---|
| Suspension towers.... | 76 ft. 5¾ in. |
| Small-angle strain towers............ | 65 ft. 4 in. |
| Large-angle strain towers............ | 67 ft. 8 in. |

The cross-arm of the tower is a simply-supported beam with the middle-phase conductor suspended at or near its centre line, the actual point of suspension being governed by the necessary clearance between the conductor and Leg No. 5. The cross-arm has cantilevered ends for supporting the outer phase conductors. The cross-arm has a constant width between web plates of approximately 26 inches. The portion between the caps is approximately 48 inches deep and the upper flange drops down from the caps towards the ends, where the depth is 24 inches. The cross-arms were designed to take care of a broken conductor on either the middle or outer phases.

Resistance against twisting in the cross-arms is important on account of the eccentric application of *P* loads. The eccentricity of *V* loads was eliminated by the adoption of special suspension yokes for the insulator assemblies.

The cross-arms were sectionalised for ease in transportation. The original requirement for transportation by helicopter limited the maximum length of the sections to 22 feet and the maximum weight of an individual piece to 1,700 pounds. These limits were maintained in the actual design for convenience in handling, despite elimination of the necessity for helicopter transportation, by construction of a road roughly paralleling the transmission line from Kemano to Kitimat. The angle-strain and suspension tower cross-arms were fabricated in either three and four sections, as governed by weight or length limitations. Splices are field bolted.

The cross-arms are rivetted aluminum structures, welding being used only for affixing stiffeners to the webs and bottom plates. The thickness of the cross-arm web plates is 3/16 inch, except for the heavy-type suspension cross-arms, where ¼ inch was used. Web plate and lower cover-plate stiffeners are 3 x 3/16 and 3 x ¼ inches, respectively. Noncontinuous fillet welds are used. The thickness of upper and lower cover plates varies for the different cross-arms, being 3/16, ¼, 5/16, and 3/8 inch, depending on the strength requirements.

Upper and lower flange angles in all cross-arms are 4- x 3- x 5/16-inch. Two 10- x 3-inch channels are used to secure necessary strength in the lower flange.

All cross-arms are strengthened at the points of support and of application of conductor loads. Three manholes are provided in the bottom of the cross-arm and two in the top. These manholes are oval, 24 x 16 inches, fitted with covers. All elements, such as plates, angles and channels, are Alcan 65 S-T. Rivets used are ½-inch except the rivets in heavy-type suspension cross-arms, which are 3/8-inch. Rivets are of Alcan 16-ST, with button set heads and annular driven heads. Aluminum welding was carried out with rod of 5 per cent silicon-aluminum alloy, with inert-gas shielded equipment.

### *Foundations*

Anchor bolts connecting the shoes of the tower legs to the foundations are deformed silicon-steel bolts 2 inches in net diameter, with upset threaded ends and a yield strength of 54,000 psi. Permissible tensile stress on the net area of the anchor bolts was fixed at 36,000 psi. A bond stress of 125 psi between the steel and the grout was adopted in the determination of the embedment depth of the anchor bolts in rock. The concrete at the base of the shoe was required to have a minimum compressive strength of 2,500 psi at 28 days.

Approximately 60 per cent of the towers are founded on sound rock.

Only minor excavation and concreting for levelling of the bases of the shoes was necessary in such cases. The other towers are founded on detritus deposits or on bad rock and are provided with reinforced concrete foundations. Where rock footings are used, weathered surface rock was generally stripped at each shoe to sound rock and 3½-inch holes were diamond drilled for the anchor bolts. Bolts were grouted in these holes. The shoes were placed on the concrete pads and the bolts tightened, with either steel wedges or shims under all four corners of the bottom plate reinforcement. Necessary small vertical adjustments were made either by means of these wedges or shims and by the adjustment of nuts on the anchor bolts. The anchor bolt holes in the base plate of the shoe were 3½ inches in diameter, permitting minor horizontal adjustments with the 2 inch bolts. Grouting of the shoe was carried out after the tower was assembled. The grout, to a thickness of about 7 inches, embeds the reinforcement of the bottom plate and the adjusting wedges or shims.

*Accessories*

Access into the interior of the tower legs is provided by the manholes in the shoes, 18 x 15 inches; they are fitted with covers.

Ladders inside the legs provide access to all leg joints and to the top of the legs. The sections of the ladders are supported by brackets fastened by the bolts in the joint ring.

The manhole covers in the tops of Legs Nos. 1 and 4, when opened, serve as platforms, as shown by Fig. 69. A guard rail affords safety to workmen. From these platforms a permanent ladder gives access to the cross-arm. The manholes on the top of the cross-arm afford access to the interior of the cross-arm. Access to the insulator assemblies is facilitated through three manholes in the bottom of the cross-arm.

Provision for a temporary guard rail on top of the cross-arm has been made by means of special sockets for stanchions or uprights. U-bolts and safety hand grips have been

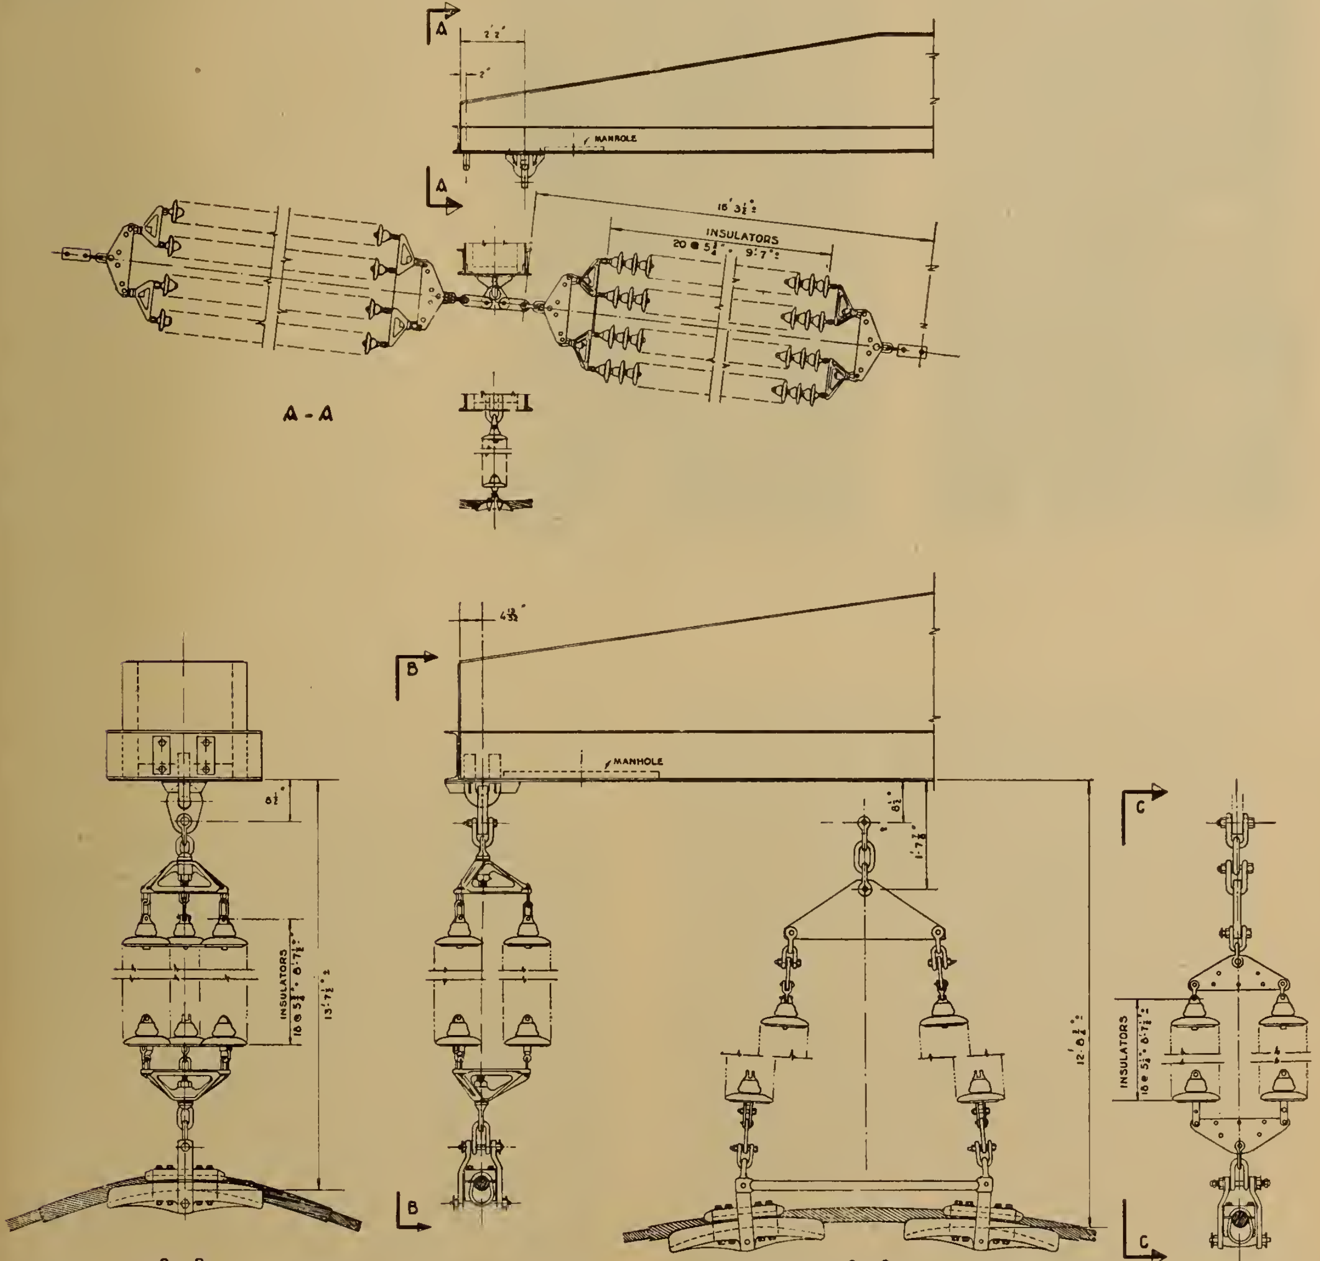

**Fig. 70. A-A Insulator assembly for angle-strain towers. B-B Triple-string insulator assembly for suspension tower. C-C Double-string insulator assembly for suspension tower.**

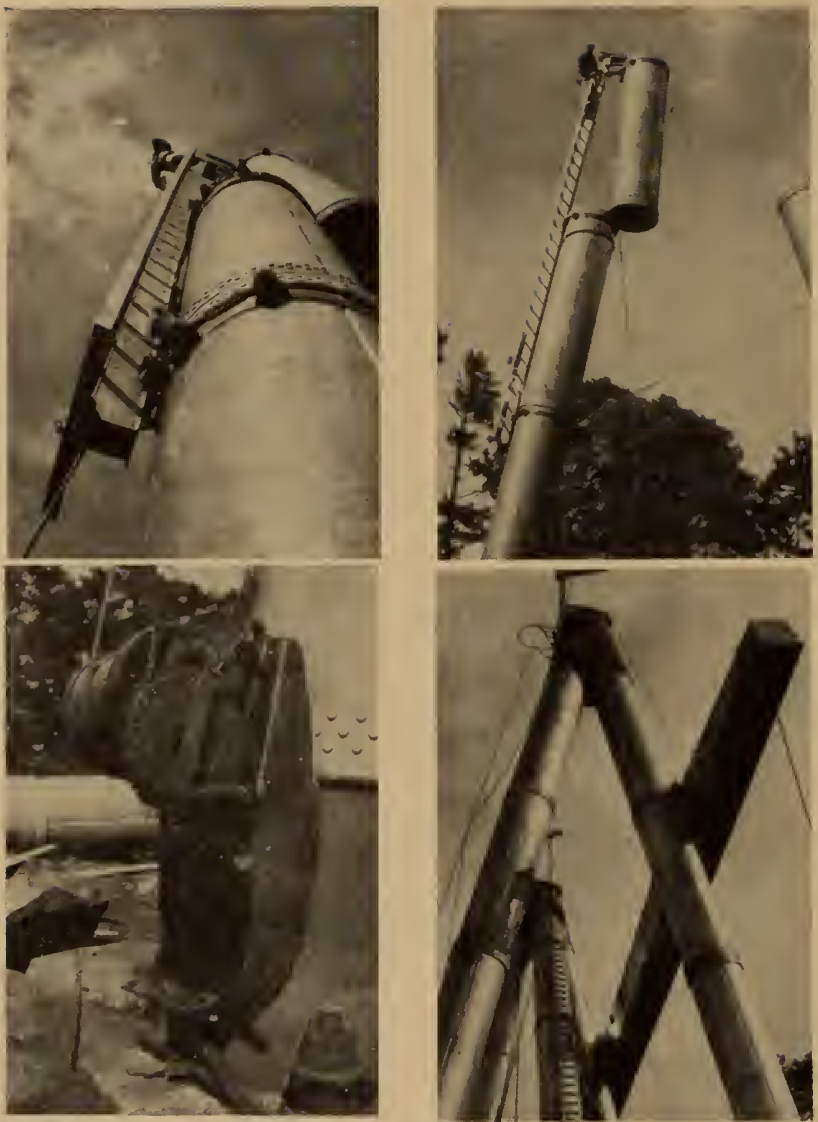

Fig. 71. Erection methods: upper views show "climbing ginpole". Lower left shows 5-ton hand winch; lower right shows cross-arm pulled up.

provided for use in stringing and servicing the line.

Two types of special insulator assembly suspension yoke were used, one for the angle-strain cross-arm (Fig. 70, upper), and the other for the suspension cross-arms (Fig. 70, lower left and right). These yokes are designed to yield essentially a torque-free application of conductor loads to the cross-arm at any line angle; they are bolted at the centre line of the cross-section of the cross-arm. The yokes are forged and welded steel members.

U-bolts for the suspension of the jumper insulator strings are fixed to the bottom of the cross-arm close to the suspension point of the yokes.

#### Fabrication of Towers

In describing the various components of the towers, attention has been drawn to certain components which were fabricated in steel plate by welding. The basic reason for this was that time available did not permit the experimentation which would have been necessary had aluminum been used. However, it is certain that all elements, with the exception of the high-tensile bolts, could have been fabricated from aluminum, possibly using castings for the shoes.

#### Erection Methods

The principal device used for tower erection was a winch-operated 28½-foot climbing ginpole furnished with a ladder, for operation by a crew of two men; see Fig. 71, upper left and right. The ginpole was an all-welded aluminum beam made from 3/16-inch sheet, a 4- x 6-inch box section providing necessary stiffness. An outrigger, approximately 3 feet long, was bolted to the upper end of the ginpole.

The first and second leg sections were assembled on the ground and the ginpole was fixed by two special steel hoop clamps to these sections, the upper end of the ginpole cantilevering. The first and second sections with the attached ginpole were erected and bolted to the shoe by means of another ginpole, supported on the ground and guyed to the anchor bolts of the leg shoes. The third and following leg sections were hoisted by means of the climbing ginpole.

For safety, the lifting wire rope ran over the sheaves of the outrigger down through the hollow ginpole to a hand winch of 5-ton capacity, fixed to the seat around the manhole in the shoe, as shown by the lower left view of Fig. 71. After the leg section had been lifted and secured by bolting, the ginpole could be freed from the grip of both hoop clamps. By removing two wedges, which secured the ginpole against lateral movement, and then a keeper, which supported it against the rim of the joint ring, the ginpole could be freed for climbing up to a new lifting position. It was pulled up by means of the same winch and wire rope. Lifted to the new position, it was fixed by the hoop clamps to the last leg section, and supported against the rim of the joint ring; it was then ready for lifting the next leg section.

Finally, the top piece was hoisted, together with a temporary davit bolted to it. When the A-frame and the tripod were assembled two temporary davits on the leg heads were used for lifting the cross-arm. The cross-arm was pulled up by two winches, the rope running over the sheaves on the davit down to the drums of the hand winches at the shoes of Legs Nos. 1 and 4. The assembled cross-arm, when pulled up, slid along Legs Nos. 2 and 3 on two rubber-wheeled dollies fixed to the cross-arm, as shown by Fig. 71, lower right view, and by Fig. 72. On the caps, the wheels of the dollies ran over a temporary clearance runner, which covered the caps. The clearance runners were removed after the cross-arm was pulled up and suspended from both davits. The cross-arm was then lowered onto the caps.

#### Relative Weight of Aluminum and Steel Towers

Although most of these aluminum transmission-line towers are high structures carrying unusually long and heavy spans, with extremely heavy loading, their average weight is only 25.8 tons. The lightest tower weighs 16.5 tons and the heaviest

33.5 tons. Weights of the tower components are:

Weight of leg section in standard length, including rivetted joint rings and joint clamps, but exclusive of high-tensile steel bolts:

| | | |
|---|---|---|
| Shell thickness | 3/6 inch | 425 pounds |
| " " | 7/32 " | 480 " |
| " " | ¼ " | 610 " |
| " " | 9/32 " | 665 " |
| " " | 5/16 " | 720 " |
| " " | 11/32 " | 870 " |
| " " | ⅜ " | 925 " |

Weight of rivetted cross-arms including splices and splice bolts:

| | |
|---|---|
| Small-angle strain cross-arm | 4,950 pounds |
| Large-angle " " | 5,390 " |
| Light-duty suspension cross-arm | 5,450 " |
| Heavy-duty suspension cross-arm | 7,130 " |

Weight of all-welded steel shoes exclusive of steel clamps and high-tensile steel bolts:

| | Legs Nos. 1, 2, 3 and 4 |
|---|---|
| Light-type shoe | 790 pounds |
| Heavy-type shoe | 950 " |
| | Leg No. 5, and No. 6 where used |
| Light-type shoe | 745 pounds |
| Heavy-type shoe | 860 " |

Weight of all-welded steel leg tops:

| | Leg. No. 1 | No. 2 | No. 3 |
|---|---|---|---|
| Light-type | 975 | 870 | 755 |
| Heavy-type | 1,145 | 1,035 | 895 |
| | No. 4 | Nos. 5 and 6 | |
| Light-type | 685 | 485 | |
| Heavy-type | 825 | 505 | |

Weight of all-welded steel caps:

| | |
|---|---|
| Light-duty cap, 3½-inch pin | 385 pounds |
| Heavy-duty cap, 4½-inch pin | 415 " |

The weights of the towers would have been moderately lower had aluminum shoes, leg tops and caps been used. The average weight of the single-circuit steel towers used on the right-hand circuit through Kildala Pass, designed to meet the same general conditions as the aluminum towers, was 42.6 tons, the lightest weighing 34.9 tons and the heaviest 48.1 tons. Thus, the weight of the aluminum towers was, on the average, only 60.5 per cent of that of the corresponding steel tower; for the lightest towers 47.2 per cent; and for the heaviest 69.6 per cent.

### Relative Economy of Aluminum Towers

What is the relative economy of the aluminum towers as developed for the Kemano-Kitimat transmission system? Many factors enter into the overall relative economy and these are dealt with in sequence, beginning with fabrication by the maker taken as complete and towers ready for shipment.

There are, in the case of a 114-foot tower, a total of 110 major components, as follows:

- 5 shoes.
- 41 leg sections.
- 5 closing leg sections, because of footings at different elevations.
- 5 top pieces (heads).
- 2 caps.
- 3 cross-arm sections.
- 45 lengths aluminum ladder inside legs.
- 2 lengths aluminum ladder for cross-arm.
- 2 guard rails at exit manholes in upper legs.
- 2,220 bolts, mostly with clamps, bagged or boxed.

For the equivalent steel tower of the same height, there are over 1,120 items of steel members in addition to some 4,740 bolts and washers. The likelihood of short- or over-shipment by the manufacturer is considerably greater with the multiplicity of parts in the steel towers.

The loading and unloading of the much smaller number of simple components for the aluminum tower requires substantially less labour, as mechanical equipment can be advantageously utilized. This is particularly important where unusual means of transportation, such as high-lines and helicopters, must be used, and is important even with trucks.

The substantially lower weight of the average aluminum tower, at 60.5 per cent of that of the steel tower, results in substantial economy in direct transportation costs of any kind.

The small number of components in the aluminum tower results in easier distribution to sites, with considerably smaller loss of pieces, which can so badly hamper erection. This is particularly true with snow on the ground. Much less labour is required for distribution; it is probably in almost direct proportion to the number of components.

The fabrication and erection costs of the aluminum towers for this line were considerably influenced by delays, due to changes in design details throughout the entire fabrication and erection period. This influence was anticipated, because the late decision to build the second pass circuit as part of the first stage of the power project required the fabrication, and even the erection, of parts of the line before the survey exactly locating the towers of the second circuit was completed. Further, the fabrication was of a new type and shop details, methods, jigs, etc., had to be worked out while the fabrication was in progress, and development was often held up waiting for engineering reports from the field, which first had to be trans-

Fig. 72. Views showing erection of aluminum towers.

lated into design drawings. It has proven impossible as yet to segregate the direct costs from the indirect costs on these accounts. However, certain principles regarding costs of the aluminum towers are self evident.

Savings in erection costs secured with the aluminum towers should be substantial. They arise partly from the simplicity of the design, with a minimum of joints; partly from the substantially smaller tonnage to be erected, labour costs varying with the weight; partly from the adaptability of the aluminum tower to erection with simple equipment of low weight; and finally, from the confidence of workmen when maximum safety of working conditions is built into the design.

At high altitudes men cannot accomplish the same output of work as at sea level. Hence, the substantially lower weight of the aluminum tower results in important savings in erection costs for transmission lines in mountainous country.

The average aluminum tower should require about 900 man-hours of labour for erection as contrasted with 2,100 man-hours for the equivalent steel tower, a saving of 57 per cent in labour requirements. There is considerable evidence indicating that the average aluminum tower should be erected with about 650 man-hours of labour using power tools, and possibly with as little as one half of this labour requirement with mobile cranes.

Maintenance costs are expected to be low for the aluminum towers, due to ease and safety of access and to optimum working safety during inspection and maintenance. Moreover, low maintenance costs over the life of the towers are anticipated, due to freedom from corrosion.

It was expected that the smooth, streamlined shapes of the aluminum tower will result in less accumulation of snow, rime and ice than would be the case with lattice tower construction; this was borne out by observations last winter. That is, the aluminum tower is inherently less severely loaded, with the probability that this condition will be reflected in lower maintenance costs.

Had the aluminum tower design not been governed by helicopter transport restrictions, the tower would have involved even fewer components, with the attendant savings in cost.

#### Field Investigations and Observations

Erection of the aluminum towers was completed in the fall of 1953 and the transmission-line conductors are being strung during the summer and fall of 1954. The towers were exposed to snow, rime and ice conditions during the winter of 1953-54, when a crew of engineering observers was maintained at the summit of the pass for recording weather conditions and for making observations on the structures.

A few minor members of the towers proved to be defective in one respect or another, but these instances were quite insignificant. Essentially, such faulty members were confined to welds in the guard rails around the manholes at the tops of the tower legs. A very few leg section joint rings proved defective to a degree. Careful examination traced the trouble to faulty fabrication. These have been replaced and no evidence has been found to indicate that all elements of the design are other than fully adequate.

As expected, some resonant vibration of aeolian origin has occurred in the leg members of certain towers. The amplitude of such vibration, as determined by manually-induced vibration, was found to range up to a maximum of 4.4 inches half amplitude, i.e., the maximum lateral movement from the position of rest. The frequency, of course, is the natural frequency of the structure and has been found to range from 1.76 to 3.55 cycles per second. Typical records for towers with legs of high slenderness ratio are shown in Fig. 73.

Wind-induced vibration has been observed on a few occasions, but at the time of writing no records have been secured. However, the half amplitude of vibration, as observed, was approximately 2.5 inches. In general, wind-induced vibration results in oscillation of a leg in the plane of its natural sag, so that all legs have a different type of vibration, related to the rigidity of the structure of the A-frame or of the tripod, respectively. The frequency of occurrence of wind-induced vibration, and the duration of the vibration when it does occur, are conservatively estimated at approximately 20 hours per year and 0.23 per cent of the time, respectively.

Stress measurements have been made on a tower subjected to manually-induced vibration. These measurements were carried out with SR4 resistance strain gauges used in combination with an oscillograph. Tests were made at several critical locations. They showed, at the most critical point of the leg shell, that the variation in stress was ±3,500 p.s.i. with a maximum half amplitude of 3.9 inches. The significance of such vibration, both as to secondary stresses induced in the tower members and as to tendency to fatigue, indicates that probably no vibration dampers will need to be installed. However, investigations have been carried out to determine suitable types of vibration dampers.

Observations on the aluminum and steel towers during the winter of 1953-54 indicate that the smooth outlines of the aluminum towers result in the accumulation of considerably less snow and rime than on the steel towers. In the case of some single-circuit steel towers, as much as 48 inches of icy snow, with a density of about 22 pounds per cubic foot, accumulated on the secondary bracing members in the top plane of the cross-arm and resulted in bending these members. The accumulation of snow and rime on the aluminum towers was much less.

The aluminum tower legs were relatively free of snow, rime and ice; as expected, this condition contrasts sharply with that of the steel towers, where snow and rime accumulated on the leg members to substantial thicknesses. Under severe winter conditions at high altitudes, maintenance workmen can gain access to the cross-arm of the aluminum towers with greater safety than in the case of the steel towers, a substantial advantage.

Devices recording snow-creep pressures were installed during the fall of 1953 and records secured, indicating that design assumptions were sound in that the maximum pressures recorded were lower than those assumed.

#### Conclusions

The work done on design and proof testing and on fabrication and erection of the towers, together with observations during the winter of 1953-54, when the towers were exposed to service conditions, except for the absence of conductors, which were strung only during the summer and fall of 1954, warrants the following conclusions:—

The aluminum towers on the Kemano-Kitimat transmission system adequately meet the loading specifications under which they were designed.

The aluminum tower represents substantial economies over the conventional steel tower. These arise from the 60.5 per cent average weight as contrasted with steel towers, substantially lower number of components, easier fabrication, easier transportation by all methods, easier transshipment and easier distribution. It offers substantial economies in erection labour requirements.

Aluminum towers are adaptable to the use of simple erection equipment.

Observations during the winter of 1953-54 indicate that aluminum towers are inherently better suited than steel towers where heavy snow, rime and ice deposits occur.

Aluminum towers provide maximum safety during erection, inspection and maintenance.

Experience gained with aluminum towers used on the Kemano-Kitimat transmission system indicates that, for loading specifications approximating more nearly the usual requirements, the design could be substantially simplified, with lower costs for fabrication and erection.

Experience gained with the aluminum towers on the Kemano-Kitimat transmission system indicates that such a simplified design will result in the recommendation of aluminum transmission towers for many high-voltage lines, where mountainous terrain and difficult transportation impose severe limitations.

Such a simplified design of aluminum tower affords a solution to the problem of high maintenance costs incurred in polluted atmospheres which cause high corrosion of galvanized steel structures.

The basic design of the aluminum towers was developed by Dr. K. Sutter of Aluminium Laboratories, Limited, Geneva, Switzerland. Actual execution of the design was carried out by a team of engineers in Montreal under A. Soosaar, engineer with the power department, Aluminium Laboratories, Limited. Many individuals contributed to the work of this team. In particular, acknowledgment is due to R. F. D. Collin for his contribution as liaison between Alcan and the design group. Acknowledgment is also due J. C. Millson and A. G. Pue-Gilchrist, of Aluminium Laboratories, Limited, Kingston, for their contribution in respect of strain measurements on the test tower, strength tests on tower components and for other services.

F. L. Lawton, M.E.I.C., is chief engineer, power department, Aluminium Laboratories, Limited, a development, investigation and research organization, which is a subsidiary of Aluminium Limited. He was closely associated with the initial investigations in connection with the power development and acted in a consulting capacity on a number of major engineering problems of the Kemano-Kitimat project.

The aluminum towers were fabricated at the Victoria, B.C., shipyard of Yarrows, Limited; thanks is due to them for the enthusiasm and co-operation with which they proceeded with the work of fabricating an entirely new product. √

# Investigations of the Effect of the Power Development on Fisheries

*by*
R. W. Kraft, M.E.I.C.
*Technical Superintendent, Kitimat Works,*
*Aluminum Company of Canada, Limited*

This paper shows how the engineer's work is often closely bound up with problems in non-engineering fields. For a time it was feared that the power development at Kemano might seriously affect the salmon runs on the rivers of the watershed. A few years of observation have indicated that these fears were on the whole, groundless; nevertheless some $400,000 have been spent on remedial works. The investigations and the steps taken to overcome any likely difficulty are the author's subjects.

In 1953 the output of the British Columbia fishing and fish-canning industry was valued at $65 million, equivalent to about 5 per cent of the province's industrial production. Salmon accounts for roughly two-thirds of the fisheries output.

There are five species of Pacific salmon: sockeye, spring, coho, pink and chum. All hatch from eggs deposited in fresh water and descend in due course to the sea, where they spend one or more years. At maturity the salmon ascend the coastal rivers and streams to appropriate spawning grounds, there to deposit their eggs and die.

The sockeye catch is of substantially greater value than that of any of the other salmon species and it is probably the most profitable. Apart from the spring salmon, the sockeye is the only salmon which as a rule spawns at any great distance from the sea, frequently 500 miles and more. Thus the sockeye is more likely to encounter man-made changes in its habitat.

### Sockeye Habits and Power Developments

For these reasons, the habits of the sockeye are reviewed in detail. The adult sockeye spawn and deposit their eggs in the gravel of streams having a favourable combination of bed material, water depth, velocity, temperature and possibly other factors as well. Generally such spawning areas are either upstream or downstream from a lake. Spawning occurs at various times in the months of August to November, depending on the particular area. After spawning the adult sockeye die.

The salmon eggs hatch the following spring and the sockeye fry emerge from the gravel. Where there is a lake on the spawning stream, the fry migrate to the lake. In cases where there is no lake, the fry descend directly to the sea. After a year or two in the lake, the young sockeye descend to the Pacific Ocean, where they spend the next several years. At maturity the sockeye return to seek out their customary spawning grounds, usually in the fourth or fifth year from egg deposition.

Obviously a power or storage dam on a river frequented by sockeye may affect directly one or more phases of the sockeye's life in fresh water. In some cases, the anticipated effect may be minor, or ameliorable in various ways. In others, the fisheries interests may conclude that the power development is completely incompatible with sockeye.

R. W. Kraft, M.E.I.C.

#### Early Phases of Alcan Studies in British Columbia

In 1948, Alcan initiated field studies of various potential water-powers in British Columbia. Ultimately the Nechako-Kemano project, was selected for development. One of its major advantages was that its development should affect fish only slightly, if at all. Another project studied would have required a dam directly in the path of migrating sockeye.

In 1949 the Canadian Department of Fisheries and the International Pacific Salmon Fisheries Commission indicated that they foresaw no basic conflict between the Nechako-Kemano project and fish. The main source of possible difficulty was thought to be lack of sufficient water after diversion of the Nechako River, for easy migration of salmon using the lower parts of the Nechako River. It was felt that such problems could be solved, but would require detailed study.

These two organizations have the main responsibility for conservation of the fish concerned. The Salmon Commission is composed of three appointees of each of the governments of Canada and the United States. Under treaty, it is responsible for making recommendations for the protection of the Fraser River sockeye salmon, which are caught by both Canadian and American fishermen.

#### Description of the Nechako-Kemano Project

Water for this development is supplied by a drainage area of 5,475 square miles, whose centre lies about 140 miles west, and slightly south, of Prince George. Until the Kenney dam was built, this area drained eastward, through two chains of lakes 2,600 to 2,800 feet above sea level. These gave rise to the Nechako River, which then flowed northerly and easterly to empty into the Fraser River at Prince George.

#### Fish in Waters Affected by Nechako-Kemano Project

Of the fish frequenting the various waters involved in the project, space permits dealing only with the salmon using the Nechako River. These have been studied the most intensively, because of their economic importance and of the immediate possibility of being affected. In addition, however, Alcan investigated and discussed with the appropriate fisheries-regulating bodies possible effects on salmon using the Nanika River; game fish using the lakes and tributaries above the Kenney dam; salmon using the Kemano River, which is now being augmented by the diversion from the Nechako reservoir; and fish in streams in the Kitimat area, in relation to the smelter's water intakes and sewage outfalls.

The average flow of the Nechako River at the Kenney dam site was 6,500 cfs. The first major downstream tributary is the Nautley River, draining Fraser and Francois Lakes and their tributaries. It enters the Nechako River 56 miles below the dam, with an average annual flow of about 500 cfs. The second major tributary, the Stuart River, drains the Stuart Lake system and discharges into the Nechako River a further 58 miles downstream, contributing an average annual flow of about 5,000 cfs. Finally, 55 miles below the Stuart River, the Nechako empties into the Fraser River at Prince George. Taking all the minor tributaries into account as well, the Kenney dam eliminated 80 to 90 per cent of the natural flow of the Nechako between the Nautley and Stuart Rivers, and about 50 to 60 per cent below the Stuart.

Three groups of salmon use the Nechako River. One run of sockeye salmon ascends the Nechako River for 55 miles, to spawn in the tributaries of the Stuart River system. A second run of sockeye continues a further 58 miles up the Nechako, to the Nautley River, to spawn in tributaries of the Fraser-Francois system. Finally, a certain number of spring salmon spawn in the Nechako River above the Nautley.

#### Study of the Project's Effect on Salmon

Preliminary study indicated that the hydroelectric development should have practically no effect on the Nechako salmon. The rapids and falls of the Grand Canyon were in the past an effective barrier, making the Nechako River above that point inaccessible to salmon. Diversion of the river at the canyon, therefore, would not obstruct any salmon runs.

In numbers and value, the sockeye are the most important of the Nechako salmon, though only a minor item in the provincial picture. The Canadian share of the Nechako sockeye is estimated to contribute about 5 per cent of the total British Columbia sockeye pack, or somewhat less than 2 per cent of the landed value of all salmon.

While the sockeye using the Nechako river would have much less water after the Nechako diversion, there would still remain in the extreme case of the sockeye going up the Nautley River, a flow somewhat larger than that of the Nautley itself and its principal tributary. Since the latter streams had ample water to convey the Fraser-Francois run, it was considered highly probable that this same amount of water still flowing in the Nechako River would suffice to get the run up to the Nautley.

The spring salmon spawning in the upper Nechako River would find only 100 to 200 cfs. after diversion, and it was thought possible they might no longer be attracted to that area. However, it was understood that the spring salmon were much less attached to specific spawning grounds than the sockeye, and that they would be inclined to spawn elsewhere—downstream in the residual Nechako River, or in its major tributaries.

#### Specific Problems Foreseen by Fisheries Bodies

Following detailed studies, the technical staffs of the Canadian Department of Fisheries and the Salmon Commission jointly issued in 1951 a "Report on the Fisheries Problems Created by the Development of Power in the Nechako-Kemano-Nanika River Systems". For the Nechako salmon, the following sources of trouble were feared:

(a) Obstacles to salmon migration in the Nechako River from the Stuart River up to the Nautley;

(b) Water temperatures in the Nechako River below Nautley high enough to be lethal to migrating sockeye (over 68° Fahrenheit); it was calculated that the reduced volume of water would heat up excessively in summer;

(c) Insufficient water for migration, spawning and egg protection of the spring salmon spawning in the Nechako between the Nautley River and the Kenney dam;

(d) Lowering of the level of Fraser Lake, which is drained by the 3,000-foot-long Nautley River into the Nechako; with the increased gradient in the Nautley caused by lowering of the Nechako after diversion, increased erosion of the former was feared, leading to a drop of six or eight feet in the lake level; Fraser Lake is an important sockeye rearing lake and since its average depth is only 44 feet, such a drop might be upsetting to biological conditions.

#### Solutions Proposed by Fisheries Bodies

The chief remedial proposal was that outlet works be installed at the Kenney dam about 200 feet below the surface, to release water from the main reservoir. This was calculated to provide cold water to solve the anticipated temperature problem, and partially solve the transportation problem and to protect the spring salmon eggs in winter. In addition, certain reaches of the Nechako River might have to be channelized in order to concentrate the reduced volume of water and provide a deep enough passage for salmon. If the Nautley River eroded, bed protection would be required.

Alternatively, the requirements of transportation and winter-cover water could perhaps be met by a storage dam on the Cheslatta River, a small tributary to the Nechako River about five miles below the Kenney dam. However, this alternative would not solve the temperature problem.

These proposals were studied thoroughly by Alcan, and discussed in detail with the fisheries organizations. It was agreed that a temporary storage dam should be constructed on the Cheslatta River, to provide water if needed to aid salmon transportation. A timber crib dam for this purpose was built and closed in April, 1952. Alcan was to make plans to provide additional water after the reservoir was filled by releasing 100 cfs. continuously into the Cheslatta system from the reservoir at a point about 45 miles from the Kenney dam. Plans would also be made to replace the temporary dam with a permanent control and storage dam. The last two measures would be dropped if further investigation showed no need for them. Possible necessity of channelization would be studied, as it might be a big factor in eliminating the need for the 100 cfs. release from the main reservoir.

These agreements covered all the questions raised, except the possible occurrence of lethally high temperatures in the lower reaches of the Nechako River. Here, Alcan felt that it could not take the responsibility for a low-level outlet in the vicinity of the Kenney dam. The 300-foot high dam would store permanently an enormous quantity of water—five years' flow of the Nechako River. This amount of water, if released abruptly, would have catastrophic consequences down stream, and every precaution was being taken to design and construct the Kenney dam so as to preclude any possibility of failure. On the other hand, a low-level outlet mechanism would be almost certain to fail eventually, even though it might last a long time as ordinary industrial structures go. In contrast to other dams having low-level outlets, it would be a practical impossibility to dewater the Kenney dam, hence the discharge mechanism could never be satisfactorily inspected and maintained. In the event of failure, only very hazardous and uncertain remedial measures would be available. Alcan could therefore not agree to take the risk of the proposed outlet.

At the same time, Alcan's assessment of the available information was that the small and problematic value of releasing cold water would not warrant doing so by any very hazardous or expensive means. The evidence was by no means conclusive that the calculated water temperature rises would occur, would be lethal to fish and could be overcome by comparatively small releases of cold water 60 to 110 miles upstream. Moreover, even in the worst case, no more than 5 to 10 per cent of the Fraser-Francois sockeye would be in the Nechako River above the Stuart during the times when it was feared water temperatures might be above 68° Fahrenheit.

#### Alcan's Field Studies of Salmon in 1952

To obtain further data on the water temperature and other questions, Alcan put parties into the field in the summer of 1952, to complement the studies of the fisheries organizations. Observers were stationed at the Nautley River to observe the times at which sockeye reached it from the Nechako River. Previously, the time of sockeye migration up the Nechako had been known only roughly by inference from the time of their arrival on the various spawning grounds. Water and air temperatures were recorded at a number of stations, for comparison with the timing of the salmon migration. The Nechako River was thoroughly reconnoitred to get further information on possible obstacles at low flows.

In this work, much assistance was provided by the Department of Fisheries and the Salmon Commission in acquainting Alcan's field people with their activities in the area, and the habits of the salmon.

The Kenney dam was closed on October 8th, 1952, following advice from the fisheries bodies that this date would be agreeable to them. Field parties were then able to inspect the Nechako River at very low flows. With one or two possible exceptions, each of the locations previously feared as potential obstacles to migrating salmon had a channel which would provide sufficient depth of water at low flows. The lower depth of water permitted counting the spring salmon nests in the upper Nechako River, hence a more accurate estimate of the number of springs in 1952. It was very close to 4,000, about half the number estimated in previous years.

#### Further Development of Cheslatta Dam

By the fall of 1952, the timber crib dam was storing some 60,000 acre-feet of water, amounting to about 5½ feet on Murray and Cheslatta Lakes, and practically no inflow was expected until the following spring. The dam still had about 9 feet of freeboard, equivalent to an estimated 110,000 acre-feet of additional storage, which was about the upper limit of annual runoff estimated for the Cheslatta.

After detailed study with the fisheries groups, it was agreed that the timber crib dam might be used for the time being as the control dam, in lieu of the permanent structure previously contemplated. Two openings were made by removing two of the cribs, and a double-acting steel gate 12 feet wide by 11 feet high was installed in each opening.

#### Alcan Field Studies in 1953

This was the first season that migrating salmon would be using the diminished Nechako River. Alcan crews patrolled the Nechako area during the summer, to watch for any signs of difficulty on the part of the salmon, to observe the timing of the sockeye passing up the Stuart and Nautley Rivers and the condition of these fish when they reached their spawning grounds, as well as to keep records of water flows and temperatures, and other pertinent factors.

The sockeye migration was found to encounter no difficulties resulting from the changed conditions. Large runs ascended both the Stuart and Nautley Rivers without untoward circumstances. Of the latter, about one-fifth constituted an early run numbering more than ever previously observed, which ascended the Nechako during the warmest part of the migration period.

Air temperatures at established stations in the area were close to, or above, normal monthly averages.

Mean daily water temperatures of 68½° to 69° Fahrenheit were recorded in the Nechako River for four consecutive days while salmon were migrating to the Nautley River; this run continued unabated during this time. The first season under the altered conditions thus indicated that, in normal summers at any rate, water temperatures would only slightly exceed the estimated lethal temperature, but that there would be no effect on the sockeye.

Conclusive and direct data were not available, but it appears probable that the flow of the Nautley River was somewhat above seasonal normals during the summer. Consequently, there was no real tryout of the residual river's passability by sockeye under average conditions. However, the inspections at low water the previous autumns had practically eliminated the possibility of this trouble.

As the time for migration of the spring salmon to the Nechako River above Nautley drew near, the flow of the former was down to 100 or 200 cfs. The fisheries engineers and biologists decided that 400 cfs. should be released from the Cheslatta reservoir. This addition of water proved sufficient to enable spring salmon to ascend to the spawning grounds without need of any channelization measures in the shallow reaches of the river. From 400 to 600 springs were found in the upper Nechako. Alcan parties found on investigation that spring salmon had spawned as well in the Nechako River below Nautley and in portions of the Stuart system, where few or none had been observed in previous years. Surveys of parts of these waters accounted for roughly 1,500 to 2,000 springs. Thus a reasonable nucleus of spring salmon was able to use the customary Nechako spawning grounds, and considerable numbers appear to have adapted themselves by using other areas.

#### Nautley River

After lowering of the Nechako River by the dam closure in October, 1952, minor erosion occurred at the mouth of the Nautley River for a time and then appeared to halt.

As the spring freshet of 1953 approached, the Nautley River was observed to be scouring and downgrading its bed severely. Measurements of the stream-bed elevation showed that the channel was being cut about six feet deeper. This erosion worked upstream, without seeming to slacken off after the flood peak was passed. The bed material consisted of four- to six-inch stones, mixed with glacial boulders. On investigation it proved to be only about one stone in thickness, and underlain by fine material which was easily washed out. Once the bed cutting was initiated by high water, it continued readily at lower flows.

By the end of July the erosion had proceeded about one-half mile upstream from the river's mouth, and was within 500 feet of a wooden pile highway bridge crossing the river, which was now threatened. From the bridge upstream the short distance to Fraser Lake the stream bed was of sand, which looked as if it would be rapidly eroded, and Fraser lake lowered, once the erosion reached the bridge.

Immediate remedial action was decided upon. With Professor Thomas Blench, M.E.I.C., of the University of Alberta as consultant, the following plans were made. The drop from Fraser Lake to the Nechako River would be concentrated in a 175-foot stretch of the Nautley River, with a 5.7 per cent gradient. The stream bed in this section would be paved with a three-foot thickness of 2,000-pound quarried rock, which was calculated from laboratory tests to be stable under the maximum floods expected. The banks of the paved section would be protected with heavy riprap. Velocities through the channel were thought to be negotiable by salmon, but if necessary, baffles of 5,000-pound rock would be placed across the paved section at 20-foot intervals. These rows of rock would create a series of riffles interspersed with relatively slow water.

These plans were then reviewed with the fisheries representatives. They agreed that work should start as proposed, but felt that some device such as the rock baffles was required in order to reduce water velocities sufficiently for the sockeye.

Construction work was started at the end of August and the remedial work, including rock baffles, was completed in November. So far the work has withstood an exceptionally heavy flood in 1954 —about 5,000 cfs. at its peak. Subsequently the sockeye have been ascending the stabilized section readily.

#### Alcan Field Studies in 1954

A program similar to that of 1953 is again being carried out. The tenour of preliminary reports from the field is one of uneventfulness. Stream flows in the area have been very much above seasonal normals. Temperatures appear to have been below normal. Much of the sockeye migration has taken place, with no noteworthy features.

#### Conclusion

One complete sockeye migrating period, and the more critical part of a second, have now been experienced since closure of the Kenney dam. During this time the company has been continually in touch with the fisheries regulating bodies. To ensure minimum interference with salmon $400,000 has been spent on remedial works and studies. To date there has been gratifyingly little effect from this major river-diversion: the sockeye runs seem to have been completely unaffected; a portion of the spring salmon have continued to use the upper Nechako spawning grounds; and others have spawned in quantity in previously unused areas. As more data are gathered, it becomes increasingly unlikely that the major temperature and transportation problems feared in the early days of the project will materialize. Should any further problems arise as the Alcan project develops, it is expected that by continued close co-operation with the fisheries organizations concerned, they will be solved equally satisfactorily. √

# The Kitimat

A large part of the raw materials required for making aluminum at the Kitimat smelter will always be received in ships from Jamaica and other far-away places. Hence, a harbour with suitable wharf facilities for berthing and unloading ocean-borne traffic is of prime importance. The wharf at Kitimat will be known as "Kitimat Terminal Wharf No. 1". This paper describes the design and method of construction of this wharf structure. Figure 74 is an aerial view of Kitimat area and of the delta of the Kitimat River. The many channels of the river as it discharges through its delta and also the long tidal flats can be seen.

The river valley stretches northward between high mountain ranges and the river winds back and forth across the valley floor. The site of the new aluminum plant is on the west side of the valley extending inland from these tidal flats on which the harbour is located. The flats fall off rapidly into deep water, and, in order to provide an economical wharf site with safe berthing for large ocean-going vessels, it was decided to dredge a channel inland to the selected wharf location, with a minimum width of about 400 feet. The dredged material from this channel was used for filling the flats behind the wharf area to provide building and storage areas.

In order to retain this dredged material, it was necessary to construct two large rock moles. One mole ran northward from the proposed wharf end to higher ground and the other mole ran westward to the shoreline. These moles were constructed by dumping quarried rock on the original ground surface. A graded sand and gravel filter was placed along the inside face of the mole to provide drainage and to

**Alcan's development at Kitimat, B.C., required much work not generally associated with most industrial projects, for example, the design and construction of the wharf described in this paper, presented at the Quebec Annual Meeting on May 14, 1954. Read it and learn how to save time and money by building concrete caissons on their sides and then careening them upright.**

prevent tidal action from washing out the dredged fill.

The axis of the wharf was selected so that a vessel approaching it would be in line with the prevailing winds which are nearly due north or due south, depending on the season.

#### Selection of Wharf Type

Because of the large amounts and wide varieties of materials required for operating the aluminum plant, a wharf large enough to berth large ocean vessels had to be constructed and equipped with suitable unloading towers for handling bulk materials and also with facilities to ship out aluminum ingots.

Several wharf arrangements and types of construction were studied before the final design was adopted. Timber is plentiful in this area for a timber pile type wharf, but, because of the presence of marine borers, it would be necessary to creosote all such piling. Figure 75 shows the cross section of an untreated pile exposed in the harbour for a period of about six months, completely destroyed by Teredo Navalis. Steel H pile and pipe pile were also considered, but as steel was scarce at that time due to the Korean War, the idea of using them was abandoned. Concrete piles were also considered, but it was felt that their length would be so great that they would be too costly to cast, handle and install.

In any case, it was desired to have a fire-proof wharf structure because of its vital importance to the operation of the plant. Even a structure with a concrete deck supported on creosoted timber piles was regarded as a hazard. It was, therefore, decided to study the possibility of an all-concrete wharf. Consulting engineers were therefore retained to study and make recommendations for this type of wharf.

**Fig. 76. Platforms for soil borings, on stilts to take care of 22 ft. tides.**

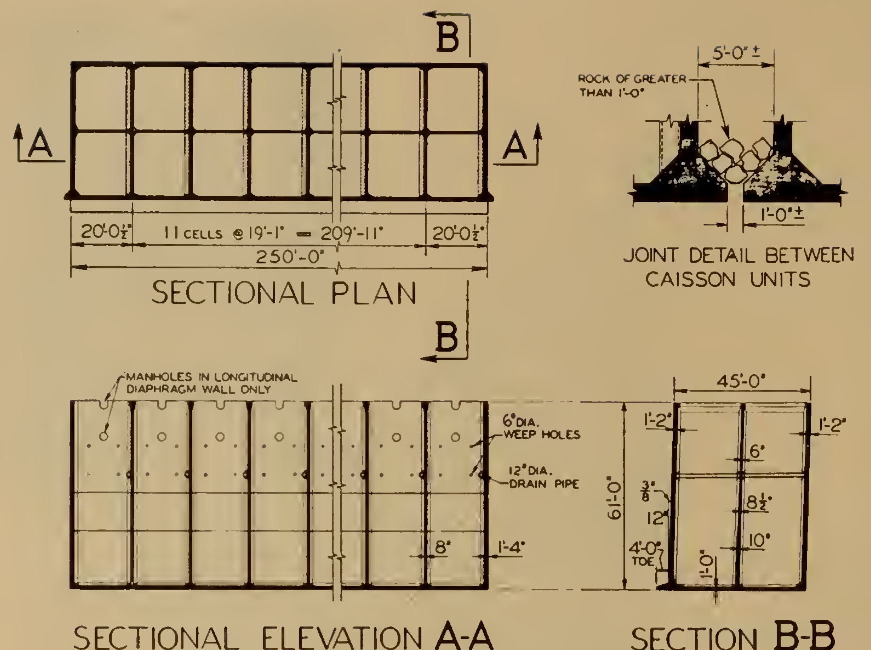

**Fig. 77. Typical details of the wharf caisson.**

At present, berthing a single large freighter requires a wharf length of 750 feet. The wharf had to be extensible to a length of about 2,200 feet to meet future requirements.

The extreme high tide at the wharf site is at about elevation +23.08 feet. The extreme low tidal elevation is +0.58 feet. A minimum depth of 32 feet was required for ship draft at low tide, and the wharf design had to be such that this could be increased to 34 feet in the future. The harbour is reasonably protected, but there is the possibility of wind-whipped, 7-feet waves occurring in the bay. Based on these data, the El. +30.0 was established for the wharf deck surface. El. −31.0 was established for the bottom of the dredged ship channel.

The consulting engineers suggested sinkable concrete boxes or caissons for the wharf structure. These caissons in place form a gravity retaining wall, with overturning resistance furnished by the weight of the internal fill. As such, they were designed to resist the external thrust of the backfill material and their concrete walls are designed to have sufficient strength to contain the fill material.

This type of wharf structure was finally adopted. Precast concrete units have previously been used for wharves, but this is one of the first applications where the units have been built on their sides, because of shallow water conditions, and then careened into final position.

### Soil Conditions

The soils encountered at Kitimat represent a complex history as indicated by borings. The general topography was formed by the eroding action of a glacier leaving high rugged peaks and deep valleys. The soils are a composite of alluvial and modified glacial deposits. The alluvial deposits are represented by the fine-grained soils and are stable and fairly dense, as indicated by the range of grain sizes. The coarser grained soils are of glacial outwash origin and are of lower density, as indicated by their range of grain sizes. It was thus anticipated that the stratification would be variable; however, each stratum should be fairly uniform.

To obtain first-hand knowledge of the subsoil conditions at the wharf site, a program was outlined for a series of drill holes to be sunk along the line of the wharf. Twelve borings were made, spaced about 120 feet apart for the first 1,100 feet, and then about 400 feet apart to provide information for the possible future wharf extension. Figure 76 shows the platforms used for the drill rigs because of the high tidal range. These platforms were moved as required.

Split-tube samples were taken in the coarse grained soils, Shelby-tube samples in the finer grained soils and wash samples when other samples were not recovered. These wash samples were not representative, as most of the fines had been washed out. However, they did indicate, in a general way, the granular characteristics of the soil; they were taken to complete the record. Six-inch, 4-inch and 3-inch casings were used. The 6-inch casing was driven through the upper gravel stratum and the 4-inch casing was telescoped inside it. This was necessary as the frictional resistance of the gravel would prevent salvaging the casing.

The depth of any boring was determined by the assumed wharf load and the necessity of terminating the boring in a relatively pervious stratum, so that no question would arise concerning the thickness of a loose, fine-grained stratum, if the boring terminated in such a layer. Drainage conditions would also be established by the coarse soil. All borings were carried to such a penetration, that the assumed stress intensity at that depth would not be of sufficient magnitude to cause appreciable settlement.

Samples were taken approximately every 10 feet, except immediately beneath the proposed bottom elevation of the wharf caisson; here they were taken at 5-foot intervals for a depth of approximately 25 feet. This closer spacing was required for verification of the stratification and test results, since the greatest load would be carried by the soils in this region. The soil samples obtained indicated the anticipated complex system of stratification and the existence of only granular non-cohesive soils. The soil immediately underlying the wharf area is fine silty sand, in a medium dense state.

The samples were shipped to Edmonton for testing. These results indicated that the average angle of internal friction was about 30°; that a compression index of 0.16 is representative of the soil under the wharf; and that the soil was granular with a suitable range of grain sizes and in a medium compact state.

### Design of Caissons

The wharf structure finally adopted is composed of three separate reinforced concrete caisson units. Each unit is 250 feet long, 45 feet wide and 61 feet high. The individual units contain a central longitudinal diaphragm wall of variable thickness and transverse 8-inch thick diaphragm walls spaced at about 19 feet centers, resembling an open-top egg crate. Figure 77 illustrates some of the typical details of one of these caissons.

The front and rear wall slabs are designed to resist the interior filling and backfill loading stresses, respectively. The interior diaphragm walls are designed for a maximum 5-foot differential in height of the interior filling. The main function of the bottom slab is to make the box watertight for floating into place. This slab extends four feet beyond the front wall to provide a toe to assist in distributing the foundation loads. The walls have a backward slope of ⅜ inches per foot of height in order to throw the center of gravity of the loading as far back as possible.

The reinforcing steel was proportioned on the basis of a unit stress of 20,000 psi, except during launching a stress of 24,000 psi, was allowed. Concrete was proportioned to secure 3,000 psi, compressive strength at 28 days.

### Design Loadings

The internal fill in the cells was assumed in design as of mixed gravel and rock with a unit weight of 110 pcf. The angle of internal friction was assumed as 40° and angle of wall friction as 25°. The pressures on the front wall were computed on the basis of soil at rest, including the effect of a 750 psf. surcharge at the deck level. Bin effect and the effect of wall friction were also included in the computations. Free drainage of the material above mean low water was also assumed. Backfill pressure against the cells was assumed as that from a combined gravel-rock fill with a dry weight of 110 pcf. and a submerged weight of 65 pcf. The angle of internal friction was assumed as 40°. The deck live loading assumed consists of the 750 psf, uniform load, combined with two standard railway track loadings, the loading of the unloading cranes and the impact or pull from ships.

### Caisson Drainage Provisions

Special drainage provisions were required to insure that water would not be trapped inside and behind the caissons, since the caissons were designed on this assumption for maximum economy. These special provisions consist of two rows of 6-inch weepholes through the three longitudinal walls and a 12-inch pipe drain cast into each transverse diaphragm wall, extending from the wharf face through to the backfill. This pipe will also aid in draining the back cells. The weepholes are spaced so that there will be two, together with the 12-inch pipe drain, in each cell. The weepholes should help to drain both the internal and external backfills, although some of them will probably become clogged. Then those in the front wall, the more important, can be cleared so that they will drain the front cells. It is improbable that all the weepholes in the back cells will become clogged, so some degree of drainage will always be provided in the back cells. The 12-inch pipe drains will not clog easily; if they do, it is possible to clean them by rodding and jetting from the front face of the wharf. Drainage of the backfill is thus permanently insured.

Drainage between the caisson units will be insured by the open type joint shown in Fig. 77. The front wall slab is extended two feet beyond the cell end wall to form this special joint between the caissons. This joint was designed to retain the fill between the units, provide free drainage of the fill, and allow adequate tolerance in placing of the units. It will also allow some differential movement of the caisson units in place.

### General Wharf Details

Figure 78 is a typical cross-section through the completed wharf structure.

The caissons were topped off with a 5-foot coping wall and reinforced concrete beams carry the travelling unloading crane loads directly into the caisson walls. Reinforcing bars were left projecting from the top of the caissons to anchor these beams.

The level of the wharf deck was established at El. 30.0. The deck surface was sloped upward from the wharf face to give proper drainage. The annual precipitation at Kitimat is about 90 inches. During the months of December, January and February the snowfall may amount to over 200 inches. Thus, surface drainage required serious consideration and study.

The unloading crane rails were spaced 32 feet center to center. The outer rail is 5 feet from the wharf face, providing space for bollards and a timber guard rail along the edge of the wharf. The unloading cranes span two standard railroad tracks extending the length of the wharf. A steel conveyor gallery mounted on temporary timber bents extends along the wharf, back of the unloading cranes, to convey unloaded bulk materials to storage buildings on shore. A future steel-framed transit shed is provided for; when it is built it will provide a permanent support for the conveyor gallery.

Oil pipes were located below the deck surface, with connections to discharge oil from tankers to shore tank farms. Water lines were provided for fire protection and ship supply. The surface of the wharf will

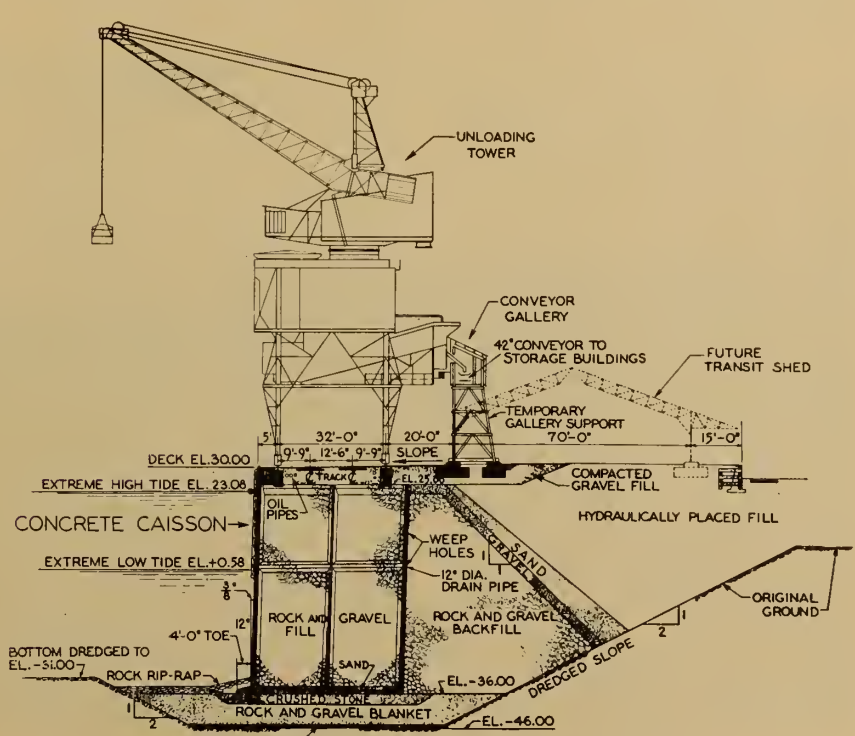

Fig. 78. Typical cross-section through wharf.

Fig. 79. The three caissons in the graving basin.

be paved with asphalt for the present, perhaps later to be replaced with concrete when all settlement of cells or compaction of cell fill materials has ceased.

Galvanized steel bolts were cast into the face of the caisson, to which a creosoted timber fender system is attached. This system is really a rubbing block arrangement for the protection of the wharf wall from the floating fender system. The floating fender was made up of untreated timber and will act as a cushion between ship and wharf.

#### Caisson Internal Fill

The internal caisson fill was selected to furnish sufficient mass for stability of the structure, to have high internal friction to reduce pressure on the caisson walls and to be free draining to reduce pressure from entrapped water. This material was specified to be composed of rock up to one cubic foot size with the largest dimension of any piece not greater than 18 inches. Gravel-sized particles could be included, but no more than 10 per cent in weight should pass a ¾ inch screen.

Before placing the fill in the caissons, the bottom was covered with a 1-foot sand cushion. The caisson fill was placed in lifts so that there was never more than a 5-foot difference in elevation between adjacent cells. The fill was placed by direct dumping, but care was taken to avoid heavy impact on the concrete.

Because of the difficulty of finding suitable and sufficient rock fill as specified, the specification was altered to permit the use of river boulders and gravel up to 1 cubic foot in size and screened to remove all fines smaller than 1 inch, but boulders and gravel only to the extent of 50 per cent of the total fill quantity. The filling operation was regulated so that rock, boulders and gravel were completely mixed. The combined fines of the quarry rock, river boulders and gravel that would pass a ¾-inch screen was not more than 10 per cent of the total volume.

#### Backfill Behind Caissons

The special gravel and rock backfill immediately behind the caisson was designed to reduce overturning and sliding forces. The material specified was similar to the caisson internal fill, except that larger rock was used when not in direct contact with the caisson concrete and at least five feet away from the sand and gravel filter. In general, the material was graded from coarse to fine towards the back of the fill, with the back two or three feet composed mostly of particles less than six inches in size to prevent the filter material from washing into the voids. The sand and gravel filter was to contain no more than 10 per cent by weight of material passing the No. 200 sieve and from 60 to 90 per cent passing the 1-inch sieve. This sand and gravel filter was carried over the top of the special rock backfill. The area behind this special fill was filled hydraulically.

#### Base Pressure and Blanket Fill

Base pressure distribution was carefully considered. It was known that the foundation would yield and that settlements would occur. The redistribution of the base pressure resulting from this yielding condition had, therefore, to be considered. The caisson is inherently a rigid structure. Therefore, the entire caisson should settle as a unit and settlement should tend to be uniform. However, only a flexible structure would be capable of withstanding large differential settlements, with resulting uniform bearing pressure. As a result of these studies, it was finally decided to design the toe slab for a maximum base pressure of 12,000 lb. per sq. ft.

The ultimate bearing capacity of the soil was determined from Terzaghi's formula for continuous footings (Article 29, *Soil Mechanics in Engineering Practice*, Terzaghi and Peck). As the relative density tests and blow counts of samples indicated a medium dense soil, an intermediate value between the loose and dense state was used in the Terzaghi formula. On this basis, the ultimate bearing capacity of the natural soil, for an angle of internal friction of 30°, was found to be 12,000 lb. per sq. ft. However, the bearing pressure at the toe of the caisson is also 12,000 lb. per sq. ft. Hence, it is apparent that the soil did not have sufficient bearing capacity to support the caisson wharf directly on the surface of the dredged cut.

Two means of supporting the

wharf were considered, namely, a pile foundation and dredging out some of the material and backfilling with soil of higher bearing capacity. A pile foundation would have been expensive and difficult to install because of the depth of water and was so ruled out, and the dredging and backfilling method was adopted.

This scheme improves conditions in two ways. First, the stress intensity at the elevation of the top of the natural soil is reduced, since the stresses are somewhat dissipated in the blanket layer. Second, the natural weaker soil is confined by the weight of the overlying blanket layer and will therefore have a higher ultimate bearing capacity. Assuming a 10-foot gravel-rock blanket, the underlying natural soil will have its ultimate bearing capacity increased to 22,000 lb. per sq. ft., as a result of confinement. This bearing capacity is ample and provides a factor of safety of two, since the bearing pressure on the natural soil beneath the blanket is reduced, due to the distribution of toe pressures by the blanket.

The possibility of a slide failure occurring beneath the caisson was investigated. It was found that the most critical slide surface is the one that passes closest to the base of the wharf. The high shearing resistance of the gravel and rock blanket lowers the slide surface and increases the safety factor to something over two, which is sufficient.

The function of the blanket is to distribute the load to the underlying soil and to help prevent sand boils and piping under the caisson when the tide is ebbing. The soil tests indicate that the underlying soil below the blanket is sufficiently dense and has sufficient bearing capacity to make further foundation provisions unnecessary.

The material for the main body of the blanket was specified to be composed of particles up to 4-inch size, with no more than 10 per cent passing the No. 30 sieve. Crushed stone would have been the ideal material for the blanket, because of the mechanical interlocking of the angular particles. As suitable rock was scarce and costly, this specification was revised and the blanket is composed chiefly of gravel with particles up to 6-inch maximum, for the lower three-foot thickness, but for the upper one-foot thickness not to exceed 4-inch maximum. The upper two to three feet of fill immediately under the caisson was composed of crushed stone.

The blanket material was placed by direct dumping and high spots leveled off by means of a drag with a variation of about ±3 inches.

#### Casting Basin Construction

Possible construction methods for the caissons were discussed for different launching schemes, such as inclined launching ways, rigid barges, graving basin and drydock.

A sectional timber drydock was available at Prince Rupert, 150 miles away. In addition to the towing hazard down the coast, there was the problem of preventing any movement of the drydock while the concrete was being placed, and until it attained substantial strength. Rigid barges could have been used as drydocks. Launching could have been done by grounding them at low tide, filling with water and utilizing the rising tide to float off the caisson. It was not practical to use this method for 250-foot long sections. Using inclined launching ways was not desirable, as this method would involve special stress and stability problems and would require extreme care to avoid difficulties. The cost of this method, because of the length of pile supported ways, would be greater than that of other methods. Launching the caissons in a graving dock was considered to be the safest and simplest of the methods and was finally adopted. This method is particularly adaptable to units of great length and width.

Adjacent to the wharf site was an area large enough to accommodate the three caissons in a basin as shown in Fig. 79. Existing ground was a little above low tide level. Natural soil was not impervious enough for a completely water-tight dike around the basins, but with the bottom a few feet below low tide, full head would be against it only part of the day. No serious damage could result from a try, so part of the necessary excavation was

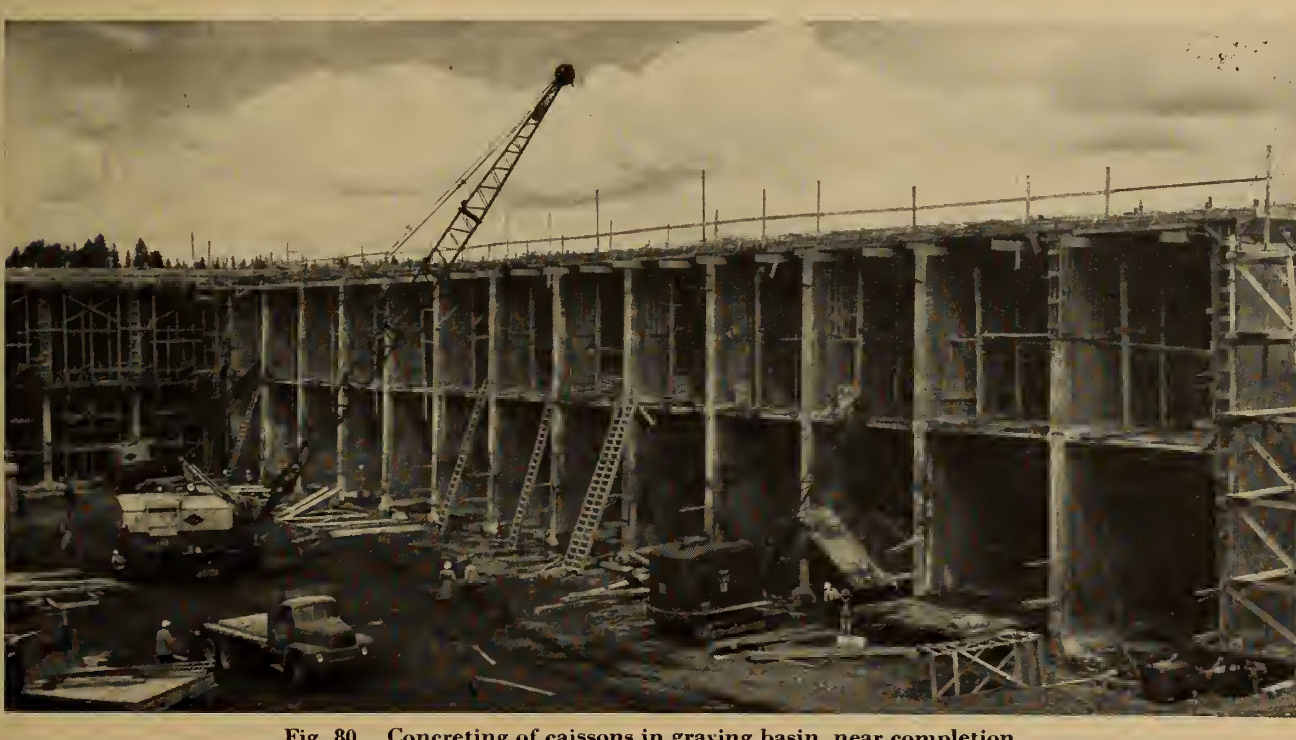

**Fig. 80. Concreting of caissons in graving basin, near completion.**

Fig. 81. Caissons ready for launching, bulkheads, ladders, lighting plants, etc., all in place.

removed by drag-lines and bulldozed into dikes to form the basin walls. These dikes were reasonably satisfactory after the outer slopes had been sanded to reduce leakage. Timber sheet piling was also considered to aid in reducing leakage, but it was impossible to drive it into the fill.

The consulting engineers had figured that if the caissons were cast in an upright position, a draft of 30 feet would be required to float them. This would have required a deep and costly casting basin. By casting the caissons on their sides, a draft of approximately 19 feet would be required, so this method was adopted. They also advised that an additional two feet of depth be provided as a safety margin. The casting basin floor had, therefore, to be at least 21 feet below mean high tide level during the period when the caissons were expected to be floated. Available information indicated that mean high tide level during a seven-day high-tide period would be at approximately El. +17. Thus, the top of the finished casting floor was established at El. —4.

The casting basin floor was approximately 260 feet wide by 330 feet long in the north-south direction. There was a berm about 20 feet wide at El. +8 around the basin, used as a roadway, with a ramp to the basin floor in the center of the south end. A ramp ran from the berm to the top of the dike at about El. +25 at each of the south corners. The basin was drained by a timber sheeted ditch around the edges connected with sumps. In addition, there was a well point system with headers at El. +8. Maximum seepage was estimated at about 4,000 gpm.

The caissons were arranged in the form of the letter U with one caisson at the north end of the basin, running east and west, to form the bottom of the letter, and one caisson along each of the east and west sides of the basin, running north and south, and forming the sides of the letter. The caisson edge was only five to six feet from the inside toe of the basin dike on all sides.

#### Construction of Caissons

The casting basin was completed, the floor leveled and the first formwork for the caissons was started on February 1, 1953. Forms had been prefabricated as far as possible while the casting basin was being completed. The first concrete was poured in the east caisson on February 20; in the west caisson on February 24, and in the north caisson on February 27.

The concreting of each cell was carried out in five different lifts. The back slabs of the cells rested directly on the floor of the casting basin. The lower sections of the diaphragm cross walls and ends were then poured; next, the longitudinal diaphragm; next, the upper sections of the diaphragm cross walls and ends, and then the top slab, which is the exterior wall of the caisson in its final position. This method of pouring was adopted so that full control of the pouring and finishing of the critical outside face wall could be done under ideal conditions.

It is known that an imperfection in the original concrete surface of a structure exposed to sea water action is the first point of attack or disintegration. It is expected that the pouring method adopted will minimize this possibility of failure.

Transit-mix trucks and dumpcretes were used to haul concrete from the central batching and mixing plant to hoppers on the bank of the casting basin. From these hoppers, power and hand buggies carried the concrete to the forms over a system of runways about five feet above the level of the slab being poured. Cranes and buckets were also used to handle some of

Fig. 82. The dikes breached and the caissons floating on their sides.

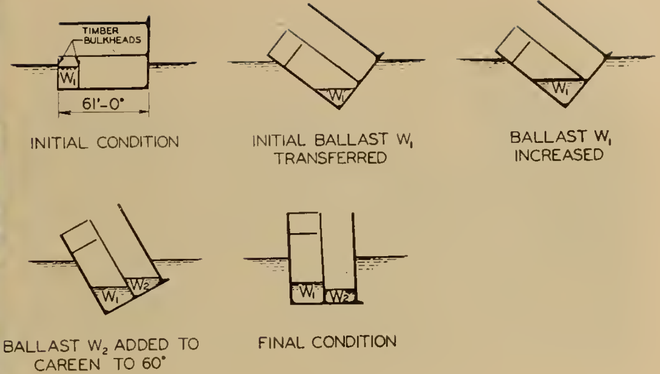

**Fig. 85. Careening a caisson.**

**Fig. 84. (Left)—The caissons in place and the third being careened into place.**

the concrete for the top pours. Each pour was a continuous operation. Figure 80 shows the caisson construction near completion with some of the forms removed.

Concrete was placed in the lower half of the cross walls and ends by means of elephant trunks and pockets in the sides of the forms. The remainder of the walls were filled by dumping into the top of the form. Particular attention was given to vibration and a plastic mix was used to avoid honeycombing, but some did occur in the first pours. These areas were repaired by first chipping out the defective concrete and then filling the voids with gunite.

The concrete for the east caisson was completed on April 11, 1953, for the west caisson on April 13, and for the north caisson on April 15. There was a total of 10,715 cu. yd. of concrete in the caissons.

The concreting was carried out in fairly cold weather, but all concrete was kept under specified curing conditions with the aid of oil salamanders and steam heating. The caissons were totally enclosed by tarpaulins. The temperature of the concrete delivered to the site varied from 63°F. to 72°F. with an average of about 65°F.

Type II cement was specified for this concrete because of its high sulphate resistance. The aggregates were natural sand and screened gravel graded to specified limits. The water-cement ratio was specified to be not greater than 0.50 by weight. An air entraining agent was used to achieve a final air content of 4 to 6 per cent in the fraction of the mix below 1½ inch size. A plasticizer was also used to aid in securing a very dense concrete.

The caissons were designed on the basis of 3,000-pound concrete. The mix was designed to give as high a grade of concrete as possible, because durability was superior to all other requirements. The ultimate strength of the concrete averaged about 2,200 to 2,400 lb. per sq. in. at three days; 3,600 to 4,000 lb. per sq. in. at seven days, and 5,100 to 5,900 lb. per sq. in. at twenty-eight days.

In order to float the caissons for launching, it was necessary to close the lower cell openings with temporary bulkheads. Figure 81 shows this work completed. These bulkheads were prefabricated and erected after the caisson forms had been removed. They were faced with canvas to improve their watertightness, and all gaps where the timber did not fit the concrete walls were caulked with grout.

#### Preparation for Launching

Figure 81 also shows the installation of ladders, gauges, catwalks, etc., completed on all three caissons. A lighting plant was installed in slings on each caisson. The discharge manifold, to be used when pumping water ballast into the cells, was installed on each caisson. Mooring and fendering facilities inside the graving dock were installed in accordance with recommendations of the consultants. The bottom of the graving dock was graded to El. —4 and all debris removed ready for launching.

On Friday, May 8, the drainage pumps were shut off and removed from the graving dock in final preparation for the trial launching scheduled for Saturday, May 9. On Saturday, May 9, flood gates in the south dike of the graving basin

**Fig. 86. Placing the sand filter blanket behind the caissons.**

Fig. 87. Looking south along wharf, backfill completed.

were opened and the water level in the basin was allowed to rise with the tide. Considerable leakage through the timber bulkheads became apparent and caulking was started immediately on the east and west caissons. Suitable 1½- and 2-inch pumps were brought in and one pump was placed in every cell of each caisson. It was found that one pump per cell was not sufficient to dry all three caissons quickly enough, so all valves in the north caisson were opened and it was allowed to rest on the bottom until the other two were ready for towing from the basin.

As soon as the flood gates were opened, work was commenced on cutting a channel through the south dike. Two carryalls, four bull-dozers and three 2½-yard draglines worked continuously from Saturday morning until Monday afternoon, May 11. The dike was breached at 11.00 a.m. on Monday, shortly after the carryalls stopped work. Figure 82 shows the dike breached and the caissons floating inside the casting basin. The three draglines continued widening and deepening the cut until just before the last two caissons were towed from the dock. The dredge was also used to remove high sections in the central portion of the breach, which the draglines could not reach.

The trial launching of the east and west caissons was carried out on Monday morning shortly after the dike had been breached. Both caissons floated with characteristics very close to those calculated. Both floated and grounded on each tide cycle thereafter until they were towed from the basin.

At 1:00 a.m., Wednesday, May 13, the west caisson was towed from the graving dock into the dredged harbour. Two 400 h.p. tugs were used for this work. The weather was clear, the sea was dead calm and this caisson was towed to the south end of the permanent wharf site and moored. The water in the ballast tanks was then transferred to the back cells to careen the caisson partially and to lift the timber bulkhead out of water. All but three pumps were then removed and set up aboard the north caisson.

Figure 83 is a general view of the wharf site looking west and showing the first caisson removed from the casting basin and anchored in a partially careened position, and the two remaining caissons still in the casting basin.

At 2:00 a.m., Thursday, May 14, an attempt was made to tow the east caisson out of the graving dock. It was first shifted straight west from the east side of the graving dock to the channel entrance. Then as the tug started moving the caisson southward, it grounded on the east side of the channel and had to be pulled back into the graving dock. By the time these operations had been completed, the peak of the tide was past, and it was necessary to moor the caisson in the graving dock until the next suitable tide. At 1:30 a.m., Friday, May 15, it was finally towed out of the graving dock.

While the east caisson was being towed into deep water, lines were run from the north caisson to tractors on the shore, which turned the caisson in the basin. The east caisson was left in deep water and at 3:00 a.m., the tugs came back for the north caisson and towed it through the channel into the dredged harbour. Driving the temporary mooring dolphins on the east side of the ship channel was completed on Sunday, May 17. All three caissons were moored to these dolphins and remained there until grading of the foundation blanket was completed. Placing and grading this blanket was completed on Thursday, May 28.

On Friday, May 29, Caisson No. 1 was moved from its temporary mooring on the east side of the ship channel to its final location and careened to its upright position. At approximately 7:00 a.m., Friday, the tugs started moving the caisson to its final location. This operation was completed without incident and at 9:12 a.m., pumping into the lower cells was started. This continued until 11:13 a.m., at which time pumping into the upper cells commenced. At 4:30 p.m., the caisson had reached the upright position and the pumps were temporarily shut off. Additional water was pumped into the caisson to increase its draft so that it would rest on the bottom at low tide Saturday morning at about 9:00 a.m. During the careening operation, the caisson was held in position by the two tugs and mooring lines to dolphins and to tractors on shore. The pumps used were mounted on a scow alongside the east side of the caisson.

Caisson No. 2 was moved from the east side of the ship channel to its final location on Saturday afternoon, was careened during the night and set on the bottom at approximately 7:00 a.m., Sunday, May 31.

Caisson No. 3 was moved to its final location on Sunday morning, May 31, and careened during the day. It was set on the bottom at 8:30 a.m., Monday morning, but failure of a winch on one of the holding tugs at a crucial moment allowed the caisson to settle off position. The caisson was refloated on a rising tide and placed on the bottom again at approximately 7:00 p.m. Figure 84 is a view looking south along the wharf showing Caissons Nos. 1 and 2 landed in their final position, and No. 3 just being careened.

The maximum deviations of the actual front faces of the caisson from the design location of the front face are 0.08 feet east and 0.48 feet west. Caisson No. 1 is located 2.17 feet north of the design location. The space between the exterior end walls of Caissons Nos. 1 and 2 is 4.06 feet, thus making Caisson No. 2, 3.11 feet north of the design location. The space between the exterior end walls of Caissons Nos. 2 and 3 is 5.93 feet, thus making Caisson No. 3, 2.18 feet north of the design location. These figures indicate that the entire wharf is 2.17 feet north of its design location.

Stripping of the bulkheads and removal of the equipment from the caissons commenced as soon as they had been placed.

#### Description of Careening Procedure

A brief description of the careening procedure should be of interest. This was worked out in detail by the consulting engineers, who have had extensive experience with floating drydock structures. Figure 85 is a sketch showing the various stages of the careening operation.

In the first view of the sketch the initial condition of the caisson in its floating position is shown. By putting two temporary timber bulkheads at and near the open end of the caisson, it could be properly ballasted with water to float level for removal from the casting basin. This ballast was necessary to counterbalance the weight of the bottom slab or the closed end of the caisson. After the caisson had been towed to deep water, the water ballast was transferred as shown in the second view of the sketch.

A six-inch pump lifted water to the top of the caisson where a full length pipe header with 1-inch valves in each compartment made control of ballast water for sinking easy. Filling by gravity through valves in the bottom of the caissons could have been used, but it gives less positive control of the operation.

With the caisson partly careened by permitting the original ballast water to flow to the bottom, the pumps were used to add water in the same compartment to sink the low edge to about 36-foot draft as shown in the third view of the sketch. This was necessary to insure stability in the final upright position. Water levels in adjacent compartments were kept within a foot of each other and trim of the caisson was held within a foot for its full length. Next, water was pumped into the upper compartments to bring the caisson vertical at 33 feet draft as shown in the fourth view of the sketch.

About an hour before low tide, the caisson was accurately positioned and evenly ballasted. Ballast was then added to increase the draft to about one foot greater than the depth of water predicted at low tide. As the tide ebbed the caisson settled on the bottom; plugs in weepholes below water level were knocked out and water pumped in from the top to fill the caissons ahcad of the rising tide. If final positioning was not accurate, as was the case with Caisson No. 3, the water was pumped out and the caisson allowed to be lifted by the tide and positioned again.

The filling of the caissons was started as soon as possible after their being finally positioned. The type of fill material has already been described. Mine side dump cars were used at first until the fill was brought up to an elevation where motor trucks could be used.

Figurc 86 shows the placing of the sand filter blanket over the rock backfill behind the caissons. The remaining area behind the caissons was then completely filled by material placed hydraulically from the dredge.

Figure 87 is a view looking south along the wharf showing the cell filling and backfill nearly completed. The projecting reinforcing bars for anchoring the coping wall and unloading tower track beams to the cells can also be seen.

Figure 88 is an aerial view looking over the completed wharf. The casting basin where the caissons were constructed can be seen to the right. Looking closely, a shadow in the water shows the dredged approach channel leading to the wharf site through the tidal flats from deep water. The mountains surrounding the plant site can also be seen in the background.

#### Acknowledgments

The general arrangement and preliminary design of the wharf caissons, as well as full launching and careening details was carried out by the consulting engineers, Frederic R. Harris, Inc., of New York and Toronto, for whom C. J. Murphy and L. G. VanHouten were the project engineers.

The final design and detail construction drawings were prepared under the author's general direction by the General Engineering Department staff of the Aluminum Company of Canada, Limited. J. F. Braun, M.E.I.C., assistant chief engineer, R. F. Ogilvy, M.E.I.C., project engineer, and Viggo Andersen, M.E.I.C., senior concrete design engineer, directed this work in detail.

The contractor for this work was Kitimat Constructors, a joint venture of several British Columbia contractors, for whom H. M. Whiting was project manager. √

*Consulting Engineer, C. F. Ripley and Associates, Vancouver*

This paper, which was presented at the Annual Meeting in Quebec in May, 1954, describes the soil tests and studies required to foretell the settlement behaviour of the 44-acre fill, up to 30 feet deep, on which the great aluminum plant at Kitimat is founded. It also outlines the methods adopted to compensate for the inevitable settlement which took place during construction and which will continue for an unpredictable period.

The smelter site at Kitimat is underlaid by sedimentary deposits varying in depth to a maximum of 350 feet. They are of a complex nature including sand, gravel, silt and marine clays. The necessity of using a fill varying in depth to a maximum of 30 feet and covering an area 1200 feet by 1600 feet in order to raise the site to a working level presented major problems in the forecasting of the amount and rate of settlement below the fill in the irregular natural soil deposits. Based on preliminary soil investigations it was estimated that the maximum settlement would be about 18 inches and that the major portion of the settlement would be complete within a period of a few months after placing of the fill.

However, in view of the wide variation in subsoil conditions a series of settlement gauges was installed over the area of the site to permit irregularities in the amount and rate of settlement as compared to the forecasted values to be determined. The data from these showed the rate of settlement to be proceeding at a somewhat lower rate than anticipated and that the maximum estimated settlement would be exceeded in certain areas.

The settlement data were used to adjust the elevations of the building elements so that future settlements should not result in certain critical tolerances set by plant operation requirements being exceeded.

The discussion of the problems and their solution is given in chronological order. It is hoped that it will permit a clearer understanding of the reasons for the procedures which were followed.

### Geology

The geological conditions of Kitimat are typical of the coastline of British Columbia at the heads of

C. F. Ripley, M.E.I.C.

R. M. Hardy, M.E.I.C.

the many inlets or fjord channels. Kitimat Arm is about 2 miles wide at the mouth of the Kitimat River. The mountain slopes rise steeply from the shore line providing practically no space for habitation. It is thought that the upper end of the fjord now occupied by the Kitimat River was filled with sediments during glacial and interglacial periods of the Pleistocene age. The Kitimat River is entrenched in these sediments and flows southward, emptying into Douglas Channel at Kitimat. A high ridge across the valley about three miles upstream from the smelter site appears to mark the terminus of the sediments of one glacial period. From the ridge northward the general land area is from 300 to 500 feet above present sea level. Southward of the ridge the land surface drops off rapidly to the tidal flats of the Kitimat River delta on which the plant is located. Beneath the smelter site the thickness of sediments above bedrock varies to a maximum of 350 feet. The geology of the sediments is complex because they include alluvial fan deposits of sand and gravel laid down by Moore and Anderson Creeks and by the Kitimat River, deltaic sand silt deposits brought in by the Kitimat River, and marine clays, all interlaid in an irregular manner. Thus, the subsoil profile varies considerably from point to point below the delta area.

#### Foundation Investigations

Foundation investigations were commenced at the site immediately after the establishment of a beach head construction camp. At this time, however, the exact locations of the dock and smelter sites had not been chosen. The initial boring, sampling and laboratory testing program was therefore planned to assess the general nature of the subsoil conditions over an extensive area around the head of the channel.

At that time access to and around the site with drilling equipment was difficult except on the water, because of the heavy forest growth and the large number of drainage channels. The first series of test holes of the initial program included 12 churn drill holes and nine wash bore holes made with a portable diamond drill rig. These were put down on the tidal flat near the shore line. Access to these test holes was by water. A second series of test holes of the initial program was undertaken farther inland as access facilities improved. This consisted of a grid on a spacing of about 500 feet each way, extending northward from Moore Creek. Holes varied in depth to a maximum of 200 feet. Only those close to the west shore line reached bedrock. About 80 holes were drilled in these programs.

During the following two years, subsequent drilling programs were undertaken at the dock and plant site areas for the purpose of obtaining more detailed subsoil information at specific locations after the general plant layout had been determined. The location of all test holes are shown in Figure 89. The log of one of the test holes, typical of the later ones, is shown in Figure 90.

In the initial program, most of the samples obtained were of the disturbed type and were primarily for the purpose of identifying the general nature of the subsoil. In addition, however, some 35 undisturbed samples were recovered for the purpose of obtaining quantitative data on the physical properties of the subsoil strata. Penetration resistance data were recorded and a few pile loading tests were made in the Bay area.

#### Subsoil Conditions

The preliminary investigation indicated a wide range of soil types, from gravels through sands and silts to silty clays. Silt is predominant in the profiles. The sands and gravels are of low to medium density as determined by the results of the penetration resistance data. Over the tidal flat and in the forested area highly organic material occurred to depths ranging from about two feet to as much as 20 feet, with the material frequently being interlaid in pockets with gravel and silt. Many logs and stumps were found at shallow depths. Generalized subsoil profiles are shown in Figure 91.

Soil tests on samples from the preliminary borings showed natural moisture contents of the silts and clays ranging from 15 to 36 per cent. The liquid limits of the clays and silty clays ranged from 32 to 27 and the plastic limits from 22 to 19. In general, the silts were nonplastic, but contained some organic matter. The compressive indices of the fine grained soils ranged from 0.06 to 0.20.

#### Plant Foundation Type

The final locations of the dock and plant sites were made late in 1951. The finished grade of the smelter area was chosen to prevent flooding by tides and by mountain freshets from Moore and Anderson Creeks. This required the placement of a fill over the smelter site area, ranging in thickness from zero to 30 feet. The only alternative was to move the site to higher ground away from the shore line. This would have resulted in increased costs in handling all materials entering and leaving the plant from the dock. Moreover, the deep fill presented some advantages in eliminating irregular settlement in the organic material underlying the area at shallow depths.

The dimensions of the area to be filled were 1,600 by 1,200 feet, with a total volume of 1.8 million cu. yd. and a total weight of over 3 million tons. The intensity of net loading ranged from 0.2 to 2.0 tons per sq. foot. The distribution of the total loading, including building and fill, is shown in Figure 92. The average building load applied over the area of the buildings is of the order of 0.25 ton per sq. ft, which constitutes only a small fraction of the total loading of the fill itself.

**Fig. 89. The smelter site showing location of test holes.**

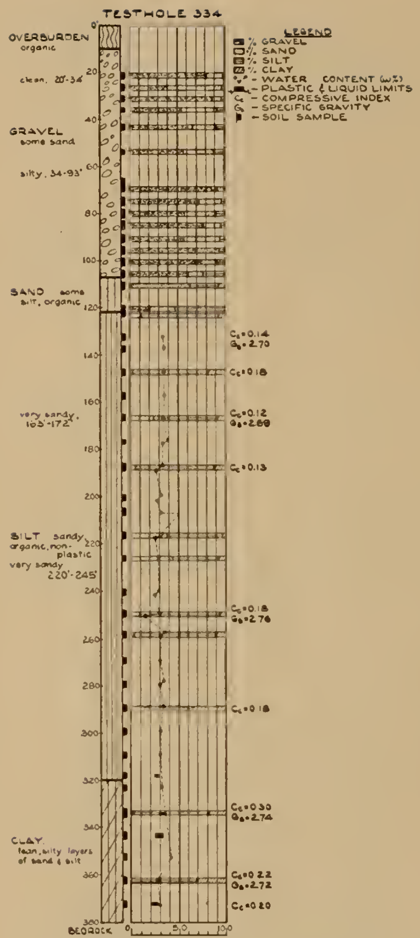

Fig. 90. Log of a typical test hole.

The calculation of the amount and rate of consolidation involved the computation of the stress distribution in the soil below the applied load and a knowledge of the compressibility of the underlying soil strata and of the position of porous strata in the profile. The Boussinesq equations[1] were used to estimate the stresses in the soil. Laboratory consolidation tests[1] on undisturbed soil samples from which pressure-voids ratio and time curves are obtained, were used to determine the compressibility characteristics of the soil.

The calculation of settlements by this procedure has proved to be reasonably accurate where a single layer of fairly uniform, highly compressible soil occurs, so that most of the settlement takes place in this one layer. As the soil profile over a site becomes less uniform and the number of soil strata in which appreciable consolidation will occur increases, the mathematical analysis becomes more difficult and the accuracy of the predictions decreases, particularly with respect to the rate of settlement.

The laboratory tests on soil samples from the preliminary investigation indicated comparatively low compressibility characteristics for the subsoil strata. A measure of the compressibility of a soil is the "compressive index." This is a coefficient obtained from a laboratory consolidation test. Ordinary building loads would not produce appreciable consolidation in materials with compressive indices of the order of magnitude obtained from the Kitimat samples.

However, to appreciate the settlement problem at the Kitimat site an understanding of the nature of the stress distribution below a loaded area is necessary. An area 1,200 by 1,600 feet is loaded and the depth to bedrock beneath the site is as much as 350 feet. At this depth the principal compressive stress below the center of the loaded area would be about 95 per cent, and below a corner 25 per cent, of the intensity of the surface loading. This signifies that appreciable settlements are induced throughout the entire thickness of compressible sediments above bedrock by the applied fill load. By comparison for a loaded area of say 100 by 150 feet, significant settlements would be induced within the upper 150 feet of compressible soil only. Thus the effect of the comparatively large

[1]Taylor; Fundamentals of Soil Mechanics, Chap. 10, p. 208 and Chap. 11, p. 250; Wiley; 1948.

A compacted granular fill was selected for the site of Potlines 1 and 2 because of the availability of excellent material and because of its good drainage characteristics under the wet climatic conditions at Kitimat. This compacted gravel fill was considered to be a suitable pad on which to carry the plant buildings on spread footings.

### Process of Consolidation

The hazard in the use of the fill was the magnitude and rate of settlement which would occur in the underlying soil during the process of consolidation under the weight of the fill. This process involves slow settlement, which may extend over months or years in saturated silt or clay soil types as the water is slowly squeezed out of the soil by superimposed loads on the soil mass. During this process the water in the soil is under a gradually decreasing excess hydrostatic pressure. The rate of consolidation is a function of the permeability of the soil and of the distance that the water must move through the consolidating soil to reach a more permeable layer, such as a sand or gravel stratum.

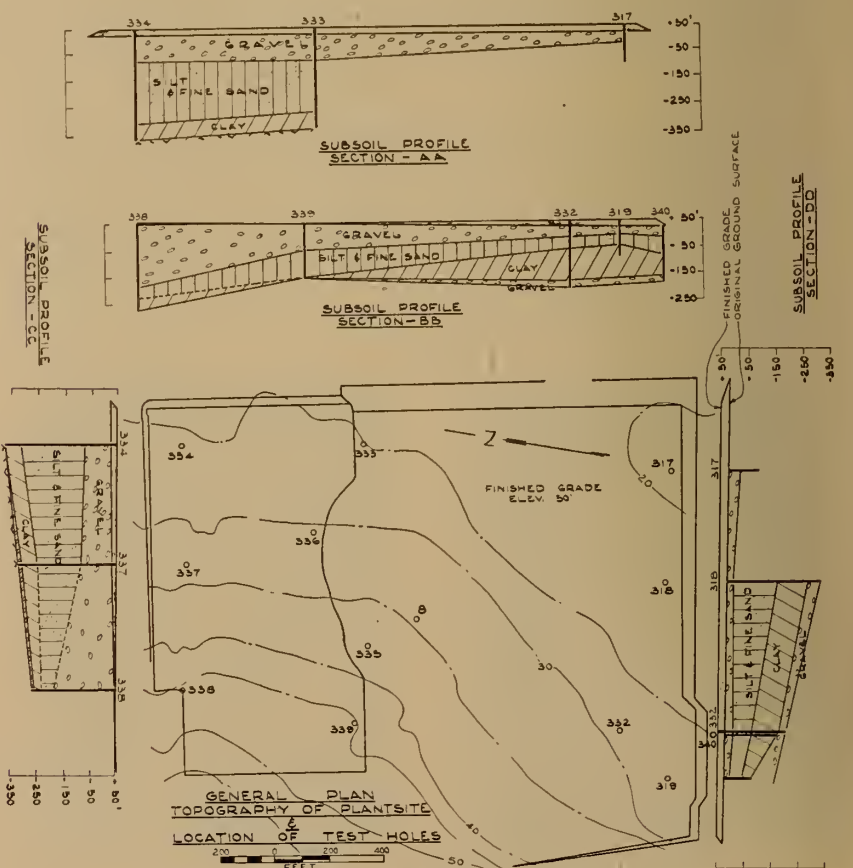

Fig. 91. Generalized soil profiles.

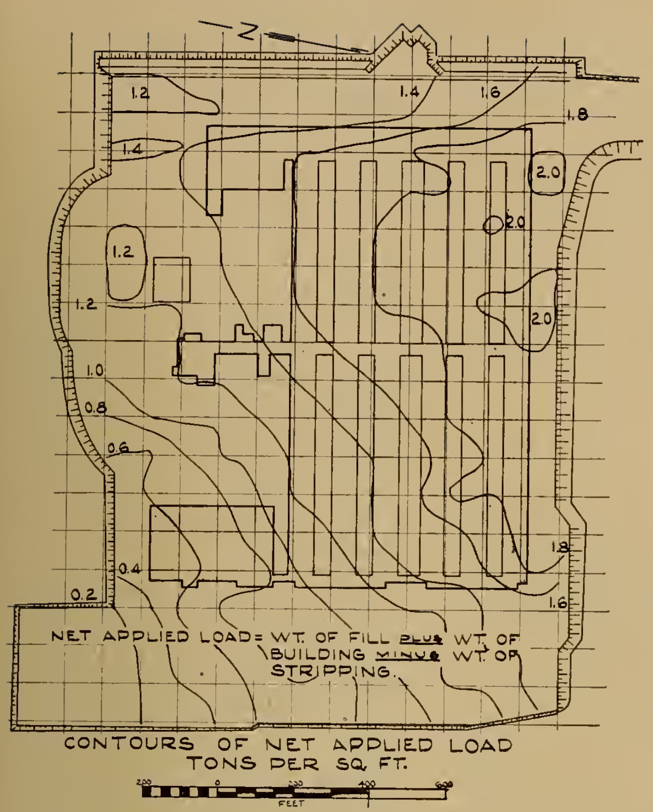

**Fig. 92. Distribution of loads over plant site area for Potlines 1 and 2**

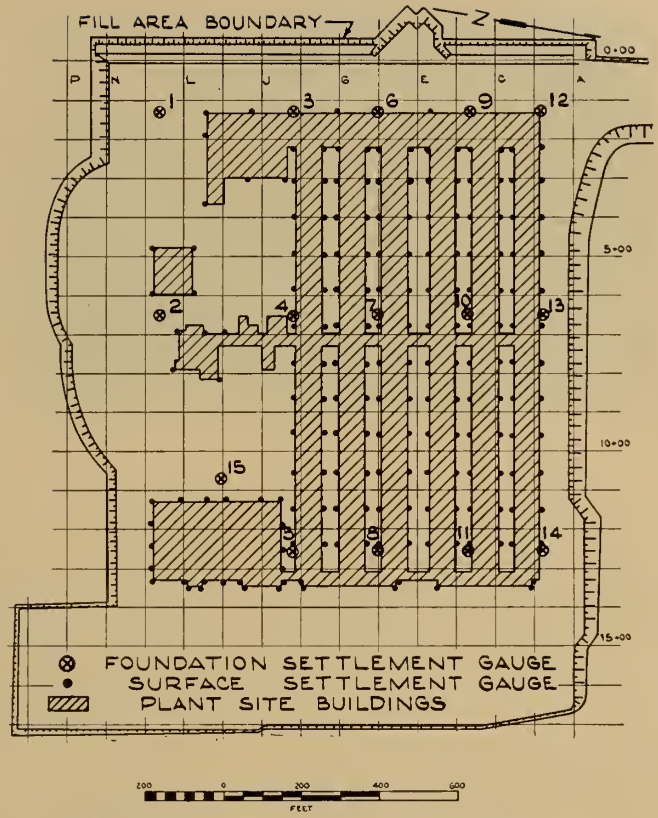

**Fig. 93. Plan showing location of settlement gauges.**

loaded area is to produce high stresses for the full depth to rock, and therefore even with relatively low values of compressive index, the total amount of settlement can be high.

### Estimated Settlements

On the basis of the compressibility characteristics of the soil samples from the preliminary foundation investigations, it was estimated that the maximum settlement below the fill due to consolidation would be about 18 inches, and that the rate of consolidation would be such that about one-third of the total would take place during the placing of the fill and another third within one month after the fill was placed. With these magnitudes and rates of settlement, it was considered that the differential settlements over the area of the fill would not be great enough to cause damage to buildings or to affect adversely the operating conditions for the plant.

### Settlement Gauges

However, it was realized that the soil profile was irregular and that the depth to bedrock probably varied considerably over the area of the fill. For these reasons it was decided to place a series of settlement gauges based at the bottom of the fill and distributed in a regular pattern over the building area, so that the actual settlement behaviour of the area under load could be observed. These observations would permit a correlation with the theoretical analysis to be made and would provide a basis for adjustment during construction to accommodate the actual settlement pattern.

Subsequent to the initial theoretical analysis outlined above, additional soil test results became available from test holes which were put down at the dock and smelter sites during later stages of investigation. These latter data were used for verification of the original analysis, which had been based on the results of the preliminary investigation.

The settlement gauges were three-foot square timber platforms set at the level of the stripping prior to the placing of fill. Pipe extensions were connected to the centre of the platforms and additional lengths were added as the fill was built up. Later, as buildings were erected, 190 settlement plugs were set in the building foundations. A plan of the building area showing location of the settlement gauges is shown in Figure 93. All settlement readings are referenced to a permanent bench mark set in rock adjacent to the site.

### Compacted Granular Fill

The granular fill material was obtained from the Sandhill borrow pit located about three miles north of the smelter site. A view of the face of this pit is shown in Figure 94. The material consisted of an exceptionally well graded and clean gravel-sand. The range in its grain size distribution is shown in Figure 95.

The compacted gravel fill was placed in the summer and fall of 1952. Placement of fill materials was preceded by stripping of surface organic deposits overlying the site. The depth of stripping ranged from three to 15 feet. The granular fill was truck-hauled to the site. An initial base layer of about three feet thickness was placed on the stripped base to provide a stable surface for support of the construction vehicles. Subsequently, the fill was placed in six-inch layers and compacted with four passes of a 50-ton pneumatic tired roller. This particular layer thickness was adopted for reasons of maximum efficiency of travel and dumping of the hauling vehicles, rather than as being necessary for attainment of the specified density. A view of the typical fill operation is shown in Figure 96.

Fig. 94. "Sandhill" gravel pit.

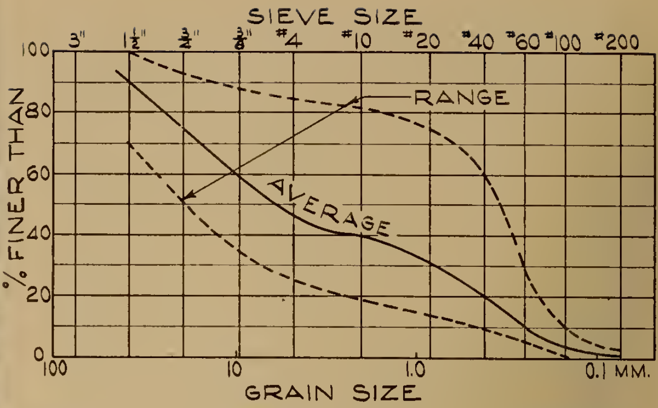

Fig. 95. Range of grain size distribution. Sandhill pit material.

#### Inspection of Fill Placement

Close inspection of the fill operation was maintained to assure proper selection of material and uniformity of compaction for the entire fill. Compaction tests and grain-size tests were made at a field laboratory set up on the site. Both standard Proctor compaction tests and relative density tests were used for control purposes. Due to the lack of fines, the material was not sensitive to changes in moisture content and therefore did not exhibit an optimum moisture content. The density of the compacted fill was determined by in-place field density tests. Dry densities ranging from 130 to 140 lb. per cu. ft. were obtained. These densities corresponded to an average of 97 per cent of standard Proctor optimum density and 95 per cent of maximum density.

A significant property of the granular fill material was its ease of placement under the wet climatic conditions which occur at Kitimat. The fill operation was not stopped at any time by wet weather. Under extreme conditions, the operations were carried on during periods of five inches of rainfall in three days. The fill is of exceptionally high quality. It can be excavated on vertical faces to depths of 10 feet. A view of excavation in the compacted granular fill is shown in Figure 97. No measurable settlement has occurred within the fill.

#### Settlement Records

The observed settlements at the foundation gauges proceeded normally during the placement of the fill and in the one-month period following. However, it became apparent that considerable variation in future settlements from point to point over the smelter site area could be expected. Up to December 1, 1952, the average settlement from the 15 gauges was 1.25 feet, with a range of from 0.6 feet to 1.7 feet. It became apparent during the winter of 1952-53 that the settlements were proceeding somewhat more slowly and would be of somewhat greater magnitude than had been estimated on the basis of the original theoretical analysis. While the settlements were not developing strictly in accordance with the estimated values, a fairly definite pattern was apparent from the observations. The general effect of the settlements was a tipping of the surface downwards toward the southwest corner of the building area. Moreover, a trough of maximum settlement appeared to be developing at the southwest corner of the building area and extending diagonally toward the centre of the fill area. However, the differential settlements were transitional and, when spread over the large dimensions of the plant site, were relatively small.

In view of the observed settlements it became necessary in the late fall of 1952 to assess the effects of future settlements on the building construction program and to revise the assessment during the winter of 1952-53 as additional settlement observations became available. All building construction had been put off for a period of one month following completion of the fill in any area in anticipation of the estimated settlements within this period. The concrete footings and substructure for part of the buildings had been poured in the fall of 1952 and the major portion of the building construction program was scheduled for the summer of 1953. It will be appreciated that settlements which occurred prior to the pouring of footings would produce no harmful effects. Moreover, only the differential settlements occurring after the start of building construction would be significant in causing damage to buildings or in affecting operations of the plant.

#### Adjustments During Construction

The soil test data and the settlement observations were carefully analysed during the winter of 1952-53. Additional soil test data indicated the existence of somewhat more highly compressible clay at depths from 100 to 200 feet below the area of maximum settlement and a more granular soil profile below the area of minimum settlement. Otherwise the soil profile beneath the major portion of the site was fairly uniform. Future settlements were extrapolated for several years ahead on the basis of theoretical time-consolidation curves. Certain tolerances were agreed upon for differential settlements throughout the plant from the point of view of satisfactory plant operation. These concerned such factors as the level of the individual smelter pots and the tolerable differential settlements of the crane rails running the 1,200-foot length of the pot-room buildings. From these considerations it was concluded that if the buildings were constructed sufficiently high above their design elevations so that they would settle to a level position as of January 1, 1955, then differential settlements after this date would not exceed the tolerances set for satisfactory plant operations.

This procedure involved setting each column foundation in the plant at an elevation computed from the recorded settlements in the particular area and from the settlements forecast to January 1, 1955. In the potroom buildings there were two points at which further adjustments could be made during construction after the foundations were set, to compensate for inconsistencies which subsequent settlements records revealed. These were at the bases of the steel columns and at the potroom floor slabs. Each individual smelter pot is also being set so as to be level on January 1, 1955. The adjustment required in a pot setting is usually a half-inch or less, but in some cases has been as high as one inch. However, some foundations for the south potline required adjustments of as much as 12 inches.

One of the complicating factors of this procedure was that the building construction period extended over two seasons. The footings of individual buildings and of sections of buildings were constructed at different times, yet all of these had to be set in proper relation to one another and adjusted to compensate for future settlement, which varied from section to section. Had it been possible to build all of the foundations over the entire building area instantaneously, the problem of setting the building levels to compensate for future settlement would have been relatively simple. It was necessary, however, to take into account the settlements in the periods between setting of adjacent sections of footings. This considerably increased the amount of work and computation involved. The full time services of an engineer were required to make the settlement observations and to compute the building level settings and adjustments in accordance with the above procedure.

The adjustment of building levels did not interfere with normal construction to any appreciable extent, except for a few difficulties with the first settings. In fact, in the case of the individual smelter pots it appears to have facilitated their installation.

### Carbon Paste Plant

A special problem arose in connection with the carbon paste plant building. This is located at coordinates (L, 7 + 00) as shown in Figures 99 and 100. One section of the building is only 50 by 60 feet in plan, but is 136 feet high. It is fairly rigid and heavily loaded. It is located in an area of comparatively low settlements, but the settlement records indicated that future movements would tip the building out of plumb across a northeast-southwest diagonal by several inches. The building foundations were therefore adjusted in the opposite direction to compensate for the settlement to the target date of January 1, 1955 and the steel frame was erected out of plumb by 3 inches at the top. Some 150 strain gauges are being set on the steel frame of the building to detect any serious overstressing in the steel work due to nonuniform settlement. If necessary, it will be possible to relieve such stresses by jacking the columns in the building.

No particular difficulty was encountered by the steel erectors in erecting the steel frame out of plumb. In fact they seemed rather to enjoy the operation, perhaps because of its novelty. The building has been completed for about seven months and it has now been rotated by settlements about half way to the level position with no evidence of any damage to the building.

### Magnitudes and Effects of Settlements

Figure 98 shows a typical settlement plot of the readings from one of the foundation settlement gauges. The total settlement of 2.7 feet up to March, 1954, as shown in this figure, was about average, but the

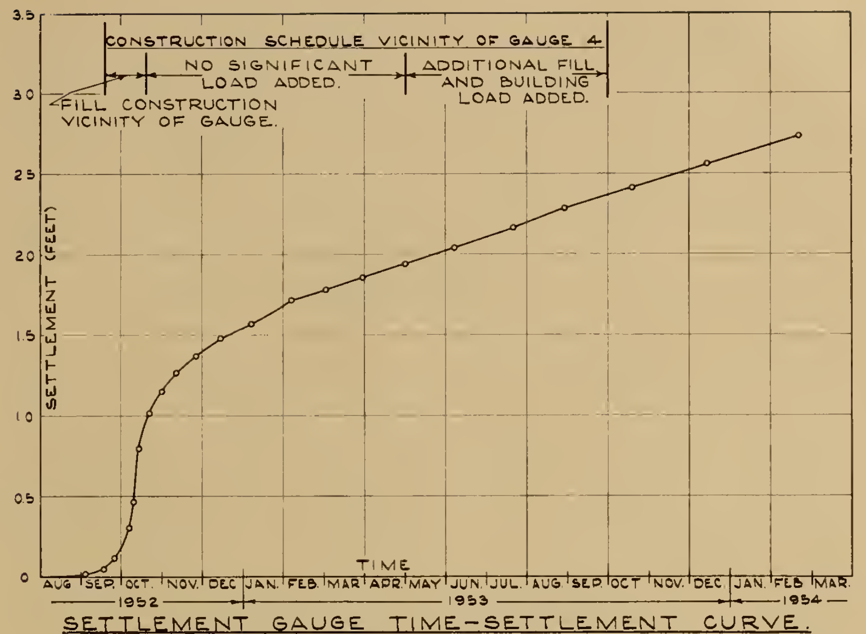

**Fig. 98. Typical settlement plot for one settlement gauge.**

**Fig. 96. (Above) Placing operations for compacted gravel fill.**

**Fig. 97. (Right) Potline looking south. Placing concrete for main air duct entrance to potroom 2C. Excavations for room 2C behind. Footings being poured for room 2A.**

range of total settlements at the various gauges to that date was from 1.2 to 3.6 feet. Of more significance than the plots of total settlements from the start of the fill operation, is the plot of settlement contours over the site during the period from December, 1952, to March, 1954, corresponding to the period since the start of construction of the major portion of the buildings. This plot is shown in Figure 99, and a similar plot for the period of July, 1953 to March, 1954, is shown in Figure 100.

In order to assess the effects of the settlements on the buildings, a program of periodic examination of the buildings has been set up. In general, the sections of the buildings to a height of about 10 feet above ground are of concrete construction. It is to be expected that the effects of settlements on the buildings will be revealed first in these sections of the buildings in the form of cracks. The concrete work in general is of high quality and few cracks have occurred. Records are being kept on those which have developed. Some of these could not possibly be due to differential settlement, but in a few cases they possibly may be. The magnitudes of the cracks which have developed are insignificant with respect to structural damage or unsightliness.

One of the first buildings to be erected is located at the west end of the potroom buildings and within the area of maximum settlement. This building is 250 feet long. Its south end has moved down seven inches relative to its north end, but there is no evidence of structural damage or unsightliness.

### General Considerations

There are many locations in the British Columbia coastal area where similarly irregular subsoil conditions exist and where more highly compressible soils than at Kitimat occur. Foundation settlements associated with fill-loaded areas of large dimensions present a particular problem under the British Columbia coastal conditions. There is a definite economic limit to the extent to which the drilling and laboratory investigations of the subsoil can be justified in establishing the properties and the stratigraphy of the sediments for the purpose of estimating the probable settlement behaviour. Due to the complexity of the geology and the nonuniform deposition of sediments in the coastal terrain, it is doubtful if differential settlements can be accurately predicted from the subsoil investigation alone, regardless of its extent. It is essential, however, to establish the general subsoil conditions, and if these indicate that large settlements are to be expected, then the practical and economical procedure is to assess the magnitudes which can be tolerated and to make provision throughout design and construction to accommodate them. Provision for settlement during construction stages necessitates accurate observation of the settlement pattern. The settlement observations indicate the basis on which the adjustments during construction should be made. The importance of the settlement observations in such cases is paramount and can hardly be overemphasized.

The authors have acted as soil and foundation consultants to the Aluminum Company of Canada. H. G. Dutz, JR.E.I.C., is the resident engineer for the foundation consultants at Kitimat. The contractors are Kitimat Constructors, Ltd.

Engineers of the Aluminum Co. of Canada have contributed materially to the preparation of this paper and to meeting the problems arising from the foundation conditions at the site. √

# Design and Construction of the Kitimat Smelter

*Compiled by the staff of the General Engineering Department, Aluminum Company of Canada, Limited.*

**It is not every day that a large industrial plant is built in the wilds, 500 miles from a base of supply and with only limited transportation facilities. These are among the reasons why readers should find this paper more than ordinarily interesting, describing as it does the design and construction of the Kitimat smelter. The fact that some $5 million worth of construction equipment was used gives some idea of the size of the job.**

The design and construction of a large aluminum smelter at Kitimat presented many problems which would not arise in a conventional industrial area. The location at the head of Douglas Channel is mountainous, heavily timbered and uninhabited except for a few scattered Indian settlements. The only access, for both men and materials, was by air or sea. Thus the original establishment of a beachhead from which to carry out operations was in many ways parallel to a military landing operation.

### Beachhead

Construction commenced during the latter part of March, 1951, when Horie-Latimer Construction Co., Ltd. contracted to build a temporary wharf and scow grid. Construction of the temporary wharf facilities was started before any camps, roads or cleared areas existed. Hence the contractor had to provide a floating pile driving unit, complete with repair shop, accommodation and messing facilities.

The general contractor, Kitimat Constructors, of Vancouver, B.C. chartered a 72-foot coastal boat known as the *Arrowac* and moved into the area on April 16 with 10 men to establish the first beach camp. The first barge, loaded with a bulldozer, small tools, power saws, lighting plant, camp equipment, food supplies, etc., and several prefabricated camp buildings arrived the day after. No docking or unloading facilities were then available. The barge was beached on the tidal flats at high tide, where the bulldozer was unloaded and the materials packed ashore by manpower.

The crew lived aboard the *Arrowac* while a small area was cleared and the first camp buildings erected. Progress was slow, hampered by heavy timber, soggy ground from the spring run-off, and several feet of snow. Fortunately, the contractor was able to bolster his working force by employing Indians from the Kitimat Indian village that lies on the east side of the channel, three miles from the plant site. The first camp buildings were ready for occupancy early in May. Additional forces were brought in by aircraft as quickly as the camp facilities could be expanded. The location of the first camp is shown at D on Figure 101. Figure 102 shows a general view of the camp.

### Temporary Wharf

The temporary wharf was 200 by 60 feet, with a 500- by 20-foot approach section and provided one berth for coastal vessels. The maximum depth of water at low tide was 20 feet. Small freighters having drafts of less than 10 feet could berth on the approach section.

Oil lines were provided on one side of the wharf to discharge fuel to the tank farm nearby. Water lines were provided for fire protection and to supply fresh water to ships and water front equipment.

A scow grid, capable of handling scows up to 120 feet in length with a 50-foot beam and 10-foot draft was built immediately north of the wharf for the off-loading of heavy equipment and supplies.

### Access Roads

Building of access roads over the rugged mountain slopes presented many problems. Not only was the timber heavy and difficult to handle in the rough terrain, which was wet and soft from numerous small mountain streams, but considerable rock and thousands of large tree stumps had to be removed with dynamite. The holes left by blasting filled with water, turning the right-of-way into a sea of mud, bogging down the bulldozers. No gravel deposits existed in the immediate area and a tractor road had to be built two miles north to a deposit near Moore Creek. Heavy equipment moved over the tractor road to the gravel deposit

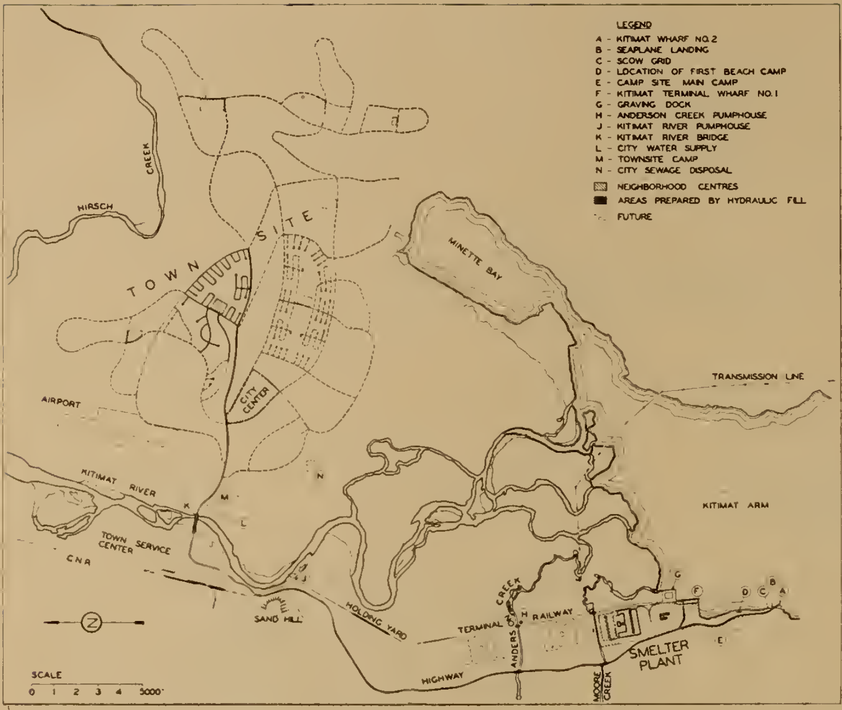

**Fig. 101. General plan of Kitimat area.**

and the construction of roads, preparation of areas for construction buildings, repair shops and permanent camps became possible. Figure 103 shows the construction of a small temporary bridge over one of the small streams. By early December a good tote road had been built four miles up the valley to an excellent supply of gravel. A temporary timber bridge was erected over the Kitimat River and preparations were made to extend the road through to the townsite area.

### Clearing

Clearing operations were slow and costly. Loggers first moved into the area, felled the merchantable timber and moved it out with donkeys and logging arches to where it could be cold decked or transported direct to the saw mill, Figure 104, on logging trucks. The rest of the timber was then felled, bucked up and yarded into huge piles with high lines and burned. Stumps were removed with heavy equipment and stumping powder and piled by cranes.

Burning the green logs and wet stumps was difficult. Picking up the stumps with a crane and dropping them to remove the dirt and mud, careful piling and the use of old tires, fuel oil and blowers to fan the fires produced the best results.

Considerable success was obtained by felling trees into windrows, using a 5-ton steel ball measuring eight feet in diameter, pulled by two large tractors travelling parallel to each other approximately 125 feet apart and several hundred feet in advance of the ball. The felled trees were bunched together as tightly as possible for burning, using several tractors on either side of the windrow. This method was limited to areas where trees did not exceed 12 to 14 inches in diameter after all merchantable timber had been removed. The occasional tree up to 24 inches did not seriously hamper the operation.

### Camps

To complete the first stage of the development at Kitimat on schedule, accommodation for 2,300 men was required. Three camps were established, so men could be housed near the areas in which they were working.

The main camp, established near the smelter site, accommodated 1,000 men and consisted primarily of nine two-story, 72-man bunkhouses. A stern wheeler river boat known as the *Delta King* was purchased, beached on the tidal flats and converted into excellent accommodation for 250 men. One hundred and four temporary houses were erected in the same general camp area for key personnel. A trailer camp was also established for 65 trailers, complete with water, sewerage and power systems.

A second camp for approximately 600 men was established at Anderson Creek, two miles north of the main camp. As road construction and clearing operations for the new townsite got underway, a third camp for 600 men was erected on the east side of the Kitimat River opposite the permanent bridge site. A fourth camp for 500 men was built later to provide additional accommodation for crews working on the housing program.

To provide communications between the various camps, stores, post office, hospital and recreation centre, a regular bus system had to be operated for the convenience of the workmen.

### Shops and Maintenance of Equipment

In order to maintain continuous operation of all equipment and plant, large temporary shops were erected, fully equipped and protected from fire by sprinkler systems and portable fire fighting equipment. Machine work and heavy repairs were carried out in a building 65 by 140 feet. All trucks, busses, jeeps, cars, etc., were maintained in an adjacent building 150 by 100 feet, with spare parts stores on the mezzanine floor. An electrical shop and shops for other trades were all provided in one building 40 by 230 feet. The carpenter shop and saw mill were separate large structures.

### Transport and Handling of Materials and Equipment from Vancouver

Heavy construction and permanent plant equipment and the major part of the building materials were shipped from Vancouver, where large dockside cranes are available for transferring the material and equipment to scows and coastal freighters. The scows were then towed 500 miles up the coast to Kitimat where they were placed on the grid and unloaded.

Some large transformers were shipped direct to Prince Rupert, where the cars and transformers were loaded on a rail barge and towed south to Kitimat. At Kitimat an 85-ton low bed trailer was backed onto the barge. The transformers were jacked up and skidded onto it and hauled to their permanent locations. Unloading of the heavy transformers could only be carried out during low tide periods when the scow was resting solidly on the grid.

Miscellaneous construction material and all foods were brought in by Union and C.P.R. steamship lines and the various coastal freighters.

### Dredging

Providing an access channel to the permanent wharf required the dredging of over three million cubic yards of material from the tidal flat to a minimum elevation of −31. The material ran from silty sand to excellent gravel and was deposited on the tidal flat behind rock moles to provide storage areas and building sites. A 24-inch suction dredge was used, powered by two 2,000 hp. diesel engines. Approximately two and a half million cubic yards of material were deposited in the area south of Potlines 1 and 2 and built up to El. 28.5 or 6.5 feet above high tide.

The building site for Potlines 1 and 2 was filled to grade by gravel hauled in by trucks and consolidated by tractors and 50-ton rollers. However, due to the high cost of preparing building sites thus, it was decided to fill the area for Potrooms 3 and 4 hydraulically. This involved dredging in the harbour area to El. −31, and pumping through 5,700 feet of discharge line to El. 45.5, which required the installation of a booster pump in the discharge line to obtain an economical production rate.

The forest floor and soft silty material was first stripped from the area to be filled. Truck hauled gravel was spread over the area and consolidated to provide a good subbase. The surface was finished on a one per cent slope to a weir, installed in one corner of the area to handle the dredge water. This gradient, which was maintained throughout the dredging operations, kept the water moving at sufficient velocity to carry off all organic material and silt. Figure 105 shows fill being placed in the storage area and tractors being used to compact the gravel.

#### Construction Equipment

Construction equipment required at Kitimat involved an expenditure of approximately $5 million and consisted mainly of the following: 25 cranes, shovels and draglines, 30 bulldozers of various sizes, 82 heavy duty dump trucks, 9 semi trailers, 9 transit mixers, one 6-cubic yard combination mixing and batching plant, 1 aggregate washing and screening plant, 10,000 cubic feet of compressed air capacity, 6,000 kw. of electric power, 43 welding machines and 40 four-wheel drive jeeps and light pick-up trucks.

#### Waterway Improvements

The smelter area is located at the foot of the eastern slope of a mountain range on the west side of Kitimat River. Two mountain streams, Moore and Anderson Creeks, flow down this slope, drop about 100 feet in falls and then continue with decreasing gradient across the plant site and into Kitimat Arm with the Kitimat River as shown by Figure 101. These streams lack natural reservoirs and flash floods occur on them after heavy rainfall and during the spring thaw. In the past, both creeks overflowed their banks due to blockage by fallen trees and other obstructions. While these creeks cross the plant site

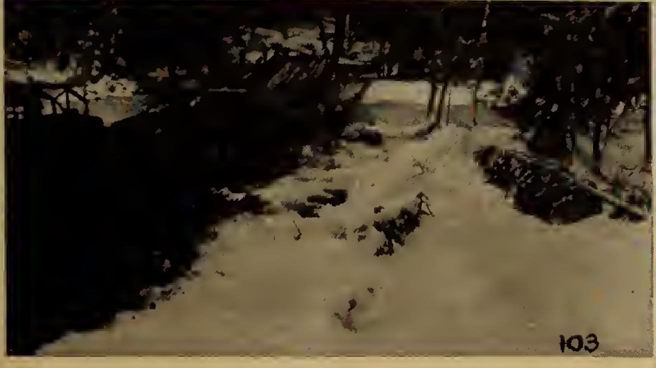
**Fig. 102. First beach camp at low tide, temporary wharf in background.**

**Fig. 103. Construction of a small temporary bridge over one of the numerous small mountain streams.**

**Fig. 104. Sawmill and cold deck. View looking across plant site area.**

**Fig. 105. Bulldozers placing hydraulic fill in storage building area.**

**Fig. 106. Aerial view, showing improved Moore Creek channel crossing plant site area.**



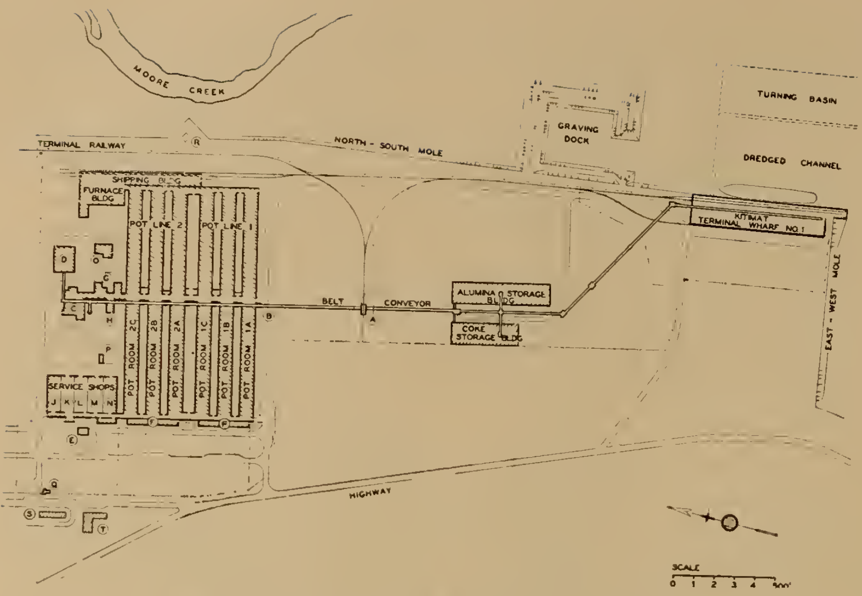


**Fig. 107. Plan of smelter plant and wharf area.**

north of the area under immediate development, their bed levels at the west side of the plant area were higher than the adopted finished grade of the smelter plant. Thus, improvements of the creek channels received considerable study.

Moore Creek, which is approximately 1,000 ft. north of the present smelter plant, crosses the electrical high tension installations, and therefore required complete control. It was necessary to drop the creek channel abruptly in a relatively short distance where it enters the west side of the plant site. This was accomplished by adopting a heavily rip-rapped rapids section 450 feet long on a 6.28 per cent gradient.

In this section, for the designed maximum flow of 3,000 cfs., the width of the channel is 90 feet. At the bottom of this rapids section the flow is controlled by a 50-foot-long cistern and a 90-foot-long convergence into a 40-foot-wide channel with a 0.67 per cent gradient. The improved Moore Creek channel can be seen on Figure 106.

Anderson Creek is approximately three-quarters of a mile north of the present plant and required only partial channel improvement. In spite of a watershed area larger than that of Moore Creek, it was necessary to improve the creek channel only at the two bridges. The upstream section of this creek, at the permanent highway bridge, required realignment and rip-rapping under and upstream of the bridge. The original watercourse remains unchanged from this bridge to within 530 feet of the railway bridge on the terminal railway, where it was necessary to excavate considerably to provide a suitable clearance. The gradient for this channel was established at 2.65 per cent, which necessitated heavy rip-rapping to well beyond the bridge. The excavated gravel material from the channel improvements was used for railway fill.

The studies and design for these waterway improvements were carried out under the direction of Professor Thomas Blench, M.E.I.C., of the civil engineering department, of the University of Alberta, who was retained as consultant.

### Initial Plant Development

The ultimate smelter plant is expected to consist of three groups of smelter or "potline" buildings each containing four potlines. One group will be located south of Moore Creek, another between Moore and Anderson Creeks, and the third group north of Anderson Creek, as shown by Figure 101. The initial plant constructed consists of the southern half of the building group nearest the harbour area and contains Potlines Nos. 1 and 2. In addition the necessary storage buildings, administration buildings and wharf and conveying facilities were included in the initial development.

The area of initial development is shown on Figure 107. The terminal wharf contains ship unloading facilities for the raw materials. A conveyor system delivers these to the storage buildings. Each of the two potlines consists of three separate potroom buildings connected at their ends and centers by passageways. Electrical power for producing aluminum is fed to the west end of the potrooms from the substations and rectifier buildings. Finished aluminum ingots are placed in railway cars in the shipping building, which is immediately adjacent to the furnace or casting building. Auxiliary buildings included in the initial development are located north of the potlines. These include the carbon paste plant for producing electrode and pot lining material; the compressor, boiler, and diesel standby plant buildings; and the necessary service shops required for maintenance.

### Building Concrete Design

The building foundations in the smelter area are spread footings placed on top of the compacted fill with a maximum allowable soil load of 6,000 lb. per sq. ft. The only excavations required were for ducts and pits, etc. After the foundations were in place, fill up to final grade was placed around them.

***Potroom Concrete:*** In the potrooms, Figure 108, concrete is used up to 8 ft. 10 in. above the finished floor to keep all structural steel above the reach of men working around the pots. The concrete columns are

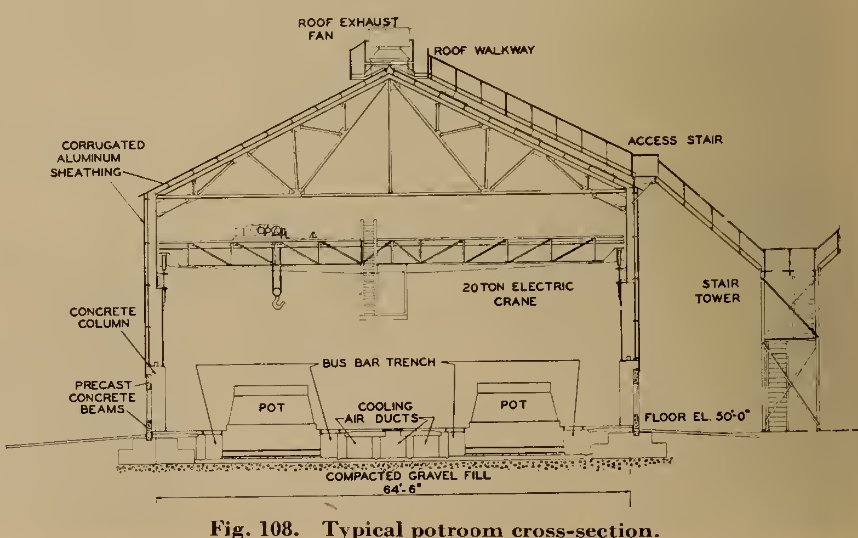

**Fig. 108. Typical potroom cross-section.**

reinforced with vertical steel bars extending into the ground for electrical grounding. The column footings are of plain concrete to prevent disintegration by electrolysis of steel. Between columns, two rows of precast reinforced concrete beams, Figure 109, make up the exterior wall. The lower beams, 2 ft. 10 in. deep by 8 in. wide, were placed on the footings before the columns were poured. The upper beams, 2 ft. deep by 8 in. wide, were placed in seats in the columns after they had been poured and form the lintels over the 19 ft. 6 in. long by 4 ft. 3 in. high openings for the aluminum ventilating doors.

The concrete base floor, 8 in. thick below the pots and 6 in. thick below the air ducts, is placed directly on the compacted fill and is without reinforcing, to prevent stray currents passing between the pots. The pots rest on insulating bricks on this floor. The walls at the sides of the pits and between the air ducts were poured in place. Precast floor slabs with a 6-in. wearing slab form the working floor at the center and side of the building. Removable precast concrete slabs span the pits in which the aluminum bus bars run. The potroom floors are designed to take a 6-ton truck and the passageway building floors to take a semitrailer with a 90-ton load.

***Storage Buildings:*** The alumina and coke storage building foundations are spread footings placed 8 to 10 in. into the hydraulic fill, with allowable soil pressures of 3,500 lb. per sq. ft. The concrete cantilever retaining walls extend to 15 feet above ground and have an expansion joint every 50 feet. These retaining walls are designed to withstand the pressure from stored material at its natural angle of repose. Fig. 110 shows the interior of the alumina storage building. These storage buildings have reinforced concrete reclaiming tunnels below floor level.

The pitch storage building is of similar design, but without tunnels, the walls being designed to resist the pull of reclaiming scrapers.

***Miscellaneous Buildings:*** The conveyor gallery support towers that lie between the storage building area and the smelter area have concrete footings on wood piles. The conveyor galleries have a 2½-in. concrete floor slab.

The two pump houses, the settling basin and the river intake are on spread footing on original soil. A maximum allowable soil pressure of 3,500 lb. per sq. ft. was used.

Among the many concrete structures which may only be mentioned, are foundations for all buildings; foundations for electrical equipment, towers, machinery and tanks; the upper floors in the paste plant; the switch rooms; the wash and locker buildings; the highway bridge over Anderson Creek, which is designed to take 90-ton semitrailer loads; the abutments of both railway bridges; and other miscellaneous structures.

Concrete was specified throughout as 3,000-lb. and a working stress in bending of 1,200 psi. was allowed. Reinforcing steel was specified as structural grade deformed bars and a tensile stress of 18,000 psi. was allowed. Except for these allowable stresses, all concrete design followed the American Concrete Institute *Specification ACI-318-51.*

#### Structural Steel

In general all structural steel was designed in accordance with the American Institute of Steel Construction *Specification for the Design, Fabrication and Erection of Structural Steel for Buildings.* Some modifications to the crane runway horizontal forces were made as noted below.

The most important variations from standard Canadian design practice occur in the assumed snow and earthquake loadings. The snow load was taken as 60 lb. per sq. ft. of horizontal projection for the design of all roof purlins, beams and trusses and 50 lb. per sq. ft. for the design of columns and footings. These loads were reduced in accordance with the National Building Code for all roofs with slopes of 30° or greater.

The earthquake loading for all towers and tanks plus contents was taken as 20 per cent of the vertical load acting in any horizontal direction through the center of gravity of the structure. This is a much higher earthquake factor than is commonly used for this class of structure.

The wind loads listed in the National Buildings Code were used, but were increased by 50 per cent for all conveyor structures and for structures on the wharf. Earthquake and wind loads were not considered to act simultaneously.

The crane loads listed in the A.I.S.C. specification were adopted with the following modifications. The longitudinal horizontal force was doubled for all cranes except the 100-ton electrical repair shop crane. This force was increased to allow for the effect of high speeds on the relatively long runways. The potroom crane runways were also checked for a 50-per cent overload, neglecting impact and horizontal forces, and using a 25-per cent increase in allowable stresses. This overload condition is for pot maintenance only and is not a regular operating condition.

The effect of relatively large foundation settlements required the use of the most flexible type of building frame possible. Buildings were set out allowing for the expected differential settlement, to make the final structure true. Settlement problems also had to be considered in some of the building details. For example, the anchor bolts on most of the crane columns were set with extra projection to allow for possible jacking of the crane runway.

The potroom buildings form a good example of mill type buildings constructed for this plant. (See Figure 108). Six buildings each 64 ft. 6 in. wide and 1,137 feet long were required for Potlines Nos. 1 and 2. The typical bent was made with stepped columns and a Fink type roof truss. This bent was analyzed as a simple structure for vertical loads and as a rigid structure with pinned bases for transverse loads. The pinned bases were used to keep stresses resulting from transverse differential settlement to a minimum. The heavy snow load made it necessary to use a close spacing for the purlins. Sliding type expansion joints were provided in every sixth bay. Figure 111 shows construction of concrete, structural steel and sheeting in progress on the potroom buildings.

The coke, alumina and hard pitch storage buildings have roof trusses designed as three-hinged arches spanning 105 feet, and are spaced at 25 feet center to center. They carry a longitudinal stocking conveyor in the peak. The roof slopes at the angle of repose of the material being stored, as shown by Figure 110.

The conveyor gallery structures presented some interesting design problems. About 4,560 feet of gallery was required. Most of these galleries consist of simple through truss spans about 65 feet long. They have one lateral bracing system located in the plane of the bottom chord. Rigid transverse rings at each panel point resist the lateral wind loads on the walls. Expansion joints are provided by means of pin connected vertical bars.

The total weight of structural steel used throughout the plant amounted to approximately 10,000 tons.

#### Architectural Finish

Aluminum has been employed extensively for the sheathing of the plant buildings. Wherever practic-

**Fig. 109. Precast potroom wall lintels, in place but not yet grouted.**

**Fig. 110. Interior view of alumina storage building, partially filled with alumina.**

**Fig. 111. Potroom buildings under construction showing progress of concrete, structural steel and aluminum cladding.**

**Fig. 112. Carbon paste plant.**

**Fig. 113. Main gatehouse building, service shops in background.**

able, buildings have been designed with sloping roofs sheathed with corrugated aluminum, thus eliminating the maintenance work inseparable from built-up tar and gravel flat roofs. Where low buildings adjoin higher buildings with sloping roofs, the roofing sheets on the lower buildings were applied double, as they are subject to the impact of sliding snow and falling icicles. Where flat roofs were used, the built-up roofing and insulation were supported on aluminum decking. Both the narrow, roll-formed, continuous span type and the standard wider single span type decking were used. They were attached to the tops of steel purlins with standard clips or stainless steel drive screws; the fibreboard insulation and the built-up roofing materials were then applied in the usual manner.

The material used for covering sloping roofs and side walls of all but a few special buildings is industrial weight stucco-embossed corrugated aluminum. This product is a special aluminum alloy sheet 0.032 in. thick, with an integral skin of high purity aluminum on both faces, which provides a maximum of resistance to the corrosive action of chemicals in the atmosphere. The corrugations are 7/8 in. deep at 2⅔ in. pitch and the strength of the finished sheet is such that the same span between supporting members as is normally required for ordinary galvanized corrugated steel sheeting can be maintained. In all cases the corrugated aluminum cladding is attached directly to steel purlins and girts by means of Nelson studs having a special aluminum rivet type tip. These studs were jig welded to the steel and the aluminum cladding was applied by placing the sheet in position and punching the tips of the studs through the aluminum sheet by means of a rubber hammer. The tip of the stud was then riveted down over an aluminum washer. The installation has proved completely satisfactory and is entirely free of rattles. The side laps of all sheets are fastened by means of Southco rivets, a special fastening which, like the Nelson stud, can be installed from the exterior face of the building without requiring the services of a back-up man.

Where insulation was required the same method of application was used, the studs being lengthened to suit, and the insulation being drilled or punched over the studs. Both asphalted fibreboard and rigid type fibreglas insulating boards were used.

Where appearance is important, standard aluminum extrusions of alloy 50S designed for use as cladding were employed. Variations were provided by installing panelling of embossed or plain surfaced aluminum sheets. These extrusions were applied to the face of the steel girts by means of aluminum nuts and bolts, holes for which had been punched in the structural steel. The holes for attaching the panelling were all drilled in place and either nuts and bolts or self-tapping screws used.

It was desired to have the walls of offices, lunch and rest rooms, and toilet rooms of masonry construction

Table 1: Material Chosen

| Bolts, tension, | 12,000 | 3.0 on guaranteed yield strength |

so that the interior finish could be painted in restful colours. The exterior walls of these buildings were clad with aluminum attached by Nelson studs to steel angle girts built into the masonry joints at intervals. The exterior face of the masonry was painted with two coats of pitch to provide a vapour barrier, before the insulation and cladding were attached.

Standard aluminum windows were used throughout. Doors in locations where appearance is important are made of aluminum or of solid wood faced with aluminum sheet. Stair-railings are also made of aluminum. Turnstiles in the entrance gatehouses are of aluminum construction.

In the reduction pot and furnace buildings large ventilating openings are provided at the bottoms of the exterior walls. These openings are closed in cold weather by top-hung adjustable hinged doors fabricated of standard aluminum extrusions by rivetting.

Figures 111, 112 and 113, illustrate the typical architectural finish of various plant buildings.

### Aluminum Structures

It is often necessary to paint steel structures located in an industrial atmosphere, but painting structures that support electrical equipment is invariably difficult, costly, and hazardous. If a complete painting job is necessary the conductors must first be de-energized. This may mean that production must be temporarily stopped. To eliminate this, aluminum is used in place of steel in the supporting structures for the electrical equipment in the switchyard at Kitimat. Aluminum is most suitable for this use, because of one very important characteristic, excellent corrosion resistance.

A special specification was prepared *For Towers of Aluminum Alloy for Supporting Electrical Equipment at Kitimat, B.C.* It covers materials, loads, unit working stresses, ratio of slenderness, details of design, bolted connections, fabrication, cleaning and painting, anchor bolts, tower bases and foundations as follows:—

***Material:*** Alcan 65-S alloy—chosen mainly for its medium high strength and corrosion resistant quality. (Table 1).

***Loads:*** (a) *Dead load;* on the basis of a unit weight of 170 lb. per cu. ft. of aluminum in the structure.

(b) *Dead weight of conductors;* given by the electrical engineer.

(c) *Horizontal pulls;* given by the electrical engineer.

(d) *Live load;* 8 lb. per sq. ft. wind on projected area of conductors encased in ½ in. thickness of ice, plus the weight of a ½ in. thickness of ice on all exposed surfaces.

(e) *Wind load on tower structure;* 13 lb. per sq. ft. on all members as projected on vertical plane, disregarding any shielding action.

***Unit Working Stresses:*** Axial tension on net section, 17,500 psi. This

Fig. 114. Ground assembly of aluminum tower structure.

Fig. 115. Erection of aluminum structure in substation area.

Fig. 116. (Right) Aluminum roof access walkway structure.

value represents a factor of safety of two based on the guaranteed yield strength.

Axial compression on gross section

$0.50\left(48{,}000 - 400\frac{Kl}{r}\right)$ for $\frac{Kl}{r}$ equal to or less than 77, with a maximum of 17,500 psi. and $0.50\left[\frac{102{,}000{,}000}{\left(\frac{Kl}{r}\right)^2}\right]$ for $\frac{Kl}{r}$ greater than 77. The expression in brackets is the ultimate compression unit stress. The 0.50 before the brackets represents a factor of safety of two, $K$ is a constant dependent upon the degree of fixity of the ends of the member, $r$ is the least radius of gyration in inches, and $l$ is the unsupported length of column in inches.

Bending on extreme fibres is also 17,500 psi. and other limiting stresses are shown in Table 2.

*Minimum Material:* Minimum size of angles: 2 x 2 x 3/16 in.; minimum thickness of metal 3/16 in.

*Connections:* All the members were joined by ⅝-in. aluminum bolts with the exception of a few locations where ¾-in. bolts were used for extra strength. Welding was not considered because it lowers the strength locally. The bolts and nuts have unfinished hexagonal heads and conform to American Standard B18-2-1941. The threads are National coarse, Class 2 fit, conforming to American Standard B1-1-1935. Eighth-inch washers are used under the nuts, the unthreaded bolt shanks extending completely through the joined parts.

Bolt holes were made 1/32 in. greater in diameter than the nominal diameter of the bolts. Holes were punched in ⅜-in. and thinner material, whereas on thicker than ⅜-in. material they were drilled to finished size.

*Fabrication and Pre-assembly:* Material up to ½-in. thick was either sheared or sawn and material more than ½-in. thick was sawn. Flame cutting is more tedious in aluminum than in steel and it also reduces the strength of the aluminum, therefore this practice was not permitted.

When the material had to be heated for forming, temperature and duration were carefully observed and controlled so as not to impair the inherent strength.

All the structures were pre-assembled in the fabricator's yard to check for any errors in fabrication. This assured a perfect fit and no field modifications were necessary. Where assembly was carried out in a horizontal position, there was no trouble in erecting to the vertical position by means of a mobile crane, because of the lightness of the structure.

*Erection:* The light weight of the component parts and ground level assembly enabled erection to be carried out with ease. (See Figures 114 and 115). Bolts were tightened to a uniform tension by means of an impact wrench.

Structural aluminum is used in many places throughout the Kitimat Smelter. The most extensive structure is the 11,100 feet of walkway on top of the potroom roofs. This walkway is made entirely of aluminum, because of its light weight and its resistance to corrosion. The walkway and its connecting access stairs (See Figure 116) are necessary for potroom exhaust fan maintenance. The supporting members are made of extruded Alcan 65S-T channels and angles. These are bolted to the structural members of the roof. The walkway floor and the servicing platforms are open gratings made from Alcan 65S-T flattened rectangular bars.

#### Overhead Travelling Cranes

As is shown in Table 3 there are 17 electric overhead travelling cranes. The power supply for all cranes is 550 v., 3 ph., 60 c. The bridge travel motions of the 12 potroom cranes and the one furnace building crane are powered by dual motor drives, i.e. one motor is used for driving one of the two wheels at each end truck. The bridge travel motions for each of the other cranes are powered by one motor driving a line shaft which drives one of the two wheels at each end truck.

Because of the long span of the furnace building crane, the trolley and the bridge were constructed of aluminum alloy and in conformity the end trucks also were constructed of aluminum alloy.

To provide for comfort and efficiency of the operators, the cabs of the 12 potroom cranes and of the furnace building crane are air conditioned by a self-contained unit mounted over the top of the cab.

Figure 117 shows the 100 ton electrical repair shop crane.

#### Heating and Ventilating Systems

The larger buildings, such as the service shops and the wash and locker building, are heated by means of unit heaters, while in the smaller buildings and offices convectors or continous finned tube units are used. All units operate on low pressure steam supplied from the central plant and the majority of the unit heaters have individual thermostatic control. In isolated buildings convector-type electric heaters are used. Summer cooling is provided only in the potroom lunch rooms and restrooms, where package air-conditioning units are installed. Separate systems of exhaust are provided wherever dust, fumes, odors or heat are liberated, such as in the food preparation areas, laboratory, welding, forge and sand-blasting shops and the garage.

The largest single system of ventilation is in the wash and locker building, where the supply fans deliver about 40,000 cfm. of filtered and heated air to replace that exhausted from toilet, shower and locker rooms. The locker room exhaust is unusual in that all air from the room is exhausted through the banks of "wet" lockers, where working clothes, often saturated with perspiration, are stored to dry. The lockers are specially constructed to form ducts at the top and bottom, and additional heating coils are provided at the entrances to the bottom ducts to hasten the drying in warm, damp weather. This air may be partly recirculated through activated

**Table 3: Electric Overhead Travelling Cranes**

| Location | Number of cranes | Rated capac. tons | * AISE class | Span | Handles | Supplier |
|---|---|---|---|---|---|---|

carbon filters, although the supply system has sufficient heating capacity to operate with 100 per cent fresh air.

Because of the high humidity in many locations, all ductwork is fabricated of aluminum, except where corrosive fumes or abrasive dust necessitates other materials. Since design velocities and pressures have been maintained at relatively low levels, conventional fabrication methods, with rectangular ducts and bar or pocket slip joints, have been used. The majority of the fans are of the belt-driven centrifugal type, although a considerable number of direct driven propeller fans, with diameters up to 5 feet, are installed in locations where large quantities of heat are generated. These units, mounted on the roofs, have fabricated aluminum housings, thus eliminating the need for protective paint and conforming to the general pattern of the building construction.

#### Plant Electrical System

The electrical system has been designed for maximum security, essential for supplying the aluminum reduction lines. The design at Kitimat envisions the removal of important electrical equipment for maintenance work without shutting down any potline.

The 3 phase, double circuit transmission line from the Kemano hydroelectric development crosses Kitimat Arm and enters the plant area from the east, paralleling Moore Creek, as shown by Figure 101. The high tension lines cross to the substation area at the west end of the potline buildings.

Each potline has its own substation. The main transformers in these banks are rated at 37 mva. High speed air circuit breakers are provided on the high tension side of each transformer bank. The output voltage is regulated by 13.2 kv., step type voltage regulators.

The rectifier buildings, which form the west end of the potline buildings, are supplied with the regulated 13.2 kv. power. Each building contains a bank of ignitron rectifier units supplying direct current, at the required voltage, to the potroom bus. Special attention has been given to the grounding connections throughout this system.

***Diesel Standby Plant:*** A diesel standby plant has been provided to supply emergency power to the plant distribution system and to the townsite area. This plant will ultimately contain five units of approximately 800 kw. each.

***Plant Distribution System:*** The general plant distribution system for lighting and power follows standard industrial practice. Aluminum insulated wire has been used extensively for plant wiring and has proved to be entirely satisfactory.

#### Communications

***Telephone System:*** A 220-line PAX system is installed, 200 lines serving the general plant and 20 lines serving the power operators. The system is capable of ready extension to over 1,000 lines. An emergency sound powered system is installed for the power operators. A telecode unit is incorporated in the PAX and operates in conjunction with the plant signal system.

***Power Line Carrier Equipment:*** Three duplex channels are in operation between Kitimat and Kemano. Each channel provides a voice band and six super audio frequencies for supervisory control, telemetering, etc. Two of the duplex voice channels are connected to the PAX equipment at the terminals for direct plant to plant telephone communication. The third voice channel is utilized for direct communication between power operators.

***Radio Communication:*** Radio communication on various frequencies has been in use during the construction period. These facilities still exist, but have not yet been taken over for the permanent plant.

#### Plant Service Building

***Repair Shops:*** The electrical and mechanical repair and maintenance shops for the initial plant are located at the northwest corner of the present potline buildings and include the forge shop, warehouse, machine shop and electrical shop. Figure 113 shows this building in the background.

The electrical shop is intended to be the permanent center for all major electrical maintenance work for the ultimate plant. It is specially laid out and equipped to service the largest transformers and to permit complete overhaul of rectifier units, in addition to handling other elec-

**Fig. 117. 100-ton transformer crane in electrical repair shop. Showing transformer about to be lowered into pit.**

trical maintenance common to an industrial plant. Large transformers can be brought into the west end of the shop on a semi-trailer. There a 100-ton electric travelling crane (Figure 117) transfers them to a pit for untanking. A 5-ton crane operates on a lower runway to service the main working bay of the shop. The present mechanical shops will eventually be used for routine maintenance of equipment from the first four potlines only and larger mechanical shops and warehouse facilities will then be constructed near the center of the ultimate plant.

***Steam Plant:*** The initial permanent steam generating plant has been limited to an 8,000 kv. electric steam generator of the water resistance type. The steam is used primarily for building heating and is generated at 125 psi. A fuel fired standby boiler will be added later, but an emergency supply of steam is now available from the oil-fired boiler installation that was used during construction.

***Air Compressor Plant:*** Three 1,040 cfm. two stage, electrically driven air compressors are installed adjacent to the boiler room. Two compressors are required to provide air for normal plant services and the third provides reserve capacity.

### Plant Water Supply System

***Water Requirements:*** The principal use for water in the plant is for cooling rectifiers and transformers; these uses account for 92 per cent of the total requirements. Scrubbing of the exhaust gases from the pots also requires large quantities of water; however, cooling water from the transformers and rectifiers is re-used in the gas scrubbers.

The maximum water demand for Potlines Nos. 1 and 2 is five cfs. The future demand is 10 cfs. after Potlines Nos. 3 and 4 have been constructed and 30 cfs. for the ultimate plant development.

The study of possible sources of water supply was hampered by the lack of long-term hydrological data, but four principal sources were considered — Moore Creek, Anderson Creek, Kitimat River and wells. The final decision was to use Anderson Creek as the primary source of supply and to supplement it when necessary by water from Kitimat River. This decision permitted an economical installation for the early stages of the plant with provision for flexible expansion to match plant growth. It also provided a safety factor by having two independent sources of supply.

The services of a consulting engineer, F. C. Stewart, M.E.I.C., of Vancouver, were engaged for the design of water intakes, settling basins and pumping stations.

***Settling Basin System:*** At Anderson Creek the water is collected in a natural pool at the base of a waterfall, from which it flows by gravity to two shallow reinforced concrete settling basins for removal of silt. Four additional units are projected for the ultimate plant requirements. The basins are situated outdoors and are 33 by 70 by 8 ft. deep. Water is distributed across one end by means of seven 10-inch pipes and is removed through similar outlet pipes at the opposite end, from which it flows under a small positive gravity head through a travelling 14-mesh screen to the pump. The depth of water in the basins is maintained automatically at seven feet by a spillway at the inlet end which overflows to the creek. Inlet and outlet pipes may be closed by gates and the basins cleaned by means of plug valves in the bottoms.

***Pumping Station and Intakes:*** The Anderson Creek pumping station is designed to accommodate four horizontal centrifugal pumps each driven by 150-hp. electric motors, three of which are now installed. Two more similar pumping stations are projected for the ultimate plant development.

The Kitimat River intake consists of a closed sheet-pile flume that projects 75 feet from the river bank. The covered top of the flume is 6 feet above low water level and 14½ feet below high water level. The entrance to the flume can be electrically heated by means of elements in vertical 3-in. pipes to contend with slush ice. At the shore end of the flume there is a trash rack, beyond which the water passes through 100 feet of 36-in. buried concrete pipe to a traveling screen in the well of the pumphouse. This pumphouse is designed to accommodate four 200-hp. pumps for the ultimate plant, but only two 100-hp. pumps are installed now. Electrically-driven vertical pumps of the deepwell turbine type are used. The Kitimat River station delivers water to the Anderson Creek settling basins whenever the creek flow is insufficient.

***Type of Piping:*** All pipe lines are buried. Reinforced spun concrete pipe with grouted joints is used for low pressure service, such as the gravity intake lines. The concrete pipeline from Anderson Creek to the settling basins consists of 3,275 feet of 20-in. and of 18-in. pipe. Eighteen inch steel pipe having a wall thickness of ¼ in. is used for pump discharge lines, there being 11,500 feet between the Kitimat River station and the settling basins and 4,100 feet between the Anderson Creek station and the plant. This latter section includes a crossing under Moore Creek. Additional cross-connected lines will be added as the plant expands so that there will be multiple pumping and piping arrangements to guard against failure of the water supply to the plant. The 18-in. steel pipe was supplied in 40-foot lengths, factory-coated inside and out with coal tar enamel and wrapped, according to AWWA specification. Dresser couplings were used for all field joints. The joints were electrically bonded by means of jumper wires over the couplings and electrical leads were connected to the pipe and brought to the ground surface at 1,000-foot intervals, to enable testing the pipe coating and making checks on corrosion.

***Chlorination and Control:*** The entire pumping system is automatically controlled and requires no steady attendance. Chlorine is fed to the suction side of the Anderson Creek pumps by an automatic proportional chlorinator. Operation of the Anderson Creek pumps and regulation of chlorination is governed by a flow meter in the 18-in. pipeline. As a safety precaution, all the Anderson Creek pumps are stopped by abnormal pressures in the line and a surge relief valve is provided to guard against water hammer. The travelling screens are washed automatically as required. The pressure at the inlet to the plant watermains is maintained at 90 psi. by an automatic pressure regulating station at the plant end of the pipeline. Supervisory control of all functions of the entire system is exercised at the plant by means of suitable electrical circuits carried in a cable buried in the ground above the pipeline.

***Water Pipelines — Plant Area and Harbour:***

The water pipelines in the plant area are laid out in a grid system. This permits sections of the system to be shut off for repairs or additions without interrupting the water supply to essential points.

Included in the pipeline system are the fire hydrants, transformer cooling systems, boiler and compressor rooms, wash and locker building and miscellaneous services. A cast iron buried water main carries the water from the plant grid to the harbour area.

All underground water pipelines

in the area are built with Class 250 cast iron pipe equipped with mechanical or bolted gland joints. About 17,500 feet of pipe in sizes from 4 inches to 12 inches were used.

### Sewer Systems

*Storm Sewers:* A study of available meteorological data dealing with precipitation indicated an annual rainfall of about 90 in. and that the Kitimat area is not regularly subject to severe rainstorms. It was, however, considered advisable to design the storm sewers large enough to take care of a rainfall of 5 in. per hour. Since the plant area is, in general, a paved surface, a run-off of 100 per cent was assumed, which, because of large sloping roof surfaces and paved courts, would reach the sewers without any appreciable time lag. Altogether about 13,000 feet of pipe were used in constructing the storm sewer system.

An asphaltic compound jointing material was used which, in addition to withstanding the hydrostatic pressure, would be pliable enough to allow for differential settlement in the filled ground of the plant area. Since the plant area is considerably above sea level it was necessary to use drop manholes at points where the grade line of the plant area slopes sharply towards the tidal flats. These manholes are constructed of reinforced concrete and are lined with vertical planking to protect the concrete from erosion.

*Sanitary Sewers and Septic Tank:* The sanitary sewer system consists of a main trunk sewer and branch lines to the various buildings where sanitary fixtures are installed. About 7,000 feet of vitrified clay pipe ranging in size from 6 in. to 15 in. were used.

The septic tank is of reinforced concrete and consists of two compartments, each being 13 x 26 x 7 ft. deep, and providing a 24 hour retention period. The effluent is discharged into a nearby storm sewer. The sludge is purged through a valve into the sea during receding tides.

### Ship Unloading Plant

In planning the equipment for the wharf, emphasis was placed on the unloading of bulk alumina from ocean-going ships. Although substantial quantities of other bulk materials, such as coal, coke and hard pitch, are also imported by sea, bulk alumina, because of its fine powdery and abrasive nature required special consideration. Also, the shipping requirement of special bulkheads in the holds to prevent cargo shifting while at sea and large feeder chutes in the hatchways to compensate for possible shrinkage due to densification required particular study of unloading methods.

After extensive investigation and study it was decided to equip the wharf with one positive type of unloading equipment in the form of a specially designed crane for discharging all materials and one suction unloading plant for discharging bulk alumina.

*Pneumatic Suction Plant:* The pneumatic suction plant is a completely self-contained travelling tower type of unit and is shown in Figure 118. This plant was designed and built by an English firm, after extensive preliminary experimental work in their pilot plant and consultation with Alcan regarding general requirements and specifications. The plant was erected by Alcan's general contractor under the supervision of an erector supplied by the makers.

As may be surmised from the name, the principle of operation of the pneumatic unloading plant is that of air suction; in operation it may be likened to a large vacuum cleaner. It is equipped with three suction nozzles supported by outreaching pipe booms to allow the nozzles access to the ships' hatches. Air separators, filters, vacuum pumps and other associated equipment are all enclosed in one mobile aluminum-clad steel tower. The rated capacity of the complete plant is 200 tons per hour. Vacuum up to 12 inches of mercury is produced by four 42-in. diameter short stroke pistons operating at approximately 140 strokes per minute. The suction side of these pumps draws air through a nest of cloth filters in series with a large cyclone separator and thence from a central material receiving and settling tank. Leading to this tank are three pipe booms each suspending an 8-in. diameter intake pipe at the end of which is the intake nozzle.

During operation, alumina is induced into the air stream flowing into the nozzle and rises in the vertical pipe, eventually reaching the main receiver in the tower structure. The material is then extracted from this vacuum chamber by two tipper dischargers, which release the alumina into an open hopper without destroying the vacuum in the receiver. From the hopper below the tippers, the alumina is conveyed by means of two 16-in. airslides to the rear of the tower and thence is deposited on the wharf receiving belt.

*Kangaroo Crane:* The kangaroo crane is a 16,000 lb., two-drum, level-luffing, full portal travelling

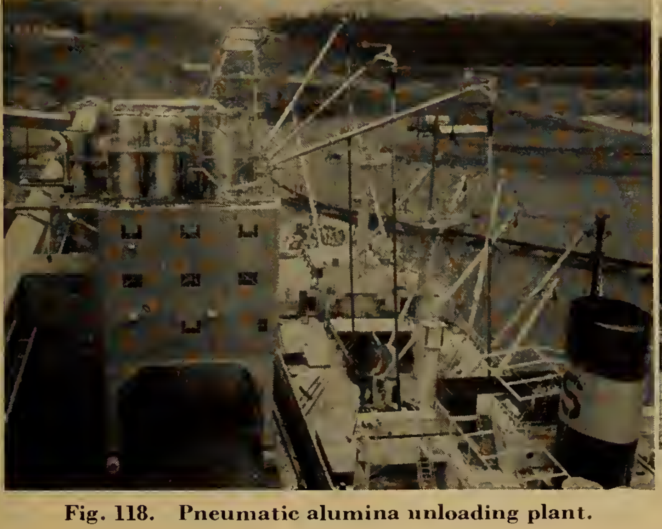

**Fig. 118. Pneumatic alumina unloading plant.**

**Fig. 119. Kangaroo crane—shown helping in assembly of pneumatic unloading plant.**

Fig. 120. Plant conveyor system as seen from Kangaroo crane. Smelter plant in background, storage building in center, and part of pneumatic unloading plant in foreground.

Fig. 121. Aerial view of smelter, showing conveyor gallery crossing potrooms to the carbon paste plant at left.

gantry type. It is named a "kangaroo" crane because it has a hopper located in the gantry structure which permits clamshell operation with hoisting and luffing only. It was designed and built in Bath, England, and was erected during the winter of 1953-54 by Alcan's general contractor under the supervision of the makers. Figure 119 shows a view of the crane in use assisting in the erection of the pneumatic tower.

The kangaroo crane was designed as a general purpose crane capable, with equal ease, of handling bulk commodities with a clamshell and general cargo with a regular crane hook. The properties of alumina indicated that considerable attention must be given to the control of dust loss when using a clamshell, hence special buckets and a dustless receiving hopper were planned with this crane.

The a-c. crane control provides for the following operating speeds: rotation, one rpm.; travel, 50 fpm.; hoist with five-step acceleration to 350 fpm.; and luff at an average of 150 fpm. The two hoisting drums are each driven by a 125-hp. wound rotor motor through spur and helical gearing. Micro switches on each of the four bogie screw jacks are wired in series with a pilot light in the operator's cabin to indicate that the crane is either locked or free to travel. The rail screw-down jacks on the bogies are for the purpose of preventing travel of the crane due to strong winds.

The planned operating cycle of the crane is approximately 50 sec., and the maximum free-digging rate for alumina discharge is approximately 150 tons per hour. "Free-digging rate" is the term used when the clamshell has full unobstructed access through the hatchway to dig into the material in the hold and when the depth of material in the square of the hatch is sufficient to allow the clamshell to fill properly.

The principle of dust control used in the down draft receiving hopper provides a thin air blanket at the top of the hopper with a strong down-draft into the hopper which is induced by a suction fan operating through a large cloth filter.

The kangaroo crane can readily be converted to hook operation by disconnecting the clamshell and installing a hook attached to an equalizer bar. With this bar the crane has a capacity of 16,000 lb. with all four cables — the two closing and two holding lines or—of 10,000 lb. using the closing lines only.

#### Materials Handling and Storage

The plant conveyor system carries bulk materials from the ship unloading towers to the storage and plant buildings. The principal materials handled are alumina, coke, coal, pitch, and smaller quantities of cryolite and aluminum fluoride.

Material leaves the unloading towers by cantilevered conveyors which are a part of each tower structure. These conveyors project through a slot in the covered wharf conveyor gallery. This slot is closed by a series of aluminum shutters which are automatically opened and closed by the cantilevered tower conveyors, as the unloading towers travel back and forth along the wharf. In Figure 118, the cantilevered conveyor of the pneumatic handling plant can be seen extending through the slot in the side of the wharf conveyor gallery. A 42-in. belt conveyor in the wharf gallery carries the unloaded material over a belt scale at the inshore end of the wharf.

From the wharf, a 42-in. belt conveyor system continues to a tower between the alumina and coke storage buildings approximately 2,000 feet from, and 100 feet above, the wharf. From this tower the conveyor system branches three ways; a 42-in. belt crosses over to the roof peak of the 30,750-ton capacity alumina storage building, another 42-in. belt crosses over to the 20,400-ton capacity coke storage building and a 30-in. belt continues on between the storage buildings to a transfer building at ground level at the north end of the storage buildings.

From this transfer building a conveyor gallery containing a 36-in. belt for alumina and a 30-in. belt for other materials run at ground level and under the railway siding at the railway car unloading station. These belts continue beyond this point and rise to the roof peak of the first potroom building. The 30-in. conveyor belt continues over the potroom buildings to the carbon paste plant and pitch storage building, which are approximately 4,000 feet from the wharf. The alumina is carried from the end of the 36-in. belt to each potroom storage bin by a 16-in. airslide system rated at 150 tons per hour. The general layout of the conveyor galleries is shown by Figure 107. Figures 120 and 121 show general views of the conveyor system.

The routes followed by the various materials may be summarized as follows:

All materials travel on the 42-in. belts as far as the storage buildings.

The alumina crosses over to the alumina storage building, where it is distributed by a peak conveyor and a system of air slides. Alumina is recovered from storage by air-slides and a tunnel conveyor under the storage building and is then conveyed by the 36-in. belt and air-slides to the potroom bins.

Coke is distributed within the coke storage building by means of a shuttle conveyor. When coal is being handled, this shuttle conveyor is run out through the south end of the coke storage building, where the coal is stored in the open. Coke or coal reclaimed from storage by tunnel conveyors travels from the transfer building as far as the carbon paste plant by the 30-in. belt conveyor over the potrooms.

The 42-in. conveyors will have an ultimate capacity of 1,000 tons per hour, the 36-in. belts 600 tons per hour, and the 30-in. belts 400 tons per hour.

### Roads, Railways, Drainage, and Fences

***Roads:*** The system of roads at the Kitimat smelter plant is somewhat more extensive than in other Alcan plants because the large transformers will be transported by means of a low-bed semi-trailer. It is also expected that occasionally it will be expedient and economical to truck materials between the smelter and the wharf.

Because of the compacted gravel foundation fill for the smelter plant and a similar road fill over the hydraulically placed area in the harbour, an excellent foundation resulted for the road pavements. The roads, over which the semi-trailer will operate, were paved with a 3-in. hot mix asphaltic concrete pavement placed on a primed, compacted, granular base course. The other roads, designed for normal truck traffic, were paved with a 2-in. hot mix asphaltic concrete pavement. Curbs, gutters and catch basins were not used, except along sidewalks from the main entrance gatehouse to the smelter plant and from the wharf gatehouse to the Kitimat Terminal Wharf No. 1. Elsewhere, the crowned road pavements have a compacted shoulder over which the surface run-off drains into side ditches.

***Railways:*** The Canadian National Railway line from Terrace, passing through the Kitimat River valley will service the light industrial section of the Kitimat townsite, known as "Town Service Centre", and extends southward, terminating at the holding yard. At this point the exchange of railway cars between C.N.R. and Alcan will be made.

The holding yard is 2,000 feet long and, initially, both C.N.R. and Alcan are installing one siding each, on opposite sides of the main line. From this point, the Alcan Terminal Railway is being constructed southward to the Kitimat Terminal Wharf No. 1, approximately 2½ miles distance, with sidings into the smelter plant.

In general, the terrain traversed by the Terminal Railway was wooded up to Moore Creek, south of which the railroad embankment was placed over the prepared fill for the smelter and harbour areas. A 100-ft. right-of-way was cleared, but removal of stumps was carried out only in cuts and in sections where the fill was 3½ feet or less. Two railway bridges, which were formerly used by Alcan on construction of power developments in Quebec, were transferred and re-erected on the Terminal Railway over Anderson and Moore Creeks. Corrugated metal culverts were used as smaller drainage outlets.

A maximum track grade of 0.5 per cent and a 4° curve were used on the Terminal Railway. The conditions at the smelter plant, however, required the use of 14° curves and a compensated grade of 1.35 per cent between the smelter plant and the wharf. The supplied turnouts were manufactured from new 85-lb. rails, but due to shortages 80-lb. relaying rails were used for the rest of the railway. Creosoted turnout ties and untreated track ties of local material were used.

***Drainage:*** The surface drainage from the smelter plant area, except from the electrical substation area, is carried away by storm sewer systems to the original Moore Creek channel. The remaining plant and harbour areas are drained by open ditches to the sea.

Since the terrain westward rises abruptly and the tributary run-off area is considerable, it was necessary to provide deep ditches and large culverts at road crossings. Due to the long ditches and to the outfall elevations determined by the high tide, a minimum grade of 0.33 per cent was adopted.

Provisions were also made for sub-surface drainage by installing a perforated pipeline in an original construction ditch, subsequently backfilled and running along the west end of the compacted fill for the smelter plant. By this means, the ground water table has been maintained at approximately 20 feet below the plant floor level.

***Fencing:*** The Kitimat smelter plant and harbour are enclosed by an all-aluminum security fence. In general, standard fencing specifications applied, using suitable aluminum alloys for various components. The outside security plant and harbour fence is composed of 6-foot high, No. 6 gauge, 2-in. mesh, chain link fabric with three strands of barbed wire overhang. The interior fence enclosures for electrical transformers and the substation differ only in the use of No. 9 gauge fabric and in the elimination of the barbed wire topping. Standard diameter round posts were set in concrete bases.

**Fig. 122. View of nearly complete initial development. Compare with Fig. 104 taken from same location.**

### Conclusion

The various phases of the design and construction of the Kitimat smelter have been covered. Some of the problems of constructing a large industrial plant in an underdeveloped area have been presented. The methods by which they were overcome have been treated in as much detail as space has allowed.

Figure 122 gives a graphic illustration of the progress made over the construction period. This photograph was taken from the same place as Figure 104. The same saw mill building appears in the foreground of both photographs. √

## Rational Design for Building Frames with Semirigid Connections

by J. L. de Stein, M.E.I.C., Associate Professor, Department of Civil Engineering, McGill University
*The Engineering Journal*, October 1954 issue, page 1227

**W. Mathison, M.E.I.C.**[1]

The author of this paper is to be congratulated on presenting a clear and very interesting paper which illustrates forcibly how irrational the "conventional" method of design can be under certain conditions.

It is common for rigid frames to be very closely analyzed by calculating the bending moments and axial forces under various conditions of loading with, in some case, allowance for side sway. Very much less time, however, is spent on the design of a structure with semi-rigid connections although the structure itself may be just as important. As pointed out, the design may be very much out of balance, with the beams over-designed and the columns under-designed. While little immediate economy in material may result in allowing for the rigidity of the connections, the over-all factor of safety must be higher, justifying an increase in allowable stresses and consequent economy.

Sufficient data is available for analyzing structures subject to vertical loading and for revising the sections designed by the conventional method as required. As further information comes available perhaps another stage in the successive approximations can be removed by obtaining closer approximations to the eccentricities of the assumed pin-jointed beams to the columns and also closer approximations to the effective lengths of the columns. A further step in the right direction would be the obtaining of $M,\phi$ characteristics for standard column bases.

Other questions raised are:

1. What should the maximum permissable rotation of the connection be? This may be obtained by the analysis of existing structures.
2. How to determine the change in the restraining moment on the beam caused by the wind acting with the dead and live load? When the wind force is removed the final position along line *ce* on figure 4 is not known.
3. The effect of sway with non-symmetrical loading.
4. The effect of the physical properties of the steel on the connection characteristics.

The erection procedure and clearances should also be allowed for. For example, some loading may be applied prior to making the final connection.

[1]Senior Engineer, Montreal Engineering Co.

**S. D. Lash, M.E.I.C.**[2]

Steelwork designers have long been accustomed to design structures assuming that the joints have little resistance to rotation and then to build them with relatively stiff joints. They take the stiffness into account when it is evident that such stiffness is essential to the safety of the structure and ignore it at other times. A historical study will show the reasons for this apparently irrational procedure. At one time most trusses were pin-connected and building frames consisted of simple beams resting either on the top of cast iron columns or on simple brackets or walls. In these circumstances there was little difference between theory and practice. Today this is no longer true and Mr. de Stein has performed a useful service by drawing our attention to the fact.

One probable reason for the irrational behaviour of steel designers is that they feel happier about neglecting bending moments in columns if at the same time they are also neglecting restraining moments in beams. It is common for example to assume the effective span of a girder framed into columns as the centre to centre spacing of the columns. This assumption is usually quite unjustified. The column itself does not induce any appreciable end slope in the beam and the connection of the beam to the column transmits a considerable moment. As a consequence of these two effects, the true effective span of the beam may be from 4 to 6 *feet* less than the centre to centre spacing of the columns (See for example the Final Report of the Steel Structure Committee pp. 133 and 183). There can be no justification for neglecting such a large factor.

As far as beams are concerned, an allowance for end restraint means a saving in weight. For columns, increased moments will usually mean increased weight. The values of moments given in Tables I and II by Mr. de Stein are impressive, but it would have been more convincing if he had shown what influence these moments would have upon the final weight of the structure.

It can be argued of course that the moments are being applied to the columns whether the designer recognizes the fact or not, and that so far failures of columns have not occurred. Therefore it will be maintained that it is not necessary to make allowance for moments in columns due to ordinary vertical loadings. This argument simply means that the factor of safety used in the design of columns is sufficiently great to take care of known factors deliberately ignored by the designer. It is not an entirely satisfactory situation.

The problem of making proper allowance for the restraint of connections when designing beams is not fundamentally difficult but there are several variables to be considered. Mr. de Stein has mentioned beam depth and the properties of the connection itself; in addition, the following will also affect the degree of restraint:

(a) The magnitude of the load—a connection giving 60% restraint at working load may only give 40% at twice working load.

(b) The distribution of the load—the degree of restraint will not be the same for a concentrated load as for a uniformly distributed load, and

(c) The moment of intertia of the beam—the restraint will not be the same for a heavy WF beam as for a standard I. The writer made an attempt to devise a simple design procedure which gave consideration to all these variables and this appeared as Appendix "G" to the first edition of the National Building Code. It is not known whether much use has been made of the provisions of this Appendix but it seems probable that it has been largely ignored. At least it does not appear in the new edition of the Code. Possibly steel designers are not really interested in saving steel.

[2]Professor of Civil Engineering, Queens University.

Whilst it is easy to suggest a simple and rational method of designing beams in steel frameworks the same is not true with respect to columns. A continuous column is a highly involved structural member, a fact made abundantly clear by the Progress Reports of the Column Research Council of Engineering Foundation. It is possibly significant that Mr. de Stein does not discuss this problem at all. Yet it is surely reasonable to expect some consideration of it in a paper entitled "Rational Design for Building Frames". One eould go further and point out that Mr. de Stein's paper is more concerned with analysis than design. This is to some extent inevitable with any indeterminate structure but this inevitably may explain the apparent unpopularity of a rational approach. Steel designers unlike their colleagues concerned with reinforced concrete, do not seem to be much interested in relatively complicated design procedures.

**R. H. Quintal, M.E.I.C.[3]**

The analysis of semi-rigid connections for structural steel members, presented by Professor de Stein shows quite clearly that the actual stresses in a beam or a column may be quite different than the values which we would find by using standard design assumptions. This, of course, appears quite disturbing in view of the fact that a certain amount of under-design may take place due to the partial redistribution and carry-over of some efforts from one member to the next.

However, the carry-over factors as described by Professor de Stein have been obtained in the only possible way that we know of, which is through measurement of stresses on laboratory test structures probably loaded only to values which will keep the stresses below the elastic limits.

We wonder, therefore, if an analysis based on the limit design theory, which would take into consideration the plastic flow of over-loaded members, would not give for many critical cases carry-over values somewhat below the values indicated by Professor de Stein's theory.

We realize, of course, that in many cases it may prove more satisfactory and it would be definitely safer to limit the stresses to values well below those which will produce plastic flow, but the question here becomes one of the refinement of the design and since in some cases justification can be found for the introduction of semi-rigid connection factors, we see no reason why the further step of estimating the stresses through limit design should not be considered.

It should also be noted that steel erection, especially with rivet connections, can be subjected to parasitic stresses and conversely field connections may not have a rigidity comparable to that of laboratory test members.

It is felt, therefore, that the present paper may serve a useful purpose for certain designs but only if other factors such as the ones already mentioned are studied as well.

[3]Foundation Engineering Division, Racey, MacCallum and Associates.

**Dr. G. G. Meyerhof, M.E.I.C.[4]**

In an interesting paper the author advocates a method of semi-rigid frame design, which was developed by the Steel Structures Research Committee of the Department of Scientific and Industrial Research of Great Britain some 20 years ago.(1) This Committee investigated for seven years the behaviour of steel building frames by extensive theoretical analysis, laboratory research and full-scale observations on a number of large buildings in London. As a result of this work a suggested Design Code was published in 1936 (1), which not only contained all the information required for the design of steel building frames with semi-rigid beam-column connections, but also raised the allowable steel stress from the previous 18,000 p.s.i. to 20,000 p.s.i. (corresponding to a reduction of the factor of safety from 2.2. to 2.0) on account of the more rational method of design.

Application of the new design procedure in practice showed, however, that it did not lead to any significant economy in steel but merely reduced the weight of the steel in the beams by up to about 20 per cent and increased the steel in the columns by a similar amount when compared to the standard design of frames ignoring the rigidity of connections. Since in addition the new method was more laborious and time consuming in the design office, it unfortunately did not gain support from the engineering profession.

In the meantime further research on the behaviour of bare steel frames has shown(2) that the real factor of safety of structures can only be determined from an estimate of the collapse load of frames, which requires an approach based on a plastic method of design (limit design). Moreover, the encasement of steel members in many buildings and the provision of floors and walls leads to a composite behaviour of structures, which differs appreciably from that of bare frames and has recently become the subject of further study(3). It is suggested that these recent methods will lead to a more rational design of steel building frames than the previous elastic analyses.

[4]Supervising Engineer, Foundation of Canada Engineering Corporation Limited.

**J. L. de Stein, M.E.I.C.**

The writer would like to thank those who have submitted discussions to his paper.

Mr. Mathison agrees that when a rational analysis is made an increase in allowable stresses is justified. He also indicates other problems which are pertinent to the design of structures with semi-rigid connections.

Prof. Lash suggests that a rational design method for steel structures would not be popular with steel designers due to the complexity of the analysis. He notes however that a method which parallels the true behaviour of the frame has some merit. The forces on each component of the frame are known. The deformation of each component at design loads is known. Even though a rational method may not be warranted for every-day design, it would appear that an occasional analysis would help the designer to better understand the behaviour of structures. This would probably be of benefit to his general design methods.

Both Mr. Quintal and Dr. Meyerhof indicate that a rational design method should be "based on a plastic method of design (limit design)." For many structures with standard web connections it would appear that an excessive deformation of the connections would take place before any major portion of a beam or column was in the plastic stress range. Maximum permissible movements and rotations might eventually be specified, and these would govern the design in many cases.

## BRITAIN MODIFIES POLICY ON MACHINERY IMPORTS

*Foreign Trade*, v. 102, n. 3, August 7, 1954, pp. 26-27

British industry has been given the green light on re-equipping its factories with American and Canadian machinery that will reduce production costs. The Minister of State, Board of Trade, made the following announcement late in June.

" . . . the Government, while still unable in our present balance of payments situation to remove licensing restrictions on imports of dollar machinery, consider that some of the severity of the existing restrictions can be relaxed. Accordingly, in future, more favourable consideration will be given to applications for import licences whenever the Board of Trade are satisfied . . that a dollar machine will reduce costs and that no alternative non-dollar machine offering roughly similar advantages is available."

### *Priority Requirements Dropped*

Couched in these terms, import restrictions still look formidable. Where, then, does the "relaxation" come in? It consists of eliminating the paramount criterion by which import licence applications have hitherto been judged—essentiality. Up to now, applications not passing the test of end-use essentiality have generally been refused, unless savings in cost weighed very heavy in the balance. Machinery in the main, will henceforth be admitted regardless of the relative importance of the industry in which it will be used.

The Government has not given a precise definition of the types of machinery that will be affected by the new ruling. For the present it will apply to all machinery, parts and ancilliary equipment required for manufacturing, production and services (either commercial or public). The bulk of the items affected are electrical and other machinery listed under Class D, Division 15 and 16 of the Import List, 1954, of which the following are the main headings:

Division 15—Machinery other than Electric:

Power generating (except electric) machinery; engines of all types; agricultural machinery; metal-working machinery; pumps; mechanical handling equipment; excavating, earth-moving machinery; mining machinery; woodworking machinery; portable power tools; paper-mills and pulp-mill machinery; printing and bookbinding machines; laundering and dry-cleaning machines; textile machinery; air-conditioning machines; refrigerating machinery; air and gas compressors; boot and shoe-making machinery; centrifugal drying and separating machines; electric lamp and valve-making machinery; food and drink preparation machinery; tanning and leather-working machinery; tobacco, cigar and cigarette-making machinery; bearings, ball and roller; cocks and valves.

Division 16—Electric Machinery, apparatus and appliances:

Generators; motors; valves; electronic, cathode ray tubes; apparatus for telegraphy, telephony, radio, television and radar; welding machinery; signalling apparatus (including traffic signals); industrial radio-frequency equipment; electro-medical apparatus; portable power tools; electric cables, wires, strips and strands, insulated; accumulators; electrical ware (including insulators) of porcelain; insulating materials; radio-testing equipment; scientific electrical instruments; electric machinery, apparatus and appliances, not elsewhere specified.

In addition to the foregoing a number of eligible items drawn from other sections of the Import List are subject to the new ruling: e.g., electronic tubes, hand tools and scientific instruments. In all cases, however, import licences will only be considered for machinery or equipment for production purposes. For example, electronic tubes will be considered for commercial or industrial use but not for private television receivers.

## MACHINING HARD METALS WITH ELECTRIC SPARKS

*The Engineer*, v. 198, n. 5136, July 2, 1954, pp. 11-12

The "Sparcatron" process makes use of the energy in an electric spark to blast away particles of metal as the arc strikes the workpiece.

The principle of the "Sparcatron" process is that an electric spark is caused by the sudden breakdown of a dielectric separating two electrodes: if the workpiece to be machined is made to be one electrode and another electrode of opposite polarity is brought to within the breakdown point of the dielectric separating them, the ensuing spark will remove a minute particle of the workpiece. For a spark to occur at all, a finite gap must always exist between the two electrodes. With any dielectric under a given set of conditions, the occurrence of a spark discharge depends on the size of the gap and the potential difference across the electrodes. Another elementary factor upon which the "Sparcatron" process relies is that an electric spark will always bridge the shortest point of the gap between the electrodes. Because of this fact, whatever cross section or contour the electrode may have, the removal of metal in the workpiece will follow the pattern of the electrode exactly. Although the original spark discharge may take place from any point on the face of the electrode, as soon as this discharge has occurred, material at that point on the workpiece is removed and the gap there becomes larger than elsewhere; sparking must therefore take place from another point on the electrode and so on until the complete surface of the electrode is covered. At this stage a minute thickness of material will have been removed from the workpiece, following the exact shape of the electrode. Theoretically, sparking will then cease because the overall gap between the electrode and the workpiece is greater than that required for a spark discharge under the prevailing conditions. However, if a practical means of maintaining the gap at the optimum value can be applied, and the generation of spark discharges made repetitive and continuous, metal removal will continue indefinitely or until the hole is fully pierced or the desired sunken contour is achieved.

We have established that the base profile and surface contour of the electrode is exactly the same as the aperture to be cut. However, the fact that a gap, however small, exists between the electrode and workpiece, means that the electrode must be smaller on all dimensions, by an amount equal to the spark gap, for a given finished size. Also, for a given voltage difference between the electrode and the workpiece and for a given dielectric separating them, the spark gap must be maintained at the correct "breakdown" distance. Provision must also be made for generating properly spaced spark discharged in a continuous sequence.

Here three practical factors must be considered. First, the length and intensity of the individual spark impulses and the length of the intervals between them must be carefully controlled to prevent the formation of a continuous arc. Secondly, provision must be made to control the intensity of the sparking effect over a wide range because the surface quality obtained with this process (as in others) depends upon the cutting rate; the higher the surface quality required the slower must be the cutting rate. Thirdly, the point of spark application must be kept under precise control, because the accuracy of the resulting cavity is related to the spark gap. For example, the resulting diameter of a plain circular hole will be that of the electrode plus the radial clearance which constitutes the spark gap. As the accuracy of machining is so closely related to the spark gap and is therefore bound up with the electrical characteristics of the system, it follows that the spark gap should be kept as small as compatible with operational requirements, including that of cutting speed.

Although spark machining may, in theory, be carried out with electrode and workpiece separated only by air, in practice a liquid dielectric is used, principally for its cooling effect, but also for certain electrical properties. Generally, the liquid employed is ordinary paraffin, although specially prepared liquids may be used. Although paraffin is inflammable, no ignition of the liquid can take place because the cutting point is fully immersed and insufficient oxygen is present to support combustion.

The electrode may be fashioned from almost any soft material which forms a good electrical conductor, brass is generally recommended because it is easily worked and almost any form of electrode, from an intricate die shape to a simple piercing tool, can be produced quickly. In many cases it is necessary to machine only the first electrode since, if the product is an extrusion or forging die, it is a simple matter to arrange for a number of pieces to be worked in brass from the original die to serve as future electrodes. In all such cases a very simple method of reducing the workpieces on all dimensions in order to provide the clearance required for the spark gap is to dip it in a suitable reducing acid, thereby converting it into an electrode.

The surface produced by spark-cutting has a non-directional finish (unlike the grooved finish of mechanical grinding and turning) and has special oil retention properties. Furthermore, the changeover from rough to finish machining involves merely the switching out of condensers and can be carried out instantaneously without interrupting the cutting. For example, suitably "stepped" or tapered electrodes enable holes to be rough pierced at a fast rate (using a high condenser value) during the first part of the electrode and then finished machined for the latter part of the electrode simply by switching to a low condenser value.

The process can be applied to the grinding of carbide tool tips where the absence of friction heat eliminates surface stresses and microcracks. It is also possible to completely finish-harden parts and then finally machine by spark-cutting without fear of distortion.

## GADGETS—THEIR PRACTICAL PERFORMANCE IN WATER CONDITIONING

B. Q. Welder, Everett P. Partridge, *Refrigerating Engineering*, v. 62, n. 6, June, 1954, pp. 49-53, 108-116

Most human beings want to get something for nothing. Even the engineer with his basic knowledge that one can get out only what one puts in as far as energy and matter are concerned will hopefully buy a ticket that may give him a new auto if his number happens to be drawn. Add to this basic human trait the current belief that, tomorrow or possibly the day after, science will provide an easier way of meeting each of our needs and you have an explanation for the many millions of dollars gambled annually on gadgets.

Let's define what we mean by gadgets. For the purpose of this paper they are special devices requiring substantially no technical control which are alleged to treat water by nonchemical means so that the familiar troubles caused by depositions of scale or sludge, by corrosion and cracking, or by the accumulation of organic slimes will plague us no more. Usually it is claimed they have additional powers for good—for example, one or another will eliminate any objectionable taste and odor from water, or remove slag deposits from the outside of the tubes in a boiler fed with water passed through the gadget, or improve the taste of a cigarette laid on it.

The promotion of gadgets is currently at one of its periodic peaks. Any thoughtful scientist or engineer naturally tends to suspect the claims of universal utility, the explanations in pseudoscientific gobbledygook of how each gadget is supposed to function by electrical or catalytic or supersonic means, and the warm testimonials from obviously well meaning but uncritical users. The scientist and engineer may even feel compelled to state with courage and conviction their conclusion that these promotions are the bunk. Always, however, the practical man in the plant wonders if the experts could be missing some new truth not yet fully appreciated.

In the present paper we propose to take an objective look at what the gadgets themselves have accomplished when applied to specific water problems in specific plants. The body of this paper will therefore comprise condensed case histories each observed at first hand by one of our field engineers.

The case histories end rather monotonously with the gadget tossed on the junk pile. Here and there in the technical literature, however, there is a claim of a beneficial effect or a possible explanation. Finally, we consider the methods customarily employed in promoting gadgets and what can be done by the man in the plant to protect his equipment, his company, and himself.

For obvious reasons we have not considered testimonial letters as adequate evidence that a gadget had solved a problem of scale or corrosion. We have not offered to spend the substantial amount of money which would be required to study in detail the facts behind such testimonial letters.

The answer from our experience is "gadgets do not prevent scale and corrosion under the varied conditions met in practice." If there were a way of achieving a consistent record of satisfactory results, then some gadget should have succeeded in establishing itself more generally than has been the case.

In the main, gadgets are actually sold to plants by men of good reputation working for an established local company handling plumbing supplies or small items of plant equipment. In the early stages of a promotion, these salesmen are honestly enthusiastic. Later, faced with more and more instances in which a gadget has failed to produce the anticipated results, they may respond with anything from apology to argument. Admittedly, they know only what has been told them by the promoter.

The man with a gadget to promote faces an intriguing series of problems. If he is aware of past experience, he realizes that he must make some fast bucks and get out. He can, of course, dissolve a dying venture under one name and start up again with a similar gadget under a new name. He can also shift his campaign from one part of the country to another, keeping one jump ahead of a disappearing reputation. He can even work on a global scale, bringing to eager Americans the gadget which no longer is able to find a market in England or France.

The promoter has two powerful influences working for him, social hysteresis and personal pride. He can count on a period of from one to three years before the lag in communication of practical results from plant to plant has pretty well killed off further prospects. This period of hysteresis may be prolonged by the very human reluctance of the person who has been taken to admit the fact. Customers who have given testimonials during an early period of enthusiasm are not prone to confess that the gadget actually did not perform during the long haul.

Faced with the necessity of working fast, the promoter naturally avoids as much as possible the man with technical training. Instead, he aims his campaign below the engineer and above him. If he cannot sell the nontechnical operator, perhaps he can intrigue the plant manager or the vice-president.

What course of action is practical for the man in the plant besieged annually by a new promoter with a new gadget? Some engineers of native intelligence and good training have been known to follow a policy of trying out each device offered to them. Such a solution is perhaps an eminently practical one when the gadget has been recommended to the vice president by an influential friend over the luncheon table. It does lead immediately to the citation of the company by the promoter as a satisfied customer. Many a large corporation has been startled to find itself in such a position as a result of having installed—and subsequently discarded—a gadget in some obscure corner of the organization.

Another course of action might be to ask for evidence that the practical performance of the gadget in question has been reported objectively by a reputable engineer before some technical society. This is a slow, hard way of building acceptance employed by companies which intend to remain in business indefinitely. If a gadget has achieved a useful result, then let the engineering profession have the opportunity to take a thorough, critical look at all the pertinent data.

## STANDARDISATION OF PALLETS

*The Engineer*, v. 198, n. 5136, July 2, 1954, p. 1

There was much trade and general interest manifest in the recent meeting of the Pallets Committee of the International Organisation for Standardisation, which was held at the British Standards Institution's headquarters in London in June. It was attended by forty-four delegates from many parts of the world and at the meeting of the main committee, six resolutions concerning the dimensions and loading of standard pallets were agreed. It was decided that the maximum height from the ground to the underside of the top deck should be 5 in., the minimum height for the passage of forks from any side should be 3⅞ in. and the width of wing pallets should be 3½ in. Maximum tolerances to be allowed on the length and width of standard pallets were specified. The minimum rating for pallets of 32 in. by 40 in. and 40 in. by 48 in. should be 1000kg. and the minimum stacking load 4000 kg, the question of test loads being deferred. A third I.S.O. standard size of pallet of 32 in. by 40 in. was recommended for final approval. The group's next meeting, which is to be held in a few months' time in Amsterdam, will be concerned mainly with matters affecting the handling of pallets at ports, with particular reference to a proposed international stevedores pallet. Requests were made that expendable pallets, chamfering of pallets, and the minimum percentage area of bottom decks of pallets should be added to the agenda and it was also agreed that in future discussions of pallets consideration should be given to their use by all forms of transport, whether by sea, river, road, rail or air.

## SITTING DOWN TO ONE'S WORK

*The Engineer*, v. 198, n. 5136, July 2, 1954, p. 18

There are, of course, people in this world who expect their employees when at work not only to work hard but also to look as if they were working hard. That, no doubt, is one of the reasons why so many appliances continue to be designed for operation by people standing up instead of sitting down. There is a lesser air of activity about people who are sitting down. There is even a suspicion in some people's minds—we recall a memory from childhood of an over-active aunt—that to permit people to sit down is to encourage slackness. Such people, of course, would regard the provision of comfortable seats of ample width and a padded back rest as a positive invitation to sloth. Why, an employee might even fall asleep in one of them! Yet, in fact, what is there wrong in making people as comfortable as possible at work? There was a time, was there not, when drivers of omnibuses sat on hard uncomfortable boards with no more protection from the inclement elements than a multiplicity of overcoats and a stretched piece of canvas could afford. We cannot say that we have observed any noticeable falling away in their driving skill since they have been shut away in warm glass cubicles and seated upon upholstered comfort; though, no doubt, their powers of caustic comment upon others' driving has suffered now that they are less audible than they used to be. In any event, we should retain a sense of proportion about this matter of standing or sitting. For as is remarked in the annual report of the Chief Inspector of Factories "as a cause of fatigue, prolonged sitting is secondary only to prolonged standing." Perhaps that is why editors, in common with many other sedentary workers, feel so tired by the day's end, though we like to pretend the cause is the amount of work we get through.

In industry there is a growing tendency for managements to provide seats for workers even when they are not compelled by law to do so. If seats are not provided all kinds of things tend to be pressed into service as a substitute, sometimes to their own detriment, sometimes to that of those using them. There was the operator observed sitting on the edge of an opened drawer which can hardly have been designed to carry such a cantilevered load. For ourselves, we remember in our younger days balancing upon a piece of four-by-four timber in the pattern shop. Of course, it will be argued that even when seats are provided those for whose comfort they are intended often scorn to sit upon them. But this is not always merely another example of human contrariness. It is more likely that something is wrong with the seats! For if seats are provided they need to be set in the right places and to be of the right height. To those whose opinion of human nature is low the fact that unsuitably designed, unsuitably placed, seats are not used ought, indeed, to be immensely encouraging. Does not their neglect suggest that far from workers being tempted into slackness by such consideration for their comfort, they are much more concerned to get on with their jobs? Nor when seats are well-placed and of the correct height and are yet not occupied should one leap hastily to the conclusions that they are not appreciated. "There is an amusing explanation as to why girls in an ice-cream factory were seen sitting on milk-drums instead of the more orthodox seats available; it was a cold day and the drums were filled with warm water."

We could not help wondering how much of the work still done standing in many engineering works could, in fact, be done at least as satisfactorily sitting. In the past when operators were constantly machining jobs of an "on-off" character, when the operation of the machine required the exertion of much muscular effort, when the worker was expected to grind his own tools, set his own machine, pick up rough parts for machining and set down or take away completed work, standing, because it allows so easily for movement around and about, was obviously more convenient than sitting. But nowadays, many machines are designed for repetitive production and controls are so well-placed that the operator hardly has the need to move his feet from the start to the finish of the day's work. Would there by any insuperable difficulty, for example, in designing a turret lathe for a sitting operator? We do not know. Yet we do think that in the majority of engineering works a number of jobs are done standing that could as easily be done sitting.

## CONTINUOUS ALUMINIUM-EXTRUSION PRESS FOR CABLE SHEATHING

*Engineering*, v. 177, n. 4612, June 18, 1954, pp. 794-795

Great interest has been shown in recent years in the development of techniques for sheathing electric cables with aluminium instead of lead, largely because of the high cost and comparative scarcity of the latter metal. Considerable progress has been made and some thousands of miles of aluminium-sheathed cables are already in use. Hitherto, such cables have generally been produced by what is known as the "tube-sinking" process, in which the conductors and insulating material are first drawn into a long aluminium tube of suitable diameter, which is then reduced by drawing the tube with the conductors and insulating material in position through a die, thus closing the aluminium down into close contact with the insulation. Such cables have proved quite satisfactory, but suffer from the drawback that they cannot be made in continuous lengths as can lead-sheathed cables.

One of the difficulties of sheathing cables by the extrusion process used in lead sheathing is that the temperature necessary for aluminium sheathing by extrusion is normally higher than is required for lead, so that there is some risk of impairing the properties of the insulation. British Insulated Callender's Cables, Limited, have been studying the problem for some years and have now overcome the initial difficulties, at least as far as low-voltage cables are concerned, so that they are able to produce aluminium-sheathed cables by the direct extrusion process in practically unlimited lengths.

After careful preliminary studies and experimental work the company reached the conclusion that in a normal production process of sheathing cables with aluminium by extrusion, it would be necessary to use commercial grades of aluminium in the form of solid billets; that extrusion temperatures should not exceed 300 deg. C.; that it must be possible to produce sheathed cables in long continuous lengths; that there must be satisfactory welds between successive billets; that the charging time must be kept as brief as possible to prevent overheating while the cable is stationary in the press; and that deformation and metallurgical defects at "stop marks", that is the point of the sheath which is in the die while the cable is stationary for re-charging, must be avoided.

As no existing press covering all these requirements was available, the company co-operated with the Loewy Engineering Company, Limited, in designing a suitable press and the result of their combined efforts, known as the Alsheath press, is now installed in the Prescott works. The press comprises two horizontally-opposed hydraulic cylinders, each of which is 45 in. in diameter and is operated at a pressure of 4,280 lb. per square inch giving a force of about 3,000 tons. The cable passes through the press in a direction at right angles to the axis of the cylinders, which permits the use of solid billets and reduces to a minimum the length of cable exposed to the heat of the press. Twin billets are used and are extruded through a common core and die to form sheaths ranging from 1.4 in. to 3.5 in. in diameter.

The billets, which are cylindrical, are charged into an electrically-heated furnace six at a time, leaving from the other end of the furnace in pairs at a temperature of about 280 deg. C. They then run down roller conveyors to a point below the level of the extrusion chamber of the press, whence they are raised, in a cradle, and turned round at right angles so that they lie on the axis of the hydraulic cylinders. They are pushed simultaneously into opposite ends of the extrusion chamber, by the action of the rams, the continued slow motion of which forces the metal out through the dies in the form of a sheath surrounding the cable. The extrusion chamber is heated and is kept under a vacuum while extrusion is proceeding. It should be mentioned that the extrusion tools are mounted in such a way that their positions and the gap between them remain constant, irrespective of expansion or contraction due to temperature variations. Special controls ensure that the extrusion of the two billets is constantly balanced and the mechanical loading facilities provided enable a pair of billets to be re-charged in a few seconds. The major movements of the press are controlled by servo-operated valves and the control can be made fully-automatic or individual, as desired.

Sufficient experience has now been obtained to show that the "stop-marks" are satisfactory from the dimensional and metallurgical aspects, and they have been found to comply with bend-test requirements and to withstand a high hoop stress. The welds formed between successive billets (as distinct from the "stop-marks") cannot be discerned on the extruded sheath and the top and bottom welds, which are unavoidable in right-angle extrusion, resemble those formed in the conventional lead press. Aluminium of 99.8 per cent purity is employed and with an extrusion temperature of 280 deg. C. the sheaths are in the lightly-annealed condition. The tensile strength is 5 to 6 tons per square inch, and the elongation is 30 to 50 per cent on a length of 2 in., in the longitudinal direction of the sheath, depending on diameter and thickness. A fine grain is found in all parts of the sheath, including the "stop-marks,". With these properties it will be clear that the springiness associated with cold working is largely eliminated.

## CALIFORNIA SUNSHINE AT WORK

*Chemical Engineering*, v. 61, n. 7, July, 1954, pp. 124-126

Hottest spot on earth—that's the focal point of this solar furnace now being used by engineers at Consolidated Vultee Aircraft Corp. for testing basing properties of materials at high temperatures.

With ideal sky conditions, estimated temperature at the 5/16 in. dia. focal point of the parabolic reflector is 8,500 deg. F. This is well above temperature levels achieved by the oxyacetylene torch (5,800 deg.) and the carbon arc (6,300 deg.).

Basic part of the solar furnace is the 120-in.-dia. polished aluminum mirror. Radiation from the sun is collected by the mirror and reflected to the focal point at a distance of 34 in. from the center of the mirror.

In order to keep the focal spot in one location over an extended period of time, the mirror is mounted in a gimbal ring so that the polar axis of the mounting is parallel to the earth's axis. A clock mechanism driven by a synchronous motor coordinates movement of the mirror with that of the sun.

Sky haze and clouds greatly reduce the efficiency of the solar furnace. In order to obtain more dependable performance, Convair plans to move the quipment from its present San Diego, Calif., location to a nearby mountain top—possibly Mt. Palomar—where sky conditions would be vastly superior.

The solar furnace is eminently suited for testing materials at high temperatures. The heat is "clean"—there is no interference from combustion products or other possible contaminants. Nor is there any interference from electric or magnetic fields. Heat-treating or melting and freezing of samples can be observed up to the highest temperatures available, and heating and cooling times are very short. And any other type of furnace which even approaches these temperatures would face the problem of preventing the furnace structure itself from melting.

Materials to be tested can be enclosed in a quartz envelope filled with any desired atmosphere. The glass itself, outside the focal point, is not destroyed by the high temperatures at the focal point within.

A bridge structure spanning the mirror a short distance beyond the focal spot supports the specimen holder. After part of the sample melts, adjacent regions are moved into the focal spot by means of a motor-driven screw. The bridge also supports a cylindrical barrel about 18 in. in diameter. This is used to shade a part of the mirror from the specimen so that the intensity of solar radiation concentrated on the specimen can be controlled.

The mirror has a central opening 22 in. in diameter which permits easy observation of the focal spot area from a position on the ground behind the mirror. A telescope mounted at this opening permits the observer to see details of heating or melting, magnified about 20 times.

Convair is testing many different kinds of materials, both ceramics and metals. Information developed in this program is expected to be of great value in solving problems associated with engines and friction.

## BELGIAN NATIONAL RAILWAYS

### Survey of the Electrification Programme

*Electrical Review*, v. 155, n. 1, July 2, 1954, pp. 3-7

The electrification of the Belgian National Railway system is being carried out at 3,000 V d.c. and up to the present four lines have been electrified; Brussels Nord to Antwerp Central (in 1935), Brussels Midi to Charleroi (in 1949), Linkebeek to Antwerp Nord (in 1950), and Brussels Midi to Ghent (in 1954). To these should be added the six tracks of the Nord-Midi loop, which connects the Nord and Midi stations in Brussels.

The grid system in Belgium is highly developed so that adequate supply facilities are available for the establishment of traction substations wherever they may be required.

The Belgian National Railways adopted trolley wires of the compound type and this system has been retained. In certain cases, however, use is made of simple catenary suspensions with one or two contact wires or of a simple tramway type suspension.

Until 1950, the lines of the two tracks were permitted to be suspended on independent supports consisting either of latticework posts or of I-beams with large flanges. Since then the lines have been suspended on rigid gantries, all the units of which are made up of I-beam section irons with large flanges, spaced at 63 m on straight sections.

The mechanical tension of the contact wires is regulated by means of automatie counterweight tension devices installed at about every 1,200 m. The principal and auxiliary carrier cables are interrupted only at the section divisions.

The tracks at platforms may be either insulated separately or in groups; the lines outside the stations may be split up into sections, both to facilitate maintenance and to simplify fault location. The corresponding sections are normally shunted by disconnecting switches, which are often remote controlled, and can be operated on load. The protection of the lines against lightning is carried out by over-voltage fuses installed in the substations and section boxes.

At present the Belgian National Railways have available 47 electric rail-cars and 26 electric locomotives, representing rolling stock supplied during the years from 1935 to 1950. A further 15 rail-cars and 50 locomotives are in the process of being supplied. Two sets of rail-cars comprising 79 and 38 units respectively are on order, as well as 83 locomotives.

The 25 rail-cars brought into service in 1950 were ordered on account of the electrification of the Brussels-Charleroi line. Their construction is lighter than in the preceding cases, and the JH starting equipment was installed in them after the test carried out on the 1946 prototype. Their maximum speed is restricted to 105 km.-hr. to reduce the consumption of electric power by stopping trains (more rapid elimination of starting resistances). For the first time general use was made of electric lighting using fluorescent tubes (fed by d-c.).

The rail-car brought into service in 1951 is a prototype built in the workshops of the Belgian National Railways with a view to carrying out tests at 140 km.-hr.

The motors are nose-suspended, and the transmission is by rigid gears. All the bogies are fitted with a traction motor. The bogie chassis are made of cast steel. The guiding of the axle boxes is carried out by connecting rods according to the system already used by Alsthom on a large number of locomotives of the French National Railways, in Holland and in Spain. The axle boxes run in roller bearings.

Studies of locomotives were carried out during the war and the Belgian National Railways chose the BB type, having a weight of 80 tons, with nose-suspended motors, a power of 2,200 hp. and a maximum speed of 100 km.-hr. The locomotives would be suitable for towing both passenger and goods trains.

While Belgian manufacturers sent in an offer for locomotives of this type, a Swiss concern proposed the purchase of three locomotives similar to the machines Ae 4/4 used by the Berne-Loetschberg-Simplon Company (but naturally designed for 3,000 V d-c.), with bogies according to the S.L.M. (Winterthur) system, motors completely suspended, Brown-Boveri disc transmission and a maximum speed of 130 km./hr. The Belgian National Railways agreed to try these out.

The Belgian manufacturers, when invited to present an offer for mixed high-speed locomotives, put forward a different solution: nose-suspended motors with unilateral transmission using rigid gears (according to the American method), and bogies with horn plates.

The choice was guided by the criterion of satisfying certain important conditions: the use, as far as possible, of equipment and units which were identical with those already in service; the choice from among the units in service of those which had reached the highest stage of improvement and development while at the same time offering sufficient guarantee of good working; the adoption of systems which had already been tried out in actual service, which offered ease of maintenance and overhaul, and which simplified the running of the train; while taking the above considerations into account, the purchase price had to be the lowest possible and the cost of operation the minimum.

The new locomotive, series 122, is a carefully worked out combination of the particular features of the locomotives of series 120 and 121 (locomotive 120 already possessed certain features in common with locomotive 101; pantographs, ultra-high-speed disconnecting switch, motor-fan groups, motor-compressor groups).

The traction motors are identical with those of the locomotives of series 120 (the difference in power is solely due to a modification in the rules of definition laid down by the International Electrical Engineering Committee). They are of the series type, without compensating windings, and can be shunted 72 per cent. The electrical equipment incorporates contactors controlled by camshafts.

The equipment is grouped into blocks. One of these blocks comprises the starting resistances with their fans, two camshafts controlling respectively the 33 contactors of the resistances and couplings and the 10 contactors of the shunting, control and safety relays, and the electro-magnetic contactors of the auxiliary motors. Another group comprises the ultra-high-speed disconnecting switch and the auxiliary apparatus.

The starting of the locomotive is automatic. There are four economic running positions in series (full field and different positions of shunt) and six in the series-parallel coupling. Starting is carried out under the control of an acceleration relay, the setting of which may be regulated as desired by means of a control installed on the driver's switchboard. These locomotives are controlled by a single driver and the equipment is fitted with a "dead-man's" handle.

The work of electrification has brought with it in many places important alterations to stations as well as far-reaching modifications in the signalling arrangements. Advantage has been taken of this fact to bring about the general substitution on electrified lines of luminous signalling for systems using signalling arms. A type of luminous signal is being used which, besides the normal lights, has a panel for indicating direction (luminous arrows) and one to indicate speed restrictions (luminous figures).

# FROM MONTH TO MONTH

**Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers**

## Nechako-Kemano-Kitimat

Once again the *Journal* presents a fascinating story of engineering achievement. The great power and industrial development in British Columbia on which the world has been gazing for so many years is now an accomplished fact. The story in all its details is to be found within the pages of this volume of the *Journal.*

Back in the April, 1944 issue, the *Journal* was devoted exclusively to telling the story of another great engineering achievement. That story was called "The Saga of the Saguenay", and was made up of five excellent papers, which described the history, design and construction of the great Shipshaw power development at Arvida. There is a close relationship between that project and the one described in this issue. The main point tying the two together is that the owner in each case is the same. The Aluminum Company of Canada, Limited is the enterprising organization that has seen the great potential of Canada and has backed its faith so substantially. Such confidence in this young nation has been a great factor in aiding Canada's startling development.

The story of Kitimat is the greatest of its kind as far as this country is concerned. The *Journal* is delighted to bring it in one volume to the engineers of Canada. *There have been papers presented before this, some technical, some popular, but this is the whole story, told for the first time as a single story.

The *Journal* feels that it has a responsibility to provide an outlet for Canadian engineering stories. This feeling of responsibility springs not only from a desire to encourage Canadians to write their stories, but as well from the realization that they are the literature of the profession and there must be a repository for them.

The *Journal* is indebted to the officers and engineers of the Aluminum Company. They have given splendid co-operation and support. The result, as shown herein, is believed to be the "biggest and best" ever produced in Canada. It is the hope of the editor and staff that the company will derive as much pleasure and satisfaction from this publication, as do the publishers.

*Published earlier in *The Engineering Journal:*
Nechako-Kemano-Kitimat Hydro Electric Power Development and Aluminum Reduction Plant, F. L. Lawton and J. S. Kendrick, v. 35, n. 9, Sept. 1952, p. 915.
Electrical Engineering and Operating Aspects of Alcan's B.C. Project. J. T. Madill, v. 36, n. 4, April 1953, p. 362.

## The Cover Picture

The cover picture is a sketch map illustrating the territory where the Nechako-Kemano-Kitimat development was carried out. It shows the relative locations of the principal features, i.e., the Kenney dam, the existing tunnel (double line), the future tunnel, and the powerhouse at Kemano, the transmission line and the smelter at Kitimat.

## UPADI 1954

The Pan American Federation of Engineering Associations, whose title in Spanish provides the abbreviation "UPADI", held their third conference in Sao Paulo, Brazil, from August 2 to 6, 1954.

The Engineering Institute is a member of UPADI and was represented at this meeting by James A. Vance, Vern B. King and E. R. Jacobsen of Sao Paulo.

There are 21 countries represented in the membership of UPADI. Besides Canada and the United States there are: Argentina, Bolivia, Brazil, Colombia, Costa Rica, Cuba, Chile, Republica Dominicana, Ecuador, El Salvador, Guatemala, Honduras, Mexico, Panama, Paraguay, Peru, Puerto Rico, Uruguay, Venezuela.

The United States' membership is in the name of the Engineers Joint Conference, the membership of which is made up of seven of the leading engineering societies.

The conference program was made up of business sessions for five days and concluded with excursions to other parts of Brazil and other South American countries. Reports from the Institute delegates indicate that the conference was a great success. Much business was completed and

**Luis Giannattasio, Uruguay, president of UPADI, opened the discussions of the third conference in Sao Paulo. From left to right: James A. Vance, M.E.I.C., Carada; James Todd, United States; Dr. Giannattasio; Luis V. Migone, Argentina; President-elect Francisco Saturnino de Brito, Brazil; and Enrique M. Pelaez, Uruguay, alternate for El Salvador.**

on the social occasions many new friendships were made and old ones renewed.

The Institute delegates have emphasized the values to be obtained from such a Pan American conference. Next to the United States, South America is our nearest neighbor and might well become a great factor in the economic life of Canada. The people of that continent can use many things we have in Canada, including our industries for the practical training of their engineers and our universities for their theoretical training. It is believed by those who have studied these things, that a conference of professional people such as is UPADI, can become a real factor in developing good international relations and promoting the interchange of ideas between the engineers and the industries.

The Canadian delegates point out the desirability of getting more Canadians to attend UPADI conferences. They believe that Canada has a real part to play in this field. One delegate says in his report, "Our participation in UPADI should not be influenced by distance. The next conference will be in Mexico City in 1956. Can we not have many Canadians there who have an interest in South and Central America and in Mexico? These people can use our initiative, our ability to get along with others, our friendship and our sincere interest in them. Shall we pass up such opportunities? I hope not."

The minutes of the business sessions have not been received and therefore there can be no report on that important part of the conference at the moment. However, as the material is received, it will be reported in the *Journal.*

# Engineering Education

In its 68 years of existence the Engineering Institute has participated in many conferences and discussions on education. It is doubtful if any of them have provided as much useful and interesting information as did the joint ASME-EIC conference held at Clarkson College, Potsdam, N.Y. on October 7 and 8.

The fact that the conference was an invitation affair, limited to 200 people, meant that everyone present had come because he was interested. Thus it was that everyone attended every minute of every session, which was the real reason why the meeting was so outstanding.

The opinion of delegates, expressed on all sides, was that this was the best conference of its kind they had ever attended. That opinion was held by educationalists as well as by employers. The resolution passed unanimously at the concluding session summed up the approval of all, when it recommended that the ASME-EIC International Council, give prompt consideration to a follow-up conference to develop the ideas further—perhaps to conclusions that would be revolutionary in the engineering education systems on both sides of the border.

The theme of the Conference was "Trends in Mechanical Engineering Education." From the beginning it was evident that the word "mechanical" could have been left out of the title. Everything that was said was just as applicable to any or all branches of engineering as to mechanical.

The main theme was broken into two parts, one for discussion each day. The first day's subdivision was "Can Present Mechanical Engineering Curricula be Improved?" The answers were all firmly in the affirmative. Some of the suggested improvements were startingly novel, but

**The academic procession at Clarkson College.**

**Members of a panel discussing the subject, "Can Present Mechanical Engineering Curricula be Improved?" From left to right: E. G. Bailey, R. J. Askin, M.E.I.C., H. N. Meixner, Thos. D. Jolly, D. C. R. Miller, M.E.I.C., Wm. G. Van Note, Henri Gaudefroy, M.E.I.C., E. A. Allcut, M.E.I.C., Geo. B. Thom, and C. Richard Soderberg.**

after due explanation and consideration, were quite generally approved. The revolutionary thinking of at least one panel member, is indicated by his statement that mathematics is greatly overrated as a gauge of a person's aptitude for engineering. He pointed out that only a very small percentage of engineers ever used their higher mathematics and yet many potentially good engineers are kept out of the field because they do not meet the high requirements in mathematics. He thought the basic sciences were much more useful.

For the second day the subdivision of the main topic was "Dangers of Over Specialization in the Curriculum." Here again it was soon apparent that the word "over" could have been left out of the title. The speakers and discussors were attacking all specializations, even advocating in some instances that the recognized branches such as civil, electrical, mechanical, etc., should be eliminated as separate courses in an undergraduate curriculum. It was surprising to discover that almost everyone, even the educationalists on the platform and on the floor, agreed that specialization was a mistake.

It was evident that these ideas should be studied further. They are revolutionary of course, but with the unanimity apparent at this conference, it seems the educationalists and the employers are looking for a change. It is likely the International Council of the two societies at their meeting in New York in December will determine some program of further study.

### Speakers and Discussions

The panel members for the first day when the subject was "Can Present Mechanical Engineering Curricula be Improved?", were R. J. Askin, vice-president, Abitibi Power and Paper Co., Limited, Toronto, and E. G. Bailey, a past-president of A.S.M.E. and chairman of the board of Bailey Meter Company. These two represented industry and the employer. Representing the universities were E. A. Allcut, professor of mechanical engineering, University of Toronto and C. Richard Soderberg, dean of engineering, Massachusetts Institute of Technology. The discussion leaders were Henri Gaudefroy, dean of engineering, Ecole Polytechnique, Montreal, and George B. Thom, chairman, department mechanical engineering, Newark College of Engineering, representing the academic side. For industry there was H. N. Meixner of E. I. du Pont de Nemours & Co., Inc. and D. C. R. Miller, director and general manager, Dow Corning Silicones Limited, Toronto.

Presiding over the session was Thomas D. Jolly, vice-president, Aluminum Company of America, Pittsburgh.

On the second day the subject was "Dangers of Overspecialization in the Curriculum". The moderator was Dr. A. G. Christie, professor emeritus of mechanical engineering, Johns Hopkins University, Baltimore, an ex-Canadian and a graduate of Toronto University.

The panel members for the universities were D. L. Mordell, professor and chairman, department of mechanical engineering, McGill University, Montreal, and Jess H. Davis, president, Stevens Institute of Technology, Hoboken, N.J. For industry the representatives were Karl B. McEachron Jr., General Electric Company, Erie, Pa., and R. S. Sproule, manager, hydraulic department, Dominion Engineering Works, Montreal.

### Dinner and Banquet

The lunches both Thursday and Friday were held informally in the cafeteria of the beautiful new Lewis House, but for the dinners on the same days there were more formal programs. On the Thursday the speakers were the presidents of the

**Part of the head table at dinner on Friday evening. From left to right: Ralph S. Damon, David W. R. Morgan, D. L. Thomson, M.E.I.C., W. A. MacIntosh, Wm. G. Van Note, D. L. Mordell, M.E.I.C., I. R. Tait, M.E.I.C., A. G. Christie, M.E.I.C., Edward McHugh, D. M. Stephens, M.E.I.C., and C. E. Davies.**

two societies, Dr. Lewis K. Sillcox and D. M. Stephens. Dr. Wm. G. Van Note, president of the college was in the chair.

On Friday the locale was changed to the spacious dining room of the new Clarkson dormitories. Dr. W. A. MacIntosh, principal and vice-chancellor of Queen's University was chairman and Dr. D. L. Thomson, dean of the faculty of graduate studies and research of McGill University, spoke on "Post Graduate Education in Engineering".

#### Convocation

A feature of the two day program was a special convocation on Friday afternoon, tendered as a tribute to the profession. Under the presiding genius of Dr. Van Note, four engineers were honoured — two Americans and two Canadians.

The convocation speaker was Ralph S. Damon, chairman of the board of trustees of Clarkson College, and president, Trans World Air Lines.

For Canada, two officers of the Institute were presented to Dr. Van Note, one, D. M. Stephens, the president of the Institute, to receive a doctorate of engineering, the other I. R. Tait, a vice-president of the Institute to receive a doctorate of science.

The two Americans were David W. R. Morgan, vice-president Westinghouse Electric Corporation who was made doctor of engineering, and Frederick S. Blackall Jr., president and treasurer of the Taft-Pierce Manufacturing Co. and a past-president of A.S.M.E., who became a doctor of science.

The whole faculty of Clarkson participated in the academic procession. Their colorful gowns and hoods, added brilliance to the already brilliant scene, and rivalled the colour of the leaves and the sparkle of the sunlight, filtering through the trees. It was a perfect day for a great occasion.

#### Attendance

As in any other conference it is the type of people who attend that give the conference significance. The attendance at Potsdam was made up of persons whose attendance and attention was of unusual significance to engineering education.

There were presidents of four distinguished educational institutions, Rensselaer, Stevens, Clarkson and Queen's. In all there were representatives, and in many cases they were the deans of engineering, of twenty-four universities. From Canada representatives were sent from eight institutions, Nova Scotia Technical College, University of New Brunswick, Ecole Polytechnique, McGill, Queen's, R.M.C., Toronto and Saskatchewan.

**Panel members for the discussion on "Dangers of Overspecialization in the Curriculum". From left to right: Karl B. McEachron, Jr., Jess H. Davis, A. G. Christie, M.E.I.C., D. L. Mordell, M.E.I.C., and R. S. Sproule, M.E.I.C.**

From the United States the following institutions were represented: Clarkson, Rensselaer, Johns Hopkins, New York, Cornell, Rochester, Connecticut, General Motors Institute, Rhode Island, Stevens, Norwich, Lafayette, Pratt, New Hampshire, M.I.T., and Newark, sixteen in all.

As far as Canada was concerned the two delegates from the geographic extremes were Dean I. M. Fraser, Saskatoon, and Professor Max Baker from Nova Scotia Technical College at Halifax. Canada's representation included all degree granting institutions except four, which was a very gratifying showing.

#### Appreciation

To Dr. Van Note the president of Clarkson, to Edward H. McHugh, dean of engineering and Professor Mochel and his committee workers, the members of the Institute are greatly indebted. It was Dr. Van Note who sparked this whole project and who gave inspirational leadership throughout all the arrangements and the conference itself.

It would be difficult to find more delightful surroundings and facilities than those offered at Potsdam. Even the weather was perfect, which showed up to great advantage the beautiful campus of Clarkson. The hospitality of the Clarkson people, offered so generously and so frequently gave the whole gathering a feeling of friendliness and ease. From every aspect it was a successful conference.

Transactions will be published as soon as possible, to include the addresses and many of the discussions. Members of the Institute interested in securing copies should advise Headquarters as soon as possible. Such information will be helpful in determining the number to be printed.

## Papers for the Annual Meeting, Toronto 1955

It is Council's desire to make it known to the membership that papers are now being sought for the annual meeting in Toronto next May. The Papers Committee is ready to receive submissions, which should be addressed to Headquarters.

The personnel of the committee are as follows: E. R. Smallhorn, chairman, Montreal; J. Benoît, vice-chairman, Montreal; L. P. Bonneau, Quebec; A. W. G. Clark, Vancouver; C. E. Frost, Montreal; H. Gaudefroy, Montreal; R. M. Hardy, Edmonton; A. R. Harrington, Halifax; F. L. Lawton, Montreal; W. H. Paterson, Toronto; H. S. Van Patter, Montreal.

# Nominees for Office

A list of nominees for office, as reported by the Nominating Committee, appeared on page 1270 of the October 1954 issue of the *Journal*. Since that time the committee has reported the selection for president as follows:

President.................. Richard E. Heartz................ ..Montreal, Que.

# Correspondence

**Comment on the *Journal***

Dear Mr. Editor:

I would like to comment on the ever improving high quality and interesting variety of papers printed by *The Engineering Journal*. The care and detailed organization of the *Journal* are a reflection of the thoroughness of the publication committee. Engineers in every phase of Canada's industry, education and government find the "acquirement and interchange of professional knowledge" stimulating and informative.

(The correspondent also made some useful comments on one of the *Journal's* technical papers, which will be printed in an early 'Discussion' section. Ed.)

Henry A. Spencer, M.E.I.C.,
Industrial Engineer,
Research Council of Alberta,
Edmonton.

**Record of Distinguished Engineers**

To the Editor:

Canada has every right to be proud of her engineers and of their accomplishments, but especially so of the more distinguished ones. Yet I know of almost nothing in print to commemorate them. If biographical material is not soon collected and recorded, they will become only memories and tenuous memories at that.

How should distinguished engineers be selected? My own idea is that the subject should have been deceased long enough for public opinion to have accepted him as really distinguished. As falling in this category, I can think of some of the military engineers of the French regime, of Colonel By, of Sir Sanford Fleming, of Sir Casimir Gzowski and of Sir John Kennedy; doubtless there are others whose names do not occur to me.

As a project for the branches, I suggest that each go back into the engineering history of its area and see how many engineers it can find there who qualify under the above rough criterion. With a list prepared in this way, a writer would know what he was looking for and could go about collecting the necessary information for a biography from all available sources, not forgetting family records.

I do not envision any of these biographies as long. Rather they would be short enough so that they could be published in two or three instalments in the *Journal*, perhaps finally to be combined into a modest book. I believe our readers would find them interesting.

I should be happy to hear from any of the branches concerning this matter, which I have been turning over in my mind ever since I learned that the late Professor Peter Gillespie, M.E.I.C., was thinking along similar lines.

R. De L. French, M.E.I.C.,
7481 Upper Lachine Road,
Montreal.

# Voulez-vous des écrits en français?

Nous nous sommes aperçu qu'on a l'impression que les écrits publiés dans les pages du *Journal* doivent être exclusivement en anglais. Ce n'est pas le cas. Le *Journal* existe pour présenter les points de vue des membres dans les deux langues. Mais si les auteurs canadiens-français ne nous donnent pas l'opportunité de connaître leurs travaux techniques, comment pourrons-nous atteindre notre but. Par conséquent, les amis français, nous vous prions de soumettre vos écrits. Nous les recevrons avec plaisir et espérons publier une proportion en français de temps à autre.

# E.I.C. Branches Entertain the President

**The Brockville, Kingston and Cornwall Branches entertained President Stephens at a dinner meeting on October 5 in Brockville. From right to left: Councillor H. B. Brewer, Mrs. Hawkes, C. H. R. Campling, chairman of the Kingston Branch, Mrs. Wright, J. S. Waddington, chairman of the Brockville Branch, President D. M. Stephens, Past-President R. L. Dobbin, and J. Hawkes, chairman of the Cornwall Branch.**

Upper left. President D. M. Stephens presented O. M. Solandt with a certificate of Honorary Membership in the Institute during the luncheon given in his honour in Ottawa on October 4. From left to right: L. Austin Wright, Dr. Solandt, Mr. Stephens, and R. E. Hayes, chairman of the Ottawa Branch.

Lower left. At the Ottawa luncheon. From right to left: W. E. Macklon, E. H. Bowler, W. G. Robson, M. P. MacMartin, A. R. Morse, W. G. Purvis, R. R. Jackson, Gordon Sutherland and Claude Howard.

Upper right. Reception held on the evening of October 4 by the Ottawa Branch in the Gloucester Street mess, R.C.A.F., in honour of President Stephens and Dr. O. M. Solandt. In this group, left to right: Mrs. Laidlaw, D. S. Laidlaw, R. E. Hayes, Mrs. Pennock, W. B. Pennock, Mrs. Sutherland, Thomas Foulkes, S. M. Steeves, M. C. Baker, Mrs. Baker and Mrs. Steeves.

Lower right. Ottawa reception. Left to right: Mrs. Ballard, B. G. Ballard, Mrs. Wright, L. Austin Wright, Mrs. Stephens, D. M. Stephens, Mrs. Hayes, and R. E. Hayes.

Below. Eastern Townships Branch dinner held in the president's honour on September 15. From left to right (seated): Mrs. J. B. Stirling, Mrs. Sylvio Rousseau, L. Austin Wright, Mrs. D. M. Stephens, Gaston Masse, chairman of the Eastern Townships Branch, Mrs. G. M. Dick, D. M. Stephens, Mrs. Gaston Masse, and J. B. Stirling. Left to right (standing): J. H. Barnacal, Bruce Bradley, Mrs. Gaetan Cote, G. M. Dick, Mrs. R. L. Dunsmore, Alderman Sylvio Rousseau, Mrs. Bruce Bradley, Mrs. J. H. Barnacal, R. L. Dunsmore, and Gaetan Cote.

# *Thirty-five Years Ago*

**Comment on the *JOURNAL* of November 1919**

The *Journal's* standards have changed over the years, as is well illustrated by a paper entitled "Can the Standard Measure of Value be Improved?" by an unknown author, but dated from Winnipeg, that appeared in the issue we are reviewing. It was a detailed and somewhat contentious discussion of the gold standard, with the conclusion that perhaps gold had outlived its usefulness and that value should be based on something else. The writer offered a unit he called a "navillus" (for nothing), to be used as a basis for any future payments, e.g., a contract price would be fixed in terms of "navilusses" ("navilli"?). When the contract was signed the value of the dollar and the navillus would be the same, but the value of the latter would fluctuate with the selling price of a long list of materials. As an example, the author suggests including gold and other metals; steel rails; coal; cement; grain; apples; meat; wool, cotton and flax; sugar, coffee and tea in the list, each item in proportions varying from 0.1 per cent to 10.0 per cent of the total. Then when a payment was to be made on the contract, the first step would be to calculate the current value of a navillus. If this had increased by, say, 6 per cent since the contract was signed, the contractor would be entitled to 6 per cent more in dollars than the engineer's estimate indicated was due him.

The purpose of the paper was a laudable one. In effect it was an attempt to accomplish by rather intricate means what we can now accomplish by the use of index figures of costs issued by government agencies. Readers must have noted with a smile that, after discussing his proposals at length, the author added a postscript, which expressed some surprise that his thoughts were not original. A somewhat similar scheme had been advocated by Lowe and Scope in 1825 and a book dealing with the matter by Prof. Irving Fisher, the distinguished Yale economist, was in press.

Reading of this kind on economic matters never hurt any engineer, but the *Journal's* present policy would probably be not to publish such a paper. It would no doubt gladly accept papers of an economic nature which apply directly to engineering affairs, but the author of a general paper, such as this, would probably be told that he would be better advised to seek publication elsewhere.

### A Member in Legislature

The *Journal* crows a little over the election of an Institute member, A. W. Gray, of Westport, Ont., to the Ontario legislature, "where it is expected he will soon make a name for himself." An engineer in politics is still something of a curiosity; in spite of urging from within and without the profession, engineers just don't take to public life.

The *Journal* was not very optimistic about the employment outlook, but "conditions in civil engineering show a slight improvement . . . it is in the industrial field that the greatest and most hopeful prospects for engineering employment are promised . . . There is also noticeable a slight but well defined stiffening of salaries being offered." The only two positions advertised with salaries mentioned were both in the teaching field — an instructor in civil engineering at $1,800 and a professor of mechanical engineering at $2,400.

### The Advertisers

Our regular advertisers were still with us in November, 1919, but we fail to find any new ones. And, according to modern ideas, the advertising hadn't much punch, just a list of products in many cases, with an occasional advertiser going so far as to include a cut or two. Today we hope and believe that our advertising pages get almost as much attention as the text, but who could work up much enthusiasm over the 1919 version?

After some months of study, the committee appointed by the Toronto Branch to draw up a schedule of acceptable salaries for engineers submitted its report, and this schedule was published in the *Journal* for November, 1919. We cannot, of course, reproduce it in full here and there would be no point in so doing, as it is not of much interest today. However, so that readers may compare the committee's recommendations with those of more recent schedules, we may quote a few typical items.

Chief engineers were rated at from $10,000 to $12,000 per year; engineers at the heads of departments at from $4,000 to $7,500; resident engineers at from $2,000 to $2,400 with expenses; designers and draftsmen at from $1,500 to $3,000 and surveyors at from $1,500 to $2,400. It is noticeable that in a number of cases, although the committee provided a classification, it did not make any salary recommendation, perhaps because it felt incompetent to do so.

This schedule was published without comment other than the committee's own introductory remarks — that it is based on pre-war living costs. One wonders if the committee expected the high cost of living brought on by the war to decline much. If so, it was mistaken; the cost of living did decline after 1918, but it never got back to prewar figures.

### The Branches

Council's report in this *Journal* occupied only half a column, because its October meeting was held too late to allow of publication in November, but three of the branches were out in full force. The Niagara Peninsula Branch had had some social doings — a dinner dance, and some technical activities — an inspection trip over the new Welland Canal. The Toronto Branch was asking for nominations for its annual elections.

The Ottawa Branch had recently listened to Gen. C. H. Mitchell, who spoke to it on "Reconstruction and Civic Development", and to Noulan Cauchon, who talked about the planning of Ottawa. It also provided the *Journal* with some notes about seven engineers from the staff of the Hydrographic Survey who were granted commissions in the R.N.V.R. and thus joined the Surveying Service of the Admiralty. They helped in some degree to replace members of this service who had enlisted for active service or who had already become casualties. The Montreal Branch published its program for the 1919-20 season. It also extended its congratulations to Past-president G. H. Duggan, who had just received an L.L.D. from Queen's University.

On August 9, 1919, there was a disastrous dust explosion in a grain elevator at Port Colborne, Ont., so it was appropriate that the Montreal Branch should hear an explanation and account of the affair from J. A.

Jamieson, who had designed the elevator.

**Honorary Member**

The *Journal* announced that H.R.H. the Prince of Wales had accepted honorary membership in the Institute and published not one, but two, portraits of him, one in full military uniform and the other in civilian dress, acknowledging the greetings of the crowd.

Messrs. William Gore and William Storrie described "The Toronto Drifting Sand Water Purification Plant" in this *Journal's* leading paper. The Ransome filter operated by gravity. It was so designed that the upper portion of its sand bed was continuously removed, washed and replaced, which made it possible to operate for long periods without shut-downs for complete washing. This filter did not use preliminary sedimentation; the alum dosage was from 0.85 to 1.50 grains per Imperial gallon.

The Toronto plant had ten units and its average capacity was 60 million Imperial gallons per day; it was used to supplement the output of the existing slow sand filters. There were, of course, the usual screens, pumps, chemical feeding apparatus and the like. Storage for 1,500 tons of coal was provided; the temperature in the interior of the coal pile could be taken by dropping a thermometer into pipes permanently installed in the coal bunker.

This plant operated for some years, but was ultimately abandoned for reasons of which this writer is not aware. So far as he knows, this was the only plant of its kind ever built in Canada and it may have been unique. The bacterial efficiency of the pilot plant, operated for some months before the main plant was built, was good — 99 per cent — so poor efficiency was probably not the reason for putting it out of commission.

## C.C.A. Meeting at St. Andrews

Construction industry executives convened at the Algonquin Hotel, St. Andrews, N.B., September 10-12, to mark the 1954 Maritime regional meeting of the Canadian Construction Association. The conference was attended mainly by Maritime construction men but delegations from Central and Western Canada were also in attendance.

The co-ordinated efforts of government, industry, owners and designers to reduce seasonal unemployment in the construction industry even further was urged by Raymond Brunet, O.B.E. of Hull, president of the Association. He stated that on the average there were 25 per cent fewer construction men working in February than in the peak month of September.

C.C.A. officers at Maritime regional meeting, St. Andrews, N.B. From left to right: John N. Flood, M.E.I.C., immediate past-president, Saint John; W. G. Malcom, national vice-president, Winnipeg; R. Brunet, president, Hull; and A. Turner Bone, M.E.I.C., national vice-president, Montreal.

Mr. Brunet warmly approved the recent announcement by the Federal Minister of Labour, Hon. M. F. Gregg, that Federal public works would be so timed as to provide "the maximum amount of employment during the winter months". Canadian industrialists were commended for their setting up of a committee to study similar action in the case of industrial buildings. "Success in any program to reduce seasonal unemployment in the construction trades would depend on the participation of owners and architects and engineers who were designing the projects."

Factors tending to restrict wintertime construction cited by Mr. Brunet included habit, pressure of work in design offices and the widespread idea that winter construction work was excessively costly. "Winter construction costs are not as high as is commonly believed," said Mr. Brunet. Factors reducing the costs were: lower prices frequently quoted by contractors during the off season; more plentiful supply of materials and labour; better supervision and planning due to the availability of key men. Mr. Brunet stated that earlier completion dates through wintertime construction often compensated the owner for any additional construction costs involved.

Mr. Brunet advocated getting projects "closed in" before bad weather set in so that interior work could be carried out during the winter; utilization of developed winter construction techniques; scheduling repair and maintenance work during the winter months and the award of contracts in the spring to allow an early start of construction operations.

"A brief glance at the large sum of money paid out of the unemployment insurance due to seasonal unemployment last winter surely is sufficient reason in itself to show that a levelling out of industrial activity during the various seasons is very decidedly in the public interest" concluded Mr. Brunet.

Other matters discussed during the business sessions included a report on the year's labour negotiations in the building trades, the St. Lawrence Power and Seaway Project, seasonal unemployment in the construction industry, "pre-qualification" systems for bidders on public projects, housing and highway construction, apprenticeship training and relationships between general and trade contractors.

## News of Other Societies

The eighth Canadian soil mechanics conference will be held this year in Ottawa, Ont., on December 16 and 17. Sessions will be held in the Building Research Centre at the Montreal Road Laboratories of the **National Research Council.**

The program will include short papers on a variety of subjects, as well as a business meeting, and sessions on December 17 will be devoted to a discussion of soil mechanics laboratory techniques and problems related to frost action.

Information may be obtained by writing to the secretary of the Associate Committee on Soil and Snow Mechanics, National Research Council, Ottawa.

---

There will be an international conference on combustion during 1955 under the joint sponsorship of the **Institution of Mechanical Engineers** and the **American Society of Mechanical Engineers** (29 West 39th St., New York 18).

The main conference will be held at the Massachusetts Institute of Technology, Cambridge, Mass., on June 15-17, and will be followed by a conference in London, England, on October 25-27, at which the same papers will be presented.

An advance program lists forty papers, and groups them into five main topics: general, boilers, industrial furnaces, internal combustion engines, and gas turbines.

---

The golden anniversary annual meeting and engineering display of the **Society of Automotive Engineers** (29 West 39th St., New York 18, N.Y.) will be held January 10-14, 1955, in Detroit, Michigan.

---

A schedule of events planned by the **Institute of the Aeronautical Sciences** (2 East 64th Street, New York 21) is as follows: December 17, the eighteenth Wright Brothers Lecture, at the U.S. Chamber of Commerce Building Auditorium, Washington, D.C., (Bo Lundberg, director, Aeronautical Research Institute of Sweden, lecturer); December 20, Los Angeles, and December 22, Cleveland, the Wright Brothers Lecture (repeated); January 24-28, 1955, the twenty-third annual meeting and honors night dinner, Hotel Astor, New York City.

---

The Vancouver section of the **American Institute of Electrical Engineers** opened the current season with a smoker on September 30, and has also put into effect the plan to hold a 5.30 p.m. discussion group dinner meeting and an 8.00 p.m. meeting on the first Monday of each month.

Officers of the Section are: H. O. Bulmer, chairman; J. T. Turner, vice-chairman; R. B. Carter, secretary-treasurer; M. A. Thomas, assistant secretary-treasurer; and committee chairmen L. B. Stacey, R. C. Stewart, M. Bradwell and E. Wolstencroft.

Information about the program can be obtained from J. T. Turner (c/o B.C. Electric Railway Co. Ltd., Oakridge Transit Centre, Vancouver, B.C.)

---

The congress of the **European Federation for Chemical Engineering** for 1955 will take place in Frankfurt am Main, May 14-21, 1955, on the occasion of the ACHEMA XI—chemical apparatus and equipment exhibition and congress.

The preparatory work for the congress is being done by the DECHEMA Deutsche Gesellschaft fur chemisches Apparatewesen, Frankfurt a.M. 13.

---

## Elections and Transfers

At a meeting of Council held in Montreal on October 15, 1954, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected:

*Members:*

R. J. Balfour, *Ottawa*
A. E. Bradley, *Toronto*
J. Brown, *Sherbrooke*
W. Collinson, *Toronto*
R. F. DeGrace, *Ottawa*
M. Dorais, *Quebec*
T. C. Fenton, *Jasper*
J. H. Goodwin, *Toronto*
A. Harvey, *Toronto*
J. G. Knowlton, *Ottawa*
R. P. Matthews, *Montreal*
C. C. McLaren, *Montreal*
R. W. Powell, *Toronto*
A. A. Ravins, *Sarnia*
N. W. Smithson, *Toronto*
J. M. E. L. Tummers, *Montreal*

*Juniors:*

A. P. V. Bennett, *Toronto*
E. D. Blix, *Montreal*
J. M. Booth, *Hamilton*
I. J. H. Clarke-Pounder, *Sherbrooke*
P. A. Conway, *Oshawa*
J. N. Greggain, *Kapuskasing*
R. W. McBain, *Windsor*
H. R. Schaeffer, *Sherbrooke*

*Transferred from the class of Junior to that of Member:*

G. E. Cook, *Fort William*
S. E. Halme, *St. John's*
A. F. Inderwick, *Ottawa*
C. N. Kirby, *Ottawa*
G. D. Sharon, *Vancouver*
D. W. G. White, *Cambridge, Mass.*
D. Maclaren, *Buckingham*

*Transferred from the class of Student to that of Junior:*

B. N. Runnalls, *London*

*The election of the following candidates can only become effective when the prescribed examinations have been passed:*

*For Admisison as Junior:*

W. D. Knopp, *Goose Bay*

*The following Students were admitted:*

*University of Alberta*

F. K. Hess

*University of Toronto*

R. K. Brayley, J. M. Hubicki
G. Campitelli, R. V. Robinson

*McGill University*

H. O. Byleveld, K. A. Kontus
A. Ghitis, J. D. O. Morgan
J. B. Haire, P. de Villers

*Nova Scotia Technical College*

D. V. Crowe, J. E. Howard

*Mount Allison University*

R. H. Jones

*St. Mary's University*

D. H. Currie

*University of New Brunswick*

A. H. Cunningham, D. E. B. Moffatt

*Cambridge University*

D. C. J. H. Meredith

**Applications through Associations:**

By virtue of the co-operative agreements between the Institute and the Association of Professional Engineers, the following elections and transfers have become effective:

Alberta

*Members:*

H. Bailey, G. A. McNeill
J. R. Harvey, R. E. R. Stanfield
D. M. Marshall

*Junior:*

R. J. Durrant

*Students:*

G. W. Carter, N. G. Stanford

*Junior to Member:*

W. M. Balke, J. A. L. Smith
J. M. Matthew

Saskatchewan

*Members:*

G. L. Bell

*Juniors:*

H. A. Sejbjerg

*Junior to Member:*

P. A. Inglis

Quebec

*Member:*

H. Z. Goldstein

# NEWS OF THE ASSOCIATIONS & CORPORATION

**Information received through co-operation with the provincial organizations**

## Nova Scotia

### Personal Notes

**T. B. Lusby,** has been recently appointed Deputy Minister of Public Works for the Department of Highways and Public Works of Nova Scotia. Mr. Lusby has recently served as councillor for the Nova Scotia Association.

**Dr. J. H. Sexton,** the energetic chairman of the Public Relations Committee, has recently been a patient at the Victoria General Hospital in Halifax, and has now returned to Wolfville. Best wishes are extended to Doctor Sexton for an early recovery.

**Morris Dean,** chairman of the Examining Board for the Association, who has been seriously ill for the past two months is slowly improving, and it is hoped that he will be able to take part in affairs of the Association soon.

### Maritime Meeting and C.G.A.

The month of September was a very interesting one for the engineers of the three Maritime Provinces and Newfoundland. Many members from each province attended the Maritime Professional Meeting at the Pines Hotel, Digby, Sept. 8-11. Some of the members also had the privilege of attending the meeting of the Eastern Branch of the Canadian Good Roads Association which was held at Keltic Lodge, Sept. 14-16. At this meeting, congratulations were extended to Dr. R. W. McColough, for his contribution to the success of the organization of this important branch of the Canadian Good Roads Association.

### The Journal Erred

J. E. Clarke, president and news editor for the Association of Professional Engineers recently received a letter from J. P. Vaughan of the department of highways and public works regarding the shield representing Nova Scotia in the heading of this section. In part the letter reads as follows:

Dear Mr. Clarke:

. . . The shield shown for the province of Nova Scotia is not the proper shield of this province. The shield shown was in use for a time following Confederation, but in 1929 was revoked by a Royal Warrant of King George V, in favour of the proper Armorial Achievement of Nova Scotia, which was granted this province by King Charles I in 1625.

I think that you, as president of the Association of Professional Engineers of Nova Scotia, should advise the editor of the Engineering Journal concerning this matter so that Nova Scotia may be represented by the proper Armorial Achievement.

J. P. VAUGHAN.

Editor's Note:

Our thanks go to Mr. Vaughan and Mr. Clarke for bringing our attention to this error. The province of Nova Scotia is now correctly represented with the shield, "a cross of St. Andrews, ---, charged with an Inescutcheon of the Royal Arms of Scotland."

## Quebec

### Quebec Now Has Six Universities, Not Five

In the October "News of the Corporation" we announced the opening of Sherbrooke University and we stated that it was the fifth university in the Province of Quebec. Actually it is the sixth.

In March 1948, a Provincial Charter was granted to Sir George Williams College conferring upon it degree-granting authority as "a college or university within the Province of Quebec". Up to the time, the College had operated under the Charter of the Montreal Y.M.C.A. with which it is still integrated organizationally.

Besides Sherbrooke University and Sir George Williams College, the four other Quebec Universities are: Laval, McGill, Montreal and Bishop's.

### Courses on Effective Speech

For the past two years, the Corporation has organized highly successful courses on the art of effective speech.

It was felt by Council that its public relations program encompassed the sponsoring of such courses. They were established particularly to develop among the members of the profession, speakers who could voice the achievements of engineering. This policy is in conformity with the general motto of our P.R. program: "Silent Service is not enough".

A third series of courses is now in progress. All told, a hundred professional engineers have been trained to master the important art of the spoken word. Each one of them has been enthusiastic about the encouraging results he has experienced.

### Pot Pourri

Le **docteur Adrien Pouliot,** doyen de la Faculté des Sciences de l'Université Laval à Québec et ancien président de la Corporation, revient d'un séjour au Royaume-Uni et en France, où il a été invité à donner des conférences devant plusieurs sociétés savantes. A Toulouse, on lui a décerné un titre honorifique d'un nouveau genre en le créant "Grand Module de l'Ordre de l'Engrenage". Sa tournée en Angleterre avait été organisée par le British Council. En France, il était l'invité du gouvernement et des Chambres de Commerce.

Laval University in Quebec City is now offering engineering courses in all major departments: civil, electrical, mechanical, mining, metallurgical, geological, and chemical. A school of mechanical engineering has been opened this year with nine students entering the fourth of the five year course. **Mr. L. P. Bonneau,** a member of the Corporation's Board of Examiners has been appointed director of studies of the new school.

The Council is pleased to announce the appointment of **Mr. Lucien Tremblay, Q.C.,** as legal adviser of the Corporation. Mr. Tremblay is highly regarded in legal circles; he is one of the two legal counsel for the Tremblay Commission (Royal Commission of Inquiry on Constitutional Problems). Following a new policy, the Council of the Corporation has retained his services to attend all Council meetings.

## Ontario

### News of the Members

**H. U. Graf,** of the Massey-Harris-Ferguson organization has recently been moved from Marquette-les-Lille, France, to Cologne, Germany, where he is works manager of Massey-Harris-Ferguson G.m.b.H.

Mr. Graf, who is a graduate of the Swiss Federal Institute of Technology, Zurich, was earlier with the company's plants in Toronto and Brantford.

**Dr. J. A. Sparrow,** who for ten years has been in charge of penicillin and five chemicals for Ayerst, McKenna and Harrison, of Montreal, has been transferred to the International Division of the same company. He is presently in Sao Paulo, Brazil, as technical adviser for the new Fontoure Wyeth penicillin plant.

**Herbert C. Powell,** has recently retired from the Toronto Hydro-Electric System after forty-four years' service in that organization.

Following public and high schooling in his birthplace, Hamilton, Ont., Mr. Powell graduated in electrical engineering from the Pratt Institute of Brooklyn, N.Y., in 1909. The following year he joined the Toronto Hydro-Electric System as a power engineer. In 1919 he was placed in charge of the statistical department and has held the title of statistician since that date.

**E. A. Washburn,** of Stratford, has succeeded A. B. Manson, as general manager and secretary-treasurer of the Stratford Public Utilities Commission. Mr. Manson retired from that post on August 1st after serving the City of Stratford for forty-two years.

Mr. Washburn, a Queen's graduate of 1943, was manager of Ingersoll's public utilities before moving to Stratford in 1950 and becoming assistant general manager of Stratford's P.U.C.

**William P. Bobbs,** of Toronto, has entered private practice in the field of machine and tool design. To his new work he brings considerable engineering experience and practical knowledge in tool design and making. Former positions held by Mr. Bobbs include that of chief tool designer of the A. V. Roe gas turbine development section, Malton; chief draughtsman at Modern Tool Works Ltd., Toronto; and chief engineer Canaero Consultants Ltd., Toronto.

**Ralph B. Chandler,** of Port Arthur was recently tendered a complimentary dinner by a large number of fellow workers and friends on the occasion of his retirement as manager of the Public Utilities Commission of Port Arthur.

Following his graduation from the University of Toronto in 1912, Mr. Chandler spent several years in Alberta and Saskatchewan. In 1917 he moved to the Lakehead and until 1933 was associated with C. D. Howe & Co., of Port Arthur. From 1923 to 1933 he was consulting engineer and a partner in that company. In 1935 he was appointed manager of the public utilities commission of Port Arthur.

E. A. Vigars, who since 1946 has been assistant manager, succeeds Mr. Chandler.

**J. J. Traill,** has retired from the Hydro-Electric Power Commission of Ontario and is now engaging in private practice as a consulting hydraulic engineer at 4 Ludlow Avenue, Toronto 18, Ontario.

Mr. Traill is a graduate of the University of Toronto from which he also received the professional degree of C.E. From 1910 to 1920 he was on the staff of the University, latterly as assistant professor of hydraulics. In 1920 he joined Ontario Hydro's hydraulic engineering staff. Prior to his retirement he was hydraulic engineer of the Commission.

**William Turner, Jr.,** has moved from Toronto to Montreal where he has assumed the position of controller for Canadian Ingersoll Rand Co. Ltd.

## Manitoba

### Highway Officials' Chairman

**Gerald B. Williams,** chief engineer, Highways Branch, for the Province of Manitoba and president of the Association of Professional Engineers of Manitoba, has been elected chairman of the Association of Western Canada Highway Officials at their annual convention in Victoria, B.C. This group is mainly concerned with highway construction standards for Canada. Mr. Williams was elected to this body in absentia.

### Resignation

**E. M. Scott,** has recently resigned his position as chairman of the Engineering Professional Development Course sponsored by the Winnipeg Branch of the E.I.C., in order to participate in a power systems engineering course sponsored by the General Electric Company. Mr. Scott, who is an engineer in the assistant planning division of the Manitoba Hydro Electric Board, has been transferred to Schenectady, N.Y., in order to take the course.

## British Columbia

### B.C. Electric Forms New Firm

On September 17 A. E. Grauer, president of the B.C. Electric, announced the formation of a new engineering company, a subsidiary of the B.C. Electric, to be known as the British Columbia Engineering Company Limited.

The new company combines the engineering staff of the B.C. Electric's engineering division with the staff of the British Columbia International Engineering Company Limited.

Thomas Ingledow, has been named the president of the new company and W. G. Huber, the general manager, the same position he presently holds with the B.C. International Engineering Co. Limited.

The new firm will do civil, mechanical and electrical engineering and will not confine its work to that for the parent company, although this is estimated at $150,000,000 over the next five years. Mr. Grauer said, "Every effort will be made to secure jobs of a heavy engineering nature and bring this business to British Columbia."

The B.C. Engineering Company will operate from 717 West Pender Street, the present offices of the B.C. International Engineering Co.

### New Appointments

At the same time Mr. Grauer announced the following top executive changes within the B.C. Electric Company:

**Dr. Harry L. Purdy** has been named executive vice-president and now takes over the responsibility for the firm's general sales division and industrial relations sub-division.

**Thomas Ingledow,** who has been in charge of most of the post-war expansion program becomes vice-president and executive engineer.

**Jack H. Steede,** who has been the executive assistant to Mr. Ingledow for nine years, has been named chief engineer.

**Sigurdur Sigmundson** has been appointed general manager of the Transit Division.

**John R. P. Powell,** a U.B.C. graduate in 1945, becomes the executive assistant to Dr. Purdy.

### Short Course in Photogrammetry

A short course directed to the practicing engineer, geologist, forester or cruiser who uses aerial photographs and simple air-survey tools will be held at U.B.C. from Dec. 13 to Dec. 17. The introductory sessions, comprising the first three days of the course, will be devoted to basic techniques of translating photographs into planimetric maps and determining differences of elevation, using simple instruments and draughting equipment. Final sessions will be concerned with specialized topics such as forestry interpretation, geological interpretation, and civil engineering applications.

Full time course lecturers will be Professors H. R. Bell, S. H. DeJong, J. H. G. Smith of the university staff, and Dr. Lyle G. Trorey.

Limited accommodation will be available in the university dormitories in the Youth Training Centre. Room and board can be provided at the rate of $3.40 per person per day. For further information write to the Extension Department, University of British Columbia, Vancouver 8, B.C.

### Canadian Committee on Counselling in Engineering and Science

The Canadian Committee on Counselling in Engineering and Science was formed some years ago by the Engineering Institute of Canada, The Canadian Institute of Mining and Metallurgy and The Chemical Institute of Canada to provide counselling services for students interested in engineering and science. In 1952 the committee was reactivated after being dormant for some time and invitations were issued to the Associations throughout Canada to join in its activities. Council of the B.C. Association considered that any participation which the Association played in this committee should be through Dominion Council. Other Associations preferred to participate independently, but recently advised that contributions for 1954 had been few and the committee was faced with a deficit of some $800. Several of the other Associations had contributed to the committee independently, in addition to the contribution made by Dominion Council. It was therefore decided that the B.C. Association should also contribute to the activities of the committee, but that this contribution should be through Dominion Council; consequently, a grant of $100 was authorized to be forwarded to Dominion Council to be added to their contribution to the committee.

# Personals

**News of the Personal Activities of Members of the Institute**

**Dr. David B. Steinman,** M.E.I.C., New York consulting engineer, has been recently honoured with the Legion of Honour by the Government of France, and with the gold medal by the Government of Italy. The citation accompanying the French award recorded Dr. Steinman's professional achievements and his contributions toward strengthening international relations. In the presentation of the Italian award to Dr. Steinman who has prepared plans to span the Strait of Messina to Sicily, he was referred to as the "greatest bridge designer". The Rev. Felix A. Morlion, rector of the International Catholic University for Social Studies, made the presentation in the name of a committee of representative Italians.

**Dr. C. J. Mackenzie,** HON.M.E.I.C., former president of Atomic Energy of Canada, Ltd. was recently named recipient of the 100-guinea R. B. Bennett Empire Prize.

The award is the fourth since being established in 1945 by the late Viscount Bennett, once Prime Minister of Canada, and the second to a Canadian.

It is awarded every three years "for the most outstanding contribution from the Dominions, India, Burma and colonies to the promotion of the arts, agriculture, industries and commerce of the overseas Empire during each intervening period."

Dr. Camsel, Canadian geologist, received the first award in 1945.

**A. W. Howard,** M.E.I.C., general manager of Calgary Power Ltd., has been elected president of the Canadian Electrical Association.

A native of Calgary, Mr. Howard attended Central High School there and later graduated with a B.A.Sc. degree from the University of Toronto.

He joined the staff of Calgary Power in 1935 and four years later became associated with Montreal Engineering Co. Ltd. in Montreal. In 1948 he rejoined Calgary Power Ltd. and was appointed general manager in 1952.

**R. M. Robertson,** M.E.I.C., manager of operations for Dominion Bridge Company Limited, has been selected by the Rt. Hon. C. D. Howe, HON.M.E.I.C., Minister of Defence Production, to succeed A. P. Craig, now vice-president in charge of sales for Trans-Canada Pipe Lines Ltd., to direct Canada's $450,000,000 naval ship-building program.

Mr. Robertson joined the Dominion

R. M. Robertson, M.E.I.C.

Bridge Company in 1909 as a junior draughtsman. He entered McGill University in 1913, but his studies were interrupted from 1916 to 1919 when he served with the Canadian Engineers with the rank of captain. He continued his studies at McGill after the war, graduating in 1920 with a B.Sc. degree. That same year he joined the bridge department of the Canadian Pacific Railway.

He returned to the Dominion Bridge Company in 1924. He was appointed designing engineer of the Eastern Division in 1948, and assistant chief engineer of the Company in 1952. He was appointed to his present position with the Company in 1953.

**R. W. Willis,** M.E.I.C., formerly chief engineer in the structural steel division of the John T. Hepburn Company in Toronto has been appointed chief structural engineer of the St. Lawrence Seaway Authority in Montreal. He will be responsible for all structural engineering design, and will have under his direction three major divisions, namely lock structures, retaining walls, bridge piers and all other heavy foundations; lock equipment, including gates, fenders, valves and other miscellaneous structural features; and bridge superstructures.

A graduate of Queen's University, class of 1937, Mr. Willis has been previously associated with Canadian Bridge Company at Walkerville, and the Standard Steel Construction Company at Welland.

**L. J. Scott,** M.E.I.C., has been appointed managing director and assistant secretary of Canadian Zurn Engineering Limited.

A graduate in mechanical engineering of McGill University, class of 1923, Mr. Scott has been associated as manager of the company's operations in Canada. Canadian Zurn Engineering Limited is an affiliate of the J. A. Zurn Manufacturing Company of Erie, Pa., and is engaged in the manufacture and sale of building drainage, industrial, marine and power transmission products.

L. J. Scott, M.E.I.C.

**F. Austin Brownie,** M.E.I.C., has been elected president of Canadian Utilities Limited in Edmonton.

Mr. Brownie received his B.A. and B.Sc. degrees from the University of Alberta. In 1935 he joined Northwestern Utilities Limited, and five years later became assistant to the general manager of Canadian Western Natural Gas Co. Ltd. Subsequently he served as assistant to the president, was appointed general manager and named president of Alberta's two large natural gas utilities in 1949. He has been a director of Canadian Utilities Limited for several years.

**H. G. Hughson,** M.E.I.C., construction engineer for the province in the New

H. G. Hughson, M.E.I.C.

Brunswick Department of Public Works, has resigned as councillor of the Institute. He has been elected to the council of the City of Fredericton, and in view of the fact that he was the candidate of the Fredericton Branch he feels that he should devote all his spare time to city affairs. It is a matter of interest to note that Mr. Hughson headed the poll.

**M. F. Keith Leighton,** M.E.I.C., structural engineer with Canadian National Railways in Moncton, has been elected chairman of the Moncton Branch of the Engineering Institute.

Mr. Leighton, a native of Moncton, received his civil engineering degree from the University of New Brunswick in 1949.

Previous to graduation, from 1941 to 1943, Mr. Leighton was a member of the original crew that surveyed and laid out the Goose Bay Airport in Labrador. During this time he held the positions of rodman, foreman and inspector, and worked on various types of construction with the Department of Transport.

During the summers of 1947 and 1948 he served as instrumentman with the highway division of New Brunswick Department of Public Works and was employed on highway diversions, draughting, mapping and setting grades. The following summer he was instrumentman with Canadian National Railways with the terminal engineer at Cape Tormentine, N.B., where he was in charge of surveys, setting grades and taking soundings for dredging.

Upon graduation Mr. Leighton was appointed structural engineer with the bridge department of Canadian National Railways. In this position he is responsible for the inspection of steel bridges and timber trestles, design of steel and timber bridges, design of reinforced concrete structures such as abutments, piers, retaining walls and slabs.

**P. V. Palmer,** M.E.I.C., has been appointed chief engineer of Howard Smith Paper Mills Limited in Montreal.

Mr. Palmer, a graduate of Ecole Polytechnique, class of 1945, has been formerly employed by Manitoba Paper Company Limited and Arborite Company Limited as plant engineer in Ville LaSalle, Que.

**J. C Anderson,** M.E.I.C., is vice-president of Atlas Asbestos Company Limited of Montreal. He was previously production manager of the company.

Mr. Anderson graduated in civil engineering from the University of Toronto in 1939.

**Frank Edward Ayers,** M.E.I.C., Fort William city engineer, has been elected chairman of the Lakehead Branch of the Engineering Institute.

A native of Saskatoon, Sask., Mr. Ayers is a graduate of the Saskatoon Technical Collegiate and of the University of Saskatchewan, receiving his B.Sc degree in civil engineering in 1943. During 1945 to 1946 he undertook postgraduate study on advanced strength of materials at the University of Saskatchewan.

During the summer of 1942 Mr. Ayers served as chainman in the Saskatoon division of the Canadian National Railways and upon graduation joined the Royal Canadian Engineers with the rank of lieutenant.

At the close of the war he was an instructor for a year at the University of Saskatchewan, after which he joined the Canadian National Railways as instrumentman in the Port Arthur division. He was appointed to his present position in 1947.

**D. H. Johnston,** M.E.I.C., has been appointed manager of manufacturing in the Canadian General Electric Company's electronic equipment department.

Mr. Johnston is a graduate in electrical engineering of Queen's University, class of 1941. His wartime service included two years on the Inspection Board of the United Kingdom at Research Enterprises, Toronto, and two years "on loan" as an air radio officer to the Royal Navy's Fleet Air Arm.

D. H. Johnston, M.E.I.C.

He joined Canadian General Electric in 1947 and was engaged in sales and product planning work on mobile communication, broadcast and television, and defence equipment until 1952, when he became successively supervisor of production control and manager of the manufacturing sub-section in the electronic equipment department. In his new position, Mr. Johnston is responsible for material control, production control, planning and wage rate, assembly and test, quality control and works facilities.

**Frederick Hubert Clark,** M.E.I.C., hydro-electric engineer with Bowaters Newfoundland Pulp and Paper Mills Co. Ltd., has been elected chairman of the Corner Brook Branch of the Engineering Institute.

Mr. Clark was born in St. John's, Nfld., and attended Bishop Field College and Memorial University College there. He enrolled in the Nova Scotia Technical College in 1941, graduating with a B.Eng. degree in mechanical engineering in 1943.

During the summer months of 1937 to 1939 he was employed by the Department of Natural Resources as chainman, instrumentman and chief of party on topographical surveying in St. John's, Nfld. During the following summer he served as mechanic's helper with the McNamara Construction Company at Torbay, Nfld.

In 1940 and 1941 Mr. Clark was employed first as draughtsman and later as assistant chief draughtsman with the United States Army Engineers at Fort Pepperrell, Nfld.

Upon graduation in 1943 he joined the Royal Canadian Air Force as aeronautical engineer officer, serving until 1945 when he entered Construction Equipment Co. Ltd. in Toronto as sales and service engineer.

He was associated briefly in 1946-1947 as power plant design engineer with Canadair Ltd. in Montreal, and then entered Bowaters Nfld. Pulp and Paper Mills Co. Ltd. of Corner Brook, as hydro-electric engineer.

**T. R. Wingate,** M.E.I.C., previously assistant to production director with Dowty Equipment Limited in Cheltenham, England, has joined Messrs. Associated Industrial Consultants Limited of London. He expects to return to Canada later this year to join the Canadian office of the company.

Mr. Wingate is an associate member of the Institution of Mechanical Engineers of Great Britain.

**William Watson,** M.E.I.C., St. John's, Newfoundland branch manager of Canadian General Electric Co. Ltd., has been elected chairman of the Newfoundland Branch of the Engineering Institute.

Mr. Watson was born in St. John's, Nfld., and was educated at Bishop Field College, Mt. Allison Academy and University, and McGill University where he obtained his B.Sc. degree in electrical engineering in 1924.

William Watson, M.E.I.C.

He began his engineering career in the summer of 1923 as junior engineer with the Sir W. G. Armstrong Whitworth Company at Deer Lake, Nfld. He remained with this company for a

year after graduation and then undertook the test course of the General Electric Company in Schenectady, N.Y. and Pittsfield, Mass. In 1927 he entered the commercial engineering department of the company in Schenectady. Toward the end of the same year he was appointed company representative in St. John's, Nfld.

He was named to the position of manager of Canadian General Electric Co. Ltd. in St. John's in 1949.

**Dr. F. W. Gray,** M.E.I.C., of Victoria, B.C., has been a member of the Institution of Mining Engineers of Great Britain for 50 years and his name has been recorded by Council in the Annual Report.

N. Webster, president of the Institution, recently offered Mr. Gray on behalf of the Council cordial congratulations on his achievement, and sincere appreciation of his valuable support of the Institution over this very long period.

**W. R. Way,** M.E.I.C., vice-president of The Shawinigan Water and Power Company in charge of the generation and transmission department has announced the following department organizational changes. **E. W. Knapp,** M.E.I.C., who has been with the department since 1925, and chief electrical engineer for the past three years, is appointed engineering assistant to the vice-president. Manager and assistant manager, respectively, of the department are **J. M. Sharpe,** M.E.I.C., and **A. L. Hough,** M.E.I.C.

Also announced were the formation of an engineering division of the department to merge the former communication division and the system planning division; the appointment of personnel to that new division; and the change of name of the field engineering division, with headquarters at Shawinigan Falls, to be known now as the field services division.

**J. M. Crawford,** M.E.I.C., formerly superintendent of the planning division, has been appointed chief engineer of the newly-formed engineering division. **B. C. Hicks,** M.E.I.C., assistant superintendent of the former system planning division and protection engineer, is named superintendent of protection in the new division.

**Eugene E. Gareau,** M.E.I.C., formerly assistant to the division engineer in the generation and transmission department of the Field Engineering Division of the Shawinigan Water and Power Company in Shawinigan Falls, Que., has been promoted to the position of divisional engineer.

Mr. Gareau has been associated in various positions with the company since graduation in electrical engineering from McGill University in 1943.

**C. H. R. Campling,** M.E.I.C., assistant professor on the staff of the Royal Military College, has been appointed chairman of the Kingston Branch of the Engineering Institute.

**C. H. R. Campling, M.E.I.C.**

A native of Melville, Sask., Mr. Campling attended Melville Public School and Queen's University where he received his B.Sc. degree in electrical engineering in 1944.

During 1944 and 1945 Mr. Campling served with the Royal Canadian Signals with the rank of lieutenant, and at the close of the war became instructor in the department of mathematics at Queen's University. In 1948 he became research engineer in the servomechanisms laboratory of the Massachusetts Institute of Technology where he also received his S.M. degree.

The following year he was employed in research on magnetic amplifiers with the National Research Council; and in 1950 he was appointed assistant pro-

fessor at the Royal Military College where he was responsible for the installation of the electrical power laboratory, and the organization and teaching of courses on the power aspects of electrical engineering.

He is a member of the Institute of Radio Engineers.

**Dr. Lyle G. Trorey,** M.E.I.C., announces that he has combined with Blanchet and Associates Limited, geological engineers, to form Blanchet, Trorey and Associates Limited, civil, geological and photogrammetric engineers, of Calgary and Vancouver.

Since the war, Dr. Trorey has been associated as a principal in the development and application of aerial survey of techniques to many major industrial developments in this country. During this time he has acted as consultant and adviser to Commonwealth and other governments and agencies, and to industry.

In World War II he organized, trained and commanded the aerial mapping company of the Royal Canadian Engineers, carrying out operational mapping for the Canadian Army overseas in the northwest European theatre. Concurrently he initiated classified radar-photogrammetric and all other development projects for the War Office and for the Canadian Army.

Dr. Lyle G. Trorey, M.E.I.C.

Dr. Trorey was born in Vancouver. He received his B.Sc. degree in engineering from the University of British Columbia, and his Ph.D. degree from the University of London.

He was employed on the engineering staff of the contractors on arterial highway construction in the United Kingdom, and upon his return to Vancouver, he was associated for some years with the B.C. Forest Service during which time he was closely connected with early developments in aerial survey and photomensuration techniques. After several years of highway, river protection, transmission line, and airport work for both the British Columbian and Federal governments, he opened an office in Vancouver as a consulting engineer.

Dr. Trorey is a graduate member of the Institution of Mechanical Engineers, London, a member of the Association of Professional Engineers of British Columbia and Ontario and of the Dominion of New Zealand, the Canadian Institute of Forestry, the Empire Forestry Association, the American Society of Photogrammetry and an associate member of the Royal Photographic Society.

**J. W. Millar,** M.E.I.C., chief mechanical

J. W. Millar, M.E.I.C.

officer of the Ontario Northland Railway in North Bay, Ont., has been elected chairman of the Nipissing and Upper Ottawa Branch of the Engineering Institute.

Mr. Millar was born in Scotland and came to Canada at the age of three. He received his public and high school education in Revelstoke, B.C., and his B.A. and B.A.Sc. degrees from the University of British Columbia in 1926 and 1927, respectively.

He served from 1923 to 1930 as a machinist apprentice with Canadian Pacific Railways in Revelstoke and Winnipeg, acting as assistant dynamometer car operator in Winnipeg in 1929. The following year he was appointed assistant chief draftsman (mechanical) in the locomotive and car department, and two years later locomotive shop foreman in Sutherland, Sask., and Kenora, Ont.

He was appointed shop engineer in the Winnipeg Weston shops in 1934, becoming locomotive foreman in Wynyard, Sask., in 1936.

Mr. Millar was transferred to Vancouver as general locomotive foreman in 1938.

He joined the department of Railways of the Province of British Columbia in 1943 and remained in that position until 1947 when he was appointed superintendent of Pacific Great Eastern Railway in Vancouver. A year later he was named to his present position as chief mechanical officer with Ontario Northland Railway in North Bay.

Mr. Millar is a member of the Association of Professional Engineers of British Columbia and of Ontario, the American Society of Mechanical Engineers, the Canadian Railway Club and the Toronto Railway Club.

**G. B. Thompson,** M.E.I.C., is assistant engineer with McCurdy Radio Industries Limited in Toronto.

A B.A.Sc. graduate in engineering physics of the University of Toronto, class of 1947, Mr. Thompson was formerly associated as development engineer with Northern Electric Co. Ltd. in Belleville, Ont.

**H. Brian White,** M.E.I.C., has joined the Aluminum Company of Canada, Ltd. in Montreal where he is with the transmission line section of the electrical development division.

From 1949 to 1954 Mr. White was with B.C. International Engineering Co. Ltd., Vancouver, where he worked on the design of the transmission line and other phases of the Alcan Kemano Kitimat project.

A graduate of the University of Toronto in structural engineering, class of 1944, he is a member of the Corporation of Professional Engineers of Quebec.

**Campbell Fraser,** M.E.I.C., division engineer of the Ontario Department of Highways for the Kingston area for past two years, has been transferred to Toronto.

He is a graduate of Queen's University in civil engineering, class of 1934.

**William M. Walker,** M.E.I.C., assistant system planning engineer with the British Columbia Electric Co. Ltd. in Vancouver, is now on loan for a two-year period with Atomic Energy of Canada Ltd. in Chalk River where he will conduct research into applying atomic energy to industry.

Mr. Walker is a graduate of the University of British Columbia in electrical engineering, class of 1945.

**J. Richard Cavanagh,** M.E.I.C., a 1944 graduate civil engineer of the University of Toronto, has entered private practice in Toronto. Mr. Cavanagh, who is from Winnipeg, is one of five brothers who are all professional engineers.

He was formerly a consultant in patent matters with Fetherstonnaugh & Co. in Toronto.

**Lt. Cmdr. W. J. Reynolds, R.C.N.,** M.E.I.C., 1949 chemical engineering graduate of the University of Toronto, has been transferred from H.M.C.S. *Naden*, Esquimalt, B.C., to H.M.C.S. *Algonquin*, Halifax.

**R. M. Rutherford,** M.E.I.C., formerly assistant chief engineer with the Public

Utilities Commission in Victoria, B.C., is now chief engineer with Inland Natural Gas Co. Ltd. in Vancouver, B.C.

Mr. Rutherford graduated in electrical engineering from McGill University in 1938.

**P. S. Sidney-Smith,** M.E.I.C., formerly municipal engineer for the Township of Chilliwack, B.C., has been appointed city engineer at Hopkins, Minn.

He is a civil engineering graduate of Queen's University, Belfast, Ireland, class of 1949.

**Samuel Glover Anderson,** M.E.I.C., is attached to the special contract department of the Bell Telephone Company of Canada in Montreal. He was previously in the special services engineering department of the Manitoba Telephone System in Winnipeg.

Mr. Anderson graduated in electrical engineering from the University of Manitoba in 1949.

**John S. Slater,** M.E.I.C., is associated with Pembina Pipe Line Company Limited in Edmonton, Alta. He was formerly senior civil engineer with Consulting Engineers B. D. Bohna and J. L. Miller Ltd. of Vancouver.

Mr. Slater graduated in civil engineering from the University of British Columbia in 1944.

**G. L. Archambault,** M.E.I.C., formerly sales manager of Northern Equipment Limited, has been appointed manager of Raymond Distributing Company Ltd., manufacturers of industrial aluminum windows in Montreal.

G. L. Archambault, M.E.I.C.

Mr. Archambault is a 1939 mechanical engineering graduate of McGill University.

**E. J. Robertson,** M.E.I.C., formerly associated with Bepco Canada Limited in Montreal, is now installation project supervisor with Canadian Aviation Electronics Ltd. in Montreal.

He received his B.Sc. degree from the University of Manchester in 1930

**P. E. Goodwin,** M.E.I.C., recently formed with two others the Defiance Engineering and Microwave Corporation, designers and manufacturers of electronic components in Wakefield, Mass. He is treasurer and chief engineer.

Mr. Goodwin was previously assistant to the president of Diamond Manufacturing Corporation and Diamond Microwave Corporation in Wakefield, Mass.

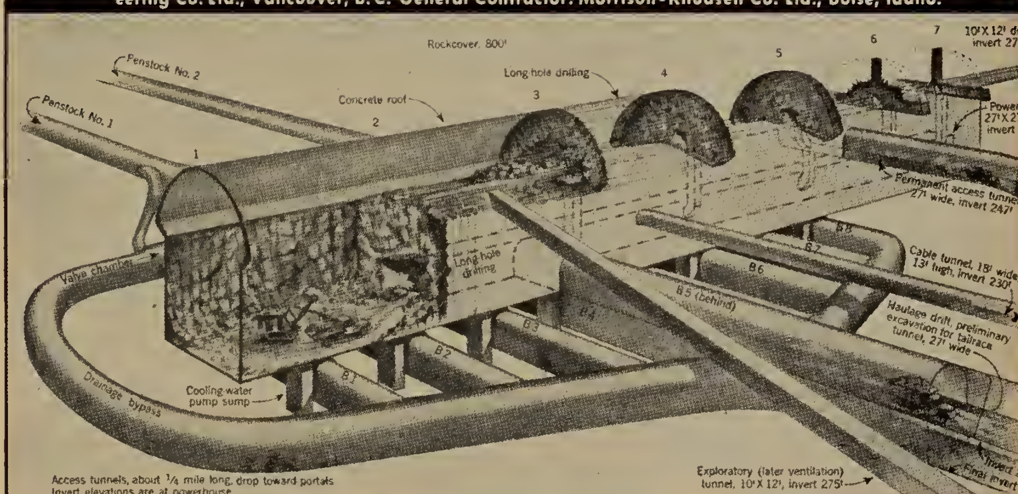
He is a member of the Institution of Mechanical Engineers of Great Britain and of the American Society of Mechanical Engineers.

**G. MacGregor,** M.E.I.C., is associated with the Manitoba Power Commission in Winnipeg, Man. He was previously electrical draughtsman with Canadian Vickers Ltd. in Montreal.

Mr. MacGregor received the higher national certificate in electrical engineering in 1949.

# *largest of its kind...*

**ALCAN-KEMANO-KITIMAT POWER DEVELOPMENT**
Owner: Aluminum Company of Canada, Ltd. Engineer: British Columbia International Engineering Co. Ltd., Vancouver, B.C. General Contractor: Morrison-Knudsen Co. Ltd., Boise, Idaho.



## another noteworthy ALCAN power project where POZZOLITH* was employed in concrete

Alcan's 13-year experience with Pozzolith—Shipshaw Dam in 1941, Arvida Plant, Peribonka Power Developments No. 1 and No. 2 and others—led to its use in building the great Kemano-Kitimat power project, a portion of which is shown here.

Alcan engineers employ Pozzolith to assist them in meeting their high standards of strength control, and requirements of flow and workability without excessive bleeding or segregation.

Whatever the materials or conditions, Pozzolith with its adaptations facilitates the production of concrete of specified qualities, and at a lower cost than by any other means.

***POZZOLITH** . . . reduces unit water content up to 15% for a given placeability, and fully complies with the water-cement ratio law. Adaptations of Pozzolith permit rigid control of entrained air. Produced in three standard formulations—High Early Pozzolith, Normal Pozzolith and Low Heat Pozzolith—to give the results required under varying job conditions.

TORONTO 9, ONTARIO

**Henri F. Beique,** M.E.I.C., has been appointed assistant general manager of the Quebec Power Company and the Quebec Railway, Light and Power Company.

Henri F. Beique, M.E.I.C.

Born in Montreal, Mr. Béique studied at the College Ste. Marie and Mont St. Louis College, and later at Lycee Louis-le-Grand in Paris for two years, receiving his B.A. from the Sorbonne in 1930. Returning to Canada, he obtained his degree in electrical engineering from McGill University in 1936.

Joining the Shawinigan Water & Power Company in 1936, he was transferred to Quebec Power Company in May of 1937 and was successively appointed assistant superintendent of the power division in 1938, superintendent in June of 1942, general superintendent of the Quebec Power Company in 1946 and general superintendent of the Quebec Railway, Light and Power Company in 1950.

Mr. Béique is a member of the Corporation of Professional Engineers of Quebec and of the American Institute of Electrical Engineers.

**Lionel Swift,** M.E.I.C., superintendent of the electricity division of the Quebec Power Company has been appointed

Lionel Swift, M.E.I.C.

Nearly
400,000 KVA
of high-voltage
FERRANTI TRANSFORMERS
distribute power for Aluminum Company of Canada at
KEMANO & KITIMAT
One of the four—71,000 kva, OFW, single-phase, 60 cycle, 55°C, Ferranti generating transformers is shown here ready for installation inside the 134 foot high, arched cavern at Kemano. Ferranti also supplied three—37,000 kva, OFW, single-phase, 60 cycle transformers, which were installed at Kitimat to step the voltage down for the smelter and the city of Kitimat. Ferranti was the only company called upon to supply transformers for both the generating and receiving end of this tremendous project... a total of nearly 400,000 kva. We are proud to have contributed our engineering and manufacturing experience and we extend our heartiest congratulations to the men of Alcan for their courage and foresight.

general superintendent of operations.

Mr. Swift is a native of Shawinigan Falls, where he received his early schooling and where he worked for some years before starting his studies at McGill University; he graduated in electrical engineering in 1934 and spent the following two years on the Shawinigan Water and Power Company training course.

He worked at Thetford Mines and the system office at Shawinigan Falls up to 1939 when he came to the Quebec Terminal Station as assistant to E. Chartier.

In 1945 he was transferred to the Quebec Power Company and successively occupied the positions of superintendent of the engineering department, assistant superintendent of the power division, and finally in October, 1946, superintendent.

He is a member of the Corporation of Professional Engineers of Quebec, and the American Institute of Electrical Engineers. He is also assistant professor in the electrical department of Laval University.

**Maurice D'Amours**, M.E.I.C., has been named superintendent of operations in the electricity division of the Quebec Power Company.

Mr. D'Amours was born in Rivière du Loup. He received his B.A. in 1941 and graduated from Laval University as electrical engineer in 1945.

Maurice D'Amours, M.E.I.C.

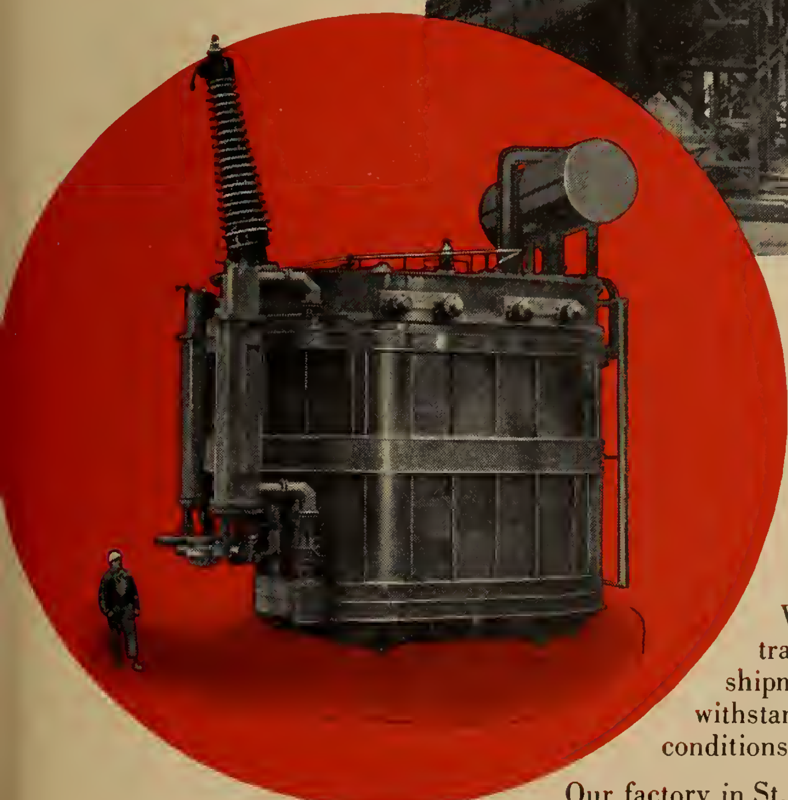
He entered the service of the Quebec Power Company in the same year and has since successively occupied the positions of distribution engineer, superintendent of the Quebec district, and superintending engineer of transmission and distribution until June of this year when he was named assistant superintendent of the electricity division.

He is a member of the Corporation of Professional Engineers of Quebec, and is also the president of the Engineering Alumni Association of Laval University.

**Pierre A. Duchastel**, M.E.I.C., superintendent of the engineering department of the Quebec Power Company, has recently been appointed chief engineer.

Born in Outremont, Mr. Duchastel studied at Mont St. Louis. He entered McGill University in 1934 and gradu-

# ONE OF THREE AT KEMANO



One of three 71,000 KVA English Electric power transformers goes into position at Kemano. The bank steps up the 213,000 KVA output from two generators to 301,400 volts for transmission to the smelter at Kitimat.

We completely impulse tested these transformers for 1050 KV BIL before shipment to prove the transformers could withstand anticipated lightning or other surge conditions.

Our factory in St. Catharines is equipped to design, build and impulse test the largest high voltage transformers.

English Electric Company of Canada Limited. Head Office and Factory: St. Catharines, Ontario

Pierre A. Duchastel, M.E.I.C.

ated in electrical engineering in 1938.

He started his career with Ferranti Limited in England and was later transferred to the Company's Toronto office. From 1941 to 1945 he was on loan to the National Research Council in Ottawa on war work as assistant research engineer.

He joined the Quebec Power Company in April, 1946, and occupied the position of electrical engineer. In 1950 he was named superintendent of the engineering department.

He is a member of the Corporation of Engineers of the Province of Quebec, and of the American Institute of Electrical Engineers.

**G. F. Kelly,** M.E.I.C., has been recently named assistant chief engineer of the Quebec Power Company.

A native of Halifax, Mr. Kelly studied at St. Mary's University and the Nova Scotia Technical College from which he graduated in 1943.

From the time of his graduation until March, 1946, he served with the Royal Canadian Navy in Ottawa, on the North Atlantic and with the British Admiralty in England.

He joined the Quebec Power Company in April, 1946, as assistant electrical engineer and became assistant superintendent of the engineering department in February, 1950.

G. F. Kelly, M.E.I.C.

He is a member of the Corporation of Professional Engineers of Quebec and of the American Institute of Electrical Engineers.

**C. S. Nicoll,** M.E.I.C., formerly associated with Fraser Brace Terminal Constructors in Saint John, N.B., has been appointed branch manager of Defence Construction (1951) Ltd. in Halifax.

He received his B.Sc. degree from Acadia University in 1935.

**C. J. Jamieson,** M.E.I.C., formerly chief engineer with Sylvanite Gold Mines Ltd. of Kirkland Lake, has organized the firm of Junek & Jamieson Construction Co. Ltd. in Sarnia, and has served as its president and general manager since 1951.

Mr. Jamieson is a McGill University mining engineering graduate of 1935.

**L. A. W. Davis,** M.E.I.C., is defence research technical officer with C.A.R.D.E. in Quebec City. He was previously electrical test engineer with Canadian Vickers Ltd. in Montreal.

Mr. Davis received his national certificate from Melbourne Technical College in 1950.

He is a member of the Institution of Electrical Engineers.

**E. G. Taylor,** M.E.I.C., is associated with the Department of National Defence (Army) as deputy to the engineer in charge of sanitation and roads section, design division. He is located in Ottawa.

Mr. Taylor was previously senior engineer with C. A. Meadows & Associates Ltd. in Toronto. He is a 1948 graduate in civil engineering of Queen's University, Belfast.

**H. G. E. Rhodes,** M.E.I.C., is associated with the city's engineering department in Regina.

A graduate in electrical engineering of the University of Manitoba, 1933, Mr. Rhodes has been engaged since his return from R.C.A.F. service, in equipment sales and private consulting work.

**H. G. E. Rhodes, M.E.I.C.**

**P. H. Morgan,** M.E.I.C., is construction consultant with Aluminum Laboratories in Montreal. He was previously British West Indies project manager with Sprostans Ltd. in Shooters Hill, Jamaica.

**Herbert M. Edwards,** M.E.I.C., has been appointed to the permanent staff of Queen's University as assistant professor of civil engineering.

He recently returned from Purdue University where he received his master's degree in traffic and highway engineering. He received his B.Sc. degree from Queen's University in 1944.

**Donald R. Kline,** M.E.I.C., has been appointed director of the sub-contract department of the H. F. Campbell Construction Company in Detroit, Mich. He was formerly purchasing agent of the company.

Mr. Kline is a mining engineer graduate of the Nova Scotia Technical College, class of 1941.

**Capt. (L) John Deane, R.C.N.,** who was formerly stationed at Sorel, Que., as principal naval overseer of Marine Industries Ltd., is now at Naval Headquarters in Ottawa where he is assistant chief of Naval Technical Services (Ships). In his present position he is assistant to Rear Admiral Knowlton who is responsible for all ship building and ship repair in the Royal Canadian Navy.

Capt. Dean is a 1934 graduate in electrical engineering of the University of British Columbia.

**Kenneth R. Shipley,** M.E.I.C., has been transferred by Imperial Oil Limited in Toronto to the pipeline division as assistant chief engineer.

A graduate of the University of Toronto, class of 1935, Mr. Shipley has been associated with the company for many years.

**P. Maguire,** M.E.I.C., formerly structural engineer with the Canadian Bridge Company in Walkerville, Ont., is now design and contracting engineer with the Sarnia Bridge Company in Sarnia, Ont.

Mr. Maguire received the higher national certificate from South East Sussex Technical College in 1951.

**A/C V. H. Patriarche, R.C.A.F.,** M.E.I.C., has been promoted from the rank of group captain and his position is that of chief of training at Air Force Headquarters in Ottawa. He was previously with No. 2 group, Ottawa.

A/C Patriarche received his B.Sc. degree from the University of Manitoba in 1929.

**D. L. MacKinnon,** M.E.I.C., has been transferred by Foundation Company of Canada Ltd. from Gaspe, Que., to Montreal.

Mr. MacKinnon received his B.Sc. and M.Sc. degrees in civil engineering in 1939 and 1944, respectively.

**Raymond A. Frigon,** M.E.I.C., who, for the past two years has been program officer in the United Nations Technical Assistance Administration in New York, has joined the Department of Public Works of the Federal Government as executive assistant to the chief engineer.

**A. D. Lindsay,** M.E.I.C., formerly associated with the Stone & Webster (Canada) Company in Trail, B.C., has joined the Hydro-Electric Power Commission of Ontario at Cornwall, Ont.

He is an associate member of the Institution of Civil Engineers of Great Britain.

**Geoffrey P. Webb,** M.E.I.C., a 1952 London University graduate, has joined the Aluminum Company of Canada as a system operation engineer at Shipshaw, Arvida.

Mr. Webb was previously associated with the power and transformer sales section of the apparatus division's marketing department of the Canadian General Electric Company in Toronto.

The following engineers have accepted positions with the St. Lawrence Seaway Authority: **Frith Jof Ness,** M.E.I.C., **Duncan McIntyre,** M.E.I.C., **Keith Ogilvie Whyte,** M.E.I.C., **William James Weymark,** M.E.I.C., **Charles Elmer Scott,** Jr.E.I.C., **Keith Leslie Coldwell,** Jr.E.I.C., **Donald McLeod Ripley,** Jr.E.I.C., **Frederick Ivor Morton,** Jr.E.I.C., **Ernest Joseph Rossi,** Jr.E.I.C., **Kenneth Saville Flitton,** Jr.E.I.C., **Douglas St. Elmo Cameron,** Jr.E.I.C., **Arland Edgar Benn,** Jr.E.I.C., **Walter Edward Webb,** Jr.E.I.C., and **Emeric George Leonard,** Jr.E.I.C.

**William L. Booth,** Jr.E.I.C., who graduated in civil engineering from the University of Toronto in 1946, is design engineer with Abitibi Power and Paper Company Limited, and is at present located at the Iroquois Falls Mill.

Previous to joining the company, Mr. Booth was on the staff of the Hydro-Electric Power Commission of Ontario and Margison & Babcock in Toronto.

**H. Raymond Beck,** Jr.E.I.C., one of the first Canadian industrial engineers to receive the Athlone Fellowship, has returned to Toronto after two years' studies in the United Kingdom. He completed advanced training in electrical engineering including the application, design, manufacture, test and operation of electrical signal equipment, and earned the Diploma of Membership of the Imperial College in London.

Mr. Beck, a signal engineer for Canadian National Railways in Toronto, was granted leave of absence to accept the Athlone Fellowship award.

He is a graduate of the University of Manitoba, class of 1947, and holds a B.Sc. degree in electrical engineering with gold medal honours.

**R. R. Ritchie,** Jr.E.I.C., a 1947 graduate in electrical engineering of the University of New Brunswick, has joined Calgary Power Limited in Calgary. He was previously associated with Montreal Engineering Co. Ltd. in Montreal.

**E. Lundman,** Jr.E.I.C., a 1947 graduate in civil engineering of the University of Manitoba, has resigned as town engineer of Dauphin, Man., and is now employed by the Harper Construction Company in Winnipeg.

**J. C. Finch,** Jr.E.I.C., a 1947 graduate in civil engineering of McGill University, is on the staff of DuPont Company of Canada Ltd. as design engineer in Montreal.

He was previously technical assistant with Canadian Industries Limited in Maitland, Ont.

**J. L. Kendry,** Jr.E.I.C., is industrial engineering supervisor of the Canadian products division of Canadian Johns Manville Co. Ltd. in Asbestos, Que.

A graduate in mechanical engineering of the University of Saskatchewan, class of 1947, Mr. Kendry was formerly associated as methods engineer with the Stanley Tool Co. of Canada Ltd. in New Britain, Conn.

**William Koropatnick,** Jr.E.I.C., assistant district engineer with the highways branch of the Department of Public Works, has been transferred from Boissevain, Man., to Winnipeg.

Mr. Koropatnick has been associated with the Department of Public Works since graduating in 1949 in civil engineering from the University of Manitoba.

**Kenneth Henry Williamson,** Jr.E.I.C., is on the staff of the special contract department of the Bell Telephone Company of Canada in Montreal.

Previous to joining the company, Mr. Williamson was in England on an Athlone Fellowship. While there he was associated with Messrs. Siemens in London for two years.

Upon graduation from the University of Manitoba in electrical engineering in 1949, Mr. Williamson became telephone transmission engineer with the Manitoba Telephone System.

**R. W. McQueen,** Jr.E.I.C., a graduate of the University of Alberta in chemical engineering, class of 1949, has been appointed operations engineer in the producing department of Imperial Oil Limited's Edmonton district.

He was previously development engineer in the producing department of the Leduc District.

**Donald F. Martin,** Jr.E.I.C., a graduate of the University of Saskatchewan in civil engineering, class of 1949, is now district engineer with the Department of Public Works at Penticton, B.C.

He was formerly associated with Stone & Webster of Canada, Limited in Trail, B.C.

**F/L Norman Bruce Flavin, R.C.A.F.,** Jr.E.I.C., is now specialist officer on test equipment of armament systems at Air Material Command in Rockcliffe, Ont.

He was previously technical armament officer at R.C.A.F. Station North Lufienham, Rutland, England.

F/L Flavin received his B.Sc. degree in chemical engineering from the University of Alberta in 1950.

**F. H. Bruce Chisholm,** Jr.E.I.C., a 1950 graduate of McGill University in mechanical engineering, is now mill engineer with the Canadian International Paper Company in Temiskaming, Que. He was previously associated with the New Brunswick International Paper Company in Dalhousie, N.B.

**J. A. MacGregor,** Jr.E.I.C., has been appointed manager of the Public Utilities Commission of Sault Ste. Marie, Ont.

He has been with the Public Utilities Commission since 1950 and for the past two years has been in charge of all outside work.

Mr. MacGregor graduated in electrical engineering from the University of New Brunswick in 1950.

**George Schotch,** Jr.E.I.C., has been transferred as assistant superintendent with Canada Cement Company Limited from plant No. 1 in Montreal East, to plant No. 8 in Port Colborne.

Mr. Schotch is an electrical engineering graduate of the University of New Brunswick, class of 1950.

**James L. Carveth,** Jr.E.I.C., formerly employed by Interprovincial Chemicals Limited, has joined the staff of L. E. Neil Carr, Calgary consulting engineer.

Mr. Carveth received his B.Sc. and M.Sc. degrees in chemical engineering from the University of Alberta in 1950 and 1953, respectively.

**F. J. Caissie,** Jr.E.I.C., formerly resident engineer with Central Mortgage and Housing Corporation at R.C.A.F. Station Bagotville, Que., has been appointed a project engineer with Defence Construction (1951) Limited at Valcartier Military Camp.

Mr. Caissie received his civil engineering degree from the University of New Brunswick in 1950.

**J. Robert Demers,** Jr.E.I.C., is a consulting engineer in Rimouski, Que. He was formerly structural engineer on the staff of the City of Montreal.

Mr. Demers graduated in civil engineering from McGill University in 1950.

**J. P. Beauregard,** Jr.E.I.C., recently returned from the United Kingdom where he was a graduate trainee with Rolls-Royce Ltd. in the Aero-Engine Division, and has joined the gas dynamics section of the mechanical engineering division of the National Research Council in Ottawa.

Mr. Beauregard received his B.Eng. and M.Eng. degrees in mechanical engineering from McGill University in 1950 and 1952, respectively.

**P. J. Rivard,** Jr.E.I.C., has been granted leave of absence by the soil mechanics and materials division of P.F.R.A. at Saskatoon to accept a temporary appointment as an exchange visitor at Harvard University where he will serve as assistant to Professors Casagrande and Terzaghi and will also provide a liaison for the research work on highly plastic clays being carried on at Harvard and at the University of Saskatchewan by P.F.R.A.

Mr. Rivard received his B.Sc. degree in civil engineering from the University of Alberta in 1948, and his M.Sc. degree in 1950.

**G. L. Bancroft,** Jr.E.I.C., a 1950 graduate in chemical engineering of the University of British Columbia, is now manager of Bumstead-Woolford Ltd. in Vancouver, B.C.

Previous to joining this company, Mr. Bancroft was sales representative with Canadian Industries Limited in Regina.

**J. M. Lawrence,** Jr.E.I.C., was recently appointed refinery engineer with the British American Oil Company at the Calgary refinery.

Mr. Lawrence joined the company after graduation in chemical engineering from the University of Alberta in 1950.

**F. R. Mullen,** Jr.E.I.C., a graduate of the University of British Columbia in electrical engineering, class of 1950, is now Canadian Aviation Electronics representative at the R.C.A.F. Station in North Bay, Ont.

Previous to joining Canadian Aviation Electronics in Montreal in 1953, Mr. Mullen was associated with Northern Electric Co. Ltd. in Montreal.

**F. D. Priestly,** Jr.E.I.C., has been transferred by Canadian Westinghouse Company Limited from Hamilton to the apparatus division in Montreal.

Following graduation in electrical engineering from the University of Alberta in 1950, Mr. Priestly was associated with Saskatchewan Power Corporation in Regina.

**Harold Edson Thornham,** Jr.E.I.C., a 1950 graduate in mechanical engineering of the Nova Scotia Technical College, is on the staff of Construction Equipment Company Ltd. in Halifax.

Since graduation he has been employed by Milton Hersey Co. Ltd., Cameron Contracting Limited in Halifax, and Richard and B. A. Ryan Ltd. in Montreal.

**W. G. Thompson,** Jr.E.I.C., has accepted the position of plant manager with Pioneer Electric Alberta Ltd. in Red Deer, Alta.

A 1950 graduate in electrical engineering of the University of Manitoba, Mr. Thompson was previously associated with Reliance Electric & Engineering (Canada) Ltd. in Welland, Ont.

**L. R. Bergklint,** Jr.E.I.C., a University of British Columbia 1951 graduate in electrical engineering who joined the Canadian Westinghouse Company in 1951 as a student engineer, has been appointed manager of standard motor and control sales in the industrial products division.

L. R. Bergklint, Jr.E.I.C.

Upon completion of the company's graduate student apprentice training course, Mr. Bergklint entered the estimating and pricing section of the motor and control sales department. In 1952 he became supervisor of industrial control sales and has since carried out numerous important industrial projects for Westinghouse.

During World War II he saw service in Europe with the Canadian Armoured Corps and at present holds the rank of major in the 5th Technical Regiment, R.C.E.M.E. (Militia). He is a member of the Association of Professional Engineers of the Province of Ontario and of the American Institute of Electrical Engineers.

**H. F. McCoubrey,** Jr.E.I.C., a 1951 graduate in civil engineering of the Nova Scotia Technical College, has returned from Tanganyika, British East Africa, where he has been associated with the Public Works Department, and has joined the staff of Kilborn Engineering Co. Ltd. in Toronto. He is design engineer in the municipal branch.

**N. Sawitski** Jr.E.I.C., is now located at the R.C.A.F. Station at Uplands Airport as technical representative for Canadian Aviation Electronics.

Mr. Sawitski is a 1950 graduate in electrical engineering of McGill University.

**Stanley Mazure,** Jr.E.I.C., a 1950 graduate in electrical engineering of Queen's University, has been transferred within the DuPont Company of Canada Limited from the Textile Fibre Division in Kingston, to the Engineering Department in Montreal.

**Dr. Ross Edwin Chamberlain,** Jr.E.I.C., who received his B.Eng. degree in civil engineering from McGill University in 1951 and his Ph.D. degree in structural engineering from the University of Birmingham in 1953, is now associated with the structural design department of Dominion Bridge Co. Ltd. in Lachine, Que.

**K. Czerwinski,** Jr.E.I.C., who is on the staff of A. D. Margison and Associates in Toronto, is now on loan to the design division of the Department of National Defence (Army) in Ottawa.

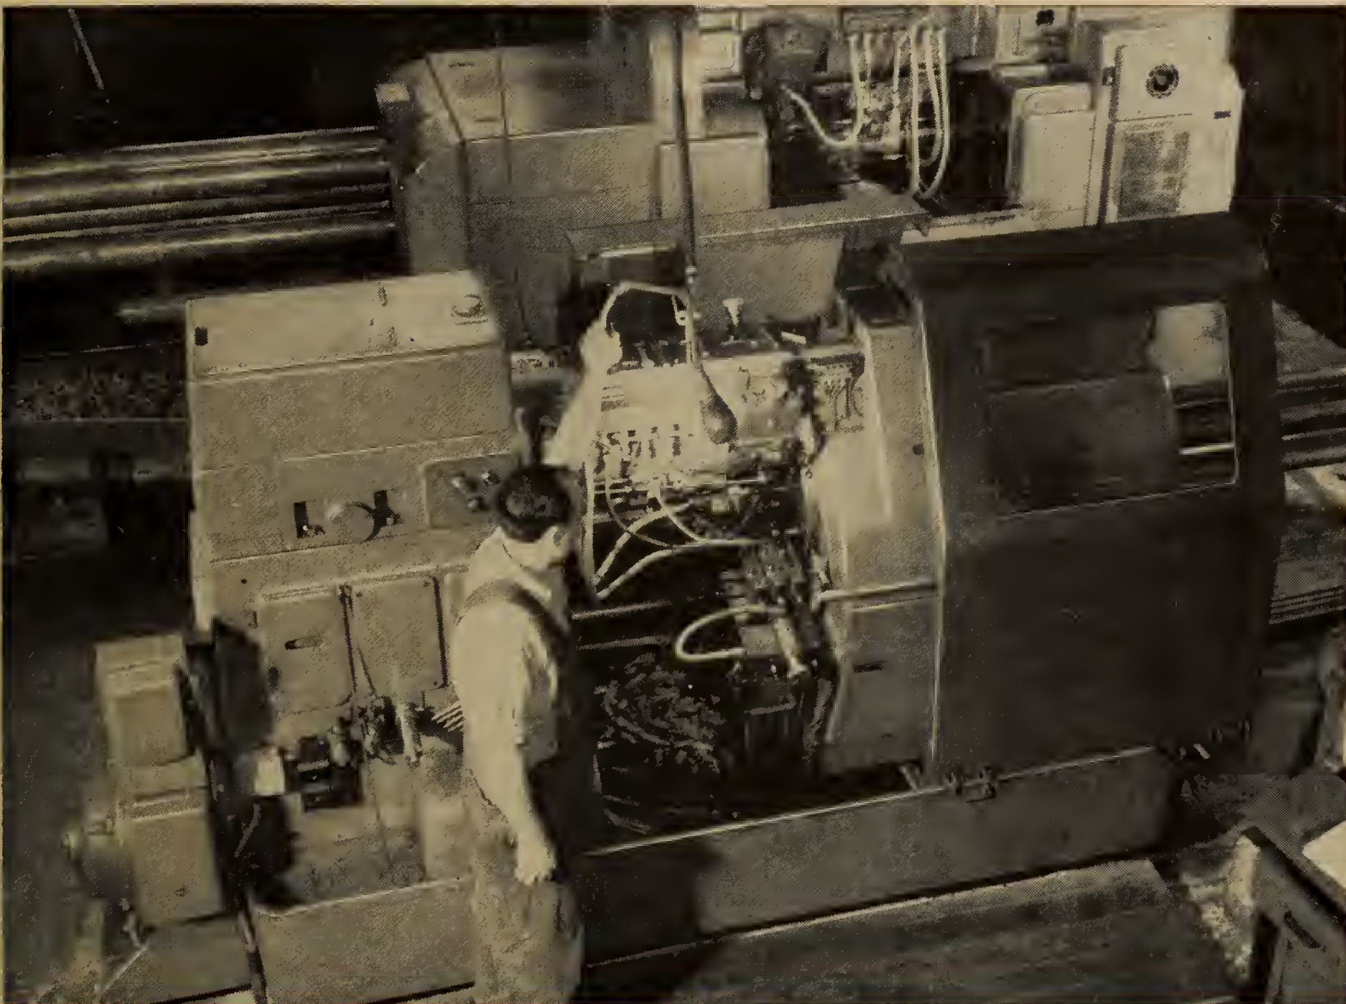
Mr. Czerwinski, a 1951 graduate in civil engineering of Polish University College London, was previously assistant engineer with Dr. P. L. Pratley, Montreal consulting engineer.

**R. L. Denison,** Jr.E.I.C., a 1952 graduate in mechanical and electrical engineering of the University of Sydney, has been transferred by Canadian Locomotive Company, Ltd. from Nelson, B.C. to Kingston.

**H. E. Sears,** Jr.E.I.C., formerly junior design engineer with Aluminum Company of Canada Ltd., is resident construction engineer with the engineering department of the City of Hamilton.

He is a graduate in civil engineering

---



of the University of Toronto, class of 1952.

**W. J. Bell,** JR.E.I.C., a 1952 graduate in mechanical engineering of McGill University, is field engineer with Fischer & Porter (Canada) Ltd.

**R. L. Raskin,** JR.E.I.C., who graduated in 1952 in electrical engineering from the University of Alberta is now employed on the staff of the special contract division of the Bell Telephone Company of Canada.

He was formerly associated with Alberta Government Telephones in Edmonton.

**Yves Hamel,** JR.E.I.C., of the engineering staff of the Canadian Broadcasting Corporation, has been transferred as electrical engineer from Quebec to Montreal.

Mr. Hamel is a 1952 graduate in electrical engineering of Laval University.

**F/O P. J. H. Sheasby, R.C.A.F.,** JR. E.I.C., previously telecommunications officer at the R.C.A.F. Station in Clinton, Ont., is now located at Keesler Air Force Base in Mississippi.

F/O Sheasby is an electrical engineering graduate of the University of Manitoba, class of 1952.

**B. I. Maduke,** JR.E.I.C., a graduate of the University of Saskatchewan in agricultural engineering, class of 1948, and of civil engineering, class of 1952, is employed as soils engineer with the Geotechnical Services in Montreal.

He was formerly resources engineer with the Canadian Department of Resources and Development in Vancouver.

**H. W. Russell Smith,** JR.E.I.C., is junior engineer in the air services branch of the Department of Transport's Winnipeg division.

A graduate of Glasgow University in civil engineering, class of 1953, Mr. Smith was previously associated as construction inspector with the corps of engineers at Goose Bay Airport, Labrador.

A prize of $50.00 and an Engineer's Handbook were recently awarded by the Canadian Construction Association to each of the following in the fourth annual competition for theses on construction subjects: to **N. Cressey,** S.E.I.C., and **H. Sejbjerg** of the University of Saskatchewan for the paper "Modified Soil-Cement Base Course for Rosetown Streets"; to **Eric C. Garland,** S.E.I.C., of the University of New Brunswick for "Precast Concrete Buildings"; to **G. V. Roney,** JR.E.I.C., of Queen's University, for "Combined Cantilever and Simple Beam Design"; and to **R. L. Waddell,** S.E.I.C., of the University of Toronto, for "Factors in the Design of Earthquake-Resistant Structures".

The purpose of the Association's thesis competition is to stimulate interest among engineering students on construction problems with a view to developing new job-site techniques.

**Norman Moysa,** S.E.I.C., a graduate of the University of British Columbia in mechanical engineering, class of 1953, is employed as junior engineer on construction of the Sir Adam Beck No. 2 Generating Station at Niagara Falls, Ont.

**Norman G. Needham,** S.E.I.C., is on the staff of the Yukon Consolidated Gold Corporation, which has seven dredges and one hydraulic operation for the recovery of alluvial gold.

Mr. Needham received his B.A.Sc. degree in mining engineering from the University of British Columbia in 1953.

**Gordon P. Luke,** S.E.I.C., has returned to Kingston to complete his course at the Royal Military College after spending his summer training on road and bridge work with the Highway Maintenance Establishment, Royal Canadian Engineers. His headquarters were at Fort Nelson, B.C., on the Northwest Highway.

**D. Paul Andrews,** S.E.I.C., a 1954 graduate of the Nova Scotia Technical College in civil engineering, is junior petroleum engineer trainee with Imperial Oil Limited in Calgary.

**W. E. Jubien,** S.E.I.C., a graduate this year in civil engineering of McGill University, is now attending the University of Alberta where he is taking his master's degree in soil mechanics and foundations.

**R. E. Hennigar, Jr.,** S.E.I.C., a graduate of the Nova Scotia Technical College in electrical engineering this year, is now junior engineer-in-training with the Hydro-Electric Power Commission in Toronto.

**F. J. Bollinger,** S.E.I.C., a civil engineering graduate of McGill University, class of 1954, is field engineer with the Canadian Kellogg Construction Company.

**F/O C. Fontyn, R.C.A.F.,** S.E.I.C., formerly stationed at the R.C.A.F. Station in Aylmer, Ont., has been transferred to the R.C.A.F. Station at Penhold, Alta.

He is a 1954 graduate of Queen's University in mechanical engineering.

**Brian P. Dowsley,** S.E.I.C., a graduate this year in civil engineering from the University of Toronto, is now employed as lecturer on the staff of the Royal Military College in Kingston.

**William A. Burgess,** S.E.I.C., a mechanical engineering graduate of the University of Saskatchewan, class of 1954, is employed as mechanical engineer at the Regina Refinery of Imperial Oil Limited.

**J. D. Kingston,** S.E.I.C., is employed as a computor on a geophysical survey with the Seismic Party No. 11 of the Socony-Vacuum Oil Co. of Canada Ltd., and is located at Grande Prairie, Alta.

Mr. Kingston graduated in civil engineering from Queen's University this year.

**Andre Hebert,** S.E.I.C., a graduate this year in electrical engineering of Laval University, is now on the staff of the Quebec Hydro Commission in Montreal.

**Peter T. Hodgkins,** S.E.I.C., a civil engineering graduate of Queen's University this year, has been appointed by the Board of Control as assistant engineer in the design branch of the City of Ottawa's engineering department.

**Fred Gane,** S.E.I.C., who graduated this year in mechanical engineering from the University of British Columbia, is on the plant maintenance department of the wire and cable plant of Northern Electric Company Limited in Montreal.

**T. H. Shepertycki,** S.E.I.C., who received his B.Sc. degree in electrical engineering from the University of Manitoba this year, is now attached to the Navy section of the radio and electrical engineering division of the National Research Council.

**S. A. Stone,** S.E.I.C., a mechanical engineering graduate of the University of Manitoba, 1954, is on the staff of the microwave section, radio and electrical engineering division of the National Research Council.

**F. A Villela,** S.E.I.C.. has been structural engineer with the Nova Scotia Department of Highways since graduation in civil engineering from the Nova Scotia Technical College this year.

**Gerald Gagnon,** S.E.I.C., has been employed as process metallurgist in the casting shop of Noranda Copper and Brass Co. Ltd. in Montreal since his graduation with first class honours in metallurgical engineering from Ecole Polytechnique this year.

**D. G. Riecken,** S.E.I.C., a graduate this year of the University of Saskatchewan in mechanical engineering, is employed on the staff of the construction and maintenance department of the North Star Oil Company in Winnipeg.

**Donald H. Pyne,** S.E.I.C., a graduate civil engineer of the University of New Brunswick this year, has accepted the position of junior engineer with the Ontario Hydro-Electric Power Commission.

**Yves Pelletier,** S.E.I.C., a 1952 graduate in chemical engineering of Laval University, is on the staff of the production department of Du Pont de Nemours of Canada Ltd. in Shawinigan Falls.

**Nicholas Lee,** S.E.I.C., who graduated in 1953 in engineering from King's College, London University, is now associated with Howard, Needles, Tammen & Bergendoff, consulting engineers in Kansas City, Mo.

He was previously at Purdue University where he undertook post-graduate work in civil engineering.

**E. F. Cook,** S.E.I.C., has been transferred to the switch-gear and industrial control marketing section of the Canadian General Electric Company in Peterborough. He was previously on the company's test course in Toronto.

Mr. Cook graduated in electrical engineering from the Nova Scotia Technical College in 1953.

**D. A. Pannabaker,** S.E.I.C., formerly of the Western Geophysical Company of Canada in Edson, Alta., is now on the staff of the City of Ottawa.

Mr. Pannabaker is a 1953 civil engineering graduate of Queen's University.

**R. P. Malis,** S.E.I.C., a 1954 graduate in civil engineering of the University of Manitoba, is park engineer for Kootenay National Park, Department of Northern Affairs and National Resources at Radium Hot Springs, B.C.

He was previously associated with the Department of Transport as inspector at Gimli, Man.

**Robert Roberge,** S.E.I.C., has been appointed municipal engineer by the Town of Mont-Laurier, Que. He was previously associated with Canadian National Railways, Levis division, at Quebec City.

Mr. Roberge is a graduate this year in civil engineering of Laval University.

**Jack H. Boyd,** S.E.I.C., is now equipment development engineer in the woodlands division of Marathon Paper Mills of Canada Ltd. in Caramat, Ont.

Mr. Boyd graduated this year in mechanical engineering from Queen's University.

**Tache Boisvert,** S.E.I.C., is on the staff of the Shell Oil Company in Calgary.

He is a geology graduate of Laval University, class of 1954.

**R. G. Nicholls,** S.E.I.C., a graduate this year in mechanical engineering of the University of Manitoba, is junior mechanical engineer with the gas division of the Shell Oil Company in Calgary.

**Frederic Cronn,** S.E.I.C., is junior instrumentman with the Ontario Department of Highways in Toronto. He was previously inspector with Lucas Rotax in Scarborough.

**Donald K. Turner,** S.E.I.C., who graduated this year in civil engineering from the University of Toronto, is on the staff of the City of Toronto.

**I. A. Gibbons,** S.E.I.C., a 1954 graduate in mechanical engineering of the University of Toronto, is on the staff of Imperial Oil Limited, in Sarnia.

**Fernand DeSerres,** S.E.I.C., is on the general engineering staff of Canit Construction Limited in Montreal.

He is a graduate of Ecole Polytechnique in civil engineering, class of 1954.

**K. R. Walker,** S.E.I.C., who graduated in civil engineering from the University of Alberta this year is resident highway engineer with the Department of Highways in Edmonton.

**Thomas Hugh Oxland,** S.E.I.C., a graduate of the University of British Columbia in civil engineering this year, is assistant resident engineer with the British Columbia Power Commission in Victoria.

**C. H. Stephens,** S.E.I.C., is assistant transmission and distribution engineer with the British Columbia Power Commission in Vancouver.

Mr. Stephens is a 1954 graduate of the University of British Columbia in electrical engineering.

**Rene Martel,** S.E.I.C., a graduate of Laval University in chemical engineering this year, is development engineer with Canadian Industries (1954) Limited at Shawinigan Falls, Que

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Edward S. Holloway,** M.E.I.C., who was associated with O. J. McCullock and Company in Montreal West, passed away on July 23, 1954.

Mr. Holloway was born in Montreal on July 18, 1885. Upon receiving his general education there, he entered McGill University, graduating with a B.Sc. degree in civil engineering in 1908. While attending McGill, he was employed during the summers with the Canadian Pacific Railway, first as instrumentman on surveys and construction; then in charge of bridge substructures on the Severn River, Shaws Creek, Bala, Otter Creek, and Point Carling Road; and later as instrumentman on the construction of shops, round houses, track maintenance, and the elevation of track for the Union Station in Toronto.

In 1908 Mr. Holloway became engineer in charge of surveys and location for the Canada and Gulf Terminal Railway, and two years later was placed in charge of construction by the same company. During the winters of 1910 and 1911 he was responsible for the exploration for a 250-mile line to the Gaspé and for the design and construction of all bridge substructures.

In 1911 he was appointed locating engineer from Sherbrooke to Levis by the Quebec Eastern Railway, and the following year he was named chief engineer, and as such, was responsible for the design of all structures.

From 1912 until 1920, with the exception of a period of service with the Canadian Armed Forces, Mr. Holloway was chief engineer with the Canada and Gulf Terminal Railway, and at the same time was engaged in design and construction work.

From 1920 until 1927 he was associated with the Hammermill Paper Company as engineer in charge of Matane operations. During this period he was responsible for the design and construction of wharves, loading plants, piers and booms.

In the summer of 1927 he was employed by Kerry and Chace Co. Ltd. as engineer in charge of surveys for hydro-electric power on the Ottawa River. In 1932 he was on the staff of Canadian Sheet Piling Company. He was subsequently associated with F. A. Gaby, M.E.I.C., the Anglo Canadian Pulp and Paper Company, and the H. E. McKeen Company. In 1939 he served with the National Electricity Syndicate on Ottawa River power developments, and in 1943 he was placed in charge of plant maintenance, repairs and construction by the Commonwealth Plywood Company in Ste. Therese, Que. He opened offices as a consulting engineer in Ste. Therese in 1946, and in 1949 became consulting engineer and managing director for S. & H. Construction Co. Ltd. there. During recent years he was associated with O. J. McCullock and Company.

Mr. Holloway joined the Engineering Institute of Canada as a Student in 1905, transferring to Associate Member in 1910 and to Member in 1928. In January, 1947, he attained Life Membership in the Institute.

**Arthur Benjamin Normandin,** M.E.I.C., technical advisor for the Department of Hydraulic Resources of the Province of Quebec, and a past vice-president of the Engineering Institute, passed away in Quebec City on September 18, 1954.

Mr. Normandin was born at St. Constant, County of Laprairie, Que., on March 29, 1883. He received his general education at Jacques Cartier Normal School, and in 1903 entered Ecole Polytechnique, graduating in 1907 with a B.A.Sc. degree in civil engineering. Previous to graduation, he was employed during the summers with Consulting Engineer F. C. Laberge of Montreal, and with the Department of Public Works in Montreal.

Upon graduation he returned to the office of F. C. Laberge where he was employed for two years on survey and municipal work. In 1909 he was appointed city engineer for Three Rivers, Que., a position he occupied until 1911 when he became associated with Messrs. Grenon and Lavoie of Chicoutimi, engineers engaged in surveying, municipal works and in water power development.

In 1912 he was appointed assistant chief engineer of the hydraulic service of the Department of Lands and Forests for the Province of Quebec, serving as engineer in charge of the approval of

**Arthur Benjamin Normandin, M.E.I.C.**

plans for dams. He was appointed chief engineer of the Department in 1939.

He was named vice-president of the Public Services Board of the Province of Quebec in 1940 and held this position until 1945 when he was made vice-president of the Provincial Electricity Board of the Province.

Mr. Normandin was Canadian delegate at the World Power Conference in Berlin in 1930. He was also a member of the Canadian-American Commission on the study of the St. Lawrence Seaway project, and a member of the Canadian Commission on Marine Utilization, and of numerous other commissions concerned with the study of drainage and aqueduct systems in Quebec City.

Mr. Normandin was a member of the Corporation of Professional Engineers of the Province of Quebec for nearly 20 years, and served as a councillor. He was also a member of the Corporation of Quebec Land Surveyors.

He was very active in the affairs of the Engineering Institute of Canada, having served as vice-president representing Eastern Canada from 1932 until 1937 and as councillor representing the Quebec Branch in 1924 and from 1926 to 1929. He also served as chairman of the Quebec Branch from 1925 until 1929.

Mr. Normandin joined the Engineering Institute as a Student in 1907, transferring to Associate Member in 1912 and to Member in 1933. On January 1, 1948, he attained Life Membership in the Institute.

**Roy Henry Parsons,** M.E.I.C., city engineer of Peterborough for 33 years, passed away after a brief illness at the Civic Hospital on September 6, 1954.

Mr. Parsons was born at Grand Blanc, Mich. on March 7, 1875. He received his early education there and at the University of Michigan. From university he went to the Pennsylvania Railway as rodman and engineering assistant, and in 1900 became topographer with the Algoma Central and Hudson Bay Railway.

In 1901 Mr. Parsons was appointed assistant engineer with the City Engineer's Office of the City of Ottawa, remaining there four years until his appointment as superintendent of the Warren Bituminous Paving Company in Toronto, Ottawa and Regina. He returned to the City Engineer's Office in Ottawa in 1906 and continued in the position of assistant city engineer until 1913 when he was named city engineer of Peterborough, which position he held until his retirement in 1946.

Some of Mr. Parsons' major works in Peterborough were the planning of the Hunter Street bridge, the sewage disposal plant, the extension of the storm sewer system during the depression years as emergency employment, and the supervision of the planting of trees on and about Armour Hill. Mr. Parsons had a broad knowledge of trees, and for a considerable time as city engineer he carried on most of the details of tree planting and maintenance that are now assigned to the parks committee of the council.

Mr. Parsons was a member of the Old Nicholls Hospital board, the Chamber of Commerce and the Peterborough Horticultural Society. He was particularly interested in the Children's Aid Society, having served as secretary for a number of years. He was also active in securing the property for the Children's Shelter and establishing the home as one of the valuable community properties. He was named an honorary member in 1951.

He was a member of the Association of Professional Engineers of Ontario.

Mr. Parsons was one of the founders of the Peterborough Branch of the Engineering Institute and served as its first chairman. He joined the Institute as a Member in 1915, and attained Life Membership in 1947.

**Ashton Burton Cooper,** M.E.I.C., president of Ferranti Electric Limited in Toronto, passed away at his home on September 20, 1954.

He was born in Bloomfield, Ont., on December 31, 1883. He received his early education in Prince Edward County schools and in Boston, and graduated from Tufts College in electrical engineering in 1903.

After two years with the General Electric Company in the testing department in Schenectady, N.Y., and two years as resident engineer with the Westinghouse Company in Pittsburg, Penn., Mr. Cooper joined the Brazilian Traction Company as assistant electrical engineer in charge of power house electrical construction in Rio das Lages, Brazil. He returned to the General Electric Company in 1909 and until 1913 served as engineer in the transformer sales department in Schenectady.

Mr. Cooper came to Canada in 1913 to occupy the position of transformer engineer with Canadian General Electric Co. Ltd. in Toronto. In 1922 he joined Ferranti Electric Limited as general manager, serving subsequently as vice-president and president, which office he retained after retirement from active management in 1947.

He was active in the organization of the Canadian Electrical Manufacturers' Association, and served as its first president. He was a director of the Toronto Industrial Association from its incep-

**Ashton Burton Cooper, M.E.I.C.**

tion and served as president from 1951 until 1954. He was a past president of the Association of Professional Engineers of Ontario, a past vice-president and director at large of the American Institute of Electrical Engineers, and a former chairman of the Canadian Manufacturers' Association. He was also a director of the Canadian National Exhibition.

Mr. Cooper joined the Engineering Institute of Canada as a Member in 1921. In January of this year he attained Life Membership in the Institute.

**Ronald Burns Smith,** M.E.I.C., of the Department of Public Works of Canada in Charlottetown, and chairman of the Charlottetown Branch of the Engineering Institute, died as a result of poliomyelitis on August 18, 1954.

Mr. Smith was born in Saint John, N.B., on November 10, 1924. He received his general education at Victoria School and the Saint John High School.

In 1942 he enlisted in the Royal Canadian Air Force and received his wings and commission. Upon his discharge in 1945 he entered the University of New Brunswick, graduating with a B.Sc. degree in civil engineering in 1949.

During the summer months of his university training he was employed by the Department of Public Works, and upon graduation, continued with the Department until the time of his death.

Mr. Smith was a member of the Professional Institute of Public Service of Canada.

He was actively interested in the affairs of the Engineering Institute of Canada which he joined as a Student in 1947, transferred to Junior in 1951 and to Member in 1951. In 1951 he served as secretary-treasurer of the Prince Edward Island Branch, and in 1953 he was elected chairman of the Branch.

# Employment Service

**THIS SERVICE is operated for the benefit of members of The Engineering Institute of Canada and for industrial and other organizations employing technically trained men—without charge to either party. It would be appreciated if employers would make the fullest use of these facilities to list their requirements—existing or estimated.**

**NOTICES appearing in the SITUATIONS WANTED column will be discontinued after three insertions. They will be reinstated, on request, after a lapse of one month.**

**REPLIES to advertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Canada, 2050 Mansfield Street.**

**INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLateau 5078—may be arranged by appointment.**

## SITUATIONS VACANT

### CHEMICAL

GRADUATE CHEMIST, required to be trained as assistant to cnief chemist. Plant located at Cardinal in Ontario in one of Canada's oldest food industries. Forward all details of experience, education, with pictures, and anticipated salary to File No. 4837-V.

GRADUATE CHEMICAL ENGINEER from Canadian University required by manufacturer of organic chemical products. Attractive opening in new project located in Ontario. Seven years of practical experience production and process development is required. File No. 4930-V.

CHEMICAL ENGINEER or chemist, preferably with experience in paint, printing inks, rubber or plastic industries. To sell chemicals in Toronto district. Apply fully in writing to File No. 4960-V.

SALES ENGINEER required by progressive Vancouver company specializing in process equipment in Western Canada. Canadian graduate preferred with experience in chemical or petroleum industries. Excellent opportunity for man with initiative and personality. File No. 4961-V.

CHEMICAL SALES OPPORTUNITIES for engineering graduates. Young graduates to develop thru-on-the-job training within sales organization and graduates with sales experience in chemical or allied field. File No. 4964-V.

CHEMICAL ENGINEERS required for refinery located in South America. Must be experienced in process engineering including design, economic studies, and/or scheduling of operating programs. Write giving age, education, marital status and complete details of experience. File No. 4970-V.

CHEMIST OR CHEMICAL ENGINEER for control department of a newsprint and specialty mill in P.Q. Preferably some experience in pulp and paper. Duties to include development and mill investigations. Give details of experience and references in initial letter. File No. 4982-V.

### CIVIL

CIVIL ENGINEER required by established construction firm operating in the west suburbs of Toronto. Duties entail sewer, water and road layouts planning and general construction problems. Opportunity for a young man wanting to advance. Please reply stating age, education and experience. File No. 4939-V.

CIVIL ENGINEER required in a city in Western Canada to assist in the planning and designing and supervising of construction in extensions of sewers and also sewage treatment plant. File No. 4940-V.

OFFICE ENGINEER AND ESTIMATOR REQUIRED BY LARGE CONSTRUCTION organization opening new office in Montreal. Services of bilingual graduate engineer experienced in heavy construction. Duties involve quantity take-offs, estimating and design. Good opportunity with permanent position for right party. File No. 4945-V.

CIVIL ENGINEER or architect engineer to act as assistant to chief engineer with large organization in the flour, feed and associated industries. Ten years in civil engineering required. Five years of design, foundations, superstructures, steel and reinforced concrete, 3 years in construction, 2 years in project co-ordination and administration. $12,000. starting with annual improvements, benefits include health insurance, retirement plan, etc. File No. 4946-V.

GRADUATE CIVIL ENGINEERS required for specialized work in soil mechanics and foundation engineering. Post graduate study essential. Locations Montreal and Toronto with some travelling. File No. 4968-V.

APPLICATIONS WILL BE received by The Federal District Commission for the position of Junior Engineer on highway work in the Ottawa area. Duties would be to assist in design and supervision of highway location and construction. A recent graduate would be suitable preferably with experience on highway work. Salary will depend on qualifications and experience. Position may lead to permanent employment. File No. 4969-V.

AN OUTSTANDING OPPORTUNITY for a qualified graduate engineer. Applicants must have had extensive supervisory experience in the construction of highways, dams, tunnels, bridges and like projects, together with a thorough knowledge of estimating and the preparation of tenders. This is a permanent position with an established firm. Write giving full particulars. File No. 4975-V.

WORLD RENOWNED INSTITUTE requires immediately a research engineer to work full time in the materials field for a highway research project. Work includes as well as practical testing, emphasis at the present time on bituminous pavement problems. Young civil engineer with at least a bachelor's degree. He should be interested in research and be able to work on his own. Experience in the materials field will be helpful. The opportunity is given to take one course per term. The salary is in the range of about $350. to $450. per month depending upon education and experience. File No. 4984-V.

CIVIL ENGINEER required by a municipal corporation in Western Canada. Recent graduate having some experience in railroad maintenance preferred. Other duties will cover the design and construction of water and sewage works. This job offers a good variety of experience in the municipal engineering field. File No. 4991-V.

CIVIL ENGINEER required for power department of large industrial concern. Duties include office duties and occasionally field work not necessarily in Canada, in the field of hydro-electric power investigations and development. Applicants must have had fifteen years previous experience. Fluency in French or Spanish in addition to English essential. File No. 4997-V.

ASSISTANT MUNICIPAL engineer for the Town of Pointe Claire, P.Q. Population 12,000. Preferably with experience in maintenance and construction of streets surface water drainage, sewage and watermains. Applicants are required to state qualifications and salary expected. File No. 4999-V.

YOUNG CIVIL ENGINEER required with 3 years or so experience in construction to supervise service station construction Location Ontario. File No. 5003-V.

CONSTRUCTION ENGINEER to act as general superintendent for a rapidly expanding organization of general contractors in Toronto. Minimum 10 years outside experience as general superintendent. Main requisite practical experience. This position is that of assistant to general manager, and carries excellent salary and opportunity for right man. Please reply in confidence stating age, marital status, previous employer and references. File No. 5005-V.

PROFESSIONAL ENGINEER for position of manager of moderate sized construction company. Broad experience in estimating, construction and installation supervision essential. Age in mid forties to work from Toronto office serving mining and newsprint industries across Canada. File No. 5010-V.

RECENT GRADUATE CIVIL engineer required in the track section of a large transportation company in Montreal. File No. 5011-V.

GRADUATE CIVIL ENGINEER for responsible duties in connection with hydraulic research on a large, outdoor erodible-bed tidal river model of the Fraser River estuary on the campus of the University of British Columbia. Must be able to carry out tests, analyze results and prepare engineering reports. Problems deal mainly with river regulations and the maintenance of navigable channels. Reply stating age, experience, education, salary expected. File No. 5017-V.

### ELECTRICAL

TWO COMPETENT EXPERIENCED graduate electrical engineers, with approximately 10 years experience in design, operations and maintenance of distribu-

# WANTED

by the

## City of Hamilton

## ASSISTANT ENGINEER

**Must be a professional engineer holding a degree of Civil Engineer as recognized under the Professional Engineers' Act of Ontario. Applicant should have a minimum of ten years experience in the design, construction and supervision of engineering projects particularly as related to a large municipality. Will be required to assist and work in close co-ordination with the city engineer. This position offers an attractive salary, future security and an opportunity for advancement.**

**Reply stating age, experience, education and relevant information to**

**Personnel Director**
**Corporation of the**
**City of Hamilton**

---

tion facilities in established rapidly growing utility located South America. Reply giving resume education, experience and personal data to File No. 4950-V.

A LARGE MANITOBA UTILITY requires a graduate electrical engineer to fill the position of assistant to the distribution engineer. Applicant should have at least three years experience in distribution practices, including layouts of large distribution areas; estimating of costs of distribution changes and extensions; improvement of voltage conditions and expansion of existing systems, basic economic studies and design of transformer and other special distribution system structure. Ability to write clear and concise reports to supervise one or more junior engineers and a group of draughtsmen and to deal with field staff is essential. A limited amount of travel within the province will be required. Location is in Winnipeg. Applicants should submit details of family status, age, educational background and experience. Applications will be treated confidentially. File No. 4948-V.

ELECTRICAL ENGINEER with at least five years experience on electrical maintenance and operating problems of generating stations and substations of public utility companies. Permanent positions with long established consulting organization New York. Some travel in Latin America. Spanish or Portuguese useful. Salary commensurate with experience. Reply stating age, education, experience and personal particulars. File No. 4950-V.

ELECTRICAL ENGINEER required as junior or assistant distribution engineer. Graduate with at least 3 years field experience operating utility company. Permanent position with long established consulting organization New York. Some travel Latin America necessary in future. Knowledge of Spanish or Portuguese useful. Salary commensurate with experience. Reply giving age, education, experience and personal particulars. File No. 4950-V.

CITY IN WESTERN CANADA requires an electrical engineer. Duties: to prepare reports on problems of electrical distribution and utilization; to consult with large wholesale power customers concerning their electrical supply; to maintain technical records and perform related engineering tasks as required. Salary $335 to $408 per month (graduated scale). Qualifications: graduation in electrical engineering from a recognized university with some experience preferably in electrical distribution system work. File No. 4976-V.

SENIOR DESIGN ENGINEER with a degree in electrical engineering is required for our rotating machines, direct current design section. Applicants should be between 30-45 years of age, with at least six years experience on design of rotating electrical direct current machines in all sizes, including motors, generators, convertors and rotating regulators. He must possess ability to organize, plan, schedule, promote cost reduction and product improvement in engineering. In addition, he must have a thorough knowledge of direct current machine application, and the ability to promote teamwork. This is a senior appointment with excellent opportunity for promotion. Reply in confidence, giving full personal resume, experience, salary expected. File No. 4980-V.

AN OTTAWA ORGANIZATION requires research engineers to investigate problems in the practical application of electro thermal aircraft de-icing. This will include tests in flight and in icing tunnels, and the development of heater pads, and control in co-operation with aircraft firms. University graduation in electrical engineering with experience in aeronautical engineering and preferably in aircraft electric design and development is required. Flying experience is desirable. Salary up to $5,750 per annum depending on qualifications.

---

# Sales Engineer

**Location Montreal required by large Canadian manufacturer for technical sales promotion of building products. Applications are invited from graduate engineers with civil or mechanical background and an aptitude for sales work. Age preferred 30 to 45. Address full details of education and experience to File No. 5023-V.**

---

Apply by letter and enclose resume of qualifications and experience. File No. 4996-V.

YOUNG ELECTRICAL MECHANICAL ENGINEER required for the position of cost estimator. This position offers wide scope for advancement and presents the opportunity for a young engineer to demonstrate his ability and initiative, and to grow with a young company. Location Montreal. File No. 5001-V.

ELECTRICAL ENGINEER required by an Eastern Township paper mill. Recent graduate for layout work, procurement and installation of apparatus for paper mill under supervision of superintendent, apply stating age, qualifications and experience. File No. 5019-V.

### MECHANICAL

TOOL DESIGNER REQUIRED, mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools, light, sheet dies, forging dies, fixtures, jigs and gauges. Canadian background required. Location in Montreal. Write giving full details of training experience and state salary desired. File No. 4884-V.

GRADUATE MECHANICAL ENGINEER required by Quebec (Eastern Townships) paper mill to act as assistant to mechanical superintendent. Some experience preferred but not essential. File No. 4944-V.

MECHANICAL PLANT ENGINEER required by operating division of service organization. University graduate preferred, having 5 to 10 years experience in operation and betterment of steam plants operated by public utilities. Location New York, some travel. Spanish desirable, but not essential. Reply by letter giving age, education, experience, personal data, and minimum salary acceptable. File No. 4950-V.

SENIOR TOOL DESIGNER required by high class tool and gauge manufacturer in Southern Ontario. Must be mechanical engineering graduate or equivalent in actual experience. Should have approximately five years experience in design of cutting tools screw thread systems, fixtures, jigs and fixed and indicating types of gauges. Position provides good prospects for the future. Salary will be commensurate with ability. Reply in writing, stating details of age, experience, education and salary desired. Applications will be kept confidential. File No. 4951-V.

YOUNG MECHANICAL ENGINEER required for sales work. Must be energetic, have a good personality and the ability or a real desire to sell. Some knowledge of heating and ventilating equipment and their applications is desirable. Good opportunity for ambitious man, with right future in a growing business. Location Montreal. Write giving full particulars including training, experience, age and marital status. File No. 4954-V.

GRADUATE MECHANICAL DESIGN ENGINEER experienced in heavy industry machine design. He should have three or more years of applicable experience. His general duties would include, supervision of work of several draughtsmen, stress analysis of structural steel machine frames and machine parts. Evaluation of new designs and improvements to existing designs. Good salary and opportunity for the right man with a well established medium sized manufacturer of pulp and paper-mill equipment. Location, northern New York State. Enclose full details as to qualifications, experience, salary expected, and recent photograph. File No. 4955-V.

MECHANICAL ENGINEER required in Regina, Sask., who is a graduate mechanical engineer and has at least five years practical experience in the design of heating, ventilating, air conditioning and refrigeration systems for buildings. Applicants reply giving full details and expected salary in first letter. File No. 4963-V.

PLANT MAINTENANCE ENGINEER, mechanical graduate with three to five years of applicable experience and the ability to supervise personnel for a chemical works engineering department located in the Province of Quebec. Please reply with full particulars to File No. 4967-V.

MECHANICAL ENGINEERS REQUIRED for refinery located in South America.

---

## RESEARCH CHEMICAL

OR

## MECHANICAL ENGINEER

**Required by Pulp and Paper Research Institute of Canada for research in unit operations and chemical reactions involved in new processes for pulp and paper manufacture. Necessary qualifications include a Bachelor's (or higher) degree in chemical or mechanical engineering, and 1-5 years of pertinent experience.**

**This offers an opportunity to gain experience in the planning, executing and reporting of engineering research projects. Salary will be commensurate with previous training and experience. Applicants should address a comprehensive resume of qualifications and career to the Scientific Personnel Officer, 3420 University Street, Montreal, P.Q., Canada.**

## HOWARD SMITH PAPER MILLS
LIMITED

CORNWALL DIVISION • CORNWALL, ONT.

**Permanent staff positions are available for 3 graduate engineers in layout and design, maintenance and operating department.**

**Minimum qualifications include graduation from recognized university and 3-10 years experience preferably including alkaline pulping or paper mill design or maintenance.**

**Salary commensurate with experience.**

**Write giving full details of education, age, experience, marital status and references to:**

**E. N. Alquire, Personnel Supervisor, Howard Smith Paper Mills Ltd., Cornwall, Ontario.**

Must be thoroughly qualified and experienced in design of refinery or chemical plant equipment including piping, pressure vessels heat exchangers, etc. Write giving age, education, marital status and complete details of experience. File No. 4970-V.

MECHANICAL ENGINEER, required by paper mill located in Province of Quebec with head offices in Montreal. Applicant should have some paper mill experience or interest to be trained for such a position. File No. 4972-V.

YOUNG MECHANICAL ENGINEER required for sales work. Must be energetic with a good personality and the ability or a real desire to sell. Some knowledge of heating and pumping equipment and their applications desirable. Location, Toronto. Good opportunity with long established business concern. Write giving full particulars including training, experience, age and marital status. File No. 4981-V.

MECHANICAL ENGINEERS required for sales positions with prominent Canadian manufacturer. Experience in gear and mechanical power transmission field would be an asset. Will be located in Ontario or Quebec. Write giving full details of training, experience and salary desired. File No. 4988-V.

JUNIOR DESIGN ENGINEER to be a graduate mechanical engineer, required for designing and making layouts of piping and equipment installations in a chemical engineering plant. Two years experience essential. Location Ontario. File No. 4990-V.

## Engineering Opportunity

**Established Engineering Company in Montreal doing Civil, Mechanical and Electrical Engineering work would consider participation by individual or group of engineers. Some investment would be required. State full particulars to Box 893, Station "B", Montreal.**

SENIOR MECHANICAL ENGINEER. Salary up to $8,200. Department of Public Works Ottawa. Details and application forms at nearest Civil Service Commission Office, Post Office or National Employment Office. Quote No. 54-1211. File No. 4993-V.

RECENT MECHANICAL GRADUATE or one with evidence or interest in mechanical or technical problems and experience or aptitude for sales. He should be bilingual and able to deal with all levels of personnel and management. The work involves study of actual conditions related to the use of tires and formulation of procedure and policies which must be sold at the level of top management. This offers an excellent opportunity to develop a highly interesting field of customer contact and product research. For the right person a car will be provided. File No. 4995-V.

MECHANICAL ENGINEER required sales and outline schemes, for world famous mechanical handling company. Interesting position. Good prospects for right man. Apply with full details to File No. 5000-V.

GRADUATE MECHANICAL ENGINEER interested in a career in Latin America with a Canadian owned electric light and power utility company located Maracaibo, Venezuela. Age limit 30 years and should have 5 years experience in a steam electric generating station. Immediate prospects for promotion to assistant production superintendent and ultimately to executive position if qualified. File No. 5013-V.

SALES ENGINEER with steam plant experience wanted as executive of a new Canadian company to sell, service and assemble combustion controls and industrial instruments in Ontario and Quebec, for well known American manufacturer. Must be native Canadian and a graduate of a Canadian engineering university. File No. 5018-V.

GRADUATE MECHANICAL engineer to eventually take over as production manager. Company manufactures industrial and construction products from sheet metal, plate and light structurals, including material handling products, fluorescent fixtures, special fabricated sections and weldments, plus a full line of construction products. Due to rapid growth, unlimited opportunity offered. File No. 5021-V.

### MISCELLANEOUS

NATIONAL PARK ADMINISTRATIVE OFFICERS, $4,260.00-$4,860.00. National Parks and Historic Sites, Department of Northern Affairs and National Resources, Ottawa. Details and application forms at your nearest Civil Service Commission Office, Post Office or National Employment Office. Quote No. 54-652. File No. 4934-V.

SPECIALIST ON WEAPON Analysis. Salary up to $7,900.00 depending upon qualifications. Department of National Defence, Ottawa. Preferably graduation in mechanical or electrical engineering. Details and application forms at your nearest Civil Service Commission Office and National Employment Office. Quote No. 54-1205. File No. 4935-V.

TECHNICAL ASSISTANT to the Chief Cartographer. Department of Mines and Technical Surveys, Ottawa. Salary $5,760.00 to $6,480.00. Address all enquiries to the Civil Service Commission of Canada, Ottawa, and quote competition numbers 54-1707. File No. 4933-V.

ASSISTANT CHIEF ENGINEER. Salary $10,000.00 per annum. Harbours and Rivers Branch Department of Public Works, Ottawa. Details and application forms at your nearest office of the Civil Service Commission, Post Office and National Employment Office. Competition number 54-1258. File No. 4937-V.

DESIGN ENGINEER REQUIRED to undertake, under general supervision, the design and development of a wide range of mechanical products and devices. Preference given to applicants having higher N.C. and with design experience on aero engines or their accessories, alternatively to University graduates with post graduate experience in design of highly stressed light weight mechanical devices. Small engineering company located in Toronto Suburb. File No. 4941-V.

## THE DEFENCE RESEARCH BOARD

REQUIRES

# ELECTRONICS ENGINEERS

AND

# PHYSICISTS

FOR EMPLOYMENT IN OTTAWA, ONTARIO

***Duties:***

**For the electronics engineers the work will be in connection with the technical administration of a development programme. The duties will include liaison work, etc. There are secretarial committee work, contractual negotiations, vacancies for physicists interested in research and development on the more fundamental aspects of electronic components, e.g. dielectrics and magnetic materials.**

***Qualifications:***

**Electronics Engineers should have technical experience in the field of electronic components.**

***Salary:***

**Starting salaries will be in the range $3600 to $5750 depending upon qualifications and experience.**

***Employee Benefits:***

**There is generous provision for vacation and sick leave. Superannuation and group hospital-medical insurance plans, and a five day week.**

***How to Apply:***

**Application forms will be sent to qualified applicants on receipt of letters outlining qualifications and experience.**

**Please write, mentioning 54-DRP-4 to:**

**Director of Research Personnel, Defence Research Board, National Defence Headquarters, "A" Building, Cartier Square, Ottawa, Ontario.**

Reply giving full particulars including salary requirements. File No. 4993-V.

SENIOR GUN INSPECTOR with salary up to $6,500 per annum depending upon qualifications required by inspection service department of National Defence, Ottawa. To supervise inspection and proof of light and heavy ordnance equipment in Canada. Details and application forms at Post Office, National Employment Office or Civil Service Commission, Competition No. 54-1212. File No. 4994-V.

SALES ENGINEER wanted by established transformer manufacturer, for Montreal district. Bilingual preferred. Excellent future prospects. State age, education and experience. File No. 4999-V.

SENIOR ESTIMATOR WANTED. Experienced man with extensive heavy and medium construction experience. Must have good knowledge of estimating, and pricing. Apply with full details to File No. 5000-V.

ENGINEER WITH some heating experience to act as chief engineer required by manufacturer of automatic oil and gas burning heating units of several types. Prefer a young man who has from 2 to 8 years experience in heating and air conditioning and who is prepared to come in and grow with the company. The position is a senior one and would offer a very attractive future for the right man. File No. 5002-V.

ENGINEER REQUIRED FOR a metal working industry in the Ottawa valley to work on the design and maintenance of a variety of machines as well as do general plant engineering. Must have a good fundamental knowledge of machine shop practice and be able to direct the work of machinists through their foreman. Graduation from a recognized Canadian university and a few years experience in a machine shop are requisites for this position. Apply giving full particulars and recent photograph. File No. 5004-V.

AN OTTAWA ORGANIZATION requires hydraulic engineers to undertake in the hydraulics laboratory research work in either fundamental or applied studies. Fundamental work is in the field of open channel flow, wave motion, sediment transport and allied subjects. Applied studies include the development work of river regulation, harbour development and hydraulic structures — locks, dams, breakwaters and similar installations. A master of science degree with specialization in hydraulics of fluid mechanics, is required. Hydraulic laboratory work is desirable but not essential. Salary up to $5,750 per annum depending on qualifications. Apply by letter and enclose a resume of qualifications and experience. File No. 5006-V.

TWO GRADUATE MECHANICAL or electrical engineers. One as plant engineer in a small Ontario town. The other for technical and administrative work in the office of the chief engineer of the company in Montreal. File No. 5012-V.

FIRM IN MONTREAL requires high calibre personnel to fill the following executive positions. Sales manager with sound engineering background and experience in the conveyor industry. Ability to negotiate at high level. Chief engineer with wide experience on design and layout of all types of heavy material handling plant. First class knowledge of bulk handling necessary. Generous salary and commission in both cases. File No. 5020-V.

AGRICULTURAL FIRM Eastern Townships requires graduate and/or practical engineer to assume gradually responsibility for all plant mechanical, electrical, heating and construction problems. This is a good opportunity for a young man, preferably not over 35 years of age and which can lead to plant engineer within 3 years at a minimum salary of $5,000. The man we are looking for must have administrative ability and good personal characteristics to work up to management level. Starting salary commensurate with qualifications. File No. 5022-V.

WELL KNOWN MANUFACTURING firm requires the service of a fully qualified industrial engineer to survey and report on manufacturing processes. Must have knowledge and experience of production methods. Knowledge and experience of machines and tools with particular reference to low cost production. Knowledge and experience of the modern concept of quality control methods. Apply stating both qualifications and experience in full to file No. 5032-V.

# SITUATIONS WANTED

MECHANICAL ENGINEER age 32, Polytechnique 1945, bilingual. Employed as combustion engineer with large distributon of coal and fuel oil in Montreal. Extensive field experience on all aspects of fuel utilization, sales and service. Seeks employment with oil company or equipment manufacturers related to power engineering as combustion and/or sales engineer. File No. 2554-W.

ELECTRICAL ENGINEER, P.Eng., M.E.I.C., B.Sc. (U.N.B., 1927), age 42, married, 1 child, 7 years with large Canadian Electrical Manufacturer including test course, 2 years switchboard design and 3 years apparatus correspondence sales. Hold technical secondary school teacher's certificate with university and school teaching experience. Heating engineering experience (2 years) in the design of hot water heating systems and service of automatic steam generators. Am seeking a responsible position as industrial training supervisor, power plant engineer or other responsible position. Residing in Toronto and free to accept immediate employment anywhere. File No. 2878-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng., (Ont.) B.Sc. (Queens) 1941, age 33, 13 years experience in manufacturing methods, process engineering, production engineering of high precision components, plant layout and engineering desires position as plant engineer or mechanical superintendent; available immediately. File No. 3272-W.

ELECTRICAL ENGINEER, B.Sc. (E.E.) 1950 Jr.E.I.C., age 33, married. Presently employed managerial capacity in sales and sales promotion, directing small sales staff. Present earnings in excess $5000.00. Varied experience in sales, sales promotion office management and with Public Utilities. Desires responsible position in sales, sales representative or in line with experience. Details of education, experience and reference upon request. File No. 3375-W.

CIVIL ENGINEER, Jr.E.I.C., Alberta 1951, Veteran, age 33, single. 3½ years experience in hydro-electric field, both in design and field work. Also experience in municipal engineering. Two years experience in airport construction with the Department of Transport. Location preference, Alberta or British Columbia. Desires position in hydro electric field, but will welcome offers from other civil engineering fields. Available on month's notice. File No. 3439-W.

CIVIL ENGINEER, M.E.I.C., 1944 graduate, now residing Toronto, desires position in commerce or industry. Experienced in heavy construction, consulting, contract negotiation, administration and personnel fields. File No. 3796-W.

ELECTRICAL ENGINEER, B.Eng., McGill, 1950, P.Eng., Jr.E.I.C., C.G.E. Test Course. Experience: design; polyphase motor design and application ½ to 600 H.P., industrial; design and construction of distribution, lighting and power installations, power factor correction, frequency conversion, system control, air conditioning and plant engineering work general; artillery officer overseas in World War II, working knowledge of French, age 35, married, three children. File No. 3859-W.

MECHANICAL ENGINEER, P.Eng., Jr.E.I.C., experienced in machine design and mechanical drafting seeks part time employment in Calgary, Alberta area. File No. 3902-W.

GRADUATE ENGINEER 1951 (Mining), age 30, is interested in position offering scope and responsibility where an engineering background is helpful (not necessarily in the mining field). Other training includes military engineering, RCAF service and business management course. Mining experience as miner, surveyor, layout engineer and mine engineer in base metal and industrial mineral operations. More recent duties have included engineering reports and studies and supervision of construction. Married, one child, available on reasonable notice. File No. 4000-W.

GRADUATE MECHANICAL ENGINEER, Jr.E.I.C., age 28, with four years experience in design and research in the hydraulic field is seeking position with a progressive company as designer and/or sales engineer. File No. 4102-W.

METALLURGICAL ENGINEER, Jr.E.I.C., P.Eng., B.Sc. (Chemistry), B.E. Nova Scotia T.C. 1952. Married, age 32. Experience includes one years as metallurgical chemist in a control lab., one year as assistant welding engineer with a steel fabricator and about one year with a research firm on ore preparation and reduction of ores. Desires technical position with firm located in Toronto area. Available on short notice. File No. 4128-W.

CIVIL ENGINEER, M.Sc., M.E.I.C., P.Eng. (Ont.), graduate 1947 is available. First class designer of all types of modern structures, inventive, enterprising and with flair for structures involving complex statistical problems. File No. 4173-W.

GRADUATE ENGINEER, B.Sc. 1951, Jr.E.I.C., P.Eng., married, 3 years varied experience in mechanical handling and municipal engineering desires position in plant, mechanical handling or industrial engineering. File No. 4207-W.

MECHANICAL ENGINEER, Jr.E.I.C., 1950 graduate, Toronto, veteran, 32, single; some research experience, over three years in chemical industry on project and design work, involving process and services, equipment and piping, instrumentation and building construction, including some estimating, purchasing, expediting and inspection. Desires position of greater responsibility in similar work or in maintenance work of a general nature. File No. 4418-W.

CIVIL AND STRUCTURAL ENGINEER, Jr.E.I.C., P.Ont. Cambridge University, 1947. 6½ years experience, civil and structural engineering in industry, consulting engineering and research. Expert knowledge in structural analysis, specialising in prestressed concrete. Presently employed in Toronto. Desires change of employment where experience could be best utilized. File No. 4467-W.

ELECTRICAL ENGINEER, B.A.Sc. Toronto, 1950, P.Eng. (Ont.), Jr.E.I.C., age 30, married, experience in industrial construction, field supervision, electrical generation and distribution, paper mill operation and maintenance. Desires position offering opportunity. Will locate anywhere. File No. 4545-W.

ELECTRICAL ENGINEER, Power, McGill 1953, S.E.I.C., age 26, married, presently employed. Experience includes Westinghouse Training Course; small motors, switchgear, household appliances. Interested in a permanent position with an opportunity for further professional development in electrical engineering field. Good references. Location Montreal only. File No. 4553-W.

CIVIL ENGINEER, McGill, 1951, Jr.E.I.C., P.E.Q., married. Presently employed as area field engineer, on large project. Experience—6 months drafting, 2½ years office engineer (quantities, costs, progress reports etc.) and 1½ years varied field engineering in heavy construction. Seeks responsible and permanent position in Montreal with firm requiring above experience, or in design office. File No. 4579-W.

CHEMICAL ENGINEER, M.E.I.C., 1937 graduate, married, Canadian, would like to locate in the Toronto area. Experienced in pilot plant design, production and management phases of organic chemical plants both in Canada and the U.S. Interested in production and in sales in the field of chemical plant equipment or engineering services. File No. 4530-W.

ENGINEERING AND BUSINESS graduate Jr.E.I.C., P.Eng. Ontario, B.A.Sc. Toronto (honours) 1953, age 24, single, C.G.E. test course, graduate tool design and sales experience. Desires position with small or medium sized company in Toronto or South Central Ontario area. Prefers manufacturing or industrial engineering position leading to supervision and management. File No. 4581-W.

A YOUNG CIVIL ENGINEER, 27, married, with Master's degree in hydro-electric structures from Columbia University, New York, and with 4½ years' practical experience in design and construction of hydro-electric projects and reinforced and steel structures in U.S.A., India, and Canada. Knows Eastern and Indian languages. Desires a suitable job with any concern working overseas in any part of the world, preferably in Eastern or Middle Eastern countries. Presently employed. File No. 4582-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng. (Que.) B.Eng. McGill 1951, single, age 26, 1½ years' experience technical assistant sales in rubber industry, assistant construction engineer for new pulp and paper mill in New Zealand, assistant power engineer pulp and paper mill in Australia. Desires position with small manufacturing company in Montreal. File No. 4584-W.

CIVIL ENGINEER, university graduate, P.Eng., age 38, married, one child, with practical experience in road construction, surveying, steel structures and reinforced concrete (industrial structures and heavy foundations for power stations steel mills etc.) both with contractors and with consulting engineers, used to work on own initiative and responsibility, attending to correspondence, site meetings and negotiations with clients, some knowledge of accounting and financial matters, at present with consulting firm, desires responsible position with construction company, consulting engineers or investment organization requiring the services of a competent engineer, preferably but not exclusively in Toronto. Apply File No. 4586-W.

MECHANICAL ENGINEER (Polish University College, London, 1951) specializing in aero and thermodynamics. Three years' experience as designer and draftsman in pneumatic and electric equipment. One year in Canada. Interested in position in research or development. Age 35. Will go anywhere File No. 4587-W.

CIVIL ENGINEER, McGILL 1950, with five years excellent construction experience (design, supervision of construction, costing). Two and a half years on construction with Canada's largest textile company. Recent overseas experience in pulp and paper mill construction, oil refinery construction, building design. Desires position with company allied with the construction industry where there is a chance for responsibility and advancement. Willing to work anywhere but preferably in the Toronto-Montreal area. File No. 4588-W.

DIPLOMA ENGINEER—CIVIL, age 41, with 10 years of varied continental and British experience on the design of concrete buttress, gravity and arch dams, weirs, sluices, tanks, fishpasses, large steel welded pipe lines, and structural steelwork, reinforced concrete and prestressed concrete bridges and industrial structures with shel. roofs. Seeks responsible position in British Columbia, Ontario or Quebec. File No. 4590-W.

MECHANICAL ENGINEER, London University 1948. Experience includes 6 years, project and plant engineering in chemical industry, U.K. and Argentina. Presently employed in Canada in non-technical capacity. Desire position in line with previous experience. Location immaterial. File No. 4596-W.

CIVIL ENGINEER, B.Sc. Manitoba, M.E.I.C., ten years varied experience as designer and field engineer on plant construction and maintenance. Supervised structural and mechanical installations in Canada's largest pulp and paper, foundry, and automotive industries. Seeks position as assistant to resident or plant engineer with progressive company. Highest references and executive evaluation reports. File No. 4597-W.

PROFESSIONAL ENGINEER with master's degree in business administration, bachelor's degree engineering, 3½ years utility, 6 years manufacturing and sales, test course. Author technical papers. Accustomed to responsibility. Age 30. Seeks position with future. File No. 4599-V.

MUNICIPAL ENGINEER, M.E.I.C., age 46, bilingual, seeks managerial or senior engineering position with an expanding municipality. Also would consider work for a consulting firm specialising in town planning, design of subdivisions and municipal services. The advertiser would require some 2 or 3 months notice from his present position of project engineer for a large urban subdivision. File No. 4600-W.

MECHANICAL ENGINEER Jr.E.I.C., P.Eng., married, 7 years design experience in pulp and paper equipment, heavy industrial and marine equipment. 4 years research and development in combustion engines mainly diesel. File No. 4601-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng., grad. U. Riga, Latvia, age 43, family, 8 years preliminary and 14 years responsible practice. Latter includes: heating and plumbing, design and installation; industrial engineering, process, research, production, maintenance, design and supervising of plant expansions; construction engineering; roads—survey, design, construction. Four years of this experience in Canada and five under U.S. army in Germany. Available for an engineering appointment in Montreal area, end of April 1955. Interview—Jan. 1955. File No. 4602-W.

ELECTRICAL ENGINEER, B.Sc. E.E., Man. 1950, Jr.E.I.C., age 26, married, 1 child. Four years with public electric power utility, including supervision of transformer repair dept., supervision of recloser servicing, experience in metering installations and meter testing, and experience in various operational problems of power lines and associated equipment. Seeks position in work related to experience, preferably design, with manufacturer, power utility, or industrial concern where conscientious work and ability result in opportunity for advancement. Available on suitable notice to present employer. File No. 4603-W.

MECHANICAL ENGINEER, age 33, married, no children, University of Toronto 1943, veteran. Ten years industrial experience, four years design, engineering, manufacturing, production and purchasing, six years application, marketing, sales and service. Experience covers power plant equipment, pumps, feed water conditioning apparatus, boiler controls, materials handling equipment, electric, hydraulic and pneumatic control systems, petroleum products, mining machinery and power transmission machinery. Presently employed but desires challenging work for aggressive firm with opportunity for administrative and/or management career in sales, service or manufacturing. Would prefer Ontario, Alberta, or British Columbia. Particulars willingly supplied to interested emloyers. File No. 4604-W.

MECHANICAL ENGINEER, Australian. Graduated 1943. A.M.I.E. Australia, 32, married. No children. Experience includes field installation of mechanical or electrical plant, army workshop. Supervision large scale refrigeration unit. Design development and manufacture of welded steel pipe plant. Physical testing, instrument calibration, materials investigation, lecturing in mechanical engineering and laboratory supervision. Factory management. Consultant on steel fabrication factory design and layout. Recently arrived Canada. Desires position in or near Montreal. Available immediately. References. File No. 4605-W.

CIVIL ENGINEER, B.Sc., P.Eng., M.E.I.C., age 30, family. Desires to become permanently established in large city, preferably in Western Canada. Three years experience as city engineer in charge of public works and utilities. Experienced in sewer and water main installation, sidewalk and curb construction, drainage, paving. Four years experience as resident engineer on highway construction, four summers on federal government geodetic and irrigation surveys. Further particulars will gladly be forwarded to interested employers. File No. 4606-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng., age 36, married, wide experience in plant engineering, maintenance, plant layout, design and development in industrial and aeronautical field. Proven executive ability. Presently employed in managerial capacity. Wishes permanent position in progressive organization requiring initiative and ability. Montreal area preferred. Resume on request. File No. 4607-W.

MECHANICAL ENGINEER, P.Eng., Jr. E.I.C., veteran 4 years R.C.N. B.Sc. mechanical engineering, Queen's 1950. Age 34, married, 2 children. Administrative experience obtained in a large chemical plant, engineering and maintenance department, which included 3 years supervising maintenance and 1½ years engineering work on material handling, corrosion piping, and packaging problems. Sound practical experience gained when obtaining machinist fitter's Journeyman's papers. Desires a challenging responsible position with good opportunities situated in Ontario. File No. 4613-W.

MECHANICAL AND INDUSTRIAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.), 5 years experience in plant engineering and layout, structural steel design, foundations, buildings, heavy machinery installation, piping, and process investigations. Above included drafting, detailing, cost estimation, and construction supervision. Have also had 2 years experience in townsite engineering and development, lot surveys and related work. Desires part time work with construction or engineering firm or private individuals in Montreal, Ottawa, Cornwall area. Free to travel. File No. 4614-W.

ELECTRICAL ENGINEER, M.Sc., graduate Delft Technological University, Holland, 25 years old, married, specialised in the power side: electric and diesel electric traction, generators, motors, transformers, high and low tension cables and lines, control and protective equipment, experience 8 months. Fluent English, German, French and Dutch. Seeks position in line with his education. Available in 2 weeks anywhere. File No. 4615-W.

CIVIL ENGINEER, Jr.E.I.C., Polytechnique '51, 26, single, 4 years experience with the RCAF construction engineering branch, supervision of roads and runways construction, reconstruction of various buildings, experience with all construction trades, inspection of construction sites. One year as resident engineering officer at RCAF unit requiring knowledge of maintenance and operation of diesel engines, air conditioning equipment, refrigeration, municipal engineering and related subjects. Will be ready for employment in April '55. Administration experience, perfectly bilingual, would feel capable of handling assistant town engineer position for medium size community. Will travel if necessary. File No. 4616-W.

CIVIL ENGINEER, Jr.E.I.C., graduate N.S.T.C., 1952, age 31, married with children, desires position in maintenance with firm engaged in residential construction and/or community planning. Also interested in inspection services related to the above. Presently employed by research organization in Ontario. Available on reasonable notice to present employer. File No. 4617-W.

ELECTRICAL ENGINEER, Jr.E.I.C., B.A.Sc. (E.E.) U.B.C. 1950, married. C.G.E. Test course. 3 years experience with electrical manufacturer. Presently employed. Can arrange interview in Ontario or Quebec. Will accept opportunity anywhere in Canada. Public Utility or Industrial Plant maintenance preferred. File No. 4618-W.

ELECTRICAL ENGINEER, (Belfast, N. Ireland 1949), P.Eng., Jr.E.I.C., graduate I.E.E., age 25, married with 2 children desires position in Montreal. Experience includes 5 years indentured electrical engineering apprenticeship, 2 years test and inspection engineer, 2 years electrical machine design, 3 years Canadian experience in power lighting and distribution. Available on one months notice to present employer. File No. 4619-W.

MECHANICAL ENGINEER, M.E.I.C., age 36, British, 2½ years in Canada, seeks immediate employment. 12 years experience in the army and civilian life in mechanical handling and construction equipment. Since arrival in Canada employed as lubrication and maintenance engineer in the pulp and paper industry. Will consider work in any field of mechanical engineering. File No. 4620-W.

MECHANICAL ENGINEER Swedish Technical Institute, age 38, married. Experience includes 15 years in the oil industry, as project engineer and on the construction of oil plants which includes installation of pipelines, production and methods planning; design and service of burners and equipment for gasoline, fuel oil, butane-propane gas and petroleum industries. One and half years in Canada employed as oil burner mechanic and draughtsman. Seeks opportunity where former experience can be best utilized. Location immaterial. Available immediately. File No. 4625-W.

## Belleville

J. G. Todds, M.E.I.C.,
*Secretary-Treasurer*

E. L. Littlejohn, M.E.I.C.,
*Branch News Editor*

***Hurricane Hazel Intervened***

The Belleville Branch of the Engineering Institute of Canada held its first meeting of the 1954-55 season on October 18 at the Masonic Temple. Approximately 35 members were present.

The chairman, Mr. Drysdale, opened the meeting. After a brief business discussion, Mr. Whittemore was called on to introduce the guest speaker. The speaker, R. J. Law, is corrosion engineer with the International Nickel Company of Canada, Ltd., at their development and research section in Toronto. Mr. Law had planned to present a film on corrosion, but Hurricane Hazel intervened and the film did not arrive in Belleville in time for the meeting. An expert on corrosion, this bothered Mr. Law not a bit and he went on to conduct a question and answer discussion on corrosion problems of general interest.

The speaker was thanked by S. Sillitoe.

## Eastern Townships

J. P. Champagne, Jr.E.I.C.,
*Secretary-Treasurer*

H. W. Percival, Jr.E.I.C.,
*Branch News Editor*

***President's Visit***

Some 100 members and their wives were present at the opening dinner meeting of the Eastern Townships Branch held at Hillcrest Lodge on Sept. 15.

President D. M. Stephens, was guest of honour and gave a short address to the members on the physical aspects of nation building. He outlined the part played by engineers in the development of Canada over the years, and particularly in the last decade since the development of the north has started. This has widened Canada's "economic ribbon". He attributed this development to sound investment policy on the part of the government, outstanding statesmanship and tremendous engineering competence.

Mr. Stephens, was paying one of his two official visits to Quebec Branches, and he thanked members of the Eastern Townships Branch, as well as officials of Sherbrooke, for their kind hospitality.

***More Engineers Needed***

In making an appeal to the group, Mr. Stephens told them that Canada, at the present time, is in need of more and more engineers to help speed up the economic growth of the country so it will coincide with Canada's geographic breadth.

Mr. Stephens was welcomed on behalf of the Provincial Minister of Lands and Resources, Hon. J. S. Bourque, by Gaetan Coté, and on behalf of the city by Pro-mayor Sylvio Rousseau, who also thanked the members of the Institute for their fine work on the study of Sherbrooke's water problems.

Said Mr. Rousseau, "The Institute decided one thing but the citizens decided another."

Chairman of the Eastern Townships Branch, Gaston Massé, officially welcomed all members and their wives and said that they should be honoured in receiving the visit of their newly-elected president, who was making only two visits to Quebec branches, one in Sherbrooke and the other in Montreal.

Mr. Massé urged members to keep their branch alive by attending the regular monthly meetings which will be held in the New Sherbrooke Hotel. He paid tribute to retiring chairman, J. C. Critchely, of Magog, and honorary Chairman George Dick, for the work they have done promoting the Eastern Townships Branch.

The general secretary, Austin Wright, delivered a short address and mentioned the tremendous expansion of the Institute over the past year. He mentioned that the budget this year has been set at a half a million dollars, and added that, to his knowledge, it was the largest budget of any professional group in Canada.

The speakers were introduced by Bruce Bradley, vice-chairman of the Eastern Townships Branch, and were thanked by J. H. Barnacal.

## Kitchener

J. F. Runge, Jr.E.I.C.,
*Secretary-Treasurer*

J. L. Fair, M.E.I.C.,
*Branch News Editor*

***Shell-moulded Castings***

The first technical meeting of the season was addressed by Robert Andrews of Shell Cast Alloys, of Guelph, Ontario. Mr. Andrews' paper was titled "Significance of Precision Shell-moulded Castings, and included a brief sketch of the history of the process, originating in Europe and being developed in Britain and America.

The paper described the precision obtained—generally about two thousands inch per inch of length; and the finish—frequently better than one hundred micro-inches, as well as the rela-

tive tool costs compared to conventional sand casting methods. Using samples of several castings now being produced Mr. Andrews illustrated his talk. He called attention to the economies effected by using the process, comparing it with other methods such as forging, permanent molding, die casting, and lost wax castings. Noting the great reduction in removal of metal to produce finished parts he ventured a prophecy that the trend in equipment used in metal working might be in the direction of substituting grinding for the heavy cutting work usual with conventional castings.

A lengthy discussion followed the presentation indicating a very lively interest among the members. A. J. Girdwood, past chairman thanked the speaker and the meeting was adjourned for refreshments.

The Branch Chairman James Todd has recently moved to Toronto, Vice-Chairman L. J. R. Sanders is therefore acting chairman.

## Nipissing and Upper Ottawa

E. A. Watson, M.E.I.C.,
*Secretary-Treasurer*

Allan T. McKerrall, M.E.I.C.,
*Branch News Editor*

#### Dinner Meeting

Twenty-eight members and guests of the Nipissing and Upper Ottawa Branch of the Engineering Institute of Canada assembled at the Marine Room, Trout Mills, Wednesday evening, September 15, for the first dinner meeting of the season.

J. W. Millar, chairman of the Branch for the current season, was in charge of the meeting. Following dinner and a short business session, a most informative talk on sign making was presented by Ced Price of Price Signs, North Bay, ably supported by demonstrations of the silk screen process and glass blowing by Emmett Rainville and A Blondin, respectively.

Mr. Price who was introduced by R. R. Prescott, briefly outlined his extensive background in the advertising field before becoming established in North Bay. He explained how advertising has grown from a comparatively simple beginning to a complicated business with unlimited power when properly interpreted and applied. The many regulations and restrictions governing the use of signs and displays are a constant problem for the advertising man though necessary for adequate control.

Mr. Rainville performed a demonstration of the silk screen process for reproducing coloured signs and displays in quantity, turning out a two-colour sketch graphically illustrating this method.

Mr. Blondin described the manufacture of illuminated tubular signs with particular reference to the cold cathode process now coming into prominence.

A question period followed the demonstrations after which a hearty vote of thanks was extended to Mr. Price and his associates on behalf of those present, by J. Chandler.

#### October Meeting

The October meeting of the Nipissing and Upper Ottawa Branch was held on Oct. 20 at the Manor Hotel. J. W Millar, Branch chairman was in charge of the dinner meeting which was attended by thirty-two professional engineers and guests from Sturgeon Falls, Temiskaming and North Bay.

#### Jet Age

A sound film entitled "Jet Age" was presented through the courtesy of the A. V. Roe Company of Canada. Flt. Lt. Paul Kent of the R.A.F. and Flt. Lt. W. J. Brown of the R.C.A.F. stationed at North Bay were present to take part in the discussion period following the film.

"Jet Age" was made to publicize the accomplishments of Canadians who have designed and built jet planes. Specifically the film deals with the manufacture and assembly of the CF-100 at the Avro plant at Malton. It shows the construction and explains the principle of operation of the famous Orenda turbo jet engine and follows the making of the component parts of the engine and body through to the assembling of the completed plane.

It was pointed out that the CF-100 is the most heavily gunned fighter in the world. Weighing 17 tons it has supersonic performance and is highly manoeuverable.

The enthusiastic discussion following the film indicated that the jet airplane has high local interest. Flt. Lt. Brown and Flt. Lt. Kent very capably an-

swered questions in an intelligent and interesting manner. Norm Burke expressed appreciation for their efforts on behalf of those present.

Frank Marshal outlined the plans being formulated for the annual Ladies' Night. It is to take the form of a buffet supper at the White Oaks Inn, Temiskaming on November 5. The Sophisticates will provide music.

## St. Maurice Valley

L. A. Pattison, Jr.E.I.C., *Secretary-Treasurer*

*Branch News Editors:*

C. Kerry, Jr.E.I.C., Shawinigan Falls

M. Wood, Jr.E.I.C., Trois-Rivieres

***Active Year Foreseen***

An extremely active year is foreseen by the St. Maurice Valley Branch. A new organizational set-up is being tried out with local group meetings in each of the cities of Shawinigan Falls and Trois-Rivieres and more comprehensive joint branch meetings are being planned.

***Woodlands Organization***

The Three-Rivers group opened their meetings with an interesting talk by L. L. Wetmore, manager of the woodlands division of the St. Lawrence Corporation on October 5, 1954, at the St. Maurice Hotel.

Mr. Wetmore's paper dealt with the organization necessary to keep a newsprint mill producing 200,000 tons per year supplied with sufficient wood. He pointed out that as much as 50 per cent of the cost of the finished product will be woodlands expense. The mill must have extensive cutting areas to insure a steady supply of wood—2,000 square miles in fact and this necessitates a huge capital outlay. Rights of tenure, obtained from the government, may cost upwards of $800.00 per square mile. In addition ground rentals, royalties on wood cut and education taxes must all be paid for and constitute a heavy base load of expense.

Although more mechanization of logging operations is being steadily carried out, Mr. Wetmore pointed out that much handling must still be done by horses, with tractors being used for heavy grades. This together with transportation of woods workers and the absolute necessity of access to fires requires an extensive system of roads in the forest. Not unusual is 200 miles of road costing $5,000 per mile to build. Winter upkeep is particularly arduous and expensive.

Base camps are built on which subsidiary camps depend. These must have supply depots, accommodations for personnel, and garages capable of handling everything from tractors to outboard motors. Such a base camp might cost around $200,000 and contain many thousands of dollars of supplies. Subsidiary camps might cost $10,000 and are now built to last 2 or 3 years. They are built with an eye to the comfort of the workers and have comfortable quarters and electricity.

Questions resulted in the interesting sidelight that the average worker consumes 6,000 calories compared with 2,500 for an office worker. His power saw cuts out the tedious task of sawing but his production is up and it takes brawn to tote the saw.

Construction of dams to control the waterways, booms to control the logs and tugs and other watercraft, make up another heavy expense which must be met by the woodlands division. Some of the larger dams might cost as much as $75,000. Many headaches exist for the drivemen, such as sudden freeze-ups and thaws with consequent risk of loss of a large part of the cut.

In addition to these more or less estimable operations, the woodlands division must spend much time and money for more indirect but essential services; fire prevention and detection, insect extermination and control, and protection against tree disease.

All these operations and services require a considerable amount of administration and control both in the woods and at central headquarters. Since man-

# *Improved with* polythene

Polythene is being put to steadily widening use in industry. Each of the two examples shown here posed its own special problems; yet for both storage battery and telephone cable the answers lay in polythene's remarkable range of properties: corrosion resistance; moisture-proofness; great dielectric strength; lightness; toughness; flexibility; resistance to deterioration.

These applications are just two of many where polythene's useful properties are proving invaluable in industry. Additional news of plastic developments in industry is reported regularly in the "Plastics Sphere"; just send the coupon below.

For information or technical service, write to C-I-L.

***Exide "Ironclad" Batteries*** now last 20% longer . . . have 20% more capacity. Previously, oxidation and corrosion of internal parts greatly reduced the battery's life. Now battery life is increased through use of non-corroding polythene tubes and sealing bars. There is no need for sediment space at the bottom of the battery, thus permitting use of larger plates with greater capacity.

***Northern Electric "Alpeth" telephone cable*** is extensively used where adverse corrosive or moisture conditions exist, where superior dielectric properties are required and where light weight is an advantage in construction and cost. This cable makes use of polythene which gives it moisture and corrosion resistance, flexibility, light weight and high dielectric strength.

agement must know what their raw material costs will be in order to predict selling prices, the woodlands division must predict events for a year ahead. It is a tribute to good administration and efficient operation to record that actual costs seldom vary by more than 2 or 3 per cent from estimates.

Mr. Wetmore's talk was very much appreciated and all agreed with his closing remark that woodlands operations affect every Canadian and should be of interest to everyone.

## Quebec

R. Desjardins, m.e.i.c.,
*Secretary-Treasurer*

The golf championship of the Quebec Branch again changed hands over the weekend of Sept. 11.

P. A. Dupuis, 1952 winner, chalked up a gross score of 87 in the annual tournament at the Royal Quebec Golf Club to oust last year's champion, C. E. Rochette, of Murray Bay by a two-stroke margin, and regain possession of the Davie Cup.

Emilien Dagenais of Montreal, placed third with 90.

Ludger Gagnon captured the Talbot Cup, awarded the player scoring the best net with a count of 71. Guy Archambault, of Montreal, placed second among the net scorers with 76, while Pierre Duchastel was third with 77.

Fifty-three men and 13 ladies took part in the tournament proper, with the ladies playing but nine holes. Mrs. Jean Proulx topped the ladies field with gross 48, followed by Mrs. Jachim Tessier with 55, Mrs. Paul Vincent had the best net, 42, followed by Mrs. A. E. Paré with 45.

Fred Cribb set the pace among the invited guests with a gross 91, while Daniel Noel chalked up the best net, 81.

A putting contest was held for men and ladies not taking part in the tournament. Mrs. Guillaume Piette led the ladies' section with 23 for the nine-hole round, with Mrs. Roger Desjardins and Mrs. René Rioux tied for second with 24. Mrs. Y. Jobin, Mrs. G. Sarault and Mrs. E. DesRivieres had 25. P. Langlais won the men's putting contest.

Charles E. Plamondon was chairman of the tournament, and carried out the prize presentation ceremonies, which followed the buffet. Roger Desjardins was the starter.

A dance at the Royal Quebec, topped off a lively day's activities.

## Sudbury

A. D. Finlayson Jr., e.i.c.,
*Secretary-Treasurer*

A. Eldridge, m.e.i.c.,
*Branch News Editor*

The first fall meeting of the Sudbury Branch of the Engineering Institute of Canada was held on Saturday, October 2. Forty-five members and visitors attended and were taken on a tour of the International Nickel Company's Copper Cliff plant. There was considerable interest shown in the various sections of the plant visited, which included the concentrator, roasters, reverberbatory furnaces and converters.

The field trip was followed by dinner at the Granite Club in Sudbury. During the business session, Frank Orange, Branch chairman, introduced the various committee chairmen to the gathering and they outlined their programs for the coming year.

It was announced that Bob Moore had been appointed for a two-year term as Branch councillor, succeeding Russ Eaton.

Several visitors from the Nipissing and Upper Ottawa Branch at North Bay were present and were welcomed by Bill Black. Jim Millar, chairman of the Nipissing Branch, expressed the thanks of the visitors.

## Toronto

L. F. Bresolin, Jr.e.i.c.,
*Secretary-Treasurer*

H. Fealdman, Jr.e.i.c.,
*Branch News Editor*

**Members' Social Evening**

As an "ice breaker" to the new season a members' social evening attended by about 100 members was held in the Prince George Hotel on September 30. After a buffet supper of gargantuan proportions, a "Gambling Casino" was

operated so that members could try their skill at such time honoured pastimes as "shooting crap," roulette, crown and anchor, etc.—all with phoney money, of course. At the end of the evening when prizes were to be awarded to the winner of the most phoney money, it was found that the piles had to be measured instead of counted! All those present voted it a most enjoyable evening and an excellent start to what is hoped will be a successful 1954-55 season.

#### The Engineer and the Contractor

G. W. Miller, president, American Railroad Engineering Association, and Engineer Maintenance of Way, Canadian Pacific Railroad, Toronto, addressed the Branch on October 7 on the complicated relationships between the engineer and the contractor. Mr. Miller spoke as an authority on the subject of the CPR and, indeed, has recently given evidence before the Select Committee of the Ontario Legislature, investigating the practices of the Department of Highways.

As an engineer for a privately owned concern Mr. Miller feels that an invitation to tender sent out to selected contractors is likely to result in more realistic and satisfactory bidding than the open invitation, although it is realized that this can not always be done in the case of public concerns. Mr. Miller felt, very strongly, that the engineer has responsibilities to the contractors, not only to the successful bidder but to the unsuccessful ones as well. The responsibilities include: ensuring that pre-engineering is adequately carried out before calling for tenders so that the contractors may know accurately on what they are bidding; setting the closing date for tenders so that contractors neither have to work over a weekend in figuring the bids nor wait more than a day in learning of the contract award; to ensure that any "extras" which might crop up are adequately authorized in writing by the engineer.

Mr. Miller is in favour of the "cost plus fixed fee" system in cases where there may be some doubt as to the extent of the work until it is actually carried out. However, he is insistent that a top figure for the cost of this work be agreed before commencement.

These and many other topics intimately connected with the whole subject of bidding and tendering were discussed in a most pleasant and interesting manner. Following the talk, a lively discussion ensued which, unfortunately, had to be cut off by the time limit. In all a most interesting evening was enjoyed by those present and a hearty vote of thanks was accorded to Mr. Miller by the chairman of the Toronto Branch of ASME since this had been a joint meeting.

### Lethbridge

R. D. Hall, Jr.E.I.C.
*Secretary-Treasurer*

P. Harding, Jr.E.I.C.
*Branch News Editor*

#### Joint Meeting with A.S.C.E. and Field Trip

A call for more engineers to enter the construction industry, and a visit to the mighty Tiber dam which is under construction in the valley of the Marias River about 50 miles southeast of Shelby, Mont., highlighted a joint meeting of more than 50 members of the Lethbridge Branch of the Engineering Institute of Canada, their wives and families, and members of the Montana section of the American Society of Civil Engineers Saturday, September 11, 1954.

The construction firm of James and Wunderlich began work on the $12,900,000 project in September 1952 and is expecting to complete the job during December 1955. At the present time the project is between 50 and 60 per cent completed, on a dollar basis.

#### The Tiber Dam

The immense dam, 38 feet higher and 900 feet longer than Niagara Falls, is the key structure of an undertaking to irrigate 127,000 acres of 990 farm units to the north and east of the Marias River, and is also integrated for flood control purposes with other dams in the

Aluminum Company of Canada officials inspect in transit an all-welded runner for an impulse type turbine installed at the Kemano Power Development. Operating under a 2,500 ft. head, this turbine generates up to 150,000 hp.

# Heart of a 150,000 hp. Giant ...*On Its Way To Work*

Production of aluminum demands an abundance of low-cost electricity — the kind that Allis-Chalmers hydraulic turbines help provide.

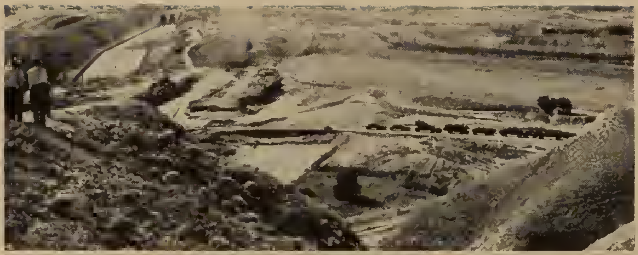
But hydraulic turbines are only one of many types of equipment Allis-Chalmers builds for this great industry. Generators, rotary kilns, grinding mills, vibrating screens, slurry pumps, electric motors and mercury arc rectifiers are included on the list of Allis-Chalmers products designed to help lower aluminum production costs. Allis-Chalmers stands ready to serve all industry today, through every stage from laboratory testing and pilot plant runs to the design and construction of equipment for full-scale production.

For complete information on how Allis-Chalmers products and facilities can help you, call the CA-C office nearest you, or write Canadian Allis-Chalmers Ltd., P.O. Box 37, Montreal.

MADE IN CANADA

**CANADIAN ALLIS-CHALMERS**

54-CAJ-2



Left: A view of construction of the Tiber dam, Montana. Lower left: R. D. Hall, Jr.E.I.C., secretary-treasurer, Lethbridge Branch; A. E. Lawrence, M.E.I.C., chairman, Lethbridge Branch; J. G. Hoge, president, Montana Section A.S.C.E. Lower right: American and Canadian engineers in front of the U.S. Bureau of Reclamation office at the Tiber damsite.

Missouri River Basin. The work was engineered by, and is under the direction of the United States Bureau of Reclamation.

When completed the Tiber dam, named after a tiny railway siding 14 miles north, will have a crest length of 4,300 feet, be 205 feet high, and 1,300 feet wide at the base. Adjoining the western end of the dam is a 17,000-foot long dike which has a maximum height of 60 feet. Both dam and dike are of rolled-earth fill type construction.

The dam and dike will contain a grand total of 11,310,000 cubic yards of earth, sand, and gravel.

The reservoir will hold 1,337,000 acre-feet of storage extending 24 miles to the north-west with a maximum width of four miles, supplied from a drainage area of 4,375 square miles. The reservoir will have a surface area of 22,180 acres.

When fully completed the water will flow through a mile long tunnel into 77 miles of main canal and 140 miles of laterals. In some places the main canal will flow through cuts 80 feet deep.

The horseshoe-type canal outlet has a twin-tube inlet, with a capacity of 2,200 cubic feet per second. The length of the outlet structure is 600 feet under the present contract, and will be completed in the future under another contract.

To enable construction of the dam, the river is at present flowing through a 14-foot dia., 1,700 ft. long concrete diversion tunnel which has a capacity of 5,000 c.f.s. at 100 feet of head. Upon completion of the dam the diversion tunnel will serve as the river control outlet. However, the present entrance will be sealed and the water will flow into the tunnel through concrete trash racks constructed well above the reservoir bottom so as to permit the outlet to be above any sedimentation.

Saturday, following a welcome by W. A. Sanford, construction engineer of the U.S.B.R. and F. A. Bleeker, superintendent of the contracting firm, the Southern Alberta and Montana engineers drove to a vista point overlooking the project. They then moved on to the canal outlet-works, walked through the concrete tubes, and saw where the control gates will be placed.

Following this the tour drove over the dam to one of the borrow areas where gravel was being loaded into 30 yard bottom-dump Euclid earth-movers at a rate up to 30 yards per minute. The Euclid loader was pulled by two Allis-Chalmers crawler tractors—one a model five and the other a model 15. As the loader moved forward it cut into a bank of the borrow pit and loaded the Euclids by means of belt conveyors.

The borrow area is two and a half miles from the damsite with the earth carriers taking approximately 20 minutes per round trip. Powered by Cummins diesel engines, the giant movers are capable of speeds up to 40 miles per hour empty, and 25 miles per hour loaded.

Almost all of the 21,300-foot long dam and dike structures will be faced with riprap blasted from quarries in the Sweet Grass Hills, 40 miles from the dam, and only 10 miles south of the Canadian border. The riprap will vary from a minimum of half a cubic foot to half a cubic yard in size.

From the borrow area the tour drove to the dike, and along its crest to the spillway bridge. Here U.S.B.R. and com-

pany engineers explained the method of construction of the spillway and its design. Overflow will be controlled by three 32-foot by 20-foot gates, and the spillway will have a capacity of 51,700 c.f.s. The spillway varies in width from 100 feet at the crest to 200 feet in the stillbasin. The concrete structure is 1,336 feet long.

From the spillway bridge the tour was able to overlook the construction of the dam where the earth-movers dumped their loads which were pressed down into an impervious barrier with sheepfoot rollers. At the present time, 7,000,000 cubic yards of fill have been rolled into place. They try to move 50,000 yards every day, or 1,000,000 yards a month.

Immediately northwest of the spillway bridge the visitors were able to watch the aggregate processing plant in operation. The aggregate plant has a capacity of 100 tons per hour and the "Noble" concrete batch plant, with two 2.25 cubic yard mixers, has a capacity of 120 yards per hour.

The tour spent almost an hour on the spillway bridge watching the many operations of the project being carried out.

From the bridge the visitors drove back to the U.S.B.R. office where they looked over plans and maps of the project.

#### Dinner and Welcomes

At 7 p.m. the engineers and their wives were served dinner in the contractor's mess hall and heard short talks by Jim Hoge of Great Falls, president of the Montana section of the A.S.C.E., E. A. Lawrence of Lethbridge, chairman of the Lethbridge Branch and Mr. Bleeker.

Mr. Hoge welcomed the Canadians and introduced Dr. W. H. Fairfield of Lethbridge, and two East Asian engineers, Mr. William Chen of the Taiwan Power Co., Taipei, Formosa; and Mr. Uthai Charm Reon Prucksa of Thailand, who were visitors at the project.

Mr. Bleeker explained the set-up of the construction camp and described the $3,000,000 worth of machinery used on the project, and gave a brief outline of the problems of the construction industry.

#### More and Better Engineers Needed

Mr. Bleeker said that today the construction industry has outranked farming as being the leading industry in America. However, he added, the competition is steadily getting keener, and explained that last year construction firms averaged a two per cent profit.

He said that cost of labour and machines is steadily rising and the industry is beginning to look sick. One reason for the industry's present crisis, Mr. Bleeker said, was the lack of skilled and efficient personnel.

"We need more and better engineers. We have a good field for engineers in construction work," he said, and added that he thought the universities may be letting the industry down. He suggested more emphasis be placed on construction work, supervising construction work, estimates, machinery and its maintenance.

Mr. Bleeker, himself a graduate engineer, said he wished more young engineers would be willing to take advantage of the opportunities of the industry.

# For *positive* bearing protection on Military Jeeps-

KLOZURE Garter Spring Model 65

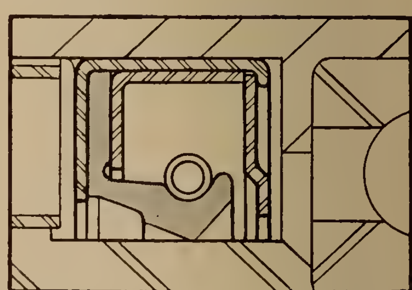
Every Willys Military Jeep has a "transfer case" which provides for 2 functions: (1) Engaging the front axle drive; (2) Engaging the emergency low gear ratio. Spicer uses dependable Garlock KLOZURES to protect the front and rear bearings on the output shaft of this important mechanism.

## Spicer uses KLOZURE* Oil Seals

The Spicer "transfer case" in a Military Jeep must be able to function smoothly under the most adverse operating conditions. Thus, the bearings on the output shaft (which operates at speeds up to 4,000 R.P.M.) need *positive* protection against dust, mud, and water; the bearing lubricant must be sealed in. This job calls for a superior oil seal. Spicer engineers rely on KLOZURE garter-spring Model 65.

Take a tip from Spicer, who for 50 years has been manufacturing precision parts for the automotive industry. Standardize on KLOZURE Oil Seals—the best bearing protection money can buy.

There's a service-tested KLOZURE model for every bearing application. For complete information contact your Garlock representative or write for KLOZURE Catalog No. 10.



Installation of Model 65 KLOZURE Oil Seal on the output shaft bearing of the Spicer "transfer case."

## Additions to the Institute Library

**Reviews — Book Notes — Abstracts**

### BOOK REVIEW

**Techniques of plant maintenance and engineering, 1954.** New York, Clapp and Poliak, 1954. 291 pp., $7.50 (U.S.).

This volume, the fifth in the series, contains the proceedings of the Fifth Plant Maintenance and Engineering Conference, held concurrently with the 1954 National Plant Maintenance and Engineering Show in Chicago. As in previous years, all the prepared papers delivered at the meeting are reprinted in this book, as are the questions and answers following them, and summaries of the twenty round table discussions, each of which lasted five hours.

The topics considered at the two general sessions were "planning and scheduling maintenance work", and "maintenance cost control and budgeting". At both sessions the presentation of papers on the topics was followed by question and answer periods.

The sectional conferences followed the same pattern, and dealt with a variety of topics; preventive maintenance, training for maintenance work, sanitation, work measurement, corrosion control, hospitals, medical departments and first aid rooms, and waste disposal.

Several of the round table discussions were devoted to specific industries, such as paper mills, steel mills, chemical plants, etc., whilst others covered a variety of topics involved in maintenance work.

Many of the papers are illustrated with charts and diagrams, and the inclusion of the questions prompted by the papers increases both the value and interest of the book. The editors estimate that the answers to thirteen hundred questions are given.

As in previous years this symposium will be of great interest to all maintenance engineers, and is a valuable addition to library. S.C.

### BOOK NOTES

**Prepared by the Library**

**The Engineering Institute of Canada**
*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

**Bibliography of books and published reports on gas turbines, jet propulsion, and rocket power plants.** E. F. Fiock and Carl Halpern. Washington National bureau of standards, 1954. 110 pp., 50 cents (Suppl. to N.B.S. circular 509).

This bibliography covers publications issued from January 1950 to December 1953, and contains some five thousand references. Literature covered includes both books and periodicals and the references are arranged chronologically under subject, the subjects being listed in the table of contents. There is no author index.

**Chimie et structure cristalline.** R. C. Evans. Paris, Dunod, Montreal, Fomac, 1954. 331 pp., figs., $17.50.

The author's aim in this book, as stated in the preface, is to make a critical study of the results obtained from the X-ray analysis of crystals and to evolve several principles from these results. He has termed his study "crystallochemistry" and relates it to the fields of the chemist, physicist, metallurgist, geogolist and biologist. Only enough crystal structures are described to illustrate the theories presented. The first section of the treatise discusses the crystalline lattice; the different types of interatomic bonds and quantitative theory. The second section applies the theories of crystallochemistry (i.e. the relation between the internal structure of a body and its physical and chemical properties) to metals, alloys, ionic and molecular compounds.

**Comparative bridge designs.** J. G. Clark, ed. Toronto, Lincoln Electric Co., 1954. 211 pp., diagrs., $2.50 (U.S.).

Published in the United States by the James F. Lincoln Arc Welding Foundation, this book presents plans illustrating the advantages obtained by using welded bridges. All the material included was selected from the award program sponsored by the Foundation in 1952.

Various types of bridge are covered: continuous girder bridges, prestressed girder bridges, simple beam spans, simple trusses, continuous trusses, and arches. Reproductions of the original drawings are included, together with the designers' discussions and descriptions.

***Electrical transients.** L. A. Ware and G. R. Town. Toronto, Macmillan, 1954. 222 pp., $4.75.

This textbook, designed for junior and senior students, uses the Laplace transform freely in a quasi-rigorous manner suitable for students with no mathematics beyond differential equations. In the treatment of certain topics, classical methods are also employed. Material covered includes RL, RC, RLC, and vacuum tube circuits; compound, switching, and transition transients; non-sinusoidal applied emfs; and repeated and discontinuous functions.

**Electronics for everyone.** Monroe Upton. New York, Devin-Adair, 1954. 370 pp., illus., $6.00 (U.S.).

The author assumes no electrical knowledge on the part of his reader, but explains in simple language the discoveries and inventions of the past which have made possible the present day applications of electrical energy.

The workers whose names are associated with the early work on electricity are discussed, Faraday, Volta, Tesla, Ohm, Ampère and Franklin, as are Zworykin and Farnsworth of more recent date. The author also discusses radio, high-fidelity phonograph reproduction, radar, television, electronic cooking, etc.

This book should interest everyone from the high school student on, and the various diagrams and the index increase its value.

***Engineers' dreams.** Willy Ley. Toronto, Macmillan, 1954. 239 pp., illus., $4.25.

**Subscriptions**

Members are reminded that many of their subscriptions to periodicals, placed through the Library, expire at the end of December. If they wish their subscriptions to continue, orders should be placed with the E.I.C. Library immediately. Please send NO REMITTANCE until an invoice is received.

## LIBRARY REGULATIONS

### Hours

Mon.–Fri. . . . . . . . . 9 a.m. - 5 p.m.
Saturdays . . . . . . 9 a.m. - 12 noon

### Bibliography and Reference Service

Short subject bibliographies are compiled on request. When placing these requests, please give as much detail and background information as possible.

### Borrowing

Books, periodicals, pamphlets and films may be borrowed for two weeks at a time. All books included in the Library Notes Section of *The Engineering Journal* are available for loan. **A fine of 25c per day is charged for each day borrowed items are retained beyond the two-week period.**

A library deposit of $5.00 at par in Montreal is required, for which two items may be borrowed at a time. Temporary deposits (30 days or less) $10.00. Books are sent anywhere in Canada, and carrying charges are payable by the member concerned.

### Ordering

Any book or pamphlet may be ordered through the library. All publications of affiliated societies, whether books, pamphlets, or periodicals, should be ordered through the library, as reduced rates are applicable on these to all members. Except in the case of library deposits **please make no payments in advance.** Non-members may consult the library, but may not borrow material. Please address all requests to **The Library.**

Nine projects that could be accomplished if it were not for political and economic difficulties are the subject of this book. These include a tunnel under the English Channel, "seadromes", harnessing volcanoes and hot springs, creating a lake in the Congo Basin, shrinking the Mediterranean by building a dam at the Strait of Gibraltar, and obtaining power from the sun, waves and wind.

**Flow properties of disperse systems.** J. J. Hermans, ed. New York, Interscience, 1953. 445 pp., illus., $9.90 (U.S.). (Deformation and flow, v. 5).

The dispersions treated here are protein and polymer solutions, suspensions, emulsions, liquid sprays, smoke, gels, foams and powders. The chapters on suspensions and emulsions cover the general rheological properties e.g., viscosity, Newtonian and non-Newtonian flow, thixotropy, etc. and include the entire field from coarse suspensions to dilute solutions of macromolecules. Modern concepts on gel structure are presented as well as recent theories of swelling and deformation. The ten authors are from various British and European universities and have wide background experience on which to base their views.

**Formal job evaluation and some of its economic implications.** L. G. Nicolopoulos. Montreal, McGill University. Industrial relations centre, 1954. 43 pp., $1.00.

This is a study of the relation between job evaluation as an administrative practice and labour market forces. The author, who was in direct contact with experienced practitioners in the field, discusses the development of formal job evaluation, administration and maintenance, union participation, labour relations, the advantages and disadvantages, and the economic implications of job evaluation. Included in the appendices are a salary evaluation and a case study of union-management co-operation.

**A glossary of terms in nuclear science and technology.** U.S., National research council, Conference on nuclear glossary. New York, American society of mechanical engineers, 1953. 9 sections, spiral binding, $7.00 (U.S.).

The nine sections of this preliminary edition cover general terms, reactor theory, reactor engineering, chemistry, chemical engineering, biophysics and radiobiology, instrumentation, isotopes separation, and metallurgy. Following these divisions there is an alphabetical arrangement of terms. Within the glossary the terms are well connected by cross references and liberal use is made of formulae.

***Hydraulic systems and equipment.** R. Hadekel. Toronto, Macmillan, 1954. 224 pp., figs., $3.00.

The concern in this book is with hydraulic circuits, control gear, and other equipment necessary for orthodox power equipment. Detailed information on control systems for aircraft, automatic machine tools, etc., and on power transmission in various types of machinery is included. Design, manufacture and installation of equipment — seals, valves, piping, and so on — are also dealt with. Much of the material was previously published in Machine Design, 1953.

***Linear transient analysis. Volume I: Lumped-parameter two terminal networks.** Ernst Weber. New York, Wiley, 1954. 348 pp., figs., $7.50.

This text for a basic graduate course emphasizes comparison of a variety of methods, offering a review of classical and operational methods of analysis as well as treatment of the Laplace transform and Fourier integral methods. Appendices review the mathematics needed for the various sections and provide a brief bibliography. A second volume will deal with the transform methods in the treatment of the more difficult network structures.

**Manual on cutting of metals with single-point tools,** 2nd ed. A.S.M.E. research committee on metal cutting data and bibliography. New York, American society of mechanical engineers, 1952. 546 pp., illus., $10.00 (U.S.).

As a result of much research and experimentation this volume presents metal cutting data in a form which can be directly used by the engineer, executive, designer, or shop mechanic. The chapters cover: types, uses and preparation of single-point tools; mechanical characteristics and structures of work material; cutting fluids; cutting forces; net unit power for machining a great number of metals using a single size of cut; economics of metal cutting; tabular data on cutting speeds and horsepower for various feeds and depths of cut when turning steel and cast iron. There is more descriptive presentation of tool materials and other subject matter than in the first edition.

**Metal industry handbook & directory, 1954 ed.** London, Cassier, 1954. 472 pp., 21/8.

This well-known reference book covers the general properties of metals and alloys, including British Standard specifications; the main metal finishing processes, and data regarding all the common rod, bar, sheet and strip products. The last section is a directory of associations and institutions as well as information for buyers.

**Model analysis of structures.** T. M. Charlton. Toronto, British Book Service, 1954, 142 pp., figs., $3.80.

In this book the methods of model analysis considered have been selected on the basis of being easy to use with speed and accuracy in the design office, without expensive tools and apparatus. It explains the theoretical principles and techniques of some of these methods of analyzing structures with linear load-deflection characteristics. The theories of the direct and indirect methods, with variations of the latter, are first considered with some attention being given to their commercial aspects. The author's original direct method, using an "isodynometer", is described, followed by detailed examples of the application of indirect and direct techniques of model analysis.

**The modulor; a harmonious measure to the human scale universally applicable to architecture and mechanics,** 2nd ed. Le Corbusier. Toronto, British Book Service, 1954. 243 pp., illus., $5.00.

The modulor is the name given to the new measuring tool evolved by the French architect, Le Corbusier, and is based upon the proportions of the human body and on mathematics. It is intended as an architectural reference to be applied to the problems of proportion, design, prefabrication and mass production. This book traces its developments and its origins in past architecture and sets forth its mathematical and philosophical bases. The position of the modulor in this day and age is outlined, as well as its application to several different buildings. This new and startling departure from ordinary units of measurement may provide some solution to the complexities of modern technology.

***Operations research — challenge to modern management.** Harvard University. Graduate school of business administration. Cambridge, Operations research group, 1954. 120 pp., spiral binding, $10.00 (U.S.).

This report, written to aid management in evaluating the possibilities of applying the methods of operations research to specific situations, discusses the need, historical development, and applications of the method in planning production, setting time standards, etc. Separate chapters describe the methodology, and the relation of computers to the subject. A selected bibliography is included.

**Paper chromatography,** 2nd rev. and enl. ed. Friedrich Cramer. Toronto, Macmillan, 1954. 124 pp., illus., $4.25.

This is principally a laboratory manual covering the microanalytical separation method known as paper chromatography. The first part deals with the theoretical background of partition methods and in the second part the operating methods are described: experimental technique, quantitative evaluation, and paper electrophoresis. The third, and largest, section covers the separation of particular substances, including amino-acids, sugars, alcohols, phenols, porphyrins, synthetic dyestuffs and optical isomers. Inorganic paper chromatograph is briefly discussed. Two charts are provided for the indentification of chromatograms and a nine-page bibliography is included.

**Physique nucléaire.** Théo. Kahan. Paris. Colin, 1954. 224 pp., figs., 250 fr.

In this book, the author who is a specialist in his subject, presents an outline of nuclear physics, reviewing the fundamentals of nucleonics, without ignoring more recent developments.

Topics covered include: detection of charged particles, natural radioactivity, $\alpha$, $\beta$ and $\gamma$ rays, nuclear structure and forces, nuclear reactions, and atomic reactors.

**Planning residential subdivisions.** V. J. Kostka. Foreword by J. A. Russell. Winnipeg, Manitoba. University. School of architecture, 1954. 127 pp., illus., $3.50.

This book, written in a practical and straightforward manner by a well qualified Canadian, will be enthusiastically received by civic administrators, planning consultants, architects and students. It is well illustrated by actual plans and examples of Western Canada subdivisions and contains an up-to-date bibliography.

The first part discusses site survey and in Part 2 the author co-ordinates site design and development from the viewpoints of planning, engineering, landscaping and architecture. A brief description is also given of the duties and professional services of those specialists who together plan and create residential subdivisions.

**Principles of geomorphology.** W. R. Thornbury. New York, Wiley, 1954. 618 pp., illus., $8.00.

Geologists and others interested in the subject will find this new text valuable because of the author's practical treatment of the concepts of geomorphology. He abandons the usual emphasis on comparative descriptions of landforms and geologic processes, concentrating instead on the historical development of geomorphic ideas, the tools of the geomorphologist, topography of the ocean floors, and soil characteristics with their geomorphic significance. More specifically he includes

4

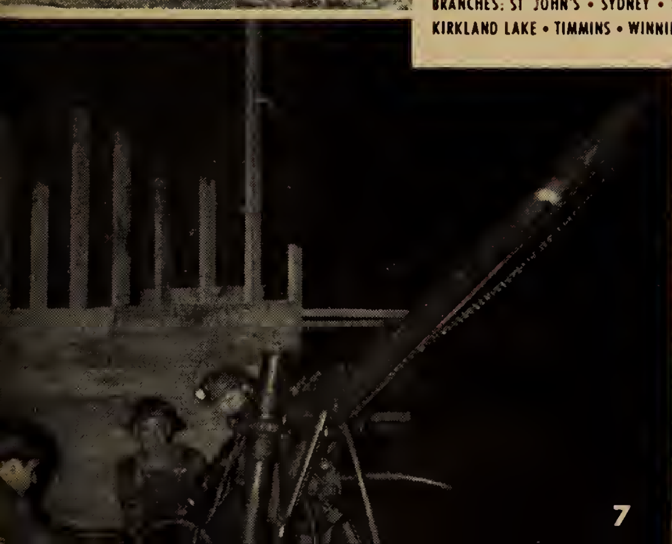
8

5

9

6

10



7

11

chapters on the fluvial cycle, stream deposition, the peneplain concept, the arid cycle, Eolian land forms and karst topography. An outstanding feature of the book are the numerous illustrations.

**Principles of road engineering.** H. J. Collins and C. A. Hart. Toronto, Macmillan, 1936. 628 pp., illus., maps, $11.75.

This book could well be compared with another reviewed in this section, "Traité des routes" by J. L. Escario for a fairly complete picture of road engineering theories in Europe. While many modern techniques of road building and maintenance, brought into practice since its publication, are omitted, there is interesting material on the development of highway engineering in England from the earliest times, on the problem of accidents, the factor of cost, the use of photographic surveying from the air, surfacing, and legal questions.

***Proceedings of a conference on the utilization of scientific and professional manpower.** National Manpower Council. New York, Columbia University Press, 1954. 197 pp., $3.50 (U.S.).

This volume contains papers and discussion reports on the problem of the effective use of trained personnel, especially in engineering, medicine, and teaching. Aspects of the problem considered include the possible transfer of work to semi-professionals, incentives to prevent turnover, reassessment of the education and training of professionals, improved administration and leadership, and others. Throughout the volume, present utilization policies are critically examined.

***Les réseaux d'égouts.** Pierre Koch. Paris, Dunod, Montreal, Fomac, 1954. 348 pp., figs., $14.65.

A detailed treatment of the design of sewer systems of various types including all auxiliary equipment. Necessary calculations are carefully worked out, and a group of useful monograms is provided in an appendix. The final section deals with the preparation and presentation of reports concerning sanitary projects or programs.

**Statistical year-hook of the World power conference, no. 7, 1950-1952.** Frederick Brown, ed. London, Lund Humphries, Montreal, Engineering Institute of Canada, 1954. 160 pp., $6.50.

This new collection of annual statistics again relates to fuel and power production, distribution, and consumption and covers 1950, 1951, 1952 and 1953, where possible, with a few new or revised data for earlier years. Most statistics were especially reported according to standard definitions and some, which are usually approximately comparable, have been extracted from other publications.

All countries are listed alphabetically by continent in the present volume and are grouped under convenient headings such as "Iron Curtain" countries and the "Western World" for purposes of continental and world totals of fuel and power resources, the term "Western World" denoting those countries from which recent statistics are more readily available.

As in previous volumes, the chapters are divided into solid, liquid and gaseous fuels, and water power and electricity. For more detailed statistics, users of the Year-book are referred to a bibliography of publications which contain more complete information on fuel and power statistics of the various countries. The publications listed in this bibliography were submitted for inclusion by countries contributing to the Year-book.

**The technique of handling people,** rev. ed. D. A. Laird and E. C. Laird. Toronto, McGraw-Hill, 1954. 189 pp., $4.75.

It is doubtful whether the art of getting along with colleagues and employees in the business world can be condensed into eleven rules yet this book, which presents these rules, is interesting reading. The many illustrative stories will be useful to those who have similar problems in their personal relations and the authors, who have studied and analyzed these cases, offer some sound and valuable advice on winning co-operation, controlling others, arousing enthusiasm, overcoming opposition, uncovering ability, boosting loyalty and generating harmony.

**A text-book of metallurgy.** A. R. Bailey. Toronto, Macmillan, 1954. 560 pp., illus., $5.00.

This addition to the growing number of general metallurgical books appearing from time to time is written for the university student. It deals with the nature, structure and properties of metals and alloys, and the methods used for the examination of metallic structures, including an introduction to atomic theories. This is followed by sections on metal production, working processes, metals finishing and the testing of metals. Appendices include equilibrium diagrams of important binary alloy systems.

**A textbook of radar,** 2nd ed. E. G. Bowen, ed. Toronto, Macmillan, 1954. 617 pp., figs., $7.65.

Written by the staff of the Radiophysics Laboratory of the Commonwealth Scientific and Industrial Research Organisation, Australia, which was set up in 1939 as a centre of radar research and development, this edition is unchanged in the first part except for more up-to-date references. This section deals with the basic principles of radar and covers headings such as the magnetron, triode power oscillators, modulators, microwave transmission, aerials, receivers, convertors, amplifiers and circuits. The last three chapters concern the application of these principles to practical use and have been completely rewritten. The main types of military radar systems are described and a new account is given of the civil uses of radar e.g. in aerial and marine navigation and as aids to surveying. Finally, the applications of radar to physical science are discussed.

**Traité des routes.** J. L. Escario and B. Escario. Paris, Dunod, Montreal, Fomac, 1954. 1,119 pp., illus., $30.40.

The original edition, in Spanish, was published in 1951 and, because of the author's reputation as a road engineer, was translated into French. It is a large undertaking and extends in scope from the general questions of traffic, highway planning with its economic and political considerations, through the construction of the roadbed to the various surfacing materials. It includes discussions of road drainage, the difficulties of curves, tunnels and level crossings and also touches on the related questions of highway signs, lighting, obstruction by trees and the effect of weather on roads. An interesting section shows the cost of tar and asphalt materials in France, Great Britain, the United States, Germany and Spain. In his preface the author lauds the highway system of the United States and urges European engineers, whose problems are much the same, to follow its lead. Road-building machinery is fully described, with illustrations, and methods of construction in various countries are noted.

**Transient analysis of alternating-current machinery: an application**

**of the method of symmetrical components.** W. V. Lyon. New York, Wiley, 1954. 310 pp., figs., $7.00.

The author of this book claims that it presents the first systematic application of Fortescue's method of symmetrical components to the solution of transient conditions in a-c. machinery. It shows how this method can be used to determine the transient behavior of polyphase machines under different operating conditions. The analysis is founded on the Kirchhoff differential equations that apply to the machine and connected system. Because the analysis is rigorous the reader may have a clearer perception of the accuracy of other simpler, though approximate, methods of solution. The equations are generalized by using the per unit system, and all results are in terms of measurable quantities.

An important section contains the general analyses of sixty typical problems and a chronological bibliography is included.

**V-2.** Walter Dornberger. Toronto, Macmillan, 1954. 281 pp., illus., $5.95.

This memoir by one of the world's leading engineers will be fascinating reading for anyone whose imagination is fired by the words 'rockets' and 'space travel'. It is a well-written, factual and dramatic account of ten years of experiments and labour to develop the weapon which shook Great Britain and the world in the last stages of the war. General Dornberger is first and foremost a scientist and, as such, his sense of perspective rises above political levels. His story traces the development of the liquid-fuel V-2 rocket by his army of qualified men at Peenemunde to that day in September, 1944, when the first one fell on English soil, and describes the crippling British bombing raid on the project, its recovery and the later production of rockets.

This is more than a technical book, however, as it gives an inside account of a German army establishment, the bitter political rivalry then rampant and provides glimpses of Hitler and his right hand men. Students of history and politics will find as much to interest them as will engineers and scientists.

The introduction written by Willy Ley is a vital addition and the group of photographs are an added appeal.

**Welding processes and procedures.** J. L. Morris. New York, Prentice-Hall, 1954. 255 pp., illus., $5.00.

This basic welding book is directed to college and technical students and also to the practising engineer and industrial worker. Included is information on electric arc, oxy-gas and electric resistance welding, welding of commercial metals, testing, welding design, metal spraying, braze welding and oxygen cutting. The history, description, details of use and applications and limitations of the more important welding processes are given in that order. The last chapter treats welding economy, and exercises to be used in the welding laboratory are found at the end of the book.

## BOOKS RECEIVED

**Bibliography on prestressed concrete.** American concrete institute. Detroit, The Institute, 1954. 83 pp., $2.00 (U.S.).

**Chemical engineering in practice.** J. I. Harper, ed. New York, Reinhold, 1954. 140 pp., $3.00 (U.S.).

**Chemical engineering materials.** Frank Rumford. Toronto, Longmans, Green, 1954. 380 pp., illus., $5.75.

**The dam.** Murray Morgan. Toronto, Macmillan, 1954. 162 pp., illus., $4.00.

**Design and use of instruments and accurate mechanism.** T. N. Whitehead. New York, Dover, c.1934. 283 pp., illus., pa. $1.95 (U.S.).

**Dielectric materials and applications.** A. R. von Hippel, ed. New York, Wiley, 1954. 438 pp., illus., $17.50.

**Dielectrics and waves.** A. R. von Hippel. New York, Wiley, 1954. 284 pp., illus., $16.00.

**Electroacoustics.** F. V. Hunt. New York, Wiley, 1954. 260 pp., diagrs., $6.00.

**Elements of number theory.** I. M. Vinogradov. New York, Dover, 1954. 227 pp., pa. $1.75 (U.S.).

**Farm buildings,** 4th ed. D. G. Carter. New York, Wiley, 1954. 291 pp., illus., $5.50.

## E.I.C. Technical Papers

The Institute maintains a fund for the separate publication of high-calibre original technical papers. Interest in such papers is limited to a relatively small audience of specialists in the subjects to which the papers relate, and it is not economically sound to publish them in the *Journal* which aims at the interest of some 15,000 engineers in all branches of the profession.

It is an obligation of the Institute to publish original works which contribute to the reference literature of the profession. The Technical Papers are distributed to the world's major engineering societies and technical libraries. Similarly it is an obligation of those engineers qualified to write these papers to submit them for possible inclusion in the literature. The publications committee invites authors to present such manuscripts for submission to qualified reviewers and publication if warranted. Written discussion will be accepted and published as supplements.

**Technical papers issued to date are:—**

**No. 1—Flow in Conduits and Canals:** *French and Wood.* Comprises tables and diagrams for the solution of problems of flow in open and closed channels. Price . . . . . . . . . . . . $1.50

**No. 2—A Revised Manning Flow Formula:—***Blench.* A discussion of the various hydraulic flow formulae in use or proposed. The author, formerly Director of Irrigation Research, Punjab, Pakistan, and now on the staff of the University of Alberta, concludes that the Manning formula, with modifications, is the best now available. Price . . . . . . . . . . . . . . .$1.00

giving substance to dreams
Installation of this English Electric 106,000 KVA generator at Kemano marks another step in translating the vision of the planners into reality. English Electric is proud to have shared in equipping another of the world's great projects.
For hydro-electric stations the world over English Electric produces complete turbine generator units and associated equipment for any head and output. The quality of their design and workmanship has been proved under all conditions. There is an English Electric office near you, equipped to provide all necessary information on your electrical requirements.
English Electric generator stator in transit from the service bay to its permanent location in unit No. 3 in the background. (Alcan B.C. project—photo courtesy Aluminum Co. of Canada Ltd.)

# Business & Industrial Briefs

## A Digest of Information received by The Editor

## Appointments and Transfers

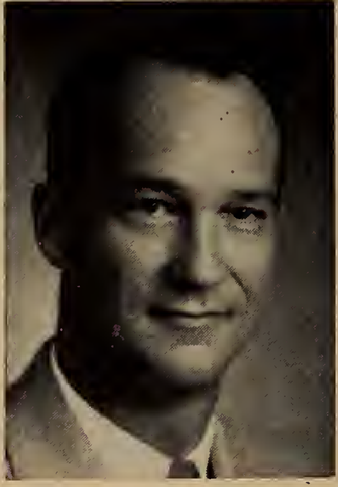
**C.G.E.'s Electrical Equipment Department.**—A realignment of responsibilities within Canadian General Electric Company's electronic equipment department has been announced by W. D. Schofield, department manager.

Mr. Schofield announced the following new appointments: Henry S. Dawson, manager-engineering; David H. Johnston, manager-manufacturing; James R Warren, manager-marketing.

In his new position, Mr. Dawson is responsible for advanced, system, and product engineering, installation and maintenance.

Mr. Johnston is responsible for material control, production control, planning and wage rate, assembly and test quality control and works facilities.

As manager-marketing, Mr. Warren is responsible for marketing research, marketing administration, product planning, product service, sales, and advertising and sales promotion.



J. R. Warren

H. S. Dawson

●

**Quebec Power Company.**—Charles F. Scribner has recently been appointed director of supplies by J. N. Sicard, vice-president and general manager of Quebec Power Company.

He entered the service of the Quebec Power Company in 1928 and worked in the payroll, accounting and purchasing departments. During the war years, he was on active service with the Royal Canadian Air Force. At the end of hostilities he returned to the company and was later named chief of the supply division.

Mr. Scribner is a member of the Canadian Electrical Association, the Canadian Transit Association and the Canadian Manufacturers Association.

●

**Shawinigan Water and Power Company.**—The formation of an engineering division of Shawinigan's generation and transmission department was recently announced by W. R. Wray, vice-president of the company. In addition to the changes noted in Personals, T. S. Dutton until now superintendent of the communication division, is appointed superintendent of communication in the new division. The newly formed engineering division combines the former communication division and the system planning division.

The appointment of Keevin Burnham as purchasing agent for The Shawinigan Water and Power Company, succeeding H. A. Elliott who retired September 1 after almost 40 years' service, was also announced.

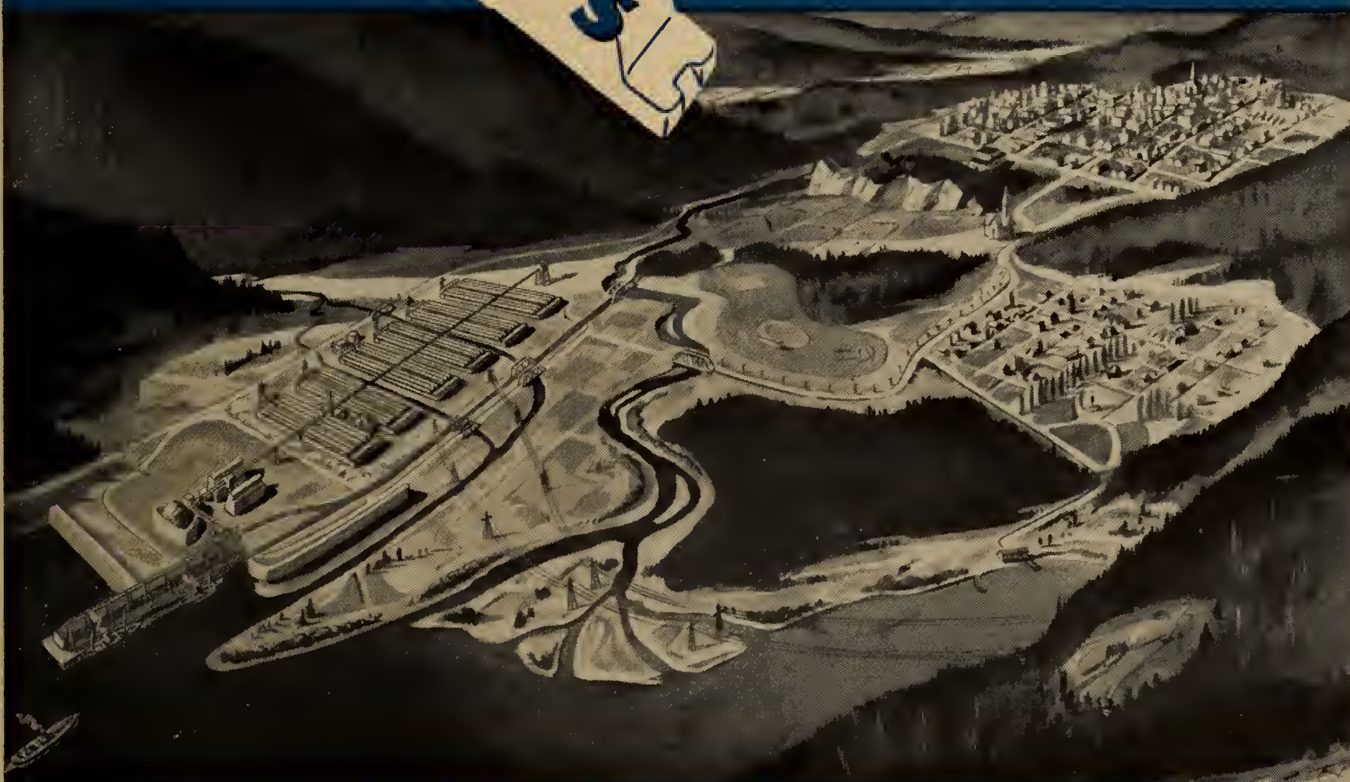
Mr. Burnham, who has been with the Shawinigan company since 1926, was formerly purchasing agent for The Shawinigan Engineering Company Limited.

Three other appointments in the purchasing department were also announced—they are:

David M. Yule, since 1952 assistant purchasing agent responsible for purchases on behalf of B. A. Shawinigan Limited and St. Maurice Chemicals Limited, who now takes charge of purchases for The Shawinigan Engineering Company as assistant purchasing agent.

W. E. R. Jones, formerly staff assistant, who has been promoted to assistant purchasing agent with responsibility for purchases on behalf of St. Maurice Chemicals and for liaison with the Department of National Revenue on matters relating to federal sales tax, customs and duties.

*(Continued on page 1582)*



Donal A. Aitken, to be attached to the purchasing department as engineer and standards co-ordinator and continuing his work on standards as well as taking responsibility for inspection service and technical matters as required.

●

**Crosley's Electronics Dept.**—A British trained electronics specialist who participated in the development of radar during World War II has been named manager of Crosley Radio and Television's newly established industrial electronics department.

Appointment of Dennis W. Holdsworth to the new Crosley position was announced this month by Ivor M. Leslie, vice-president and general manager, Crosley Radio and Television Division, Avco of Canada, Ltd.

The company's new industrial electronics department will engage in design, development and production of electronic equipment for industry, aviation and other fields.

●

**Dow's Plastic Sales Division.** — Appointment of G. H. Laird to the plastics sales division is announced by R. H. Wright, sales manager of Dow Chemical of Canada, Limited, Mr. Laird will specialize in sales development work on styrofoam (Dow's expanded polystyrene).

Mr. Laird has been with the Dow organization for eight years in Sarnia and Toronto, and most recently was associated with the coatings and solvents sales division. He will continue to reside in Toronto.

The transfer of D. T. Jager from Montreal to Toronto and his appointment as assistant manager of the heavy chemicals sales division is also announced. Mr. Jager was formerly sales supervisor of the eastern district sales office at Montreal. In taking over his new duties, Mr. Jager will specialize in market study and development for such Dow products as ammonia and hydrochloric acid.

●

**James E. Kelley, Jr.**—Formerly of Stone and Webster Engineering Corp., New York City, has been appointed general manager of Don Mills Developments Limited and Greater Hamilton Shopping Centre Limited.

As general manager of Don Mills Developments, Mr. Kelley supervises installation of municipal services in the $200,000,000 development under construction at Don Mills, Ont. He also assumes the job of detailing construction of the $15,000,000 shopping centre at Don Mills.

As general manager of Greater Hamilton Shopping Centre Ltd., he is responsible for the construction engineering of the $18,000,000 shopping centre on a 71-acre site in the heart of downtown Hamilton, Ontario.

●

**Thomas A. Edison of Canada Limited.** — The Thomas A. Edison Company Limited announces the appointment of Lieutenant Colonel K. R. Swinton to be general manager for Canada.

Col. Swinton, a native of Vienna, Austria, graduated with the degree of Master of Science in radio and television engineering. Following a period of research work for the British Admiralty in England, Col. Swinton came to Canada in 1940. During the last war he served with the Royal Canadian Corps of Signals until the termination of hostilities when he retired as assistant director of radio design.

After the war, Col. Swinton, for a period of four years, was with the R.C.A. Victor Company as manager of the electronics division. Previous to his present appointment he was for five years the vice-president and general manager of Sonograph Ltd.

●

**Garlock Packing Company.**—Edwin W. Reese of Montreal has been elected vice-president of The Garlock Packing Company of Canada Limited, effective October 1. He succeeds J. P. Sewell, new general sales manager for Garlock in Canada and the United States.

●

(*Continued on page 1585*)

K. R. Swinton

**Robertson-Irwin Moves Offices.** — Robertson-Irwin Limited, makers of industrial steel products and building materials, have announced that their sales offices in Montreal and Hamilton have moved to new addresses.

The Montreal sales office is now located at 5165 Sherbrooke Street West, Montreal 29, P.Q., and the Hamilton office is now in the Hamilton Harbour Commission Building, 605 James Street North, Hamilton. The new Hamilton telephone number is JA. 8-8481.

•

**Canadian Electrical Manufacturers Association.**—Kenneth V. Farmer of Niagara Falls, Ont., was elected president of the Canadian Electrical Manufacturers Association at the group's tenth annual meeting. Mr. Farmer is vice-president and general manager of the Canadian Ohio Brass Co. Ltd. C.E. M.A. represents Canada's third largest manufacturing industry which had a gross national product of close to a billion dollars for 1953.

Vice-presidents elected for the new term of office include: H. M. Turner, president, Canadian General Electric Co. Ltd., Toronto; R. D. Harkness, M.E.I.C., president Northern Electric Co. Ltd., Montreal; and T. J. Bell, vice-president and general manager, Federal Wire & Cable Co. Ltd., Guelph.

Other officers are: treasurer, Thos. Edmondston, president Packard Electric Co. Ltd., St. Catharines; secretary, Keith H. Rapsey, vice-president and general manager, Allen-Bradley Canada Ltd., Galt.

•

**Canadian Ingersoll Rand.**—M. S. (Merck) Lothrop has been appointed manager of the Montreal branch of the Canadian Ingersoll-Rand Company Limited.

Mr. Lothrop joined the company in 1924. Working for many years with customers in the Montreal area, he has acquired a broad knowledge of the equipment field and its problems. He is a member of the Canadian Institute of Mining and Metallurgy.

•

**Canadian Zurn Engineering.** — The appointment of John Shreve as sales manager of the Canadian Zurn Engineering Limited has recently been announced. Mr. Shreve has been associated with the Zurn Company in the U.S.A. for many years and more recently has been in charge of the Toronto sales office. District sales offices are located in Montreal, Quebec City, London, and Vancouver.

•

**Public Works.**—Works Minister Winters recently announced changes in senior personnel of the Harbours and Rivers Engineering Branch of the Department of Public Works.

J. M. Vogin, Ottawa district engineer, has been appointed to a senior position in the Harbours and Rivers Engineering Branch at Ottawa under chief engineer A. A. Anderson. Appointed temporarily to replace Mr. Vogin is C. W. Morgan, district engineer at Toronto.

During Mr. Morgan's temporary absence, C. A. Stocking will be acting district engineer in Toronto.

•

**Changes at MacDonald Bros. Aircraft.** —Following the recent acquisition of Macdonald Bros. Aircraft Limited of Winnipeg by The Bristol Aeroplane Company Limited, the following executive appointments become effective October 1: general manager, W. S. Haggett; secretary, R. G. Small; treasurer, W. Dunbar; assistant general manager, Wm. Auld; and contracts administrator, D. A. Newey.

•

## New Equipment and Developments

**Canada Cement Company's New Plant.** —Canada Cement Company's new cement grinding plant now being planned will be completed in 1955. This plant will have facilities for shipping cement in both bags and bulk by motor trucks or on cars of either the Canadian Pacific or Canadian National Railways. The mill will have a capacity to grind over 7,000,000 bags of cement per year and sufficient storage will be provided for 800,000 bags of finished cement. The heavy machinery has been ordered and engineering plans are now being prepared so that construction work may be commenced at an early date. The plant will be located in the Municipality of Strathcona, about six miles from the center of the City of Edmonton. While the first installation is for grinding cement only, it is being designed so that it could become an integral part of a complete portland cement manufacturing plant, to be

built later if it is required. The purpose in building this plant is to extend the company's service to its customers and also reduce the cost of the product to them.

●

**Iron Deposit in Northwest Territories.**—What may possibly prove to be a sizable iron deposit has been brought to light in Northwest Territories just north of the Saskatchewan boundary by the Geological Survey of Canada, George Prudham, Minister of Mines and Technical Surveys, announced recently.

The discovery, believed to be a body of magnetite iron, was made at latitude 60° 16′ and longitude 102° 53′, late in August by a field party of the Geological Survey while carrying out an aeromagnetic survey of a 15,000-mile area in the Territories. This disclosed an anomaly of exceptional intensity, indicating a high concentration of magnetic iron in the deposit. At a height of 1,000 feet it registered 7,000 gammas. Its intensity is better seen when compared with that of the Marmora magnetite deposit about 35 miles east of Peterborough in southern Ontario, which is being brought into production next month by Bethlehem Mines Corporation, and which when flown at a height of 500 feet registered 6,800 gammas.

The anomaly has an areal extent of four square miles. It will have to be further investigated by ground work, however, to ascertain whether or not it has economic possibilities.

It is off the beaten trail being about 8 miles southeast of Lake Atzinging, 200 air miles from Beaverlodge north of Lake Athabasca in Saskatchewan, and 300 miles west of Hudson Bay.

The surrounding country is flat and sandy with muskeg, although there are outcroppings nearby.

●

**Ceramic-Coated Aluminum.**—Ceramic-coated aluminum is now available from The Bettinger Corporation, Waltham, Massachusetts, porcelain enamel manufacturers, it was announced by Nathaniel Cannistraro, general sales manager.

Through the signing of a ten-year sales agreement with The Halrick Company, Danbury, Connecticut, which has facilities for the ceramic coating of aluminum, The Bettinger Corporation will be responsible for 100 per cent of Halrick's sales.

Ceramic-coated aluminum will be widely used in industry, and particularly in the aviation field, where the metal's light weight is desired and the porcelain coating's protection against fire, corrosive gases, moisture, steam, smoke and salt air, is an important factor.

●

**Canadian Westinghouse Expands.**—Electrical apparatus service facilities of the Canadian Westinghouse Company have undergone further expansion with the building of a large new repair centre in Moncton, N.B. Opening of the new building October 1 marked the second time in the past seven years that the increased volume of repair business handled by Westinghouse in the Maritimes has called for a doubling of service space.

The modern structure in the geographical heart of the city will handle repairs to all types of power and electrical equipment throughout the Maritimes. In 1947, when the company added a Moncton branch to its Canada-wide chain of service shops, the existing business outlook suggested a structure containing some 5000 square feet of floor space as adequate for both repair operations and warehousing. A short time later, however, it became necessary to devote the entire building to repair work.

Continued increase in business volume has now necessitated this latest increase in the Westinghouse service chain. The 10,000 square feet of space will also house offices and a small stock of fast-moving electrical equipment products. A high crane bay has been included in the building to conveniently handle transformer and large motor repairs.

●

**New Plant of Automatic Electric.**—At an impressive ceremony on September 22, before a large gathering of invited guests, employees and citizens, the Honourable Lionel Chevrier, President of the St. Lawrence Seaway Authority, officially opened the new plant of Automatic Electric (Canada) 1953 Limited at Brockville, Ontario. This modern building is indicative of Canadian progress in communications.

With an initial floor area of 125,000 sq. ft. and a present staff of 550 employees, automatic telephone equipment, electrical control apparatus and allied communication products are being manufactured, backed by the 60 years of experience of the world-wide Automatic Electric group, originators of the automatic telephone.

## SWELLING THE SURGE OF OIL

New oilfields and more production call for greater refinery capacity. As the industry expands Inglis is called on to make more steel or alloy vessels. Already many of the big refineries are equipped with Inglis pressure vessels.

With a plant ideally equipped for this specialized type of steel fabrication, and with a staff familiar with the problems involved, no manufacturer is better equipped to build pressure vessels for the oil, or any other industry.

In addition, as manufacturers in Canada of Worthington Pumps and Compressors, Inglis offers the most advanced designs available anywhere.

**Three-Phase Distribution Transformers.**—A new line of three-phase, oil-insulated, self-cooled distribution transformers in sizes from 9 to 225 kva is announced by Reliance Electric & Engineering (Canada) Limited, Welland, Ontario.

These transformers have been designed for use in locations where transformation of three-phase power is required and where up to now three separate single-phase transformers have been installed in preference to a three-phase unit. The new Reliance transformer is said to have the reliability and flexibility of the conventional bank of three, single-phase transformers with the advantage that only one transformer need be installed instead of three.

The unique feature of this transformer is that the core and coil unit is constructed using three separate single phase components so that any one phase component can be readily replaced if necessary. If one phase fails for any reason, the transformer can remain in service by re-connecting the other two phase components in "open-delta". This is not possible with the conventional three-phase transformer having the core and coils assembled as a single unit.

Other features of the new transformer that make it comparable with three—single phase units are as follows: Easy connection of the windings above the oil level for either star or delta operation. Taps can be readily changed by means of tap switches with handles above the oil level. Sizes up to 75 kva can now be mounted on pole cross arms. Higher ratings can be platform mounted on poles.

Known as the Reliance 3-phase E☆L☆S CORE Transformer, the new transformer will have the exclusive construction introduced by Reliance in Canada earlier this year.

# Publications

**For copies of the publications mentioned below please apply to the publishers at the addresses given in the items.**

**Please mention *The Engineering Journal* when writing.**

**Air Pollution Corrected by Sonic Energy.**—The American Institute of Chemical Engineers got technical about agglomeration, "the process of making big ones out of little ones" during the second day of the National Meeting at the resort Hotel Colorado in Glenwood Springs.

The effects of agglomeration have been apparent to the housewife in the form of anti-sneeze and dustless soap powders and detergents. However, this art is being widely applied in fertilizers, steel manufacturing, carbon black collection and coal briquettes.

Robert S. Boyd research engineer, Godfrey L. Cabot, Inc., described a new agglomeration operation which consists of utilizing sound energy to collect microscopic carbon particles being lost in waste gas of carbon black manufacturing plants. Areas surrounding carbon plants are continually being harassed by this nuisance problem. This system not only corrects the air polution but saves the valuable product.

The rapid depletion of the reserves of high grade iron ore is causing the steel companies deep concern. Agglomeration is being used to produce steel from taconite, an abundant source of low grade iron ore. Several pilot plants are operating on this low grade ore and Strathmore R. B. Cooke, Professor of Metallurgy and Mineral Dressing, School of Mines and Metallurgy, University of Minnesota, predicts that by 1958 commercial plants will be using 20 million tons of this processed concentrated ore.

Other papers were as follows: The technical aspects of agglomeration in the chemical process industries by Cecil H. Chilton, associate editor of Chemical Engineering; "Granulation of Mixed Fertilizers by Agglomeration" by John O. Hardesty, fertilizer and agricultural lime section, soil and water conservation research branch, Agricultural Research Service, U.S. Department of Agriculture; "Snowball Pelletizing" by H. E. Rowen, vice-president, Dwight-Lloyd, Inc., Division of Sintering Machinery Corp.

●

**Die Casting.**—A new 28-page, two-color, illustrated booklet describing the die casting process and its application is now available from the American Zinc Institute, Inc., 60 East 42nd Street, New York 17, N.Y.

The booklet, entitled "Die Casting — Molten Metal to Finished Part — Direct," discusses this important production method as it affects product design, machining requirements and surface finish. The basic steps of the die casting process itself are shown pictorially. Also included are concise descriptions of the dies and machines used to produce uniform parts of complex shape within close dimensional limits.

Zinc, aluminum, magnesium and copper base die casting alloys are discussed. A section on each alloy outlines its advantages and limitations with regard to cost, dimensional accuracy, surface finish, strength and machinability. Each of these sections also includes a chart which lists for each alloy: ASTM and SAE designations, composition by weight, mechanical properties and other properties and constants of each alloy in the as-cast condition.

Four pages of photographs illustrate 15 examples of typical die-cast products using the four alloy types. Each case history is accompanied by an explanation of the basic considerations that led to the selection of die casting for that particular application.

●

**Nickel Alloyed Cast Irons.**—Recently issued by The Inernational Nickel Company of Canada, Limited is a bulletin for design engineers called: "Nickel Alloyed Cast Irons — Guide to the Selection of Engineering Irons".

The bulletin describes the many valuable characteristics of modern alloyed cast irons and illustrates their broad acceptance throughout industry.

A complimentary copy may be obtained by writing, on company letterhead, to The International Nickel Company of Canada, Limited, 25 King Street West, Toronto 1.

●

**Crane For Many Uses.**—An 8-page illustrated bulletin (AD-2253) describing its indoor-outdoor hydraulic crane has just been issued by Austin-Western Company, 601 Farnsworth Avenue, Aurora, Ill. Included with specifications and performance data are diagrams on working ranges, manual boom extensions, minimum aisle widths for turns, etc. Also described are attachments and special equipment. The Austin-Western hydraulic crane is setting a revolutionary new standard for versatility and work capacity.

●

**Woods.** — The following booklets are available from Western Woods, 550 Burrard St., Vancouver 1, B.C. **Trends in Timber Construction.**—A 20-page illustrative booklet depicting new uses of B.C. Coast Woods in assembly, commercial and residential buildings as well as in industrial, marine, utility and recreational structures. **Ten Canadian Trend Houses.** — Canada's famous Trend Houses have received a great deal of attention in the past few months. The 32-page booklet illustrates how Western woods have been used to advantage in these outstanding, contemporary houses. **Handsplit Red Cedar Shakes.**—This 6-page folder on Canada's "luxury" roofing material will provide you with factual information on its manufacture and application. It is a valuable supplement to the Certigrade Handbook on red cedar shingles.

# Armament Development

*by*

E. W. Greenwood

*Superintendent, Ballistics Wing,*
*Canadian Armament Research*
*and*
*Development Establishment*
*Val Cartier, Que.*

Although this paper, presented at the Quebec Annual Meeting, deals with a special application of photography, its contents offer many suggestions for its use in industry. The admittedly high cost of the equipment required would no doubt be a deterrent to such use. In any event, one cannot but respect the ingenuity of the physicists and engineers who made such apparatus practicable.

The applications of photography to armament development are so many and the variety of instruments and techniques so great, that only a brief outline can be presented in a short paper. Even this outline is incomplete; however, the main features of photography for weapon studies have been included and those whose interest is aroused are referred to the sources of information listed at the end of the paper.

Indirect applications of photography to armament work such as photomicrography and oscillography have been omitted in the interests of brevity. These techniques are already well documented. Attention is concentrated on methods for the direct observation of weapon phenomena, and in particular on methods and equipment for high speed photography, which is of major importance in armament development work.

Photographic recording extends visual observational methods far beyond the normal range of the human eye. In armament development, distortion of the observational time scale is the most important single feature of photography. Events taking seconds or minutes, may be recorded in a single exposure and the resulting picture seen at a glance, or an exposure of a fraction of a microsecond may be viewed for as long as desired. Motion pictures projected at the same frame rate used in the camera give zero time scale distortion; by taking motion pictures at frame rates lower or higher than the projection rate, events may be observed speeded up or slowed down by very large factors. Since many weapon functioning phenomena are extremely rapid, high speed photography is widely used to extend the time available for observation.

### Record Photography

By far the largest volume of photographic work for armament studies consists of ordinary record photography. Photographs of weapons, ammunition, trial set-ups and results such as recovered rounds, fired targets and damage to equipment are required every day to supplement written records. This is an extremely valuable service, quite aside from the more technical types of photography.

There are many applications of ordinary photographic methods to weapon trials: a good example is the use of a 35-mm. camera and colour film to record the colour and size of smoke clouds from coloured smoke grenades.

One of the most interesting techniques employed for special purposes is an extremely simple one. The camera shutter is opened, the event caused to occur in the field of view and the shutter closed. A complete record is obtained of all events occurring during the time the shutter was open. Naturally, this method is best suited to observing self-luminous phenomena in the dark, such as the flight of a tracer (Fig. 1), the overall flash of a gun or the flash produced by a shot striking armour (Fig. 2). There are, however, other applications which will be described later.

In direct contrast to the open shutter technique, which compresses what may be long duration events into a single composite photograph, high speed still photography freezes a single instant in the history of an event for study at leisure. A common application of the method is the photography of projectiles in flight with exposures of one or two millionths of a second. This application will be discussed in some detail later, because of its great importance.

One way of controlling the exposure time for high speed photography is by using a high speed shutter. The term "high speed" is flexible, and is perhaps best defined in terms of the action being observed. In ballistics work shutters with exposure times of less than a millionth of a second are commonly employed.

### Shutter Types

The rather wide variety of shutter types is broken down in some detail, with particular attention to microsecond shutters. Mechanical shutters are used with almost all cameras in ballistics work, either to control

**Fig. 1. Open-shutter photograph of an anti-tank gun firing tracer shot.**

the exposure by themselves or as capping shutters for shutters of much higher speed. These shutters may again be subdivided into several major groups, according to their fastest exposure ratings and the kind of camera with which they are used.

Diaphragm shutters (speeds up to 1/400 second) are used with ordinary still cameras. They are situated inside the lens and open and close in the manner of an iris diaphragm, hence the name.

Curtain shutters (speeds up to 1/2,000 second) are used chiefly in miniature, press and aerial cameras. This shutter resembles a curtain or roller blind with a transverse slot, the exposure being made by causing the slot to traverse the light path between lens and film. The exposure time is controlled by the width of the slot and the speed of the curtain. Usually, such shutters are installed very close to the film plane, and are then called "focal plane" shutters.

A very important feature of focal plane shutters is that, unlike the diaphragm shutters, the instant at which a particular point on the film is exposed is a function of shutter travel. In other words, one end of the film is exposed before the other, and if positions of objects are to be measured on the film this time difference must be known very precisely.

Rotating disc shutters (speeds up to 1/10,000 second) are found mostly in motion picture cameras, in highly specialized sequence cameras such as the Hulcher, or in ballistic phototheodolites. This type consists essentially of a disc with a pie-shaped cut-out which produces an exposure each time the open sector passes the lens. Other versions may use two synchronized discs to control the sequence rate, which is achieved by rotating the two discs at different speeds, exposure occurring only when both open sectors are in line with the lens.

This class is the rotating version of the curtain shutter and like it has no theoretical limit to the exposure time which can be obtained. The rotating disc shutter is best suited for rapid sequence exposures, as in motion picture work.

Slotted cylinder shutters (speeds up to 1/50,000 second) are used in a few highly specialized rapid sequence cameras, notably in the Bowen ribbon-frame camera. The shutter is a simple cylinder of metal with slots parallel to its axis and the film feed and transport mechanism is placed entirely within the cylinder. The action of the shutter is exactly the same in principle as that of the curtain shutter.

### Kerr Cell Shutters

For the photography of really rapid events, such as the motion of the jet from a shaped charge at a velocity of the order of 25,000 feet per second, mechanical shutters are far too slow. Kerr cell shutters have been made to give exposures as short as 0.004 microseconds.

The Kerr cell shutter is based on the property shown by some substances of becoming doubly refracting when placed in an electrostatic field. This property is known as the "Kerr effect" after its discoverer.

A Kerr cell camera comprises the following elements in the order given: a plane polarizer (sheet of Polaroid), an optical glass tank containing nitrobenzene between two sheet metal electrodes parallel to the light path, a second plane polarizer with its polarization direction at 90° to that of the first polarizer and a camera equipped with a mechanical shutter. Light passing through the first polarizer traverses the nitrobenzene and is stopped by the second polarizer. However, when high voltage d-c potentials are applied to the electrodes, the nitrobenzene becomes doubly refracting (it has the highest Kerr constant of any common substance), the plane of polarization of the light is rotated 90°, and the light therefore passes through the second polariod into the camera. Actual cell design is complex, since field intensity and path length in the nitrobenzene must be accurately controlled.

It will be noted that the open time of the cell is controlled by the duration of the electric pulse. With good circuit technique it is relatively simple to obtain exposure times shorter than one microsecond. A commercially available unit has a fixed exposure time of 1/10 microsecond.

It must not be imagined that this shutter has no defects. First of all, the d-c potentials used are as high as 40,000 volts, creating a real handling hazard and leading to operating difficulties in conditions of high humidity. Secondly, the very pure nitrobenzene employed freezes above the freezing point of water, making cold weather operation troublesome. Perhaps the worst fault is that at full opening the cell transmits less than 20 per cent of the light falling on it, because of absorption in the polaroids and in the nitrobenzene. In the closed condition the cell transmits some light, principally red, due to the characteristics of the polaroid. The mechanical shutter is synchronized with the event to prevent exposure of the film to this "leakage" light.

In common with all really high speed shutters, the Kerr cell can be used only for intensely self-luminous events, such as detonations, unless extra high-intensity lighting is supplied.

The magneto-optic (Faraday) shutter is another very high speed shutter for exposures at speeds up to a millionth of a second. Generally similar to the Kerr cell, it uses a block of special glass to replace the nitrobenzene and a coil of a few turns of heavy wire, with the helix parallel to and surrounding the glass, to replace the electrodes. The Faraday effect on which this shutter is based is that double refraction occurs in some substances placed in a very strong magnetic field.

The Faraday shutter avoids the low temperature difficulties encountered with the Kerr cell, although it is not possible to design useful magneto-optic shutters with the extreme speeds provided by Kerr cells.

The wide open transmission of this shutter is only about 4 per cent, even lower than the Kerr cell, but its closed transmission is only about one part in ten million, making it very well suited indeed for photography of intensely brilliant, long duration phenomena. ("Long" is here relative to the exposure duration of one-millionth-second).

Explosive shutters are used in a few instances where the camera may be open up to the time an event occurs, but must be closed afterwards at an extremely high speed. They are essentially capping shutters and have been used as such with Kerr cells and high-speed rotating mirror cameras for the observation of explosive phenomena. Two common types of explosive shutter are described below.

Putty shutters consist of a mass of putty or grease surrounding an opening in the optical path. The opening is usually covered with a tough glass plate which is shielded from the explosion. The operating power is supplied by a loop of cordtex surrounding the plastic mass and connected by suitable explosive links to the explosive system being studied. The explosion is initiated and, after the desired interval, the cordtex loop detonates, smearing the putty over the glass plate and closing the shutter. The whole closing action requires only a few microseconds.

Glass explosive shutters depend on the fracturing of glass to reduce the light transmission very greatly. A glass plate mounted in a heavy metal holder is shattered by the explosion of a detonator placed at one edge of the glass and initiated at the proper moment. Under concentrated explosive attack, a compression wave traverses the glass followed by a very intense rarefaction wave. The tensile stresses set up by the latter smash the glass practically to powder, reducing its transmission to a small fraction compared with the transmission of solid glass. Since there is still some transmission of light, an auxiliary capping shutter may be employed.

**Fig. 2. Open-shutter picture of the flash produced by a high velocity shot striking thin armour.**

### Subject Illumination

The alternative to controlling exposure time by means of a shutter is to control the time during which the subject is illuminated. If no shutter is used, all other light must be excluded; however, from a practical point of view it may not be necessary to work in the dark. It is necessary only that, except for the controlled illumination, the total exposure must not be sufficient to register on the film. Some slight exposure of the background may actually be useful in helping to locate the subject in space.

Very high-speed light sources may have extremely high intensity. They are therefore used with very high-speed shutters to provide sufficient light for good exposures. In these cases either the light source or the shutter may control the exposure time, depending on which is the faster.

### High Speed Light Sources

Several types of high-speed light sources are employed for different purposes. The most important types are described below.

Explosive flash lamps are used only for the study of explosive phenomena, since they are highly damaging in themselves. However, they are relatively cheap, completely non-electronic (a very real advantage) and produce extremely bright flashes of light of very short duration. They are usually used for auxiliary lighting with a high-speed shutter, such as a Kerr cell.

The explosive flash lamp is based on the extremely high luminosity of an intense shock wave in argon. A spherical charge of high explosive (usually pentolite), with a detonator at the centre, is mounted in a glass container (made by sawing a florence flask in half) so that there is a uniform air gap between the explosive and the glass. The joint in the glass is sealed with scotch tape and the air flushed out with argon. Upon detonation of the charge, an extremely high pressure shock wave emerges from the charge surface quite symmetrically and traverses the argon in the gap. During this passage very brilliant light is emitted. The flash duration is controlled by the thickness of the argon layer.

Although the explosion products themselves and the shock wave in air produce bright illumination, the amount is small compared with that which persists only for the very few microseconds in which the shock wave exists in the argon. A high-speed shutter blocks the unwanted light effectively.

Synchronization of the flash and the explosion to be studied is achieved by using primacord leads for timing, and Kerr cell synchronization is secured usually by an ionization pick-up in the explosive train and an electronic timer, although the ionization pick-up alone may suffice, if an extra detonation train is used as a "primacord clock".

Exploding wires provide extremely high intensity light sources. The wires to be exploded are clamped between heavy electrodes and shorted across a high voltage, high capacitance condenser by spark gap or thyratron switching. The wire vapourizes almost instantly (Kerr cells have been used to study the process) and produces very bright light which fades slowly, that is, in 10 or 20 microseconds. A Kerr cell or Faraday shutter is used to control the exposure time.

One important advantage in the observation of detonations is common to the exploding wire and explosive flash lamp. Both require only completely expendable and cheap components at the flash source and hence may be used where they will be destroyed by the experiment.

Open spark gaps can produce flashes of light of extremely short duration, but ordinarily of low intensity, and are therefore used only for shadow photography, which is discussed later.

### Guided Sparks

Guided sparks are sometimes used for reflected light photography of high-speed objects. Ordinary spark gaps are erratic light sources if high light output is required, since the spark path through air is not repeated from one flash to the next. If the spark gap is bridged by an insulating rod of glass or plastic, the spark will span the gap along the surface of the insulator; if a groove is made along the rod, the spark will almost invariably occur along the groove. With this device very high voltages and power capacitors can be used, giving sufficient light output for reflected light photography. The only commercially available apparatus of this type is the French "Defatron".

Enclosed sparks are used where the light source must be as small as possible in size. This requirement arises in shadowgraph and schlieren photography, which is discussed later. An enclosed spark gap is made by surrounding the two electrodes with an insulating tube and by drilling a hole lengthwise through one electrode. The spark is therefore seen end-on with the smallest possible presented area. The enclosure also confines the air heated by the spark, causing a local rise in pressure which increases the light intensity. The best-known example of the enclosed spark is the Libessart spark gap.

Electronic flash tubes are essentially developments of the enclosed spark gap designed for reflected light work. The electrodes are enclosed in a sealed glass tube containing a rare gas such as xenon (for a white light) at atmospheric pressure. A mixture of xenon with about 20 per cent hydrogen gives a brighter flash of somewhat shorter duration. The flash is powered as in the spark gap types by a capacitor connected across the tube and charged to several thousand volts. The flash is initiated by applying a high voltage pulse to a third electrode in the tube or to a wire wrapped around the tube. This pulse can be obtained from a spark coil or other high-voltage source, controlled by a switch or a thyratron operated by a suitable trigger circuit. A typical commercial flash unit is the General Radio "Microflash", which produces a single flash lasting approximately two microseconds.

Some lamps of this type may be flashed in sequence to give a series of exposures for motion picture work. In this application the total light output of each flash is usually much reduced.

### Photographing Gun Projectiles

The method of photographing gun projectiles in flight used at CARDE is simple and highly satisfactory. Permanent photographic installations are used and the gun brought to them for firing, since this is far easier than making temporary photographic set-ups.

The gun is arranged to fire through a small building about 50 feet from the muzzle. A heavy blast wall with an escape hole plate absorbs the main shock from the gun and protects the photographic equipment, some of which is not very rugged. The photographic shelter proper is a frame structure about 12 feet wide, 20 feet long and 9 feet high, without windows, but with small apertures in each end through which the projectiles enter and leave. Before a round is fired, these openings are covered with black paper.

Ordinary 4 x 5-inch press cameras are set up and focussed on the point in space at which it is desired to photograph the projectile. The microflash equipment is arranged so that its beam will illuminate the desired area. From the ceiling a simple optical system illuminated by an automobile headlight projects a parallel beam of light about ½ x 9 inches in cross-section vertically downward to the floor, where a similar system focusses the light on the cathode of a photocell. The photocell is connected to an amplifier which is designed to produce a large voltage pulse to operate the microflash trigger circuit. An electronic shutter synchronizer is normally used, connected to a mercury inertia switch fastened to the breech ring of the gun.

The sequence of events which results when the gun is fired is as follows:—

1. The gun begins to recoil, closing the mercury switch.
2. The mercury switch operates the shutter synchronizer.
3. The shutter opens.
4. The projectile moves into the photographic shelter and noses into the light beam.
5. The change in photocell current caused by the shadow of the projectile is amplified and passed to the microflash trigger.
6. The microflash lamp flashes, lighting the projectile for two-millionths of a second.
7. The projectile moves on out of the shelter.
8. The shutter closes.

With this method, extremely sharp photographs are obtained of even very fast projectiles. The motion of a shell travelling 2,500 feet per second is about 6/100 of an inch during the exposure. A typical photograph is reproduced as Fig. 3.

### The Shadowgraph

For many purposes a "picture" of an object is not required. The methods of reflected light photography may, in fact, obscure the very fine points of greatest interest. A major phenomenon of this nature is the air flow pattern around rapidly moving objects, for which there are several observational methods in common use.

The shadowgraph is the simplest of all the shadow methods and may be used for determining the position of an object in space and the air-flow around it. No optical apparatus whatever is used. Instead, the projectile is fired so that it passes between a photographic film and a light source of extremely small physical size, such as a Libessart spark. When the spark occurs in synchronism with the passage of the projectile, the latter throws its shadow on the film. Upon development, the film shows the shadow as a clear area on a darkened background. Fig. 4 is a shadowgraph of a rifle bullet in flight. If the space positions of the spark and photographic plate are accurately surveyed, the position of the projectile at the time the spark flashed can be computed in two dimensions. If three-dimensional co-ordinates are required, two spark-film systems at right angles to each other are used. Because of the long time required for surveying, plate measuring and computation, the method is employed only when the extreme precision attainable is worth the cost in man-hours.

The sharpness of the shadow is determined by three factors. The spark size must be small, the flash duration must be short and the ratio of the distances from film to spark and from film to projectile must be large. The last factor also reduces geometric distortion to a minimum.

The air-flow pattern around a projectile is visible in a shadowgraph. Motion of the projectile through the air produces various compressions and expansions, including shock waves, if the projectile velocity exceeds that of sound in air. There are pressure gradients, therefore, in the neighbourhood of the projectile and as a result there are local changes in the index of refraction of the air. This causes small zones to act as lenses bending the light towards the higher pressure side. If the pressure differences are sufficiently large and abrupt, the differences in light intensity which they cause will be seen on the film as shadows, giving a clear picture of the local non-uniformities in the airflow around the projectile. That these differences need not be large can be observed by watching the air shimmering above the hot surface of a stove. Such "heat waves" are gentle indeed compared with those caused by a supersonic projectile; nonetheless if a beam of sunlight falls through them onto a plain surface the wavy shadows are easily visible.

Parallel-beam shadowgraphs are much the same in principle as ordinary shadowgraphs. However, a large lens or concave mirror is used to make the light from the spark parallel before it strikes the film. This method has two advantages. First, it eliminates geometric distortion and, second, it permits removing the film to a greater distance from the object being observed without greatly reducing sharpness. Diffraction effects limit the second advantage.

The main drawback of the method is the cost of the lens or mirror, which is high for a large diameter field of view. For this and the preceding method the film must be at least as large as the field of view required, which sets practical limits of operating size.

### Schlieren Systems

Schlieren systems are also based on changes of refraction in air caused by pressure differences. Their principle of operation is best illustrated by an example.

Accompanying a projectile moving at supersonic speed is a system of shock waves, of which the nose shock is the strongest. In still air this shock wave is conical in shape, with the projectile at its point and the axis of the cone lying along the direction of motion of the projectile. This is termed the "Mach cone" after its discoverer, Ernst Mach.

If the shock front is examined in minute detail, it will be found to consist of an extremely thin surface of air at a pressure and temperature much above normal. The front of the shock wave—the side towards which the wave is moving—is marked by an extremely abrupt change in pressure and temperature, while the changes in the other direction are more gradual.

Considering now a parallel beam of light which passes through the shock cone surface in a tangential direction, it will be readily apparent that the light which just misses the edge of the wave and travels in undisturbed air will not be deflected. If the light passes just inside the shock front it will, n accord with usual optical principles, be bent slightly towards the region of greater density, that is, towards the shock front. At some little distance past the point of passage through the edge of the shock wave, the light beam will no longer be of uniform brightness. Instead, the light which passed behind the shock front will have been bent towards the front, leaving a zone of lower light intensity, and the undisturbed light which just missed the shock will have this deflected light added to it, increasing its intensity. If one simply recorded this directly on a film a shadowgraph would result, the shock wave being shown as a discontinuity between a bright zone and a dark zone, both zones fading out to background intensity at some little distance from the shock.

The schlieren system employs optical methods of amplifying the contrast between light and shadow and is therefore capable of detecting

**Fig. 3. Microflash photograph of a 6-pounder shot in flight at 2,800 ft. per second.**

disturbances too weak for direct shadowgraph methods. Obviously, it will thus enhance the sensitivity of the system for detecting flow disturbances of any kind.

A simple schlieren system is composed of a spark light source or small area flash tube and a large lens or mirror, which forms a very sharp image of the source. At the image is placed a "knife-edge", a very sharp-edged strip of blackened metal which is carefully positioned so that part of the light is stopped by the knife-edge and the light forming the rest of the image is permitted to pass by. A camera is placed behind the knife-edge and focussed on the plane occupied by the object to be observed. This plane may be almost anywhere between light source and knife-edge, but is usually near the large lens or mirror in order to give the largest field of view.

Considering the discussion of the effect on a tangent beam of light by a shock wave, it will be seen that the light arriving at the knife-edge when a shock wave or other disturbance is present will be non-uniform in brightness. If the shock wave image is parallel to the knife-edge, the change in uniformity of the beam will cause a large portion of the light to be either stopped or passed, depending on whether the knife-edge is on one side or the other of the beam. This effect provides the amplification of contrast essential for the detection of weak disturbances.

The sensitivity of a schlieren system of the type described is highly directional. A disturbance occurring in the proper orientation is emphasized; those oriented differently may be discriminated against. For special purposes, knife-edges may be formed as sharp-edged holes or opaque circular dots, both non-directional. It is more usual to rotate a straight knife-edge to the angle required to examine a particular disturbance.

Variations in the major optical arrangements are sometimes made. The most common is the use of two mirrors to produce a parallel beam through the region of space to be observed. This set-up is extremely useful where the distance along the beam to the disturbance is not exactly predictable, since the camera need only be focussed on the plane of the nearer mirror; all positions lying between the two mirrors are then in focus. This is the usual method used for wind tunnel observations. A sample wind tunnel schlieren photograph is shown in Fig. 5.

Schlieren systems have one important advantage over simple shadowgraph equipment. The film size depends not on the schlieren system, but on the camera lens and may be small. On the other hand, the lenses and mirrors are very costly in large sizes.

Multiple schlieren systems consist of a number of light sources and knife-edges with one camera for each pair. They are arranged at conjugate focal points on the opposite sides of a large lens. A mirror could be used, but since the disturbance to be investigated can be permitted to occur only in one of the light paths to the mirror to avoid great confusion in the record, a mirror must be very much larger than a lens to cover the same field of view. Exposures are made by flashing the lamps in sequence to give observations throughout a short period. It should be noted that each picture is made from a slightly different point of view, although this feature is of little consequence for many purposes.

These systems have been used for such widely varying purposes as study of gas flow from gun muzzles, of scale model projectiles attacking armour and of the velocity of shock waves from a shell exploded in flight.

#### Interferometers

Interferometers are extremely precise, delicate and costly devices if large in size, but provide direct measurements of the densities and density gradients in the air volume within their field of view, which is usually the test section of a wind tunnel or ballistic range.

Although the precision of optical finish and alignment of components needed for satisfactory operation of an interferometer are extremely difficult to achieve, the principle of their operation is quite simple.

A parallel beam of light is split into two beams by a semi-transparent mirror. One of the beams is

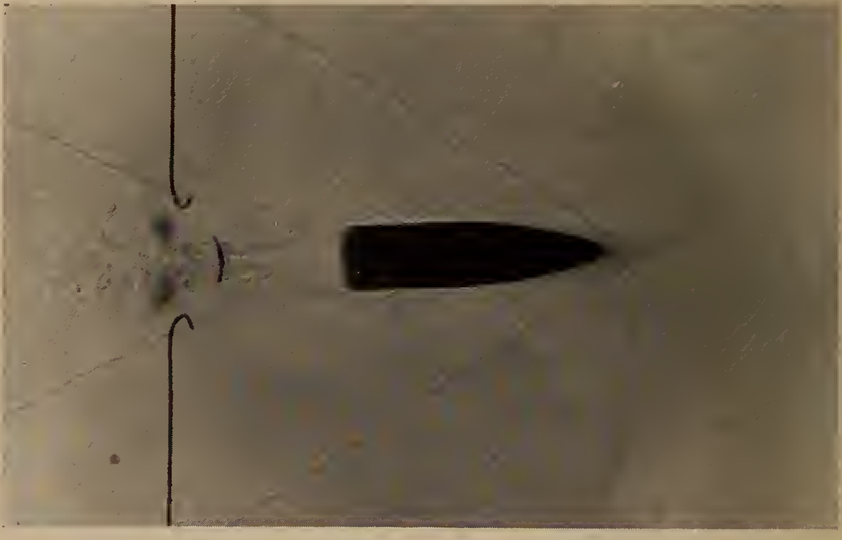

**Fig. 4. Spark shadowgraph of a service rifle bullet in flight.**

directed through the system to be observed and the other is passed around the system and re-combined with the first beam by another semi-transparent mirror. Now comes the most difficult structural and alignment problem: the path lengths of the two beams are adjusted so that, first of all, the wave-fronts of light exactly match each other over the entire area of the beams, and then put out of adjustment so that across the beam the light waves alternately are in and out of phase, producing a pattern of parallel interference fringes. To be really useful, the resultant fringes must be exactly parallel and of exactly even spacing, although corrections can be applied if this condition is not quite obtained. The minimum acceptable optical finish of the components is about one-twentieth wavelength of light for producing such high quality fringes and the adjustments in angle and spacing of the components must be of the same order of accuracy.

The fringe pattern is usually set up normal to the direction of air flow or projectile motion being observed. Variations in the direction and spacing of the fringes caused by differences in air density are determined by precision measurements on camera plates. These measurements and the ensuing computations are laborious and time consuming if carried out to produce a complete density plot. Because of this and their great cost, large interferometers are rare.

### Motion Pictures

Motion pictures are employed to record trains of events in time. They are used to display sequences of events which are in actual fact incoherent, using selective photography and editing procedures to eliminate unimportant items and to emphasize the continuity of processes and the relationships between them.

The availability of a motion picture record makes possible the repeated examination of a complex event with attention to one particular aspect at a time, providing observational data which it might not be possible to obtain with observers actually on the spot.

Normal speed cameras cover the range of frame rates up to 64 frames per second. This is an arbitrary limit set by the camera manufacturing industry and provides frame rates high enough for ordinary "slow motion" photography without raising too many difficulties in the design of camera mechanisms.

Cameras in this class are used in 16-mm. or 35-mm. film sizes for general recording work. They have been used for such technical jobs as measuring the oscillation frequency and damping time of gun mountings, the position of the barrel against a fixed scale being read off each frame and plotted on a graph.

High-speed, intermittent cameras move their film through the exposure gate intermittently as do those of the preceding group. The

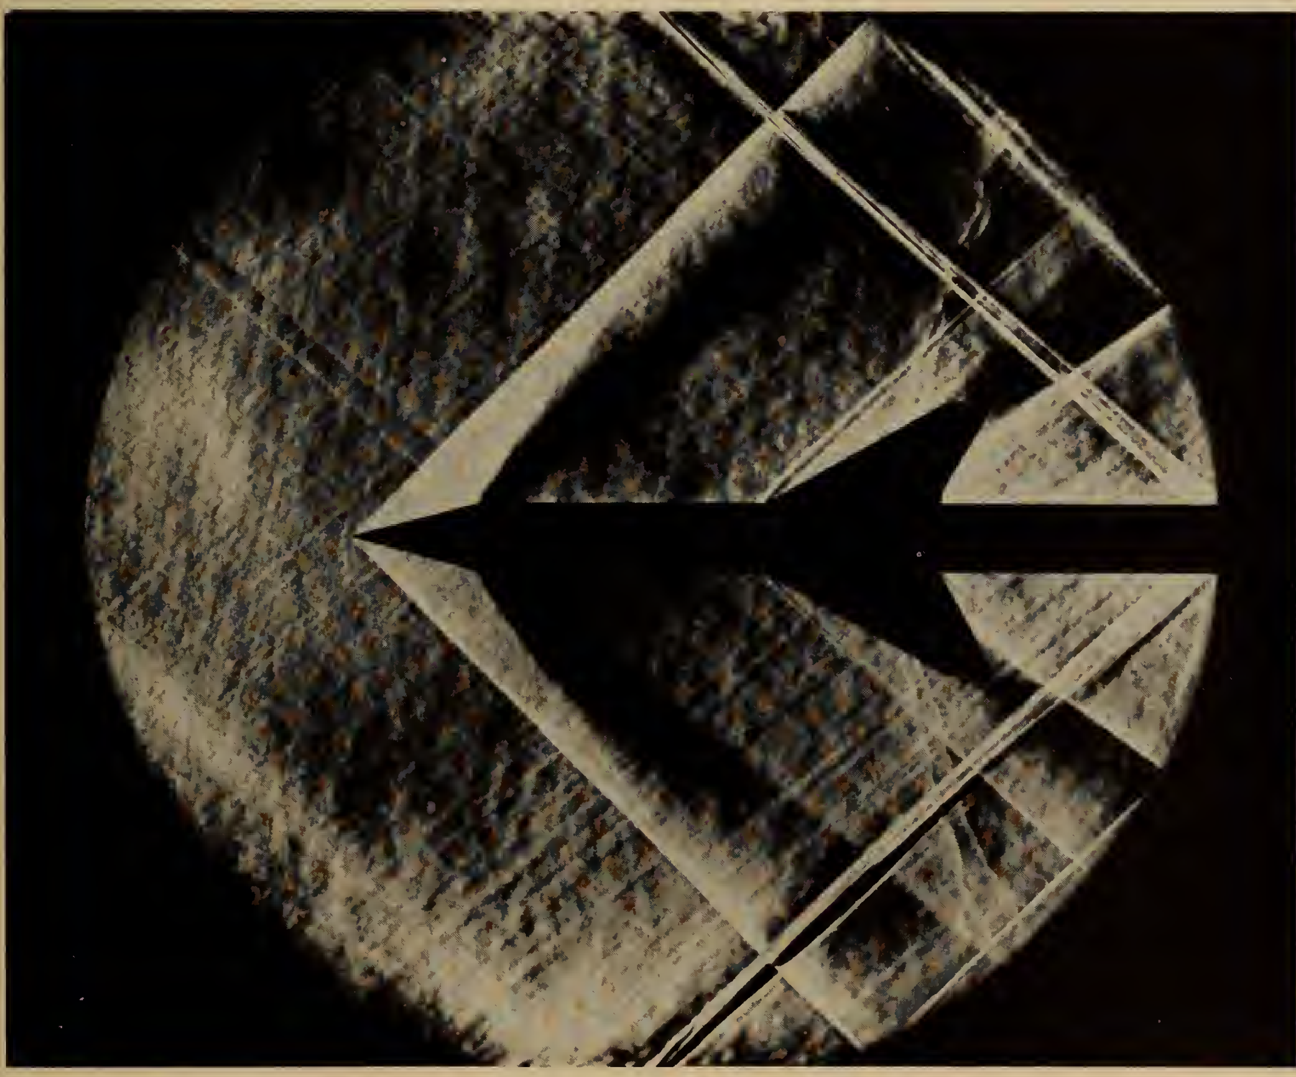

**Fig. 5. Schlieren photograph of air flow around a model in a supersonic wind tunnel.**

film is stationary during exposure and is moved to the next frame position during the time the shutter is closed.

The maximum frame rate of existing high-speed cameras is low, of the order of 200 to 275 frames per second. A special-purpose, single-speed Bell and Howell 16-mm. camera runs at 200 frames per second and the Vinten HS 300 35-mm. camera can run at speeds from 40 to 275 frames per second.

The design limits for intermittent cameras are set by the physical strength of the photographic film. Obviously, careful design and construction can do no more than make the load on the film uniform and smooth in application. It is still necessary to have the mechanism engage the film perforations, accelerate the film to speed, decelerate it to stop and hold it fixed during the exposure. Ordinary plastic-base film can endure only a limited load; what it can stand is indicated by the Vinten HS 300 camera, possibly the camera most nearly approaching the physical limits of design, which requires a 5 hp. electric motor for high-speed runs.

Cameras in this class are used similarly to ordinary cameras, but for more rapid events. They have been used for measuring gun buffer velocities in recoil and run-out, and are widely used as tracking cameras for observing the flight of guided missiles.

The frame rates available with intermittent film motion are much too low for observing really fast action. The limiting factor in their design is the loading placed on the film by starting and stopping it many times a second. This limitation is by-passed completely by having the film run continuously for a full magazine load. Even if several feet of film is used up during acceleration to speed, many events of extreme interest have durations of a few milliseconds, so that the event may be timed to occur after the film is up to speed.

The upper limit of film speed for continuous film cameras is well over 100 feet per second. A typical camera of this class, the 16-mm. Fastax, runs through a 100-foot-long spool of film in 0.9 second at top speed, including starting from zero and an acceleration period lasting about 0.5 second.

With continuously moving film the obvious difficulty is the production of a sharp picture. This problem has been solved in several ways, for example, by using high-speed repetitive flash lamps without a shutter. The individual flash duration of about one millionth second or less is too short to cause appreciable blurring and the repetition rate is synchronized with the film speed by contacts on the film drive sprocket, in order to produce frames at the correct spacing along the film for projection in standard projectors.

Commercially available flash apparatus provides frame rates up to 7,000 frames per second. The picture quality is high, because of the extremely short exposure time of each frame.

At the higher speeds, this arrangement can be used in a normally lighted room without fogging the film. The limited light output of the flash lamps restricts its use to small area photography, the limit of the usable field of view being of the order of 3 x 4 feet.

High-speed shutters of the types previously discussed can be used if sufficient illumination is provided. One shutter, not yet generally available, which is ideally adapted for this application is the image converter.

#### Image Converter

The image converter is a highly specialized vacuum tube with a photosensitive cathode. If an image is formed on the cathode by a lens, electrons are emitted from the back of the cathode proportionately to the intensities of the light image. The light image is thus converted into an electron image. A suitable array of electrodes inside the tube form an electrical lens for producing a second image on a fluorescent screen which can be photographed by a camera lens. However, the transferred image is formed only if a potential is applied between cathode and fluorescent anode to drive the electrons from one to the other. By applying voltage pulses to the tube the image can be made to pass only for definitely controlled times at a controlled repetition rate. The exposure time can be as short as the minimum pulse width obtainable (of the order of a millimicrosecond), and the repetition rate up to several million frames per second, far beyond the capacity of a continuously moving film camera. If pulsed once, it is of course a still shutter.

A major advantage of the image converter is that it can be a light amplifier, yielding an image brighter than the original, a characteristic of great promise for extremely high-speed work. However, image resolution is not high with existing image converters.

#### Image Movement Compensators

Image movement compensators are by far the most widely used devices for obtaining sharp pictures with continuously moving film cameras.

The principle of the image motion compensator is simple. The reader will be familiar with the experiment of holding a thick piece of glass between the eye and a distant object and rotating the glass about an axis in its own plane, producing apparent movement of the distant object.

The image movement compensator consists of a thick glass prism with four, eight or more sides placed between the camera lens and the moving film and rotating on an axis parallel to the plane of film motion. The rotation of the prism moves the image laterally without destroying its sharpness, and the speed and direction of rotation of the prism are controlled by gearing to the camera drive so that the image moves in the same direction as the film and at the same speed, giving a sharp picture.

The simple explanation given above is true within practical limits only for limited rotation of the prism. Exposure outside these limits is prevented by housing the prism in a metal cage which grips the corners of the prism, acting as a shutter when the prism is rotated at an unfavourable angle.

Typical commercial cameras in this class are the Acmade 35-mm. (2,000 f.p.s.), the Fastax 35-mm. full frame (2,500 f.p.s.), the Fastax 16-mm. (7,000 f.p.s.), the Kodak High Speed 16-mm. (3,000 f.p.s.) and the Fastax 8-mm. (14,000 f.p.s.).

Cameras of this type are widely used for the study of weapon functioning. A typical wartime investigation of repeated jamming of Oerlikon guns during proof firings was unsolved, until Fastax photographs showed that a minor and unnecessary bracket on the proof mounting interfered with case ejection, causing some cases to clear the gun and then bounce back in front of the breech-block, jamming it. A typical application as a measuring instrument is the determination of fragment velocities of detonating weapons. In grenade trials a Fastax may be set up to photograph both a target plate at a surveyed distance from the grenade and a mirror reflecting the grenade itself. Timing marks placed on the edge of the film by a flash lamp driven by a timing oscillator permit timing the flight of each fragment striking the plate by counting frames from the appearance of the grenade flash to the flash of each fragment on the plate.

Sequence cameras make a series of photographs of an action automatically. The dividing line between sequence cameras and motion picture cameras is indefinite; the difference may be considered to be in the method of examination of the final pictures, since sequence camera records are not usually projected as motion pictures. In many instances they cannot be so projected, because of lack of frame registration or differences in image orientation. However, even for the most intricate frame arrangements, special-purpose printing machines can provide prints for motion picture projection. Some of the specific features of these cameras are discussed below, the list being far from complete.

Slow-speed sequence cameras are employed to obtain pictorial records of slow events, or synchronized pictures of several repetitions of a repetitive cycle. In the latter application they are equivalent to automatic film changers.

Typical examples are ordinary aerial cameras, which may be operated in some cases up to two or three cycles per second, and the Robot 35-mm. camera which can run at up to six or eight frames per second. These speed ranges overlap those of motion picture cameras, which can, of course, be operated at one frame per day if anyone needs such a low rate. The sequence cameras often have larger film sizes, which may be of great importance for some work.

High-speed sequence cameras are best described as higher-frame-rate versions of the preceding class, differing from motion picture cameras in having larger frame size.

The Hulcher 70 camera is the most generally available machine in this class. The Hulcher camera uses 70-mm. perforated film to take pictures 2¼ x 2½ inches or 2¼ x 5 inches at rates of up to 50 or 25 frames per second respectively. A double-disc rotating shutter provides exposure times down to one thousandth second per frame.

#### Ultra-Speed Framing Cameras

Ultra-speed framing cameras operate on very different principles from those previously described. One type developed to a practical level at Los Alamos and now manufactured by Beckman and Whitley operates at up to 2,400,000 frames per second in the following manner.

An objective lens forms an image of the subject on a rotating mirror. The mirror sweeps the beam of light around, directing it into a series of lenses set around a circle centred on the rotational axis of the mirror. These lenses form secondary images on a strip of 35-mm. film placed in a suitable film holder behind them.

It should be carefully noted that the images on the film are not moving, since the "object" which the secondary framing lenses observe is the primary image positioned on the axis of rotation of the mirror. Rotation of the mirror acts only as a shutter controlling the time during which each secondary lens views the object.

This arrangement yields sharp pictures at high frame rates and short exposure times, at the cost of low optical speed, requiring extremely high intensity illumination. The major difficulty in the design of such cameras is the mirror drive. since rotational speeds of 100,000 revolutions per minute or higher are needed. Air turbines are often employed.

Usually either self-luminous subjects, such as detonations, are photographed, or explosive flash lamps are used for small-area observation of non-luminous objects. Since the camera must be open for only one revolution of the mirror to avoid double exposures, a high-speed shutter is required to close the camera. The Los Alamos camera uses an explosive/glass shutter for this purpose.

Examples of applications of this camera are the study of the motion of metal surfaces under explosive attack and the early stages of expansion of atomic explosions.

#### Image Dissectors

Image dissectors provide another method of obtaining high frame rates. An optical system is used to break up the original image into strips rather like the pattern of a venetian blind. These image elements are then placed end-to-end across the film. This permits the recording of a picture frame on much less than its normal length of film. As a result, the film need move only the height of an image element between frames. Using high-speed drums as film carriers, cameras of this type can reach frame rates of about 200,000 per second.

#### Grid Analyser

In a grid analyser, the original image is formed on a grid made by scribing parallel lines about 0.0005 inch wide on an opaque coating on glass, the lines being separated by a fairly large multiple of their width. A second lens is used to form a 1 : 1 image of the grid on a photographic plate, but a large area rotating mirror is inserted between the second lens and the final image, causing the latter to move across the film.

Considering a photograph taken with the mirror stationary, the resulting picture will consist of a series of lines separated by areas with no image. To the eye the picture will appear somewhat the same as a television picture, having a line pattern not too clearly resolved. Providing the size of the object in the picture is large compared with the line spacing, a fairly sharp picture is obtained.

Now if the mirror is rotating, there will be constant exposure of the film and the resulting picture will be a blur. However, if the original grid is placed in contact with the picture, the result is similar to the preceding case in that the appearance of the subject at the moment corresponding to the grid position used can be examined. If, then, the grid is moved normal to the line direction by one line width another stage of the process can be observed. In a similar manner, separate views of the event can be obtained by moving the grid until the whole space between grid lines has been traversed, line width by line width. Although the exposure is continuous, a "frame rate" can be defined as the reciprocal of the time taken for the image to move one slit width. By this definition the United States Ballistics Research Laboratories camera has a frame rate of 100,000,000 per second.

This is a decidedly special-purpose camera intended for the study of the motion of shock waves near small charges of explosive. For this purpose it is often convenient to permit multiple exposures to give a record of successive positions of the shock wave on the same frame.

Image converters have been used as high speed framing devices by adding magnetic deflection coils to the image converter shutter. Each image formed by a single exposure is deflected to a different position on the fluorescent screen. Commercially available equipment provides six pictures at a maximum repetition rate of about 1,000,000 per second.

For many purposes a pictorial image of an object or event is not necessary. For example, only in the time at which some event occurs may be of interest or the intervals between similar events, or, perhaps, a combination of the time and distance along a straight line, as in the measurement of the velocity of detonation of explosives, may be of interest.

### Streak Cameras

Applications of this nature are often best served by a method of continuous exposure, since the dark interval between exposures in a framing camera may obscure the most interesting portion of an event. Cameras designed to give continuous recording usually sweep the image along a film giving a picture which is composed of smears or streaks, and so they are often called "streak" cameras.

Moving film streak cameras use a fixed optical system and move the film past the point of exposure. To avoid inaccuracies due to image extension along the time axis of the film, a slit is used, either inside the camera or at the subject, to confine the field of view to as short a length as may be desired.

There is a very large number of cameras in this class differing in detail, but not in principle. The Hulcher 70 camera may be used as a streak camera by disengaging the intermittent drive and can give film speeds of up to 10 feet per second. The General Radio continuous film camera uses 35-mm. film at up to 100 feet per second.

A typical application of this class to armament work is the determination of fuze functioning time. The camera is set up to view the edge of a target from a point at right angles to the trajectory and has its slit oriented parallel to the trajectory. A burst of gunfire at the target results in streaks of light which originate at the burst point of the shell. If a light is mounted on the target, the distance between target and burst can be obtained, and the time computed from the observed velocity of the shell. In this particular case, a still camera might suffice, but the streak camera permits using automatic fire and also moves the image on the film so that if the explosion gases expand towards the target, they do not obscure the original point of burst.

### Drum Cameras

Drum cameras form another class of moving film cameras with higher film speed than can be obtained with continuous film cameras. They have been used for similar purposes, but with higher time resolution.

Rotating mirror streak cameras raise the limit of image velocity attainable to much higher levels than do the preceding types. Image speeds of 5mm. per microsecond are attained by commercially available cameras and this is by no means an upper limit.

Most cameras of this type have an objective lens which forms the primary image on a slit. A second lens transfers the image of the slit to a fixed film by way of a mirror which rotates on an axis parallel to the slit. This arrangement establishes a virtual slit at the object being photographed, which is frequently a most convenient feature.

The most common applications of this camera type are to the study of detonation phenomena. A stick of explosive oriented parallel to the slit and initiated at one end produces a streak image which can be analyzed to give the detonation velocity at all points along the stick, showing variations where the mechanism of detonation changes. If the end of such a charge is imaged on the slit, the resulting record shows the shape of the detonation wave traversing the explosive, since each portion of the detonation wave is recorded as it arrives at the free end of the charge. In this manner the effect of various systems of initiation and confinement on wave shape can be investigated, matters of considerable importance in, for example, shaped charge design.

### "Ballistic Camera"

The term "ballistic camera" is applied only to cameras used for the precision measurement of trajectories of projectiles, rockets and other free-flying objects. The major features of these cameras are the extreme precision of their construction and the provision of accurate methods of reading their position and orientation. There are two major subdivisions of the class, fixed and tracking cameras.

Fixed ballistic cameras are very precisely set up and fixed in position. They record the flight of objects across their fields of view and are the most accurate of all optical instruments used in ballistics work. Phototheodolites are the simplest in principle of all ballistic cameras. They consist of a precise lens, a light-tight box and a plate-holder, the whole assembly being mounted on horizontal and vertical bearings of extreme precision and rigidity.

These cameras are used in pairs on a long base line, and are equipped with rotating disc shutters accurately synchronized. Usually, they are used at night with projectiles fitted with tracers or other light sources, and record views of the trajectory interrupted at precisely determined intervals by the shutters. The three-dimensional trajectory is then computed by triangulation from the known survey positions of the cameras and their orientations.

For work of high precision the orientation of the cameras cannot be obtained with sufficient accuracy from any conceivable scales. In such cases, firings are carried out on clear nights and the photographic records are calibrated for each small part of their areas by measurements of the relative positions of the background star field, the positions of stars being known to great accuracy from astronomical observations.

This method avoids all mechanical errors and neutralizes the effects caused by slight dimensional changes in the emulsion during processing, as well as allowing for lens distortion. Position accuracies of the order of one inch at ranges of many miles can be achieved under the best conditions.

Ribbon-frame cameras are actually high-speed sequence cameras designed for precision position measurements. The CZR-1 Bowen camera may be taken as typical of the class. This camera uses 5¼-inch wide aerial camera film to make exposures of full film width, but as little as one-quarter inch high at rates up to 180 frames per second. A multiple-slot drum shutter produces exposures down to 25 microseconds at very precise intervals. The field of view includes an array of timing lights which record exact time of exposure and a series of reference crosses which are recorded on the film at each exposure and which are used to calibrate the field of view by making exposures of a precisely surveyed set of targets.

The camera includes a mounting which can be oriented around all three axes to about 0.002°. This allows the long axis of the camera frame to be oriented parallel to the missile trajectory, the position of the missile image in subsequent frames being measured with a travelling microscope and used to compute position, velocity and acceleration versus time.

This camera was originally designed for the observation of rocket trajectories during burning and still provides the most satisfactory method for this work.

Tracking cameras are used for determination of position versus time of larger missiles and aircraft and differ from the fixed cameras in two major respects; tracking cameras usually use motion picture film for sequence photographs and are equipped with long focus lenses. They must therefore be pointed at the missile at all times in order to keep it in the field of view.

Kinetheodolites are the tracking equivalents of phototheodolites, though of necessity of much lower precision. The Askania kinetheodolite is typical of the class. This instrument has a very rigid camera body with a long-focus, usually 24 inch, lens and an intermittent motion-picture film-feed mechanism. A moderately fast shutter is used with a synchronizing drive, which can be adjusted so that all cameras of a group can be made to expose at the same instant.

The camera body is mounted on horizontal and vertical bearings of high precision, both axes being equipped with precision calibrated circles. Lens and prism optical trains are used to transfer images of both circles into the field of view of the camera aperture, so that each exposure shows the target, fiducial marks indicating the centre of the field and two scale readings giving the azimuth and elevation of the optical axis for the particular frame.

At least two cameras must be used in a set-up. Operators track the target manually during a flight, and the position of the target at each exposure is computed from the time, scale readings, survey base and corrections for tracking error which are read off the individual frames.

Tracking cameras when used as ballistic cameras are similar to kinetheodolites in principle, but usually of somewhat lower precision. They may use lenses of focal lengths up to 20 feet or more and are primarily intended for obtaining measurements of pitch, roll and yaw of guided missiles at very long ranges. The great size of the optical systems usually requires the use of power-driven mountings.

The same equipment is frequently employed without any attempt at quantitative measurements, but with high frame rate cameras as a method of viewing the operation of external devices, such as moving wings or the separation of booster rockets.

Radiographic techniques are of wide application in armament work. Most applications can be classified as inspection, but there are purely ballistic uses as well.

Industrial radiography is carried out with commercial X-ray equipment or gamma radiation sources, such as radio-active cobalt.

Aside from applications to the inspection of items of equipment, perhaps the most important use of radiographic techniques is the examination of explosives and propellants for the detection and measurement of physical flaws. Cracks and voids in these substances cause irregularities in their performance and examination is used to determine whether the samples are usable and, if so, what irregularities may be attributed to flaws.

A very common use of radiography is the examination of fuses to determine whether they have been assembled correctly, or after recovery to investigate how they have operated.

Flash radiography is closely allied in principle to flash photography. X-rays are used where ordinary light photographs cannot give the required information. Examination of the discarding process of sabot projectiles in the muzzle smoke or flash can readily be accomplished by flash X-ray exposures lasting one or two millionths of a second. If the exposure time is reduced to one-tenth microsecond, detonation waves in explosives can be resolved and the structure and formation of jets from shaped charges, or the break-up of metals under explosive attack, can be observed.

#### References

Information on technical photography, particularly that concerning high speed methods is widely scattered in the literature and a complete or even comprehensive bibliography would be extremely bulky. For this reason only a few references are cited. Those who are interested enough to examine them will find copious references listed in all these sources.

## Natural Gas Pipe Line System

The Government of Alberta has authorized Trans-Canada Pipe Lines Limited to export 4 trillion 350 million cubic feet of natural gas from the province. It may be taken from Alberta at the rate of 183 billion cubic feet per year, or 540 million cubic feet per day.

The Government of Canada, through the Board of Transport Commissioners, has granted the company a permit to construct a pipeline from a point in Alberta, near the Saskatchewan border, across Canada to Montreal; and to build a branch from the main line from Winnipeg to Emerson, on the Manitoba-Minnesota border, to carry gas, through a U.S. system, to the St. Paul-Minneapolis area. Other branches will serve south-western Ontario and the Ottawa-Hull district.

Federal approval of the $300 million, 2,200-mile project was granted on July 26, 1954. The final permit will be issued as soon as authorities are satisfied as to the adequacy of financing arrangements. The company was to report to the Transport Board on this, and several other points, prior to December 31, 1954.

***Niagara Falls—Toronto Branch***

Construction of this line, the first phase of the natural gas system, is well ahead of schedule. The line will serve the Toronto area which, originally, was promised natural gas by November, 1954.

Primary purpose of building the Niagara Falls-Toronto pipe line at this time is to develop the Toronto market area ahead of the arrival of Alberta gas. Under the permit issued by the Board of Transport Commissioners at Ottawa, this line will carry American natural gas to Toronto until November, 1956. The Board has ruled that, once Alberta natural gas shall be available to Toronto, surplus gas, after filling the needs of Eastern Canada, may be piped to the Buffalo-New York area.

Laying of pipe and negotiations for the right-of-way are proceeding simultaneously. At this time, three-quarters of the pipeline is already laid.

# Instrumentation in Armament Development

by

E. J. Bobyn

*Canadian Armament Research and Development Establishment, Valcartier, Que.*

**In this Quebec Annual Meeting paper, the author discusses in general terms the methods and instruments used in the collection of the data required in modern armament design. Some are adaptations of those developed for use in industry, but many are unique. The high cost of proper armament instrumentation will surprise those unfamiliar with it, which naturally includes most readers.**

All phases of armament development from early research to final acceptance trials involve special instrumentation to measure the many parameters which affect basic design or performance. Indeed, without proper instrumentation, it would be almost impossible to attempt a scientific approach to armament design, except possibly by trial and error, which would not only be time consuming, but fruitless and frustrating.

Regardless of the type of armament involved, it is often surprising to note that relatively few basic parameters need be measured. However, the method of measuring any particular phenomenon may be complicated by its nature and the location of its origin. The provision and subsequent application of proper instrumentation for evaluating the performance of an armament or parts thereof may often be the most expensive portion of the program, both in time and in money.

With respect to guns, rockets, guided missiles, aircraft, submarines torpedos, and other projectiles, bombs and associated devices of devastation, one may divide the instrumentation involved into two basic classes. Equipment used to evaluate the *effects* or *results* of a weapon, or its manoeuvre and external condition during flight, is classed as "external" instrumentation. "Internal" instrumentation, however, is concerned with the measurement of the various internal parameters which govern *causes* and is normally more basic in concept. For example, instrumentation to measure the velocity of a projectile is classed as external, whereas the instruments for measurement of the pressure-time curve in a gun barrel during firing are considered internal.

In any experimental analysis in which a measurement is required, there are several significant steps in setting up an instrumentation system:

a. Transforming the physical phenomenon into some measurable impulse by means of a suitable transducer.
b. Transmitting or telemetering this impulse to a recording unit.
c. Recording the signal on an instrument having the response and accuracy required by the experiment or trial.
d. Reducing the accumulated recorded data into some convenient form for analysis.

This paper describes some of the various methods used to accomplish the above steps and their relative importance with respect to armament design and development.

### External Instrumentation

External instrumentation is sometimes referred to as "range" instrumentation, because the equipment involved is normally permanent and is interconnected into a complicated system of facilities, which may extend over a large area. This is particularly true of external instrumentation required for guided missile or long range rocket tests.

The types of measurements involved with armaments include:

a. Space position vs. time.
b. Velocity vs. time.
c. Acceleration vs. time.
d. Altitude vs. time.
e. Miss distance of projectile with respect to a target.
f. Detailed behaviour of a missile or rocket in the early launching phase.
g. Effects or magnitude of blast of a bomb.
h. Shock wave patterns on aircraft, missile models or projectiles.
i. Meteorological data, such as temperature, humidity and pressure.
j. Spin, pitch and yaw of projectiles.

Perhaps the most common and useful type of instrument for external instrumentation is the photographic camera. Special tracking and viewing cameras, some with long telescopic lenses, others of the high speed, short focus type, combined in various ways and involving complicated electronic speed regulating and timing devices, are available on the market today. These, combined with high speed movie cameras and high speed microflash single frame cameras, constitute a special field of instrumentation itself and are covered in the paper "Photography in Armament Development."

Velocity, one of the measurements most commonly required for missiles or projectiles, may be determined by means of photoelectric screens, spaced a known distance apart, through which the projectile is fired. The time interval may be measured on a high accuracy chronograph or electronic timer. The latter are now made to enable accuracies of the order of at least one part in ten million. Among the newer devices for velocity measurements are single point and continuous doppler sets. The latter provide doppler frequencies which are proportional to the velocity during the complete trajectory of the projectile. The single point doppler set measures the velocity at only one point in the projectile's trajectory.

Pulse radar equipment, including beacons and chain radar systems with associated plotting boards and computers, are relatively common for obtaining range, azimuth and elevation data on an aircraft, missile rocket or projectile. These often replace the photographic kinetheodolites, which, although highly accurate, are too dependent upon weather conditions and require a large volume of data reduction to obtain trajectory information.

A large range, especially one concerned with guided missile development, is fully equipped with scores of the above instruments. In addition, complex chains of communications are required to synchronize all the instruments as a team during any single trial.

It may be interesting to note some of the costs involved with equipment of this type. A fully instrumented kinetheodolite station may cost as much as $60,000. At least three of these stations are required to provide useful trajectory information. A tracking radar set complete with computers and plotting boards may run as high as $350,000. Several of these, with their maintenance and operating crews, quickly bring the capital costs up to several millions of dollars.

Recent atomic explosions bring to mind the fact that blast and radiation measurements must be obtained for proper evaluation of such explosions. Special pressure-sensitive transducers, as well as simple interferometer devices, have been developed to measure blast intensity. Geiger counters, of course, are common in detecting and determining the intensity of radioactivity.

Meteorological measurements are important in the armament field. The measurement of temperature, pressure and humidity in the upper atmospheres is required in calculating the expected trajectory of a projectile. The use of special radiosonde equipment, combined with balloons, is the most common method of observing these parameters.

Some of the most difficult measurements involve the determination of yaw and spin of projectiles travelling at extremely high velocities. Spin sondes and similar electronic devices have been used but many of the problems involved remain unsolved.

Instrumentation incorporating electronic and photographic devices for determining the fragmentation pattern and velocities in warhead design is another special requirement.

These and many other requirements provide daily challenges to the ingenuity of the instrument engineer involved with armament development.

### Internal Instrumentation

The instrumentation problems involved in measuring the basic parameters which affect the performance and operational limits of an armament are usually the most interesting. In the field of ballistics experimental techniques must be worked out to measure quantities such as transient pressure, temperature, flash intensity, detonation and ignition time. Such measurements are increased in complexity because of the short duration or rapid transient nature of the events.

The design of suitable propellants and igniters for shells involves measurements of pressure, burning rate, rate of pressure change and similar quantities. Measurements of temperature in guns are important in determining whether the barrel will tolerate those involved.

The development of new aircraft and guided missiles involves measurements of strains, pressure, accelerations, positions of various actuators, pitch or roll angles, fuel flow, skin temperatures, altitudes, vibrations and many other quantities. In most cases, the space and weight problem necessitates the development and design of reliable miniature transducers and recording systems.

Perhaps the greatest accession to instrumentation in the past ten years has been the development of special telemetering techniques, which make it possible to record and measure on elaborate ground-based equipment the behaviour of an aircraft, missile or rocket while in full flight. Engineering personnel, who only a few years ago were loath to look at telemetered results, are now quite willing to accept them as an excellent substitute for data previously taken in test pits or wind tunnels. No longer is there any question whether or not telemetering methods provide good instrumentation; instead, the question is only what system will provide the best data.

Recent rapid advances in electronics, stimulated by the problems created and solved during the late war and those wars now being conducted on an experimental basis by the various nations, have almost completely revolutionized instrumentation systems. Virtually, every instrument at present involves applied electronics of one type or another, whereas twenty years ago optical and mechanical measuring systems were predominant. Future development will be speeded up by the great potentialities resulting from the intensive research programs being carried on in the solid state physics field.

### Transducers

The first step in any measurement problem after a study of the characteristic to be measured is to select a proper transducer, sometimes called "pickup," "sensing element," "command" or "monitoring device". Electronic measuring and indicating equipment, characterized by rapid response, high sensitivity and accurate control, are so commonly used that most transducers now are designed to convert a physical phenomenon into a suitable electrical signal.

Frequently, the nature of the experiment dictates the selection of a specific transducer. For instance, where long cables are necessary, piezo electric transducers may not perform satisfactorily; where temperatures are high, crystals may disintegrate with heat; capacitive devices, though relatively sensitive, usually require intervening electronic circuitry; magnetic transducers should not be used in the presence of strong magnetic fields.

In general all transducers providing electrical outputs operate on the following basic principles:

a. Resistance change—SR4 strain gauge thermisters.
b. Capacitive change—condenser microphone.
c. Magnetic changes—tachometers, saturable reactors and variable reluctance pressure gauges.

d. Piezoelectric phenomena—piezo pressure gauges, vibration pickups and phono pickups.
e. Photoelectric phenomena—photo cells.
f. Thermoelectric phenomena—thermocouples.
g. Electroic phenomena—vacuum tube accelerometers and ionization counters.
h. Radioactive phenomena—thickness gauges.

Transducers now available are far from optimum in versatility, size, weight, construction or cost. Manufacturers and users are beginning to realize that fancy machined surfaces, coupled with intricate electromechanical converters requiring multiple adjustments, are not necessarily of much advantage.

Many basic measurement problems are unsolved for lack of proper transducers or associated elements. For example, how can one measure the mass of a rocket or missile at any time during flight? Can the drag of a projectile or missile be measured within 0.1 ft. per sec.[2] Can continuous measurements of air density during flight be made?

#### Transmitting Systems

After the transducer has been chosen and located, the electrical output must be transmitted either by a wired or wireless link to a recorder. If several quantities are to be transmitted simultaneously, it is sometimes advantageous economically and electrically to use multi-plexing techniques. For static and dynamic measurements on guns wired links are predominant. However, the great interest in rockets and guided missiles has stimulated the growth and development of the radio telemetry link as a replacement for the on-board recording techniques commonly used in the development phase of aircraft work.

When the idea of radio telemetry was first considered, many organizations in Great Britain and the United States began independently to develop telemetering systems. This created complete chaos because of the numerous permutations and combinations of systems that can be made to function. A few survived to be extensively developed and, luckily for Canada, to be eventually available commercially. The drive toward standardization was sparked by the Telemetering Working Group of the Panel on Test Range Procedures and Instrumentation of the Research and Development Board in the United States. In 1948, the FM-FM, the most common telemetering system, was recognized and adopted as a standard. Since then the PWM-FM system has been added as a standard and the PTM-AM system is being encouraged.

All the above systems permit the transmittal of multi-channel measurements from numerous transducers in a test vehicle, missile, rocket or aircraft by a single wireless carrier signal in coded form. These are recorded in a central receiving station, where decoding and subsequent recording on paper may be accomplished automatically.

The factor which will most influence telemetering during the next few years will be the application of transistors. The advantages of decreased volume, weight and power requirements will be exploited for airborne applications. It is hoped that subsequent reduction in costs may follow. A single channel of information telemetered by the FM-FM principle, including the cost of a transducer, one amplifier and a sub-carrier oscillator, may run into six or seven hundred dollars or even higher. Multiplying this by ten channels, and including a four hundred dollar transmitter and a three hundred dollar commutating switch, brings up the total cost of a telemetering transmitting system to several thousands of dollars.

#### Recording Systems

The choice of a recording system depends upon many factors some of which are not dictated by technical reasons. These include the following considerations:

a. Nature of function to be recorded—duration, frequency, magnitude, independent variable.
b. Method of reducing and assessing data.
c. Location of recorders with respect to source of quantity to be measured.
d. Type of transmitting or receiving system.
e. Method of storing recorded data.
f. Number of channels required.
g. Telemetry system.
h. Environmental conditions.
i. Type of transducer.
j. Cost of equipment.
k. Type of maintenance and operating personnel.
l. Provision—by development, or by purchase from standard commercial sources.

In general, the oscilloscope with an associated single frame or moving frame camera is the most common and versatile recorder. This is available in single channel or multichannel form. Its wide frequency characteristics make it applicable to most recording problems. For lower frequency operation, pen type recorders closely followed by galvanometer-paper-record type systems may be found in most laboratories. The development of good magnetic tape recorders is now well enough advanced to make them applicable to many recording systems, especially to provide secondary coverage. Transmitting data by digital and pulse systems makes the tape recorder still more useful, especially since automatic data reduction equipment may be tied in with greater facility. The tape may be played back innumerable times to assure that the information is as accurate as possible.

The simplest and most basic recording unit is the recording pressure gauge, operating on the Bourdon tube or bellows principle, to which an inking pen is attached. Self balancing, potentiometer type recorders, in addition to such instruments have been used in pressure, thrust and force measurements in long burning rockets for many years. These are low frequency devices and are not applicable to guns, where the phenomena are of transient nature with high frequency components.

Measurements on aircraft have been normally made by pen type instruments or more commonly by the galvanometer-paper-record type machines. These are giving way to telemetering systems, especially on small, high speed fighter aircraft where space is at a premium.

#### Data Reduction and Analysis

The great demand for measurements during armament development programs has provided the designers with so much qualitative information that the task of reducing the data to quantitative values usually creates a bottleneck and consequently delays the application of the test results to design.

This may be exemplified in reviewing some of the assessments necessary in sample measurement systems. Consider the use of kinetheodolites to obtain trajectory information vs. time of a rocket in flight for 45 seconds.

Each camera station takes about five frames per second and on each frame the azimuth and elevation of the tracking camera appears with a photograph of the rocket at some distance from the centre cross hairs. A total of 45 by 5 by 3 or 675 frames

# ARCTIC APPLICATION

of

# THE HEAT PUMP

*by*

James B. Templeton

*Head, Engineering Section,*
*Defence Research Northern Laboratory,*
*Fort Churchill, Man.*

This paper was read at the Quebec annual meeting in May, 1954. It calls attention to the special advantages of the heat pump when used in hard-to-get-at locations, such as our Arctic and sub-Arctic defence installations. The particular pump described is a standard refrigerating unit driven by a diesel engine and with ingenious means for getting rid of the ice formed from the water used as a source of heat.

In the Arctic and sub-Arctic regions of North America there exist a number of installations which are manned by fewer than a dozen persons. The supply of food, fuel and equipment to these establishments is a costly undertaking. The inland posts are supplied by air or by winter caterpillar train, and the posts on the Arctic sea are usually supplied by ship during the brief summer season, or by air.

While little can be done to reduce the requirement for food and equipment, it is possible that some saving can be effected in fuel consumption. The saving in oil fuel is important during wartime since oil becomes a strategic material because it can be converted to higher grade fuels by improved cracking processes, because it is the base for various other products by the chemical industry and because of the scarcity of transport equipment.

Another problem associated with the supply of power and heating in the Arctic is the supply of water during the long winter period. The present answer is the melting of ice cut from nearby rivers and lakes, which also requires the consumption of fuel.

The solution to the problem then would seem to be the development of a device or devices which would perform three functions with the minimum fuel consumption. These functions would be to supply heat for dwellings, fresh water at such a temperature that it could be pumped from building to building without danger of freezing, and electrical power for the operation of various appliances and equipment.

The improvement of existing types of fuel oil heaters does not seem to offer much promise of large savings, so the heat pump was investigated on a theoretical basis to determine its possible application.

### Design and Operation

It should be emphasized at the outset that the design and operation of the pump itself is by no means complicated nor even new; its possible use was first pointed out by Lord Kelvin in 1854. We hear so much about it nowadays because there have been improvements in compressors, motors and heat exchangers in the past few years and because fuel and transportation costs have risen to a point where in some cases the heat pump now has an economic advantage over other methods of heating. The refrigerator in your kitchen is a heat pump. It extracts heat at a low temperature level from within the refrigerated enclosure and rejects it at a higher temperature level into the room. In that case we consider the extraction of heat to be the useful and desirable thing. In the case of the heat pump we consider the rejection of heat to be the useful and desirable thing. From a practical point of view this is the only difference between a refrigerating machine and a heat pump.

The heat pump is merely a means of recovering heat at a low temperature and raising the temperature of this heat so that it may be put to some useful work.

The first step in heat pump design is completed when the use to which the heat is to be put is decided and the temperature level of this heat is established. The important consideration with respect to the temperature level hinges on the theoretical coefficient of performance of the cycle.

### Coefficient of Performance

The coefficient of performance is the ratio of heat pumped to work expended. The theoretical coefficient of performance depends only on the temperatures of extraction and of rejection. If $T_s$ be the absolute temperature at which the heat is received and $T_d$ be the absolute temperature at which the heat is rejected, the theoretical coefficient of performance on the heating cycle is

$$\frac{T_d}{T_d - T_s}$$

Thus the smaller the difference between these temperatures and the higher they both are, the greater is the theoretical coefficient of performance.

It becomes obvious that we must use the heat at a temperature as near that of the source as possible and that the higher the source temperature, the greater the coefficient of performance. In heating of dwellings, it appears that the best method would be panel or radiant heating for which a temperature of 90°F. is sufficiently high for the heat transfer fluid. This temperature would also be sufficiently high for the circulation of water for drinking and washing purposes. The design temperature would have to be about 20°F. higher than this, or about 110°F., in order to deliver the heat to the heat transfer fluid through some type of heat exchanger. The working fluid would most naturally be water, since this is most readily available, or perhaps a water-glycol mixture to guard against freezing during shut downs.

### Heat Source

The second criterion of heat pump design is the selection of a suitable heat source. This source quite logically should be at the highest possible temperature and an economic method of heat extraction must be established. The normal heat sources, exclusive of industrial sources, are as follows:

1. Air.
2. Ground and/or ground water.
3. Water.

Using air as a source of heat is ruled out for several reasons. A finned coil type of heat exchanger would have to be employed and the incidence of blowing snow would cause a great deal of difficulty. The mean temperature during January and February for Fort Churchill at 58°N. latitude is about −15°F.; for Ennedai Lake at 61°N. latitude, about −20°F.; and at Resolute Bay at 75°N. latitude, about −30°F. The refrigerant temperature required to extract heat from air at −20°F., for example, would be about −40°F. and, aside from the low coefficient of performance incurred, the problems of defrosting iced-up coils would be extremely difficult to solve and costly from an operating standpoint.

Several installations have been made in Canada where the heat source used is the ground. These have operated fairly well, but in the Arctic and sub-Arctic regions, the incidence of permafrost and the complete freezing of the ground almost completely rules out this source. There are certain relatively small areas where the ground does not freeze completely, or where water is moving through sand and gravel strata throughout the year, but they occur so rarely that they cannot be taken into account in a general design problem. At any rate, heat recovery from the surface would be non-existent and we could expect rapid freezing of these areas if any sizeable heat extraction were attempted.

The water source seems to show the greatest promise. The northern lakes and rivers are not often very deep, but ice thicknesses of six to eight feet are about normal during the winter. The average water temperature below the ice is about 33½°F., and it is obvious that very little sensible heat can be removed. Any type of submerged coil would quickly acquire an ice cover which would seriously reduce the coefficient of heat transfer. The coil would also tend to float as the ice mass increased and the problem of anchoring it properly is almost insurmountable. Another drawback to this approach is the almost certain damaging of the coils during breakup in the spring.

The answer here is to pipe the water to a device which will then freeze it in such a form that it can be easily disposed of. Dr. Misener, now head of the Department of Physics of the University of Western Ontario, conceived such a device in 1950, and Mr. Hooper, of the Department of Mechanical Engineering of the University of Toronto, designed a machine which was built by the Canadian Ice Machine Company, Ltd. This machine has been installed at Fort Churchill for the past four winters. It employs a 15 hp. diesel engine driving a compressor which extracts the latent heat of fusion from water frozen on the horizontal stainless steel drum of a York DER Flakice machine.

This ice-making machine turns out about 7,500 lb. of ice per day in the form of flakes about 1/16 in. thick, 1 in. long and ⅜ in. wide. The ice flakes are carried by a screw conveyor to the inlet of a fan which breaks the ice up and discharges it from the building vertically through a stack. The ice is then dispersed by the wind.

This unit was primarily designed for water heating, and will heat about 35 g.p.m. from 33°F. to 90°F. The latent heat of fusion is extracted by the Freon-12 refrigerant at 0°F. and rejected to the water in the refrigerant condenser at about 120°F. The theoretical coefficient of performance of this refrigeration machine is

$$\frac{Td}{Td-Ts} \text{ or } \frac{580}{580-460} = 4.83,$$

which is, of course, unattainable and is based on the actual work done in the cylinder of the compressor. The losses between the shaft input and the cylinder work must be taken into account.

This figure is again materially reduced by the losses in the diesel engine and transmission system. The shaft output of the diesel engine is only about 30 per cent of the fuel potential. The heat in the diesel exhaust, however, is mostly recovered through an exhaust heat exchanger and the combustion products are exhausted at about 60°F., thus recovering the latent heat of vapourization of the water formed during the combustion process. The cylinder jacket heat is also recovered by direct circulation through the jacket.

### Overall Performance

The overall coefficient of performance by actual field test is 1.61, which means that the useful heat transferred to the water is 61 per cent greater than the higher calorific value of the fuel consumed. In reality the actual coefficient of performance is about 1.8, since the former figure does not take into account the fact that the building in which the machine is housed is heated by the heat losses from the machine, a useful function. This represents approximately three times as much heat as would be obtained from the burning of the fuel in the conventional type of oil burning space heater.

Another factor worth mentioning here is the ever-present wind of the Arctic and sub-Arctic. If a suitable system could be found for storing the output of wind-driven generators in some form readily accessible to the heat pump, it should be possible to increase the operating efficiency to a great extent and to reduce the cost and complexity of the equipment.

The greatest problem to be overcome with this system is in the supply of water. Very few of the northern waters drop off suddenly from shore to deep water. This necessitates long water lines. Near and at the shore a bottom laid pipeline must pass through areas whose temperatures are considerably below the freezing point. The flow rate required for this particular unit is about 0.6 g.p.m. and if the machine is shut down for any reason the water in the pipeline must be drained immediately. As an emergency measure a resistance wire must be run in the pipe to thaw the line when it freezes up. Flow in the pipe must be turbulent at all times, since laminar flow would be conducive to freezing. The line must be insulated from the point where it leaves the under surface of the ice to where it enters the building. If the run over the ground surface covers any distance, then a snow fence must be put up to build snow over it as added insulation. It may be advisable to build a pier or fill in a section of the lake or river so that the water line will be as short as possible.

The heat pump capacity is now matched to the load by manual control of the diesel engine speed. For a complete installation—one which supplied electrical power as well as drinking, washing, and cooking water and heat for dwellings—a slightly different approach would be used. Two diesel engines of equal power would be arranged so that one drives an alternating current generator at constant speed and the other, also at constant speed, transmits its power to a line shaft and then to the compressor through a variable speed transmission automatically controlled by the heat demand. The two engines would be arranged so that each could carry the load of the other should shut down occur. Each engine would have capacity adequate for the one load, either power supply or heat pump, whichever is the larger. This would make it possible for routine maintenance to be carried out and an annual overhaul completed in the summer with no discontinuity of service.

#### Design Comments

The design of the system as set forth here is for the usual type of Arctic station which consists of a number of detached buildings. This has been the rule of construction in order to minimize damage by fire. Once a fire has a good start it cannot be effectively fought at very low temperatures. One outstanding advantage of the heat pump system, aside from its economy, is the almost complete absence of fire hazard since the fuel is burned only within the cylinders of the diesel engine. A single building could therefore be constructed to house the entire installation, and the heat pump could then use an air-cooled condenser in place of the present water-cooled condenser and discharge its heat directly into the air circulating through the building. The fan circulating this air would be driven from the constant speed line shaft. The water supply would then take its heat from the jacket water and exhaust heat exchangers.

While this present system is not at the stage where it could be termed absolutely reliable, it should not take a great deal of effort to bring it to a high standard. It has proven its remarkable economy, and within the next several years should be in shape for an actual field installation. √

## Instrumentation in Armament Development

(*Continued from page 1606*)

must be analyzed individually. Each azimuth and elevation reading must then be corrected for tracking errors and substituted into trigonometric equations to obtain the trajectory points in space with respect to the time axis. The work involved is considerable, so much so, that often this method of measurement is neglected because of the heavy effort involved in data reduction. Newer systems using automatic computers have eased the burden somewhat, but at the expense of added equipment which requires additional skilled personnel for maintenance and operation.

Analog and digital computers and automatic data reduction facilities, however, are decreasing considerably the time and effort formerly required to provide quantitative information from the recorded data.

#### Conclusions

Instrument engineering may be defined as the art and science by which the properties of matter and the laws of nature are made useful to man in the observation and control of physical processes. The ever-increasing pace in the race for new and better armament systems will create a greater demand for specialized instrumentation to provide high accuracy experimental evidence to the ballistician, the aerodynamacist, the structural and mechanical engineer, the electronic design engineer, the mathematician, the chemist and the physicist. Although the cost and effort of providing proper instrumentation may be heavy in armament development programs, one well-executed test is worth a thousand expert opinions. √

THE NECHAKO-KEMANO-KITIMAT DEVELOPMENT

## Aluminum Towers on the Transmission Line

(Refer to Relative Weights, *The Engineering Journal*, November, 1954, p. 1442)

Dr. K. Sutter of the Aluminium Laboratories, Geneva, Switzerland, and a co-author of the paper "Aluminum Towers on the Transmission Line" wished to make the following addition. Unfortunately this was not received in time for inclusion in the November issue. The addendum is included here to avoid misinterpretation.—Editor.

"The above relative weights are, in reality, no measure of the efficiency of the aluminum design as they refer to towers of different heights and of different strengths in spite of identical basic loading conditions. The aluminum strain towers are designed to withstand 45 kips *P* loads as compared with only 25 kips for the corresponding steel towers. In addition, the aluminum towers include from 4.2 to 5.3 tons of steel which, in order to determine the efficiency of the aluminum used, must be deducted from both the steel and the aluminum tower weights."

# The Shell Moulding Process

*by*

W. A. Campbell

*Sales Development Manager.*
*Division of Union Carbide Canada Ltd.,*
*The Bakelite Co.,*
*Belleville, Ontario.*

**This paper gives an excellent description of the mechanics of the shell moulding process. Trade opinion however, appears to be somewhat divided on the advantages of the "shell moulding" process unless the shell moulded castings are cast to such fine tolerances as to make certain machining operations unnecessary. It is questionable if this can be done with castings for most applications.**

"Shell Moulding" is the current name applied to the process of casting metals, developed by Johannes Croning in Germany during the early years of World War II. From its originator it was first known as the "Croning Process" which later was shortened to the "C" process. Its current name derives from the thin shell-like moulds produced and employed in foundry casting.

The process was patented on February 1st, 1944 in Germany, and was used at Hamburg for the production of munitions. It was kept on the German secret list until May 30, 1947, when W. W. McCulloch of the U.S. Technical team revealed it in his final Fiat Report No. 1168.

During the seven years intervening, the use of the process has grown to such an extent that it is being used in the casting of practically all metals. The recognition of its place in the foundry industry is well summarized in the words of Bernard N. Ames, then supervising physical metallurgist, New York Naval Station, Brooklyn, New York in these words: "In the past few years shell moulding, sometimes referred to as the "C" process, has been recognized as one of the major technical advancements in the foundry industry. It is, perhaps, the first substantial change in the method of mould construction since the inception of the foundry art."

An equally strong endorsement was made by a small Ontario foundry-head in his statement "The hand-writing is on the wall for the small foundryman in competition with the big boys, unless he ean produce more economically with better finish to closer limits than he is now doing. This is only possible, in my opinion, through the use of shell moulding, where such moulding makes certain machining operations unnecessary."

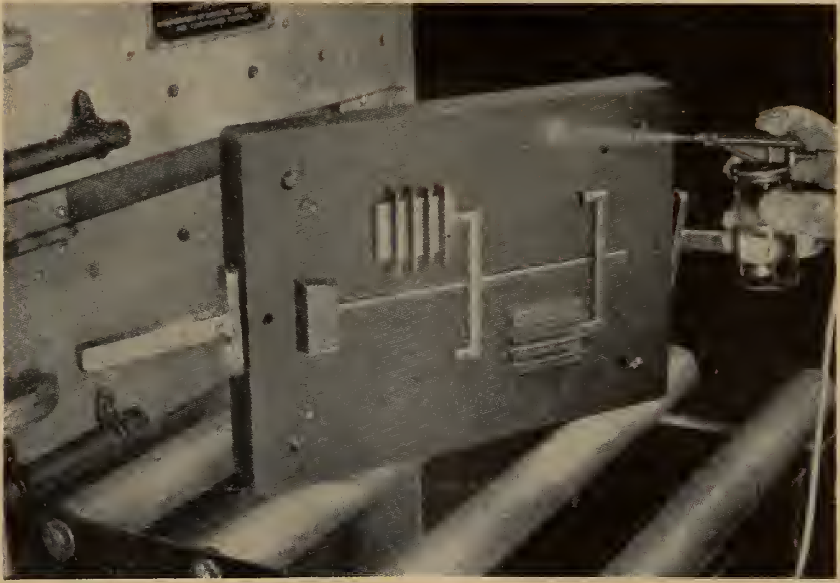

**Fig. 1. Application of parting agent to hot pattern plate.**

### Uses Metallic Pattern

To describe the process it may be said that it involves the use of a metallic pattern capable of withstanding cycles of heating to about 600° F. and cooling to about 400° F.

**Fig. 2. Oven-curing freshly formed mold half.**

repeatedly, and of a mixture of a synthetic resin and foundry sand in the approximate proportions of 5 per cent to 95 per cent.

The resin-sand mixture is thrown onto the surface of the pattern and allowed to rest there for a matter of seconds until a soft "tender" coating in the required thickness of melted resin and sand is formed. This skin is then baked for a few minutes until it is cured and hard enough to be handled.

When removed from the pattern this shell is a hard, porous and somewhat brittle structure. Possessing approximately 50 per cent voids, it has sufficient permeability to allow the free passage through it of air and combustion products. This porous property permits the elimination, normally, of air vents in the mould.

The pattern, as has been mentioned, is metal, to withstand warping under the strain of repeated heating and cooling. Cast gray iron for the base has been found most suitable. This base is provided with kick-out pins spring mounted, and equally spaced about the design pattern so that the hardened shell can be lifted off without strain. The design-pattern itself may be cast iron, wrought iron or other suitable metal while the pouring basin, the down sprues, the runners and gates may be aluminum or iron as convenient.

Since the tolerances and finish of the finished casting is a function of those of the pattern, it is obvious that the design-pattern must be carefully and accurately produced and mounted. The pattern is usually so designed that the cope is on one side and the drag on the other. Through the use of this device a pair of shells may be clamped together face to face to form the complete mould.

**Materials Used**

The raw materials for the production of shells consist of foundry sand, synthetic resin, wetting agent and parting or release agent. The sand is silica, either bank or synthetic, containing not more than 3 per cent clay or fusible oxides. The sand constitutes 96-90 per cent of the resin sand mix. The best resin is a finely ground phenolic resin which in the finished mix varies from 4 to 10 per cent. The usual proportion of resin in the mix is 5 to 6½ per cent for moulds with 4 per cent for cores.

The wetting agent is a mineral oil, commonly kerosene, mixed with the sand before the addition of the resin in the proportion of about one pound kerosene to one ton of sand. The parting agent is a silicone resin in either an emulsion form or in a solution. This is sprayed on the pattern at about 400° F. and baked to a hard film. (Fig. 1.)

The equipment by which the shells are formed is more or less conventional. The mixer is usually a muller found in almost any foundry, but may be a ball mill,

**Fig. 3. Mold backed up for pouring.**

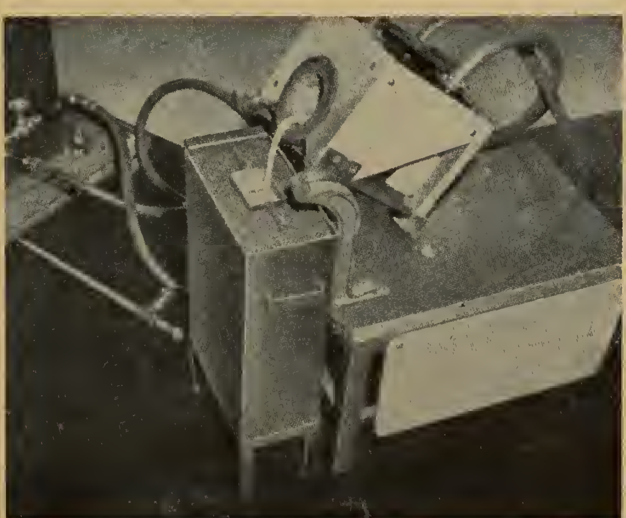

**Fig. 4. Pouring molten metal.**

a dough mixer, a blender or any other machine to produce efficiently uniform powder mixes.

**The Process**

A dump box whose top is the shape and size of the pattern is mounted on axles placed off-centre. The hot pattern is clamped face down on the open top of the box which contains a quantity of the sand-resin mix. The box is turned upside down so that the mix is thrown onto the face of the pattern. It is kept in this position for 1-1½ minutes depending on the thickness of shell desired. When righted, the unmelted loose mix falls back into the box, leaving a uniform coating of soft melted resin and sand adhering to the pattern.

The pattern with its coating of mix is then transferred to an oven, where it is cured at about 600° F. for long enough to harden the resin, usually 1½—3 minutes. (Fig. 2.) The hot pattern is then placed face up in a frame, so that the kick-out pins are forced up to raise the shell from the pattern. The shell is removed and the pattern recycled to the dump box.

In pouring, a pair of shells are clamped, bolted, or cemented face to face. In casting lighter metals they may be poured into without any backing. General practice, however, calls for the use of steel shot, or sometimes foundry or beach sand, to surround the shell mould and provide support during the pouring operation. (Figs. 3 and 4.) The shell receives the metal, usually in a vertical position, though this is not essential.

**Trade Comments**

The economics of the process have given rise to more discussion than probably any other feature. The cost of the pattern is very high. In order that this high cost can by amortized long runs have always been deemed essential. It was reported that at a meeting of the local chapter of The American Foundrymen's Society in Montreal, the contention was made that there were in Canada no jobs of a type and quantity where shell moulding would be economical. However, at the time the meeting was held a paper by C. R. Dutton, superintendent of foundries, Crane Limited, Montreal, was being published in the 1954 February issue of *The American Foundryman*. In it he described a method of producing patterns (not production) by the shell mould process. Mr. Dutton adopted shell moulding because he could produce pattern parts:

1. With almost no hand finishing before mounting.
2. With a saving of almost 30 per cent on the cost of producing pattern plates due to elimination of machining.
3. With castings from the shell mould requiring single contraction allowance similar to metal match plate patterns.
4. With castings requiring only surface grinding and polishing with emery cloth before mounting, and
5. From moulds which may be used immediately or stored indefinitely.

These five points have been listed from the paper because they summarize the main advantages of the process.

Another Canadian foundryman claims, because of close tolerances and consequent low finishing costs, he produces parts much cheaper than was formerly obtained in green sand. He claims that he gets tolerances down to .001″ per inch parallel to the parting line and almost as good across it, which appears unlikely in view of the tolerance of .005 to .010 usually obtained.

In addition, his melted metal efficiency is 70-75 per cent against 50-55 per cent in the foundry formerly making the part. This of course merely reflects more careful study of casting design, metal analysis and gate and riser design before making the shell moulds, than with the previous method.

**May Revolutionize Foundry Technique**

Costs vary in different foundries. No hard and fast rule can be formulated to guide anyone in his choice of method. Each job must be evaluated on its own merits. In general, only reasonably long production runs will absorb the high pattern cost.

It is certain that shell moulding has a very definite place in the foundry industry and, like any other engineering process, can occupy certain fields of operation better than other processes. The extent of this position in the industry has been perhaps prophesied by James H. Smith, general manager, General Motors Central Foundry Division at Saginaw Michigan in words quoted from his paper at the Chicago A.F.S. meeting in 1953:

> "I consider the shell process one of the greatest technical developments of our time in the foundry industry. In my estimation it may revolutionize foundry moulding technique to the point where it will be more economical to produce most small castings and some large castings by the shell mould process as compared with conventional green sand moulding.
>
> "At Central Foundry Division we are approaching the shell program from the standpoint of producing a better casting for less money and at the same time holding dimensional tolerances to closer limits than with our green sand casting." √

# Air Pollution Control

*A panel discussion on the program of the Annual General and Professional Meeting of The Engineering Institute of Canada, Chateau Frontenac, Quebec, May 14, 1954.*

***Chairman:***

E. A. Allcut, M.E.I.C.

*Professor of Mechanical Engineering, University of Toronto.*

R. L. Broad, M.E.I.C.

*Manager, Combustion Engineering Dept., Rochester & Pittsburgh Coal Co. (Canada) Ltd.*

Dr. E. A. Watkinson

*Chief, Occupational Health Division, Department of National Health and Welfare.*

J. G. Hall, M.E.I.C.

*District Manager, Combustion Engineering Corp. Ltd.*

Dr. Morris Katz, M.E.I.C.

*Chairman, Canadian Section, Technical Advisory Board on Air Pollution, International Joint Commission, Defence Research Chemical Laboratories.*

*Prof. E. A. Allcut*—May I say, in introducing this very controversial subject, that there are many other factors in addition to smoke which can be of a more deleterious or harmful nature. We are therefore going to discuss today the question of air pollution control as it applies to the situation in general.

I propose to give each of the main speakers ten minutes. I know they will not tell all they have to say in that time, so I hope that each of the members will reserve some portions of their remarks for the discussion that will follow. After all, the success of a panel discussion depends mostly on audience participation.

As far as the members of the panel are concerned, we have on my right, Dr. Morris Katz, a Defence Research scientific officer and chairman of the Technical Advisory Board on Air Pollution of the International Joint Commission. Dr. Katz is a chemist and, I suppose, is one of our foremost experts on sulphur dioxide.

On my immediate right, we have Dr. E. A. Watkinson, chief of the Occupational Health Division, Department of National Health and Welfare, Ottawa. Dr. Watkinson is a medical man, with wide knowledge of this particular field. He can handle those aspects of atmospheric pollution that are related to health.

On the left we have Mr. Robert Broad, who is head of the Combustion Engineering Department of the Rochester and Pittsburgh Coal Company, and Mr. J. G. Hall, who is district manager of Combustion Engineering Corporation Limited. It is scarcely necessary to introduce Mr. Hall to an Engineering Institute audience, but his presence here on our panel is a source of satisfaction to me particularly. These two gentlemen will deal with combustion in its various aspects, but our discussion of this problem is not to be limited to combustion matters. As we know, there are many other things to consider, but in view of the fact that air pollution control has been closely linked with combustion processes, we thought it wise to start with that and then to have the other aspects of the subject introduced, as the panel or the audience may see fit.

I will now call on Dr. Katz to open the discussion by telling us something about the nature of the pollution; the various kinds of pollution and the consequences.

### The Nature of Air Pollution

*Dr. Morris Katz*—I am afraid ten minutes is an exceedingly short time in which to deal with some of the matters at issue here. However, if I can stimulate a few questions, there may be time later to go into the subject in more detail.

It is very true, that we take in much more air than we do food or water. The approximate proportion for the average adult is two to three quarter pounds of food, about four and a half pounds of water, and about thirty pounds of air. Ordinarily, we would not be too much concerned with the air we inhale and use in such large quantities, but the increasing growth of industry and population of large cities and communities has faced us with a considerable number of air pollution problems.

We are currently investigating an international problem in the Windsor-Detroit area, on the basis of complaints submitted to the governments of the United States and Canada in 1949. There is also a very familiar problem on this continent in connection with air pollution in the Los Angeles area. These two typical areas I am going to use as examples of certain types of pollution which may give rise to problems.

Ordinarily, air can be looked upon as a natural means for the disposal of waste products of industry and of the various activities of the public. There is no reason to question this practice, until the contamination becomes too great, or until we have a visible nuisance.

If we are confronted with an air pollution problem, the first thing we should do is to find out the nature of it. In some areas, particularly in urban areas, a lot of coal and other fuels are used and also there are a considerable number of traffic vehicles running about. Such areas also have a variety of industries, metallurgical, chemical, manufacturing, and others. The three simplest things that one can do in order to determine the nature of pollution is to measure, first of all, the dustfall rate; secondly, the suspended particulate pollution, and thirdly, the sulphur dioxide.

In connection with dustfall, we estimate that in heavily concentrated areas the dustfall rates run around 50, 60, 70, to upwards of 100 tons per square mile per month. By comparison, in semi-rural areas the dustfall, which is mainly that due to causes of natural origin—the wind blown dust, sand, particles of vegetation, top soil, etc.—will run around 10 to 15 tons per square mile per month. So you have a considerable spread.

Then, we have cities where the main source of fuel is not solid fuel, but either natural gas or oil, and there the dustfall may be lower than the figures quoted—say somewhere around 35 to 40 tons per square mile per month, because fly ash and other solids of that type are not a problem in that particular city.

These particles which contribute to dustfall are comparatively large in size and most of them will be over 44 microns in size, or greater than about 335 screen mesh size. In other words, the particle sizes range from about 40 microns to well over 100 microns, and only a minor fraction is less than 10 microns in size.

The suspended impurities which reduce visibility and result in the staining or soiling of surfaces are very much smaller in size. These consist of particles that range from less than 5 microns down to 1/100 of a micron; particles that you can never actually see but which obscure light, and coat walls and the surfaces of buildings with a somewhat sticky substance.

Then, there are gases. We have sulphur dioxide, hydrogen sulphide and fluoride in certain places; chlorine gas, chlorides, oxides of nitrogen and so on. Many hydrocarbon vapours and organic gases, including carbon monoxide, which is fairly abundant in certain localized areas of heavy traffic, are also present. I am not going to consider carbon dioxide which, in some respects, is actually beneficial to plant life or vegetation.

We find that these contaminants, if they are present together in city air and sufficiently concentrated, can produce very distinctive smogs, depending on the meteorological conditions. Normally, weather plays an important role in disseminating and diffusing these contaminants, so that they are scattered and dissipated into harmless proportions. But whenever special conditions prevail, such as temperature inversion, we can have a typical smog over a city, and if this is prolonged and is severe enough we can have disastrous effects.

A photograph taken to show "smog" over a city will show extremely low visibility near the ground. One taken from higher up will show clear sky above, then the inversion layer up to that level, and smog below. A photo taken in late morning in clear weather should show good visibility, but the air, in trying to disperse the contaminants may cause reduced visibility by breaking up the inversion layer and mixing it, thus bringing the contaminants down to ground level. This condition may persist for several hours until with increasing turbulence the pollutants are dispersed and visibility improved.

I hope that I may have, a little later, an opportunity to amplify some of my remarks, especially in this matter of the role of meteorology in dispersing contaminants.

*The Chairman:*—Having had a sketch of the atmospheric situation in a certain part of Canada, which is fairly representative, not only of Canada but also of the United States, I will now ask Mr. Broad to present his views on combustion or other similar operations.

## Scientific Selection of Fuel

*Mr. R. L. Broad*—Although my purpose here today is not to defend the coal industry, no matter how much coal has been blamed for atmospheric pollution for so long a time—I would feel remiss if I did not point out that the City of Los Angeles, which has had a very serious problem, burns no coal.

Any fuel can be burned improperly and can create atmospheric pollution, and I think that all of us are well aware that gasoline used in automobiles is responsible for the resulting contamination by carbon monoxide. We have all ridden behind Diesel busses and I am sure some of us live in oil-burning neighborhoods where, when we walk down a street on a quiet winter evening, we have smelled that old familiar Diesel odour and perhaps did not realize it might be coming from our own oil burner — or one of the neighbors'. These are problems which are becoming more and more important and problems that we really have not started to attack.

We, in the fuel industry, are able to do quite a bit and I think that we are just starting to think about doing our bit about alleviating some of these problems. Now, in the coal industry, we have been attempting to make a study of the problems of heating buildings, small industrial buildings, office buildings, larger industries, and so on, and we think that we are going to be able to help in this field.

We have several problems however. One of them is obsolete equipment. That is one area where I think we have a selling job to do with the equipment people, and we are attempting to do it. Poorly installed new equipment is another problem which should not occur, but it is one that we come across very often. Poorly trained operators also present a difficult problem, and we are able to help these men considerably, often giving them information or instruction—and of course, the most important problem is poor fuel application, and that sits right on our own doorstep.

It is not many years since the coal man sold mine-run or lump coal, whichever the plant required. We have moved a long way from that period, and today we have tried to approach the problem much more scientifically. I think most of you are familiar with the sources of coal, at least you have a rough idea of the sources, but it might be well just for a moment to discuss briefly its origin.

I think you all learned in school or since that coal originated from tropical swamps. Some 300 million years ago a very large swamp ran all the way from Nova Scotia and New Brunswick to Pennsylvania and West Virginia, through East Kentucky and down to Tennessee. That tropical swamp grew for several thousand years.

It was finally covered over with silt, due to flood conditions, and the resulting muskeg which had been formed lay buried there. After the flood subsided another tropical swamp grew on top of the covering material. That cycle continued until there was material for as many as 120 seams of coal, one above the other, perhaps separated only by a few feet, perhaps separated by several hundred feet of clay and silt.

In West Virginia, there is a 250

foot total thickness of coal produced in that way. The time interval involved might be of interest. One thousand years of tropical growth will produce enough material to form seven inches of coal. So we can see 250 feet of coal represent a terrific time interval.

After those beds had been formed, a tremendous folding took place, and that folding centered east of the City of Altoona in Pennsylvania. The pressures and temperatures involved in those muskeg beds were very high and the organic material was transformed into what we know as anthracite. Radiating out from that area, the temperatures and pressures decreased, and we have coals of varying ranks from anthracite to high volatile bituminous.

Now, the range of characteristics we have available is almost infinitely variable. Radiating out from what we call the Altoona zone, the chemical nature and characteristics of the coal will change due to the difference in pressure and temperature. In addition to that, the vegetable material that grew there varied over a distance of perhaps ten or fifteen or twenty miles, just as it does today around here.

We might drive through this country and see at one place spruce and fir or balsam trees, and a few miles farther, perhaps birch and poplar—so in addition to the variation in pressure and temperature, we had during the growing period a range of types of vegetation as well. From the period of one seam to the next there was considerable evolution in plant life. Thus we would suspect a seam laid down above the previous one, might differ considerably in characteristics from just below it, and that is just what we do find.

To make proper application of coals we must make tests to determine what these characteristics are, and that is one of the toughest problems we have to contend with, in that the tests available are quite inadequate. We have tests which are helpful to us, of course; chemical and physical analyses are carried on and other tests by which we determine physical characteristics. One of the most important is the measuring of the content of volatile matter or gaseous and tarry matter, which is generally considered to be the main source of smoke emission in burning coal.

Now, this volatile content varies widely. Starting in the centre in Pennsylvania, the content increases as you travel in any direction away from the centre. These variations are not just as nice and uniform as all that, but, nevertheless, from its location we can get a rough estimate as to what the volatile content of a coal might be. Volatile content is not the whole story as far as smoke is concerned. I could name any number of examples where we have perhaps employed a higher volatile content on some particular job to alleviate a smoke problem.

The next factor is the fixed carbon, and that is simply the difference between the sum of moisture, ash and volatiles and 100 per cent. It means the residual carbon left after the coal has been heated in the volatile test, less the ash that remains in the sample. Another factor is usually reported as the ash content. It is important from the pollution point of view, but it also has a very important economic effect. We measure the economic importance of ash content in terms of fuel cost. It is very important that we try to keep the ash content as low as possible, and of course we automatically reduce dust loadings correspondingly.

Ash content in coal is controlled, as far as the producer is concerned, not only by selecting a coal with high carbon and low ash content to start with, but by using various cleaning processes, such as water flotation, we are able to remove most of the rocky material. The specific gravity of the impurities will run perhaps from two to seven. The coal itself is a relatively low gravity material, running from 1.45 to 1.65, and this gravity difference facilitates removal of part of the ash content.

Dr. Katz has mentioned sulphur, but in the fuel industry, we are more concerned with sulphur content in connection with damage to the equipment and other operating problems, rather than with air pollution. We have to endeavour to keep the sulphur content low to get around our mechanical problems, and so, to the best of our ability, we are already taking care of the sulphur problem.

Another factor of importance is ash fusion temperature. A low ash

**Left to right: Dr. Morris Katz, Dr. E. A. Watkinson, Prof. E. A. Allcut, R. L. Broad, J. G. Hall.**

melting point can cause serious problems in a power plant by upsetting the air flow and distribution and so creating a smoke problem and other operating troubles. We have to keep ash fusion temperatures at reasonable levels.

There are quite a number of other tests; some of which are beginning to receive more attention. One of these is a test which indicates the extent to which the coal swells when the volatiles are being driven off in the laboratory, and this factor has quite an affect in the various types of fuel beds. It probably influences the dust carry-over in firing, and has quite a lot to do with air pollution. However, we don't yet know enough about it to say of how much benefit this test will be. The values are expressed in numbers referred to as the free swelling indices, or British swelling indices.

What I have been trying to say is that the proper selection of fuel and proper application of fuel burning equipment from houschold burning up to the utilities,—is not yet a very scientific procedure. We are trying to make it more so but it is still fairly much of an art. The reason is that we don't have enough yardsticks; we are not able to express the characteristics well enough through numbers.

We are making progress along those lines however, and so I think it is a good idea to avoid, as far as possible, introducing references to coal specifications in air pollution by-laws. We would like that to be left out. In some cases, it creates an unnecessary economic dislocation, as there are factors involved which cannot as yet be specified, and we feel it is better to leave that aspect of air pollution by-laws to us in the industry, who feel we can do the job without those specifications. I thank you.

*The Chairman*—Thank you, Mr. Broad. Now, having heard something about the nature of fuel, I will call upon Mr. Hall to tell us what we can do with it.

### Integrated Equipment Design

*Mr. J. G. Hall*—Mr. Broad covered a part of the subject as far as coal itself is concerned in a very helpful and intelligent way. In view of the importance of what is to come,—I am going to make my remarks very short, particularly in view of your statement to me, Mr. Chairman, that most people know all about coal anyway. At least, that is the feeling some people have.

I believe Mr. Broad inferred there were lower grade coals. That is a term which is sometimes misconstrued. I object to the term "poor coal" or "poor grade coal" because coal is something like human beings. We don't like a man because we don't know him and we sometimes call coals "poor" because we have not yet learned their burning characteristics. But generally speaking now, within reason, the manufacturer can design equipment which will successfully burn almost any grade of coal. However, when a man makes the statement that he has equipment that will burn all grades of coal with equal success or satisfaction, that is the man to be suspicious of.

There is also the question of oil. Many people up until recently had the idea that all their problems would be over if they used oil. It may interest some of you to know, —and here I am referring to the larger, not the household type of equipment,—that an efficient oil burning installation is just on the verge of smoking at all times. True, you can cut down the smoke if you increase the air, but that is going to make it an uneconomical proposition. In fact our lads in the Navy, found if they wanted to throw a smoke screen, the best way was to burn oil with a deficiency of air.

I have mentioned already that the manufacturer can design equipment to burn coal successfully, but there are three factors that determine the success or failure of an installation. First comes the design of the equipment and the layout. Secondly, there is the installation—and thirdly, the operation, and Mr. Broad touched on this last point. That is one of the factors which so many of the anti-smog departments or anti-air pollution departments in the various cities are confronted with today—the lack of proper operation.

Operation is regulation of performance. This is a type of work requiring constant attention as well as considerable experience. Too often owners tend to underpay the men who control operation and it is in the interest of all concerned that proper remuneration be paid. If a boiler room is to produce satisfactory results, management must realize the important part which operation plays. The operation of the boiler room must not be looked upon as an expensive nuisance but should be regarded as an essential part of plant management and treated accordingly.

Consider the matter of combustion which Dr. Katz has mentioned. I am not now talking about motor cars, which present an entirely different combustion problem. I am talking about power plants. When we try to alleviate the air pollution problem in our boiler rooms, we run up against two different problems. First, of course, there is the old installation. Many of our heating and process plants were designed years ago, before we knew as much as we do today. We still have a great deal to learn—and where we have inefficient equipment, lack of furnace volume and lack of stack heights and diameters, etc., to a great extent we have to consider the burning of very low volatile coal, anthracite or coke.

I know of one particular case in a certain city, where one of the officials asked me what could be done about a certain plant which was in a residential area and was giving serious trouble. I looked it over and said, "George, there is only one thing you can do and that is to throw out all this old equipment and put in new equipment." After about ten years, he is just completing that job.

There are other cases where you can alleviate the situation very materially by over-fire air and turbulence (time, temperature and turbulence). By getting enough air properly controlled in the right places, you can help the situation very materially. But there are many cases where the only solution is to throw out the equipment and start with new.

When we come to new installations, manufacturers can, within reason, design equipment to suit the fuels economically available in that area. There are different types of firing; I will run over, roughly, the different types. You can have hand firing, and it is surprising what a good fireman can do with a hand-fired installation with coals that formerly could not be burned without smoke. Here again the use of over-fire air and under-fire air, under proper control, is one of the big factors.

Underfeed and chain grate stokers can cause a great deal of trouble with smoke, but not so much with fly ash emission, although there is always a certain amount of fly ash with either of these two types of equipment. Probably the newest popular type of combustion equipment is the spreader stoker, but this is not very new because I recall 30 years ago we had the pleasure of throwing out a great many badly designed spreader stokers. But in my opinion the spreader stoker is coming to the point where it will be the most popular type on the market.

However, we must remember or consider the fundamental principles on which that stoker is designed. It is a combination of burning in suspension and on the grate. Now, in this case, your selection of fuel, is an important factor. If you have very fine coal, naturally there will be more of it burning in suspension, and with some types of coal you will have a tremendous carry-over as well as heavy smoke. Probably the type of firing which will give you the widest selection of fuel is burning entirely in suspension. Properly designed pulverized fuel equipment, I think, would give you the widest selection of solid fuel.

But we must remember that, in both spreader stoker firing and pulverized coal firing, you are facing the problem of fly ash, which a great many people did not realize was of any particular importance until a few years ago. We formerly thought of air pollution as smoke pollution; however a stack can be fairly clear, but may be emitting a tremendous amount of fly ash which will be a nuisance, if not a hazard. I will leave it to my good friend Dr. Watkinson to say to what extent it is either; but to meet that objection we have dust collectors.

The design of dust collectors, or dust collection equipment, has become very much of an art. It has developed materially in the last few years, and to me it is a question of the extent to which the employment of dust collectors is justified. We know that with spreader stokers or firing with pulverized fuels, we should have dust collection, but when that plant is out in the country or with a very high stack, the dust is spread over a very wide area.

*The Chairman*—Thank you, Mr. Hall. Your remarks remind me of a little problem that developed up in Toronto a few months ago where they had three entirely similar boilers. Two were working properly without smoke and one was smoking quite badly. They were all the same kind of boiler, all fired with the same fuel and all with the same amount of air.

Finally, however, after investigation, we found that the air, as usual, was taking a short cut. Most of it was going through the first two boilers and did not go into the third to the extent required, so that there was smoke emission from that source. It is not only a question of having the right amount of air, but it is necessary to have it in the right place.

Now, having heard from Mr. Hall as to what can be done in that regard, we come to the effects of pollution, and by far the most important of these is the human aspect of it. We have here Dr. Watkinson, who is an expert in that field, to tell us about it.

## Air Pollution and Public Health

*Dr. E. A. Watkinson*—Regardless of what our special interest may be in air pollution, I am sure that we are also interested in the effects which air pollution may have upon health. While much information in this field is already available, by no means is the full story known. Various studies are proceeding in different countries, but it would be a mistake to delay action regarding the control of present amounts of air pollution until we have answers to all our questions.

From what has occurred elsewhere, we know that certain levels of pollution, combined with certain atmospheric conditions, can cause widespread illness and even death. Certainly the evidence is such that the subject of air pollution should receive the highest consideration by engineers, health officers, and others, concerned with control measures and the maintenance of health of the people of this country.

Until recently we have been concerned mainly with the economic aspects of air pollution, and it was not until the occurrence of such disasters as that of the Meuse Valley in Belgium of 1930, when sixty persons died, that serious consideration was given to the possible effects on health. The Meuse Valley disaster was followed by the Donora incident of 1948, when 20 persons died and 6,000 of a community of 13,000 became ill within a period of four or five days. There was also the incident of Poza Rica, Mexico, when 22 persons died and some 300 persons became ill.

In December, 1952, in London, England, there occurred a disaster of great magnitude, one that compared with the flu epidemic of 1918-19, and with the cholera epidemic of the previous century. In this episode, 4,000 people are estimated to have died, and I understand that there are now figures to show that deaths attributed to that four-day London fog may actually be much higher. Furthermore, the death rate continued at an abnormally high rate for another two and one-half months.

These may be just figures for many of us. However, living as we do in urban communities, there are certain general facts in which we are personally concerned and which I now propose to mention briefly. First of all, there is the matter of fresh air. Persons living in rural areas or near the sea take fresh air for granted.

But for urban dwellers it is a different matter. For the latter, vacation time may be the only time of the year when they can really enjoy the benefits of fresh air. It is a fact that we believe the fresh air of the seashore or of the mountains has a special quality, because our sense of well-being is restored and we return to the routine of the shop or the office with a fresh outlook on life.

And then, what about sunshine? In our communities the sun may shine and there may not be a cloud in the sky, but if an appreciable amount of air pollution is present, we and our children are not receiving the maximum amount of sunshine to which we are entitled. Our children, particularly, depend in part on the rays of the sun to prevent such conditions as rickets.

There is also the effect of the sun upon green vegetables to be considered. Such vegetables are necessary in our diet for the prevention of certain disease processes and, consequently, are an important factor in the maintenance of health. In some communities, these vegetables cannot be grown or perhaps, when they can only be purchased from other localities at a higher price, such vegetables cannot be afforded by some families.

Odour is another factor in air pollution. We all know, for example, the smell of hydrogen sulphide, and this odour may be continuously present in some degree in some of our communities. The smell of certain fumes is quite unpleasant, and for some people causes discomfort varying from loss of appetite to a feeling of illness.

The mental health of those obliged to live in heavily polluted areas may also be affected to some degree. Apart from the loss of bright sunlight, it can be very depressing to have to live in a community devoid of the freshness and colour of green grass, trees, and flowers. This is especially true if there is no opportunity to get away to more colourful surroundings from time to time.

The mental attitudes of people living in areas devoid of vegetation may well be reflected, for example, in the poor maintenance of homes or the lack of proper facilities for rearing children. In any case, the end result is scarcely conducive to the maintenance of health or the development of strong and healthy children.

In addition to these general effects on health, we should keep in mind such disasters as Donora and London. In these episodes, deaths occurred within a short period of time and thousands became ill. Of those affected, the majority were either older people or the very young and, in the case of the older age groups, many were weakened by chronic illness. However, those affected were not limited to these groups,—even healthy persons in their prime became seriously ill.

While the immediate effects upon health from exposure to harmful amounts of air pollution are of the greatest concern, it is also important that consideration be given to the problem of possible effects on health from long exposure to a polluted atmosphere. As I have already mentioned, studies on health and air pollution are being conducted in various countries but, as yet, we do not know conclusively if a relationship exists between air pollution and certain types of human illness. One study of interest is that presently being undertaken in the Windsor-Detroit area, where 1,000 families are co-operating in a survey of illness as related to changes in pollution and atmospheric conditions.

In conclusion and in view of the available evidence regarding the possible effects of air pollution on health, may I suggest that each of us should take whatever preventive steps we can now—not next year or sometime in the future—to ensure the health of Canadians no matter where they live. As the future will undoubtedly present new and perhaps greater problems in air pollution, I also believe that, in addition to coping with the present, we should be initiating whatever research may be required to assist in future control methods.

*The Chairman*—Thank you, Dr. Watkinson. I think at this stage, before calling on Dr. Katz to amplify his remarks more particularly with regard to sulphur trioxide, I will throw the meeting open to questions and discussions from the floor.

Many things have been touched upon but not elaborated upon because there was not time to do so. There are many things we should have liked to hear more about, but the things you want to hear about are known only to yourselves. I can imagine that there may be a representative of the oil industry present and in that event there would be all the elements available for an argument between him and Mr. Hall.

## Questions and Answers

*Mr. Sharp*[1]—I have in mind a flagrant case in the area in which I live, in Montreal. I am not aware if there are any federal laws governing this yet or if it is governed by municipal by-laws, and to what authority I should complain. For instance, at Beauharnois, near the lumber plant, there is a plant that makes nickel alloys, I believe, and I have seen that smoke many a time drifting for 30 miles in a visible cloud that drifts right over Montreal. Now, does Montreal have any chance to do anything about that, or is it the affair of the local community?

Here is a plant where, quite obviously, nothing is being done about it. It is a very bad condition, because at times you cannot see across the road. Do we have to wait for years for experiments in the industry, when we well know that some system might be devised which would alleviate the situation?

*The Chairman*—Before you spoke, I always thought Montreal was a city with a particularly pure atmosphere, but as Dr. Katz has carried on experiments with matters of this kind, I will ask him to reply.

### Determining Cause and Effect

*Dr. Katz*—A very interesting point has been brought up, but I would not be too sure about a remedy for anything. In the Los Angeles area in 1947 and 1948, when the smog problem became so bad that the authorities felt they had to do something about public clamor, they introduced very drastic legislation. The regulation which was adopted was based on what was, at that time, a wide law against excessive pollution. It prohibited industries from emitting from individual plants more than 40 pounds of dust per hour.

This meant, of course, that if the maximum emission was greater than that, the owner had to go out of business or else put in the most expensive equipment. Even so, and even if you put in equipment that will cut out 95 to 98 per cent of your impurities, if your operations are on such a scale that the remaining 2 per cent totals more than 40 pounds per hour, then, in Los Angeles, you 'have had it'. Furthermore, in the case of sulphur dioxide, it was stipulated that only 2/10 of 1 per cent would be allowed in the stack discharge gas and so on, down the line.

Now, you would think, with these very severe measures, within a year or two the smog problem would have vanished. Millions of dollars have been spent in two years using methods of every kind, but the problem is still there, which indicates that control action was too hasty in the first place. So, one can see that anything that might on the surface look to be not complicated, may in reality represent a very complicated problem.

In the case of the plant referred to, it may not be a simple matter to reduce that visible effect. That is to say, though you have evidence as seen from the ground, whether you have a visible dust discharge or a chemical reaction in that operation is another thing. In the case, for instance, of an efficient sulphuric acid plant, a very small amount of sulphur trioxide in the waste gas will react with the moisture in the air, and produce a haze which will give a very bad visible appearance.

I am merely pointing out that problems which are apparently simple, in reality may be very complicated. Before you take drastic measures against any situation, therefore, you should make an investigation, and establish first of all the cause and effect basis.

### The Matter of Jurisdiction

*The Chairman*—I think there is one aspect of the question, however, to which Dr. Katz did not refer and I think this was implicit in the question. The jurisdictional factor, as I understand it, was that the Montreal by-law covers only the City of Montreal, but I must point out that the Committee on Atmospheric Pollution in Canada, formed two or three years ago, recommended that these matters be put on a regional basis, despite opposition from politicians.

We have seen this done in lots of places, other than Montreal. We have sent copies of that report to all the provinces in the hope that they will enact similar legislation, thereby doing the sort of thing that we want to be done, in the way that we want it done. I am pleased to say that a recommendation has gone to the Legislature in Ontario, to the effect that, with the setting up of a metropolitan area in Toronto, our juris-

[1]The Hart Company, Montreal.

diction should be extended to include the whole area.

We are hoping that other municipalities will make similar applications. Whether this project will go through or not is more than I can say, but the course of politics is generally against such decisions. We have however made an attempt to find a solution to our problem and, if successful, we shall have an opportunity to try it out. If it is adopted and works well, then it is quite possible that somebody in Montreal will get the same idea.

*T. C. Main*[2]—With regard to the pollution caused by motor vehicles, and what can be done about it, may I ask if there is further information on that ?

**Traffic is a Factor**

*Dr. Katz*—The motor car problem is one which is receiving increasing attention because, in the overall pollution problem, we must not neglect the habits of the public. I think that in the case of a car, using on the average two gallons of gas a day, you can have about 2000 cubic feet of exhaust generated.

If you have a large area, let us say one where you have a million vehicles operating, you have two billion cubic feet of exhaust gas to contend with. This contains aldehydes, hydrocarbons, nitrogen oxides, and other complex compounds. For example, in the Los Angeles area where we have 2,000,000 vehicles operating, there is a certain amount of air pollution which must be attributed to industry. In the overall contamination picture, excluding carbon dioxide and monoxide, we have about 1,800 tons of contaminants released daily, but about 1,000 tons of that will be due to public operations, including traffic, transportation, the combustion from home-made incinerators, and so on.

*The Chairman*—Some time ago in Toronto, we had a violent protest from some people near a widely-travelled highway with regard to the pollution taking place at that point, particularly at rush hours, and so two men were sent there to look into the situation and to make a report. They found no evidence of any considerable concentration of carbon monoxide or of carbon dioxide.

The smell which remains often gives people the impression that exhaust gases are entirely responsible, rather than the combination of stuff in the atmosphere. Nevertheless, where a temperature inversion takes place and the gases are unable to get away, particularly if the area is a low lying one, I can quite imagine that large amounts of carbon monoxide remain in the air at ground level.

*A. R. Harrington*[3]—A problem arises at many large oil-burning plants where they are burning heavy oil. They are getting great paint damage on automobile finishes and houses in the surrounding settlements. I wonder if Dr. Katz knows of this offending product.

*Dr. Katz*—One of the offending products is sulphur dioxide, which is of course present in most fuels, and which would be fairly high in heavy oils as compared with lighter oils. Then we have organic acids and aldehydes. But the corrosion probably is due not only to the acids but also to the fine particulates in the products of combustion.

These very small particulates I mention have a tendency to stick to surfaces, and that, together with the acid nature of the sulphur dioxide and the organic acids, induces a corrosion problem. This problem is encountered quite frequently in the vicinity of foundries and forge shops which use oil for combustion purposes, and operations of that kind.

*The Chairman*—There was a court case in Ontario last year that did involve a foundry, where the paint finishes on new automobiles were seriously affected, causing considerable damage. In that instance, there was no oil used at all, so it does not follow that oil is the bad factor. There may be other factors coming into it too, and in the case that I speak of, there were.

**Effect of Improved Combustion**

*T. C. Main*—Let us assume that combustion is about as perfect as man can make it. Will there still not be a serious pollution problem ?

*Mr. Hall*—That depends on what you mean by perfect combustion, and also perfect combustion of what?

*Mr. Main*—I am referring to coal, oil, gas, and gasoline.

*Mr. Hall*—Well, to begin with perfect combustion, it is impossible to have perfect combustion in a practical way in a steam plant. I presume you are referring to a steam plant.

*Mr. Main*—Yes.

*Mr. Hall*—I do not believe this question of air pollution control as it refers to steam plants can be eliminated entirely. To what extent are we justified in spending money to make the gases from a smoke stack absolutely harmless or devoid of any nuisance value ? In this regard, our chairman referred to a report by the Committee on Air Pollution in Canada. Here is one sentence that was included, and I am quoting from the 1951 edition:

> "The objective throughout is to uphold the common right of all citizens to have the air that they must breathe come to them in a reasonably uncontaminated state.
>
> "However, to establish a permissible value for atmospheric pollution in any community, that which is possible must be distinguished from that which is ideal, and the responsible authorities must not forget that our civilization depends for its very existence on industrial activity."

We can reduce atmospheric pollution to a minimum but, as I said in my opening remarks, it is a question of how far we are justified in going.

*The Chairman*—In addition, of course, the fact has been mentioned repeatedly in the course of this discussion that no matter how perfect the combustion may be, if you are dealing with solid fuels, you will still have ash. That has to go somewhere, you cannot catch it all. The rest of it must go into the air. With most gaseous fuels, you will still have carbon dioxide. Whether you call that a pollutant or not, as Dr. Katz pointed out, depends on your point of view, because in some respects, carbon dioxide is valuable, but at the same time, what limits you can have in that regard depend largely on local circumstances.

For instance, when we proposed to include in the operation of the Toronto by-law the metal processing industries (including foundries), that had already been exempted by the Provincial government, the foundrymen came along in a body with a lawyer and said (in effect), "If you are going to do that, we shall have to move out of the city, because our costs will go up to such an extent that we shall no longer be able to compete." At that, the city fathers took fright and as a consequence, the action proposed was not taken, although perhaps in the general interest, it should have been.

**Concentration of Population and Industry**

*E. R. Davis*[4]—I have two questions. One is: "Has there been any success in correlating population density to areas in which a pollution condition exists ?", and the second which follows from it is: "If you

[2]Main, Rensaa and Minsos, Toronto.

[3]Nova Scotia Light and Power Company, Halifax.

[4]Consulting Engineer, Toronto.

permit a concentration of pollution of a given kind to exceed permissible values, will you have a condition that no one can do anything about?"

The conception of progress in any community is often based on the degree to which you can attract industry to it, and I can think of this as leading to a dead end. For instance, if a particular area in which I was living manufactured chemically its product say, of leather goods, immediately the probability is created of a concentration in that area, where a second and third tannery would add materially to the problem. Has there been any progress or thought given to the difficulties peculiar to industry on a population or area basis?

*The Chairman*—The question of towns and what may arise from them and of the concentration of population in certain areas is an interesting question; it is quite evident that the authorities who are doing the sort of things that you described are doing the wrong kind of things from the pollution standpoint. I should like to hear from Dr. Katz on this subject.

*Dr. Katz*—The question of community planning and of population density is intimately related to the air pollution problem. As I have indicated before, it is quite evident that in an area like Los Angeles and certain other areas, the major problem is probably due to the fact that there is too great a concentration of population and industry.

Los Angeles had no air pollution problem until after about the middle of the Second World War, when tremendous numbers of industries moved into the area; the population increased rapidly and then by 1946, people awoke to the fact that they had a persistent air pollution problem.

Up to that time, the existing topography and meteorological conditions were such that natural air cleaning processes could take care of whatever pollution was produced within the area. Now, there are other areas which are approaching the same state, and while some of us also like to live close together and be neighborly and feel more at home when we are not separated by too great distances, I think nevertheless in the overall growth of a city or area, we must not let residences encroach on industry, and vice versa.

I might say however that some elements of industry rightly have recognized the air pollution problem. In some of the newer plants they are considering air pollution as one of the important factors to contend with, just as they would their raw materials, transportation and markets. These industries design their plants in such a way as to produce no air pollution problems of a serious nature from their operation. If industry generally had done that in the past, we would have very few such problems today.

*The Chairman*—I think that in your reply, Dr. Katz, you omitted to state that there has been established a definite relationship between the amount of atmospheric pollution and the density of population. If I remember correctly, in the report on a survey made at Leicester some years ago, there were some definite figures and a formula devised, indicating the average amount of pollution resulting from cities of different sizes. I think if you will refer to this report you will find the figures given there and the evidence obtained thus far.

*Dr. Katz*—That is correct. In fact, they even calculated the concentration of sulphur dioxide in a particular coal burning area where they used fuels of comparable sulphur content, by simply taking the population as a factor and dividing it by the distance from a principal area, so that you can then get the concentration at a certain point.

*Dr. Watkinson*—I believe that a relationship has also been shown between the acreage of chimney stacks and the incidence of certain illnesses. In regard to the other factor, that is, the need to decentralize industry, I think that the way to handle it should be similar to that used in connection with the water pollution problem.

Already, in Canada there are areas with limited water resources, and it is a difficult problem to decide which industries should be permitted to build up in those areas. The answers to such questions as the following should be known beforehand: How much water is going to be required and where is it to be obtained? How much is going back into the river and in what condition? What are the products of pollution and how are they to be handled?

I think that we are faced with a similar type of situation in regard to air pollution. We have just so much atmosphere for so many people and for so many different kinds of occupations. We are going to have to tackle the problem of seeing that whatever is returned to the atmosphere will provide a proper balance in relation to the use of the air by other people, and particularly in regard to the requirement of safety.

**Relation to Meteorological Conditions**

*P. B. Dilworth*[5]—Is not this problem of air pollution subject to control by the concentration with which a pollutant is discharged into the atmosphere? In other words, Rutland tried to control the absolute amount discharged. Could it not be controlled on the basis of the proportion of those pollutants to the air with which it was intimately linked prior to being discharged into the atmosphere.

*The Chairman*—I think perhaps Mr. Hall can help us here.

*Mr. Hall*—I don't know. I think Mr. Dilworth refers more to the meteorological aspect, and not just to gases, but rather to smog.

*Mr. Dilworth*—I was thinking principally of gaseous products or suspended particles which in themselves, do not tend to concentrate, once they have been intimately mixed with a greater proportion of, say, fresh air.

*Mr. Hall*—In steam plant work, that is, where dust and fly ash emission is concerned, I think it is a question of economics. Now, all by-laws, or most of them, today set down standards by which the concentration of solids that can be emitted from smoke stacks is controlled, and this varies with the size of the plant. But it all comes down, really, to percentages in each case. It varies with the small plant as compared with the large plant.

Take for instance dust collectors. I think most people admit that dust collectors should be installed where you have either burning in suspension, or burning partly in suspension and partly on the grate. You can take out almost 100 per cent of the solids above a certain size but this may leave an enormous number of small particles. It is a question in my mind how far we are justified in going in demanding a very high efficiency dust collector.

In the larger plant, yes, because they throw out such a large volume of weight of materials, even though in some of them the material that does go out is of such a fine nature that it will be diffused over a very large area and will not cause much trouble. When it comes to the metallurgical industry, I don't know. I will have to refer again to Dr. Katz.

*Dr. Katz*—The question that you ask is intimately related to the meteorological conditions of a particular area, because you see, there are times of the day and periods of the year when a certain mass rate of emission will be dissipated and dif-

[5]Paul Dilworth and Company, Toronto.

fused quite readily and you won't have a pollution problem. On the other hand, there are other periods when, because of meteorological factors, those products cannot be diffused or dissipated properly.

We recently mentioned the problem of cause and effect. It is difficult, except in a very general way, to lay down a regulation or standard as to what one should expect at ground level. One could say perhaps that a certain maximum should not be exceeded, but to relate the problem in the way you mentioned, to certain specific concentrations in the air, is virtually impossible. Did you mean that these concentrations should be at ground level or in the air ?

*Mr. Dilworth*—Under normal conditions, the absolute amount of these contaminants that are ejected into the atmosphere by industry or by motor cars is not so important. The key factor in the problem is the concentration which is maintained, or at least the rate at which they are discharged into the atmosphere, as actually related to the prevailing atmospheric conditions, and of course, those vary from time to time. It seems to me that, rather than try and control the amounts of foreign matter discharged into the atmosphere, where there are very fine particles—if these were mixed with a sufficiently large proportion of fresh air before being freed to the atmosphere they would never reconcentrate, and their nuisance value would be considerably reduced thereby.

*Dr. Katz*—I am afraid your suggestion is contrary to the laws of diffusion. What you are suggesting is that if you are going to emit from a stack, say, 1,000 pounds per day of sulphur dioxide, that you mix that with enough air in the stack so that when it gets out, you will not have a pollution problem.

Unfortunately, diffusion which goes on in the atmosphere—not molecular diffusion—is such a rapid progress that it does not much matter relatively what the concentration in the stack is. What matters is the mass rate of emission from the stack.

In other words, you can put in twice as much air as waste material in that stack, but that is not going to do much to your concentration in the atmosphere, because there the concentration is diluted 10,000 times or more. In the laws of diffusion there is no room for any such factor as volume dilution, because you don't operate on volumes, you operate on masses.

The important thing is this: are you going to discharge 1,000 pounds for 24 hours, or 1,000 tons in 24 hours. If you are going to discharge 1,000 pounds you will have a certain type of stack and certain other conditions. If you are going to discharge 1,000 tons successfully, you must have a much taller stack and a higher velocity, and higher temperature levels, and so on. To attempt to solve the problem by dilution with excess air in the stack is useless.

### The Present Situation

*Dr. L. F. Grant*[6]—Referring to Mr. Dilworth's question and Mr. Davis' question: supposing we take a typical North American city of say, 100,000 people, where everybody is free and happy. Are we doing a permanent injury to the atmosphere ? Does it completely purify it, or will a solution of this question possibly be found in poisoning everybody ? Is the atmosphere getting progressively worse ?

*Dr. Katz*—I don't think we are in any danger of poisoning ourselves to that extent and for this reason. Natural air cleaning processes operate, and where we have pollution problems they are due to a great concentration of industry or population, or to too great a rate of emission or lack of proper control over particular areas, or else they are due to the peculiar conditions, those of meteorology, in these areas.

However, all areas—even the worst of them,—are periodically provided with a system which cleans up the air. First, there is the action of the wind. In high winds, the pollution tends to be less than at low wind velocity. Then, you have turbulence, which is something made up of two main variables, the wind variations and temperature gradients. Ordinarily the temperature decreases as you go higher up.

The third process is that of temperature anomaly, and that is related to the passage of warm and cold fronts. Now, the temperature anomaly is the difference between the normal mean temperature and the prevailing temperatures, and let us say that it is on the negative side. In other words, let us say it is a lot colder than it is usually, which means that a cold mass of air has moved in, which is generally a clean mass. This reduces the pollution. If the reverse is taking place, you have a warm air mass, and unfortunately it is usually a dirt-carrying mass which is not so clean.

However, in addition to that, you have another factor; I mean the passage of a clean front. Every time a front passes over an area, it brings clear air into that particular area and particularly after it changes the wind direction when some of it may be air from the uncontaminated rural districts. Finally, you have got precipation; every time it rains you have a clean-up of the atmosphere by the dissolving of impurities, and so on.

[6]Engineering Institute of Canada, Toronto.

*T. C. Chown*[7]—I would like to ask, is it the idea of the Engineering Institute to have all Provinces put in certain by-laws to cover smoke pollution or elimination ? I know that Mr. Hall has talked about different kinds of stoker equipment and I can remember 20 years ago when the first collection equipment was sold in Canada for a smoke stack. We quite agree that on an underfeed stoker or a chain-grate stoker we do not get the fly ash that we do with pulverized fuel or spreader stokers. We have found that on an underfeed stoker 15 per cent of the ash goes up the stack.

Spreader stokers run around 40 per cent and pulverized fuel from 75 to 80 per cent, and maybe a little higher than that in some cases. I know a case right here in the city, on the top of a hill, where a man can't get rid of fly ash, so he puts it in the bottom of the stack and opens the door and away it goes all over the city. In other cases, I have seen a similar thing. I know of people who used tons of paper and gallons of paint every year, and who tried to keep a painting crew with them all year round, who put in dust collectors. I would emphasize that if you are going to put in these dust collectors, you should put in some type of standard equipment. We have a bid in now, where the request came in for "dust collectors with 85 per cent efficiency". There is no analysis of the equipment, we don't know whether it is going to be used for pulverized coal or for spreader stokers, or what.

*Mr. Hall*—The question is in two parts. First, referring back to that report, I will read you a sentence which you might find interesting:

> "It is strongly recommended that the problem should be dealt with on a regional basis, by means of appropriate control areas to be set up by the various provinces themselves, because only those governments have the power to take such action."

In air pollution, there is no civic boundary, and therefore it should be dealt with on an area basis.

Now, with regard to the policy of the Engineering Institute. When this report was submitted to the

[7]T. C. Chown Limited, Montreal.

various organizations represented on the Committee, one of them passed a resolution requesting the Engineering Institute to take into consideration the organization of the Canadian Standards Association which could take up the problem and develop a model specification. That is now in the hands of the Canadian Standards Association. The E.I.C. is cooperating very closely with the A.S.M.E. Air Pollution Control Committee.

#### Study of Radioactivity Dissemination

*L. H. Dickson*[8]—In the request for regulations, is there anything to cover the amount of radioactivity dissemination? I am referring particularly to Chalk River.

*Dr. Watkinson*—The Department of National Health and Welfare, through its Radiation Section, has the responsibility for the health supervision of radioactive isotopes outside of Chalk River. However, I can tell you that in the history of public health in this country or in any other country, there never has been a greater amount of study on a problem beforehand, in order to ensure safeguards of every kind. Such study is going on constantly in the Radiation Control Section of Chalk River. As far as the future use of radio activity in Canada is concerned, you can be assured that the Federal Department of Health, the Provincial Departments of Health, and every physician and physicist who is concerned with radiation generally, are watching every advance step by step.

#### Studies on Light Scattering

*A. F. Brooks*[9]—Dr. Katz and Dr. Watkinson have both emphasized light scattering as leading to lack of sunshine. That, possibly, is due to a large extent to sub-micron fuel and gases which are not normally collectible. Some are, but not always within mechanical possibilities. Can this problem of light scattering be resolved or handled by legislation, particularly as legislation usually emphasizes masses rather than numbers of particles? I ask this question in view of Dr. Katz's remarks that a major light scattering problem still exists in Los Angeles in spite of legislation.

*Dr. Katz*—These sub-micron particles are the subject of intensive study, and a successful approach has been made in removing them in the case of metallic fume, zinc oxide fume, or sulphur trioxide, by use of suitable types of mechanical equipment, such as venturi scrubbers, electrostatic and various other types of equipment. Now, there is always a residue of small particles which cannot be collected. The optimum light scattering is caused by particles which are 3/10ths to 4/10ths of a micron, but particles down to 1/100th of a micron can cause haze, so that a certain amount of haze is inevitable over industrial areas.

I don't think we should worry too much about it or attempt to legislate in that field. If we do our best to control obvious sources of pollution and also to control certain habits of the public, and do a little planning in regard to city and industrial areas, I know the major part of the problem will be successfully solved.

#### Conclusion

*The Chairman*—I have perhaps said enough this afternoon on this particular subject but I know there is much more that might be said. There are many other aspects of the matter that might be considered and probably should be, but in the space of one afternoon it is impracticable to deal with a subject which would require many days and weeks and months to handle adequately.

Perhaps one note that might be struck at this particular time is this; there is a time factor concerning this particular problem. With the increasing sizes of communities, with increasing sizes and concentration of industry and other similar things, the atmospheric pollution in certain areas is likely to become progressively worse.

There is great difficulty at the present time in getting municipalities and other people concerned to provide even a reasonable amount of money for the purpose of finding out what the situation actually is. Until we know what the situation is, what pollutants are concerned therewith and where they come from, we cannot take any successful steps to deal with the situation, or at least we shall have considerable difficulty in doing so.

The only thing that I fear is this, that effective action in this regard will be postponed until the cost of handling the situation becomes vastly greater than it is at the present time.

## Philadelphia's Air Pollution Control Ordinance

On March 9 Philadelphia's Mayor Joseph S. Clark signed an Air Pollution Ordinance that is considered by many as the most advanced and constructive in the U.S.

The new law prescribes fees for permits, calls for an increase in penalties for violators and gives the city's Department of Health and the Air Pollution Control Board stronger enforcement and administrative powers. Its definitions are:

"Air Pollution"—The emission or escape of dust, fume, gas, mist, odor, smoke, vapor, or any combination thereof, in a quantity and of a character which constitutes a direct health hazard or detriment, or the contamination of the air in any manner detrimental or harmful to the health, comfort, living conditions, welfare and safety of the inhabitants of the City of Philadelphia.

"Air Pollution Nuisance"—The emission or discharge into the open air of dust, fume, gas, mist, odor, smoke or vapor, or any combination thereof, of a character and in a quantity which as to any group of persons interferes with their health, repose or safety or causes severe annoyance or discomfort, or tends to lessen normal food and water intake, or produces irritation of the upper respiratory tract, or produces symptoms of nausea, or is offensive or objectionable, or both, to normal persons because of inherent chemical and physical properties, or causes or is likely to cause injury or damage to real or personal property of any kind, or which interferes with normal conduct of business, or is detrimental or harmful to the health, comfort, living conditions, welfare and safety of the inhabitants of the City of Philadelphia.

One of the unique features of the new ordinance is that it makes provision for the important problem of controlling odors.

"Odor"—Smells or aromas or stinks, which are commonly recognized as offensive or objectionable, or which are very unpleasant to persons possessing normal olfactory senses, or which tend to lessen human food and water intake, interfere with sleep, upset normal appetite, produce irritation of the upper respiratory tract, or create symptoms of nausea, or which by their inherent chemical or physical nature, or method of processing are detrimental or dangerous to health, or which are of a quantity or character that violates any of the provisions of this Ordinance or any of the regulations promulgated pursuant thereto. Odors and smells are used herein interchangeably.

# Discussion of Technical Papers

## Transistors and the Electrical Industry

by E. L. R. Webb, Head of Air Force Section, and P. A. Redhead, Research Officer, Radio and Electrical Engineering Division, National Research Council, Ottawa
*The Engineering Journal*, June 1954 issue, page 678

**L. G. Eon, M.E.I.C.**[1]

I find myself asked to discuss a paper which is not at all controversial. The facts stated by the authors are to my knowledge correct and their conclusions are satisfactory. I will therefore give briefly my thoughts on the possible impact of the transistor on our Canadian electrical industry.

Various statements have been made during recent years by many important people to the effect that transistors are about to revolutionize electronics. Let us take a closer look and see just what the effect of the transistor will be on Canadian industry during, say the next five years.

Messrs. Webb and Redhead have indicated that completely new techniques in circuitry are required to utilize the transistor. These techniques require a re-education for the design engineers, and also the provision of associated parts such as resistors, condensers, transformers, etc., which are compatible with the operation and size of the transistor.

Military equipments generally are designed to very stringent standards to enable them to operate under conditions of extreme shock, temperature, humidity and atmospheric pressure. It is generally known that today's transistor will not meet these requirements. Again the wide variation in some of the characteristics of present transistor production requires an approach to circuitry which will enable the transistor to be useful and yet not affect the requirements of circuits when certain of its characteristics are varied. This, by the way, is quite possible. Our Defence Research Telecommunications Establishment is a leader in this field.

To have an impact on industry, military orders must be for large quantities of equipment. Generally speaking, even in a time of emergency, military orders represent but a small percentage of our electrical industry's potential. I therefore foresee very little impact on the production capacity of Canadian industry by transistors for *military* orders in the next five years.

However, from the development point of view, our Defence Laboratories are continually reviewing new devices in order to determine how effective these will be in meeting military requirements. Transistors are no exception. Therefore, it can be expected that within a few years, new circuits will have been proven which are ready for engineering development in industry.

If industry is to get its fair share of this development, it must ensure that the training of its own design engineers is in step with the work carried out in Defence Laboratories. Otherwise, the tendency will be for those Laboratories to go beyond the step of proving feasibility to that of developing engineered prototypes.

The success of our Canadian electrical industry in meeting the many requirements of our armed forces has been mainly due to the know-how acquired in designing and manufacturing commercial equipments. It therefore follows that to be successful in meeting the design needs of the Services which may arise in a few years, industry should now be introducing the transistor in the design of commercial equipment.

Industry is faced at the present time with a device which is still relatively expensive, which demands new circuitry, whose performance still leaves much to be desired and whose reliability has yet to be assessed. I am no expert in this field, but I would suggest that except in very limited applications, transistors are unlikely to be used in such mass produced items as mantel radio sets, car radios, etc.

On the other hand, there are many electrical control circuits manufactured for the industry, which may very well be made simpler and more reliable by the use of this new device.

While I agree with the authors that the application of transistors to computers is one of those most likely to take place in the near future, I should add that the telephone industry is another, which may very well be the first one to use this device in large quantities. These specialized fields are unlikely to have an impact on the Canadian electrical industry as a whole.

[1]Senior Scientific Officer (Electronics), Defence Research Board, Ottawa.

**J. R. Houghton, M.E.I.C.**[2]

The impact on the electrical industry of the advent of the transistor can be divided into two phases: (a) the effect of the transistor itself; and (b) the miniaturization of associated apparatus such as resistors, capacitors, inductors, etc.

Let us discuss the latter first. To obtain full advantage of the minuteness of the transistor, it follows that these associated components must be reduced in size as well. Great strides in this direction have already been made through the use of very high permeability materials such as ferrite and permalloys for the construction of inductors and transformers. Coils not much larger than the transistor itself have already been produced. Capacitors, manufactured from tantalum, have been reduced to the size of a matchhead and have a capacity of 25 mf. In the resistor field the carbon deposited type has been reduced to a diameter not much larger than the terminal leads.

When these miniaturized components are assembled and used with printed circuits, then it is possible to attain the overall miniaturization commensurate with the transistor. The low heat dissipation of the transistor favours the practice of packaging these components in a minimum space either in plastics or potting compounds. To reduce maintenance costs, these assemblies can be of the plug-in unit type construction.

[2]Superintendent of Manufacturing Engineering, Northern Electric Company Limited, Montreal.

While it may be true that the commercial use of transistors in equipment has not kept pace with the laboratory developments, it is a fact that a very large number of companies in the United States and at least a couple in Canada have been licensed by the Western Electric Company to manufacture transistors. Speaking on behalf of the Northern Electric Company, we have been in production of the point contact type transistor since January, 1953. While facilities are set up on what might be termed a pilot plant basis, sizable quantities are being produced and facilities could be expanded very rapidly should larger demands arise. Grown junction type transistors can also be produced in reasonably large quantities in this pilot plant and are available now.

What does all this mean to industry in general? It probably can be assumed that heavy capital investment will be necessary on the part of transistor manufacturers since it is doubtful if present vacuum tube or other facilities could be used. As the use of the transistor and other miniaturized components increases, it will be necessary to spend further capital to revamp the methods of assembly both in the apparatus and the equipment factories. In short, the whole field of miniaturized apparatus and subsequent equipment will in the future necessitate either full or semi-automation. The automatic factory will involve considerable expenditure with perhaps lower than normal utilization of facilities. Selection of operating personnel for dexterity and vision will be preferable and more than normal training will be necessary.

To return to the transistor, it is felt that the manufacturer and public will expect that so small an item, containing fewer parts and simpler in construction than the vacuum tube, should cost a few pennies. Hence it will be necessary to plan for semi-automatic production processes at least in order to lower the cost. How soon this will be necessary will, of course, depend upon the demand. Pilot plant production will remain until enough transistors are produced and in the hands of the designers so that the demand is created which will warrant mass production techniques. To date, only small requirements for development purposes have been forthcoming. This is, of course, logical since the design of the transistor is only recently reaching any degree of stabilization, and the design of equipment and circuit application has not as yet been proven conclusively in very many instances.

Finally, there are many who believe that quantities of transistors many times more than present day vacuum tube usage will be required in the future. Transistors are used in current manufacture of national toll dialing equipment and very shortly a rural carrier system using sizeable quantities will be in production. In the communications field indications are that transistors will play a part in every phase of the art and it is certain that demands will arise in many other fields.

## Fire Protection Aspects of Building Design

by W. E. Emmerson, Jr.E.I.C., and D. R. Abbey, M.E.I.C., Fire Protection Division, Underwriters Laboratories of Canada, Toronto, Ont.

*The Engineering Journal*, April 1954 issue, page 426

---

**F. E. Wellwood, M.E.I.C.**[3]

The authors are to be congratulated on the clear manner in which they have presented the various fire protection aspects of building design. All too often, we engineers are prone to be content to confine our attention to structural safety if engaged in structural design, and to mechanical efficiency if engaged in mechanical design.

As a member of a municipal buildings department, I feel that all engineers should be made aware that their function in safeguarding life and property should go farther than the prevention of collapse of the structure or the efficient operation of the plant or the various mechanical or electrical contrivances entering into a modern building. I believe the work of the engineer should also include a detailed study of the hazards involved in the processing of material in a factory, or the possibility of fire spread in other occupancies.

The authors have referred to the tremendous fire loss, due to improper design, which resulted in rapid unrestrained fire spread at the General Motors plant near Detroit. The loss of buildings and equipment was tremendous, but the loss to the company from the interruption of the use of such plant and equipment was equally important.

Another aspect of the serious consequences resulting from large fires was touched on by the authors in their reference to the Cocoanut Grove fire in Boston and the LaSalle Hotel fire in Chicago. In these buildings, and in others such as the Hotel Winecoff in Atlanta, Georgia, and the Knights of Columbus Recreation Hall for service men at St. John's, Newfoundland, the property damage was extensive, but of more serious consequence was the heavy loss of life. In these four fires alone, seven hundred and seventy-five persons lost their lives. Yet the two hotels were advertised as "absolutely fireproof". In all these cases, certain weaknesses existed in fire protection, in design, or in subsequent application of interior combustible finishes; and in all four cases inadequate exits were provided or the exits were unavailable for use in simpler control of the building.

I would like, in this connection, to sound a note of warning against the use of heat actuated devices in the operations of closers on doors leading to stair or other shaft enclosures. Most loss of life in fires arises from the panic hazard of smoke, rather than from fire itself. Unless such doors are kept in a normally closed position, smoke will spread through the full height of the building long before the heat rise has been sufficient to close any doors except those immediately adjacent to the fire's origin. By this time there exists not only the hazard of a crowd in a panic, but also the reduced efficiency or perhaps total loss of the exitways due to poor visibility, and discomfort in breathing due to high smoke density.

It is this latter aspect of building design for fire protection that all building officials feel should be stressed, for it is always possible to renew property but life is irreplaceable.

[3]Deputy Commissioner of Buildings, Department of Buildings, City of Toronto.

**T. R. Durley, M.E.I.C.**[4]

It is a pleasure again to see a paper having to do with fire protection and this is a valuable one. I do

[4]Assistant Vice-President and Engineer, Manufacturers Mutual Fire Insurance Company, Montreal.

not agree entirely with the order in which the tools of the fire protection designer are mentioned, but it would be a dull world if we all thought alike.

To me the most important aspect of fire protection design is to study the hazard and isolate it, to provide automatic extinguishing equipment. There seems to be no need to discuss hazards—in general, they are well recognized and are usually adequately taken care of. The problem, in any building, is that knowing what automatic protection is necessary, and of developing the necessary judgment in the designer himself. As the authors point out, justifying automatic protection by a saving in insurance cost is seldom possible. It must be based, in part, on the fact that with proper fire protection the property owner knows with certainty that his property will still be there the next morning and can continue to operate safely for many years. This confidence is difficult to evaluate but is usually ample justification.

The real measure of the need for automatic protection is undoubtedly the number of B.t.u.'s which will be liberated, by the structure or occupancy, or both, in a fire. The amount of heat, expressed in weight of burnable material per square foot, just as live loads in a building are computed, dictates what protection is required, whether by distance, fire walls or automatic extinguishing equipment. Protection must be balanced very carefully against loss of life and property values.

This concept has been introduced into the new National Building Code, but since it is new, we must proceed slowly, and we also run into the old problem that many of our friends in the building trades still don't know how quickly wood burns. It is, in the main, a question of education, and architects and engineers must obtain and study the wealth of information available, not only from the National Fire Protection Association and the Dominion Board of Insurance Underwriters but also if I may be permitted to mention my own organization, the Factory Mutuals. There are others too that maintain loss prevention services, and all do excellent work.

I don't know too accurately what the national loss ratio is, but, according to the report of the superintendent of insurance for Canada, the last recent 5-year average is about 33c. per $100.00 insured. We, the Factory Mutuals, know that this figure can be reduced to about one-tenth of its present level when proper fire protection is provided. This figure, as the paper indicates, is a great challenge to all engineers and represents a saving of many millions of dollars annually.

Let us hope that the new National Building Code and all other available information will be used—and in particular by the Federal Government which seems to be amongst the worst offenders when it comes to building unprotected properties which contain very high values. And, finally, let us hope that those of us in the fire prevention field may be able to help in the steady reduction of the large fire loss in this country.

---

## The Application of Computors to Industry

by W. J. M. Moore, M.E.I.C., Assistant Research Officer, Radio and Electrical Engineering Division, National Research Council, Ottawa
*The Engineering Journal*, September 1954, page 1068

---

**Henry A. Spencer**[5]

It is of interest to me to read articles like "The Application of Computors to Industry". Much has been said about the ethics of a mass production system of manufacture. One of its obvious faults is the deteriorating influence of routine jobs. If the modern computors mentioned by Mr. Moore can be applied in this direction there is a twofold advantage. The emphasis on the mental development of the nation should be increased and the chances of costly errors through disinterest in tedious jobs decreased, which benefits industrial management.

One or two comments by Mr. Glinski concerning the development of computor components raise another point which sometimes is overlooked. In any computor the designs are limited in scope by the limitations of the tubes, solenoids, springs, electrical contacts and thousands of other basic parts. Maintenance of these unit parts is a tremendous task where designers have not been familiar with the average life span of, say, a relay. Anyone who has watched as simple an electronic mechanism as television wonders what kind of repairman would be required to maintain an electronic "brain". Thus it seems that some effort should be bent in the direction of improved unit parts and groups of parts which at present are inadequate.

In the design of desk calculators, much effort has gone into mechanical design. Programmed sequences are carried out by cams, levers and latches made by mass production techniques. Very few desk calculators have been made from electronic components. From all appearances it seems that they are not reliable enough to give continuous service.

I would invite further comment on these points from engineers who are familiar with computors. Certainly the future of this field looks extremely interesting.

## NEW RESULTS IN TOOL AND DIE WELDING

Robert Groman, *The Welding Journal*, v. 33, no. 6, June, 1954, pp. 543-545.

The majority of people working with tools and dies are familiar with the present methods of repair and salvage with oxy-acetylene torch and electric arc-welding equipment. Much has been written about procedures for such repairs and their use is increasing daily. More and more people are realizing the savings from tool and die salvage welding.

However, there is a field in which very little work has been done because of the specialized equipment required and the extensive training necessary to complete the salvage work (reheat treatments, etc.). Examples are the repair of sharp cutting edges of high-speed tools, small chips or cracks on plastic dies, punches, clicker dies as used in the shoe industry, etc.

Building up a sharp cutting edge on a high-speed tool such as a drill or reamer with the electric arc is difficult because of burning the sharp cutting edges of the tool. Plastic dies are intricate in design and almost impossible to weld with the electric arc. Annealing of the base metal is detrimental when the oxy-acetylene torch is used.

Because of these problems a survey was made to determine what could be done to induce people to do more salvage welding and show them the savings that could be had by so doing.

### Carbon Arc Method

As a result the carbon arc method was introduced. Not the carbon arc torch which employs the twin carbons, but the single carbon method using a d-c machine, straight polarity.

For this type of work, a special coated carbon electrode has been developed. This special coated carbon electrode has a mineral and metallic coating which has produced results equaling in importance the introduction years ago of the coated mild steel electrodes.

The special coated carbon electrode is used at lower amperage giving it longer life, greater workability and gas coverage similar to metallic arc welding.

The single carbon method is excellent because it provides a pin point source of heat, extremely localized, which will melt the base metal as soon as the arc is struck.

The carbon arc method produces welds that are spatter free and, if the proper technique is used, no undercutting will occur adjacent to the weld deposit.

The filler metal used is the special low-watt input tool steel electrode used for conventional electric-arc welding. The prescribed technique used is very similar to torch welding, as follows:

1. Put a taper point on the coated carbon electrode using a grinding wheel.
2. Grip the special coated carbon electrode on the brushed end in an electrode holder.
3. Place the holder in the right hand.
4. Hold the special low-watt input tool steel electrode in the left hand and feed it into the arc as soon as the arc has started.

### Procedure for Salvage Welding

The recommended procedure is to grind out all defects in the die or tool so as to remove all chipped or broken areas. Preheat the die or tool to 400°F. (blue heat).

Use a small carbon electrode, preferably 1/8 and 1/4 in., set the arc machine at 60 amp. or less. Use a 3/32-in. diam. size special low-watt input electrode of the type of steel being welded, oil hardening low-watt input electrode for oil hardening steel or high-speed low-watt input electrode for high-speed steel, etc.

While there might be wide variations in the analysis of tool steels, the heat treatments, in each respective classification, are similar. Therefore, in welding it is not a question of matching the analysis of the steel, but of matching the heat treatment in its classification as closely as possible.

Strike the arc with the coated carbon electrode and feed the special low-watt input tool steel electrode into the arc using the torch welding technique. Build up the chipped area until the repair is completed. Excessive puddling is not necessary nor desirable.

Peening is recommended immediately after each pass or whenever the welding has been stopped. The chief effects of peening consists of relieving shrinkage stresses and improving the metallurgical structure of the weld deposit.

Sometimes peening is overemphasized and the tool welder will use a large hammer, thinking of forging the deposit. This must be avoided as too heavy a hammer blow will fracture the deposit and cracking will result. Always use a small hammer and a light hammer peening.

On corners or sharp edges, leave all the extruded coating on the filler metal electrode. If a fillet weld is to be made, it is advisable to remove 50% of the coating on the filler metal electrode, either by grinding or breaking it off with a hammer. Caution — never at any time remove more than half of the coating. If too much of the coating is removed, the weld deposit will be brittle, low in tensile strength and considerable porosity will be evident. Much can be derived from the alloying elements of the coatings as they help to compensate the percentage of alloying elements lost during the welding operation.

Drawing or tempering is usually done with the oxy-acetylene torch as the above technique is used only on small repairs. The drawing or tempering operation relieves contracting stresses set up by the cooling of the weld deposit.

In a salvage repair of this type, it is not wise to make repair that is greater than 3/8 in. in depth. If the break is larger than this, the normal arc welding procedure is recommended, using the cushion method of repair.

In all cases the part being welded must not be exposed to draughts of air as this would cause checking and cracking of the weld deposit. It is obvious that time and money can be saved by this type of reclamation.

## THE HISTORY AND CONSTRUCTION OF THE FOUNDATIONS OF THE ASIA INSURANCE BUILDING, SINGAPORE

William Joseph Robert Nowson, *Proceedings of The Institution of Civil Engineers*, P. 407—v. 3 no. 4, July 1954, p. 407.

This paper describes the underpinning of partially sunk reinforced-concrete cylinders by means of a precast concrete segmental lining. The early history of the foundations is related and reference is made to the main points in the design. The partial sinking of the cylinders, of which a brief account is given, was carried out by another contractor.

The cylinders form the main part of the foundations for the 18-storey steel-framed Asia Insurance Building in Singapore. The site is located over an old beach reclaimed within the past 70 to 80 years. The beach formation is 10 to 14 feet thick. Overlying it is 15 to 18 feet of fill and below it is decomposed shale and sandstone. Four borings, sunk at various points on the site, came to refusal at depths ranging from 30 to 42 feet. Firm sandstone chippings were obtained in each case. The consistency of these results suggested the existence of a firm rock stratum. Lack of suitable drilling equipment in Malaya at that time prevented the rock from being proved at depth.

On the basis of this information, cylinder foundations were selected to be sunk to rock level. The cylinders were designed for a bearing pressure of 10 tons per square foot exclusive of their own weight.

During the sinking of the cylinders the soil analyses were confirmed, except that the sandstone at depth proved to be core boulders of sandstone. The situation was aggravated by the inrush of soil during the sinking of the cylinders through the beach formation, causing considerable trouble and delay. The surrounding ground showed a series of cracks and, close to one side of the building line, the pavement had sunk from 2 to 3 feet.

The subsidence is attributed to the disregard, on the part of the previous contractor, of the specifications relating to the method of sinking the cylinders. Control of the water table was erratic and excavation inside the cylinders was allowed to proceed too far ahead of the cutting edge.

To avoid further risk of loss of ground, sinking of the cylinders was stopped. The cylinders were carried to their final level by underpinning them with a precast concrete segmental lining. The bearing pressure was reduced to 3.5 tons per square foot by belling out the bases. All cylinders were back-grouted, and also each ring of the lining as it was assembled. In certain cases underpinning through the beach formation was carried out in compressed air.

After sealing the bottoms of the shafts and encasing the segmental rings in a secondary lining, the tops of the cylinders were trimmed to a common level and a 4-foot-thick reinforced-concrete raft was cast over them. Into the raft were grouted the holding-down bolts and base plates for the stanchions of the steel superstructure.

The paper also gives a detailed account of the soil surveys. It describes the manufacture of the precast concrete segmental lining and gives notes on the plant and tools used during the execution of the work.

## FORWARD WITH THE TURBOPROP

D. M. Desoutter, *Aeronautics*. v 30 n 6 July 1954, pp. 60-62.

The Bristol Britannia suffers from one noticeable drawback: it looks like an ordinary aeroplane, albeit a very elegant and attractive one.

The first thing to grasp about the machine is that it is a big aeroplane. Its pleasing lines mean that in drawings and photographs it does not look very big: but it is. In span it is slightly greater than the Boeing Stratocruiser, and considerably greater than either the Douglas 7 or the Constellation 1049. In length it well exceeds all of these machines. Its maximum take-off weight, too, is far beyond that of the Stratocruiser and even farther beyond those of the Douglas and the Lockheed. In fact the disposable load of the machine is found to be greater than those of the other widely-used commercial machines that have been mentioned.

One has to bear in mind that just as the machine is bigger and heavier than one expects, so the engines are more powerful. They are, in fact, the most powerful civil engines in the world, eclipsing the Wright turbo-compound by a handsome margin. Indeed, only the gas turbine can offer a practical means of achieving the scale of power output needed for an aeroplane of this size. High power for small unit size is an accepted quality of the gas turbine in any field of application, but here the application is to the airscrew. Here is the core of the turboprop's claim to efficiency and economy, its enlisting of the airscrew's aid to apply the turbine's high power output in the best way.

### The "Free Turbine" Principle

The advantages of the propeller turbine are winning for it a steadily widening group of adherents in the world at large. Apart from being one of the leaders in this field, Bristol has put itself in a special position by the adoption of the 'free turbine' principle, that is by the use of two separate turbines of which one drives the compressor and the other the airscrew.

The free turbine is a very attractive idea because it separates two devices which have their own peculiarities of performance and their own critical conditions: that is the compressor and the airscrew. The compressor, which is the essence of the gas producer, gives a satisfactory performance only within a comparatively narrow range of rotational speeds, but the airscrew's relationship between rotational speed and power output is required to be more flexible as its pitch is varied to suit the differing cases of take-off, cruise and landing.

The free turbine avoids the issue by making the two entities independent, at once easing the task of the designer and simplifying the engine controlling apparatus. There are other advantages, among them the lessening of the starting load because the airscrew and its reduction gear do not have to be turned, and the low drag of the free-spinning airscrew in the event of an engine failure. There is naturally an increase of weight due to the double shafting and the necessary bearings, but that seems a comparatively negligible price to pay for the advantage of having an engine in which the power section can operate at its most advantageous condition without being hampered by the propeller, while the propeller in turn is equally free of the power section. The ultimate result, of course, must be measured in fuel consumption. Consumption figures for any engine vary over the range of operating conditions, but typical figures cited for the Proteus 755 by the makes are 0.218 kg./e.s.h.p. (0.48 lb./e.s.h.p.) at the maximum five-minute power, at 0.225 kg./-e.s.h.p.) (0.495 lb./e.s.h.p.) at maximum continuous power at an altitude of about 10,000 metres.

### Design for Economy

Given this economical form of propulsion with its low noise level, low installed weight and great power, the Britannia airframe has been designed to take advantage of it. The machine has a high disposable load coupled with a lay-out that leaves it to the operator's choice how that load shall, in fact, be disposed. The disposable load is mainly made up of fuel and payload, and although these two items are mathematically interchangeable they are not always physically interchangeable because one cannot put passengers, or even mail, in the fuel tanks. In the Britannia the volume of the cabin and of the under-floor holds is such that there is plenty of opportunity to devote lifting potentiality to revenue-earning load.

All these qualities of good load-carrying, low fuel consumption and so forth have one object in view—the earning of a profit. The assessment of an aeroplane's ability to earn a profit is no easy matter and many of the wise men of aviation seem to prefer to adopt the method of standing on the sidelines to watch another operator put the matter to the test. There are always a few, even wiser, who have confidence in their own ability to know a good thing when they see it. But at this point it is not our purpose to say too much about the estimated economics of the Britannia. For the moment the aim is to show in what class of aeroplane it falls.

Now it is a commonplace that an aeroplane's economic worth depends upon the difference between the rate at which it can earn money and the rate at which money has to be spent to operate it. The earning rate is the product of the payload carried and the average speed, and the exact relationship of these two variables is the field in which the aircraft designer can exercise his discretion to the best (or worst) effect. Now the Britannia can be characterised as a machine which achieves a high productivity by means of a high (but not very high) speed and a very high payload. This approach to productivity also has its effect upon operating costs, because the choice of a moderate speed reduces the fuel consumption, and this in turn is one of the things that makes possible a higher payload. Thus the machine is neither of the very slow and ponderous carriers nor of the extremely fast (circa Mach 0.85) light load carriers. While avoiding both these extremes it yet achieves a high productivity.

## HUMAN FACTORS IN TECHNOLOGICAL CHANGE

Professor C. A. Mace, *The Institution of Production Engineers Journal*, v 33 no 7, July 1954, pp. 421-425.

Theoretical science and practical engineering resources have now advanced to a point at which it is no longer fantastic to conceive the possibility of an electronic factory—one in which the human operator is replaced at almost every point by an automatic contrivance of a mechanical or electronic kind. The next step presumably would be to distribute the goods produced through automatic machines. This producer's pipe dream has at least the merit of drawing attention to the fact that, as we progressively displace the human agent, we reduce both the major sources of resistance to desired change and the major sources of inspiration of desired change.

In the electronic factory there would indeed be change—the wearing out of parts and eventual breakdown; but desired change and the resistance to desired change spring from something inherent in life itself: they derive in part from the homeostatic tendency characteristic of all living things. This is true not only of living things composed of organic tissues, but also of those living things which we call societies and social organizations, government departments, public and private bodies of every kind, including even those that exist in order to promote reforms. All are resistant to departures from established norms.

That resistance to change arises in part from the need to conserve and consolidate past achievements is illustrated by the function of standardization of tools, components and procedures. The uncontrolled spirit of invention and experiment makes for an uneconomic degree of variation in procedures and products. Hence the advantages of standardization. Hence, too, the difficulty in further advances. The dangers of premature standardization are greater when standardization is brought about not by conscious intention and deliberate organization, but by tradition and custom. Many things have been standardized by custom. It is most improbable that the ideal unit of building construction is the brick of any of the conventional dimensions. But what has been standardized by custom is not the bricks, but the skills of men who use these bricks in building. In the scientific study of the process of industrial production we have come to think of the "man-machine unit". We ought perhaps to think of the man-machine-materials unit. Pending the perfection of the automatic factory, production is effected by human beings performing certain operations with tools or machines upon given materials or components. We cannot standardize any one of these contributors to the end result without due regard to the others.

### Increased Rate of Discovery

There can be no doubt that the rate of discovery has increased enormously, and is still increasing. The pace has so quickened that in many fields of production technological change has been geared, through the seasonal interests of man, to the circuit of the earth round the sun. Each annual model of every make of car is expected to embody improvements.

Were we concerned to make the pace still hotter there would be several things to do. One would be to upgrade and develop our primitive system of technical and technological education. Originality of mind is something more than skill in the use of scientific method. It springs from certain attitudes which at present are fostered only in certain special places. If we review the greater educational institutions of the world the impression received is that those most productive of creative minds are precisely those in which trained and disciplined intellects are applied to the coolest consideration of the craziest ideas.

There is indeed a powerful case to be argued for making a liberalized system of technical education the main trunk of our education tree. It would need to be "liberalized" by introducing into the curriculum an appropriate selection of arts subjects, for the arts subjects contribute to inventiveness and originality as much as is contributed by science. A liberalized secondary technical education could lay the foundations for a balanced appreciation of the scientific, the aesthetic and the practical aspects of life. So far as discovery and invention is concerned the pace, it might well be said, is surely hot enough. The problem is to break down the resistance of consumers and producers. The consumer's resistance to change, and his demand for change, are combined in curious ways. The customer is not always right. He would be always right if he could always say what he really needs. When he says only what he thinks he needs he is not more likely to be right than wrong.

Hence the importance of advisory services. One of the most significant features of the times in which we live is the expansion of these services. In his personal affairs a citizen in the modern world has at his disposal medical, educational and innumerable other specialized bureaux dispensing the latest and best advice on any subject of concern to himself or his wife. Nor are such advisory services restricted to official bodies. Large-scale industry has developed similar services which are conducted in a responsible and professional way. In large part, the problems of getting ideas into production are of overcoming consumer resistance and are problems of "communication", meaning by "communication" not merely the transmission of information, but also the induction of a willingness to act in certain ways.

The lines of transmission are of various kinds. There is, for example, the line from the inventor through the research laboratories and test stations to the field of operation. In the process of production there is the line from higher management through the supervisory grades to the operators at the bench who actually do the job. Typically, the introduction of a new machine, a new piece of equipment, or a new procedure follows a now fairly well-established routine. Tests are first performed in the research laboratory. The new machine is then transferred to the field station in which it is still tested scientifically, but under as near as may be realistic conditions. Surviving all these tests, it is then tried out under the normal industrial conditions in the hands of ordinary operatives working in the ordinary way and with normal motivations. This third phase is apt to be the most critical, but it is one that receives the least attention. There is all the difference in the world between the man in the field station who is excavating a trench in order to test an excavator, and a man on building site who is using an excavator in order to excavate a trench. Technological inventions need to be tested not only for their physical capacities but also for "acceptability", and the latter tests require to be as searching and as rigorous as the former and every bit as much subject to scientific control.

### Resistance to Change

It is a basic misunderstanding to suppose that all resistance to change arises from sheer irrationality and prejudice. Men are not in general implacably opposed to the acceptance of something to their own advantage, but it is only common prudence to look a plausible gift horse in the mouth. Sheer prejudice is on the whole a less serious obstacle to progress than prejudice reinforced, as it so often is, by a measure of reason and good sense. When a man has invested not only his money but also his self-respect in the acquisition of rare skills, it is not a joke to find these skills supplanted by a gadget. The engineer, thinking only of the time it takes to design, construct and install a new and better machine, is naturally impatient at the delays imposed by the need endlessly to explain and convince and reassure everyone concerned, not least those in whose interest and for whose benefit the machine has been conceived. Even a labour-saving device makes work harder and calls for further effort for a time—during a longer or shorter period of transition from the old to the new.

There are cases in which technological changes come about not by changes in persons, but in personnel. New ways of sucking eggs are introduced through the passage of the generations, and this may apply to the techniques of egg production as well. Youth is proverbially susceptible to the arts of the propagandist for any new ideas, and this susceptibility can be turned to good account in technological education. This is yet another reason for the upgrading of the technical schools and colleges, for their closer integration with the organizations for technological research. Even before the age of nuclear fission, it was being suggested that one of the traits of character most needed for life in the modern world is that of being "adapted to insecurity". There would seem to be an almost equal need for being "adapted to change". Extreme attitudes in either direction are equally inappropriate, and equally unconducive to ordered progress. There is scope through our educational system and our publicity services to inject into society a pervasive sense of optimum rates of change, and to diffuse among consumers of goods appropriate habits of obsolescence and replacement. Things are made to last a certain time. A razor blade may be intended to serve the purpose only of a single shave; a pyramid is built to last ten thousand years. How long a thing should last is an item to be included in its specification. How long it is intended to last is something which the buyer of a blade or a pyramid has the right to know. Some goods are sold with a guarantee that they will endure for $x$ years. A buyer might as reasonably ask for a guarantee that they will wear out not so long after that. We hear of motorists who trade in their cars when the ashtrays are full. We all know motorists who contrive "to run the old bus" long after the cost of maintenance has exceeded what is economic.

It is sometimes suggested that industry has overemphasized the importance of durability and quality, and that it would do much better if it designed clothing, cars and buildings so that they wore out. On this there may be more than one opinion. But there can hardly be two opinions on the suggestion that, whatever we do, we should know what we are doing and do what we do with conscious intention.

### Control of Technological Change

The prospects of rational control of the rate of technological change have been significantly enhanced during the present century by the improvement of techniques of publicity, advisory and educational services, and by the development of higher ethical and professional codes in the use of these techniques. Publicity today tends to be factual, informative, genuinely advisory and educational.

Advisory services themselves stand in need of advice scientifically based. Although the relevant knowledge is still very sketchy, much more is established than has yet been applied. It is clear from first principles than an advisory service must be based upon knowledge of actual needs, and of the attitudes, tastes and interests of those to be served. It is clear also from first principles that the effectiveness of any communication will depend upon the extent to which the message is delivered to the right person, by the right person, in the right form and at the right time. It will also depend upon the extent to which the delivery of the message is followed up, its impact assessed and further communications modified in accordance with the "feed back" received. In this way, the results of "mass diffusion" methods of publicity are supplemented by the direction of specific beams of intelligence upon persons and groups in key situations, timed to arrive at the opportune moment, and the effects produced so checked up that future communications can be suitably adapted to the changing situation. Such techniques of communication admit of development in precision and in a scientific way, and through their systematic application the rate of technological change comes increasingly under control.

Here again the fact emerges that advance depends upon the application of scientific method to the human factors in the situation. In a world of electronic factories, directed by an electronic management, assisted by electronic servicing engineers, disposing of its products by electronic salesmen to electronic consumers, there might well be no resistance to technological change. But things have not yet come to that pass. Human management will employ human operators to produce goods and services for human consumers for some time to come. Control of the rate of technological change depends on control of the human factor. The rate of technological change depends upon the rate at which new ideas occur, it depends on the rate new ideas can be transmitted through the relevant lines of communication in production and it depends on the rate of consumer assimilation.

If predictions are not entirely out of order, the guess might be hazarded that the next great phase of technological advance will be one in which human factors in the technological situation are accorded the same scientific regard as is given to raw materials and machines; and when technologists begin to think in terms of the man-machine-materials unit.

How and when and where can we set about it ? Research and development in the human sciences do not follow quite the same sequence as that of research and development in physics, chemistry and the major branches of engineering. Human reactions can be tested in the laboratory and in the field station, but all the most crucial tests are in the field itself.

To summarize: the subject of this discussion has been the control of technological change—control not essentially with a view to its acceleration, since in some directions the pace, perhaps, needs to be slackened.

The major instruments of control are those of formal education, those of the advisory services and the new techniques of "communication", and not least the function of research. There would appear to be three major lines of action, the first directed to increasing the output of inventive minds, the second to the promotion of favourable consumer reactions and the third to facilitating the passage of new ideas into actual goods and services.

## ENGINEERING'S DIRTY WORD

John M. Allderige, *Yale Scientific*, April 1954, pp. 34-36.

Statistics is practically a "dirty" word these days to many engineers. Accordingly, the custom is to begin discussing statistics and engineering with some disarming bit of whimsy and proceed gently, very gently, into the subject. Making fun of statisticians is an accepted gambit, e.g., a statistician is one who has his head in the ice box, his derriere in the oven (burners lit), but on the average feels fine. This is of doubtful utility, however, for some engineers react as that now famous child in the New Yorker cartoon, "I say it's spinach (statistics) and I say the hell with it."

Every engineer in the country has had contact with modern statistical techniques. To some this has been frightful; to others it has been boring; but to an ever-increasing number it has been exhilarating. This last group—this happy band of warriors on the frontier of learning—are using statistics constantly to guide them in procuring and analyzing data, and they are enjoying spectacular success.

A glance through statistics texts would indicate the wide usage of statistics by engineers. Engineering problems form the bulk of problem material. Here is one, just for flavor and to show that this battle can be fought on any level—in this case, the crass, practical one. The following are measurements of the tensile strength of cap screws. The engineer has tested 17 of them and wants to know:

a. How reliable is the average tensile strength figure from these 17?

b. How many cap screws must he test to be sure that he has an answer within 100 lbs. of the right answer?

Tensile Strength
in 1000 lbs.

| $X$ |
|---|
| 18.1 |
| 18.7 |
| 17.3 |
| 18.3 |
| 18.2 |
| 19.0 |
| 18.5 |
| 17.8 |
| 18.3 |
| 16.4 |
| 18.1 |
| 18.3 |
| 17.8 |
| 18.0 |
| 19.4 |
| 17.7 |
| 17.7 |
| 18.7 |

$$\bar{\bar{X}} = \frac{EX}{N} = \frac{308.6}{17} = \underline{\underline{18.15}}$$

$$S^2 \sqrt{\frac{EX^2 - \frac{(EX)^2}{N}}{N-1}}$$

$$= \sqrt{\frac{5609.4 - 5602.0}{16}} = .68$$

$$2.12s_x = \frac{2.12s}{\sqrt{N}} = \frac{(2.12)\,(.68)}{\sqrt{17}} = .35$$

$$N = \left(\frac{2.12s}{.1}\right)^2 = \left[(21.2)\,(.68)\right]^2 = 208$$

His conclusions:

a. The average of 18,150 lbs. is within 350 lbs. of the right answer. That is, there is 95% assurance that the interval from 17,800 lbs. to 18,500 lbs. contains the average that would result from testing a very large (technically infinite) sample of these cap screws with the same testing device.

b. Approximately 208 cap screws will have to be tested to get within 100 lbs. of the "right" answer (as defined above).

The technique used here is not important. Those who know statistics will recognize it; the unfamiliar won't without some study. What is important is to note that two vital questions were answered, and that statistics offered the only objective way in which to answer them. These are two of many questions that statistics could have answered. Some others might have been: What are the major causes for variation? Is this sample the same as another sample just tested? Is there a relationship between tensile strength and, say, the machines used for production?

The fundamental problem facing every engineer is epitomized in this example. This is the usual situation (predicament):

1. The engineer has measured a phenomenon and has some data;
2. The data exhibit variation;
3. The data are just a sample of what the phenomenon can produce in the way of data;
4. He wants to make some statement about what would happen if he were to look at everything, i.e., all data from this phenomenon. Or, in other terms, he wants to make an inference about the total picture.
5. He wants to know just what risk he is taking in making his inference.

The key words are "variation," "sample," and "risk." Here we have the heart of statistics: that discipline which coherently relates variation, the behavior of samples, and risk or probability. So it is only logical that engineers do turn to statistics to learn, unequivocally, what inference to make and the associated risk, just as was done in the example.

Now, this line of reasoning applies regardless of the engineer's specialty whether the data are pounds, inches, time, or dollars. It very specifically applies to the latter—to general administrative work, reverently referred to as "management," which some engineers get to eventually. Organizational problems more and more are being tackled by statistical techniques. The whole field of operations research attests to this growing application of statistics (and mathematics). The manager of today is considerably better off if he has an idea of what these specialists are doing; some have worked hard on their own to do so.

The typical situation described, then, is easily seen to be universal; statistics offers the universal basis for resolving it. It is thus that many engineers in all capacities do and can use statistical techniques.

### Statistics and Scientific Method

But, is such apparently "vocational" material admissible in a course of study that is trying to be purely "educational"? Perhaps as a start it might be well to locate this discipline of statistics within the framework of the scientific method to see if it is just a "gimmick," or if it is fundamental. The scientific method has six traditional steps:

1. Definition of the problem by appropriate study of the facts at hand;
2. Formulation of a hypothesis—a purely tentative explanation relating the facts;
3. Design of an experiment to test the validity of the hypothesis;
4. Gathering the data from the experiment;
5. Analysis of the data;
6. Drawing a conclusion that the hypothesis is either affirmed or denied. This often offers more facts leading to a new hypothesis and so forth.

One school holds that statistical methodology only enters in Steps 3, 5, and 6. Statistics is generally recognized as a cornerstone of experimental design; it is vital in data analysis as we have seen in our example; and it suggests a conclusion by stating, quantitatively, the probability associated with accepting or rejecting the hypothesis. Another group maintains this to be a limited view, that experimentation is scientific method and, hence, statistical method is synonymous with scientific method.

The above discussion alone should convince the doubter that statistics is no "gimmick." From the previous remarks it is apparent that statistical training can help an engineer develop his abilities for formal thinking. Formal thinking implies objective reasoning or mutually understandable reasoning. This reasoning process quite often employs numbers—indeed, the more often, the more likely is objectivity—and statistics automatically comes into the picture since it is the mutually understandable manner of handling numbers.

Clear expression is usually linked with words—both written and spoken. Yet, in a profession, the avenues of expression are wider; they include symbols, numbers, and diagrams, as well as words. In the previous example there is no more succinct expression for the analysis used than that shown. At its own level, the meaning is immediately apparent. For those unfamiliar with the jargon, there is no meaning. Granted. Explanation at that level would be far more involved; it would entail a basic course in statistics. But how eloquently this fact points up the power of expression of this new language! How much it then behooves the engineer to embrace statistics with its great capacity for clear, compact expression.

Statistics appears to have deep roots. No discussion of the philosophy of science can disregard the impact of statistical methodology on science and, therefore, engineering. All this is not surprising; no really powerful tool, such as statistical inference, could possibly be without solid foundation. The subject matter is not just vocational, although most engineers can put statistics to work quite rapidly and with stunning success. It is definitely and thoroughly educational.

Quite frankly, an engineer with statistics can tap the mother lode. That's why it is used so much.

# From Month To Month

**Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers**

## Columbia River Power

From time to time the *Journal* has given space to comment on the state of the discussion on Columbia river power, which has been going on before the International Joint Commission since 1944. Briefly, the situation is that a proposed development near Libby, Mont., would back the river up some 40 miles into Canada to a depth of about 150 feet at the border, flooding roads, railways, settlements, agricultural and forest lands and other improvements and making some future forest and mineral development impossible. Storage of water in Canada would not only increase the available head and flow at Libby, but would also increase the flow at all plants on the river below Libby.

These general facts are agreed upon by both Canada and the United States. Both are also agreed that Canada should receive just compensation for the damages which its citizens would suffer from the scheme and for the benefits which the Libby and other developments would receive from water storage in Canada. Both are agreed on compensation, but they are far from agreement on the equitable method of compensation. The United States wishes to assess both damages and benefits in terms of money; Canada wishes to receive its share of the power which storage and head from Canada will produce — and there the matter rests.

Canada appears to be quite right in its position, and it is to be hoped its views will prevail. Not only does this position seem right in equity, but there are two factors supporting that belief.

A powerful one is that twenty-five years ago the International Joint Commission heard a case involving the flooding of a small area in Maine by a dam built across the St. John river at Grand Falls, N.B. Here it was successfully argued by the United States that the party whose land was to be flooded might permit it or not at its discretion, and that if it did permit flooding, then it could make the flooding subject to any conditions it wished. Counsel for the United States argued that compensation could be ordered in any form desired by the United States, including the delivery of power.

Gen. A. G. L. McNaughton, M.E.I.C., chairman of the Canadian Section of the International Joint Commission, in speaking recently to the Canada-United States Committee of the Canadian Chamber of Commerce and the Chamber of Commerce of the United States, said:

> "Out of this first experience of the International Joint Commission (i.e., the Grand Falls Case) in the allocation of power in compensation for flooding, has emerged the principle that the upstream state is entitled to receive an allocation of on-site power proportional to the increase in level at the boundary, or at the point where 'boundary waters' commence, as the case may be, multiplied by the flow pertaining to it at that point, that is, the whole flow in the case of 'rivers flowing across the boundary' and half the flow in the case of waters flowing out of 'boundary waters' where the two states have 'equal and similar rights'."

It would seem that this principle, arrived at twenty-five years ago upon the insistence of the United States, applies just as much to the Columbia as it did — and does — to the St. John. We do not profess to know all the ins and outs of the law, but we do feel strongly that the attitude of the Canadian Section of the International Joint Commission is the right one and we hope they will stick to it. It has precedent and it is equitable. It is to be hoped that Canada does not suddenly withdraw its resistance to the United States claims, as they appear to have done recently in the St. Lawrence seaway project.

Second, it may be mentioned as a hopeful trend that claims between the states of the United States for compensation in connection with the development of the Columbia, which it was first proposed to settle by money payments, now look as though they might be adjusted by compensation in power. If this is a fair method as between states, why

## Cover Picture

The cover picture is a view of the main assembly bay at the Guelph Works of the Canadian General Electric Co. Ltd. The test area is in the background.

The bay, 804 feet long by 80 feet wide, is part of C.G.E.'s 8.5 acre plant recently opened to manufacture power transformers with a lower limit of 201 k.v.a. and 15 k.v., and an upper limit of 200,000 k.v.a. and 287 k.v. Total personnel when in full production will be about 1,000.

is it not equally fair as between nations?

The International Joint Commission has arrived at workable compromises in some sixty cases since it was set up and there is no reason to believe that it is going to fail in this one, but the Columbia case needs to be kept before the public. It should not be forgotten merely because it is not in the headlines every day. Members of the Institute and all other Canadian engineers can do much to see that it gets the publicity it deserves during the four or five years yet which are required for the completion of surveys, for study and for discussion.

## The Pendulum Swings

In the News of the Associations, from British Columbia, readers will find details of an event which will mean relief to a group of young engineers in that province, and to the profession generally it marks another important step toward freedom from unfair labour laws. Far too long we have had the unpleasant spectacle of a group of professional men being forced to belong to a union against the wishes of their majority. Some felt that the pendulum of fair play and justice had become stuck on the wrong side. However, the situation appears to be righting itself at last, and the *Journal* wishes to commend those of the B.C. Association, and the others, who are fighting with such determination to correct this fault. The final whistle in this struggle has not yet blown, but our team have made a nice gain and they are getting in position to score.

## Famous French Dam Builder Visits Canada

For a period of about three weeks in October the E.I.C., through seven of its branches, was host to one of France's most eminent engineers. Monsieur André Coyne, one of the world's foremost authorities on the design and construction of dams, made a speaking tour by air transportation to seven of the larger branches between Montreal and Vancouver. His subject at each meeting was the same — "Twenty-five Years Designing and Building Dams". Mr. Coyne's lecture was well illustrated both with slides and moving pictures, and reports reaching Headquarters indicate that it was received with interest and enthusiasm.

The visitor arrived first at Montreal on October 8, where he was met by a representative of Headquarters staff and final itinerary details were arranged. Mr. Coyne flew next to Saskatoon where he was booked to spend Thanksgiving week-end, although he did not speak in that city until later in the trip. The P.F.R.A. arranged for him, while there, to visit the site of the proposed South Saskatchewan River Dam, in which he showed keen interest.

The speaker then went on to open his lecture schedule in Edmonton on Tuesday October 12, and repeated it in Vancouver on the 14th. The West Coast city branch executive were able to include a trip to the Vancouver Capilano water system where Mr. Coyne saw the new Cleveland Dam. His itinerary then took him eastward again, and the lecture was delivered at Calgary, Regina, Saskatoon and Winnipeg from October 18 through the 21st. The final presentation was before the Montreal branch on Tuesday the 26th.

At every branch he visited, the reception given to Mr. Coyne's address was testimony to the high calibre of his work and ideas. This is certainly borne out by the many distinctions he enjoys, which include the past presidency of the International Commission on Large Dams, occupancy of chairs at Ecole Nationale des Ponts et Chaussées and the Ecole Supérieure d'Electricité, and honorary membership in the American Society of Civil Engineers, to mention only a few.

The Institute is indeed fortunate in having been able to arrange a lecture tour by such an eminent French colleague.

## New Officers for ASCE

William Roy Glidden, of Richmond, assistant chief engineer of the Virginia State department of highways, has been elected the 86th president of the American Society of Civil Engineers, succeeding Daniel V. Terrell, of Lexington, dean of engineering at the University of Kentucky.

A native of Boston, Mr. Glidden graduated from the Massachusetts Institute of Technology in 1912. For several years he was on the staff of the Massachusetts Highway Commission. Upon recommendation of the U.S. Bureau of Public Works, he was invited by the State of Virginia in 1916 to take charge of the bridge division of its highway department. He has been engaged since then in Virginia's many millions of dollars of highway and bridge construction.

Mr. Glidden has made important contributions to the evolution of highway bridge engineering during the past generation through his own practice and through membership on various technical committees. He is also well known as a lecturer on engineering subjects at colleges and universities and before professional societies throughout the United States.

The newly-elected vice-presidents of the Society are Frank L. Weaver, Washington, D.C., chief, division of river basins, Bureau of Power, Federal Power Commission, and Louis R. Howson of Chicago, partner in Alvord, Burdick & Howson.

The Society's new directors are Don M. Corbett, Washington, D.C., district engineer, U.S. Geological Survey; Lawrence A. Elsener, San Francisco; Jewell M. Garrelts, professor at Columbia University; Frederick H. Paulson, Providence, R.I.; George S. Richardson, Pittsburgh, and Graham P. Willoughby, Birmingham, Ala.

### Athlone Fellowships

The existence of Athlone Fellowships for Canadian engineering students completing a bachelor's or higher degree, and for engineers who have already spent some time in industry, is well known.

Prospective candidates can find a complete outline of provisions and regulations in *The Engineering Journal* for November 1953. The closing date for applications is January 15, each year.

The upturn in registration of engineering students at Canadian universities which started in the fall of 1952 is still continuing.

Total registration for the 1954-55 term as compiled by The Engineering Institute shows 10,292 as against 9,047 a year ago, an increase of approximately 1,250.

Two institutions have registered students in first year engineering for the first time this fall. These are the Collège Militaire Royal de Saint-Jean at St. Johns, Que., and The University of Western Ontario at London, Ont. where engineering has now been added to the other courses given previously. Including the registration of these two newcomers in the field of engineering education the total of first year students is 3,441. This represents an increase of almost exactly 10 per cent over that in the fall of 1953. Of the twenty institutions which reported first year students last year, fourteen show an increase this year, five show a decrease and one reported the same number.

As was anticipated, the graduating class for next spring is larger than the 1954 class was by just over 10 per cent. Furthermore the number who should graduate in 1956 is likely to exceed the number of 1955 graduates by approximately 20 per cent. This will represent an increase over the small class of last spring approximating 50 per cent.

Registration in the different courses has departed only slightly from the pattern already established. Most of the courses are larger in proportion to the amount of the overall registration. Only one course —forest engineering—contains fewer students. On the other hand the increases in aeronautical and mining engineering are somewhat greater relatively than the overall average increase.

# C.A.I.-I.A.S. International Meeting

About 400 aviation people registered in Montreal on October 14-15 for an international professional conference of special significance. This meeting marked the first advance of the Canadian Aeronautical Institute in the field of international exchange of technical knowledge, as well as a new avenue of professional co-operation for the Institute of the Aeronautical Sciences. Dr. J. J. Green, M.E.I.C., of Ottawa referred to it as a milestone in Canadian aviation.

Dr. Green is the president of the C.A.I., a Canadian organization founded earlier this year with the object of advancing the art, science and engineering relating to aeronautics. At the invitation of the I.A.S. the joint meeting was arranged, with a program which was in effect a thorough survey of the art and science of aeronautics on this continent as of today—and a look at the future. The program is printed here as a matter of interest:

**The Role of Fluid Mechanics in Aeronautical Development**
Dr. G. N. Patterson, Director, Institute of Aerophysics and Head, Department of Aeronautical Engineering, University of Toronto.

**Flying Techniques on Research Airplanes**
A. Scott Crossfield, Aero Research Scientist, NACA High-Speed Flight Station, Edwards Air Force Base.

**The Nature and Stiffness of Swept Wing Deformations with Reference to the Prediction of Normal Modes and Frequencies**
Albert H. Hall, Associate Research Officer, National Aeronautical Establishment of Canada.

**The Orenda and the Future; Mechanical Design Considerations of Canada's First Production Turbo Jet**
B. A. Avery, Assistant Chief Design Engineer, Gas Turbine Division, A. V. Roe Canada Limited.

**Bases Unlimited**
Ernest G. Stout, Chief of Naval Aircraft Research, Convair Division of General Dynamics Corporation.

**Production of an All-Weather Long-Range Jet Fighter**
R. K. Anderson, Assistant Industrial Engineering Manager, Aircraft Division, A. V. Roe Canada Limited.

**Air Traffic Control for Turbine Transports**
Charles W. Carmody, Civil Aeronautics Administration.

**R.C.A.F. Training Operations**
W/C C. H. Mussels, C.O., R.C.A.F. Central Flying School, Trenton.

**Design Aspects of the Boeing Model 707**
Kenneth C. Gordon, Boeing Airplane Company.

The response was enthusiastic. This was evident early in the proceedings—when a good attendance could be reported by I.A.S. secretary H. C. Luttman, as the first session began on Thursday, October 14. As the registration continued, Montreal, Ottawa and Toronto provided the greatest part of the group, though there were representatives from all over Canada, and more than 100 from the United States.

Members from the technical staffs of the manufacturing firms, and from the government departments, the airlines and the Services made up an audience with real interest in what the speakers had to report. For the layman, too, there was information of value in many of these stories of development, for example, the evolution of the Avro Orenda 9 and 10 turbo-jet engines; the system of design and production that saves two years' time in the delivery of production models; the story of Boeing's first venture into jet transport; the plans for air traffic control of jet transportation.

Canadair Limited provided for the group a tour of inspection of the manufacturing facilities for the Sabre (F-86) and Silver Star (T-33) aircraft.

Dinner on Thursday evening, brought together more than five hundred members, guests and friends of the two sponsoring societies, with Dr. Green presiding, and with Rear-Admiral L. B. Richardson representing I.A.S. Here again, in the social part of the conference, there was an impression of a rapidly advancing aviation industry lending support to the successful initial efforts of its professional society.

Dr. Green and Admiral Richardson each expressed hope in the effectiveness of this new link between Canada and the United States. The further close contact of the two societies with the Royal Aeronautical Society, Admiral Richardson said, would tend to benefit the aeronautical profession and contribute to the peace of the world.

Dr. Green announced the award of honorary fellowship to George H. Dowty in recognition of his contribution to aeronautical science. Through the Royal Aeronautical Society of which he is a past president, Mr. Dowty had given encouragement and help in the formative stages of the Canadian institute.

Dr. Hugh L. Dryden, director of the U.S. National Advisory Committee for Aeronautics, was the principal speaker for the dinner meeting. He mentioned the inaugural

**Some of the head table guests at the Montreal C.A.I.-I.A.S. meeting. Left to right, Dr. E. P. Warner, I.C.A.O.; Dr. O. M. Solandt, Defence Research Board; Dr. Hugh L. Dryden, the speaker; Dr. J. J. Green, president of C.A.I.; Rear-Admiral L. B. Richardson, Canadair Limited; John Baldwin, Department of Transport.**

technical meeting of the Institute of Aeronautical Sciences in 1933, at which one of the topics was "The Application of Science to Design".

Then, Dr. Dryden said, it was advocated that designers keep abreast of advances in aerodynamic theory and study their possible practical applications. A few months earlier the United States had achieved the land plane speed record of 296.287 miles per hour. The projects occupying design engineers today differ to the extent that we can now talk about a research plane that has attained a speed of about 1,650 miles per hour.

While this improvement in performance has been accomplished during 20 years by scientific method, Dr. Dryden expressed the opinion that there remains an art as well as a science of aeronautics, and he went on to discuss the interplay of scientific research and the art of design in aeronautical progress.

"Research advances knowledge by isolation of limited aspects of development problems which are analyzed by specialists in specific fields", said Dr. Dryden. "The designer of an aeroplane or missile must solve all of the many problems in a single integrated prototype. Design is still an art practiced by individuals or groups of individuals in a design team. They must have general knowledge of many fields and the ability to synthesize information from many sources."

The collaboration of scientist, designer and user which has multiplied speed more than 5 times in 22 years, will solve new problems already being encountered, Dr. Dryden predicted. Supported by a vigorous scientific activity in aeronautical research, the art of design will flourish, and visions hitherto unrealizable, will become practical engineering projects.

T. R. Loudon, M.E.I.C., the well-known professor of civil and aeronautical engineering at University of Toronto until his retirement this year, spoke briefly in appreciation of Dr. Dryden's contribution to the program.

---

# IATA Meets in Paris

The tenth annual general meeting of the International Air Transport Association, head office for which is in Montreal, was held September 13 to 16, inclusive, at the Maison de la Rochefoucauld, Paris, France, its first general meeting to be held in that city.

Some 250 delegates from 40 countries, representing 47 member and associated airlines which carry 86 per cent of the free world's scheduled air traffic, as well as observers from other international organizations and aviation and transport groups, were welcomed by spokesmen from the French government. Max Hymans, president of Air-France, presided as the first president of the organization from the French Republic. Juan Trippe, president of Pan American World Airways was elected IATA president for the ensuing year.

Sir William Hildred, director general of the association, in surveying the global operations of member companies at the opening session, told delegates that the margin between Airline costs and revenues "has steadily narrowed down until it is in many cases non-existent. One can foresee no miracles, technical or otherwise, in the near future which can be expected to change this balance."

### Economic Situation of the Industry

Airlines, he said, are now collectively paying almost 13 cents out of every dollar collected to governments in taxes and charges, and are left with only one cent to pay interest on their indebtedness, to satisfy shareholders and to keep as reserves. Present and proposed new passenger taxes and landing fees are "a problem for the trunk carriers and a disaster for the short-haul airlines, particularly in Europe".

He urged "scrutiny of our own operations to make certain we are not wasting a penny on a single unnecessary procedure or paper". Increased productivity through technical efficiency alone, he said, was no longer sufficient in itself to offset other cost increases.

### Airline Performance

Continuing, Sir William reported that an increase in productivity of IATA airlines in terms of seat-kilometres during 1953 of 22 per cent had been achieved, with only a five per cent net increase of airline fleets. This had been due to modernization, conversion of many aircraft to tourist seating, and to increased efficiency generally. Traffic itself had increased in all categories over the 1952 records, but while passenger traffic increased 16 per cent, cargo traffic only rose four per cent. The seven per cent increase in airmail carried had been small, considering the reduction in the rate paid to airlines.

Airlines still derive 70 per cent of revenue from passengers, and would continue to rely on them for their main income. But fares had been cut to a point where the margin was extremely small. "Our remaining hope for expansion, then", he predicted, "lies primarily in the cargo field. The cargo rate structure needs careful examination. If risk is involved, we can take comfort from the fact that we have taken equal risks in the passenger field and they have paid off."

### Tourist Service

Growth in extent and popularity of tourist service had been gratifying. Almost two thirds of North Atlantic traffic now flew tourist, and before long the bulk of world passenger traffic would be tourist, he stated. Nevertheless, conversion to tourist class had in some cases been too swift and sweeping, resulting in first class passengers being refused while tourist seats had gone unfilled. Aircraft, he warned, should be kept as fully adaptable as possible until the differences between first and tourist are fully crystallized.

### Helicopter Development

"Helicopter operations have been spreading rapidly", reported Sir William, "The helicopter is ideally suited to certain types of scheduled operations, especially in Europe and in other regions of high population densities, but limitations placed on single engine helicopters keep them from being ideal vehicles for scheduled traffic at the moment."

### Technical Committee Report

Paul W. Goldsborough of TWA, reporting as chairman for the IATA Technical Committee, told delegates that the airlines' chances of having governments provide adequate air navigation services and facilities would be improved, only if they keep the requirements for the number of ground systems to a bare minimum consistent with safety and efficiency. Airlines stand to gain both technically and economically, he said, by purchasing modern airborne equipment as soon as possible.

The present high frequency radio telephony system in Europe was not adequate to fulfil the present need, though it was coming into ever more widespread use, the report said, but more extensive examination of the whole regional system was needed.

More effective co-ordination of civil and military aircraft operation was another pressing need in Europe, stated the committee report. It continued, however, "There are now first indications, at long last, that the importance of this problem has been recognized by military authorities." Another repeated problem was lack of agreement on uniformity of altimeter setting procedures. A uniform system was almost achieved by ICAO last year, but inability of some states to accept an ICAO system leaves the choice to the discretion of individual countries.

Airline search for the ideal turbine fuel for jet and turboprop craft is proceeding well, the Committee reported, defining the ideal fuel as one "which would have lowest cost consistent with other requirements; be no less safe than kerosene; be generally available at world airports; preferably marketed already for other users; ensure reliable and economic engine operation; and have as high a heat content per gallon as practicable".

"Up to now high grade and costly fuels had to be developed for high performance aircraft and engines", the committee reported. "Looking to the future, we (hope) to present to manufacturers a specification for a cheap turbine fuel so (they) will design the engines and aircraft for the fuel we want."

Development of an economically satisfactory helicopter for regular transport is outpacing provisions of adequate facilities and regulations for its operation, the committee warned. Present helicopters are limited by high operating costs in relation to payload, and a commercially attractive helicopter suitable for public transportation is still in the development stage. However, airlines have developed specifications of what they require. To keep pace, IATA is working on such questions as flight rules, different requirements between conventional aircraft and helicopters as regards air traffic control, communications, meteorology, navigation, licensing and integration of operations.

With regard to training and licensing, discussions of pilot training indicated a need for greater concentration on the problems of the men who fly the airline's planes, the Committee said. "Airlines themselves can do useful service in attempting to curb government regulations: flexibility in training is essential to ensure safety of operation. Excess regulations can impede this flexibility, and hence impede safety."

The committee declared that airlines over the next five to ten years would have to spend money on a new type of instrument to replace the present conventional altimeters, which are becoming obsolete as aircraft begin to operate in more and more rarified atmosphere. Levels would have to be based on constant pressure intervals, instead of the number of linear units above the ground, it pointed out.

Special importance was also attached to the establishment of future operational requirements for long distance navigational aids. A further imperative objective must be to lower the operating limits within which flights are capable of landing and taking off under adverse weather conditions. Whether improvements could be achieved by the development of automatic landings would have to be revealed by further research. An international review of national legislation affecting air transport operations from the point of view of economic sufficiency as well as of safety, was also becoming necessary, the committee reported.

# Thirty-five Years Ago

**Comment on the *JOURNAL* of December 1919**

The first thing that struck this writer when he leafed through the December, 1919, *Journal*, preparatory to getting out these notes, was the obvious shake-up in its advertising pages. Not only was there a general improvement in typography, including more use of illustrations, but many firms appear for the first time, firms some of which are still with us as advertisers. Somebody had very evidently been stirring the advertising pot with good results.

### Peterborough Branch

Council meetings for October 28 and November 25, 1919, were reported, both with fairly heavy agenda. The formation of the Peterborough Branch was approved; elsewhere in this *Journal* there was a short account of its installation, which attracted quite a concourse of engineers from the area. The Toronto Branch salary schedule, of which we have previously written in these notes, came up for discussion, but, because of its importance, consideration of it was postponed.

The Society of Chemical Industry was granted permission to meet in the Institute's hall in Montreal twice a month. The design of the Plummer Medal was approved. A suggestion from H. M. Morrow for the reclassification of the Institute's membership was held over for discussion. It took many years to get any such scheme into effect. It would be interesting to know why the Institute's bank accounts were ordered transferred to the Canadian Bank of Commerce, but no hint is given, just the bare fact.

In the long list of admissions and transfers the name of J. N. Aggiman appears; he was then chief engineer of the Ha Ha Sulphite Co., Ltd. Aggiman was a Turk who had been educated in Canada and who subsequently went back to his own land, where he built up a most successful contracting business. He was an ardent supporter of the new order in Turkey and did much of the work incident to setting up Ankara as the new capital of the country. He also served as consultant to the government on numerous projects. Aggiman was—and perhaps still is—the kind of man who enhances Canada's reputation abroad.

An editorial apology notes that the author of "Can the Standard Measure of Value be Improved?", of which we had something to say here last month, was John G. Sullivan, of Winnipeg, and a similar apology was extended to another author whose name had been omitted in the November, 1919, *Journal*. The tradition of editorial errors extends back a long way.

### Research in Canada

In the course of some remarks on research in Canada, the editor said:

> "The word 'research' is much like 'calculus' to the engineering student. Just when the engineer-to-be is becoming thoroughly convinced that calculus is an invention of the evil one . . . he discovers that it is not merely an instrument of torture in the hands of a professor, but an extremely practical help in the solving of such matter-of-fact

problems as the design of steam turbines."

The *Journal* is, of course, all for the proposal that the Federal Government should set up a research bureau and thinks that the Institute could "do a great deal in . . . promoting the furtherance of research in the Dominion." This proposal was the genesis of the National Research Council which has developed to the point where there is hardly anything in which it is not interested.

Reclassification of the Civil Service was still in the news. The bill had become law, to take effect effect on April 1, 1920. The general features of the act were set forth in another editorial by C. V. Putnam. He concluded that the new arrangements would "give Canada, if not the best, at least one of the best and most workable civil service acts in any country."

**Technical Discussions**

S. B. Wass discussed "The Economy of Treating Railway Ties." Tie treatment in the United States began in 1880 in a small way; by 1914 about 44 million ties were being treated annually, while in Canada the figure was 3,915,000 for 1915. According to Mr. Wass, a treated tie cost about 19c a year, against 22c for an untreated one. The saving amounted to about $68 per mile of track per year.

Slightly out of the engineering groove was "Duty-of-Water Investigations in Alberta," by F. H. Peters. "Duty of water" means the quantity of water required to irrigate one acre of land for the irrigation season and naturally varies with the crop grown. The Alberta experiments showed that wheat needed the most water and sugar beets the least. The chief value of this paper lay in the graph summarizing the results, which is presumably as good today as when it was drawn.

A paper by P. A. N. Seurot, "Coal Briquetting and Conservation," may have been of great interest in 1919, but would not be today. The arguments for making a marketable product out of slack and dust may yet be strong, but changes in our fuel situation have made the financial aspects of the process less attractive than formerly. Mr. Seurot's paper showed evidence of careful preparation and was certainly one of the best to appear during 1919.

**Report of Boundary Commission**

J. J. McArthur published a summary of the "Report of the International Alaska-Yukon Boundary Commission," which had just been submitted to Parliament by the Commissioners appointed in 1906.

In 1825 the 141st Meridian was set as the boundary between Russian and British possessions in the northwest, and this boundary remained in effect, of course, after the sale of Alaska to the United States. No effort was made to locate it until 1887, when Ogilvie located the point where it crossed the Yukon river. He used a spruce stump for his instrument stand and worked in temperatures down to 30° below zero. During the gold rush, Ogilvie's line was extended to prevent international complications.

The 1906 Commissioners, O. H. Tittman for the United States and Dr. W. F. King for Canada, found the meridian 17.62 feet west of Ogilvie's line. 1913 saw the end of the field work and the rest of the time up to the submission of the report was occupied in preparing maps and the like. These included a triangulation map along the boundary and a topographic map at 1:62,500 with 100-foot contours covering a strip two to two and half miles wide.

Mr. McArthur paid especial tribute to the complete co-operation between the forces of the two countries. They functioned as a single unit and nobody ever stopped to think whether he were American or Canadian. Engineers seem generally to get along with less friction in international relations than some other people.

**The Branches**

The Halifax Branch was shooting for an attendance of 200 at its forthcoming professional meeting to beat Saint John's record of 125 in 1919. The Saint John Branch had recently listened to papers on the Cape Bald breakwater and on New Brunswick highways. The Montreal Branch was debating the formation of a Quebec Provincial Division. The Ontario Division was getting ready to present a bill, based on the Institute's model, to the provincial legislature, to regulate the practice of engineering. The Toronto Branch had had a "social evening", with magic, music and recitations, mostly by its own members. The Niagara Peninsula Branch was trying to persuade Premier Drury to appoint an engineer as provincial minister of public works. The Ottawa, Edmonton, Vancouver and Victoria Branches were granted only a paragraph or two each, as they had little to report.

A letter from a member in England asked for drawings of frame buildings as "There is a big movement now taking place to adopt Canadian style of housing." He also wanted data on hot air heating, as "People cannot realize here how simple and inexpensive such installations are in Canada."

Even if the *Journal* has never published special holiday numbers, members in 1919 got a Christmas present of a better than usual issue.

---

# The St. Lawrence Had a Lover

**by G. R. Stevens**

The article which follows, concerning the St. Lawrence River and Thomas Keefer's life-long association with it, first appeared in the *Montreal Star* of April 6 of this year. The *Journal* feels that in addition to its general interest, Mr. Stevens' article can well be reproduced at this time in view of the start recently made on the consummation of his great dream—a steamer passage from the lakes to the sea. The article, however, fails to mention another striking fact concerning Mr. Keefer's life. In addition to being the first president of the Institute in 1887, in the following year he achieved the same office in the American Society of Civil Engineers—a feat which has never been duplicated to this day.—Ed.

Every year, when the ice goes out, the master of the first ship to reach Montreal gets a gold-headed cane and his picture in the newspapers; but nothing ever is done about the river. The pleasant Indian and Italian custom of casting garlands upon streams in springtime spate is not observed upon this continent, where Ol' Man River is expected to keep rolling along. Nevertheless the St. Lawrence has had its devotees. For nearly three-quarters of a century it had one constant lover, a diverse and talented man of many parts—engineer, poet, evangel and social philosopher. Today he would be classified as Public Relations. He regarded himself as a dreamer of dreams.

His name was Thomas Coltrin Keefer, born of loyalist stock at the village of Thorold in the Niagara peninsula in 1821. Throughout his life he insisted upon the mystic and indissoluble union of Canada with its parents, Great Britain and France. At eighteen he was an engineer upon the Erie Canal; he soon returned to Canadian waterways, to become their protagonist and special pleader for the remainder of his long life. In 1845 he was

Chief Engineer of the Ottawa River Works, in charge of the log chutes and skidways which expedited the passage of timber to ports of lading.

Eight years later he was Chief Harbor Commissioner of Montreal. But he never was chair-borne for very long at a time. Throughout the sixties and the seventies he planned and supervised scores of waterway projects, mostly for the improvement of traffic conditions upon the Canadian rivers. He became the Grand Old Man of Canadian engineering and honors were heaped upon him, not only by Canada but also by Great Britain and the United States. He died in 1915.

### Writing Was His Joy

The prolific period of his life lay between 1848 and 1863. In the former year he lost his job through a change of government. Whereupon he took up the pen; in a series of books and in scores of pamphlets, articles and addresses he hymned his devotion to the bounty of nature as revealed in Canadian lakes, streams and rivers. As one writer put it, "Keefer believed that the good God (with due regard for the theories of Jeremy Bentham) had located the St. Lawrence in such a way as to promote the greatest happiness for the greatest number." He saw that river as the tie which had bound New France together; which had given Quebec the cohesiveness and stability which it retains until this day. It was both a material and a spiritual highway. It had made Canadians out of Frenchmen.

That cohesiveness and stability, according to Keefer, was only the first of the great gifts of the St. Lawrence. The river was a broad passage into the heart of a virgin continent whose commerce sooner or later must take to the seas. There were two great water-roads to the oceans—the Mississippi and the St. Lawrence. Keefer was certain that the St. Lawrence could command the traffic of the West; as proof he drew what was perhaps the first strategic map; he tilted North America to show that the St. Lawrence flowed towards Europe while the Mississippi flowed away from that continent. The Erie Canal, which had made New York the metropolis of the Atlantic seaboard, disturbed him no whit. The three factors which bestowed or withheld greatness from a transportation system were time, expense and convenience. On each count Keefer believed that the St. Lawrence could win.

As an engineer he was not blind to the imperfections of his beloved river. It was frozen for five months of the year; therefore there must be railways and ocean ports to supplement it. But although in one of his books ("The Philosophy of Railroads" which is perhaps the first essay in distinctively Canadian economics) he argues strongly for the social and material benefits of land lines, he always maintained that railways should be auxiliary to water transport, which is handier and cheaper. Insofar as natural obstacles were concerned on the St. Lawrence system—falls, rapids, and portages—he had one sovereign remedy—to cut more and more canals, until there was uninterrupted navigation for a thousand miles to the west, so that the ships of all nations could pick up cargoes at every cove on the Great Lakes. If New York could cut in on Great Lakes traffic by means of the Erie Canal, Montreal, declared Keefer again and again, could help herself to Hudson and Lake Champlain traffic by means of a canal no more than fourteen miles in length between the St. Lawrence and the Richelieu. He fought vehemently for this particular waterway. To his great sorrow it never came to pass.

### The Prophet

It was H. G. Wells who coined the phrase "Transportation is Civilization." Keefer had expounded the same idea explicitly forty years before the Fabian Essays appeared. He drew a vivid picture of what communications meant to pioneers:

"A town arises. Land increases rapidly in value. The neglected swamp is cleared and the timber is converted into all sorts of wooden notions. Tons of vegetables, grains and grasses grow where none grew before. The tick of the loom, the rush of the shuttle, the thundering of steam hammers mingle in a continuous sound of active industry." But it did not stop there. Keefer saw the St. Lawrence as another Ganges, not only enrichening the land but purifying its inhabitants. He declared that commercial intercourse as engendered by better communications, would raise the tone of Canadian life, which he plainly regarded as low. He speaks of "agricultural rustics" beholden to the local storekeepers in such matters as "mortgages, long credits, tea and tobacco" and dependent for their political opinions upon "nisi prius wranglers." How the St. Lawrence was going to clean up this situation remains a little obscure. It was asking a lot of the river. But it was the measure of Keefer's faith that he demanded so much.

When the St. Lawrence Seaway finally goes through his name should be preserved upon one or another of its works, for it was he who first dreamed the dream of its consummation.

---

## Addresses Wanted

The records office at E.I.C. Headquarters requests information about the present addresses of the following members with whom it has lost contact. The last known location of each is listed, and any current information will assist in making membership records complete. The list will be concluded in the January issue.

### Members

Ansley, F. C., Riverside, Ont.

# News of Other Societies

The 41st annual meeting of the **Canadian Pulp and Paper Association,** technical section, is scheduled for January 26-28, 1955, in Montreal.

Other officers, are J. J. Waller, vice-chairman; A. H. Lewis, past-chairman, A. W. Smith, honorary treasurer, and H. Neville Mason, secretary.

---

Meetings of all sections of the three divisions of the **Canadian Electrical Association** (Room 714 Tramways Building, Montreal 1) in eastern and western zones, will be held in Niagara Falls, Ont., January 25-28, 1955, and at Saskatoon, Sask., March 7-9, 1955.

---

The Ontario Section of the **American Society of Lubricating Engineers** is sponsoring a course in industrial lubrication through the facilities of the extension department of the University of Toronto.

Information about the course, beginning February 9, 1955, can be obtained from C. I. R. McDougall of the Ontario Hydro, or from Mr. Kirk of the University of Toronto Extension Department.

---

Professor James U. MacEwan, chairman of the department of metallurgical engineering, McGill University, was elected chairman of the Montreal chapter of the **American Society for Metals for 1954-55.**

---

The **Chemical Institute of Canada** (18 Rideau Street, Ottawa 2, Ontario) announces the following schedule of meetings: February 24, 1955, conference of the Protective Coatings Division, Toronto; February 25, conference of the Protective Coatings Division, Montreal; March 7-9, conference of the Chemical Engineering division, Ottawa; April 14-15, sixth Canadian High Polymer Forum of C.I.C. and the National Research Council, St. Catharines, Ont.; May 30-June 1, the thirty-eighth annual conference and exhibition, Quebec City.

---

The annual meeting of the **American Society of Heating and Ventilating Engineers** (62 Worth St., New York 13, N.Y.) will take place at Philadelphia Pa., January 24-27, 1955.

---

The **American Concrete Institute** (18263 West McNichols Road, Detroit 19, Mich.) will hold the fifty-first annual convention at the

Hotel Schroeder, Milwaukee, Wis., February 21-24, 1955.

---

The winter general meeting of the **American Institute of Electrical Engineers** (33 West 39th, New York 18) will be held in New York, January 21 to February 4, 1955.

---

**The American Institute of Mining and Metallurgical Engineers** (29 West 39th St., New York 18) announces the annual meeting for February 13-17, 1955, at Chicago, Ill.

---

The 1955 committee week of the **American Society for Testing Materials** (1916 Race Street, Philadelphia, Pa.) will take place from January 31 to February 4, at the Netherland Plaza Hotel, Cincinnati, Ohio.

---

# Elections and Transfers

At the meeting of Council held at Lethbridge, Alta. on Saturday, November 27, 1954, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

*Members:*

D. A. Aitken, *Montreal*
K. H. Barnard, *Kingston*
A. M. Clark, *Toronto*
G. H. Crase, *Calgary*
N. Gritzuk, *Whitehorse*
H. C. Gunning, *Vancouver*
W. H. Hall, *Kitchener*
I. M. Hamer, *Ajax, Ont.*
W. C. Hedge, *Montreal*
A. P. E. Hopkins, *Toronto*
W. B. Landers, *Calgary*
A. Leinasars, *Toronto*
F. Macenko, *London*
R. F. Mucklestone, *Brockville*
O. Mykleby, *Toronto*
E. W. Oddleifson, *London*
A. M. Tallman, *Winnipeg*
L. K. Tempelman-Kluit, *Vancouver*
O. R. Wuczkowski, *Montreal*

*Juniors:*

W. F. Allen, *Hamilton*
I. Bayduk, *Sarnia*
C. F. Blancher, *Asbestos*
D. J. Clough, *Toronto*
A. Cohen, *Medicine Hat*
D. K. Dickey, *London*
I. D. Hynd, *Montreal*
N. Kudrenecky, *Chandler*
W. V. McKnight, *Sudbury*
A. F. Piggott, *Grand'Mere*
R. A. van Eck, *Montreal*

*Transferred from the class of Junior to that of Member:*

D. R. Burns, *Toronto*
J. C. Cant, *Terrace*
R. Dubuc, *Montreal*
G. A. Hamel, *Amueseo, S.A.*
B. A. Hastings, *London*
N. A. Lau, *P. of Spain*
G. Meilleur, *Montreal*
G. I. Mulvihill, *Winnipeg*
M. F. Painter, *Okanagan M.*
H. E. Seely, *Hamilton*

*The following Students were admitted:*

*McGill University*

G. A. Adams
P. G. Albert
L. R. Arseneault
W. D. Bailey
H. D. Bailey
P. E. Barolet
K. G. Bartlett
A. J. Bergel
P. Biron
B. D. Blair
P. G. Bowie
M. Brossard
C. R. Brown
Wm. Brownlee
D. G. Butler
B. J. Clavet
A. J. Craig
T. W. Crowe
C. C. Dakers
H. P. Desfosses
R. M. Desjardins
N. A. Dinovitzer
A. W. Easton
P. E. Engler
S. J. Fainbloom
M. C. Feher
M. M. Ferenczy

# NEWS OF THE ASSOCIATIONS & CORPORATION

**Information received through co-operation with the provincial organizations**

## Quebec

**Policy of Council for 1954-5**

Some time ago the following policy was established by Council to guide the Corporation's activities during the year.

During the present term Council will again follow the long range policy first adopted by the Corporation in 1949. Council however will devote special attention to the important problem of increasing the prestige of the professional engineer as an individual.

It is evident that, in order to fulfil its main duty of promoting the welfare of the public of this province, the engineering profession must be well organized, strong and respected, and it is with this objective in mind that your Council has adopted the following broad program for the year 1954-55:

I—*It will attempt to clarify the status of the professional engineer in Quebec by:*

a) Specifying precisely who shall be permitted to practice engineering and under what conditions.
b) Enforcing strictly the provisions of the Professional Engineers' Act regarding the use of the title "engineer".
c) Preparing necessary amendments to the Act to clearly establish the rights and privileges of professional engineers in all fields in which they are qualified to practice.
d) Establishing definite rules and regulations governing the admission to special yearly membership of non-Canadian applicants and the scope of their practice.

II—*It will increase the prestige of the professional engineer by:*

a) Improving the Code of Ethics and enforcing same more strictly to eliminate all practices not consistent with the welfare of the public.
b) Directing the Public Relations program towards achieving greater recognition of the services of engineers to the community in general and to industry in particular.
c) Intensifying the program of elimination of illegal practice and abuse of the title.

III—*It will promote the welfare of the professional engineer by:*

a) Continuing the search for improved methods of obtaining and maintaining adequate remuneration for engineers' salaries.
b) Adopting an improved schedule of minimum fees for engineering services, and collaborating with other provincial associations so that a uniform schedule of fees may be adopted throughout the country.
c) Improving the co-operation with other engineering bodies in all matters affecting the welfare and status of professional engineers.

IV—*It will consolidate the Corporation as an organization by:*

a) Providing additional staff.
b) Providing adequate facilities and space at headquarters.
c) Supporting the organization of local groups by providing assistance and guidance whenever required.
d) Securing greater membership participation in Corporation affairs through committees, meetings, etc.
e) Undertaking a serious campaign to secure by persuasive means the registration of all qualified engineers in this province.

**"Engineering Is Your Profession"**

The newest publication of the Corporation of Professional Engineers of Quebec was distributed to the membership a few weeks ago. The result of long and careful preparation, this booklet, entitled "Engineering is Your Profession", discusses various aspects of engineering as a profession, and contains a great deal of information of interest to every person engaged in the broad field of engineering endeavour, whether or not he is a registered member of the Corporation. Basic facts about the Corporation, its purpose, its method of operation, its activities and the advantages it offers its members are contained in this illustrated booklet. It deals with the legal status of non-Canadian graduate engineers, and describes the national affiliations of the Corporation, the growth of membership, the activities designed to protect the public, and the activities designed to protect the professional engineer.

Designed for easy reading, this booklet has been prepared in bilingual form for wide distribution to anyone interested in the activities of the Corporation.

Persons wishing to receive a complimentary copy should contact Corporation of Professional Engineers of Quebec Headquarters, 1600 Pine Avenue West, Montreal, Que.

## Ontario

***News of the Members***

**Capt. B. H. Goodings**, of R.C.E.M.E. will shortly attend the Canadian Army Staff College following duty with the Commonwealth Division in Korea. In 1949 he graduated in mechanical engineering from the University of Toronto and since that time has made the Army his career.

**J. A. Bossert**, has joined the staff of the Approvals Laboratories of the Canadian Standards Association and is located at the new research and approvals building in Etobicoke, Ontario. Mr. Bossert graduated in electrical engineering in 1951 from Queen's University and prior to the above change was with the Canadian Carborundum Co. at Niagara Falls, Ontario.

The appointment of **Fred A. Sweet** as general manager of the Canadian Standards Association, Ottawa, has been announced. He succeeds the late Col. Walter R. McCaffrey in this office.

Mr. Sweet graduated from the University of Toronto in civil engineering in 1936 and for the past fourteen years has been the chief technical officer of C.S.A.

Two members, **Harold C. Pinder** and **H. C. Dawson** are officers of the newly incorporated Evershed and Vignoles (Canada) Ltd., of 2781 Dufferin Street, Toronto.

This company is sponsored by Evershed & Vignoles of Chiswick, London, England, a firm engaged in the manufacture of electrical instruments. The new Canadian company will handle exclusively the telemetering and process control side of Evershed's business. R. H. Nichols Ltd. will continue as sole representative for Megger and other electrical testing instruments.

At the recent fall meeting of the board of directors of the General Alumni Association of Queen's University, Kingston, **W. A. Dawson,** of Dawson, Rhoades Thibodeau Machinery Co. Ltd., Hamilton, and **D. G. Geiger,** of Bell Telephone Co. of Canada, Toronto, were elected vice-presidents.

Also elected to the board of directors was **H. I. Marshall,** consulting engineer, and patent agent with Alex E. MacRae & Company, Ottawa.

**R. B. Carson** retired on October 31 after 41½ years with the Canadian General Electric Co. Ltd. At the time of his retirement he was engineering consultant at the Davenport Works of the company where he was formerly works engineer for a number of years.

A son of the manse in Pictou, N.S., Mr. Carson first attended Dalhousie University in Halifax and in 1913 graduated in electrical engineering from the Nova Scotia Technical College of the same city.

Immediately joining the Canadian General Electric organization he first completed the test course at Peterborough. For two years he was chief of test before being attached to the engineering department as transformer designer. In 1921 the transformer section was moved to the Davenport Works in Toronto, at which time Mr. Carson was placed in charge of power transformer design engineering. In 1943 he was named assistant works engineer and in 1948 he was appointed works engineer. Prior to his appointment as engineering consultant this year, Mr. Carson was for a time manager of engineering policy and service.

# Manitoba

### Operation and Goals

This article was written for the purpose of giving the engineering group in Manitoba as a whole, some idea of the operation of its association and the goals that it has set for itself and which require the complete co-operation of its members.

The Association of Professional Engineers of Manitoba is fortunate to have many distinguished persons as members of its organization. They are greatly interested in pioneering engineering knowledge as well as being good citizens of our country.

#### *Engineers-in-Training*

The young engineering student meets these men in every day life. Many of the professors of the faculty of engineering at the University of Manitoba are members and through their guidance and knowledge the student is prepared for his engineering future. It is very important the graduate students keep in touch with these men. To do this the association offers them the opportunity of becoming Engineers-in-Training. As such they become members of the Association of Professional Engineers shortly after graduation and during their early practical training are able to gain from the experience and knowledge of more mature men.

This is only one phase of the work being done by the Manitoba association. The aim of the Council is to make the engineers of the province of Manitoba a well knit unit, and by means of salary schedules, consulting fee schedules, and standardization of qualifications for admission to the association, it hopes to accomplish this aim.

#### *Salary Schedules*

Recently the Manitoba association adopted a salary schedule as approved by most of the other provincial associations and corporation. This outlines a suggested minimum salary for various classifications of engineers that can be used as a guide by engineer and employer, classification of engineers will combine two excellent effects. It will provide the younger engineer with a yardstick for measuring his progress in the profession and it will offer the employer a satisfactory method of keeping his personnel happy. This schedule, of course, is not rigid and does not have to be strictly adhered to, but it is a step in the right direction to better employer-employee relationships. Every member should have a copy of it.

#### *Fees for the Consultant*

Professor J. Hoogstraten has recently been named chairman of a committee whose duties consist of studying the work and fees of consultant engineers across Canada and devising a satisfactory schedule of consulting fees to be adopted by the Manitoba Association. The consulting engineering business in this province is growing and the need for an accurate and fair schedule of this type is becoming extremely important. Evidence of this is the increasing number of enquiries received by your Council in the past few months. Professor Hoogstraten has selected for his committee members of various consulting engineering firms as well as purchasers of engineering services.

#### *Qualifications for Admission*

At the Dominion council meeting held in Toronto, it was decided that certain rigid qualifications for admission to the Provincial Associations and Corporation of Professional Engineers were required in order to maintain a high standard of engineering personnel across the country. The Manitoba Association has adopted these decisions and the Council is doing everything in its power to analyze carefully the qualifications of anyone seeking admission to the association. In the long run this type of discipline will make the Association of Professional Engineers of Manitoba and all its members a respected group in the community. This new prestige, it is hoped, will place engineering at the high level enjoyed by certain other professions.

Mr. C. S. Landon, who is presently, and has been for the past 21 years, a member of council and Secretary-Treasurer and Registrar of the Association, will be happy to receive enquiries about our Association from interested members and non-members.

# Saskatchewan

### Water and Sewage Conference

The sixth annual convention of the Western Canada Water and Sewage Conference was held in Regina on September 22-24. Over 300 delegates and visitors were in attendance.

Among the Saskatchewan Professional Engineers who presented papers were: Eric Davis, assistant sanitary engineer with the Saskatchewan Government; M. D. MacKenzie of Associated Engineering Services Ltd.; M. H. Prescott, senior sanitary engineer for Saskatchewan; H. M. Bailey, city engineer of Yorkton; Prof. C. R. Forsberg of the University of Saskatchewan; Allan Shattuck of the Regina Water Works staff.

Other Saskatchewan engineers who participated were: W. G. McKay of Saskatoon; W. L. Sharpe, city engineer of Weyburn; J. W. D. Farrell, Regina Water Works Superintendent; I. B. Sveinbjornson of Yorkton, and W. A. Friebel, Saskatoon's city engineer.

### Saskatoon Builds Water Supply Pipe Line

A project of considerable engineering interest is now being completed in Saskatoon. It involves placing a 30-inch welded steel pipe line across the South Saskatchewan River to connect the Nutana area water system to the main pumps. The new pipe replaces a 24-inch cast iron pipe that had been used for many years but is now leaking very substantially. Design work in connection with the project was carried out by the City Waterworks Engineer, Don Graham, with R. A. Spencer as consultant. The construction contract was awarded to Piggott Construction Company whose project engineer is Russ Ormiston, a recent University of Saskatchewan engineering graduate.

In making the river crossing the pipe was assembled on the north bank of the river on dollies and was then pulled across as a unit by winching from the south bank. This part of the work was in the hands of key personnel from the Missouri River Pipe Line Company whose equipment had been floated down river from Outlook, where it had been used in making a 20-inch oil pipe line river crossing.

### Potash Industry Described

Engineers in Saskatoon met at dinner on October 27, 1954, to hear a paper on "The Potash Industry" by Mr. J. B. Cummings, resident manager for the Potash Company of America's operations near Saskatoon. With the assistance of film he brought out the importance and uses of potash as well as methods of mining and processing. Certain features of the local project created considerable interest among the engineers.

The deposit is located some 3,000 feet below the surface with an intervening water-bearing sedimentary strata. To sink through this strata it has been decided to freeze the whole shaft area prior to excavation. To do this a number of shot drill holes are being drilled in a circular pattern and down to the full 3,000 feet. Refrigeration piping is to pass through these holes with the required capacity of the plant amounting to some 800 tons.

Included among the 80 engineers present were 30 guests from the Western Meeting of the Cement and Concrete Research Group of the National Research Council. A special guest was Dr. C. J. Mackenzie, former president of the National Research Council and the first Dean of Engineering at the University of Saskatchewan.

The meeting was conducted by Prof. W. R. Staples, as chairman. The guest speaker was thanked by Dr. J. B. Mawdsley.

#### André Coyne Presents Lectures on Arch Dams

Mr. André Coyne, an internationally known French authority on arch dams presented lectures dealing with designs he had been associated with in many countries in Europe and Asia. Some 70 engineers in Regina heard his lecture on October 19, and approximately 60 in Saskatoon on October 20, the latter including a number of senior students in civil engineering from the University of Saskatchewan.

Mr. Coyne's lecture was well illustrated by beautiful colored slides and a moving picture. In both cities, the lecture stimulated a lively discussion period. Mr. Coyne was thanked by Mr. H. Nicholl at the Regina meeting, and by Prof. F. H. Edmunds at the Saskatoon meeting.

## British Columbia

#### Engineers and Unions

On November 9, the culmination of some four years of effort on the part of the Association and those Engineers-in-training with the B.C. Electric Co. Ltd. who have been forced to belong to a union was reached, when the Engineers-in-training with the newly-formed B.C. Engineering Co. Ltd. and the B.C. Electric Co. Ltd. voted overwhelmingly in favor of relinquishing "membership in the Office Employees' Association, or any association of employees or any labour organization founded for the purpose of challenging the jurisdiction or certification of the O.E.A. or its successors". Fifty-two voted in favour with nine voting against. A total of sixty-six ballots were sent out.

The Office Employees' Association objected to recognition of the bargaining unit for which former employees of the B.C. International Engineering Co. Ltd. applied for certification when they became employees of the B.C. Engineering Co. Ltd. As a result of this, a meeting of all the interested parties was called at which the O.E.A. agreed to a secret ballot vote being taken among all Engineers-in-training of both the B.C. Engineering Co. Ltd. and the B.C. Electric Co. Ltd., the ballot to determine whether they wished to be members of the O.E.A. or any similar organization. In return it was agreed that the application for bargaining rights for the B.C. Engineering Co. Ltd. employees would be withdrawn. The O.E.A. further agreed that if the E.I.T.'s showed by majority vote that they did not wish to be members of the O.E.A. or any similar organization, the O.E.A. would exclude E.I.T.'s from O.E.A. membership. Subsequently, the ballot was carried out by the Association and scrutineered by representatives of the O.E.A. and the other interested parties.

The next step will be for the O.E.A. to have the exclusion of E.I.T.'s written into their agreement with the company.

In the meantime, Council will press once again when the legislature convenes in January for exemption of Engineers-in-training from the provisions of the Labour Relations Act.

#### Annual Meeting

The thirty-fifth annual meeting of the Association was held at the Hotel Vancouver in Vancouver, on Friday and Saturday, December 3 and 4. This notice went out to the members.

Information concerning the meeting has already been mailed to members and engineers-in-training. Members are urged to attend to use this, their principal opportunity, to have a voice in the affairs of their Association. When members are silent, Council can only interpret this to mean that they are satisfied with the way that the Association is being run. If this is the case, they should come and thank Council for doing such a good job. If it is not the case, the annual meeting is the time and place to be vocal, not at some other time or place. This applies to engineers-in-training and members.—If you want to be heard, be there.

Members have an additional method to express their opinion on the ballot for Council, which they should have received last week.

*"Silent Service Is Not Enough."*

#### Society Affairs

In December, members will receive the annual Salary Survey Questionnaire. It will be noted that this year's survey will be conducted under the auspices of Dominion Council, thus providing a Canada-wide survey as well as detailed data regarding salaries in B.C. Making the salary survey in December instead of in April, as it was previously done in B.C., makes it possible to compile the analysis of salaries within days after the end of the year and at a time when the data will be of greatest aid to all concerned.

The Salary Survey Questionnaire is a source of important information and this value increases yearly. It is obvious that the higher the percentage of returns, the greater will be the value of the resulting tabulations. Last year only 31.8% of the members and engineers-in-training returned their questionnaires, this compared to 45.5% return of the previous year. It means that only 1 out of 3 members gave their assistance in a matter which affects all.

Incorporated in the 1954 Salary Survey Questionnaire are several new questions. It will be noted that the annual "rate" of remuneration, as of December 1, 1954, is requested. New questions generally relate to any bonus received over and above salary; the annual value of any profit sharing plan; annual commissions; the annual contribution of the employer to pension, group plan, hospital, insurance, sickness plans. The question on the field in which work is done.

Experience has proved beyond doubt the value of the Annual Salary Survey. While its use as a reference has been valuable in the past year, participation by every member would provide data of incomparable worth.

#### Executive Changes

F. M. Cazalet, supervisor of mechanical engineering for the B.C. Electric Power and Gas Company, is the new chairman of the Vancouver Branch of the B.C. Engineering Society for 1954-55. He succeeds W. Thornber, of the B.C. Coastwoods Extension Bureau, who will continue on the executive as immediate past chairman.

Others elected to the executive at the annual meeting in the Engineering Building at U.B.C. last night were, W. C. McKenzie, vice-chairman; H. Taylor, secretary; and J. Sandrin, treasurer. H. T. Libby will be member at large, representing the professional engineers; and W. K. Broughton for the engineers-in-training. A. Webster and W. H. Doran, of last year's executive, will be the continuing members for the coming year.

#### Engineers-in-the-News

The Board of Directors of the Granby Consolidated Mining, Smelting and Power Company Limited has announced changes in officers. **Julian B. Beaty,** formerly president of the company is now chairman of the board. **L. T. Postle,** formerly vice-president and general manager, has been named president. **J. A. C. Ross,** formerly general superintendent, has been appointed general manager.

**R. C. Boyes,** who recently returned from England has accepted the position of Assistant Zoning Planner in the Vancouver City Planning Department.

**F. Hancock** has accepted a position on the teaching staff of the Vancouver Technical School.

**V. C. Fenton,** who was formerly with the Department of Mines in Victoria has taken up a position in the structural department of the chief architectural branch of the Department of Public Works at Ottawa.

**W. D. Hammond,** of Kennco Explorations (Canada) Limited has been transferred to Toronto to take charge of the Company's exploration program in Central Canada.

**I. L. Johnston** has left the Water Rights Branch, Department of Lands & Forests to accept a new position as hydraulic engineer with the St. Lawrence Seaway Authority in Montreal.

**George Wallbank** has accepted a position with Letson & Burpee Ltd. He was formerly with Stange Construction Co. Ltd. at Salmo, B.C.

**W. D. Cripps** is now employed by J. L. Miller. He was formerly with Associated Consulting Engineers.

**R. C. Robson,** who was with Alaska Pine and Cellulose Ltd. in Vancouver, has accepted a position with H. A. Simons Ltd. **E. H. Talbot** has accepted a position with J. L. Miller. He was formerly employed by H. A. Simons Ltd.

**C. G. Hewlett,** who received a Ph.D. degree in geology from the University of Wisconsin this June, is now on the staff of the British Columbia Department of Mines.

**A. L. Nicholls** is now industrial sales manager with Kemp Agencies. He was formerly employed by H. A. Simons Ltd.

*Chairman*, A. E. BERRY
*Vice-Chair.*, G. R. HENDERSON
*Treasurer*, G. R. TURNER
*Secretary*, G. H. ROGERS

# Personals

## News of the Personal Activities of Members of the Institute

**Brian H. Colquhoun,** M.E.I.C., senior partner in the firm of Brian Colquhoun & Partners, London, has recently accepted the appointment of engineering advisor to the International Bank for Reconstruction and Development (World Bank) for a period of two years on secondment. During the period of his appointment, Mr. Colquhoun will be based at the headquarters in Washington, but will also visit the countries in the development of which World Bank is interested.

Brian H. Colquhoun, M.E.I.C.

A graduate of London University in 1924, Mr. Colquhoun was elected a Member of the Institute in 1950. For some years he was engaged in tunnelling works in and around the London area, and, later on oil exploration surveys and the construction of railways and port installation works in connection with the refinery at Minatitlan, Mexico.

In 1930 he was appointed resident engineer, then engineer-in-charge, on the construction of the Mersey vehicular tunnel under the river between Birkenhead and Liverpool, England. During this period he was also adviser on tunnel ventilation to the authorities responsible for the construction of the Maas Tunnel in Holland.

In 1938 he was appointed engineer-in-charge on the design and construction of a large Ordnance factory in Lancashire, and, at the outbreak of the War, was responsible for further large plants at Risley and Kirby, near Warrington, England.

Mr. Colquhoun was later appointed director-general of aircraft production factories in the Ministry of Aircraft Production, in which capacity he was responsible not only for aircraft production factories in the United Kingdom, but also for railway and port works overseas in connection with the transport and shipping of the raw materials for the manufacture of aircraft.

Mr. Colquhoun opened an office as consulting engineer in London in the latter part of the War and his firm has, over the last few years, been responsible for engineering works of all categories in various parts of the world including the United Kingdom, South Africa and the Rhodesias, India, Pakistan and the Argentine.

As a result of Mr. Colquhoun's appointment to the International Bank, the firm has taken into partnership three of its senior civil engineers, one of whom is **Alan U. Shiach,** M.E.I.C., who was elected a Member of the Institute in 1950.

At the 65th annual meeting of the Engineering Institute held in Montreal in May, 1951, Mr. Colquhoun presented a paper entitled, "Some Modern Aspects of Tunnelling".

**D. S. Abbott,** M.E.I.C., has been elected president of Alliance Paper Mills Ltd. and its subsidiary, Don Valley Paper Co. Ltd. He has also been appointed a director of Howard Smith Paper Mills Ltd.

Mr. Abbott joined the staff of Howard Smith Paper Mills Ltd. in 1944 as manager of the plastics division, now The Arborite Co. Ltd., of which he was elected president in 1953. He will continue to hold this office in addition to his new duties.

He is a 1930 mechanical engineering graduate of Queen's University.

**T. P. Lusby,** M.E.I.C., has been appointed deputy minister of public works for the Province of Nova Scotia. He has been chief engineer of the department of highways and public works since 1948.

A mechanical engineering graduate of the Nova Scotia Technical College, class of 1930, Mr. Lusby has been associated with the Department since 1947.

He has just completed a two-year term as councillor for the Association of Professional Engineers of Nova Scotia.

**N. S. Bubbis,** M.E.I.C., general manager of Winnipeg's Greater Sanitary District, was named president of the Canadian Institute on Sewage and Sanitation at the organization's 21st annual meeting in Montreal. **C. G. R. Armstrong,** M.E.I.C., consulting engineer, Windsor, Ont., was elected vice-president; **R. V. Anderson,** M.E.I.C., consulting engineer, Toronto, and **E. E. W. Oke,** M.E.I.C., city engineer, Waterloo, Ont., were elected trustees.

**A. E. Chalmers,** M.E.I.C., city engineer, Peterborough, Ont., is immediate past-president. **L. B. Allan,** M.E.I.C., metropolitan Toronto commissioner of works, is a trustee whose term will expire next year. **Nicol MacNicol,** M.E.I.C., will continue as federation director, and **Albert E. Berry,** M.E.I.C., as secretary-treasurer. **A. J. Deslauriers,** M.E.I.C., Lachine's city engineer, discussed incineration at a symposium on refuse disposal. One of the speakers in the forum was **G. H. Richards,** M.E.I.C., city engineer, Brantford, Ont.

Speakers during the three-day convention were **G. T. G. Scott,** M.E.I.C., manager of Canadian British Engineering Consultants, Toronto; **J. F. MacLaren,** M.E.I.C., of James F. MacLaren Associates, Toronto; and **J. G. Schaeffer,** M.E.I.C., director of the sanitation division of the Saskatchewan Department of Health, Regina.

Twenty-year membership certificates were presented to **N. G. McDonald,** M.E.I.C., of Gore & Storrie, consulting engineers, Toronto; **W. L. McFaul,** M.E.I.C., city engineer, Hamilton; **J. F. MacLaren,** M.E.I.C.; **W. B. Redfern,** M.E.I.C., of Proctor, Redfern & Laughlin, consulting engineers, Toronto; and **W. Storrie,** M.E.I.C., of Gore & Storrie, consulting engineers, Toronto.

**Thomas Ingledow,** M.E.I.C., has been appointed president of B.C. Engineering Co. Ltd., a new subsidiary of B.C. Electric Co. Ltd. which has been formed by the amalgamation of the company's engineering division and a newly-purchased private company, B.C. International Engineering Co. Ltd.

Mr. Ingledow, an engineering graduate of Glasgow University, is vice-president and executive engineer of B.C. Electric Co. Ltd.

**E. K. Dokken,** M.E.I.C., assistant superintendent of the Piggott Construction Company in Moose Jaw, has been elected chairman of the Moose Jaw section of the Saskatchewan Branch of the Engineering Institute.

Mr. Dokken was born at Olds, Alta. Upon completion of his studies at Thornton School, Saskatoon, and the Saskatoon Technical Collegiate Institute, he entered the University of Saskatchewan, graduating in 1944 with a B.Sc. degree in mechanical engineering.

Upon graduation he became maintenance engineer with the Consolidated Paper Corporation in Grand'Mere, Que. A year later he was appointed construction engineer and assistant mechanical superintendent.

In 1948 Mr. Dokken joined Montreal Cottons Limited in Valleyfield, Que., as

assistant plant engineer. He then served for a brief period in 1949 as field superintendent of Dokken Pipe Line Limited in Edmonton, afterwards joining the Prairie Well Servicing in Redwater, Alta.

In April, 1950 he entered the Piggott Construction Company as field superintendent in the pipe line division in Edmonton, and a year later was appointed resident engineer and assistant superintendent of the company at the Moose Jaw airport.

Mr. Dokken is a member of the Association of Professional Engineers of Alberta.

**Brigadier J. R. B. Jones,** M.E.I.C., has been promoted from the rank of colonel and is commander at the New Brunswick area headquarters in Fredericton.

Brigadier Jones, a 1935 mining engineering graduate of the University of Alberta, was formerly chief engineer at Army headquarters in Ottawa.

**W. A. Ketchen,** M.E.I.C., has been appointed to the position of technical director of Fraser Companies, Limited in Edmundston, N.B. As technical director he will be concerned with industry trends and development in materials, processes and products and their application to company operations. He will also be responsible for the operations of the technical departments and research divisions of the company and its subsidiaries, Fraser Paper, Limited and Restagouche Company, Limited.

A native of Montreal, Mr. Ketchen graduated from McGill University in chemical engineering in 1928 following which he was employed by Shawinigan Chemicals Limited, Shawinigan Falls, Que. For over a quarter of a century he has been with the Fraser organization being first employed as a chemist with Fraser Paper, Limited, Madawaska, Maine. In 1932 he became assistant to the chief chemist at Edmundston, later becoming head chemist at Madawaska. In 1937 he was named chief chemist of the company and its subsidiaries. From 1949 until recently Mr. Ketchen was also directly concerned with the company's kraft mill at Newcastle, N.B.

**Paul E. Cooper,** M.E.I.C., president of Crown Zellerbach Canada Limited and of Elk Falls Company Limited, will retire on January 1 due to ill-health. He will continue, however, as director of Crown Zellerbach Canada Limited, and also act as a consultant to the firm.

Mr. Cooper has been associated with the pulp, paper and allied forest industries for more than 30 years in Canada, the United States and abroad.

A native of Ottawa and a graduate in civil engineering of McGill University, Mr. Cooper began his career in business and industry as resident engineer of the Piercefield mill of the International Paper Company in New York State. Later, he became manager of the Continental Paper & Bag Corporation at Rumford, Maine.

In 1934 he went to Great Britain as chief engineer in charge of design and construction of a new board mill for the Thames Board Mills, Ltd. in Purfleet, one of the largest organizations of its kind in the world. He then became deputy director and general manager of the Thames organization, remaining in that office for nine years.

He was then appointed in 1943 vice-president and general manager of Pacific Mills, Limited, now Crown Zellerbach Canada Limited. The following year he was named president of Pacific Mills, which under his direction, developed into one of the largest integrated companies in the province. In the multi-million dollar expansion of the company during Mr. Cooper's term, the firm acquired three subsidiaries, Canadian Boxes Limited, Northern Pulpwood Limited, and Badwater Towing Company, which greatly widened plant and woods operations.

Mr. Cooper is credited with being the driving force behind many developments at the company community of Ocean Falls where he was instrumental in the establishment of a modern hotel and a low-cost housing development for employees. He also played a leading role in the formation in 1951 of the new Elk Falls Company and construction of a huge newsprint mill on Vancouver Island.

Mr. Cooper has been director and vice-president of Hudson Paper Company Limited, a distributing subsidiary with head office in Winnipeg.

**E. S. Chandler,** M.E.I.C., of Chappell & Company, Charlottetown, has been elected chairman of the Prince Edward Island Branch of the Engineering Institute.

Mr. Chandler was born in Charlottetown. He received his general education at the West Kent School, Prince of Wales College and Mount Allison University. In 1928 he entered the Nova Scotia Technical College, graduating with a B.Sc. degree in electrical engineering in 1931.

After graduation he was appointed acting superintendent of the Wolfville Electric Commission and in 1932 was named provincial electrical inspector for the Province of Prince Edward Island.

During World War II he served from 1940 until 1944 with the Royal Canadian Artillery on searchlights, and upon his discharge, was appointed superintendent of the Vocational Training School at Charlottetown. After a brief period as electrical contractor, Mr. Dokken became district meter inspector for the Department of Trade and Commerce in Charlottetown.

He is a member of the Illumination Engineering Society.

### H. G. Acres Organization

With the change in organization of H. G. Acres & Company Limited, consulting engineers, Niagara Falls, the board has announced that **S. W. Andrews,** M.E.I.C., continues as president and director; **A. P. McQueen,** M.E.I.C., continues as vice-president and director; and **H. E. Barnett,** M.E.I.C., has been appointed vice-president and chief engineer. Messrs. Andrews, McQueen and Barnett, together with **R. A. H. Hayes,** M.E.I.C., electrical engineer, will continue as the principals of the firm and there will be no change in policy or management.

**R. M. Hardy,** M.E.I.C., dean of engineering of the University of Alberta, has been appointed to the board of directors of Foundation of Canada Engineering Corp. Ltd.

Dean Hardy is president of R. M. Hardy Associates Ltd. and vice-president of Materials Testing Laboratories Ltd. of Edmonton and Calgary. He is a past-president of the Association of Professional Engineers and of the Canadian Good Roads Association. He is also an associate member of the American Society of Civil Engineers.

**Leroy Thorssen,** M.E.I.C., is president of Lightweight Aggregates of Canada Limited in Calgary, whose new Mcleod Trail plant began operations this summer.

Mr. Thorssen is a former professor of civil engineering at the University of Alberta where he served on the staff from 1939 until 1952. He received his B.Sc. degree in civil engineering from the University of Alberta in 1939 and his M.Sc. degree from the University of Iowa in 1946.

**B. A. Monkman,** M.E.I.C., is managing director of Light Weight Aggregates of Canada Limited in Calgary.

Previous to joining the company in 1953, he was associated with the Newfoundland Light and Power Company in St. John's where he served as operating superintendent for three years.

Upon graduation from the University of Alberta in civil engineering in 1940, Mr. Monkman was associated during the succeeding ten years with Calgary Power Company on construction and hydro development. In 1947 he was appointed resident engineer on the Berrier project.

Mr. Monkman is a past chairman of the Newfoundland Branch of the Institute.

**W. Douglas Baines,** M.E.I.C., research officer with the National Research Council of Canada in Ottawa, has been awarded the J. C. Stevens Award of the American Society of Engineers for technical papers published by the Society during the past year. Mr. Baines' paper was entitled "Application to an Hydraulic Problem".

Mr. Baines, formerly in the civil engineering department of Michigan State College, is an honour graduate in engineering physics of the University of Alberta, class of 1947. He received his M.Sc. degree from the State University of Iowa in 1948.

**Lt. Col. A. L. Maclean,** M.E.I.C., is a member of the Canadian delegation of the International Supervisory Commission in Cambodia, Indo-China, and is serving as senior Canadian representative in the provinces of Kampot and Takeo.

A graduate of the University of Toronto in metallurgical engineering in 1941, Lt. Col. Maclean served during the war with the R.C.E.M.E., after which he undertook a ten-month advance ordnance officers' course at the United States Army ordnance school in Maryland. He served from 1948 until

1952 as associate professor in the department of mechanical engineering at the Royal Military College of Canada, and was then posted to the directorate of quartermaster operations and plans at Army headquarters in Ottawa.

Lt. Col. Maclean is a past chairman of the Kingston Branch of the Engineering Institute.

**George N. Munro,** M.E.I.C., assistant chief engineer of the P.F.R.A., Department of Agriculture, Regina, has been elected chairman of the Saskatchewan Branch of the Engineering Institute.

A native of Deloraine, Man., Mr. Munro received his public and high school education in Winnipeg and North Battleford, Sask., after which he served with the Royal Canadian Dragoons during the first World War. He then attended the University of Saskatchewan, graduating with the degree of B.Sc. in civil engineering in 1926.

Previous to graduation he served during the summer as rodman and instrumentman with the Saskatchewan Department of Highways. In 1926 he joined Canadian National Railways as instrumentman, becoming resident engineer in 1928.

In 1931 he returned to the Saskatchewan Department of Highways as resident engineer, and in 1932 was appointed inspector with the Department of Public Works of Canada. He joined the Saskatchewan Department of Natural

George N. Munro, M.E.I.C.

Resources, water rights branch, in 1939, and in 1949 transferred to P.F.R.A. as assistant chief engineer.

**Fred A. Sweet,** M.E.I.C., has been appointed general manager of Canadian Standards Association to succeed the late Colonel W. R. McCaffrey. This announcement was made recently by **Dean R. E. Jamieson,** M.E.I.C., president of the Association.

Mr. Sweet, a civil engineering graduate of the University of Toronto, has been chief technical officer of the Association for the past 14 years.

He is a member of the Association of Professional Engineers of Ontario.

**Geddes M. Webster,** M.E.I.C., formerly manager of Bralsaman Petroleums Limited, is now vice-president and general manager of Franklin Exploration Limited.

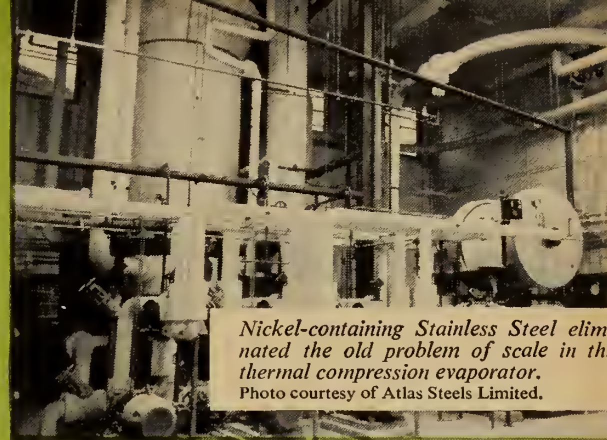
He received his B.Eng. degree in mining engineering from McGill University in 1941. After industrial work with Defence Industries Limited and Canadian Industries Limited he was active in the Yellowknife area from 1945 to 1951, first as a mining consultant and later as assistant mining inspector and mining recorder for the Yellowknife Mining District.

In 1951 he joined Transcontinental Resources Ltd. as a field engineer and in 1952 was transferred to Calgary with Bralsaman Petroleums Limited.

Mr. Webster in association with Norman S. Edgar, mining engineer, has recently formed Franklin Exploration Limited which is concerned with consulting in mining as well as with exploration and development of minerals in western and northern Canada and in the Western United States. His offices are located in Calgary.

**R. T. Hollies,** M.E.I.C., a past councillor of the Engineering Institute and

# YEARS AND YEARS OF DEPENDABLE SERVICE



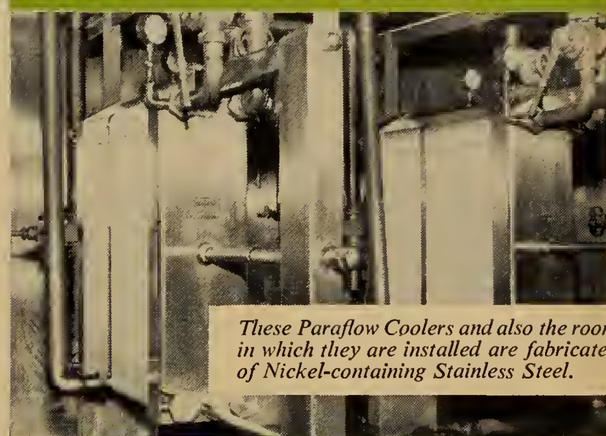
*Nickel-containing Stainless Steel eliminated the old problem of scale in this thermal compression evaporator.*
Photo courtesy of Atlas Steels Limited.

## NICKEL-CONTAINING

# STAINLESS STEEL

*This Cottage Cheese Vat is lined with Nickel-containing Stainless Steel.*

Dependability is the most important requirement of processing equipment. Important because it is not only necessary that equipment has long, easily maintained service life but that its ability to safeguard product purity is never reduced. These are tough standards for any metal. Nickel-containing Stainless Steel has excellent resistance to corrosion, ready formability and ability to keep high purity products free from harmful discolouration and contamination.



*These Paraflow Coolers and also the room in which they are installed are fabricated of Nickel-containing Stainless Steel.*

### SOURCE OF SUPPLY

Nickel-containing Stainless Steel can be obtained either direct from the mill or from warehouse stocks located in the principal cities of Canada.

## INCO *proven* SERVICE

Inco's Technical Service has, over the years, collected and catalogued information from laboratory studies, plant surveys and practical experience in a great variety of industrial equipment problems. This information and the qualified experience of Inco's Technical Staff is always available to help you with your metal problem.

*The pipes, fittings and kettles of this baby food process equipment are of Nickel-containing Stainless Steel.*

EMBLEM OF INCO NICKEL SERVICE
TRADE MARK

**THE INTERNATIONAL NICKEL COMPANY OF CANADA, LIMITED**
**25 KING STREET WEST, TORONTO**

a past chairman of the Calgary Branch, has retired as city waterworks engineer for the City of Calgary.

Mr. Hollies was born at Fort Macleod where he received his early education. He entered the University of Alberta before World War I, but at the outbreak of hostilities, interrupted his studies and enlisted in the Army. From 1916 until 1919 he served on the western front and saw action at the Somme, Vimy Ridge, Passchendale, Canal du Nord and Valenciennes with the 46th Battalion from Moose Jaw. He was wounded three times and at Passchendale was one of 15 of his entire company who returned from the battle.

After the war he resumed his engineering studies and graduated from the University of Alberta in 1920. He received his M.Sc. degree in 1921.

Mr. Hollies spent the following six years as assistant research engineer for the Research Council of Alberta and then went to Southern California for further studies and was employed on the construction of a 1,000,000 hp. steam plant at Long Beach.

After a brief period in the Caribou country he came to Calgary in the summer of 1929 as field engineer in the City's service on the construction of the Glenmore dam, the filter plant, pumping station and installation of mains from the reservoir. When the dam went into operation in 1933, he was named superintendent of production.

Mr. Hollies remained in this post until the fall of 1939 when he enlisted in the Royal Canadian Engineers. He was commissioned and went overseas in 1940, arriving in time for the Battle of Britain and in time to serve in the defensive corps set up for the protection of the south coast in the fall and winter of 1940 and 1941. After serving in England in the construction of camps, airports, roads and hospitals, he went to Normandy in July, 1944. Later in the year he was invalided home and in November was discharged with the rank of captain.

Returning to the city waterworks department in 1945, Mr. Hollies was promoted to assistant waterworks superintendent and in the summer of 1953 was appointed waterworks engineer.

In 1946 and 1947 Mr. Hollies was chairman of the Calgary section of the Chemical Institute of Canada; in 1948, chairman of the Calgary Branch of the Engineering Institute, and in 1950 and 1951, councillor of the Institute, representing that Branch. He was elected vice-president of the Association of Professional Engineers of Alberta in 1952.

**H. T. Miard,** M.E.I.C., has been transferred from Nelson, B.C., to New Westminster, B.C., as divisional engineer by the British Columbia Department of Public Works.

Mr. Miard joined the department at Nelson in 1947 coming from Lethbridge where he was assistant district airway engineer for the Department of Transport. He was appointed divisional engineer at Nelson in 1950.

A 1933 graduate in civil engineering of the University of British Columbia, Mr. Miard was employed by the Department of Mines and Resources until 1940 at which time he joined the Department of Transport.

**T. M. MacIntyre,** M.E.I.C., is associated with Cartier Construction Limited in Labrieville, Que. He was previously associated with Gulf Power Company in Clarke City, Que.

Mr. MacIntyre graduated in civil engineering from Queen's University in 1920.

**Andrew G. Watt,** M.E.I.C., has been appointed general manager of the new structural steel fabrication and steel material sales division of Consolidated Steel Corporation Ltd. in Saint John, N.B.

Mr. Watt, who was formerly assistant chief engineer of the St. John Drydock & Shipbuilding Co. Ltd. in Saint John, is immediate past chairman of the Saint John Branch of the Engineering Institute.

**Otis S. Cox,** M.E.I.C., district engineer of the Department of Public Works of Canada in Halifax has recently retired.

Mr. Cox was born in Upper Stewiacke, N.S. He attended public school there *things happen fast when*

**THE CURRENT SHOOTS THE CHUTE!**

*National Vulcanized Fibre barriers in the circuit breaker arc chute illustrated above really "torture" the arc—distort, elongate and tame it—so that no damage is done. Such severe service calls for excellent electrical properties and arc resistance. And, because it is a tough, strong material, vulcanized fibre also gets the nod for mechanical applications in the "breaker"—as bushings, pins, sleeves, washers, connector bars, etc. Maybe these applications will give you a clue as to how this material can help you. If you'll give us an idea of your intended end-use, we'll send appropriate technical and descriptive literature. Write to either of the addresses listed, attention Dept. AB-12.*

*Also manufacturers of Phenolite Laminated Plastic, Vul-Cot Waste Baskets, Peerless Insulation, Materials Handling Equipment, and Textile Bobbins.*

In a circuit breaker when current overload occurs, the contacts open . . . a violent arc jumps across the gap . . . then is drawn upward through the breaker's "safety valves"—the arc chutes. In a split second, intense heat and dangerous gases are dissipated . . . the arc is quenched without harm to life or equipment.

National Vulcanized Fibre plays a vital and reliable role in this drama of industrial safety. It is utilized widely as a basic material in the sides and plates of arc chutes. Its inherent properties enable it to stand up under the rigorous punishment dealt by electrical energy "on the loose," and to help curb it effectively! These properties also make National Vulcanized Fibre the ideal material for dozens of other applications in power switching equipment and in thousands of uses within the broad electrical field. High dielectric and mechanical strength—excellent machinability—splendid formability—lightness of weight—great resistance to heat, shock and abrasion . . . name what you want in characteristics and capacity, and National Vulcanized Fibre is likely to have it, and more!

The chances are strong that there are many uses in your own business for versatile, economical National Vulcanized Fibre. Why not let us help you to find out?

*Nothing takes the place of Vulcanized Fibre*

**NATIONAL**

**FIBRE COMPANY OF CANADA, LTD.**

ATLANTIC & HANNA AVES., TORONTO • 1411 CRESCENT ST., MONTREAL and later graduated from Colchester County Academy. After pre-engineering study at Dalhousie University, he graduated from the Nova Scotia Technical College in 1913 with the degree of B.Sc. in civil engineering. While at the technical college he was employed for a time on the engineering staff of the Dartmouth to Deans railway for the Department of Railways and Canals.

Upon graduation Mr. Cox accepted the position of assistant engineer with the Department of Public Works of Canada at Halifax. In 1931 he was promoted to senior assistant engineer and in 1935, to district engineer for the province, which position he held until his retirement.

Mr. Cox has always been active in the interests of his profession. He is a charter member and past councillor of the Association of Professional Engineers of Nova Scotia, and has been associated with the Engineering Institute since its beginning.

**J. J. Traill,** M.E.I.C., has resigned his position as consulting hydraulic engineer with the Hydro-Electric Power Commission of Ontario and has opened offices as hydraulic consulting engineer in Toronto.

A civil engineering graduate of the University of Toronto, class of 1906, Mr. Traill has been associated with the Commission for many years.

**Lt. Col. D. H. Rochester,** O.B.E., M.E.I.C., is assistant adjutant general (plans) at Army headquarters in Ottawa. He was formerly on the Canadian Army Staff College in Kingston.

A 1941 mining engineering graduate of the University of Toronto, Lt. Col. Rochester was awarded the O.B.E. for services in Korea.

**W. H. Ackhurst,** M.E.I.C., has been transferred by Canadian General Electric Co. Ltd. from Toronto to Peterborough where he will serve as manager of the sales, motor and control department.

A graduate in electrical engineering of the Nova Scotia Technical College, class of 1939, Mr. Ackhurst has been associated with the company before and after World War II during which he served as a captain in the Royal Canadian Electrical and Mechanical Engineers.

**Paul Pelletier,** M.E.I.C., Montreal consulting engineer, has been elected a councillor for the City of Montreal in the recent civic elections.

A graduate in civil engineering of Ecole Polytechnique, class of 1938, Mr. Pelletier began his engineering career as assistant to the chief engineer of the Montreal Catholic School Commission. In 1940 he was appointed consulting engineer to the Montreal Coke and Manufacting Company, and a year later, became service manager of the Montreal Coke and Manufacturing Company (LaSalle Coke Company).

In 1942 he was loaned by the LaSalle Coke Company to Collet Frères, engineers and contractors, as field engineer on construction of the Westmount Tool Works of Defence Industries Limited, and the following year to the Department of Munitions and Supply as technical adviser to the Solid Fuel Controller in Montreal.

In 1946 he became consulting engineer with Creaghan & Archibald of Montreal, and a year later, was appointed vice-president and chief engineer of Frank Ross Construction Co. Ltd. in Montreal.

Mr. Pelletier opened his own offices as a consultant in Montreal in 1952.

He is a member of the Corporation of Professional Engineers of the Province of Quebec.

**J. R. Grant,** M.E.I.C., and **T. B. Williams,** M.E.I.C., have been granted honorary life membership in the Association of Professional Engineers of British Columbia.

A graduate in civil engineering of Queen's University in 1905, Mr. Grant was one of the founder members of the British Columbia Association of Professional Engineers, becoming registered in 1920, and later serving as a member of the Council.

He came to British Columbia in 1908 and served overseas with the Royal Engineers in the First World War. Since that time he has been identified with many of the outstanding civil engineering developments in the province, including the Pacific Great Eastern Railway, the Greater Vancouver Water District intakes and reservoir, and Vancouver's Burrard Bridge. He was also a consultant on the new Granville Street Bridge in Vancouver.

Dr. T. B. Williams, until his retirement last year, was controller of the coal, petroleum and natural gas branch of the British Columbia Department of Lands. He is a graduate in mining engineering of Queen's University and holds a Ph.D. degree in geology from the University of Wisconsin.

He is a founder member of the Association of Professional Engineers of Alberta, where he discovered and brought in the "Red Coulee" oil field. In early years he was active in coal mining and later was prominent as a consultant in both mining and oil developments in Alberta before he came to British Columbia in 1946. He is the author of many technical publications such as "Coking Processes for Western Canada", "Geology of the Comox Coal Basin", and "Identification of Coals".

**C. D. Worby**, M.E.I.C., has been appointed district engineer for the Saskatchewan district of Canadian National Railways with headquarters in Saskatoon. He was formerly assistant engineer, maintenance of way, in Winnipeg.

A native of Winnipeg, Mr. Worby joined the Canadian National Railways in 1939 as a chainman at Atikokan. He served with the Royal Canadian Air Force from 1943 until 1945 and upon his return to the railway worked as draughtsman in Winnipeg, advancing to assistant division engineer in 1950. He was appointed division engineer at Regina in 1952 and later the same year became regional engineer of track at Winnipeg. He was promoted to assistant engineer, maintenance of way, early this year.

**Professor Alan H. Meldrum**, M.E.I.C., received his Ph.D. in petroleum engineering from the Pennsylvania State University in August of this year, and has been appointed associate professor of mining engineering at the University of North Dakota.

Professor Meldrum received his B.Sc. degree in chemical engineering from the University of Alberta in 1938, and his B.S. and M.S. degrees in petroleum engineering from the State of Oklahoma University in 1947 and 1949, respectively.

**Paul G. W. Walker**, M.E.I.C., former Penticton city engineer, has recently established a private practice in Vancouver.

Immediately before and after the war during which he saw active service as a pilot in the R.A.F., Mr. Walker was associated with Sir Alex Gibb and Partners in London, England. He came to Canada in 1947 as assistant city engineer of St. Thomas, Ont. and later spent two years in structural and hydraulic design work for Spruce Falls Power and Paper Company and for Longlac Pulp and Paper Company. He went to Penticton as city engineer in 1951.

Mr. Walker received his M.A. degree in mechanical sciences from Cambridge University in 1941.

**B. Paul Wisnicki**, M.E.I.C., associate professor at the University of British Columbia, is on leave of absence and is now residing in Montreal where he is serving as structural engineer with the Canadian section, St. Lawrence River Joint Board of Engineers.

Mr. Wisnicki is a mechanical and aeronautical engineering graduate of Lwow University, Poland, class of 1936.

**George Olson**, M.E.I.C., has been transferred by the Northwest Territories Power Commission from the Snare River Power plant in the Northwest Territories, where he served as superintendent, to Ottawa where he is electrical engineer on the head office staff.

Mr. Olson is a 1950 graduate of the University of Alberta in electrical engineering.

**R. M. Heaton**, JR.E.I.C., is assistant electrical engineer with H. G. Acres in Great Falls, Man. He was formerly associated with Canadian Westinghouse Co. Ltd. on field work.

# Reduce Steel Erection Costs with STELCO HIGH-STRENGTH BOLTS

## . . . AND ACHIEVE STRONGER, MORE ADAPTABLE STRUCTURES!

**Stelco High-Strength Bolts** bring to the construction industry the many proven benefits of high-tensile bolting for structural steel joints. This tested, accepted, and rapidly growing technique offers the following marked advantages over other methods:

**Economy.** High-Strength bolting has consistently shown on recent installations definite savings when compared with riveting. The initial cost of the bolt is higher, but reduced labour more than compensates for the difference.

**Speed.** High-Strength Bolts can be installed at an average rate of 150 per man day. To drive 200 rivets per day requires four men, plus a furnace.

**Strength.** Joints fastened with High-Strength Bolts are considerably stronger — both statically and in fatigue — than those fastened with either hot or cold driven rivets. This has been proven in both laboratory and field tests.

**Adaptability.** Bolted structures are in a class by themselves for simplicity of addition or alteration. Bolts are easily removed by wrench, and just as easily replaced for further use.

For fully descriptive information on STELCO HIGH-STRENGTH BOLTS apply direct to the Heavy Bolt Division, The Steel Company of Canada, Limited, Toronto 3, Ontario, or to any Stelco Sales Office.

5411 I.B.

Mr. Heaton is a graduate of the Institution of Electrical Engineers of Great Britain.

**J. M. Bird,** Jr.E.I.C., has been promoted to the position of general manager of General Equipment Limited in Vancouver.

A graduate in mechanical engineering of the University of British Columbia in 1946, Mr. Bird previously held the position of manager.

**G. J. Chalmers,** Jr.E.I.C., formerly manager of the midwestern office of Ross Engineering of Canada Ltd. in Port Arthur, Ont., has been transferred to the head office of the company in Montreal as Canadian sales manager.

Mr. Chalmers is a 1947 McGill University graduate in mechanical engineering.

**E. N. MacKay** Jr.E.I.C., has been transferred as A & S district manager to Montreal from Quebec City by the Canadian Westinghouse Supply Company.

Mr. MacKay is a 1947 graduate of McGill University.

**D. A. H. Farmer,** Jr.E.I.C., is on the staff of the canal services branch of the Department of Transport in Ottawa. He was formerly sales engineer with Canadian Westinghouse Co. Ltd., Ottawa.

Mr. Farmer graduated from Queen's University in electrical engineering in 1947.

**Rudolph John Scarabelli,** Jr.E.I.C., a 1947 civil engineering graduate of McGill University, has joined Spino Construction Limited in Montreal.

Since graduation he has been employed by Grant Mills Ltd., Montreal, general contractors; the Department of Public Works in Ottawa; and Gardner-Denver Company (Canada) Ltd. in Quincy, Ill.

**John David Dorey,** Jr.E.I.C., a 1948 engineering physics graduate of McGill University, is now systems engineer with Rogers Majestic Electronics Ltd. in Toronto. He was formerly associated with Federal Electrical Manufacturing Co. Ltd., as assistant project engineer

**G. A. Robb,** Jr.E.I.C., until recently associated as design engineer with the New Brunswick International Paper Company in Dalhousie, New Brunswick, has joined the staff of Atomic Energy of Canada Ltd., in Chalk River, Ont.

Mr. Robb, who has been chairman this year of the Northern New Brunswick Branch of the Institute, graduated in mechanical engineering from McGill University in 1948.

**R. L. Payer,** Jr.E.I.C., who has been associated with the Aluminum Company of Canada Ltd. in Montreal, is now on the staff of N. Slater Co. Ltd. in Hamilton, Ont.

He is an electrical engineering graduate of the University of New Brunswick, class of 1948.

**R. R. Cheyne,** Jr.E.I.C., is now in his second year of the M.B.A. course in business administration at the University of Western Ontario.

He was formerly on the staff of the Demerara Bauxite Co. Ltd. in British Guiana, and with General Steel Works Ltd. in London, Ont.

Mr. Cheyne graduated in mechanical engineering from the University of Saskatchewan in 1949.

**W. M. James,** Jr.E.I.C., manufacturing engineer with Canadian Westinghouse Co. Ltd. in Hamilton, has joined the H. O. Trerice Company in Toronto as branch manager.

He is a 1949 graduate in mechanical engineering of the Nova Scotia Technical College.

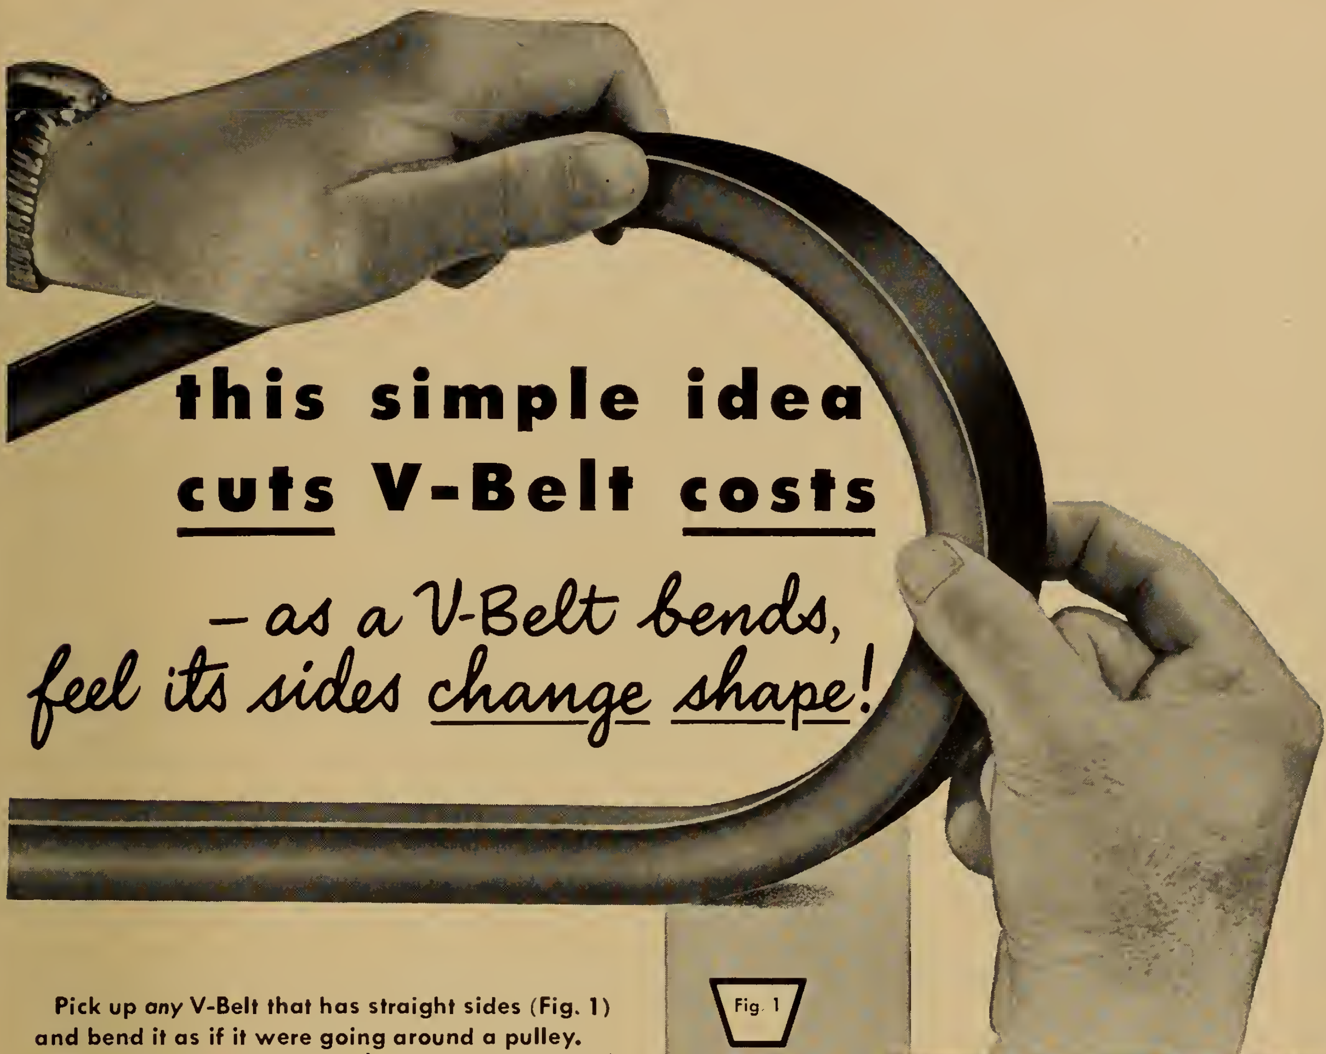
**A. A. Hills,** Jr.E.I.C., has been promoted to the position of senior mechanical engineer in the research department of Ferranti Electric Limited in Mount Dennis, Ont. He was previously with the research department.

Mr. Hills graduated with honors in physics from Queen's University in 1949.

**Ivan G. MacFarlane,** Jr.E.I.C., who was granted his M.Eng. degree in civil engineering by McGill University in October, is now on the staff as assistant research officer of the building research division of the National Research Council.

Mr. MacFarlane received his B.Eng. degree from the University of New Brunswick in 1949.

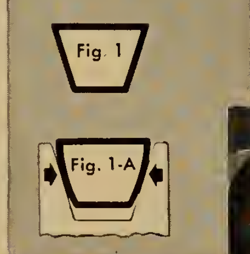
**Julius Weiss,** Jr.E.I.C., formerly associated with Nicolas Fodor & Associates in Toronto, has joined the staff of Flanagan & Black in Toronto.



# this simple idea cuts V-Belt costs

## — as a V-Belt bends, feel its sides change shape!

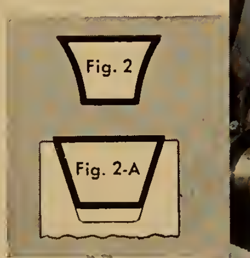
Pick up *any* V-Belt that has straight sides (Fig. 1) and bend it as if it were going around a pulley. At the same time, *grip its sides* with your fingers! You will feel the sides *bulge out* as in Fig. 1-A. Clearly, the bulging belt is forced to press *unevenly* against the V-pulley—and this concentrates wear at the points shown by arrows (Fig. 1-A).

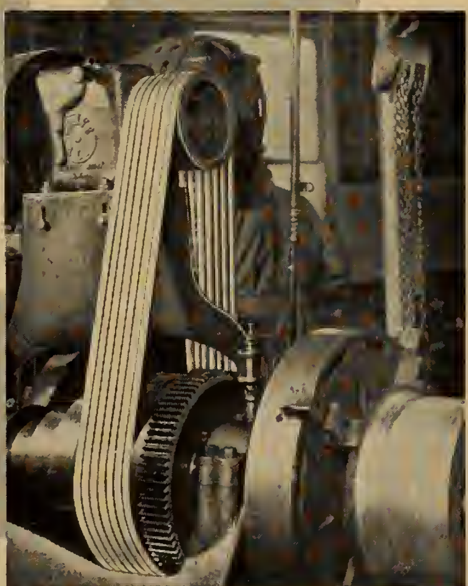


**Now bend the belt with CONCAVE SIDES** (U.S. PAT 1813698)

**. . . the GATES VULCO ROPE (Fig. 2)**

Instead of *bulging*, the precisely engineered CONCAVE SIDES merely *fill out* and become perfectly straight. This belt, when bent, *precisely fits* its sheave groove (Fig. 2-A). The sides press *evenly* against the V-pulley. Therefore, wear is distributed *uniformly* across the full width of the Gates Vulco Rope—and this means longer belt life and *lower belt costs* for you!





Typical Gates Vulco Rope Drive

Gates

GATES RUBBER OF CANADA Ltd.
Brantford, Ontario

TPA 14

*Gates distributor stocks and drive engineering service are quickly available throughout Canada*

He is a 1949 graduate in mechanical engineering of McGill University.

**M. E. Thompson,** JR.E.I.C., formerly associated with Sperry Gyroscope Co. of Canada Ltd. in St. Hubert, Que., has joined the Bristol Aeroplane Company in Winnipeg.

Mr. Thompson graduated in electrical engineering from the University of Manitoba in 1949.

**Arthur P. Earle,** JR.E.I.C., has been promoted from the position of assistant superintendent to that of superintendent of the generation and transmission department of the Shawinigan Water and Power Company in the Three Rivers district.

Mr. Earle has been associated with the company since his graduation in electrical engineering from McGill University in 1949.

**Bruce Emslie Moore,** JR.E.I.C., a 1950 graduate in engineering and business of the University of Toronto, is now on the staff of the Canadian Underwriters Association in Montreal.

He was formerly associated with William Kennedy and Sons Ltd. in Owen Sound, and with National Table Company Ltd. in that city.

**A. R. Sandall,** JR.E.I.C., until recently with the Ontario Northland Railway, has joined the National Steel Car Corporation in Hamilton.

Mr. Sandall received his B.Eng. degree in mechanical engineering from the Nova Scotia Technical College in 1950.

**Ferris J. Abbass,** JR.E.I.C., is installation engineer of Cossor (Canada) Limited, designers and manufacturers of electronic equipment in Halifax.

A graduate in electrical engineering of the Nova Scotia Technical College in 1950, Mr. Abbass was previously foreman in the special lamps department of Canadian Westinghouse Co. Ltd.

**G. J. Foley,** JR.E.I.C., is branch manager of Defence Construction (1951) Ltd. in Winnipeg. Prior to accepting this position he was army projects engineer in Ottawa and building estimator Central Housing and Mortgage.

Mr. Foley is a 1950 graduate in civil engineering of the University of Saskatchewan.

**Charles E. G. Smith,** JR.E.I.C., a graduate in electrical engineering of the University of Toronto, class of 1950, has resigned his position with Pembroke Electric Light Co. Ltd., and has joined Atomic Energy of Canada Limited, engineering division, in Chalk River.

**André A. Albert,** JR.E.I.C., has been transferred by the highway division of the Department of Public Works from Bathurst to Fredericton where he was employed as district highway engineer.

Mr. Albert is a 1950 graduate of the University of New Brunswick in civil engineering.

**W. D. Alexander,** JR.E.I.C., who recently received his master's degree in mechanical engineering from the University of Michigan, has been appointed test officer of the Canadian Army at the Vehicle Experimental and Proving Establishment in Ottawa.

Mr. Alexander received his B.Sc. degree in mechanical engineering from the University of Manitoba in 1950.

**William M. Wilson,** JR.E.I.C., has recently accepted the position of sales representative with the chemical division of Canadian Industries Limited in Toronto.

He was formerly associated with Building Products Limited in Havelock, Ont. and with British American Oil Co. Ltd. in Montreal.

Mr. Wilson is a 1951 mining engineering graduate of McGill University.

**Johannes DeFeyter,** S.E.I.C., a 1953 mechanical engineering graduate of the Technical University, has joined Canadian Industries (1954) Ltd. in Brownsburg, Que.

**R. G. Nicholls,** S.E.I.C., a graduate this year in mechanical engineering of the University of Manitoba, is junior mechanical engineer with the gas division of the Shell Oil Company in Calgary.

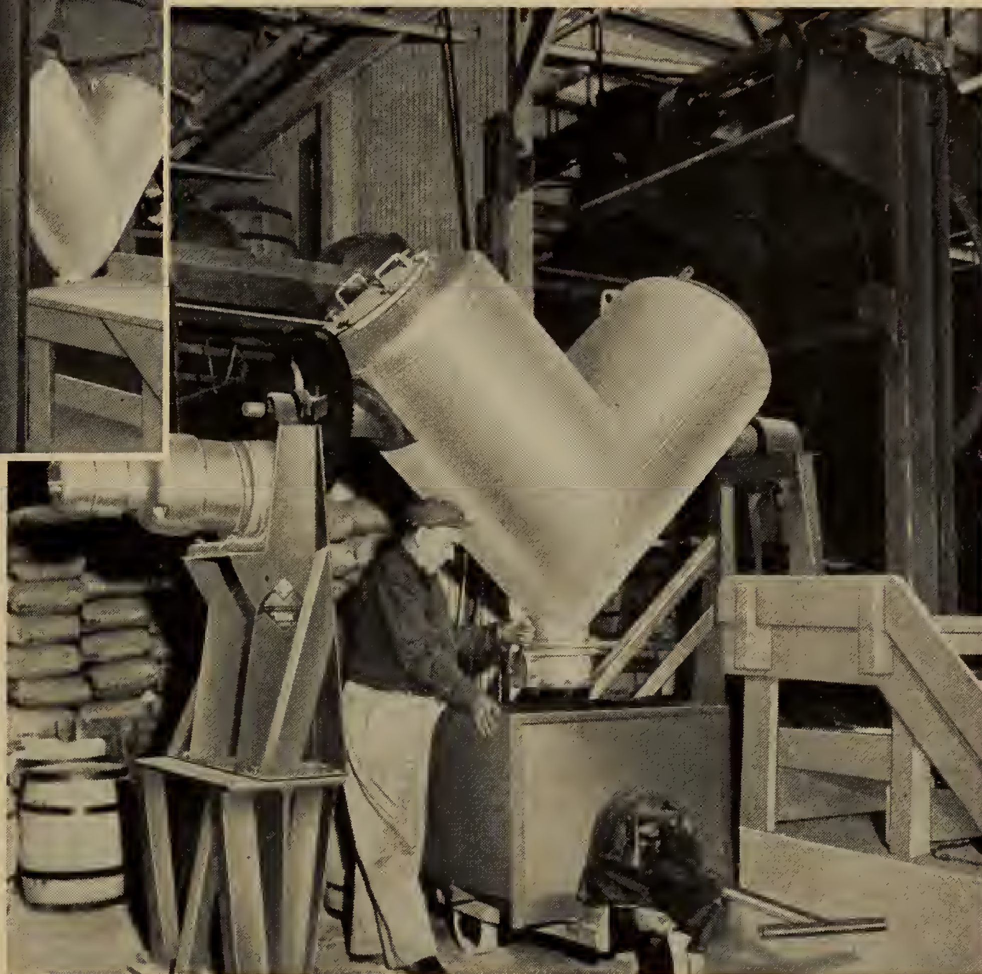
**L. A. Coles,** S.E.I.C., who graduated this year in civil engineering from the University of New Brunswick, has joined M. G. Schurman Co. Ltd., general contractors, Summerside, P.E.I.

**H. M. Tomlinson,** S.E.I.C., has been transferred by Shawinigan Engineering Co. Ltd. from Montreal to Shawinigan Falls as field engineer.

He is a 1954 civil engineering graduate of the Nova Scotia Technical College.

**Frederic Cronn,** S.E.I.C., is junior instrumentman with the Ontario Department of Highways in Toronto.

He was previously inspector with Lucas Rotax in Scarborough.



Loading and unloading a blender can be easy when it's correctly designed. Above, a worker at Precision Grinding Wheel Co., uses a skip hoist to load a p·k twin shell blender of 20 cu. ft. capacity. At right, after mixing, he opens a valve to discharge the perfectly blended mass into a mobile hopper. The smooth interior of p·k blenders are entirely free of obstructions to allow easy discharge and cleaning.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Robert Arthur Rankin,** M.E.I.C., president of Rankin Company Limited, consulting engineers of Montreal, passed away on August 14, 1954.

Mr. Rankin was born in Glasgow, Scotland, on November 19, 1902. He received his early education at Bellahouston Academy and the Royal Technical College in Glasgow. In 1925 he obtained his B.Sc. degree in mechanical and electrical engineering from Glasgow University, and after his arrival in Canada he received in 1933 and 1937, respectively, his M.Eng. degree in industrial economics and his M.Sc. degree in metallurgy from McGill University.

Previous to graduation from Glasgow University he was employed by Ferme Colliery, Messrs. John McNeil and Company, the Armstrong Construction Company, and the Naval Dockyard at Dalmuir, Scotland.

Mr. Rankin came to Canada in 1927 and joined the Anglo-Canadian Pulp and Paper Mills in Quebec City as supervisor of mechanical and electrical installations, and later, as supervisor of power plant and general mill operation. In 1930 he was appointed manager of the Morton Engineering and Drydock Company in Quebec.

The following year he became engaged in general industrial consulting work in Montreal, first with Ernest Cormier, architect, on the mechanical and electrical work in *Le Petit Journal* press room and plant, the University of Montreal and the Supreme Court of Canada, as well as other projects. Then, in 1938 he formed his own consulting engineering company under the firm name of Robert A. Rankin and Company in Montreal. The services of his firm were used by the Algonquin Paper Company in Ogdensburg, N.Y., and the St. Lawrence Paper Company in Three Rivers; they were also retained by Ogilvie Flour Mills Company Limited and the Brown Corporation (Canada) in the supervision of all maintenance engineering and development of new projects. The name of the company was subsequently changed to Rankin Company Limited.

Mr. Rankin was a member of the Corporation of Professional Engineers of Quebec.

He joined the Engineering Institute as a Member in 1941.

**William Henry Riehl,** M.E.I.C., city engineer of Stratford, Ont., for the past 26 years, died suddenly in Boston on August 16, 1954, during a holiday motor trip.

Mr. Riehl was born in Sebringville, Perth County, Ont., on April 30, 1897. He received his B.A.Sc. degree from the University of Toronto in 1920. Previous to graduation he was employed as rodman by Canadian Pacific Railways and as transitman by the Grand Trunk Railway.

In 1920 he was appointed assistant engineer for the City of Stratford, and five years later, accepted the position of engineer of the Town of Brampton. He returned to Stratford as city engineer in 1928.

Mr. Riehl joined the Engineering Institute as a Student in 1919, transferring to Associate Member in 1925, and to Member in 1940.

**Lawrence Sulis Cossitt,** M.E.I.C., plant engineer with the Turcot works of Canadian Car and Foundry Co. Ltd. in Montreal, passed away on May 9, 1954.

Mr. Cossitt was born at Smith's Cove, N.S., on May 3, 1899. He attended Acadia University, interrupting his studies to serve during World War I as a lieutenant in the Royal Air Force. He received his B.Sc. degree in mechanical engineering in 1924, but previous to that was employed in machine shop work with Clarke Bros. Ltd. in Bear River, N.S., and as draughtsman with Atlantic Sugar Refineries.

Upon graduation Mr. Cossitt became production clerk with Northern Electric Co. Ltd. In 1926 he joined The Robert Mitchell Company as a mechanical draughtsman, and was promoted to the position of estimator in 1929. In 1930 he joined the Canadian Car and Foundry Company in the master mechanics department. He was subsequently associated with R.C.A. Victor Limited and with Canadian Marconi Limited in Montreal, after which he returned to Canadian Car and Foundry Limited in 1938 as plant engineer.

An outstanding Canadian fencer, Mr Cossitt was a past-president of the Province of Quebec Fencing Association, and a past-chairman of the National Fencing Committee of the A.A.U. of C. Not long ago he voluntarily gave up the opportunity of fencing for Canada in the Olympic and Empire Games.

Mr. Cossitt joined the Engineering Institute of Canada as a Student in 1921, transferring to Junior in 1926, to Associate Member in 1932, and to Member in 1940.

**Archie Menso Allen,** M.E.I.C., former general plant superintendent of Alberta Government Telephones in Edmonton, passed away on August 11, 1953.

Mr. Allen was born at Cameron, New York on July 17, 1883. After receiving his public and high school education and completing private study, he joined the Century Telephone Construction Company as lineman and inspector in 1901. In 1909 he became inspector with the Northwest Telephone and Telegraph Company.

He joined Alberta Government Telephones in 1910 as district foreman and chief inspector, becoming local agent and wire chief in 1914. He was appointed plant chief in 1920 and construction engineer in 1929, and was subsequently named general plant superintendent, which position he held until his superannuation in 1948.

Mr. Allen joined the Engineering Institute as an Associate Member in 1937, and transferred to Member in 1940.

**Alexander Andrew Vorres,** JR.E.I.C., purchasing engineer with Canadian Industries Limited in Montreal, passed away on October 31, 1954.

A native of Athens, Greece, Mr Vorres was born on May 8, 1926. He received his general education at the American High School of Athens, and in 1946 entered Queen's University, Kingston, Ont., where he graduated in chemical engineering in 1950. In the summer of 1947 he served as assistant surveyor for the County of Waterloo

A sports enthusiast, Mr. Vorres was particularly interested in hunting, swimming, tennis, golf, sailing and football. He was also keenly interested in writing and painting, both of which he pursued. While at Queen's he served not only as a member of the staff, but also as editor of the "Tricolor".

Mr. Vorres joined Aluminum Company of Canada, Limited in Arvida in 1951. Two years later he accepted the position of purchasing engineer with Canadian Industries Limited in Montreal. At the time of his death he was preparing to take over a new position with Aluminum Company of Canada, Limited in Jamaica.

Mr. Vorres joined the Engineering Institute as a Student in 1948 and transferred to Junior Member in 1952.

**John Hiebert,** JR.E.I.C., of A. V. Roe (Canada) Limited, lost his life on August 23, 1954, in a crash which occurred during test flight of a CF-100 jet aircraft out of Malton, Ont. Mr. Hiebert had been serving as observer at the time.

Born in Ekatrinaslav, Russia, on November 27, 1920, Mr. Hiebert received his high school education at Arnaud, Man. During World War II he served as navigator with the Royal Canadian Air Force, and upon his discharge, entered the University of Manitoba, graduating with a B.Sc. degree in mechanical engineering in 1950.

Previous to graduation he was employed during the summers as operator with the Hudson Bay Mining and Smelting Company in Flin Flon, and as grade inspector, instrumentman and assistant resident engineer with the Manitoba Department of Highways.

After receiving his degree, Mr. Hiebert joined Universal Contsruction Co. Ltd. as project engineer in Winnipeg, and two years later became associated with the engineering staff of A. V. Roe Canada Limited in Malton.

He joined the Engineering Institute as a Student in 1949, and transferred to Junior Member in 1952.

# Employment Service

**THIS SERVICE is operated for the benefit of members of The Engineering Institute of Canada and for industrial and other organizations employing technically trained men—without charge to either party. It would be appreciated if employers would make the fullest use of these facilities to list their requirements—existing or estimated.**

**NOTICES appearing in the SITUATIONS WANTED column will be discontinued after three insertions. They will be reinstated, on request, after a lapse of one month.**

**REPLIES to advertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Canada, 2050 Mansfield Street.**

**INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLateau 5078—may be arranged by appointment.**

## SITUATIONS VACANT

### CHEMICAL

GRADUATE CHEMICAL ENGINEER from Canadian University required by manufacturer of organic chemical products. Attractive opening in new project located in Ontario. Seven years of practical experience production and process development is required. File No. 4900-V.

CHEMICAL SALES OPPORTUNITIES for engineering graduates. Young graduates to develop thru-on-the-job training within sales organization and graduates with sales experience in chemical or allied field. File No. 4964-V.

CHEMICAL ENGINEERS required for refinery located in South America. Must be experienced in process engineering including design, economic studies, and/or scheduling of operating programs Write giving age, education, marital status and complete details of experience. File No. 4970-V.

CHEMIST OR CHEMICAL ENGINEER for control department of a newsprint and specialty mill in P.Q. Preferably some experience in pulp and paper. Duties to include development and mill investigations. Give details of experience and references in initial letter. File No. 4982-V.

CHEMICAL ENGINEER or chemist with experience in analysis of metals. Working knowledge of spectographic techniques and practical physical chemistry preferred. Qualified to set up and operate laboratory for control of foundry analysis. File No. 5026-V.

### CIVIL

AN OUTSTANDING OPPORTUNITY for a qualified graduate engineer. Applicants must have had extensive supervisory experience in the construction of highways, dams, tunnels, bridges and like projects, together with a thorough knowledge of estimating and the preparation of tenders. This is a permanent position with an established firm. Write giving full particulars. File No. 4975-V.

WORLD RENOWNED INSTITUTE requires immediately a research engineer to work full time in the materials field for a highway research project. Work includes as well as practical testing, emphasis at the present time on bituminous pavement problems. Young civil engineer with at least a bachelor's degree. He should be interested in research and be able to work on his own. Experience in the materials field will be helpful. The opportunity is given to take one course per term. The salary is in the range of about $350 to $450 per month depending upon education and experience. File No. 4984-V.

CIVIL ENGINEER required by a municipal corporation in Western Canada. Recent graduate having some experience in railroad maintenance preferred. Other duties will cover the design and construction of water and sewage works. This job offers a good variety of experience in the municipal engineering field. File No. 4991-V.

CIVIL ENGINEER required for power department of large industrial concern. Duties include office duties and occasionally field work not necessarily in Canada, in the field of hydro-electric power investigations and development. Applicants must have had fifteen years previous experience. Fluency in French or Spanish in addition to English essential. File No. 4997-V.

ASSISTANT MUNICIPAL engineer for the Town of Pointe Claire, P.Q. Population 12,000. Preferably with experience in maintenance and construction of streets surface water drainage, sewage and watermains. Applicants will require to state qualifications and salary expected. File No. 4999-V.

YOUNG CIVIL ENGINEER required with 3 years or so experience in construction, to supervise service station construction. Location Ontario. File No. 5003-V.

CONSTRUCTION ENGINEER to act as general superintendent for a rapidly expanding organization of general contractors in Toronto. Minimum 10 years outside experience as general superintendent. Main requisite practical experience. This position is that of assistant to general manager, and carries excellent salary and opportunity for right man. Please reply in confidence stating age, marital status, previous employer and references. File No. 5005-V.

THE CITY OF HAMILTON requires an assistant engineer. Must be a professional engineer holding a degree of civil engineering as recognized under the Professional Engineers Act of Ontario. Applicant should have a minimum of ten years experience in the design, construction and supervision of engineering projects particularly as related to a large municipality. Will be required to assist and to work in close co-ordination with the city engineer. This position offers an attractive salary, future security and an opportunity for advancement. Reply stating age, experience, education, and relevant information. File No. 5009-V.

PROFESSIONAL ENGINEER for position of manager of moderate sized construction company. Broad experience in estimating, construction and installation supervision essential. Age in mid forties to work from Toronto office serving mining and newsprint industries across Canada. File No. 5010-V.

RECENT GRADUATE CIVIL engineer required in the track section of a large transportation company in Montreal. File No. 5011-V.

STRUCTURAL DESIGN ENGINEER, $6,420 to $7,200, department of Public Works, Ottawa. Details and application forms at nearest Civil Service Commission Office, Post Office or National Employment Office. Quote Competition 54-1259. File No. 5015-V.

GRADUATE CIVIL ENGINEER for responsible duties in connection with hydraulic research on a large, outdoor erodible-bed tidal river model of the Fraser River estuary on the campus of the University of British Columbia. Must be able to carry out tests, analyze results and prepare engineering reports. Problems deal mainly with river regulations and the maintenance of navigable channels. Reply stating age, experience education, salary expected. File No. 5017-V.

CHIEF DRAUGHTSMAN required. Thoroughly experienced chief draughtsman for structural steel plant. Complete details of educational and employment background and salary required. File No. 5047-V.

ESTIMATOR REQUIRED with experience in the estimating of the fabrication and erection of structural steel. Location Ontario. File No. 5047-V.

DESIGN ENGINEERS wanted by a rapidly expanding firm specializing in prestressed and precast concrete throughout Canada. Several years experience in reinforced concrete is required. Positions offer salary, participation in company's hospitalization and pension plans. Applicants should give full details including age, education, experience, marital status, salary requirements. Personal interview will be arranged with selected applicants. File No. 5049-V.

ESTIMATOR experienced in industrial buildings, bridges and heavy construction required by expanding firm operating throughout Canada. Position offers salary, participation in company's hospitalization and pension plans. Applicants should give full details, including age, education and background, experience, marital status, salary requirements. File No. 5049-V.

SALES ENGINEER for promotion and sales in professional field with background in structures and construction required by firm specializing in prestressed and precast concrete throughout Canada. Position offers salary and commission, participation in company's hospitalization and pension plans. Applicants should give full details including age, education and background, experience, marital status, salary requirements. File No. 5049-V.

CIVIL ENGINEER required by pulp and paper company situated in the Maritime Provinces. He will be in charge of lay-out in the field and also design and draughting in the office. File No. 5053-V.

### ELECTRICAL

CITY IN WESTERN CANADA requires an electrical engineer. Duties: to prepare reports on problems of electrical distribution and utilization; to consult with large wholesale power customers concerning their electrical supply; to maintain technical records and perform related engineering tasks as required. Salary $335 to $408 per month (graduated scale). Qualifications: graduation in electrical engineering from a recognized university with some experience, preferably in electrical distribution system work. File No. 4976-V.

SENIOR DESIGN ENGINEER with a degree in electrical engineering is required for our rotating machines, direct current design section. Applicants should be between 30-45 years of age, with at least six years experience on design of rotating electrical direct current machines in all sizes, including motors, generators, convertors and rotating regulators. He must possess ability to organize, plan, schedule, promote cost reduction and product improvement in engineering. In addition, he must have a thorough knowledge of direct current machine application, and the ability to promote teamwork. This is a senior appointment with excellent opportunity for promotion. Reply in confidence, giving full personal resume, experience, salary expected. File No. 4980-V.

SENIOR DESIGN ENGINEER required with a degree in electrical engineering for our rotating machines. Small motor design section. Applicants should be between 30-45 years of age, with at least four years experience on design of all types of fractional horsepower motors. He must possess ability to organize, plan schedule, promote cost reduction and product improvement in engineering. In addition he must have a thorough knowledge of small motor application and the ability to promote teamwork. This is a senior appointment with excellent opportunity for promotion. Reply in confidence, giving full personal resume, experience, salary expected. File No. 4980-V.

AN OTTAWA ORGANIZATION requires research engineers to investigate problems in the practical application of electro thermal aircraft de-icing. This will include tests in flight and in icing tunnels, and the development of heater pads, and control in co-operation with aircraft firms. University graduation in electrical engineering with experience in aeronautical engineering and preferably in aircraft electric design and development is required. Flying experience is desirable. Salary up to $5,750. per annum depending on qualifications. Apply by letter and enclose resume of qualifications and experience. File No. 4996-V.

ELECTRICAL ENGINEER required by an Eastern Township paper mill. Recent graduate for layout work, procurement and installation of apparatus for paper mill under supervision of superintendent, apply stating age, qualifications and experience. File No. 5019-V.

GRADUATE ELECTRICAL ENGINEER to work in electrical department of paper mill in the Province of Quebec as assistant to the electrical superintendent. Paper mill experience desirable but not prerequisite. Applicant to write giving age, education, experience and salary requirements. File No. 5027-V.

ELECTRICAL SALES ENGINEER required by manufacturer of switchboards high and low tension, panelboards, bus ways and switches to cover Toronto district. Opportunity for the right man to become district sales manager. File No. 5034-V.

YOUNG ELECTRICAL ENGINEER to be employed as sales engineer in the storage battery division of manufacturer located in Montreal. File No. 5038-V.

TWO COMPETENT EXPERIENCED GRADUATE electrical engineers with approximately 10 years experience U.S. or Canadian public utilities, in design, operation and maintenance of distribution facilities in established rapidly growing utility located South America. Reply giving resume education, experience, and personal data. File No. 5041-V.

ELECTRICAL ENGINEER required as junior or assistant distribution engineer. Graduate with at least 3 years field experience operating U.S. or Canadian public utility. Permanent position with long established consulting organization New York. Some travel Latin America necessary in future. Knowledge of Spanish or Portuguese useful. Salary commensurate with experience. Reply giving age, education, experience and personal particulars. File No. 5042-V.

FIVE JUNIOR ELECTRIC ENGINEERS required by Western Utility. Two engineers for hydro-generating stations, one engineer for communications and relay and plant metering, one engineer for sub-station and local distribution systems, and one engineer for system planning and design division. File No. 5044-V.

ELECTRICAL ENGINEER required by transformer manufacturing company in Manitoba. Applicants should have a degree in electrical engineering preferably from a Canadian university, be interested in design work and have worked for a utility or manufacturing company for one or two years. Reply giving details of experience, age, qualifications and proposed salary. File No. 5046-V.

AN ELECTRICAL ENGINEER required to design telephone cable. Prefer an experienced man but will be pleased to review applications from anyone interested in learning this field. Permanent position and salary will depend upon experience and qualifications. Location Ontario. File No. 5052-V.

### MECHANICAL

MECHANICAL ENGINEERS REQUIRED for refinery located in South America. Must be thoroughly qualified and experienced in design of refinery or chemical plant equipment including piping, pressure vessels heat exchangers, etc. Write giving age, education, marital status and complete details of experience. File No. 4970-V.

MECHANICAL ENGINEER required by paper mill located in Province of Quebec with head offices in Montreal. Applicant should have some paper mill experience or interest to be trained for such a position. File No. 4972-V.

YOUNG MECHANICAL ENGINEER required for sales work. Must be energetic with a good personality and the ability or a real desire to sell. Some knowledge of heating and pumping equipment and their applications desirable. Location, Toronto. Good opportunity with long established business concern. Write giving full particulars including training, experience, age and marital status. File No. 4981-V.

MECHANICAL ENGINEERS required for sales positions with prominent Canadian manufacturer. Experience in gear and mechanical power transmisison field would be an asset. Will be located in Ontario or Quebec. Write giving full details of training, experience and salary desired. File No. 4988-V.

JUNIOR DESIGN ENGINEER to be a graduate mechanical engineer, required for designing and making layouts of piping and equipment installations in a chemical engineering plant. Two years experience essential. Location Ontario. File No. 4990-V.

SENIOR MECHANICAL ENGINEER. Salary up to $8,200. Department of Public Works Ottawa. Details and application forms at nearest Civil Service Commission Office, Post Office or National Employment Office. Quote No. 54-1211. File No. 4993-V.

RECENT MECHANICAL GRADUATE or one with evidence or interest in mechanical or technical problems and experience or aptitude for sales. He should be bilingual and able to deal with all levels of personnel and management. The work involves study of actual conditions related to the use of tires and formulation of procedure and policies which must be sold at the level of top management. This offers an excellent opportunity to develop a highly interesting field of customer contact and product research. For the right person a car will be provided. File No. 4995-V.

GRADUATE MECHANICAL ENGINEER interested in a career in Latin America with a Canadian owned electric light and power utility company located Maracaibo, Venezuela. Age limit 30 years and should have 5 years experience in a steam electric generating station. Immediate prospects for promotion to assistant production superintendent and ultimately to executive position if qualified. File No. 5013-V.

SALES ENGINEER with steam plant experience wanted as executive of a new Canadian company to sell, service and assemble combustion controls and industrial instruments in Ontario and Quebec, for well known American manufacturer. Must be native Canadian and a graduate of a Canadian engineering university. File No. 5018-V.

# MECHANICAL ENGINEER to be SERVICES ENGINEER for

**Large manufacturing plant in Eastern Ontario. Work will involve supply, distribution, and use of plant services including: steam, water refrigeration, compressed air, vacuum, ventilation and air conditioning.**

**Duties will include control of all services departments and distribution systems, supervision of maintenance of services equipment, and studies, estimates, and reports on services distribution and consumptions.**

**Must be graduate engineer, age 28 to 35, with several years of practical experience with supply of plant services. Must have the ability to take over leadership of a group and be prepared to make his own decisions and be responsible for them. Preferably should also have first class stationary engineer's certificate. Position will be permanent and offers excellent opportunity for advancement to the right man.**

**Applications should contain all necessary personal data, and full information about previous engineering experience. Reply stating experience and other relevant information to File No. 5062-V.**

---

GRADUATE MECHANICAL engineer to eventually take over as production manager. Company manufactures industrial and construction products from sheet metal, plate and light structurals, including material handling products, fluorescent fixtures, special fabricated sections and weldments, plus a full line of construction products. Due to rapid growth, unlimited opportunity offered. File No. 5021-V.

MECHANICAL ENGINEER required by long established Montreal manufacturing firm to take over duties of plant engineer. Duties involve usual plant maintenance, machine shop, etc., also product development and tool design. Applicant must be English speaking and preferably between the ages of 25-35. Position offers good future and carries usual benefits including pension plan. Please reply in detail stating experience, education, etc. All replies received will be kept in confidence. File No. 5036-V.

GRADUATE MECHANICAL ENGINEER required to work on steam power plant design. Applicant must have at least five years experience on the design and layout of modern high pressure, high temperature control stations. The company is now actively engaged in extensive plant extensions of 25 and 45 MW size, the latter 900 lbs. 900°F on a long term basis, opportunity is offered for advancement in both technical and executive lines of public utility work. Salary paid will be according to ability, academic qualifications and experience. Apply giving age, training experience and approximate salary required. Location Maritime Provinces. File No. 5037-V.

MECHANICAL PLANT ENGINEER required by operating division of service organization. University graduate preferred having 5 to 10 years experience in operation and betterment of steam plants operated by U.S. or Canadian public utilities. Location New York, some travel, Spanish desirable but not essential. Reply by letter giving age, education, experience, personal data and minimum salary acceptable. File No. 5043-V.

MECHANICAL ENGINEER required by manufacturer of wire and cables located in Ontario, for plant engineering department. Preferably one who can do machine design work. Permanent position and salaries will depend upon experience and qualifications. File No. 5052-V.

MECHANICAL ENGINEER required in Edmonton, Alberta, who has graduated from a recognized Canadian University, and who has about 3-5 years experience in a chemical plant or refinery. He will deal mostly in equipment used in the manufacture of petro-chemicals and synthetic fibres. Duties will consist of general engineering, which will include design, layout and estimating. File No. 5055-V.

### MISCELLANEOUS

DIRECTOR ENGINEERING and water resources Branch. Salary up to $11,000 depending upon qualifications. Department of Northern Affairs and National Resources, Ottawa. Details and application forms at Office of the Civil Service Commission, Post Office or National Employment Office. Quote No. 54-685. File No. 4965-V.

VEHICLE EXPERIMENTAL and Proving Officer. $5,100 to $5,820. Department of National Defence, Orleans, Ontario. Details and application forms at nearest office of the Civil Service Commission, Post Office or National Employment Office. Quote No. 54-1210. File No. 4971-V.

ELECTRO CHEMICAL ENGINEER for plant operating electric arc furnaces. College graduate or equivalent with two years plant experience to carry out technical investigations and process studies. Ability to picture ideas by drawings essential. A working knowledge of French, mechanically inclined, have initiative and able to work with other members of our staff are all necessary qualities. File No. 4989-V.

DESIGN DRAUGHTSMAN required for designing and making layouts of piping and equipment installations in a chemical engineering plant. Five years experience essential. Age 24 to 30. File No. 4990-V.

CONTROL ENGINEER for paper mill and pulp mills situated in urban area in the Province of Quebec. Applicants must be university graduates with a minimum of 3 to 5 years experience. Opportunity for advancement excellent. Salary commensurate with experience. File No. 4992-V.

MECHANICAL OR CIVIL ENGINEER required by large mining and milling firm in Eastern Townships for design of plant mechanical installations under supervision of a senior engineer. Will be responsible for layout, specifications, scheduling and engineering supervision of installations. Blue Cross, group life and pension plans available. Personal interview will be arranged at company's expense for suitable applicants. Reply giving full particulars including salary requirements. File No. 4993-V.

SENIOR GUN INSPECTOR with salary up to $5,500.00 per annum depending upon qualifications required by inspection service department of National Defence Ottawa. To supervise inspection and proof of light and heavy ordnance equipment in Canada. Details and application forms at Post Office, National Employment Office or Civil Service Commission. Competition No. 54-1212. File No. 4994-V.

SALES ENGINEER wanted by established transformer manufacturer, for Montreal district. Bilingual preferred. Excellent future prospects. State age, education and experience. File No. 4998-V.

AN OTTAWA ORGANIZATION requires hydraulic engineers to undertake in the hydraulics laboratory research work in either fundamental or applied studies. Fundamental work is in the field of open channel flow, wave motion, sediment transport and allied subjects. Applied studies include the development work of river regulation, harbour development and hydraulic structures-locks, dams, breakwaters and similar installations. A master of science degree with specialization in hydraulics of fluid mechanics is required. Hydraulic laboratory work is desirable but not essential. Salary up to $5,750 per annum depending on qualifications. Apply by letter and enclose a resume of qualifications and experience. File No. 5006-V.

RESEARCH CHEMICAL OR MECHANICAL ENGINEER required by pulp and paper research institute of Canada for research in unit operation and chemical reactions involved in new processes for pulp and paper manufacture. Necessary qualifications include a Bachelor's (or higher) degree in chemical or mechanical engineering and 1-5 years of pertinent experience. This offers an opportunity to gain experience in the planning, executing and reporting of engineering research projects. Salary will be commensurate with previous training and experience. Applicants should address a comprehensive resume of qualifications and career. File No. 5007-V.

THE DEFENCE RESEARCH BOARD requires electronics engineers and physicists for employment in Ottawa, Ontario. Duties: for the electronics engineers the work will be in connection with the technical administration of a development programme. The duties will include secretarial committee work contractual negotiations, liaison work, etc. There are vacancies for physicists interested in research and development on the more fundamental aspects of electronic components, e.g. dielectrics and magnetic materials. Qualifications: electronics engineers should have technical experience in the field of electronic components. Salary: starting salaries will be in the range of $3,600-$5,750 depending upon qualifications and experience. Employee benefits: there is generous provision for vacation and sick leave, superannuation and group hospital medical insurance plans, and a five day week. How to apply: application forms will be sent to qualified applicants on receipt of letters outlining qualifications and experience. Please write mentioning 54-DRP-4 to File No. 5008-V.

TWO GRADUATE MECHANICAL or electrical engineers. One as plant engineer in a small Ontario town. The other for technical and administrative work in the office of the chief engineer of the company in Montreal. File No. 5012-V.

ASSISTANT PROFESSOR of draughting. Royal Military College of Canada, Kingston, Ontario. Salary up to $5400 per annum. Civil or mechanical engineer preferred. Further information may be obtained by writing the Civil Service Commission, Ottawa. Quote Competition 54-2008. File No. 5014-V.

DESIGN AND DEVELOPMENT engineer required for modern materials handling equipment plant in Western Ontario. Must be prepared to take charge of drawing office and to deal with all matters of design and development appertaining to materials handling equipment. Salary commensurate with responsibility and experience. File No. 5016-V.

FIRM IN MONTREAL requires high calibre personnel to fill the following executive positions. Sales manager with sound engineering background and experience in the conveyor industry. Ability to negotiate at high level. Chief engineer with wide experience on design and layout of all types of heavy material handling plant. First class knowledge of bulk handling necessary. Generous salary and commission in both cases. File No. 5020-V.

AGRICULTURAL FIRM Eastern Townships required graduated and/or practical engineer to assume gradually responsibility for all plant mechanical, electrical, heating and construction problems. This is a good opportunity for a young man, preferably not over 35 years of age and which can lead to plant engineer within 3 years at a minimum salary of $5,000. The man we are looking for must have administrative ability and good personal characteristics to work up to management level Starting salary commensurate with qualifications. File No. 5022-V.

PERMANENT STAFF POSITIONS ARE available for 3 graduate engineers in layout and design, maintenance and operating department. Minimum qualifications include graduation from recognized university and 3-10 years experience preferably including alkaline pulping or paper mill design or maintenance. Salary commensurate with experience. Write giving full details of education, age, experience, marital status and references. Location Ontario File No. 5024-V.

SALES ENGINEER location Montreal required by large Canadian manufacturer for technical sales promotion of building products. Applications are invited from graduate engineers with civil or mechanical background and an aptitude for sales work. Age preferred 30 to 45. Address full details of education and experience to file No. 5023-V.

VENTILATING SALES ENGINEER required. Young man with experience in ventilation work to manage Montreal office of Fan manufacturing company. Unique opportunity for right man. Car supplied. Advise age, experience and particulars. File No. 5028-V.

CHEMICAL OR METALLURGICAL ENGINEER, class '48-'52, sales experience preferred for technical sales with growing industrial division of worldwide organization manufacturing centifuges, heat exchangers, pumps, vibrating screens for use throughout industry. Location, Ontario or Quebec File No. 5029-V.

DETAIL AND ASSEMBLY tool designers required for extensive aircraft program. Experience desired: 10 years experience in sheet metal fabrication industry with five years on aircraft tool design. Location Ontario. File No. 5031-V.

WELL KNOWN MANUFACTURING FIRM requires the services of a fully qualified industrial engineer to survey and report on manufacturing processes. Must have knowledge and experience of production methods. Knowledge and experience of the modern concept of quality control methods. Apply stating both qualifications and experience in full to File No. 5032-V.

YOUNG GRADUATE MECHANICAL engineer, age 21, to 25 to work in the Toronto area under the supervision of the chief engineer of the pump manufacturing plant. He will act in the capacity of job process engineer, prepare all bills of material, test pumping units and as experience gained, opportunity to learn design. File No. 5033-V.

ASSISTANT PLANT ENGINEER required for manufacturing plant located on the lower mainland of B.C. Good opportunity for an aggressive man. Duties to consist of plant layout, process improvement, materials handling, machinery and equipment replacement and related duties. Prefer applicant with one or two years experience after graduation. All replies will be kept in strict confidence. File No. 5035-V.

CIVIL OR ELECTRICAL ENGINEER, university graduate of two or three years' experience in civil or electrical fields and above average literary ability. Permanent employment in Ottawa with well known industrial association. Pension plan. File No. 5039-V.

SALES ENGINEER not over fifty years of age, living in Montreal area and to be responsible for the province of Quebec. Required to contact industrial, utility, and contracting companies, liberal salary for satisfactory man and excellent opportunity for advancement to executive responsibility. Only highest grade, responsible man of experience, will satisfy our requirement. Montreal interview will be promptly arranged. File No. 5040-V.

SOIL MECHANICS ENGINEER required by Vancouver engineering firm. Post graduate training essential. Two to four years practical experience preferred but not absolutely necessary. Excellent opportunity leading to responsible position for engineer with initiative and personality. Reply stating age, education and experience. File No. 5045-V.

TWO MECHANICAL OR ELECTRICAL ENGINEERS required by elevator manufacturer located in Montreal to act as sales and or service engineer. Applicants should be recent graduates, no previous experience necessary. Must be bilingual. Age 30 years or under. File No. 5050-V.

YOUNG ENGINEER or metallurgist with experience in the light metals field, either in a light metals development laboratory or as a technical service representative for a base producer of light metals. Required by large Canadian organization establishing a market for magnesium in Canada to work out of Toronto. After suitable training with parent company he will be given full responsibility and authority to increase the market. Top salary open. File No. 5056-V.

# SITUATIONS WANTED

MECHANICAL ENGINEER, age 32, Polytechnique 1945, bilingual. Employed as combustion engineer with large distributer of coal and fuel oil in Montreal. Extensive field experience on all aspects of fuel utilization, sales and service. Seeks employment with oil company or equipment manufacturers related to power engineering as combustion and/or sales engineer. File No. 2554-W.

ELECTRICAL ENGINEER, P.Eng., M.E.I.C., B.Sc. (U.N.B., 1937) age 42, married, 1 child, 7 years with large Canadian Electrical Manufacturer including test course, 2 years switchboard design and 3 years apparatus correspondence sales. Hold technical secondary school teacher's certificate with university and school teaching experience. Heating engineering experience (2 years) in the design of hot water heating systems and service of automatic steam generators. Am seeking a responsible position as industrial training supervisor, power plant engineer or other responsible position. Residing in Toronto and free to accept immediate employment anywhere. File No. 2878-W.

ELECTRICAL ENGINEER, B.Sc. (E.E.) 1950, Jr.E.I.C., age 33, married. Presently employed managerial capacity in sales and sales promotion, directing small sales staff. Present earnings in excess $5,000.00. Varied experience in sales, sales promotion, office management and with Public Utilities. Desires responsible position in sales, sales representative or in line with experience. Details of education, experience and reference upon request. File No. 3375-W.

MECHANICAL ENGINEER, Jr.E.I.C., U. of S. 1950, age 27, single. Four years experience in design and layout of steam boiler plants. Have also acted as residential engineer on some installations. Seeking interesting position with possibilities in mechanical or power field. File No. 3495-W.

MECHANICAL ENGINEER, Jr.E.I.C., 1950 graduate University of Saskatchewan. Excellent practical background combined with sales and administrative ability. Thoroughly familiar with the pulp and paper, automotive and farm implement industries. Able to work well with others. No objection to travel and will accept a position anywhere in Canada or U.S.A. Please reply to File No. 3536-W.

CIVIL ENGINEER, M.E.I.C., 1944 graduate, now residing Toronto, desires position in commerce or industry. Experienced in heavy construction, consulting, contract negotiation, administration and personnel fields. File No. 3796-W.

ELECTRICAL ENGINEER, B.Eng., McGill, 1950, P.Eng., Jr.E.I.C. C.G.E. Test Course. Experience: design; polyphase motor design and application ½ to 600 h.p., industrial; design and construction of distribution, lighting and power installations, power factor correction, frequency conversion, system control, air conditioning and plant engineering work, general; artillery officer overseas in World War II, working knowledge of French, age 35, married, three children. File No. 3859-W.

MECHANICAL ENGINEER, P.Eng., Jr. E.I.C., experienced in machine design and mechanical drafting seeks part time employment in Calgary, Alberta area. File No. 3902-W.

METALLURGICAL ENGINEER, Jr.E.I.C., P.Eng., B.Sc. (Chemistry), B.E., Nova Scotia T.C. 1952. Married, age 32. Experience includes one year as metallurgical chemist in a control lab., one year as assistant welding engineer with a steel fabricator and about one year with a research firm on ore preparation and reduction of ores. Desires technical position with firm located in Toronto area. Available on short notice. File No. 4128-W.

CIVIL ENGINEER, M.Sc., M.E.I.C., P.Eng. (Ont.), graduate 1947, is available. First class designer of all types of modern structures, inventive, enterprising and with flair for structures involving complex statical problems. File No. 4173-W.

ELECTRICAL ENGINEER, age 29, with 3 years experience in heavy industry, 2 years in communications, test course graduate, desires responsible work in West, preferably Edmonton area. File No. 4349-W.

MECHANICAL ENGINEER Jr.E.I.C., P. Eng. (Ont.), B.Eng. 1952, age 30, married, with two years of experience on plant maintenance in a chemical plant, also one year's experience in industrial engineering, 3 summers general workshop practice including overhaul of diesel engines. Desires work on plant maintenance or production. File No. 4453-W.

YOUNG ELECTRICAL ENGINEER interested in learning the generation and distribution field with a consulting engineer, contractor or utility. Presently working in a large petrochemical plant on all phases of the electrical system. Will send resume on request. File No. 4510-W.

ELECTRICAL ENGINEER B.A.Sc. Toronto, 1950, P.Eng. (Ont.), Jr.E.I.C., age 30, married, experience in industrial construction, field supervision, electrical generation and distribution, paper mill operation and maintenance. Desires position offering opportunity. Will locate anywhere. File No. 4545-W.

ELECTRICAL ENGINEER, Power, McGill 1953, S.E.I.C., age 26, married, presently employed. Experience includes Westinghouse Training Course; small motors, switchgear, household appliances. Interested in a permanent position with an opportunity for further professional development in electrical engineering field. Good references. Location Montreal only. File No. 4553-W.

MECHANICAL ENGINEER, London University 1948. Experience includes 6 years, project and plant engineering in chemical industry, U.K. and Argentina. Presently employed in Canada in non-technical capacity. Desire position in line with previous experience. Location immaterial. File No. 4596-W.

CIVIL ENGINEER B.Sc. Manitoba, M.E.I.C., ten years varied experience as designer and field engineer on plant construction and maintenance. Supervised structural and mechanical installations in Canada's largest pulp and paper, foundry, and automotive industries. Seeks position as assistant to resident or plant engineer with progressive company. Highest references and executive evaluation reports. File No. 4597-W.

PROFESSIONAL ENGINEER with master's degree in business administration, bachelor's degree engineering, 3½ years utility, 6 years manufacturing and sales, test course. Author technical papers. Accustomed to responsibility. Age 30. Seeks position with future. File No. 4599-V.

MUNICIPAL ENGINEER, M.E.I.C., age 46, bilingual, seeks managerial or senior engineering position with an expanding municipality. Also would consider work for a consulting firm specialising in town planning, design of subdivisions and municipal services. The advertiser would require some 2 or 3 months notice from his present position of project engineer for a large urban subdivision. File No. 4600-W.

MECHANICAL ENGINEER Jr.E.I.C., P. Eng., married. 7 years design experience in pulp and paper equipment, heavy industrial and marine equipment. 4 years research and development in combustion engines mainly diesel. File No. 4601-W.

MECHANICAL ENGINEER, M.E.I.C., P. Eng., grad. U. Riga, Latvia, age 43, family, 8 years preliminary and 14 years responsible practice. Latter includes: heating and plumbing, design and installation; industrial engineering, process, research, production, maintenance, design and supervising of plant expansions; construction engineering; roads—survey, design, construction. Four years of this experience in Canada and five under U.S. army in Germany. Available for an engineering appointment in Montreal area, end of April 1955. Interview—Jan. 1955. File No. 4602-W.

ELECTRICAL ENGINEER, B.Sc.E.E., Man. 1950, Jr.E.I.C., age 26 married, 1 child. Four years with public electric power utility, including supervision of transformer repair dept., supervision of recloser servicing, experience in metering installations and meter testing, and experience in various operational problems of power lines and associated equipment. Seeks position in work related to experience, preferably design, with manufacturer, power utility, or industrial concern where conscientious work and ability result in opportunity for advancement. Available on suitable notice to present employer. File No. 4603-W.

MECHANICAL ENGINEER, age 33, married, no children, university of Toronto 1943, veteran. Ten years industrial experience, four years design, engineering, manufacturing, production and purchasing, six years application, marketing, sales and service. Experience covers power plant equipment, pumps, feed water conditioning apparatus, boiler controls, materials handling equipment, electrical, hydraulic and pneumatic control systems, petroleum products, mining machinery and power transmission machinery. Presently employed but desires challenging work for aggressive firm with opportunity for administrative and/or management career in sales, service or manufacturing. Would prefer Ontario, Alberta, or British Columbia. Particulars willingly supplied to interested employers. File No. 4604-W.

MECHANICAL ENGINEER, Australian Graduated 1943. A.M.I.E. Australia, 32, married. No children. Experience includes field installation of mechanical or electrical plant, army workshop. Supervision large scale refrigeration unit. Design development and manufacture of welded steel pipe plant. Physical testing, instrument calibration, materials investigation, lecturing in mechanical engineering and laboratory supervision. Factory management. Consultant on steel fabrication factory design and layout. Recently arrived Canada. Desires position in or near Montreal. Available immediately. References. File No. 4605-W.

CIVIL ENGINEER, B.Sc., P.Eng., M.E.I.C., age 30, family. Desires to become permanently established in large city, preferably in Western Canada. Three years experience as city engineer in charge of public works and utilities. Experienced in sewer and water main installation, sidewalk and curb construction, drainage, paving. Four years experience as resident engineer on highway construction, four summers on federal government geodetic and irrigation surveys. Further particulars will gladly be forwarded to interested employers. File No. 4606-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng., age 36, married, wide experience in plant engineering, maintenance, plant layout, design and development in industrial and aeronautical field. Proven executive ability. Presently employed in managerial capacity. Wishes permanent position in progressive organization requiring initiative and abilty. Montreal area preferred. Resume on request. File No. 4607-W.

MECHANICAL ENGINEER, P.Eng., Jr. E.I.C., veteran 4 years R.C.N. B.Sc. mechanical engineering, Queen's 1950. Age 34, married, 2 children. Administrative experience obtained in a large chemical plant, engineering and maintenance department, which included 3 years supervising maintenance and 1½ years engineering work on material handling, corrosion piping, and packaging problems. Sound practical experience gained when obtaining machinist fitter's Journeyman's papers. Desires a challenging responsible position with good opportunities situated in Ontario. File No. 4613-W.

MECHANICAL AND INDUSTRIAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.). 5 years experience in plant engineering and layout, structural steel design, foundations, buildings, heavy machinery installation, piping, and process investigations. Above included drafting, detailing, cost estimation, and construction supervision. Have also had 2 years experience in townside engineering and development, lot surveys and related work. Desires part time work with construction or engineering firm or private individuals in Montreal, Ottawa, Cornwall area. Free to travel. File No. 4614-W.

ELECTRICAL ENGINEER, M.Sc., graduate Delft Technological University, Holland, 25 years old, married, specialized in the power side: electric and diesel electric traction, generators, motors, transformers, high and low tension cables and lines, control and protective equipment, experience 8 months. Fluent English, German, French and Dutch. Seeks position in line with his education. Available in 2 weeks anywhere. File No. 4615-W.

CIVIL ENGINEER, Jr.E.I.C., Polytechnique '51, 26, single, 4 years experience with the R.C.A.F. construction engineering branch, supervision of roads and runways construction, reconstruction of various buildings, experience with all construction trades, inspection of construction sites. One year as resident engineering officer at R.C.A.F. unit requiring knowledge of maintenance and operation of diesel engines, air conditioning equipment, refrigeration, municipal engineering and related subjects. Will be ready for employment in April '55. Administration experience, perfectly bilingual, would feel capable of handling assistant town engineer position for medium size community. Will travel if necessary. File No. 4616-W.

CIVIL ENGINEER, Jr.E.I.C., graduate N.S.T.C. 1952, age 31, married with children, desires position in Maritimes with firm engaged in residential construction and/or community planning. Also interested in inspection services related to the above. Presently employed by research organization in Ontario. Available on reasonable notice to present employer. File No. 4617-W.

ELECTRICAL ENGINEER, (Belfast, N. Ireland, 1949) P. Eng., Jr.E.I.C., graduate I.E.E., age 26, married with 2 children, desires position in Montreal. Experience includes 5 years indentured electrical engineering apprenticeship, 2 years test and inspection engineer, 2 years electrical machine design, 3 years Canadian experience in power lighting and distribution. Available on one month's notice to present employer. File No. 4619-W.

MECHANICAL ENGINEER, M.E.I.C., age 36, British 2½ years in Canada, seeks immediate employment. 12 years experience in the army and civilian life in mechanical handling and construction equipment. Since arrival in Canada employed as lubrication and maintenance engineer in the pulp and paper industry. Will consider work in any field of mechanical engineering. File No. 4620-W.

MECHANICAL ENGINEER Swedish Technical Institute, age 38, married. Experience includes 15 years in the oil industry, as project engineer and on the construction of oil plants which includes installation of pipelines, production and methods planning; design and service of burners and equipment for gasoline, fuel oil, butane-propane gas and petroleum industries. One and half years in Canada employed as oil burner mechanic and draughtsman. Seeks opportunity where former experience can be best utilized. Location immaterial. Available immediately. File No. 4625-W.

CIVIL ENGINEER, P.Eng., Jr.E.I.C., 1951 graduate. Seeks part time employment in Montreal. Experience in design of R.C. structures, field work in construction and general maintenance in chemical processing industry. Some draughting. File No. 4627-W.

ELECTRICAL ENGINEER, M.E.I.C., McGill 1943, married. Experience in electronic communication and power principally in sub-station design. Desire position with responsibility. Speaks French and English fluently. File No. 4628-W.

GRADUATE ENGINEER 1941 Civil M.E.I.C., age 25, married with family. Considerable experience as job engineer and superintendent. Have a responsible position in a growing construction firm, seeking similar position preferably in Ontario. Particulars willingly supplied. File No. 4629-W.

MECHANICAL AND METALLURGICAL ENGINEER, Jr.E.I.C., P.Eng. Dipl. Ing. age 39, married, no children. 10 years experience in various phases of metal fabricating processes: machining, stamping, deep drawing, forging, casting, heat treating etc. Desires position with a progressive company to take care of all technical problems combined with supervision, cost reduction program, methods improvement and general development of plant facilities. File No. 4632-W.

MECHANICAL ENGINEER S.E.I.C., B. Engineer with honours McGill 1953. Presently located in Montreal. Thorough background of machine shop experience, production planning and allied engineering office problems. Some experience also in surveying field work. Desires part time employment evenings and Saturdays in draughting, calculating, surveying, tutoring mathematics and sciences or as consultant in production planning and control problems. File No. 4634-W.

## Hamilton

N. A. Parry, Jr.E.I.C.,
*Secretary-Treasurer*

F. S. Gue, Jr.E.I.C.,
*Branch News Editor*

***Annual Ball***

Hamilton engineers enjoyed another highly successful Annual Ball on Friday evening, October 16, despite the worst efforts of Hurricane Hazel. With excellent music supplied by Chris Lovett and his orchestra, prizes donated by local business firms, an appetizing buffet lunch and refreshments provided by Fischer's Hotel, the Ball once more proved a popular fall-season rendezvous for members of the profession and their friends.

Responsible for this year's ball was a committee consisting of Mike McAuliffe, chairman, Frank Barnard, secretary, Norm Parry, treasurer; Andy Frame, arrangements; Jack Skinner, prizes and favors; Charlie Kain, vice chairman and ticket sales; Joe Harbell, promotion and advertising; and Hugh Seely, publicity.

Patrons of the function were Mr. and Mrs. L. C. Sentance. Mr. Sentance is a past chairman of the Hamilton Branch. Guests were Mr. D. Switzer, chairman, Hamilton Section, Chemical Institute of Canada, and Mrs. Switzer; Mr. W. A. Wheten, chairman, Hamilton Branch, E.I.C., and Mr. N. A. Parry, secretary-treasurer, Hamilton Branch, E.I.C.

***October Meeting***

The regular October meeting took place Oct. 21, when Mr. C. P. Monteith, of the Aluminum Company of Canada, presented an up to date report on Alcan's vast Kitimat-Kemano project. Accompanied by an excellently narrated movie "The Man with a Thousand Hands", Mr. Monteith's address threw fresh light on some of the less familiar details of this fantastic undertaking, a project having more than its share of "firsts". The audience was treated to a glimpse into the future of a vast region in northern British Columbia, destined to become the cradle of new cities and a new industrial empire.

## Huronia

L. Morgante, Jr.E.I.C.,
*Secretary-Treasurer*

***Dr. A. E. Berry, Guest Speaker***

The Huronia Branch held a meeting in Owen Sound on October 1. The speaker was Dr. A. E. Berry, chief sanitary engineer of the Ontario Department of Health. He talked on pollution generally.

This is a timely subject in Owen Sound where there may be a sewage disposal problem. The sewage now is dumped into the harbour and has created conditions which must be corrected before very long.

The Hon. Dr. MacKinnon Phillips, Minister of Health for the Province, was to have introduced the speaker, but unfortunately was late due to very

**At the Hamilton Branch Engineers' Ball. Upper left, an unidentified, but happy engineer receives a prize from Chairman W. A. Wheten. Right, Mrs. A. P. Delaney is presented with a prize by Mr. J. Skinner. Mr. Delaney looks on. Lower left, Mrs. and Mr. Don Switzer, Mr. and Mrs. L. O. Sentance (patrons), and Mr. and Mrs. J. A. Tyerman. Lower right, around a table, Art Reid, Ona and Herb Houston, Rosemary and Marsh Rasberry, Joan Reid, Al and Glenora Tite, Ross and Dot Northrup.**

heavy traffic. He spoke after Dr. Berry and gave us some very interesting sidelights on different phases of prevention of disease by cleaning up polluted areas. He covered the case of fluoridization of water supplies to prevent tooth decay. He said the Medical Association has not yet given the addition of fluorine its blessing probably due to the fact that one of the salts of fluorine is a deadly poison; also because fluorine does not appear to be the complete answer.

After the speakers had given their addresses, there was a "question and answer" period which was most interesting.

The meeting finally broke up at about 12.30 a.m.

## Edmonton

R. B. Kerr, Jr.E.I.C.,
*Secretary-Treasurer*

P. H. Buckland, M.E.I.C.,
*Branch News Editor*

**M. Coyne Is Guest Speaker**

On the evening of October 12, the Edmonton Branch of the Engineering Institute held its regular dinner meeting. The speaker for the evening was Monsieur André Coyne a prominent French consulting engineer, and inspecteur général des ponts et chaussées; he was introduced by Dean R. M. Hardy of the University of Alberta.

M. Coyne's topic for the evening was "Twenty-five Years Designing and Building Dams". This outlined various projects the speaker had worked on over the past twenty-five years. The speaker is well qualified to speak on this topic because he is one of the leading dam designers in Europe.

M. Coyne was born in Paris and served in the French Air Force during the first World War. After graduating from university and serving with the French Civil Service, M. Coyne started on his career as a dam designer. He has worked on seventy different dam projects, not only in France, but in Spain, Africa and as far off as India; and was prominent in the designing of Europe's highest dam. M. Coyne is a past president of both the French Committee on Large Dams and the International Committee on Large Dams.

**Two Specialities**

M. Coyne has two specialities in dam design; namely, arch shaped dams which due to their structural shape require a minimum of concrete, and ski-jump spillways. Slides were shown illustrating both these specialities. M. Coyne pointed out that the arch type dam required much less concrete than the common gravity type dam, and is therefore cheaper where material costs are the major consideration. However, the speaker pointed out that in Canada and the United States gravity dams are most commonly used and most economical because they require much less labour than arch type dams. On the North American Continent labor is relatively expensive, and material plentiful and relatively less expensive.

The principle of ski-jump spillways, the speaker's second favorite, was illustrated with a motion picture and several slides. As the name implies, the spillway directs excess water down stream from the dam, and thus prevents progressive erosion near the down stream face of the dam.

M. Coyne also illustrated the principle of prestressing concrete dams. He pointed out that this principle is not only applied in new dams, but is also used to increase the capacity of existing concrete dams.

After the speaker had finished, questions were directed to him from the floor. M. Coyne was thanked for his very interesting talk by Mr. L. Jehn of the Edmonton Branch.

**Problems Of Lightning**

On October 21, 1954, members of the Niagara Peninsula Branch met for a dinner meeting at the Queensway Hotel, St. Catharines.

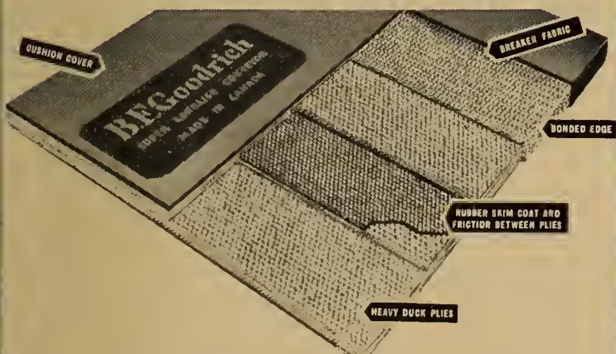
C. Killoran introduced the guest speaker, C. Stairs of General Electric Company. Mr. Stairs, with the aid of slides, gave a vivid account of the problems of lightning with regard to insulation and co-ordination.

For ages, in the history of man, there has been much controversy regarding

# B.F.Goodrich CONVEYOR BELTS

## carry noodles or nitrates equally well... because there's a "BFG" belt for every purpose

from



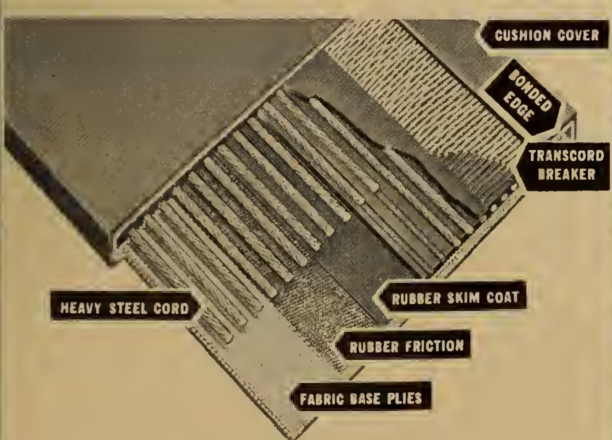
**REGULAR CONSTRUCTIONS:**

**Super Longlife**—covers are built to withstand sharp abrasive materials. For use in mines, quarries and the most severe applications. Highest quality B. F. Goodrich fabric belt.

**Longlife**—designed to give economical service on tough installations where high tonnages, impact and abrasion are factors.

**Maxecon**—for less severe conveyor service under normal operating and loading conditions.

to

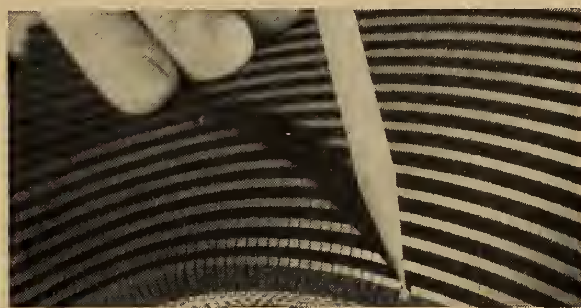


**The B. F. Goodrich Steel Cord Belt** is made for unusually long centre installations beyond the tensile range of all other types of belts. Available for working tensions up to 3,000 pounds per inch of belt width.

*Complete "BFG" line includes*

*New* **RIBFLEX GRIPTOP**

*with flexible fingers*



Designed to carry loads at incline angles up to 45 degrees. Saves floor space, belt length, conveyor length. Lasts longer and is SELF CLEANING.

**THERE'S A B. F. GOODRICH BELT FOR EVERY NEED!**

★ *Grain Conveyor Belting*
★ *Bucket Elevator Belting*
★ *Hot Material Conveyor Belting*
★ *Food Handling Conveyor Belting*
★ *Package Handling Conveyor Belting*

**The head table at Ottawa's luncheon meeting on the occasion of the president's visit. Left to right, W. R. Pennock, Dr. L. A. Wright, President D. M. Stephens, R. Hayes, A. H. Graves, B. G. Ballard, Dr. O. M. Solandt, Hon.M.E.I.C., and Rev. Arthur Leaker.**

the theory of lightning and how it is formed. It has been accepted that in order to create lightning there must be currents of air and the presence of moisture, and a way of ionizing the air. Much of this information has been recorded on instruments sent up into clouds by means of balloons.

#### Accepted Theory

The accepted theory for lightning indicates the presence of air currents, or winds, entering the bottom of a cloud bank. The moisture in this rising air condenses and on colliding with the cloud moisture produces rain drops. These drops increase in size as they fall.

Meanwhile, the light negative ions are swept upward toward the cloud. Positive ions of moisture collect at the bottom of the cloud while positive ions at the top of the cloud form into frozen particles of moisture. As a result of the upward currents the cloud soon becomes stratified: with negative charges at the bottom and positive at the top. This buildup of potential is relieved by a lightning step-ladder which zig-zags down to the earth and sets up a return flash which is the lightning as we see it. There may be as many as 20 return flashes in a fraction of a second, but to the human eye it appears as one bright flash.

#### Lightning Protection

The presence of lightning creates a major problem for the electrical distribution systems in all the world. The earliest protection from lightning was in the form of choke coils. The trend then seemed to switch to lightning arrestors, but the solution did not seem complete.

In order to be able to arrest the lightning, and its effects, a study of lightning on the clydonograph revealed its intensity by measurement. An accurate measurement for lightning charges had to be made before the magnitude of voltage and current surges could be established. Having established a basis of calibration for such surges it soon followed as to what the insulation requirements would be for electrical transmission circuits.

#### Insulation

The problem was to establish a relationship between insulation and a set of standard operating voltages. This resulted in a test set-up for 115 volt systems wherein normal frequency 230 volts is applied for one minute. A standard wave was thus set up, where, in 1.5 microseconds a critical flashover occurred at crest voltage. With the average lightning current being approximately 10,000 amps, it becomes obvious that ungrounded structures are subject to an overvoltage of 70 per cent, and for grounded structures 30 per cent.

The problem of lightning has instigated the wide use of the thyrite Magne-valve Station-type arrestors. This harnessing of wild lightning has lead to the recent developments of insulation and lightning co-ordination methods of today.

H. D. Davison, chairman, moved a vote of thanks to Mr. Stairs for his fine address.

#### President's Visit

The President's visit to the Ottawa Branch took place on October 4, 1954, at a luncheon meeting held in Lauder Hall. R. E. Hayes was in the chair.

Mr. D. M. Stephens spoke on "The Engineer in the Civil Service", a mes-

sage addressed to the young engineers. He said, in essence, that it was maintained in some circles that first class engineers should not join the public service and pointed out that this was a very wrong point of view. He said that the civil service has and needs the very finest types of engineers and can offer ample scope for the most talented. W. B. Pennock thanked the president.

##### *Honorary Membership*

At the meeting Dr. O. N. Solandt, chairman of the Defence Research Board was presented with an Honorary Membership in the Institute by President Stephens. He is the youngest member ever to receive this award. In the evening a very pleasant reception was held for Mr. and Mrs. Stephens at the R.C.A.F. Gloucester St. Mess where guests, Branch members, and their wives mingled for a social evening.

##### *"Health, Happiness, and Hospitals"*

The opening meeting of the Branch was held on Thursday, September 23, 1954, when Gordon Hughes, F.R.A.I.C., chief of the hospital design division, Department of National Health and Welfare spoke on "Health, Happiness, and Hospitals." He said, "hospitals more and more are concerned with the community hospital as a health center. Dealing with the health of the people they are actually working to keep people out of hospitals rather than seek patients." Mr. Hughes traced the development of hospitals from the early days of the Egyptians and the Hindus to the present days.

Canada's oldest hospital is the Hotel Dieu of Quebec, established in 1634. But in Mexico Cortez established hospitals as long as 435 years ago, he said. The past 50 years have been, however, the golden age of advancement in medicine and science in the treatment of disease.

##### *Vertical Development*

Hospital design was described by the architect as the most complex of designing endeavor. In recent years the plan has been the vertical development of hospitals, rather than the horizontal. This permits a more efficient operation system though it gives an additional difficulty in expansion.

Fees paid to hospitals for scientific diagnosis are an insurance against longer life, the speaker said. The aim of modern hospital design is to increase its efficiency of operation. The ideal plan is that beds in a ward should be no more than 80 feet from the central facilities of the ward.

##### *Modern Developments*

Many modern developments were revealed. There are in some hospitals pneumatic tubes to speed blood and other samples to the laboratory. There are intercommunication devices which permit conversation with patients, and an audible check on their welfare. One of the most remarkable modern devices is a radio type of apparatus which is carried by the doctor on duty and permits him to be summoned by a "buzz" whenever he is required. This buzzer when it first operates can be shut off. But if there is no answer and it is put in operation again it cannot be stopped until the doctor returns to the central office. It can be effective for a distance of 10 miles from the hospital to summon a doctor to a telephone.

The speaker was introduced by R. E. Hayes, chairman of the Ottawa Branch, and thanked by Claude Howard.

## Montreal

R. J. HARVEY, M.E.I.C.,
*Secretary-Treasurer*
J. A. PAGET, M.E.I.C.,
*Branch News Editor*

##### *Annual Golf Tournament*

The golfing members of the Montreal Junior Section held their annual tournament on September 11 at the Ste. Hyacinthe Golf Club at Ste. Hyacinthe, Que.

Although the weather was on the wet side, it did not dampen the spirits of the enthusiasts. Net scores were based on the Atlantic Handicap System and nearly everyone managed to obtain at least one prize. The renovated Layton Trophy was won for a second time by Graham Cunningham with a low gross score of 78. Julien St. Pierre ran a close second with a gross score of 80. The low net scores were also very competitive, C. G. Kerr taking first place with 73½ and K. W. Davies in second place with 74.

Following the dinner the presentation of the Layton Trophy was made by Leo J. Hammerschmid and prizes distributed by John Gratton who was in charge of the tournament.

##### *Extra High Voltage Systems*

The fall season of the Montreal Branch was opened on October 4, 1954, with a joint meeting of the Engineering

WAHLEACH, BRITISH COLUMBIA

*Another Penstock job made easier with*

# DRESSER COUPLINGS

**Lighter, high-yield steel pipe cuts tonnage, shipping, installation costs . . . speeds completion of 1760-foot Wahleach penstock.**

Six weeks after construction began, this 70″ penstock—the fourth Dresser-Coupled installation made by the B. C. Electric Company—was ready to deliver water to a 75,000-kva power plant near Vancouver, British Columbia.

Eliminating extensive excavation, resilient gaskets in Dresser Couplings allowed the penstock to be deflected to the natural contour of the right of way. The lighter weight and longer lengths of high-yield steel pipe meant easier handling, fewer joints and anchors. A field crew of 20 men—with a minimum of skill, supervision and heavy equipment —*Dresser-Coupled 1,000 tons of steel penstock in 21 working days.* Under test, the line proved absolutely bottle-tight.

Dresser Couplings permitted faster completion of the line and assured permanently tight, maintenance-free joints. This resulted in *earlier revenue* from plant operation . . . *uninterrupted service* to power consumers.

*Above*—Overbends made by 1° deflections at each field joint eliminated shop-made bends and special anchors.

*Left*—Four men averaged less than four hours making bottle-tight joint . . . 975 psi working pressure, 1500 psi shop test on couplings.

Project designed by B.C. International Engineering Co., Ltd.
Penstock installation by Arrow Transfer Co., Vancouver

BE SURE you get a *better, faster* penstock installation. Put high-yield steel pipe and Dresser Couplings in *your* specifications.

Institute and the American Institute of Electrical Engineers. The meeting, under the chairmanship of W. R. Way heard an interesting paper by B. G. Rathsman of the Swedish State Power Commission on the Swedish 400 k.v. power system.

Mr. Rathsman stated that the decision of the Swedish State Power Commission to develop a 400 k.v. system was made in 1946 after investigation had shown that this voltage would be the most economical to transmit the large amount of power required in the populous south from the large undeveloped water power sources of the north.

The 400 k.v. system was designed for an impulse level of 1775 k.v. at the stations and 1600 k.v. on the transmission lines. Lightning arresters are used to limit the impulse levels at the stations to safe values. Impulse levels have now been reduced to 1500 k.v. on all station apparatus and lines with the exception of instrument transformers and circuit breakers. The reduction has resulted in considerable saving in station cost.

The experience of the Swedish State Commission has shown that the largest transformer units capable of being transported to the sites are the most economical.

The transmission lines use multiple or bundle conductors which at present consist of 2 x 1,170,000 C.M., A.C.S.R. conductors per phase and can easily be increased to 3 x 1,170,000 C.M. cables. Towers are of gantry type and are constructed of high grade steel. Two overhead ground wires are run and since good grounding is difficult to obtain in Sweden, a counterpoise of 50 M.C.M. copper cable is now run the length of the lines, except where the ground resistance is 30 ohms or less.

Series capacitors are being added to the system and increase transmission capacity from 400,000 k.w. to 650,000 k.w. for a 300 to 400 miles single circuit line.

Radio disturbance was overcome in areas of weak reception by connecting small transmitters to the lines and using the lines as antennae. This often resulted in better reception than had previously prevailed.

Mr. Rathsman stated that the 400 k.v. system had proved very satisfactory and had resulted in considerable gain in power transmission for Sweden.

Mr. Rathsman also gave a brief talk on the 100 k.v. d-c. system between the Swedish mainland and the Island of Gotland. This system was the result of experiments in high voltage direct current by Swedish manufacturers and the Power Commission.

A rectifier station on the mainland is connected by a single conductor cable to an inverter station on the island. The length of this cable is about 60 miles. The return path of the high voltage d-c. current utilizes the ocean with suitable grounding electrodes at each end.

Although the installation is experimental in scope, a large amount of power is being economically transmitted to the island.

A film was shown which described the d-c. system in detail.

A large number of questions were answered by Mr. Rathsman after which D. M. Farnham thanked the speaker on behalf of the meeting.

Refreshments were served to complete a very enjoyable and instructive evening.

***Plant Tour***

The mechanical section of the Montreal Branch visited the Angus Shops of the Canadian Pacific Railway on Tuesday evening, October 5.

The shops comprise, as a unit, the largest railway building and repair shop on this continent. The plant occupies an area of 200 acres and consists of 31 main buildings and as many smaller structures. At present they employ 6,500 persons who are engaged in such diversified fields as repair and maintenance of diesel and steam motive power units, the building and maintenance of all types of passenger and freight rolling stock, a cast iron wheel foundry, a bolt and nut shop, etc.

The comprehensive tour included almost every department in the works, and made it possible for the visitors to gain valuable information about railroad equipment and its maintenance. Perhaps the most outstanding feature due to the recent dieselization program, was the greatly decreased amount of work being done on steam engines, and the corresponding increase in the amount of diesel engine maintenance. The unique production and maintenance machine tools used by the railways were of much interest to those from other industries and many of the visitors must certainly have gone home with a wealth of new ideas applicable to their own particular line of work.

A group of approximately two hundred attended. The meeting chairman was P. J. Kunstler and arrangements were made by R. M. Freeman.

***Plant Tour***

October 12, 1954, was the day the chemical section of the Montreal Branch was treated to an outstanding plant tour by the chemical division of the Montreal East Refinery of the Shell Oil Company of Canada Ltd.

The refinery chemical plant, which has the unique distinction of being the first petro-chemical plant owned by an oil company in Canada, went on "steam" in April, 1953. The two principal products are acetone and and isopropyl alcohol, and raw materials consist essentially of a propane-propylene mixture fed from the oil refinery.

Just as isopropyl alcohol is used as a raw material in making acetone, acetone, in turn, is the starting point for another chemical diacetone alcohol. This is the source of a whole line of important chemicals: mesityl oxide, methyl isobutyl ketone, methyl isobutyl carbinol, hexylene glycol. All of these chemicals have different properties and they are put to many uses, yet they all come from one material—the propylene in the gas from the petroleum cracking process. All these products, plus secondary butyl alcohol and methyl ethyl ketone, are being produced today in Shell plants in several countries of the world. Now that the initial step of making isopropyl alcohol and acetone has been taken in Canada, they could be made here as well.

After a complete description of the chemical plant's technology and operation by Stan Williamson, plant manager, the 100 members present were broken up into groups of about 10 and conducted on a detailed tour by Shell engineers.

The plant which was built by C. F.

# E.I.C. ANNUAL MEETING

**May 11-12-13**
**1955**
**Royal York Hotel,**
**Toronto, Ont.**

•

**May 23-24-25**
**1956**
**Montreal, Que.**

---

Braun and Co. of California, consists essentially of a reaction and hydrolysis unit into which the raw propane-propylene is fed, a stripping and distillation unit, an acid converter and an acid concentrator, an isopropyl alcohol dehydrater and a distillation unit for each of the products.

Interesting mechanical and other features were the abundant use of lead and silicon-iron in pipes and tank linings, etc., the heavy duty pumps and compressors necessary in this kind of industry and the unique heat exchangers.

The tour lasted for approximately two hours and refreshments were served in the plant cafeteria afterwards.

Meeting chairman was L. A. Phillips and arrangements were made by E. W. Codère.

#### "Modern Crawler Tractors for Construction"

A three-man panel, R. Hewitt, Hewitt Equipment Ltd.; L. L. Goddard, Chas Cusson Ltd.; and J. S. Newman, Beaver Construction Ltd., discussed "Modern Crawler Tractors for Construction" on Oct. 14.

#### Development

The first speaker, Mr. Hewitt, presented a very informative outline of the development of the crawler tractor since the beginning of the century. He illustrated, by means of slides, the changing trends over the years, and the versatility afforded by the introduction of rear end or trailing equipment such as logging winches, compaction rollers, scrapers and track type wagons to mention but a few. Although the prime role of the crawler tractor is in earth moving, examples were shown of tractors rigged as cranes, or as mobile air compressors, or capable of hauling heavy loads in difficult locations by means of a power winch at the rear. Mr. Hewitt also showed colour movies of operating details of scrapers and similar equipment.

#### Equipment

Mr. Goddard continued with remarks on "front end" equipment, design features of crawler tractors, and economic considerations. He discussed blade types and their uses, the high productivity of machines employing the overhead rear dump loader, various aspects of tractor transmissions, steering, pros and cons of cable versus hydraulic control, and presented comparative performance and economic data on some of the equipment mentioned. A coloured film of earth-moving operations of the Alcan Kitimat project served to further illustrate comments by both Mr. Hewitt and Mr. Goddard.

The first two members of the panel, having expressed their views as suppliers, J. S. Newman addressed the meeting as a user of the crawler tractor. He described the successful development by his firm of a front end drill rig permitting rapid drilling of holes of twenty foot depth within a large radius of the tractor—another example of versatility. Mr. Newman mentioned the usefulness of the crawler tractor in hauling other heavy equipment unable to negotiate grades without assistance. In this day of rapidly expanding communities, he mentioned that the accompanying problem of garbage disposal can be economically solved with the help of the crawler tractor, using the method of sanitary land fill.

A short question and answer period concluded the evening, and the panel members were thanked by J. H. Leitch.

Meeting arrangements were made by R. J. Kane.

#### Micro-techniques in Research

A special meeting was held on Thursday, October 21, at 5.30 p.m., sponsored by Dr. W. H. Gauvin.

A small group of members gathered at the Mansfield Street Headquarters where refreshments were served before the meeting, giving a good opportunity for the attendants to get acquainted. The meeting was over early and the evening was still young. Although the attendance was small, everybody appreciated the first meeting of a very promising series.

Philip B. French presented the speaker, Harold Green, who has been working at the Pulp and Paper Research Institute of Canada for over 20 years, and who is now in charge of the Photography-Microscopy Section at the Institute.

#### Microscope and Camera

Mr. Green made mention of the fact that, of recent years, there has been increasing recognition, both in the Institute and in the pulp and paper industry, that the microscope and the camera are exceedingly valuable research tools, not only for studies of fibres and pulps but also for examination of wood in various stages of processing, for visual recording of research results and for presentation of data in reports.

He then went on to describe the design and construction of a unique micro-digester and auxiliary equipment. The micro-digester was designed to conform to an optical working distance, and is of such a size as to fit on the stage of a microscope. Light is passed into the tiny digester through a glass port in the bottom, and the thin wood section being subjected to chemical treatment is observed and photographed through a similar port in the top. The glass used in these ports is surface-tempered pyrex capable of withstanding pressures up to 1,000 p.s.i. The accumulator is electrically heated, the rate being controlled by a large Powerstat transformer. Stainless steel was used throughout for the construction of this equipment.

Mounted above the micro-digester is a motion picture camera and time-lapse mechanism by means of which cinephotomicrographic records of the pulping process may be produced. If completely successful, this will represent the first time continuous direct observation of the chemical pulping process has been accomplished.

#### Chemical and Mechanical Treatments

Mr. Green next made mention of the effects produced by chemical and mechanical treatments on the surface structures of fibres. He pointed out that, in order to better study these surface structures, the Institute had developed methods of metallizing fibres and thin wood sections. Photomicrographs taken of fibres and sections so treated and illuminated with a low-angle beam of light showed up surface detail which was difficult or even impossible to depict by the usual microscopical methods. Indeed, some of the micrographs so produced appeared to be almost third-dimensional.

Brief mention was made of an interesting device for observing and studying the rotations and interactions of model particles and fibres in a field of liquid shear. Mr. Green then described the part that cinephoto-micrography was playing in recording these complex rotations and collisions. He said that so far one complete reel of motion pictures had been produced using this interesting Couette Apparatus.

Slides, both monochrome and colour were shown during this talk. After a short discussion period, members were invited to examine a group of colour photomicrographs of fibres and wood sections.

Mr. Green was heartily congratulated by O. R. Brumell for having presented a very fascinating talk on subjects which were little publicized.

#### Designing and Building of Dams

On October the 26, 1954, a meeting was held sponsored by R. J. Kane, Raymond Boucher, of l'Ecole Polytechnique of Montreal, acting as chairman, introduced André Coyne, the guest speaker of the evening.

Mr. Coyne was born in Paris in 1891. He started his professional education at "Ecole Polytechnique" de Paris and graduated from "Ecole Nationale des Ponts et Chausées" in Paris, France. He is a veteran of World War I in which he served with distinction in the Engineering Corps and subsequently joined the Air Force.

At the age of 63, Mr. Coyne has behind him a full life of practical experience. He started his career in the "Département des Ports Nationaux" in France, and for eight years was engineer for the port of Brest. He then became chief engineer of the "Département des Travaux Publics" for the section of "Haute Dardogne". His career as dams builder started in that position; his efforts were turned towards the perfection of arch-dams.

Mr. Coyne held the senior post in the "Service des Travaux Publics Français" and is now a consulting engineer of international reputation. In twenty-five years of work, he has built 70 dams. From 1946 to 1952 he was president of the International Commission of big dams and has been for many years the chairman of "l'Ecole Nationale des Ponts et Chaussées" and also, of the "Ecole Supérieure d'Electricité" of France.

In 1952 he was made an honorary member of the American Society of Civil Engineers and this year received additional honor in getting the Grand Prix d'Architecture given by the French Society for Architectural Study.

#### Arch-dams

In his speech, Mr. Coyne talked about arch-dams. He explained the calculations and applications of dams arched in the horizontal plans only, and also the special design of dams arched in two plans as used in Africa and Europe in the last few years.

He is the designer of a new kind of spillway which is made like a ski-jump and projects water 300-400 feet to avoid erosion of the foundations. He noted that this kind of spillway should be used at Niagara Falls to protect the natural foundation of the rock which regularly caves in and causes damage to their natural beauty.

Mr. Coyne is now doing special studies in the application of prestressed concrete to dams. He intends to use this new theory in India and in Pakistan.

It is interesting to note that Mr. Coyne delivered his speech in English although French is his native tongue.

F. L. Lawton, chief engineer of Aluminum Laboratory Ltd. congratulated the speaker for his highly interesting speech.

#### Trends in Motor Car Design

On Thursday, October 28, a general meeting was held, sponsored by the mechanical section under the chairmanship of P. J. Kunstler, at the E.I.C. headquarters on Mansfield Street. The speaker, H. Richard Steding, chief engineer, executive staff of the Chrysler Corporation, was introduced by the meeting chairman, H. S. Marmoock.

Mr. Steding gave a talk on the "whys" of motor car design and included a few anecdotes by way of illustration. He discussed body dies made of plastic; the economic difficulties of using plastic as a body material; Chrysler's gas turbine powered automobile experiments and the difficulties both economic and technical prohibiting production of such a unit at this time; horsepower, its attractive aspects and its relation to safety; general safety considerations; and styling trends.

#### Proving Ground

A film was then shown of the opening of Chrysler's new multi-million dollar proving ground in Michigan which included some interesting shots of many cars going "flat-out" around the high-speed oval, including some Indianapolis racers and some of Chrysler's "ideal" cars; other shots of cars undergoing abusive high speed treatment on rough gravel roads; still others receiving a thorough soaking in two to three feet of water at moderate speed, steering pad tests; and many other interesting pictures.

A question period followed. Many interesting questions were asked from the floor, which Mr. Steding answered quite well, considering the fact that some tended to put him "on the spot". Answers to questions concerning better winter traction and cheaper simpler automobiles were a little evasive. Disc brakes were reported expensive at present. Fuel injection was reported to be undergoing study. There were also questions and answers concerning horsepower, torque, compression ratios, gas turbines, automatic transmissions, front wheel drive, rear engines, steam power, electric drives and engine octane requirements.

The speaker was thanked by Prof. P P. Vinet, of l'Ecole Polytechnique, and the meeting adjourned.

#### "Canada and International Trade"

The first meeting of the fall season was held at The Kawartha Club on Sept. 24. Guest speaker was S. A. Shepherd, manager of the Mortgage Lending Department of the Bank of Montreal. His subject was "Canada and International Trade".

Mr. Shepherd's banking experience included service with the National Bank of South Africa, and Barclays Bank, London, before joining the Bank of Montreal in 1929. He was on loan to the Wartime Prices and Trade Board during the war, and when recalled to The Bank of Montreal in 1947, became manager of the Foreign Exchange Department. He will be conducting a series of lectures on "International Trade and Finance" for McGill University Extension this year.

#### Free Trade

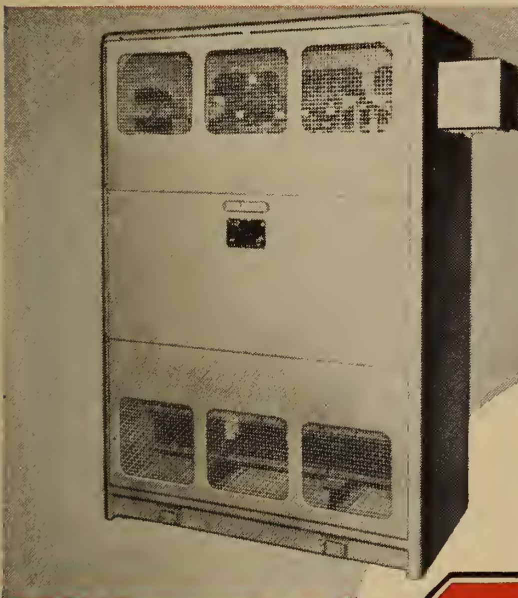
The speaker explained the desirability of free trade, from the point of view that production would be thus limited to those who could produce most efficiently. This would result in the highest standard of living for the world as a whole.

The utopia of free trade presently does not exist due to the need or desire of various nations to maintain control over the manufacture of certain products. Mr. Shepherd emphasized that he did not believe that tariff barriers or subsidies should be used to protect inefficient industries. Some industries however, should be protected to a certain extent to allow them to streamline their operations and become more competitive with other sources. Protection may be justified to safeguard either investments or employment of large numbers of people. He felt that the answer to the problem did not lie in increased protection but rather in a "reappraisal of production costs and marketing methods".

The speaker was introduced and thanked by John Lucas.

these 3 different types of **RELIANCE** transformers

are **POWER** *Proved* daily in Industries across Canada



Reliance 750KVA, "Class B", insulated Dry Type power transformer. All panels are removable for easy access to core and coils and tap changer.

## St. Maurice Valley

L. A. Pattison, Jr.E.I.C.,
*Secretary*

J. K. Murphy, Jr.E.I.C.,
*Branch News Editor*

**Canadian Aviation**

"Canada ranks high in the scale of free nations which design and build aircraft," members of the Three Rivers group of the Engineering Institute of Canada district Branch, were told on October 6. The speaker was R. D. Richmond, chief engineer in charge of aeronautical design at Montreal's Canadair Ltd. plant, and the occasion was the local group monthly meeting in the St. Maurice Hotel.

Continuing, Mr. Richmond, who spoke on "Canadian Aviation Past, Present and Future", pointed out that the aircraft industry depends a great deal upon military contracts from government but that they are continuously striving to broaden their interests in the commercial field. Mr. Richmond's address dealt with both airplanes and guided missiles.

"Ever increasing speeds are required for military aircraft in order to strike quickly at the enemy and to present a small target," he stated. "The importance of operating economy of such aircraft is not as great as in commercial planes."

The types of motors and equipment may therefore be quite different. Ram jets, for example, the speaker said, are very expensive to operate and it will probaly be quite some time before they are in commercial use.

**Development**

Touching on development, Mr. Richmond mentioned that development of a new aircraft is a very exacting job, requiring many thousands of engineering hours. Basic scientific facts are often supplied by government agencies, but much work is required to apply them. This requires large engineering staffs which include many specialties.

**"Human Relations in Industry"**

On Wednesday, October 20 a meeting of the St. Maurice Valley Branch was held at the Cascade Inn, Shawinigan Falls. The guest speaker for the evening was R. A. Fortier of the Public Relations Department of the Aluminum Company of Canada, Limited. His topic, one of considerable interest to engineers today, was "Human Relations in Industry".

Mr. Fortier stated that the failure to recognize the fact that another point of view can exist in a crucial situation is one of the primary blocks to better understanding in industry. The ultimately successful administrator is the one who can do two things in a crucial situation: 1) accept the fact that another point of view can exist, and 2) withhold action until this other viewpoint has been evaluated.

For most of us that is not a natural thing, especially when dealing with a subordinate. Invariably, the superior in such a situation feels that he has sufficient reasons for his contemplated course of action and acceptance of new ideas can be a painful process. It is not, however, an intellectual exercise. The ability and willingness to see and evaluate a point of view different from one's own involves an emotional as well as an intellectual achievement.

**Listen**

The biggest block to successful communication in industry is the inability or refusal to listen intelligently and understandingly to another person. Only too often do we recognize this inability in others, but perhaps too seldom do we recognize this same limitation in ourselves. Mr. Fortier stated, the way we have been conditioned by past experience will materially affect the way we perceive the present situation.

Mr. Fortier concluded his talk with perception demonstrations which served to give visual evidence to the remarks he had made during the evening.

## Saint John

J. A. B. Brenan Jr.,
*Secretary-Treasurer*

H. S. McCleave,
*Branch News Editor*

**Industrial Development Of Saint John**

The Saint John Branch held their first meeting of the 1954-55 season at the Admiral Beatty Hotel, Oct. 14. 1954. The speaker for the evening was H. H. Smith, newly appointed industrial commissioner for the city whose topic for the evening was "The Industrial Development of Saint John".

Mr. Smith believes that, while the long range picture of the economy of the country is bright, not enough attention is being paid to the next few years The influx of foreign goods which captured ¼ of the home market last year was a bad sign considering the fact that our export had not kept pace, and the situation is not improving.

"In the face of these facts it is somewhat surprising that many Canadian manufacturers have not paid sufficient attention to the proper promotion of their goods in foreign markets. Our government, so far, does not seem to have taken particular trouble to exhibit our goods at foreign points of sale. If it would be argued that this is a job for individual manufacturers rather than for the government, we should reply that several European countries have arranged exhibitions of their products in foreign countries and apparently are more than satisfied about the results.

**Foreign Affairs**

"Very recently, I am happy to report, I have learned that in Ottawa several officials are promoting this idea of 'foreign affairs'. Let us hope that this promotion will bear fruit in the very near future." Also Canadian companies have not followed the lead of American manufacturers in establishing factories in foreign countries, thus missing a chance of capturing more markets. Attention to these matters might provide our Canadian manufacturers with badly needed markets.

**It Can Be Done**

Mr. Smith then went on to matters directly concerning the port of Saint John and pointed out that our port has not been making any headway. By increasing facilities for the handling of certain types of goods and establishing small manufacturing plants here the economy of the Maritimes could be much brighter.

In closing, Mr. Smith stated, "our real job, gentlemen, is to get rid of any old conception we might harbour that it can not be done. The job of making a port work and of attracting industries to a certain area is by no means impossible; all it requires is good hard work, experience, and the will to win. To you who are active in all the different fields of engineering, goes a large part of this job.

**Dupont's Nylon Intermediates Plant**

A very enjoyable meeting was held on Thursday, October 21 last, in conjunction with the Toronto branch of the Chemical Institute of Canada, when Dr. H. R. Lyle Streight of the Dupont Company of Canada, gave a description of the new Nylon Intermediates Plant at Maitland, Ontario.

Although it was not possible to discuss the process in detail, the meeting enjoyed hearing a very detailed description of the considerable planning work (including some scale models) that was carried on previous to construction. All the designers and operators in this plant had no previous experience on anything similar, and considerable training programs had to be carried out whilst the plant was being designed and built. One item which should be taken note of by all members of similar plants, is that wherever possible, the materials were Canadian-made. It is also of interest to note that out of the total staff of approximately 570 operating this plant, 150 or one-fifth of them are university graduates.

## Winnipeg

C. S. Landon, M.E.I.C.,
*Secretary-Treasurer*

B. F. Webster, M.E.I.C.,
*Reporter—Electrical Section*

**Imperial Oil Refinery Visit**

Approximately 55 members of the Electrical Section of the Winnipeg Branch were guests of the Imperial Oil Limited on October 7, when a visit to the East St. Paul Refinery was arranged from 4.30 p.m. to 7.00 p.m. The group was welcomed at the refinery by G. H. Dyer, assistant general superintendent, and then the party was split in two with the first half touring the refinery while the second half was introduced to the art of refining by lectures and a movie. Mr. Maurice Magnoin, mechanical superintendent, in a short talk pointed out the pertinent features of the electrical distribution of the refinery itself.

Mr. Magnoin's talk was followed by a movie entitled "What Makes Gasoline Good", which in humorous manner gave a brief and lucid explanation of the techniques involved in making gasoline.

This movie served as an introduction to an explanation of the refinery flow chart by T. C. Elliott, chief chemist. Mr. Elliott by means of a pictorial presentation showed how Redwater crude from the Interprovincial Pipe Line was refined to finished products.

The groups then were conducted through the refinery by Mr. T. Cowtan, Mr. J. Townsend, Mr. C. G. Elder, Mr. E. A. Martin and were able to see first hand the features previously pointed out.

## BOOK REVIEW

**Inventions and patents in Canadian practice.** A. E. MacRae, M.E.I.C. Toronto, Canada Law Book, 1954. 127 pp., $4.50.

It was a pleasure to receive this book devoted to the subject of inventions and patents in Canada, both because there is little available information on this subject, and because it is written by a well-known Canadian engineer who is also a long-standing member of the Engineering Institute.

Mr. MacRae's purpose in writing this book was to give the inventor-scientist, the engineer and the industrialist information on inventions and patents which would enable them to obtain the most profit from new, useful, ideas, as envisioned by the Patent Act.

The book commences with a definition of the word "invention" as used in the Patent Act, and from this passes to the definition of "patent", and the purpose of patent legislation. These problems solved, the author discusses the methods of obtaining patents, and various special problems connected with this. Another chapter is devoted to the Patent office, the Patent Institute and the Patent Agent. The last chapter is concerned with a comparison of Canadian and United States practices, which should prove of great benefit to those concerned with patents in the two countries.

In writing this book the author has drawn on his wide experience in the patent field, and puts forward the suggestion that patents provide the incentive for the invention of new products and that agriculture, lacking this incentive, lags behind industry. The volume should prove of great interest to all those who may have an idea they wish to patent but are not sure of the steps to take. Throughout, the language is kept simple, and there is a useful index. S.C.

## BOOK NOTES

**Prepared by the Library**
**The Engineering Institute of Canada**

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***Alternating-current machines,** 3rd ed. A. F. Puchstein, T. C. Lloyd and A. G. Conrad. New York, Wiley, 1954. 721 pp., illus., $8.50.

This revision is similar in scope and character to previous editions, with consideration of only steady-state phenomena, and with the following topics treated for the various types of machines: construction, operating characteristics and their calculation from tests, and discussion and analysis of related phenomena. Principal changes are new methods of approach to theory and additional material on adjustable-speed drives, rectifiers, and self-synchronous machines.

**Bibliography on prestressed concrete.** Detroit, American concrete institute, 1954. 83 pp., $2.00 (U.S.).

Prepared by a joint American Concrete Institute—American Society of Civil Engineers committee on prestressed concrete, this bibliography lists some two thousand references on the subject.

Both American and foreign literature is included, the period covered being 1896 to 1953. The references are listed chronologically, and unfortunately there are neither author nor subject indices, but in spite of this, the bibliography will be very useful to all those interested in prestressed concrete.

A separate section lists sixty American, British, German and French patents.

**Chemical engineering in practice.** J. I. Harper, ed. New York, Reinhold, 1954. 140 pp., $3.00 (U.S.).

A symposium on "Chemical engineering in the process industries", sponsored by the American Institute of Chemical Engineers and the Department of Chemical Engineering, University of Pennsylvania, produced this collection of papers.

The subject of the discussions are the varied roles of the chemical engineer in industry. These roles include participation in process research, development and engineering; economic analysis; project, construction, operational and market research engineering. The coordination of research and activities to produce the best overall result is stressed.

The authors are all successful engineers and their articles, which are the outcome of practical experience, will be useful to students and to all chemical engineers.

**Chemical engineering materials.** Frank Rumford. Toronto, Longmans, 1954. 380 pp., illus., $5.75.

Specifically this book deals with the essential properties and limitations of the materials from which chemical plant is constructed. It describes the general mechanism of chemical attack and the methods of material testing. In a more detailed manner the range of available material is then covered, from cast iron to nickel, cements and wood, and the method of making them up into chemical plant is discussed.

The appendices provide corrosion-resistance data and the mechanical properties of metals, and some relative costs are suggested, although, in this field of construction, strength and economy are second in importance to the corrosion resistance of materials.

**The dam.** Murray Morgan. Toronto, Macmillan, 1954. 162 pp., illus., $4.00.

Many readers will have read an excerpt from this book in a recent issue of the Readers' Digest and will welcome an opportunity to complete this interesting account of a near-disaster. The author, who won renown with his "Skid Road", tells of the human mistake which almost brought to a halt the operations of the Grand Coulee powerhouse, and uses the skill of a dramatist to do so.

## LIBRARY REGULATIONS

### Hours

Mon.–Fri. . . . . . . . . 9 a.m. - 5 p.m.
Saturdays . . . . . . 9 a.m. - 12 noon

### Bibliography and Reference Service

Short subject bibliographies are compiled on request. When placing these requests, please give as much detail and background information as possible.

### Borrowing

Books, periodicals, pamphlets and films may be borrowed for two weeks at a time. All books included in the Library Notes Section of *The Engineering Journal* are available for loan. **A fine of 25c per day is charged for each day borrowed items are retained beyond the two-week period.**

A library deposit of $5.00 at par in Montreal is required, for which two items may be borrowed at a time. Temporary deposits (30 days or less) $10.00. Books are sent anywhere in Canada, and carrying charges are payable by the member concerned.

### Ordering

Any book or pamphlet may be ordered through the library. All publications of affiliated societies, whether books, pamphlets, or periodicals, should be ordered through the library, as reduced rates are applicable on these to all members. Except in the case of library deposits **please make no payments in advance.** Non-members may consult the library, but may not borrow material. Please address all requests to **The Library.**

While this section of the book will keep the reader in a state of suspense and admiration there is much more that will also hold his attention. He will find an absorbing story of the background of the Grand Coulee dam, including facts and figures, with a description of the use made of the power in the Northwest, and of the government town of Coulee Dam. There is also an interesting sidelight on the Hanford Atomic Works. In all this Mr. Morgan displays his ability to discover and portray the feelings and attitudes of the common man affected by the gigantic power development.

A series of photographs shows exterior and interior views of the dam and power-house.

**Dielectric materials and applications.** A. R. Von Hippel, ed. Cambridge, Technology Press, New York, Wiley, 1954. 438 pp., illus., $17.50.

As a companion volume to "Dielectrics and Waves", this collection of papers by twenty-two contributors is directed to the research worker, development engineer, manufacturer, and field engineer. The five divisions include a section on dielectric theory, covering the macroscopic properties of dielectrics followed by the molecular properties. The next chapter describes methods and techniques for measuring permittivity and permeability. In the third section, dealing with dielectric materials and their applications, consideration is given to gases and vacuums, liquids, plastics and ceramics, with their use in a variety of fields: power, distribution and electronics equipment; as rectifiers, magnetic and dielectric amplifiers and memory devices. Section IV is entitled "Dielectric requirements of the armed services," and the last chapter contains the tables of dielectric materials of the Laboratory for Insulation Research at the Massachusetts Institute of Technology.

**Dielectrics and waves.** A. R. von Hippel. New York, Wiley, 1954. 284 pp., illus., $16.00.

Written for physicists, chemists and electrical engineers, the subject of this book "dielectrics" covers not only a narrow class of so-called insulators, but any nonmetal, and even metals, where their interaction with electric, magnetic, or electromagnetic fields is considered. It progresses beyond the subject of dielectric analysis to that of dielectric synthesis, in which the properties of materials are made to order.

The work is divided into two parts having, first, the macroscopic and, second, the molecular approach. Part I deals with the complex permittivity and permeability as the basic parameters and derives the macroscopic theory in a unified manner for the electrical and optical frequency spectrum from the field and circuit aspect. Part II re-interprets this by considering the action of induced and permanent moments and of mobile charge carriers in gases, liquids and solids. Many valuable problems, tables and references are found in the appendices.

***Electroacoustics.** F. V. Hunt. Cambridge, Harvard University Press, and New York, Wiley, 1954. 260 pp., diagrs., $6.00 (Harvard Monographs in Applied Science, No. 5).

Includes an historical account of electroacoustical transduction, a new method for the analysis of electrostatic and electromagnetic systems of electromechanical coupling, and examples of this method as applied to moving-conductor (dynamic), electrostatic, and moving-armature (magnetic) transducer systems. There are bibliographical footnotes.

***Data book for civil engineers. Volume III: Field Practice,** 2nd ed. E. E. Seelye. New York, Wiley, 1954. 394 pp., illus., $7.50.

Provides the field engineer with essential data for inspection and supervision of virtually all types of civil engineering work. It contains check-lists and procedures for inspection for concrete, masonry, structural steel, welding, bridges, soils, pipe laying, etc. A section on construction surveying has been added, tables and other data have been brought up to date, and considerable new material is included in this revision.

**Farm buildings,** 4th ed. D. G. Carter. New York, Wiley, 1954. 291 pp., illus., $5.50.

Agricultural engineers and students will welcome this new and almost completely revised edition on the subject of farm buildings. A scientific approach is maintained throughout, and the author deals with buildings as a phase of the broader subject of farm improvement. Building objectives, planning resources, functional aspects, and environment are considered instead of specific materials and requirements, which are soon out of date.

Different types of buildings, housing beef cattle, hogs, sheep, poultry, grain and machinery, are described as well as the farmhouse. The appraisal of farm buildings, for income tax purposes, etc., is covered in one chapter, followed by another on farm-building management.

**Guide for safety in the chemical laboratory.** General safety committee of the Manufacturing chemists' association. Toronto, Van Nostrand, 1954. 234 pp., illus., $4.75.

"This book should be kept as a guide and ready reference wherever chemicals are used." This claim is substantiated by the contents of this manual which covers a variety of important subjects ranging from general rules for laboratory safety, handling glassware and containers, flammability, and toxicity, to radiation safety, pressure vessel hazards, protective equipment, and first aid. The last chapter discusses the packaging and transportation of chemicals. Several chapters apply to high schools and elementary technical schools although the manual is primarily for those working in college, university, and industrial chemical laboratories.

**Highway engineering.** L. I. Hewes and C. H. Oglesby. New York, Wiley, 1954. 628 pp., illus., $8.00.

While quite a number of books have recently appeared on the subject of highway engineering, this stands somewhat apart because of its authors' qualifications and also because of the emphasis placed on design and principles rather than on construction practices.

**Notice**

Members intending to borrow books are reminded that they are personally responsible for items signed out in their name, and that one member may not borrow on another's library card.

Subjects which have legal or economic aspects are developed, including rights of way, highway financing and the role of federal aid in it, and traffic engineering. Other chapters are devoted to surveys and plans, drainage, roadside development, and subgrade structure.

Some consideration must, of course, be given to practical roadbuilding, and such matters as gravel and crushed rock roads, base courses, macadam surfaces, bituminous pavements and Portland-cement-concrete pavements are covered. Design techniques and the results of recent research findings are stressed in these sections.

**La machine-outil, v. 3 Usinage par outils en rotation. v. 6 Usinage par abrasion.** A. R. Métral, ed. Paris, Dunod, Montreal, Fomac, 1954. v. 3. 432 pp., illus., $23.60; v. 6. 168 pp., illus., $11.25.

Two previous volumes of this work dealing with machine tools in general and machines in the field of planing, shaping and slotting are already in the library. Volume 3, which has now appeared, is devoted to the use of rotation tools and consists of six separate papers. These discuss the principles of boring, drilling and milling machines and the best uses which can be made of them. A short section is included on tool holders.

Volume 6 has for its subject abrasive tools and the first chapter describes these in a general way. In the next papers machines used for grinding and polishing are discussed in detail and the last chapter covers sharpening tools.

Again in these volumes the illustrations are an outstanding feature.

**Manual of British water supply practice,** 2nd ed. A. T. Hobbs, ed. London, Institution of water engineers, 1954. 963 pp., illus., 55/-.

While the changes in this edition consist mainly of some re-arrangement of chapters, a new section on the economics of water engineering, and up-to-date references, it will be welcomed by those unable to obtain the out-of-print first edition.

This survey of waterworks practice is the work of many authoritative writers and there is a clear fundamental outline of the subjects dealt with. These include hydrology, hydrogeology, hydraulics, reservoirs, intakes, aqueducts, wells, purification and softening of water, hygiene, chemical, physical, bacteriological and biological examination of water, prevention of pollution, and organization and management of water policies.

**Materials of construction,** 9th ed M. O. Withey and G. W. Washa. New York, Wiley, 1954., irreg. paging, illus., $9.00.

The first edition of this book was published in 1899, but through the years each succeeding edition has been revised to keep abreast of new developments in the field of construction materials and their manufacture. New data and new sections have been added to the present work which presents the mechanical and physical properties of materials, and the influence of various factors on these properties. New testing machines and strain-measuring devices, and non-destructive tests, are discussed, as well as the latest information on chemical seasoning, wood products, and timber connectors.

In the field of concrete and cement new types of testing methods are given and a section is devoted to concrete aggregates and to mix design methods.

Other materials considered are wrought iron, alloy steels, and non-ferrous metals.

**Microscopical techniques in metallurgy.** Henry Thompson. Toronto, Pitman, 1954. 146 pp., illus., $3.50.

Intended as a reference work for students, inspectors, examiners and others in the metal industries, this book presents the methods used in the microscopical examination of metals. Particular attention is paid to the sampling and preparation of specimens, and there are detailed descriptions of the various types of metallurgical microscopes in use, including the electron microscope.

Other subjects covered are photomicrography, both black and white and coloured and various special methods, such as flake and grain size determination.

**Pratique de l'organisation industrielle.** Ernest Hijmans and Eva Hijmans. Paris, Dunod, Montreal, Fomac, 1954. 196 pp., illus., $13.00.

This is a practical book on industrial organization presenting only those theories developed by the authors from personal experience. While this may be a limited approach, it is usually possible to draw parallels between the conditions and methods described and those familiar to the reader.

The authors use graphs and diagrams to illustrate their viewpoint on such subjects as material handling, filling orders, salary scales, quality control, job analysis and work measurement, and the training of workers.

The book is translated from the English edition, and, unfortunately, does not include an index.

**Principles of engineering thermodynamics,** 2nd ed. P. J. Kiefer, G. F. Kinney and M. C. Stuart. New York, Wiley, 1954. 539 pp., figs., $7.75.

A large number of new features and subjects are introduced in this edition to bring it up-to-date with the advances in thermodynamic thought since the first edition was published in 1934. It covers the thermodynamic basis of fluid mechanics and aerodynamics and unifies the mechanical, chemical and aerodynamic applications.

The contents are divided into four parts: the classification and accounting of energy, covering energy in transition, stored energy and energy equations; the availability of energy, with the subheadings Reversible processes and cycles, Carnot principle, Absolute temperature scale, and Entropy; properties of fluids, including ideal and non-ideal gases, and the thermodynamics of combustion; engineering applications, relating to power-generation cycles, heat-pump and refrigeration cycles and dynamic forces. In these chapters new formulae, charts, methods of analysis, etc., are used.

**Pulp and paper manual of Canada,** 22nd ed., 1954. Gardenvale, National Business, 1954. 446 pp., illus., flow sheets, $7.50.

This twenty-second edition of the Manual contains all the valuable sections found in previous editions; woodlands equipment and operation, flow sheets of pulp and paper mills, engineering data, lists of machinery, supply and service companies, arranged alphabetically both by company and by product, a list of trade names, and another of foreign companies represented in Canada.

Two of the five technical papers included were previously presented at branch meetings of The Engineering Institute of Canada; one, by E. C. Cooley on the Elk Falls paper mill, and the other, by J. F. Hayward, on deaeration and dealkalization of boiler feedwater.

This Manual will prove of value and interest to all those connected in any way with the pulp and paper industry.

**Rocket propulsion,** 2nd ed. rev. Eric Burgess. Toronto, British Book Service, 1954. 235 pp., illus., $3.60.

Although the author makes a claim in his preface that additional material will be found in nearly all chapters of this new edition there seems to be very little actual change from the first edition which appeared in 1952. The chapter headings and the illustrations are almost identical and the material on corresponding pages is very similar.

Nevertheless, this book will have a wide appeal to both the layman and the scientist for it includes the basic theories, the possibilities and the difficulties surrounding rockets, long-range projectiles, the artificial moon and interplanetary travel. The appendix, among other material, contains the laws of rocket motion and efficiencies, and a brief history of the rocket and interplanetary movement in Great Britain.

***Simplified site engineering for architects and builders.** Harry Parker and J. W. MacGuire. New York, Wiley, 1954. 250 pp., illus., tables, $5.00.

Explains in detail the solution of problems that arise in the analysis of building sites and in preparation of the site plan, including interpretation of deed descriptions, dimensioning when angles are other than right angles, computation of areas of irregular plots, dimensioning and laying out of circular curves for driveways, computation of volume of cut and fill, etc. Problems requiring computations are accompanied with logarithmic computations shown in detail.

**Successful commercial chemical development.** H. M. Corley, ed. New York, Wiley, 1954. 374 pp., $7.75.

Authorized and sponsored by the Commercial Chemical Development Association, this is an interesting, new type of book in the field of industrial chemistry. It will be of value to research engineers, managers and design and sales engineers for it follows the chemical product from the embryo stage to full development.

The history of the chemical industry in North America is briefly discussed and the value of research group activity is noted. In describing the introduction of a new product every problem is covered from project selection, objectives, management, handling, sampling, and trade names to advertising, pricing, and marketing. Several case histories of new product developments bring the foregoing stages of the whole process into focus. The last chapter deals with some of the important qualifications for commercial chemical development work.

***Television: the electronics of image transmission in color and monochrome,** 2nd ed. V. K. Zworykin and G. A. Morton. New York, Wiley, 1954. 1,037 pp., illus., $17.50.

In the present edition of this detailed survey of the field the greatest emphasis is on the camera and viewing tubes, along with their physics background and the associated television fundamentals. In addition, specific aspects of circuitry, such as the video amplifier, are treated in detail. Most chapters have been rewritten and there are new chapters on colour and industrial television.

**Textbook of servomechanisms.** J. C. West. London, English Universities, Toronto, Musson, 1953. 238 pp., diagrs., 25/–.

Intended primarily for undergraduate students, this book assumes an elementary knowledge of electronics on the part of the reader, and describes the scope and principles of automatic control and design techniques used in control systems.

The author develops the subject from simple examples, and each new topic is introduced with a specific example before general principles are discussed.

There is a bibliography covering control systems and non-linear mechanics, and students and others interested in the subject should find this a useful book.

**Twinning and diffusionless transformations in metals.** E. O. Hall. Toronto, Butterworth, 1954. 181 pp., illus., $5.00.

The author has taken for his subject one mode of metal deformation and has dealt with the metallurgy, crystallography, and physical principles underlying twin formation. He has also included a chapter on an allied phenomenon, that of the diffusionless types of phase change.

The first two chapters cover elementary crystallography, the stereographic projection, and the growing of single crystals for the benefit of students. Other chapters discuss the formation of twins under stress and by heat treatment, and the theories of twin formation. The appendices contain information on the crystal structure of the metallic elements and crystallographic formulae and data.

***Water supply and waste-water disposal.** G. M. Fair and J. C. Geyer, New York, Wiley, 1954. 973 pp., diagrs., $15.00.

Treatment of the two subjects is integrated, with the first half of the book devoted to the collection and removal of water and waste-water, and the second half to their treatment and to the natural purification of water. Emphasis is on principles rather than practice in dealing with sanitation; supply and disposal systems; ground water collection, transmission, and distribution; the biology of water and waste-water; methods of treatment and purification; and related topics. The book is intended for students and practicing engineers.

***What every engineer should know about rubber.** W. J. S. Naunton. Washington, Natural Rubber Bureau, 1954. 128 pp., illus., $0.50 (U.S.).

Discusses briefly the sources, manufacture, properties, and testing of natural rubber and, at greater length, its engineering applications. Among the latter are anti-vibration systems, sound insulation, flexible couplings, belts, seals, and other uses.

***Yearbook of the heating and ventilating industry, 1954.** Compiled in collaboration with the Association of heating, ventilating and domestic engineering employers. London, Technitrade journals, 1954. 329 pp., 8/4

The eighth annual issue contains a bibliography of heating and ventilating literature, lists of pertinent British standards and codes, a directory of the industry, and several articles on technical or trade topics, for example, on smog and on panel heating.

# BOOKS RECEIVED

**Automatic selling.** G. R. Schreiber. New York, Wiley, 1954. 195 pp., $5.00.

**Blast cleaning manual.** Society of automotive engineers. New York, The Society, 1954. 54 pp., figs., pa. , $4.00 (U.S.).

**Centralization and decentralization in industrial relations.** Helen Baker and R. R. France. Princeton, University. Industrial relations section, 1954. 218 pp., $4.00 (U.S.).

**Crystal rectifiers and transistors.** M. G. Say, ed. Toronto, British Book Service, 1954. 170 pp., figs., $3.60.

**Electrical engineer's reference book,** 7th ed. E. Molloy, M. G. Say and R. C. Walker, eds. Toronto, British Book Service. 1954. Irreg. paging, diagrs., $12.00.

**The fundamentals of electric log interpretation.** M. R. J. Wyllie. New York, Academic press, 1954. 126 pp., figs., $3.60 (U.S.).

**Horizon mining.** C. H. Fritzsche and E. L. J. Potts. Toronto, Nelson, 1954. 614 pp., illus., $15.00.

**How to use test probes.** A. A. Ghirardi and R. G. Middleton. New York, Rider, 1954. 172 pp., illus., pa., $2.90 (U.S.).

**Jet: The story of a pioneer.** Sir Frank Whittle. Toronto, Saunders, 1953. 320 pp., illus., $3.50.

**Newnes engineer's reference book,** 6th ed. F. J. Camm, ed. Toronto, British Book Service, 1954. 1970 pp., diagrs., $12.00.

**Norwegian-English technical dictionary.** John Ansteinsson. Trondheim, Bruns Bokhandels, New York, Kraus Periodicals, 1954. 327 pp., $7.75 (U.S.).

**Obtaining and interpreting test scope traces.** J. F. Rider. New York, Rider, 1954. 186 pp., illus., pa., $2.40 (U.S.).

**Picture book of TV troubles, v. 1, Horizontal AFC-oscillator circuits.** John F. Rider laboratories staff. New York, Rider, 1954. 80 pp., illus., pa., $1.35 (U.S.).

**Power system transients.** E. O. Taylor, ed. Toronto, British Book Service, 1954. 176 pp., figs., $3.60.

**Production engineering, jig and tool design.** E. J. H. Jones. Toronto, British Book Service, 1954. 324 pp., illus., $3.00.

**The repair of the small electric motor.** Karl Wilkinson. Toronto, British Book Service, 1954. 180 pp., diagrs., $3.50.

**The scientific basis of road design.** F. L. D. Wooltorton. Toronto, Macmillan, 1954. 364 pp., figs., $11.75.

**Steam, air and gas power,** 5th ed. W. H. Severns, H. E. Degler and J. C. Miles. New York, Wiley, 1954. 502 pp., illus., $6.50.

**Strength and resistance of metals.** J. M. Lessells. New York, Wiley, 1954. 450 pp., illus., $10.00.

**A treatise on applied hydraulics.** Herbert Addison. Toronto, British Book Service, 1954. 724 pp., illus., $9.65.

**Television and special tubes vademecum,** 11th ed., 1954. J. A. Gijsen, ed. Antwerp, Brans, 1954. 244 pp., pa.

# TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

**British electrical and allied industries research association. Technical reports:**

C/T111—The economic value of hydrogen produced by wind power, by A. H. Stodhart. C/T112—The use of wind power in Denmark, by E. W. Golding and A. H. Stodhart. G/T275—Gas-blast circuit-breakers. Effect of arcing on the mass-flow of air through the nozzle and on nozzle pressure (third progress report), by A. A. Hudson. G/T283—Factors affecting the temperature-rise of fuse terminals. Fuses in free air without cases, by H. W. Baxter and M. T. Cree. L/T306—The hollow cathode effect and the theory of glow discharges, by P. F. Little and A. Von Engel.

**Canada. National research council. Government specifications board. Specifications:**

3-GP-2B—Oil; fuel. 3-GP-336—Lubricant; gear, universal (sub-zero). 3-GP-340A—Lubricant; gear, universal (grade 75). 3-GP-360A—Lubricant; gear universal (grade 80). 3-GP-390A—Lubricant; gear, universal (grade 90). 3-GP-685A—Grease; auto motive and artillery. 4-GP-5 0A—Duck; cotton light water resistant treatment. 4-GP-51A—Duck: cotton light rot resistant treatment. 4-GP-52A—Duck; cotton rot resistant and light water resistant treatment. 4-GP-53A—Duck; cotton heavy rot and water resistant treatment. 4-GP-54A—Duck; cotton heavy rot, water and flame resistant treatment. 5-GP-23—Leather; cattlehide, vegetable tanned, case. 39-GP-15—Pullers; nail. 43-GP-9—Barrier materials, grease resistant; flexible, non-corrosive, self-adhering coating. 45-GP-5—Wrenches; impact, pneumatic, portable. 45-GP-8—Shears; pneumatic, portable.

**Provisional specifications:**

1-GP-120P—Coating, strippable, protective.

**Canadian standards association. Approvals laboratories:**

List of approved equipment, 4th ed., supplement "E", May, 1954.

**Edison electric institute. Specification:**

MS-9-1954—Test switches for transformer rated meters.

**International bank for reconstruction and development:**

Ninth annual report, 1953-1954.

**Montreal. Civil service commission:**

Ninth annual report for the fiscal year ending April 30th, 1954.

Chemistry research, 1953. 65 cents. Industrial Britain.

**United States. Highway research board. Bulletin:**

No. 89—Night visibility.

**Windsor, Ont.**

First annual year book, 1954.

# STANDARDS REVIEWED

**Canadian standards, Canadian standards association, National research building, Ottawa, Canada.**

**C.S.A. C22.2 No. 36: 1954 — Construction and test of hair dressing equipment,** 2nd. ed. $1.00.

This standard applies to appliances for potentials of not more than 250 volts between conductors and to so-called pedestal and pre-heat "permanent-wave machines," hair dryers, steamers and curling irons, and is for general domestic and commercial use.

**C.S.A. C22.4 No. 111: 1954 — Antenna towers and antenna supporting structures,** .75c.

The towers and structures covered in this specification are over 80 feet in height above the ground or over 50 feet in height above their base when mounted on a building or other structure. The standards do not apply to ship or mobile equipment or antenna installations connected with carrier current equipment. Included under tower construction are specifications for steel and timber construction.

**C.S.A. C22.4 No. 112: 1954 — Amateur and domestic antenna supporting structures,** .75c.

This standard was compiled for use by municipalities contemplating legislation controlling the erection of domestic antenna structures. It applies to structures between 15 and 80 feet in height from the ground level or under 50 feet in height if the base is mounted on a building. It has the same reservations in scope as does the preceding standard, with the addition of the design of the antenna array itself, and it covers steel, aluminum, timber and magnesium tower construction.

**British standards. British standards institution, 2 Park Street, London, W.I. British standards are available from the Canadian standards association, National research building, Ottawa, Canada.**

**B.S. 2490: 1954 — Waterproof drawing inks.** 3/–.

The scope of the specification is limited to water soluble dyes and it considers eleven colours which are defined, with suitable tolerances, in terms of the X, Y and Z stimuli of the International Commission on Illumination. Tests are also specified for good drawing ink covering draughting, keeping and erasing qualities required, and resistance to light and solvents. These tests of quality include waterproof black carbon inks as well. Standard sizes of containers and methods of sealing are recommended.

**B.S. 2491: Part 1: 1954 — Domestic cooking appliances for use with Butane Propane gases. Part 1: Appliances for use with butane gases.** 6/–.

The appliances to which the standard relates are those for use in the home and in caravans, houseboats, etc., and it specifies the construction, operation and safety requirements and tests for cookers, ovens, hot plates, boiling burners and grillers used with butane gas at 11 in. w.g. pressure.

# Business & Industrial Briefs

## A Digest of Information received by The Editor

## Appointments and Transfers

**Shawinigan Water and Power.**—Appointment of three men to senior positions in The Shawinigan Water and Power Company was announced by J. A. Fuller, president, effective November 30.

Leo E. Boissonault becomes assistant vice-president, finance; A. C. Joncas is appointed assistant treasurer; and Alex Timon is named comptroller of the company. The first two positions are new ones, and that of comptroller has been filled since 1946 by C. W. Hemming, who is retiring after 34 years with the company.

●

**Robertshaw-Fulton Elects Officers.**—The board of directors of Robertshaw-Fulton Controls (Canada) Limited, recently-formed subsidiary of Robertshaw-Fulton Controls Company, has elected John A. Robertshaw, president, George A. Elliott, vice president and general manager, Walter H. Steffler, secretary and treasurer, B. D. Taylor, comptroller, and H. William Biggar, assistant secretary and assistant treasurer. Messrs. Robertshaw, Steflller and Taylor hold similar positions with the parent firm, Robertshaw-Fulton Controls Company, whose headquarters are at Greensburg, Pa.

W. R. Anderson

●

**Allis-Chalmers Sales.** — Norman H. Hollefriend, manager of the industrial division, Canadian Allis-Chalmers, for the past seven years, has been appointed director of sales for the entire company's operations. He joined the firm in 1926.

●

**Trans-Canada Pipe Lines.**—Four appointments to the staff of Trans-Canada Pipe Lines Limited have been announced by N. E. Tanner, president of the company which will export Alberta natural gas to eastern Canada and the mid-western United States.

The appointments are: D. R. Pflug, chief engineer; R. J. "Don" Wallace, manager of gas supply; Douglas G. Simpson, controller and assistant treasurer; and D. W. Brown, information officer.

●

**Du Pont of Canada.**—Appointment of Walter R. Anderson as supervisor of the Du Pont of Canada plant being built at Maitland, Ontario, to manufacture "Freon" fluorinated hydrocarbons, was recently announced by the company's chemicals department.

Born in Hamilton, Ontario, Mr. Anderson is a graduate of Queen's University. He joined the company in 1946 as a chemical engineer, and four years later was made process engineer in the textile fibres division. He moved to Maitland in 1952 in connection with the construction of the nylon intermediates plant there, and returned to Montreal this year as a member of the chemicals department.

**P. H. Desrosiers Honoured.** — P. H. Desrosiers of Montreal has been honoured as a member of the Quarter Century Club of the Canadian Good Roads Association at its annual meeting in Toronto on November 8, 9, 10. Mr. Desrosiers is a member of the Executive Committee of the C.G.R.A. In Montreal he is president of Ciment Fondu Lafarge (Canada) Limited, executive vice-president of Joliette Steel Division of Dominion Brake Shoe Company, Ltd. as well as president of several building materials companies.

●

**British Insulated Callender's Board Changes.**—G. A. Rendle has been appointed to the Board of British Insulated Callender's Construction Co., Ltd. He becomes manager, cable contracts, in succession to C. H. Frankland, who, while remaining a director of B.I.C. Construction Co., Ltd., has undertaken special duties at the Trafford Park Works of British Insulated Callender's (Submarine Cables) Ltd.

P. H. Desrosiers

RAPID DELIVERY...
WAREHOUSE STEEL SERVICE
coast-to-coast!
Because Dominion Bridge maintains complete stocks of warehouse steel at nine strategic locations across Canada you are never far from the source of supply. This assures prompt delivery right to your plant, thereby eliminating the need for costly storage and handling facilities under your own roof.
Every Dominion Bridge warehouse has modern cutting, storage, handling and shipping facilities to take care of your urgent requirements — LARGE or Small.
FROM A BAR TO A TRUCKLOAD
WAREHOUSE DIVISION*
DOMINION BRIDGE
COMPANY LIMITED
Warehouses at: Montreal • Ottawa • Toronto
Winnipeg • Calgary • Vancouver
Associate Warehouses at:
Amherst • Sault Ste. Marie • Edmonton
*Other Divisions: Structural • Platework • Mechanical • Boiler

C. Kibblewhite has also been appointed to the Board of B.I.C. Construction Co., Ltd. as an executive director.

**English Electric.**—J. G. Warnock has been appointed hydraulic engineer in charge of the new hydraulic department of the English Electric Company of Canada Limited, which is located at the headquarters of the general engineering division of the John Inglis Co. Limited in Toronto, where the manufacture of heavy hydro-electric plant will be centred.

Mr. Warnock is a graduate of the University of Glasgow. He was engaged on hydro-electric work in the United Kingdom with 'English Electric' since 1945, and has been with the English Electric Company of Canada Limited since 1952.

**Integrated Operation.** — Maynard H. Patterson has been named vice-president and general manager of integrated operations of Minnesota Mining and Manufacturing of Canada Ltd., London, Ontario, and Irvington Varnish and Insulator Co. of Canada Ltd., Hamilton. The Hamilton plant becomes a varnish and insulator unit in the 3M company, effective Nov. 1, with the head office in London.

# New Equipment and Developments

**Portable Oxy-Acetylene Outfit.** — A lightweight, fully portable oxy-acetylene outfit in the low price range has been introduced by Dominion Oxygen Company, division of Union Carbide Canada Limited. The new unit, for light-to-medium welding and cutting work in auto repair shops, welding and sheet metal shops, and industrial plants, is called the Prest-O-Lite Welding and Cutting Outfit, and features an exclusive "all-in-one" blowpipe with interchangeable welding and cutting tips. The same blowpipe heats, bends, solders, brazes, welds, and cuts. No special attachments are needed. As furnished, the outfit welds up to 3/16 in., and cuts through ⅜ in. of solid steel. Additional tips are available for welding up to ⅜ in. and cutting up to 2 inches.

**Textile Mill Re-opened.**—Textile Sales Limited, Montreal, recently announced the signing of an agreement with Milltown Textile Co-operative Limited which will re-open the company's St. Croix Mill at Milltown, New Brunswick.

The arrangement is the result of discussions between executives of Textile Sales Limited and representatives of the employees. The company had announced, late in August, that this mill would be closed due to the depressed conditions common to the Canadian textile industry as a whole.

The management of the mill will now be under Milltown Textile Co-operative Limited, an organization composed exclusively of mill employees. The new management has announced the appointment of Phillip Boel as plant manager. The production will cover the same full range of synthetic fabrics including linings, dressgoods, plaids, and suitings, as was formerly manufactured there. As in the past, the merchandising of these products will be carried out by Textile Sales Limited through their sales organization in Montreal, Toronto, Winnipeg and Vancouver. The arrangement has been entered into for an indefinite period.

The mill resumed operations November 1st with about 150 employees and it is expected to employ about 300 by the year end. Approximately 400 were employed when the mill closed down.

**New Kraft Pulp Mill.**—Crown Zellerbach Canada officials announced recently that plans for a new kraft pulp mill at Duncan Bay, on Vancouver Island, are in final engineering stages, with the mill scheduled to begin producing in mid-summer, 1956.

Excavations for the new mill buildings are already under way and actual construction is scheduled to begin as soon as spring weather permits.

Cost of the Duncan Bay kraft mill has been estimated at $15,000,000.

The kraft mill represents the second stage of a planned development which began in 1952 with construction of a newsprint mill by the Elk Falls Company Limited, which is jointly owned by Crown Zellerbach Canada Limited and Canadian Western Lumber Company, Limited.

**Silicone Rubber Gum.**—A new, low-shrinkage, general-purpose silicone rubber gum is available from Canadian General Electric Company's chemical department.

Designated as SE-30, the new gum is being used in compounds from which parts requiring close tolerances may be produced. Because the shrinkage of such material is extremely low, molds and dies designed for organic rubber may often be used with compounds made from SE-30 silicone rubber gum.

Compounds for conventional type molding, extrusion, calendering, knife coating or dip coating are readily formulated with the new gum. They offer high tensile strength, excellent low compression set and good resistance to elevated temperatures.

Good electrical properties, flexibility down to minus 65° F., and excellent hot tear strength from the mold are other features offered by compounds incorporating SE-30 silicone rubber gum.

Further information may be obtained from Chemical Materials Sales, Canadian General Electric Co. Ltd., 940 Lansdowne Ave., Toronto.

**New Siporex Plant.**—Dominion Tar & Chemical Company, Limited announce the construction of a $1,250,000 plant at Delson, near Montreal, for the production of a light weight cellular building material by its "siporex" division.

The latest development in the Canadian construction field, "siporex" is an autoclaved precast light cellular concrete that is built in slabs for walls, roofs and floors. It was developed in Sweden over 20 years ago and introduced to the Canadian market after extensive investigation by Dominion Tar & Chemical officials in North America and Europe.

In Sweden the use of "siporex" was found to reduce building costs from 10 to 15 per cent as its use permitted rapid construction as well as affording high insulation and being fire and vermin proof. "Siporex" is manufactured by a patented process from finely ground sand, Portland cement and chemical additives.

The new factory at Delson, 16 miles south of Montreal, is being constructed of "siporex" which has been imported from Sweden. The plant which covers 40,000 square feet, will be completed at the end of the year with production scheduled for next March. A staff of 55 will be employed in this new addition to the industrial life of the Province of Quebec.

# Publications

**For copies of the publications mentioned below please apply to the publishers at the addresses given in the items.**

**Please mention *The Engineering Journal* when writing.**

**Folder Illustrates Tournatractor.** — A 28-page folder in color, describing and illustrating features of the 208 hp. rubber-tired tractor built by LeTourneau-Westinghouse Company, Peoria, Illinois, has been issued by the company.

By extensive use of photos, diagrams and charts, the folder shows how the unit's range of speeds cuts minutes from the work cycle, and reasons why the machine requires low maintenance and few repairs. Colorful blow-ups illustrate how anti-friction bearings put more horsepower to work, how the machine's heavy, all-welded steel case provides a big, rugged mounting for every operating assembly, and how electric motors at point of action give fast, positive, accurate control.

This folder may be obtained by requesting Tournatractor Features Folder, Form 54-005-T, from Advertising Department, LeTourneau - Westinghouse Company, Peoria, Illinois.

**Die-Casting Film.**—A story of the die-casting process, its achievements, and its promise for the future is the subject of a 30 minute 16 mm. colour and sound motion picture which has just been released entitled "How Else Would You Make It?" This film was produced by the American Zinc Institute in co-operation with the American Die Casting Institute and covers the die-casting of zinc, aluminum, magnesium and copper alloys.

The film gives an interesting, highly educational pictorial description of the scope of the die-casting process. It vividly illustrates and describes the vast range of sizes and widespread application of die-castings. A comprehensive discussion and evaluation of die-casting alloys is included. Modern die-casting practice is portrayed by an examination of the types of machines, dies and principal operations. The economy of die-casting is outlined by showing how production costs are reduced to a minimum by the nature of the process.

Sample castings demonstrate how the design engineer utilizes this process to achieve by die-casting, improved appearance, optimum functional properties, strength and compactness at lowest cost.

Case histories of various outstanding die casting applications show numerous examples of castings that respond to the demands of practically every aspect of life. Automobiles contain a large number of die castings including such items as the radiator grille, hood ornament, horn ring, carburetor, door handles and automatic transmission housings. A high percentage of the chrome trim on refrigerators, stoves, washing machines, etc., is composed of chromium plated zinc alloy die castings, while the lightness of vacuum cleaners is due in part to the use of aluminum die-cast components.

The film is available for distribution for showing before industrial, technical and educational groups. Canada's largest producer of zinc for die-casting, the Consolidated Mining and Smelting Company of Canada Limited is handling the Canadian distribution of this film.

●

**Bristol's General Bulletin.** — A new general bulletin, listing and illustrating the complete line of recording automatic controlling, and telemetering instruments manufactured by The Bristol Company of Canada Limited, 71-79 Duchess Street, Toronto, has just been published.

The bulletin illustrates and describes briefly the full line of recorders and controllers for temperature, flow, liquid level, mechanical motion, running time, count, and operation, and speed. Also included are Bristol's electric and electronic instruments for measuring current, voltage, power, and other variables which can be translated into electrical quantities, such as strain, capacitance, resistance, and smoke density.

Copies of the bulletin, DMO35, are available from The Bristol Company of Canada Limited, 71-79 Duchess Street, Toronto, Ontario.

●

**Film Directory.** — Many thousands of Canadian organizations now regularly use 16 mm. sponsored films in their programs. Several hundred sponsors have free films available.

With the aim of bringing together these two groups—users and sponsors—two years ago the staff of Crawley Films compiled and published Canada's first Directory of Sources of Free 16 mm. Sponsored Films. The first printing was quickly over-subscribed. Second and third printings were required to answer requests totalling more than 15,000 copies Certainly the demand dramatized the wide use of sponsored films in this country.

This new enlarged edition lists 256 sources, giving access to more than 8,000 free films. For your copy write to Crawley Films Limited, 19 Fairmont Avenue, Ottawa 3, Canada.

# Publications of Other Engineering Societies

Exchange arrangements exist between The Engineering Institute of Canada and engineering societies in the British Empire and the United States whereby members of the Institute may secure the publications of these societies at special rates which, in most instances, are the same as charged to their own members. A list of these publications with the amounts charged is given below. Subscriptions should be placed at E.I.C. Library, 2050 Mansfield St., Montreal 2, Que., but **no remittance** should be made until an invoice has been received. **These prices are subject to change without notice.**

| | *Rate to E.I.C. Members* | *Rate to Non-Members* |
|---|---|---|
| **AMERICAN INSTITUTE OF CHEMICAL ENGINEERS** | | |
| Chemical Engineering Progress (including postage to Canada) | $5.75 | |
| **AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS** | | |
| Electrical Engineering—Per year (including postage to Canada) | $7.50 | $16.00 |
| Transactions — annual, bound (including postage to Canada) | 8.00 | 16.00 |
| Combined subscription (including postage to Canada) | 10.00 | 20.00 |
| **AMERICAN SOCIETY OF CIVIL ENGINEERS** | | |
| Separates of papers published during year, per year (including postage to Canada) | $13.50 | $20.00 |
| Civil Engineering — Per year (including postage to Canada) | 5.50 | 7.00 |
| Transactions — annual per year | 10.00* | 15.00† |
| (Other publications 50% reduction on Canadian price to E.I.C. members) | | |

* *If subscription received before Jan. 1st, otherwise $15.00.*

† *If subscription received before Jan. 1st, otherwise $20.00.*

| **AMERICAN SOCIETY OF MECHANICAL ENGINEERS** | | |
| Mechanical engineering — Per year (including postage to Canada) | $ 5.00 | $10.00 |
| Transactions & Journal of Applied Mechanics (available only in combination subscription; including four issues of the Journal of Applied Mechanics, and eight issues of Transactions) | 12.00 | |
| Transactions & Journal of Applied Mechanics (available in bound form in April) | 17.00 | |
| Applied Mechanics Reviews—Per year (including postage to Canada) | 11.00 | |
| Journal of Applied Mechanics | 5.00 | |
| **INSTITUTION OF CIVIL ENGINEERS** | | |
| Proceedings — three parts per year | | |
| Part I (General) | $4.00 | |
| Part II (Airport, Maritime, Railway and Road Engineering) | 2.00 | |
| Part III (Public health, Structural, Works construction, Hydraulics engineering) | 2.00 | |
| All three parts together | 6.00 | |
| **INSTITUTION OF ELECTRICAL ENGINEERS** | | |
| Journal (General Papers) | $2.25 | |
| Part A (Power Engineering) | 3.00 | |
| Part B (Radio and Electronic Engineering) | 3.00 | |
| Part C (Collected Monographs) | 1.25 | |
| Journal and three parts together | 8.50 | |
| **INSTITUTION OF MECHANICAL ENGINEERS** | | |
| The "Chartered Mechanical Engineer" and 'separates' of Proceedings | | $15.00 |
| The C.M.E. and 'separates', bound volumes of Proc. and Automobile Div. Proc. | | 21.00 |
| The C.M.E., bound volumes of Proc. and Automobile Div. Proc. | | 19.50 |
| Automobile Div. Proc. | | 3.00 |
| C.M.E. only | | 4.00 |
| **INSTITUTION OF ENGINEERS, AUSTRALIA** | | |
| Journal — monthly, per year | $8.00 | $16.00 |
| **INSTITUTION OF ENGINEERS (INDIA)** | | |
| Journal — quarterly, per year | $3.00 | $4.50 |
| **NEW ZEALAND INSTITUTION OF ENGINEERS** | | |
| New Zealand Engineering | $4.00 | |
| **SOUTH AFRICAN INSTITUTE OF ELECTRICAL ENGINEERS** | | |
| Transactions — monthly, single copies | $ .75 | $1.00 |

*Members wishing their subscriptions to commence with the January issue should place orders with the E.I.C. Library immediately. Every effort will be made to comply with requests. However, receipt of the January issue cannot be guaranteed.*
